The Critical Role of Rho Associated Coiled-Coil Containing Protein Kinase 2 for the Enhancement of Actomyosin Contractility in Podocytes

Hsiao-Hui Lee. Cytoskeleton and Cell Mechanics *National Yang-Ming University, Taipei, Taiwan.*

Background: The highly differentiated podocytes elaborate interdigitated foot processes (FP) to cover the glomerular capillaries and form slit diaphragm (SD) for blood filtration. Therefore, podocytes adhere tightly to glomerular basement membrane (GBM) and generate RhoA/ROCK-mediated contraction force to tolerate the filtration pressure. Two ROCK isoforms, ROCK1 and ROCK2, were identified in mammal. In this study, we characterized that ROCK2 is critical for the enhancement of contractility in cultured podocytes.

Methods: The conditionally immortalized mouse podocytes were used in this study. By Western blotting and immunostaining, the ROCK signaling and cell architecture were detected. ROCK kinase activity was inhibited by the treatment of cells with Y27632 and ROCK2 gene was knockout by CRISPR/Cas9 method.

Results: After temperature switch, the expression of podocyte differentiation marker synaptopodin was increased. The formation of focal adhesions (FA), stress fibers and the

SD-like protrusions labelled by ZO-1 staining were also observed. We found that ROCK2, but not ROCK1, was significantly activated in differentiated cells. The phosphorylation status of MLC and ERM, two ROCK downstream substrates, were also increased. treatment of cells with Y27632 diminished both the phosphorylation of MLC and ERM and the formation of FA and stress fibers. We then generated ROCK2 knockout podocytes by CRISPR/Cas9 and found that loss of ROCK2 decreased MLC phosphorylation, while ERM phosphorylation was not affected. In addition, ROCK2-dificiency also diminished the formation and stress fibers and cellular protrusions.

Conclusions: Our results suggest that ROCK2 is critical for the enhancement of actomyosin contractility in podocytes. The regulation of ROCK2 activation shall plays an important role in the maintenance of cell adhesion and cytoskeletal architecture for podocyte function.

Vasohibin 1 Is Essential for the Post-Transcriptional Modification of α-Tubulin on Microtubules in Podocytes

Tomoyo Morioka, Katsuyuki Tanabe, Satoshi Tanimura, Hitoshi Sugiyama, Jun Wada. *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Microtubules in podocytes are important for maintaining the characteristic cell shape as well as normal intracellular transport and dynamic morphologic alterations. The microtubule functions are affected by various post-transcriptional modifications on tubulin proteins. Recent studies have shown that vasohibin-1 (VASH1), an endothelium-derived angiogenesis inhibitor, has an enzymatic activity that catalyzes the detyrosination of α-tubulin in neurons and cancer cells. In the present study, we examined the roles of VASH1 in the modification of α-tubulin and microtubules in podocytes.

Methods: We used B6 wild-type and *Vash1*$^{+/-}$ mice to confirm the localization of detyrosinated (detyr) α-tubulin in the kidney. In addition, 8-week-old female BALB/c wild-type mice received single intravenous injection of 15mg/kg of adriamycin (ADM) or saline to induce podocyte injury and proteinuria. Finally, we cultured immortalized human podocytes, and VASH1 knockdown was performed by siRNA transfection.

Results: In wild-type mice, detyr-α-tubulin was shown to be restricted in podocytes by double immunofluorescence with podocalixyn. The detyr-α-tubulin staining was markedly attenuated in *Vash1*$^{+/-}$ mice. ADM-induced podocyte injury in BALB/c mice led to massive albuminuria and decreased detyr-α-tubulin staining in glomeruli compared to the control group, suggesting the detyrosination of α-tubulin could be altered by morphological changes of podocytes. *In vitro* experiments, immunoblot analysis demonstrated that detyr-α-tubulin remarkably increased in differentiated podocytes compared to undifferentiated cells. In addition, VASH1 knockdown by transfection of siRNA in differentiated podocytes significantly inhibited the detyrosination of α-tubulin.

Conclusions: These results indicate that VASH1 expression is necessary for the detyrosination of α-tubulin in podocytes, and may be involved in the regulation of their microtubule function.

Transcriptional Reprogramming by Wilms Tumor 1 and FoxC2 Mediates a Repair Response During Podocyte Injury: Studies in Mice and Human Kidney Organoids

Sandrine S. Ettou,[1,2] Youngsook L. Jung,[3] Tomoya Miyoshi,[4,5] Ken Hiratsuka,[4,5] Ryuji Morizane,[4,5] Peter Park,[3] Jordan A. Kreidberg.[1,2] *[1]Boston Children's Hospital, Boston, MA; [2]Surgery, Harvard Medical School, Boston, MA; [3]Biomedical Informatics, Harvard Medical School, Boston, MA; [4]Brigham and Women's Hospital, Boston, MA; [5]Medicine, Harvard Medical School, Boston, MA.*

Background: We previously reported that WT1 is a master regulator of gene expression in podocytes, binding nearly all genes known to be crucial for maintenance of the glomerular filtration barrier. We have now performed ChIP-Seq for FoxC2 transcription factor that also binds nearly all the same target genes as WT1, suggesting that WT1 and FoxC2 act as a cell lineage-specific transcriptional activating complex in podocytes.

Methods: We used Adriamycin (ADR)-induced podocyte injury as a model for human Focal Segmental Glomerulosclerosis. WT1 and FoxC2 binding to enhancers and the transcriptional start sites of the *Nphs2* and *Synpo* genes was determined by direct ChIP-qPCR at multiple time points after ADR-induced injury, using both Balb/C and mTmG Nphs2-Cre mice. We also integrated RNA-seq and WT1/FoxC2 ChIP-seq data sets to determine how transcriptional reprogramming occurs during the course of podocyte injury.

Results: WT1 and FoxC2 transiently increase after injury, before decreasing to low levels. *Synpo* and *Nphs2* mRNA levels also transiently increase in response to increases in WT1 and FoxC2 binding. Interestingly, distinct patterns of WT1 and FoxC2 binding were observed dependent on the enhancer or transcriptional start site being interrogated. The transient increased expression after injury was also observed in human kidney organoids, allowing us to identify a window of opportunity for treating glomerular disease in humans. ChIP-seq studies identified sets of WT1 binding sites only bound after treatment with ADR suggesting that WT1 may acquire new target genes during the response to injury. Since transcription factors DNA binding is modulated by chromatin accessibility, we used immortalized podocytes as an *in vitro* model to study epigenetic reprogramming after treatment with ADR or knockdown of *Wt1*. Both treatments result in conversion from activating to repressive histone marks at WT1/FoxC2 bound-enhancers.

Conclusions: Our results demonstrate that WT1 and FoxC2 mediate transcriptional reprogramming during the course of podocyte injury, and specifically that decreased levels of WT1 result in epigenetic silencing of gene expression during the course of podocyte injury.

The Ephrin Signaling Pathway Is a Novel Target of Wt1-Induced Gene-Regulatory Reprogramming in FSGS Progression

Tsimafei Padvitski,[2] David Unnersjö-Jess,[3] Bernhard Schermer,[1] Thomas Benzing,[1] Andreas Beyer,[2] Martin Kann.[1] *[1]Department II of Internal Medicine, University of Cologne, Cologne, Germany; [2]University of Cologne, Köln, Germany; [3]Royal Institute of Technology, Solna, Sweden.*

Background: While mutations in podocyte transcription factors (TF) can cause FSGS, gene-regulatory processes governed by TFs in glomeruli are unclear. Here, we investigate gene-regulatory reprogramming due to Wt1 depletion in an early and progressed stage of murine FSGS using an epigenomic and transcriptomic approach.

Methods: The Wt1 heterozygous null mouse model (Wt1-hetdel) and littermate controls were used for RNAseq of glomeruli in early proteinuric and progressed sclerotic stages of disease, as well as ChIPseq for Wt1 at an early disease stage. Proteomics and STED microscopy were used to investigate glomerular protein abundance and ultrastructure.

Results: Wt1-hetdel mice show a consistent FSGS phenotype with proteinuria starting at age 4 wks progressing to sclerosis at age 12 wks. Transcriptomic profiling of glomeruli by RNAseq discriminated 4wk from 12wk FSGS. Signaling pathway impact analysis of RNAseq data identified pathways predominantly dysregulated in early vs late FSGS disease phases. The ephrin signaling pathway was exclusively dysregulated in the sclerotic stage of FSGS. Integrative analysis of Wt1 ChIPseq data from healthy and diseased mice and RNAseq data confirmed differential binding of Wt1 at differentially expressed genes relevant to ephrin signaling indicative of Wt1-mediated gene-regulatory reprogramming of ephrin pathway genes. Exclusively in progressed FSGS, targeted proteomics showed reduced protein abundance of EphrinB1, an interactor of nephrin and key molecule to podocyte ephrin signaling. Ultrastructural investigation of EphrinB1 using STED microscopy confirmed co-localization of EphrinB1 with podocin, with clustering of EphrinB1 in presumed signaling hubs. EphrinB1 signals were specifically reduced in sclerotic and preserved in non-sclerotic glomerular areas, respectively.

Conclusions: Transcriptomic profiling differentiated signaling pathways predominantly dysregulated in the proteinuric vs. sclerotic stage of FSGS. Integration of transcriptomics with glomerular Wt1-ChIPseq provided unbiased insight into contribution of Wt1 to FSGS disease progression. The ephrin signaling pathway and specifically EphrinB1 were identified as a differentially expressed in progressed FSGS, affected by Wt1-mediated reprogramming, and reduced specifically in sclerotic glomeruli on the protein level

The JAK-STAT Pathway in Podocytes Is Activated and Modulated by Monomeric Cardiotrophin-Like Cytokine Factor 1 (CLCF1)

Mukut Sharma,[1,2] Jianping Zhou,[1] Maohui Chen,[1] Ram Sharma,[1] Tarak Srivastava,[3] Ellen T. McCarthy,[4] Jean-francois Gauchat,[6] Virginia J. Savin.[5] *[1]KCVA Medical Center, Kansas City, MO; [2]Kidney Institute, KUMC, Kansas City, KS; [3]Children's Mercy Hospital, Kansas City, MO; [4]University of Kansas Medical Center, Kansas City, KS; [5]KC VA Medical Center, Kansas City, KS; [6]University of Montreal/Montreal Neurological Institute, Montreal, QC, Canada.*

Background: We detected CLCF1 in recurrent FSGS plasma and showed that it increased glomerular permeability (P_{alb}). Cytokine Receptor-Like Factor 1 (CRLF1) was not detected although it may be secreted and circulate as a heterodimer with CLCF1. CLCF1-CRLF1 or JAK2/STAT3 inhibitors blocked the increase in P_{alb} induced by FSGS serum or by monomeric CLCF1 (Sharma et al, Trans Res 2015;166:384-398). A role for JAK-STAT signaling is supported by its activation in PBMC and kidney tissue of FSGS patients (Tao et al, 2018 Kid Int 94:795-808). The current studies aimed to determine the podocyte effects of CLCF1, CLCF1-CRLF1 and JAK inhibitors on the JAK-STAT system.

Methods: Immortalized murine podocytes were treated with CLCF1, CLCF1-CRLF1 or JAK inhibitors Tofacitinib (Tofa), Baricitinib (Bari) and Ruxolitinib (Rux). Total and phosphorylated (p) STATs and JAKs and expression of SOC and PIAS were analyzed using SDS-PAGE and Western blotting with β-actin as the loading control. Expression of CLCF1 receptor sub-units was determined using RT-qPCR and immunofluorescence.

Results: Podocytes express the components of the CLCF1 receptor complex, CNTFRα, gp130 and LIFRβ, and express (in order of protein expression) JAK2>JAk3>JAK1, and STAT3>STAT1>STAT6 >STAT5, as well as SOCS isoforms (3>2>1) and PIAS (3>4>1). CLCF1 (10-1000ng/mL) upregulated pJAK2 (max at 100ng/mL CLCF1) and pJAK3 (max at 1000ng/mL CLCF1) (each P<0.001). Tyr1007 was the major site of phosphorylation on JAK2. CLCF1 (10-1000ng/mL) upregulated pSTAT3 ^{Tyr705} in a time-dependent manner (max at 100ng/mL CLCF1, 15 min, P<0.001). Heterodimer CLCF1-CRLF1 attenuated CLCF1-induced phosphorylation of JAK2^{Tyr1007} and STAT3^{Tyr705} in a dose-dependent manner (max at 1:2 mol, P<0.001). JAK inhibitors Tofa, Bari, and Rux also attenuated CLCF1-induced pSTAT3^{Tyr705}. SOCS were upregulated by CLCF1 (100ng/mL) in the order SOCS3>SOC2 (P<0.001). CLCF1 (100ng/mL, 15 min) upregulated only PIAS3.

Conclusions: Monomeric CLCF1 influences FSGS-associated podocyte pathophysiology through JAK-STATs and their modulators. CRLF1 may inhibit these effects while clinically available JAK inhibitors may provide effective therapy.

Podocyte-specific expression of JAK, STAT, SOCS and PIAS isoforms provides opportunity for developing additional targets for treating FSGS.

Genetic or Pharmacologic Activation of Nrf2 Worsens Glomerular Injury and Proteinuria

Brittney M. Rush, Corry D. Bondi, Sean D. Stocker, Roderick J. Tan. *University of Pittsburgh, Pittsburgh, PA.*

Background: Proteinuric chronic kidney disease (CKD) is a major cause of progressive renal failure. Nrf2 (nuclear factor 2 erythroid 2) is a transcription factor and master regulator of a multitude of target genes with roles in antioxidant protection, electrophile detoxification, and overall cytoprotection. Nrf2-activating compounds such as CDDO-Me (bardoxolone methyl) and CDDO-Im have been and continue to be explored as treatments for proteinuric CKD in both clinical trials and experimental animal models. The results of some of these studies have suggested that Nrf2 may paradoxically increase proteinuria. To examine this, we tested the effects of genetic or pharmacologic Nrf2 activation on proteinuria in mice.

Methods: Wild type mice and mice with genetic Nrf2 activation (via reduction in the Nrf2 inhibitor Keap1) were compared. Proteinuria was induced experimentally via exposure to 1) adriamycin, 2) angiotensin II, or 3) albumin overload. Injury was assessed with urine albumin excretion, immunohistochemistry, podocyte foot process effacement, and expression of injury genes. Systemic blood pressures were measured with radiotelemetry. We also examined the effect of pharmacologic Nrf2 activation by CDDO-Im in wild type mice during proteinuric injury.

Results: There were no differences in proteinuria at baseline in the wild type and mutant mice. However, genetic Nrf2 activation led to increases in proteinuria in all three proteinuria models, and this was associated with worsened glomerular injury, podocyte foot process effacement, and renal fibrosis. Blood pressures were slightly higher in the mutant mice, due to a lack of dipping during the sleep cycle. In wild type mice, the addition of CDDO-Im to angiotensin-induced injury led to a dramatic increase in proteinuria which could be reversed upon CDDO-Im withdrawal.

Conclusions: Both genetic and pharmacologic Nrf2 activation led to increased proteinuria after injury. This appears to have deleterious effects on the kidney chronically. Increased blood pressures may contribute to this effect. Our results suggest that Nrf2 activation should be used cautiously in proteinuric CKD.

TH-PO1083

Role of Renal PCSK9 in the Rrm2b Mouse Model of Nephrotic Syndrome

Eduardo Molina-Jijon,[1] Stephanie Gambut,[1] Camille E. Mace,[2] Carmen Avila-Casado,[3] Lionel C. Clement.[2] *[1]Internal Medicine, Rush University Medical Center, Chicago, IL; [2]Rush University Medical Center, Chicago, IL; [3]University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: 85% of US chronic disease patient presenting nephrotic syndrome (NS) have high levels of low density lipoprotein cholesterol (LDL-c), compared to 31.5% in the general population. Proprotein convertase subtilisin/kexin type 9 (PCSK9) was shown to play an important role in the regulation of LDL-c levels in the liver. PCSK9 is expressed in the collecting duct (CD) where it plays a role of chaperon protein for the epithelial sodium channel (ENaC). We studied the expression of PCSK9 in NS in the Rrm2b$^{-/-}$ mouse, a model of collapsing glomerulopathy.

Methods: (1) Rrm2b Control (+/+) and knock-out (-/-) mice were followed weekly between the age 5 and 12 weeks. Albuminuria, PCSK9 and cholesterol serum levels were assessed. PCSK9 gene and protein expression in liver, kidney, intestine and serum were studied by RealTime PCR, Western blot, and confocal microscopy. (2) 8 week-old mice were treated or not with amiloride, a specific inhibitor of ENaC located in the renal CD.

Results: Rrm2b$^{+/+}$ mice do not develop albuminuria, hypercholesterolemia, or high levels of serum PCSK9. Rrm2b$^{-/-}$ develop albuminuria from the age of 7 weeks (425±239 μg/18h, P<0.001) and serum PCSK9 and total cholesterol levels significantly increase from the age of 8 weeks (19.75±5.21 ng/ml, P<0.05, and 124.16±10.27 mg/dl, P<0.05, respectively). PCSK9 protein expression was shown by Western blot to increase in the renal cortex from the age of 9 weeks, and decrease in the liver from the age of 7 weeks. By confocal microscopy, PCSK9 was shown to co-localize with Aquaporin-2, indicating expression in the CD where its expression is increased from the age of 7 weeks. When treated with amiloride, Rrm2b$^{-/-}$ mice show elevated levels of blood PCSK9 and cholesterol compared to mice without treatment. Amiloride blocks ENaC, the CD cells then increase the number of active ENaC present in the plasma membrane and the secretion of PCSK9, initiating hypercholesterolemia.

Conclusions: As Rrm2b$^{-/-}$ mice age and develop NS, PCSK9 protein levels increase in the kidney and serum, and decrease in the liver. Amiloride treatment showed that PCSK9 secreted by CD cells into the circulation induces earlier and higher hypercholesterolemia. CD expressed PCSK9 may play an important role in hypercholesterolemia in NS in the Rrm2b mouse model, as a link between the kidney and the liver.

TH-PO1084

Automated High Content Imaging to Identify New Therapeutics for Podocytopathies

Simone Romoli,[1] Thea S. Zabell,[1] Wioletta Pijacka,[1] Carl Matthews,[2] Steven Rust,[2] Kevin Woollard,[1] Lorraine M. Irving.[2] Bioscience Renal In-vitro Team UK *[1]Bioscience Renal, Early CVRM, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [2]High Content Imaging Team, ADPE, R&D Biopharmaceuticals, AstraZeneca, Cambridge, United Kingdom.*

Background: Damage and eventual loss of podocytes is a hallmark of CKD. A key hurdle in the investigation of podocyte loss/damage is the lack of automated relevant cell-based screens. Existing techniques are time consuming and low throughput and cannot be used effectively in drug discovery. Here we describe a novel automated high throughput assay to evaluate and quantify podocytes in animal models of kidney disease.

Methods: Sprague Dawley rat glomeruli were isolated by differential sieving without enzymatic digestion, and plated in 384 well plates. Podocyte quantification was performed using a triple immunofluorescence detection of WT1, Nephrin and DAPI using confocal microscopy Opera QEHS. 3D glomeruli images created by 60X acquisition of 42 planes with 2 μm spacing were quantified using a customised algorithm using Columbus Analysis System that was developed to exclude artefacts, allow normalisation and ensure unbiased analysis. Tailored readouts include glomeruli number and morphology, podocyte number and nephrin expression.

Results: Podocyte identification was based on co-localization of WT1 and nephrin in a specific pattern in a 3D tilt glomerular reconstruction. Capsule cell positive for WT1 were excluded. Analysis was normalized for glomerular area by DAPI staining. We validated the assay using various doses of adriamycin (ADR) to induce podocyte loss. At low dose (50 nM), ADR decreases nephrin expression and changed its localisation, consistent with podocyte damage. At high ADR doses 500nM and 1μM, podocyte loss was evident (31.5-50%), with extensive glomerular damage at 1 μM. We then studied the effect of Ang II on podocyte damage using the same technique: preliminary data indicates that Ang II (100pM-1μM) caused significant podocyte damage (nephrin membrane reorganization) but no podocyte loss.

Conclusions: We have successfully developed a tool to allow high throughput automated assessment of podocyte health in isolated glomeruli. This automated 3D-High Content Imaging platform enables candidate target validation and drug identification.

TH-PO1085

Rapid Progression of Glomerulosclerosis due to Concurrent Diabetes and Hypertension Correlates with Podocyte Damage Shown by Expansion Microscopy

Yalcin Kuzay,[1] Euan Clark,[1] Sara Medina balbuena,[2] Benito Yard,[2] John Mullins,[3] Wilhelm Kriz,[4] Hermann-Josef Gröne,[5] Sigrid C. Hoffmann.[1] *[1]Medical Research Centre, University Heidelberg, Mannheim, Germany; [2]V Medical Clinic, University Heidelberg, Mannheim, Germany; [3]University of Edinburgh, Edinburgh, United Kingdom; [4]University Heidelberg, Mannheim, Germany; [5]university of Marburg, Paderborn, Germany.*

Background: Glomerulosclerosis is a hallmark of diabetes (D) and hypertension (HT) induced kidney failure. Here we studied the combined effect of D-HT on the kidney using expansion microscopy for nanoscale imaging of podocyte foot processes (FP).

Methods: In 6-week-old male double transgenic rats (dTGRNeph-hAT1R;Cyp1a1mRen2dF1=dTGR) and TGRCyp1a1mRen2d (TGR) we induced for 8 weeks D by streptozotocin (60mg/kg i.p.) and HT by indol-3-carbinol (0.0125% in chow), alone or in combination (D-HT). After perfusion with 2%PFA, kidneys were ~4.5 times expanded using acrylamide/sodium-acrylate gel embedding, SDS/75°C+90°C denaturation, podocin immunohistochemistry and imaging by confocal microscopy after expansion in H2O. We measured FP width as the distance between two podocin signals and normalized for the expansion factor.

Results: D-HT-WT rats developed massive albuminuria (D-HT 240mg vs HT 20mg, controls 1.5 mg per 24hr) and a drop in GFR (D-HT: 4-fold, HT: 1.6 fold vs. controls), which correlated with histological alterations in glomeruli, including mesangial expansion, podocyte loss and adhesion of the glomerular tuft to the Bowman's capsule. HT rats showed very mild histological injury. D rats did not differ from controls. AT1R overexpression in podocyte aggravated the glomerular damage, drop in renal function in HT and D-HT but did not affect controls. Glomerular size increased similarly in both HT and D-HT and did not differ between dTGR and TGR. In dTGR- and TGR-controls, podocyte FP architecture was regular with long thin processes (200±20 nm width). In HT, FP were homogenously shortened and widened. In D-HT, FP structure within one glomerulus varied from regular with shortened and widened FP to irregular structures to regions with total loss of FP (average FP width 400±20 nm).

Conclusions: In contrast to D and HT, combined HT+D induced rapid progression of glomerulosclerosis and podocyte damage. Podocyte's AT1Rs aggravate damage index. ExM enabled visualization of nanoscale alterations in FPs in 3-D by using traditional immunohistochemistry and confocal microscopy. *Acknowledgements: This study was funded by DFG, CRC 1118 to SH*

TH-PO1086

New Animal Model of Non-HIV Collapsing Glomerulopathy

Eduardo Molina-Jijon,[1] Stephanie Gambut,[2] Carmen Avila-Casado,[3] Lionel C. Clement,[4] Maria Del Nogal Avila,[4] Sumant S. Chugh,[4] Camille E. Mace.[4] *[1]Internal Medicine, Rush University, Chicago, IL; [2]Rush Medical Center, Chicago, IL; [3]University Health Network, University of Toronto, Toronto, ON, Canada; [4]Rush University Medical Center, Chicago, IL.*

Background: Collapsing glomerulopathy, usually classified as a form of focal and segmental glomerulosclerosis (FSGS), is the most severe and progressive form of glomerular disease. Most patients end up developing end stage kidney disease that requires dialysis or transplantation. There is presently no specific treatment for non-HIV collapsing glomerulopathy. Absence of animal models of non-HIV form of this disease was a problem in the past.

Methods: Transcriptional factor Zhx2 was overexpressed in rat podocytes under the control of the native human NPHS2 promoter. Two transgenic (TG) rat lines were generated: 142 and 144 which show increased expression of glomerular Zhx2 mRNA by 50.7% and 309.8% respectively. These 2 lines do not have any phenotype at baseline. We induced Adriamycin nephrosis, a model of FSGS, in wild type and heterozygous transgenic rats (7.5 mg of Adriamycin per kg/BW) and assessed for proteinuria and light microscopy at day 3 and 7 after injection. Different doses of Adriamycin (6.5 and 5.0 mg per kg/BW) were also injected in 144 transgenic rats, and studied at day 2, 5 and 9.

Results: TG 144 and TG 142 rats had significantly higher proteinuria than wild type rats following induction of Adriamycin nephrosis (7.5 mg per kg/BW). Renal histology in TG 144 rats on Day 7 revealed extensive glomerular collapse whereas no collapsing phenotype was noted in TG 142. Injection of 6.5 and 5.0 mg of Adriamycin per kg/BW in TG 144 rats, induced significant proteinuria starting at day 5 and that still continue to rise at day 9. Light microscopy images show classic feature of collapsing glomerulopathy (Collapsed glomeruli, retraction, prominent VEC…) only in TG 144 rats injected with 6.5 mg. 144 TG rats injected with 5.0 mg dose show classic feature of FSGS.

Conclusions: ZHX2 transgenic rats injected with Adriamycin represent a new animal model of non-HIV collapsing glomerulopathy. Longitudinal glomerular gene expression analysis will be performed to study molecular mechanisms of development of the disease in wild type and ZHX2 144 TG rats at 6.5 mg per kg/BW dose.

TH-PO1087

Common Cold-Induced Cytokines Storm Induces Glomerular Disease Relapse in the ZHX2-Deficient State

Maria Del Nogal Avila,[1] Hector Donoro blazquez,[1] Joubert B. Kharlyngdoh,[1] Ranjan Das,[1] Eduardo Molina-Jijon,[1] Carmen Avila-Casado,[2] Camille E. Mace,[1] Lionel C. Clement,[1] Sumant S. Chugh.[1] *[1]Rush University Medical Center, Chicago, IL; [2]Department of Pathology, Toronto General Hospital, University of Toronto, Toronto, ON, Canada.*

Background: Relapse or worsening of glomerular diseases like MCD and FSGS is commonly found after a common cold. Different cytokines and soluble receptors increase in circulation by or in response of the infection agent. We developed and tested a 'cytokine cocktail' composed of 7 of these cytokines and we assessed it in different animal models of Zhx2 deficiency or FSGS.

Methods: A common cold cytokine cocktail (dose X) containing IL-2, IL-4R, IL-6, IL-10, INF-γ, TNF-α and ICAM-1 was injected into control (BALB/c, n=-5) and Zhx2 deficient mice (BALB/cJ, n=5). Different doses of the cocktail and the effect of individual cytokines was assessed. Podocyte specific Zhx2 deficient ($Zhx2^{flox/flox}$ $cre^{+/+}$, n=3) and floxed control mice ($Zhx2^{flox/flox}$, n=3) (dose X/15); mice deficient in Ephrin B1 or both Zhx2 and Apa were also injected with the cytokine cocktail (dose X/5). Buffalo Mna (B. Mna) rats were injected with the cytokine cocktail (X/50) to study relapse in FSGS (n=7).

Results: Common cold cytokines induced acute albuminuria in BALB/cJ mice (65.3±24.3 μg per 18h), but not in BALB/c (10.8±1.5 μg per 18h), compared with baseline (BALB/cJ 5.1±1.1 μg per 18h; BALB/c 6.5±1.1 μg per 18h) ($p<0.05$), having higher nuclear expression of Zhx1 but not Zhx3. Individually, none of these cytokines caused albuminuria in either strain. Reducing 50% the dose X still induced significant albuminuria in BALB/cJ mice (15.3±0.6 μg per 18h) compared with baseline (2.8±0.9 μg per 18h) ($p<0.05$). Eliminating individually from the cocktail 3 different cytokines against which antibodies are in clinical use (IL-4R, IL6, TNF-α) also eliminated albuminuria in BALB/cJ mice. Cytokine induced albuminuria was also noted in $Zhx2^{flox/flox}/cre^{++}$, but not in control $Zhx2^{flox/flox}$ mice. Mice deficient in APA also developed albuminuria, and it is higher when mice are deficient in both Zhx2 and APA. Mice lacking Ephrin B1 in podocytes did not develop albuminuria. B. Mna rats had a significant increase in proteinuria (61.5±4.2) from baseline (47±4.1), using a much lower dose (X/50) of the rat "cytokine cocktail".

Conclusions: These findings suggest that an altered Zhx2 expression and its transmembrane partners predispose to MCD and FSGS relapse following a common cold.

TH-PO1088

Identification of Podocyte Secreted Proteins That Drive Parietal Epithelial Cell Proliferation in a Murine Model of Proliferative Glomerulopathy

Jesse A. Pace, Yiqing Guo, Chelsea C. Estrada, Sandeep K. Mallipattu. *Stony Brook Medicine, Stony Brook, NY.*

Background: Podocyte injury contributing to parietal epithelial cell (PEC) proliferation is a dominant histologic feature in both rapidly progressive glomerulonephritis and subtypes of focal segmental glomerulosclerosis (FSGS), however factors mediating this cross-talk remain unclear. We recently showed that podocyte-specific loss of Krüppel-like factor 4 (*Klf4*), a zinc-finger transcription factor, activates STAT3 signaling leading to mitotic catastrophe in podocytes and eventual FSGS, while triggering PEC proliferation in mice. We utilized this model to identify novel factors secreted by the injured podocyte that drive PEC proliferation.

Methods: Initially, RNA-seq was conducted on glomeruli isolated from mice with podocyte-specific deletion of *Klf4* ($Klf4^{\Delta POD}$) and controls ($Klf4^{fl/fl}$). Since our previously reported data demonstrate that conditioned media (CM) isolated from cultured human podocytes with *KLF4* knockdown (*KLF4-shRNA*) triggers PEC proliferation, we performed quantitative mass spectrometry (iTRAQ) on CM from *KLF4-shRNA* and EV-*shRNA* cultured human podocytes from day 1 to 3 of differentiation. Subsequent differential expression and ChIP-enrichment analysis was performed to identify STAT3-dependent and independent secreted factors by the podocyte that drive PEC proliferation.

Results: Pathway analysis revealed that 421 genes were upregulated in $Klf4^{\Delta POD}$ glomeruli and were related to ECM organization and focal adhesion, whereas 179 identified downregulated genes were enriched for genes critical to podocyte protein-protein interactions, actin cytoskeleton, and cell differentiation. Proteins upregulated in *KLF4-shRNA* as compared to EV-*shRNA* CM were involved in similar pathways. These differentially expressed transcripts from RNA-seq were cross-matched with upregulated proteins from iTRAQ to identify factors that drive PEC proliferation. Published ChIP-seq datasets were used to identify top candidates containing STAT3 binding sites (PAI-1 and CYR61) and those without (PRSS23 and S100A6). These transcripts were then validated by qPCR in $Klf4^{\Delta POD}$ treated with STAT3 inhibitor, S3I-201.

Conclusions: Using a model of proliferative glomerulopathy (podocyte-specific Klf4 knockdown), we identified novel signaling molecules secreted by the injured podocyte that might drive aberrant PEC proliferation.

Reciprocal Regulation Between ANLN and AKT Modulates Podocyte Proliferation

Gentzon Hall,[1] Guanghong Wu,[4] Shelby Strickland,[2] Maria E. Kovalik,[2] Benjamin A. Sempowski,[1] Brandon M. Lane,[2] Megan Chryst-Stangl,[3] Robert F. Spurney,[1] Rasheed A. Gbadegesin.[1] *[1]Duke University Medical Center, Durham, NC; [2]Duke University, Durham, NC; [3]Duke Molecular Physiology Institute, Durham, NC; [4]Duke university, Durham, NC.*

Background: We previously reported that mutations in anillin (ANLN) cause familial FSGS; however, the physiologic functions of ANLN in podocytes remain unknown. ANLN is widely recognized as a driver of cell survival signaling and proliferation through its CD2AP-mediated interactions with the PI-3K/p85/AKT signaling module. We previously showed that ANLN expression is upregulated in proliferating podocytes and described a dynamic modulation of AKT activation with alterations in ANLN expression. Here, we evaluated the reciprocal influence of AKT on ANLN activity and expression in podocytes.

Methods: We established stably expressing $ANLN_{WT}$-, $ANLN_{S659E}$-, $ANLN_{S659A}$, *ANLN siRNA, AKT1 siRNA, STAT3 siRNA,* β-*Catenin siRNA* and scrambled siRNA podocyte lines. We evaluated the lines in proliferation and apoptosis assays and in complimentary biochemical pathway analyses.

Results: *ANLN Expression* - ANLN expression was markedly reduced with AKT inhibitors and in *AKT1* knockdown (KD) podocytes. We screened the ANLN promoter to search for transcription factors regulated by AKT and identified multiple candidate binding sequences for β-Catenin and STAT3. ANLN expression was significantly reduced in β-*Catenin* and *STAT3* KD podocyte lines and phosphorylation/activation of β-Catenin was downregulated in *AKT1* KD podocytes. Conversely, STAT3 phosphorylation was upregulated in *AKT1* KD podocytes suggesting a compensatory function of STAT3 activation in *AKT1* KD podocytes. *ANLN Phosphorylation* - We identified a highly conserved AKT phosphorylation motif (i.e. R-X-X-S_{658}) in the ANLN F-actin binding domain. We generated a phospho-specific $ANLN_{S658}$ antibody and observed that phosphorylation of ANLN at Ser658 was abrogated in $ANLN_{S658A}$-expressing podocytes demonstrating the specificity of the antibody. Podocytes expressing $ANLN_{S658E}$ exhibited significantly enhanced proliferation relative to $ANLN_{WT}$- and $ANLN_{S658A}$-expressing podocytes suggesting that AKT may enhance the activity/stability of ANLN via direct phosphorylation of Ser658.

Conclusions: ANLN and AKT dynamically regulate one another to modulate podocyte proliferation. This study delineates the mechanisms of this reciprocal regulation and highlights potential therapeutic targets for the treatment of ANLN-induced podocyte dysfunction.

Deletion of p38 MAPK in Podocytes Aggravates Glomerular Injury by Aldosterone in Podocyte-Specific GC-A Knockout Mice

Sayaka Sugioka,[1] Yukiko Kato,[1] Akira Ishii,[1] Keita P. Mori,[2] Keisuke Osaki,[1] Takeshi Tokudome,[3] Taiji Matsusaka,[4] Motoko Yanagita,[1] Hideki Yokoi.[1] *[1]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]TMK Project, Medical Innovation Center, Kyoto University Graduate School of Medicine, Kyoto, Japan; [3]Department of Biochemistry, National Cerebral and Cardiovascular Research Institute, Osaka, Japan; [4]Department of Basic Sciences, Tokai University School of Medicine, Isehara, Japan*.

Background: Previously, we demonstrated that uninephrectomized aldosterone-infused, high salt-fed podocyte-specific guanylyl cyclase-A (natriuretic peptide receptor 1) conditional KO (pod-GC-A cKO) mice exhibited glomerular injury and that pharmacological inhibition of p38 MAPK ameliorates podocyte damage. However, the effects of genetic deletion of p38 MAPK in podocytes of pod-GC-A cKO mice have been unknown.

Methods: We generated p38 MAPK(fl/fl);Nephrin-Cre (pod-p38 MAPK cKO) mice and p38 MAPK(fl/fl);GC-A(fl/fl);Nephrin-Cre (pod-p38MAPK/GC-A DKO) mice. For induction of glomerular injury, we treated them with aldosterone and high salt at 2 months of age for 3 weeks without nephrectomy (B-ALDO). *In vitro*, we examined the effect of p38 MAPK inhibitor in cultured human podocytes transfected with GC-A siRNA.

Results: B-ALDO-treated pod-p38 MAPK/GC-A DKO mice resulted in significant elevation of serum Cr (0.29 ± 0.04 mg/dl), massive albuminuria (42,660 ± 20,200 mg/mgCr) and severe foot process effacement in addition to intracapillary fibrin thrombi which indicated endothelial damage. Vehicle-treated DKO mice, B-ALDO-treated pod-GC-A cKO mice, and B-ALDO-treated pod-p38 MAPK cKO showed normal serum Cr levels (0.14 ± 0.01, 0.18 ± 0.02, 0.20 ± 0.01 mg/dl, respectively), mild increase of albuminuria (223 ± 6.5, 1496 ± 592, 649 ± 303 mg/mgCr, respectively) and only segmental foot process effacement. Blood pressure was not elevated in either mutant mice compared with that of B-ALDO control mice. Furthermore, glomerular mRNA expressions of MCP-1, PAI-1, and FN were upregulated and that of VEGF-A was downregulated in DKO mice. Consistent with this, suppression of GC-A mRNA expression by siRNA in combination with p38 MAPK inhibitor downregulated VEGF mRNA in human cultured podocytes.

Conclusions: Genetic p38 MAPK deletion in GC-A-nul podocytes exacerbated aldosterone-induced glomerular endothelial cell injury as well as podocytes, and resulted in renal dysfunction, probably through VEGF downregulation. These results suggest p38 MAPK in podocytes is necessary to protect endothelial and epithelial cells from aldosterone-induced injury.

TH-PO1091

ARHGEF7 (β-PIX) Protects Podocytes from Cell Apoptosis via Cdc42 Activation

Jun Matsuda, Mirela Maier, Lamine Aoudjit, Tomoko Takano. *McGill University Health Centre, Montreal, QC, Canada*.

Background: Rho-family small GTPases (Rho GTPases), including Rac1 and Cdc42, are important for podocyte functions. β-PIX, encoded by ARHGEF7, is a guanine nucleotide exchange factors (GEF) that activates Rac1 and Cdc42. Recently, we established that podocyte-specific β-PIX deficient (KO) mice develop progressive proteinuria starting at ~8 weeks of age, and glomerulosclerosis and podocyte loss by 13 weeks of age. Here, we investigated the mechanism of podocyte loss induced by β-PIX deficiency, with a particular focus on the pro-survival transcriptional co-activator, Yes-associated protein (Yap), which is known to be activated by Cdc42.

Methods: Cultured mouse podocytes (MP) with β-PIX knockdown (KD) and their controls were established using shRNAs. Rac1/Cdc42 activity was assessed by pull-down assay. Rho/Rac/Cdc42 Activator I (Cytoskeleton, CN04) and Adriamycin (ADR) were used as a general Rho GTPase activator and a podocyte toxin, respectively. Apoptosis was studied by TUNEL staining and immunoblotting for cleaved caspase 3 (CC3). Nuclear translocation and activity of Yap were assessed by immunostaining and the TEA domain (TEAD)-luciferase assay. Data are provided as the mean ± SE.

Results: Cdc42, but not Rac1 activity, was significantly decreased by 34% in isolated glomeruli from 5-week-old β-PIX KO mice, compared with controls (n=7-10, $p<0.05$). Similarly, Cdc42, but not Rac1, activation in β-PIX KD MP was significantly blunted by 46%, compared with control MP (n=4, $p<0.01$). At 6 hrs after ADR treatment, KD MP showed 9.4±2.5 % TUNEL-positive cells, as compared with 3.8±0.7 % in control MP (n=3, $p<0.05$). CC3 was also increased in KD MP. Correspondingly, there were less adherent KD MP at 8 hrs of ADR treatment, compared with control MP. Control MP showed predominant nuclear localization of Yap, while KD MP exhibited partial cytoplasmic retention (Nuclear/Total Yap ratio; Control: 0.90±0.02; KD: 0.80±0.04, n=10, $p<0.05$). The TEAD-luciferase activity was significant lower in KD MP than in control MP (Control: 10.3±1.3; KD: 6.9±0.76 a.u., n=9, $p<0.05$). mRNA expression of the Yap target genes by RNA-seq were significantly reduced in the glomeruli of KO mice.

Conclusions: Loss of β-PIX in podocytes resulted in increased apoptosis and detachment from matrix. This may be mediated by the cytoplasmic retention and decreased transcriptional activity of Yap via decreased Cdc42 activity.

TH-PO1092

Role of Pyruvate Kinase M2-Mediated Metabolic Reprogramming During Podocyte Differentiation

Qi Sun, Junwei Yang. *Second Affiliated Hospital, Nanjing Medical University, Nanjing, China*.

Background: Podocyte, a type of highly specialized epithelial cells with sophisticated foot processes and unique slit diaphragm, requires substantial levels of energy to maintain its integrity and function, but little is known on the regulation of podocyte's energetics. Lack of metabolic analysis during podocyte development led us to explore the role of cellular metabolism and mitochondrial biology during *in vitro* differentiation.

Methods: To study the metabolic alterations caused by differentiation, nuclear magnetic resonance (NMR) spectroscopy was performed to analyze the metabolomic profiling of differentiated and un-differentiated cultured mouse podocytes. Cell metabolism was measured by seahorse XF analyzer. Mitotracker Red CMXRos and MitoProbe JC-1 Assay Kit were used to identify mitochondrial morphology, mass and membrane potential. *Pkm2*-RNAi-Lentivirus was used to explore the regulating role of PKM2 during podocyte differentiation.

Results: In this study, we observed a huge increase in mitochondrial biogenesis. Changes in mitochondrial mass, morphology and function were correlated with the upregulation of the master regulators of mitochondrial biogenesis, TFAM and PGC-1α. Unexpectedly, concomitant with mitochondrial biogenesis, we observed an increase in glycolysis during podocyte differentiation, which was linked to the overexpression of glycolic enzymes. Among them, PKM2 was of particular interest. The real-time quantitative PCR and PK activity assay kit showed both pyruvate kinase M2 (PKM2) expression and activity were upregulated. Knockdown of *Pkm2* showed dramatic reduction of glycolysis and mitochondrial function, resulting in the defects of podocyte differentiation.

Conclusions: Usually, differentiated cells have repressed glycolysis, as they mostly rely on OXPHOS for energy demand. Our findings here first demonstrate that differentiated podocytes boost both glycolysis and mitochondrial metabolism to meet their augmented energy demand. We identified PKM2 as a critical regulator of energy metabolism in podocytes. Selective inhibition of PKM2 indicate existence of metabolic checkpoint that need to be satisfied in order to allow podocyte differentiation.

TH-PO1093

Human Podocyte Modifies Energy Metabolism During Differentiation

Jessica M. Vasquez, Sandeep K. Mallipattu. *Stony Brook Medicine, Stony Brook, NY*.

Background: Previous studies have shown increased oxidative phosphorylation (OXPHOS) with podocyte differentiation and decreased OXPHOS with hyperglycemia. Little is known about the rate of synthesis of mitochondrial proteins or how other components of metabolism, such as the TCA cycle and fatty acid oxidation, change with podocyte differentiation. The goal of this project is to identify metabolic pathways that are required for podocyte differentiation.

Methods: MTS, ATP abundance, and ATP/ADP ratios were done to ensure human podocyte viability and confirm changes in metabolism during differentiation. Oxygen consumption rate (OCR) and Extracellular Acidification Rate (ECAR) were done by SeaHorse at 3, 7, 10, and 14 days of differentiation and compared to undifferentiated cells. Immunostaining for TOMM20 was performed and quantified. SILAC was done in 12 hour pulses with heavy arginine and lysine and subsequent mitochondrial isolation was performed to determine mitochondrial protein synthesis in differentiating podocytes (with pathway enrichment analysis).

Results: We observed a stepwise increase in OXPHOS during differentiation characterized by an increase in mitochondrial biogenesis (TFAM protein quantification), network (TOMM20 staining), and increased mtDNA copy number. With differentiation, we observed an increase in total ATP but a decrease in ATP/ADP ratio. MTS assay showed no significant changes with cell differentiation. Unlabeled proteomics abundance showed the greatest increase in OXPHOS (specifically in complex 1 and 5) followed by TCA cycle. We also observed a significant decrease in mitochondrial fission proteins and an increase in mitochondrial fusion with differentiation. The most dynamic proteins with high abundance and high heavy to light (H:L) ratios during differentiation were ATP5B, NDUFS6, and OXA1l, reinforcing the importance of OXPHOS with differentiation. The most stable proteins with high abundance and low H:L ratios were involved in TCA cycle, fatty acid degradation, arginine and proline metabolism and valine, leucine and isoleucine degradation pathways (KEGG 2019 Human).

Conclusions: These data suggest that podocyte differentiation is dependent on an increase in mitochondrial biogenesis and network with a switch in metabolic programming to oxidative phosphorylation.

Using CRISPR/Cas9 to Generate Second-Generation Cell Lines Used for Detecting Recurrent Focal Segmental Glomerulosclerosis (rFSGS) Patients

Pankaj Srivastava, Ashish K. Solanki, Ehtesham Arif, Bushra Rahman, Peifeng Deng, Deepak Nihalani. *Medical University of South Carolina, Charleston, SC*.

Background: The gold standard for diagnosing glomerular diseases including FSGS requires invasive procedures such as renal biopsy, which may not be safe or feasible to perform in all patients. Recently, we published a cell-based assay for diagnosing rFSGS

patients, which involved constructing cell lines using the rFSGS responsive genes BMF, IL-1β and IGFBP3. While the assay specifically diagnosed rFSGS pateints, the overall assay response was low (~1.5 fold increase over control). To boost the assay response and increase its specificity, a CRISPR/Cas9-based precise genome editing approach was employed, where highly specific and responsive second generation cell lines were created.

Methods: The Genome-CRISPR/Cas9 human AAVS1 Safe Harbor *knock in* kit-Puro (Cat# SH012) from GeneCopoeia, Inc. was used to individually *knock in* BMF, IL1-β or IGFBP3 gene promoter-Luciferase ORF' cassette at the AAVS1 locus in HEK293 cells. PCR analyses were used to determine correct insertion of donor cassette at the AAVS1/ safe harbor site. The response of constructed cell lines towards patient plasma from rFSGS and control patients was tested using a luciferase-based reporter assay.

Results: Remarkably, these cell lines showed significantly increased response to rFSGS patient plasma when compared to plasma from either control or non-rFSGS patients. An increase from ~1.5 fold (originally reported) to more than 10 fold was observed. Moreover, the response was consistent and showed more than 90% specificity in detecting rFSGS patients.

Conclusions: We present here the development and validation of a second-generation cell lines used for diagnosing rFSGS patients that are superior to conventional stably transfected cell lines. Unlike the first-generation cell lines, the second-generation cell lines have defined integration at the "safe harbor locus". These cell lines are highly responsive and demonstrate low variability. Overall, our assay is noninvasive, highly sensitive and specific, and studies are being planned for conducting clinical trials to utilize its full diagnostic potential.

Lanosterol Synthase Genetic Variant rs2254524 V642L and Its Role in the Pathogenesis of Kidney Disease

Lorenza Macrina,[1,2] Paolo Manunta,[2] Judith T. Molina David,[1] Lorena Citterio,[2] Sipontina Faienza,[2] Marco Simonini,[2] Javier T. Varona Santos,[1] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]University of Miami, Miami, FL; [2]San Raffaele Scientific Institute, Milan, Italy.*

Background: A single nucleotide polymorphism in the Lanosterol Synthase (LSS) gene, rs2254524, has been recently associated with an increased susceptibility to renal damage and increased Endogenous Ouabain (EO) content in human kidney. Our hypothesis is that the presence of the genetic variant rs2254524 causes increased susceptibility to EO-mediated glomerular damage and impairs cholesterol metabolism leading to podocyte injury.

Methods: Two immortalized human podocyte cell lines, one homozygous (LSS AA) the other heterozygous (LSS AC) for the LSS mutant variant, were used in this study. LSS expression in podocytes was verified by RT-PCR, Western blot and immunofluorescence. Apoptosis and cytotoxicity were assessed 5 days post-treatment with EO using the ApoTox-Glo Triplex Assay. The number of lipid droplets (LDs) per cell was assessed by Nile Red staining after 24h of treatment with EO 10^{-9} M, puromycin 100 μg/ml and TNFα 100 ng/ml, alone and in combination with $CoCl_2$ 100 μM.

Results: We demonstrate for the first time that LSS is expressed in human podocytes. Dose-dependent cytotoxicity of EO was observed only in LSS AA podocytes while dose-dependent apoptosis occurred in both, LSS AA and AC podocyte cell lines. Using *in vitro* models of podocyte injury (e.g. exposure to puromycin or inflammatory cytokine TNFα alone and in combination with $CoCl_2$), we demonstrated that LSS AA podocytes are more susceptible to LDs accumulation when compared to LSS AC podocytes. However, there was no increase in LDs when cells were exposed to EO.

Conclusions: Our data indicate that individuals that carry two LSS mutant variants (rs2254524) are more susceptible to EO-mediated podocyte cytotoxicity. Moreover, the mutation might render podocytes susceptibleto accumulate LDs under certain stress conditions which may contribute to podocyte injury.

TH-PO1096

Bag3 as Potential Mechanoprotector in Renal Podocytes

Ingo Plagmann,[1,2] Markus M. Rinschen,[3,1] Karim Heinlein,[1,2] Jan C. Degenhardt,[1,2] David Unnersjö-Jess,[4] Bernhard Schermer,[1,2] Thomas Benzing.[1,2] *[1]Department II of Internal Medicine and Center for Molecular Medicine, University of Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; [3]The Scripps Research Institute, La Jolla, CA; [4]Department of Applied Physics, KTH Royal Institute of Technology, Stockholm, Sweden.*

Background: Loss of podocytes in the course of glomerular diseases leads to glomerulosclerosis and progressive kidney disease. Due to their exposed location on the outside of the glomerular basement membrane podocytes are subjected to extensive mechanical strain by perfusion and filtration. These forces are even higher in disease states such as diabetic nephropathy. Overtaxing adaptive mechanisms causes podocyte detachment which in turn increases the mechanical stress for remaining podocytes. The precise mechanisms involved in this vicious circle are yet insufficiently defined. Bag3 is an important mechanoprotector protein in mechanically strained tissues. It replaces mechanically unfolded proteins by chaperone-assisted-autophagy (CASA) and regulates proteins like Filamin A and Synaptopodin, that play a central role in podocyte biology. Above all Bag3 is an important player in diabetic nephropathy in a mouse model. All this brings Bag3 in a prime position as a candidate mediator of mechanical stress protection in podocytes.

Methods: We examined podocytes by immunofluorescence, super-resolution-microscopy and mass-spectrometry for Bag3 expression and characterized the Bag3 interactome using immunoprecipitation. Mechanical stress was induced by stiff matrices and cyclic stretch. The role of Bag3 *in vivo* is being evaluated in two different mouse lines (Bag3.P209L mutation and a conditional knockout).

Results: Bag3 expression can be shown inside the glomerulus with podocytes displaying a Bag3 enrichment in mass-spectrometry data. Furthermore Bag3 expression is regulated by mechanical clues in podocyte cell lines and first interactome results point towards a function at the liquid stress-granula interface. Preliminary analyses of the myopathy causing mutation Bag3.P209L revealed a mild albuminuria starting at an age of 8-12 weeks in a whole-body overexpression mouse line.

Conclusions: Our findings point towards an important role of Bag3 and chaperone-assisted-selective-autophagy in podocytes and their mechanical stress protection. Bag3 localization at the slit diaphragm in STED-imaging further corroborates this hypothesis. Further studies based on two podocyte specific mouse lines (Bag3 mutation and conditional knockout) are currently ongoing to understand the role of podocyte-Bag3 *in vivo* under healthy conditions and in glomerular disease.

TH-PO1097

PAR-CLIP Identification of Cell Type and Context-Specific miRNA/mRNA Interactions

Debra L. Walter, Huanqing Zhang, Hongyu Zhang, Christopher L. O'Connor, David L. Turner, Markus Bitzer. *University of Michigan, Ann Arbor, MI.*

Background: miRNA have been implicated as mediators of acute and chronic kidney diseases and as intervention targets. miRNA:mRNA interactions are highly complex and are poorly explored in kidney cells. We applied *in vitro* and *in silico* methods to identify miRNA:mRNA interactions in two cultured kidney epithelial cells and in response to TGFB1, a common damage-associated cytokine.

Methods: Immortalized human podocytes and proximal tubular (HK2) cells were treated with TGFB1 (20 ng/mL) or vehicle for 24 hours (approx. 1 mio cells per sample; n=2). Photoactivatable ribonucleoside-enhanced crosslinking and immunoprecipitation (PAR-CLIP) was used to identify miRNA:mRNA interactions. Target genes identified by PAR-CLIP were compared with miRNA targets identified by computational prediction algorithms. RNA-seq and small-RNA-seq were performed in parallel.

Results: PAR-CLIP identified 3,645 genes targeted by miRNAs in both cell types, while 117 and 24 genes were targeted only in podocytes or HK-2 cells, respectively. 3,744 genes were targeted in TGFB1 and vehicle-treated samples, while 39 and 3 genes were targeted only in cells exposed to TGFB1 or vehicle, respectively. Integration of cell type and treatment revealed that podocyte specific genes targeted by miRNAs after TGFB1 treatment, but not vehicle, were detected as targets in vehicle-, but not TGFB1-, treated HK2 cells, and vice versa. miR-21-5p had one cell type specific target in each podocytes and HK-2 cells, while miR-21-3p had only one gene specific target in HK2 cells. miRDB predicted 10-11%, Target Scan predicted 18-42% and RNA22 predicted 30-19% of PAR-CLIP identified genes per 5p and 3p arms, with limited overlap between different algorithms. RNA-seq identified 3,001 and 3,235 expressed genes in podocytes and HK2 cells, with 3,510 and 2,712 genes differentially expressed after TGFB1. 172 and 135 miRNAs were detected in podocytes and HK2 cells, with expression of 45 and 94 altered by TGFB1.

Conclusions: Together, we identified cell type and context specific targets for miRNAs, with the vast majority of miRNA targets detected in both epithelial cell types. However, miRNA target gene profiles may differ more in non-epithelial cells. Importantly, miRNA targets identified by PAR-CLIP are largely not predicted using computational algorithms.

TH-PO1098

Functional APOL1-miR193a Axis (AMA) Prevents Podocyte Injury

Vinod Kumar,[3] Himanshu Vashistha,[2] Xiqian Lan,[3] Harsha Adnani,[4] Maleeha Qayyum,[6] Sushma Chinnapaka,[6] Kamesh R. Ayasolla,[3] Ashwani Malhotra,[5] Karl Skorecki,[7] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Ochsner Health System, New Orleans, LA; [3]Feinstein Institute for Medical Research, Manhasset, NY; [4]Medicine, Feinstein Institute of Research, Manhasset, NY; [5]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [6]Northwell health, Jamaica, NY; [7]Rambam Health Care Campus, Haifa, Israel.*

Background: APOL1-miR193a axis plays a vital role in the maintenance of podocyte molecular phenotype. It is bifunctional in podocytes expressing APOL1G0 (wild-type). APOL1 inversely regulates miR193a expression and vice versa in podocytes. Both Puromycin aminonucleoside (PAN) or Adriamycin (ADR) are known to induce apoptosis in human podocytes. However, the role of APOL1-miR193a axis remain to be elucidated. We asked whether modulation of this axis carries a potential to prevent PAN- and ADR-induced podocyte injury.

Methods: Human podocytes (immortalized) stably expressing either vector (V-podocytes) or APOL1G0 (G0-podocytes) were differentiated (incubating in special media for ten days, V-D or G0-D). V-Dpodocytes and G0-Dpodocytes were incubated in media containing different concentrations of Adriamycin (5, 15, 30, and 35 nM) or PAN (0, 5, 10, 25, 50, and 100 nM) for 48 hours (n=6); in other sets, VD-podocytes and G0-Dpodocytes were treated with Adriamycin (30 mM) or PAN (50 nM), with/without miR193a inhibitor (25 nM) for 48 hours (n=6). Cells were evaluated for reactive oxygen

species (ROS) generation (DCF detection assay), caspase-3 cleavage, and apoptosis (TUNEL assay). Proteins and RNAs were extracted from cells treated under similar conditions (n=6). Protein blots were probed for APOL1 and caspase-3; RNAs were assayed for mIR193a. Differentiated podocytes (DPDs) were transduced with either empty vector or miR193a plasmid and evaluated for APOL1 and caspase-3 expression.

Results: G0-Dpodocytes showed a two-fold increase in expression of APOL1, but a 2.8-fold decrease in miR193a levels when compared to V-Dpodocytes. V-Dpodocytes showed increased (P<0.01) ROS generation and a higher (P<0.01) percentage of TUNEL +ve cells when compared to G0D-podocytes in Adriamycin and PAN milieus. Both Adriamycin and PAN displayed an upregulation in miR193a and caspase-3 expression in both V-D and G0-Dpodocytes from their baseline. MicroRNA193a inhibitor decreased miR193a levels, increased APOL1 expression, and attenuated number of TUNEL +ve cells in both Adriamycin and PAN milieus. DPDs overexpressing miR193a displayed reduced expression of APOL1 and enhanced cleavage of caspase-3.

Conclusions: Functional AMA prevents podocyte injury in adverse milieus through down-regulation of miR193.

TH-PO1099

P2X7 Expressed in Injured Podocytes May Spread the Kidney Injury Through Caspase 3

Kazuyoshi Yamamoto,[2,1] Masahiro Okabe,[1,2] Takashi Yokoo,[1] Taiji Matsusaka.[2]
[1]The Jikei University School of Medicine, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan.

Background: We previously generated a mosaic mouse model in which a fraction of podocytes express hCD25 and can be injured by a hCD25-directed immunotoxin, LMB2. After injection with LMB2, not only hCD25(+) but also hCD25(-) podocytes were injured along with dramatic induction of P2X7 mRNA in both types of podocytes. P2X7 is a receptor of extracellular ATP and is known to activate inflammation and induce cell death in immune cells. In the present study, we aim to analyze P2X7 protein expression in the mosaic mouse model and investigate the role of P2X7 in podocyte injury.

Methods: Kidneys were harvested from mosaic mice before or 2 weeks after injection with LMB2 (25ng/gBW). Immunofluorescence staining was performed with primary antibodies against P2X7 and cleaved-caspase 3. For functional study, primary cultured mouse podocytes were transiently transfected by electroporation with P2X7-expression or mock plasmid together with EGFP or tdTomato expression plasmid. Before or 1-2 hours after administration of ATP (0 or 2 mM), the same visual fields were photographed.

Results: No P2X7 staining was observed in the kidney without LMB2. In the kidneys injured by LMB2, which developed FSGS, 69.2±9.2% of glomeruli were positive for P2X7 staining. Some P2X7 staining was observed in GFP-labeled hCD25(-) podocytes, which indicated that indirect injury activated P2X7 expression. Cleaved-caspase 3 staining was also positive in 12.4±3.1% of glomeruli of LMB2-damaged kidneys, but not in those without LMB2. In *in vitro* studies, administration of ATP caused leakage of co-introduced EGFP in 51.7±1.4% of P2X7-transfected cells, incorporation of propidium iodide in 18.1±0.9%, and activation of caspase 3 in 17.9±2.8%. However, increase in LDH activity in the medium remained minimum, corresponding to only 3.0±1.7% of cell death. These phenomena were not observed in mock-transfected cells treated with ATP or P2X7-transfected cells without ATP administration. Caspase-3 inhibitor significantly attenuated the leakage of EGFP induced by ATP (26.4±2.6 vs 37.9±3.3%), whereas Caspase-1 inhibitor did not (37.0±3.0%).

Conclusions: These results indicate that injured podocytes express P2X7, which may further augment injury by inducing caspase-3 dependent apoptosis.

TH-PO1100

Expression Profile of the cGAS-STING Pathway in Podocytes: Implications for Glomerular Diseases

Antonio M. Fontanella,[1] Shamroop Kumar Mallela,[1] Judith T. Molina David,[1] George W. Burke,[2] Sandra M. Merscher,[1] Alessia Fornoni,[1] Alla Mitrofanova.[1]
[1]University of Miami, Enterprise, AL; [2]University of Miami Miller School of Medicine, Miami, FL.

Background: Recent studies suggest that podocytes express elements of the innate immune system which may be involved in the local immune response and contribute to glomerular damage. As part of the innate immune system, the cGAS-STING pathway is activated in response to cytosolic DNA and is involved in disease pathogenesis for systemic lupus erythematosus. Whether or not podocytes express genes in the pathway remains unknown. This study aims to investigate if genes in the cGAS-STING pathway are expressed in murine and human podocytes and if activation of this pathway by cyclic dinucleotides (CDNs) contributes to podocyte injury in glomerular diseases.

Methods: Immortalized human and murine podocytes were cultured. For treatments, podocytes were differentiated for 14 days and serum starved for 24h starting day 12. STING knockdown human podocytes were established by lentiviral infection with siRNA. c-diAMP treatment was performed in RPMI medium at concentration 10 uM for 24h starting day 13. Plasma membranes were separated by ultracentrifugation (100,000xg, 1h). Several mouse models of glomerular disease of metabolic (db/db, ob/ob) and non-metabolic origin (Alport, NFAT) were used. mRNA was extracted using Qiagen RNAeasy kit according to the manufacturer's protocol. Proteins were separated in 4-20% SDS-PAGE gels (BioRad) and transferred to nitrocellulose membranes for Western blot analysis. All monoclonal antibodies were obtained from Cell Signaling.

Results: Both murine and human podocytes showed expression of cGAS-STING pathway genes under physiological conditions. Treatment with c-diAMP increased expression of cGAS and phosphorylation of STING, IRF3 and TBK1. Notably, inactive STING was localized in the endoplasmic reticulum, while activate STING is translocated to the cytosol. STING knockdown podocytes did not respond to pathway activation after c-diAMP treatment. Among the mouse models of glomerular disease used in this study, only db/db and Alport mice showed increased cGAS-STING activity.

Conclusions: Genes of the cGAS-STING pathway are expressed in murine and human podocytes and the pathway can be activated by CDNs. Activation of the cGAS-STING pathway in mouse models of glomerular disease suggests a possible contribution of this pathway to podocyte injury.

Loss of Ubiquitin-Specific Protease 40 in Podocyte Enhances Kidney Injury

Naoaki Mikami,[1] Taiji Matsusaka,[2] Eriko Tanaka,[4] Kunio Kawanishi,[3] Michio Nagata,[3] Kunimasa Yan.[4]
[1]Kyorin University, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan; [3]University of Tsukuba, Tsukuba, Japan; [4]Kyorin University School of Medicine, Tokyo, Japan.

Background: Although an indispensable role of ubiquitin specific protease-40 (USP40) in podocyte development of zebrafish was revealed, downstream of USP40 function is still unknown. Since there is a close relationship between ubiquitin system and endoplasmic reticulum function, we aimed to explore the protein function of USP40 in the podocyte injury and to determine the interacting partner by focusing on ER resident chaperone.

Methods: USP40-knockout (USP40KO) mice were generated and showed no apparent kidney abnormality. To explore the role of USP40 in podocyte injury, we crossed USP40KO with NEP25 mice, in which selective podocyte injury can be induced by injection with an immunotoxin, LMB2. Urinary protein was analyzed until day 9 after LMB2 injection, and then kidney tissues were subjected to light microscopy, immunohistochemistry of p57 and immunofluorescence microscopy of the ER stress marker BIP and calreticulin (CRT). The glomeruli were isolated and subjected to immunoblot analysis of BIP and CRT. The effect of USP40 knockdown on BIP and CRT expression was studied in cultured mouse podocytes. Finally, the protein binding of BIP and CRT with USP40 was determined by immunoprecipitation using cultured mouse podocytes.

Results: NEP-USP40KO mice developed higher levels of proteinuria compared with NEP mice. Light microscopy and immunohistochemistry showed higher levels of kidney injury in NEP-USP40KO mice compared with NEP mice in terms of hyalinosis (p<0.01), crescent formation (p<0.01), and cell proliferation (p<0.01) in the glomeruli, podocyte loss (p<0.05), and tubulointerstitial injury (p<0.01). Immunoblot analysis and immunofluorescence revealed increased expression of CRT, but not of BIP, in podocytes of NEP-USP40KO mice compared with NEP mice. Gene knockdown of USP40 in cultured podocytes increased the protein expression of CRT, but not of BIP. Finally, apparent protein binding of USP40 with CRT, but not with BIP, was observed.

Conclusions: USP40 may be involved in a self-defense mechanism in podocyte injury probably through interacting with CRT.

TH-PO1102

A Urinary Metabolite Constellation to Detect Acute Rejection in Kidney Allografts

Miriam C. Banas,[3] Sindy Neumann,[2] Eric Schiffer,[2] Georg Bohmig,[1] Philipp Pagel,[2] Katharina Schäffler,[3] Bernhard K. Krämer,[4] Bernhard Banas.[3]
[1]Medical University Vienna, Vienna, Austria; [2]numares AG, Regensburg, Germany; [3]University of Regensburg - Nephrology, Regensburg, Germany; [4]Internal Medicine V, University Hosptal Mannheim, Mannheim, Germany.

Background: Post-transplant surveillance for acute rejection is mainly based on regular monitoring of serum creatinine levels and transplant biopsies upon functional renal impairment. Recently, we developed a novel method to detect kidney allograft rejection via a characteristic constellation of the urine metabolites alanine, citrate, lactate, and urea investigated by nuclear magnetic resonance (NMR) spectroscopy (Banas M et al., Metabolomics 2018).

Methods: Within the prospective, observational UMBRELLA study 986 urine specimens were collected from 109 consecutively enrolled renal transplant recipients and metabolite constellations were analyzed by NMR spectroscopy. A metabolite rejection score was calculated and compared to histopathological results of corresponding allograft biopsies (n=206).

Results: The metabolite constellation was found to be a useful biomarker to non-invasively detect acute allograft rejection (AUC = 0.75; 95% confidence interval (CI) 0.68 to 0.83; based on 46 cases with biopsy-proven rejection and 520 controls). A combination of the metabolite rejection score and the estimated glomerular filtration rate (eGFR) at the time of urine sampling further improved the overall test performance significantly (AUC = 0.84; 95% CI 0.76 to 0.91; based on 42 cases and 468 controls). In a subgroup of patients without rejection episodes the test results remained well below a diagnostic threshold associated with high risk of acute rejection. In other cases a marked increase above this threshold indicated an acute allograft rejection already 6-10 days before diagnostic renal biopsies were performed.

Conclusions: In conclusion, a combination of an NMR-based urine metabolite analysis and glomerular filtration rate is promising as a non-invasive test for post-transplant surveillance and to support decision making whether renal allografts need histopathological evaluation.

Plasma Neutrophil Gelatinase Associated Lipocalin (NGAL) Predicts Long-Term Graft Survival in Stable Kidney Transplant Recipients

Ricarda M. Hinz,[1,2] Jutta S. Swolinsky,[1,2] Carolin E. Markus,[1,2] Eugenia Singer,[1,2] Pimrapat Gebert,[3,5] Klemens Budde,[1] Kai-Uwe Eckardt,[1] Timm H. Westhoff,[4] Kai M. Schmidt-Ott.[1,2] AG Schmidt-Ott *[1]Nephrology and Medical Intensive Care, Charité-Universitätsmedizin Berlin, Berlin, Germany; [2]Max-Delbrück-Center for Molecular Medicine, Berlin, Germany; [3]Biometry and Clinical Epidemiology, Charité-Universitätsmedizin Berlin, Berlin, Germany; [4]Ruhr-University Bochum, Germany, Herne, Germany; [5]Berlin Institute of Health (BIH), Berlin, Germany*.

Background: Neutrophil gelatinase-associated lipocalin (NGAL) has been evaluated as a biomarker of acute tubular injury in the kidney. The utility of NGAL to predict long-term outcomes in stable kidney transplant recipients (KTR) is unknown.

Methods: We conducted a monocentric, prospective observational study enrolling 709 stable KTR more than two months after renal transplantation. Baseline characteristics, standard laboratory values, and plasma NGAL (pNGAL) levels were determined at the time of inclusion. Patients were followed up for death-censored graft loss, defined by a continued requirement for renal replacement therapy. The utility of pNGAL levels to predict graft loss was evaluated by Receiver Operating Characteristics (ROC) analyses, Cox regression as well as competing risk analyses and Kaplan-Meier estimates.

Results: During a median follow-up of 58 months, death-censored graft loss occurred in 49 patients. The median pNGAL within the entire cohort was 189 [IQR 130-257] ng/ml. Patients who later experienced graft loss had a pNGAL of 304 [IQR 234.5-358] ng/ml (p<0.001). Time-dependent ROC analyses indicated an Area-Under-the-Curve value for pNGAL of 0.795 to predict graft loss within 5 years. pNGAL >230ng/ml had a sensitivity of 0.82 and a specificity of 0.71. Multivariate Cox regression analyses as well as competing risk analyses showed that pNGAL was an independent predictor of graft loss after adjustment for clinical parameters and kidney function. Patients with serum creatinine (sCrea) values ≥ 1.75mg/dl and pNGAL ≥ 230ng/ml had an approximately 9-fold higher risk of graft loss compared with patients with sCrea ≥ 1.75mg/dl and pNGAL < 230ng/ml. (p<0.001).

Conclusions: pNGAL levels in stable KTR may help to predict long-term graft survival.

TH-PO1104

Urinary Biomarkers TIMP-2 and IGFBP7 Are Predictive for Recovery from Ischemia-Reperfusion Injury After Kidney Transplantation

Ute Eisenberger,[1] Onurcan Ertasoglu,[1] Hana Rohn,[1,3] Friebus-Kardash Justa,[1] Andreas Kribben,[1] Oliver Witzke,[3] Suzan Dahdal,[2] Spyridon Arampatzis,[2] Anja H. Gaeckler.[1] *[1]Nephrology, University Hospital Duisburg-Essen, Essen, Germany; [2]Inselspital, University of Bern, Bern, Switzerland; [3]Infectious Diseases, University Hospital Duisburg-Essen, Essen, Germany*.

Background: Conventional clinical markers often fail to predict recovery from ischemia-reperfusion injury in the early phase after kidney transplantation (KTx). Urinary tissue inhibitor of metalloproteinase-2 (TIMP-2) and insulin-like growth factor 7 (IGFBP7), markers for G1 cell cycle arrest, have been identified and validated for the early detection of renal injury in critical ill patients. We evaluated whether post-transplant urinary [TIMP-2]*[IGFBP7] can predict renal recovery early after KTx.

Methods: In a prospective observational multicenter cohort study of renal transplant recipients, urinary [TIMP-2]*[IGFBP7] (NephroCheck®; Astute Medical, San Diego, CA, USA) was evaluated daily from day 1-7 after KTx. Different stages of graft function were defined: immediate graft function (IGF) (decrease ≥ 10% s-crea within 24 h post KTx); slow graft function (SGF) (decrease <10% s-crea within 24 h post KTx) and delayed-graft function (DGF)(any dialysis during first week after KTx). Clinical and laboratory parameter were documented.

Results: A total of 186 KTx patients were analyzed, 138 (74%) with a deceased donor, 48 (26%) with a living donor KTx. IGF was observed in 58.6%, SGF in 23.1% and DGF in 18.3% of the cohort. [TIMP-2]*[IGFBP7] was significantly elevated in patients with DGF compared to other groups during the first week of transplant (Fig. 1). Renal function parameters were not able to differentiate between DGF and SGF early after Ktx. ROC-Analysis of [TIMP-2]*[IGFBP7] at day1 posttransplant for event "Non-DGF" revealed a cut-off value of 0,9 $(ng/ml)^2/1000$ (sensitivity 87%; specificity 71%). Positive predictive value for non-DGF was 93%.

Conclusions: Early [TIMP-2]*[IGFBP7] measurement can predict recovery from ischemia-reperfusion-injury post Ktx. [TIMP-2]*[IGFBP7] is a promising biomarker for clinical decision-making after KTx.

TH-PO1105

Predicting Transplant Rejection by a Composite Urinary Injury Score

Joshua Y. Yang,[1] Reuben D. Sarwal,[2] Tara Sigdel,[1] Minnie Sarwal.[1] *[1]University of California San Francisco, San Francisco, CA; [2]University of California, San Francisco, Portola Valley, CA.*

Background: While sequencing or PCR have been used for quantifying donor-derived cell-free DNA in plasma to detect allograft rejection, they remain expensive and inconvenient for patients and physicians. We assessed the performance of a novel urinary assay measuring nucleic acid, protein, and metabolic markers to provide a quantitative composite risk score without sequencing or PCR to detect kidney transplant (KT) rejection.

Methods: 206 urine samples from 95 KT patients were collected and categorized as stable (n = 157) or acute rejection (AR, n = 49). Samples were processed for quantification of urinary cfDNA and 5 additional protein markers using a custom microwell-based assay, to develop a translant rejection score. The score from longitudinally collected samples (n = 47) from 8 KT patients who were stable and had no evidence of subclinical rejection was correlated with days post-transplant to generate a 95% prediction curve which was used to generate a normalized rejection score for all samples.

Results: The urinary rejection score is significantly increased immediately post-transplant and decreases to a steady baseline by 3 months post-transplant (**Figure 1A**). The median level of 95% prediction interval-normalized rejection score was significantly higher in AR as compared with stable samples (0.64 vs. -0.71, P < 0.0001) (**Figure 1B**). The urinary rejection score showed high performance in discriminating the stable and AR samples, with an AUC of 0.9649 (P < 0.0001). At a threshold set at a normalized value of 0, the sensitivity and specificity of the assay was 93.88% and 94.90% respectively (**Figure 1C**), suggesting that the assay could be used to screen patients at risk of rejection to avoid unnecessary biopsies in the clinical setting.

Conclusions: This novel urinary rejection score enables rapid and accurate discrimination of AR from stable patients without the costs associated with sequencing. As collection of urine requires no training and can be performed as often as needed, this assay can provide inexpensive, accurate, and longitudinal assessment of AR in KT patients.

Funding: NIDDK Support

Utility of a Novel dd-cfDNA Test to Detect Injury in Renal Post-Transplant Patients

Zachary Demko,[4] Czarlota Valdenor,[1] Paul R. Billings,[3] David Paculdo,[1] Daniel Novinson,[1] John Peabody.[1,2] *[1]QURE Healthcare, San Francisco, CA; [2]UCSF School of Medicine, San Francisco, CA; [3]Natera Inc, Berkeley, CA; [4]Natera, San Carlos, CA.*

Background: Serum creatinine (SC) and biopsy are the standard of care for detecting renal allograft injury and rejection. SC has poor specificity and sensitivity, and biopsies are costly, invasive, and have attendant complications. We report on the clinical utility of a novel method that measures donor-derived cell-free DNA (dd-cfDNA) using a single SNP-based NGS methodologyto diagnose allograft injury/rejection.

Methods: We conducted a randomized controlled trial sampling 154 fellowship-trained nephrologists with two to 40 years of post-residency practice and an active panel

of at least five renal allograft patients. Over two rounds, providers cared for six online, virtual patients—Clinical Performance and Value (CPV) vignettes—a validated tool that accurately measures clinical utility and clinical practice. CPV patients were aged 30-75, were 3-24 months post-transplant, and presented in one of three ways: (1) active rejection with moderate SC increase and proteinuria; (2) subclinical rejection with no change in SC; and (3) elevated SC from another nephrotoxic insult but not rejection. Doctors randomized into the intervention arm were given educational materials on the dd-cfDNA test between rounds and dd-cfDNA results before they cared for patients in round 2. The primary outcome determined whether using dd-cfDNA demonstrated clinical utility and improved patient care as manifested by the workup, diagnostic accuracy, and medical management of these patients.

Results: At baseline, providers correctly determined primary diagnosis in only 50% of cases (p=0.853). In round 2, intervention providers improved 32.9 percentage points (p<0.001); control providers did not improve (p=0.257). Providers in both groups made a correct biopsy or referral decision in 58% of cases at baseline. Intervention improved 30.0 percentage points (p<0.001) while control did not improve in round 2 (p=0.501). Similarly, intervention providers' medical management improved significantly (+14.3 percentage points, p<0.001) in round 2, while controls' did not (p=0.483).

Conclusions: Nephrologists shown dd-cfDNA levels were significantly more likely to accurately diagnose, and make better biopsy, referral and medically management decisions for renal transplant patients.

TH-PO1107

Serial AlloSure Testing with Donor-Specific Antibodies in Renal Transplant Recipients Can Avoid Kidney Biopsy

Sudhir R. Thaduri,[1,2] Anshul Bhalla,[1,2] Fizza F. Naqvi,[1,2] Daniel C. Brennan.[1,2]
[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins Hospital, Baltimore, MD.

Background: Donor derived Cell free DNA testing with targeted next gen sequencing assay (Allosure) has been shown to predict renal allograft rejection at a threshold of 1% having a PPV/NPV of 44%/96% for antibody mediated rejection (AMR). The utility of positive Allosure in the diagnostic algorithm is not well defined and we believe looking at clinical patterns in this subset may shed light on optimal strategy of use.

Methods: A total of 155 patients (pts) transplanted between 2016 - 2019 had 289 Allosure tests. 40 were tested at predetermined intervals (KOAR registry) and remaining 115 had for-cause testing. Pts with Allosure levels >1% were assessed for DSA, indication for biopsy, serum creatinine (Cr), rejection, alternate etiology and therapy change.

Results: Allosure results ranged from detection threshold <0.15% to 13%. 24/155 pts had Allosure >1%. 4/24 were in KOAR registry of which 2 had ACR 1B, 1 had AMR, and 1 had AKI 2/2 obstruction. 19/24 underwent allograft biopsy. 10/24 had AMR, 3/24 had ACR 1B and 1/24 had mixed rejection. 5/24 had no rejection on biopsy 3/10 with AMR and 3/5 with other causes had rise of Cr >0.3mg from baseline at the time of positive result. 5/24 who did not have biopsy had stable Cr with negative/improved DSA. 15/24 had change in therapy, 2 with positive biopsy/Allosure had stable DSA/Cr with no change in therapy. 2 pts were started on Losartan for AT1 R antibody & AMR. 1/24 pt with initial Cr> 12 mg/dl did not recover and declared ESRD. All 15 pts with therapy change stabilized/improved renal function. 2/3 wtih ACR 1B who had >1 value showed a clear trend correlating with renal function. Median peak Allosure was 3 and mean peak was 3.09. The lowest positive result was 1.1 and highest was 13, both in pts with ACR 1B.

Conclusions: Allosure performs well as a test to "rule out " rejection. Serial Allosure combined with DSA and serum Cr trend can safely avoid kidney biopsy. It allows detection of AMR before rise of Cr in the majority of pts. No correlation was found with level of Allosure and Cr. The mean value was higher than the threshold of a positive result. DSA was stable/negative in all patients with positive renal outcome supporting safety of such an approach. Our study adds to a growing repository of Allosure use in kidney transplant. Study limited by small sample, mixed cohort and non adherence to testing protocol.

TH-PO1108

The Serum CTRP9 Concentration Correlates with Cardiovascular Risk in Renal Allograft Recipients

Nobuhiko Miyatake, Hiroki Adachi, Keiichiro Okada, Kazuaki Okino, Keiji Fujimoto, Kengo Furuichi, Hitoshi Yokoyama. *Kanazawa Medical University, Uchinada, Japan.*

Background: Cardiovascular disease (CVD) due to atherosclerosis is a major cause of death in renal allograft recipients. Recently, C1q/TNF-α related protein-9 (CTRP9), which is a paralog of adiponectin (ADPN), has been suggested to be related to the suppression of atherosclerosis and the occurrence of CVD, but this relationship has not been confirmed in renal allograft recipients. We evaluated the relationships among the serum CTRP9 concentration, serum ADPN concentration, and vascular calcification were investigated in 50 Japanese kidney allograft recipients.

Methods: Calcification of the abdominal aorta was evaluated according to the aortic calcification area index (ACAI) calculated from CT images. Changes in the serum CTRP9 and ADPN fractions and ACAI were examined for 8 years. In addition, the expression of CTRP9 and ADPN and their respective receptors AdipoR1 and R2 in small arteries of the transplanted kidney was examined by immunofluorescence.

Results: In renal allograft recipients, the serum CTRP9 concentration at the start of the observation was not significant correlated with eGFR or serum high-molecular-weight (HMW)-ADPN concentration (rS=-0.009, p=0.950; rS=-0.226, p=0.114, respectively). However, the change in the serum CTRP9 concentration was positively correlated with the change in the serum HMW-ADPN concentration (rS=0.315, p=0.026) and negatively correlated with the change in ACAI (rS=-0.367, p=0.009). Multiple regression analysis revealed that the serum HMW-ADPN concentration was a significant positive factor for the change in the serum CTRP9 concentration. Moreover, for ACAI, an increase in the serum CTRP9 concentration was an improving factor, but aging was an exacerbating factor. Furthermore, colocalization of CTRP9 and AdipoR1 was noted in intrarenal arterial endothelial cells.

Conclusions: In renal allograft recipients, CTRP9 and HMW-ADPN were suggested to produce vascular protective effects mediated by AdipoR1 to suppress the progression of aortic calcification.

Circular RNA in Urine-Liquid Biopsy Biomarker of Acute Rejection in Kidney Transplantation

Malte Kölling,[1] George Haddad,[1] Andreas D. Kistler,[2] Harald Seeger,[1] Kerstin Huebel,[1] Hermann G. Haller,[3] Rudolf P. Wuthrich,[1] Johan Lorenzen.[1]
[1]University Hospital Zurich, Zurich, Switzerland; [2]Frauenfeld Cantonal Hospital, Frauenfeld, Switzerland; [3]Division of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.

Background: Circular RNAs (circRNAs) are long non-coding RNA transcripts with strong gene regulatory function. Their circular structure guarantees stable detection in blood. We hypothesized that circRNAs are detectable in urine as well and serve as biomarker of acute T cell-mediated kidney allograft rejection.

Methods: A global urinary circRNA expression analysis was performed in patients with acute rejection compared to patients without rejection. Differentially concentrated circRNAs were validated in patients with acute rejection (n=62), in stable transplant patients (control, n=18) and rejection dependent concentrations were additionally analyzed after successful anti-rejection therapy (n=10). Biomarker specificity was verified in stable transplant patients with urinary tract infection (disease control, n=13).

Results: A distinct urinary circRNA transcriptome signature identified patients with acute rejection. CircRNAs *hsa_circ_0001334* and *hsa_circ_0071475* were strongly altered and thus validated in the whole cohort. Increased *hsa_circ_0001334* concentrations were specifically confirmed in patients with acute rejection and returned to base level after anti-rejection therapy. *Hsa_circ_0001334* showed promising biomarker value and prognostic potential in predicting higher decline of creatine clearance after one year of transplantation.

Conclusions: In conclusion, patients with acute rejection were identified by a specific urinary circRNA transcriptome signature and circRNA *hsa_circ_0001334* was discovered as novel non-invasive diagnostic and prognostic biomarker of acute T cell-mediated kidney allograft rejection. Measuring concentrations of circRNAs in urine might thus serve as novel liquid biopsy in kidney transplant patients.

TH-PO1110

Longitudinal and Cross-Sectional Analysis of Kidney Transplant Urine mRNAs Reveals Glomerular Disease as an Important Driver of Long-Term Graft Loss

Abhijit S. Naik,[1] Milagros D. Samaniego-Picota,[3] Diane M. Cibrik,[2] Su Q. Wang,[1] Mahboob A. Chowdhury,[1] Roger C. Wiggins.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Kansas Hospital, Parkville, MO; [3]Henry Ford Health Services, Detroit, MI.*

Background: Biopsies from failing allografts (El-Zoghby) and longitudinal protocol biopsies in two studies (Nankivell; Stegal) suggest that glomerular disease (GD) is associated with late graft loss. In a10yr study Stegal reported GD to be more prevalent than IFTA. To understand why kidney transplants fail over time, we utilized nephron segment specific urine pellet mRNA markers to enable non-invasive analysis of injury patterns

Methods: Longitudinal and cross sectional urine samples covering 20years post-TP for all comers were collected. Two podocyte markers (podocin, nephrin), a distal tubular/collecting duct marker (aquaporin2) and marker of innate immune/profibrotic activity (TGFBeta1) were measured in spot urine samples and normalized to creatinine. Baseline 2kidney (2K) values for 4 markers were obtained from 98 healthy controls and used to derive 1K normal values.

Results: 380 recipients provided 1997 urine pellets. All markers increased immediately after TP but downtrended towards expected ranges. Over 20yrs there was a steady increase in both podocyte markers (UPod:CR,UNeph:CR) compatible with increasing podocyte detachment rate. The ratio of podocin to nephrin (UPod:Neph) a marker of podocyte hypertrophic stress increased markedly after TP, and remained elevated above 2K control. Downstream tubular injury marker (Aqp:CR) remained elevated in the short-intermediate term compatible with tubule-interstitial injury but by 3years decreased to 2K level. The ratio of the glomerular to tubular marker (UPod:Aqp2) continued to increase after TP reflecting increasingly glomerular vs. tubular injury. Urine pellet TGFbeta1CR remained elevated above 2K level suggesting ongoing TP injury.

Conclusions: Urine pellet mRNA data are compatible with long-term protocol biopsy data suggesting that GD is an important driver of long-term kidney allograft failure.

Urinary CXCL9 Levels Correlate with Quantitative Tubulitis in Kidney Allograft Biopsies

Marco Delsante,[1] Ilaria Gandolfini,[1] Ilaria Diblasi,[1] Francesco P. Pilato,[2] Nicoletta Campanini,[2] Giovanni maria Rossi,[3] S.M. Bagnasco,[3] Umberto Maggiore,[1] Avi Z. Rosenberg,[3] Enrico Fiaccadori.[1] *[1]Dip. Medicina e Chirurgia, Universita di Parma, Parma, Italy; [2]Patologia, Universita di Parma, Parma, Italy; [3]The Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Acute and chronic cell mediated rejection (CMR) are histologically characterized by the presence of interstitial inflammation (i) and tubulitis (t), with or without endarteritis, as defined by Banff Classification system [Haas M, et al. AJT, 2018]. The Banff tubulitis score (t) is semi-quantitative, based on the most inflamed tubular profile. These values are then used to establish the grade of CMR. Tubulitis can be difficult to assess using standard staining, and its interobserver reproducibility is poor. Urinary CXCL9 has been shown to correlate with the diagnosis of CMR, and their levels decrease after successful therapeutic interventions [Gandolfini I, et al. KI Rep, 2017]. We used immunohistochemical CD3 stain with a PAS counterstain to elicit a continuous quantitative tubulitis score in kidney allograft biopsies and correlated the findings with urinary CXCL9 levels (Figure 1).

Methods: On digitized whole slide images of CD3+PAS slides (n=12; CMR = 5 biopsies, borderline lesions= 1 and no rejection=6) mean CD3+ cells per tubule (mCD3/t), percentage of tubules showing at least 1 CD3+ cells (tubulitis ratio, tr) and number of CD3+ cells in the most inflamed tubule (maxt) were manually assessed using ViewPoint software (PreciPoint). Urinary CXCL9 levels at the time of diagnosis were measured using ELISA kit (R&D, Quantikine ELISA). Prism GraphPad 5 was used for statistical analysis.

Results: We found significant correlation between urinary CXCL9 levels and mCD3/t (r2 0.75, p=0.0003), tr (r2 0.66, p=0.0012) and maxt (r2 0.70, p=0.0006).

Conclusions: CD3+PAS stain augments current approach's by generating a continuous score quantify tubulitis. This quantification correlates with urinary CXCL9 levels, a biomarker of CMR. Studies on larger cohorts are underway to better establish the clinical significance and utility of quantitative tubulitis evaluation.

TH-PO1112

Donor Nephrectomy Selectively Increases Proximal Tubular Proteins in Urinary Vesicles

Charles J. Blijdorp,[1] David Severs,[1] Ricardo Budde,[1] Joost Hoenderop,[2] René J. Bindels,[2] Catherina A. Cuevas,[1] Robert Zietse,[1] Ewout J. Hoorn.[1] *[1]Erasmus Medical Center, Rotterdam, Netherlands; [2]Radboud university medical center, Nijmegen, Netherlands.*

Background: Donor nephrectomy causes hyperfiltration and hypertrophy of the remaining kidney. Uninephrectomy in rats causes a selective increase in proximal tubular proteins. Accordingly, we hypothesize that human donor nephrectomy increases proximal tubular proteins.

Methods: Nineteen kidney donors were included in this study. Kidney volume was calculated from CT scans prior to donation. Urine was collected prior to and three months after donor nephrectomy. Urinary extracellular vesicles (uEVs) were isolated and used as non-invasive read-out for renal tubular protein abundance. uEVs were quantified using nanoparticle tracking analysis. The following proteins were analyzed in uEVs using ultracentrifugation and immunoblotting: NHE3, NaPi-IIa and cubilin (proximal tubule), NKCC2 (thick ascending limb), NCC (distal convoluted tubule), and AQP2 (collecting duct). Relative protein abundance was expressed per remaining kidney volume.

Results: Donor nephrectomy reduced kidney volume by 50±3%, creatinine clearance by 38±10%, and uEV excretion by 20%. The relative abundance of proximal tubular proteins in uEVs increased significantly, whereas no change occurred in distal nephron proteins (Figure).

Conclusions: Donor nephrectomy selectively increases proximal tubular proteins in uEVs. This may be due to hyperfiltration and hypertrophy occurring in this segment. It may also explain why a kidney volume reduction of ~50% is accompanied by a decrease in uEV excretion of only 20%. These results provide insight in the changes after kidney donation and are relevant when analyzing uEVs in kidney donors.

Biomarker Implementation: Evaluation of the Decision-Making Impact of CXCL10 Testing in a Pediatric Cohort

Caroline Lamarche,[1] Atul K. Sharma,[3] Tyki Sueyoshi,[2] Tom D. Blydt-Hansen.[2] *[1]Surgery, BC Children Hospital, Vancouver, BC, Canada; [2]University of British Columbia, Vancouver, BC, Canada; [3]University of Manitoba, Winnipeg, MB, Canada.*

Background: Children are at high risk for subclinical rejection and invasive kidney biopsy is currently used for active surveillance. Urinary CXCL10 hold the most promise as a biomarker for post-transplant monitoring of rejection. How it will influence clinical decision has never been tested. As such, our objective was to test whether CXCL10 can improve the clinical decision-making to identify organ rejection risk.

Methods: We first assembled a panel of experts to establish a minimum dataset for standard clinical decision-making for an indication biopsy. Clinical vignettes were then built from 15 prevalent pediatric kidney transplant recipients who had surveillance or indication biopsy and biobanked urine sample. Urine samples were tested for CXCL10 and reported as ratio to creatinine. Pediatric nephrologists were recruited review serial clinical vignettes and A) predict rejection risk and B) decide to biopsy; without then with urinary CXCL10 result and rejection diagnosis sensitivity/specificity information for different levels. Biopsy decisions were then correlated with the biopsy results. Inter-rater agreement (IRA) was assessed by Fleiss Kappa (K) for binary choice and interclass correlation (ICC) for probabilities.

Results: Eleven pediatric nephrologists were enrolled. IRA for choice to biopsy was fair both before (K=0.48, p<0.01) and after (K=0.43, p<0.01) incorporating CXCL10 data. ICC of probability assessment for rejection was poor before (0.28, p<0.01) and improved to fair (0.48, p<0.01) with addition of chemokine data (p=0.6 for difference). Clinicians did consider the CXCL10 in their decision making process and CXCL10/Cr correlated with the change in the estimated probability of rejection (r2=0.7756, p<0.0001), with 2.77 as the cutoff for a biopsy-based intervention. The decision-accuracy (majority ordering a biopsy when rejection was found or not ordering one when there was no rejection) improved from 8/15 (53.3%) cases to 11/15 (73.3%) with CXCL10 results. Using the cut-off value for CXCL10/Cr ratio of 2.77 would have been accurate in 12/15 cases (80%).

Conclusions: There is high variability in decision-making on biopsy indication. Urinary CXCL10/Cr improves probability estimates for risk of rejection. However, training may be required to assist nephrologists in using biomarker information for clinical decision-making.

TH-PO1114

Low Soluble Klotho Levels Are Associated with Renal Function Decline in Kidney Transplantation

Yasuto Shikida,[1] Masahide Mizobuchi,[1] Osamu Yoshitake,[4] Tadashi Kato,[3] Hiroaki Ogata,[3] Fumihiko Koiwa,[2] Tadao Akizawa.[1] *[1]Showa University Hospital, Tokyo, Japan; [2]Division of Nephrology, Department of Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan; [3]Department of Internal Medicine, Showa University Northern Yokohama Hospital, Yokohama, Japan, Yokohama, Japan; [4]Showa university, Shinagawa, Japan*.

Background: Serum soluble klotho levels have been shown to be associated with renal function in pre-dialysis patients with chronic kidney disease. However, there are few reports regarding the association between soluble klotho levels and renal function in kidney transplant (KTx) recipients. Thus, we investigated the association of soluble klotho levels of the pre-KTx with renal function decline in living KTx recipients.

Methods: This is a retrospective, observational study of 41 living KTx recipients who received standard immunosuppressive therapy between 2002 and 2017 in our hospital. The serum soluble klotho levels were divided into 2 groups according to the median value: ≧ 456 pg/ml (High group, n=21), or < 456 pg/ml (Low group, n=20). Renal function decline was defined as a 30% or more decrease in estimate glomerular filtration rate (eGFR) compared with that of baseline within 3 months after KTx. A multivariable time-to-event analysis between the groups was performed.

Results: 4.9% of the recipients received preemptive KTx. 75.6% and 19.5% of the recipients were treated with hemodialysis and peritoneal dialysis before KTx, respectively. Median dialysis vintage was 408 days (interquartile range, IQR :168-1132 days). Median follow-up period was 913 days (IQR: 318-2015 days). KTx recipients in the Low group showed a significant higher incidence of 30% decrease in eGFR than those in the High group (p=0.036). In multivariable Cox models adjusting for patient-age, donor-age, the presence of rejection, and the number of HLA mismatch, the low soluble Klotho levels remained to be associated with a higher risk of 30% decrease in eGFR (HR: 2.78, 95%CI: 1.02-8.26).

Conclusions: These results suggest that lower soluble klotho levels of the pre-KTx are associated with increased risk of renal function decline in KTx recipients. Maintenance of higher serum soluble klotho levels before KTx may be preferable for renal function preservation.

TH-PO1115

Increased Delta Neutrophil Index Is Associated with Poor Prognosis in Cadaveric Donor Kidney Transplantation

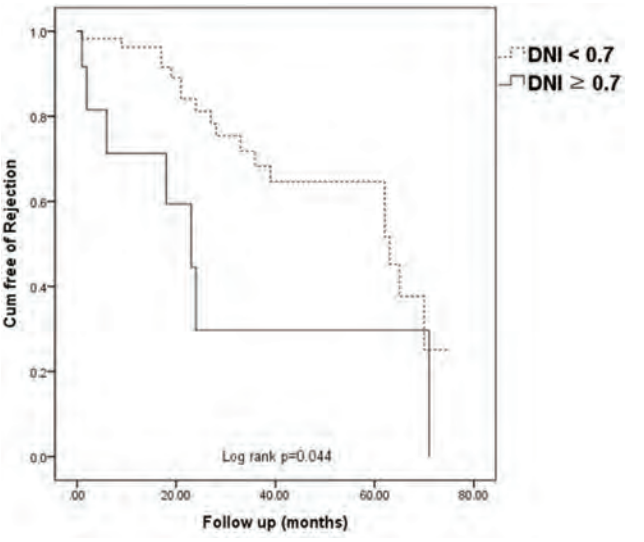
Jae Won Yang,[1] Jun Young Lee,[1] Jae seok Kim,[1] Moonhee Chai,[1] Minseob Eom,[2] Seung-Ok Choi,[1] Jin-Jae Jeong.[1] *[1]Wonju Christian Severance Hospital, Wonju, Kangwon do, Republic of Korea; [2]Yonsei Univ. Wonju College of Medicine, Wonju, Republic of Korea*.

Background: Delta Neutrophil Index (DNI) is the fraction of circulating immature granulocytes. In many studies, DNI has been demonstrated as a useful prognostic marker in critical patients. We hypothesized that increased level of DNI in the recipient is associated with poor prognosis in cadaveric donor renal transplantation (CRT).

Methods: We reviewed medical records of a total of 73 patients undergoing CRT from March 2013 to January 2018 retrospectively. The transplant rejection (TR) was assessed using Banff classification, and subclinical rejection was excluded in the study.

Results: Twenty-five (34.2%) patients were diagnosed with TR. Among them, 11 patients were classified as early TR. The post-operative DNI (po-DNI) was higher in the patients with early TR than that of patients without it (1.21 vs. 0.18, p<0.001). In univariate logistic regression test, cold ischemic time, last creatinine level of the donor before transplantation (last-Cr), po-DNI level, and peri-operative infection predicted early TR. In multivariate-adjusted logistic regression test, only high level of po-DNI predicted early TR (Odds ratio 12.31, 95% CI 1.22-129.82, p=0.034). The c-statistic value of po-DNI in the logistic model was 0.78 (95% CI 0.60-0.95, p=0.004). Multivariate Cox regression analysis showed that last-Cr (Hazard ratio (HR) 2.25, 95% CI 1.26-4.13, p=0.006) and pre-operative DNI (HR 14.02, 95% CI 2.62-75.26, p=0.002) predict renal survival in CRT.

Conclusions: Increased DNI of the recipient in CRT is thought to be a useful marker for predicting early TR and renal survival.



Cumulative early acute rejection free period according to DNI level

TH-PO1116

Predicting Deceased Donor Kidney Transplant Outcomes: Comparing KDRI/KDPI with Machine Learning

Eric Pahl. *OmniLife, Coralville, IA.*

Background: Kidney transplantation is an effective cure for patients suffering from end-stage renal disease. Kidney transplantation is cost-effective, provides a significant survival benefit, and improves the quality of life for patients. One limitation on kidney transplantation is the appropriate assessment of donor quality, for which several indices have been created.

Methods: Machine learning methods (MLM) were compared to kidney donor risk index (KDRI aka KDPI) for the ability to predict graft failure by 12, 24, and 36 months after deceased donor kidney transplantation (DDKT). The MLM model, an ensemble of thousands of randomly generated decision trees, was trained with the same data initially used to develop KDRI.

Results: An MLM trained with the readily available recipient and donor variables performs significantly better than KDRI/KDPI when predicting graft failure by 12, 24, and 36 months after DDKT. When comparing equal prediction failure rates of 10%, MLM successfully predicted 126% more successful DDKTs (an additional 2,148) than KDRI/KDPI from 1995-2005. Over the entire ROC curve, the MLM performed statistically significantly better c-statistic than KDRI/KDPI in all predictions.

Conclusions: Using MLM, many high-KDRI kidney offers resulted in thousands of successful patient outcomes without increasing risk of predicted graft failure. The MLM provided a significant improvement over KDRI for the assessment of kidney offers and give clinical professionals an improved basis for making the critical decisions. This work lays the foundation for future MLM in organ transplantation and describes the steps to measure, analyze, and validate future models.

TH-PO1117

Predicting Health Outcomes for Elderly Renal Transplant Recipients with Machine Learning

Rui Fu,[1] Nicholas Mitsakakis,[3,1] Kai Luo,[2] Peter C. Coyte.[1] *[1]Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada; [2]Department of Mechanical and Industrial Engineering, University of Toronto, Toronto, ON, Canada; [3]Toronto General Hospital Research Institute, THETA Collaborative, Toronto, ON, Canada*.

Background: Application of machine learning to nephrology research has been scarce. In this study, we demonstrated the use of classification algorithms in predicting all-cause death at three-year among elderly deceased-donor renal transplant recipients.

Methods: This is a retrospective, population-based, cohort study of all cases of deceased-donor renal transplants performed in Ontario, Canada from March 31, 2002 to April 1, 2013. Recipients aged over 70 years were followed up until death or to April 1, 2016. Bootstrap-aggregating classification tree and K-Nearest Neighbors (KNN) were used to train a predictive model for death at three-year post-transplant. Patient-level attributes at the time of transplantation, including demographic characteristics, lab results, transplant information, comorbidities, and pre-transplant health care utilization, were examined as potential determinants of post-transplant death. A ratio of 3:2 was used to construct training and testing sets. Synthetic Minority Oversampling Technique was applied to generate artificial positive cases (death) and under-sample negative cases (alive) in the training set to reduce bias. Models were trained and tuned using ten-fold cross-validation on the training set and tested on the specificity and sensitivity of prediction using the testing set.

Results: Among 275 elderly transplant recipients, the majority (n=271, 98.5%) were transplanted at 71-80 years and four (1.5%) were older than 80 years. Death occurred in 52 (18.9%) cases at three-year post-transplant. Before sampling, classification tree and KNN had test sensitivity of 0.11 (95% confidence interval [CI], 0.01-0.33) and 0.07 (95% CI, 0-0.18), respectively, while both achieving 0.95 (95% CI, 0.88-0.98) specificity. After sampling, classification tree and KNN achieved test sensitivity of 0.21 (95% CI, 0.06-0.46) and 0.26 (95% CI, 0.03-0.50), respectively, as well as test specificity of 0.89 (95% CI, 0.81-0.95) and 0.84 (95% CI, 0.74-0.90), respectively.

Conclusions: Our findings add to the growing body of knowledge aimed at improving the performance of risk calculators (e.g., iChoose Kidney) that help patients and families to make informed decisions in renal care. Furthermore, our study confirmed the strength of machine learning techniques in population-based nephrology research despite our limited sample size and the rarity of the outcomes assessed.

TH-PO1118

Optimization of Machine Learning Models for Predicting Delayed Graft Function in Renal Allografts

Kuang-Yu Jen,[1] Felicia Yen,[1] Junichiro Sageshima,[1] Hooman H. Rashidi.[2] *[1]University of California, Davis, Sacramento, CA; [2]UC Davis School of Medicine, Sacramento, CA.*

Background: Delayed graft function (DGF) is associated with worse short- and long-term renal allograft outcomes. Several groups have previously developed models that compute the theoretical risk of DGF for allograft recipients using standard statistical inference methods. In this study, we apply automated computational algorithms to generate tens of thousands of DGF prediction machine learning models based on donor characteristics alone. In this en masse approach, we are able to empirically optimize these machine learning models for the prediction of DGF.

Methods: Deceased donor data available from UNOS for 1,694 renal transplants at our center from 2010-2018 were used in this study, which included various elements of demographics, medical history, and circumstances of death. Cold ischemia time (CIT) and KDPI were included as well. The number of cases was further trimmed randomly to achieve a 50%/50% split in DGF-positive and negative cases, with a final total of 922 cases. These data were used to create 10 runs for each specific parameter combination [each using 90% (n=830) of cases for training phase and 10% (n=92) of cases for each run's validation test] to generate a total of 45,980 unique models within these parameter combinations on 4 distinct machine learning algorithms (logistic regression, k-nearest neighbor, support vector machine, random forest). Models were also produced with fewer donor features, KDPI alone, CIT alone, and KDPI with CIT. The mean accuracy, standard deviation, and area under the curve (AUC) for the best models were calculated.

Results: Of the 45.980 models generated, the best performing models had an accuracy of 74% (5.7) and AUC of 77. A common theme to these optimized models was that they excluded KDPI as a feature but included CIT. KDPI alone performed poorly (accuracy 49-57%; AUC 0.51-0.55). CIT alone was also suboptimal (accuracy 57-63%; AUC 0.56-0.62).

Conclusions: Machine learning algorithms can help to produce improved and optimized prediction models for DGF.

TH-PO1119

Factors Impacting the Disparity in Receipt of Live Donor Kidneys by Women vs. Men

Mariana S. Markell, Angelika C. Gruessner. *SUNY Downstate Medical Center, Brooklyn, NY.*

Background: It was noted in the early 2000's that women received fewer live donor kidneys (LDK) than men. Since that time, more women have entered the workforce, transplantation of highly sensitized individuals has improved and there has been an increase in altruistic donation; factors that might improve the LDK transplant rate in women. We examined the rate of LDK transplants in women compared with men since 1998-00, as well as factors that might affect it.

Methods: All 105,729 primary adult living donor kidney transplants reported to UNOS/OPTN between 1998 and 2018 were analyzed. Only adult recipients were included in the analyses. The time period was divided into 3-year intervals to adjust for yearly fluctuations. Logistic regression models were used to assess the odds to receive a LDK for women adjusted for possible risk factors.

Results: The overall rate of LDK for women was 39%. Odds ratio (OR) for women vs men significantly worsened over time, with a OR of 0.866 (CI 0.845-0.93) for 2004-06, 0.756 (CI 0.719-0.795) in 2010-12 and 0.727 (CI 0.691-0.765) in 2016-18 compared to 1998-00. The OR decreased significantly with increasing age (>70yr, OR 0.192, CI 0.113-0.328). Interestingly, black women were more likely than whites (OR 1.315, CI 1.267-1.365), and women on dialysis were less likely than men (OR 0.791, CI 0.770, 0.813) to receive a LDK transplant. Women were also less likely to receive a non-biological kidney (whether spousal or altruistic) OR 0.806, CI 0.785-0.828, but women with a PRA >20 had a much higher chance of receiving a LDK (OR 3.547 CI 3.389-3.712).

Conclusions: 1. The gender disprity in LDK rate for women has worsened since 1998-00, with a 28% difference in 2016-18. 2. Older women have the least likelihood of receiving a live donor kidney, with women over the age of 70 years 80% less likely. 3. Black women are more likely than whites to receive a LDK. 4. Women on dialysis are 20% less likely to receive a kidney than those who have not yet started. 6. Although biological reaons have been postulated in the past to explain gender disparity, the above findings and the observations that women who are sensitized are 3.5 times more likely to receive a live donor kidney than those who are not and that women are less likely to recieve a non-biologically related kidney suggests that sociocultural and practice patterns may be more important and should be investigated further.

TH-PO1120

Prognostic Value of Standardized Deceased Donor Kidney (DDK) Procurement Biopsies

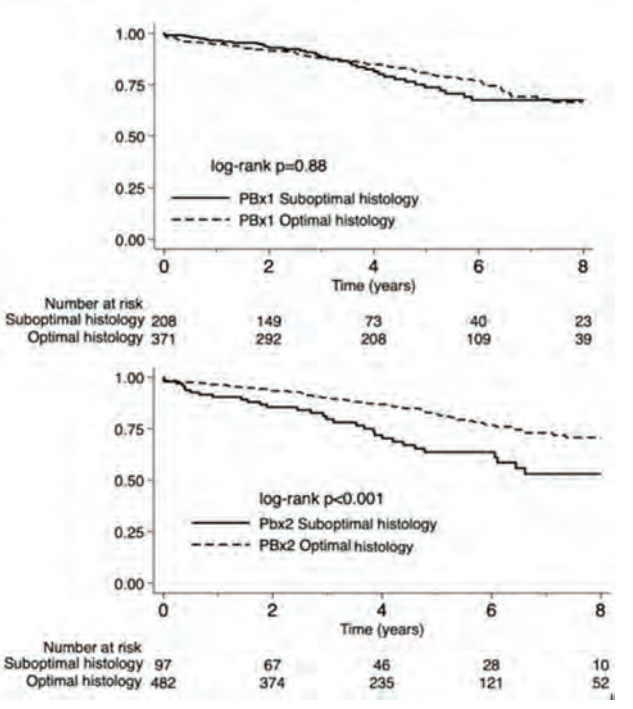
Hector Alvarado verduzco,[1] Kristen L. King,[1] Ibrahim Batal,[2] Sumit Mohan,[3] Syed A. Husain.[1] *[1]Columbia University Medical Center, New York, NY; [2]New York Presbyterian Hospital (Columbia Campus), New York, NY; [3]Columbia University, New York, NY.*

Background: Procurement biopsy (PBx) histology is the most common reason for DDK discard but has been shown to be of limited prognostic value. Occasionally DDK are biopsied twice when transported between OPOs, allowing us to assess the standardized approach to performing and interpreting PBx at our OPO.

Methods: We identified 591 DDKs transplanted at our center from 1/2006-12/2016 (imported from 60 OPOs) with an initial PBx (PBx1) that was repeated by our local OPO (PBx2). "Suboptimal histology" was defined as glomerulosclerosis (GS)>10%, interstitial fibrosis/tubular atrophy (IFTA)>25%, and/or vascular disease (VD) graded as moderate or severe. We calculated kappa coefficients to assess agreement between PBx and used time-to-event analyses to evaluate the association between suboptimal histology on PBx1 and PBx2 with death-censored allograft survival.

Results: 36% PBx1 and 17% PBx2 were classified as having suboptimal histology. 75% of DDK with suboptimal PBx1 had optimal PBx2. Overall histologic concordance (optimal versus suboptimal) between PBx1 and PBx2 was 65% (κ =0.13). Categorical agreement was higher for VD (κ=0.13, 52% concordance) than for IFTA (κ=0.08, 67% concordance) or GS (κ=0.11, 44% concordance). In contrast to PBx1, suboptimal PBx2 histology was associated with death-censored allograft survival in bivariable and multivariable analysis (adjusted hazard ratio 2.17, 95% CI 1.72-3.45, p<0.001).

Conclusions: PBx performed at different OPOs were frequently discordant, likely due to variable PBx technique and interpretation between OPOs. Our results suggest that standardization may improve utility and reliability of PBx for assessing DDK quality.



TH-PO1121

Machine Learning-Guided Measurement of Visceral Fat Area in Computed Tomography and Delayed Graft Function After Kidney Transplantation

Ji Eun Kim,[1] Hajeong Lee,[2] Seung Seok Han,[2] Yon Su Kim.[2] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Innovative machine learning can be applied to efficiently provide the information on medical imaging and be useful in the prediction model. Accordingly, the present study measured visceral fat area (VFA) with updated machine learning algorithm in kidney transplant recipients and evaluated its correlation with delayed graft function (DGF).

Methods: A total of 287 adult kidney recipients who examined abdominal computed tomography with full range of torso before transplantation were enrolled. VFA in the

abdominal cavity was measured in cubic meters throughout machine learning algorithm. DGF was defined as the need for dialysis during the first transplantation week.

Results: The mean age was 47.8 ± 11.3 years and male was 66.2%. The mean body mass index was 24.6 ± 3.5 kg/m^2. The VFA was 2.88 ± 1.92 m^3, and the body surface area-adjusted value was 1.59 ± 0.95 m. The adjusted VFA had a linear relationship with the surgery time (β = 0.12; *P* = 0.040). The risk of DGF increased depending on an increase of 1 unit in adjusted VFA with an odds ratio of 1.80 (1.07–3.02). However, body mass index was not associated with DGF (odds ratio, 0.99 (0.83–1.19). The area under receiver operating characteristic curve of adjusted VFA was 0.73, which was greater than 0.50 in body mass index (*P* = 0.032).

Conclusions: Machine learning algorithm may efficiently provide information on VFA of kidney recipients. This issue will improve the predictive capacity of transplant outcomes such as DGF.

TH-PO1122

Construction of a Predictive Model of Delayed Graft Function Using Machine Learning Techniques

Silvana D. Costa,[1,2] Claudia M. Oliveira,[3] Paula frassinetti C. Fernandes,[4] Elizabeth D. Daher,[5] Luis gustavo M. De andrade,[7] Ronaldo M. Esmeraldo,[2] Tainá V. Sandes-Freitas.[6] *[1]Federal university of ceara, Fortaleza, Brazil; [2]Hospital Geral de Fortaleza, Fortaleza, Brazil; [3]Centro de Pesquisas Doenças Hepatorenais, Fortaleza, Brazil; [4]Universidade Federal do Ceara and Universidade Estadual do Ceara, Fortaleza, Brazil; [5]Federal University of Ceara, Fortaleza, Brazil; [6]Universidade Federal do Ceará, Fortaleza, Brazil; [7]UNESP, Univ Estadual Paulista, Botucatu, Brazil*.

Background: Brazilian studies have been reported incidences of delayed graft function (DGF), 2-3 fold the incidences described by American and European cohorts. The available predictive models of DGF, based on distinct clinical realities, are not validated in our population. The purpose of the study was evaluate the accuracy of the available predictive models and, since none of these models present good accuracy, construct a local prediction model

Methods: Retrospective cohort study including DD KT performed between Jan 2014 and Dec 2017 in two transplant centers (n=443). The predictive DGF models tested were those described by Irish et al., Jeldres et al., Chapal et al., and Zaza et al. For the construction of the new predictive model, machine learning was used

Results: Patients were predominantly men (56.7%), young adults (44.2 ± 14.7 years), mixed race (84.4%), who remained 46.8 ± 45.2 months on dialysis. Donors had a mean age of 31 ± 12.7 years, most of them died from trauma (70.9%), 5.4% were hypertensive (HA), 0.7% were diabetic, and the final creatinine was 1.1 ± 0.6 mg/dL. Only 4.3% were expanded criteria donors. 83.1% of the grafts were perfused with HTK and the mean cold ischemia time (CIT) was 20.9 ± 4 hours. The incidence of DGF in this sample was 53%. The predictive models of DGF available presented regular or poor discriminant power: Irish (AUC 0.686), Chapal (AUC 0.638), Jeldres (AUC 0.613), Zaza (AUC 0.591). The three models with the best performance were decision tree, neural networks and support vector machine. In the final model, the variables considered were: from recipients : age, diabetes and time on dialysis; from donors: age, body mass index, HA, serum sodium, creatinine phosphokinase, final creatinine, cause of death, high dose of vasoactive drugs and diuresis; CIT. The final model showed excellent discriminant power (AUC 0.942)

Conclusions: The incidence of DGF in the sample was high, despite the predominance of standard criteria donors. In addition to variables classically associated with DGF, variables related to donor maintenance were pointed out in non-linear statistical methodologies. The available predictive models had poor accuracy in predicting DGF in our population. The developed model presented excellent performance.

Funding: Government Support - Non-U.S.

TH-PO1123

Patient Survival After Kidney Transplantation: Important Role of Graft-Sustaining Factors as Determined by Predictive Modeling Using Random Survival Forest Analysis

Irina Scheffner,[1] Matthias Gietzelt,[2] Tanja Abeling,[1] Michael Marschollek,[2] Wilfried Gwinner.[1] *[1]Department of Nephrology, Hannover Medical School, Hannover, Germany; [2]Peter L. Reichertz Institute for Medical Informatics of TU Braunschweig and Hannover Medical School, Braunschweig and Hannover, Germany*.

Background: Identification of the relevant factors for death can improve patient's individual risk assessment and decision making. A well-documented patient cohort (n=892) in a renal transplant program with protocol biopsies was used to establish multivariable models for risk assessment at 3 and 12 months posttransplantation by random survival forest analysis.

Methods: Patients transplanted between 2000 and 2007 were observed up to 11 years. Loss to follow-up was negligible (n=15). 2251 protocol biopsies and 1214 biopsies for cause were performed. All rejections and clinical borderline rejections in protocol biopsies were treated.

Results: 10-year patient survival was 78%, with inferior survival of patients with graft loss. Using all pre- and posttransplant variables until 3 and 12 months (n=65), the obtained models showed good performance to predict death (concordance index: 0.77-0.78). Validation with a separate cohort of patients (n=349) showed a concordance index of 0.76 and good discrimination of risks by the models, despite substantial differences in clinical variables. Random survival forest analysis produced robust models over a wide range of parameter settings. Besides well-established risk factors like age, cardiovascular disease, type 2 diabetes, and graft function, posttransplant urinary tract infection and rejection treatment were important factors. Urinary tract infection and rejection treatment were not specifically associated with death due to infection or malignancy but correlated strongly with inferior graft function and graft loss.

Conclusions: The established models indicate the important areas that need special attention in the care of renal transplant patients, particularly modifiable factors like graft rejection and urinary tract infection.

TH-PO1124

External Validation of Predictive Score for Post-Transplantation Outcome in US Deceased Kidney Transplant Recipients

Masahiko Yazawa,[1,3] Fridtjof Thomas,[4] Orsolya Cseprekál,[5,1] Suryatapa Kar,[6,2] Ahmad Abdelaal,[1,2] Manish Talwar,[1,2] Vasanthi Balaraman,[1,2] Csaba P. Kovesdy,[7] James D. Eason,[1,2] Miklos Z. Molnar.[1,2] METEOR (MEthodist Transplant EpidemiOlogy Research) Group *[1]Division of Transplant Surgery, Department of Surgery, University of Tennessee Health Science Center, Memphis, TN; [2]James D. Eason Transplant Institute, Methodist University Hospital, Memphis, TN; [3]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [4]Department of Preventive medicine, University of Tennessee Health Science Center, Memphis, TN; [5]Department of Transplantation and Surgery, Semmelweis University, Budapest, Hungary; [6]Department of Transplantation and Surgery, University of Tennessee Health Science Center, Memphis, TN; [7]University of Tennessee Health Science Center, Memphis, TN*.

Background: We previously published a prediction model (www.transplantscore.com (TS)) for allograft and patient survival, which consisted of only predictors available at the time of kidney transplant (KT). Here, we aimed to perform external validation to assess the robustness, reliability, and applicability of our model.

Methods: Five hundred eleven patients who underwent first deceased KT in our Institute between 2010 to 2017 were included. We computed the original prediction score for these patients and compared the results with the observed outcome in terms of the score's calibration (goodness of fit) and discrimination (AUC: Area Under the Curve). We also assessed the predictive performance in terms of re-classification (NRI: Net Reclassification Improvement) when compared with a binary classifier based on the EPTS raw score.

Results: In the entire cohort, the mean age was 51.2±11.8 years old, 83% were African-American, most of the patients were on hemodialysis (81%) before KT and mean time on dialysis was 5.4 years. The TS-predicted mortality probabilities clearly separate patients as demonstrated in the Kaplan-Meier curves using all available follow-up (Figure, panel A). The AUCs based on TS for 1- and 2-year mortality (panel B) were 0.737 and 0.682, respectively. These were higher than those for the classifier based on the EPTS score (AUC of 0.649 and 0.623 for 1 and 2 year mortality, respectively) and the NRI computed to 0.302 and 0.149 for 1 and 2 year classifications in favor of TS. However, the differences in the AUCs were not statistically significant (p = 0.138 and p = 0.149 for 1 and 2 year comparisons). The Hosmer and Lemeshow goodness of fit test of TS indicated some inadequate fitting (p = 0.015 and 0.038, respectively) apparently especially an overestimation for higher-score patients.

Conclusions: TS appears to broadly correctly classify patients with respect to their 1 and 2 year mortality rate.

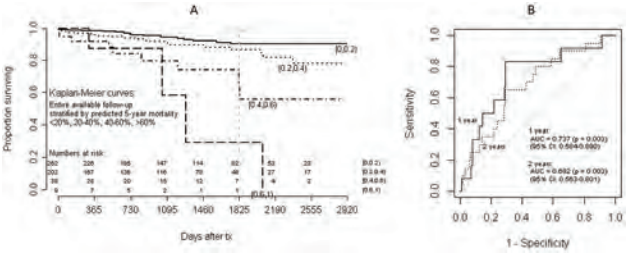


Figure 1

TH-PO1125

Development of Donor Kidney Age: A Simple Score Summarising Deceased Donor Risk

Emma C. Morganti,[1] Rupert B. Bright,[4] Anamika Adwaney,[2] Dhriti Dosani,[4] Damien Ashby.[3] *[1]Imperial College Healthcare, London, United Kingdom; [2]Hammersmith Hospital, London, United Kingdom; [3]Imperial College, London, United Kingdom; [4]Imperial College Healthcare NHS Trust, London, United Kingdom*.

Background: Although a number of donor factors are known to affect outcome following deceased donor kidney transplantation, many units have no clear criteria for acceptance. Donor quality scoring systems such as KDRI are based on historic data sets, performing less well in the modern comorbid donor pool, and are difficult for patients to understand.

Methods: All deceased-donor kidney offers at a single centre were analysed over a 12 month period in order to develop a patient-friendly scoring system. Donor age is modified according to the presence or absence of a number of risk factors to generate a "donor kidney age" to predict post-transplant outcome.

Results: Out of 388 offers, from 301 donors aged 6 - 84, 109 (28%) were acepted and transplanted. At 3 months post-tranplantation, recipient GFR over 30 was seen in 80%. Organs were declined due to recipient factors in 26% and donor quality concerns in 46%. Donor Kidney Age was derived incorporating 12 risk factors: donor cardiac death, hypertension, diabetes, vascular disease, baseline kidney function, creatinine rise, oliguria, proteinuria, HLA match, cardiac arrest, use of adrenaline, and duration of hospitalisation before donation. Quintiles of donor risk for all offers were identified using DKA cutoffs: 50, 60, 70, and 80. Increasing DKA quintile was associated with poorer post transplant outcome, with low 3 month GFR (below 30ml/min) in 97, 85, 73, 81 and 38% of patients respectively ($p<0.001$). In those with functioning grafts (N=105), GFR at 3 months was strongly correlated with DKA ($R=0.430$, $p<0.001$) and was seen to reduce across increasing DKA quintiles (61, 52, 42, 41, and 29ml/min).

Conclusions: DKA is a simple score based on donor age, adjusted for 12 donor-related risk factors, which strongly predicts post-transplant outcome and is conceptually easy for patients to understand. Prospective evaluation of its influence on deceased donor acceptance decisions will be undertaken.

TH-PO1126

Influence of Donor Characteristics and Delayed Graft Function (DGF) on Renal Function 12 Months After Kidney Transplantation

Fernanda B. Roberto,[2,1] Renato D. Foresto,[2] Maria A. Hazin,[2] Maria E. Vilanova,[2] Diego E. Gonzalez,[2] Luiz E. Takara,[2] Marina P. Cristelli,[2] Laila A. Viana,[2] Claudia R. Felipe,[2] Helio T. Silva,[2] J. Medina-Pestana.[2] Hospital do Rim *[1]Escola Paulista de Medicina - UNIFESP, Sao Paulo, Brazil; [2]Hospital do Rim - UNIFESP, Sao Paulo, Brazil.*

Background: The KDPI (Kidney Donor Profile Index) index is a score based on donor characteristics used to predict long-term graft survival. Delayed graft function (DGF), a variable not included in the KDPI score, is associated with reduced graft survival. We hypothesized that increasing KDPI scores and DGF concur to reduce renal function 1 and 12 months after kidney transplantation.

Methods: This single center retrospective study included all consecutive deceased donor kidney transplant recipients (n=1221) between January 2014 to December 2015. Analysis was carried out according to deciles of KPDI. Renal function was evaluated by estimated glomerular filtration rate (eGFR, calculated by the MDRD4 formula).

Results: The mean cold ischemia time was 25±7 hours and it was similar across the deciles of KPDI. The incidence of DGF increased from 39% to 75% ($p = 0.001$) from 0-10% to 91-100% KDPI deciles. The 1 month eGFR showed a negative association with KDPI deciles, 59.5 vs. 39.0 ml/min/1.73m^2 ($p<0.001$) for 0-10% and 91-100% KDPI deciles. This trend persisted in the 12 month analysis (64.6 vs. 46.0 ml/min/1.73m^2; $p<0.001$), respectively. DGF was associated with lower 1 month eGFR across all the KDPI deciles (KDPI [0-10%] 67.9 vs. 46.2 ml/min/1.73m^2, $p=0.029$; KDPI [91-100%] 47.7 vs. 36.2 ml/min/1.73m^2, $p<0.001$), but this trend decreased at 12 months (KDPI [0-10%] 65.5 vs. 63.1 ml/min/1.73m^2, $p=0.84$; KDPI [91-100%] 47.5 vs. 45.4 ml/min/1.73m^2, $p=0.425$).

Conclusions: Renal function 1 and 12 months after kidney transplantation is determined primarily by donor characteristics (KDPI) and the development of DGF.

TH-PO1127

Analysis of Donor Factors for Clinical Prediction of Recipient After Deceased Donor Renal Transplant in a Non-US Transplant System

Joon Seok Oh,[2,1] Joong Kyung Kim,[1] Edgar L. Milford,[2] Anil K. Chandraker.[2] *[1]Division of Nephrology, Department of Internal Medicine, Bong-Seng Memorial Hospital, Busan, Republic of Korea; [2]Transplant Research Center, Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: There is little data on allograft survival based on deceased donor characteristics outside the United States. Conservative use of deceased donors based on concern for longer term allograft outcomes likely increases the discard rate of deceased donor kidneys despite international deficit of kidney donors. Using South Korea as a model, we analyzed deceased donor characteristics using 1-year creatinine in the recipient as a surrogate marker for longer term outcomes.

Methods: We analyzed 2,858 cases contained within the Korean Organ Transplant Registry data which had conducted renal transplant from 2009 to 2017. Univariate, multivariate linear regression analysis and 5-fold cross validation was performed to make a formula for estimating the serum creatinine of the recipient for 1 year after deceased donor kidney transplant.

Results: Univariate analysis indicated a number of different factors were significant in determining outcome, however only donor age, donor serum creatinine and current smoking status without hypertension were statistically significant in a multivariate model for predicting serum creatinine of the recipient after 1 year of transplant (Table 1). We also found that serum creatinine at 1 year predicted 3 year outcomes in a log rank test.

Conclusions: Currently deceased donor kidney transplant outcomes are extremely good in South Korea (despite a much longer period on dialysis prior to transplant) compared to the US. Given differences in cultural, economic and racial characteristics compared to the US the Korean prediction model obtained from this study relies on checking only 3 donor factors, and thus can be obtained relatively quickly and conveniently and yet provides more information to the recipient candidates before transplant. In particular, we also believe this study indicates that there is underutilization of potential decreased donors in Korea and that a wider pool of deceased donors could be used safely.

A model of expected 1-year post-transplant serum creatinine (mg/dL) of recipient who received deceased donor Renal Transplant in Korea. (Exp: Exponential)

$$\text{Exp}[0.009 \times \text{Donor Age} + 0.015 \times \text{Donor Creatinine} - 0.060 \times \text{If Donor Hx. of Smoking} - 0.276]$$

(Donor's Hx. of Smoking, 0: No Smoking or Former Smoking or Current Smoking with HTN, 1: Current Smoking without HTN), 5 fold cross validated $R2=0.184$, F-statistic: 64.79, p value <0.01

TH-PO1128

Risk Factors, Prediction, and Outcomes of Delayed Graft Function (DGF): An Analysis from a German Cohort of Extended Criteria Donor Kidneys with Post-Explantation Biopsies

Florian G. Scurt,[1] Peter R. Mertens,[1] Hermann G. Haller,[3] Jan U. Becker,[2] Christos D. Chatzikyrkou.[1] *[1]Otto von Guericke University Magdeburg - Medical Faculty, Magdeburg, Germany; [2]University Hospital Cologne, Köln, Germany; [3]Clinic for Nephrology, Hannover Medical School, Hannover, Germany.*

Background: DGF occurs frequently after transplantation and is associated with worse short- and long-term outcomes and associated with higher rejection rates. Risk factors include both donor and recipient characteristics, although their prediction is imprecise. Therefore, we tested known risk factors of DGF and validated the performance of existing risk scores in predicting DGF in recipients of extended criteria donor kidneys with procurement biopsies.

Methods: We retrospectively evaluated the records of 223 consecutive adult cadaver renal transplant recipients with donor evaluation biopsies. 135 patients developed DGF (defined as the need for hemodialysis during the first week after transplantation). Clinical donor and recipient characteristics as well as histological features of the biopsy were compared between the two groups and the following risk scores were evaluated regarding their association with observed DGF: Navarro (2011), Ortiz (2004), Balaz (2013), Lopes (2004), Snoeijs (2008), Remuzzi (1999), Nyberg (2003), Rao (2009), Foucher (2009), Schold (2005), Port (2002), Anglicheau (2008), Leuven (2013) Irish (2010), KDRI/KDPI and EPTS.

Results: Severity of acute kidney injury (similar to AKIN Classification) at ICU stay, last creatinine, proteinuria, macroscopic organ quality, microthrombi by histology, prolonged warm ischemia time, recipient body mass index, and recipient duration of dialysis were significant risk factors for the development of DGF in the recipient in univariable analysis. None of the evaluated scores could accurately predict DGF. In multivariable analysis only severity of acute kidney injury and microthrombi by biopsy remained statistically significant (OR 1.89 95%CI 1.26-2.84, $p=0.002$; OR 3.06, 95%CI 1.00-9.34, $p=0.049$, respectively).

Conclusions: None of the established clinical, histological or combined scores for quality assessment of deceased donor kidneys appeared sufficiently prognostic for DGF in our cohort. We are currently working on a novel combined clinicopathological score better suited for clinical application in the Eurotransplant network.

TH-PO1129

Diffusion MRI Detects an Increase in Interstitial Fibrosis Earlier Than the Decline of Renal Function

Lena Berchtold,[1] Solange Moll,[2] Pierre-Yves F. Martin,[3] Sophie M. De Seigneux.[1] *[1]Hôpitaux Universitaire de Genève, Geneva, Switzerland; [2]University Hospital of Geneva, Geneva, Switzerland; [3]Hospital Universitaire de Geneve, Geneva City, Switzerland.*

Background: Interstitial fibrosis(IF) is one of the major predicting factors in CKD. Diffusion Weighted Magnetic resonance imaging(DWI-MRI) is a new tool for non–invasive IF assessment, but its value for IF follow up is unknown. We recently adapted a DWI sequence, allowing for the discrimination between the kidney cortex and medulla. The cortico-medullary ADC difference(ΔADC) was better correlated to IF than absolute ADC. We aimed at analyzing the use of DWI-MRI for the follow up of IF in patients having undergone repeated biopsies in comparison to renal function evolution.

Methods: In this prospective study, we included patients having undergone repeated biopsies for clinical purpose and who agreed to undergo repeated DWI-MRI at the time of biopsy.

Results: 19 kidney allografts patients had repeated biopsies for clinical purposes and parallel MRI examinations. The average interval between the two biopsies was 1.7year. There was no significant correlation between eGFR and IF at baseline($r=-0.39$,$p=0.10$), whereas baseline ΔADC correlated negatively with IF($r=-0.76$,$p<0.001$). Between the two visits, IF as estimated from the biopsy, increased significantly from a fibrosis score of 20% to 32.5%($p=0.03$) in individual patients, whereas estimated renal function remained stable(eGFR 54 to 52ml/min/1.73m^2;$p=0.19$). ΔADC decreased significantly from 30 to -23 x10^{-6}mm^2/S(Figure A). Considering the difference between the basal and follow-up values, there was a good correlation between the evolution of IF and ΔADC ($r=-0.51$,$p=0.03$)(Figure B) but not between the evolution of IF and eGFR ($r=0.24$,$p=0.34$).

Conclusions: Thus modifications of ΔADC derived from DWI-MRI outperformed eGFR to follow IF evolution within a given patient. ΔADC may be more reliable than eGFR to allow earlier detection of an increase in IF.

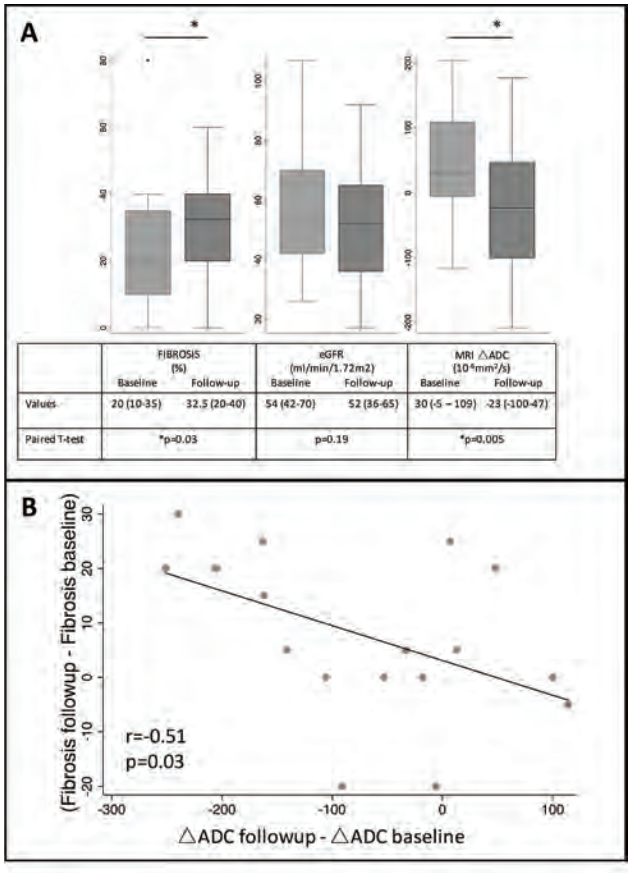

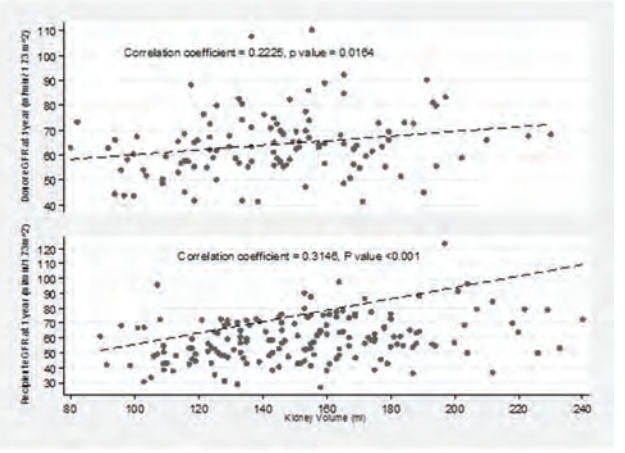

Figure 1: Correlation of renal volume and eGFR in donors and recipients at 1 year

TH-PO1130

Donor Kidney Renal Volume Predicts Recipient and Donor Graft Function at 1 Year

Chaudhry Adeel Ebad, Julio L. Chevarria, Donal J. Sexton, David J. Brennan, Yvonne E. Williams, Conall M. O'Seaghdha, Peter J. Conlon. *Beaumont Hospital, Dublin, Ireland.*

Background: Renal transplantation is treatment of choice in end stage renal disease of which Living donor kidney transplantation is optimal. The role of renal volume measurement in predicting long-term donor and recipient graft outcome is not clear.

Methods: This retrospective cohort study of living donor kidney transplantaion (2010-2017) from the National Kidney Transplant Service (NKTS) of Ireland. Renal volume was measured bilaterally in living kidney donors using TeraRecon USA. Low eGFR for recipients and donors defined as < 60ml/min 1-year post donation was used in logistic regression modeling with donor volume categorized into tertliles. Donor and recipient characteristics were included in the models as potential confounding variables.

Results: There were 166 living donor kidneys in the study period. Mean donor age was 44.8 years (SD = 10.8). Donor mean BMI was 25.5 (SD = 2.9). Donor kidney volume mean was 152.7 mls (SD = 31.6), divided into tertiles was; 1: 89.2 – 135 mls, 2: 136 – 164 mls, 3:165 – 240 mls. Median donor eGFR at 1 year post transplant was 63.3 (IQR[2]=56.1–70.4).Recipientsoflivingdonorkidneyshadameanageof43.5years(SD=13.3). Median recipient eGFR at 1 year post transplant was 58.3 (IQR = 48.4 – 69.4). Donor kidney volume is slightly correlated with donor eGFR at 1 year post transplant (figure 1) and is marginally non significant in logistic regression for low eGFR using the above tertile categories; Odds Ratio 0.65 [95% conf. int. 0.40 – 1.04, p value = 0.075]. Donor kidney volume is correlated with recipient eGFR at 1-year post transplant (figure 1) and is significant in multivariable logistic regression; Odds Ratio 0.48 [95% conf. int. 0.26 – 0.90, p value = 0.021].

Conclusions: Donor kidney volume predicts recipient graft function 1-year post transplant but is less conclusive for donor kidney function. Cognizance of donor renal volume may help optimise potential kidney donor selection.

TH-PO1131

Interstitial Fibroblasts in Donor Kidney Predict Late Post-Transplant Anemia

Mayuko Kawabe, Aki H. Mafune, Izumi Yamamoto, Takafumi Yamakawa, Haruki Katsumata, Ai Katsuma, Yasuyuki Nakada, Akimitsu Kobayashi, Yudo Tanno, Ichiro Ohkido, Nobuo Tsuboi, Hiroyasu Yamamoto, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Post-transplant anemia (PTA) is associated with the progression of kidney disease and mortality in kidney transplant recipients. In general, PTA is categorized into early and late types, commonly appearing during the two years following transplantation. Although the main causes of PTA are recipient factors, donor factors have not been fully investigated. In this study, we investigated the association of donor pathological findings with the incidence of PTA in kidney transplant recipients after 3 y (late PTA).

Methods: We conducted a retrospective cohort study at a single university hospital. A total of 50 consecutive adult recipients and donors were enrolled. To assess the structure of interstitial lesions, immunohistochemical staining of interstitial fibrosis and of fibroblasts were assessed in 0-hr biopsies for quantitative analysis.

Results: The incidence of late PTA in this cohort was 30%. Mean hemoglobin (Hb) was 11.6 ± 0.8 g/dL in patients with late PTA, and 14.3 ± 1.5 g/dL in patients without PTA. An inverse association was observed in biopsies between interstitial fibrosis area and interstitial fibroblast area (P<0.01), and each pathological finding was examined for its association with late PTA incidence after multivariate adjustment. For interstitial fibrosis area, the odds ratio (OR) was 1.94, with a 95% confidence interval (CI) of 1.26 to 2.99; P<0.01. For interstitial fibroblast area, OR was 0.01, 95% CI was 0.00 to 0.16, and P<0.01. Receiver operating characteristic curve analysis indicated that interstitial fibroblast area had high predictive power for the incidence of late PTA.

Conclusions: The presence of interstitial fibroblasts in donor kidney may play an important role in predicting the incidence of late PTA.

TH-PO1132

Presence of Renal Dysfunction Even at the Time of Listing Predicts Risk of ESRD in Isolated Heart Transplant Patients

Abhishek Kumar,[1] Christie P. Thomas.[2,3] [1]*Internal Medicine, University of Vermont, Burlington, VT;* [2]*Internal Medicine, University of Iowa, Iowa City, IA;* [3]*Internal Medicine, VA Medical Center, Iowa City, IA.*

Background: Presence of chronic kidney disease (CKD) at the time of heart transplant is an independent predictor of post-transplant ESRD (end stage renal disease) and all-cause mortality. We wished to look at the effect of the presence and severity of CKD at the time of listing on post-heart transplant ESRD and mortality.

Methods: We analyzed 2000-2015 UNOS heart transplant data. Adults receiving first isolated heart transplant, who were not on dialysis were included in study. We divided our cohort into four clinically relevant groups based on their listing eGFR (<30 ml/min, 30-44 ml/min, 45-59 ml/min and ≥60 ml/min). Survival analysis was used to generate Kaplan-Meier curves. Results were adjusted for multiple confounding factors.

Results: We had 27,169 patients in our cohort. In the follow up period there were 7595 deaths and 2335 patients reached ESRD (Table 1). Kaplan-Meier curves for ESRD are shown in Figure 1.

Conclusions: Our findings shows that risk of renal replacement therapy post heart transplant increases with worsening eGFR at listing even after adjusting for multiple confounders with the highest risk in the group with eGFR <30 ml/min. This information may help identify patients for combined heart-kidney transplant in a more reasonable time frame.

Risk of post heart transplant ESRD by listing eGFR

eGFR at time of listing	ESRD N (%)	Adj hazard ratio with p value	Mortality N (%	Adj hazard ratio with p value
eGFR <30	157 (21.7)	2.77 (p<0.001)	284 (39.6)	1.10 (p=0.148)
eGFR 30-44	572 (15.7)	2.16 (p<0.001)	1289 (35.5)	1.11 (p<0.001)
eGFR 45-60	617 (10.1)	1.40 (p<0.001)	1961 (32.4)	1.05 (p=0.092)
eGFR > 60	989 (7)	1	4061 (28.9)	1

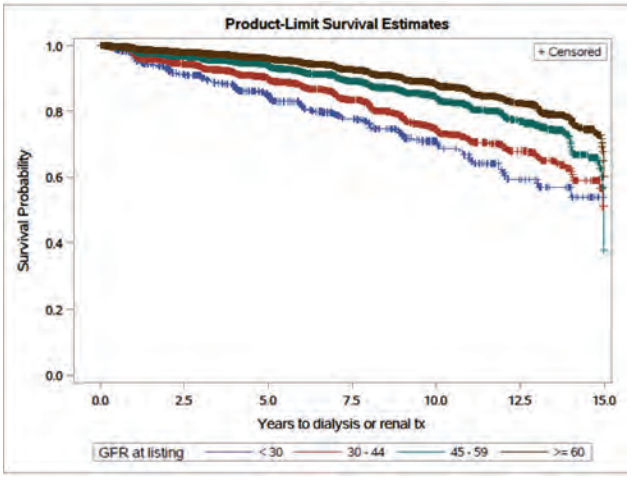

Figure 1: Kaplan-Meier estimate for renal survival

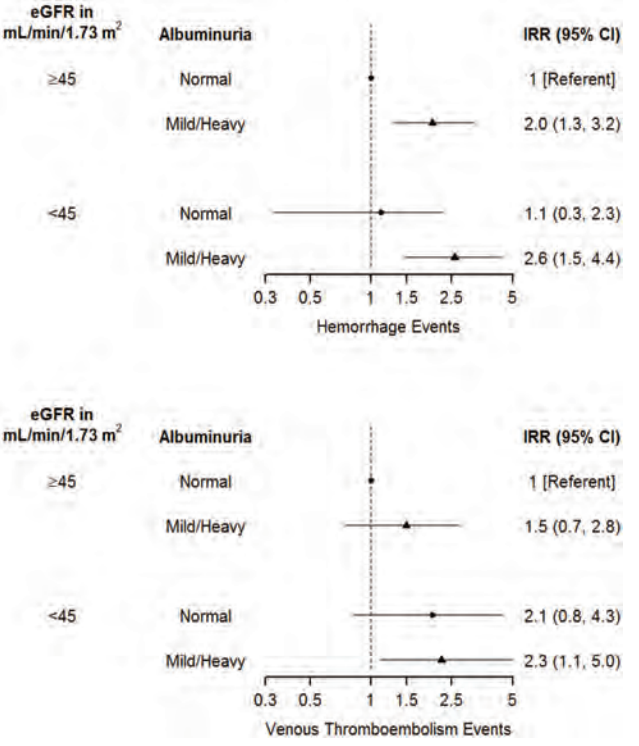

Adjusted Incidence Rate Ratios by Level of eGFR and Albuminuria in Recipients

TH-PO1133

Kidney Function, Albuminuria, and the Risk of Hemorrhage and Thrombosis After Kidney Transplantation

Rachel H. Jeong,[1] Robert R. Quinn,[2] Pietro Ravani,[2] Manish M. Sood,[3] Marcello Tonelli,[2] Feng Ye,[1] Brenda Hemmelgarn,[2] David Massicotte-Azarniouch,[3] Ngan Lam.[1] *[1]University of Alberta, Edmonton, AB, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Compared to the general population, kidney transplant recipients are at increased risk of hemorrhage and thrombosis. Whether this risk is affected by kidney function and albuminuria is unknown.

Methods: We conducted a retrospective cohort study using linked healthcare databases to identify adult kidney transplant recipients from 2002-2015 in Alberta, Canada. Estimated glomerular filtration rate (eGFR) and albuminuria measurements at 1-year posttransplant were used to categorize recipients (eGFR: ≥45 vs. <45 mL/min/1.73 m^2; albuminuria: normal vs. mild-heavy). We determined the association between categories of eGFR and albuminuria and posttransplant hemorrhage and venous thrombosis based on diagnostic and procedural codes.

Results: Of 1,284 kidney transplant recipients at 1-year posttransplant, 21% had an eGFR <45 mL/min/1.73 m^2 and 40% had mild-heavy albuminuria. The mean age of the cohort was 53 years [IQR 41-62]. Previous thrombosis was higher in recipients with lower eGFR, but previous hemorrhage was similar across all groups. Over a median follow-up of 6 years, the age- and sex-adjusted rate of hemorrhage and thrombosis was over 2-fold higher in recipients with lower eGFR and mild-heavy albuminuria compared to recipients with higher eGFR and normal albuminuria (hemorrhage: incidence rate ratio, IRR, 2.6, 95% CI 1.5-4.4, p=0.001; thrombosis: IRR 2.3, 95% CI 1.1-5.0, p=0.046).

Conclusions: Among kidney transplant recipients at 1-year posttransplant, the risk of hemorrhage and venous thrombosis is higher with lower eGFR and mild-heavy albuminuria. Thus, eGFR and degree of albuminuria may help prognosticate kidney transplant recipients long-term.

TH-PO1135

Evaluation of Functional and Nutrition Status in the Older Transplant Candidate

Olivia A. Moss,[2] Golnaz G. Friedman,[2] Anusha S. Yerraguntala,[1] Macey Sockolov,[2] Ling-Xin Chen.[2] *[1]UC Davis, Davis, CA; [2]UC Davis Health, Sacramento, CA.*

Background: Measures of functional and nutrition status (NS) at time of kidney transplant (KT) have been shown to be predictive of post-KT outcomes. No gold standard tool to best assess functional status exists. Assessment of physiological reserve is important in the older KT candidate who may have additional risk factors such as malnutrition. Our purpose is to identify the functional and NS measures predictive of ineligibility for KT listing.

Methods: All patients >65 years old evaluated for KT were recruited. Participants completed the short physical performance battery (SPPB) and Fried Frailty assessment (FFA). Nutrition status was assessed using standardized malnutrition criteria. Patient charts were reviewed for KT listing status (ineligible or listed). Differences between SPPB, FFA, NS, and the components of each assessment were tested between groups by ANOVA, Chi-squared and logistic regression analyses.

Results: A total of 105 patients were enrolled and 73 had complete follow-up data at time of analysis. Scores for the SPPB and FFA were not predictive of ineligibility of KT listing [Table 1]. However, slower chair stand time (OR $_{1.05}1.28_{1.55}$, p=0.01) and slower walk time (OR $_{1.11}2.37_{5.10}$, p=0.03) were predictive of KT ineligibility. Those ineligible for KT tended to report lower physical activity levels, have lower handgrip strength and be malnourished compared to those who were listed, but this did not reach significance [Table 1].

Conclusions: Objective measures like walk and chair stand time may be more predictive of KT ineligibility than SPPB and FFA when used at the time of KT candidacy evaluation, but further investigations are needed.

Funding: Private Foundation Support

TH-PO1136

Managing High Cardiovascular Risk Patients on Kidney Transplant Waiting List: Costs and Outcome

Joey Junarta,[2] Isaac W. Chung,[2] Debasish Banerjee.[1,2] *[1]St George's Hospital, London, United Kingdom; [2]St George's, University of London, London, United Kingdom.*

Background: High cardiovascular risk patients on the kidney transplant waiting list undergo multiple cardiovascular investigations to ensure fitness for transplant surgery, yet suffering from adverse events. The ideal protocol for managing these patients is unknown. We investigated the benefits of cardiorenal multidisciplinary meetings in managing these patients.

Methods: We analysed data from 126 patients discussed between September 1/10/14 and 30/9/17 in biannual multidisciplinary team (MDT) meetings as per protocol, followed up until 11/05/19. We analysed the results of post-MDT cardiac testing and outcomes, including CV events, mortality, and transplantation status. The cost of post MDT cardiac testing was estimated from NHS best practice tariffs.

Results: Clinical characteristics of 126 patients were: age (median 62 years, Interquartile range [IQR] 57-67), sex (male 60%), Diabetes Mellitus (58%), Smoker (41%), Hypertension (96%), cholesterol (median 3.8 mmol/L, IQR 3.1-4.8), and PTH (median 33 ng/L, IQR 16-67). The patients were followed-up for a median of 970 days (IQR 584-1334). During the follow up, 44 patients were transplanted. 42 patients had adverse outcomes: 13 patients died, 14 suffered ACS, 5 suffered stroke, 1 suffered TIA, 15 underwent PCI, 7 underwent CABG. Diabetic patients were more likely suffer from adverse events (log-rank test p=0.007). Patients with positive stress echocardiogram tended to have more events, but the difference was not statistically significant (log-rank test p = 0.085). There was no difference comparing the group with or without events with respect to age, gender, smoking, hypertension, cholesterol, PTH, phosphate or ferritin levels. The costs of post MDT cardiac tests were as follows: 62 stress echo = £1500, 32 Coronary Angiograms = £88632, 13 PCIs = £52325, and 5 CABG = £38350, and total cost = £193897. The approximate cost per patient is £1538, which is approximately £600 per patient per year.

Conclusions: The biannual cardiorenal MDT maintained 126 high risk patients on the kidney transplant waitlist for 2.7 years with successful transplants in 35%, adverse events in 33%, and mortality in 13%. A cardio-renal MDT approach for high CV risk patients can ensure successful transplantation one-third patients in 2.7 years with acceptable cost of cardiac testing despite adverse outcomes.

TH-PO1137

Prevalence of Pulmonary Hypertension in Patients Listed Active for Kidney Transplantation

Sam Kant, Christin Iroegbu, Sami Alasfar, Fizza F. Naqvi, Daniel C. Brennan. *Nephrology, Johns Hopkins University Hospital, Baltimore, MD.*

Background: Pulmonary hypertension (PH) is variably defined, with estimated prevalence in CKD and ESRD of 9% and 19%, respectively. PH at the time of kidney transplantation (KTx) can portend a lower graft survival and the prevalence in wait-listed patients is unknown. We sought to ascertain the prevalence of PH in patients listed active for KTx and characterize based on demographics, comorbidities and ECHO characteristics at our center

Methods: A chart review of EPIC EMR was conducted by assessing problem lists, clinic evaluations and ECHO results for patients listed active for KTx at our institution from 2014-2019. We recorded basic demographics, ESRD cause, type of dialysis access, vintage and modality, listing duration, associated comorbidities and comprehensive ECHO measurements. PH was defined as RVSP>35 mm Hg on ECHO

Results: Of 634 patients listed active during this period, 104(17%) patients had ECHO evidence of PH. Demographics and ECHO data are shown in Table 1. Mean age of patients was 57 years, with 61% male, 59% African-American and mean BMI of 29.1. Diabetes was the most prevalent cause of ESRD (38%),75% were on HD and 70% had an AVF as dialysis access. Median dialysis vintage was 36 months and listing duration was 20 months; 25% had a history of obstructive sleep apnea (OSA) and 30% had coronary artery disease. The mean RVSP was 44.7 mm Hg (SD 8.7, range 35-83), 25% of patients with evidence of PH on ECHO were formally reviewed by a cardiologist, only 3 of whom had PH diagnosed and classified as per WHO criteria. Other ECHO findings showed 57% had HFpEF and 22% had valve abnormalities (moderate-severe)

Conclusions: This is the one of the largest studies to elucidate prevalence, clinical and ECHO characteristics in patients with PH listed active for KTx. PH appears to be under-addressed and efforts should be made to ascertain its cause and direct intervention(eg. ultrafiltration, improving lung disease, and pulmonary vasculature vasodilators). Future studies could assess the effect of interventions on post KTx outcomes, particularly in groups stratified by PH severity.

TH-PO1138

Exercise Stress Electrocardiogram for Pretransplant Cardiac Evaluation: A Costly but Generally Useless Effort

Bruno Watschinger, Stefan Scherr, Elias L. Meyer, Katharina Hohenstein-Scheibenecker. *Medical University of Vienna, Vienna, Austria.*

Background: There is an ongoing debate on the informative values of cardiac evaluation tests in renal transplant candidates. Exercise stress electrocardiogram (ES-ECG) is advocated and widely used as a non-invasive test to rule out significant coronary artery disease before renal transplantation. The precondition of a test sufficient for interpretation is the achievement of an age adjusted maximal work capacity. We were interested in the fundamental question, whether the test yields meaningful results in transplant candidates at all and how achieved exercise capacities compare to healthy individuals.

Methods: Of 1319 dialysis patients transplanted at our institution (between 29/02/2000 and 30/09/2017) 453 (mean age 51,2+/-12,6 yrs) underwent cycle-ergometer ES-ECG testing during their pre-transplant work-up. 137 kidney donors (mean age 50,4+/-9,8 yrs), who were also evaluated by ES-ECG served as control group. We evaluated two endpoints related to the tests meaningfulness and sufficiency: 1) whether study subjects reached maximal work capacity (according to exercise resistance level, measured in Watts or expected heart rate (HR) reached) and 2) whether patients had sufficiently diagnostic test results (i.e. achievement of the maximal work capacity (Watt) or the expected HR or experienced symptoms at lower work intensities. In order to assess test result sufficiency of transplant candidates and kidney donors, absolute and relative frequencies plus 95% CIs for both endpoints were computed and compared by a two-sided two proportion z-Test.

Results: see Table

Conclusions: While maximum exercise capacity (measured in Watt) was achieved by 82 % of healthy kidney donors only a minority of dialysis patients was fit enough to adequately perform during ES-ECG. Consequently meaningful results during ES-ECG were observed in only 37 % of dialysis patients, making Exercise stress electrocardiogram a generally useless, but with regard to time and resources costly effort in the cardiac evaluation of renal transplant candidates.

	Transplant candidates	Kidney donors	P-Value

TH-PO1139

Embolization of Polycystic Kidneys as an Alternative to Nephrectomy Before Kidney Transplant

Enric Broseta,[1] Francisco Gómez-Palomo,[1] Saturnino Luján,[1] Jose Martinez-Rodrigo,[2] Daniel Perez-Enguix,[2] Raul Garcia-Marcos,[2] Jordi Espí,[1] Francisco Boronat.[1] *[1]Kidney Transplant Unit, La Fe University Hospital, Valencia, Spain; [2]Interventional Radiology Unit, University Hospital, Valencia, Spain.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is responsible for progressive end-stage renal disease. In case of a massive enlargement of polycystic kidney, renal transplantation surgery may be hindered due to the limited pelvic space. In such cases a radical nephrectomy prior to renal trasplantation is warranted. Recently, transcatheter arterial embolization (TAE) has been described as an alternative to nephrectomy. We prospectively evaluated the safety and efficacy on long-term kidney volume reduction of TAE procedures in a group or patients with ADPKD before renal transplantation.

Methods: Between January 2016 and December 2018, 16 patients with end-stage renal disease associated to massive ADPKD were prospectively recruited. Informed consent was obtained from all participants. All procedures were carried out according to the ethical standards of the institutional and national research committee and with the 1964 Helsinki declaration. All TAE were performed under local anesthesia and sedation and using cyanoacrylate as embolic agent. A previous CT scan and further CT at 6 and 12 months after TAE were performed. The variables collected were: age, gender, size, renal volume measured by volumetry before and after TAE and score on the visual analog scale (VAS) for pain and complications. A descriptive statistical analysis was made.

Results: A total of 16 patients (9 men and 7 women) were included. The average age was 52.38 (± 9.19) years. The average hospital stay was 3.71 (± 1.32) days. 11 patients presented with mild complications (Clavien-Dindo I). The average score on the VAS scale was 3.38 (± 2.46) points. Only one patient presented a partial embolization of the renal artery, which was resolved by a new TAE with cyanoacrylate and a coil. Before embolization average kidney volume was 2509.08 ± 946.7 cc. Six months later volume was 1303.71 ± 836.2 cc. and 12 months later 1098.41 ± 684.9 cc. During the first 6 months a reduction of 48.05% in renal volume was observed. Of these patients, 9 (56.25%) have received a kidney transplant without problem of space.

Conclusions: Our results indicate that TAE is a safe and effective alternative to nephrectomy before renal transplantation in patients with ADPKD.

TH-PO1140

Liver Biopsy Does Not Change Transplant Candidacy Decisions for Hepatitis B Virus-Positive Living-Donor Kidney Transplant Recipients

Jung a Yoon,[1] Keun-hoi Park,[1] Hyosang Kim,[3] Soon Bae Kim,[1] Su-Kil Park,[2] Chung Hee Baek.[1] *[1]Nephrology, Asan Medical Center, Seoul, Republic of Korea; [2]Asan Medical Center, Seoul, Republic of Korea; [3]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: Hepatitis B virus (HBV) infection in kidney transplantation (KT) recipients is associated with increased overall mortality, graft loss, and progression of liver disease after KT. Liver biopsy is the gold standard for hepatic diagnosis, but it is an invasive and painful procedure. This study evaluated the necessity of liver biopsy in the decision concerning transplant candidacy among HBV-positive living-donor KT recipients.

Methods: This single-center retrospective study reviewed 3,532 patients who underwent KT from February 1997 to March 2015. Outcomes were analyzed for 144 hepatitis B surface antigen (HBsAg)-positive patients with end-stage renal disease who underwent liver biopsy. To compare clinical characteristics, we divided the patients into two groups according to the degree of fibrosis based on METAVIR score. Pathologic findings without fibrosis (F0) were found in 65 (49.6%) cases, and 79 (50.4%) patients were included in the fibrosis group (fibrosis score F1 to F4).

Results: There was no significant difference in age, sex, mode of dialysis before KT, proportion of deceased-donor KT, aspartic acid transaminase levels, total bilirubin, albumin levels, and prothrombin time between non-fibrosis patients and fibrosis patients The Child–Pugh scores were similar between patients with or without fibrosis (p=0.155). There was no liver failure after KT in non-fibrosis patinets, and five (6.3%) fibrosis patients progressed to liver failure (p=0.064). Hepatocellular carcinoma was diagnosed in 2 (3.1%) non-fibrosis patients and 6 (7.6%) fibrosis patients (p=0.294). Biopsy-confirmed acute rejection occurred in 12 (18.5%) non-fibrosis patients and 22 (27.8%) fibrosis patients (p=0.187). The 5-year graft survival rate was 96.9% in non-fibrosis patients and 94.6 % in fibrosis patients. There were no significant differences in graft and patient survival between patients with or without fibrosis (p=0.381 and p=0.113, respectively).

Conclusions: The graft and patient survival were not affected by fibrosis detected by pre-KT liver biopsy. Additionally, fibrosis status did not significantly affect liver-related outcomes among HBsAg-positive recipients. In the new antinucleos(t)ide era, liver biopsy findings might not be helpful for guiding the management of HBsAg-positive KT candidates.

TH-PO1141

Pre-Transplant Cognitive Impairment Is Associated with Increased Rates of Early Post-Transplant Rehospitalization

Aditi Gupta,[1] Neal Montgomery,[1] Victor Bedros,[7] John Lesko,[1] Tashra S. Thomas,[2] Shweta Chakraborty,[3] Jonathan D. Mahnken,[4] Jeffrey M. Burns,[6] Diane M. Cibrik.[5] *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of Kansas Health System, Leawood, KS; [3]The University of Kansas Health System, Kansas City, KS; [4]The University of Kansas Medical Center, Kansas City, MO; [5]University of Kansas Hospital, Parkville, MO; [6]University of Kansas School of Medicine, Kansas City, KS; [7]University Of Kansas Medicar Center, Manhattan, KS.*

Background: Cognitive impairment is common in patients with kidney disease and can affect patients understanding of transplant care and kidney transplant (KT) outcomes.

Methods: We conducted a single-center longitudinal cohort study to evaluate the association of pre-transplant Montreal cognitive assessment (MoCA) scores with length of hospitalization for KT and post-transplant rehospitalization rates. We used multiple regression for duration of hospitalization for KT and logistic regression for rehospitalization within 30 days.

Results: In total, 207 patients underwent MoCA testing before transplant and were included in the analysis. Patients with cognitive impairment were more likely to be older, black, and smokers (Table 1). The duration of hospitalization was independent of MoCA score, but associated with a history of coronary artery disease (β coeff=2.29, p= 0.002) and duration of dialysis before KT (β coeff=0.56, p<0.001). The odds of readmission within 30 days was higher with lower MoCA scores (Table 2).

Conclusions: Pre-KT cognitive impairment does not affect length of hospitalization for KT, but is associated with higher odds of 30-day rehospitalization after KT.

Funding: Other NIH Support - NIA K23

Table 1.

Patient Characteristics	MoCA <26 (n=92)	MoCA ≥26 (n=115)
Age at KT (years)	48.3 ± 12.4	46.7 ± 15.1

TH-PO1142

Non-Candidacy for Kidney Transplant: An Experience from Rural Eastern North Carolina

Debargha Basuli,[1] Geetha Samuel,[2] Hsiao L. Lai,[1] Samuel Dadzie.[2] [1]*East Carolina University, Greenville, NC;* [2]*ECU Nephrology & Hypertension, Greenville, NC.*

Background: Kidney transplant is the optimal therapy for the end-stage renal disease patients in order to improve the expectancy and quality of life. Recently there are many studies investigating how to improve the referral process to improve the access to kidney transplantation. However, there is not much data looking into the rate and causes disapproval of these referred patients by the transplant program to be activated in the waiting list. Thus it is important to study the disapproved population so that we can identify the barriers and intervene to improve kidney transplant rates.

Methods: The electronic health records of 309 ESRD patients undergoing dialysis by one major dialysis practice, East Carolina University were accessed manually to obtain information about the referral by the nephrologists for a transplant and the decision of the transplant selection committee. Disapproval rate for transplant was calculated by percent, and any disparities in disapproval was measured based on gender and race of the patients. Statistical analysis was conducted with t-test and a $p<0.05$ was considered significant.

Results: Our preliminary data shows although all ESRD patients were referred for transplant within 1 year of initiation of dialysis, about 63 percent of the referred ESRD patients were initially disapproved for further evaluation for a transplant. 40 percent of these patients were disapproved because of modifiable factors like smoking, alcohol abuse, overweight, not completing age appropriate screening tests. Only 40% of these patients were able to successfully modify the risk factors and were accepted as transplant candidates in following transplant evaluation visits. Interestingly, 83% of the disapproved patients were African-Americans, and 41% were females.

Conclusions: Our reports shows that there are major barriers to transplant in ESRD patients in eastern North Carolina even after patients have been referred early. Majority of the disapproved patients were African-Americans and only less than half of the patients with modifiable risk factors were able to be enlisted for transplant after proper intervention. More quality improvement endeavors are required to reduce the disparity in race and to support ESRD patients to overcome modifiable barriers to improve transplant rates in this population.

TH-PO1143

Longer Distance from Dialysis Facility to Transplant Center Is Associated with Lower Access to Transplantation

Adrian Whelan,[1] Kirsten L. Johansen,[2] Deborah B. Adey,[1] Garrett R. Roll,[1] Salpi Siyahian,[1] Elaine Ku.[1] [1]*University of California, San Francisco, CA;* [2]*Hennepin Healthcare, Minneapolis, MN.*

Background: The distance between patients' residence and their kidney transplant center is not associated with access to transplantation. However, distance from the dialysis facility to the transplant center (DFTC distance) may be important for access to transplantation, as dialysis providers closer to the transplant center may maintain better communication with the transplant center and expedite patient work-up. We hypothesized that longer DFTC distance would associate with longer time to transplantation.

Methods: We included adults who started dialysis between 2005-2015 according to the US Renal Data System. The primary predictor was DFTC distance ≥100 miles vs. <100 miles (reference group). Outcome was time from dialysis initiation to kidney transplantation. We used adjusted Cox models and tested for interactions by region of the US, calendar year, and dialysis modality.

Results: 172,995 patients were included; mean age was 51.6 yrs; 30.3% were black. DFTC distance varied by region of the US (table). Overall, DFTC distance ≥100 miles (vs. <100 miles) was associated with lower access to transplantation regardless of dialysis treatment modality, (table), but the association was modified by region of the US and calendar year ($p<0.05$ for interaction). Longer DFTC distance was associated with lower access especially among patients living in the South and West. The association between DFTC distance and access to transplantation has attenuated over time (table).

Conclusions: Longer DFTC distance was associated with lower access to kidney transplantation even after accounting for distance between patients and the transplant center. Our data suggest that system-level factors such as proximity between referring and transplant providers may contribute to access to transplantation, but this association varies across the US.

Funding: Veterans Affairs Support

Table. Adjusted Cox models of the association between dialysis facility-to-transplant center (DFTC) distance and outcome of transplantation.

	DFTC distance in miles, median (IQR)	Access to transplant by DFTC distance ≥100 miles vs. <100 miles (HR*, 95% CI)
All patients (n=172,995)	19.8 (6.8-67)	0.94 (0.92-0.96)
Region of the US*		
West (n=42,033)	23.4 (9.7-80.6)	0.94 (0.90-0.99)
Midwest (n=33,904)	19.3 (6.1-62.9)	1.05 (1.01-1.10)
South (n=63,325)	28.1 (7.9-86.4)	0.90 (0.87-0.93)
Northeast (n=33,693)	11.0 (3.2-28.1)	1.00 (0.92-1.08)
Dialysis modality		
Hemodialysis (n=143,843)	19.6 (7.0-65.9)	0.93 (0.91-0.96)
Peritoneal dialysis (n=29,042)	20.4 (5.3-71.4)	0.95 (0.90-0.996)
Time period*		
2005-2009 (n=88,354)	19.3 (6.4-67.9)	0.93 (0.90-0.95)
2010-2015 (n=84,601)	20.4 (7.1-65.9)	0.97 (0.93-1.00)

TH-PO1144

Utilizing the Estimated Post-Transplant Survival Score (EPTS) to Assess Dialysis Facility Referral for Pre-Transplant Evaluation

Antonia Harford, S. Paine, Huan Jiang, Ronald Sanders, Ambreen Gul, Philip Zager. *Dialysis Clinic Inc, Albuquerque, NM.*

Background: Although transplant (txp) is the optimal treatment for End Stage Kidney Disease (ESKD), only ~ 15% of prevalent patients (pts) are waitlisted annually. It is estimated that approximately half of ESKD pts would have a survival advantage from txp. The 4-factor (age, vintage, diabetes, & prior txp) EPTS in conjunction with the Kidney Donor Profile Index maximizes the use of donor kidneys with the highest predicted survival by allocating them to potential recipients with the highest predicted post txp survival. Lower EPTS is associated with higher projected longevity. With the exception of diabetes, the 4 factor EPTS does not include comorbidities. We calculated EPTS for incident ESKD pts cared for in outpatient dialysis facilities operated by a nonprofit provider, to determine if pts with a favorable prognosis were being appropriately referred for evaluation.

Methods: We studied 14,043 hemodialysis (HD) & 2,739 peritoneal dialysis (PD) pts, 18 -71 years who started dialysis between 2009-2018 & were followed for 1 year unless transplanted. SAS & R statistical packages were utilized for data analysis.

Results: EPTS distributions in HD & PD pts differed (see figure). The median (IQR) scores were 36 (19- 54) & 29 (14- 46) in HD & PD pts, respectively. Overall, 47.9% of HD & 71.0% of PD pts were evaluated in the first year. The % pts in the lowest EPTS quintile was higher among PD (36.7%) vs. HD (27.9%) pts. Among pts with the best predicted longevity by EPTS, 41.3% HD vs. 20.9% PD pts were not evaluated in the first year. Reasons included patient referred but not evaluated, patient refusal of referral, medically unsuitable or unknown reason.

Conclusions: Overall, the present referral practices within this nonprofit dialysis provider demonstrate that pts are being actively referred for pre-txp evaluation. Better referral rates & EPTS scores among PD vs. HD pts likely reflect the overall health of those pts selected for home dialysis. EPTS use in conjunction with an incident comorbidity review will allow dialysis facilities to optimize transplant referral practices.

TH-PO1145

Accessibility and Graft Outcome According to Economic Inequality in South Korea: A Widening Gap After Expansion of Insurance Coverage

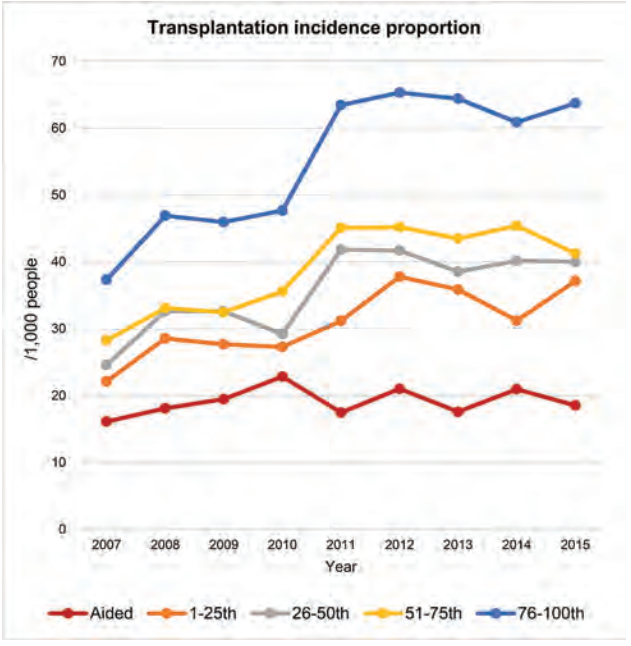
Sehoon Park, Ji Eun Kim, Yong Chul Kim, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Disparity in accessibility to and prognosis of kidney transplantation according to wealth inequality has been an important issue.

Methods: We performed a nationwide, population-based cohort study using the national claims database of Korea in which nationwide health insurance is provided. End-stage renal disease (ESRD) patients from 2007 to 2015 were included. As their wealth status was identifiable annually, the financial states were collected and stratified into five subgroups in each year. Time-trends of incidence proportion of kidney transplantation among ESRD patients in each year was initially assessed. The risk of graft failure was analyzed as prognostic outcome within the transplant recipients.

Results: Significant disparity in kidney transplantation accessibility was present and it was further widening, particularly from the year 2009 in which the national health insurance service started to cover desensitized kidney transplantation. Desensitized or preemptive transplantation was less common in the poorest group who were more frequently receiving transplantation after 5 years of dialysis in the recent periods. The prognosis of kidney transplantation was significantly worse in the poorer people, and this disparity also worsened during the study periods.

Conclusions: Prominent disparity regarding accessibility to and prognosis of kidney transplantation presented in Korea according to wealth inequality and was further worsening. Worsening pressure of donor shortage was less severe in the richer people who were preferentially benefited from the recent expansion of donor pool.



TH-PO1146

It's Now or Never: A Retrospective Audit of Patients Suspended from the Deceased Donor Transplant List

Michael Toal. *Belfast City Hospital, Belfast, United Kingdom.*

Background: The primary purpose was to evaluate the outcomes of patients suspended from the deceased donor renal transplantation list in Northern Ireland. A three year follow-up period was used from October 2015 to December 2018. The primary outcomes measures were to assess the proportion of patients who were alive and had been transplanted by December 2018. Secondary outcomes were to measure the duration patients were suspended, the reasons for this and to examine the relationship between duration and reason for suspension and likelihood of transplantation.

Methods: A list of patients suspended from the deceased donor transplant list on 28thOctober 2015 was obtained from the regional transplant centre in Belfast City Hospital. Regional medical databases were used to extract data on the date of initial listing on the active list, dates of suspensions, reasons for suspensions and outcomes. The end of follow-up period was 10thDecember 2018.

Results: 56 patients were identified on the initial deceased donor renal transplant list. 41 patients (73%) were alive at the end of follow-up, 14 (25%) were deceased and 1 (2%) unknown (moved out of region). 30 patients (53%) had received a renal transplant, 25 patients (45%) had not, with 1 (2%) unknown outcome. The three most common causes for suspension were: the patient was medically unfit to undergo transplant surgery, the patient was awaiting a specialist opinion or investigation and suspension on patient request. Mean time suspended was 645 days and from original listing to transplantation was 807 days. In patients suspended for under one year, 11 of 14 patients were transplanted (79%), however in patients suspended for over one year, only 13 of 34 patients were transplanted (38%). Patients suspended as they were medically unfit had the lowest rate of transplantation (6/20). All patients suspended on patient request, awaiting radiological investigaton or obesity were transplanted (12 patients).

Conclusions: In a three year follow-up period, most patients who had been suspended in October 2015 were alive and had undergone renal transplantation. The fitness of recepients was the most common reason for suspension from the list and is associated with poorer outcomes. Patients suspended for over one year had a significantly lower rate of transplantation. Regular multi-disciplinary review is required to try to minimise the duration of suspensions.

TH-PO1147

Does This Patient Still Want a Kidney Transplant? Changing Treatment Preferences Among African Americans on the Kidney Transplant Waiting List

Tyler M. Barrett,[1] Matthew J. Ellis,[1] Debra Sudan,[1] Tara S. Strigo,[1] Clementina A. Davenport,[1] Xiyuan Zhang,[1] Jennie Riley,[1] Aviel N. Alkon,[1] Patti Ephraim,[2] Ashley N. Cabacungan,[1] Dinushika Mohottige,[1] L. Ebony Boulware.[1] *[1]Duke University, Durham, NC; [2]Johns Hopkins University, Baltimore, MD.*

Background: African Americans spend substantial time on the kidney transplant waiting list. However, it is not known if their desires to receive transplants change while waiting for a kidney.

Methods: We studied self-reported treatment preferences among 300 African Americans on the deceased donor kidney transplant waiting list. Using a standard questionnaire, we listed each treatment option and asked, "As of today, which treatment option for kidney failure do you prefer?" We considered participants preferences as concordant (preference for kidney transplant) or discordant (preference for non-transplant treatment). We also measured participants' decisional conflict using the validated Decisional Conflict Scale (DCS), including subscales assessing the role of information, value clarity, support, uncertainty, and perceived decision effectiveness in decisional conflict. In multivariable analyses adjusting for participant demographics and history of nephrology care, we quantified associations between decisional conflict and discordant treatment preferences.

Results: Participants' mean (SD) age was 52 (11) years, 56% were male, 18% were in or near poverty, 39% had a high school education or less, and their median (IQR) waitlist time was 0.8 (0.2-1.9) years. Most were undergoing dialysis (82%). Fewer than half (44%) had concordant treatment preferences, while 30% preferred in-center hemodialysis, 4% home hemodialysis, 11% peritoneal dialysis, 9% conservative management, and 1% were unsure. Most (63%) had at least some decisional conflict (score >0 on the DCS [range 0-100]). After adjustment, participants with conflict about the clarity of their values (OR [95% CI]: 1.72 [1.0-2.94], $p<0.05$) and about their ability to make an effective decision (OR [95% CI]: 2.06 [1.06-4.01], $p<0.05$) had statistically significant greater odds of discordant treatment preferences.

Conclusions: When provided with a range of potential treatment options, many African Americans on the kidney transplant waiting list stated that a kidney transplant was not their preferred therapy. Screening for decisional conflict among patients on the waiting list may help identify those who need further decision support.

TH-PO1148

Willingness to Consider Increased-Risk Public Health Service Organs Among Waitlisted African Americans

Dinushika Mohottige,[1] Matthew J. Ellis,[2] Debra Sudan,[2] Clementina A. Davenport,[2] Xiyuan Zhang,[1] Tara S. Strigo,[2] Patti Ephraim,[4] Tyler M. Barrett,[3] Ashley N. Cabacungan,[5] L. Ebony Boulware.[3] *[1]Duke University, School of Medicine, Durham, NC; [2]Duke University Medical Center, Durham, NC; [3]Duke University School of Medicine, Durham, NC; [4]Johns Hopkins University, Baltimore, MD; [5]Division of General Internal Medicine, Durham, NC.*

Background: It is unknown if African Americans (AAs), who have historically experienced medical mistrust and health care discrimination, are willing to accept Public Health Service increased risk (PHSIR) kidneys with increased risk of transmitting hepatitis B, C and HIV.

Methods: We conducted a cross-sectional study among AAs listed for a kidney transplant. We assessed participants' willingness to accept PHSIR kidneys using transplant center written consent forms. In logistic regression models, we quantified the independent association of willingness with participants' sociodemographics, attitudes including medical mistrust, concerns about medical experimentation (e.g. 'how likely is it that you or people like you might be used in experiments without your consent'), trust in doctors (e.g. 'I trust doctors to put my needs above all others'), and racial, gender, income, and age-based discrimination experience (e.g., 'Do you believe you have ever received worse medical care than other patients because of your race').

Results: Among 300 AA participants, mean (SD) age was 52 (11), 77% were dialysis dependent for a median of 3 (IQR 1,4) years, 45% were female, and 61% college educated. Most (89%) were willing to accept PHSIR kidneys. Participants' trust in doctors was high (95%), while prior perceived racial or income-based discrimination was lower (20% and 22%). Individuals willing (vs. not) to accept PHSIR kidneys were older (mean 52 vs. 48 years), had lower prevalence of high health literacy (21% vs. 42%), poorer (18% vs. 9%), and reported more racial (16% vs. 10%) or income (19% vs. 12%) discrimination. After adjustment, those with greater than HS literacy (versus less) had lower odds of willingness (OR [95% CI] 0.36 [0.13, 0.99]). Medical mistrust measures were not associated with willingness.

Conclusions: AA potential kidney transplant recipients had high willingness to accept PHSIR kidneys, suggesting utilization of these kidneys could help to increase transplant rates among minorities.

Decision Aid to Inform Patients of Transplant Centers That Transplant Patients Like Them

Ajay K. Israni,[1,2] Cory Schaffhausen,[3] Warren T. Mckinney,[3,2] David P. Schladt,[5] Bertram L. Kasiske,[1,2] Sauman Chu.[4] *[1]Medicine, Hennepin Healthcare, Minneapolis, MN; [2]Medicine, University of Minnesota, Minneapolis, MN; [3]Hennepin Healthcare Research Institute, Minneapolis, MN; [4]University of Minnesota-Twin Cities, St Paul, MN; [5]Minneapolis Medical Research Foundation, Minneapolis, MN.*

Background: Patient feedback to the Scientific Registry of Transplant Recipients (SRTR) and Organ Procurement and Transplantation Network (OPTN) indicated interest in tailoring the transplant center search based on patient-specific characteristics such as age, and comorbidities such as body mass index (BMI) (Clin Transplant. 2017; e13125).

Methods: We conducted 20 interviews and 13 focus groups with local kidney transplant candidates and their family members plus 3 focus groups with recipients of kidney transplants recruited nationally (n=89 in total). Participants were shown prototypes of the patient specific search decision aid to evaluate the efficacy of reporting customized

search results for identifying transplant centers that treat patients like them. We used this feedback to develop a new website.

Results: A website based decision aid informed subjects about transplant center's use of high KDPI organs and PHS increased risk organs. It also informed subjects about transplant centers that perform transplants in candidates with age over 70 and other comorbidities such as high BMI. [figure1] [figure2]

Conclusions: Patient-specific information using SRTR data can be provided to patients using an interactive web-based decision tool.

Care Practices for Patients with Advanced Kidney Disease Who Were Evaluated for Transplant but Did Not Receive a Kidney

Catherine Butler,[1] Janelle S. Taylor,[4] Peter P. Reese,[2] Ann M. O'Hare.[3] *[1]Medicine, University of Washington, Seattle, WA; [2]University of Pennsylvania, Ardmore, PA; [3]VA Puget Sound Health Care System, Seattle, WA; [4]University of Washington, Seattle, WA.*

Background: There is strong public and professional support for increasing access to kidney transplant for patients with advanced kidney disease. However, more liberal referral practices will likely also increase the number of patients who are evaluated for transplant but do not receive a kidney. A deeper understanding of the implications of being referred for transplant evaluation but not receiving a kidney may help to support shared decision-making about transplant referral.

Methods: Qualitative analysis using documentation in the electronic medical record for 148 adults with advanced kidney disease referred to the Veterans Affairs Puget Sound Health Care System's transplant coordinator from 2008-2018 who did not receive a kidney during the follow-up period (among a total of 209 adults evaluated for kidney transplant). Participants were followed through their date of death or January 1, 2018. We performed an inductive content analysis to ascertain dominant emergent themes related to transplant evaluation.

Results: By the end of follow-up, 148 of 209 patients evaluated for transplant (71%) had not received a kidney. Three dominant themes emerged from analysis of the electronic medical record for this subset of patients: 1) Sources of forward momentum in the transplant evaluation process: Patients were often referred for transplant evaluation reflexively and the process tended to move forward until an absolute contraindication was identified or patients passively disengaged. 2) Potential for transplant shapes other medical decisions: Engagement in the transplant evaluation could have far-reaching effects on many other aspects of patients' medical care. 3) Personal responsibility and psychological burden: Patients felt personally responsible for their progress through the transplant evaluation and the process could take a significant emotional toll on both patients and families.

Conclusions: Most patients evaluated for transplant at our center did not receive a kidney. The evaluation process could be burdensome and emotionally taxing for these patients and their families and could intrude on many other aspects of their care. These findings highlight the potential tradeoffs involved in being evaluated for kidney transplant and argue for engaging patients in a deliberate and shared approach to referral decisions.

TH-PO1151

Donation After Cardiac Death for Pediatric Kidney Transplantation

Sarah J. Kizilbash, Scott T. McEwen, Michael D. Evans, Blanche M. Chavers. *University of Minnesota, Minneapolis, MN.*

Background: Donations after cardiac death (DCD) constitute 20% of adult deceased-donor kidney transplants. There is a paucity of data on long-term transplant outcomes associates with the use of DCD donors in children.

Methods: We used the Scientific Registry of Transplant Recipients to identify all pediatric (< 18 years at transplant) deceased donor kidney transplants that were performed in the US using DCD kidneys between 1987 and 2017. We used 4:1 propensity score matching (for age at transplant, gender, race, pretransplant dialysis, and transplant center and year) and exact matching by center to create a comparison group. Patient and graft survival were evaluated using mixed effects Cox proportional hazards modeling and delayed graft function using logistics regression.

Results: Our final analysis cohort included 285 DCD and 1132 non-DCD recipients. The demographic and clinical characteristics of recipients and donors are given in tables 1 and 2. DCD donors were younger (21.8 vs. 23.5 years; p 0.03), and more likely to be white (89.5 vs. 79%; p <0.001). We found no difference in 5-year graft survival (76.1% vs. 72.6%; p 0.55) and 5-year patient survival (95.1% vs. 95.7%; p 0.58) between DCD and non-DCD recipients. The differences in graft survival (aHR: 0.93; 95% CI: 0.72 – 1.3; p 0.45) and patient survival (aHR: 1.02; 95% CI: 0.60 – 1.7; p 0.99) remained insignificant

after multivariate adjustment. DCD recipients demonstrated a higher risk of delayed graft function (adjusted OR: 3.2; 95% CI: 2.1 – 4.7; p <0.001).

Conclusions: Although DCD recipients are at higher risk of delayed graft function, we found no difference in 5-year patient or graft survival between DCD and matched non-DCD recipients.

Demographic and baseline characteristics of donors and recipients

Variables	Donation after cardiac death N = 285	Non-cardiac death donation N = 1132	p value
Recipients age at transplant (years) Mean (SD)	13.4 (4.4)	13.0 (4.6)	0.12
Recipient gender n (%) Male	162 (56.8)	642 (56.7)	0.99
Recipient race n (%) White Black Other	187 (65.6) 74 (26.0) 24 (8.4)	755 (66.7) 297 (26.2) 80 (7.1)	0.78
Pre-emptive transplant n (%)	50 (17.5)	240 (21.2)	0.20
Delayed graft function n (%)	56 (19.6)	91 (8.0)	<0.01
Age at donation (years) Mean (SD)	21.8 (9.0)	23.3 (10.1)	0.025

TH-PO1152

Use of Expanded Criteria Donors for Pediatric Kidney Transplantation in the United States

Sarah J. Kizilbash, Scott T. McEwen, Michael D. Evans, Blanche M. Chavers. *University of Minnesota, Minneapolis, MN.*

Background: The use of marginal kidneys for transplantation has increased in the recent years to expand the deceased donor pool. Transplant outcomes associated with the use of expanded criteria donors (ECD) in children are unknown.

Methods: We used the Scientific Registry of Transplant Recipients to identify all pediatric (<18 years at transplant) deceased donor kidney transplants that were performed in the US using ECD (donors older than 60 years or older than 50 years with co-morbidities) between 1987-2017.

Results: Our final cohort included 96 ECD and 375 non-ECD recipients. The demographic and baseline characteristics of donors and recipients are presented in table 1. ECD donors were older (58.4 vs. 25.1 years; p<0.001), and less likely to be males (33.3 vs. 62.4%; p<0.001). Compared with non-ECD recipients, ECD recipients were at significantly higher risk of delayed graft function (aOR: 3.2; 95% CI: 1.8 5.6; p< 0.001), graft failure (aHR: 1.6; 95% CI: 1.2 2.1; p 0.001) and mortality (aHR: 1.6; 95% CI: 1.02–2.3; p 0.01). Five-year acute rejection free survival tended to be lower in ECD vs. non-ECD recipients (24.3 vs. 34.4%; p 0.06).

Conclusions: ECD kidney transplants in children are associated with higher risks of delayed graft function, graft failure and mortality compared with matched non-ECD recipients. We recommend that kidneys from ECD donors not be considered for pediatric candidates.

Demographic and baseline characteristics of kidney transplant recipients and donors

Variables	Expanded criteria donor recipients N = 96	Non-expanded criteria donor recipients N = 375	p value
Recipients age at transplant (years) Mean (SD)	13.4 (4.3)	12.7 (4.4)	0.18
Recipient gender n (%) Male	51 (53.1)	212 (56.5)	0.63
Recipient race n (%) White Black Other	57 (59.4) 34 (35.4) 5 (5.2)	235 (62.7) 117 (31.2) 23 (6.1)	0.92
Pre-emptive transplant n (%)	13 (13.5)	62 (16.5)	0.58
Delayed graft function n (%)	35 (36.5)	66 (17.6)	<0.001
Age at donation (years) Mean (SD)	58.4 (5.6)	25.1 (14.4)	<0.001
Donor gender n (%) Male	32 (33.3)	234 (62.4)	<0.001
Donor race n (%) White Black Other	84 (87.5) 9 (9.4) 3 (3.1)	311 (82.9) 54 (14.4) 10 (2.7)	0.06
KDPI Mean (SD)	82.5 (11.4)	31.3 (23.2)	<0.001

TH-PO1153

The Pediatric Renal Transplant Experience: Reflecting Through Photographs

Ari Pollack,[1,3] Jodi M. Smith,[1,3] Wanda Pratt,[2] Jaime Snyder.[2] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington, Information School, Seattle, WA; [3]University of Washington, Seattle, WA.*

Background: Poor self-management contributes to reduced renal allograft survival during adolescence and young adulthood. For many pediatric patients and their families, the symptoms, complications, and natural history related to ESRD and its treatments are unfamiliar. These unmet information needs lead to uncertainty, interfere with goal setting and result in ineffective self-management. Providing patients with self-reflection tools to help explore the question "Is my experience normal?" may help mitigate these challenges. We present data from a pilot study exploring how photo-elicitation, a qualitative method where images are used to prompt individuals to talk about their personal experiences and values, engages pediatric transplant recipients and their families to generate insight into their experiences living with kidney disease.

Methods: Pediatric renal transplant recipients from a single center, along with one family member, were invited to participate. All participants were asked to submit 5 photographs telling their transplant story. No restrictions were placed on what photos individuals could submit. During interviews, participants were asked to tell their story utilizing the photos as prompts. Interviews were recorded, transcribed and analyzed using an inductive grounded theory approach to identify common themes.

Results: 13 individuals (7 patients: ages 9 - 19, >1 year post transplant, and 6 parents) completed the study. The photographs generated conversations on four emergent themes: (1) feeling different/isolated from their peers; (2) importance of peer support, including those with and without kidney disease; (3) fear about transitioning to self-care; and (4) the need to create a "normal" child/adolescent experience. Finally, subjects reported significant value in the self-reflection that took place during the photo elicitation process and wanted to share their photos with their clinicians to provide additional insight into their personal experiences.

Conclusions: Photo elicitation generated a rich dataset describing a range of pediatric renal transplant experiences, showing potential as a clinical intervention to support patient and family self-reflection. Finally, the process of self-reflection and sharing visual stories with peers and clinicians can result in greater empathy from caregivers and medical professionals, ultimately improving self-management.

TH-PO1154

Is Age Just a Number? Outcomes of Older Living Donors for Pediatric Kidney Transplant Recipients

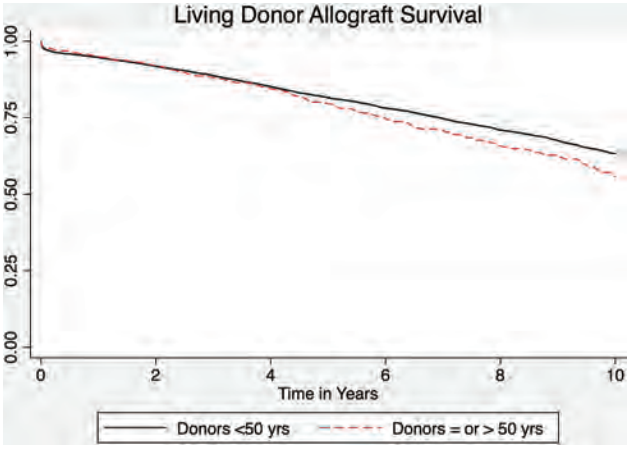
Swee-Ling Levea, Malcolm Macconmara, Christine S. Hwang. *University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Living donor kidney transplantation is encouraged in the pediatric population due to better long term allograft survival compared to deceased donor kidney transplantation. Often, pediatric recipients are listed inactive while awaiting evaluation of their living donors. However, there are limited data addressing the impact of age on allograft survival from living donor. We therefore examined the association of living donor-recipient age combinations with allograft survival in children.

Methods: Using the Scientific Registry of Transplant Recipients (SRTR), we analyzed graft survival among living donor kidney transplant pediatric recipients from older living donors (≥50 years old) compared to younger donors (< 50 years old) between 1993 - 2017. Statistical analysis was performed using STATA and a p value of <0.05 was considered to be significant.

Results: The age of the younger living donors was 35.4 ± 7.6 years while that of the older living donors was 53.4 ± 3.6 years (p< 0.05). The pre-operative creatinine for the younger donors was 0.86 ± 0.34 mg/dL vs. 0.89 ± 0.19 mg/dL for the older donors (p=NS). The average post-operative creatinine for the younger donors was significantly lower at 1.26 ± 0.42 mg/dL while that of the older donors was 1.34 ± 0.30 mg/dL (p<0.05). The BMI, presence or absence of hypertension or diabetes, and cigarette use were not significantly different between the two groups. The HLA mismatch in younger donors was 2.6 ± 1.2 and 2.8 ± 1.3 in the older donors (P<0.05). The allograft survival from younger living donors were superior compared to those from older donors (Figure 1) (p<0.05).

Conclusions: Allograft survival from younger living donors is superior at ten years compared to older living donors. In potential pediatric kidney transplant recipients on the wait-list, deceased donor kidney transplant consideration is beneficial if these individuals have older living donors.



TH-PO1155

Kidneys from African American Donors Are Associated with Accelerated Podocyte Detachment After Kidney Transplantation

Abhijit S. Naik,[1] Jawad Aqeel,[1] Diane M. Cibrik,[2] Milagros D. Samaniego-Picota,[3] Su Q. Wang,[1] Mahboob A. Chowdhury,[1] Roger C. Wiggins.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Kansas Hospital, Parkville, MO; [3]Henry Ford Health Services, Detroit, MI.*

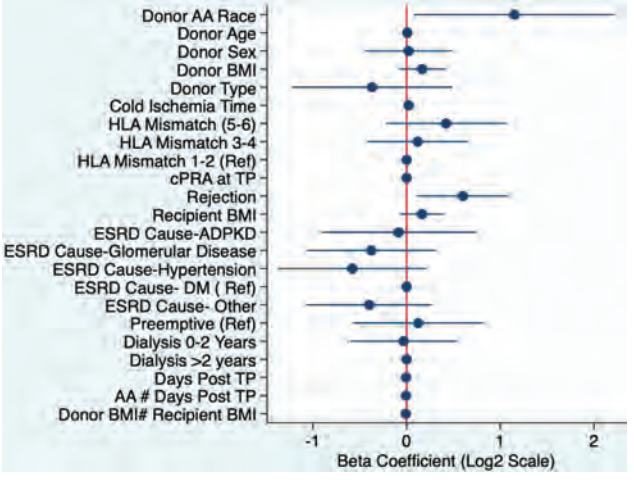
Background: Kidneys from AA donors have reduced survival compared to kidneys from non-AA donors. Longitudinal histological data to better delineate the relationship of donor race, post-transplant histology and outcomes is lacking. We used urine ***nephron segment specific mRNA markers*** to understand whether kidneys from AA donors have different injury patterns than non-AA donors. We tested the hypothesis that high prevalence of glomerular disease in AA donors would be associated with differences in urine podocyte markers

Methods: We used a published cohort (*Naik AS, et al, NDT, 2018*) with linear mixed model with random intercept (pt. level) and slope (time post-transplant) with Urine Podocin mRNA:Urine creatinine ratio (UPodCR) as the dependent variable. The model was adjusted for an ***a priori*** selected group of variables

Results: 534 urine samples from 125 recipients were analyzed. 14 recipients recieved kidneys from AA donors contributing to 59 urine samples. AA donors were younger (34 vs.41,p=0.04). Other characteristics were well balanced. One-year surveillance biopsy revealed no difference in burden of observable glomerular disease between AA and non-AA groups (p=0.21). There was no difference in proteinuria by donor race. Although at time of TP there was no difference in nephrin expression, by 1yr post-TP nephrin expression was significantly down-regulated in AA vs. non-AA groups. Figure 1 demonstrates factors associated with podocyte detachment.

Conclusions: These data are compatible with AA donors developing podocyte injury and loss that is observable prior to development of proteinuria or glomerular disease on surveillance biopsies. Further studies expanding the current cohort and assessing relationships of accelerated podocyte loss with APOL1 genotype are ongoing.

Funding: NIDDK Support, Other NIH Support - MNORC



Donor AA race and rejection in 1st year were associated with accelerated podocyte detachment.

TH-PO1156

Early Post-Donation Hyperfiltration Is Associated with Accelerated Podocyte Detachment

Abhijit S. Naik, Dustin Le, Su Q. Wang, Mahboob A. Chowdhury, Roger C. Wiggins. *University of Michigan, Ann Arbor, MI.*

Background: Living kidney donation is associated with increased long-term risk of CKD/ESRD post-donation. The remaining kidney is rarely biopsied and thus mechanisms behind progression remain unproven. Parallel data from uni-nephrectomized rat models shows podocyte hypertrophic stress, detachment and depletion, progressive proteinuria and FSGS. While proteinuria is common among donors vs. matched non-donors, it is often low grade

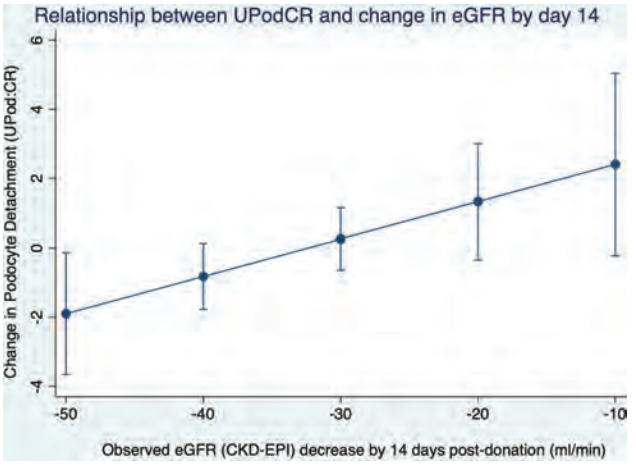
Methods: SpotUrine pellet mRNAs from 87 living donors were used. Data was normalized to creatinine for one podocyte markers (podocin), and urine protein. UPod:CR is a marker of podocyte detachment rate and UProt:CR as marker for proteinuria (both log transformed). We measured differences in UPod:CR, UProt:CR and eGFR before (day 0) and after donation (day 14) to estimate their "delta" values. Multivariable linear regression using either podocyte detachment or proteinuria were used as the dependent variable adjusted for baseline eGFR, donor age, BMI, MAP (Mean Arterial Pressure)at donation and the change in eGFR by 14 days post donation.

Results: In a multivariable linear regression model the change in eGFR by 14 days post donation was significantly associated with podocyte detachment rate but not proteinuria.

Conclusions: Early post donation hyperfiltration is associated with accelerated podocyte detachment even in the absence of proteinuria. Longer term follow up is required to understand relationship of hyperfiltration, podocyte detachment and progressive kidney dysfunction after donation.

Funding: NIDDK Support

UPod:CR	B. Coef	Std. Err.	P value	LCL	UCL
Delta eGFR (ml/min)	0.11	0.05	0.04	0.005	0.21
Donor Age	0.016	0.04	0.68	-0.06	0.1
BMI at Donation (Kg/m2)	-0.01	0.09	0.89	-0.19	0.16
MAP before donation	-0.006	0.05	0.91	-0.10	0.09
Baseline eGFR	0.07	0.04	0.12	-0.02	0.15



TH-PO1157

Living Kidney Donation Is Accompanied by Persistently Increased Urine Pellet Nephrin mRNA in the First Year After Donation

Abhijit S. Naik,[1] Diane M. Cibrik,[2] Milagros D. Samaniego-Picota,[3] Su Q. Wang,[1] Mahboob A. Chowdhury,[1] Roger C. Wiggins.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Kansas Hospital, Parkville, MO; [3]Henry Ford Health Services, Detroit, MI.*

Background: Living kidney donation is associated with increased long-term risk of CKD/ESRD post-donation. Diabetes and hypertension are reported to be associated with ESRD. The remaining kidney is rarely biopsied and thus mechanisms behind progression remain unproven. Parallel data from uni-nephrectomized rat models shows podocyte hypertrophic stress, detachment and depletion, progressive proteinuria and FSGS. While proteinuria is common among donors vs. matched non-donors, it is often low grade

Methods: We used urine pellet nephron segment specific mRNA markers expressed per creatinine to understand biology of the remaining kidney early post-donation. Donor urine samples were divided by time of collection. Group 0, before donation; Group 1, 1-2days post donation; Group 2, 10-14days and Group 3, 6-12months post donation. Linear mixed model clustering for patients was used to assess trends across two podocyte specific markers (podocin, nephrin), a distal collecting duct marker (Aqp2) and a marker of innate immunity/profibrotic activity (TGFbeta1) and proteinuria

Results: 72 donors provided 178 urine samples for the analysis. Figure 1 reveals that proteinuria and podocin, Aqp2 and TGFbeta1 mRNAs were increased immediately post donation (referenced to Group 0) but normalized by 2weeks post-donation. Nephrin remained significantly increased over the first year.

Conclusions: All markers showed evidence for hypertrophic kidney stress immediately post-TP. Sustained increased urinary nephrin mRNA in living donors after TP may represent hypertrophic adaptation to the single kidney state requiring up-regulation of nephrin to maintain increased filtration slit length. Whether higher level nephrin mRNA expression is related to future risk of progressive kidney disease remains to be tested.

Clinical Significance of AKI and Kidney Donor Profile Index on Clinical Outcomes in Deceased Donor Kidney Transplantation: A Multicenter Cohort Study

Woo Yeong Park,[1,2] Jeong Ho Kim,[5,4] Cheol Whee Park,[3,4] Chul Woo Yang,[3,4] Kyubok Jin,[1,2] Seungyeup Han,[1,2] Byung ha Chung.[3,4] *[1]Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea; [3]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [4]Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [5]Daejeon St. Mary's Hospital, Daejeon, Republic of Korea*.

Background: It is important to evaluate the donor quality before allocation in deceased donor kidney transplantation (DDKT). Kidney Donor Profile Index (KDPI) is an effective tool, but the association with acute kidney injury (AKI) is uncertain. The aim of this study was to investigate the clinical significance of AKI and KDPI on clinical outcomes in DDKT.

Methods: Four transplant centers enrolled 657 kidney transplant recipients (KTRs) from 526 deceased donors (DDs). We divided the high KDPI and low KDPI by the median of 65%, and each group was divided into AKI-KT and non-AKI-KT subgroups according to DDs with AKI.

Results: There was no significant difference in the incidence of delayed graft function between high KDPI-KT and low KDPI-KT groups, but AKI-KT subgroup showed significantly higher incidence of delayed graft function compared with non-AKI subgroup in the two groups (P=0.001, P<0.001). There was no significant difference in the incidence of biopsy-proven acute rejection between high KDPI-KT and low KDPI-KT groups regardless of DDs with AKI. Death-censored graft survival rate was significantly lower in the high KDPI-KT group compared with the low KDPI-KT group (P=0.005), but there was no significant difference in the death-censored graft survival rate between AKI-KT and non-AKI-KT subgroups in the each group. Only in the high KDPI-KT group, the KT group from DDs with AKI stage 3 was lower in death-censored graft survival rate compared with that from DDs with non-AKI, AKI stage 1, or 2.

Conclusions: KTs from DDs with AKI showed an adverse effect on the allograft outcome, especially from DDs with AKI stage 3 in the high KDPI-KT group. Therefore, closed observation and prevention of severe AKI will be required, especially for KTs from DDs with high KDPI.

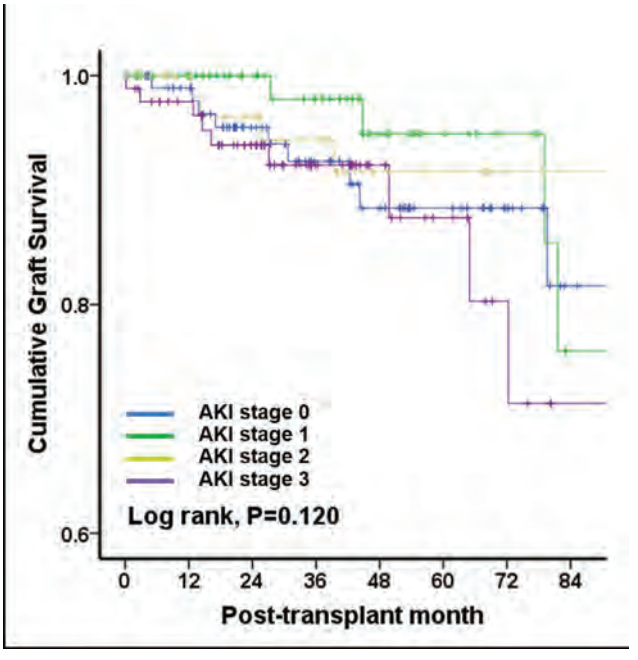

Figure 1. Death-censored graft survival according to AKI stage in high KDPI group

TH-PO1159

Kidney Transplantation from Small Pediatric Donors May Be Feasible to Those Who Developed Chronic Refractory Dialysis Hypotension: A Single-Center Experience

Jia Hanying. *The first affiated hospital of Zhejiang University, Hangzhou, China*.

Background: Chronic refractory dialysis hypotension (CRDH) is a serious issue in dialysis patients waiting for transplants. CRDH leads to fatal clinical outcomes and disqualification from kidney transplantation. Kidney transplantation from small pediatric donors to adult patients with lower blood pressure(BP) may be an option. To our knowledge, there has been no report on the benefit of transplantation from pediatric donors to CRDH recipients.

Methods: Ten single-kidney transplantations from five small pediatric donors after cardiac death in our center between August 2016 and April 2018 were analyzed. Half of the recipients were CRDH (group A) and each of them was matched with no-CRDH patient (control, group B) from same deceased pediatric donor. The operation method of vascular anastomosis and ureterocystoneostomy was the same as that of adult donors. Clinical characteristics, post-operative treatment and outcomes were retrieved. Postoperative BP, graft function and size were compared between the two groups. The follow-up time was up to April 2019.

Results: There were no acute rejection, graft loss or death in CRDH patients after kidney transplantation. The postoperative systolic BP in four recipients in group A was above 100mmHg persistently. Their renal function was recovered despite three transient delayed graft function (2 in group A and 1 in group B). There was no significant difference in serum creatinine or graft size (P=0.84, 0.94) after transplantation between two groups.

Conclusions: In conclusion, kidney transplantation from small pediatric donors may be feasible to CRDH patients and their BP may return to normal after transplantation.

Figure1 The change of Scr after transplantation in two groups

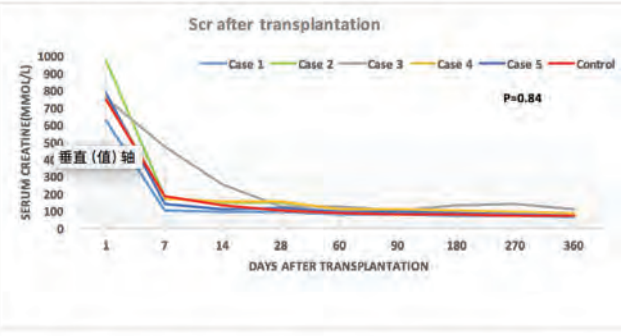

Figure1 shows the changes of serum creatinine (Scr) after transplantation in two groups. The levels of Scr were recorded for all recipients 1,7,14,28,60,90,180 and 360 days after transplantation. The post-operative Scr in group A was listed respectively(case1-5). The post-operative Scr in group B was expressed by the average Scr of four recipients because the other one(control 4) was a five-year-old child whose renal function recovered obviously better than others and Scr was much lower. There was no significant difference in serum creatininebetween two groups (group A vs group B 191.24±211.64 vs 169.94±205.82, P=0.84).

TH-PO1160

Donor Source of Kidney Transplantation in New Zealand by Ethnicity: A Longitudinal Cohort Study

Sine Donnellan,[2] Nicholas Cross,[2] Suetonia Palmer.[1] *[1]University of Otago, Christchurch, New Zealand; [2]Christchurch Hospital, Christchurch, New Zealand*.

Background: Marked disparity is present in access to kidney transplantation based on ethnicity. We explored whether donor source for kidney transplantation in New Zealand was associated with recipient ethnicity adjusting for socioeconomic and clinical factors.

Methods: We performed a longitudinal cohort study in patients ≥18 years with ESKD who commenced kidney replacement therapy in New Zealand between 2006-2015, using ANZDATA. Deprivation score and treating centre were obtained by data linkage with the National Health Index. Primary outcomes were time to receiving first transplant (live and deceased donor) and proportion who received a pre-emptive kidney transplant. Poisson regression was performed for pre-emptive and competing risks regression for live and deceased donor transplantation (accounting for competing risks of death and alternate donor source) with 95% confidence intervals. Estimates were adjusted age, sex, smoking, deprivation, BMI, late referral, treating centre, diabetes, and coronary artery disease.

Results: Among the 5106 participants, 822 received a kidney only transplant (479 living and 343 deceased donor). Māori and Pacific patients were younger, more frequently had diabetes and referred late to specialist care, and lived in more socioeconomically deprived areas than Europeans. In European patients, 65% received a live donor kidney transplant, while the proportion was smaller for Asian (44%), Māori (44%), and Pacific (39%) patient groups. Compared to European participants, those who identified as Māori, Pacific and Asian were markedly less likely to receive a pre-emptive and live donor kidney transplant even after adjustment for socioeconomic factors, comorbidity, and referral practices (Table 1). The difference in transplantation rates between participant groups was less marked for deceased donor kidney transplantation and was not evident in Māori and Asian groups after adjustment.

Conclusions: Transplantation rates for pre-emptive and live donor transplantation but not deceased donor transplantation vary with ethnicity, socioeconomic factors and late referral to specialist services within New Zealand after adjustment for comorbidity.

Variable	Pre-emptive Adjusted IRR (95% CI)	Living donor Adjusted SHR (95% CI)	Deceased donor Adjusted SHR (95% CI)
Maori (ref: European)	0.34(0.18-0.64)	0.40(0.28-0.56)	0.72(0.50-1.03)
Pacific (ref: European)	0.09 (0.02-0.36)	0.24 (0.12-0.41)	0.60 (0.38-0.96)

TH-PO1161

Association of Perceived Information and Knowledge with Pursuit of Live Donor Kidney Transplants (LDKTs) Among African Americans

Ashley N. Cabacungan,[3] Matthew J. Ellis,[3] Debra Sudan,[4] Clementina A. Davenport,[3] Patti Ephraim,[5] Tara S. Strigo,[3] Iris Pounds,[3] Aviel N. Alkon,[3] Dinushika Mohottige,[3] Nicole DePasquale,[1] Sarah B. Peskoe,[3] Jane F. Pendergast,[3] Clarissa J. Diamantidis,[3] Jennifer St. Clair Russell,[2] L. Ebony Boulware.[3] *[1]Duke University School of Medicine, Durham, NC; [2]National Kidney Foundation, Washington, DC; [3]Duke University, Durham, NC; [4]Duke University Medical Center, Durham, NC; [5]Johns Hopkins University, Baltimore, MD.*

Background: It is unknown whether African Americans' (AAs) pursuit of LDKT is related to their perceived information or knowledge about LDKT.

Methods: We conducted a cross-sectional analysis among AA kidney transplant candidates enrolled in the Talking about Living Kidney Donation Support (TALKS) trial. We quantified associations between participants' perceived sufficiency of LDKT information and knowledge with pursuit of LDKT or the occurrence of live donor inquiries. We asked: "How well informed do you feel you are about live donor kidney transplant?" and "How much knowledge do you feel you have now about live donor kidney transplant?" We characterized pursuit of LDKT by self-reported behaviors reflecting low (no family/friends LDKT discussion, no donor), moderate (family/friends LDKT discussion, no donor) or high (family/friends LDKT discussion and potential donor identified) activation toward LDKT. In adjusted logistic regression models, we quantified the association between perceived sufficiency of LDKT information and knowledge with LDKT activation or live donor inquires.

Results: Among 300 AAs, the mean age was 52 (SD 11), 56% were male, 61% had a greater than high school education, and 50% had below 9th grade-level health literacy. The median time on the waitlist was 292 (IQR 81, 697) days. A total of 117 (39%) felt "very" or "extremely" well informed about LDKT and 114 (38%) reported "a great deal of knowledge" about LDKT. Compared to those less informed, participants who reported feeling "very" or "extremely well" informed had statistically significantly greater odds of having moderate or high LDKT (versus low) activation (OR: 2.71, 95% CI 1.02, 7.17), but there was no difference in live donor inquiries. Greater perceived knowledge was not associated with LDKT activation or live donor inquiries.

Conclusions: Fewer than half of African Americans on the deceased donor kidney waiting list felt well informed or very knowledgeable about LDKT. Efforts to increase African American potential recipients' perceived LDKT information and knowledge could enhance their access to LDKT.

TH-PO1162

A Cultural Competence Assessment of the Living Donor Navigator Program Reveals Sex Differences

Rhiannon D. Reed, Beverly M. Berry, Margaux N. Mustian, Paul A. Maclennan, Brittany A. Shelton, Alexis J. Carter, Raynesha Grant, Jayme E. Locke. *University of Alabama at Birmingham, Birmingham, AL.*

Background: The Living Donor Navigator (LDN) Program aims to separate the patient's burden of asking for a kidney transplant and improve potential living donor comfort with the evaluation process and has been particularly successful among African Americans. Care that is sensitive to the cultural needs of patients can result in improved health outcomes, especially among a high minority patient population. We sought to assess the cultural competence of the LDN program.

Methods: A modified Iowa Cultural Understanding Assessment was mailed to advocates from the LDN program and potential living donors who were screened on behalf of transplant candidates in the program. Response choices were on a Likert scale from 1 (strongly disagree) to 5 (strongly agree). Proportions who agreed/strongly agreed were compared by sex and race using Fisher's exact test.

Results: There were 13 responses from 62 surveys (21% response rate). Twelve (92%) respondents were African American, and 61.5% were female. Overall, satisfaction with cultural competence was high, with > 60% of respondents reporting that they agreed/strongly agreed with 24/25 items. When comparing by sex, all female respondents (vs. 40% of males) agreed that the program helped them deal with problems in their day-to-day life (p=0.04) (Table). All female respondents (vs. 60% of males) agreed that the navigators were flexible and provided alternate approaches to meet their cultural needs (p=0.10). When exploring by race, the single Caucasian respondent agreed strongly with all items.

Conclusions: Though limited by small sample size, these preliminary data suggest that the LDN program reflects cultural sensitivity and meets the needs of participants socially, culturally, and linguistically. However, further qualitative exploration to understand sex differences is warranted.

Knowledge and Receipt of Information About Living Donor Kidney Transplant Among Individuals with Advanced CKD

Dinushika Mohottige,[4] Patti Ephraim,[3] Hui-Jie Lee,[1] Clementina A. Davenport,[2] Jane F. Pendergast,[1] Nicole DePasquale,[4] Clarissa J. Diamantidis,[4] L. Ebony Boulware.[4] *[1]Duke University, Durham, NC; [2]Duke University Medical Center, Durham, NC; [3]Johns Hopkins University, Baltimore, MD; [4]Duke University School of Medicine, Durham, NC.*

Background: Knowledge about live donor kidney transplant (LDKT) is modifiable and is associated with access to LDKT. Yet, little is known about factors associated with LDKT knowledge or receipt of information about LDKT.

Methods: We conducted a cross-sectional study among nephrology clinic patients who were eligible for pre-emptive LDKT and enrolled in a trial on interventions to improve access to LDKT. We assessed participants' LDKT knowledge [10 pt. scale based on correct answers to questions about prognosis, donation, and financial aspects of LDKT; (high knowledge >8)], self-reported receipt of LDKT information from health professionals, and self-reported information sharing with family/friends. Using logistic regression (adjusting for participants age, race, and income), we quantified the association of LDKT knowledge with participants' receipt of LDKT information and their sharing of LDKT information with family/friends.

Results: The 130 participants had mean (SD) age 58.3 (9) years, 60% were female, 47.7% were African American, and 49% had a high school education or less. Participants' had a mean (SD) GFR of 26.6 (9.1) ml/min/1.73m2 and they had seen their nephrologists for 3.4 (4) years. Over half (55.4%) had high LDKT knowledge, and 33.1% reported having received LDKT information. Few (28.5%) had shared LDKT information with family/friends. Participants who reported receipt (vs. not) of LDKT information were more likely to have high knowledge (45.8% vs. 17.2%, p=0.001). Those who shared (vs. did not) information about LDKT with a family/friend were also more likely to have high LDKT knowledge (38.9% vs. 15.5%, p=0.006), as were those who received (vs. did not) LDKT info from health professionals (24.6% vs. 10.3%, p=0.001). After adjustment, those who received (vs. did not) LDKT information from health professionals had 4-fold higher odds of high LDKT knowledge (adjusted OR [95% CI]: 4.01: [1.49, 12.18], while those who shared information with family/friends had 3-fold higher odds of high LDKT knowledge (3.05 [1.24, 8.08]).

Conclusions: Improved provision of LDKT information to patients with advanced CKD and involvement of family members or friends could aid efforts to improve LDKT rates.

TH-PO1164

Use of Opioids and Nonsteroidal Anti-Inflammatory Drugs in Living Kidney Donors: Clinical Correlates and Early Outcomes

Krista L. Lentine,[1] Luke S. Vest,[1] Nagaraju Sarabu,[3] Ngan Lam,[2] Farrukh M. Koraishy,[1] Mark Schnitzler.[4] *[1]Saint Louis University, St. Louis, MO; [2]University of Alberta, Edmonton, AB, Canada; [3]Cleveland Med Center, Cleveland, OH; [4]Saint Louis Univ, Shiloh, IL.*

Background: Limited data are available on pain medication use in living kidney donors (LKD). While there is growing national concern related to opioids, there is also concern for non-steroidal anti-inflammatory (NSAID) use due to potential nephrotoxicity.

Methods: We examined a novel database wherein national LKD registry identifiers were linked to records from a large U.S. pharmaceutical claims warehouse (2007 to 2017 fills). We selected LKD with 1 year of postdonation pharmaceutical fill records. Associations of baseline demographic and clinical factors with opioid and NSAID use (adjusted odds ratio, 95% $_{LCL}$ aHR 95% $_{UCL}$) were quantified by multivariate logistic regression.

Results: Among 23,564 eligible LKD, opioid use declined postdonation: 36.6%, mos. >0-0.5; 14.7%, mos. 0.6-6; 12.6%, mos. 7-12. NSAID use was uncommon, but increased: 0.5%,

mos. >0-0.5; 2.2%, mos. 0.6-6; 3.3%, mos. 7-12. With adjustment including predonation estimated glomerular filtration rate, hypertension, donor-recipient relationship and nephrectomy type, opioid use in mos. 7-12 was associated (P<0.05) with female sex ($_{1.13}$1.24$_{1.35}$), black race ($_{1.03}$1.17$_{1.32}$), obesity ($_{1.24}$1.38$_{1.53}$), lower education ($_{1.19}$1.31$_{1.43}$), not working ($_{1.02}$1.12$_{1.24}$), smoking ($_{1.33}$1.45$_{1.58}$), and surgical complications ($_{1.11}$1.29$_{1.49}$) (Fig.). NSAID use was more common in women, black and Hispanic LKD, obese LKD, those with lower education, not working, and with surgical complications. Patterns were similar in earlier postdonation periods. Neither opioids nor NSAIDs were associated with eGFR change or proteinuria to 2 years

Conclusions: Opioid and NSAID use in LKD vary with demographic and clinical traits. Work is needed to define safety and optimal choice of pain medications in LKD.

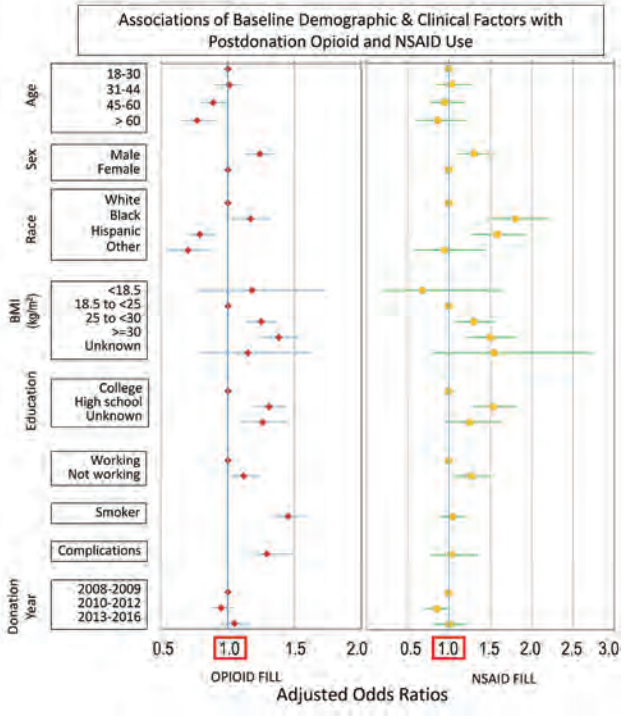

Fig 1. Associations of baseline traits with pain medication use

TH-PO1165

Public Survey of Financial Incentives for Kidney Donation in Bahrain

Amgad E. El Agroudy. *Medicine, College of Medicine and Medical Sciences, Arabian Gulf University, Manama, Bahrain.*

Background: With the increasing prevalence of end-stage kidney disease in Bahrain, kidney donation is of vital importance. In this study we want to assess how financial incentives will influence peoples' views and decisions regarding kidney donation. The aim is to establish strategies to increase the number of kidneys for transplantation in Bahrain.

Methods: We adapted a previously established questionnaire on financial incentives for living kidney donations. The questionnaire assessed the public opinion in Bahrain on how kidney donation can be influenced by two different financial incentives, namely 10,000 BHD and life-long health insurance. We collected a convenient sample of 446 participants by distributing an electronic version of the questionnaire. SPSS-23 software was used for data entry and analysis

Results: Of the total participants 39% were male and 61% were female. Eighty-percent of the participants believed that their chances for kidney donation will not increase in turn of receiving a financial compensation, while 20% of them believed that it will increase. Our study found that generally married participants (70%) find it a preferable development for health insurance companies to offer financial compensation for kidney donation, while non-married participants (30%) found it not a preferable but also not an adverse development (P-value 0.038). Furthermore, there is a positive correlation between age and preferable views toward financial incentives to increase kidney donation (P-value <0.001).

Conclusions: Although financial incentives for kidney donation might encourage a minority of the population, the majority will not be influenced by implanting a financial incentives' system for kidney donation.

TH-PO1166

Living Kidney Donors with Metabolic Risk Increased in South Korea

Eunjeong Kang,[1] Sehoon Park,[2] Yaerim Kim,[1] Miyeun Han,[3] Jung Pyo Lee,[6] Jong Cheol Jeong,[5] Dong-Wan Chae,[4] Yon Su Kim,[2] Hajeong Lee.[2] *[1]Keimyung University Dongsan Hospital, Daegu, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Pusan National University Hospital, Busan, Republic of Korea; [4]Seoul National University Bundang Hospital, Seongnam-si, Gyeonggi-do, Republic of Korea; [5]Ajou University Hospital, Suwon, Republic of Korea; [6]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Living donor kidney transplantation is the best treatment option with regard to patients' prognosis for end-stage renal disease(ESRD) if only donor safety is secured. Hence, it is worthwhile to review of epidemiology of living kidney donors nationwide and living kidney donors with higher risk including metabolic syndrome.

Methods: Living kidney donors in 4 national university hospital of South Korea were enrolled. Demographic and laboratory data were collected. Hyperuricemia was defined as uric acid greater than 7 mg/dL. Underweight, overweight and obesity were defined as body mass index (BMI) <18.5, 25-29.9 and ≥30 kg/m^2, respectively. The era of the transplant was classified into 4 groups with quartiles of the number of donors as follows; 1982-2001, 2002-2009, 2010-2014, and 2015-2019.

Results: A total of 2,002 living kidney donors were enrolled and the number of living kidney transplants increased rapidly from 109 in the 1980s to 987 in the 2010s. Mean age were 42.6±11.5 years and 45.9% were male. The most common donor-recipient relationship was parent-child (39.5%), followed by siblings(30.6%), and husbands-wife(21.1%). Husband-wife relationship was increased over time(4.5% at 1982-2001, 34.7% at 2015-2019). The proportion of old donors(age >60 years) were increased across the era of transplant(3.7% at 1982-2001, 11.2% at 2015-2019). Mean estimated glomerular filtration rate(eGFR) was 90.9±20.5 and 98.8±16.3 mL/min/1.73m^2 by MDRD and CKD-EPI equation, respectively. The baseline eGFR were increased in course of time. Patients with diabetes and impaired glucose tolerance (IGT) were 5(0.25%) and 37(1.85%), respectively. Patients who had history of dyslipidemia accounted for 18% and mean total cholesterol value tended to increase over time. Mean BMI was 23.75±3.39 kg/m^2. Overweight and obese donors were 527(27.05%) and 93(4.77%), respectively. The proportion of donors with IGT, dyslipidemia, and overweight /obesity tended to increase over time.

Conclusions: The factors related to metabolic syndrome generally tended to increase in kidney donor over time, and living kidney transplants between couples increased. Whether the donors' metabolic syndrome affect post-donation morbidity or not should be further evaluated.

Financial Strain and Pursuit of Live Donor Kidney Transplants Among African Americans on the Kidney Transplant Waiting List

Ashley N. Cabacungan,[1] Matthew J. Ellis,[1] Debra Sudan,[4] Clementina A. Davenport,[1] Patti Ephraim,[5] Tara S. Strigo,[1] Iris Pounds,[1] Aviel N. Alkon,[1] Dinushika Mohottige,[1] Nicole DePasquale,[1] Sarah B. Peskoe,[1] Jane F. Pendergast,[1] Clarissa J. Diamantidis,[1] Jennifer St. Clair Russell,[3] L. Ebony Boulware.[2] *[1]Duke University, Durham, NC; [2]Duke University School of Medicine, Durham, NC; [3]National Kidney Foundation, Washington, DC; [4]Duke University Medical Center, Durham, NC; [5]Johns Hopkins University, Baltimore, MD.*

Background: The extent to which financial strain may influence African American's (AAs) pursuit of LDKT is unclear.

Methods: We studied cross-sectional associations between financial strain and LDKT activation or live donor inquiries to the transplant center among AAs on the kidney transplant waiting list. We measured financial strain using the InCharge Financial Distress/Financial Well-being 8-item Scale (IFDFWS-- responses ranging from 1 (high) to 10 (low/no) distress). We measured LDKT activation as participants' self-reported behaviors reflecting low (no family/friends LDKT discussion, no donor identified), moderate (family/friends LDKT discussion, no donor identified) or high (family/friends LDKT discussion and donor identified) activation. In logistic regression models, we quantified the association between financial strain and LDKT activation or inquiries.

Results: Among 300 participants, the median time on the wait list was 292 (IQR 81, 700) days. The mean age was 52 (SD 11), 56% were male, 50% were retired due to disability, 43% had household income < $40,000 and 25% were near or below poverty. The mean (SD) IFDFWS score was 6.2 (2), indicating moderate financial distress. Subscale mean (SD) scores were: 4.7 (2.8) for current and 4.7 (2.8) general financial stress; 4.5 (2.9) for financial concern, 5.4 (2.7) satisfaction and 5.6 (2.6) comfort, 6 (3.2) for confidence to obtain emergency funds, 5.2 (3.3) for paycheck-to-paycheck living and 3.5 (2.7) for ability to afford recreational activities. Overall financial distress was not associated with LDKT activation (OR: 1.04, 95% CI 0.91, 1.19) or donor inquiries (OR: 1.08, 95% CI 0.95, 1.22). However, participants with greater (versus less) confidence in obtaining emergency funds had statistically significantly greater odds of having a donor inquiry (OR: 1.14, 95% CI 1.04, 1.24).

Conclusions: Financial confidence may be associated with access to LDKT, including the receipt of live donor inquiries. The impact of financial strain on pursuit of LDKT among African American transplant candidates requires further study.

TH-PO1168

Attitudes and Beliefs About Organ Donation in a Cohort of Physicians Attending Medical Grand Rounds

Mariana S. Markell, Annette Cerrato, Moro O. Salifu. *SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Lack of referral of appropriate candidates for deceased donor evaluation may result from attitudes or education of the primary physician.

Methods: We evaluated the knowledge, attitudes and beliefs of a cohort of physicians attending Medical Grand Rounds at a University teaching hospital using a validated questionnaire which was returned anonymously to a box. It contains questions related to brain death, willingness to donate and perception of fairness in the system, using yes/no answers and 5-point Likert scales. Between group comparisons were performed with X square and associations by Pearson r or Spearman rho.

Results: 12 Faculty and 28 Resident physicians responded. There were 13 men and 27 women, 3 Black, 17 Asian, 14 Caucasian, and 4 other, with 13 identified as Atheist/unaffiliated, 9 Muslim, 5 Jewish, 9 Christian, 3 Hindu. 17 (43%) had signed an organ donor card (ORGD) and they were more likely to have discussed donation with their family (r=0.5, p=0.001) and to have taken an organ donation course (p=0.025). There was no difference in age group, religion, training level, gender, ethnicity, or marital status. 10 (25%) of respondents did not know the definition of brain death and 17 (43%) believed organs could be harvested before brain death. ORGD were more likely to agree to donate a family member's organs (r=0.4, p=0.01), and believe the system is fair (r=0.32, p=0.047). Religion affected the decision to donate a family member's organs with no Muslim or Hindu agreeing (p=0.011). Faculty were more likely to strongly believe that organ donation should be taught in Med School (p=0.018).

Conclusions: 1. The majority of MDs attending Medical Grand Rounds at a University teaching hospital had not signed an organ donor card or discussed donation with their family. 2. Organ donors were more likely to have taken a course on donation and to donate a family member's organs. 3. 25% did not know the definition of brain death and 43% believed that it was not necessary before organ harvesting. 4. Religious beliefs did not affect signing the card but did affect willingness to donate a family member's organs. 5. Faculty were more likely to agree that organ donation should be taught in Med School. 6. Education programs for graduate MDs should be created as misunderstanding of organ donation and personal beliefs may affect referral of patients under their care.

TH-PO1169

Kidney Transplantation in Females: Impact of Living Donor Relationship on Outcomes

Bhavna Chopra, Kalathil K. Sureshkumar. *Division of Nephrology and Hypertension, Allegheny Health Network, Pittsburgh, PA.*

Background: Female kidney transplant recipients(KTRs) are likely exposed to different HLA types through pregnancy and child birth. This may make them susceptible to memory response when re-challenged with same HLA types through organ transplant from child or spouse may increase the risk for rapid development of donor specific antibodies (DSA); increasing risk of early antibody mediated rejection; thus compromising transplant outcomes. To test this, we assessed long-term outcomes in female living donor KTRs based on their relationship to the organ donor.

Methods: Using OPTN/UNOS database, we identified all adult female living donor KTRs from 2001-2015 who received induction and CNI/MMF maintenance. Group was divided based on relationship to the donor: biologically related (sibling vs. child) and unrelated (spouse vs. all other unrelated). A subgroup of the latter was also identified in order to account for donor gender disparity: (spouse vs. unrelated males). Using a Cox model that adjusted for donor, recipient and transplant variables, we calculated overall and death-censored graft failure risks as well as patient death risk for the female recipients based on donor category: sibling vs. child; spouse vs. all unrelated and spouse vs. unrelated males.

Results: The results shown in table 1. Adjusted overall graft failure risk and patient death risk were significantly lower in sibling compared to child in female KTRs.

Conclusions: Increased patient death risk associated with child to mother transplant when compared to sibling could be related to the immunological risk from child as a consequence of maternal exposure to neonatal HLA during delivery. This can lead to DSA formation from memory response increasing risk of humoral injury, microvascular inflammation, leading to worse allograft function which has a graded association with mortality. Siblings on the other hand could have an immunological advantage by being identical twin or by providing 6 antigen match. Interestingly this phenomenon was not observed in spouse to female transplant despite limiting unrelated donor gender to male in order to minimize the impact of renal volume on outcomes.

Biological category	Living related	Living unrelated	
Donor category	Sibling (n=3560) vs. child (n=2852)	Spouse (n=1405) vs. all unrelated (n=4513)	Spouse (n=1405) vs. male unrelated (n=1453)
Overall graft failure risk [HR (95%CI)]	0.75 (0.59-0.95)*	1.13 (0.97-1.31)	1.08(0.89-1.31)
Death-censored graft failure risk [HR (95%CI)]	0.76 (0.56-1.04)	1.10 (0.92-1.32)	1.03 (0.81-1.30)
Patient death risk [HR (95%CI)]	0.70 (0.53-0.93)**	1.07 (0.88-1.31)	0.93 (0.70-1.22)

p-value; * = 0.017; ** = 0.015

TH-PO1170

Low GFR in Healthy Individuals Is an Important Factor Preventing Kidney Transplantation from Living Kidney Donors in India

Sreejith Parameswaran,[1] Satish H,[1] Ramanitharan Manikandan,[1] Priyamvada P. S,[1] Jai Radhakrishnan.[2] *[1]JIPMER, Ponidcherry, India; [2]Columbia University Medical Center, New York, NY.*

Background: More than 80% kidney transplantation (KT) are from Living Kidney Donors (LKD) in India. There are no validated equation for GFR estimation or CKD risk prediction in Indians, making the use of GFR criteria for accepting LKD problematic. Previous studies using inulin clearance have demonstrated relatively low GFR in healthy LKDs in India. How often LKDs are found unfit to donate based on GFR criteria is unknown.

Methods: A LKD database was created in 2012 & data were collected prospectively using a pre-defined data collection form. Screening evaluation include blood group, history taking with pre-specified data points, measurement of BMI & BP & lab tests (Serum creatinine, fasting & postprandial blood glucose, lipid profile and Urine R/E) & LKD having no abnormalities on screening were enrolled in the database & evaluated further. A minimum GFR (by DTPA renogram - multiple plasma sampling technique) of 70ml/minute/1.73m^2 was necessary for a LKD to be accepted for kidney donation. All LKDs registered for KT from 1st January 2012 to 31st December 2018 were included in the analysis.

Results: A total of 316 LKDs were evaluated during the study period, with mean age of 44.11 (±10.85) years & 253 (80%) were females. 274 (89.5%) of our LKDs were 'Below Poverty Line (BPL)', with family income less than INR 2000 ($28) per month. Only 101 (33%) ESRD - LKD pairs initiated on evaluation eventually underwent KT. On 92 instances factors related to the LKD prevented the KT. Low GFR (n=40, 43.5%) and impaired OGTT (n=12, 13%) were the major LKD factors precluding KT, along with withdrawal of consent (n=18, 19.5%). 40 LKDs found to have GFR <70ml/minute/1.73m^2 were rejected as VKD. None of them had hypertension or any other abnormality on evaluation. In a subset of LKD studied, the average protein intake estimated by urine Urea Nitrogen excretion was 0.6gm/kg/day & Renal Reserve Study done by IV Amino Acid infusion showed an average rise by 34.6% in GFR; with GFR >70ml/minute/1.73m^2 in 75% of LKDs who had baseline GFR <70ml/minute/1.73m^2

Conclusions: Only one third of LKD were eventually able to donate their kidney. Low GFR in otherwise healthy LKDs was an important reason precluding KT. The low baseline GFR may be related to low dietary protein intake, as suggested by significant renal reserve.

TH-PO1171

Suboptimal Renal Recovery and Progressive CKD After Living Kidney Donation

Yaerim Kim,[1] Eunjeong Kang,[1] Jin hyuk Paek,[2] Woo Yeong Park,[3] Seungyeup Han,[2] Miyeun Han,[5] Jung Pyo Lee,[4] Dong-Wan Chae,[7] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[6] Hajeong Lee.[6] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Keimyung University School of Medicine, Daegu, Republic of Korea; [3]Dongsan Medical Center, Daegu, Republic of Korea; [4]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [5]Pusan National University Hospital, Busan, Republic of Korea; [6]Seoul National University College of Medicine, Seoul, Republic of Korea; [7]Seoul National University Bundang Hospital, Seongnam-si, Republic of Korea.*

Background: Post-operative renal recovery after nephrectomy is a substantial problem to be addressed in living kidney donors. Herein, we explored factors associated with renal recovery and progression to chronic kidney disease (CKD) in living kidney donors.

Methods: Kidney donors who underwent nephrectomy in 5 different tertiary hospital were retrospectively reviewed. We extracted donors who had estimated glomerular filtration rate (eGFR) at 1 month after kidney donation with follow-up period over one year. Percent change of eGFR from initial to one month after donation was calculated. The sub-optimal renal recovery was defined as percent change of eGFR at 1 month after donation with the lowest quartile range. The development of CKD, latest eGFR < 60 ml/min/m^2 was the clinical end-point. Cox-regression and logistic regression analysis were used to determine the risk factor related with sub-optimal renal recovery and progressive CKD.

Results: In total, 883 donors were included in the study. The mean follow-up period was 59.0 ± 50.3 months. Of which 129 donors progressed to CKD, eGFR <60 ml/min/m^2. A patient with CKD showed older age, male sex, higher body mass index, higher hemoglobin, calcium, uric acid, cholesterol, lower eGFR, higher percent change in eGFR at 1 month after donation. Also, older age (adjusted HR 1.02, 95% CI 1.00-1.04, p=0.048), initial eGFR (adjusted HR 0.95, 95% CI 0.93-0.96, p <0.001) and decreased percent in eGFR at 1 month(Q3 adjusted HR 3.54, 95% CI 1.97-6.36, p <0.001; Q4 adjusted HR 5.71, 95% CI 3.10-10.54, p <0.001)) were the significant risk factors for development of CKD in multivariate Cox-regression analysis.

Conclusions: Percent change of eGFR at 1 month after donation is significant risk factor for development of CKD. Earnest evaluation and management to reduce eGFR decreasing at 1 month after donation could be helpful in improving long-term renal outcomes in living kidney donors.

TH-PO1172

Are We There Yet? Meeting the Goal of Increased Utility Under the New Kidney Allocation System

Kael Wherry,[1,2] Patricia M. Mcgovern,[1] Karen Kunct.[1] *[1]University of Minnesota, Minneapolis, MN; [2]Medtronic, Inc., Mounds View, MN.*

Background: The Kidney Allocation System (KAS) was designed to improve limitations of the previous deceased donor kidney transplant (DDKT) allocation algorithm in the United States. A key feature in the KAS is a scoring system that matches longest recipient life expectancy with longest donor graft survival expectancy, trading fairness for utility by prioritizing the best kidneys to the healthiest candidates. This study compared outcomes between patients aged 50 years and younger (<50) versus patients aged 51 and older (>50), the patient groups specifically impacted by the longevity matching scores.

Methods: This study used patient-level data from the Scientific Registry of Transplant Recipients. Relative risk of DDKT and waitlist mortality or removal from the waitlist due to deteriorating health was estimated in the pre- versus post-KAS eras with logistic regression models including fixed effects for organ supply and several patient clinical and demographic characteristics. The post-KAS era was divided into four distinct periods (0-6 months, 6-12 months, 12-24 months, 24-36 months) to assess trends over time. Survival benefit of transplant compared to remaining on the waitlist by KAS era and age group was estimated with a Cox proportional hazard regression model.

Results: This study included 239,265 incident and prevalent adult candidates on the kidney transplant waitlist between December 4, 2011 and December 3, 2017. Relative risk of DDKT for younger candidates versus older candidates was greatest in the first six months post-KAS compared to the pre-KAS era (1.17 95% CI 1.11-1.23). Candidates aged <50 years and >50 years had 1.15 (95% CI 1.00-1.30) and 1.19 (95% CI 1.07-1.30) times the risk of mortality on the waitlist or removal due to deteriorating condition in the third year post-KAS compared to the pre-KAS era, respectively. There was no difference in relative risk of mortality within age group in the first two years post KAS compared to the pre-KAS era. The survival benefit of DDKT compared to remaining on the waitlist was greater in the post-KAS era compared to the pre-KAS era among both age groups.

Conclusions: This study suggests the KAS is at least partly meeting the goal of improved utility in DDKT in the first years of implementation; however, inefficiencies in DDKT still exist. Continued analysis is needed to assess the sustained benefit of the KAS.

Contraindications to Transplant and Home Dialysis: Variation in Nephrologist Practices

Adam S. Wilk,[1] Rachel E. Patzer,[2,1] Kelsey M. Drewry,[1] Cam Escoffery,[1] Janice P. Lea.[2] *[1]Rollins School of Public Health, Emory University, Atlanta, GA; [2]Emory University, Atlanta, GA.*

Background: There is notable variation in ESRD patients' transplant waitlisting rates and home dialysis use across care providers. This variation persists after controlling for differences in patients' clinical need and community factors. It is unclear how much variation there is in nephrologists' decisions about whether a given patient is eligible for transplant or home dialysis.

Methods: We are administering a new and innovative survey—the Transplant and Home Dialysis Recommendations Survey of Nephrologists, or THRoNe—in a nationally representative sample of n=120 nephrologists (non-pediatric). The THRoNe, which we have pre-tested and validated rigorously using a modified Delphi approach with 12 nephrologists and subject experts, collects data on nephrologists' decision processes and other practice and physician characteristics that may affect treatment choices. Nephrologists are asked to rate 35 clinical and psychosocial patient evaluation criteria (e.g., not hypotensive, adequate social support) individually—as a major or relative contraindication, a minor concern, or not a concern—in the contexts of determining whether to recommend transplant, peritoneal dialysis, or home hemodialysis for a given patient. We will construct indices—overall and by modality—to support classifying nephrologists as highly restrictive (i.e., more often interpreting criteria as major or relative contraindications vs. minor concerns), moderately restrictive, and unrestrictive. We will describe the distributions of nephrologists' restrictiveness overall and by modality, and we will test for differences in these distributions across different nephrologist characteristics—by geographic region, sex, race/ethnicity, and years in practice—using Pearson's χ^2 tests and linear regression models adjusting for other physician and practice characteristics.

Results: Data collection is ongoing. We anticipate obtaining a response rate of ≥70%, in line with response rates achieved in other difficult-to-reach clinician samples using our evidence-based recruitment protocol.

Conclusions: We will determine how meaningfully U.S. nephrologists' judgments differ about whether a given patient should be referred for transplant evaluation or home dialysis training. There are important implications for developing interventions to improve the evidence basis of ESRD treatment.

TH-PO1174

Kinetic Estimated Glomerular Filtration Rate (KeGFR), a New Tool to Predict Delayed Graft Function (DGF)?

Alejandro Garcia Rivera,[1] Ana L. Garcia-Vera,[1] Omar H. Sanchez Vazquez,[1] Marlene D. Cisneros-Carbajal,[1] Antonio M. Murga,[1] Carlos D. Jimenez Mejia,[2] Carlos F. Fonseca cerda,[1] Teresa Muñoz,[1] Jhonatan Velador Mendoza,[1] Renato Parra Michel.[3] *[1]Instituto Mexicano del Seguro Social, Zapopan, Mexico; [2]Instituto Mexicano Del Seguro Social, Guadalajara, Mexico; [3]Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Hospital General Regional No.46, Instituto Mexicano del Seguro Social., Zapopan, Mexico.*

Background: Delayed graft function (DGF) is a common clinical problem in pediatric patients and in deceased donor kidney transplantation. Early prediction of DGF could be beneficial. It could improve the adjustment of nephrotoxic drugs, such as CNI and antibiotics are routinely used as prophylaxis.

Methods: A retrospective study was carried out, from une 2016 to August 2018, which included 145 kidney transplant patients, either living or deceased kidney donor transplantation, in the immediate postoperative period, in a hospital in Western Mexico. Creatinine was measured at the time of reperfusion (hour 0), and 10 and 18 hours after kidney reperfusion. The Kinetic estimated Glomerular Filtration Rate (KeGFR) was calculated were sCr10h constituted both the basal creatinine and creatinine at first point, and sCr18h was used as creatinine at second point. The primaryoutcome was DGF, defined as need for dialysis (according to the nephrologist consideration) during the first time of transplantation.

Results: 157 patients, between 17 and 69 years old, received a kidney transplant during that period, 113 males (71.9%) and 44 females (28.02%); in most of the patients (146/92.9%) the etiology of CKD was unknown. 108 patients (68.7%) received a kidney from a related living donor, 32 patients (20.3%) from a non-related living donor, and 17 (10.8%) patients from a deceased donor. 20 patients presented DGF (12.7%), with a mean GFR estimated with creatinine kinetics (KeGFR) of 5.09 ml/min, while137 patients (87.2%) didn't present DGF and had a mean KeGFR of 14.9 ml/min, with a statistically significant difference and a p value of 0.000. When establishing a KeGFR threshold value of 7 ml/min, it had a sensibility of 70% and a specificity of 81% to predict DGF, with an area under the curve of 0.759.

Conclusions: An eGFR was determined using unstable creatinine values. Our goal was to evaluate the KeGFR using serum creatinine values at 10 and 18 hours after reperfusion of the kidney, which is the time the blood samples are routinely taken in our center. When establishing a KeGFR threshold value of 7 ml/min, we could predict DGF with a sensibility of 70%, a specificity of 81%, and an AUC of 0.759.

TH-PO1175

Changes in Kidney Function After Live Donor Nephrectomy

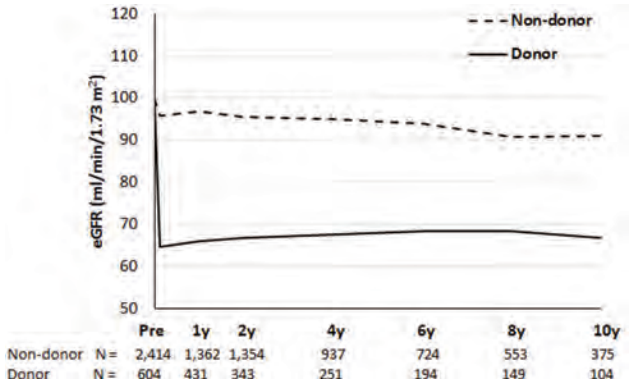
Ngan Lam,[1] Anita Lloyd,[1] Krista L. Lentine,[2] Robert R. Quinn,[3] Brenda Hemmelgarn,[3] Scott Klarenbach,[1] Amit X. Garg.[4] *[1]University of Alberta, Edmonton, AB, Canada; [2]Saint Louis University, St. Louis, MO; [3]University of Calgary, Calgary, AB, Canada; [4]London Health Sciences Centre, London, ON, Canada.*

Background: Better understanding the decline in kidney function after live donor nephrectomy and how this differs by donor characteristics can inform counselling, selection, and follow-up care.

Methods: We conducted a retrospective matched cohort study of living kidney donors in Alberta, Canada between 2002 and 2016 using linked healthcare administrative databases. We matched 604 donors to 2,414 healthy non-donors from the general population based on age, sex, year of cohort entry, urban residence, and estimated glomerular filtration rate (eGFR) before cohort entry (nephrectomy date for donors and randomly assigned date for non-donors). The primary outcome was rate of eGFR change over time (median follow-up 7 years, maximum 15 years).

Results: The median age was 43 years, 64% were women, and the baseline (predonation) eGFR was 100 mL/min/1.73 m^2. Overall, from 6 weeks onwards, the eGFR increased by +0.32 mL/min/1.73 m^2 per year (95% CI +0.17 to +0.46) in donors and decreased by -0.88 mL/min/1.73 m^2 per year (95% CI -0.96 to -0.79) in non-donors ($p<0.001$). The change in eGFR between 6 weeks to 2 years, 2 to 5 years, and ≥5 years onwards in donors was +1.05, +0.61, and -0.09 mL/min/1.73 m^2 per year, respectively. The change in eGFR over time in donors varied by sex, percent decline in eGFR within the first 6 weeks, and eGFR category at 1 year, but not by age category at donation, predonation hypertension, or predonation eGFR category.

Conclusions: The function in the remaining kidney of a living donor initially increases by 1 mL/min/1.73 m^2 per year due to hyperfiltration; however, this begins to plateau by 5 years postdonation. In contrast, non-donors experience a steady age-related decline of 1 mL/min/1.73 m^2 per year.



Mean estimated glomerular filtration rate (eGFR) over time in living kidney donors (solid line) and matched, healthy non-donor controls (dotted line).

TH-PO1176

Survival Benefit of HLA-Incompatible Living Donor Kidney Transplantation Compared with Deceased Donor Kidney Transplantation or Dialysis in Korea

Tai yeon Koo, Ji-Jing Yan, Honglin Piao, Jaeseok Yang. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: HLA-incompatible(HLAi) living donor(LD) kidney transplantation(KT) is one of efforts to increase KT opportunity for sensitized ESRD patients. Although removing anti-HLA antibodies may be high risk, to find a compatible LD or wait for a deceased donor(DD) may be long. Recently, there are controversies for outcomes of HLAi KT. US data showed better outcomes of HLAi LDKT compared to HLA-compatible(HLAc) DDKT or dialysis, whereas UK data demonstrated that waiting for HLAc DDKT or HLAc LDKT by donor exchange has good outcomes comparable to HLAi LDKT. Therefore, we tried to compare outcomes of HLAi LDKT with those of DDKT or dialysis in Korea.

Methods: One hundred eighty-nine patients underwent HLAi LDKT after desensitization that consisted of rituximab, plasmapheresis, and intravenous immunoglobulin between 2002 and 2018 in Seoul National University Hospital and Severance Hospital. Indications of desensitization were positive cytotoxicity cross-match, positive flow-cytometric cross-match, and positive donor-specific antibodies with negative cross-match. We compared outcomes among HLAi LDKT patients, DDKT patients(HLAc-DDKT group;n=930), wait-listed patients who had continued to undergo dialysis(dialysis-only group;n=930), or patients who underwent either dialysis or DDKT(dialysis-or-DDKT group;n=930) using propensity score matching.

Results: In the HLAi LDKT group, patient survival rates were 98% at 5-year and 96 % at 7-years post-KT. Patient survival rates at 5- and 7-years in the HLAc-DDKT group were 92%, and 91%, respectively, those in the dialysis-only group were 90%, and 85%, respectively, and those in the dialysis-or-DDKT group were 91%, and 88%, respectively. HLAi LDKT group showed significantly better patient survival rate compared to HLAc-DDKT group, dialysis-only group and dialysis-or-DDKT group. And there was no significant difference in the graft survival rates between HLAi LDKT and HLAc-DDKT group. In multivariate analysis, waiting or DDKT was a significant risk factor for mortality(HR,3.93; 95% CI,1.44-10.74) indepently of old age, diabetes and blood type O.

Conclusions: In conclusion, patients undergoing HLAi LDKT has a survival benefit as compared with patients who were still on the waitlist for HLAc DDKT or received HLAc DDKT in Korea that has longer waiting time for DDKT than Western countries.

TH-PO1177

Low Nephron Numbers and Larger Glomerular Size Are the Predictors of Long-Term Kidney Function in Kidney Donors

Massini Merzkani,[3] Camden Lopez,[1] Ramya Narasimhan,[3] Joseph Larson,[3] Walter K. Kremers,[3] Aleksandar Denic,[3] Walter Park,[4] Mariam P. Alexander,[3] Sandra J. Taler,[3,2] Harini A. Chakkera,[5] Naim S. Issa,[3,2] Mark D. Stegall,[3] Andrew D. Rule.[3,2] *[1]Alzheimer's Therapeutic Research Institute, San Diego, CA; [2]Nephrology, Mayo Clinic, Rochester, MN; [3]Mayo Clinic, Rochester, MN; [4]The Mayo Clinic, Rochester, MN; [5]Mayo Clinic Arizona, Phoenix, AZ.*

Background: Microstructural findings of larger nephron size and nephrosclerosis on kidney biopsy are predictive of kidney function after donation at short-term follow up. Our hypothesis is that kidney structural findings also predict long-term kidney function after donation.

Methods: We contacted living kidney donors who were at least 5 years post-donation to obtain blood pressure and kidney function test results. Microstructural (biopsy) and macrostructural (contrast CT scan) findings of the kidney at the time of donation were assessed as predictors of estimated glomerular filtration rate (eGFR), proteinuria, and hypertension with adjustment for years since donation and baseline clinical characteristics.

Results: Among 1687 donors contacted, 807 (48%) participated a mean 10.5 years after donation. At follow-up, 6.4% had developed an eGFR<45 ml/min/1.73 m^2, the mean residual eGFR ratio (post-/pre-donation eGFR) was 75%, proteinuria (self-reported) occurred in 5.1 %, and new onset hypertension occurred in 19% (119/653). An eGFR <45 ml/min/1.73 m^2 was predicted by larger glomerular volume per SD (OR=1.48, p=0.01) and low nephron number (below age-specific 5th percentile) (OR=3.40, p=0.01). Residual eGFR ratio was predicted by low nephron number (-6.1%, p=0.004) and cortical volume per BSA (1.3%, p=0.03). Proteinuria was predicted by glomerular volume per SD (OR=1.42, p=0.01). Hypertension was not predicted by any structural finding. Nephrosclerosis (glomerulosclerosis, interstitial fibrosis, or arteriosclerosis) did not predict any outcome.

Conclusions: Lower nephron numbers and large glomeruli appear to be the most important structural determinants of long term kidney dysfunction after donation.

TH-PO1178

Non-Simultaneous Kidney Exchange Cycles in Resource-Restricted Countries Without Nondirected Donation

Himanshu V. Patel,[1] Ansy H. Patel,[2] Vivek B. Kute.[1] *[1]Nephrology, IKDRC-ITS, Ahmedabad, India; [2]BJ Medical College, Ahmedabad, India.*

Background: Recent reports suggest that bridge donor renege is rare (1.5%) as part of non-simultaneous kidney exchange chains. In developing countries, surgical space and resources limit the number of simultaneous kidney exchange transplant surgeries.

Methods: The aim of this study was to evaluate the bridge donor renege rate during non-simultaneous kidney exchange cycles in a prospective single center cohort study (n=44). We describe the protocol to prepare donor-recipient pairs for non-simultaneous surgeries designed to reduce the renege rate. We propose using standard criteria deceased donor kidneys in the event of a bridge donor renege to protect vulnerable recipients

Results: We report 12 successful non-simultaneous kidney exchange cycles resulting in 44 living donor kidney transplants. These cycles involved 16 bridge donors who were trusted to donate after their incompatible recipient was transplanted, placing 15 recipients at risk (two were at risk from two bridge donors), and no donor reneged. We propose that non-simultaneous kidney exchange cycles could increase living donor kidney transplantation, especially for difficult to match sensitized pairs (17 of 44), in countries with limited transplantation resources

Conclusions: Our study confirms that non-simultaneous kidney exchange cycles can be safely performed with careful patient-donor selection and non-anonymous kidney exchange.

TH-PO1179

Glomerular Filtration Rate Measurement by Iohexol Plasma Clearance in an Ethnically Diverse Living Donor Population

Nasim Wiegley, Yihung Huang, Ling-Xin Chen. *University of California, Davis, Sacramento, CA.*

Background: Iohexol is a good agent for measurement of GFR (mGFR) due to its low extrarenal excretion, tubular secretion or reabsorption, and protein binding affinity. We compared mGFR by plasma clearance of iohexol with serum creatinine (sCr) based GFR estimations in our living kidney donor candidates and investigated the association between GFR and donor demographic characteristics.

Methods: All potential living donors with GFR measurement by iohexol plasma clearance at our center between 10/2016 – 4/2019 were included. Linear regression was performed for comparison of mGFR by ethnicity, sex, age, and BMI. Medical records were reviewed for age, BMI, ethnicity, and sCr to calculate eGFR by CKD-EPI and MDRD.

Results: Of 407 potential living donors evaluated, 35% were men and the mean age was 42. Racial distribution: 47% Caucasian, 29% Hispanic, 28% Asian, 4% Black. Median mGFR was 102 ml/min/1.73m2. Median mGFR was higher for Hispanics (106) and Asians (108) compared to Caucasians (96) [Figure1]. Women > 50yrs had faster mGFR decline than men the same age. Correlation between mGFR and sCr-based eGFR showed that CKD-EPI had a closer correlation (slope=0.42, R = 0.27) than MDRD (slope=0.37, R =0.25) [Figure 2]. Compared with Caucasians, Hispanics had higher mGFR than eGFR by CKD-EPI. Both Hispanics and Asians had higher mGFR compared to eGFR by MDRD.

Conclusions: Hispanic and Asian ethnicities have higher mGFR compared to Caucasians in our potential living donor population, which is an important finding that requires further delineation. CKD-EPI and MDRD eGFR calculations may also underestimate mGFR when used in these ethnicities.

Temporal Trends in Transplant Modalities Used for Highly Sensitized Kidney Transplant Candidates and Recipients

Kyle R. Jackson, Jennifer D. Motter, Dorry L. Segev. Epidemiology Research Group in Organ Transplantation *Johns Hopkins Hospital, Baltimore, MD.*

Background: Prioritization of highly sensitized (HS) candidates under the Kidney Allocation System (KAS) and expansion of kidney-paired donation (KPD) have broadened the transplant options available to HS candidates.

Methods: To quantify temporal trends in utilization of these differing transplant modalities, we used national SRTR registry data from 2009-2017 to study 45,759 adult HS (cPRA≥80%) waitlisted candidates and 19,003 HS transplant recipients. We used competing risks regression to quantify temporal trends in likelihood of deceased donor kidney transplantation (DDKT), KPD, and non-KPD living donor kidney transplantation (LDKT) for HS candidates over time (Era 1: 01/01/2009-12/31/2011; Era 2: 01/01/2012 – 12/3/2014; Era 3: 12/4/2014 – 12/31/2017).

Results: Although the likelihood of DDKT and KPD increased over time for all HS candidates (adjusted subhazard ratio [aSHR] for Era 3 vs. 1 for DDKT: $_{1.64}1.72_{1.80}$, p<0.001; aSHR for KPD: $_{1.30}1.57_{1.88}$, p<0.001), the likelihood of LDKT decreased over time (aSHR for Era 3 vs. 1: $_{0.71}0.82_{0.95}$, p=0.007). However, these changes affected HS recipients differently depending on their cPRA. For example, an increased proportion of cPRA 80-89% recipients were transplanted with KPD over time (8.6% of candidates in Era 3 vs. 3.8% in Era 1, p<0.001), whereas DDKT was used for fewer recipients (80.1% in Era 3 vs. 86.2% in Era 1). In contrast, an increased proportion of cPRA 98-99.9% and 99.9%+ recipients were transplanted with DDKT (96.2% in Era 3 vs. 59.1% in Era 1 for cPRA 99.9%+, p<0.001), at the expense of fewer recipients being transplanted with either LDKT (1.9% in Era 3 vs. 30.9% in Era 1 for cPRA 99.9%+) or KPD (2.0% in Era 3 vs 10.0% in Era 1 for cPRA 99.9%+).

Conclusions: HS candidates had an increased likelihood of DDKT and KPD over time, although the effect of this varied across cPRA. In the KAS era, the most HS candidates (cPRA 98%+) have seen significant declines in use of KPD and LDKT.

Funding: NIDDK Support

Table. Changes in the transplant modalities used for HS recipients by cPRA categories by era of transplantation.

cPRA	Era 1	Era 2	Era 3	p-value*
80-89% (%)				
DDKT	86.2	89.7	80.1	
LDKT	10.0	6.2	11.3	<0.001
KPD	3.8	4.1	8.6	
90-97% (%)				
DDKT	85.4	86.8	87.9	
LDKT	10.2	7.2	6.2	<0.001
KPD	4.3	6.1	5.9	
98-99.9% (%)				
DDKT	78.6	80.3	96.2	
LDKT	16.9	9.4	1.9	<0.001
KPD	4.5	10.3	1.9	
99.9%+ (%)				
DDKT	59.1	68.7	96.2	
LDKT	30.9	20.2	1.9	<0.001
KPD	10.0	11.2	2.0

Patients with Pretransplant eGFR < 20 mL/min Are at High Risk for ESRD Within 2 Years of an Isolated Heart Transplant

Abhishek Kumar,[1] Christie P. Thomas.[2,3] *[1]Internal Medicine, University of Vermont, Burlington, VT; [2]Internal Medicine, University of Iowa, Iowa City, IA; [3]Internal Medicine, VA Medical Center, Iowa City, IA.*

Background: Preexistent advanced chronic kidney disease can progress to ESRD after heart transplantation. We examined if risk of ESRD and mortality was different in isolated heart transplant patients with a pre-transplant eGFR between 20 and 30 ml/min as compared to an eGFR <20 ml/min. We chose a cutoff between groups of 20 ml/min as, at this level of kidney function, patients qualify for a kidney transplant as per current kidney allocation rules.

Methods: We analyzed UNOS heart transplant data in adults receiving an isolated heart transplant between 2000 and 2015 who had a pretransplant eGFR ≤30 ml/min. Survival analysis was used to generate Kaplan-Meier curves. Results were adjusted for multiple confounding factors.

Results: We had 1093 patients with a pretransplant eGFR of ≤30 ml/min in our cohort. Of these 915 patients had data on a renal event (ESRD and/or kidney transplant) and 1057 had data on mortality. Incidence and hazard ratios for renal events and mortality are shown in Table 1. Kaplan Meier curve for renal event is shown in Figure 1.

Conclusions: Patients with an eGFR <20 ml/min had 61% higher risk of renal event than the group with eGFR between 20-30 ml/min. 50% of the renal events in the cohort with an initial eGFR <20 ml/min, occurred within the first two years post transplant. 76.4% of patients with an eGFR of 20-30 ml/min did not develop ESRD or need a kidney transplant over a 15 year followup period. These observations may help refine criteria for patients who could benefit from a combined heart kidney transplant rather than having to face the need for ESRD care with uncertain access to a kidney transplant within 2 years of their heart transplant.

eGFR at time of Heart Transplant	Renal event N (%)		Adjusted Hazard Ratio	p value with 95% CI	Mortality N (%)		Adjusted Hazard Ratio	p value with 95% CI
	YES	NO			YES	NO		
eGFR <20	64 (36.6 %)	111	1.61	0.003 (1.17-2.22)	148 (64.1%)	83	1.22	0.148 (0.92-1.62)
eGFR 20-30	182 (24.6 %)	558			416 (50.4%)	410

Prelisting Cancer Diagnosis and Outcomes in Candidates Waitlisted for Kidney Transplant

Allyson Hart,[1,2] David A. Zaun,[2] Bertram L. Kasiske,[1] Ajay K. Israni,[1] Eric A. Engels.[3] *[1]Hennepin County Medical Center, Minneapolis, MN; [2]CDRG, Minneapolis, MN; [3]National Cancer Institute, Bethesda, MD.*

Background: As outcomes for kidney transplant candidates with a previous history of cancer are not well described, transplant centers have difficulty determining whether and when to list such patients.

Methods: We used data from the Transplant Cancer Match Study, which links data on all solid organ transplant candidates and recipients in the US with data from 18 state and regional cancer registries, to describe outcomes for kidney transplant candidates with a pre-listing cancer diagnosis.

Results: Of 7017 kidney transplant candidates with a pre-listing history of cancer starting in 1983 (Table 1), 2600 (37.1%) were female and 4417 (62.9%) were male. Median age at listing was 59.0 years. Kidney (n=1238, 17.6%), prostate (n=1102, 15.7%), breast (n=703, 10.0%), liver (n=565, 8.1%), and colorectal (n=611, 8.7%) cancers were the most common; 5140 (73.2%) cancers were in situ or localized, 1316 (18.7%) were regional or distant stages. Median time from cancer diagnosis to listing was 4.7 years. In total, 5901 patients (84.1%) subsequently underwent transplant; 689 (9.8%) were removed from the list due to death, medical unsuitability, or deteriorating medical condition. Median time to transplant from listing was 1.2 years, with 1-year patient and graft survival 93.6% and 89.0%, respectively.

Conclusions: Many waitlisted kidney transplant candidates have a previous history of cancer, and many underwent transplant. Their data can be used to estimate likely outcomes for similar patients presenting for transplant evaluation, compared with waitlisted patients with no history of cancer.

FR-PO001

Significant Numbers of Hospitalized Patients with AKI Are Seen in Primary Care Before Admission, Representing Opportunities for Early Intervention

Alexandra Riding, Kate Berresford, Clare Morlidge, Suresh Mathavakkannan, Andrew Findlay. *Renal Medicine, East and North Herts NHS Trust, Stevenage, United Kingdom*.

Background: Acute kidney injury (AKI) confers increased morbidity and mortality and e-alerts are evenly distributed between hospital and community settings (Holmes et al, CJASN, 2016). Primary care physicians (PCPs) are well-placed to enact sick-day guidance, forming a critical juncture to reduce potential hospital admission, length of stay and emergency intervention. PCPs make decisions with limited time and information, hampering adherence to 'Think Kidneys' guidance (UK Renal Registry, Renal Association). In light of recent advice balancing the opposing risks of ACE inhibitor (ACEi) or angiotensin receptor blocker (ARB) cessation during AKI on cardiorenal outcomes, greater support from renal services at the primary/secondary care interface is required to effectively manage these patients (Thomson & Tomlinson, CJASN, 2019 and Clark et al, Heart, 2019). We sought to determine the proportion of patients with AKI, who might benefit from advice in primary care.

Methods: Retrospective data were collected on hospitalized patients (Nov 2018-May 2019) identified by elevated serum creatinine results (as per national AKI reporting guidance). Data sources were patient records and computerized reporting systems.

Results: 150 patients were identified (data available for 148). 38/148 (26%) saw a PCP in the fortnight pre-admission (11/38 subsequently referred) and 27/148 (18%) were referred by a PCP to hospital. 41/148 (28%) were inpatients in the preceding month and 48/148 (32%) were care home residents.

Conclusions: A quarter of patients saw a PCP before admission, representing an opportunity to intervene. Patients were elderly and co-morbid therefore decisions involving medication cessation and cardiovascular review require specific expertise and training, through enhanced physician relationships. Better community support and admission avoidance may represent the best possible medical care for some patients and urgent improvement in links between primary care and secondary renal service is recommended for all.

AKI risk factors by stage

AKI	Stage 1 (n=58)	Stage 2 (n=58)	Stage 3 (n=32)	All AKI (n=148)
Age (median years)	82	83	78	82
History of CKD (%)	30 (52)	22 (38)	12 (38)	64 (43)
Previous AKI (%)	19 (33)	24 (41)	13 (41)	56 (38)
Prescribed ACEi/ARB (%)	18 (31)	22 (38)	11 (34)	51 (34)

Underreporting of In-Hospital AKI in Taiwan: A Nationwide Study

Jinn-Yang Chen. *Taipei Veterans General Hospital, Taipei, Taiwan*.

Background: Hospital-acquired AKI is associated with high morbidity and mortality. We used ICD-9 CM code and Taiwanese National Health Insurance (NHI) dialysis procedure codes to identify in-hospital acute kidney injury and evaluate their outcomes over a twelve years period in Taiwan.

Methods: In a nationwide retrospective study based on the NHI Database, we identified all adult patients requiring the first in-hospital dialysis, or with ICD-9 code 584 between 2003 and 2014. We excluded patients with previous renal transplantation or chronic dialysis from 2000 to 2002.

Results: A total of 628,120 in-hospital AKI episodes were identified, and 203,064 episodes were dialysis-requiring AKI. Among 203,064 dialysis-requiring AKI episodes, 22,746 patients (11.2%) had advanced chronic kidney disease (CKD); 121,054 patients (59.6%) had history of CKD; 59,271 patients (29.2%) received dialysis during admission without documented CKD. Among patients without pre-existing CKD, 46.7% had sepsis; 6.6% were related to cardiac surgery; 91.2% had been admitted to ICU and 42.5% received CRRT. Patients without pre-existing CKD showed the highest in-hospital mortality (71.1%). Time trend analysis showed that there were decreased trends of in-hospital mortality and increasing trends of long-term dialysis from 2003 to 2014. For those who was discharged without receiving regular dialysis, 25% and 12% of patients died within 1 and 2 years after discharge.

Conclusions: We found in-hospital AKI was severely under-reported and was associated with high mortality. Strategies to increase the accuracy of discharge diagnosis is required to improve patient safety.

Epidemiology of Patients Receiving Continuous Renal Replacement Therapy: The Multicenter CRRTNet Study

Oleksa G. Rewa,[1] Michael Heung,[2] Andrew A. House,[4] Divya Monga,[5] Javier A. Neyra,[6] Michelle Secic,[7] Robin Piazza,[8] Stuart Goldstein,[3] Sean M. Bagshaw.[1] *[1]Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada; [2]University of Michigan, Ann Arbor, MI; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]LHSC University Hospital, London, ON, Canada; [5]University of Mississippi Medical Center, Madison, MS; [6]University of Kentucky Medical Center, Lexington, KY; [7]Secic Statistical Consulting, Inc., Cleveland, OH; [8]Watermark Research Partners, Inc, Indianapolis, IN*.

Background: There have been limited studies evaluating key performance metrics of patients undergoing continuous renal replacement therapy (CRRT). Our aim was to assess the case-mix, acuity, diagnosis, clinical course and outcomes of patients undergoing CRRT.

Methods: CRRTnet is an international multicenter data registry of adult patients undergoing CRRT to assess the variations in CRRT prescription and delivery across quality domains and to develop and benchmark CRRT specific key performance indicators. We evaluated the demographic criteria of adult critically ill patients undergoing CRRT for greater than 24 hours. Data was analyzed descriptively.

Results: In total, 1116 patients treated with CRRT were included in the registry. The mean (SD) age 57.9 (14.2) years, 58.5% were male, mean (SD) APACHE II and SOFA score were 28.8 (7.3) and 13.8 (3.9), respectively, 81.2% of patients were mechanically ventilated and 83.0% required vasopressor support. The most common admission diagnosis was respiratory failure (20.1%), followed by sepsis (16.2%), cardiovascular emergency (14.3%) and acute liver failure (6.0%). Mean serum creatinine at ICU admission was 331.9 (256.7) umol/L. The most common triggers for CRRT initiation were volume overload (47.8%), oligo-anuria (27.5%) hyperkalemia (5.7%), metabolic acidosis (3.7%) and uremia (1.9%). 46.9% of patients survived the ICU stay and 43.6% survived to hospital discharge. 34.2% of patients had complete renal recovery, 19.5 % of patients had partial renal recovery while 46.4% had ongoing need for RRT. Mean ICU and hospital lengths of stay were 20.5 (26.2) and 43.2 (44.4) days, respectively.

Conclusions: In this large multi-centre prospective registry of critically ill patients treated with CRRT the most common etiology of AKI requiring CRRT was sepsis and the most common specific indication was volume overload.

Dialysis Initiation in AKI: An Evaluation of the Wait and See Approach

Etienne Macedo,[1] Marlies Ostermann,[5] Ashita J. Tolwani,[3] Alexander Zarbock,[2] Josee Bouchard,[6] Ravindra L. Mehta.[4] *[1]University of California San Diego, La Jolla, CA; [2]University Hospital Münster, Münster, Germany; [3]University of Alabama, Birmingham, AL; [4]University of California San Diego Medical Center, La Jolla, CA; [5]Guy's & St Thomas' Hospital, London, United Kingdom; [6]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada*.

Background: The optimal timing of RRT initiation in critically ill patients has been an area of intense investigation. Recent trials have suggested that dialysis may be avoided in patients with severe AKI by waiting to initiate therapy unless there are life-threatening complications requiring emergent intervention. We evaluated the outcomes of this "wait and see approach" (WS) in comparison to elective intervention based on the severity of AKI and non-emergent indications. We hypothesized that the WS approach would be associated with higher mortality and resource utilization.

Methods: We conducted a retrospective multinational cohort study of critically ill adult patients admitted to four centers in Germany, UK and USA between Jan2014 and Dec2017. We excluded patients with ESRD, kidney transplant and those who stayed <72hrs. in the ICU. Need for dialysis was classified as emergent, defined as AKI Stg2 or higher, in the presence of any one of the criteria 1) arterial blood gas pH<7.15, 2) K>= 6.5 Meq/L, 3) BUN>112 mg/dl or 4) PO2/FIO2<=150 with cumulative fluid balance from admission >= 15%. Urgent initiation was considered if patients had AKI Stg3 and none of the emergency criteria, and elective for the rest of the indications. The primary outcome was ICU and hospital mortality.

Results: Of 20,560 eligible patients, 9712 (47.2) developed AKI (2,156;10.5) received dialysis (D); of whom 438(20) at dialysis initiation were at Stg1, 124(5) Stg2, 380(17) Stg3 and 953(44) no AKI. They were categorized as elective (2156;76), urgent (252;11) and emergent (252;11). Among 18404 non-dialyzed (ND) patients, 253(1.4%) met the urgent and 127(0.7%) the emergent criteria. Dialyzed patients had higher SOFA scores, vasopressor need, mechanical ventilation, and cumulative fluid balance. Hospital mortality in D patients was almost 2 fold higher as compared to urgent and elective groups, and in the ND patients hospital mortality was > 2 fold higher when urgent and 4.5 fold higher when emergent criteria were present. D and ND patients had similar mortality in emergent category.

Conclusions: Reaching emergency criteria was associated with higher ICU and hospital mortality in dialyzed and non-dialyzed patients. Further studies are needed to identify appropriate criteria for initiating dialysis in ICU patients.

FR-PO005

Outpatient Dialysis for AKI: A Nonprofit Provider Experience

Eduardo K. Lacson,[1,2] Gideon N. Aweh,[2] Harold J. Manley,[3] Daniel E. Weiner,[4] Taimur Dad,[4] Doug Johnson,[2] Charuhas V. Thakar.[5] *[1]Tufts University School of Medicine, Boston, MA; [2]Dialysis Clinic, Inc., Nashville, TN; [3]Dialysis Clinic, Inc., Albany, NY; [4]Tufts Medical Center, Boston, MA; [5]University of Cincinnati, Cincinnati, OH*.

Background: Medicare approved reimbursement of outpatient hemodialysis (HD) for patients with acute kidney injury (AKI) in 2017. Lack of national data hinders a consensus on optimal management. We describe the experience of a multi-state non-profit dialysis provider.

Methods: We reviewed electronic medical records of all patients treated for AKI between 1/1/17 and 12/31/18 with follow-up until 3/31/19. We describe demographics, dialysis prescriptions/practices, and disposition from 187 outpatient centers with a mean (median) population of 4.4 (3.0) AKI patients treated during the two-year study period.

Results: A total of 815 AKI patents (2017 = 318; 2018 = 497) were admitted across units with a mean age 65.1 (range: 15.7 to 97) years, 56% male, 56% Caucasian and over 98% were treated via HD catheter. Thrice weekly HD was prescribed on admission for 92% (rest <3/week) with median treatment time of 3.5 (Q1-3.0, Q3-4.0) hours and blood/dialysate flow rate of 400/600 (350/600, 400/700) ml/min, and 60% on 3K bath (36% 2K). Lab draws (e.g. creatinine, Cr) averaged weekly (lowest quartile: bi-weekly). Mean duration of AKI therapy was 47 (range: 1 to 327) days, with 45% transitioning to ESRD (averaging 61 days as AKI). Among discharges, 66% had >25% decline in Cr, indicating potential renal recovery rate of 37%. After being deemed ESRD, 22% died and 5% recovered kidney function over the study period.

Conclusions: Since Medicare changed reimbursement, successful treatment of stable AKI occurs in the outpatient setting. By leveraging patient-level treatment data, dialysis providers are uniquely positioned to contribute studies that may help define best practices and to benchmark clinical outcomes.

FR-PO006

Medication Prescribing Patterns in AKI Patients Undergoing Outpatient Dialysis

Harold J. Manley,[1] Gideon N. Aweh,[4] Daniel E. Weiner,[3] Taimur Dad,[3] Charuhas V. Thakar,[2] Doug Johnson,[4] Eduardo K. Lacson.[5] *[1]Dialysis Clinic Incorporated, Albany, NY; [2]University of Cincinnati, Cincinnati, OH; [3]Tufts Medical Center, Boston, MA; [4]Dialysis Clinic, Inc., Nashville, TN; [5]Tufts University School of Medicine, Boston, MA.*

Background: Beginning 2017, Medicare patients with acute kidney injury (AKI) could receive outpatient dialysis care. We describe medication prescribing trends as recorded in electronic medical records of a large non-profit dialysis provider.

Methods: A retrospective review of AKI patients treated between 1/1/17 and 12/31/18 with follow-up until 3/31/19 at 187 outpatient dialysis clinics. Medications were classified for home/clinic use and by Medi-Span® categories. Demographics, polypharmacy prevalence (PolyRx; ≥ 10 medications) and medication classes were determined at 1 week and 30 days.

Results: A total of 799 patients were identified, 415 (52%) having continuous AKI treatment at least 30 days. Patients were 65 ±14 years, 52% male, 56% white and 95% had at least 1 medication order. We identified 5,035 medications orders at week 1 and 8,185 medications at 30 days. Number of medications and PolyRx occurrence at end of week 1 and 30 days was 7.8 ± 6.6 (median 5) medications vs. 14.4 ± 8 (median 13) ($p<0.05$) and 32.3% vs. 68% ($p<0.001$), respectively. As expected, over time, larger proportion of patients were undergoing management of bone-mineral dysfunction or anemia. There were 71 (0.9%) potentially contraindicated or nephrotoxic medications: 5 metformin; 8 NSAIDs; 5 digoxin; 3 rivaroxaban; 50 aminoglycoside. Changes in top medication classes are shown in table.

Conclusions: Patients with AKI have complex medication regimens, high PolyRx incidence and significant changes over time. Incorporating medication reconciliation processes can flag potential unsafe or nephrotoxic medication, and improve patient safety and improve prospects for recovery in AKI patients.

Medi-Span® Medication Class	AKI patients @ week 1 (n=415)			AKI patients @ 30 days (n=415)		
	% Patients	Clinic Rx	Home Rx	% Patients	Clinic Rx	Home Rx
HEMATOPOIETIC GROWTH FACTORS	44%	181		86%	355	1
IRON	32%	118	15	86%	355	1

FR-PO007

Epidemiology of Hospitalization Preceding Initiation of Outpatient Dialysis for AKI Among Medicare Beneficiaries

Eric D. Weinhandl,[1,2] Lorien S. Dalrymple.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]University of Minnesota, Minneapolis, MN*.

Background: Little is known about hospital admissions preceding initiation of outpatient (OP) dialysis for acute kidney injury requiring dialysis (AKI-D), which presumably represent transitions of AKI-D care from inpatient to outpatient settings. We examined Medicare claims to assess hospitalizations preceding the initiation of OP dialysis for AKI-D.

Methods: We analyzed the 100% sample of institutional claims in 2014–2017 Medicare Limited Data Sets. To identify initiation of OP dialysis for AKI-D, we located the first OP dialysis facility claim in 2017 with condition code 84 and Healthcare Common Procedure Coding System code G0491. We excluded any patients with Medicare claims history of OP dialysis indicated for end-stage kidney disease, dating to January 1, 2014. We retained the subset of patients with Medicare coverage during the 6 calendar months preceding the month of initiation of OP dialysis for AKI-D. We then analyzed hospitalization claims, including ICD-10 diagnosis codes.

Results: The cohort comprised 8500 patients. Mean age was 70.5 ± 11.0 years, 77% were white, and 44% were female. During the 6 months preceding the initiation of OP dialysis for AKI-D, 8209 (97%) patients were hospitalized, with cumulative totals of 1.9 admissions and 27 hospitalized days. Regarding the last hospitalization preceding initiation of OP dialysis for AKI-D, mean (median) length of stay was 20 (15) days; 29% were discharged home under self-care, 25% to home health care, 42% to a skilled nursing facility, and 3% to intermediate care settings. The number of days between hospital discharge and initiation of OP dialysis for AKI-D was ≤1 in 34% of patients, 2–3 in 52%, 4–7 in 8%, and >7 in 6%. During the last hospitalization preceding initiation of OP dialysis for AKI-D, chronic kidney disease (CKD) was documented in 86% of admissions, diabetes in 59%, heart failure in 53%, and atrial fibrillation in 34%. Clinical events included acute respiratory failure in 29% of admissions and sepsis in 20%.

Conclusions: In Medicare beneficiaries, hospitalizations preceding initiation of OP dialysis for AKI-D are typically long and often complex, with 1 in 5 experiencing sepsis and 1 in 3 acute respiratory failure. CKD is common in this population, as is concurrent care in a skilled nursing facility at initiation of OP dialysis for AKI-D.

FR-PO008

Predictors of Recovery of Kidney Function and Transition to ESKD in Patients on Outpatient Dialysis for AKI

Eric D. Weinhandl,[1,2] Lorien S. Dalrymple,[1] Yuping Sun,[1] Norma J. Ofsthun,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]University of Minnesota, Minneapolis, MN.*

Background: Most patients initiating outpatient hemodialysis (OP HD) for acute kidney injury requiring dialysis (AKI-D) recover function or transition to end-stage kidney disease (ESKD) within 3 months. Identifying factors predisposing patients to either outcome may improve clinical care processes. We assessed associations of baseline patient characteristics and biochemistry at initiation of OP HD for AKI-D with competing risks of recovery of kidney function and transition to ESKD.

Methods: We analyzed patients initiating OP HD for AKI-D in a Fresenius Kidney Care (FKC) dialysis facility between May 1, 2017, and December 31, 2018, excluding those discharged from FKC facilities within 7 days of initiation of OP HD or with incomplete biochemical data. We followed patients to the earliest of recovery of kidney function, transition to ESKD, death, or loss to follow-up (typically, transfer to another dialysis provider), with end of follow-up on March 31, 2019. We used Fine-Gray regression to model subdistribution hazards of recovery of function and transition to ESKD, as a function of age, sex, and biochemistry measured within 7 days of initiation of OP HD; death was classified as a competing risk.

Results: The cohort comprised 12,221 patients. During follow-up, 4786 (39%) recovered kidney function, 5606 (46%) transitioned to ESKD, and 1136 (9%) died. Adjusted hazard ratios of recovery of function and transition to ESKD per standard deviation (SD) of each factor are displayed in the table.

Conclusions: Younger age, female sex, lower serum creatinine, lower serum potassium, higher serum phosphorus, and lower serum parathyroid hormone are most strongly associated with recovery of kidney function after initiation of OP HD for AKI-D, whereas higher serum creatinine is most strongly associated with transition to ESKD.

	SD	Recovery of Function		Transition to ESKD	
		AHR	95% CI	AHR	95% CI
Age (years)	14.6	0.78	0.76-0.81	1.05	1.02-1.09
Female sex		1.24	1.17-1.32	0.86	0.82-0.91
Creatinine (mg/dL)	2.3	0.65	0.62-0.68	1.27	1.24-1.31
Potassium (mEq/L)	0.6	0.85	0.82-0.88	1.12	1.09-1.16
Sodium (mEq/L)	3.9	1.10	1.07-1.13	1.02	0.99-1.04
Hemoglobin (g/dL)	1.3	1.08	1.05-1.11	0.93	0.91-0.96
Ferritin (ng/mL)	747	1.11	1.08-1.15	0.83	0.79-0.86
Transferrin saturation (%)	12.7	0.86	0.83-0.89	1.06	1.03-1.08
Phosphorus (mg/dL)	1.5	1.31	1.26-1.35	0.84	0.81-0.87

Albumin (g/dL)	0.6	1.14	1.10-1.17	0.99	0.96-1.01

FR-PO009

The Relationship Between Intra-Parenchymal Renal Resistive Index Variation and Renal Functional Reserve Under Physiologic and Pathologic Conditions

Sara Samoni,[3,1] Gianluca Villa,[4] Silvia De Rosa,[3] Mauro Neri,[3] Faeq Husain Syed,[5] Massimo de Cal,[3] Federico Nalesso,[6] Mario Meola,[1] Claudio Ronco.[2] *[1]Institute of Life Sciences, Sant'Anna School of Advanced Studies, Pisa, Italy; [2]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy; [3]IRRIV - San Bortolo Hospital, Vicenza, Italy; [4]University of Florence, Florence, Italy; [5]University Clinic Giessen and Marburg-Camps Giessen, Giessen, Germany; [6]DIMED- University of Padua, Igaly, Padova, Italy.*

Background: The assessment of renal functional reserve(RFR), which is the increase of glomerular filtration rate after a protein load, has been proposed for the risk stratification of patients undergoing potentially nephrotoxic procedures. In a previous study, we described a bedside ultrasound(BUS) test (intra-parenchymal renal resistive index variation, IRRIV test) to identify the presence of RFR. The aim of the present study is to externally validate IRRIV test in a validation cohort of healthy subjects and preliminary explore the correlation between IRRIV and RFR under pathologic conditions.

Methods: We enrolled a group of healthy subjects and a group of patients scheduled for cardiac surgery. Each underwent protein loading test and IRRIV test. It relies on a mechanical abdominal stress consisting of compressing renal vessels through an externally applied weight on the abdomen (fluid-bag 10% of subject's body weight) which reduces blood flow and activates the autoregulation mechanism. This leads to afferent vasodilation which can be measured by a fall in RRI. Pearson and logistic regression analyses were used to assess the correlation between IRRIV and RFR in both groups.

Results: In 47 healthy subjects, Pearson correlation coefficient between RFR and IRRIV is 0.83, CI95%[0.71-0.90], p<0.01. Among these, concordance between RFR and IRRIV is described in 45 subjects (95.7%). IRRIV predicts RFR with a ROC-AUC of 0.86, CI95%[0.68-1]. In 31 cardiac surgery patients, Pearson correlation coefficient between RFR and IRRIV is 0.81, CI95%[0.63-0.90], p<0.01. Among these, concordance between RFR and IRRIV is described in 27 (87.1%) patients. IRRIV predicts RFR with a ROC-AUC of 0.80, CI95%[0.64-0.96].

Conclusions: IRRIV test is a feasible BUS test that significantly predicts the presence of RFR in healthy subjects. Correlation between IRRIV and RFR seems to be also maintained in pathologic conditions.

FR-PO010

Pathological Characteristics and Prognosis of Community-Acquired AKI: Risk Factors of AKI to CKD Transition

Mengna Ruan,[1] Jing Xu,[2] Zhiguo Mao.[3] *[1]Changzheng Hospital, Second Military Medical Universisy, Shanghai, China; [2]Shanghai Changzheng Hospital, Shanghai, China; [3]Changzheng Hospital, Shanghai, China.*

Background: Community-acquired acute kidney injury(CA-AKI) wins more attentions from society. Underlying pathological damages are regraded as major determinants to AKI to CKD transition. In this study, we clarified the pathological characteristics of CA-AKI and evaluated the influence of morphologic changes in the renal biopsy on the rapid loss of renal function and AKI-CKD transition.

Methods: This single-centered cohort study enrolled CA-AKI patients with renal biopsy examination from January 1, 2010 to September 30, 2017 admitted to Shanghai Changzheng Hospital. All patients were followed up for 90 days after diagnosis. The demographic characteristics, pathological lesions and outcomes were recorded and analyzed. Cox proportional hazard models were used to evaluate the risk factors for all-cause mortality and renal replacement therapy requirement after diagnosis. Logistics regression analyses were used to identify the risk factors associated with progression to CKD or maintained dialysis, and renal recovery as well.

Results: A total of 251 eligible CA-AKI patients were recruited into the cohort, of whom 144(57.4%) were male and age ranged from 18 to 85 years old(median 53). Our results showed that pathological lesions played critical role in AKI-CKD progression and renal recovery. With regard to progression on 90th day, segmental glomerulosclerosis(Relative Ratio(RR) 6.44; 95%CI, 2.03 to 20.38, p=0.002), severe vascular lesion(RR 14.92; 95% CI, 2.35 to 94.80, p=0.004), and crescent index (RR 3.50; 95% CI, 2.07 to 5.91, p=0.037) were significantly associated with progression to maintained dialysis. Over 50% area of Interstitial inflammation(RR 8.09; 95%CI 2.54 to 25.77, p<0.001) and crescent index(RR 3.30; 95%CI 1.78 to 6.12, p<0.001) were risk factors for progression to CKD. Moreover, interstitial fibrosis and crescent were risk factors for partial renal recovery. While, renal morphologic changes showed little impact on in-hospital all-cause mortality and RRT requirement by Cox proportional hazard modeling analysis.

Conclusions: Pathological damages played a part in the rapid loss of renal function and AKI-CKD transition of CA-AKI patients in a short term,affected renal recovery as well. Whereas, it did not interfere with severity of AKI: all-cause mortality and RRT requirement.

Funding: Government Support - Non-U.S.

FR-PO011

Association Between Pre-ESRD Outpatient AKI and Post-ESRD Mortality

Praveen Kumar Potukuchi,[1] Ankur A. Dashputre,[1] Keiichi Sumida,[1] Abduzhappar Gaipov,[5] Suryatapa Kar,[1] Fridtjof Thomas,[1] Justin Gatwood,[1] Yoshitsugu Obi,[2] Miklos Z. Molnar,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA; [5]National Scientific Medical Center, Astana, Kazakhstan.*

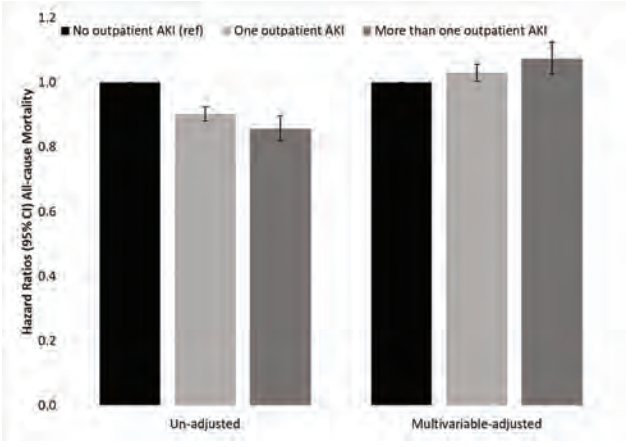
Background: Acute kidney injury (AKI) often occurs in patients with advanced CKD. The incidence of AKI and its impact on outcomes in hospitalized patients has been reported. However, information about the association between pre-ESRD outpatient AKI (oAKI) and post-ESRD outcomes is lacking.

Methods: We examined 54,085 US veterans who transitioned to dialysis during 2007-2014 and had serum creatinine measured in three years preceding the dialysis initiation. oAKI was defined as a 50% increase in creatinine compared to the preceding creatinine value. We compared patients with no oAKI (N=38,348) to patients who had 1 oAKI (N=12,399) and patients who had ≥2 oAKI (N=3,338). The association between pre-ESRD oAKI and post-ESRD all-cause mortality was assessed using Cox proportional hazards model adjusted for demographics, comorbidities, medications, nephrology care, number of outpatient visits, cumulative length of hospitalizations and vascular access type.

Results: The mean (SD) age of the cohort was 70 (11) years; 98% were male; 27% were African American; and 75% were diabetic. Patients with oAKI were younger (age 71 (11) vs. 67 (11) vs. 64 (11) years in patients with no vs. one vs. ≥2 oAKI events). Also, patients with oAKI displayed significantly higher multivariable adjusted mortality than patients without oAKI, with incrementally higher risk observed in patients experiencing ≥2 episodes of oAKI [Figure]. The hazard ratios (95%CI) associated with 1 and ≥2 (vs. no) oAKI were 1.03 (1.00-1.06) and 1.07 (1.03-1.13), respectively.

Conclusions: Prior AKI event in outpatient setting is associated with higher risk of all-cause mortality in advanced CKD patients who transition to maintenance dialysis therapy. Clinical trials are indicated to examine whether preventing AKI can improve CKD outcomes.

Funding: NIDDK Support



FR-PO012

Underreported AKI in Pediatric Intensive Care: Incidence, Risk Factors, and Outcomes

Sunil P. Keshwah, Vidya Mahavadi, Shireen Hashmat. *University of Chicago Comer Children's Hospital, Chicago, IL.*

Background: Acute kidney injury (AKI) is increasingly recognized in critically ill pediatric patients. AKI is frequently underreported leading to the potential for increased morbidity and mortality associated with this disorder. Our study seeks to identify the incidence, risk factors, and outcomes of patients with undocumented AKI in the pediatric critical care population.

Methods: We conducted a retrospective chart review of patients admitted to the PICU at Comer Children's Hospital between January 1, 2017-December 31, 2017. Patients with a rise in serum creatinine (SCr) levels consistent with the KDIGO AKI criteria were considered to have AKI. Patients with a physician note in their electronic medical record (EMR) containing the terms "AKI", Acute Kidney Injury" or "Acute Renal Failure" were labeled as having "Documented AKI". The primary outcome of interest was a comparison between AKI patients with and without EMR documentation of disease. All statistical analyses were performed using STATA software with a p-value of < 0.05 considered statistically significant.

Results: AKI was identified in 8.3% of the total population, with 71% of these patients not having any documentation of AKI in the EMR. There was a significant increase in documentation of AKI in patients with oliguria, nephrotoxic medication and inotropic/vasopressor exposure. Patients with documented AKI had a statistically significant increase in their median length of PICU admission (13.5 days vs 2 days, p=0.00) and median length of mechanical ventilation (12.94 days vs 6.84 days, p=0.034). A nephrology consultation was placed in 2.2% of patients with undocumented AKI.

Conclusions: Our data shows that a substantial number of all AKI diagnosis were not documented in the EMR. Of note, this does not indicate that the provider failed to recognize AKI, but it does represent a deficiency to convey to the medical team the occurrence of this disorder. There were also a significant number of patients with AKI that did not receive a nephrology consultation, an intervention that has been shown to reduce morbidity and mortality of AKI.

Clinical Outcomes

Outcome	Documented AKI (n=38)	Undocumented AKI (n=93)	p-value
Mortality (Within 90 days)	0 (0%)	6 (6.5%)	0.109
Length of PICU Admission, Median [IQR]	13.5 [3, 20]	2 [1, 8]	0.000
Length of Mechanical Ventilation, Mean (+/- SD)	12.94 (+/- 15.44)	6.84 (+/- 6.96)	0.034

FR-PO013

Burden and Outcomes of Drug-Induced AKI

Prakash S. Gudsoorkar,[1] Karthikeyan Meganathan,[1] Amy Sears,[1] Evan P. Singleton,[1] Samantha M. Kramer,[1] Kathleen Harrison,[1] Charuhas V. Thakar.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Renal, Cincinnati VAMC, Cincinnati, OH.*

Background: Acute kidney injury (AKI) affects up to third of all hospitalizations. Although drug induced AKI (DI-AKI) is reported to be frequent, limited data exists in determining its true burden, and description of associated risk factors and outcomes.

Methods: All AKI consults (defined by KDIGO guidelines) across an academic health system were retrospectively recorded in an approved electronic registry. Of the available 500 cases of AKI (January to June 2018), 321 were studied (exclusion: kidney transplants, end stage renal disease, transfers on dialysis). AKI was classified by etiology on the day of consult as either nephrotoxic, biologic, or multifactorial; multifactorial was then scored (1 to 10 scale) based on contribution of the drug class. Drug induced (DI-AKI) was defined as either nephrotoxic or those with a multifactorial score > 5, and others as Biol-AKI. AKI was also classified as community acquired (CA-AKI), < 2 days or 2 or more days after admission (hospital acquired, HA-AKI),. The composite outcome was death, hospice discharge, dialysis dependence at discharge or 1.5 times median length of stay. Chi-square tests, and logistic regression were used for covariate adjustment (demographic, co-morbidities, and admission details).

Results: Of the 321 AKI cases (62% Male, 29% Black, median age 59 years, median baseline creatinine 1.3 mg/dl) DI-AKI occurred in 88 cases (27%). DI-AKI cases were more likely to be Black (40% vs 25%, p=0.01). Compared to Biol-AKI, DI-AKI admissions were mostly Medical (91% vs 78%, p=0.008). The most common drug classes associated with DI-AKI were diuretics 48%, antimicrobials 42%, renin-angiotensin system inhibitors 39%, contrast agents 30%, chemotherapy 7%. Most common source of DI-AKI was community acquired (64%). Need for dialysis was similar across two groups (DI-AKI - 22% vs Biol-AKI 34%). Overall, 50% of cases met the primary composite outcome [(DI-AKI – 38% vs Biol-AKI – 54%, p=0.008); risk-adjusted odds ratio (OR) 0.52 (95% CI, 0.31 – 0.86)].

Conclusions: Almost 1-in-3 AKI consults are drug induced, and attributable to commonly prescribed agents. Although Biol-AKI cases had a greater risk of composite outcome, DI-AKI cases continue to face devastating consequences, including similar risk of dialysis dependence. Strategies to mitigate drug induced AKI could improve clinical outcomes.

FR-PO014

Drug-Induced AKI: Can We Prevent It?

Amy Sears,[1] Kathleen Harrison,[1] Prakash S. Gudsoorkar,[1] Karthikeyan Meganathan,[1] Samantha M. Kramer,[1] Evan P. Singleton,[1] Charuhas V. Thakar.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Renal, Cincinnati VAMC, Cincinnati, OH.*

Background: Acute kidney injury (AKI) can affect 1-in-3 hospitalizations, with an adverse impact on both patients and health systems. AKI is far too commonly drug induced (DI_AKI). Limited data exists in identifying whether DI_AKI can be prevented, and whether patient or provider interventions could improve kidney safety.

Methods: We studied all inpatient nephrology consults with AKI (defined by KDIGO guidelines) at two centers across our academic health system between January and June of 2018. Based on a prior quality improvement program, AKI cases were retrospectively adjudicated to be Biologic (Biol_AKI) or Drug Induced (DI_AKI). We further identified DI_AKI as Preventable (Prv_AKI) when the use of the culprit drug(s) was not considered to be of life-saving value for diagnosis or treatment. Source of AKI was defined as community acquired (CA_AKI = AKI criteria met < 2 days of admission) or hospital acquired (HA_AKI). A composite outcome was hospital death, discharge to hospice or dialysis dependence on discharge. Chi-square tests were used for comparison.

Results: Of the 500 AKI consults, 321 were studied (exclusion: kidney transplants, end stage renal disease, transfers on dialysis). DI_AKI occured in 27% (88/321), and was deemed preventable (Prv_AKI) in 24/88 (27%) of cases. Prv_AKI cases were 63% Men, 54% Black (median age 60.5 years; median baseline creatinine 1.3 mg/dl) Prv_AKI predominantly occurred in Medical settings (96%), and admissions for sepsis or cardiovascular causes comprised 50% of all cases. The top two drug classes associated with Prv_AKI were diuretics (63%) and Renin-Angiotensin System (RAS) blockers (54%). For non-Prv_AKI cases, anti-microbial use (50%) and diuretics (42%) were the top two offending drug classes. Contrast agents were third common class for both groups. Source of AKI in the Prv_AKI group was CA_AKI 54% vs HA_AKI 46% and not significantly different with non-Prv_AKI group (p=0.26). The composite outcome was similar in Prv_AKI (38%) and non-Prv_AKI (38%) groups.

Conclusions: Almost third of drug induced AKI can be preventable, and the majority of these AKI cases manifest within 2 days of admission. Preventable AKI cases faced the same devastating outcome as their counterparts. These findings suggest that patient or provider education about medication safety could improve clinical outcomes in AKI.

AKI Associated with Fenofibrate

Jeonggu Na,[1] Dong Jun Park,[1] Tae won Lee,[3] Eunjin Bae,[1] Junhyeong Cho,[2] Ha nee Jang,[4] Hyun Seop Cho,[3] Se-Ho Chang.[3] *[1]Gyeongsang National University Changwon Hospital, Changwon-si, Republic of Korea; [2]Change-won Gyungsang National University, Chang-won, Republic of Korea; [3]Gyeongsang National University Hospital, Changwon-si, Gyeongsangnam-do, Republic of Korea; [4]Gyeongsang National Univ. Hospital, Jinju, Republic of Korea.*

Background: Fenofibrate was widely used to treat hypertriglyceridemia for many years. It was well known that fenofibrate can trigger acute kidney injury. We studied to investigate the relationship between acute kidney injury and fenofibrate.

Methods: We retrospectively evaluated the medical records of patients to start fenofibrate prescription for hypertriglyceridemia from January 2010 to December 2018 in the tertiary hospital. We reviewed their underlying disease, laboratory findings, dose of fenofibrate, duration of fenofibrate, and concomitant drug use. We did the effort to find factors related to acute kidney injury by fenofibrate.

Results: Total 169 patients were included. The mean age was 63.3 ± 11.5 years old. 40 of 169 patients had acute kidney injury(n=40, 23.6%), and 17 patients had chronic kidney disease(n=17, 10.0%). Patients with diabetes mellitus showed significantly increased risk of acute kidney injury without diabetes mellitus (29.0% vs 15.9%, p=0.04). We found significant correlation between hypertension and acute kidney injury. (30.8% vs 12.3%, p=0.006). Patients with concomitant use of RAS blockers showed significantly decreased

renal function compared with non-user of RAS blockers(31.4% vs 10.9%, p=0.002). In subgroup analysis, patients with chronic kidney disease have statistically significant risk of acute kidney injury by fenofibrate (47.1% vs 21.1%, p=0.017). Mean estimated glomerular filtration rate(eGFR) by MDRD was each 28.4 ± 12.1 mL/min/1.73m2 in chronic kidney disease group and 66.2 ± 20.3 mL/min/1.73m2 in non-chronic kidney disease group.

Conclusions: Diabetes mellitus, hypertension, and concomitant use of RAS blocker have a statistically significant association with acute kidney injury by fenofibrate in our study. And patients with chronic kidney disease have greater risk in acute kidney injury by fenofibrate.

FR-PO016

The Incidence, Risk Factors, and Clinical Outcomes of Rhabdomyolysis Associated with Fenoverine Prescription: A Retrospective Study in South Korea (1999–2014)

Junhyeong Cho,[1] Jeonggu Na,[1] Eunjin Bae,[1] Tae won Lee,[1] Ha nee Jang,[5] Hyun Seop Cho,[5] Se-Ho Chang,[4,3] Dong Jun Park.[2,3] *[1]Gyeongsang National University Changwon Hospital, Changwon, Republic of Korea; [2]Gyeongsang National University Changwon Hospital and Gyeongsang National University College of Medicine, Changwon, Republic of Korea; [3]Institute of Health Science, Gyeongsang National University, Jinju, Republic of Korea; [4]Gyeongsang National University Hospital and Gyeongsang National University College of Medicine, Jinju, Republic of Korea; [5]Gyeongsang National University Hospital, Jinju, Republic of Korea.*

Background: Fenoverine is a spasmolytic drug that has been used to treat abdominal pain. Although sporadic case reports of rhabdomyolysis associated with fenoverine have been published, there are no studies evaluating the correlation of this drug with rhabdomyolysis.

Methods: We retrospectively reviewed the medical records of 22 patients admitted with rhabdomyolysis associated with fenoverine from January 1999 to December 2014, while excluding other well-known risk factors of rhabdomyolysis. This period was subdivided into two periods, January 1999–December 2007 and January 2008–December 2014. We analyzed the clinical and laboratory characteristics, and the prognosis of fenoverine associated with rhabdomyolysis for these times.

Results: The incidence of rhabdomyolysis associated with fenoverine was 0.27% during the total period (22/8257), 0.34% in the first period (18/5298), and 0.14% in the second period (4/2959) ($p < 0.001$). Rhabdomyolysis occurred in 22 liver cirrhosis (LC) patients (2.03%), whereas only 3 cases (0.04%) occurred in non-LC patients ($p < 0.001$). Drug duration, total dose, muscle enzymes, and clinical characteristics were not different between the LC and non-LC groups. Acute renal failure (ARF) occurred in 5 patients in the LC group and 2 patients in the non-LC group ($p = 0.227$). Severity of hepatic derangement according to the Child-Pugh classification was not different between the ARF group and non-ARF group ($p = 0.227$). Four patients died, having complications of oliguric ARF ($p = 0.005$) and underlying severe LC ($p = 0.017$). Higher serum lactate dehydrogenase, blood urea nitrogen, creatinine, and potassium levels but lower serum sodium levels were found in the group that died ($p = 0.001$).

Conclusions: Physicians should not use fenoverine in patients with LC because of a high incidence of rhabdomyolysis and its poor prognosis.

FR-PO017

Postoperative AKI and Intraoperative Mean Arterial Pressure Variability: A Multi-Cohort Observational Study

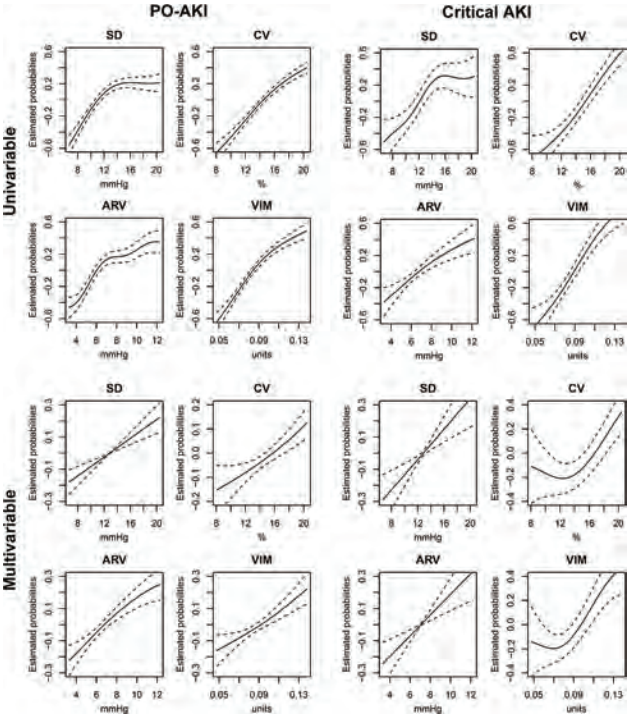
Sehoon Park,[2] Sejoong Kim,[1] Ho Jun Chin,[1] Yong Chul Kim,[2] Dong Ki Kim,[2] Kwon Wook Joo,[2] Yon Su Kim,[2] Hajeong Lee.[2] *[1]Seoul National University Bundang Hospital, Seongnam, GyeonGgi-Do, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Clinical evidence for the association between intraoperative mean arterial pressure (MAP) variability and the risk of postoperative acute kidney injury (PO-AKI) in non-cardiac surgeries is rare.

Methods: This study included three distinct cohorts in Korea with different time intervals for recording blood pressure during surgery. Non-overlapping first surgery cases were included, excluding those without creatinine measurements or with preexisting renal failure. The main study outcome was PO-AKI, defined by KDIGO serum creatinine criterion cutoffs, and critical AKI, which merged stage 2 KDIGO PO-AKI and post-AKI death or dialysis within 90 days. Standard deviation, coefficient of variation, variation independent of mean, and average real variability were calculated with measured MAP values.

Results: We analyzed 45,575/3,182,502, 29,724/1,354,820, and 7,435/48,923,796 patients/measured MAP values from the three cohorts, respectively. On discovery analysis, the variability parameters were significantly associated with the risk of the studied AKI outcomes, even after adjusted for duration of significant intraoperative hypotension (MAP < 65 mmHg). An increment of 10 mmHg average difference between the measured MAPs, which were measured at a median interval of 2 minutes, was associated with higher risks of PO-AKI [adjusted OR 1.549 (1.307-1.820)] and critical AKI [adjusted OR 1.566 (1.098-2.211)] events. The above results were similar in the other two validation cohorts, and the average real variability was the most significant variability parameter.

Conclusions: High intraoperative MAP variability is an independent risk factor for the risk of PO-AKI and associated patient-oriented outcomes in non-cardiac surgeries.



FR-PO018

Influence of Perioperative Statin Use on Risk of AKI Following Cardiac And Noncardiac Major Surgery: A Nationwide Population-Based Cohort Study

Hoon Young Choi,[1] Minkyung Han,[2] Gyu ri Kim,[2] Hyeong cheon Park,[1] Chung-Mo Nam,[2] Beom seok Kim.[1] *[1]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Postoperative acute kidney injury (AKI) is independently associated with high morbidity and mortality following surgery. The effects of perioperative statin use on the occurrence of AKI are not well understood. The present study investigated the association between perioperative statin use and AKI following cardiac and non-cardiac major surgery in the Korean population.

Methods: All patients aged 30 years and over who underwent cardiac or non-cardiac major surgery between 2013 and 2015 were included in this nationwide population-based cohort study (n = 382,198). The primary outcome was defined as the occurrence of AKI after surgery. Four patterns of statin use were analyzed in this study according to perioperative and/or previous statin use. The generalized logit model was used to evaluate the association between statin use and the risk of AKI. Subgroup analysis was conducted to investigate the differences in the effect sizes of statin use patterns.

Results: Perioperative statin use was associated with an increased risk of AKI after surgery in patients who were naïve to statin prior to both cardiac and non-cardiac surgery (OR 1.35, 95% CI 1.11–1.64; OR 1.20, 95% CI 1.01–1.44, respectively). Non-cardiac patients who underwent perioperative statin therapy and who had previously taken statins had a higher risk of AKI following surgery, whereas withdrawal of statins led to a significant reduction in the occurrence of AKI in these patients (OR 0.82, 95% CI 0.76–0.87).

Conclusions: The results presented here demonstrate the association between perioperative statin use and the increased incidence of AKI following major surgery. Our findings reveal that the risk of AKI of non-cardiac major surgery is reduced when statin treatment is withdrawn at the time of surgery.

FR-PO019

Preoperative Medication Use and Development of Postoperative AKI

Thorir E. Long,[1,2] Dadi Helgason,[1,2] Runolfur Palsson,[2,1] Martin I. Sigurdsson,[2,1] Olafur S. Indridason.[2] *[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [2]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland.*

Background: The use of medications such as angiotensin-converting enzyme inhibitors (ACEi), angiotensin receptor blockers (ARB) and proton pump inhibitors (PPI) has been associated with acute kidney injury (AKI), whereas animal data suggest that aldosterone antagonists (AA) may be protective. The aim of this study was to examine the relationship between the preoperative use of these medications and development of postoperative AKI.

Methods: This was a retrospective study of adult patients (excluding those with CKD stage 5) who underwent abdominal, cardiothoracic, vascular or orthopedic surgery at the University Hospital in Reykjavik in 2006-2015. Clinical data and disease diagnoses was retrieved from electronic medical records. AKI was defined based on serum creatinine (SCr) according the the KDIGO criteria. Information on medication use was obtained from the National Prescription Drug Database of the Directorate of Health and patients were considered to be using a medication if they had filled a prescription within six months prior to surgery. A daily defined dose (DDD) was determined for all patients. Risk of AKI was assessed using multivariable logistic regression analysis.

Results: A total of 42,047 abdominal, cardiothoracic, vascular or orthopedic surgeries were performed on 28,418 patients during the study period. Pre- and postoperative SCr was available for 19,279 cases. Postoperative AKI occurred in 1,455 (7.5%) cases. A total of 6,568 (34%) patients filled a prescription for a PPI prior to surgery, 547 (8.3%), of whom developed AKI. Of 6,717 (35%) patients who received ACEi, ARB or AA before surgery, 724 (10.8%) developed AKI. In adjusted analysis, the odds ratio (95% CI) for AKI was 1.00 (0.89-1.13) for PPI, 1.07 (0.93-1.23) for ACEi, 1.30 (1.15-1.48) for ARB and 0.83 (0.62-1.09) for AA. When DDD were examined, there was no evidence of a dose-response relationship between medication use and postoperative AKI.

Conclusions: In this surgical cohort, we found that preoperative use of ARB associated with postoperative AKI. However, no such a risk was evident for PPI and a protective effect of AA was not observed.

AKI After Lung Transplantation: A Meta-Analysis

Charat Thongprayoon,[1] Ploypin Lertjitbanjong,[4] Wisit Kaewput,[2] Michael A. Mao,[1] Wisit Cheungpasitporn.[3] *[1]Mayo Clinic, Rochester, MN; [2]Phramongkutklao College of Medicine, Bangkok, Thailand; [3]university of mississippi Medical Center, Jackson, MS; [4]Bassett medical center, Cooperstown, NY.*

Background: Lung transplantation has been increasingly performed worldwide and considered as an effective therapy for patients with various end-stage lung diseases. We performed this meta-analysis to evaluate the incidence and impact of acute kidney injury (AKI) in patients after lung transplantation

Methods: A literature search was conducted utilizing MEDLINE, EMBASE and Cochrane Database from inception through April 2019. We included studies that evaluated the incidence of AKI, severe AKI requiring renal replacement therapy (RRT), and impact of AKI among patients after lung transplantation. Pooled incidence and odds ratios (OR) with 95% confidence interval (CI) were calculated using random effects meta-analysis.

Results: 25 cohort studies with a total of 40,293 patients after lung transplantation were enrolled. Overall, the pooled estimated incidence rates of AKI (by standard AKI definitions) and severe AKI requiring RRT following lung transplantation were 52.1% (95%CI: 45.0%-59.1%) and 9.5% (95%CI: 7.7%-11.8%). Meta-regression analysis showed that year of study did not significantly affect the incidence of AKI (p=0.11) and severe AKI requiring RRT (p=0.54). The pooled OR of hospital mortality among patients after lung transplantation with AKI and severe AKI requiring RRT were 2.75 (95% CI, 1.18-6.41) and 10.89 (95% CI, 5.03-23.58). At 5 year, the pooled OR of mortality among patients after lung transplantation with AKI and severe AKI requiring RRT were 1.47 (95% CI, 1.11-1.94) and 4.79 (95% CI, 3.58-6.40), respectively.

Conclusions: The overall estimated incidence rates of AKI and severe AKI requiring RRT in patients after lung transplantation are 52% and 9.5%, respectively. Despite advance in medicine, incidence of AKI in patients after lung transplantation does not seem to decrease over time. In addition, AKI after lung transplantation is significantly associated with reduced short-term and long-term survival.

FR-PO021

The Association of AKI with Hospital Readmission or Death After Pediatric Cardiac Surgery

Sophia Nunes,[1] Jason H. Greenberg,[2] Chirag R. Parikh,[3] Jeremiah R. Brown,[4] Heather Thiessen Philbrook,[3] Prasad Devarajan,[5] Ana Palijan,[6] Michael Zappitelli.[7] TRIBE-AKI *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Yale University, Woodbridge, CT; [3]Johns Hopkins University, Newton, MA; [4]The Dartmouth Institute, Lebanon, NH; [5]Cincinnati Children's Hospital, Cincinnati, OH; [6]McGill University Health Centre, Montreal, QC, Canada; [7]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.*

Background: AKI in children undergoing cardiac surgery (CS) is strongly associated with increased hospital morbidity, however post-discharge AKI outcomes are less studied. Hypotheses: In children undergoing CS with cardiopulmonary bypass (CPB), a) AKI is associated with increased risk for readmission or death within 30 days and 1 year of CS discharge, and b) the association of AKI with outcomes is modified by surgical severity and cyanotic heart disease.

Methods: Prospective 3-centre cohort study of children surviving to hospital discharge after CS with CPB. Main exposure: AKI during index CS admission defined by KDIGO. Composite outcome: readmission to hospital or death at a) 30 days and b) 1 year from CS hospital discharge. Other data: detailed pre/post-op CS patient/treatment variables (including Risk Adjustment for Congenital Heart Surgery-1 [RACHS-1] score; presence of cyanotic heart disease). Association of AKI with time to outcomes was determined using multivariable Cox-proportional hazards analysis (adjusted for age, RACHS-1 score ≥3, CPB time>120 mins). RACHS-1 score≥3 and cyanotic heart disease were evaluated as effect modifiers.

Results: Of the 360 participants included (mean age 4.0±4.6 years, 155 [43%] AKI, 47 [13%] ≥Stage 2 AKI), 4 (1.1%) and 6 (1.7%) died and 30 (8.3%) and 99 (27.5%) were readmitted within 30 days and 1 year post-discharge, respectively. Figure illustrates a graded increase in the risk of the composite outcome with increasing AKI stage. AKI and ≥Stage 2 AKI were associated with time to outcome within 30 days (adjusted HR 2.14 [95%CI 1.04-4.41] and 2.39 [95% CI 1.08-5.27], respectively) but not within 1 year of CS discharge. RACHS-1 and cyanotic heart disease did not modify these relationships (interaction p value>0.1).

Conclusions: Children with AKI post-CS were more likely to be readmitted or die within 30 days of CS discharge, compared to children without AKI. Future research should evaluate measures to reduce short-term morbidity and mortality risk in children who develop AKI after CS.

Funding: NIDDK Support

FR-PO022

Correlation Between Incidence and Attributable Mortality Fraction of AKI: A Systematic Review

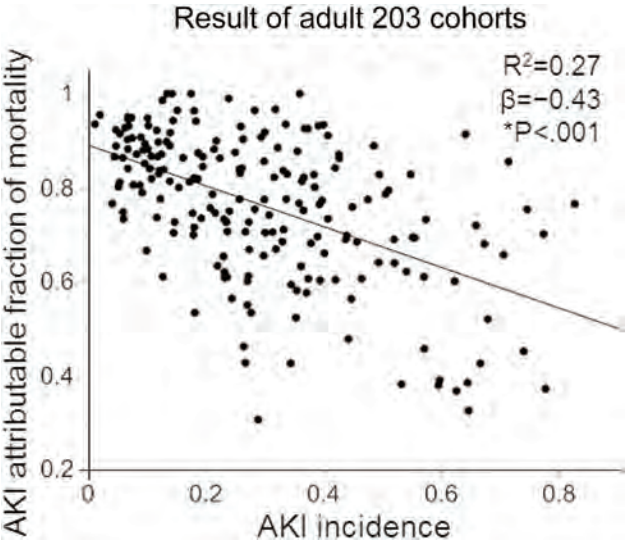
Yohei Komaru,[1] Masao Iwagami,[2] Yoshifumi Hamasaki,[1] Masaomi Nangaku,[1] Kent Doi.[1] *[1]University of Tokyo, Tokyo, Japan; [2]University of Tsukuba, Tsukuba, Japan.*

Background: The incidence and mortality of acute kidney injury (AKI) has extremely varied, even after the introduction of RIFLE, AKIN and KDIGO criteria. The quality of AKI diagnosis and management may also be influential. The present study aimed to investigate the association between AKI incidence and mortality of each cohort. We also investigated the effect of publication year and economic index on AKI mortality.

Methods: Our study aggregated the incidence and mortality of AKI through a systematic review of manuscripts on AKI patients diagnosed by Kidney Disease: Improving Global Outcomes (KDIGO)-equivalent criteria from 2004 to May, 2018. The search was conducted in MEDLINE, EMBASE, and Cochrane Library. We investigated the correlation between AKI incidence, mortality, and AKI attributable fraction of mortality. AKI attributable fraction of mortality in each cohort was calculated as follows: {(mortality of AKI patients)-(mortality of patients without AKI)} / (mortality of AKI patients). The impact of publication year and gross domestic product (GDP) on the mortality were also studied.

Results: The systematic review screened total 4149 manuscripts, and finally yielded 287 eligible cohorts (adults: 203 cohorts consisted of 7076459 patients; children: 84 cohorts of 69677 patients). In the adult cohorts, the mortality of AKI patients became higher (R^2=0.023, β=0.12, P=0.033) but the attributable fraction of mortality otherwise decreased (R^2=0.27, β=−0.43, P<0.001), as incidence of AKI augmented. Although the crude mortality of AKI patients decreased in more recent publications and in reports from higher GDP countries, the AKI attributable fraction did not decline in the same settings.

Conclusions: The AKI attributable fraction of mortality in the cohorts with high AKI incidence was relatively low, which possibly indicated the advantage of more experience in AKI diagnosis and management.



FR-PO023

The Value of Plasma Inflammatory Biomarkers in Sepsis-Associated AKI

Yuenting D. Kwong,[1] Jay L. Koyner,[2] Kirsten N. Kangelaris,[1] Carolyn Calfee,[1] Jason Abbott,[1] Kathleen D. Liu.[1] *[1]University of California at San Francisco School of Medicine, San Francisco, CA; [2]University of Chicago, Chicago, IL.*

Background: Sepsis-associated acute kidney injury (SA-AKI) may be mediated by inflammation. We evaluated the association of plasma inflammatory biomarkers with SA-AKI beyond traditional AKI risk factors and markers of structural damage (uNGAL and UACR).

Methods: We included 453 adults with sepsis (SIRS and adjudicated infection) with collected samples within 24 hours of ICU admission. Admission AKI risk factors were adjudicated into the following categories: hypotension, hypovolemia, nephrotoxins, obstruction and other (e.g. rhabdomyolysis). AKI was defined by ≥ 50% serum creatinine (SCr) rise within 7 days from preadmission SCr or nadir SCr if the former was missing. Plasma and urine biomarkers were $\log_{10}$-transformed. We evaluated the relationship between plasma biomarkers and AKI using univariate and multivariable logistic models with and without backwards stepwise selection ($p<0.05$). Analysis was repeated for severe AKI (KDIGO stage 2-3).

Results: 275 subjects (60%) had AKI, 100 (22%) had severe AKI, 42 (9%) required dialysis and 140 (31%) died in-hospital. A model with demographics and clinical variables (Table 1) had AUC of 0.68 for AKI. The addition of structural damage markers improved the AUC to 0.71, and all plasma biomarkers further increased the AUC to 0.73 ($p\leq0.01$). No plasma biomarkers remained after backwards selection for AKI. Findings were replicated for severe AKI. Inclusion of all plasma biomarkers improved the AUC from 0.75 to 0.79 (p=0.03). Only ICAM remained during backwards selection.

Conclusions: Inflammatory biomarkers only modestly improve SA-AKI prediction. Inflammation and structural damage are likely to have occurred before ICU admission. Efforts targeting systemic inflammation to prevent SA-AKI in the ICU may be limited.

Funding: NIDDK Support

Renin-Angiotensin System Blockade After AKI and Risk of Recurrent AKI

Chi-yuan Hsu,[1,2] Kathleen D. Liu,[1] Jingrong Yang,[2] David V. Glidden,[1] Thida C. Tan,[2] Leonid Pravoverov,[2] Sijie Zheng,[2] Alan S. Go.[2,1] *[1]UCSF, San Francisco, CA; [2]Kaiser Permanente Northern California, Oakland, CA.*

Background: How to best medically manage patients who survived hospitalized acute kidney injury (AKI) is unclear. These patients are at higher risk of further loss of renal function so angiotenin converting enzyme inhibitors (ACE-I) or angiotensin receptor blockers (ARB) may be reno-protective. However, recurrent AKI is common and use of ACE-I/ARB in this setting may increase risk of recurrent AKI.

Methods: This is a retrosepctive cohort study of 10,242 members of an integrated healthcare delivery system in Northern California who experienced AKI and survived a hospitalization between January 1, 2006 and December 31, 2013. All study participants did not have prior heart failure or previous use of ACE-I or ARB therapy up to five years prior. New receipt of ACE-I/ARB was identified based on dispensed prescriptions found in outpatient health plan pharmacy databases. The pirmary outcome of interest was subsequent episode of hospitalized AKI after discharge from an initial index hospitalization complicated by AKI. Recurrent AKI episode was defined using acute changes in serum creatinine concentrations. Marginal structural models (MSM) were used to adjust for baseline and potential time-dependent confounders.

Results: During follow-up, we observed 22.0 episodes of recurrent AKI/100 person-years while taking ACE-I/ARB (95% CI: 20.5 to 23.6 episodes per 100 person-years) compared to 14.1 episodes/100 person-years while not receiving ACE-I/ARB (95% CI: 13.7 to 14.5 episodes per 100 person-years). However, in MSM causal inference models that adjusted for baseline and potential time-dependent confounders, exposure to ACE-I or ARB use was not associated with higher incidence of recurrent AKI (adjusted odds ratio 0.71, 95% CI: 0.45 to 1.12).

Conclusions: Our study provided reassuring data about the safety of initiating ACE-I or ARB after an episode of AKI.

Hospitalized AKI Among Black and White Individuals with CKD: The CRIC Study

Anthony N. Muiru,[1] Vimal K. Derebail,[2] Kathleen D. Liu,[1] Alan S. Go,[3] Michelle M. Estrella,[4] Chi-yuan Hsu.[1] *[1]University of California at San Francisco School of Medicine, San Francisco, CA; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Kaiser Permanente Northern California, Oakland, CA; [4]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA.*

Background: Although black race and *APOL1* high-risk genotypes are risk factors for various forms of kidney disease, few studies have rigorously examined whether an independent association of black race and *APOL1* genotypes exists for occurrence of hospitalized AKI. Prior studies have not accounted for baseline eGFR and proteinuria levels near the time of AKI and have relied only on diagnostic codes to define AKI.

Methods: We studied black and white participants enrolled in the CRIC Study, a multicenter prospective cohort study of CKD, who had an annual in-person study visit between July 2012-June 2013. The primary outcome was hospitalized AKI in the subsequent 2 years (defined as a ≥50% increase from nadir to peak inpatient serum creatinine). We evaluated the association of race, *APOL1* genotype and AKI using multivariable logistic regression.

Results: Among 1,162 eligible CRIC participants, 481 were black with 86 (18%) having a high-risk *APOL1* genotype. The overall mean (SD) eGFR was 47 (16) mL/min/1.73m^2 and neither eGFR or proteinuria significantly differed by *APOL1* risk status (**Table**). The crude risk of AKI was similar between black and white patients (5.2% vs. 5.3%). After adjusting for eGFR and urine protein-to-creatinine ratio, age, sex, educational attainment, blood pressure, prevalent cardiovascular disease, diabetes and receipt of ACE-I/ARB, there was no significant association of race or *APOL1* status with AKI (**Table**).

Conclusions: Among black and white participants with similar baseline eGFR, neither black race nor *APOL1* genotype is significantly associated with subsequent hospitalized AKI.

Funding: NIDDK Support

Renal Outcomes and Recovery in a Large Cohort of Critically Ill Patients Requiring Venoarterial or Venovenous Extracorporeal Membrane Oxygenation and CRRT

Christopher Hebert. *Kidney and Hypertension Associates of Dallas, Dallas, TX.*

Background: The development of acute kidney injury in adult patients requiring venoarterial or venovenous ECMO is very common. Many of these patients will require renal replacement therapy. Despite an extremely high mortality in such a patient population, centers are reporting improving outcomes with respect to survival. Little is known about the renal outcomes and renal recovery rate of those who required renal replacement therapy patients who survive to discharge.

Methods: Over the last 6 years, we have performed over 600 cannulations for VA or VV ECMO at our institution. Of these patients, 268 of them required renal replacement therapy for acute kidney injury. We have collected demographic and epidemiologic data as well as outcome data on those that have survived.

Results: Of the survivors, the cohort of patients most likely to recover renal function were patients with no prior known renal dysfunction who were on venovenous ECMO. The patients most likely to require ongoing hemodialysis at the time of discharge were patients with heart failure who were on venoarterial ECMO. Diabetes seemed to be a major risk factor in overall renal recovery, as did preadmission creatinine levels. Patients that recovered renal function after 30 days were typically those with no prior renal disease

Conclusions: Many of the traditional predictive measures for renal recovery after critical illness apply to the ECMO population. Despite having a large cohort of ECMO patients requiring renal replacement therapy, there is no clear pathway to being able to predict renal recovery.

FR-PO027

Initial Lactate Level and Lactate Clearance on Renal Outcomes in Critically Ill Patients with Sepsis

Jihoon Jung,[2] Ji in Moon,[3] Jin Ho Hwang,[4] Su Hyun Kim,[5] Jungho Shin.[1] *[1]Chung-Ang University College of Medicine, Seoul, Republic of Korea; [2]Chung-Ang university hospital, Seoul, Republic of Korea; [3]Chungang university, Seoul, Republic of Korea; [4]Department of Internal Medicine, Chung-Ang University Hospital, Seoul, Republic of Korea; [5]Chung-Ang University Hospital, Seoul, Republic of Korea.*

Background: Lactate level and lactate clearance have been implicated as predictors of mortality in patients with sepsis. However, their roles for renal outcomes remain uncertain. In this study, we investigated the impacts of initial lactate level and lactate clearance on renal outcomes in critically ill patients with sepsis.

Methods: We retrospectively reviewed a total of 151 adult patients with sepsis who met the Sepsis-3 definition. Serum lactate levels were measured at initial and 24 hours from the intensive care unit admission. Among patients with initial lactate level ≥2 mmol/L, the lactate clearance was calculated as (initial lactate–24-hour lactate)/initial lactate × 100, then, they were divided as those with lactate clearance <20% and ≥20%. Acute kidney injury (AKI) was defined using the KDIGO guideline.

Results: AKI occurred in 52 (68.4%) patients with initial lactate level <2 mmol/L and 69 (92.0%) in those with initial lactate level ≥2 mmol/L (P<0.001). In addition, patients with initial lactate level ≥2 mmol/L had higher probabilities of renal replacement therapy than those with its level <2 mmol/L, independent of age, sex and the sequential organ failure assessment (SOFA) score (OR 2.9, 95% CI 1.1–7.3, P=0.025). However, the lactate clearance was not related with AKI occurrence and renal replacement therapy use (P=1.000 and 0.293). The lactate clearance <20% was associated with 28-day mortality, independent of age, sex and the SOFA score (HR 3.8, 95% CI 1.5–9.7, P=0.005), but Initial lactate level was not (P=0.164). Among 116 survivors, estimated glomerular filtration rate (eGFR) at discharge were assessed, and we found that the eGFR did not differ according to initial lactate level and lactate clearance in multivariate linear regression analyses (P=0.954 and 0.203).

Conclusions: In critically ill patients with sepsis, initial lactate level can predict the AKI occurrence and renal replacement therapy need, however, lactate clearance cannot. In addition, renal function recovery may be associated with neither initial lactate level nor lactate clearance.

FR-PO028

Diastolic and Systolic Dysfunction on Renal Outcomes in Critically Ill Patients with Sepsis

Ji in Moon,[2] Jihoon Jung,[3] Jin Ho Hwang,[4] Su Hyun Kim,[5] Jungho Shin.[1] *[1]Chung-Ang University College of Medicine, Seoul, Republic of Korea; [2]Chungang university, Seoul, Republic of Korea; [3]Chung-Ang university hospital, Seoul, Republic of Korea; [4]Department of Internal Medicine, Chung-Ang University Hospital, Seoul, Republic of Korea; [5]Chung-Ang University Hospital, Seoul, Republic of Korea.*

Background: Diastolic and systolic dysfunction have been regarded as predictors of mortality in patients with severe sepsis and septic shock. Myocardial dysfunction may contribute to hemodynamic instability and may result in organ failure, but their impacts on renal outcomes remain uncertain. In this study, we investigated the impacts of diastolic and systolic dysfunction on renal outcomes in critically ill patients with sepsis.

Methods: We retrospectively reviewed a total of 164 adult patients with sepsis who met the Sepsis-3 definition. Left ventricular (LV) function was assessed using echocardiography within 5 days from the intensive care unit admission. Systolic dysfunction was defined as an ejection fraction <50%, and diastolic dysfunction was defined as the septal E/e' ratio >15 among patients with ejection fraction ≥50%. Acute kidney injury (AKI) was defined using the KDIGO guideline.

Results: There were 86 (52.4%) with normal LV function, 37 (22.6%) with diastolic dysfunction and 41 (25.0%) with systolic dysfunction. The incidence rate of AKI was 68.6%, 83.8% and 87.8% in the respective groups (P=0.029). Patients with diastolic and systolic dysfunction had more highly required renal replacement therapy than those with normal LV function, and these results persisted after the adjustment for age, sex and the sequential organ failure assessment (SOFA) score (OR for diastolic dysfunction 3.6, 95% CI 1.0–12.3, P=0.045 and OR for systolic dysfunction 3.1, 95% CI 1.0–9.4, P=0.045). Moreover, diastolic dysfunction predicted 28-day mortality, independent of age, sex and the SOFA score (HR 3.3, 95% CI 1.1–9.9, P=0.033), but systolic dysfunction did not (P=0.094 in multivariate analysis).

Conclusions: Both diastolic and systolic dysfunction could predict the AKI occurrence and renal replacement therapy need in critically ill patients with sepsis. More studies are needed to investigate individualized approaches according to LV function in this disease population.

FR-PO029

Outcomes of Patients on Extracorporeal Membrane Oxygenation with AKI Requiring Dialysis

Ankit Sakhuja,[1,2] Paul J. Mccarthy,[1] John A. Kellum.[2] *[1]West Virginia University, Morgantown, WV; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) is a common complication among critically ill patients including those receiving Extracorporeal Membrane Oxygenation (ECMO). Despite increasing application of ECMO and improved outcomes for patients receiving it, little is known about outcomes of AKI requiring dialysis (AKI-D) in these patients. We therefore sought to investigate the epidemiology and outcomes of AKI-D among patients receiving ECMO.

Methods: We utilized data from National (Nationwide) Inpatient Sample from 2007-2014. ECMO and with AKI-D were identified using ICD-9-CM codes. We compared proportions of patients meeting various outcomes use the Chi square test. Our primary outcome was inpatient mortality. We also stratified our analysis by time comparing 2007-2010 and 2011-2014. Finally we conducted multivariable logistic regression adjusting for patient/hospital demographics, co-morbidities, acute organ dysfunction, and cardiac surgery during the index hospitalization to assess the impact of AKI-D on mortality.

Results: Of estimated 16,368 (95% CI: 14,185-18,551) hospitalizations receiving ECMO, 2,266 (13.8%) had AKI-D. The proportion of AKI-D was similar between the two time periods (14.3% vs 13.7%, p=0.8) as was the proportion of those started on dialysis on the same day or after ECMO initiation (64.8% vs 73.6%, p=0.1). Compared to patients without AKI-D, those with AKI-D were more male (67.2% vs 61.2%, p=0.03), less often on Medicare/Medicaid (41.4% vs 53.2%, p=0.02) and admitted more often at larger hospitals (91.5% vs 87.2%, p=0.02). Mortality was significantly higher in those with AKI-D (70.9% vs 54.0%, p<0.001) and did not differ by time period. In multivariate analysis AKI-D was an independent predictor of mortality (OR 1.43; 95% CI: 1.09-1.87).

Conclusions: About 14% of patients on ECMO develop AKI-D with majority started on dialysis on the day of or after ECMO initiation. Though there has been a reduction in mortality, it remains significantly high in patients with AKI-D.

FR-PO030

Underrecognition of Neonatal AKI and Lack of Follow-up

Jean-Philippe Roy, Meredith P. Schuh, Stuart Goldstein. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Recent data show an incidence of 30% of acute kidney injury (AKI) in neonatal intensive care units (NICU). AKI is associated with increased mortality and risk of chronic kidney disease (CKD) in children. To assess the follow-up of these patients (pt) and early CKD signs, we retrospectively reviewed long-term outcomes of Cincinnati Children's Hospital Medical Center (CCHMC) cohort of neonates included in the AWAKEN trial (2014).

Methods: 81 CCHMC pt were extracted from AWAKEN data. KDIGO criteria for serum creatinine (SCr) and urine output (UOP) < 1 mL/kg/h, reported per 24h on post-natal days 2-7, were used to define AKI. Charts were reviewed until May 2019 for pt death, inpatient nephrology consult, AKI diagnosis on discharge summary, follow-up anywhere at CCHMC, as well as potential early CKD signs at > 6 months of age and after AKI (defined as any one of an estimated GFR (eGFR) by Schwartz < 90 ml/min/1.73m^2, hyperfiltration, proteinuria, hypertension, or abnormal ultrasound). Pt were considered to have a renal follow-up if they had at least one visit anywhere in that timeframe with at least one of the following: SCr, urinalysis or a blood pressure measurement.

Results: 77 pt had sufficient data to ascertain an AKI diagnosis. 47/77 (61%) were AKI+ by either SCr or UOP criteria (13 stage 3, 14 stage 2 and 20 stage 1). Of those, 4 died during their initial admission (2 AKI- and 2 AKI+, stage 1 and 2) and 5 pt with significant urologic anomalies were removed from the CKD analyses. Taken separately, AKI-UOP alone outnumbered AKI-SCr (respectively 45 AKI+ vs 5 AKI+ for all stages, 10 and 27 pt with insufficient data for AKI ascertainment). 33% of pt had < 2 SCr measured in the NICU. Only 3/47 AKI+ pt had a nephrology consult (all stage 3 by SCr) and 2/47 had AKI reported on their discharge summary. 67% of AKI+ pt had some form of renal follow-up. 10/43 (23%) AKI+ vs 12/25 (48%) AKI- pt had ≥1 marker of early CKD signs measured after 6 months. Only hyperfiltration was positive in 3/7 (43%) AKI+ vs 0/7 (0%) AKI- pt with SCr available (p=0.19). Median eGFR in AKI+ pt was 120 vs 126 ml/min/1.73m^2 for AKI- (p=0.46).

Conclusions: AKI is vastly under-recognized in the NICU, especially if based on SCr alone. This leads to insufficient follow-up to ascertain renal sequelae in this high risk population despite a trend toward more hyperfiltration.

FR-PO031

Adherence to AKI Best Practice Guidelines in Hospitalized Children

Ibrahim Sandokji, Yu Yamamoto, Aditya Biswas, Jason H. Greenberg, Francis P. Wilson. Program of Applied Translational Research *Yale School of Medicine, New Haven, CT.*

Background: The Kidney Disease Improving Global Outcomes (KDIGO) Clinical Practice Guidelines recommends a non-invasive diagnostic workup and cessation of nephrotoxins in all stages of AKI. We evaluated the provider adherence to these consensus guidelines in hospitalized children

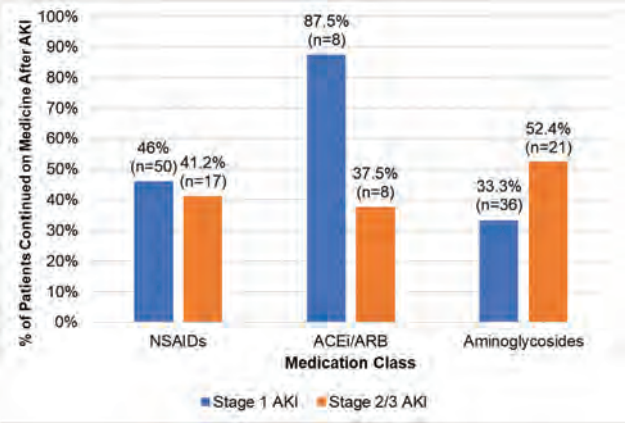
Methods: We reviewed the medical records of children <18 years old, who had at least two creatinine values measured during a hospital admission in a large, tertiary care hospital. We defined AKI based on serum creatinine per the KDIGO guidelines, with a minimum absolute creatinine value of 0.5 mg/dL. We calculated the baseline daily rates of performing non-invasive diagnostic tests such as urinalysis in children with AKI compared to all patients in the cohort. To evaluate adherence to general preventive measures, we calculated the percentage of patients who continued to receive nephrotoxic agents such as nonsteroidal anti-inflammatory drugs (NSAIDs) after the development of AKI

Results: Among the 8634 encounters studied, AKI occurred in 779 (9%) encounters. Median age was 4.5 years [IQR, 0-13.2], 4559 (52.8%) were male, and 48% were admitted to the ICU (PICU or NICU). Development of AKI increased the rate of receiving a repeat creatinine measurement from a baseline 54% to 81% per day in children with AKI, a urinalysis from 6% to 19%, and a renal ultrasound from 1% to 6%. Children with AKI were 5 times more likely to have a nephrology consultation as compared to those without

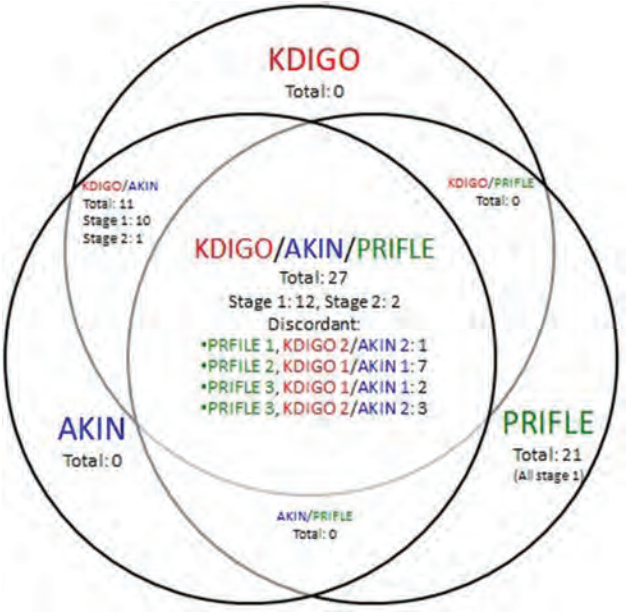
AKI. After developing AKI, 30/67 (44.8%) children receiving NSAIDs and 10/16 (62.5%) children receiving angiotensin-converting-enzyme inhibitors or angiotensin II receptor blockers continued receiving them (Figure)

Conclusions: We identified gaps in provider adherence to AKI management guidelines in hospitalized children. We recommend establishing electronic health record-integrated best practice bundles to improve care for children with AKI

Funding: NIDDK Support



Percentage of patients continued on nephrotoxic medications after developing AKI



FR-PO032

Pediatric Kidney Stone-Associated AKI

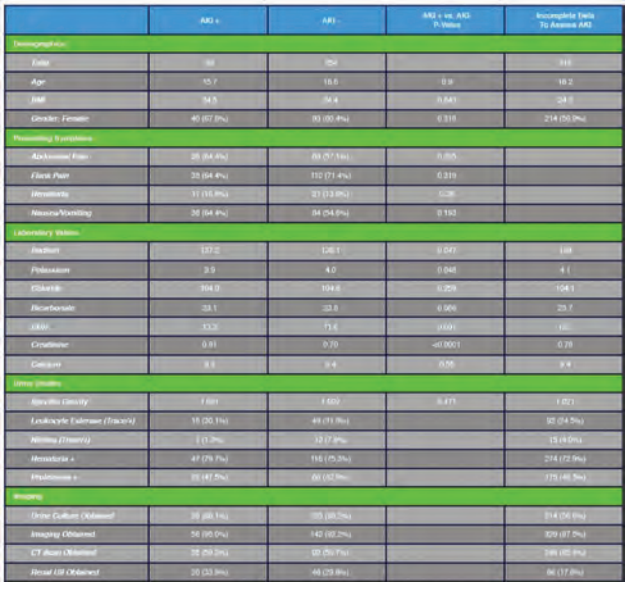
Kirsten Kusumi,[1,2] Andrew L. Schwaderer,[3] Rupesh Raina.[4] *[1]Akron Children's Hospital, Akron, OH; [2]The Northeast Ohio Medical University, Rootstown, OH; [3]Indiana University, Zionsville, IN; [4]Cleveland Clinic at Akron General Medical Center, Akron, OH.*

Background: Rates of stone AKI in children may be as high as 30%. Retrospective review examined children for AKI at emergency department (ED) visits for renal colic.

Methods: Retrospective: 1-26 years Akron Childrens Hospital 1/08-1/17. ICD code and radiographic evidence of stones or documentation by nephrologist. ED visits with + imaging for stones or physician documentation. Anthropometric, lab and management data were collected. AKI defined by Kidney Disease: Improving Global Outcomes, Acute Kidney Injury Network and Pediatric Risk Injury Failure End Stage criteria.

Results: 399 patients with 589 visits. 39% unique patients had data to assess AKI, with 33% AKI+. 36% visits had data to assess AKI with 27.7% +AKI. Data was not sufficent to assess for AKI in 65.6% of patients and 63.8% visits. Among AKI patients, 15% had documentation of AKI; 22% with Cr in lab documentation, but no mention of abnormal cr assessment/plan. 55.9% of AKI+ visits, patients were treated with NSAID in the ED; 47% of AKI visits were discharged home with NSAIDs.

Conclusions: Pediatric AKI due to stones is under recognized. 27.7% of ED stone visits AKI+. Only 64% of visits had data to asses for AKI. Only 15% of AKI+ had documentation by physician of AKI, and 55% of AKI patients received NSAIDs. Concerning given known association of stones with chronic kidney disease.



FR-PO033

The Incidence and Frequency of Diagnosing AKI in Non-Critically Ill Pediatric Patients

Tai M. Pham,[1] Julia W. Tzeng,[2] Laide Jinadu.[2] *[1]Valley Children's Hospital, Fresno, CA; [2]Valley Childrens Hospital, Madera, CA.*

Background: Acute kidney injury (AKI) is commonly seen among hospitalized pediatric patients. Most studies have focused on critically ill patients and the incidence in non-critically ill (NCI) patients is less well studied. There has been only one study, McGregor et al (2016), that has looked at the incidence of AKI in this population and no studies evaluating the frequency of AKI diagnosis during NCI admissions. McGregor et al found that the rate of AKI among NCI patients to be 5%. The purpose of our study is to validate the finding of McGregor et al. and to assess the frequency of provider diagnosis of AKI in NCI patients during admission.

Methods: We performed a retrospective cohort study on all patients admitted to the NCI hospitalist service at our tertiary care pediatric hospital between July 1 2017 and June 31 2018. Patients included in the study were between the ages of 2 weeks and 18 years without history of chronic kidney disease or intensive care unit admission at any time of their hospitalization, and who had 2 or more serum creatinine values. We used the KDIGO criteria, defined as serum creatinine increase by ≥0.3mg/dL within 48 hours or increase by ≥1.5 times the baseline within 7 days, to identify patients with AKI. Of those identified with AKI, we reviewed the chart to assess whether providers had identified the AKI during the admission.

Results: Of the 14,495 patients admitted, 1,223 (8%) patients were included in the study. 132 (10.8 %) patients met the KDIGO criteria for AKI. Of these 132 patients, only 51 (37.8%) were identified to have AKI by providers during their admission.

Conclusions: Our study suggests that the incidence of AKI in the NCI setting is higher than previously reported; 10.8% of NCI patients in our institution had AKI, compared to the 5% reported by McGregor et al. Since we were only able to analyze 8% of the total patients admitted, due in part to lack of data, it is possible that the rate of AKI is even higher. This shows the limitations of applying the KDIGO criteria in diagnosing AKI in the clinical setting. We also found the frequency of identifying AKI was low at 37.8%. As prompt identification of AKI is crucial in preserving kidney function, new strategies are needed to help providers identify these patients.

FR-PO034

Use of Tramadol and Reduced Risk of AKI in Hospitalized Children

Mingjing Pi,[1] Xin Xu.[2] *[1]Nanfang Hospital, Southern Medical University, Guang Zhou, Guang Zhou, China; [2]Renal Division, Nanfang Hospital, Southern Medical University; National Clinical Research Center for Kidney Disease, Guangzhou, China.*

Background: Various interventions have been reported to prevent the development of AKI, but only few have been validated in children. This study is aimed to investigate the potential renoprotective effect of tramadol on the risk of pediatric AKI.

Methods: We conducted a multicenter retrospective cohort study in hospitalized children aged 1 month to 18 years from 25 tertiary hospitals across China during 2013-2015. Patient-level data were obtained from the electronic hospitalization information system. The outcome was hospital-acquired (HA-)AKI. AKI was defined and staged by Kidney Disease Improving Global Outcomes criteria. Patients who developed AKI after two days of admission were identified as having HA-AKI. We used a cox proportional hazards model to estimate the risk of HA-AKI, in which exposure to tramadol was modeled as a time-varying variable.

Results: Among 46295 children analyzed, 1779 (3.8%) used tramadol and 3555 (7.68%) had HA-AKI events during hospitalization. Most of tramadol (53.18%) was prescribed for postoperative analgesia. After adjusting for demographics status, prevalent comorbidities and concomitant use of medications, use of tramadol was associated with a significantly reduced risk of HA-AKI compared with non-users (HR 0.20; 95% CI, 0.15-0.27). The results were consistent in subgroups and multiple sensitivity analysis. An increasing cumulative dosage of tramadol use was associated with a graded lower risk of HA-AKI.

Conclusions: Tramadol was associated with a reduced risk of HA-AKI in hospitalized children. Future intervention study should evaluate whether tramadol use could prevent AKI in high risk patients.

Funding: Government Support - Non-U.S.

Prevalence, Risk Factors, and Prognosis of AKI in Pediatric Nephrotic Syndrome

Eun mi Yang,[1] Keehyuck Kim,[11] Seong heon Kim,[3] Jin-Soon Suh,[8] Yo Han Ahn,[10] Kee Hwan Yoo,[9] Jung won Lee,[7] Min Hyun Cho,[5] Heeyeon Cho,[6] Jiwon M. Lee,[4] IL-Soo Ha,[2] Hae Il Cheong,[2] Hee Gyung Kang.[2] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Seoul National University Children's Hospital, Seoul, Republic of Korea; [3]Pusan National University Children's Hospital, Yangsan, Republic of Korea; [4]Chungnam National University, Seoul, Republic of Korea; [5]Kyungpook National University Hospital, Daegu, Republic of Korea; [6]Samsung Medical Center, Seoul, Republic of Korea; [7]Ewha Womans University, school of medicine, Seoul, Republic of Korea; [8]Bucheon St.Mary's Hospital, Catholic University, Bucheon-si, Gyeonggi-do, Republic of Korea; [9]Korea University Guro Hospital, Seoul, Republic of Korea; [10]Seoul National University Bundang Hospital, Seongnam, KyungGi-DO, Republic of Korea; [11]NHIS Ilsan Hospital, Goyang-shi, Republic of Korea.*

Background: Children with nephrotic syndrome (NS) are at an increased risk of severe infection, thrombosis, and acute kidney injury (AKI). In NS patients, AKI is associated with an increased risk of chronic kidney injury, and its incidence is increasing. Despite this, there is limited data regarding the epidemiology and risk factors of AKI in pediatric NS patients. Thus, the aim of this study was to investigate the incidence, clinical profiles, and risk factors of AKI in pediatric NS patients.

Methods: This was a retrospective multicenter study involving 14 pediatric nephrology centers. From 2013 to 2017, a total of 814 patients with idiopathic NS were reviewed, and 487 patients hospitalized for NS were analyzed.

Results: Among 363 children, 574 hospitalizations occurred. AKI occurred in 10.9% (89 patients) of the 814 children with NS and 16.2% of the 363 children who were hospitalized. Among the 588 cases of hospitalization, AKI was found in 93 (16.2%) cases: 30 (33.3%) had stage 1 AKI; 24 (25.8%), stage 2 AKI; and 39 (41.9%), stage 3 AKI. Refractory NS was the major predisposing factor for AKI in 26 (28.0%) cases. Pediatric NS patients with AKI were older; had a longer disease duration, steroid resistance, and a lower serum albumin level; and were administering of calcineurin inhibitors. Logistic regression analysis revealed that longer disease duration, lower albumin level, and steroid resistance were significantly associated with the development of AKI in pediatric NS patients. AKI was associated with a longer length of hospital stay (median duration, 10 days compared to 7 days for hospitalized patients without AKI; P = 0.001). A total of 84 (90.3%) children recovered from AKI, whereas 6 (6.5%) developed chronic kidney injury, and 3 children had neurologic sequelae related to an accompanying infection.

Conclusions: AKI, often leading to chronic kidney injury, is common in children who are hospitalized with NS. Risk factors for AKI include a longer disease duration, steroid-resistance, and infection; these can be potential tools in the recognition and management of AKI in children with NS.

FR-PO036

Rhabdomyolysis in Young Adults

Asif Khan. *Staten Island University Hospital, Brooklyn, NY.*

Background: Rhabdomyolysis is a clinical entity that directly causes AKI and is associated with a subsequent increase in patient mortality. The primary means of diagnosis is made via clinical suspicion from patient history, clinician knowledge of risk factors, and laboratory testing such as the utilization of CK for diagnosis. However, patient risk factors are dependent upon age and if not adequately assessed can lead to a missed diagnosis. Furthermore, other serum markers can potentially be used to aid in prognosis. Our study seeks to describe the risk factors for rhabdomyolysis in adults younger than 50 years. It explores etiology and demographic characteristics in relation to severity of illness, length of stay, and short-term outcomes. Finally, it indicates the accuracy of NLR as a prognostic tool.

Methods: A single-center retrospective cohort study was completed to evaluate patients admitted to hospital for primary diagnosis of rhabdomyolysis. NLR was calculated and compared to CK levels to determine association and assistance with diagnosis.

Results: 331 Rhabdomyolysis patients were included in the study. Data were stratified into 3 groups based on CK level (1500-5000, 5000-50000, >50000 IU/L). 34.83% of cases were due to illicit drugs with 80% attributed to Heroin and/or Cocaine use. Drug use was also the major etiology (28.1%) when CK level was 1500 - 50000 IU/L. The second leading cause of Rhabdomyolysis was exercise-induced (16.47%). Exercise was the major etiology (40%) in subjects with CK levels above 50,000 IU/L. Subjects with exercise-induced rhabdomyolysis had a median serum CK (8,840) more than twice the median for the entire group (4,012), but their median length of stay (2 days) was half the entire group's median (4 days). On the other hand, there was a statistically significant positive correlation between the NLR (4.79, 5.61, and 10.19 respectively) and the length of stay (4.58, 6.59, 7.8 days respectively) (p= <0.001; Spearman correlation 0.22).

Conclusions: Illicit drug use was the major cause of rhabdomyolysis in adults < 50 years old. Exercise was the second leading cause of rhabdomyolysis with a higher median serum CK but lower than the median length of stay indicating that CK is not an accurate prognostic indicator. NLR has a positive correlation to serum CK and the total length of stay suggesting it is an important prognostic biomarker. Larger studies in different patient populations are warranted to validate findings.

FR-PO037

Change in Right Ventricular Systolic Function After CRRT Initiation and Renal Recovery

Khaled Shawwa, Panagiotis Kompotiatis, Brandon M. Wiley, Jacob Jentzer, Kianoush Kashani. *Mayo Clinic, Rochester, MN.*

Background: Echocardiographic parameters have been associated with outcomes in patients on continuous renal replacement therapy (CRRT). We investigate the impact of CRRT on echocardiographic parameters and the association between improvement of these parameters with renal recovery and mortality.

Methods: This is a retrospective analysis of patients admitted to the intensive care units (ICU) at a tertiary care hospital from December 2006 through November 2015 who underwent CRRT and had an echocardiogram available within ±2 weeks from CRRT initiation. The primary outcome was Major Adverse Kidney Events at day 90(MAKE90). Multivariate logistic regression was performed to identify independent predictors of MAKE90. Secondary outcome included mortality at 30 days.

Results: The cohort included 303 patients with acute kidney injury (AKI). The median age was 62 (IQR 52-71) years with 130 (43%) female and median SOFA on the day of CRRT initiation 12 (IQR 10-14). Overall MAKE90 occurred in180 (60%) patients. The median time of echocardiogram relative to CRRT initiation was 1 day prior to CRRT and 4 days after the CRRT initiation. Among 136 patients, 35 (25%) had improvement in RV systolic function on the repeat echocardiogram. Among 106 patients, 47 (44%) had improvement in their RVSP, and 23 (21%) had at least 20% lower RVSP. Rates of MAKE90 were lower in patients who had improvement in their RV systolic function (43% vs. 67%), or had 20% reduction in RVSP (35% vs 59%), p<0.05 for both. On multivariate logistic regression, the improvement in RV systolic function (adjusted OR 0.33; 95%CI: 0.14-0.76, p=0.008) and decrease in RVSP by >20%(OR 0.36; 95%CI: 0.13-0.98, p=0.047) were associated with lower MAKE90 after adjusting for age, SOFA score, fluid balance before CRRT initiation and baseline serum creatinine. For 30-day mortality, adjusted hazard ratio (HR) for improvement in RV systolic function was 0.48 (95%CI: 0.24-0.93, p=0.031). Patients who had an improvement in their RV systolic function were in negative fluid balance leading to the day of repeat echocardiogram -2.1L vs. + 0.22L p=0.026.

Conclusions: Right ventricular dysfunction has been previously shown to predict mortality in ICU patients. Improvement in RV systolic function after CRRT was associated with decreased mortality and better renal recovery and this might be affected by volume overload.

FR-PO038

Net Ultrafiltration Rate and Its Impact on Mortality in Patients with AKI Receiving CRRT

Shahrzad Tehranian,[1] Khaled Shawwa,[1] Kianoush Kashani.[1,2] [1]*Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN;* [2]*Division of Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN.*

Background: Fluid overload, a critical consequence of acute kidney injury (AKI), is associated with worse outcomes. The optimal volume of fluid removed per day during continuous renal replacement therapy (CRRT) is unknown. The purpose of this study is to evaluate the impact of ultrafiltration rate on mortality in critically ill patients with AKI receiving CRRT.

Methods: We retrospectively reviewed 1,398 patients with AKI who received CRRT between December 2006 and November 2015 at Mayo Clinic, Rochester, MN. The net ultrafiltration rate (UF^{NET}) was categorized into low- and high-intensity groups (< 35 and ≥ 35 ml/kg/day, respectively). The impact of different UF^{NET} intensities on 30-day mortality was assessed using logistic regression after adjusting for age, sex, body mass index, fluid balance from ICU admission to CRRT initiation, APACHE III and SOFA scores, baseline serum creatinine, ICU day at CRRT initiation, Charlson comorbidity index, and need for mechanical ventilation.

Results: The mean age was 62±15 years, 827 (59%) were male. There were 696 patients (49.8%) in low- and 702 (50.2%) in high-intensity groups. Thirty-day mortality was 755 (54%). There were 420 (60.4%) deaths in low-, and 335 (48%) in high-intensity group (p<0.001). UF^{NET} ≥ 35 ml/kg/day remained independently associated with lower 30-day mortality (adjusted odds ratio (aOR): 0.49; 95% Cl: 0.39-0.63, p<0.001) compared to < 35 ml/kg/day.

Conclusions: More intensive fluid removal, UF^{NET} ≥ 35 ml/kg/day among AKI patients receiving CRRT is associated with lower mortality. Future prospective studies are required to confirm such a finding.

FR-PO039

CKD and AKI Outcomes After Left Ventricular Assist Device Implantation

Muhammad S. Ajmal, Umang Parikh, Harveen Lamba, Carl P. Walther. *Baylor College of Medicine, Sugar Land, TX.*

Background: Left ventricular assist devices (LVAD) are used as a bridge to heart transplant or destination therapy for patients with end-stage heart failure. Acute kidney injury (AKI) or need for renal replacement therapy (RRT) post LVAD implant can lead to poor outcomes. Identifying risk factors of AKI post LVAD can help stratify LVAD candidates.

Methods: A retrospective study of all patients who received continuous-flow LVAD at our institution from January 2015 until August 2017. We calculated incidence of AKI and need for RRT post LVAD implant, rate of renal recovery and survival rates at 30 days and 1-year post implant. Presence of Chronic kidney disease (CKD) with staging and proteinuria was assessed and a prior kidney ultrasound (KU) was reviewed for all patients if available. CKD was present if eGFR<60 ml/min per 1.73m^2 for >3 months preceding LVAD implant and/or proteinuria> 20mg/dl on 2 or more urine analysis prior to implant and/or an abnormal KU with increased echogenicity or small size <9 cm. AKI was defined per KDIGO guidelines

Results: A total of 137 patients received LVAD. 112 males and 25 females with mean age of 59.2 years. Race: 64 Caucasians, 38 Africans, 30 Hispanics and 5 Asians. Incidence of AKI and need for RRT during hospitalization post LVAD implant were calculated in all patients and in sub-groups based on the presence of CKD, underlying CKD stage, proteinuria and KU findings. See table. 30 day and 1-year mortality rates post LVAD implant were 4.3% and 21.1% respectively. Out of the 27 patients requiring RRT, 9 (33%) were off RRT at 1 year. Compared to eGFR on day of LVAD implant, eGFR at 30 days post LVAD showed 57% patients with higher and 42% with lower eGFR. At 1 year, eGFR was higher in 32% and lower in 67% patients.

Conclusions: Incidence of AKI and need for RRT post LVAD implant are very high. Of all patients, 2 out of 3 patients had a lower eGFR at 1-year post implant and only 1 out of 3 patients requiring RRT recovered at 1-year post implant. Presence of CKD, advanced CKD stage and abnormal KU are statistically significant (P <0.05) risk factors of AKI post LVAD and/or need for RRT.

Incidence of AKI and need for RRT

	All Patients	No CKD	CKD Present	CKD stage 1-2	CKD stage 3-5	No Proteinuria	Proteinuria Present	Normal Kidney Ultrasound	Abnormal Kidney Ultrasound
Incidence of AKI	88/137=64%	18/42=43%	64/84=76%	15/25=60%	41/47=87%	49/85=58%	33/45=73%	63/103=61%	17/24=71%
		P value=0.028		P value=0.0081		P value=0.0778		P value=0.376	
Need for RRT	27/137=19.7%	4/42=9%	23/84=27%	6/25=24%	11/47=23%	15/85=18%	10/45=22%	16/103=15%	8/24=33%
		P value=0.0153		P value=0.775		P value=0.5288		P value=0.0448	

FR-PO040

The Influence of Left Ventricular Assist Device Implantation on Short-Term and Long-Term Renal Functions in End-Stage Heart Failure Patients

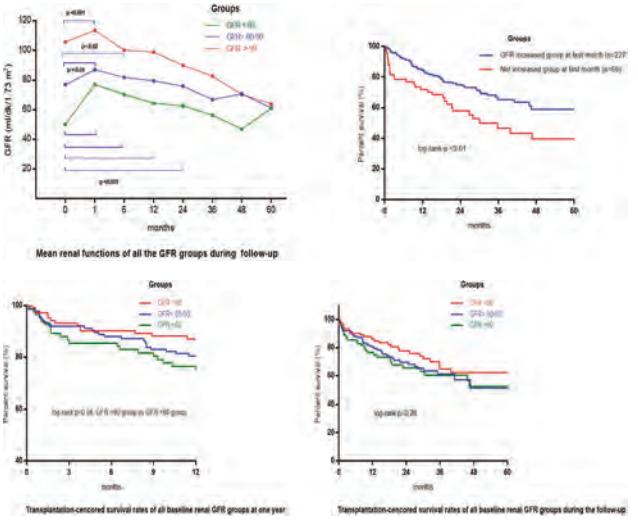
Anar Sadigov,[2] Emre Demir,[2] Sanem Nalbantgil,[2] Cenk Demirci,[1] Cagatay Engin,[2] Tahir Yagdi,[2] Pelin Ozturk,[2] Mustafa Ozbaran,[2] Meltem Sezis Demirci.[2] Ege University [1]*Fresenius Medical Care, Izmir, Turkey;* [2]*Ege University Medical Faculty, Izmir, Turkey.*

Background: Left Ventricular Assist Devices(LVAD) are used as an interventional treatment method for patients with decompensated heart failure(HF). The aim of this study is to retrospectively evaluate the short and long-term effects of LVAD implantation on renal function and survival in patients with end-stage HF.

Methods: 329 patients with LVAD were investigated. Basal and follow-up GFR(CKD-Epi) values were calculated retrospectively. Patients were divided into three groups according to baseline GFR; group 1(GFR<60,n=85), group 2(GFR 60-90,n=138) and group 3(GFR>90,n=106). SPSS 22.0 software was used for all statistical analyses.

Results: The mean age of the patients was 50.8±13.2, 86% was male, mean basal GFR was 77.6±25.7 ml/min, 29.5% patients had DM, 34.1% had HT. Mean follow-up time was 22.6±17.9(0,2-71,6) months. There was a significant increase in mean GFR values of all patients in the postop first month(p <0.01). In group 1, there was a significant increase in GFR at 1, 12, 24 months after implantation compared to baseline(p<0.001), but this increase was not significant at 36 months(p=0.08). One-year transplantation-censored survival was 81.9%, 70.3% for 2-year, 55.8% for 4 and 5-years. The survival rate at first year was 87.9% in group 3, 81.9% in group 2 and 76.2% in group 1. Patients with postoperation first month GFR increased(n=227); 2-year survival rate was 73%, 4-year was 58% and patients with not increased group(n=69), 2-year survival rate was 56% and 4-year was 38%(p <0.01).

Conclusions: In patients with LVAD, short- and long-term results are quite good in terms of renal function. Even though GFR was low before, we observed that there was a significant improvement in GFR after LVAD implantation and this improvement continued for the first 3 years.



FR-PO041

Safety and Efficacy of In-Series Continuous Renal Replacement Therapy in Patients on Venoarterial and Venovenous Extracorporeal Membrane Oxygenation

Christopher Hebert.[1,2] [1]*Kidney and Hypertension Associates of Dallas, Dallas, TX;* [2]*Cardiothoracic Intensive Care, Baylor Scott and White, Dallas, TX.*

Background: There is no standardization or consensus on performing continuous renal replacement therapy in patients on extracorporeal membrane oxygenation in the adult population. Given the limited access points available for patients on extracorporeal membrane oxygenation, it has been the practice at our institution to run CRRT in line with ECMO and then transition to a tunneled dialysis catheter at the time of ECMO decannulation.

Methods: We have performed over 600 ECMO cannulations, 268 of which have required dialysis for renal failure and metabolic clearance or primarily for ultrafiltration and volume removal. Of these 268, we performed CRRT in series on 265 of them using the Nxstage System One with both the Maquet Rotaflow as well as Cardiohelp ECMO systems. There are two separate connections used on the rotaflow ECMO circuit, and a single connection in the Cardiohelp system detailed in the images attached.

Results: In 265 patients, we successfully performed well over 1000 dialysis days of treatments in series with ECMO with virtually no complications. Efficacy was determined by adequate control of acid/base abnormalities as well as overall clearance of urea. Volume removal was typically determine by the overall hemodynamics of the patient, but there were no machine or circuit imitations regarding ultrafiltration.

Conclusions: We have found and demonstrated safety and efficacy of in series CRRT with ECMO in the adult population in a large cohort of patients.

FR-PO042

Use of Nesiritide in Total Artificial Heart to Rescue From Dialysis Dependence

Christopher Hebert. *Kidney and Hypertension Associates of Dallas, Dallas, TX.*

Introduction: It is well described in the literature that patients with total artificial heart implantation as a bridge to transplant have low atrial natiuretic peptide levels. Patients post ventriculectomy may lose the ability to produce urine in some cases as a consequence to having low ANP levels

Case Description: We present a 62yo man who underwent total artificial heart implantation. Post operatively, he developed severe shock and was placed on VA ECMO as well as CRRT. He was initially on niseritide post operatively but after a relatively quick decannulation and cessation of niseritide in 48 hours, he became anuric and required ongoing hemodialysis. After 10 days of hemodialysis, it was decided to restart niseritide as a trial to see if we could promote some urine production. On day 1, he made a liter of urine and by day 6 his creatinine had gone from 6 down to 1.3 and he no longer required dialysis. He was discharged home and received a heart transplant a month later. To date, he remains off dialysis with creatinine level of 1.0

Discussion: There are a few case reports detailing such a response to niseritide. This particular case was an extreme example of a patient going from an anuric state on hemodialysis with really no ability to discharge him from the hospital, to making ample urine and recovering renal function.

FR-PO043

The Role of Perioperative Renal Replacement Therapy in Heart Transplantation

Sua Lee,[1] Byung ha Chung,[1] Bumsoon Choi,[2] Cheol Whee Park,[1] Chul Woo Yang,[1] Tae Hyun Ban.[2] *[1]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea; [2]Eunpyeong St. Mary's Hospital, Seoul, SEOUL, Republic of Korea.*

Background: Heart transplantation (HT) is the treatment of choice for patients with end-stage heart failure. Although several studies had reports about association with acute kidney injury (AKI) and HT, little is known about the impact of perioperative renal replacement therapy (RRT) on clinical outcomes of HT. We compared the clinical characteristics and outcome of patients according to RRT at the time of HT.

Methods: A total of 23 patients were underwent heart transplantation from January 1995 to May 2019 at Seoul St. Mary's hospital and Eunpyeong St. Mary's hospital. The most recent patient was excluded because of the short follow-up duration. We reviewed data including the cause of heart failure, cardiac function and renal function based on electronic medical records. The patients were divided as heart transplant recipients (HTRs) who underwent perioperative RRT (RRT group, n=9) and HTRs who did not received RRT (non-RRT group, n=14). Renal function was analyzed at baseline, 1 month, 3 months, 6 months and 12 months after HT.

Results: The most common cause of HT was dilated cardiomyopathy (n=11, 50%), then followed by ischemic cardiomyopathy (n=8, 36%). The LVEF before HT in the RRT group was significantly lower than that of the non-RRT group (LVEF 15.2 % vs 24.8%, P=0.014, respectively). In the RRT group, six patients (27.6%) underwent RRT before HT including with five patients of continuous renal replacement therapy (CRRT) and a patient of peritoneal dialysis. Finally, eight patients (36.4%) received RRT before and after HT, including five patients who initiated RRT prior to transplantation. After 1 month and 6 months post-transplantation, the renal function of RRT group were significantly worse than that of non-RRT patients (eGFR 40.95 vs 63.48 ml/min/1.73m^2, p=0.031, after 1 month; 39.40 vs 71.01 ml/min/1.73m^2, p=0.011, after 6 months). However, after 12 months post-transplantation, there was no significant difference of renal function between RRT group and non-RRT groups (eGFR 54.98 vs 68.30 ml/min/1.73m^2, p=0.294). All the patients in the RRT group were tolerated without dialysis after HT.

Conclusions: RRT at the perioperative period in the heart transplant recipients will be a good bridge therapy for recovery of renal function in the cases with a high risk of cardiorenal AKI with low LVEF.

FR-PO044

Impact of Intermittent Online Hemodiafiltration vs. High-Flux Hemodialysis on Markers of Inflammation and Fluid Status Assessed by Bioimpedance Analysis in Septic AKI Patients: A Randomized Trial

Saurabh Nayak,[1] Krishan Lal L. Gupta,[1] Raja Ramachandran,[2] Ashok K. Yadav,[1] Nancy Sahni.[1] *[1]Postgraduate Institute of Medical Education and Research, Chandigarh, India; [2]Nehru Hospital, Chandigarh, India.*

Background: In sepsis, fluid assessment is a widely accepted challenge. Traditional approaches have limited utility. Bioimpedance (BI) has been used in CKD patients for dry weight assessment and studies have shown cardiovascular benefits when BI was utilised for fluid status assessement. We aimed at comparing impact of two modes of clearance i.e online HDF and high flux HD on fluid status and inflammation markers as assessed by BI analysis.

Methods: This pilot study was conducted in PGIMER, India between Sep 2017 to Sep 2018. Non critically ill septic AKI patients requiring dialysis were included. Patients in ICU and those requiring more than one ionotrope and/or mechanical ventilation were excluded. Alternate day RRT was provided till renal recovery using either HD or online HDF with target effluent rate of 25 ml/Kg/Hour. High flux polysulphone dialyzer was used in both the arms. BI was performed using single frequency bioimpedance analyser at prespecified intervals i.e before commencement of RRT, alternate day for 1st week, weekly till discharge and during 1st and 3rd monthly visits. All patients were followed for a period of 3 months from discharge. Plasma cytokine (IL6 a& TNF alpha) levels were assessed before and after one week of RRT initiation.

Results: 80 patients were randomized in each RRT arm. Baseline characteristics and sepsis parameters (qSOFA) were similar. Phase angle(PA), body cell mass(BCM), fat free mass(FFM) and Total body water(TBW) at baseline were comparable. No significant improvement in BCM and PA were noted at 1st month however significant improvement seen at 3rd month. Mean PA at initiation of RRT and at 1 month after discharge was 6.05 and 10.5 respectively (P= 0.628). Likewise, no difference in plasma cytokine clearance was noted between the arms. At 3 months, change in PA within the arms was significant (p<0.005), with no difference across the arms. BCM and PA correlated with qSOFA score and plasma cytokine levels throughout. Mean eGFR at day 30 was 37.28 ml/min and 30 day mortality was 12.5%.

Conclusions: Phase angle and body cell mass correlated with other traditional markers of sepsis. There was no differential impact of convective and diffusive clearance on PA and BCM when applied intermittently.

Funding: Government Support - Non-U.S.

FR-PO045

Mortality in Patients with Sepsis and Non-Sepsis AKI Requiring CRRT: A Retrospective Single-Center Experience

Sahityan Viswanathan,[1] Prashanth Reddy,[1] Saravanan Balamuthusamy,[2] Manonmani Ellappan,[3] Aruna Govindaraju.[4] *[1]Medical City Fort Worth, Fort Worth, TX; [2]Tarrant Nephrology Associates, FortWorth, TX; [3]PPG Health/ TRI, Fortworth, TX; [4]PPG Health, Fort Worth, TX.*

Background: Short term and long term renal and survival outcomes of pts who undergo CRRT is highly variable in published literature. We have done a retrospective analysis on patients who have required CRRT at our institution over a 3 year period and have analyzed their survival outcomes based on their reason for initiation of CRRT.

Methods: Single center retrospective analysis on all patients who underwent CRRT between January 2015 and December 2017 were included for the analysis. Patients who expired within 12 hours after initiation of CRRT were excluded. All the patients underwent CRRT (CVVHDF) using the PrismaFlex machine. Patients were grouped under sepsis (sepsis group) vs other etiologies (non-sepsis group) based on the reason for initiation of CRRT. Renal and overall survival outcomes were analyzed between the 2 groups across multiple variables including comorbidities. Comparisons were made using T-test and correlations on primary outcomes based on need for CRRT was done using Pearson's test. Each variable was independently correlated with etiology of CRRT using logistic multiple regression analysis.

Results: Sepsis was the underlying etiology for initiating CRRT in 64% of pts. Cardiogenic shock was the most common cause for the rest. Patient groups were comparable across all variables analyzed. There was 51% mortality in the patients who needed CRRT in the study population. Mortality was 55% in patients in the sepsis group and 48% in non-sepsis group (p=0.4). Mean duration of CRRT in patients with sepsis who were alive at the end of 1 month was 7.1 (5.5) days and 3.2 (2.8) days in pts who were in non-sepsis group (p< 0.001).

Conclusions: Hemodynamically unstable patients who were initiated on CRRT irrespective of sepsis or non-sepsis etiology had a significantly high mortality at the end of 30 days. Patients initiated on CRRT due to sepsis required CRRT 3.9 days more than patients in the non-sepsis group. However randomized clinical trials are needed to compare the need and efficacy of CRRT on renal and survival outcomes in patients requiring continuous slow dialysis.

Mean duration of CRRT

Mean duration of CRRT (days)	Sepsis (n=83)	Non-sepsis (n=46)
Dead	3.4 (3.1)	4(2.9)
Alive	7.1(5.5)	3.2(2.8)

FR-PO046

Outcomes with Implementing CRRT in a Community Hospital

Maggie Meier,[1] Harinderjeet Kaur,[1] Rajat Shailly,[1] Ramza Haque,[1] Nishith Alva,[1] Ricardo J. Camacho,[1] Amir soheil Talebian,[1] Muhammad Farhan Asghar,[1] Thomas R. Pohlman.[2] *[1]St. Luke's Hospital, Chesterfield, MO; [2]St. Luke's Medical Specialists, St. Louis, MO.*

Background: Acute kidney injury incidence in critically ill patients ranges from 20 to 50% and is associated with a high mortality rate. The CDC reports a 2.29% increase in acute kidney injuries treated with dialysis from 2000 to 2014. Renal replacement therapy is commonly required in patients with severe acute kidney injury. AKI was associated with higher hospitalization costs than myocardial infarction and gastrointestinal bleeding, and costs were comparable to those for stroke, pancreatitis, and pneumonia. In February 2016, continuous renal replacement therapy (CRRT) became available in our community hospital in Chesterfield, Missouri. We analyzed our initial usage of CRRT to evaluate outcomes and costs.

Methods: We conducted a retrospective study of adult patients initiated on CRRT at St. Luke's Hospital in Chesterfield, MO between February 2016 and May 2018. The data was collected via Cerner Powerchart. Data collection included baseline characteristics, hospitalization costs and disposition.

Results: Among 52 qualified patients, the average age was 66.75. 92% were Caucasian with a male predominance (62%). The prevalence of Hypertension was 75%, Anemia 70%, CKD 47%, Multiorgan Failure 79%, Mechanical Ventilation 73% and ECMO 12%. Our mean duration of CRRT days was 3.84 in 2016, 2.53 in 2017, and 2.2 in 2018. The average direct total cost of hospitalization was $82,858. Our mortality rate was 51%. Patient dispositions: home 21%, LTAC 11%, Rehab 9%, SNF 8%, Hospice 6% and Deceased 45%.

Conclusions: Our community hospital implementation of CRRT over a two year period had a mortality rate of 50.9%, which was better than mortality rates found in the literature of ~62%. CRRT in our community setting was associated with similar to better outcomes than reported in literature. We attribute this to a common CRRT EMR order set, limited settings in which CRRT is utilized (medical and surgical ICU) and initiation of CRRT limited to nephrology.

FR-PO047

Continuous Renal Replacement Therapy with AN69ST Membrane Reduces Plasma IL-8 in Sepsis Patients

Shunsuke Takahashi,[1] Ayumu Nakashima,[2] Yuki Handa,[1] Naoko Kyoda,[1] Takahiro Arima,[1] Takao Masaki.[2] *[1]National Hospital Organization Kure Medical Center, Kure-shi, Japan; [2]Hiroshima University, Hiroshima, Japan.*

Background: Polyethylenimine-coated polyacrylonitrile (AN69ST) membrane has a hydrogel structure, which enables adsorption and thereby exhibits an increased capacity for cytokine removal in continuous renal replacement therapy (CRRT). This capability is expected to improve the outcomes of severe sepsis and septic shock. IL-8 is a chemokine with a molecular weight of 8000 MW and is known as a neutrophil chemotactic factor in sepsis.

Methods: APACHE II scores after ICU admission were evaluated for 23 sepsis patients. Patients with sepsis underwent CRRT using the AN69ST membrane. Plasma IL-8 was measured at the start of CRRT and 24 hours after the start of CRRT. At the start of CRRT, plasma IL-8 was measured pre AN69ST membrane and post. Patients were divided into two groups: survival group and death group.

Results: There were 12 cases in the survival group and 11 cases in the death group. The APACHE II score was 25.0 (20.5-30.0). Plasma IL-8 at the start of CRRT was 87.3 (28.1-182.8) pg/mL and was significantly reduced to 35.9 (19.6-62.0) pg/mL 24 hours after initiation of CRRT ($P < 0.01$). At the start of CRRT, plasma IL-8 was significantly reduced to 31.2 (13.1-65.9) pg/mL downstream of the AN69ST membrane ($P < 0.01$). Logistic analysis for death was associated with age (1.15, 95%CI: 1.02-1.49, $P = 0.02$), and plasma IL-8 reduction rates at 24 hours after CRRT initiation (0.89, 95%CI: 0.74-0.96, $P < 0.01$).

Conclusions: CRRT with the AN69ST membrane reduces plasma IL-8 in sepsis patients. Our results suggest that plasma IL-8 reduction rate 24 hours after initiation of CRRT is an independent contributing factor to death.

FR-PO048

Effects of a Novel CRRT Fluid Protocol on Electrolyte Stability

Hyo jin Boo, Song in Baeg, Kyungho Lee, Kyungho Park, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae joong Kim, Hye Ryoun Jang. *Division of nephrology, department of medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Gangnam, Republic of Korea.*

Background: Continuous renal replacement therapy (CRRT) is the standard treatment for critically ill patients with acute kidney injury. During CRRT, electrolyte disturbance such as hypokalemia or hypophosphatemia frequently occurs unless dialysate and replacement solutions are adequately adjusted. Samsung Medical Center CRRT team developed a new protocol to prevent electrolyte disturbance by adjusting dialysate and replacement fluids depending on serial changes in serum potassium and phosphorus levels. We evaluated the impact of the new CRRT fluid protocol on electrolyte stability.

Methods: Adult patients who received CRRT for 3 days or more during the previous two years (2013 to 2014; pre-protocol group) and the last two years (2016 to 2017; protocol group) following the development of the fluid protocol were compared. Individual coefficient of variation (CV) and the number of abnormal measurements for electrolytes during CRRT were analyzed. The frequency of potassium, phosphorus, or magnesium replacement therapy was also compared. The Wilcoxon rank sum test was used for analysis.

Results: A total of 1456 patients were included. There were no significant differences in age, gender, and CRRT duration between the two groups. The CV of serum potassium was lower in the protocol group (pre-protocol group vs. protocol group, 0.113 [0.066 - 0.160] vs. 0.092 [0.052 - 0.132], $p<0.0001$). The CV of serum phosphorus was also lower in the protocol group (pre-protocol group vs. protocol group, 0.292 [0.173 - 0.411] vs. 0.248 [0.140 - 0.356], $p<0.0001$). The event rates of abnormal potassium levels (pre-protocol group vs. protocol group, 0.205 [0.199 - 0.211] vs. 0.083 [0.079 - 0.087], $p<0.0001$) and abnormal phosphorus levels (pre-protocol group vs. protocol group, 0.406 [0.398 - 0.415] vs. 0.280 [0.273 - 0.286], $p<0.0001$) were lower in the protocol group. The CV of serum magnesium, sodium, and ionized calcium was also lower in the protocol group. The frequency of potassium, phosphorus, and magnesium replacement was significantly reduced after application of our new CRRT fluid protocol ($p<0.001$).

Conclusions: Our novel CRRT fluid protocol significantly increased electrolyte stability and consequently prevented electrolyte disturbance during CRRT.

FR-PO049

Potential Adverse Hemodynamic Effects of Higher-Intensity Continuous Renal Replacement Therapy

Yvelynne P. Kelly,[1] Shilpa Sharma,[1] Finnian R. McCausland,[1] Sushrut S. Waikar.[2] *[1]Division of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Higher intensity continuous renal replacement therapy (CRRT) has been studied as a potential therapeutic advance for the treatment of severe acute kidney injury (AKI). We hypothesized that compared to standard intensity CRRT, higher intensity CRRT leads to greater hemodynamic instability due to the increased removal of small solutes.

Methods: Using detailed hemodynamic data recorded during the Acute Renal Failure Trial Network (ATN) trial, we assessed the incidence of hemodynamic instability in those randomized to higher (35 ml/kg/hour) versus lower intensity (20 ml/kg/hour) CRRT treatment. We used Poisson regression to model the count of hypotensive events, defined as a composite outcome including hypotension requiring an increase in vasopressor dose sufficient to increase the Sequential Organ Failure Assessment (SOFA) score, hypotension requiring cessation of RRT and hypotension requiring other interventions.

Results: Of 1124 individuals enrolled in the ATN Trial, 817 were managed with CRRT (N = 399 standard intensity and 418 higher intensity therapy). 204/817 (25%) patients experienced hypotension during the study period, with hypotensive events occurring most frequently on day 1 of treatment (Figure 1). Patients randomized to higher intensity CRRT had a 1.34-fold (95% CI, 1.02-1.76; p = 0.03) higher rate of hypotensive episodes than those randomized to standard intensity CRRT, using a Poisson model adjusted for age, gender and oliguria.

Conclusions: Higher intensity CRRT is associated with a significantly greater risk of hypotensive events compared to standard intensity CRRT.

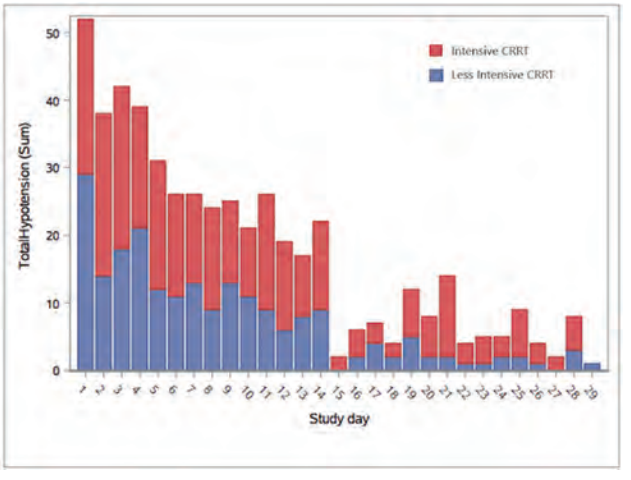


Figure 1: Temporal distribution of hypotensive events between higher intensity and standard intensity CRRT treatment groups in the ATN trial

FR-PO050

The Effect of Therapeutic Hypothermia on Urine Output After Cardio-pulmonary Resuscitation

MinJeong Lee. *Ajou University School of Medicine, Suwon, Republic of Korea.*

Background: Therapeutic temperature management (TTM) was strongly recommended by the 2015 International Lision Committee on Resuscitation as a component of post-resuscitation care. It has been known to be effective in improving the survival rate and neurologic functional outcome of patients after cardiac arrest. While commonly described cold diuresis, renal tubular function is diminished in the induction and maintenance phase of TTM, few studies have characterized cold-induced diuresis or rewarm anti-diuresis during TTM. In this study, we sought to characterize urine output changes during postcardiac arrest therapeutic hypothermia.

Methods: We conducted retrospective cohort study to determine urine output changes during TTM of the postcardiac arrest patients. We analyzed 104 patients who underwent all phase TTM for 3 years from Jan 1, 2012 to Dec 31, 2014. We calculated the hourly IV fluid input and urine output rates for each TTM phase. We fit a generalized linear mixed model with each TTM phase as a categorical variable to compare the urine output at each phase of analysis.

Results: Four-fifths of the patients suffered out-of-hospital arrest. Approximately 70% survived to hospital discharge. Urine output rate was highest at 249.1 ± 255.7 mL/hr in the hypothermia induction phase but lowest at 96.4 ± 65.3 mL/hr during rewarming phase even though total I/O showed the most positive balance during the rewarming phase.

Conclusions: We observed modest increases in urine output during induction phase of TTM. This has important implications for fluid management in patients undergoing therapeutic hypothermia. We will collabrate with the statistics team to analyze changes in continuous urine output and overall I / O data rather than average data of the larger number of patients.

Fluid input and output during therapeutic hypothermia

	Hypothermia induction	Hypothermia maintenance	Hypothermia rewarm	Post-rewarm	P-value
IV fluid input (mean, mlL/hour)	300.5 ± 189.1	206.7 ± 92.3	181.9 ± 77.5	165.0 ± 63.7	<0.001
Urine Output (mean, mL/hour)	249.1 ± 255.7	130.4 ± 97.5	96.4 ± 65.3	119.9 ± 72.7	<0.001
Output except urine output (mean, mL/hour)	15.8 ± 94.2	3.5 ± 8.6	3.5 ± 7.7	4.1 ± 8.5	0.193
Total Output (mean, mL/hour)	264.9 ± 259.9	133.9 ± 98.1	99.9 ± 67.1	124.0 ± 71.7	<0.001
Total I/O balance (mean, mL/hour)	35.7 ± 261.8	72.8 ± 92.2	82.9 ± 81.8	39.6 ± 73.2	0.081
MAP (mmHg)	107.0 ± 26.2	95.6 ± 11.6	89.8 ± 11.8	89.6 ± 12.7	<0.001

FR-PO051

A Study of Severe Tropical AKI Requiring Renal Replacement Therapy in a Tertiary Care Hospital in South India

Praveen K. Kolla. *Nephrology, Narayana Medical College, Nellore, India.*

Background: The etiology of tropical AKI can be divided into infections, toxins, poisons and miscellaneous causes like heat stroke and obstetric AKI etc. Acute tubular injury occurring secondary to community acquired infections remains the commonest cause of tropical AKI. Through this study we attempt to study the causes and factors associated with morbidity and mortality of severe AKI requiring RRT in south India

Methods: This is a retrospective observational study done in Narayana Medical College, Nellore. Patients admitted in the ICU with AKI within a period of 3 years (2016-2018) were screened. Patients with non-tropical causes of AKI and AKI not requiring RRT were excluded from the study. The baseline eGFR was calculated according to the MDRD 75 formula. All patients eGFR was calculated 3 months after discharge to look for recovery or classify as CKD. Complete recovery was defined as improvement in the eGFR to more than the calculated baseline eGFR, at the end of 3 months after discharge. Descriptive analysis and univariate regression analysis were done to find factors associated with recovery, progression to CKD and death

Results: A total of 130 patients were studied with the mean age of presentation being 42.7 years and 62.3% (n=81) of the patients were males. The mean duration of stay in the hospital was 12.35 days. 8.4 % (n=11) patients received peritoneal dialysis and 91.5 % (n=119) received hemodialysis (HD). The most common etiology of AKI was acute gastroenteritis (40.7%) followed by snake bite (15.3%), hair dye poisoning (11.5%), malaria (9.2%), obstetric AKI (6.9%), dengue (5.3%), leptospirosis (3.8%), scrub typhus (3.0%), rhabdomyolysis (1.5%), paraquat poisoning (0.7%) and petroleum product consumption (0.7%). 96.9% patients presented with KDIGO stage 3 of AKI with average eGFR of 9.72. The average eGFR after 3 months of discharge was 40.93. Out of 130 patients 18.4% recovered completely, 14.6% (n=19) expired and 66.92% progressed to CKD. Snake bite, dengue fever, thrombocytopenia, presence of diabetes mellitus, hypertension and coronary artery disease were independently associated with progression towards to CKD. Paraquat poisoning and petroleum product ingestion were independently associated with death

Conclusions: Severe tropical AKI requiring RRT holds a poor prognosis with majority of patients progressing to CKD

FR-PO052

The Interactive Effects of Input and Output on Managing Fluid Balance in Patients with AKI Requiring Continuous Renal Replacement Therapy

Kyoung Hye Kong,[1] Hyung Jung Oh,[2] Dong-Ryeol Ryu.[1] *[1]Ewha Womans University, Seoul, Republic of Korea; [2]Ewah Womans' University, Mokdong Hospital, Seoul, Republic of Korea.*

Background: Fluid balance is a key factor for better survival rate in patients with acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT). However, appropriate regulation of input and output to achieve optimal fluid balance is not well elucidated yet. This study aimed to evaluate the effect of fluid components on mortality in patients with AKI requiring CRRT.

Methods: A total of 258 patients who were in the intensive care units of Ewha Womans University Hospital and with AKI required CRRT were enrolled (from 2016 to 2018). The amounts of fluid input and output were assessed by electronical medical charts with 24-hr and 72-hr intervals immediate after initiation of CRRT. The study endpoints were 7-, 14-, and 28-days all-cause mortality.

Results: The mean age of study subjects were 64.7 ± 15.8 years and 165 (64.0%) were male. The 28-day mortality was observed 118 (53.9%) cases during the follow-up. The amounts of cumulative fluid balance and cumulative input were higher and cumulative output was lower in non-survivors compared to survivors during 72-hr after CRRT initiation. A positive value of both 24-hr and 72-hr assessed cumulative fluid balance was associated with increased risk for 7-, 14-, and 28-days mortality. When the subjects were classified according to tertiles of total input or output, the increasing amount of cumulative fluid balance assessed with 24-hr and 72-hr was associated with the increased risk for mortality irrespective of tertiles of total input. However, increasing amount of cumulative fluid balance was not associated with the mortality risk according to tertiles of output.

Conclusions: The impact of CFB on mortality might be more dependent on cumulative output. The physicians need to decrease the CFB of CRRT patients as much as possible and consider increasing patient removal.

FR-PO053

Fluid Balance After Continuous Renal Replacement Therapy Initiation Is a Predictor of Mortality

Jung Nam An,[1] Hyung Jung Oh,[2] Jung Pyo Lee,[1] Dong Ki Kim,[3] Dong-Ryeol Ryu,[4] Sejoong Kim.[5] *[1]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [2]Ewah Womans University, Mokdong Hospital, Seoul, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Ewha Womans University, Seoul, Republic of Korea; [5]Seoul National University Bundang Hospital, Seongnam, GyeonGgi-Do, Republic of Korea.*

Background: Higher cumulative fluid balance in critically ill patients was associated with hospital mortality. Inbody, impedance body fat analyzer, can measure body water, and segmental water values. In this study, we examined the fluid balance by time using bioimpedance analysis (inbody), and investigated the association of fluid balance with clinical outcomes in the CRRT patients.

Methods: Among the patients who started CRRT at multi-center from May 2017 to March 2018, Inbody was measured at D0, D1, D2, and D7. Fluid overload was defined when either of the following two conditions is met; total body water (TBW)/height^2 more than 13 L/m^2 or the change of body weight more than 5%. Reaching euvolemia was defined when either of the following two conditions is met; at day 7, TBW/height^2 was less than 13 L/m^2 or the change during 7 days was less than -2.1 L/m^2. The association with 60-days mortality was investigated.

Results: 72% patients showed fluid overload. These patients were younger and had lower urine amount during 2 hours before CRRT, and started CRRT later compared to those without fluid overload. The change of body weight and TBW/height^2 at CRRT initiation were much more than those without fluid overload. There is no statistical significance; however, the patients with fluid overload at CRRT initiation were shown to have a higher risk for mortality. Among the patients with fluid overload, 36 patients reached euvolemia at 7 days after CRRT initiation. Comparing with patients who failed to reach euvolemia, TBW/height^2 at each time point and delta value during 7 days were significantly lower in the patients who reached euvolemia. Failing to reach euvolemia was a risk factor of 60-day mortality. After adjusted for age, gender, BMI, charlson comorbidity index, APACHE II, and SOFA score, failing to reach euvolemia were closely correlated with 60-day mortality, doubling the risk of mortality.

Conclusions: Fluid overload at CRRT initiation, defined based on the change of body weight and TBW/height^2, was associated with the 60-day mortality. Based on the definition using TBW/height^2 measured by InBody®, patients who failed to reach euvolemic status within 7 days after CRRT initiation showed a higher mortality rate, compared to those who reached euvolemic status.

The Use of Machine Learning to Predict the Renal Replacement Therapy-Free Survival in Patients Who Require Continuous Renal Replacement Therapy

Pattharawin Pattharanitima, Suraj Jaladanki, Aine Duffy, Ishan Paranjpe, Tielman T. Van Vleck, Steven G. Coca, Lili Chan, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: AKI in critically ill patients is common and continuous renal replacement therapy (CRRT) is the preferential mode of renal replacement therapy patients who are hemodynamically unstable. Prior studies have yielded conflicting results for predictors of CRRT discontinuation and mortality. Therefore, we tested machine learning algorithms for predicting renal replacement therapy-free survival (RRTFS) in patients who required CRRT

Methods: We used the Medical Information Mart for Intensive Care III database to identify patients ≥18 years old, and who had AKI requiring CRRT for ≥24 hours. ESRD patients were excluded. RRTFS was defined as patients who were discharged alive and did not require RRT 7 days prior to hospital discharge. Five machine learning algorithms: the multi-layer perceptron neural network (MLP), random forest (RF), support-vector machine (SVM), logistic least absolute shrinkage and selection operator (LASSO) and logistic regression were trained. We evaluated model performance using area under the receiver operating characteristic (AUROC). Features included laboratory values and patient features and were selected for inclusion based off of prior published data.

Results: Out of 566 patients, 179 (31.6%) patients had RRTFS. Patients who had RRTFS were younger (60 years vs. 65 years, p =0.006), and more likely to be white (73% vs. 67%, p=0.001). MLP had the highest AUROC, 0.694 (95% CI 0.586-0.791), followed by RF 0.523 (95% CI 0.469 – 0.583), logistic regression 0.516 (95% CI 0.457 – 0.575), logistic LASSO 0.512 (95% CI 0.456 – 0.571), and SVM 0.500 (95% CI0.500-0.500).

Conclusions: Compared to the standard logistic regression model, machine learning models, particularly the MLP method, had better performance at predicting RRTFS in patients started on CRRT using features prior to CRRT initiation.

Funding: NIDDK Support

Figure 1 The receiver operating characteristic curves and the area under the receiver operating characteristic (AUROC) for predicting the RRT-free survival after CRRT using machine learning algorithms the multi-layer perceptron neural network (MLP), random forest, support-vector machine (SVM), logistic least absolute shrinkage and selection operator (LASSO) and logistic regression

Machine Learning Algorithm to Predict Mortality in Patients Undergoing Continuous Renal Replacement Therapy

Min woo Kang,[1] Dong Ki Kim,[1] Kook-Hwan Oh,[2] Kwon Wook Joo,[1] Yon Su Kim,[2] Seung Seok Han.[1] [1]*Seoul National University Hospital, Seoul, Republic of Korea;* [2]*Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Many scoring systems such as the Acute Physiologic Assessment and Chronic Health Evaluation II (APACHE II) and the Sequential Organ Failure Assessment (SOFA) have been used in predicting outcomes in patients admitted to the intensive care unit (ICU), but these original systems show poor predictability in the subset of patients undergoing continuous renal replacement therapy (CRRT). Accordingly, this study developed the machine learning model to improve the predictability in this subset.

Methods: 1,571 adult patients undergoing CRRT were reviewed from 2010 to 2016 years: 70% and 30% of patients were randomly assigned into training and testing set. The primary outcome was mortality in the ICU or hospital admission. To develop the machine learning model, several algorithms were used. (logistic regression, linear discriminant analysis, κ-nearest neighbors, support vector machine, multivariate adaptive regression spline, random forest, extreme gradient boosting and neural networks model) Area under the receiver operating characteristic curves (AUCs) from original scoring systems and the machine learning models were compared using the DeLong test.

Results: Among the machine learning models for ICU mortality, the linear support vector machine showed the highest AUC (0.733), and logistic regression and linear discriminant analysis were the second (0.730 in both). The AUCs of APACHE II and SOFA scores were 0.611 and 0.677, respectively. The support vector machine showed greater predictability than the original systems (*Ps*<0.05). The machine learning models for in-hospital mortality had a similar trend.

Conclusions: Machine learning models show a better performance in predicting mortality of CRRT patients than the original scoring systems. Accordingly, incorporating the machine learning-based mortality-prediction may be needed when starting CRRT.

Inpatient Kidney Function Recovery Among Septic Shock Patients Who Initiated Hemodialysis in the Hospital

Joy C. Chen, Bo Hu, Ryan Frank, Kianoush Kashani. *Mayo Clinic, Rochester, MN.*

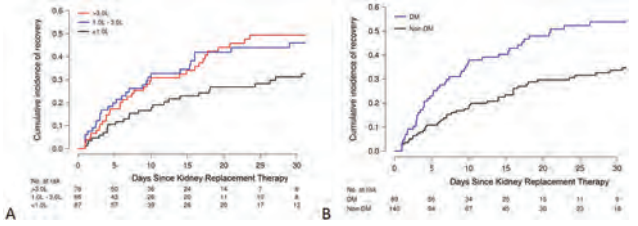
Background: Sepsis and septic shock are life-threatening causes of acute kidney injury (AKI) frequently seen and managed in the intensive care unit. Sepsis-associated AKI independently contributes to the mortality of sepsis. Understanding the potential predictors of recovery may aid in the prevention and management of sepsis-associated AKI. This study aimed to describe the clinical features of septic shock patients who required kidney replacement therapy and to examine the rate of kidney recovery and factors associated with recovery.

Methods: We conducted a retrospective cohort study using data from 229 adult septic shock patients who started in-hospital kidney replacement therapy at Mayo Clinic Rochester medical intensive care unit (MICU) from January 2006 to May 2018. Kidney recovery was defined as sufficient kidney function for stopping kidney replacement therapy prior to hospital discharge. Associations between clinical features and kidney recovery were analyzed with multivariable Fine and Gray regression accounting for death as a competing event.

Results: This cohort consisted of 229 patients with a median (IQR) age of 64 (52-74) years, 55% men, 75% Caucasian, 39% with diabetes, 16% with heart failure, APACHEIII of 105 (84-123) and SOFA of 12 (9-14). Patients received 1,567(524-4,108) mL intravenous fluid in the first 3 hours of resuscitation, 92% required vasopressor support and 83% required mechanical ventilation. The median MICU and hospital stays were 7(4-13) and 19 (10-31) days, respectively. Total kidney replacement duration was

7 (3.5-17.1) days. 41% patients discontinued dialysis prior to discharge and 38% died. Higher volume of fluid resuscitation in the first 3 hours (HR 1.07; CI 1.01-1.14; p = 0.03) and diabetes (HR 1.75; CI 1.17-2.61; p = 0.006) were associated with kidney recovery.

Conclusions: Among septic shock patients who initiated kidney replacement therapy in MICU, 41% recovered kidney function prior to hospital discharge. A higher initial fluid resuscitation volume was associated with recovery, and interestingly, patients with diabetes had a higher chance of recovery.



Kidney recovery stratified by **A** Fluid in 1st 3 hrs; **B** Diabetes

FR-PO057

Clinical Usefulness of Contrast-Enhanced Computed Tomography in Patients with Nonobstructive Acute Pyelonephritis-Associated AKI

In O Sun, Ju hwan Oh. *Presbyterian Medical Center, Jeonju, Korea, Jeonju, Republic of Korea.*

Background: The aim of this study is to investigate the clinical utility of contrast-enhanced computed tomography (CE-CT) in patient with non-obstrcutive acute pyelonephritis (APN).

Methods: From 2007 to 2013, 537 APN patients who underwent a CE-CT scan within 24 hours after hospital admission were enrolled. We divided these patients into greater (50% or greater involvment, n=143) and lesser (less than 50% involvement, n=394) groupsbased on renal parenchymal involvement in CE-CT examination. We compared clinical characteristics between two groups and analyzed the clinical value of CE-CT scan asa reliable marker for predicting clinical severity and disease course in patient with non-obstructive APN.

Results: The mean age of these patients was 55.2±17.9 years and 93.9% were women. The mean estimated glomerular filtration rate was 70.6±25.5 mL/min/1.73m^2. Compared with patients in lesser group, the patients in greater group had lower serum albumin levels (3.5 ± 0.5 vs 3.8± 0.6, p<0.01) and longer hosptal stay (10.1± 4.7 vs 8.8± 4.5, p<0.05). In addition, AKI (23.1% vs 11.4%, p<0.005) and bacteremia (36.4% vs 26.8%, p=0.02) were frequently developed in greater group, respectively. The overall incidence of AKI was 14.8%; of which 9.3%, 4.9% and 0.6% were classified as risk, injury and failure, respectively, according to RIFLE criteria. In a multivariate logistic regression analysis for predciting AKI, age, presence of diabetes mellitusand the presence of renal parenchymal involvement of greater than 50% in CE-CT were significant predictors of AKI.

Conclusions: The CE-CT scancould be useful to predict the clinical severity and course including AKI in non-obstructive APN patients with preserved renal function.

FR-PO058

Early High-Dose Thiamine Supplementation for Dialysis-Requiring Septic AKI: A Nationwide Inpatient Database Study

Yoshihisa Miyamoto,[1] Masao Iwagami,[4] Yoshifumi Hamasaki,[3] Masaomi Nangaku,[2] Kent Doi.[3] *[1]the University of Tokyo Hospital, Tokyo, Japan; [2]the University of Tokyo School of Medicine, Tokyo, Japan; [3]University of Tokyo, Tokyo, Japan; [4]the University of Tsukuba, Tsukuba, Japan.*

Background: Recent studies have reported that high dose thiamine supplementation potentially reduces mortality and progression of acute kidney injury (AKI). However, these studies had small sample size and the impact of thiamine is still controversial. Therefore, we investigated the association of early thiamine supplementation with mortality and short-term non-recovery from renal replacement therapy (RRT), using a propensity-score inverse probability of treatment weighting in a cohort of septic dialysis-requiring acute kidney injury.

Methods: In this retrospective observational study using the Japanese nationwide Diagnosis Procedure Combination inpatient database during a period between April 2010 and March 2017, we identified patients with septic AKI who required continuous renal replacement therapy within 2 days of admission. Patients were divided into those who received high dose (100 mg or more) thiamine supplementation within 2 days of admission (thiamine group) and those who did not (control group). We performed propensity-score inverse probability of treatment weighting to adjust for measured confounders. Primary outcome was 28-day mortality and secondary outcome included in-hospital mortality and major adverse kidney events (MAKE), which was defined as death and RRT-dependence at discharge.

Results: A total of 9,927 patients (2809 in thiamine group and 7118 in control group) were eligible. The 28-day mortality was 31.5% (884/2809) in thiamine group and 30.5% (2168/7118) in control group. After adjustment for confounders (a total of 49 covariates, including comorbidities and co-interventions by inverse probability of treatment weighting, there were no significant differences in 28-day mortality between the two groups (adjusted risk difference, 0.2%; 95% adjusted confidence interval [CI], -2.0% to 2.3%). There were no significant differences in in-hospital mortality (adjusted risk difference, 0%; -2.4% to 2.3%), in MAKE (adjusted risk difference, -0.4%; -2.8% to 2.0%), nor in RRT dependence at discharge (adjusted risk difference, -0.4%; -1.5% to 0.7%).

Conclusions: Early high dose thiamine supplementation was not associated with decrease in mortality or MAKE, in patients with septic dialysis-requiring AKI.

FR-PO059

Short-Term Dietary Restriction for Prevention of Contrast-Induced AKI in Patients at Risk Undergoing Percutaneous Coronary Angiography: A Randomized Controlled Pilot Trial

Franziska Grundmann, Roman-Ulrich Mueller, Martin R. Späth, Thomas Benzing, Volker R. Burst. *Department II of Internal Medicine and Center for Molecular Medicine Cologne, Faculty of Medicine and University Hospital Cologne, University of Cologne, Cologne, Germany.*

Background: Short-term dietary restriction (DR) has been proven effective to prevent acute organ damage from ischemic or toxic insults in animal models but clear evidence for effectiveness in humans is missing. Contrast media-induced acute kidney injury (CI-AKI) represents a leading cause of hospital-acquired acute kidney injury and both, ischemia and cytotoxic effects contribute to its pathophysiology. The objective of this trial was to determine the effectiveness of a 4-day dietary restriction for the prevention of CI-AKI in patients undergoing percutaneous coronary intervention (PCI).

Methods: Patients scheduled for PCI were randomized to receive either a formula diet containing 60% of calculated daily energy requirement (DR group, n=40) or ad-libitum food (control group, n=40) in the 4-day interval before PCI. Primary endpoint was the change of serum creatinine 48h after PCI (Δcreatinine). Further exploratory analyses included various renal function parameters, incidence of CI-AKI, and safety evaluation.

Results: With a median Δcreatinine post PCI of 0.03 (-0.15,0.14) mg/dL in the DR group vs. 0.09 (-0.03,0.22) mg/dL in the control group there was no difference in the primary endpoint (p=0.797). Subgroup analyses revealed a significant beneficial impact of DR in patients that received ≤100ml of contrast agent (DR n=26: Δcreatinine -0.03 (-0.20,0.08) mg/dL vs. control n=24: Δcreatinine 0.10 (-0.08,0.24) mg/dL; p=0.041) and in patients with ≤2 risk factors for CI-AKI (DR: n=27; Δcreatinine -0.01(-0.18,0.07) mg/dL vs. control n=31: Δcreatinine 0.09 (-0.03,0.16) mg/dl; p=0.030). Most patients in the experimental group reported a good physical condition (59.4%) with respect to DR and only 5.6% reported a profound sensation of hunger.

Conclusions: Although the primary endpoint was not met, the results of this trial suggest a beneficial impact of DR in low-to-moderate risk patients. Moreover, in this setting DR appears safe and feasible. Further investigations are needed in order to optimize DR protocols and to exploit its therapeutic potential.

Timing of Initiation of Renal Replacement Therapy in Critically Ill Patients with AKI: A Systematic Review and Meta-Analysis

Mohamad A. Kalot,[1] Yazan Aljabiri,[3] Sultan Chaudhry,[4] Nedaa Husainat,[2] Rhea Bhargava,[5] Reem Mustafa.[2] *[1]University of kansas medical center, Kansas city, MO; [2]Kansas University Medical Center, Kansas City, MO; [3]Shmaisani Hospital, Amman, Jordan; [4]McMaster University, Hamilton, ON, Canada; [5]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Acute Kidney Injury is common in critically ill patients and has been associated with increased morbidity and mortality. The timing of initiation of renal replacement therapy(RRT) has been controversial in Acute Kidney Injury with no guidelines to help physicians make this decision. We aimed to analyze the prospective randomized clinical trials (RCTs) addressing this question and synthesize the evidence to guide clinical decision making for acutely ill patients who suffer from acute renal failure (ARF).

Methods: We performed a literature search using PubMed, Embase, clinicaltrials.gov, National Kidney Foundation and American Society of Nephrology meeting abstracts for 5 years. We identified RCTs involving critically ill patients and initiation strategies for renal replacement therapy. We then performed a meta-analysis, using Review Manager version 5.3. The outcome of interest included mortality, dialysis dependence, length of stay (LOS) in the hospital and in the intensive care unit (ICU).

Results: We identified 13 randomized control trials. The pooled estimates did not show a mortality difference between “early RRT” versus “Late RRT” with a RR of 1.01 (95% CI 0.99-1.10, p=0.88). We did not find a significant difference in the dialysis dependence at 90 days with a RR of 0.77 (95% CI 0.40-1.48, p=0.44). There was a decreased ICU LOS with a mean difference of 1.52 days (95% CI 0.6-2.44, p = 0.001) and hospital LOS with a mean difference of 6.26 days (95% CI 4.97-7.56, p<0.001) in the early RRT versus late RRT. Early RRT was associated with decreased hyperkalemia with RR of 0.57 (95% Cl 0.34-0.97, p=0.04) and respiratory complications with RR of 0.86 (95% CI 0.77 – 0.97, p=0.01).

Conclusions: Early initiation of RRT in ARF in critically ill patients does not seem to alter mortality or the dependence on long term dialysis. However, it does shorten the ICU and hospital LOS, and is associated with decreased hyperkalemia and respiratory complications.

FR-PO061

Incidence and Clinical Outcomes of Outpatient Hemodialysis for AKI in a Large Dialysis Organization

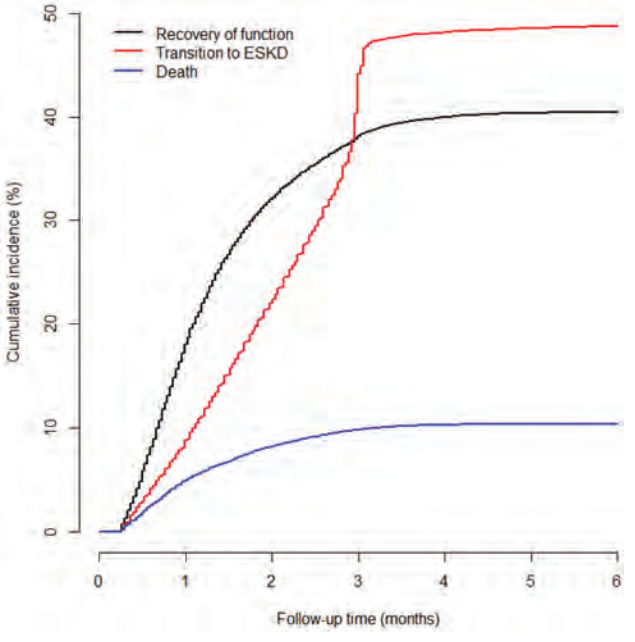
Eric D. Weinhandl,[1,2] Lorien S. Dalrymple,[1] Yuping Sun,[1] Norma J. Ofsthun,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]University of Minnesota, Minneapolis, MN.*

Background: Little is known about patients undergoing outpatient hemodialysis (OP HD) for acute kidney injury requiring dialysis (AKI-D) in the US. We examined the incidence and clinical outcomes of such patients in a large dialysis organization.

Methods: We examined patients initiating OP HD for AKI-D in a Fresenius Kidney Care (FKC) dialysis facility between May 1, 2017, and December 31, 2018; we excluded those discharged from FKC facilities within 7 days of initiation of OP HD. Patients were followed from initiation until the earliest of recovery of kidney function, transition to end-stage kidney disease (ESKD), death, or loss to follow-up (typically, transfer to another dialysis provider), with end of follow-up on March 31, 2019.

Results: The cohort comprised 15,606 patients with AKI-D; monthly counts increased from approximately 650 during mid-2017 to 850 during late 2018. Mean age was 63.6 ± 14.6 years and 41% were female. The vast majority (97%) were prescribed thrice-weekly HD, with mean session duration of 223 ± 26 minutes. During follow-up, 6028 (39%) recovered kidney function, 7104 (46%) transitioned to ESKD, and 1550 (10%) died. Cumulative incidence of these events is displayed. At 1 month after initiation of OP HD for AKI-D, 18% had recovered function, 9% had transitioned to ESKD, and 5% had died; at 3 months, percentages were 38%, 44%, and 10%. In 14,682 patients who reached any endpoint, mean (median) days between first and last OP HD sessions was 50 (45).

Conclusions: During 2017 and 2018, an increasing number of patients underwent OP HD for AKI-D in one large dialysis organization. Within 3 months after initiation of OP HD, approximately 40% of patients recovered enough kidney function to discontinue dialysis and 45% transitioned to ESKD.



FR-PO062

AKI in Renal Trauma Patients

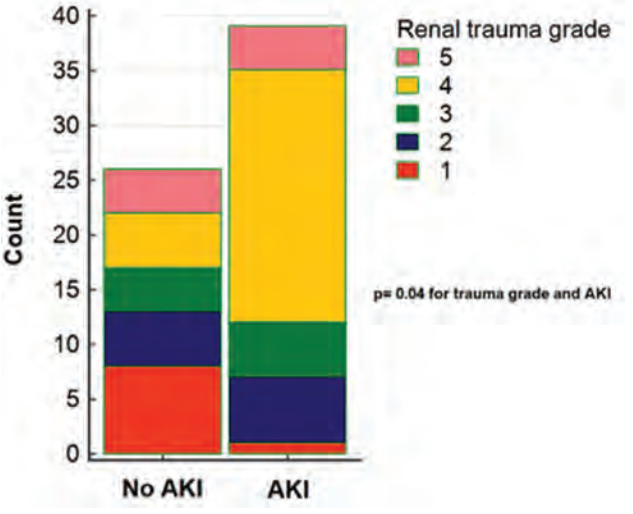
Jonathan Chavez,[1,6] Miguel A. Ibarra-Estrada,[2] Rodolfo A. Moreno,[1,6] Guillermo Garcia-Garcia,[3,6] Veronica Valdivia cerda,[4,6] Cynthia G. Cervantes,[5,6] Enrique Velarde.[5,6] *[1]Hospital Civil de Guadalajara, Guadalajara, Mexico; [2]Intensive Care Unit, Hospital Civil Fray Antonio Alcalde, Guadalajara, Mexico; [3]Hospital Civil de Guadalajara, University of Guadalajara, Zapopan, Mexico; [4]Hospital Civil de Guadalajara, La Barca, Mexico; [5]Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Mexico; [6]Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Mexico.*

Background: Kidney is the most commonly injured organ of the genitourinary system during trauma; little is known about the relationship that this event has with the incidence of acute kidney injury (AKI). In this cohort we describe the associated risk factors for the development of AKI in patients with renal trauma (RT).

Methods: In a prospective cohort, we analyzed patients with RT during 2015 to 2019 at the Hospital Civil de Guadalajara. We describe their demographic, clinical characteristics and risk factors for development of AKI with univariate and multivariate analysis.

Results: During the study period 65 patients were analyzed, sixty (92.3%) were men, mechanism of trauma was firearm in 26 (40%), transfusion was indicated in 18 (25%), and 46 (70%) required emergent surgery, nephrology was consulted in 12 (18%) cases. AKI was present in 39 (60%) patients. Creatinine and urea at hospital admission was highest in AKI group (1.56 ± 0.91mg/dL vs. 0.85 ± 0.24mg/dL, p = <0.001 and 56 ± 41mmol/L vs 34 ± 20mmol/L, p = 0.005; respectively). Nephrectomy was not different between those with 14 (35.9%) and without AKI 5 (19.2) (p=0.15), left kidney is the most affected (57%), Intestine and liver were the most common organs affected (37, 32%, respectively), there were only 4 deads, all in AKI group. RT was considered high-grade (4-5) in 37 (56.9%), which has a significant association (p = 0.04) with the incidence of AKI in the univariate analysis, but this association was lost in the multivariate analysis. We built a model for prediction of AKI with the most relevant variables: firearm injury, shock, emergent surgery, high grade RT, and liver injury (p= 0.02, AUC 0.74).

Conclusions: RT occurs mainly in young men, 60% of cases are complicated with AKI, the most significant risk factor is high grade RT. It is necessary to confirm this association in other populations and larger sample sizes.



FR-PO063

Unresolving Renal Failure After Treatment of UTI

Sukit Raksasuk, Ratana Chawanasuntorapoj, Boonyarit Cheunsuchon. *Siriraj Hospital, Bangkok, Thailand.*

Introduction: Malakoplakia is a rare granulomatous inflammation. Most of the patients had the history of previous urinary tract infection and around one-third were immunocompromised hosts. The most common pathogen is *Escherichia Coli*. Pathogenesis postulated by inadequate lysosomal enzyme in the bactericidal process of macrophages resulting in the specific histological finding of Michaelis-Gutmann bodies. Due to lack of specific radiological morphology, histological diagnosis is mandatory.

Case Description: A 46-year-old alcoholic woman has presented with prolonged fever without any specific organ symptoms after UTI treatment. Laboratory showed Hb 9.6 g% WBC 11990 cell/uL N 92% Platelet 21,000 cell/uL, Cr 6.44 mg/dL, UA: RBC 100-200/HP, WBC 30-50/HP, few bacteria. Hemoculture was *E.Coli*. After 2 weeks of ATB, she still had septic shock and high creatinine with persistent pyuria. CT scan showed rt.kidney 11x7 cm. and lt.kidney 14x10.6 cm. with heterogeneous density without demarcation of cortex and medulla. Kidney pathology showed 2/3 glomeruli infiltrated with cells described in tubulointerstitial area into Bowman space. The interstitium showed massive infiltration of cells with granular eosinophilic cytoplasm (PAS+, PASD resistant). These cells were marked with CD68, a histiocytic marker. There were a few round basophilic lamellated bodies identified as Michaelis-Gutman bodies. AFB and GMS stains were negative. She was continuing antibiotic and surgical drainage of pus. Due to oliguric AKI with pulmonary edema, she was transiently done hemodialysis. Her clinical was improved and kidney function was recovery with 6 weeks of ATB.

Discussion: Un-resolving renal failure and persistent pyuria after proper antibiotic treatment of UTI in immunocompromised host (alcoholism) with *E.Coli* sepsis and enlarged heterogeneity kidney introduced the differential diagnosis of complication of UTI such as abscess, malakoplakia, and xanthogranulomatous pyelonephritis or otherwise kidney mass. Due to unexplained cause of kidney injury in our patient, kidney biopsy should be considered. Typical Michaelis-Gutmann bodies in cytoplasm of histiocyte were found. Treatment of renal malakoplakia is prolonged ATB and surgical drainage or resection depend on the severity of kidney damage. Therefore, promptly diagnosis and proper treatment are essential to keep the kidney tissues and function in renal malakoplakia.

FR-PO064

Postoperative AKI in Noncardiac Surgery and Long-Term Renal Outcome

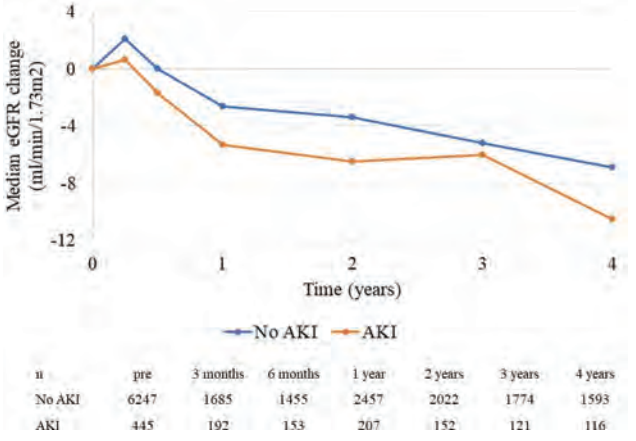
Miho Tagawa,[1] Masatoshi Nishimoto,[1] Maiko Kokubu,[3] Takayuki Hamano,[2] Masaru Matsui,[3] Masahiro Eriguchi,[1] Ken-ichi Samejima,[4] Yasuhiro Akai,[1] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Nara, Japan; [2]Osaka University Graduate School of Medicine, Suita, Japan; [3]Nara Prefecture General Medical Center, Nara, Japan; [4]First Department of Internal Medicine, Nara Medical University, Kashihara, Japan.*

Background: It is well known that acute kidney injury (AKI) is an independent predictor of long-term renal dysfunction. As a result, the KDIGO guideline recommended evaluation of renal function 3 months after AKI. However, there has been no data to support the recommendation.

Methods: This is a retrospective cohort study on adult patients who underwent non-cardiac surgery under general anesthesia from 2007 to 2011 at Nara Medical University. Exclusion criteria were pre-operative dialysis, urologic, obstetric surgery, or missing creatinine levels pre- and post-operatively. Postoperative AKI (within 1 week from surgery) was determined by the KDIGO criteria. Association between AKI and renal outcome (development of end-stage renal disease or doubling of creatinine) was analyzed using Cox regression and time course of renal function between those with and without AKI was compared by a mixed effects model.

Results: Among 6,692 patients, 445 developed AKI. During a median follow-up of 1.4 years, 493 renal outcomes were observed. Postoperative AKI was an independent predictor of the renal outcome (adjusted HR 3.18 [2.38-4.25]). Decline of estimated glomerular filtration rate (eGFR) was faster among those with AKI (p=0.001). The eGFR decline started at 6 months postoperatively. Even when analysis was limited to those with eGFR≥60 at baseline and 3 months, AKI was significantly associated with development of incident chronic kidney disease (eGFR<60) (HR 1.81 [1.09-3.03]).

Conclusions: AKI after non-cardiac surgery was an independent predictor of renal outcomes. Decline in renal function was more prominent more than 6 months after AKI. Those with preserved renal function at 3 months after AKI have higher risk of progressive renal dysfunction compared with those without AKI. Longer follow-up than KDIGO recommendation is necessary.



ti	pre	3 months	6 months	1 year	2 years	3 years	4 years

Quality of Life and Long-Term Survival After Persistent AKI in Sepsis Patients

Tezcan Ozrazgat-Baslanti,[1] Tyler J. Loftus,[2] Scott Brakenridge,[1] Babette A. Brumback,[1] Philip A. Efron,[1] Anna Gardner,[1] Frederick A. Moore,[1] Lyle L. Moldawer,[1] Mark S. Segal,[1] Azra Bihorac.[1] *[1]University of Florida, Gainesville, FL; [2]University of Florida Health, Gainesville, FL.*

Background: Acute kidney injury (AKI) is one of the most common complications among hospitalized patients. It is important to consider the duration of renal recovery in order to characterize the natural history of this complex condition and its effect on kidney health and long term functional status. We have determined the epidemiology of persistent AKI and its effect on long-term functional status and survival in sepsis patients.

Methods: In the prospective observational study of 245 sepsis patients, AKI types were adjudicated using KDIGO criteria and ADQI recommendations. In contrast to rapidly reversed AKI, persistent AKI is characterized by the persistence of KDIGO creatinine beyond 48 hours of the onset. The Zubrod Scale has been used to measure and compare the performance status of a patient's ambulatory nature and Zubrod score of 0 indicated that patients were fully active. One-year survival was compared using log-rank test and Cox proportional hazards model was fit to examine association between AKI type and long-term mortality.

Results: Two percent (6/245) had preexisting end-stage renal disease (ESRD) and 15% (36/245) had pre-existing chronic kidney disease (CKD). Sixty-two percent of the study population developed AKI. Only one third of AKI episodes rapidly reversed within 48 hours and had sustained renal recovery at discharge while the remaining 68% had persistent AKI. Prevalence of 1 year mortality in patients with persistent AKI (44%) was significantly higher than patients with rapidly reversed AKI (11%) and patients who did not develop AKI (9%). Percentage of those who were fully active and able to carry out activities without restrictions at 1 year of sepsis onset were only 8% among for patients with persistent AKI, whereas it was 29% for both patients who had rapidly reversed AKI and those who did not develop AKI. Hazard rate (HR) was about five-fold for persistent AKI group (HR 5.38, 95% confidence interval 2.74-11.80) compared to patients who did not develop AKI, while there was no evidence of significant difference in hazard ratios of those with rapidly reversed AKI and no AKI.

Conclusions: Among critically ill septic patients, persistent AKI is a significant risk factor for reduced functionality and increased long-term mortality.

Clinical Outcomes of Patients Admitted to the ICU with AKI in a Jordanian Tertiary Hospital

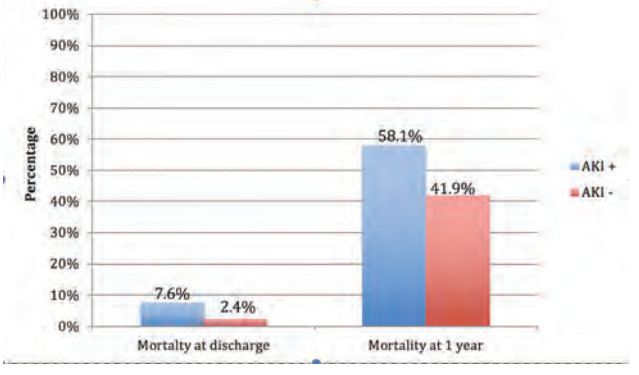
Ashraf O. Oweis,[1] Sameeha A. Alshelleh.[2] *[1]Jordan University Of Science and Technology, Amman, Jordan; [2]Internal Medicine, The University Of Jordan, Amman, Jordan.*

Background: Despite advances in medical technologies, therapeutic options, acute kidney injury (AKI) still a major contriputor of death in intesive care units (ICU) regardless of renal replacment therapy used to treat severe AKI

Methods: We retrospectively reviewed electronic patients records for all patients admitted to our ICU. We used acute kidney injury network (AKIN) classification to define and stage AKI, For continuous variables; mean, standard deviation, minimum and maximum were used, and for differences between normally distributed values we used unpaired t test. Percentages used for categorical variables. Pearson Chi- square test was used to test categorical variables. Univariate and multivariate regression analyses were performed to determine the independent predictors of AKI.

Results: We evaluated 1500 patient electronic records who were admitted to our ICU between 2014 -2015 with at least one year follow up. Using univariate analysis age was predictor of AKI, Serum albumin at admission was a strong predictor of AKI, mean serum albumin for the AKI group 30.1 g/l (SD 9.4), and 33.5 g/l (SD 8.9) for the non AKI group, P=0.001, also admission Hb predicted AKI, mean Hb for the AKI was 10.9 (SD 3.1) vs. 11.4 (SD 2.9), P=0.0004. The incidence of AKI was 35.6%, most of them were with stage1 AKI. Mean serum creatinine was 150.7 mmol/l (SD 147.7) for patients with AKI vs. 118.2 mmol/l (SD 135.3) for the other group, P=0.001. Out of the patients who developed AKI, 52.2% (82 patients) started on dialysis for different reasons (Hyperkalemia 15%, fluid overload 46.6%, combination of both 38.4%). of whom 22 patients continued dialysis as outpatients. Renal recovery (defined as return to baseline creatinine) at discharge was 17.2% (51 patients), Mortality by the time of discharge was 4.3% (62 patients).

Conclusions: AKI incidence in Jordan is comparable to worldwide incidence with significant effect on long term survival after discharge, correctable factors should be addressed to decrease incidence in the future.



FR-PO067

Three-Year Outcomes After AKI in a Prospective Cohort: Effects on CKD, Survival, and Cardiovascular Events

Isma Kazmi,[1] Rebecca A. Packington,[2] John Monaghan,[3] Nicholas M. Selby.[1,2] ARID study investigators *[1]Centre for Kidney Research and Innovation, University of Nottingham, Derby, United Kingdom; [2]Department of Renal Medicine, University Hospitals of Derby and Burton, Derby, United Kingdom; [3]Department of Clinical Biochemistry, University Hospitals of Derby and Burton, Derby, United Kingdom.*

Background: Acute Kidney Injury (AKI) is associated with adverse long-term outcomes. There is a need for prospective studies to identify those at highest risk and to improve understanding of the effect size across different outcomes and patient groups. Here we report three-year outcomes from a large prospective parallel group cohort study.

Methods: In a single UK centre, hospitalised patients who sustained AKI were recruited and matched 1:1 with controls (hospitalised patients without AKI) for age,

baseline eGFR stage and diabetes. Biochemical parameters including renal function and proteinuria were measured at 3 months, 1 year and 3 years following index hospitalisation. CKD progression was defined as ≥25% decline in eGFR with decline in eGFR stage, and a composite renal endpoint as a doubling of serum creatinine, eGFR<15ml/min or initiation of renal replacement therapy.

Results: 1125patients were recruited of whom 866 were successfully matched. There was no difference between AKI and control groups in age (71 yrs (IQR 14) vs. 71 yrs (IQR 13), p=0.7) or baseline eGFR (70.3±20ml/min vs 69.6±20ml/min, p=0.58). Two-thirds of AKI episodes were stage 1 with median duration 3 days (IQR 3). Mean eGFR was lower at all-time points in AKI group. At 3 years, eGFR was 61±20ml/min in AKI group versus 70±20ml/min in controls (p<0.001), and CKD progression occurred in 26.7% of the AKI group, as compared to 6.6% in the control group (p<0.001). The greatest odds of CKD progression rates were seen at three months, with progressive attenuation over time. Proteinuria was also more common and more severe in the AKI group at each time point. The composite renal endpoint occurred in 3% of AKI group versus 0.7% of controls (OR 4.4, 95% CI 1.3-15.7, p=0.012). Mortality rates were also significantly higher in the AKI group (15.7% versus 9.7%, p=0.008), as were heart failure events. Binary logistic regression demonstrated that presence of AKI and non-recovery by 90 days had independent associations with CKD progression.

Conclusions: AKI is associated with long term renal dysfunction, proteinuria, higher rates of ESKD and increased mortality. This is true even in a general hospitalised population in which a majority of patients had AKI stage 1. Non-recovery of renal function by 90 days is an important predictor of subsequent CKD.

FR-PO068

Comparison of Outcomes of Early vs. Delayed Renal Replacement Therapy in Critically Ill Patients: A Meta-Analysis of Randomized Controlled Trials

Ajai S. Rajabalan, Satyanarayana R. Vaidya, Niraj Karki, Jonathan J. Suarez, Jason Cobb, James L. Bailey. *Emory University School of Medicine, Atlanta, GA.*

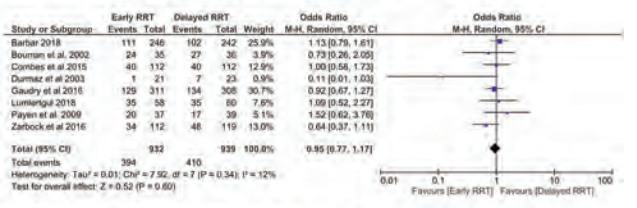
Background: The question of optimal timing of Renal Replacement Therapy (RRT) initiation in Acute Kidney Injury (AKI) remains unanswered. We collected data from available randomized controlled trials (RCTs) comparing the early RRT (ERRT) with delayed RRT (DRRT) and performed a meta-analysis of outcomes.

Methods: A literature search was done using electronic databases from Pubmed, Cochrane and Embase from inception until April 2019 for RCTs comparing early RRT with delayed RRT. The relevant data was extracted and statistical analysis was done using RevMan 5.3.

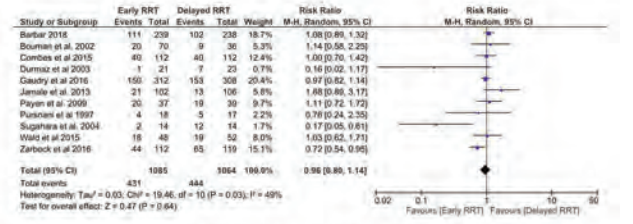
Results: A total of 12 RCTs comparing ERRT vs DRRT in patients older than 18 years were included, yielding 2267 patients of which 1143 were in early RRT group and 1124 were in delayed RRT group. Mortality at 30 days (8 RCT) [OR 0. 95, 95%CI (0. 77, 1. 17), p=0. 60, I^2 =12%] and 90 days (11 RCTs) [OR 0. 96, 95%CI (0. 80, 1. 14), p=0. 64, I^2 =49%] did not show any difference between the 2 groups. There was no significant difference between the 2 groups in dependence on RRT at 90 days (5 RCTs) [OR 0. 80, 95%CI (0. 52, 1. 23), p=0. 31, I^2 =0%] or incidence of arrythmias (5 RCTs) [OR 1. 01, 95%CI (0. 74, 1. 38), p=0. 94, I^2 =29%]. Patients in DRRT group had significantly lower rates of catheter related complications (5 RCTs) [OR 1.80, 95%CI (1.08, 3. 01), p=0. 02, I^2 =0%].

Conclusions: ERRT did not show any benefit in mortality, dependence on RRT or arrythmias. However, ERRT did show increased rates of catheter related complications. This suggests that DRRT may not offer benefits in mortality or renal outcomes, but may lead to less vascular access related complications. More data is needed to better elucidate the cause of less catheter related complications in the DRRT group.

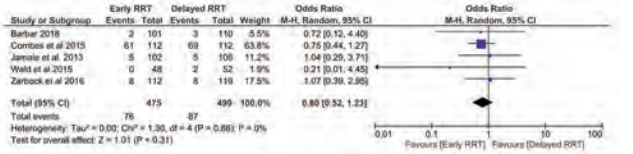
Forest plot comparing Mortality at 30 days in ERRT vs DRRT



Forest plot comparing Mortality at 90 days in ERRT vs DRRT



Forest plot comparing RRT dependence at 90 days in ERRT vs DRRT.



Forest plot comparing arrythmia in ERRT vs DRRT

FR-PO069

Myoglobin Clearance in Acute Rhabdomyolysis: Theralite and Theranova

Ilaria Godi,[3] Alessandra Brendolan,[1] Anna Lorenzin,[2] Claudio Ronco.[3] *[1]St Bortolo Hospital, Vicenza, Italy; [2]IRRIV, Vicenza, Italy; [3]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy.*

Background: Rhabdomyolysis is a cause of acute kidney injury (AKI) in a large number of cases where traumatic or non-traumatic causes induce muscle cell disruption. Although the rationale for a quick and effective removal of myoglobin in acute rhabdomyolysis would be strong and logical, the practical results obtained with extracorporeal therapies are modest. Theralite2100 and Theranova400 (Baxter) are new generation membranes designed to increase the removal of larger middle molecules like myoglobin. While Theralite takes advantage of the membrane high cut-off (HCO), the high retention onset (HRO) and internal filtration are the peculiarities of Theranova. We report a critically ill patient case to describe and compare two novel strategies for extracorporeal elimination of myoglobin in rhabdomyolysis-associated AKI with Theranova and Theralite continuous venovenous hemodialysis (CVVHD).

Methods: The treatment included 22 hours of HRO-CVVHD (Qb 200 ml/min, Qd 4000 ml/h, Quf 150 ml/h), followed by 6 hours of HCO-CVVHD (Qb200 ml/min, Qd 4000 ml/h, Quf 0 ml/h). Samples were collected from arterial, venous, and effluent lines in two timepoints: t1 (30 minutes after starting each session) and t2 (before changing hemodialyzer). Plasmatic clearance for myoglobin (K_m) was calculated at t1 and t2 to evaluate the efficiency in myoglobin removal. The intensity (K_m x hours of treatment) was estimated using the mean value of calculated K_m.

Results: During CVVHD the K_m in t1 and t2 were 37.99 and 16.88 ml/min and 66.05 and 46.68 ml/min, using HRO and HCO respectively (Fig 1). The blood volume cleared of myoglobin after the entire treatment was 36.22l and 20.29l for twenty-two hours of HRO-CRRT and six hours of HCO-CRRT, respectively (Fig 2).

Conclusions: Theralite-CVVHD guaranteed quick and efficient removal of myoglobin. Theranova-CVVHD might be considered as efficient for longer treatment and even more when an adjunctive convective mechanism is desirable, customizing the prescription on the basis of the patient clinical status.

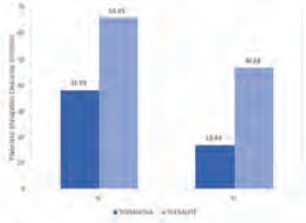

Fig 1 - Theranova (dark blue bars) and Theralite (light blue bars) efficiency in myoglobin removal.

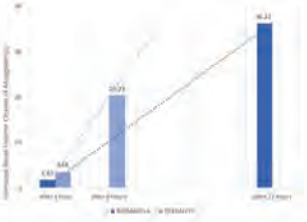

Fig 2 - Theranova (dark blue bars) and Theralite (light blue bars) intensity for myoglobin removal after 1 hour and at the end of each treatment.

FR-PO070

Standardization of a Furosemide Stress Test in the Pediatric Intensive Care Unit

Jean-Philippe Roy, Kelli A. Krallman, Ranjit S. Chima, Alexandra Schmerge, Bradley S. Gerhardt, Lin Fei, Stuart Goldstein. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Early prediction of patients (pt) at risk of severe acute kidney injury (sAKI) and need for renal replacement therapy (CRRT) in pediatric intensive care unit (PICU) is a desired strategy for early intervention. Functional assessment of tubular reserve with diuretic, furosemide stress test (FST), has been validated in acutely ill adults with promising prediction for sAKI and CRRT requirement but has not been evaluated in critically ill children.

Methods: Prospective observational study. All PICU admissions have an automated renal angina index (RAI) calculated 12h after admission. RAI positive pt (≥8, RAI+) are assessed with a urine NGAL to improve risk prediction. RAI+/NGAL+ (>150ng/mL, NGAL+) pt are assessed for the FST. The FST include a standard dose of furosemide (1mg/kg if naïve or 1.5mg/kg if exposed within 24h) and hourly urine output (OUP) monitoring 6 hours prior and after the dose administration. Increase in (iOUP) at 2 and 6h were calculated by subtracting the mean hourly UOP per kilogram using the same time length before and after administration. FST was considered positive (FST-responder) if the iOUP met a certain threshold at either one of the time marks.

Results: From 7/1/2018 to 2/28/2019, 1730 pt were admitted, 15 had a FST done, 3 (20%) of which required CRRT. Incremental hourly iOUP cutoff from 1 to 10ml/kg/h show an excellent AUC of 0.847 for CRRT prediction. 5ml/kg/h iOUP had the best Youden's J index at 0.58 but a 4ml/kg/h cutoff, with second best index, was deemed more clinically relevant due to a better specificity. At this cutoff, 2/4 (50%) FST non-responder vs 1/10 (10%) FST responder required CRRT (p=0.15) (see table).

Conclusions: FST seems applicable in acutely ill children to predict CRRT requirement but with an increase threshold of iUOP. However this prospective cohort will need more FST pt to make any definitive conclusions.

Funding: NIDDK Support

Table - CRRT need prediction with variable iOUP threshold after an FST

iOUP cutoff (ml/kg/h)	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value	Youden
1	33%	100%	100%	86%	0.33
2	33%	92%	50%	85%	0.25
3	33%	83%	33%	83%	0.17
4	67%	83%	50%	91%	0.50
5	100%	58%	38%	100%	0.58
6	100%	50%	33%	100%	0.50
7	100%	50%	33%	100%	0.50

Effect of CME on Nephrologists' Knowledge and Confidence Related to Management of Hepatorenal Syndrome Type 1

Amy Larkin,[1] Donald Blatherwick,[2] George Boutsalis,[2] Juan Carlos Q. Velez.[3] *[1]Medscape Education, Nicholasville, KY; [2]Medscape, Medford, NJ; [3]Ochsner Clinic Foundation, New Orleans, LA.*

Background: As emerging therapies hold promise to improve management of hepatorenal syndrome type 1 (HRS-1), clinicians are in need of improved understanding of these therapies and the current management of HRS. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge and confidence of nephrologist in HRS.

Methods: The online CME activity consisted of a video-based roundtable discussion with leading faculty in the area of HRS-1. The educational effects were assessed using a repeated pairs pre-assessment/post-assessment study design, where individual participants served as his/her own control. For all questions combined, the chi-squared test assessed whether there was improvement in the proportion of participants who answered questions correctly at post as compared to pre. P values <.05 are statistically significant. Cramer's V was used to calculate the effect size (0.06-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activities launched between December 4, 2018 and data were collected through February 14, 2019.

Results: Improved knowledge and confidence was demonstrated among nephrologists: Overall, the effect of the education was considerable (V=.153, P<.001, N=115) 21% demonstrated improved identification of predictors of death or renal replacement therapy in patients with liver disease and stage 3 acute kidney injury (*P*<.05, V=.139) 21% demonstrated improved related to timing of dosage adjustment of terlipressin (*P*=.0727, V=.118) 36% demonstrated improved recognition of the goal of initial vasopressor therapy in HRS-1 (*P*<.001, V=.330) 38% reported increased confidence in their ability to appropriately diagnosis HRS-1 Persistent knowledge/competence gaps remain: 46% incorrectly identified predictors of death or renal replacement therapy in patients with liver disease and stage 3 acute kidney injury 30% did not understand timing of dosage adjustment of terlipressin 23% failed to recognize of the goal of initial vasopressor therapy in HRS-1

Conclusions: This study demonstrates the success of an online, video-based CME activity on improving knowledge and confidence of nephrologists related to current and emerging treatment for HRS-1. Continued knowledge gaps were identified for future educational targets.

Implementation of Clinical Decision Support for AKI: Mixed-Methods Evaluation of Healthcare Providers' Perceptions and Experiences

Meha Bhatt,[1] Juli Finlay,[1] Megan Howarth,[2] Eleanor C. Benterud,[1] Neesh I. Pannu,[3] Matthew T. James.[1,2] *[1]Department of Medicine, University of Calgary, Calgary, AB, Canada; [2]Department of Community Health Sciences, University of Calgary, Calgary, AB, Canada; [3]Department of Medicine, University of Alberta, Edmonton, AB, Canada.*

Background: Clinical decision support (CDS) initiatives can be effective strategies for enhancing healthcare delivery and improving patient outcomes. However, such interventions for acute kidney injury (AKI) have reported variable effectiveness. Involvement of end-users in the development and implementation may help optimize accessibility and uptake of CDS systems for AKI. Evaluation of healthcare providers' experiences can inform the process.

Methods: We used a multi-phase approach involving healthcare providers, decision-makers, and implementation science experts to deploy an electronic CDS system on surgery units in Calgary, Alberta. The system consisted of: AKI stage alerts, Adverse medication alerts, AKI clinical summary display, and AKI order set. Implementation included usability testing of tools, co-development of tailored strategies for using the tools, education programs for staff, and audit and feedback of AKI quality indicators. The perceptions and experiences of end-users were evaluated using surveys and interviews; the latter were analyzed using a qualitative descriptive approach.

Results: During the initial 12 month post-implementation period, 318 AKI alerts and 48 adverse medication alerts were generated on the units. 104 clinical end-users have completed surveys and 10 have participated in interviews. Overall 88% of physicians and 98% of nursing staff stated it was important to improve AKI care on their hospital units. There was variable uptake of the specific tools with interview responses indicating that the AKI stage alerts and flagged medications were most valuable for the users. Interviews identified themes related to CDS implementation; 1) culture of increased AKI awareness, 2) credibility around communicating about AKI within an interdisciplinary team, 3) system barriers for recognition and timely AKI management.

Conclusions: End-user engagement in the process of developing and implementing CDS tools for AKI can enhance the acceptability and perceived value of tools by care providers outside the discipline of nephrology. Further strategies may be needed to address system-wide barriers to early management for AKI and to evaluate whether this degree of intensive end-user engagement enhances the impact of CDS interventions on processes of care and outcomes of AKI.

FR-PO073

Chloride-Liberal vs. Chloride-Restrictive Intravenous Fluids to Prevent Contrast-Induced AKI

Felix S. Seibert, Timm H. Westhoff. *University Hospital Marien Hospital Herne, Herne, Germany.*

Background: For decades plasma expansion by intravenous volume application constituted the central cornerstone in the prevention of contrast-induced acute kidney injury (CI-AKI) for patients with preexisting chronic kidney disease (CKD). The recent AMACING study challenged this approach and showed no benefit by isotonic saline solution. Consequently, several institutions have stopped prophylactic fluid application in CKD. Based on considerations regarding the tubuloglomerular feedback there are increasing data from intensive care and emergency room settings showing that chloride restrictive fluids might be superior to isotonic sale in the prevention of AKI.

Methods: Based on the above mentioned data, we changed our standard operating procedure for the management of CKD patients with contrast media enhanced computed tomography scans from periprocedural infusion of chloride-liberal to chloride-restrictive solutions. The present work compares the CI-AKI rates of the first n=100 CKD patients with Ringerlactat (Cl^- concentration 112 mmol/l) or Jonosteril (Cl^- concentration 110 mmol/l) to a historical cohort of 100 subjects with 0.9% saline solution as periprocedural fluid application (1l before and 1l after contrast application in each group). CI-AKI was defined as a ≥ 0.3 mg/dl increase of serum creatinine concentration from baseline to day 2-3 after radio contrast application.

Results: CI-AKI occurred in 14 subjects of the overall cohort (7%). The incidence of CI-AKI was 44% lower in those subjects receiving chloride-restrictive fluids (n=5, incidence 5%) than in those ones with isotonic saline application (n=9, incidence 9%) without reaching statistical significance (chi-squared p=0.27). In multiple logistic regression analysis, use of diuretics turned out to be an important risk factor for a periprocedural decrease of eGFR (B=-7.5). In contrast, the effects of congestive heart failure, diabetes, and use of inhibitors of the renin angiotensin system were below significance level.

Conclusions: The present analysis compares the potency of chloride-liberal vs. chloride-restrictive fluid application in the prevention of CI-AKI for the first time. It reveals a trend to a lower incidence of CI-AKI using chloride-restrictive fluid application and may thereby constitute a rationale for a sufficiently powered randomized prospective trial.

FR-PO074

The Effect of 0.9% NaCl Compared with Plasma-Lyte on Biomarkers of Kidney Damage in Patients Undergoing Primary Uncemented Hip Replacement

Ann M. Oestergaard, Frank H. Mose, Jesper N. Bech. *University Clinic in Nephrology and Hypertension, Department of Medical Research, Regional Hospital Holstebro and Aarhus University, Denmark, Holstebro, Denmark.*

Background: Isotonic saline (0.9% NaCl) induces hyperchloremic acidosis and is suspected to increase risk of acute kidney injury (AKI) and the need for renal-replacement-therapy in critically ill patients. Novel biomarkers such as neutrophil gelatinase associated lipocalin (NGAL) and kidney injury molecule-1 (KIM-1) may have potential as early indicators of AKI.

Methods: In a double-blinded, placebo-controlled study, 38 patients undergoing primary uncemented hip replacement surgery were randomized to 0,9% NaCl or Plasma-Lyte (PL). Infusion was given during surgery as 15 ml/kg the first hour and 5 ml/kg the following two hours. Urinary spot samples were collected upon admission and the day after surgery. As surgery initiated, urine was collected over the course of 4 hours. Hereafter another urine collection proceeded until the following morning. Urine was analyzed for concentrations of NGAL, KIM-1, Cl, Na, and albumin. Arterial and venous blood samples for measurements of pH and plasma electrolytes were collected as surgery was initiated, at the end of surgery and the following morning.

Results: NaCl induced an increase in P-Cl (111±2 mmol/L after NaCl and 108±3 after PL, p = 0.004) and a drop in pH (7.39±0.02 after NaCl and 7.43±0.03 after PL, p = 0.001). Urinary excretion of NGAL increased significantly in both groups (ΔNGAL: 5.5 [4.1;11.7] µg/mmol creatinine p=0.004 after NaCl vs. 5.5 [2.1;9.4] µg/mmol creatinine after PL, p<0.001). There was no difference in the increase between groups (p=0.839) Similarly, urinary excretion of KIM-1 also increased significantly in both groups (ΔKIM-1: NaCl 115.8 [74.1;156.2] ng/mmol creatinine, p<0.001 vs. PL 152.4 [120.1;307.9] ng/mmol creatinine, p<0.001). There was no difference in the increase between groups (p=0.064) eGFR decreased after surgery for both groups (116±26 ml/min after NaCl vs. 111±21 after PL, p =0.470), but no difference in response was found between groups (p=0.891).

Conclusions: A hyperchloremic acidosis was present in the group receiving isotonic saline. No difference was found between the groups in the excretion of u-NGAL and u-KIM-1 and responses to fluid infusion. However, both NGAL and KIM-1 were dramatically increased in both groups after surgery, despite no changes in eGFR. These results may indicate that surgery induced subclinical kidney damage.

Adherence to Best-Practice Guidelines in Severe AKI: A Multicenter Study

Tanima Arora,[1] Dennis G. Moledina,[1] Yu Yamamoto,[2] Aditya Biswas,[2] Kyle Carey,[3] Matthew M. Churpek,[3] Sherry Mansour,[1] Jay L. Koyner,[3] Francis P. Wilson.[1] *[1]Yale School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT; [3]University of Chicago, Chicago, IL.*

Background: In the absence of a specific therapy for acute kidney injury(AKI), consensus guidelines recommend certain supportive measures to improve patient outcomes. We quantified adherence to those measures in patients with severe AKI.

Methods: We reviewed the Kidney Disease: Improving Global Outcomes (KDIGO) guidelines for recommended diagnostic and therapeutic interventions after AKI. We quantified rates of adherence to 22 best practice measures at 3 hospitals within 2 health systems for patients with severe AKI (KDIGO stage 2 or higher).

Results: We identified 13,039 patients with severe AKI. The cohort was 52% women, 34% black and had a mean age of 63 years. Baseline creatinine ranged between 0.9-1.0mg/dl. Of this cohort, 42% were surgical patients and 62% were in the ICU. Among the 22 best practice measures, we found a low rate of discontinuation of nephrotoxic agents. Of patients on ACEi/ARBS 24 hours before AKI, 51% continued to use this drug upto 24hours after AKI. Similarly, 38% of patients were continued on Aminoglycosides and 42% on NSAIDs. We also observed inadequate maintenance of some hemodynamic metrics (61% of patients still had a mean arterial pressure <65mmHg upto 24hours post AKI) in patients with severe AKI (**Figure**).

Conclusions: We noted a low rate of adherence to certain best practice measures, particularly a failure to discontinue nephrotoxic agents in patients with severe AKI. Future research could attempt to improve adherence to best practice guidelines using electronic health record-based alerts.

A Simplified, Weight-Based CVVHDF-RCA Prescribing Algorithm That Works Regardless of Citrate Metabolism Is Verified in Ex Vivo Simulations

Balazs Szamosfalvi, Lenar T. Yessayan. *University of Michigan, Ann Arbor, MI.*

Background: In practice great variations in CRRT-RCA protocols exist with many centers avoiding RCA in severe shock and liver failure patients and most small intensive care units avoiding RCA completely. Complications of hypocalcemia and hypercalcemia, hypo- or hypernatremia, and metabolic- alkalosis or acidosis are reported with most protocols. We present a new, simplified approach to CRRT-RCA prescribing and demonstrate in an ex vivo simulation system devoid of citrate metabolism that all electrolyte complications due to CRRT-RCA can be avoided by careful protocol design.

Methods: We used a recently FDA-approved CRRT system to deliver CVVHDF-RCA in an ex vivo system (Figure 1). IV pumps delivered infusions of urea/creatinine, ACDA and calcium. PRBCs and plasma filled the CRRT circuit and reservoir to target Hct. We tested QB 20, 40, 60 ml/min and Hct 45, 33, 21. Commercial 140Na, 4K, 35HCO3, 1.5Mg, 0Ca, 5.5mMGlu CRRT fluid spiked to phosphate 4.2 mg/dL (1.5 mM) was used. A 136 mM CaCl2 solution was prepared in 0.9% saline. Dosing weight (DW) = round(weight)+10 if patient weight (Kg) <100 otherwise round (weight)+20 (kg). QB (ml/min) = 0.5 * DW. ACDA (ml/h) = 2.5* QB, QDialysate (ml/h) = 30 * QB, QReplacement (ml/h) = 10 * QB and QCa (ml/h) about 0.7 * QB and Qurea (ml/h) = QB. Blood and fluid samples were collected and analyzed by I-stat and in the laboratory.

Results: We had no CRRT alarms. The reservoir iCa was 1-1.3 mM. All circuit iCa was < 0.25 mM. Reservoir Na was 135-140 and other major electrolytes were at physiologic values. Single pass citrate removal was 80-90%. Effluent dose was 25-35 ml/kg/hour.

Conclusions: We showed that a simple approach to CVVHDF-RCA prescribing using commercially available equipment achieved target effluent dose, below 0.25 iCa in the CRRT circuit and normal iCa and systemic electrolytes in the patient without any concern for citrate metabolism.

Design of the 1128-CL-0201 Study: A Phase 2 Proof of Concept, Double-Blind, Randomized, Placebo-Controlled Study of ASP1128 in Patients at Risk for AKI After Cardiac Surgery

Olivier Van till,[1] Ronny Renfurm,[2] George Mulligan,[5] Effie Tozzo,[3] Chisato Kameoka,[1] Bruce A. Molitoris,[6] Andrew Shaw,[8] Daniel Engelman,[7] John A. Kellum.[4] *[1]Astellas Pharma Inc., Tokyo, Japan; [2]none, Rotterdam, Netherlands; [3]Mitobridge, an Astellas company, Cambridge, MA; [4]University of Pittsburgh, Pittsburgh, PA; [5]Mitobridge Inc., Cambridge, MA; [6]Indiana University School of Medicine, Indianapolis, IN; [7]Baystate Medical Center, Springfield, MA; [8]University of Alberta, Edmonton, AB, Canada.*

Background: AKI occurs in approximately 20-30% of cardiac surgery patients, but can reach 70% in high risk or biomarker-defined populations. No treatments are approved to treat AKI. ASP1128 is a peripherally active selective modulator of PPARd that improves metabolic and mitochondrial function. In AKI animal models, ASP1128 ameliorated renal function, histopathology, and injury biomarkers. It was shown to be safe in healthy human volunteers.

Methods: This is a randomized, double-blind, placebo-controlled, proof-of-concept, phase IIa study, to be conducted in patients at risk for AKI following cardiac surgery. A maximum of 220 patients will be randomized at ~40 sites in North America. The study comprises three parts: 1) pre-surgery screening period, 2) CABG and/or valve surgery, and 3) post-surgery double-blind treatment period with a 90-day follow-up. To evaluate patient outcomes, patients with moderate/severe risk of AKI (based on urinary biomarkers TIMP-2/IGFBP-7) at 2-6 hours post-surgery will be randomized, while the biomarker negative patients will be followed-up as an observational standard-of-care cohort. Randomized patients will receive ASP1128 (n=110) or matching placebo (n=110) IV once daily for 3 days. Primary end point: %patients developing AKI based on KDIGO serum creatinine criteria within 72 hours post-surgery. Secondary endpoints include AKI rate based upon all KDIGO criteria and within 7 days, as well as Major Adverse Kidney Events (defined as all-cause mortality, renal replacement therapy, and/or ≥ 25% sustained reduction in eGFR) within 30 and 90 days. **Ethics**: This study is approved by the relevant institutional review boards/independent ethics committees and conducted in accordance with the Declaration of Helsinki, guidelines of Good Clinical Practice, Code of Federal Regulations and all other applicable regulations. Trial registration: NCT03941483.

Results: Study results are expected in the second half of 2020.

Conclusions: The Aim of this study is to develop a short-term early intervention treatment for AKI to improve patient outcomes following cardiac surgery. The study will provide insight into the role of mitochondrial injury and fatty-acid oxygenation in propagating AKI.

Clinical Efficacy of Intraoperative Hemodialysis During Open-Heart Surgery with CKD Stage G4 and G5

Takahiro Inoue,[1] Hiroshi Kuji,[1] Kanako Nagaoka,[1] Takafumi Akanuma,[1] Munakata Yu,[2] Yoshihiko Watanabe,[2] Junko Fukuda,[1] Mamiko Ohara,[1] Tomo Suzuki.[1] Department of Nephrology, Kameda Medical Center *[1]Kameda Medical Center, Kamogawa, Japan; [2]Munakata Clinic, Chiba, Japan.*

Background: Severe acute kidney injury after cardiac surgery frequently requires renal replacement therapy (RRT) and moreover increases mortality rates and a prolonged length of hospital stay. Recently, we performed intraoperative hemodialysis (IHD) during open-heart surgery for the patients with chronic kidney disease (CKD) to prevent postoperative RRT. However, the clinical implication is unclear, therefore we investigated the efficacy of IHD.

Methods: This is a single-center cohort study with patients undergoing non-emergency cardiac surgeries between Jan, 2008 to Dec, 2018 in our hospital. The subjects were 61 patients classified as CKD G4 or G5 without chronic dialysis and post-transplant. Until Aug 2013, patients underwent surgery without IHD. Since Sep, 2013, patients were dialyzed intraoperatively. We evaluated the efficacy of IHD, comparing an IHD group (IHD) with a non IHD group (non-IHD).

Results: Comparing IHD and non-IHD, the patient number was 19 vs. 28 (CKD G4) and 9 vs. 5 (CKD G5). Preoperative eGFR (CKD G4) was 19.1±5.6 vs. 22.0±5.2 mL/min/1.73m^2 (p = 0.039), and 19.1±5.6 vs. 22.0±5.2 (CKD G5). Diabetic mellitus accounted for 35.7% vs. 42.4% (P=0.384), and operative duration 331±99 vs. 295±65 min (p = 0.16). Clinical characteristics and preoperative renal function were similar between two groups. Ninety-day mortality, hospital days, duration of postoperative intubation, renal function at discharge were not significantly different between IHD and non-IHD. Regarding CKD G4, the rate of RRT within 30 days after surgery (30-day RRT) was significant lower in IHD.

Conclusions: IHD had lower incidence of 30-day RRT than non-IHD in patients with CKD G4 prior to surgery.

Clinical features and Outcome between IHD group and non IHD group

patients undergoing cardiac surgery (N = 61)	IHD (N=28)	non IHD (N=33)	P value
Age, years	74.5±7.0	72.9±9.4	0.744
Male, n, %	17(60.7)	16(50.3)	0.339
Preoperative eGFR, G4 ml/min/1.73m2.	22.2±3.7	23.8±3.2	0.123
G5 ml/min/1.73m2	19.1±5.6	22.0±5.2	0.663

Glucose, Citrate, Calcium, Na, HCO3-, and Phosphate Mass Balance Studies in Ex Vivo Simulations of a Simplified CVVHDF-RCA Protocol That Works Regardless of Citrate Metabolism

Lenar T. Yessayan, Balazs Szamosfalvi. *University of Michigan, Ann Arbor, MI.*

Background: We developed a new, simplified approach to CRRT-RCA prescribing with commercially available equipment and CRRT fluids. It is important to study the mass balance of glucose (Glu), citrate, Ca, Na, HCO3-, and phosphate in an ex vivo system to demonstrate that a new CRRT protocol will approximate physiologic values of these solutes in the patient even in the absence of citrate metabolism.

Methods: We used a recently FDA-approved CRRT machine to deliver CVVHDF-RCA in an ex vivo system (Figure 1). IV pumps delivered infusions of urea/creatinine, ACDA and calcium. Human PRBCs and plasma filled the CRRT circuit and reservoir to target Hct. Commercial CRRT fluids were spiked to 139 or 140Na, 4K, 35HCO3, 1.5Mg, 0Ca, 1.5mMPhos with 0 or 5.5mMGlu. A 136 mM CaCl2 solution in D50.9% or 0.9% saline was paired with 0 or 5.5mM Glu CRRT fluid, respectively. We tested QB 20, 40, 60 ml/min and Hct 45, 33, 21. ACDA (ml/h) = 2.5* QB, QDialysate (ml/h) = 30 * QB, QReplacement (ml/h) = 10 * QB, QCa (ml/h) about 0.7 * QB and Qurea (ml/h) = QB. Blood and fluid samples were collected and analyzed by I-Stat point-of-care device and in the laboratory.

Results: The reservoir iCa was 1-1.3 mM. All circuit iCa was < 0.25 mM. Reservoir Na was 135-140 and other major electrolytes were around physiologic values. The reservoir glucose remained in the 70-150 mg/dL range with either CRRT fluid/Ca-infusion pair and glucose dialysance was 80-90% of CRRT circuit plasma flow. Single pass citrate removal on the filter was 80-90% and clinically significant citrate accumulation in the reservoir was avoided.

Conclusions: Ex vivo simulation suggests that the new CVVHDF-RCA protocol will approximate normal systemic solute levels without citrate metabolism. I-stat bedside glucose dialysance may be used in a clinical study to indirectly monitor plasma citrate- and Ca-clearance.

Crossover Study Comparing Bioavailability of Captisol-Enabled (CE) Iohexol Injection with Reference Iohexol Injection in Healthy Subjects

Keith Marschke,[1] Vincent Antle,[1] Eric G. Vajda,[1] Lin Zhi,[1] Daniel Cushing,[2] James Pipkin.[1] *[1]Ligand Pharmaceuticals Incorporated, San Diego, CA; [2]Medical and Regulatory Affairs, Phoenixville, PA.*

Background: Iodinated contrast agents may place patients with certain risk factors at an increased risk for acute kidney injury during cardiac imaging procedures.[1] Studies in renally-compromised mice and rats demonstrated that the addition of sulfobutylether β-cyclodextrin (Captisol®) to a clinically administered dose of Iohexol significantly reduced renal pathology scores, and increased survival in rats from 50% to 88%.[2] A Phase 1, single-center, randomized, double-blind, two-period crossover study was conducted to determine relative bioavailability of CE-Iohexol and a reference Iohexol injection (OMNIPAQUE™) after intravenous (IV) administration in healthy adults.

Methods: A total of 24 subjects were enrolled in the study as 2 groups of 12 subjects in 2 treatment periods. Subjects received each of the following treatments as a single IV dose (80 mL infused over 20 seconds): CE-Iohexol -755 mg/mL iohexol (350 mgI/mL)/50 mg CAPTISOL/mL; OMNIPAQUE - 755 mg/mL iohexol (350 mgI/mL). Serial blood samples were collected for Iohexol plasma concentration determination, and safety was assessed during the 48 hours following each dose. Subjects were discharged on day 3.

Results: 22 subjects completed the study; 2 subjects were withdrawn for technical reasons. Bioequivalence was demonstrated by calculation of geometric mean ratios (GMR) between CE-Iohexol and OMNIPAQUE for key pharmacokinetic parameters. GMR of the area under the concentration-time curve for time 0-infinity ($AUC_{0\text{-}inf}$) was 1.00 (90% confidence interval [CI], 0.98-1.02). GMR of the maximum concentration (C_{max}) was 1.00 (90% CI, 0.95-1.06). Other PK parameters, including time to maximum observed concentration (T_{max}), half-life ($t_{½}$) and elimination rate constant (K_{el}) were similar between treatments. All treatment-emergent adverse events during the study were mild to moderate in severity. No subject had a serious adverse event or discontinued from the study due to an adverse event.

Conclusions: The observed PK profile supports clinical development of CE-Iohexol as a next-generation contrast agent with a reduced risk of renal toxicity (NCT03869983).

FR-PO081

Membrane Therapeutic Plasma Exchange (mTPE) with Citrate Regional Anticoagulation: A Single-Center Experience

Priscila Dias goncalves,[1] Thiago A. Reis,[2] Geraldo R. Freitas.[3] *[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]CDRB - Clinica de Doencas Renais de Brasilia, Brasilia, DF., Brazil; [3]USP, Brasilia, Brazil.*

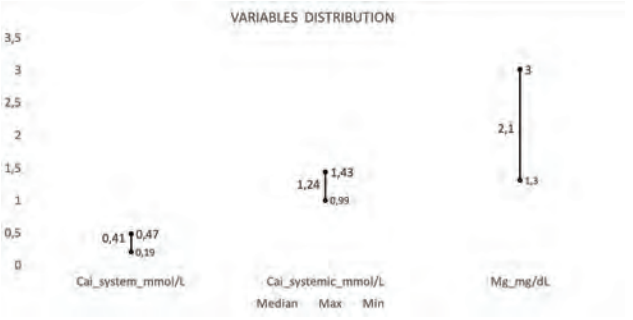
Background: Membrane Therapeutic Plasma Exchange (mTPE) is an extracorporeal blood therapy that uses convection through pressure applied upon a semi permeable membrane to remove from plasma elements such as antibodies, cytokines, lipids and viral particles. Usually, the anti coagulation method utilized is systemic unfractionated heparin (UFH). Coagulation components loss in mTPE in association with UFH enhances bleeding risk. Considering that risk, our center proposed the use of regional citrate anticoagulation as a safe option in patients undergoing mTPE. Below, we describe 12 sequential sessions performed using our citrate protocol.

Methods: mTPe was performed on the PrismaFlex with TPE 2000 membrane. We used 4% Sodium Citrate with a target concentration of 3mmol/L of treated blood. We delivered 10% Calcium gluconate to the patient at 3+-0.1mmol/L of effluent flow. A Solution 5% Albumin plus 10% Magnesium sulfate (1mmol/L) was used as replacement fluid. Within 2 hours of treatment we measured ionized calcium in the extracorporeal circuit, systemic ionized calcium and systemic magnesium.

Results: No changes were observed on serum concentrations of magnesium in all treatments. Median systemic ionized calcium concentration was 1,24mmol/L. No symptoms of hypocalcemia, arrhythmias or bleeding were reported. Median ionized calcium in the extracorporeal circuit was 0,36mmol/L. No sessions were interrupted due to system clotting. The median time of therapies was 170 minutes with similar costs to our center.

Conclusions: mTPE using regional citrate anticoagulation can be used by the nephrologist to provide a safe and cost effective option of plasma exchange. This modality of anticoagulation is an option for patients at risk or with active bleeding.

Funding: Private Foundation Support



Variables of distribution : ionized calcium in the extracorporeal circuit, systemic ionized calcium and systemic magnesium.

FR-PO082

Effect of Remote Ischemic Preconditioning to Prevent AKI in CKD Patients Undergoing Contrast-Enhanced Computed Tomography: A Randomized Controlled Trial

Pruedtinart Goyadoolya, Bancha Satirapoj, Pamila Tasanavipas, Narittaya Varothai, Theerasak Tangwonglert, Naowanit Nata, Ouppatham Supasyndh, Amnart Chaiprasert. *Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Chronic kidney disease (CKD) is an important risk factor of contrast-induced acute kidney injury (CI-AKI). Remote ischemic preconditioning (RIPC); transient ischemia followed by reperfusion of the extremity may subsequently protect against ischemia-induced injury in the other organs. Whether RIPC can prevent CI-AKI after contrast-enhanced computed tomography (CT) is not known.

Methods: We conducted a randomized controlled trial in CKD patients, glomerular infiltration rate (GFR) less than 60 mL/min/1.73m^2, whom underwent contrast-enhanced CT during July 2018 to January 2019 at Phramongkutklao Hospital. All patients received standard protocol to prevent CI-AKI. Patients were allocated in 1:1 ratio to receive RIPC or not (control) by using block of 4 randomization. RIPC consistsof 4 cycles of 5 minutes of cuff to induce arm ischemia with 5 minutes of reperfusionbefore undergoing contrast-enhanced CT. All patients were closely monitored for possible complications.

Results: A total of 70 CKD patients (35 in the RIPC group, 35 in the control group) were enrolled. Mean age was 73.6±9.9 years and baseline GFR was 45.3±12.2 mL/min/1.73m^2. Forty-two (60%) patients were male. The incidence of CI-AKI is lower in the RIPCgroup than the control group (8.57% vs 0%), p-value=0.07. Changes of serum creatinine from baseline to 48-hour and from 24-hour to 48-hour were better in the RIPC group than the control group; -0.09 ±0.16 vs -0.02±0.20 mg/dL, p-value=0.13 and 0.00±0.12 vs 0.08±0.17 mg/dL, p-value = 0.03, respectively. Change of GFR from 24-hour to 48-hour was also better in the RIPC group than the control group; -0.0±5.4 vs -2.4±6.3 mL/min/1.73m^2. In the RIPC group, 25 (71.4%) patients had local numbness. Eighteen (51.4%) patients experienced armpain, mean pain score 3.1±1.2 out of 10, which immediately resolved after the procedure. No serious complication was observed.

Conclusions: RIPC may decrease the risk of CI-AKI in CKD patient undergoing contrast-enhanced CT, without any serious side effect.

FR-PO083

Mind the Gap: Achieving Less Than Prescribed Net Ultrafiltration with CRRT Associates with Mortality

Paul M. Adams,[1] Madison K. Sands,[2] Victor M. Ortiz-Soriano,[1] Bhavya Kothari,[1] Stuart Goldstein,[3] Javier A. Neyra.[4] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky College of Medicine, Lexington, KY; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]University of Kentucky Medical Center, Lexington, KY.*

Background: Management of fluid overload (FO) via ultrafiltration (UF) is an important goal of continuous renal replacement therapy (CRRT). Clinicians carefully assess volume status, recommending individualized UF goals. Unfortunately, UF goals are not always met, which may worsen FO. As FO is associated with poor outcomes, we hypothesize that failing to achieve UF goals will also be detrimental.

Methods: Prospective cohort study of 656 ICU adult patients requiring CRRT admitted to the University of Kentucky Hospital from 08/2017 to 04/2019. We excluded

anyone missing UF data or with a mean net UF goal less than 500 mL/day. We calculated the mean percentage of achieved net UF from the prescribed net UF and the net fluid balance throughout the time on CRRT (UF_{net} goal achieved). Using Cox regression models adjusting for relevant confounders, we evaluated the association between UF_{net} goal achieved and hospital mortality.

Results: Mean age (SD) was 63.6 (25.6) years, 60% were male and 91% white. 536 (81.7%) patients required CRRT for AKI with the remainder being ESKD. Median [IQR] Charlson score was 5 [2-7] and SOFA at CRRT initiation was 13 [11-16]. Median time on CRRT was 5 [3-9] days. Hospital mortality rate was 59.5%. Time from ICU admission to CRRT initiation and prescribed net UF were not different between survivors and non-survivors. However, total fluid removal rate (ml/kg/day) was higher in survivors vs non-survivors (median 27 vs 21, p<0.001) while FO% per CRRT day was lower in survivors vs non-survivors (median -0.5% vs 0.6%, p<0.001). UF_{net} goal achieved was higher in survivors vs non-survivors (median, IQR: 44%, -40 to 83 vs 4.3%, -115 to 54, p<0.001). In fully adjusted models, every unit decrease in UF_{net} goal achieved was independently associated with hospital mortality (HR, 95% CI: 1.003, 1.001-1.006, p=0.018).

Conclusions: Our study examined UF_{net} goal achievement, a CRRT deliverable that requires closer attention. We found that UF_{net} goal underachievement was independently associated with higher mortality. Our study reinforces the value of optimizing fluid management with CRRT. Future work should focus on closing this net UF prescribed vs achieved gap by developing better tools for assessing UF goals and monitoring patient response to fluid removal.

FR-PO084

Fluid Overload, AKI, and Mortality in Influenza Patients: Our Two-Year Experience

Luis I. Bonilla,[1] Raymundo Vera,[4] Claudio Ronco,[2] Lilia M. Rizo Topete.[3] *[1]IRRIV, Renal Research Institute of Vicenza, Vicenza, Italy; [2]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy; [3]Hospital Universitario, UANL, Monterrey, Mexico; [4]Hospital Universitario, Monterrey, Mexico.*

Background: Influenza virus, especially A(H1N1) has been associated with high mortality in critically ill patients who develop Acute Distress Respiratory Sydrome (ADRS). ARDS is considered as a septic condition and one of the cornerstones for its treatment is an adequate fluid resuscitation. Fluid overload (FO) is now a recognized as a cause of acute kidney injury (AKI), and its association with mortality in critically ill patients has been well documented. The impact of FO in mortality of ARDS influenza patients has not been well described

Methods: This is a retrospective 2-year study of patients admitted to the ICU with ARDS and suspicion of influenza infection during the Influenza seasons 2016-2017 and 2017-2018. Demographic, laboratory, and clinical data were obtained. We calculated FO as the algebraic sum of the inputs and outputs during the ICU stay divided by the patient's weight at admission and expressed as a %. We divided patients in grouo: A) < 10% FO and B) > 10% FO and compared mortality and AKI incidence among both groups

Results: 40 records met the inclusion criteria. Mean age in our cohort was 43.5yrs, 60% were male. Influenza was confirmed in 55% of the patients; 22.7% with A(H1N1). Mortality among A(H1N1) patients was 100%. AKI was diagnosed in 24 patients (60%) with 12.5%, 7.5% and 40% of KDIGO stages 1-3 respectively. RRT was initiated in 13 (32%) of AKI patients. Among groups A and B AKI was diagnosed in 52% and 73% of patients respectively p=0.182. ICU mortality was 55% among the whole cohort. Median fluid balance (FB) among survivors was +3,813ml (2,131-7,284) and among non-survivors +8,370ml (4,477-16,502) p=0.008. Mortality in group A was 40% and in group B 80% p=0.014. The OR for AKI development in group B was 2.53 (CI 95% 0.634-10.166) p=0.182, and for mortality was 6.0, (CI 95% 1.34-26.8), p= 0.014

Conclusions: In our two-year retrospective study of ARDS patients, FO >10% was significantly associated with increasing incidence of AKI and mortality. Ah1N1 diagnosis involved 100% mortality. With these findings, we can strongly recommend a conservative fluid strategy in the treatment of this kind of patients. And we can advise to implement strategies to maintain the fluid gain in less than 10% of the initial patient's weight. More studies with bigger cohorts are needed to clearly demonstrate these associations

FR-PO085

Laparoscopic Gastrectomy Lowers Postoperative AKI in Stomach Cancer Patients: A Propensity Score Analysis

Ji Young Ryu,[1] Kipyo Kim,[1] Ho Jun Chin,[1,2] Ki Young Na,[1,2] Dong-Wan Chae,[1,2] Sejoong Kim.[1,2] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Acute kidney injury (AKI) is a common and morbid complication in the surgical patient, but there are insufficient reports on AKI after abdominal surgery. Thus, we compared the renal outcomes, including AKI, of stomach cancer patients who underwent laparoscopic surgery (LS) and open surgery (OS).

Methods: We conducted a retrospective cohort study of 6603 patients who underwent stomach cancer surgery between 2003 and 2017. Postoperative AKI was determined according to the serum creatinine criteria of the Kidney Disease: Improving Global Outcomes classification.

Results: Of the 6603 patients, 5190 patients (78.6%) underwent LS and 1413 patients (21.4%) underwent OS. The incidence of postoperative AKI in LS group was significantly lower than in OS group (2.9% vs. 7.8%, respectively, p < 0.001). After matching propensity scores (1:1), 714 patients were included in each group. Cox proportional hazard models adjusted for age, sex, smoking, BMI, American Society of Anesthesiologists (ASA) score, tumor size, preoperative hemoglobin (Hb), and cancer stage in entire cohort revealed that the LS group had lower incidence of postoperative AKI than the OS group (HR, 0.545; 95% CI, 0.400-0.742; p < 0.001, respectively). The effects were also consistent in matched cohort (HR, 0.527; 95% CI, 0.333-0.834; p=0.006). But, there was no significant difference in the risk of 1 year survival after surgery between groups in matched cohort (HR, 0.836; 95% CI, 0.413-1.697; p=0.618). Its reduction in risk for postoperative AKI in the LS group was also consistent with subgroup analysis including all groups of age, sex and BMI. And, the effect of reducing the incidence of postoperative AKI in the LS group was remarkable in the lower preoperative Hb, ASA score, and cancer stage.

Conclusions: Our findings suggest that postoperative AKI with stomach cancer after gastrectomy has been attenuated in the LS group, especially in the subgroup including low ASA score, low hemoglobin, small tumor size, low grade cancer stage and smoking.

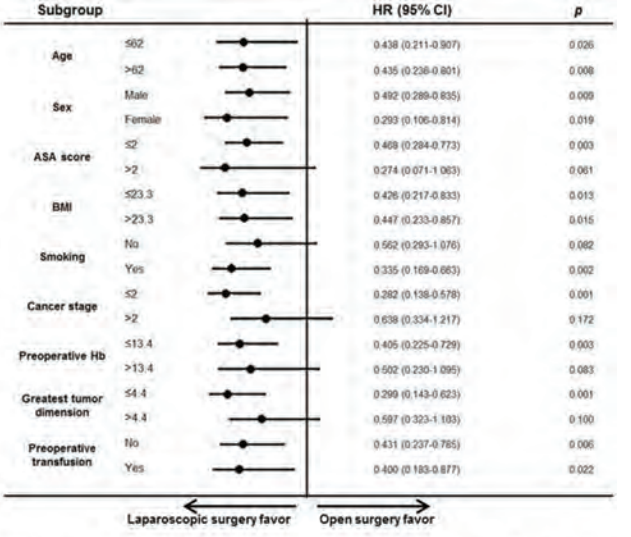


Figure 1. Cox proportional hazards analyses of type of operation and acute kidney injury in the subgroups among propensity matched patients.

FR-PO086

Preceding High-Phosphate Diet Exacerbates AKI in Rats

Yosuke Nakagawa,[2] Hirotaka Komaba,[2,1] Hiroaki Ishida,[3] Naoto Hamano,[2] Kaichiro Sawada,[2] Abul Fajol,[2] Takehiko Wada,[2] Michio Nakamura,[3] Masafumi Fukagawa.[2] *[1]Interactive Translational Research Center for Kidney Diseases, Tokai University School of Medicine, Isehara, Japan; [2]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [3]Department of Transplant Surgery, Tokai University School of Medicine, Isehara, Japan.*

Background: Animal studies and epidemiological studies suggest that high phosphate diet accelerates the progression of chronic kidney disease. However, little is known whether high dietary phosphate intake affects the severity of acute kidney injury (AKI).

Methods: Six-week-old male rats were subjected to 35-min bilateral ischemia reperfusion injury (IRI) or sham surgery. For 1 week preceding the surgery, the rats were fed either standard diet (0.9% calcium and 0.8% phosphate) or high phosphate diet (0.9% calcium and 1.2% phosphate). After surgery, all rats were placed on standard diet. We evaluated the time course of changes in renal function and mineral metabolism for 3 days following IRI.

Results: Compared to rats on standard diet, rats fed high phosphate diet for 1 week showed normal renal function, normophosphatemia, non-significant increases in FGF23 and PTH, and markedly increased urinary phosphate excretion. In rats kept on standard diet, IRI led to a 10-fold increase in blood urea nitrogen on day 1, which were accompanied by a 1.7-fold increase in serum phosphorus, a 2.4-fold increase in PTH, an 8-fold increase in FGF23, and a 2-fold decrease in 1,25-dihydroxyvitamin D. Rats fed high phosphate diet for 1 week prior to IRI showed more severe kidney injury and alterations in mineral metabolism. The renal and metabolic changes following IRI stared to regress by day 3 in rats kept on standard diet, but persisted for 3 days in rats fed high phosphate diet prior to surgery.

Conclusions: We show that high phosphate diet exacerbates AKI in rats even if they are switched to standard diet at onset. Our results suggest the need for routine dietary phosphate restriction in individuals who are at high risk for AKI.

FR-PO087

Role of Macrophages in Human AKI

Myung-Gyu Kim, Kijoon Lim, Kyungmi Lee, Sang-Kyung Jo. *Korea University Anam Hospital, Seoul, Seoul, Republic of Korea*.

Background: Macrophages are an important player in the injury and repair of experimental ischemia/reperfusion injury (IRI). While M1 macrophage contribute to IRI, phenotypic shift from pro-inflammatory M1 to anti-inflammatory M2 macrophages is important in repair process. However, emerging evidence also show persistence of M2 macrophages is associated with fibrosis. The purpose of this study is to examine the role of macrophages in human acute kidney injury (AKI).

Methods: We retrospectively reviewed the medical records of 72 patients with biopsy proven acute tubular necrosis (ATN) without chronic lesions, including 29 cases of native kidneys and 43 cases of deceased donors. M1 and M2 macrophage infiltration was determined by immunohistochemistry of CD68 and CD163 respectively. Healthy kidney sections obtained from nephrectomy was used as control.

Results: CD163+ macrophage outnumbered CD68+ cells in control kidneys and both of these macrophage subtypes increased significantly in ATN. The number of CD68+ M1 macrophage was significantly higher in stage 3 AKI compared to stage 1 or 2. However, there was no difference in the number of CD163+ M2 macrophages according to different stages of AKI. During the mean follow up period of 35.4 ± 30.9 months, 72.2% showed renal functional recovery defined as eGFR≥60ml/min/1.73m2. In contrast to CD68+ M1 macrophage that showed no association with renal recovery, the number of CD163+ M2 macrophage was significantly lower in patients with renal recovery (3.34 ± 2.3 vs 5.23±2.92 cells/HPF, X200, p=0.005). This association was evident especially in native kidney ATN, more advanced stage AKI and also in late biopsy groups. The number of CD168+ M2 macrophage was found to be an independent predictor of no recovery of renal function at 3 months in advanced stage AKI.

Conclusions: This is a first human study demonstrating the possible important role of macrophages with heterogenous phenotypes in injury and repair of AKI.

FR-PO088

Kidney-Resident Macrophages Exist in Unique Subsets and Demonstrate Subset-Specific Responses to AKI

Jeremie M. Lever, Michal Mrug, Bradley K. Yoder, Anupam Agarwal, James F. George. *University of Alabama at Birmingham, Birmingham, AL*.

Background: Myeloid cell-mediated inflammation plays a key role in AKI. Kidney resident macrophages (KRMs) are embryonically derived, self-renewing, and are a distinct lineage from infiltrative macrophages. The means by which these cells differentiate and facilitate these events is unknown. Our objectives were to define KRM subsets using single cell RNA-sequencing (scRNAseq), identify subsets that are responsive to AKI, and determine target genes for intervention.

Methods: C57BL/6J mice were subjected to 20 min bilateral ischemia-reperfusion AKI (n=3) under ketamine/xylazine anesthesia. At 6 d post-injury, KRMs ($F4/80^{Hi}$/$CD11b^{lnt}$) were isolated by FACS and subjected to scRNAseq using the Chromium 10X genomics platform. KRMs from untreated mice were used for controls. 6885 and 4253 cells were sequenced, for AKI and control, respectively.

Results: We used Seurat V3.0 to cluster cells with UMAP (uniform manifold approximation and projection) to reveal four major and two minor subsets. Cluster 0 constituted the majority of cells (57%). After IRI, cluster 0 decreased to 14% and cluster 1 increased from 0.2% to 36%. There were minimal changes to proportions of clusters 2 to 5. Expression of MHCII related transcripts (H2-Aa, H2-Ab1, and Cd74) in cluster 1 were decreased by 2 to 8-fold compared with cluster 0 ($p<10^{-100}$). Transcripts increased in cluster 1 included Ctsd, F13a1, Fabp5, Fos, Cxcl2 ($p<10^{-20}$). Pseudotemporal ordering produced by the Monocle algorithm (V2.3.6), which constructs a "trajectory" of cellular progress through differentiation, predicted that cluster 0 transitions to cluster 1 and that there are 2 potential decision points during that transition. Gene ontology analysis suggests cluster 1 is enriched for transcripts involved in an immune defensive response (e.g. innate immune response $p=2.9x10^{-12}$, leukocyte differentiation $p=1.6x10^{-11}$, inflammatory response $p=2.0x10^{-11}$).

Conclusions: Six transcriptionally unique KRM subsets exist and demonstrate subset-specific responses to AKI. The largest subset (cluster 0) demonstrated injury-responsive changes defined by downregulation of transcripts associated with MHCII that are consistent with a defensive posture involving innate immunity. KRM heterogeneity at the single cell level provides an opportunity to leverage KRM biology for interventions for AKI or the AKI to CKD transition.

Impact of Aging on Transition of AKI to CKD

Myung-Gyu Kim, Jihyun Yang, Sewon Oh, Sang-Kyung Jo. *Korea University Anam Hospital, Seoul, Seoul, Republic of Korea*.

Background: Although acute kidney injury (AKI) in the elderly is thought to contribute to a higher incidence of end-stage renal disease, mechanisms underlying the transition from AKI to chronic kidney disease (CKD) in elderly is poorly understood. Here, we investigated the effects of aging on AKI to CKD transition in animal model of ischemia-reperfusion injury (IRI).

Methods: Aged (48wks) and young (8wks) C57BL/6 mice were subjected to bilateral IRI. Cytokine level as well as functional, histological changes were examined on days 1, 3, 7, and 28 days.

Results: Baseline level of proinflammatory cytokines were slightly but significantly elevated in the kidneys of aged mice than in young mice, suggesting the presence inflammaging. Compared to young mice, kidneys from aged mice showed a persistent M1 dominant inflammation with increased iNOS, TNF-a and IFN-r expression during the recovery phase. Among several factors for macrophage M2 polarization, increase of colony stimulating factor-1 (CSF-1) and interferon regulatory factor-4 (IRF-4) were significantly blunted in aged mice. However, the in vitro macrophage polarization into M2a or M2c by IL-4/IL-13 or IL-10/TGF-b stimulation was not different between young and aged bone marrow derived mononuclear cell, suggesting that macrophage interaction with adjacent cells might be responsible for persistent M1 mediated inflammation in aged mice. Immunohistochemistry and western blot analysis showed that tissue inhibitor of metalloproteinase-2 (TIMP2) expression significantly increased in tubules of aged mice, suggesting that increase of tubule cells that are in the state of cell cycle arrest. In vitro transwell experiment showed that bone marrow derived mononuclear cells cocultured with mouse tubular cells pretreated with inducer of cell cycle arrest showed significantly impaired M2 polarization compared with those without cell cycle inducer, suggesting that prolonged G1 arrest of tubule cells might be partially responsible for persistent M1 mediated inflammation during the recovery phase in aged mice. Finally, M1 predominant renal inflammation in old mice resulted in fibrosis progression on day 28.

Conclusions: Our data show that persistent M1 mediated inflammation driven by adjacent arrested tubule cells is thought to be one of the mechanisms of impaired recovery and progression to CKD in aged mice.

FR-PO090

Deletion of the EGFR Ligand Amphiregullin Attenuates Renal Fibrosis After Severe Ischemic Injury by Inactivating Renal Macrophage Responses

Guannan Jin,[1] Yu Pan,[1] Yinqiu Wang,[3] Aolei Niu,[1] Suwan Wang,[1] Xiaofeng Fan,[2] Ming-Zhi Zhang,[1] Raymond C. Harris.[1] Vanderbilt nephrology *[1]Medicine, Vanderbilt University Medical School, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University, Nashville, TN*.

Background: The activation EGFR signaling pathway is a mediator of recovery from acute kidney injury (AKI) but is also a mediator of renal fibrosis in chronic kidney diseases. EGFR can be activated by a family of ligands including amphiregulin (AREG). Macrophage polarization plays a key role in propagation of AKI and in the development of chronic renal damage. The role of AREG in macrophage polarization and recovery from AKI and subsequent renal fibrosis has not been previously investigated.

Methods: AREG-/- and wild type mice (male, 3 months, C57BL/6) were uninephrectomized, immediately followed by unilateral ischemia-reperfusion for 29 min or 30 min for survival and fibrosis development. An AKI/CKD fibrotic model was also used. Renal macrophages were isolated with a mixture of CD11b and CD11c microbeads. Both a murine macrophage cell line Raw264.7 and a human macrophage cell line THP1 were used.

Results: In both Raw264.7 and THP1 cells, M1 polarization with LPS/IFNγ increased AREG expression. After AKI, AREG was the only EGFR ligand that markedly increased in both kidney and isolated renal macrophages. Surprisingly, renal macrophages of AREG-/- mice exhibited a less activated, M0-like phenotype, being lower in both Th1/M1 (TNF-α, IL-6, IL-1α, IL-1β, CCL-2, IRF5) and Th2/M2 (CD206, IL-4Rα, Arginase 1, YM-1, CD209, CD150) cytokines under normal condition or 2 days after AKI. AREG-/- mice had faster functional recovery after AKI. AREG-/- mice developed less renal fibrosis after severe AKI, as indicated by Sirius red and Masson's trichrome staining, decreases in profibrotic and fibrotic components (TGF-β, collagen I, III, IV, FSP-1, α-SMA, fibronectin, vimentin, CTGF, IL-11), as indicated by qPCR, immunoblotting, and immunohistochemistry, in association with decreases in renal macrophage and neutrophil infiltration, renal proinflammatory cytokines, and renal injury (less renal KIM-1 and NAGAL expression). AREG-/- also developed less fibrosis in AKI/CKD fibrotic model. Finally, AREG-/- had increased survival rate after severe AKI.

Conclusions: Amphiregulin deficiency protects against AKI and renal fibrosis after severe AKI, at least in part due to less renal macrophage activation in response to kidney injury.

FR-PO091

P2X4 Receptor Deficiency Protects Against Ischemic AKI in Mice

Sang Jun Han,[1] Mihwa Kim,[1] Vivette D. D'Agati,[2] H. Thomas Lee.[1] *[1]Anesthesiology, Columbia University College of Physicians and Surgeons, New York, NY; [2]Pathology, Columbia University College of Physicians and Surgeons, New York, NY*.

Background: Ischemic acute kidney injury (AKI) is a major clinical problem with high mortality and morbidity. Although P2X4 receptor induces inflammation and cell death in some cell types, the role for P2X4R in ischemic AKI is unknown. Here, we tested the hypothesis that P2X4R activation by ATP released from necrotic renal cells exacerbates ischemic AKI by promoting renal tubular epithelial inflammation and apoptosis.

Methods: Wild type or P2X4R knockout mice were subjected to sham surgery or 30 min kidney ischemia reperfusion (IR) injury. Twenty-four hours later, plasma and kidney were harvested to measure markers of kidney injury (plasma creatinine, blood urea nitrogen, kidney NGAL expression, necrosis scores), inflammation (neutrophil infiltration, pro-inflammatory cytokine/chemokine mRNA induction) and apoptosis (TUNEL staining).

Results: P2X4R knockout mice were protected against renal IR injury with decreased plasma creatinine (1.33 ± 0.17 mg/dL), blood urea nitrogen (91.4 ± 8.6 mg/dL), and NGAL mRNA (395.3 ± 74.4 fold increase over sham) compared to wild type mice (PCr = 2.36 ± 0.1 mg/dL, BUN = 115.1 ± 4.1 mg/dL, and NGAL mRNA = 1194.2 ± 169.2 fold increase over sham, N=4 for all groups). In addition, P2X4R knockout mice had lower necrotic (Jablonski Score reduction of 31 ± 5.6%, N=4) and apoptotic (reduced TUNEL positive cells by 78.2 ± 1.5%, N=4) tubular cells compared to wild type mice. P2X4R knockout mice were also protected against renal inflammation with lower pro-inflammatory cytokine/chemokine mRNA induction after renal IR (monocyte chemoattractant protein-1 [MCP-1] = 2.2 ± 0.7, macrophage inflammatory protein [MIP-2] = 34.1 ± 6, Interleukin 6 [IL-6] = 19.3 ± 0.1, and intercellular adhesion molecule 1 [ICAM-1] = 0.98 ± 0.2 fold increase over sham) compared to wild type mice (MCP-1 = 11.1 ± 1.7, MIP-2 = 206 ± 65.2, IL-6 = 123.5 ± 29.6 and ICAM-1 = 3.7 ± 0.4 fold increase over sham) after renal IR injury. Consistent with this, kidney neutrophil infiltration was reduced by 49.3 ± 5.7% (N=4) in P2X4R knockout mice compared to wild type mice after renal IR injury.

Conclusions: Taken together, our studies suggest that P2X4R activation exacerbates ischemic AKI by promoting renal tubular inflammation and apoptosis after renal IR injury. Our studies provide a novel insight into the pathophysiology of P2X4R in ischemic AKI, suggesting a potential therapy for ischemic AKI.

A Novel Noncoding RNA (LRNA9884) Promotes AKI via Maintaining Mincle-Dependent M1 Macrophage Phenotype

Yingying Zhang,[1] Chen Yu.[2] [1]*shanghai tongji hospital, Shanghai, China;* [2]*Shanghai Tongji Hospital, Shanghai, China*.

Background: Macrophages are key inflammatory cells and play a critical role in renal inflammation in acute kidney injury (AKI). M1 inflammatory macrophage and M2 anti-inflammatory macrophage act reverse role. Phenotype of macrophages is highly flexible and can be changed over time. However, the underlying mechanism of M1 and M2 macrophage phenotype switching during AKI is still largely unclear. In our previous study, we identified a novel lncRNA (LRNA9884) might contribute to inflammation according to modifying macrophages. The present study was designed to uncover the pathogenic role and the underlying mechanism of LRNA9884 in cisplatin-induced AKI.

Methods: Expression level and pattern of LRNA9884 were examined in cisplatin-induced AKI mice. The regulatory mechanisms of LRNA9884 was investigated in cultured bone marrow–derived macrophages (BMDMs) *in vitro* by silencing or overexpressing of LRNA9884. Flow Cytometer, fluorescence in situ hybridization (FISH) and other multiple molecular biological techniques were applied to figure out the role of LRNA9884 under acute kidney injury.

Results: LRNA9884 was significantly upregulated in the kidney of cisplatin-induced mice and was associated with the progression of the renal inflammation by using RT-PCR and ISH assay. FISH assay with IF co-staining detected that LRNA9884 was largely expressed in the nucleus of macrophage in cisplatin-induced mice kidney compared with the sham group at day 1 after AKI injury. LRNA9884 was remarkedly induced by TNF-α (10ng/ml) in BMDMs as time- and dose- dependent. Western blot and RT-PCR showed that silencing of LRNA9884 effectively inhibited upregulated of macrophage-inducible C-type lectin (Mincle) and iNOS induced by TNF-α. More importantly, we identified that LRNA9884 maintained M1 macrophages phenotype by triggering mincle production at transcriptional level as evidenced by ChIP assay.

Conclusions: LRNA9884 is a mincle-dependent lncRNA that highly-expressed in macrophages under AKI development. Targeting of LRNA9884 effectively blocked the inflammatory response via promoting the transition M1 macrophage to M2 macrophage phenotype. This study will shed new lights on the understanding of pathological role of novel LRNA9884 in AKI.

FR-PO093

Kidney Residency of VISTA-Positive Macrophages Accelerates Repair from Ischemic Injury

Seung Seok Han,[1] Dong Ki Kim,[2] Seung Hee Yang.[3] [1]*Seoul National University College of Medicine, Seoul, Republic of Korea;* [2]*Seoul National University Hospital, Seoul, Republic of Korea;* [3]*Kidney Research Institute, Seoul National University, Seoul, Republic of Korea*.

Background: V-domain Ig suppressor of T cell activation (VISTA), expressed primarily in myeloid cells, promotes the progression of cancer via acting as an inhibitory immune-checkpoint molecule. Nevertheless, the VISTA-dependent role of tissue myeloid cells within the normal organ environment remains unresolved.

Methods: VISTA expression was analyzed in homeostatic condition and compared between tissues. To address the role of VISTA, we adopted ischemia-reperfusion injury. Human renal mononuclear phagocytes were used to translate the mouse results to the human condition.

Results: In contrast to lung, liver, and skin, the renal residency of macrophages highly expressed VISTA in ischemic injury as well as homeostasis. When these kidney-resident macrophages were predominantly depleted, the repair from ischemic injury was hindered. VISTA functioned as a scavenger of apoptotic cells and served as a checkpoint to control kidney-infiltrating T cells upon T cell receptor-mediated stimulation. All of these functions eventually improved the repair process after ischemic injury. $CD14^+$ $CD33^+$ mononuclear phagocytes of human kidney also expressed VISTA, which had similar functions to the mouse counterpart.

Conclusions: VISTA is upregulated in kidney macrophages in a tissue-dependent manner, which plays a repair role from ischemic injury.

FR-PO094

Single-Cell Deconvolution of Macrophage Heterogeneity in Mouse Ischemia-Reperfusion Kidney Injury

Weijian Yao,[2] Shanzhao Jin,[1] Zehua Li,[2] Fan Bai,[1] Li Yang.[2] [1]*Biomedical Pioneering Innovation Center (BIOPIC), School of Life Sciences, Peking University, Beijing, China;* [2]*Renal Division, Peking University First Hospital, Beijing, China*.

Background: Acute kidney injury (AKI) is a clinically critical illness without effective treatment. It has been known that macrophage plays important roles in the repair and fibrosis after acute injury, whereas its heterogeneity in subtypes and the related pathophysiological functions during the progression of AKI have not been well established.

Methods: Unilateral ischemia reperfusion (uIRI) acute kidney injury model was set up in C57BL/6J male mice (37°C for 45minutes). Macrophages were collected from the injured kidney on day 1, 3,10,17 post surgery by flowcytometry cell sorting through costainting with F4/80 and Cd11b. Meanwhile, monocytes costaining with Ly6c and Cd11b were sorted from peripheral blood and spleen respectively. Single cell transcriptome sequencing was performed through 10X genomics method.

Results: Altogether eleven clusters of macrophages were discovered in the kidney. There were three subclusters of kidney resident macrophages in normal kidney and they almost disappeared after injury. On day 1 post uIRI surgery, $S100a4^{high}$ and $S100a8^{high}$ macrophage took the majority of macrophage subtypes in the kidney, while $Stmn1^{high}$ macrophage was the major populations on day 3, which had a strong ability of proliferation. $Cxcl2^{high}$ macrophage and $Gdf15^{high}$ macrophage mainly existed in the chronic phase (day 17). According to Gene Oncology analysis, $Cxcl2^{high}$ macrophage exhibited inflammatory response and TNF signaling pathway activation, while $Gdf15^{high}$ macrophage had more repair related genes and thus might promote repair after injury. Through single-cell trajectory analysis on integrated datas, MHC-II^- $Gpx3^{high}$ kidney resident macrophage developed into $S100a4^{high}$ macrophage through $Stmn1^{high}$ macrophage and $S100a8^{high}$ macrophage mainly derived from spleen in the acute phase. In the chronic phase, MHC-II^+ $MMP13^{high}$ and MHC-II^- $F13a1^{high}$ kidney resident macrophage developed into $Cxcl2^{high}$ macrophage while $Stmn1^{high}$ macrophage proliferate and different into $Hspa1a^{high}$ macrophage and $Gdf15^{high}$ macrophage.

Conclusions: Macrophages have strong heterogeneity in AKI. $S100a4^{high}$ and $S100a8^{high}$ macrophages might contribute to inflammation during acute injury phase. $Gdf15^{high}$ macrophage was likely to promote repair, while $Cxcl2^{high}$ macrophage could be involved in the chronic inflammation and fibrosis processes. Kidney resident macrophages and monocytes derived from spleen might play important role in AKI.

FR-PO095

Increased Expression of the Ca2+ Channel Orai1 and IL-17 in Blood CD4+ Cells in Critically Ill Patients with AKI

Purvi Mehrotra,[1] Javier A. Neyra,[2] David P. Basile.[3] [1]*Indiana School of Medicine, Indianapolis, IN;* [2]*University of Kentucky Medical Center, Lexington, KY;* [3]*Indiana University School of Medicine, Indianapolis, IN.*

Background: Acute kidney injury (AKI) affects up to 50% of critically ill patients and is associated with high mortality rates approaching 60%. In surviving patients, reduced kidney function is reversible, however AKI increases the risk developing of chronic kidney disease (CKD). IL-17, a pro-inflammatory cytokine secreted by CD4+T cells (Th17 cells), has been linked to the activation of the store-operated calcium channel, Orai1. Th17 cells, have been associated with various autoimmune diseases such as psoriasis and SLE and also in delayed graft function. In rodent models of kidney injury, Th17 cells have been shown to enhance the severity of AKI and AKI-to-CKD transition. However, no direct evaluation of Th17 cells has been conducted in AKI patients.

Methods: Prospective, case-control study of critically ill patients with AKI (KDIGO stage ≥2, n=9) and ICU matched-controls without AKI (n=8). Matching criteria included age, gender and baseline eGFR. Venous blood was collected 12-24 hours post AKI diagnosis and 12-24 h ICU admission and analyzed for expression of CD4+/IL17+ cells and the expression and activity of Orai1.

Results: The percent of CD4+/IL17+ was significantly higher in AKI patients (0.98%±0.11) vs ICU controls (0.15%±0.06, $p<0.05$). In addition, there was a enhancement in the expression of Orai1, from 3.5% in ICU controls vs with 30% in the AKI group. To determine if the increase in Orai1 expression was involved in mediating IL17 activity, we isolated CD4+ cells and stimulated in vitro for ~12 hours with either elevated extracellular sodium (170mM) and/or AngII (10^{-7} M), which was previously shown to enhanced IL17 production in kidney T cells of post-AKI rats. In blood from AKI patients, there was significant increase in IL17 producing CD4+ in response to in vitro stimulation (from 2.3% to 5.2%, $p<0.05$). Furthermore, the increased IL17 response from blood of AKI patients was completely blocked by the inclusion of the Orai1/SOCE inhibitor YM58483 ($p<0.05$ vs. stimulated). Interestingly, there was no IL17 response in CD4+ cells from ICU controls without AKI.

Conclusions: These results suggest that circulating Th17 cells are activated early in critically ill patients with AKI vs ICU controls without AKI. Th17 cells and/or IL17 may represent a target as a potential early biomarker of AKI in the ICU, and Orai1 may represent a therapeutic target.

Regulatory Innate Lymphoid Cells Suppress Innate Immunity and Reduce Renal Ischemia-Reperfusion Injury

Qi Cao,[1] Yiping Wang,[2] Titi Chen,[3] Vincent W. Lee,[4] Guoping Zheng,[5] David Harris.[6] [1]*Centre for Transplant and Renal Research, Westmead Millennium Institute, University of Sydney, Westmead, NSW, Australia;* [2]*Centre for Transplantation and Renal Research, Westmead Millennium Institute, The University of Sydney, Westmead, NSW, Australia;* [3]*The Westmead Institute for Medical Research, Westmead, NSW, Australia;* [4]*Westmead Hospital, Westmead, NSW, Australia;* [5]*The University of Sydney, Westmead, NSW, Australia;* [6]*Sydney Medical School - University of Sydney, Duffys Forest, NSW, Australia.*

Background: Innate lymphoid cells (ILCs) are a recently recognized group of immune cells with critical roles in tissue homeostasis and inflammation. Regulatory innate lymphoid cells (ILCregs) are a newly identified subset of ILCs, which play a suppressive role in the innate immune response, favoring the resolution of intestinal inflammation. However, the expression and role of ILCregs in kidney has not been reported.

Methods: ILCregs were assessed by flow cytometry in human and mouse kidney. Mouse ILCregs isolated from IL-10-GFP mice were used for phenotypic and functional analysis. Bilateral renal ischemia was imposed in C57BL/6 or Rag-/- mice. Adoptive transfer of ILCregs into mice with ischemia/reperfusion injury (IRI) was used to assess their *in vivo* functions. IL-2/IL-2Ab complexes (IL-2C) was given by 3 consecutive daily injections prior to IRI operation to inducing expansion of ILCregs in vivo.

Results: Here, we show that ILCregs are present in both human and mouse kidney. Human and mouse renal ILCregs expressed similar surface markers and formed a similar proportion of total kidney ILCs. ILCregs from kidney were expanded *in vitro* with a combination of IL-2, IL-7 and TGF-β. The expanded ILCregs exhibited immunosuppressive effects on innate immune cells, such as ILC1 and macrophages, via secretion of IL-10 and TGF-β. Adoptive transfer of *ex vivo* expanded ILCregs improved renal function and attenuated histologic damage when administered before or after induction of IRI, in association with reduction of neutrophil infiltration and induction of M2 macrophages in kidney. Moreover, treatment with IL-2C promoted expansion of ILCregs *in vivo*, and prevented renal IRI in Rag-/- mice. Depletion of ILCregs with anti-CD25 Ab abolished the beneficial effects of IL-2C in Rag-/- mice.

Conclusions: This study shows that ILCregs protect against renal IRI through suppressing innate renal inflammation. This demonstrates a novel strategy of manipulating ILCregs to treat kidney disease.

Ex Vivo Gene Editing and Pharmacologic Modification of T Cell Keap1/Nrf2 Towards Immunotherapy for Experimental AKI

Johanna T. Kurzhagen,[1] Sanjeev Noel,[1] Mohanraj Sadasivam,[1] Abdel Hamad,[1] Hamid Rabb.[2] [1]*Johns Hopkins University, Baltimore, MD;* [2]*Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Adoptive transfer of Keap1 deficient T cells with enhanced Nrf2 activity has been shown to lead to significant protection from IR-induced AKI in mice (*JASN 2015*), and gene editing of Keap1 in human T cells enhances Nrf2 products (*J Immunol 2018*). Pre-clinical studies in mice with Keap1/Nrf2 gene editing and pharmacologic manipulation in AKI are needed to set the stage for human cell-based therapies.

Methods: Primary mouse CD4+ or pan T cells were isolated from B6 WT spleen by negative selection using Dynabeads. Nrf2 activity was modulated either by treating T cells with different concentrations (10nM, 20nM and 50nM) of the pharmacologic Nrf2 activator CDDO-Im or using CRISPR/Cas9 system to edit Keap1 gene. The efficiency of gene editing was assessed by using ATTO 550-labeled tracrRNA. Various T cell culture conditions were tested and viable cells were enriched using flow-sorting. Viable cells were detected by 4′6-diamidino-2-pheylindole (DAPI). Functional effects of *ex vivo* Nrf2 activation and Keap1 editing were assessed on Nrf2 dependent antioxidant genes NADPH dehydrogenase quinone 1 (NQO1), heme oxygenase 1 (HO-1) and Glutamate-Cysteine Ligase Catalytic Subunit (GCLC) expression using quantitative real-time PCR.

Results: *Ex-vivo* murine CD4+ T cell CDDO-Im treatment resulted in a dose dependent response in Nrf2 target gene expression. The higher dosage of 50nM CDDO-Im had the highest impact on NQO1 (~16.4-fold), HO-1 (~3.6-fold) and GCLC (~2.8-fold) mRNA expression. T cells cultured longer before gene editing using CRISPR/Cas9 technique resulted in significantly higher (32.5%) viable CRISPR edited (ATTO 550 positive) cells compared to cells that underwent CRISPR editing soon after isolation (1%). CRISPR/Cas9 based Keap1 editing resulted in significant increase in NQO1 (~15.5-fold), HO-1 (~3.0-fold) and GCLC (~2.5-fold). Changes in levels of IL-10, IFN-γ and IL-17 were measured.

Conclusions: Pharmacologic and gene editing techniques increased murine T cell Nrf2 target genes *ex vivo* for infusion in studies to prevent AKI and accelerate repair during AKI. These studies set the stage for immunotherapy treatment for AKI and other immune mediated kidney diseases.

Ischemia-Reperfusion Injury Affects Co-Signaling Molecules TIGIT/CD226 in Kidney T Cells

Sanjeev Noel,[1] Sul A Lee,[1] Johanna T. Kurzhagen,[2] Mohanraj Sadasivam,[1] Somayeh Gharaie fathabad,[2] Abdel Hamad,[2] Phillip M. Pierorazio,[3] Hamid Rabb.[4] [1]*Johns Hopkins University, Baltimore, MD;* [2]*Johns Hopkins University, Baltimore, MD;* [3]*Brady Urological Institute, Johns Hopkins University, Baltimore, MD;* [4]*Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: T-cells play important roles in AKI pathogenesis and repair processes, but detailed mechanisms are not known. Unbiased cell specific RNAseq is a powerful tool to discover new therapeutic targets, and led to the discovery of AKI stimulated kidney CD4 cell co-inhibitory molecule, T-cell immunoreceptor with Ig and ITIM domain (TIGIT) and its co-stimulatory counterpart CD226

Methods: 8-week-old male C57BL6/J wild type (WT) mice underwent bilateral IR surgeries to induce AKI. CD4 T-cells from post ischemic and control kidney were flow sorted 24 hours after inducing AKI and RNA sequencing (RNA-seq) performed. Flow cytometric analysis was performed to validate RNA-seq findings in T-cells from post ischemic mouse kidney, and "normal" portion of pre and post-clamp human kidney samples of renal cell carcinoma nephrectomies

Results: RNA-seq analysis showed significant increase in TIGIT expression (63.0±12.6 vs 21.8±2.6; p≤0.03) in CD4 T-cells from post IR mouse kidneys compared to control. Alternatively, CD226 mRNA was significantly reduced (13.0±1.8 vs 78.4±4.0; p≤0.0001) in post IR kidney CD4 T-cells. Flow cytometric analysis showed significant TIGIT protein expression in CD4 (11.7±5.0 vs 2.3±1.6; p≤0.008) and CD8 (13.0±6.7 vs 4.3±0.7; p≤0.04) T-cells from post IR kidneys compared to control. CD226 protein expression was not different in CD4 and CD8 T-cell isolated from post IR and control kidneys, however, double negative T-cells (CD3+CD4-CD8-; DN) showed significantly reduced (17.1±6.8 vs 56.3±10.2; p≤0.0002) expression in post IR kidneys. Human kidney assessment showed significant increase in absolute number of TIGIT positive CD8 (74.9±22.7 vs 14.4±5.1; p≤0.04) and DN T-cells (18.1±4.9 vs 1.3±0.9; p≤0.01) as well as CD226 positive DN T-cells (23.8±6.2 vs 2.4±1.4; p≤0.01) in post-clamp "normal" human kidney compared to pre-clamp kidney tissue

Conclusions: These data demonstrate that ischemia reperfusion leads to marked changes in TIGIT and CD226 in mouse and human kidney T-cells. Given the effectiveness as well as renal side effects of traditional anti CTLA4 and anti PD1 therapies, TIGIT/CD226 may be a novel target for developing next generation check point inhibitor therapies for AKI and other kidney diseases

Multifaceted Role of ST2/IL-33 Axis During Kidney Injury

Vikram Sabapathy,[2] Rajkumar Venkatadri,[2] Murat Dogan,[2] Saleh Mohammad,[2] Nardos T. Cheru,[1] Airi Price,[2] Brian K. Stevens,[2] Rahul Sharma.[2] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD; [2]Division of Nephrology and CIIR, Charlottesville, VA.*

Background: Renal diseases are a major cause of morbidity and mortality. Inflammation elicited by variety of cytokines and chemokines are a major player in initiation and progression of the disease. Interleukin 33 (IL-33) belongs to IL-1 family of cytokines, which was identified for eliciting T helper-2 (Th2) cytokines. IL-33 acts as an 'alarmin' that regulates the immune response during injury. IL-33 acts in an autocrine/paracrine manner on the ST2 membrane receptor IL33R or Il1rl1, triggering innate and adaptive immune response. ST2 is widely expressed in immune cells including regulatory T cells (Tregs). Importance of ST2/IL-33 signaling in Tregs has been demonstrated in multiple inflammatory conditions. However, cell specific contribution of ST2/IL33 signaling is not understood. Here, we investigated the cell specific ST2/IL33 signaling activity using murine renal injury models.

Methods: Murine ischemia-reperfusion injury (IRI) model was used to investigate cell specific ST2/IL-33 signaling using IL1RL1^{tm1a} and cell specific Pepck, Foxd1 and Foxp3 -cre mice to delete ST2 expression in proximal tubular cells (PTC), pericytes and Tregs respectively. The structure and function of the kidney were probed using flow cytometry, histology, immunohistochemistry, qRT-PCR and biochemical analysis.

Results: In vivo experimental data indicated that deletion of ST2 in PTC and pericytes attenuated renal injury suggesting that activation of ST2/IL33 signaling in these cells leads to impaired renal function following IRI, leading to fibrosis. On the contrary, elimination of ST2/IL33 signaling from Tregs resulted in greater renal injury to the indicating that activation of ST2/IL33 signaling in Tregs mediate renal protection during inflammation and injury.

Conclusions: This study addresses the cell specific role of ST2/IL33 signaling in immune-regulation, fibrosis and repair. Our findings try to delineate the multifaceted role of ST2/IL33 axis in renal injury. We conclude modulation of ST2/IL33 siganling as a promising therapeutic option.

CC-Chemokine Receptor 7 Deficient Mice Are Resistant to Renal Ischemia-Reperfusion Injury

Hiroshi Kojima,[1,2] Erik H. Koritzinsky,[2] Myung-Gyu Kim,[2] Jonathan Street,[2] Timothy Break,[3] Michail Lionakis,[3] Peter S. Yuen,[2] Robert A. Star.[2] *[1]Department of Nephrology and Renal Replacement Therapy, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Renal Diagnostics and Therapeutics Unit, NIDDK, NIH, Bethesda, MD; [3]Fungal Pathogenesis Unit, NIAID, NIH, Bethesda, MD.*

Background: One of the most prominent chemokine receptors in the adaptive immune system is CC-chemokine receptor 7 (CCR7), which has been established as an important component of lymphocyte-driven immune function. CCR7 promotes homing of T cells and antigen presenting cells to areas of lymphoid tissues where T cell priming occurs. Apart from chemotaxis, CCR7 defines a precursor for natural killer T (NKT) cells in the thymus and periphery. Manipulation of the CCR7 axis has either protective or deleterious role in mouse kidney injury models. We sought to clarify the role of CCR7 in the pathogenesis of renal injury after ischemia reperfusion injury (IRI).

Methods: Experiment (Exp.) 1: CCR7 deficient mice (KO) or wild-type mice (WT) underwent IRI. Mice were euthanized at 1, 3 or 7 days after the surgery. Kidney & serum were collected for biochemical analysis & histological evaluation. Exp. 2: KO or WT were injected intravenously with alpha-galactosylceramide: a specific ligand for NKT cells. NKT cells were isolated from spleen 24 hours later, and cytokine profiles were assessed by qPCR. Exp. 3: Prior to IR surgery on Day 0, KO mice were injected intraperitoneally with IFNγ or vehicle on Days -3, -2, -1, and 0. Kidney & serum were harvested on Day 1.

Results: Exp. 1: Blood urea nitrogen & creatinine levels in KO were lower than WT throughout experimental periods. Similarly, KO developed milder tubulointerstitial injuries than WT. Exp. 2: Serum IFNγ concentration & IFNγ mRNA expression in isolated NKT cells were lower in KO than WT. Exp. 3: KO injected with IFNγ showed similar kidney damage to KO injected with vehicle.

Conclusions: CCR7 KO mice are resistant to IRI. KO mice show blunted production of IFNγ. We speculate that less production of IFNγ in KO induces insufficient development of an effector T cell response and reduces kidney damage. However, supplementation of IFNγ alone was not sufficient to increase the susceptibility to IRI in KO mice. Although we need further investigation to resolve the mechanism(s), intervention of CCR7 axis could have therapeutic potential for AKI, especially IRI.

FR-PO101

Superagonistic CD28 Protects Against Renal Ischemia Injury-Induced Fibrosis Through a Regulatory T Cell Expansion Dependent Mechanism

Yiran Liang, Yi Fang, Xiaoqiang Ding. *Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: To investigate the potential protective effect of superagonistic CD28 (CD28sa) on the chronic outcome post acute kidney ischemia injury and related mechanism.

Methods: Male C57BL/6N mice were treated with CD28sa via peritoneal injection 6 days before the induction of ischemia renal injury (IRI), IRI was induced by bilateral clamping of renal pedicles for 35 min followed by reperfusion. 7, 14 and 28 days after the IRI surgery, mice were euthanized and specimens were harvested. The role of regulatory T cells (Tregs) expansion in the renal protection conferred by CD28sa treatment was examined using an anti-CD25 antibody (PC61) to partially deplete Tregs. The chronic pathological outcome of mice renal was identified by Masson staining, Sirius Red staining and renal fibrosis related extracellular matrix immunochemistry (IHC) staining.

Results: CD28sa treatment significantly promoted the percentage of Tregs in the spleen, kidney and peripheral blood 24 h after the IRI. Serum creatinine level was remitted by CD28sa administration in a short term (7 days). Histological analysis indicated that CD28sa attenuated renal tubular damage. CD28sa also attenuated the extracellular matrix deposition in the renal medulla site 28 days after IRI. Immunoblot showed that Collagen IV expression of kidney was lowered by CD28sa administration 28 days after IRI. Immune cells in kidneys from CD28sa pre-treated IRI mice were characterized by an increased percentage of Tregs and MHCII^{+} CD11c^{+} dendritic cells, significantly decreased Th17 cells and also increased secretion of Tregs effector cytokine IL-10. CD28sa pretreatment also resulted in less cells apoptosis and less oxidative stress of renals marked by less TUNEL and 8-OHdg positive stained cells. On the other hand, the renal protection bestowed by CD28sa was abolished by PC61 administration.

Conclusions: CD28sa alleviated renal chronic outcome after the acute ischemic injury, probably associated with the inchoate up-regulation of Treg cells.

Enhancement of Tregs with IL233 Hybrid Cytokine Rescues Kidney Function in Aristolochic Acid-Induced Nephropathy

Murat Dogan,[1] Rajkumar Venkatadri,[2] Vikram Sabapathy,[3] Brian K. Stevens,[2] Rahul Sharma.[2] Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia *[1]Division of Nephrology and CIIR, Charlottesville, VA; [2]University of Virginia, Charlottesville, VA; [3]The Rector and Visitors of the University of Virginia, Charlottesville, VA.*

Background: Aristolochic acid (AA) is used as a "traditional medicine" to induce labor and for treatment of arthritis and inflammation. The Balkan nephropathy is supposedly caused by chronic dietary consumption of AA and genetic predisposition. However, recent studies showed that consumption of AAleads to tubular epithelial cell (TEC) injury and inflammation, which triggers acute and chronic renal dysfunction. Our goal in this study was to investigate the role of T-regulatory cells (Tregs) and susceptibility of TEC in experimental AA nephropathy.

Methods: We induced renal injury in male C57Bl/6 mice with AA injection (i.p.) and evaluated the progression of acute nephropathy for 4 weeks. Additionally, PC61 (anti-CD25 Ab to deplete Tregs) and IL233 (a novel Treg-enhancing hybrid cytokine bearing the activities of IL-2 and IL-33) were appliedto evaluate the progression of nephropathy. Sera samples were collected and used for plasma creatinine (PCr) and blood urea nitrogen (BUN) assessment with the commercially available kits. Tubular necrosis in the kidneys was assessed on H&E sections. KIM-1 and NGAL were used for kidney injury markers. Flow cytometry was used to evaluate inflammatory cells and cytokine profile in kidneys, spleen and blood. The effect of IL233 in PD1 and IL-33R (ST2) KO mice in AA nephropathy was also studied to understand the underlying mechanisms. All animal procedures and personnel were approved by institutional animal care and care committee.

Results: Mice treated with AA developed severe renal dysfunction, inflammation and tubular necrosis. Immune cells were elevated alongside renal inflammation. Administration of anti-CD25 mAb PC61 worsened renal dysfunction in AA-treated mice, increased the susceptibility of mice to AA-induced nephrotoxicity, suggesting a role of Tregs. Treatment of mice withIL233 (a Treg-enhancing hybrid cytokine containing IL-2 and IL-33), after the onset of injury suppressed inflammation, renal dysfunction and injury, evident by the reduced levels of plasma creatinine, BUN and in these animals, whereas PC61 mAb ameliorated the IL233-mediated protection indicating Tregs as primary immune cells rendering protection.

Conclusions: IL233 protects from AA induced nephrotoxicity in a Treg-dependent manner with a role for ST2 and PD-1, and bears therapeutic potential.

TCR+CD4-CD8- (Double-Negative) T Cells Protect from Cisplatin-Induced Renal Epithelial Cell Apoptosis and AKI

Jing Gong,[2] Sanjeev Noel,[1] Joshua Hsu,[4] Errol L. Bush,[3] Lois J. Arend,[4] Mohanraj Sadasivam,[1] Sul A Lee,[1] Johanna T. Kurzhagen,[1] Abdel Hamad,[1] Hamid Rabb.[5] *[1]Johns Hopkins University, Baltimore, MD; [2]The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China; [3]Johns Hopkins, Baltimore, MD; [4]Johns Hopkins Hospital, Baltimore, MD; [5]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Acute kidney injury (AKI) due to cisplatin is a significant problem that limits its use as an effective chemotherapeutic agent. TCR+CD4-CD8- (double negative - DN) T cells constitute a major T cell population in human and mouse kidney and protect from ischemic AKI. However the pathophysiologic roles of DN T cells in cisplatin-induced AKI is unknown

Methods: Mice were treated with cisplatin (30mg/kg) or vehicle and effect on kidney DN T cell numbers and function assessed using flow cytometry. *In vitro* studies evaluated effects of kidney DN T cells on cisplatin-induced apoptosis and PD ligand 1 (PD-L1) in renal epithelial cells. *In vivo* adoptive transfer studies assessed role of DN T cells on kidney structure and function during cisplatin-induced AKI

Results: Kidney DN T cell population increased ($p<0.01$) at 24 hours and declined ($p<0.01$) by 72 hours after cisplatin treatment. Cisplatin increased kidney DN T cell proliferation ($p<0.05$), apoptosis, CD69 ($p<0.05$) and IL10 ($p<0.01$) expression whereas CD62L ($p=0.03$), CD44, IL-17A, IFN-γ and TNF-α were ($p<0.05$) downregulated. Cisplatin decreased both kidney DN T cell PD1 ($p<0.05$) and NK1.1 ($p<0.05$) subsets with pronounced effect on PD1 subset. *In vitro* kidney DN T cells co-culture decreased cisplatin-induced apoptosis ($p<0.05$) in kidney proximal tubular epithelial cells (PTECs), increased expression of Bcl-2 ($p<0.05$) decreased cleaved caspase 3 ($p<0.05$), and attenuated PTEC PD-L1 expression ($p<0.05$). Adoptive transfer of DN T cells attenuated kidney dysfunction ($p<0.05$) and structural damage ($p<0.05$) from cisplatin-induced AKI

Conclusions: These results demonstrate that kidney DN T cells respond rapidly and play a protective role during cisplatin-induced AKI. DN T cells may have important translational implications for humans undergoing cisplatin and immune checkpoint inhibitor therapy for cancer

FR-PO104

B Cells Are Associated with Renal Recovery After AKI

Silvia Coelho,[1,2] Rute Salvador,[2] M. guadalupe Cabral,[2] Ana S. Corte-Real,[1] Ana Martins,[1] Filomena I. Matos,[1] Paulo Freitas,[1] Antonio Jacinto.[3,2] Tissue Repair and Inflammation *[1]Hospital Prof. Dr. Fernando Fonseca, Amadora, Portugal; [2]CEDOC, NOVA Medical School, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal; [3]Nova Medical School, Lisboa, Portugal.*

Background: The mechanisms associated with renal recovery after an episode of Acute Kidney Injury (AKI) are still poorly understood but immune factors seem to play a role. We aim to determine the association between the urinary immune profile of AKI patients and renal recovery.

Methods: Adult patients with AKI ≥stage 2 by KDIGO and sterile leukocyturia at admission in 2 Intensive Care Units (ICUs) of a Portuguese tertiary Hospital were prospectively included in a consecutive way. Anuria, CKD > stage 3, dialysis one week previous admission and absence of informed consent were exclusion criteria. Urinary flow cytometry was performed at Day 1 (D1) and 3 (D3). Renal recovery was defined as a decreased of at least one stage of AKI classification by KDIGO at 7days of ICU admission.

Results: From January to September 2018, a total of 552 patients were admitted in both ICUs, 108 with AKI ≥stage 2 by KDIGO at admission. Of these, 18 had sterile leukocyturia and no exclusion criteria. Median age was 75 years, 83.3% male, 88.9% caucasian, 33.3% diabetic and 66.7% hypertensive. Median baseline serum creatinine was 1.14mg/dl. APACHE II score was 30.5, 66.7% medical and 33.3% surgical admissions. Sepsis alone 44.4% or sepsis+hypoperfusion 38.9% were the most common causes of AKI, 33.3% needing Renal Replacement Therapy. Mortality at ICU and hospital discharge was 25.0% and 38.9%, respectively. Half the patients recovered renal function (REC) and half did not (NREC). Serum creatinine and cystatin C at admission did not differ between REC and NREC groups (3.06 SD0.56 vs 3.74 SD1.90 mg/dl, NS; and 3.25 SD1.24 vs 4.08 SD1.21mg/dl, NS, respectively). At D1, REC patients had similar % of T Cells (CD45+CD3+) (0.5 vs 0.6%, NS) and more B Cells (CD45+CD19+) (19.6 vs 4.3%, $p=0.046$), NK Cells (CD45+CD161+) (4.5 vs 1.1%, NS), neutrophils (28.7 vs 16.5%, NS) and dendritics (CD45+CD1c+) (4.9 vs 1.7%, NS). Patients who recovered also had a higher macrophages M1 (CD45+CD11b+CD68+) ratio D1/D3 (3.4 vs 1.3%, NS).

Conclusions: Immune mechanisms seem to play a role in renal regeneration and recovery after an episode of AKI. In our critically ill population, urinary B Cells were statistically significantly associated with renal recovery at 7 days after AKI at ICU admission.

FR-PO105

CpG C Dinucleotide Is a TL9 Agonist That Increases IgM Levels and Attenuates AKI in Mice

Nataliya Skrypnyk,[1] Peter I. Lobo,[2] Mark D. Okusa.[2] *[1]Nephrology, University of Virginia, Charlottesville, VA; [2]University of Virginia, Charlottesville, VA.*

Background: Acute kidney injury (AKI) is a common complication in hospitalized patients with high mortality rates and no FDA approved therapies available except dialysis and kidney transplant. CpG oligodinucleotides (ODNs) are short synthetic single-stranded DNA molecules containing unmethylated CpG dinucleotides in particular sequence contexts (CpG motifs). CpG class B has been approved by FDA in vaccine therapy as it strongly activates B-cells and IL-6 secretion but weakly stimulates interferon (IFN)-alpha secretion. CpG class C equally activates B-cells and IFN-alfa secretion but mild IL-6 secretion. It is known that CpG has protective effect on ischemic brain and heart injury. We hypothesize that CpG can have protective effect on the AKI.

Methods: C57BL/6 mice were anesthetized and subjected kidneys to ischemia-reperfusion (IR: 26 min of ischemia and 24 hrs of reperfusion). 50μg of CpG B or CpG C were administered i.v. 5 days before IR. Serum creatinine and BUN were measured and survival rates were recorded. In *in vitro* assays, freshly isolated murine splenocytes were activated with CpG C and intracytoplasmic IgM levels in B cells were evaluated by flow cytometry on day 5 (Figure 1).

Results: As depicted in Table 1, following IR the increase in plasma creatinine as well as mortality was significantly reduced by CpG C. In vitro studies CpG significantly increased intracytoplasmic IgM (Figure 1).

Conclusions: CpG C is more effective in ameliorating ischemia induced AKI than CpG B and also reduces post injury mortality rates. Potential mechanisms include increasing natural IgM levels (see Figure 1) and inducing regulatory activity in B cells and antigen presenting cells (Lobo PI, Frontiers in Immunology, 2017). CpG C has a broad range of applications that could be useful for preventive treatment of patients with AKI.

Funding: NIDDK Support

Table 1

	Day1 (creatinine)	Day3 (creatinine)	Survival
Control	1.8±0.1	1.5±0.3	45% on Day 12

Inhibition of BRD4 Leads to Reduced Activated Neutrophils and Adhesion to Endothelium After Ischemia-Reperfusion Injury

Shelby Reid,[2] Noah A. Fine,[2] Vikrant K. Bhosle,[1] Lisa Robinson,[1] James W. Scholey.[2] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada.*

Background: Following ischemia reperfusion injury (IRI), pro-inflammatory cascades partly dependent on NFkB, lead to neutrophil recruitment to the site of injury. Neutrophil accumulation then contributes to tissue injury through the release of pro-inflammatory cytokines, reactive oxygen species and proteases. We hypothesize that blockade of NFkB with the BRD4 inhibitor, MS417, will reduce neutrophil recruitment to the kidney following IRI.

Methods: Male C57BL/6 mice were treated with 1μM of MS417 for 7 days before unilateral ischemia was performed followed by reperfusion for 24 hours. Kidney tissue, blood and bone marrow was collected for neutrophil analysis using a custom flow cytometry panel. For *in vitro* studies, freshly isolated neutrophils from healthy volunteers were labeled with Calcein AM and incubated with MS417 media for 1 hour. HUVEC were activated by TNFα for 4 hours and then incubated with neutrophils and allowed to adhere for 30 minutes. Non-adherent cells were removed and neutrophil adhesion was quantified using a fluorescent plate reader.

Results: Absolute neutrophil counts increased in the bone marrow ($p<0.0001$ vs sham) and blood ($p<0.04$ vs sham) 24 hours after IRI and there was a trend towards increased neutrophils in the kidney ($p=0.12$ vs sham). Primed neutrophils (upregulated CD66a expression) did not increase in the bone marrow and blood at 24 hours, but increased in the kidney ($p=0.06$ vs sham). BRD4 inhibition reversed IRI induction of neutrophil counts in the bone marrow ($p<0.0001$ vs IRI) and blood ($p<0.03$ vs IRI), and in the kidney (trend). In contrast, BRD4 inhibition did not lead to significant decrease in primed neutrophils in the bone marrow and blood, but did reduce primed neutrophils in the kidney ($p<0.03$ vs IRI), reversing the effects of IRI alone. *In vitro* studies showed that TNFα increased neutrophil adhesion to HUVEC ($p<0.0001$ vs control). Pre-treatment of neutrophils with the BRD4 inhibitor led to a significant decrease in neutrophil adhesion ($p<0.0001$ vs TNFα–activated HUVEC).

Conclusions: BRD4 inhibition blocked neutrophil upregulation of the adhesion receptor, CD66a, neutrophil adhesion to activated endothelial cells, and recruitment of neutrophils to the kidney, following IRI. BRD4 inhibition may represent a therapeutic approach to limiting IRI in the kidney.

FR-PO107

The HMGB1-IL17A Axis Promotes Neutrophil Infiltration in Renal Ischemia-Reperfusion Injury

Jia Wang,[1] Jiong Zhang.[2] *[1]Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Chengdu, China; [2]Renal Department, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, China.*

Background: Renal ischemia/reperfusion (I/R) injury is the leading cause of acute kidney injury (AKI), which is associated with increased morbidity and mortality. Neutrophils are first to be recruited to the site of inflammation and also play a central role in the inflammatory cascade. We reported previously that inhibition of HMGB1 release ameliorated IR-induced neutrophils infiltration in mice. However, it is poorly understood whether HMGB1 was involved in regulating and activating the IL23/IL17 axis in renal IR injury. In this study, we aim to delineate whether the HMGB1/TLR4 signaling provokes the IL23/IL-17 axis and inducing the renal IR injury in mice.

Methods: C57BL/6 mice ischemia was induced by 60 min clamping of the left renal pedicle and followed by right nephrectomy and up to 24 h of reperfusion. The involvement of HMGB1 and IL17A was assessed in functional assays by neutralizing HMGB1, IL23 or IL17A antibody, and recombinant HMGB1 (rHMGB1), IL23 or IL17A (rIL17A), respectively. Urea nitrogen, creatine kinase and lactate dehydrogenase levels were measured. Renal histopathological changes and neutrophils infiltration were assessed by immunohistochemistry. The expression of HMGB1, TLR4, IL23, IL17A were assessed by western blot analysis and mRNA expression. The levels of MCP-1, IL8 and RANTES were assessed by ELISA.

Results: IL23, IL17A and neutrophils infiltration were increased after renal IR injury in mice. HMGB1 antibody significantly ameliorated IR induced neutrophils infiltration, renal injury and IL23, IL17A levels. TLR4-/- mice following renal IR injury were treated with rHMGB1 significantly reduced the expression of IL23, IL17A and neutrophils infiltration. Furthermore, IL-23 or IL17A antibody significantly inhibited IR induced neutrophils infiltration. Moreover, HMGB1 or IL17A antibody remarkably decreased production of neutrophil chemoattractant MCP-1, IL8 and RANTES, whereas rHMGB1 or rIL17A may promote production of them.

Conclusions: These results suggested that HMGB1 facilitated the injury effect of the IL23/IL17 axis, which contributed to neutrophils infiltration in renal IR injury.

Dexamethasone Pretreatment Prevented Chemotherapy-Induced Acute Renal Failure by Inducing Polymorphonuclear Myeloid-Derived Suppressor Cells

Yi-Dan Qiao,[1] Li-Yun Zhao,[1] Jie Chen,[1] Gao-Hui Zhu,[1] Yan-Fang Xing,[2] Xiang-Yuan Wu,[1] Xing Li.[1] *[1]the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]the Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China.*

Background: Chemotherapy for cancer patients leads to renal toxicity which was the main cause for chemotherapy discontinuation. Current preventive measures failed to be successful. Previous studies indicated dexamethasone cured renal diseases. The present study was aimed to reveal the efficacy and mechanism of dexamethasone in preventing chemotherapy induced renal toxicity.

Methods: Cisplatin was utilized to build acute renal failure mice model. Th17, Treg, polymorphonuclear myeloid-derived suppressor cells (PMN-MDSC) and monocytic MDSC (M-MDSC) was tested in injured kidney. Dexamethasone pretreatment was used to relieve renal failure with the immune mechanism investigated.

Results: Cisplatin induced acute liver failure confirmed by increased serum creatinine. Th17 cells were increased in injured kidney, with increased PMN-MDSC and decreased Treg cells. Dexamethasone pretreatment decreased serum creatinine and induced PMN-MDSC and Treg in kidney and increased Th17 cells. Gr-1 antibody was utilized to eliminate PMN-MDSC after dexamethasone pretreatment. PMN-MDSC depletion eliminated the efficacy of dexamethasone in relieving renal failure. Dexamethasone induced PMN-MDSC was transferred to mice before cisplatin administration, which decreased serum creatinine. Dexamethasone induced PMN-MDSC suppressed T cell proliferation through reactive oxygen species (ROS) pathway.

Conclusions: Dexamethasone pretreatment relieved chemotherapy induced renal failure by inducing PMN-MDSC, which suppressed Th17 cells and induced Treg cells.

FR-PO109

Sepsis Alters Renal Tubular Epithelial Phenotype and Disrupts Intercellular Communication

Danielle Janosevic,[1] Jered Myslinski,[1] Thomas W. McCarthy,[1] Takashi Hato,[2] Pierre C. Dagher.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University, Indianapolis, IN.*

Background: The success of sepsis therapy requires an understanding of time and cell-specific responses to infection. Such knowledge will allow accurate staging of septic patients and precise spatial and temporal therapy. We recently showed that the renal response to endotoxin (LPS) involves the sequential activation of inflammation, antiviral signaling and translation shutdown leading to organ failure. This propagation of injury was mediated in part by tubular epithelial and macrophage cross-talk. However, the kidney is composed of over twenty cell populations including epithelial, endothelial, immune and stromal cells. We therefore hypothesize that many of these cell types have precise roles in injury propagation along the sepsis timeline. To address this hypothesis, we used single cell RNAseq to dissect each cell subpopulation's contribution to endotoxin injury over time.

Methods: We harvested single cell suspensions from murine kidneys at time points spanning the injury and recovery phases of sepsis. Cells were processed via 10x Chromium RNA sequencing platform and analyzed with Seurat R package.

Results: We identified 26 clusters representative of major renal cell populations defined by known canonical markers. Endothelial cells and macrophages showed early transcriptional changes but opposite metabolic profiles. Interestingly, the pericyte also showed early signaling activation that persisted well into the recovery phase. In contrast, tubular epithelia exhibited a delayed response characterized by loss of expression of traditional markers such as the tubular SGLT2 transporter while simultaneously acquiring novel phenotypes such as the unexpected expression of antigen presenting MHC-II-related genes. This may indicate that under stress, epithelial cells assume the role of defenders rather than transporters. Remarkably, CellPhone Database analysis identified global shutdown of intercellular communication in the absence of cell death.

Conclusions: We propose that, in addition to propagation of injurious signaling, organ shutdown in sepsis also results from failure of cell-cell communication. This time-layered, cell-specific approach to the pathophysiology of sepsis may reveal biomarkers that allow the accurate staging of septic patients and identify temporally and spatially precise therapeutic targets.

Photoacoustic Microscopy Reveals Early Decrease in Peritubular Capillary (PC) O_2 Tension Associated with Temporal Changes in Cell Metabolism and Injury Despite Unimpaired PC Flow in Sepsis-Induced AKI

Shuqiu Zheng,[1] Naidi Sun,[2] Rui Cao,[2] Nabin Poudel,[1] Junlan Yao,[1] Shinji Tanaka,[1] Diane L. Rosin,[1,3] Song Hu,[2] Mark D. Okusa.[1] *[1]Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Biomedical Engineering, University of Virginia, Charlottesville, VA; [3]Department of Pharmacology, University of Virginia, Charlottesville, VA.*

Background: The ability to monitor dynamic changes in the renal metabolic rate of oxygen (MRO_2) is critical to understanding the time course of changes in local microenvironmental factors that lead to acute kidney injury (AKI). Technical limitations have impeded *in vivo* measurement of three key hemodynamic parameters—total hemoglobin concentration (C_{Hb}), oxygen saturation of hemoglobin (sO_2) and peritubular capillary blood flow (PCBF)—at the microscopic level. To address this, we developed a new technique - intravital multi-parametric photoacoustic microscopy (PAM).

Methods: To validate our system C57BL/6 mice were subjected to 1) hypoxia or 2) LPS-induced sepsis (5 mg/kg LPS, ip). The new intravital PAM platform uses nanosecond-pulsed lasers (532 and 558 nm) for dual-wavelength excitation-based spectroscopic measurement of sO_2. *In vivo* PAM imaging was performed over time on kidneys at depths of up to 200 μm. Plasma and kidneys were collected for measurement of creatinine, Kim1, NGAL, ATP, and various injury markers.

Results: *In vivo* PAM performed in mice challenged with 12 or 100% oxygen showed a strong correlation between sO_2 and inhaled oxygen concentration. After LPS, time-dependent changes in hemodynamic parameters and injury markers were observed. PCBF increased within 10 min but returned to and remained normal from 20-200 min. PC sO_2 began to decline immediately and a 30% decrease persisted from 20-200 min. Kidney ATP decreased by ~80% at 40 min. Abrupt increases in *Kim1* (~20-fold) and *Ngal* (~300-fold) and decreases (~80%) in *Nrf2* mRNA were observed at 12 hr. Creatinine increased at 24 hrs. *Tlr4* and *Myd88* mRNA increased at 12 hr.

Conclusions: *In vivo* PAM enables dynamic monitoring of renal MRO_2 in AKI. The immediate decrease in sO_2 but maintenance of PCBF indicates that blood flow was maintained yet sO_2 was limiting and produced marked temporal changes in biochemical parameters of cell metabolism and injury. This technical innovation lays the foundation for dynamic monitoring of renal oxygen metabolism in AKI, as well as chronic kidney disease, providing a new tool for AKI and CKD studies. BAM15, A New Mitochondrial Uncoupler, Improves Sepsis AKI

Naoko Tsuji, Takayuki Tsuji, Jonathan Street, Tetsushi Yamashita, Xuzhen Hu, Peter S. Yuen, Robert A. Star. Renal Diagnostics and Therapeutics Unit, NIDDK, NIH *National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD*.

Background: (2-fluorophenyl){6-[(2-fluorophenyl)amino](1,2,5-oxadiazolo[3,4-e] pyrazin-5-yl)}amine (BAM15) is a new mitochondrial uncoupler protects mitochondria with more specificity and less cytotoxicity than other uncouplers. Kenwood et al. (Mol. Metab. 2013) demonstrated that BAM15 treatment improved renal outcomes after renal ischemia/reperfusion injury. We evaluated the therapeutic potential of BAM15 for sepsis AKI.

Methods: Cecal ligation and puncture (CLP) was performed to 10-week-old CD-1 mouse to induce sepsis. BAM15 (5mg/kg, i.p.) was injected 0 hours after CLP. We also evaluated kidney injury and systemic organ damage and inflammation 18 hours after CLP. A survival study was conducted with both early (0hrs) and delayed (6hrs) BAM15 treatmement.

Results: BAM15 treatment at the time of CLP surgery improved both survival (fifteen of twenty of non-treatment group and five of twenty of treatment group were died in 7days: $P<0.05$) and kidney function at 18 hours along with reduced tubular histological damage, tubular hypoxia, systemic inflammation (e.g. IL-6 and IL-10) and splenic apoptosis (a marker of late immunosuppression), but did not improve other organs (e.g. liver and muscle). Furthermore, delayed treatment of BAM15 (6 hours after CLP) also improved survival (seventeen of twenty of non-treatment group and ten of eighteen of treatment group were died in 7days: $P<0.05$) and kidney dysfunction after sepsis.

Conclusions: Sepsis increased mitochondrial damage, tubular hypoxia, renal histological damage and, accelerated splenic apoptosis and systemic inflammation resulting in AKI and death. BAM15 significantly attenuated these processes, improved survival, and selectively improved septic AKI.

Circulating Peroxiredoxin 1 Is a Novel DAMP and Aggravates Acute Kidney Induced by Lipopolysaccharide via Promoting Inflammation

Zhangzhe Peng. *Xiangya Hospital, Central South University, Changsha, China*.

Background: Damage-associated molecular patterns (DAMPs) are initiators of sterile inflammation, which is a key contributor to acute kidney injury (AKI). However, the current knowledge on those DAMPs that activate renal inflammation under AKI remains incomplete. Peroxiredoxin-1 (Prdx1) is a small protein in the Peroxiredoxins family, which are ubiquitous expressed enzymes reducing peroxide levels. Interestingly, recent studies indicated that intracellular Prdx1 could be released to extracellular space under certain stimuli and extracellular Prdx1 has been recently identified as a novel DAMP due to its pro-inflammatory property by binding to Toll-like receptor (TLR) 2/4. However, the crucial role of Prdx1 in AKI remains unclear.

Methods: Prdx1-deficient mice and patients with AKI were used to determine its function in AKI, potential mechanisms and human relevance.

Results: Intraperitoneal injection of lipopolysaccharide (LPS) elicited a progressive course of AKI in mice developed from 12 to 24-hour post injection along with renal inflammation evident by macrophage infiltration and upregulation of cytokines (IL-1β, IL-6); these alterations were concurrently occurred with a robust and progressive production of serum Prdx1. Similar observations were also obtained in ischemia-reperfusion-induced AKI mouse model in mice. Removal of the source of serum Prdx1 protected mice deficient in Prdx1 from LPS-induced liver injury, and decreased macrophage infiltration, IL-1β and IL-6 production. As a result, Prdx1-/- mice were strongly protected from LPS-induced death that was likely progressed from AKI. Additionally, intravenous re-introduction of recombinant Prdx1 (rPrdx1) in Prdx1-/- mice reversed or reduced all the above events, demonstrating an important contribution of circulating Prdx1 to AKI. rPrdx1 potently induced in primary macrophages the expression of pro-IL-1β, IL-6, TNF-α, and IL-1β through the NF-κB signaling as well as the NOD2 signaling. Furthermore, a significant elevation of serum Prdx1 was demonstrated in patients (n=31) with AKI; the elevation is associated with serum creatinine.

Conclusions: Our findings reveal a previously unrecognized detrimental role of prdx1 in LPS-induced renal inflammation and tissue damage and thereby identify novel and important therapeutic target for LPS-induced AKI.

Renal Proteome Changes Reveal a Substantial Renal Acute Phase Response in Sepsis-Induced AKI in Mice

Peter Hamar,[1,2] Beáta Róka,[1,2] Pál Tod,[1,2] Tamás Kaucsár,[3] Marko Fonovic,[4,5] Boris Turk,[4,5] Matej Vizovisek,[4] Robert Vidmar,[4] Gábor Szénási.[6] *[1]Institute of Clinical Experimental Research; Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [2]Institute for Translational Medicine, University of Pécs, Pécs, Hungary; [3]Institute of Clinical Experimental Research, Semmelweis University, Budapest, Hungary; [4]Department of Biochemistry and Molecular and Structural Biology, Jozef Stefan Institute, Ljubljana, Slovenia; [5]Centre of Excellence for Integrated Approaches in Chemistry and Biology of Proteins, Ljubljana, Slovenia; [6]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary*.

Background: Sepsis-induced acute kidney injury (AKI) is the most common form of AKI with poor outcomes. Both differential diagnosis and management of septic AKI are unresolved issues. Our aim was to study the temporal profile of the renal proteome changes in bacterial lipopolysaccharide (LPS)-induced AKI.

Methods: Male NMRI mice were injected with LPS or saline (control). AKI was studied at early (EP, 1.5 and 6 h after LPS at 40 mg/kg i.p.) and late phases (LP, 24 and 48 h after LPS at 10 mg/kg i.p.) by HPLC-MS/MS screening. Renal mRNA expression of 13 acute phase proteins (APP) was measured by qPCR.

Results: AKI was indicated by increased renal TNFα, IL-6 and neutrophil gelatinase-associated lipocalin (Lcn-2) mRNA expression from 1.5 h after endotoxin administration. At 24 and at 48 h 53% of the top 30 significantly upregulated proteins were APPs, with complement C3, fibrinogen, haptoglobin and hemopexin demonstrating the greatest increases. LPS upregulated renal ceruloplasmin and haptoglobin mRNA expression from 1.5 h, and fibrinogen-α, -β, -γ, serum amyloid A, hemopexin, ferritin heavy chain and inter alpha-trypsin inhibitor 4 mRNA from 6 h. Complement C3 and transferrin mRNA were upregulated only in LP. Expression of most APP mRNAs peaked at 24 h and some mRNA started to recover by 48 h. Albumin mRNA was downregulated in LP.

Conclusions: Our proteomic analysis demonstrated a marked upregulation of local renal APR that commenced a few hours after treatment and peaked at 24 h in LPS-induced AKI in mice. Many more APPs were involved in the renal APR than previously identified.

Renal Ischemia-Reperfusion Followed by Sepsis Increases Mortality Despite Reducing Multiorgan Damage: Reversal by IL-6

Takayuki Tsuji,[1] Myung-Gyu Kim,[4] Jonathan Street,[1] Hua Zhou,[2] Asada Leelahavanichkul,[3] Xuzhen Hu,[1] Peter S. Yuen,[1] Robert A. Star.[1] *[1]NIDDK/NIH, Bethesda, MD; [2]The Affiliated Shengjing Hospital of China Medical School, Shenyang/China, China; [3]Chulalongkorn University, Bangkok, Thailand; [4]Korea University Anam Hospital, Seoul, Republic of Korea*.

Background: Sepsis frequently develops after AKI and portends a poor prognosis. We previously showed that sepsis 48 hours after ischemia reperfusion (I/R) AKI worsened kidney function and survival compared to sepsis alone, although there was less liver, muscle, spleen damage, and systemic cytokines. Thus, AKI unexpectedly dissociated renal function from systemic responses to sepsis. We hypothesized that the I/R injured kidney could alter the systemic response to subsequent sepsis. We investigated pathophysiological conditions of sepsis after AKI focusing on IL-6 and its upstream mediator Tumor necrosis factor-inducible gene 6 (TSG-6) which has anti-inflammatory properties.

Methods: We used 12 weeks old male C57/BL6 mice. We performed 40 minutes bilateral I/R for AKI, waited 48 hours, then performed cecal ligation and puncture (CLP) for sepsis. We measured outcomes at 48 hours after I/R and 24 hours after CLP. We also performed a 4 day survival study. In some animals, bilateral nephrectomy was performed at the same time of CLP surgery.

Results: I/R intensified sepsis-induced AKI [sCr; I/R+CLP vs $sham_{I/R}$+CLP, 1.40±0.58 vs 0.82±0.37 mg/dl ($p<0.05$)]. Survival rate in I/R+CLP was significantly worse than $sham_{I/R}$+CLP. In contrast, AST, LDH and CK, systemic inflammatory cytokines (HMGB-1, IL-10 and IL-6) and spleen apoptosis (immunohistochemistry of active caspase 3) were significantly lower in I/R+CLP than $sham_{I/R}$+CLP. Although I/R caused a slight elevation of systemic IL-6 at 48 hours, prior I/R surgery suppressed subsequent CLP stimulated IL-6, that was reversed by bilateral nephrectomy. Surprisingly, continuous administration of IL-6 starting immediately before CLP surgery improved the mortality of sepsis after I/R. In contrast, it worsened mortality in sepsis alone. Systemic and kidney TSG-6 was significantly increased at 48 hours after I/R injury and 24 hours after CLP in I/R+CLP compared to CLP alone.

Conclusions: AKI, followed by sepsis, worsened survival and kidney function, although liver and muscle enzymes, systemic cytokines and spleen apoptosis were improved compared with sepsis alone. Treatment with IL-6 improved survival of sepsis after AKI, counterintuitively. TSG6 derived from I/R injured kidney might contribute to changes in systemic and organ responses to subsequent sepsis.

Integrated Stress Response Mediates Epithelial Transport Dysfunction During Septic AKI

Jing Luo, Qi Yuan, Lei Jiang, Junwei Yang. *Nanjing Medical University, Nanjing, China*.

Background: Septic acute kidney injury (AKI) is a common cause of in hospital morbidity and mortality. Sepsis induced AKI is known to be associated with significant impairment of urine concentration, which requires establishment and maintenance of epithelial transport. However, the pathogenesis of endotoxemic tubular dysfunction with the failure of epithelial transport is poorly understood. Integrated stress response (ISR) is a common adaptive pathway for restoring cellular homeostasis under stress conditions such as infection and hypoxia. Previous studies have demonstrated that ISR is activated in AKI. Therefore, we investigate that ISR plays key roles in epithelial transport dysfunction during septic AKI.

Methods: Male C57BL/6 mice (6-8 weeks, 20–25g) received a single-dose of LPS (E. coli serotype 0111:B4, Sigma, 5 mg/kg) or sterile saline with tail vein injection and were killed at 1,3,6,12,24 and 48h (n=6 per group). To further explore the relationship between epithelial transport and ISR, C57BL/6 mice were treated with saline or ISRIB (ISR inhibitor, Sigma, 4 mg/kg) intraperitoneally 30 min after LPS injection and sampling at 3 and 24h. Kidney injury, inflammation, the expression of epithelial transport and ISR were measured.

Results: LPS-AKI model have demonstrated an inflammatory state with increased levels of IL-1β and TNF-α,and serious kidney injury indicated by BUN, plasma NGAL and KIM-1. At the same time, we determined that activation of the eukaryotic translation initiation factor 2-α kinase 2/eukaryotic translation initiation factor 2α (Eif2ak2/Eif2α) axis, which is the key mediator of ISR. We divided epithelial transport into 5 categories: Na+/K+-ATPase, tubular ion transport (ENaC, NKCC2, ROMK, NCC, CLCK), acid-base transport(NHE), glucose and urea transport(SGLT1,2,GLUT1,2,UTA,UTB) and water transport(AQP). The mRNA and protein levels of those transport proteins were all downregulated following ISR activation. ISRIB was an inhibitor of ISR. We found that ISRIB could ameliorate inflammatory state and restore renal function and the expression of those epithelial transport proteins after LPS injection.

Conclusions: ISR mediates the dysfunction of renal epithelial transport during septic AKI.

FR-PO116

Role of Intestinal Alkaline Phosphatase (IAP) in Lipopolysaccharide (LPS)-Induced Septic AKI

Siddhartha S. Ghosh,[1] Austin J. Mullaly,[2] Morgan H. Denecke,[2] Vatsal Lal,[2] Shobha Ghosh,[2] Todd W. Gehr.[2] *[1]VCU Medical Center, Richmond, VA; [2]Virginia Commonwealth University, Richmond, VA.*

Background: LPS plays a significant role in septic AKI. IAP is known to dephosphorylate LPS and render it inactive. LPS has also been suggested to play a role in leaky gut associated with septicemia. We hypothesized that overexpressing IAP will be beneficial for septic AKI. To test this hypothesis, we developed IAP transgenic mice (IAPTg). This was compared with IAP knock out (IAPKO) and wild type mice of the same background.

Methods: Septic AKI was induced by IP injection of 10 mg/kg LPS. Mice used were IAPTg which had human chimeric IAP under the control of villin promoter making them intestine and kidney specific. This chimeric human IAP (IAPTg) contains domains from human placental alkaline phosphatase which has a high turnover number and selectivity for LPS. The second group was IAP knockout (IAPKO). Both groups received LPS and compared with LPS-treated wild type (LPS-WT) and saline-treated wild type mice (Control). FITC-Dextran (FD) was given by gavage 2 hours before sacrifice to measure intestinal permeability. Blood and kidneys were harvested for biochemical and immunoblot analysis

Results: The table clearly shows the IAPTg mice have significantly improved renal function compared to LPS-WT and IAPKO mice. Creatinine and BUN of IAPKO mice were not significantly different from LPS-WT; serum FD levels were highest in IAPKO>LPS>IAPTg>Control. The kidney inflammasome markers measured by western blot of IAPKO mice were significantly higher than in the LPS-WT, IAPTg, and control groups. High mobility group box protein (HMGB-1), a late phase mediator of LPS, and gasdermin D, a marker for pyroptosis, were significantly high in IAPKO followed by LPS.

Conclusions: Increased serum FD in IAPKO and LPS-WT group suggests that endotoxemia can breach intestinal barrier function resulting in the leakage of intestinal toxins from the gut and aggravating inflammation. IAP abates leaky gut, inflammation, and cell death (pyroptosis) and improves renal function by inactivating LPS.

The Kidney Protects Other Organs During Sepsis by Producing and Circulating Tamm-Horsfall Protein (Uromodulin)

Kaice A. LaFavers,[2] Radmila Micanovic,[2] Takashi Hato,[1] Shehnaz Khan,[3] Seth Winfree,[2] Tarek M. El-Achkar.[1] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indina university of school of medicine Nephrology, Indianapolis, IN.*

Background: Acute kidney injury (AKI) significantly increases the mortality in patient with sepsis. Although retention of uncleared toxins could potentiate this effect, the loss of a protective factor released by the kidney could also play a role. Tamm-Horsfall Protein (THP) is uniquely made in the kidney. The majority of THP is secreted into the urine, but a portion is also released into the circulation. We previously showed that AKI is an acute state of THP deficiency and that circulating THP protects against systemic inflammation. Therefore, we propose that increased systemic release of THP from the kidney protects the organism with sepsis, and that the loss of THP is a major cause of increased mortality during septic AKI.

Methods: We used the cecal ligation and puncture (CLP) model of sepsis in $THP^{+/+}$ and $THP^{-/-}$ mice and measured plasma THP in small patient cohorts admitted to the intensive care unit (ICU) with sepsis.

Results: In THP+/+ mice, the level of serum THP increases within 6 hours after CLP, and remains elevated up to 48 hours in surviving mice. This trend was also observed in ICU patients with sepsis, where increased plasma THP correlated with worsening SOFA scores (a measure of organ failure) within 48 hours of admission. We also detected high levels of THP in the bronchoalveolar lavage fluid of patients who had developed acute respiratory distress syndrome, whereas levels were undetectable in healthy controls, demonstrating that THP localizes to dysfunctional organs during sepsis. To study the effect of THP deficiency on mortality, we compared $THP^{-/-}$ to $THP^{+/+}$ mice, and found that $THP^{-/-}$ mice have decreased survival (10% vs. 60% survival, respectively. $p<0.05$) within 48 hours after CLP. Additionally, treatment of $THP^{-/-}$ mice with purified exogenous THP restores survival to the levels seen in $THP^{+/+}$ mice. Mechanistically, THP increases the phagocytic activity of macrophages, which could partially explain the benefits of THP in the setting of a systemic infection.

Conclusions: Our work strongly supports that THP potentiates a protective cross-talk between the kidney and other organs during sepsis, and underscores the importance of maintaining kidney health in septic patients. This work could lead to the development of a new therapy for sepsis by administering THP or modulating its potential targets.

FR-PO118

Increased Gut Permeability in Septic AKI: Role of Na Butyrate (NaB)

Austin J. Mullaly,[2,1] Vatsal Lal,[2] Morgan H. Denecke,[2] Austin J. Gonzalez,[2] Siddhartha S. Ghosh,[1] Shobha Ghosh,[2] Todd W. Gehr.[2] *[1]VCU Medical Center, Richmond, VA; [2]Virginia Commonwealth University, North Chesterfield, VA.*

Background: Increased intestinal permeability is associated with multiple organ dysfunction syndromes in sepsis. In septic AKI, TLR 4 receptors located on the basolateral side of the intestine can be targeted by systemic lipopolysaccharide (LPS) and cause leaky gut. Intestinal leakage further exaggerates the kidney inflammation and deteriorates AKI. NaB produced by gut microbiota has been shown to curb inflammation and gut permeability. We hypothesize that NaB will protect against LPS-induced leaky gut and ameliorate inflammation and septic AKI.

Methods: Septic AKI was induced by injecting 10 mg/kg LPS (IP). C57Bl6 mice were divided into 3 groups: Control (Ctl), AKI group received LPS (AKI) and treated (TR) group received 300 mg/kg NaB by gavage 30 mins before LPS. Mice were sacrificed after 10 hours. To measure intestinal permeability FITC-Dextran (FD) was given by gavage 2 hours before sacrifice. Blood, kidneys, and colon were harvested for biochemical and immunoblot analysis.

Results: Serum creatinine and BUN of AKI were 0.74±.05 mg/dl and 169±5 mg/dl which measured 2-fold higher than the Ctl ($p<0.01$). NaB significantly reduced both creatinine and BUN ($p<0.05$). Serum FD (14±1 μg/ml) of AKI was more than 3-fold higher than Ctl($p<0.01$). NaB treatment reduced FD levels by 13% ($p<0.05$). Compared to Ctl, colonic tight junction protein ZO-1 was significantly reduced in the colon of AKI ($p<0.05$), but was restored in TR. Inflammatory markers such as high mobility group box protein (HMGB-1), NFkB and IL-1β in the kidney of AKI were 2 to 3 fold higher than Ctl ($p<0.05$) but NaB treatment decreased them suggesting that NaB can decrease kidney inflammation in LPS induced AKI.

Conclusions: Higher levels of serum FD and loss of intestinal tight junction protein shows that endotoxemia can increase intestinal permeability which may cause leakage of toxic biomolecules from the intestine. LPS can activate inflammatory responses through HMGB-1. NaB activates intestinal alkaline phosphatase which dephosphorylates LPS and renders it inactive. In addition, NaB can act as a HMGB-1 antagonist and a GPR109A agonist, both of which support intestinal barrier integrity. These might be some of the mechanism by which NaB can decrease the inflammatory burden and improve renal function in AKI.

FR-PO119

A Novel Circular RNA-has_circ_0114427 Regulates Inflammation via miR-494 in AKI

Wanxin Tang, Yiling Cao, Xuhua Mi, Dongmei Zhang, Zheng Wang, Yongdi Zuo. *West China Hospital of Sichuan University, Chengdu, China.*

Background: Acute kidney injury (AKI) is a common serious syndrome characterized by a rapid decrease of glomerular filtration rate and the progressive increase of serum creatinine. CircRNAs are novel regulatory RNAs that recently became popular among researchers of various diseases. However, the expression profile and function of circRNAs in AKI remain largely unknown. CircRNAs act as competing endogenous RNAs (ceRNAs) to regulate transcription level by binding with microRNAs (miRNAs), as indicated by recent research.

Methods: In the current study, we established a cisplatin-induced AKI mice model and then extracted circRNAs from isolated renal tubular tissues for next-generation sequencing at different time points during AKI's early stage. By using bioinformatic analysis, we identified out a certain number of significant differentially expressed mmu-circRNAs in AKI. Furthermore, we validated the expression pattern and explored the function of the significant homologous circRNAs in HK2 cells.

Results: We successfully identified differentially expressed circRNAs related to AKI. By finding homologous genes between mouse and human, we identified a new circRNA, circ-0114427, in humans. Circ-0114427 expression was significantly up-regulated in different AKI cell models. Knockdown of circ-0114427 indicated that circ-0114427 bound to miR-494 as a miRNA sponge to regulate ATF3 expression and further affected the expression of downstream cytokine IL-6.

Conclusions: Elevated circ-0114427 may play an important role in anti-inflammation in the early stage of AKI. Our findings provide a novel insight into the regulatory mechanism of circRNAs in AKI and may become a new molecular target resource for early diagnosis and treatment strategies.

Genome-Wide Association Study for AKI in the ASSESS-AKI Study

Pavan K. Bhatraju,[1,2] Shreeram Akilesh,[1] Chi-yuan Hsu,[3] Kathleen D. Liu,[4] Amit X. Garg,[5] James S. Kaufman,[6] Paul L. Kimmel,[7] Alan S. Go,[8] Chirag R. Parikh,[9] Talat Alp Ikizler,[10] Jonathan Himmelfarb,[11] Mark M. Wurfel,[1] Jennifer A. Schaub.[12] ASSESS-AKI *[1]University of Washington, Seattle, WA; [2]Medicine, Division of Nephrology, Kidney Research Institute, University of Washington, Seattle, WA; [3]University of California San Francisco, San Francisco, CA; [4]University of California at San Francisco School of Medicine, San Francisco, CA; [5]London Health Sciences Centre, London, ON, Canada; [6]VA New York Harbor Healthcare System, New York, NY; [7]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [8]Kaiser Permanente Northern California, Oakland, CA; [9]Johns Hopkins University, Baltimore, MD; [10]Vanderbilt University Medical Center, Nashville, TN; [11]Kidney Research Institute, Seattle, WA; [12]University of Michigan, Ann Arbor, MI.*

Background: Identifying genetic risk factors for AKI could provide insights into pathophysiology and help identify novel pathways for therapeutic development.

Methods: We conducted a genome-wide association study in a multi-ethnic population of 1,370 prospectively enrolled subjects in the ASSESS-AKI Study. Genotyping was completed using the Illumina MEGA chip and the Haplotype Reference Consortium was used for genome-wide multiple imputation. Genetic association testing for AKI was conditioned on: age, sex, diabetes, center and first three principal components of ancestry. Threshold for significance included single-nucleotide polymorphisms (SNPs) with a $p < 5 \times 10^{-6}$.

Results: Among 637 AKI and 733 non-AKI participants, 5,645,675 SNPs were tested for the association with AKI. Among AKI participants, 72% had Stage 1 AKI and 7% required new dialysis during hospitalization. We found that 56 SNPs in six novel loci were associated with the development of AKI (**Figure 1**). The SNP with the strongest association with AKI was rs17538288>A. The minor allele of rs17538288 was associated with an increased risk for AKI (adjusted odds ratio 1.53, 95% confidence interval 1.30 – 1.79, $p=2.08 \times 10^{-7}$). Utilizing integrated functional epigenomic analyses, we found that top-performing SNPs localized to regulatory DNA elements in primary human glomerular and cortex cell culture. We also investigated 22 SNPs identified in two prior AKI GWAS studies and found that none of the SNPs replicated in ASSESS-AKI ($p<0.05$).

Conclusions: We identified six novel genetic loci that were associated with prevalent AKI. Functional annotation in kidney cells/tissue provides insights into the mechanism of kidney injury. Future work will require replication in well-phenotyped AKI cohorts and mechanistic studies to understand the relationship of genetic variation and AKI development.

Mechanisms of Remote Organ Dysfunction in AKI

Katherine J. Kelly,[1,2] Danhui Xie,[3] Jesus H. Dominguez.[1] *[1]Indiana University, Indianapolis, IN; [2]Medicine, Roudebush VA Medical Center, Indianapolis, IN; [3]IUPUI, Indianapolis, IN.*

Background: While ~1.7 million acute kidney injury (AKI) patients die each year, the very high mortality rate is largely due to failure of extra-renal organs and not typically caused by renal dysfunction. We and others have shown persistent coagulation abnormalities and impaired renal microvascular function in experimental AKI. We hypothesize that the clotting abnormalities are systemic and contribute to multi-organ dysfunction in AKI.

Methods: The role of activated coagulation, microvascular dysfunction and impaired perfusion were assessed in a model of ischemic AKI using multiphoton, intravital imaging. The effects of a fibrinolytic agent were also examined.

Results: In addition to diffuse renal microvascular thrombi, we found heterogeneous clotting in the microvasculature of the brain, intestine, mesentery, liver, spleen and lung

after renal ischemia. Microvascular flow was significantly decreased 48 hours after renal ischemia, to 24-58% of sham levels in different organs. In addition, tissue factor was increased postischemia in the kidney, heart, lung, liver and serum (2.4-4.2 fold, $p<0.04$). In the heart, expression of tissue factor pathway inhibitor was 0.54 +/- 0.1 fold that seen in shams ($p<0.05$). In addition, left ventricular function was impaired. Plasma flow and microvascular thrombi in remote organs improved with fibrinolytic therapy given after renal failure was established.

Conclusions: Our data indicate persistent systemic coagulation abnormalities after ischemic renal injury contributes to sustained, heterogeneous ischemia, leading to inflammation and tissue injury in multiple extra-renal organs. We have previously shown decreased cardiac function in experimental AKI. The systemic abnormalities likely contribute to the morbidity and mortality of AKI, but are amenable to therapeutic intervention.

Modulation of Oxidative Stress Prevents Deleterious Lung Kidney Interactions in a Novel Experimental Model of Pulmonary Renal Syndrome

Firoozeh Farahmand. *Nephrology, Saint Louis, Saint Louis, MO.*

Background: AKI is the most common organ dysfunction in acute lung injury (ALI) and ARDS. In fact, AKI increases the mortality rate to more than 40%, with the rate rising with AKI severity. Deleterious interactions between kidney and lung play a major role in multiorgan failure in critically ill patients. But, the casual relationships between lung injury and kidney injury is not well understood. Large body of evidence suggests oxidative stress mediates lung-kidney organ crosstalk. However, specific therapies are lacking. Since ALI/AKI, once initiated, is much less susceptible to treatment we need to investigate potential protective treatment which requires developing experimental model to translate drug findings from bench to bedside.

Methods: In a novel model of ALI/AKI induced by a toxic alkaloid (Tox-ALK) injection to evaluate the effects of antioxidant treatment, rats were treated with an Angiotensin II Type 1 (AT1) receptor blocker with antioxidant activity daily starting a week before and continued for 1 wk post-(Tox-ALK) injection. Serial echocardiography was performed weekly to non-invasively monitor evolution of pulmonary hypertension secondary to lung injury. At 4 weeks lungs and kidneys were analyzed for antioxidant enzyme activities including superoxide dismutase, glutathione peroxidase, catalase and oxidative stress. Lungs wet/dry weight ratios were measured to assess edema. After sacrificing the animals, the renal cortex and the lung were removed for histology

Results: At 4 wks post-Tox-ALK, there was acute lung injury, characterized by lung edema, neutrophil infiltration, hypoxemia and acute tubular necrosis in the Kidney. Losartan treatment attenuated Tox-ALK induced oxidative stress in lung and the kidney, ALI, PH and importantly, increased the activities of SOD and GSHPx in the lung and the kidney.

Conclusions: In this experimental model ALI and AKI in rats correlates with a decrease in antioxidant and increase in oxidative stress in the lung & the kidney. Inhibition of the RAS prevent ALI and AKI, improved survival as well as oxidative stress parameter in the kidney. This study suggest the beneficial effects of AT1 receptor blocker as a kidney–lung protective strategy in critically ill patients.

Metabolomics in the Lung After Ischemic AKI Reveals Increased Oxidative Stress, Altered Energy Production, and Energy Depletion

Sophia L. Ambruso,[2,1] Benjamin Fox,[3] Hyo-Wook Gil,[5] Rushita A. Bagchi,[6] Peter R. Baker,[4] Sarah Faubel.[2,1] *[1]Renal, Rocky Mountain Regional VA Medical Center, Denver, CO; [2]University of Colorado Denver, Denver, CO; [3]CU Anschutz Medical Campus, Goleta, CA; [4]University of Colorado, Aurora, CO; [5]Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea; [6]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Acute kidney injury (AKI) is a systemic disease with deleterious effects on distant organs, including the lung. Lung function is dependent upon redox homeostasis and ATP generation through oxidative phosphorylation. Acute lung injury (ALI) after AKI is characterized by acute inflammation and neutrophil accumulation. Metabolically, ALI shows increased oxidative stress, energy depletion, and altered energy production. We sought to determine the effect of AKI on lung metabolism.

Methods: Normal mice and mice after sham (surgery alone) or surgery for ischemic AKI (22 minutes of bilateral renal pedicle clamping) were studied at 4-hours, 24-hours or 7 days post procedure. Lung metabolomics was performed via ultra high-pressure liquid chromatography coupled to online mass spectrometry (UHPLC-MS). Untargeted UHPLC-MS-based metabolomics analysis provided the measurement of 132 annotated metabolites in the lung. Commercially available reagents (Abcam; ab833355) were used to measure lung ATP.

Results: AKI had a significant effect on the lung metabolome at 4- and 24-hours post-procedure. There was evidence of 1) increased catabolism characterized by decreased amino acids and their metabolites (ie. Leucine/Isoleucine, Phenylalanine, S-Adenosyl-L-Methionine at 4 hours and lysine, D-O-phosphoserine, L-adrenaline, L-carnitine and O-propanoylcarnitine at 24 hours), 2) increased oxidative stress and dysregulated redox system via decreased levels of glutathione, thioredoxin disulfide, nicotinamide and adenosine, and 3) use of alternative energy sources characterized by decreased intermediates in glycolysis (ie. lactate and D-glucose) and the pentose phosphate pathway (ie. D-Ribitol-5-Phosphate and D-Ribose). Lung ATP levels were reduced in the lung after AKI compared to sham and control at 4 hours [control CI 2.5-6.8 ($p<0.0001$), sham CI 2.3-6.0 ($p<0.0001$)] and 24 hours [control CI 0.8-5.6 ($p=0.003$), sham CI 0.5-4.9 ($p=0.007$)].

Conclusions: This is the first study to examine the metabolome and ATP levels post-ischemic AKI in the lung. Our findings show depleted ATP levels and evidence of increased oxidative stress, energy depletion and use of alternative energy production. Further metabolomic profiling in the lung post-AKI is needed to identify pathways for future clinical interventions.

Elucidation of the Mechanism of Kidney-Gut Cross-Talk via the D-Serine Derived from Gut Microbiota

Yusuke Nakade,[1] Yasunori Iwata,[2] Shinji Kitajima,[1] Tadashi Toyama,[1] Akinori Hara,[2] Miho Shimizu,[3] Norihiko Sakai,[2] Takashi Wada.[2] *[1]Kanazawa University Hospital, Kanazawa, Japan; [2]Kanazawa University, Kanazawa, Japan; [3]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan.*

Background: While dysbiosis of the gut microbiota has been closely associated with kidney disease, the precise underlying mechanisms remain unclear. Recent advances have shed light on the chirality of amino acids. Free D-amino acids and their L-forms were quantified by 2D HPLC. Accumulating data revealed that D-amino acids were the primary microbial products, which showed physiologic roles in several organs. However, the involvement of D-amino acids in kidney diseases have yet to be revealed. Thus, we explored the pathophysiological role of D-amino acids in association with the gut microbiota in kidney disease.

Methods: Six-week-old male C57BL/6 (B6) mice and germ-free (Gf) B6 mice were subjects to sham or ischemia-reperfusion (I/R) operation, and evaluated 2, 5, 7 and 10 days after surgery. D-serine was administered to mice via drinking water during I/R induced kidney injury. We performed 16S rRNA gene sequencing analysis of the mouse gut microbiota and evaluated D- and L-amino acids in the mouse feces, plasma, kidney and urine using 2D HPLC system. We also obtained blood samples from patients with AKI to evaluate D- and L-amino acids.

Results: Specific gut bacteria were influenced by I/R. Further, I/R induced kidney injury was more severe in Gf B6 mice compared to B6 mice. Interestingly, fecal transplantation from normal mice attenuated the renal pathology in the Gf B6 mice. Next, we performed comprehensive analyses of chiral amino acids in I/R induced kidney injury. While various D-amino acids were detected in the feces, only D-serine was detected in the injured kidney. Furthermore, D-serine was not detected in the feces of Gf B6 mice, suggesting that gut microbiota produced D-serine in response to kidney disease. Further, the oral administration of D-serine attenuated I/R injury in normal mice. In addition, we assessed the association between D-serine and renal function in patients with AKI. The plasma levels of D-serine in patients with AKI was higher than in the plasma of healthy subjects, showing a high correlation with creatinine ($r > 0.9$).

Conclusions: These results demonstrate the renoprotective effects of gut-derived D-serine in AKI, shed light on the novel interactions between the gut microbiota and the kidney, and highlight D-serine as a potential new therapeutic target and biomarker for AKI.

Sham Surgery Suppresses Autophagy in the Kidney and Heart

Carolyn N. Brown, Sara Holditch, Nataliya Skrypnyk, Chris Altmann, Jelena Klawitter, Sarah Faubel, Charles L. Edelstein. *UC Denver Anschutz Medical Campus, Aurora, CO.*

Background: Renal ischemia/reperfusion (IR) and compensatory hypertrophy induced by unilateral nephrectomy (UNX) activate mTOR, a suppressor of autophagy. Autophagy maintains proteostasis by sequestering proteins into autophagosomes for delivery to the lysosome where cargo is recycled. The aim of the study was to determine the effect of sham surgery (SHAM), UNX, or IR on mTOR and autophagy in the kidney & heart in wildtype mice.

Methods: IR was induced by bilateral renal pedicle clamp; mice were sacrificed 24 or 72hr later. UNX was performed; mice were sacrificed 2hr later. Normal mice without surgical manipulation (NORM), SHAM, IR, and UNX mice were treated with vehicle or bafilomycin (BAF) 2hr before sacrifice. LC3-II and p62 were measured by immunoblot. Increased LC3-II (autophagosome marker) after BAF or decreased p62 (degraded by autophagy) were used as markers of autophagy.

Results: Autophagy was suppressed in the kidney 2hr after UNX and SHAM compared to NORM kidneys, but only 2hr after UNX in the heart. There was suppressed autophagy in the heart at 24hr of both IR & SHAM that normalized by 72hr. Suppressed autophagy in the kidney & heart in SHAM, UNX, & IR was associated with statistically significant increases in mTOR (pS6, p4E-BP1, pAkt). To determine a possible mechanism of suppressed autophagy, metabolomics analysis was performed on 2hr NORM, SHAM, & UNX kidneys. Of 225 metabolites measured, folate, fructose phosphate, & glycine with known roles in autophagy regulation were significantly decreased (P<0.05) in both SHAM and UNX vs. NORM kidneys.

Conclusions: SHAM suppresses autophagy in the kidney & heart. Increased mTOR and suppressed autophagy in the kidney & heart caused by SHAM have important implications for researchers using models requiring surgery. The connection between suppressed autophagy & folate, fructose phosphate, & glycine merits further study.

Real-World Use of Calcimimetics in Small and Independent Hemodialysis Facilities

Shan Xing,[1] Tzu-Chieh Lin,[1] Nisha Bhatt,[1] Pooja Desai,[1] Kevin J. Martin,[5] Michel Chonchol,[2] Michelle Gleeson,[4] Mark D. Danese,[6] Deborah Lubeck.[3] *[1]Amgen, Thousand Oaks, CA; [2]University of Colorado, Aurora, CO; [3]Outcomes Insight, Westlake Village, CA; [4]Outcomes Insights, Westlake Village, CA; [5]Saint Louis University Med Ctr, St. Louis, MO; [6]Outcomes Insights, Inc., Westlake Village, CA, CA.*

Background: In 2018, when etelcalcetide [ETE] became commercially available, dialysis organizations became newly responsible for providing calcimimetics to Medicare patients due to a reimbursement change from Part D to Part B. This study describes calcimimetic utilization and control of circulating parathyroid hormone (PTH), calcium (Ca) and phosphorous (P) in adults with a record of calcimimetics during the first 9 months of 2018 in small and independent hemodialysis facilities (SDO/IDOs).

Methods: This is a retrospective study of electronic health records from SDO/IDOs (Visonex) from 10/1/2017 to 12/31/2018. Adults ≥18 years of age were identified as a Cinacalcet (CIN) or ETE user based on their first calcimimetic in 2018. Patients were followed until kidney transplant, death, or end of data collection. Descriptive analyses of patient characteristics and laboratory control at baseline and follow-up were conducted.

Results: In the first 9 months of 2018, 2601 patients received a calcimimetic (CIN (n=1346, mean (SD) age=60.5 (14.0), 43.5% female, 47.1% black) or ETE (n=1255, mean (SD) age=63.4 (14.5), 46.6% female, 38.5% black). Median (IQR) months of follow-up was 5.0 (2-9) for CIN, and 8.0 (4-11) for ETE. Median (IQR) PTH (pg/mL), P (mg/dl) and Ca at baseline were 670 (356-1094), 5.6 (4.7-6.8), and 9.2 (8.7-9.7)) for CIN; and 686 (453-1044), 5.6 (4.7-6.7), and 9.1 (8.7-9.6), respectively for ETE users. Cut-offs for in-range laboratory measures were: PTH=150-600 pg/mL; P=3.5 – 5.5 mg/dL; and Ca=8.4 – 10.2 mg/dL. See figure for proportion of patients in control for PTH by month.

Conclusions: ETE users in SDO/IDOs had improved control during a longer follow-up compared with CIN, with 61% of patients having PTH in control at 9 months.

Funding: Commercial Support - Amgen

Timing of PTH Reduction with Cinacalcet (CIN) or Etelcalcetide (ETL) Treatment and Effect of Previous CIN Dose

Anjay Rastogi,[1] Sue Zhang,[2] Sandro Rossetti,[2] David A. Bushinsky.[3] *[1]Division of Nephrology, UCLA, Los Angeles, CA; [2]Amgen Inc., Thousand Oaks, CA; [3]University of Rochester Medical Center, Rochester, NY.*

Background: The calcimimetics ETL and CIN reduce serum parathyroid hormone (PTH) in subjects with secondary hyperparathyroidism (sHPT) on hemodialysis (HD) (NCT1896232; Block *JAMA* 2017). This post-hoc analysis investigated the timing of PTH reductions following CIN or ETL treatment and their relation to previous CIN treatment.

Methods: Data were derived from a phase 3, randomized, active control, dose-titration trial comparing the safety and efficacy of CIN and ETL in adults with sHPT receiving HD with PTH ≥500 pg/mL. Subjects received CIN (titrated from 30-180 mg PO QD) and IV placebo (TIW); or ETL (titrated from 5-15 mg IV TIW) and placebo (PO QD) for 26 weeks to target a PTH ≤300 pg/mL. Subjects could not have received CIN during the 3 months prior to screening. Achievement of >30% PTH reduction by 8 or 18 weeks and maintenance of the target PTH reduction during the efficacy assessment phase (weeks 20-27) were analyzed. Stratified by previous CIN dose, PTH levels over time were summarized using descriptive statistics.

Results: At baseline, subjects (N=683 [343 CIN; 340 ETL]) had a median PTH of 930 and 900 pg/mL in the CIN and ETL groups, respectively. By week 8, >70% of subjects had achieved >30% PTH reduction from baseline (Table). Of these, 80% receiving ETL vs 68% receiving CIN maintained >30% PTH reduction in weeks 20-27. By week 18, >85% of subjects had achieved >30% PTH reduction from baseline. Of these, 77% receiving ETL vs 65% receiving CIN maintained >30% PTH reduction in weeks 20-27. In both groups, subjects with a lower previous CIN dose showed mostly consistent declines in PTH over time, with the ETL group achieving a greater magnitude reduction from baseline by week 26.

Conclusions: CIN and ETL can effectively reduce PTH levels within 8 weeks, and ETL may better preserve this reduction over time.

Funding: Commercial Support - Amgen Inc.

Table. Reduction in PTH following treatment with etelcalcetide or cinacalcet and its relation to previous calcimimetic treatment.

	Head-to-Head Trial	
Treatment Group	**Cinacalcet (N = 343)**	**Etelcalcetide (N = 340)**
>30% PTH reduction from baseline by week 8, N1	252	245
Maintained >30% PTH reduction in week 20-27, n (%)[a]	172 (68.3)	195 (79.6)
>30% PTH reduction from baseline by week 18, N1	299	299

PTH Levels Prior to Initiating Hemodialysis: Associations with Prescription of PTH-Lowering Therapies and Risk of Uncontrolled PTH During the First Year of Hemodialysis

Eric W. Young,[8] Angelo Karaboyas,[1] Philipp Csomor,[7] David M. Spiegel,[2] Masafumi Fukagawa,[3] Issa Al Salmi,[6] Pieter Evenepoel,[4] Stefan H. Jacobson,[5] Xinling Liang,[9] Ronald L. Pisoni,[1] Bruce M. Robinson.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Relypsa, Inc., Denver, CO; [3]Tokai University School of Medicine, Isehara, Japan; [4]University Hospitals Leuven, Leuven, Belgium; [5]Danderyd Hospital, Stockholm, Sweden; [6]The Royal Hospital, Muscat, Oman; [7]Vifor Fresenius Medical Care Renal Pharma Ltd., Glattbrugg, Switzerland; [8]Arbor Research, Ann Arbor, MI; [9]Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: PTH levels during pre-dialysis may influence subsequent management and achieved PTH levels after onset of ESRD.

Methods: We studied 5683 incident HD patients from 21 countries in phases 4-6 (2009-2018) of the Dialysis Outcomes and Practice Patterns Study (DOPPS) with information on PTH measured immediately prior to HD initiation. We stratified by PTH prior to HD start and reported the monthly prescription prevalence of active vitamin D and calcimimetics over the first year of HD, and risk of PTH >600 pg/mL after 9 months on HD.

Results: Median (IQR) PTH prior to HD start was 275 (155, 472) pg/mL and 16% of patients initiated HD with PTH >600 pg/mL. Patients who initiated HD with higher PTH levels were more likely to be prescribed active vitamin D in the early months of HD, and these differences were steady over the first year of HD (Figure A). Patients starting HD with PTH >600 pg/mL were much more likely to initiate calcimimetic treatment during the first year of HD, amplifying differences in calcimimetic use by PTH at HD start over the first year of HD (Figure B). Among a subset of 2728 patients who remained in DOPPS with PTH measured 9-12 months after HD initiation, the prevalence of PTH >600 pg/mL was much greater for patients who initiated HD with PTH >600 (29%) vs. 150-300 (7%) pg/mL.

Conclusions: The findings were consistent with the hypothesis that management of PTH in the pre-ESRD phase influences subsequent PTH management and levels after onset of ESRD. Patients with greater PTH concentrations prior to start of dialysis were more likely to receive active vitamin D and calcimimetic therapy in the first year of HD. However, despite more aggressive management, high PTH prior to initiation of dialysis was associated with high PTH (>600 pg/ml) 9 months after the start of hemodialysis. These findings help inform clinical management and research goals and provide insight into cost drivers for PTH management in HD.

Parathyroidectomy vs. Cinacalcet for Secondary Hyperparathyroidism in Patients Undergoing Hemodialysis

Hirotaka Komaba,[1,2] Takayuki Hamano,[1,3] Naohiko Fujii,[1,4] Atsushi Wada,[1,5] Ikuto Masakane,[1,6] Kosaku Nitta,[1,7] Masafumi Fukagawa.[2] *[1]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan; [2]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [3]Department of Inter-Organ Communication Research in Kidney Disease, Osaka University Graduate School of Medicine, Suita, Japan; [4]Department of Internal Medicine, Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan; [5]Department of Nephrology, Kitasaito Hospital, Asahikawa, Japan; [6]Department of Nephrology, Honcho Yabuki Clinic, Yamagata, Japan; [7]Department of Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Parathyroidectomy (PTx) and cinacalcet are both effective in treating secondary hyperparathyroidism in patients undergoing hemodialysis. However, there is a paucity of data comparing the long-term outcomes of these treatments.

Methods: We analyzed data from a nationwide cohort of hemodialysis patients in Japan who had intact parathyroid hormone (PTH) levels >300 pg/ml and no history of prior PTx on December 2007. Patients who underwent PTx or initiated cinacalcet between January 2008 and December 2009 were matched for baseline intact PTH levels and propensity score in a 1:3 ratio. Mortality follow-up started on December 2009 and continued until December 2015. Mortality risk was assessed using Cox proportional hazards models.

Results: A total of 894 patients who underwent PTx and 2,682 patients who initiated cinacalcet had similar propensity scores and were included in the analysis. Median baseline intact PTH levels were 588 pg/ml (interquartile range [IQR], 422-809 pg/ml) and 566 pg/ml (IQR, 427-777 pg/ml) in the PTx and cinacalcet groups, respectively. Following either treatment, the intact PTH levels decreased to 83 pg/ml (IQR, 19-225 pg/ml) in the PTx group and 218 pg/ml (IQR, 138-364 pg/ml) in the cinacalcet group. During the 6-year of follow-up period, 201 patients in the PTx group and 736 patients in the cinacalcet group died. PTx was associated with a significantly lower risk of death compared with cinacalcet (hazard ratio, 0.78; 95% confidence interval, 0.67-0.91). The survival benefit associated with PTx versus cinacalcet was more pronounced in patients with baseline intact PTH levels >500 pg/ml and in patients with baseline serum calcium levels >10.0 mg/dl (both P <0.001 for interaction). The difference in mortality between PTx and cinacalcet was attenuated by adjustments for time-varying intact PTH, calcium, and phosphorus levels.

Conclusions: PTx compared with cinacalcet is associated with a lower risk of death, particularly among patients with severe secondary hyperparathyroidism.

FR-PO130

Thrice Weekly vs. Daily Cinacalcet: Virtual Clinical Trial and Its Subsequent Clinical Validation in a Large US Hemodialysis Population

Gudrun Schappacher-Tilp,[1] Jeffrey L. Hymes,[3] Doris H. Fuertinger,[2] Amanda Stennett,[2] Peter Kotanko.[4] *[1]University of Graz, Graz, Austria; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Fresenius Medical Care North America, Franklin, TN; [4]Renal Research Institute, New York, NY.*

Background: Secondary hyperparathyroidism affects most hemodialysis (HD) patients. Current therapies include cinacalcet. Its label indicates a daily, oral administration with food. However, high pill burden and gastrointestinal side effects limit patient adherence. The aim of this study was to explore in a virtual clinical trial (VCT) whether directly observed 3x weekly in-center (IC) administration is sufficient to control parathyroid hormone (PTH) levels. The VCT findings were compared to observations in a subsequent roll-out of 3x weekly IC cinacalcet in a large U.S. HD population.

Methods: We utilized 2 mathematical models, a cinacalcet pharmacokinetic model (Schappacher-Tilp, Cell Phys Biochem 2019) and a comprehensive model of parathyroid gland biology (Schappacher-Tilp, Phys Rep 2019). We simulated 2 populations, cinacalcet naïve patients and patients on cinacalcet for ≥ 12 weeks. We then compared PTH levels attained with directly observed 3x weekly vs. daily administration; for the latter we considered a real-life adherence rate of 64%, based on pharmacy data. A subsequent clinical roll-out involved 4865 HD patients on daily cinacalcet for ≥ 12 weeks who were subsequently switched to 3x weekly IC cinacalcet for ≥ 12 weeks.

Results: Our VCT showed that patient adherence significantly impacts PTH levels. The PTH lowering effects of prescribed daily cinacalcet administration with limited patient adherence were almost identical to directly observed 3x weekly IC administration. Model predictions were corroborated by subsequent clinical observations (Fig 1).

Conclusions: Directly observed 3x weekly IC administration of cinacalcet is not inferior to daily administration with realistic adherence rates. Our results support the utility of VCTs for exploring alternative therapy regimens.

Efficacy and Safety of Cinacalcet in Chinese Maintenance Hemodialysis Patients with Different Stages of Secondary Hyperparathyroidism: Rationale and Design of ACTIVE Study

Zhihong Liu. ACTIVE study group *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China*.

Background: Secondary hyperparathyroidism (SHPT), as a common complication in advanced Chronic kidney disease (CKD) has become a global public health problem. Patients with CKD and uncontrolled SHPT are at high risk of cardiovascular events and associated mortality. Cinacalcet, a calcimimetic agent was reported to effectively and safely reduce PTH levels in CKD patients with SHPT previously. However there has been no large-scale study and stratified analysis of cinacalcet in China and the optimal therapeutic doses of different levels of severity of SHPT still remain unknown.

Methods: A phase IV, open-label, multicenter study was designed and conducted in 23 hospitals in China. The study was performed in two phases. In phase 1, a cohort study for 32 weeks follow-up was designed to explore the efficacy and safety of cinacalcet. In phase 2, a real-world study of 20 additional weeks was designed in which patients completing the cohort study decided on their own whether to continue taking cinacalcet at their own cost or not. Patients with a baseline iPTH ≥300 pg/mL should receive at least 12 weeks of maintenance hemodialysis before enrollment. The primary efficacy endpoint is the proportion of patients achieving iPTH targets (iPTH between 150-300pg/mL) at 20 and 32 weeks after the initiation of cinacalcet treatment (shown in Fig.1)

Results: Up to 2019/05/12, a total of 750 maintenance hemodialysis patients with SHPT were enrolled and stratified into 3 groups according to baseline iPTH level (mild 300~600, moderate 600~900 and severe ≥900 pg/mL respectively). The trial is still in progress and enrollment has been completed. Analysis of the baseline data is ongoing and the corresponding results will be released at ASN meeting this year.

Conclusions: We expect that the results of this study will allow us to draw valuable conclusions related to these objectives and expand the medical knowledge of end stage kidney disease(ESKD) especially for patients with SHPT

Role of Etelcalcetide in the Management of Secondary Hyperparathyroidism in Hemodialysis Patients After 10 Months of Therapy

Ioannis Griveas.[1,2] [1]*Dialysis Unit "Nefroiatriki", Athens, Greece;* [2]*Helenic Open University, Athens, Greece*.

Background: Secondary hyperparathyroidism (sHPT) is common in hemodialysis (HD) patients. The present study aimed to evaluate the efficacy and safety profile of etelcalcetide in an observational study for the treatment of SHPT in CKD patients on hemodialysis.

Methods: 60 HD stable patients with sHPT were received etelcalcetide for 10 months, who were receiving oral or iv VDRA's and/or cinacalcet or were naïve before start of the protocol. Dose of VDRA's remained stable and adjustments to etelcalcetide dose were taken place every month. PTH levels, Ca, Ph, alb were measured before starting etelcalcetide and every month until the end of the protocol. Heart function of patients evaluated at the start and at the end of the study. The primary outcome was estimation of intact-parathyroid hormone (PTH) concentrations. Secondary outcomes were monitoring of calcium, phosphate (ph) albumin. Our study population was divided to sub-groups: a. diabetics and non-diabetics, b. patients over and below 65 years old, c. patients that were naïve regarding CKD-MBD therapy, or were receiving monotherapy or replaced cinacalcet with etelcalcetide and d. according to their previous PTH levels (below 500 pg/ml, between 500-700 pg/ml and over 700 pg/ml|). Adverse events (AEs) were also evaluated.

Results: PTH significantly decreased from the first month of the treatment with etelcalcetide (771.53±438.58 vs 586.55±497.30, p<0.05, approximately 24% reduction from baseline). This trend carried out until the end of the study period (363.08.±373.90.60, p<0.05, approximately 47% reduction from baseline). We also noticed significant reduction of the ph levels even from the second month of treatment (from 4.98.±1.24 to 4.64±1.86 mg/dl, p<0.05). This trend also carried out for 8 months period (4.67±1.22 mg/dl, p<0,05). Heart function remained stable. In all the sub-groups we had significant reduction of PTH and Ph during the whole study period. Remarkable finding was the stable bevaviour of Ca levels from the first week until the end of the study period along with albumin. None of the patients of the protocol dropped out due to adverse events.

Conclusions: Etelcalcetide is safe, well tolerated and effective in reducing iPTH in HD s patients with sHPT. As the only available intravenous calcium-sensing receptor agonist, etelcalcetide is likely to provide a new treatment option for sHPT in HD patients.

FR-PO133

Effect of Switching from Cinacalcet to Etelcalcetide on Secondary Hyperparathyroidism in Patients with Hemodialysis: An ESCORT Trial

Kei Fukami, Yuka Kurokawa, Junko Yano, Goh Kodama, Tomofumi Moriyama, Yosuke Nakayama, Yusuke Kaida. *Division of Nephrology, Department of Medicine, Kurume University School of Medicine, Kurume, Japan*.

Background: Cinacalcet (Cina) is used in the management of secondary hyperparathyroidism (SHPT) in patients undergoing hemodialysis (HD). Etelcalcetide (Etel) is a novel intravenous calcimimetic for the treatment of SHPT, which could improve drug adherence and reduce adverse gastrointestinal events. Here, we evaluated the efficacy of switching from Cina to Etel in the management of SHPT and constructed the dose conversion factor in this ESCORT trial.

Methods: A total of 138 HD patients on Cina were screened, and 93 patients with serum-intact parathyroid hormone (iPTH) ≥60 pg/mL and serum albumin-corrected calcium (cCa) ≥8.4 mg/dL were enrolled. The patients were divided into three groups (Cina 25 mg, 50 mg, and ≥75 mg). Etel was administered intravenously for 24 weeks. The primary endpoint was the dose distribution of Etel in patients who achieved target iPTH levels (60–240 pg/mL) after 24 weeks. Further, we investigated serum bone alkaline phosphatase (BAP), tartrate-resistant acid phosphatase 5b (TRACP 5b), and fibroblast growth factor 23 (FGF23).

Results: A total of 90 patients completed the study. At the end of the study, mean iPTH levels significantly decreased in the Cina 25 mg group (Cina 25 mg: from 179.8 ± 97.1 to 137.4 ± 62.9 pg/mL, $p = 0.003$; Cina 50 mg: from 177.0 ± 122.5 to 177.2 ± 80.3 pg/mL, $p = 0.996$; Cina ≥75 mg: from 289.4 ± 300.7 to 236.9 ± 211.6 pg/mL, $p = 0.110$). cCa levels significantly decreased ($p < 0.001$). Serum BAP, TRACP5b, and FGF23 levels also decreased following the drug switching ($p = 0.001$, $p < 0.001$, $p = 0.009$, respectively). Sixty patients (66.7%) maintained target iPTH levels before and after the study (pre: 133.5 ± 45.6 pg/ml; post: 148.2 ± 46.9 pg/ml). In these patients, the dose of Cina before the switch was 42.9 mg/day, and the final dose of Etel was 6.17 mg/HD. The dose conversion factor for the switch from Cina to Etel was 4.640 + 0.036*pre-dose (Cina/day). No adverse events, such as hypocalcemia and gastrointestinal symptoms, led to study discontinuation in this trial.

Conclusions: Switching from Cina to Etel effectively improved MBD and ameliorated high iPTH in patients undergoing HD for 24 weeks. No serious adverse events were observed. These results suggest beneficial effects of Etel administration in managing SHPT in patients undergoing HD.

FR-PO134

Role of Etelcalcetide in the Management of Secondary Hyperparathyroidism: Clinical Experience

Candela Moliz, Elizabeth Canllavi fiel, Beatriz Redondo navarro, María Fernández vidal, Teresa Bada Bosch, Hernando Trujillo Cuellar, Lucia Aubert, Justo Sandino Perez, Elena Gutierrez-solis, Evangelina Merida. *Hospital Universitario 12 de Octubre, Madrid, Spain*.

Background: Etelcalcetide is the first intravenous calcimimetic authorized for the treatment of SHPT in haemodialysis (HD). It has proven to be effective in lowering parathyroid hormone (PTH), with an acceptable and comparable safety profile. There have only been a few reports regarding treatment of SHPT using etelcalcetide in clinical practice.

Methods: The aim of this deriptive study was to evaluate the results of using etelcalcetide in patients on HD with SHPT.

Results: Thirty patients on HD received etelcalcetide were enrolled (figure 1). The minimum observation period was 6 months. Fifteen (50%) were previously with cinacalcet (group 1) and 15 (50%) received etelcalcetide at onset (group 2). In global, serum PTH levels were significantly decreased at the end of follow up compared to baseline levels (PTH pretreatment 784 +/- 707 *(p 0.0077) vs* PTH end of follow- up 671 +/- 680 *(p 0.0077))*. When comparing both groups, we found a significant decrease of Ca, P and PTH in group 2. However, we only found significant decrease of Ca in group 1 (figure 2). The dosage of calcium binders (33.3% pretreatment vs 56.7% at the end of follow-up, p 0.054), non-calcium binders (40% pretreatment vs 63.3% at the end of follow-up, p 0.02) and vitamin D analogues (56,7% pretreatment vs 66,7% at the end of follow-up, p 0,3) were increased when etelcalcetide treatment was started. No changes were made in dialysate calcium concentration. Six patients, presented hypocalcemia (Ca < 7.5 mEq/l)

Conclusions: In our cohort, etelcalcetide has shown to be effective in reducing serum PTH. An increase in the use of vitamin D analogues, calcium binders and non-calcium binders has been observed, probably due to the hypocalcemia.

Etelcalcetide Utilization and CKD-MBD Marker Responses in US Hemodialysis Patients

Douglas S. Fuller,[1] Tzu-Chieh Lin,[2] Nisha Bhatt,[2] Bruce M. Robinson,[1] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Amgen, Thousand Oaks, CA.*

Background: Etelcalcetide is a new intravenous calcimimetic approved in February 2017 for treating secondary hyperparathyroidism in US adult hemodialysis (HD) patients. Real-world etelcalcetide utilization practices are not well understood.

Methods: Monthly cross-sectional data from a national sample of 6041-9113 HD patients/month treated at 113-157 HD units/month in the US Dialysis Outcomes and Practice Patterns Study (February 2017-February 2019) were used to describe: (1) etelcalcetide use (% of patients prescribed ≥1 dose each month) and dose at etelcalcetide initiation, by dialysis organization (DO) size (LDO sample, 10+ units; non-LDO and hospital-based sample, <10 units), and (2) trends in serum parathyroid hormone (PTH), total calcium (Ca), and phosphorus (PO_4) levels up to 12 months after etelcalcetide initiation.

Results: In February 2019, 6.1% of US HD patients were prescribed etelcalcetide, representing 21% of all US calcimimetic use. Etelcalcetide use was markedly higher in non-LDO facilities (25-26% of patients/month) than LDO facilities (2-3%). Mean initial etelcalcetide dose was 13.1 mg/wk (median: 11.5; IQR: 7.2, 13.4). At drug initiation, serum PTH was higher in LDO (median: 976 pg/ml, IQR: 596, 1709; >600: 75%) than non-LDO (median: 735 pg/ml; IQR: 448, 983; >600: 61%) facilities, mean serum total Ca was 9.0 mg/dl (median: 9.0; IQR: 8.5, 9.4), and mean serum PO_4 was 5.7 mg/dl (median:5.4; IQR: 4.4, 6.6). Among patients remaining on treatment: (1) mean and median serum PTH decreased 32% and 46% by month 6, respectively; (2) mean total Ca decreased 0.35 mg/dl by month 2, and hypocalcemia (<7.5 mg/dl) was uncommon (4.8%; range by month: 2.1-7.5%); and (3) mean PO_4 levels were relatively unchanged (range by month: 5.5-5.9 mg/dl).

Conclusions: Rapid uptake of etelcalcetide occurred in the US through February 2019, with substantial differences by DO size. Serum PTH steadily declined while treated with etelcalcetide, while calcium levels remained in the recommended range. Continued monitoring of etelcalcetide utilization will offer insights regarding titration patterns and laboratory target achievement.

Effect of Active Vitamin D and Calcium-Sensing Receptor Agonists on the Responsiveness of Bone to the Parathyroid Hormone in Hemodialysis Patients

Naoto Tominaga,[1,2] Tomoki Yonaha,[6] Masayuki Yamanouchi,[5] Hirofumi Sumi,[1,2] Yasuhiro Taki,[1,2] Yugo Shibagaki,[2] Kazuhiro Shiizaki,[3] Shozo Yano.[4] *[1]Division of Nephrology and Hypertension, Kawasaki Municipal Tama Hospital, Kawasaki, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [3]Jichi Medical University, Shimotsuke, Japan; [4]Shimane University Faculty of Medicine, Shimane, Japan; [5]Okinaka Memorial Institute for Medical Research, Tokyo, Japan; [6]Yonaha Medical Clinic, Ishigaki, Okinawa, Japan.*

Background: Levels of the serum parathyroid hormone (PTH) and serum tartrate-resistant acid phosphatase-5b (TRACP-5b), a bone resorption marker derived from osteoclasts, show a positive correlation. In hemodialysis (HD) patients, however, the responsiveness of bone to the serum PTH level varies widely among individuals, and the serum TRACP-5b level relative to the serum PTH level varies. This study examined factors related to the responsiveness of bone to PTH in HD patients.

Methods: This study of HD patients in Kawasaki Municipal Tama Hospital (Kanagawa, Japan) and Yonaha Medical Clinic (Okinawa, Japan) excluded those with HD for <6 months, a combination of peritoneal dialysis, cancer bone metastases, and myeloma. The TRACP-5b/intact PTH (iPTH) ratio was newly created as an index of responsiveness of bone to PTH, categorized by tertiles of the ratio (low, medium, and high), and a cross-sectional study was conducted. In each analysis, P<0.05 was considered statistically significantly different.

Results: One hundred six patients were analyzed. Age (P=0.010), body mass index (BMI) (P=0.003), use of calcium-sensing receptor (CaSR) agonists (P=0.008), use of active vitamin D (VD) (P=0.012), iPTH level (P=0.0001), $1,25(OH)_2D$ level (P=0.003), and TRACP-5b level (P=0.0001) were statistically significantly different among the three categories. In the simple linear regression analysis, age (P=0.016), corrected serum calcium level (P=0.007), and ln [$1,25(OH)_2D$] (P=0.044) showed a statistically significant positive correlation with ln (TRACP-5b/iPTH), whereas BMI (P=0.026), use of CaSR agonists (P=0.001), use of active VD (P=0.009), and serum phosphorus level (P=0.018) showed a statistically significant negative correlation. When conducting multiple linear regression analysis incorporating significant variables in the simple linear regression analysis, a statistically significant negative correlation was shown between the TRACP-5b/iPTH ratio and use of active VD and CaSR agonists.

Conclusions: The administration of active VD or CaSR agonists may reduce the stimulatory effect of PTH on bone resorption in HD patients.

FR-PO137

Relationship Between Parathyroid Hormone and Renin Angiotensin Aldosterone System in Hyperparathyroidism

Keiji Kono, Hideki Fujii, Shuhei Watanabe, Shunsuke Goto, Shinichi Nishi. *Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Parathyroid hormone (PTH) is known to be one of the regulators for calcium and phosphate metabolism. On the other hand, it has been reported that PTH has several effects on the cardiovascular system. However, its mechanism remains to be not fully elucidated. As a possible mechanism, PTH is thought to be associated with the renin angiotensin aldosterone system (RAS). Therefore, we investigated their hormonal interaction in patients with primary and secondary hyperparathyroidism (HPT).

Methods: Twenty-seven HPT patients (primary HPT: N=10, secondary HPT: N=17) were included in this study. All the study patients underwent parathyroidectomy (PTx) in our institution. We measured serum intact PTH, plasma renin activity (PRA) and plasma aldosterone levels (ALD) before and after PTx. In addition, we evaluated blood pressure before and after PTx.

Results: Baseline estimated glomerular filtration rate (eGFR) was 44.3±35.4 ml/min/1.73m^2 in the primary HPT group. All patients in the secondary HPT group received maintenance hemodialysis. Pre-operative serum intact PTH levels were positively correlated with pre-operative ALD and PRA in both HPT groups (primary HPT group (ALD: r= 0.685, p< 0.05, PRA: r= 0.661, p< 0.05), secondary HPT group (ALD: r=0.493, p< 0.05, PRA: r=0.446, p= 0.072)). Along with changes of serum intact PTH levels after PTx, both PRA and ALD were also significantly decreased after PTx in both HPT groups. In addition, changes of serum intact PTH levels were positively correlated with changes of PRA and ALD in both groups (primary HPT group (ALD: r= 0.774, p< 0.05, PRA: r=0.815, p<0.05), secondary HPT group (ALD; r= 0.451, p= 0.069, PRA; r= 0.466 p= 0.059)). Although blood pressure was significantly decreased after PTx in the primary HPT group, it did not change in the secondary HPT group.

Conclusions: Our findings suggest that the effects of HPT on the cardiovascular system could be partially mediated by RAS in secondary and primary HPT.

FR-PO138

Parathyroidectomy: Good for the Bones, but a Pathway to Metabolic Syndrome

Eduardo J. de Sa C. Filho,[1] Shirley F. Crispilho,[2] Rosa M. Pereira,[1] Vanda Jorgetti,[1] Rosilene M. Elias,[1,2] Rosa M. Moyses.[1] *[1]Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Nove de Julho, São Paulo, Brazil.*

Background: Increased levels of parathyroid hormone (PTH) are associated with weight loss, weakness, and muscle atrophy. Recent publications point out that PTH can regulate muscle and adipose tissues metabolism by the activation of thermogenic and atrophy-related genes. The aim of this study is to investigate the effect of parathyroidectomy (PTX) on body composition, biochemical and metabolic parameters in chronic kidney disease (CKD) patients on dialysis.

Methods: We are prospectively evaluating body composition of 30 patients before and after 6 months of PTX by using dual-energy x-ray absorptiometry (DXA), and correlating with CKD-MBD parameters.

Results: In those patients that have already completed the protocol (n=8), we observed a significant drop in PTH and alkaline phosphatase (1,329 ± 332 vs. 155 ± 151 pg/ml and 264 ± 36 vs. 79 ± 30 IU/L, p<0.001). A significant increase in body mass index (24.6±5 vs. 25.2 ± 5 kg/m^2), fat mass (FAT; 17.8 [16-23] vs. 23.2 [19-29] kg; p= 0.02), body fat percentage (%FAT; 27.7 [20-37] vs. 32 [31-42] %; p=0.006] and bone mineral content (BMC; 1.8 [1.4-2.1] vs. 2.1 [1.8-2.7]; p=0.0008] was seen. However, lean body mass (LBM) decreased (42.2 [38-55] vs. 38.9 Kg [37-51]; p=0.001]. We noticed a tendency toward an increase in fast glucose (74 [67-82] vs. 85 [80-90] mg/dl, p=0.058) and in HOMA index (1.6 [0.5-2.7] vs. 2.4 [1.3-7.1]; p = 0.10). There was a significant correlation between the percentage decrease in PTH and in LBM (r = 0.90; p = 0.0046) and a trend toward the percentage decrease in PTH and in BMC (r = -0.62; p = 0.12) and in FAT (r = -0.52; p = 0.19).

Conclusions: We demonstrated that reduction in PTH levels after PTX is associated with FAT increasing, most likely related to energy production regulation, and LBM loss. Future prospective studies should evaluate the crosstalk between muscle and fat mediated by PTH, and its impact in insulin resistance and muscle wasting.

FR-PO139

Relationship of Serum Parathyroid Hormone (PTH) Levels with Objective Measures of Nerve Function in ESRD

Simit Doshi,[1] Alissa A. Cranor,[2] Kimberly Swinney,[1] Keith G. Avin,[3] Sharon M. Moe,[2] Ranjani N. Moorthi.[2] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University-Indianapolis, Indianapolis, IN.*

Background: Advanced kidney disease is a risk factor for motor and sensory nerve deficits, independent of diabetes. The pathophysiology for nerve deficits in renal failure remains unclear. We tested the hypothesis that secondary hyperparathyroidism is associated with a distinct nerve function profile in ESRD patients.

Methods: Seventeen patients with ESRD underwent testing after their routine dialysis session. We measured action potentials (amplitude) and nerve conduction velocity (NCV) in motor (ulnar, peroneal) and sensory (ulnar, sural) nerves in the upper and lower extremities. Symptoms were assessed using the neuropathic pain questionnaire (NPQ). Muscle function was measured as handgrip strength and knee extension strength using a dynamometer. Physical performance was measured as gait speed during a 4 meter walk test. Labs drawn closest to date of testing were used for all analyses. Predefined and validated cut-offs were used to define a deficit. Statistical analyses were done using SPSS 24.

Results: Seventeen pts were enrolled: aged 23-66, 9 male, 15 black, 10 diabetic, median dialysis vintage 5.4 yrs. Ten patients had high PTH ie > 500 pg/ml (median 522 pg/ml; range 25-2364). Neuropathic pain was noted in ~60% patients overall. NCV deficits were prevalent but mean motor NCV (ulnar: 46 vs 46, peroneal 39 vs 40 m/s) or sensory NCV (ulnar 26 vs 26, sural 26 vs 28 m/s) measures were not different between high vs low PTH groups. Vibration detection threshold (48 vs 52 microns) was also similar. A deficit in ulnar motor amplitude was seen in 2 patients with high PTH levels (566 and 528) (1/2 diabetic). Both patients had neuropathic pain (function score >0), low grip strength (<20 kg) and low gait speed (<0.8 m/s).

Conclusions: Deficits in NCV, a marker of myelination, were noted in most patients on dialysis and did not differ between groups. Deficits in amplitude, a marker of axonal damage, were noted exclusively in patients with elevated PTH levels. Whether elevated PTH levels predispose to axonal neuropathy will be evaluated by ongoing enrollment of subjects and follow up testing after decreases PTH in this study.

FR-PO140

Etelcalcetide for Managing Secondary Hyperparathyroidism in Hemodialysis Patients

Tomohiro Saito, Masahide Mizobuchi. *Showa University School of Medicine, Yokohama, Japan.*

Background: We retrospectively assessed the efficacy of a new calcimimetic, etelcalcetide, in Japanese chronic hemodialysis patients with secondary hyperparathyroidism (SHPT). The aim of this study was to assess the factors related to the therapeutic effects of etelcalcetide.

Methods: The subjects were 43 patients (average age: 60 years; average dialysis period: 90.7 months) with serum intact parathyroid hormone (iPTH) >240 pg/mL. Intravenous injection of etelcalcetide was started at 15 mg/week for 12 weeks and the dose was adjusted to control the serum levels of iPTH, corrected calcium (cCa), and phosphorus (P).

Results: In total, 81.3% of the patients had a reduction of iPTH of ≥50% at 12 weeks, and 32% achieved the target levels for P, cCa and iPTH. In multivariate analysis, female sex and a history of cinacalcet administration were independent inhibitory factors for iPTH reduction. Compared to patients with a history of cinacalcet administration (n=22), those without this history (n=21) had higher rates of reduction of iPTH of ≥50% (63.6% vs. 95.2%, p=0.007) and of achievement of target levels for P, cCa, and iPTH (22.7% vs. 42.9%, p= 0.15). The side effects in all the subjects during the study period were hypocalcemia (44%), nausea (7%), and muscle spasms (2.3%).

Conclusions: Our results suggest that etelcalcetide can improve management of iPTH together with cCa and P levels in Japanese hemodialysis patients with SHPT. Thus, adherence enhancement and better control of SHPT with etelcalcetide might allow improved management of mineral metabolism, compared to cinacalcet. There was a tendency for iPTH levels to decrease more slowly in patients with a history of cinacalcet administration.

Summary of the MBD markers at the end of observation period

	All patients (n=43)	History of cinacalcet treatment		P-value
		Yes (n=22)	No (n=21)	
≧50% reductions in iPTH, n (%)	34 (79.0)	14 (63.6)	20 (95.2)	0.007
60≦iPTH<240 pg/ml, n (%)	26 (60.5)	12 (54.6)	14 (66.7)	0.41
P, cCa, and iPTH , n (%) ✣	14 (32.6)	5 (22.7)	9 (42.9)	0.16

Abbreviations: iPTH, intact parathyroid hormone; cCa, corrected calcium; P, phosphorus.
✣ Patients who achieved all the target levels for P, cCa, and iPTH.

Summary of MBD markers at the end of the 12-week observation period in patients with ((+), n=22) and without ((-), n=21) a history of cinacalcet treatment before etelcalcetide administration.

FR-PO141

Impact of Parathyroidectomy on Left Ventricular Function in ESRD Patients

Shaohua Chen, Ying Shen, Ping Zhang, Hua Jiang, Xin Lei, Lihui Qu, Chunping Xu, Jianghua Chen. *Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: Secondary hyperparathyroidism is a common complication in End Stage Renal disease patients, and parathyroidectomy is an effective treatment of SHPT. The biochemical parameters and clinical symptoms has been proven to be drastically improved after the surgery, but the curative impact of parathyroidectomy on left cardiac function is still controversial. To evaluate the impact of parathyroidectomy on left cardiac function in ESRD patient, we conducted this retrospective study.

Methods: We collected and analyzed the basic data including serum calcium, phosphor, ALB, PTH, alkaline phosphatase(ALP) pre and post-operation, and the ultrasonic cardiogram including EF, FS, LA, AO, LVSd, LVSs, LVDd, LVDs, PWd, PWs, LVM and LVMI before and after 1 year of patients who accepted total parathyroidectomy (PTX) with forearm Autograft.

Results: There were totally 135 patients invovled, all of whose postoperative serum calcium, phosphor, PTH, ALB has been obviously improved compared with preoperative group, but the statistical change of EF and FS which stand for left cardiac function after 1 year didn't exist. We then carried out a further subgroup analysis, picking out patients whose EF were lower than or equal to 60%(n=35) before the surgery. Compared with preoperative group, the EF, FS of postoperative group increased, and LVDs, LVM.LVMI declined($p<0.05$).

Conclusions: PTX+AT is an effective curative method to secondary hyperparathyroidism which can significantly improve the postoperative biochemical parameters. For patients whose EF≤60%,PTX+AT can markedly increase their left cardiac function.

Table 3 ultrasonic cardiogram and dry weight change of ESRD patients whose EF%≤60% before the surgery

FR-PO142

Loss of PTH Circadian Secretion in Peritoneal Dialysis Patients: A Case Series

Francesca K. Martino,[1] Gianpaolo Amici,[2] Anna Giuliani,[1] Carlo Crepaldi,[1] Claudio Ronco.[3] *[1]San Bortolo Hospital, Vicenza, Italy; [2]AAS3 Friuli Venezia Giulia, San Daniele del Friuli, Italy; [3]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy.*

Introduction: Chronic Kidney disease (CKD) affects calcium and phosphorus metabolism and in PTH secretion. Under normal conditions, PTH is secreted by parathyroid gland with circadian rhythm and can be influenced by calcium, phosphate and vitamin D levels. These factors find peculiar expression in peritoneal dialysis patients. We report PTH levels, serum calcium and phosphorus in six patients on peritoneal dialysis during the 24-hours period.

Case Description: In 6 patients, PTH, calcium and phosphorus were evaluated at the following times every 4 hours at 8 am o'clock, 12 am, 4 pm, 8 pm, middle night and 4 am (+ 1day) and 8 am (+ 1day). Some parameters related to peritoneal dialysis (such as type of dialysis, peritoneal solution), hemoglobin, creatinine, sodium, and albumin levels were evaluated for each patient. Moreover, when present we described calcium, and phosphate urine excretion in 24 hours collection. Patients characteristics are described in table 1. In figure 1 are described the levels of PTH for each patient and in figure 2 the levels of calcium and phosphate for each patient.

Discussion: These clinical reports suggest the loss of circadian rhythm in PTH secretion in peritoneal dialysis patients.

Paricalcitol for Severe Secondary Hyperparathyroidism in Hemodialysis Patients

Carlos D. Jimenez Mejia,[2,1] Jorge fernando Topete reyes,[2,1] Javier Soto-Vargas,[1] Arantxa K. Aguilar,[2,1] Luz Y. Villegas,[2,1] Ríos C. Katia yuritzi.[2,1] Departamento de Nefrologia HGR 46 [1]*Instituto Mexicano Del Seguro Social, Guadalajara, Mexico;* [2]*Universidad de Guadalajara, Aguascalientes, Mexico*.

Background: Severe secondary hyperparatiroidism (SSHP) is associated with renal osteodystrophy, extraosseous calcifications, fractures, and increased mortality in end-stage kidney disease (ESKD) patients, especially those in hemodialysis (HD). Currently, their treatment consists on control of hyperphosphatasemia with phosphate binders, vitamin D or its analogues, as well as calcimimetics to suppress PTH release and ultimately surgery. Our main objective was to determine the effectiveness of paricalcitol to control PTH levels in HD patients with SSHP

Methods: Phase 2 placebo control double blinded trial that included patients with ESKD on HD for more than six months with SSHP resistant to management with calcitriol. The patients were assigned to receive paricalcitol (at dose dependent on their iPTH levels/80) or placebo and conventional treatment with phosphate binders

Results: During March to April 2019 there were screened 650 patients in our center, after application of selection criteria ten patients were allocated to paricalcitol group and nine to the control group. The median PTH level in the paricalcitol group was 1162 pg/ml, while in the placebo group was 925 pg/ml. After one month of treatment, the paricalcitol group had a mean reduction of 798.5 pg, and the control group had a median increase of 179.2 pg (p=0.013). There were no reported adverse effects in either group

Conclusions: Paricalcitol showed an important reduction in PTH levels in patients with SSHP on HD, without increased risk for hyperphosphatemia or other adverse events

EOS789, a Novel Pan-Inhibitor of NaPi-IIb/PiT-1/PiT-2, Suppressed Intestinal Phosphate Absorption in Healthy Subjects: A Phase 1 Clinical Trial

Nozomi Hisada,[1] Shingo Maisawa,[1] Jotaro Sato,[1] Ippei Ikushima,[2] Takei Kake.[1] [1]*Chugai Pharmaceutical Co., Ltd., Tokyo, Japan;* [2]*SOUSEIKAI Sumida Hospital, Tokyo, Japan*.

Background: Hyperphosphatemia in patients with chronic kidney disease is not well managed by existing treatments. Sodium-dependent phosphate co-transporters NaPi-IIb, PiT-1, and PiT-2 are considered to play a central role in intestinal phosphate (P) absorption, and are recognized as promising targets for a novel therapeutic strategy for hyperphosphatemia. Past clinical trials suggest blocking only NaPi-IIb is not sufficient for suppressing intestinal P absorption. We identified EOS789, a novel pan-inhibitor against NaPi-IIb, PiT-1, and PiT-2. Here we report the safety, tolerability, pharmacokinetics, and pharmacodynamic activity of the novel pan-inhibitor EOS789 in the first-in-human clinical trial in healthy subjects.

Methods: A randomized, double-blind, placebo-controlled, Phase 1 clinical trial in healthy subjects was conducted. It consisted of single (32 Japanese) and multiple (32 Japanese and 8 Caucasian) ascending dose parts. Primary endpoints were safety and tolerability of EOS789; exploratory endpoints included pharmacokinetics and pharmacodynamics, including P excretion in feces and urine.

Results: In the single ascending dose part, EOS789 was tolerated up to 600 mg and the most common adverse events were gastrointestinal (GI) disorders. In the multiple ascending dose part, EOS789 was tolerated up to 200 mg/day. Moderate GI disorders were observed in the 600 mg/day cohorts and dosing was discontinued in these cohorts. EOS789 increased fecal P and decreased urinary P excretion in a dose-dependent manner. Exposure-response analysis showed that thrice-daily dosing of EOS789 has the potential to show good efficacy at about 200 mg/day.

Conclusions: EOS789 was well tolerated up to 200 mg/day at repeated dosing for 14 days. This was the first clinical trial that showed a decrease of intestinal P absorption by inhibiting intestinal P transporters, and it suggests a new strategy for the treatment of hyperphosphatemia by pan-inhibiting NaPi-IIb, PiT-1, and PiT-2. The safety, tolerability, and efficacy of EOS789 in patients with hyperphosphatemia will be further investigated in future clinical trials.

Associations of Calciprotein Particle Transformation with Arterial Calcification, Arterial Stiffness, and All-Cause Mortality in Hemodialysis Patients

Wei Chen,[1,2] Jessica Fitzpatrick,[3] Jose M. Monroy-Trujillo,[9] Stephen M. Sozio,[4] Bernard G. Jaar,[5] Michelle M. Estrella,[8] Jishyra V. Serrano,[6] Michal L. Melamed,[1] David A. Bushinsky,[6] Rulan S. Parekh.[7] PACE *[1]Albert Einstein College of Medicine, Bronx, NY; [2]University of Rochester School of Medicine and Dentistry, Rochester, NY; [3]The Hospital for Sick Children, Toronto, ON, Canada; [4]Johns Hopkins University School of Medicine, Baltimore, MD; [5]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [6]University of Rochester Medical Center, Rochester, NY; [7]The Hospital For Sick Children, Toronto, ON, Canada; [8]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [9]Johns Hopkins University, Baltimore, MD.*

Background: Transformation of primary to secondary calciprotein particles (CPP) in the serum may be a marker for arterial calcification as suggested by *in vitro* studies. Using dynamic light scattering, we can measure the size of secondary CPP aggregates (CPP2) and time of transformation (T_{50}). We hypothesized that a higher ratio of CPP2 to T_{50} (CPP2:T_{50}) is associated with greater arterial calcification, arterial stiffness, and mortality among hemodialysis (HD) patients.

Methods: We measured baseline CPP2:T_{50} in 387 incident HD patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) cohort. We examined cross-sectional associations of CPP2:T_{50} with serum markers of arterial calcification (fetuin-A, matrix Gla protein and osteoprotegerin), coronary arterial calcification (CAC), thoracic aortic calcification (TAC) and pulse wave velocity (PWV), as well as its longitudinal associations with PWV and all-cause mortality. Models were adjusted for demographics, co-morbidities, smoking history, body mass index, serum calcium and phosphorous.

Results: Mean age was 55 ± 13 years; 41% were female; 71% were black and 58% had diabetes mellitus. Median CPP2 was 295 nm (IQR 208-382); T_{50} was 303 min (IQR 229-387); CPP2:T_{50} was 1.01 nm/min (IQR 0.57-1.66) and follow up length was 3.5 years (IQR 1.7-6.2). Per 0.1 nm/min higher CPP2:T_{50}, fetuin-A level was 9 mg/L lower (95% CI: -10 to -7) and matrix Gla protein level was 1.0% higher (95% CI: 0.1-2.0%). CPP2:T_{50} was not associated with osteoprotegerin, baseline CAC, TAC and PWV, or with changes in PWV. Higher CPP2:T_{50} was associated with greater all-cause mortality [HR 1.02 (95% CI 1.00-1.04) per 0.1 nm/min higher CPP2:T_{50}, p=0.02].

Conclusions: In incident HD patients, higher serum CPP2:T_{50} was associated with lower fetuin-A, higher matrix Gla protein levels, and higher risk of all-cause mortality, but not with arterial calcification or arterial stiffness. These findings support CPP transformation as a marker for calcification inhibitors and mortality, but not for arterial calcification.

Sevelamer Use Is Associated with Decreased Vitamin K Levels in Hemodialysis Patients: Results from the Vitamin K Italian (VIKI) Study

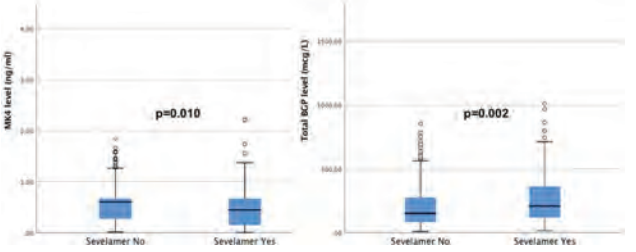
Maria Fusaro,[1,2] Andrea Aghi,[2] Pascale Khairallah,[3] Maurizio Gallieni,[4] Mario Cozzolino,[5] Domenico Russo,[6] Maria cristina M. Mereu,[7] Maura Ravera,[8] Giovanni Tripepi,[9] Tom Nickolas.[3] *[1]National Research Council – Institute of Clinical Physiology, Pisa, Italy; [2]Department of Medicine, University of Padova, Padova, Italy; [3]Division of Nephrology, Department of Medicine, Columbia University, New York, NY; [4]Ospedale San Carlo Borromeo, University of Milano, Milano, Italy; [5]Department of Health Sciences, University of Milan, Milan, Italy; [6]University Federico II, Naples, Italy; [7]Ospedale NS Bonaria, San Gavino Monreale, Italy; [8]Nephrology and Dialysis Unit, St Martino Hospital, Genova, Italy; [9]National Research Council – Institute of Clinical Physiology, Reggio Calabria, Italy.*

Background: Sevelamer (S) is a phosphate binding drug used to treat hyperphosphatemia in patients with CKD. Our aim was to evaluate the hypothesis that the use of (S) could interfere with Vitamin K absorption in hemodialysis (HD) patients of VIKI study.

Methods: We tested this hypothesis in VIKI, a cross-sectional study of 387 hemodialysis patients, we established the prevalence of vitamin K deficiency and to assessed the relationship between vitamin K status, vertebral fractures, vascular calcification. We determined serum concentrations of vitamin 25(OH)D; alkaline phosphatase (ALP); vitamers K1, MK4, MK5, MK6, MK7; osteocalcin (BGP) and Matrix Gla Protein (MGP). We highlighted that MK4 deficiency was the strongest predictor of aortic calcification (OR, 2.82; 95% CI, 1.14–7.01) while vitamin K1 deficiency was the strongest predictor of vertebral fractures fractures (OR: 2.94; 95% CI, 1.38–6.26).

Results: 163 of 387 patients (42.1%) were treated with S. There were no differences in levels of 25(OH)D, K1, MK5, MK6 and MK7 among patients treated with and without S. Remarkably, the prevalence of MK4 deficiency was higher in S treated patients (13.5% vs 5.4%, **p=0.005**). S treated patients also had higher median levels of ALK (89 UI/L vs 77.5 UI/L, **p=0.001**) and total BGP (210 mcg/L vs 152 mcg/L, **p=0.002**) and lower median levels of total MGP (16.4 nmol/L vs 20.3 nmol/L, **p=0.037**). In multivariable logistic regression, the odds ratio of MK4 deficiency (dependent variable) in patients treated with compared to without S was ~3-fold higher (OR: 2.64, 95% CI: 1.25-5.58, **p=0.011**) after adjustment for confounders of Vitamin K levels, including older age, previous myocardial infarction, type of HD, ALP, PTH, MGP, BGP, cholesterol and albumin.

Conclusions: These data support the hypothesis that S could interfere with MK4 absorption in HD patients. Longitudinal interventional studies are needed to prove the causal nature of these associations.



FR-PO147

Achievement of In-Range Serum Phosphorus (sP) and Decrease in Pill Burden Among Peritoneal Dialysis Patients Prescribed Sucroferric Oxyhydroxide for 12 Months

Anjay Rastogi,[1] Vidhya Parameswaran,[2] Linda Ficociello,[2] Claudy Mullon,[2] Robert J. Kossmann.[3] *[1]UCLA, Los Angeles, CA; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: Elevated levels of sP are associated with increased risk of cardiovascular and all-cause mortality in dialysis patients (pts). Phosphate binders (PB) are routinely prescribed for management of hyperphosphatemia. A cohort of peritoneal dialysis (PD) pts prescribed the PB sucroferric oxyhydroxide (SFO) as part of routine care was analyzed for changes in sP and PB pill burden over 12 months.

Methods: De-identified clinical data was extracted from electronic health records of a large dialysis organization (LDO; DaVita Inc) and prescription data extracted from the LDO's pharmacy service. Adult PD pts who received 1 year of SFO monotherapy prescriptions between 5/1/2014 and 9/30/2018 were included in this retrospective database analysis. Baseline (BL) and follow-up (Q1-Q4) were divided into 3-month intervals. Mixed effects linear regression and Cochran's Q test were used to test for statistical significance.

Results: Pts (n=82) had a mean BMI of 29 ± 28 kg/m^2 and dialysis vintage of 41 ± 29 months. 55% of pts were male and 51% had diabetes. At BL, 35 pts had no PB prescriptions recorded in the pharmacy and the remaining pts were prescribed sevelamer (68%), calcium acetate (17%), lanthanum (8.5%), or switched between PB (6.4%). The table describes changes in laboratory measurements and PB pill burden. The % of patients achieving sP ≤ 5.5 mg/dl increased from 25.6% at BL to 34.2-41.5% during SFO. This was accomplished with fewer PB pills/day (8.6 at BL vs 4.5-5.5 SFO pills/day). Pts with sP ≤ 5.5 mg/dL during SFO had a mean sP of 4.69 mg/dL.

Conclusions: PD pts from an LDO prescribed SFO as part of routine care, experienced significant reductions in sP along with a >40% reduction in PB pills/day and increase in % of patients with sP ≤5.5 mg/dl.

Serum Phosphorus and Pill Burden Decreases Among In-Center Hemodialysis (ICHD) Patients Switched to Sucroferric Oxyhydroxide for 12 Months

Anjay Rastogi,[1] Linda Ficociello,[2] Vidhya Parameswaran,[2] Claudy Mullon,[2] Robert J. Kossmann.[3] *[1]UCLA, Los Angeles, CA; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: According to DOPPS data, >75% of ICHD patients (pts) are prescribed phosphate binders (PB) for the control of serum phosphorus (sP); however, >35% of pts have hyperphosphatemia (sP>5.5 mg/dl). The current analysis is a 12-month follow-up on sP and PB pill burden changes in ICHD pts switched from another PB to sucroferric oxyhydroxide (SFO) as part of routine care.

Methods: This retrospective database analysis utilizes de-identified clinical data extracted from electronic health records from a large dialysis organization (LDO; DaVita Inc) and prescription records from the LDO's pharmacy service. Adult ICHD pts who received 1 year of SFO monotherapy between 5/1/2014 and 9/30/2018 were included in the analysis. Baseline (BL) and follow-up (Q1-Q4) were divided into 3-month intervals. Mixed effects linear regression and Cochran's Q test were used to test for statistical significance.

Results: Pts (n=364) had a mean BMI of 29.8 and dialysis vintage of 52.6 months. 53% of pts were male and most (74%) had a fistula for vascular access. Sevelamer was the most frequently prescribed monotherapy BL PB (64%), followed by calcium acetate (18%) and lanthanum carbonate (7%), and the remaining pts either switched between PB or had combination therapy. Comparisons between BL and SFO follow-up on mineral bone disease markers and PB pill burden are shown in Table. There were consistent improvements in pts achieving sP ≤5.5 mg/dL (increased from 18% at BL to 36.8-38.7% during SFO, p<0.001). Pts were prescribed an average of 9.3 pills/day at BL and 4.3 to 4.9 pills/day during Q1-Q4. Pts who achieved quarterly sP ≤ 5.5 mg/dl had a mean pill burden of 4.7 pills/day and mean sP of 4.72 mg/dL.

Conclusions: ICHD pts from an LDO prescribed to switch PB to SFO as part of routine care for 12 months, experienced significant reductions in sP along with a 47% reduction in PB pills/day and increase in the % of pts with sP ≤5.5 mg/dl.

FR-PO149

Phosphate Binder Therapy with Sucroferric Oxyhydroxide Reduces Calcification Propensity in Hemodialysis Patients: Results from a Randomized, Controlled, Crossover Trial

Daniel Cejka,[1] Bernhard Robl,[1] Ewa Watorek,[1] Sabine Blum,[1] Alexandra Dumfarth,[1] Rodrig Marculescu,[2] Andreas Pasch,[3] Maria C. Haller.[1] *[1]Ordensklinikum Linz - Elisabethinen hospital, Linz, Austria; [2]Medical University of Vienna, Vienna, Austria; [3]Calciscon AG, Nidau, Switzerland.*

Background: High calcification propensity (i.e. short T50 times in the calciprotein particle formation test) is associated with a higher risk of cardiovascular events and mortality in ESRD patients. So far, no clinical trial has investigated the effect of lowering serum phosphate with oral phosphate binder therapy on calcification propensity in ESRD patients.

Methods: Single-center, open-label, controlled, randomized, cross-over study in chronic hemodialysis patients with hyperphosphatemia. Patients were randomized in a 1:1 ratio to either low-dose (250mg/d) sucroferric oxyhydroxide (PA21) followed by high-dose (2000mg/d) PA21 or vice versa, with wash-out phases (no phosphate binder therapy) in between. The primary endpoint was change in T50 time between wash-out and high dose PA21 treatment in patients with ≥85% adherence to the prescribed PA21 dose (per protocol analysis). There was no carry-over effect as determined by a linear mixed model, and thus a paired t-test was calculated.

Results: Thirty-nine patients were randomized and 28 patients were available for per-protocol analysis. Compared to phosphate binder wash-out, 2000mg/d PA21 treatment resulted in a mean increase in T50 times of 66 min (95% CI 49-84 min, p<0.0001), from 243 (± 63 min) to 309 (± 74 min). Serum phosphate decreased from 2.28 (±0.5) to 1.63 (±0.43) mmol/l. In the secondary intention to treat (ITT) analysis, treatment with 2000 mg/d PA21 resulted in a mean increase in T50 times of 60 min (95% CI 36-83 min, p<0.0001) compared to phosphate-binder wash-out. Serum phosphate decreased from 2.18 +/- 0.5 to 1.64+/- 0.46 mmol/l. In patients achieving a decline in serum phosphate ≥ 0.5 mmol/l between wash-out and the 2000 mg/d treatment phase (N=20, pre-specified subgroup), T50 time increased by 85 min (95% CI 58-112 min, p<0.0001). PA21 at 250 mg/d did not influence T50 times (p=0.4) or serum phosphate values (p= 0.9) compared to phosphate binder wash-out. No major adverse cardiovascular event, case of calciphylaxis or death occurred during the study.

Conclusions: Lowering serum phosphate with PA21 therapy reduces calcification propensity of serum of hemodialysis patients.

Effect of Dietary Phosphate, Binder, and Pill Burden on Phosphate Control in Dialysis Patients

Veronica Zamora-Olivencia, Stuart M. Sprague. *NorthShore University HealthSystem University of Chicago, Chicago, IL.*

Background: Management of hyperphosphatemia is a major problem in end-stage renal disease (ESRD) with dietary control and phosphate (Phos) binders being the mainstay of therapy. Most ESRD patients require numerous medications, resulting in a high pill burden which may affect adherence and achievement of serum phosphate (sP) levels ≤ 5.5 mg/dL.

Methods: A prospective comparative study was performed in 31 chronic dialysis patients. Subjects underwent a baseline evaluation in which they continued their routine binder regimen for 4 weeks, with weekly blood draws. This was followed by a 2 week washout in which all binders were stopped and labs obtained weekly. They were then randomized to either sucroferric oxyhydroxide (SO) or sevelamer (SEV) for 6 weeks, with weekly blood draws except during week 4 when they had daily blood draws. Subjects then underwent a second 2 week washout with weekly labs, followed by 6 weeks with the alternative binder and the same blood draws. Subjects maintained a food diary which was reviewed with a dietician to estimate average daily dietary Phos intake. Total pill burden and achievement of target sP was determined.

Results: Complete data was collected for 24 subjects. Subjects were divided in three dietary Phos groups (n=8): low (334-796 mg/day), medium (821-1129 mg/day) and high (>1140 mg/day). Baseline sP with SEV was 6.21±2.55 mg/dL with a decrease to 5.50±2.40 mg/dL (mean 6 pills/day), whereas with SO baseline sP was 6.20 + 2.50 mg/dL with a decrease to 5.30 ± 2.41 mg/dL (mean 4 pills/day). Table demonstrates the pill burden and achievement of target sP while taking SO and SEV stratified by Phos intake.

Conclusions: Comparable number of subjects achieved target sP in both groups. However, SEV resulted in a 50 % higher average pill burden compared to SO. A direct correlation was observed between Phos intake and daily pill burden. Despite increase in binder doses, the percent of subjects that achieved sP ≤ 5.5 was significantly lower in the high Phos diet group compared to the low and medium groups. This suggests that high pill burden may be associated with non-adherence to treatment.

Longitudinal Serum Phosphorus Levels over 2 Years in Incident Dialysis Patients Who Initiate Sucroferric Oxyhydroxide (SO) as a First-Line Phosphate Binder

Kamyar Kalantar-Zadeh,[1] Linda Ficociello,[2] Vidhya Parameswaran,[2] Claudy Mullon,[2] Robert J. Kossmann,[3] Stuart M. Sprague.[4] *[1]University of California Irvine, School of Medicine, Orange, CA; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA; [4]NorthShore University HealthSystem University of Chicago, Chicago, IL.*

Background: Phosphate binder (PB) therapy is usually initiated in the first year of dialysis therapy in chronic hemodialysis (HD) patients (pts). A historical cohort study was conducted to examine longitudinal serum phosphorus (sP) among pts who begin sucroferric oxyhydroxide (SO) as a first-line PB within the first year of HD as part of routine care in real world setting.

Methods: Adult HD pts first prescribed SO between 4/1/14-9/30/17 during their first year of HD were included in this database analysis. Pts were required to have no PB prescription during a 3-month baseline (BL) and continue SO for 2 years. All clinical data was extracted from Fresenius Kidney Care electronic health records, deidentified, and averaged over each quarter (Q1-Q8). Mixed effects linear regression and Cochran's Q test were used for statistical significance testing.

Results: Pts (n=59) had a mean age of 56±13 years and dialysis vintage of 7.3±2.9 months at BL. Changes in mean sP, serum calcium, PTH, and Kt/V are provided [table]. After SO initiation, overall mean sP decreased by 0.7 mg/dl and % of pts achieving sP ≤ 5.5 mg/dl increased from 36.5% at BL to a high of 64.9%. After limiting to pts with BL sP > 5.5 mg/dl, mean sP decreased by 1 mg/dl, from 6.86 to 5.86 mg/dl, with a high of 48.4% of pts achieving sP ≤ 5.5 mg/dl. These pts were prescribed, on average, 4.9-5.9 SO pills/day.

Conclusions: HD pts initiating SO as a first-line PB within the first year of dialysis were able to reduce mean sP levels by 0.7 mg/dl with mean phosphate binder pills/day of 4.4 to 5.2 pills over the 2-year follow-up. The % of patients with ≤ 5.5 mg/dl increased from to 36.5% at baseline to 41.5-64.9% during follow-up. SO is an effective first-line PB therapy with least pill burden.

Low-Protein Rice Plus Low-Phosphorus Whey Improve Hyperphosphatemia in Hemodialysis Patients

Song Wang, Xinkui Tian. *Nephrology Department, Peking University Third Hospital, Beijing, China.*

Background: Hyperphosphatemia is common in end stage renal disease patients. Although adequate dialysis, dietary restriction, and phosphorus binders are prescribed, phosphorus control is still poor in dialysis patients.

Methods: Hemodialysis patients who had average serum phosphorus ≥5.5 mg/dl for consecutive three months were enrolled in this self-controlled trial. First, the patients received low phosphorus diet instruction. Then the patients received low protein rice plus low phosphorus whey for ten weeks. The protein gap between low protein rice and normal rice was replaced by low phosphorus whey. Finally the patients returned to normal rice for eight weeks. The changes of serum phosphorus, calcium, intact parathyroid hormone (iPTH), serum albumin and nutritional evaluation were observed and analyzed.

Results: 29 patients were enrolled. Serum phosphorus at baseline was (6.66±0.87) mg/dl. After four weeks diet instruction, serum phosphorus decreased to (6.27±1.54) mg/dl but with no significance (p>0.05). Serum phosphorus further decreased to (5.43±1.71) mg/dl, (5.36±1.50) mg/dl, (5.79±1.35) mg/dl respectively after changed to low protein rice for 2, 6 and 10 weeks (p<0.05 compared to the baseline). Serum phosphorus increased to(6.05±0.98) mg/dl after returned to normal rice. Dietary analysis showed the phosphorus intake was significantly low for low protein rice compare to normal rice (p<0.05). Besides, serum albumin increased significantly with low protein rice plus low phosphorus whey (p<0.05). There was no change in serum calcium, iPTH levels, dialysis strategy and phosphorus-binding agents throughout the study.

Conclusions: For hemodialysis patients who consume rice as their main source of calories, low protein rice plus low phosphorus whey can reduce serum phosphorus and improve serum albumin.

48-Hour Post-Dialysis Serum Phosphate Rebound in Hemodialysis Patients Consuming a Controlled, Low-Phosphorus Diet

Elizabeth Stremke,[1] Laurie Trevino,[2] Simit Doshi,[3] Ranjani N. Moorthi,[2] Sharon M. Moe,[2] Kathleen M. Hill Gallant.[1,2] *[1]Purdue University, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University, Indianapolis, IN.*

Background: Studies have demonstrated poor phosphorus (P) control with thrice weekly hemodialysis (HD). However, these studies did not control for dietary P intake, nor test blood frequently during the intradialytic interval. We aimed to determine serum P reduction and rebound over 48h in HD patients consuming a controlled low P diet.

Methods: Serum P (mg/dL) was analyzed pre-HD and post-HD for 48h in patients (N=13) consuming a controlled diet of ~900 mg P/day taking part in a placebo arm of a clinical trial. Subjects had been off phosphate binders for 10 days. Linear regression was used to determine relationships between the decline in serum P post-HD (post-HD drop); 48h area under the curve of serum P (48h AUC); and pre-HD serum P (Pre-HD). Repeated Measures ANOVA with Dunnett's post-hoc test was used to determine return to pre-HD serum P levels.

Results: In our controlled diet study, 5 of 13 subjects returned to >90% of their pre-HD serum P within the first 24h post-HD, and 11 of the 13 subjects by 48h after the completion of HD. Pre-HD serum P is positively associated with 48-hr AUC (P<0.001). We found an expected correlation (r= 0.58; P= 0.04) between post-HD drop in serum P and 48h AUC of serum P post-HD. All serum P measures in the 48h post-HD period were statistically different than pre-HD serum P (p<0.0001) until 48h post-HD (p=0.15).

Conclusions: Adhering to a low P diet, even in the absence of P binders, may benefit patients receiving HD by delaying post-HD serum P rebound. Delaying the return of serum P values to pre-HD levels to between 24h and 48h post-HD may lessen overall P exposure and may translate into achieving long-term target serum P values in HD patients.

FR-PO154

Association Between Abnormalities of Serum Phosphate and Increased Mortality in Incident Australian and New Zealand Dialysis Patients

Lee Skeat,[1] Shahid Ullah,[2,3] Stephen P. McDonald,[2,4] Nigel D. Toussaint.[1,5] *[1]Nephrology, Royal Melbourne Hospital, Melbourne, VIC, Australia; [2]Australian and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; [3]Adelaide Medical School, The University of Adelaide, Adelaide, SA, Australia; [4]Central Northern Adelaide Renal and Transplantation Service, Adelaide, SA, Australia; [5]Department of Medicine, The University of Melbourne, Melbourne, VIC, Australia.*

Background: Abnormalities of mineral and bone metabolism in chronic kidney disease (CKD) are associated with increased cardiovascular and all-cause mortality. Serum phosphate is associated with adverse outcomes in a U-shaped relationship, with levels above and below the normal range associated with increased mortality in end stage renal failure. The optimal target for serum phosphate levels in CKD remains unclear. Therefore, the aim of this study was to determine if abnormalities of serum phosphate are associated with cardiovascular death and all-cause mortality in Australian and New Zealand dialysis patients.

Methods: The Australia and New Zealand Dialysis and Transplant (ANZDATA) registry was utilized to identify incident adult dialysis patients between 2005 and 2015 with ≥1 phosphate level. Phosphate levels were stratified into 3 groups; <1.6 mmol/L, 1.6-1.7mmol/L and >1.8 mmol/L. Adjusted risk of all-cause death were calculated for categories of phosphate using multivariate Cox proportional hazards regression models with phosphate levels, comorbidity and dialysis modality as time-varying covariates. Competing risk analysis was also used for cause-specific risk of death.

Results: The cohort consisted of 42,735 patients with a mean age of 58.8 (SD=15.8) years and male predominance (60.8%). Dialysis modality was 73.8% hemodialysis (HD) and 26.2% peritoneal dialysis (PD). 45.6% of patients were diabetic and 43.9% had coronary artery disease. Multivariate regression for all cause-mortality demonstrated a U-shaped relationship with highest mortality in those with phosphate <1.6 mmol/L (HR 1.17, 95%CI 1.11-1.22, p<0.001) and phosphate >1.8mmol/L (HR 1.31, 95%CI 1.24-1.38, p<0.001). Cardiovascular mortality was highest for phosphate levels >1.8mmol/L (SHR 1.25, 95%CI 1.15-1.35, p<0.001).

Conclusions: The lowest mortality was observed in patients with phosphate levels between 1.6-1.7mmol/L. Levels outside this range were associated with increased all-cause and cardiovascular mortality. This has clinical implications for target phosphate levels to reduce mortality the Australian and New Zealand dialysis population.

Mortality Risk with Serum Phosphorous in Twice-Weekly vs. Thrice-Weekly Hemodialysis Patients

Cachet Wenziger,[2] Antonio Aguirre,[2] Christina Park,[2] Jui-Ting Hsiung,[2] Csaba P. Kovesdy,[1] Kamyar Kalantar-Zadeh,[2] Connie Rhee,[2] Elani Streja.[2] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA.*

Background: Patients on dialysis commonly have abnormally elevated serum phosphorous levels. Both high and low serum phosphorous have been associated with greater mortality risk in thrice weekly incident hemodialysis (HD) patients. However, less is known about this relationship in patients undergoing twice weekly HD. This study examines the phosphorous-mortality relationship in twice weekly compared to thrice weekly HD patients.

Methods: From a large national dialysis cohort of incident HD patients (2007-2011), we identified 78,849 thrice weekly and 3,989 twice weekly HD patients. For each dialysis type, patients were divided into four groups of phosphorous levels: <3.5, 3.5-<5.5 [ref.], 5.5-<7 and ≥7 mg/dL. We examined the association of phosphorous levels and all-cause mortality using Cox models adjusted for case-mix and markers of malnutrition and inflammation.

Results: In thrice and twice weekly patients respectively, the mean age was 63 ± 15 and 68 ± 14 years, 43% and 47% were female, 31% and 15% were African American. Higher phosphorous was associated with a higher mortality risk in both twice and thrice weekly patients; however, the risk appeared stronger for twice weekly [Figure]. Lower phosphorous was not associated with any difference in mortality risk compared to the reference group, while it appeared to trend toward lower mortality risk in twice weekly HD patients. The p-for-interaction was 0.02 indicative of a significant effect of dialysis type on the phosphorous-mortality relationship.

Conclusions: The relationship of phosphorous and mortality differs in patients receiving twice and thrice weekly HD treatment. Patients with lower phosphorous levels receiving twice weekly HD treatment overall had lower mortality rates compared to thrice weekly HD patients.

FR-PO156

Spurious Hyperphosphatemia in Patients with ESRD on Hemodialysis

Dheera Tamvada, Robert Mark Black. *Saint Vincent Hospital, Worcester, MA.*

Background: Hyperphosphatemia is common in patients with CKD. In most instances, the high phosphorus is due to a combination of increased intake and reduced urinary excretion. Despite the frequency of this finding, some patients with high phosphorus levels have normal kidney function. This can be associated with hypoparathyroidism, a monoclonal gammopathy or extracellular shifts as can be seen with lactic acidosis or rhabdomyolysis. Here we present three patients on hemodialysis with sudden, transient very high phosphorus levels.

Methods: Three patients with ESRD on hemodialysis were noted to have high phosphorus levels of 29.6 mg/dL, 31.5 mg/dL and 25.0 mg/dL during routine monthly laboratory evaluation. All were compliant with phosphate binders and a low phosphate diet. Blood samples were drawn from the hemodialysis catheter ports which had been locked with tissue plasminogen activator (tPA). In these patients, tPA was used to limit blood clot formation and poor blood flow through the hemodialysis catheters. tPA contains phosphoric acid to balance the pH.

Results: Below are the phosphorus levels in patients before tPA (first column) and with tPA (second column) administration. In these three patients, 5 ml of blood or less was discarded from the dialysis catheters at the time the highest phosphorus levels were resulted (second column). The third column shows improvement in phosphorus levels after we removed at least 10 ml of blood from the dialysis catheters containing tPA before sending for laboratory evaluation for phosphorus levels.

Conclusions: The severe hyperphosphatemia in our three patients appears to be secondary to the blood draw technique employed. If tPA contaminates the blood sample, high phosphorus levels are likely to result. Hence we recommend always discarding the first 10 ml of blood drawn from the hemodialysis catheter with tPA dwelling before sending the required sample for analysis. While these findings are unusual, even small quantities of tPA could lead to inappropriate conclusions of patients' non-compliance with oral phosphate binders. When possible, phosphorus levels should not be drawn if tPA has been administered and is still dwelling in the dialysis catheter.

	No tPA	With tPA (5 ml)	With tPA (10 ml)
Patient 1	5.4 mg/dL	29.6 mg/dL	6.1 mg/dL
Patient 2	3.5 mg/dL	31.5 mg/dL	4.0 mg/dL
Patient 3	8.1 mg/dL	25.0 mg/dL	6.0 mg/dL

FR-PO157

Analysis of the Association Between Serum Phosphorus Concentration and Mortality in Patients with Decreased Renal Function: Results from NHANES 2003-2006

Luís C. Mendonça, Luciano Pereira, Susana M. Norton. *Nephrology, Centro Hospitalar São João, Porto, Portugal.*

Background: High serum phosphorus concentration is associated with increased mortality among the different stages of chronic kidney disease (CKD). However, studies are very heterogeneous and most of them lack an appropriate adjustment for relevant confounders. This concern is particularly notable in the pre-dialysis setting. We investigated the association between serum phosphorus concentration and mortality in individuals with decreased renal function using a prospective nationwide cohort of adults from the United States of America.

Methods: We analyzed non-dialysis-dependent adults with an estimated glomerular filtration rate (eGFR) inferior to 90 ml/min/1.73m2, using data from the National Health and Nutrition Examination Survey (NHANES) 2003-2006. Serum phosphorus concentration and several covariates including albuminuria, intact parathyroid hormone (PTH), 25-OH-vitamin D, C-reactive protein (CRP) and ingested phosphorus were evaluated at baseline. All-cause and cardiovascular deaths were recorded through 31 December 2011. We used the terciles of serum phosphorus concentration which were < 3.6 (T1), 3.6-4.1 (T2) and > 4.1 mg/dL (T3). Adjusted Cox proportional hazard models were fitted to estimate hazard ratios (HR) for all-cause and cardiovascular mortality.

Results: We included 3480 individuals (males 56.9%, age 61.1±18.5 years). A total of 735 deaths was recorded over a median follow-up of 80 months. Comparing with the T1, the adjusted HR for all-cause mortality was 0.84 (95% confidence interval (CI) 0.66-1.08) for T2 (p=0.178) and 1.31 (95% CI 1.1-1.6) for T3 (p=0.013). Decreasing eGFR (p<0.001) and 25-OH-vitamin D (p=0.019) and increasing PTH (p=0.038) and CRP (p=0.02) presented a significant independent association with all-cause mortality, however, none of them had a significant interaction with serum phosphorus terciles. For cardiovascular mortality, the adjusted HR was 0.94 (95% CI 0.56-1.57) for T2 (p=0.823) and 1.24 (95% CI 0.88-1.76) for T3 (p=0.201).

Conclusions: We observed a significant independent association between the highest tercile of serum phosphorus and all-cause mortality in patients with decreased eGFR. Despite a numerical trend, it was not found a significant association with cardiovascular mortality.

FR-PO158

Zinc Supplementation for 3 Months Increases Serum Levels of C-Terminal FGF-23 in Zinc-Deficient Children with CKD

Vladimir Belostotsky,[1] Caroline Moore,[2] Julia H. Ma,[3] Steven Arora,[1,3] Stephanie A. Atkinson,[3] Guido Filler.[4] *[1]McMaster Children's Hospital, Hamilton, ON, Canada; [2]Dept of Pediatrics, McMaster University, Hamilton, ON, Canada; [3]McMaster University, Hamilton, ON, Canada; [4]London Health Sciences Centre, London, ON, Canada.*

Background: Chronic Kidney Disease (CKD) has been associated with increased fibroblast growth factor 23 (FGF23), decreased Klotho concentrations and subclinical zinc (Zn) deficiency (Fukushima 2019). FGF23 promotes phosphate clearance but is dependent on Klotho expression by tubular cells. In animal models Zn supplementation stimulates Klotho production (Morishita 2001) and reduces vascular calcification, frequently seen in CKD (Voelkl 2018). This study investigated whether 3 months of Zn therapy corrects the deficiency in CKD and leads to changes in circulating FGF23 and Klotho concentrations.

Methods: Children with primary CKD and CKD secondary to declining function of kidney transplant from two tertiary pediatric nephrology centers in Southern Ontario, Canada were screened for Zn deficiency (plasma Zn < 11.5 μmol/L). Deficient children were treated with Zn citrate tablets (10 mg Zn/day for age 4-8 yr and 20 mg/day for age 9-18 yr) for 3 months. Plasma Zn was measured at baseline and 3 months by High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry. Serum c-terminal FGF23 (cFGF23, Biomedica) and human soluble alpha-Klotho (TECO medical) were measured by ELISA, serum 25-hydroxyvitamin D (25-OHD) by LC/MS-MS (Waters). Paired t-tests and Wilcoxon tests were performed for normally and non-normally-distributed data, respectively. Children taking calcitriol were excluded from the final analysis due to its significant impact on FGF23 and Klotho metabolism.

Results: Table 1

Conclusions: In most patients we observed changes toward normal levels of Zn following three months of Zn supplementation in Zn deficient children with CKD (p=0.028). The concentration of cFGF23 also increased (p=0.008) while no change was observed in the level of Klotho. 25-OHD levels remained stable and did not affect the results. Either higher Zn doses or longer treatment may be needed before changes in Klotho might be seen.

FGF-23 and Cause-Specific Mortality in Community-Living Individuals (Health ABC Study)

Shilpa Sharma,[1] Ronit Katz,[4] David A. Drew,[3] Orlando M. Gutierrez,[6] Michael Shlipak,[5] Mark J. Sarnak,[3] Joachim H. Ix.[2] *[1]UCLA, Los angeles, CA; [2]UCSD, San Diego, CA; [3]Tufts Medical Center, Boston, MA; [4]University of Washington, Seattle, WA; [5]San Francisco VA Medical Center, San Francisco, CA; [6]UAB School of Medicine, Birmingham, AL.*

Background: FGF23 is a protein that was initially identified as a key regulator of phosphorus and vitamin D metabolism. Elevated concentrations of FGF23 are associated with poor clinical outcomes in different patient populations, but cause-specific mortality is under-studied.

Methods: Among 2763 healthy community-living older adults who participated in the Health, Aging, and Body Composition (Health ABC) study, plasma intact FGF23 levels were measured from samples drawn in 2000 and 2001, and participants were followed through 2012. Mortality was adjudicated by a reviewing committee. Associations of FGF23 with total and cause specific mortality were evaluated using Cox proportional hazards models.

Results: At baseline, the mean age was 75 (±3) years old, 40% were black, and 55% were women. Median FGF23 was 47 (IQR 37, 60) pg/ml and was inversely correlated with eGFR (rs= -0.260). During 8.3 years (median) follow-up, there were 821 deaths. In the multivariable Cox PH regression analysis (**Table**), each two-fold higher concentration of plasma FGF23 was associated with all-cause mortality and cardiovascular, gastrointestinal bleed, and kidney failure deaths, but not with cancer, dementia, sepsis or pulmonary related deaths.

Conclusions: Although high FGF23 concentrations are associated with total mortality, the association appears restricted to certain death types. Future studies are needed to evaluate potential mechanisms linking FGF23 concentrations with specific causes of death.

An FGF-23-Independent Association Between Serum Phosphorus and Left Ventricular Hypertrophy: Findings from the KNOW-CKD Study

Young Youl Hyun,[1] Jimin Han,[1] Hyang Kim,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Kyu-Beck Lee.[1] KNOW-CKD Study Investigators *[1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Previous studies have shown that serum phosphorus is related to left ventricular hypertrophy (LVH) in chronic kidney disease (CKD). However, those studies were small in size or did not show significant association when fibroblast growth factor-23 (FGF23) was included in the analysis. The aim of this study was to verify the FGF23-independent association between serum phosphorus and LVH in a CKD cohort of Korean adults.

Methods: This cross-sectional study analyzed 1,545 predialysis CKD patients from the KNOW-CKD cohort. Left ventricular mass index (LVMI) and presence of LVH were assessed by echocardiography. Multivariate regression analysis was adjusted for various cardiovascular risk factors including FGF23.

Results: The LVMI was higher among the higher serum phosphorus groups (88.6±20.7, 90.3±22.5, 91.1±22.0, and 96.2±25.4 for the 1st to 4th phosphorus quartiles, respectively, P<0.001). LVH was more prevalent among the higher serum phosphorus groups (15.2%, 15.8%, 23.7%, and 35.9% for the 1st to 4th phosphorus quartiles, respectively, P<0.001). For each 1 mg/dL increase in serum phosphorus, LVMI increased by 3.88 g/m^2. The adjusted odds ratio for LVH in the 4th quartile of serum phosphorus compared to the 1st quartile was 1.79 (95% CI, 1.19-2.70; P=0.005). Results were summarized in the Table 1.

Conclusions: High serum phosphorus was associated with high LVMI and LVH in predialysis CKD patients. This relationship was independent of various cardiovascular risk factors, including FGF23.

Funding: Government Support - Non-U.S.

Table 1. The association between serum phosphorus quartile and left ventricular hypertrophy

Serum phosphorus quartiles	Model 1		Model 2		Model 3	
	OR (95% CI)	P value	OR (95% CI)	P value	OR (95% CI)	P value
1	reference		reference		reference	
2	1.04 (0.72-1.52)	0.823	0.91 (0.61-1.36)	0.650	0.97 (0.65-1.45)	0.893
3	1.73 (1.21-2.48)	0.003	1.17 (0.78-1.74)	0.445	1.27 (0.85-1.89)	0.251
4	3.12 (2.21-4.39)	<0.001	1.68 (1.12-2.52)	0.011	1.79 (1.19-2.70)	0.005

Determinants of C-Terminal vs. Intact FGF-23 in CKD: The COMBINE Trial

Joachim H. Ix,[1] Cynthia A. Kendrick,[2] Andrew N. Hoofnagle,[3] Kalani L. Raphael,[4] Dominic S. Raj,[5] Alfred K. Cheung,[6] Stuart M. Sprague,[7] Rupal Mehta,[8] Jennifer J. Gassman,[2] Linda F. Fried,[9] Myles Wolf,[10] Tamara Isakova.[11] *[1]UCSD, San Diego, CA; [2]Cleveland Clinic, Cleveland, OH; [3]University of Washington, Seattle, WA; [4]VA Salt Lake City Health Care System, Salt Lake City, UT; [5]GWU Medical Faculty Associates, Washington, DC; [6]University of Utah, Salt Lake City, UT; [7]NorthShore University HealthSystem University of Chicago, Chicago, IL; [8]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [9]VA Pittsburgh Healthcare System, Pittsburgh, PA; [10]Duke University, Durham, NC; [11]Feinberg School of Medicine, Northwestern University, Chicago, IL.*

Background: C-terminal FGF23 assays measures full-length and c-terminal fragments and intact assays measure full-length only. Iron deficiency and inflammation may enhance FGF23 production and cleavage and CKD may impair FGF23 cleavage. Few studies have measured both FGF23 assays concurrently in CKD. We sought to identify determinants of the FGF23 C terminal / Iintact (C/I) ratio in CKD stage 3b-4.

Methods: 203 patients with eGFR 20-45 ml/min/1.73m^2 participated in a randomized trial evaluating lanthanum and nicotinamide for phosphate and FGF23 lowering. FGF23 was measured using the Immutopics C-terminal and Kainos intact assays at baseline. We calculated the C/I ratio and used linear regression to identify independent determinants.

Results: Mean eGFR was 32±7 ml/min/1.72m^2. Mean C-terminal FGF23 was 271±186 RU/ml and intact FGF23 was 123±92 pg/ml, which were moderately correlated (r=0.40, p<0.001). The mean C/I ratio was 2.62±2.2RU/pg. Female gender and lower calcium were independently associated with higher C/I ratio. We found no associations of eGFR, anemia, iron deficiency, or inflammation with C/I ratio.

Conclusions: Gender and calcium are differently associated with C-terminal vs. intact FGF23; associations that appear stronger than iron deficiency, anemia, inflammation, or CKD severity, in CKD stages 3b-4.

Improvement in Biomarkers in Pediatric X-Linked Hypophosphatemic Rickets After 1 Year of Treatment with Burosumab

Neil J. Paloian,[1] Blaise A. Nemeth,[2] Peggy Modaff,[1] Robert Steiner.[1] *[1]Pediatrics, University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Orthopedics, University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: X-linked hypophosphatemic rickets (XLH) is the most common genetic cause of rickets in children. Burosumab, an FGF-23 monoclonal antibody, was approved in 2018 for the treatment of XLH. Prior therapy consisted of phosphate supplementation and calcitriol, but therapeutic response was often incomplete. Clinical trial results with burosumab have been promising, but real world data regarding effectiveness in clinical practice is lacking.

Methods: 11 patients <= 18 years with XLH and treated with burosumab were identified, all of whom received calcitriol and phosphorus prior to starting burosumab. Retrospective laboratory data obtained during standard of care visits was analyzed. Monthly laboratory testing was performed for 3 months after intiation of burosumab and with dose changes. Serum phosphorus, alkaline phosphatase, PTH, and urinary fractional excretion of phosphorus were measured. Statistical analysis utilized paired T-test with p<0.05 deemed significant.

Results: The mean age of patients was 7 years old (range 2 -18). The mean length of burosumab therapy was 9.7 months (range 6-11 months). The mean pre-treatment and post-treatment lab values are displayed in Table 1. Mean serum phosphorus and alkaline phosphatase over time is displayed in Image 1. Fractional excretion of phosphorus fell below 15% in 82% of our patients following treatment with burosumab.

Conclusions: Burosumab, a newly approved FGF-23 monoclonal antibody, is effective in improving the biochemical profile of children with X-linked hypophosphatemic rickets previously treated with phosphorus and calcitriol.

Postprandial Serum Phosphorus and Calcium Concentrations in Adults and Children with X-Linked Hypophosphatemia (XLH) Are Within Normal Range During Burosumab Treatment

Anthony A. Portale,[1] Erik Imel,[4] Suzanne Jan de beur,[2] Craig Munns,[5] Pisit Pitukcheewanont,[6] Javier San martin,[3] Karl Insogna.[7] *[1]University of California San Francisco, San Francisco, CA; [2]John Hopkins University, Balitmore, MD; [3]ultragenyx, Novato, CA; [4]Indiana University School of Medicine, Indianapolis, IN; [5]The Children's Hospital at Westmead, Westmead, NSW, Australia; [6]Ascendis Pharmaceutical, Palo Alto, CA; [7]Yale University, New Haven, CT.*

Background: In patients with XLH, excess FGF23 causes hypophosphatemia leading to musculoskeletal impairments. In Phase 3 trials (NCT02526160, NCT02915705), subcutaneous burosumab, 1 mg/kg every 4 weeks in adults or 0.8 mg/kg every 2 weeks in children, significantly improved *fasting* serum phosphorus (Pi) in subjects with XLH. Burosumab also improved fracture healing, stiffness, and physical function compared to placebo in adults; and rickets severity and growth compared to oral phosphate and active vitamin D in children. We evaluated the effect of burosumab on *postprandial* serum Pi and calcium in a sub-set of trial subjects.

Methods: Postprandial assessments were made in 26 adults and 13 children, 10-14 days after the prior dose of burosumab. Serum samples were obtained in the morning after an overnight fast. Subjects then consumed a typical phosphorus-containing breakfast, and samples were obtained 1 and 2 hours after breakfast. In adults, additional samples were obtained before and 1 and 2 hours after lunch.

Results: Adults (mean [SD] age 43 [12] years, 77% female, 89% white) and children (mean [SD] age 6 [3] years, 77% female, 92% white) had received burosumab for a mean of 24 and 15 months, respectively. At baseline, before any doses of burosumab, mean (SD) fasting serum Pi concentration was below the normal range (Table). After burosumab treatment, mean morning fasting Pi level increased significantly in each group. In adults, Pi levels decreased slightly if not significantly after breakfast, increased slightly before lunch, and remained stable 1 and 2 hours after lunch. In the children, serum Pi levels increased slightly if not significantly 1 and 2 hours after breakfast. Importantly, no subject had post-prandial hyperphosphatemia. There were no changes in serum calcium.

Conclusions: In adults and children with XLH receiving stable doses of burosumab, fasting and postprandial serum Pi and calcium concentrations are maintained within the normal range.

Serum Phosphorus mg/dL

Subjects (Phosphorus Normal Range)	Pre-Burosumab	With Burosumab

FR-PO164

Intact FGF-23, Intact PTH, and Other CKD-MBD Markers After Successful Living Renal Transplantation: A Longitudinal Study

Sandeep Mahajan. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Markers of CKD-MBD cause LVH & CV mortality. Compared to general population CV mortality remain high post RT. MBD abnormalities post RT can be due to persistence of CKD induced abnormalities or can develop *de novo* due to immunosuppressive drugs & lower GFR & may contribute to increased CV mortality. Though, few studies have prospectively looked at MBD markers post RT, their course in post RT period remains poorly defined particularly in patients receiving living donor RT (LDRT) where renal function normalizes faster. This prospective, longitudinal study analyses serial changes in these variables pre & post LDRT

Methods: 83 consecutive & consenting adults aged 18-65 years undergoing first LDRT were enrolled. Investigations were done pre-RT & at 1, 6 & 12 months post RT. Patients with diabetes & those having persistent eGFR <40 ml/min post RT were excluded

Results: 74 patients completed study. 91.8% were male, mean age was 35.5±10.6 years & median dialysis vintage was 14 months. Basic disease was presumed CTID in 45.9% & presumed CGN in 39.1%. All were on 3-drug immunosuppression of MMF, steroids & CNIs. Intact FGF 23 was assayed using ELISA method (Kainos Labs Japan). 25-OH Vit D levels & iPTH levels were measured by chemiluminescence method (Abbott Labs, IL USA) Table shows study parameters at baseline & their course post RT. Taking standard cut-off values: 7% patients had hypocalcemia while 3% had hypercalcemia before RT while none in post RT period had hypo or hypercalcemia. Before RT 97% had hyperphosphatemia while 32.3, 4 & 0% had hypophosphatemia at 1,6 & 12 months post RT. 100% patients had hyperparathyoidism pre RT while 64.8, 24.3 &10.7% had hyperparathroidism at 1,6 & 12 months post RT. 100% patients had high iFGF 23 levels pre RT while 36.4, 12. & 0% had increased iFGF23 levels at 1, 6 & 12 months post RT

Conclusions: In younger CKD-5D cohort having shorter dialysis vintage who underwent LDRT we document rapid & significant decline in iPTH & iFGF 23 levels post RT. iFGF23 normalised faster as compared to iPTH

Parameter	Baseline	1 month	6 month	12 month	Friedman test (p)
eGFR ml/min	8.4±4.1	88.1 + 36.5	72.6 + 20.4	74.9 + 21.8	0.001

Interaction Between FGF-23 and Soluble Klotho on Cardiovascular Events in Patients Receiving Hemodialysis

Hisae Tanaka,[1] Hirotaka Komaba,[1] Hiroaki Ishida,[4] Hiroo Takahashi,[1] Takehiko Wada,[1] Takatoshi Kakuta,[1] Michio Nakamura,[4] Yuichiro Takahashi,[3] Toru Hyodo,[2] Miho Hida,[2] Masafumi Fukagawa.[1] *[1]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [2]Kurata Hospital, Hiratsuka, Japan; [3]Jinken Clinic, Ebina, Japan; [4]Department of Transplant Surgery, Tokai University School of Medicine, Isehara, Japan.*

Background: Membrane Klotho binds to FGFR1 and forms a specific receptor for FGF23. Recent investigations have demonstrated that soluble Klotho, a cleavage product of membrane Klotho, also mediates FGF23-dependent bioactivity. Elevated FGF23 may have detrimental effects on several tissues that do not express membrane Klotho. It is not known whether this process is mediated through the binding of soluble Klotho to FGFR1 and FGF23.

Methods: We conducted a 3-year prospective cohort study of 654 maintenance hemodialysis patients. We examined the interaction between FGF23 and soluble Klotho for the composite of all-cause mortality and cardiovascular events using multivariate Cox regression.

Results: During the follow-up period, 103 patients reached the primary composite endpoint. After adjustments for confounding, elevated FGF23 was independently associated with a higher risk of the primary composite end point only in patients with soluble Klotho greater than the median value (HR per doubling, 1.20; 95% CI, 1.04-1.39; P=0.005 for interaction). Likewise, elevated soluble Klotho was associated with a higher risk of the primary composite end point only in patients with FGF23 greater than the median value (HR per 100 pg/ml increase, 1.25; 95% CI, 1.08-1.46; P=0.005 for interaction). When we categorized the patients into 4 groups according to their medians of FGF23 and soluble Klotho, the highest risk for the primary composite endpoint was observed in patients with high FGF23 and high soluble Klotho.

Conclusions: These data suggest that elevated levels of FGF23 and soluble Klotho contribute to cardiovascular disease in a coordinated manner.

FR-PO166

Performance of Soluble Klotho Assays in Clinical Samples of Kidney Disease

Javier A. Neyra,[2] Orson W. Moe,[3] Johanne V. Pastor,[3] Fabiola Gianella,[3] Mark J. Sarnak,[1] Joachim H. Ix,[4] David A. Drew.[1] *[1]Tufts Medical Center, Boston, MA; [2]University of Kentucky Medical Center, Lexington, KY; [3]University of Texas Southwestern Medical Center, Dallas, TX; [4]UCSD, San Diego, CA.*

Background: There is considerable interest in investigating soluble Klotho as a biomarker in patients with different types and severity of kidney diseases. Unfortunately, there remains uncertainty regarding the best method to measure soluble Klotho in human serum samples.

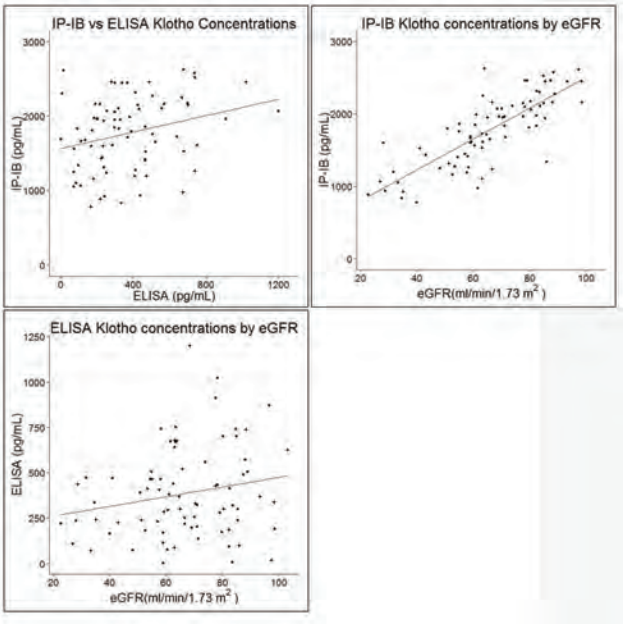
Methods: Using human serum samples obtained from several clinical cohorts with a wide range of kidney function, we measured soluble Klotho using a commercial enzyme linked immunosorbent assay (ELISA - IBL America) as well as with an immunoprecipitation-immunoblot (IP-IB) assay utilizing a synthetic antibody with high affinity and specificity for Klotho. Recovery of spiking with known amounts of exogenous Klotho was tested. A subset of samples was analyzed with and without the addition of a protease inhibitor cocktail at time of collection or after first freeze/thaw cycle.

Results: The IP-IB assay was superior to the ELISA at recovery of exogenous Klotho (81-115% vs. 60-81%) across the spectrum of kidney function. The IP-IB and ELISA assay were modestly correlated (R = 0.28, p = 0.01). Klotho concentrations by IP-IB were highly correlated with eGFR (R=0.80, p<0.001) in comparison to the commercial ELISA, which exhibited minimal correlation with eGFR (R=0.18, p=0.12) [Figure 1]. Use of a protease inhibitor cocktail neither improved nor impaired performance of the IP-IB assay; however, a subsequent freeze-thaw cycle resulted in a significant reduction in Klotho recovery and dissipated the correlation between Klotho levels and eGFR. With the ELISA, use of a protease inhibitor cocktail resulted in an increase of intra-subject variability.

Conclusions: The IP-IB assay is preferable to the commercial ELISA to measure soluble Klotho concentrations in never-thawed serum samples with varying severity of kidney disease.

Funding: NIDDK Support

Figure 1: A) Correlation between IP-IB and ELISA (R = 0.28, p = 0.01); B) Correlation between IP-IB and eGFR (R = 0.8, p < 0.001); C) Correlation between ELISA and eGFR in SPRINT CKD participants (n=77) (R = 0.18, p = 0.12)



FR-PO167

Vitamin K-Dependent Proteins After Kidney Transplantation: Results from a Prospective Study

Maria Fusaro,[2] Pascale Khairallah,[1] Andrea Aghi,[3] Mario Plebani,[7] Martina Zaninotto,[4] Chiara Cosma,[4] Maria A. Aponte farias,[1] Natalia E. Cortez,[5] Giovanni Tripepi,[6] Tom Nickolas.[1] *[1]Columbia University Medical Center, New York, NY; [2]National Research Council (CNR) e Institute of Clinical Physiology (IFC), Pisa, Italy; [3]Nephrology Unit, University of Padua, Padova, Italy; [4]University Hospital, Padova, Italy; [5]University of California, Davis, Davis, CA; [6]IFC-CNR, Calabria, Italy; [7]Laboratory Medicine Unit, Department of Medicine, University of Padova, Padova, Italy.*

Background: Two Vitamin K-dependent proteins (VDKPs) link bone and vasculature in CKD-MBD: Bone Gla Protein (BGP) and Matrix Gla Protein (MGP). In ESKD, Vitamin K deficiency is highly prevalent and leads to increased levels of inactive VKDPs (undercaboxylated(uc) BGP and dephosphorylated(dp)-uc MGP), which are linked to greater risk of fractures and severity of vascular calcification. We hypothesized that kidney transplantation (KT) would improve Vitamin K status and lower levels of inactive VKDPs.

Methods: Between 2014-2017, we conducted a study in 34 patients to assess changes in VKDPs during the 1st year of KT. In a specialized lab we determined VKDPs pre- and 1-year post-KT: total BGP, uc BGP, total MGP, and dp-uc MGP. We determined the prevalence of Vitamin K deficiency based on levels of uc-BGP and dp-uc MGP

Results: Our cohort had a mean+/-SD age of 48+/-14 years, 32% were female and 97% were Caucasian. 1 year post-KT, there was a decrease in the levels of all VKDPs and the prevalence of Vitamin K deficiency(Table). Patients with greatest severity of Vitamin K deficiency pre-KT had the largest decreases of inactive VDKPs post-KT (Figure).

Conclusions: KT was associated with improvement in Vitamin K status as manifested by decreased levels of inactive VKDPs. These are the first prospective data on VKDPs in CKD patients pre- and post-KT. Studies are needed to assess the impact of improvement in VKDP status after KT on CKD-MBD outcomes.

Funding: Private Foundation Support

VKDPs pre- and post-KT

Association of Serum Phosphate with Peripheral Artery Disease (PAD) in Hemodialysis Patients: Ten-Year Outcomes of the Q-Cohort Study

Sho Shimamoto,[1] Shunsuke Yamada,[1] Hiroto Hiyamuta,[1] Masatomo Taniguchi,[2] Masanori Tokumoto,[3] Kazuhiko Tsuruya,[4] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Kyushu University, Fukuoka, Japan; [2]Fukuoka Renal Clinic, Fukuoka, Japan; [3]Department of Internal Medicine, Fukuoka Dental College, Sawara-ku, Japan; [4]Nara Medical University, Kashihara, Japan.*

Background: Peripheral artery disease (PAD) is caused by arteriosclerosis and is one of the critical cardiovascular complications in hemodialysis patients. Although serum phosphate is a known risk factor for cardiovascular events, it is unclear whether serum phosphate is associated with PAD. The aim of the present study was to clarify the relationship between serum phosphate level and the risk for PAD in hemodialysis patients.

Methods: A total of 3,506 hemodialysis patients registered to the Q-cohort Study was followed up for 10-years. PAD was defined as intervention for PAD including endovascular therapy, revascularization, and amputation. Patients were divided into quartiles based on baseline serum phosphate level; Q1 (n=886), <4.2 mg/dL; Q2 (n=838), 4.2 to 4.8 mg/dL; Q3 (n=909), 4.9 to 5.6 mg/dL; Q4 (n=873), 5.7≤ mg/dL. Multivariable-adjusted Cox proportional hazards risk model was employed to examine the association between serum phosphate level and the risk for PAD.

Results: During the follow-up period, 257 patients developed PAD. Cox proportional hazards risk model showed a significant association between baseline serum phosphate level and PAD: hazard ratio [HR] (95% confidence interval [CI]) per 1 mg/dL increase in serum phosphate level, 1.23 (1.09 -1.37). The risk for PAD in Q4 was significantly increased compared with that in Q1: HR (95% CI), 1.72 (1.19-2.50). When a multivariable-adjusted restricted cubic spline curve was depicted, the HR for PAD increased nonlinearly as the serum phosphate level increased. Furthermore, the effect of hyperphosphatemia on the risk for PAD was significantly enhanced in patients without diabetes, patients with history of cardiovascular events or patients with high serum C-reactive protein levels.

Conclusions: Elevated serum phosphate level was associated with an increased risk of intervention for PAD in hemodialysis patients.

FR-PO169

Differential Effects of Phosphate Binders on Vitamin D Metabolism in CKD

Charles Ginsberg,[1] Leila R. Zelnick,[2] Geoffrey A. Block,[3] Glenn M. Chertow,[4] Michel Chonchol,[5] Andrew N. Hoofnagle,[6] Bryan R. Kestenbaum,[6] Ian H. de Boer.[7] *[1]UCSD, San Diego, CA; [2]Kidney Research Institute, Seattle, WA; [3]Reata, Denver, CO; [4]Stanford University School of Medicine, Palo Alto, CA; [5]University of Colorado, Aurora, CO; [6]University of Washington, Seattle, WA; [7]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA.*

Background: Phosphate binders are commonly used in the treatment of patients with advanced chronic kidney disease (CKD) and end stage renal disease. While phosphate binders are used to lower phosphate, the effects of specific phosphate binder types on vitamin D metabolism is unknown.

Methods: We performed a secondary analysis of the phosphate normalization trial, in which 148 patients with moderate to severe CKD were treated with either sevelamer carbonate, lanthanum carbonate, calcium acetate or placebo. We used linear mixed models to evaluate the relationship between treatment arm and changes in 24,25-dihydroxyvitamin D3 [24,25(OH)2D3], 1,25-dihydroxyvitamin D3 [1,25(OH)2D3], the ratio of 24,25(OH)2D3, to 25-hydroxyvitamin D (the vitamin D metabolite ratio or VMR) and the ratio of 1,25(OH)2D to 25-hydroxyvitamin D.

Results: Compared to placebo, randomization to the calcium acetate arm was associated with a 0.6 ng/ml (95%CI 0.2,1) and 13.5 ng/µg (95%CI 5.5,21.5) increase in $24,25(OH)_2D$ and VMR, respectively, and a 5.2 pg/ml (95% CI 1.1,9.4) reduction in $1,25(OH)_2D$. Randomization to sevelamer carbonate was associated with a 0.5 ng/ml (95% CI -0.9,-0.1) and 11.8 ng/µg (95% CI -20,-3.5) reduction in $24,25(OH)_2D_3$ and VMR respectively. There was no association of sevelamer arm with change in $1,25(OH)_2D_3$, and randomization to lanthanum carbonate was not associated with a change in any of the vitamin D metabolites.

Conclusions: Administration of different phosphate binder classes to patients with moderate-severe CKD results in unique changes in vitamin D metabolism. These findings may have important clinical implications in the management of hyperphosphatemia and vitamin D deficiency.

Serum Phosphate and Microvascular Function in a Population-Based Cohort: The Maastricht Study

Charles Ginsberg,[1] Alfons J. Houben,[2] Rakesh Malhotra,[1] Tos Berendschot,[2] Jeroen Kooman,[2] Carroll A. Webers,[3] Coen Stehouwer,[2] Joachim H. Ix.[1] *[1]UCSD, San Diego, CA; [2]Maastricht University, Maastricht, Netherlands; [3]University Eye Clinic Maastricht, Maastricht, Netherlands.*

Background: Higher serum phosphate is associated with cardiovascular events and all-cause mortality. Explanations of this association have focused on large vessel-calcification and stiffness. Studies suggest that higher serum phosphate induces microvascular dysfunction, but relationships in humans with direct measures of microvascular function are lacking.

Methods: We performed a cross-sectional analysis of 3,189 community-living participants that underwent skin capillaroscopy, laser-Doppler flowmetry, or flicker-light induced retinal vessel responses. The primary outcome was capillary recruitment during post-occlusive peak reactive hyperemia by capillaroscopy. Secondary outcomes included capillary recruitment during venous congestion, heat-induced skin hyperemic response, flicker-light induced retinal arteriolar and venular dilation.

Results: The mean age of the cohort was 59 years, 48% were women, 7% had an eGFR< 60ml/min/1.73 m^2, and the mean serum phosphate concentration was 3.2±0.5 mg/dl. A 1 mg/dl higher serum phosphate was independently associated with a 5.0% lower post-occlusive capillary recruitment (95%CI -10.0%,-0.1%). Results were similar for capillary recruitment with venous congestion (**Table**). A 1 mg/dl higher serum phosphate was also independently associated with a 0.23% lower retinal venular dilation in response to flicker-light (95%CI -0.44%,-0.02%). A higher serum phosphate was not associated with change in flicker-light induced retinal arteriolar dilation or heat-induced skin hyperemic response, however a higher serum phosphate was associated with a lower heat-induced skin hyperemic response among men (-149% 95%CI -260,-38, per 1 mg/dl higher serum phosphate).

Conclusions: Higher serum phosphate concentrations are associated with microvascular dysfunction in community-living individuals.

FR-PO171

Effect of Hypomagnesemia on Vascular Calcification in Peritoneal Dialysis Patients

Minjung Kang, Eunjeong Kang, Hyunjin Ryu, Curie Ahn, Kook-Hwan Oh. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Vascular calcification is a non-traditional risk factor for cardiovascular disease in patients with chronic kidney disease (CKD) and main cause of this is disturbance in the mineral and bone metabolism. Magnesium (Mg) was known as a calcification inhibitor and there was a high prevalence of hypomagnesemia in peritoneal dialysis (PD) patients. However, a longitudinal study of the effects of hypomagnesemia on vascular calcification in PD patients was rare.

Methods: 167 patients with PD were included from Seoul National University Hospital. We investigated the relationship between lower serum magnesium and vascular calcification progression. Patients were categorized as hypomagnesemia (n=20), normomagnesemia (n=85), and hypermagnesemia (n=62). Vascular calcification was assessed by abdominal aortic calcification (AAC) score with lateral lumbosacral X-ray. The study end point was vascular calcification progression, defined as the change in AAC score per year >0.

Results: During the median follow-up period of 3.1 years [interquartile range 2.0-4.3 years; maximum 7.6 years], 38 (42.7%) patients developed vascular calcification progression. In a multivariable logistic regression model, the hypomagnesemia group was associated with higher risk of vascular calcification progression (C1, serum Mg ≤ 1.7 mg/dl, OR 27.3 [1.07 – 691.2]; *P*=0.045), as compared with the normal range magnesium group. All-cause mortality was not associated with hypomagnesemia in a multivariable hazard model (C1, serum Mg ≤ 1.7 mg/dl, HR 0.7 [0.07 – 6.89]; *P*=0.755).

Conclusions: Hypomagnesemia is associated with vascular calcification progression in peritoneal dialysis patients.

FR-PO172

Effect of Spironolactone on the Progression of Coronary Calcification in Hemodialysis Patients

Jose E. Gueiros,[1] Ana Paula Gueiros,[1] Karina T. Oliveira,[2] Marina C. Matta,[3] Leuridan C. Torres,[3] Alex S. Souza,[3] Dulce E. Casarini,[4] Aluizio B. Carvalho.[4] *[1]Nephrology Division, Instituto de Medicina Integral Prof. Fernando Figueira, Recife, Brazil; [2]Radiology Division, Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil; [3]Clinical Reserach Division, Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil; [4]Nephrology Division, Federal University of Sao Paulo, São Paulo, Brazil.*

Background: Aldosterone, through its action on the mineralocorticoid receptor, has been recognized as a factor involved in osteoinductive pathways of vascular calcification (VC). Clinical and experimental studies have shown that the use of spironolactone is related to the prevention of VC progression. The aim of this study was to evaluate the effect of spironolactone on the progression of coronary calcification (CC) in hemodialysis patients.

Methods: Patients witha coronary calcium score (CCS) > 30 AU, evaluated by multiple-detector computed tomography (MDCT), were randomized into two groups: treatment group (GT group, n=22) corresponding to patients receiving spironolactone and control group (GC group, n=23), those who did not undergo drug intervention and did not receive placebo. The main outcome was a percentage change in CCS (relative progression), at the end of the follow-up period, which was one year. The patients were evaluated monthly, through consultations and collection of laboratory tests. At the end of the study, a new MDCT was performed in order to evaluate the progression of CC. Patients with a relative progression rate> 15% were considered progressive.

Results: Data from 35 patients who completed the follow-up period were analyzed, being 18 in the GT group and 17 in the CG group. The relative progression of CCS was similar in both groups, being 21.5% and 27% in the GT and GC groups, respectively. The majority of the patients progressed to the CC, 61.1% in the GT group and 70.6% in the CG group. At the end of the follow-up, there was an increase in intact parathyroid hormone (p=0.035) and a decrease in sclerostin (p=0.002) in the GT group. Among the groups, also at the end of the study, total alkaline phosphatase was lower in the GT group when compared to the GC group (p=0.002). Treatment with spironolactone determined an increase in high-density lipoprotein in the GT group (p=0.007). The use of spironolactone did not increase the frequency of side effects.

Conclusions: The use of spironolactone did not attenuate the progression of the CC in patients undergoing hemodialysis. The use of spironolactone was safe in the study population.

FR-PO173

Coronary Calcification in Peritoneal Dialysis Patients: The Contribution of Traditional and Uremia-Related Risk Factors

Ana Paula Gueiros,[1] Jose E. Gueiros,[1] Karina T. Oliveira,[2] Marina C. Matta,[3] Leuridan C. Torres,[3] Alex S. Souza,[3] Dulce E. Casarini,[4] Aluizio B. Carvalho.[4] *[1]Nephrology Division, Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil; [2]Radiology Division, Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil; [3]Clinical Research Division, Instituto de Medicina Integral Prof. Fernando Figueira, Recife, Brazil; [4]Nephrology Division, Federal University of Sao Paulo, São Paulo, Brazil.*

Background: Coronary calcification (CC) is commonly observed in dialysis patients and is associated with cardiovascular and all-cause mortality. Its pathogenesis is complex and involves a series of markers that interact in the vascular microenvironment. There are very few studies that assess the presence of CC in peritoneal dialysis (PD). The aim of this study was to evaluate the frequency and the factors associated with CC in PD patients.

Methods: A total of 81patients were enrolled. Coronary calcification was assessed using a multislice coronary tomography. Patients with a coronary calcium score (CCS) ≥ 30 Agatston units were considered as having CC. Demographic data were collected and the serum levels of biochemical and bone-derived biomarkers, including sclerostin and fetuin-A, were measured.

Results: Thirty-eight patients (47%) presented with CC. Calcified patients were older adults (p <0.001), presenting with more comorbidities, such as diabetes mellitus (p=0.043), dyslipidemia (p=0.040), and smoking (p=0.003) Calcified patients presented higher serum levels of sclerostin (p=0.005). There was a tendency for calcified patients to have lower levels of fetuin-A (p = 0.05). In a multivariate logistic regression analysis, age, serum sclerostin level, and smoking were independently associated with CC. For each increase of 100 units in the serum level of sclerostin, there was a 13% increase in the likelihood of CC. CCS was positively correlated with age, time on PD, and serum sclerostin levels

Conclusions: Coronary calcification is highly prevalent in PD patients and is associated with older age, diabetes and smoking. Serum levels of sclerostin were independently associated with CC.

FR-PO174

Effect of Warfarin on Progression of Vascular Calcification

Harish R. Alappan,[1] Gurleen Kaur,[3] W. Charles O'Neill.[2] *[1]Emory University - Undergraduate, Atlanta, GA; [2]Emory University, Atlanta, GA; [3]Emory, Decatur, GA.*

Background: Advanced chronic kidney disease (CKD) and end-stage renal disease (ESRD), as well as diabetes are potent risk factors for medial arterial calcification, a lesion associated with poor cardiovascular outcomes. Warfarin use may be an additional risk factor, possibly by reducing levels of matrix gla protein, a vitamin K-dependent inhibitor of vascular calcification. To quantify the effect of warfarin on medial arterial calcification and determine if this is augmented in CKD and ESRD or diabetes, we retrospectively measured the progression rate of breast arterial calcification (BAC), a marker of systemic medial arterial calcification in women with or without warfarin use.

Methods: Subjects with and without warfarin use were identified from an electronic medical record search of all digital mammograms at Emory Healthcare. Records were manually reviewed to identify mammograms performed during warfarin use. Subjects without baseline calcification were excluded. Control patients were selected to match the eGFR range in warfarin patients. Lengths of calcified arteries were measured on digital mammograms separated by ≥ 1 year. Progression rates are reported as mm/breast/y and expressed as medians and interquartile ranges. Statistical significance was determined by the Mann-Whitney U and Wilcoxon tests.

Results: Of the 77 sets of mammograms, eGFR was >60 in 36 and <60 in 28, and ESRD was present in 11. Diabetes was present in 44%. In subjects with eGFR >60, warfarin use was associated with faster progression of BAC compared to controls: 10.0 (3.8-17); n=36 vs. 2.6 (0.8-7.0); n=58, *p=0.002*. A similar effect was seen in ESRD but resulted in much higher rates: 46.9 (31-183); n=11 vs. 15.2 (7-52); n=32, *p=0.025*. Warfarin's effect was not augmented in patients with CKD (eGFR 17-58) or in diabetics vs. non-diabetics. Mammograms before or after warfarin use were available in 11 and 13 patients. BAC rate increased after starting warfarin (13.8 [7.8-39] vs. 2.1 [0.3-3.9]; p=0.01) and slowed, but not significantly, after stopping warfarin (1.9 [-7.4-6-8] vs. 8.8 [1.3-10]; p=0.11).

Conclusions: Warfarin accelerates progression of medial arterial calcification. This effect is magnified in ESRD, resulting in marked increases in calcification in this population. These data suggest that warfarin should be used with caution in ESRD, particularly in patients with extensive vascular calcification.

FR-PO175

Associations Between Undercarboxylated Osteocalcin and Peripheral Vascular Calcification in CKD5

Pascale Khairallah,[1] Maria Fusaro,[2] Andrea Aghi,[3] Mario Plebani,[8] Martina Zaninotto,[7] Chiara Cosma,[7] Sanchita Agarwal,[5] Maria A. Aponte farias,[1] Natalia E. Cortez,[4] Giovanni Tripepi,[6] Tom Nickolas.[1] *[1]Columbia University Medical Center, New York, NY; [2]National Research Council (CNR) e Institute of Clinical Physiology (IFC), Pisa, Italy; [3]Nephrology Unit, University of Padua, Padova, Italy; [4]University of California, Davis, Davis, CA; [5]Columbia University, New York, NY; [6]IFC-CNR, Calabria, Italy; [7]University Hospital, Padova, Italy; [8]Laboratory Medicine Unit, Department of Medicine, University of Padova, Padova, Italy.*

Background: Increasing evidence proposes a link between bone and vasculature in CKD. Osteocalcin (OCN) is the most abundant non-collagenous peptide found in the mineralized bone matrix. In vitamin K deficiency, such as advanced CKD and dialysis, OCN is predominantly in the undercarboxylated form (ucOCN). We hypothesized that ucOCN levels are associated with peripheral VC in patients with advanced CKD.

Methods: We studied 34 patients with CKD5-5D. Radial artery (RA) and Tibial artery (TA) VC were quantified by high-resolution peripheral computed tomography (HRpQCT), a validated tool to assess VC. Using specialized assays, we measured total OCN (LIASON® Osteocalcin Assay 310950 DiaSorin Inc., Stillwater MN, USA) and ucOCN (Glu-OC EIA Kit MK118 Takara Bio Inc., Otsu, Shiga, Japan). Spearman correlation analysis determined relationships between uc- and total circulating OCN and VCs.

Results: Our cohort had a mean+/-SD age of 48+/-14 years, 32% were female and 97% were Caucasian. Higher levels of ucOCN were associated with: (1) the presence of VC at the radius (r=0.4, p=0.03) but not at the tibia (r=0.3, p=0.06); and (2) greater severity of VCs at the TA (r=0.4, p=0.04) but not at the RA (r=0.3, p=0.07). Total OCN was not associated with either the presence of RA or TA VCs (p=0.1 and p=0.2 respectively) or the severity of RA and TA VCs (p=0.1 and p=0.3 respectively).

Conclusions: ucOCN is associated with the presence and severity of peripheral VC in patients with advanced CKD. This association has not been previously described in the literature. Larger studies are needed to confirm and determine mechanisms underlying this association and whether vitamin K supplementation improves peripheral VC severity.

FR-PO176

Prevalence and Risk Factors of Vascular Calcification Among Chinese Patients with Early CKD

Ying Tang, Wenjuan Yu, Junzhe Chen, Shengnan Ge, Sha Fu. *Sun Yat-sen Memorial Hospital, Sun Yat-sen University, GuangZhou, China.*

Background: Extensive evidence suggests that vascular calcification(VC) independently predicts the risk of all-cause and CVD mortality. Here, we retrospectively studied the prevalence and risk factors of VC among Chinese patients with chronic kidney disease(CKD).

Methods: 138 patients diagnosed with CKD in Sun Yat-sen Memorial Hospital were included for analysis. Abdominal aortic calcification (AAC), Coronary artery calcification (CAC) were assessed by plain lateral lumbar radiograph and multi-detector computed tomography (MDCT) respectively. The AAC score will be classified into three levels(0-5, 5-16 and ≥16) and the CAC score will be classified into four levels(0-100, 100-400, 400-1000 and ≥1000). Risk factors were analyzed using logistic regression.

Results: Among the 138 patients, 63 (45.7%) were diagnosed with early CKD(stage 1-3) who had an eGFR of 30 mL/min/1.73 m or greater. Of the 63 patients, 30 (47.6%) were found abdominal aortic calcification who had AAC score greater than 0; Specifically, level 1 accounted for 30.2%; level 2 for 17.5% and level 3 for 1.6%. The high prevalence rate of AAC among patients with CKD stage 1-3 is similar to stage 4-5(49.3%) but the latter is more severe on calcification degree. At the same time, we found that 41.1% patients of early CKD have coronary artery calcification while 52.8% patients of advanced CKD(stage 4-5). Both the prevalence rate and severity of CAC among patients with stage 4-5 are higher than stage 1-3. The multivariate logistic regression identified that older age [OR (95%CI) 1.131 (1.060, 1.206), *P*<0.001], DM [OR (95%CI) 6.523(1.490, 28.544), *P*=0.013] and increased SUA [OR (95%CI) 1.006(1.001, 1.011), *P*=0.028] were the risk factors of VC among Chinese patients with early CKD. However, except for age and DM, it was SBP [OR (95%CI) 1.037(1.005,1.070), *P*=0.022] but not the SUA(*P*=0.533) increased the risk of VC among patients with advanced CKD.

Conclusions: There is limited knowledge about the impact of VC on Chinese patients with CKD, causing poor prognosis and inadequate management. We were surprised to find such a high prevalence of VC in patients with early CKD. Now, we are conducting a multi-center, large sample prospective study (ChiCTR1900020925) for establishing a predictive model for VC in patients with chronic kidney disease(stage 1-3) and hope to help us prevent it more effectively.

FR-PO177

Quantitative Systems Pharmacology Model of Metabolic Bone Disorder and Vascular Calcification in CKD

Devin E. Mcbride,[1] Adam E. Gaweda,[1] Michael E. Brier,[1] Eleanor D. Lederer.[2] *[1]University of Louisville, Louisville, KY; [2]University of Louisville; Robley Rex VA Medical Center, Louisville, KY.*

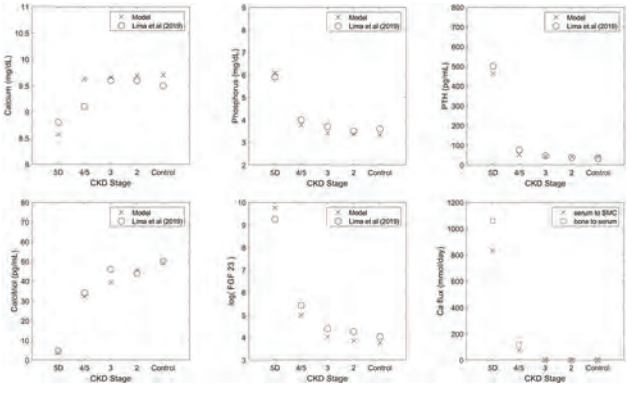
Background: Changes in Calcium (Ca) and Phosphorus (P) metabolism in patients with Chronic Kidney Disease (CKD) and the associated Mineral Bone Disorder (MBD) and Vascular Calcification (VC) pose significant morbidity and mortality risk in this patient population. We propose a Quantitative Systems Pharmacology (QSP) model of CKD-related MBD / VC to enable precision dosing of pharmacologic agents used in treatment of these conditions.

Methods: Based on the published data, we developed a QSP model of Ca / P metabolism. The model represents the movement of Ca and P between serum, gut, bone, kidney, and the soft tissue. The model also includes the FGF23 pathway and the effects of calcimimetic, vitamin D, and P binders. We validated the model against recently published clinical data describing the effect of CKD on the markers of MBD progression. We also investigated the ability of the model to predict different treatment effects in a virtual CKD patient.

Results: The impact of kidney function decline on Ca, P, PTH, Calcitriol, FGF23, and the Ca fluxes between serum, bone, and soft tissue predicted by the model is shown in the six plots below. The model correctly captures the decrease in serum Ca and the increase in P and PTH. In addition, the model correctly identifies the changes in Calcitriol and FGF23. Predicted changes in bone-to-serum and serum-to-soft tissue Ca fluxes are consistent with the pathophysiology of CKD-MBD/VC. The effects of combined P binder, Calcitriol, and a calcimimetic administration are consistent with the expected mechanism of action.

Conclusions: We propose a QSP model of Ca / P homeostasis and their effect on bone and vascular health. Validation against published clinical data proves the feasibility of the model. The model will be used to benchmark personalized treatment options to minimize the impact of MBD/VC in CKD patients.

Funding: Veterans Affairs Support



Predicted levels of Ca, P, PTH, Calcitriol, FGF23, and the Ca fluxes between serum, bone, and soft tissue at different levels of CKD.

FR-PO178

CPP (Calciprotein Particle) Is a More Sensitive Marker That Predicts Vascular Calcification in Patients with CKD

Hidekazu Moriya, Yasuhiro Mochida, Kunihiro Ishioka, Sumi Hidaka, Takayasu Ohtake, Shuzo Kobayashi. *Shonan Kamakura General Hospital, Kamakura, Japan.*

Background: Vascular calcification in atherosclerotic diseases is an important issue related to the prognosis in patients with chronic kidney disease (CKD). Since vascular calcification occurs in an early stage of CKD, it should be evaluated to improve the prognosis by early intervention. Phosphorus, parathyroid hormone and FGF-23 are identified as markers of CKD-mineral bone disease, but are within normal range in an early stage of CKD. CPP stands for calciprotein particles, which are nanoparticles composed of calcium-phosphate (CaP) crystals and mineral binding proteins such as Fetuin-A. Serum CPP levels could be a useful marker of vascular calcification in an early CKD patients. In this study, we determined whether CPP is a more sensitive marker of vascular calcification of patients with CKD than existing markers.

Methods: In a single-center longitudinal study of 58 patients with CKD stage G1-5, we evaluated clinical parameters (s-Cr, eGFR, CPP, FGF-23, intact-PTH, 1.25 VitD) and arterial calcification score (ACS) of lower extremities by MDCT at the start and one year later to determine the risk factors related to the development of vascular calcification in CKD.

Results: Average age and average s-Cr were 69.0±12.9 years and 1.78±1.26mg/dl, respectively. CPP significantly correlated with serum phosphorus but not with s-Cr or eGFR. The rate of change in s-Cr, eGFR, FGF-23, intact-PHT, and 1.25 VitD did not show significant correlation with the rate of change in ACS of the lower extremities, but the rate of change in CPP showed significantly negative correlation with the rate of change in ACS ($r = -0.292$, $P = 0.0258$), and the rate of change in CPP was also an independent risk factor ($p = 0.0144$) in the progression of vascular calcification in multivariate analysis.

Conclusions: CPP effects protectively for vascular calcification by capturing calcium and phosphorus. CPP is a more sensitive marker of arterial calcification than other CKD-MBD markers such as FGF-23.

FR-PO179

Clarification of the Mechanism of Acute GFR Change by SGLT2 Inhibition with In Vivo Imaging Technique

Yoshihisa Wada, Kengo Kidokoro, Megumi Kondo, Atsuyuki Tokuyama, Hiroyuki Kadoya, Hajime Nagasu, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Kawasaki Madical School, Kurashiki, Okayama, Japan.*

Background: SGLT2 inhibition (SGLT2i) exerted the effects to lower the risk of kidney failure in patients with type 2 diabetic kidney disease (DKD). Improvement of glomerular hyperfiltration via tubuloglomerular feedback (TGF) has been considered to be involved in this mechanism. We have successfully developed the novel method to measure single nephron GFR (SNGFR) in mice using multiphoton laser microscopy (MPM). We demonstrated that adenosine/adenosine 1a receptor (A1aR) pathway plays a pivotal role in the TGF mechanism in type 1 diabetic model, Akita mice (Circulation 2019). The purpose of this study is to clarify the acute effects of SGLT2i on glomerular hemodynamic in type 2 diabetic rat.

Methods: Zucker lean (ZL) rats and zucker diabetic fatty (ZDF) rats were used. Both rats were divided to the following groups; luseogliflozin (10mg/kg, gavage) group, luseogliflozin + adenosine A1 receptor (A1aR) antagonist (8-cyclopentyl-1,3-dipropylxanthine, 1mg/kg) group, and insulin group. SNGFR was measured after four weeks of treatment. For the acute phase study, catheter was inserted into the ureter to collect urine. Serial urine-collections of urine were performed every 30 minutes after administration of luseogliflozin. Urinary excretions of glucose, sodium, and adenosine were measured. At the same time points, SNGFR was measured to evaluate the correlation between urinary excretions of these parameters and GFR change.

Results: SNGFR in the untreated ZDF group was significantly higher than in the ZL group. Luseogliflozin treatment increased urinary sodium and glucose excretion and reduced serum glucose level in the ZDF group. SNGFR significantly declined after 30 minutes and became stabilized until 90 minutes after administration, with inverse relationship to urinary sodium. The A1aR-antagonist group showed similar urinary excretion pattern, but initial decline of SNGFR was not observed.

Conclusions: Adenosine/ A1aR pathways play an important role in the regulation of GFR and is involved in the acute decline of GFR by SGLT2i treatment.

FR-PO180

Empagliflozin Attenuates PGE2-Mediated Inhibition of Arginine Vasopressin-Stimulated Water Reabsorption in Type II Diabetic (db/db) Mouse Collecting Duct

Rania Nasrallah,[1] Joe A. Zimpelmann,[1] Kevin D. Burns,[1,2] Richard L. Hébert.[1] *[1]Kidney Research Centre, University of Ottawa, Ottawa, ON, Canada; [2]The Ottawa Hospital - Riverside Campus, Ottawa, ON, Canada.*

Background: Sodium-glucose cotransporter 2 inhibitors such as empagliflozin (EMPA) are promising therapeutics in diabetic kidney disease (DKD) since they lower blood glucose, induce diuresis, and reduce glomerular hyperfiltration and proteinuria. Prostaglandin E_2 (PGE_2), the main renal product of cyclooxygenase 2 (COX2), inhibits vasopressin (AVP) mediated water reabsorption in the collecting duct via its EP1 and EP3 receptors. We examined whether PGE2 inhibition of AVP-mediated water transport is affected by EMPA.

Methods: Four groups of male mice were studied: control (db/m), db/m+EMPA (10 mg/kg/day in chow for 6 weeks), diabetic (db/db), and db/db+EMPA. Collecting ducts were microdissected for quantitative PCR and water transport studies. Isolated perfused inner medullary collecting ducts were stimulated with 10^{-12} M AVP followed by 10^{-7}M PGE_2.

Results: Collecting ducts from db/db mice expressed elevated mRNA for COX2, EP1 receptors, and vasopressin V2 receptors (n=4-6) compared to db/m mice, but levels were unaffected by EMPA. Urine PGE_2 by ELISA was increased in db/db mice (n=5), but not altered by EMPA. AVP-stimulated water reabsorption was comparable in db/m and db/m+EMPA mice, and equally attenuated by up to 50% by PGE_2. In db/db mice, the AVP response was reduced by 50%, and this reduction was unaffected by EMPA. However, a greater attenuation of AVP-mediated water transport in response to PGE_2 was observed in db/db mice (62%), and this PGE_2 attenuation was significantly reduced in response to EMPA, to 28% (n=3-4).

Conclusions: PGE2 levels and EP1 receptor expression are increased in type II diabetic mice, leading to attenuation of collecting duct AVP-stimulated water reabsorption. This attenuation is reduced in response to EMPA treatment, which may prevent excessive water losses.

SGLT2 Inhibition Attenuates ROS Production by Regulating Cytochromes P450 and Their Metabolites in Diabetic Kidney

Batoul Dia,[1] Sami Azar,[2] Assaad Antoine Eid.[3] *[1]American University of Beirut, Beirut, Lebanon; [2]American University of Beirut Medical Center, Beirut, Lebanon; [3]American University of Beirut/Faculty of Medicine, Beirut, Lebanon.*

Background: Diabetic kidney disease (DKD) is currently the major common cause of end-stage renal disease worldwide. DKD is a main contributor to the increased risk of cardiovascular death in diabetes consequently increasing the global burden of diabetes-associated morbidity and mortality. Sodium–glucose cotransporter 2 (SGLT2) inhibitors, a new class of oral antihyperglycemic agents, revealed promising cardiac and renal protection in diabetic patients. However, the complete spectrum of pathways that can be affected by SGLT2 inhibition is not yet fully elucidates. Arachidonic acid (AA) is metabolized by several cytochrome 450 (CYP) isoforms to produce 20-hydroxyeicosatetraenoic acid (20-HETE) and epoxyeicosatrienoic acids (EETs). CYPs of the 4A and 4F subfamilies form 20-HETE, the 2B, 2C and 2J subfamilies form EETs. Previous data from our lab show that alteration in CYPS metabolites contribute to renal damage in a diabetic milieu by altering ROS production. Moreover, CYPs have been shown to be significant sources of oxidative stress in kidneys and other organs. In this study we aim to investigate the mechanistic pathway by which SGLT2 inhibition exerts its reno-protective effect.

Methods: Dapagliflozin (SGLT2 inhibitor), HET0016 (20-HETE inhibitor), and AUDA (sEH inhibitor increasing EETs availability) were administered to Type-2 diabetic mice. Functional, histological and biochemical studies were performed.

Results: In our study, we show that diabetes-induced extracellular matrix accumulation, increases glomerular hypertrophy, induces glomerulosclerosis and albuminuria. These observations were accompanied by increased ROS production associated with alteration in CYPs 4A and 2C11 expression concomitant with alteration in 20-HETE and EETs formation. Diabetes-induced glomerular injury was blocked by HET0016, an inhibitor of CYPs 4A or by the use of AUDA, an EET activator. Of interest, SGLT2 treatment restored glomerular integrity and renal function by decreasing 20-HETE production and increasing EETs formation. Concomitantly, SGLT2 inhibition regulated the observed increase in the expression and accumulation of TGF-Beta, known to Play a major role in glomerular injury.

Conclusions: These findings suggest a new mechanistic pathway by which SGLT2 inhibitors exerts their protective effect in DKD

FR-PO182

SGLT2 Inhibition Promotes Restoration of Podocyte Number and Regression of Diabetic Nephropathy in BTBR ob/ob Mice

Kelly L. Hudkins, Xianwu Li, Alexander L. Holland, Charles E. Alpers. Alpers Lab *University of Washington, Seattle, WA.*

Background: The SGLT2 inhibitor empagliflozin (EMPA) lowers blood glucose in diabetic patients via enhanced urinary excretion of glucose and ameliorates complications of type II diabetes, including cardiovascular disease and nephropathy (DN) through additional mechanisms, not fully defined.

Methods: Cohorts of 18 week old BTBR *ob/ob* and BTBR WT littermates (n=12) were fed chow formulated with 300 mg/kg EMPA with and without concurrent losartan (LOS) treatment, normal chow or were given leptin (LEP) for 6 weeks.

Results: Treatment with LEP, EMPA and EMPA+LOS but not LOS alone all resulted in significant reductions of blood glucose and HbA1c. BTBR *ob/ob* mice have elevated albumin creatinine ratio (ACR) (737 ug/mg); treatment with LEP, EMPA, LOS and EMPA+LOS all reduced ACR (88, 224, 162 and 112 ug/mg respectively, $p<0.01$). Morphologic analysis of silver stained tissue sections demonstrated significant reductions in mesangial matrix accumulation as percentage of glomerulus (G) tuft area in all treatment groups except LOS (*ob/ob* 20.8%, LEP 13.3%, EMPA 14%, and EMPA+LOS 12.5%, $p<0.01$; LOS 18.4%, ns). Podocyte density increased with EMPA treatment vs. untreated *ob/ob* (*ob/ob* 89.2, LEP 124, $p<0.05$; EMPA 145.3, $p<0.001$; EMPA+LOS 171.1 podos/$x10^6$ um^3, $p<0.001$). EMPA treatment decreased Mac2+ macrophages within glomeruli (*ob/ob* 1.85, EMPA 0.95 Mac2+ cells/G, $p<0.01$), but EMPA+LOS had numbers of glomerular macrophages similar to the untreated *ob/ob* mice (1.64 Mac2+ cells/G, ns). In contrast, qPCR for 3 inflammatory cytokines, MCP-1, IL-6 and TNFa were unchanged with EMPA, but significantly decreased with LOS and EMPA+LOS ($p<0.05$). In the interstitium, F4/80+ macrophages were decreased only with LEP treatment. Oxidative stress, measured by urinary 8OHdG/Cre and in tissue sections by cellular localization of nonspecific protein oxidation was decreased in all groups.

Conclusions: EMPA and EMPA+LOS treatment is similar to leptin replacement in ameliorating many of the pathologic and clinical manifestations of DN in the leptin deficient BTBR *ob/ob* mouse. Podocyte density was restored, oxidative stress and proteinuria decreased with SGLT2 inhibition. These may all be contributing factors in the improvement seen in human diabetic patients treated with SGLT2 inhibitors.

FR-PO183

Identification of a Novel Smad Target in SGLT2-Mediated CTGF/CCN2 Expression

Xinlu Pan,[1,2] Deborah L. Baines,[2] Mysore K. Phanish,[1] Mark E. Dockrell.[1,2] *[1]South West Thames Institute for Renal Research, London, United Kingdom; [2]St George's, University of London, London, United Kingdom.*

Background: Drugs inhibiting Sodium Glucose Transporter 2 (SGLT2) activity are providing unexpected and significant benefits by the reduction of a number of conditions including CVD and mortality in diabetic patients. The precise mechanisms underlying the benefits are not fully understood. Proximal tubule cell SGLT2 is believed to be the major site of action for these drugs. We have investigated putative signaling pathways in these cells regulating SGLT2 induced effects, and have now identified a target already known to be involved in cardiovascular disease and fibrosis.

Methods: PTECs (primary proximal tubule epithelial cells) were cultured on collagen IV. They were treated with D glucose 7 mM (control), 25mM (high) or 7 mM + 18 mM L glucose (osmotic control), +/- TGFβ1 at 0.75ng/ml. The cells were also administered Dapagliflozin and MEK Inhibitor U0126 (0.1μ -10μM). Western blotting was used to detect the level of Connective Tissue Growth Factor (CTGF/CCN2), phosphorylated extracellular signal regulated kinase 2 (ERK 2), Smad3, and Smad3 linker region serine 204 (LR) protein.

Results: Our high glucose (HG) +TGFβ1 treated PTECs significantly upregulated CTGF/CCN2 protein ($P^*<0.05$). This rise was significantly attenuated by Dapagliflozin ($P^{**}< 0.01$). Hence, we investigated a potential convergence of the glucose and TGFβ signaling. TGFβ1 phosphorylated ERK 2 (42kDa) from 5 - 60 min after treatment with HG ($P^{**}<0.01$), while HG treatment exclusively phosphorylated ERK 2 from 15 - 45 min ($P^*<0.05$). Smad3 (52kDa) was phosphorylated by TGFβ1 from 5 - 60 min, +/- high glucose ($P^{**}<0.01$). HG+TGFB1 treatment at 30 min caused a significant rise of LR (25kDa) phosphorylation ($P^*<0.05$), which was significantly reduced in the presence of U0126 ($P^*<0.05$).

Conclusions: SGLT2 mediates high glucose induced CTGF/CCN2 in the presence of TGFβ1. We have identified a novel alternative mechanism by the convergence of TGFβ1 and HG treatment; phosphorylation of a serine on the Smad3 LR. Hayashida (2013) showed that glucose mediated ERK activation of LR potentiated Smad regulated transcription in mesangial cells. As MEK inhibition was able to reverse LR phosphorylation in our PTECs, our data indicates an important role for ERK in facilitating the observed glucose mediated pro-fibrotic effect.

FR-PO184

Nuclear Factor Erythroid 2-Related Factor 2 (Nrf2) Deficiency Attenuates Hyperglycemia, Hypertension, and Nephropathy via Downregulation of Sodium-Glucose Co-Transporter 2 Expression in db/db Mice

Shuiling Zhao,[1] Anindya Ghosh,[4] Kana N. Miyata,[1] Chao-Sheng Lo,[3] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[5] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]CRCHUM, University of Montreal, Montreal, QC, Canada; [2]Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [3]CRCHUM, Universite de Montreal, Montreal, QC, Canada; [4]CRCHUM, University of Montreal, Montreal, QC, Canada; [5]The New England Journal of Medicine, Boston, MA.*

Background: Sodium-glucose co-transporter 2 (Sglt2) expression is up-regulated in renal proximal tubules (RPTs) in the diabetic kidney. The underlying molecular mechanisms, however, remain undefined. We have identified putative nuclear factor erythroid 2-related factor 2 (Nrf2)-responsive elements (REs) in mouse and human Sglt2 gene promoters. We investigated the impact of global Nrf2 knockout (KO) in db/db mice and transgenic (Tg) mice specifically overexpressing Nrf2 in renal proximal tubules (RPTs) on Sglt2 expression and studied the underlying mechanisms of NRF2-regulation of SGLT2 transcription in vitro.

Methods: Male and female db/m, db/m Nrf2 KO, db/db and db/db Nrf2 KO mice were studied up to age 16 weeks. Body weight (BW), blood glucose (BG), systolic blood pressure (SBP) and urinary albumin/creatinine ratio (ACR) were measured at week 16. Nrf2 and Sglt2 expression in isolated RPTs were assessed by RT-qPCR and western blotting. Tg mice specifically overexpressing Nrf2 in their RPTs by employing kidney-specific androgen-regulated promoter were studied. *In vitro*, the effect of oltipraz (Olz, an Nrf2 activator) and overexpression of NRF2 cDNA on SGLT2 expression and SGLT2 promoter activity in human RPTC (HK-2) were assessed.

Results: BW, BG, SBP, kidney weight/tibia length ratio, ACR, Nrf2 and Sglt2 expression in RPTs were significantly increased in db/db mice as compared to db/m mice. Genetic deletion of Nrf2 significantly attenuated these changes except BW in db/db Nrf2 KO mice. Nrf2 and Sglt2 expression were also significantly increased in RPTs of Nrf2-Tg mice compared to non-Tg mice. *In vitro*, Olz or overexpression of NRF2 cDNA significantly increased SGLT2 expression and SGLT2 promoter activity via NRF2-REs in the SGLT2 promoter in HK-2.

Conclusions: Nrf2 deficiency attenuates hyperglycemia, hypertension, kidney injury and RPT Sglt2 expression in db/db mice. Overexpression of Nrf2 increases RPT Sglt2 expression in Nrf2-Tg mice. NRF2 stimulates SGLT2 transcription via NRF2-REs in HK-2. These results identify a novel mechanism by which Nrf2 mediates hyperglycemia-stimulation of Sglt2 expression in diabetes.

FR-PO185

Loss of Heterogeneous Nuclear Ribonucleoprotein F in Renal Tubules Attenuates Hyperfiltration and Kidney Injury in Diabetic Mice via Downregulation of SGLT2 Expression

Kana N. Miyata,[1] Chao-Sheng Lo,[2] Shuiling Zhao,[6] Isabelle Chenier,[1] Michifumi Yamashita,[4] Janos G. Filep,[3] Julie R. Ingelfinger,[5] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]CRCHUM, University of Montreal, Montreal, QC, Canada; [2]CRCHUM, Universite de Montreal, Montreal, QC, Canada; [3]Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [4]Cedars-Sinai Medical Center, Los Angeles, CA; [5]The New England Journal of Medicine, Boston, MA; [6]CRCHUM, Montreal, QC, Canada*.

Background: We previously showed that tubular deficiency of heterogeneous nuclear ribonucleoprotein F (hnRNPF) results in up-regulation of renal angiotensinogen (Agt) and down-regulation of sodium-glucose co-transporter-2 (SGLT2) in mice. Non-diabetic tubule-specific hnRNPF knockout (FKO) mice developed hypertension and renal fibrosis but had similar blood glucose (BG) levels or glomerular filtration rate (GFR) as control mice. Here, we investigated the effects of FKO in diabetic Akita mice, a murine model of type 1 diabetes.

Methods: FKO mice were generated via cross-breeding of Pax8-Cre mice with floxed hnRNPF mice on a C57BL/6 background. Akita-FKO mice were created by cross-breeding of female FKO mice with male heterozygous Akita mice. Both male and female Akita-FKO mice and Akita control littermates were studied (n=8/group). Body weight (BW), BG, and systolic blood pressure (SBP) were monitored up to age 24 weeks. GFR was measured by inulin-FITC clearance in awake mice; kidneys were processed for histology (PAS, Masson's trichrome, electron microscope).

Results: Akita-FKO mice had better glycemic control, lower kidney weight/BW ratio, and lower GFR/BW ratio than Akita control mice. SBP was significantly higher in male but not in female Akita-FKO mice as compared to Akita. Urinary albumin/creatinine ratio did not differ in the two groups. Renal histology in Akita-FKO mice showed an attenuated glomerulomegaly and tubulointerstitial fibrosis with improved GBM thickness and foot process effacement cf. Akita. Real-time qPCR on kidney cortex confirmed down-regulated expression of SGLT2 and fibrosis marker genes (fibronectin 1, α–smooth muscle actin, collagen 1) and up-regulated Agt expression in Akita-FKO mice cf. Akita.

Conclusions: Kidney hypertrophy and glomerular hyperfiltration were attenuated in Akita-FKO mice, likely due to SGLT2 down-regulation activating tubuloglomerular feedback. The renoprotective effect of SGLT2 down-regulation overcomes the renal injurious effect of Agt when these opposing factors coexist. The Akita-FKO mouse is a unique tool for studying the molecular mechanisms of SGLT2 regulation in diabetes.

Empagliflozin Attenuates Diabetic Tubulopathy by Improving Mitochondrial Fragmentation and Autophagy

So-young Lee,[2] Yu ho Lee,[1] Jaehee Kim,[3] Sangho Lee.[4] *[1]Department of Nephrology, CHA University, Sungnam, Republic of Korea; [2]CHA Bundang Medical Center, CHA Univ., Seongnam, Republic of Korea; [3]CHA university, Seongnam, Republic of Korea; [4]Kyung Hee University, Seoul, Republic of Korea*.

Background: We examined the effects of empagliflozin, a selective inhibitor of sodium glucose cotransporter-2 (SGLT-2) on mitochondrial quality control and autophagy in renal tubular cells in a diabetic environment in vivo and in vitro.

Methods: Human renal proximal epithelial cells (hRPTCs) were incubated in high-glucose conditions. Diabetes was induced with streptozotocin in male C57/BL6J mice.

Results: Improvements in mitochondrial biogenesis and balanced fusion/fission protein expression were noted in hRPTCs after treatment with empagliflozin in high-glucose media. Empagliflozin also increased autophagic activities in renal tubular cells under high glucose environment which was accompanied with mTOR inhibition. Moreover, reduced mitochondrial ROS production and decreased apoptotic and fibrotic protein expression were observed in hRPTCs after treatment with empagliflozin, even in hyperglycemic circumstance. Importantly, empagliflozin restored AMPKα phosphorylation and normalized the levels of AMP/ATP ratios in human renal tubular cells subject to a high-glucose environment which suggested the way of empagliflozin to involve in mitochondrial quality control. Empagliflozin effectively suppressed SGLT2 expression and ameliorated renal morphologic changes in the kidneys of STZ-induced diabetic mice. Electron microscopy analysis showed that mitochondrial fragmentation was decreased, and 8-OHdG content was low in the renal tubular cells of the empagliflozin treatment groups compared with those of the diabetic control group.

Conclusions: We suggest one mechanism related to the renoprotective actions of empagliflozin, which reverse mitochondrial dynamics and autophagy.

Effect of Canagliflozin on Glomerular Hyperfiltration Evaluated by Transcutaneous GFR Monitor in Spontaneously Diabetic Torii Fatty Rats

Goh Kodama, Yosuke Nakayama, Sakuya Ito, Yunosuke Yokota, Kei Fukami. Division of Nephrology, Department of Medicine, Kurume University School of Medicine *Kurume University School of Medicine, Fukuoka, Japan*.

Background: Sodium glucose cotransporter 2 (SGLT2) inhibitors reduce glomerular hyperfiltration, thereby preventing the progression of diabetic kidney disease. However, since consecutive measurements of total nephron GFR in a same experimental model is not fully established, it is difficult to assess the precise effects of SGLT2 inhibitors on tubuloglomerular feedback (TGF). Transcutaneous GFR monitor (MediBeacon®) allows consecutive measurements by detecting fluorescence of FITC-sinistrin on the same animal, including multiple measurements with no sampling. Therefore, we assessed the effects of canagliflozin (CANA) on glomerular hemodynamic effects using transcutaneous GFR monitor in Spontaneously Diabetic Torii fatty rat (SDT-fatty rat), an obese type 2 diabetic model.

Methods: Eight week-SDT-fatty rats were given 100 mg/kg of CANA. Sprague Dawley (SD) rats were used as control. Fluorescence monitoring device was placed onto back of rats, and FITC-sinistrin was injected intravenously. After 2 hours, device was removed and half-life of sinistrin was measured, and then GFR was calculated. GFR could be measured one day before, 2 hours after, and 1 week after the treatment with CANA in a same rat. Adenosine production in response to increased sodium chloride reabsorption by CANA is evaluated by measuring urinary adenosine levels. SDT-fatty rats are treated with selective A1 adenosine receptor (A1aR) antagonist before administration of CANA.

Results: Serum glucose levels significantly increased in SDT-fatty rats (235.0mg/dL vs 133.8mg/dL). Baseline GFR in SDT-fatty rats was significantly higher than that in SD rats (23.7ml/min/kg, 15.3ml/min/kg, respectively). Treatment with CANA dramatically reduced diabetes-induced increased GFR at 2 hours after administration (17.3ml/min/kg) compared to baseline ($p<0.01$ vs baseline GFR). GFR at 1 week after administration with CANA in a same rat returned to baseline level without glucosuria (22.7ml/min/kg, $p=0.49$ vs baseline GFR). Urinary adenosine levels at 2 hours after administration with CANA and the effects of co-administration with A1aR antagonist on CANA-induced reduction of GFR will be evaluated.

Conclusions: SGLT2 inhibition plays a pivotal role in the regulation of GFR via TGF in SDT-fatty rats, which may contribute to renal protective effects reported in clinical trials.

FR-PO188

Liraglutide Reduces Renal Tubular Ectopic Fat Deposition in Rats with Diabetic Nephropathy by Inhibiting Sterol Regulatory Element Binding Proteins

Ke Su. *Wuhan University, Wuhan, China*.

Background: Liraglutide, a long-acting GLP-1 receptor agonist, has show significantly improved renal outcomes in patients with T2DM and delayed the development of DN. But we still not know the renal protective mechanism of liraglutide.

Methods: 30 SPF male Sprague-Dawley rats weighing 180-200 g were randomly divided into 3 group (n=10). Normal control group, DN group: diabetes+single nephrectomy group, Liraglutide treatment group: DN + liraglutide intervention group. Intraperitoneal injection of 35 mg/kg STZ and high fat diet to establish a T2DM model. The tail vein random blood glucose over 16.7 mmoL/L was determin to establish a T2DM model. T2DM group underwent unilateral nephrectomy at 1 week after modeling. After 1 week of nephrectomy, the subcutaneous injection of Liraglutide was given at a dose of 0.3 mg/kg/12 h for 12 weeks. Rat body weight was measured every 4 weeks during Liraglutide injection. Automated biochemical analyzer detected serum TG, TC, SCr, BUN, ALB, 24h urine protein at 12th week sacrificed. Sterol regulatory element binding protein (SREBP1) and fat differentiation-related protein (ADRP) were detected by immunohistochemical in 4% paraformaldehyde fixed rat renal.

Results: Liraglutide could decrease body weight of DN rat after 8th week ($P<0.05$). 24-hour urine protein quantitation showed a slight increase in the 10th week in DN group (867.03±17.2 0μg/24 hours), which was significantly higher in control group (289.98±37.85) ($P<0.05$), SCr, Urea and ALB were no significant change in 3 group. TG and TCh level were higher in DN than that in Liraglutide group ($P<0.05$) (Figure2). ADRP and SREBP1 tesed by immunohistochemistry expressed in renal tubules were significantly higher in DN than Liraglutide and control group (Figure1).

Conclusions: Liraglutide can reduce TG levels of DN rats via inhibiting SREBP1 in renal tubular and reduce fat ectopic deposition.

Funding: Government Support - Non-U.S.

Reno-Protective Effect of GLP-1 Receptor Agonists: Silencing the Cross-Talk Between TRPC6 and NADPH Oxidases

Natalie Youssef,[1] Nassim Fares,[3] Assaad Antoine Eid.[2] [1]*American University of Beirut, Beirut, Lebanon;* [2]*American University of Beirut/Faculty of Medicine, Beirut, Lebanon;* [3]*Saint Joseph University of Beirut, Beirut, Lebanon.*

Background: Diabetic kidney disease (DKD) is a life-threatening complication of Diabetes. DKD is characterized by podocyte injury which compromises the glomerular filtration barrier leading to proteinuria. Podocyte injury is thought to be mediated by reactive oxygen species (ROS) production via NADPH oxidases. DUOX 1 & 2 are NADPH oxidases that acquire in their structure a calcium binding site. Calcium signaling through TRPC channels is essential in podocyte function and disruption of its homeostasis leads to cytoskeleton disorganization, foot process effacement and disruption of slit diaphragm. Besides, hypoglycemic treatments such as GLP-1 receptor agonists (GLP-1RA) have been shown to exert a reno-protective effect, yet this mechanism is still not well elucidated. Herein, we aim to investigate the role of TRPC-6 channel and NADPH oxidases in kidney injury and the effect of GLP-1RA on reversing this process.

Methods: Sprague Dawley rats were allocated into five groups: control, STZ induced type I diabetic group, STZ induced type 1 diabetic group treated with Metformin or GLP-1RA or combination for a duration of 8 weeks. Functional, histopathological, biochemical and molecular studies were performed on kidney tissues from all groups.

Results: GLP-1RA treatment ameliorates kidney injury. This was transduced by a reduction in BUN, SCr, proteinuria, collagen deposition and fibrosis. Kidney tissues showed downregulation of collagen IV & fibronectin mRNA expression versus an upregulation of nephrin mRNA expression upon treatment. In addition, we noticed decreased ROS production, NADPH oxidases activity and mRNA expression of DUOXs. Moreover, reduced expression of TRPC6 but not TRPC3 was noticed upon treating with GLP-1RA. GLP-1R and AMPK expression were assessed too.

Conclusions: GLP-1RA seems to retard diabetic nephropathy by modulating the cross-talk between TRPC6 and NADPH oxidases. These clues could pinpoint novel molecular mechanisms in DKD.

FR-PO190

Sitagliptin Ameliorated Mitochondrial Dysfunction in Diabetic Kidney Disease via SDF-1α/CXCR4/STAT3

Qunzi Zhang, Li He, Ying Fan, Niansong Wang. *Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Dipeptidyl peptidase-4 (DPP-4) inhibitors, which can hinder degradation of bioactive incretins, have been developed as a new type of glycemic control agent in both clinical and basic studies. Moreover, recent studies indicate that DPP4 inhibitors can improve albuminuria suggesting a favorable effect on kidney,but the exact mechanism remains unclear. We test whether an SDF-1α/CXCR4/STAT3 signaling pathway regulates mitochondrial dysfunction when inhibited DPP4 in DKD.

Methods: *In vivo,* male DBA2/J mice were subjected to streptozotoxin to form diabetic mice models, then sitagliptin was used for gavage to inhibit DPP4. We collected and analyzed kidney samples, urine and serum. *In vitro,* human HK2 cells were exposed to human serum albumin (HSA), then regulated DPP4, CXCR4 and STAT3 with inhibitors, siRNAs and mutant plasmids. Outcome measures included mitochondrial dynamics, expression of SDF-1α, CXCR4 and STAT3, mitochondrial membrane potential and mitochondrial ROS production.

Results: In diabetic mice, Sitagliptin decreased renal DPP4 expression, improved renal function, attenuated tubular damage, and partly attenuated mitochondrial dysfunction, yet sitagliptin cannot significantly control glycemia of these mice. Besides, sitagliptin obviously upregulated SDF-1α/CXCR4 expression and mitochondrial STAT3. *In vitro,* HK2 cells exposed to HSA exhibited increased DPP4 accompanied by mitochondrial fragmentation, altered mitochondrial dynamics and elevated mitochondrial ROS production. Inhibited DPP4 improves SDF-1α/CXCR4 expression, which has a positive effect on diabetic mitochondrial function, whereas upregulated DPP4 aggravated these mitochondrial perturbations. Moreover, partly through SDF-1α/CXCR4 pathway, inhibition of DPP4 regulated mitochondrial STAT3 and phosphorylation of Ser^{727} in STAT3,which is required for STAT3 to import into mitochondria. Our work found that the inhibition of DPP4 ameliorated mitochondrial dysfunction in DKD partly through SDF-1α/CXCR4/STAT3 signaling pathway.

Conclusions: The results suggest a novel mechanism linking DPP4 to impair mitochondrial quality control during tubular injury in the pathogenesis of DKD and suggest SDF-1α/CXCR4/STAT3 pathway may become a potential therapeutic point to ameliorate DKD.

FR-PO191

GSK3-α/β Inhibition Attenuates Progression of CKD in Lepr-/- Mice with Type 2 Diabetes (T2D) Beyond Standard-of-Care Therapy (SOC) with Metformin/Ramipril/Empagliflozin

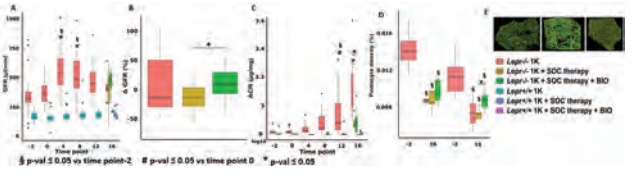
Motrapu Manga,[1] Lidia Anguiano-Gomez,[1] Maria Lucia Angelotti,[2] Paola Romagnani,[3] Hans J. Anders.[1] [1]*Klinikum der Universität München, München, Germany;* [2]*Excellence Center for Research, Transfer and High Education Denothe, University of Florence, Florence, Italy;* [3]*University of Florence, Firenze, Italy.*

Background: Dual RAS/SGLT2 inhibition significantly reduces cardiovascular, renal morbidity in patients with T2D but further retarding progression of CKD remains a global unmet medical need. GSK3α/β inhibitor BIO (6-bromo-indirubin-3'-oxime) was shown to promote podocyte differentiation in vitro, to limit Adriamycin-induced podocyte loss in vivo, hence we hypothesized that BIO's specific mechanism-of-action would have therapeutic effects beyond SOC therapy on diabetic kidney disease (DKD)

Methods: Male BKS-*Lepr*-/- mice with obesity-related T2D their respective non-diabetic BKS-*Lepr*+/+ controls underwent uninephrectomy (1K) at 6 weeks of age to mimic CKD G2, accelerated progression of DKD. From week 12-16, all 1K mice were put to SOC therapy (1500mg/kg metformin, 6mg/kg ramipril, 480mg/kg empagliflozin) and randomized to either additional BIO (2μmol/kg) or vehicle therapy. *Lepr*-/- mice without proteinuria at week 12 were excluded from the study. N=10-11 per group. GFR, albuminuria, Blood glucose were monitored at regular intervals. Glomerular tuft area, density of WT-1+ podocytes and glomerulosclerosis were quantified in cortical and juxtamedullary glomeruli. Density of tertiary podocyte foot processes was analyzed as a marker of terminal podocyte differentiation by STED microscopy

Results: Primary endpoint: *Lepr*-/- mice, GFR increased after uninephrectomy with a progressive decrease later (A). SOC+BIO significantly attenuated GFR loss during treatment interval compared to SOC therapy alone (B). Secondary endpoints: In *Lepr*-/- mice, albuminuria was significantly attenuated bySOC therapy (C). SOC+BIO therapy significantly increased podocyte densityin juxtamedullary glomeruli (D). BIO showed significantly better preservation of tertiary podocyte foot processes (E)

Conclusions: GSK3-α/β inhibitor BIO has renoprotective effects beyond SOC therapy in a clinically meaningful model of progressive DKD. Optimizing animal models of DKD to better mimic the study population, co-medication, study endpoints used in clinical trials may improve the notoriously poor predictive value of animal models of DKD



FR-PO192

Elevated Podocyte DAAM2 Expression in Diabetic Nephropathy

Chenyang Qi, Haichun Yang, Raymond C. Harris, Agnes B. Fogo. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Previously, by using proteomic analysis in isolated glomeruli, we identified several novel differentially expressed proteins in human diabetic nephropathy (DN) vs control, including DAAM2. DAAM2, the dishevelled associated activator of

morphogenesis 2 protein, binds the Wnt effector Disheveled, nuclear actin and mediates Wnt-induced cytoskeletal changes. We now aimed to study possible contributions of DAAM2 to DN.

Methods: We assessed DAAM2 by immunostaining in non-cancer regions of human nephrectomy (Nx), DN and normal transplant donor kidney tissues. Nx patients were middle-aged with varying arterionephrosclerosis. ACEI- or glipizide-treated DN mice (db/db/eNOS$^{-/-}$ model) were compared with vehicle-treated DN mice. Primary cultured podocytes were exposed to high glucose or mannitol, and DAAM2 was knocked down by siRNA to study effects on podocyte injury.

Results: In human glomeruli, DAAM2 was expressed only on podocytes. DAAM2 expression was increased in both nephrectomy and DN vs normal donors. DAAM2 gradually decreased with increasing severity of DN, from class II to class III or IV (2.21±0.15 vs 1.58±0.14 vs 1.40±0.14). Glipizide and ACEI reduced DAAM2 podocyte expression in mice DN, accompanied with reduced proteinuria and maintained GFR and more preserved WT1^{+} podocytes. DAAM2 mRNA was increased in cultured podocytes treated with high glucose vs mannitol (0.36±0.01 vs 0.77±0.03). ROCK1, the downstream kinase of Wnt/Rho/ROCK signaling pathway, regulates podocyte process elongation. High glucose induced more ROCK1 expression than mannitol (1.04±0.04 vs 0.79±0.13), which was reversed by DAAM2 knockdown (0.64±0.07).

Conclusions: DAAM2 is up-regulated in podocytes in both nephrectomy and DN, which we postulate could be contributed to both by glomerular hypertrophy, prevalent in both DN and Nx, and high glucose. We hypothesize that DAAM2 may regulate podocyte function through the Rho/ROCK signaling pathway.

FR-PO193

Podocyte and Endothelial-Specific Elimination of BAMBI Identifies Differential TGF-β Pathways Contributing to Diabetic Glomerulopathy

Han Lai,[1] Anqun Chen,[2,1] John C. He,[1] Detlef O. Schlondorff,[1] Kyung Lee.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]ZhongShan Hospital, Xiamen University, Xiamen, China.*

Background: Transforming growth factor-β (TGF-β) is considered a central mediator of diabetic nephropathy (DN). The effect of TGF-β, mediated by type I TGF-β receptor, ALK5, and subsequent Smad2/3 activation is shown to result in podocyte apoptosis and loss. We previously demonstrated that the genetic deletion of BAMBI (BMP and Activin Membrane-Bound Inhibitor), a negative modulator TGF-β signaling, accelerates DN progression. Interestingly, worsening of DN phenotype in BAMBI-deficient mice was associated with heightened activation of ALK1 type I TGF-β receptor, whose expression is largely restricted to endothelial cells (ECs). ALK1 acts in an opposing manner to ALK5 in ECs via Smad1/5/8 activation, which results in EC activation, proliferation, and neo-angiogenesis.

Methods: Therefore, to evaluate the glomerular cell-specific effects of TGF-β in DN, we examined the effects of the podocyte- or EC-specific loss of *Bambi* in streptozotocin-induced diabetic mice with eNOS deficiency (eNOS$^{-/-}$). Kidneys were examined at 20 weeks post diabetes induction.

Results: Interestingly, while hyperglycemia and body weight loss were similar in all groups of diabetic mice, significant hypertension was present only the diabetic mice with EC loss of BAMBI. Diabetic mice with podocyte- or EC-specific loss of BAMBI (Pod-Bambi$^{-/-}$ or EC-Bambi$^{-/-}$) displayed markedly worsened albuminuria and DN severity in comparison to the control diabetic eNOS$^{-/-}$ mice. However, activation of Smad3 was further heightened in the glomeruli of diabetic Pod-Bambi$^{-/-}$ mice, whereas Smad1/5 activation was observed only in the glomeruli of diabetic EC-Bambi$^{-/-}$ mice. Consistent with the increased ALK1-Smad1/5-mediated angiogenesis in DN, significant EC proliferation was observed only in the glomeruli of diabetic EC-Bambi$^{-/-}$ mice.

Conclusions: These results identify cell type-specific TGF-β signaling in DN and further underscore the endothelial TGF-β signaling as a major contributor of diabetic glomerulopathy progression. Thus, attenuation of ALK1 and ALK5 signaling through BAMBI may be a potential therapeutic approach against DN progression.

A Novel Role for NPY-NPY2R Signalling in Albuminuric Kidney Disease

Abigail C. Lay,[1] Fern Barrington,[1] Jenny Hurcombe,[1] Edward Mountjoy,[2] Viji Nair,[3] Denize Atan,[1] Robert G. Nelson,[4] Wenjun Ju,[3] Matthias Kretzler,[5] Gavin I. Welsh,[1] Richard Coward.[1] *[1]University of Bristol, Bristol, United Kingdom; [2]Wellcome Sanger Institute, Hinxton, United Kingdom; [3]University of Michigan, Ann Arbor, MI; [4]National Institutes of Health, Phoenix, AZ; [5]U. Michigan, Ann Arbor, MI.*

Background: Albuminuria is an independent risk factor for the progression to end-stage kidney failure and premature mortality. It is well-established that podocyte damage is a major cause of albuminuria, yet the pathways involved are incompletely understood. In this study, we analysed the transcriptomes of insulin-sensitive and insulin-resistant podocytes to identify molecules regulated in podocyte damage and novel pathways regulating albuminuria in diabetes. This revealed that *Neuropeptide Y* (*Npy*) was highly downregulated in insulin-resistant podocytes. While NPY is implicated in many conditions including obesity, diabetes and insulin resistance, a role for NPY in albuminuric kidney disease has not been described.

Methods: Gene expression was analysed *in vitro* in conditionally-immortalised podocytes using RNA sequencing and focused qPCR arrays, and *in vivo* in the Pima type-2 diabetic nephropathy cohort and the "nephroseq" database. The effect of reduced *Npy* expression on albuminuria was analysed in streptozotocin (STZ)-induced diabetic nephropathy and Adriamycin-nephropathy models, using wild-type and NPY-deficient (NPY-/-) mice. Conditionally-immortalized human and mouse podocytes were studied *in vitro* to determine the effects of NPY signalling. The effects of pharmacological NPY2R inhibition were investigated *in vitro* and *in vivo*, using BIIE0246.

Results: Transcriptome analysis demonstrated that *Npy* was significantly down-regulated in insulin-resistant vs insulin-sensitive mouse podocytes. Human diabetic nephropathy (DN) patients also had reduced glomerular *NPY* expression in both early- and late-stage DN. However, NPY-/- mice had reduced levels of albuminuria and podocyte injury in both diabetic and non-diabetic kidney disease models. Furthermore, both human and mouse podocytes responded to NPY stimulation, via activation of PI3K and ERK MAPK signalling cascades, as well as the calcium-dependent activation of NFAT; responses which were mediated through NPY2 receptor (NPY2R) activity. The pharmacological inhibition of NPY2R *in vivo* significantly reduced albuminuria in adriamycin-treated mice.

Conclusions: Our findings reveal a novel role for the NPY system in the glomerulus and suggest that manipulating NPY-NPY2R signalling in albuminuric kidney disease may be therapeutically beneficial.

The Evolving Importance of mTORC2/Rictor in Autophagy Dysregulation and Diabetes-Associated Kidney Disease

Sahar Alkhansa,[1] Fuad N. Ziyadeh,[3] Assaad Antoine Eid.[2] *[1]American University of Beirut, Beirut, Lebanon; [2]American University of Beirut/Faculty of Medicine, Beirut, Lebanon; [3]AUB, New York, NY.*

Background: Accumulating evidence suggests that autophagy plays an important role in many critical aspects of normal and disease states of the kidney including diabetic kidney disease (DKD). Podocyte integrity has been described to rely on basal autophagy. However, the exact role of autophagy in podocyte dysfunction and the mechanisms underlying diabetic-induced podocyte injury remain to be elucidated. Several signaling pathways such as mTORC1, NADPH oxidase, and the Liver-X-Receptor (LXR) pathways have been shown to orchestrate podocyte integrity in DKD. Yet, the role of mTORC2 in autophagy and its crosstalk with these key mechanistic pathways remain to be identified. For that, we investigated the role of the Nox4/LXR/mTORC2 axis on autophagy and their possible link to podocyte integrity *in vitro* and in animal models of type 1 and type 2 diabetes.

Methods: A conditionally immortalized human podocyte cell line was used for the *in vitro* studies. In parallel, type 1 diabetes was induced in mice by streptozotocin (STZ) injections and type 2 diabetes was initiated by high-fat diet followed by low-dose STZ injections. Pharmacological means were utilized to alter the expression of Nox4 (GKT), LXR (T0) and the mTORC2 (JR) signaling pathways and functional, pathological and biochemical studies were performed

Results: High glucose (HG)-induced podocyte injury is reflected by alterations in the slit diaphragm proteins and podocyte depletion accompanied by autophagy dysregulation. This was paralleled by activation of the mTORC2 pathway. HG also increased the levels of Nox4 and NADPH oxidase activity. Inhibition of mTORC2, activation of LXR, or inhibition of Nox4 decreased HG-induced ROS generation, restored autophagy homeostasis, regulated podocin levels, and reduced podocyte loss. In isolated glomeruli from the diabetic mice, there was a similar activation of the mTORC2 signaling pathway with an increase in Nox4 and NADPH oxidase activity. Inhibition of mTORC2, activation of LXR or inhibition of Nox4 restored podocin levels, reduced podocyte depletion, attenuated glomerular injury and albuminuria and regulated autophagy levels. More importantly, Chloroquine treatment, an autophagy inhibitor, mimicked the effect of HG/hyperglycemia.

Conclusions: Our data provide evidence for a novel function of mTORC2 in regulating autophagy and its role in DKD.

FR-PO196

Mesenchymal Stem Cells Attenuate Diabetic Kidney Disease by Inhibiting the mTOR Signaling Pathway

Rachel Njeim,[1] Natalie Youssef,[1] William Azar,[1] Sami Azar,[3] Fuad N. Ziyadeh,[4] Assaad Antoine Eid.[2] *[1]American University of Beirut, Beirut, Lebanon; [2]American University of Beirut/Faculty of Medicine, Beirut, Lebanon; [3]American University of Beirut Medical Center, Beirut, Lebanon; [4]AUB, New York, NY.*

Background: Diabetic kidney disease is one of the most serious complications of diabetes worldwide. The earliest clinical manifestation of DKD is increased albuminuria, which eventually progresses to overt proteinuria. Glomerular injury is characterized by hypertrophy, mesangial matrix expansion, basement membrane thickening, and podocyte loss. Emerging body of evidence has revealed that mesenchymal stem cells treatment induces glomerular repair either through differentiation or by acting in a paracrine manner. However, the mechanistic pathway has not yet been identified. We and others have previously shown that in the glomeruli of diabetic animals, the mTORC1/p70 S6Kinase and Rictor/mTORC2 pathways are activated, promoting podocyte injury. In addition, we demonstrated that mTORC1 and mTORC2 inhibition attenuates HG-induced NADPH oxidase activity and decreases Nox1 and Nox4 expression. The present study aims to assess the reno-protective role of MSCs and to investigate the mechanistic pathway by which MSCs exert this protective role.

Methods: Sprague-Dawley rats were divided into the following groups: a control group and a streptozotocin-induced type 1 diabetic group each treated with medium, MSCs-derived medium, or $1x10^6$ MSCs. After eight weeks of treatment from diabetes onset, functional, histological, biochemical, and molecular parameters of the kidneys were assessed.

Results: MSCs treatment restored normal urinary albumin excretion levels. Protection against DKD imparted by MSCs was denoted by decreased glomerulosclerosis. Moreover, MSCs treatment restored podocyte foot process effacement and glomerular basement membrane thickening and reversed podocyte depletion. More importantly, and for the first time, we show that MSCs treatment restored the mTORC1/mTORC2 complex integrity. This was paralleled by a decrease in NADPH oxidases activity and NOX4 protein expression. All of these observations were mirrored when diabetic rats were treated with MSCs-derived medium.

Conclusions: Our results suggest that MSCs have a potential therapeutic effect in the treatment of DKD by attenuating mTOR signaling pathway. Furthermore, and to our knowledge, this is the first study to report that MSCs-derived medium mimics the beneficial effect of MSCs suggesting that the trophic factors secreted by the MSCs exert the observed reno-protective effect.

Honokiol Improves Diabetic Kidney Disease by Activating SIRT3 to Regulate Podocyte Mitochondrial Function

Ming Li,[1] Canming Li,[2] Zengchun Ye,[2] Hui Peng,[2] Tan-qi Lou.[2] *[1]Nephrology department of The Third Affiated Hospital of Sun Yet-sen University, Guangzhou, China; [2]The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*.

Background: Diabetic kidney disease(DKD) is the main cause of end-stage renal disease. Current studies have shown that podocyte mitochondrial dysfunction is closely related to the progression of DKD.

Methods: Eight-week-old db/db and db/m mice were injected with honokiol(HKL,5 mg/kg)intraperitoneally for 5 consecutive days. STZ was used to induce diabetes mellitus models in wild type(WT) and SIRT3 knockout (SIRT3 KO) mice and HKL was injected intraperitoneally for 5 days. ACR of mice in each group were detected. The morphological changes of mitochondria were observed under electron microscopes. The activity of podocytes mitochondrial complex I and II were detected by extracting mitochondrial DNA. The expression of mitochondrial metabolism related genes and mitochondrial DNA copys was detected by RT-PCR. In vitro, western blot was used to detect the expression of SIRT3 in podocytes after high glucose stimulation for 48h with or without HKL(5umol/L). Mitotraker, Mitosox and TMRM kits were used to detect the morphology and function of mitochondria. Flow cytometry (V-FITC/PI) was used to detect the apoptosis of podocytes.

Results: The expression of mitochondrial complex I and II in podocytes of db/db mice was lower than that of db/m mice, accompanied by the decrease of mitochondrial DNA Copys. The expressions of SIRT3, PGC1α and TFAM in db/db mice were significantly lower compared with db/m mice. The number of podocytes in db/db mice was decreased by immunohistochemistry. It was found that HKL restore the expression of SIRT3 in podocytes of db/db mice and STZ-induced diabetic mice. Aslo, the mice treated with HKL had lower ACR and improved mitochondrial morphology, but no significant improvement in SIRT3 KO mice. The expression of mitochondrial complex I, II, mitochondrial DNA Copys in podocytes of db/db mice and WT mice were upregulated by HKL. In vitro, it was also found that HKL could upregulate the expression of SIRT3 in podocytes. Compared with high glucose alone, mitochondrial membrane potential decreased in podocytes co-stimulated by high glucose and HKL, and ROS production decreased. Also, flow cytometry (V-FITC/PI) showed that podocyte apoptosis was reduced with HKL incubation.

Conclusions: Honokiol can improve the morphology and function of podocyte mitochondria by upregulating the expression of SIRT3, thus reduce the apoptosis of podocytes.

FR-PO198

The Insulin/Insulin-Like Growth Factor Axis Is Critical for Podocyte Function but Partial Inhibition of IGF1 Signalling Is Physiologically Beneficial

Jenny Hurcombe,[1] Micol Marchetti,[4] Fern Barrington,[1] Lan Ni,[1] Abigail C. Lay,[1] Paul T. Brinkkoetter,[2] Martin Holzenberger,[3] Gavin I. Welsh,[1] Richard Coward.[1] *[1]University of Bristol, Bristol, United Kingdom; [2]University Hospital Cologne, Cologne, Germany; [3]INSERM, Paris, France; [4]Uppsala University, Uppsala, Sweden*.

Background: Abnormalities in insulin signalling through the insulin receptor (IR) have previously been found to be critical for podocyte function and this study aims to define the physiological importance of the related insulin-like growth factor 1 receptor (IGF1R) and combined IR/IGF1R in podocytes.

Methods: The Cre-loxP system was used to generate mice with podocyte-specific IGF1R and simultaneous IR/IGF1R gene inactivation. *In vitro* models of receptor knockdown were engineered by applying extrinsic lentiviral Cre recombinase to podocytes derived from IR, IGF1R and IR/IGF1R floxed mice.

Results: We initially generated podocyte IGF1R knockout (podIGF1RKD) mice by crossing IGF1R floxed with mice expressing conventional Cre recombinase under the control of a podocin promotor. Despite 80% knockdown of the IGF1R in this model, podIGF1RKD mice exhibited no changes in renal histology or urinary albumin:creatinine (uACR) at 9 months when compared with littermate controls. However, when these mice were stressed with Adriamycin we, surprisingly, found that podIGF1RKD mice were protected against disease progression with uACR 50% lower than IGF1R sufficient controls. To increase the efficiency of knockout and understand if there was compensation within the IR/IGF1R axis we also generated two additional models using a new podocyte specific Cre driver that is not subject to epigenetic degradation (podIGF1RKO and podIR/IGF1R DKO mice). podIGF1RKO mice were albuminuric at 24 weeks while podIR/IGF1R DKO mice developed a severe kidney phenotype with global sclerosis, renal failure and death between 4 and 24 weeks. >95% loss of IGF1R in cultured podocytes augmented AKT and ERK activation in response to insulin but resulted in ~50% cell death after 7 days. To identify further differentially regulated signalling pathways, IR, IGF1R and IR/IGF1R knockout cells were subjected to TMT phosphoproteomic analysis in the basal state and when acutely stimulated with insulin or IGF1.

Conclusions: Collectively this work reveals the critical importance of podocyte IGF/insulin signalling and that only a fraction of receptor activity is required to maintain function. We also show that partial inactivation of podocyte IGF1R is beneficial in some disease settings.

FR-PO199

Therapeutic Effects of Klotho on Palmitate-Induced Podocyte Damage

Jeong suk Kang. *Department of Internal Medicine, Soonchunhyang University Cheonan Hospital, Cheonan-si, Chungcheongnam-do, Republic of Korea*.

Background: Anti-aging gene klotho has been identified as a multi-functional humoral factor and implicated multiple biological processes. However, the effects of klotho on podocyte injury of diabetic nephropathy (DN) are not known. We therefore investigated the renoprotective effects of exogenous klotho on podocyte injury in DN.

Methods: Lipid accumulation and klotho expression were examined in the kidneys from diabetic patient and animals. Cultured podocytes were stimulated with palmitate to induce diabetic mimic condition with or without recombinant klotho (rKL). Western blot, quantitative real time-PCR, immunofluorescence, and albumin permeability analysis were carried out to evaluate the effects of rKL on palmitate-induced podocyte injury.

Results: Glomeruli from diabetic patients showed an increased lipid accumulation. The klotho expression in kidney from diabetic animals and in palmitate-treated podocytes was decreased. Palmitate-treated podocytes increased apoptosis, intracellular ROS, ER stress, inflammation, and fibrosis, and these were significantly attenuated by rKL stimulation. Palmitate-induced downregulation of an antioxidant molecules was ameliorated by rKL. Furthermore, Palmitate-mediated actin cytoskeleton reorganization and increased albumin permeability were recovered significantly by rKL.

Conclusions: The results suggest that palmitate-mediated functional and morphological podocyte injury were recovered by exogenous klotho, and this may implicate klotho as a potential therapeutic target for treatment of podocyte injury of DN.

Podocyte Nox5 Expression Increases Microparticle Formation and Oxidative Stress in Mice

Hannah L. Battaion,[2] Chet E. Holterman,[2] Dylan Burger,[1] Chris R. Kennedy.[1] *[1]Kidney Research Centre, Ottawa, ON, Canada; [2]Ottawa Hospital Research Institute, Ottawa, ON, Canada*.

Background: Urinary microparticles (MPs) released from podocytes are predictive of injury associated with diabetic kidney disease (DKD) prior to albuminuria. Oxidative stress due to reactive oxygen species (ROS) overproduction is one factor that contributes to MP formation. Podocyte NADPH oxidase 5 (Nox5) produces superoxide and is upregulated in human DKD. Transgenic mice expressing podocyte-specific Nox5 ($Nox5^{Pod+}$) show increased blood pressure, glomerular basement membrane thickening and albuminuria. However, whether podocytes expressing Nox5 produce more MPs under conditions of stress associated with diabetes and hypertension, and whether these microparticles contain Nox5 and are capable of producing reactive oxygen species remains unknown.

Methods: For *in vitro* studies, Nox5 was activated in conditionally immortalized human podocytes through exposure to ionomycin for 24 hours. MPs released into the media were isolated and quantified by nanoparticle tracking analysis. Nox5 content and ROS production from isolated MPs were assessed by immunoblotting and DHE/HPLC, respectively. For mouse studies, $Nox5^{Pod+}$ mice and nontransgenic littermate controls were either implanted with angiotensin II-containing miniosmotic pumps (400mg/kg/day) or sham operated. Systolic blood pressures were determined by tail cuff plethysmography. Urinary MPs were quantified once per week for 5 weeks using 24 hour urine collections.

Results: MP formation was increased two-fold in cultured human podocytes when stimulated with Ionomycin compared to unstimulated controls. Isolated podocyte MPs expressed Nox5 and demonstrated increased ROS formation compared to unstimulated controls. Urinary MP formation was increased in $Nox5^{Pod+}$ mice compared to controls. Angiotensin II administration increased systolic blood pressure in both $Nox5^{Pod+}$ and nontransgenic mice. However, MP formation was further increased following angiotensin administration.

Conclusions: Nox5-expressing podocytes release MPs. These MPs contain Nox5 and are capable of producing ROS. Podocyte Nox5 expression in mice show enhanced urinary MP formation in the context of high blood pressure. Thus, Nox5 may be a contributing factor in the onset of damage in DKD and/or hypertension.

Coupling of Transient Receptor Potential Canonical Channel (TRPC6) and Phosphodiesterase 1 (PDE1) Activity in Diabetic Nephropathy

Asim B. Dey,[2,1] Fang Li,[2] Mark Kowala,[2,1] Simon J. Atkinson,[3,1] Mark D. Rekhter.[4] *[1]IUPUI, Carmel, IN; [2]Eli Lilly and Company, Indianapolis, IN; [3]Indiana University - Purdue University Indianapolis, Indianapolis, IN; [4]Integral Health, Carmel, IN.*

Background: Diabetic Nephropathy (DN) is a major complication of diabetes and the incomplete understanding of its molecular mechanisms is highlighted by the limited treatments options. Our investigation focused on the link between TRPC6 and the calcium activated PDE1. Three isoforms of PDE1 are differentially expressed in vascular smooth muscle cells, renal tubular epithelial cells, podocytes, and mesangial cells. While TRPC6 renal expression is associated with DN and inhibition of PDE1 causes vasodilation, their interaction in the context of DN has not been studied. We hypothesized that the diabetic milieu stimulates TRPC6-mediated calcium flux which in turn activates PDE1and propagates kidney injury.

Methods: To investigate the role of PDE1 and TRPC6 mediated calcium flux and apoptosis, cultured primary human mesangial cells or isolated rat glomeruli were treated with TRPC6 agonist HYP9 with or without a pan-PDE1 inhibitor. Apoptosis was measured using high throughput imaging platform using caspase 3/7 as a marker. The role of PDE1 in hypertension and DN was evaluated in telemeterized spontaneously hypertensive rats (SHR) and in hypertensive type 2 diabetic (db/db) mice over expressing the renin gene.

Results: TRPC6 mediated calcium flux induced apoptosis in human mesangial cells and isolated rat glomeruli, which was attenuated by bothTRPC6 and PDE1 inhibitor thereby suggesting a functional coupling between TRPC6 (as a source of calcium) and PDE1 activation. Renal cell protection with PDE1 inhibition was tested in mouse model of DN, featuring a combination of diabetes, nephron loss and arterial hypertension. In this model a novel PDE1 inhibitor caused a significant reduction of albuminuria up to 69% after 6 weeks of treatment compared to vehicle. This was accompanied by a significant reduction in serum creatinine and several urine biomarkers of inflammation and injury. Histopathological analysis revealed substantial improvement in glomerular sclerosis, interstitial fibrosis and reduction in mesangial matrix compared to vehicle. Gene expression analysis of the kidney revealed changes the gene clusters associated with innate immunity and fibrosis.

Conclusions: The results demonstrates that TRPC6 mediated calcium flux is linked to the activation of PDE1 and its inhibition leads to renoprotective effects in DN.

Hyperoside Inhibits Podocyte Epithelial-Mesenchymal Transition in Diabetic Kidney Disease via Regulating Insulin Resistance-Related Signaling Pathways, Compared with Rosiglitazone

Wei Wu, Yinglu Liu, Yigang Wan. Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School *Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China.*

Background: Hyperoside (HYP), a bioactive component of *Abelmoschus manihot*, has been widely applied to clinical therapy in the diabetic kidney disease (DKD) patients. However, it remains elusive whether HYP can alleviate podocyte damage in DKD. The disordered activation of insulin resistance (IR)-related signaling pathways in the kidney induces podocyte epithelial-mesenchymal transition (EMT), further resulting in podocyte injury in DKD. Therefore, this study aimed to clarify the therapeutic effects of HYP on podocyte EMT in DKD and its underlying mechanisms, compare to rosiglitazone (ROS).

Methods: All rats were randomly divided into 4 groups, the Sham, the Vehicle, the HYP and the ROS groups. The appropriate doses of HYP, ROS and distilled water were administrated with oral for 6 weeks after the induction of DKD by high fat feed, mononephrectomy and streptozotocin intraperitoneal injection, respectively. The changes in podocyte EMT-related parameters in urine and blood were analyzed. The kidneys were isolated for histomorphometry, immunohistochemistry and Western blotting (WB) at sacrifice. *In vitro*, murine potocytes were used to investigate the inhibitory actions of HYP on IR-associated signaling pathways by WB, compared to ROS.

Results: For the DKD model rats, HYP and ROS ameliorated IR, glomerulosclerosis (GS), glomerular basement membrane (GBM) thickening and foot process effacement, and the effects of HYP on GS and GBM thickening were superior to ROS; HYP and ROS improved the protein expressions of podocyte EMT markers in the kidney including nephrin, P-Cadherin, collagen-1 and desmin, and the effects of HYP were similar to ROS; In addition, HYP and ROS regulated the protein expressions of the key signaling molecules in IR-related signaling pathways including TGF-β1/Smad3, GLUT4 and Erk1/2 pathways, respectively, and the targets of HYP were similar to ROS. *In vitro*, the disordered phosphorylation of TGF-β1/Smad3, GLUT4 and Erk1/2 pathways in podocyte induced by high-glucose was reversed by the treatment of HYP or ROS.

Conclusions: We expounded that HYP inhibits podocyte EMT in DKD via regulating IR-regulated signaling pathways including TGF-β1/Smad3, GLUT4 and Erk1/2 pathways in the kidney, respectively. Overall, this study provided the first evidence that HYP directly contributes to the prevention of podocyte lesion in DKD.

FR-PO203

The COX 2-Thromboxane Axis Plays a Critical Role in Podocyte Injury Induced by High Glucose

Shicong Song, Wang Cheng. *The Fifth Affiliated Hospital of Sun Yat-Sen University, Zhuhai, China.*

Background: Podocyte injury is a vital factor in the onset and progression of diabetic nephropathy (DN), thus is a promising therapeutic target to prevent DN. The cyclooxygenase 2 (COX 2)- thromboxane axis has been proved to play a critical role in podocyte injury whereas the underlying mechanism is still unknown. The aim of this study is to get a further insight of COX 2-thromboxane axis in podocyte injury.

Methods: In vitro study was performed with a high glucose medium of 30mmol/L to set up a podocyte injury model as previous described. Both the inhibitor and activator of the axis, small interfering RNA, ELISA, western blot and confocal were used to investigate the underlying mechanism of COX 2-thromboxane axis mediating podocyte injury.

Results: High glucose induced podocyte injury accompanied with increasing expression of COX 2 and excessive TXA_2, indicating that the COX 2-thromboxane axis was activated. Small interfering RNA was used to silence the thromboxane/prostaglandin receptors (TP-r) or block the TP-r with inhibitor SQ29548 alleviated the injury. Furthermore, the stimulation of high glucose led to the over-activation of Rho/ROCK1 pathway, resulting in an increased phosphorylation of Drp1, a critical protein regulating mitochondrial fission. As expected, pretreatment of Y26432 could block the ROCK1 release protective effect when the cells were exposed to high glucose. What's more, regulating of TXA2-TPr pathway with SQ29548, U46619 or small interfering RNA can affected the activity of Rho/ROCK pathway in podocytes stimulated with high glucose.

Conclusions: High glucose may activate the COX 2- thromboxane axis, leading to an activating activity of TP-r to induce the downstream effect of ROCK1 activated, resulting in excessive mitochondrial fission, and finally induced podocyte injury (Fig 1).

Puerarin Attenuates Diabetic Nephropathy by Promoting Autophagy in Podocytes

Xueling Li, Qingqing Zhu, Jiayi Yan, Yifei Zhong. *Division of Nephrology, Longhua Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China.*

Background: Puerarin, an active compound of *radix puerariae*, is a major compound used in Chinese herbal medicines to treat patients with diabetic nephropathy (DN). In the previous studies, we showed that puerarin exerts renoprotective effects in a mouse model of streptozocin (STZ) induced diabetic nephropathy (DN) through activation of Sirt1 and anti-oxidative effects. Here, we further investigated the underlying mechanism mediating the renal protective effects of puerarin in DN.

Methods: We tested the effects of puerarin in STZ-induced diabetic mice and in cultured immortalized mouse podocytes treated with either normal (NG) or high glucose (HG). We performed western blot analysis, PCR analysis, immunohistochemistry to determine the molecular mechanisms mediated by puerarin in DN using both vivo and in vitro models. Immunoprecipitation combined with western blot analysis was used to determine acetylation of LKB1. shRNAs were used to knockdown HMOX1 and Sirt1 in cultured podocytes.

Results: We found that puerarin ameliorated STZ-induced kidney injury as shown by kidney histology. We also found that puerarin restored podocyte differential markers such as P-cadherin and ZO-1 in diabetic glomeruli. We also found that expression of HMOX-1 and Sirt1 was suppressed in diabetic glomeruli but restored by puerarin treatment as shown by both real-time PCR, western blot analysis, and immunostaining. In conditionally immortalized mouse podocytes, puerarin inhibited HG-induced apoptosis and restored the protein and mRNA levels of ZO-1, P-cadherin, HMOX-1, and Sirt1. Interestingly, we showed that puerarin decreased LKB1 acetylation, thereby promoting AMPK-dependent autophagy. Knockdown of HMOX-1 and Sirt1 expression or treatment with the autophagy inhibitor 3-MA abolished the protective effects of puerarin in HG-treated podocytes.

Conclusions: Taken together, these results suggest that puerarin protects podocytes from diabetes-induced injury through HMOX1 and Sirt1-mediated upregulation of autophagy, a novel mechanism explaining its renal protective effects in DN.

FR-PO205

Effect of Exosomes from High Glucose-Treated Mesangial Cells on Healthy Podocytes

Antonio S. Novaes,[2] Nicole D. Hosni,[2] Raphael F. Felizardo,[2,1] Niels O. Camara,[2,1] Mirian A. Boim.[2] *[1]University of São Paulo, Sao Paulo, Brazil; [2]Federal University of São Paulo, São Paulo, Brazil.*

Background: Mesangial cells can communicate with podocytes *in vivo*, contributing to podocytes damage in the diabetic environment. This paracrine communication may have a relevant role in the diabetic nephropathy (DN). This study investigated whether exosomes secreted by high glucose-treated mouse mesangial cells (MMC) are able to induce dysfunction in normal podocytes.

Methods: MMC were cultured under standard (SG, 5 mM) or high glucose concentrations (HG, 30 mM) for 24 hr. Exosomes (Exos) secreted to the culture medium (SG-Exos or HG-Exos) were purified by ultracentrifugation. The vesicles size/concentration ratio was estimated by the particle tracking (NanoSigth). Vesicles characterization was performed by the presence of markers CD63 and CD81 by western blot. Podocytes in culture were exposed to either SG-Exos or HG-Exos for 24hr. In parallel, HG-MMC and podocytes were co-cultured using a transwell system. Exos secretion by MMC was inhibited by GW4869. Expressions of podocytes makers (actinin IV, p-cadherin and synaptopodin) and profibrotic markers (desmin, TGF-β1 and collagen IV) were analyzed by qPCR. Levels of synaptopodin, desmin, vimentin, podocin, alpha-actinin 4 and nephrin was determined by western blot. Expressions of ZO-1 and Nephrin were evaluated by immunofluorescence.

Results: HG stimulus induced a change in the amount, but not in the size of Exos released by MMC. HG-Exos induced phenotypic transition of podocytes that underwent epithelial mesenchymal transition, demonstrated by a downregulation of actinin 4, p-cadherin, synaptopodin together with an upregulation of desmin and TGF-β1. HG-Exos induced increases in vimentin and desmin proteins while protein expressions of nephrin, synaptopodin, alpha-actinin 4 and podocin were decreased. Levels of ZO-1 and nephrin were decreased in podocytes treated with HG-Exos by immunofluorescence. The co-culture experiments showed that the inhibitor of exosome secretion, attenuated the effects of HG-Exos on the expression of nephrin, synaptopodin, alpha-actinin 4 and podocin. These data suggest that Exos secreted by HG-MMC can cause dysfunction in health podocytes.

Conclusions: Results *in vitro*, demonstrated that exosomes can mediate the paracrine communication between MMC and podocytes, and suggest that high glucose stimulus in MMC can modified podocytes function contributing to DN.

Diabetic Nephropathy Is Associated with Reduced Fraction of Glomerular Basement Membrane Surface Area Opening into the Subpodocyte Space

Forough Sargolzaeiaval,[1] Roni Farkash,[2] Michael Mauer,[4] Robert G. Nelson,[3] Behzad Najafian.[2] *[1]Pathology, University of Washington, Seattle, WA; [2]University of Washington, Seattle, WA; [3]National Institutes of Health, Phoenix, AZ; [4]University of Minnesota, Minneapolis, MN.*

Background: Diabetic nephropathy (DN) is the leading cause of end stage kidney disease in the US and better understanding of mechanisms of kidney dysfunction in DN is needed. Current structural functional relationship models, including classical lesions are poor predictors of GFR decline, these imply the possible role of other factors involved in DN progression. Subpodocyte space (SPS) defined as the space between interdigitating foot processes covering GBM and the bottom surface of cell bodies has been characterized through serial sectioning and electron microscopy studies. The SPS is able to retain macromolecules and act as a resistance to fluid flow. However, knowledge about this space is very limited due to lack of validated methodologies for quantification of SPS properties. We developed unbiased quantitative approaches to quantify SPS properties using transmission electron microscopy and validated using SBF-SEM and 3D modeling. Our study will provide an approach to understand how SPS interplays with other structural changes in affecting kidney dysfunction in DN.

Methods: 9 Kidney biopsies of type 2 diabetes were selected and the results were compared with 5 normal controls. Structural studies were performed using these approaches: (1) segmentation of urinary spaces and identification of exit pores; (2) quantification of surface fraction and total surface of GBM opening into SPS/IPS/PUS and volumes of those spaces; (3) quantification of average in-flow areas and out-flow areas of SPS/IPS/PUS and lengths of outflow areas of those spaces

Results: Comparison of glomeruli from 9 T2D patients and 5 normal controls showed classical changes of DN. While the volume and the GBM surface exposed to each of the urinary space compartments were increased in DN, surface density of SPS and IPS were reduced and this reduction was more prominent for SPS (over 2 folds). Moreover, in DN patients, %GBM surface which is exposed to SPS was reduced and, in contrast, %GBM exposed to IPS was increased ($P=0.001$). The data indicates significant reduction in in-flow and widening of out-flow areas in DN compared to control ($P<0.05$).

Conclusions: Structural properties of urinary spaces are differentially regulated and reduced %GBM exposed to SPS may be a compensatory mechanism against GFR loss in DN.

The Mineralocorticoid Receptor Antagonist Finerenone Limits Podocyte Injury in High-Salt Loaded db/db Mice

Daigoro Hirohama, Mitsuhiro Nishimoto, Nobuhiro Ayuzawa, Wakako Kawarazaki, Shigeyoshi Oba, Takeshi Marumo, Toshiro Fujita. *Research Center for Advanced Science and Technology, The University of Tokyo, Tokyo, Japan.*

Background: Diabetic kidney disease (DKD) is a leading cause of end-stage kidney disease worldwide; however, the underlying mechanisms have not been fully elucidated. Previously, we identified cross-talk between mineralocorticoid receptor (MR) and the small GTPase Rac1, and found that activation of Rac1-MR pathway is implicated in proteinuric nondiabetic kidney disease (*Nat Med* 2008, *JCI* 2011). However, few mouse models of DKD hinder the progress of research on DKD.

Methods: We tried to establish the new mouse model of DKD with typical nodular lesion, in order to evaluate the involvement of Rac1-MR pathway in DKD. We performed uninephrectomy at young age (4-week postpartum) and fed a high-salt (HS) diet for 10 weeks to accelerate kidney damage in type 2 diabetic model of db/db mice. We evaluated urinary albumin excretion and kidney phenotype including Rac1-MR pathway, and the renoprotective role of the MR antagonist Finerenone in this DKD mouse model.

Results: HS loading induced prominent elevation of albuminuria and increased glomerular damage with typical nodular lesion in uninephrectomized db/db mice, which were accompanied by the podocyte injury. In db/m control mice, however, albuminuria and glomerular damage did not increase by uninephrectomy and HS loading. Expressions of active Rac1 and Sgk1, a downstream molecule of MR signaling, in the cortex and isolated glomeruli, were elevated in uninephrectomized and HS-treated db/db mice compared with the treated db/m mice. Of note, glomerular active Rac1 expressions were merged with podocyte specific markers including podocin, suggesting Rac1-MR activation in podocytes of the DKD model mouse. Finerenone inhibited the elevated Sgk1 expressions in glomeruli, associated with the improvement of the glomerular damage and podocyte injury, resulting in the significant reduction of albuminuria.

Conclusions: HS loading induces enhanced MR signaling, podocyte injury, and albuminuria in uninephrectomized db/db mice, which are ameliorated by the treatment of Finerenone, suggesting the involvement of activation of Rac1-MR pathway in the progression of DKD, and highlighting MR antagonism as a novel approach to treat DKD.

Diabetic Condition Induces Hypertrophy and Mitotic Catastrophe in Parietal Epithelial Cells Through Cell Cycle Re-Entry

Takahisa Kawaguchi, Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Keio University, Tokyo, Japan.*

Background: Parietal epithelial cells (PECs) have recently been reported to be involved in the pathogenesis of crescentic glomerulonephritis (GN) and focal segmental glomerulosclerosis (FSGS); however, little information is available about changes in PECs under the diabetic condition. Therefore, we performed a detailed analysis of the morphological changes of PECs in diabetic mice and in human.

Methods: Conditionally immortalized mouse PECs were exposed to 5 mmol/L glucose (LG), 30 mmol/L glucose (HG). Hypertrophy and cell cycle were assessed by flow cytometry. Apoptosis was ascertained by Annexin V/PI staining, and caspase 3/7 staining. ROS analysis was evaluated by fluorescent intensity of CM-H2DCFDA. Streptozotocin-treated mice, db/db mice were used as diabetic mouse models. In the analysis of human kidney biopsy samples, the renal histology of the patients with diabetic kidney disease (DKD) were compared with that in the patients with other diseases. Histomorphology of the renal tissue was examined by using light microscopy and transmission electron microscopy (TEM).

Results: In cultured PECs, HG induced hypertrophy and apoptosis in a dose-dependent manner as compared to LG. This effect is not through HG-induced ROS production. Flow cytometry showed that HG increased the percentage of cells in the S phase, indicating some PECs in G0/G1 phase re-entered into S phase. In TEM, PECs exhibited enlargement of cytoplasm at the ultrastructural level in all diabetic mouse models and in human DKD kidneys from early stage before the expression of CD44, which is activated PEC marker of crescentic GN and FSGS. Although rare, binuclear cells were observed in early diabetic model mice, which suggest mitotic catastrophe. PAX 8 staining revealed PEC nuclear hypertrophy in diabetic mice, whereas the cell number of PECs remained unaltered, suggesting that PECs in diabetic condition underwent DNA replication with a mitotic defect.

Conclusions: PECs in diabetic condition are in a state of dysregulation of proliferation similar to mitotic catastrophe from early stage without the expression of PEC activation marker CD44. As PECs are considered a precursor of podocytes, this injury to PECs might impair glomerular regeneration. Further studies are warranted to elucidate the potential pathological role of these morphological changes in PECs in DKD.

FR-PO209

Intraglomerular Cross-Talk Between Mesangial Cells and Podocytes Inhibits Normal Endoplasmic Reticulum-Associated Degradation Processes and Induces Podocyte Injury in Diabetes

Daisuke Fujimoto,[1] Takashige Kuwabara,[2] Yusuke Hata,[2] Shuro Umemoto,[3] Tomoko Kanki,[6] Yoshihiko Nishiguchi,[4] Teruhiko Mizumoto,[5] Manabu Hayata,[6] Yuichiro Izumi,[6] Yutaka Kakizoe,[2] Masashi Mukoyama.[2] *[1]Department of Nephrology, Kumamoto University, Kumamoto, Japan; [2]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [3]Kumamoto University Graduate School of Medicine, Kumamoto, Japan; [4]Kumamoto University Hospital, Kumamoto, Japan; [5]Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [6]Kumamoto University, Kumamoto, Japan.*

Background: Mesangial lesion and podocyte injury are essential for the progression of diabetic kidney disease (DKD). Although cross-communication between mesangial cells (MC) and podocytes is recently suggested by single cell RNA-seq analyses, its molecular mechanisms remain elusive. Our previous experiment on cDNA microarray of diabetic mice glomeruli suggested that ER stress might be involved in DKD progression. The aim of this study is to clarify the effects of MC-podocyte crosstalk on ER stress response of podocytes in diabetic conditions.

Methods: First, we conducted quantitative PCR array focused on ER stress-associated genes. Using cultured mouse podocytes (MPC5) and mouse macrophages (Mϕ) stimulated with MC-cultured medium (MC-sup) under high-glucose condition (HG), we evaluated podocyte-specific responses. Further evaluations of ER stress responses of MPC5 were made by Western blotting, real-time PCR and TUNEL staining. The effects of an ER-associated degradation (ERAD) inhibitor Eeyarestatin I (EerI) in MPC5 and db/db mice were also examined.

Results: In vitro, stimulation with HG MC-sup suppressed ERAD-related factors (XBP1, Derlin), and enhanced apoptotic responses in both protein and mRNA levels specifically in MPC5, but not in Mϕ. TUNEL staining of MPC5 also showed increased apoptotic cells by HG MC-sup. Those results were augmented by HG MC-sup compared to MC-sup under low-glucose condition. Of note, treatment with EerI recapitulated similar responses, namely suppressed IRE1α, spliced XBP1 and Derlin-2 in MPC5. In vivo, such alterations were also observed in isolated diabetic glomeruli. Administration of EerI significantly exacerbated albuminuria in db/db mice. Expression of genes related to inflammation and fibrosis increased, and immunohistochemistry showed lowered expression of Derlin-2 and nephrin in the glomeruli.

Conclusions: It is recently reported that ERAD pathway may play important roles in the maintenance of podocytes to avoid ER stress in several glomerular diseases including DKD. In this study, we first reveal that intraglomerular crosstalk between MC and podocytes inhibits normal ERAD processes, potentially causing podocyte injury in diabetic conditions.

FR-PO210

Calcitriol Plays a Protective Role in Podocytes of Diabetic Nephropathy Rats by Regulating Autophagy

Zhixia Song,[1] Chao Xiao,[3] Shizhong Zhang,[3] Xiaoli Jia,[3] Chunhua Luo,[2] Lang Shi,[3] Rong Xia,[1] Lin Yang.[1] *[1]Institute of Nephrology, Center People's Hospital of Yichang, Three Gorges University, School of Medicine, Yichang, China; [2]Department of Clinical Laboratory, Center People's Hospital of Yichang, Yichang, China; [3]Three Gorges University, School of Medicine, Yichang, China.*

Background: Podocyte injury is the core link of the development of diabetic nephropathy(DN). The nature of podocyte proliferation determines the important role of intracellular degradation system in maintaining podocyte homeostasis. Evidences show that autophagy plays a critical role in the progression of podocyte disease. Previous research in our group has confirmed that calcitriol effectively reduce proteinuria and podocyte injury in DN rats. This study aimed to investigate whether calcitriol can reduce podocyte injury in DN rats by regulating autophagy.

Methods: DN model was established in male SD rats by intraperitoneal injection of streptozotocin(60mg/kg). The rats were subsequently given calcitriol or vehicle(0.1μg/kg/d) by gavage and then sacrificed at three time points(week8, 14, 18). Specimens were used for biochemical, histopathological and molecular biology tests.

Results: DN rats exhibited renal pathological damage accompanied by proteinuria. The expression of slit diaphragms proteins(low expression of nephrin, podocin, synaptopodin), VDR(low expression), autophagy-associated proteins(low expression of LC3B/A, Beclin1, overexpression of P62) were abnormal in DN rats. The number of autophagosomes in podocytes were significantly reduced. The fluorescence of LC3B and synaptopodin proteins were highly overlapping, the fluorescence intensity of both proteins in DN rats were significantly reduced. whereas calcitriol reversed these above changes.

Conclusions: Calcitriol reduces podocyte injury in DN rats by regulating autophagy, thereby reducing proteinuria.

Renal Olfactory Receptor 1393 Contributes to the Development and Progression of Type 1 Diabetes

Alexis R. Schiazza, Elizabeth G. Considine, Blythe D. Shepard. *Georgetown University, Washington, DC.*

Background: Olfactory receptor 1393 (Olfr1393) is a G-protein coupled receptor with vital functionality outside of its native environment of the nose. Recently, we determined that this receptor is expressed in the renal proximal tubule where it aids in glucose reabsorption via the sodium-glucose co-transporters (Sglts). We also found that Olfr1393 is linked to the progression of type II diabetes in a diet-induced obesity mouse model. As Sglt inhibitors have emerged as a novel therapeutic option for type I diabetes (T1D), we sought to extrapolate the role of renal Olfr1393 in the context of this metabolic disorder.

Methods: To induce T1D in whole-animal Olfr1393 wildtype (WT) and knockout (KO) mice, low dose injections of Streptozotocin (STZ; 55 mg/kg BW) or vehicle control were administered for 5 consecutive days to deplete pancreatic β-cells and induce insulin deficiency in both male and female mice. Progression of diabetes was tracked by measuring 2 hour fasting blood glucose and glucose tolerance via intraperitoneal glucose tolerance tests at 2, 5, and 12 weeks post-STZ injections. Glomerular filtration rate was determined using transdermal measurement of FITC-Sinistrin and urinalysis was performed by dipstick.

Results: STZ administration induced phenotypes of hyperglycemia and impaired glucose tolerance in male, but not female, Olfr1393 WT mice. Notably, these diabetic phenotypes were significantly attenuated in the Olfr1393 KO males by 2 weeks post-STZ injection and the differences became more pronounced after 5 weeks. This improvement was accompanied with a reduction in proteinuria, glycosuria, and hemoglobinuria. No significant differences were detected in insulin sensitivity between diabetic WT and KO mice. One hallmark of T1D is the development of glomerular hyperfiltration; notably, neither diabetic WT nor KO mice presented with hyperfiltration 12 weeks post-STZ.

Conclusions: Collectively, this study indicates that diabetic phenotypes are attenuated in Olfr1393 KO mice suggesting that Olfr1393-mediated glucose handling is important for the progression of T1D. Efforts are currently underway to determine the expression and activity of the renal Sglts in the setting of T1D to elucidate the mechanism by which Olfr1393 contributes to the diabetic phenotype.

FR-PO212

A Novel All-Trans Retinoic Acid Therapy Directly Suppresses Bone Morphogenetic Protein 4 in Mouse Diabetic Nephropathy

Masanori Tamaki, Tatsuya Tominaga, Yui Fujita, Taichi Murakami, Seiji Kishi, Hideharu Abe, Kojiro Nagai, Toshio Doi. *Department of Nephrology, Tokushima University, Tokushima, Japan.*

Background: Diabetic nephropathy (DN) causes mesangial matrix expansion, resulting in glomerulosclerosis and renal failure. Collagen IV (COL4), a major component of the mesangial matrix, is positively regulated by bone morphogenetic protein 4 (BMP4)/ suppressor of mothers against decapentaplegic (Smad1) signaling. Treatment with all-trans retinoic acid (ATRA), a potent ligand of the retinoic acid receptor (RAR), shows a beneficial effect on kidney disease; however, its effects on glomerular matrix expansion in DN remain unclear. RAR/retinoid X receptor (RXR) heterodimer binds directly with retinoic acid (RA) response element (RARE) and regulates transcription of various genes. In the present study, we investigated the therapeutic potential of retinoids in DN, focusing on the regulatory mechanism of BMP4.

Methods: Diabetes was induced with streptozotocin in 12-week-old male Crl:CD1(ICR) mice. One month later, we initiated intraperitoneal injection of ATRA (15 μg/gBW) or corn oil three times a week, from 16 to 24 weeks of age. ATRA or specific agonists for each subtype of RAR were added to cultured mouse mesangial cells from 1 nM to 1 μM with or without advanced glycation end products (AGE, 200 μg/ml) for 24 hours. We analyzed glomerular matrix expansion, BMP4/Smad1/COL4 axis, RAR/RXR binding capacity, and putative RAREs.

Results: Glomerular matrix expansion, associated with increased BMP4, phosphorylated Smad1, and COL4 expression, worsened in diabetic mice at 24 weeks of age. ATRA administration alleviated DN and downregulated BMP4, phospho-Smad1, and COL4. In cultured mouse mesangial cells, treatment with ATRA or a retinoic acid receptor α (RARα) agonist significantly decreased BMP4 and COL4 expression, more so in AGE-treated cells. Genomic analysis suggested two putative RAREs for the mouse *Bmp4* gene. ChIP analysis and reporter assays indicated a putative RARE of *Bmp4*, located 11488–11501 bp upstream of exon1A, which bound to RARα and RXR in animals' kidney and in cultured cells, and the luminescence signal decreased after ATRA or RARα agonist addition.

Conclusions: ATRA suppressed BMP4 via binding of RARα/RXR heterodimer to a unique RARE, alleviating glomerular matrix expansion in diabetic mice. These findings provide a novel regulatory mechanism for treatment of DN.

A New Perspective on the Pathogenesis of Diabetic Nephropathy: Changes in Thyroid Hormone Signaling Trigger Diabetes-Induced Podocyte Pathology

Valentina Benedetti, Angelo M. Lavecchia, Monica Locatelli, Daniela Corna, Marta Todeschini, Valerio Brizi, Rubina Novelli, Ariela Benigni, Carlamaria Zoja, Giuseppe Remuzzi, Christodoulos Xinaris. *Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Bergamo, Italy.*

Background: In diabetic patients, hypothyroidism – both clinical and subclinical – is the most common diabetes-associated disorder, while thyroid dysfunction and low T_3 levels are strongly associated with worse renal clinical outcomes and increased mortality. Based on these data, we investigated the role of thyroid hormone (TH) signaling changes in diabetic nephropathy (DN).

Methods: ZSF1 rats were used as *in vivo* model of DN and human immortalized podocytes exposed to high glucose or H_2O_2 as *in vitro* model of diabetic stress. Rat systemic parameters were evaluated at different time-points. Immunohistochemical and western blot analysis were performed on rat renal tissue and human podocytes. Patient biopsies were analyzed using immunohistochemical assays.

Results: In ZSF1 rats, plasma T_3 levels decreased during DN, and this was inversely correlated with metabolic and renal disease worsening, and glomerular histological changes. We observed the re-expression of the fetal TH receptor (TR) isoform TRα1 in podocytes and parietal cells of diabetic rats and patients with DN, and increased glomerular expression of the TH-inactivating enzyme deiodinase 3 (DIO3). In ZSF1 rats, TRα1-positive cells also re-expressed fetal, mesenchymal and damage-related podocyte markers, such as Pax2, Six2, GDNF, desmin, Ret and GFRα1. Podocyte depletion and glomerular and podocyte hypertrophy were evident. *In vitro* studies showed that podocytes that were exposed to components typical of the diabetic milieu exhibited a significant increase in TRα1 and DIO3 expression, as well as cytoskeleton rearrangements, adult podocyte marker down-regulation and fetal kidney marker up-regulation, in addition to maladaptive cell cycle induction/arrest and TRα1-ERK1/2-mediated hypertrophy. Strikingly, T_3 administration significantly decreased TRα1 and DIO3 expression and reversed the above changes.

Conclusions: Our data show that diabetic stress induces the TH-TRα1 axis to adopt a fetal ligand/receptor relationship pattern that plays a key role in DN-associated podocyte pathology, and create a new perspective on the pathogenesis of DN, suggesting that TRα1 could be a new pharmacological target.

Salvianolate Ameliorates Oxidative Stress and Podocyte Injury Through Modulation of AMPK/NOX4 Axis in db/db Mice

Yan Dai,[1,2] Yiran Liang,[1,2] Yi Fang.[1,2] Division of Nephrology, zhongshan hospital, fudan university *[1]Zhongshan Hospital, Fudan University, ShangHai, China; [2]Kidney and Blood Purification Laboratory of Shanghai, Shanghai, China.*

Background: Changes in podocyte morphology and function are associated with albuminuria and progression of diabetic nephropathy (DN). NADPH oxidase 4 (NOX4) is the main source of reactive oxygen species (ROS) in the kidney and NOX4 is upregulated in podocytes in response to high glucose.

Methods: In the present study, the effects of Salvianolate on DN and its underlying mechanisms were investigated in diabetic db/db mice and human podocytes.

Results: We confirmed that Salvianolate injection administration exhibited similar beneficial preventive results with the NOX1/NOX4 inhibitor, as reflected by attenuated albuminuria, reduced podocyte loss and mesangial matrix accumulation. We further observed that Salvianolate exerted its renoprotective role via reducing high-glucose induced NOX4-based NADPH oxidase activity, podocyte apoptosis and restoring podocyte differenation marker (synptopodin) expression in the isolated glomeruli of db/db mice. In human podocyte, NOX4 was expressed in the mitochondrial compartment and Salvianolate treatment blocked NOX4-derived mitochondrial superoxide generation and activated AMPK kinase expression, thereby ameliorating podocyte apoptosis. Therefore, Salvianolate possesses the renoprotective capabilities in part through AMPK-mediated control of NOX4 expression, confirmed by AMPK inhibitor (Compound C).

Conclusions: Taken together, our results identify that Salvianolate could prevent glucose-induced oxidative podocyte injury through modulation of AMPK/NOX4 axis in DN and have a novel therapeutic potential for DN.

FR-PO215

Diabetic Milieu-Induced Mitochondrial Oxidative Damage and Loss of Mitochondrial Proteostasis in Glomerular Endothelial Cells

Gabriella Casalena,[2] Liping Yu,[1] Ilse S. Daehn.[1] *[1]Mount Sinai School of Medicine, New York, NY; [2]Icahn school of medicine at mount sinai, New York, NY.*

Background: Oxidative stress and mitochondrial dysfunction are considered central mediators in the pathogenesis of diabetic complications including diabetic kidney disease (DKD). We have demonstrated that mitochondrial stress and dysfunction in glomerular endothelial cells precede and mediate in part albuminuria, podocyte defects and depletion, and glomerulosclerosis in DKD susceptible DBA/2J mice. We hypothesize that DKD-susceptibility is characterized by glomerular endothelial mitochondrial stress-dependent endothelial dysfunction and secretion of crosstalk factors required for podocyte injury and depletion. **Aim:** To examine mitochondrial oxidative stress and quality control mechanisms in glomerular endothelial cells exposed to a diabetic milieu and assess the impact of endothelial cell dysfunction on podocytes in co-culture.

Methods: We treated murine glomerular endothelial cells (mGECs) with high glucose media (HG) and 2.5% v/v of sera from non-diabetic control (CS) and diabetic (DS) DBA/2J mice. We measured mitochondrial function (oxygen consumption), fragmentation (mitotracker), mitochondrial ROS (mtROS; mitoSOX), accumulation of oxidized products (DNA lesion frequency, γ-H2AX, 8-oxoG, 3-Nitrotyrosine), mitochondrial unfolded protein response (UPR^{mt}), endothelial function (NOS activity) and cell death (Annexin/PI).

Results: Treatment of mGECs with HG or DS resulted in increased mtROS, oxidative mtDNA damage, mitochondria fission and reduced mitochondrial function compared to controls, this in turn impaired the synthesis of electron transport chain components. mtROS specific scavenger (mitoTEMPO) prevented these changes. Chronic exposure of mGECs to the diabetic milieu (up to 72h) resulted in accumulation of oxidized products due to inadequate clearance and loss of mitochondrial proteostasis, leading to cellular dysfunction. Co-incubation of podocytes with conditioned media from stressed mGECs resulted podocytes cell death.

Conclusions: Our results demonstrate that the diabetic environment can mediate GEC dysfunction by triggering mitochondria stress. Furthermore the inability to restore mitochondrial function and proteostasis, suggests a maladaptive response under chronic exposure to diabetic milieu and in turn the secretion of pro-apoptotic factors affecting podocytes in co-cultures.

Funding: NIDDK Support

FR-PO216

Placental Growth Factor Deficiency Aggravates Diabetic Nephropathy

Yaeni Kim, Ji Hee Lim, Eun Nim Kim, Yongjie Jin, Donghyuk Kang, Hyung Duk Kim, Bumsoon Choi, Cheol Whee Park. *The Catholic University of Korea, Seoul, Republic of Korea.*

Background: Placental growth factor (PlGF) is a member of the vascular endothelial growth factor (VEGF) family. PlGF exerts favorable angiogenenic and lymphangiogenic activity by binding to VEGF-R1 and -R3. Due to its functional synergy with VEGF-A, it is required for a correct neovascularization during pathological conditions while inactivation of PlGF contributes to decreased angiogenesis. Because reduced angiogenesis and lymphagiogenesis that contribute to defective lipid drainage are implicated in the

progression diabetic kidney disease (DKD), we investigated the role of PlGF in the development of DKD by using PlGF-knockout mice.

Methods: Diabetes was induced by a low-dose streptozotocin injection in 9-week-old male C57BL/6J PlGF-KO and wild-type mice and biochemical and morphological parameters were examined at 12 weeks later.

Results: In diabetic PlGF-KO mice, fasting blood glucose and HbA1c levels increased significantly and the development of glomerular sclerosis and mesangial area expansion were accompanied by albuminuria. They exhibited increased expression of type IV collagen, transforming growth factor-β1 and glomerular IHC staining for nephrin, PECAM-1 and WT-1-positive cells and VEGF-R1,-R2,-R3 expression decreased, suggesting decreased endothelial cell and podocyte structure. Intrarenal expression of pLKB1, and pAMPK decreased and that of PPARα, PGC1α, ERRα, p-eNOS, and urinary Nox concentration decreased while iNOS increased, indicating disturbed lipid metabolism and endothelial dysfunction in the same group. Diabetic PlGF-KO mice showed increased intrarenal FFA, TG, and cholesterol concentration representing presence of lipid accumulation and F4/80- and TUNEL-positive cells increased, suggesting increased inflammatory cell infiltration and apoptosis. CD68 and arginase-II increased indicating that macrophage subtype M1 polarization is involved in the inflammatory process. Expression of Bcl2/bax decreased and that of SOD1 and 2 decreased, indicating increased apoptosis and oxidative stress, respectively. Increased expression of intrarenal 8-OHdG and urinary isoprostane level indicates increased oxidative stress.

Conclusions: Impaired angiogenesis and lymphangiogenesis are implicated in PlGF deficiency and this promotes lipotoxicity-induced inflammation, oxidative stress and deteriorates renal functional and phenotypic parameters in DKD.

FR-PO217

Endothelial Nitric Oxide and the Podocyte NFAT2/Heparanase Axis in Diabetic Nephropathy

Daisuke Katagiri,[1,2] Shinya Nagasaka,[3] Keiko Takahashi,[2] Suwan Wang,[2] Ming-Zhi Zhang,[2] Akira Shimizu,[3] Raymond C. Harris,[2] Takamune Takahashi.[2] *[1]Nephrology, National Center for Global Health and Medicine, Tokyo, Japan; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Nippon Medical School, Tokyo, Japan.*

Background: A reduction in endothelial nitric oxide synthase (eNOS) activity serves as a key driver in the development and progression of diabetic nephropathy (DN), which has been studied using global eNOS knockout (eNOSGKO) mice for a decade. However, eNOSGKO mice have several inherent problems including a tendency to develop progressive renal disease regardless of diabetic status. Diabetic eNOSGKO mice exhibit advanced podocytopathy, but the detailed mechanism is unknown. The calcineurin-nuclear factor of activated T cells (NFAT) signaling pathway has been reported to cause podocyte injury.

Methods: To determine the precise role of eNOS in DN, we created floxed eNOS mice. We conditionally deleted endothelial cell-specific eNOS expression (E-eNOSKO) after the onset of diabetes in mice to more closely represent the clinical course of human DN. Streptozotocin was used to generate diabetes. Tamoxifen was used to conditionally knock out endothelial cell-specific eNOS. To evaluate the role of NFAT2 in podocyte injury in diabetic eNOSKO mice, Podocin-Cre NFAT2 floxed eNOSGKO mice were also generated. A cyclin-dependent kinase 4-transformed podocyte line was treated with an NO donor in high glucose conditions.

Results: Diabetic E-eNOSKO mice showed significantly increased albuminuria with progressive glomerular lesion changes. We evaluated NFAT isoforms and found that NFAT2 was upregulated in podocytes in advanced DN patients and diabetic E-eNOSKO mice. NFAT2 activation in cultured podocytes was upregulated by high glucose and suppressed by NO donor treatment in a dose-dependent manner. Heparanase (HPSE), the only mammalian endoglycosidase that degrades heparan sulfate, was expressed in podocytes in both advanced DN patients and our model. HPSE was upregulated in cultured podocytes under high glucose conditions and was suppressed by NO donor treatment. Transfection of constitutively active NFAT2 increased HPSE in cultured podocytes. Podocyte-specific NFAT2-deleted diabetic eNOSGKO mice showed attenuated albuminuria with decreased HPSE expression in podocytes.

Conclusions: Our findings indicate that eNOS has a crucial role in the regulation of HPSE in podocytes through NFAT2 activation, which suppresses proteinuria in advanced DN.

FR-PO218

The Mechanism of Mfn2 Regulating ABCG1-Mediated Cholesterol Efflux in Glomerular Endothelial Cells of Diabetic Kidney Disease

Qinghua Yin,[1] Ping Fu,[1] Liang Ma.[2] *[1]West China Hospital of Sichuan University, Chengdu, China; [2]Kidney Research Institute, Division of Nephrology, West China Hospital of Sichuan Univeristy, Chengdu, China.*

Background: Diabetic kidney disease (DKD), is one of the most common microvascular complications of diabetes mellitus. Increasing evidence has shown that renal lipotoxicity plays an important role in the pathogenesis of DKD. The ATP-binding cassette transporter (ABC) G1 mediates intracellular cholesterol efflux. It has been found that overexpression of mitochondrial fusion protein 2 (Mfn2) in macrophages promotes ABCG1-mediated cholesterol efflux. In this study, we investigated the mechanism of Mfn2 regulating ABCG1-mediated cholesterol efflux in glomerular endothelial cell of diabetic kidney disease.

Methods: Glomerular endothelial cell specific knockout ABCG1 (ABCG1-GEC KO) mice and C57BL/6J (WT-N) mice were induced to type 2 diabetes. Another mice in each group were injected with Ad-Mfn2 adenovirus to establish diabetes model. After 8 weeks, mice were sacrificed and collected peripheral blood for detecting creatinine, lipids and glycosylated hemoglobin (HbA1c),and cholesterol efflux and mitochondrial function were detected. The kidney cortex tissue was taken freshly to extract the expression of ABCG1, inflammatory factors. In vitro, adenoviro-induced overexpression of Mfn2 and ABCG1 in glomerular endothelial cells were cultrued with high glucose to clearfy the relationship between Mfn2 and ABCG1. Specific inhibitors of PPAR-γ and PPAR-β were used to reveal the relationship of Mfn2 and ABCG1.

Results: In vivo experiments, cholesterol content increased significantly and mitochondrial respiratory was dysfunction obviously. Immunohistochemical demonstrated that the expression of inflammatory factors increased, while the expression of ABCG1 and Mfn2 decreased. The oxidative phosphorylation (OXPHOS) of kidney mitochondria complex I/II (CI/CII) and electron transfer ability (ETS) decreased significantly in experimental group ($P < 0.05$). In vitro experiments, the mitochondrial function regulated by Mfn2. The expression of ABCG1 was reduced and cholesterol efflux was blocked by specific inhibitors of PPAR-γand PPAR-β compared with control group.

Conclusions: Mfn2 mediated mitochondrial dysfunction plays an important role in cholesterol homeostasis incued by ABCG1 deficiency. In diabetic kidney disease, overexpression of Mfn2 could relieve the renal damage caused by cholesterol accumulation, which increased the expression of ABCG1 depending on PPAR-γ/PPAR-β.

FR-PO219

The Relative Roles of Nox4 vs. Nox5 in Diabetic Kidney Disease

Jay C. Jha,[1] Sofia Urner,[3] Mark E. Cooper,[1] Chris R. Kennedy,[2] Karin Jandeleit-Dahm.[1,3] *[1]Monash University, Melbourne, VIC, Australia; [2]Kidney Research Centre, Ottawa, ON, Canada; [3]German Diabetes Center (DDZ), Düssedorf, Germany.*

Background: Renal oxidative stress plays a crucial role in diabetic kidney disease (DKD). Recent studies have identified that Nox5 could be a main culprit in the context of human DKD. Nox5 is present in humans and rabbits but not in mice or rats. We examined the role of Nox4 vs. Nox5 in human DKD, in human renal cells as well as in rabbit and Nox5 transgenic (Tg) mouse model of DKD.

Methods: Expression of Nox5 was examined in human kidney biopsies. In vitro, Nox4 and Nox5 was silenced in human renal cells and were exposed to high glucose. In vivo, we have exposed the rabbits to high fat feeding (HF) as well as inducing insulin deficient diabetes using alloxan. We have generated a Nox5 knockout rabbit and a unique humanised Nox5 Tg mouse with concomitant Nox4 deletion.

Results: Expression of Nox5 was increased in kidney biopsies obtained from diabetic individuals. Nox5 shows the highest upregulation in response to high glucose in comparison to other Nox isoforms. Silencing of Nox5 reduces ROS formation and expression of proinflammatory and profibrotic cytokines and growth factors as well as putative elements that are implicated in DKD. Moreover, Nox5 is upstream of Nox4 and that Nox5 inhibition also downregulates Nox4, but not vice versa. HF and alloxan induced diabetic rabbits showed increased renal Nox5 expression in association with increased mesangial area and ECM accumulation along with upregulation of CTGF, fibronectin and MCP-1 as well as enhanced ROS production in the kidney. Expression of Nox5 in mesangial cells of Nox4KO diabetic mice demonstrated 30% increase in albuminuria, mesangial expansion, increased renal injury and inflammation via enhanced ROS production.

Conclusions: These findings suggest that Nox5 derived ROS accelerates renal injury in diabetes and provide proof of principle for the development of a new renoprotective agent in diabetes.

FR-PO220

YAP Activation in Renal Proximal Tubule Epithelial Cells Contributes to Development of Tubulointerstitial Fibrosis in Diabetic Nephropathy

Jianchun Chen,[1] Ming-Zhi Zhang,[2] Agnes B. Fogo,[3] Raymond C. Harris.[3] *[1]Medicine/Nephrology, Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University Medical School, Nashville, TN; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: Excessive production of CTGF in kidney has been implicated in the development and progression of DN. YAP (Yes-associated protein) is a transcription factor activator for multiple critical transcription factors. The goal of these studies is to determine the potential role and underlying mechanisms of YAP activation in renal proximal tubule epithelial cells (RPTC) during DN development and progression.

Methods: YAP activation in RPTC was evaluated in deidentified diabetic patient and control kidneys, type I and II diabetic mouse kidneys and cultured human renal proximal tubule epithelial cells (hRPTC). Unilateral nephrectomized (UNX) inducible RPTC specific YAP deletion (Yap^{ptiKO}) and wild type (Yap^{ptWT}) mice, FVB/NJ or $eNOS^{-/-}$ mice were subjected to streptozotocin injections to induce type I diabetes. The diabetic mice were treated with or without verteporfin (a YAP-TEAD association inhibitor), Y-27632 (a Rho association Kinase (ROCK) inhibitor). Mouse urinary albumin excretion and tubulointerstital fibrosis were evaluated. Expressions of YAP, CTGF and profibrotic or fibrotic proteins in RPTC were analyzed. hRPTC was exposed to 25mM glucose treated with or without verteporfin or Y-27632, or YAP, RhoA GTPase siRNA followed by analysis of YAP activation.

Results: YAP expression and nuclear translocation were upregulated in the RPTC of kidneys from diabetic patients and type I and type II diabetic mice, or in the hRPTC exposed to culture medium containing 25mM of glucose. RPTC specific YAP deletion, or treatment of the diabetic $eNOS^{-/-}$ or FVB/NJ mice with verteporfin or Y-27632

inhibited CTGF and α-SMA expression in diabetic renal cortical tissues and attenuated tubulointerstitial collagen I deposition. Proteinuria was ameliorated in verteporfin or Y-27632 treated mice but not in Yap^{ptKO} mice. Y-27632 treatment also decreased YAP activation in diabetic RPTC. In hRPTC, inhibition of YAP activation blocked CTGF and inhibition of RhoA GTPase attenuated YAP and CTGF expression in response to high glucose.

Conclusions: RhoA GTPase-dependent YAP activation and subsequent increases in CTGF and ECM production mediated myofibroblast transition may be potential underlying mechanisms for diabetic tubulointerstitial fibrosis and targeting YAP activation may serve as a therapeutic intervention in diabetic nephropathy.

Identification of Gene Signatures and Molecular Pathways Associated with Urine Albumin Creatinine Ratio Response to Renal Protective Drugs

Wenjun Ju,[1] John R. Hartman,[1] Viji Nair,[1] Shannon M. Harlan,[6] Frédéric Burdet,[3] Hana Baker,[6] Josef G. Heuer,[6] Maria F. Gomez,[4] Kevin L. Duffin,[6] Hiddo J. L Heerspink,[5] Matthias Kretzler.[2] Biomarker enterprise to attack DKD (BEAt-DKD) *[1]University of Michigan, Ann Arbor, MI; [2]U.Michigan, Ann Arbor, MI; [3]Swiss Institute of Bioinformatics, Lausanne, Switzerland; [4]Lund University, Malmö, Sweden; [5]University Medical Center Groningen, Groningen, Netherlands; [6]Eli Lilly and Company, Indianapolis, IN.*

Background: Renal protective drugs reduce the risk of progression and urine albumin/creatinine ratio (UACR) in some but not all patients with type 2 diabetes and CKD. Previous studies showed that the response in each individual is consistent to different drugs. Here we aim to identify gene signatures and molecular pathways that are associated with the individual response to renal protective drugs.

Methods: ReninAAV db/db uNx mice were treated with the angiotensin-converting enzyme inhibitor Lisinopril, the angiotensin receptor blocker Losartan, the Janus-associated kinase inhibitor Ruxolitinib, the sodium glucose transporter 2 inhibitor Canagliflozin or vehicle control for 2 weeks (n=8 per group). ACR was measured at baseline and after treatment. RNAseq profiling of kidney cortex was performed. weighted gene co-expression network analysis and machine learning approaches were used to identify genes associated with UACR; ingenuity pathway analysis was used to identify enriched molecular pathways.

Results: The fraction of mice that responded to treatment, defined as >35% decline in UACR varied depending on the drug, with all mice responding to Lisinopril, 5/8 to Losartan, 4/8 to Ruxolitinib, and none to Canagliflozin. Network analysis identified 35 co-expression modules, several of which were distinctly associated with phenotype variables. Selecting 12 of the modules, a cross-validated logistic lasso regression model was able to predict responders with 83% accuracy (40/48). The cross-validated model was compared to results from 1000 random permutations of its class labels, and found to be significant ($p<0.001$). Enriched signaling pathways include genes involved in tight junction-, mTOR- and sirtuin signaling, as well as in nicotine degradation.

Conclusions: Our study identified gene signatures and molecular pathways associated with UACR response to renoprotective treatments, as well as pathways previously reported to be associated with human kidney disease progression. Results may increase our understanding of the molecular mechanisms underlying responses to treatment and help stratify patients to predict their response to treatment. Our findings will be compared to clinical trial data sets.

Divergent Changes in Kidney Extracellular Matrix Stiffness in Different Mouse Models of Diabetic Nephropathy

Snehal Sant, Nicholas J. Ferrell. *Vanderbilt University Medical Center, Nashville, TN.*

Background: The mechanical properties of the extracellular matrix (ECM) are important in regulating cell and tissue function, and changes in ECM stiffness contribute to a number of pathological conditions. Diabetes is characterized by dramatic changes in the structure of the kidney ECM. Glomerular and tubular basement membrane thickening and expansion of the mesangial matrix are hallmarks of diabetic nephropathy. It is not clear how structural alterations in the ECM translate into changes in the biophysical properties of the ECM in diabetic kidney disease. The goal of this work was to evaluate the stiffness of tubular basement membranes and glomerular ECM in multiple models of diabetic nephropathy of varying severity.

Methods: Tubules and glomeruli were isolated from db/db and eNOS$^{-/-}$ db/db mice. Tubules were subjected to tensile testing using a custom mechanical characterization method. Stress-strain response for tubular basement membrane was evaluated by measuring the force required to stretch the tubules a given length. Hyperelastic materials theory was used to model the tubular stress-strain response. Glomeruli were decellularized and subjected to compression testing to evaluate the compressive modulus of the glomerular ECM. A high deformation Hertzian contact model was used to determine glomerular stiffness.

Results: Biomechanical testing showed that tubular basement membrane stiffness was reduced in the db/db mouse at 16 weeks of age. At this time point, there was no evidence of tubulointerstitial fibrosis, but there were initial signs of renal functional declines based on increased urine albumin to creatinine ratio. In the eNOS$^{-/-}$ db/db mice, there was histologically evident glomerular sclerosis at 18 weeks of age. Glomerular ECM stiffness was significantly increased in a subset of glomeruli from these mice. The amount of stiffness may be related to the degree of glomerular fibrosis.

Conclusions: These data suggest that there are divergent changes in the stiffness of the kidney ECM in different animal models of diabetic nephropathy. These differences may be related to differences in the severity and/or progression of the disease in these different models. The pathophysiological consequences of these progression dependent changes in ECM stiffness will be the focus of future investigation.

Renoprotective Effects of Canagliflozin in CREDENCE May Be Independent of Glucose-Lowering Mechanisms

David M. Charytan,[1,2] Kenneth W. Mahaffey,[3] Meg J. Jardine,[4,5] Rajiv Agarwal,[6] Scott Bull,[7] Pei-Ling Chu,[7] Dick de Zeeuw,[8] Tom Greene,[9] Hiddo J. L Heerspink,[8] Bruce Neal,[4,10] Richard Oh,[7] Carol A. Pollock,[11] Bernard Zinman,[12] Vlado Perkovic,[4,13] David C. Wheeler.[14] *[1]Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, Bronx, NY; [2]Baim Institute for Clinical Research, Boston, MA; [3]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [4]The George Institute for Global Health, UNSW, Sydney, NSW, Australia; [5]Concord Repatriation General Hospital, Sydney, NSW, Australia; [6]Indiana University School of Medicine and VA Medical Center, Indianapolis, IN; [7]Janssen Research & Development, LLC, Raritan, NJ; [8]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [9]Division of Biostatistics, Department of Population Health Sciences, University of Utah, Salt Lake City, UT; [10]Imperial College London, London, United Kingdom; [11]Kolling Institute of Medical Research, Sydney Medical School, University of Sydney, St. Leonards, NSW, Australia; [12]Lunenfeld-Tanenbaum Research Institute, Mt Sinai Hospital, University of Toronto, Toronto, ON, Canada; [13]The Royal North Shore Hospital, Sydney, NSW, Australia; [14]Department of Renal Medicine, UCL Medical School, London, United Kingdom.*

Background: In the CREDENCE study, the SGLT2 inhibitor canagliflozin (CANA) improved renal and CV outcomes in patients with type 2 diabetes and CKD. Whether effects on CV and renal outcomes are explained by glucose lowering and how baseline kidney function modifies the glycemic effects of CANA are not completely understood.

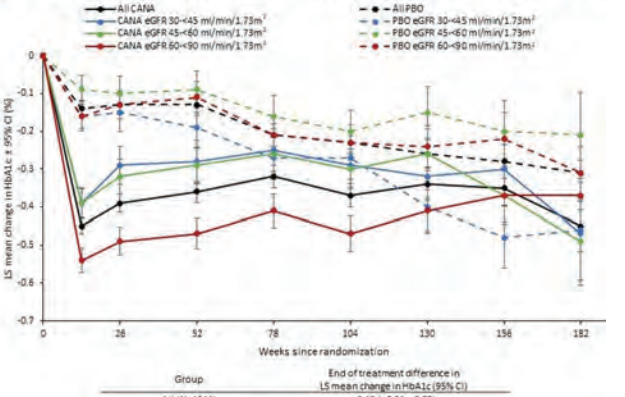
Methods: Analyses were performed in the 4401 patients randomized to CANA (N=2202) or placebo (N=2199). ANCOVA was used to analyze differences in HbA1c at end of treatment. Cox models stratified by screening eGFR and including HbA1c and systolic BP as time-varying covariates were used to analyze time to event.

Results: Least squares (LS) mean (SE) changes in HbA1c during treatment were small: –0.38% (0.03) for CANA vs –0.25% (0.03) for PBO. LS mean differences between CANA and PBO in HbA1c from baseline to end of treatment overall and in subgroups by screening eGFR are shown (Figure). Despite no reduction in HbA1c in the lowest eGFR group, risk reduction for the primary composite endpoint of ESKD, doubling of serum creatinine, or renal or CV death did not differ by screening eGFR (HRs of 0.75, 0.52 and 0.82 for eGFR 30-<45, 45-<60, and 60-<90 ml/min/1.73m^2, respectively; P-interaction=0.11). Risk reduction with CANA vs PBO after adjusting for running mean HbA1c (HR 0.74, 95% CI 0.63-0.88, P<0.001) was similar to the primary results (HR 0.70, 95% CI 0.59-0.82, P=0.00001). Running mean HbA1c was modestly associated with the primary outcome (HR per 1% change 1.13, 95% CI 1.06-1.21, P<0.001).

Conclusions: In patients with type 2 diabetes and CKD enrolled in CREDENCE, renoprotective benefits of CANA appear to be independent of HbA1c reduction and may be linked to non-glycemic properties of CANA.

Funding: Commercial Support - Janssen Research & Development, LLC

Figure. Effects of CANA vs PBO on HbA1c by eGFR strata (on-treatment).



Group	End of treatment difference in LS mean change in HbA1c (95% CI)
All (N=4244)	−0.13 (−0.21, −0.05)
eGFR 30-<45 ml/min/1.73m² (N=1252)	0.03 (−0.13, 0.18)
eGFR 45-<60 ml/min/1.73m² (N=1238)	−0.18 (−0.33, −0.03)
eGFR 60-<90 ml/min/1.73m² (N=1754)	−0.21 (−0.33, −0.08)

FR-PO224

Renal Efficacy and Safety of Canagliflozin by Baseline Medication Use: Results from the CANVAS Program

Brendon L. Neuen,[1] Hiddo J. L Heerspink,[2] Bruce Neal,[1,3] David R. Matthews,[4] Dick de Zeeuw,[2] Kenneth W. Mahaffey,[5] Greg Fulcher,[6] Wayne Shaw,[7] Richard Oh,[7] Qiang Li,[1] Vlado Perkovic,[1] Meg J. Jardine.[1] *[1]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [2]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [3]Imperial College London, London, United Kingdom; [4]Oxford Centre for Diabetes, Endocrinology and Metabolism and Harris Manchester College, University of Oxford, Oxford, United Kingdom; [5]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [6]Royal North Shore Hospital, Sydney, NSW, Australia; [7]Janssen Research & Development, LLC, Raritan, NJ.*

Background: Canagliflozin is thought to confer renoprotection partly by enhancing natriuresis and intravascular volume status. We sought to assess the renal efficacy and safety of canagliflozin in patients using other medications that also alter sodium excretion or volume status.

Methods: The CANVAS Program randomized participants with type 2 diabetes at high cardiovascular risk to canagliflozin or placebo. Other treatments, including the use of renin-angiotensin system (RAS) blockade, loop and non-loop diuretics were managed by treating physicians. Hazards ratios (HR) and 95% confidence intervals (CI) were estimated with Cox regression models, with selected medication by baseline treatment interaction terms added to test for heterogeneity. The primary renal composite outcome was sustained 40% reduction in eGFR, end-stage kidney disease or renal death.

Results: Of 10,142 participants in the CANVAS Program, 8116 (80%) were receiving RAS blockade, 1308 (13%) received loop diuretics, and 3182 (31.4%) received non-loop diuretics at baseline. The effect of canagliflozin on the primary renal composite outcome (HR 0.60, 95% CI 0.47-0.77) was consistent irrespective of baseline use of RAS blockade or diuretics (all *P*-heterogeneity>0.10; Figure). There was no evidence that the risk of renal-related serious adverse events was elevated by background use of medications that influence natriuresis or volume status, although few of these events occurred (Figure).

Conclusions: Canagliflozin appears to reduce the risk of progression of kidney disease in patients with type 2 diabetes, irrespective of use of some medications that also affect natriuresis or volume status, without additional renal-related safety concerns.

Remission of Tubulointerstitial Nephropathy and Its Correlation to the Reduction of Albuminuria by SGLT2 Inhibitor in Patients with Advanced Stages of Diabetic Kidney Disease

Saeko Sato, Koichi Kanozawa, Kaori Takayanagi, Mai Aoyagi, Mariko Sato, Masaaki Terao, Kento Hirose, Yuta Kogure, Hiroaki Hara, Taisuke Shimizu, Hajime Hasegawa. *Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Background: The aim of this study is to examine the clinical advantages of SGLT2 inhibitor predominantly focusing on the amelioration of tubulo-interstitial nephropathy (TIN) through the prospective clinical study.

Methods: Patients with diabetic kidney disease were enrolled, and the patients were received 50 mg of Iplagliflozin. Their blood and urine were sampled at 0 M as baseline, 1 M and 12 M for measurement of parameters including urine Liver Fatty Acid Binding Protein (L-FABP), urine N-acetyl β-D-glucosaminidase (NAG), urine monocyte chemoattractant protein-1 (MCP-1), urine type IV collagen (T4C), 8-hydroxy-2'- deoxyguanosine (8OHdG) in addition to the regular biochemical parameters.

Results: All enrolled patients (n=25, 57.6 of mean age) showed no significant change in their blood pressure and body mass index during the observation period. Their eGFR was not changed either (57.7±21.3 at 0 M, 56.5±21.9 at 1 M, 58.0±24.4 mL/min at 12 M). Urine albumin-to-Cr ratio (ACR) was significantly reduced at 1 M and maintained until 12 M (median: 298.3 at 0 M, 136.0 at 1 M, 141.5 mg/gCr at 12 M). The reduction of ACR was even significant in xx patients who showed GFR<60 mL/min (median: 298.3 at 0 M vs 111.7 mg/gCr at 1 M, p=0.002). We also examined the correlation between baseline ACR and other parameters by single regression analysis, indicating that TIN-related parameters showed weak correlation (LFABP: R2=0.242, p=0.032, MCP-1: R2=0.252, p=0.029) but T4C and eGFR did not. When the patients were divided into two groups based on the ACR reduction responding to SGLT2 inhibitor by the median value of percent-reduction rate of ACR at 1 M, parameters related to TIN showed significant difference among the two groups (LFABP median: 6.58 vs 3.07 μg/gCr, NAG index median: 9.63 vs 7.19 U/gCr, MCP-1 median: 2.42 vs 1.77 pg/gCr) whereas T4C and eGFR were not different.

Conclusions: SGLT2 inhibitor significantly reduced the albuminuria even in patients with advanced renal damage. In these subjects, the reduction of ACR might be highly involved in the severity and restoring of TIN than glomerular damages.

FR-PO226

Acute Changes in Estimated Glomerular Filtration Rate and Related Factors and Subsequent Renal Function in Type 2 Diabetes Mellitus After Initiating Luseogliflozin

Kentaro Kohagura,[1] Yusuke Ohya.[2] *[1]University of the Ryukyus Hospital, Nishihara-cho, Japan; [2]University of the Ryukyus, Nishihara-cho, Japan.*

Background: Acute fall in estimated glomerular filtration rate (eGFR), typical finding after initiating sodium glucose transporter 2 (SGLT2) inhibitors link to maintaining renal function among patients with diabetes mellitus. However, the relationship between magnitude of acute fall in eGFR and course of eGFR thereafter are not known.

Methods: A pooled analysis of four 52-week Phase III trials of luseogliflozin 2.5 mg daily (or up to 5 mg daily) in Japanese patients (N=941) with type 2 diabetes mellitus stratified according to the tertile of magnitude of acute changes in eGFR during 2 weeks after initiating it was conducted.

Results: The mean for age, HbA1c, estimated glomerular filtration rate, and urinary albumin were as follows: 60 years, 7.8%, and 79.6 ml/min/1.73m^2, 62.7 mg/gCr respectively. Acute changes in eGFR were widely varied among the patients with type 2 diabetes mellitus (mean,-2.3; min, -35.5; max, 27.6). Course of eGFR after 2 weeks of initiating luseogliflozin were rather recovered or maintained regardless of acute changes in eGFR. The patients with greater acute decline in eGFR, who were characterized by higher eGFR and body mass index, higher prevalence of using diuretics and lower uric acid, showed rapid recovery and maintenance of eGFR thereafter. Multivariate regression analysis revealed that higher body mass index, higher eGFR and use of diuretics were associated with greater acute decline in eGFR.

Conclusions: Although acute changes in eGFR widely varied among the type 2 diabetes mellitus with preserved renal function, the course of eGFR thereafter was maintained regardless of the degree of acute changes in eGFR. State of basal glomerular filtration rate and interaction of diuretics may relate to acute changes in eGFR after initiating SGLT2 inhibitor.

Short-Term Changes in Albuminuria and Risk of Cardiovascular Outcomes in Type 2 Diabetes: A Post Hoc Analysis of the EMPA-REG OUTCOME Trial

Di Xie,[1] Simke W. Waijer,[1] Maximilian von Eynatten,[2] Audrey Koitka-Weber,[2,3] Silvio E. Inzucchi,[4] Bernard Zinman,[5] Christoph Wanner,[3] Hiddo J. L Heerspink.[1] *[1]Department of Clinical Pharmacy and Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [2]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [3]Department of Medicine, Division of Nephrology, Wurzburg University Clinic, Wurzburg, Germany; [4]Section of Endocrinology, Yale University School of Medicine, New Haven, CT; [5]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada.*

Background: Previous studies, primarily with RAAS inhibitors, have demonstrated that a reduction in albuminuria (UACR) during the first months of treatment is associated with improved long-term cardiovascular (CV) outcomes. Whether an early reduction in UACR with SGLT2 inhibition is also a positive indicator of long-term CV benefit is unknown. We therefore assessed the association between changes in UACR over the first 12 weeks of treatment with empagliflozin or placebo and subsequent long-term CV risk in a post-hoc analysis from the EMPA-REG OUTCOME trial.

Methods: We calculated UACR change as the percentage difference from baseline to week 12 in 6820 participants who did not experience a CV outcome during the first 12 weeks. Cox regression models were used to estimate the hazard ratio (HR) for the primary MACE outcome (non-fatal MI, non-fatal stroke, CV death) and CV death or hospitalization for heart failure (CVD/HHF) for each 30% reduction in UACR after adjustment for treatment assignment, laboratory measurements and medication use.

Results: Empagliflozin compared to placebo reduced UACR by 18% (95%CI 14-22%), and increased the likelihood of a ≥30% reduction in UACR at week 12 compared to placebo (odds ratio 1.42 [95%CI 1.27-1.58]). Over a median follow-up of 3.0 years, 704 (10.3%) primary CV and 440 (6.5%) CVD/HHF outcomes were observed. Each 30% reduction in UACR during the first 12 weeks was independently associated with an average 5% lower hazard for the MACE outcome (HR 0.95; 95%CI 0.91–0.98, p=0.002), and 8% lower hazard for the CVD/HHF outcome (HR 0.92; 95%CI 0.88–0.96, p<0.001). Results were consistent in subgroups by baseline characteristics or medication use, or empagliflozin/placebo treatment assignment(Figure).

Conclusions: Short-term reduction in UACR was more common with empagliflozin and was independently associated with a decreased risk of long-term CV outcomes. These results suggest that a change in albuminuria is a prognostic marker for CV outcomes.

Change in Albuminuria and Renal Risk: A Post Hoc Analysis of the EMPA-REG OUTCOME Trial

Simke W. Waijer,[1] Di Xie,[1] Silvio E. Inzucchi,[2] Bernard Zinman,[3] Audrey Koitka-Weber,[4,5] Maximilian von Eynatten,[4] Christoph Wanner,[5] Hiddo J. L Heerspink.[1] *[1]Department of Clinical Pharmacy and Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [2]Section of Endocrinology, Yale University School of Medicine, New Haven, CT; [3]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [4]Boehringer Ingelheim International GmbH, Mainz-Drais, Germany; [5]Department of Medicine, Division of Nephrology, Wurzburg University Clinic, Wurzburg, Germany*.

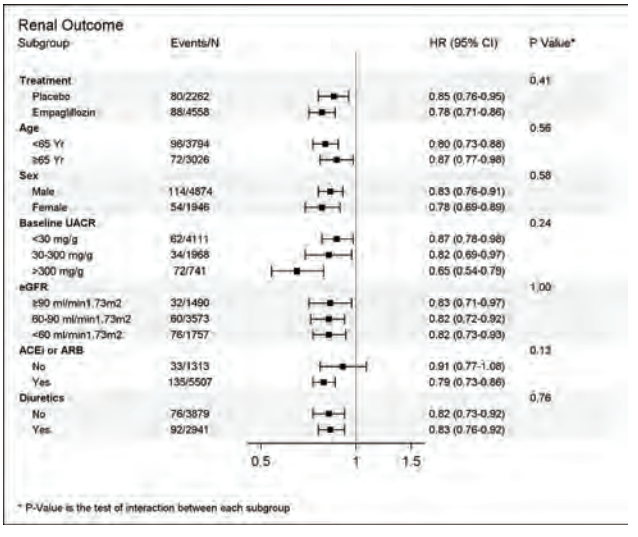
Background: Previous studies have shown that an early reduction in albuminuria (UACR) during RAAS inhibition is associated with improved renal outcomes. Empagliflozin is a SGLT2 inhibitor that decreases UACR. We assessed the association between an early reduction in UACR during treatment with empagliflozin or placebo and long-term renal risk in a post-hoc analysis from the EMPA-REG OUTCOME trial.

Methods: We calculated UACR change as the percentage difference from baseline to week 12 in 6820 participants who did not experience a renal outcome (>40% decrease in eGFR, end-stage renal disease or renal death) during the first 12 weeks. Cox regression models were used to estimate the hazard ratio (HR) for each 30% reduction in UACR with renal outcome after adjustment for treatment assignment, laboratory measurements and medication use.

Results: Empagliflozin, compared to placebo, reduced UACR by 18% (95%CI 14-22%) and increased the likelihood of a ≥30% reduction in UACR at week 12 (odds ratio 1.42 [95%CI 1.27-1.58]). Over a median follow-up of 2.9 years, 168 renal endpoints were observed. Each 30% reduction in UACR from baseline to week 12 was associated with an average 18% lower hazard for the renal outcome (HR 0.82 [95%CI 0.76-0.88]). The adjusted HR for each 30% reduction in UACR in patients with normo-, micro-, or macroalbuminuria at baseline was 0.87 (95%CI 0.78-0.98), 0.82 (95%CI 0.69-0.97) and 0.65 (95%CI 0.54-0.79), respectively (p for interaction 0.24). The association between change in UACR and renal outcomes was consistent in various subgroups and similar in the placebo and empagliflozin groups (Figure).

Conclusions: An early reduction in albuminuria was more common with empagliflozin and was independently associated with a reduced renal risk in patients with type 2 diabetes and cardiovascular disease.

Funding: Commercial Support - Boehringer-Ingelheim



FR-PO229

Early Dip in Estimated Glomerular Filtration Rate (eGFR) on the Efficacy of Ertugliflozin at Week 26

David Cherney,[1] Robert Frederich,[2] Jie Liu,[3] Mario Maldonado,[4] Annpey Pong,[5] Ira Gantz,[6] Steven G. Terra.[7] *[1]Division of Nephrology, University of Toronto, Toronto, ON, Canada; [2]Pfizer Inc., Collegeville, PA; [3]Merck & Co., Inc., Rahway, NJ; [4]MSD, London, United Kingdom; [5]Merck & Co., Inc., Rahway, NJ; [6]Merck & Co., Inc., Rahway, NJ; [7]Pfizer Inc., Andover, MA*.

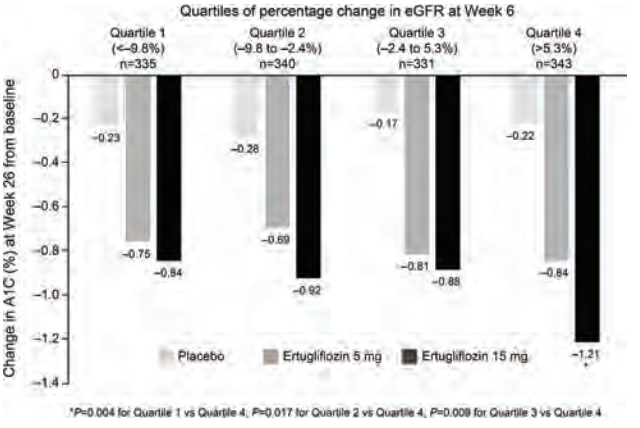
Background: In light of positive results from CREDENCE and previous cardiovascular outcome trials, sodium-glucose cotransporter 2 (SGLT2) inhibitors are frequently compared with renin-angiotensin-aldosterone system blockers, since some members of both drug classes reduce cardiorenal risk. The aim of this *post-hoc* analysis was to assess possible modulatory effects of the early eGFR dip observed with ertugliflozin on measures of treatment efficacy including changes in glycated hemoglobin (A1C), systolic blood pressure (SBP) and body weight (BW).

Methods: Data were pooled from three placebo-controlled studies of ertugliflozin 5 mg and 15 mg in adults with type 2 diabetes mellitus (N=1544). Patients were analyzed by quartiles (Q) of percent reduction in eGFR at Week 6 for changes from baseline in A1C, SBP and BW at Week 26. Pearson correlation was used to measure the strength of the linear relationship between the percent change in eGFR from baseline to Week 6 and changes in those endpoints.

Results: Patients in quartiles with the greatest eGFR decrease (Q1 and Q2) at Week 6 showed similar reductions in A1C at Week 26 compared with patients undergoing only small changes in eGFR (Q3) at Week 6 (**Figure**). Among patients with an increase in eGFR (Q4), those in the ertugliflozin 15 mg group, but not ertugliflozin 5 mg group, showed a greater reduction in A1C at Week 26 compared with other quartiles. Changes in SBP and BW were similar across all quartiles. A weak correlation (r=–0.138) between the change in eGFR at Week 6 and change in A1C at Week 26 was found in ertugliflozin 15 mg group.

Conclusions: Ertugliflozin causes an early decrease in eGFR but its degree has no meaningful impact on reductions in A1C, SBP or BW at Week 26. Ertugliflozin 15 mg may augment A1C reduction in patients with an eGFR rise during early treatment.

Funding: Commercial Support - This study was sponsored by Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA, and Pfizer Inc., New York, NY, USA.



Change in A1C at Week 26 from baseline by quartiles of eGFR change at Week 6

Effects of Blood Pressure After Sodium-Glucose Cotransporter 2 Inhibitor Treatment on Renal Composite Outcomes in Japanese Type 2 Diabetes Patients with CKD

Kazuo Kobayashi,[1,2] Masao Toyoda,[3] Hiroyuki Sakai,[4] Takayuki Furuki,[1] Nobuo Hatori,[6] Kouichi Tamura.[5] *[1]Kanagawa Physicians Association, Yokohama, Kanagawa Prefecture, Japan; [2]Department of Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [3]Tokai University School of Medicine, Isehara, Japan; [4]Committee of Hypertension and Kidney disease, Kanagawa Physicians Association, Yokohama, Japan; [5]Yokohama City University Graduate School of Medicine, Yokohama, Japan; [6]Kanagawa Physicians association, Odawara, Japan*.

Background: Previous large clinical trials using sodium–glucose cotransporter 2 inhibitors (SGLT2is) demonstrated improved renal outcomes in patients with type 2 diabetes mellitus (T2DM). Pleiotropic effects are considered important, but the mechanisms involved are not fully understood. The aim of this study is to clarify the mechanism by who the blood pressure (BP) after SGLT2i treatment influence renal composite outcomes in Japanese T2DM patients with chronic kidney disease (CKD).

Methods: We retrospectively assessed 626 Japanese T2DM patients with CKD who underwent SGLT2i treatment for over 1 year. The renal composite endpoint was the progression of albuminuria stage or a decrease in the estimated glomerular filtration rate (eGFR) by ≥15% per year. For comparative analyses, we included patients comprising

those with >92 mmHg in mean arterial pressure (MAP) after SGLT2i treatment and those with <92mmHg in MAP and used propensity score matching methods to address the imbalances in age, sex, body weight, hemoglobin A1c, eGFR, and urinary albumin–creatinine ratio (ACR) at baseline. The propensity score matching used an algorithm involving a 1:1 ratio of the nearest neighbor match with a ±0.025 caliper and no replacement.

Results: The standardized differences in the backgrounds for propensity-matched patients were calculated to be <0.1. Comparisons between the 210 propensity-matched patients in each group were performed. The incidence of renal composite outcomes was occurred in 42 cases totally and it was significantly lower in patients with <92 mmHg in MAP after SGLT2i treatment than in those with ≥92 mmHg in MAP (6.2% [n=13]and 16.0%[n=29], respectively, p=0.009 by chi-square test). The estimated hazard ratio for the renal composite outcomes, determined using a Cox proportional hazards model, was 1.361 (95% confidence interval, 1.011 to 1.832, p=0.042)in patients with ≥92 mmHg in MAP. There was no significant difference in the logarithmic value of ACR between the two groups.

Conclusions: The BP after SGLT2i treatment influenced renal composite outcomes in Japanese T2DM patients with CKD. These results reaffirmed the importance of BP management in T2DM patients with CKD, even during SGLT2i treatment.

Pretreatment Extracellular Volume Expansion Predicts Body Fluid Response to SGLT2 Inhibitor in Diabetic Kidney Disease

Ken Ohara,[1] Takahiro Masuda,[1] Masato Morinari,[3] Mari Okada,[5] Atsushi Miki,[1] Saki Nakagawa,[7] Takuya Murakami,[6] Kentaro Oka,[1] Maki Asakura,[1] Yasuharu Miyazawa,[2] Akito Maeshima,[1] Tetsu Akimoto,[4] Osamu Saito,[1] Daisuke Nagata.[1] *[1]Jichi Medical University, Shimotsuke, Japan; [2]Nasu-Minami Hospital, Nasukarasuyama, Japan; [3]Nasu Minami Hospital, Nasukarasuyama, Japan; [4]Department of Nephrology, Jichi Medical University, Shimotsuke, Japan; [5]Jichi Medical University Hospital, Shimotsuke, Japan; [6]Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Japan; [7]Division of Nephrology, Department of Internal Medicine, Jichi Medhical University, Shimotsuke, Japan.*

Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitors are an antihyperglycemic drug with diuretic action. We recently reported that SGLT2 inhibitor dapagliflozin ameliorates extracellular volume expansion with a mild increase in urine volume (Nephrology 2018). However, the predictors of fluid response to SGLT2 inhibitors remain unclear.

Methods: Thirty diabetic kidney disease (DKD) patients were treated with dapagliflozin (5mg/day). Body fluid volume including intracellular water (ICW), extracellular water (ECW) and total body water (TBW) was measured on days 0 and 7 using a bioimpedance analysis (BIA) device (InBody S10). Patients were divided into low and high responders by the median value of change in the ECW/TBW for 1 week, which is a marker of extracellular volume expansion. Baseline clinical parameters were compared between the low and high responders.

Results: The body weight significantly decreased (68.0±2.8 vs. 63.0±3.2 kg, p<0.001), but the estimated glomerular filtration rate (eGFR) was not significantly changed (29.2±2.7 vs. 26.1±2.3 mL/min/1.73 m^2, p=0.143) after 1 week. BIA showed that the median value of the change in the ECW/TBW for 1 week was -1.2% (0.416±0.005 vs. 0.400±0.012, p=0.054). The ECW (high responders 17.0±1.2 vs. low responders 14.2±1.2 L, p=0.056), the TBW (39.8±2.6 vs. 34.8±2.6 L, p=0.093), the ECW/TBW (0.426±0.001 vs. 0.406±0.001, p=0.021) and serum brain natriuretic peptide (318±53 vs. 92±50 pg/mL, p=0.003) in the high responders were higher than in the low responders. The eGFR (24.5±3.6 vs. 33.3±3.6 mL/min/1.73 m^2, p=0.046) and serum albumin level (2.9±0.2 vs. 3.4±0.2 g/dL, p=0.075) in the high responders were lower than in the low responders. Significant partial correlations adjusted for the eGFR were observed between the baseline ECW/TBW and changes in the ECW/TBW (r=-0.469, p=0.009) and the TBW (r=-0.528, p=0.027).

Conclusions: Extracellular volume expansion predicts body fluid response to SGLT2 inhibitor dapagliflozin in DKD patients. This result suggests that SGLT2 inhibitor may change its diuretic action depending on the pretreatment extracellular volume status.

How Does Canagliflozin Confer Renoprotection? Results From a Mediation Analysis of the CANVAS Program

Jingwei Li,[1] Bruce Neal,[1,2] Vlado Perkovic,[1] Dick de Zeeuw,[3] Roger Simpson,[4] Richard Oh,[4] Kenneth W. Mahaffey,[5] Hiddo J. L Heerspink.[3] *[1]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [2]Imperial College London, London, United Kingdom; [3]Department Clinical Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [4]Janssen Research & Development, LLC, Raritan, NJ; [5]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA.*

Background: Canagliflozin reduced renal risk in patients with type 2 diabetes participating in the CANagliflozin cardioVascular Assessment Study (CANVAS) Program. This study explored potential mediators of the beneficial effects of canagliflozin on renal outcomes.

Methods: The percent mediating effect of 18 biomarkers, hypothesized to be likely changed by canagliflozin treatment and associated with renal risk, was determined by comparing the hazard ratios for the effect of randomized treatment from an unadjusted model and from a model adjusting for the biomarker of interest. Multivariable analyses assessed the joint effects of biomarkers that mediated most strongly in univariable analyses. The renal outcome was a composite of 40% eGFR decline, end-stage kidney disease, or renal death.

Results: Early changes after randomization in levels of 7 biomarkers (systolic blood pressure (9.5% of effect explained), urinary albumin:creatinine ratio [UACR] (18.2%), gamma glutamyltransferase (9.3%), hematocrit (40.7%), hemoglobin (29.1%), erythrocytes (40.5%), and serum urate (19.0%) were identified as individually mediating the effect of canagliflozin on the renal outcome. The same biomarkers and serum albumin were identified as significant mediators based on average post-randomization levels. In a parsimonious multivariable model, erythrocyte concentration, serum urate and systolic blood pressure were the three biomarkers that maximized cumulative mediation (115% [95%CI 72.96 to 203.66]). Mediating effects of UACR, but not other mediators, were highly dependent upon the baseline level of the mediator; UACR mediated 42% of the effect in those with baseline UACR >30 mg/g but only 8% in those with baseline UACR <30 mg/g.

Conclusions: The identified mediators support existing hypothesized mechanisms for the prevention of renal outcomes with SGLT2 inhibitors. The disparity in mediating effects across subgroups defined by baseline UACR suggests mechanisms of protection may vary in importance across patient subsets.

Renal and Cardiovascular (CV) Outcomes of Canagliflozin (CANA) According to Race and Ethnicity: A CREDENCE Secondary Analysis

Adeera Levin,[1] Kenneth W. Mahaffey,[2] James S. Baldassarre,[3] Pei-Ling Chu,[3] Dick de Zeeuw,[4] Hiddo J. L Heerspink,[4] Mary Kavalam,[3] Carol A. Pollock,[5] Tao Sun,[3] Bernard Zinman,[6] Vlado Perkovic,[7,8] George L. Bakris.[9] *[1]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [2]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [3]Janssen Research & Development, LLC, Raritan, NJ; [4]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [5]Kolling Institute of Medical Research, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia; [6]Lunenfeld-Tanenbaum Research Institute, Mt Sinai Hospital, University of Toronto, Toronto, ON, Canada; [7]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [8]The Royal North Shore Hospital, Sydney, NSW, Australia; [9]Department of Medicine, University of Chicago Medicine, Chicago, IL.*

Background: CANA reduces kidney failure and CV events in people with type 2 diabetes who have chronic kidney disease. Given the international scope of the CREDENCE study, we assessed the efficacy of CANA according to self-reported race and ethnicity.

Methods: 4401 participants with eGFR 30-<90mL/min/1.73m^2 and urinary albumin:creatinine ratio >300-5000mg/g were randomized to CANA 100mg daily or matching placebo. Outcomes were analyzed in prespecified analyses by race and ethnicity, and results are reported without adjustment for multiplicity.

Results: The cohort enrolled were racially and ethnically diverse (n=2931 [67%] White, n=224 [5%] Black or African American, n=877 [20%] Asian, n=369 [8%] Other race, n=1423 [32%] Hispanic/Latino, n=2978 [68%] Non Hispanic/Latino [including not reported/unknown ethnicity]). CANA reduced the primary outcome of end-stage kidney disease (ESKD), sustained doubling serum creatinine (dSCr), or renal or CV death overall, with no evidence the effect differed in racial (P interaction=0.91) and ethnic subgroups (P interaction=0.31; Figure). Similarly, CANA reduced CV outcomes and the renal composite of ESKD, sustained dSCr or renal death, with no differences among the different racial and ethnic groups (all P interaction≥0.06).

Conclusions: CANA reduces the incidence of renal and CV events in people with type 2 diabetes and substantial albuminuria, with no evidence that effects differ in racial or ethnic groups, thereby supporting the breadth of use across a diverse group of patients.

FR-PO234

Elevation of Hematocrit and Decrease in Hemoglobin A1c After the Administration of SGLT-2 Inhibitors Have Different Relation with Parameters Reflecting Diuretic Effect

Yoshiharu Wada,[1] Yoshiyuki Hamamoto,[3] Yoshihisa Nakatani,[2] Satoshi Yoshiji,[1] Sachiko Honjo,[1] Megumi Aizawa-Abe,[1] Yamato Keidai,[1] Yohei Seno,[1] Kanako Iwasaki,[1] Yorihiro Iwasaki,[1] Jun Fujikawa,[1] Hiroko Kakita,[1] Akihiro Hamasaki.[1] *[1]Tazuke Kofukai Medical Institute Kitano Hospital, Osaka, Japan; [2]Kinki University, Osaka, Japan; [3]Kansai Electric Power Hospital, Osaka, Japan.*

Background: Recently, sodium-glucose cotransporter 2 (SGLT-2) inhibitors were indicated to have hematopoietic effect, but it is still unclear whether the effect is independent from its anti-diabetic effect. In this study, we investigated changes in hematocrit and parameters reflecting diuretic change according to HbA1c reaction after administration of SGLT-2 inhibitors in patients with type 2 diabetes.

Methods: A total of 96 patients (male: n=59, age: 54.7±11.8 [mean±SD] years, BMI: 29.6±4.4 kg/m^2, HbA1c: 8.7±1.4 %) with type 2 diabetes who were newly administered SGLT-2 inhibitors from July 2014 to January 2018 were retrospectively identified. The patients were divided into two groups according to HbA1c change (responded [ΔHbA1c<-0.5 %] patients; group A: n=52 [male: n=32], age: 53.9±12.1 years, BMI: 29.9±4.5 kg/m^2; non-responded [ΔHbA1c≥0.5 %] patients; group B: n=44 [male: n=27], age: 55.5±11.5 years, BMI: 29.3±4.5 kg/m^2, HbA1c: 7.9±1.2 %). Changes in HbA1c, hematocrit, urine specific gravity, blood urea nitrogen, serum creatinine and plasma osmolarity levels between before and 30 days after the administration of the drugs were evaluated. Plasma osmolarity was calculated by the formula (2x(Na[mEq/l]+K[mEq/l]))+(BUN[mg/dl]/2.8)+(glucose[mg/dl]/18).

Results: HbA1c was significantly decreased in only group A (group A: -1.03±0.42 %; p<0.001, group B: -0.11±0.46; p=0.65) whereas both groups showed significantly increased hematocrit (group A: 1.8±2.0 %; p=0.007, group B: 2.0±1.8; p=0.035) and urine specific gravity (0.008±0.009 g/mL; p<0.001, 0.011±0.011; p<0.001). Blood urea nitrogen (0.86±3.52 mg/dL; p=0.31, 1.28±3.99; p=0.23), serum creatinine (0.04±0.08 mg/dL; p=0.35, 0.04±0.08; p=0.41), plasma osmolarity (1.11±3.82 mOsm/L; p=0.26, -1.16±5.66; p=0.12) and BMI (-0.61±0.48 kg/m^2; p=0.26, -0.51±0.51; p=0.58) did not change in both groups. Group A showed negative correlation between changes in BMI and plasma osmolarity (r=-0.28; p=0.04), whereas group B did not (r=0.14; p=0.36).

Conclusions: Our data suggest that the elevation of hematocrit and decrease in HbA1c after the administration of SGLT-2 inhibitors have different relation with parameters reflecting diuretic effect.

FR-PO235

The Study on the Transition of Renal Function of SGLT2 Inhibitors for Type 2 Diabetes with Moderate to Severe Renal Impairment

Koichi Kanozawa, Saeko Sato, Yuta Kogure, Akira Kurosawa, Minoru Hatano, Hiroaki Hara, Taisuke Shimizu, Takatsugu Iwashita, Tomonari Ogawa, Hajime Hasegawa. *Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan.*

Background: From the results of recent large-scale clinical trials, it has been clarified that SGLT2 inhibitors (SGLT2i) have protection of renal function independent of blood glucose. However, the renoprotective effect of SGLT2i in type 2 diabetes (T2DM) patients with advanced renal dysfunction less than eGFR 30 ml/min/1.73m^2 has not been studied. The aim of study is to investigate the effect of SGLT2i on renal function in patients with moderate to severe renal insufficiency, retrospectively.

Methods: We included Japanese T2DM patients less than eGFR 45 ml/min/1.73m^2, whose SGLT2i was administered for more than one year since October 2011 in Saitama madical center. We compared changes eGFR from 6 months before administration of SGLT2i to the start of administration, and from initiation of administration of SGLT2i to 6, 12 months after administration, and last month of administration (when SGLT2i is discontinued, just before discontinuation). We also examined safety.

Results: The subjects were 36 cases (12 cases were less than eGFR 30 ml/min/1.73m^2), and eGFR at the start of SGLT2i administration was 33.3 ± 12.2 ml/min/1.73m^2. The patients were received either ipragliflozin, canagliflozin, empagliflozin luseoglifrozin, tofoglifrozin or dapaglifrozin. The monthly change in eGFR from 6 months before to the initiation of SGLT2i administration, and from the initiation to 6, 12 months after administration, and to last chance (27 ± 13 months) were -0.7±1.3, -0.0±1.2, +0.1±0.6, and –0.0±0.4 ml/min/1.73m^2/month, respectively. The decrease in eGFR was significantly suppressed after SGLT2i administration (p <0.05, respectively). During the period, renal replacement therapy (RRT) was initiated only in 3 cases. Assuming that RRT is started when eGFR 6-8 ml/min/1.73m^2 remains unchanged from changes in eGFR before SGLT2i administration, it is predicted that 27 (75%) of the 36 cases could avoid RRT induction during the observation period. On the other hand, no adverse events related to SGLT2i other than RRT were observed during the period.

Conclusions: The administration of SGLT2i to T2DM with moderate to severe renal impairment can strongly and safely suppress the decline of eGFR, and can lead to enormous medical economic benefits by extending dialysis induction.

FR-PO236

The Effect of Oral Carnosine Supplementation on Urinary TGF-Beta in Diabetic Nephropathy: A Randomized Controlled Trial

Narongrit P. Siriwattanasit, Bancha Satirapoj, Pamila Tasanavipas, Narittaya Varothai, Amnart Chaiprasert, Naowanit Nata, Theerasak Tangwonglert, Ouppatham Supasyndh. *Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Activation of TGF-beta pathway is a significant contributor to the pathogenesis of diabetic nephropathy. Carnosine is an amino acid that can inhibit TGF-beta synthesis. We tested the hypothesis that carnosine supplement added to a standard therapy will result in a reduction in urinary TGF-beta levels in patients with diabetic nephropathy.

Methods: We randomly assigned 40 patients with diabetic nephropathy and albuminuria 30-299 mg/day to treatment with carnosine (2 g/day) or placebo for 12 weeks. Urinary TGF-beta level by a solid-phase specific sandwich enzyme-linked immunosorbent assay (ELISA), urine albumin by immunonephelometric assay, renal function and metabolic profiles were determined at baseline and during 12 weeks of active treatment. Primary outcome was the decrease in the level of urinary levels of TGF-beta.

Results: The two groups were comparable for baseline characteristics, blood pressure, urine albumin, urine TGF-beta and renal function measurements. Urinary TGF-beta significantly decreased with carnosine supplement (-17.8% of the baseline values), whereas it tended to increase with placebo (+16.9% of the baseline values) (between-group difference P < 0.05). Whereas, blood urea nitrogen, serum creatinine, serum electrolytes and other biochemical parameters did not change during the study period including urinary albuminuria. The both groups were well tolerated with no serious side-effects.

Conclusions: These data indicate an additional renoprotective effect of oral supplementation with carnosine for decreasing urinary TGF-beta level that is marker of renal injury in diabetic nephropathy.

Dapagliflozin Stabilizes the Tubulointerstitial Fibrosis Marker Urinary Dickkopf-3

Michelle Pena,[1] Gozewijn D. Laverman,[2] Christoph Wanner,[3] Stefan J. Schunk,[4] Thimoteus Speer,[4] Danilo Fliser,[4] Hiddo J. L Heerspink.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]ZGT Almelo, Almelo, Netherlands; [3]University Hospital, Wuerzburg, Germany; [4]Saarland University Hospital, Homburg, Germany.*

Background: Urinary Dickkopf-3 (DKK3) is a stress-induced tubular epithelia-derived profibrotic glycoprotein that induces tubulointerstitial fibrosis through its action on the canonical Wnt/β-catenin signaling pathway. A previous study showed that DKK3 concentrations are higher in patients with CKD than in the general population, and that a

rise in urinary DKK3 was associated with significant eGFR decline. Prior experimental and clinical studies have suggested that SGLT-2 inhibition may reduce renal fibrosis. We therefore assessed the effect of the SGLT-2 inhibitor dapagliflozin on urinary DKK3.

Methods: 24hr urine samples were used from a double-blind, randomized, placebo controlled crossover trial in 31 patients with type 2 diabetes and albumin:creatinine ratio (UACR) >100 mg/g on a stable dose of an ACE inhibitor or angiotensin receptor blocker. Patients were assigned to 6-week treatment periods with dapagliflozin 10 mg/d or placebo in random order. Urinary DKK3 was measured by ELISA at the start and end of each 6-week treatment period. A mixed effects repeated measures model was used to assess the effect of dapagliflozin on urinary DKK3.

Results: Dapagliflozin decreased UACR by 43.9% (95%CI: 30.3 to 54.8) and eGFR by 5.1 (2.0 to 8.1) mL/min/1.73m^2 compared to placebo. At baseline, urinary DKK3 concentration was 574.8 [1st, 3rd quartile: 304.3, 1223.7] ng/24hr. After 6 weeks placebo treatment, urinary DKK3 levels increased by 41.7% (95%CI: 2.2 to 96.4), p=0.0373, whereas they remained stable after dapagliflozin treatment (-1.2% (-29.3 to 38.2), p=0.9421). Accordingly, dapagliflozin lowered DKK3 compared to placebo by 30.3% (2.0 to 50.3), p=0.0384. After dapagliflozin, change in urinary DKK3 was significantly correlated with change in UACR (r=0.41, p=0.0309). No correlations with changes in other clinical markers (HbA1c, eGFR, SPB, Hb, Hct) were observed.

Conclusions: Dapagliflozin stabilized urinary DKK3 after 6 weeks of treatment in patients with type 2 diabetes and increased albuminuria, while an increase was observed during placebo treatment, suggesting that dapagliflozin may lessen tubular stress and fibrosis. Future studies of longer treatment duration and clinical outcomes are needed to confirm the clinical impact of these findings.

FR-PO238

Effects of the SGLT2 Inhibitor Dapagliflozin on Plasma Volume in Patients with Type 2 Diabetes and Various eGFR Levels

Claire Dekkers,[1] David Sjostrom,[4] Peter J. Greasley,[2] Valerie Cain,[3] David W. Boulton,[2] Hiddo J. L Heerspink.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]AstraZeneca, Mölndal, Sweden; [3]Bogier Clinical and IT Solutions, Inc, Haddonfield, NJ; [4]AstraZeneca LP, Molndal, Sweden*.

Background: Sodium glucose co-transporter 2 (SGLT2) inhibitors reduce the rate of renal outcomes and heart failure events in patients with type 2 diabetes and chronic kidney disease possibly as a result of volume contraction. In this study we compare the effects of dapagliflozin on estimated and measured plasma volume and we investigate whether kidney function and other relevant characteristics modify effects of dapagliflozin on estimated plasma volume.

Methods: The Strauss formula was used to calculate changes in estimated plasma volume (ePV). Change in plasma volume measured with ^{125} I-human serum albumin (mPV) was compared with change in ePV in a study of patients with type 2 diabetes randomized to dapagliflozin 10 mg/day or placebo. Subsequently, changes in ePV were measured in a pooled database of 13 phase 2b/3 placebo controlled clinical trials involving 4533 patients with type 2 diabetes randomized to dapagliflozin 10 mg/day or placebo.

Results: Median change in ePV was similar to median change in mPV (-9.4 and -9.0 %) during dapagliflozin treatment. In the pooled analysis, dapagliflozin compared to placebo decreased ePV by 9.6 % (95% CI: 9.0 to 10.2%) after 24 weeks. This effect was consistent in various eGFR-groups (ePV changes of -9.5, -9.7 and -9.5 in eGFR subgroups <60, 60-90, and ≥90 ml/min/1.73m^2 [Figure 1]).

Conclusions: Dapagliflozin consistently decreased estimated plasma volume compared to placebo in a broad population of patients with type 2 diabetes underpinning heart failure benefits observed in patients with type 2 diabetes and chronic kidney disease.

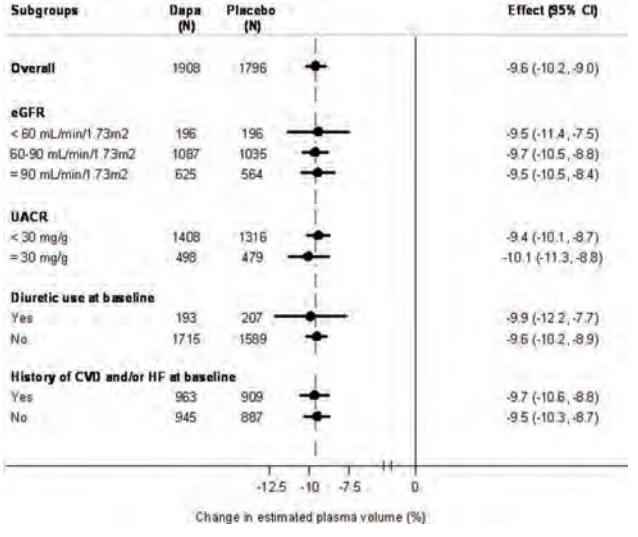

Figure 1: Changes from baseline in estimated plasma volume (%) during 24 week treatment with dapagliflozin relative to placebo in various subgroups

FR-PO239

The GLP-1R Agonist Liraglutide and Its Hypotensive and Natriuretic Effect in Diabetic CKD

Malgorzata J. Wajdlich, Michal P. Nowicki. *Medical Univercity in Lodz, Lodz, Poland*.

Background: The impaired sodium excretion with fluids retention, high activity of renin-angiotensin-aldosterone system (RAAS) are dominant pathogenetic factors in the development of hypertension in diabetic kidney disease. The GLP-1R agonist-liraglutide is an antidiabetic drug that has showed blood pressure lowering effect most probably mediated by increased natriuresis and inhibition of RAAS. The aim of the study was to investigate the hypotensive and nariuretic effect of a single dose of liraglutide compared to placebo in patients with type 2 diabetes mellitus and impaired renal function.

Methods: The study included 17 patients with eGFR below 30, and 17 patients with eGFR above 60 ml/min/1.73 m^2. In a cross-over study each subject received in a random order a single subcutaneous dose of 1.2 mg liraglutide and placebo with subsequent 24h blood pressure monitoring and 24h urinary samples collection to assess natriuresis. Before and after each medication the blood samples were collected to measure the serum concentration of renin, aldosterone and atrial natriuretic peptide (ANP).

Results: After 1.2 mg liraglutide 24h MAP increased from 97.8±8.1 to 102.4±8.6 mmHg, p=0.003 compared to placebo in patients with eGFR below 30 ml/min/1.73 m^2. In patients with eGFR >60 ml/min/1.73 m^2 no significant change of blood pressure was revealed. After liraglutide mean 24h urine sodium excretion increased in both groups (p=0.003) but the increase was significantly larger in patients with eGFR >60 ml/min/1.73 m^2 p=0.046. The difference of mean 24h sodium excretion between liraglutide and placebo correlated negatively with a difference of 24 mean arterial pressure (r=-0.7 p=0.01) in the group with eGFR >60 ml/min/1.73 m^2. The concentration of ANP increased after injection of liraglutide compared with placebo in both groups, but the increase was significantly larger in patients with worse kidney function (p=0.012). In the same group with eGFR <30 ml/min/1.73 m^2 significant decrease of the serum concentration of aldosterone was noted after liraglutide (p=0.013).

Conclusions: Liraglutide administration in the patients with advanced CKD may cause a transient increase of systemic blood pressure due to reduced natriuretic effect. The natriuretic effect of liraglutide in diabetic kidney disease depends on increased atrial natriuretic peptide and decreased aldosterone secretion.

FR-PO240

The Hemodynamic Effect of the GLP-1R Agonist Liraglutide in Diabetic Kidney Disease

Malgorzata J. Wajdlich, Michal P. Nowicki. *Medical Univercity in Lodz, Lodz, Poland*.

Background: The impact of GLP-1R agonists on blood pressure is a resultant of its vasodilatory and natriuretic effect and the increase of heart rate and sympathetic activity. The increased peripheral resistance resulting from the imbalance in factors regulating vascular tone and autonomic nervous system are important pathogenetic factors in the development of hypertension in diabetic kidney disease. The aim of the study was to investigate the hemodynamic effect of a single subcutaneous dose of 1.2 mg liraglutide compared to placebo in patients with type 2 diabetes mellitus and impaired renal function.

Methods: This cross-over study included 17 patients with eGFR below 30 ml/min/1.73 m^2 and 17 patients with eGFR above 60 ml/min/1.73 m^2. Blood pressure and heart rate were monitored noninvasively for 24 hours. Before and after each medication, systemic vascular resistance, heart rate variability, pulse wave velocity and central blood pressure were measured with signal morphology impedance cardiography and applanation tonometry.

Results: Significant increases of both 24h mean heart rate and cardiac output were noted in both groups. In patients with eGFR >60 ml/min/1.73 m^2 mean 24h heart rate was 73±8 after liraglutide compared with 68±5 beats per minute after placebo (p=0.005), whereas in patients with eGFR <30 ml/min/1.73 m^2 the respective values were 76±9 and 67±9 beats per minute (p<0.001). In the latter group it was additionally accompany by sympathetic predominance after GLP-1R agonist (p=0,005). The systemic vascular resistance was reduced after injection of liraglutide compared with placebo only in the study group with better preserved kidney function (p=0,002), whereas the pulse wave velocity was increased after GLP-1R analogue compared with placebo (p=0,0006), only in patients with eGFR <30 ml/min/1.73 m^2. Additionally also only in this group after liraglutide 24h mean arterial pressure significantly increased from 97.8±8.1 to 102.4±8.6 mmHg compared to placebo (p=0.003).

Conclusions: Liraglutide administration in the patients with advanced chronic kidney disease may cause a transient increase of systemic blood pressure probably due to the increase of cardiac output. Increased cardiac output mainly depends on an acceleration of heart rate, which is probably associated with a sympathetic predominance. The vasodilatory effect can be preserved only in earlier stages of CKD.

FR-PO241

Metformin Discontinuation in Type 2 Diabetes Patients Associated with Higher Risk of Diabetic Nephropathy: Finding from a Retrospective, Propensity Score-Matched, Common Data Model-Based Cohort Study

Yongjin Yi, Kipyo Kim, Jong Cheol Jeong, Ho Jun Chin, Ki Young Na, Dong-Wan Chae, Sejoong Kim. *Seoul National University Bundang Hospital, Seongnam-si, GyeonGgi-Do, Republic of Korea.*

Background: Metformin is a first-line drug in patients with type 2 diabetes (T2DM) worldwide. There are several evidences supporting benefits to T2DM patients in cardiovascular and renal outcomes with metformin, however, a long-term use of metformin is occasionally limited owing to risk of lactic acidosis or gastrointestinal side effects. This common data model-based study aimed to compare continuous metformin user with non-metformin user for risk of diabetic nephropathy (DN) in a real-world setting.

Methods: We performed a retrospective, propensity score matched, observational cohort study by using The Observational Medical Outcomes Partnership common data model version 5 (OMOP-CDMv5). We used medical data of 1.82 million patients in a tertiary hospital in South Korea from 2003 to 2017. Study participants were identified by drugs, diagnosis codes and laboratory test values in combination with event time. Among newly diagnosed T2DM patients without DN, more than one year ongoing of metformin treatment were considered as treatment group. Never use of metformin after four months since time of T2DM diagnosis were considered as comparative group. DN defined as onset of spot urine albumin to creatinine ratio (uACR)>30 mg/g, protein to creatinine ratio (uPCR)>150 mg/g or EPI-CKD eGFR<60 ml/min/1.73m^2. After 1:1 propensity score-based matching (PSM), the Cox proportional hazards model was used to analyze hazard ratio (HR) for DN events.

Results: A 2,003 of metformin using patients and a 222 of non-metformin using patients were identified. After 1:1 PSM, we matched each of 207 patients in both groups. Mean follow-up duration was 7.2 and 6.5 years, respectively. There were no significant differences of mean age, sex ratio, mean HbA1c, EPI-CKD eGFR, uACR and uPCR value between two groups at baseline. Metformin treatment group had lower risk for progression to DN (HR=0.66, 95% CI [0.47-0.93], p=0.018) than comparative group.

Conclusions: Continuous use of metformin in T2DM without DN was associated lower risk for progression of diabetic nephropathy. This longitudinal, real-world setting study may support protective effect of metformin for progression to diabetic nephropathy in T2DM.

FR-PO242

The Effects and Prognosis of Bariatric Surgery on Diabetic Nephropathy and Retinopathy in Obese Patients with Type 2 Diabetes Mellitus

Shiqi Li, Ying Fan, Niansong Wang. *Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: The prevalence of obesity has increased dramatically during the past 3 decades, resulting in a large number of diabetes mellitus (DM) and its complications, including diabetic nephropathy (DN) and diabetic retinopathy (DR), the two most common microvascular complications. Bariatric surgery has been approved as an effective and potentially useful method to improve hyperglycemia condition in T2DM patients as well as reduce patient's body weight. However, the association between bariatric surgery and the onset and the progression of DN or DR in obese patients with type 2 diabetes mellitus (T2DM) hasn't been well studied.

Methods: A total of 127obese obese patients diagnosed with T2DM underwent bariatric surgery in Shanghai Jiao Tong University Affiliate Sixth People's Hospital from Jan. 2013 to Jan. 2018 and prospectively followed up for one year. The inclusion criteria included: (1) patients aged from 18-65 years old, (2) BMI over 28 kg/m2, (3)a diagnosis of T2DM, (4) a fasting C-peptide by the oral glucose tolerance test >1 ng/mL and a ratio of peak to fasting value >2 ng/ ml. Those with type 1 diabetes, latent autoimmune diabetes in adults, established diagnoses of non-diabetic nephropathy, malignancy, debilitating disease, unresolved psychiatric illness, or substance abuse were excluded from the study. Anthropometric and biochemical parameters were assessed at baseline and 1 year after surgery.

Results: In all patients, body mass index (BMI), blood pressure, fasting blood-glucose, HbA1c, uric acid, blood lipid, urine albumin creatinine ratio (UACR) all decreased significantly 1 year after surgery compared with baseline. 77 out of 127 patients (60.6%) had albuminuria at baseline, and the total remission of albuminuria was 57.9%, no patients had new-onset of albuminuria during the follow-up period. Logistic regression analysis showed that obesity, hypertension, glycemia, dyslipidemia and DR were associated with DN, and DR correlated with DN more strongly than other factors (OR=1.904). Preoperativesystolic pressure and UACR levels, as well as DR could be predictors for DN remission. However, there was no significant difference between baseline and 1 year after intervention in the changes in retinopathy.

Conclusions: Bariatric surgery could be a potential therapy in obese patients with T2DM and might have a protective role in diabetic kidney injury.

FR-PO243

Efficacy and Safety of Low-Dose Metformin for Improving Glycemic Control in Type 2 Diabetic Patients Receiving Maintenance Hemodialysis (HD): An Assessment by Continuous Glucose Monitoring (CGM)

Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[2] Kenji Sawase,[1] Tayo Kawazu,[2] Takuya Kubara,[2] Sayaka Miyazaki,[2] Masatoshi Hayashida,[5] Takashi Harada,[2] Tomoya Nishino,[3] Yutaka Mori,[4] Mashumi Ide.[2] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki Kidney Center, Nagasaki, Japan; [3]Nagasaki University School of Medicine, Nagasaki, Japan; [4]Jikei University, Tokyo, Japan; [5]Nagasaki Renal Center, Nagasaki, Japan.*

Background: Studies show that the use of metformin in HD patients may potentially increase the risk of lactic acidosis. The aim of our study was to evaluate the safety and effect of metformin with appropriate dose reduction to improve glycemic control in patients with type 2 diabetes (T2D) on HD.

Methods: Subjects were six HD patients in our hospital, with T2D (av. BMI=29.7±5.9, glycoalbumin: GA>27%), treated with insulin degludec (8-35 units/day) + dulaglutide (0.75mg/week), with obesity and poor glycemic control. After adding low-dose metformin (250-500mg/day) to the medication, serum lactate level and pH of all six patients were monitored once in two weeks. Glycemic control (assessed by CGM) was calculated before and 4 weeks after the initial administration, and the mean amplitude of glycemic excursions (MAGE) was calculated.

Results: As shown in Figure (each color represents the mean glycemic profile of one patient), glycemic control improved by low-dose metformin as MAGE significantly decreased from 128.4±69.1 mg/dL to 83.4±43.3 mg/dL (p<0.05) without episodes of hypoglycemia. Mean GA significantly reduced from 32.0% to 22.62% (p<0.01), whereas there were no significant changes in the serum pH and lactate levels for 3 months.

Conclusions: After a single hemodialysis session, more than 90% of metformin and lactate were cleared, and the acid-base balance corrected. Unlike in pre-HD patients with impaired renal function, in patients on maintenance HD, metformin may potentially be safe and useful in controlling plasma glucose level when the dosage is appropriately reduced.

FR-PO244

Metformin Use Is Associated with Asymptomatic Hyperlactatemia in Elderly Diabetic Men with Stage 3 CKD

Elvira Gosmanova,[1,2] Sheikh Raza Shahzad,[2] Samshita Yalamanchili,[2] Keiichi Sumida,[3] Csaba P. Kovesdy,[3,4] Aidar Gosmanov.[1,2] *[1]Medicine, Stratton VA Medical Center, Albany, NY; [2]Medicine, Albany Medical College, Albany, NY; [3]University of Tennessee Health Science Center, Memphis, TN; [4]Medicine, Memphis VAMC, Memphis, TN.*

Background: Current recommendations allow metformin use in patients with chronic kidney disease stage 3 (CKD3). Whether metformin increases risk of hyperlactatemia in elderly CKD3 diabetic patients is unknown.

Methods: This was a case-control study including 92 stable CKD stage 3 male veterans attending Albany VAMC outpatient clinics in 2018. Patients were grouped according to presence of diabetes (D) and metformin use (M) into 3 groups: CKD3 and no diabetes (CKD3 -24pts), CKD3 and D with no M (CKD3/D -28 pts), and CKD3 and D on metformin (CKD3/D+M -40 pts). Hyperlactatemia was defined as lactic acid (LA)>2mmol/L and lactic acidosis as LA>4mmol/L in association with anion-gap metabolic acidosis. Characteristics associated with hyperlactatemia were evaluated in multivariable logistic regression analyses adjusted for age, race, BMI, eGFR, proteinuria, A1C, liver enzymes, Charlson comorbidity index, number of prescription drugs, and metformin and insulin use.

Results: In the total cohort, mean(SD) for age was 73.4(5.9) yrs and mean(SD) eGFR was 46.7(8.1)ml/min/1.73m^2. For CKD3, CKD3/D and CKD3/D+M groups mean(SD) LA levels were 1.3(0.3), 1.3(0.4) and 2.1(1.0)mmol/L (p<0.001) and eGFR were 43.2(7.8), 44.3 (8.7) and 50.6(6.1) ml/min/1.73m^2(p<0.001), respectively. Hyperlactatemia was present in 1(4.2%), 1(3.6%) and 17(42.5%) of CKD3, CKD3/D and CKD3/D+M patients, correspondingly. A single case of asymptomatic lactic acidosis was seen among CKD3/D+M group. Daily metformin dose correlated with LA levels (r=0.35, p=0.027). In multivariable adjusted regression analysis metformin use was significantly associated with hyperlactatemia (Figure 1).

Conclusions: Metformin use in elderly diabetic patients with CKD stage 3 was associated with high incidence of asymptomatic hyperlactatemia. Routine monitoring of LA levels may be warranted in diabetic CKD 3 patients treated with metformin.

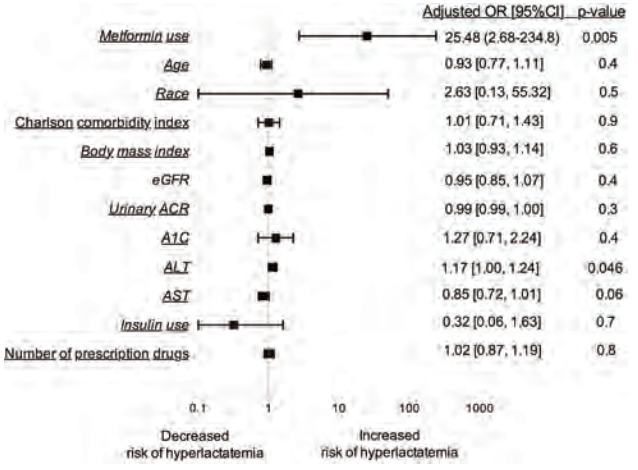

Figure 1

FR-PO245

A Safety Comparison of Metformin vs. Sulfonylurea Initiation in Patients with Type 2 Diabetes and CKD: A Retrospective Cohort Study

Reid Whitlock,[1] Ingrid Hougen,[2] Paul Komenda,[1,2] Claudio Rigatto,[4] Kristin Clemens,[3] Navdeep Tangri.[1,2] *[1]Seven Oaks Hospital Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]Western University, London, ON, Canada; [4]Chronic Disease Innovation Centre, Winnipeg, MB, Canada.*

Background: Metformin is the initial oral antihyperglycemic agent of choice in most patients with type 2 diabetes (T2D). However, in patients with chronic kidney disease (CKD), guidelines often recommend that metformin not be used due to slower clearance and risk of lactic acidosis. Sulfonylureas are a common alternative to metformin but have been associated with hypoglycemia, weight gain and cardiovascular events. We sought to compare the safety of metformin versus sulfonylureas in patients with T2D by CKD stage.

Methods: This retrospective cohort study included adults in Manitoba, Canada with T2D, an incident monotherapy prescription for metformin or a sulfonylurea, and a serum creatinine measurement from April 2006 to March 2017. Patients were stratified by estimated glomerular filtration rate (eGFR) into the following groups: eGFR ≥90, 60-89, 45-59, 30-44 or <30 ml/min/1.73 m^2. Outcomes included all-cause mortality, cardiovascular events, and major hypoglycemic episodes. Baseline characteristics were used to calculate propensity scores and perform inverse probability of treatment weights analysis and eGFR group was examined as an effect modifier for each outcome.

Results: The cohort consisted of 21,996 individuals (19,990 metformin users and 2,006 sulfonylurea users). Metformin use was associated with a lower risk of all-cause mortality (HR 0.48, 95% CI 0.40-0.58, p<0.001), cardiovascular events (HR 0.67, 95% CI 0.52-0.86, p=0.002), and major hypoglycemic episodes (HR 0.14, 95% CI 0.09-0.20, p<0.001), when compared to sulfonylureas. CKD was a significant effect modifier for all-cause mortality (p=0.002), but not for cardiovascular events or major hypoglycemic episodes.

Conclusions: Sulfonylurea monotherapy is associated with a higher risk of all-cause mortality, major hypoglycemic episodes and cardiovascular events compared to metformin. Although the presence of CKD attenuated the mortality benefit, metformin may be a safer alternative to sulfonylureas in patients with CKD.

FR-PO246

Pleiotropic Effects of Oral Anti-Hyperglycemic Drugs on Renal and Cardiovascular Outcomes: A Meta-Analysis

Paweena Susantitaphong,[1] Api Chewcharat,[2] Suramath Isaranuwatchai,[1] Kullaya Takkavatakarn,[3] Kearkiat Praditpornsilpa,[1] Somchai Eiam-Ong.[1] *[1]Chulalongkorn University, Bangkok, Thailand; [2]Harvard University, Boston, MA; [3]Division of Nephrology, King Chulalongkorn Memorial hospital, Bangkok, Thailand.*

Background: Recently, there are a lot of data of novel oral anti-hyperglycemic drugs claiming to slow progression of kidney function decline and decrease cardiovascular events and all-cause mortality. Therefore, we performed the meta-analysis to explore the pleiotropic effects of oral anti-hyperglycemic drugs including sodium-glucose co-transporter-2 (SGLT2) inhibitors, glucagon-like peptide 1 (GLP-1) receptor agonists, and dipeptidyl peptidase-4 (DPP-4) inhibitors on renal and cardiovascular outcomes.

Methods: A systematic literature search was performed in PubMed, Embase and Cochrane Central Register of Controlled Trials to identify randomized controlled trials examining the effects of SGLT2 inhibitors, GLP-1 receptor agonists, and DPP-4 inhibitors on the incidence of new albuminuria, regression of albuminuria, doubling increase in serum creatinine, renal composite outcomes, renal replacement therapy (RRT), renal death, cardiovascular events and all-cause mortality. We used random effect model to compute the pooled adjusted hazard ratios (HR) for interested outcomes.

Results: Fourteen studies with 95,717 participants were included. SGLT2 inhibitors, GLP1 receptor agonists, and DPP4 inhibitors provided significantly lower HR of new incidence of albuminuria. SGLT2 inhibitors and DPP4 inhibitors had significantly higher HR of regression of albuminuria. In terms of renal composite for increasing in serum creatinine more than 40%, RRT, and renal death, there were significantly lower HR by SGLT-2 inhibitors and GLP-1 receptor agonists. In addition, significantly lower HR of doubling in serum creatinine was noted in SGLT-2 inhibitors. Regarding RRT events, HR was lower in SGLT-2 inhibitors. All-cause mortality was significantly reduced by SGLT-2 inhibitors. Finally, SGLT2 inhibitors had significantly lower HR of heart failure events.

Conclusions: SGLT-2 inhibitors exhibited nephroprotective effects in terms of regressing albuminuria, preventing the incidence of new albuminuria, doubling in serum creatinine, RRT events, renal composite outcome, heart failure events, and all-cause mortality. GLP-1 receptor agonists could attenuate the incidence of new albuminuria and renal composite outcomes, while DPP-4 inhibitors could only prevent the incidence of new albuminuria and regress albuminuria.

FR-PO247

Spironolactone for the Prevention of Microalbuminuria in High-Risk Type 2 Diabetes: Results from the Multicenter Randomized Double-Blind Controlled Trial PRIORITY

Morten Lindhardt,[1] Nete Tofte,[1] Marie Frimodt-Moller,[1] Gemma Currie,[2] Christian Delles,[2] Heiko E. von der Leyen,[4] Harald Mischak,[3] Peter Rossing.[1] PRIORITY Study Group *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]University of Glasgow, Glasgow, United Kingdom; [3]Mosaiques Diagnostics, Sehnde, Germany; [4]Hannover Medical School, Hannover, Germany.*

Background: The 'Proteomic prediction and Renin angiotensin aldosterone system Inhibition prevention Of early diabetic nephRopathy In TYpe 2 diabetic patients with normoalbuminuria trial' (PRIORITY) tested if the aldosterone antagonist spironolactone (25 mg daily) could reduce progression to microalbuminuria in patients with type 2 diabetes (T2D) and normal urinary albumin creatinine ratio (UACR) (< 30 mg/ g) but at high risk for progression based on a urinary proteome-based classifier (CKD273).

Methods: Multicenter randomized double-blind controlled trial. The CKD273 classifier was assessed at baseline in 1775 subjects; 209 (12 %) had elevated risk and were randomized to spironolactone or matching placebo on top of ongoing treatment. Primary endpoint was development of confirmed microalbuminuria (moderate albuminuria) in 2 of 3 first morning urine samples (UACR) >30 mg/g and ≥30 % increase from baseline).

Results: Baseline mean ± SD: Age 63 ± 6.4 years, blood pressure 135 ± 12/ 79 ± 9 mmHg, eGFR 81 ± 17 ml/min/1.73m^2, and UACR 9.1 ± 7 mg/g, 88 % on ACEi or ARB. Mean follow up time was 2.5 years from 7 days to 4.3 years. Development of persistent microalbuminuria was seen in 35 (33 %) of placebo and 26 (26 %) spironolactone treated subjects, hazard ratio (HR) 0.81 (CI 95%: 0.49-1.34) p=0.41. In total 58 (28 %) did not complete the full follow up period, of which 16 had suspected side effects or safety considerations. Hyperkalemia was seen in 4 vs 13 and gynecomastia in 0 vs 3 subjects on placebo vs spironolactone, respectively, and 28 were excluded due to lack of adherence or lost to follow up. In 151 subjects treated per protocol HR was 0.71 (CI 95 %: 0.40 – 1.25) p = 0.23.

Conclusions: Treatment with spironolactone was not able to prevent or delay progression to persistent microalbuminuria in normoalbuminuric subjects with type 2 diabetes and high risk of kidney disease based on urinary proteomics risk score CKD273.

Direct Renin-Inhibitors for Preventing the Progression of Diabetic Kidney Disease: A Systematic Review and Meta-Analysis

Ahmed A. Awan,[3] Giovanni F. Strippoli,[2] Sankar D. Navaneethan.[1] *[1]Baylor College of Medicine, Sugar Land, TX; [2]University of Bari, Bari, Italy; [3]Baylor college of medicine, Houston, TX.*

Background: Renin-angiotensin-aldosterone system blockade using angiotensin converting enzyme inhibitors (ACEI) and angiotensin receptor blockers (ARB) therapy is incomplete and may lead to compensatory rise in angiotensin precursors, including renin. Addition of direct renin-inhibitors (DRIs) to ACEI/ARB treatment might potentially slow down the progression of diabetic kidney disease (DKD). In this systematic review, we examined the benefits and harms of DRIs in preventing the onset or progression of DKD.

Methods: We searched CENTRAL, MEDLINE, and EMBASE (until Oct 2018) for relevant clinical trials that compared DRIs to placebo or other agents among those with type 1 or type 2 diabetes and kidney disease (defined by presence of UAER > 30 mg/d or urine albumin creatinine ratio (UACR) > 30 mg/g). Two authors independently screened studies for inclusion and extracted data. Following outcomes were included: all-cause and cardiovascular mortality, progression or regression of albuminuria, changes in blood pressure, and adverse events such as hyperkalemia. Treatment effects were summarized as relative risks (RR) or mean difference (MD) and 95% confidence intervals (CI) using random effects models.

Results: Nine clinical trials (n=10,051) were included. Addition of DRI to ACEI/ARB had no effect on all-cause mortality (2 studies, 9151 participants; RR 0.93, 95% CI: 0.4-2.19), cardiovascular mortality or change in GFR (2 studies, 638 participants, Mean difference 1.29, 95% CI: -0.44-3.02 ml/min/1.73 m^2) compared to ACEI/ARB use alone. Addition of DRIs to ACEI/ARB was associated with reduced progression to macroalbuminuria (RR 0.82, 95% CI:0.72-0.93) and improvement in regression to microalbuminuria (RR 1.19, 95% CI:1.19-1.29) in one study enrolling 8561 participants. Withdrawal due to adverse events or due to any other reason was similar in both groups. Risk of hyperkalemia was increased by the addition of DRIs to ACEI/ARB therapy (2 studies, 9153 participants, RR 1.34, 95% CI: 1.26-1.42).

Conclusions: Current evidence demonstrate that the addition of DRIs to ACEI/ARB therapy in patients with DKD doesn't reduce cardiovascular or all-cause mortality. However, it might impart kidney benefits by reducing albuminuria at the cost of higher risk of hyperkalemia.

FR-PO249

Five-Year Kidney Outcomes of Bariatric Surgery in Adolescents Compared with Adults

Petter Bjornstad,[1,5] Todd Jenkins,[4] Edward Nehus,[3] Mark Mitsnefes,[3] Marva M. Moxey-Mims,[2] Thomas H. Inge.[5] *[1]University of Colorado School of Medicine, Aurora, CO; [2]Children's National Health System, Washington, DC; [3]Cincinnati Children's Hospital, Cincinnati, OH; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [5]Children's Hospital Colorado, Aurora, CO.*

Background: Bariatric surgery improves markers of kidney health in severely obese adults and adolescents, yet it remains unclear whether kidney disease outcomes differ according to age at surgery.

Methods: We examined health effects of Roux-en-Y gastric bypass between adolescents (n=161; enrolled 2006-2012) and adults (n=396; enrolled 2006-2009) participating in two related but distinct studies. Estimated glomerular filtration rate (eGFR) by serum creatinine and cystatin C and urine albumin-to-creatinine ratio (UACR) were compared between cohorts through 5 years after surgery. Elevated UACR (≥30mg/g) and hyperfiltration (eGFR ≥ 135 ml/min/1.73m^2) were also compared. Analyses were stratified by the presence of pre-operative type 2 diabetes (pre-op T2D).

Results: The pre-op prevalence of elevated UACR was higher in adolescents than adults irrespective of pre-op T2D status. In adolescents with pre-op T2D, elevated UACR decreased from 29% prior to surgery to 6% 1 year after surgery (p=0.0041), whereas elevated UACR did not decrease significantly until year 5 after surgery in adults with pre-op T2D (p=0.0040) (**Fig 1**). The change in prevalence of UACR was not significantly different over time in adolescents vs. adults without pre-op T2D (p=0.95). Adolescents with pre-op T2D had an increased prevalence of hyperfiltration that remained throughout the study period (p=0.01), whereas hyperfiltration prevalence was similar in all study participants without T2D (p=0.94).

Conclusions: Adolescents with T2D experienced more hyperfiltration and earlier attenuation of elevated UACR after gastric bypass compared to adults and these differences were not observed in adolescents and adults without pre-op T2D.

FR-PO250

Testosterone Replacement Therapy (TRT) Delays Early Progression of CKD in Diabetes Mellitus (DM2)

Mariana Garcia-Touza,[6] Aditi Gupta,[2] Mukut Sharma,[3] Virginia J. Savin,[4] Ram Sharma,[5] Archana Goel,[5,1] Peter S. Wiegmann.[1] *[1]Midwest Biomedical Research Foundation, Kansas City, MO; [2]University of Kansas Medical Center, Kansas City, KS; [3]KCVA Medical Center, Kansas City, MO; [4]KC VA Medical Center, Kansas City, KS; [5]Kansas City VA Medical Center, Kansas City, MO; [6]Kansas City VA, Kansas City, MO.*

Background: We have previously shown that TRT provides significant survival benefits in hypogonadic men with kidney disease. Faster progression of chronic kidney disease (CKD) in DM2 is well known. Testosterone deficiency is common in both CKD and DM2. Here we examined if TRT slows CKD progression, cardiovascular disease and mortality in patients with DM2.

Methods: Data from a large cohort of veterans diagnosed with low total testosterone were used to determine the effect of TRT on the progression of CKD, cardiovascular diseases and all-cause mortality in patients with DM2. Increase in serum creatinine > 1.5 mg/dl was taken as a measure of progression of CKD. Data were extracted using the Veterans Administration Informatics and Computing Infrastructure (VINCI), and analyzed using SAS. Propensity matching for age, followup time and prior vascular disease was used to adjust groups. Results were compared by means tests, frequency tables, odds ratio and p values (p=<0.01).

Results: Of 57,985 patients with testosterone deficiency, 14,496 with DM2 had treatment (DM2_TRT) and 4319 had none (DM2_No_TRT), compared to controls without DM2 (Ctrl_TRT, N=29,938, Ctrl_No_TRT, N=9,232). Baseline DM2 age was higher (58.3 vs 61.6 yr). Followup and creatinine were was similar (Ctrl vs DM2 : 6.0 vs 5.7 yrs; 1.02 vs. 1.06 mg/dl). TRT provided significant reduction in all-cause mortality in both groups, (Odds DM2 0.69, 95% CI 0.65-0.74; Odds Ctrl 0.72, 95% CI 0.69-0.77). TRT reduced the progression of CKD (Odds DM2 0.71, 95% CI 0.67-0.75; Odds Ctrl 0.85, 95% CI 0.81-0.89). TRT reduced CVA (Odds DM2 0.86, 95% CI 0.76-0.98; Odds Ctrl 0.86, 95% CI 0.77-0.94). TRT reduced new MI in both groups (Odds DM2 0.74; Odds Ctrl 0.79). TRT reduced new retinopathy slightly. Prior cardiovascular disease was more common with DM2 (% difference Dx/Ctrl), e.g. CAD (158%), CHF (229%), CVA (89%), HTN (112%), MI (118%), PAD (185%).

Conclusions: TRT is associated with significant reductions in progression of early CKD[AG1], all-cause mortality and new cardiovascular diagnoses in patients with DM2 even while DM2 is associated with increased prior cardiovascular disease.

FR-PO251

The Mechanism of Anti-Albuminuric Effect by Topiroxostat

Sawako Kato,[1] Shoichi Maruyama,[1] Hiroyuki Kobori.[2] *[1]Nagoya University Graduate School of Medicine, Aichi, Japan; [2]Tulane University Hypertension and Renal COE, New Orleans, LA.*

Background: In 2018, we demonstrated the anti-albuminuric effect of topiroxostat, a selective xanthine oxidoreductase inhibitor (XORi), in the ETUDE trial (24-week, multicenter, open-label, randomized trial; 1:1, high dose vs low dose) for hyperuricemic patients with diabetic nephropathy. XORis have been reported to have renoprotective power via reduction of oxidative stress, inflammation, and renin angiotensin system (RAS) activation. Therefore, we investigated reduction in oxidative stress (8OH-dG), inflammation (MCP-1) and RAS activation (angiotensinogen) in urine samples of patients actually administered topiroxostat.

Methods: Urinary levels of 8OH-dG, MCP-1 and angiotensinogen in the samples collected in the ETUDE study were measured. We compared these parameters between high dose and low dose of topiroxostat by analysis of variance (ANOVA) using the treatment group, eGFR, age and gender and the baseline levels as fixed effects. In addition,

in each group of high dose and low dose of topiroxostat, the intra-group comparison was performed by t-test with the changes in these parameters after intervention relative to the baseline values.

Results: There was no significant differences in changes in 8OH-dG, MCP-1 and angiotensinogen between the two treatment groups by ANOVA (P = 0.69, 0.59 and 0.50, respectively). In comparison with the baseline values at the end of intervention, 8OH-dG (P = 0.08 high dose, 0.24 low dose) and MCP-1 increased in high dose group (P = 0.02 high dose, 0.51 low dose). The levels of angiotensinogen showed no statistically significant increase as well as decrease (P = 0.48 high dose, 0.72 low dose).

Conclusions: Our additional analysis failed to detect any suppressive effect of inflammation, oxidative stress and RAS activation with topiroxostat and could not reach an evidence that led to the mechanism of albuminuria lowering action.

Treatment of CKD Stage III-IV Diabetic Nephropathy Patients with Tripterygium wilfordii Hook F Extract and the Serum and Urine Metabolomic Analysis

Ming-Xi Li. *Peking Union Medical College Hospital, Beijing, China.*

Background: Diabetic nephropathy (DN) is the most common cause of end-stage renal failure. Although angiotensin II receptor blockers (ARBs) can be used to attenuate proteinuria in DN patients, their efficacy remains limited in CKD stage III-IV DN. This study aimed to evaluate the efficacy of Tripterygium wilfordii Hook F (TwHF) extract in the treatment of type 2 DN patients with CKD stage III-IV and compare the serum and urinary changes of metabolic pathways after TwHF treatment using metabolomics.

Methods: From Oct. 2018 to Jan. 2019, type 2 DN patients with 25≤eGFR<60 ml/min/1.73m2 followed up in renal outpatient clinic of Peking Union Medical College Hospital, who were receiving ARBs and still suffered from severe proteinuria were enrolled as treatment group (TwHF extract 60mg daily). The patients matched by gender, age, proteinuria, and serum creatinine were selected as controls. treated with the maximum dose of ARBs. The urinary protein and eGFR levels were measured at one month after the commencement of treatment. The serum and urine metabolomic analysis before and after treatment in the TwHF group, using UPLC-LTQ-Orbitrap high-resolution mass spectrometry was performed to detect the changes in metabolic pathways.

Results: A total of 28 patients were included, 14 patients (52.9±15.2 ys, eGFR 45±16ml/min/1.73m^2) in the TwHF group and 14 patients in the control group (53.1±11.6 ys, eGFR 46±19ml/min/1.73 m^2). After 1 month treatment, the urinary protein of the TwHF group decreased significantly from 6.2±2.0g/24h to 3.4±1.7g/24h (P<0.05), and the control group decreased significantly from 5.0±1.8g/24h to 3.5±2.0g/24h (P<0.05). There was a significant difference in the reduction rate of proteinuria between the two groups (P=0.03). There were 18 metabolic pathways changed significantly in the urine metabolomic analysis after treatment, including leukotriene, peroxidase fatty acid, and eicosapentaenoic acid metabolic pathways which were associated with inflammation and oxidative stress. A similar change of metabolic pathways was found in the serum metabolomic analysis.

Conclusions: The TwHF extract can reduce the urine protein level of type 2 DN patients with CKD stage III-IV. The serum and urine metabolomic analysis implies TwHF extract may have anti-inflammation and attenuate oxidative stress effects.

FR-PO253

Association Between Individual Cholesterol and Albuminuria Response and Exposure to Atorvastatin or Rosuvastatin

Marjolein Kroonen,[1] Jasper Stevens,[2] Dick de Zeeuw,[2] Hiddo J. L Heerspink.[2] Clinical Pharmacy and Pharmacology *[1]University Medical Centre Groningen, Groningen, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands.*

Background: The PLANET trials showed that atorvastatin 80 mg (ATOR) but not rosuvastatin at either 10 or 40 mg (ROSU) reduced urinary protein:creatinine ratio (UPCR) while effects on LDL cholesterol were similar. However, individual changes in both UPCR and LDL cholesterol to these statins varied widely between patients. This interindividual variability could not be explained by patients' physical or biochemical characteristics. We assessed whether the plasma concentration of the statins were associated with LDL cholesterol and albuminuria response.

Methods: the PLANET trials randomized patients with an urine protein:creatinine ratio of 500 – 5000 mg/g, fasting LDL cholesterol >2.3 mmol/L and stable treatment with ACE or ARB to a 52 week treatment period with ATOR 80 mg, ROSU 10 mg or 40 mg. For the current analysis patients with available samples at week 52 and treatment compliance >80% by pill count were included (N=295). Main outcome measurements were percentage change in UPCR and absolute change in LDL cholesterol (delta LDL), comparing baseline to week 52.

Results: Median (interquartile range) plasma concentration at week 52 for ATOR 80 mg was 3.9 (2.1 – 8.7); for ROSU 10 mg 1.0 (0.7 – 2.0) and for ROSU 40 mg 3.5 (2.0 – 6.8). Higher plasma concentration of statin was associated with larger LDL-cholesterol reductions at week 52 and not with UPCR change nor UACR change (Table). Serum albumin (β = 0.63, p = 0.05) and eGFR per 10 ml/min1.73m^2 (β = -0.09; p = 0.04) were independently associated with ROSU plasma concentration. Active metabolites concentration of either ROSU or ATOR did not correlate with LDL and UPCR changes.

Conclusions: Individual variation in plasma concentrations of rosuvastatin and atorvastatin explained the LDL-cholesterol changes of the patients. The individual variation in UPCR change was not explained by the plasma concentration of both statins.

Pearson correlations between plasma concentration of atorvastatin and rosuvastatin and delta LDL-cholesterol (mmol/L) and log Delta UPCR and UACR at week 52.

	LDL change		UPCR change		UACR change	
	Pearson correlation	P-value	Pearson correlation	P-value	Pearson correlation	P-value
Atorvastatin	-0.28	0.006	0.16	0.13	0.14	0.16
Rosuvastatin	-0.40	<0.001	0.07	0.30	0.03	0.70

Efficacy and Safety of Patiromer by Baseline Serum Potassium Level <6.0 vs. ≥6.0 mEq/L: Pooled Results of Three Studies

Matthew R. Weir,[1] Martha Mayo,[2] Jinwei Yuan,[2] Ansgar Conrad,[2] Zubaid Rafique.[3] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [3]Baylor College of Medicine, Houston, TX.*

Background: Patiromer (PAT) is a sodium-free non-absorbed potassium (K^+) binder that uses calcium as the counter-exchange ion. In this post-hoc analysis, we assessed the efficacy and safety of PAT by baseline severity of hyperkalemia (HK).

Methods: We analyzed pooled data (patients with starting dose up to 25.2 g/day) through week 4 from 3 trials of PAT (AMETHYST-DN, OPAL-HK, TOURMALINE). Patients who took ≥1 PAT dose and had ≥1 post-baseline serum K^+ measurement (sK^+) were included, stratified according to sK^+ ≥6.0 mEq/L and sK^+ <6.0 mEq/L, and assessed for sK^+ change from baseline at week 4, sK^+ over time, and % with any sK^+ measurement in target range (3.8–5.0 mEq/L).

Results: 623 patients were evaluated; 53 had baseline sK^+ ≥6.0 mEq/L and 570 had baseline sK^+ <6.0 mEq/L. Mean (SD) baseline eGFR was 33.0 (16.6) and 40.2 (19.2) mL/min/1.73m^2 in those with sK^+ ≥6.0 and <6.0 mEq/L, respectively. >90% of patients in both groups were taking RAASi. Mean sK^+ was reduced to <5.5 mEq/L at Day 3 (48 hours after the first dose) in both subgroups (**Figure**). 97% of patients with sK^+ <6.0 mEq/L and 93% with sK^+ ≥6.0 mEq/L achieved any sK^+ measurement in the target range through week 4. Mean (95% CI) reductions from baseline at week 4 were -0.67 (-0.71, -0.63) and -1.67 (-1.91, -1.43) mEq/L in the sK^+ <6.0 and sK^+ ≥6.0 mEq/L subgroups, respectively. Adverse events (AEs) were reported in 31% of patients with sK^+ <6.0 mEq/L and 43% with sK^+ ≥6.0 mEq/L, with PAT-related AEs (most commonly constipation and diarrhea) reported in 13% and 19%, respectively.

Conclusions: Patiromer was effective and well-tolerated in patients with mild/moderate HK and severe HK. Regardless of the severity of HK, treatment with patiromer lowered sK^+ to 3.8–5.0 mEq/L in >93% of patients in 4 weeks. A higher rate of constipation occurred in the sK^+ ≥6.0 mEq/L subgroup and may be related to the fact that these patients appear to have worse overall health (e.g. lower eGFR).

Serum K^+ Over 4 Weeks by Baseline Serum K^+ <6.0 vs ≥6.0 mEq/L: Pooled Analysis Across 3 Trials

FR-PO255

Patiromer Controls Serum Potassium for Up to 1 Year in Hyperkalemic Patients with Diabetes and Advanced Kidney Disease on RAAS Inhibitors Regardless of Age

Matthew R. Weir,[1] Martha Mayo,[2] Dahlia Garza,[2] Jeffrey J. Budden,[2] Susan Arthur,[2] George L. Bakris.[3] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [3]The University of Chicago Medicine, Chicago, IL.*

Background: Patiromer (PAT) is a sodium-free, non-absorbed potassium binder approved for the treatment of hyperkalemia (HK). Published data from the OPAL-HK study describes the efficacy and safety of patiromer in controlling serum potassium (sK^+) while maintaining RAAS inhibitor therapy in younger and older adult HK patients (pts) over 3 months of study treatment.

Methods: AMETHYST-DN was a 52-week, multicenter, open-label trial of 304 pts on RAAS inhibitors with eGFR 15–<60 mL/min/1.73m^2, type 2 diabetes, hypertension, and documented HK (sK^+ >5.0 mEq/L). PAT was titrated, if needed, to achieve and maintain sK^+ ≤5.0 mEq/L. Pts <65 (n=122), 65–74 (n=122), and ≥75 (n=60) years of age were randomized and received ≥1 dose of PAT.

Results: Baseline mean (SE) sK^+ levels were 5.32±0.35, 5.31±0.37, and 5.19±0.38 mEq/L in pts <65, 65–74, and ≥75 years of age respectively. By Day 3 (~48 hr after the first PAT dose), mean sK^+ levels were reduced in all 3 age groups (4.97±0.42, 4.90±0.44, 4.89±0.45 mEq/L respectively). The least squares (LS) mean (SE) changes in sK^+ from baseline to Week 4 were –0.67 mEq/L (*P*<0.0001), –0.82 mEq/L (*P*<0.0001), and –0.65 mEq/L (*P*<0.0001), respectively. After 52 weeks (end of treatment), the LS mean (SE) changes from baseline in sK^+ were –0.66 mEq/L (*P*<0.0001), –0.68 mEq/L (*P*<0.0001), and –0.61 mEq/L (*P*<0.0001), respectively. The figure shows mean sK^+ over 52 weeks for all age groups; patiromer cessation led to a rise in mean sK^+ during follow-up. Through 1 year, 18%, 23%, and 17% of pts reported ≥1 PAT-related AE (most common: constipation). There were few AEs leading to discontinuations through 1 year: 9%, 9%, and 10% of pts across the 3 cohorts.

Conclusions: Regardless of patient age, daily treatment with PAT reduced and maintained control of sK^+ for up to 1 year in hyperkalemic pts with advanced diabetic kidney disease receiving RAAS inhibitors. PAT was generally well tolerated.

FR-PO256

Antidiabetic Medication Use in Patients with Type 2 Diabetes and CKD

Jinnie J. Rhee,[1] Jialin Han,[2] Maria E. Montez-Rath,[1] Glenn M. Chertow.[1] *[1]Stanford University School of Medicine, Palo Alto, CA; [2]Stanford University, Menlo Park, CA.*

Background: Diabetes care and relevant clinical practice guidelines are continuously evolving, yet little is known about how to optimize type 2 diabetes mellitus (T2DM) care in patients with chronic kidney disease (CKD). We therefore sought to describe treatment approaches for glycemic control in patients with T2DM and CKD by examining patterns of newer (GLP1-ra and DPP-4i) and conventional (metformin, SU, TZD, and insulin) antidiabetic medication use in this patient population by using data from 2015.

Methods: We used data from a large claims and integrated database that includes employed and commercially insured patients in the United States (Optum). We selected adults age ≥18 years who had continuous enrollment between January 1, 2014 and January 1, 2015, restricting the cohort to patients who had T2DM and CKD prior to January 1, 2015. We defined medication use according to pharmacy fill information for two newer classes (GLP-1ra and DPP-4i) and four conventional classes of antidiabetic medications (metformin, SU, TZD, and insulin). We stratified our analyses by age, sex, race, ethnicity, income, geographic region, CKD stage, and prescribing provider specialty. The final cohort consisted of 38,577 patients.

Results: In 2015, metformin was the most common medication prescribed to patients in this cohort (49.2%). Among the newer medications, 3.4% of patients were prescribed GLP-1ra and 12.3% of patients were treated with DPP-4i. Among patients in CKD stage 1-3a, metformin remained the most commonly prescribed medication. The proportion of patients who were prescribed DPP-4i and insulin was higher in advanced CKD whereas the proportion of patients who were prescribed GLP-1ra was highest in patients with CKD stage 1. There were wide variations by sociodemographic factors. Generally, patients who received prescriptions for antidiabetic medications from nephrologists remained low (0.4-1.9%). Among patients who received prescriptions for GLP-1ra, most received their prescriptions from endocrinologists whereas patients treated with other classes of medications had their prescriptions written most frequently by PCPs.

Conclusions: Prescriptions for newer antidiabetic medications with known safety and efficacy remained low. Prescriptions for agents that are contraindicated in advanced CKD continued to be written. GLP-1ra were favored primarily by endocrinologists.

FR-PO257

Anti-Diabetic Medication Use and Kidney Function in US Adults

Daniel P. Murphy, Robert N. Foley. *University of Minnesota, Minneapolis, MN.*

Background: The concordance of diabetes mellitus (DM) and chronic kidney disease (CKD) constitutes a major public health problem. Though notable therapeutic advances have occurred in the last decade, diabetes medication patterns in the U.S. DM-CKD population remain poorly delineated, particularly associations with declining kidney function. Hence, we examined anti-diabetic medication (ADM) use among adult National Health and Nutrition Examination Survey participants (2001 to 2016) with self-reported diabetes or HbA1c ≥ 7.0%.

Methods: Comparisons were based on two thresholds of creatinine-based estimated glomerular filtration rate (eGFR, 60 and 45 ml/min/1.73m^2) and one threshold of urinary albumin to creatinine ratio (ACR, 30 mg/g).

Results: Renal function in US adults with DM was distributed as follows: eGFR ≥ 60 and ACR < 30 (≥ 60/<30~60.1%, ≥ 60/≥30~20.1%, 45-59/<30~7.4%,45-59/≥30~3.9%, <45/<30~3.1% and <45/≥30~5.4%. Use of ≥ 1 ADM was more prevalent with CKD than without kidney dysfunction (79.5% vs. 75.3%, *P*=0.004). Following these same eGFR and ACR categories, use of ≥ 1 ADM was associated with worsening kidney function category (75.3%, 75.4%, 82%, 84.5%,80.9%, and 86.7%, *P* < 0.001), as were sulphonylurea (26.3%, 33.3%, 29.5%, 29.9%, 36.7%, and 36.5%, *P*=0.002), insulin (23.3%, 27.3%, 30.9%, 41.0%, 40.6%, and 54.3%, *P* < 0.001) and amylin analog (0%, 0.6%, 0%, 0%, 0%, and 1.2%, *P*=0.03) use. Worsening kidney function category was associated with lower proportions of ≥ 2 ADM (35.6%, 41.5%, 34.0%, 38.9%, 26.4%, and 33.2%, *P*=0.032), biguanide (51.8%, 50.7%, 40.9%, 41.3%,16.4%, and 11.2%, *P* < 0.001) and SGLT-2 inhibitor (2.9%, 1.8%, 0.9%, 1.3%, 1%, and 0.1%, *P*=0.044) use. No association was present for thiazolidinedione, dipeptidyl peptidase-4 inhibitor, alpha-glucosidase inhibitor, GLP-1 receptor agonist and meglitinide use.

Conclusions: One in five in the U.S. DM-CKD population do not use anti-diabetic medications, and medication patterns vary substantially with kidney function.

FR-PO258

Temporal Trends in Pharmacologic Management of Diabetes Mellitus Among Patients with CKD in the United States

Daniel P. Murphy, Robert N. Foley. *University of Minnesota, Minneapolis, MN.*

Background: The nexus of diabetes mellitus and chronic kidney disease (DM-CKD) constitutes a major public health problem. Though substantial therapeutic advances have occurred in the last decade, diabetes management patterns in the US DM-CKD population remain poorly delineated. Hence, we examined trends in anti-diabetic medication use among adult National Health and Nutrition Examination Survey participants from years 2001 to 2016.

Methods: Eligible participants had self-reported diabetes or HbA1c ≥ 7.0 % and creatinine-based estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m2 or urinary albumin to creatinine ratio (ACR) ≥ 30 mg/g.

Results: Increases were observed in the proportions taking at least 1 anti-diabetic medication (1+ADM, 73.1% in 2001-2004, 79.2% in 2005-2008, 81.8% in 2009-2012 and 81.9% in 2013-2016, *P*=0.024). A biphasic pattern was observed for 2+ADM (33.6%, 43.7%, 42.0%, 31.9%, *P*=0.002). Regarding individual classes of ADM, values rose for biguanides (32.8%, 40.0%, 39.5%, 45%, *P*=0.048), insulin (26.9%, 27.8%, 38.7%, 39.4%, *P*=0.001) and meglitinides (0%, 3.5 %, 8.8%, 9.1%, *P* < 0.001); fell for sulphonylureas (35.9%, 38.3%, 37.1%, 23.6%, *P* < 0.001) and thiazolidinediones (19.2%, 21.1%, 9.8%, 3.6%, *P* < 0.001); exhibited a rise-and-fall pattern for alpha-glucosidase inhibitors (0.2%, 1.9%, 0.7% and 0.1%, *P*=0.015) and amylin analogs (0%, 1.9%, 0%, 0%, *P*=0.005) and remained statistically unchanged for dipeptidyl peptidase-4 inhibitors (6.5%, 6.5%, 4.5%, 3.7%, *P*=0.333) and SGLT-2 inhibitors 0%, 0.9%, 1.2% and 2.4%, *P*=0.091).

Conclusions: Thus, anti-diabetic medication use in the US DM-CKD populations has changed considerably between 2001 and 2016.

FR-PO259

Estimating the Effectiveness of Home-Based Kidney Care in Persons with Diabetes Using Propensity Scores

Vallabh O. Shah,[1] Donica M. Ghahate,[3] Jeanette Bobelu,[3] V. Shane Pankratz,[1] Robert G. Nelson.[2] *[1]UNM Health Sciences Center, Albuquerque, NM; [2]National Institutes of Health, Phoenix, AZ; [3]University of New Mexico-ZKP, Zuni, NM.*

Background: Home-based kidney care (HBKC) is a pragmatic approach incorporating the healthcare preferences of individuals to address cultural barriers to standard kidney care. We carried out a 12-month randomized clinical trial (RCT) of HBKC in 72 American Indians, identified as having CKD with diabetes.

Methods: Participants were randomized to receive usual care (UC) or HBKC. After initial lifestyle coaching, the HBKC group received frequent additional reinforcement by CHWs about adherence to medicines, diet and exercise, self-monitoring, and coping strategies for living with stress. The primary outcome was the change from baseline to 12-months in the patient activation measure (PAM). Secondary outcomes included BMI, A1C, hsCRP, and KDQOL measures. Outcomes were compared between study groups using linear models with generalized estimating equations to account for household clustering and propensity scores to account for the fact that we did not randomize specifically for those with diabetes.

Results: Accounting for imbalances in group membership at baseline by applying propensity weights, the estimated average change in the difference in PAM scores was 15.6 points higher in HBKC compared to the UC while also adjusting for baseline PAM scores (Figure 1). When PAM score was categorized into PAM levels, we observed that participants in HBKC were 8.4 times more likely to be activated compared to the UC while adjusting for baseline PAM scores. Body mass index declined by 1.2 kg/m^2 (P=0.02) and hsCRP protein by 2.7-fold (P<0.001) more in HBKC group compared to UC. There was a modest decline in A1C by 0.8 % (P=0.14) in HBKC group relative to UC.

Conclusions: A home-based kidney care intervention improves the activation of participants in their own health care. It may also reduce risk factors for poor diabetes outcomes in a rural disadvantaged population.

Associations Between Facility Use of an Electronic Patient Care Plan and Foot Check Rates in Dialysis Patients

Hao Han, Sheetal Chaudhuri, Wendy Millette, Marta Reviriego-Mendoza, John W. Larkin, Len A. Usvyat, Jeffrey L. Hymes, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Electronic care plans have the potential to streamline the management of patient meetings to create, follow, and optimize patient centric interventions for unstable conditions. A large dialysis organization (LDO) deployed an electronic Plan of Care (ePOC) tool for clinicians to improve and personalize care coordination. We assessed if use of the ePOC tool by facilities was related to improvements in the percentage (%) of patients receiving diabetic foot checks.

Methods: The ePOC application was deployed at an LDO in October of 2017. We analyzed monthly data from dialysis patients that had the ePOC application used by the care team during October of 2017 (baseline) and October 2018. We selected the top 15% of the clinics performing the highest % of diabetic foot checks, and the bottom 15% of clinics performing the lowest % of foot checks. Of those, we selected the top and bottom 33% of the clinics with the highest and lowest use of the ePOC tool, respectively. We compared the difference from baseline in % of patients receiving foot checks between facilities with high and low ePOC usage stratified by high and low achievement of baseline foot checks.

Results: We included data from 2432 dialysis facilities. We selected 400 clinics with care teams who were the highest and lowest users of the ePOC tool. Clinics starting with a low or high % of foot checks that were high ePOC users had greater increases in the % of foot checks after follow-up compared to clinics with low ePOC usage (Figure 1).

Conclusions: Use of the ePOC system in the dialysis setting may be have the potential to lead to improvements in the workflow of care in conducting diabetic foot checks. Further analyses are needed to support these findings as these may be confounded by clinics that are more compliant with internal policies.

FR-PO261

Developing Iron Thresholds to Predict Heart Failure Hospitalization Risk in Veterans with CKD

Monique E. Cho,[1,2] Jared Hansen,[1,2] Brian C. Sauer,[1,2] Alfred K. Cheung,[1,2] Tom Greene.[2] *[1]George E. Wahlen Department of Veterans Affairs Medical Center, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: Iron deficiency is closely associated with heart failure (HF) risk. The specific thresholds for serum transferrin saturation (Tsat) or ferritin associated with HF are unknown in CKD.

Methods: We developed a historical cohort using the Veterans Affairs Informatics and Computing Infrastructure. We identified Veterans with pre-dialysis CKD (MDRD eGFR <60 mL/min/1.73m^2) with at least one set of iron indices between 2006-2015. Veterans with ESRD, genetic or chronic disorders affecting iron metabolism, or those who received intravenous iron or erythropoietin stimulating agents within 3 months of the iron indices were excluded. A generalized additive Cox model was applied to the cohort to explore the joint dose-response relationship of the hazard for HF hospitalization following the iron assay. A full 3-D response surface relating the HF covariate-adjusted hazard to both Tsat and ferritin was developed using cubic regression splines.

Results: Of the 1,159,371 Veterans with CKD, 141,477 met the inclusion criteria. The mean±SD for age and eGFR were 72±11 years and 43±11 mL/min/1.73 m^2, respectively. The median (IQR) Tsat and ferritin values were 22 (16, 28)% and 109 (55, 205) ng/mL. At the median values of Tsat and ferritin, 1-year cumulative incidence of HF hospitalization was 2.3%. Compared to the median value, Tsat ≤16% was associated with 25% increased risk for HF hospitalization while no specific threshold could be identified for ferritin. Tsat values ≤13% and ≤9% were associated with 50% and 100% increased risk of HF hospitalization at one year, respectively.

Conclusions: In Veterans with pre-dialysis CKD, decreased Tsat is closely associated with HF hospitalization risk, while serum ferritin levels do not provide a predictive value.

Funding: Veterans Affairs Support

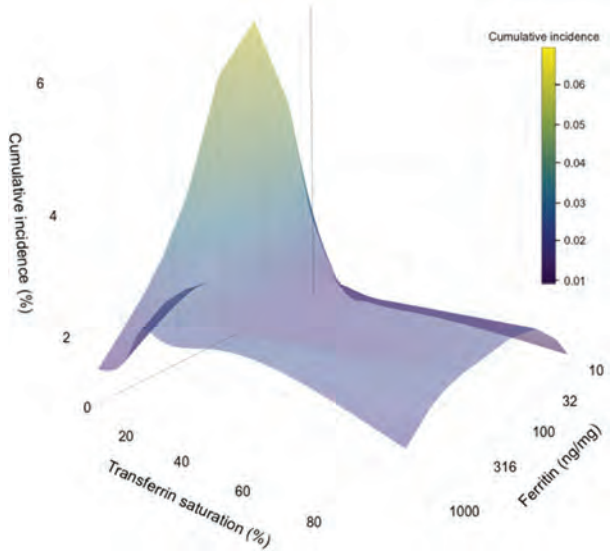

Figure. One-year cumulative incidence of HF hospitalization

FR-PO262

Coronary Artery Calcification but Not Aortic Pulse Wave Velocity Predicts CKD Incidence and Early Progression

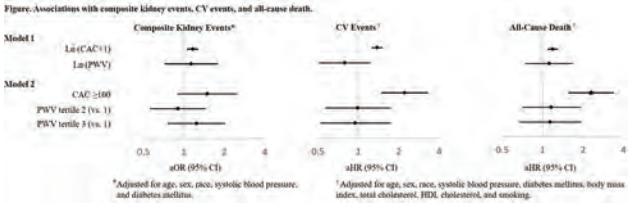
Geoffrey D. Huntley,[1] L Parker Gregg,[2] Julia Kozlitina,[4] James Delemos,[3] Susan Hedayati.[2] *[1]Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX; [2]Nephrology, University of Texas Southwestern Medical Center, Dallas, TX; [3]Cardiology, University of Texas Southwestern Medical Center, Dallas, TX; [4]Biostatistics, University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Both aortic arch pulse wave velocity (PWV), a marker of medial arterial stiffness, and coronary artery calcification (CAC), a marker of coronary atherosclerosis, have been shown to be associated with all-cause death, cardiovascular (CV) events, and end-stage renal disease. We investigated whether CAC and PWV predict earlier kidney events, such as incident albuminuria and loss of estimated glomerular filtration rate (eGFR), when interventions targeting these measures may improve long-term outcomes.

Methods: We conducted a prospective, community-based cohort study of Dallas Heart Study participants who underwent PWV and CAC measurement. eGFR was calculated using the 4-variable MDRD formula. The primary outcome of composite kidney events after 7 years of follow-up was incident chronic kidney disease (CKD) (albuminuria or eGFR <60 mL/min/1.73 m^2) or a decrease in eGFR >2.5 mL/min/1.73 m^2 per year. Secondary outcomes were CV events (myocardial infarction, stroke, coronary revascularization, and CV death) and death at a median follow-up of 13 years. Associations with composite kidney events and CV events and death were measured using logistic and Cox Proportional Hazards regression, respectively.

Results: A total of 2,062 participants had a mean age 45±9.3 years, 56% were female, 47% were African American, 10% had diabetes mellitus, and 7% had CKD at baseline. There were 187 kidney events, 177 CV events, and 165 deaths. Log transformed CAC taken continuously was associated with composite kidney events, aOR (95% CI), 1.16 (1.06, 1.27), CV events, aHR (95% CI) 1.38 (1.27, 1.51), and death, aHR (95% CI) 1.19 (1.10, 1.29) (Figure). CAC ≥100 Agatston units was associated with CV events, aHR (95% CI), 2.21 (1.49, 3.28) and death, aHR (95% CI) 2.30 (1.57, 3.37), but not kidney events. PWV taken continuously or in tertiles was not associated with kidney events, CV events, or death.

Conclusions: CAC, but not PWV, was independently associated with CKD incidence and progression, CV events, and death. These results suggest that CAC may be a useful tool to predict clinically meaningful early kidney outcomes in addition to CV events and death.



FR-PO263

Association of Arterial Stiffness with Kidney Function Among Adults Without CKD

Seiji Itano,[1] Yuichiro Yano,[2] Hiroshi Kanegae,[3] Hajime Nagasu,[1] Yusuke Kobayashi,[4] Hirofumi Makino,[5] Raymond R. Townsend,[6] Matthew J. Budoff,[8] George L. Bakris,[7] Naoki Kashihara.[1] *[1]Department of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan; [2]Department of Community and Family Medicine, Duke University, Durham, NC; [3]Genkiplaza Medical Center For Health Care, Kudanminami, Chiyoda-ku, Tokyo, Japan; [4]YCU Center for Novel and Exploratory Clinical Trials (Y-NEXT), Yokohama, Japan; [5]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [6]University of Pennsylvania School of Medicine, Villanova, PA; [7]The University of Chicago Medicine, Chicago, IL; [8]UCLA School of Medicine, Torrance, CA.*

Background: Associations of aortic stiffness with chronic kidney disease (CKD), including albuminuria and low estimated glomerular filtration rate (eGFR) have been reported in CKD patients. However, it is unclear that whether arterial stiffness is associated with an increased risk for kidney dysfunction among persons without CKD, and whether the association differs by sex.

Methods: We analyzed data from the national health check-up system in Japan, which enrolled persons who completed assessments of cardio-ankle vascular index (CAVI) and kidney function in 2005 and 2015. CAVI is a measure of arterial stiffness based on stiffness parameter β. We excluded participants who had CKD at baseline, defined as the presence of proteinuria or eGFR <60 mL/min per 1.73 m^2. The primary outcome was incident CKD events. Cox proportional hazards models were used to assess the associations between CAVI measurements, assessed as the highest versus lower quartile groups (CAVI measurements≧8.1 versus <8.1), and subsequent CKD events.

Results: The mean (±standard deviation) age of the 24,297 included participants was 46±13 years and 56% were female. Over a mean follow-up of 3.1 years, 1,435 CKD events occurred. In a multivariable analysis, the highest versus lower quartile of CAVI measurements was associated with an increased risk for CKD events (hazard ratio [HR], 1.3; 95% confidence interval [CI], 1.1, 1.5) with interaction by sex (p <0.001). Adjusted HR (95% CI) for CKD events was 1.5 (95% CI, 1.2, 1.9) in men and 1.1 (95% CI, 0.95, 1.4) in women for the highest versus lower quartile of CAVI measurements.

Conclusions: CAVI measurements ≧8.1 versus <8.1 was associated with an increased risk for CKD events, and the association was stronger in men than in women. CAVI measurements may help identify persons at higher risk for CKD events.

FR-PO264

Aortic Valve Calcification (AVC) Is Associated with All-Cause Mortality Independent of Coronary Artery Calcification (CAC) in Patients with ESRD

Lu Dai,[1] Oscar Plunde,[2] Abdul Rashid T. Qureshi,[1] Bengt Lindholm,[1] Torkel B. Brismar,[2] Jonaz Ripsweden,[2] Magnus Bäck,[2] Peter Stenvinkel.[1] *[1]Renal Medicine and Baxter Novum, CLINTEC, Karolinska Institutet, Stockholm, Sweden; [2]Karolinska University Hospital, Stockholm, Sweden.*

Background: AVC is common in ESRD patients (pts). However, the prognostic significance of the overlap between AVC and CAC in ESRD is not well established. We investigated whether AVC is associated with all-cause mortality independent of CAC in ESRD pts.

Methods: 259 ESRD pts (median age 55 years, 67% males) undergoing cardiac CT for AVC and CAC scoring (Agatston units) were included. Framingham's score (FRS), presence of cardiovascular disease (CVD), statin use, protein energy wasting (PEW, subjective global assessment), high-sensitivity C-reactive protein (hsCRP) and other relevant biochemistry and demographic data were determined at baseline. During follow-up for median 36 months, 44 (17%) pts died, and 68 pts underwent renal transplantation. Descriptive, multivariate logistic regression for determinants of AVC, and competing-risk regression analysis for AVC vs all-cause mortality, were performed to define the role of AVC in clinical outcome.

Results: Based on presence (+) or absence (-) of AVC and CAC at baseline, pts were divided into four groups: AVC (-) CAC (-), n=72, 28%; AVC (+) CAC (-), n=5, 2%; AVC (-) CAC (+), n=87, 33%; AVC (+) CAC (+), n=95, 37%. Pts with AVC had older age, higher BMI, more comorbidities, higher FRS, more statin use, lower hand grip strength, higher triglycerides and higher hsCRP. FRS (odds ratio [OR 2.25; 95% confidence interval [95%CI], 1.43 to 3.55] and CAC score (OR [95%CI], 2.18[1.34 to 3.59]) were identified as independent determinants of AVC. After adjustment for presence of CAC, inflammation (hsCRP >10 mg/L), PEW, CVD, 1-SD of FRS and statin use, AVC remained independently associated with all-cause mortality (subdistribution hazard ratio, SHR [95%CI] 2.57 [1.20 to 5.51]) while CAC lost its significant association with mortality (SHR [95%CI], 2.25 [0.46 to 11.01]).

Conclusions: The overlap of AVC and CAC was three times higher (37% vs 11 %) in this ESRD cohort than such overlap previously reported in general population. AVC associated with increased risk of all-cause mortality in ESRD pts, independent of presence of CAC, traditional risk factors and inflammation.

FR-PO265

Skin Autofluorescence as a Risk Factor for Cardiovascular Events and All-Cause Mortality in Persons with CKD Stage 3

Maarten W. Taal,[1,2] Adam Shardlow,[1] Natasha J. McIntyre,[2] Nitin V. Kolhe,[1] Richard J. Fluck,[1] Christopher W. McIntyre.[3] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Division of Medical Sciences and Graduate Entry Medicine, University of Nottingham, Derby, United Kingdom; [3]London Health Sciences Centre, London, ON, Canada.*

Background: Tissue advanced glycation end product (AGE) accumulation has been proposed as a marker of cumulative metabolic stress (glycation and oxidation) that can be assessed non-invasively by measurement of skin autofluorescence (SAF). SAF has been identified as an independent risk factor for cardiovascular events (CVE) and all-cause mortality (ACM) in the general population, persons with diabetes or on dialysis but data at earlier stages of CKD are inconclusive. We sought to investigate SAF as a risk factor for CVE and ACM in a prospective study of persons with CKD stage 3.

Methods: Participants with CKD stage 3 were recruited from primary care and assessed at baseline, 1 and 5 years. At each visit, SAF was measured using an AGE reader (DiagnOptics), alongside biochemical and biometric data. Data on subsequent hospital admissions with CVE (fatal and non-fatal myocardial infarction and stroke, transient ischemic attack, cardiac failure, peripheral vascular event and revascularisation; based on ICD-10 coding) and deaths were obtained from NHS Digital. Cox proportional hazards models were used to investigate determinants of CVE and ACM.

Results: 1,707 participants had measurements of SAF at baseline; mean age 72.9±9.0y, mean eGFR 53.5±11.9ml/min/1.73m^2, mean SAF 2.7±0.6 arbitrary units. We observed 319 deaths and 590 CVE during mean 5.1±2.2 years of follow-up. After multivariable analysis we identified SAF at baseline as an independent risk factor for CVE (HR 1.13 per standard deviation (SD) increase, 95% CI 1.04 to 1.24, p = 0.006) and ACM (HR 1.17 per SD increase, 95% CI 1.04 to 1.32, p = 0.007). There was no significant change in mean SAF over 5 years but change in SAF over 1 year was independently associated with CVE (HR 1.13 per SD increase, 95% CI 1.03 to 1.23, p=0.01) and ACM (HR 1.24 per SD increase, 95%CI 1.10 to 1.41, p=0.001).

Conclusions: We have identified SAF as an independent risk factor for CVE and ACM in persons with early CKD. These findings suggest that SAF measurements are clinically useful to risk stratify persons with CKD. Further, interventions to reduce AGE accumulation, such as dietary AGE restriction, may reduce cardiovascular risk in CKD but this requires testing in prospective randomised trials.

Continuous Ambulatory Blood Pressure Monitoring: A Viable Option in CKD?

Muna T. Canales,[1,2] Shahab Bozorgmehri,[2] Richard Berry,[3,2] Rebecca Beyth.[4] *[1]Malcom Randall VAMC, Gainesvile, FL; [2]University of Florida, Gainesville, FL; [3]Malcom-Randall VAMC, Gainesville, FL; [4]Dept of VA & Univ. of Florida, Gainesville, FL.*

Background: Traditional cuff-based ambulatory blood pressure monitoring (ABPM) is cumbersome and fragments sleep. Continuous ABPM utilizes a simple pulse oximeter and 2-lead electrocardiogram to calculate blood pressure beat to beat from pulse transit time(PTT). While continuous ABPM overcomes the challenges of traditional ABPM, its validity in CKD—a population with a high burden of vascular disease—is unclear.

Methods: Two separate cohorts (20 Veterans and 20 University hospital-based) were enrolled for this study. Inclusion criteria were: age 18-89, MDRD eGFR 15-44, not on dialysis or transplant. Participants underwent simultaneous 24 hour cuff-ABPM (Spacelabs) and PTT-ABPM (Somnomedics). We determined the correlation between 24-hour blood pressure for cuff and PTT-ABPM. We used McNemar's test for correlated proportions to assess the degree of concordance between cuff and PTT-ABPM to determine dipping status (p<0.05 suggests lack of concordance).

Results: Among Veterans, mean age(SD) was 76(9) years, 95% male, mean BMI 31(5) kg/m^2, 95% hypertensive, 60% diabetic and 5% with peripheral vascular disease(PVD). At the University site, mean age(SD) was 67(11) years, 50% male, mean BMI 31(8) kg/m^2, 85% were hypertensive and 35% diabetic. None had PVD. The table below shows, by method, the average number of blood pressure readings, mean 24-hour blood pressure and the correlation between cuff and PTT-ABPM. Among Veterans, there was concordance with systolic dipping(McNemar's p 0.10) but not diastolic dipping(p=0.02). Among University participants, concordance was not observed for diastolic dipping(p=0.02) and the test could not be performed for systolic dipping as none of the PTT-ABPM had dipping though 8 were dippers by cuff-ABPM.

Conclusions: Among Veterans with CKD, PTT-ABPM correlates reliably with cuff ABPM for overall and systolic blood pressure as well as systolic dipping status. Among University CKD patients, PTT-ABPM does not correlate well with cuff-ABPM. Additional validation studies with larger sample sizes are required to confirm our findings.

Association of Low-Density Lipoprotein Cholesterol and Atherosclerotic CVD and Non-Atherosclerotic CVD Hospitalization Rate Across CKD Stages in 2 Million US Veterans

Jui-Ting Hsiung,[1] Melissa Soohoo,[1] Christina Park,[1] Maria V. Marroquin,[1] Hamid Moradi,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: A prior study has demonstrated that risk of myocardial infarction decreased with higher low-density lipoprotein cholesterol (LDL) levels across worsening estimated glomerular filtration rate (eGFR) category. It was postulated that this attenuated risk with progressing chronic kidney disease (CKD) may be attributed to competing risk of non-atherosclerotic cardiovascular disease events (ASCVD).

Methods: In 1,969,797 US veterans with a serum LDL between 2004 and 2006, associations between LDL and ASCVD and non-ASCVD hospitalizations were estimated using Poisson models adjusted for demographics, comorbid conditions, smoking status, use of statins and non-statins, body mass index and albumin across eGFR category (CKD stage).

Results: The cohort consists of 5% female, 14% African American, 19% diabetic, 32% statin-users, and 44% current smokers, with a mean patient age of 64±14 years. The median [IQR] of serum LDL level and eGFR were 103[81,128] mg/dL and 75[60,91] mL/min/1.73m2, respectively. Patients with higher LDL (>100 mg/dL) had an incrementally higher risk of ASCVD hospitalization rate across all CKD stages compared to the reference (LDL 70-<100 mg/dL); however, associations attenuated with higher CKD stage. Patients with low LDL (<70 mg/dL) had a higher risk of non-ASCVD hospitalization rate across all CKD stages. Patients with LDL≥190 mg/dL also had a higher non-ASCVD hospitalization risk across all CKD stages, except CKD stage 5. Risk of non-ASCVD hospitalization with higher LDL increased between non-CKD to CKD stage 4.

Conclusions: In US veterans, higher LDL level was associated with both higher ASCVD and non-ASCVD hospitalization rate across all CKD stages. The magnitude of association with high LDL for ASCVD events increased across worsening CKD stage, and decreased for non-ASCVD events. Further studies are need to understand why elevated LDL may be associated with higher risk of non-ASCVD events compared to risk of ASCVD events in chronic kidney disease.

FR-PO268

Dietary Protein Intake and Outcomes in Patients with CKD

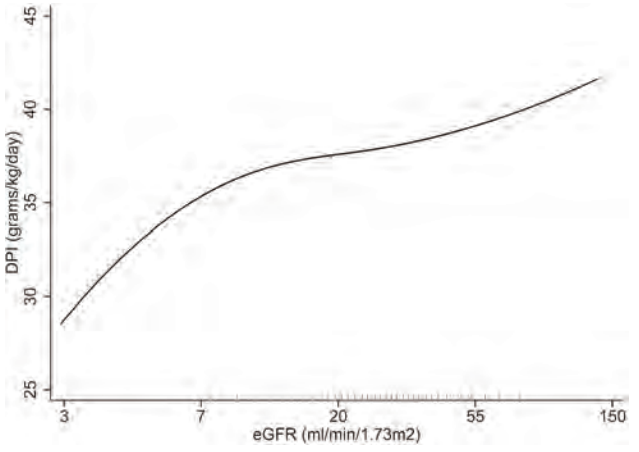
Hisham N. Abu Farsak,[1] Abhishek J. Patel,[1] Jawed Akhtar,[1] Mahmoud A. Mahmoud,[3] Keiichi Sumida,[1] Miklos Z. Molnar,[1] Barry M. Wall,[2] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Veterans Affairs Medical Center, Memphis, TN; [3]University of Teneessee Health Science Center, Memphis, TN.*

Background: Protein energy wasting is common in patients with CKD, but the trajectory of dietary protein intake (DPI) in patients with worsening CKD and the outcomes associated with DPI in this population are unclear.

Methods: We performed repeated collections of spot urine for the measurement of urine urea nitrogen and creatinine in 605 patients with non-dialysis dependent CKD followed at a single institution. We used the urine urea nitrogen-to-creatinine ratio to estimate daily excretion of urea nitrogen, and the Maroni formula to estimate dietary protein intake (DPI). We examined the association of DPI with estimated GFR using mixed effect models and penalized splines, and the association of baseline DPI with all-cause mortality and ESRD in multivariable adjusted Cox models with adjustment for demographic characteristics, smoking status, eGFR and comorbidities.

Results: Patients were 66±11 years old, 97% were men and 37% were African American. The baseline eGFR was 37±20 ml/min/1.73m^2, 210 patients died (mortality rate, 95%CI: 113/1000PY, 98-129) and 121 patients developed ESRD (65/1000PY, 57-78) over a median follow-up of 3.8 years. Patients underwent a median of 7 urine collections (range: 1-16). Lower eGFR was associated with a linear decrease in DPI (0.92 gm/kgBW/day lower DPI for every 15 ml/min/1.73m^2 lower eGFR, 95%CI: 0.38-1.46, p=0.001), with a steeper decline below an eGFR of ~20 ml/min/1.73m^2 (Figure). Higher baseline DPI was associated with higher mortality (adjusted hazard ratio associated with 1 gm/kgBW/day higher DPI, 95%CI: 1.015, 1.002-1.028, p=0.021) and higher ESRD risk (1.023, 1.006-1.041, p=0.009).

Conclusions: In patients with moderate to advanced CKD, DPI declines with progressive loss of kidney function, and higher DPI is associated with increased risk of all-cause mortality and ESRD.



FR-PO269

Insulin Sensitivity and Systemic Inflammation Are Potential Mediators of the Association Between Serum Uromodulin and Arterial Stiffness Among Nondiabetic Patients with CKD

Elvis A. Akwo,[2] Aseel Alsouqi,[2] Serpil muge Deger,[4] Edward D. Siew,[3] Talat Alp Ikizler,[2] Adriana Hung.[1] *[1]VA & Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University School of Medicine, Nashville, TN; [4]Vanderbilt University Faculty of Medicine Department of Nephrology, Nashville, TN.*

Background: Patients with chronic kidney disease (CKD) have an elevated risk of premature death due to cardiovascular disease (CVD) beyond what is predicted by traditional CVD risk factors. Serum uromodulin (sUmod) is a potential non-traditional CVD risk factor. The relationship between sUmod and subclinical CVD is not well described. We investigated the relationship between sUmod and aortic pulse wave velocity (PWV).

Methods: Participants included 73 CKD and 116 normal GFR patients who underwent a comprehensive clinical assessment including PWV measurement (via applanation tonometry) and clamp-derived insulin sensitivity index (ISI). Biomarkers included sUmod, creatinine-based eGFR and high sensitivity C-reactive peptide (hsCRP). Sequential linear models with robust standard errors were used to examine the relationship between sUmod and PWV and perform mediation analyses.

Results: Mean age was 55 (15) years; 45% were female, 34% African American. sUmod had a significant positive correlation with eGFR ($r = 0.65$; $p < 0.01$) and log ISI ($r = 0.27$, $p < 0.01$) and inverse correlations with log hsCRP ($r = -0.27$; $p < 0.01$) and PWV ($r = -0.46$, $p < 0.01$). A one interquartile range lower sUmod was associated with a 1.45 m/s increase (95% CI: 1.02, 1.89; $p < 0.01$) in PWV in the unadjusted model. Adjustment for demographics and mean arterial pressure attenuated the effect estimate [0.42 m/s; 95% CI: 0.05, 0.79; $p = 0.03$]. Additional adjustment for log hsCRP and log ISI further diminished the sUmod effect [0.18 m/s; 95% CI: -0.18, 0.53; $p = 0.3$].

Conclusions: Declining sUmod levels is associated with increased PWV, a subclinical marker of CVD that reflects arterial stiffness. This relationship appears to be mediated, in part, by systemic inflammation and insulin resistance.

Ambulatory Blood Pressure Patterns, Cognitive Function, and Frailty in CKD: Chronic Renal Insufficiency Cohort (CRIC) Study

Lama Ghazi,[1] Kristine Yaffe,[2] Manjula Kurella Tamura,[3] Mahboob Rahman,[4] Chi-yuan Hsu,[5] Amanda H. Anderson,[6] Jordana B. Cohen,[7] Michael J. Fischer,[8] Edgar R. Miller,[9] Sankar D. Navaneethan,[10] Jiang He,[11] Matthew R. Weir,[12] Raymond R. Townsend,[7] Debbie L. Cohen,[7] Harold I. Feldman,[13] Paul E. Drawz.[1] *[1]University of Minnesota, Saint Paul, MN; [2]UCSF, San Francisco, CA; [3]Stanford University, Palo Alto, CA; [4]Case Western Reserve University, Cleveland, OH; [5]University of California San Francisco, San Francisco, CA; [6]Tulane University, New Orleans, LA; [7]University of Pennsylvania School of Medicine, Philadelphia, PA; [8]University of Illinois Hospital and Health Sciences Center, Chicago, IL; [9]Johns Hopkins University, Baltimore, MD; [10]Baylor College of Medicine, Sugar Land, TX; [11]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [12]University of Maryland School of Medicine, Baltimore, MD; [13]University of Pennsylvania, Philadelphia, PA.*

Background: Hypertension (HTN) is highly prevalent in patients with chronic kidney disease (CKD) as is the risk of cognitive impairment and frailty. Our objective was to determine the association between ambulatory blood pressure (BP) patterns, cognitive impairment and frailty among patients with CKD.

Methods: We performed ambulatory BP monitoring (ABPM) on 1502 participants enrolled in CRIC. We evaluated the following exposures: 1) BP patterns: white-coat, masked, sustained HTN vs. controlled HTN and 2) dipping patterns: reverse, extreme, non dippers vs. normal dippers. Our outcomes included: 1) cognitive impairment: modified mini-mental status (3MS) score <85 for participants <65yrs, score <80 for 65-79 yrs and score <75 for >80yrs and 2) frailty: defined as meeting ≥3 of the following criteria - slow gait speed, muscle weakness, low physical activity, exhaustion and unintentional weight loss. Both outcomes were assessed at the time of ABPM and annually thereafter. Logistic regression models were used to assess the cross-sectional relationship between BP or dipping patterns and cognitive impairment and frailty. For longitudinal analysis, Cox discrete models were used.

Results: Mean age of the participants was 63 yrs, 56% were male, and 39% were Black. 9%(n=129) had cognitive impairment and 18%(n=275) were frail at the time of ABPM. After multivariable adjustment, there was no association between any BP or dipping patterns and prevalent cognitive impairment or frailty. 629 participants had incident frailty and 255 had incident cognitive impairment over a median follow up of 3 yrs. After adjustment, participants with white-coat HTN had 0.6 times the risk of incident frailty compared to controlled HTN [95%CI: 0.4, 0.9]. Participants with reverse dipping had marginally greater incident cognitive impairment compared to normal dippers (HR=1.5, 95% CI: 1, 2.3).

Conclusions: CKD patients with white-coat HTN have lower rates of incident frailty compared to controlled HTN. There was no consistent association between BP or dipping patterns and incident or prevalent cognitive impairment or prevalent frailty.

FR-PO271

Association Between Endogenous Sex Hormones and Kidney Function: Cross-Sectional Findings from the Hispanic Community Health Study/ Study of Latinos (HCHS/SOL)

Jessica M. Madrigal, Ana C. Ricardo, Mary Turyk, Robert Sargis, Sally Freels, James P. Lash, Victoria Persky, Martha L. Daviglus. *University of Illinois at Chicago, Chicago, IL.*

Background: The prevalence of end-stage renal disease is higher in males than females, despite the higher prevalence of chronic kidney disease (CKD) among females, suggesting that men are at higher risk of CKD progression. Sex steroid hormones have been proposed as a potential mechanism for these disparities. Few studies have examined the associations between endogenous sex hormone and kidney function.

Methods: We evaluated the cross-sectional associations between serum levels of endogenous sex hormones (luteinizing hormone (LH), follicle stimulating hormone (FSH), sex-hormone binding globulin (SHBG), dehydroepiandrosterone sulfate (DHEAS), estradiol, and testosterone) and measures of kidney function among participants in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) Persistent Organic Pollutants, Endogenous Hormones and Diabetes in Latinos Ancillary Study. The ancillary study inclusion criteria selected male and post-menopausal female participants with normal glucose or prediabetes at baseline. Sex-stratified survey-weighted linear regression models were used to examine if ranked quartile hormone concentrations were associated with estimated glomerular filtration rate (eGFR) and urinary albumin-creatinine ratio (UACR), after adjusting for age, ethnicity, body mass index, systolic blood pressure, and fasting blood glucose.

Results: The study included 1,854 participants (mean age 55 years, 33% post-menopausal female, 52% prediabetic, geometric mean UACR 7.8 mg/g, and mean eGFR 93 ml/min/1.73 m^2). Among females, LH and FSH were inversely associated with eGFR (β for highest versus lowest LH quartile= -8.7, 95% CI -13.9, -3.5, $p=0.001$; β for highest versus lowest FSH quartile= -12.4, 95% CI -19.0, -5.7, $p=0.0003$). Among males, LH was inversely associated with eGFR (β for highest versus lowest LH quartile= -5.5, 95% CI -9.4, -1.5, $p=0.01$), and LH and FSH were positively associated with UACR.

Conclusions: In our diverse subsample of Hispanics/Latinos that did not have diabetes, we observed associations of LH and FSH with kidney function measurements, after adjustment for multiple CKD risk factors. Our findings suggest that these gonadotropins may play a role in CKD.

Vitamin D Replacement Improves Renal Function, Hemodynamics, and Inflammatory and Morphological Parameters in Vitamin D-Deficient Rats After Renal Ischemia-Reperfusion Injury

Ana Carolina de Braganca, Rildo A. Volpini, Daniele Canale, Maria H. Shimizu, Janaina G. Goncalves, Antonio C. Seguro, Michele S. Santos. *Faculty of Medicine - University of Sao Paulo, São Paulo, Brazil*.

Background: The initial damage after an ischemia/reperfusion injury (IRI) plays an important role in the pathogenesis of acute kidney injury (AKI) and predisposition to CKD. Vitamin D deficiency (VDD) is associated with hemodynamic changes, activation of inflammatory pathaways and renal disease progression following IRI-AKI. Conversely, vitamin D sufficiency may be considered a protective factor. We evaluated the effect of vitamin D replacement (VR) in IRI rats under VDD.

Methods: We performed bilateral 45 min IRI on day 30 in all groups. Male Wistar rats were randomized into three groups: **(1) IRI** [fed a standard diet (SD) for 120 days]; **(2) VDD+IRI** [fed a vitamin D-free diet (D) for 120 days]; and **(3) VDD+IRI+R (**fed a D diet for 30 days and just after IRI, on day 31, we reintroduced the SD). We evaluated inulin clearance (Cin); mean arterial pressure (MAP); renal blood flow (RBF); renal vascular resistance (RVR); proteinuria; plasma levels of 25(OH)D and aldosterone as well as renal tissue levels of collagen 3 (COL3) and MCP1 by ELISA; and immunoblotted for VDR.

Results: VDD+IRI+R animals had 25(OH)D levels restored (~42 ng/mL). VR improved renal function and hemodynamic parameters. Also, decreased proteinuria and the amount of MCP1 and COL3 in renal tissue (Table 1).

Conclusions: Our study suggests that VR improved the recovery of renal fuction, hemodynamics, inflammatory and morphologycal features in IRI-AKI associated with VDD. Thus, vitamin D monitoring and replacement should be considered in renal patients.

FR-PO273

Association of Body Mass Index and Clinical Outcomes of Advanced CKD in T2DM: A Population-Based Analysis from the National Health Security System

Manoch Rattanasompattikul,[1] Sukit Raksasuk,[2] Moltira Promkan,[3] Sumana Masoodi,[3] Kanyaphak Ngerninta,[1] Nuttawut Rongkiettechakorn,[1] Aungkura Supokawej.[3] *[1]Golden Jubilee Medical Center, Faculty of Medicine Siriraj Hospital, Mahidol University, Nakhon Pathom, Thailand; [2]Medicine Department, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [3]Faculty of Medical Technology, Mahidol University, Salaya, Phutthamonthon, Thailand.*

Background: The reversal of the obesity–mortality association has been very robust in patients with end-stage renal disease, but a limited number of studies show conflicting results in patients with non-dialysis-dependent chronic kidney disease (NDD-CKD). Several earlier studies found that the association of body mass index (BMI) with CKD is not straightforward in patients with type 2 diabetes mellitus (T2DM). The relationship of obesity with CKD has not been fully explored in Asian populations.

Methods: This study evaluated patients aged ≥18 years with T2DM obtained from the largest database of the National Health Security System (NHS) of Thailand from 2011to 2014. We aimed to determine the apparent optimum BMI range based on the World Health Organization's (WHO) criteria concerning the risk of advanced CKD (stages G4 and G5).

Results: With regard to the 27,392 patients, 62% were female, 3% had CKD stage G4 and 1% had CKD stage G5. The mean (±SD) age of the patients was 64±12years old. Mean BMI was 24.9±4.5 kg/m^2. The prevalence of having advanced CKD by BMI groups wasBMI (15–20 kg/m^2) 6.5%, BMI (20–25 kg/m^2) 4.3% (as reference), BMI (25–30 kg/m^2) 3.1%, and BMI (>30 kg/m^2) 2.6%. The multivariate analysis identified the odds ratio (OR) of BMI (adjusted OR; 95% confidence interval [CI]; *P*-value) as an independent risk factor for advanced CKD as 1.39; 1.15–1.6; 0.001, 0.8; 0.67–0.94; 0.008, and 0.75; 0.58–0.97; 0.03, respectively (**Figure 1**).

Conclusions: Patients with advanced CKD in public healthcare practices have strikingly higher rates of low BMI. The negative association of BMI with CKD could reflect reverse causality. This is the first epidemiological paradox that may of concern and be reported in a Southeastern Asian population.

Funding: Government Support - Non-U.S.

FR-PO274

Metabolic Acidosis Is an Independent Predictor of Adverse Renal Outcomes and Higher Costs in Patients with CKD

Nancy L. Reaven,[1] Susan E. Funk,[1] Vandana S. Mathur,[2] Navdeep Tangri.[3] *[1]Strategic Health Resources, La Cañada Flintridge, CA; [2]Mathur Consulting, Woodside, CA; [3]University of Manitoba, Winnipeg, MB, Canada*.

Background: Metabolic acidosis (MA) is a risk factor for chronic kidney disease (CKD) progression, but less is known about its effect on health care costs and resource utilization. We describe the association between MA, adverse renal outcomes and costs in non-dialysis patients with CKD stages 3-5.

Methods: De-identified medical records (Optum® EMR), 2007–2017 were used to identify non-dialysis CKD patients with ≥2 serum bicarbonate test values 28–365 days apart, ≥3 eGFR values >10 and <60 mL/min/1.73m^2 and ≥2 years of post-index data or death. Patients were followed for 2 years for the composite outcome (DD40) of death, dialysis, renal transplant, or eGFR decline ≥40%. Metabolic acidosis and normal serum bicarbonate groups were defined by 2 serum bicarbonate values between 12 and <22 mEq/L and 22–29 mEq/L, respectively. General linear regression models in a subset of patients with linked medical claims established predicted costs, which were applied to the larger EMR population based on demographic and clinical factors. Logistic and generalized linear regression models assessed serum bicarbonate as a predictor of DD40 outcomes and costs (log) respectively, controlling for age, sex, race, eGFR, log albumin-to-creatinine ratio, diabetes, hypertension, heart failure, and Charlson comorbidity score.

Results: 51,558 patients qualified for this longitudinal observational study. Compared to patients with normal serum bicarbonate, patients with MA experienced CKD progression at much higher rates, (DD40 rates 48% vs. 17%, p<0.0001) and significantly higher per patient per year costs, ($65,152 vs. $24,681, p<0.0001). This pattern was consistent across all stages of CKD, except stage 5. Serum bicarbonate independently predicted DD40 events and costs; odds ratio of CKD progression (DD40) for each 1 mEq/L increase in serum bicarbonate was 0.87, (CI: 0.866-0.879); parameter estimate -0.076 (p<0.0001) for costs.

Conclusions: In this analysis of >51,000 non-dialysis CKD patients followed for two years, patients with metabolic acidosis had higher rates of adverse renal outcomes and higher costs compared to patients with normal serum bicarbonate. Each 1 mEq/L increase in serum bicarbonate was associated with a 13% decrease in 2-year DD40 events and a 7% decrease in monthly costs.

FR-PO275

Association of Total CO2 Levels with Albuminuria Progression in Patients with CKD: Results from the KNOW CKD Cohort

Kipyo Kim, Yongjin Yi, Jong Cheol Jeong, Sejoong Kim, Ho Jun Chin, Ki Young Na, Dong-Wan Chae. *Seoul National University Bundang Hospital, Gyeonggi-do, Republic of Korea*.

Background: Metabolic acidosis is a common manifestation of CKD and contributes to various adverse effects. Although previous animal studies demonstrated that dietary acid induces an increase in proteinuria, the association between total CO2 and albuminuria progression have not extensively investigated in clinical studies. We aimed to identify the relationship between total CO2 levels and albuminuria progression in a multicenter prospective cohort.

Methods: A total of 503 patients with at least two urinary albumin-to-creatinine ratios (UACR) measurements 1 year apart and no change in the dose of ACEi/ARB were enrolled. Participants were divided into the quartiles based on the time-averaged total CO2 levels during the 1-year follow-up; Q1(<24.7 mmol/L), Q2 (24.7-26.6 mmol/L), Q3 (26.7-28.5 mmol/L), and Q4(>28.6 mmol/L). We examined the albuminuria progression which is defined as A1 (<30 mg/g Cr) to A2 (30-300 mg/g Cr), A2 to A3 (>300mg/g Cr), and A1 to A3 according to the quartiles of total CO2.

Results: At baseline, 159 patients had A1 albuminuria, and 344 patients had A2 albuminuria. After 1 year follow-up, 96 patients revealed albuminuria progression; 26 from A1 to A2, 62 from A2 to A3, and 4 from A1 to A3. The percentage of subjects

with albuminuria progression was higher in upper quartiles (P for trends <0.001). In multivariable logistic regression, the highest quartile of total CO2 was also significantly less likely associated with albuminuria progression compared with the lowest quartile (adjusted OR 0.31; 95% CI 0.13-0.77). In addition, multivariable linear regression using total CO2 as a continuous variable and UACR fold change also showed significant negative associations (β=-0.22, *P*=0.009).

Conclusions: In patients with CKD, total CO2 levels were independently associated with albuminuria progression over the 1-year interval. These results may suggest that high total CO2 levels could have beneficial effects on proteinuria progression in CKD patients even within the normal range of total CO2 levels.

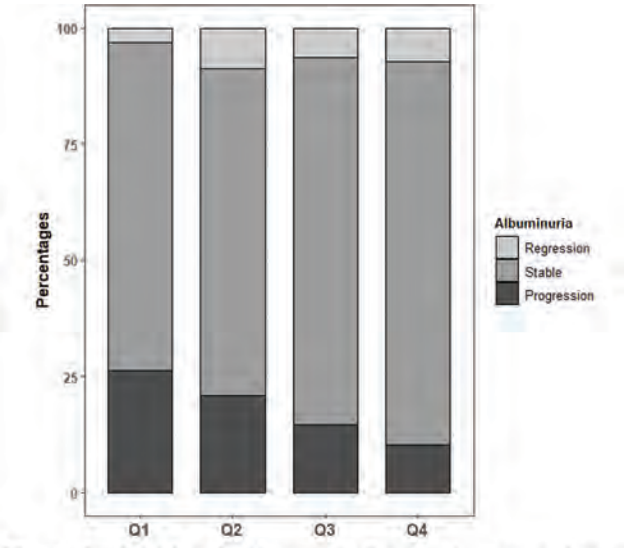

Figure 1. A higher incidence of albuminuria progression is associated with lower quartiles of total CO2 levels in patients with CKD. Q1 < 24.67 mEq/L, Q2=24.67-26.67 mEq/L, Q3=26.67-28.05 mEq/L, Q4>28.05 mEq/L.

Interaction Between Alcohol Intake and Diabetes in Relation to the Risk of ESRD in the Singapore Chinese Health Study

Tingting Geng,[1] Tazeen H. Jafar,[4] Jian-Min Yuan,[2] Woon-Puay Koh.[3] *[1]National University of Singapore, Singapore, Singapore; [2]University of Pittsburgh, Pittsburgh, PA; [3]Duke-NUS Medical School, Singapore, Singapore; [4]Duke-NUS Graduate Medical School, Singapore, Singapore*.

Background: The relationship between alcohol intake and risk of end-stage renal disease (ESRD) is controversial. Moreover, whether the association is modified by diabetes status is unknown.

Methods: We examined the association between alcohol intake and risk of ESRD in the Singapore Chinese Health Study, a prospective population-based cohort of 63,257 adults aged 45-74 years at recruitment (1993-1998). Information on alcohol intake, diet, medical history and other lifestyle factors was collected at recruitment. We identified 1,217 ESRD cases via linkage with National Singapore Renal Registry through 2015. Cox proportional hazards regression method was used to estimate hazard ratios (HRs) and 95% confidence interval (CI) of ESRD in relation to alcohol intake by diabetes status over an average 17.5 years of follow-up.

Results: Among the participants without diabetes at baseline, monthly to weekly alcohol intake was associated with a decreased risk of ESRD (HR 0.69, 95 % CI 0.55-0.88) compared to the non-drinkers, whereas the reduced risk was no longer significant among the participants with diabetes ($P_{interaction}$=0.21). Comparatively, alcohol intake with ≥2 drinks/day was significantly associated with an increased risk of ESRD compared to the abstainers among the diabetic patients (HR 2.12, 95% CI 1.19-3.78) but not associated with the risk among those without diabetes ($P_{interaction}$=0.02). Presence of heavy alcohol drinking and diabetes was associated with a 12-fold increased risk of ESRD compared with the absence of both factors (HR 12.0, 95% CI 7.00-20.7).

Conclusions: In conclusion, low-dose alcohol intake may have potential renal protective effect among individuals without diabetes. However, alcohol intake with ≥2 drinks/day could act synergistically with diabetes in increasing ESRD risk.

Progression of Diabetic Retinopathy and Declining Renal Function in Patients with Type 2 Diabetes

Ajin Cho,[1] Jung-woo Noh,[2] Juhee Kim.[3] *[1]Hallym university Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [2]Chun & Cho's Medical Clinic & Dialysis Center, Seoul, Republic of Korea; [3]Department of Internal Medicine-Nephrology, Gangnam Sacred Heart Hospital, Korea, Republic of, Seoul, Republic of Korea*.

Background: Diabetes mellitus (DM) causes microvascular complications that are major causes of morbidity and mortality. Diabetic retinopathy (DR) is an important microvascular complication and is the most common cause of preventable blindness in adults. Diabetic nephropathy is a leading cause of chronic kidney disease (CKD). The retina and the kidney share similar microvascular complications resulting from DM. Although many cross-sectional studies have reported associations between renal function and prevalent DR, this might be the result of enrolling patients with long disease durations. Therefore in this study, we investigated how declining renal function affects on DR progression of patients with type 2 diabetes and whether patients with decreased renal function need evaluation of DR status.

Methods: We enrolled 1527 patients with type 2 diabetes from the diabetes clinic in the Department of Endocrinology of Kangnam Sacred Heart Hospital who underwent fundus photographic examinations for DR and whose renal profiles were studied between August 2006 and February 2014. The presence of DR was assessed by an expert ophthalmologist using dilated fundoscopy. Patients were classified into the following categories: (1) normal: no apparent sign of DR; (2) non-proliferative DR (NPDR); (3) proliferative DR (PDR) according to the Global Diabetic Retinopathy Project Group. The presence and severity of DR in a participant were determined based on the eye showing the worst retinopathy. DR progression was defined as a change either from no DR progress to NPDR or from NPDR to PDR.

Results: The baseline prevalence of non-proliferative DR (NPDR) and proliferative DR (PDR) was 26.5% and 14.7%, respectively. The mean period for follow-up fundus exams was 4.0 ± 2.0 years. Among 1303 patients with no DR and NPDR, 134 (10.3%) patients progressed to NPDR or PDR. The progression group had longer duration of diabetes, higher fasting plasma glucose, higher HbA1c and a higher rate of > 20% decline in eGFR during the follow-up period. After multivariate analysis, > 20% decline in eGFR was an independent risk factor for progression of DR in patients with NPDR.

Conclusions: Decrease of renal function was associated with progression of DR, especially in patients with NPDR. This result supports the notion that an individualized screening schedule according to the individual patient's risk might be needed.

FR-PO278

Prevalence and Prognostic Significance of Systolic Orthostatic Hypotension in CKD

Mohamed Rouabhi,[1] Sadeer Al-Kindi,[1] Raymond R. Townsend,[2] Jordana B. Cohen,[2] Mahboob Rahman.[1] *[1]Case Western Reserve University, Cleveland, OH; [2]University of Pennsylvania School of Medicine, Villanova, PA.*

Background: The prevalence of orthostatic hypotension (OH) and its prognostic significance is not well known in patients with chronic kidney disease (CKD). The aim of this study is to determine the prevalence and clinical factors associated with OH, and whether it is associated with risk of adverse kidney or cardiovascular outcomes in patients with CKD.

Methods: Data from the Chronic Renal Insufficiency Cohort study, a multi-center prospective study of subjects with mild to moderate CKD, were used. OH was defined as ≥20 mmHg decrease in systolic blood pressure in the standing compared to the seated position. Multi-variable logistic regression analyses were performed to identify factors associated with OH. Cox regression analyses were performed to examine the association between OH and renal outcomes (composite of end-stage renal disease [ESRD] and/or 50% decline in GFR), ischemic cardiovascular disease (CVD; composite of myocardial infarction, stroke, or peripheral artery disease), heart failure (HF) and all-cause mortality.

Results: The mean age of the study population (n=3873) was 58.2 (±11 SD) years, and mean estimated GFR was 42.9 ml/min/1.73m^2 (±13.5); 48.0% had diabetes. OH was present in 180 (6.9%) patients. In adjusted cross-sectional analyses, Hispanic ethnicity (odds ratio (OR): 1.75, 95% CI: [1.11,2.76]), diabetes (OR: 2.04, 95% CI: [1.37,3.06]), lower body mass index (OR: 0.92, 95% CI: [0.89,0.94] per 1 kg/m^2), elevated total cholesterol (OR: 1.01, 95% CI: [1.00,1.01] per 1 mg/dL), and beta-receptor blocker use (OR: 1.51, 95% CI: [1.05,2.2]) were associated with OH. After a median follow up of 8 years, models adjusted for demographic and clinical factors demonstrated that OH was independently associated with higher risk of renal outcomes (hazard ratio [HR]: 1.40, 95% CI: 1.10,1.78), but not ischemic CVD (HR: 1.18, 95% CI: 0.82,1.69), HF (HR: 1.37, 95% CI: 0.93,2.02) or all-cause mortality (HR: 1.00, 95% CI: 0.73,1.37).

Conclusions: Systolic OH was seen in 6.9% of participants in this study population with mild-moderate CKD. Several clinical and demographic factors were associated with higher prevalence of OH. The presence of OH was independently associated with higher risk of adverse renal outcomes, but not ischemic CVD, HF or mortality.

FR-PO279

Association of Pre-Diabetes with CKD Progression and Adverse Cardiovascular Outcomes in Patients with CKD in the Chronic Renal Insufficiency Cohort (CRIC) Study

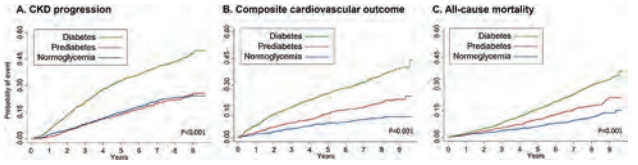
Simon Correa,[1,2] João Sérgio Neves,[3,4] Rute Baeta Baptista,[6] Miguel Bigotte Vieira,[5] Sushrut S. Waikar,[1,2] Finnian R. McCausland.[1,2] *[1]Division of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Department of Endocrinology, Diabetes and Metabolism, São João Hospital, Porto, Portugal; [4]Facultade de Medicina, Universidade do Porto, Porto, Portugal; [5]Centro Hospitalar Lisboa Norte, Lisbon, Portugal; [6]Centro Hospitalar de Lisboa Central, Lisbon, Portugal.*

Background: Despite our understanding of diabetes (DM) as an established risk factor for renal and cardiac complications in CKD, the prognostic significance of prediabetes in this population remains largely unknown. We aimed to evaluate the association of prediabetes with CKD progression, adverse cardiovascular events and all-cause mortality in patients with CKD.

Methods: Participants of the Chronic Renal Insufficiency Cohort (CRIC) were categorized as having normoglycemia, prediabetes or DM according to fasting plasma glucose, HbA1c and treatment with anti-diabetic drugs at baseline. Adjusted Cox proportional hazards models (clinical variables, eGFR, 24-h urine protein, hematocrit and serum albumin) were fit to estimate the association of prediabetes and DM (versus normoglycemia) with CKD progression (development of ESRD or 50% decline in eGFR to ≤15 ml/min/1.73 m^2), a composite cardiovascular outcome (congestive heart failure, myocardial infarction or stroke) and all-cause mortality.

Results: Of the 3,701 individuals analyzed, 945 were classified as normoglycemic, 847 had prediabetes and 1909 had DM. Median follow-up was 7.5 years. While prediabetes was not associated with the risk of CKD progression (HRadj 0.96, 95% CI 0.76-1.21), it was associated with a 39% higher risk of the composite cardiovascular outcome (HRadj 1.39, 95% CI 1.06-1.83) (Figure 1) and a trend towards an increased risk of all-cause mortality (HRadj 1.28, 95% CI 0.99-1.67). Patients with DM had an increased risk of CKD progression (HRadj 1.38, 95% CI 1.12-1.70), composite cardiovascular outcome (HRadj 1.65, 95% CI 1.28-2.13) and all-cause mortality (HRadj 1.55, 95% CI 1.21-1.97).

Conclusions: In patient with CKD, prediabetes was not associated with CKD progression but was associated with an increased risk of adverse cardiovascular outcomes.



Kaplan-Meier curves for chronic kidney disease progression (A), composite cardiovascular outcome (B) and all-cause mortality (C) in participants with normoglycemia, prediabetes or diabetes.

FR-PO280

Association of Serum Triglycerides and Mortality Across Albuminuria Stages Among US Veterans

Melissa Soohoo,[1] Jui-Ting Hsiung,[1] Christina Park,[1] Maria V. Marroquin,[1] Hamid Moradi,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Elevated serum triglycerides (TG) are a risk factor for mortality in the general population, however the relationship is less clear among chronic kidney disease (CKD) patients. Prior studies have evaluated the relationship of TG with mortality in CKD with estimated glomerular filtration rate (eGFR). However, data is lacking on how albuminuria, or urinary albumin-creatinine ratio (UACR), may impact the TG-mortality association.

Methods: Our cohort comprised 994,338 US veterans with a TG measurement between 2004-2006 and were followed until 2014. Albuminuria or UACR prior to TG measurement were extracted either as a calculated ratio, or via dipstick methods. We used Cox proportional hazard models with adjustments for demographics, comorbidities, body mass index and albumin levels to evaluate the association of TG with all-cause and cardiovascular (CV) mortality stratified by UACR groups.

Results: Mean (±SD) cohort age was 63±14 years old, with a median [IQR] TG of 128[87,192] mg/dL. A majority of patients had low levels of UACR <30 mg/g, whereas 2% had high levels of UACR >300 mg/g. The proportion of patients with UACR>300 mg/g increased with increasing TG. We observed a slight U-shaped association between TG and all-cause and CV mortality, among UACR <30 mg/g and UACR 30-300 mg/g stages. In particular, high TG ≥240 mg/dL were associated with the highest risk of CV mortality compared to TG 120-<160 mg/dL among those with UACR<30 mg/g [HR [95%CI]: 1.17[1.14, 1.20]]. These associations were incrementally lower for UACR 30-300 mg/g. Among UACR >300 mg/g patients, higher TG was associated with an even lower to null relationship with CV mortality. For low TG <80 mg/dL mortality risk estimates were higher for higher UACR stages, particularly for all-cause mortality.

Conclusions: We observed a U-shaped association between TG with all-cause and CV mortality among patients with UACR ≤300 mg/g, while TG-CV mortality associations for UACR>300 were weaker. Further studies are needed to evaluate how albuminuria may impact cardiovascular risk with elevated TG.

Trends of Obstructive Sleep Apnea (OSA) Among US Veterans with and Without CKD

Monica Shieu,[1] Diane Steffick,[1] Hal Morgenstern,[1] Kara Zivin,[4] Delphine S. Tuot,[2] Neil R. Powe,[3] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of California, San Francisco, San Francisco, CA; [3]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA; [4]University of Michigan and Department of Veterans Affairs, Ann Arbor, MI.*

Background: Increasing attention has been paid to sleep problems among patients with CKD. OSA is one of the most common sleep-breathing disorders but is often under-recognized, particularly among persons with CKD. We examined trends in OSA by CKD status over the past ten years.

Methods: The study population were outpatients and inpatients in the Veterans Health Administration from FY2009-18, who were alive at the end of each fiscal year and aged >18 at the start of that year. Crude 1-year period prevalence (PP) of OSA was computed as the number of OSA cases identified from medical records in that year, divided by the number of persons in the study population that year. CKD was defined by at least one of 3 criteria: 1) a diagnostic ICD-9/10-CM code for CKD, 2) estimated glomerular filtration rate <60 ml/min/1.73m^2, or 3) albumin-to-creatinine ratio >30 mg/g. Two definitions of OSA were used: one based on a single ICD-9-CM or ICD-10-CM code (327.23 or G47.33); and one based on multiple ICD-9/10-CM codes, including CPAP treatment and organic sleep apnea.

Results: Throughout the study period, the 1-year PP of OSA was higher in CKD than non-CKD patients. Using either OSA definition, the PP in both groups increased gradually from FY2009 to FY2015, rose more sharply to FY2016, then increased gradually again to FY2018. The use of multiple ICD codes increased the PP by approximately15% throughout the decade. By FY2018, in patients with CKD, the PP rose to 26.5% using a single ICD code and to 36.8% using multiple codes

Conclusions: The gradual increase in the crude PP of diagnosed OSA in VA patients both with and without CKD may be attributable to the increasing incidence of OSA due to changes in OSA risk factors such as obesity and comorbidities, and likely to the increased detection of OSA due to greater awareness of the condition. The sudden increase in OSA PP in FY2015-16 probably resulted from the switch from ICD-9-CM to ICD-10-CM coding. Further studies are needed to document and explain OSA prevalence trends in veterans and other populations.

The Relationship Between Thyroid Status and Kidney Function Among 24 Million Patients in the National OptumLabs Data Warehouse

Amy S. You,[1] Kamyar Kalantar-Zadeh,[2] John J. Sim,[7] Gregory Brent,[3] Stephan C. Dunning,[4] Csaba P. Kovesdy,[5] Danh V. Nguyen,[1] Connie Rhee.[6] *[1]University of California, Irvine, Orange, CA; [2]University of California Irvine, School of Medicine, Orange, CA; [3]VA Greater Los Angeles Healthcare, Los Angeles, CA; [4]OptumLabs, Eden Prairie, MN; [5]University of Tennessee Health Science Center, Memphis, TN; [6]University of California Irvine, Huntington Beach, CA; [7]Kaiser Permanente Southern California, Los Angeles, CA.*

Background: Experimental data suggest hypothyroidism contributes to the development of chronic kidney disease (CKD) due to alterations in kidney structure and function. We thus examined the relationship between thyroid status defined by serum thyrotropin (TSH) levels with estimated glomerular filtration rates (eGFRs) in a large US cohort.

Methods: We examined the association of thyroid status with kidney function using the OptumLabs® Data Warehouse (OLDW), which contains administrative claims data

including medical claims and eligibility information from a large national US health insurance plan and electronic health record data from a nationwide network of provider groups. In patients who underwent ≥1 TSH and ≥1 eGFR measure(s) within 90-days over 2007-2017, we examined associations between TSH and severe, moderate-to-severe, and moderate kidney dysfunction (eGFR <30, <45, and <60 ml/min/1.73m^2, respectively) using logistic regression.

Results: In 24,103,735 patients who met eligibility criteria, 18.6% had eGFRs consistent with moderate, moderate-to-severe, or severe kidney dysfunction. Incrementally higher TSH levels of >3.0-5.0, >5.0-10.0, and >10.0mIU/L were associated with increasingly higher risk of severe kidney dysfunction (ref: 0.5-3.0mIU/L): adjusted ORs (95%CI) 1.12 (1.11-1.3), 1.63 (1.61-1.64), and 2.14 (2.10-2.18), respectively. Lower TSH levels in the hyperthyroid range (<5.0mIU/L) were also associated with severe kidney dysfunction: adjusted OR (95%CI) 1.82 (1.81-1.84). Sensitivity analyses showed similar findings for moderate-to-severe and moderate kidney dysfunction.

Conclusions: In a nationally representative cohort of patients, both hypo- and hyperthyroidism were associated with kidney dysfunction. Further studies are needed to determine underlying mechanisms, and whether correction of thyroid status improves kidney function in this population.

Development of Malignant Disease Associated with Glomerular Hyperfiltration in Asian Population

Yaerim Kim,[2] Jin hyuk Paek,[2] Woo Yeong Park,[3] Kyubok Jin,[2] Seungyeup Han,[2] Hajeong Lee,[4] Kwon Wook Joo,[1] Yon Su Kim,[4] Dong Ki Kim.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Keimyung University School of Medicine, Daegu, Republic of Korea; [3]Dongsan Medical Center, Daegu, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Renal hyperfiltration (RHF) is associated with all-cause mortality. Herein, we evaluated the association between RHF and the development of malignant diseases, which is the most common cause of mortality.

Methods: We retrospectively reviewed the National Health Insurance Service (NHIS) database for a people who received nationwide health check-up in 2009. The population with age <18 years old, estimated glomerular filtration rate (eGFR) <60ml/min/m^2, presence of history for malignant disease or renal disease was excluded. RHF was defined as eGFR ≥95 percentile with age- and sex-matching. The primary outcome was a risk for development of the malignant diseases. Site-specific malignant disease was categorized according to body systems and organs using ICD-10 diagnostic codes. We used Cox regression analysis to identify relative risk ratio with multiple adjustments using age, sex, body mass index, income, and smoking status.

Results: A total of 1,953,123 examiners were included in this study with 1,853,114 (94.9%) and 100,009 (5.1%) in RHF negative and positive group, respectively. Overall cancer risk was significantly higher in the RHF group (adjusted HR 1.12, 95% CI 1.07-1.16, p <0.0001). Type-specific cancer risk was increased in digestive, stomach, colorectal, liver, uterus and ovary, multiple myeloma, and leukemia in RHF group. In the subgroup analysis according to sex, risks of cancer in digestive, stomach, colorectal, liver, respiratory and lung were higher in male with RHF. On the contrary, digestive, stomach, uterus and ovary, multiple myeloma, and leukemia showed significantly increased risk for female with RHF. After adjusting the variables including age, sex, smoking, drinking, physical activity, economic status, BMI, systolic blood pressure, eGFR, history of hypertension and diabetes, RHF was significantly associated with the development of digestive (aHR 1.12, 95% CI 1.05-1.19, p<0.001), stomach (aHR 1.16, 95% CI 1.05-1.29, p=0.005) and colorectal cancer (aHR 1.16, 95% CI 1.01-1.33, p=0.04).

Conclusions: The cancer risk in digestive organ was increased in an Asian population with RHF. Healthcare providers should consider the RHF could have a relationship with the development of malignant disease, especially in digestive organ.

FR-PO284

Determinants of Extracellular Volume Status in CKD Stage 3-5: A Cross-Sectional Study of Bioimpedance Analysis

Ken Ohara,[1] Takahiro Masuda,[1] Kazutoshi Ono,[1] Takuya Murakami,[1] Izumi Nagayama,[1] Hiromichi Yoshizawa,[1] Atsushi Miki,[1] Mari Okada,[1] Saki Nakagawa,[1] Erika Hishida,[1] Marina Kohara-Miura,[1] Mutsumi Kawamata,[1] Kentaro Oka,[1] Maki Asakura,[1] Miwa Shuto-Kaneko,[1] Hiroaki Kaminaga,[1] Mami Hirata,[1] Yasuharu Miyazawa,[2] Akito Maeshima,[1] Tetsu Akimoto,[1] Osamu Saito,[1] Daisuke Nagata.[1] *[1]Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Japan; [2]Department of Internal Medicine, Nasu-Minami Hospital, Nasukarasuyama, Japan.*

Background: Extracellular volume expansion predicts higher mortality and adverse cardio-renal outcomes in patients with chronic kidney disease (CKD). The higher value of the extracellular water (ECW) to total body water (TBW) ratio (ECW/TBW) measured by bioimpedance analysis (BIA) is a marker of extracellular volume expansion. However, the determinants of the ECW/TBW in CKD stage 3-5 have not yet been fully evaluated.

Methods: One hundred and one non-dialysis CKD patients (stage 3-5) were enrolled in this study. Body fluid volume including intracellular water (ICW), ECW and TBW was measured by bioelectrical impedance analysis device (InBody S10).

Results: Average values are the following: age 63.7±14.5 years, male 61.4%, body mass index (BMI) 24.8±4.7, systolic blood pressure 135±20 mmHg, estimated glomerular filtration rate (eGFR) 33.3±16.4 mL/min/1.73m^2, hemoglobin 11.6±2.3 g/dL, serum albumin 3.4±0.8 g/dL and the ECW/TBW 0.393±0.028 (normal range 0.36-0.39). The ECW/TBW correlated positively with age (r=0.373, p=0.0001), systolic blood pressure (r=0.248, p=0.014), and ECW (r=0.336, p=0.0006), while it correlated negatively with hemoglobin (r=-0.328, p=0.001), eGFR (r=-0.398, p<0.0001) and serum albumin (r=-0.533, p<0.0001). On the other hand, the ECW/TBW was not correlated with BMI (r=0.087, p=0.385), serum Na (r=-0.074, p=0.463), ICW (r=-0.146, p=0.146) and TBW (r=0.056, p=0.581), respectively. A stepwise multiple regression analysis revealed that serum albumin (p<0.0001), age (p=0.0002) and eGFR (p=0.0002) were independent determinants of the ECW/TBW.

Conclusions: Low serum albumin, high age and low eGFR are independently associated with higher extracellular volume status in CKD stage 3-5. Further prospective studies are needed to evaluate the impact of extracellular volume status and these factors on long-term outcomes.

Deoxycholic Acid (DCA) and Coronary Artery Calcification (CAC) in the Chronic Renal Insufficiency Cohort (CRIC)

Anna J. Jovanovich,[1] Xuan Cai,[2] Rebecca Frazier,[3] Joshua D. Bundy,[4] Jiang He,[5] Panduranga S. Rao,[6] Claudia M. Lora,[7] Mirela A. Dobre,[8] Alan S. Go,[9] Tariq Shafi,[10] Harold I. Feldman,[11] Eugene P. Rhee,[12] Michel Chonchol,[13] Makoto Miyazaki,[14] Tamara Isakova.[15] *[1]Denver VA / University of Colorado, Denver, CO; [2]Northwestern University, Chicago, IL; [3]Northwestern, Chicago, IL; [4]Northwestern University Feinberg School of Medicine, Evanston, IL; [5]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [6]University of Michigan Health System, Ann Arbor, MI; [7]University of Illinois at Chicago, Chicago, IL; [8]Case Western Reserve University, Cleveland, OH; [9]Kaiser Permanente Northern California, Oakland, CA; [10]University of Mississippi Medical Center, Jackson, MS; [11]University of Pennsylvania, Philadelphia, PA; [12]Massachusetts General Hospital, Newton, MA; [13]University of Colorado, Aurora, CO; [14]University of Colorado-Denver, Aurora, CO; [15]Feinberg School of Medicine, Northwestern University, Chicago, IL.*

Background: Circulating levels of the secondary bile acid, DCA, are elevated in chronic kidney disease (CKD). In a small cohort of individuals with CKD 3b-4, higher plasma DCA was associated with prevalent CAC. Whether circulating DCA levels are associated with CAC prevalence, incidence, and progression in a large diverse CKD population is unknown.

Methods: We cross-sectionally and longitudinally evaluated the association between fasting serum DCA levels and CAC among 1057 CRIC participants using multivariable-adjusted regression models. CAC was measured in Agatston units at baseline and follow-up.

Results: Mean age was 57±12 years, 47% were female, and 41% were black. At baseline 676 (64%) had any CAC (CAC score >0 Agatston units), 405 (38%) had CAC ≥100, and 236 (22%) had CAC ≥400. In cross-sectional analyses, multivariable models adjusted for demographics and clinical factors including statin use showed no significant association between circulating DCA levels and CAC >0 compared to no CAC (CAC=0) (prevalence ratio per 1-SD increase in log DCA: 1.09, 95% CI 0.92-1.28). Similar results were observed when baseline CAC thresholds of ≥100, ≥200, ≥300, and ≥400 vs. no CAC (CAC=0) were used. 672 participants had follow-up CAC measurements. Over a mean follow-up of 3.2±0.6 years, of the 277 (41%) participants with no baseline CAC (CAC=0), 60 (22%) developed incident CAC (CAC >0). In the fully adjusted model, DCA was not significantly associated with incident CAC (CAC >0) (incidence ratio per 1-SD increase in log DCA: 1.06, 95% CI 0.83-1.34). Of the 395 (59%) participants with any baseline CAC (CAC >0), 20% and 7% had an increase of ≥100 and ≥200 Agatston units/year, respectively, at follow-up. In the fully adjusted model, DCA was not associated with CAC progression (risk ratio for increase in ≥100 and ≥200 Agatston units/year per 1-SD increase in log DCA: 1.08, 95% 0.87-1.34 and 1.18, 95% CI 0.77-1.82, respectively).

Conclusions: In CRIC participants, DCA was not associated with prevalent, incident, or progression of CAC.

Increasing and Declining Estimated Glomerular Filtration Rates Predict Mortality Among a Community-Based Cohort

Yuji Sato,[1] Shouichi Fujimoto,[2] Kunitoshi Iseki,[3] Tsuneo Konta,[3] Toshiki Moriyama,[3] Kunihiro Yamagata,[3] Kazuhiko Tsuruya,[3] Ichiei Narita,[3] Masahide Kondo,[3] Masato Kasahara,[3] Yugo Shibagaki,[3] Koichi Asahi,[3] Tsuyoshi Watanabe.[3] *[1]University of Miyazaki Hospital, Miyazaki, Japan; [2]University of Miyazaki, Miyazaki, Japan; [3]Steering Committee for "Examination of the Positioning of CKD in Specific Health Check and Guidance,", Fukushima, Japan.*

Background: Serum creatinine based glomerular filtration rate (eGFR) is widely used to estimate the true glomerular filtration rate (eGFR) and as a tool for predicting risks of end-stage kidney disease (ESKD) and/or death in the field of public health. Most studies have focused on populations with a declining eGFR.

Methods: We enrolled a Japanese community-based cohort (N = 321,028; age 63.0 ± 7.8 years; men, 41.2%) via the public health check-up system. The follow-up period was 1,566 ± 501 days. The participants were classified into 12 annual eGFR change rate groups. Cox regression analyses were performed to calculate risks for all-cause mortality as the primary outcome measure. Stratified analyses were also conducted according to the level of dipstick proteinuria, annual body weight (BW) change of <0% and ≥0%, baseline eGFR ≥60 mL/min/1.73 m^2 and 15–59 mL/min/1.73 m^2, age ≤64 years old and >65 years old, sex, and the presence or absence of diabetes.

Results: There were 13.8% participants with an eGFR of 15–59 mL/min/1.73 m^2, and 8.9% reported a history of cardiovascular disease (CVD) Thus, our cohort was not at a high risk of both ESKD and CVD. During the study period, 2,604 (0.81%) died. Multivariable Cox regression analysis showed that increasing, as well as declining, eGFR was significantly associated with mortality when an annual eGFR change rate of 0%–4.9% was set as the reference range (U-shaped pattern). For example, the adjusted hazard ratio and 95% confidence interval of an annual eGFR change rate of ≥25% and ≤−25% was 14.17 (10.40–19.31) and 13.84 (9.69–19.76), respectively. Stratified analyses revealed that every stratification still demonstrated a significant U-shaped relationship, even though participants were grouped by dipstick proteinuria level, annual BW change, age, eGFR level, age, sex, and diabetes.

Conclusions: Increasing as well as declining eGFR is an important factor in patient mortality. Proteinuria, BW change, baseline eGFR level, age, sex, and diabetes did not affect this relationship.

FR-PO287

Albuminuria Is a Biomarker for Severity of White Matter Hyperintensities on Brain MRI in a General Elderly Population of Japanese: The Hisayama Study

Keisuke Yamasaki,[1,2] Jun Hata,[1,2] Naoki Hirabayashi,[1,3] Yoshihiko Furuta,[1,2] Tomoyuki Ohara,[1,4] Yoichiro Hirakawa,[1,2] Toshiaki Nakano,[2] Takanari Kitazono,[2] Toshiharu Ninomiya.[1] *[1]Department of Epidemiology and Public Health, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [3]Department of Psychosomatic Medicine, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [4]Department of Neuropsychiatry, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: White matter hyperintensities (WMH), which are often observed in brain magnetic resonance imaging (MRI) among the elderly, have been reported to be associated with an increased risk of symptomatic stroke. Albuminuria and reduced estimated glomerular filtration rate (eGFR) have been acknowledged to be independent risk factors for stroke, but the studies addressing the association of albuminuria and reduced eGFR with WMH volume in general Japanese elderly populations are limited.

Methods: A total of 1,214 community-dwelling Japanese subjects aged ≥65 years underwent brain MRI scans and a comprehensive health examination in 2012. Urine albumin-creatinine ratio (UACR) was categorized as normoalbuminuria (<30 mg/g),microalbuminuria (30-299 mg/g), and macroalbuminuria (≥300 mg/g). Subjects with normoalbuminuria were further divided into the following tertile categories: low-normal (≤7.3 mg/g), medium-normal (7.4-12.8 mg/g), and high-normal (12.9-29.9 mg/g). Reduced eGFR was defined as eGFR <60 mL/min per 1.73 m2. The severity of WMH was evaluated with the ratio of WMH volume to intracranial volume (WMHV/ICV). The association of UACR levels or reduced eGFR with WMHV/ICV ratio was estimated using the analysis of covariance.

Results: The age- and sex-adjusted geometric mean value of the WMHV/ICV ratio increased significantly with higher UACR levels (low-normal: 0.19%, medium-normal: 0.21%, high-normal: 0.25%, microalbuminuria: 0.25%; macroalbuminuria: 0.30%; P for trend <0.001). This association remained significant after additional adjustment for hypertension, diabetes mellitus, hypercholesterolemia, body mass index, eGFR, electrocardiogram abnormalities, smoking habits, alcohol intake, regular exercise, and cerebrovascular lesions on MRI (P for trend =0.001). In contrast, there was no clear association between reduced eGFR and WMHV/ICV ratio.

Conclusions: Our data suggest that albuminuria, even within the normal range, is a useful biomarker for estimating the severity of WMH in a general elderly population of Japanese.

FR-PO288

Body-Weight Fluctuation Is Associated with Rapid Kidney Function Decline

Dae-Suk Han, Byounghwi Ko, Shinchan Kang, Youngu su Joo, Ki heon Nam, Jung Tak Park. *Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: The association between body-weight fluctuation and renal outcomes is unclear. We aimed to evaluate the effects of body-weight fluctuation on the rate of renal function deterioration in a prospective cohort of individuals with normal renal function.

Methods: Data were obtained from the Korean Genome and Epidemiology Study (KoGES). Body-weight fluctuation was determined using average successive variability (ASV), which was defined as the average absolute body weight change using repeated measurements for all participants. The decline rate of estimated glomerular filtration rate (eGFR) over time was calculated using linear regression analysis of serial eGFR measurements for each patient. Rapid eGFR decline was defined an average decline in eGFR ≥3 ml/min/1.73 m^2 per year.

Results: In total, 7075 participants were analyzed. During a median follow-up of 11.7 (5.2-12.7) years, rapid eGFR decline was observed in 964 (13.6%) participants. When the participants were categorized into tertiles according to ASV, rapid eGFR decline was more prevalent in the highest ASV tertile group than in the lowest ASV group. Analyses using multiple logistic regression models revealed that the risk of rapid eGFR decline was significantly increased in the highest ASV tertile group compared to the lowest group (odds ratio, 1.51; 95% confidence interval 1.22-1.87). When ASV was treated as a continuous variable, an 1 kg increase in ASV was associated a 22% increased risk of rapid eGFR decline.

Conclusions: Body-weight fluctuation was significantly associated with an increased risk of rapid renal function decline in participants with normal renal function

FR-PO289

Reduced Serum Total CO2 Associates with Lower Urine Citrate Excretion in Clinic Outpatients

Nimrit Goraya,[1] Abdullah A. Mamun,[4] Nicolaos E. Madias,[2] Donald E. Wesson.[3,1] *[1]Internal Medicine, Baylor Scott and White Health, Temple, TX; [2]Internal Medicine, St.Elizabeth's Medical Center and Tufts University School of Medicine, Boston, MA; [3]Baylor Scott and White Health and Wellness Center, Dallas, TX; [4]Baylor Scott & White Health, Dallas, TX.*

Background: Emerging data supporting the GFR benefit of reducing the acid (H+) milieu of patients with CKD with serum total CO2 (STCO2) above that for which current KDIGO guidelines recommend alkali therapy suggest the need for a biomarker to identify candidate patients for treatment. Recent small-scale studies suggest that low urine excretion of the a pH-sensitive metabolite citrate (UcitrateV) predicts underlying acid (H+) retention in patients with CKD and serum [HCO3] > 24 mE/L and that dietary H+ reduction reduces H+ retention and increases UcitrateV in these patients (Goraya, et al. Kid Int 95:1190, 2019). Showing an association of low UcitrateV with low serum [HCO3] in a large database of unselected patients would further support the utility of UcitrateV for identifying patients with an increased H+ milieu.

Methods: We queried our electronic database for unique adult outpatients who had simultaneous values obtained for STCO2 (mM) and urine citrate (Ucitrate, mg/l) concentration. Because current KDIGO guidelines recommend alkali treatment for CKD patients with serum [HCO3] < 22 mEq/l and most clinical laboratories consider "normal" serum [HCO3] to be > 24 mEq/l, we compared Ucitrate among patients with serum [HCO3] < 22 mM and >24 mM.

Results: Our electronic database identified 264 unique patients, 55.3% male, with mean age ± SD = 50.7±20.3 years. Ucitrate was lower in patients with STCO2 <22 mEq/l compared to >24 mmEq/l (251±38 vs. 432±26 mg/l, respectively, p=0.003). Linear regression showed a significant relationship between Ucitrate and serum [HCO3] as continuous variables (p=0.025).

Conclusions: This database of unselected patients shows that reduced STCO2 associates with low Ucitrate and supports that an acid milieu promotes citrate conservation that is reflected by reduced urine citrate excretion. The data supports further investigation of urine citrate excretion as a biomarker of an increased acid milieu that might identify patients who are candidates for dietary H+ reduction as a kidney-protection strategy.

FR-PO290

Plasma Renin Activity in CKD: A Descriptive and Prognostic Analysis

Ali Mehdi, Georges Nakhoul, Susana Arrigain, Jesse D. Schold, Jonathan J. Taliercio. *Cleveland Clinic Foundation, Cleveland, OH.*

Background: Elevated plasma renin activity (PRA) is associated with poor clinical outcomes including death and cardiovascular events. There is conflicting studies regarding associations of PRA with incident CKD, CKD stages, and renal prognosis.

Methods: We evaluated patients included in the Cleveland Clinic CKD registry with documented PRA values from 2005-2017. Patients with primary hyperaldosteronism or renal artery stenosis were excluded. PRA values were stratified into quartiles and adjusted

Cox models were utilized to evaluate survival. Adjusted mixed models were used to test the interaction between PRA and slope of eGFR over time.

Results: Among 1124 patients analyzed, PRA correlated inversely with eGFR (1.9 vs 1.2ug/L/hr for eGFR 15-29 vs 60-89 mL/min/ 1.73 m^2; p<0.001). Table 1 shows the patient characteristics by PRA quartiles. Patients in Q1 were older, more African American, had lower BMI, and more were on beta blocker therapy. They had higher systolic and diastolic blood pressures and were more likely to require 3+ blood pressure medications. All these associations were statistically significant (table 1). With median follow-up of 3.2 years, mortality was not different across PRA quartiles on adjusted Cox model analysis (P=0.16). On mixed model analysis, a significant association was noted between log PRA and time (slope of monthly eGFR decline = 0.02; p=0.014) suggesting a protective effect of higher PRA levels. In stratified analyses, this association was significant with baseline eGFR >50mL/min/ 1.73 m^2 but not lower eGFR.

Conclusions: While the mechanism remains unclear, PRA appears to correlate inversely with eGFR. Findings suggest a protective effect of higher PRA against CKD progression when eGFR is above 50 mL/min/1.73 m^2. Congruent with prior studies, lower PRA values are evident in older age, African Americans, and Beta Blocker therapy. Our study also suggests that lower PRA is associated with a more resistant hypertension. Whether this represents high salt intake or undiagnosed autonomous hyperaldosteronism is unclear.

Table 1. Patient Characteristics by PRA Quartiles

PRA Quartiles (ug/L/hr)	Q1: <0.1-0.7 (N=283)	Q2: 0.73-1.46 (N=270)	Q3: 1.5-3.5 (N=292)	Q4: 3.53-172 (N=279)	p-Value

Glomerular Hyperfiltration Is Associated with Dementia: A Nationwide Population-Based Study

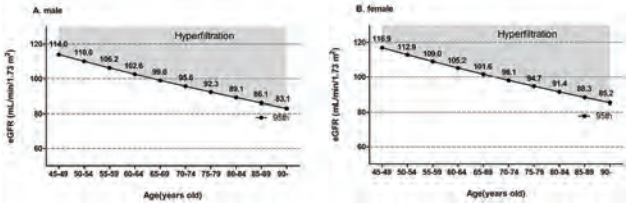
Min woo Kang,[1] Soojin Lee,[1] Yeonhee Lee,[2] Yaerim Kim,[1] Hajeong Lee,[2] Jung Pyo Lee,[3] Kwon Wook Joo,[1] Chun Soo Lim,[3] Yon Su Kim,[2] Dong Ki Kim.[1]
[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.

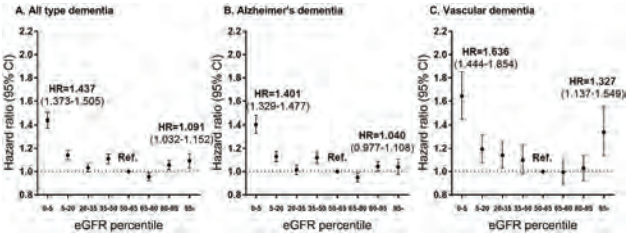
Background: Because prevention of dementia is critical before it occurs, identifying the risk factor of dementia is important. The object of this study is to identify the risk of dementia in people with glomerular hyperfiltration.

Methods: Using Korean National Health Information Database (NHID), we retrospectively reviewed total of 2,244,582 people, excluding ESRD patients and people with dementia before taking national health screening. Study population was divided into gender and age of five-years interval group. All eGFR≥95 percentile subjects in each group which was divided into sex and age of five-years were defined as hyperfiltration group. All 50 percentile≤eGFR<65 percentile subjects in each group which was divided into sex and age of five-years were defined as reference group. The hazard ratios (HR) for all type dementia, vascular dementia and Alzheimer's dementia were calculated within the study groups after adjustment for multiple variables.

Results: The corresponding eGFR values of hyperfiltration (95 percentile of eGFR) group were ≥114 mL/min/1.73m^2 in 45-49 years old male, ≥83 mL/min/1.73m^2 in ≥90 years old male and ≥117 mL/min/1.73m^2 in 45-49 years old female, ≥85 mL/min/1.73m^2 in ≥90 years old female. (Figure 1.) The hyperfiltration group (eGFR≥95percentile) showed a higher risk of all type dementia compared with the reference group (50percentile≤eGFR<65percentile), with the following HRs: 1.09 (95% CI: 1.032–1.152). The hyperfiltration group had higher risk of vascular dementia with the following HR: 1.33 (95% CI: 1.137–1.549). The relationship between hyperfiltration and Alzheimer's dementia was not statistically significant, with the following HRs: 1.040 (95% CI: 0.977–1.108). (Figure 2.)

Conclusions: Glomerular hyperfiltration is associated with increased risk of dementia, especially vascular dementia.





FR-PO292

Evaluation of Renal and Retinal Outcomes in the Northern Ireland Cohort of Longitudinal Ageing (NICOLA)

Rachael O'Neill, Alexander P. Maxwell, Frank Kee, Ian Young, Bernadette Mcguinness, Ruth E. Hogg, Gareth J. McKay. *Queen's University Belfast, Belfast, United Kingdom.*

Background: Microvascular pathology is a common feature of both eye and kidney diseases. Renal microvascular damage is not easy to identify without renal biopsy. Advances in imaging the retinal microvasculature may offer an alternative opportunistic evaluation of microangiopathic changes that correlate with kidney dysfunction. Retinal imaging might provide an earlier, non-invasive screening assessment for the presence of chronic kidney disease (CKD). We assessed retinal microvascular parameters for association with against measures of renal function measures in a prospective cohort study of older persons (>55 years): Northern Ireland Cohort of Longitudinal Ageing (NICOLA).

Methods: Retinal microvascular parameters (central retinal arteriolar/ venular equivalents (CRAE/CRVE) arteriolar to venular ratio (AVR), fractal dimension and tortuosity) were measured from optic disc centered fundus images and analysed using semi-automated software. Linear and logistic regression models were used to assess associations between microvascular parameters and the continuous variables of renal function (eGFR Creatinine (SeCr) and Cystatin C (Scys)) and the binary trait of CKD status, respectively. Minimally adjusted models included age and gender with fully adjusted models also including diabetes, smoking, alcohol, education, body mass index, antihypertensive medication, mean arterial blood pressure, triglycerides, high and low-density lipoproteins.

Results: Retinal and renal measures were available for 1,860 of the 3,518 NICOLA participants. In unadjusted, minimally adjusted and fully adjusted linear regression models, no significant associations were detected between CRAE, CRVE, AVR, fractal dimension or tortuosity and eGFRSeCr or eGFRScys. CKD status, defined by eGFRSeCr < 60 mL/ min per 1.73 m2, was significantly associated with venular tortuosity in all models (β=0.8; 95%CI: 1.3, 4.1; P=0.004). There was no significant associations detected between CKD status and any of the other retinal parameters assessed.

Conclusions: Our findings indicate that variation in retinal venular geometry is associated with renal dysfunction in an older population. These non-invasive retinal measures may help identify early mechanistic pathways for microvascular complications in individuals at high risk for future CKD.

FR-PO293

Serum Albumin and All-Cause Mortality Across Varying Levels of Kidney Function

Amanda R. Tortorici,[1] Neda Naderi,[5] Ying Tang,[6] Christina Park,[1] Amy S. You,[1] Keith C. Norris,[2] Yoshitsugu Obi,[1] Elani Streja,[1] Kamyar Kalantar-Zadeh,[4] Connie Rhee.[3] *[1]UC Irvine Medical Center, Irvine, CA; [2]UCLA, Marina Del Rey, CA; [3]University of California Irvine, Irvine, CA; [4]University of California Irvine, School of Medicine, Orange, CA; [5]Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran; [6]Shengjing Hospital of China Medical University, Shenyang, China.*

Background: Serum albumin (sAlb) may be a strong predictor of longevity in the general population and in chronic kidney disease populations. Our objective was to determine the relationship between sAlb concentrations and mortality risk independent of kidney function.

Methods: We analyzed a retrospective cohort of 31,274 adults from the 1999-2010 National Health and Nutrition Examination Survey. Estimated glomerular filtration rate (eGFR) was examined as both a confounder and modifier of the association of sAlb with mortality risk. We examined the association of sAlb categorized in 7 strata with mortality using Cox models. Covariates in the adjusted model included age, sex, race/ethnicity, level of education, diabetes, smoking status, systolic blood pressure, serum total cholesterol level, and eGFR. We then conducted spline analyses to estimate the association of sAlb with all-cause mortality across varying eGFR levels.

Results: In unadjusted analyses, participants with incrementally lower sAlb concentrations <4.6g/dL had increasingly higher mortality risk compared to those with sAlb ranging 4.6-<4.8g/dL (reference), whereas those with higher sAlb ≥4.8g/dL had lower mortality risk: HRs (95%CI) 3.88 (3.26, 4.62), 3.59 (3.01, 4.27), 2.79 (2.37, 3.29), 2.10 (1.79, 2.48), 1.72 (1.45, 2.03), and 0.71 (0.55, 0.92) for sAlb concentrations of <3.8, 3.8-<4.0, 4.0-<4.2, 4.2-<4.4, 4.4-<4.6, and ≥4.8g/dL, respectively. Case-mix + eGFR adjusted analyses showed similar findings, although the association of higher sAlb ≥4.8g/dL

with greater survival was attenuated to the null. Spline analyses showed participants with sAlb <4.6g/dL had higher mortality across all levels of eGFR ranging from 30 to 120 ml/min/1.73m^2 (reference: sAlb ≥4.6g/dL) [Figure].

Conclusions: Among a representative US cohort, there was a graded association between lower sAlb concentrations with higher death risk, which was robust across varying levels of kidney function.

FR-PO294

CKD in Patients with Pre-Diabetes from Two Large Healthcare Systems

Radica Z. Alicic,[1] Obidiugwu Duru,[2] Kenn B. Daratha,[4] Cami R. Jones,[3] Kelly A. Hennessey,[8] Sterling McPherson,[6] Susanne B. Nicholas,[5] Keith C. Norris,[7] Katherine R. Tuttle.[8] *[1]Providence Medical Research Center, Spokane, WA; [2]David Geffen School of Medicine, Los Angeles, CA; [3]Providence St. Joseph Health, Spokane, WA; [4]Providence Health Care, Spokane, WA; [5]UCLA Medical Center, Los Angeles, CA; [6]Washington State University College of Medicine, Spokane, WA; [7]UCLA, Marina Del Rey, CA; [8]University of Washington School of Medicine, Spokane, WA.*

Background: Chronic kidney disease (CKD) in pre-diabetes (PDM) is not well-characterized. The study aim was to determine CKD prevalence and risk factors of patients with PDM treated at two large healthcare systems in the western United States.

Methods: The Center for Kidney Disease Research, Education and Hope (CURE-CKD) registry was created from clinical and administrative data in electronic health records of Providence St. Joseph Health and University of California Los Angeles Health (years 2006-2017). PDM, CKD, and hypertension (HTN) were identified by diagnostic codes and condition-specific criteria: PDM by HbA1c 5.7-6.4% or two measures of fasting (100-125 mg/dL) or random (140-199 mg/dL) blood glucose at least one day apart; CKD by two measures of serum creatinine-based estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m2 (CKD-EPI), urine albumin-to-creatinine ratio ≥30 mg/g, or protein-to-creatinine ratio >150 mg/g at least 90 days apart; HTN by blood pressure ≥140/90mmHg on two measures at least 14 days apart.

Results: CKD was present in 20% of patients with PDM (101,868/497,233). Patients with CKD and PDM were predominately white (71%), women (58%), and older compared to those without CKD (72±15 years versus 56±17 years, p<0.001). HTN occurred in 72% of patients with CKD and PDM (73,788/101,868) with mean blood pressure of 131±17/70±10 mmHg. HbA1c was similar in those with and without CKD (5.8±0.3% and 5.8±0.4%). eGFR was 53±18 mL/min/1.73m^2 in patients with CKD and PDM versus 89±20 mL/min/1.73m^2 (p<0.001) in those without CKD. Among patients with PDM and CKD, individuals with HTN had higher eGFR compared to those without HTN (55±18 versus 50±21 mL/min/1.73m^2, p<0.001) and fewer had CKD stages 4-5 (7% versus 13%, p<0.001). Among small number of patients tested, albuminuria >30 mg/g or proteinuria >150 g/g occurred in 24% (3,027/12,470) and 42%(2,519/6,026), respectively.

Conclusions: CKD and major risk factors of HTN and albuminuria/proteinuria are often present in PDM without overt diabetes. In patients with PDM, CKD assessment and risk factor management are warranted

FR-PO295

Mediation Analysis of Proteinuria and Serum Phosphate: Insight from the KNOW-CKD Study

Ji Yong Jung,[1] Han Ro,[1] Yun Jung Oh,[2] Chungsik Lee,[2] Jae Hyun Chang,[1] Ae jin Kim,[1] Hyun Hee Lee,[1] Kook-Hwan Oh,[3] Curie Ahn,[4] Wookyung Chung.[1] *[1]Gachon University Gil Medical Center, Incheon, Republic of Korea; [2]Cheju Halla General Hospital, Jeju, Republic of Korea; [3]SNU College of Medicine, Seoul, Republic of Korea; [4]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Proteinuria and hyperphosphatemia are risk factors for cardiovascular disease in patients with chronic kidney disease (CKD). While experiencing the interaction between proteinuria and serum phosphate level, there is an insufficient mechanistic link between the two, particularly the extent to which is mediated by phosphate regulating factors. Therefore, we examined their association and potential mediators including circulating FGF23/Klotho and 24hr urinary excretion rate of phosphate to glomerular filtration rate (24hr EP/GFR) and 24hr tubular reabsorption rate of phosphate to GFR (24hr TRP/GFR).

Methods: We analyzed 1793 patients for whom 24hr urine protein and phosphate, serum phosphate, FGF23 and Klotho level were measured simultaneously using data from the KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD). Multivariable linear regression and mediation analyses were performed. Total, direct, and indirect effects were also estimated.

Results: The group of patients with high serum phosphate levels was likely to have higher proteinuria and FGF23 and lower Klotho levels. 24hr EP/GFR increased with increasing proteinuria and CKD progression, but 24hr TRP/GFR showed a tendency to decrease. Simple mediation analyses showed that 15.4% or 67.9% of the relation was mediated by FGF23/Klotho ratio or 24hr EP/GFR, respectively. In addition, 73.1% of the relation was mediated by two serial mediators.

Conclusions: These findings represents that proteinuria increases 24hr EP/GFR through FGF23/Klotho axis as a mechanism to regulate increased phosphate burden per unit nephron much earlier than reduction in renal function.

Association of the Trajectories of Metabolic Component and Outcomes in Patients with CKD

Kyung Don Yoo,[1] Yunmi Kim,[2] Hyo Jin Kim,[3] Ji In Park,[4] Jong Soo Lee,[1] Ho seok Koo.[5] *[1]Ulsan University Hospital, Ulsan, Seoul, Republic of Korea; [2]Inje University Busan Paik Hospital, Busan, Republic of Korea; [3]Dongguk University College of Medicine, Gyeongju-si, GyeongSangBuk-do, Republic of Korea; [4]Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [5]Inje university, Seoul, Republic of Korea.*

Background: Patients with chronic kidney disease (CKD) were known to increase the risk of chronic diseases including hypertension (HTN), diabetes mellitus (DM), dyslipidemia while they also affect deterioration of renal function. However, little is known about the relation of changeable aspect for metabolic component to CKD progression.

Methods: We assigned patients to be clustered High and Low group followed by trajectory analysis using K-means clustering on the basis of systolic and diastolic blood pressure (SBP,DBP), total cholesterol(TC), triglyceride(TG) and LDL cholesterol measurement at least two time point. The optimal number of clustering was selected by the Calinski-Harabasz index. Primary outcome was risk factor analysis by clustering group for eGFR decline, and death.

Results: The mean age of overall participants was 65.7±9.7 years, 50.4% for men and 11.8% for current smoker. The mean SBP was 127.8±15.8 mmHg, DBP was 83.6±8.4 mmHg. Total choresterol, TG and LDL was 196.4±40.9, 147.1±89.8, 115.5±37.2 mg/dl, respectively. The mean SBP of cluster High group was 138.9±13.2, and Low group was 118.9±10.9mmHg. In TC clustering, High group was 223.4 ± 33.0, and Low group was 167.5 ± 26.6 mg/dl. The mean TG in High group was 266.1 ± 116.7, and Low group was 118.8 ± 46.1 mg/dl. In LDL clustering, cluster High group was 139.7 ± 31.2, and Low group was 89.9 ± 24.3 mg/dl. In multivariate logistic regression, SBP high group (OR 1.13 95%CI 1.066-1.212), TG high group (OR 1.15, 95% CI 1.069-1.240) were independently associated with eGFR decline. And, also SBP high group (OR 1.82, 95%CI 1.070-3.123) and BMI lowest group (OR 2.19, 95%CI 1.07-4.38) were independently associated with death.

Conclusions: High SBP trajectory, and high TG trajectory have negative impacts on eGFR decline. And also, High SBP trajectory, and low BMI trajectory affected overall survival. In CKD patients, more meticulous following up was needed for better clinical outcomes.

FR-PO297

Examining the Characteristics of US Veterans on Triglyceride or HDL Altering Therapy Across Kidney Disease Stage Between 2004-2014

Melissa Soohoo,[1] Jui-Ting Hsiung,[1] Christina Park,[1] Maria V. Marroquin,[1] Hamid Moradi,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Current nephrology guidelines do not advocate for pharmacological therapy for triglycerides (TG) or high density lipoprotein (HDL) management in patients with chronic kidney disease (CKD), despite the fact that these lipids may be associated with a higher cardiovascular risk. Nonetheless some patients with CKD receive these medications. We sought to describe the characteristics of US veteran patients receiving fibrate or niacin and whether these characteristics differed by presence of CKD or across CKD stage.

Methods: We identified male veterans with an elevated TG(≥150 mg/dL) or low HDL (<40 mg/dL) who initiated a fibrate or niacin within 90 days of the lipid measurements between 2004-2014. We examined clinical characteristics at the time of fibrate or niacin initiation (N=78,957 and 100,356, respectively), stratified by CKD stage.

Results: In both treatment groups, there was a decreasing trend in fibrate and niacin initiation across higher CKD stage, where a majority of patients were non-CKD, with <1% of patients in stage 5 or end-stage renal disease (ESRD). Veterans with advanced CKD were more likely to be older at the time of fibrate or niacin initiation. In non-CKD and between CKD stage 3A-4, approximately 6-12% of patients on therapy were African-American, however that proportion more than doubled to 20-25% in ESRD/CKD stage 5. Across CKD stages, there was an increase in the proportion of concurrent statin users, with a peak at stage 4 or 5, and then a decline with ESRD. There were similar relationships of comorbidities across CKD stage among fibrate users, where the greatest proportion of cardiovascular conditions was among CKD stage 4 patients.

Conclusions: In US veterans, the proportion of patients with high TG or low HDL prescribed fibrate or niacin decreases with worsening CKD. In future analysis, we will investigate if use of these therapies in CKD patients with elevated TG or low HDL have a lower risk of cardiovascular events.

Correlation Between Blood Pressure and Development of CKD in 5.6 Million Korean Adults with Normal Renal Function

Kyeong Pyo Lee, Young soo Kim, Sunae Yoon, Young ok Kim. *Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea Uijeongbu St. Mary's Hospital, Uijeongbu-si, Gyeonggi-do, Republic of Korea.*

Background: Although hypertension is well known for a major risk factor of renal progression in patients with chronic kidney disease (CKD), there are few studies on whether hypertension is also a risk factor of renal progression in the population with normal renal function. So we analyzed correlation between blood pressure (BP) control and development of CKD in Korean adults with normal renal function.

Methods: We utilized medical checkup database of the Korean National Health Service (NHIS). We enrolled 5,638,320 subjects including people who underwent medical checkups both in 2009 & 2015 in a row and excluding people whose estimated glomerular filtration rates (eGFRs) were already less than 60 ml/min/1.73m^2 or whose urinalyses already showed proteinuria in 2009. New development of CKD was defined by the decline of eGFR to below 60 ml/min/1.73m^2 in 2015. We compared age, sex, obesity, and various medical illnesses such as hypertension, diabetes, and dyslipidemia between the CKD group (n=161,044) and the non-CKD group (n=5,477,276). We also stratified subgroups by initial systolic BP and diastolic BP by 10 mmHg, and investigated the risks of progression to CKD after adjusting these clinical factors.

Results: The CKD group showed higher incidence of old age, female, obesity, hypertension, diabetes, and dyslipidemia, compared with the non-CKD group. Subjects whose SBP were more than 120 mmHg or whose DBP were more than 70 mmHg showed higher incidence of progression to CKD, compared with subjects whose SBP were less than 120 mmHg and whose DBP were less than 70 mmHg, respectively (odds ratio 1.037, 95% confidence interval 1.014~1.061 / OR 1.021, 95% CI 1.004~1.038).

Conclusions: We suggest strict BP control is helpful for preventing CKD in the population with normal renal function.

Serum Bicarbonate Levels Are Not Associated with Total Kidney Volume in Patients with Polycystic Kidney Disease

Lorena Ramirez-Renteria,[1] Zhiying You,[2] Berenice Y. Gitomer,[3] Michel Chonchol,[4] Jessica B. Kendrick.[1] *[1]University of Colorado School of Medicine, Aurora, CO; [2]UC Denver, Aurora, CO; [3]Div. Renal Diseases and Hypertension, Aurora, CO; [4]University of Colorado, Aurora, CO.*

Background: Enhanced ammoniagenesis has been proposed as a potential mechanism of kidney cystic disease progression in patients with polycystic kidney disease (PKD). Animal studies have found that administration of sodium bicarbonate slows cyst enlargement and prevents development of interstitial inflammation and chronic fibrosis. We tested the hypothesis that higher serum bicarbonate levels in patients with PKD are associated with lower total kidney volume (TKV).

Methods: We included 383 patients from the HALT-PKD Study A with baseline serum bicarbonate levels and at least two measurements of TKV. Bicarbonate was examined as a continuous variable and in categories (≤ 24, 25-28 and >28 mEq/L, with 25-28 mEq/L as the reference group). Total kidney volume was measured using imaging from a 1.5T MRI scanner. The outcome was yearly change in slope of TKV. Linear regression models were used to examin the association between serum bicarbonate and change in TKV.

Results: The mean (SD) age was 37.4 (8.0) years. The mean (SD) serum bicarbonate and estimated glomerular filtration rate at baseline was 27.0 (2.4) and 90.0 (17.0) ml/min/1.73m,^{2} respectively. Participants with lower serum bicarbonate ≤ 24 mEq/L were more likely to be younger, female and to have higher systolic blood pressure than those with a serum bicarbonate > 28 mEq/L. There was no association between serum bicarbonate and change in annual slope of TKV when serum bicarbonate was examined as a continuous variable or in categories (Table 1).

Conclusions: Serum bicarbonate levels are not associated with total kidney volume in patients with PKD.

Funding: Other NIH Support - NHLBI

Annual Change in Slope of TKV (β Estimate (95% CI))

Alteration of Physical Activity and Its Association with Cardiovascular Outcomes Among Pre-Dialysis CKD Patients

Soojin Lee,[1] Min woo Kang,[2] Yaerim Kim,[2] Semin Cho,[1] Jung Pyo Lee,[3] Chun Soo Lim,[3] Kwon Wook Joo,[2] Yon Su Kim,[4] Dong Ki Kim.[2] *[1]Seoul national university hospital, Seoul, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Cardiovascular disease is major cause of mortality among chronic kidney disease (CKD) patients, and it is fundamental to focus on reducing the potential risk factors. Regular physical activity is known to reduce the risk of cardiovascular disease in general population. However, whether the change of physical activity habits is beneficial for pre-dialysis CKD patients had not been examined thoroughly.

Methods: We performed a nationwide population based cohort study using the database of Korean National Health Insurance System. Among adult patients who received national health screening program ≥2 times between 2012 and 2016, CKD patients were identified using the serum creatinine and dipstick albuminuria measurements. Those who previously underwent dialysis or diagnosed cardiovascular disease were excluded. The frequency and the intensity of the physical activity were obtained at least twice, from self-reported questionnaire during the health examination. The study groups were divided according to the status of physical activity habit alteration; active, quit exercise, start exercise, and inactive group. Then, the development of myocardial infarction (MI), stroke or death was assessed using the multivariate Cox regression analysis.

Results: During the median follow up of 3.18 years, 549,187 CKD patients were examined for adverse outcomes. Compared to those who remained inactive, the active group patients who consistently continued physical activity exhibited lower risk of MI (hazard ratio (HR); 0.76, 95% confidence interval (95% CI); 0.69-0.85), stroke (HR (95%CI) 0.69 (0.62-0.78)), and death (HR (95%CI) 0.62 (0.57-0.67)). Moreover, those who newly started physical activity also showed lower risk of adverse outcomes, compared to the inactive group (HR (95%CI) 0.83 (0.76-0.89)).

Conclusions: Continuation of physical activity in pre-dialysis CKD patients is beneficial to reduce the risk of cardiovascular disease development. Therefore, clinicians should encourage even mild intensity of physical activity to CKD patients.

FR-PO301

Hyperuricemia Is Associated with Progression of CKD: Uric Acid Aggravates Renal Function

Li Wang,[2] Daqing Hong,[1] Amanda Y Wang,[3] Guisen Li.[4] *[1]Renal Department and Nephrology Institute, Sichuan Provincial People's Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China; [2]Department of Nephrology, Sichuan Provincial People's Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China; [3]The George Institute for Global Health, Newtown, NSW, Australia; [4]Sichuan Provincial People's Hospital, Chengdu, China.*

Background: Hyperuricemia (HUA) is common in chronic kidney disease (CKD). There is paucity of literature on the association between serum uric acid levels and the progression of CKD. This study aimed at assessing the effect of serum baseline uric acid level on the progression of CKD.

Methods: This retrospective study included 800 CKD patients in our center. The information on baseline and follow-up characteristics were collected from Renal Treatment System (RTS) database, including age, gender, serum uric acid (UA), glomerular filtration rate (eGFR), serum creatinine (Cr), urea, albumin (Alb), 24 hours urine protein quantitation (24h-u-pro) and blood pressure (BP). Cox regression analysis was used to evaluate the risk factors for CKD progression. The Kaplan–Meier analysis was used to test associations between serum uric acid levels and renal survival rates.

Results: A total of 800 patients were included in the study, and the mean age at entry was 36.6±14.4 years. There was no significant difference in gender distribution. The mean eGFR, Cr, serum uric acid at baseline were 99.23±31.54 ml/min/1.73m^2, 82.08±41.40 μmol/L, 371.60±103.18 μmol/L, respectively. 306 (38.3%) patients had HUA and 494 (61.7%) had non-HUA. We established different adjusted models and found that HUA was a risk factor for CKD patients to reach the composite endpoint after adjustment in six models. All models show that HUA was a risk factor for the progression of CKD. Among them, model 4 (adjusted for Cr+Alb+age+BP+gender) was the best model with the largest HR value (HR:2.010, 95%CI:1.310-3.084, P<0.05). The cumulative survival rate of non-hyperuricemia group was higher than that of hyperuricemia group (P=0.046).

Conclusions: HUA is prevalent in CKD and a risk factor for CKD progression. Anti-hyperuricaemic therapy may need to be considered in CKD patients to slow the disease progression, which needs to be tested further in clinical studies.

The Association Between Serum Uric Acid Levels and Incidence of Proteinuria: A Large-Scale Cohort Study in a Community-Based Population

Kazunobu Ichikawa,[1] Tsuneo Konta,[2] Shouichi Fujimoto,[3] Kunitoshi Iseki,[4] Toshiki Moriyama,[5] Kunihiro Yamagata,[6] Kazuhiko Tsuruya,[7] Ichiei Narita,[8] Masahide Kondo,[6] Yugo Shibagaki,[9] Masato Kasahara,[10] Koichi Asahi,[11] Tsuyoshi Watanabe.[12] *[1]Yamagata University School of Medicine, Yamagata, Japan; [2]Yamagata University Graduate School of Medical Science, Yamagata, Japan; [3]University of Miyazaki, Miyazaki, Japan; [4]Nakamura Clinic, Urasoe, Japan; [5]Osaka University Health Care Center, Toyonaka, Japan; [6]University of Tsukuba, Tsukuba, Japan; [7]Nara Medical University, Kashihara, Japan; [8]Niigata University, Niigata, Japan; [9]St Marianna University Hospital, Kawasaki, Japan; [10]Institute for Clinical and Translational Science Nara Medical University Hospital, Kashihara, Japan; [11]Iwate Medical University, Morioka, Japan; [12]Fukushima Medical University School of Medicine, Fukushima City, Japan.*

Background: Hyperuricemia is associated with the development and the progression of renal disease. However, the threshold value of serum uric acid for the increased risk for proteinuria has not been determined. To clarify this point, we conducted a large-scale cohort study in a community-based population.

Methods: We used a nationwide database of 328,582 subjects without overt dipstick proteinuria at baseline (134,227 men, 194,355 women, aged 40–74) who participated in the annual "Specific Health Check and Guidance in Japan" check-up between 2008 and 2013, and were followed up for 6 years (median 3.0 years). We examined the association of serum uric acid levels at baseline with incident dipstick proteinuria (1+ or greater) in this population.

Results: During the follow-up period, 24,419 subjects (7.4%) newly developed dipstick proteinuria. In unadjusted Cox proportional hazard model, the hazard ratio (HR) for incident proteinuria was significantly increased both in men and women with high serum uric acid levels. In the adjusted model with possible confounders including age, renal function, smoking, alcohol consumption, and comorbidities, a similar significant trend was observed. The lowest HR was observed in men with serum uric acid 5.0-5.9 mg/dL and in women with 4.0-4.9 mg/dL, respectively. The significantly increased HRs for incident proteinuria was observed in the high range of serum uric acid in both men and women (≥ 8 mg/dL in men, ≥ 5 mg/dL in women, respectively). The adjusted HRs of the conventional cut-off point of hyperuricemia (> 7.0 mg/dL) for incident proteinuria was 1.10 (95% confidence interval [CI] 1.05-1.15) in men, and 1.75 (95%CI 1.58-1.93) in women, respectively.

Conclusions: In this community-based population, the high serum uric acid level was an independent risk for incident proteinuria in both men and women and the threshold values of serum uric acid for incident proteinuria might be different for men and women.

Relationship of Uric Acid with Cardiovascular Mortality: A Systematic Review and Meta-Analysis

Leonard Browne,[1,2] Eoghain Quinn,[1] Oisin O'Ceallaigh,[1] Richard J. Johnson,[3] Austin G. Stack.[1,4] *[1]Graduate Entry Medical School, University Of Limerick, Limerick, Ireland; [2]Health Research Institute, University of Limerick, Limerick, Ireland; [3]University of Colorado Denver, Aurora, CO; [4]Division of Nephrology, University Hospital Limerick, Limerick, Ireland.*

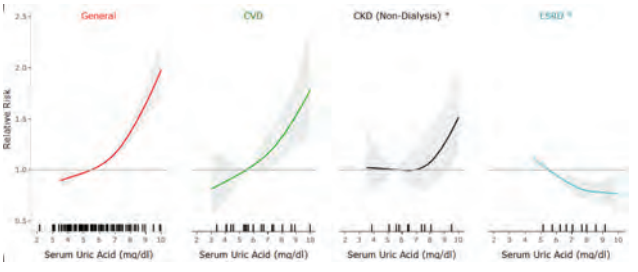
Background: Uric acid (UA) levels predict cardiovascular (CV) and all-cause mortality, but uncertainty remains regarding optimal threshold values for intervention. The aim of this systematic review and meta-analysis was to investigate risk thresholds for UA on CV mortality in four distinct populations: general population, cardiovascular disease (CVD), chronic kidney disease (CKD) and end stage kidney disease (ESKD).

Methods: We searched electronic databases up to 1 July 2018 for observational studies reporting associations for three or more groups of UA with all-cause and CV mortality in the four distinct populations:general, CVD, CKD and ESKD. Study-specific associations between UA and adjusted relative risks (RR) were estimated using restricted cubic splines with three knots at 10th, 75th and 90th percentile of the UA distribution and a generalised least squares method before pooling study estimates with a multivariate random-effects meta-analysis.

Results: We included 1,665,013 participants from 37 cohorts with 25,334 CV deaths. The overall pattern of association between serum UA and CV-mortality was non-linear (p-value, non-linearity < 0.001). Mortality risks increased beyond UA of 6.0 mg/dL [RR: 1.03 (1.01-1.05)], with an almost linear increase in risk for higher concentrations (7.0 mg/dL, [RR: 1.13 (1.08- 1.18)]) compared to a referent of 5.5 mg/dL. There was evidence of heterogeneity across studies (I^2=63.5). The shape of the UA-mortality association was similar for participants in the general, CKD, and CVD populations but differed significantly from ESKD (p<0.001). In ESKD, the pattern was completely reversed, with a reduced mortality for UA values above 5.5 mg/dL.

Conclusions: Uric acid exhibits a J-shaped association with CV mortality with increasing risk above 5.5 mg/dL in the general and CVD populations. This relationship was attenuated in CKD and completely reversed in ESKD. Large randomised clinical trials of urate-lowering therapy should test whether targeting this threshold will confer cardioprotection.

Funding: Government Support - Non-U.S.



Nonlinear dose-response analyses of UA and risk of CV mortality by population type

FR-PO304

Comparative Renoprotective Effect of Febuxostat and Allopurinol in Pre-Dialysis Stage 5 CKD Patients: A Nationwide Database Analysis

Yun-Shiuan (Olivia) Hsu,[1,2] Huang-Yu Yang.[1] *[1]Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Medicine, Chang Gung University, Taoyuan, Taiwan.*

Background: Hyperuricemia has been associated with chronic kidney disease (CKD) progression. Slowed CKD progression has also been observed in stage 1-3 CKD patients treated with the anti-hyperuricemic febuxostat. Large-scale studies comparing the renoprotective potential of febuxostat and allopurinol in pre-dialysis stage 5 CKD are lacking.

Methods: In our population-based retrospective cohort study, we used the National Health Insurance Research Database in Taiwan from 2012 to 2015 to select eligible pre-dialysis stage 5 CKD patients. Patients were included and grouped based on the prescription of allopurinol (n=3424) or febuxostat (n=2633) within 90 days after first-time erythropoiesis-stimulating agents (ESA) prescriptions. Long-term dialysis and all-cause mortality or dialysis (composite outcome) among febuxostat users and allopurinol users were analyzed and compared using the Cox proportional hazards model. Propensity-score matching and subgroup analysis were additionally performed.

Results: We identified 6057 anti-hyperuricemic users. 69.57% of allopurinol users and 42.01% febuxostat users required long-term dialysis (p<.0001). The adjusted hazard ratio was 0.65 (95% confidence interval, 0.60-0.70), indicating near 35% lower hazards of long-term dialysis from febuxostat compared with allopurinol use. The renal benefit of febuxostat use was consistent across most patient subgroups and/or using the propensity score-matched cohort. Similarly, the adjusted hazard ratio was 0.66 (95% confidence interval, 0.61-0.70) for the composite outcome of long-term dialysis or death.

Conclusions: Compared to allopurinol, febuxostat was associated with lower risk of progression to dialysis in pre-dialysis stage 5 CKD patients. Febuxostat's associated renal benefit does not compromise patient survival.

Funding: Private Foundation Support

FR-PO305

The Association Between Serum Uric Acid Levels and Cardiovascular Disease in Japanese Patients with CKD: The FKR Study

Keita Takae,[3] Kentaro Nakai,[3] Shigeru Tanaka,[1] Megumi Inoue,[3] Chiaki Kohara,[3] Shutaro Yamamoto,[3] Koji Mitsuiki,[3] Toshiaki Nakano,[1] Kazuhiko Tsuruya,[2] Takanari Kitazono.[1] *[1]Kyushu University, Fukuoka, Japan; [2]Nara Medical University, Kashihara, Japan; [3]Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.*

Background: Growing evidence suggests that high serum uric acid (SUA) level is related to increased risk of cardiovascular disease (CVD). However, limited studies have investigated the influence of elevated SUA level on the prevalence of CVD in Japanese patients with chronic kidney disease (CKD). Besides, the nature of disease in Asian populations differs markedly from that in North American populations and European.

Methods: The Fukuoka Kidney disease Registry (FKR) is designed as one of the largest prospective, multicenter, observational cohort studies in non-dialyzed CKD patients. A total of 3,366 Japanese patients with CKD were eligible for this study. The association between SUA level and the prevalence of CVD was analyzed. CVD was defined as ischemic heart disease, hemorrhagic stroke, ischemic stroke, congestive heart failure, atrial fibrillation, and aneurism of thoracic or abdominal artery. The odds ratios (ORs) for the prevalence of CVD were estimated according to SUA levels as follows: ≤5.9 mg/dL, 6.0-7.9 mg/dL, and ≥8.0 mg/dL.

Results: The CVD was present in 857 (25.5%) patients. Mean serum uric acid was 6.2 ± 1.5 (standard deviation) mg/dL. The age- and sex-adjusted prevalence of CVD increased significantly (SUA ≤5.9 mg/dL: 22.9%, 6.0-7.9 mg/dL: 26.1%, and ≥8.0 mg/dL: 33.2%, [p for trend <0.05]). Compared with those with SUA ≤5.9 mg/dL, the multivariable-adjusted ORs for the prevalence of CVD were 1.11 (95% confidence intervals, 0.92-1.35) and 1.38 (1.04-1.84) in those with SUA 6.0-7.9 mg/dL and ≥8.0 mg/dL, respectively. Among CVD subtypes, higher SUA levels were associated with increased prevalence of atrial fibrillation (ORs [95% CI]: 1.38 [0.97-1.98] and 2.41 [1.50-3.89], respectively).

Conclusions: Higher SUA levels are associated with higher prevalence of CVD, especially with atrial fibrillation. The FKR study will prospectively clarify whether higher SUA levels increase risk for developing CVD in Japanese patients with CKD.

FR-PO306

Longitudinal Serum Uric Acid Level and Long-Term Outcome in CKD by Trajectory Analysis from the Korean Cohort Study for Outcomes in Patients with CKD (KNOW-CKD)

Yunmi Kim,[1] Ho seok Koo,[5] Yun Hee Park,[1] Taehee Kim,[2] Sunwoo Kang,[2] Kook-Hwan Oh,[3] Curie Ahn,[4] Yeong Hoon Kim.[6] *[1]Inje University Busan Paik Hospital, Busan, Republic of Korea; [2]Inje University, Busan, Republic of Korea; [3]SNU College of Medicine, Seoul, Republic of Korea; [4]Seoul National University Hospital, Seoul, Republic of Korea; [5]Inje university, Seoul, Republic of Korea; [6]Inje University Medical School, Busan, Republic of Korea.*

Background: Hyperuricemia is an independent risk factor for microalbuminuria and decline of renal function. Though, it has not been proven whether high serum uric acid on longitudinal basis predicts renal outcome in chronic kidney disease patients.

Methods: Among the 2,238 patients enrolled in the KoreaN cohort study for Outcomes in patients With Chronic Kidney Disease (KNOW-CKD), 1,039 patients whose serum uric acid were measured more than 3 times were included. Patients were classified into three groups according to repeatedly measured uric acid levels by trajectory analysis using K-means. We investigated baseline characteristics and outcomes of each group. Renal events were defined as either doubling of creatinine, estimated glomerular filtration rate halving, or end-stage renal disease. Composite events were defined as either death, non-fatal cardiovascular disease, or renal event.

Results: Mean uric acid level was 4.91 ± 1.36 mg/dL for low uric acid group, 6.29 ± 1.28 mg/dL for middle uric acid group, and 8.53 ± 1.26 mg/dL for high uric acid group. Men accounted for 42.4%, 64.1%, and 70.4% in low, middle, and high uric acid group, respectively. Proportion of patients with hypertension (99.0%) and diabetes mellitus (DM) (24.2%) were the greatest in high uric acid group. The risk of renal event was 2.01-fold higher in high uric acid group (95% CI 1.43-2.84, P < 0.001) than middle uric acid group when adjusted for age, sex, hypertension and DM, and 2.16-fold higher (95% CI 1.24-3.75, P = 0.006) when additionally adjusted for other relative factors. The risk of composite event of high uric acid group was also significantly higher compared with middle uric acid group after adjustment for age, sex, hypertension, and DM (HR 2.37, 95% CI 1.62-3.47), and after adjustment for additional factors (HR 2.99, 95% CI 1.60-5.68, P <0.001).

Conclusions: High uric acid level in longitudinal aspect was associated with adverse renal outcome and composite outcome in chronic kidney disease patients.

Acid Retention Decreases Urine Citrate Excretion Through Reduced Kidney Clearance and Reduced Plasma Concentration of Citrate

Nimrit Goraya,[1] Jan Simoni,[5,4] Abdullah A. Mamun,[4] Nicolaos E. Madias,[2] Donald E. Wesson.[3,1] *[1]Internal Medicine, Texas A&M HSC College of Medicine, Temple, TX; [2]Tufts University School of Medicine, Boston, MA; [3]Baylor Scott and White Health and Wellness Center, Dallas, TX; [4]Internal Medicine, Baylor Scott & White Health, Dallas, TX; [5]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Decreased urine excretion of the pH-sensitive metabolite citrate is a potential biomarker of H+ retention in patients with CKD and reduced eGFR but no metabolic acidosis (Goraya.KI 95:1190, 2019). We explored contributions of reduced plasma citrate (Pcit) and/or reduced kidney citrate clearance (UV/Pcit) to decreasing urine citrate excretion associated with increasing H+ retention over time.

Methods: We measured H+ retention, 8-hour urine citrate excretion (UcitrateV), Pcit, and UV/Pcit in macroalbuminuric, non-diabetic CKD 2 patients with hypertension associated nephropathy without metabolic acidosis (plasma total CO2 >24 mM) at baseline and after treatment with 0.5 meq/kg bw/day NaHCO3 (HCO3, n=40), 0.5 meq/kg bw/day NaCl (NaCl, n=40), or usual care (UC, n=40) and assessed after 5 years.

Results: Baseline H+ retention, UcitrateV, Pcit, and UV/Pcit were not different among groups. The 5-year vs. respective baseline value in HCO3 patients was not different for H+ retention (16.1±12.9 vs 18.1±14.8 mmol, p=0.46) or UcitrateV (1.063±0.244 vs 1.032±0.259 mmol, p=0.69). However, the 5-year vs respective baseline value in NaCl patients was higher for H+ retention (23.2±14.0 vs 19.2±16.7 mmol, p<0.01) and lower for UcitrateV (0.910±0.233 vs 1.021±0.275 mmol, p<0.01). Similarly, 5-year vs baseline value in UC was higher for H+ retention (22.1±11.2 vs. 17.4±9.9 mmol, p<0.01) and lower for UcitrateV (0.899±0.217 vs 0.989±0.212 mmol, p<0.01). Five-year vs.baseline value for Pcit was not different for HCO3 (0.050±0.016 vs. 0.048±0.016 mM, p=0.46) and NaCl (0.051±0.023 vs. 0.054±0.025 mM, p=0.08) but was lower for UC (0.050±0.020 vs. 0.052±0.020 mM, p<0.02). Five-year vs. baseline value for UV/Pcit was not different for HCO3 (0.048±0.011 vs. 0.047±0.008 ml/min/1.73m2, p=0.94) but was lower for NaCl (0.043±0.016 vs. 0.047±0.018 ml/min/1.73m2, p<0.002) and UC (0.045±0.024 vs. 0.048±0.024 ml/min/1.73m2, p<0.004)

Conclusions: Both reduced UV/Pcit and reduced Pcit mediated decreased UcitrateV in CKD patients without metabolic acidosis whose H+ retention increased after 5 years without alkali therapy but both parameters were unchanged in those treated with alkali in whom H+ retention did not increase. Increasing H+ retention initiates kidney and extra-kidney mechanisms for citrate conservation.

FR-PO308

A Serum Magnesium Concentration Lower Than 2 mg/dL Predicts Mortality in CKD Patients: A Propensity Score-Matching Study

Cristian Rodelo-Haad,[1,2] Rafael Santamaria,[1,2] Isabel López-López,[1,2] Victoria Pendon-Ruiz de Mier,[1,2] Cayetana M. Peregrin,[1,2] Raquel Ojeda lopez,[1,2] Mariano Rodriguez,[1,2] Juan R. Munoz-Castaneda,[2,1] Alejandro Martin-Malo,[1,2] Sagrario Soriano.[1,2] *[1]University Hospital Reina Sofia, Córdoba, Spain; [2]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Cordoba, Spain.*

Background: Decreased serum mg may be associated with mortality and vascular calcifications. There is limited information on the impact of low mg (mg) in CKD stage 4 patients. We aimed to evaluate whether serum mg levels are associated with mortality in a matched population of CKD patients.

Methods: Patients were stratified into tertiles according to serum mg (T1<2.0 mg/dl, T2 =2.01-2.39 mg/dl and T3>2.4 mg/dl). For survival analysis, we used log-rank tests to compare Kaplan–Meier (KM) probability of death curves and performed uni- and multivariable Cox regression analysis. Given the comparable survival among T2 and T3 patients, serum mg <> 2 mg/dl was used to further perform propensity score matching (PSM) to minimize potential confounding and selection biases within tertiles. We used the derived propensity scores to match the groups in a 1:1 ratio. Further, KM analysis with the matched population was performed.

Results: This study included 1002 patients evaluated in the advanced-CKD outpatient clinic from 2009 to 2018. During the study follow-up, 158 died, 84 from T1, 34 from T2, and 35 from T3. Furthermore, 616 patients started dialysis, whereas 242 remained under follow-up in the outpatient clinic. KM showed that patients from T1 had a worse survival as compared with T2 and T3 (p<0.001; Figure 1A). Multivariate Cox proportional hazard showed that patients with mg <2 mg/dl had a higher mortality risk (HR 1.61, CI 1.05—2.46) as compared to the other groups. After matching, it was obtained an adjusted population of 343 patients with mg <2 mg/dl and 343 with higher concentrations of mg. Survival analysis with PSM-adjusted cohorts showed that patients with mg <2 mg/dl had worse survival compared to T2 and T3 (log-rank p=0.01; HR 1.73, CI 1.02—2.36, p=0.44; Figure 1B)

Conclusions: In appropriately-matched patients, a serum mg <2 mg/dl predicts mortality.

Funding: Government Support - Non-U.S.

FR-PO309

Urine Hydroxyproline as a Marker of Renal Dysfunction in Patients with CKD

Jongho Son, Eun Sil Koh, Cheol Whee Park, Sungjin Chung. *The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Hydroxyproline (Hyp) is major component of the protein collagen in the tissues. Most of the Hyp released by the breakdown of collagen is degraded to free amino acid that circulates in plasma, is filtered, and is almost entirely reabsorbed by the kidney while some of the Hyp circulates in the peptide-bound form and are excreted in urine without further metabolism. This study was designed to examine whether the measurement of urinary Hyp could be useful for assessing renal function in the patients with chronic kidney disease (CKD).

Methods: A total of 298 patients with various stages of non-dialytic CKD were included in this study. Values of total and free Hyp were measured from 24 hours urine and urininary free-to-total Hyp ratio was calculated to compare with known renal functional parameters (from January 5th, 2016 to May 7th, 2018)

Results: Median levels of urinary free Hyp and total Hyp are 0.70 mg/day (IQR 0.30-2.10 mg/day) and 125.00 μmol/day (IQR 80.00-196.00 μmol/day), respectively. Univariate linear regression analysis showed that urinary free-to-total Hyp ratio was correlated with creatinine (β=0.399, P<0.001), estimated glomerular filtration rate (eGFR; β=-0.213, P=0.001), cystatin C (β=0.338, P<0.001), proteinuria (β=0.181, P=0.004) and fractional excretion of sodium (β=0.141, P=0.023). Results of multiple linear regression analysis showed that beta-coefficient of eGFR was –0.155 (P=0.084) for urinary free Hyp, 0.134 (P=0.091) for urinary total Hyp and –0.172 (P=0.042) for urinary free-to-total Hyp ratio, even after controlling for covariates, including age, gender and proteinuria.

Conclusions: Our results suggest that urinary free-to-total Hyp ratio would be used as a novel endogenous marker of renal dysfunction.

FR-PO310

Interaction Between Apolipoprotein L1 (APOL1) Genetic Risk and Air Pollution for Kidney Disease in African Americans

Nicholas B. Defelice,[1] Lili Chan,[2] Steven G. Coca,[2] Carol Horowitz,[2] Richard Cooper,[3] Girish N. Nadkarni.[1] *[1]Icahn School of Medicine, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Loyola University Chicago, Maywood, IL.*

Background: The *APOL1* high-risk genotype is frequent in African Americans (AAs) and is associated with increased chronic kidney disease (CKD). However, only a fraction of individuals with *APOL1* risk have CKD, indicating the presence of disease modifiers ('second hits'). Air pollution, measured by particulate matter ≤2.5 micrometers ($PM_{2.5}$) is an emerging risk factor for CKD and AAs are disproportionately exposed to higher levels. We assessed whether *APOL1* and environmental ($PM_{2.5}$) risk interact.

Methods: We used data from an urban biobanked cohort (Bio*Me* Biobank). This includes linked genotype, demographic and clinical data. We geocoded address level data from initial enrollment date and assigned a census track to link $PM_{2.5}$ estimates from EPAs Downscaler Model. We assigned annual average concentrations using daily $PM_{2.5}$ exposure from the 365 days before enrollment. We considered CKD after enrollment and fit a logistic model accounting for *APOL1*, $PM_{2.5}$ and their interaction, after adjusting for confounders.

Results: We had data on 4800 AAs and 675 (14%) had *APOL1* high-risk. Individuals with *APOL1* high-risk had lower baseline eGFR vs. low risk (75 vs. 81 ml/min). There were no other significant differences. The median $PM_{2.5}$ concentrations were 12.5 $\mu g/m^3$ and did not differ by *APOL1* risk. There were significant associations with CKD for both *APOL1* (adjusted OR 1.5; 95% CI 1.2-1.8) and with $PM_{2.5}$ (adjusted OR 1.09; 95% CI 1.08-1.10 per $\mu g/m^3$ increase) in fully adjusted models. In models accounting for interaction between *APOL1* and $PM_{2.5}$, although both significantly were associated with CKD, there was a possible interaction ($P_{interaction}$=0.06)

Conclusions: *APOL1* and $PM_{2.5}$ may interact for CKD. If validated, air pollution may be a novel environmental 'second hit' for baseline *APOL1* genetic risk.

Funding: NIDDK Support

Table 1. Logistic Regression Model including APOL1 and Air Pollution

	Adjusted Odds Ratio (95% Confidence Interval)	P Value
APOL1 Risk Genotype	1.51 (1.20-1.81)	<0.01
PM2.5 concentration (per μg/m3 increment)	1.09 (1.08-1.10)	<0.01
Interaction term between APOL1 and PM2.5 (continuous)	0.83 (0.7-1.02)	0.06
Age per year increment	1.03 (1.02-1.04)	<0.01
Body Mass Index per 1kg/m2 increment	1.02 (1.01-1.03)	<0.01
Baseline eGFR per 1ml/min decrease	1.06 (1.05-1.07)	<0.01
Education less than high school	0.82 (0.62-1.10)	0.19
African genetic ancestry	0.93 (0.45-1.93)	0.84

FR-PO311

The Effects of Serum Hemoglobin on Renal Survival in Pre-Dialysis CKD: Results from the Korean Cohort Study for Outcomes in Patients with CKD (KNOW-CKD)

Ji Young Ryu,[1] Yongjin Yi,[1] Kipyo Kim,[1] Sejoong Kim,[1,2] Ho Jun Chin,[1,2] Ki Young Na,[1,2] Dong-Wan Chae.[1,2] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: The currently recommended hemoglobin (Hb) targets in CKD based on interventional studies using erythropoiesis stimulating agents (ESA) with outcomes such as cardiovascular events might be inappropriate for Hb target aiming for renal survival in CKD. Thus, we analyzed the effect of Hb on renal outcomes in a prospective pre-dialysis CKD cohort.

Methods: We analyzed the data from 2,197 subjects in KNOW-CKD which is a currently on-going prospective cohort study of CKD in Korea (NCT01630486 at www.clinicaltrials.gov). Renal event (RE) was defined by the doubling of serum creatinine or 50% decrease in estimated GFR (eGFR) by CKD-EPI equation from the baseline, or the initiation of renal replacement treatment. The subjects were grouped according to quartile value of Hb, with ranges of Q1 < 11.2 g/dL, Q2 11.3-12.7 g/dL, Q3 12.8-14.2g/dL and Q4 >14.3g/dL respectively.

Results: Out of 2,197 subjects, a total of 577 subjects (26.3%) developed RE during the mean follow up of 1,289.3±659.5 days. Cox regression analysis adjusted by sex, age, eGFR, urine albumin creatinine ratio, systolic blood pressure, medical history of diabetes mellitus(DM), hypertension, coronary artery diseases (CAD), hypercholesterolemia, smoking and alcohol revealed that each 1g/dL increase of Hb was associated with 19.4% risk reduction for RE (HR=0.806; 95% CI 0.758-0.858, p=0.000). Time dependent Cox regression adjusted by the same variables revealed that RE decreased along with Hb quartile groups (Q1: reference, Q2: HR=0.463; 95% CI 0.303-0.709; p=0.000, Q3: HR=0.176; 95% CI 0.094-0.328; p=0.000, Q4: HR=0.099; 95% CI 0.041-0.234; p=0.000, respectively). The favorable effects of Hb on RE were also consistent in subjects with higher cardiovascular risk factors such as DM, CAD, or coronary artery calcium score>100. ESA were used in only 167 subjects (7.6%) in which RE developed in 101 subjects (60.5%). It was also evident in ESA-receiving group in which each 1g/dL increase of Hb was associated with 21.1% risk reduction for RE (HR=0.799; 95% CI 0.677-0.943, p=0.000).

Conclusions: Targeting higher Hb level than current guideline was associated with the favorable renal outcomes in pre-dialysis CKD irrespective of the presence of higher cardiovascular risks or the usage of ESA.

FR-PO312

Clinical Factors, Non-Neoplastic Histological Variables and Kidney Function in Patients Undergoing Partial Nephrectomy in Solitary Kidneys or Bilateral Partial Nephrectomies

Jair Munoz Mendoza, Kelsey Pan, Oleksii Iakymenko, Dipen Parekh, Gabriel Contreras, Liz Y. Bayes santos, David B. Thomas. *University of Miami, Miami, FL.*

Background: Significant nephron mass reduction after nephrectomies carries the risk of substantial worsening kidney function. We aimed to evaluate the relationship among clinical, non-neoplastic histological abnormalities and glomerular filtration rate (eGFR) after partial nephrectomy (PN) in solitary kidneys or bilateral PN.

Methods: We studied 57 patients, 24 with PN in a solitary kidney and 33 with bilateral PN. We used Pearson coefficient correlations and logistic regression analyses to evaluate the association between age, hypertension (HTN), diabetes, baseline eGFR, histological variables and post-nephrectomy eGFR at discharge.

Results: The mean age was 62 ± 13 years. The majority had HTN (81%), 23% had diabetes and 46% had chronic kidney disease. The baseline eGFR was 64 ± 26 ml/min/1.73m^2. Of the 36 patients with non-neoplastic histological data available, 75% had interstitial fibrosis (IF), 83% had global glomerulosclerosis (GGS) and 92% had arteriosclerosis (AS). Post-nephrectomy eGFR correlated with baseline eGFR (r=0.7; p<0.001) and IF% (r=-0.4, p<0.05), although not statistical significant, there was a trend in the correlation between post-nephrectomy eGFR and GGS% (r=-0.3; p=0.07). In multivariable-adjusted logistic regression analyses, post-nephrectomy eGFR < 45 ml/min/1.73m^2 was significantly associated with lower baseline eGFR (odds ratio [OR] per 10 units change in eGFR, 0.5[95% confidence interval (CI), 0.3-0.7)]) and PN in a solitary kidney compared to bilateral PN (OR, 6.6[95% CI, 1.3-34.2])

Conclusions: Lower baseline eGFR levels and PN in a solitary kidney compared with bilateral PN were independently associated with significant greater odds of post-nephrectomy eGFR < 45 ml/min/1.73m^2. IF% was significantly correlated with post nephrectomy eGFR.

FR-PO313

A Novel Single Domain, I-Body AD-114, Attenuated Kidney Fibrosis Through Targeting CXCR4

Qinghua Cao,[1,2] Hao Yi,[1] Chunling Huang,[3] Michael Foley,[4] Carol A. Pollock,[2] Xinming Chen.[3] Renal Medicine of Kolling Institute *[1]Kolling Institute, St. Leonards, NSW, Australia; [2]The University of Sydney, St. Leonards, NSW, Australia; [3]University of Sydney, Sydney, NSW, Australia; [4]La Trobe University, Melbourne, NSW, Australia.*

Background: Kidney fibrosis, the final common pathway of various forms of chronic kidney disease (CKD), affects 10% of the world's population. However, the efficiency of current therapies is limited. The G-protein coupled C-X-C chemokine receptor 4, CXCR4, is a potential therapeutic target for tissue fibrosis. To date, the only approved CXCR4 antagonist (AMD3100) was terminated due to its off-target cardiotoxicity. Recently we have developed a fully human single-domain antibody-like scaffold termed i-body AD-114 with specific high binding affinity to CXCR4. AD-114 selectively blocks CXCR4 signaling and has shown anti-fibrotic effects in pulmonary fibrosis. The present studies have demonstrated the renoprotection of AD-114 in kidney fibrosis.

Methods: CXCR4 expression in the kidney biopsies from patients with diabetic kidney disease (DKD) and kidneys from three mouse models of CKD was detected using immunohistochemistry (IHC). To determine the preventive role of AD-114 in the development of CKD, a mouse model of folic acid (FA)-induced nephropathy was used. C57/BL6 mice (6-8 weeks, N = 10) were challenged with 250 mg/kg of FA followed by daily administration of AD-114(10 mg/kg) intraperitoneally for 21 day. Nonspecific i-body that doesn't bind CXCR4(10 mg/kg) and AMD3100(10 mg/kg) served as negative and positive controls. To assess the therapeutic role, i-body administration commenced when renal injury was established at Day 8 of FA injection and continued for 14 days. Renal function, histology and ECM deposition were assessed by urine creatinine/albumin kits, IHC and Masson's trichrome staining.

Results: CXCR4 expression was significantly upregulated in patients with DKD and fibrotic kidneys of three mouse models of CKD compared to control groups (P<0.001, N=6). In both prophylactic and therapeutic models, the results showed AD-114 markedly ameliorated renal function impairment (24h urine albumin/creatinine ratio) and fibrotic kidney remodeling (Masson's trichrome staining) and attenuated the FA-induced overexpression of collagen-4 (COL-4), fibronectin (FN), collagen-1(COL-1), collagen-3 (COL-3) and α-SMA (IHC) in kidneys compared to negative control i-body.

Conclusions: AD-114 effectively ameliorated fibrotic kidney remodeling through targeting CXCR4 signaling in a murine model of kidney fibrosis.

Assessment of the Feasibility of Measuring Salivary Urea by Attenuated Total Reflection-Fourier Transform Infrared Spectroscopy to Diagnose and Stage CKD

Tzu-Ling Lin,[1] Rhys D. Evans,[1] Robert J. Unwin,[1,3] Jill T. Norman,[1] Peter R. Rich.[2] *[1]Renal Medicine, University College London, London, United Kingdom; [2]Structural and Molecular Biology, University College London, London, United Kingdom; [3]Early Clinical Development, Cardiovascular, Renal and Metabolism (CVRM), AstraZeneca Biopharmaceuticals R&D, Gothenburg, Sweden.*

Background: Attenuated total reflection Fourier-transform infrared (ATR-FTIR) spectroscopy has been shown to provide a straightforward, reagent-free method for the staging and diagnosis of different diseases including pancreatic cancer, and kidney stones. Recently, disposable ATR-FTIR internal reflection elements have been developed. It is plausible, given further advancements, for this technology to be miniaturised and utilised in portable diagnostic devices. Previous studies have shown a correlation between salivary and serum urea in chronic kidney disease (CKD) patients. However, these studies employed costly, labour-intensive commercial kits which limits wider applicability, therefore we assessed the feasibility of ATR-FTIR spectroscopy as an alternative method to measure salivary urea in patients with different stages of CKD.

Methods: The ATR-FTIR spectra of dried saliva samples from 6 healthy controls and 20 CKD patients (stage1-5) were recorded and analysed to provide their urea concentrations in the clinically-relevant range. The correlation between salivary urea and serum urea was also determined. The diagnostic performance of ATR-FTIR spectroscopy to diagnose CKD was assessed from the sensitivity and specificity parameters of a receiver operating characteristics (ROC) curve analysis.

Results: The limit of detection of salivary urea by ATR-FTIR spectroscopy is 2 mM. Statistically significant differences in salivary urea concentration were demonstrated between healthy subjects (4.6±1.4 mM) and CKD patients stages 3-5 (CKD 3: 6.8±0.7 mM, p<0.05; CKD 4: 9.1±1 mM, p<0.001; CKD 5: 14.8±1.6 mM, p<0.001). However, no significant differences were detected between CKD stage 1-2 and healthy controls. ROC analyses (the value ranging from 0.95-1) confirmed the suitability of the method for determination of salivary urea concentrations in the clinically-relevant range, with the sensitivities of 0.86-1 and specificities of 0.93-1.

Conclusions: This study showed that salivary urea can be measured by ATR-FTIR spectroscopy with significant differences in salivary urea levels between CKD stage 3-5 and normal subjects. The development of simple single-use ATR-FTIR spectroscopy devices may be a screening tool for rapid quantitation of salivary urea to diagnose CKD.

FR-PO315

CT Mapping of Spinal and Vascular Abdominal Urate Deposition with Correlation to Uric Acid Level

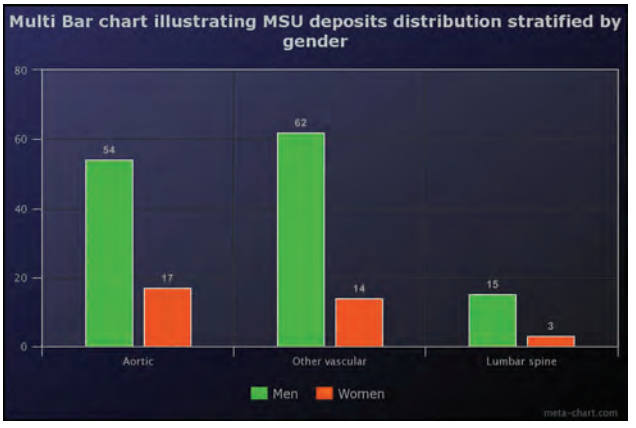
Waleed Abdellatif,[1,2] Juvel Lee,[1] Sunghan Jung,[1] Ahmed Negida,[3] Bo Gong,[1] Savvas Nicolaou.[4] *[1]University of British Columbia, Vancouver, BC, Canada; [2]Radiology, Vancouver general hospital, Vancouver, BC, Canada; [3]Zagazig University, Zagazig, Egypt; [4]Vancouver General Hospital, Vancouver, BC, Canada.*

Background: Gout prevalence is about 1-5% in the western world, predominantly in elderly men. Monosodium urate (MSU) deposition outside extremities has been scarcely investigated yet may be a potential indicator of tophus burden and impending clinical deterioration.

Methods: After IRB approval, retrospective single center analysis of all Dual Energy CT abdomen and pelvis scans from January 2007 to July 2018 was conducted. The inclusion criteria were: age > 50 years, gout asymptomatic with high or normal uric acid level. All cases were then assessed by two radiologists using a validated software. The study was divided into two sub-cohorts based on gender, and assessed along three main parameters: aortic, other vascular (e.g. renal, iliac. etc) and lumbar deposits.

Results: 351 cases met the inclusion criteria (197 males, 56% and 154 females, 43.9%). Aortic, other vascular and spinal deposits were detected in 20.2%, 21.7% and 5.1% respectively. A statisical significant association between gender and gout deposits in all the three groups was detected with deposists more prevalent in men than women in all groups (27.4%, 31.5% and 7.6% for men and 11.0%, 9.1% and 1.9% for women in abdominal aorta, other vessels and lumbar spine respectively). Regression analysis showed that uric acid levels cannot predict aortic deposits in neither men (p = 0.91) nor women (p= 0.198) groups. On the other hand, uric acid level can significantly predict other vascular deposits in women only (r=0.005, p= 0,003) and the spinal deposits in both men (r= 0.01, p= 0.003) and women (r=0.002, p= 0.037) groups. Study limitations include retrospective analysis and feasibility sample.

Conclusions: MSU CT mapping was positive in gout-asympomatic patients with normal or high uric acid levels and are more prevalent in men than women. Uric acid level cannot predict aortic deposits but can predict other vascular deposits in women only and spinal deposits in both men and women.



FR-PO316

Pilot Study of Reloxaliase in Subjects with Severe Enteric Hyperoxaluria and Hyperoxalemia: A Pro Tem Analysis of Study ALLN-177-206

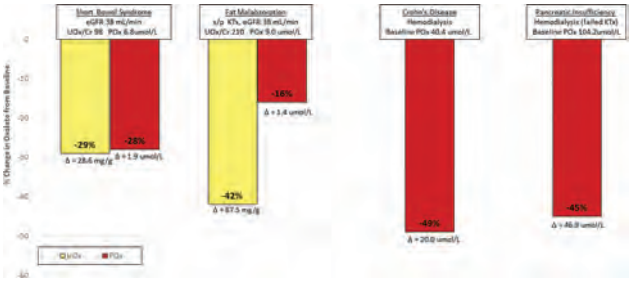
Felix Knauf,[1] John C. Lieske,[2] Anja C. Pfau,[1] Danica Grujic,[3] Kristine E. Bernard,[3] Annamaria T. Kausz.[3] *[1]University Hospital Charite Berlin, Berlin, Germany; [2]Mayo Clinic, Rochester, MN; [3]Allena Pharmaceuticals, Newton, MA.*

Background: Enteric hyperoxaluria (EH) refers to increased urinary oxalate (UOx) excretion as a complication of fat malabsorption due to GI surgery, or other gastrointestinal conditions. Hyperoxaluria, a major risk factor for kidney stones, can also lead to chronic kidney disease (CKD), including end-stage kidney disease. With decreasing kidney function, plasma oxalate (POx) levels can rise, resulting in oxalate deposition in the kidneys and other tissues. Reloxaliase is an oral enzyme which degrades oxalate in the GI tract. This study is enrolling patients with EH and CKD to examine the potential of reloxaliase to reduce UOx and POx.

Methods: This open label study is enrolling patients with EH, CKD and hyperoxalemia (UOx ≥40 mg/24h, eGFR <45 mL/min/1.73m^2 and POx >5 µmol/L), who receive reloxaliase 7,500U orally 5 x/d for 12 weeks. POx and 24h UOx are obtained monthly; in subjects on dialysis, POx is collected immediately before a dialysis session following the longest weekly interval between sessions. Efficacy is assessed based upon change from baseline to on-treatment average POx and UOx.

Results: To date, 4 EH subjects have completed the study; two have Stage 3 and 3bT CKD (short bowel syndrome, fat malabsorption s/p kidney transplant) and 2 are on hemodialysis (Crohn's disease, pancreatic insufficiency). Treatment compliance was >90% on average, and therapy was well tolerated. Reloxaliase reduced 24-hr UOx (normalized to creatinine) by 29-42%, and POx by 16-49%. The figure below provides high level case summaries, and the bars show the % change in UOx (yellow) or POx (red) from baseline.

Conclusions: In this population, reloxaliase was well tolerated and reduced both UOx and POx, suggesting the potential for reducing systemic oxalate deposition with chronic therapy. These preliminary data support further testing of reloxaliase in patients with severe EH. To our knowledge, this is the first therapeutic reduction in plasma oxalate in patients with EH and CKD with oxalosis.



FR-PO317

Association of Serum Alkaline Phosphatase with CKD and Cognitive Function in Patients with Diabetes and Acute Coronary Syndrome

Mathias Haarhaus,[1,2] Kausik K. Ray,[3] Gregory G. Schwartz,[4] Ewelina Kulikowski,[5] Jan O. Johansson,[6] Michael Sweeney,[6] Aziz Khan,[5] Christopher Halliday,[5] Kenneth E. Lebioda,[5] Norman C. Wong,[5] Bengt Winblad,[7] Henrik Zetterberg,[8] Vincent Brandenburg,[9] Srinivasan Beddhu,[10] Marcello Tonelli,[11] Carmine Zoccali,[12] Kamyar Kalantar-Zadeh.[13,14] *[1]Division of Renal Medicine and Baxter Novum, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [2]Diaverum Sweden, Stockholm, Sweden; [3]Department of Primary Care and Public Health, School of Public Health, Imperial College London, London, United Kingdom; [4]School of Medicine, University of Colorado, Aurora, CO; [5]Resverlogix Corp., Calgary, AB, Canada; [6]Resverlogix Inc., San Francisco, CA; [7]Department of Neurobiology, Care Sciences and Society, Center for Alzheimer Research, Division of Neurogeriatrics, Karolinska Institutet, Huddinge, Sweden; [8]Department of Psychiatry and Neurochemistry- Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [9]Department of Cardiology and Nephrology, Rhein-Maas-Klinikum, Würselen, Germany; [10]Division of Nephrology and Hypertension and Medical Service, Veterans Affairs Salt Lake City Healthcare System, Salt Lake City, UT; [11]Department of Medicine, University of Calgary, Calgary, AB, Canada; [12]CNR IFC, Clinical Epidemiology of Renal Diseases and Hypertension, Reggio Calabria, Italy; [13]Division of Nephrology and Hypertension, Harold Simmons Center for Kidney Disease Research and Epidemiology, University of California Irvine, School of Medicine, Orange, CA; [14]Nephrology Section, Tibor Rubin Veterans Affairs Medical Center, Long Beach, CA.*

Background: Patients with diabetes and chronic kidney disease (CKD) have increased risk for cardiovascular disease events and vascular dementia. Alkaline phosphatase (ALP) is a risk marker and possible risk mediator for cardiovascular (CV) disease, Alzheimer's disease and vascular dementia. ALP has been reported to cross the blood brain barrier and to predict cognitive risk in CKD patients, potentially via vascular mechanisms or dephosphorylation of tau. Apabetalone is a bromodomain and extraterminal (BET) inhibitor selective for bromodomain 2, lowers ALP in a dose-response fashion and is being evaluated for prevention of CV disease events in the phase 3 BETonMACE trial. We examined baseline data from that trial to define the associations of ALP with CKD and cognitive function.

Methods: BETonMACE compares cardiovascular outcomes with apabetalone or placebo in 2425 patients with diabetes and acute coronary syndrome. CKD was defined by eGFR < 60 mL/min/1.73m^2. Cognition was assessed by the Montreal Cognitive Assessment tool (MoCA) in patients aged 70 and older at baseline (n=467) including in CKD patients (n=86).

Results: CKD was present in 11% (n=263) and was associated with age, female sex, longer history of diabetes, and higher ALP. Approximately half of the population showed MoCA score <26 suggesting early cognitive impairment. Lower MoCA score was associated with: a) higher ALP, and, b) with presence of CKD.

Conclusions: Elevated ALP is associated with poorer cognitive function and greater prevalence of CKD. Apabetalone, which lowers ALP, is being evaluated for effects on CV events, CKD, and cognitive function in the phase 3 BETonMACE trial reporting 2019.

FR-PO318

The KDIGO 2012 CKD Classification System Improves Physician Recognition and Management of Kidney Disease: A Randomized Vignette Study

Stein I. Hallan,[1] Dena E. Rifkin,[2] O. Alison Potok,[2] Knut Asbjørn R. Langlo,[3] Friedo W. Dekker,[4] Joachim H. Ix.[2] *[1]NTNU, Trondheim, Norway; [2]UCSD, San Diego, CA; [3]St. Olavs Hospital HF, Trondheim, Norway; [4]Leiden University Medical Center, Leiden, Netherlands.*

Background: Chronic kidney disease (CKD) is common worldwide with high morbidity and mortality rates. New international guidelines based on estimated glomerular filtration rate (eGFR) versus albuminuria were introduced 2012 to help with diagnosis, classification, referral, and treatment, but their clinical utility has not been evaluated. We therefore wanted to determine if KDIGO guideline helps physicians recognize and appropriately care for CKD patients.

Methods: We conducted a randomized vignette experiment with fractional factorial design based on 6 kidney-related scenarios and 3 laboratory presentation methods reflecting the KDIGO guideline. Participants evaluated one of three subsets of the 18 vignettes (i.e. 6 vignettes each with 4 answer alternatives). Kidney related results (serum creatinine and urine albumin) were presented as the "Old" (high/low levels), "Modern" (eGFR reported automatically), or "Future" (eGFR + albuminuria categorization + risk for complications = full 2012 KDIGO classification) laboratory report. Logistic regression modelled correct CKD management with laboratory presentation technique, clinical scenario, and other physician covariates. We included 249 interns, general practitioners, and residents/fellows from Norway and the US participating in post-graduate meetings and courses provided to physicians in training.

Results: When kidney laboratory data was presented as the "Modern report" (automatic eGFR calculation), there was a significantly higher probability for correct patient management compared to the "Old report" (OR 1.57, p<0.0001). Additional significant improvement was obtained with the "Future report" (OR 2.28 for correct answer, p<0.001 vs. "Old report"; OR 1.45, p=0.005 vs. "Modern report"). The 2012 KDIGO classification system improved physician management in 4 of the 6 clinical scenarios covering a wide range of kidney-related topics. Interaction analysis showed that GPs and those with 1-3 years of internal medicine experience had the strongest improvements with the new presentation techniques

Conclusions: Automatic GFR estimation, albuminuria categorization, and notification of the associated risk for complications improve most physicians' recognition and management of a wide range of CKD clinical scenarios.

Residential Greenness Improves Clinical Outcomes of Patients with CKD

Jae Yoon Park,[1] Jiyun Jung,[4] Yong Chul Kim,[3] Kyung Soo Kim,[6] Yon Su Kim,[5] Ho Kim,[4] Jung Pyo Lee.[2] *[1]Dongguk University Ilsan Hospital, Gyeonggido, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [3]SNUH, Seoul, Republic of Korea; [4]Seoul National University, Seoul, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea; [6]Dongguk University Hospital, Goyang City, Republic of Korea.*

Background: As industrialization has progressed, green areas have been decreasing. The association between the distribution of green spaces and health outcomes is becoming global issues, especially regarding cardiovascular and respiratory diseases. However, little is known for relationship between residential greenness and survival of patients with chronic kidney disease (CKD).

Methods: 64,780 patients who visited 3 medical centers (Seoul National University Hospital, Seoul National University Bundang Hospital, Seoul National University Boramae Medical Center) from January 2001 to December 2016 were enrolled in the cohort study. Cox proportional hazard models were used to identify the association between long-term exposure of green space and mortality of patients with CKD, occurrence of end-stage renal disease (ESRD) and major adverse cardiovascular events (MACE) which were adjusted by age, sex, estimated glomerular filtration rate, hemoglobin albumin, hypertension, diabetes and mean particulate matter < 10 μm in aerodynamic diameter (PM_{10}). Green space was defined as average normalized difference vegetation index (NDVI) in summer (Jun-Aug) around patients' residence within 250m and 1250m area measured by MODIS satellite.

Results: The mean age of patients was 54 years, and 49 % of them were male. During the mean 6.75 follow-up years, 8,557 deaths (13%) occurred. Higher levels of residential greenness within 250m area (0.1 increases in residential NDVI) had lower HRs for all-cause mortality (HR 0.91, CI 0.89-0.94), MACE (HR 0.94, CI 0.90-0.97) and progression to ESRD (HR 0.88, CI 0.83-0.93), which were adjusted by PM_{10} of observation stations within 5km around the residence. Those who were highly educated, non-smokers and non-drinkers were more affected by residential greenness. These results were consistent for the 1,250m area which were adjusted by mean PM_{10} within 3km and 5km around residence.

Conclusions: CKD patients who lived in areas with higher levels of greenness had reduced risks of all-cause mortality, MACE and progression to ESRD.

FR-PO320

Role of Demographic Variables on Prevalence of Anxiety and Depression (AAD) in CKD Patients and Its Co-Relation with Quality of Life and CKD Outcome Parameters

Pratim Sengupta.[1,2] *[1]Nephrology, Bellevue Clinic, Kolkata, India; [2]Nephrology, ILS Hospital, Dumdum, Kolkata, India.*

Background: Adapting with AAD in presence of CKD is challenging. Being multifactorial addressing AAD needs better etiological understanding. The purpose of this study is to find the relationship between different riders of demography with AAD and to investigate whether AAD has any correlation with quality of life(QOL) or overall CKD outcome.

Methods: 583 CKD patients (18-80yrs) of different stages and etiology, were enrolled in this prospective observational study. Any previous or ongoing treatment of psychiatric disorder, medical ailments or sorrowful events during recent past at the time of inclusion were excluded. The Hospital Anxiety and Depression Scale (HADS) were used as a tool to measure the AAD level. Demographic data, medical history, education level, professional details, nature composition and support from family, number of dependents, financial burden, and healthcare insurance coverage data were recorded. Baseline serum creatinine, estimated GFR(MDRD), routine clinical and lab data, QOL parameters, hospitalization, cardiovascular events and mortality data were captured quarterly until the end of study. HADS was recorded every 3 months to assess the severity of AAD. All patients were longitudinally followed up for 5 years. SPSS v 25.0 was used for statistical analysis, $p \leq 0.05$ were considered as statistically significant

Results: Out of 583 CKD patients [145(24.9%) dialysis and 438(75.1%) pre-dialysis], 59.3% were male and 40.6% were female. Mean age was 57.75 ±13.53 years. Anxiety was predominant in pre-dialysis patients whereas depression was prominent in dialysis subgroup. AAD were significantly more among male than female and in middle-aged than in elderly. Socioeconomic status, family support, dependent members in family and insurance coverage were variably associated with AAD. Maximum AS was observed while first encounter with nephrologist and when being advised for RRT. AS >8.0 and DS >7.0 was significantly correlated with poorer QOL parameters. Poorer blood pressure control, faster decline of GFR and frequent hospitalization were significantly correlated with AS >8. A positive trend toward association of all-cause mortality was observed with DS >7.

Conclusions: Different demographic variables has significant impact on AAD in CKD. AAD has variable impact on QOL, BP control, CKD progression and hospitalization or all-cause mortality.

FR-PO321

Location and Preference for Place of Death in Those Supported by a Kidney Supportive Care Clinic

Sadia Jahan,[1] Louise Purtell,[2,3] Ann Bonner,[2,3] Helen G. Healy,[1,3] Cassandra Rawlings.[1] *[1]Metro North Hospital and Health Service, South Brisbane, QLD, Australia; [2]Queensland University of Technology, Brisbane, NSW, Australia; [3]NHMRC Chronic Kidney Disease Centre of Research Excellence, Brisbane, QLD, Australia.*

Background: Kidney supportive care (KSC) multidisciplinary clinics aim to improve quality of life and respect a person's wishes in death. One important outcome indicator of meeting a person's wishes is place of death (POD). The literature reports patients' preferred POD is most frequently their home or palliative care unit. Despite this body of literature, 54% of deaths in those aged over 65 occur in hospitals and 14% at home in Australia. We aim to assess if POD is concordant with actual POD in those known to KSC clinic.

Methods: Retrospective cohort study of patients attending a single center KSC clinic from February 2016 and who died prior to April 2019. Data including demographics, kidney replacement therapy pathway, prefered POD, actual POD, details of hospital deaths, timing of KSC clinic review were extracted from medical records. Early referal was defined as being seen in an out-patient setting and late referral defined as those not seen until the terminal hospital admission. Late and early group POD were compared using a Chi-Square test.

Results: 141 people were included in the analysis with the median age at death of 77 years (range 29-92 years), 40.4% female. Treatment pathways prior to death were haemodialysis (45.4%), peritoneal dialysis (6.4%) and conservative (48.2%). Referrals to KSC were early (73%) or late (27%). If seen early the preference for POD was in the community (80.6%; home or palliative care unit), hospital (9.7%) or it was unknown (9.7%). The preferred POD in those referred late was unknown (47.4%), community (36.8%) or hospital (15.8%). The early referral group were more likely to preference a community POD compared to late referrals (p=0.03). Concordance between preferred POD and actual POD in the early referral group was positive (63.1%), discordant (27.2%) or unknown (9.7%). Concordance in the late referral group was positive (31.6%), discordant (21%) or unknown (47.4%). The rate of concordance between groups was not statistically different.

Conclusions: Timely referral to a KSC clinic can assist with ensuring that death occurs in the preferred location. Late referrals do not allow adequate time for ascertaining or facilitating wishes. Ways to maximise quality of life and avoid medically futility need to be considered in this population.

FR-PO322

Experience of a Tertiary Center in the Training of Nephrology Fellows on Performing Real-Time Ultrasound-Guided Percutaneous Kidney Biopsy

Guilherme P. Santa Catharina, Igor Smolentzov, Precil D. Neves, Cristiane B. Dias, Luis Yu, Viktoria Woronik, Roberto Zatz, Lectícia Jorge. *University of Sao Paulo (USP), Sao Paulo, Brazil*.

Background: Percutaneous kidney biopsy is a fundamental diagnostic tool in Clinical Nephrology, but there is concern as to whether it can be performed by Fellows. The aims of this study were to report a 10-year experience of a tertiary academic center in the qualification of Fellows to perform ultrasound-guided percutaneous biopsies of native kidneys.

Methods: This is a retrospective cohort study of native kidney biopsies performed between January/2009 and December/2018. The procedures were performed by Fellows and supervised by experienced Nephrologists. Predictors of complications, clinical outcomes and sample quality were analyzed.

Results: A total of 1387 biopsies was performed; the mean age was 40.7±16.2 years, with 60% of women (n=830) and the Body Mass Index was 25.2 kg/m^2. At the time of biopsy, lab exams were: serum Creatinine 2.2 ± 1.9 mg/dL, BUN 31±16 mg/dL, Hemoglobin 11.7±1.8 g/dL and Platelet count 262±95x10^3/mm^3. As to complications, 91.4% (n=1268) had none, 4.5% (n=63) had hematuria; 2% (n=28) had symptomatic hematoma; 2% (n=28) had majorcomplications, defined by the need for transfusion and/or arteriography. Independent predictors of major complications were female gender (OR 2.9; CI 1.01 to 8.1; p=0.049), hemodialysis (OR 8.0; CI 2.9 to 9.2; p<0.001), low platelet count (OR 0.99; CI 0.98 to 0.99; p=0.035) and hemoglobin level (OR 0.61; CI 0.40 to 0.96; p=0.032). The average sample contained18±10 glomeruli for light microscopy, 11±8 for immunofluorescence, while and 90% of samples contained at least 8 glomeruli.

Conclusions: Supervised kidney biopsies performed by Fellows in training were safe and efficient. Female gender, hemodialysis, low platelet count and hemoglobin levels were independent predictors for major complications.

FR-PO323

Online Peer Mentoring Is Associated with Improved Burden Score Among Caregivers of Patients with CKD

George C. Ezeji, Eric Mark J. Lopez, Jose C. Romeu, Korey Bartolomeo, Vernon M. Chinchilli, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA*.

Background: Caregivers experience significant burden resulting from providing care to patients with chronic kidney disease (CKD). Peer mentoring (PM) has been proposed as an effective strategy which may result in improvement in caregiver burden. This study evaluates the differences in the effect of online PM, face-to-face (FTF) PM, and usual care on burden among caregivers of patients with CKD.

Methods: A 16-hour structured program trained CKD patients and their caregivers to become peer mentors to newly diagnosed patients with CKD and their caregivers. Caregivers of patients with stage 4 or stage 5 CKD (n=86) were randomly assigned to online PM (n=29), FTF PM (n=29) or usual care (n=28). Online PM consisted of weekly communication through an interactive online platform, and more frequently through posts by the mentee. For the FTF group, the frequency of contact by a mentor was weekly by phone and monthly visit. PM was maintained for at least 6 months. Usual care participants received an information book about care of CKD patients. We used the 22-item Zarit Burden Interview (ZBI) to measure caregiver burden at baseline and months 12 and 18. Higher ZBI scores indicate heavier burden. We used linear mixed effect models to estimate the slope of change of ZBI score over time. SAS, version 9.4 was used for data analysis.

Results: A total of 70 caregivers completed the 18 month assessment. Baseline ZBI score and demographic characteristics (race, ethnicity, gender, age, marital status, education, employment status and rural/urban location) were similar among the groups. The online PM group showed a significant improvement in the mean ZBI score between baseline and 12 months (23.6±12.1 vs. 16.5±9.1); this improvement was sustained at 18 months (15.2±9.9) (Slope estimate [SE]:-3.44; 95% confidence interval [CI]:-6.31, -0.57 [P=0.02]). The decrease in ZBI was not significant in the FTF group (SE:-2.50;CI: -5.85, 0.87 [P=0.14]), or the control group (SE: -1.26;CI: -4.06, 1.54 [P=0.36]). Improved ZBI with online PM was independent of demographic characteristics.

Conclusions: Online PM is associated with a significant improvement in burden score among caregivers of patients with advanced CKD. The improvement is sustained at 18 months and is independent of demographic characteristics. Funding by: PCORI

Funding: Other U.S. Government Support

FR-PO324

Association of eGFR Slopes Before and After CKD Education with Renal Prognosis

Takayuki Uemura,[1] Masaru Matsui,[1] Maiko Kokubu,[1] Kazuhiko Tsuruya.[2] *[1]Nara Prefecture General Medical Center, Nara, Japan; [2]Nara Medical University, Kashihara, Japan*.

Background: Multidisciplinary education for patients with CKD plays a critical role in the prevention for CKD progression and development of ESRD. In this study, we thus aimed to determine the relationship between eGFR slopes before and after CKD education and renal prognosis.

Methods: This is a retrospective cohort study on 617 patients who underwent in-hospital CKD education in Nara Prefecture General Medical Center between Jan. 2013 and Dec. 2016. Baseline data were collected at the time of CKD education. Patients with acute kidney injury, urologic malignancies, or collagen disease were excluded, leaving 194 patients for analysis. We calculated two eGFR slopes before and after education with three eGFR levels which were measured at 3 months to 1 year before CKD education, baseline and at least 1 year after education. We divided into 4 slope categories according to median levels of two eGFR slopes before and after education: slope categories were defined as slow-slow, fast-slow, slow-fast, fast-fast eGFR decliner. Outcomes are ESRD and eGFR decline of > 30%. Kaplan-Meier curve and Cox proportional hazards model with propensity adjustment were used to assess the association between slope categories and incidence of renal events. Patients with fast-slow eGFR decline were used as a reference group.

Results: The median age of study participants was 68 (59-78) years and 130 (67%) were male. The median levels of baseline eGFR were 33 (21-48) mL/min/1.73m^2. During the median follow-up period of 35 months, renal events occurred in 53 participants. Crude Kaplan-Meier analysis showed patients with slow-fast and fast-fast eGFR declines were significantly associated with renal events compared with those with slow-slow and fast-slow eGFR declines (p<0.001). In adjusted Cox hazard analysis, hazard ratios for outcomes were 1.72 (95%CI 0.38-8.8) for slow-slow, 5.15 (95%CI 1.72-22.2) for slow-fast and 7.27 (95%CI 2.53-30.7) for fast-fast eGFR decliner. Additionally, c-statistics of eGFR slope before education for renal events was 0.596 but that of eGFR slope after education was 0.843 and the cut-off level was -2.5 mL/min/1.73m^2/year.

Conclusions: Improvement from fast to slow eGFR decline via CKD education was significantly associated with better renal prognosis. However, CKD patients with rapid eGFR decline of ≤-2.5 mL/min/1.73m^2 after education have poor renal outcomes.

FR-PO325

Are Patients' Needs for Shared and Informed Decision Making About Kidney Replacement Therapy Being Addressed?

Tyler M. Barrett,[1] Jamie A. Green,[2] Patti Ephraim,[3] Sarah B. Peskoe,[1] Jane F. Pendergast,[1] Tara S. Strigo,[1] Chelsie Hauer,[2] Felicia Hill-Briggs,[3] Teri Browne,[4] George L. Jackson,[5,1] Raquel C. Greer,[3] Clarissa J. Diamantidis,[1] L. Ebony Boulware.[1] *[1]Duke University, Durham, NC; [2]Geisinger Medical Center, Danville, PA; [3]Johns Hopkins University, Baltimore, MD; [4]University of South Carolina, Columbia, SC; [5]Durham VA Medical Center, Durham, NC*.

Background: Little is known about how patients perceive shared and informed decision making (SDM) about kidney replacement therapy.

Methods: As part of the PREPARE NOW trial, we asked adults with CKD if they desired shared decision making [SDM] about CKD treatments (i.e., "the doctor and I make the final decisions together"). We also asked participants to what extent they had discussed different kidney replacement treatments and potential treatment impacts with their kidney treatment teams as well as their satisfaction with discussions. We derived 2-year kidney failure risks from medical records. In multivariable models, we quantified associations of participants' characteristics with treatment discussions and associations of discussion quality with participant satisfaction.

Results: Among 456 participants, 322 (70.6%) desired SDM. These 322 had a mean (SD) age of 70.2 (12.7) years, 60% were female, 96% White, and 62% high school or less educated. They received nephrology care for a median (IQR) of 3.85 (1.94-6.49) years. Half (52%) saw their nephrologists at least every 6 months, and 17% had a 2-year risk of kidney failure >10%. Only a third (35%, n=113) of those desiring SDM had discussed any treatments (peritoneal dialysis [45%], in-center hemodialysis [86%], home hemodialysis [50%], kidney transplant [59%], and conservative management [70%]). Few discussed treatment impacts on their finances (26%), family's wellbeing (29%), need for help from family (37%), length of life (49%), or quality of life (60%). Still, a majority (64.6%) were 'completely' satisfied with discussions. After adjustment, those seeing nephrologists for longer had greater odds of having discussed transplant (OR [95% CI]: 1.16 [1.02-1.32] per 1-year increase, p=0.02). Those whose teams discussed more modalities (OR [95% CI]: 1.66 [1.19-2.33], p<0.01) or treatment impacts (OR [95% CI]: 1.69 [1.26-2.27], p<0.01) had greater odds of being 'completely' satisfied.

Conclusions: Most patients prefer sharing CKD treatment decisions with their physicians, but treatment discussions are infrequent and do not address key treatment aspects. More frequent and thorough discussions could improve patients' SDM experiences.

FR-PO326

Timing of Decisions About Conservative Management of Advanced CKD: Are We Adding to Patient Burden?

Shahid M. Chandna,[1] Maria Da silva-gane,[2] Ken Farrington.[3] *[1]Lister Hospital, Stevenage, United Kingdom; [2]Lister Hospital (Renal Unit), Stevenage, United Kingdom; [3]Lister Renal Unit, Hitchin, United Kingdom*.

Background: Non-dialytic, Conservative management (CM) is an increasingly prevalent option for the management of advanced chronic kidney disease (CKD) – especially in patients of advanced age or with high comorbidity. There is an increasing trend for making the CM decision earlier in the course of CKD. Whilst this offers an advantage in avoidance of unnecessary preparations for dialysis, there is a risk of subjecting some patients, with very low likelihood of progression to ESRF, to unnecessary distress.

Methods: In this retrospective study, we examined all patients who had the CM decision made in our regional renal centre.

Results: From 1 January 2006 to 31 December 2015, 338 patients had the CM recorded in their diagnosis list. Median age was 82.1 (IQR 92) years. 79.8% of patients

were judged as having moderate or high comorbidity. The median eGFR at the time of initiation of CM discussion with patients was 13.8 (IQR 5.7) ml/min/1.73 m^2. 281 (83.1%) had died at the date of last follow up. 46% of patients had a median eGFR > 10 ml/min/1.73 m^2 at last follow-up. Median eGFR at the time of death in CM patients was 9.1 ml/min/1.73 m^2 (IQR 7.0). 42% of those who died had a last recorded eGFR > 10 ml/min/1.7 m^2. 32 patients (9.4%) developed severe acute kidney injury during follow-up and 8 of these (2.4%) received dialysis. 15 patients (4.4%) changed their decision from CM to dialysis. The median rate of eGFR decline in the year before CM decision was 3.8 (IQR 6.5) ml/min/year in the whole group. eGFR at CM decision was inversely related to rate of eGFR decline in tertiles (tertile 1 [slowest decline] - 14.7 (IQR 6.7), tertile 2 -13.6 (IQR 5.4), tertile 3 – 12. 9 (IQR 5.3): p = 0.006). eGRF at CM decision was higher in patients with high comorbidity compared to those with low-moderate levels (14.7 [1QR 5.7] vs 13.5 [IQR 5.5]: p = 0.032)

Conclusions: Many patient on the conservative pathway die at relatively high levels of kidney function (eGFR >10 ml/min/1.73 m^2), probably related to extrarenal comorbidity. Decision making seems to focus more on age, comorbidity, and absolute levels of eGFR than on eGFR trajectory. As a result of this it is possible that some patients are unnecessarily burdened with decisions relating to choices between options of renal replacement therapy.

FR-PO327

Health-Related Quality of Life Is Associated with Disease Progression in Adults with Advanced CKD Not on Renal Replacement Therapy

Matthew D. Jose,[1,2] Charlotte M. Mckercher.[2,3] Tasmanian CKD Study Investigators *[1]Royal Hobart Hospital, Hobart, TAS, Australia; [2]University of Tasmania, Hobart, TAS, Australia; [3]On behalf of Tasmanian CKD study investigators, Hobart, TAS, Australia*.

Background: Chronic kidney disease (CKD) is associated with reduced health-related quality of life (HRQOL). However, the association between HRQOL and disease progression prior to renal replacement therapy (RRT) is unclear. We examined the influence of HRQOL on disease progression in adults with Stage IV CKD (eGFR 15-29mls/min/1.73m^2) not on RRT.

Methods: Overall, 172 adults living in Tasmania, Australia provided data at baseline (2010-2012, 2016-2018). Of these, 152 participants attended a clinic where the Kidney Disease Quality of Life–Short Form was completed. Disease progression was examined using i) percentage annual change in eGFR [(eGFR at follow-up/eGFR at baseline)^(1/years elapsed between measurement)-1]*100 and ii) progression to CKD Stage V (eGFR<15mls/min/1.73m^2) or death. Generalized linear models were used to examine associations between HRQOL and disease progression adjusted for sociodemographic variables, comorbidities and laboratory factors.

Results: Overall, participants were predominantly male (63%) with a mean age of 72.2±10.2 years. At baseline, mean eGFR was 22.1±4.2 mls/min/1.73m^2 and serum creatinine was 242.3±56.4 μmol/L. Mean annual decline in eGFR was -4.2 mls/min/1.73m^2. Mean percentage annual change in eGFR was 8.8% with 61 (35%) participants progressing to CKD Stage V or death. Mean time to outcome was 446±289 days. Mean mental component summary (MCS) was 50.9±10.3 and physical component summary (PCS) was 38.6±10.4. Mean subscale scores were 81.8±17.5 for cognitive functioning and 74.0±24.9 for burden of disease. Improved cognitive functioning was positively associated with % annual change in eGFR (β=0.46, 95% CI 0.05-0.88, R^2=0.04,p<0.05). Both improved cognitive functioning (OR 0.98, 95% CI 0.95-0.99, R^2=0.23, p<0.05) and lower burden of disease (OR 0.98, 95% CI 0.96-0.99, R^2=0.24, p<0.05) were associated with lower odds of CKD Stage V or death. Baseline MCS and PCS were not associated with disease progression.

Conclusions: HRQOL involving self-reported cognitive functioning and burden of disease is associated with disease progression in adults with Stage IV CKD. Identifying modifiable risk factors is an important step in reducing the risk of RRT and premature death in this patient population and improving quality of life.

A Prospective Randomized Controlled Trial of Lifestyle Management for Preventing Respiratory Tract Infection in Patients with CKD

Meifang Liu,[2] Xusheng Liu,[2,1] Lei Zhang.[2,1] *[1]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; [2]The Second Clinical Medical College of Guangzhou University of Chinese Medicine, Guangzhou, China*.

Background: Respiratory tract infection (RTI) is a risk factor for progressive loss of kidney function. Lifestyle management has shown potential effect to prevent RTI in chronic kidney disease (CKD) patients. The study assessed the efficacy and safety of lifestyle management in reducing RIT of CKD patients.

Methods: In this prospective randomized controlled trial (RCT), 540 patients with CKD vulnerable to RIT were randomly assigned 1:1 to either lifestyle management group or control group for 48 weeks. Both groups received conventional care according to guideline recommendations, while patients in lifestyle management group additionally accepted health lifestyle management involving life behavior mission, acupoints massage and dietary guidance. The primary outcome was the interval of first occurrence of RIT. Secondary outcomes included the incidence of endpoint events, immunity indices, urinary protein creatinine ratio (PCR), liver and kidney function, cardiovascular events. This study was registered with Chinese Clinical Trials Registry, ChiCTR-IOR-17012654.

Results: 540 patients were screened, of whom 262 were randomly assigned: 161 to the lifestyle management group, 161 to the control group (30 patients were excluded) from January 1st, 2016 to December 31st, 2018. 77 (66.4%) patients in the life management group and 78 (67.2%) patients in the control group developed RTI over 48 weeks. Among them, 49 patients (42.2%) and 52 patients (44.8%) had RTI more than twice respectively. The interval of first occurrence of RTI in the life management group was 85.65±84.97 days, which was similar to the control group (84.36±90.63 days). The survival analysis showed that the patients with high frequency of RTI (>3 times within one year before enrollment) in the life management group had a lower risk of RTI than the control group (68 days vs. 65 days) (HR 0.87,95%CI 0.57-1.31). The level of IgA, C4, CH50, CD3CD4, CD3CD4/CD3CD8 in the life management group was higher than the control group, suggesting that immunity function of the patients was enhanced after lifestyle management. There was no significant difference in endpoint events, liver and kidney function, PCR and other safety indexes between the two groups.

Conclusions: Lifestyle management shows the effect to reduce the prevalence of RTI in CKD and slow CKD progression.

Dialysis vs. Conservative Care to Treat ESRD: A Systematic Review and Meta-Analysis

Rui Fu,[1] Nigar Sekercioglu,[2] Joseph Kim,[5] Rachel Couban,[3] Luciane C. Lopes,[4] Peter C. Coyte.[1] *[1]Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada; [2]Faculty of Health Sciences, McMaster University, Hamilton, ON, Canada; [3]Michael G. DeGroote National Pain Centre, McMaster University, Hamilton, ON, Canada; [4]Universidade de Sorocaba, Sorocaba, Brazil; [5]Toronto General Hospital, University Health Network, Toronto, ON, Canada*.

Background: The advantage of treating selected ESRD patients with dialysis over non-dialysis, conservative therapy, is unclear. We addressd this gap by providing a comprehensive evidence synthesis on the outcomes of dialysis vs. conservative care in ESRD patients.

Methods: MEDLINE and EMBASE were searched from January 2009 to April 2019 for prospective and retrospective cohort studies that examined outcomes of ESRD patients receiving dialysis vs. conservative care. We calculated pooled risk ratios (RRs) and 95% confidence intervals (CIs) as well as statistical measures of variability in results across studies using random-effects models for all-cause mortality at years 1, 2, 3 and 5. Annual hospital inpatient days were pooled using standardized mean differences (SMD).

Results: Among 1,075 citations, 14 were included that involved 16794 and 3857 patients initially treated with dialysis or conservative care. Dialysis was associated with lower risk of all-cause mortality at year 1 (RR, 0.40, 95% CI, 0.26-0.63), year 2 (RR, 0.57, 95% CI, 0.44-0.72), and end of study (RR 0.66, 95% CI, 0.51-0.84), while no difference was detected at year 3 (RR, 0.68, 95% CI, 0.41-1.14) and year 5 (RR, 0.87, 95% CI, 0.71-1.06). There was no difference of annual hospital inpatient days (SMD, 14.64, 95% CI, -173.56-202.84).

Conclusions: Dialysis results in lower mortality in the short-term (the first two years) but may not improve survival thereafter (after the third year).

Sustained Effect of Online Peer Mentoring on Activation of Patients with CKD

Korey Bartolomeo, Jose C. Romeu, George C. Ezeji, Eric Mark J. Lopez, Vernon M. Chinchilli, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Peer mentoring (PM) has been proposed as a model for active patient engagement. This study evaluates the differences in the effect of online PM, face-to-face (FTF) PM and usual care on patient activation among chronic kidney disease (CKD) patients.

Methods: A total of 155 patients with stage 4 or stage 5 CKD were randomly assigned to online PM, FTF PM or usual care. Online PM consisted of weekly communication through an interactive online platform, and more frequently through posts initiated by the patient. For the FTF group, the frequency of contact by a mentor was weekly by phone and monthly visit. PM was maintained for 6 months. Usual care participants received an information handbook and were encouraged to discuss questions with their care team. We administered the 13-item validated Patient Activation Measure® (PAM) at baseline, at 12 months and at 18 months. We used linear mixed effect models to estimate the slope of change of PAM score over time. SAS, version 9.4 was used for data analysis.

Results: A total of 117 patients completed the 18 month assessment. Baseline PAM scores and demographic characteristics were similar among groups. The online PM group showed a significant improvement in mean PAM score between baseline and 12 months (67±15.7 vs. 77.5±12.7); improvement was sustained at 18 months (78.0±14.2) (Slope estimate [SE]:5.65;95% confidence interval [CI]:2.75, 8.52 [P=0.0001]). Among the FTF group, there was no significant change in PAM score in the 3 periods (SE:0.95;CI: -1.96, 3.86 [P=0.52]). Among the control group, there was no significant change in PAM score in the 3 periods (SE:0.02;CI:-3.03, 3.08 [P=0.99]). Slopes of change in PAM were significantly different between online and FTF groups (p=0.02), as well as online and control groups (p=0.009); there was no difference in the slopes of change in PAM between FTF and control groups (p=0.66). In subgroup analyses, the difference between the online group and other groups in slope of change in PAM was significant among male, but not female participants and among married, but not unmarried participants.

Conclusions: Online peer mentoring is associated with improved scores in Patient Activation Measure among patients with advanced CKD. This improvement is influenced by gender and marital status. Funding: PCORI

FR-PO331

Online Peer Mentoring and Quality of Life Among Patients with CKD

Eric Mark J. Lopez, George C. Ezeji, Jose C. Romeu, Korey Bartolomeo, Vernon M. Chinchilli, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Quality of Life (QOL) is an important medical outcome in patients with chronic kidney disease (CKD). Peer mentoring (PM) is a potentially effective intervention to improve QOL. This study evaluates the differences in the effect of online PM, face-to-face (FTF) PM and usual care on QOL patients with CKD.

Methods: A total of 155 patients with stage 4 or stage 5 CKD were randomly assigned either to online PM (n=52), FTF PM (n=52) or usual care (n=51). Online PM consisted of at least weekly communication through an interactive online platform, and more frequently through posts initiated by the patient. For the FTF group, the frequency of contact by a mentor was weekly by phone and monthly FTF visit. PM was maintained for at least 6 months. Usual care participants received a printed copy of an information handbook and were encouraged to discuss questions with their care team. All participants completed the Short Form Kidney Disease Quality of Life (KDQOL) tool designed specifically for patients with CKD, at baseline, at 12 months and at 18 months. We used linear mixed effect models to estimate the slope of change of subsets of KDQOL score over time. SAS, version 9.4 was used for data analysis.

Results: A total of 117 patients completed the 18 month assessment. Baseline KDQOL scores and demographic characteristics were similar among the 3 groups. Among the online PM group, there was a significant improvement in the following components of the KDQOL score: Effects of Kidney Disease (EKD) (Slope estimate [SE]:4.13; 95% confidence interval [CI]:0.87, 7.4 [P=0.01]); Burden of Kidney Disease (BKD) (SE:5.44; CI: 1.24, 9.64 [P= 0.01]);SF-12 Physical Composite (SE:2.50; CI:0.95, 4.06 [P=0.002]); SF-12 Mental Composite (SE:3.46; CI:1.78, 5.13 [P<0.0001]). In subgroup analyses, the improvements noted among the online PM in the EKD and BKD subscales were significant among white patients, but not among non-white patients. The improvements in the Physical and Mental Composite subscales were significant among non-white patients, but not among white patients. There were no statistically significant changes in KDQOL scores among the FTF PM group and the control group.

Conclusions: Online PM is associated with improved scores in subsets of the KDQOL among patients with advanced CKD. This improvement is influenced by race. Funding: PCORI

FR-PO332

High Incidence of Adverse Drug Reactions in Patients with Advanced CKD

Solene M. Laville,[1] Marie Metzger,[1] Benedicte Stengel,[1] Christian Jacquelinet,[2] Maurice Laville,[3] Luc Frimat,[7] Denis Fouque,[3] Christian Combe,[4] Valérie Gras,[6] Julien Moragny,[6] Ziad Massy,[5,1] Sophie Liabeuf.[6] *[1]CESP, Inserm U1018, Kidney and Heart Team, Villejuif, France; [2]Agence de la biomedecine, Saint-Denis La Plaine, France; [3]University Claude Bernard, Pierre Benite, France; [4]CHU de Bordeaux, Bordeaux, France; [5]Ambroise Pare University Hospital, Boulogne Billancourt/ Paris cedex, France; [6]Amiens University Hospital, Amiens, France; [7]Nancy University Hospital, Vandoeuvre les Nancy, France.*

Background: Little is known about adverse drug reactions (ADRs) in chronic kidney disease (CKD). We assessed the incidence rate and type of ADRs by CKD stage.

Methods: The CKD-REIN study includes 3033 outpatients (65% men) with CKD (eGFR<60mL/min/1.73m^2). ADRs were identified from medical records, hospital discharge reports, or patient interviews and adjudicated by pharmacist experts. A serious ADR is any event that is fatal, life-threatening, permanently/significantly disabling, requires or prolongs hospitalization or medically important. Determinants of first serious ADR-events were assessed by multivariate Cox regression model.

Results: At baseline, patients' median age was 69 (IQR, 60-76), median eGFR was 32 (IQR, 23-41) mL/min/1.73m^2 and the median number of medications was 8 per day. During a median follow-up of 2 years, 751 ADRs were reported in 536 patients, of which 150 were serious. The incidence rate of ADRs in patients with CKD stage 4 or 5 was 19.5[95%CI,17.6;21.4] per 100 person years (PY), against 10.9[9.7;12.1] per 100 PY in patients with CKD stage 3. We observed the same pattern for serious ADR with an incidence rate respectively of 4.0[3.2;4.8] per 100 PY in the former group and 1.8[1.3;2.2] per 100 PY for the latter one. Antithrombotics (34%), diuretics (12%) and renin-angiotensin system inhibitors (12%) represented the most frequent pharmacological classes associated with serious ADRs. Antithrombotics-linked serious ADRs were more common in patients with a low baseline eGFR (43% in CKD stages 4-5 vs. 20% in CKD stage 3). This marked difference between stages severity was not found for serious ADR related to diuretics or RAS inhibitors. On 10 deaths directly or indirectly related to an antithrombotic-linked serious ADRs, 8 occurred in CKD stage 4 or 5 patients, and 2 in CKD stage 3 patients. After adjusting for relevant covariates, hazard ratios for ADRs and for serious ADRs were significantly higher in patients with baseline eGFR < 30 vs. ≥30mL/min/1.73m^2 (respectively 1.6[13;1.9], 1.8[1.25-2.62]).

Conclusions: The burden of ADRs is high in CKD patients. A low eGFR appears as a risk factor of undergoing ADRs and serious ADRs. When taking care to CKD patients, especially advanced stages, antithrombotic agents need to be used with caution.

Physician-Guided CKD Self-Management via Smartphone App Is Associated with Proteinuria Reduction: A Retrospective Cohort Study

Rui Song,[1] Xuyong Chen,[6] Min Zhuo,[2] Suraj Sarvode Mothi,[4] Yueming Luo,[3] Li-Li Hsiao,[5] Jiahua Li.[4] *[1]Brigham and Women's Hospital, Boston, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Guangzhou university of Chinese Medicine, Guangzhou, China; [4]Brigham and Women's Hospital, Boston, MA; [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [6]Beijing Kidney Health Technology Company, Beijing, China.*

Background: Smartphone apps are increasingly popular for chronic disease management. However, the feasibility and effectiveness of smartphone apps to manage Chronic Kidney Disease (CKD) are unknown. This study assessed the feasibility and effectiveness of a smartphone app for self-management of CKD.

Methods: "Kidney online" is a patient-facing, algorithm assisted, physician-guided, and interactive app in Chinese. Patients with a self-reported diagnosis of CKD used the app to track their symptoms, physical activities, vital signs, and laboratory test results. Patients received automatic recommendations by the proprietary algorithm and consulted their assigned tele-nephrologists on an ad-hoc basis. Patients who were enrolled in this app for more than 3 months between Dec. 2016 to Nov. 2018 with proteinuria ≥ 500mg/24hr were eligible for analysis. Changes in blood pressure (BP), estimated glomerular filtration rate (eGFR), and 24-hr proteinuria level were evaluated as outcomes between quartile groups, stratified by the total number of patient-physician conversations. Content analysis of the conversations was performed.

Results: Among the 2351 adult app users, 468 patients were identified for analysis. The total number of patient-physician conversations was 26 ± 10, 60 ± 10, 103 ± 16, and 259 ± 148 from the 1st to the 4th quartile respectively; and the reduction of 24-hr proteinuria was 162.2 ± 195.3, 859.8 ± 193.6, 676.4 ± 194.5, and 889.3 ± 194.5mg respectively (p=0.03). The odds ratio of <30% proteinuria reduction in the 4th quartile compared to the 1st quartile was 0.452 (p=0.007) after adjusting for age, sex, clinical parameters, and medications. Compared to the 1st quartile, the 4th quartile received more alerts in hypertension (43.6% vs. 24.1%, p=0.02), and hypotension (53.9% vs. 31.9%, p<0.0001). The textual analysis of the patient-physician conversations revealed themes on self-monitoring of BP, awareness of laboratory results, medication optimization and adherence, dietary modification, and education in CKD and the comorbidities.

Conclusions: More frequent patient-physician interactions via smartphone app are associated with better proteinuria control. A patient-friendly smartphone app for record keeping and communication is feasible and effective for physician-guided CKD self-management.

FR-PO334

Timing of Arteriovenous Access Creation in CKD Patients: The French CKD-REIN Study

Natalia Alencar de Pinho,[1] Celine Lange,[2] Christian Combe,[3] Maurice Laville,[7] Denis Fouque,[4] Luc Frimat,[7] Ziad Massy,[5] Benedicte Stengel.[6] The CKD-REIN cohort study *[1]CESP, Inserm U1018, Kidney and Heart Team, Villejuif, France; [2]Biomedicine Agency, La Plaine Saint-Denis, France; [3]CHU de Bordeaux, Bordeaux, France; [4]University Claude Bernard, Pierre Benite, France; [5]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France; [6]CESP, Inserm U1018, Kidney and Heart Team, Villejuif, France; [7]CHU de Lyon, Lyon, France.*

Background: Most guidelines on vascular access recommend to create an arteriovenous (AV) access in eligible patients when estimated glomerular filtration rate (eGFR) is 15-30 ml/min. We sought to assess whether clinical practices align with these recommendations.

Methods: We identified participants undergoing a first AV access creation in CKD-REIN, an ongoing prospective cohort study that includes 3033 adult patients under nephrology care for CKD in 40 clinics in France. We assessed the timing of AV access creation according to eGFR within a period of -90 to +30 days from surgery. We described patient characteristics and cumulative incidence of hemodialysis start and death according to the timing of AV access creation.

Results: Of the 335 participants who underwent a first AV access during a median follow-up of 2.6 years, 270 (81%) had contemporaneous information on eGFR level and were included in this analysis. Median eGFR at AV access creation was 13 ml/min (IQR 10-16). AV access creation at eGFR 15-30 ml/min (n= 83) vs <15 ml/min (n= 187) was more frequent in men then in women (78% vs 65%, p=0.03), and in patients with then without diabetes (63% vs 47%, p=0.02), cerebrovascular disease (26% vs 15%, p=0.04) and coronary artery disease (42% vs 24%, p=0.003). Conversely, participants with AV access creation at eGFR <15 had more nephrology visits over the last 6 months prior to surgery (29% vs 13% with ≥3 visits, p=0.001). The 2-year cumulative incidence of hemodialysis initiation was 79% in participants with eGFR 15-30 and 89% for participants with eGFR <15, with a median time from surgery of 11 (IQR 6-20) and 5 (2-11) months, respectively (p<0.001). Thirteen patients died before requiring hemodialysis. Cumulative incidence of death tended to be higher in the 15-30 (9%) vs <15 (4%) eGFR group, but this difference was not statistically significant (p=0.23).

Conclusions: In patients under nephrology care in France, later AV access creation seemed to be favored over the recommended earlier creation. This practice may limit unnecessary AV access creation (i.e. patients dying before requiring dialysis), but its impact on transitory catheter use is to be assessed.

FR-PO335

Self-Rated Health Is Associated with Functional Limitations in Patients with CKD

Jacqueline Lee,[1] Khaled Abdel-Kader,[2] Jonathan Yabes,[3] Manisha Jhamb.[1] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: In patients with chronic kidney disease (CKD), self-rated health (SRH, "In general, how do you perceive your health?") is associated with mortality. However, it is unclear how functional status associates with SRH. This study assessed the relationship between the SRH and functional status limitations in a cohort of patients with stages 3-5 CKD.

Methods: Adult patients with CKD seen at a nephrology outpatient clinic in Western Pennsylvania from Sept 2015 to Dec 2016 were invited to complete a survey as part of a quality improvement project. The survey included questions on patient's SRH (Likert scale, 1=Poor, 2=Fair, 3=Good, 4=Very Good, 5=Excellent) and activities of daily living (ADLs, Yes/No response). The five standardized ADL questions assessed physical- (ambulation, dressing, shopping) and cognitive- (executive and memory) based ADLs. The association of SRH with limitations to 3 or more total ADLs, physical ADL limitations only, or cognitive ADL limitations only were assessed using chi-square analysis.

Results: SRH was completed by 1310 participants (mean age 60 years), out of which 41% reported poor-to-fair health. Overall, 71% of those with poor-to-fair SRH had at least one ADL limitation. In the total cohort, the most commonly reported ADL limitation was difficulty with ambulation at 34%. Ambulatory limitations were seen in 58% of participants with poor-to-fair SRH versus 17% in persons with good-to-excellent SRH. Persons with poor-to-fair SRH were more likely to report ≥3 limitations of ADLs (26% vs. 3%, $p < 0.001$), ≥1 physical limitation (61% vs. 18%, $p < 0.001$), and ≥1 cognitive limitation (35% vs. 13%, $p < 0.001$), compared to those with good-to-excellent SRH, respectively. Older adults (age ≥65) were more likely to report good-to-excellent SRH compared to younger adults (63% vs. 56%, $p = 0.008$); however, in those with 31% of good-to-excellent older adults had at least one ADL limitation versus 22% of younger adults.

Conclusions: Lower self-perception of health is associated with a larger number of functional limitations in patients with CKD. Older CKD patients have better SRH despite a higher functional limitations burden and potentially greater frailty. Lower SRH may identify patients who could benefit from additional healthcare resources (e.g., physical therapy and rehabilitation) to improve person-centered outcomes.

Eliciting Patient and Caregiver Priority Outcomes in CKD: An International Nominal Group Study

Talia M. Gutman,[2,1] Jonathan C. Craig,[3,1] Nicole J. Scholes-Robertson,[2,1] Allison Tong.[2,1] Standardised Outcomes in Nephrology (SONG) Initiative - Chronic Kidney Disease *[1]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, NSW, Australia; [2]Sydney School of Public Health, University of Sydney, Sydney, NSW, Australia; [3]College of Medicine and Public Health, Flinders University, Adelaide, SA, Australia.*

Background: Patients with chronic kidney disease (CKD) are at an increased risk of premature death and cardiovascular disease, and experience symptoms that impair quality of life. We aimed to identify patient and caregiver priority outcomes in CKD.

Methods: Patients with CKD (stages 1-5, dialysis or transplant) and caregivers were purposively sampled from seven centers (10 groups) across United States, Australia, and United Kingdom. Participants identified outcomes that were important in CKD Stages 1-5 (prior to commencing kidney replacement therapy (KRT)) and individually ranked their top 10 from most important to least important. A relative importance score (0 to 1) was calculated for each outcome based on frequency and rank.

Results: In total, 54 patients and 13 caregivers aged over 18 years participated, with 36 outcomes identified. The five top ranked outcomes for patients were: kidney function (importance score = 0.42; 95%CI 0.31-0.53), end stage kidney disease (0.29; 0.21-0.38), fatigue (0.26; 0.19-0.35), mortality (0.25; 0.17-0.35) and life participation (0.20; 0.14-0.27). For caregivers the top five outcomes were: life participation (0.38; 0.19 -0.59), kidney function (0.37; 0.18-0.59), mortality (0.23; 0.07-0.45), fatigue (0.21; 0.10-0.37) and anxiety (0.20; 0.08-0.35). Blood pressure, cognition and depression were consistently ranked in the top ten outcomes across role (patient/caregiver), country and stage of CKD (CKD vs KRT).

Conclusions: Patients and caregivers gave highest priority to kidney health, mortality, fatigue, life participation, and mental wellbeing. Consistent reporting of these outcomes in research can inform shared decision-making based on outcomes that are relevant and critical to patients and caregivers in CKD.

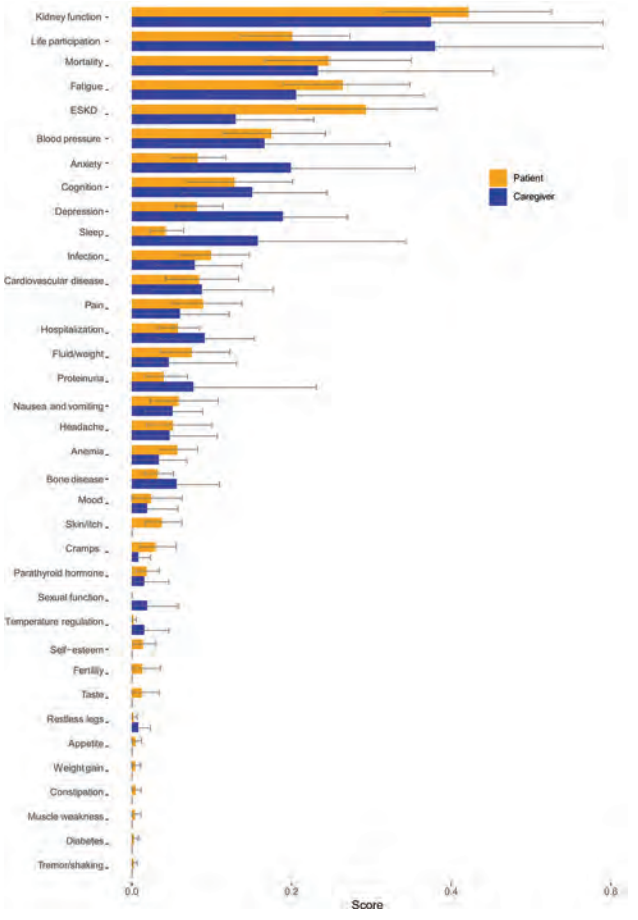

Figure 1. Top ranked outcomes by role

FR-PO337

Patients' Reliance on Non-Nephrologists for CKD Treatment and Advice

Tyler M. Barrett,[1] Patti Ephraim,[2] Jamie A. Green,[3] Sarah B. Peskoe,[1] Jane F. Pendergast,[1] Chelsie Hauer,[3] Tara S. Strigo,[1] Felicia Hill-Briggs,[2] Teri Browne,[4] George L. Jackson,[5,1] Raquel C. Greer,[2] Clarissa J. Diamantidis,[1] L. Ebony Boulware.[1] *[1]Duke University, Durham, NC; [2]Johns Hopkins University, Baltimore, MD; [3]Geisinger Medical Center, Danville, PA; [4]University of South Carolina, Columbia, SC; [5]Durham VA Medical Center, Durham, NC.*

Background: Chronic kidney disease (CKD) care is often fragmented across multiple health care providers, and it is unclear who patients rely on most.

Methods: We conducted a cross-sectional study of adults receiving nephrology care and enrolled in the PREPARE NOW trial to assess their reliance on their nephrologist, primary care provider (PCP), another specialist, or all their providers equally for CKD treatment and advice. We also asked participants about the frequency and patient-centeredness (range 0 [least] to 12 [most]) of their nephrology care. We assessed participants' kidney function and comorbidity (Charlson Comorbidity Index, range 0-37) using data from their electronic health records. In multivariable analyses, we quantified associations between participants' reliance on their nephrologists (vs. others) for their CKD treatment and demographics, comorbidity, kidney function, and perceived patient centeredness for their most recent nephrology visit.

Results: The 453 study participants had a mean (SD) age of 71.2 (12.1) years, 59% were female, 99% were White, and 66% had a high school education or less. Participants had seen nephrology for a median (IQR) of 3.8 (2.0-6.6) years, and 50% saw their nephrologist at least every 6 months. The median (IQR) patient-centeredness score was 11 (9-12). Participants' mean (SD) eGFR was 33.2 (11.7) mL/min/1.73m^2, and their median (IQR) Charlson score was 5 (3-7). Only half (56%) reported they relied primarily on their nephrologist for CKD treatment and advice, while 23% relied on their PCP, 18% relied on all providers equally, and 3% relied on another specialist. After adjustment, participants who saw their nephrologists for longer (OR [95% CI]: 1.09 [1.02-1.17] per additional year, p=0.01) and perceived nephrology visits as more patient centered (OR [95% CI]: 1.31 [1.17-1.47] per unit score increase, p<0.0001) had greater odds of relying mostly on nephrologists for CKD treatment and advice.

Conclusions: Many nephrology patients rely on non-nephrologists for CKD treatment and advice. Establishing longitudinal, patient-centered nephrology care and partnerships with patients' other physicians may help ensure patients adhere to nephrologists' CKD treatment and advice.

FR-PO338

Clinical Context for RBC Transfusions in CKD Patients: Results of the START-CKD Trial

Matthew R. Weir,[1] Jeffrey S. Berns.[2] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]University of Pennsylvania School of Medicine, Philadelphia, PA.*

Background: Anemia is a common complication for patients with progressive CKD which untreated can lead to increased RBC transfusions (TX). Tx avoidance wherever possible is recommended in such patients to prevent the risk of allo-sensitization. Erythropoiesis-stimulating agents (ESA) have been used in CKD patients to reduce the need for Tx. The START-CKD trial evaluated an ESA treatment (darbepoetin) on the incidence of RBC Tx in anemic CKD subjects using either a hemoglobin (Hgb)-based titration algorithm (TD) or a fixed dose (FD). This study collected prospectively Tx data.

Methods: This was a US phase 3, multicenter, randomized, double-blind, parallel group study. 377 participants with stage 3-5 CKD were treated in the TD and in the FD arms for a period of up to 2 years. Tx, per protocol, were performed as deemed necessary by the treating physician and were prospectively adjudicated with the reasons and context for Tx recorded.

Results: The average age of the subjects, baseline Hgb and estimated GFR were balanced between the arms: 69 yrs, 9,0 g/dL and 22 ml/min//1.73m2. The primary endpoint of the study was similar between the TD and FD, 24% in both arms with an average Hgb at the time of first Tx of 7.4 vs 7.3 g/dL respectively. All Tx events are shown below:

Conclusions: The main reason for Tx was symptoms which were principally constitutional. Bleeding accounted for approximately 20% of Tx. The Hgb at the time of Tx was consistent with transfusion practice guidelines.

Kibow Multisite Hope Study-CKD IV Randomized Clinical Trial Protocol: A Unique Double-Blind Placebo-Controlled Cross-Over Design Using Renadyl™ with Standard-of-Care Therapy (n=500-600, 20-25 sites in the United States)

Natarajan Ranganathan,[1] Usha N. Vyas,[1] Pari Ranganathan,[1] Anthony Irvin,[1] Alan D. Weinberg.[2] *[1]Kibow Biotech, Inc., Newtown Square, PA; [2]Mount Sinai, Hackensack, NJ.*

Background: CKD patients experience poor quality of life due to high levels of uremic toxins in the blood. Treatment option for CKD patients are restricted diet and medications for primary comorbidities like hypertension and diabetes. Outcomes like fatigue pain and anxiety though major concerns and critically important to patients and clinicians may not be reported in clinical trials (Kid Int 2019; 95:1280-1283). The Standardized Outcomes in Nephrology (SONG) initiative 2014 established core outcome sets for nephrology trials (https://songinitiative.org/). An alternative regime to address some of these issues would benefit all stages of CKD patients. Renadyl™, a Pro/Prebiotic dietary supplement is proven to reduce several uremic toxins in 3 pilot clinical trials with no reports of adverse outcomes. We propose to carry out large scale RCT to validate it as a Live Bio-Therapeutic (LBT) drug with US FDA approval.

Methods: One-year RCT cross over design in an outpatient setting. Renadyl™ will be orally given at 90 B CFU/day.

Results: Measured end points: 1: eGFR, Quality of Life (QOL). 2: Uremic metabolite panel, CBC, liver function test 3**:** Biomarkers including KIM-1, NGAL, TMAO, IL-6 and CRP.

Conclusions: This is the first-ever RCT proposed using Renadyl™ as a Live Bio-Therapeutic (LBT) drug for CKD IV patients. Being noninvasive the intervention avoids any possible infection. As a rare unconventional crossover design, patients will be their own control for prudent data analysis. Secondly, every patient gets the interventional product, thus accelerating better patient recruitment. Significance of p-value alone does not help in the decision of the application of results to clinical care and its policy (Kid Int. 2019; 95:28-30). P < 0.05 and P > 0.05 can affect interpretation and lead to bias. The study design, quality of measurements, and the logical basis of assumptions are also important. (Kor J Pain 2017; 30(4): 241-242). Addition of Renadyl™ with standard care of therapy may possess excellent potential towards CKD applications worldwide. Seriously interested clinical PI's please contact: rangan@kibowbiotech.com

Evolution of Patient Partner Roles in a Canadian, Patient-Oriented Kidney Research Network: A Qualitative Study

Meghan J. Elliott,[1] Kara Schick-Makaroff,[3] Shannan Love,[1] Braden J. Manns,[2] Nicolas Fernandez.[4] *[1]University of Calgary, Calgary, AB, Canada; [2]Foothills Medical Center, Calgary, AB, Canada; [3]University of Alberta, Edmonton, AB, Canada; [4]Université de Montréal, Montreal, QC, Canada.*

Background: Engagement of patients as partners in health research is a mandate of the patient-oriented kidney research network, Can-SOLVE CKD. However, how patients assume and integrate their unique roles within the Network has not been examined. The aim of this study was to explore how researchers and patient partners characterize the roles and responsibilities of patients in the context of their individual projects and broader Network governance.

Methods: This study used a qualitative descriptive methodology informed by Role Theory. We purposively sampled across all research teams within Can-SOLVE CKD and conducted interviews and focus groups with researchers (i.e. project leads, co-investigators, and research coordinators) and patient partners (i.e. persons living with chronic kidney disease and their informal supports) from 17 of 18 Network projects. We conducted 4 focus groups (2 patient and 2 researcher groups; N=26) and 28 interviews (N=12 patients, N=16 researchers). We analyzed transcript data using an inductive, thematic analysis approach. Coding was done in duplicate (MJE, NF), and themes were developed in relation to the objectives.

Results: With increasing familiarity and comfort engaging together in research partnership, participants described an evolution of perspectives on patient partner roles within the Network and patient-oriented research more generally. We identified 3 themes to support this: 1) Receptivity to novel engagement opportunities – patient partners assume roles that align skills and interests with project needs; 2) Acknowledgement of role fluidity – roles and responsibilities evolve naturally with increasing experience and confidence; 3) Commitment to moving knowledge forward – patient partners increasingly engage in knowledge translation and moving research into practice.

Conclusions: The perceived roles of patient partners within the Can-SOLVE CKD Network have evolved since the Network's inception, as has participants' receptivity toward patient-oriented research. Future work will further characterize unique opportunities for patients to engage in kidney health research and the perceived impact of this engagement.

FR-PO341

Establishment of a Virtual Slide System Linking to the Japan Renal Biopsy Registry

Ryohei Kaseda,[1] Shoichi Maruyama,[2] Hitoshi Sugiyama,[5] Akira Shimizu,[3] Hitoshi Yokoyama,[6] Hiroshi Sato,[4] Ichiei Narita.[1] *[1]Niigata University, Chuo-ku, Niigata, Japan; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Nippion Medical School, Tokyo, Japan; [4]Clinical Pharmacology and Therapeutics, Graduate School of pharmaceutical Sciences, Tohoku University, Sendai, Japan; [5]Okayama University Graduate School, Okayama, Japan; [6]Kanazawa Medical University, Ishikawa, Japan.*

Background: A virtual slide is a high-resolution digital image created from scanning specimens on glass slides. Digital images are saved in a storage system and viewed on a computer screen using slide viewing software that is accessed via a web browser. These images can be assessed in the same way as with microscopy. The Japan Renal Biopsy Registry (J-RBR) has been operated since 2007 by the Japanese Society of Nephrology's Kidney Disease Registry Committee. As of December 2018, 143 facilities have joined the registry and data have been registered for more than 40,000 patients who underwent renal biopsy. The J-RBR is now one of the largest national registries in Japan and provides a wealth of information for examining actual conditions, conducting secondary research, and developing clinical practice guidelines. We attempted to establish a virtual slide system of renal biopsy specimens that is linked to the J-RBR in order to increase the registry's utility.

Methods: Installation of a server computer was made possible by a Grant-in-Aid for Intractable Renal Diseases Research, Research on Rare and Intractable Diseases, Health and Labour Sciences Research Grants from the Ministry of Health, Labour and Welfare of Japan. The server computer was constructed at Niigata University, image view software was installed (Aperio eSlide Manager®, Leica Microsystems K.K.), and the server was connected to the J-RBR server. When logged into their J-RBR accounts, users can access the J-RBR server to view the histopathology images via a web browser.

Results: The virtual slide system was linked to the J-RBR in March 2019, and virtual slides from more than 100 patients were registered during the first 2 months of operation. The digital images are available to all researchers with a J-RBR account.

Conclusions: The virtual slide system enables renal biopsy specimens to be viewed and diagnoses made via teleconsultations, and it can help pathologists establish a clinical consensus for diagnosis. The system should also increase the reliability of J-RBR data, which in turn will promote more secondary research, including machine learning, to be undertaken and provide precise information for guideline development.

Electronic Health Record Based Population Health Management for Improving CKD Care: The Kidney-Coordinated Health Management Partnership (CHAMP) Study

Manisha Jhamb,[1] Jonathan Yabes,[1] Gary Fischer,[1] Chung-Chou H. Chang,[1] Bruce L. Rollman,[1] Thomas D. Nolin,[1] Khaled Abdel-Kader.[2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Primary care providers (PCPs) care for most CKD patients but report limited knowledge, familiarity with guidelines, and time, leading to suboptimal care and clinical outcomes including progression to end-stage kidney disease (ESKD). CKD population health management (PHM) using electronic health records (EHRs) can be a sustainable, resource-efficient strategy to overcome clinician- and system-level barriers in the delivery of CKD care. **The Kidney CHAMP study will test the effectiveness of a multifaceted EHR-based PHM intervention to improve evidence-based CKD care in patients with high-risk CKD** (NCT03832595, www.kidneychamp.pitt.edu).

Methods: This is a 42-month pragmatic, cluster randomized controlled trial comparing an EHR-based PHM intervention versus usual care in 1,650 high-risk CKD patients. Patients are recruited using an opt-out approach from the University of Pittsburgh's PCP network (>330 PCPs; >480,000 patients). The CKD PHM dashboard uses risk prediction models to identify patients at high risk of CKD progression. The intervention combines timely PCP-targeted nephrology guidance (primarily as E-consults), pharmacist-led medication reviews, and patient-targeted CKD education. This builds on our prior work using EHRs to identify gaps in CKD care (e.g., suboptimal HTN control and RAASi use, unsafe medication use, late nephrology referrals). Primary outcome is a composite of 40% reduction in eGFR or ESKD.

Results: The CKD dashboard has been developed and includes the validated Kidney Failure Risk Equation, patient demographics, dates of PCP visits, lab values, and active medications. Additionally, an internal CKD risk prediction model has been developed and validated. The dashboard will be used to identify eligible patients, track the intervention components, and monitor CKD progression. Study enrollment began in May 2019. We have partnered with 80 practices and randomized the first 8. Enrollment will continue for 18 months, with 4 practices randomized each month.

Conclusions: Our study tests a novel approach to deliver CKD care that minimizes patient and PCP burden. This will inform efforts to use heath IT, risk prediction modeling, and PHM to augment evidence-based CKD care.

FR-PO343

Using Lean-Six Sigma Principles to Develop a Telenephrology Dashboard to Monitor Rural Veterans at Risk of Kidney Disease Progression

Melissa L. Swee,[1,2] M. Lee Sanders,[1,2] Kantima Phisitkul,[2] Angie R. Thumann,[2] Nikki L. Neuzil,[2] Bradley S. Dixon.[1,2] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Iowa City Veteran's Health Administration, Iowa City, IA.*

Background: Chronic kidney disease (CKD) affects about 14% of Americans, with a 34% greater prevalence in Veterans than the general population. Although early identification and consultation improves outcomes and lowers costs, access is challenging for rural Veterans. To improve access, we developed a telenephrology dashboard to monitor Veterans with CKD and intervene accordingly.

Methods: Lean Six-Sigma principles and the DMAIC (Define-Measure-Analyze-Improve-Control) framework were employed in this quality improvement project. During the "Define" phase, a project charter was drafted defining the scope and key stakeholders. This informed the "Measure" and "Analyze" phases, where the voice of the customer, current and future state maps, and process observation were utilized. In the "Improve" phase, PDSA (Plan-Do-Study-Act) cycles refined dashboard design. The "Control" phase is ongoing.

Results: A telenephrology dashboard was created to monitor patients with kidney disease within the Iowa City VA Health Care System. Voice of the customer (primary care providers and case managers) revealed 3 objectives: (1) timely identification of CKD risk and progression, (2) rapid access to specialty care, and (3) improvement of patient satisfaction. Process observation and mapping revealed opportunities for early identification and intervention for CKD using telenephrology protocols (Figure). From April 2018 to March 2019, 1080 charts were flagged and reviewed by the telenephrology case manager. Among these, e-consultations by nephrologists were performed for 364 Veterans (33.7%).

Conclusions: A telenephrology dashboard was created to monitor Veterans with CKD within the Iowa City VA Health Care system. This enables real-time access to nephrologists, thereby reducing wait-times to the next appointment and allowing for active surveillance of renal problems, and may improve overall quality of care.

FR-PO344

Effect of Virtual Patient Simulation at Improving Management of Chronic Hyperkalemia

Amy Larkin,[1] David R. Anderson,[2] Martin Warters,[3] Gwen S. Littman.[4] *[1]Medscape Education, Nicholasville, KY; [2]Medscape LLC, New York, NY; [3]Medscape / WebMD, New York, NY; [4]WebMD, Durham, NC.*

Background: We sought to determine if an online, virtual patient simulation (VPS)-based continuing medical education (CME) intervention could improve performance of nephrologists related to identification of patients with hyperkalemia, and chronic management of hyperkalemia.

Methods: The intervention comprised two patients presenting in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments in a manner matching the scope and depth of actual practice. Tailored clinical guidance (CG), based on current evidence and expert recommendation, was provided following each decision, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user's baseline (pre-CG) decisions using a 2-tailed paired t-test to determine *P* values. The activity posted April 30, 2019; data for initial abstract submission was collected through May 22, 2019.

Results: To date after being live for 3 weeks, 37 nephrologists have participated (larger sample size expected by ASN conference). Significant improvements were observed after CG: Case 1: Initiate a loop diuretic: 24% absolute improvement (41% pre-CG vs 65% post-CG; P<.05) Order nutritional counseling: 19% absolute improvement (41% pre-CG vs 60% post-CG; P=.05) Initiate a potassium binder: 41% improvement (8% pre-CG vs 49% post-CG; P<.01) Discontinue spironolactone: 22% improvement (41% pre-CG vs 43% post-CG; P<.05) Case 2: Diagnose chronic kidney disease stage 3a: 43% absolute improvement (5% pre-CG vs 48% post-CG; P<.01) Diagnose heart failure, NYHA (WHO) Class II: 38% absolute improvement (14% pre-CG vs 52% post-CG; P<.01) Diagnose chronic hyperkalemia: 24% absolute improvement (29% pre-CG vs 53% post-CG; P=.05) Initiate potassium binder therapy: 57% absolute improvement (19% pre-CG vs 76% post-CG; P<.01)

Conclusions: VPS that immerses and engages specialists in an authentic and practical learning experience can improve evidence-based clinical decisions related to patient identification and management of hyperkalemia.

FR-PO345

Renal Hemodynamic Effects of Soluble Guanylyl Cyclase Activation vs. ACE Inhibition in a CKD Model in Conscious Rats

Karen A. Griffin,[1] Geoffrey A. Williamson,[3] Perriannan Sethupathi,[1] Agnes M. Benardeau,[2] Tibor Schomber,[2] Frank Eitner,[2] Anil K. Bidani.[1] *[1]Loyola University Med Ctr and Hines VA Hospital, Maywood, IL; [2]Bayer AG, Wuppertal, Germany; [3]Illinois Institute of Technology, Chicago, IL.*

Background: BP control using renin-angiotensin system (RAS) blockade is the current standard of care for CKD. However, outcomes remain suboptimal in part because adequate BP reductions are difficult to achieve in the volume expanded CKD states with RAS blockade even with additional antihypertensives. Given that endothelial dysfunction and/or NO loss accelerate the progression of diabetic and non-diabetic CKD, soluble guanylate cyclase (sGC) activators represent potential novel therapeutic interventions in CKD.

Methods: Two wks after 3/4 nephrectomy, male rats were instrumented for chronic BP radiotelemetry and RBF recordings and started on a 4% NaCl diet. Conscious BP and RBF recordings (1-2 hr; 2-4/wk) were initiated 1 wk later and continued over 3 wks while they were sequentially receiving: vehicle only by gavage (5 ml/kg), a low and a high dose of either the sGC activator (BR-11257) (3,10 mg/kg), enalapril (20,50 mg/kg) or the combination (3-4 days/wk with a ~3 day washout period). Effects on mean arterial pressure (MAP), RBF, renal vascular resistance (RVR) and the autoregulatory (AR) ability to buffer spontaneous BP fluctuations were assessed using a methodology developed in our lab.

Results: Table (mean ± SEM) In this CKD model with volume (salt) dependent hypertension (HTN), BR-11257 but not enalapril significantly reduced BP and RVR (high dose), but in combination the two were synergistic. Effects on RBF were more variable. No adverse effect on AR ability to buffer spontaneous BP fluctuations was observed with any of the regimens.

Conclusions: These data suggest that sGC activators may have significant therapeutic potential in CKD states with volume dependent and/or RAS blockade resistant HTN that merit further investigation.

Funding: Commercial Support - Bayer AG

FR-PO346

Increased Urinary Prostaglandin E_2 (PGE_2) Precedes Overt Albuminuria in Hyperfiltration-Induced Renal Injury in Children with Solitary Functioning Kidney (SFK)

Tarak Srivastava,[1] Uri S. Alon,[1] Ram Sharma,[2] Vincent S. Staggs,[1] Virginia J. Savin,[2] Ellen T. McCarthy,[3] Mukut Sharma.[2] *[1]Children's Mercy Hospital, Kansas City, MO; [2]Kansas City VA Medical Center, Kansas City, MO; [3]University of Kansas Medical Center, Kansas City, KS.*

Background: Children born with SFK are at risk for end stage renal disease from hyperfiltration-induced injury. Urinary albumin and epidermal growth factor (EGF) are established biomarkers of glomerular and tubular injury, respectively. A biomarker to detect glomerular changes preceding microalbuminuria will be valuable in defining early effects of hyperfiltration. In a model of hyperfiltration as a continuum of glomerular changes caused by biomechanical forces, namely fluid flow shear stress (FFSS) and tensile stress, we showed that FFSS upregulates PGE_2, cyclooxygenase-2 and PGE_2 receptor EP2 in cultured podocytes as well as in unilateral nephrectomized mice. We hypothesized increased urinary PGE_2 in children with SFK.

Methods: Urine samples from children with SFK and controls were analyzed for PGE_2 by LC-MS/MS, albumin on VITROS autoanalyzer and EGF by ELISA. Patient characteristics of age, gender, Z-scores for height, weight, BMI, and BP were obtained. Wilcoxan-Mann-Whitney test was used group for comparisons and Spearman analyses for correlations.

Results: Children with SFK were comparable to controls except for having lower weight and BMI Z-scores. The median and interquartile range in control vs. SFK children were elevated for urine PGE_2 [5.7 (4.0, 8.8) n=72 *vs.* 9.1 (4.4, 16.7) n=57, p=0.009] ng/mgCr and albumin [7.0 (4.0, 10.3) n=41 *vs.* 7.6 (4.7, 24.0) n=40, p=0.085] µg/mgCr, but not for EGF [18637 (15298, 25622) n=44 *vs.* 20098 (13238, 30263) n=44, p=0.746] pg/mgCr. Urine albumin was within the normal reference range. A significant increase in urine PGE_2 (p=0.024) and albumin (p=0.019) but not EGF (p=0.412) was observed in SFK when sex, age, weight z-score, height z-score, DBP z-score, and SBP z-score were controlled for in regression modeling. Patient characteristics did not correlate with urine PGE_2, albumin or EGF. Urinary PGE_2 and albumin, PGE_2 and EGF, and EGF and albumin were not correlated.

Conclusions: Urinary PGE_2 and albumin, but not EGF, were elevated in children with SFK compared to controls, and were independent of each other reflecting distinct pathophysiologic mechanisms. Urinary PGE_2 is a potential biomarker for early glomerular injury caused by hyperfiltration associated increase in FFSS prior to overt microalbuminuria.

FR-PO347

Adaptive and Maladaptive Kidney Repair Models Reveal Distinct Pathways of Myeloid and Lymphoid Cell Recruitment and Activation

Leyuan Xu, Lloyd G. Cantley. *Internal Medicine/Section of Nephrology, Yale University School of Medicine, New Haven, CT.*

Background: Incomplete repair after acute kidney injury (AKI) can lead to progressive fibrosis and development of chronic kidney disease (CKD). We have previously shown that unilateral ischemia-reperfusion kidney injury with contralateral nephrectomy (IRI/CL-NX) results in significantly less fibrosis in the injured kidney than does unilateral IRI with the contralateral kidney intact (U-IRI). Here, we investigated the mechanism of this difference by comparing an identical time of ischemic injury between mice subjected to U-IRI and those subjected to IRI/CL-NX.

Methods: Male wild-type mice were subjected to warm U-IRI or IRI/CL-NX (27 min). The injured kidney was removed on day 1, 7, 14 or 30 after IRI (n=10/group). Renal function was assessed by serum creatinine and BUN. Renal fibrosis and macrophage accumulation were assessed by Sirius red staining and IHC staining for F4/80. Kidney injury, inflammation, accumulation of myeloid and lymphoid cells, chemoattractant and survival factor expression levels were assessed by qPCR at each time point.

Results: This analysis revealed that initial recruitment and activation of macrophages, dendritic cells and T cells as well as myofibroblast activation and profibrotic gene expression were equivalent through day 7 in these two models. However, in the IRI/CL-NX model macrophage numbers declined after day 7 with tubule regeneration and only modest interstitial fibrosis on day 30. In contrast, macrophages persisted and expressed significantly higher levels of profibrotic growth factors *Pdgfb* and *Tgfb1* while dendritic cells and T cells significantly increased in numbers and expressed greater amounts of *Tnfa* and *Il1b*. These sustained immune responses correlated with progressive expression of collagen and fibronectin, sustained expression of *Havcr1* and *Lcn2*, less tubule regeneration and greater kidney atrophy. The persistence of macrophages, dendritic cells and T cells in injured U-IRI kidneys highly correlated with sustained expression of the chemokines *Ccl1*, *Ccl2* and *Cx3cl1*.

Conclusions: Abnormal accumulation of macrophages, dendritic cells and T cells may lead to progressive interstitial fibrosis, sustained inflammation and kidney injury in the setting of maladaptive kidney repair following IRI. Blocking homing chemokines may serve as a therapeutic target to attenuate CKD progression.

Expression of an Anti-Fibrotic Molecule Smad Anchor for Receptor Activation (SARA) Is Differentially Regulated in Epithelial Cells and Fibroblasts at a Translational Level

Vidhi Dalal,[1] Xiaoyan Liang,[2] Xingyue D. Hao,[2] H. William Schnaper,[2,1] Tomoko Hayashida.[2,1] *[1]Pediatrics, Lurie Children's Hospital of Chicago, Chicago, IL; [2]Northwestern University, Chicago, IL.*

Background: We reported last ASN meeting that overexpression of SARA specifically in pericytes prevents them from transdifferentiating into fibroblasts, hence mitigates fibrotic changes in a mouse model of interstitial fibrosis. These findings suggest that SARA is a key molecule that regulates cellular phenotype. Here, we aimed to explore the mechanism by which SARA levels are regulated.

Methods: SARA protein and mRNA expression levels were evaluated in cultured epithelial cells and fibroblasts derived from rat kidney (NRK52E and 49F, respectively), with or without transfection of a plasmid expressing human SARA cDNA or HA-tagged focal adhesion kinase (FAK). RNA from NRK52E and 49F was subjected to RNA sequencing.

Results: SARA protein was abundantly expressed in NRK52E, while it was barely detected in NRK49F. In contrast, SARA mRNA levels were similar in NRK52E and 49F. When a plasmid expressing human SARA driven by a constitutive promoter was transfected, SARA protein overexpression was apparent in NRK52E cells, but not in 49F, while HA-FAK protein expression used as a control was equivalent both in NRK52E and 49F, indicating that the difference in 52E and 49F are not due to transfection efficiency. Indeed, human SARA RNA driven by SARA overexpression plasmid was significantly and equally increased in both NRK52E and 49F. RNA sequencing revealed 107,000 genes expressed both in NRK52E and 49F, and 922 and 754 genes were unique to NRK52E and 49F, respectively. KEGG enrichment analyses revealed that genes associated with metabolic pathways were most commonly differentially regulated (N=630), followed by those associated with PI3K-Akt signaling pathways (N=197) and endocytosis (N=176). Most significantly enriched genes were found in adherens junction related genes, and Hippo signaling and HIF-1 signaling pathway-related genes.

Conclusions: These results suggest that, in fibroblasts, a mechanism exists that keeps SARA levels low at a translational level. Some of the differentially expressed genes revealed by RNA sequencing in epithelial cells and fibroblasts are likely to be involved this regulation and could be a novel therapeutic target.

FR-PO349

Par1a Deletion Protects Against Folic Acid and Unilateral Ureteral Obstruction-Induced Fibrosis in Mice

Vellia Zhou,[2] Zhongfang Du,[2] Kimberly J. Reidy.[1] *[1]Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronxville, NY; [2]Albert Einstein College of Medicine, Bayside, NY.*

Background: We recently identifed Par1 serine threonine kinases as regulators of Notch signaling in the developing kidney: dual loss of Par1a/b led to impaired Notch activation and glomerular and proximal tubular development. Par1a expression increases following unilateral ureteral obstruction (UUO) and folic acid (FA) induced injury. However, the effect of Par1a deletion on renal fibrosis is not known. We hypothesized: Loss of Par1a would attenuate Notch signaling activation and renal fibrosis.

Methods: Immunoflorescence staining was used to examine the expression of Par1a/b and Notch signaling components. To test effect of Par1a deletion on fibrosis in vivo, FA (250 mg/kg dissolved in 300 mM NaHCO3) or vehicle was injected in 5 week old male *Par1a -/-* (Par1a KO) and *Par1a +/+* (Par1a) WT littermates. Kidney phenotype was assessed at 4 weeks post injection. UUO was performed in adult (10 week old) male Par1a KO and WT littermates; phenotype was examined at 7 days. 6-8 mice/group were studied. To detect renal fibrosis, Picrosirius red staining of collagen was performed. Polarized light and Image J was utilized to quantify fibrosis on 200 x images. Primary tubular cell cultures were generated from inducible Par1 knockout (Pax8rtTA:tetOCre: Par1flox/flox) mice. Cultures were exposed to TGFbeta (10 ng/mL) and examined at 72 hours. Doxycycline was used to induce Par1 deletion.

Results: Both Par1a and Jag1 expression increase following FA and UUO injury in mice. Par1a and Jag1 co-localized in kidney tubules following FA and UUO induced injury. Par1a deletion was protective against renal fibrosis in mice: as quantified by sirius red staining, % area of fibrosis was 1.4 ± 0.9 vs. 0.8 ± 0.5 in FA treated Par1a WT vs. KO kidneys. Following UUO, % area fibrosis was 2.75 ± 2.3 vs. 0.76 ± 0.29 in Par1a WT vs. KO kidneys.($p<0.01$) Par1 deletion was protective against TGFbeta induced renal tubular damage in vitro. Whereas E-cadherin expression was lost with TGFbeta treatment in control primary tubular cells, Par1 knockout cells had preserved E-cadherin expression following TGFbeta exposure.

Conclusions: Par1a deletion is protective against renal fibrosis in mice. Par1 deletion was protective against renal tubular injury in vitro, suggesting tubular Par1 mediates its protecitve effects. Colocalization of Par1 and Jag1 suggests Par1 may affect Jag1 mediated Notch activation.

FR-PO350

12/15-Lipoxygenase Knockout Mice Exhibit a Resistance to Kidney Damage in CKD

Naohiro Takahashi,[1] Hiroaki Kikuchi,[1] Makoto Arita,[2] Fumiaki Ando,[1] Shintaro Mandai,[1] Kiyoshi Isobe,[1] Koichiro Susa,[1] Takayasu Mori,[1] Naohiro Nomura,[1] Tatemitsu Rai,[1] Shinichi Uchida,[1] Eisei Sohara.[1] *[1]Tokyo Medical and Dental University, Tokyo, Japan; [2]RIKEN-IMS, Yokohama, Japan.*

Background: It has been reported that polyunsaturated fatty acids(PUFA) and their metabolites are related with inflammation and its resolution in several organs. The roles of these metabolites in kidneys, however, have been unclear. In addition, which metabolite is a key player in exacerbation and remission of chronic kidney disease (CKD) remains unknown. 12/15-Lipoxygenase (ALOX15) is one of the key molecules which has a function to produce bioactive lipid metabolites from PUFA. Although there are some reports to present linkage between ALOX15 and inflammatory diseases, it is still unknown whether and how ALOX15 has effects on the progression of CKD.

Methods: Kidney tissue from subtotal nephrectomy mice was analyzed with lipidomics to reveal lipid profiles of CKD kidneys. To establish CKD models, subtotal nephrectomy or oral administration of adenine was performed to C57BL/6J mice and ALOX15 knockout mice. Histologic examination, western blot and quantitative PCR were performed to investigate the phenotype of ALOX15 knockout mice.

Results: Lipidomics analysis revealed that ALOX15-mediated lipid metabolites were significantly decreased in kidneys of mice with subtotal nephrectomy in comparison with those of control mice. Therefore, we examined two CKD models of ALOX15 knockout mice, subtotal nephrectomy and adenine-induced nephropathy. Renal functions of ALOX15 knockout mice were more preserved than those of wild type mice in the both CKD models. Alfa-SMA and NGAL were also suppressed in ALOX15 knockout mice. Quantitative-PCR revealed that mRNA level of alpha-1 type I collagen in kidneys of ALOX15 knockout mice was reduced comparing with that of wild type mice in the both CKD models. Masson's trichrome staining revealed decreased interstitial fibrosis of ALOX15 knockout CKD mice in comparison with wild type mice. These results suggested that reduction of some ALOX15-mediated lipid metabolites which induce renal damage could have beneficial effects on CKD.

Conclusions: Lipidomics of the kidneys from subtotal nephrectomy mice revealed the significant change in the amount of ALOX15-mediated lipid metabolites. ALOX15 knockout mice exhibited a resistant phenotype to CKD. ALOX15 and some ALOX15-mediated lipid metabolites might be novel therapeutic targets of CKD.

FR-PO351

Erythrocyte Sphk1 Activation Coupled with PP2A Inhibition: A Missing Component to Counteract CKD

Tingting Xie,[1,2] Weiru Zhang,[2] Zhangzhe Peng,[3] Anren Song,[1] Yang Xia.[1] Dr. Angelo D'Alessandro's group *[1]Biochemistry and Molecular Biology, University of Texas Health Science Center at Houston, Houston, TX; [2]Rheumatology and Immunology, Xiangya Hospital, Central South University, Changsha, China; [3]Nephrology, Xiangya Hospital, Central South University, Changsha, China.*

Background: Hypoxia drives chronic kidney diseases (CKD) and promotes end organ damage. The erythrocyte is the only cell type delivering oxygen (O2) and O2 releasing capacity is finely regulated by hypoxia. However, its role and regulatory mechanisms in CKD remain unknown.

Methods: Untargeted metabolomics screening in the plasma and erythrocyte of mice infused with or without angiotensin II (Ang II) at 500ng/kg/min up to 14 days was conducted. Mice with specific ablation of Sphk1 in erythrocytes and patients with CKD were used to determine its function in CKD, potential mechanisms and human relevance.

Results: Genetic depletion of erythrocyte specific Sphingosine Kinase 1 (Sphk1, the only enzyme to generate S1P in erythrocytes) leads to severe renal hypoxia, persistently active HIF-1a, sustained inflammation, imbalanced vasoactive factors and fibrosis comparing to the Ang II-infused controls. Mechanistically, using untargeted erythrocyte metabolic profiling, we found that Ang II-infused controls but not erythrocyte Sphk1 knockout mice show highly active glycolysis, which fuels erythrocyte energy supply and O2 release mediator. These studies led us further discover that Sphk1 activation induces AMPK-mediated activation of BPG mutase and thus the production

of 2,3-biphosphoglycerate (2,3-BPG), an erythrocyte specific glycolysis metabolite negatively regulating hemoglobin-O2 binding affinity and eventually triggers O2 delivery to the kidney. Furthermore, we then provide both pharmacological and genetic evidence that AMPK phosphorylation and activation of BPGM in erythrocytes, is regulated by sphingolipid mediated protein phosphatase 2A (PP2A) inhibition. Finally, human translational studies validated mouse findings that erythrocyte BPG mutase and Sphk1 activity were significantly induced in the erythrocytes of CKD patients compared to normal controls and their elevations were correlated to disease severity.

Conclusions: Overall, our study elucidates that erythrocyte Sphk1 activation induced S1P production promotes 2,3-BPG production and O2 delivery via a PP2A-AMPK-dependent signaling cascade to counteract CKD. These findings add a significant molecular new insight to CKD and immediately suggest new therapeutic avenues.

Complete Pik3c3 Deletion in Renal Proximal Tubule Cells Causes AKI Leading to CKD

Ting Liu,[1] Jialing Yuan,[1] Benjamin D. Humphreys,[2] Caihong Dai,[1] Jian-Kang Chen.[1] *[1]Medical College of Georgia at Augusta University, Augusta, GA; [2]Washington University School of Medicine, Clayton, MO.*

Background: Renal proximal tubules form the bulk of the kidney and are particularly sensitive to ischemic, toxic, and metabolic stress contributing to the pathogenesis of kidney disease. Class 3 phosphatidylinositol 3-kinase (Pik3c3) is the only PI3-kinase evolutionarily conserved from yeast to humans. However, the role of Pik3c3 in the proximal tubules in adult kidneys is unknown.

Methods: We generated a *Pik3c3* gene-floxed mouse and crossed it with *SLC34a1.CreER*^{T2} mice to produce tamoxifen (TAM)-inducible renal proximal tubule cell (RPTC)-specific Pik3c3 heterozygous (*Het*) and homozygous knockout (*KO*) mice for comparison with appropriate control (*Ctrl*) littermates. Pik3c3 deletion was not induced until the mice reached 8 weeks old.

Results: Our data revealed that the proximal tubule expresses the highest level of Pik3c3 among all renal tubule segments. The *Het* mice are fertile and normal. However, the *KO* mice exhibited marked RPTC injury, indicated by cytoplasmic vacuolization, nuclear condensation and fragmentation as well as TUNEL-positive cells in the proximal tubules, leading to cell death and infiltration of inflammatory cells (including neutrophils) within 13 days after TAM induction of Pik3c3 deletion. Subsequently, the *KO* mice developed chronic kidney disease (CKD), evidenced by marked proliferation of a-smooth muscle actin-positive myofibroblasts, persistent infiltration of inflammatory cells (including macrophages and lymphocytes), and tubulointerstitial fibrosis, with elevated serum creatinine and BUN, after 3 months of Pik3c3 deletion. Mechanistically, *in vivo* animal studies and *in vitro* RPTC culture studies unveiled strikingly increased levels of LC3II/I, LAMP1 and activation of the initiator caspase 12 and the effector caspase 3 in response to Pik3c3 inactivation.

Conclusions: Our data indicate that complete Pik3c3 deletion in RPTC disturbed the endocytic and autophagic pathways and disrupted the homeostasis of intracellular protein sorting, leading to intracellular vacuolation and cell death involving activation of caspases 12 and 3. This study not only reveals an essential role of Pik3c3 in maintaining the homeostasis and survival of proximal tubule cells, but also provides a new model of progressive CKD.

FR-PO353

Proximal Tubule-Specific KLF6-Mediated Amino Acid Metabolism Is Critical for the Progression of Kidney Injury

Sian Piret, Yiqing Guo, Sandeep K. Mallipattu. *Stony Brook Medicine, Stony Brook, NY.*

Background: Transcriptional regulators of DNA-damage pathways leading to renal fibrosis are not well characterized. Krüppel-like factor 6 (KLF6), a zinc finger transcription factor, is expressed in the proximal tubule (PT) and highly upregulated in renal ischemia-reperfusion injury, sepsis, and DNA damage models, but its role in PT injury and tubulointerstitial fibrosis is unknown.

Methods: PT-specific *Klf6* knockdown (*Klf6*^{PTKO}) mice were generated by breeding *Klf6*$^{fl/fl}$ and *Pepck*-Cre mice (controls- *Klf6*$^{fl/fl}$ littermates). The "Tet-On" system was used to generate global inducible human *KLF6* (h*KLF6*) overexpressing mice (controls- TRE-h*KLF6*). Mice were given AAI or vehicle DMSO i.p. every 3 days for 2-3 weeks and euthanized 3 days after the final injection for functional, histological, RNA-Seq and ChIP-enrichment analysis of renal cortex.

Results: AAI-treated *Klf6*^{PTKO} mice had lower serum creatinine and urea nitrogen, preserved PT, and reduced inflammation and fibrosis, versus AAI-treated *Klf6*$^{fl/fl}$ mice. Conversely, AAI-treated h*KLF6* mice had worse renal function, more loss of PT, and increased inflammation and fibrosis versus AAI-treated control mice. RNA-Seq analysis identified 388 genes that were downregulated in *Klf6*$^{fl/fl}$ mice and significantly higher (preserved) in *Klf6*^{PTKO} mice after AAI. These were predominantly metabolic genes, including in amino acid metabolic and fatty acid oxidative pathways. ChIP-enrichment analysis of genes with KLF6 binding sites <1kb from a transcription start site (TSS) enriched for genes encoding enzymes critical to the essential branched-chain amino acid (BCAA) pathways, suggesting direct regulation by KLF6. AAI inhibits mitochondrial function causing production of reactive oxygen species, and the BCAA pathways preserved in *Klf6*^{PTKO} mice supply TCA cycle intermediates (e.g. succinyl-CoA), and enhance glutathione production, which may counteract the effects of AAI. Analysis of expression arrays of human CKD biopsies showed similar downregulation of BCAA genes with KLF6 binding sites close to the TSS, versus control samples.

Conclusions: Loss of PT KLF6 was associated with preserved BCAA metabolic enzymes that may help maintain the TCA cycle and increase glutathione, thus reducing injury after AAI. The potential role of transcriptional regulation of amino acid metabolism in driving PT injury has not previously been described.

FR-PO354

Genome-Wide Identification of Active Enhancers in Renal Aging

Akiko Oguchi,[1,2] Motoko Yanagita,[2] Yaushiro Murakawa.[1] *[1]Center for Integrative Medical Sciences, RIKEN, Yokohama city, Japan; [2]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Aging is one of the major risk factors for acute kidney injury and chronic kidney disease. The aging kidney undergoes complex changes that predispose people to renal diseases. However, the regulatory circuitry governing the transcriptional network in renal aging is unclear. Here we aim to reveal specific transcriptional programs that underlie renal aging. In particular, enhancers are distal non-codingDNA elements that are crucial for spatiotemporal control of gene expression. Disease-associated SNPs are highly enriched within enhancers, highlighting the functionality. Bidirectional RNA transcription (referred to as eRNA) originates from enhancers.

Methods: The CAGE (Cap Analysis of Gene Expression) is a method used to comprehensively map transcription start sites (TSSs) using next-generation sequencing. Using CAGE, promoters and enhancers can be identified by analyzing TSSs of mRNAs and eRNAs, respectively. However, in the usual CAGE method, detection of eRNAs is inefficient, because these transcripts are actively degraded in the nucleus by the nuclear exosome complex soon after their synthesis. To overcome this issue, our group devised a simple and novel NET-CAGE technology, in which nascent RNA is used as input. We successfully achieved ultra-sensitive detection and quantification of active enhancers at single nucleotide resolution.

Results: We apply this NET-CAGE technology to describe active cis-regulatory landscape across renal aging and analyze differentially regulated enhancers and genes. NET-CAGE data for kidney show increased detection of enhancers in each age compared to CAGE data. In addition, we identify a number of kidney-specific enhancers.

Conclusions: Our comprehensiveanalysis of enhancers will provide key biological insights into cis-regulatory mechanism in renal aging.

FR-PO355

Follistatin-Like Protein 1 (FSTL1) Expression Is Correlated with Measures of Kidney Injury in the Nephrotic Syndrome Study Network (NEPTUNE) Cohort

Nicholas Maksimowski,[1] York P. Pei,[2] Heather N. Reich,[3] James W. Scholey.[1] *[1]University of Toronto, Toronto, ON, Canada; [2]University Health Network and University of Toronto, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada.*

Background: The pathogenesis of progressive kidney injury has not been fully elucidated in chronic kidney disease (CKD). Gene expression profiling of renal cortical mRNA samples was performed in male Col4a3-/- and Col4a3+/+ mice at 4 and 7 weeks of age. Our microarray analysis showed that FSTL1 was one of only three genes upregulated at 4-weeks of age. FSTL1 is expressed in interstitial fibroblasts. It activates NFkB and increases COL1α1 expression in proximal tubule cells. There is limited data on FSTL1 in human CKD.

Methods: The NEPTUNE cohort was used to relate clinical variables to candidate gene expression to FSTL1 mRNA levels in the tubulointerstitial compartment of the kidney. Our study focused on patients with nephrotic syndrome due to primary focal segmental glomerulosclerosis (FSGS), immunoglobulin A nephropathy (IgAN), and membranous nephropathy (MN).

Results: Analysis revealed FSTL1 was inversely correlated with eGFR in the FSGS (r=-0.4473, p=<0.0001), IgAN (r=-0.6751, p=0.0011), and MN cohorts (r=-0.4122, p=0.0101). Additionally, FSTL1 correlated with proteinuria in FSGS (r=0.3368, p=0.0007) and IgAN (r=0.4352, p=0.0162) but less so in MN (r=0.2665, p=0.0515). In terms of histopathology FSTL1 was also related to interstitial fibrosis in FSGS (r=0.4477, p=<0.0001), IgAN (r=0.751, p=0.0001), and MN (r=0.5445, p=0.0004). FSTL1 was also related to tubular atrophy in FSGS (r=0.4465, p=<0.0001), IgAN (r=0.7523, p=0.0001), and MN (r=0.5246, p=0.0007). Finally, FSTL1 mRNA levels were also positively correlated with injury makers NGAL and KIM-1, extracellular matrix protein genes, cytokine gene expression (COL1α1 and TGFβ1), and genes involved in inflammation (CCL2 and TNF-α) in all three cohorts (p=<0.0026).

Conclusions: FSTL1 was inversely correlated with eGFR and positively correlated with interstitial fibrosis and tubular atrophy in all three of the cohorts. FSTL1 mRNA levels also correlated with injury markers and extracellular matrix protein gene expression. These findings support the hypothesis that FSTL1 may be a novel determinant of progressive CKD in primary nephrotic syndrome.

Impact of Periostin in Aging Kidney

Jiwon Ryoo,[2] Yun Jae Kwon,[2] Hyung Duk Kim,[2,1] Eun Nim Kim,[1] Yongjie Jin,[1] Ji Hee Lim,[1] Yaeni Kim,[2,1] Cheol Whee Park,[2,1] Bumsoon Choi.[3,1] *[1]The Catholic University of Korea, Seoul, Republic of Korea; [2]Seoul St. Mary's Hosp, Catholic Univ of Korea, Seoul, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea.*

Background: Periostin is a matricellular protein which plays important role in tissue adaptation to injury. In kidney disease, periostin is known to be highly expressed in tubulointerstitial fibrosis and correlated with renal function inversely. In this study, we investigated the effect of periostin in aging process and progressive renal interstitial fibrosis.

Methods: 1. UUO model We conducted unilateral ureteral obstruction (UUO) surgery in wild type (WT) mice and periostin knockout (KO) mice. And compared interstitial fibrosis and pericyte changes. 2. Aging model We compared interstitial fibrosis and changes of pericytes in 4 groups; WT young age group, WT old age group, periostin KO young age group and periostin KO old age group.

Results: In UUO model, periostin KO mice shows less interstitial fibrosis and increased number of pericytes. And periostin KO aging mice shows attenuated fibrosis and abundant pericytes compared to WT aging mice.

Conclusions: Periostin inhibition ameliorated renal interstitial fibrosis in UUO model and aging process. It is thought that it affects pericyte and shows a reno-protective effect.

V1a Receptor-Mediated Kidney Tissue Oxygenation Is Independent of Vasopressin V2 Receptor Blockade

Hana Cernecka, Karoline Droebner, Thomas Mondritzki, Marie-Pierre L. Collin, Frank Eitner, Peter Kolkhof. *Bayer AG, Wuppertal, Germany.*

Background: AVP binds to two subtypes of receptors in the kidney, the V1a and V2 receptors mediating different cellular effects. Selective V2 receptor antagonism induces aquaresis and is an efficacious decongestive approach. We showed that selective V1a receptor inhibition improves kidney oxygenation and kidney function which might be relevant for conditions of increased AVP levels such as chronic kidney disease. We investigated the potential interference of selective V2 antagonism with V1a antagonism on kidney oxygenation.

Methods: The effects of selective V2 antagonism (tolvaptan or satavaptan), selective V1a antagonism (relcovaptan) or a combination of both on renal blood flow (RBF) and tissue oxygenation (pO2) were investigated in isolated perfused rat kidneys (IPK) and in anesthetized Sprague Dawley rats (n=7 per group) via Laser Doppler Flowmetry in settings of increased AVP levels.

Results: Tolvaptan (0.3–100 nM) had no effect on the AVP-mediated (50 nM) reduction of perfusate flow while increasing urine excretion (p=0.07). *In vivo*, infusion of AVP (50 ng/kg/min i.v.) significantly increased mean arterial pressure (MAP) and reduced both RBF and tissue pO_2 (Table 1). Dose-dependent infusion of tolvaptan did not reduce the increased MAP values and did neither restore RBF nor kidney pO_2 levels. Similar results were achieved with satavaptan. Combination of V1a antagonism (relcovaptan) with V2 antagonism (tolvaptan) normalized AVP-increased MAP and restored RBF and pO2 back to basal values similar to the individual V1a antagonism (Table 1).

Conclusions: Selective V2 inhibition has no impact on renal oxygenation in settings of increased AVP levels and does not interfere with V1a receptor blockade-mediated beneficial effects on kidney oxygenation. Therefore, addressing the individual vasopressin

receptors alone or in combination in cardiorenal diseases is dependent on the presence of congestion and/or kidney hypoxia.

Hypoxia Reduced Renal Injury and Inflammation in Rats with Chronic Nitric Oxide Inhibition

Fernanda F. Zambom, Amanda H. Albino, Helena M. Tessaro, Orestes Foresto-Neto, Lisienny C. Rempel, Janice Pião, Denise M. Malheiros, Niels O. Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Chronic NO inhibition by Nω-nitroarginine methylester (NAME) leads to severe hypertension (HT) and Chronic Kidney Disease (CKD). Tissue hypoxia (HYP) has been postulated as a pathogenic factor in CKD, but we showed recent evidence that it may instead be renoprotective. We investigated whether this salutary effect would also be observed in NAME rats and whether it would involve NLRP3 and/or NFκB inhibition.

Methods: Male Munich-Wistar rats received NAME, 80 mg/kg/d in tap water. Ten Control (C) and 10 NAME rats were kept under 21% O_2 (NOR), while 12 C and 12 NAME rats breathed 12% O_2. After 4 wk, we assessed hemoglobin (Hb,g/dL), tail-cuff pressure (TCP, mmHg), urine albumin/creatinine (U_{Alb}/U_{Cr}), glomerulosclerosis (GS, %), % ischemic glomeruli (% IG), cortical density (mm^{-2}) of macrophages (MΦ), Angiotensin II+ (AII+) and NLRP3+ cells, cortical Collagen-1 (%Coll-1) and the renal content of nuclear p65, IL6, Casp1, HO1 and SOD2 (WB), and IL1β (pg/mg). HYP was confirmed by pimonidazole staining.

Results: HYP reduced HT, inflammation, o xidative s tress, r enal injury, a nd the content of NLRP3, CASP1, IL1β, nuclear p65 and IL6.

Conclusions: Tissue HYP exerted a protective effect in NAME, suggesting that it may influence a common pathogenic mechanism, which may relate to downregulation of the NLRP3 inflammasome/Casp1/IL1β and NFκB/IL6 pathways, and to limitation of oxidative stress. FAPESP/CNPq.

INO80 Inhibits Tubulointerstitial Apoptosis Under Hypoxia

Rika Miura, Imari Mimura, Dai Sato, Tetsuhiro Tanaka, Masaomi Nangaku. *the University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Chronic kidney disease (CKD) is known to be caused by various kinds of factors including epigenetic factors. Among them we focused on the role of INO80. INO80 is an ATPase and nucleosome spacing factor. Biological function of INO80 is known to be ATP-dependent chromatin-remodeling, and it regulates transcription, DNA repair and replication. Our aim of this study is to clarify the pathophysiological role of INO80 in the kidney.

Methods: In order to investigate the expression levels of INO80 in the impaired kidney, we utilized 5/6 nephrectomy rats. To clarify the biological function of INO80 in the kidney, we performed *in vitro* experiments using HK2 (human kidney-2) cells in which INO80 was knocked down by using siRNA. In addition, genome-wide analysis using RNA-seq was performed to identify the downstream target genes of INO80 under hypoxia. Furthermore, we examined the effects of INO80 on apoptosis of tubular cells.

Results: In 5/6 nephrectomy rats, we found that the expression of INO80 was significantly suppressed at the mRNA level compared to sham rats. When HK2 cells were cultured under 1% hypoxic conditions for 24 hours, the expression level of INO80 significantly decreased. Genome-wide analysis by RNA-seq identified 32 downstream target candidate genes whose expressions decreased less than half compared with control siRNA when INO80 was knocked down by siRNA. While, knockdown of INO80 in HK2 cells promoted tubulointerstitial apoptosis by 24 hours, the expression of mRNA of tumor suppressor gene p53 and transcription factor E2F1 was significantly increased.

Conclusions: INO80 plays an important role in suppressing apoptosis in renal tubular cells, and it is considered that E2F1-mediated regulation may be involved in the apoptosis suppression pathway by INO80.

FR-PO360

Direct Inhibitory Effect of Sodium on Nrf2 Expression in Collecting Duct Cells

Mi Liu. *Southern Medical University Shunde Hospital, Foshan, China.*

Background: High salt is associated with the progression of CKD. High salt also contributes to oxidative stress in renal tissue and cells. However it remains unclear if high salt is involved in the pathogenesis of CKD through the regulation of oxidative stress. Nuclear factor E2-related factor 2 (Nrf2) is a transcriptional factor which regulates the expression of downstream antioxidant and detoxifying genes. The study was aimed at clarifying whether high salt will affect Nrf2 expression and Nrf2-dependent pathway.

Methods: Mice was treated with acute salt loading. Nrf2 expression in the kidney were detected by western blotting and immunostaining. mpkCCD cells were cultured in high osmolarity medium by adding NaCl. We measured the expression of Nrf2 and Nrf2-dependent genes via western blotting and qRT-PCR. Pretreatment with NAC, spironolactone or NS-398 in mpkCCD cells were performed and Nrf2 mRNA expression were monitored.

Results: Nrf2 protein levels in the kidney were markedly downregulated after acute salt loading. Nrf2 was remarkably downregulated in mpkCCD cells after NaCl treatment. Sodium gluconate had a similar effect on Nrf2 expression as NaCl, whereas neither Choline-Cl nor mannitol changed Nrf2 protein level. The mRNA levels of Nrf2-dependent genes were downregulated by NaCl mainly dependent on the effect of Na^+. The downregulation of Nrf2 was not affected by NAC, spironolactone or NS-398.

Conclusions: Sodium has a direct inhibitory effect on the expression of Nrf2 and Nrf2-dependent genes.

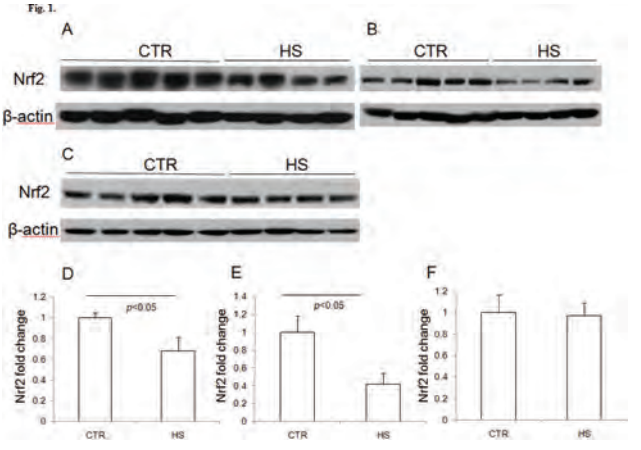

Figure 1. Nrf2 protein expression in kidneys after acute high salt loading.

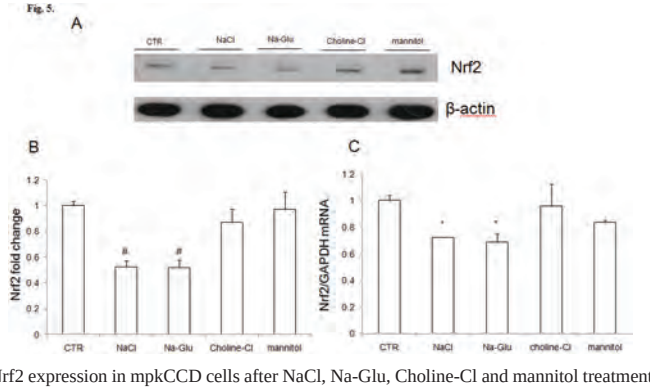

Nrf2 expression in mpkCCD cells after NaCl, Na-Glu, Choline-Cl and mannitol treatment

Abnormal Cytokine-Induced Responses in IgA1-Subpopulations Enhance Production of Galactose-Deficient IgA1, the Main Autoantigen in IgA Nephropathy

Colin Reily,[1] Bruce A. Julian,[1] Dana Rizk,[1] Jan Novak.[1,2] [1]*Medicine, University of Alabama at Birmingham, Birmingham, AL;* [2]*Microbiology, University of Alabama at Birmingham, Birmingham, AL*.

Background: IgA nephropathy (IgAN), the most common primary glomerulonephritis in the world, is characterized by glomerular IgA1 immunodeposits enriched for galactose-deficient IgA1 (Gd-IgA1). Patients with IgAN have elevated blood levels of Gd-IgA1. Gd-IgA1 blood levels also predict disease progression. IgAN patients often present with synpharyngitic hematuria, and have elevated serum levels of IL-6, indicating ongoing inflammation. Some cytokines increase Gd-IgA1 production by IgA1-secreting cells from IgAN patients. We hypothesized that Gd-IgA1 overproduction induced by a cytokine stimulation may involve only a subpopulation(s) of IgA1-producing cells and used single-cell transcriptome analysis of cells from IgAN patients and controls to test that hypothesis.

Methods: A mixture of cytokines mimicking those of T-follicular helper (Tfh) cells (IL-4, IL-6, IL-21, CD40L; 50 ng/mL) was used to activate immortalized Ig-producing cells from IgAN patients and healthy controls (HC) for 30 min before single-cell transcriptomic analysis. IgA1-secreting cells were identified using a splice-variant analysis to differentiate membrane vs. secreted isoforms. Resultant data were normalized using Seurat V2.4 and the curated data were analyzed with Alteryx. Gd-IgA1 production was assessed after cytokine stimulation for 72 h.

Results: Gd-IgA1 production increased in Ig-producing cells from IgAN patients but not HC after stimulation with Tfh cytokines. Several subpopulations of IgA1-secreting cells from IgAN patients exhibited substantial repression of genes associated with regulation of cytokine responses (*e.g.,PTPN11, SOCS3, PTPN2,*) due to Tfh cytokine stimulation (N=3, p <0.05). The same subpopulations also exhibited abnormal changes in glycosyltransferase genes implicated in Gd-IgA1 production.

Conclusions: We identified subpopulations of IgA1-secreting cells from IgAN patients that exhibited differential regulation of expression of glycosyltransferases due to abnormal Tfh-cytokine signaling. These data suggest that there are subpopulations of IgA1-producing cells that may be primarily responsible for Gd-IgA1 overproduction.

Apolipoprotein C3 Induces Systemic Inflammation and Organ Damage in CKD by Alternative Inflammasome Activation via a Novel Pathway

Thimoteus Speer,[1] Jochen Reiser,[2] Stefan J. Schunk,[1] Danilo Fliser,[3] Stephen Zewinger.[1] [1]*Saarland University Hospital, Homburg/Saar, Germany;* [2]*Rush University Medical Center, Chicago, IL;* [3]*Saarland University Hospital, Homburg/Saar, Germany*.

Background: CKD is associated with systemic sterile inflammation promoting the progression of CKD. Activation of the NLRP3 inflammasome plays an important role by inducing the release of the key alarminin Interleukin-1β (IL-1β). Identification of endogenous inflammasome activators in CKD patients is essential for the development of new anti-inflammatory treatment strategies.

Methods: Lipoproteins from CKD patients were fractioned. Their effect on IL-1b release was determined in human monocytes and in murine macrophages. Mechanistically, the NLRP3 activation by lipoproteins was studied in detail in vitro and several murine models. The relevance of these findings was studied in humanized mice subjected to unilateral ureter obstruction (UUO) or carotid perivascular injury.

Results: The VLDL fraction of lipoproteins from CKD patients substantially stimulated IL-1β release from human monocytes. Using proteomics, we found apolipoprotein-C3 (ApoC3) to accumulate within VLDL from CKD patients. ApoC3 stimulated pro-inflammatory activation of human monocytes in vitro and promoted a pro-inflammatory state in vivo in mice with accumulation of macrophages within the kidneys. Mechanistically, ApoC3 activated the NLRP3 inflammasome in human monocytes by inducing an alternative NLRP3 inflammasome via caspase-8 and dimerization of Toll-like receptor-2/4 leading to alternative inflammasome activation, a novel and previously unknown pathway. In general, we found that alternative inflammasome activation in human monocytes is mediated by Toll-like receptor adapter protein SCIMP. In humanized mice, ApoC3 activated human monocytes to impede endothelial regeneration and to substantially promote kidney injury. ApoC3 plasma levels were increased in patients with incipient CKD and associated with higher mortality in a large clinical trial (N=3,313) of patients undergoing coronary angiography after a median follow-up of 9.9 years.

Conclusions: These data provide novel insights into the regulation of the NLRP3 inflammasome activation in general and the pathophysiological role of triglyceride-rich lipoproteins containing ApoC3 in the progression of CKD and in CKD-associated cardiovascular disease. Targeting ApoC3 has the potential to prevent kidney damage and to provide an anti-inflammatory treatment strategy in patients with CKD.

Effects of Bone Marrow Mesenchymal Stem Cell-Derived Exosomes on Renal Fibrosis by Regulating Macrophage Phenotypic Transformation

Xiaolan Chen. *The Affiliated Hospital of Nantong university, Nantong, China*.

Background: In recent years, bone marrow mesenchymal stem cells (BM-MSCs) have received extensive attention due to their biological characteristics such as self-replication, high proliferative potential and multi-directional differentiation. This hinders the clinical transformation of MSCs in the treatment of kidney disease. Recent studies have shown that homing of MSCs to the injury site in the circulatory system is not the main mechanism for their continued therapeutic effects.

Methods: Establishment of unilateral ureteral obstruction (UUO) model in mice and random grouping: (1) sham operation group; (2)UUO group; (3)UUO+PBS group; (4)UUO+MSC(1×10^6/animal); (5)UUO+ exosomes (30μg/animal) group. Stem cells and exosomes were injected intravenously in the caudal vein on the day of modeling. Specimen collection and detection: HE staining and Masson staining were used to detect the pathological changes of renal tissue in each group of mice. Western Blot was used to detect the expression of α-SMA protein. Immunohistochemistry was used to detect renal interstitial fibrosis, macrophage infiltration and phenotype in each group. Flow cytometry was used to detectmacrophage subtypes.

Results: In vivo: Compared with UUO group, the renal pathology of the two groups of mice intervened by MSC and exosomes tail vein injection was significantly improved. the expression level of CD86 was significantly decreased after MSC and exosomes intervention, while the expression level of CD206 was increased;the ratio M2/M1 of macrophage subtypes in MSC and exosomes intervention groups was significantly increased.**In vitro:** the proliferation ability of macrophages in LPS group was significantly decreased. the secretion of IL-12 by macrophages in LPS group increased significantly, but the secretion of IL-10 did not change significantly($P>0.05$).the expression of iNOS and ARG1mRNA in LPS group increased. Compared with LPS group, the proliferation ability of macrophages increased after exosomes intervention. the expression of IL-12 decreased and the expression of IL-10 increased after exosome intervention. iNOSmRNA expression was down-regulated and ARG1mRNA expression was up-regulated after exosomes intervention.

Conclusions: Exosomes derived from bone marrow mesenchymal stem cells can regulate macrophage phenotypic transformation, thus improving renal fibrosis.

FR-PO364

The Expansion and Phenotype of HLA-DR^{hi} Intermediate Monocytes in CKD

Sarah Cormican, Serika D. Naicker, Neema Negi, Michael C. Dennedy, Matthew D. Griffin. *National University of Ireland Galway, Galway, Ireland*.

Background: A chronic microinflammatory state occurs in CKD, one aspect of which is monocyte subset dysregulation. Monocytes are comprised of one major ("classical") and two minor ("intermediate" and "nonclassical") subsets. The intermediate monocyte (IM) subset is pro-inflammatory and numerically increased in CKD. Having recently reported that human IM may be further subdivided into HLA-DR^{mid} and HLA-DR^{hi} subpopulations and that IM increase in CKD is specific to the HLA-DR^{hi} IM subpopulation, we aimed to determine whether HLA-DR^{hi} IM display distinctive expression of surface proteins required for endothelial adhesion and transmigration in health and in CKD.

Methods: Adult outpatients with CKD or healthy controls (HC) provided blood samples by informed consent. Peripheral blood mononuclear cells (PBMC) were isolated and analyzed by multi-colour flow cytometry for monocyte subpopulation numbers and surface protein expression levels (CD45, CD14, CD16, HLA-DR, CCR2, CCR5, CCR7, CX3CR1, CD11a, CD11b, CD11c, CD62L, CD49d and CD162).

Results: Consistent with prior results, higher numbers of total IM ($p=0.03$) and in HLA-DR^{hi} IM ($p=0.015$) were present in PBMC from CKD vs HC. IM had higher expression of CCR5 than classical and non-classical monocytes ($p<0.0001$). Among the IM, high CCR5 was specific to HLA-DR^{hi} IM ($p=0.002$). Surface expression of the integrin chains CD11b and CD11c was also highest among HLA-DR^{hi} IM ($p<0.001$). For CCR5, CD11b and CD11c, HLA-DR^{hi} IM surface expression was similar for CKD and HV. In contrast, HLA-DR^{hi} IM surface expression of CX3CR1 (the receptor for fractalkine/CX3CL1) was higher in CKD vs. HV ($p=0.02$). Finally, we also observed that surface expression of the selectin ligand PSGL-1/CD162 was higher on classical monocytes ($p=0.008$) and HLA-DR^{mid} IM ($p<0.001$) in CKD compared to HC. Other surface proteins analyzed also showed distinctive patterns of expression among the monocytes subsets that were not modulated in CKD.

Conclusions: Among circulating monocyte subpopulations, several surface proteins which mediate endothelial adhesion and transmigration are highly expressed by HLA-DR^{hi} IM, a distinctive subpopulation that is numerically increased in CKD. Functional analyses may help to determine whether CKD-associated expansion of HLA-DR^{hi} IM contributes to microvascular inflammation and progressive fibrosis.

Comparative Analysis of Regulatory T Cell Subpopulations in CKD Outpatients and Healthy Controls

Neema Negi, Sarah Cormican, Eanna O Coileain, Matthew D. Griffin. *National University of Ireland Galway, Galway, Ireland.*

Background: Regulatory T cells (T-reg) suppress autoimmunity/inflammation and allo-antigen-specific immune response in transplantation. Consequently, ex vivo-expanded T-reg are a promising immunomodulatroy therapy. In CKD/ESRD, circulating T-reg numbers are peserved and can be culture-expanded. Nonetheless, T-reg sub-phenotypes and their relevance to CKD pathophsiology are not fully characterised. We aimed to compare relative proportions and surface phenotype characteristics of circulating T-reg subpopulations in adult CKD outpatients and healthy adults.

Methods: Blood samples and clinical information were provided by CKD outpatients without immune-mediated disease (n=35, eGFR:11-64) and by healthy volunteers (HV, n=20). Multi-color flow cytometry was performed on fresh PBMC for CD4, CD25, CD127 and FoxP3 (to identify T-reg) and for CD45RA, HLA-DR, TNFR2, CCR7, CD62L and CD39 (to define subpoulations and their functional markers).

Results: Peripheral blood $CD4^+$ $CD25^+$ $CD127^{lo}$ T-reg (confirmed to be $FoxP3^+$) were identified and subdivided into 3 subpopulations based on expression of CD45RA and HLA-DR [RA^+ DR^-, RA^- DR^+, RA^- DR^-]. No difference in T-reg frequency (expressed as % of total CD4+ T-cells) was seen between CKD and HV. However, RA^- DR^- T-reg were proportionately increased and RA^+ DR^- T-reg were proportionately decreased in CKD ($p<0.0001$), consistent with a relative expantion of "antigen experienced" T-reg. In regard to surface proteins of potential functional importance, the selectin CD62L was expressed at higher level on total T-reg of CKD vs. HC (average MFI 3810 vs 1299, p=0.0002) as well on each of the 3 T-reg subpopulations. In contrast, surface expression of the ectonuclease CD39 (which dephosphorylates ATP and ADP) was lower on total T-reg (average MFI 665 vs 6936, $p<0.0001$) and was present on lower proportions of RA^- DR^+ T-reg (average 53.0% vs 87.1%, p=0.001) and RA^- DR^- T-reg (average 36.6% vs 73.8%, $p<0.0001$) in CKD vs. HV. Expression of CCR7 and TNF receptor 2 (TNFR2) did not differ for T-reg and T-reg subpopulations of CKD and HV.

Conclusions: Although adults with CKD had comparable blood T-reg numbers compared to HV, they differed in the relative frequencies of CD45RA/HLA-DR-defined T-reg subpopulations and in expression of proteins that could reflect alterations in migration patterns (CD62L) and specific regulatory functions (CD39).

FR-PO366

Klotho Restrains RIG-1/NF-κB Signaling Activation and Monocyte Inflammatory Factor Release Under Uremic Conditions

Ting He. *Department of Nephrology, Xinqiao Hospital, Chongqing, China.*

Background: Systemic inflammation is a main hallmark of chronic kidney disease (CKD). However, the mechanisms underlying the pathogenesis of CKD-associated systemic inflammation are unclear. Our study aimed to investigate the relationship between indoxyl sulphate (IS) and CKD-associated systemic inflammation, and the protective effect of Klotho against IS-induced systemic inflammation in CKD.

Methods: Serum Klotho was measured by ELISA. Heterozygous *kl/kl* (*kl/*$^+$) mice or WT mice were treated with 5/6 renal damage and then injected with recombinant Klotho protein.

Results: It shows that in 286 CKD patients, the serum levels of inflammatory factors are positively related with IS, but negatively related with Klotho. Klotho can significantly inhibit IS-induced retinoic acid-inducible gene I (RIG-I) /NF-κB activation and the productions of IL-6 and TNF-α in cultured monocytes. *In vivo*, RIG-I/NF-κB activation is observed in monocytes in both CKD mice and patients. Notably, higher levels of IL-6 and TNF-α are detected in $kl^{+/-}$ mice with CKD. Klotho administration can evidently attenuate RIG-I/NF-κB activation in monocytes and systemic inflammation in CKD mice.

Conclusions: These results suggest that Klotho can suppress CKD-associated systemic inflammation through inhibiting IS-induced RIG-1/NF-κB activation and monocyte inflammatory factor release.

The basic information of 286 CKD patients

CKD stage	CKD 2(n=36)	CKD 3(n=51)	CKD 4(n=55)	CKD 5(n=144)	P
Age, years	39.86±11.9	49.88±13.88	47.27±14.89	46.29±14.18	＜0.05

Single-Cell Genomics Applied to Unilateral Ureteral Obstruction Kidneys with Lymphatic Vessel Knockdown Identifies the Key Role of Adaptive Immunity in Renal Fibrosis

Jianliang Wu,[1] Zhimei Ma,[2] Jing Guo,[2] Gang Xu,[1] Rui Zeng.[1] *[1]Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China; [2]Wuhan Biobank Co., Ltd., Wuhan, China.*

Background: Lymphangiogenesis in chronic kidney disease has been reported in a large number of literatures. However, it is still unclear how the lymphatic vessels (LVs) act as a transport channel regulating the infiltration of immune cells in the kidney. The purpose of this study was to clarify the mechanisms by which LVs regulate the infiltration of immune cells and the following chronic kidney disease and fibrosis.

Methods: We constructed four lymphatic knockdown mouse models. The new-born proliferated LVs were knockdown by injection of Ganciclovir after unilateral ureteral obstruction (UUO) in Lyve-1-tk and Prox-1-tk mice, and resident LVs were knockdown by injection of DT in Lyve-1-DTR and Prox-1-DTR mice. Then, we performed RNA-Seq and single-cell transcriptomics on the kidneys of lymphatic knockdown group and control group.

Results: It showed that the UUO kidney had less LVs, less inflammatory cell infiltration and reduced fibrosis after new-born proliferated LVs or resident LVs knockdown. The ischemia reperfusion injury model yields the similar results. Both differentially expressed genes (DEGs), GO and KEGG pathway analysis identified that DEGs are mainly enriched in chemokine related genes. The heat map showed that chemokines and renal extracellular matrix deposition related genes were significantly down-regulated after lymphatic knockdown. The single-cell transcriptomics showed that lymphatic knockdown attenuated UUO induced intrarenal inflammatory infiltration (from 60% to 25%) and preserved renal tubular epithelial cells (from 40% to 75%). The main reduced inflammatory cells were T cells and DCs. Interestingly, the reduction in T cells included all subpopulations, while the subpopulation reduced in DCs was lymphoid DCs, but not myeloid DCs. The other immune cells, such as macrophages, B cells, and neutrophils, were not altered. In addition, we found that B cells expressed more abundant genes associated with cell senescence such as p21cip1 and p16ink4a after lymphatic knockdown.

Conclusions: We verified that lymphatic knockdown alleviates renal inflammation and fibrosis in UUO kidneys. The decreased immune cells after lymphatic knockdown are T cells and lymphoid DCs, accompanied with B cell senescence, suggesting the adaptive immunity participates in UUO induced renal inflammation and fibrosis.

Heritability Enrichment Analyses in Kidney Function Genome-Wide Association Study Identifies Trait-Specific Kidney Cell Types

Matthias Wuttke, Yong Li, Anna Kottgen. CKDGen Consortium *Department of Biometry, Epidemiology and Medical Bioinformatics, Faculty of Medicine and Medical Center - University of Freiburg, Institute of Genetic Epidemiology, Freiburg, Germany*.

Background: Identifying relevant tissues and cell types underlying kidney function and disease informs experimental follow-up studies to understand disease biology. Novel statistical methods allow for unbiased identification of trait-relevant cell types by incorporating RNA-seq data with GWAS summary statistics.

Methods: We used LD score regression for specifically expressed genes (LDSC-seg) to partition heritability in GWAS summary statistics of European ancestry participants from the CKDGen Consortium of estimated glomerular filtration rate (eGFR, n=567,460), urinary albumin-to-creatinine ratio (UACR, n=547,361), blood urea nitrogen (BUN, n=243,031) and serum urate (n=288,666). GWAS of asthma (UK Biobank, n=452,264), and schizophrenia (CLOZUK+PGC Consortia, n=105,318) were used as negative controls. Publicly available kidney single-cell RNA-seq datasets (human, 24 cell types; mouse, 16 cell types) were used to construct the top 10% specifically expressed genes per cell type followed by testing heritability enrichment in each trait. For examination at tissue level, the same procedure was applied using GTEx V7 data.

Results: Across tissues, we found significant enrichment of heritability in trait-associated loci containing genes that are highly expressed in kidney (eGFR: 2.2-fold enrichment, p=9.1e-8; urate: 2.1-fold enrichment, p=1.2e-5); liver was also enriched. Within the kidney, enrichment was observed in regions containing genes specifically expressed in proximal tubule cells in human (eGFR 2.3-fold, p=8.5e-5; BUN 1.7-fold, p=0.005; urate 2.3-fold, p=7.8e-6) and mice (eGFR 2.3 fold, p=0.0003; BUN 1.8-fold, p=0.02; urate 2.3-fold, p=0.0002), as well as in human podocytes (UACR 1.7-fold, p=0.009). Both asthma and schizophrenia did not show significant enrichment of heritability in regions with genes that are highly expressed in kidney cell types, but instead in brain tissues (schizophrenia, smallest p=9.8e-16).

Conclusions: GWAS signals of kidney function traits are enriched for genes that are highly expressed in relevant tissues and cell types such as proximal tubular cells for eGFR, BUN and urate, and glomerular cells for UACR. These results allow for identifying relevant cell types for experimental research to translate GWAS loci into a mechanistic understanding.

The Antioxidant Activity of Neurotropin Contributes to the Kidney Protective Effect

Masaki Fukunaga,[1] Akemi Uchida,[2] Miyu Sueyoshi,[1] Hitoshi Maeda,[1] Yuki Narita,[1] Hiroshi Watanabe,[1] Toru Maruyama,[1] Hakaru Seo,[2] Sumio Hirata,[1] Daisuke Kadowaki.[2] *[1]Faculty of Pharmaceutical Sciences, Kumamoto University, Kumamoto, Japan; [2]Faculty of Pharmaceutical Sciences, Sojo University, Kumamoto, Japan.*

Background: Neurotropin (NTP) is an extract from inflamed cutaneous tissue of rabbits inoculated with vaccinia virus and contains various non-protein components. NTP has long been used for the treatment of neuropathic pain such as postherpetic neuralgia. Recently, NTP have been reported that various organ protective effects by its antioxidant action. Furthermore, it is also suggested that NZ-419, which is one of the components of NTP, has the antioxidant activity and contributes to the renoprotective effect. Therefore, the aim of this study is to evaluate the antioxidant activity and renoprotective effect of NTP by in vitro and in vivo.

Methods: The radical scavenging ability for reactive oxygen species (ROS) was examined by electron spin resonance (ESR) method, chemiluminescence method or fluorescence analysis. The effect of NTP on oxidative stress induced by uremic toxins was evaluated using human renal proximal tubule epithelial cells (HK-2). Furthermore, 5/6 nephrectomized rats (CKD) were divided into 3 groups (CKD, CKD + NTP, and CKD + aspirin) and were orally administered each drug once daily for 4 weeks. Survival rate, kidney function parameters, oxidative stress marker, and kidney fibrosis were measured.

Results: NTP had concentration-dependent $O_2^{\cdot-}$ and $ONOO^-$ scavenging ability and scavenged $OH^{\cdot}$ at high concentrations. The inhibitory effect on intracellular ROS production was observed in only H_2O_2 under the simultaneous addition of NTP and irritant. On the other hand, the irritant-induced ROS production was inhibited under the preincubation of NTP for 9 hour. Survival rate of CKD rats was shown a trend of decreased in the aspirin group. NTP didn't affect survival rate and had a tendency to suppress kidney damage. Also, compared to the CKD group, the NTP group was observed that thiol concentration, antioxidant marker, increased in blood and decreased in fibrotic area in kidney.

Conclusions: In this study, it is considered that NTP has the direct radical scavenging ability and alters intracellular signal transduction to suppress oxidative stress. In conclusion, NTP may contribute to the renoprotective effect by not only the antioxidant effect but also the antifibrosis.

FR-PO370

Regulation and Role of NADPH Oxidase 4 in CKD

Sophie M. De Seigneux,[1] Renuga Devi Rajaram,[1] Anna Faivre,[1] Vasiliki Delitsikou,[1] Vincent Jaquet,[1] Maja Lindenmeyer,[2] Clemens D. Cohen.[3] *[1]University of Geneva, Geneva, Switzerland; [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Klinikum Munchen, Munchen, Germany*.

Background: While low-levels of reactive oxygen species (ROS) are important for physiological signaling, excessive ROS production has been implicated in CKD progression. Therefore, understanding the contribution of renal redox signaling in physiological and pathological context is essential to develop new therapeutics. NADPH oxidase 4 (NOX4) catalyzes the formation of hydrogen peroxide (H_2O_2). NOX4 is highly expressed in the kidney, but its role in renal damage is unclear and may depend on its specific tissue localization.

Methods: We performed immunostaining with a specific anti-NOX4 antibody and measured *NOX4* mRNA expression in human renal biopsies encompassing diverse renal diseases. We generated transgenic mice specifically overexpressing mouse Nox4 in renal tubular cells and subjected the animals to acute and chronic unilateral ureteral obstruction (UUO) model of fibrosis.

Results: In normal human kidney, NOX4 protein expression was at its highest on the basolateral side of proximal tubular cells. NOX4 expression increased in mesangial cells and podocytes in diabetic nephropathy. In tubular cells, NOX4 protein expression decreased in all types of chronic renal disease studied. This finding was substantiated by decreased *NOX4* mRNA expression in the tubulo-interstitial compartment in a repository of 176 human renal biopsies. Overexpression of tubular NOX4 in mice resulted in enhanced renal production of H_2O_2, increased NRF2 protein expression and decreased glomerular filtration, likely via stimulation of the tubulo-glomerular feedback. Tubular NOX4 overexpression had no obvious impact on kidney morphology, apoptosis, or fibrosis at baseline. Under acute and chronic tubular injury induced by UUO, overexpression of NOX4 in tubular cells did not modify the course of the disease.

Conclusions: NOX4 expression was decreased in tubular cells in all types of CKD tested. Tubular NOX4 overexpression did not induce injury in the kidney, and neither modified microvascularization, nor kidney structural lesions in fibrosis.

FR-PO371

Hypoxia Attenuates Tubulointerstitial Injury, Inflammation, and Oxidative Stress in the Adenine Overload Model

Fernanda F. Zambom, Helena M. Tessaro, Amanda H. Albino, Orestes Foresto-Neto, Janice Pião, Denise M. Malheiros, Niels O. Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Adenine excess (ADE) leads to renal deposition of crystals (Crys) and tubulointerstitial nephritis via NFκB. Tissue hypoxia (HYP) has been considered a pathogenic factor in Chronic Kidney Disease (CKD). We showed recently that chronic HYP was renoprotective in rats with 5/6 renal ablation (Nx). Here we investigated a possible beneficial effect of HYP in ADE.

Methods: Male Munich-Wistar rats received standard (C) or 0.5% ADE chow. Six C and 8 ADE rats breathed 21% O_2 (NOR), while 8 C and 8 ADE rats were kept under 12% O_2 (HYP). After 2 wk, we assessed hemoglobin (Hb, g/dL), tail-cuff pressure (TCP, mmHg), urine albumin/creatinine (U_{alb}/U_{cr}), left kidney/body weight (x100), crystal density (Crys/mm^2), urine KIM1 (ng/mL), cortical macrophages (MΦ) and angiotensin II+ (AII+) cells/mm^2 and collagen-1 (%Coll-1), as well as the renal content of nuclear p65, IL6, CASP1, HO1, SOD1 (WB) and IL1β (pg/mg). Renal HYP was confirmed by pimonidazole staining.

Results: HYP reduced renal hypertrophy, tubular injury, interstitial inflammation/fibrosis and the content of p65 and IL6, but not CASP1 or IL1β, suggesting specific NFκB inhibition, while lowering HO1 and increasing SOD1.

Conclusions: As in Nx, breathing 12% O2 limited renal injury in the ADE model and attenuated NFκB and oxidative stress, suggesting the existence of a common pathogenic mechanism and the need to review the role of tissue hypoxia in CKD. FAPESP/CNPq.

The Analysis of Chaperone-Mediated Autophagy in Hypertensive Kidney Disease

Yoshihisa Nakatani, Masahiro Takami, Shuji Arima. *Division of Nephrology, Department of Internal Medicine, Kindai University Faculty of Medicine, Osaka-Sayama, Japan.*

Background: Three different types of autophagy coexist in mammalian various cells. Chaperone-mediated autophagy (CMA) in kidney disease such as acute kidney injury and diabetic nephropathy has been reported. However, it is unclear whether CMA is involved in hypertensive kidney disease. So we examined whether CMA is involved in hypertensive renal disease and its mechanism.

Methods: First, we examined CMA levels in WKY (Wister Kyoto Rat) and MSHRSP (Malignant Stroke-Prone Spontaneously Hypertensive Rat) and treated with antihypertensive therapy by extracting lysosome fractions and using immunoprecipitation. In fact analysis of hypertensive model rats revealed that Lamp2A was strongly expressed in the proximal tubule and collecting duct, and co-staining with Hsc70 was also observed and could confirmed CMA. Therefore by using HK2 cells treated with endoplasmic reticulum stress (ERS) chemical inducer tunicamysin (Tun), we examined cell damage and mitochondrial injury if CMA was regulated by siRNA, Trichostatin A (TSA) and Humanin (HMN).

Results: First, compared with WKY, lysosome-Lamp2A expression was significantly increased in the renal medulla of MSHRSP but not in the renal cortex of MSHRSP. By antihypertensive therapy, ly-Lamp2A expression was significantly increased and CMA activity upregulated, so CMA failure was confirmed. Second, in HK2 cell with treated Tun, CMA was rapidly increased at 1 hour of administration and lasted for 3 hours. After12 hours, CMA activity returned to the initial condition, and at 24 hours, it decreased to about 50 percentages. When expression was reduced in Hsc70 and Lamp2, CMA decreased and cell induced apoptosis. In addition, in TSA treatment which involved in Hsc70 transport, ly-Lamp2A did not change and almost no CMA occurred. In HMN treatment such as CMA enhancer, pAKT was increased, but Bax and pJNK were also increased in lysosome, we would be able to consider that ERS induced CMA ameliorates cell damage, but it also seems to increase apoptosis of unnecessary abnormal mitochondria and damaged cells.

Conclusions: We found CMA induced ERS pathway was associated with cell apoptosis and mitochondria injury in hypertensive kidney disease.

FR-PO373

Niban Protein Regulates Apoptosis in HK-2 Cells via Caspase-Dependent Pathway

Shiqi Tang, Jianwen Wang, Jishi Liu, Hao Zhang. *The Third Xiangya Hospital of Central South University, Changsha, China.*

Background: To investigate whether Niban protein plays a role in renal interstitial fibrosis by regulating apoptosis of renal tubular epithelial cells.

Methods: Unilateral ureteral obstruction (UUO) model was established by using 24 C57B / 6J mice, which were divided into sham operation group, UUO 3 day group, UUO 7 day group and UUO 14 day group. Renal pathological changes were observed by HE staining and Masson staining, Immunohistochemistry was used to detect the expression of Niban, collagen I, collagen III and E-cadherin, Western blot was used to detect the expression of Niban, E-cadherin, collagen I, caspase3, P53, Bip and Chop, TUNEL assays were used to detected apoptosis; Niban siRNA were transfected in HK-2 cells to silence the expression of Niban, Niban plasmid were transfected in HK-2 cells to overexpresse the expression of Niban, Angiotensin II (Ang II) is used to induce apoptosis in HK-2 cells, while tunicamycin (TM) induces endoplasmic reticulum stress response, Western blot was used to detect the expression of Niban, α-SMA, E-cadherin, caspase8, caspase9, caspase12, Bip and Chop.

Results: 1. Apoptosis increased in the UUO model, with the development of obstruction, Niban's expression decreased gradually, the expression of P53, Bip and Chop gradually increased, reached the peak on days 7, and the expression decreased to the normal level on days 14. 2. After AngII stimulates HK-2 cells, Niban expression is decreased and apoptosis is increased. Silencing of Niban up-regulated the levels of caspase 8, caspase 9, α-SMA and apoptosis, while down-regulated the level of E-cadherin. Overexpression of Niban down-regulated the level of caspase 8, caspase 9, α-SMA, and apoptosis, while up-regulated the levels of E-cadherin. 3. After tunicamycin stimulated HK-2 cells, the expression of Niban decreased, compared with the control group,while the endoplasmic reticulum stress marker proteins Bip and Chop increased significantly. Inhibition of Niban expression, the expression of Bip and Chop in HK-2 cells increased, but it was not statistical difference; after stimulation with tunicamycin, the expression of Bip and Chop in HK-2 cells was significantly increased, and there was a statistically significant difference between the two groups compared with Niban siRNA group.

Conclusions: Niban protein is involved in apoptosis regulation in HK-2 cells, and most likely via Caspase-dependent pathway.

SIRT3 Regulates the Mitochondrial Lysine Acetylation and Metabolic Networks in Proximal Tubular Epithelial Cells in Renal Fibrosis

Lei Jiang, Yu Zhang, Jing Luo, Hongdi Cao, Junwei Yang. *Nanjing Medical University, Nanjing, China.*

Background: Proximal tubular epithelial cells (PTCs) are high energy demanded relying on mitochondrial oxidative phosphorylation as the main energy source which is disturbed in renal fibrosis. Acetylation is recognized as an important posttranslational modification for mitochondrial function. SIRT3 is the major mitochondrial protein deacetylase and regulates mitochondrial metabolic function. In this study, we investigated whether SIRT3 could mediate the progress of renal interstitial fibrosis by regulating mitochondrial acetylation.

Methods: In vivo, unilateral ureteral obstruction (UUO) or ischemia-reperfusion (I/R) were used to induce renal fibrosis. In vitro, primary tubular epithelial cells were stimulated by TGF-b1. Proteomics and acetylation proteomics were performed on PTCs separated from UUO-operated mice at day 1. Westernblot and immunofluorescence staining were used to detect the SIRT3 expression and the acetylation levels in mitochondria. Immunoprecipitation was used to analyze the acetylation level of the PDHA. Honokiol was used as SIRT3 activator. SIRT3 shRNA adenovirus was used to knockdown SIRT3 expression.

Results: SIRT3 expression was decreased and mitochondrial protein acetylation was increased in tubular epithelial cells in the early phase of renal fibrosis. We identified 1900 unique acK site across 895 proteins between sham and UUO mice. The majority of proteins with 91.84% were hyper-acetylation. The increased acetylized proteins with 26.76% were mitochondrial protein. Notably, all proteins involved in mitochondrial oxidative phosphorylation were acetylated. We found pyruvate dehydrogenase a1(PDHA1) which provides the primary link between glycolysis and the TCA cycle was hyper-acetylation at K63, K149, K267, K277, K385. Immunoprecipitation analysis further confirmed that PDHA1 was acetylated under pro-fibrosis stimulation. And the PDH activity was decreased. Inhibiting SIRT3 could amplify the acetylation of PDHA1, inhibit PDH function and aggravate mitochondrial dysfunction. Activation SIRT3 could inhibit the acetylation of PDHA1, restore the PDH activity, improve the mitochondrial function, and further ameliorate renal fibrosis.

Conclusions: SIRT3 as a regulator of lysine acetylation in mitochondria and present a mechanism for regulating metabolic pathway through PDHA1 in Proximal tubule in renal fibrosis.

Funding: Government Support - Non-U.S.

Leukaemia Inhibitory Factor Promotes Fibroblast Activation via ERK-Egr-1 Pathway and Increasing Mitochondrial Biogenesis

Shihui Xu, Zhiyuan Su, Miaomiao Zhou, Fengxin Zhu, Jing Nie. *Division of Nephrology, Nanfang Hospital, Southern Medical University, Guang Zhou, China.*

Background: Fibrosis is the common pathway of various progressive kidney diseases. Fibroblasts are major players in the pathogenesis of renal fibrosis. Recent researches have shown that Leukemia Inhibitory Factor (LIF) exerts beneficial effects on various diseases. However, the role of LIF in the pathogenesis of kidney diseases remains largely unknown. Our study is to investigate the role of LIF in renal fibrosis.

Methods: Animal model of renal fibrosis was induced by unilateral ureteral occlusion (UUO) and ischemia reperfusion injury (IRI). Western blot (WB) and real time PCR were performed to evaluate the expression of LIF, LIF receptor (LIFR) and GP130, etc. Immunofluorescence staining was performed to evaluate the localization of LIF, LIFR and GP130. LIF neutralizing antibody was subcutaneously injected to evaluate the role of LIF in renal fibrosis induced by UUO. H&E, Masson and Sirius red staining were used to estimate renal pathology. Transforming growth factor β1 (TGF-β1) was used to stimulate cultured NRK-49F cells and primary mouse fibroblasts.

Results: LIF and its receptors (LIFR and GP130) were mainly expressed in interstitial fibroblasts, and significantly upregulated in fibrotic renal tissues induced by both UUO and IRI. LIF promoted the activation and proliferation of both NRK-49F cells and primary mouse fibroblasts through ERK-Egr-1 pathway. ERK inhibitor U0126 or silencing endogenous Egr-1 significantly inhibited LIF-induced fibroblast activation in NRK-49F cells. LIF stimulates mitochondrial biogenesis in both NRK-49F cells and primary mouse fibroblasts. LIF neutralizing antibody significantly inhibited TGF-β induced fibroblast activation in vitro, attenuated interstitial fibrosis induced by UUO.

Conclusions: Our experimental results indicate that LIF-LIFR/GP130-ERK-Egr-1 pathway plays a detrimental role in fibroblasts activation and thus contributes to interstitial fibrosis. LIF stimulates mitochondrial biogenesis to promote the activation and proliferation of both NRK-49F cells and primary mouse fibroblasts. Blocking LIF production is a plausible strategy for therapeutic intervention of chronic kidney disorders.

PGC-1α Inhibits the NLRP3 Inflammasome via Preserving Mitochondrial Viability to Protect Kidney Fibrosis

Jimin Park,[1] Seonghun Kim,[1] Boyoung Nam,[1] Tae-Hyun Yoo.[2] *[1]Yonsei University, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: NOD-like receptor, pyrin domain containing-3 (NLRP3) contributes to inflammation, cell death, and fibrosis in animal models of kidney disease. The NLRP3 inflammasome is activated by mitochondrial damage. However, it is unknown whether PPARγ-coactivator 1α (PGC-1α), a key mitochondrial biogenesis regulator, can modulate NLRP3 pathway. Here, we demonstrated that PGC-1α inhibits activation of NLRP3 inflammasome via preserving mitochondrial viability.

Methods: We isolated primary tubular epithelial cells (TECs) from C57BL/6 mice. The NLRP3 inflammasome pathway, mitochondrial dynamic proteins and morphology, oxidative stress marker, and profibrotic markers were examined after the TECs were treated with TGF-β1 (5 ng/ml) alone, TGF-β1+PGC-1α plasmid DNA (1 ug), TGF-β1+siPGC-1α (50 nM), and TGF-β1+PGC-1α activators (Metformin, AICAR, and Resveratrol). For animal study, C57BL/6 mice underwent unilateral ureteral obstruction (UUO) and were treated with PGC-1α activators.

Results: *In vitro*, TGF-β1 treatment suppressed PGC-1α, dysregulated mitochondrial dynamics, and impaired mitochondrial morphology. In addition, the NLRP3 inflammasome pathway was activated and the expression levels of profibrotic markers and oxidative stress marker were increased in TGF-β1-treated TECs. These changes were further accentuated by PGC-1α knock-down. In contrast, restoration of PGC-1α with the activators and the plasmid improved mitochondrial dynamics and morphology and attenuated the NLRP3 inflammasome activation and profibrotic marker expression. The release of mtDNA in the cytosol, the expression of TNFAIP3 and the increased degree of oxidative stress, which are inducers of the NLRP3 inflammasome after mitochondrial damage, were increased by TGF-β1 and PGC-1α knock-down. Restoration of PGC-1α significantly reversed these alterations. *In vivo*, UUO resulted in the decreased expression of PGC-1α and mitochondrial defects, while the NLRP3 inflammasome was activated and fibrosis was increased by UUO. These changes were significantly improved by PGC-1α activators.

Conclusions: This study demonstrates that kidney injury is ameliorated by PGC-1α-induced inactivation of the NLRP3 inflammasome.

Oligomerization of APOL1 Risk Variants After Mitochondrial Translocation

Shrijal Shah,[1] Herbert F. Lannon,[3] Martin R. Pollak,[2] David J. Friedman.[2] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [3]Beth Israel Deaconess Medical Institute, Boston, MA.*

Background: Inheriting two copies of APOL1 risk variants (G1 and G2) increases susceptibility to chronic kidney disease in African Americans. G1 and G2 are toxic, gain-of-function variants despite their recessive mode of inheritance. APOL1 multimerization has been proposed as an explanation for recessive gain-of-function.

Methods: Immunoprecipitation experiments were performed in HEK293 cells with co-transfection of constructs expressing APOL1 (G0, G1, or G2) tagged with FLAG or MYC. Oligomerization of untagged APOL1 was assessed in tetracycline inducible APOL1-expressing HEK293 TRex cells using blue native PAGE. Mitochondrial-enriched and cytosolic fractions were prepared by differential centrifugation. TOMM20 was knocked down with siRNA 48 hours prior to induction of APOL1 expression. APOL1-induced cytotoxicity was determined using the Muti-Tox Fluor Mutliplex cytotoxicity assay kit from Promega.

Results: After co-transfection of FLAG- and MYC-tagged APOL1, immunoprecipitation of FLAG followed by Western blot for MYC demonstrated APOL1-APOL1 binding. Blue native PAGE of APOL1 expressing cell lines revealed that G1 and G2 tend to form large oligomers whereas G0 remains mostly monomeric. When we fractionated cells via differential centrifugation, we found that the oligomers were present mostly in the mitochondrial-enriched fractions. Knockdown of the mitochondrial outer membrane protein TOMM20 blocked APOL1 mitochondrial import and eliminated both APOL1 oligomer formation and APOL1-induced cytotoxicity.

Conclusions: APOL1 molecules can interact with other APOL1 molecules and risk variants have a greater tendency to form large oligomers. The oligomers are mostly located in the mitochondrial-enriched cell fraction and inhibiting mitochondrial import of APOL1 dramatically reduces the formation of oligomers, suggesting that mitochondrial import of APOL1 is necessary for subsequent oligomerization of G1 and G2. Whether these APOL1 oligomers directly cause cytotoxicity remains to be answered.

Energy Production System Is Suppressed in Kidneys of Low-Birth-Weight Rats, Which Develop FSGS

Toshiyuki Imasawa. *National Hospital Organization Chibahigashi National Hospital, Chiba, Japan.*

Background: Intraglomerular hypertension should be associated with the pathogenesis of FSGS lesion of low-birth-weight (LBW) related nephropathy, because LBW is significantly associated with a decreased number of nephrons. However, there is a possibility that other mechanisms participated in the pathogenesis of LBW-related nephropathy. We purposed to investigate innate factors which should be involved in the pathogenesis of LBW-related nephropathy at adulthood.

Methods: Low-birth weight rats (N = 7) were obtained by intra-peritoneal injection of dexamethasone into pregnant rats. Normal-birth weight rats (N = 7) were obtained by saline injection. At 4 weeks of age, left kidneys were removed. After that, until 9 weeks of age, rats were fed with high salt diet.

Results: At 9 weeks of age, serum creatinine levels of LBW rats were significantly higher than NBW rats (p=0.03). Furthermore, at 9-week-age, focal segmental sclerosis (FSGS) lesions were observed in 7.43% of glomeruli in LBW rats, but only 0.48% in NBW rats. On the other hand, at 4 weeks of age, there were no sclerotic lesions and any other pathological changes both in LBW rats and in NBW rats. A quantitative proteomics by using histologically normal cortexes at 4-week-age revealed marked suppression of energy metabolism in kidneys of LBW rats. For examples, 15 proteins related to TCA cycle, 15 proteins of fatty acid metabolism, 14 proteins glycolysis, and 12 proteins of mitochondrial oxidative phosphorylation were significantly suppressed in LBW rats. Bioinformatics analysis by using Ingenuity Pathway Analysis revealed RICTOR should be key regulator of these proteomic changes.

Conclusions: Kidneys in low-birth-weight rats should have suppressed energy production system before the occurrence of histological kidney damage. Not only intraglomerular hypertension, but also such innate defects of energy production, might to form FSGS lesions in LBW-related nephropathy.

Effect of Magnesium on the Processes of Inflammation and Oxidative Stress Associated with CKD

Maria Encarnacion Rodriguez Ortiz,[1] Rodrigo López baltanás,[1] Juan M. Diaz Tocados,[1] Antonio Canalejo,[3] Mariano Rodriguez,[2] Juan R. Munoz-Castaneda,[1] Yolanda Almaden peña.[4] *[1]Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Córdoba, Spain; [2]Hospital Universitario Reina Sofia, Cordoba, Spain; [3]University of Huelva, Huelva, Spain; [4]Lipid and Atherosclerosis Unit. Department of Internal Medicine/ IMIBIC/Reina Sofia University Hospital/University of Cordoba, Cordoba, Spain.*

Background: The development and progression of vascular calcifications (VC) is a prevalent complication in advanced stages of chronic kidney disease (CKD). Previous observations show that magnesium (Mg) may be beneficial in preventing the development of VC. Uremia is considered to be an inflammatory state, and both chronic inflammation and oxidative stress appear to have a causal effect in VC by directly affecting vascular smooth muscle cells (VSMC). The main goal of this work was to assess, through both *in vivo* and *in vitro* approaches, the effect of Mg on inflammation and oxidative stress associated with CKD.

Methods: *In vitro* studies were based on the culture of VSMC in the presence of high phosphorus (P), with or without Mg. *In vivo* experiments were performed in an experimental model of uremic rats feeding with high P diet and Mg dietary supplementation during 14 days. All experimental protocols were reviewed and approved by the Ethics Committee for Animal Research of the University of Cordoba (Cordoba, Spain) and adhered to the recommendations included in the Guide for Care and Use of Laboratory Animals (US Department of Health and Human Services, NIH) and European laws and regulations on protection of animals, under the advice of specialized personnel.

Results: VSMC incubated with high P exhibited an increase in pro-inflammatory mediators, the inflammatory cytokines and the levels of oxygen reactive species (ROS). The addition of Mg prevented the elevation in inflammatory markers. Uremic rats receiving normal dietary Mg showed elevated levels of ICAM-1 and high oxidative stress By contrast, dietary Mg supplementation abolished all these processes.

Conclusions: Taken together, these results suggest the protective role of Mg in the generation of oxidative stress and inflammation in the context of renal disease.

Therapeutic Approaches in Mitochondrial Dysfunction, Inflammation, and Autophagy in Uremic Cachexia: The Role of Aerobic Exercise

Yumei Zhang. *Shanghai Ninth people's hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: Chronic kidney disease (CKD) causes several systemic changes, including muscular homeostasis, and eventually results in muscle atrophy. CKD-induced muscle atrophy is highly prevalent, and exercise is well known to enhance muscle function, although the exact mechanism remains unclear. Here, we aimed to assess whether the protective effect of aerobic exercise in CKD mice was associated with mitochondrial dysfunction, autophagy or inflammation.

Methods: C57BL/6J mice were randomly allocated into 3 experimental groups: Sham, CKD, and CKD+aerobic exercise (CKD+AE). Renal function was assessed via serum creatinine and urea levels, and histological PAS and Masson staining were performed. Muscle wasting was determined based on grip strength, cross-sectional area (CSA), and MyHC protein expression. We measured mitochondrial dysfunction by assessing mtDNA, ROS and ATP production, and mitochondrial configuration. Autophagy was determined via assessments for Atg7, LC3, and SQSTM1 on western blotting. Inflammation was identified via pro-inflammatory cytokines and NLRP3 inflammasome components using real-time PCR and western blotting.

Results: CKD mice exhibited higher BUN and creatinine levels and more severe glomerulosclerosis and tubulointerstitial fibrosis, relative to the Sham group; all these effects were relieved by aerobic exercise. Moreover, grip strength, CSA, and MyHC protein expression were improved after 8 weeks of aerobic exercise. Furthermore, aerobic exercise significantly decreased MDA levels, increased SOD2 activity and ATP production, and improved mitochondrial configuration, relative to the CKD group. In addition, aerobic exercise down-regulated the overexpression of pro-inflammatory cytokines and NLRP3 inflammasome components, and balanced the mitochondrial biogenesis and autophagy.

Conclusions: Aerobic exercise may ameliorate CKD-induced muscle wasting by improving mitochondrial dysfunction, inflammation and autophagy in uremic cachexia.

Mechanisms of Aerobic Exercise on CKD-associated Muscle Atrophy in Mice

FR-PO381

Markers of Mitochondrial Mass and Biogenesis Are Reduced in Non-Dialysis-Dependent CKD and Not Restored Following Exercise

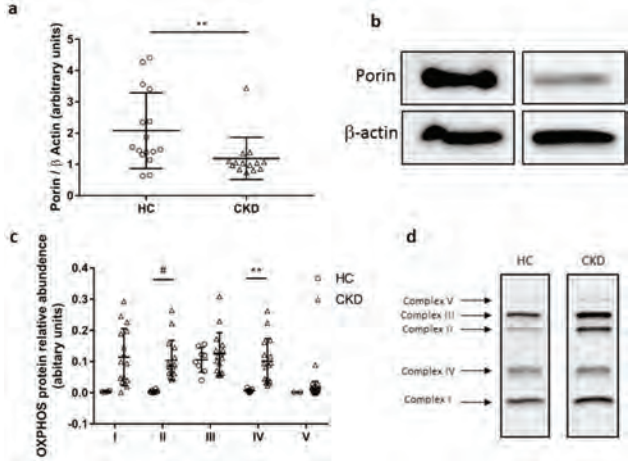
Luke A. Baker, Alice C. Smith, Emma L. Watson. Leicester Kidney Lifestyle Team *University of Leicester, Leicester, United Kingdom.*

Background: Patients with non-dialysis dependent chronic kidney disease (NDD-CKD) exhibit reduced exercise capacity, poor physical function and symptoms of fatigue. The mechanisms that contribute to this are not clear but may involve mitochondrial dysfunction. We investgated the effect of NDD-CKD on mitochondrial mass and the expression of transcription factors involved in mitochondrial biogenesis compared to healthy controls, and the effect of 12-weeks of exercise on these markers.

Methods: Skeletal muscle biopsies were collected from the vastus lateralis of 16 NDD-CKD patients (Stage 3b-5) and 16 matched healthy controls (HC). To investigate the effect of exercise training VL biopsies were collected from 17 NDD-CKD patients stage 3b-5 pre and post a 12-week exercise intervention. Mitochondrial mass (porin/β-actin ratio) was analysed by western blotting and the expression of transcription factors involved in mitochondrial biogenesis was investigated by real-time PCR.

Results: NDD-CKD exhibited significantly reduced porin/β-actin ratio (86%, $p<0.001$) and reduced mRNA expression of PGC-1α, NRF-1/2, TFam, mfn2 and SOD1/2 compared to HC ($p\leq0.05$). 12-weeks of exercise training resulted in a significant increase in PGC-1α expression only ($p=0.04$), but no change in mitochondrial mass was observed ($p>0.05$).

Conclusions: NDD-CKD patients exhibit a reduction of skeletal muscle mitochondrial mass and suppression of mRNA expression of transcription factors that are involved in mitochondrial biogenesis, which may contribute to the detrimental muscle related symptoms experienced in this population. After 12-weeks of exercise training no improvement was observed. Reasons for this lack of improvement warrant further investigation in NDD-CKD.



CKD results in a reduction in mitochondrial mass within skeletal muscle. a) Western blot of porin/β-actin ratio; b) Densitometry of porin/β-actin ratio. **denotes $P<0.001$ vs healthy controls; c) Western blot analysis of OXPHOS proteins, relative to loading control; d) Densitometry analysis of OXPHOS complex abundance.

FR-PO382

PET Imaging of Renal Mitochondria in Acute and Progressive Kidney Disease Models Using a Novel PET Probe ^{18}F-BCPP-BF

Satoshi Saeki,[1] Hiroyuki Ohba,[2] Takashi Shimada,[3] Hideo Tsukada,[2] Kenji Nagao.[1] *[1]Kyowa Hakko Kirin Co., Ltd., Shizuoka, Japan; [2]Hamamatsu Photonics K.K., Hamamatsu, Japan; [3]Research and Development Division, Kyowa Hakko Kirin Co. Ltd., Tokyo, Japan.*

Background: The kidney is a highly energy-demanding organ and rich in mitochondria. In addition to physiological importance of mitochondria as a powerhouse, mitochondrial dysfunction is often associated with overproduction of ROS, which is believed to play a critical role the pathogenesis of kidney diseases. Nonetheless, only a few studies have reported the renal mitochondrial status in the clinical settings partly due to a paucity of methodologies. Recently, Ohba et al. developed a novel PET probe ^{18}F-BCPP-BF specifically binding to mitochondrial complex I (MC-I). ^{18}F-BCPP-BF has a favorable pharmacokinetic property for kidney imaging, which enables us to non-invasively visualize and quantitate the amount of MC-I in whole kidneys in vivo (EJNMMI Research 2016; 6: 82).

Methods: In this study, we demonstrated high-resolution animal PET analyses for kidneys in glomerulonephritis and AKI model animals using ^{18}F-BCPP-BF.

Results: In anti-GBM glomerulonephritis model rats, the uptake level of ^{18}F-BCPP-BF in kidney showed only slight decrease at the acute phase (74% vs. normal control), while it became more remarkable at the later phase (33% vs. normal control). The significant decrease in the PET signal was accompanied with robust reduction of mitochondrial complex proteins including MC-I, demonstrated by Western blotting analysis. The slight change in PET signals at acute phase despite massive protein urea may reflect less damage in tubular epitheliums. In rat acute renal I/R model, the renal uptake of ^{18}F-BCPP-BF was slightly decreased at 3 hours after reperfusion (75% vs. sham), when kidney function was slightly declined accompanying morphological abnormality of mitochondria in S3 proximal tubular cells though the loss of proximal tubular epithelial cells was still minimal.

Conclusions: The novel PET probe opens up new possibilities for studying pathophysiological meanings of mitochondrial status in kidney disease, which may be applicable to new clinical diagnosis for patients with various types of kidney diseases.

FR-PO383

APOL1 Alternative Splice Isoforms Localize to the Endoplasmic Reticulum with Distinct Topologies and Do Not Associate with Endosomes

Suzie J. Scales, Francesca Oltrabella, Nidhi Gupta. *Genentech, South San Francisco, CA.*

Background: Two risk variants of the *APOL1* gene, G1 and G2, are associated with chronic kidney disease in African Americans. APOL1 risk variants have been proposed to cause podocyte toxicity by a variety of pathways, including inhibition of endosomal maturation via direct binding to cytoplasmic VAMP8 on endosomes. APOL1 G0 (wild type), G1 and G2 variants all localize to the endoplasmic reticulum (ER) and the cell surface of podocytes, suggesting that direct interaction with VAMP8 is unlikely. However, those studies utilized isoform APOL1.vA, whereas three minor splice isoforms (vB1, vB3 and vC) exist, with different N-termini and so may be not be secreted. While transient transfection of all four isoforms leads to their apparent secretion, this may be an overexpression artifact. We therefore aimed to determine the localization of APOL1 isoforms stably expressed in podocytes.

Methods: We generated inducible *APOL1* stable podocytes and determined the localization of each isoform by immunofluorescence and flow cytometry. We assessed APOL1 isoform levels in immortalized human podocytes by qRT-PCR, immunofluorescence and western blotting.

Results: By immunofluorescence with Triton X-100 permeabilization, all four isoforms localized to the ER, but selective permeabilization of the plasma membrane with digitonin revealed topological differences: isoforms vA and vB1 are inside the ER lumen, while vB3 and most of vC are on the outer face of the ER, like APOL2. Consequently, only vA and vB1 are appreciably detected on the cell surface by flow cytometry, indicating those two isoforms are secretory, while vB3 and vC are cytoplasmic. Wild type podocytes express the three splice isoforms at much lower levels than vA by RT-PCR, but *APOL1* mRNA and protein levels are notoriously poorly correlated. Western blotting of endogenous podocyte APOL1 with sensitive in-house APOL1-specific antibodies revealed the major band was vA, but a minor upper band became detectable upon gamma interferon stimulation. This could represent vB3 or a post-translational modification.

Conclusions: APOL1 isoforms vA and vB1 are secretory, whereas vB3 and most of vC are cytoplasmic, but on the outer ER membrane, not endosomal. APOL1 is therefore unlikely to directly interact with VAMP8 to interfere with endosomal trafficking.

Integrative Omics Reveal Molecular Signatures of Endoplasmic Reticulum Stress in Tubular Epithelial Cells

Dan Yi,[2] Behram S. Radmanesh,[2] Esther Liu,[2] Jennie Lin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University, Chicago, AL.*

Background: Over the past decade, dysregulated and prolonged endoplasmic reticulum (ER) stress has been observed in acute kidney injury and chronic kidney disease (CKD). However, how ER stress contributes to disease pathophysiology in the kidney remains unclear. Here we take an unbiased approach to identify potential modulators of ER stress pathways in human proximal tubular epithelial cells.

Methods: We performed bulk RNA sequencing (RNA-seq) and untargeted LC-MS metabolite profiling on HKC-8 proximal tubular epithelial cells cultured with and without 2.5 uM of tunicamycin, an inducer of ER stress. Single-cell RNA-seq (scRNA-seq) was performed on kidney organoids differentiated from induced pluripotent stem cells, grown to day 25, and treated with tunicamycin.

Results: RNA-seq revealed 2912 differentially expressed genes after 4 hours and 2436 differentially expressed genes after 24 hours of tunicamycin treatment. These genes were enriched for pathways relevant to inflammatory response ($P < 0.001$), Wnt signaling (P=0.015), protein processing in the ER (P=0.022), and extra-cellular matrix receptor interaction (P=0.04). A subset of the most highly differentially expressed genes were validated in tubular cells profiled in scRNA-seq of tunicamycin-treated 3D kidney organoids. Thirty genes differentially expressed in HKC-8 cell ER stress were also genes at kidney trait loci identified in recent genome-wide association studies; these genes are involved in cellular differentiation (PAX8) and fibrosis pathways (ACVR2A, SMAD3, TRIB1). Although network analyses identified known ER stress protein ATF4 as the main upstream transcriptional regulator, ATF4 target genes comprised only a small fraction of the differential expression gene set. Our metabolite profiling revealed decreased 2-HG (FC -2.25, P=0.021) and a-KG (FC -1.63, P=0.002) levels in ER stress: these metabolites are known epigenetic modulators, with implications for differential methylation activated by ER stress. Decreased abundance of these metabolites is also consistent with the commensurate increase in PHGDH expression (FC 2.87, P<0.001).

Conclusions: Taken together, these results demonstrate pervasive injury-relevant and ER stress induced transcriptional changes in kidney cells, with potential modulation by genetic variation and intermediate metabolites.

Renal Failure Induced by Deletion of the Gene Encoding Canonical Transient Receptor Potential 1 (TRPC1) Channels: A Mouse Model of Normotensive CKD

Bonnie Eby,[1] Meghan M. Pantalia,[1] Chris D. Skaggs,[1] Lindsay J. Barron,[1] Usman A. Khan,[1,2] Kai Lau.[1,2] *[1]University of Oklahoma Health Science Center, Oklahoma City, OK; [2]Medical Service, Oklahoma City VA Hospital, Oklahoma City, OK.*

Background: TRPC1 plays a key role in cardiac hypertrophy, vascular smooth muscle proliferation & glomerular mesangial cell contractility. It is reduced in diabetes, but exact relationship is unknown. Since TRPC1 deletion produces diabetes & cardiomyopathy, we tested for renal phenotypes in TRPC1 deficiency.

Methods: In age-matched wild types, +/- & null males, from 1 - 20 mon, we measured serial blood glucose, blood & urine creatinine (Cre) by HPLC. Renal ultrasound was done at 7, 11, & 20 mon. Glomerular filtration rate (GFR) was estimated by Cre clearance (C) & confirmed by inulin C. Blood pressure (BP) was measured directly by arterial cannulation.

Results: Despite hyperglycemia from 3 mon on & diabetes at 6 mon, kidney volume at 7 mon (0.38 vs 0.46 cc) & kidney weight (KW) to body (B) W (1.2 vs 1.5 %) were 17% lower in null. From 11- 20 mon, kidney volume (0.4 vs 0.5 cc) stayed 16% lower & KW:BW (1.1 vs 1.5 %) 28% lower. Renal echogenicity was similar at 7 & 11 mon but increased by 37% at 20 mon, sugggesting injury & scarring. Normal at 12 mon, serum Cre (0.1 vs. 0.06 mg%) was elevated at 17 mon. Cre C fell by 42% (0.66 vs. 1.13 ml/min/mouse) & by 50% when factored for BW (1.7 vs. 3.4 ml/min/100g). Renal failure was confirmed by 44 to 48% reduction in GFR (214 vs 384 µl/min per mouse; 603 vs 1,155 µl/min per100 g BW; 362 vs 681 µl/min/ per g KW). There was no hypertension based on systolic BP (in torr) (113 vs. 121), diastolic (77 vs. 86) or mean (89 vs. 98). Urine concentration ability was intact by osmolality after 17 h dehydration. Urine acidification was impaired in null based on urine pH (6.0 vs 5.2). Urine albumin was increased in null (12 vs 7 µg/d or 23 vs 14 µg/mg Cre). Haploid deletion prduced similar renal phenotypes.

Conclusions: 1. Both haploid & diploid TRPC1 deletion produces nephropathy based on 50% GFR loss, reduced kidney volume, and increased echogenicity. It offers an excellent model to study non-hypertensive CKD. 2. Though renal failure emerges ~12 mon after diabetes, the small kidney size at the outset & the minimal proteinuria favor hypoplastic over diabetic nephropathy. 4. We propose that the TRPC1 protein is key in normal growth & development for the kidney (as for the heart) & a possibl role in hyperfiltration in response to diabetes.

Functional Impact of Endogenous ATRAP, a Novel Angiotensin II Type 1 Receptor-Associated Protein, on Human Renal Proximal Tubule Cells

Takahiro Yamaji,[4] Shingo Urate,[4] Eriko Abe,[4] Toru Suzuki,[4] Takayuki Yamada,[1] Shohei Tanaka,[4] Sho Kinguchi,[2] Kengo Azushima,[3] Tomohiko Kanaoka,[2] Hiromichi Wakui,[2] Yoshiyuki Toya,[2] Kouichi Tamura.[4] *[1]Mount Sinai Beth Israel, New York, NY; [2]Yokohama City University, Kanagawa, Yokohama city, Japan; [3]Duke-NUS Medical School, Singapore, Singapore; [4]Yokohama City University Graduate School of Medicine, Yokohama, Japan.*

Background: The proximal tubule is a particularly important site for aging-related kidney damage. Sirtuin 1 (SIRT1), an NAD^+-dependent deacetylase in the proximal tubule, is involved in renal damage associated with aging. However, the mechanisms of SIRT1 regulation remain to be elucidated. We recently reported that ATRAP-deficient mice displayed an exacerbation of age-associated renal function decline and tubulointerstitial fibrosis. Although the molecular mechanisms by which ATRAP deficiency exacerbates age-associated tubulointerstitial fibrosis has not yet been defined, renal SIRT1 protein expression was more decreased in aged ATRAP-deficient mice compared with aged wild type mice. Further investigations of ATRAP-dependent SIRT1 protein expression are important to resolve aging-associated kidney dysfunction. in this study we aimed to establish an ex vivo model of the proximal tubule to determine the role of ATRAP in SIRT1 protein expression.

Methods: We established an immortalised RPTEC line by expressing hTERT and shRNA-targeted CDKN2A. Next, we cloned this immortalized RPTEC and then characterised the cells based on the expression of a proximal tubular marker (SGLT2, DPP4). We call this cloned immotarised RPTEC, ciRPTEC. To analyze the ATRAP function in the proximal tubule cells, we use siRNA-mediated ATRAP knockdown in ciRPTEC and CRISPR-CAS9 mediated ATRAP knockout.

Results: *SIRT1* mRNA expression, which was induced by serum starvation, was unaffected by transient ATRAP knockdown. On the other hand, SIRT1 protein expression was not induced by serum starvation in our ciRPTEC cells, although transient ATRAP knockdown reduced the expression of SIRT1 protein under both normal and serum-starved conditions. Like ATRAP knockdown, ATRAP knockout did not affect *SIRT1* mRNA expression under either the normal or serum-starved condition. However, SIRT1 protein expression was significantly decreased by serum starvation in ATRAP knockout cells, while no significant reduction in SIRT1 protein was observed in control cells.

Conclusions: These results indicate that ATRAP mediates SIRT1 protein abundance in ciRPTEC by regulating its synthesis and/or stability but does not affect the level of *SIRT1* mRNA transcription or stability.

FR-PO387

Combined Treatment with Losartan and an NF-κB Inhibitor Affords Better Renoprotection Than AT1R Blockade Alone in Aging Rats

Helena M. Tessaro, Fernanda F. Zambom, Sara C. Ribeiro, Viviane D. Faustino, Janice Pião, Denise M. Malheiros, Niels O. Camara, Clarice K. Fujihara, Orestes Foresto-Neto, Roberto Zatz. *Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: The mechanisms underlying aging nephropathy (AN) are unclear. Renal angiotensinII (AII) and NF-κB activation are important factors in the pathogenesis of Chronic Kidney Disease (CKD). We investigated whether combined treatment with Losartan (L) and the NF-κB inhibitor Pyrrolidine Dithiocarbamate (PDTC) would attenuate experimental AN.

Methods: Male Munich-Wistar rats were divided in 4 groups: **12M** (n=10), 12-month-old rats; **15M** (n=10), 15-month-old rats; **15M+L**(n=8) rats receiving L (50 mg/kg/d) and **15M+L+PDTC** (n=8), rats receiving L and PDTC (15 mg/kg/d). Both compounds were given orally from 12 to15 mo of age. We assessed body weight (BW, g), tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/24h), serum creatinine (Scr, mg/dL), glomerulosclerosis (GS,%), cortical macrophages (MΦ, cells/mm^2) and AII+ (cells/mm^2), Collagen-1 (Coll-1, %), as well as renal TLR4 and IL-6 (WB).

Results: Group 15M exhibited mild hypotension, creatinine retention, albuminuria, glomerulosclerosis, Coll-1 deposition and cortical infiltration by MΦ. Renal abundance of TLR4 and IL-6 was also increased, suggesting activation of the NF-κB pathway. L decreased cortical MΦ and Coll-1, but not TLR4 or IL-6, failing to reduce ALB or GS%. Combined L+PDTC prevented the increase of renal TLR4, IL-6 and MΦ, reduced AII+ and strongly attenuated ALB and GS%.

Conclusions: Simultaneous inhibition of renal AII and of the NF-κB system can contribute to reduce the decline of renal function with age. FAPESP/CNPq

Progression of Established CKD Is Halted by Metformin Treatment in Rats

Raphaëlle Corremans, Benjamin A. Vervaet, Patrick C. D'Haese, Anja Verhulst. *University of Antwerp, Antwerp, Belgium.*

Background: Metformin, the first-line drug for type-2 diabetes mellitus, also exerts multiple benign pleiotropic actions on different organs. Recent preclinical and clinical data point towards a beneficial impact of metformin on the kidney. Chronic kidney disease (CKD) is a worldwide recognized public health problem and represents a progressive loss of renal function over a period of months or years. Current treatment strategies for CKD mainly focus on controlling important risk factors. To date, effective treatment directly targeting the kidney is lacking. Here, the efficacy of metformin to attenuate progression of already established CKD was investigated.

Methods: A rat model of adenine-induced CKD (n=64) was used. Metformin (200 mg/kg) or vehicle (1% carboxymethylcellulose) treatment, by daily oral gavage (7 days/week), was initiated after 4 and 5 weeks of adenine (0.25%) administration; *i.e.* after CKD had developed. Treatment was continued during 4 weeks until the end of the study (*i.e.* week 8 and 9, respectively). A constant dose volume of 10 mL/kg was used. The effect of metformin on renal function and histopathology was studied.

Results: Serum creatinine levels dramatically rose in vehicle-treated CKD rats: from 0.6 ± 0.1 mg/dL (week 0) to 1.3 ± 0.2 mg/dL (week 4) and 2.6 ± 1.2 mg/dL (week 5) and further to 5.7 ± 0.6 mg/dL (week 8) and 4.8 ± 1.1 mg/dL (week 9). This increase from week 4 and 5, respectively, was almost completely prevented by metformin treatment as indicated by serum creatinine levels after 8 (2.0 ± 0.5 mg/dL) and 9 (2.9 ± 0.5 mg/dL) weeks respectively ($p<0.05$ vs. vehicle). Histological examination of periodic acid–Schiff-stained renal sections revealed less tubular dilation, epithelial flattening, brush border loss and, basement membrane thickening in metformin-treated rats in comparison to vehicle-treated animals. The renal tubulointerstitial area percentage, consisting of both extracellular matrix and infiltrating cells, in metformin treated CKD rats, was significantly lower, as compared to vehicle treatment (33% and 23% lower in rats receiving metformin from week 4 and 5, respectively, as compared to vehicle).

Conclusions: Metformin is able to attenuate the progression of pre-existing adenine-induced CKD in rats.

Latent Transforming Growth Factor Beta Biding Protein 4 (LTBP4) Attenuates Tubulointerstitial Fibrosis and Ameliorates Inflammation and Mitochondrial Dysfunction in CKD

Chi-Ting Su,[2,1] Tzu-Ming Jao,[4] Jenq-wen Huang,[3] Zsolt Urban.[2] *[1]Renal Division, Internal Medicine, National Taiwan University Hospital, Taipei & Yun-Lin Branch, Dou-Liu, Taiwan; [2]Human Genetics, Graduate School of Public Health, Univeristy of Pittsburgh, Pittsuburgh, PA; [3]Internal Medicine, National Taiwan University, Taipei, Taiwan; [4]Graduate Institue of Toxicoloy, National Taiwan University, Taipei, Taiwan.*

Background: Transforming growth factor beta (TGFβ) has been well known as a key factor for fibrosis and inflammation. LTBPs regulate TGFβ signaling in complicated ways. Disruption and loss of LTBP4 expression is associated with abnormal accumulation of extra-cellular matrix (ECM) and altered TGFβ activation. However, the role of LTBP4 in chronic kidney disease remains largely unknown.

Methods: To investigate the impact of LTBP4 on tubulointeresitial fibrosis (TIF), we generated LTBP4-overexpression and LTBP4-deficiency human renal proximal tubule cells (HK-2), treated with exogenous TGFbeta and established a fibroblasts-HK-2 co-culture system using rat fibroblasts (NRK-49F) and HK-2 cells. Moreover, to create TIF model, we performed unilateral ureteral ligation (UUO) in *Ltbp4S*-/- mice and wild-type (WT) mice to check ECM deposition and phenotypic alterations.

Results: Up-regulation of Ltbp4 in fibrotic kidney was noted in TIF model with UUO. Markers and mediators of fibrosis, α-SMA, fibronectin, collagen I, Pdgfrβ and TGFβ in gene and protein levels were reduced significantly in LTBP4-knock down HK-2 cells treated with additional TGFbeta. LTBP4-overexpression enhanced epithelial-mesenchymal transition (EMT) with showing decreased epithelial-cadherin, increased vimentin and collagen I in the co-culture system. In addition, lower expression of Pdgfrβ with higher expression of Nrf2 signaling was noted in fibrotic kidneys in *Ltbp*4S-/- mice compared with changes in WT mice, suggesting inflammation condition could be altered by the absence of Ltbp4S. Ltbp4-deficiency also reduced inflammatory gene expression such as IL-6 and altered IL-6-associated mitochondrial biogenesis.

Conclusions: Ltbp4 acts as a regulator of fibrosis and inflammation. Ltbp4 appears to inhibit antioxidant Nrf2 pathway and enhance fibrosis in a TGFβ-related manner in a murine UUO model of TIF and in a cell co-culture system. In addition, LTBP4 deficiency ameliorates mitochondrial dysfunction and alleviates renal fibrosis.

FR-PO390

Tolvaptan and Bardoxolone Methyl Synergistically Activate the Nrf2/HO-1 Pathway

Tamami Fujiki, Fumiaki Ando, Shintaro Mandai, Kiyoshi Isobe, Takayasu Mori, Koichiro Susa, Naohiro Nomura, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Tolvaptan, a vasopressin type2 receptor antagonist, has been approved for the treatment of autosomal dominant polycystic kidney disease. Furthermore, tolvaptan has been shown to improve the renal function in rodent models of chronic kidney disease (CKD); however, the underlying molecular mechanisms remain unknown. CKD is characterized by increased levels of oxidative stress, and an antioxidant transcription factor-nuclear factor erythroid 2-related factor 2 (Nrf2)-has been gaining attention as a therapeutic target. Therefore, we investigated the effects of tolvaptan and a well-known Nrf2 activator, bardoxolone methyl (BARD) on Nrf2.

Methods: We investigated the effect of tolvaptan and bardoxolone methyl on Nrf2 using mouse cortical collecting duct (mpkCCD) cells and mice kidneys.

Results: Tolvaptan led to Nrf2 nuclear translocation and induced mRNA and protein expression of heme oxygenase 1 (HO-1) in mpkCCD cells and the outer medulla of mice kidneys. Phosphorylation of unfolded protein kinase RNA-like endoplasmic reticulum kinase (PERK) by tolvaptan played an important role in activation of Nrf2/HO-1 pathway. Moreover, tolvaptan and BARD synergistically activatied Nrf2/HO-1 antioxidant pathway in mpkCCD cells.

Conclusions: We found the novel pharmacological property of tolvaptan that activated the PERK/Nrf2/HO-1 signaling pathway. Nrf2-regulated antioxidant systems were synergistically activated by tolvaptan and BARD. Tolvaptan is a potential therapeutic candidate in renal disease.

Adipose Tissue Macrophage Infiltration in CKD

Goni Katz-Greenberg,[1] Zhao Lin,[2] Cristina Martos-Rus,[2] Maria P. Martinez Cantarin.[2,1] *[1]Thomas Jefferson University Hospital, Philadelphia, PA; [2]Thomas Jefferson University, Philadelphia, PA.*

Background: Patients with advanced chronic kidney disease (CKD) present higher levels of inflammatory markers, associated with significant morbidity and mortality. Increased adipose tissue macrophages (ATM) may play an important role in a state of chronic inflammation seen in CKD patients. Historically, macrophages were divided into two main phenotypes, M1 or pro-inflammatory, and M2 associated with tissue repair. The aim of this study is to examine the degree of macrophage infiltration and macrophage characteristics of adipose tissue in patients and mice models with CKD.

Methods: We studied adipose tissue from 4 pairs of control-advanced CKD patients undergoing kidney donation or transplantation the same day. Stromal vascular fractions (SVF) were isolated from subcutaneous (SCF) and visceral (VF) adipose tissue. Macrophage populations were studied by flow cytometry. In a model of advanced CKD mice, macrophage populations were studied in adipose tissue SVF and peripheral blood. The same experiment was replicated in a model of advanced CKD in IL-6 knock-out (KO) mice.

Results: Patients with CKD had higher number of macrophages in adipose tissue compared to controls [fold change 1.9 for SCF and 2.7 for VF $p<0.01$]. In CKD mice, there was an increase in total number of macrophages in SCF versus control [42.24% vs 5.96%; $P<0.01$]. SCF of CKD mice also had lower CD301-/CD11c+ macrophages [1.5% vs 16.15%; $P=0.005$] and higher CD301+/CD11c-macrophages versus controls [96.6% vs 71.4%; $P<0.001$]. No difference was seen between the CKD and controls in VF. When SVF were studied in an IL-6 KO mice CKD model, there were no differences in ATM numbers in SCF or VF. In peripheral blood and despite lower total number of leukocytes [CD45+ 10.5% vs 16%; $P<0.05$], CD163+, CD11c+ and CD206+ macrophages were significantly increased in CKD mice compared to controls [47% vs 27%, 4.3% vs 2.6%, and 2% vs 1.3% respectably; $P<0.05$ for all]. There was also a higher number of T-cell sub-populations seen in CKD mice compared to controls [CD4+ 13.6% vs 11.4% and CD8+ 7.5% vs 5.4%; $p<0.001$ for both].

Conclusions: In humans, there was higher macrophage infiltration in adipose tissue. This was reproduced in a mice model of CKD. The lack of increased ATM numbers in the IL-6 KO mice model, suggest IL-6 may play a role in the recruitment of macrophages to adipose tissue in advanced CKD.

FR-PO392

Kidney Injury Molecule-1 (KIM-1) Promotes Tertiary Lymphoid Tissue (TLT) Development in the Kidney Through LTaβ/LTβR Signaling

Min Yang, Yutaro Mori, Naoka Murakami, Takaharu Ichimura, Joseph V. Bonventre. *Division of Renal Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: TLTs, inducible ectopic lymphoid tissues formed in chronic inflammatory conditions, have been described in various pathologic kidney diseases. However, the links between activation of the inflammation and the triggering cascade of B/T-cell clusters in the kidney are not understood. Here we investigated the role of KIM-1 on tubular epithelial cells (TECs) in affecting the formation of TLTs and modulation of the immune response in kidney injury.

Methods: The immune response associated with TLT formation was investigated using a kidney injury model induced by aristolochic acid (AA) in wild-type (WT) or

KIM-1$^{\Delta}$ (functional knockout of KIM-1) mouse. Studies in vitro were also done using renal primary TECs isolated from WT or KIM-1$^{\Delta}$ mouse kidney, or macrophage cells. Cells were treated with AA and incubated with endothelial cells (ECs, primary mouse kidney endothelial cells and bEND3), followed by measurement of the lymphotoxin pathway, lymphoid chemokines and pro-inflammatory characteristics.

Results: Under AA treatment, WT, but not KIM-1$^{\Delta}$, mice developed multiple TLTs in the kidney, morphologically characterized by high endothelial venules (HEVs) expressing PNAd, germinal centers within B cell follicles and T cells infiltration. These characteristics were associated with higher expression of lymphorganogenic chemokines (CXCL13-CXCR5, CCL21/CCL19-CCR7 axes), adhesion molecules (ICAM1, VCAM1), and IFN-γ in WT mice. Furthermore, in KIM-1$^{\Delta}$ mouse IF and qPCR revealed significantly less LTβ expression both on TECs and interstitial inflammatory cells than WT. LTα expression also showed the same trend. However, there was no obvious difference on LTβR expression of ECs. PNAd expression on ECs was induced by incubation with TECs substituted for macrophages or without co-culture conditions in the presence of AA treatment. Compared with WT, KIM-1$^{\Delta}$ TECs also displayed reduced expression of LTα, LTβ and induction of HEV marker PNAd following AA stimulation, similar to in vivo.

Conclusions: KIM-1 plays a critical role in initiation of the inflammatory response by activating HEV through LTαβ/LTβR signaling, providing inflammatory milieu to enhance immune cell infiltration. These findings provide a new insight that TECs modulate immune reaction in kidney injury and can be a therapeutic target for inflammatory renal diseases.

FR-PO393

Experimental CKD Reduces Tubuloglomerular Feedback Synchronization and Impairs Autoregulation

Tayyaba Zehra,[1] Heather L. More,[2] Shereen M. Hamza,[1] William A. Cupples,[2] Branko Braam.[1] *[1]University of Alberta, Edmonton, AB, Canada; [2]Simon Fraser University, Burnaby, BC, Canada.*

Background: Tubuloglomerular feedback (TGF) is an important component of autoregulation of renal blood flow and can prevent transmission of high blood pressure to glomeruli. We have previously shown that the TGF mechanism operates in a network fashion, leading to TGF synchronization. Eventually, this ensures that each nephron receives appropriate perfusion to match the energy-intensive reabsorption of Na^+. We have shown that loss of synchronization impairs autoregulation which is implicated in chronic kidney disease (CKD). We hypothesized that structural damage to the nephron-network would impair TGF-synchronization.

Methods: Male Lewis rats underwent uni-nephrectomy followed by partial nephrectomy to induce CKD (n=6) or underwent sham-operations (n=6). Six weeks later, the rats were anesthetized and mean arterial pressure (MAP), renal blood flow (RBF), and glomerular filtration rate (GFR) were assessed. Renal cortical perfusion was recorded with laser speckle contrast imaging (LSCI; Moor Instruments). After filtering to isolate TGF frequencies, we quantified phase coherence (PC) and used graph analysis to provide information about TGF synchronization between nephrons.

Results: Within the CKD group, RBF (8.0±0.6 to 6.7±1.0 mL/min) and GFR (0.89±0.33 to 0.37±0.7 mL/min) were decreased compared to controls (7.4±1.3 to 7.0±1.4 mL/min), (0.63±0.38 to 0.55±0.14 mL/min) respectively, although this did not reach significance. MAP showed no differences between CKD (102±7 to 89±5 mmHg) and controls (104±6 to 91±4 mmHg). Strength of TGF-synchronization between nephrons is indicated by higher values for phase coherence (PC). PC values were decreased for CKD rats (0.3±0.02) versus controls (0.5±0.03) which indicates weaker synchronization ($p<0.005$). Each pixel in the image is treated as a node and connected to other nodes via edges with significant PC; the CKD group had a lower number of connecting edges (780±532) compared to controls (36932±22589) ($p<0.005$). The number of synchronized regions (clusters) decreased for CKD rats (1±0.08) compared to controls (2±0.3) ($p<0.005$).

Conclusions: In this model of CKD, we demonstrate an impaired ability of nephrons to synchronize TGF in the renal cortex as assessed by LSCI. Since this network synchronization could prevent hypertensive injury further investigations are on improving network function.

FR-PO394

CKD of Unknown Etiology (CKDu) in Sri Lanka (SL): A Tissue Analysis

Neeraja Kambham,[1] Nishantha Nanayakkara,[2] Karen L. Artiles,[1] Vivek Bhalla,[1] Andrew Fire,[3] Shuchi Anand.[1] CKDu Sri Lanka *[1]Stanford University, Stanford, CA; [2]Teaching Hospital, Kandy, Kandy, Sri Lanka; [3]Stanford University, Stanford, CA.*

Background: CKDu is a leading cause of kidney disease in Central & North Central SL. Based on a prospective renal biopsy study, we hypothesized that higher acuity reflects recent exposure to a putative toxin. Tissue evidence of hypothesized causes was sought in high acuity CKDu biopsies.

Methods: Forty-three patients had biopsy-confirmed CKDu (10/2016-9/2017); activity index (AI: tubulitis & interstitial inflammation in nonatrophic cortex) and chronicity index (CI: global glomerulosclerosis, periglomerular fibrosis, tubular atrophy, interstitial fibrosis) (scale 0-3) were scored. Thirteen biopsies met our definition of AI≥ 2 & CI ≤ 4 for active tubulointerstitial nephritis (AIN). A subset of AIN was analyzed for semiquantitative element content by mass spectrometry (MS) (n= 4) and electron microscopy (EM) (n=2). Non-CKDu SL biopsies were controls for histology (n=5) and MS (n=2).

Results: CKDu patients with AIN were 45 yrs old (mean; ±10.8), mostly men (75%), all born in endemic areas and drank well water as a primary source. Only 4 (33%) had dysuria, but 9 (75%) reported acute symptoms (fever, back/joint pain) within 6 mo prior to biopsy. None had hematuria, proteinuria was rare (8%) & mean sCr was 1.9 mg/dL. Rare silver stained dense granules visualized in tubular epithelial cells of both CKDu (67%) and controls (40%) corresponded to atypical lysosomes on EM. MS revealed no cadmium or arsenic; lead was minimal, lower than in control paraffin (Table). A high-throughput shotgun sequencing approach to detect infectious pathogens is underway.

Conclusions: We confirm an active phase in a subset of CKDu patients. Rare tubular atypical lysosomes were noted in both cases and controls. No lead, cadmium, or arsenic deposition was seen in the kidney. Further advanced tissue techniques may help elucidate causes of CKDu.

Content of select elements (of 70 analyzed) in SL Kidney Biopsies

Mean Content (ug/g)	Paraffin (1)	AIN (4)	Controls (2)

FR-PO395

Gut Flora-Dependent Metabolite Trimethylamine-N-Oxide Accelerates Kidney Aging Through p53/p21/Rb Pathway and Age-Related CircRNAs

Fanfan Gao, Hongli Jiang. *Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: Gut microbiota can influence the aging process and may modulate aging-related changes in cognitive function. Trimethylamine-N-oxide (TMAO), gut microbiota-dependent metabolites, has been shown to be associated with kidney diseases and other disease. However, the relationship between TMAO and aging, especially renal aging, has not been fully elucidated.

Methods: We analyzed age-related palsma levels of TMAO and circRNAs in 3-month-old and 24-month-old C57BL/6 mice. Then HK-2 and TCMK-1 cell were incubated with different concentrations of TMAO (0, 1uM, 10uM, 100 uM, 1mM, 10mM, 100mM, 200, 500mM) for 24h, 48h and 72h to measure cell viability using a cell counting kit-8. Western blotting and qRT-PCR was used to detect the changes of related proteins and RNA after exposure to TMAO (100mM) for 48h and 72h.

Results: In the present study, we found that circulating TMAO increased with age in mice. In vitro, we demonstrated that prolonged TMAO treatment induced senescence in HK-2 and TCMK-1 cell, characterized by reduced cell proliferation, increased expression of senescence-associated β-galactosidase (SA-β-gal). Meanwhile, TMAO increased the expression of p53, p21, p16 and decreased phosphorylation of Rb expression. Furthermore, TMAO changed the expression of circRNAs.

Conclusions: In summary, these data suggest that elevated circulating TMAO during the aging process may deteriorate HK-2, TCMK-1cell senescence and renal aging, which is probably associated with the activation of the p53/p21/Rb pathway and the change of circRNAs.

FR-PO396

CircRNA_15698 Exacerbates Folic Acid-Induced Renal Interstitial Fibrosis via the miR-185/TGF-β1 Pathway

Dongdong Wang,[2] Junjun Luan,[1] Hua Zhou.[1] *[1]The Affiliated Shengjing Hospital of China Medical School, Shenyang/China, China; [2]China medical university, Shenyang, China.*

Background: Circular RNAs (circRNAs) are a novel type of noncoding RNAs that modulate the pathogenesis of multiple diseases. A study reports that circRNA_15698 aggravates the renal mesangial extracellular matrix of diabetic nephropathy via miR-185/TGF-β1. However, the role of circRNA_15698 in renal tubulointerstitial fibrosis remains unclear. In this study, we aim to investigate whether circRNA_15698 plays an important role in folic acids (FA)-induced renal interstitial fibrosis and its corresponding mechanism.

Methods: Male CD1mice were peritoneally injected 250 mg/kg of FA or its vehicle. We collected kidney tissue after removing blood by PBS perfusion on day 30 after FA injection and evaluated renal interstitial fibrosis by PAS and Masson staining. We measured mRNA levels of pro-inflammatory cytokines such as interleukin-6 (*Il6*), tumor necrosis factor-α (*Tnfα*), and inflammatory cells including T lymphocytes and macrophages in the kidneys. We also examined the expression of pro-fibrosis factors, alpha smooth muscle actin (a-SMA), Collagen I (COL-1), and Fibronectin. Finally, we examined the renal expression of circRNA_15698, miR-185, transforming growth factor-beta (Tgfb) and analyzed the math seeds between circRNA_15698 and miR-185 as well as between miR-185 and Tgfb on TargetScan and miRanda.

Results: Peritoneal injection of FA induced obvious renal interstitial fibrosis (RIF) seen on PAS and Masson staining on day 30 after the injection. Pro-inflammatory cytokines, both *Il6* and *Tnfα* elevated remarkably in FA-injected mice compared to normal control mice. The infiltration of T lymphocytes and macrophages were seen in the kidneys. Pro-fibrosis factors, a-SMA, COL-1, and Fibronectin were increased in renal FA-injected mice on both mRNA and protein levels of the above factors. In addition, the

renal expression of circRNA_15698 was upregulated, renal miR-185 was downregulated and *Tfgb* was *also* upregulated. Finally we found perfect match seed displayed between circRNA_15698 and miR-185 as well as between miR-185 and *Tgfb* on TargetScan and miRanda analysis.

Conclusions: Our results suggested that circRNA_15698 might play an important role in FA-induced renal interstitial fibrosis by sponging miR-185 and increasing production of profibrotic TGF-β1. This is a novel pathway in pathogenesis of renal fibrosis and circRNA_15698 might be a new therapeutic target for renal fibrosis.

Racial/Ethnic Disparities in Atrial Fibrillation Treatment and Outcomes in US Dialysis Patients

Paul L. Kimmel,[1] Salina P. Waddy,[2] Allen J. Solomon,[3] Adan Z. Becerra,[4] Julia B. Ward,[4] Kevin Chan,[1] Chyng-Wen Fwu,[4] Jenna M. Norton,[1] Paul Eggers,[1] Kevin C. Abbott.[1] *[1]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [2]Atlanta Veterans Administration, Decantur, GA; [3]The George Washington University, Washington, DC; [4]Social & Scientific Systems, Inc., Silver Spring, MD.*

Background: Stroke prevention is a major goal in the management of end-stage renal disease (ESRD) dialysis patients with atrial fibrillation (AF). In the general AF population, racial/ethnic minorities have higher stroke rates, lower rates of anticoagulation and higher anticoagulation complication rates. We desribe differential treatment patterns by race/ethnicity and their association with racial/ethnic disparities in stroke outcomes among dialysis patients with AF.

Methods: We used the United States Renal Data System to identify ESRD patients diagnosed with AF who initiated hemodialysis from 2006-2013 with Medicare Part A, B, and D coverage. Patients were followed for all-cause stroke, mortality, prescription of oral medications for AF, and cardiovascular disease procedures (CVD) for AF. We used a causal inference mediation approach that accounts for time varying mediators and confounders to quantify what proportion of excess strokes can be attributed to lower use of AF therapies by race/ethnicity.

Results: The study included 56,587 ESRD dialysis patients with AF. Black, non-Hispanic White, Hispanic, and Asian patients accounted for 19%, 69%, 8%, and 3% of the population, respectively. In adjusted analyses, Black, Hispanic, and Asian patients were 13%, 18%, and 22% more likely to experience stroke within 1 year and 10%, 17%, and 28% times less likely to fill a prescription for warfarin compared to White patients, respectively. Prescription of warfarin was associated with decreased stroke rates (HR=0.82). Mediation analyses suggested that 7%, 10%, and 12% of excess strokes among Black, Hispanic, and Asian patients could be prevented if the warfarin distributions in these groups were equalized to that in the White population. We did not find racial/ethnic disparities for all-cause mortality or use of CVD procedures. All results achieved $p<0.05$.

Conclusions: Increased racial/ethnic disparities in stroke rates among ESRD dialysis patients with AF are partially explained by lower use of oral anticoagulants among Blacks, Hispanics, and Asians. The reasons for these racial disparities in practice are unknown, but the results support the development of strategies to maximize stroke prevention in minority populations that address patient, physician, and system barriers to optimal treatment.

Dialysis Modality and Cardiac Function at the Time of Kidney Pre-Transplant Patients' Evaluation

Lawrence R. Butros,[1] Omar Malik,[1] Mohanad O. Soliman,[1] Mohamed Elyamny,[1] Maria Yaseen,[1] Eman Elsawalhy,[1] Karolina Viquez,[1] Marc Paranzino,[1] Belal Suleiman,[1] Amro Elrefaei,[1] Elijah Kakani,[1] Roberto Gedaly,[1] Xiaonan Mei,[1] Andrew Kolodziej,[1] Maya Guglin,[1] David Booth,[1] Amr E. Mohamed,[1] Ana L. Castellanos,[1] Thomas H. Waid.[2] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY.*

Background: Hemodialysis (HD), peritoneal dialysis (PD) and pre-emptive kidney transplant are different options at the time of the pre-transplant patients' evaluation; however, it is not clear how each dialysis modality affects cardiac structure and function. This study explores the association of different dialysis modalities and the cardiac function in this patient population.

Methods: This is a single-center, retrospective and descriptive study for patients who had completed pre-transplant cardiac evaluation in the renal transplant program at University of Kentucky between January 2010 and December 2015. We classified patients into 3 groups according to the dialysis modality. Group 1 included pre-emptive patients (n=74), group 2 included PD patients (n=61), and group 3 included HD patients (n=144). We analyzed the echocardiographic parameters for all patients and correlated them with the different dialysis modalities.

Results: There were no differences in demographic parameters between the 3 groups. Pre-emptive patients had a lower rate of diabetes mellitus (p=0.046) and marginally lower coronary artery diseases (p=0.055). There was no significant difference between the three groups regarding the left ventricular ejection fraction or right ventricular systolic function as measured by end diastolic and systolic dimensions, severity of tricuspid and mitral regurgitations and diastolic function as measured by E/e'. Moreover, the pulmonary artery pressures as measured by velocity of tricuspid regurgitation and pulmonary artery acceleration time were not significantly different between groups. Left ventricular mass index was significantly higher in patients on hemodialysis and lower in patients on peritoneal dialysis (p=0.010).

Conclusions: Patients being evaluated for kidney transplantation and not yet on dialysis had lower rates of diabetes and a trend toward lower coronary artery disease compared to patients who are already on dialysis. The left ventricular mass index was the highest in HD patients and the lowest in PD patients.

FR-PO399

Association of CPR Duration with Discharge Outcomes in Maintenance Dialysis Patients

Fahad Saeed,[1] Haris F. Murad.[2] *[1]University of Rochester Medical Center, Pittsford, NY; [2]Yale School of Medicine, New Haven, CT.*

Background: Cardiopulmonary resuscitation (CPR) is associated with high mortality rates in patients receiving maintenance dialysis. There are no large studies to date that relate the duration of CPR to discharge outcomes in these patients.

Methods: Using electronic medical records, we identified all the adult patients (≥18years) who underwent CPR and were admitted to the hospital from January 2006 to December 2014 and then used chart review to select patients who were on maintenance dialysis. The charts documented CPR duration, CPR characteristics, in-hospital mortality, and discharge to home. In multivariate analyses, candidate variables were patient demographics, dialysis duration, number of co-morbidities, in-hospital vs out-of-hospital CPR, and initial heart rhythm.

Results: Of the 402 ESRD patients who had undergone CPR, duration of CPR was documented in 296 patients. Among these, CPR duration was ≤10 minutes in 111 patients and >10 minutes in 185 patients. Of those who had received CPR ≤10 minutes, 46.2% died within the same hospitalization; of patients receiving CPR >10 minutes, 83.2% died within the same hospitalization. Those receiving CPR for >10 minutes had higher odds of in-hospital death (OR 8.91 4.44, 17.89, p=<.0001) and survivors had lower odds of discharge to home (OR 0.08, 0.01,0.63, p=0.017) after adjusting for confounding variables.

Conclusions: Longer CPR duration was independently associated with poor discharge outcomes. These data may help clinicians determine prognostic information to guide discussions with families. Moreover, It may be appropriate to limit the CPR duration in patients deemed to have a poor prognosis.

FR-PO400

Pericardial Effusions in Patients with Renal Disease: A Single-Centre Experience

Amarpreet K. Thind. *West London Renal and Transplant Centre, Hounslow, United Kingdom.*

Background: Pericardial effusions are common in renal patients and frequently thought to be uraemia related. However alternative aetiologies do exist and the best management approach remains unclear.

Methods: All renal inpatients with pericardial effusions at a tertiary renal centre from 2010-2018 were identified, and data was collected on patient factors, investigation results, treatment, interventions, and outcomes. This was used to compare cases undergoing pericardiocentesis versus those that did not, identify causes of pericardial effusion and create diagnostic groups for comparison.

Results: Fourty-six patients with pericardial effusions were identified, aged 18-83, 63% male. Renal modalities included haemodialysis (72%), peritoneal dialysis (9%), CKD (6%), transplant (6%), and AKI requiring renal replacement therapy (RRT) (7%). Twenty-four patients underwent pericardiocentesis. The commonest reason for this was cardiovascular compromise, with 21/24 cases having a large effusion (>2cm) on imaging. The commonest cause of pericardial effusion was uraemia related (15), followed by idiopathic/incidental (10), surgical (7), tuberculosis (Tb) related (6), autoimmune (4), pyogenic (3) and unknown (1). Pericardial fluid microbiology culture was positive in only 3 cases, and no positive Tb cultures were obtained. Of the drained cases 13 had fluid protein levels measured; in all cases the protein level was >35g/L. Fluid LDH was measured in 15 patients; in 11 cases this was >2/3 the upper reference range.

Conclusions: In our cohort uraemic pericardial effusions were the commonest cause, in keeping with previous studies. This uraemic group included patient's pre-RRT initiation, RRT non-compliant patients, and patients switching modality, suggesting that poor dialysis contributed to effusion development. Other aetiologies did exist and so a wide differential must be maintained. Pericardiocentesis was only necessary for therapeutic relief, as drainage did not aid diagnosis, therefore it should be reserved for cases with clinical compromise. Although fluid LDH and protein levels in our cohort suggested mostly exudative effusions, current literature states that these factors do not reliably distinguish between pericardial effusion types nor help in establishing the cause. Our findings have revealed diagnostic groups that will be further analysed to help identify differentiating factors between these effusions.

FR-PO401

Electrocardiogram Findings at the Initiation of Hemodialysis and Types of Future Cardiovascular Events

Satoshi Yamaguchi,[1] Takayuki Hamano,[1] Yohei Doi,[1] Tatsufumi Oka,[1] Yusuke Sakaguchi,[1] Isao Matsui,[1] Akira Suzuki,[2] Yoshitaka Isaka.[1] *[1]Osaka University Graduate School of Medicine, Suita, Japan; [2]Japan Community Health Care Organization Osaka Hospital, Osaka, Japan.*

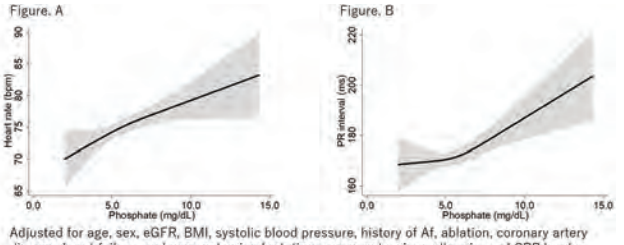
Background: Prognostic value of electrocardiogram (ECG) was reported in pre-dialysis patients. However, it remains to be revealed in hemodialysis (HD) patients. Since

incident HD patients suffer from volume overload and electrolyte abnormalities, ECG at the initiation of HD is thought to be a kind of "stress ECG test".

Methods: We performed a retrospective multicenter cohort study of incident HD patients. We collected the latest data just before the initiation of HD. The primary outcome was atherosclerotic and non-atherosclerotic cardiovascular diseases (CVD) after the initiation of HD. Using Cox proportional hazards models, we examined whether ECG parameters (PR, QRS, QT interval, heart rate, and left ventricular hypertrophy [LVH] by voltage criteria) predict the primary outcome.

Results: Among the enrolled 683 patients, 21 and 16% of the patients showed LVH and PR interval >200 ms (PR prolongation), respectively. Serum phosphate levels were positively associated with heart rate and PR interval (Figure). Over a median follow-up period of 3 years, 19 and 16% of the patients developed atherosclerotic and non-atherosclerotic CVD, respectively. Backward stepwise multivariate Cox regression models including ECG parameters and baseline characteristics of patients revealed that LVH predicted atherosclerotic CVD (hazard ratio [95% CI: Confidence Interval]): 1.96 [1.24-3.11]). In contrast, PR prolongation was a significant risk factor of non-atherosclerotic CVD (hazard ratio [95%CI]: 2.00 [1.17-3.42]).

Conclusions: LVH and PR prolongation were significant risk factors of atherosclerotic and non-atherosclerotic CVD, respectively. Fibroblast growth factor 23 might explain the positive association of serum phosphate levels with heart rate and PR interval.



Adjusted for age, sex, eGFR, BMI, systolic blood pressure, history of Af, ablation, coronary artery disease, heart failure, and pacemaker implantation, serum potassium, albumin, and CRP levels, corrected calcium levels, hemoglobin levels, prescription of β-blocker, and calcium channel blockers, heart rate (only in Figure.B), and hospital.

FR-PO402

Impact of Electrolytes and Acid-Base Changes During Hemodialysis Session on Incidence of Arrhythmia

Emi Anno, Keiichiro Hori, Ainori Hoshimoto, Makiko Harano, Rina Hisada, So Hagiwara, Yusuke Tsukamoto. *Itabashi Chuo Medical Center, Tokyo, Japan*.

Background: Patients on hemodialysis (HD) have a high incidence of sudden cardiac death. Since we often observed increasing incidence of arrhythmia during and just after dialysis session, drastic changes in electrolytes and/or acid-base may prolong QTc interval and cause arrhythmia. To investigate occurrence and frequency of arrhythmias chronologically and to examine the effects of electrolyte and acid base change on QTc interval during dialysis session.

Methods: We recorded ECG by 24-hour Holter and simultaneously measured changes in serum electrolytes and acid-base during a single hemodialysis session in 50 patients (F/M=15/35, 64% were diabetes, 1993 days of mean HD vintage, 70.1 years of mean age). HD parameters were: 3h (n=1), 3.5hr (n=1) or 4hr×3/week, dialyzer; polysulfone, QB=150-200ml/min. Concentration of electrolytes in dialysate were Na^+ 140 mmol/l, K^+ 2.0 mmol/l, Ca^{2+} 3.0 mmol/l, Mg^{2+} 1.0 mmol/l, Cl^- 110 mmol/l, CH_3COO^- 8 mmol/l and HCO_3^- 30 mmol/l.

Results: ECG was recorded from the start of dialysis session. The highest incidence of SVPC and VPC was recorded during 1st 4-hour(during dialysis; 25%) and 2nd 4-hour (right after dialysis; 26%). QTc did not increase in 18 patients and increase in 32 patients during dialysis session. Between these two groups, mean initial QTc was not different but logistic regression revealed that serum HCO_3^- (odds=0.64) and pH (odds=1.05E+009) were strong determinants among others (Ca^{2+}, K^+, Mg^{2+}, Na^+ and QTc). Multiple regression analysis revealed not only initial QTc but also QTc change during single dialysis session was affected by initial level or changes in serum Ca^{2+}(p=0.0001/0.01), K^+ (p=0.0007/0.03) and HCO_3^- (p=0.02)/pH(<0.0001) among others (Mg^{2+} and Na^+) by weighted least squares multiple regression (r=0.83/0.85).

Conclusions: These results suggest that QTc prolongation during dialysis session is caused by not only magnitude of changes in serum Ca^{2+} and K^+ as reported previously but also magnitude of alkalization in our dialysate composition. In order to prevent prolongation of QTc and arrhythmia, changes in acid-base should be minimized specifically.

FR-PO403

Silent Arrhythmias In Hemodialysis Patients Does Not Increase Major Cardiovascular Events over Short-Term Follow-Up

Tarun K. Jeloka, Jaymin P. Somani, Manishkumar S. Mali, Gajanan K. Kale. *Nephrology, Aditya Birla Memorial Hospital, Pune, India*.

Background: This study was conducted to know the incidence and outcome of silent cardiac arrhythmias in hemodialysis patients.

Methods: A total of 25 patients on regular hemodialysis (HD) were enrolled for studying cardiac arrhythmias. At screening phase, all HD patients were subjected to fluid optimization and adjustment in the BP medicines over a period of 2 weeks. Only those patients, who had no history of or evidence of arrhythmias in baseline electrocardiogram were enrolled. Holter monitoring for evidence of arrhythmia was done for 24 hours, including 4 hours of hemodialysis session on two occasions: long interdialytic (LIDP) and short interdialytic period (SIDP). Incidence and types of arrhythmia was noted. Factors associated with arrhythmias and effect of interdialytic period on arrhythmia were studied. All these patients were followed for a period of 12 months to study the impact of cardiac arrhythmias to adverse cardiovascular events.

Results: Out of 25 patients studied, 17 patients (68%) developed arrhythmia. Of all the arrhythmias, sinus bradycardia was the most common type, which occurred in 60% of patients. Incidence of supraventricular tachycardia (SVT) was 24% followed by atrial tachycardia 16%, premature ventricular complex 12%, atrial fibrillation 8%, premature atrial complex 4% and ventricular tachycardia 4%. The baseline demographic parameters of patients with or without arrhythmias were similar. In laboratory parameters, serum creatinine was higher in arrhythmia group (9.2 mg/dl vs 6.9 mg/dl, P=0.003). Mean ultrafiltration was higher in arrhythmia group after long inter-dialytic period (2.86 ± 0.68L vs. 2.12 ± 0.93L, P = 0.036). Incidence of arrhythmia was higher after LIDP as compared to SIDP (64% vs. 52%, p=0.004). A total of 4 patients died over 1 year of follow up - three patients died in non-arrhythmia group while one in the arrhythmia group. One patient in arrhythmia group developed heart failure. None of the patients developed symptomatic cardiovascular event over 12 months of short observational period.

Conclusions: Asymptomatic silent arrhythmia is a common complication seen in patients on maintenance hemodialysis (68%) with bradycardia being the commonest (60%). Impact of arrhythmia on long term cardiovascular outcome needs long term follow up of these patients.

FR-PO404

Cardiac Arrest in Hospitalized Maintenance Hemodialysis Patients

Katherine M. Scovner,[1] João Sérgio Neves,[2] Simon Correa,[1] Samuel Short,[1] Zoé A. Kibbelaar,[1] Finnian R. McCausland.[1] *[1]Renal Division, BWH, Boston, MA; [2]Department of Endocrinology, Diabetes and Metabolism, São João Hospital, Faculty of Medicine, University of Porto, Lisbon, Portugal*.

Background: Sudden cardiac death accounts for half of cardiac-related deaths in maintenance hemodialysis (HD) patients. Data regarding the frequency of shockable rhythms at presentation to or during a hospital stay is limited.

Methods: A retrospective cohort study was performed to evaluate the characteristics, laboratory values and treatment of HD patients with a hospital stay due to or complicated by cardiac arrest between 2015-2018. Arrests following continuous renal replacement therapy were excluded (n=4). Differences in predictors of interest according to the use of defibrillation during cardiac arrest were analyzed by chi^2 tests or t-tests.

Results: Of the 34 subjects included, mean age was 64 years, 83% were male, 29% were black, 53% had heart failure and 44% had atrial fibrillation. 25 arrested during admission, while 9 had out-of-hospital arrests. 71% died during their admission. 29% had ventricular tachycardia (VT) or fibrillation (VF) during their arrest; 70% of these received at least one shock. 50% had asystole/pulseless electrical activity (PEA) without VT or VF. The remaining 21% rhythms were not described; one of these had no documentation regarding whether or not defibrillation was used. The median duration since the preceding HD session was 24 hours (25-75th percentile:12-45) with pre-arrest serum electrolytes as follows: potassium 4.9±0.7mmol/L, bicarbonate 22±4.6mmol/L, phosphorus 4.6±1.9mg/dL and calcium 8.8±0.8mg/dL. Comparisons according to receipt of defibrillation are presented in Table 1.

Conclusions: Asystole/PEA appear to be more frequent than VT/VF in HD patients with a hospital stay due to or complicated by cardiac arrest. Of patients with VT/VF, 30% were not defibrillated. Further studies are needed to better understand the etiology and treatment of cardiac arrest in HD patients during hospitalization.

Characteristic	Defibrillated (n=7)	Not Defibrillated (n=26)	P
Mean Age (years)	58.7 ± 15.6	64.6 ± 16.4	0.40
Male	6 (86%)	21 (81%)	0.76
Black	2 (29%)	8 (31%)	0.91
Median Duration Since Preceding HD session (hours)	24 (21-61)	24 (12-45)	0.63
Heart Failure	4 (57%)	13 (50%)	0.74
Mean Left Ventricular Ejection Fraction	50 ± 19%	54 ± 17%	0.34
Atrial Fibrillation	4 (57%)	10 (39%)	0.37
Mean Serum Potassium (mmol/L)	4.6 ± 0.4	5.0 ± 0.7	0.26
Mean Serum Bicarbonate (mmol/L)	24.0 ± 7.4	22.1 ± 4.1	0.54
Mean Serum Phosphorus (mg/dL)	5.0 ± 2.6	4.7 ± 1.8	0.80
Mean Serum Calcium (mg/dL)	8.5 ± 0.6	8.8 ± 0.8	0.51
Died During Admission	5 (71%)	18 (69%)	0.91
Out of Hospital Arrest	4 (57%)	5 (19%)	0.046

FR-PO405

Effects of Spironolactone (SPL) on Arrhythmias in Hemodialysis Patients: Secondary Results of the SPin-D Trial

David M. Charytan,[1] Jesse Y. Hsu,[4] Jonathan Himmelfarb,[8] Talat Alp Ikizler,[3] Dominic S. Raj,[7] J. R. Landis,[4] Rajnish Mehrotra,[8] Sushrut S. Waikar,[9] Paul L. Kimmel,[6] Alan S. Kliger,[5] Finnian R. McCausland,[9] Laura M. Dember.[2] Hemodialysis Novel Therapies Consortium *[1]New York University School of Medicine, New York, NY; [2]University of Pennsylvania School of Medicine, Philadelphia, PA; [3]Vanderbilt University Medical Center, Nashville, TN; [4]University of Pennsylvania, Philadelphia, PA; [5]Yale New Haven Health System, New Haven, CT; [6]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [7]GWU Medical Faculty Associates, Washington, DC; [8]Kidney Research Institute, Seattle, WA; [9]Harvard Medical School, Boston, MA.*

Background: Aldosterone may contribute to the development of arrhythmias in HD patients. Whether treatment with SPL affects the risk of arrhythmias in this setting is unknown.

Methods: The Spironolactone in Dialysis (SPin-D) trial evaluated the safety of SPL for 36 weeks at 12.5 mg, 25 mg, or 50 mg vs placebo in maintenance HD patients. We analyzed data from a subset of participants with arrhythmia monitoring for 7 days at baseline (N=35), 6-weeks (N=37), and end of study (N=53). Adjusted Poisson models including treatment, time point and randomization stratification factors were used to analyze associations of SPL, SPL dose, and serum potassium (K) with the incidence rates of arrhythmias during follow-up.

Results: Conduction blocks or bradycardia and atrial fibrillation or flutter (AF) were common while ventricular arrhythmia was infrequent (Table). Conduction defects or bradycardia were more frequent with SPL compared with placebo in unadjusted and adjusted models. Reduction in AF risk with SPL vs. placebo was less robust at higher SPL dose: (adjusted rate ratios [RR], 95% CI) SPL 12.5 mg (0.09, 0.01-0.77), 25 mg (0.40, 0.06-2.72) and 50 mg/daily (0.89, 0.21-0.80), and conduction block or bradycardia was more frequent at higher SPL dose: (adjusted RR, 95% CI) SPL 12.5 mg (1.56, 0.93-2.52), 25 mg (1.45, 1.06-1.97) and 50 mg (3.00, 1.73-5.20). The RR per 1 mEq/L increase in serum K was 1.54, 95% CI: 0.89-2.65 for AF and 1.20, 0.78-1.86 for bradycardia/block.

Conclusions: Arrhythmias occur with a high incidence in maintenance HD patients with AF and bradycardias/conduction blocks occurring more frequently than ventricular arrhythmias. SPL may reduce AF but increase conduction blocks and bradycardia. Additional studies are needed to confirm these findings, evaluate the effects of SPL dose, and determine if increased K mediates SPL-associated arrythmias.

Arrhythmia Rate at Baseline and Follow-Up

	Overall Rate at Baseline	Placebo	SPL 12.5 mg	SPL 25 mg	SPL 50 mg	Combined SPL During Follow-Up
Arrhythmia Type						
Atrial Fibrillation or Flutter	5.6	13.2	1.2	5.3	11.7	6.3
Conduction Block or Bradycardia	3.4	15.5	24.4	22.3	46.5	33.6
Ventricular Tachycardia or Fibrillation	0.4	0.8	0.0	0.0	0.7	0.2
Sinus Bradycardia or Asystole	0.7	1.4	1.4	0.0	15.4	6.1
Sinus Tachycardia, Supraventricular Tachycardia, or Wide Complex Tachycardia	14.9	13.7	12.5	10.9	15.3	13.0

Rates are provided as events per 100 patient-days and are show for combined placebo and spironolactone group at baseline and by randomized treatment group during follow-up.

FR-PO406

Arrhythmia in Chronic Hemodialysis as a Function of Pre-Dialysis Electrolytes and Interdialytic Interval

Amy Mosman,[1] Taewoo Lee,[2] John C. Edwards.[1] The SLU Arrhythmia in Hemodialysis Study Investigators *[1]St. Louis University, St. Louis, MO; [2]Saint Louis Univeristy School of Medicine, Saint Louis, MO.*

Background: Sudden cardiac death is a leading cause of death in hemodialysis patients. For patients on thrice weekly dialysis, these deaths are most common before and during dialysis following the three day interdialytic period. Cummulative fluid, electrolyte, and metabolite accumulation during the longer interdialytic period have been correlated with increased arrhythmia, but the specific imbalances that are driving this cardiac instability have not been identified.

Methods: 60 stable patients on chronic thrice weekly hemodialysis with a tendency to hyperkalemia provided informed consent. Cardiac rhythm was continuously monitored for one week starting at the midweek dialysis session (day 1). Pre-dialysis chemistries and 12 lead EKG were determined at the pre and post weekend dialysis session (days 3 and 6). Frequency of ventricular ectopy, superventricular ectopy, bradycardia, and average QTc were reported in 4 hour blocks. Rates of arrhythmias through the week and correlation with individual clinical parameters were analyzed using standard statistical methods.

Results: Total arrhythmia frequency was low and did not correlate with dialysis in the whole population. Neither ventricular ectopy nor bradycardia correlated with dialysis or interdialytic interval. Superventricular ectopy showed peaks during dialysis on both days 3 and 6, but these did not reach statistical significance. None of the arrhythmias correlated with pre-dialysis electrolytes, BNP or ultrafiltration volumes. Pre-dialysis PR intervals, QRS duration, and QTc did not correlate with arrythmias or with electrolytes. QTc, one known risk factor for ventricular arrhythmia, was significantly prolonged during dialysis on both days 3 and 6: ΔQTc pre- to intra-dialysis 18.6 ± 38.9 ms (P=0.0007) and 13.6 ± 53.6 (P=0.031) on days 3 and 6, respectively. Patients with lower pre dialysis serum Ca were more likely to prolong QTc during dialysis.

Conclusions: In this cohort of 60 stable chronic hemodialysis patients, there was significant prolongation of the QTc during each dialysis session which was more prominent in patient with lower pre-dialysis serum Ca. However, prolonged QTc was not correlated with observed arrhythmia and we did not find a significant increase in arrhythmia related to pre-dialysis electrolytes or intradialytic period.

FR-PO407

Natural History of Atrial Fibrillation in Patients with ESKD on Hemodialysis

Melissa S. Makar,[1] Lauren E. Wilson,[2] Laura P. Svetkey,[3] Bradley G. Hammill,[2] Patrick H. Pun,[3] Asheley Skinner.[2] *[1]Division of Nephrology, Department of Medicine, Indiana University School of Medicine, Indianapolis, IN; [2]Department of Population Health Sciences, Duke University School of Medicine, Durham, NC; [3]Division of Nephrology, Department of Medicine, Duke University School of Medicine, Durham, NC.*

Background: Anticoagulation for nonvalvular atrial fibrillation (AF) is controversial in patients with end-stage kidney disease (ESKD) maintained on hemodialysis (HD). Reserving anticoagulation for periods of highest stroke risk and lowest bleeding risk may help maximize the benefits of anticoagulation while minimizing the risks. To identify any such periods, we examined the natural history of untreated AF among those with ESKD maintained on HD.

Methods: We reviewed Medicare claims for HD patients aged >65 years that developed AF from 2011 to 2013 that did not have prescription claims for warfarin or direct oral anticoagulants in the months prior and post the AF diagnosis. Incident AF was defined as no prior claim for atrial fibrillation for at least a year before the index AF claim. Examining the twelve months following the AF diagnosis, we calculated the instantaneous hazard rates of ischemic stroke, major bleeding, and all-cause mortality. Patients were censored at date of death, date of kidney transplantation, or end of follow-up.

Results: We included 14,803 HD patients who had incident AF claims from 2011 to 2013 but no anticoagulation prescription claims. Almost all (99.9%) had a $CHADS_2$-VASC score of 2 or higher with 34% of all patients having a score of 7 or higher. The majority of patients did not have a stroke or major bleed in the year prior to the index AF date (61% and 64%, respectively). We found low rates of ischemic stroke (40 events per 1000 person years); intermediate rates of major bleeding (232 events per 1000 person years); and high rates of all-cause mortality (739 events per 1000 person years). Hazard function plots illustrated that both ischemic stroke and bleeding rates were high immediately after the AF diagnosis but that both rates declined and stabilized around 30 days post-AF diagnosis.

Conclusions: Our results suggest that the risk of major bleeding may be highest immediately after the diagnosis of AF and that major bleeding may occur more frequently in this time period than ischemic stroke. The risks for both ischemic stroke and major bleeding appear to then decline and stabilize over time. Further research is needed to determine if reserving anticoagulation until one month post-AF diagnosis helps maximize the benefits of anticoagulation while minimizing the risks.

FR-PO408

Hypocalcemia-Induced Bradycardia Is More Pronounced in Male Hemodialysis Patients

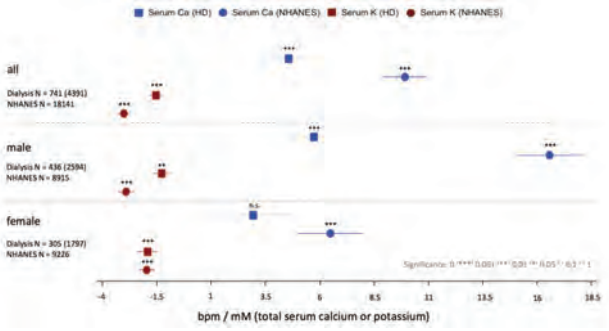
Deborah Nairn,[1] Xiaoling Ye,[2] Doris H. Fuertinger,[2] Peter Kotanko,[2] Axel Loewe,[3] Jochen G. Raimann.[2] *[1]Karlsruhe Institute of Technology, Karlsruhe, Germany; [2]Renal Research Institute, New York, NY; [3]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany.*

Background: The risk of sudden cardiac death (SCD) is increased 14-fold in chronic hemodialysis (HD) patients compared to patients with normal kidney function suffering from cardiovascular diseases. This high rate is not explained by traditional cardiovascular risk factors. Recently, severe bradycardia has been implicated in SCD in HD patients. Mathematical modelling suggests an electrophysiological link between low serum calcium (Ca) levels and bradycardia. Therefore, we analyzed the correlation between heart rate (HR) and Ca as well as potassium (K).

Methods: Data were obtained from 18,141 individuals taken from the NHANES 2011-16 US cross-sectional survey and 741 chronic HD patients. To determine the correlation between HR (dependent variable), Ca and K, respectively, linear mixed effects models for HD patients included dialysis vintage as random effect. For NHANES subjects simple linear regression was employed.

Results: In HD patients, a significant inverse correlation was found between HR and Ca. The effect was statistically significant only in males. The same effect with a similar factor of approximately 2 between the results for males and females was seen in the NHANES subjects. K had a significant inverse correlation with HR in both sexes.

Conclusions: Our results corroborate predictions of physiology-based mathematical models regarding the relation between HR and serum levels of K and Ca, respectively. In addition, we observed that the effect size of the HR-to-Ca relationship was larger in males. This unexpected finding warrants further investigation in other cohorts. If confirmed, the modulatory effects of sex on cardiac electrophysiology need to be explored.



FR-PO409

Association of Functional Outcomes of Sleep and Intermediary Cardiovascular Outcomes in Incident Hemodialysis Patients

Eric S. Kerns,[1] Jessica Fitzpatrick,[2] Stephen M. Sozio,[3] Bernard G. Jaar,[3] Michelle M. Estrella,[4] Jose M. Monroy-Trujillo,[3] Rulan S. Parekh,[5] Ghada Bourjeily.[6] *[1]Lahey Clinic, Burlington, MA; [2]The Hospital for Sick Children, Toronto, ON, Canada; [3]Johns Hopkins University, Baltimore, MD; [4]UCSF/San Francisco VA Medical Center, San Francisco, CA; [5]The Hospital For Sick Children, Toronto, ON, Canada; [6]Miriam Hospital/Brown University, Providence, RI.*

Background: Prior studies show that sleep conditions are associated with an increased risk of cardiovascular (CV) disease and mortality in adults initiating hemodialysis (HD). It is not known whether functional outcomes of sleep (fatigue, concentration difficulty, and memory impairment) are associated with CV morbidity in incident HD patients. We sought to examine whether functional outcomes of poor sleep were associated with intermediary cardiovascular outcomes in incident HD.

Methods: In 228 incident hemodialysis patients from the Predictors of Arrhythmic and Cardiovascular risk in ESRD (PACE) study, Functional Outcomes of Sleep Questionnaire-10 (FOSQ-10), a validated questionnaire that assesses the functional effect of daytime sleepiness through 5 domains (general productivity, activity level, social outcomes, vigilance and intimacy and sexual relationship), was administered within 6 months of enrollment. Baseline comorbidities, including history of CV disease and diabetes, were ascertained by chart review, and baseline cardiac testing, including ECG and echocardiogram, was obtained. Intermediary cardiovascular outcomes included (QTc [ms], heart rate variability [ms^2], left ventricular mass index [g/m^2, LVMI], and left ventricular hypertrophy [LVH]). Associations of log transformed FOSQ-10 scores with intermediary outcomes were examined using linear regression.

Results: Mean age was 55 years, median body mass index was 28 (IQR 24,33), median Charlson comorbidity index was 5 (IQR 4,6), with 68% African American. Lower FOSQ-10 scores, indicating greater impairment from sleep disturbances, were associated with greater QTc duration and lower heart rate variability after adjustment for clinical factors.[Table] There were no significant associations of FOSQ-10 score and LVMI or LVH.

Conclusions: In adults initiating hemodialysis, poor functional outcomes of sleep are associated with increased risk of intermediary CV outcomes. Screening for sleep disturbances in incident hemodialysis patients may identify individuals at increased risk for adverse CV outcomes.

Funding: NIDDK Support

Table. Association of FOSQ-10 score and intermediary CV outcomes

FOSQ-10 score, per 0.1 log increase	QTc (ms)	Heart rate variability (ms^2)	LVMI (g/m^2)	LVH
	β (95% CI)	β (95% CI)	β (95% CI)	PR (95% CI)
Unadjusted	-0.49 (-0.85, -0.13)	16.0 (3.22, 28.9)	0.02 (-0.11, 0.16)	1.00 (0.99, 1.01)
Adjusted	-0.42(-0.79, -0.05)	14.7 (1.44, 27.9)	0.04 (-0.10, 0.19)	1.00 (0.99, 1.01)
Model adjusted for age, sex, and ethnicity, comorbidity index, QT-prolonging medication use, beta blocker use, alpha blocker use, DBP, and serum potassium				

FR-PO410

Functional Outcomes of Sleep Predict All-Cause Mortality in Incident Hemodialysis Patients

Jessica Fitzpatrick,[2] Eric S. Kerns,[1] Stephen M. Sozio,[3] Michelle M. Estrella,[4] Bernard G. Jaar,[3] Rulan S. Parekh,[5] Ghada Bourjeily.[6] *[1]Lahey Clinic, Burlington, MA; [2]The Hospital for Sick Children, Toronto, ON, Canada; [3]Johns Hopkins University, Baltimore, MD; [4]UCSF and San Francisco VA Medical Center, San Francisco, CA; [5]The Hospital For Sick Children, Toronto, ON, Canada; [6]Miriam Hospital/Brown University, Providence, RI.*

Background: Patients with ESRD commonly experience sleep disturbances. Fatigue, difficulty concentrating, and memory impairment are functional outcomes of poor sleep measurable by validated questionnaire. Although sleep disturbances are associated with increased risk of mortality in patients initiating hemodialysis, it is unclear if functional outcomes of sleep impact mortality risk. We sought to examine whether functional outcomes of poor sleep are associated with an increased risk of mortality in patients initiating hemodialysis.

Methods: In 228 participants enrolled in the Predictors of Arrhythmic and Cardiovascular risk in ESRD (PACE) study, the validated Functional Outcomes of Sleep Questionnaire-10 (FOSQ-10), which assesses functional outcomes of daytime sleepiness through 5 domains (productivity, activity level, social outcomes, vigilance and sexual relationship), was administered within 6 months of enrollment. Proportional hazards regression was used to examine the association of FOSQ-10 score with all-cause mortality. Effect modification was tested using multiplicative interaction terms.

Results: Mean age was 55 years, median body mass index was 28 (IQR 24,33), with 68% African American. During 816 person-years of follow-up, there were 95 deaths. Each 0.1 log decrease in FOSQ-10 score was associated with increased risk of mortality (HR 1.09, 95%CI 1.01-1.18), independent of clinical covariates. [Figure] This association was not modified by age, sex, race, or history of diabetes.

Conclusions: In adults initiating dialysis, poor functional outcomes of sleep are associated with increased risk of overall mortality. Future studies should assess the impact of screening for sleep disturbances in ESRD patients to identify individuals at increased risk of death.

FR-PO411

Hypomagnesemia with High FGF-23 Is a Significant Risk Factor for Cardiovascular Disease in Hemodialysis Patients

Manabu Tashiro. *Division of Nephrology, Kawashima Hospital, City of Tokushima, Japan.*

Background: In patients with chronic kidney disease, cardiovascular disease is the major cause of mortality and morbidity. Magnesium has been shown to impact cardiovascular health positively. Most previous cohort studies and their meta-analysis have shown a link between high serum phosphate levels and high FGF23 levels and an increased cardiovascular risk. However, few studies have investigated parameters associated with magnesium levels in hemodialysis (HD) patients. Accordingly, we examined the clinical significance of magnesium (Mg) cross-sectionally, and investigated the relationship between Mg levels and FGF23 levels.

Methods: Eighty-nine HD patients were enrolled. Their mean age was 66.9 ± 11.3 years, and the mean duration of HD treatment was 10.9 ± 8.1 years. Twenty-six patients had diabetes mellitus (DM) and eighteen patients had cardiovascular diseases. We analyzed their medical history, echocardiography, computed tomography, biochemical measurements, cardiovascular morbidity, mortality, etc. We identified prospective studies reporting associations between Mg and FGF23 concentrations and parameters. Statistical significance of the difference between groups was determined by the chi-square test. All statistical analyses in this study were performed with SPSS statistics software 22 for Windows.

Results: The number of cardiovascular disease patients was significantly higher in the group with a serum Mg level of less than 2.5 mg/dl (P = 0.015) but was not correlated to serum Mg level. The serum FGF23 level was related to cardiovascular disease (P = 0.04). There was no relationship between cardiovascular disease and serum P level. Comparing high FGF23 to low FGF23, cardiovascular disease was significantly increased in the low Mg group (P = 0.021) but not in the high Mg group (P = 0.426). The odds ratio for cardiovascular disease in the high FGF23 group compared with the low FGF23 group was 3.38. The association between FGF23 and cardiovascular disease was modified significantly by Mg level.

Conclusions: We suggest that in cardiovascular disease, FGF23 and serum Mg levels are more influenced by the serum P level. High serum FGF23 was associated with cardiovascular disease in hemodialysis patients with low Mg level, but not in those with high Mg level. In particular, the combination of low Mg level and high FGF23 level is a risk factor for cardiovascular disease.

FR-PO412

Fibrate Therapy in Hemodialysis Patients: A Prospective 10-Year Study

Sathit Kurathong, Wanjak Pongsittisak, Thananda Trakarnvanich. *Faculty of Medicine Vajira Hospital, Navamindradhiraj University, Bangkok, Thailand.*

Background: KDIGO guideline suggests that statin should not be initiated in hemodialysis (HD) patients. Fibric acid derivative (fibrate) is another lipid-lowering drug class capable of reducing plasma triglyceride (TG), cholesterol and LDL-cholesterol (LDL-C), but has been rarely used in HD patients due to potential adverse events, namely myositis and transaminitis. Recent study demonstrated that low-dose fenofibrate (100 mg) was safe in HD patients. The efficacy of low-dose fenofibrate (LF) and gemfibrozil (G), two most commonly-used fibrates, has not been compared before in patients with advanced CKD. This research aims to study the lipid-lowering effect and safety profiles of LF and G in HD patients with hyperlipidemia.

Methods: This was a prospective study of all HD patients with hyperlipidemia who were initiated on fixed-dose fibrates at Vajira Hospital between January 2009 and December 2018. The data collected were baseline characteristics, kidney function, body mass index and type of fibrate. All patients were followed for 6 months. Changes in fasting lipid profiles were recorded and compared at 3 and 6 months after initiating treatment. Liver function tests and muscle enzyme were monitored at the beginning and two months after starting drug.

Results: There were overall 94 HD patients recruited to receive fibrate therapy (33 LF and 61 G) without additional lipid lowering drug. At 6 month, LF 100 mg effectively lowered both fasting TG and LDL-C (-34% and -21%; p=0.004 and 0.01 respectively) whereas G 600 mg significantly reduced fasting TG (-29%, p=0.003) but not LDL-C level (-11%; p=0.06). Myalgia and myositis were reported in 5 patients (13.7%) in LF group and 6 patients (11.3%) in G groups. No patient experienced rhabdomyolysis or severe myositis requiring discontinuation of fibrate. Transaminitis occurred in 5 patients from each LF and G group (15.2% and 8.2% respectively). Only 1 patient receiving LF had significant transaminitis (ALT>3 x upper limit of normal) that required fenofibrate discontinuation. Three patients died (2 in F group and 1 in G group) from causes determined not to be fibrate-related.

Conclusions: Both low-dose fenofibrate and gemfibrozil were effective in lowering plasma TG but only fenofibrate could significantly reduce LDL-C in HD patients. Both drugs were well-tolerated and could be useful alternatives to statin in HD patients with hyperlipidemia.

Statin Dose Prior to Dialysis Transition with Post-Transition Hospitalization Frequency

Christina Park,[1] Jui-Ting Hsiung,[1] Melissa Soohoo,[1] Maria V. Marroquin,[1] Hamid Moradi,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: In a prior study, we demonstrated that statin use prior to dialysis start was associated with lower mortality and hospitalization risk. Although current guidelines advocate for initiation of a moderate dose statin in late stage chronic kidney disease (CKD), we sought to examine whether risk of hospitalization, in particular septicemia, in the year after dialysis start differed according to statin dose in the year prior to transition.

Methods: In a cohort of veterans transitioning to dialysis from 2007-2015, we identified 32,439 patients on low-, moderate- and high-dose statin therapy for at least 181 days in the year prior to dialysis start. Poisson models with adjustment for demographics, comorbidities and use of other lipid altering medications were used to examine associations between statin dose of hospitalization incidence.

Results: Cohort mean±SD age was 72±10 years old, 4% were female, 21% African American, 6% Hispanic, 80% diabetic and 39% had a prior myocardial infarction. High-dose patients were more likely to be younger, African American and diabetic but less likely to have liver disease or cancer. In unadjusted and adjusted analyses, statin dose had a linear association with hospitalization rates. Compared with moderate statin dose (reference), low- and high-dose statin therapy were associated with higher and lower hospitalization rates, respectively [IRRs (95% CIs) 1.03 (1.01, 1.06) and 0.95 (0.93, 0.97), respectively]. Associations were similar for septicemia hospitalizations.

Conclusions: Risk of hospitalization, particularly septicemia, in the year after transition to dialysis was lower with higher statin dose therapy. Statins are known to have anti-inflammatory benefits and further studies are needed to investigate whether the use of higher dose statins confers benefits that outweigh risk of adverse events in patients transitioning to dialysis.

FR-PO414

A Scoring System for Predicting Individual Effects of Statin Treatment in Type 2 Diabetes Mellitus Patients on Hemodialysis

Christoph Wanner,[2] Bernd Genser,[1] Winfried März.[3] *[1]University of Heidelberg, Heidelberg, Germany; [2]University Hospital, Wuerzburg, Germany; [3]Synlab Holding Deutschland GmbH, Mannheim, Germany.*

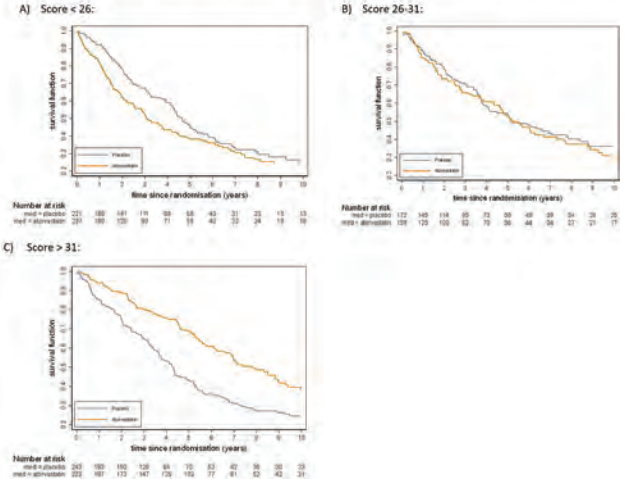
Background: Randomized clinical trials did not show a benefit of statins in hemodialysis (HD) patients. However, post-hoc analyses of the German Diabetes Dialyse (4D) study indicated that there are subgroups defined by theragnostic markers showing heterogenous treatment effects. We combined the information of multiple markers to a score predicting individual treatment effects.

Methods: We used data from the 4D study, a randomized trial including 1,255 HD patients with type 2 diabetes, randomized to atorvastatin or placebo. We calculated two scores, score 1 (23 predictive markers) and score 2 (17 clinically available markers) and classified patients in groups based on score cut-points indicating changes in effect. In each group we calculated effect estimates with respect to a composite cardiovascular endpoint and all cause death using both trial follow-up (FU) (median: 4 yrs) and long-term FU data (median: 11.5 yrs).

Results: The groups based on score 1 showed completely differential treatment effects: G1) (score < 26, 458 (36%) pts) showed harm: HR=1.54 (95%CI: 1.16-2.03) [Fig. 1a]; G2) (score 26-31, 331 pts (26%)) showed no effect: HR=1.03 (95%CI: 0.72-1.48) [Fig. 1b] and G3) (score>31, 466 pts (38%) showed benefit: HR=0.43 (95% CI: 0.30-0.60) [Fig. 1c]. In G3 statins also reduced all-cause mortality: HR=0.63 (95% CI: 0.48-0.83). Results for score 2 were similar with a smaller group G3 (N=360 pts). For long-term FU the effects were less heterogenous among groups.

Conclusions: The effect of statins in patients on HD is heterogenous and can be predicted by markers that relate to plausible effect modifying mechanisms including cholesterol metabolism, atherosclerosis, protein energy wasting or competing risks. The score will be useful in clinical practice not only to select patients that benefit from statins but also to identify those where treatment is harmful.

Fig. 1) Survival curves with respect to cardiovascular endpoint in patient groups identified by prediction score, N=1,255 HD patients with type 2 diabetes (adjusted for age, sex and coronary heart disease).



FR-PO415

The Target Cholesterol Level for Favorable Prognosis in Hemodialysis Patients: 10-Year Outcomes of the Q-Cohort Study

Toshiaki Nakano,[1] Hiroto Hiyamuta,[1] Ryusuke Yotsueda,[3] Shigeru Tanaka,[1] Masatomo Taniguchi,[4] Kazuhiko Tsuruya,[2] Takanari Kitazono.[5] *[1]Kyushu University, Fukuoka, Japan; [2]Nara Medical University, Kashihara, Japan; [3]Kyushu University, Graduate School of Medical Sciences, Fukuoka City, Japan; [4]Fukuoka Renal Clinic, Fukuoka, Japan; [5]Department of Medicine and Clinical Science, Fukuoka, Japan.*

Background: The prevalence of atherosclerotic diseases is higher in hemodialysis patients. The aim of the current study was to determine the target cholesterol level for the best prognosis in patients undergoing long-term hemodialysis.

Methods: A total of 3,517 participants undergoing maintenance hemodialysis were followed up for 10 years. The outcomes were the incidences of cardiovascular disease (CVD) and mortality. Total cholesterol (TC) in mg/dL was divided into the following quartiles derived from baseline data: Q1 < 131, Q2 ≥ 131 and < 152, Q3 ≥ 152 and < 178, and Q4 ≥ 178. To determine the cholesterol level of the best prognosis, we used a multivariable-adjusted restricted cubic spline model.

Results: During the follow-up period 1,033 patients had CVD, and 1,742 patients died. Compared with Q1, the respective multivariable-adjusted hazard ratios and associated 95% confidence intervals for ischemic heart disease (IHD), peripheral artery disease (PAD), and CVD in Q4 were 1.40 (1.05–1.85), 1.35 (0.93–1.98), and 1.28 (1.07–1.54). The incidences of IHD, PAD, and CVD were significantly positively associated with higher cholesterol levels after adjustment for confounding factors (p for trend < 0.05). Compared with Q4, the respective multivariable-adjusted hazard ratios and associated 95% confidence intervals for CVD mortality, infection-associated mortality, cancer-associated mortality, and all-cause mortality in Q1 were 1.13 (0.89–1.43), 1.09 (0.82–1.45), 1.69 (1.14–2.51), and 1.24 (1.07–1.43). The TC level at which all-cause mortality risk was lowest was 179 mg/dL.

Conclusions: Higher TC predicts IHD, PAD, and CVD events, and lower TC predicts cancer-associated mortality and all-cause mortality in patients undergoing hemodialysis. We determined the favorable value of serum cholesterol level was 179 mg/dL.

FR-PO416

Circulating Levels of CD34⁺ Cells Predict Long-Term Cardiovascular Outcomes in Patients on Maintenance Hemodialysis

Ahmad B. Kaihan,[1,2] Manabu Hishida,[1] Takahiro Imaizumi,[1] Takayuki Katsuno,[5] Tomoki Kosugi,[3] Naotake Tsuboi,[4] Yoshinari Yasuda,[3] Shoichi Maruyama.[3] Clinical research of Nagoya University Graduate School of Medicine *[1]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Nephrology, Faculty of Medicine Balkh University, Mazar-i-Sharif, Afghanistan; [3]Nagoya University Graduate School of Medicine, Nagoya, Japan; [4]Fujita Health University School of Medicine, Toyoake, Japan; [5]Aichi Medical University, Nagakute, Japan.*

Background: CD34⁺ cells maintain vascular homeostasis and predict cardiovascular outcomes. We previously evaluated the association of CD34⁺ cells with cardiovascular disease (CVD) events over 23 months, but long-term CVD outcomes in relation to levels of CD34⁺ cells in patients on maintenance hemodialysis are unclear. Herein, we analyzed the long-term predictive potential levels of CD34⁺ cells for CVD outcomes and all-cause mortality.

Methods: Between March 2005 and May 2005, we enrolled 215 patients on maintenance hemodialysis at Nagoya Kyoritsu Hospital and followed them up to 12.8 years. According to the CD34⁺ cell counts, patients were classified into the lowest, medium, and highest tertiles. Levels of CD34⁺ cells were analyzed in association with four-point major adverse CV events (MACEs), CVD death, and all-cause mortality.

Results: The mean CD34⁺ cell count was 0.09 (range, 0.01 to 0.35 for all study patients). Patients in the lowest tertile were more likely to be older, have higher prevalence of cardiovascular disease, and to smoke than patients in the medium and highest tertiles. Age, smoking habit, lower geriatric nutrition risk index, lower calcium × phosphate product, and lower intact parathyroid hormone were significantly associated with the lowest tertile. Among 139 (64.7%) patients who died during a mean follow-up period of 8.0 years, 39 (28.1%) patients died from CVD. Patients in the lowest tertile had a significantly lower survival rate than those in the medium and highest tertiles (p ≤ 0.001). Using multivariable analyses, the lowest tertile was significantly associated with four-point MACEs (hazard ratio 1.80, p = 0.023) and CVD death (hazard ratio 2.50, p = 0.011).

Conclusions: our long-term observational study revealed that a low level of CD34⁺ cells in the circulation predicts CVD outcomes among patients on maintenance hemodialysis.

Oral Mucosal Lesions and Association with Mortality in Hemodialysis Patients: A Prospective Cohort Analysis (ORAL-D Substudy)

Marinella Ruospo,[1] Suetonia Palmer,[2] Giusi Graziano,[1] Patrizia Natale,[1,3] Valeria M. Saglimbene,[1,4] Jonathan C. Craig,[5] David W. Johnson,[6] Marcello Tonelli,[7] Eduardo J. Celia,[1] Jan J. Dulawa,[8] Anna Bednarek,[1] Marietta Török,[1] Paul Stroumza,[1] Domingo Del castillo caba,[9] Amparo Bernat,[1] Jorgen B. Hegbrant,[1] Charlotta Wollheim,[1] Letizia Gargano,[1] Giovanni F. Strippoli.[1,3] *[1]Diaverum, Lund, Sweden; [2]University of Otago, Christchurch, New Zealand; [3]University of Bari, Bari, Italy; [4]University of Sydney, Sydney, NSW, Australia; [5]Flinders University, Adelaide, NSW, Australia; [6]Princess Alexandra Hospital, Brisbane, QLD, Australia; [7]University of Calgary, Calgary, AB, Canada; [8]SUM Katowice, Katowice, Poland; [9]Health Service, Spain, Spain.*

Background: Impaired oral health is prevalent and frequently severe for adults treated with long term hemodialysis. We aimed to evaluate the prevalence of oral mucosal lesions and association with mortality outcomes among hemodialysis patients.

Methods: We did a planned analysis of ORAL-D. ORAL-D is a prospective multinational cohort study evaluating a standardized oral and dental examination among 4726 hemodialysis. Oral mucosal lesions included ulceration, red lesion, white lesion, geographical tongue, fissured tongue, candidiasis and herpes using WHO recommended methods. The association between mucosal lesions and all-cause and cardiovascular mortality was estimated using a Cox proportional hazard regression model adjusted for age, sex, education, smoking history, prior myocardial infarction, diabetes, hemoglobin, serum albumin, serum phosphorus, time on dialysis and body mass index. Analyses were clustered by country. The outcomes were prevalence and all-cause and cardiovascular mortality.

Results: 4205 adults (mean age 61.6 ± 15.6 years) had a complete oral examination. 40% had at least one oral lesion. The point prevalence of oral lesions was (in ascending order of frequency): oral herpes 0.5%, mucosal ulceration 1.7%, neoformation 2.0%, white lesion 3.5%, red lesion 4.0%, oral candidiasis 4.6%, geographical tongue 4.9%, petechial lesions 7.9%, and fissured tongue 10.7%. During median follow-up of 3.5 years, 2114 patients died (1013 from cardiovascular causes). Oral candidiasis was associated with all-cause mortality (adjusted hazard ratio (aHR) 1.37, 95% CI 1.00 to 1.86) and cardiovascular mortality (aHR 1.64, 95% CI 1.09 to 2.46). There was no association observed for any other oral mucosal lesion with mortality.

Conclusions: Oral mucosal lesions are prevalent in hemodialysis patients. Oral candidiasis appears to be a risk factor for death.

Oral Symptoms and Salivary Function and Association with Mortality in Hemodialysis Patients: A Prospective Cohort Analysis (ORAL-D Substudy)

Marinella Ruospo,[1] Suetonia Palmer,[2] Giusi Graziano,[1] Patrizia Natale,[1,3] Valeria M. Saglimbene,[1,4] Jonathan C. Craig,[5] David W. Johnson,[6] Marcello Tonelli,[7] Jan J. Dulawa,[8] Anna Bednarek,[1] Marietta Török,[1] Paul Stroumza,[1] Domingo Del castillo caba,[9] Amparo Bernat,[1] Jorgen B. Hegbrant,[1] Charlotta Wollheim,[1] Letizia Gargano,[1] Giovanni F. Strippoli.[1,3] *[1]Diaverum, Lund, Sweden; [2]University of Otago, Christchurch, New Zealand; [3]University of Bari, Bari, Italy; [4]University of Sydney, Sydney, NSW, Australia; [5]Flinders University, Adelaide, NSW, Australia; [6]Princess Alexandra Hospital, Brisbane, QLD, Australia; [7]University of Calgary, Calgary, AB, Canada; [8]SUM Katowice, Katowice, Poland; [9]Health Service, Spain, Spain.*

Background: Oral symptoms and impaired salivary function are frequently reported by adults treated with long term hemodialysis. We evaluated the association of oral symptoms and salivary function and with all-cause and cardiovascular mortality.

Methods: We did a planned sub-analysis in the ORAL-D study, a multinational cohort study involving a standardized oral and dental examination among 4726 hemodialysis patients. We assessed oral mucosal self-reported symptoms (thirst and xerostomia) and salivary characteristics (pH, buffer capacity, flow rate pre/post dialysis). The association with all-cause and cardiovascular mortality was estimated using a Cox proportional hazard regression model adjusted for country, age, sex, education, smoking history, prior myocardial infarction, diabetes, and time on dialysis.

Results: In 4205 adults (mean age 61.6±15.6 years), the mean salivary pH was 7.45 (SD 1.35), with more than 60% of patients (n=1621) with high salivary buffering capacity. The mean pre-dialysis salivary flow rate was 0.83 (SD 0.74) ml/min, and slightly decreased at the end of dialysis (0.76 ± 0.80 ml/min). During median follow-up of 3.5 years, salivary flow rate was associated with lower all-cause (adjusted hazard ratio (aHR) 0.85, 95% CI 0.76 to 0.95 for pre-dialysis flow rate and aHR 0.84, 95% CI 0.75 to 0.94 for post-dialysis flow rate) and cardiovascular mortality (HR 0.74, 95% CI 0.62 to 0.90 for pre-dialysis flow rate and HR 0.74, 95% CI 0.61 to 0.90 for post-dialysis flow rate). When considering the risk of mortality associated with Xerostomia Inventory items, requiring to sip a drink to swallow better was associated with all-cause and cardiovascular mortality (HR 1.26, 95% CI 1.07 to 1.48 and 1.30, 95% CI 1.02 to 1.66, respectively). Similarly, Thirst Inventory items were associated with all-cause mortality.

Conclusions: Oral symptoms are prevalent in haemodialysis patients. Salivary characteristics and related symptoms are associated with mortality.

FR-PO419

Development and Application of Sequential Enrichment Approach for ApoL1 Purification

Joshua Carty,[1] Jon B. Klein,[2,3] Michael Merchant.[1] *[1]University of Louisville School of Medicine, Louisville, KY; [2]University of Louisville Kidney Disease Program, Louisville, KY; [3]Robley Rex VAMC, Louisville, KY.*

Background: Apolipoprotein L1 (ApoL1) is associated with either HDL3 or the Trypanolytic Factor (TLF) complex. The TLF complex also includes Haptoglobin-Related Protein (HRP) and Apolipoprotein A1 (ApoA1). Both human and transgenic mouse data suggest genotype is insufficient to cause renal disease. We hypothesized that circulating ApoL1 variants undergo PTM that promote renal disease progression or severity. To test address this hypothesis, a method for the selective enrichment of ApoL1 containing lipoprotein particles would be essential for ApoL1 characterization by mass spectrometry. Our objective here was to develop a affinity enrichment method that enabled selective TLF purification from patient plasma and serum samples.

Methods: Serum lipoproteins were isolated from healthy controls (HC) and from diabetic-/non-diabetic-African American (AA) dialysis patients using differential dextran-sulfate precipitation. TLF enrichment methods were based on known high affinity interaction of hemoglobin (Hb) with Hb-savaging receptors haptoglobin (Hp) and haptoglobin-related protein (Hpr). Ligands tested for TLF enrichment included Hb-agarose, hemin- (Hm-) agarose, and control agarose resins. Analysis of the enriched TLF was based on ApoL1, ApoA1, and Hpr immunoblot (IB) analysis or proteomic analyses.

Results: ApoA1, Hpr, and ApoL1 IB and proteomic studies demonstrate both Hb-agarose and Hm-agarose enrich ApoL1, ApoA1 and Hpr from serum HDL. IB data suggest enhanced enrichment of ApoL1, ApoA1 and Hpr using Hm-agarose beads compared to Hb-agarose beads. IB analysis of control, diabetic, and non-diabetic AA serum samples suggests specific enrichment of Hpr protein in AA TLF samples. Proteomic studies identified (1) a significant decrease of ApoL1 in Hm-bead TLF isolates of 2-fold for diabetic and 6-fold for non-diabetic AA dialysis patients as compared to healthy controls and (2) decreased phosphorylation of ApoL1 Ser-327 and Ser-S330 in dialysis patients samples.

Conclusions: An affinity-isolation method based on Hm-agarose was developed to enrich Hpr-containing lipoproteins from dilute solutions. This method may be parallelized into 96-well plates to enables higher throughput processing of patient samples. TLF ApoL1 abundance is decreased in non-diabetic AA ESRD patients versus diabetic AA ESRD patients versus healthy controls.

Asymptomatic Cerebral Microbleeds in Hemodialysis Patients with a History of Stroke

Toshihide Naganuma, Yoshiaki Takemoto, Junji Uchida, Tatsuya Nakatani. *Department of Urology, Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: T2*-weighted magnetic resonance imaging (MRI) is an extremely sensitive technique for detecting hemorrhagic lesions. It is especially superior for detection of previously asymptomatic cerebral microbleeds (CMBs), compared to other MRI methods. T2*-weighted MRI has increased the detection rate of CMBs, and as a consequence, the prevalence of CMBs has attracted attention in various patient populations. Clinically, CMBs are a risk factor for stroke, and especially intracerebral hemorrhage, and are also often detected after stroke, including in cases of intracerebral hemorrhage and ischemic cerebrovascular disease. They are also highly prevalent in hemodialysis (HD) patients. In this study, we examined CMBs in HD patients with a history of stroke.

Methods: A cross-sectional study of the prevalence of CMBs and related factors was performed in 309 HD patients (45 with and 264 without a history of stroke) who underwent T2*-weighted MRI at Osaka City University Hospital and affiliated hospitals from 2005 to 2017. The study protocol was conducted in accordance with the Principles of the Declaration of Helsinki and was approved by the ethics committee of Osaka City University Graduate School of Medicine (No. 1415). Informed consent was obtained from all subjects prior to their participation in the study.

Results: CMBs were detected in 103 patients (33.3%). The prevalence of CMBs was significantly higher in patients with a history of stroke compared to those without this history (57.8% vs. 29.2%, p<0.001). In multivariate analysis adjusted for background characteristics, a history of stroke was a significant independent factor related to CMBs (OR: 3.7, 95%CI: 1.7-8.8), as were age and hypertension. A history of intracerebral hemorrhage was more strongly associated with CMBs compared to cerebral infarction (OR: 29.3, 95%CI: 3.4-253.0 vs. OR: 2.1, 95%CI: 0.9-5.3).

Conclusions: Our results show a high prevalence of CMBs in HD patients with a history of stroke, and indicate that a history of stroke is significantly associated with CMBs in HD patients. In particular, a history of intracerebral hemorrhage has a strong association with CMBs.

FR-PO421

Outcome of Hemorrhagic Stroke in Patients on Hemodialysis

Alok Kumar. *Medicine, SGRR Institute of Medical and Health Sciences, Dehradun, India.*

Background: Patients on maintenance hemodialysis (MHD) on greater risk of hemorrhagic stroke or ischemic stroke. There is paucity of literature on outcome of hemorrhagic stroke (HS) in patients on MHD. Hypertension (HTN) and use of heparin during dialysis could be risk factors. We performed this study to identify risk factors associated with hemorrhagic stroke in patients on maintenance hemodialysis and outcome of such patients.

Methods: This study is a retrospective analysis of patients admitted with acute hemorrhagic stroke on MHD at our center. Study population comprised of 28 patients of hemorrhagic stroke with intracerebral hemorrhage. Study duration was from January 2008 to December 2018. All patients were on MHD for > 3 months. Hemorrhagic stroke was diagnosed with clinical examination and CT scan. Their demographic data, relevant investigations and clinical parameters were recorded. Student t test was used to compare data between survivors and non survivors.

Results: We had 28 patients (15 males and 13 females). Mean age of patients was 51.4± 16 .5 years. Comorbidities were Hypertension (100%), diabetes (12 of 28),CAD (9 of 28), hyperlipidemia (8of 28) and history of cerebrovascular accidents (5 of 28). Duration of HD was 27± 9.2 months. All patients had severe hypertension at presentation (BP > 200/110). Mean GCS at presentation was 9.8± 4.1. Site of intracerebral hemorrhage (ICH) was putamen (11 of 28), Thalamus (7 of 28), brain stem (4 of 28), massive (3 of 28) and others (3 of 28). Mortality was 68%(19 of 28). Mean time to death was 9.2± 5.2 days. Neurological deterioration was cause of mortality. GCS at presentation and serum albumin were factors influencing survival. GCS was 13.8± 3.7 in survivors and 4.7± 1.9 in non survivors. S. albumin was 3.8 ± .4 gm% in survivors and 2.7±.5 gm% in non survivors.

Conclusions: Patients of hemorrhagic stroke on hemodialysis had dismal outcome with mortality of 68% and survivors had better GCS and s. albumin at presentation.

FR-PO422

Intradialytic Hypoxemia In ESRD Patients on Hemodialysis

Ryan A. Kunjal, Tingting Li, Vicki M. Haldaman, Brenda Bingel, Frank J. O Brien. *Washington University in St. Louis, St. Louis, MO.*

Background: Mortality rates amongst end- stage renal disease (ESRD) patients on hemodialysis (HD) are high and death is most often due to cardiovascular disease. Based on previously published retrospective data, low oxygen levels during HD have been associated with all-cause hospitalization and mortality. We aimed to explore this association in our two university managed HD units.

Methods: We looked at HD patients with central venous catheters (CVC) and those with arterio-venous access (AVA). We measured oxygen levels using crit-line monitors (CLM) for 3-4 routine dialysis sessions. For those with CVC, we considered those with mean ScvO2 <63% to have intradialytic hypoxemia. Amongst patients with AVA, we identified those with prolonged intradialytic hypoxemia (PIH) as having SaO2 <90% for > 1/3 of the session. We then examined the differences in clinical characteristics between

these high-risk groups with hypoxemia and their control cohorts without desaturation. These characteristics include demographic, session- related, laboratory and CLM parameters.

Results: We enrolled 222 patients, of which 35 had CVC and 187 had AVA. Amongst those with CVC, 22 (62.8%) experienced mean ScvO2 <63% and they had an average 1.4 g/dl higher hemoglobin (95% confidence interval [CI], 0.3 to 2.5, P=0.014). However, they did not have any other significant differences from those with higher mean ScvO2. Amongst those with AVA, 5 (2.7%) experienced PIH and they tolerated 11.2% smaller change in blood volume per hour, (95% CI, 1.1 to 21.3, P= 0.030). No other statistically significant differences were observed. We did however note that amongst patients with either access type, those with intradialytic hypoxemia tended to have higher hospitalization rates in the preceding 6 months and had more C- curve profiles on CLM.

Conclusions: We did identify patients who experienced low oxygen levels during HD. However, the proportion of our AVA cohort with PIH was almost one quarter of that previously reported by Meyring-Wosten, 2016. Desaturation rates among those with CVC were similar to previously published studies. We intend to further determine if the use of supplemental oxygen during dialysis can correct the intradialytic hypoxemia. If this can be successfully accomplished, it may be worthwhile to conduct larger prospective studies to evaluate the impact of this intervention on patient outcomes.

FR-PO423

Feasibility of an Electronic Neurocognitive Battery for Assessing Cognitive Function in New-Start Hemodialysis Patients: A Pilot Study

Melissa Schorr,[1,2] Mariah C. Zalitach,[4] Conor J. Wild,[5] Cindy E. House,[3] Christopher W. McIntyre.[3] *[1]London Health Science Center, London, ON, Canada; [2]Kidney care research unit, London, ON, Canada; [3]London Health Sciences Centre, London, ON, Canada; [4]London Health Sciences Centre & Lawson Research, London, ON, Canada; [5]Western University, London, ON, Canada*.

Background: Hemodialysis (HD) is the dominant form of renal replacement therapy used in Canada and around the world. It provides effective management of uremia, however, it is associated with significant morbidity and mortality. Cognitive abnormalities are almost universal in HD patients and appear early after treatment. Impaired cognition leads to functional decline and reduced quality of life. Despite the prevalence of cognitive impairment in HD patients, it is not well characterized or a major focus of care. The purpose of this study is to confirm feasibility of utilizing the well-validated, culturally-independent Cambridge Brain Sciences (CBS) battery in this population. Additionally, we aim to assess need for assisstance in completing these tests, refine the process and provide initial data on the performance of CBS assessment in this population to allow planning of a large-scale study.

Methods: We included patients from eight HD centres across the London Health Sciences Centre program. Adult patients (age > 18 years), with no pre-existing dementia or communication impairment, receiving HD treatment for more than 30 days and less than 12 months were included. Cognitive function was assessed using the CBS cognitive test series. This consists of 12 tests that assess a broad range of cognitive abilities. Individual patients cognitive scores were compared against age and sex matched normal values.

Results: Thirty patients completed a full set of testing and were included in our analysis. Across all measured domains, patients on HD scored significantly lower scores than their age and gender matched controls.

Conclusions: In hemodialysis patients, the CBS is a feasible tool that can be used in large-scale studies to identify domain-specific cognitive impairment. Preliminary results from this pilot study suggest significant cognitive impairment within the first year of hemodialysis.

Evaluation of Screening Tests for Severe Cognitive Impairment in Maintenance Hemodialysis Patients

David A. Drew,[1] Hocine Tighiouart,[1] Jasmine S. Rollins,[1] Sarah Duncan,[2] Seda Babroudi,[1] Daniel E. Weiner,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]Icahn School of Medicine at Mount Sinai, New York, NY*.

Background: Detailed neurocognitive testing shows that cognitive impairment is common among patients requiring maintenance hemodialysis. Identification of a well performing and easy to administer test for cognitive impairment could facilitate broader screening in dialysis units.

Methods: In 150 hemodialysis patients, we performed a comprehensive battery of neurocognitive tests (considered the "gold standard" for this study). Participants were classified as having normal cognitive function versus mild, moderate, or severe cognitive impairment by comparing scores in multiple cognitive domains to normative data. We examined the predictive screening ability of the Mini-Mental State Examination (MMSE), the Modified Mini-Mental State Examination (3MS), the Montreal Cognitive Assessment (MoCA), Mini-Cog, Clock Drawing test, Trails Making B (Trails B), and Digit Symbol Substitution tests to identify participants with severe cognitive impairment using area under the curve analysis.

Results: Mean age was 64 years; 61% were men, 39% were black and 94% had at least a high school education. Of the 150 participants, 21% had normal cognitive function, 17% mild cognitive impairment, 33% moderate impairment, and 29% severe impairment. The MoCA had the best predictive ability for severe cognitive impairment (AUC = 0.81 [0.73, 0.89]). A score on the MoCA of less than 21, which maximized the sum of sensitivity and specificity, displayed a sensitivity of 86% and specificity of 55% for severe impairment. The Trails B and Digit Symbol tests also performed reasonably well with AUC of 0.73 [0.59, 0.87] and 0.78 [0.68, 0.88], respectively. The MMSE, 3MS, Mini-Cog, and Clock Drawing tests had the lowest predictive performance.

Conclusions: Nearly one third of participants had severe cognitive impairment. The MoCA, a widely available, brief assessment that requires relatively simple training to administer, showed high sensitivity and moderate specificity in detecting severe cognitive impairment in prevalent hemodialysis patients.

Cognitive Impairment and Mortality in Maintenance Hemodialysis (HD) Patients: A Longitudinal Study

Sayaka Miyazaki,[2] Satoshi Funakoshi,[1] Mashumi Ide,[2] Jyunichiro Hashiguchi,[2] Kenji Sawase,[2] Tayo Kawazu,[3] Takuya Kubara,[3] Tomoya Nishino,[4] Takashi Harada,[3] Masatoshi Hayashida.[1] *[1]Nagasaki Renal Center, Nagasaki, Japan; [2]Nagasaki Kidney Center, Nagasaki, Japan; [3]Nagasaki Kidney Center, Nagasaki, Japan; [4]Nagasaki University School of Medicine, Nagasaki, Japan*.

Background: We examined the transition of the Mini-Mental State Examination (MMSE) results and the mortality rate of maintenance HD patients in our hospital over a 130-week period, in order to compare the cognitive functions and mortality.

Methods: Using the longitudinal cohort of 181 HD patients aged ≥65, we examined the MMSE in March 2016, and a follow-up MMSE was conducted on 112 surviving patients in September 2018. We also tracked the serological data during this period. MMSE score of 28 to 30 was classified as the normal group, 24 to 27 as mild cognitive impairment (MCI) group, and less than 23 as dementia group.

Results: In 2016, 76 patients were within the normal group(41.9%, mean age 72.1), 48 were within the MCI group(26.5%, mean age 77.9), and 57 were within the dementia group(31.5%, mean age 80.2). As shown in figure 1 below, compared to the normal group, mortality rate decreased significantly as the severity of dementia further deteriorated. There was no significant difference in the nutritional status index such as albumin or Cholinesterase among these groups. The pneumonia-associated death in patients with dementia was twice as high as among those without dementia or MCI (64% vs 36%, 39%; $p < 0.05$).

Conclusions: This longitudinal study indicated that the presence of dementia is an independent predictor of mortality in patients on HD.

Hemodialysis Can Contribute to Acute Changes in Cerebral Volume and White Matter Structure

Madeleine T. Dacey,[1,2] Janice Gomes,[1,3] Stefan E. Poirier,[1,2] Udunna C. Anazodo,[1,2] Christopher W. McIntyre.[1,3] *[1]Lawson Health Research Institute, London, ON, Canada; [2]Medical Biophysics, Western University, London, ON, Canada; [3]Lilibeth Caberto Kidney Clinical Research Unit, London, ON, Canada.*

Background: Cerebral atrophy, silent cerebral infarcts, and leukoaraiosis are common brain injuries in chronic kidney disease (CKD) patients undergoing hemodialysis (HD), but their etiology is poorly understood. To elucidate the acute effects of HD on the brain, we used a novel system designed in-house to perform magnetic resonance (MR) imaging during HD. Diffusion tensor imaging (DTI) is an MR modality used to characterize white matter (WM) structure. Mean diffusivity (MD) is a DTI metric associated with cellularity and edema in WM. We predict that HD will induce a transient increase in MD and cerebral volume volume, potentially due to osmotic stress and edema.

Methods: 12 CKD patients receiving hemodialysis ≥3 times/week underwent diffusion and T1 weighted MR scans (Siemens 3T Biograph mMR) prior to and in the last 60 minutes of HD. The MR data were processed to correct for noise, motion, and artifacts prior to tensor fitting. Spatially normalized scalar maps were compared pairwise using tract-based spatial statistics (TBSS) and a general linear model with threshold-free contrast enhancement. Cerebrospinal fluid (CSF), WM, and gray matter (GM) volumes were extracted from T1 maps in CAT12 and compared before and during HD by Wilcoxon paired t-tests (α=0.05).

Results: During dialysis, MD was elevated (p<0.05) in regions of the superior corona radiata (fig. A) and peripheral WM near the cingulate gyrus (fig. B). CSF volume decreased by an average of 50.2 ± 12.2 ml (p<0.05) while the GM volume increased by an average of 28 ± 11.1 ml (p<0.05), as shown in figure C.

Conclusions: Increased MD in conjunction with increased brain volume suggests cerebral edema, potentially caused by osmotic stresses associated with HD. Further investigations are ongoing to determine if edema contributes to the brain injury and cognitive impairment observed in HD patients.

Funding: Private Foundation Support, Government Support - Non-U.S.

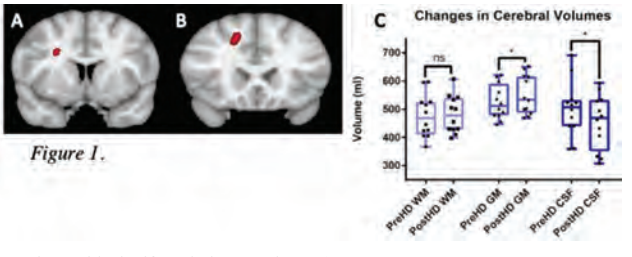

Figure 1.

The regions with significantly increased MD (p<0.05) during HD are shown in red in A and B. C gives the volumes of WM, GM, and CSF before and during HD.

Depression Screening Is Associated with Lower Mortality and Hospitalization Among Adults Initiating Chronic Hemodialysis

Michael J. Fischer,[1,8] Elani Streja,[2] Jui-Ting Hsiung,[5] Susan T. Crowley,[9] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh,[4] Wissam M. Kourany.[6,7] *[1]Jesse Brown VA Medical Center, Chicago, IL; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [3]University of Tennessee Health Science Center, Memphis, TN; [4]University of California Irvine, School of Medicine, Orange, CA; [5]University of California Irvine, School of Medicine, Orange, CA; [6]Veterans Affairs Durham Healthcare System, Durham, NC; [7]Duke University Medical Center, Durham, NC; [8]University of Illinois Healthcare System, Chicago, IL; [9]Veterans Health Administration, West Haven, CT.*

Background: Transitioning to chronic hemodialysis (HD) continues to be a vulnerable period for adults with end-stage renal disease (ESRD). Depression commonly develops among these patients and negatively impacts quality of life, treatment adherence, hospitalization, and mortality. Depression screening may be an important tool in identifying depression and improving outcomes. Among a large national cohort of Veterans, we examined whether depression screening in the year prior to chronic HD transition led to lower mortality and hospitalization in the first year of HD.

Methods: Using data from the USRDS Transition of Care in CKD study, an observational study that focuses on Veterans who transitioned to chronic dialysis between 2007 to 2015, we identified adults with an outpatient nephrology, geriatric or primary care visit in the year prior to transition to HD. Pre-ESRD depression screening was defined as completion of a Patient Health Questionnaire-2 (PHQ-2) in the 12 months prior to transition. The main outcomes were all-cause mortality and hospitalization in the 12 months post transition. Associations were examined with Cox proportional hazards models (mortality) and Poisson regression models (hospitalization). Hierarchal adjustment models were used to account for sociodemographics, comorbidity and laboratory values, pre-ESRD care intensity, and post-ESRD dialysis characteristics.

Results: After excluding adults with a diagnosis/treatment of depression, bipolar disease, or dementia prior to the index outpatient visit, the final analytic cohort consisted of 30,013 Veterans who transitioned to HD. Sixty-one percent of patients had PHQ-2 screening during the 12 months prior to HD transition. During the 12 months post-transition, the crude all-cause mortality rate was 32/100 person-year for those screened and 35/100 person-year for those not screened, while the median (IQR) hospitalizations were 2 (2,2) per year for both groups. In fully adjusted models, PHQ-2 screening was associated with a significantly lower risk of mortality (HR 0.94, 95% CI: 0.90-0.98) and hospitalization (IRR 0.97, 95% CI: 0.95-0.99).

Conclusions: Screening for depression among adults with ESRD in the year prior to transition to chronic hemodialysis was associated with improved outcomes after dialysis initiation.

An Analysis of Delirium in Elderly Patients with ESRD During Hospitalization for Starting Maintenance Hemodialysis

Yohei Arai,[2,1] Hiroyuki Tanaka,[3] Shingo Shioji,[3] Isao Kondo,[2] Emi Sakamoto,[2] Minami Suzuki,[2] Daisuke Katagiri,[2] Manami Tada,[2] Fumihiko Hinoshita.[2] *[1]Tokyo Medical and Dental University, Bunkyo-ku, Japan; [2]National Center for Global Health and Medicine, Shinjuku-ku, Japan; [3]Yokosuka Kyosai Hospital, Yokosuka-shi, Japan.*

Background: Delirium is an acute and usually reversible disturbance in mental abilities that causes confused thinking and emotional disruption. It has recently been reported that delirium is an independent predictor of death in patients undergoing maintenance dialysis for end-stage renal disease (ESRD). Although it is well known that delirium occurs much more easily in the elderly, it remains unproved whether the occurrence of delirium during hospitalization for starting dialysis is associated with early mortality after the start of dialysis in elderly populations.

Methods: We conducted a retrospective cohort study to investigate the association between delirium and early mortality after starting dialysis in the elderly. The cohort consisted of patients aged 75 years old or older who started hemodialysis for ESRD at the National Center for Global Health and Medicine from 2010 to 2017 and at Yokosuka Kyosai Hospital from 2007 to 2011. Delirium was defined as patients who, during hospitalization for starting dialysis, newly showed confused thinking and reduced awareness of their environment and were prescribed anti-psychotic medications. The primary outcome was death within a year of the start of dialysis. Data were analyzed using Cox proportional hazard models with adjustments for baseline characteristics. To assess underlying characteristics of the patients with delirium, we identified the determinants using a multinomial logistic regression.

Results: We enrolled 264 patients (males, 59%); 34 patients were diagnosed with delirium. The primary outcome was observed in 19 patients with delirium (55%) and 26 patients without delirium (11%) (p < 0.01). In a Cox proportional hazards model, delirium was independently associated with a higher risk of all-cause mortality within a year of the start of dialysis (hazard ratio 6.96, 95% confidence interval 3.84-12.63; adjusted hazard ratio 5.78, 95% confidence interval 2.93-11.41). In a multinomial logistic regression, delirium was positively correlated with “cognitive impairment” and “the use of steroid” and inversely correlated with “the presence of arteriovenous fistula”.

Conclusions: Delirium predicts early mortality after starting dialysis in the elderly.

FR-PO429

Patient Treatment Adherence in the ASCEND Trial for Depression in Patients Undergoing Maintenance Hemodialysis

Daniel Cukor,[1] Tessa Rue,[2] Mark L. Unruh,[3] Patrick J. Heagerty,[2] Scott D. Cohen,[4] Laura M. Dember,[5] Yaminette Diaz-Linhart,[6] Amelia Dubovsky,[2] Tom Greene,[7] Nancy K. Grote,[2] Nancy G. Kutner,[8] Madhukar Trivedi,[9] Davin Quinn,[10] Nisha Ver halen,[11] Steven D. Weisbord,[12] Bessie A. Young,[2] Paul L. Kimmel,[13] Susan Hedayati,[14] Rajnish Mehrotra.[2]
[1]Rogosin Institute, NY, NY; [2]University of Washington, Seattle, WA; [3]University of New Mexico, Los Ranchos, NM; [4]George Washington University, Washington, DC; [5]University of Pennsylvania School of Medicine, Philadelphia, PA; [6]Brandeis University, Cambridge, MA; [7]University of Utah, Salt Lake City, UT; [8]Emory University School of Medicine, Atlanta, GA; [9]UT Southwestern Medical Center, Dallas, TX; [10]University of New Mexico Health Sciences Center, Albuquerque, NM; [11]Weill Cornell Medicine/New York-Presbyterian, New York, NY; [12]University of Pittsburgh Medical Center, Pittsburgh, PA; [13]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [14]University of Texas Southwestern, Dallas, TX.

Background: The multi-center clinical trial, ASCEND, demonstrated a modestly larger effect of 12-week treatment with sertraline (SER) on depression scores, compared with cognitive behavioral therapy (CBT).

Methods: We undertook a *post-hoc* analysis to characterize patient adherence to these treatments and to examine the association of patient treatment adherence with depression scores at the end of the intervention.

Results: The average age of participants (n=120) was 51 ± 13 years, 57% were male, and 43% were white. Among those randomized to CBT, 82% completed at least 7 of the 10 sessions, 72% were rated by the therapist as engaged in at least 7 CBT sessions and 47% of the participants attempted/completed CBT homework > 50% of the time. SER dose titration was done algorithmically; 73% of participants randomized to drug, took their prescribed dose for at least 8 weeks. Depression was assessed by the Quick Inventory of Depression Scores, Clinician Rated (QIDS-C) at 12 weeks. There was a weak negative association between number of CBT sessions attended and QIDS-C score (R=-0.19) and number of days SER was taken and QIDS-C score (R=-0.27). We examined the association of baseline parameters (demographics, depression diagnosis, severity, and history, participation in a pre-enrollment motivational interviewing session, and initial treatment preference) with treatment adherence separately for CBT and SER. The only significant predictor for CBT adherence was a history of depression; participants with no history of depression attended on average 1.8 more sessions and were 26% more likely to attend a session (p=.02) than participants with a history of depression. There was no relationship between baseline parameters and SER use.

Conclusions: High levels of treatment adherence for depression, with both CBT and SER, can be achieved in patients on maintenance hemodialysis. Baseline characteristics are generally poor predictors of future adherence to treatment. The identification of patient and treatment level factors that promote adherence to treatments for depression are needed.

Retrospective Analysis of Serum Albumin and Other Biomarkers in Chronic Hemodialysis Patients Dialyzed with the Optiflux F180NR Dialyzer

Linda Ficociello,[1] Yisha Li,[1] Claudy Mullon,[1] Mark Costanzo,[1] Robert J. Kossmann.[2] *[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Optiflux® dialyzers are commonly used in US ESRD patients. Considering that low serum albumin (sALB) levels are associated with increased risk of mortality, albumin loss during hemodialysis (HD) should be minimized, especially in patients (pts) with hypoalbuminemia. A retrospective analysis was conducted to assess changes in sALB and other biomarkers in pts dialyzed with the Optiflux F180NR (OPTI).

Methods: In-center HD pts (n=284) treated with OPTI dialyzers for 6 months were analyzed. Pts maintained the same vascular access type and were without a diagnosis of liver disease or cancer. Changes in pre-dialysis (Pre-HD) labs at month 1 (M1) and month 6 (M6) were compared using paired t-tests. A sub-analysis of pts with hypoalbuminemia (sALB ≤3.5 mg/dL) was conducted.

Results: After 6-months of HD treatments, significant increases in mean sALB (0.07 g/dL), nPCR (0.05), and hemoglobin (0.42 g/dL) were observed with increased mean ultrafiltration volume (UFV) and adequacy (Table). A sub-analysis of 47 pts with hypoalbuminemia at M1 showed increases in sALB (0.36 g/dL) at M6 for 44 pts. Three pts had concomitant decreases in sALB (0.4 g/dL) and nPCR (0.44) during the same period.

Conclusions: During a 6-month follow-up, HD patients dialyzed with Optiflux F180NR dialyzers showed increased levels of serum albumin, nPCR, hemoglobin, ultrafiltration volume, and Kt/V.

Low Proteinuria Is Associated with Increased Mortality in Incident Dialysis Patients: Results from the CRIC Study

Manabu Hishida,[1,2] Junichi Ishigami,[3] Tariq Shafi,[4] Claudia M. Lora,[5] Raymond R. Townsend,[6] Jing Chen,[7] Jiang He,[8] Anand Srivastava,[9] Hernan Rincon-Choles,[15] Jonathan J. Taliercio,[10] James H. Sondheimer,[12] Matthew R. Weir,[11] Lawrence J. Appel,[13] Kunihiro Matsushita.[14] *[1]Epidemiology, Johns Hopkins School of Public Health, Baltimore, MD; [2]Nephrology, Nagoya University, Nagoya, Japan; [3]Johns Hopkins School of Public Health, Baltimore, MD; [4]University of Mississippi Medical Center, Jackson, MS; [5]University of Illinois at Chicago, Chicago, IL; [6]University of Pennsylvania School of Medicine, Villanova, PA; [7]Tulane School of Medicine, New Orleans, LA; [8]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [9]Northwestern University Feinberg School of Medicine, Chicago, IL; [10]Glickman Urological and Kidney Institute, Cleveland, OH; [11]University of Maryland School of Medicine, Baltimore, MD; [12]Wayne State University School of Medicine, Detroit, MI; [13]Johns Hopkins Medical Institutions, Baltimore, MD; [14]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [15]Cleveland Clinic, Cleveland, OH.*

Background: In multiple studies, increased levels of proteinuria are associated with worse outcomes. However, in individuals with glomerular filtration rate <30 ml/min, some studies have reported a J-shaped association of proteinuria with mortality. However, this association has not been examined in incident dialysis patients.

Methods: Among 725 incident dialysis participants in the CRIC Study (mean age 60.1 [SD 11.4] years, 32.4% White, 54.2% Black, 59.0% men), we evaluated the association of pre-dialysis urinary protein-to-creatinine ratio (PCR) within two years of dialysis initiation (<0.5, 0.5- 0.9, 1.0- 3.4, ≥3.5 [g/g]) with mortality (333 deaths during the median follow-up of 3.5 years) using Cox models adjusting for potential confounders (e.g. blood pressure, serum albumin, history of cardiovascular disease including heart failure).

Results: Participants with the lowest PCR level, <0.5 g/g, were likely to be older and had lower blood pressure compared to those with higher proteinuria. We observed a J-shaped association with the highest mortality risk in the lowest PCR category (<0.5 [g/g]) (crude hazard ratio 2.69 [95%CI 1.79-4.04] vs. PCR of 0.5- <0.9) followed by the highest PCR category (1.46 [1.01-2.10]) (Table). The excess risk in persons with the lowest PCR level was attenuated but still statistically significant after accounting for potential confounders.

Conclusions: Among incident dialysis patients, there was a J-shaped association between pre-dialysis proteinuria and elevated risk of mortality, with the highest risk in the lowest PCR category. While the reasons for this association are uncertain, our findings suggest that healthcare providers should be aware that low protein excretion, not just high protein excretion, is a marker for an increased risk of mortality in patients who start dialysis.

Funding: Private Foundation Support

Table. Hazard ratios (95% CI) of all-cause mortality according to PCR (g/g) levels

	<0.5 (n=88)	0.5- 0.9 (n=90)	1.0- 3.4 (n=266)	≥3.5 (n=281)
All-cause mortality (333 deaths)	62 deaths	30 deaths	104 deaths	137 deaths
Model 1	2.69 (1.79-4.04) **	ref	1.13 (0.78-1.65)	1.46 (1.01-2.10) *
Model 2	2.62 (1.74-3.95) **	ref	1.20 (0.82-1.74)	1.58 (1.10-2.28) *
Model 3	2.48 (1.64-3.75) **	ref	1.21 (0.83-1.76)	1.49 (1.03-2.16) *
Model 4	1.78 (1.08-2.93) *	ref	1.14 (0.72-1.80)	1.23 (0.75-2.02)

Model 1 was unadjusted
Model 2 adjusted for age and gender
Model 3 additionally adjusted for a clinical history of diabetes mellitus, CVD history, heart failure, stroke
Model 4 further adjusted for systolic blood pressure, total cholesterol, eGFR, serum albumin, hemoglobin, white blood cell, diuretics, and angiotensin-converting-enzyme inhibitor/angiotensin receptor blockers.

FR-PO432

Elevated $PM_{2.5}$ Increases Daily Hospital Admission and Readmission Risk in Chronic Hemodialysis Patients

Lauren Wyatt,[1] Yuzhi Xi,[3] Abhijit V. Kshirsagar,[3] Timothy J. Wade,[2] Ana G. Rappold.[2] *[1]ORISE at the Environmental Protection Agency, Chapel Hill, NC; [2]US EPA, RTP, NC; [3]University of North Carolina, Chapel Hill, NC.*

Background: Fine particulate matter (diameter < 2.5 um, $PM_{2.5}$) increases the risk of hospitalization through acute exacerbations of underlying conditions. We examine the role of $PM_{2.5}$ on all-cause and cause-specific admissions and readmissions among hemodialysis patients, a population with elevated hospital and 30-day readmission rates.

Methods: Health data from the United States Renal Data System included individual-level inpatient hospitalizations and events classified as rehospitalizations between 2008 and 2012 in 552 US counties. Admission rates were calculated for 1,799,928 inpatient hospitalizations. We evaluated immediate (same day) and delayed effects of a 10$\mu g/m^3$ increase in $PM_{2.5}$ on all-cause and cause-specific (cardiovascular, respiratory, and cerebrovascular) health associations. Daily county admission risk was measured with admission counts and expressed as a risk ratio (RR) using Conditional Poisson models stratified by county-day. This time stratified case crossover approach adjusted for changes in population size and risk characteristics by design, where each population served as its own control. Patient readmission risk was expressed as a RR and evaluated using Cox proportional hazard models with time-dependent environmental covariates controlling for meteorology, patient-specific, and event-specific variables.

Results: Same day elevated $PM_{2.5}$ was associated with a 0.4% (95%CI: 0.05-0.7%) increase in the RR of all-cause daily county admissions and even greater risk for increased 30-day readmission. Daily RRs associated with same day $PM_{2.5}$ were increased by 1.1% (0.6-1.6%) for all-cause and 4.9% (2.3-7.7%) for cerebrovascular readmissions. At delayed

exposure times cardiovascular and respiratory readmission risks were also observed but are not shown due to space constraints.

Conclusions: Our results show increased risk of hospital admission and 30-day readmission associated with elevated $PM_{2.5}$ for patients receiving chronic hemodialysis. These findings suggest that daily ambient air quality may impact morbidity and healthcare costs for patients with End Stage Renal Disease. This abstract does not reflect EPA policy.

FR-PO433

The Predictive Role of Serum MRP8/14 (S100A8/A9) on Mortality in Hemodialysis Patients

Tomoko Kanki, Takashige Kuwabara, Jun Morinaga, Hirotaka Fukami, Shuro Umemoto, Daisuke Fujimoto, Teruhiko Mizumoto, Manabu Hayata, Yutaka Kakizoe, Yuichiro Izumi, Masashi Mukoyama. *Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan*.

Background: The inflammatory mediator myeloid-related protein 8 (MRP8: S100A8), which forms a heterodimeric complex with a binding partner MRP14 in the bloodstream, plays important roles as an endogenous ligand in various diseases. Serum MRP8/14 reportedly became a potential biomarker in patients with acute coronary syndrome and ANCA-associated vasculitis. The aim of this study was to investigate the predictive role of serum MRP8/14 levels on all-cause mortality in hemodialysis patients.

Methods: We conducted a multicenter, observational cohort study of 388 Japanese subjects undergoing maintenance hemodialysis in Kumamoto, Japan. Serum MRP8/14 levels were measured using an ELISA. The potential associations between serum MRP8/14 levels and clinical variables were examined in a cross-sectional study. Multivariable Cox regression was used to estimate the association between serum MRP8/14 levels and mortality, adjusting for possible confounding variables including age, sex, diabetes and others. Median follow-up was 6.6 years.

Results: The mean age of the subjects was 65.3 years, 36.9% were female, and the median vintage was 5.8 years. The median MRP8/14 level was 6108 ng/ml [normal range in healthy subjects: 500–3500] at baseline. Serum MRP8/14 levels positively correlated with white blood cells (ρ=0.54, P<0.0001) and high-sensitivity C reactive protein (hs-CRP) values (ρ=0.34, P<0.0001). We classified MRP8/14 and hs-CRP into tertile, and estimated the hazard ratios (HR) for all-cause mortality in comparison with the lowest tertile. As for hs-CRP, the middle tertile (HR, 1.90; 95%CI, 1.04–3.61) and the highest tertile (2.87; 1.54–5.54) were each significantly associated with all-cause mortality in the low-phosphate group (cut-off, 6.0 mg/dl), after adjustment for relevant confounding factors. In contrast, elevated MRP8/14 levels were evidently associated with all-cause mortality in the middle tertile (12.3; 1.64–271.6) and in the highest tertile (26.8; 3.49–610.4) in the high-phosphate group, but not in the low-phosphate group.

Conclusions: High serum MRP8/14 levels should give a potential predictive marker on mortality in hemodialysis patients with high-phosphate levels, which characteristic differs significantly from that of a conventional inflammatory marker, hs-CRP.

FR-PO434

Trimethylamine N-Oxide and Cardiovascular Outcomes in Hemodialysis Patients

Pan Zhang. Division of Nephrology, Zhongshan Hospital, FuDan University,; Shanghai Institute of Kidney Disease and Dialysis; Shanghai Key Laboratory of Kidney Disease and Blood Purification, Shanghai, China. *Division of Nephrology, Zhongshan Hospital, FuDan University, Shanghai, China*.

Background: Trimethylamine-N-Oxide (TMAO) has a definite role in promoting atherosclerosis, which is an independent risk factor of cardiovascular disease. Cardiovascular disease is the leading cause of death in hemodialysis patients. The plasma level of TMAO in hemodialysis patients increases significantly, which is more than 20 times over the non-dialysis patients, but the relationship between TMAO and the cardiovascular outcomes in hemodialysis patients has not been well defined.

Methods: A prospective cohort study design was adopted. 252 patients who were eligible for the inclusion criteria were enrolled, and baseline clinical data were collected. Then these patients were followed for 9 years, the primary endpoints were all-cause and cardiovascular death, and the secondary endpoints were cerebrovascular death. The plasma TMAO concentration was determined, the Kaplan-Meier method and Cox proportional risk model were used to analyze the relationship between TMAO concentration and cardiovascular mortality and all-cause mortality.

Results: Median follow-up was 73.4 (42.9-108) months. During the follow-up, there were 123 cases of death totally, among them 39 cases of cardiovascular death, 19 cases of cerebrovascular death, 65 cases of other causes death. 20 cases transferred to other dialysis centers, and 15 cases received kidney transplantation. The median plasma TMAO concentration was 63.1μmol/L. Based on the median concentration of TMAO, the patients were categorized as High TMAO group (TMAO > 63.1μmol/L) and Low TMAO group (TMAO ≤ 63.1μmol/L). Kaplan-Meier analysis found that the incidences of all-cause death (Log-Rank P < 0.001) and cardiovascular death (Log-Rank P = 0.006) in High TMAO group were significantly higher than those of Low TMAO group. Multivariate Cox regression demonstrated that plasma TMAO was significantly associated with all-cause death (TMAO as continuous variable : HR 1.123, 95%CI(1.067-1.183), P < 0.001; TMAO as dichotomous variable : HR 2.147, 95%CI(2.149-3.117), P < 0.001) and cardiovascular death (TMAO as continuous varible : HR 1.126, 95%CI(1.027-1.235), P = 0.011; TMAO as dichotomous variable: HR 2.517, 95%CI(1.275-4.969), P = 0.008). After adjustment of conventional and non-conventional risk factors, the relationship of plasma TMAO and all-cause and cardiovascular death remained significant.

Conclusions: Plasma TMAO is an independent risk factor of cardiovascular outcomes in hemodialysis patients.

Circulating PCSK9 Level Predicts Risk of Cardiovascular Events and Death in Hemodialysis Patients

Min hye Kang,[1] Jin sug Kim,[1] Yang gyun Kim,[2] So-young Lee,[3] Shin-Young Ahn,[4,5] Gang Jee Ko,[5] Hong Joo Lee,[6] Dong-Young Lee,[7] Kyung hwan Jeong,[1] Hyeon Seok Hwang.[1] *[1]Kyung Hee University Hospital, Seoul, Republic of Korea; [2]Kyung Hee University College of Medicine, Seoul, Republic of Korea; [3]CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea; [4]Korea University Medical Center, Seoul, Republic of Korea; [5]Korea University Guro Hospital, Seoul, Republic of Korea; [6]Seoul Red Cross Hospital, Seoul, Republic of Korea; [7]Veterans Health Service Medical Center, Seoul, Republic of Korea*.

Background: The proprotein convertase subtilisin/kexin type 9 (PCSK9) is a promising new target for prevention of cardiovascular event (CVE). However, the clinical significance of circulating PCSK9 is unclear in HD patients

Methods: A total of 353 patients were prospectively enrolled from June 2016 to May 2018 in K-cohort study groups. Serum PCSK9 level was measured at the time of study enrollment. Serum levels of high-sensitivity C-reactive peptide (hsCRP), monocyte chemoattractant protein (MCP)-1, interleukin (IL)-6, osteoprotegerin and receptor activator of nuclear factor kappa-B ligand (RANKL) were also measured. The primary endpoint was defined as composite of CVE and death from any cause.

Results: Serum PCSK9 level was positively correlated with total cholesterol level, but not with inflammatory (hsCPR, MCP-1 and IL-6) and calcification-related markers (osteoprotegerin and RANKL). Multivariate linear regression analysis revealed that statin treatment, serum albumin and total cholesterol levels at baseline were independent determinants of circulating PCSK9 levels. In multivariate Cox-regression analysis, PCSK9 tertile 3 was associated with 1.99-fold risks for composite event (95% confidence interval [CI], 1.08-3.66), and it was independently associated with 2.26-fold risks for CVE (95% CI, 1.11-4.62). PCSK9 tertile 3 also provides additional prognostic significance to predict composite event in subgroups with higher level of hsCRP and LDL, and no statin treatment.

Conclusions: Circulating PCSK9 level independently predicts CVE and death in HD patients, and these results anticipate future studies for the effect of PCSK9 inhibition in HD patients.

FR-PO436

Sex-Specific Association Between Serum Uric Acid and Cause-Specific Mortality in Maintenance Hemodialysis Patients: A Multicenter Prospective Cohort Study

Yaya Yang, Min Liang. *Nanfang Hospital, Guangzhou, China*.

Background: Studies have shown inconsistent results about the association between serum uric acid (SUA) and mortality in maintenance hemodialysis (MHD) patients. Moreover, no studies have explored the possibilities of the relationship between SUA and non-cardiovascular (CVD) mortality.

Methods: We conducted a multicenter prospective cohort study among 1039 MHD patients. The blood samples of all participants were obtained prior to the hemodialysis session at baseline. Multivariable adjusted Cox proportional hazards models were used to estimate the HRs and 95%CIs for the risk of all-cause mortality, CVD mortality and non-CVD mortality associated with SUA.

Results: Over a median follow-up of 28 months, 230 deaths were recorded, of which 140 (60.9) were due to cardiovascular disease. overall, a U-shaped relationship was found between SUA and all-cause mortality. Moreover, the patients in the lowest SUA showed a higher risk of CVD mortality (HR: 1.57, 95%CI: 1.03-2.40), whereas no significant association was found with non-CVD mortality. By contrast, the patients in the highest SUA group showed a higher risk of non-CVD mortality (HR:1.82, 95%CI: 1.04-3.17) and no significant association was found with CVD mortality. The association between SUA and all-cause mortality were consistent across different subgroups.

Conclusions: There was a U-shaped relationship between SUA and all-cause mortality. Furthermore, lower SUA had an increased risk of CVD mortality and higher SUA had a higher risk of non-CVD mortality. Whether SUA reduction therapy is beneficial to the MHD patients should be the subject of the future research work.

The association between sex-specific serum uric acid levels and mortality

SUA, mg/dl	No. events(%)	Adjusted HR(95%CI)	P
All-cause mortality			
Tertile 1	100 (28.9%)	1.45 (1.04, 2.03)	0.029
Tertile 2	61 (17.6%)	1.0(Ref)	--
Tertile 3	69 (19.9%)	1.46 (1.02, 2.11)	0.040
CVD mortality			
Tertile 1	68 (19.7%)	1.57 (1.03, 2.40)	0.035
Tertile 2	37 (10.7%)	1.0(Ref)	--
Tertile 3	35 (10.1%)	1.24 (0.76, 2.01)	0.384
Non-CVD mortality			
Tertile 1	32 (9.2%)	1.22 (0.71, 2.13)	0.476
Tertile 2	24 (6.9%)	1.0(Ref)	--
Tertile 3	34 (9.8%)	1.82 (1.04, 3.17)	0.036

FR-PO437

Erectile Dysfunction Is Associated with increased Coronary Artery Calcification But Not Mortality in Incident Dialysis Patients

Neil Roy, Danwen Yang, Sylvia E. Rosas. *Joslin Diabetes Center, Boston, MA.*

Background: Erectile dysfunction (ED) is prevalent among the hemodialysis population. Increasing age, diabetes and nonuse of ACE inhibitors has been associated with a higher incidence of ED in our previous work. ED predicts mortality in the general population likely through its association with CVD risk factors.

Methods: Objective: To determine the relationship between ED, coronary artery calcification and mortality in incident dialysis patients without prior coronary events using the Dialysis, Heart and Bone Study. **Methods:** Sixty-three male participants were enrolled in this prospective study and completed the fifteen-item validated questionnaire, the IIEF-15 as well as MSCT to measure coronary artery calcification. Subjects having a score 25 or less in the self-administered questionnaire were considered to have ED. Detailed information regarding demographics, medical history, and medication usage was obtained by self-report.

Results: The mean age of participants was 49.2 (13.1) years and two-thirds were AA. Forty-four percent of participants had severe ED, 23.8% had moderate ED, 15.8% had mild ED and 15.8% had no ED. The median (IQR) Agatston score was 56.8(0.5-406.5) for those with ED and 0(0-0) for those without ED [p=0.007]. Twenty-three percent of the participants died during an average follow-up of 5 (1.5) years. Twenty-one percent of the participants with ED died compared to ten percent of people without ED (p=0.4). Using a proportional hazard model with covariate adjustment by propensity score, ED was not significantly associated with mortality (p=0.64)

Conclusions: ED is common in new to dialysis patients. ED was significantly associated with increased CAC score. However, it was not associated with increased mortality in incident dialysis patients.

FR-PO438

Relationship Between Serum Uric Acid and Vascular Calcification in Patients Treated with Hemodialysis

Qimei Luo, Xianrui Dou. *Shunde Hospital of Southern Medical University, Foshan, China.*

Background: Vascular calcification (VC) is highly prevalent among hemodialysis (HD) patients and predicts cardiovascular mortality. The level of serum uric acid (SUA) may be related with endothelial dysfunction, which may involve in VC. However, whether uric acid concentrations are associated with VC in HD patients is unknown. The aim of our study was to assess the association of SUA and VC in HD patients.

Methods: This was a cross-sectional study including 313 patients receiving HD therapy for at least 3 months between January 2014 and December 2018. The simple vascular calcification score (SVCS) in plain X-rays of the pelvis and hands was used to evaluate VCs.

Results: Mean age was 57.1±14.0 (SD) years, and 32.2% had diabetes. Mean uric acid level was 476.06±111.68 umol/L, 73.8% had hyperuricemia. The SVCS detected VC in 179 (57.1%) patients, including 160 patients presenting VC of pelvis arteries and 95 patients presenting VC of hands arteries. In total of patients, a SVCS≥ 3 was present in 104 (33.2%) patients. By binary logistic regression, age (P<0.001), HD duration (P<0.001), diabetes (P<0.001) were independently associated with a SVSC≥ 3, the levels of SUA was not associated with a SVSC≥ 3. Adjusted logistic regression models showed that the ORs per 1umol/L higher uric acid level for VC of pelvis arteries was 0.996 (95% CI, 0.994-0.999; P=0.015) in total patients and 0.995 (95% CI, 0.991-0.999; P=0.010) in non-diabetic HD patients. However, there was no association between SUA and VC of hands arteries.

Conclusions: Higher uric acid levels were associated with lower risk of VC of pelvis arteries in patients treated with HD.

FR-PO439

Atheromas and Peripheral Vessel Physiology in Relation to Culinary Habits in ESRD: Diversion Between Peritoneal Dialysis and Hemodialysis Population by Adopting the Mediterranean Diet Regime

Panagiota E. Giannou,[1] Athanasios Angelis,[2] Constantina Aggeli,[2] Athanasia Kapota,[1] Emelina Stambolliu,[1] Charalambos Vlachopoulos,[2] Dimitrios I. Petras.[1] *[1]Nephrology, General Hospital of Athens "Hippokration:, Athens, Greece; [2]Hippokration Hospital, 1rst Department of Cardiology, University of Athens, Greece, Athens, Greece.*

Background: End stage renal disease (ESRD) relates to atheroma formation and typically amplifies cardiovascular risk. Patients on hemodialysis (HD) impose strict dietary restrictions. On the contrary, patients on peritoneal dialysis (PD) may consume a wide variety of alimentary goods.

Methods: 92 male ESRD patients, 52 of them on HD and the rest 40 on PD without apparent cardiovascular disease were matched to enroll the study. The 2 groups did not differ statistically in age, (64,9 ± 15.2 vs 64 ± 11.4) prevalence of hypertension, diabetes mellitus, smoking and lipid profile. All underwent common carotid ultrasound examination for detecting plaque formation and intima –media thickness (IMT) evaluation as indices of subclinical atheromatosis. Peripheral vessel rheology was assessed by the SHIM-5 score that grades erectile potency. A lower score indicates severe erectile dysfunction unmasking thus endothelial dysfunction. Dietary habits were evaluated through a special diet score (Med-Diet score, range 0-55), which assesses adherence to the Mediterranean diet. Lower values indicate poor adherence to this alimentary pattern.

Results: Patients on HD had statistically higher IMT (1.5 ± 0.7 vs 0.85 ± 0.2), lower SHIM-5 score grading (8.8 ± 6.9 vs 12.8 ±4.5) and lower Med-Diet score(22 ± 4 vs 29 ±3) as compared to PD patients (all P<0.05). Carotid IMT and carotid plaque formation were inversely associated (r=-0.32, P<0.01) and SHIM-5 was positively correlated (r=0.29, P<0.01) to the Med-diet score. The associations remained significant in linear regression analysis after adjustment for age, body mass index, presence of hypertension, diabetes mellitus, tobacco use and statin therapy (all P<0.01).

Conclusions: ESRD male patients on peritoneal dialysis may exhibit lower atheromatic load and enhance peripheral vessel rheology by adopting the Med-diet regime. Healthy dietary choices may improve quality of life and cardiovascular outcome in this specific ESRD population.

FR-PO440

Association of Serum Indoxyl Sulfate Level with Peripheral Artery Occlusive Disease in Patients with Hemodialysis

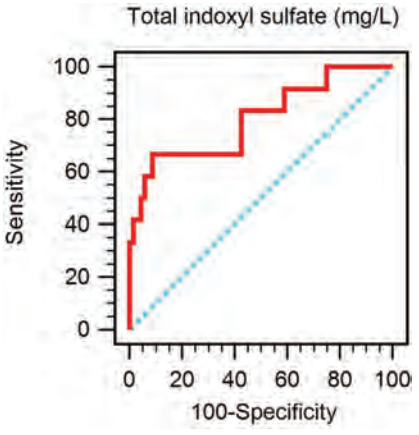
Lin Lin,[1] Liang-Te Chiu,[1] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan.*

Background: Indoxyl sulfate (IS) can be considered as a cardiovascular toxin and a nephrotoxin that has been associated with intima media thickness, vascular disease, coronary artery disease, progression of kidney disease and increased mortality. Peripheral arterial occlusive disease (PAOD) is associated with an increased risk of death in hemodialysis (HD) patients. The aim of this study was to evaluate the relationship between IS level and PAOD by ankle-brachial index (ABI) in HD patients.

Methods: Blood samples were obtained from 80 chronic HD patients. Serum total IS level was performed with high-performance liquid chromatography and mass spectrometry. ABI values were measured using the automated oscillometric method (VaSera VS-1000). ABI values that were < 0.9 were included in the low ABI group.

Results: Among the 80 HD patients, 12 of them (15.0%) were in the low ABI group. Compared with patients in the normal ABI group, the patients in the low ABI group had higher prevalence of diabetes (P = 0.010), higher serum C-reactive protein (P < 0.001), and IS (P < 0.001) levels, while lower had statin used (P = 0.042). In addition, the multivariable logistic regression analysis showed that serum IS (Odds ratio [OR]: 1.115, 95% confidence interval [CI]: 1.015-1.225, P = 0.023) and CRP levels (each increase 0.1 mg/dL, OR: 1.187, 95% CI: 1.046-1.346, P = 0.008) were the independently associated with PAOD in HD patients. The area under the receiver-operating characteristic (ROC) curve predicting PAOD by serum IS level in HD patients was 0.800 (95% CI: 0.696-0.881, P = 0.0002).

Conclusions: In this study, serum total IS level was found to be associated with PAOD in HD patients.



FR-PO441

Tumoral Calcinosis in Hemodialysis Patient

Ioannis Griveas.[1,2] [1]*Dialysis Unit "Nefroiatriki", Athens, Greece;* [2]*Nephrology, 417 Army Share Fund Hospital, Athens, Greece.*

Introduction: Uremic tumoral calcinosis is an uncommon but serious complication of end-stage renal disease. It is characterized by massive extraosseous calcification in periarticular tissues, leading to limited range of joint movement, pain, and skin ulceration.

Case Description: A 52-year-old man developed a progressively enlarging painless mass on the posterior surface of the right leg and on the back surface of the right shoulder with limited range of flexion following 5 years of hemodialysis. Magnetic resonance showed amorphous, cystic, and multilobulated calcification. Pathology report revealed tumoral calcinosis. We started intensifying hemodialysis program (5 days per week, 4 hours each session), low calcium bath, aggressive control of hyperphosphatemia, initiation of cinacalcet, antibiotics and administration of sodium thiosulfate 25 mg i.v per each session. After 6 weeks we noticed significant reduction in the magnitude of the masses and in 8 weeks complete resolution. We turned hemodialysis schedule to 3 times a week and continued to have close monitoring of the patient.

Discussion: Effective treatment options for tumoral calcinosis remain elusive. The primary focus of therapy should be to optimize calcium and phosphate homeostasis. Avoidance of a positive calcium balance should be a high priority. Experienced nephrologists recommend a course of dialysis 5–7 days per week for the first couple weeks of treatment, with the duration of this intensified dialysis therapy depending on clinical response. Sodium thiosulfate is a chelating agent that has antioxidant activity and increases activity of endothelial nitric oxide synthetase. Sodium thiosulfate is believed to act by dissolving insoluble tissue calcium salts to form calcium thiosulfate, which is many thousand times more soluble than many other calcium salts.

FR-PO442

Effectiveness and Safety of Modified Sodium Thiosulfate Therapy for Calciphylaxis in Chinese Patients

Xin Yang, Yuqiu Liu, Xiaotong Xie, Haifeng Ni, Xiaoliang Zhang, Bi-Cheng Liu. Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China.*

Background: Calciphylaxis is a generally fatal condition without acknowledged effective treatment. Some case reports and clinical studies have described intravenous sodium thiosulfate (STS) prevent the progression of calciphylaxis. Nevertheless, this therapy for individuals presented serious complications resulting in withdrawal of treatment in our experience. Based on the ethnic diversity, we modified the usage of STS and evaluated the effectiveness and safety of modified STS therapy for calciphylaxis in Chinese patients.

Methods: 20 patients who were diagnosed calciphylaxis and treated with STS in our center were enrolled. Evaluation of effectiveness and safety was based on items including demographics, clinical data and laboratory measurements. Therapeutic schedule were named Zhongda Therapy with 5 course of treatment and 2-3weeks of interrupt between 2 courses. STS from the initial dose (3.2g) were administered intravenously in 100 ml once a day gradually increasing day by day up to the highest dose (6.4g). Patients maintained the condition of highest dose for 2-3 weeks and finished one course of treatment.

Results: The Mean age of the cohort was 45.50±14.95 years, 75% of patients was male and the median time span was 87 (52, 120) months range from entering the dialysis to diagnosed as calcipylaxis. In our research, 90% patients got improved and 12/20 patients were follow-up more than 12 months with 100% one-year survival rate. Of these patients, lesions involved different body parts such torso, limb, fingertips or compound type and throughout the body were 20% with powerful pain. The therapy relieved pain and promote early healing of skin lesions, even help one avert amputation. Reduction of phosphorus ($P=0.035$) and the NPRS ($P<0.001$) correlated significantly with STS treatment courses. Although adverse events occurs up to the 35% (nausea/vomiting 10%, hypotension 10%, infection 5% and multi-complication 10%), no one interrupted treatment due to mild discomfort. And if the incidence rate were calculated according to frequency divided by the total course, it will reduced to 14%.

Conclusions: Chinese patients need to modified the usage of STS to treat the calciphylaxis. And Zhongda Therapy offered a safe and effective treatment.

FR-PO443

Impact of Hemodialysis on the Concentrations of Sodium and Potassium During Infusion of Sodium Thiosulfate Using an In Vitro Hemodialysis Model

Sagar U. Nigwekar,[1] Amy B. Pai,[2] Bruce A. Mueller,[2] Gabrielle M. Costello,[2] Michael C. Dean,[2] Craig Sherman.[3] [1]*Massachusetts General Hospital, Boston, MA;* [2]*University of Michigan, Ann Arbor, MI;* [3]*Hope Pharmaceuticals, Scottsdale, AZ.*

Background: The purpose of this study was to evaluate the impact of hemodialysis on the concentrations of sodium and potassium in the blood when a 25 g dose of sodium thiosulfate injection is infused over 60 minutes in combination with hemodialysis.

Methods: Sodium thiosulfate (25 g) was prepared by diluting 100 mL of 250 mg/mL Sodium Thiosulfate Injection with 800 mL of 5% dextrose. This was added to the circulating blood surrogate solution at a rate of 15 mL/minute using an infusion pump of an *in vitro* model of dialysis machine [Figure]. Serial samples were collected before the administration of the sodium thiosulfate solution, after 15 minutes, 30 minutes, and 60 minutes of infusion from pre-and post-dialyzer ports in both the dialysate circuit and the extracorporeal circuit.

Results: The concentration of sodium thiosulfate in pre-dialyzer and post-dialyzer samples of the circulating blood surrogate solution peaked at 30 minutes and 15 minutes, respectively and then remained relatively unchanged during the remainder of the infusion. Mean sodium concentrations (mEq/L) in the circulating blood surrogate solution collected after exposure to a dialyzer were 103.2 ± 12.2, 114.2 ± 18.8, 117.2 ± 7.5, 93.5 ± 5.9 at 0, 15, 30, and 60 minutes, respectively ($p=0.248$). Mean potassium concentrations (mEq/L) in the circulating blood surrogate solution collected after exposure to a dialyzer were 1.4 ± 0.3, 1.6 ± 0.3, 1.5 ± 0.1, 1.2 ± 0.1 at 0, 15, 30, and 60 minutes, respectively ($p=0.365$). Sodium and potassium concentrations in dialysate increased marginally after exposure to the dialyzer.

Conclusions: Our study demonstrates that neither potassium nor sodium accumulated in a circulating blood surrogate solution when a dose of sodium thiosulfate was infused in conjunction with hemodialysis.

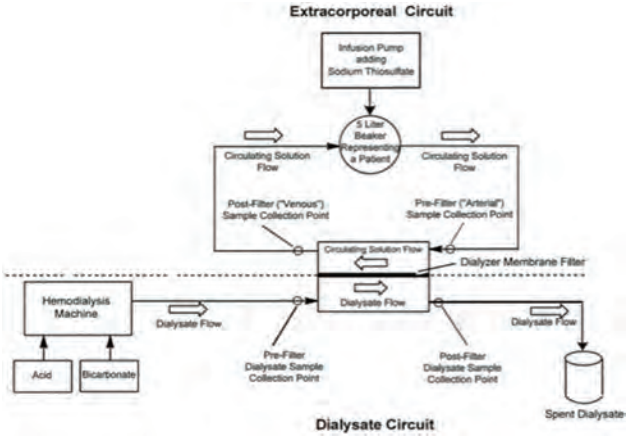


Figure. Schematic diagram of in vitro hemodialysis model used in this study

FR-PO444

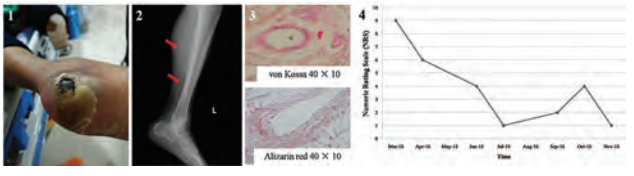
Avoidance of the Third Amputation with Remission of Intolerable Pain by Sodium Thiosulfate Administration in a Severe Calciphylaxis Patient

Canlin Yang,[1] Yuqiu Liu,[1] Haifeng Ni,[1] Bi-Cheng Liu,[2] Xiaoliang Zhang.[1]
[1]Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China; [2]Zhong Da Hospital, Southeast University Medical School, Nanjing, China.

Introduction: Calciphylaxis is a rare but fatal vascular calcification disease characterized by ischemic skin damage and severe pain, often leading to amputation. Currently, there is no specific therapy, but sodium thiosulfate (STS) shows potential curative effects in many related reports. We report a calciphylaxis patient with recurrent skin necrosis which seems the third amputation is inescapable. STS significantly relives the sharp pain and delays deterioration of skin ulcer.

Case Description: A 64-year-old Chinese male with 23-year hemodialysis history had recurrent and progressively worsen acro-skin ulcer accompanied by extremely pain. His highest pain score for numeric pain rating scale (NRS) was 9, which made him behave suicidal tendency. He had twice amputations of left fingers and right lower limb, there is still an emerging ulcer on his left heel (Fig.1) with unmanageable pain. His previous amputating wound was also poor-healed after half a year of surgery. X-rays showed the large vessel calcification (red arrows) which suspected of supplying blood at the necrotic site(Fig.2). A skin biopsy on his amputated right lower leg showed extensive calcium deposition in small vessel walls(Fig.3). He was diagnosed as severe calciphylaxis and we conducted a comprehensive therapy based on intravenous STS with the daily increasing dose from 3.2 g/d to maintain with 6.4 g/d after 5 days. After one-week treatment, the patient felt pain significantly relieved (Table) and 3 months later, his amputating wound gradually crusted so that a third amputation was avoided.

Discussion: Although there is no large randomized clinical trial to confirm the effect of STS in calciphylaxis patients, the use of STS significantly reduces pain and the patient avoids the third amputation. It is suggested that STS also has a certain therapeutic effect on severe calciphylaxis, which mainly relies on relieving pain and delaying the progression of skin ulcers.



FR-PO445

Dialysis Initiation Improves Calcification Propensity

Belen Ponte,[1] Andreas Pasch,[2] Pierre-Yves F. Martin,[1] Sophie M. De Seigneux.[1]
[1]University Hospital of Geneva, Geneva, Switzerland; [2]Calciscon AG, Nidau, Switzerland.

Background: Cardiovascular morbidity and mortality is high in patients starting dialysis and could be related to modifications of calcification inducers and inhibitors by dialysis, promoting cardiovascular events. The impact of dialysis initiation on serum calcification propensity evolution and arterial stiffness is however not known. We therefore, prospectively determined the evolution of the T_{50}-value and its main determinants, as well as pulse wave velocity (PWV) over the first three months of dialysis initiation.

Methods: We analyzed the evolution of T_{50}, fetuin-A and phosphocalcic parameters before dialysis initation (M0), and monthly until month three (M3) of incident patients starting hemodialysis (HD) or peritoneal dialysis (PD) in two tertiary Swiss University Hospitals. Arterial stiffness was assessed by pulse tonometry at M0 and M3, and biological parameters were compared between M0 and M3 and before/after HD. Linear mixed models were used to assess parameter evolution over time taking into account repeated measures and other influencing variables.

Results: Forty-six patients on HD and 12 on PD were followed. Among them, 45 were male (78 %) with median age of 67 years (25^{th}-75^{th}: 54-77). T_{50} significantly increased between M0 and M3 from 183 (120-266) to 246 (175-330) minutes, p<0.001. Fetuin-A, calcium and magnesium also increased while phosphate decreased. Factors associated with T_{50} changes over time were fetuin-A, phosphate and magnesium (p<0.001). Fetuin-A changes were associated with inflammation-related factors (albumin, crp) but not phosphocalcic parameters. Arterial stiffness was not significantly modified over 3 months. PD and HD initiation showed similar trends.

Conclusions: Dialysis initiation significantly improves calcification propensity and fetuin-A levels. These modifications do not explain the high mortality related to dialysis initiation. The clinical relevance of using T50 values to initiate dialysis awaits further studies.

FR-PO446

Acid-Base Dynamics in Allo-Hemodialysis Treatments: Quantitative Insights from a Novel Physiology-Based Mathematical Model

Alhaji Cherif,[1] Vaibhav Maheshwari,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2]
[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.

Background: In some areas of the world access to conventional hemodialysis (HD) is elusive, resulting in millions of premature deaths every year. Allo-hemodialysis (alloHD) is a substantially simplified and less costly dialysis modality, in which the blood of a healthy subject ("buddy") flows counter-current to the patient's blood through the dialyzer. Solutes, including bicarbonate, are transferred across the membrane. In this study, we proposed a physiology-based mathematical model to explore the impact of alloHD on the patient's and buddy's acid-base status.

Methods: A dynamic model of physiological regulation of HCO_3^-/CO_2 buffering system with Henderson-Hasselbalch mass-action kinetics is used to describe a coupled transfer between patient and buddy via alloHD. The model incorporates production of CO_2 and H^+, loss due to non-bicarbonate buffering, and ventilation. In addition, we assume a normal renal function and regulation of HCO_3^-/CO_2 in the buddy, but not in the patient. The patient model is parameterized to yield various degrees of metabolic acidosis, while the buddy model is parameterized to physiological values.

Results: Figure 1 shows an example of acid-base dynamics. AlloHD is able to correct patients' acid-base status. Interestingly, there are only minimal changes to the buddy's acid-base status. The buddy's kidney function affects the extent to which the patient's acid-base status is corrected. Furthermore, since buddy's renal function is fully intact, we observe a secondary compensation where HCO_3^-, pCO_2 and pH initially decrease before regulatory compensations restore the buddy's acid-base status.

Conclusions: Our findings indicate that an alloHD session can restore the patient's acid-base status. Our modeling suggests that there is minimal disturbance in buddy's acid-base status while providing substantial corrective regulation of patient's acid-base homeostasis. Although our modeling results are promising, there is a need for further empirical investigation to verify the predictive power of the model.

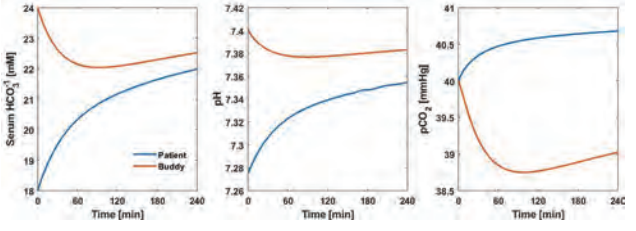

Figure 1: Temporal dynamics of acid-base status in patient and buddy during alloHD

Cardiac Stunning During Haemodialysis: The Therapeutic Effect of Intradialytic Cycling

Scott Mcguire,[2] Gordon Mcgregor,[1,2] Nithya Krishnan,[1,2] Derek Renshaw,[2] Elizabeth Horton.[2] *[1]University Hospitals Coventry & Warwickshire NHS Trust, Coventry, United Kingdom; [2]Coventry University, Coventry, United Kingdom.*

Background: Cardiovascular risk is elevated in end stage renal disease (ESRD). Left ventricular dysfunction is linked to repetitive transient ischemia occurring during maintenance haemodialysis (HD); cardiac stunning can subsequently occur defined as myocardial regional wall motion abnormalities (RWMA). Ischemic RWMA have been documented during HD resulting in maladaptive cardiac remodelling and increased risk of heart failure. Intra-dialytic exercise is well tolerated and can improve quality of life and physical function. It may also attenuate HD induced cardiac stunning. The aim of this exploratory study was to assess the effect of intra-dialytic cycle ergometry on cardiac stunning.

Methods: Twenty exercise naïve participants on maintenance HD (59 ± 11 yrs) underwent resting echocardiography and maximal cardiopulmonary exercise testing.

Subsequently, cardiac stunning was assessed with myocardial strain derived RWMAs at four time-points during 1) standard HD, and 2) HD with 30 mins of sub-maximal intra-dialytic cycle ergometry at a workload equivalent to 90% of oxygen uptake at the anaerobic threshold (VO_2AT).

Results: Compared to HD alone, HD with intra-dialytic exercise significantly reduced RWMAs after 2.5hrs of HD had elapsed (Total 110 ± 4, mean 7 ± 4 segments vs. total 77 ± 3, mean 5 ± 3 respectively; p = 0.008). Global cardiac function, intra-dialytic haemodynamics and left ventricular volumetric parameters were not significantly altered with exercise.

Conclusions: Intra-dialytic exercise, completed after one hour of maintenance HD, significantly reduced cardiac stunning. Thirty minutes of sub-maximal exercise at 90% VO_2AT was sufficient to elicit this acute cardio-protective response.

Examining Mortality in the Multinational Observational Study of Continuous Renal Replacement Therapy (CRRT) Practices

Javier A. Neyra,[1] Michelle Secic,[2] Oleksa G. Rewa,[3] Andrew A. House,[4] Divya Monga,[5] Luis A. Juncos,[6] Robin Piazza,[7] Sean M. Bagshaw,[3] Stuart Goldstein,[8] Michael Heung.[9] *[1]University of Kentucky Medical Center, Lexington, KY; [2]Secic Statistical Consulting, Inc., Cleveland, OH; [3]University of Alberta, Edmonton, AB, Canada; [4]LHSC University Hospital, London, ON, Canada; [5]University of Mississippi Medical Center, Madison, MS; [6]Central Arkansas Veterans Healthcare System, Little Rock, AR; [7]Watermark Research Partners, Inc, Indianapolis, IN; [8]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [9]University of Michigan, Ann Arbor, MI.*

Background: Risk-stratification of patients receiving CRRT to guide practice is direly needed. Utilizing data from a registry of critically ill adults receiving CRRT, we report mortality and kidney recovery rates and examine clinical parameters associated with mortality.

Methods: Multi-national observational registry study including critically ill adults (age ≥18 and ≤89 years) receiving CRRT. Patients who received CRRT for <48 h or other type of acute RRT before CRRT were excluded. Moderate and severe kidney disease at baseline were defined as baseline serum creatinine >265 μmol/L and ESKD/kidney transplant, respectively.

Results: 566 critically ill patients receiving CRRT were included. Mean (SD) age was 58.7 (14.3) yrs., 58.5% were male. Mean BMI was 31.1 (8.0) kg/m^2. Median [range] Charlson and APACHE-II scores were 2.0 [0.0-18.0] and 29.0 [9.0-50.0], respectively and 106 (18.7%) patients had moderate/severe kidney disease at baseline. Median days from ICU admission to CRRT initiation was 1.0 [0.0-52.0] and 213 (37.6%) patients had fluid overload (FO%) ≥10% at CRRT initiation. Median SOFA at CRRT initiation was 15.0 [6.0-23.0]. Mean delivered CRRT dose was 33.1 (14.1) ml/kg/h and the median FO% per CRRT-day was 1.4% [0.3%-7.0%]. ICU mortality rate was 48.4%. In a multivariable Cox model, age (>60 vs ≤60), BMI (>29.7 vs ≤29.7), moderate/severe kidney disease at baseline, FO% per CRRT-day (>1.4% vs ≤1.4%), the absence of circuit anticoagulation, diagnosis of sepsis or acute-on-chronic liver failure, and serum bicarbonate at CRRT initiation (≤20 vs >20 mmol/L) independently associated with higher ICU mortality. Among 217 survivors without moderate/severe kidney disease at baseline, 142 (65.4%) recovered kidney function no longer needing RRT at hospital discharge.

Conclusions: Approximately one of two critically ill adults receiving CRRT died in the ICU. However, almost two-thirds of survivors recovered kidney function sufficiently enough to be independent of RRT. We identified clinical parameters independently associated with ICU mortality. This registry can help develop and validate risk-stratification tools in this susceptible population, and identify modifiable risk factors for evaluation in clinical trials.

FR-PO449

Predictors of Hypophosphatemia and Outcomes During Continuous Renal Replacement Therapy

Rachel J. Hendrix,[1] Margaret C. Hastings,[2] Michael J. Samarin,[1] Joanna Q. Hudson.[2,3] *[1]Methodist University Hospital, Memphis, TN; [2]University of Tennessee College of Medicine, Memphis, TN; [3]University of Tennessee College of Pharmacy, Memphis, TN.*

Background: Hypophosphatemia occurs in up to 80% of patients undergoing continuous renal replacement therapy (CRRT) and is associated with poor outcomes. Whether pre-emptive phosphate supplementation is warranted in select patients has not been adequately explored. This single-center, retrospective cohort study evaluates predictors of hypophosphatemia and characterizes treatment approaches in adult patients undergoing CRRT.

Methods: Patients requiring CRRT for at least 12 hours were divided into two groups based on the presence or absence of hypophosphatemia as defined by serum phosphorus <2.5 mg/dL. Select laboratory values at baseline and during CRRT, medications and nutritional sources affecting phosphorus, and CRRT parameters were compared. Patient outcomes including acute kidney injury (AKI) resolution, freedom from renal replacement therapy (RRT) at hospital discharge, duration of intensive care unit (ICU) and hospital stay, duration of mechanical ventilation, and ICU mortality were evaluated.

Results: Seventy-two patients were included. The group was 43% female and 51% African American. CRRT was ordered for AKI in 83% and for end-stage renal disease in 15% of patients. Hypophosphatemia occurred in 45 patients (63%). Mean time to development of hypophosphatemia was 34 ± 22 hours. Patients who developed hypophosphatemia received a longer duration of CRRT (p=0.001), were more likely to have a diet ordered (p=0.005), less likely to have received calcium infusions (p=0.045), and had lower phosphorus (p=0.017) and potassium levels (p=0.038) and higher calcium levels at baseline (p=0.048). Development of hypophosphatemia was associated with an increased duration of ICU stay (p=0.014) but not with the other patient outcomes evaluated. Twenty-seven of the 45 patients (60%) who developed hypophosphatemia received phosphorus supplementation with near equal use of intravenous, oral, and combination routes. Only 16 patients (36%) achieved resolution of hypophosphatemia while on CRRT.

Conclusions: Hypophosphatemia is common, difficult to correct, and contributes to longer ICU stays in patients requiring CRRT. A pre-emptive approach to address hypophosphatemia including aggressive supplementation strategies to correct phosphorus is warranted in patients requiring CRRT.

FR-PO450

Development and Validation of a Predictive Model for Delivered Dose in Continuous Renal Replacement Therapy

Pablo E. Galindo, Armando Jezael Martinez-Rueda, Ricardo Correa-Rotter, Olynka Vega. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubirán, Mexico City, Mexico.*

Background: Continuous renal replacement therapy (CRRT) has become one of the most relevant therapies for acute kidney injury and critical patients. Since the beginning there has been controversy about delivering, measuring, and defining ideal dose. Measuring effluent volume related to body weight has been the method of choice for the last years. It's well known that prescribed dose and delivered dose differ significantly, mainly because of down time, the effect of pre-dilution replacement, and the dialyzer capacity to saturate the effluent. Current practice recommends prescribing 25% more dose to achieve the desired goal. A tool that could account for the three main factors that lower the dose and could predict de delivered dose, could be of great help for the daily prescription of CRRT. The objective of this study is to validate the results of the proposed model in our Institution.

Methods: We developed an app-based model programed in Xcode® for IOS, with a prescription step method, and patient based format, that considers: down time, pre-dilution replacement, and effluent saturation. The model is given a desired therapy, and then calculates the simulated delivered dose. For validation we evaluated since March 2019, 5 treatments of CRRT in CVVHDF mode, and run 15 dose evaluations by measuring simultaneously: BUN pre-filter pre-dilution, BUN pre-filter post-dilution, and UN of the effluent solution. We then compared the delivered dose with the results of the predictive model.

Results: We found good correlation compared to the delivered dose. We conducted a Pearson correlation that showed: r =0.91, 95% CI= (0.74 - 0.97), R^2=0.82, and a P value of <0.0001. To evaluate agreement we conducted a Bland Altman plot we demonstrated that 100% of results where between the 11% error: (Bias= -2, SD of Bias 4.2,95% Limits of agreement (-11– 5.5).

Conclusions: Even though the sample was small, the delivered dose predictor computes accurate results as compared to the delivered dose. The App based tool can help predict de delivered dose given to a patient, it can be of great utility to simulate different therapies with different prescriptions, and compare different results. At present more patients and treatments are being continuously evaluated to strengthen even further the results.

FR-PO451

Prognostic Potential of Calcitriol in the Patients Requiring Postoperative Continuous Renal Replacement Therapy After Liver Transplantation

Haksoo Kim,[1] Seong hoon Kim,[1] Hyang-Sook Park,[2] Eun kyoung Lee,[3] Jai won Chang.[1] *[1]Division of Nephrology, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Department of Nursing, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, Dankook University College of Medicine, Cheonan-si, Republic of Korea.*

Background: The mortality of the patients with End-Stage Liver Disease and renal dysfunction is high. It is important to know and correct the predicting risk factors of mortality in the patients requiring continuous renal replacement therapy (CRRT) after liver transplantation (LT). lmmunomodulatory and anti-inflammatory effects of calcitriol, produced by liver and kidney, improved survival rate in the animal experiment underwent solid organ transplantation. We investigated whether lower calcitriol level is associated with the mortality in in the patients requiring CRRT after LT.

Methods: We conducted a retrospective study consisted of 65 patients requiring CRRT after LT. Their demographic data and biochemistry parameters were obtained at the initiation of CRRT by reviewing electronic medical records. The deficiency of calcitriol was defined as its plasma level < 10 pg/ml. Primary end point was 180-day mortality from the initiation of CRRT after LT.

Results: The subjects were divided into calcitriol deficient group (CDG, n=36) and calcitriol non-deficient group (CNDG, n=29). There were no significant differences in demographics between two groups. Compared with CDG, hematocrit (26.3 ± 2.3 vs. 20.5 ± 5.1 (%), p=0.045) and 25(OH)D3 (7.2 ± 2.8 vs. 2.8 ± 1.2 (ng/ml), p=0.011) were higher in CNDG at the initiation of CRRT. In contrast, 180-day mortality in CDG (30.6%, 11/36) was higher than that of CNDG (3.4%, 1/29, p=0.005). By Cox regression analysis, calcitriol deficiency (OR 25.9, 95% CI 2.72-246.9, p=0.005) and Risk, Injury, Failure, Loss of kidney function, and End-stage kidney disease (RIFLE) classification (OR 0.4, 95% CI 0.16-0.99, p=0.046) was risk factor of mortality after adjusting Model for End-Stage Liver Disease (MELD) score, RIFLE and 25(OH)D3.

Conclusions: Calcitriol deficiency is associated independent risk factor with the mortality in the patients requiring CRRT after LT. In the future, randomized interventional trial is necessary to confirm whether calcitriol is a correctable risk factor to improve the survival in them.

FR-PO452

Accelerated Venovenous Hemofiltration (AVVH): Piloting a Transitional Renal Replacement Therapy in the Intensive Care Unit

Paul Endres,[1] Tyler Parris,[2] Sophia Zhao,[1] Megan F. May,[2] Mary H. Sylvia-Reardon,[1] Nicole Bezreh,[1] Roberta L. Culbert-Costley,[1] Lillian Ananian,[1] Russel J. Roberts,[1] Natasha Lopez,[1] David M. Charytan,[3] Nina E. Tolkoff-Rubin,[1] Andrew S. Allegretti.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]BWH/MGH, Boston, MA; [3]New York University School of Medicine, Bronx, NY.*

Background: The need for continuous renal replacement therapy (CRRT) is associated with high mortality and resource use in the ICU. There are no guidelines establishing optimal timing of transition from CRRT to intermittent hemodialysis (iHD). AVVH is a form of CRRT that allows for higher blood flows, increased hemofiltration rates, no anticoagulation, and a 10 hour treatment period, as a transition between CRRT and iHD, and assessed treatment characteristics.

Methods: Quality improvement pilot aimed to achieve a safe and effective transition between CRRT and iHD using AVVH at large academic medical center between October 2017 and August 2018. AVVH treatment doses, blood flows, clearances, filter clotting, and patient outcomes were recorded.

Results: 51 patients received a total of 142 complete AVVH treatments. 11 (8%) patient treatments were not completed due to inadequate blood flows (3), filter clotting (7), and change to comfort measures (1). Average prescription was: treatment time 9.3 (± 1.6) hours, blood flow 350 (± 22) mL/min, replacement fluid rate 4.1 (± 0.3) L/hr, ultrafiltration volume 2.0 (± 1.1) L/treatment, urea reduction ratio 28 (± 17)%/10 hrs. 32/51 (69%) patients received sequential daily treatments (range 2-13 treatments). In-patient mortality was 31%, length of stay 53 (± 49) days. 36/51 (70%) patients successfully transitioned to iHD, 10/51 patients (20%) recovered renal function after AVVH, and 4/46 (8%) patients required readmission to the ICU after developing hypotension on iHD.

Conclusions: AVVH was successfully integrated into our ICU program as an innovative transition therapy between CRRT and iHD. It has tremendous potential to reduce ICU readmission and healthcare costs. Further study is needed to determine its impact on resource utilization and patient outcomes.

Patient Characteristics

AKI Cases	44 (86%)
Age (years)	61 (±15)
Apache Score	25 (±7)
Use of Vasopressors	43 (30%)
In-Hospital Mortality	16 (31%)
Pre-AVVH BUN (mg/dL)	44 (±17)
Post-AVVH BUN (mg/dL)	31 (±14)

FR-PO453

Efficacy and Safety of High-Volume Hemofiltration (HVHF) in Patients with Septic Shock and AKI: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Sherida N. Edding, Brian Michael I. Cabral. *Department of Medicine, St. Luke's Medical Center - Global City, Taguig City, Philippines.*

Background: Septic Shock is among the most common causes of death in the intensive care unit (ICU). The underlying pathophysiology involves an overactive immune response. It has been theorized that blood purification technique that reduces the levels of inflammatory cytokines and/or bacterial toxins could mitigate this response. High-volume hemofiltration (HVHF) is a blood purification technique that has been studied to improve outcome associated with septic shock. Our aim is to do a systematic review of randomized controlled trials that assessed the use of HVHF in septic shock.

Methods: A comprehensive literature search from the PubMed, Embase, Cochrane Library, and Ovid was performed with the following search terms: Hemofiltration, Septic Shock, Acute Kidney Injury. The search was limited to randomized-controlled trials that compared HVHF to Conventional (as dictated by the Surviving Sepsis Guidelines) and/or Standard-Volume Hemofiltration (SVHF). Six prospective clinical trials were selected and analysed using Cochrane Revman v5.3. The primary outcome was 28-day mortality. Other outcomes assessed were dialysis dependence, length of ICU and hospital stay, vasopressor requirement and adverse events.

Results: Six trials comprising 745 patients were selected. 373 patients treated with HVHF and 372 patients in the control group were included. Pooled analysis of the 6 trials for 28-day mortality did not show a statistically significant difference between HVHF and control (745 participants, OR: 0.90, 95% CI 0.67-1.21). There were no noted significant difference between groups for any of the secondary outcomes. Adverse events, including electrolyte abnormalities and secondary infections, were more commonly observed in HVHF-treated patients, although reporting was inconsistent across studies.

Conclusions: There is insufficient evidence to support the therapeutic benefit for routine use of high-volume hemofiltration in patients with septic shock. Larger trails are needed to fully assess clinically relevant outcomes as well as cost-effectiveness.

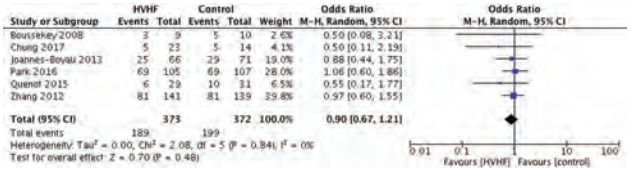

Figure 1. Forest Plot for 28-Day Mortality

FR-PO454

Effectiveness of Implementation of Hemodiafiltration and Achieving Target Convective Volume: Results from HDFit Trial

Murilo H. Guedes,[1] John W. Larkin,[2] Ana C. Santos,[1] Ana Beatriz L. Barra,[2] Carlos E. Poli de Figueiredo,[3] Americo L. Cuvello neto,[4] Maria Eugenia F. Canziani,[5] Jorge P. Strogoff-de-Matos,[7] Sinaia C. Yazawa,[6] Jochen G. Raimann,[8] Peter Kotanko,[8] Bernard J. Canaud,[9] Roberto Pecoits-Filho.[1] *[1]Pontificia Universidade Católica do Paraná, Curitiba, Brazil; [2]Fresenius Medical Care, Waltham, MA; [3]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil; [4]Hospital Alemão Oswaldo Cruz, Sao Paulo, Brazil; [5]Federal University of Sao Paulo, Sao Paulo, Brazil; [6]Fresenius Medical Care, Rio de Janeiro, Brazil; [7]Universidade Federal Fluminense, Niteroi, Brazil; [8]Renal Research Institute, New York, NY; [9]FMC Deutschland GmbH, Bad Homburg, Germany.*

Background: Hemodiafiltration (HDF) is associated with better outcomes compared to hemodialysis (HD), provided adequate convective volumes (CV) are achieved. Implementation of protocols targeting optimal CV have not been well described.

Methods: HDFIT was a randomized controlled trial studying the impact of postdilution high-volume online HDF versus high-flux HD on measured physical activity (NCT02787161). HDFIT included stable patients (Kt/V ≥1.2, permanent access, vintage ≥3 to ≤24 months). Clinic staff were trained to use Fresenius 5008 CorDiax® HDF machines the day before/morning of randomization visit. HDF was performed in 6-month follow-up with a CV target of 22L/treatment. We assessed implementation of HDF with a median achieved CV >22L across treatments.

Results: HDFIT randomized 195 patients (HDF n=97, HD n=98) at 13 clinics with mean age 53±15.1 years and 11% used a permanent catheter. There was an 8% and 11% dropout rate in HDF and HD groups. HDF group had 95 patients with CV data recorded (median=70 treatments/patient). Median treatment time was 235 (IQR 232 to 240) and 235 (IQR 233 to 240) minutes for HD and HDF. Median CV >22L was achieved in 86% (82 of 95) of HDF patients during follow-up. Monthly mean CV ranged from 24L to 25L (Figure 1). At 3-months, distinctions were found in mean Kt/V (HDF=1.8±0.4, HD=1.6±0.4; p<0.001) and phosphate (PO4) (HDF=4.8±1.3, HD=5.2±1.4 mg/dL; p=0.022). Distinctions were maintained at 6-months in mean Kt/V (HDF=1.8±0.5, HD=1.7±0.4; p=0.028), yet not PO4.

Conclusions: HDF was successfully implemented in the HDFIT trial with 86% of patients achieving protocol CV target. Monthly mean CV was consistently >22L in follow-up. HDF provided higher Kt/V throughout follow up and more PO4 removal at 3 months. HDF appears to be an easily implementable technique with brief training required.

FR-PO455

Improved Survival with High-Volume Hemodiafiltration in Argentina: A Propensity Score-Matched Cohort Study

Marcelo D. Ferder,[3] Xiaoling Ye,[1] Jochen G. Raimann,[1] Peter Kotanko,[1] Marcelo H. Puddu,[2] Cristina Marelli,[3] Adrian M. Guinsburg.[3] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care Argentina, buenos Aires, Argentina; [3]Fresenius Medical Care Latin America, Buenos Aires, Argentina.*

Background: While hemodialysis (HD) is the current standard of care, hemodiafiltration (HDF) adds high convective volume to remove middle molecules. We compared all-cause mortality in Fresenius Medical Care Argentina patients treated with either HDF or high-flux HD.

Methods: Data were extracted from Fresenius EuCliD® database and comprise treatments between 11/2011 and 05/2018. Pts were divided patients into those treated with HD (control group), high-volume (HV) HDF (>70% of treatments with >23 L substitution volume), and low-volume (LV) HDF (< 23 L substitution volume). The baseline period comprised 3 months before the HD-to-HDF switch, it was followed by 1 month washout period. Pts were for 1 year, death, or lost to follow-up. To minimize bias by indication, HDF pts were propensity score matched to HD pts by age, gender, diabetes, vintage, fluid status (determined by bioimpedance), vascular access, systolic blood pressure, phosphate, and albumin.

Results: We selected 12,911 pts from 73 centers (11,111 HD; 1,800 HDF). Propensity score matching resulted in 537 HD and 545 HDF patients (Table 1). Kaplan-Meier analysis showed a survival benefit of HV-HDF vs. HD (11.46 vs 22.5 deaths/100 pt-years, p=0.039, figure 1), but not for LV-HDF (23.4 vs 22.5 deaths/100 pt-years).

Conclusions: Within the known limitations of observational trials (patient selection bias, residual confounding) our propensity score matched multicenter study shows a survival benefit of HV-HDF, but not LV-HDF, over HD in Argentinian patients.

Table 1:

	HD	HDF	
	Mean (SD)	Mean (SD)	p
Age (yrs)	57.9 (16.9)	56.2 (15.7)	0.14
Male %	60	70	0.03

FR-PO456

Safety and Efficiency of Low-Molecular-Weight Heparin (LMNH) Administered in the Venous Line of Patients Treated by Online Hemodiafiltration and High Flux Hemodialysis

Hebibi Hedia,[1,3] David Attaf.[2,4] *[1]NephroCare, Villejuif, France; [2]Fresenius, Fresnes, France; [3]NephroCare, Bièvres, France; [4]Beregovoy Hospital, Nevers, France.*

Background: Removal of low molecular weight heparin (LMWH) occurs during high flux hemodialysis (HF-HD) and online hemodiafiltration (OL-HDF) if administered before the dialysis session in the arterial line of the extracorporeal HD circuit. It is recommended to administer (LVMH) through the venous line to improve anti-coagulation efficacy. The goal of our study is to evaluate efficacy, and safety of LMWH administered through the venous line in OL-HDF and HF-HD patients

Methods: We enrolled 49 OL-HDF and 48 HF-HD patients from February to October 2018 (mean age 66 yrs.arteriovenous fistula 90%, the average dialysis time 240 min). Three consecutive 6-week periods (i.e. 5400 dialysis sessions) were analyzed according to the path and dose of (LMWH) administration: Phase I (arterial line), phase II (venous line), phase III (reduced dose). Phase I and II involved HF-HD + OL-HDF patients, and phase III involved only Ol-HDF patients. In each session we evaluated filter and chamber clotting (semi-quantitative visual scale), venous pressure, KT/V, volume infused in OL-HDF. The 3 periods were done with FX membranes (90%), BK, BG

Results: 34 %, 63 % and 66% of membranes were scored as "clean" during phases I, II, III respectively (p<0.05). 9%, 0.6% and 0.4 % of membranes clotted during phases I, II, III respectively. 75%, 93% et 95% of venous chambers were clean during phases I, II, III respectively (p<0.05). 1%, 0%, 0% were clotted with loss of circuit during phases I, II, III respectively (p<0.05). Average LMWH doses were: 0.43 ml (0.2-0.6) and 0.3 ml (0.2-0.6) of Nadroparin during phases I, II respectively (p<0,001). During phase III, LMWH dose decreased from 33 to 50% for 58% of patients with an anti-Xa target = 0.3ui/ml. Between phases I -III, KT/V improved from 1.71 to 1.83 (p<0.005), Infused volume from 20.7 to 23.7 l. Bleeding time was identical during Ph I - Ph III. In the HF-HD sub-group during phases I and II, venous LMWH administration decreased the average LMWH dose from 0.55 ml to 0.34 ml respectively and improved the quality of blood restitution.

Conclusions: Venous line administration of LMWH at the start of dialysis allows a dose reduction and improvement of dialysis adequacy parameters.

FR-PO457

Hemodialysis (HD) Using Super High-Flux Dialyzer Provides Comparable Efficacy with High-Volume Post-Dilution Online Hemodiafiltration (ol-HDF): A Prospective Crossover Randomized Controlled Trial

Theerachai Thammathiwat,[1,3] Pajaree Chariyavilaskul,[2] Paweena Susantitaphong,[1] Nattachai Srisawat,[1] Somchai Eiam-Ong,[1] Kearkiat Praditpornsilpa,[1] Khajohn Tiranathanagul.[1] *[1]Division of Nephrology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [2]Department of Pharmacology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Department of Medicine, Faculty of Medicine, Naresuan University and Naresuan University hospital, Phitsanulok, Thailand.*

Background: Although high volume post-dilution online hemodiafiltration (ol-HDF) that could remove large toxin such as beta-2 microglobulin (B2M, MW 11.8 kDa) as well as protein-bound toxins especially indoxyl sulfate (IS) and subsequently improve survival of HD patients is now accepted as the best modality for chronic HD patients, the procedure is sophisticated and expensive. The present study was conducted to compare the efficacy in term of large and protein-bound uremic toxin removals between HD using novel super high-flux (SHF) dialyzer which has large pore size close to albumin, PES 17D alpha (Nipro, Japan) and ol-HDF in a non-inferiority fashion.

Methods: A prospective cross-over randomized controlled trial included twelve prevalent HD patients who were randomly allocated into 2 sequences of treatment period of SHF-HD treatment and later ol-HDF period or vice versa. Each treatment period took 12 weeks and divided by wash out phase of 4 weeks of HD using regular high-flux (HF) dialyzer. The primary outcome was removal of B2M in term of reduction ratio (RR). Other small, protein-bound and large uremic toxin removals, albumin loss, and nutritional parameters were also compared.

Results: SHF-HD provided comparable B2M RR with ol-HDF (78.8±4.7 and 76.8±8.1 respectively, p=0.152). In addition, B2M clearance, alpha-1 microglobulin (A1MG, MW 33 kDa) RR, A1MG clearance, and IS RR were also comparable. The spKt/Vurea was not different. Although the albumin loss in dialysate was higher in SHF-HD than ol-HDF(4.2±2.8 and 0.6±0.8 g/session, respectively), the serum albumin levels at baseline and after 12 weeks of SHF-HD treatment were significantly improved from 3.71±0.38 to 3.88±0.22 g/L (p<0.001) while they did not change during ol-HDF period. In addition, normalized protein catabolic rate was significantly increased in SHF-HD compared to ol-HDF (p=0.012) with no significant changed of lean tissue index after 3-month period of the study.

Conclusions: SHF-HD that lower cost and accessibility was non-inferior efficacy to ol-HDF in term of large, protein-bound and small uremic toxin removals without adverse effect on serum albumin which potentially improve long-term survival.

FR-PO458

High-Volume Postdilution Online Hemodiafiltration Is Possible Even at Low Blood Flow Rates

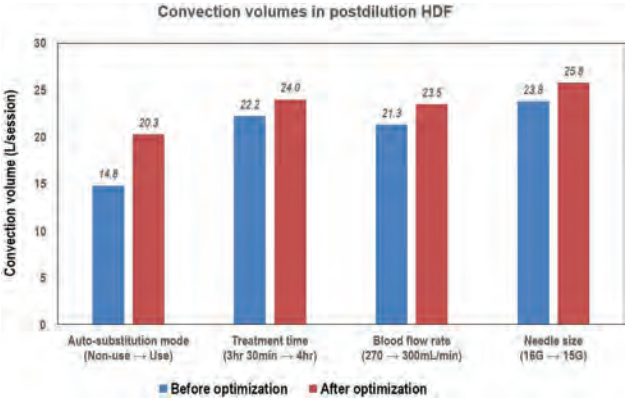
Young-Il Jo,[1] Ki sung Kim,[1] Kyung-Hee Chung,[2] Mi-Jung Seo.[2] *[1]Nephrology, Konkuk University Medical Center, Seoul, Republic of Korea; [2]Dialysis center, Konkuk University Medical Center, Seoul, Republic of Korea.*

Background: Recent evidence suggests that high-volume hemodiafiltration (HDF) improves patient survival. However, in patients with low blood flow rate (BFR), it is not easy to obtain a high convection volume (CV) with postdilution online HDF. The aim of this study was to investigate whether it is possible to achieve high CV, defined as ≥22 L/session, with postdilution HDF even for patients with low BFR.

Methods: A total of 33 consecutive patients undergoing thrice-weekly postdilution HDF were included. In order to obtain a high CV, we optimized treatment parameters such as treatment time (TT), BFR, needle size and filtration fraction (FF) in all patients according to a stepwise protocol, depending on patent's condition. All dialysis machines were equipped with auto-substitution system. Data of 2592 sessions for one month before and after completion of optimization of treatment parameters were analyzed. The mean CV was determined.

Results: The mean age of patients was 62.5±12.5 years, and 45.5% male. Before the initiation of a stepwise protocol, TT was 233.6±10.9 min, BFR was 267.1±11.1 mL/min, and 84.8% of needles were 16G and 15.2% were 15G. The mean CV was 23.8±2.4 L/session and 75.8% of patients reached CV of ≥22 L/session. After completion of optimization, 90.9% of patients reached a high CV with mean of 24.4±2.3 L/session. Of note, TT was 241.8±16.1 min, BFR was 293.6±12.5 mL/min, and 69.7% of needles were 16G and 30.3% were 15G. Interestingly, in 96.70% of patients who reached a high CV, BFR was less than 300 mL/min with mean of 293.5±12.5 mL/min. In addition, 90.0% of patients with BFR of less than 300 mL/min reached a high CV. The changes of CV after optimization of parameters is shown in the figure.

Conclusions: The high convection volumes could be achieved by increasing of BFR and treatment time and optimization of FF even if high BFR was not obtained. High-volume postdilution HDF is possible in routine clinical practice even for patients with low BFR less than 300 mL/min.



FR-PO459

Predilution Online Hemodiafiltration Improves Health-Related Quality of Life (HRQoL) in Patients Undergoing Hemodialysis

Takahiro Kuragano. *Internal Medicine Division of Kidney and Dialysis, Nishinomiya, Japan.*

Background: Sarcopenia and frailty condition cause aggravation of the health-related quality of life (HRQoL) including physical, psychological, and social aspects. Furthermore, these conditions are associated with a high risk of hospitalization and mortality of mantenance hemodialysis (MHD) patients. The effect of OL-HDF on the HRQoL has not been established. In this study, we compared the effect of nutritional conditions and HRQoL between patients treated by OL-HDF and conventional HD using a superflux dialyzer.

Methods: Thirty-eight MHD patients were enrolled in this crossover study. All patients were treated with conventional HD using a superflux dialyzer for first the 4 months (1st CHD period), were switched to predilution OL-HDF for 4 months (OL-HDF period) and then were returned to conventional HD using the superflux dialyzer for the next 4 months (2nd CHD period). We evaluated clinical parameters, the fat mass and muscle mass, and HRQoL using the KDQOL-SF™

Results: No significant difference in serum albumin in the patients with a higher serum albumin level was observed. However, in patients with low albumin, the levels significantly increased (3.6±0.1 to 3.8±0.1 g/dL) during the OL-HDF period. Moreover, although there was no significant difference in the patients with a higher fat mass, fat mass significantly increased (8.0±2.1 to 8.6±2.4 kg) in patients with a lower fat mass during the OL-HDF period. Increased serum albumin and fat mass values during the OL-HDF period returned to baseline levels during the 2nd CHD period. No significant difference in the mental health and body pain score was found during the study period. Although there was no significant difference in the patients with a higher score of physical functioning (PF), role physical (RP), vitality (VT), and social functioning (SF), the patients with a lower score during the 1st CHD period showed significantly increased in these scores (PF: 28.3 ±11.7 to 30.3±11.5, RP: 33.5±9.5 to 37.9, VT: 41.4±5.6 to 43.8±7.4, and SF: 32.4±7.5 to 36.7±8.3, respectively) during the OL-HDF period. These scores decreased to base line levels during the 2nd CHD period.

Conclusions: In this crossover study, we revealed that compared with conventional HD using a superflux dialyzer, OL-HDF significantly improved the nutritional conditions and score of HRQoL in MHD patients with sarcopenia.

FR-PO460

A Comparative Analysis of Clinical Outcomes in Hemodiafiltration and High Flux Hemodialysis: A Retrospective Cohort Study

Yoradyl D. Sunga. *St. Lukes Medical Center, quezon City, Philippines.*

Background: Conventional Hemodialysis is the most common treatment modality of renal replacement therapy. It clears uremic toxin by diffusion with insufficient removal of middle sized molecules. Online hemodiafiltration was introduced to increase its clearance. olHDF is considered to have more clinical benefits due to its combined diffusive and convective mechanism. It has better clearance of phosphate, improves erythropoietin response, better intradialytic hemodynamic stability and quality of life. Primary objective was to compare the effectiveness of HDF and HFHD among ESRD patients on maintenance hemodialysis at SLMC-Global City and SLMC-QC in terms of survival rate, dosage requirement of Erythropoietin Stimulating Agent, rate of patients who achieved the target hemoglobin, phosphorus and Kt/V. Secondary outcome determined the substitution volume that provides survival benefits among patients on online hemodiafiltration.

Methods: This is a retrospective cohort study of all adult patients who underwent two to three sessions a week of high flux HD and hemodiafiltration. The study population included all ESRD patients aged 19 and above, on maintenance dialysis for more than or equal to 3 months on January 2015- March 2017. Online hemodiafiltration at SLMC-Global City uses auto-substitution volume for each treatment session.

Results: A total of 171 patients were included. 83 patients on HDF and 88 patients on HFHD group. There is a higher survival rate for patients on HDF at 1st and 2nd year of dialysis 93.97 and 92.77% respectively. No significant difference in dosage requirement of ESA, rate of patients who achieved target hemoglobin, phosphorus level and kt/V at 3rd, 6th and 12th month. Substitution volume of 15-19 Liters has higher survival rate that those with

20-25 liters. For every unit increase in substitution volume at 12 months, the odds of mortality decreases by 21.46%.

Conclusions: The result showed that there is higher survival rate for patients on HDF than on HFHD, no significant difference on requirement of ESA dose, achieving target phosphorus, hemoglobin and dialysis adequacy between the two modality. There is a trend of survival benefit and improvement in Kt/V for patients with higher substitution volume. We recommend caution in interpretation of these retrospective data. A randomized clinical trials is still needed to validate findings.

FR-PO461

Impact of Hemodiafiltration on Serum Interferon Levels in Patients with CKD: Results from the HDFIT Study

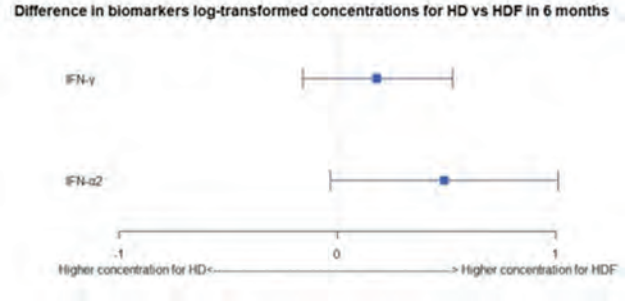
Ana clara S. Almeida,[1] Luiz F. Franco de Lima,[1] Murilo H. Guedes,[1] Caroline Silva,[1] Ana Beatriz L. Barra,[2] Maria Eugenia F. Canziani,[3] Americo L. Cuvello neto,[4] Carlos E. Poli de Figueiredo,[6] Giovani Gadonski,[6] Roberto Pecoits-Filho,[5] Andrea N. Moreno-Amaral.[1] *[1]Pontifícia Universidade Católica do Paraná, Curitiba, Brazil; [2]Fresenius Medical Care, Rio de Janeiro, Brazil; [3]Federal University of Sao Paulo, Sao Paulo, Brazil; [4]Hospital Alemão Oswaldo Cruz, Sao Paulo, Brazil; [5]Arbor Research Collaborative for Health, Ann Arbor, MI; [6]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil.*

Background: Interferons are cytokines that play an important role in immunomodulatory processes. Hemodiafiltration (HDF) optimizes the removal of medium-sized molecules, and although HDF has been associated with a reduction in pro-inflammatory biomarkers, its effect on serum interferon levels have not been described until the present.

Methods: HDFIT was a multicenter randomized controlled trial comparing HDF to high flux hemodialysis, in which biosamples were collected at baseline and after 6 months (HD n=67; HDF n=63). Cytokines measurement was performed through Milliplex® Human Cytokine Magnetic Bead Panel (IFN-g and IFN-a2) (EMD Milipore Corporation, USA).

Results: There was no significant difference in patients demographic characteristics between groups regarding age (53 years old in HD ± 15 vs 53 ± 16 in HDF), gender (68% male in HD vs 71% in HDF) and diabetes (44% in HD vs 28% in HDF). The mean difference (95% confidence interval) between HDF and HD in 6 months was 0.18 (-0.16 — 0.53) and 0.49 (-0.03 — 1.01) for IFN-g and IFN-a2, respectively (Figure 1). This effect was mainly driven by a reduction in interferons observed in the HD group (IFN-a2 0.35 ± 1.8 vs 0.07 ± 1.8 and IFN-g 1.21 ± 1.08 vs 1.11 ± 1.08) and their maintenance on HDF group (IFN-a2 0.78 ± 1.79 vs 0.78 ± 1.79 and IFN-g 1.55 ± 1.12 vs 1.46 ± 1.12).

Conclusions: This study demonstrates that after 6 months of treatment, patients on HDF maintained the concentrations of circulating interferons (IFN-a2 and IFN-g) compared to HD, where the concentration of IFN decreased over time. Based on the knowledge of IFN actions and functions, these findings suggest that HDF may have immunomodulatory effects that could be beneficial to patients with CKD.



FR-PO462

Flexitrate Regional Citrate Anticoagulation in Continuous Venovenous Hemodiafiltration

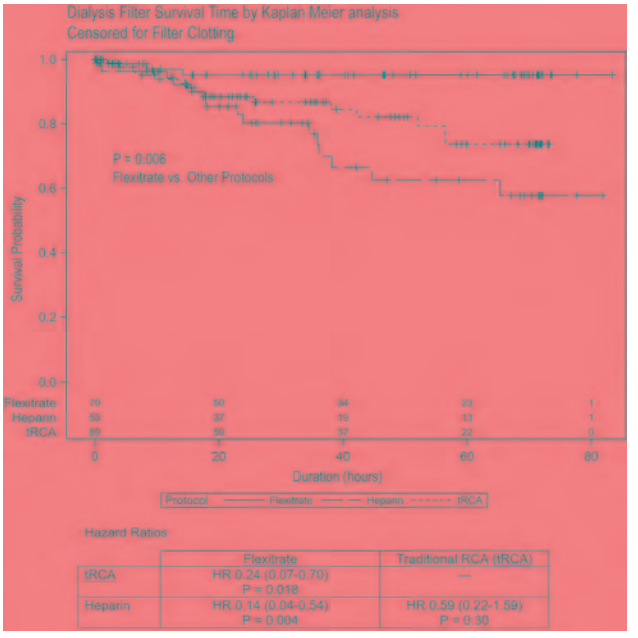
Ilan Lenga,[1,2] Wilma M. Hopman,[3] Adam J. O'Connell,[1] Francesca Hume,[1] Charles C. Wei.[1] *[1]Lakeridge Health, Oshawa, ON, Canada; [2]Faculty of Medicine, University of Toronto, Toronto, ON, Canada; [3]Queen's University, Kingston, AB, Canada.*

Background: This study compared Flexitrate, an innovative regional citrate anticoagulation (RCA) protocol, to traditional RCA (tRCA) and Heparin anticoagulation protocols in intensive care patients treated with continuous renal replacement therapy (CRRT).

Methods: A single-center, retrospective, cohort study, was conducted in a 26-bed ICU in a large community hospital. Consecutive patients from a 6 month pilot of Flexitrate CRRT were compared to consecutive patients from the preceding 9 months receiving tRCA and Heparin CRRT anticoagulation. 80 dialysis sessions (Flexitrate = 2,852 hours, tRCA = 3,580 hours and Heparin = 2,026 hours), performed in 53 patients, were evaluated for filter life, RCA control, and metabolic control.

Results: Filter survival was significantly improved with Flexitrate compared to tRCA (HR 0.24, p=0.018) and Heparin (HR 0.14, p=0.004); see attached Figure. Anticoagulation control was superior with Flexitrate with Patient Ionized Calcium out of target a median of 16% of the time, compared to 27% for tRCA (p<0.001). Filter Ionized Calcium was out of target a median of 6.8% of the time, compared to 23% for tRCA (p= 0.03). Flexitrate produced significantly less alkalosis, hypernatremia, and hypocalcemia than tRCA, and was comparable to Heparin anticoagulation. The only adverse metabolic outcome with Flexitrate was more Hypomagnesemia.

Conclusions: The Flexitrate protocol extended filter life, delivered more consistent anticoagulation, and provided superior metabolic control compared to a tRCA protocol. Filter life was also superior to Heparin anticoagulation, with similar metabolic control. A randomized control trial comparing these protocols is recommended.



Dialysis Filter Survival for the three protocols, censored for filter clotting.

FR-PO463

Haemodialysis (HD) vs. Online Haemodiafiltration (HDF) and Mixed Haemodiafiltration (MHDF): What Place?

Kunigal A. Shivakumar. *Renal Medicine, Russells Hall Hospital, Dudley, United Kingdom.*

Background: HD has been a gold standard of dialysis. High-efficiency on-line HDF is recognised as an advanced modality of treatment improving patient outcome. Yet post-dilution HDF has limitations like increased blood viscosity, protein concentration, high transmembrane pressure impairing uraemic solute removal. Pre-dilution method can partially overcome this but the price to pay is decreased overall efficiency. Joining both modalities can potentially improve conductive and convective solute removal and maintain patients haemodynamic stability.

Methods: Eighteen ESRD adults established on HD for at least one year were chosen. They received 6 months conventional HD, followed by 6 months HDF (with 1.2 HDF factor), then 6 months MHDF. Fresenius 5008 machines were used with FXCorDiax1000 dialysers and therapy monitoring system (TMON). A central delivery system supplied 3 types of fluid and ultrapure water direct to the machines. All patients had cardiovascular instability. Various parameters were measured monthly as per standard UK Renal Association guidelines. SF24 Quality of Life questionnaire was analysed by an independent observer.

Results: Results are summarised in the table with mean values. The increased urea reduction rate on HDF and MHDF over conventional HD was statistically significant, p=0.002 and 0.003 respectively. There was no difference between HDF v MHDF. Similarly the difference in Kt/V between HD v HDF and MHDF was significant, p=0.005 and 0.009 with no difference between HDF and MHDF. Differences in pre-dialysis phosphate level between the 3 modalities was not statistically significant although the post-therapy phosphate value between HD v HDF and MHDF showed a p value of 0.003. The haemoglobin and PTH had no significant differences between modalities. We measured β2 microglobulin and proBNP in the MHDF group, the diffence in 6 months was insignificant. HDF and MHDF patients had higher physical and mental component scores.

Conclusions: On-line HDF and MHDF are superior to conventional highflux dialysis, we could not observe additional benefit between HDF and MHDF. Perhaps using a higher HDF factor for dilution and substitution fluid is required to achieve better results.

Funding: Government Support - Non-U.S.

	URR %	Kt/V	Phosphate (mmol/l)	Haemoglobin (gm/l)	PTH (pmol/l)
HD	64±4.5	1.25±0.43	1.93±0.35	107	31.2±20.3
HDF	71±2.5	1.53±0.40	1.67±0.41	104	25.1±19.4
MHDF	68±3.6	1.41±0.36	1.90±0.38	110	24.1±16.4

FR-PO464

Removal of Middle Molecules Using Medium Cut-Off Membranes in Hemodialysis Mode vs. High-Flux Membranes in Post-Dilutional Online Hemodiafiltration Mode: The REMOC Study

Alexander H. Kirsch,[1] Tanja Komericki-Strimitzer,[2] Alexander R. Rosenkranz.[1]
[1]Medical University of Graz, Graz, Austria; [2]Austrian Agency for Health and Food Safety, Graz, Austria.

Background: Medium-cut off (MCO) dialyzers were shown to provide better clearance of larger middle molecules compared to high-flux HD and hemodiafiltration (HDF). Whether this results in lower predialysis levels in decreased exposure is not clear.

Methods: In this randomized, open-label, cross over study, 27 HD patients were randomized to either 12 weeks of HD with MCO dialyzers (Theranova 400, Baxter) or online post-dilution HDF with high-flux dialyzers (FxCorDiax 800, Fresenius medical care) using maximally achievable substitution volumes. After 12 weeks, patients were crossed-over to the other treatment modality for 12 weeks. Pre-dialysis serum levels of middle molecules (λ- and κ-free light chains [FLC] were assessed at the beginning and end of each treatment period. The primary outcome was efficiency as assessed by predialysis treatment levels of λ- and κ-FLC, as well as safety (serum albumin levels and frequency of adverse events). A mixed linear model based on the delta value to baseline was used to compare the effect of MCO-HD and HDF on FLC levels. Here, treatment modality and randomization order were assumed as fixed effects, the patient as random effect.

Results: Twenty-seven patients were randomized, six dropped out doe to unability to receive randomized study treatment. Twenty-one patients completed the study and were included in the analysis (14 [66.7%] males; mean age 56.9±14.9 years; mean BMI 28.2±7.4; median dialysis vintage 16 [8-40] months). For κ- and λ-FLC, the delta to baseline after 12 weeks of MCO-HD compared to HDF (κ: -0.8±52.3 vs. -8.0±61.0 mg/dL; λ-FLC: 4.2±24.1 vs. -4.2±26.6 mg/dL) was not significantly influenced by treatment modality or order (κ-FLC: p=0.29; λ: p=0.37) but rather by the patient (κ-FLC: p=0.004; λ-FLC: p=0.02). There was no difference in AE incidence or delta serum albumin levels (MCO-HD vs. HDF: 0.0±0.2 vs 0.0±0.3 g/dL) between treatment modalities.

Conclusions: Twelve weeks of MCO-HD treatment compared to twelve weeks of HDF did not signifantly change pre-dialysis levels of κ- and λ-FLC in prevalent dialysis patients. This suggests that MCO-HD clears larger middle molecules as effectively as high-efficiency HDF, which may allow to extend the benefits of HDF to patients and areas where this treament modality is not available.

FR-PO465

In Vitro Cytokine Removal: Comparison of Conventional High-Flux Dialyzers and Middle-Cut-Off Dialyzer (Theranova HDx)

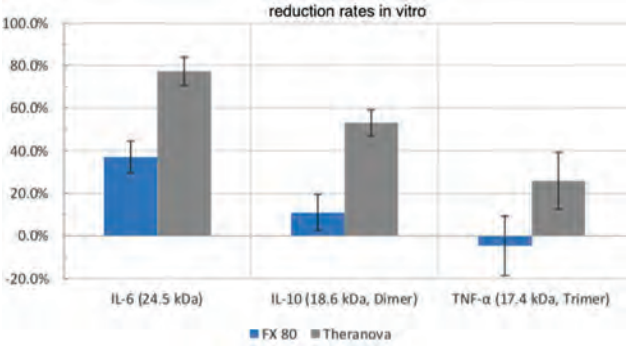
Sebastian Koball,[1] Benjamin Heskamp,[2] Andreas Körtge,[4] Silvius Frimmel,[3] Michael Hinz,[5] Steffen R. Mitzner.[1] *[1]University of Rostock, Rostock, Germany; [2]Fraunhofer, Rostock, Germany; [3]Rostock University Medical Center, Rostock, Germany; [4]Fraunhofer Institute for Cell Therapy and Immunology IZI, Rostock, Germany; [5]Universität Rostock, Rostock, Germany.*

Background: The removal of inflammatory mediators is important for the treatment of acute (ARF) or chronic renal failure (CRF). In ARF and sepsis, attempts is made to achieve removal through the use of high-volume treatments or adsorbers. In CRF, this has so far not been sufficiently addressed, but is important for mortality (MIA syndrome). By using new MCO filters (Baxter Theranova (HDx)), an improvement of cytokine status seems to be possible in both areas. The effectiveness of HDx in the removal of interleukins (interleukin 6, interleukin 10 and TNFalpha in hemodialysis treatments will be assessed.

Methods: The efficacy of HDx was compared to conventional high-flux dialyzers (Fresenius FX80). The measurements were performed in vitro in a 3l pool of fresh frozen plasma (citrate and heparin anticoagulation). IL6 (24.5 kDa) IL10 (18.6 kDa, dimer)) and TNFalpha (17.4 kDa, trimer) were added to plasma (1.5 µg/l each). Samples were taken before and after the dialyzer (after 5, 15, 30, 60, 120 and 180 minutes). In addition to cytokines, albumin and total serum protein concentrations were measured (LEGEND MAX Human IL-6/IL-10/TNF-α; Cobas Mira Plus; Roche LT-AB0103, LT-TP0253). Every test was repeated 5 times.

Results: Theranova HDx showed significantly higher removal rates of all tested cytokines over a period of 180 minutes. A comparison of the concentrations at the beginning and end of the measurements showed: IL-6 reduction - HDx about 80% / FX80 about 40%. IL-10 reduction - HDx about 50% and FX80 about 10%. TNF-αReduction - HDx about 25%; FX80 no reduction The concentration of albumin and total serum protein was not significant different during the treatment in both groups.

Conclusions: Hemodialysis therapy with Theranova HDx appears to be a superior therapy option for the removal of cytokines. This opens up new treatment options for both acute and chronic dialysis patients. However, clinical studies are still necessary to assess the significance in patient treatment.



FR-PO466

Easy, Simple, and Effective Pressure Control by Pinch Valve in CRRT Directly Connected to Extracorporeal Membrane Oxygenation

Haksoo Kim,[1] Seulgi Shin,[2] Jai won Chang.[1] *[1]Division of Nephrology, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Department of Nursing, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: The simultaneous use of continuous renal replacement therapy (CRRT) and extracorporeal membrane oxygenation (ECMO) is increasing in the patients with AKI coexisting with respiratory or circulatory failure in ICU. However, there are no recommended techniques to combine them. Pinch valve is suitable for handling flow capacity by throttling line without corrosion or contamination. Therefore, we investigated whether the external use of pinch valve on the blood lines of CRRT connected to ECMO is helpful to maintain the pressures of CRRT lines in the acceptable pressure range without modifying ECMO settings or inhibiting pressure alarms of CRRT.

Methods: We conducted a prospective observational study in 14 patients (M:F=8:6, age median 50.5 (range 21~75) years, SOFA score 12 (4~16)) requiring CRRT (blood flow rate 150 ml/min) and ECMO (veno-arterial:veno-venous=12:2, FiO_2 60 (40~100) %, cardiac support 90 (70~125) % of normal cardiac index, blood flow rate 3.8 (2.9~5.0) L/min, sweep gas flow 3.0 (1.0~5.0) L/min) between Aug and Oct 2018. The connections of CRRT to ECMO were performed 41 times. Inflow CRRT line is connected after the oxygenator and the outflow CRRT line, before the blood pump in the ECMO circuit. Pinch valve was externally used on inflow and outflow lines of CRRT.

Results: The initial blood flow rate of CRRT was 150 ml/min. Any reduction of blood flow in CRRT on ECMO was not necessary. Before the application of pinch valve, the pressures of CRRT were too high or too low to maintain CRRT directly connected to ECMO circuit. However, after the application of pinch valve, the pressures of CRRT were tolerable and significantly different ($^{*}p<0.05$, $^{**}p<0.001$) from those before the use of pinch valve. CRRT alarms disappeared owing to pinch valve. The changes of CRRT pressures were summarized in Table(Mean±SEM). The median life span of CRRT filter was 63 (range 10~72) hours.

Conclusions: Management of line pressures in CRRT connected to ECMO could be easy, simple and effective by the external application of pinch valve without inhibiting CRRT alarms.

CRRT Pressures on ECMO (mmHg)	Tolerable Range by company	Before use of pinch valve	After use of pinch valve			
			0 hour (n=41)	24 hours (n=32)	48 hours (n=28)	72 hours (n=19)

Outside-In Filtration Technology for Prolonged Filter Life

Dimitrios Stamatialis,[1] Thomas D. Kelly,[2] Mohamed E. Labib.[3] *[1]University of Twente - Faculty of Science and Technology, Enschede, Netherlands; [2]MedCatalyst Consulting, LLC, Highland Park, IL; [3]NovaFlux Inc., Princeton, NJ.*

Background: Maintaining circuit patency is a prerequisite for optimal treatment efficacy and is essential for continuous renal therapies. In currently marketed dialyzers, blood flows in the intra-luminal (IL) space where formation of thrombi inside the fibers leads to filter blockage. This effect limits set life in continuous acute therapies. NovaFlux is developing Outside-In (OI) hemodialyzers in which blood flows in the inter-fiber (IF) space and dialysate flows in the IL space.

Methods: In a simulated extracorporeal circuit we measured pressure drop and filter life using both bovine and donated human blood. Clearance of small and middle solutes were measured in the Outside-In and Inside-Out filter configurations using standard methods. Clotting of different zones of the filter was made by disecting the filter and estimating the number of clots in each zone.

Results: In-vitro data using a conventional dialyzer in an OI configuration (blood outside fiber) reveals significantly lower membrane clogging and extended filter life. OI increases filter life to over 100 h vs ~24 h with standard filter flow with statistically

equivalent clearance[i]. These advantages are due to new hydrodynamics where blood flows in 3-D interconnected flow channels created in the IF space. When a conventional hemodialyzer is used in the OI configuration, we discovered that stagnant zones are created within the filter. Such zones can be eliminated with a modified filter housing that maintains an optimal blood shear rate and uniform velocity distribution. NovaFlux is developing prototype housings to overcome such limitations. [i] Dukhin SS, Labib ME, et al. OI HF for prolonged operation. Jour Mem Sci, 464 (2014) 173–178.

Conclusions: Two key refinements are required for completing commercial OI dialyzers, namely: modified membrane and housing design. Current membranes are characterized by an asymmetrical membrane structure with a smooth tight inner luminal skin (active membrane layer). This membrane structure is reversed for OI so that the blood contacts a smooth active membrane layer on the outer surface of the fiber. We have made progress in developing a hemocompatible OI PES hollow fiber with an outer active hydrophilic membrane layer. OI dialyzers with these modifications should be able to be produced by current production equipment with relatively minor modifications, enabling longer set life and lower anticoagulation.

FR-PO468

Study of Dilution Modes Under Different Operational Conditions in Continuous Venovenous Hemofiltration

Zhongping Huang,[1] Anilchandra Attaluri,[3] Jeffrey J. Letteri.[2] *[1]West Chester University, Glenmoore, PA; [2]Baxter, Nantucket, MA; [3]Pennsylvania State University - Harrisburg, Middletown, PA.*

Background: The landmark CRRT dose trial (Ronco et al, Lancet 2000) was performed in the post-dilution CVVH mode. The clinical benefits provided by different CRRT modes may influence MM clearance. The purpose of this experimental CVVH study was to measure the clearance of small solutes (urea, creatinine) and MM surrogates (vancomycin, inulin) in different dilution modes, degree of pre-dilution, and flow conditions along with MM sieving coefficient (SC) values over extended periods.

Methods: The Prismaflex (Baxter) machine was used to deliver replacement fluid at different dilution points [pre-blood pump dilution (PBP), pre-dilution (PRE) and post-dilution (POST)]. Simulated treatment involved 6 liters of bovine blood (Hct ~ 35%) processed at zero net ultrafiltration for a duration of 240 minutes. A 1.4 m^2 hemofilter (HF 1400) was used. The three experimental conditions were: 1) blood flow rate (Q_B): 190 mL/min; replacement flow rate (Q_R): 2 L/hr, 2) Q_B: 290 mL/min; Q_R: ~3 L/hr, 3) Q_B: 380 mL/min; Q_R: ~4 L/hr. These conditions were chosen to maintain filtration less than 25% in POST. Solute clearance at various times were calculated based on mass balance.

Results: There were significant differences ($p < 0.001$) in urea & creatinine clearance for the different experimental conditions. There was a significant decrease ($p < 0.01$) in urea and vancomycin clearance from POST to PRE and from POST to PBP, although there were no significant differences between PRE and PBP for any of the solutes. Neither urea nor creatinine clearance changed significantly over time for any of the operational conditions and dilution modes. There were significant differences ($p < 0.001$) in inulin and vancomycin clearance in these 3 experimental conditions. No significant differences ($p > 0.05$) in inulin clearance between post-dilution and pre-dilution mode, post-dilution and pre-pump-dilution mode, and pre-dilution and pre-pump-dilution mode were observed. A significant decrease in inulin and vancomycin SC occurred over time under all conditions was most evident in POST.

Conclusions: 1) Small MW solute clearance increased as the extent of pre-dilution decreased 2) MM SC decreased substantially (especially in POST) with time, most likely due to secondary membrane effects. 3) The data obtained by varying pre- and post-dilution percentages are predictable for small solutes but are not entirely consistent for MMs.

FR-PO469

Urea Transfer Kinetics in Allo-Hemodialysis: Results from an Ex Vivo Study

Vaibhav Maheshwari,[1] Nadja Grobe,[1] Xia Tao,[1] Joshua E. Chao,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] RRI_alloHD *[1]Renal Research Institute, New York, NY; [2]Department of Nephrology, Icahn School of Medicine at Mount Sinai, New York City, NY.*

Background: Allo-hemodialysis (alloHD) is a novel, low-cost extracorporeal dialysis modality where the conventional dialysate is replaced by blood from a healthy subject ("buddy"). We are not aware of literature reporting urea transfer across hemodialyzer membranes with counter-current blood flow through the conventional blood and dialysate compartments.

Methods: We developed a mathematical model of alloHD setup comprising the patient and the buddy beaker, the extracorporeal circuit, and the dialyzer. To calibrate the model, we conducted an *ex vivo* alloHD experiment with human whole blood. We dialyzed a 500-mL patient bucket against a 500-mL buddy bucket for 60 minutes. Heparin (5,000 U/L) was used as anticoagulant. Average blood flow rate of 110 mL/min on both sides was achieved by peristaltic pumps. The patient side was initially spiked with urea to simulate pre-dialysis conditions. Blood samples from both sides were collected at multiple time-points into the experiment. Serum urea was measured using automated spectrophotometry.

Results: The urea concentrations on the patient and buddy sides equilibrated rapidly (**Figure 1**). The estimated urea mass transfer coefficient (K_oA) was 853 mL/min. Using this estimated K_oA, the model-based urea concentrations predicted the observed concentration profiles very well.

Conclusions: The estimated urea K_oA of 853 mL/min is similar to a typical urea *in vivo* K_oA reported for conventional hemodialysis (~1000 mL/min). The presence of blood on both sides of the dialyzer membrane did not appear to affect the urea mass transfer capacity of the dialyzer in a clinically meaningful way, and rapid urea equilibrium was achieved in this *ex vivo* alloHD setup. These findings are an important step towards validation of the alloHD concept and planning of future animal experiments.

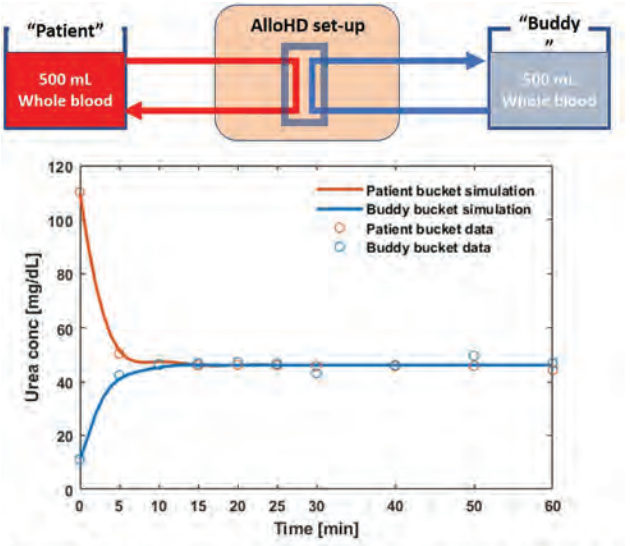

Figure 1: Time-course of urea concentration in the patient and buddy bucket during alloHD. On the patient side, we used two pumps, and their flow rate differential was used to target zero net ultrafiltration.

FR-PO470

A Single-Center Experience Piloting the Tablo Hemodialysis System for Intermittent Hemodialysis (IHD) in an Acute Hospital Setting: A Quality Improvement Project

Mary H. Sylvia-Reardon,[1] Roberta L. Culbert-Costley,[1] Alexis A. Robbins,[2] Andrew S. Allegretti,[1] Nina E. Tolkoff-Rubin.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]MGH, Boston, MA.*

Background: The TABLO hemodialysis system integrates on-demand dialysate production, reverse osmosis (RO) water purification and computerized data collection into a single mobile unit. The system provides a maximum dialysate flow rate (Qd) of 300ml/minute. Kinetic modeling and outpatient clinical experience show that adequacy targets (urea reduction ratios [URR] greater than 65%) can be achieved. This Quality Improvement project was undertaken to evaluate the performance of TABLO in patients undergoing intermittent hemodialysis (IHD) in an acute care setting.

Methods: Between January and February 2019, 25 hospitalized patients with acute (17) or end stage renal failure (8) received hemodialysis therapy with the TABLO. Treatment parameters including URR, ultrafiltration (UF) accuracy, serum potassium and treatment complications were recorded.

Results: TABLO was used for a total of 46 hemodialysis treatments. Thirty two % of patients had weights greater than 100 kg. Vascular access was tunneled catheter (57%) AV fistula (21%) non-tunneled catheter (14%) and AV graft (8%). Ninety two percent used an Opti 180 and 8% used an Opti 200 dialyzer. The average URR was 68% (SD11) with an average dialysis time of 3.7 hours. Pre-dialysis potassium averaged 4.5 mmol/L. Potassium obtained the day after dialysis averaged 4.1 mmol/L. Blood flow rates averaged 371 (SD54) cc/minute. Average prescribed and achieved UF for patients was 1.7 L. Six treatments were terminated early due to access problems, hypotension or clotting. Seven therapies required a second setup due to clotting. These runs were subsequently completed.

Conclusions: This QI project demonstrates that the TABLO provides adequate URR with Qd 300ml/min and accurately meets UF targets in the majority of patients requiring IHD in the acute care setting. Water pressure problems frequently encountered with Fresenius 2008T machines were not encountered with TABLO. The TABLO's small footprint (size of a dormitory refrigerator) facilitates travel to multiple ICUs. The TABLO was welcomed within the space constraints of ICU rooms. Low dose heparin and/ or periodic saline flushes may be required to prevent clotting. Further studies will be required to assess potassium removal in highly catabolic patients.

Ten Thousand Consecutive Treatments Using the Tablo Hemodialysis System in Hospitals and Clinics

Michael A. Aragon,[1] Brittany Lim,[1] Sarah S. Prichard.[2] *[1]Outset Medical, San Jose, CA; [2]Independent Consultant, Montreal, QC, Canada.*

Background: The Tablo® Hemodialysis System is an all-in-one system indicated for use in clinic and hospital settings. Features include an integrated water purification system, the ability to produce dialysate on demand, a simplified user interface, and two-way wireless connectivity for data transfer. This study reports on the clinical experience using Tablo for 10,000 treatments (txs) in the clinic and hospital settings.

Methods: Data on treatment performance and clinically significant alarms (air in venous bloodline, high/low venous pressure, low systolic blood pressure, and blood leak in dialyzer) for 10,000 consecutive dialysis txs was collected using the Tablo system and transmitted wirelessly in real-time to a cloud-based, HIPAA compliant platform.

Results: Tablo was used to treat hemodialysis patients in the clinic and hospital settings using a wide range of treatment times and ultrafiltration rates. The average number of clinically significant alarms was 1.1 and 2.5 per treatment in the clinic and hospital settings, respectively.

Conclusions: In 10,000 treatments within the clinic and hospital settings, Tablo can successfully complete dialysis and ultrafiltration with minimal interruption from clinically significant alarms. This data can be successfully transmitted wirelessly to Tablo's cloud-based, HIPAA compliant server. This extensive clinical experience with Tablo confirms earlier reports of its successful use in smaller studies.

Results for patients treated in the clinic and hospital settings

CLINIC	RESULTS
Txs	5758
Txs ≤ 4 hr (mean tx time ± sd) (%)	5402 (3.4 ± 0.6) (93.8%)
Txs > 4 hr (mean tx time ± sd) (%)	356 (4.6 ± 0.3) (6.2%)
Blood flow rate (mean ± sd)	383.3 ± 33.0 mL/min
Dialysate flow rate (mean ± sd)	299.5 ± 8.8 mL/min
Fluid removed (mean ± sd)	1796.8 ± 1130.9 mL
Avg # of clinically significant alarms (per tx)	1.1
HOSPITAL	RESULTS
Txs	4265
Txs ≤ 6 hr (mean tx time ± sd) (%)	4242 (2.8 ± 1.0) (99.5%)
Txs > 6 hr (mean tx time ± sd) (%)	23 (7.8 ± 1.0) (0.5%)
Blood flow rate (mean ± sd)	325.8 ± 48.6 mL/min
Dialysate flow rate (mean ± sd)	297.8 ± 20.0 mL/min
Fluid removed (mean ± sd)	1758.8 ± 1096.5 mL
Avg # of clinically significant alarms (per tx)	2.5

FR-PO472

Reuse of Dialysis Reverse Osmosis System Reject Water for Aquaponics and Hydroponics

Eason Chang, Chun leong Low. *Nephrology Unit, Hospital Sultan Abdul Halim, Sungai Petani, Malaysia.*

Background: Hospital Sultan Abdul Halim hemodialysis unit located in the district of Sungai Petani in Kedah, Malaysia has started operation since 1998. The dialysis unit has 19 hemodialysis machines and is located in 2 separate buildings which caters to about 90 patients. Hemodialysis is provided by single-pass, proportioning dialysis systems paired with reverse osmosis (RO) system water filtration that rejects 60–70% of the presented mains at the RO system membrane. This reject water is discarded to drain almost universally.

Methods: In our unit, the reject water is used for aquaponics and hydroculture since July 2018. The reject water from one of the building has been repiped and the reject water is then pumped into fish tanks. The amount of reject water is estimated to be between 10000 – 12000 litres per day. The state fisheries department collaborated with us by supplying fish tanks, fingerlings and feed for the fishes. Four 1800 litres capacity tanks, three 700 litres capacity tanks and one 1000 litres capacity tank were used.

Results: The fisheries department performed water testing to determine the suitability of the water for aquaculture. The test revealed water temperature of 31 degrees celcius (25-35), pH of 7.76 (6.5-8.5), ammonia level of 0.001 (<0.02 ppm/mg/l) and dissolved oxygen level of 5.84 (>4ppm). The species of fishes that were bred include Oreochromis aures x Oreochromis mossambicus (Red Tilapia), Oreochromis niloticus (Genetically Improvised Farmed Tilapia), Scortum barcoo (Jade Perch) and Oxyeleotris marmorata (Marble Goby). The fries released were initially 2-3 inches long and weighed about 20-30 grams in average. After a period of 5 months, the fishes grew to an average of 10-11.5 inches and weighed about 400-470 grams. The nutrient rich water from the fish tanks are then recirculated to the vegetable pots via deep water culture. The vegetables that were grown included Amaranthus dubius (red spinach), Sissoo (brazillian spinach), Brassica juncea (mustard), Mentha (mint) and Allium schoenoprasum (chives). These vegetables were harvested and given to patients for consumption.

Conclusions: Reject water that is actually clean and uncontaminated water can be reused to promote water conservation and used for aquaculture and hydroponic activities with encouraging results. It also provides a good biosecurity enviroment for the fishes to grow.

FR-PO473

Hybrid Conductivity/Urea Kinetic Modeling Approach to Calculate Kt/V and Normalized Protein Catabolic Rate with Reduced Need for Postdialysis BUN

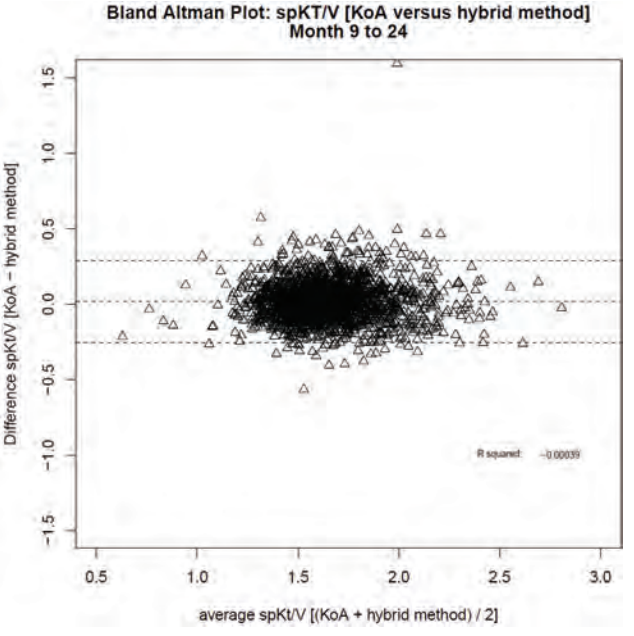
Jochen G. Raimann,[1] Xiaoling Ye,[1] Peter Kotanko,[1] John T. Daugirdas.[2] *[1]Renal Research Institute, New York, NY; [2]University of Illinois College of Medicine, Chicago, IL.*

Background: We present a novel hybrid conductivity /urea kinetic modeling (UKM) method to calculate Kt/V and normalized protein catabolic rate (nPCR) that markedly reduces the need for routine post-dialysis BUN measurement.

Methods: Data from midweek dialysis sessions of patients monitored over a 2-year period were studied. During the initial 8 months (baseline), measured average conductivity clearance, Kecn, and URR were entered into a UKM program to calculate a median patient-specific modeled solute distribution volume, Vcal. During months 9–16 (period 1) and 17–24 (period 2) Kt/V was computed by UKM using URR and estimated dialyzer clearance (conventional method) as well as by the proposed method, which can compute Kt/V using Vcal along with the treatment-specific average Kecn without the need for a postdialysis SUN.

Results: In 1087 patients, the mean (SD) of the median single-pool Kt/V by the conventional method were 1.62 (0.245), 1.66 (0.24) and 1.67 (0.25) during baseline, periods 1 and 2, respectively. During periods 1 and 2, median Kt/V with the new method averaged 1.64 (0.24) and 1.65 (0.24), respectively; differences between the new method and conventional method averaged –0.6% (8.0) and –0.8% (8.4), respectively. nPCR rate was comparable between the two methods. **Figure:** Bland-Altman plot of the bias in median (single-pool) Kt/V using the proposed method compared to the KoA based classic method during Months 9 to 24.

Conclusions: The novel hybrid conductivity-UKM based method of monitoring hemodialysis adequacy is non-inferior to the standard approach. It has the potential to avoid Kt/V errors related to improper peridialytic BUN sampling.



FR-PO474

Clinical Study to Assess the Performance of a Novel Dialyzer with Endexo™ in ESRD Subjects

Jill M. Meyer,[1] Dylan Steer,[1] Lisa A. Weber,[3] Abeer A. Zeitone,[2] Mayuri Thakuria,[2] Chiang-Hong Ho,[2] Sharanya Vemula,[2] Shakil Aslam,[2] Claudy Mullon,[2] Robert J. Kossmann.[2] *[1]Balboa Nephrology Medical Group, La Jolla, CA; [2]Fresenius Medical Care North America, Waltham, MA; [3]Kansas Nephrology Physicians, P.A., Wichita, KS.*

Background: Surface modifying macromolecules (SMM) may improve the hemocompatibility of hemodialyzers in the development of heparin free hemodialysis (HD). The aim of this clinical trial was to assess the performance and safety of a new dialyzer using a novel fluorinated SMM additive (Endexo™) in ESRD Subjects.

Methods: This prospective, sequential, multi-center, open-label study (NCT# 03536663) was designed according to the FDA's Guidance for the premarket testing of hemodialyzers. Adult subjects, prescribed thrice-weekly HD for at least 180 days, were enrolled at 3 HD clinics in the US. After completing 12 HD sessions (4 weeks) with an Optiflux® F160NR dialyzer (Opti), subjects received 36 HD sessions with the dialyzer with Endexo (EndX). Evaluated parameters included spKt/V, URR, albumin, β2-microglobulin (β2M), complement activation for Opti and EndX, and hemoglobin and platelet count for EndX only.

Results: A total of 23 subjects (60.5±15.1 yr., BW 70.9±17.4 kg, 17 males) were enrolled and 17 subjects completed the study, 6 subjects were withdrawn due to missed visits not related to the dialyzers. Mean treatment times (208 vs. 207 min), blood flow rates (447.7 vs. 447.5 ml/min), dialysate flow rates (698.5 vs. 698.0 ml/min), URR (80%± 8 vs. 80.2%±4.8) and spKt/V (2.0±0.43 vs. 1.9±0.31) were comparable for EndX and Opti, respectively. There was no evidence of overt complement activation as C5a and C3a levels remained unchanged from pre-HD, and a slight trend for increase in sC5b-9 levels at 30 min was observed for both dialyzers. Comparable increase in serum albumin was observed from pre to post HD, 7.45%±8.5 Opti and 7.40%±7.4 EndX, however, β2M removal rate was 67% higher with EndX vs. Opti. Post-HD hemoglobin increased by 4.75%±8.2 vs. pre-HD (EndX), and post-HD platelet count decreased by 2.7%±5.6 vs. pre-HD (EndX). Three serious adverse events were reported, none of them were device related.

Conclusions: In a prospective, sequential, multi-center, open-label clinical trial, the Optiflux dialyzer and the novel dialyzer with Endexo were well tolerated with high URR

and spKT/V. The β2-microglobulin removal efficiency was 67% higher with the dialyzer with Endexo.

High-Volume Predilution Online Hemodiafiltration (HVPO-HDF) Is the Ideal Blood Purification Method from an Amino Acid Nutritional View

Motoko Kato,[1] Shunichiro Urabe,[1] Toru Hyodo,[2] Makoto Kitamura,[3] Miho Hida,[3] Yasuhisa Kurata,[3] Keiichiro Sakashita,[5] Kenichi Kokubo.[4] *[1]Eijin Clinic, Hiratsuka, Kanagawa, Japan; [2]Eijin Clinic and Cambodian Association of Nephrology, Hiratsuka, Japan; [3]Kurata Hospital, Hiratsuka, Kanagawa, Japan; [4]Kitasato University School of Allied Health Sciences, Sagamihara, Japan; [5]Laboratory of Dialysis Medical Care and Technology, Nagoya-city, Aichi, Japan.*

Background: Elderly ESRD patients with sarcopenia and frailty have been recently increased in Japan. It was reported the amino acid losses were up to 6 to 12 g per HD session (Kidney Int. 1994;46: 830-7). It seems to be important to restrain these amino acid losses during dialysis session from the point of nutritional view. We analyzed the amino acid losses that occur on performing high volume pre-dilution on-line HDF (HVPO-HDF) and HD.

Methods: We compared the amino acid and albumin amount into the total waste fluid, reduction rate of β_2-microgloblin (β_2-MG) and Kt/V (urea) in same 9 patients (7 males, 4 diabetics, mean age: 71.4±2.5 years) when they received HVPO-HDF and HD. The treatment time is 4 hours, respectively. The mean blood flow rate was 200 mL/min, respectively. The dialysate flow rate was 200 and 500 mL/min, respectively. The replacement fluid flow rate was 400 mL/min and total replacement fluid volume was 90 in HVPO-HDF. Hemodiafilter MFX-21Meco(Nipro, Ltd) was used for HVPO-HDF and Dialyzer FX-220(Fresenius Ltd) was for HD. These hemodiafilter and dialyzer were designed to suppress albumin leakage as possible as during dialysis session.

Results: In the O-HDF group, the total amino acid, total non-essential, essential, branched-chain amino acid losses (4511±797* mg, 2892±772* mg, 1619±286* mg, 739±167* mg, respectively) were significantly lower than in the HD group (6309±1072mg, 4008±772mg, 2301±414mg, 1058±263mg, respectively) (* $p < 0.01$). The albumin losses of both methods were almost same and extremely low (HVPO-HDF: 0.15±0.0 g, HD: 0.12±0.0). In the HVPO-HDF group, the β_2-MG reduction rate (69.8±5.0** %) was higher than in the HD group (65.3±5.0%) (** $p < 0.05$). The Kt/V (urea) values in the former and latter were 1.33±0.17** and 1.45±0.23, respectively. The HVPO-HDF can restrain the amino acid loss more effectively than HD. Both of hemodiafilter and dialyzer which were used in this study showed extremely low albumin leakage. In the HVPO-HDF group, the β_2-MG reduction rate was higher than in the HD group. The Kt/V (urea) of HVPO-HDF was within favorable range (>1.2).

Conclusions: This method is most powerful method to restrain amino acid and albumin losses in order to keep nutritional condition to avoid sarcopenia and frailty in elderly ESRD patients.

FR-PO476

Variability Between Prescribed and Measured Dialysate Sodium in the Acute Care Hemodialysis: Effects of Additives and Other Electrolytes

Nasim Wiegley, Vincent Paracuelles, Maureen Craig, Burl R. Don, Andrew I. Chin. *University of California, Davis, Sacramento, CA.*

Background: Significant variance in ordered versus measured dialysate Na has been noted in the outpatient HD setting. We examined this variance in a large hospital acute care hemodialysis program.

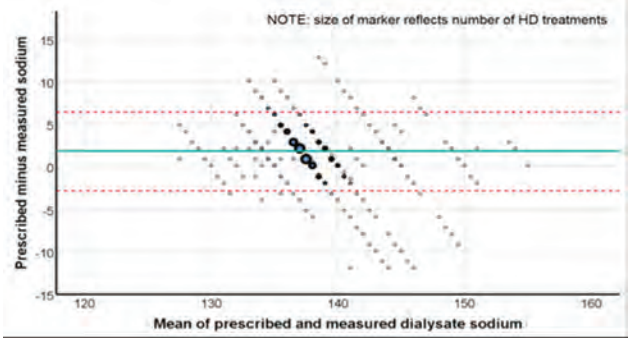
Methods: Dialysate electrolyte panels (DEP) were examined with point of care concentrates in an inpatient HD unit (Fresenius machines). DEP labs included Na, K, HCO3, PO4, and Mg. Ordered versus measured values for each electrolyte were analyzed by linear mixed model that included the particular HD machine for random effect. Logistic regression modeling was used to determine factors associated with significant variance between ordered and measured values.

Results: 5416 HD treatments identified. Significant differences noted between ordered and measured Na, HCO3 and Mg, but not K (Table 1). We focused on Na; 94% of HD's had differences of ± 5 mEq/L between ordered and measured dialysate Na levels. Bland-Altman plot showed skew towards a lower delivered versus ordered dialysate Na concentration. In 694 HD treatments, dialysate Na was manually corrected based on the first out of range measured Na. On repeat, 86.3% of treatments were within ± 3 mEq/L of the ordered Na. On logistic regression modeling for factors associated with measured dialysate Na >5 mEq/L out of range, phosphorus added to the dialysate and ordered dialysate Na > or < 140 were both statistically significant; 2.63 (1.38 - 5.02) and 1.10 (1.04 - 1.15), respectively.

Conclusions: There were significant differences between prescribed and measured dialysate Na, HCO3 and Mg, but not with K. Measured Na was on average 1.75 mEq/L lower than ordered; a difference of >5 mEq/L was found in 6% of HDs. Manual adjustment of dialysate Na setting, when performed, corrected this difference 86% of instances when rechecked on the same HD. Additives to the dialysate solution and ordered dialysate Na > or < 140 were associated with out of range measured Na

Funding: Clinical Revenue Support

Ordered - Measured	Mean	95% CI	2-tailed p-value
Na	1.75	1.68 to 1.82	<0.001
K	0.0053	0.0040 to 0.013	0.191
HCO3	0.30	0.26 to 0.35	<0.001
Mg	-0.030	-0.033 to -0.028	<0.001



FR-PO477

A 1-Year Study on the Effects of Hemodialysis Using Dialyzer with Medium Cut-Off Membrane

Jong-Hwan Jung, Heerim Kang, Seon-Ho Ahn. *Nephrology, Internal Medicine, Wonkwang university hospital, Iksan, Jeonlabukdo, Republic of Korea.*

Background: Medium cut-off (MCO) membrane is a dialyzer with enhanced sieving properties for soultes. An internal filtration of MCO membrane facilitated filtration of large middle molecules, and enhanced fitration of small molecules withtout replacement fluid. A long-term study for several markers after use of MCO membrane is few. We evaluated the various effects related with MCO membrane for 1 year in patients with ESRD.

Methods: Total 40 patients were analyzed for 1 year. The enrolled patients were > 18 years old and were on hemodialysis (HD) using high flux (HF) membrane for >3 months before enrolment. We prospectively collected serum samples with 3-month interval for 1 year. All patients were divided into control (HF, n=20) and MCO (MCO, n=20) group. The patients with serum albumin of > 3.5 g/dL and clinical sign, such as uncontrolled hyperparathyroidism or hyperphosphatemia, were included in MCO group. We measured and calculated serum markers, including parathyroid hormone (PTH), C-reactive protein (CRP), phosphate, hemoglobin (Hb), total protein, albumin, and spKt/V with 3-month interval.

Results: Compared to control group, patients in MCO group were younger and showed higher values of serum albumin and phosphate. In MCO group, serum protein and albumin decreased significantly over time (p <0.05), but serum albumin compared with serum protein did not decrease significantly since 6 months (p =0.056). Serum albumin increased significantly after 6 months in MCO group (p =0.012). The spKt/V increased until 6 months, but it didnot increased significantly since 6 months in MCO group (p =0.072). Several markers such as serum phosphate, calcium, CRP and Hb except for PTH did not show significant changes in both groups. Unexpectedly, PTH increased singnificantly in both groups. In analysis of differences between two groups over time, there was a significant difference only in change of serum phosphate (p =0.030).

Conclusions: Baseline levels of serum phosphate and albumin were high in MCO group due to selection bias. However, this study showed that albumin loss in MCO group was not significant after 6 months, and the spKt/V value in MCO group increased until at least 6 months. Moreover, we could recognize the possibility for hyperphosphatemia reduction in MCO group. Thus, HD using MCO membrane may be superior in clearance of small solutes and be not inferior in albumin loss for 1 year.

FR-PO478

Clinical and Operational Results of In-Center Nocturnal Hemodialysis (INHD) Programs in a Large Dialysis Organization (LDO)

Martin J. Schreiber, Sean Muir, Lillian Mecum, Brooke Bowlby, Bram Van hout, Zachariah W. Peterson. *DaVita Inc, Denver, CO.*

Background: INHD offers a combination of efficacy, safety, and improved treatment tolerability. Recognizing the specific clinical and laboratory results that indicate INHD might be beneficial for a given patient requires an understanding of modality-specific therapeutic differences. Here, we report the operational characteristics and clinical laboratory results of INHD programs in an LDO.

Methods: All patients admitted to LDO INHD programs during 2017 and 2018 were included in the analysis. Patient demographic information, dialysis prescription data, laboratory markers, blood pressure, target weight, and hospitalization rates were assessed and compared to those for in-center hemodialysis (ICHD) patients treated at the LDO during the same period.

Results: Data from 2747 patients treated in 176 INHD programs were assessed. Across the LDO, 19 INHD programs started operation during 2018, 24 closed; the most common closure reasons were transition of patients to the working shift (82%) and staffing constraints (9%). Mean INHD program census was <10 patients, mean operating time was 8.9 hours/shift, and staff retention rate was 83%. Mean age of INHD patients was

52 years; 29.5% were female; access use was 68.9% AVF, 15.1% AVG, 10.6% CVC, and 5.4% other. Laboratory and clinical parameters for INHD vs ICHD patients are shown.

Conclusions: INHD was associated with improved solute clearance, lower ultrafiltration (UF) rates, improved nutritional parameters, and lower hospitalization rates compared to ICHD. Patients receiving standard ICHD who are not achieving risk factor control, are experiencing increased organ stunning risk with elevated UF rates, or with hemodynamic instability should be considered for transition to INHD.

Funding: Commercial Support - DaVita Inc

FR-PO479

Controlling High Pre-Dialysis Serum Total Carbon Dioxide Concentration with Low Dialysate Flow Systems During Frequent Nocturnal Hemodialysis

J. Ken Leypoldt,[1] Michael A. Kraus,[2] Allan J. Collins.[3] *[1]Nalecz Institute of Biocybernetics and Biomedical Engineering Polish Academy of Sciences, Warsaw, Poland; [2]NxStage Medical, Inc, Fishers, IN; [3]NxStage Medical, Inc., Lawrence, MA.*

Background: Although use of low dialysate bicarbonate concentration ([bicarbonate]) during in-center, thrice weekly in-center hemodialysis (ICHD) is a common strategy to control high serum predialysis serum total carbon dioxide concentration ([TCO2]), such an approach is not always possible with commercial lactate dialysates. We used clinical data in patients who transferred from ICHD using bicarbonate dialysate to 6 times per week hemodialysis during the FREEDOM Study and the H^+ mobilization model (Sargent et al, Semin Dial 31:468-78, 2018) to calculate the effect of using 30 L versus 60 L of dialysate volume per treatment to reduce [TCO2] during frequent nocturnal hemodialysis (NHD).

Methods: The H^+ mobilization model was first used to simulate ICHD treatments using dialysate [bicarbonate] of 34, 37 & 40 mEq/L at [TCO2] of 22, 24 & 26 mEq/L to calculate a weekly acid generation rate. Assuming a constant weekly acid generation rate, patients were assumed transferred to NHD with treatment (Tx) frequencies of 3.5 (every other day), 4 & 5 times per week and dialysate volumes per Tx of 30 L & 60 L. Blood flow rate was assumed as 300 mL/min, Tx time of 420 min, and dialysate [lactate] was 40 mEq/L during NHD.

Results: Summary results are tabulated. Lowering dialysate volume per Tx from 60 to 30 L resulted in lower [TCO2] by approximately 2-3 mEq/L.

Conclusions: Patients who may achieve excessively high [TCO2] during NHD using lactate as dialysate buffer can use of 30 L instead of 60 L per treatment to reduce [TCO2]. Such reductions in dialysate volume during NHD are not expected to substantially lower dialysis adequacy.

Funding: Commercial Support - NxStage Medical Inc. (Fresenius Medical Care)

[TCO2] During NHD (mEq/L)

	3.5 Tx/wk		4 Tx/wk		5 Tx/wk	
[TCO2] during ICHD	DV=30 L	DV=60 L	DV=30 L	DV=60 L	DV=30 L	DV=60 L
22	20	23	21	24	24	26
24	21	24	23	25	25	27
26	23	26	25	27	27	28

All values averaged during ICHD treatments (Tx) using dialysate [bicarbonate] of 34, 37 & 40 mEq/L; the standard deviation of all values was 1 mEq/L. (DV denotes dialysate volume per treatment.)

FR-PO480

Plasma Viscosity Can Explain the Marked Reduction in Dialyzer Mass Transfer Area Coefficient for Urea and Other Solutes In Vivo Compared with In Vitro Values

Daniel Schneditz,[1] John T. Daugirdas.[2] *[1]Division of Physiology, Otto Loewi Research Center, Medical University of Graz, Graz, Austria; [2]University of Illinois College of Medicine, Chicago, IL.*

Background: The dialyzer area membrane transfer coefficient product (K_0A) characterizes the diffusive performance of a dialyzer and is one of the key components to prescribe a dialysis dose. However, in-vivo dialyzer K_0A for urea is always much smaller and only 50 to 60% of in-vitro K_0A tabulated in dialyzer manufacturer sheets and typically obtained from clearance measurements using crystalloid water solutions. The reason for this reduction has not been clearly determined. We hypothesized that the known effect of viscosity on solute diffusivity might partially or fully account for this reduction.

Methods: In-vitro dialyzer clearance of urea and glucose was measured in low- and high-flux dialyzers under different operating conditions using crystalloid solutions as well as bovine blood with different hematocrit and plasma viscosity. Viscosity of plasma, blood, and aqueous solutions was measured at 37°C. Diffusivity and relative K_0A values were computed for each solute under these different conditions.

Results: Relative K_0A was negatively correlated to relative plasma viscosity ($p<0.001$, $r^2=0.38$) and solute diffusivity ($p<0.001$, $r^2=0.48$) for urea and glucose (Fig. 1). Plasma was 1.84±0.31 times more viscous compared to crystalloid test solutions with a viscosity of 0.72 mPa.s, suggesting a correction multiplier of 0.54 (=1/1.84) for in-vivo solute diffusivity and K_0A relative to the in-vitro value. The average multiplier based on individual measurements was 0.67±0.09.

Conclusions: The known effect of viscosity on solute diffusivity is sufficient to explain the reduction of dialyzer K_0A for urea and glucose in-vivo compared to in-vitro measurements. The residual scatter in the K_0A to viscosity relationship suggest that additional mechanisms may be operative.

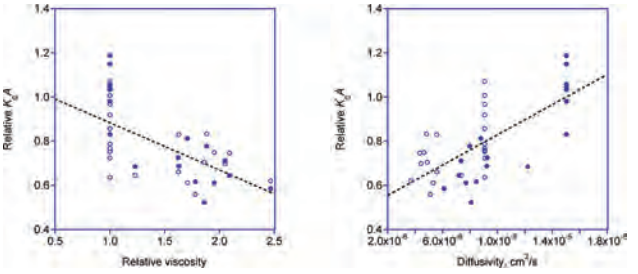

Fig. 1 Relative K_0A for urea (closed circles) and glucose (open circles) as function of relative plasma viscosity (left panel) or solute diffusivity (right panel). Dashed lines show the linear regressions for both urea and glucose.

FR-PO481

Hemoperfusion Associated with Impairment in Hemostasis in Patients with Acute Pesticide Intoxication

Samel Park, Eun-Young Lee. *Soonchynhyang University, Cheonan, Korea, Cheonan, Republic of Korea.*

Background: Hemoperfusion is one of the important treatment modalities in extracorporeal therapy for patients with acute intoxication. Its use has declined during the past 20 years despite its efficacy due to bleeding.

Methods: Twenty-five patients who underwent hemoperfusion due to acute pesticide intoxication participated. The changes in CBC, platelet function, platelet shape by SEM, platelet glycoprotein expression by FACS, and coagulation profiles were evaluated.

Results: After initiation HP, platelet count decreased by 40%. Delayed closure time that represents platelet dysfunction was observed; however, SEM showed activated shape-changed platelets adhered to activated charcoal. Platelet expressing CD61 (fibrinogen receptor) significantly decreased, while those expressing CD42b (vWF receptor) did not show significant change; however, platelet expressing CD49b (collagen receptor) significantly increased. Thrombin-antithrombin complex (a marker for thrombin generation) appeared to decrease without significance. FDP and d-dimers (markers for fibrinolysis) increased significantly during HP.

Conclusions: Our data suggest that hemoperfusion leads to increased platelet adhesion with decreased platelet aggregation, which might be associated with reduced thrombin generation and increased fibrinolysis.

The Proteome of Hemodialysis Membranes: A Discovery Proteomic Pilot Study

Nans Florens,[1,3] Frédéric Delolme,[2] Laurent Juillard.[1,3] *[1]Hospices Civils de Lyon, Lyon, France; [2]CNRS, Lyon, France; [3]University of Lyon, Lyon, France.*

Background: Hemodialysis (HD) membranes have been continuously upgraded during the past decades. Nevertheless, little is known about the real pattern of protein removal among different HD membranes. We aimed to explore the proteome of depuration from a mid-cut-off HD membrane (Theranova, Baxter, IL, USA) and from a high flux membrane in HD and hemodiafiltration (HDF) (FX1000, Fresenius Medical Care, Bad Homburg, Germany).

Methods: 9 HD patients were separated in 3 groups: Theranova, FX1000 in HD and FX1000 in HDF. During their mid-week session, 1 liter of dialysate was sampled and 30 ml were freeze-dried. Additionally, the dialysis membrane was eluted and both dialysate and eluate were prepared for LC/MS-MS analysis (liquid chromatography coupled with a tandem mass-spectrometer). Samples were analyzed using an nano-RSLC (high performance liquid chromatographer, Thermo Fischer, Waltham, MA, USA) coupled on line with a Q-Orbitrap mass spectrometer. Data were processed by database searching using SequestHT with Proteome Discoverer 2.2 software against a human Swissprot database and quantified with a TMT-labeling approach. Semi-quantitative analysis was expressed as a ratio. Proteins were analysed using STRING tool for reactome pathway analysis.

Results: 526 proteins were found in the dialysate samples from all the membranes and 360 onto dialysis membranes. 455 proteins were found in the dialysate from FX1000 HDF group, 437 for Theranova and 410 for FX1000 HD. 360 proteins were also found adsorpbed onto the membranes. For Theranova, 45 proteins were found significantly more depurated by diffusion and/or convection than adsorption and 101 more by adsorption than diffusion/convection. For FX1000 HD, 56 and 100. For FX1000 HDF, 61 and 56 respectively. With Reactome pathway analysis, numerous removed proteins were involved in innate immune system, hemostasis, extra-cellular matrix organization, platelet aggregation, lipid metabolism and molecular signaling pathways.

Conclusions: More than 500 proteins were identified in the proteome of depuration from HD and HDF membranes among which a significant number are specific from each membrane and modalities. Further analysis are required to understand the issues of the depuration of these proteins in improving HD patients outcomes.

Ex Vivo Validation of Allo-Hemodialysis for Removal of Creatinine and Protein-Bound Uremic Toxins

Joshua E. Chao,[1] Nadja Grobe,[1] Vaibhav Maheshwari,[1] Xia Tao,[1] Stephan Thijssen,[1,2] Peter Kotanko.[1,2] Renal Research Institute *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Unlike conventional hemodialysis, allo-hemodialysis (alloHD) has a patient dialyzed against a healthy subject ("buddy"). This *ex vivo* study aimed to explore the feasibility of removing creatinine and protein-bound uremic toxins (PBUTs) with alloHD, where whole blood constitutes the "dialysate".

Methods: Two buckets of whole blood (anticoagulated with 5,000 U/L heparin) were designated as "patient" and "buddy" and dialyzed against each other for 2 hours with initial flow rates of 110 mL/min for both circuits using a high-flux cellulose triacetate dialyzer (Nipro Cellentia 17H, surface area 1.7 m^2) and targeting zero net ultrafiltration. The "patient" bucket was initially spiked with creatinine, indoxyl sulfate (IS), and p-cresyl sulfate (pCS) to establish a diffusion gradient between patient and buddy. This was followed by a 2nd spike 1 hour into the experiment. After each spike, blood samples from both sides were collected after each spike every 5 min for 30 min, then every 10 min for the next 30 min. IS and pCS were measured via liquid chromatography–mass spectrometry after liquid-liquid extraction, while creatinine was determined via spectrophotometry.

Results: Solute concentration differences between "buddy" and "patient" dissipated rapidly (**Figure 1**). As expected, creatinine concentrations equilibrated faster (within about 5 min), while PBUT concentrations equilibrated more slowly (within 15 to 25 minutes), presumably due to their high degree of protein binding. No blood clots were present even after 2 hours of *ex vivo* recirculation.

Conclusions: This bench experiment demonstrates the ability of alloHD to not only remove water-soluble unbound solutes but also PBUTs. These findings support alloHD's viability as a potential alternative to conventional hemodialysis.

Dialysate Citrate and Mortality in the Dialysis Outcomes and Practice Patterns Study

Pablo A. Urena Torres,[6] Brian Bieber,[4] Fitsum Guebre Egziabher,[2] Christian Combe,[3] Michel Y. Jadoul,[1] Masaaki Inaba,[7] Bruce M. Robinson,[4] Friedrich K. Port,[4] Christian Jacquelinet.[5] *[1]Cliniques Saint-Luc, University of Louvain Medical School, Brussels, Belgium; [2]Hospital Albert Michallon, La Tronche, France; [3]CHU de Bordeaux, Bordeaux, France; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]Agence de la biomedecine, Saint-Denis La Plaine, France; [6]AURA Nord Saint Ouen, Saint Ouen, France; [7]Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: Metabolic acidosis is a common threat for hemodialysis patients, managed by alkaline dialysis baths. The main base is bicarbonate, to which small amounts of acetate or citrate may be added. These additives are metabolized to bicarbonate, mostly by the liver. In view of uncertainties about benefits and potential harms associated with citrate-containing dialysate we assess here whether citrate dialysate is associated with mortality in the international Dialysis Outcomes and Practice Patterns Study (DOPPS).

Methods: Detailed patient-based information on dialysate composition was collected in DOPPS phases 5 and 6 (2012 to 2017). Cox regression was used to model the association between dialysate containing bicarbonate with versus without citrate and mortality among DOPPS country/phases with at least 15 patients using citrate containing dialysate.

Results: Citrate-containing dialysate use was most common in Japan, Italy, and Belgium (25, 23, 21% of DOPPS phase 6 patients) and used in < 10% of patients in other countries. Among 10,618 patients in DOPPS country/phases with at least 15 patients using citrate-containing dialysate, patient demographics, comorbidities, and labs were similar among patients using (14%) vs. not using (86%) dialysate citrate. After accounting for case mix, we did not observe an association between citrate containing dialysate use (any vs. none) and mortality, HR (95% CI) = 1.03 (0.85-1.23). Nor did we find evidence of a dose-dependent relationship when parameterizing dialysate citrate concentrations as 1, 2, and 3+ mEq/L.

Conclusions: The use of this emergent practice of citrate-containing dialysate was not associated with the risk of all-cause mortality in hemodialysis patients participating in the DOPPS. Clinical indications for the use citrate dialysate deserve further investigation in future studies.

Hemodialysis with Citrate Dialysate Does Not Harm Patients: Results from an European NephroCare Cohort

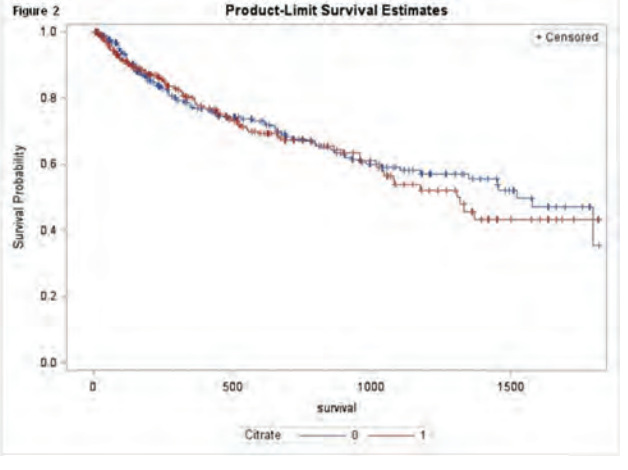
Charles Chazot,[1] Luca Neri,[3] Francesco Bellocchio,[3] Guillaume Jean,[5] Tomas Jirka,[2] Fatih Kircelli,[2] Martial Levannier,[6] David Attaf,[4] Carlo Barbieri,[2] Stefano Stuard,[2] Bernard J. Canaud.[7] *[1]NephroCare France, Fresnes, France; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Fresenius Medical Care Italia, Vaiano Cremasco, Italy; [4]Fresenius, Fresnes, France; [5]NephroCare Tassin-Charcot, Sainte Foy Les Lyon, France; [6]Nephrocare Beziers, Beziers, France; [7]FMC Deutschland GmbH, Bad Homburg, Germany.*

Background: Chronic hemodialysis (HD) using citrate dialysate is prescribed for improving dialysis tolerance and reducing heparin needs. Recently the safety of citrate (Ci) has been challenged by a French retrospective study. We report a mortality analysis in incident HD patients treated in the NephroCare dialysis centers in France, Turkey and Czech Republic in which citrate concentrate were prescribed.

Methods: This a retrospective study including 10020 incident HD patients between 2014 and 2018. Data were extracted from the EuCliD5 database. Patient survival was analyzed from three cohort studies designed to address different potential sources of biases. Patients were considered Ci+ if 70% of dialysis sessions were performed with Ci all along their lifetime (Study 1) or during the first 3 months of dialysis (Study 2). Study 3 included time-varying Ci exposure and time-varying PS score (monthly and 6-monthly averages) in a proportional hazard Cox regression to address variation in dialysate composition and patients' characteristics.

Results: Among 10020 enrolled patients, 435 were classified as Ci+. These patients were older with more severe comorbidities. In Study 1, the mortality was higher in Ci+ patients (p<0.0001). After propensity score matching (PSM; 345 patients Ci+ and Ci-) mortality remained strictly superimposable (Figure 1). In Study 2, no difference in survival was found before or after PSM. The monthly exposure analysis (Study 3), including 3671 patients with 835 deaths, clearly showed that the risk of mortality was related to the propensity score reflecting more sever condition (HR:5.06 (2.05-12.51)) but not with the Ci (HR:0.83 (0.67-1.03)).

Conclusions: In the European NephroCare experience, no significant impact on survival was found in chronic HD patients under Ci+ dialysate as compared to standard dialysate treated patients.



FR-PO486

Impact of Dialysate Calcium Concentration on Clinical Outcomes in Incident Hemodialysis Patients

Jong yun Lee,[1] Hyung Wook Kim,[1] Yong Kyun Kim.[2] *[1]Division of Nephrology, St. Vincent's Hospital, The Catholic University of Korea, Gyeonggi, Republic of Korea; [2]Catholic University of Korea, Seoul, Republic of Korea.*

Background: The association between dialysate calcium (DCa) concentration and mortality in hemodialysis (HD) patients is controversial. In this study, we evaluated the impact of DCa concentration on mortality in incident HD patient.

Methods: Incident HD patients were selected from the Clinical Research Center registry—a prospective cohort study on dialysis patients in Korea. Patients were categorized into 3 groups according to the prescribed DCa concentration at the time of enrollment. High DCa was defined as a concentration of 3.5 mEq/L, mid-DCa as 3.0 mEq/L, and low DCa as 2.5 to 2.6 mEq/L. The primary outcome was all-cause mortality and secondary outcomes were cardiovascular or infectionrelated hospitalization.

Results: A total of 1182 patients with incident HD were included. The number of patients in each group was 182 (15.4%) in high DCa group, 701 (59.3%) in the mid-DCa group, and 299 (25.3%) in the low DCa group. The median follow-up period was 16 months. The high DCa group had a significantly higher risk of all-cause mortality compared with the mid-DCa group (hazard ratio [HR] 2.23, 95% confidence interval [CI] 1.28–3.90, P=0.005) and the low DCa group (HR 3.67, 95% CI 1.78–7.55, P<0.001) after adjustment for clinical variables. The high DCa group was associated with higher risk of cardiovascular and infection-related hospitalization compared with the low DCa group (HR 3.25, 95% CI 1.53–6.89, P=0.002; and HR 2.77, 95% CI 1.29–5.94, P=0.009, respectively). Of these 1182 patients, 163 patients from each group were matched by propensity scores. In the propensity score matched analysis, the high DCa group had a significantly higher risk of all-cause mortality compared with the mid-DCa group (HR 2.52, 95% CI 1.04–6.07, P=0.04) and the low DCa group (HR 4.25, 95% CI 1.64–11.03, P=0.003) after adjustment for clinical variables.

Conclusions: Our data showed that HD using a high DCa was a significant risk factor for all-cause mortality and cardiovascular or infection-related hospitalization in incident HD patients.

FR-PO487

A High Magnesium Concentration in Citrate Dialysate Prevents Oxidative Stress and Damage in Human Monocytes

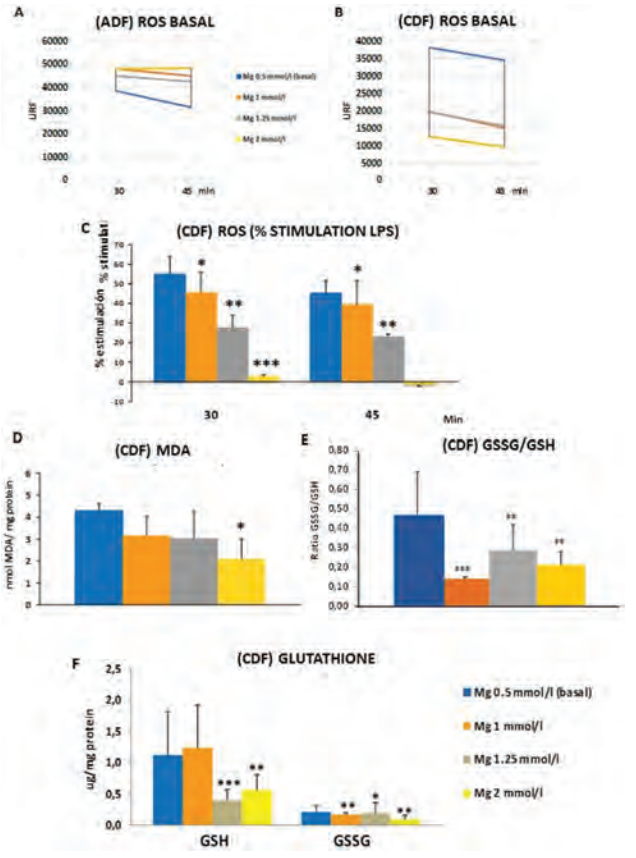
Carmen Vida,[2] Matilde Alique,[2] Patricia De Sequera,[1] Julia Carracedo,[3] Guillermo Bodega,[2] Rafael Ramirez.[2] *[1]University Hospital Infanta Leonor, Madrid, Spain; [2]University of Alcalá de Henares, Alcalá de Henares (Madrid), Spain; [3]Complutense University, Madrid, Spain.*

Background: The use of dialysis fluids (DF) during haemodialysis has been associated with an increased oxidative stress and reduced serum levels of magnesium (Mg), contributing to inflammation and immune system disorders. Since it has been demonstrated the role of Mg in modulating immune function and reducing oxidative stress, in this study we have characterized whether higher Mg concentrations in DF could protect from oxidative-inflammatory stress in immunocompetent cells.

Methods: The effect of citrate (CDF, 1 mmol/L) or acetate (ADF, 3 mmol/L) dialysates with 0.5 mmol/l Mg (routinely used) or with higher Mg concentrations (1, 1.25 and 2 mmol/L) were assessed in human monocyte culture (THP-1). The levels of reactive oxygen species (ROS), malondialdehyde (MDA) and reduced (GSH) and oxidized (GSSG) glutathione were quantified under basal and/or inflammatory conditions (stimulation with lipopolysaccharide, LPS, 1 μg/ml).

Results: In monocytes, 0.5 mmol/L Mg CDF produced lower basal ROS production in relation to ADF (p<0.05). Moreover, the increase of Mg in CDF resulted in a significant reduction of ROS production under basal and inflammatory conditions, which was extremely marked in 2 mmol/L Mg (p<0.001). These effects were not observed in ADF. Interestingly, in a dose-dependent manner, high doses of Mg in CDF reduced the oxidative stress observed in monocytes under basal conditions. In fact, 2 mmol/L Mg significantly decreased the levels of GSH, GSSG and MDA and the GSSG/GSH ratio in relation with 0.5 mmol/L Mg.

Conclusions: The CDF produces a lower ROS production compared to ADF. Increasing the concentration of Mg in the DF, especially in CDF, could have a positive and protective effect reducing oxidative stress and damage in immune cells.



FR-PO488

Efficacy and Safety of Expanded Hemodialysis Enabled by a Medium Cut-Off Membrane: A Randomized Control Trial

Daniel E. Weiner,[1] Luke Falzon,[2] Werner Beck,[2] Mengqi Xiao,[2] Ha Tran,[2] Angelito A. Bernardo.[2] *[1]Tufts Medical Center, Boston, MA; [2]Baxter Healthcare Corporation, Deerfield, IL.*

Background: End stage kidney disease patients suffer high morbidity and mortality. Evidence suggests that accumulated uremic toxins, including larger middle molecules poorly cleared with conventional hemodialysis (HD), have a significant role in inflammation, cardiovascular disease and immune modulation. Expanded HD with a medium cut off membrane may effectively and safely remove middle molecules compared to conventional HD.

Methods: A 24 week, open-label RCT in thrice weekly in-center HD patients assessed whether a medium cut-off dialyzer (Theranova 400) compared to a high flux dialyzer (Elisio-17H) was superior in reduction ratio (RR) of lambda free light chains (λ FLCs) as a representative larger middle molecule (primary efficacy outcome) and non-inferior in maintaining pre-dialysis serum albumin levels (primary safety outcome). Primary analyses used an ANCOVA model with fixed effects for treatment and site, with multiple imputation for missing values performed using all post-baseline values. Secondary outcomes (shown in the table) used a mixed-effects repeated measures model.

Results: Among 172 patients randomized at 21 sites, mean age was 59 years, 39% were women and 40% African American. Median vintage was 4 years and 45% had diabetes as the cause of ESRD. The λ FLC reduction ratio was significantly higher with the Theranova membrane, while albumin levels were similar between groups (Table). Adverse and serious adverse events also were similar between groups.

Conclusions: The Theranova 400 dialyzer provides superior removal of larger middle molecules as compared to a similar size high flux dialyzer while maintaining serum albumin level without adverse safety signals. Larger studies of longer duration are needed to to assess if better larger middle molecule clearance is associated with improvements in clinical outcomes, including vascular disease, quality of life and mortality.

Funding: Commercial Support - Baxter

The Comparison of Vancomycin Removal Between Medium Cut-Off (Theranova®) and Other Dialyzers

Haksoo Kim,[1] Keun-hoi Park,[1] Jung a Yoon,[1] Eun kyoung Lee,[2] Jai won Chang.[2] *[1]Division of Nephrology, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Division of Nephrology, Department of Internal Medicine, Dankook University College of Medicine, Cheonan-si, Republic of Korea*.

Background: For more perfect treatment of *Staphylococcus aureus* infection in patients with end-stage renal disease (ESRD) on hemodialysis (HD), the maintenance of the target level of vancomycin (molecular weight 1,448 Dalton), 15~20 mg/L, is very important. Recently developed medium cut-off dialyzer, Theranova®, revealed superior clearance of waste product with large middle molecular weight (~ 45,000 Dalton). Hence, Theranova® may cause the suboptimal level of vancomycin in HD patients. The aim of this study is to investigate whether the reduction ratio of vancomycin (RRoV) in HD patients on Theranova® is greater than that on low-flux/high-flux dialyzer.

Methods: We analyzed prospectively collected vancomycin levels between April 2018 and April 2019. HD dialyzer was randomly assigned to the patients underwent intravenous vancomycin. In the first study (n=31, M:F=21:10, age 66 (55~73) years, dry body weight (DBW) 55.0 (50.8~63.5) Kg), RRoV by Theranova® was compared with that by low-flux dialyzers (FX 10®, Fresinius or Polyflux 17L®, Baxter). In the second study (n=24, M:F=15:9, age 63 (46~75) years, DBW 52.0 (46.0~63.0) Kg), RRoV by Theranova® was compared with that by high-flux dialyzers (FX 80®, Fresinius or Polyflux 170H®, Baxter).

Results: In two studies, there were no significant differences in the total amount of vancomycin, dosing interval, the level of vancomycin just before HD, the time of HD session, and the net ultrafiltration between two groups, respectively. The RRoV by Theranova® was greater than that by low-flux (45.5 (36.4~51.2) % vs. 33.3 (28.8~41.7) %, p=0.001). However, there was no significant difference in RRoV between Theranova® and how-flux dialyzer (50.6 (41.4~54.5) % vs. 46.4 (40.5~55.1) %, p=0.597).

Conclusions: Although the RRoV by Theranova® was significantly greater than that of low-flux dialyzer, there was no significant difference between Theranova® and high-flux dialyzer. Therefore, existing vancomycin dosing protocol on high-flux dialyzer could be valid in treatment of *Staphylococcus aureus* infection in patients with ESRD on HD using Theranova®, too.

FR-PO490

Effect of Different Dialysis Procedures on Monocyte Subsets

Detlef H. Krieter,[1] Karin Merget,[2] Marieke Rueth,[2] Horst-Dieter Lemke,[2] Christoph Wanner.[1] *[1]University Hospital Würzburg, Würzburg, Germany; [2]eXcorLab GmbH, Obernburg, Germany*.

Background: In cardiovascular and end-stage kidney disease, monocyte subsets are associated with cardiovascular events and mortality. The aim of the present study was to monitor monocyte subsets over a 6-week period in individuals on different extracorporeal dialysis procedures.

Methods: In a prospective, randomized, controlled, cross-over study enrolling 15 maintenance dialysis patients (*DRKS00010788*), low-flux and high-flux hemodialysis (HD) were compared to high convective volume (≥25 L) postdilution hemodiafiltration (HDF). Each patient was subjected thrice weekly to each treatment mode for 6 consecutive weeks. Dialysis membrane material was always identical (PUREMA® L and H, resp.). Dialysate flow rates differed in HD and HDF (500 vs. 700 mL/min). Blood flow rates and treatment time were kept identical for individual patients. Monocyte subsets were determined at baseline (t0), after 3 (t3) and 6 weeks (t6) of each treatment period. Monocytes subtypes were differentiated in classical ($CD14^{++}/CD16^{-}$), intermediate ($CD14^{++}/CD16^{+}$) and non-classical ($CD14^{+}/CD16^{++}$) by flow-cytometric analysis. In addition, highly sensitive serum CRP was monitored by ELISA.

Results: While there were no differences in monocyte subsets over time within and between treatment modes, ANOVA revealed a lower number of total monocytes at t6 in HDF compared to low-flux HD (885±245 vs. 993±349 cells/µl; P=0.019). Classical monocytes ranged between 677±191 (high-flux HD, t3) and 763±297 (low-flux HD, t6) cells/µl, intermediate monocytes between 91±31 (HDF, t3) and 125±89 (HDF, t0) cells/µl, and non-classical monocytes between 83±39 (HDF, t3) and 109±54 (low-flux HD, t3) cells/µl. Furthermore, no differences in CRP levels were found within and between treatments (range 5.12±7.18 mg/L in HDF at t6, and 11.42±19.17 mg/L in low-flux HD at t6). CRP correlated with total monocytes (r=0.638, P<0.001) as well as with classical (0.608, P<0.001), non-classical (0.216, P=0.017) and intermediate (0.520, P<0.001) subtypes.

Conclusions: Over a 6-week period, large differences in toxin removal of extracorporeal dialysis therapies have no impact on monocyte subsets and inflammation. Monocyte phenotypes may be useful to characterize inflammation in patients on maintenance dialysis.

FR-PO491

Experience with a Novel Hemodialysis System: User Satisfaction and Clearance

Mohammed F. Rahman,[1] Belinda Albaugh,[2] Harold M. Szerlip.[2] *[1]Nephrology, Baylor University Medical Center, Dallas, TX; [2]Baylor University Medical Center, Dallas, TX*.

Background: The need for IHD in hospitalized patients with AKI and ESRD has been increasing. Delivery of this care has a significant cost. An inpatient hemodialysis unit requires a large financial outlay for water treatment and performing IHD in an ICU room involves transporting heavy equipment and often ties up a dialysis nurse. Outset Medical's Tablo is an easily transportable, all-in- one system with a user-friendly touch screen interface that requires minimal training. This pilot project was designed to assess whether the Tablo system was both easy to use and provided adequate urea clearance.

Methods: 25 hospitalized patients with AKI or ESRD requiring IHD were treated using the Tablo system. 15 of these patients were in the ICU and 10 patients were in the inpatient dialysis unit. Tablo was set up and run by a hemodialysis nurse or technician using a Revaclear 300 dialyzer. Blood flow was between 300-400 ml/min and dialysate flow rate was 300 ml/min. Dialysis prescription, duration and ultrafiltration rate were left to the discretion of the attending nephrologist. Nursing satisfaction was assessed by a Likert scale questionnaire. Dialysis adequacy was estimated by KT/V (Daugirdas) and Urea reduction ratio (URR).

Results: The majority of nurses/technicians found Tablo easier to use than a conventional dialysis machine (average score 5/5), most nurses felt comfortable providing treatment with this system after a short training session (average score 4.9/5) and they were also satisfied with Tablo as a treatment option (average score 4.9/5). Several participants also reported that the system was easy to transport and took up less space in an ICU room. Mean Kt/V was 1.18 (0.68 - 2.37), mean URR was 62.39 (44.44 - 87.04), mean patient weight was 81.98 kg (53.50 - 187.60), mean time and blood flow were 3.6 hours (3.5 – 4.5) and 366 ml/min (300 - 400) respectively.

Conclusions: Most of the operators found the Tablo system easy to use and transport. Although urea clearance was less than goal, we attribute this both to the shorter treatment time used in our center and the fact that treatment time was not adjusted for patient weight. Previous small studies have confirmed this system can deliver adequate clearance despite lower dialysate flow; larger randomized controlled trials are needed to validate this.

Funding: Commercial Support - Outset medical provided the Tablo machines.

FR-PO492

Optimizing Serum Total Carbon Dioxide Concentration During More Frequent Hemodialysis Using Low Dialysate Flow and Lactate Dialysate

J. Ken Leypoldt,[1] Michael A. Kraus,[2] Allan J. Collins.[3] *[1]Nalecz Institute of Biocybernetics and Biomedical Engineering Polish Academy of Sciences, Warsaw, Poland; [2]NxStage Medical, Inc, Fishers, IN; [3]NxStage Medical, Inc., Lawrence, MA*.

Background: There have been few studies to determine the optimal dialysate lactate concentration ([lactate]) during more frequent hemodialysis (MFHD) at low dialysate flow rates using the NxStage System One dialysis delivery system to achieve a predialysis serum total carbon dioxide concentration ([TCO2]) of 22-26 mEq/L. We used clinical data in patients who transferred from in-center, thrice weekly hemodialysis (ICHD) using bicarbonate dialysate to 6 times per week hemodialysis using lactate dialysate during the FREEDOM Study and the H^+ mobilization model (Sargent et al, Semin Dial 31:468-78, 2018) to calculate the effect of dialysate [lactate] during MFHD on [TCO2] after transfer from ICHD.

Methods: The H^+ mobilization model was first used to simulate ICHD treatments using dialysate bicarbonate concentration ([bicarbonate]) of 34, 37 & 40 mEq/L at [TCO2] of 20, 22 & 24 mEq/L to determine a weekly acid generation rate. Assuming a constant weekly acid generation rate, patients were assumed transferred to MFHD with treatment (Tx) frequencies of 4, 5 & 6 times per week with dialysate volume per Tx &Tx times of 40 L & 210 min, 30 L & 180 min, and 25 L & 170 min, respectively. Blood flow rate was assumed as 450 mL/min and dialysate [lactate] as either 40 or 45 mEq/L during MFHD.

Results: Summary results are tabulated. After transfer from ICHD, [TCO2] during MFHD increased when using a dialysate [lactate] of 45 mEq/L but not when using a dialysate [lactate] of 40 mEq/L. [TCO2] during MFHD was higher at higher [TCO2] during ICHD. Calculated results were predominantly dependent on the weekly dialysate volume (150-160 L/wk) and relatively independent of Tx frequency.

Conclusions: KDOQI guidelines suggest that [TCO2] should be ≥22 mEq/L; therefore, these results suggest that patients transferring from ICHD with [TCO2] ≤24 mEq/L should initially be prescribed a dialysate [lactate] of 45 mEq/L when using 150-160 L/wk of dialysate volume during MFHD.

Funding: Commercial Support - NxStage Medical Inc. (Fresenius Medical Care)

[TCO2] During MFHD (mEq/L)

	Dialysate [Lactate] of 40 mEq/L			Dialysate [Lactate] of 45 mEq/L		
[TCO2] During ICHD	4 Tx/wk	5 Tx/wk	6 Tx/wk	4 Tx/wk	5 Tx/wk	6 Tx/wk
20 mEq/L	18	19	20	22	23	24
22 mEq/L	20	21	22	24	24	25
24 mEq/L	22	22	23	25	26	27

All values averaged for dialysate [bicarbonate] during ICHD of 34, 37 and 40 mEq/L; the standard deviation of all values was 1 mEq/L.

FR-PO493

Patient-Reported Outcome Measures (PROMs) and Expanded Hemodialysis (HDx) with Medium Cut-Off Dialyzers in a Large Cohort of Patients in Colombia: The COREXH Study

Mauricio Sanabria,[1] Angela S. Rivera,[2] Angelito A. Bernardo,[2] Lars-Goran Nilsson,[3] Jasmin Vesga,[1] Alfonso Bunch,[1] Ricardo Sanchez.[4] *[1]RTS, Bogotá, Colombia; [2]Baxter Healthcare Corporation, Deerfield, IL; [3]Baxter International Inc., Lund, Sweden; [4]Universidad Nacional de Colombia, Bogotá, Colombia.*

Background: Increasing importance and focus have been directed towards quality of life measures (QoL) and patient experience in end stage kidney patients on hemodialysis (HD). A new therapy, expanded hemodialysis(HDx) with Theranova membane improved clearance of middle molecular uremic toxins but to date its effects of QoL are lacking

Methods: Historical cohort, multicenter study in prevalent patients older than 18 years under the HDx therapy with MCO membrane that complete the twelve months of follow up in the COREXH Registry, in Renal Therapy Services (RTS) Colombia network. PROMs were assessed by KDQOL-36, Dialysis Symptoms Index (DSI), and diagnostic criteria for Restless Legs Syndrome (RLS) tools. The ANOVA and Cochran's Q test was used.

Results: Out of 992, the 619 men (62.4%) with mean age 60.4±15.7 years. For KDQoL 36 domains, symptoms, burden and effects of kidney disease and mental component, significant increase in score at 6 and 12 mos was noted (Table1). ANOVA for DSI shows statistically significant differences in mean severity scores over the follow-up with improvement from 30.7, 29.9 and 28.5 at baseline, six months and one year respectively, ($F(2, 1450) = 6.92$, $p = 0.0087$)). The proportion of patients with RLS scores improved from 22.11% at baseline, to 12.47% at 6 m and 9.98 at 12 m (Cochran's Q, 2 df) = 145.42, $p < 0.0001$.

Conclusions: In this large multicenter study, HDx with Theranova resulted in improved patients' related outcomes.

Funding: Commercial Support - Baxter Healthcare Corporation, Government Support - Non-U.S.

What Is the Most Cost-Effective Strategy to Rinse a Re-Processed Dialyser Before a Dialysis Session?

Kamal D. Shah,[1] Venkatraman Ganapathi Subramanian,[1] Guruvulu Venkata,[1] Sataynarayana R. Puvvada,[1] Vivekanand Jha.[2,1] NephroPlus Dialysis Centres, India *[1]NephroPlus Dialysis Centres, Hyderabad, India; [2]George Institute for Global Health, New Delhi, India.*

Background: Dialyser reuse is practised in developing countries to reduce cost. The Indian Society of Nephrology (IndSN) Hemodialysis Guidelines recommend using 2L of Normal Saline (NS) to flush the blood compartment of a dialyser before each reuse to ensure elimination of air and residual sterilant. It is also recommended that the dialysate compartment of the dialyser be rinsed for 5 minutes. In this study, we tested several strategies to determine the smallest volume of NS that could lead to elimination of residual sterilant from a reprocessed dialyser and thereby lead to cost savings.

Methods: We pilot tested combinations of flushing (after draining the dialyser completely) with different volumes of NS (2L, 1L and 500 ml) and 0 or 10 minutes dialysate compartment rinsing in 5 sessions each. After determining the smallest flush volume that consistently eliminated the sterilant (4% peracetic acid, 21% hydrogen peroxide and 10% acetic acid), we reduced the rinsing time in decrement of 2 minutes, starting from 10 minutes. Residual sterilant was checked with a commercial strip (Serim Research Corporation, IN, USA) that detected the presence of >1 ppm of hydrogen peroxide. We also noted the time taken for the entire process and the cost. The final selected strategy was compared with the 'IndSN gold standard' in 150 sessions each.

Results: The first step of the pilot showed us that the smallest volume of NS that was able to consistently get rid of the sterilant from the reprocessed dialyser was 500 ml. Next, we found that a minimum of 8 minutes of rinsing was needed to eliminate the sterilant completely. Adding 2 minutes as a safety margin, we then compared 500 ml flush + 10 min rinsing with the strategy recommended by the IndSN in 150 sessions each. This strategy showed no residual sterilant in any session. The cost (INR 30 versus INR 100) and the time taken (15 min vs 25 min) were less than that with the protocol recommended by the IndSN.

Conclusions: Flushing of the dialyser blood compartment with 500 ml of NS followed by 10 minutes of rinsing of the dialysate compartment leads to complete removal of sterilant prior to initiating dialysis using a reprocessed dialyser. This strategy results in a significant saving in terms of cost and time taken to initiate dialysis compared to currently recommended protocol.

FR-PO495

Glycosaminoglycan Modified-Dialysis Membranes Improve Blood Biocompatibility In Vitro

Maria Margalef,[1] Dooli Kim,[2] Dimitrios Stamatialis,[2] Johan Van der vlag.[1] *[1]Department of Nephrology, RIMLS, Radboud University Medical Centre, Nijmegen, Netherlands; [2](Bio)artificial organs chair TechMed Institute, University of Twente - Faculty of Science and Technology, Enschede, Netherlands.*

Background: The number of patients requiring renal replacement therapies is increasing with an estimated number of 5.4 million a year in 2030. Most patients use (hemo)dialysis (HD) therapy. Major drawbacks of HD are: (i) poor removal of toxic larger middle-sized molecules and protein-bound uremic solutes; (ii) large fluctuations in water balance and uremic waste, potassium and phosphate of the patients, since it is non-continuous (iii) not fit for prolonged use due to clogging and coagulation of the membranes. Recently, we showed *in vitro* that combining dialysis and adsorption in one step using mixed matrix membranes (MMM) improves removal of protein-bound uremic solutes from human plasma as compared to conventional dialysis membranes. Although the results with MMM are promising, for continuous use further optimization is required. Due to the well-known contribution of glycosaminoglycans (GAGs) to the barrier and anti-fouling properties of the natural filtration barrier in the kidney, this work aimed to improve hemo- and biocompatibility of MMM by application of novel GAGs either as coatings post membrane fabrication or by incorporation of the GAG into the membrane polymer via blending.

Methods: Flat MMM were coated or blended with the following GAG sources: Heparin, GAGs from porcine intestine (GPI), heparan sulphate (HS) isolated from cultured glomerular endothelial glycocalyx, HS from bovine kidney (HSBK), and heparinase III digested HSBK. Both GAG coating and blending showed a high stability on the MMM. Water permeance, and a panel of anti-coagulation and platelet adhesion assays were studied in all cases.

Results: The new MMM with 3 out of 5 GAGs have higher water permeance in comparison to non-modified MMM whereas heparin and GPI modified MMM were superior in their anti-coagulation and platelet adhesion properties.

Conclusions: GAG-modified MMM have superior biocompatible properties that may improve current dialysis treatment and ultimately enable incorporation into future portable artificial kidney devices.

Discrepancy Between In Vivo and In Vitro (Dialyzer Mass Transfer-Area Coefficient) KoA in Patients on Chronic Intermittent Hemodialysis (IHD): A Retrospective Analysis

Neil K. Agarwal, Natalia Plotskaya, Ziauddin Ahmed, Ellie Kelepouris, Jesse M. Goldman, Sandeep Aggarwal. *Drexel University College of Medicine, Philadelphia, PA.*

Background: KoA is a measure of the dialysis membranes clearance efficiency. Manufacturer KoA values are determined from in-vitro studies. The achieved in-vivo KoA using these membranes in IHD is not known.

Methods: We retrospectively reviewed measured hemodialysis kinetic results in 70 patients receiving IHD at an outpatient free-standing dialysis unit. Over a 2-month period, we reviewed 140 dialysis sessions. Age, Gender, Weight, Height, length of session, blood flow rate (Qb), dialysate flow rate (Qd), pre-BUN, post-BUN, urea reduction rate (URR), type of dialyzer and manufacture KoA, UF, pre-weight, post-weight and spKt/V were recorded. Specimens were obtained according to specifications of the dialysis unit. We then calculated the Kt/V using Daugirdas 2 equation (D2), body surface area (m^2) calculated using Mostellar equation (M-BSA), and total body water (L) calculated using Watson's formula (W-TBW). MS Excel® was used for mathematical calculations ("what if analysis") and IBM SPSS® v22 was used for statistical analysis – correlations and t-tests. In-vivo KoA was back calculated from D2 using AS Michaels equation: Clearance (K) = Qb ((exp(KoA(1-Qb/Qd)/Qb) -1)/(exp(KoA(1-Qb/Qd)/Qb) -1)-b/Qd))

Results: There were 70 patients, 39 females, mean age 58.9±13.4 years, mean time on HD 233±18 minutes, mean Qb 404±44.8 mL/min, mean Qd 800±0 mL/min, mean

pre-BUN 53.7±21.3 mg/dL, mean post-BUN 14.6±7.2 mg/dL. Of the 140 IHD sessions, 2 were excluded for incomplete data. When comparing Kt/V, calculated using manufacture KoA with Michaels equation, we found a moderate correlation to UKM (r = 0.5646, p=0.0001). When comparing D2 to UKM, we found a strong positive correlation (r=0.97, p=0.0001). When compared, the in vitro KoA (1231±116ml/min) was 72.8% lower than in vivo KoA (340±156ml/min), mean difference 891±17mL/min (p=0.0001). The reduction in KoA (rKoA) was calculated using equation: 1-(in-vivo KoA/ in vitro KoA). rKoa had a strong positive correlation to body surface area (r=0.8, p=0.0001) and W-TBW (r=0.83, p=0.0001), but no other significant correlations could be discovered.

Conclusions: Our study showed a significantly lower in vivo KoA as compared to in vitro KoA. Larger studies are needed to further evaluate the variables affecting the in-vivo KoA.

FR-PO497

A Randomised Study Investigating the Effect of Medium Cut-Off Haemodialysis on Markers of Vascular Health Compared with Online Haemodiafiltration (MoDal Study)

Kunaal Kharbanda,[1,2] Fiona L. Wilkinson,[3] Annie E. Herring,[3] Sandip Mitra.[1,2] *[1]Manchester University Hospitals, Sale, United Kingdom; [2]University of Manchester, Manchester, United Kingdom; [3]Manchester Metropolitan University, Manchester, United Kingdom.*

Background: Medium Cut-Off (MCO) Haemodialysis (HDx) provides improved clearance of larger middle molecules (up to 45kda) compared with high-flux haemodialysis. Inflammation and cardiovascular (CV) disease, characterised by endothelial dysfunction (ED) are intimately linked in this patient group. Expanded solute removal, through HDx could be biologically significant in modifying endothelial function and CV risk. Endothelial microvesicles (EMV) are a marker of ED and each log increase correlates with a 20-fold increase in CV and all-cause mortality in HD patients. The primary aim of this study was to investigate the effects of HDx treatment on EMV compared with haemodiafiltration therapy(HDF).

Methods: A single-centre, pilot, open-label, randomised controlled study with 1:1 simple randomisation to 6 months MCO therapy or continue on existing HDF therapy(NCT03510520). Pre-dialysis EMV (CD144+) was measured at baseline (T0), 3 months (T12) and 6 months (T24). Secondary outcome measures included inflammatory cytokines, a panel of larger middle molecules, body composition monitoring and patient-reported outcome measures.

Results: 63 participants were randomised to either MCO or HDF and 50 participants (25 each group) completed the full protocol. Mean age was 62.8±16 years, 70% male, 60% Caucasian, 34% diabetic, 68% AVF/G as AV access with no significant difference between groups in these domains. Mean substitution volume in the HDF group was 20.8L±2.84 per session. There was a rise in EMV in the HDF group (change in mean EMV 0.145 logCD144+ EMV/ml at T12 [p>0.05], 0.269 at T24 [p<0.05) and fall in EMV in the MCO group (-0.18 T12 [p<0.05], -0.145 T24 [p<0.05]). Mean albumin change in the MCO group was -1.8±2.93 g/l vs 0 ±1.89g/l in the HDF group (p<0.05).

Conclusions: Switching from HDF to HDx therapy is associated with a reduction in plasma EMV levels at 3 months with a sustained reduction at 6 months. This is in contrast with a rise in plasma EMV levels seen within the same time period in those remaining on HDF. A fall in serum albumin is seen with HDx treatment within the limits expected. Mechanisms behind the changes seen require further exploration. In an era where equipoise still exists between diffusive and convective treatment modalities, HDx could be an important future direction.

FR-PO498

The Relationship of Frequency of Hemodialysis Treatments per Week to Improved Clinical Outcomes in Patients in Skilled Nursing Facilities

Allen Kaufman, Nathan W. Levin. *Dialyze Direct, Brooklyn, NY.*

Background: Dialysis patients residing in a skilled nursing facility (SNF) are characterized by advanced age, frailty, and hemodynamic instability, with multiple comorbid conditions. Based on previous increased frequency studies it was postulated that SNF residents could benefit from frequent hemodialysis (HD) when compared to conventional therapy. Given the potential for less traumatic treatments we compared the effects of HD performed 5 times per week (MFD5) with 4 times per week (MFD4) on mortality and hospitalization rates for patients in skilled nursing facilities.

Methods: We studied patients enrolled in Dialyze Direct staff-assisted, on-site SNF home HD programs in five states: OH, TX, FL, NY, PN, analyzing 1177 patients under care for 260 patient-years. 83% were dialyzed MFD5 (77,745 patient-days) and 17% (15,545 patient-days) were dialyzed) using NxStage technology for approximately 2.7 and 3.1 hrs per treatment respectively.

Results: Patient characteristics of MFD4 vs MFD5 were comparable with respect to age (69y vs 70y), gender (49% F vs 45% F), HD vintage (3.14 vs 2.79 yrs), and mean blood pressure upon program entrance (135 vs. 130 mmHg). Weekly time on HD differed (3.1 vs 2.7 hrs => 12.2 vs 13.4 hours per week). Patients were divided into length of stay quartiles: 15, 33, 90, and 1127 days. Mortality: relative risk in MFD5 patients was lower for per patient-year (0.25 vs 0.54 p<0.05); significant differences were present in quartile one (0.15 vs 0.28) and four (0.07 vs 0.21). Hospitalizations: relative risk in MFD5 was lower per patient year (2.64 vs 4.88 p<0.05); a significant difference in hospitalization was present in quartile one (1.78 vs 4.25). Blood Pressure: MFD5 and MFD4 pre-hemodialysis systolic blood pressure were (136 vs 132 mmHg); for both groups pre-HD.

Conclusions: Five times a week dialysis significantly reduces mortality and hospitalization rates in patients confined to nursing homes, possibly related to more effective and gentler fluid management strategy, that with better blood pressure control and fewer episodes of intradialytic hypotension may have protected organ systems. Its success in this frail population confirms the importance of volume control.

Circulating Angiopoietin-Like Protein 2 Levels and Mortality Risk in Patients Receiving Maintenance Hemodialysis: A Prospective Cohort Study

Jun Morinaga,[1,2] Hirotaka Fukami,[1,2] Tomoko Kanki,[1] Manabu Hayata,[1] Yutaka Kakizoe,[1] Yuichiro Izumi,[1] Takashige Kuwabara,[1] Yuichi Oike,[2] Masashi Mukoyama.[1] *[1]Department of Nephrology, Kumamoto University, Graduate School of Medical Sciences, Kumamoto, Japan; [2]Department of Molecular Genetics, Kumamoto University, Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Prognosis of patients undergoing hemodialysis treatment is poor, as many of them exhibit premature aging. Systemic inflammatory conditions often underlie premature aging phenotypes of the uremic population. Thus, we asked whether Angiopoietin-like protein (ANGPTL) 2, a factor that accelerates progression of aging-related and non-infectious inflammatory diseases, was associated with mortality of hemodialysis patients.

Methods: We conducted a multicenter prospective cohort study of 412 patients receiving maintenance hemodialysis treatment and evaluated relationships between circulating ANGPTL2 levels and risk for all-cause mortality. Circulating ANGPTL2 levels were log-transformed to correct for skewed distribution, and analyzed as continuous variable.

Results: Of 395 subjects analyzed statistically, time-to-event data analysis revealed high circulating ANGPTL2 levels associated with increasing risk for all-cause mortality after adjustment for age, sex, hemodialysis vintage, nutrition status, metabolic parameters, and circulating high sensitivity C-reactive protein values [HR: 2.04, 95%CI (1.10, 3.77)]. High circulating ANGPTL2 levels were also strongly associated with increased mortality risk, particularly in patients with a relatively benign prognosis [HR: 3.06, 95%CI (1.86, 5.03)]. Furthermore, the relationship between circulating ANGPTL2 levels and mortality risk was especially strong in populations showing less senescent phenotypes, such as younger patients [HR: 7.99, 95%CI (3.55, 18.01)], short hemodialysis vintage [HR: 3.99, 95%CI (2.85, 5.58)], or non-diabetes [HR: 5.15, 95%CI (3.19, 8.32)].

Conclusions: We conclude that circulating ANGPTL2 levels are positively associated with mortality risk of patients receiving maintenance hemodialysis, and that ANGPTL2 may uniquely reflect progression of premature aging and subsequent mortality risk in that population.

Risk Factors and Clinical Impact of Early-Onset Peritonitis in Peritoneal Dialysis Patients

Jin hyuk Paek,[1,2] Yaerim Kim,[1,2] Woo Yeong Park,[1,2] Seungyeup Han,[1,2] Sung Bae Park,[1,2] Kyubok Jin.[1,2] *[1]Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea.*

Background: Peritoneal dialysis (PD) related peritonitis is a serious complication of PD and the leading cause of technique failure. However, the impact of early peritonitis on PD survival is not clearly proven. This study aims to analyze the risk factors and outcomes of early-onset peritonitis.

Methods: We retrospectively reviewed 1336 patients who performed PD catheter implantation between 1996 and 2017. Of the 1336 patients, 614 patients who had at least one episode of peritonitis were enrolled. According to time from start of PD to first episode of peritonitis, patients were divided into early-onset (≤6 months) and late-onset (>6 months) peritonitis group.

Results: Among 614 patients, 164 (26.7%) patients developed their first episode of peritonitis within 6 months. The early-onset peritonitis group had more prevalence of diabetes mellitus (P = 0.004), lower serum albumin level at initiation of PD (P = 0.002) and higher peritonitis rate (P < 0.001) than the late-onset peritonitis group. Multivariate logistic regression analysis showed that risk factors associated with early-onset peritonitis were diabetes mellitus (OR 1.510, 95% CI 1.036-2.201, P = 0.032) and a lower serum albumin level at the start of PD (OR 0.629, 95% CI 0.434-0.910, P = 0.014). In multivariate Cox regression analysis, early-onset peritonitis was not an independent risk factor for technical failure and mortality. However, a negative correlation was observed between the time to first peritonitis and technical failure (HR 0.995, 95% CI 0.991-0.999, P = 0.023) and mortality (HR 0.991, 95% CI 0.987-0.997, P = 0.001). In the Spearman analysis, the time to first peritonitis was negatively correlated with the incidence of peritonitis (r = -0.437, P = 0.000).

Conclusions: Diabetes mellitus and a lower serum albumin level at initiation of PD were independent risk factors of early-onset peritonitis. Early-onset peritonitis was associated with higher incidence of peritonitis, technical failure and mortality.

FR-PO501

Microbiology Laboratory Practices Influences a Capacity of Pathogen Identification from Peritoneal Effluent in PD Patient with Peritonitis: A Result from the Thailand PDOPPS

Talerngsak Kanjanabuch,[1] Pongpratch Puapatanakul,[2] Kriang Tungsanga.[3] Thailand PDOPPS Steering group *[1]Medicine, Pathumwan, Thailand; [2]Chulalongkorn University, Bangkok, Thailand; [3]King Chulalong Memorial lHospital, Bangkok, Thailand.*

Background: Effective treatment of peritonitis relies mostly on the identification of pathogenic organisms from the PD effluent. However, culture-negative peritonitis is common in Thailand, a country with "PD First" policy.

Methods: This prospective case-cohort study was conducted in 21 PDOPPS centers in Thailand during May 2016 to October 2017. All cloudy PD bag prior to starting antibiotic from consented PD participants who had peritonitis were submitted to local and central laboratories. Facility practices regarding culture technique and microbiology laboratory practices were collected via survey of microbiology laboratory directors in each facility.

Results: During the cohort period, there were 360 peritonitis episodes (241 participants). The crude peritonitis rate was 0.40 episodes/year. Only 202 episodes (169 participants) had specimen submitted to both laboratories. By local laboratory result, Gram-positive bacteria were accounting for 26.2% of episodes followed by Gram-negative bacteria (23.4%), polymicrobial infection (2.5%), and fungal infection (5.0%). Of note culture negative rates was 42.5%. Central laboratory culture additionally identified organisms in 26 episodes whose local laboratory culture was negative, increasing positive culture rate to 70.3%. Central laboratory culture provided additional yield mainly in fungal, mycobacterium, and polymicrobial infections. Only 1 facility had complete equipment, reagents, and media to culture mold and mycobacteria while obligate anaerobe could be isolated from 4 facilities. None but one performed large volume culture.

Conclusions: Microbiology laboratory practices influence a capacity of pathogen identification from the PD effluent in PD patient with peritonitis and should warrant a competency assessment program.

FR-PO502

Reduction of Peritonitis in an Integrated Health Care System: Collaboration Between Nephrologists, Dialysis Provider, and Health Plan

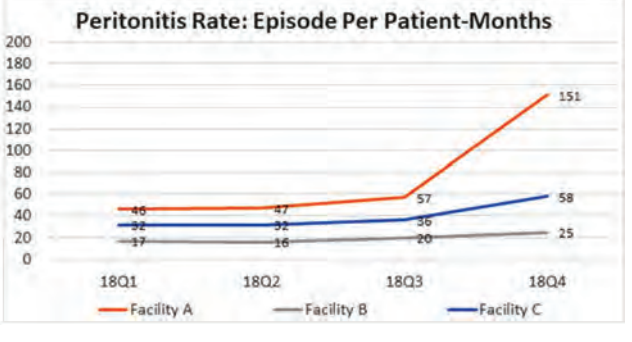
Sijie Zheng,[1,2] Chitra R. Reddy,[2] Gary V. Halick,[2] Maribeth A. Alcaraz,[2] Neelam M. Bhalla.[1] *[1]The Permanente Medical Group, Oakland, CA; [2]Kaiser Permanente, Daly City, CA.*

Background: Peritonitis is a serious complication in patients on peritoneal dialysis (PD). Centers for Medicare and Medicaid Services (CMS) has set peritonitis rates as a performance metric for PD clinics. Kaiser Permanente (KP) Northern California is an integrated health care system with 4.4 million members. In 2018, a workgroup was created to monitor and reduce peritonitis rates in 3 non KP PD clinics with high rates.

Methods: A KP workgroup was formed consisting of 3 non KP PD Medical Directors, a RN Clinical Practice Consultant, and a Regional Health Plan Director. The work group outlined performance improvement tools: 1. The facility's P&Ps were aligned with ISPD guidelines and adherence to P&P monitored; 2. Workflow for patient education and training; 3. Root cause analysis for peritonitis. After an initial site visit, monthly conference calls were held with the work group and facility staffs to review all peritonitis episodes and perform a Root Cause Analysis.

Results: The work group identified several factors that had contributed to peritonitis: 1. Patients that experienced peritonitis were not incident patients, but with a vintage of 2+ years; 2. Patient training and retraining was not consistent; 3. The education and training was not done in an organized manner and there was no enforcement and oversight of this process. The following actions were taken by KP in conjunction with the facility team- 1. P&Ps were reviewed, and staff informed of goals; 2. Staff and management buy-in was obtained to empower and drive improvement. As a result, of the initiative, there was a reduction in the peritonitis rates in all the three facilities (Figure).

Conclusions: In an integrated health care system, creating a dialysis provider and health plan partnership to implement a culture of cooperation is a unique approach to improve patient care. The partnership led to collaboration of care for better outcomes.



FR-PO503

Influence of Season and Climatic Conditions on Peritoneal Dialysis-Associated Peritonitis in a Subtropical Monsoon Climate Region of China

Hao Zhang. *The Third Xiangya Hospital of Central South University, Changsha, China.*

Background: Peritoneal infections are a common complication in patients undergoing peritoneal dialysis (PD) and are frequently the cause of the failure of the technique. Knowing the factors that can lead to theirappearance helps to establish preventative measures. The aim of this research is to understand the influence of season, temperature and humidity on peritoneal dialysis-associated peritonitis in the subtropical monsoon climate region(Hunan provence) in China.

Methods: A retrospective observational study of all peritoneal dialysis-associated peritonitis that occurred in our PD center over a period of 9 years (2009-2017). Our PD center is located in hunan province, China which has the subtropical monsoon humid climate. Demographic data of patients, biochemical indicators at the time of onset, culture results of dialysate fluid, and data of the humidity and temperature of the months from 2009 to 2017 in hunan province were collected.

Results: There were 448 cases of peritonitis(0.17episodes/patient/year) in 885 patients (47±13 years, 56.4% males, 8.7% diabetics, 50.2±19 months on technique). There was significant seasonal variation in the rate of overall peritonitis and gram-negative bacteria peritonitis, with peak incidence in June. When comparing the incidence of peritonitis in different seasons, we found the incidence rates of overall peritonitis and gram-negative bacteria peritonitis were the highest in summer, respectively($p<0.05$). But we did not find this variation upon analysing the incidence rates of peritonitis caused by gram-positive bacteria. There was significant correlation between monthly peritonitis rate and the average monthly temperature ($r=0.258$, $p=0.018$). There was significant correlation between monthly gram-negative bacteria peritonitis rate and the average monthly temperature ($r= 0.278$, $p=0.010$) either. Butwe did not find correlation between the incidence rates of peritonitis and average humidity.

Conclusions: The rates of overall peritonitisand and gram-negative bacteria peritonitisperitonitis are the highest in summer. The higher the temperature, the higher the risk of overall peritonitis and especially of gram-negative bacteria.

FR-PO504

Prophylactic Oral Antibiotics for Post-Endoscopic Peritonitis in Peritoneal Dialysis Patients

Hideaki Oka, Takaki Iwamoto, Kento Fukumitsu. *Matsuyama Red Cross Hospital, Matsuyama, Japan.*

Background: Gastrointestinal endoscopy (GIE), especially lower GIE, is a risk factor for peritoneal dialysis (PD)-related peritonitis. However, there are currently no recommendations regarding preventive antibiotic regimens for GIE-associated peritonitis.

Methods: We retrospectively reviewed the association between prophylactic oral antibiotic administration and GIE-associated peritonitis.

Results: Among 140 patients who received PD treatment in our hospital from April 2008 to March 2018, 91 patients underwent a total of 360 GIEs, excluding patients who received therapeutic antibiotics for exit-site or other infections. None of the 30 GIEs (0%) (1 upper, 29 lower) accompanied by prophylactic oral antibiotic use led to PD-related peritonitis. The oral antibiotics included levofloxacin (n=24, 80%), amoxicillin-clavulanic acid (n=4, 13%) and others (n=2, 7%). In contrast, two of the 330 GIEs (0.6%) conducted without prophylaxis (1/289 upper, 0.3%, 1/41 lower, 2.4%) resulted in PD-related peritonitis, including one upper GIE procedure involving biopsy and one lower GIE involving oral double-balloon enteroscopy for suspected small intestinal bleeding. The incidence of peritonitis following upper GIE with invasive procedures was 1.0% (1/104), similar to past reports, and the incidence of peritonitis following lower GIE with or without invasive procedures was 2.4%, which was lower than previously reported.

Conclusions: Although it was not possible to show any significant effect of prophylactic oral antibiotics on the frequency of total GIE-associated peritonitis because of the small numbers, we could not conclude that prophylactic antibiotics were not beneficial in patients undergoing lower GIE. The administration of prophylactic oral antibiotics covering *Enterobacteriaceae* may thus be a convenient and promising option for preventing GIE-associated peritonitis.

FR-PO505

Dialysate and Plasma Meropenem Concentrations in Continuous Intraperitoneal Regimen During Peritoneal Dialysis-Related Peritonitis

Thatsaphan Srithongkul, Sukit Raksasuk, Bulaporn Techajongnumchai, Suchai Sritippayawan. *Division of Nephrology, Internal Medicine, Siriraj Hospital, Bangkok, Thailand.*

Background: Peritonitis is a major complication in peritoneal dialysis (PD) patients. Currently, the increase of intraperitoneal (IP) meropenem used regarding the rise in resistant organisms. A single dose of IP meropenem was recommended. However, data on the continuous regimen of IP meropenem is still limited. We examined plasma and dialysate meropenem level in the continuous IP meropenem in PD related peritonitis.

Methods: A prospective, descriptive study was performed in 8 patients with PD related peritonitis. Seven patients received a loading dose of meropenem 500 mg IP followed by meropenem 125 mg/L IP (4 exchanges daily). Another patient received the recommended intermittent IP meropenem 1 g daily. Concentrations of meropenem in plasma and dialysate were measured at specified intervals over 24 h with a high-performance liquid chromatography method.

Results: In the continuous group, the mean of maximum meropenem level was 340.6 mg/L (standard deviation [SD] ± 21.5) and 28.7 mg/L (SD ± 21.5) in dialysate and plasma, respectively. At 24 hour, mean dialysate drug level was minimum at 45.3 mg/L (SD ± 36.2). Dialysate meropenem concentrations from this regimen exceeded MIC of the pathogenic resistance organism (MIC > 8 mg/L) at every time points. For the intermittent regimen, mean plasma and dialysate meropenem levels were 11.8 mg/L (SD ± 8.2) and 34.2 mg/L (SD ±35.7), respectively. Interestingly, dialysate meropenem concentration at 12 hours after 1 g of meropenem was 4.9 mg/L which may not provide adequate drug level for resistant organisms. Five patients (71%) responded to the treatment, but two patients (29%) developed treatment failure from fungal peritonitis. No major side effect was observed.

Conclusions: Meropenem loading 500 mg and continue with 125 mg/L provide adequate dialysate meropenem concentration and could be considered for effective treatment in PD related peritonitis.

A New Workflow Using Artificial Intelligence to Reduce Peritonitis for Patients Treated with Peritoneal Dialysis

Andrew Long, Hao Han, Joanna Willetts, Sheetal Chaudhuri, Len A. Usvyat, Kylee K. Cameron, Brian C. Ellison, Judith Moran, Jeffrey L. Hymes, Dinesh K. Chatoth, Franklin W. Maddux. *Fresenius Medical Care, Waltham, MA.*

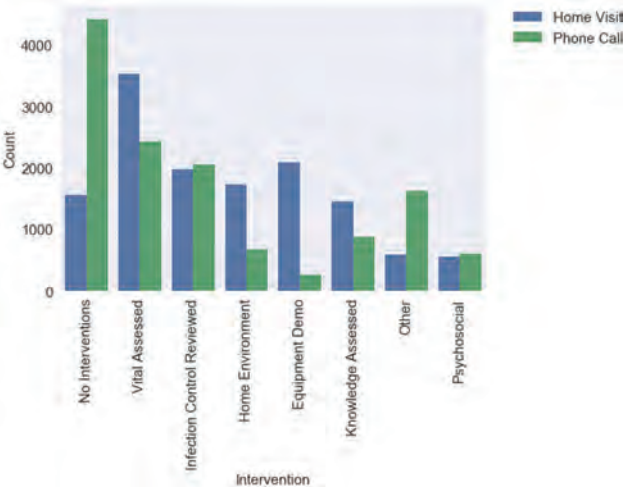
Background: ~10% of patients with kidney failure are treated with peritoneal dialysis (PD). To reduce peritonitis risk (a major complication of PD), we trained a model to predict which patients were at risk of peritonitis in the next month. The model was trained with an XGBoost classifier and had an area under the receiver operating characteristic curve of 0.66. This abstract outlines a new workflow implemented by a large dialysis provider.

Methods: Starting in Dec 2018, we used the peritonitis predictive model to generate risk scores on a monthly basis for the entire PD population treated by Fresenius Medical Care North America. We scheduled a home visit for patients within the first 30 days and a phone call for patients on dialysis between 30 and 90 days. For the remaining patients, we used the model to segment into three groups: high risk (~10%), medium risk (~10%) and low risk. Those patients with high risk were scheduled for a home visit and those with medium risk were scheduled for a phone call. An assessment was created in Feb 2018 to track specific interventions.

Results: We have performed over 14000 phone calls and over 7000 home visits due to this personalized care effort. Many of the home visits resulted in reviews of infection control, home environment or equipment. More of the phone calls resulted in no intervention than the home visits, which is logical given that those patients have lower risk scores. Analysis of outcomes such as peritonitis rates and modality changes is underway.

Conclusions: Integrating artificial intelligence into clinical decision support allows us to intervene with the right patient at the right time for the right reason. Future work must be conducted to improve the model to include additional reasons for intervention such as psychosocial or educational needs.

Funding: Commercial Support - Fresenius Medical Care North America



FR-PO507

Does Single-Dose Conjugated Pneumococcal Vaccine Provide Enough Antibody Response in Peritoneal Dialysis Patients?

Necmi Eren,[1] Hayrunnisa Albayrak,[3] Sibel Bek.[2] *[1]Nephrology, Kocaeli University, Kocaeli, Turkey; [2]Kocaeli University School of Medicine, Kocaeli, Turkey; [3]Kocaeli University, Kocaeli, Turkey.*

Background: Dialysis patients have 10-100 fold-increased risk of sepsis and pneumonia related mortality. The incidence of pneumonia increased and over half of reported pneumonia cases in dialysis patients are caused by Streptococcus pneumonia. Immunization against infectious diseases is a fairly simple, prevention strategy in dialysis patients. Implementation of polysacharidde pneumococcal vaccination (PPSV23) has led to an considerable decrease in pneumonia incidence. In accordance to PPSV23, conjugated pneumococcal vaccine (PCV13) has an increased and sustainable immunogenic response. In dialysis patients, antibody response to vaccination is decreased. This is the first study that investigates whether PCV13 vaccination provides enough antibody response in peritoneal dialysis (PD) patients.

Methods: Participants received a single dose of 0.5 ml of PCV13 administered intramuscularly. Blood samples were drawn prior to vaccination and at 1 month after vaccination. Serum antipneumoccal antibody level is measured by ELISA method.

Results: 69 PD (39 male, 30 female) patients and 10 healthy volunteers were inrolled in our study. Mean age was 52,6 ± 12,9 years (Image 1). In PD patients and control groups, first month antibody levels were increased statistically significant than prevaccination (p=0,001, p=0,008, respectively). First month antibody levels were higher in control group compared to patients (p=0,013). In PD group, statistically significant relationship were observed between antibody levels and serum albumin, CRP, Kt/V, weekly CrCl, nPCR parameters (Image 2).

Conclusions: In PD patients, PCV13 vaccination resulted enough but lower antibody levels than control group. Malnutrition, inflammation and lower dialysis adequacy were associated with lower antibody response.

FR-PO508

Is Peritoneal Dialysis a Good Technique for Patients with Autosomal Dominant Polycystic Kidney Disease?

Gustavo A. Useche Bonilla, Ana Vilar, Sara Aparicio, Ángel Palacios castillo, Margarita Gimenez Edo, Antonio Galan Serrano. *Hospital General Universitario de Valencia, Valencia, Spain.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most frequent genetic cause of Chronic Kidney Disease, progressing in most cases to End-Stage Renal Disease. Initially, Peritoneal Dialysis (PD) was contraindicated in this kind of patients, because it was thought that an already elevated abdominal volume would decrease the tolerance and promote a higher incidence of complications. However, this trend is in reverse and every day there are more patients with ADPKD in PD without showing more complications, with good tolerability and adequacy.

Methods: Descriptive, retrospective, unicentric study design; we selected all the patients with a diagnosis of ADPKD and that entered our PD program between April 1st, 1999 and March 31st, 2018. Every one of these patients was matched with 2 non-ADPKD patient who also entered our PD program in the same time period. We proceed to compare the incidence of dialysate leaks, eventrations, peritonitis; the number of hospitalizations and technique failures, and the PD adequacy in both groups through their Kt/V and nPCR at 6, 12, 18 and 24 months of beginning the technique.

Results: Comparing the basal characteristics of both groups, there was only significant difference in the Charlson index score. The ADPKD group had a mean of 2.9 ±1.07, while the non-ADPKD group had 4.2 ± 1.97. The most common cause to enter on PD program was patient choice. The mean technique survival was similar in both groups 969.6 ± 667.4 vs 847.5 ± 666.4 days. The proportion of patients in APD was higher in the ADPKD group, 71 vs 46% (p = 0.1). The means of episodes of peritonitis, dialysate leaks and hospitalizations were similar. The most common cause of withdrawal from the program was transplant (50 vs 32%); the percentage of infradialysis was higher in the non-ADPKD group (7 vs 18%). Kt/V mean was > 1.7 in both groups, but it was overall lower in the ADPKD group. A value of p < 0.0.5 was only achieved when the peritoneal Kt/V was contrasted.

Conclusions: ADPKD patients not show higher risk of PD complications or technique failure when compared with non-ADPKD with similar characteristics. PD is an effective treatment modality for ADPKD patients, and ADPKD should not be taken as an absolute contraindication. PD adequacy thresholds are achievable in ADPKD patients.

FR-PO509

Peritoneal Dialysis Outcomes of Patients with Nephrotic Syndrome: A Propensity Matched Study

Sijia Zhou, Wen Tang. *Peking University Third Hospital, Beijing, China*.

Background: Whether or not nephrotic syndrome (NS) patients developed to end stage renal disease (ESRD) stage could be treated by peritoneal dialysis (PD) were not clear. The aim of this study is to investigate the outcomes of PD treatment on ESRD patients with or without NS.

Methods: In this retrospectively cohort study, all incident PD patients with NS who started PD during February 1, 2006, to December 31, 2017, were identified and matched with patients who without NS by using propensity scores based on age, gender, diabetes mellitus and serum albumin. Both the mortality and technique failure on PD were compared.

Results: A total of 53 NS PD patients and 53 matched control non-NS PD patients with a median follow-up of 3.32(0.84, 5.95) years were included. The median survival of NS PD patients (6.60 years, 95% CI 4.95-8.25 years) was comparable to that of non-NS PD patients (5.20 years, 95% CI 4.05-6.34 years, p=0.261). An interaction effect was observed between survival time and baseline NS status. Thus, patients' outcomes within 1.5 years and after 1.5 years were analyzed separately. Both the mortality rate (log-rank test, p=0.235) and technique failure (log-rank test, p=0.543) within 1.5 years in the patients with NS were comparable to those of non-NS group. However, after 1.5 years, as compared to patients without NS, NS status at baseline had both lower all-cause mortality (p=0.020) and lower technique failure rate on PD (p=0.008). Multivariable Cox regression analysis showed that as compared to non-NS patients, PD patients with NS (HR 0.38, 95% CI 0.17-0.86, p=0.019) were significantly associated with both lower all-cause mortality adjusting for age (HR 1.05, 95% CI 1.02-1.08, p<0.001) and serum albumin levels at baseline (HR 0.86, 95% CI 0.75-1.00, p=0.047) and lower technique failure rate after adjusting for age (HR 1.03, 95% CI 1.00-1.05, p=0.020) and hypertension.

Conclusions: Our study demonstrated that both the short and long-term PD outcomes of ESRD NS patients were not inferior to their matched control, which indicated that PD could be considered as a long-term renal replacement therapy for ESRD patients with baseline NS.

FR-PO510

Impact of Obesity in Peritoneal Dialysis Patients

Maria Quero,[1] Inés Rama,[1] Jordi Comas farnes,[2] Emma Arcos,[2] Miguel Hueso,[1] Diego Sandoval,[1] Nuria Montero,[1] Josep M. Cruzado.[1] *[1]Hospital Universitario de Bellvitge, l'Hospitalet de Llobregat, Spain; [2]Organització Catalana de Trasplantaments, Barcelona, Spain.*

Background: Some studies reveal that obesity is associated with a decrease in mortality in hemodialysis patients. However, few studies have addressed the association between BMI in peritoneal dialysis (PD) patients.

Methods: We performed this longitudinal, retrospective study, to evaluate the impact of obesity in PD patients, using data from the Registry of Renal Patients of Catalonia from 2002 to 2015 (n = 1573). Obesity was defined as BMI> 30; low weight: BMI <18.5; normal range: BMI 18.5-24.99; and pre-obesity: BMI 25-29.99. Variations in BMI were calculated during follow-up. The main variables evaluated were the technique and patient survival.

Results: Obesity was observed in 20% of patients starting PD. We did not find differences in sex or PD modality, being older the obesity group (65.9% are ≥55 years versus 59% non-obese p=0.003) and presenting more DM and cardiovascular disease (47.9% obese versus 25.1% non obese and 41.7% versus 31.5% respectively). We did not observed differences in hemoglobin, albumin and KTV in obese patients. Concerning peritonitis rate we did not find any difference between groups, presenting more peritonitis patients on CAPD and ≥65 years (subhazard ratio (SHR) 1.75 (p= 0.000) and 1.56 (p=0.009)). Related to technique survival, we found higher transfer to HD in obese group in the univariate analysis that was not confirmed in the multivariate analysis (SRH 1.12 (p=0.4)), and we did not found differences in mortality rate. In relation to be transplanted, underweight group, olders and patients with cardiovascular disease or diabetic nephropathy presented less probability (SHR 0.65, 0.24. 0.5 and 0.54 p <0.05). Obese patients did not present differences in survival with weight changes, but in non-obese patients, the gain of 7% of the basal weight during the first year supposed a protective factor of dying (HR 0.6 p=0.034).

Conclusions: We did not observe differences in PD adequacy parameters, technique and patient survival or probability of being transplant in obesity group. However, we found that obese patients presented more DM and cardiovascular diseases that are related to higher morbi-mortality in the multivariate analysis.

FR-PO511

Long-Term Patient Survival Was Not Influenced by the Initial Modalities in Peritoneal Dialysis Patients: A Propensity Score-Adjusted Single-Center Study

Hironori Nakamura, Anayama Mariko, Yasushi Makino, Masaki Nagasawa. *Department of Nephrology, Shinonoi General Hospital, Nagano, Japan*.

Background: The association between the modalities of peritoneal dialysis (PD) and long-term patient survival considerably differs among countries and remains unknown.

Methods: We retrospectively investigated the long-term survival rate of 146 Japanese patients, including those who switched from PD to hemodialysis (HD), and evaluated the correlation between survival time and clinical features at PD initiation, and the effect of using different dialysis modalities, continuous ambulatory peritoneal dialysis (CAPD) or automated PD (APD), on patient survival and their associated factors.

Results: The following patient characteristics were as follows: age (median, interquartile range), 65.0 (55.0–73.5) years; body mass index (BMI), 22.6 (20.8–25.9) kg/m^2; diabetes, 35.0%; serum albumin level, 3.4 (2.9–3.8) g/dL; serum creatinine level, 8.3 (6.2–9.9) mg/dL; dialysate-to-plasma creatinine concentration ratio (D/PCr), 0.66 (0.54–0.77); and urine volume, 700 (305–1000) mL. Time on PD was 36.0 (17.0–64.5) months, and time on patient survival was 53.0 (20.0–103.0) months. The 5- and 10-year patient survival rates were 65.4% and 40.0%, respectively. Cox proportional hazard analysis revealed that patient survival was significantly affected by age (hazard ratio [HR], 1.08; 95% confidence interval [95% CI], 1.05–1.11; p < 0.001), diabetes (HR, 2.07; 95% CI, 1.18–3.63; p = 0.011), and D/PCr (HR, 8.31; 95% CI, 1.38–49.9; p = 0.021). When comparing CAPD (n = 57) with APD (n = 84), the Kaplan–Meier analysis showed the values for patient survival time as 61.0 (45.1–76.9) months for CAPD versus 140 (76.9–203.0) months for APD, log-rank test; p < 0.001. Baseline characteristics showed significant differences between CAPD and APD in age (70.0 vs. 60.5 years), ACE-I/ARB intake (41% vs. 68%), icodextrin (39% vs. 16%), and serum creatinine levels (8.1 vs. 9.0 mg/dL), respectively. After propensity score adjustment for choosing CAPD, the superiority for APD over CAPD disappeared (p = 0.756).

Conclusions: We conclude that patient survival in this population was superior to that in previous worldwide reports. Moreover, the selection of CAPD or APD for initial dialysis was not associated with long-term patient survival, following adjustment of the baseline characteristics.

FR-PO512

Outcome Measures for Technique Failure Reported in Randomized [AT1] Trials in Patients on Peritoneal Dialysis: A Systematic Review

Emma H. Elphick,[3] Matthew J. Holmes,[3] Matthew Tabinor,[4] Simon J. Davies,[3] Karine E. Manera,[1] David W. Johnson,[2] Jeffrey Perl,[6] Allison Tong,[1] Neil Boudville,[5] Mark Lambie.[3] *[1]The University of Sydney, Westmead, NSW, Australia; [2]Princess Alexandra Hospital, Brisbane, QLD, Australia; [3]Keele University, Crewe, United Kingdom; [4]Royal Wolverhampton Hospital, Stoke on Trent, United Kingdom; [5]University of Western Australia, Nedlands, WA, Australia; [6]St. Michael's Hospital, Toronto, ON, Canada*.

Background: Peritoneal dialysis (PD) technique failure (TF) has been identified as a core outcome by the Standardized Outcomes in Nephrology - Peritoneal Dialysis (SONG-PD) initiative to be reported in trials. However, the definition and measures used for TF are not standardized. We aimed to assess the scope and consistency of definitions and measures used for TF in trials in patients on PD.

Methods: MEDLINE, Embase and CENTRAL databases were searched for randomized trials conducted in patients on PD that reported TF as an outcome up until July 2018. The definition and measures used were extracted and independently assessed by two reviewers.

Results: We included 23 from 187 trials involving 41 to 371 participants, with follow-up durations ranging from 6 weeks to 4 years. The duration of hemodialysis required to define TF was reported in 6 (26%) trials, specifically: 30 days (2 trials), "permanent" without further definition (2 trials), continuing HD until censoring (1 trial) and "any duration" (1 trial). In 9 trials it was unclear how transfer to HD/death/transplant was accounted for in the analysis of TF. Eight trials reported only "transfer to HD" without further definition regarding transplantation/death, whereas death was a cause of TF in 4 trials and censored in the remaining 2 studies. No study included transplant in their definition of TF. TF was reported as a frequency in 21 trials. Eighteen trials compared TF rates in the intervention and control groups, with 15 using a hazard ratio and the remaining 3 using unclear methodology. Attribution of TF was reported in 14 trials. Three trials reported only peritonitis-related TF without mentioning other causes of TF, with the remaining 11 studies reporting different reasons in each case.

Conclusions: There is substantial heterogeneity in how PD technique failure is defined and reported, likely contributing to substantial variability in reported rates. Standardized measures for reporting technique failure in PD trials are required.

FR-PO513

IoT (Internet of Things) Follow-Up vs. Conventional Care in Patients with Continuous Ambulatory Peritoneal Dialysis: A Retrospective, Case-Control Study

Aihua Li, Mengjun Liang, Zongpei Jiang. *The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Peritoneal dialysis (PD) has been accepted as a home-based, more cost-effective renal replacement therapy worldwide. Increasing evidence indicates that patients on PD have clinical outcomes that are not optimistic than those on hemodialysis. The reasons for these observations are multifactorial and include lack of experience on self health-care and limited modality of follow-up. Internet of things (IoT), a novel technology that would improve access to and compliance in PD patients, has been designed and deployed to PD patients in our center for the nursing follow-up.

Methods: A retrospective, case-control study enrolled 30 patients on continuous ambulatory peritoneal dialysis (CAPD) in our center from 2018.09 to 2018.10. The patients were categorized into IoT group (15 patients) and conventional group in which patients was selected by propensity score matching for the gender, age, dialysis age and basic nephropathy. All the patients had been followed up for 3 months to assess their quality and compliance of PD. IoT follow-up was defined as the framework of home-based sphygmomanometer, electronic scale, weighing scale and portable application description (PAD) via bluetooth and the nurses in PD group could review the data timely over the internet and provide care management advice. Conventional care was defined as telephone or outpatient follow-up monthly.

Results: There were no differences among gender, age, dialysis age, and basic nephropathy distribution between the two groups. After 3-month follow-up, the weight compliance rate in IoT group seemed better than that in conventional group, with rate of 100% and 80%, p=0.068; the blood pressure compliance rate in IoT group seemed higher than that in conventional group, with rate of 60% and 46.7%, p=0.464. Nine patients (the rate of 60%) in IoT group, while only 2 patients (13.3%) in conventional group, had got alterations of hypotensive drugs, p=0.008. Eight patients (53.3%) in IoT group had acquired adjustments of PD doses, while no patient in conventional group had any changes, p=0.001.

Conclusions: Our preliminary results had indicated that IoT technology could provide innovations and timeliness for basic nursing care in PD follow-up. IoT devices would help to improve the availability and effectiveness of peritoneal dialysis.

FR-PO514

Thirty-Day Readmissions in the Peritoneal Dialysis Population Have High Clinical Variability

Jackson Kim,[2] Eugene Lin.[1] [1]*Department of Nephrology, LAC USC Medical Center, Los Angeles, CA;* [2]*LAC USC Medical Center, Los Angeles, CA.*

Background: Dialysis facilities are evaluated on their all-cause 30-day readmission rate. We investigated the clinical heterogeneity of 30-day readmissions in the peritoneal dialysis (PD) population and the relatedness of readmissions to index hospitalizations.

Methods: In adults with Medicare receiving PD in the United States from 1/1/2013-12/31/2014, we classified index hospitalization and 30-day readmission pairs as "related" if the principal diagnoses were of the same organ system. Using multinomial logistic regression and adjusting for the patient, facility, and geographic factors, we studied whether prior hospitalization burden was associated with a higher likelihood of related readmission. For each of the most common index hospitalization diagnoses, we summarized the most likely reason for 30-day readmission.

Results: The adjusted probability of an unrelated 30-day readmission was 19.2% (95% CI: 18.7%, 19.7%) in patients with 0-1 hospitalizations in the prior year and 26.3% (95% CI: 25.0%, 27.2%) in patients with 4 or more hospitalizations (relative increase 1.4, 95% CI: 1.3, 1.5). Cardiovascular index hospitalizations were most likely followed by a related 30-day readmission (11.8%, 95% CI: 11.3, 12.4%), while renal index hospitalizations were least likely (3.4%, 95% CI: 2.4, 4.3%). For the most common index hospitalizations (peritonitis, sepsis, hypertension, and pneumonia), the most common reason for 30-day readmission was the same as the index hospitalization. Rates of these readmissions varied widely: 43% of peritonitis admissions were followed by peritonitis, sepsis, or peritoneal catheter complications; 34% of sepsis admissions by infections; 21% of hypertension admissions by hypertension or volume overload; and 21% of pneumonia admissions by pneumonia, sepsis, or pulmonary complications.

Conclusions: High background hospitalization rates were associated with increased unrelated 30-day readmissions. When stratifying by index hospitalization diagnosis, there was substantial variability in the rate of and reason for 30-day readmission. Medicare could improve 30-day readmission metrics in PD by accounting for clinical heterogeneity and background hospitalization burden.

FR-PO515

The Transition Care Programme: Our Experience in the Last 10 Years

Sadia Jahan,[1,2] Kara Summers,[1] Rachel Giugni,[1] Pauline A. Nicholas,[1] Dwarakanathan Ranganathan.[1,2] [1]*Kidney Health Service, Metro North Hospital and Health Service, Brisbane, QLD, Australia;* [2]*Faculty of Medicine, The University of Queensland, Brisbane, QLD, Australia.*

Background: Home therapies including peritoneal dialysis (PD) & home haemodialysis (HHD) are associated with better outcomes in patients with end stage kidney disease (ESKD) as compared to in-centre dialysis. Home therapies allow patients autonomy and flexibility with proven improved quality of life. Treating end-stage kidney disease at home means less travel & its associated cost. The cost of HHD to the health care system is the lowest of all dialysis modalities while incentre dialysis is the most expensive. 'Home, Independent dialysis and Transition Service' (HITS) was commenced in July 2009 within the Kidney Health Service. Since its inception, the uptake of home therapies has increased over the 10 years.

Methods: A retrospective analysis of patients referred to HITS and incident patients requiring kidney replacement therapy (KRT) between Jan 2009 and Dec 2018 with 6 months follow-up after their chosen modality. Incident home therapies pre- HITS and all prevalent dialysis patients via HITS were also analysed.

Results: Incident Home therapies increased from 44% in 2006 (pre-HITS) to 69% in 2018. There was an increased uptake of PD by 13.5% with 25 patients choosing PD in 2006 and 45 patients in 2018. The uptake of HHD remained at 20%. From the prevalent dialysis pool there was an increase in patients choosing HHD from transplant, incentre dialysis and PD from 28.6% in 2013 to 50% in 2018. Patient were followed up for 6 months and due to reasons including PD peritonitis, technique failure, haemodynamic instability rendering HHD unsafe, between 5-15% patients transitioned from home therapies to incentre haemodialysis.

Conclusions: Home therapies was relocated to the suburbs and away from the main hospital campus in 2006. The Transition unit followed in 2015. Since this initiative, the uptake of home therapies has increased which is largely due to the increased availability of pre-dialysis and specific home therapies nurses, medical support and a dedicated multi-disciplinary team. However, KRT modality in home therapies at 6-months are still not being maintained which necessitates stringent patient selection criteria with rigorous and intense education. Our transition unit has seen the increase in the uptake of home therapies however more work is required to keep patients on these modalities.

FR-PO516

Effect of Switching Dialysis Modalities on Metabolic and Nutritional Parameters: Analysis from USRDS

Farah Abifaraj,[1] Omar A. Aleter,[1] Enshuo Hsu,[1] John Badalamenti,[2] Hania Kassem.[1] [1]*University of Texas Medical Branch, Galveston, TX;* [2]*University of Texas Medical Branch, Dickinson, TX.*

Background: The effect of renal disease and the two dialysis modalities (hemodialysis (HD), and peritoneal dialysis (PD)) on metabolic and nutritional parameters has been well-studied. Compared to HD, PD is associated with low parathyroid hormone and calcium (Ca) levels, low albumin (alb) and increased BMI. In 2011, the prospective payment system dialysis bundle provided incentive for providers to place patients (pts) on PD, leading to more pts switching from HD to PD. To our knowledge, the impact of switching modalities on these parameters has not been described. We aim to elucidate the effect of switching dialysis modalities and the direction of the switch on metabolic and nutritional parameters in end-stage renal disease (ESRD) pts.

Methods: Using USRDS data, we reviewed 2,955,601 pts and analyzed 16,203 pts who switched modalities from 2012 to 2016. Pts were included if they were age >18, were switched from HD to PD or PD to HD after being on the first modality for at least 2 months, and had data available in Crownweb records before and after switch. Transplant pts and pts who switched modalities more than once during the research period were excluded. After excluding data for the last 3 months of the first modality and the first 3 months of the second, we used t-test to compare average Ca, phos, alb, BMI, and normalized protein catabolic rate (NPCR). We further used linear models to show differences between the two groups, adjusting for demographics and time on first modality.

Results: In both groups, phos and Ca increased after switch. In the HD to PD group, alb decreased (0.25mg/dL) and BMI increased (0.42kg/m2); NPCR did not change significantly. In the PD to HD group, alb (0.26) and NPCR (0.06) increased, though BMI decreased (2.1kg/m2). Compared to HD to PD switch patients and after adjusting for demographics and time on initial dialysis modality, PD to HD pts had higher phos (0.15mg/dL), Ca (0.09mg/dL), alb (0.41mg/dL), and NPCR (0.07g/kg/d), and lower BMI (2.23 kg/m2). All results were significant ($p<0.0001$).

Conclusions: Regardless of the direction of the switch, HD was associated with a higher alb and lower BMI. After adjusting for demographic variables and time on initial dialysis, switching from HD to PD results in lower phos, Ca, alb, but higher BMI than PD to HD pts.

FR-PO517

Prospective Follow-Up of Peritoneal Function in New PD Patients: Comparison Between a Conventional and a More Biocompatible Dialysis Solution

Anouk V. Diepen,[1] Raymond T. Krediet.[2] *[1]Internal Medicine, Elisabeth-Tweesteden ziekenhuis, Tilburg, Netherlands; [2]Academic Medical Center, Amsterdam, Netherlands.*

Background: Preservation of peritoneal membrane function is essential for patients on long-term peritoneal dialysis (PD). Biocompatible dialysis solutions characterized by a higher pH and a lower concentration of glucose degradation products, are hypothesized to prevent or postpone the membrane alterations that result in ultrafiltration failure and consecutive morbidity and mortality. The objective of this study was to make an in vivo comparison between conventional and biocompatible solutions and the time course of peritoneal solute and fluid transport.

Methods: We analyzed prospectively collected peritoneal transport data from 251 incident patients treated between 1994 and censoring in 2016. The maximal follow-up was 5 years. 135 patients were treated with conventional and 116 with biocompatible solutions. Linear mixed models including change point analyses were performed to compare the time course of peritoneal transport between both groups. Adjustment was made for comorbidity. The interaction with peritonitis was examined

Results: 67% (conventional) and 64% (biocompatible) of the patients underwent minimally 3 transport measurements during follow up. Follow-up during the first years was characterized by consistently faster solute transport and lower ultrafiltration in the biocompatible group. After a change point at 3 years in the conventional group an increase in small solute transport occurred in these patients group ($p=0.01$). Thereafter solute transport increased progressively in the conventional compared to the biocompatible group. This was accompanied by a marked decrease in net ultrafiltration, which became lower in the conventional group between 3 and 4 years. Patients with a previous peritonitis in the conventional dialysis group, showed a significant decrease of transcapillary ultrafiltration already after 2 years on PD ($p=0.02$) while this was not present in the biocompatible dialysis group or in patients without peritonitis. The decrease in ultrafiltration was caused by both reduced free water transport ($p=0.08$) and small pore fluid transport ($p=0.06$).

Conclusions: this study emphasizes the detrimental relationship between conventional dialysis solutions, peritonitis and the acceleration of peritoneal transport abnormalities in long-term PD patients.

FR-PO518

"We Try Not to Let PD Control Us": Patient and Caregiver Perceptions of Empowerment in Managing Peritoneal Dialysis

Amanda Baumgart,[1,2] Karine E. Manera,[1,2] Yeoung Jee Cho,[3,4] Jenny I. Shen,[5] Jonathan C. Craig,[2,6] David W. Johnson,[3,4] Allison Tong.[1,2] *[1]The University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, Sydney, NSW, Australia; [3]Princess Alexandra Hospital, Brisbane, QLD, Australia; [4]Australian Kidney Trials Network, Brisbane, QLD, Australia; [5]Los Angeles Biomedical Research Institute, Torrance, CA; [6]Flinders University, Adelaide, SA, Australia.*

Background: While peritoneal dialysis (PD) can offer patients more independence and flexibility compared with hemodialysis, the demanding regimen can impose a burden on patients. Patient empowerment can strengthen capacity for self-management and improve outcomes. We aimed to describe patient and caregivers' perceptions, attitudes and experiences of empowerment in PD.

Methods: Adult patients on PD (n = 81) and their caregivers (n = 45) from nine dialysis units in Australia, Hong Kong, and the United States participated in 14 focus groups. Transcripts were thematically analyzed.

Results: We identified six themes: *lacking clarity for self-management* (limited understanding of rationale behind necessary restrictions, muddled by conflicting information); *restricted flexibility and freedom in doing dialysis regimen* (burden in budgeting time, confined to be close to home); *strength with supportive relationships* (gaining reassurance with practical assistance, comforted by considerate health professionals, alleviated with involvement of friends and family); *defying constraints* (reclaiming the day, undeterred by treatment, refusing to be defined by illness); *regaining lost vitality* (enabling physical functioning, restoring energy life participation) and *personal growth through adjustment* (building resilience and enabling positive outlook, accepting the dialysis regimen). Illustrative quotations are provided in Table 1.

Conclusions: For patients and caregivers, understanding the rationale behind lifestyle restrictions, practical assistance and family support in managing PD facilitated empowerment, whereas being constrained in time and capacity for life participation outside the home undermined it. While some refused to allow PD to control their lifestyle, education and counseling enhancing practical skills and time management can help patients accept and minimize the disruption of PD, and may improve treatment satisfaction and outcomes.

Table 1. Selected quotations

Theme	Quotations
Lacking clarity for self-management	*Yeah, and if not, why not? I want to know the physics, the mechanics behind why it's going to damage this, and if I'm going to get hurt... that's what I need to know. So then I understand. Not just tell me "you can't do that". Why?* *The dietitian for my kidneys says you can't do this and you can't do that, and I say hang on, I'm a diabetic. I say this and you say that, which is right and which is wrong? Then they said, as long as you don't overdo anything, just do what you do. So it's confusing, I mean one dietitian says you do this, another one says that, and they conflict.*
Restricted flexibility and freedom in doing dialysis regimen	*Before, I can go out whenever I want. But now I have to schedule every day... the only thing is that I have no time anymore for everything. Every time must be budgeted.* *Like I was working, I've been working for how many years? And just for two years I am not working, so it could be affecting me, staying home, seeing everybody going, working, and I'm at home and staying there doing my dialysis and things like that... At the moment it's like a full stop. I can't move forward in my life. It's like you have to stay home, you have to do this.*
Strength with supportive relationships	*I made the trip with no hassle whatsoever. The people in the center, they have got lots of tricks up their sleeve, like you know, when you're doing travelling you find yourself in all sorts of situations. Doing an exchange may be something you need to take care of, but the setting is not something that you can choose, so they gave me a couple of tricks up my sleeve.* *So I think that what's important to me is the relationship with me and the PD unit has really helped, like all the nurses are really compassionate and really get to know me. They sort of help me along through the journey.* *So they know I have to be back home or I can't stay out, if I'm going somewhere in the morning or whatever. So they all work with me, and everybody is just like, it is what it is.*
Defying constraints	*Since you're sleeping while your machine is on at night - I do the automated - I'm done as soon as I wake up, and make sure the hours are taken care of. Then I'm free to go about my day just like I regularly did before. So there's really no change in my activities during the day, basically.* *We try not to let the dialysis control us, you know. I say forget about the time, you do it whenever, as a family together we go out, but we come back on the time. We don't lose the time, but we just, six hours away from the machine, and in that time, that is where we find to put what we want to do as a family.* *Most people don't even know I'm on dialysis unless I tell them. Because I don't feel like it's a big deal to me.*
Regaining lost vitality	*First of all I thank God and the doctors. I had been swollen for about three years, I couldn't walk, and I ended in the hospital and I thank God again and the doctors that are helping me and I feel fine now. [translated]* *Since she's been on dialysis, at least it's giver her a bit of pep in her step again nowadays. I can see, from my point of view, she was going downhill rapidly until the diagnosis. At least now we can get out and enjoy the grandkids.*
Personal growth through adjustment	*As crazy as it may sound, I feel like being on dialysis really pushed me more in life, of becoming independent. Through dealing with my personal issues, my self-issues, it really helped me. It made me see life better by being on dialysis, it's crazy but that's how it made me.* *The hardest is acceptance... I used to think that I wasn't going to do dialysis. I didn't want to do that. "Why would I want a life where I'm going to be slave to a machine?" I had to be in treatment to accept that it is life changing. I we all should go through that. [translated]*

FR-PO519

Physician-Led CKD Education Improves Quality and Reduces Cost of Care in Patients with ESRD

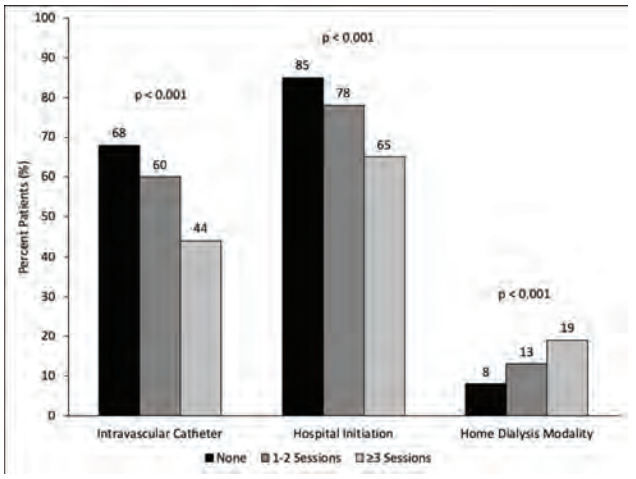
Bernard V. Fischbach,[2] Stevan A. Gonzalez,[1] Roberto L. Collazo-Maldonado,[2] Ankit Mehta,[2] Alexander Liang,[2] Sandra M. Lauriat.[2] *[1]Baylor Scott & White, Fort Worth, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Background: Healthcare providers are tasked with reducing costs and improving patient awareness of chronic kidney disease (CKD). Patient educational initiatives may reduce costs and improve outcomes.

Methods: We developed a large-scale physician-led CKD education program. We performed a retrospective review of all dialysis initiates over a 24-month period and evaluated outcomes based on participation in educational programs.

Results: A total of 1294 dialysis initiations were analyzed and 621 patients (48%) attended at least one class. No differences in participation were observed based on gender, race, or primary language spoken. Overall participation in educational workshops was associated with decreased intravascular catheter use, increased home dialysis modalities, and decreased hospitalization for dialysis initiation ($p<0.001$). Attendance when stratified by no participation vs. 1-2 sessions vs. ≥ 3 sessions revealed a progressive trend towards decreased intravascular catheters, in-center dialysis modalities, and hospitalization for dialysis initiation ($p<0.001$; Figure). In multivariate analysis, the associations between participation in CKD education and decreased likelihood of intravascular catheter access (OR 0.55; $p<0.001$), decreased in-center hemodialysis modality (OR 0.48; $p<0.001$), and increased in-center hemodialysis initiation vs. hospital (OR 2.02; $p<0.001$) were independent of race, gender, age, or primary language spoken.

Conclusions: Patients with CKD who participate in physician-led educational programs are less likely to need urgent dialysis, which results in decreased use of intravascular catheters, and hospitalization for dialysis initiation. They are also more likely to utilize home dialysis modalities. Development of patient educational programs could significantly reduce costs and improve outcomes in this population.



CKD Edu - Outcomes; n=1294

FR-PO520

Lower Utilization of Home Dialysis in Non-White and Dual-Eligible Dialysis Patients

Debabrata Ray,[1] Eric D. Weinhandl.[1,2] *[1]Fresenius Medical Care North America, Waltham, MA; [2]University of Minnesota, Minneapolis, MN.*

Background: Past studies have associated non-white race with lower utilization of home dialysis. We aimed to assess the joint influence of race and dual eligibility (*i.e.*, concurrent enrollment in Medicare and Medicaid), a surrogate for poverty, on home dialysis utilization in each state.

Methods: Using Medicare Limited Data Sets, we identified all patients with Medicare Part B claims documenting outpatient dialysis from January 2014 to December 2017. For each calendar week (Monday to Sunday), we identified patients with at least one day of either home hemodialysis or peritoneal dialysis treatment. Within each of the 50 states, we modeled utilization of home dialysis with logistic regression, using a generalized estimating equation. Risk factors comprised non-white race, dual eligibility (DE), the interaction of race and DE, age, sex, and calendar year. We applied a Bonferroni correction to the set of tests of race, DE, and the interaction thereof ($\alpha = 0.05/150$).

Results: The cohort comprised 633,288 patients and 61,522,192 patient-weeks. Overall, 1.8% of patient-weeks were marked by home hemodialysis and 8.9% were marked by peritoneal dialysis. Relative to white patients without DE, state-specific adjusted odds ratios (AORs) of home dialysis in non-white patents without DE were centered at 0.58; among 34 states in which the effect of race was significant, AORs ranged from 0.28 to 0.76. State-specific odds ratios of home dialysis in white patients with DE were centered at 0.42; among 43 states in which the effect of DE was significant, AORs ranged from 0.25 to 0.78. Relative to white patients without DE, state-specific AORs of home dialysis in non-white patients with DE were centered at 0.25. However, interactions of race and DE were significant in only 2 states. In 46 states, non-white patients with DE were less likely to undergo home dialysis than both non-white patients without DE and white patients with DE.

Conclusions: Both non-white race and DE are associated with lower likelihood of home dialysis utilization in most states. The effects are generally log-additive, thus placing non-white patients with DE at profoundly lower likelihood of home dialysis utilization. Substantial growth in home dialysis will necessitate identifying and addressing the reasons for these disparities.

FR-PO521

Early Peritoneal Dialysis Start: Is There Room for More?

Francisco Ferrer,[1] Ana rita Abrantes,[2] Hernâni R. Gonçalves,[3,1] Ana V. Lobos.[4] *[1]Nephrology, CHMT - EPE, Torres Novas, Portugal; [2]Centro Hospitalar Médio Tejo - EPE, Torres Novas, Portugal; [3]Centro Hospitalar do Medio Tejo, Torres Novas, Portugal; [4]Centro Hospitalar do Médio Tejo, Lisbon, Portugal.*

Background: Despite educational care, a considerable number of End Stage Renal Disease (ESRD) patients present to Nephrology without a plan for dialysis and in the urgent need of it. Most of them could be suitable for Peritoneal Dialysis (PD), but concerns with PD access placement, makes hemodialysis (HD) through a central venous catheter as the only viable option. Early PD start (in the first 14 days after catheter placement) could be an option in this subset of patients and favor the increment of PD programs. The purpose of our study was to demonstrate that early PD start could be a safe option for patients in the urgent need of dialysis.

Methods: Retrospective, single-center study, with 18 ESRD patients without a dialysis care plan, who started PD in the first 14 days after catheter placement (Early start group - ESG) and 34 patients who started PD after planned dialysis care (Late start group - LSG). For each group we collected demographic data, previous nephrology follow up, type of catheter placement and initial PD prescription. We also measured short-term (90-day) clinical outcomes (Kt/V, creatinine clearance, daily ultrafiltration (UF), hemoglobin, ferritin, parathyroid hormone, phosphorus, calcium and albumin), as well as PD related complications (peritonitis, exit-site infections, leaks and catheter dysfunction).

Results: Patients on ESG begun PD in about 4.9 days after catheter placement, mainly due to overhydration. These patients were predominantly of male gender (88 vs 59%, p= 0.025) and without previous follow-up by Nephrologist (67 vs 97%, p=0.001). Although there weren't any differences in PD modality and type of catheter placement, exchange volumes were lower in the ESG (p=0.001). Short term outcomes were equal among groups, except for daily UF (higher in ESG; p= 0.013). Concerning mechanical complications, the number of leaks and episodes of catheter dysfunction were also similar, as well as the rate of infectious complications.

Conclusions: Despite being a single center study, with a small number of patients enrolled, our results demonstrate the safety and feasibility in beginning PD in patients with kidney failure, without a previous plan for renal replacement therapy. Early PD start in patients with the urgent need of dialysis could be an important step to improve PD worldwide, overcoming the initiation of HD through a catheter and its well known risks.

FR-PO522

Evaluation of a Wearable Artificial Kidney for Peritoneal Dialysis in a Uremic Pig Model

Maaike K. van Gelder,[1] Frank Simonis,[4] Anneke S. Monninkhof,[1] Diënty Hazenbrink,[1] Maria A. Bajo,[2] Rafael Selgas,[2] Elena Bianchini,[3] Silvia Giovanella,[3] Giulia Ligabue,[3] Gianni Cappelli,[3] Karin G. Gerritsen.[1] *[1]Nephrology & Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; [2]Hospital University La Paz, Madrid, Spain; [3]University of Modena and Reggio Emilia, Modena, Italy; [4]Nanodialysis, Oirschot, Netherlands.*

Background: A WEarable Artificial KIDney (WEAKID – H2020 SC1) for peritoneal dialysis (PD) was designed that recirculates dialysate *via* a tidal mode using a single lumen peritoneal catheter. We hypothesize that continuous dialysate regeneration by the WEAKID system containing sorbents, will maintain a high plasma-dialysate concentration gradient and increase the mass transfer area coefficient (MTAC). Thereby, WEAKID may enhance clearance while reducing the number of exchanges. Application is envisaged at night as a bedside device (12 kg, nighttime system). A wearable system (1.6 kg, daytime system) may further enhance clearance during the day.

Methods: The day- (n=3) and nighttime system (n=8) were tested separately for 8 h/treatment in a uremic pig model for PD (n=2). Plasma clearance and the MTAC of urea, creatinine and phosphate with the day- and nighttime system were compared with a standard peritoneal membrane permeability analysis (SPA, n=13).

Results: The daytime system caused a 2.0-fold (p=0.01) and 1.6-fold (p=0.07) increase in creatinine and phosphate clearance and 1.9-fold (p=0.01) and 1.6-fold (p=0.04) increase in MTAC creatinine and phosphate, resp., *vs* a SPA (Table 1). With the nighttime system, creatinine clearance and MTAC increased by a factor of 1.2 (p=0.002) and 1.4 (p=0.01), resp.

Conclusions: WEAKID increases small solute clearance compared with a SPA. This provides a rationale for a first in human clinical trial to evaluate safety and efficacy of WEAKID in PD patients.

Funding: Government Support - Non-U.S.

Table 1. Plasma clearance and the MTAC of urea, creatinine, phosphate during WEAKID and SPA experiments.

	Peritonitis	SPA (n=13)	Daytime (n=3)	Nighttime (n=8)	Daytime *vs* SPA	*p**	Nighttime *vs* SPA	*p**

FR-PO523

Assessing the Impact of Dialysis Modality on Hospitalization in a Large Population of ESRD Patients

Martin J. Schreiber, Bram Van hout, Zachariah W. Peterson, Michelle Cassin. *DaVita Inc, Denver, CO.*

Background: Hospitalizations and readmissions pose a significant burden to ESRD patients and result in significant costs to the US health care system. There is increasing focus on patient outcomes and cost advantages for patients starting ESRD treatment on a home dialysis modality. Understanding the impact that specific modalities can have on hospitalizations may assist in changing physician behavior regarding initial modality selection.

Methods: Data were derived from adult patients receiving dialysis treatments in a large dialysis organization between 01 March 2016 and 31 March 2019. Hospitalization rates (overall and cause-specific), length of stay, and readmission rates were assessed

separately for in-center hemodialysis (ICHD), peritoneal dialysis (PD), and home hemodialysis (HHD) patients. All outcomes were considered monthly and as 12-month rolling averages.

Results: As of March 2019, 12-month rolling average hospitalization rates were 1.24, 1.41, and 1.80 admits/year for PD, HHD, and ICHD patients, respectively; 30-day readmission rates were 26.2%, 24.3%, and 32.1% and mean length of stay was 6.62, 6.60, and 6.52 days, respectively. Significant variability was observed across geographic regions, with PD hospitalization rates ranging from 0.95 to 1.42 admissions/year and HHD hospitalization rates ranging from 1.13 to 1.66 admissions/year. Causes of hospitalization differed across modalities and programs: ICHD patients had higher rates of respiratory-related admissions and lower rates of admissions for gastrointestinal- and infection-related causes than patients on home modalities.

Conclusions: There is a pressing need to reduce hospitalization rates among ESRD patients to limit rising health care costs and improve outcomes. Here we demonstrate that hospitalization and readmission rates are consistently lower, and length of stay shorter, for patients using home dialysis modalities (PD and HHD) than those receiving ICHD. However, significant variability was observed across home programs, by program size and geographic location. Findings from this study have been used to develop a proactive approach to decreasing hospitalizations and readmissions based on program characteristics.

FR-PO524

Timing of Peritoneal Dialysis Initiation and Mortality: A Retrospective Clinical Study

Yuan Peng,[1] Xi Xiao,[1] Xuan Huang,[1] Meiju Wu,[1] Xueqing Yu,[2] Xiao Yang.[1] *[1]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]Department of Nephrology, Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: The impact of timing of peritoneal dialysis (PD) initiation on mortality is controversial. We conduct this study to investigate the association between timing of PD initiation and mortality.

Methods: In this single-center cohort study, incident PD patients from January 1, 2006, to December 31, 2016 were enrolled. All patients were followed up until December 31, 2018. Patients were categorized into 3 groups according to the estimated glomerular filtration rate (eGFR) at the initiation of PD using the Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) equation. Defined early, mid, and late starts as eGFR ≥ 7.5, 5-7.5 and < 5 ml/min/1.73 m^2, respectively. Cox regression analysis was used to compare mortality (overall and cardiovascular [CV]) among the 3 groups.

Results: A total of 2,151 incident PD patients were enrolled. The number of patients in early group was 319, mid group was 726, and late group was 1,106. Compared with the early-start group, the overall and CV mortality rates were not lower for the mid- (hazard ratio [HR] 0.88, 95% confidence interval [CI] 0.69-1.12 and HR 0.89, 95% CI 0.63-1.25) or late-start (HR 0.82, 95% CI 0.64-1.05 and HR 0.78, 95% CI 0.55-1.11) groups. In age-stratified model, elderly patients (age≥65 years) showed a significant lower risk of overall and CV mortality in late-start group (HR 0.65, 95% CI 0.45 – 0.95 and HR 0.50, 95% CI 0.30-0.83) and a significant decreased risk of CV mortality in mid-start group (HR 0.55, 95% CI 0.33-0.92) compared with early-start group; however, there was no significant difference in overall or CV mortality between the 3 groups in younger patients (<65 years).

Conclusions: Lower eGFR at PD therapy initiation was not associated with lower mortality risk. However, an eGFR < 5 ml/min/1.73m^2 at the initiation of PD was associated with lower risk of mortality among elderly patients, while not among younger patients.

FR-PO525

The Effect of Hemodialysis with Central Venous Catheterization on Urgent-Start Peritoneal Dialysis

Zhang Wen-jing, Jia Lv, Zhi-gang Wang, Yan Li, Ji-ping Sun. *The First Affiliated Hospital Of Xi'an Jiaotong University, Xi'an, China.*

Background: Urgent-start peritoneal dialysis(USPD)has received worldwide attention. A number of clinical studies have shown that USPD has great advantages in early complications, technical survival, and medical economics. Due to differences in economic conditions and acceptance, there is no pre-dialysis preparation in most ESRD patients in China. So most patients accept hemodialysis with central venous catheterization (HD-CVC) before deciding on long-term dialysis alternatives. Patients who eventually choose peritoneal dialysis will begin USPD treatment. Whether HD-CVC has effect on USPD that has not been studied. So we investigated the effects of the HD-CVC on USPD.

Methods: Retrospective analysis was performed on patients who received USPD from 2008/08/01 to 2017/03/31 in our hospital. According to whether the patient had HD-CVC before USPD, it was divided into USPD group (HD-CVC was not performed before peritoneal dialysis) and HD-PD group (HD-CVC was given first, and then peritoneal dialysis catheterization was performed within 2 week). The follow-up time was 1 year. The differences in clinical biochemical indexes, dialysis dose, urine volume, residual renal function, dialysis adequacy, peritoneal dialysis complications and technical survival rate between the two groups were observed.

Results: 1. A total of 482 patients were included in this study, including 315 patients in the USPD group and 167 patients in the HD-PD group. The gender, age, the proportion of diabetic nephropathy patients, creatinine, glomerular filtration rate, blood potassium before admission were similar between the two groups(P>0.05). 2. At 1 month of peritoneal dialysis, residual renal function, UKt/V and TKt/V in the USPD group were significantly higher than those in the HD-PD group, blood urea nitrogen and creatinine were significantly lower than those in the HD-PD group(P<0.05). At 6 months, the urine volume in the USPD group was significantly higher than those in the HD-PD group(P=0.002). 3. The export infection rate, peritonitis infection rate, mechanical complications and technical survival rate were similar between the two groups(P>0.05).

Conclusions: HD-CVC before USPD may affect the residual renal function and dialysis adequacy of patients. Therefore, HD-CVC is not recommended for ESRD patients who need peritoneal dialysis but have no indication of emergency dialysis.

FR-PO526

Perceived Exercise Barriers and Benefits in Haemodialysis and Peritoneal Dialysis Patients

Courtney J. Lightfoot, Thomas J. Wilkinson, Alice C. Smith. *University of Leicester, Leicester, United Kingdom.*

Background: Patients receiving dialysis are extremely inactive. This may be due to uncertainty and lack of appropriate guidance about exercise, or due to a number of barriers that patients may perceive. Understanding dialysis patients' perceived exercise barriers and benefits can inform interventions to address the barriers and promote the benefits, and increase exercise participation.

Methods: Perceived exercise barriers and benefits of 1017 haemodialysis patients (HD) [age: 63.1 (15.3) years; males: 653 (64%); white: 585 (58%)] and 124 peritoneal patients (PD) [age: 62.1 (15.2) years; males: 86 (69%); white: 95 (77%)] were assessed using the 'Dialysis Patient-perceived Exercise Benefits and Barriers Scale' (DPEBBS). Barriers and benefits to exercise were classed as binary variables (i.e. yes and no). Frequency analysis and chi-squared tests were conducted to compare the barriers and benefits perceived by HD and PD patients.

Results: The proportion of HD and PD patients who reported barriers and benefits to exercise is displayed in Figure 1. Significantly more HD patients than PD patients reported 'reduces body pain' (p=.013), 'delays decline in body function' (p=.010), and 'improves quality of life' (p=.033) as benefits. No significant differences in barriers were observed between the groups. Tiredness was the most commonly reported barrier by both groups.

Conclusions: The findings suggest that HD patients are more aware of the physical benefits of exercise than PD patients. This may be due to HD patients being better informed about the benefits and more actively encouraged to exercise than PD patients via regular contact with healthcare professionals. However, more evidence is needed to determine factors that may influence HD and PD patients' physical activity levels prior to developing exercise interventions.

Pilot of Assisted PD in an Integrated Health Care System

Neelam M. Bhalla,[1] Neiha Arora,[2] George Lai,[1] Elaine B. Benson,[3] Lerisa D. Villaflor,[4] Wesley Lisker.[2] GSAA Nephrology *[1]nephrology, The Permanente Medical Group, Hayward, CA; [2]The Permanente Medical Group, Union City, CA; [3]Kaiser Permanente, Hayward, CA; [4]Kaiser Permanente, San Leandro, CA.*

Background: Peritoneal dialysis (PD) is a home based modality that has many benefits. However, it can be challenging for patients with physical disabilities and psychosocial barriers, particularly the elderly. Assisted PD can provide support to overcome these barriers and promote PD utilization and retention. Assisted PD programs have been in use worldwide for over 20 years and have demonstrated good results. There are no such programs in the US. Kaiser Permanente Northern California (KPNC) is an integrated health care system that serves over 4.4 million members. Our PD unit in the Greater Southern Alameda Area is an internal PD program in KPNC, serving over 150 patients. In 2018 a pilot program of assisted PD was developed by the our unit to help overcome common barriers to PD and expand it as modality of choice.

Methods: A seven month pilot of temporary assisted PD was completed from April to October 2018. Patients were identified using certain selection criteria and assisted PD was offered for a time limited period of 90 days per patient. A single PD RN was designated as the assist PD nurse. The assistance included cycler set up and connections; lifting bags; performing CAPD exchanges; adding antibiotics; retraining and psychosocial support.

Results: Sixteen PD patients (7 incident, 9 prevalent) were assisted with a total of 59 visits. Reasons were anxiety/psychosocial (7); ankle fracture (1); frail elderly (4);

peritonitis (3) and respite (1). Visits per patient ranged from 1-10. 50% (8) stayed on PD; 13% (2) switched to hemodialysis (HD); 31% (5) expired and 1 relocated.

Conclusions: Assisted PD provides an effective means to support frail or functionally limited PD patients, encouraging them to select it as a modality and/or remain on PD. In our pilot, providing this assistance enabled us retain 50% of our patients on PD, who would otherwise have had to transfer to in center HD. Assisted PD is a valid and safe alternative to in center HD and should be used to expand modality choices, overcome barriers to PD and shift care to home.

Comparison of Outcomes Between Percutaneous and Surgical Placement of Peritoneal Catheters in Dialysis Patients: A Meta-Analysis

Linxi Huang,[1] Cheng Xue,[2] Jing Xu,[2] Zhiguo Mao.[3] *[1]Division of Nephrology, Kidney Institute of CPLA, Changzheng Hospital, Second Military Medical University, Shanghai, China; [2]Shanghai Changzheng Hospital, Shanghai, China; [3]Changzheng Hospital, Shanghai, China.*

Background: The successful insertion of the peritoneal dialysis catheter (PDC) ensures effective catheter function and technique survival. The most commonly used technique is the surgical approach by laparotomy or laparoscopy. Minimally invasive techniques are currently developing and seem to be an alternative. We evaluated the efficacy and safety of the percutaneous insertion methods compared to conventional surgical methods.

Methods: Studies comparing percutaneous and surgical methods of PDC insertion were identified through databases of PubMed, EMBASE, Cochrane and Web of Science. Catheter survival, dialysate fluid leakage, mechanical and infectious complications were analyzed using random effects model and results were presented as odds ratio (OR) and 95% confidence intervals (CIs).

Results: Sixteen studies were finally identified. The pooled data demonstrated no differences in catheter survival, dialysate fluid leakage and mechanical complications between percutaneous and surgical way (OR = 1.24, 95% CI = 0.81–1.91, *P*= 0.33; OR =1.49, 95% CI = 0.98–2.26, *P*= 0.06; OR = 0.65, 95% CI = 0.39–1.08, *P*= 0.08, respectively). Infectious complications occurred less in percutaneous group (OR = 0.56, 95% CI = 0.32–0.96, *P*= 0.04). The malposition incidence was obviously lower in percutaneous method compared with surgical method (OR = 0.51, 95% CI = 0.32–0.82, *P*= 0.005). The detailed analysis on bleeding, omental wrapping, hernia, exit site infection, peritonitis and tunnel infection did not show difference.

Conclusions: The percutaneous method is a safe and effective alternative to insert peritoneal catheters and could be an optimal choice besides the conventional surgical way.

Funding: Government Support - Non-U.S.

Main Outcomes	No. of studies	No. of patients	Mean Difference [95%CI]	P value	I^2(%)
survival	13	2,375	1.24[0.81,1.91]	0.33	74
leakage	14	1,972	1.49[0.98,2.26]	0.06	30
mechanical complications	13	1,991	0.65[0.39,1.08]	0.10	76
infectious complications	14	2,436	0.56[0.32,0.96]	0.04	74

FR-PO529

Local Anaesthesia Peritoneal Dialysis Catheter Insertion: A Single-Centre Tertiary Care Renal Unit Experience from the United Kingdom

Benjamin Perren,[2] Abhay Sharma,[2] Subash Somalanka,[2,1] Bhrigu Raj Sood.[2] *[1]South West Thames Institute for Renal Research, Carshalton, United Kingdom; [2]St Helier Hospital, London, United Kingdom.*

Background: Peritoneal dialysis [PD] is one of the modalities for renal replacement therapy and requires inserting a PD catheter[PDC] into the peritoneal space and is traditionally a surgically assisted PD catheter insertion[SPDCI] under general anaesthesia[GA]. CKD5 patients are at high risk for GA. Local anaesthesia PDC insertion [LPDCI] has been done in those without previous abdominal surgery[PAS]. Peritoneal adhesions due to previous surgery can complicate insertions. We share our experience of LPDCI vs SPDCI from a tertiary care renal unit in the UK.

Methods: Retrospective data was collected from April 2017 to April 2018 and retrieved from electronic patient records and peritoneal dialysis unit notes. The analysis was performed using Microsoft Excel 2010.

Results: A total of 86 catheters were inserted in 83 patients. 35% (29) have diabetes. Figure 1 shows the procedure group characteristics.

Conclusions: Physician-led LPDCI is usually performed in patients without PAS. In our cohort, 43% who underwent LPDCI had PAS. Some of these cases were performed under fluoroscopy guidance. There was no significant difference in immediate complications and catheter function. Peritonitis after six months of LPDCI was higher but unrelated to PAS and LPDCI. PDC loss and modality change were high due to patient choice and infections and is being addressed by further improvements in patient education on hand hygiene and assessment of PDC care. Peritonitis should be treated promptly and where possible PDC should be reconsidered if clinically appropriate. LPDCI is a safe and effective way of providing definitive access to PD. It is cost-effective, performed in a shorter time, spares surgical theatre time and space, improves patient satisfaction by reducing patient stay and avoids the risk of GA.

Type of PDC insertion	LPDCI [n=63] (%)	SPDCI [n=23] (%)
Sex [M:F]	38:25	9:11
Previous abdominal surgery	27(43)	19(83)
Failure of the procedure	2(3.2)	1(4.3)
Bleeding	1(1.6)	1(4.3)
Mechanical failure	6(9.5)	4(17.4)
Tunnel infection	2(3.2)	1(4.3)
Peritonitis after 6 months	17(27)	3(5)
Pleural leak	4(6.4)	0
Bowel, bladder & blood vessel injury	0	0
PDC still in use	23(36.5)	9(39.1)
Transplantation	5(7.9)	1(4.3)
Switched to HD	25(39.7)	5(21.7)
Procedure switch	1 had SPDCI (1.6)	2 had LPDCI (8.7)
Death due to non PDC related cause	2(3.2)	2(8.7)
Duration of PDC in-situ days in PDC removed cases [Mean; Median; SD]	232.7; 140.8; 196.4	181.7; 196.9; 84.7

Comparative analysis of physician-led [LPDCI] vs surgeon-led [SPDCI] peritoneal dialysis catheter insertions has been shown in figure 1.

FR-PO530

Point-of-Care Ultrasound in Peritoneal Dialysis Catheter-Related Infection: An Observational Study

Hugo Diniz,[1,2] Ana Oliveira,[1] Luciano Pereira.[1,2] *[1]Centro Hospitalar de São João, Ermesinde, Portugal; [2]Nephrology & Infectious Diseases R&D, i3S - Instituto de Investigação e Inovação em Saúde, Porto, Portugal.*

Background: Peritoneal dialysis (PD) catheter-related infection (PD-CRI) is the most common complication of this form of renal replacement therapy. The diagnosis of PD-CRI is made with physical examination (PE), but the physical findings lack sensitivity or specificity. Point-of-care ultrasound (POCUS) is an emerging discipline in the Nephrology community that allows the physician to incorporate real-time information from the ultrasound into his clinical evaluation. POCUS could improve the diagnostic accuracy of PD-CRI and reduce patient exposure to antibiotics. This single-center observational study aimed to compare the accuracy of POCUS and PE for the diagnosis of PD-CRI.

Methods: POCUS was performed by a Nephrology fellow using a linear transducer when PD-CRI was suspected. POCUS was repeated in every patient visit. PD-CRI was defined as purulent discharge with or without inflammatory signs, and a positive microbiological culture collected from the exit-site. We considered a positive POCUS as an anechoic collection around the external cuff, and its largest dimension was recorded. PE findings were coded using a validated clinical score.

Results: A total of 25 patients (58 % male) were enrolled. We also recruited nine patients with no signs of PD-CRI as controls. A total of 13 PD-CRIs were diagnosed, from 22 suspected cases. The most common isolated agent was *Corynebacterium spp.* In this population, the diagnostic accuracy of PE was low, with an area under the ROC curve (AUROC) of 0,6 (95% CI 0,37-0,84). Purulent drainage alone, although highly specific (100%), showed a low sensitivity (61,9%) for the diagnosis of PD-CRI. In contrast, POCUS had an AUROC of 0,91 (95% CI: 0,73-1) for PD-CRI diagnosis. All the PD-CRI cases had a positive POCUS evaluation, and we did not find this sonographic sign in controls ($p < 0,001$). The optimal cut-off point of the collection dimension was equal to or greater than 1,4 mm (Sensitivity 100%; Specificity 89%). Suspected PD-CRI cases with negative POCUS and not exposed to antibiotic therapy, had similar PD-CRI rates in one-month follow-up as the control group ($p = 0,929$).

Conclusions: POCUS is superior to PE for the diagnosis of PD-CRI and should be considered by nephrologists with access to an ultrasound machine. POCUS may decrease unnecessary antibiotic exposure in PD patients due to an increase in PD-CRI diagnostic sensitivity.

FR-PO531

Quality Improvement Strategies to Reduce Peritoneal Dialysis Catheter Insertion Wait Times: A 10-Year Experience

Bourne L. Auguste,[2,1] Michael Y. Girsberger,[3,1] Ali Z. Ibrahim,[3,1] Zita C. Abreu,[3] Joanne M. Bargman.[3,1] *[1]University of Toronto, Toronto, ON, Canada; [2]Sunnybrook Heatlh Sciences Centre, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada.*

Background: Bedside peritoneal dialysis (PD) catheter insertions have been effective in reducing wait-times, however laparoscopic insertions are still needed in patients with prior abdominal surgeries, high risk of leaks and hernia repairs. Our study aim was to assess the impact of local quality improvement initiatives on wait-times for laparoscopically inserted PD catheters over a 10-year period.

Methods: We reviewed our database at the Toronto General Hospital for laparoscopic wait-times for PD catheter insertions between January 1, 2008 to December 31, 2018. Wait-times for catheter removals, manipulations and hernia repairs were reviewed. Buried PD catheters were excluded from analysis. A control chart analysis of mean quarterly wait-times for laparoscopically inserted PD catheters was performed. We captured the effect of three local interventions on wait times: interventional radiology program (fluoroscopic-guided), bedside insertion program and transition to becoming a centre of regional practice, wherein patients from other parts of the province were referred to us for more complex catheter procedures.

Results: A total of 379 new patients had laparoscopically inserted catheters between 2008 and 2018. Quarterly mean wait-time for catheter insertion was between 21.3 to 28.5 days (Figure 1). After becoming a regional centre of practice in 2016, mean wait-time for new insertions increased dramatically to 39.3 days. There was no change in access to operating room (OR) time during this period. After 2016, there was a 56.4 % increase in external patients receiving procedures at our institution without increase in access to OR time. 51% of procedures were hernia repairs, catheter manipulations along with removal and reinsertion.

Conclusions: Quality improvement strategies may initially help to reduce wait-times for PD catheter insertions. However, long-term success of these improvement strategies must be supported with administrative policies that lead to proportional increases in access to OR time.

FR-PO532

Barriers to Peritoneal Dialysis in Saskatchewan Canada: Results from a Province-Wide Survey

Lucas Diebel,[3] Christine Day,[1] Sachin Shah,[4] Maryam Jafari,[2] Bhanu Prasad.[1] *[1]Nephrology, Regina General Hospital, Saskatchewan Health Authority, Regina, SK, Canada; [2]RQHR- Research and Performance Support, Regina, SK, Canada; [3]College Of Medicine, University of Saskatchewn, Regina, SK, Canada; [4]Nephrology, St Pauls Hospital, Saskatoon, SK, Canada.*

Background: Peritoneal dialysis (PD) offers similar clinical outcomes to hemodialysis (HD) at a fraction of the cost. PD remains underutilized as remote HD patients in Saskatchewan often relocate or travel hundreds of kilometers weekly in order to receive dialysis related care. The purpose of this study was to determine the barriers to receiving PD in our province.

Methods: We conducted a cross sectional survey of in center HD patients across the province of Saskatchewan. 740 in center HD patients at two academic sites and 7 satellite units were approached by study coordinators. 421 patients (n=268 in the main units and n=153 in the satellite units) agreed to participate in the study. A questionnaire using a five-point Likert scale was created to identify barriers to PD with questions addressing PD awareness and knowledge, accessibility, and risks/fears/beliefs surrounding PD. Responses were anonymous and tabulated using a data collection tool.

Results: Only 82% of patients were aware of PD as a treatment option. 35% of patients felt they had no understanding of the benefits or risks of PD. Prominent barriers to PD that we identified were: excellent care in the HD unit (62%), proximity to dialysis unit (41%), unwilling to dialyze daily (36%), and unwilling to learn a new technique (34%). Beliefs held by patients that figured prominently in their decision to choose HD over PD included not wanting to take their disease home (32%), fear of being a burden on family (32%), lack of space (28%), risk of infection, issues with self-image while on PD, and PD being an inferior modality to HD (all approximately 24%).

Conclusions: In this study, we identified patient specific barriers to PD in a prevalent cohort of HD patients. Several barriers were identified with a few consistent themes being identified, including deficiencies in knowledge, patient specific beliefs and poor patient education. The most frequently reported knowledge barrier was a lack of understanding of benefits and risks of PD. While the study does not reflect the views of all patients, the information gained will be valuable in designing an educational program to improve adoption of PD within our province.

FR-PO533

Early Start Peritoneal Dialysis: How to Increment This Modality?

Francisco Ferrer, Ana rita Abrantes, Hernâni R. Gonçalves, Ana V. Lobos. *Centro Hospitalar Médio Tejo - EPE, Torres Novas, Portugal.*

Background: Despite the increasing incidence of end-stage renal disease (ESRD), peritoneal dialysis (PD) is offered to a minor subset of patients. One way to increment PD rates is the early start of technique after catheter placement without the usual break in times but there are concerns with mechanical and infectious complications that could compromise PD outcomes. The aim of this study was to compare the outcomes and safety of early PD start, after 12 and 24 months.

Methods: Retrospective analysis performed in a single-center; 52 patients: 34 started PD after planning (late start group - LSG) and 18 in the first 14 days after catheter placement (early start group - ESG). Demographic data, comorbidities, Charlson comorbidity index (CCI) were collected. PD related complications and dropout cases were identified.

Results: ESG present a male predominance (88.2 vs 58.8%; p=0.025) and higher CCI (35.9 vs 59.4% estimated 10-year survival) with a significantly prevalance of cardiovascular diseases (p=0.03). Average time between catheter placement and PD starting in the ESG was 5 days. LSG stayed longer under PD (813 vs 555 days). Kidney transplantation was the main cause of dropout in the LSG group whereas in the ESG the causes were mechanical issues and death. First episode of peritonitis (FP) occurred earlier in the ESG (478 vs 831 days) but this difference was not statistically significant among the 2 groups. Unadjusted Kaplan-Meier estimated that the difference in dropout-free survival was statistically significant in bouth groups (p=0.006, long rank test). Multivariate analysis with Cox regression demonstrated that, even though the risk of dropout was higher during the first 12 months in the ESG (HR=5.503; p=0.014), this decreases after 24 months (HR=2.363; p=0.036) of PD. The frequency of dropout was higher in the ESG (77.1% versus 61.8%) but this difference was not significant (p=0.242). When comparing the frequency of dropout after excluding patients that were transplanted, results were similar.

Conclusions: Urgent-start PD can be a valid and safe alternative to hemodialysis via central venous catheter and should be offered to patients without contraindications. Other factors not related to the early start of technique (age and higher CCI), can have a negative impact on the morbidity and mortality of those patients influencing the outcomes of DP technique.

FR-PO534

International Variation in Outcomes After PD-Related Peritonitis

Jeffrey Perl,[2] Douglas S. Fuller,[1] Neil Boudville,[10] Yasuhiko Ito,[6] Talerngsak Kanjanabuch,[9] Sharon Nessim,[5] Beth M. Piraino,[4] Ronald L. Pisoni,[1] Isaac Teitelbaum,[8] Graham Woodrow,[7] David W. Johnson.[3] PDOPPS Infection Prevention and Management Workgroup *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]Princess Alexandra Hospital, Brisbane, QLD, Australia; [4]University of Pittsburgh, Pittsburgh, PA; [5]Jewish General Hospital, McGill University, Montreal, QC, Canada; [6]Aichi Medical University, Nagakute, Aichi, Japan; [7]Renal Unit, St. James University Hospital, Leeds, United Kingdom; [8]University of Colorado, Aurora, CO; [9]Chulalongkorn University, Bangkok, Thailand; [10]University of Western Australia, Nedlands, WA, Australia.*

Background: Peritoneal dialysis (PD)-associated peritonitis is a major source of morbidity, mortality, and technique failure for patients receiving PD. We sought to understand if there were regional differences in peritonitis outcomes.

Methods: We used Peritoneal Dialysis Outcomes and Practice Patterns Study phase 1 (2014-2017) data from Australia and New Zealand (A/NZ), Canada (CA), Japan (JP), Thailand (TH), the UK, and the US to report variation in peritonitis outcomes (up to 50 days after peritonitis) by country and to estimate associations with organism type using logistic regressions adjusted for country, age, sex, diabetes, and serum albumin. Cure was defined as the lack of any outcome except hospitalization. Technique failure (TF) was defined as permanent transfer to hemodialysis or failure to resume PD within 12 weeks.

Results: We observed 2270 peritonitis episodes in 6949 patients during 7816 years of follow-up (crude rate: 0.29 episodes/year). Cure proportion was 64% (range by country: 54-68%), and death occurred in 6% (JP: 2%; TH: 16%, others: 4-5%). Hospitalization was common for both peritonitis-related causes (55%, range: 41-75%) and for any cause (72%; range: 59-91%), with >80% occurring within 14 days. Relapsing/recurrent peritonitis occurred in 9% (range: 7-14%), and concurrent exit-site infection occurred in 12% (JP, UK: 19-21%; TH: 6%; others: 9-10%). Catheter removal occurred in 21% (TH, JP, UK: 24-29%; others: 18-20%), and TF occurred in 16% (TH: 10%; others: 16-19%). Higher odds of death, TF, or catheter removal were seen for Gram-negative (OR=2.78, 95% CI=2.03, 3.8), culture negative (OR=1.3, 95% CI=0.92, 1.83), polymicrobial (OR=4.43, 95% CI=2.89, 6.79), and missing/unknown peritonitis (OR=2.64, 95% CI=1.89, 3.69), compared to Gram-positive peritonitis.

Conclusions: High proportions of peritonitis resulting in death (Thailand) and TF (all countries) suggest novel interventions to prevent peritonitis are needed. Emphasis on

identification methods and development of organism-specific treatment strategies may help reduce morbidity associated with these episodes.

Declining Peritonitis Rates Incompletely Translate into Improved Technique Survival in Australian Peritoneal Dialysis Patients

Vinod Khelgi,[1] Suresh Murthy,[1] Stephen P. McDonald.[1,2] *[1]Royal Adelaide Hospital, Adelaide, SA, Australia; [2]University of Adelaide, Adelaide, SA, Australia.*

Background: Peritoneal Dialysis (PD) peritonitis rates are declining, but not matched by a uniform reduction in technique failure (TF) rates. Understanding the reasons for this disconnect will potentially help identify new targets for intervention.

Methods: 13653 incident PD patients undergoing first PD treatment episodes in Australia between 2003 and 2017 were analysed for TF in 3-year cohorts. Instances of TF were segregated into infective or non-infective causes and cumulative incidences (CI) calculated at 1- and 2 years of death-censored technique failure (transfer to HD for >30 days) with death as competing risks. CI calculated using the Fine and Grey method.

Results: The peritonitis rate in Australia halved over the observation period. There were substantial improvements in death rates during PD treatment. However, there were minimal or no changes in death-censored PD technique failure (DCTF). Adjustment for age and diabetes made of DCTF events at 1 year, the proportion attributed to infection fell from 44% to 28%, with a similar fall at 2 years. After adjustment for age and diabetes, there was a suggestion of moderate improvement among the most recent cohort.

Conclusions: PD peritonitis rates have declined substantially over the study period as have death rates, but overall technique survival has changed only modestly. Non-infective causes of DCTF are proportionately higher; identification of modifiable risk factors provide the next target to enhance PD outcomes.

Results

Year of PD start	2003-2005	2006-2008	2009-2011	2012-2014	2015-2017

Risk Factors for Early Mortality After Switch from Peritoneal Dialysis to Hemodialysis: A Multinational Registry Study

Annie-Claire Nadeau-Fredette,[1] Nidhi Sukul,[2] Mark Lambie,[8] Jeffrey Perl,[3] Kitty J. Jager,[9] David W. Johnson,[4] Simon J. Davies,[8] Ronald L. Pisoni,[5] Anneke Kramer,[9] Wim Van Biesen,[7] Christopher T. Chan.[6] INTEGRATED study group *[1]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]University of Michigan, Ann Arbor, MI; [3]St. Michael's Hospital, Toronto, ON, Canada; [4]Princess Alexandra Hospital, Brisbane, QLD, Australia; [5]Arbor Research Collaborative for Health, Ann Arbor, MI; [6]Toronto General Hospital, Toronto, ON, Canada; [7]Ghent University, Ghent, Belgium; [8]Keele University, Crewe, United Kingdom; [9]ERA-EDTA Registry, Amsterdam, Netherlands.*

Background: Transfer to hemodialysis (HD) is frequent in peritoneal dialysis (PD), and mortality risk is highest in the early transition period to HD. We sought to identify risk factors of mortality after a PD to HD transition.

Methods: Incident PD patients (started on PD within 180 days of RRT initiation) who switched to HD for ≧1 day between 2000 and 2014 were identified, using registries from Australia/New Zealand (ANZDATA), Canada (CORR), Europe (ERA-EDTA), and the United States (USRDS). Separate multivariable Cox models were built for early (<90 days), medium (90-180 days) and late (>180 days) periods after switch to HD. Patients were followed after switch from PD to HD from the first day (model 1), day 90 (model 2) or day 180 (model 3) until death, censoring at time of kidney transplantation and end of follow-up.

Results: Overall, 6,669, 5,848, 21,574, and 80,459 patients were included from ANZDATA, CORR, ERA-EDTA and USRDS, respectively. Risk of mortality after switch to HD was lower in the most recent cohorts. Older patients were at increased risk of death, particularly during the first 90 days after switch. Similarly, the mortality risk associated with longer PD vintage was highest during the early periods after switch to HD, but attenuated afterwards. Males experienced lower risk of mortality early after transition to HD, but higher mortality risk after 180 days on HD.

Conclusions: In this multinational registry study, mortality risk factors varied by time period after switch from PD to HD. Females, older patients and patients with PD vintage >3 years before switching to HD were at greater risk of early mortality and should be followed more closely when transitioned to HD.

Interesting Relationship Between Levels of Thioredoxin and Vitamin D on Antioxidant System in Peritoneal Dialysis Patients

Sara Yavuz Ileri. *Nephrology, Yeditepe University, Istanbul, Turkey.*

Background: The reactive oxygen species produced continuously during oxidative metabolism are generated at very high rates in chronic kidney failure. Therefore, defending against oxidative stress is an essential task with the patients who suffering from that disease. An important cellular system against oxidative stress is the cytosolic mammalian thioredoxin system (TS) which consist of thioredoxin (trx), nicotinamide adenine dinucleotide phospate (NADPH) and thioredoxin reductase (TrxR) has emerged as a major anti-oxidant which involved in the maintenance of cellular physiology and survival. Vitamin D is also an other strong antinflammatory molecule and it has a growing of number of studies revealing its pleiotropic roles beyond the bone and calcium metabolism. The aim of this study is to find a significant relation between these two systems.

Methods: We conducted a study of 69 patients with end stage of kidney disease who were under the treatment of continuous ambulatory peritoneal dialysis or automated peritoneal dialysis. Serum thioredoxin level were measured. Measurements were corrected according to comorbid diseases, medications, duration and type of peritoneal dialysis and residual renal function. In addition, they were also evaluated for the correlation between hemoglobin, uric acid, CRP, albumin, ferritin, lipid parameters and iPTH levels. Our aim was to prove the effect of the use of Vitamin D supplementation on thioredoxin as an anti-oxidant system. 40 out of 62 patients were already under the vit D supplemantation but the rest of the group was not eligible.

Results: There was no statistically significant difference between Thioredoxin measurements according to PD type, etiology and drugs ($p > 0.05$) but Thioredoxin levels in patients with vit D supplemantation were significantly higher than those without vit D supplemantation. ($p < 0.01$). The results were evaluated in a confidence interval of 95% and a significance level of $p < 0.05$.

Conclusions: This result of study was not suprising but important because it emphasized that Vit D anti-inflammatory effect especially in chronic kidney failure patients except the bone-mineral metabolism and pointed to strict follow –up vit D level in this group which is already under the inflamatory situation to reduce complications related to oxidative stress by contributing the augmentation of thioredoxin serum level.

FR-PO538

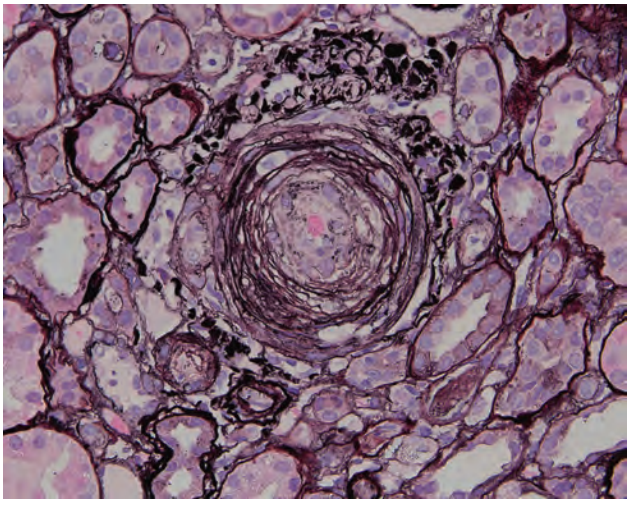
A Case of Scleroderma Renal Crisis in a Patient with Systemic Sclerosis Sine Scleroderma

Janis Cho,[1] Yashpal S. Kanwar,[2] Cybele Ghossein.[1] *[1]Northwestern University-Feinberg School of Medicine, Chicago, IL; [2]Northwestern University Medical School, Chicago, IL.*

Introduction: Scleroderma renal crisis (SRC) typically presents with abrupt onset of accelerated hypertension (HTN) and acute kidney injury (AKI) usually in patients with diffuse cutaneous Systemic Sclerosis (dcSSc). We report a case of SRC in a patient with systemic sclerosis sine scleroderma (ssSSc), a rare form that presents with visceral involvement in the absence of skin manifestation.

Case Description: A 64 year old female with a history of Raynaud's phenomenon, seronegative rheumatoid arthritis and HTN was admitted to Northwestern Memorial Hospital with shortness of breath, uncontrolled HTN and AKI. Her blood pressure (BP) ranged from 165/94 to 194/100 mmHg. She had bilateral crackles, no lower extremity edema and no skin manifestations of scleroderma. Anti nuclear antibody was positive >1:1280 with a negative serologic work up including anti-SCL-70, anti-centromere and RNA polymerase III antibodies. Urinalysis was without protein or blood. HTN was uncontrolled and captopril was started with good BP response. AKI worsened and a kidney biopsy was performed (Fig). Pathology showed ischemic glomerulopathy, marked arteriosclerosis with onion skinning and vascular lesions suspicious for thrombotic microangiopathy concerning for SRC. Her clinical course deteriorated rapidly with the development of severe pulmonary HTN, heart and renal failure.

Discussion: ssSSc is a rare form of systemic sclerosis. Two types of ssSSc patients have been described and the course can follow either limited scleroderma or dcSSc. The latter can have delayed sclerodactyly and early vital organ involvement similar to our case. Clinicians need high degree of suspicion to diagnose ssSSc given the lack of skin findings. While serologic testing can help with diagnosis, SRC is a clinical diagnosis that can be enhanced by renal biopsy. This case highlights the difficulty in diagnosing patients with SRC in the setting of ssSSc.



Arteriosclerosis with onion skinning

FR-PO539

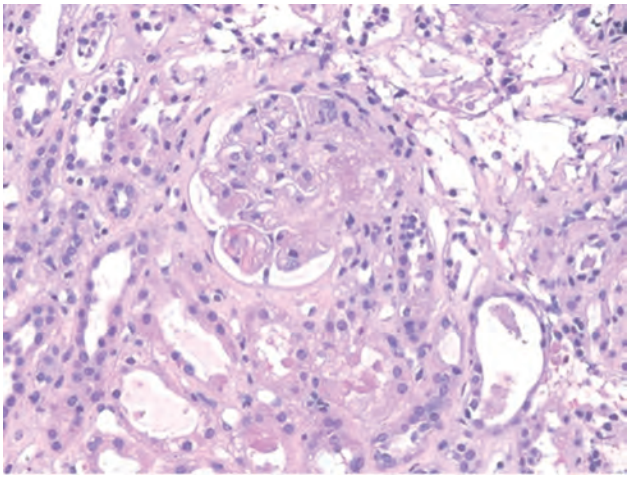
Scleroderma Renal Crisis in a Patient with Paraneoplastic Syndrome

Ayesha Ahmed,[1] Lilian Saro-Nunez,[2] Cory Handelsman.[2] *[1]Rwjmh, Piscataway, NJ; [2]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ.*

Introduction: Scleroderma renal crisis affects 5-10% of patients with systemic sclerosis, with 5-year survival rate of 59%. Anti-RNA polymerase IIIAb are associated with risk of SRC and cancer. We describe a patient with paraneoplastic scleroderma who presented with AKI and HTN after steroid use and diagnosed with SRC.

Case Description: A 55-year-old woman with h/o HTN, Endometrial cancer (3/ 2017) s/p TAH-BSO, tumor debulking, paraneoplastic scleroderma (diagnosed a month back with + autoantibodies to RNA polymerase III) was sent to ER for worsening creatinine(2 mg/dl to 4.6 mg/dl in 2 weeks). Of note patient was noted to have worsening liver enzymes 2 months back and underwent liver biopsy which showed ductopenia and fibrosis. Given suspicion of an autoimmune process prednisone was initiated. On admission, patient was in acute respiratory distress requiring intubation, hypertensive (SBP 180mmHg) and in renal failure. Diagnosis of SRC was made, Captopril was initiated and steroid was discontinued. Renal biopsy showed TMA with extensive involvement of arteries, arterioles, extensive (50%) ischemic glomerular alteration, segmental duplication of glomerular capillary wall and moderate tubular injury. No significant interstitial fibrosis/tubular atrophy. She was discharged on dialysis.

Discussion: SRC is characterized by presence of high blood pressure with variable degrees of renal insufficiency.5-20% of patients with diffuse scleroderma are at risk of developing SRC. A positive RNA Pol IIIAb, present in our patient, further increases the risk of developing renal crisis. SRC associated with paraneoplastic scleroderma is even rarer. An extensive review of the literature showed only 4 cases of SRC in patients with ovarian, lung, breast and renal carcinoma. Given that SRC is a potentially life-threatening disease, we should have a high degree of suspicion in patients with scleroderma who present with hypertension and acute renal failure.



Glomerular microthrombi

FR-PO540

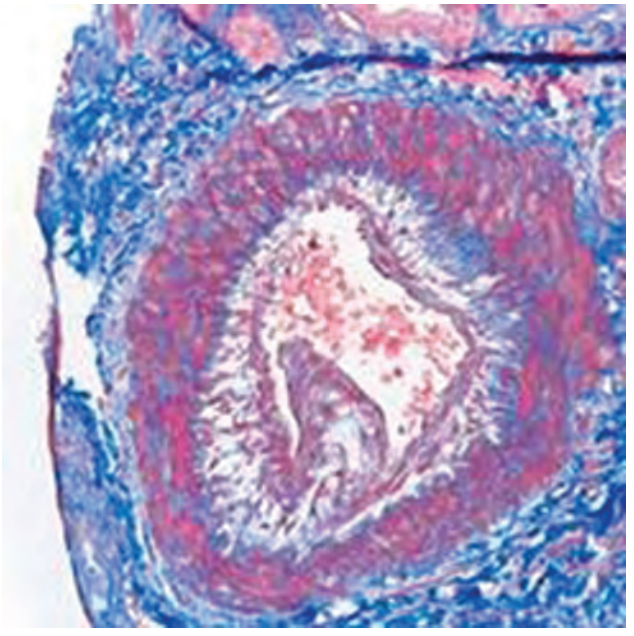
Systemic Sclerosis Sine Scleroderma Renal Crisis: An Atypical Presentation

Princella Olalo,[1] Kavita G. Sharma,[2] Deborah K. Mccurdy,[3] Gangadarshni Chandramohan.[1] *[1]Harbor UCLA Medical Center, LA Biomed, Torrance, CA; [2]Harbor UCLA Medical Center, Irvine, CA; [3]UCLA, Los Angeles, CA.*

Introduction: Scleroderma renal crisis (SRC) is a rare complication that occurs in 5% of all systemic sclerosis (SSc) patients. Previously reported one-year mortality of 76% decreased to 15% when captopril became the preferred treatment. Usually, SRC is triggered by high dose steroids in patient with SSc. Our patient instead, presenting with signs of Hemolytic Uremic Syndrome (HUS) diverting the workup towards infectious/ autoimmune/genetic causes of HUS until, renal biopsy and response to captopril became the key elements of diagnosis.

Case Description: This is a 19-year-old female presenting with vomiting, diarrhea and abdominal pain that progressed into dyspnea, oliguria, anasarca, malignant hypertension and renal failure. No evidence of skin or joint manifestations. Lab tests: low platelets, low Hg with schistocytes, stools (-)ve for E. coli and Shiga-toxin, normal ADAMTS13 activity and (-)ve Scl-70 antibodies. But, positive antinuclear antibody (ANA) and Sjogren's antibody (SsA) implied an autoimmune process. After failing a course of steroid pulse, plasmapheresis and plasma exchange transiently increased platelets and Hg. But, anuria persisted, requiring daily dialysis. Renal biopsy: onion peel lesion in medium sized arterioles, likely scleroderma renal crisis, prompted the decision to start captopril. After one dose, she had 2 liters of urine and eventually, renal function returned to normal.

Discussion: This is the first case report of a suspected HUS, later being diagnosed as SSc sine SRC based on clinical findings, positive ANA and SsA, renal arteriolar vasculopathy and response to captopril treatment without cutaneous manifestations and negative Scl-70 panel. Thus, it is important to consider SSc sine SRC when presenting with such clinical picture to attain complete renal recovery and decrease mortality.



FR-PO541

Low Alanine Aminotransferase in Hemodialysis Patients: A Marker for Pyridoxine Deficiency

Nolan M. Giehl, John Howard, Brian Y. Young. *University of California Davis Medical Center, Sacramento, CA.*

Introduction: Hemodialysis (HD) patients often have lower serum alanine aminotransferase (ALT) levels than those with normal kidney function. There are multiple proposed mechanisms with controversy surrounding the contribution of pyridoxine (vitamin B6) deficiency, a cofactor for liver aminotransferase synthesis. We present a remarkable case of pyridoxine deficiency diagnosed in a HD patient by an undetectable ALT.

Case Description: A 71-year-old woman on HD for 6 years was admitted for an infected hand wound. She also had a duodenal switch surgery for obesity 17 years prior. Home medications included a dialysis multivitamin and pyridoxine 100 mg daily, though she hinted at variable adherence to both due to insurance issues. Admit labs incidentally showed an undetectable ALT level, confirmed on repeated testing. Bilirubin and AST were normal. She had a normal ALT 4 months prior and past imaging showed no cirrhosis. Subsequent pyridoxine testing, measured in its active form of pyridoxal 5'-phosphate, was low at 7.3 nmol/L [Normal 20-125 nmol/L]. Other water-soluble vitamin levels including thiamine and cobalamin were normal. She was given 10 mg pyridoxine IV daily for one week with maintenance 100 mg oral daily. Follow up 4 weeks later revealed improved pyridoxine levels to 29.3 nmol/L and a now detectable ALT level of 9 U/L. She remains on a dialysis multivitamin and oral pyridoxine 100 mg daily.

Discussion: Aminotransferases are often drawn with routine labs in the dialysis population, with elevations signaling concern for pathology such as infectious hepatitis. However, undetectable or borderline levels may not alarm practitioners, particularly as aminotransferases are known to be lower in HD patients. This poses a risk of missing a diagnosis of pyridoxine deficiency, which may ultimately cause progressive anemia, neuropathy, and confusion. Vitamin B supplementation in HD is accepted as routine due to a restrictive diet and dialytic removal, though insurance coverage may be sporadic. Our patient had an additive risk factor of malabsorption due to her bariatric surgery. This case highlights a noteworthy presentation that should prompt providers to investigate water-soluble vitamin levels and adherence to supplementary vitamins. Our patient showed that dramatically low ALT levels may be an early and only sign of pyridoxine deficiency in HD patients.

FR-PO542

Perils of Renal Revascularization for Severe Hypertension

Sriram Sriperumbuduri,[1] Swapnil Hiremath,[2] Marcel Ruzicka.[3] *[1]The Ottawa Hospital, Ottawa, ON, Canada; [2]University of Ottawa, Ottawa, ON, Canada; [3]University of Ottawa, Canada, Ottawa, ON, Canada.*

Introduction: Revascularization is not superior to medical therapy in atherosclerotic renal artery stenosis (RAS). This may be partly attributed to renal complications from revascularization but also from extra renal complications due to the drop in systemic blood pressure (BP). We highlight this with a case of a man who developed an extrarenal complication following renal angioplasty.

Case Description: A 58 year old man was referred to the hypertension clinic at a tertiary care hospital. He was on 5 BP lowering drugs with a 5-minute office resting BP of 213/99 mm Hg. Magnetic resonance angiogram showed extensive atherosclerotic disease of the aorta and branches including bilateral (B/L) RAS, 80 % on right and 50% on left. In view of this and resistant hypertension, he underwent B/L renal angioplasty and stenting. Post intervention BP in the clinic was 123/89 mmHg despite a 50% decrease in BP medications. On day 3, he developed diffuse, progressively worse abdominal pain, along with nausea and vomiting. Laboratory tests showed leukocytosis and elevated lactate. Computed tomography scan confirmed diagnosis of subacute mesenteric ischemia due to superior mesenteric artery (SMA) occlusion and progressive stenosis of celiac trunk. He underwent stenting and angioplasty of the latter which resolved his symptoms. At 1 month, his BP was 106/68 on 3 drugs.

Discussion: Renal artery stenting for drug resistant hypertension improved this patient's BP. However, the decrease in systemic BP made the hitherto non-critical stenoses of aortic branches clinically critical, thus precipitating bowel ischemia. This highlights some of the mechanisms behind the morbidity associated with renal revascularization. Our data also suggests that critical review and awareness of the extent of extrarenal atherosclerosis prior to renal angioplasty may prevent or at least hasten the diagnosis of post-revascularization complications.

FR-PO543

Unique Cause of Renal Infarction: A Case of Pheochromocytoma

Sandiya Bindroo, Lubna Zuberi. *Internal Medicine, Crozer Chester Medical Center, Upland, PA.*

Introduction: Pheochromocytomas (PHEOs) are rare chromaffin cell derived neuroendocrine tumors. Common presentations include paroxysmal episodes of headache, palpitation, sweating and hypertension. Life threatening complications including renal artery stenosis, and acute myocardial infarction had been reported from the possible mechanism of catecholamine-induced vasospasm and/or extrinsic compression of renal artery in some reported cases. Here, we report an interesting case of PHEOs associated with renal infarction, unrelated to artery thrombosis/stenosis.

Case Description: A 48 year old male with no significant past medical history presents to the emergency room (ER) with sudden onset headache and blurring of vision. Vital signs revealed blood pressure of 215/120 mm of Hg. No focal neurological deficits were noted. Laboratory work was unremarkable. CT head and CT angiogram of head and neck obtained revealed no evidence of intracranial hemorrhage. He left against medical advice at that time, but returned two days later to the ER with left flank pain. This time his vital signs showed blood pressure of 100/60 mm of Hg, and he had left sided abdominal tenderness. Laboratory work revealed troponin of 23.65 ng/mL [normal, <0.04ng/ml]. Abdominal and chest CT scan showed large wedge like non-enhancing region in the lateral mid to upper pole of left kidney and solid heterogeneous 4.9 cm right adrenal gland mass. PHEOs was suspected, and he was started on doxazosin plus apixaban. Cardiac catheterization was deferred. Specific laboratory work revealed high levels of total plasma catecholamine, plasma metanephrine, nor metanephrine, and chrmogranin A respectively. Twenty-four hour total urinary metanephrines, normetanephrines, and catecholamines were also markedly raised. The patient underwent uncomplicated laparoscopic right adrenalectomy few weeks after this admission. Surgical pathology confirmed the diagnosis of PHEOs.

Discussion: The workup and definitive diagnosis of PHEOs continue to be challenging. We present a case of PHEOs with renal infarction. Renal infarction from renal artery stenosis/thrombosis has been well documented in the literature. Our case is unique in its presentation, in that his renal infarct was independent of renal artery stenosis or thrombosis. We hypothesize, this was most likely from wide variation in blood pressure, and possible hypotensive episode, in the absence of renal artery pathology.

FR-PO544

Renal Artery Aneurysm in Dialysis Patients

Maryam K. Saeed,[1] Rajeev Raghavan.[2] *[1]Baylor College of Medicine, Houston, TX, Sugar Land, TX; [2]Baylor College of Medicine, Houston, TX.*

Introduction: Renal artery aneurysms(RAAs) are rare(less than 1% in the general population), with most found incidentally on abdominal imaging. Aneurysm rupture has a high mortality and morbidity if not recognized in a timely manner

Case Description: We present two case-both end stage renal disease(ESRD) patients who presented with RAA rupture. The first patient was a 56 year old African American male on intermittent hemodialysis who presented with complaints of right sided flank pain for one day, without associated trauma, fevers, hematuria and hemoglobin of 7.7mg/dl on labs. A CT scan showed a right retroperitoneal hematoma. CT angiogram revealed two small pseudoaneurysms in the right renal artery with active extravasation that was successfully coiled. The second patient, a 72 year old Hispanic male, on peritoneal dialysis, was admitted to the critical care unit after an ischemic stroke. He was found to have Atrial fibrillation and started on a heparin drip for anticoagulation. His anti hypertensive medications were held to allow for permissive anti-hypertension. However, his hemodynamics worsened shortly afterwards requiring pressor support and stat labs revealed a drop in hemoglobin to 3.6mg/dl from 9.9mg/dl. Point of care ultrasound demonstrated a hypoechoic area around the left kidney. CT angio showed multiple areas of contrast blush in the left kidney consistent with active bleeding. IR guided coil embolization of the left renal artery was performed successfully and bleed was stopped.

Discussion: RAAs are associated most commonly with hypertension, followed by connective tissue diseases like fibromuscular dysplasia, Ehler–Danlos syndrome, Marfan syndrome, and vasculitis(such as polyarteritis nodosa and chronic granulomatosis with polyangiitis). Atherosclerosis is also associated with RAA but exact causative mechanism is not known. RAA rupture may present with back pain, abdominal pain, ileus, and hemorrhagic shock with CT showing retroperitoneal hematoma. Patients with chronic kidney disease and end stage renal disease have several risk factors for development of RAAs and rupture. Clinicans should have high suspicion for RAA rupture in dialysis patients presenting with abdominal pain, uncontrolled hypertension and sudden drop in hemoglobin. Endovascular treatment is a minimally invasive option available to treat renal artery aneurysm even in setting of aneurysmal rupture and bleeding as is gaining favor over open surgical repair.

FR-PO545

MobiusHD® Device: Controlling Refractory Hypertension in ESRD

Spencer Hodgins, Michael J. Germain. *Nephrology, UMMS Baystate Medical Center, Springfield, MA.*

Introduction: We discuss an interesting case of a patient on dialysis with severe hypertension. As a life saving measure we were granted compassionate use of the MobiusHD device, a baroreflex modulator implanted in the carotid artery. We discuss the outcomes and potential benefits of this device seen in this case.

Case Description: The patient is a 22-year old female with history of ESRD due to FSGS. She was diagnosed at a young age and underwent kidney transplantation at 11. She unfortunately went back on dialysis in 2016 at age 19 due to recurrent rejection and obstruction from a ureteric stricture. On dialysis she was noted to have extremely labile BP. In the 12 months prior to MobiusHD implantation, she had 22 admissions. Most were for hypertensive emergency requiring clevidipine. She also had an admission for PRES syndrome with seizures. Work up for secondary causes of hypertension was negative. Given the severity of her illness the MobiusHD device was implanted in Feb. 18 through Compassionate Use approval granted by the FDA. In the 12 months following MobiusHD implantation she had only 9 admissions (Fig. 1). We also evaluated her dialysis flowsheets and pre-dialysis systolic BP in her unit dropped from an average of 169.1 in the 6 months prior to the device to 152.5 in the 6 months following (Fig 2).

Discussion: Our case highlights the potential benefits of the MobiusHD device in a patient with life-threatening complications due to hypertension. It is noted that up to 50% of dialysis patients have a blunted baroreflex response which suggests that this device may be helpful in this population.[1,2] Since implantation of this device the patient has had a drastic improvement in quality of life and we are hoping to get her back on the transplant list with maintained stability.

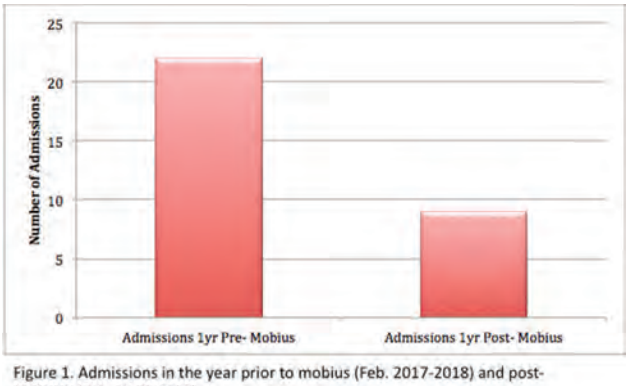

Figure 1. Admissions in the year prior to mobius (Feb. 2017-2018) and post-MOBIUS (Feb. 2018-2019).

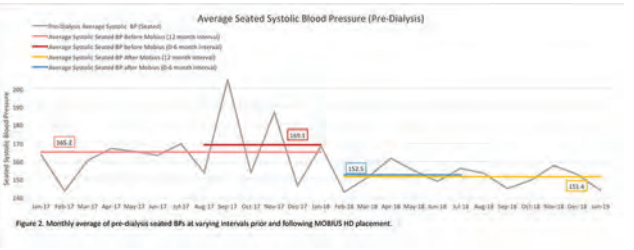

Figure 2. Monthly average of pre-dialysis seated BPs at varying intervals prior and following MOBIUS HD placement.

FR-PO546

Secondary Hyperoxalemia Causing Cardiac Failure in an ESRD Patient

Samuel J. Peeples,[1] Manish K. Saha,[2] Vimal K. Derebail,[3] Lucia Balos,[4] Alan L. Hinderliter,[1] Rocco C. Venuto.[5] University of North Carolina Kidney Center *[1]University of North Carolina Health Systems, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Jacobs School of Medicine, Buffalo, NY; [5]Erie County Medical Center, Buffalo, NY.*

Introduction: Secondary hyperoxaluria is a known complication of bariatric surgery due to impaired fat absorption. Oxalate deposition leading to organ dysfunction is poorly defined outside of primary oxalosis. We describe a case of cardiac and renal oxalosis with end-organ failure secondary to gastric bypass surgery.

Case Description: A 65-year-old male on hemodialysis for 3 years with history of heart failure with preserved ejection fraction (EF), jejunoileal bypass at age 18 and right nephrectomy due to cystic mass presented for exertional dyspnea and orthopnea after newly establishing care with us. His ESRD was presumed due to chronic nephrolithiasis after his jejunoileal bypass surgery. Electrocardiogram demonstrated atrial fibrillation and low QRS voltage. Transthoracic echocardiography (TTE) showed mildly thickened left ventricular wall with granular, sparkling texture to the myocardium, preserved EF, and biatrial enlargement concerning for cardiac amyloid. Serum immunofixation revealed an IgA lambda spike of 0.9 g/dL with kappa and lambda serum free light chains of 19mg/dL and 28mg/dL (ratio 0.67). Bone marrow aspiration showed 5-10% plasmacytosis, a lambda predominance and negative Congo red stain. Fat pad biopsy was negative for amyloid. Myocardial biopsy demonstrated diffuse cardiac oxalosis and interstitial fibrosis; Congo red stain was negative. Retrieval and staining of frozen tissue from prior nephrectomy revealed diffuse oxalosis with interstitial fibrosis. Serum oxalate levels before and after dialysis were 27 and 8 mcmol/L (normal <1.6), respectively, with an oxalate reduction ratio of 67%.

Discussion: Cardiac and renal oxalosis may have resulted from jejunoileal bypass, a now uncommon surgery. Oxalate is well cleared by HD, but long-standing hyperoxalemia prior to ESRD and between dialysis sessions likely led to myocardial deposition. Patients with ESRD due to secondary hyperoxalemia should continue to adhere to a low oxalate diet and regular dialysis sessions to prevent extra-renal oxalate deposition. Our case also illustrates that low QRS voltage in association with increased left ventricular wall thickness and a sparkling, granular appearance of the myocardium on TTE is not specific for cardiac amyloid, but may suggest cardiac oxalosis in the appropriate setting.

FR-PO547

Different Faces of PRES in Adolescent Lupus Nephritis on Hemodialysis

Alexandra Mazo, Anil K. Mongia, Oluwatoyin F. Bamgbola. *SUNY Downstate Medical Center, Brooklyn, NY.*

Introduction: Posterior reversible encephalopathy syndrome (PRES) is a neurologic condition characterized by seizures, altered mental status, headache, visual changes and specific findings on MRI. For pediatric PRES atypical involvement of frontal lobes, basal ganglia or cerebellum is not rare. Risk factors include SLE, renal disease, dialysis, hypoalbuminemia, hypertension, immunosuppression. Recurrent PRES and status epilepticus (SE) have rarely been described in children.

Case Description: We analysed all cases of PRES in pediatric renal patients in our hospital in the last 5 years and found only 3 cases. All of them are adolescents with active lupus nephritis (LN) on hemodialysis (HD).

Discussion: All our patients had multiple risk factors for PRES: LN, new onset HD, cyclophosphamide, hypoalbuminemia, hypertension. Despite the common predisposing factors, they all had different but atypical course of PRES. Case 1 had PRES one year after an initial lupus cerebritis and had a concurrent pulse therapy following seizure event because of concern for recurring cerebritis. Case 2 had recurrent PRES while she was on nicardipine drip. Case 3 had SE associated with PRES, a very rare condition. Both cases 2 and 3 received the cycle#2 of cyclophosphamide 2 weeks before onset of PRES. However, there was no PRES with the subsequent cycle#3. Current hypothesis of PRES involves vasogenic edema due to an endothelial injury. Hypertension is a consequence rather than the cause of the disorder; and it may be absent in PRES. LDH was suggested as a useful marker for identification of patients before onset of clinical symptoms. Unfortunately, in our cases LDH was not done. Further studies are needed on the role of LDH as a predictive tool for establishing potential preventive measures such as strict BP control, empirical antiepileptic drug, and optimal fluid control in high risk individuals.

Clinical characteristics during the PRES episode with seizures

	1st case	2nd case 1st episode/2nd episode		3rd case Status Epilepticus
Age/Sex	18/F	16/F		19/M

An Unusual Vaginal Discharge: The First Reported Case of Peritoneal Dialysis Catheter-Fallopian Tube Fistula

William J. Kennedy,[2] Rajendra Mandalapu,[2] Sandia Iskandar,[2] Manisha Singh,[2,1] Nithin Karakala.[2] *[1]CAVHS, Little Rock, AR; [2]University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Complications of peritoneal dialysis(PD) include obstructions and fistulas. Obstructions can result from various reasons including omental or fallopian tube wraps while communications/fistulas between the bladder and colonic walls are also possible. Vaginal discharge of PD fluid with an anatomically intact pelvis is not yet reported.

Case Description: The patient is a 42-year old African American woman with a past medical history of Lupus Nephritis and End-Stage Renal Disease on Peritoneal Dialysis(PD) for the past 5 years with poor compliance and repeated episodes of peritonitis. The patient reported an episode of abdominal pain and reported intermittent incontinence with painless vaginal discharge. These symptoms were not initially considered to be related to PD. She was treated for repeat peritonitis and vaginitis/cervicitis. She also reported that the discharge happens only during the fills on PD. She was admitted for peritonitis and PD was resumed. Within an hour of resuming dialysis, she had a large amount of fluid leak from the vagina. Obstetrics and Gynecology performed a pelvic examination that did not reveal an overt fistula or any abnormal findings. CT scan with contrast showed PD catheter coiled in the pouch of Douglas. The contrast went through the catheter to the right fallopian tube, entered the uterus and extended through the cervix into the vagina. It appears that the patient had formed collections on the pelvic floor, and one had PD Cath in direct communication with the fallopian tube. The patient underwent an open exploratory lap with salpingectomy. She transitioned to hemodialysis electively.

Discussion: This case highlights the differentials of vaginal discharge in a woman on PD. The patient had reported various concerns like possible intermittent incontinance, sudden vaginal discharge. All these symptoms were not considered to be related to PD, thus delaying diagnosis. Her abdominal pain was related to peritonitis and loculating collection in the abdomen. The painless vaginal discharge was happening through natural communications between the peritoneum, fallopian tube, and vagina. Abnormal fistulas are possible with excoriations and infections leading to friable organs, as also through natural orifices. Vaginal discharge in PD patient should lead to detailed exam and imaging.

FR-PO549

A Queer Case of Rapidly Progressive Metastatic Pulmonary Calcification (MPC) in a Patient with ESRD: Are We Doing Enough?

Ramla Abbas,[1] Hasan Zahid,[1] Ghulam M. Aftab,[1] Ramesh M. Kotihal.[2] *[1]Orange Park Medical Center, Orange Park, FL; [2]Nephrology Associates of NE Florida, Orange Park, FL.*

Introduction: Metastatic pulmonary calcification (MPC) is a metabolic lung disease which is poorly understood and can prove fatal. Despite its high prevalence, it remains undetected. We describe a case of MPC in a young female patient with ESRD which ultimately lead to patient's demise.

Case Description: A 32 year old female with history of end stage renal disease (ESRD) secondary to autosomal dominant polycystic kidney disease presented with generalized weakness for 2 months. She had been on hemodialysis (HD) for 3 years but was not compliant with dialysis. Physical exam was grossly unremarkable and vital signs were within normal limits. Relevant laboratory findings included BUN of 73 mg/dl, Cr of 11.7 mg/dl, phosphorus of 8.2 mg/dl, calcium of 11.1 mg/dl and PTH was 1284 pg/ml. Broad spectrum antibiotics were initiated. Few hours into admission, she rapidly deteriorated, became confused and was subsequently intubated and transferred to the Intensive Care Unit. High Resolution CT scan of the chest showed very dense airspace opacification (measuring a mean attenuation of 329 HU), involving the right middle lobe and left upper lobe (including the lingula) with patchy dense opacification elsewhere. Patient remained afebrile. Blood cultures, sputum cultures, tuberculosis quantiferon and bronchoalveolar lavage were negative for any infection. Technetium (Tc) 99 bone scan disclosed diffuse activity in the pulmonary parenchyma, strongly supporting metastatic pulmonary calcification Despite escalating supportive measures, the patient became increasingly hypoxic and died 4 days later.

Discussion: In contrast to other conditions leading to death in ESRD patients, metastatic pulmonary calcification does not usually cause symptoms, can result in quick respiratory decline and is often identified only at autopsy as routine chest X-rays are mostly negative. MPC may remain undiagnosed and untreated, at times progressing to severe acute respiratory failure. It is of paramount importance that we not only do timely detection and treatment but also explore new diagnostic and therapeutic methods for MPC to decrease overall mortality in ESRD patients.

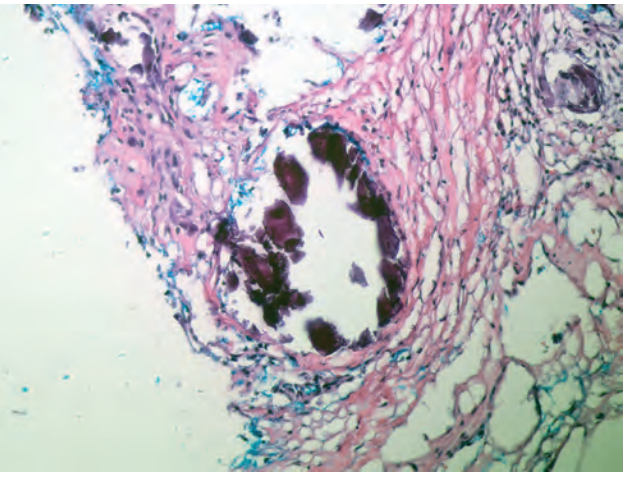
The Heart of Calcium

Prakrati C. Acharya, Karthik Kovvuru, Pradeep Vaitla, Swetha Rani Kanduri. *University of Mississippi Medical Center, Ridgeland, MS.*

Introduction: Calciphylaxis or calcific uremic arteriopathy is a rare disorder causing diffuse calcification of arterioles in dermis and subcutaneous tissue. We here by present a case of systemic calciphylaxis presenting as non infective endocarditis with stroke.

Case Description: 59 year old Caucasian female with End stage Renal disease secondary to Microscopic polyangitis (with only renal involvement +PANCA) for 2 years initially on hemodialysis for a year and then switched to peritoneal dialysis, presented to the hospital with subjective fever and shortness of breath concerning for multifocal pneumonia. Echo showed 1.5 x 2 cm mitral valve vegetation and PFO. Her infectious work up was persistently negative including blood cultures for bacterial, fungus and AFB. She did not have fever during hospitalization. Hospital course was complicated by stroke thought to be embolic from valve vegetation. With worsening clinical conditions she underwent mitral valve replacement and mitral valve pathology showed myxoid degeneration, with no inflammation or organism but calcification and cultures remained negative. On presentation patient also complained of painful hard nodules from ankle to knee of posterior bilateral lower extremities for 6 months. Biopsy was diagnostic for calciphylaxis. She had elevated phosphorus to 11 and PTH of 780 on presentation The mobile masses seen on echocardiography were likely to represent healed vegetations that had calcified as a result of calciphylaxis. She was started on intensive daily dialysis and sodium Thiosulfate with good outcome.

Discussion: High clinical suspicion is warranted to make the diagnosis of calciphylaxis. Despite a multi-interventional approach for calciphylaxis, the disease remains associated with a high morbidity and mortality. To our knowledge this is the first reported case of non infective endocarditis with complication of stroke as the initial manifestation of calciphylaxis followed by further work up showing skin involvement, with ultimate good outcome.



FR-PO551

Osteitis Fibrosa Cystica in Renal Osteodystrophy Masquerading as Malignancy

Samira Z. Chandra,[1,2] Kriti Devkota,[2] Belinda Jim.[3] *[1]Nephrology, Jacobi medical center, NYCHHC, Bronx, NY; [2]Nephrology, Upstate Medical University, Syracuse, NY; [3]Albert Einstein College of Medicine, New Hyde Park, NY.*

Introduction: High bone turnover in renal osteodystrophy is a rare clinical entity nowadays due to early diagnosis and treatment of secondary hyperparathyroidism. Since it is a diagnosis of exclusion, a formidable diagnostic challenge exists when the likelihood of malignancy is high in an elderly ESRD patient.

Case Description: A 64-year-old African American man with a history of HTN, cardiomyopathy with ICD and ESRD on hemodialysis was admitted for pathological fracture of L2 with no neuro deficit. Imaging showed generalized osteopenia, burst fracture of L2, radiolucent foci all over the spine. Preliminary diagnosis of malignancy was made, and cord compression was ruled out. Biopsy from L2 revealed- i. reactive bone with prominent peri-trabecular fibrosis, ii. patchy hemosiderin-laden macrophages and iii. increased number of multinucleated osteoclasts indicative of bone resorption. Skeletal survey was inconclusive for malignancy or myeloma. Contrast CT abdomen and pelvis reported cortical erosion of symphysis pubis by a mass measuring 3.7 cm x 4.3 cm.

Biopsy from the mass revealed- focal granulation tissue and hemosiderin-laden macrophages. Blood work for myeloma showed only polyclonal gammopathy on SPEP. Serology for tumor markers was negative and TB was ruled out. Meanwhile, the patient received multiple units of PRBC, periodic filgrastim and darbepoetin injection for pancytopenia. Bone marrow biopsy reported high normocellular marrow, polyclonal plasma cells, hemosiderin-laden macrophages, extensive peri-trabecular fibrosis and bony remodeling with osteoblasts. Then the PTH level was checked and found to be 2020 pg/ml. Neck ultrasound showed all four parathyroid hyperplasias. Finally, the patient underwent parathyroidectomy. The patient improved slowly and was sent home after a while. On follow up visit, the patient reported an increased sense of well-being. Follow up lab revealed- normalization of CBC requiring no further PRBC transfusion or filgrastim injection.

Discussion: This case illustrates the importance of considering secondary hyperparathyroidism as the possibility of a lytic bony lesion in the ESRD population. High bone turnover in hyperparathyroidism can manifest as osteitis fibrosa cystica (lytic lesion), brown tumor (both lytic and expansile mass) and/or peri-trabecular bone marrow fibrosis. Clinical and histopathological co-relation is crucial for such a diagnosis.

FR-PO552

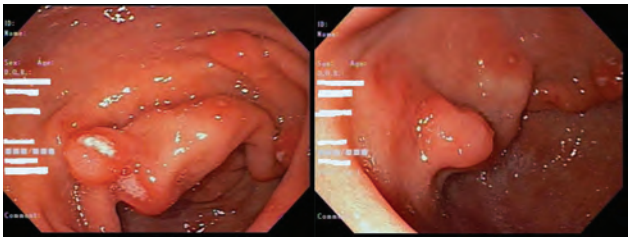
Metastatic Calcinosis of Gastric Mucosa

Vatsalya Kosuru,[4] Sandeep A. Padala,[1] Rajan Kapoor,[2] Imran Y. Gani,[3] Asad Ullah.[4] *[1]Augusta University, Augusta, GA; [2]Augusta University / Medical College of Georgia, Augusta, GA; [3]SELF, Augusta, GA; [4]Augusta University Medical Center, Martinez, GA.*

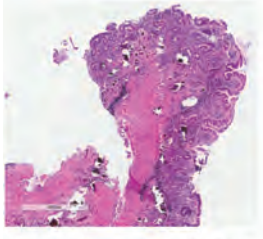
Introduction: Metastatic calcinosis is a rare and serious complication of chronic renal failure. The striking feature is the calcification seen around large joints. While it mostly involves the blood vessels and dermis, it can also rarely affect the mucosal layers of the gastrointestinal tract.

Case Description: A 49-year-old African-American male with history of chronic GN leading to ESRD followed by an initial renal transplant in 1980 with subsequent graft failure in 1991, requiring re-initiation of dialysis. Had a second transplant in 2016 with stable graft function. Two years later, he started experiencing persistent worsening dysphagia and weight loss despite normal appetite. Labs and vitals were stable. He was referred for EGD, which showed extensive patchy exudates with underlying friable ulceration of upper esophagus, erythema of antrum and few nodular regions in pre-pyloric area. Duodenal Villi showed extensive whitish tips. The pathology was consistent with Candida esophagitis and Helicobacter pylori gastritis that was treated appropriately. The biopsies also revealed mucosal calcinosis in the gastric antrum and body, which could be explained by the long-standing history of dialysis and could also be supported by the evidence of extensive calcification of common iliac and external iliac arteries, bilateral native kidneys and prior transplanted kidney. The symptoms improved with the treatment of Candida esophagitis and H. pylori gastritis.

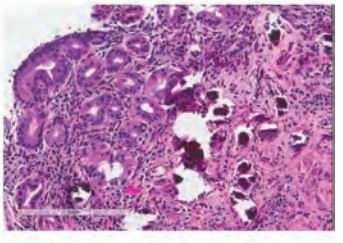
Discussion: Metastatic calcinosis is a severe consequence of chronic renal failure, as there is a disruption in calcium and phosphorus metabolism. Failure of management of hyperphosphatemia in chronic renal failure leads to secondary hyperparathyroidism and precipitation of calcium products in multiple organs. Though Calcinosis of vascular media is the common finding, it can rarely involve the mucosal layers of the GI tract causing ulcerations.



Pre pylorus and Antrum



Hematoxylin and Eosin stain 100x. Calcium deposits distributed along the lamina propria and under foveolar epithelium.



Hematoxylin and Eosin stain 200x. Prominent cyanophilic calcium crystals arising from lamina propria vasculature. Concomitant chronic gastritis is present with increased lymphoplasmacytic infiltrates.

FR-PO553

Dialysis-Related Amyloidosis with Fever

Yasuhiro Oda, Kunihiro Ishioka, Takayasu Ohtake, Yasuhiro Mochida, Hidekazu Moriya, Sumi Hidaka, Shuzo Kobayashi. *Department of Kidney Disease and Transplant Center, Shonan Kamakura General Hospital, Kamakura, Japan.*

Introduction: Although dialysis-related amyloidosis (DRA) is generally afebrile, literature shows that some cases of DRA manifest fever and its treatment has not been well established. Herein, we report a case of 74-year-old woman with febrile DRA, and discuss optimum treatment for this condition with a review of literature.

Case Description: A 74-year-old woman with 34-year history of hemodialysis due to end-stage renal disease caused by chronic glomerulonephritis presented with four months of intermittent fever of 99-102°F coinciding with recurrent bilateral shoulder and hip joint pain. Laboratory testing revealed WBC 6,300/μL, Neut 76%, Hb 8.0 g/dL, CRP 17.0 mg/dL, and β_2-microglobulin (β_2M) 21.0 mg/L. Blood cultures were negative. Imaging studies of the shoulder and hip joints revealed periarticular soft-tissue thickening, bone cysts, and intense accumulation of ^{99} mTc and ^{67} Ga in scintigraphy. Biopsy of the articular synovial membrane of the right shoulder joint revealed amyloid deposition, leading to the diagnosis of DRA. Hemodialysis was switched to online hemodiafiltration (HDF) and then to combination use of β_2M adsorption column with online HDF, where the latter modality yielded a higher clearance (76, 84, 102 mL/min) and reduction rate (67, 77, 80%) of β_2M. Intermittent fever and joint pain decreased remarkably in frequency and intensity but were still present after two months. Promptly after starting prednisolone 10 mg/day, her fever and joint pain disappeared, CRP level normalized, and anemia alleviated. The prednisolone dosage is gradually decreased without exacerbation.

Discussion: Our case and three reported cases of DRA with fever all manifested polyarticular pain with amyloid deposition in articular synovial membrane. Three of the four cases were prescribed with prednisolone and achieved prompt normalization of temperature and CRP level within ten days, while the remaining case without steroids had fever for five months. One case with early use of prednisolone but with no change in β_2M clearance initially achieved normalization of temperature but experienced a relapse of the symptoms, which ceased by using β_2M adsorption column. These cases imply that increasing β_2M clearance is crucial to control this condition in the long run, while concurrent early use of steroids has the advantage of promptly alleviating fever, joint pain, and progression of anemia.

FR-PO554

Activation of Blood Leak Alarm During Hemodialysis Secondary to Hydroxocobalamin Therapy of Cyanide Toxicity

Justin L. Yancey,[1] Barry M. Wall,[2] Omer M. Asif Siddiqui.[1] *[1]University of Tennessee Center for Health Science, Memphis, TN; [2]Veterans Affairs Medical Center, Memphis, TN.*

Introduction: Toxic levels of cyanide, which may develop with prolonged infusions of sodium nitroprusside, can be treated with hydroxocobalamin. A noted side effect of hydroxocobalamin is red discoloration of plasma and urine. Hydroxocobalamin may also lead to red discoloration of dialysate with activation of blood detector alarms during conventional hemodialysis.

Case Description: 61 year old female with advanced renal disease due to poorly controlled hypertension presented with severe blood pressure elevation of 247/125 mmHg with imaging findings concerning for 5.6 cm abdominal aortic aneurysm with impending rupture. Sodium nitroprusside was started for blood pressure control at low dosages for 9 days. On the 9th day, she developed a wide anion gap metabolic acidosis: sodium 145, potassium 4.5, chloride 96, bicarbonate 18, BUN 24, SCr 2.52, and anion gap 31. Cyanide toxicity was diagnosed and treated with intravenous hydroxocobalamin. Conventional hemodialysis was initiated with a Fresinius FMC machine, but could not be performed due to activation of blood leak dectector alarms with visibly reddish colored dialysate. CVVHD was subsequently initiated through use of NxStage machine. The red discoloration of the dialysate gradually resolved over a 48 hr period, at which time intermittent hemodialysis was reinitiated with no further blood leak alarms.

Discussion: Blood leak detection alarms on dialysis machines have been designed to cease operations when blood is detected in the dialysate. Fresenius dialysis machine contains blood leak alarm consisting of two-color light source transmitter/sensor (red light and green light) that monitor clarity of effluent dialysate. The photodetector is triggered when green light (wavelength 562–575 nm) is absorbed by blood. A leak detector is placed in dialysis solution outflow line, using sensor in dialysate effluent path. When blood leaks are detected, the alarm is activated and blood flow through dialyzer stops. NxStage CRRT machine does not have hydroxocobalamin-related false blood leak alarms. The blood leak detector of NxStage machine uses a single optical emitter with 880-nm wavelength designed to detect light scatter. It does not depend on light absorption, and, therefore, was not activated by discoloration of the dialysate by hydroxocobalamin, such that renal replacement therapy could be administered.

FR-PO555

Use of CardioMEMS in Dialysis Patients with Heart Failure

Karolina Viquez, Amr E. Mohamed, Mohamed Elyamny, Karim Fahmy, Maya Guglin. *University of Kentucky, Lexington, KY.*

Introduction: Volume overload is a major problem in patients with chronic kidney disease (CKD) and heart failure (HF). Fluid removal during dialysis treatment is the cornerstone management in these conditions but, assessing the amount of volume that

should be removed is a challenge. We present two cases of remote ambulatory pulmonary artery (PA) pressure measurements in dialysis patients with HF using cardioMEMS.

Case Description: Case 1. Heart Failure with Preserved Ejection Fraction 65-year-old Caucasian female, history of type II diabetes, hypertension, CKD, hepatitis C, liver cirrhosis, NYHA class III diastolic HF. Echocardiogram left ventricular ejection fraction was (LVEF) >55%. CardioMEMS was implanted in 2016. Patient was started on intermittent hemodialysis (iHD) via a tunneled catheter in 2018. Patient was switched to continuous cyclic peritoneal dialysis (CCPD) in 2019. Her PA pressure by CardioMEMS increased after initiation of the HD but decreased significantly after CCPD was established (Figure 1). **Case 2. Heart Failure with Reduced Ejection Fraction** 73-year-old Caucasian male with history of type II diabetes, hypertension, and CKD, NYHA class III systolic HF. Echocardiogram LVEF <20%. CardioMEMS was implanted in 2016. Patient had declining kidney function and a right upper arm arteriovenous fistula was placed, iHD was initiated in 2018. His PA pressure readings by CardioMEMS gradually declined after initiation of dialysis (Figure 2).

Discussion: Hemodialysis resulted in significant changes in the PA pressure in HF patients. Remote ambulatory monitoring of PA pressures is a promising strategy in dialysis patients with HF since it might guide the management of volume status and allowing early interventions.

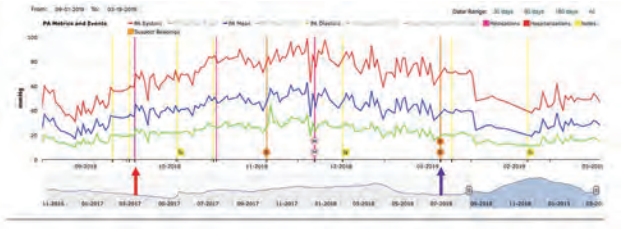


Figure 1. PA pressures. Red arrow indicated when HD was initiated and the purple arrow indicated when CCPD was established.

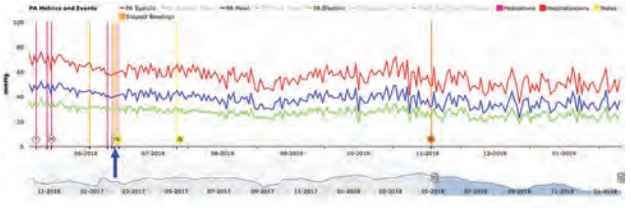

Figure 2. PA pressures. Arrow indicated when hemodialysis was started.

FR-PO556

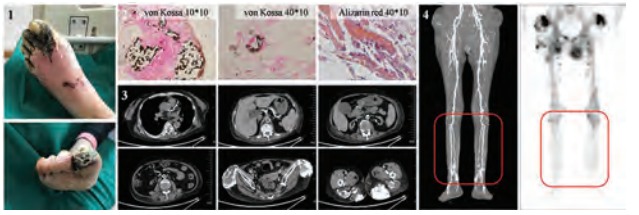
Striking Radiological Findings of Visceral Arteries Calcification in a Severe Calciphylaxis Patient

Canlin Yang,[1] Yuqiu Liu,[1] Xiaotong Xie,[1] Bi-Cheng Liu,[2] Xiaoliang Zhang.[1]
[1]Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China; [2]Zhong Da Hospital, Southeast University Medical School, Nanjing, China.

Introduction: Calciphylaxis is a rare complication of end stage renal disease characterized by calcification, fibrointimal hyperplasia, and thrombosis in the subcutaneous adipose tissue and dermis. Skin biopsy is the standard method for confirmed diagnose but it's still controversial for creating new wounds. The imaging characteristics of calcification may help diagnose calciphylaxis. This article reports a severe visceral calciphylaxis patient confirmed by skin biopsy with striking calcification of the visceral vessels.

Case Description: A 45-year-old female with systemic lupus erythematosus have a 14-year medication history of oral glucocorticoids and 10-year maintenance hemodialysis. She had an erythema on toes and deteriorated into painful dry gangrene with infection 1 month before admission (Fig.1). Skin biopsy (Fig.2) confirmed the diagnosis of severe calciphylaxis. Interestingly, her imaging fingdings showed striking calcification of visceral blood vessels. Extensive calcification of arteries of pancreas, kidneys and intestinal canal can be seen in the computed tomography scan (Fig.3). Although she doesn't have symptoms of visceral ischemia such as chronic abdominal pain or gastrointestinal bleeding, it may be a predictor of visceral calciphylaxis and she may show symptoms of visceral ischemia or bleeding one day. Computed tomography angiopraphy (CTA) of the lower limbs shows diffuse calcification the lower extremity arteries and soft tissues. Exactly, bone scintigraphy scan proved abnormal diffuse high uptake of subcutaneous soft tissue in crus that is in consistence with what shown in CTA (Fig.4). The efficacy of therapies based on sodium thiosulfate is still in follow-up.

Discussion: Characteristic histological features of calciphylaxis include medial arterial calcification and thrombosis in arterioles. This patient has typical clinical manifestations of severe calciphylaxis and striking imaging features of visceral vascular calcification. Biopsy in visceral arterioles is difficult, so that the combination of multiple imaging methods is valuable to early diagnosis of visceral calciphylaxis.



FR-PO557

Effluent Colors in Continuous Hemodiafiltration

Priscila Dias goncalves,[1] Thiago A. Reis,[2] Geraldo R. Freitas.[3] *[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]CDRB - Clinica de Doencas Renais de Brasilia, Brasilia, DF., Brazil; [3]USP, Brasilia, Brazil.*

Introduction: Continuous venovenous hemodiafiltration (CVVHDF) is widely used as a renal replacement therapy modality on patients with acute kidney injury. It usually generates a yellow citrine outflow that is stored as effluent. Bellow we describe 2 cases of unusual effluent color changes due to special clinical situations in our center.

Case Description: Case Report 1- Red effluent fluid: An 38 year- old female patient admitted to the ICU after mitral valve replacement surgery developed Acute Kidney Injury (AKI). CVVHDF was attempted and on the 14th day after surgery, effluent fluid was red colored, concomitant with the spike of CPK and the diagnosis of rhabdomyolysis. Dipstick analysis revealed the presence of hemoglobin (false positive). Microscopic evaluation of the effluent fluid was negative for the presence of red blood cells, thus excluding the possibility of rupture of the filter. Myoglobin concentration on the effluent was 1765 UI/L. Case report 2- Green effluent fluid :An 50 year-old male patient admitted to the ICU after myocardial revascularization surgery developed AKI and CVVHDF was attempted. Due to refractory shock methylene blue was added to the vasoactive drugs arsenal and 30 minutes later the effluent fluid removed by CVVHDF was green colored.

Discussion: Changes on the CVVHDF effluent color to red should alert the nephrologist to the possibility of hemolysis or dialyzer membrane compromise. Because of it's high molecular weight and a Sieving coefficient of less than 0,1% hemoglobin is not expected in the dialysate. However myoglobin has a much smaller molecular weight and a Sieving Coefficient of 40%, therefore it should be considered as a possible cause of red dialysate. Blue colored effluent occurred most likely due to and additive effect of the methylene blue with the usual citrine yellow effluent color.

FR-PO558

Acquired Autoimmune Hemophilia A After Initiation of Hemodialysis

Teresa Fowler,[1] Michael J. Wilkowski.[2,1] *[1]Mercer University School of Medicine--Savannah Campus, Savannah, GA; [2]Medical Associates of Savannah, Savannah, GA.*

Introduction: Acquired hemophilia A is a rare autoimmune disorder in which circulating IgG antibodies inhibit and deplete coagulation factor VIII. It is common in patients with congenital hemophilia A after factor VIII transfusions but rare without preexisting hemophilia. Presentation in adults is similar to the congenital form, with spontaneous hemarthroses or bleeding in the setting of isolated PTT prolongation. No consistent triggers have been identified, though associations have been suggested with connective tissue disorders, malignancies, and immunomodulators, among others.

Case Description: A 60 yo man was admitted for painful unilateral thigh swelling and severe anemia with hemoglobin nadir 3.5 g/dL. PMH included ESRD due to hypertension, hemodialysis (HD) had been initiated 1-month prior. Family history negative for bleeding or autoimmune disorder. Laboratory values were significant for leukocytosis (17.8 K/uL) and prolonged PTT (107.8 s) with normal PT, INR, platelets, and reticulocytes. Iron studies were consistent with anemia of chronic disease. On hospital day 2 he developed an unprovoked right upper extremity hematoma requiring emergent fasciotomy on the side of his tunneled HD catheter. A naïve left arm AV fistula was unaffected. Concern for factor VIII inhibitor was raised, and confirmed with circulating anticoagulant screen and undetectable factor VIII level. Recombinant factor VIIa & factor VIII inhibitor bypassing agent were utilized to control bleeding, concurrent with high-dose prednisone, cyclophosphamide, and plasmapheresis to decrease inhibitor activity. After a complicated course, he was discharged on prednisone, cyclophosphamide, and tranexamic acid with a PTT of 45.2s.

Discussion: We suspect that the recent initiation of HD triggered this autoimmune response. The right IJ catheter was the presumed bleeding site. A small series of HD-associated hemophilia is reported in the literature, though the mechanism of this association is speculative. HD is known to activate the complement system and trigger cytokine release, though the severity of this effect is decreasing with improved biocompatible dialyzer membranes. Autoantibody formation in ESRD or due to HD is not well described or recognized. Acquired hemophilia is a hematologic emergency with high mortality and should be considered for patients presenting with bleeding complications and coagulation abnormalities after HD initiation.

FR-PO559

Hypereosinophilia in Haemodialysis Patients

Kathryn J. Griffiths,[1] David Makanjuola,[1] Michael J. Austin,[2] Corinne F. De lord,[2] Hannah Cheney lowe,[1] Simon C. Stern,[2] Simon K. Winn.[1] *[1]Nephrology, Epsom and St Helier University Hospital NHS Trust, London, United Kingdom; [2]Haematology, Epsom and St Helier University Hospital NHS Trust, London, United Kingdom.*

Introduction: The incidence of hypereosinophilia (>2 x 10^9/L) in our haemodialysis population in London over the last 13 years is 9.7 per 100 patients per year. We present 9 cases of significant hypereosinophilia which occured alongside significant haemodynamic instability during haemodialysis (HD) sessions.

Case Description: All the patients survived these episodes; 7 of 9 had prompt reduction in eosinophil counts following high dose corticosteroids. All patients were on haemodiafiltration, with ultra-pure water. There was a high recurrence rate following wean of steroid treatment. Adaptations to the HD circuits including changing the line lock, dialyser type and dialyser surface area were made, but the inconsistent response suggests more than bioincompatibility. We did specific allergy testing for ethylene oxide (ETO), latex and chlorhexidine in 3 patients, 1 of which raised to latex. All 9 patients were ANCA negative, Hepatitis B, C and HIV negative. 1 patient had positive strongyloides serology.

Discussion: The reason for the hypereosinophilia is unclear, but it has made HD challenging in these patients. It is possible that there may be other precipitants not related to the HD circuit. Joint management between nephrologists, haematologists and HD unit staff is important for the management of hypereosinophilic patients experiencing severe haemodynamic instability during HD.

Investigations for patients 1-9

Patient	Peak eosinophil count (X10<9>/L) Normal range: <0.4 X10<9>/L	Mast cell tryptase (µmol/L) Normal range: 2- 14 µmol/L	Total IgE (kUA/L) Normal range: <75 kUA/L	BMAT, FIP1L1-PDGRFA performed (Y/N)	Cause of end stage renal failure	Dialysis access	ACEi or ARB therapy (Y/N)	CT scan performed (Y/N)

Erythropoietin Stimulating Agent (ESA)-Resistant Vitamin B6 Deficiency Anemia in a Pediatric Patient on Hemodialysis

Sagar Patel, Leah E. Goswick, Majed Jeroudi, Radhakrishna Baliga. *LSU Health Sciences Center, Shreveport, LA.*

Introduction: Vitamin B6 is a water soluble vitamin, the active form of which is Pyridoxal 5'-phosphate, that functions as a coenzyme of erythroid specific 5-aminolevulinate synthase (ALAS2) which is involved in the synthesis of heme. Vitamin B6 deficiency is often associated with inflammation as observed in chronic kidney disease, particularly those requiring dialysis. Administration of an ESA has also been shown to be associated with increased erythrocyte consumption of vitamin B6. We report here a pediatric patient who developed an ESA resistant anemia that significantly improved following vitamin B6 supplementation.

Case Description: 16-year-old African American male with end stage renal disease secondary to obstructive uropathy, on chronic hemodialysis, experienced a decrease in his hemoglobin over a 3-month period from 11 to 6.5 g/dL, while receiving darbepoietin alfa (ESA) [0.9mcg/kg/week] intravenously for one month. His transferrin saturation was 41%, ferritin level 706 [80-388] ng/mL, mean corpuscular volume (MCV) 87 [78- 98] fL. His corrected reticulocytes count was 2.3% [0.2-1.8%]. Additional laboratory data included the following: Direct antiglobulin testing and stool for occult blood were negative; Vitamin B12, 635 [193-986] pg/ml; folate, 8.4 [3.1-17.5] ng/mL; copper, 1413 [665-1480] mcg/l; zinc, 77 [60-120] mcg/dL and Ceruloplasmin, 31.4 [15-30] mg/dL. PTH was elevated at 258 [9-69] pg/ml. Vitamin B6 level was low at 1.2 [5.3-46.7] ug/L. Bone marrow biopsy was normocellular (65%) with erythroid hyperplasia and rare dyserythropoiesis. Prussian blue staining showed increased iron storage. Supplemental Vitamin B6 (100mg daily) was initiated, at which time his hemoglobin was 7.3 g/dL. Three months later, his hemoglobin was 11.6 g/dL with transferrin saturation of 18%.

Discussion: Vitamin B6 clearance is increased with standard hemodialysis and a further 50% increase in vitamin clearance is noted when receiving high flux high efficiency hemodialysis as seen in our patient. Vitamin B6 deficiency anemia should be considered in any pediatric patient on high flux hemodialysis who is not responding to standard ESA and iron therapy.

FR-PO561

Role of Extracorporeal Treatments in Management of Massive Bee Attack

Basel Channis, Chandandeep Takkar. *University of Texas Health Science Center, San Antonio, TX.*

Introduction: Bee stings can cause severe allergic reaction which can be triggered by a single sting, prognosis worsening with increasing number of stings. More than half of the victims who experience multiple bee stings develop Acute Kidney Injury (AKI), which is due to multiple factors, such as intravascular hemolysis, rhabdomyolysis, hypotension and direct renal tubular toxicity of the venom components. We present a case of anuric acute renal failure due to massive bee attack, managed by renal replacement therapy and plasmapheresis.

Case Description: 53 year old male with history of hypertension, presented to our facility after an attack from killer bees (reportedly > 2000 bees). Upon initial presentation(16 hours after attack); he was intubated, in shock requiring vasopressors despite fluid resuscitation, and noted to be anuric. Patient was initiated on a high dose

continuous renal replacement therapy (CRRT) with CVVHDF promptly after arrival, in conjunction with Plasmapheresis (PLEX), circuits connected in parallel, to manage renal failure as well as potentially assist with bee venom removal. He received 2 sessions of PLEX (days 1, and 3); CRRT for a week, followed by intermittent hemodialysis (iHD) for another two weeks. Partial renal recovery was noticed and patient was discharged home with a Cr of 4.9 mg/dl. Upon follow up 2 weeks later, further improvement of Cr to 2.5 mg/dl was noted.

Discussion: Massive bee stings is a rare cause for hospital admission and AKI. Patients could also present with cardiomyopathy, and multi-organ dysfunction, perpetrated by shock and/or direct toxicity of venom. Short term mortality could approach 25%, particularly in setting of AKI. Bee venom is a heterogenous toxin with molecular weight of toxins ranging from 2.8 to 43 KDa. One of the major toxins, Mellitin (2.8Kda) is water soluble, and potentially dialyzable. Prompt initiation of dialysis with PLEX could offer benefits in removal of bee venom as well as inflammatory mediators. While there is no consensus in the literature regarding mode of dialysis in such setting, a large case series suggested a higher rate of renal recovery in patients who received CRRT (+/-PLEX) versus iHD. Our patient showed promising trend towards full recovery of renal function.

FR-PO562

Getting Off on the Wrong Foot: Trichosporon inkin Peritonitis

Nolan M. Giehl,[1] Brian Y. Young.[2] *[1]UC Davis Internal Medicine Residency, Sacramento, CA; [2]UC Davis Medical Center, Sacramento, CA.*

Introduction: Peritonitis is a serious complication of peritoneal dialysis and 3-6% are fungal in etiology. Trichosporon inkin, a yeast-like fungus associated with the superficial hair shaft infection "white piedra," seldom causes invasive infections. Treating invasive Trichosporon spp. can be challenging given limited data. We present a rare case and describe the treatment of resistant T. inkin peritonitis in an end stage renal disease (ESRD) patient on automated peritoneal dialysis (APD).

Case Description: A 56 year old man with ESRD from membranoproliferative glomerulonephritis on APD presented with abdominal pain and cloudy dialysate. PD fluid cultures were drawn and he was empirically treated for bacterial peritonitis with intraperitoneal cefazolin + ceftazidime, while nystatin was used for fungal prophylaxis. 6 days later, pain and cloudy fluid persisted, and his fluid culture grew Trichosporon inkin. The patient, who also had onychomycosis, later admitted to picking at his right 2nd toenail to remove a splinter prior to handling his PD catheter. The PD catheter was removed due to his fungal infection, and he was converted to HD. Initial use of IV micafungin failed to improve his symptoms. Testing showed the T. inkin to be resistant to Echinocandins, but susceptible to voriconazole. Voriconazole was given for 10 weeks with resolution of his symptoms and onychomycosis. Now off antifungals for 2 months, he is waiting re-evaluation to return to PD.

Discussion: The etiology in our case was likely poor hand hygiene after manipulation of his toe. Multiple cases of Trichosporon spp. onychomycosis have been described but only 3 prior T. inkin peritonitis cases have been reported, the last in 2003 and treated with caspofungin. Voriconazole, FDA-approved in 2002, was used in our case as it performed best in vitro against T. inkin, which is typically resistant to echinocandins. Therapy duration is not as clear and has ranged from 2-8 weeks in the literature, often being anecdotal. T. inkin is also associated with biofilm formation, causing up to a 1000x higher MIC required by voriconazole in 1 in vitro model. With these concerns, the patient was treated with a lengthy course to give the best hope for cure and to restart PD eventually. This is the first case to describe voriconazole treatment in T. inkin peritonitis, with further research needed to define optimal therapy duration.

FR-PO563

Treating Resistant Mycobacterium abscessus in Peritoneal Dialysis-Associated Infection

Tiana Jespersen,[1] Priyanka Wani,[1] Wahid N. Syed,[2] Brian Y. Young.[1] *[1]University of California Davis, Sacramento, CA; [2]UC Davis Medical Center, Sacramento, CA.*

Introduction: Mycobacteria-associated peritoneal dialysis (PD) infections should be considered in culture-negative or refractory cases. Non-tuberculous mycobacteria (NTM) are abundant in soil and water, and can rarely cause PD infections. NTM are associated with high rates of catheter loss and hemodialysis (HD) conversion. Of the NTM, *Mycobacterium abscessus* grows rapidly and is resistant to standard therapies. We present a challenging case of an exit site infection (ESI) due to multidrug-resistant *M. abscessus* that progressed to peritonitis despite antibiotics and PD catheter revision.

Case Description: An 80-year-old man on PD was treated for ESI and a culture collected by his dialysis unit showed gram-variable bacilli requiring outside lab send out for identification. On day 8, he developed a tunnel track abscess necessitating drainage and catheter revision. On day 15, abscess cultures grew acid-fast bacilli (AFB), thus doxycycline was added. On day 21, *M. abscessus* was identified from the original ESI culture. Antibiotics were broadened to clarithromycin and moxifloxacin. PD fluid analyses were previously negative. However, by day 33, the patient developed recurrent tunnel infection and cloudy PD fluid with AFB. The PD catheter was removed, and he transitioned to HD. On day 41, the original culture finally reported that the *M. abscessus* was resistant to multiple antibiotics including aminoglycosides, cephalosporins, doxycycline, and fluoroquinolones. A four-drug treatment regimen of eravacycline, imipenem, clarithromycin, and linezolid was ultimately selected.

Discussion: PD-associated infections due to NTM are difficult to distinguish from more common organisms, with our patient initially showing gram-variable bacilli. A delay in appropriate treatment occurs frequently because a minimum of 3-5 days on special medium is necessary for NTM to grow and speciation lags for weeks, as was seen in our case. *M. abscessus* causes less than 10% of PD-associated NTM infections, thus therapy guidelines are based on limited experience. Macrolides are the most reliable option and should be combined with a parenteral antibiotic tailored to susceptibility data. Our case highlights the difficulty faced with very resistant strains. A high index of suspicion and early catheter removal remain the cornerstone for successful management of *M. abscessus* and other NTM infections.

FR-PO564

A Twisted Fate: A Case of PD Catheter Malfunction due to Fallopian Tube Migration

Ajay K. Thakur,[1] Catherine A. Moore.[2] *[1]University of Rochester, Rochester, NY; [2]Strong Memorial Hospital, Rochester, NY.*

Introduction: Management of peritoneal catheter malfunction is an important aspect of peritoneal dialysis care. Most often peritoneal catheter dysfunction is related to omental wrapping, but rarely other intraperitoneal structures can cause outflow obstruction. We report a case of PD catheter dysfunction secondary to fallopian tube migration and wrapping, managed by conversion to hemodialysis.

Case Description: 27 y.o.female with ESRD secondary to Class- IV Systemic Lupus Erythematous (SLE) Nephritis initiated peritoneal dialysis (PD) 14 days following catheter insertion. From the outset, she reported severe abdominal pain and cramping associated with filling and draining, occasionally noting blood tinged PD effluent. She was sent to IR for a catheter check, found to have a small non-occlusive filling defect inside the PD catheter around 10 cm from the catheter tip. tPA was instilled in the catheter with transient resolution of the filling defect but no impact on pain symptoms. 6 weeks post catheter insertion she underwent exploratory laparotomy to further evaluate catheter dysfunction. Intraoperative findings were notable for left oviductal fimbriae adherence to the PD catheter in the pouch of Douglas. The fallopian tube was gently separated from the PD catheter and the catheter was removed due to concern about recurrence, as the patient wished to preserve fertility. The patient converted to hemodialysis.

Discussion: Fallopian tube migration, although cited as a rare cause of PD catheter dysfunction, is an important consideration when managing PD associated abdominal pain in female patients. To date, there are 12 reported cases of PD catheter outflow obstruction due to fallopian tube entanglement in the literature, with three reports of oophoropexy resulting in ongoing successful use of the peritoneal catheter. In our case, the decision was made intraoperatively not to attempt oophoropexy or oophorectomy due to the patient's inability to consent and her prior wishes to preserve fertility.

FR-PO565

An Unusual Presentation of an Unusual Disease: Cryptococcus Neoformans Peritonitis in a Patient on Peritoneal Dialysis

Rodolfo A. Moreno,[1] Jorge J. Font,[2] Pablo Maggiani,[2] Fernanda Muñoz-Garibi,[3] Silvia G. Esquivel razo,[4] Rafael Magana-Gonzalez,[3] Aida S. Ramirez-Gonzalez,[6] Pablo Garcia,[5] Jonathan Chavez,[1] Guillermo Garcia-Garcia.[7] *[1]Hospital Civil de Guadalajara, Guadalajara, Mexico; [2]Hospital civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Mexico; [3]Universidad de Guadalajara, Guadalajara, Mexico; [4]Hospital Civil Fray Antonio Alcalde, Zapopan, Mexico; [5]Stanford University, Palo Alto, CA; [6]Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Mexico; [7]Hospital Civil De Guadalajara, University of Guadalajara, Zapopan, Mexico.*

Introduction: Mexico is the country with more peritoneal dialysis (PD) patients in the world, and it's used by the majority of the patients requiring RRT. Cryptococcus neoformans is an opportunistic infection in the immunocompromised population. The central nervous system is the most common organ affected. Peritonitis is an unusual complication of infections caused by C. neoformans and has rarely been reported in patients on PD. We present a case of peritonitis due to C. neoformans in a patient on PD in Mexico.

Case Description: A 36-year old Mexican female came to the ED with headaches and photophobia for about one week. These symptoms were associated with weight loss (60 pounds), for about 5 months. The patient had ESKD secondary to DM. She lived in a rural area located in the central western coast of Mexico. She owned chickens, cats, and dogs. She reported three sexual partners with no condom use. On admission, she had fever, photophobia, bilateral Babinski, hyperreflexia of upper and lower extremities and nuchal rigidity. The initial labs didn't reveal significant abnormalities; except for a positive-HIV test. We performed a lumbar puncture (LP) and also obtained PD fluid samples. Both were positive for C. neoformans. We started therapy with liposomal amphotericin B (6mg/kg/day) and fluconazole; the nephrology team removed the PD catheter, and transitioned her to HD. Her hospital course was complicated with hospital-associated infections, and despite all efforts, the patient died after 20 days of therapy.

Discussion: To our knowledge there are around 4 cases of C. neoformans's peritonitis associated to PD since 1988 when the first case was reported. The previously case presented is the first one reported in Mexico and Latin America. The reported cases had a predominance of female gender and comorbidities such as HIV infection, hypertension, DM and 25% had fatal outcome. C. neoformans is a deadly and underdiagnosed pathology worldwide. The diagnosis can often be challenging in areas with limited access to healthcare, and thus, the treatment is delayed. The determination of peritonitis by C. neoformans must be considered in patients on PD and must lead to the suspicion of a disseminated infection.

FR-PO566

Actinomyces neuii Peritonitis in Peritoneal Dialysis

Swe Zin Mar Win Htut Oo,[1] Jayesh B. Patel,[1] Melissa L. Swee.[2] *[1]Nephrology, University of Iowa, Iowa City, IA; [2]University of Iowa, Iowa City, IA.*

Introduction: Due to impaired immunity and increased microbial exposure, peritonitis is the most common complication seen in peritoneal dialysis (PD). Although staphylococcal infections are most common, a variety of other microorganisms can colonize and subsequently infect the peritoneal cavity. We report a case of continuous ambulatory peritoneal dialysis (CAPD) peritonitis due to Actinomyces neuii.

Case Description: A 71-year-old female with end-stage renal disease on home continuous cycler peritoneal dialysis and prior history of clostridium difficile colitis presented with two days of severe watery diarrhea and severe abdominal cramps. Vital signs were stable and examination was notable for abdominal distention and cloudy PD fluid. Stool samples were positive for C. diff and gram-positive bacteria were identified in PD fluid. She was prescribed oral metronidazole and intraperitoneal vancomycin. Final fluid cultures were positive for Actinomyces neuii susceptible to Vancomycin and have been successfully treated with 2 weeks of vancomycin. We educated her on the importance of hand hygiene and sterile technique.

Discussion: Actinomyces is a gram-positive bacillus comprising normal gut flora. It is rarely associated with soft tissue infections, but may occur in those with impaired immunity. Because the peritoneal cavity lacks robust innate immune responses, it is a favored site for infection. We speculate that increased bacterial translocation from the gut due to colitis or contamination of the PD catheter may have contributed to the peritonitis. Actinomyces is a likely underrecognized cause of peritonitis in PD patients due to its fastidious nature, but identification is important because actinomyces infections may be indolent and may not respond to repeated short courses of antibiotics. If left untreated, sinus tracts and abscesses may form, which can lead to secondary infections.

FR-PO567

Compounded Amino Acid Peritoneal Dialysate as an Alternative Volume Management Strategy in a Diabetic Patient

Michael Ajuria,[1] Graham E. Abra,[1,2] Brigitte Schiller.[2] *[1]Nephrology, Stanford University, Palo Alto, CA; [2]Satellite Healthcare, San Jose, CA.*

Introduction: Volume control in diabetic patients with end stage renal disease (ESRD) on peritoneal dialysis (PD) can be challenging. Common glucose sparing volume control strategies for these patients include dietary sodium restriction, diuretics, and the use of icodextrin dialysate. Another potential strategy is the use of amino acid based dialysate, which may maintain ultrafiltration by avoiding hyperglycemia and loss of the osmotic gradient between dialysate and blood. In the United States amino acid peritoneal dialysate is often not covered by insurance, leading to limited experience.

Case Description: A 63 year old female diabetic with history of ESRD treated with continuous cycler PD developed increasing challenges to maintain dry weight with frequent use of 4.25% dextrose along with a 2L icodextrin day dwell. On exam the weight was 86.5 kg (dry weight 83 kg) and blood pressure was 173/59, with bilateral crackles and trace edema in the extremities. Daily peritoneal ultrafiltration was between 500-700 ml with no residual urine output. Labs showed BUN 47, creatinine 12.4 mg/dl, albumin 3.4 g/dl, glucose 104 mg/dl, sodium 136 meq/L, HgA1c 6.0%, total weekly Kt/V 2.45. Given hypoalbuminemia and worsening volume status despite frequent use of 4.25% dextrose and icodextrin, the decision was made to substitute a compounded dialysate with amino acids (1.0% amino acids in 5L of 2.5% dextrose) during CCPD with continued daytime 2L icodextrin dwells. Daily ultrafiltration improved to an average of 1L per day. Weight decreased to 79.2 kg, edema resolved, and blood pressure improved with a reduction from 5 to 4 antihypertensives. Due to insurance, the amino acid supplemented dialysate was lost in September with a subsequent increase in weight and blood pressure. In October the next year, insurance reauthorized the amino acid solution, which was restarted with similar improvement in weight and blood pressure.

Discussion: Volume control can be challenging despite typical glucose sparing strategies in diabetic PD patients. Our patient had improvements in volume control during periods when an amino acid based solution was used in place of standard dextrose solutions. We hypothesize that the tonicity of the above solution allowed for superior ultrafiltration and volume control compared to 4.25% dextrose due to avoidance of hyperglycemia and loss of osmotic gradient.

FR-PO568

It Is Never Too Late: A Case of Renal Artery Angioplasty for Resistant Hypertension in ESRD

Dheera Tamvada, Suzanne G. Martin. *Saint Vincent Hospital, Worcester, MA.*

Introduction: Atherosclerotic renovascular disease is an important and potentially treatable cause of secondary hypertension. In patients with end-stage renal disease, common contributors to uncontrolled hypertension include volume overload, sympathetic overactivity, and erythropoietin-stimulating agents. It is therefore challenging to identify ESRD patients who could benefit from angioplasty for renal artery stenosis.

Case Description: A 65 year old patient with ESRD due to BK nephropathy on peritoneal dialysis developed uncontrolled hypertension requiring multiple medications, including hydralazine 50 mg qAM and 100 mg qPM, isosorbide mononitrate 30 mg qAM and 60 mg qPM, labetalol 200 mg BID, amlodipine 10 mg daily, valsartan 160 mg BID, torsemide 40 mg BID, and doxazosin 8 mg BID. He also had extensive atherosclerosis of the aorta, bilateral common iliac and external iliac arteries requiring multiple stents. He developed resistant hypertension on PD, which was uncontrolled on the above regimen and required several hospitalizations with BP in the 200s/100s. Workup revealed a 99% stenosis of the proximal left renal artery, which was stented. After angioplasty, he had improvement in his blood pressures to 120-130/60-80 on valsartan 160 mg BID and metoprolol succinate 100 mg daily. His 24 hour urine collections for creatinine clearance confirmed increase in urine output, with a urine volume of 508 cc on the final collection pre-angioplasty and 2000 cc on the first collection post-angioplasty. In addition, his weekly Kt/V from residual renal function alone increased from 0.54 before angioplasty to 2.7 after angioplasty. He developed volume overload with a trial off PD which could not be managed with diuretics alone. PD was resumed, with a reduced frequency of four sessions per week.

Discussion: Our patient demonstrated significant improvement in blood pressure control, with a substantial reduction in the number of medications and the stabilization of his blood pressure after angioplasty for renal artery stenosis despite being dialysis-dependent. Residual renal function improved, with fewer PD sessions required weekly to maintain adequate clearance and euvolemia. Particularly in patients with other manifestations of peripheral vascular disease, the possibility of renal artery stenosis should be investigated, and perhaps treated, in ESRD patients with resistant hypertension.

FR-PO569

Pleuroperitoneal Leak in Peritoneal Dialysis Patients: Experience of a Single Center

Marcos G. Nava, Gabriela Leal, Karla B. Cano Escobar. *Instituto Nacional de Cardiología "Ignacio Chávez", Ciudad de Mexico, Mexico.*

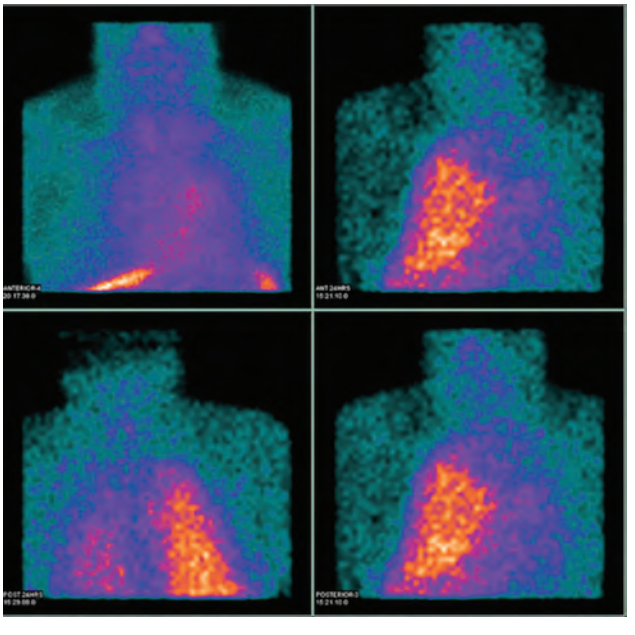
Introduction: Pleuroperitoneal leak (PPL) is a rare complication, incidence reported between 1.6-10%. Etiology include congenital and acquired defects in the diaphragmatic muscle fibres, favored by increase intraabdominal pressure due to peritoneal dialysis solutions. The objective is to report the incidence, diagnosis, treatment and evolution of PPL.

Case Description: Descriptive, retrospective study. We analyzed all cases of PPL in the last 3 years.

Discussion: We found 5 patients with the diagnostic of PPL (Table 1). The male gender predominated, vintage of peritoneal dialysis (5-22 months) Diagnosis was suspected with clinical presentation, chest x –ray, difference between plasmatic and pleural effusion glucose (the pleural higher than plasmatic), and confirmed with scintigraphy. All patients required endopleural tube and peritoneal cavity rest with change of modality to hemodialysis. In 4 of the 5 patients an attempt was made to return to peritoneal dialysis (PD), but PPL recurred in all. The prognosis is discouraging due to the high recurrence rate. We included biompedance data, none of the patients had sarcopenia, ruling out this condition as a risk factor to develop diafragmatic defect, the only biochemical association was with hypoalbuminemia.

Characteristics of all patients

	Case 1	Case 2	Case 3	Case 4	Case 5
Modality	CAPD	APD	CAPD	CAPD	APD
Time in peritoneal dialysis until diagnosis (months)	5	22	10	5	5
Albumin (g/dL)	2.74	3.28	3.03	2.35	3.32
Appendicular lean body mass index (kg/m2)	8.82	6.7	7.2	7.5	8.4
Sarcopenia (Reference Values Healthy Mexican Population)	No	No	No	No	No
Location	Bilateral	Right	Bilateral	Right	Right
Peritoneal Scintigraphy Report	Positive	Negative	Positive	Positive	Positive
Initial Treatment	Endopleural Tube	Endopleural Tube	Endopleural Tube	Endopleural tube + Pleurodesis	Endopleural Tube
Cavity Rest (weeks)	6	4	8	7	32
Final Renal Replacement Therapy	HD	HD	HD	HD	HD + Kidney Transplant



FR-PO570

Peritoneal Dialysate Tamponading a Massive Retroperitoneal Hemorrhage

Emily D. Gutowski,[1] Maria Clarissa Tio,[2] Ezra Burch,[3] David E. Leaf.[3] *[1]Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Massachusetts General Hospital, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA.*

Introduction: Spontaneous retroperitoneal (RP) bleeding is a rare but potentially fatal event. Due to its late manifestations, diagnosis is often delayed until blood loss is profound. We describe a patient in whom an RP bleed was suspected due to hypotensive episodes during peritoneal dialysis (PD) drainage.

Case Description: We describe a 47-year-old male with end stage renal disease (ESRD) on PD, on warfarin with a goal INR of 2.5-3.5 for mechanical mitral and aortic valves, who underwent a total hip arthroplasty for a left femoral fracture. Postoperatively he was continued on his home PD regimen (2L dwell, 2.5% dextrose, 5 exchanges per day) and restarted on warfarin. On postoperative day 17 he became unresponsive during PD drainage, with a blood pressure of 62/34 mm Hg. Hemoglobin dropped from 8.4 to 4.5 g/dL, and the INR was 2.2. Packed red blood cells and norepinephrine were administered, and he was transferred to the cardiac care unit, where he had a PEA arrest requiring CPR and intubation. Following return of spontaneous circulation, his blood pressure recovered and vasopressors were discontinued. Subsequent PD exchanges on the same day were complicated by repeated hypotensive episodes requiring vasopressors. This was observed only during PD drainage and resolved when fluid was re-infused. A CT scan showed a large left RP hematoma (14x11x23 cm). Angiography demonstrated a left L3 lumbar artery pseudoaneurysm as the source of bleeding. Coil embolization was performed, bleeding was well-controlled, and subsequent PD exchanges were well-tolerated.

Discussion: We report an unusual case of spontaneous RP hemorrhage in a patient with ESRD for whom PD drainage led to life-threatening hypotension. We speculate that the RP bleed was partially tamponaded by PD fluid via transmission of pressure retroperitoneally.

Abdominal CT scan with contrast and digital subtraction angiogram.

FR-PO571

PD Peritonitis from Cat Mouth Flora: Pasteurella, Not the Only Thing You Need to Worry About

Aseel Alsouqi, Guneet S. Kochar, Jeans L. Choi, Anna M. Burgner. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Neisseria weaveri, previously known as CDC group M-5, is an aerobic gram negative non-motile rod normally found in animal oral flora and associated with infections related to dog bites. We present a case of peritonitis in a patient on peritoneal dialysis (PD) due to this microorganism after a cat bit the PD tubing.

Case Description: A 61 year old female with end stage renal disease (ESRD) due to diabetes and hypertension on PD presented to the emergency department after her domestic cat bit and punctured the PD tubing while undergoing an exchange. She had no evidence of peritonitis and was discharged with prophylactic doxycycline for Pasteurella multocida peritonitis. Eight days later, she returned to the emergency department with abdominal pain and cloudy effluent. A diagnosis of peritonitis was made after peritoneal fluid studies revealed an elevated neutrophil count of 2,248 cells/mcL. The patient received IV loading doses of vancomycin and cefepime and then transitioned to intraperitoneal vancomycin, cefepime and oral metronidazole. Her peritoneal cell counts and symptoms quickly improved on antibiotics. The peritoneal fluid culture isolated Neisseria weaveri however blood cultures did not yield any bacterial growth. After all cultures finalized, antibiotics were narrowed to a two week course of oral ciprofloxacin. Resolution of peritonitis was confirmed after completion of antibiotics with negative peritoneal fluid studies.

Discussion: Neisseria weaveri is found in the normal canine oral flora and has been found in wounds from infected dog bites. A previous case report has been documented of peritonitis from Neiserria weaveri but no mechanism of infection was identified. While cats are less likely to carry Neiserria weaveri, the organism has been isolated from feline oral flora. Care and sterility of peritoneal dialysis equipment is paramount to preventing peritonitis as infection can be devastating for patients on home dialysis modalities. Consideration of the multitude of organisms that have been isolated from feline oral flora (Neisseria, Pasturella, Pasteurellaceae, Moraxella amongst others) must be kept in mind when wet contamination of PD fluid with feline oral flora occurs, with appropriate antimicrobial coverage.

FR-PO572

Anterior Cutaneous Nerve Entrapment in a Patient on Peritoneal Dialysis

Matthew A. Remz,[2] Shani Shastri.[1] *[1]UT Southwestern, Dallas, TX; [2]Parkland Memorial Hospital, Dallas, TX.*

Introduction: Anterior cutaneous nerve entrapment syndrome (ACNES) is a commonly underdiagnosed cause of abdominal pain and has been implicated in 15-30% of cases of chronic abdominal pain. It is caused by the entrapment of the cutaneous branches of the intercostal nerves at the lateral border of the rectus abdominis muscle that supply the abdominal wall. ACNES should always be considered in the differential in patients with chronic unilateral abdominal pain.

Case Description: 55-year-old man with history of end stage renal disease secondary to hypertension on peritoneal dialysis (PD) for ~ 4 months and diabetes developed 5/10, intermittent sudden onset shooting and burning right sided abdominal pain. It was not associated with nausea, vomiting, fever or changes in bowel habit. PD fluid analysis revealed clear effluent with total nucleated white cells ≤20 and negative culture. Liver function tests were normal except for mild elevation in lipase at 133 with normal amylase. Noncontrast CT of abdomen and pelvis was unrevealing except for persistent defect in the left rectus abdominis muscle with overlying surgical scar. As Liraglutide can cause elevation in lipase in the absence of pancreatitis, it was discontinued with decrease in lipase to 81. However, his pain persisted and Pregabalin was prescribed with some efficacy. He was seen by neurologist where careful history and physical examination yielded the diagnosis of ACNES. Persistent defect in the left rectus abdominis muscle with overlying surgical scar noted on abdominal CT was thought to be the likley culprit of ACNES. He was treated with a compounded lidocaine gel with resolution of his pain and discontinuation of pregabalin.

Discussion: ACNES is commonly overlooked or confused with visceral pain, often leading to extensive diagnostic testing with negative results before an accurate diagnosis is established. Diagnosis of ACNES is based on the presence of well-localized abdominal pain often along the lateral aspect of the rectus abdominis muscle sheath, increase in tenderness to palpation during muscle tensing on examination (Carnett's sign) and response to trigger point injection of a local anesthetic. Although ACNES can be quite painful and disabling, it is typically nonprogressive with no long-term sequelae. Mainstay of treatment is reassurance, activity modification, physical therapy, and pain relief with analgesics or trigger point injections.

FR-PO573

Peritoneal Dialysis-Associated Peritonitis Presenting as Catheter Dysfunction

Kevin Mitchell,[1,2] Katherine Richman,[1,2] Ankur Shah.[1,2] *[1]Nephrology, Alpert Medical School of Brown University, Providence, RI; [2]Nephrology, Providence Veterans Affairs Medical Center, Providence, RI.*

Introduction: Catheter dysfunction is a common complication among peritoneal dialysis (PD) patients. Most common causes of one-way dysfunction include constipation, catheter tip migration, kinks in external tubing, omental wrapping, intraluminal obstruction from fibrin or a clot, and peritoneal occlusion via adjacent organs. Catheter obstruction presents a major morbidity to PD patients and is a significant risk factor for modality failure. Up to 20% of patients are transitioned at least temporarily to hemodialysis when they experience catheter obstruction. We report an unusual presentation of a usual pathology, a case of peritonitis that presented initially as catheter obstruction.

Case Description: A 69-year-old man presented for to clinic because he was unable to drain his PD catheter the night prior. He had no issues with lost dwell or prolonged drain on prior treatments. On presentation he felt weak, fatigued and lethargic. On further questioning he had decreased appetite, crampy abdominal pain, diarrhea and abdominal bloating. On arrival, he was afebrile, had scattered rhonchi on lung exam, no granulation tissue or erythema at the exit site, and mild LLQ tenderness. We were able to freely instill dialysate but unable to drain. Alteplase was instilled sequentially for 30 minutes then 2 hours and large strands of fibrin cleared, permitting drainage of 50cc of cloudy effluent from which gram stain, cell count and cultures were sent. This sample returned a cell count of 2007 cells/μL with 43% PMNs, and eventual culture speciating MRSA. He was treated for staphylococcus aureus induced peritonitis with 3 weeks of intraperitoneal vancomycin. His course was complicated by CDiff enterocolitis, necessitating the addition of oral vancomycin.

Discussion: Catheter dysfunction and peritonitis are both complications of PD with significant morbidity. Here we present an atypical presentation of peritonitis, as the presenting symptoms were purely catheter dysfunction without initial complaint of abdominal pain. While fibrin can cause both one-way or two-way obstruction and is associated with peritonitis, there are no cases in the literature of peritonitis presenting this way. It is important to recognize this potential presentation as peritonitis events should prompt quality improvement efforts for both the individual patient and the PD program.

FR-PO574

Cat Bite-Induced Pasteurella multocida Peritonitis

Hanny Sawaf,[1] Birmaji Ali,[1] Bharat Neelam Raju,[1] Amit K. Rajput.[2] *[1]TriHealth Good Samaritan Hospital, Cincinnati, OH; [2]The Kidney & Hypertension Center, Mason, OH.*

Introduction: Peritoneal dialysis (PD) patients are at an increased risk of developing peritonitis, necessitating the importance of proper sterile technique. While, the majority of peritoneal infections arise from skin flora, an important, but often under-recognized

risk factor for peritonitis is pet ownership. This case report will examine an incident of zoonotic infection induced peritonitis.

Case Description: A 70-year-old PD dependent female presented with one day of progressively worsening abdominal pain and cloudy peritoneal fluid, without associated fevers. Physical examination revealed diffuse abdominal tenderness with guarding. There were no concerning findings at the catheter entry site. Initial blood work was unremarkable, except for a mild leukocytosis. A sample of peritoneal fluid was sent for analysis, but returned a nucleated cell count of 0. However, despite a lack of PMNs, the fluid culture grew Pasteurella multocida. This was an unexpected result that prompted further investigation into the patient's home environment and PD machine. The patient owns 4 cats and 1 dog, but was not restricting pet access to her bedroom with her dialysis machine. Although the fluid cell count was negative, further investigation showed inadequate dwell time in the ED. The patient was ultimately treated with IP Ceftriaxone. Careful inspection of the PD machine by the PD unit revealed several bite and scratch marks on the tubing. The patient was re-educated on sterile technique and has restricted pet access to her bedroom. She now protects her PD tubing by encasing it with a pool noodle.

Discussion: As PD patients are at an increased risk of infection, education on proper sterile technique and home environment is critical. This case illustrates several key points in the prevention and diagnosis of peritonitis. Clinical suspicion of peritonitis should remain high despite unimpressive fluid cell count. Peritoneal fluid culture should always be checked if clinical suspicion is high. Pet ownership should be assessed in all patients and the importance of restricting pet access to PD machine should be emphasized during initial training. If pets are present, patients should be instructed to limit pet access to the bedroom and storage space for PD equipment. Furthermore, patients should wrap tubing if needed. By addressing pet ownership with patients, we hope to further reduce peritonitis incidence.

FR-PO575

Hemodialysis Access Failure Caused by Hyperviscosity due to Secondary Polycythemia in Polycystic Kidney Disease

Yusra Jamal,[2,1] Christian J. Lopez-Padilla,[2,1] Peter B. Schrier.[3,2] *[1]Long Island Jewish Forest Hills Hospital, Yonkers, NY; [2]Northwell Health, Forest Hills, NY; [3]Park Avenue Nephrology, Fresh Meadows, NY.*

Introduction: Hemodialysis (HD) access failure is one the gravest complications that can lead to morbidity and mortality in End Stage Renal Disease (ESRD) patients. We present a rare case of an Autosomal Dominant Polycystic Kidney disease (ADPKD) patient with ESRD on HD who developed overt secondary polycythemia that led to hyperviscosity, recurrent hemodialysis access clotting and hemodialysis failure.

Case Description: A 44-year-old male with ADPKD on HD presented with dyspnea following several missed HD sessions. He was found to have respiratory failure secondary to pulmonary edema and required intubation. His laboratory studies revealed potassium of 6.9 mmol/L (non-hemolyzed), hemoglobin level of 18.1mg /dl and hematocrit of 58%. EKG showed widened QRS complex with peaked T waves. Emergent HD was planned but multiple attempts at hemodialysis were unsuccessful due to clotted arteriovenous fistula followed by recurrent clotting of three temporary dialysis catheters. Repeated phlebotomy was attempted with no significant drop in hemoglobin. He received multiple doses of intravenous calcium gluconate, insulin and kayexalate. Eventually, the patient developed refractory hyperkalemia of 8.7 mmol/L leading to arrythmia and cardiac arrest. Further laboratory evaluation revealed erythropoietin level (EPO) was 139.0 mIU/ml (normal range 2.6-34 mIU/ml). JAK 2 mutation was negative. There was no history of obstructive sleep apnea, smoking or use of performance enhancing agents. Autopsy confirmed ADPKD and did not reveal any evidence of malignancy. There was no evidence of abnormal cardiopulmonary physiology or chronic lung disease.

Discussion: Patients with ADPKD tend to have excess EPO production by renal cysts. Secondary polycythemia can occur in these patients as a result. In this case, patient's hyperviscosity from secondary polycythemia caused clotting of hemodialysis access sites despite treatment with repeat phlebotomy. Hemodialysis was therefore unsuccessful. In literature, there are few cases of hemodialysis access failure caused by secondary polycythemia due to ADPKD which led to such serious intractable hyperviscosity leading to the ultimate death of the patient. This case illustrates that early recognition of this complication in patients with ADPKD is essential for appropriate management and avoid subsequent complications in this population.

FR-PO576

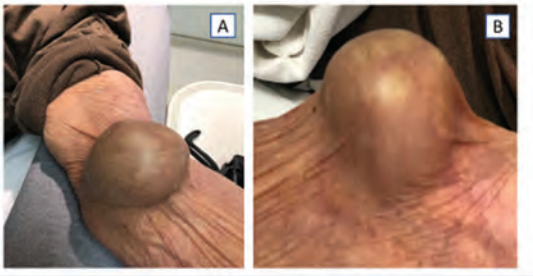
Case of Acute Pseudo-Aneurysm Formation in a Clotted and Abandoned Brachial-Cephalic Arteriovenous Fistula

David Mariuma,[2] Aisha Shaikh.[1,2] *[1]Nephrology, James J. Peters Medical Center VA, Bronx, NY; [2]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Pseudo-aneurysm formation is a known complication of dialysis arteriovenous access. Pseudo-aneurysms typically form at the site of needle puncture or at the arteriovenous anastomosis. Here we present a case of acute pseudo-aneurysm formation in a clotted and abandoned arterio-venous fistula (AVF)

Case Description: An 88-year old male on chronic hemodialysis via a right femoral vein catheter presented to the dialysis unit with sudden onset of swelling in his left arm. The swelling was in the ante-cubital fossa, near the arteriovenous anastomosis of a clotted left arteriovenous fistula (AVF) that had not been cannulated in over 6 years. He denied any trauma at the site of the swelling and attested to a significant increase in the size of the swelling over the past 48 hours. On examination the swelling was firm, pulsatile and non-tender. Vascular surgery was consulted, and same day intra-operative findings confirmed the presence of a pseudo-aneurysm which was resected. The histology and cultures of the resected tissue did not reveal any malignancy or infection

Discussion: Pseudo-aneurysms are hematomas that form due to a defect in the vessel wall. They are devoid of the endothelium or the vessel wall. In other words, they are hematomas communicating with the lumen of the vascular access, and therefore rupture of a pseudo-aneurysm can be life-threating. Typically, the pseudo-aneurysms form at the site of repeated needle cannulation. Pseudo-aneurysm formation is very rare in a clotted or abandoned AV access. It is not clear what caused the pseudo-aneurysm formation in this patient, but this case highlights the importance of continued monitoring of 'abandoned and clotted' dialysis vascular access



Pseudo-Aneurysm at the Arteriovenous Anastomosis of a Clotted Brachial-Cephalic fistula

A Successful Ultrasound-Guided Percutaneous Transluminal Angioplasty for a Patient with Arteriovenous Graft Failure Within 24 Hours of Its Creation and After 3 Months Since Failure

Tianjun Guan,[1] Anqun Chen,[1] Wan Ziming.[2] *[1]Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China; [2]Nephrology, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China.*

Introduction: The primary purpose of any hemodialysis access is to provide adequate, long-term and repeated access to the circulatory system with minimum complications. Arteriovenous graft (AVG) rarely fails acutely within the postoperative period causing graft loss with the need for subsequent creation of new hemodialysis access. We describe the rescue of the AVG which immediately failed following its creation, there was no hope for its future use, so consequently was abandoned for over three months.

Case Description: The 63 years old woman with end stage renal disease has been on chronic hemodialysis since 2014. Her right distal arteriovenous fistula was functional until November 2018 when it failed. The right elbow brachial-basilic graft was created successfully which also failed within 24 hours following its creation.3 months later after creation, this patient was referred to our centre. Ultrasonography visualized stenosis at the peripheral draining vein, severe stenosis at venous-graft anastomosis and intragraft stenosis with no flow of blood through the entire graft. Ultrasound guided Percutaneous transluminal angioplasty was performed with immediate restoration of good graft patency, good patency of brachial artery and basilic vein. The next day, patient used the AVG for hemodialysis successfully for the first time. The AVG remained patent and chronically usable for hemodialysis up to 4 months.

Discussion: Our case demonstrates the feasibility of repairing an immediately failed arteriovenous dialysis graft following its creation with restoration of good patency adequate for chronic hemodialysis by ultrasound guided percutaneous transluminal angioplasty, even after 3 months since failure.

FR-PO578

Successful Insertion and Use of Arteriovenous Graft (AVG) After Left Ventricular Assist Device (LVAD) Implantation

Katherine Toma, Jacob Stevens, Jai Radhakrishnan, Syed A. Husain. *Columbia University Medical Center, New York, NY.*

Introduction: A subset of patients requires long-term renal replacement therapy (RRT) after LVAD implantation. The success of using AVG for RRT access in these patients has not been established.

Case Description: [Fig1] Case A: A 68-year-old man developed acute kidney injury (AKI) requiring RRT 2 days after LVAD implantation. He remained RRT dependent. A brachiobasilic AVG was placed 55 days after LVAD implantation and successfully used 28 days later. Subsequent course was notable for *S. bovis* bacteremia complicated by infected AVG pseudoaneurysm requiring AVG excision. A second brachiobasilic AVG was placed and functioned well, requiring a thrombectomy 98 days after placement. Case B: A 67-year-old man developed septic shock with AKI 18 months after LVAD implantation. He remained RRT dependent and brachiobasilic AVG was placed 584 days after LVAD implantation. Balloon angioplasty of the AVG was required for stenosis at the arterial anastomosis, and AVG was successfully used 32 days after placement. He required no subsequent vascular access procedures and had no access or bloodstream infections. Case C: A 71-year-old man with stage 3b CKD developed AKI requiring RRT 4 days after LVAD implantation. He remained RRT dependent and brachiobasilic AVG was placed 107 days after LVAD implantation. Failed first cannulation attempt led to hematoma requiring evacuation and AVG revision. AVG was successfully used 40 days after placement.

He later developed polymicrobial bacteremia from a driveline infection, and AVG was excised due to concern for seeding. A second brachiobasilic AVG was placed and functioned well, requiring a thrombectomy 147 days after placement.

Discussion: AVG can be successfully used for long-term RRT access in LVAD patients. Infection and thrombosis rates need further study in larger cohorts. Outcomes between AVG, AV fistula, and dialysis catheters should be evaluated.

Treatment of Refractory Hyperammonemic Coma with CRRT in a Patient with Ureterosigmoidostomy

Adam S. Alperstein, John Wade McKeown, Sadiq Ahmed. *University of Kentucky, Lexington, KY.*

Introduction: Hyperammonemia is most common in liver disease but other rare causes exist. Serum ammonia (NH3) concentrations >150umol/L is linked to poor neurological outcomes and even death. In severe cases, extracorporeal removal of NH3 can be lifesaving.

Case Description: A 64-year-old female was admitted to the ICU with coma & NH3 level of 534umol/L with normal liver & renal function. She had ureteosigmoidestomy as a child for bladder extrophy. The high NH3 was attributed to increased colonic absorption from urine & increased NH3 production from bacterial splitting of urea in the colon. She did not respond to Lactulose & Rifaximin. Urology was consulted for percutaneous nephrostomy, however, her clinical status declined, so an urgent decision was made to remove NH3 by CVVHDF. NH3 level & coma improved in 8 hours. Next day, nephrostomy tubes were placed, the NH3 levels remained low, and her mental status improved.

Discussion: Patients with ureterosigmoidostomy can present after many years with hyperammonemia. The treatment is a new urinary diversion to avoid contact with the colon. Nephrostomy is a temporary solution followed by a permanent procedure, such as an ileal conduit. NH3 level >150 is related to cerebral edema, increased intracranial pressure (ICP) and brain herniation. Therefore, in severe cases, urgent extracorporeal removal should be considered. While the use of renal replacement therapy to remove NH3 has been reported, there is no definite guideline. Some reports favor HD over CRRT due to higher clearance. However, when the NH3 is continuously produced at a high rate, CRRT may be more beneficial since it offers fewer interruptions, less rebound, & less rapid fluid shifts which can worsen ICP. This case highlights that CRRT can be an effective bridging strategy in patients with severe hyperammonemic encephalopathy.

Familiar Hyperkalemic Hypertension Genotype with a Negative Phenotype: A CUL3 Mosaicism

Mauricio Ostrosky-Frid,[1,2] Maria Chavez-Canales,[4] Rosa B. Simsolo,[3] Miriam A. Romo,[3] Gerardo Gamba.[1,4] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico City, Mexico; [2]PECEM, UNAM, Mexico City, Mexico; [3]Hospital de Niños Ricardo Gutierrez, Buenos Aires, Argentina; [4]Instituto de Investigaciones Biomedicas, UNAM, Mexico City, Mexico.*

Introduction: The Familiar Hyperkalemic Hypertension (FHHt) is an inherited disease featuring arterial hypertension with hyperkalemia, metabolic acidosis, and hypercalciuria, that is mainly due to overactivation of the thiazide-sensitive renal NaCl cotransporter in the distal convoluted tubule, as a consequence of mutations in four different genes: two encoding the kinases known as WNK1 and WNK4 and two encoding proteins that are components of a Ring type ubiquitin ligase complex, known as KLHL3 and CUL3. Mutations in CUL3 produce the more severe phenotype that in all 36 reported cases result in a shorter protein due to skipping of exon 9 and has been described as *de novo* mutation or as autosomal dominant inherited from one parent.

Case Description: Here we report on a 12 year-old boy with arterial hypertension (150/100mmHg), hyperkalemia (7 mEq/L) metabolic acidosis (pH 7.0; HCO_3^- 17.8 mEq/L) and hyperchloremia (108 mEq/L). Two months after hydrochlorothiazide was initiated the blood pressure was 129/76 and serum electrolyte values were normal (K^+, 4.5 mEq/L; Cl^- 98 mEq/L, pH 7.37 and HCO_3^- 25.8 mEq/L). DNA from the proband and his parents were obtained with their consent to evaluate the cause of the FHHt. The proband's DNA analysis revealed a CUL3 mutation resulting in exon 9 deletion. The mutation was present in the mother's blood DNA, but not in the father's. The mother, however, exhibits no FHHt phenotype. Her blood pressure and serum electrolytes were normal. The CUL3 mutation was found in DNA extracted from the mother's oral mucosa but at lower levels than in the blood. The mother of the proband is a unique occurrence of CUL3 FHHt genotype, with no phenotype, due to a mosaicism.

Discussion: Mosaicism refers to the presence of two genetically distinct cells lines with distinct karyotype or genotype in the same individual and results from postzygotic mutational events. Individuals may present gonadal mosaicism (found only in the gametes), somatic mosaicism, or a combination of both. In somatic mosaicism, it is frequent to find different proportions of the two cell lines across tissues, even within the same embryonic lineage (ectoderm, endoderm or mesoderm). In the proband's mother, the mutation exhibits presumably little to no effect on renal tubular cells, but is present in the oocytes and was inherited by her child.

Customized Renal Replacement Therapy in a Patient with a Serum Sodium of 97 mEq/L

Shawn J. Phillips, Martha Naber, Natacha Rigual soler, Swati Mehta, Krishnakumar D. Hongalgi. *Albany Medical Center, Albany, NY.*

Introduction: Hyponatremic patients requiring continuous veno-venous hemofiltration (CVVH) offer a unique challenge as commercial replacement solution contain physiologic concentrations of sodium. Use of such fluids may cause rapid correction of hyponatremia resulting in osmotic demyelination. We present a patient with

Acute kidney injury (AKI) and severe hyponatremia who was successfully treated using custom made CVVH solutions.

Case Description: A 55-year-old male with no significant medical history was found unconscious. He suffered cardiac arrest with return of spontaneous circulation after CPR. He was diagnosed to have sepsis secondary to diarrheal illness and severe rhabdomyolysis. Patient was found to have oliguric AKI, severe anion gap metabolic acidosis and multiple electrolyte abnormalities. Labs included serum sodium of 97 mEq/L, CO2 of 8, potassium of 6.2 and pH of 7.2. He received 100 mL of 3% sodium chloride with improved serum sodium to 105 mEq/L. CVVH was initiated for oliguric AKI, hyperkalemia and metabolic acidosis. On days 1 and 5 CVVH prefilter replacement solutions were compounded by draining fluid from a Prismasol bag and replacing with 5% dextrose (D5W) to dilute the sodium. On days 2, 3 and 4 solutions were compounded by pooling 2L of D5W and 2L of normal saline and adding potassium, magnesium, and chloride to achieve a concentration of 4 mEq/L, 2 mEq/L, and 81 mEq/L respectively. Sodium acetate was then added to adjust the sodium concentration and osmolarity based on the daily serum target. Other electrolytes were replaced separately due to compatibility risks. Incremental serum sodium targets were achieved on each day. The patient achieved serum sodium target on day 6 and was started on standard CVVH fluid containing 140 mEq/L sodium. The patient was later discharged home with no need for further renal replacement therapy.

Discussion: Rapid correction of severe hyponatremia can cause osmotic demyelination syndrome. CVVH to treat oliguric AKI with severe hyponatremia using commercial premixed replacement fluid bags is a challenge. This case illustrates the utility of customized CVVH solutions as a method for the correction of severe hyponatremia in critically ill patients requiring CVVH.

FR-PO583

Management of Critical Hypernatremia During Continuous Renal Replacement Therapy and Septic Shock

Harol S. Valenzuela, Tibor Fulop, Anna Marshall. *Medical University of South Carolina, Charleston, SC.*

Introduction: The concept of osmotic stability in the critically ill during continuous renal replacement therapy is insufficient explored. Herewith, we are reporting a case of extreme hypernatremia (serum sodium [$SeNa^+$] 182 mEq/L) with septic shock and acute kidney injury addressed with continuous renal replacement therapy (CRRT) and simultaneous hypertonic saline (HTS) administration.

Case Description: A 52-year-old male suffered a motor bicycle accident with subarachnoid hemorrhage and traumatic right below-the-knee amputation[FT1]. On the 17th day of hospitalization he suffered acute decompensation with increased work of breathing and decreased alertness. He required emergency intubation with mechanical ventilation and 3 pressor agents to maintain acceptable BPs. Initial laboratory studies revealed acute kidney injury with serum creatinine (SeCr) 3.6 mg/dL (normal baseline), BUN 142 mg/dL and sodium 177 mEq/L. With intravenous fluids, SeCr improved to 3 mg/dL while $SeNa^+$ rose to 182 mEq/L. Due to subsequent anuria, resistant hypoxia and escalating vasopressor requirements, a decision was made to start CRRT in continuous hemofiltration modality. To address co-morbid hyperosmolar state, HTS with 3% saline was added to ensure a predictable rate of $SeNa^+$ correction; correction for serum protein content (5 mg/dL) was achieved by multiplying predicted $SeNa^+$ by 0.95 to calculate *in vivo* $SeNa^+$. Recovery was complicated by hypotonic polyuria and central diabetes insipidus (DI), attributable to subarachnoid hemorrhage.

Discussion: While presence of DI was difficult to recognized with anuria and AKI but undoubtedly was responsible for hypernatremia on presentation. Premixed CRRT fluids are hypotonic (Na^+ 140 mEq/L) by default, when considering the presence of serum protein content. Excessive drops of $SeNa^+$ and BUN likely would have caused harm in our index case without concurrent HTS administration. Management of dysnatremic CRRT protocols represent an important and emerging field of critical care nephrology.

CVVHD and Electrolytes

Days on CVVHD	BFR/Therapy fluid dose	Hypertonic (3%) saline infusion	SeNa+	SeOsm	SeCr	BUN	UOsm	UNa+

FR-PO584

Hyponatremia in a Hemodialysis Patient: A Common Problem with an Uncommon Cause

Latoya N. Gayle,[1] Rani D. Sittol,[1] Deborah A. Fein.[2] *[1]Englewood Health, Bogota, NJ; [2]Pattner Grodstein & Fein MD, PA, Englewood, NJ.*

Introduction: Hyponatremia is a common electrolyte disturbance in hospitalized patients and is associated with increased mortality and morbidity. It occurs in ~9-29% of hemodialysis patients. The importance of this finding in pre dialysis labs is often overlooked and assumed to be due to excessive free water intake and diminished kidney dilution capacity in the setting of ESRD.We present a case of hyponatremia in a hemodialysis patient secondary to adrenal insufficiency

Case Description: A 66-year-old Korean male presented after a flight from Korea with headache and abdominal pain. Last hemodialysis(HD) was 3 days prior. Pain resolved spontaneously, but hospitalization prolonged to establish outpatient HD.PMH of ESRD due to HTN, renal transplant(Korea 2007), that failed 6 months prior with return to HD.Admission creatinine8.5mg/dL and sodium140. Over 1 week, his sodium declined. By day 6, pre dialysis sodium was 125 and he developed malaise, anorexia, chest and abdominal pain. Fluid restriction to <750cc/day instituted but sodium further declined, with dialysis complicated by hypotension and fever. Blood cultures, QuantiFERON Gold were negative. Serum calcium increased to 10.7(8.4-10.2mg/dL) and CBC differential noted eosinophilia 0.64(0-0.5).8 am cortisol sent was 1.2mcg/dL and ACTH stimulation test showed poor adrenal reserve indicative of adrenal insufficiency. Repeated questioning done on medication and Methylprednisone found in examined pill bottles, which was absent in admission list. After restarting steroids, he clinically improved to baseline, with sodium improved to 130 at discharge

Discussion: Hyponatremia has been associated with increased mortality in numerous patient populations. In ESRD patients, it is commonly seen and attributed to poor compliance with fluid restriction, hence may not be investigated. Potentially life-threatening causes such as AI, as in our patient, can be missed. Arreggar et al, noted in their study that 6 of 15 ESRD-H patients with sustained hypotension on dialysis had secondary AI, and BP normalized with steroid administration. Our patient was found, with more careful history, to have secondary AI from long term corticosteroid use. Our case suggests that a higher index of suspicion is appropriate in hyponatremic hemodialysis patients, especially if dialysis is complicated with other signs such as intra-dialytic hypotension, as diagnosis and treatment may have benefits in mortality reduction

FR-PO585

Loss of NCC Impairs the Outgrowth of the Renal Distal Convoluted Tubule (DCT) During Renal Development

Christina Schnoz, Monique Carrel, Johannes Loffing. *University of Zurich, Zurich, Switzerland.*

Background: Gitelman syndrome is an autosomal recessive renal tubulopathy characterized by hypokalemic alkalosis, hypomagnesemia and hypocalciuria. The syndrome is caused by loss-of-function mutations in the NaCl co-transporter (NCC) in the renal distal convoluted tubule (DCT). Data from NCC ko mice suggest that DCT atrophy contributes to the pathogenesis of the disease. Since Gitelman patients are usually diagnosed during adolescence or early adulthood, we tested the idea that the late clinical onset of Gitelman syndrome is related to a progressive regression of the DCT during adolescence.

Methods: Immunofluorescent detection of distal tubule marker proteins as well as morphometric analyses of DCT fractional volume and investigation of DCT specific gene expression with real time quantitative PCR were used to analyse the structure and protein expression pattern of the DCT at different ages and stages of development (day 1, 4, 10 and 6 weeks after birth) in NCC wt and NCC ko mice.

Results: Mice of both genotypes developed normal and showed a similar body weight gain. Plasma aldosterone levels and renal renin mRNA expression were higher in NCC ko mice than in NCC wt mice already at day 10. In contrast, plasma ion levels did not differ between genotypes at age 10 days, but a significant hypomagnesemia was observed in NCC ko mice at 6 weeks. Immunofluorescent detection of parvalbumin (an early DCT marker) revealed that the fractional cortical volume of the early DCT is almost similar for mice of both genotypes at day 4, but gets significantly lower at day 10 and is almost zero at 6 weeks in NCC ko mice. The DCT atrophy correlates with a marked reduction in the protein abundance of the DCT-specific Mg^{2+} channel TRPM6 and an increased proteolytic cleavage and hence activation of the alpha- and gamma subunit of the epithelial Na^+ channel (ENaC).

Conclusions: Thus, after an initial outgrowth of the DCT up to day 4, DCT development lacks significantly behind in kidneys of NCC deficient mice. The impaired DCT development associates already at day 10 with clear signs of volume contraction with elevated renin and aldosterone levels and an activation of ENaC, suggesting that Gitelman syndrome might be present much earlier during life than usually expected. Despite an early downregulation of TRPM6, hypomagnesemia is a rather late symptom.

FR-PO586

Aldosterone Activates NCC Through the Resulting Hypokalemia and Chloride-Sensing Mechanism of WNK4

Jen-Chi Chen, Chih-Jen Cheng. *Tri-Service General Hospital, Taipei City, Taiwan.*

Background: Aldosterone increases the expression and apical abundance of ENaC via binding to the mineralocorticoid receptor (MR). However, the underlying mechanism of aldosterone-induced NCC activation is still unclear. Earlier studies have shown that a high potassium diet reversed NCC phosphorylation in aldosterone-treated mice, and vice versa for the NCC dephosphorylation in MR knockout mice. We recently demonstrated that hypokalemia reduces intracellular chloride concentration, which releases WNK4 from chloride-mediated inhibition. We hypothesized that hypokalemia resulting from aldosterone activates WNK4 via the chloride-sensing mechanism.

Methods: Aldosterone solution (100 g/kg/day) or vehicle control (5% DMSO in physiological saline) was administered to chloride-insensitive L319F/L321F WNK4 knockin mice and their control littermates using Alzet osmotic pumps. *In vivo* NCC activity was reflected by the protein abundance of total and phosphorylated NCC and also by thiazide-sensitive urinary sodium excretion rate. Moreover, other plasma and urine biochemistries were compared.

Results: After two-week aldosterone infusion, both wild-type and chloride-insensitive WNK4 knockin (KI) mice developed a similar metabolic alkalosis (HCO_3^- 25 vs. 25 mM) and hypokalemia (K^+ 2.4 vs. 2.6). Compared with wild-type mice, KI mice had higher urine output (2.1 vs. 3.2 ml/day), urinary sodium excretion (144 vs 221 mmol/day), and blood pressure. Of note, aldosterone increased the total and T58-phosphorylated NCC in wild-type mice. However, aldosterone did not further enhance the already high NCC phosphorylation in KI mice.

Conclusions: In sum, our results support the notion that aldosterone enhances NCC activity via the resulting hypokalemia and chloride-sensing mechanism of WNK4. Moreover, chronic aldosterone infusion induces natriuresis, compatible with aldosterone escape phenomenon, probably related to pressure natriuresis or natriuretic peptides.

FR-PO587

Sympathetic Nervous System Regulation of the NCC in Dahl Salt-Sensitive Hypertension

Franco J. Puleo, Alissa Frame, Richard D. Wainford. *Pharmacology, Boston University School of Medicine, Boston University, Boston, MA.*

Background: Studies suggest that sympathetic nervous system (SNS) release of norepinephrine (NE) influences the activity of the sodium chloride cotransporter (NCC) via α_1 and β adrenoceptor pathways. Regulation of the NCC involves a complex network of kinases including WNK1, SPAK, and OXSR1. Hypothesis**:** NE stimulates an α_1 adrenoceptor pathway to drive increases in NCC activity that contribute to the development and maintenance of Dahl salt sensitive (DSS) hypertension (SSH).

Methods: Groups of naïve DSS rats and DSS rats given a continuous subcutaneous (s.c.) infusion of terazosin/DMSO (α_1 antagonist, 10mg/kg/day), or propranolol/DMSO (β antagonist, 10mg/kg/day) were placed on a 21 day normal salt (0.6% NaCl, NS) or high salt (4% NaCl, HS) diet. Separate groups of DSS rats were fed a 42 day HS diet; and on day 21, rats were treated with s.c. saline or terazosin for the remaining 21 days of the diet. Basal MAP, NCC activity (peak natriuresis to hydrochlorothiazide [HCTZ]; 2mg/kg), and the expression of the NCC and its regulatory kinases were assessed via immunoblot on day 21 or day 42 of experimental diet (N=5-6/gp).

Results: DSS rats fed a 21 day HS diet develop SSH and show increases in NCC activity, expression, and its regulatory kinases expression compared to rats on a NS diet. DSS rats fed a 21 day HS diet and treated with α_1 antagonist, terazosin, show attenuated SSH, reduced NCC activity, and expression of NCC and WNK1. A β antagonist, propranolol, did not attenuate DSS SSH. Critically, α_1 adrenoceptor antagonism attenuates SSH, NCC activity/expression, and WNK1 expression in DSS rats with established hypertension.

Conclusions: SNS release of NE activates an α_1 adrenoceptor pathway to drive the development and maintenance of Dahl SSH. Significantly, α_1 adrenoceptor antagonism attenuates the development and maintenance of SSH by evoking downregulation of NCC activity, expression, and regulatory kinase WNK1 expression. Collectively, these findings suggest that NE stimulates an α_1 adrenoceptor pathway involving WNK1 signaling to drive increases in NCC activity and the development and maintenance of SSH in DSS rats.

FR-PO588

Fructose Increases the NCC Activity Through the Calcium-Sensing Receptor-WNK4-SPAK Pathway

Jessica P. Bahena-López,[1,3] Lorena L. Rojas,[1] Silvana Bazua-Valenti,[1] Jonatan Barrera-Chimal,[2,4] Norma H. Vázquez,[2] Gerardo Gamba.[1,2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico City, Mexico; [2]Instituto de Investigaciones Biomedicas, UNAM, Mexico City, Mexico; [3]PECEM-UNAM, Mexico City, Mexico; [4]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico.*

Background: We have recently shown that the Calcium Sensing Receptor (CaSR) activates NCC via the WNK4-SPAK pathway (JASN 2018). It is known that glucose and other sugars behave as positive allosteric modulators of CaSR. The effect of glucose on CaSR is particularly relevant in the apical membrane of distal convoluted tubule (DCT), which is not exposed to glucose, except during diabetic glycosuria. The exposure of DCT to fructose varies from low to high because it occurs in an intake-dependent manner. Thus, we hypothesize that sugar delivery to the DCT, by their allosteric effect on the CaSR, might activate NCC via the CaSR-WNK4-SPAK pathway.

Methods: To test if glucose or fructose induce SPAK phosphorylation, we used HEK-293 cells cotransfected with CaSR + SPAK +/- WNK4 cDNA. Expression and phosphorylation of SPAK were assessed using a constant low-calcium medium (0.5mM), but varying the glucose or fructose concentration from 0, to 5.5 or 25mM. The calcimimetic R568 was used as a positive control. To corroborate NCC activation in vivo, we analyzed WNK4-SPAK-NCC pathway in kidneys of mice subjected to a 3h treatment with vehicle, oral calcilytic NPS2143, 20% fructose (in drinking water) *ad libitum*, or 20% fructose *ad libitum* + NPS2143.

Results: Exposure of HEK-293 cells to glucose or fructose increased SPAK and ERK phosphorylation ($p<0.001$). In contrast, when WNK4 cDNA was not transfected, ERK phosphorylation (as a surrogate of CaSR activation) increased, but there was no effect on SPAK phosphorylation ($p<0.01$). In mice, 20% fructose intake resulted in increased NCC phosphorylation ($p<0.01$). Moreover, fructose intake activated WNK4 and SPAK ($p<0.05$). The effect of fructose was abrogated by coadministration of the calcilytic NPS2143 ($p<0.01$).

Conclusions: Our results show that glucose and fructose induce SPAK phosphorylation in cells in a WNK4-dependent manner. In vivo, fructose intake increased NCC phosphorylation via WNK4 and SPAK, which were in turn activated by CaSR, since the calcylitic compound NPS2143 prevented the effect. Our observations suggest that activation of NCC by glucose or fructose via CaSR could be one of the mechanisms involved in the development of increased salt reabsorption and hence hypertension in diabetes mellitus or during high fructose consumption.

Regulation of PKC-Dependent WNK4 Phosphorylation by Extracellular Potassium: Insight into Familial Hyperkalemia and Hypertension Pathophysiology

Adrian R. Murillo-de-Ozores,[2] Leoneli I. Grajeda-Medina,[3] Sebastian Gonzalez-Behn-Eschenburg,[4] Norma H. Vázquez,[5] Gerardo Gamba,[1] Maria Castañeda-Bueno.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [2]Universidad Nacional Autónoma de México, Mexico City, Mexico; [3]INCMNSZ, Ciudad de Mexico, Mexico; [4]Instituto de Investigaciones Biomedicas, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico; [5]UNAM, Mexico City, Mexico.*

Background: Familial Hyperkalemic Hypertension (FHHt) is caused by mutations in genes such as KLHL3 and WNK4, which result in higher protein levels of the kinase WNK4 and thus upregulation of the phosphorylated renal NaCl cotransporter NCC (pNCC), increasing its activity. Because NCC activity is inversely proportional to plasma K^+ in physiological conditions, it is puzzling that NCC activity is not suppressed by hyperkalemia in FHHt. We have shown that WNK4 phosphorylation by PKC/PKA at S64 is important for kinase activity and that it is increased by hypokalemia. Here we investigated how this site is regulated in hyperkalemia and FHHt.

Methods: Wild-type (WT) mice were fed with low (LKD-0%), normal (NKD-1.2%) or high (HKD-5%) K^+ diets for 7 days. Transgenic $KLHL3^{R528H/+}$ mice (with FHHt phenotype) were fed with LKD or NKD for 4 days. Blood samples were obtained to measure electrolyte levels. Western Blot assays with kidney lysates were performed to analyze total and phosphorylated WNK4 and NCC levels. WNK4-transfected HEK293 cells were incubated in low (1mM), normal (5mM) or high (10mM) K^+ media. *Ex vivo* kidney slices from WT mice were exposed for 30 min to control solutions followed by 30 min to low, normal or high K^+ media.

Results: We observed that phosho-S64 in WNK4 is increased in WT mice by LKD, but not affected by HKD, while in the same samples, we corroborated that pNCC is increased by LKD and decreased by HKD. Accordingly, in $KLHL3^{R528H/+}$ mice, WNK4-S64 phosphorylation was not suppressed by hyperkalemia as phosphorylation levels increased in a similar amount than WNK4 total levels. In these mice, both pNCC and pWNK4-S64, were further increased by LKD, showing that DCT cells can still respond to low $[K^+]$ via de $[Cl^-]$-WNK4 pathway. In addition, consistent with the observations *in vivo*, in WNK4-transfected HEK293 cells and in *ex vivo* kidney slices, we found that pWNK4-S64 was increased by incubation with low K^+, but not decreased by high K^+.

Conclusions: WNK4 phosphorylation at S64 is increased by low $[K^+]_e$. However, we did not observe the opposite process by high $[K^+]_e$. Since WNK4 remains phosphorylated at S64 in this setting, this might help to explain why elevated WNK4 levels in FHHt are enough to maintain higher NCC activity in spite of hyperkalemia.

WNK Bodies Enable WNK4-Dependent Phosphorylation of SPAK/OSR1 for Their Apical Trafficking

Martin N. Thomson,[1] Chao-Ling Yang,[2] David H. Ellison,[2] Kerim Mutig,[1] Sebastian Bachmann.[1] *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Oregon Health & Science University, Portland, OR.*

Background: The distal convoluted tubule (DCT) is vital for K^+ homeostasis. Low plasma $[K^+]$ stimulates the apical Na^+, Cl^--cotransporter (NCC), limiting electrogenic K^+ loss in the downstream tubule at the expense of increased NaCl retention and blood pressure. NCC is activated via phosphorylation by Ste-20-related proline/alanine-rich kinase (SPAK) and oxidative-stress-responsive kinase 1 (OSR1), two homologous substrates of with no lysine (WNK) kinases. During hypokalemic NCC activation, the human and rodent DCT develop cytoplasmic structures containing WNKs and SPAK/OSR1, termed WNK bodies. Their function is unclear. We hypothesized that WNK bodies serve as sites of SPAK/OSR1 activation, followed by trafficking of SPAK/OSR1 towards NCC.

Methods: To explore this hypothesis, we analyzed cellular distribution and phosphorylation of SPAK/OSR1 in different rodent models of hypokalemia (dietary K^+

deprivation, genetic WNK4 deletion, and furosemide treatment) using high-resolution immunofluorescence and electron microscopy.

Results: Feeding mice (n=5) a K^+-deficient diet for 10 days increased abundance of phosphorylated (p) SPAK/OSR1 at the apical DCT membrane and induced formation of WNK bodies enriched in pWNK and pSPAK/OSR1, suggesting that WNK bodies may facilitate phosphorylation steps. In contrast, only unphosphorylated WNK1 and SPAK/OSR1 were detected in WNK bodies of WNK4-deficient mice (n=3), which emphasizes the importance of WNK4 for SPAK/OSR1 activation in hypokalemia. Enlargement of WNK bodies along with reduction of apical SPAK/OSR1 in the WNK4-deficient DCT suggested that pSPAK/OSR1 might exit WNK bodies for apical trafficking towards NCC. To confirm this, we disrupted cellular trafficking machinery using the microtubule assembly inhibitor colchicine in rats receiving furosemide (n=4). Compared to rats receiving only furosemide (n=4), concomitant colchicine treatment resulted in accumulation of pSPAK/OSR1 in WNK bodies, along with reduced apical abundance of pSPAK/OSR1. Electron microscopy revealed that WNK bodies are membraneless, hypodense structures closely associated with microtubules.

Conclusions: In sum, our results indicate that WNK bodies are membraneless organelles performing SPAK/OSR1 activation for their subsequent apical trafficking, thereby linking plasma [K^+] to NCC phosphorylation, NaCl balance and blood pressure.

Renal TNFα Activates WNK Phosphorylation Cascade and Contributes to Salt-Sensitive Hypertension in CKD

Taisuke Furusho,[1] Shintaro Mandai,[1] Hiroaki Kikuchi,[1] Naohiro Takahashi,[1] Takuya Fujimaru,[1] Hiroko Hashimoto,[1] Yohei Arai,[1] Fumiaki Ando,[1] Takayasu Mori,[1] Koichiro Susa,[1] Kiyoshi Isobe,[1] Naohiro Nomura,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Kohei Yamamoto,[2] Shinichi Uchida,[1] Eisei Sohara.[1] *[1]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; [2]Department of Comprehensive Pathology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: The inappropriate over-activation of with-no-lysine kinase (WNK)–STE20/SPS1–related proline/alanine-rich kinase (SPAK)–NaCl cotransporter (NCC) phosphorylation cascade increases sodium reabsorption in distal kidney nephrons, resulting in salt-sensitive hypertension. Although chronic kidney disease (CKD) is a common cause of salt-sensitive hypertension, the involvement of WNK phosphorylation cascade is unknown. Moreover, the effect of immune systems on WNK kinases has not been investigated despite the fact that immune systems are important for salt sensitivity.

Methods: WNK phosphorylation cascade and its contribution to salt sensitivity was evaluated in three CKD mouse models (aristolochic acid nephropathy (AAN), adenine nephropathy and subtotal nephrectomy). The regulator of WNK signaling in CKD was also explored focusing on immune systems.

Results: Immunoblotting and immunofluorescent study revealed that the protein abundance of WNK1, but not of WNK4, was increased at the distal convoluted tubules (DCT) in the AAN kidney. Accordingly, the phosphorylation of SPAK and NCC was also increased. Moreover, a high-salt diet did not adequately suppress the activation of WNK1–SPAK–NCC phosphorylation cascade in AAN, leading to salt-sensitive hypertension. WNK1 also was increased in adenine nephropathy, but not in subtotal nephrectomy, models. By comparing the transcripts of these three models focusing on immune systems, we hypothesized that TNFα regulates WNK1 protein expression. In fact, TNFα increased WNK1 protein expression in cultured cells by reducing the transcription and protein levels of NEDD4-2 E3-ligase, which degrades WNK1 protein. Furthermore, the TNFα inhibitor etanercept reversed the reduction of NEDD4-2 expression and upregulation of WNK1–SPAK–NCC phosphorylation cascade at DCT *in vivo* in the AAN kidney.

Conclusions: TNFα activates WNK1–SPAK–NCC phosphorylation cascade in the kidney, leading to salt-sensitive hypertension in CKD. These observations provide the new mechanism how immune systems regulate salt-sensitivity in CKD.

The Novel Role of 14-3-3 Gamma in the Pathogenesis of Deoxycorticosterone Acetate Salt Hypertensive Mouse Model

Ruidian Li,[1] Xiuyan Feng,[2] Tongwang Luo,[4] Chunmei Li,[4] Ye Bi,[4] Yufeng Huang,[3] Hui Cai.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]LSU Shreveport, Shreveport, LA; [3]Fibrosis Research Laboratory, Salt Lake City, UT; [4]Emory University, Atlanta, GA.*

Background: Sodium chloride cotransporter (NCC) plays a key role in the regulation of blood pressure and electrolyte homeostasis. 14-3-3 γ belongs to a family of multifunction regulatory proteins. Previous data have shown that 14-3-3 proteins regulate renal ion channel and transporter such as ENaC. Our preliminary data showed that 14-3-3γ inhibits NCC. Thus, we hypothesized that 14-3-3 γ plays a role in affecting blood pressure regulation through NCC. The purpose of this study is to investigate the role of 14-3-3 γ in NCC regulation in DOCA-salt hypertensive mouse model.

Methods: DOCA salt mouse, western blot analysis, cell culture, siRNA knock-down experiments, and tail-cuff blood pressure (BP) measurement were used in this study.

Results: To determine whether 14-3-3 γ has a role in the pathogenesis of hypertension, we first established the DOCA salt hypertensive mouse model. Systolic blood pressure was significantly higher in DOCA salt hypertensive mice than that in control mice (148 ± 25 vs 119 ± 20, $p < 0.01$, n=4). Western blot analysis from the kidney tissues harvested from these mice showed that 14-3-3 γ protein abundance was significantly reduced in DOCA salt hypertensive mice compared to the control mice group (100 ± 11.3 % vs 58.2 ± 11.8 %, $p < 0.01$, n=4). Total NCC and phospho-NCC were significantly increased in DOCA salt group compared to the control group (1.0 ± 0.12 vs 1.4 ± 0.25; 1.0 ± 0.17 vs 1.34 ± 0.10, respectively, $p < 0.05$, n=4). ERK 1/2 phosphorylation was significantly reduced in DOCA salt group compared to the control group. To further investigate the role of ERK 1/2 signaling pathway in the 14-3-3 γ-mediated NCC regulation, we performed the 14-3-3 gamma knock-down experiments in Cos-7 cells transfected with 14-3-3 γ siRNA and NCC. Knocking down 14-3-3 γ expression significantly increased total NCC protein expression while reducing ERK 1/2 phosphorylation. Overexpression of 14-3-3γ significantly reduced NCC protein expression while enhancing ERK 1/2 phosphorylation. In the presence of knock-down ERK 1/2, 14-3-3 γ-mediated inhibition of NCC was reversed.

Conclusions: Taken all data together, we concluded that 14-3-3 γ plays an important role in NCC regulation through ERK 1/2-mediated signaling pathway in DOCA salt hypertensive mouse model, which provides a novel mechanism underlying pathogenesis of DOCA salt hypertension.

Generation and Analysis of Pseudohypoaldosteronism Type II Knockin Mice Caused by Nonsense Mutation in the Kelch Domain of KLHL3

Chien-Ming Lin,[1] Sung-Sen Yang,[1] Shih-Hua P. Lin.[2] *[1]Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Tri-Service General Hospital, Neihu, Taiwan.*

Background: Mutations in Kelch-like 3 (*KLHL3*) are the most common causative genes detected in patients with pseudohypoaldosteronism type II (PHAII). Although *Klhl3*$^{R528H/+}$ knock-in (KI) mice carrying a missense mutation in kelch repeat domain has been reported, the nonsense *KLHL3* mutation-causing PHAII in the same domain have not been fully investigated *in vivo*.

Methods: We generated and analyzed mutant *Klhl3* KI mice harboring a nonsense *W523X* mutation in the kelch domain (corresponding to human *KLHL3 W470X* mutation). The associated protein expression of their kidney tissue was evaluated by western blot and immunofluorescence. The co-immunoprecipitation (co-IP) method was conducted to clarify the role of *KLHL3* kelch repeat domain.

Results: Both heterozygous and homozygous *Klhl3*$^{W523X/+}$ KI mice exhibited a significantly elevated systolic blood pressure ($p < 0.05$), secondary hyporeninemia ($p < 0.05$), a higher serum potassium level (K^+) ($p < 0.05$) with decreased fractional excretion of K^+ (FE_K; $p < 0.05$) and a higher serum chloride level but lower bicarbonate level ($p < 0.05$). Their kidney tissues showed decreased levels of KLHL3 protein along with an enhanced downstream WNK1/4-SPAK/OSR1-N(K)CC phosphorylation. *In vitro*, co-IP demonstrated human KLHL3 harboring the PHAII-causing *W470X* mutation resulted in a decreased expression of total KLHL3 protein with truncated KLHL3 protein, leading to impaired binding affinity of KLHL3 to WNK1/4.

Conclusions: *Klhl3*$^{W523X/+}$ KI mice feature typical PHAII with a simultaneous increase of WNK1 and WNK4 through impaired binding of the KLHL3 kelch domain to WNKs.

FR-PO594

Effects of Extreme Dietary Potassium Restriction and K+ Loading on Blood Pressure and Renal Tubular Na+ Transport

Cary R. Boyd-Shiwarski,[4] Rebecca T. Beacham,[1] Claire J. Weaver,[2] Daniel J. Shiwarski,[3] Kelly Connolly,[1] Allison L. Marciszyn,[1] Arohan R. Subramanya.[4] *[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Florida, Oviedo, FL; [3]Carnegie Mellon University, Pittsburgh, PA; [4]University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: For almost a century it has been known that dietary potassium intake inversely correlates with blood pressure. Yet, it is unclear how potassium restriction leads to hypertension, or how potassium excess causes a natriuresis despite elevated aldosterone levels. Our goal was to study the effects of dietary potassium on blood pressure, acid/base balance, and ion transport.

Methods: Wild-type SV129 mice were fed K+ deficient, control, high K+ basic, and high KCl diets for 10 days. We monitored BP using radiotelemetry probes, urine electrolyte excretion via metabolic cages, and transporter expression via immunofluorescence, western blots, and diuretic challenges.

Results: Interestingly, despite the induction of hypokalemia, extreme K+ depletion had no effect on blood pressure. In contrast, K+ loading resulted in a progressive ~10 mmHg increase in blood pressure. To determine whether these effects were dependent on NaCl intake, we challenged mice with 1% saline. The K+ deficient mice developed an increase in blood pressure (~8 mmHg), whereas K+ replete mice exhibited no significant change in blood pressure with saline challenge. Notably, just 10d of K+ restriction was associated with diabetes insipidus, evidenced by polyuria and a decrease in AQP2 expression. This was associated with an increase in sodium transporters in the upstream tubule, likely the cause of salt sensitivity. The elevated blood pressure on the K+ loaded diet correlated with elevated aldosterone levels and increased ENaC activation. During K+ loading, the type of anion (basic vs. chloride-rich) had a considerable effect on key transporters along the tubule, despite no differences on blood pressure.

Conclusions: In our model, the effect of dietary K+ on blood pressure was linked to NaCl intake, due to differential effects of K+ loading and restriction on sodium transport pathways along the nephron. The inverse relationship between dietary K+ intake and blood pressure was only observed in the setting of NaCl loading, though our data strongly suggest that AQP2 expression should be closely monitored to accurately interpret such

results. Further, the accompanying anionic content should be taken into consideration when modeling the physiologic effect of K+ intake on tubular salt transport and blood pressure.

FR-PO595

Kidney-Specific and Sex-Dependent Action of the Circadian Clock Protein BMAL1 in the Renal Response to Dietary Potassium Deprivation

Gene R. Crislip,[1] Lauren G. Douma,[1] Sarah H. Masten,[1] Charles S. Wingo,[1,2] Michelle L. Gumz.[1] *[1]University of Florida, Gainesville, FL; [2]North FLorida/South Georgia Veterans Health System, Gainesville, FL.*

Background: BMAL1 is a core mammalian circadian clock transcription factor responsible for the tissue-specific regulation of thousands of genes. Male, but not female, kidney-specific BMAL1 knockout (KO) mice exhibit lower blood pressure compared to control mice (CNTL). The goal of this study was to determine the BMAL1-dependent response to five days of dietary potassium (K) deprivation in males and females.

Methods: We generated the KO using floxed exon 8 BMAL1 mice crossed with kidney-specific cadherin Cre+ mice. Floxed Cre- littermates were used as CNTL. Metabolic cages were used for 12 hr urine collections.

Results: There was not a genotype difference in food intake in either sex, however, males displayed a transient decrease throughout the treatment (M: P<0.05) but females had no change (F: P=0.4). Similarly, neither sex had a genotype difference in body weight. Body weight of males did not change from treatment (M: P=0.8) but females increased in weight (F: P<0.0001). K excretion throughout treatment was comparable between CNTL and KO in both sexes. The K excretion rate in males decreased within 24 hours of the start of treatment from baseline and remained low for the full 5 days (CNTL: 0.65±0.05 to 0.012±0.002; KO: 0.64±0.02 to 0.015±0.004 mmol; P<0.0001). Females exhibited a similar response in K excretion rates (CNTL: 0.38±0.09 to 0.03±0.009; KO: 0.42±0.08 to 0.003±0.01 mmol; P<0.0001). After an initial decrease in sodium (Na) excretion in males, rates remained lower than baseline throughout treatment in CNTL whereas KO increased back to baseline levels by day 5 of treatment (CNTL: .29±0.02 to 0.19±0.01; KO: 0.29±0.01 to 0.26±0.01 mmol; P<0.0001). Genotype-dependent differences in Na excretion were not apparent in females, however, there was a transient increase following treatment in CNTL and KO reaching its peak at day 4 (CNTL: 0.21±0.06 to 0.26±0.05; KO: 0.21±0.03 to 0.24±0.03 mmol; P<0.05). Male CNTL had greater cumulative Na compared with male KO (P<0.001) and both female groups.

Conclusions: Male kidney-specific BMAL1 KO mice exhibited a decrease in renal Na retention in response to a low K diet. Thus, BMAL1 functions in the sex-dependent response of the kidney to dietary K restriction.

FR-PO596

Role of Ammonia in the Renal Potassium Response to Dietary K^+ Deficiency

Hyun-Wook Lee,[1] Autumn N. Harris,[1,2] Michael F. Romero,[3] Paul A. Welling,[4] Jill W. Verlander,[1] I. D. Weiner.[1,5] *[1]Nephrology Division, University of Florida, Gainesville, FL; [2]Veterinary Medicine, University of Florida, Gainesville, FL; [3]Mayo Clinic College of Medicine, Rochester, MN; [4]University of Maryland School of Medicine, Baltimore, MD; [5]Nephrology and Hypertension Section, NF/SGVHS, Gainesville, FL.*

Background: Previous studies have shown that glutamine administration simultaneously increases ammonia excretion and decreases K^+ excretion. The current studies determined whether increased ammonia metabolism is necessary for the normal kaliuretic response to hypokalemia.

Methods: We used NBCe1-A KO mice, which have decreased ammonia response to metabolic acidosis, and WT littermates. We determined whether NBCe1-A KO blocked the ammonia response to hypokalemia and whether this response was necessary for normal changes in K^+ excretion. Lastly, we incubated tissue slices with defined solutions to determine direct effects of ammonia on NCC phosphorylation.

Results: In WT mice exposed to a K^+-free diet for 4 days, as compared to mice provided K^+-control diet, there was increased ammonia excretion, increased expression of cortical ammoniagenic enzymes, PDG and PEPCK, and decreased expression of the ammonia recycling enzyme, glutamine synthetase. In KO mice each of these responses was blunted significantly. NBCe1-A KO mice have a genetic mutation affecting only cortical proximal tubule segments, which is not thought to regulate K^+ excretion, yet when exposed to a K^+-free diet developed a significantly lower serum K^+, measured on day 4, and they excreted significantly more urinary K^+ on each day than did WT littermates. Distal nephron K^+ transporter, ROMK, BK channel, and H^+-K^+-ATPase $\alpha1$ and $\alpha2$, expression did not differ detectably between hypokalemic WT and KO mice. ENaC α, β and γ expression increased with K^+-free diet similarly in WT and KO mice. NCC phosphorylation, which has a key role in the renal response to hypokalemia, however, was significantly less in hypokalemic KO than in hypokalemic WT mice. Ex vivo incubation of kidney slices for 1 hour in defined solutions showed that decreased extracellular K^+ increased phospho-NCC expression over the tested range of 2-8 mM K^+. Addition of ammonia, 2 mM, also increased phospho-NCC expression. Total NCC expression was not altered by changes in extracellular K^+ or by ammonia addition.

Conclusions: The renal kaliuretic response to dietary K^+-deficiency-induced hypokalemia requires an NBCe1-A-dependent increase in cortical proximal tubule segments ammoniagenesis, which then leads to an ammonia-dependent stimulation of NCC phosphorylation that is necessary for normal K^+ conservation.

FR-PO597

Insulin Stimulates V-ATPase on Renal Proximal Tubules via the Akt/mTORC2 Pathway

Motonobu Nakamura,[1] Nobuhiko Satoh,[1] Hiroyuki Tsukada,[1] Tomohito Mizuno,[1] Wataru Fujii,[1] Shoko Horita,[1] Masaomi Nangaku,[1] Masashi Suzuki.[2] *[1]Division of Nephrology and Endocrinology, The University of Tokyo hospital, Bunkyoku, Japan; [2]Tokyo Gakugei University, Koganei, Tokyo, Japan.*

Background: Maintaining an acid-base balance is essential for homeostasis. Acid-base transport in renal proximal tubules (PTs) is mainly sodium dependent and conducted coordinately by apical Na^+/H^+ exchanger (NHE)3, vacuolar H^+-adenosine triphosphatase (V-ATPase) and basolateral Na^+/HCO_3^- cotransporter (NBC)e1. V-ATPase on the PTs well-known to play an important role in proton excretion. Previously, we reported stimulation of PT sodium transport by insulin was mediated via Akt2 mTORC2 pathway. However, it is unclear whether insulin is involved in acid-base balance on the renal PTs. We hypothesized insulin may regulate V-ATPase on PTs.

Methods: We measured luminal V-ATPase activity in freshly isolated, split-opened mouse PTs by using a pH-sensitive dye BCECF. To uncover the signaling mechanism, we examined the effect of bafilomycin, Akt1/2 inhibitor VIII, an mTORC1 inhibitor rapamycin and an mTORC1/2 inhibitor, PP242. The measurement of V-ATPase activity was as follows; Freshly isolated and split-opened PTs in the chamber were first perfused in HEPES, and then the perfusate was switched to Na^+- free HEPES. The intracellular pH recovery rates during perfusing with Na^+-free HEPES were measured, and intracellular pH change was calculated during the initial 30 seconds as V-ATPase activity. To confirm the protein expression, protein phosphorylation was analyzed by Western blotting.

Results: V-ATPase activity in PTs was markedly stimulated by insulin, and this stimulation was almost completely inhibited by bafilomycin, Akt inhibitor VIII, and PP242, but not by rapamycin. In freshly isolated mouse PTs, V-ATPase activity was increased approximately 20% by 1nM insulin above baseline and this stimulation was completely suppressed by Akt 1/2 inhibitor VIII. While PP242 completely suppressed the insulin-mediated V-ATPase stimulation in mouse PTs, rapamycin failed to affect the insulin effect. Insulin-induced phosphorylation of Akt in mouse renal cortex was completely suppressed by Akt1/2 inhibitor VIII and PP242, but not rapamycin.

Conclusions: Our results indicated that stimulation of V-ATPase activity by insulin in PTs is mediated via Akt2/mTORC2pathway. These results implicate the complex signaling in the proximal tubule acid-base balance, providing treatment targets for renal disease.

FR-PO598

Secretin Activates Pendrin-Dependent HCO_3^- Secretion in β-Intercalated Cells

Samuel L. Svendsen, Jens G. Leipziger. *Aarhus University, Aarhus C, Denmark.*

Background: The secretin receptor is expressed in the intercalated cells (IC) of the collecting duct. Using *in vivo* mice experiments, we have recently shown that secretin triggers a pronounced and rapid increase of urinary HCO_3^- excretion. Importantly, this secretin effect was completely absent in pendrin (SLC26A4) KO mice and strongly reduced in CFTR KO mice. We hypothesize that secretin directly activates β-intercalated cells (β-IC) of the collecting duct (CD) via stimulation of basolateral secretin receptors.

Methods: We used isolated perfused cortical collecting ducts and intracellular pH measurements in β-ICs to quantify the transport rate of pendrin upon fast removal of luminal chloride in the presence of 24 mM luminal HCO_3^-. Tubules were loaded with the pH indicator dye BCECF-AM from the luminal side to achieve selective IC dye loading. The experiments were done in WT and CFTR KO mice. The initial alkalization rate ($\Delta pH/\Delta t$) upon luminal chloride removal was taken as measure of pendrin activity in β-ICs. Secretin (10 nM) was applied for 10 min to the basolateral side. Analysis was performed in a strictly paired fashion in the single β-IC before and after secretin and this was compared to time controls with no secretin stimulation.

Results: Mean $\Delta pH/\Delta t$ was markedly increased with secretin (0.20±0.038 pH/min vs. 0.43±0.044 pH/min (24 cells, 4 CDs, 4 mice), p<0.0001). This increase was significantly different from time controls without secretin (p=0.0022, 20 cells, 4 CDs, 4 mice).

Conclusions: These results show that basolateral secretin directly activates pendrin-dependent HCO_3^- secretion in β-ICs. Importantly, HCO_3^- secretion in β-IC is markedly reduced in CFTR KO mice. Thus, our previously demonstrated *in vivo* effects of secretin align well with those reported here in the isolated perfused CD. This shows that secretin triggers urinary HCO_3^- excretion by activating the β-ICs.

FR-PO599

The Molecular Chaperone GRP170 Regulates ENaC Biogenesis and Salt and Water Homeostasis in the Kidney

Teresa M. Buck,[1] Stephanie Mutchler,[1] Evan C. Ray,[2] Allison L. Marciszyn,[1] Thomas R. Kleyman,[1] Jeffrey L. Brodsky.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA.*

Background: The epithelial sodium channel (ENaC) is expressed in a variety of epithelial tissues. In the distal nephron, ENaC is responsible for Na^+ reabsorption and regulates salt and water homeostasis and blood pressure. ENaC is a heterotrimeric channel composed of an α, β, and γ-subunit. Unassembled ENaC subunits are recognized by the

ER associated degradation (ERAD) machinery and degraded. Using cellular models, we determined that the ER localized molecular chaperone, GRP170, regulates both ENaC quality control and trafficking. We determined that GRP170 is required for the degradation of the unassembled αENaC subunit, but not the β or γ-subunits. However, when all three ENaC subunits are present, GRP170 promotes trafficking of ENaC to the cell surface. Therefore, we hypothesized that GRP170 promotes ENaC surface expression in the mammalian kidney.

Methods: To test our hypothesis we generated a kidney tubule-specific, inducible, GRP170 knock-out (KO) mouse. A GRP170 allele flanked by LoxP sites ("floxed") was generated, and crossed to a mouse that expresses Cre recombinase in kidney tubules upon doxycycline treatment. Adult mice were treated for 10 days with doxycycline to deplete GRP170 and given either a standard or high-salt diet. Mice were placed in metabolic cages and weight, water intake and urine output were monitored. Animals were sacrificed and blood, kidneys, lungs, and liver were harvested.

Results: GRP170 KO mice lose weight after doxycycline treatment (~20% body weight in three weeks), whereas control mice do not. Rapid weight loss is consistent with volume loss. Because Na^+ reabsorption by ENaC promotes water reabsorption, loss of volume is consistent with decreased ENaC activity. Indeed, a significant increase in plasma aldosterone, a decrease in plasma Na^+, and an increase in plasma K^+ are observed in the GRP170 KO mouse. When experiments were repeated with a high-salt diet, changes in plasma Na^+ and K^+ levels were no longer observed. Because a high-salt diet partially rescues the GRP170 KO phenotype, these data are consistent with Na^+ depletion and reduced ENaC activity.

Conclusions: The GRP170 chaperone regulates ENaC expression or activity in the mouse kidney, consistent with its effect *in vitro*. Ongoing experiments will examine whether GRP170 regulates other ion channels or transporters.

Funding: NIDDK Support

FR-PO600

Low ENaC Expression Abolishes Furosemide-Induced K^+ Excretion

Niklas Ayasse, Jens G. Leipziger, Mads V. Sorensen. *Aarhus University, Aarhus C, Denmark.*

Background: In the collecting duct (CD) ENaC-mediated Na^+ absorption drives K^+ excretion. Acute K^+ excretion is dependent on the regulated delivery of Na^+ to the aldosterone-sensitive part of the distal nephron (ASDN) and acute activation of ENaC. Furosemide is considered a K^+ wasting diuretic as it greatly enhances Na^+ delivery to the ASDN. Here, we study the magnitude of acute furosemide-induced kaliuresis under various states of CD ENaC expression.

Methods: C57/Bl6J mice were subjected to different dietary regimens altering molecular ENaC expression levels. The animals were anesthetized and bladder-catheterized. Diuresis was continuously measured before and after furosemide (2μg/gBW) was administered. Flame photometry was used to measure urinary Na^+ and K^+ and ENaC expression levels were determined by semi-quantative Western Blotting.

Results: A high K^+ and a low Na^+ diet greatly increased ENaC protein expression and furosemide-induced kaliuresis. In contrast, furosemide-induced kaliuresis was greatly reduced in animal fed a low K^+ diet and absent in animals on a high Na^+ diet, conditions with markedly reduced ENaC expression. No significant differences in furosemide-induced natriuresis were found when comparing the dietary groups but it tended to by higher in the low ENaC expressing groups. The furosemide-induced diuresis was similar in all dietary groups.

Conclusions: Acute furosemide-induced kaliuresis differs greatly and markedly depends on the *a priori* molecular expression level of ENaC. Remarkably, it can be even absent in animals fed a high Na^+ diet, despite a marked increase of tubular flow. This study provides auxiliary evidence that acute CNT/CCD dependent K^+ secretion requires both functional and molecular activation of ENaC.

Chronic Fluid Shear Stress (FSS) Induces ERK Dependent Sodium Transport in Principal Cells (PCs)

Robert L. Repetti,[1,2] Jennifer Meth,[1] Nomrota Majumder,[2] Mukut Sharma,[4] Tarak Srivastava,[3] Rajeev Rohatgi.[1,2] *[1]Northport VAMC, Northport, NY; [2]Medicine, Stony Brook University School of Medicine, Stony Brook, NY; [3]Childrens's Mercy Hospital, Kansas City, MO; [4]KCVA Medical Center, Kansas City, MO.*

Background: Nephron loss by disease or nephrectomy lead to compensatory hemodynamic and cellular effects on the remaining nephrons. Increases in single nephron glomerular filtration rate and tubular flow rate, exert FSS on tubular epithelia. Rising tubular flow rate have acute and chronic effects on epithelial Na channel (ENaC) dependent Na absorption. Acute (minutes) increase in cortical collecting duct (CCD) flow rate augments Na absorption; however, chronic (hours) flow, as in unilateral nephrectomy, is expected to augment Na excretion and increase fractional excretion of Na. *In vitro* FSS induces ERK phosphorylation in murine CD cells and ERK has been shown to be a regulator of ENaC. Thus, we hypothesize that chronic FSS-induces ERK activation in the CCD to inhibit amiloride sensitive Na transport.

Methods: To test this, murine PCs (mpkccd) were grown on snapwells under static conditions or exposed to 0.4 dynes/cm^2 of FSS for 24 hrs and amiloride sensitive Na current (*Iasc*) measured in an Ussing chamber. Kidneys from sham control and unilateral nephrectomized mice were used for immunohistochemistry (IHC) and immunofluorescence (IF).

Results: *Iasc* was 23.4±1.4 μA/cm^2 (n=6) in static PCs, but in cells exposed to 24 hours of FSS the *Iasc* was reduced to 12.9±1.0 μA/cm^2 (n=9; p<0.01). Next, we tested whether U0126, a MEK inhibitor, could recover the FSS mediated reduction in *Iasc*. PCs exposed to FSS and U0126 exhibited a lower *Iasc* of 6.9±0.3 μA/cm^2 (n=4, p<0.01 vs static and FSS without inhibitor), suggesting ERK stimulates ENaC dependent transport and that non-ERK factors repress *Iasc*. To identify ERK expression *in vivo*, we performed IHC and IF in kidneys of mice post-unilateral nephrectomy and in sham controls. IHC, in control and nephrectomized mice, showed heterogenous expression of phospho-ERK (pERK) in the CCD. Sham and nephrectomized kidneys were labelled with dolichos biflorus agglutinin (DBA), a PC marker, and anti-pERK antibody. In sham kidneys pERK co-localized with PC cells; however, in nephrectomized mice pERK chiefly co-localized with DBA and in a minority of cells localized with non-DBA stained cells of the CCD.

Conclusions: Chronic FSS induces ERK to stimulate ENaC dependent Na transport *in vitro*, and *in vivo* pERK is expressed primarily in PCs, suggesting ERK may play an identical role *in vivo*

FR-PO602

Regulation of Rhcg Protein in the Intercalated Cells of the Outer Medullary Collecting Duct by Aldosterone

Yuichiro Izumi,[1] Koji Eguchi,[1] Makoto Ono,[1] Akiko Hiramatsu,[1] Yushi Nakayama,[1] Hideki Inoue,[1] Hiroshi Nonoguchi,[2] Yutaka Kakizoe,[1] Takashige Kuwabara,[1] Masashi Mukoyama.[1] *[1]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [2]Kitasato University Medical Center, Kitamoto, Japan.*

Background: Rhcg, an ammonia transporter, is expressed mainly in the intercalated cells (ICs) of the collecting duct. Serum potassium level regulates the expression of Rhcg. Aldosterone level is increased in metabolic acidosis; however, direct effects of aldosterone on the Rhcg expression remain obscure.

Methods: C57BL/6J mice were divided into four groups: 1) sham-operation, 2) sham and NH_4Cl drinking (Sham-NH_4Cl), 3) adrenalectomy and NH_4Cl drinking (ADX-NH_4Cl), and 4) adrenalectomy with continuous administration of aldosterone and NH_4Cl drinking (ADX-Aldo-NH_4Cl). Mice were sacrificed three days after NH_4Cl drinking. Urinary ammonium excretion and localizations of Rhcg and ubiquitin were examined. For *in vitro* experiments, IN-IC cells, which we previously established as an intercalated cell-derived cell line, that stably express flag-tagged Rhcg (Rhcg-flag) were generated. The effects of aldosterone, spironolactone, Go6983 (a PKC inhibitor) and MG132 (a proteasome inhibitor) on the expression of Rhcg-flag were examined.

Results: NH_4Cl-induced increase in urinary ammonium excretion was less in ADX-NH_4Cl mice than that in Sham-NH_4Cl mice. Aldosterone increased ammonium excretion in ADX-Aldo-NH_4Cl mice as much as that in Sham-NH_4Cl mice. Immunohistochemical study revealed that NH_4Cl drinking increased the accumulation of Rhcg at apical membrane of the ICs of the outer medullary collecting duct in Sham-NH_4Cl mice. Adrenalectomy and aldosterone decreased and increased the accumulation of Rhcg at apical membrane of the ICs in ADX-NH_4Cl and ADX-Aldo-NH_4Cl mice, respectively. Ubiquitin expression was not changed between in PCs and ICs of Sham-NH_4Cl mice, while it was less in ICs than in PCs in ADX-NH_4Cl mice. Aldosterone restored the ubiquitin expression in ICs. In *in vitro* experiment, Western blotting showed that aldosterone increased the expression of Rhcg-flag in the membrane fraction of IN-IC cells. Spironolactone and Go6983 each inhibited the expression of Rhcg-flag. Treatment with MG132 increased the expression of Rhcg-flag in whole cell lysate.

Conclusions: Aldosterone could directly regulate Rhcg expression through the mineralocorticoid receptor-PKC pathway. Furthermore, aldosterone could modulate Rhcg expression through the ubiquitin-proteasome pathway.

Effect of Loading NH_4Cl in $P2Y_2$ Receptor Knockout and Wild-Type Mice

Marshall R. Roedel, Kalani L. Raphael, Tao Liu, Noel G. Carlson, Bellamkonda K. Kishore. *Univ. of Utah and VA Medical Center, Salt Lake City, UT.*

Background: Chronic lithium (Li) administration for bipolar disorder causes renal tubular acidosis. In animal models, Li invokes collecting duct remodeling (CD-R) resulting in an increased proportion of $[H^+]$-ATPase-positive intercalated cells, presumably to increase kidney H^+ excretion. We reported that genetic deletion of $P2Y_2$ receptor blunts this Li-induced CD-R response, suggesting that $P2Y_2$ receptor facilitates H^+ elimination in response to an acid load. To investigate the role of $P2Y_2$ receptor in acid-base regulation, we evaluated the effect of NH_4Cl loading on blood and urinary acid-base indices in $P2Y_2$ knockout (KO) and wild type (WT) mice.

Methods: Groups of WT or KO mice (B6D2; N=5-6/group) were fed standard rodent chow and given tap water with/without 0.28 M NH_4Cl for 9 days and humanely euthanized. Terminal urine and blood samples were collected and analyzed for indices of acid-base homeostasis.

Results: Table shows the terminal data. NH_4Cl loading induced a more severe metabolic acidosis in $P2Y_2$ receptor KO than WT mice as evidenced by the markedly lower blood pH, HCO_3 and BE, and increased water intake (not shown here). Urinary NH_3 excretion was slightly lower in KO than WT mice despite having more severe metabolic acidosis, suggesting that kidney NH_3 production or excretion is impaired in KO. The higher than expected pCO_2 (expected pCO_2 ~ 26 mm Hg) for the degree of metabolic acidosis induced by NH_4Cl loading, and the higher pCO_2 in KO than WT under basal conditions suggests that $P2Y_2$ receptor may regulate respiratory ventilation.

Conclusions: $P2Y_2$ receptor seems to have an important role in the maintenance of acid-base balance. This may be through facilitating CD-R in response to an acid load and participating in respiratory ventilation.

Adaptation to a High-Salt Diet Requires A-Type Intercalated Cell-Dependent NaCl Secretion

Chloe Rafael,[1,2] Christine Walter,[1,2] Luciana Morla,[1,2] Samia Lasaad,[1,2] Lydie Cheval,[1,2] Gilles Crambert.[1,2] *[1]Centre de Recherche des Cordeliers, INSERM, Sorbonne Université, USPC, Université Paris Descartes, Université Paris Diderot, Paris, France; [2]CNRS ERL 8228 - Laboratoire de Physiologie Rénale et Tubulopathies, Paris, France.*

Background: The kidney controls the extracellular volume and the blood pressure because of its ability to excrete efficiently Na+ and Cl- ions. We have recently identified a novel pathway that mediates the secretion of Na+ in the collecting duct (Morla, et al. 2016). This system involves A-type intercalated cells (AIC), NKCC1 and the H,K-ATPase type 2 (HKA2), which is known to be able to transport Na^+. Here, we investigated the AIC implication in NaCl renal secretion and the physiological relevance of this pathway *in vivo*. We speculate that this pathway may help the kidney to excrete large amounts of salt when needed.

Methods: Collecting ducts from control kidneys following a normal and a high-salt diet (8% NaCl, HS) were isolated and analyzed by RT-qPCR and immunofluorescence followed by 3-dimensions reconstruction. To assess the physiological relevance of this novel pathway, we placed HKA2 knockout mice (HKA2KO mice) under HS diet.

Results: On isolated collecting ducts, we observe an increase of the total AIC number under HS diet (+10%). This adaptive proliferation of AIC in response to HS diet suggests a relevant role of AIC in NaCl secretion. RT-qPCR reveal that HS diet leads to a 4- and 1.6-fold increase of HKA2 and NKCC1 expressions, respectively. Altogether these results support the role of HKA2 and NKCC1 in mediating the secretion of NaCl in AIC. Under HS diet, HKA2KO mice display increased urine output and water intake associated with a decreased urinary osmolarity compared to control mice. HKA2KO mice also display a decrease of plasma K^+ and a hypochloremic metabolic alkalosis. This phenotype, induced by salt load, resembles Bartter syndrome, a salt-losing pathology due to thick-ascending limb dysfunction. Under HS diet, furosemide induces an 80% increased natriuresis in control mice but only a 30% increase in HKA2KO demonstrating that NKCC2 is less functional in HKA2KO mice. We, therefore, propose that the absence of Na^+ secretion through HKA2 is compensated by a stronger inhibition of NaCl reabsorption through NKCC2, leading to a mild Bartter-like syndrome.

Conclusions: In conclusion, we demonstrate that AIC participate to the regulation of Na+ balance through the stimulation of the NaCl secretion pathway under HS diet *in vivo* and we highlight the critical role of HKA2 in the fine adaptation to a HS diet.

FR-PO605

The Renal AE4 Transporter (Slc4a9) Prevents Life-Threatening Hypochloremic Metabolic Alkalosis During NaCl Restriction and Base Loading

Helga Vitzthum,[1] Mirijam Koch,[1] Christian A. Hübner,[2] Heimo Ehmke.[1] *[1]University Medical Centre Hamburg-Eppendorf, Hamburg, Germany; [2]University Hospital Jena, Jena, Germany.*

Background: The renal transporter AE4 (Slc4a9) is localized to the basolateral membrane of type B intercalated cells (β-ICs) in the collecting duct. Recently, it has been shown that β-ICs contribute to renal sodium (Na^+) reabsorption during dietary salt restriction. Currently it is generally assumed that AE4 constitutes the primary basolateral Na^+ extrusion pathway in β-ICs, but there is still no direct evidence of such a role.

Methods: We subjected AE4 knockout mice and their wildtype littermates (WT) to either a salt (NaCl) deficient diet alone (10 days) or a salt deficient diet combined with an additional base load (230 mM $NaHCO_3$, 7 days). We analyzed the effects of each diet on plasma volume, renal Na^+ and Cl^- handling, renal protein expression levels of NHE3, NCC, ENaC and pendrin, plasma renin and aldosterone levels, and acid-base homeostasis.

Results: Surprisingly, AE4 knockout mice did not show any signs of Na^+ loss or volume contraction or compensatory activation of other renal Na^+ reabsorption pathways under salt deficient diet. However, we observed that AE4 knockout mice developed a mild hypochloremic metabolic alkalosis under these conditions, which severely aggravated when the animals were additionally subjected to a base load ($NaHC0_3$). In contrast, WT littermates maintained normal Na^+ and acid-base balance under both diet regimes. While WT mice markedly increased pendrin expression during the base load, this response was completely absent in AE knockout animals.

Conclusions: The findings show that the renal transporter AE4 (Slc4a9) is dispensable for Na^+ homeostasis during salt restriction, but is essential for the stimulatory effect of alkalosis on the upregulation of the apical Cl^-/HCO_3^- exchanger pendrin. Insufficient function of AE4 can cause life threatening hypochloremic metabolic alkalosis during base loading conditions (e.g. vomiting).

FR-PO606

MAGE-D2 Is Required for a Normal Cell Surface Expression of NHE3 Protein

Elie Seaayfan,[1] Aparna Renigunta,[1] Lars lennart Ruttkowski,[1] Tom L. Herrmann,[1] Nadine Schallopp,[1] Stefanie Weber,[3,1] Kamel Laghmani,[2] Martin Kömhoff.[1,3] *[1]Philipps University Marburg, Marburg, Germany; [2]INSERM-CNRS, Paris, France; [3]University Children's Hospital Marburg, Marburg, Germany.*

Background: We recently showed that mutations in *MAGE-D2* cause polyhydramnios leading to preterm birth and a severe but transient form of antenatal Bartter's syndrome (transient aBS). Reduced expression of the sodium–chloride transporters NKCC2 and NCC was shown in vivo and in vitro and explains massive salt losing (Laghmani et al, N Engl J Med. 2016). The absence of metabolic alkalosis however, which is pathognomonic feature of aBS, suggests that additional transporters may be affected. One possible explanation is that MAGE-D2 also regulates NHE3, the predominant isoform responsible for apical membrane Na(+)/H(+) exchange in the proximal tubule and thick ascending limb. Consequently, the aim of the present study was to investigate the potential role of MAGE-D2 in NHE3 biogenesis.

Methods: Protein-protein interaction was assessed by co-immunoprecipitation (COIP) assay and proximity ligation assay (PLA). NHE3 protein expression was monitored in transiently transfected HEK293 cells by immunoblotting. Stability of NHE3 protein was assessed by cycloheximide chase assay. We studied the effects of wild type MAGED2 and mutant R446CMAGE-D2 on total and cell surface expression of NHE3. In addition, the role of endogenously expressed MAGE-D2 role was investigated by small interfering RNA.

Results: CO-IP assays in renal cells showed that MAGE-D2 WT interact physically with NHE3. Accordingly, PLA revealed that MAGE-D2 is close to NHE3 in renal cells. Interestingly, R446CMAGE-D2, a missense mutation identified in a transient aBS patient, co-expression significantly decreased NHE3 cell surface expression (48.8% from the control, *P value* = 0.0172). Analogous to R446CMAGE-D2, knockdown of endogenous MAGE-D2 by small interfering RNA also decreases NHE3 cell surface abundance. Interestingly, in contrast to NKCC2 and NCC, MAGE-D2 co-expression did not affect total NHE3 protein expression. Moreover, cycloheximide chase assays (CHX) showed that in cells over expressing MAGE-D2, stability of NHE3 is not affected.

Conclusions: Our findings show that MAGED2 specifically promotes the cell surface expression of NHE3. Importantly, our data indicate that MAGED2 differentially affects multiple salt transporters in the nephron, thus explaining the severe phenotype as well as the absence of metabolic alkalosis.

FR-PO607

14-3-3 Epsilon Regulates NPT2a Activity in the Renal Proximal Tubule

Kenneth Gagnon,[1] Michelle T. Barati,[1] Kathleen Kitterman,[1] Adrienne M. Bushau,[1] Barbara Clark,[1] Eleanor D. Lederer.[2] *[1]University of Louisville, Louisville, KY; [2]University of Louisville; Robley Rex VA Medical Center, Louisville, KY.*

Background: 14-3-3 is an adapter protein implicated in the regulation of a large spectrum of signaling pathways. We have demonstrated an increased association between the Na-phosphate cotransporter type 2a (NPT2a) and 14-3-3 epsilon in the absence of the Na-H Exchanger Regulator Factor 1 (NHERF1) in proximal tubule cells. We hypothesize that 14-3-3 epsilon associates with a phosphorylated residue in the carboxy-terminal PDZ-1 binding motif of NPT2a and inhibits NHERF1-mediated Npt2a forward trafficking to the apical membrane.

Methods: We generated cDNA constructs modifying the threonine residue in the NPT2a PDZ-1 binding motif "TRL" to either mimic phosphorylation (T635D, T635E) or prevent phosphorylation (T635A). We combined these wild type and mutant NPT2a cDNAs with NHERF1 FL or 14-3-3 epsilon FL in IRES-containing bicistronic mammalian expression vectors. We then transiently transfected these constructs in NHERF1-deficient opossum kidney (OKH) cells and assessed membrane expression with confocal fluorescent microscopy and sodium-dependent phosphate cotransport activity with ^{32} P phosphate uptake assays.

Results: NPT2a FL and NHERF1 FL exhibited membrane co-localization. Phosphomimic NPT2a (DRL) appears as cytosolic punctate regions with no NHERF1 FL co-localization. Phosphomimic NPT2a (ERL) and non-phosphomimic NPT2a (ARL) exhibit both reduced membrane localization (compared to NPT2a FL) and cytosolic punctate regions but neither co-localized with NHERF1 FL. ^{32} P uptake assays corroborated the confocal immunofluorescence with a 7-fold increase in phosphate uptake in OKH cells expressing NPT2a FL and NHERF1 FL versus water-transfected OKH cells. NPT2a ERL and NPT2a ARL with NHERF1 had a 2-fold increase in phosphate uptake versus water-transfected OKH cells. NPT2a FL and 14-3-3 epsilon FL do not exhibit cytosolic co-localization. NPT2a phosphomimics (DRL & ERL) both exhibit reduced membrane localization and cytosolic punctate expression, but no co-localization with 14-3-3 epsilon.

Non-phosphomimic NPT2a (ARL) exhibits no membrane expression or co-localization with 14-3-3 epsilon FL.

Conclusions: These studies demonstrate that the phosphorylation state of T635 in the PDZ binding motif of NPT2a is a determinant in the molecular switch between NHERF1 and 14-3-3 epsilon regulation of the trafficking and functional activity of the cotransporter.

FR-PO608

The Diuretic Actions of SGLT2 Inhibitors and Loop Diuretics Induce Different Compensating Mechanisms

Takahiro Masuda,[1] Shigeaki Muto,[1] Keiko Fukuda,[2] Minami Watanabe,[2] Ken Ohara,[1] Volker Vallon,[3] Daisuke Nagata.[1] *[1]Jichi Medical University, Shimotsuke, Japan; [2]Division of Nephrology, Department of Internal Medicine, Jichi Medical Universtiy, Shimotsuke, Japan; [3]University of California San Diego, San Diego, CA.*

Background: We recently reported that SGLT2 inhibitor ipragliflozin (Ipra) exhibits a sustained diuretic and natriuretic tone that activates compensatory increases in fluid and food intake, and solute-free water reabsorption to stabilize body fluid volume (Am J Physiol Renal Physiol 2018, ASN Kidney Week 2018). Here we determined whether loop diuretics activate similar compensatory mechanisms.

Methods: Sprague-Dawley rats were treated by oral gavage with vehicle (Veh), loop diuretic furosemide (FR) [50mg/kg] or Ipra [5mg/kg] (n= 4-8) in metabolic cages for 1 week. Bioimpedance spectroscopy (ImpediVet) was used to assess body water on days 0 and 7.

Results: FR and Ipra increased urine volume (Veh 18±2, FR 27±3, Ipra 31±2 mL/day [average of 7 days], ANOVA p=0.006), but FR did not increase fluid intake (41±4, 37±6, 51±5 mL/day, p=0.188) and food intake (23±1, 8±3, 23±3 mL/day, p=0.009). As a result, FR significantly decreased fluid balance (fluid intake-urine volume) (23±2, 10±3, 21±4 mL/day, p=0.010). Urine vasopressin (1.5±0.3, 0.7±0.3, 2.4±0.4 ng/day, day 3, p=0.024) and renal solute-free water reabsorption (84±10, 42±11, 128±7 mL/day, day 7, p<0.001) were decreased in the FR group and increased in the Ipra group. Serum osmolality was similar among the groups (307±3, 311±3, 305±2 mOsm/kgH_2O, day 7, p=0.357). The change in total body water (+8±7, -34±8, -5±3 mL, from day 0 to day 7, p<0.001) and creatinine clearance (5.8±0.3, 2.7±0.6, 5.6±0.2 L/day, day 7, p=0.025) were significantly decreased in the FR group.

Conclusions: The SGLT2 inhibitor maintained body fluid volume and renal function. The loop diuretic decreased both parameters with the impaired solute-free water reabsorption unexpectedly being associated with a lack of compensatory increases in vasopressin secretion and fluid intake.

The Stimulatory Role of SPAK Kinase in the Regulation of the Large Conductance Ca^{2+}-Activated Potassium (BK) Channels Protein Expression in Kidney

Ye Bi,[3] Tongwang Luo,[3] Chunmei Li,[3] Xiuyan Feng,[2] Hui Cai.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]LSU Shreveport, Shreveport, LA; [3]Emory University, Atlanta, GA.*

Background: SPS1-related proline/alanine-rich kinase (SPAK) and the oxidative stress-responsive kinase 1 (OSR1) have been shown to be the downstream kinases of with-no-lysine (WNK). SPAK/OSR1 has been shown to mediate the regulation of WNK kinase in cation-chloride cotransporter including sodium chloride cotransporter (NCC) and potassium chloride cotransporter (KCC), etc. In addition, previous studies reported that WNK4 inhibits BK channel activity and protein expression by enhancing BK degradation through stimulating ERK 1/2 and p38 signaling pathway. One previous study showed that SPAK/OSR1 suppressed BK channel activity in *Xenopus* oocytes over-expressing SPAK/OSR1. It remains largely unknown whether SPAK/OSR1 modulate the BK protein expression in kidney tissues. Thus, in this study we have investigated the effects of SPAK kinase on renal BK protein expressions in both mammalian cells and mouse kidney.

Methods: SPAK KO mice, ERK1 global KO mice, western blot analysis, cell culture, and siRNA knock-down experiments were used in this study.

Results: When Cos-7 and HEK 293 cells were over-expressed with SPAK plasmids, BK protein expressions were increased while decreasing ERK 1/2 phosphorylation in a dose-dependent manner, whereas the cells were transfected with SPAK siRNA, BK protein expressions were decreased while increasing ERK 1/2 phosphorylation in a dose-dependent manner. In SPAK mice, BK protein abundance was decreased while increasing ERK 1/2 phosphorylation. In addition, in ERK 1 KO mice BK protein abundance was increased while dramatically increasing SPAK phosphorylation. In addition, WNK4 inhibited BK protein expression while increasing ERK 1/2 phosphorylation.

Conclusions: These data suggested that SPAK signaling positively regulates BK protein expression through negatively modulating ERK 1/2 phosphorylation, potentially by reducing BK degradation.

The Impact of TRPV-1 Genetic Polymorphisms on Serum Sodium Concentration in Elderly Patients

Thomas Bais, Michael W. Tanck, Edo Richard, Bert-jan Van den born, Liffert Vogt. *Academic Medical Center, Amsterdam, Netherlands.*

Background: Disorders of water balance, reflected as serum sodium concentration, are common in clinical practice but their pathophysiology remains incompletely understood. An N-terminal variant of transient receptor potential vanilloid-1 (delta N-TRPV-1) is important for mammalian central osmosensory transduction in hypothalamic magnocellular neurosecretory cells (MNCs) and is activated by hypertonicity, thus stimulating pituitary AVP secretion. Nevertheless, TRPV-1 single nucleotide polymorphisms (SNPs) have not yet been studied in relation to human osmoregulation.

Methods: We genotyped four common TRPV-1 SNPs in 507 acutely admitted elderly patients and 2480 ambulatory elderly patients, who were respectively at high- and low risk for hyponatremia. These SNPs include rs8065080 (I585V), rs224534 (T469I), rs222748 (H167H) and rs222749 (P91S). The effect of TRPV-1 SNPs on serum sodium concentration and the risk of hyponatremia was examined using multiple linear regression analysis and multiple logistic regression analysis. Haplotype analysis was employed to test the effect of combinations of TRPV-1 SNPs.

Results: In both cohorts, carriership of rs8065080, rs224534 and rs222748 did not significantly influence serum sodium concentrations. In acutely admitted elderly patients, univariate analysis demonstrated that serum sodium levels of rs222749 carriers were lower than of non-carriers, both in the entire cohort (133.9 ± 6.0 versus 135.7 ± 6.4 mmol/L, p=0.049) and in Western-European patients (133.7 ± 6.0 versus 135.7 ± 6.1 mmol/L, p=0.028). Acutely admitted patients rs222749 carriers were more likely to be included in the lowest sodium tertiles (serum Na <137 mmol/L; OR 2.54; 95% CI 1.18 - 5.34). In multiple linear regression analysis, carriership of the rs222749 allele was an independent predictor of serum sodium concentration in acutely admitted elderly patients but not in ambulatory patients.

Conclusions: In view of data from previous in vitro studies we hypothesize that rs222749 involves a gain-of-function mutation through enhanced delta N-TRPV-1 expression in MNCs, leading to increased pituitary AVP release and lower serum sodium levels in vulnerable patients.

ARL15 Regulates CNNM2-Dependent Mg^{2+} Transport by Modulating Its N-Linked Glycosylation

Chao Ma,[1] Yevgen Zolotarov,[3] Gijs A. Franken,[2] René J. Bindels,[1] Joost Hoenderop,[1] Jeroen H. De Baaij.[1] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]Radboud Institute for Molecular Life Science, Nijmegen, Netherlands; [3]McGill University, Montreal, QC, Canada.*

Background: A large genome-wide association study identified that ARL15, a small GTP-binding protein, is associated with urinary Mg^{2+} excretion. Within the kidney, ARL15 is highly expressed in the thick ascending limb (TAL) and distal convoluted tubule (DCT), where Mg^{2+} reabsorption is tightly regulated. However, the exact function of ARL15 and the mechanism by which ARL15 regulates renal Mg^{2+} handling are still unknown.

Methods: To identify protein-interaction between ARL15 and Cyclin M (CNNM) proteins, proximity-dependent biotin identification (BioID) and co-immunoprecipitation were performed. Immunohistochemistry were used to investigate co-localization in mouse kidney and human embryonic kidney (HEK293) cells. Furthermore, cell surface biotinylation and $^{25}Mg^{2+}$ uptake assays were used to assess cell surface expression of CNNM2 and Mg^{2+} transport activity. The glycosylation pattern of CNNMs was determined by far lectin Western blot and glycosidase assays.

Results: We identified members of the CNNM family as direct interaction partners of ARL15 by BioID. Immunoprecipitation with truncated CNNM2 proteins indicated that ARL15 interacts with CNNM2 at its carboxyl-(C)-terminal conserved CBS domain. CNNM2 and ARL15 co-localize in the DCT. Interestingly, overexpression of ARL15 in HEK293 cells showed subcellular localization in the Golgi-apparatus and resulted in an increased N-glycosylation of CNNM proteins. This ARL15-mediated glycosylation was Mg^{2+}-sensitive and encompassed hybrid and complex glycosylation. The functional consequences of ARL15-dependent glycosylation were examined by $^{25}Mg^{2+}$ uptake experiments. ARL15 increased $^{25}Mg^{2+}$ uptake via CNNM2 by increasing its cell surface expression.

Conclusions: ARL15 increases CNNM2 plasma membrane expression by regulating its N-glycosylation pattern. Altogether, our results establish ARL15 as novel regulatory mechanism of Mg^{2+} transport within the DCT.

Phenotype of Ksp-Cadherin Deficient Mice: Normal Kidney Development but Delayed Maturation of Maximal Urinary Concentrating Ability

Robert B. Thomson,[1] Diane W. Dynia,[1] Sarah Burlein,[1] Benjamin R. Thomson,[2] Carmen J. Booth,[1] Felix Knauf,[3] Tong Wang,[1] Peter S. Aronson.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]University Hospital Charite Berlin, Berlin, Germany*.

Background: Ksp-cadherin is a largely kidney-specific member of the cadherin superfamily of cell adhesion molecules. Despite ubiquitous basolateral expression throughout the tubular nephron its function remains unknown.

Methods: To address this question we have generated Ksp-cadherin deficient mice (Ksp-null) by introducing a premature stop codon into the second exon of the Ksp-cadherin gene.

Results: Homozygous Ksp-null animals were born at expected frequencies and were not overtly different from age- and gender-matched wild-type (WT) controls. Kidneys from neonate and adult Ksp-null and WT mice had no discernible differences in the ultrastructural organization of nephrogenic progenitors or mature nephrons. Analysis of E-cadherin and Na/K-ATPase indicate that E-cadherin expression is not modified to compensate for Ksp-cadherin loss and that epithelial cell polarity is unaffected. Serum electrolytes, total CO_2, BUN, and creatinine levels were not significantly different between the two groups. Under basal conditions 10 week-old Ksp-null animals produced a urine that was significantly less concentrated than that from a matching WT cohort (1463 ± 219 vs 2184 ± 164 mOsm respectively; P=0.0249). After 24 hrs of water deprivation, similarly aged Ksp-null animals were unable to concentrate their urine to the same extent as their WT counterparts (3283 ± 69 vs 3840 ± 112 mOsm respectively; P=0.0017). Expression analysis of NKCC2, UTA1-3, UTB, AQP1+2, V2R, ROMK, CLCK1, and UMOD indicated that the concentrating defect was not due to altered expression of the principal proteins involved in the generation of the cortico-medullary osmotic gradient. Immunolocalization studies suggested that the defect may be due to misexpression of AQP2 in the IMCD of the Ksp-null mutants. Under both baseline and water-restricted conditions 10 month-old Ksp-null mutants were able to concentrate their urine to the same extent as similarly aged WT animals, suggesting that the defect in urinary concentrating ability in the 10 week-old Ksp-null mice is due to a developmental delay.

Conclusions: In conclusion Ksp-cadherin is not essential for nephron formation or nephron segment delineation. Its null mutation does, however, significantly delay the maturation of maximal urinary concentrating ability.

Tacrolimus Improved Symptoms of Type 4 Bartter Syndrome Model Mice

Yoshiaki Matsuura, Naohiro Nomura, Wakana Shoda, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. Department of Nephrology *Tokyo Medical and Dental University, Tokyo, Japan*.

Background: Type 4 Bartter syndrome (BS) is a hereditary tubular disease characterized by salt-losing polyuria, hypokalemia, and metabolic alkalosis. Because barttin (coded by *Bsnd* gene, which is a disease causing gene of type 4 BS) is expressing from thick ascending limbs of Henle's (TAL) to collecting ducts, the function of distal nephron is widely impaired and the symptoms of type 4 BS are generally very severe. Although potassium replacement therapy has been mainly used for hypokalemia, there is no fundamental treatment for type 4 BS. It has been reported that calcineurin inhibitors enhance phosphorylation of sodium (Na) -potassium (K) -2 chloride (Cl) cotransporter (NKCC2) and Na-Cl cotransporter (NCC), which are key sodium transporters in TAL and distal convoluted tubule, respectively. In this study, we hypothesized that tacrolimus, a calcineurin inhibitor, would increase in phosphorylation of NKCC2 and NCC, and improve symptoms of type 4 BS.

Methods: *Bsnd*$^{neo\,/\,neo}$ mice, which is hypomorphic of barttin, were used as a model of type 4 BS. *Bsnd*$^{neo/neo}$ showed severe polyuria, hypokalemia, and metabolic alkalosis. Tacrolimus was administered subcutaneously once a day. After a week administration of tacrolimus, blood sampling and kidney harvest were performed. Phosphorylation of NKCC2 and NCC was evaluated by Western blotting. For the investigation of urine volume and urinary K excretion, urine was collected in a urine collection cage after a single intraperitoneal administration of tacrolimus.

Results: After a week administration of tacrolimus, serum potassium levels were significantly increased in *Bsnd*$^{neo\,/\,neo}$ mice. However, improvement of metabolic alkalosis was not observed after tacrolimus treatment. After single administration of tacrolimus, urinary K excretion was significantly reduced, and urine volume also tended to be decreased. Phosphorylation of NKCC2 and NCC was significantly increased in *Bsnd*$^{neo\,/\,neo}$ mice.

Conclusions: Tacrolimus administration ameliorated hypokalemia in type 4 BS model mice by suppressing urinary K excretion. Increase in phosphorylation of NCC and NKCC2 would contribute to the improvement of hypokalemia in type 4 BS. Tacrolimus might be effective for the treatment of type 4 BS.

Different NKCC2 Amino Acid Sequences Between 129/Sv and C57BL/6 Mice Affect Analysis of NKCC2 Phosphorylation with Phosphoform-Specific Antibodies

Sandra Moser, Johannes Loffing. *University of Zurich, Zurich, Switzerland*.

Background: The furosemide-sensitive Na^+-K^+-$2Cl^-$ cotransporter (NKCC2) of the thick ascending limb is critical for the renal control of electrolyte and fluid homeostasis. The activity of NKCC2 is regulated via phosphorylation of several serine and threonine (T) residues in the N-terminal tail of the co-transporter. To study NKCC2 function, phosphoform-specific antibodies directed against these phosphorylation sites (e.g. T96 and T101) have been developed and applied in studies on mouse models. The most frequently used mouse strains are 129Sv and C57BL/6 mice. Surprisingly, when we tried to detect phosphorylated NKCC2 (pNKKC2) with anti pT96/pT101 NKCC2 antibodies, we detected a strong pNKCC2 signal only in kidneys from 129Sv mice but not in kidney from C57BL/6 mice. In the latter, only some unspecific cross-reactivity of the pNKCC2 antibodies with the phosphorylated thiazide-sensitive NaCl cotransporter was seen.

Methods: To address this unexpected finding, we compared 129Sv and C57BL/6 mice via database analysis, metabolic cage experiments, quantitative RT-PCR and immunoblotting.

Results: Database analysis revealed that C57BL/6 mice have a five amino acid deletion (ΔT96-N100) in NKCC2, which lies in the region of the epitopes recognized by most anti-pNKCC2 antibodies. Although we observed strain differences in urinary Ca^{2+} and Mg^{2+} excretion and in the expression of several renal ion transporters and channels between 129Sv and C57BL/6 mice, these differences are likely not related to the five amino acid deletion in NKCC2. When we crossbred 129Sv and C57BL/6 mouse strains, mice of the F2 generation with the deletion (ΔT96-N100 mice) and mice without the deletion (control mice) were phenotypically similar. In particular, there were no differences in NKCC2 mRNA and protein abundances between the ΔT96-N100 and control mice. Nevertheless, pNKCC2 remained barely detectable in ΔT96-N100 mice using the antibodies against the full-length epitope.

Conclusions: Our study reports an important difference between the NKCC2 amino acid sequences of 129Sv and C57BL/6 mice that does not appear to significantly affect NKCC2 function, but strongly interferes with the detection of NKCC2 phosphorylation via phosphoform-specific antibodies. This needs to be considered when studying NKCC2 regulation in different mouse strains and when cross-breeding mice.

FR-PO615

MAGE-D2 and HSP40 Protect NKCC2 Against Hypoxia-Induced Endoplasmic Reticulum-Associated Degradation

Kahina Nait meddour,[1] Irfan Shaukat,[1] Sylvie Demaretz,[1] Zaineb Bronji,[1] Elie Seaayfan,[2] Martin Kömhoff,[2] Kamel Laghmani.[1] *[1]CRC, INSERM-U1138, CNRS ERL8228, Sorbonne Université, Paris, France; [2]Philipps University Marburg, Marburg, Germany*.

Background: We recently showed that *MAGED2* mutations cause polyhydramnios with prematurity and a severe but transient form of antenatal Bartter's syndrome associated with inappropriate expression of the sodium–chloride transporters NKCC2 and NCC (Laghmani et al, N Engl J Med. 2016 May 12;374(19):1853-63). However, the transient nature of the disease remains unclear. We speculated that through its interaction with HSP40, MAGE-D2 protects the co-transporters from endoplasmic reticulum (ER) associated degradation activated by ER stress due to tissue hypoxia during early pregnancy, an effect that becomes less relevant later. In support of this notion, we found that HSP40 interacts with NKCC2 at the ER. Consequently, the aim of the present study was to investigate the effect of hypoxia on NKCC2 biogenesis and explore the potential role of MAGE-D2 and HSP40 in this process.

Methods: Cellular hypoxia was induced chemically by incubating HEK cells for 16-24 hours with cobalt chloride ($CoCl_2$). NKCC2 protein expression was monitored by immunoblotting in HEK cells transfected with the co-transporter. NKCC2 stability was assessed by cycloheximide chase assay.

Results: Similar to MAGE-D2, HSP40 co-expression increases also NKCC2 biogenesis. Subjecting HEK cells, transfected either stably or transiently with NKCC2, to a hypoxic microenvironment chemically induced by $CoCl_2$ (200-600 μM) significantly decreased total NKCC2 protein expression in a dose-dependent fashion. Cycloheximide chase assay revealed that in cells subjected to chemical hypoxia, NKCC2 stability and maturation are decreased. Interestingly, the effect of hypoxia on NKCC2 maturation was more severe following HSP40 or MAGE-D2 knockdown. Even more impressive, simultaneous knockdown of MAGE-D2 and HSP40 strikingly aggravated the effect of cellular hypoxia on NKCC2 maturation (> 99%).

Conclusions: Our data indicate that cellular hypoxia chemically induced by CoCl2 alters NKCC2 stability and maturation. Most importantly, our findings strongly suggest that MAGE-D2 cooperates with HSP40 to protect NKCC2 against ER associated degradation induced by cellular hypoxia, which could explain, at least in part, the transient nature of antenatal Bartter's syndrome in carriers of *MAGED2* mutations.

FR-PO616

Actinin-4 (ACTN4) Interacts with ALMS1 and NKCC2 in Thick Ascending Limbs (TAL) to Regulate NKCC2 Trafficking

Dipak Maskey, Gustavo R. Ares, Pablo A. Ortiz. Ortiz lab *Henry Ford Hospital, Detroit, MI.*

Background: Loss-of-function mutations in the *ALMS1* gene cause Alström syndrome, characterized by hypertension, early onset obesity, type 2 diabetes and progressive loss of renal function. Single nucleotide polymorphisms (SNPs) in the *ALMS1* gene are associated with decreased renal function (lower GFR) and increased pulse pressure in the general population. However, the role of ALMS1 in the control of renal function is unclear. We recently found that ALMS1 physically interacts with the apical renal Na/K/2Cl cotransporter NKCC2 in the TAL, where it mediates its endocytosis. However, the molecular mechanisms by which ALMS1 mediates NKCC2 endocytosis are unclear. We hypothesized that ALMS1 is part of a protein complex that binds apical NKCC2 and promotes its endocytosis and recycling.

Methods: To begin studying these mechanisms we used a targeted proteomics screen to identify new binding partners for ALMS1 in the TAL as well as immuno-precipitation.

Results: GST-pull down with the C-terminus of ALMS1 identified several trafficking proteins. One of them, Actinin-4 (ACTN4), is involved in endocytosis and its mutation causes focal segmental glomerular disease. GST-ACTN4 (full length) pulled down both ALMS1 and NKCC2 from TALs. Immunoprecipitation of NKCC2 followed by mass spectrometry identified ACTN4. The role of ACTN4 in the nephron is unclear so we studied its localization. ACTN4 was abundant in glomeruli but also localized in cells along the nephron in a punctate vesicular pattern. ACTN4 was located in TALs (co-labeled with NKCC2) and co-localized with ALMS1 n the subapical space. To study the role of ALMS1 and ACTN4 we generated a mouse line with doxycycline (Dox) inducible nephron-specific deletion of ALMS1 (Dox-inducible-Pax8-Cre-ALMS1fl/fl). 4 weeks after finishing Dox treatment, ALMS1 expression in medullary tubules was decreased by 78±14% ($p<0.05$). Interestingly, ACTN4 expression was also decreased by 45±9% ($p<0.05$) in nephron specific ALMS1 KO, compared to doxycycline treated controls (ALMS1fl/fl). In isolated mouse TALs, the surface to total NKCC2 ratio was increased by 55±19% ($p<0.05$), suggesting decreased retrieval from the surface.

Conclusions: We conclude that ACTN4 binds both ALMS1 and NKCC2 and ALMS1 is required for proper NKCC2 trafficking. Our data suggest that ACTN4 plays a role in tubular Na absorption in addition to its role in podocytes.

N-Terminal Phosphorylation of Kidney Na-K-2Cl-Cotransporter Attenuates Its Endocytosis

Kerim Mutig, Anna-Lena Munk, Sebastian Bachmann. *Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: The renal Na-K-2Cl-cotransporter (NKCC2) of the thick ascending limb (TAL) is critical for renal salt handling. Its activity is stimulated by phosphorylation of conserved N-terminal threonine and serine residues (T96, T101, T114, and S126), although the underlying mechanisms are not entirely clear. We hypothesized that NKCC2 phosphorylation interferes with its clathrin-mediated endocytosis.

Methods: Cellular distribution of NKCC2 and its phosphorylated form (pNKCC2) was evaluated in rat kidney and cultured rat TAL cells by high-resolution immunofluorescence, electron microscopy and biochemical tissue fractionation by sucrose gradient. Association of NKCC2 and pNKCC2 with clathrin was studied by binding assays.

Results: Labeling of rat kidney sections for NKCC2 revealed its even distribution between the luminal membrane and apical vesicular compartment, whereas pNKCC2 resided predominantly in the luminal membrane. Analysis of NKCC2, pNKCC2 and clathrin distribution in apical membrane fragments obtained from cultured TAL cells using the rip/flip technique showed regular co-localization of NKCC2- and clathrin immunogold signals, whereas pNKCC2 signal localized to clathrin-negative electron-dense membrane domains containing the lipid raft marker flotilin-1. In line with this, isolation of detergent-resistant membrane rafts from rat kidney tissue using extraction with Triton X-100 and subsequent sucrose gradient centrifugation revealed co-distribution of pNKCC2 and flotilin-1 signals in rafts-containing low-density gradient fractions, whereas clathrin signal was present in non-raft high-density fractions. GST pull down assays showed interactions of clathrin with recombinant N-terminal NKCC2 mutants mimicking its dephosphorylation (S/T->A), whereas mutants mimicking the phosphorylated N-terminus (S/T->D) did not bind clathrin. Acute *in vivo* stimulation of NKCC2 phosphorylation by treating vasopressin-deficient Brattleboro rats with desmopressin (1ng/kg body weight for 30 min) attenuated its co-immunoprecipitation with clathrin (-72%, $p<0.05$) and increased NKCC2 surface expression (+24%, $p<0.05$).

Conclusions: In sum, these results suggest that NKCC2 phosphorylation inhibits its clathrin-mediated NKCC2 endocytosis resulting in increased NKCC2 surface expression and activity.

Role of Vasopressin V2 Receptor Signaling in NKCC2 Regulation in Diabetes Mellitus

Kazuhiro Sakai, Osamu Yamazaki, Kenichi Ishizawa, Yoshikazu Nemoto, Yoshihide Fujigaki, Shigeru Shibata. *Teikyo University, Tokyo, Japan.*

Background: Previous studies have reported that vasopressin V2 receptor is present in thick ascending limb (TAL) of loop of Henle and can regulate the abundance of Na-K-2Cl cotransporter (NKCC2). Nonetheless, the upstream signaling and the pathological significance in a disease state remains obscure. We aimed to address the role of vasopressin V2 signaling in TAL in diabetic kidney disease.

Methods: We compared the levels of aquaporin 2 and NKCC2 in the membrane fraction of the kidney between db/+ and db/db mice. We then orally administered tolvaptan, vasopressin V2 receptor antagonist, to db/+ and db/db mice for two weeks and evaluated the changes in aquaporin 2 and NKCC2. To test the role of V2 signaling in humans, we obtained urinary exosomes from diabetic subjects treated with tolvaptan and compared the levels of aquaporin 2 and NKCC2 before and after the treatment.

Results: The administration of tolvaptan reduced aquaporin 2 abundance in db/+ mice. We also found that NKCC2 abundance was reduced by tolvaptan in this model. To evaluate the role of vasopressin signaling in diabetic kidney, we compared their levels between db/+ and db/db mice, and found that both aquaporin 2 and NKCC2 were significantly elevated in db/db mice (1.87-fold increase for aquaporin 2; $P = 0.03$, and 1.90-fold increase for NKCC2; $P<0.001$). Moreover, these levels were significantly reduced by tolvaptan administration, indicating the contribution of vasopressin V2 signaling in the kidney in db/db mice. To extend these observations into humans, we evaluated NKCC2 levels in urinary vesicles in subjects with diabetic kidney disease who received tolvaptan. Among 15 subjects examined, six showed response to tolvaptan, resulting in reduced aquaporin 2 levels in urinary exosome. In these cases, NKCC2 levels tended to reduce after the treatment.

Conclusions: Vasopressin V2 receptor signaling is involved in the regulation of NKCC2, which can be dysregulated in the kidney of diabetes mellitus.

FR-PO619

Functional Substrates of Vasopressin-Responsive PARylation in Kidney Collecting Duct Cells

Eui-Jung Park,[1] Hyun Jun Jung,[2] Hyo-Jung Choi,[1] Hyo-Ju Jang,[1] Hye-Jeong Park,[1] Tae-Hwan Kwon.[1] *[1]Kyungpook National University, Taegu, Republic of Korea; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Poly (ADP-ribose) polymerases (PARPs) regulate cellular progress, such as cell cycle, cell proliferation and differentiation, through molecular regulation of protein-protein interactions and protein stability. In our previous study, cellular poly ADP-ribosylation (PARylation) was induced by vasopressin treatment in mpkCCD cells. The present study aimed to examine regulation of PARylation as a part of vasopressin signaling in renal collecting duct (CD) cells.

Methods: We examined 1) vasopressin-responsive PARylation in mpkCCD cells using pulldown assay of biotin-conjugated NAD^+ and immunoprecipitation assay using PAR (poly ADP-ribose) antibody; 2) immunoblotting for PARP1 abundance in nuclei and cytoplasm. Substrate proteins of PARP1 in kidney CD cells were identified from data mining in multiple public databases. Functional enrichment of PARP1 substrates was analyzed using Metascape.

Results: dDAVP (10^{-9} M, 24 h) remarkably increased abundance of total PARylated proteins in mpkCCD cells in biotin-NAD^+ pulldown and PAR immunoprecipitation assays. Interestingly, the cleavage of PARP1 was induced by both short-term (2 h, 6 h) and long-term (24 h, 48 h) dDAVP (10^{-9}M) treatment, suggesting that vasopressin signaling affects PARP1 action. Immunoblots using subcellular fractions of mpkCCD cells confirmed the cleaved form of PARP1 produced by dDAVP treatment was exported to the cytosolic fraction. dDAVP-induced AQP2 mRNA and protein expression was significantly attenuated under siRNA-mediated PARP1 knockdown conditions in mpkCCD cells. From a data mining approach, we identified 752 substrate proteins of PARP1 and 171 proteins interacting with PARP1 in kidney CD cells. Among them, 72 proteins were found across all the matches, suggesting as putative targets of PARP1 in the kidney collecting duct. Functional enrichment analysis revealed that these PARP1 substrates are involved in DNA damage repair, gene transcription, insulator function and DNA methylation, which have been known as cellular functions of PARP1.

Conclusions: Vasopressin-responsive PARylation is accompanied with remarkable changes in protein abundance and cleavage of PARP1 in kidney CD cells. Bioinformatic approaches identified putative PARP1 substrates and functional clustering of the identified substrates that could be involved in vasopressin signaling in the kidney CD cells.

FR-PO620

SNX27, Interacting with AQP2 in a PDZ-Dependent Manner, Regulates the Stability of AQP2 Protein

Hyo-Jung Choi,[1] Hyo-Ju Jang,[1] Eui-Jung Park,[1] Hyun Jun Jung,[2] Hye-Jeong Park,[1] Tae-Hwan Kwon.[1] *[1]Kyungpook National University, Daegu, Republic of Korea; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Sorting nexin 27 (SNX27), a PDZ domain-containing protein, is known to cooperate with a retromer complex, regulating the trafficking and stability of membrane proteins. The carboxyl-terminus of aquaporin-2 (AQP2c) has the class I PDZ-interacting motif (X-T/S-X-Φ), however, interaction between SNX27 and AQP2 has

not been studied. We aimed to examine the interaction of SNX27 for the regulation of AQP2.

Methods: GST-SNX27 constructs [SNX27-Full Length, Δ(PX+FERM), ΔFERM, ΔPDZ, and Δ(PDZ+PX)] were generated, and the purified proteins were incubated with His-tagged AQP2c protein *in vitro*. Coimmunoprecipitation (Co-IP) assay was performed using rat kidney inner medullary collecting duct (IMCD) tubule suspension. Immunoblotting and immunolabeling were carried out in SNX27 siRNA-transfected mpkCCD cells. Autophagy was examined using autophagosome marker (mRFP-GFP-LC3).

Results: Co-IP and GST pull-down assays demonstrated that PDZ domain of SNX27 directly interacted with AQP2c. Immunocytochemistry of HeLa cells co-transfected with Flag-SNX27 and HA-AQP2 revealed that AQP2 co-localized with the intact SNX27, suggesting that a PDZ domain of SNX27 is required for the interaction with AQP2. Removal of PDZ domain (SNX27-ΔPDZ) induced accumulation of AQP2 at the perinuclear region in HeLa cells. Immunohistochemistry revealed colocalization of SNX27 and AQP2 at both cytoplasm and plasma membrane in rat kidney CD cells. Subcellular redistribution of SNX27 under dDAVP stimulation/withdrawal was almost identical with AQP2 in rat kidney. Cell surface biotinylation assay showed that dDAVP-induced AQP2 translocation to the apical plasma membrane of mpkCCD was not affected by SNX27 knockdown. Immunoblotting revealed that dDAVP-induced AQP2 up-regulation was significantly blunted by SNX27 knockdown, whereas qRT-PCR showed no change of AQP2 mRNA expression. During dDAVP withdrawal, decrease of AQP2 expression in mpkCCD cells with SNX27 knockdown was significantly attenuated by chloroquine, but not by MG132. Moreover, SNX27 knockdown remarkably induced autophagy in mpkCCD cells expressing LC3.

Conclusions: SNX27, directly interacts with AQP2 in a PDZ-dependent manner, is likely to regulate stability of AQP2 protein. It acts as a component of the AQP2 controlling machinery, at least in part, through regulation of autophagy-lysosomal degradation of AQP2.

Possible Involvement of Upregulated Arginine Vasopressin in Fluid Retention on Peritoneal Dialysis

Kenya Sanada, Hiromichi Ueno, Kazutoshi Nakazono, Yoko Fujimoto, Yoichi Ueta, Yutaka Otsuji, Tetsu Miyamoto. *University of Occupational and Environmental Health, Kitakyushu, Japan*.

Background: Fluid retention is a typical complication of peritoneal dialysis (PD), and interferes with the safety and long-term delivery of PD. Arginine vasopressin (AVP), which is synthesized in the hypothalamus, is involved in water reabsorption in the collecting ducts and could be involved in fluid retention. Here, we examined hypothalamic AVP synthesis during PD in both basic and clinical research.

Methods: 1) First, after administration of 3% hypertonic saline (HTN) as dialysis solution for a short-term dwell or polyethylene glycol (PEG) as dialysis solution for a long-term dwell, we evaluated the fluorescence intensity of AVP-enhanced green fluorescent protein (eGFP) in the hypothalamus. The intensity of eGFP offers a quantitative indicator of AVP synthesis in transgenic rats. Second, we quantified Fos-like immnoreactive (IR) cells in several brain regions known to be involved in maintaining fluid homeostasis by control of AVP synthesis and/or having interactions with the hypothalamus. 2) We measured plasma AVP levels, plasma osmolality and urinary osmolality in 20 PD patients during visits.

Results: 1) Fluorescence intensities for eGFP were significantly increased in the hypothalamus after administration of HTN and PEG. Immunohistochemistry for Fos revealed activation of several brain areas after administration of HTN and PEG. 2) Plasma AVP levels (5.5 ± 0.6 pg/mL) and plasma osmolality (303.4 ± 1.6 mOsm/kgH_2O) increased significantly in PD patients, and these values were correlated (Rho = 0.56, P = 0.02, n= 20). In addition, a positive correlation was observed between plasma AVP levels and urine osmolality (Rho = 0.65, P = 0.03). Given these findings, we considered that the physiological function of AVP remained in PD patients.

Conclusions: To the best of our knowledge, this represents the first report to reveal an upregulation of hypothalamic AVP during PD by performing both basic and clinical research. Upregulation of hypothalamic AVP could induce fluid retention. These findings provide potential insights into fluid management for PD patients.

FR-PO622

WNK1 as a Central Osmosensor for Vasopressin Release and Water Homeostasis

Maniselvan Kuppusamy, Jian Xie, Chou-Long Huang. *University of Iowa Carver College of Medicine, Iowa City, IA*.

Background: The brain circumventricular organs organum vasculosum lamina terminalis (OVLT) and subfornical organ (SFO) lack blood-brain barrier and function as sensors for systemic osmolality. Hyperosmolality activates neurons in OVLT and SFO, leads to vasopressin production in cell bodies of magnocellular neurons in the paraventricular and supraoptic nuclei of hypothalamus and release through axonal termini in the posterior pituitary. Previous work focused on cell membrane resident proteins such as mechanosensitive channels TRPV1 and V4 as candidates of osmosensors. Results of knockout animal studies yet are conflicting. Compared to membrane proteins by responding to stretch, intracellular proteins may be better positioned to sense cell water content in response to changes in extracellular osmoles. WNK kinases are activated by hyperosmolality. We investigated the role of WNK1 in central osmosensing.

Methods: *Wnk1*-floxed mice were bred with synapsin-Cre mice to generate neuronal-specific *Wnk1*-knockout (KO) mice.

Results: Under *ad lib* water and food intake, average daily urine output was higher in KO mice (n = 6) than in control mice (n = 8) (1.57 ± 0.17 ml vs 1.03 ± 0.15 ml, $p < 0.05$). Daily water intake was also higher in KO than in control (4.84 ± 0.25 ml vs 4.14 ± 0.21 ml, $p < 0.05$). Serum osmolality in KO mice trended higher but not statistically significantly different from control (314 ± 4 vs 307 ± 3 mOsm/kg, p = 0.18). Urine osmolality was lower in KO than in control mice. The pattern of serum and urine osmolality suggests that defects in vasopressin release or action (i.e., diabetes insipidus) rather than primary polydipsia or osmotic diuresis as the cause of polyuria. To further distinguish between these possibilities, mice were water-deprived for 24 hrs. Urine output remained elevated in KO than control mice under water deprivation (1.17 ± 0.13 ml vs 0.63 ± 0.08 ml, $p < 0.05$). Serum osmolality was increased and the difference between KO and control was amplified by water deprivation (329 ± 4 vs 312 ± 3 mOsm/kg, $p < 0.01$). To support the hypothesis of blunted vasopressin release in neuronal *Wnk1*-KO, work is ongoing to measure serum vasopressin and copeptin levels in KO & control mice.

Conclusions: Our results suggest that WNK1 protein may function as an intracellular osmosensor for regulating vasopressin release.

FR-PO623

Functional Characterization of Gain-of-Function Mutations of the V2 Vasopressin Receptor Leading to Nephrogenic Syndrome of Inappropriate Antidiuresis (NSIAD)

Marianna Ranieri,[1] Grazia Tamma,[1] Vanessa Vezzi,[2] Annarita Di Mise,[1] Maria Venneri,[1] Mariangela Centrone,[1] Susanna Cotecchia,[1] Giovanna Valenti.[1] *[1]University of Bari, Bari, Italy; [2]Istituto Superiore di Sanità, Rome, Italy*.

Background: Nephrogenic Syndrome of Inappropriate Antidiuresis (NSIAD) is a chromosome X-linked disease associated to gain-of-function mutations of the V2 vasopressin receptor (V2R), a G protein-coupled receptor. NSIAD can be quite severe in affected male children. It is characterized by inability to excrete a free water load, hyponatremia, and undetectable vasopressin circulating levels.

Methods: In this study, we have expressed the wild type V2R and three constitutively active V2R mutants, the R137L, R137C and the F229V in MCD4 cells, a cell line derived from renal mouse collecting duct, stably expressing the vasopressin-sensitive water channel Aquaporin-2 (AQP2).

Results: In cells expressing each active mutant, AQP2 was constitutively localized to the apical plasma membrane, in the absence of vasopressin stimulation. Conversely, in cells expressing the wild type V2R, AQP2 was localized in intracellular vesicles and redistributed to the apical membrane in response to vasopressin. In line with these observations, under basal conditions, osmotic water permeability of each constitutively active mutant was significantly higher compared with that of cells expressing the wild type V2R. Interestingly, specific inhibition of PKA reduced the basal osmotic water permeability only in F229V expressing cells, indicating the activation of a PKA-dependent pathway. Conversely, for the R137L and R137C mutants a PKA-independent signalling leading to redistribution of AQP2 and consequent increase in osmotic water permeability is predicted.

Conclusions: Our findings demonstrate, for the first time, a direct link between the activating mutations of the V2R and the alteration of water permeability in cells expressing V2R mutants providing a rationale for the water balance disturbance observed in NSIAD.

FR-PO624

UT-A2-Mediated Water Transport Is Regulated by N-Glycosylation

Jessica Kabutomori, Neydiana Pina-Lopes, R. R. Geyer, Raif Musa-Aziz. *Sao Paulo Univ., Sao Paulo, Brazil*.

Background: Urea transporters (UTs) are transmembrane glycoproteins that facilitate the diffusion of urea across cell membranes, and play a crucial role in the urinary concentrating mechanisms, important for maintaining nearly constant blood plasma osmolality. Renal UTs include: UT-A1 and UT-A3, which are expressed on the apical and basolateral membranes of the inner medullary CD, respectively; UT-A2, localized in the thin descending limb of the inner and outer renal medulla; and UT-B, expressed in the endothelial cells of the descending vasa recta and red blood cells. The X-tal structure of bovine UT-B shows that three monomers assemble to form a homotrimer. Each monomer contains 10 transmembrane helices folded into independent urea channels. Helices 5 and 6 are connected by an extracellular loop that can be glycosylated. Indeed, protein glycosylation is known to modulate protein structure/activity. UT-A2 is glycosylated at Asparagine-210, yielding 45 kDa and 55 kDa glycoforms. Previously, we showed that wild-type mouse UT-A2 (mUT-$A2^{WT}$) enhances water transport when expressed in *Lithobates catesbeianus* oocytes, and that two conserved Threonine residues (T176 and T338) are required for this transport. Here, we investigated the role of glycosylation on UT-A2-mediated water transport.

Methods: First, the N210 residue of mUT-A2 was mutated to glutamine (Q), generating UT-$A2_{N210Q}$. Next, mUT-$A2^{WT}$ and UT-$A2^{N210Q}$ (c-Myc tagged) cRNA, or H_2O was injected into *Lithobates* oocytes. UT-A2 cell surface expression was assessed by biotinylation and western blot analyses, with and without PNGase F. P_f was assessed by placing the oocytes in a hypotonic solution and monitoring the rate of cell swelling with video microscopy.

Results: We observed an immunoreactive band at 34 kDa after treating mUT-$A2^{WT}$ with PNGase F, a molecular weight consistent with unglycosylated monomer. No bands

were detected in the 45-55 kDa range with mUT-A2^{N210Q}, indicating lack of glycosylation. The P_f value for mUT-A2^{WT} (0.0013±0.0001, n=27) was significantly greater than UT-A2^{N210Q} (0.0005±0.00004, n=25) and H_2O oocytes (0.0006±0.00004, n=30).

Conclusions: These results indicate that the oocytes were not only capable of adding N-linked glycans to membrane proteins, but also that this post-translational modification affects activity. This observation is relevant to urine concentration mechanisms.

Drug-Induced Hyponatremia: Vasopressin-2 Receptor-Dependent and -Independent Pathway

Gheun-Ho Kim,[1] Chor ho Jo,[2] Sua Kim.[2] *[1]Hanyang University College of Medicine, Seoul, Republic of Korea; [2]Hanyang University, Seoul, Republic of Korea.*

Background: Drugs associated with hyponatremia were traditionally classified into those enhancing vasopressin release and those potentiating the renal action of vasopressin. For the latter mechanism to act, vasopressin-2 receptor would have the pivotal role in activating aquaporin-2 in the collecting duct. However, vasopressin-2 receptor-independent pathways might be activated as well by drugs that induce renal water retention. This preliminary study was undertaken to find antidiuretic drugs acting through vasopressin-2 receptor-independent pathways.

Methods: Five drugs or active metabolites were treated in inner medullary collecting duct suspensions prepared from male Sprague-Dawley rats. The intracellular cAMP levels were determined using a competitive enzyme immunoassay kit to compare the responses with and without tolvaptan (100 nM) cotreatment. Also, dDAVP (10 nM) was used as positive control.

Results: As expected, dDAVP induced an increase in cAMP production (20.7 ± 2.0 vs. 11.4 ± 0.6 pmol/mg protein, P<0.05) Similarly, haloperidol (14.7 ± 0.9 pmol/mg protein, P<0.05), sertraline (18.7 ± 0.9 pmol/mg protein, P<0.05), and carbamazepine (17.3 ± 0.7 pmol/mg protein, P<0.05) had higher levels of cAMP. These responses were almost completely blocked by tolvaptan cotreatment (haloperidol, 8.5 ± 0.5 pmol/mg protein; sertraline, 12.6 ± 1.2 pmol/mg protein; carbamazepine 12.5 ± 0.7 pmol/mg protein, all P<0.05). Notably, the cAMP level was increased by vincristine treatment (16.7 ± 1.6 pmol/mg protein, P<0.05), but not reversed by tolvaptan cotreatment. On the other hand, chlorpropamide did not induce any change in cAMP with and without tolvaptan cotreatment.

Conclusions: As known before, chlorpropamide appears to enhance vasopressin release. Contrary to a previous notion, vincristine may induce water retention via vasopressin-2 receptor-independent pathways. Activation of vasopressin-2 receptor has a role in hyponatremia induced by haloperidol, sertraline, and carbamazepine.

Intracellular Sites of AQP2 S256 Phosphorylation in the Plasma Membrane, Cytoplasmic Vesicles, and the Trans Golgi Network Identified Using Inhibitors of the AQP2 Recycling Itinerary

Richard Bouley, Pui Susan W. Cheung, Dennis Brown. Program in Membrane Biology *Massachusetts General Hospital, Boston, MA.*

Background: Vasopressin-regulated trafficking of aquaporin 2 between cytoplasmic vesicles and the plasma membrane of kidney principal cells is essential for body water homeostasis. VP-induced phosphorylation of AQP2 at serine residue S256 is required for its accumulation at the cell membrane, but the intracellular location(s) where this phosphorylation occurs remains poorly understood. Here, we used strategies to block AQP2 trafficking at different cellular locations in LLC-PK1 cells, and we monitored phosphorylation of AQP2 S256 at these sites using anti-phospho S256 antibodies after vasopressin/forskolin (VP/FK) stimulation.

Methods: Phosphorylation extent and location were assessed by western blotting and immunocytochemistry, respectively.

Results: Methyl-b-cyclodextrin (MBCD) treatment blocks endocytosis, and recycling AQP2 accumulates at the cell surface without an increase in S256 phosphorylation. However, VP/FK applied to MBCD treated cells resulted in a significant increase in S256 phosphorylation, indicating AQP2 can be phosphorylated when present in the plasma membrane. Taxol, an inhibitor of microtubule function, results in AQP2 containing vesicles being scattered throughout the cytoplasm, and inhibits VP-induced membrane accumulation of AQP2. Taxol alone did not affect AQP2 phosphorylation, but VP/FK treatment of taxol exposed cells caused a significant increase in S256 phosphorylation, indicating that AQP2 can be phosphorylated on scattered cytoplasmic vesicles. Finally, AQP2 trafficking is blocked in the peri-nuclear, trans-Golgi network both by incubating cells at 20°C for 2 h or by using the V-ATPase inhibitor bafilomycin. VP/FK stimulated AQP2 phosphorylation significantly under both conditions.

Conclusions: These findings suggest that the VP/FK induced phosphorylation of AQP2 at S256 can occur at various locations during its recycling itinerary to and from the cell surface; at the plasma membrane itself, on cytoplasmic vesicles, or in the trans-Golgi network. Whether protein kinase A is involved in AQP2 S256 phosphorylation in all these locations is unclear, but the ability to dissect different intracellular phosphorylation stations may help to uncover new strategies to regulate AQP2 trafficking in conditions such as nephrogenic diabetes insipidus and hyponatremia.

Urinary Net Endogenous Acid Production: A Reliable Predictor of Net Acid Excretion

Tanushree Banerjee,[1] Lynda A. Frassetto.[2] *[1]San Francisco General Hospital, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA.*

Background: High acid production and positive acid balance have been associated with progression of chronic kidney disease (CKD) and degenerative aging processes. Endogenous acid production (EAP) equations that most accurately represent net acid excretion (NAE) require analyses of diet and stool unmeasured anions and a research lab to measure titratable acids and bicarbonate, a somewhat complicated research protocol. Being able to evaluate only urinary analytes might be easier. Here, we evaluate the predictive value of urinary measured (EAP) and unmeasured anions (UNEAP) to the measured value of NAE.

Methods: 24 hour urine collections from metabolic balance studies from 15 patients for repeated intervals were performed at the control period (baseline), diet intervention phase, and the recovery phase. Each phase was at least 3 days. NAE was calculated from measured values (= titratable acid + ammonium – bicarbonate). UNEAP was calculated from urinary [(phosphate+chloride)-(sodium+potassium+calcium)] + sulfate (SO4) + total organic acid (OA) production. EAP = urinary SO4+ OA salts. We used mixed effects model with repeated measures to assess agreement between the estimated and measured value of NAE.

Results: Assessment between these measures showed a high correlation between UNEAP and NAE (r=0.85, p<0.001). EAP underestimated the measured value of NAE by 9.7 mEq/d and the difference in the means was statistically significant (p=0.003) with the 95% limits of agreement between the differences being -32.5 mEq/d to 12.9 mEq/d. On the other hand, there was a non-significant difference in the means (3.24 mEq/d) between UNEAP and NAE with the 95% limits of agreement being -25.5 mEq/d to 32.0 mEq/d.

Conclusions: Using only urine measures, UNEAP was a more reliable estimate of NAE compared to EAP. Measures for estimating UNEAP may be less cumbersome than measuring NAE and help promote research into treatments that affect acid balance, such as alkali treatment for CKD.

Pseudohypobicarbonatemia Induced by Severe Hypertriglyceridemia

Vipin Varghese,[2] Juan Carlos Q. Velez.[2,1] *[1]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [2]University of Queensland - Ochsner Clinical School, New Orleans, LA.*

Background: Reports of falsely low serum carbon dioxide (sCO_2) concentration, i.e., pseudohypobicarbonatemia (psHypoHCO$_3^-$) in patients with severe hypertriglyceridemia (hyperTG) have emerged. This phenomenon results from lipid interference in some spectrophotometric analyzers. Our aim was to assess the magnitude and implications of psHypoHCO$_3^-$ in a tertiary care hospital.

Methods: We searched for cases of serum triglycerides (TG) > 1000 mg/dL with a concomitant (measured <24 hrs apart) sCO_2, between 2017 and 2018. We extracted those with $sCO_2 \leq 12$ mEq/L to focus on the more clinically relevant cases. Each measured sCO_2 was compared with the calculated bicarbonate (HCO$_3^-$) from an arterial blood gas (ABG) obtained within 6 hrs of the venous blood draw. PsHypoHCO$_3^-$ was defined as: erroneous HCO$_3^-$ (eHCO$_3^-$) gap = (calculated HCO$_3^-$ - measured sCO_2) > 5 mEq/L.

Results: We identified 1698 events (652 patients) of TG > 1000 mg/dL and a sCO_2 measured on the same day. TG inversely correlated with sCO_2 (R=-0.38, p=0.00001). We found 179 events (59 patients) with sCO_2 < 12 mEq/L. In 104 of those, an ABG was either not available or performed > 6 hrs apart from the venous blood draw. The remaining 75 events included 30 instances (11 patients) of true hypobicarbonatemia and 45 instances (24 patients) of psHypoHCO$_3^-$. Among those with psHypoHCO$_3^-$, the median values of sCO2, calculated HCO$_3^-$, anion gap and eHCO$_3^-$ gap were 8 (<5 – 12), 20 (10 - 28), 21 (15 – 29) and 13 (5 – 19) mEq/L, respectively, whereas the median pH was 7.37 (7.14 - 7.56). True metabolic acidosis was either absent (42%) or spuriously magnified (58%). TG directly correlated with the eHCO$_3^-$ gap (R=0.59, p=0.00004). Acute pancreatitis (56%) and diabetic ketoacidosis (38%) were the most common concomitant disorders but they did not fully account for the eHCO$_3^-$ gap in the psHypoHCO$_3^-$ cases. Additionally, unnecessary HCO$_3^-$ therapy was initiated in 16% and serum lactate was measured in 80% of the psHypoHCO$_3^-$ events (lactate was normal in 72%).

Conclusions: Severe hyperTG can lead to spuriously low sCO_2. The degree of hyperTG correlates with the magnitude of PsHypoHCO$_3^-$. Clinicians and laboratory personnel should be aware of this phenomenon to prevent incorrect interpretation of acid-base status and medical mismanagement.

FR-PO629

Spurious Low Serum Bicarbonate Level due to Severe Hypertriglyceridemia: A Clinical Challenge

Ali Pardis Dana,[2] Amir Kazory.[1] *[1]University of Florida, Gainesville, FL; [2]Vista Del Mar Medical Group, Inc, Oxnard, CA.*

Introduction: A low serum bicarbonate level (SBL) in the presence of a high anion gap (AG) generally indicates presence of metabolic acidosis secondary to an increase in unmeasured anions. Herein, we report 2 patients with profound hypertriglyceridemia (HTG) who presented with low measured SBL and a high AG. Evaluation revealed that the low SBL was spurious and resulted from extremely high serum triglyceride (TG) levels; once HTG was treated, the reported SBL was corrected.

Case Description: The first patient is a 48-year old man with a history of chronic pancreatitis secondary to severe HTG. He was admitted for acute pancreatitis and was found to have a serum TG of 3267 mg/dl. He had normal renal function and electrolytes but SBL was reported <5 mmol/l on chemistry panel with an AG of >28. However, arterial blood gas (ABG) revealed absence of acidemia with PH 7.4, PCO2 35, PO2 84, and bicarbonate 23 suggesting presence of spurious low SBL. Therapeutic plasma exchange (TPE) resulted in rapid improvement of HTG to 731 mg/dl the next day; SBL rose simultaneously to 18 mmol/l confirming the diagnosis. The second patient is a 26-year old woman with a history of diabetes who was admitted for acute pancreatitis. She was found to have a serum TG level of 10,950 mg/dl. SBL on routine chemistry panel was reported 9 mmol/l with an AG of 27. ABG showed pH 7.4, PCO2 37, PO2 75 and bicarbonate 23.7. She underwent 3 sessions of TPE, which lowered her serum TG to 1420 mg/dl and raised measured SBL to 18 mmol/l within 3 days with no additional intervention.

Discussion: Accurate assessment of bicarbonate is essential for the diagnosis of acid-base disturbances. Bicarbonate can be "measured" in serum as total carbon dioxide (tCO2) or "calculated" from ABG analysis (Henderson-Hasselbalch equation). In most instances, tCO2 and bicarbonate are closely related due to the constancy of the apparent dissociation constant of blood carbonic acid (pK'). Presence of a marked difference between the two values creates a clinical challenge that should prompt identification of a cause. Severe HTG interferes with laboratory testing in several ways (e.g. turbidity) and should be considered in the settings where there is no clinically apparent reason for low SBL. These 2 cases highlight the need for the clinicians to keep severe HTG in the differential diagnosis of SBL to avoid management errors.

FR-PO630

Medications Containing H^+ Salts Are Associated with Lower Serum Total CO_2 and Higher Serum Anion Gap in Patients With Non-Acidotic Diabetic Kidney Disease

John W. Gardner, Kalani L. Raphael, Kunani Tuttle. *VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Metabolic acidosis (MA) is associated with adverse clinical consequences in CKD. Many medications contain H^+-salts which could contribute to development of MA. This study determined the association between H^+ load from medications (med-H^+ load) and acid-base indices in patients with diabetic kidney disease (DKD) but without MA.

Methods: We conducted this cross-sectional study in 74 US veterans with DKD (eGFR 51±18 ml/min/1.73m^2) and serum tCO_2 24±2 meq/L. None were treated with alkali. The daily H^+ load from medications containing H^+-salts was determined using the daily dose, molecular weight, and valence of the agents. Participants were categorized into a low or high med-H^+ load group using a threshold of 7.7 meq/d, which is the equimolar amount of HCO_3^- in one 650mg $NaHCO_3$ tablet required to mitigate this H^+ load. We compared serum (tCO_2 and anion gap) and urinary (NH_4^+, titratable acids [TA], and pH) acid base indices between groups using linear regression models adjusted for eGFR, ACR, protein intake, and other potential confounders.

Results: 40 of 123 (33%) medications prescribed contained H^+-salts. Two agents contributed ≥1 meq/d of H^+, metformin (9.7±3.3 meq/d) and gabapentin (5.9±3.7 meq/d). 29 of 74 (39%) participants were in the high med-H^+ load group. In the high and low groups, 93% vs 13% received metformin and 55% vs 18% received gabapentin. Mean±SD med-H^+ load was 14.2±4.3 in the high and 1.6±2.4 meq/d in the low group. Those in the high group had significantly lower tCO_2 and higher serum anion gap after adjustment (table). Metformin use and gabapentin use (irrespective of dose) were modestly associated with lower serum tCO_2 and higher anion gap. Med-H^+ load did not seem to impact urinary acid excretion.

Conclusions: Medications containing H^+-salts, particularly metformin and gabapentin, contribute to meaningful differences in serum tCO_2 and anion gap in patients with non-acidotic DKD, suggesting that these agents may be novel risk factors for MA in DKD.

Funding: Veterans Affairs Support

Variable	High vs Low Acid Load	Metformin Use vs No	Gabapentin Use vs No
Serum total CO2 (meq/L)	-1.74 (-3.02 to -0.45)	-1.18 (-2.41 to 0.04)	-0.99 (-2.24 to 0.25)
Serum anion gap (meq/L)	2.16 (0.88 to 3.44)	1.69 (0.47 to 2.91)	1.19 (-0.08 to 2.46)
Urinary NH4+ (meq/hr)	0.15 (-0.20 to 0.50)	0.16 (-0.16 to 0.49)	0.11 (-0.22 to 0.44)
Urinary Titratable Acids (meq/hr)	0.00 (-0.25 to 0.25)	-0.12 (-0.35 to 0.11)	-0.11 (-0.35 to 0.12)
Urine pH	-0.08 (-0.33 to 0.17)	0.00 (-0.23 to 0.24)	-0.04 (-0.27 to 0.20)

FR-PO631

A Validated Anion Gap Threshold for High Anion Gap Metabolic Acidosis

Chang Yin Chionh, Wenxiang Yeon, Cheng boon Poh, Sreekanth Koduri, Debajyoti M. Roy. Changi REnal MEdicine REsearch (CREMERE) Group *Changi General Hospital, Singapore, Singapore.*

Background: The anion gap (AG), calculated by AG = $[Na^+]$–$[Cl^-]$–$[HCO_3^-]$, is often used to screen for acid-base disorders but cut-off levels used by clinical texts were based on empirical data. We recently sampled 300 healthy volunteers and the mean AG was 13±2mEq/L (manuscript in preparation). The proposed reference range (±2SD; central 95th percentile) was 9-17mEq/L. This study was to define a cut-off value for high AG metabolic acidosis (HAGMA).

Methods: Data from ICU patients from a prior study was used. Blood samples were classified into 2 groups: no HAGMA, or HAGMA present due to lactic acidosis, ketosis, citrate toxicity or severe uremia. The association of AG and HAGMA was tested by the Mann-Whitney U test. ROC analysis of AG was undertaken with optimal cut-off determined by Youden index.

Results: From 1,545 blood samples, 400 had adequate data. The median age was 64.7yrs, weight 60.1kg, 31.6% were females and 170 had HAGMA. With HAGMA, median AG was 19mEq/L (IQR 17–22) vs 15mEq/L (IQR 13–17) without HAGMA (P<0.001). AG has an AUC of 0.802 and the optimal cut-off was ≥17mEq/L (Fig. 1). The false negative rate (FNR) was 19.5%; false positive rate (FPR) 32.1%. Other AG thresholds were analysed (Table 1). As HAGMA may be life-threatening, a lower FNR is desired. The best FNR of 13.2% was with AG ≥13mEq/L, corresponding to mean AG of healthy persons, but FPR increased to 53.0%.

Conclusions: The recommended AG cut-off for HAGMA is ≥13mEq/L. This provides the best sensitivity but at the expense of specificity. As false negatives can still occur, acid-base status should be evaluated clinically, aided by repeated measurements of AG.

Table 1: Sensitivity & Specificity of AG Thresholds for HAGMA

AG cut-off	Specificity	False Positive	Sensitivity	False Negative
≥13 (Population Mean)	20.0%	53.0%	53.0%	13.2%
≥15 (Population Mean + 1SD)	44.3%	45.9%	45.9%	15.7%
≥17 (Population Mean + 2SD)	73.5%	32.1%	32.1%	19.5%

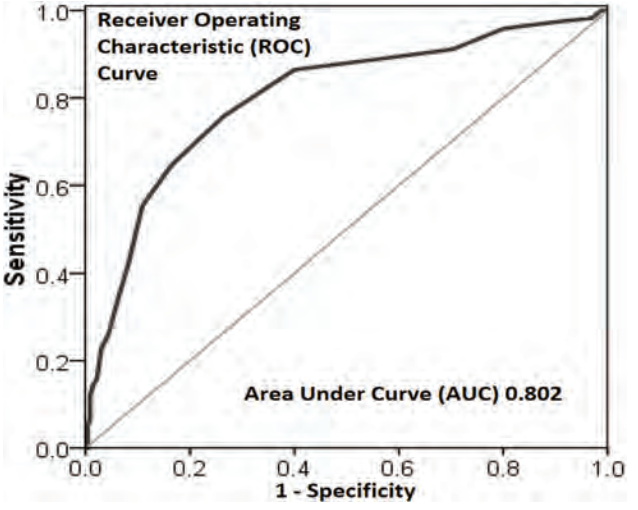

Fig. 1: ROC curve of AG for HAGMA

FR-PO632

Metabolic Acidosis Is Underdiagnosed and Undertreated in Patients with CKD

Navdeep Tangri. *Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Background: Metabolic acidosis is a common complication of chronic kidney disease (CKD) and is associated with adverse effects on physical function, accelerated CKD progression and increased mortality. Although chronic metabolic acidosis can be easily identified using routinely collected laboratory tests, there is limited data on its recognition and treatment.

Methods: We integrated laboratory data from 36 million US adults with de-identified longitudinal claims and prescription data from 280 million de-identified individuals included in the Symphony Health Solutions IDV® (Integrated Dataverse). Patients who met stringent laboratory criteria indicative of CKD and chronic metabolic acidosis were included: ≥2 eGFRs <60 ml/min/1.73m^2 with no intervening eGFR ≥60 ml/min/1.73m^2; ≥2 serum bicarbonates ≥12 to <22 mEq with no intervening bicarbonate <12 or ≥22 mEq/L; qualifying values ≥28 days apart. No patients with a diagnosis of acute kidney injury (AKI) within 28 days prior to either qualifying bicarbonate value were included. A physician diagnosis of metabolic acidosis was based on administrative claims, and treatment of metabolic acidosis was defined as a prescription for oral alkali therapy.

Results: Approximately 2.4 million individuals met laboratory criteria for CKD, 118,620 of those also met laboratory criteria for metabolic acidosis. Claims and prescription data were available for 86,782 individuals with both CKD and chronic metabolic acidosis. In this population, a diagnostic code for metabolic acidosis was present in only 21% of patients (N=19,038). The overall frequency of oral alkali therapy use was 15% (N=13,272) ranging from 10% in those without a diagnostic code for acidosis to 34% in those with the appropriate diagnostic code.

Conclusions: Metabolic acidosis is underdiagnosed and undertreated in US adults with CKD. Disease specific educational efforts as well as development of novel treatments is needed to improve outcomes for this important complication.

Dietary Protein Intake and Urinary Citrate Excretion in Asians

Leanne C. Leong,[1] Clara L. Ngoh,[1] Weng K. Wong,[1] Horng-Ruey Chua,[3] Titus W. Lau,[3] Boon Wee Teo.[2,1] *[1]National University Hospital, Singapore, Singapore; [2]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [3]National University Health System, Singapore, Singapore.*

Background: Dietary protein intake (DPI) is associated with acid loading. We hypothesize that urinary citrate excretion rate (UCER) is lower in patients with chronic kidney disease (CKD) having higher DPI. We examine the relationship between DPI and UCER in a multi-ethnic Asian population in patients with CKD and participants without kidney disease.

Methods: We used data from patients with stable CKD from the Asian Kidney Disease Study and normal participants without diabetes or hypertension from the Singapore Kidney Function Study. Participants fasted overnight, and provided a 24hr urine collection, blood sample, and underwent measured glomerular filtration test (mGFR; mL/min/1.73m^2) using ^{99m}Tc-DTPA. Daily protein intake (DPI, g/day) was calculated from 24-hour urine urea using Maroni's formula. Non-normal data was natural log-transformed for analysis. We performed univariate analysis of Ln UCER against the factors of age, gender, ethnicity, presence of CKD, Ln mGFR, and DPI. A multiple linear regression model was constructed including these variables to assess the association of DPI with UCER after adjusting for kidney disease and function.

Results: Complete data were available from 187 CKD patients (48.7%male) and 89 non-CKD participants (47.2% male) (p=NS). The mean ages were 59±12.8 years and 42±14.3 years in the CKD and non-CKD groups, respectively (p<0.001). The median mGFR in the CKD and non-CKD groups were 45 (IQR: 29-63) and 100 (IQR: 88-113), respectively (p<0.001). The median UCER (mmol/day) was lower in the CKD group (46, IQR: 11-106 vs. 303, IQR: 206-446) (p<0.001). No participant was on sodium bicarbonate supplementation. On univariate analysis, lower UCER was associated with increased age, presence of CKD, decreased mGFR, and decreased DPI (all p<0.001). Indians had higher UCER compared to Chinese and Malays (p<0.01). Gender was not associated with UCER. In a multiple linear regression model including these variables (RSq=0.53, p<0.001), daily protein intake is not significant (estimate 0.0084, p=0.0511).

Conclusions: After adjusting for presence of CKD, kidney function, age, ethnicity and gender, DPI is not significantly associated with UCER.

Funding: Government Support - Non-U.S.

A Comparison of the Effect of Sodium Bicarbonate on Acid-Base Indices in CKD Patients with and Without Diabetes: A Secondary Analysis of the BASE Pilot Trial

Kalani L. Raphael,[1,2] Brett Larive,[3] Tamara Isakova,[4] Joachim H. Ix,[5] Myles Wolf,[6] Dominic S. Raj,[7] Susan R. Mendley,[8] Linda F. Fried,[9] Cynthia A. Kendrick,[3] Jennifer J. Gassman,[3] Alfred K. Cheung.[1] The CKD Pilot Studies Consortium *[1]University of Utah, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT; [3]Cleveland Clinic, Cleveland, OH; [4]Feinberg School of Medicine, Northwestern University, Chicago, IL; [5]UCSD, San Diego, CA; [6]Duke University, Durham, NC; [7]GWU Medical Faculty Associates, Washington, DC; [8]NIDDK/NIH, Bethesda, MD; [9]VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: In CKD, those with diabetes mellitus (DM) tend to have higher urinary NH_4^+ (u-NH_4^+) excretion, lower urinary pH (u-pH), and in some studies, higher serum total CO_2 (s-tCO_2) than those without DM at the same level of eGFR. The comparative effect of $NaHCO_3$ supplementation on acid-base indices in those with and without DM is uncertain.

Methods: This was a secondary analysis from the Bicarbonate Administration to Stabilize eGFR (BASE) Pilot Trial, which was a randomized, double-blinded, placebo-controlled study to determine the safety and tolerability of two doses of $NaHCO_3$ in 194 CKD patients over 28 weeks. 90 participants received higher dose $NaHCO_3$ (0.8 meq/kg-lean/d), 52 received lower dose $NaHCO_3$ (0.5 meq/kg-lean/d; n=52), and 52 received placebo. The BASE Pilot Trial found that both doses were safe and well tolerated (Kidney Week 2018, SA-OR036). In this study, we compared the mean change in u-NH_4^+ excretion, u-pH, and s-tCO_2 from baseline between the treatment groups, stratified by DM status, using linear mixed models adjusted for demographics, eGFR, ACR, diuretic use, ACE/ARB use, protein intake, and clinical center.

Results: Mean±SD age was 67±12 years and eGFR was 36±9 ml/min/1.73m^2; 54% had diabetes. In DM vs. non-DM, baseline s-tCO_2 was 24±2 vs. 24±3 meq/L (p=0.95); u-NH_4^+ was 22±14 vs. 20±10 meq/d (p=0.19), and u-pH was 5.7±0.5 vs 5.9±0.5 (p=0.03). The lower dose reduced u-NH_4^+ excretion and increased u-pH similarly in non-DM and DM (Table). With the higher dose, additional effects on u-NH_4^+ excretion and u-pH were more robust in non-DM, however the interaction p-values were not significant. In both DM and non-DM, statistically significant increases in s-tCO_2 were only observed in those treated with the higher $NaHCO_3$ dose.

Conclusions: In individuals with CKD, $NaHCO_3$ may have an attenuated dose-response effect on urinary acid excretion in DM. However, the effect of $NaHCO_3$ on s-tCO_2 seems to be similar for those with and without DM, and only the higher dose significantly increased s-tCO_2

Alkalinization by Urologists and Nephrologists (AlcalUN): Does Oral Sodium Bicarbonate ($NaHCO_3$) Affect Extracellular Volume?

Jean-philippe Bertocchio,[2,1] Lucile Figueres,[6,2] Louis De laforcade,[10,2] Hamza Ayari,[5] Thibault Dolley-Hitze,[4,2] Victor Gueutin,[11] Leonard Golbin,[3,2] Camille Overs,[7,8] Julie Moriniere beaume.[9,2] *[1]MD Anderson Cancer Center, Houston, TX; [2]Club des Jeunes Néphrologues, Paris, France; [3]Nephrology department, CHU Pontchaillou, Rennes, France; [4]AUB Santé, Saint-Malo, France; [5]Renal and Metabolic Diseases Unit, AP-HP, European Georges Pompidou Hospital, Paris, France; [6]Renal department, Nantes University Hospital, Nantes, France; [7]Urology department, Grenoble University Hospital, La Tronche, France; [8]Association Française des Urologues en Formation, Paris, France; [9]Dialysis department, AVODD, Toulon, France; [10]Service Endocrinologie-Néphrologie, Centre Hospitalier Pierre Oudot, Bourgoin-Jallieu, France; [11]Nephrology demartment, CHU Caen, Caen, France.*

Background: Oral alkalinization with $NaHCO_3$ or citrate is widely prescribed in numerous situations from metabolic acidosis to nephrolithiasis. Most of nephrologists/urologists use it on a regular basis, while extracellular volume (ECV) increase is the main feared adverse event for $NaHCO_3$. To date, no clinical trial has specifically studied this aspect in clinical routine.

Methods: AlcalUN (NCT03035812) is a French multicentric prospective open trial aiming at determining the impact on ECV of a chronic oral alkalinization by $NaHCO_3$ during nephrologists or urologists use. Patients receiving oral alkalinization without $NaHCO_3$ composed a control group. The main criterion was the ECV increase as judged on body weight (BW), blood pressure (BP), and edema at first visit.

Results: From 01/2017 to 12/2018, 20 investigators included 122 patients whom 92 (75%) had at least one follow-up and 74 (61%) received $NaHCO_3$. If both groups were comparable as judged on demographic data, patients in the $NaHCO_3$-group had more chronic kidney diseases (74 *vs.* 28%, p<0.001) where patients in the non $NaHCO_3$-group (citrate) had more nephrolithiasis (23 *vs.* 94%, p<0.001). At baseline (inclusion), BW, BP, and presence of edema were comparable in both groups. After a mean of 98±48 days of follow-up, 70 patients (76%) had an ECV increase but the repartition was highly similar in both groups (77 *vs.* 72%, p=0.76), especially BW did not differ (*cf.* **Figure 1**).

Conclusions: Oral alkalinization with $NaHCO_3$ does not increase ECV more than citrate while it is used in a more risky population. These results should be confirmed in a widest population (recruitment continues) and now in a randomized controlled trial.

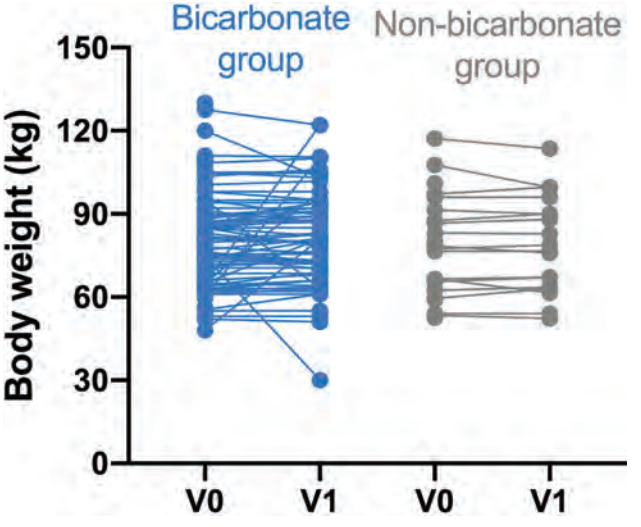

Figure 1. Evolution of body weight between inclusion (V0) and first follow-up (V1).

Drug Therapy Choices for Acquired Distal Renal Tubular Acidosis by US Nephrologists and Rheumatologists

Kamyar Kalantar-Zadeh,[2] Robbie Mccarthy,[1] Ludovic Robin.[3] *[1]Rare Insights LLC, Ardmore, PA; [2]University of California Irvine, School of Medicine, Orange, CA; [3]Advicenne S.A., Paris, France.*

Background: Drivers of drug therapy choices for acquired distal renal tubular acidosis (dRTA) are not well understood. AdRTA, which is linked with Sjogren's disease, systemic lupus erythematosus (SLE), primary biliary cirrhosis (PBC) and autoimmune hepatitis, is often encountered by rheumatologists and nephrologists. To better understand the drug therapy approaches for AdRTA patients, a quantitative market research study was undertaken

Methods: Between March 25th–April 15th, 2019, an online survey was conducted with 30 nephrologists and 20 rheumatologists in the USA on the subject of dRTA, with a focus on AdRTA. All screened respondents had direct clinical experience of AdRTA patients

Results: Sodium bicarbonate (SB) is the most commonly prescribed treatment for AdRTA, prescribed by 80% of nephrologists (Nph) and 56% of rheumatologists (Rhm), followed by sodium citrate (SC) and potassium citrate (PC). In potassium depleted patients, however, PC is the most commonly prescribed agent (Nph 55%, Rhm 57%). The majority of Rhms and Nephs consider the Neph is the most likely to prescribe all of the available treatments (range: 56% Flomax to 78% PC). 67% of Nphs report high satisfaction with SB and 53% with PC, fewer than their Rhm colleagues (high satisfaction: SB-90%, PC-100%). However, 70% of Nphs and 40% of Rhms indicate treatments for AdRTA are sub-optimal and only 60% of Nphs and 40% of Rhms considered the available treatments effective and easily accessible. Many nephrologists expressed that:*"More effective therapies that are less burdensome to patients."* and *"More new treatment options"* are needed. [Figure]

Conclusions: Most nephrologists and rheumatologists have direct experience prescribing drug therapy for AdRTA with sodium bicarbonate being the most commonly prescribed treatment. However, while they express overall satisfaction with available treatments, many believe that they are sub-optimal, not effective or/and not easily accessible

Outcomes of Correcting Metabolic Acidosis in CKD with Cirrhosis: A Retrospective Study

Praveen K. Errabelli,[2] Manisha Singh.[1,3] *[1]University of Arkansas For Medical Sciences, Little Rock, AR; [2]University of Arkansas for medical Sciences, Little Rock, AR; [3]CAVH, Little Rock, AR.*

Background: Chronic Kidney Disease complications include metabolic acidosis. There is evidence of mortality benefit to correcting acidosis to bicarbonate levels of around 22 meq/L. Conversely, in chronic liver disease, respiratory alkalosis is the most common acid-base disorder, which manifests as low serum bicarbonate on labs. Physiologically, it appears that correcting metabolic acidosis to a reasonable level may provide benefit to CKD with cirrhosis, however most practices do not get a venous or arterial blood gases to first identify the cause of low serum bicarbonate. The impact of identifying and managing metabolic acidosis in patient with cirrhosis has not been studied well. Correcting acidosis commonly requires using sodium containing salts, which can lead to sodium overload resulting in increased need for paracentesis procedures. Our hypothesis is that adding oral sodium bicarbonate (NaHco3) targeting bicarbonate 22 meq/L would lead to increased ascites and more frequent paracentesis so we should target lower bicarbonate levels in cirrhosis.

Methods: We conducted a single center retrospective chart review of all patients with CKD and Cirrhosis, managed at University of Arkansas for Medical Sciences, over a period of 5 years to study incidence of paracentesis correlated with oral bicarbonate therapy.

Results: Out of 366 patients with the diagnosis of CKD and cirrhosis, 200 patients did not get paracentesis. Out of these 31(15.5%) were on oral bicarbonate.166 patients recieved paracentesis out of which 41 (24.7%) were on bicarbonate. However, this difference was not statistically significant (P value 0.0383).

Conclusions: KDIGO guidelines recomend correcting metabolic acidosis with oral bicarbonate supplementation to prevent CKD progression targeting serum bicarbonate of about 22 meq/L. However, it is not clear if we can extend this to the population with cirrhosis and CKD. Purpose of our study is to address this question and to study the effects of bicarbonate supplementation with regard to its effect on incidence of paracentesis procedures that can lead to increased complications for these patients. Our retrospective data suggests that patients on oral NaHco3 require frequent paracentesis, but has not met statistical significance. We plan a prospective randomized control study to address this question better.

A Case of Tubulointerstitial Nephritis Complicated by Primary Biliary Cirrhosis with Renal Tubular Acidosis and Nephrogenic Diabetes Insipidus

Mao Shimizu, Ken Kitamura. *Kita-Harima Medical Center, Kobe, Japan.*

Introduction: Tubulointerstitial nephritis is often caused by drugs, infections, autoimmune disorders. We report a case of tubulointerstitial nephritis associated with primary biliary cirrhosis, which developed renal tubular acidosis and nephrogenic diabetes insipidus.

Case Description: A 50-year-old woman presented with a four-month history of left shoulder pain, back pain, dry mouth, polydipsia, polyuria. She hospitalized for weakness of limbs. Her lab studies revealed serum creatinine 2.72 mg/dL, serum potassium 1.5 mg/dl, and normal anion gap metabolic acidosis which suggested distal and proximal renal tubular acidosis. She had multiple fractures which suggested the presence of osteomalacia. Her urine output exceeded 10L/day, and urine osmolarity was low. After corrected serum potassium weakness of limbs improved, but polyuria did not improve. She was thought to nephrogenic diabetes insipidus because of resistant to antidiuretic hormone. Kidney biopsy was performed to clarify the cause of these findings. The major histologic changes were interstitial infiltration by mainly lymphocytes, tubulitis, and interstitial edema. The presence of antimitochondrial M2 antibodies suggested primary biliary cirrhosis. She was treated with oral steroids and a thiazide diuretic. Her polyuria resolved, and serum creatinine level improved to 0.9 mg/dl.

Discussion: In conclusion, our patient with tubulointerstitial nephritis and primary biliary cirrhosis had a favorable outcome from oral steroids and a thiazide diuretic. Previous studies have demonstrated Fanconi syndrome in patients with primary biliary cirrhosis, and our patient suggested that tubulointerstitial nephritis complicated by primary biliary cirrhosis could develop renal tubular acidosis and nephrogenic diabetes insipidus.

Mortality and Magnesium Levels in CKD

Rami M. Azem,[1] Remy Daou,[3] Susana Arrigain,[1] Jesse D. Schold,[1] Georges Nakhoul.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Foundation, Cleveland, OH; [3]Saint Joseph University, Beirut, Lebanon.*

Background: Magnesium disorders are common in Chronic Kidney Disease (CKD) and are typically a consequence of decreased kidney function or use of medications such as diuretics. While hypomagnesemia has been linked with increased mortality, the association between elevated magnesium levels and mortality is not clearly defined. Additionally, associations between magnesium disorders and risk of different types of death have not been reported.

Methods: Using our Electronic Health Record-based CKD registry, we identified patients with eGFR 15 to < 60 ml/min/1.73m2 who had magnesium levels within the prior year. We examined associations between magnesium levels and all-cause, cause-specific mortality and progression of CKD while adjusting for demographic factors and comorbidities using Cox models, Competing Risks regression and mixed models.

Results: Out of 10,568 CKD patients, 12.4% (N=1,314) had hypomagnesemia (Mg < 1.7 mmol/L) while 1.9% (N=205) had hypermagnesemia (Mg > 2.6 mmol/L). We observed a U-shaped association between serum magnesium levels and mortality, with both hypomagnesemia (HR=1.14, 95% CI: 1.04, 1.24) and hypermagnesemia (HR=1.23, 95% CI: 1.03, 1.48) having higher all-cause mortality. Our results showed increased subhazard of non-cardiovascular, non-malignancy deaths for hypomagnesemia (SHR=1.29, 95% CI: 1.12, 1.49), but no significant differences in other causes of death. In a sensitivity analysis excluding patients with malignancy, results were similar. Hypomagnesemia was not associated with stronger eGFR decline (P = 0.10).

Conclusions: Hypomagnesemia and hypermagnesemia were both associated with increased mortality. Hypomagnesemia was associated with increased non-cardiovascular, non-malignancy death.

Serum Magnesium, Mortality, and Cardiovascular Disease in CKD and ESRD Patients: A Systematic Review and Meta-Analysis

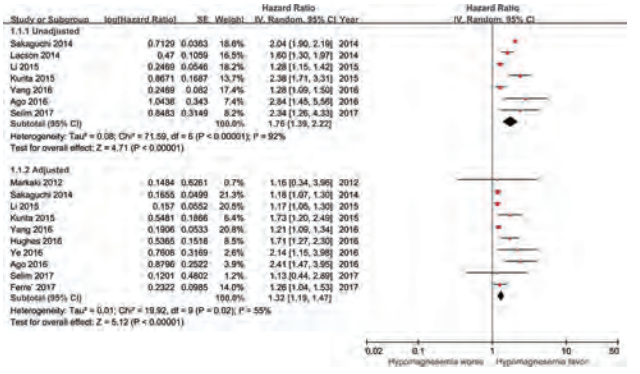
Jiachuan Xiong,[1] Ting He.[2] *[1]Xinqiao hospital, Chongqing, China; [2]Department of Nephrology, Xinqiao Hospital, Chongqing, China.*

Background: Magnesium plays an independent pathogenic role in chronic kidney disease (CKD) and end-stage renal disease (ESRD) patients. However, the results of these studies were somewhat underpowered and inconclusive.

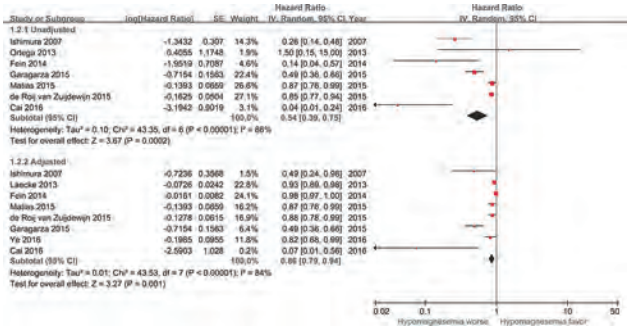
Methods: Literature was identified by searching PubMed, EMBASE, Web of Science and the Cochrane Central Register of Controlled Trials (CENTRAL). Unadjusted and adjusted hazard ratios (HRs) with 95% confidence intervals (95% CIs) were pooled.

Results: The results showed that there was a strong association between hypomagnesemia and the risk of all-cause mortality in patients with CKD and ESRD (HR 1.32; 95% CI1.19–1.47; p < 0.00001) after multivariable adjusted. On the contrary, hypermagnesemia was inversely associated with all-cause mortality in patients with CKD and ESRD (HR 0.86; 95%CI 0.79–0.94; p = 0.001). Moreover, a significant association between hypermagnesemia and decreased risk of cardiovascular mortality was observed (HR 0.71; 95% CI 053–0.97, p = 0.03) in the adjusted model. In addition, subgroup analysis found that hypomagnesemia was strongly associated with increased all-cause mortality in hemodialysis patients (HR 1.29; 95% CI 1.12–1.50; p = 0.0005).

Conclusions: Our results indicate that hypomagnesemia is significantly associated with cardiovascular and all-cause mortality in patients with CKD and ESRD.



The association between hypomagnesemia and all-cause mortality for dichotomous variables (hypomagnesemia vs. normal magnesium or hypermagnesemia group) Fig.



The association between hypermagnesemia and all-cause mortality for continuous variables (hypermagnesemia vs. normal magnesium or hypomagnesemia group)

FR-PO641

Impact of Serum Calcium Level Fluctuations on In-Hospital Mortality

Charat Thongprayoon,[1] Wisit Cheungpasitporn,[2] Michael A. Mao,[1] Stephen B. Erickson.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Mississippi Medical Center, Jackson, MS.*

Background: Calcium concentration is strictly regulated at both the cellular and systemic level, and changes in serum calcium levels can alter various physiological functions in various organs. This study aimed to assess the association between changes in calcium levels during hospitalization and mortality.

Methods: We search our patient database to identify all adult patients admitted to our hospital from January 1st, 2009 to December 31st, 2013. Patients with ≥2 serum calcium measurements during the hospitalization were included. The serum calcium changes during the hospitalization, defined as the absolute difference between the highest and lowest calcium levels, was categorized into five groups: 0-0.4, 0.5-0.9, 1.0-1.4, 1.5-1.9, ≥2.0 mg/dL. Multivariable logistic regression was performed to assess the independent association between calcium changes and in-hospital mortality, using the change in calcium category of 0-0.4 mg/dL as the reference group.

Results: Of 9,868 patients included in analysis, 540 (5.4%) died in the hospital. The in-hospital mortality progressively increased with higher calcium changes, from 3.4% in the group of 0-0.4 mg/dL to 14.5% in the group of ≥2.0 mg/dL (p<0.001). When adjusted for age, sex, race, principal diagnosis, comorbidity, kidney function, acute kidney injury, number of serum calcium measurements, and length of hospital stay, the serum calcium change of 1.0-1.4, 1.5-1.9, and ≥2.0 mg/dL were significantly associated with increased in-hospital mortality with OR of 1.67 (95% CI 1.24-2.25), 2.11 (95% CI 1.48-3.01), and 3.96 (95% CI 2.95-5.30), respectively. The association remained statistically significant when further adjusted for either the lowest, highest, or admission serum calcium.

Conclusions: Larger serum calcium changes in hospitalized patients were progressively associated with increased in-hospital mortality.

FR-PO642

Changes in Serum Phosphate Levels Associated with In-Hospital Mortality

Charat Thongprayoon,[2] Wisit Cheungpasitporn,[1] Michael A. Mao,[2] Kianoush Kashani.[2] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Mayo Clinic, Rochester, MN.*

Background: Fluctuations in serum phosphate levels have recently been shown to be associated with coronary calcification and increased mortality in end-stage renal disease (ESRD) patients. However, the impacts of serum phosphate changes in hospitalized patients remain unclear. This study aimed to test the hypothesis that serum phosphate changes during hospitalization were associated with in-hospital mortality.

Methods: We included all adult hospitalized patients from January 2009 to December 2013 that had at least two serum phosphate measurements during their hospitalization. We categorized the hospital serum phosphate change, which was defined as the absolute difference between the highest and lowest phosphate, into 5 groups: 0-0.6, 0.7-1.3, 1.4-2.0, 2.1-2.7, ≥2.8 mg/dL., Using the phosphate change group of 0-0.6 mg/dL as the reference group, the adjusted odds ratio of in-hospital mortality for various phosphate change groups was obtained by multivariable logistic regression analysis.

Results: A total of 28,149 patients were studied. The in-hospital mortality in patients with phosphate change of 0-0.6, 0.7-1.3, 1.4-2.0, 2.1-2.7, ≥2.8 mg/dL was 1.5, 2.0, 3.1, 4.4, and 10.7%, respectively ($p<0.001$). When adjusted for potential confounders, a larger phosphate change was associated with progressively increased in-hospital mortality with ORs of 1.35 (95% 1.04-1.74) in 0.7-1.3 mg/dL, 1.98 (95% CI 1.53-2.55) in 1.4-2.0 mg/dL, 2.68 (95% CI 2.07-3.48) in 2.1-2.7 mg/dL, and 5.4 (95% CI 3.94-6.45) in ≥2.8 mg/dL compared to the phosphate change group of 0-0.6 mg/dL. A similar result was noted when we further adjusted for either the lowest, highest or admission phosphate.

Conclusions: Greater serum phosphate changes during a patient's hospitalization were progressively associated with increased in-hospital mortality.

FR-PO643

Granger Causality Analysis of Regulatory Network of Phosphate Metabolism in Healthy Individuals

Guoxin Ye. *Division of Nephrology, Huashan Hospital, Shanghai Medical College, Fudan University, Shanghai, China.*

Background: Basic and clinical studies reveal that the homeostasis of phosphate is maintained by a regulatory network. The aim of our study was to explore the variation of phosphatoninin with the change of diet.

Methods: 6 healthy volunteers were treated with regular Pi diet (NPD) and high Pi diet (HPD) for 5 days. Their blood and urine specimens at 10 fixed time points on the 5th day of intervention were collected. In order to reveal the causality relationship in the phosphorus metabolism network, this study used the Granger causal analysis to determine time series relationship.

Results: HPD resulted in a significant increase in serum Pi and urinary Pi excretion. There was a significant increase in PTH. FGF23 was upward trend. By using Granger causal analysis, we found PTH was earliest change in RPD, which was the initiation factor. The change of FGF23 appeared at the latest that was the passive factor. In HPD, FGF23 was initiation factor. Serum Ca and Pi were passive factors.

Conclusions: With the traditional comparison, it was difficult to reveal the caucality relationship of phosphate network. By Granger causality analysis, we found in RPD kidney was the most significant organ in keeping serum Pi stably. In HPD, FGF23 was the main hormone to maintain homeostasis of phosphate regulatory network.

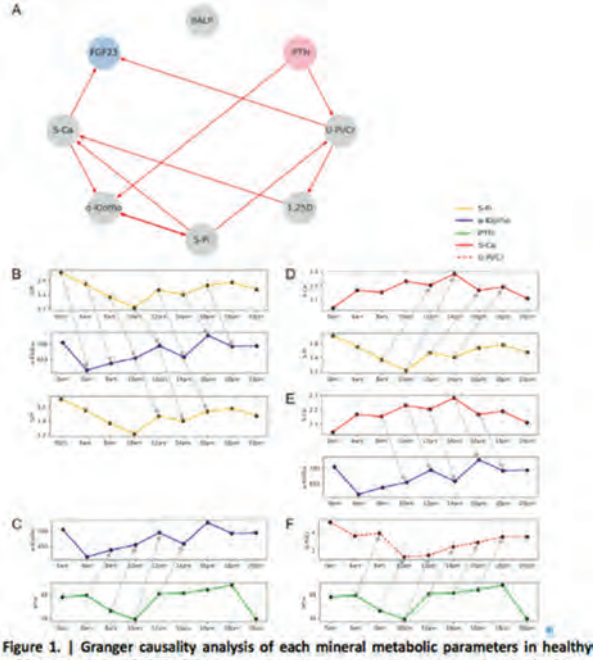


Figure 1. | Granger causality analysis of each mineral metabolic parameters in healthy subjects treated with RPD. (A) Here we show Granger causality analysis network of subjects treated with regular-phosphate diet intervention. The arrowhead points to the result of two mineral metabolic parameters' Granger causality. Double-arrowhead reflects reciprocal Granger causation of two mineral metabolic parameters. iPTH (pink) is the cause of network, and FGF23 (blue) is the result of the regulatory network. iPTH regulates FGF23 indirectly by influencing urinary phosphate excretion, $1,25(OH)_2D_3$, serum Ca, serum Pi and α-Klotho, which keeps serum Pi level stable and maintains phosphate regulatory network homeostasis. (B)(C)(D)(E)(F) Show Granger causality between α-Klotho and serum Pi, iPTH and α-Klotho, Serum Pi and serum Ca, α-Klotho and serum Ca, iPTH and urinary Pi excretion of time series analysis, respectively. Grey arrowhead reflects the "cause" of the earlier periods leads to the "result" of latter periods. For example, the decline of serum Pi level from 8 a.m. to 10 a.m. (cause) results in increased of α-Klotho expression from 10 a.m. to 12 p.m. (result) in Granger causality analysis.¶
