
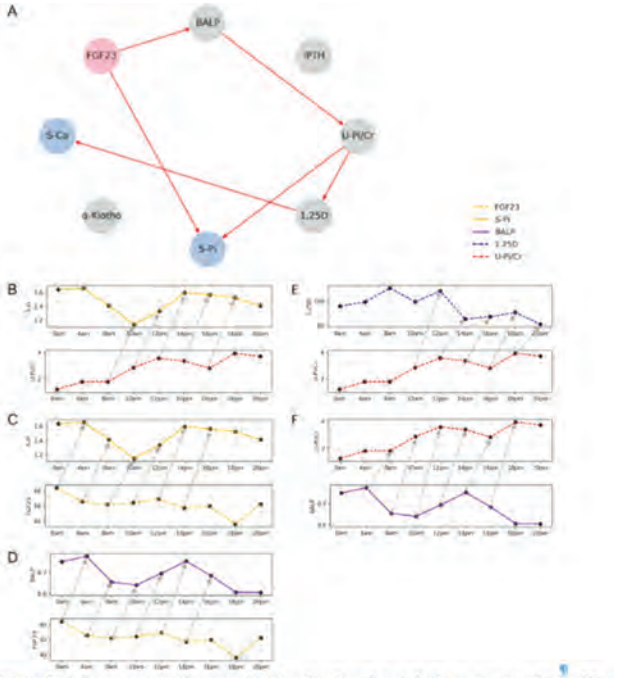

Figure 2. | Granger causality analysis of each mineral metabolic parameters in healthy subjects treated with high-phosphate diet intervention. (A) Here we show Granger causality analysis network of subjects treated with high-phosphate diet intervention. The arrowhead points to the result of two mineral metabolic parameters' Granger causality. FGF23 (pink) is the cause of network, serum Ca and serum Pi (blue) are the results of the regulatory network. (B)(C)(D)(E)(F) Show Granger causality between serum Pi and urinary Pi/Cr, FGF23 and serum Pi, FGF23 and BALP, $1,25(OH)_2D_3$ and urinary Pi/Cr, BALP and urinary Pi/Cr of time series analysis, respectively. Grey arrowhead reflects the "cause" of earlier period results in the change of "result" at latter periods. Pi, serum Pi; Ca, serum Ca; 1,25D, $1,25(OH)_2D_3$; U-Pi/Cr, Urinary Phosphate/Creatinine; 1,25D, $1,25(OH)_2D_3$.¶

FR-PO644

Hyperphosphatemia in a Patient with Mucormycosis and AKI

Raghu Konanur venkataram,[1] Nada M. Bader,[1] Jimmy T. Pham,[1] Phuong-Thu T. Pham,[2] Phuong-Chi T. Pham.[1] *[1]Olive View-UCLA Medical Center, Los Angeles, CA; [2]UCLA Medical Center, Los Angeles, CA.*

Introduction: Hyperphosphatemia may arise from ingestion, extracellular shifts (e.g. cell death or alterations in acid-base status), bone resorption, hormonal dysregulations leading to reduced renal excretion, and/or poor kidney function. Pseudohyperphosphatemia has been well-described but may be under-recognized and/or not commonly seen in clinical practice.

Case Description: A 35-year-old 7-week-pregnant woman with type 1 diabetes mellitus was admitted for mucormycosis involving the clivus and cervical vertebrae. On day 1, she was initiated on liposomal amphotericin (10mg/kg) with normal saline support. On day 4, sulfamethoxazole/trimethoprim and ampicillin/sulbactam were added for methicillin-sensitive *Staphylococcal Aureus* and *Prevotella Buccae* from her fungating mass. On day 6, patient was noted to have acute kidney injury (AKI) when her creatinine increased from 0.4-0.5 mg/dL to 1.25 mg/dL. Nephrology was consulted for AKI and concurrent multiple electrolyte abnormalities. See Table for laboratory findings. Chart review was notable for a hypotensive episode when her blood pressure dropped from a baseline of 100/80 mmHg to 79/50 mmHg over 4 hours. Physical exam was unremarkable. Primary team replaced her potassium and magnesium and started sevelamer carbonate 2400 mg tidac.

Discussion: While the etiologies of AKI, hypokalemia, and hypomagnesemia were straightforward, hyperphosphatemia was out of proportion to the degree of AKI. A full investigation for contributing factors of hyperphosphatemia other than AKI revealed that she had pseudohyperphosphatemia due to liposomal amphotericin. Methods for measuring Pi may differ among commonly used clinical analyzers, where some may read the organic phosphate contained in the lipid bilayer of the liposomes as Pi. Repeat phosphorus level on a different analyzer revealed a level of 5.8 mg/dL. Erroneous treatment of pseudohyperphosphatemia would have been detrimental in current case.

Laboratory findings

Liposomal amphotericin	Creatinine (mg/dL)	Potassium (meq/L)	Magnesium (mg/dL)	Calcium (mg/dL)/Albumin (g/dL)	Phosphorus (mg/dL)	Alkaline phosphatase (IU/L)
Day 1	0.4	3.8	1.9	8.5/3.0	2.6	278
Day 4	0.5	3.1	1.3	8.0/2.0	5.0	245
Day 6	1.25	2.7	1.2	7.8/2.5	6.0	396
Day 10	1.46	3.9 (after repletion)	1.9 (after repletion)	8.1/2.3	10.7	

Others: Parathyroid hormone 26 pg/ml, vitamin D, 25-OH 33 pg/mL, lactate dehydrogenase 106 U/L, creatine phosphokinase 21 U/L, urinalysis was without protein, blood, or cellular casts.

FR-PO645

A Simple Equation to Estimate Urinary Flow Rate Using Urine Creatinine

Luke Webster,[1] Jennifer J. Gassman,[7] Alexander Bullen,[1] Steven D. Weisbord,[6] Paul M. Palevsky,[5] Linda F. Fried,[4] Kalani L. Raphael,[3] Tamara Isakova,[2] Joachim H. Ix.[1] *[1]UCSD, San Diego, CA; [2]Feinberg School of Medicine, Northwestern University, Chicago, IL; [3]VA Salt Lake City Health Care System, Salt Lake City, UT; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]University of Pittsburgh/VA Pittsburgh Healthcare System, Pittsburgh, PA; [6]University of Pittsburgh Medical Center, Pittsburgh, PA; [7]Cleveland Clinic, Cleveland, OH.*

Background: Accurate assessment of urine flow is critical to clinical care, but challenging to estimate. We hypothesized we could dervie an equation that would accurately estimate urine flow rate.

Methods: We derived a new equation to estimate urine flow rate (eV) using the Cockcroft-Gault and the measured creatinine clearance (UV/P) equations. Accuracy was evaluated by comparing eV to measured urine flow rate (V) in persons with CKD who participated in the AASK and COMBINE trials. Participants with concordant estimated and measured creatinine excretion rates were included to define a subset with highly accurate 24 hour urine volumes.

Results: The eV equation required only urine creatinine, age, sex, and weight data. In AASK, we evaluated 570 participants who had mean GFR of 46.7 ± 15.1 ml/min/1.73m^2 and measured urine flow rate (V) 94.9 ± 34.2 ml/hour over 24 hours. A high correlation was found between eV and V (r = 0.91, p< 0.001), however Bland Altman plots showed that eV was 9.6 ml/hour lower than V, on average, in AASK. Thus a correction factor was added to the eV equation and externally evaluated in COMBINE, wherein 123 participants had mean eGFR of 34 ± 8 ml/min/1.73m^2. EV and V were highly correlated (r = 0.91, p< 0.001) and bias was improved (5.3 ml/hr). Overall, 80% of individuals had eV that was within 20% of V.

Conclusions: A simple equation using urine creatinine and demographics can accurately predict urine flow rate and may have clinical utility in situations where the accuracy of timed collections is uncertain.

Funding: NIDDK Support, Other NIH Support - U01 - COMBINE U01DK097093.

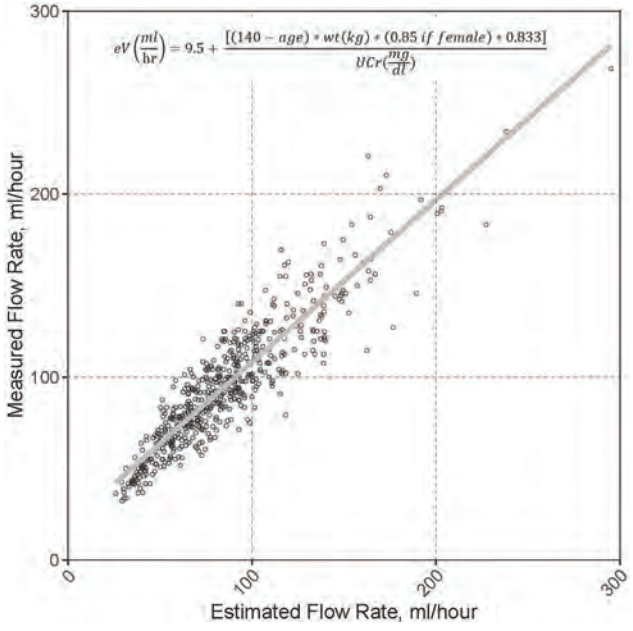

Figure 1 shows the correlation of measured vs. estimated flow rate using eV equation (top of graph) in AASK participants who had measured creatinine excretion rates within 20% of estimated excretion rates (N=570). r = 0.91, p< 0.001.

FR-PO646

Insulin Use for the Treatment of Acute Hyperkalemia

Toby J. Humphrey, Ian Wilkinson, Thomas F. Hiemstra. *University of Cambridge, Cambridge, United Kingdom.*

Background: Insulin has been the cornerstone of treatment for hyperkalaemia (HK) for many decades and remains in wide clinical use. Despite this, there is a paucity of data on the efficacy and safety of this approach. To investigate this, we interrogated a large electronic health record (EHR) dataset to explore the characteristics and consequences of insulin treatment for HK.

Methods: Patients receiving insulin for the treatment of HK were identified from a complete EHR database of all admissions to a UK tertiary hospital over 3.5 years. Variables extracted included demographics, comorbidities, concomitant medications, biochemistry results including all blood potassium values, and all in-hospital prescribing. Factors associated with the need for insulin retreatment were explored using a mixed-effects logistic regression model and odds ratios are reported.

Results: Insulin was administered to 1,284 adult patients(2,541 total administrations). Insulin-treated patients were aged 72 (IQR 59.5-84.5) years and had significant comorbidity (Charlson index 5, IQR 3 to 7). At the end of the follow-up period, only 60.3% remained alive. Potassium concentration immediately (≤ 60 min) pre-treatment was 6.34±1.2mmol/L. The mean reduction in potassium at 4-hours post infusion was 0.86±0.92mmol/L. Multiple doses were given to 542 patients (42.2%), of whom 209 (16.2%) were retreated within 4 hours of the first infusion. Patients receiving multiple insulin infusions were more likely to have chronic kidney disease (44.5% vs 36.5%, p=0.002) or heart failure (22.9% vs 17.4%, p=0.009) and to have been exposed to ACE inhibitors (33.2% vs 27.9%, p=0.02) or potassium sparing diuretics (19.4% vs 15.5%, p=0.04), although only CKD remained significantly associated with retreatment in a regression model adjusted for age, gender and co-morbidity (OR 1.4, 1.1-1.7, p=0.01). Dysregulation of glucose metabolism occurred in 672 patients (53%) following insulin. Hypoglycaemia (plasma glucose<4mmol/L) occurred in 133 patients (10.4%) within 4 hours of insulin administration, and 16 patients (1.2%) experienced a glucose < 2mmol/L.

Conclusions: HK requiring insulin treatment occurs most commonly in a more elderly and comorbid population, is associated with CKD, requires re-treatment in 4 out of 10 patients, and is associated with dysregulated glucose metabolism (either high or low) in 53%. There is an unmet need for improved emergency treatments for HK.

FR-PO647

Treatment of Hyperkalemia with Insulin: Comparative Evaluation of Patient Characteristics

Toby J. Humphrey, Ian Wilkinson, Thomas F. Hiemstra. *University of Cambridge, Cambridge, United Kingdom.*

Background: Hyperkalaemia (HK) is a comon and serious medical emergency and current standard of care consists of an insulin infusion. Here, we report characteristics of HK patients treated with insulin in a tertiary hospital in the UK, compared with HK patients not treated with insulin.

Methods: HK patients (at least 1 potassium measurement ≥6mmol/L) were identified from electronic health records of patients admitted to a tertiary hospital between April 2015 and August 2018. All HK patients treated with insulin (K-I) were identified and compared with HK patients not treated with insulin (K-noI). Categorical variables were compared by X^2-test and continuous variables by Student's *t*-test or Mann–Whitney *U*-test. Associations with insulin treatment were explored using a mixed effects logistic regression model with insulin use as the dependent variable, odds ratios (OR) are reported with associated 95% confidence intervals.

Results: HK ≥6mmol/L was identified in 5,272 of 211,993 patients (1.9%) attending the Emergency Department. Of these, 1284 received insulin for HK (K-I). Compared to K-noI patients, K-I patients were older (72 years(59.5-84.5) vs 71(53-83), p<0.001), more likely to be diabetic (35% vs 25.2%, p<0.001) and have chronic kidney disease (CKD) (39.9% vs 18.6%, p<0.001). Median length of hospital stay was longer in K-I patients (11.7 days (4.9-24.7) vs. 6.0 (1.2-17.3), p<0.001). A higher proportion of K-I patients were taking ACE Inhibitors (30.1% vs 23.1%, p<0.001), Angiotensin-2-receptor blockers (12.3% vs 9.2%, p=0.001) or potassium-sparing diuretics (17.1% vs 9.6%, p<0.001). In a mixed-effects logistic regression model, insulin treatment was associated with CKD (OR 2.4, 2.1-2.8), male sex (OR 1.6, 1.4-1.8), potassium-sparing diuretics (OR 1.6, 1.3-2.0) and hypertension (OR 1.3, 1.1-1.5). At the end of follow up, 575/1,284 patients (44.8%) in K-I vs 1,089/3,988 patients (27.3%) had died (p<0.001). In a logistic regression model adjusting for age, gender and co-morbidity, the risk of death remained higher in the K-I group (OR 1.9, 1.6-2.2). Exact cause of death was not assessed.

Conclusions: Patients that receive insulin for HK are older, more likely to be male and have hypertension, CKD, diabetes and exposure to medications that increase potassium than those that do not. Receiving insulin for HK is associated with longer hospital stay and a higher risk of death.

FR-PO648

Hyperkalemia Progression Rates Among Patients with Mild Hyperkalemia

Rubeen K. Israni,[1] Jill Davis,[1] Keith Betts,[2] Fan Mu,[2] Jessie Wang,[2] Deborah A. Anzalone,[1] Stephanie Bousleiman,[2] Sarah Koenigsberg,[2] Vivian A. Fonseca,[5] Gabriel I. Uwaifo,[4] Harold M. Szerlip.[3] *[1]AstraZeneca, Newark, DE; [2]Analysis Group, Inc., Boston, MA; [3]Baylor University Medical Center, Dallas, TX; [4]Ochsner Medical Foundation, Slidell, LA; [5]Tulane University Medical Center, New Orleans, LA.*

Background: To describe time to progression from mild hyperkalemia (HK) to moderate-to-severe or severe HK among patients with mild HK and pre-specified subgroups.

Methods: Adults with at least one mild HK event (i.e. serum potassium [K^+] > 5.0 and ≤ 5.5 mEq/L) were identified using electronic medical records from the Research Action for Health Network (2012-2018). Index date was defined as the date of the first mild HK event. Patients were required to have at least one additional serum K^+ lab value during the study period (2 years post-index date). Progression to moderate-to-severe and to severe HK was defined as the first occurrences of a serum K^+ lab > 5.5 mEq/L and > 6.0 mEq/L, respectively. Kaplan-Meier analyses were conducted to estimate the rates of HK progression over the study period for the overall population and patient subgroups including those with and without chronic kidney disease (CKD in stages 3-5), heart failure (HF), hypertension, or type 2 diabetes (T2D).

Results: A total of 35,369 patients with mild HK were included in the analysis. Mean age was 65.6 years, and 47.5% were women. At 2 years post-index, 16.9% and 8.7% of patients progressed to moderate to severe HK and to severe HK, respectively (**Table**). Patients with CKD, HF, hypertension, and T2D experienced higher rates of HK progression compared with patients without those conditions (all log-rank $p < 0.001$) (**Table**). HK progression rates also increased significantly as CKD stage increased ($p < 0.001$) (**Table**).

Conclusions: A total of 16.9% of patients with mild HK experienced HK progression during the 2-year follow-up period. HK progression rates increased significantly with CKD stage and were also higher among those with HF, hypertension, or T2D.

Funding: Commercial Support - AstraZeneca

Table. Progression to Moderate-to-severe and Severe HK among Patients with Mild HK

Progression outcome	HK progression among all patients	HK progression by subgroup (n)										
		CKD Stage					HF		Hypertension		T2D	
		No CKD	Stage 3	Stage 4	Stage 5 without dialysis	Stage 5 with dialysis	Yes	No	Yes	No	Yes	No
	(n=35,369)	(23,777)	(7,792)	(1,892)	(1,377)	(531)	(5,132)	(30,237)	(20,540)	(14,829)	(11,197)	(24,172)
Moderate-to-severe	16.9%	12.0%	21.7%	32.2%	43.6%	50.2%	32.7%	19.4%	25.0%	16.7%	29.0%	18.1%
Severe	8.7%	3.9%	7.5%	12.4%	22.8%	31.3%	15.7%	7.3%	10.1%	6.7%	12.3%	6.9%

FR-PO649

Compared Effects of Calcium and Sodium Polystyrene Sulfonate on Mineral, Bone Metabolism, and Acid-Base Equilibrium in CKD Patients with Hyperkalemia

Yosuke Nakayama, Goh Kodama, Sakuya Ito, Kei Fukami. *Division of Nephrology, Department of Medicine, Kurume University, Kurume, Japan.*

Background: Hyperkalemia is prevalent in end-stage renal disease patients, being involved in life-threatening arrhythmias. Although polystyrene sulfonate (PS) is commonly used for the treatment of hyperkalemia, direct comparison of effects between calcium and sodium PS (CPS and SPS) on mineral, bone metabolism and acid-base equilibrium has not yet been studied.

Methods: This study was designed as a prospective, open-labeled, randomized, and crossover study (n=40). Patients were orally administered CPS (ARGAMATE® 89.29 % GRANULE 5.6 g; powder 5 g) or SPS (KAYEXALATE DRY SYRUP 76%® 6.54 g; powder 5 g) after each meal. After 4 weeks treatment, each PS was immediately switched to another PS without washout interval, and followed-up for further 4 weeks. To investigate the cation-absorption capacity of CPS and SPS, we constructed an artificial colon fluid (ACF) based on the data of human diarrhea as described previously. One gram of CPS or SPS was added into the 50 ml of ACF (n=6, respectively). After filtration, the concentrations of K, Ca, Na, Mg, and NH_3 in the supernatant were determined.

Results: After 4 week-treatments, there was no significant difference of changes in serum potassium (K) from the baseline (ΔK) between the two groups. However, SPS significantly decreased serum calcium (Ca) and magnesium (Mg) and increased intact parathyroid hormone (iPTH) values, whereas CPS reduced iPTH. ΔiPTH was inversely correlated with ΔCa and ΔMg (r=-0.53 and r=-0.50, respectively). Furthermore, sodium (Na) and atrial natriuretic peptide (ANP) levels were significantly elevated in patients with SPS, but not with CPS, whereas ΔNa and ΔANP were significantly correlated with each other in all the patients. We also found that SPS, but not CPS treatment significantly increased plasma HCO_3^- and serum Na levels, while serum NH_3 levels were not changed by either PS treatment. ΔNa and Δ(Na to Cl ratio) but not ΔNH_3 were positively correlated with ΔHCO_3^- (r=0.75, p<0.0001, r=0.84, p<0.0001, and r=0.06, p=0.75, respectively). In artificial colon fluid, CPS increased Ca and decreased Na. Furthermore, SPS more decreased K, Mg, and NH_3.

Conclusions: Compared with SPS, CPS may be safer for the treatment of hyperkalemia in pre-dialysis patients, because it did not induce hyperparathyroidism or volume overload.

FR-PO650

Reflex Ordering of Polystyrene Sulfonate for "Red-Flagged" Mild Hyperkalemia: A Problem of Perception

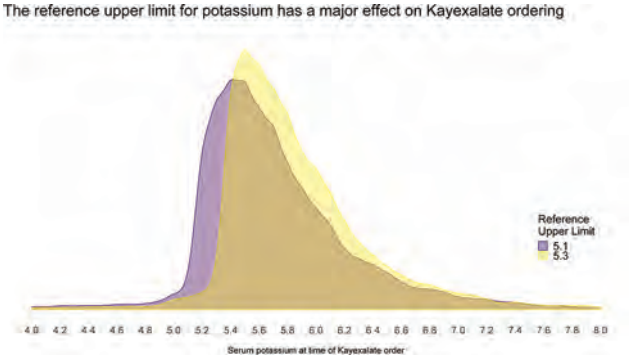
Jamie S. Hirsch,[1,2] Vipulbhai Sakhiya,[1] Kevin R. Bock,[2] Rushang Parikh,[1] Richard L. Barnett,[1] Kenar D. Jhaveri.[1] *[1]Division of Nephrology, Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]Department of Information Services, Northwell Health, New Hyde Park, NY.*

Background: Lab test results, typically reported with reference ranges, are often flagged and red when abnormal. For potassium (K), while treatment recommendations have not changed, reference limits may have. How the reference upper limit (RUL) impacts provider responsiveness to hyperkalemia treatment with polystyrene sulfonate (PS, Kayexalate) is unknown.

Methods: We queried the EHR at 14 hospitals in a large integrated health system, for orders of PS between 2012-2018. The serum K at the time of an order was deemed the result that occasioned treatment. We extracted the RUL for the result, which changed from 5.1 to 5.3 mEq/L in December, 2015. We compared PS ordering based upon RUL using a two-sample Kolmogorov–Smirnov (KS) test. KS is a nonparametric test to determine if two samples are drawn from the same distribution; the null hypothesis is that the distribution of orders by K level remains the same regardless of RUL.

Results: There were 43,497 orders for PS, almost evenly split between RUL 5.1 and 5.3. The two distributions were statistically different (D = 0.17478, p-value < 0.0001). For results with RUL 5.1, the initial peak in PS ordering occurred at K 5.2, whereas it occurred at 5.4 with RUL 5.3. The maximum absolute difference between the two cumulative curves (D statistic), 0.17, occurs at K 5.3, falling within the "high" range for RUL 5.1, but normal for RUL 5.3. For RUL 5.1, approximately 10% of results between 5.2-5.3 led to a PS order, whereas only 2% led to an order for RUL 5.3.

Conclusions: While the physiologic understanding of K and its serum levels have not changed, we found that modifying the RUL led to major changes in PS prescribing for hyperkalemia. This abrupt and sustained shift suggests a reflexive approach to treatment, whereby providers are ordering PS based upon an abnormal flag or red-colored value, rather than clinical indication. Educating providers and using appropriate nudges or defaults can lead to more thoughtful approaches to management of K and other electrolyte disorders.



FR-PO651

Efficacy and Safety of Sodium Zirconium Cyclosilicate for Reducing the Incidence of Hyperkalemia in Patients with ESRD: A Japanese Subgroup Analysis of the DIALIZE Study

Masafumi Fukagawa,[1] Steven Fishbane,[2] Tadashi Iitsuka,[3] Akio Suda,[4] Ayman Al-shurbaji,[5] Nicolas J. Guzman,[6] Vera Lisovskaja,[5] Toshitaka Yajima,[7] Nobuaki Sarai.[7] *[1]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara-shi, Japan; [2]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [3]Ibaraki Seinan Medical Center Hospital, Ibaraki, Japan; [4]Hakusuikai Suda Clinic, Shinjuku-ku, Japan; [5]AstraZeneca, Gothenburg, Sweden; [6]AstraZeneca, Gaithersburg, MD; [7]AstraZeneca K.K., Tokyo, Japan.*

Background: Patients with end-stage renal disease (ESRD) are at increased risk of developing hyperkalemia (HK), despite receiving hemodialysis (HD), even if with use of lower dialysate potassium concentration (2.0mEq/L). DIALIZE (NCT03303521), a randomized, double-blind, placebo (PBO)-controlled, phase 3b, international study, determined the efficacy and safety of sodium zirconium cyclosilicate (SZC) for the treatment of HK in ESRD patients undergoing HD. Here, we report an exploratory analysis of the Japanese subgroup.

Methods: Patients were adults on stable HD with HK, and were randomly assigned (1:1) to receive PBO or SZC. Study drugs were administered orally, starting at a dose of 5g once daily on non-dialysis days and titrated at 5g increments to a maximum of 15g daily, to maintain normokalemia (serum K: 4.0-5.0mmol/L). Primary endpoint was the proportion of responders (i.e., patients who maintained a pre-dialysis serum K between 4.0 and 5.0mmol/L on at least 3/4 dialysis treatments after a long inter-dialytic interval without requiring rescue therapy during the evaluation period), and secondary was the proportion of patients requiring rescue therapy for severe HK. Adverse events and inter-dialytic weight gain (IDWG) were evaluated for safety.

Results: A total of 56 Japanese patients were randomly assigned: 28 received SZC, and 28 PBO; 96.4% completed the study in the SZC group and 100% in the PBO group. Patients in the SZC and PBO groups had a mean age of 60.7 and 64.4 years, respectively; all other baseline characteristics were balanced between groups. 71.4% (n=20) and 0% were responders (nominal p<.001) in the SZC and placebo group, respectively. Further, 3 subjects in the placebo group but none on SZC required rescue therapy. AEs were reported in 53.6% (n=15) and 57.1% (n=16). Two SAEs were reported, one in SZC group (gastrointestinal hemorrhage) and one in placebo group (arteriovenous fistula site complication); both events were deemed unrelated to the study drug. IDWG was similar in both groups.

Conclusions: This exploratory analysis showed that the safety and efficacy profile of SZC in the Japanese subgroup is in line with that observed in the global study population.

Additional Benefit of Patiromer Under Real-Life Conditions

Eric Seibert,[1,3] Thomas Weinreich,[1] Christof Ulrich,[3] Roman Fiedler,[2] Matthias Girndt,[2] Helmut Reichel,[1] Bernd Hohenstein.[1] *[1]Nephrologisches Zentrum, Villingen-Schwenningen, Germany; [2]Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany; [3]Innere Medicine II, Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany.*

Background: Patiromer was placed on the market in Germany in April 2018. Additional Benefit was not affirmed by regulatory authorities (GBA-Gemeinsamer Bundesausschuss). In the OPAL-HK trial, in patients that were treated with Patiromer, mean serum potassium levels declined by 1.01±0.03 mmol/L and after 4 weeks 76% of the patients reached potassium levels below 5.1 mmol per liter. We sought to evaluate, whether these promising results can be achieved under real-life conditions outside of clinical trials.

Methods: We analysed potassium levels in all patients treated with patiromer in a large chronic kidney disease cohort including patients with and without renal replacement therapy. In addition, the number of patients that reached the target range below 5.1 mmol/l was evaluated. Data extraction and analysis were performed using an multi-factorial Algorithm-based approach.

Results: 7222 Patients that were treated between 1.1.2018 and 15.4.2019 were screened. 49 Patients (20 females) were treated with Patiromer (24 hemodialysis, 2 peritoneal dialysis, 23 CKD). For 37 patients at least one potassium value was available before and after initiation of Patiromer. Mean potassium levels were 5.85±0.56 mmol/L before and 5.45±0.77 mmol/L on treatment with Patiromer (p<0.01). However, only 13 out of 37 patients (35%) reached a potassium level in the target range below 5.1 mmol/l.

Conclusions: With only 35% of patients in the potassium target range below 5.1 mmol/l, additional benefit of Patiromer under real-life conditions was small compared to OPAL-HK where 76% reached the target range.

FR-PO653

Long-Term Healthcare Cost and Resource Use in Patients with Hyperkalemia

Eiichiro Kanda,[1] Naoki Kashihara,[1] Shun Kohsaka,[2] Suguru Okami,[3] Toshitaka Yajima.[3] *[1]Kawasaki Medical School, Kurashiki, Japan; [2]Keio University, Tokyo, Japan; [3]Astrazeneca, Tokyo, Japan.*

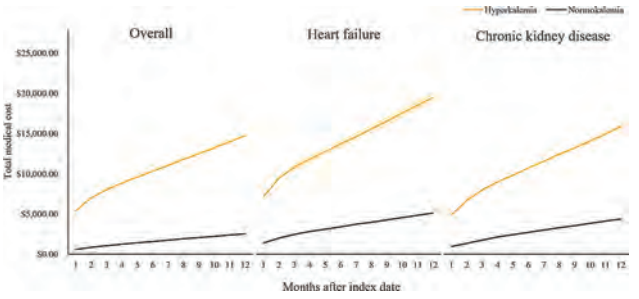
Background: Few studies provide information on economic burden of hyperkalemia (HK) especially regarding long-term healthcare cost and resource use.

Methods: A retrospective cohort study was done with a Japanese hospital claims database, Medical Data Vision. We extracted data for patients aged ≥18 years with ≥2 serum potassium (S-K) values ≥5.1 mmol/L; from April 1, 2008, to September 30, 2018 for patients with HK, and normokalemic patients without any record of S-K ≤3.5 mmol/L or ≥5.1 mmol/L. Direct healthcare cost and resource use over 1 year after the first HK episode and during follow-up after 1 year were separately assessed.

Results: 27,534 HK cases and 233,098 normokalemic controls were identified from a total of 1,208,894 patients who had at least one S-K value. Mean length of follow-up was 2.90 years in cases and 3.68 years in controls. Compared with controls, median inpatient and outpatient costs per visit over 1 year were significantly higher in HK (inpatient: $6,614 vs. $4,046; outpatient: $231 vs. $116) (p <0.001) and after 1 year (inpatient: $6,072 vs. $4,042; outpatient $253 vs. $130) (p <0.001). Median total costs in HK and controls were $7,617 (interquartile range [IQR] $3,119-$19,733) and $938 (IQR $345-$2,359) over 1 year, and $4,335 (IQR $1468-$1,1620) and $779 (IQR $269-$2,079) after 1 year, respectively. Median total costs were higher in subgroups of heart failure ($11,147) and chronic kidney disease ($8,407) (Figure). HK cases had higher resource use including incidences of hospitalization (62.6% vs. 14.4%), rehospitalization (10.0% vs. 1.1%), and emergency room (ER) visit (26.9% vs. 3.2%) over 1 year. Higher resource use continued after 1 year with cumulative incidences of hospitalization (73.7% vs. 49.7%), rehospitalization (29.3% vs. 7.3%), and ER visit (50.4% vs. 16.3%). HK cases had longer hospital stay (mean 22.97 days vs. 11.05 over 1 year, and 21.06 vs. 10.94 days after 1 year).

Conclusions: The results showed that HK is associated with significant long-term economic burden and needs careful medical attention.

Funding: Commercial Support - AstraZeneca K.K.



Mean cumulative cost over 12 months after hyperkalemia

Hyperkalemia and Progression of CKD

Christina X. Chamberlain,[1] Jill Davis,[2] Rubeen K. Israni,[2] Deborah A. Anzalone,[2] Keith Betts,[3] Fan Mu,[1] Nicolae Done,[1] Gary C. Curhan,[4] Emma Billmyer,[1] Harold M. Szerlip,[5] Gabriel I. Uwaifo,[6] Vivian A. Fonseca,[7] Eric Wu.[1] *[1]Analysis Group, Inc., Boston, MA; [2]AstraZeneca, Newark, DE; [3]Analysis Group Inc., Los Angeles, CA; [4]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [5]Baylor University Medical Center, Dallas, TX; [6]Ochsner Medical Foundation, Slidell, LA; [7]Tulane University Medical Center, New Orleans, LA.*

Background: To compare rates of chronic kidney disease (CKD) progression between CKD patients with and without hyperkalemia (HK).

Methods: Adult patients with CKD stage 3-4, with or without HK, were selected from electronic medical records from the US Research Action for Health Network (2012-2018). CKD stage was identified by diagnosis codes or estimated glomerular filtration rate (eGFR). HK was defined as having ≥1 serum K^+ lab value >5.0 mEq/L and confirmed by another HK event. Index dates were defined as 30 days after the first K^+ lab >5.0 mEq/L for HK patients and after a randomly selected K^+ lab ≤5.0 mEq/L for patients without HK. Patients were required to have ≥1 eGFR value in both the baseline (6 months pre-index date) and study period (up to 5 yrs post-index date). Two outcomes were evaluated separately: 1) progression to CKD stage 5; 2) ≥10 unit decline in eGFR. Kaplan-Meier analyses and multivariable Cox models adjusted for baseline eGFR, demographic characteristics, relevant comorbidities, and treatment use were performed. Sensitivity analyses were performed adjusting for albumin-creatinine ratio (ACR), stratifying by baseline CKD stage, and excluding patients with baseline acute kidney injury (AKI).

Results: Patients with HK (n=9,220) vs. those without HK (n=36,764) (mean age 72.3 vs. 72.7 yrs) had higher rates of CKD stage 4 (33.9% vs. 9.7%), heart failure (31.7% vs. 15.0%), and AKI (33.8% vs. 11.5%), and a higher ACR value (393.9 vs. 154.4 mg/g). In the 5-yr study period, 16.7% of HK patients and 3.5% of those without HK progressed to CKD stage 5, and 31.7% and 17.0%, respectively, had an eGFR decline ≥10 units (both log-rank p<0.001). In Cox models, patients with vs. without HK had a statistically significant higher risk of CKD progression to stage 5 (adjusted hazard ratio [aHR] 2.20; 95% confidence interval [CI], 2.02-2.38) and eGFR decline (2.40; 2.28-2.52) (both p<0.001). Cox model results were consistent when adjusting for ACR, stratifying by baseline CKD stage, or excluding AKI patients.

Conclusions: Even after adjusting for relevant comorbidities and treatments, HK was significantly associated with higher risk of progression to CKD stage 5 and eGFR decline among patients with CKD stage 3-4. Associations were robust in all sensitivity analyses.

FR-PO655

Detection of Hypoglycemia Incidents After Hyperkalemia Treatment with Dextrose 50% and Insulin

Mohamed Mansour,[1] Peter Boshara,[1] Mohammed I. Hamdi,[1] Susan M. Szpunar,[2] Joel M. Topf.[3,1] *[1]Ascension St John Hospital, Detroit, MI; [2]St. John Hospital & Medical Center, Grosse Pointe Woods, MI; [3]St. Clair Nephrology, Roseville, MI.*

Background: Hypoglycemia is a potential complication following hyperkalemia treatment with insulin. Most of the previous trials studied this risk in patients with decreased GFR. Our study assessed the incidence of hypoglycemia and its associated risk factors in patients with normal and decreased kidney function.

Methods: We conducted a retrospective study of hospitalized adult patients at a large community hospital who had hyperkalemia [potassium >5.4mmol/L] and were treated with intravenous insulin and dextrose 50%. We identified the incidence of hypoglycemia [blood glucose<70mg/dL] within six hours of insulin administration.

Results: 142 patients were eligible for analysis. 25 patients (17.6%) developed hypoglycemia. Hypoglycemia was detected at a median of 105 minutes after insulin administration. Factors associated with a higher risk of hypoglycemia included lower body mass index mean(25.2±8.2vs.30.3±9.2)p=0.01, no history of diabetes OR 5.16, 95%CI:1.67-16.0;p=0.002, and patients who didn't receive co-treatment with Polystyrene sulfonate [p=0.047]. Patients with hypoglycemia had lower pre-treatment glucose levels compared to patients who did not mean(96.9±50.5vs.154.7±87.8)p=<0.0001. Previous trials showed a lower risk of hypoglycemia in patients who received co-treatment with

albuterol. Our study showed a non-significant trend toward higher risk of hypoglycemia in patients who received albuterol co-treatment [n=19 (20.3%) vs.n=10 (14.7%);p=0.384]. There was no difference hypoglycemia incidents in patients with normal kidney function versus patients with decreased kidney function, [normal kidney function vs. acute kidney injury p=0.98; normal kidney function vs. ESRD p=0.93]. There was no significant difference in the mean eGFR in hypoglycemic versus non-hypoglycemic patients (24.75±32.4vs.24.89±26.0)p=0.98.

Conclusions: Patients with lower BMI and no history of diabetes were at a significantly higher risk for hypoglycemia. This is maybe explained by a lack of insulin resistance associated with low BMI and non-diabetic status. Lower pretreatment glucose levels were associated with hypoglycemia. Hypoglycemia was most likely to develop within 1-3 hours of treatment. This study supports the recommendations of frequent blood glucose monitoring following hyperkalemia treatment with intravenous insulin. Identifying risk factors is crucial

FR-PO656

TolvaThirst: Is Thirst Triggered to Adapt to an Acute Natremia Increase in Chronic Hyponatremic Patients?

Jean-philippe Bertocchio,[1,2] Côme Bureau,[1] Raphael R. Cohen,[1,4] Pascal Houillier,[1,4] Anne Blanchard.[3,4] *[1]Renal and Metabolic Diseases Unit, AP-HP European George Pompidou Hospital, Paris, France; [2]Genito-Urinary Medical Oncology Department, MD Anderson Cancer Center, Houston, TX; [3]Center for Clinical Investigations, AP-HP, European George Pompidou Hospital, Paris, France; [4]Faculty of Medicine, Paris Descartes University, Paris, France.*

Background: Water body content is tightly controlled by both input (mostly, thirst-driven intake) and output (mostly, renal aquaresis). The osmotic-driven thirst threshold is 10 mOsm/kgH_2O higher than that of arginine vasopressin (AVP) secretion; it takes over when AVP-induced antidiuresis fails to limit water loss. In chronic hyponatremic patients, both AVP release and/or thirst could be impaired. However, their ability to maintain natremia within a narrow range in response to acute water loss has never been reported.

Methods: We submitted chronic hyponatremic patients (n=31) to acute water loss through a single oral 15 mg tolvaptan administration, a type 2 AVP-receptor antagonist. We then monitored hourly plasma sodium and osmolality, urine output and osmolality, and water intake, as well as thirst scales.

Results: Overall, tolvaptan induced a significant weight loss (-1.2±1.2%, p<0.001) and natremia increase (+3.0±2.9mM, p<0.001). In 18 "isonatric" patients, natremia remained steady (+1.1±1.6 mM) during the first 6 hours (*cf.* **Figure 1**), whereas in 13 "dysnatric" patients, it significantly increased (+5.8±1.7 mM, p<0.001). Even if all patients had no difference in minimum urine osmolality (*i.e.* no difference regarding to the pharmacological intervention), "isonatric" patients had a better water balance (+1.22±7.2 *vs.*-16.4±7.0 mL/kg, p<0.001), mostly driven by a better water intake during the first hour (13.4±7.5 *vs.*8.8±10.0 mL/min, p=0.009).

Conclusions: Acute aquaresis-triggered water intake prevented changes innatremia in about 60% of the reported patients, whereas in 40% this mechanism was impaired. Further studies are needed to address the (patho)physiology of thirst adaptation and acute water intake in chronic hyponatremic patients, then to develop tools for identifying patients at risk for wide changes in natremia.

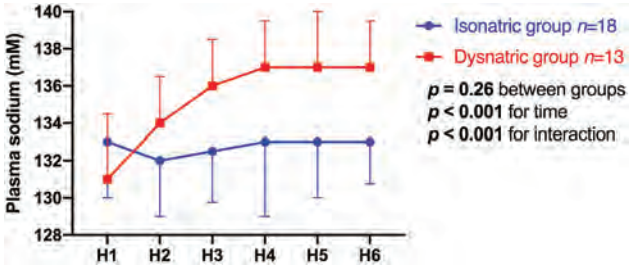

Figure 1. Evolution of natremia after a single tolvaptan administration during the first 6 hours (H1 to H6): 13 "dysnatric" patients significantly increased their natremia, when 18 "isonatric" did not.

FR-PO657

De Novo Central Diabetes Insipidus Abruptly Unmasked by Discontinuation of Intravenous Vasopressin

Jason R. Ledoux, Ivo Lukitsch, Juan Carlos Q. Velez. *Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Introduction: Central diabetes insipidus (CDI) is an uncommon disorder during septic shock. Hyponatremia is also an uncommon adverse effect of intravenous (IV) vasopressin (AVP). Rapid correction of hyponatremia is associated with ominous neurological sequelae. We describe a rare case of abrupt onset of polyuria mimicking CDI following cessation of IV AVP vasopressor use that led to rapid correction of hyponatremia.

Case Description: A 64-year-old woman admitted with small bowel obstruction developed a purulent surgical site infection 6 days post adhesiolysis that required a washout procedure, 13 L of crystalloid fluid resuscitation and transfer to intensive care unit (ICU) for shock management with IV AVP as vasopressor. In the ICU, her serum Na (sNa) gradually dropped from 134 to 121 mEq/L over a 6-day period. Kidney function remained normal. As an attempt to correct the sNa, she received 40-mg IV furosemide and the Na content in parenteral nutrition was increased to 170 mEq/L, but the sNa did not improve. On ICU day 7, she returned to the operating room for additional washout and debridement. IV AVP was discontinued post-Op. Within 2 hours, the urine output (UOP) drastically increased to 600 ml/hr for a total of 11 L of UOP in 24 hrs. At that time, her urine osmolality (uOsm) decreased from 463 to 61 mOsm/kg. Her sNa rapidly corrected from 120 to 135 in 24 hours. To slow the rate of sNa correction, she received 4 L of 5% dextrose in water (D5W) and DDAVP. Her UOP decreased to 150 ml/hr, uOsm rose to 342 mOsm/kg and sNa fell back to 130 mEq/L. Two days later, DDAVP was stopped and sNa remained stable at 137 mEq/L.

Discussion: The case highlights the importance of careful vigilance of UOP and onset of water diuresis in the context of hyponatremia in septic shock treated with IV AVP. In addition to hyponatremia itself, we speculate that prolonged exposure to IV AVP may suppress endogenous release of AVP, leading to abrupt onset of CDI following discontinuation of IV AVP. Discontinuation of IV AVP in hyponatremic patients should be executed cautiously with close monitoring of UOP and uOsm and consideration for concomitant administration of D5W or DDAVP as needed.

FR-PO658

Tolvaptan in Portal Hypertension: Real-Life Experience

Marta Tejedor,[1] Agustín A. Delgado Vázquez,[2] Maria Rosa Melero,[2] Patrocinio Rodriguez benitez,[2] Victor Fernandez-Alonso,[2] Magdalena Salcedo plaza,[2] Alberto Tejedor jorge.[3] *[1]Hospital Infanta Elena, Valdemoro, Madrid, Spain; [2]Hospital General Universitario "Gregorio Marañón", Madrid, Spain; [3]Fundación para la Investigación Biomédica del Hospital General Universitario "Gregorio Marañón", Madrid, Spain.*

Background: Tolvaptan (TVP) is an antagonist of V2 ADH receptors, used for hyponatremia in SIADH, congestive heart failure (CHF) and cirrhosis.

Methods: Retrospective review of TVP use between 2012 and 2017 to study the use of TVP in real life in patients with portal hypertension (PHT) (past history of non-malignant ascites or variceal bleed).

Results: 81 patients received TVP. Of them, 19 had PHT. CHF was more frequent in patients with PHT (53 vs 26%, p=0.03). There were no differences in natremia at the start of treatment (126±1.3 vs 128±0.6mEq/l). There was a delay in the correction of hyponatremia in the PHT subgroup over the first month, being the final serum sodium concentration 135±1.6 vs 139±0.8mEq/l (p=0.02). We found no difference in survival. In the PHT subgroup, 8 had confirmed cirrhosis and 11 severe CHF. The cause of cirrhosis was hepatitis C (n=3), alcohol (n=4) and unknown (n=1). 4 had hepatocellular carcinoma. Mean MELD score at the time of receiving tolvaptan was 12±2.3. Only one patient received a liver transplant 4 months after treatment with TVP. Cirrhotics had significant comorbidities (13% CHF; 13% microcytic lung cancer; 75% squamous cell carcinoma; 25% SIADH) and polypharmacy (13% antidepressants; 38% diuretics; 13% antiepileptics; 38% benzodiazepines; 13% cytostatics; 13% antipsychotics). Cirrhotics had fewer episodes of hyponatremia (8.4±1.1 vs 10.6±2.8), although not statistically significant. There was a trend for TVP treatment to be longer in cirrhotics (23.2±7.4 vs7.3±2.6 days, p=0.07). We studied the delay in hyponatremia correction observed in patients with PHT: it was attributable to patients with CHF, in whom the mean increase in serum sodium concentration over the first month was 1.4±1.9 vs 7.2±1mEq/l in cirrhotic patients (p=0.03). Median survival time was 105 weeks (CI95% 0-239) in CHF vs 5 weeks (CI95% 3-7) in cirrhotics, but was not statisticallt significant.

Conclusions: Even though TVP is approved for its use in hyponatremia associated to advanced cirrhosis as a bridge to liver transplant, in our centre its use is reserved to patients with significant comorbidities that can contribute to the development of hyponatremia and worsen its prognosis. Presence of ascites in CHF as a surrogate for PHT complicates management, delaying the correction of hyponatremia.

FR-PO659

Use of Selective Serotonin Reuptake Inhibitors and Risk of Hyponatremia in a Large Health Care System

Shengyuan Luo,[1] Aditya L. Surapaneni,[1] Yao (Lucy) Qiao,[4] Jung-Im Shin,[1] Lesley Inker,[2] Alex R. Chang,[3] Morgan Grams.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Tufts Medical Center, Boston, MA; [3]Geisinger Medical Center, Danville, PA; [4]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Selective serotonin reuptake inhibitors (SSRIs) use may increase the risk of hyponatremia. We aimed to quantify hyponatremia risk associated with SSRIs compared to that of serotonin-norepinephrine reuptake inhibitors (SNRIs) and determine whether it differs by eGFR and thiazide diuretic use.

Methods: Among primary care patients prescribed SSRIs between January 1, 2004 and January 30, 2017 in the Geisinger Health System, we defined mild and moderate hyponatremia as outpatient blood Na<135mEq/L and <130mEq/L in the 3 months after medication initiation. We then used propensity score matching to pair patients prescribed SSRIs with those prescribed SNRIs and evaluated differences in hospitalizations for hyponatremia (defined by ICD-9 and -10 codes) during the entire course of medication use, overall and stratified by demographic factors, level of eGFR, and thiazide diuretic use.

Results: Among 69,551 patients prescribed SSRIs, 25% had a blood sodium measurement within 3 months after initiation. The risk of mild and moderate hyponatremia was 11% and 3%. In comparison, 25% of the 30,089 patients prescribed SNRIs had monitoring, and the risk of mild and moderate hyponatremia was 7% and 1% (p<0.01 for both comparisons to SSRIs). In the propensity matched cohort, there was no difference in

hyponatremia hospitalization overall (1.1% in SSRIs vs. 0.9% in SNRIs; HR=1.08, 95%CI 0.92-1.28; p=0.35), but higher among those with thiazide diuretic use (1.7% in SSRIs vs. 0.9% in SNRIs; HR=1.45, 95%CI 1.00-2.10; p<0.05)(**Figure**). There was no difference in risk of hospitalized hyponatremia by level of eGFR.

Conclusions: Patients prescribed SSRIs had infrequent monitoring but were at risk for short-term outpatient hyponatremia. Thiazide diuretic use may potentiate the risk of hospitalized hyponatremia with SSRI use.

Funding: NIDDK Support

Figure. Risk of hospitalized hyponatremia comparing propensity-score matched patients prescribed SSRIs and those prescribed an SNRIs.

Leveraging Electronic Medical Records to Expedite Hyponatremia Management

Marie A. Sosa,[1] Maritza M. Suarez,[2] David Seo.[3] *[1]Medicine, University of Miami Miller School of Medicine, Miami, FL; [2]Medicine, University of Miami, Miami, FL; [3]University of Miami Health System, Miami, FL.*

Background: Hyponatremia is defined as serum sodium (Na) ≤135 mmol/L[1]; values ≤125 mmol/L are considered severe. Guidelines suggest Na correction should not exceed 6–8 mmol/L in 24 hours for either acute or chronic hyponatremia, regardless of clinical presentation[6,7]. We analyze the impact of electronic medical record (EMR) alerts to improve the diagnosis of hyponatremia, expedite appropriate management and prevent errors; this has never been described in the literature.

Methods: 2-cohort retrospective chart review conducted on inpatients before and after the implementation of two novel alerts. The first alert informed the physician of severe hyponatremia. The second alert displayed for nurses when the Na rose more than 1.5 mmol/L for two consecutive Na, prompting them to contact the provider. Cohort 1 comprised all inpatients at UHealth Tower in the 3 months before the alert's implementation. Data was collected for patients experiencing at least one Na of ≤125, and included pertinent blood and urine levels, as well as patterns of physician response. Cohort 2 comprised every patient who provoked a BPA in the 3-month period after go-live. Using the Mann-Whitney test and Fisher's Exact test for data analysis, primary endpoints were the percent of patients treated for hyponatremia, percent whose Na was normalized, and overcorrection difference. Secondary endpoints included time to intervention and treatment types.

Results: 41 patients had a Na ≤125 in cohort 1 vs 5 patients in cohort 2 (p<0.05). Na overcorrection was not seen in cohort 2; and was 9% in cohort 1 (p=1). 85% in cohort 1 received treatment for hyponatremia vs 80% in cohort 2. Na returned to normal in 75% of cohort 1 vs 40% in cohort 2, which could be due to the small sample size. Faster treatment intervention was seen in cohort 2: 76 mins vs. 24 mins (p=0.2798). Treatments in both cohorts primarily comprised normal saline and fluid restriction.

Conclusions: The implementation of EMR alerts significantly reduce the incidence of severe hyponatremia and may improve response provider response time, with lower overcorrection rates. These unique alerts, geared to assist in the timely management of hyponatremia, could be expanded to other tests and conditions. A follow-up study to explore standardizing management is ongoing.

FR-PO661

Severe Hypernatremia from Sea Water Ingestion Treated with Continuous Renal Replacement Therapy

Jiunn Wong, Su Hooi Teo. *Singapore General hospital, Singapore, Singapore.*

Introduction: Severe hypernatremia is uncommon and conventional management of patients with severe hypernatremia is unpredictable. Too rapid or too slow correction can both lead to catasthrophic outcome. We report a case of a patient who was lost at sea for 3 days and presented with serum sodium of 174mmol/L. He was managed with continuous veno-venous hemodiafiltration (CVVHDF) for controlled reduction of sodium.

Case Description: A 59 year-old gentleman was found at sea 3 days after being reported missing. On presentation, he was dehydrated, lethargic with first degree sun burnt over his body. He was tachycardia (heart rate of 118 bpm), BP 104/74mmHg. His weight was 80kg and height 170cm. His sodium was 174mmo/L, chloride > 140mmo/L, bicarbonate 10.3mmol/L, Creatinine 118micromol/L, urea 14.8mmol/L, glucose 5.5mmol/L and serum osmolality of 357mOsm/kg. His urine sodium 221mmol/L, urine potassium 69mmol/L and urine osmolality 1100mOsm/kg. His urine output ranged between 40-50mls/hour. He was managed initially at the emergency department with Dextrose 5% drip and kept nil by mouth. His sodium drops from 174mmol/L to 168mmol/L over the next 6 hour. Due to risk of unpredictable changes in sodium level, decision was made to initiate CVVHDF with citrate anticoagulation. His dialysis prescription was as follows: Qb of 150mL/min, Qd of 1L/hour, QR of 1.6L/hour via a left femoral dialysis catheter. Customization of dialysate and replacement fluid was performed by addition of 3% sodium chloride solution. His sodium levels decreased as expected. and achieved normal sodium level over 4 days. He was weaned off CVVHDF on day 5. (Figure 1) Patient subsequently was transferred to a private hospital for further management.

Discussion: Extreme hypernatremia is rare and changes in sodium level with conventional treatment can be unpredictable. Correction of severe hypernatremia with CVVHDF provide a slow reduction of serum sodium in a controlled manner with positive outcome.

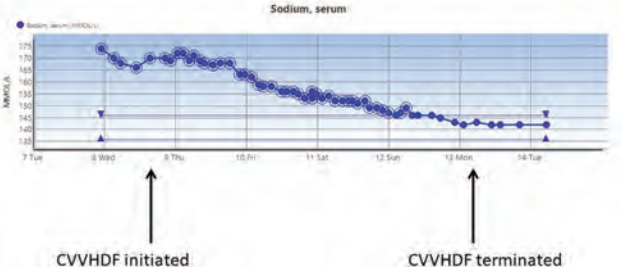

Figure 1: Serum sodium trend prior, during and after CVVHDF

FR-PO662

Acid-Base Disturbances in Multiple Myeloma

Amol M. Patel,[1] Benjamin J. Lee.[2] *[1]Houston Methodist Hospital, Houston, TX; [2]Houston Kidney Consultants, Houston, TX.*

Introduction: Multiple myeloma (MM) can be associated with several acid/base abnormalities that may not be as frequently appreciated as other clinical manifestations such as renal insufficiency, anemia, hypercalcemia, lytic bone lesions.

Case Description: A 62-year-old man with relapsed IgA kappa monoclonal MM presented with confusion and malaise. Labs showed: serum bicarbonate 13 mEq/L, serum chloride 102 mEq/L, anion gap (AG) 19, albumin 1.6 g/dL. Beta-hydroxybutyrate and lactic acid were not elevated. Additional labs included: blood urea nitrogen 29 mg/dL, creatinine 1.1 mg/dL, eGFR 72 mL/min/1.73m^2. Arterial blood gas demonstrated pH 7.50, pCO2 18 mmHg, pO2 95 mmHg. Head imaging and infectious work-up were unremarkable. Although renal function normalized with supportive care, symptoms did not improve and these acid/base abnormalities persisted. Despite no history of liver disease and normal liver function tests, serum ammonia was elevated at 142 umol/L. MM-associated hyperammonemic encephalopathy leading to hyperventilation was felt to be the cause of his respiratory alkalosis. In addition, the elevated AG was attributed to presumed negatively charged IgA. Ultimately, plasma exchange was started, and he received carfilzomib, pomalidomide, and dexamethasone. His acid/base abnormalities subsided with treatment of his MM, and mental status returned to baseline.

Discussion: This case demonstrates unusual acid/base disturbances associated with MM. Respiratory alkalosis from hyperammonemic encephalopathy is thought to be due to excess ammonia production by myeloma cells.[1] Several cases report failure with standard treatments for hyperammonemia but response to chemotherapy.[2-3] Furthermore, inpatient mortality is reduced in patients who received MM-targeted therapy compared to those who did not.[4] The AG metabolic acidosis is presumed due to negatively charged IgA immunoglobulins. An increased AG has been reported in up to 30% of patients with IgA monoclonal gammopathy, in contrast to a decreased AG that is more commonly seen in IgG gammopathy.[5] Of note, however, the magnitude of AG elevation does not correlate with monoclonal protein concentration, and AG abnormalities are not a sensitive test for screening for monoclonal gammopathies.[5] It is important for clinicians to recognize and understand these potential acid/base disturbances in MM, as early identification may expedite proper therapy.

FR-PO663

Tolvaptan Resistance in Severe SIADH

Alan Segal. *University of Vermont, Burlington, VT.*

Introduction: Approaches to treat euvolemic hyponatremia include: 1) minimizing input of hypotonic solutions (restricting positive free water); 2) administering hypertonic solutions (giving negative free water); 3) decreasing the driving force for electrolyte-free water reabsorption by a) increasing the urinary solute load (oral urea, NaCl, KCl) and b) decreasing medullary concentration (loop diuretics); and 4) decreasing the permeability for electrolyte-free water reabsorption (demeclocycline, vaptan aquaretics). The recent introduction of tolvaptan provides a molecular tool to essentially treat the syndrome of

inappropriate anti-diuretic hormone (SIADH) secretion with "nephrogenic DI in a bottle." We present a case where all of these approaches were utilized.

Case Description: A 48-year-old man developed severe hyponatremia (serum [Na] 107 mM) due to SIADH in the setting of recurrent metastatic small cell lung cancer. He was asymptomatic. Oral fluid restriction and 3% NaCl were employed to gradually increase his serum [Na] to 125 mM over 4 days. He was then placed on tolvaptan 15 mg daily without effect, so the dose was increased to 30 mg daily and he was discharged home 2 days later with a serum [Na] of 131 mM. Over the next 4 days, serum [Na] decreased to 127 mM and 3 days later he felt "off" and was re-admitted with serum [Na] 117 mM. Tolvaptan was increased to 60 mg daily—and ultimately to 60 mg twice daily—without effect, as urine osmolality remained >900 mosm/kgH_2O. Serum [Na] increased sluggishly to 122 mM two days later but then decreased again to 117 mM. Tolvaptan was discontinued and he was placed on NaCl tablets 2 g tid, KCl 20 mmoles twice daily, and furosemide 40 mg twice daily. Over the next 3 days, serum [Na] increased to 124 mM. Oral urea 15 g twice daily was started and serum [Na] only increased to 126 mM, so the dose was increased to 30 g twice daily, and over the next 4 days serum [Na] increased to 140 mM. The patient has since maintained isotonicity on twice daily use of urea 30 g, NaCl 2 g, KCl 20 mmoles, and furosemide 40 mg.

Discussion: This case illustrates that a patient with severe SIADH may be resistant to a maximal dose of tolvaptan yet still respond to traditional measures. Therefore, while aquaretic therapy aimed at the underlying free water permeability defect may be more physiologically elegant, maneuvers that modify the driving force for electrolyte-free water reabsorption may be more practical.

FR-PO664

Dysnatremia and Crude Mortality Rates: Evidence from the Sodium Metabolism and Management Experience (SoMME) Study

Peter E. Umukoro,[1] Muhammad Ishaq,[1] Babatunde Olaiya,[1] Ridhima Monga,[1] Fahad A. Lodhi,[1] Richard A. Dart.[2] Sodium Metabolism and Management Experience (SoMME) Study Team *[1]Internal Medicine, Marshfield Medical Center, Marshfield, WI; [2]Marshfield Clinic Research Institute, Marshfield, WI.*

Background: Few studies have evaluated the association of dysnatremia with mortality among hospitalized patients. It is unclear if there is a reduced mortality rate among hospitalized patients with deranged sodium levels. We evaluated the association between sodium levels on admission with in-patient mortality, 30 day mortality and long term mortality. We hypothesized that mortality rates will vary by sodium levels with worse mortality outcomes at both extremes of sodium levels.

Methods: We obtained data from 39261 patients admitted between 2012-2016 patients who had a serum sodium on admission at a tertiary referral hospital in Central Wisconsin. We classified them into five categories based on their admitting serum sodium as severe low (<125), moderate low (125-129), mild low (130-134), normal (135-145) and high (>145). We obtained their vital status (alive or deceased) at end of hospital stay, within 30 days of admission and at the end of study period on December 31, 2017. Data were stratified by age and sex.

Results: There were 39261 patients (53% males, 97% whites) with age groups: <45 (12%), 45-64 (30%), 65-84 (44%) and >=85 years (14%). A U-shaped distribution of mortality is associated with serum sodium levels with mortality associated with high sodium levels being the greatest. Mortality associated with moderate low sodium levels almost approximate that of severe low sodium levels. These results were consistent across age and sex.

Conclusions: Higher crude mortality was seen in all patients with dysnatremia. Hypernatremia was associated with the worst mortality. Exploring mechanisms that contribute to death in dysnatremia, and researching if correcting sodium levels may prevent further deaths in the future.

Funding: Private Foundation Support

Mortality during admission, within 30 days of admission or at end of study period by levels of admitting serum sodium level

Sodium on admission mmol/L	Number of admissions N	Deceased during admission* N (%)	Deceased during admission or within 30 days of admission* N (%)	Deceased at end of study* N (%)
Severe low (<125)	506	26 (5.1)	61 (12.1)	240 (47.4)
Moderate low (125-129)	1210	71 (5.9)	152 (12.6)	580 (47.9)
Mild low (130-134)	8724	282 (3.2)	592 (6.8)	2935 (33.6)
Normal (135-145)	27813	625 (2.3)	1148 (4.1)	5227 (18.8)
High (>145)	1008	97 (9.6)	187 (18.6)	489 (48.5)
Total	39261	1101 (2.8)	2140 (5.4)	9471 (24.1)

*p-value for trend is <0.0001 using the chi-square statistic for all outcomes.

FR-PO665

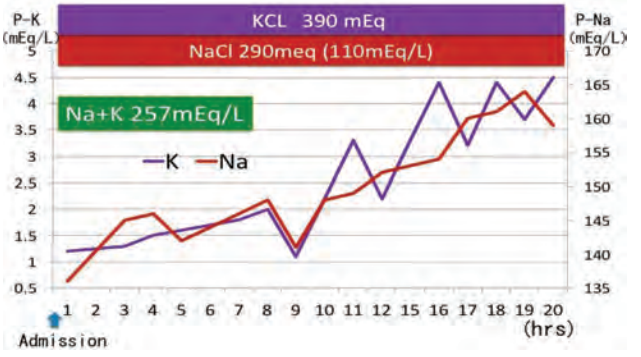
Hypernatremia Induced by Treatment for Hypokalemia in a Patient with Sjögren Syndrome and Renal Tubular Acidosis

Hideaki Shimizu. *Daido Hospital, Nagoya, Japan.*

Introduction: Hypokalemia and metabolic acidosis are severe complications of renal tubular acidosis (RTA) in Sjögren's syndrome. The concentration of sodium in the plasma water should equal the concentration of sodium plus potassium in the total body water. The sodium concentration is not always considered when treating hypokalemia.

Case Description: A 60-year-old women presented with general weakness, hypotension, hypokalemia, metabolic acidosis, and acute kidney injury. Her blood pressure was 60/44mmHg, and her heart rate was 89/min. Na^+ 144 K^+ 1.5 mEq/L, Cl^- 114 mEq/L, glucose 166 mg/dL, BUN 65.9 mg/dL, Cr 2.34 mg/dl, pH 7.052, P_{CO2} 36.2, P_{O2} 321, and HCO^{3-} 9.6 mEq/L. Urinary electrolytes Na^+ 41 mEq/L, K^+ 12.2 mEq/L, Cl^- 32 mEq/L, pH 6.5, Osmolality 244 mOsm/kg. The patient was intubated because of respiratory muscle weakness from severe hypokalemia. She was treated with intravenous potassium chloride (KCl 400 mEq) and isotonic fluid for the treatment of hypovolemic shock. This solution was actually hypertonic because of its high potassium concentration: Na^+ 110 mEq/L, and K^+ 147 mEq/L, in a total of 2.6 liters. After 18 hours the patient developed hypernatremia (Na^+ 161 mEq/L), but her serum potassium had normal sized (K^+ 4.6 mEq/L). Her urinary measurements were as follows: Na^+ 40 mEq/L, K^+ 52.7 mEq/L, Cl^- 82 mEq/L, and osmolality 405 mOsm/kg. After the hypertonic fluid was changed to a hypotonic type, she recovered. She was also found to have Sjögren's syndrome after a positive screen for anti-Lo, and anti-Ra antibodies. A positive Schirmer's test and a renal biopsy also suggested Sjögren's syndrome. She was discharged without complications. There is no physical examination or other vital signs.

Discussion: This case indicates that serum sodium concentration should be carefully monitored in patients with hypokalemia and acute kidney injury induced by distal RTA receiving intravenous potassium chloride therapy and hypertonic fluid, which contain high levels of potassium. We should keep this complication in mind when treating severe hypokalemia.



Clinical Course

FR-PO666

Symptomatic Hyponatremia: SIADH or NSIAD): Diagnostic Challenge, Surprise Diagnosis, and Successful Management with Tolvaptan for 6 Years

Vimal Chadha,[1] D. D. Beahm,[2] Uri S. Alon.[3] *[1]Children's Mercy Hospital, Kansas City, MO; [2]University of Kansas, Kanasa City, KS; [3]The Children's Mercy Hospital and Cklinics, Kansas City, MO.*

Introduction: Syndrome of inappropriate antidiuretic hormone secretion (SIADH) is the most common cause of euvolemic hyponatremia. In the absence of any identifiable cause after extensive investigations, and especially in the presence of low or undetectable serum ADH level, diagnoses such as nephrogenic syndrome of inappropriate antidiuresis (NSIAD) caused by gain-of-function mutations in the V2 vasopressin receptor (V2R) have to be entertained. Chronic management of symptomatic hyponatremia can also be a challenge.

Case Description: A 17 year old previously healthy girl presented with dizziness, and short-term memory loss. Blood tests revealed serum sodium 128 mEq/L. Clinical picture was suggestive of SIADH (euvolemic state, low serum osmolality, increased urinary osmolality, and increased urinary sodium level) but extensive investigations/imaging studies failed to delineate any underlying cause for SIADH. Review of old medical records revealed normal serum sodium (142 mEq/L) over a decade ago. She was managed as possible SIADH, with water restriction that resulted in modest improvement in her serum sodium level. A month later her symptoms recurred with recurrence of hyponatremia. Serum ADH levels returned undetectable on both occasions and were confirmed to be low 3rd time from two different labs. Later, her serum sodium acutely dropped to 119 mEq/L when she drank water prior to a renal ultrasound. She was suspected having NSIAD but DNA sequencing of V2R gene did not show any mutation. She was managed with combination of moderate fluid restriction and daily Tolvaptan. Five years later, she had seizures with severe hyponatremia (109 mEq/L) after taking SSRI for depression. 1½ year later she had another episode of unexplained hyponatremia (118 mEq/L), and a head MRI was repeated for headache after correction of hyponatremia which revealed a small enhancing mass in the right osteomeatal infundibulum. The mass turned out to be small blue cell tumor esthesioneuroblastoma, a relatively rare nasal tumor that is rarely associated with SIADH. She underwent complete tumor resection with clear margins, and now has normal serum sodium without any fluid restriction or medications.

Discussion: Patients with chronic unexplained hyponatremia should be followed very closely and reevaluated periodically with high index of suspicion for unusual tumors.

FR-PO667

Is There a Role for Concomitant Administration of Albumin and Diuretics? A Meta-Analysis

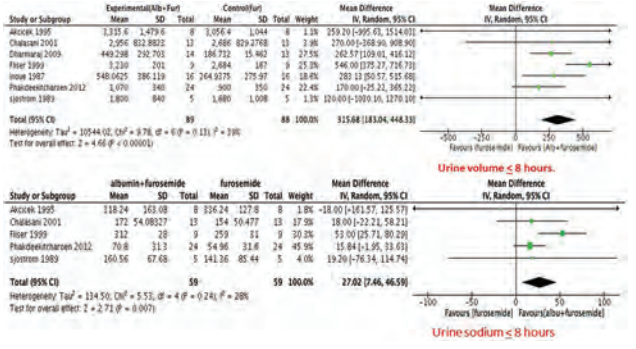
Gajapathiraju Chamarthi, Justin Lee Loy, Hannah F. Norton, Harini Bejjanki, Rajesh Mohandas. *University of Florida, Gainesville, FL.*

Background: Diuretics are the cornerstone of volume management in patients with disease states such as heart failure, nephrotic syndrome and cirrhosis. Diuretic resistance is commonly encountered in such patients and is often attributed to hypoalbuminemia. Albumin is sometimes empirically used to increase diuretic efficacy in these patients. We sought to systematically study the effect of albumin combined with diuretics on urine volume and urine sodium in patients with hypoalbuminemia.

Methods: Systemic search of electronic databases from inception until June 2018 was performed. We included clinical studies in patients with hypoalbuminemia that included more than 5 subjects, comparing co-administration of albumin and diuretics versus loop diuretics alone. A total of 754 records were screened independently by two investigators. 26 full text articles were assessed for eligibility. Synthesis of data was done using meta-analysis techniques using Revman Software.

Results: There were 9 eligible studies which met the criteria and had the required data. All of them were cross over studies. 6 of the studies were done exclusively in nephrotic syndrome patients, one of which included pediatric subjects. There was a statistically significant increase in urine volume of 315 ml (95% CI 183.04, 448.33) and urine sodium of 27 meq (95% CI 7.46, 46.59) at 8 hours with co-administration of albumin and furosemide compared to furosemide alone[fig]. There was no statistically significant increase in the 24 hour urine output 385 ml (95% CI -141.92, 911.68).

Conclusions: Our results suggest that in patients with hypoalbuminemia, co-administration of albumin and furosemide increases urine output and sodium excretion at 8 hours. There were no differences in urine volume at 24 hours, but most these studies used single doses or few hours of diuretic infusions. Randomized controlled trials in patients with defined diuretic resistance is required to confirm the efficacy of co-administration of albumin and furosemide.



FR-PO668

A Case of IgG4-RD Manifesting as Kidney Disease: Idiopathic or Lymphoproliferative Etiology?

Michael Bond,[1] Yashpal S. Kanwar,[2,1] Shubha Ahya.[1] *[1]Department of Medicine - Division of Nephrology and Hypertension, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Department of Pathology, Northwestern University, Chicago, IL.*

Introduction: IgG4-RD is a systemic inflammatory disorder characterized by infiltration of IgG4+ plasma cells into affected tissues. When IgG4-RD involves the kidneys it manifests most frequently as tubulointerstitial nephritis and/or membranous nephropathy. Imaging often demonstrates bilateral cortical nodular lesions.

Case Description: A 61-year-old male with hypertension presented for evaluation of elevated serum creatinine to 1.89 mg/dL. He noted NSAID use 2-4 times/week for back pain for much of the year prior, and home systolic BP readings 140-150mmHg. Additional workup revealed 378mg protein on 24-hour urine; and elevated free kappa and lambda light chains. SPEP showed hypergammaglobulinemia, with immunofixation electrophoresis negative for monoclonal bands. Bone marrow biopsy demonstrated multilineage hematopoiesis and 3% polytypic plasma cells without evidence of clonality; Congo red stain was negative for amyloid. Spine MRI showed no lytic lesions, but did identify a 2cm L thyroid nodule. PET/CT revealed markedly enlarged and hypermetabolic kidneys bilaterally. A diagnosis of plasma cell disorder was made. Renal biopsy showed severe lymphoplasmacytic tubulointerstitial disease with abundant IgG4+ plasma cells. Molecular analysis of the plasma cell infiltrate detected a clonal IgH gene rearrangement in a polyclonal background. Thyroid tissue from a left hemithyroidectomy for the above nodule was negative for IgG4, but an included adjacent lymph node was diffusely IgG4+. The patient's serum creatinine demonstrated a stable improvement to 1.3-1.4 mg/dL since initiation of workup.

Discussion: This is an unusual presentation of an uncommon disease, IgG4-related disease. Immunohistochemical staining indicated a polytypic plasma cell infiltrate on renal biopsy, while molecular testing identified a clonal cell population with IgH gene rearrangement, raising the possibility of multiple populations of plasma cells: one polyclonal, another IgG4+, and a third that is clonal and producing paraprotein. Further workup is needed to determine the etiology.

FR-PO669

Curious Case of Hypercalcemia

Kavitha Ramaswamy,[1] Goni Katz-Greenberg,[2] Anju Yadav.[1] *[1]Nephrology, Thomas Jefferson University Hospital, Philadelphia, PA; [2]Thomas Jefferson University Hospital, Philadelphia, PA.*

Introduction: Hypercalcemia is a well-known phenomenon in malignancy. There is humoral hypercalcemia of malignancy mediated by increased parathyroid hormone-related peptide PTHrh(80%), local osteolytic hypercalcemia(20%) but in hematological tumors, another pathway of overproduction of 1, 25(OH) 2 D3 from tumor cells can cause this accounting for 1% of cases. Hereby we present a case where the only finding was mild splenomegaly and positive 1, 25(OH)2D3 leading to ultimate diagnosis of primary splenic large B cell lymphoma.

Case Description: 71-year-old male with past medical history of neuroendocrine tumor of right middle lobe of lung resected 15 years ago with no evidence of recurrence to date, history of mild elevation in PSA with biopsy showing no prostate cancer on 12/12 cores, presented to emergency department with weakness, nausea. Found to have hypercalcemia and AKI. He received pamidronate as an inpatient. His inpatient work up included CT scans (non-contrast), bone scan, skeletal survey that was negative for malignancy. However there was mild splenomegaly (14.1 cm) noted on CT. There were several calcified lymph nodes in the mediastinum as well calcified pleural plaques. Multiple myeloma screening labs were negative. PTHrh was not elevated. Flow cytometry of peripheral blood revealed no abnormalities. TB testing is negative. ACE for sarcoidosis was in normal range. PTH was suppressed. Vit D 1, 25(OH) 2 D3 was elevated at 133. Although no malignancy was found on extensive work up, we strongly felt that it was the most likely cause and referred to oncology. He was discharged after his calcium stabilized around 11. Bone marrow biopsy was done showing no evidence of disease. Finally, PET CT was performed showing a hypermetabolic spleen. He underwent splenectomy on 7/25/2018. Pathology was consistent with primary splenic large B cell lymphoma. His hypercalcemia has completely resolved. He has recovered well from his surgery. He was given standard therapy for diffuse large B cell lymphoma, which is R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone). He received 6 cycles of R-CHOP. Post treatment PET scan showed no evidence of disease.

Discussion: Hypercalcemia is rare in patients with B cell NHL, with its insidious presentation requiring urgent treatment. Dedicated evaluation is required in these cases. The presentation with hypercalcemia has a serious impact on prognosis and survival.

FR-PO670

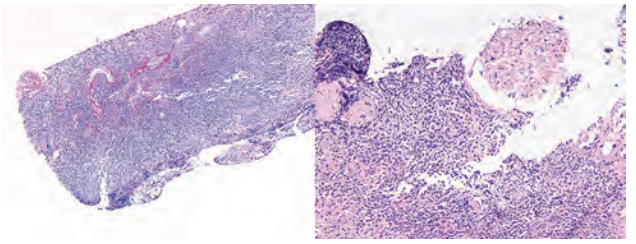
Glomerulopathy, Lymphomatous Kidney Infiltration, and AKI as the First Sign of Relapsed Mantle Cell Lymphoma

Victoria Gutgarts,[1,3] Steven Salvatore,[2] Roman A. Shingarev,[1,3] Ilya Glezerman.[1,3] *[1]Department of Medicine, Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY; [2]Department of Pathology, Weill Cornell Medical College, New York, NY; [3]Department of Nephrology, Weill Cornell Medical College, New York, NY.*

Introduction: Paraneoplastic glomerulopathy may be an early sign of malignancy. Membranous nephropathy (MN) is the most common glomerular disease reported with solid tumors and is rare in liquid tumors. We report a case of concomitant MN, lymphomatous infiltration, and acute kidney injury as the first sign of Mantle Cell Lymphoma (MCL) relapse.

Case Description: 70-year-old male with Chronic Kidney Disease stage 3 and in remission from MCL treated with autologous stem cell transplant in 2011 presented with new shortness of breath for one week. His blood pressure was 160/90, pulse 110bpm, and oxygen saturation 96% on room air. He had pitting edema to the thighs and crackles at the lung bases. Significant laboratory values included serum creatinine of 8.0 (0.7-1.3)mg/dl, baseline of 3.0mg/dl, and serum albumin of 2.2 (3.8-5.0)g/dL. Urinary protein to creatinine (UPC) ratio was 22. Urine sediment showed 5RBCs and 0WBCs per HPF. Serum immunofixation was positive for IgM kappa. Serum kappa/lambda light chain ratio was 2.0 (16/8mg/dl). Patient underwent kidney biopsy which showed widespread lymphoma infiltration (figure below) and 8/11 glomeruli globally sclerosed, the remaining had capillary wall spikes, and subepithelial deposits on electron microscopy. Immunoflourescence showed inflammatory cells positive for IgM and kappa. PLA2R staining was weakly positive. The patient recieved methylprednisolone 1 gram for 3 days and acalabrutinib for his relapsed MCL. One week later, UPC was 12, but creatinine was unchanged likely due to ongoing lymphomatous infiltration.

Discussion: This case highlights the importance of clinician suspicion for relapsed disease in patients presenting with nephrotic syndrome and prior history of liquid tumor. This case is unique since the kidney biopsy showed two distinctive pathologic findings including subepithelial deposits consistent with secondary MN and lymphomatous infiltration of the parenchyma. Treatment should focus on the underlying malignancy where earlier detection may improve outcomes.



Infiltrating lymphoma and glomeruli with capillary wall thickening.

FR-PO671

Unique Presentations of Post-Renal Transplant Gamma Delta T Cell Lymphoma

Rujuta R. Patil,[1] Anita K. Patel.[2] *[1]Wayne State University School of Medicine, Detroit, MI; [2]Henry Ford Hospital, West Bloomfield, MI.*

Introduction: Post-transplant lymphoproliferative disorder (PTLD) is serious complication occurring in up to 10% of solid organ transplant recipients (R). In monomorphic PTLD, the majority of cases arise from B cells (good prognosis) and rarely from T cells. Less than 5% of T-cell lymphomas express gamma delta T-cell receptors. Gamma delta T cell lymphomas (GDTL) are outlined into two groups: hepatosplenic (HSGDTL) and primary cutaneous (PCGDTL). We present 2 recipients that developed PCGDTL and HSGDTL.

Case Description: R1 was a 67-year-old male who received a living, unrelated renal transplant, induced with Simulect. He was EBV IgG + and mismatched CMV IgG -. He presented 1-year post transplant with 20lb weight loss, pruritic skin rash, no EBV DNAemia, and diffuse lymphadenopathy on body PET CT. Biopsy of left axillary lymph node, skin, and bone marrow revealed a mature stage 4 T-cell lymphoma (CD2+, CD3+, CD4+, CD5+, CD7+, CD8-, CD45+, TCR gamma-delta TCR+, and alpha-beta TCR-). This case of PCGDTL had an unusual phenotype of CD4 positivity with presentation in lymph nodes and bone marrow. Immunosuppression was discontinued. Following treatment with 6 cycles of EPOCH regimen with complete resolution, his disease relapsed 2 months later and he died with a functioning allograft within 1 year of diagnosis. R2 was a 44-year-old male who received a deceased donor renal transplant, induced with Thymoglobulin. He was EBV IgG+ and non-mismatched CMV IgG-. He presented 7 years post transplant with abdominal pain, abnormal liver function tests, no EBV DNAemia, and moderate hepatosplenomegaly on abdominal CT. Peripheral blood flow cytometry and bone marrow biopsy revealed HSGDTL (CD2+, CD3+, CD4-, CD5-, CD7+, CD8 (dimly positive), CD25-, gamma/delta TCR+, and alpha/beta TCR-). Immunosuppression was discontinued. He was treated with 2 cycles of CHOEP regimen with treatment failure and 3 cycles of salvage therapy (Gemcitabine, Decadron, Carboplatin) with complete resolution. He relapsed with leukemic conversion 2 months later and died with a functioning allograft.

Discussion: Our cases demonstrate that GDTL is an aggressive neoplasia with rapid onset and poor prognosis. Despite initial response, both recipients died within 1 year of diagnosis. PCGDTL seems to clinically present earlier than HSGDTL. Also, neither of our patients had CMV/EBV viremia, suggesting GDTL development is potentially independent of virology.

FR-PO672

Renal Microangiopathy and Tubulitis Following Haploidentical Stem Cell Transplant with α/β T Cell and CD19 B Cell Depletion

Amber Hertz-Tang, Vaishalee P. Kenkre, Weixiong Zhong, David Yang, Arjang Djamali, Gauri Bhutani. *University of Wisconsin Madison, Madison, WI.*

Introduction: Selective depletion of α/β T-cells and CD19 B-cells in haploidentical (haplo) hematopoietic stem cell transplantation (HSCT) is being investigated as a strategy to avoid graft versus host disease (GVHD) while preserving immune reconstitution. We describe 4 cases of renal dysfunction following haplo-HSCT.

Case Description: All cases were Caucasian males who underwent non-myeloablative peripheral blood haplo-HSCT using fludarabine, cyclophosphamide and total nodal irradiation (7Gy). All reached engraftment and received mycophenolate (MMF) for GVHD prophylaxis (30 days). All are living at last follow up. The table summarizes their presentations.

	Case 1	Case 2	Case 3	Case 4
Diagnosis	Chronic Lymphocytic Leukemia	Marginal Zone Lymphoma	Peripheral T-Cell Lymphoma	Mantle Cell Lymphoma
Age at HSCT	52	57	55	65
Baseline serum creatinine (mg/dl) (eGFR mL/min/1.73sqm) pre-HSCT	1.06 (85)	1.63 (46)	0.89 (93)	1.03 (72)
Total follow up post-HSCT (days)	1021	491	315	301
Time to 50% GFR loss (days)	127	199	277	155
Renal pathology	Thrombotic microangiopathy (TMA) and active tubulointerstitial nephritis (TIN)	Severe chronic active TIN and TMA	Mild chronic and active TMA and acute tubular necrosis (ATN)	ATN, TIN, TIN and chronic active TMA
Infections [pre-immuno-suppression (IS)]	CMV	None	•CMV •C.diff	C.diff
Other organ dysfunction (days post-HSCT)	Skin-GVHD confirmed (29)	None	•Skin-GVHD presumed (33) •Gut-GVHD confirmed (176) •Pulmonary hypertension (308)	•Skin-GVHD confirmed (45) •Lung-GVHD presumed (129) •Pulmonary hypertension (82)
GVHD treatment	•Prednisone •MMF •Rituximab •Eculizumab -Renal indication	•Prednisone •MMF •Etanercept -Renal indication	Prednisone -GI indication	•Prednisone •Sirolimus -Pulmonary indication
Infections (post-IS)	•Aspergillus •Pseudomonas •Influenza A	•Strep pneumo •C.diff •Parapertusis •Adenovirus	•H.influenza •RSV	•MSSA •Pseudomonas •E.coli sepsis
Renal response	Partial response (PR) to IS. Progressed to ESRD with infections.	PR to IS. Progressed to ESRD with infections.	PR to IS. Last known serum creatinine:2.36 eGFR:29	No IS given for renal disease. Progressed to ESRD in setting of infections and cardiac disease

Discussion: All patients had endothelial injury and most (3/4) had inflammatory tubular pathology. Given the setting of haplo-HSCT with selective T-cell depletion, timeline and degree of renal insult, as well as response to IS, renal complications were most concerning for alloimmune response (GVHD). Chemotherapy and pre-IS infections may also have contributed to endothelial/tubular injury in early post-HSCT period. Our series highlights (1) GVHD is likely an important factor in post haplo-HSCT endothelial injury and direct/indirect tubular injury; (2) This condition is difficult to treat due to high risk of infections post-HSCT. Renal risks in haplo-HSCT need further investigation.

FR-PO673

Crystalglobulinemia in Multiple Myeloma: A Rare Case of Survival and Kidney Recovery

Angela Chou,[1] Leon Vonthethoff,[2] Shir-Jing Ho,[1] Sunil Badve.[1] *[1]St George Hospital, Cabramatta, NSW, Australia; [2]NSW Heath Pathology St George Hospital, Sydney, NSW, Australia.*

Introduction: Crystalglobulinemia is a rare complication of monoclonal gammopathy wherein crystallised immunoglobulins deposit in various organs causing occlusive vasculopathy, endothelial damage and thrombosis. The reported mortality in this disease is extremely high.

Case Description: We report a case of a 74-year-old female presenting with polyarthralgia, chest pain, petechial rash and rapidly progressive oliguric acute kidney injury requiring dialysis. The serum creatinine on admission was 368 μmol/L, which peaked at 763 μmol/L on day 5 of admission. Troponin-T was 447ng/L (normal <14 ng/L), peaking at 1,223ng/L 7 days later. There were no ischemic changes on ECG. Serum protein electrophoresis showed IgG kappa paraprotein of 25.7 g/L and κ/λ ratio 21.8 (normal 0.26-1.85). Kidney biopsy revealed crystalline eosinophilic casts in the lumens of medullary tubules. Similar crystalline deposits were present in some interlobular arteries with luminal occlusion. Several glomeruli showed similar mainly crystalline deposits in glomerular capillary loops occluding lumens. Ultrastructure showed widening of subendothelial spaces of glomerular capillary loops with subendothelial flocculent material consistent with a thrombotic microangiopathy. Tubular crystal deposits had an organised parallel linear ultrastucture. Bone marrow biopsy confirmed immunoglobulin G (IgG) κ plasma cell multiple myeloma. This patient was successfully treated with 5 sessions of plasmapheresis and clone reduction chemotherapy with 11 cycles of cyclophosphamide, bortezomib and dexamethasone. This resulted in complete resolution of her symptoms, normalisation of troponin-T, reduction of paraprotein levels to <1 g/L and overall excellent kidney and hematological recovery. In 2 months, she was no longer dialysis dependent and in 32 months her latest creatinine had improved to 100 μmol/L.

Discussion: Crystalglobulinemia is a rare and life-threatening illness that should be suspected in patients with rapidly progressive acute kidney injury and monoclonal gammopathy. It can mimic other clinical entities, such as acute coronary syndrome, vasculitis and rheumatological disease due to the deposition of crystalglobulins in various organs. Our case demonstrates that timely investigation with kidney biopsy and appropriate treatment can lead to remission of multiple myeloma and excellent recovery of kidney function.

FR-PO674

Is This the Real Lyse? Is This Just Fantasy? Pseudohyperkalemia with Concurrent Tumor Lysis Syndrome in Extreme Leukocytosis

Hui Zhuan Tan, Manish Kaushik, Jason Choo Chon Jun. *Renal Medicine, Singapore General Hospital, Singapore, Singapore.*

Introduction: Hyperkalemia is a potentially dangerous electrolyte imbalance encountered in hematological malignancies, often seen in tumor lysis syndrome (TLS) and renal failure. It is increasingly recognised that potassium can be spuriously elevated in severe leucocytosis.

Case Description: A 74-year-old Chinese gentleman presented to the emergency room with 3 days of giddiness and was diagnosed with Chronic Myeloid Leukemia with blast crisis. Notable serum laboratory results included marked leucocytosis of 710x 10^9/L, platelets of 680x10^9/L, hemoglobin of 5.5 g/dL, creatinine of 289 μmol/L, potassium of

7.2 mmol/L (unlysed), phosphate of 1.69 mmol/L and markedly elevated uric acid and lactate dehydrogenase levels of 1572 µmol/L and 10,761 U/L respectively. Electrolyte abnormalities were attributed to spontaneous TLS with KDIGO Stage 3 acute kidney injury (AKI). Emergent medical therapy was instituted with insulin/dextrose, intravenous hydration and hydroxyurea. Rasburicase was withheld pending glucose-6-phosphate dehydrogenase status. Urgent renal consult was obtained for the consideration of renal replacement therapy (RRT) in view of oliguria. Simultaneous serum and whole blood potassium sample analysed via direct potentiometry subsequently revealed significantly discordant results of >8.0mmol/L and 4.7mmol/L respectively. Pseudohyperkalemia was suspected and corroborated by the absence of typical hyperkalemia changes on electrocardiographs. Serial paired samples yielded similar results, confirming the diagnosis. Despite this, decision was made to proceed with RRT in view of anuric AKI, ongoing TLS in the setting of large tumor burden, with anticipated delay of rasburicase administration and definitive chemotherapy.

Discussion: Pseudohyperkalemia occurring with extreme leucocytosis is multifactorial. It results from lysis of fragile leukocytes during clotting, compounded by mechanical stress during venepuncture, pneumatic transport and centrifugation. This phenomenon may go unrecognised in the setting of concurrent TLS and high index of suspicion is required. Diagnosis can be made by evaluating samples with direct potentiometry or sent in heparin-lithium tubes. While management of isolated pseudohyperkalemia in the absence of AKI is conservative, threshold to initiate dialysis should be lowered if there is concurrent TLS and oliguria.

FR-PO675

Solitary Renal Mass in Waldenström Macroglobulinaemia

Mairead Hamill,[2] John Quinn.[1] Beaumont Nephrology *[1]Department of Haematology, Beaumont Hospital, Dublin 9, Ireland; [2]Department of Nephrology, Beaumont Hospital, Dublin 9, Ireland.*

Introduction: Waldenström macroglobulinaemia is a rare B-cell lymphoproliferative disorder characterised by the presence of an IgM paraprotein and bone marrow infiltration by lymphoplasmacytic lymphoma. WM is more commonly found in men with a median age of onset of 60- 70 years and has an incidence of 0.3/100,000. WM may present with symptoms related to disease burden such as cytopenias, lymphadenopathy, and constitutional symptoms. Direct renal involvement by WM is a very rare occurrence. Here, we describe a WM case presenting with a large solitary renal mass.

Case Description: A 68 year old Caucasian male was referred with a persistent anaemia and weight loss. On examination, there was no evidence of palpable lymphadenopathy, or organomegaly. Initial investigations revealed a normocytic anaemia with a haemoglobin of 11g/dL, white cell count of 4 x 10^9/L, platelet count of 314 x10^9/L and normal renal function. He was referred to haematology as serum protein electrophoresis detected an IgM paraprotein band. Computed tomography of his thorax, abdomen and pelvis revealed an infiltrative mass expanding from the left pelvicalyceal system with invasion of the renal parenchyma anteriorly. There was prominent left retroperitoneal adenopathy without evidence of metastatic disease. CT-guided biopsy of the renal mass revealed cells with plasmacytoid morphology admixed with intermediate size lymphoid cells. The cells were diffusely positive with CD79 and most cells stained for CD20, consistent with lymphoplasmacytic lymphoma. Investigations at this point quantified his IgM paraprotein band to 9g/L. Serum free light chain assay revealed free kappa and lambda chains of 43.5mg/L and 19.7mg/L respectively. His ß2 microglobulin was 7.2 mg/L. Urinary Bence-Jones protein was not detected. A bone marrow aspirate and trephine confirmed infiltration by lymphoplasmacytic lymphoma. He was commenced on the dexamethasone, rituximab and cyclophosphamide regimen.

Discussion: This case describes a rare manifestation of WM. Renal involvement by lymphoma is thought to occur by direct infiltration from retroperitoneal adenopathy or haematogeneous dissemination. Our review of the literature identified only six previous cases of renal masses in association with this B-cell lymphoproliferative disorder. This case illustrates the importance of consideration of WM and other lymphomas in the differential diagnosis of a renal mass and the necessity of prompt biopsy.

FR-PO676

A Case of ANCA-Associated Glomerulonephritis Accompanied by Membranous Lesions During the Course of Recurrent Renal Cancer

Hiroko Uchida, Miho Karube, Soko Kawashima, Yoshinori Komagata, Shinya Kaname. Division of Nephrology and Rheumatology *Kyorin University School of Medicine, Mitaka, Japan.*

Introduction: ANCA-associated glomerulonephritis (ANCA-GN) has been classified as a pauci-immune type of crescentic glomerulonephritis since glomerular immune complex deposits are not demonstrable by immunofluorescent study and electron microscopy. ANCA-GN and membranous nephropathy (MN) has been rarely reported. We report an ANCA-GN accompanied by membranous lesions during the course of recurrent renal cancer.

Case Description: A 70-year-old male was referred to our hospital because of worsening renal function and persistent hematuria and proteinuria of around 0.5-1 g/gCr. He had underwent left nephrectomy for renal cancer at the age of 49 and also left lung cancer at 60 years. Laboratory examination revealed positive MPO-ANCA titers in the serum (148.4 U/ml) and an elevated serum creatinine level (1.5 mg/dl). There were no other findings that suggest organ involvement of systemic vasculitis. CT and PET-CT scans revealed nodular lesions of the right lower lung and mediastinal mass suspected of malignancy. A renal biopsy revealed necrotizing extracapillary proliferative glomerulonephritis with fibrocellular crescents, compatible with ANCA-associated glomerulonephritis (ANCA-GN). However, immunofluorescent study showed granular depositions of IgG along the glomerular capillary walls, with IgG subclass being positive for IgG1, weak positive for IgG2 and negative for IgG3 and IgG4, suggesting secondary membranous nephropathy. Interestingly, electron microscopy showed deposits along glomerular basement membranes and also paramesangial areas. There were few deposits in the subepithelial areas. He was finally diagnosed with metastatic renal cancer to the lymph node of the mediastinum and chemotherapy with sunitinib was begun. Thereafter, the serum creatinine did not change and MPO-ANCA decreased to 32.6 U/ml without using corticosteroids.

Discussion: Although ANCA-GN accompanied by MN has been rarely reported, the present case showed atypical membranous lesions suggesting unique etiology of immune complex formation.

FR-PO677

Hypophosphatemia from a Liver Spindle Cell Tumor: A Novel Site for FGF23-Related Tumor-Induced Osteomalacia

Alexander S. Leidner, Craig B. Langman, Aline Martin, Valentin David, Jason Wertheim, Heather Price, Vikram Aggarwal. *Feinberg School of Medicine, Northwestern University, Chicago, IL.*

Introduction: Tumor induced osteomalacia(TIO), presenting with hypophosphatemia driven by fibroblast growth factor 23(FGF23) production is a paraneoplastic phenomenon. We present a liver tumor with demonstrated FGF23 production, a previously unreported site.

Case Description: A 58 y/o female with a history of lupus and osteoporosis presented with fatigue, weight loss and joint pains. Medications include alendronate, plaquenil and vitamin D. She was found to have 3.6g of 24 hour urine protein and low phosphorous for four years. Fractional excretion of phosphate ranged between 40-60 % (normal 10-20%) on several occasions during a period of 3 months. Renal biopsy was performed and revealed proximal tubule vacuolation, without evidence of lupus activity. C-terminal FGF23 levels were tested at multiple points and elevated to 97 and 770 RU/ML at a serum phosphorous of 1.7 and 3.4 mg/dL respectively on high dose supplementation. Parathyroid hormone and vitamin D levels were normal. FGF23 levels remained elevated. Ga-68 dotatate PET scan revealed an irregular enhancing liver mass which upon resection was a spindle cell tumor with clear margins. **Immunohistochemical stain of the pathologic tissue was positive for FGF23 when compared to normal liver. Cell culture of tumor cells versus the patients normal liver cells showed two-fold higher FGF23 expression.** The intra-op & post-op period was uneventful except worsening of hypophosphatemia as expected with increase in FGF23 to 800-1400 RU/ml. 3 months post-op, she had a minor fall with an avulsion fracture of the 5th metatasrsal base. 5 months later the patient remains hypophosphatemic, but requires less oral supplementation. Symptoms have improved significantly, however her FGF 23 remains elevated.

Discussion: While the liver has been shown to express FGF23, TIO has not been previously described as a consequence of a liver neoplasm. TIO is a potentially curable paraneoplastic etiology of symptomatic hypophosphatemia. Symptoms usually remit quickly in tumors in which resection is possible. This adds to potential sites to explore when evaluating for TIO. Repeat PET scan will be required to evaluate our patient for residual disease given continued FGF23 elevation. Recombinant FGF23 antibody is another potential intervention if other methods of cure are impossible.

FR-PO678

Heavy Chain Deposition Disease Unmasked After Treatment of Sjogren Syndrome-Associated Glomerular Disease

Rushang Parikh,[1] Hugo Andrade paz,[1] Azzour Hazzan,[1] Daniel W. Ross,[1] Surya V. Seshan,[2] Kenar D. Jhaveri,[1] Vanesa Bijol.[3] *[1]Nephrology, Zucker School of Medicine at Hofstra/Northwell, NY, Manhasset, NY; [2]Pathology, Weill Cornell Medical Center, New York, NY; [3]Pathology, Northwell Health, Manhasset, NY.*

Introduction: Diagnosis of heavy chain deposition disease (HCDD) is often challenging. We present a case of a patient who had 2 kidney biopsies and treatment of one disease unmasked the diagnosis of HCDD.

Case Description: A 69 year old female was diagnosed with smoldering myeloma (IgG-lambda clone). Treatment was not planned. She was also recently diagnosed with Sjorgen syndrome. Few weeks later, she presented with AKI with Scr of 1.4mg/dl (baseline of 1mg/dl) and proteinuria (4gm/24hours). Serology showed positive ANA, positive SS-A antibody, antidsDNA, low C3 and C4 levels. A kidney biopsy confirmed MPGN pattern with diffuse nodular sclerosis having polyclonal IgG and IgM lambda deposits, and EM showing focal organized deposits. There was also a diffuse interstitial lymphoplasmacytic infiltrate. Based on the IF findings, the diagnosis of mixed cryoglobulinemia-associated GN was made, but a paraproteinemia related disease could not be ruled out. A Hepatitis C PCR was negative. Since the kidney disease was related to rheumatologic findings, steroids were initiated. Despite steroids, her creatinine worsened over 6 weeks and proteinuria increased to over 8gm/24 hours. A repeat kidney biopsy was diagnostic for gamma-3 heavy chain deposition disease, with a nodular sclerosing glomerulonephritis and strong (4+) IgG and C1q reactivity in the mesangium and along glomerular and tubular basement membranes; no significant reactivity for kappa and lambda light chains or C3 was noted on routine IF microscopy. IgG subclass staining showed strong (4+) gamma-3 reactivity, in the same areas corresponding to the IgG staining. Electron microscopy reveals diffuse powdery deposits along all the basement membranes and in the mesangium, supporting the diagnosis of HCDD. The steroid treatment might have unmasked the underlying HCDD, following resolution of the autoimmune mediated renal lesions. A repeat bone marrow

showed no change in percent of plasma cells. Regardless, she was started on bortezomib based therapy. Four months later, she still remains dialysis dependent.

Discussion: Diagnosis of HCDD is challenging. In this case, the initial pathology of an autoimmune process causing kidney disease masked a chronic HCDD related kidney disease. High index of suspicion is required for diagnosis of HCDD. Prognosis remains guarded.

FR-PO679

AKI from Polytypic Plasma Cell Interstitial Infiltration in Sjogren Syndrome

Muniba Javed, A. Bilal Malik. *Nephrology, University of Washington, Seattle, WA.*

Introduction: 57-year-old woman with a history of extensively treated Marginal Zone Lymphoma diagnosed with concomitant pulmonary AL Amyloidosis on lung biopsy in 2011 as well as remote history of Sjogren Syndrome, referred for acute kidney injury (AKI). She was last treated with rituximab for lymphoma 6 months ago.

Case Description: During initial evaluation (1/22/19), she was found to have a relatively brisk worsening of creatinine (Cr) from 0.9 to 2mg/dL over a 2- week period. She had new onset microscopic hematuria, glycosuria and pyuria with proteinuria quantified as 1.3g (albumin/cr of 66mg/g). Ultrasound showed edematous bilateral kidneys with serial CT imaging highlighting an insidiously worsening loss of corticomedullary differentiation over the last year. Ancillary studies showed a stably abnormal k/l ratio of 3.5 and IgG- k M- spike of 0.1g/dL, with these serologies showing chronic and fluctuating elevated titers since the diagnosis of Lymphoma. There was also a gradually worsening total serum protein of 11.1g/dL and IgG titer of 5925mg/dL (normal < 1616). Native kidney biopsy was undertaken on 2/1/19 that showed extensive interstitial infiltration with polytypic plasma cells with no morphologic or immunophenotypic evidence of lymphoma. Just prior to kidney biopsy, Cr peaked at 2.96mg/dL and prednisone 1 mg/kg was initiated for empiric management. Given absence of lymphomatous renal involvement, chemotherapy was not entertained. Renal function improved with Cr dropping to 0.7mg/dL following a tapering course of prednisone. This was accompanied by resolution of pyuria and stabilization of IgG titer to 3725mg/dL on last check. She tested positive for serum ANA (positive ss-A and ss-B) with negative double- stranded DNA.

Discussion: Patient experienced AKI from a non-lymphomatous polycloncal plasmacytic interstitial infiltrate concomitant with a severe hypergammaglobulinemia that responded briskly to prednisone. In the context of worsening sicca symptoms over the last 6 months and positive serologies, the plasmacytic infiltration was deemed a manifestation of Sjogren syndrome, which was first diagnosed in 2005 following biopsy of minor salivary glands. This presentation of renal failure from Sjogren syndrome is a rare occurrence and even more intriguing in a patient with extensive history of lymphoma. Accurate diagnosis in this case was essential to avoid unnecessary use of chemotherapy.

FR-PO680

Karyomegalic Interstitial Nephritis in a Woman with Hodgkin Lymphoma on Brentuximab Therapy

Iryna Patel,[1] Cynthia C. Nast,[2] Tiane Dai,[1] Lili Tong.[1] *[1]Nephrology, Los Angeles Biomedical Research institute at Harbor-UCLA Medical center, Torrance, CA; [2]Pathology, Cedars-Sinai Medical Center, Los Angeles, CA.*

Introduction: Karyomegalic interstitial nephritis (KIN) is a rare form of chronic interstitial nephritis that can lead to end stage renal disease. It is characterized histologically by hyperchromatic, abnormally enlarged nuclei of tubular epithelial cells, as well as interstitial fibrosis and tubular atrophy. KIN has an autosomal recessive form, associated with mutations in the FAN1 gene. Other potential etiologies include toxins (e.g. ochratoxin A), heavy metals (e.g. busulfan, lead), alkylating agents (e.g. ifosfamide), and viral infections. We present a case of KIN in a woman with Hodgkin's lymphoma on brentuximab vedotin (trade name: Adcetris) therapy. To our knowledge, this is the first case report of KIN associated with this medication.

Case Description: A 50 year-old Hispanic female was diagnosed with anaplastic high-grade Hodgkin's lymphoma with metastasis to the liver, large intestine, and adrenal gland. She had poor response to 4 cycles of ABVD (Doxorubicin, Bleomycin, Vinblastine, Dacarbazine) and 3 cycles of ICE (Ifosfamide, Carboplatin, Etoposide). She then received two doses of Brentuximab vedotin. She had a normal renal function prior to the infusion of Brentuximab vedotin, which declined rapidly afterwards. Urinalysis showed 3+ glucose, 3+protein, 1 WBC, 0RBC and 6-10 granular casts/LPF. Urine protein to creatinine ratio was 2.8 g/g. Kidney biopsy showed KIN. Despite discontinuation of brentuximab vedotin, her kidney function continued to worsen, and she was prepared for dialysis.

Discussion: Brentuximab vedotin is an antibody-drug conjugate (ADC) which targets tumor cells expressing CD30, followed by internalization and release of monomethyl auristatin E (MMAE), which binds to tubulin and disrupts the microtubule network. This results in cell cycle arrest, and may explain the markedly enlarged and hyperchromatic nuclei seen in renal tubular epithelial cells, which did not undergo apoptosis as tumor cells do. The present case is the first report of KIN association with brentuximab vedotin. While there is the possibility that KIN may be a late consequence of ifosfamide administration, the temporal relationship between treatment with brentuximab vedotin and the onset of kidney injury suggests that brentuximab vedotin was the most likely responsible agent in this case.

FR-PO681

A Unique Case of Hyponatremia

Harsha Aramada, Kalathil K. Sureshkumar, Bhavna Chopra. *Allegheny General Hospital, Pittsburgh, PA.*

Introduction: Immune check point inhibitors(ICI) have revolutionized cancer treatment. They promote activation of T cells causing programmed death of tumor cells. However they can cause life threatening immune related adverse events (irAEs) including autoimmune endocrinopathies, such as hypophysitis, thyroiditis, adrenalitis, insulinitis, and parathyroiditis. We present a case of hypophysitis caused by the use of iplimumab and nivolumab, presenting with severe hyponatremia.

Case Description: A 60 y.o. lady with metastatic renal cell carcinoma was started on treatment with ICI- Iplimumab and Nivolumab. After two cycles of treatment, patient developed thyromegaly, was diagnosed with immune thyroiditis manifesting as hyperthyroidism followed by hypothyroidism, requiring levothyroxine. Two months into ICI therapy she presented to the hospital with complaints of left-sided flank pain. A CT scan of abdomen revealed increase in growth of the left renal mass. Laboratory data revealed serum sodium (Na) level of 127 mmol/L (Na was 142 a week prior). She was placed on fluid restriction of 1.2 liters per day and salt tablets 1 gram 3 times daily. Yet Na level continued to drop to 118 by 3rd day of hospitalization. Urine osmolality was 504 mosm/kg with urine sodium of 24 mmol/L. Her TSH level was low at 0.023 (0.400 - 4.000 mcU/mL) with free T4 levels of 0.69 (0.70 - 1.90 ng/dl), A.M. cortisol level was very low at 1 mcg/dl (6.0 - 18.4 mcg/dl). Patient was diagnosed with adrenal insufficiency and central hypothyroidism thought to be secondary to immune related adverse effects resulting from the use of Ipilimumab and Nivolumab. She was started on methylprednisone 70 milligrams IV daily, her serum Na improved from 119 to 126 mmol/l in 24 hours and normalized over 3 days. She was switched to oral tapering dose of hydrocortisone.

Discussion: The combined treatment of iplimumab (anti-CTLA4 Ab) and nivolumab (anti-PD-1 Ab) increases the tumor efficacy but also increases the risk for autoimmune hypophysitis, which can cause secondary adrenal insufficiency through complement deposition, mononuclear cell infiltration and production of antibodies to adenohypophysial endocrine cells resulting in adrenal insufficiency induced hyponatremia. In this case, hyponatremia did not respond to fluid restriction and salt tablets but responded to steroids. Hyponatremia induced by ICI should be recognized and treated promptly.

FR-PO682

Mantle Cell Lymphoma Resulting in Paraneoplastic Immune Complex Mediated Glomerulonephritis

Yahya R. Ahmad,[1] Shveta S. Motwani,[2] Kelly A. Burdge.[3] *[1]North Shore Medical Center, Salem, MA; [2]Brigham and Women's Hospital and Dana-Farber Cancer Institute, Newton, MA; [3]North Shore Physicians Group, Danvers, MA.*

Introduction: Glomerulonephritis (GN) can result from paraneoplastic effect of certain malignancies. Here we report a case of a gentleman with Mantle cell lymphoma (MCL) who developed GN necessitating treatment of his cancer that otherwise did not meet hematological criteria for treatment.

Case Description: A 63-year Caucasian male with a newly diagnosed MCL, not on treatment, came in for evaluation of lower extremity edema within two weeks of diagnosis. His edema was associated with a weight gain of ten pounds, and acute kidney injury with a creatinine rise from a baseline of 1.08 to 1.72, peaking at 3.14 mg/dL over the next few weeks. Initial evaluation consisted of a normal renal ultrasound, a urinalysis with 3+ blood, positive leukocyte esterase. A microscopic evaluation of his urine sediment showed dysmorphic red blood cells (RBCs), 5 white blood cells, and no bacteria. A spot urine protein to creatinine ratio of 5.3g/g creatinine of which 3.3g was albumin. Serological work up demonstrated a normal or negative serum and urine electrophoresis, serum free light chains, complements, anti- neutrophilic cytoplasmic antibody, anti-double stranded DNA, anti-glomerular basement membrane antibody, erythrocyte sedimentation rate, C-reactive protein, hepatitis serologies, lactate dehydrogenase, haptoglobin and cryoglobulin. His anti-nuclear antibody was weakly positive. He underwent a kidney biopsy showing acute tubular necrosis with immune complex GN with a focal proliferative and mesangioproliferative pattern of injury. There was no paraprotein deposition or parenchymal infiltration with the lymphoma cells. His GN was attributed to a paraneoplastic process resulting from his underlying MCL. His GN prompted treatment with high dose steroids, bendamustine, and rituximab with improvement in creatinine to 1.2 mg/dL, and complete resolution of proteinuria. A subsequent positron emission tomography scan showed marked regression of his MCL.

Discussion: Renal involvement in mantle cell lymphoma is a rare complication. Mantle cell lymphoma is often an indolent condition that does not require treatment. However, organ-threatening GN such as that reported in our case can only respond to treatment. Serological studies are often insufficient and kidney biopsy is required for definitive diagnosis. Rituximab-based regimens are effective for treatment of paraneoplastic GN resulting from MCL.

FR-PO683

Hypophosphatemia and Fibroblast Growth Factor 23 Producing Metastatic Breast Cancer

Victoria Gutgarts,[1,2] Ilya Glezerman.[1,2] *[1]Department of Medicine, Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY; [2]Department of Nephrology, Weill Cornell Medical Center, New York, NY.*

Introduction: Fibroblast growth factor-23 (FGF23) is a key regulator of phosphate metabolism and downregulates expression of cotransporters in the kidney essential for phosphate reabsorption. FGF23 mutations cause inherited renal phosphate wasting diseases leading to osteomalacia in adults. In the paraneoplastic setting, FGF23 over secretion leads to tumor-induced osteomalacia (TIO) also known as oncogenic osteomalacia.

Case Description: 47-year-old woman with metastatic breast cancer was evaluated for persistent hypophosphatemia. First diagnosed with left mammary duct carcinoma in 2013, she underwent partial mastectomy followed by chemotherapy. She had a reoccurrence in 2016 and failed multiple lines of chemotherapy with new metastasis to the liver and several osseous lesions. Patient was initiated on monthly denosumab one year prior to current visit, with last dose one month ago, for metastatic bone involvement. Phosphorous level on consultation was <0.9 (2.5-4.5)mg/dl with no prior laboratory values. Calcium level was 7.4 (8.5-10.5)mg/dl and Alkaline Phosphatase level was 738 (< = 130)U/L. The fractional urinary excretion of phosphate was elevated at 56%. Etiology for hypophosphatemia was initially thought to be secondary hyperparathyroidism given elevated PTH 488 (12-88)pg/ml due to hypocalcemia in the setting of recent denosumab administration. Phosphorous levels remained low despite aggressive oral calcium and phosphate repletion and oral calcitriol. Given persistent hypophosphatemia, FGF23 was checked and levels returned strikingly elevated at 2430 (< = 180)RU/ml suggesting an FGF23 secreting tumor as the most likely cause for severe hypophosphatemia. Oral phosphate supplementation was continued, though unfortunately, given progression of disease, palliative measures were chosen with a focus on comfort care.

Discussion: TIO is a rare paraneoplastic syndrome, but when present, downstream effects of phosphaturia can lead to profound weakness and skeletal collapse. Though prior reports have identified bone or soft tissue as the primary site, the case above is unique since the syndrome occurred in metastatic disease with a primary breast cancer. Recognition of TIO is essential since patients that have solitary lesions may undergo resection which may be curative. In patients with several lesions or metastatic cancer, medical therapy can be attempted to improve the quality of life.

FR-PO684

Vascular Renal Amyloidosis with Waldenstrom Macroglobulinemia (WM)

Shamir Hasan, Rimda Wanchoo, Vanesa Bijol, Kenar D. Jhaveri. *Nephrology and Pathology, Zucker School of Medicine at Hofstra Northwell, Great Neck, NY.*

Introduction: Several kidney diseases have been associated with WM; they include lymphoplasmacytic lymphoma infiltration, immunoglobulin light chain (AL) amyloidosis and cryoglobulinemic glomerulonephritis. AL amyloidosis classically presents with nephrotic syndrome. We present a rare case of renal vascular AL amyloidosis in a patient with WM

Case Description: A 82-year-old white woman with history of WM presented with worsening kidney function. Nine years prior, she was diagnosed with WM and was treated with Bendamustine and Rituximab for 6 monthly cycles and then Rituximab maintenance for 2 years. She remained stable for six years. Over the last year, she was noted to have worsening anemia, rising serum creatinine from 1.3 mg/dl to 1.8 mg/dl and new onset of subnephrotic range proteinuria (1 gm/day). Her urinalysis did not reveal any blood or dysmorphic RBC. In addition, for several months, her blood pressure was harder to control. At baseline, her serum immunoglobulin free light chain ratio (Kappa/Lambda) was close to 9 and had risen to 45 at the time of presentation. Her immunofiixation was positive for IgM and IgG kappa. Physical exam was remarkable for a BP of 170/90 mm hg and trace lower extremity edema. Her serological work up was negative except for a low C4 (8 mg/dl). A kidney biopsy was performed which revealed significant non-specific chronic injury, with global glomerulosclerosis and tubulointerstitial scarring in about 50% of cortex. The better preserved glomeruli showed signs of hypoperfusion, but there was no amyloid, other paraprotein deposition, or hypercellularity in any of the glomeruli. Amyloid deposition, characterized by positive Congo red stain, was noted in a single arcuate artery with perivascular tissue involvement. Immunofluorescence revealed equal kappa and lambda staining on frozen tissue, but on paraffin sections, kappa staining was positive in the involved artery. Electron microscopy did not reveal amyloid fibers in the glomeruli. Based on these results, a diagnosis of WM associated renal vascular amyloidosis was made and she was started on treatment with bortezomib and rituximab and is currently doing well

Discussion: In a patient with WM presenting with kidney dysfunction and or proteinuria, vascular amyloidosis involving only the large vessels should also be considered in the differential diagnosis.

FR-PO685

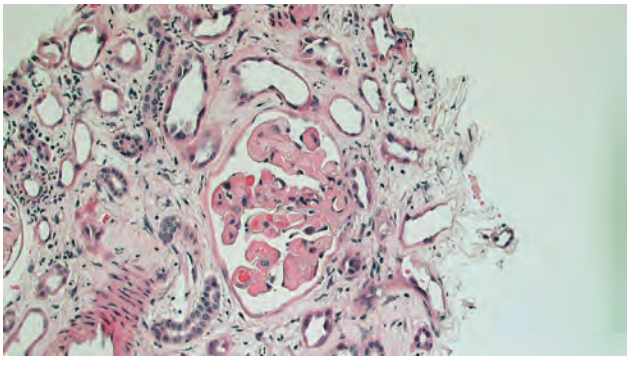
Thrombotic Microangiopathy Following Y^{90}-Dotatate Treatment

Kathryn J. Griffiths,[1] Pauline A. Swift,[1] Rukma Doshi,[2] Bhrigu Raj Sood.[1] *[1]Nephrology, Epsom and St Helier University Hospital NHS Trust, London, United Kingdom; [2]Histopathology, Epsom and St Helier University Hospital NHS Trust, London, United Kingdom.*

Introduction: Gastro-entero-pancreatic neuroendocrine tumours are rare; the expression of somatostatin receptors enables treatment with radiolabelled somatostatin analogues such as Yttrium labelled octreotide (Y^{90}-dotatate). Patients are routinely consented for non-specific renal toxicity prior to treatment.

Case Description: We present the case of a 49 year old woman with a well differentiated neuroendocrine tumour. She was treated with lanreotide (long acting somatostatin analogue) but follow up scans demonstrated progressive disease and she was then treated with three cycles of Y^{90}-Dotatate therapy (4.0 GBq). Four months later she presented with shortness of breath with a haemoglobin of 69 g/L, platelet count of 132 x 10^9/L and creatinine of 145 umol/L. She had previously normal renal function. Over the following days the platelet count fell further to 55 x 10^9/L at the lowest and she was hypertensive. A blood film demonstrated fragments. Three stool cultures were negative for shigella toxin and e.coli. An ADAMST13 demonstrated >10% activity. She was commenced on plasma exchange, receiving five 1.5L cycles with fresh frozen plasma. The case was discussed with the National Renal Complement Therapeutics Centre, Newcastle, UK. It was thought that this was not in keeping with a complement driven process amenable to Eculizumab treatment. The platelet count gradually increased to normal range with the haemoglobin remaining stable around 80g/L during plasma exchange. A renal biopsy was performed which demonstrated morphological features compatible with a TMA. Since stopping plasma exchange, the patient has been followed up in the renal clinic, with focus on good blood pressure control but renal function appears to be declining slowly.

Discussion: TMA has been described in association with Y^{90}-Dotate therapy and this case demonstrates this rare complication which carries a poor renal prognosis.



Renal biopsy: glomerulus showing thrombi in capillary loops and basement membrane thickening; mesangiolysis; aneurysmal dilatation of capillary loops; background acute tubular necrosis.

FR-PO686

Hypercalcemia Secondary to Malignancy-Associated Ectopic PTH Secretion: A Rare Mimicker of Primary Hyperparathyroidism

Norman W. Seay,[1] David I. Ortiz Melo,[2] Julia J. Scialla.[1] *[1]Duke University, Durham, NC; [2]Duke University Medical Center, Durham, NC.*

Introduction: Hypercalcemia affects nearly 30% of patients with cancer, and malignancy-related hypercalcemia is the most common cause of hypercalcemia in hospitalized patients. In most cases, hypercalcemia is due to tumor secretion of PTHrP, osteolytic metastases or increased production of 1,25 $(OH)_2D$. We present a very rare case of malignancy-related hypercalcemia due to ectopic production of intact PTH in a patient with hepatocellular carcinoma.

Case Description: A 61-year-old man with history of hepatocellular carcinoma and hepatitis C infection complicated by cryoglobulinemia and CKD stage 4 was admitted with complaints of malaise, abdominal pain, dyspepsia, constipation, and inability to ambulate after suffering a left femoral fracture. Labs upon admission were notable for ionized calcium 12.7 mg/dL (normal 8.5-10.1), PTH 397 pg/mL (normal 14-72), PTH-rp 16 pg/mL (normal 14-27), and 1,25OH-vitamin D 12 pg/mL (normal 18-72). Further hypercalcemia workup included a parathyroid ultrasound and Sestamibi scan that were negative for parathyroid adenoma or carcinoma. An abdominal ultrasound revealed known liver mass attributed to his HCC and a new left upper quadrant mass adjacent to the spleen. The para-splenic lesion was FDG-avid on PET/CT. CT-guided biopsy of the left upper quadrant mass was consistent with HCC and stained positive for parathormone, confirming the diagnosis of intact PTH-secreting HCC. He was not a surgical candidate. Hospital course was complicated by refractory hypercalcemia (serum Ca as high as 14 mg/dL) despite generous intravenous normal saline, calcitonin, furosemide, and high dose cinacalcet (90 mg BID). The patient responded to 60 mg pamidronate. His serum calcium at discharge was 10.7 mg/dL.

Discussion: This patient had hypercalcemia due to ectopic intact PTH secretion, which is exceedingly rare. Very few case reports have been described, mostly involving solid tumors, including neuroendocrine, ovarian, rhabdomyosarcoma, gastric, hepatocellular,

kidney, lung, parotid, and breast cancers. Because of elevated PTH, hypercalcemia in this setting could be mistaken for primary hyperparathyroidism, which could lead to an unnecessary neck exploration as an attempt to identify a parathyroid adenoma. Hypercalcemia in the setting of elevated PTH and non-parathyroid malignancy should thus raise suspicion for this entity.

FR-PO687

Lung Cancer Before and Acute Myeloid Leukemia (AML) After the Diagnosis of IgG4-Related Disease

Sherif Metwally,[1] Isabelle Ayoub,[1] Anjali A. Satoskar.[2] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Ohio State University, Columbus, OH.*

Introduction: IgG4-related disease (IgG4-RD) is a multi-organ immune mediated fibro-inflammatory condition. The common diagnostic features of IgG4-RD are tumefactive lesions of involved organs, lymphoplasmacytic infiltrate enriched in IgG4-positive plasma cells and storiform fibrosis. Elevated serum concentrations of IgG4 are present in 70% of cases. Glucocorticoids are first line therapy. Recurrent and refractory cases are common and may benefit from steroid sparing maintenance therapy. This case illustrates the association of IgG4-RD with an increased risk of malignancy.

Case Description: A 53 -year old woman with history of epithelioid neoplasm of the lung s/p wedge resection in 2016 presented 10 months later with dyspnea. Diagnostic work up was significant for an exudative pleural effusion without malignant cells and bilateral hydroureteronephrosis with Scr of 3.5 mg/dl and urine PCR 1.1g/g despite stent placement. Kidney biopsy showed extensive dense fibrosis with one focus of positive IgG4 staining (20cells/hpf). Archived lung tissue from wedge resection as well as thyroid tissue from remote partial thyroidectomy stained positive for IgG4. Serum IgG4 was 106 mg/dl. Remission was successfully achieved with glucocorticoids. Scr improved to 1mg/dl and IgG4 level to 30.9mg/dl. However her IgG4-RD relapsed once prednisone was tapered below 10 mg/dl. Rituximab 1g q 14 days x2 doses along with prednisone taper did not help. PET scan showed hypermetabolic activity in the cervical and chest lymph nodes, thyroid, right lung, right hepatic lobe and both kidneys. Bone marrow biopsy with flow cytometry was negative for malignancy. Oral cyclophosphamide plus rituximab and prednisone were trialed without success. While on this regimen, she continued to deteriorate and was readmitted with fever and worsening shortness of breath. The plan was to exclude infection and consider a plasma cell inhibitor for refractory IgG4-RD. Repeat work up including bone marrow biopsy was notable for AML for which she is now being treated.

Discussion: Malignancy is associated with subsequent development of IgG4-RD. Some studies also suggest that prior IgG4-RD is associated with increased risk of developing malignancy. Our patient had cancer pre- and developed a different cancer post-IgG4-RD diagnosis. This case sheds light on the importance of cancer screening in IgG4-RD.

FR-PO688

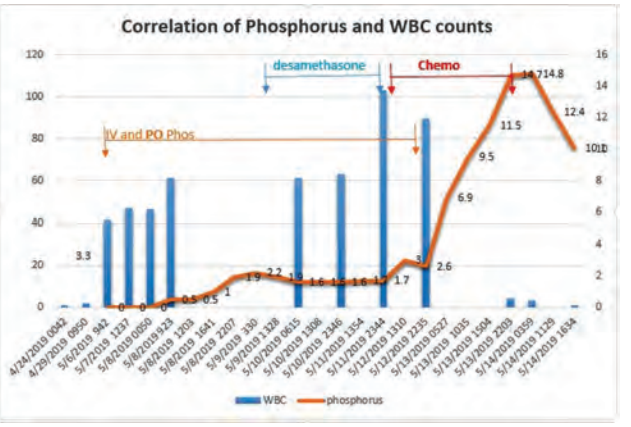
Severe Hypophosphatemia in a Patient with a Relapsing Lymphoma

Xiaoying Deng,[1] Edgar Guzman-Suarez,[2] Anju Yadav,[1] Rakesh Gulati.[1] *[1]Thomas Jefferson University Hospital, Philadelphia, PA; [2]Jefferson Hospital, Philadelphia, PA.*

Introduction: Hypophosphatemia in cancer patients is commonly ascribed to chemotherapy, renal wasting or malnutrition from anorexia and poor oral intake. We report a case of hypophosphatemia caused by rapid cancer cell proliferation.

Case Description: Hypophosphatemia was observed in a 61-year-old woman with history of marginal zone lymphoma diagnosed in 2017 presenting with fatigue and undetectable phosphate (phos) levels. Her symptoms started 5 days prior with reported decreased oral intake, but no other gastrointestinal symptoms. Blood work showed phos <1 mg/dl; iPTH level was 17. Her medications included Acyclovir 400mg daily and Allopurinol 100mg daily. Her phos further dropped to <0.3 mg/dl on admission. This severe hypophosphatemia required aggressive intravenous phos treatment and simultaneous oral phos supplementation thereafter. 24 hr urinary fraction excretion of phos was only 1.8%, ruling out renal loss of phos, including acyclovir induced phos wasting. Initial white blood count (WBC) was 41 B/L, phos was <0.3 mg/dl, compared to phos of 3.3 mg/dl with WBC of 0.9 B/L a week prior to this admission. She then developed hyperphosphatemia upon re-initiation of chemotherapy, after repeated computerized tomograhy scan and flow cytometry confirmed lymphoma relapse. She received 4 days of Dexamethasone where the hypophosphatemia converted to hyperphosphatemia, likely from tumor lysis, then further worsened by chemotherapy. Her phos peaked at 14.8 mg/dl. Acyclovir was resumed and it did not cause recurrent hypophosphatemia. A similar hypophosphatemia-hyperphosphatemia pattern was also observed in her previous hospitalization, and correlated with her WBC (Figure 1).

Discussion: The hypophosphatemia correlated with hyperproliferation of cancerous cells. Therefore, hypophosphatemia might be a surrogate biomarker of recurrence of rapidly proliferating hematological malignancy. Phos levels can serve as an excellent adjuvant, widely available, non-invasive and cost-effective biomarker.



FR-PO689

Recurrent Laryngeal Cancer with Uncommon Kidney Metastasis

Matthew Abramson,[1,3] Surya V. Seshan,[2] Roman A. Shingarev,[3] Ilya Glezerman,[3] Victoria Gutgarts.[3] *[1]New York Presbyterian, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Laryngeal cancer is the fourteenth most common malignancy worldwide, where squamous cell carcinoma (SCC) is the most prominent subtype. Distant metastases occur in less than ten percent and involve the lung, liver, and bone but kidney metastases are seldomly reported. We report a rare case of recurrent laryngeal cancer with infiltrative kidney metastases.

Case Description: 64-year-old man with recurrent metastatic laryngeal carcinoma was evaluated for worsening kidney function. First diagnosed with laryngeal carcinoma in 2011, managed with radiation therapy, with reoccurrence in 2017 requiring laryngectomy. Follow-up scans showed new metastatic lung disease treated with left upper lobe resection and cisplatin chemotherapy. Creatinine rose to 2.5 (0.7-1.3)mg/dl (baseline of 1.0mg/dl) over 3 months. He denied use of nonsteroidal anti-inflammatory drugs, and had not received intravenous contrast. He was recently started on ramipril for hypertension. Urinalysis showed no protein, with bland urine sediment. Renal ultrasound revealed enlarging kidneys, right 12.3cm (increased from 9.8cm 4 months prior) and left 11.9cm, without hydronephrosis. Positron emission tomography (PET) revealed several new areas of increased uptake by both kidneys, pulmonary nodules and diffuse hilar and retroperitoneal lymphadenopathy. Renal biopsy showed diffuse infiltrative moderately to focally well differentiated SCC replacing most of the cortical and medullary tissue. Four of 29 glomeruli were globally sclerosed, minimal changes in remaining glomeruli, with diffuse tubular atrophy and interstitial fibrosis. Immunofluorescence microscopy was not performed due to diffuse renal tissue infiltration. The patient's creatinine remained elevated at 2.5mg/dl with plan by head and neck oncology for combination carboplatin, taxol, and cetuximab given the rapidly progressive nature of the disease.

Discussion: Kidney dysfunction in the setting of malignancy is often attributed to nephrotoxic chemotherapy as a potential cause. It is important to recognize that kidney infiltration is also possible where treatment can be aimed at addressing the underlying malignancy. The above case is unique in that it highlights the rare entity of laryngeal carcinoma metastasizing to the kidneys and should be considered in patients presenting with kidney dysfunction and large kidneys.

FR-PO690

Hyponatremia Secondary to CTLA-4 Inhibition-Induced Hypophysitis

Stephen P. Regina,[1] Roberto L. Collazo-Maldonado.[2] Methodist Dallas Medical Center *[1]Methodist Health System, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: Ipilimumab is a cytotoxic T-lymphocyte associated antigen 3 (CTLA-4) inhibitor which is used in therapy of multiple types of cancers, including malignant melanoma. One side effect of ipilimumab, reported in nearly 17% of patients receiving it in clinical trials, is autoimmune hypophysitis. We present a case of a patient with a history of melanoma treated with ipilimumab and hypophysitis, who presented with symptomatic hyponatremia after being treated with CTLA-4 inhibitor therapy.

Case Description: This is a 73 year old man with history of hypertension, DM, invasive melanoma of the right earlobe requiring wide excision and sentinel lymph node biopsy, pT4a N0 M0 Stage IIIA. He completed 3 cycles of adjuvant ipilimumab and nivolumab. Patient presented to the hospital with dizziness and weakness. He was fully oriented on presentation, normotensive and euvolemic on exam. The serum sodium was 119 meq/L and calculated serum osmolality was 246 mOsm/kg, BUN 3 mg/dl and sCr 0.4 mg/dl, with a normal uric acid. UA was unremarkable, with urine sodium 29 mmol/L and osmolality 134 mOsm/kg. Further workup showed low TSH, low morning cortisol, and brain MRI showed signs of hypophysitis, confirming the diagnosis of CTLA-4 inhibitor-induced hypophysitis. He was treated with thyroid hormone and adrenocorticoid

replacement, his hyponatremia improved. He was discharged from the hospital few days later with serum sodium 130 meq/L.

Discussion: In cases of hypophysitis, hyponatremia has been shown to occur due to secondary adrenal insufficiency with loss of ACTH-secreting corticotrophs. While the cause of hypophysitis is suspected as treatment-induced autoimmune lymphocytic hypophysitis, which results in anterior hypophyseal necrosis, this can only be definitively determined on postmortem. The present case illustrates that the hypophysitis which occurs may be permanent, and requires lifelong adrenal hormone replacement. Physicians and nephrologists should be aware of the diagnosis of CTLA-4 inhibitor-induced hypophysitis and include it in the differential diagnosis of hyponatremia when there is relevant chemotherapy history.

FR-PO691

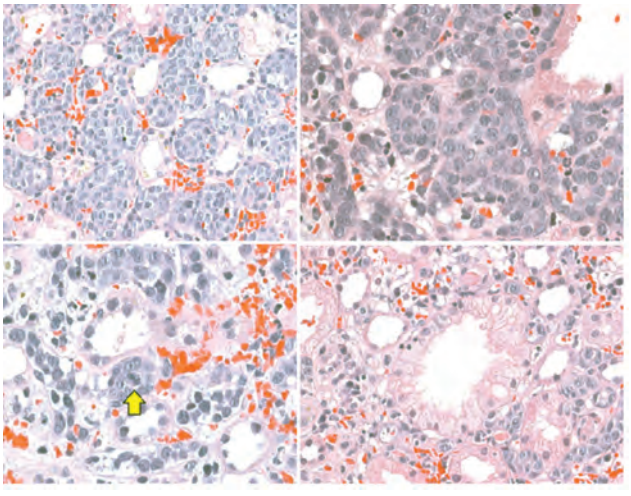
Intravascular Lymphoma of the Kidney and AKI

George Vasquez-Rios,[1] Natalia Wuliji,[1] Stephanie C. Shieh.[2] *[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]St. Louis VA Medical Center, Saint Louis, MO.*

Introduction: Intravascular lymphoma of the kidney (ILK) is an extremely rare condition characterized by malignant infiltration of small vessels.

Case Description: A 66-year-old woman presented with fatigue, altered mental status, and acute onset diarrhea. On exam, she was pale with abdominal tenderness. CBC showed leukocytosis, anemia, and thrombocytopenia. Basic chemistry showed creatinine: 2.1 mg/dL (baseline: 0.8), BUN:15 mg/dL, Na:122 mmol/L, HCO_3:17 mmol/L, markedly elevated LFTs, and lactic acid levels. Urinalysis showed: hematuria, mild proteinuria, and granular casts. Multiple studies including cancer work-up from blood, CSF, and BAL was only notable for high ESR. Pan CT scan revealed no lymphadenopathy. Bone marrow biopsy, flow cytometry, and genetic studies were also unmarkable. Despite the treatment with fluids and broad-spectrum antimicrobials, her clinical status continued to be poor with encephalopathy and acute kidney injury requiring dialysis. A kidney biopsy revealed heavy neoplastic cell infiltration of the renal cortex (nests surrounding renal tubules with marked interstitial hemorrhage) and prominent small vessel infiltration. Immunohistochemical staining showed that all malignant cells expressed CD45, PAX5, CD79a, CD20, BCL6, and MUM1, whereas staining for CD3, CD5, CD10, TdT, CD34, AE1/AE3, CAM 5.2, and MART1 was negative. Diagnosis of ILK was made. The patient was emergently treated with Rituximab, Cyclophosphamide, Etoposide, and steroids. Nevertheless, after a prolonged hospital course complicated by septic shock, and disseminated opportunistic infections, the patient expired.

Discussion: ILK is a devastating condition with a median survival of less than a year. Ante-mortem diagnosis is often missed due to the lack of detection of malignant cells in peripheral blood. Biopsy is mandatory whenever possible. Renal hemorrhage, and acute tubule-interstitial nephritis may be a presentation of this condition.



FR-PO692

Primary Large B Cell Lymphoma Mimicking Renal Cell Carcinoma

Prashanth Reddy, Sahityan Viswanathan. *Medical City Fort Worth, Fort Worth, TX.*

Introduction: Primary renal lymphoma is extremely rare and accounts for less than 1% of all kidney tumors. The prognosis is poor and the median survival is less than a year. It is extremely difficult to differentiate between renal cell carcinoma and primary renal lymphoma on initial imaging without biopsy. Primary renal lymphoma is a debated topic due to the kidneys not containing any lymphatic tissue.[1] Here we present a 81 yo CF who presented with nonspecific abdominal finding and was eventually diagnosed with a rare primary diffuse large B-cell lymphoma on CT guided biopsy.

Case Description: An 81 year-old- CF with PMHx of HTN, HLD presented with insidious onset dull epigastric dull and right sided abdominal pain. The pain was nonradiating, and nothing made it better or worst. It was associated with nausea, dry heaving, loss of appetite and weight loss. Otherwise ROS were negative. Vital signs were within normal range. Physical exam was unremarkable except minimal tenderness on palpation in the epigastric area and the right abdomen. A CBC was unremarkable, CMP was suggestive of AKI. Persistent nagging abdominal pain resulted in a CT abdomen and pelvis with contrast that was suggestive of renal mass with encasement of the IVC. She underwent CT guided renal biopsy instead of resection due to high risk of surgical removal that came back positive for a rare primary diffuse non hodgkin's B cell lymphoma. Her metastasis workup was negative. Oncology and the surgical team were consulted for further management.

Discussion: Primary Diffuse large B cell lymphoma of kidney is infrequent and management is completely different than RCC but needs renal biopsy to diagnose. With better technique and advancement in minimally invasive renal biopsy there is now a low complication rate. The use of percutaneous renal mass biopsy has expanded considerably in the last decade making it easier to differentiate between primary vs. secondary renal malignancy. We postulate that this advancement would stratify the malignant risk which could help in decreasing the number of needless extirpative therapies like nephrectomy.

FR-PO693

Use of Anti-FGF-23 Monoclonal Antibody for the Treatment of Severe Hypophosphatemia Secondary to Tumor-Induced Osteomalacia

Anika Lucas,[1] David I. Ortiz Melo,[2] Myles Wolf.[1] *[1]Duke University, Durham, NC; [2]Duke University Medical Center, Durham, NC.*

Introduction: Hypophosphatemia in patients with cancer may be due to poor oral intake or more commonly from drug-induced tubulopathies leading to renal phosphate wasting. Tumor-induced osteomalacia (TIO), also known as oncogenic osteomalacia, is a rare paraneoplastic cause of hypophosphatemia and hyperphosphaturia, as a result of constitutive release of fibroblast growth factor-23 (FGF-23). Here we present a case of profound hypophosphatemia secondary to oncogenic osteomalacia that improved with administration of burosumab, a monoclonal IgG1 antibody against FGF-23.

Case Description: A 68-year-old man with history of metastatic prostate cancer s/p prostatectomy, presented with several months of generalized weakness, worsening fatigue, muscle cramps and paresthesia. A whole-body bone scan showed extensive osseous metastatic disease. Laboratory data revealed serum phosphorus of 0.9mg/dL and inappropriately elevated random urinary phosphate (125 mg/dL; FEPO4 70%), indicative of renal phosphate wasting. His renal function was normal (serum creatinine 0.9 mg/dL) and ionized calcium was 1.07 mmol/L (normal 1.15-1.32mmol/L). Further work up revealed 25(OH)-Vitamin D level of 40 ng/mL and 1,25 $(OH)_2$Vitamin D level of 28 pg/mL. His serum FGF-23 levels were remarkably elevated (812 RU/mL, normal <180 RU/mL). Patient was diagnosed with oncogenic osteomalacia and was initially treated with oral phosphate and active vitamin D supplementation, which was unsuccessful (serum phosphorous persistently <1.0 mg/dL). He was then started on burosumab 90 mg every 2 weeks. After three doses, his phosphorus levels increased to 2 mg/dL and 1,25 $(OH)_2$Vitamin D level increased to 62 pg/mL.

Discussion: Burosumab is a human IgG1 monoclonal antibody directed against FGF-23 that has been approved for X-linked hypophosphatemia. By decreasing levels of FGF-23, burosumab increases both renal reabsorption and gastrointestinal absorption of phosphorus. Although burosumab is not yet approved for the treatment of hypophosphatemia in oncogenic osteomalacia, our case reveals another application for burosumab in this setting, specially in patients with refractory and symptomatic hypophosphatemia.

FR-PO694

Early-Stage IgG4-Related Tubulointerstitial Nephritis Incidentally Detected with a Tumor Lesion of the Ureteropelvic Junction

Tatsuhito Miyanaga,[1] Satoshi Hara,[1] Takeshi Zoshima,[1] Ryo Nishioka,[1] Kiyoaki Ito,[1] Ichiro Mizushima,[1] Hiroshi Fujii,[1] Yuki Sato,[2] Motoko Yanagita,[2] Mitsuhiro Kawano.[1] Department of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan *[1]Department of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan; [2]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Introduction: Histological examination of IgG4-related kidney disease (IgG4-RKD) is typically performed when kidney function decreases or when multiple low-density lesions are found in enhanced computed tomography (CT) images; thus, advanced-phase rather than early-phase IgG4-TIN is often detected. Here, we report a case of very early-stage IgG4-related tubulointerstitial nephritis (TIN) incidentally detected with involvement of the ureteropelvic junction (UPJ).

Case Description: A 72-year-old Japanese man was admitted to our hospital for progressive renal dysfunction. He had been followed-up for 18 years after surgical resection of a bladder tumor. Six months prior to presenting at our hospital, periodic CT showed a mass lesion on his right UPJ. He was clinically diagnosed with right ureter cancer and received neoadjuvant therapy followed by a right nephroureterectomy. Histology revealed IgG4-positive cell ($IgG4^+PC$) infiltration, obliterative phlebitis, and storiform fibrosis in the removed mass, leading to the diagnosis of IgG4-RKD. Notably, $IgG4^+PCs$ also infiltrated the tubulointerstitium of the cortex of the right kidney without storiform fibrosis, although no imaging abnormality was viewed in preoperative CT, indicative of very early-phase IgG4-TIN. In addition, mononuclear cells gathered only beneath the kidney capsule and around arteries and veins, and based on immunofluorescence, most of these aggregations were composed of T cells, B cells, and CD21-positive follicular dendritic cells, suggestive of mature tertiary lymphoid tissue (TLT). $IgG4^+PCs$ surrounded the TLT. Because renal function gradually worsened, the patient was admitted. Although neither extra-renal organ involvement nor an imaging abnormality of the left kidney was

noted, glucocorticoids were initiated and prevented renal deterioration, suggesting that IgG4-TIN was also present in the left kidney.

Discussion: IgG4-TIN was incidentally detected with involvement of the UPJ regardless of a lack of abnormalities in images of the kidney. $IgG4^+PC$ was distributed beneath the kidney capsule and around arteries and veins accompanying TLT. This case suggests that IgG4-TIN develops from common sites of TLT with TLT formation prior to the appearance of imaging abnormalities.

FR-PO695

A Case of Concurrent Multiple Myeloma and LECT2 Amyloidosis

Chidinma Ekenna, John R. Santa cruz, George M. Dolson, Natasha N. Dave. *Baylor College of Medicine, Houston, TX.*

Introduction: Multiple myeloma is a cancer of plasma cells that can lead to kidney problems. Leukocyte chemotactic factor 2 amyloidosis (ALECT2) is one of the most recently described forms of amyloid with unknown etiology, strong ethnic predominance and manifests as slow progressive renal failure.

Case Description: 44-year-old Hispanic female with no prior past medical history, presented to the ER with headache, nausea, fatigue and RLE pruritic rash x2 months and lab values concerning for acute kidney failure. Symptoms worsened 2 weeks prior to presentation with persistent headaches, emesis, hypersomnia and dyspnea on exertion. Physical exam with mild diffuse abdominal tenderness and dry RLE rash. Initial labs with BUN 58 mg/dL & Cr 5.40 mg/dL (1.1 mg/dL 5 months prior). Urine studies revealed UA with 1+ protein, protein/Cr ratio 4.52 g; CBC remarkable for anemia and thrombocytosis. Abdominal ultrasound unremarkable except moderate hepatomegaly. Work-up remarkable for positive ANA, SPEP with kappa light chain monoclonal peak in gamma region and abnormal serum & urine K/L ratio. Renal biopsy showed amyloidosis with positive congo red stain for amyloid deposits suspicious for LECT2 Amyloid and focal atypical kappa light chain dominant casts; 30% IFTA. Skeletal survey with multiple skull lytic lesions. Bone marrow biopsy and staining consistent with IgG Kappa multiple myeloma. Patient started on Velcade/Dex for IgG kappa multiple myeloma. Discharged with outpatient follow up

Discussion: Renal LECT2 amyloidosis is an uncommon form of amyloidosis of unknown etiology that causes slowly progressive renal failure with affinity to kidney and liver and more commonly seen in Hispanic patients. No available treatment except renal transplantation once end stage kidney disease is established. There are different types of myeloma, classified by the type of immunoglobulin produced by the abnormal plasma cells. IgG kappa type is the most common abnormal M protein. There has been overlap between multiple myeloma and amyloidosis with patients frequently diagnosed with both myeloma and AL amyloidosis, which is not the case in our patient with multiple myeloma and LECT2 amyloid. Thus, thorough categorization of patients presenting with renal amyloidosis should be encouraged to broaden the understanding of these subtypes and afford appropriate therapy and accurate prognosis to avoid unnecessary treatment.

FR-PO696

Cinacalcet-Induced Permanent Hypocalcemia in a Patient with Primary Hyperparathyroidism and Normal Kidney Function

Natacha Rigual soler,[4,2] Aidar Gosmanov,[3] Elvira Gosmanova.[1] *[1]Stratton VA Medical Center and Albany Medical College, Albany, NY; [2]Nephrology, Stratton VA Medical Center, Albany, NY; [3]Endocrinology, Stratton VA Medical Center, Albany, NY; [4]Nephrology, Albany Medical College, Albany, NY.*

Introduction: Cinacalcet (C) increases sensitivity of calcium (Ca) sensing receptor to extracellular Ca and suppresses parathyroid hormone (PTH) secretion. C is used in patients with primary hyperparathyroidism (PHPT) who are not surgical candidates. We report a case of irreversible hypocalcemia after 6 months of C administration in a patient with PHTP.

Case Description: A 58-year-old Caucasian male with PHPT, recurrent nephrolithiasis, osteopenia in femoral neck and normal kidney function (eGFR>90ml/min/1.73m^2) underwent surgical resection of 2 parathyroid glands. Postoperatively, PTH remained elevated (iPTH 227pg/mL, normal level [30-69]) in association with albumin-corrected Ca (aCa) 10.4mg/dL [8.2-10.2], ionized Ca (iCa) 1.4mmol/L [1.15-1.35]) and hypercalciuria (24-hr urinary Ca 427mg). Due to persistent PHPT and refusal of further surgery C 30 mg daily was initiated. C resulted in resolution of hypercalcemia, normalization of Pi and iPTH fall to 139pg/dL in 4 weeks. However, 6 months later the patient presented to the hospital with newly developed widespread paresthesia and hypocalcemia (aCa 7.2mg/dL, iCa 0.96 mmol/L), hyperphosphatemia (4.6mg/dL) and suppressed PTH (7pg/dL). C was discontinued and Ca supplements were initiated leading to normalization of iCa (1.17mmol/L) and PTH (38pg/ml). However, the patient continued to have hypercalciuria and required continuous oral Ca supplementation to avoid paresthesia and maintain eucalcemia even 12 months later. Repeat DXA showed improvement in bone mineral density.

Discussion: Reversible hypocalcemia due to C was mainly reported in patients with advanced CKD and it usually responds to a reduction or discontinuation of C. The present case has several novel features. Firstly, C-induced hypocalcemia developed in a patient with normal kidney function. Secondly, because PTH has normalized after temporal C exposure, we suggest that C can induce apoplexy of PTH-overproducing parathyroid cells. Lastly, we suspect the development of a defect resembling renal PTH resistance based on the presence of persistent hypercalciuria despite normal PTH levels with resultant hypocalcemia requiring continuous Ca supplementation. Further clinical investigations are needed to understand whether in some patients cinacalcet can cause or unmask renal PTH resistance.

FR-PO697

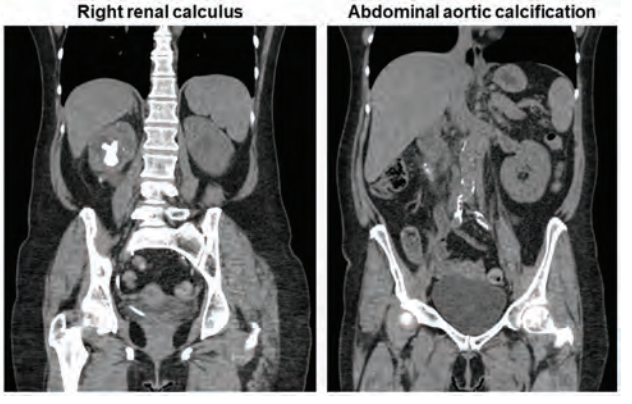
Calcium Maldistribution: A Case of Calcium Nephrolithiasis, Aortic Calcification, and Osteopenia

Rochelle Dalsan,[1] Deep Sharma,[1] Joshua M. Stern,[1] Eric J. Epstein,[1] David A. Bushinsky,[2] Wei Chen.[1,2] *[1]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; [2]University of Rochester School of Medicine and Dentistry, Rochester, NY.*

Introduction: Epidemiologic studies show that patients with nephrolithiasis have a higher prevalence of aortic calcification and bone demineralization compared to those without nephrolithiasis. We present a case of calcium nephrolithiasis with concomitant aortic calcification and osteopenia.

Case Description: A 62-year-old post-menopausal woman was seen for evaluation of nephrolithiasis. She was a smoker, but had no significant past medical history. Work up revealed serum K 4.8 mEq/L, CO_2 26 mEq/L, creatinine 0.8 mg/dL, calcium 9.6 mg/dL, phosphorous 3.9 mg/dL, intact parathyroid hormone 31 pg/mL, 25-hydroxy vitamin D 42 ng/mL and urinary pH ≥6.2 on all urinalyses (n=4), suggesting possible incomplete renal tubular acidosis. Stone analysis showed 100% calcium phosphate. Urine supersaturation showed marked hypocitraturia (235 mg/day) without hypercalciuria (153 mg/day). On computed tomography, she had numerous right kidney stones and significant abdominal aortic calcification [figure]. Dietary history revealed low calcium intake. Dual-energy x-ray absorptiometry (DEXA) was performed and showed osteopenia in the lumbar spine (T score: -2.3, Z-score: -0.7) and left femoral neck (T score: -1.4, Z-score: -0.2). As per Fracture Risk Assessment Tool, her 10-year fracture risk for a major osteoporotic fracture was 8.4%. Given above findings, we recommended smoking cessation, increasing dietary intake of calcium, fruits and vegetables, and to continue monitoring bone density.

Discussion: This is a case of calcium maldistribution, in which there was extraosseous deposition of calcium in the right kidney and aorta, and bone demineralization. The presence of nephrolithiasis and arterial calcification prompted us to perform a DEXA scan, which led to a more comprehensive treatment plan. More importantly, the case highlights an important need to better understand the pathophysiology underlying the maldistribution and extraosseous deposition of calcium.



FR-PO698

Case Study: A Report on the Efficacy of Hydroxychloroquine in Treating Hypercalcemia

Sara Hammond,[2] Parker Greenway,[1] William G. Paxton.[1] *[1]Georgia Nephrology, Lawrenceville, GA; [2]Gwinnett Medical Center, Lawrenceville, GA.*

Introduction: Sarcoidosis is a rare autoimmune disease resulting in the formation of non-caseating granulomas. Hypercalcemia occurs in 10 to 30 percent of sarcoidosis cases due to 1-alpha-hydroxylase over expression in granulomas. This enzyme increases 1,25-dihydroxy vitamin D levels, by conversion of 25-OH to 1,25-OH vitamin D. Hypercalcemia may be seen in any granulomatous disease. If hypercalcemia is uncontrolled it may lead to complications including nephrocalcinosis, renal lithiasis, and irreversible renal failure. Glucocorticoids are the mainstay of treatment of sarcoidosis, including the complication of hypercalcemia. Antimalarial agents such as chloroquine and hydroxychloroquine are known to impair production of 1,25-OH Vitamin D by blocking 1-alpha--hydroxylase activity. We report a case of a 56 year old caucasian female with sarcoidosis complicated by hypercalcemia successfully treated with hydroxychloroquine.

Case Description: A 56-year-old caucasian female with history of diabetes mellitus, hypothyroidism, and hypertension was referred for management of recent onset of worsening hypercalcemia. Her electrolytes were notable for serum calcium of 12.4 mg/dL (baseline 9.1-9.7), ionized calcium 1.49 mmol/L (NR 1.11-1.30), and serum creatinine of 1.7 mg/dL (baseline 0.9-1.1). Her calcium level remained elevated in spite of stopping daily Vitamin D3 supplementation and treatment with Denosumab injections. Differential diagnosis; included lymphoma and sarcoidosis: sarcoidosis was confirmed by tracheobronchial lymph node biopsy. Since pulmonary function was normal, there was a desire to avoid systemic steroid treatment. The patient was started on 200 mg hydroxychloroquine twice a day to control her hypercalcemia without the use of steroids. Within 2 months after initiation of hydroxychloroquine, calcium normalized and renal function returned to baseline. Hydroxychloroquine was then decreased to once a day and calcium remained normal over a period of greater than 2 years.

Discussion: This case uses hydroxychloroquine as a steroid sparing alternative in the treatment of hypercalcemia. This case demonstrates the efficacy of hydroxychloroquine in the treatment of hypercalcemia, by directly inhibiting the 1-alpha-hydroxylase activity. Based on this mechanism of action it should be considered as a treatment strategy in any disease resulting in 1-alpha hydroxylase overproduction.

FR-PO699

Overcorrection of Severe Hyponatremia in a Chronic Alcoholism Patient: A Case Report of Osmotic Demyelination Syndrome

Praveen Ratanasrimetha,[1] Inthira Khampalikit,[2] Kenneth Nugent.[3] *[1]Internal Medicine, Texas Tech University Health Sciences Center, Lubbock, TX; [2]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [3]TTUHSC, Lubbock, TX.*

Introduction: Patient with chronic alcoholism can have chronic hyponatremia from multiple mechanisms. Both chronic alcoholism and severe hyponatremia predispose patient to the osmotic demyelination syndrome. Rapid correction of serum sodium can lead to severe neurological damage.

Case Description: 45-year-old man with chronic alcoholism presented with confusion, generalized weakness, nausea, and vomiting for 3 days. He had history of heavy alcohol drinking for 3 years. Initial labs showed serum sodium level of 99 mmol/L. He was given intravenous 3% NaCl of the rate of 30 ml/hr to correct hyponatremia. Three hours later lab result showed a sodium level of 113 mmol/L. The patient was more lethargic and was found to have anisocoria. CT head showed diffuse atrophy but no acute abnormality. FLAIR MRI showed hyperintensity of supratentorial white matter, likely due to mild chronic microangiopathy. He was given intravenous 5%Dextrose at 100 ml/hr for overcorrection of hyponatremia. Later in hospital course he was more alert. His sodium level later increased to 127 mmol/L over the next 4 days. Patient was discharged to the nursing facility. He presented to hospital again with dysphagia, generalized weakness and spastic quadriparesis. His sodium level is 134 mmol/L. MRI showed abnormal restricted diffusion in the pons and bilateral thalami. There was subtle abnormal enhancement in the abnormal area in the pons which suggested osmotic demyelination syndrome.

Discussion: Patients who are high-risk for osmotic demyelination syndrome should raise awareness when correcting hyponatremia. Rapid sodium correction in this group of patients may lead to deterioration of neurological status due to neuronal shrinkage. The rate of sodium correction should not exceed 6-8 mEq/L in 24 hours period. Clinical manifestations of osmotic demyelination syndrome includes lethargy, dysarthria, dysphagia and seizure. Patients usually presented 2-6 days after correction. Our patient developed symptoms during the next 8 days. Even though it was later than the average onset, the risk factors and his symptoms are typical. MRI may not become positive until four weeks after onset. If the initial MRI is negative, it does not exclude osmotic demyelination syndrome.

FR-PO700

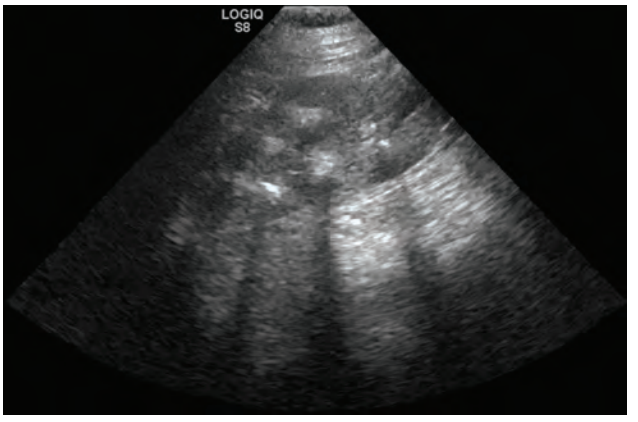
Peculiar Case of Life Threatening Hypokalemia

Yonatan A. Peleg, Wooin Ahn. *Nephrology, Columbia University Medical Center, New York City, NY.*

Introduction: Severe hypokalemia causes muscle weakness and cardiac arrhythmias. We present a case of life threatening hypokalemia due to RTA.

Case Description: 32-year-old woman presented with subacute weakness and muscle pain. She denied personal or family history of nephrolithiasis, autoimmunity, malignancy, deafness, growth retardation, fracture, anorexia, diarrhea, medication, illicit drug or heavy metal exposure. EKG showed QTc 756 ms and U waves. Labs revealed creatinine 0.75 mg/dL, K+ 1.7 mEq/L, Mg2+ 2.9 mg/dL, HCO3- 13 mEq/L, pH 7.28, urine pH 7.5, trace urine albumin, urine anion gap 7 mmol/L and urine osmolal gap 39 mOsmol/kg. 24 hour urine showed K+ 133 mEq, calcium 863 mg, phosphate 1150 mg, protein 690 mg and citrate <60 mg. Her imaging was notable for nephrocalcinosis. Calcidiol was 6.5 ng/ml and peak CPK was 5145 U/L. PTH decreased from 205.8 pg/mL (calcium 7.5 mg/dL) to 42.9 pg/mL (calcium 8.9 mg/dL). Chest imaging without hilar adenopathy. SS-A and SS-B antibodies were negative. Genetics screen was obtained and pending. After 880 mEq of K, her plasma K reached > 4. K citrate was started at 120 mEq daily and her acidosis resolved after 3 days. She was discharged with 80 mEq of K Citrate daily with stable chemistries.

Discussion: Distal RTA (dRTA) is characterized by inability to secrete H+ in the distal tubule. It is associated with hypokalemia if non-voltage mediated. It can lead to hypercalciuria, hyperphosphaturia, hypocitraturia and consequent nephrocalcinosis. dRTA yields alkaline urine but urinary pH is maintained <6.5 because bicarbonate is not significantly lost. However, this patient had urinary pH 7.5 and tubular proteinuria suggesting proximal tubule injury. The etiology of the patient's proximal tubule injury is unclear, but the hypovitaminosis D is glaring. Overall, this case represents a peculiar presentation of RTA, with likely long-standing dRTA and sub-clinical nephrocalcinosis coupled with proximal injury resulting in life threatening hypokalemia. Clinicians should consider RTA as the cause of hypokalemia.



Nephrocalcinosis

FR-PO701

Hyponatremia due to Primary Adrenal Insufficiency Treated by Cortisol Replacement

Sheikh B. Khalid,[2] Gerald A. Hladik,[2] Manish K. Saha,[1] Obiajulu Kanu.[3] *[1]UNC Kidney Center, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC; [3]Nephrology, UNC Hospitals, Chapel Hill, NC.*

Introduction: Hyponatremia complicating malignancy is most commonly seen due to the syndrome of inappropriate antidiuretic hormone secretion. We present a unique case in which metastatic non-small cell lung cancer (NSCLC) led to primary adrenal insufficiency and hyponatremia

Case Description: A 66-yr-old man was admitted for symptomatic hyponatremia. He was evaluated at an outside facility for a month history of blood-streaked sputum and weight loss. He was hypotensive with initial serum sodium (SNa) 125 mEq/L, potassium 5.3 mEq/L, bicarbonate 22 mEq/L, chloride 86 mEq/L and Creatinine 0.5 mg/dL. After receiving 1 L of normal saline, he became confused with an associated fall in SNa 116 mEq/L, prompting transfer to our institution. On arrival, he was lethargic and disoriented. His vital signs were normal. Physical examination revealed a disoriented man with digital clubbing. Laboratory studies revealed a serum osmolality 235 mOsm/kg, urine osmolality (UOsm) 271 mOsm/kg and urine sodium 74 mmol/L. CT of head showed superior cerebellar mass with vasogenic edema. Further imaging revealed right upper lobe lung mass and bilateral adrenal nodules. He was treated with dexamethasone 6 mg every 6 hours for vasogenic edema and suspicion for adrenal insufficiency. Repeat laboratory studies showed improvement of SNa to 123 mEq/L and decrease in UOsm to 129 mOsm/kg. The SNa decreased to 120 mEq/L while the UOsm increased to 382 mOsm/kg after tapering of dex. A cosyntropin stimulation test was consistent with primary adrenal insufficiency. Hydrocortisone therapy at replacement doses resulted in normalization of SNa

Discussion: Adrenal glands are commonly involved in metastatic cancer but primary adrenal insufficiency uncommonly ensues, unless majority of the adrenal cortex is destroyed. Although it has been reported with advanced breast cancer and colon carcinoma, to our knowledge only a handful of cases of adrenal insufficiency leading to hyponatremia due to NSCLC have been reported. The pathogenesis is related to loss of negative feedback of cortisol on vasopressin which acts as a secretagogue for ACTH. The rate of rise of sodium is ideally 6-8 mEq/24 hours, but needs cautious monitoring since erratic changes may be seen (observed in our case). Dex is the initial corticosteroid of choice as it doesn't interfere with cortisol assay during cosyntropin stimulation test

FR-PO702

Pseudohyperphosphatemia in Multiple Myeloma

Efren A. Chavez Morales,[1] Qais Al-Awqati.[2] *[1]Nephrology, New York Presbyterian - Columbia University Irving Medical Center, New York, NY; [2]Columbia University, New York, NY.*

Introduction: Hyperphosphatemia commonly occurs in renal failure or hypoparathyroidism. If severe it can cause severe hypocalcemia leading to cardiac or neurologic symptoms. Pseudohyperphosphatemia is rarely seen and it is due to interference by other serum elements in the phosphorous assay.

Case Description: We present here a 58 year old woman with refractory IgG kappa multiple myeloma. SCr was 0.6 mg/dL, eGFR >60 ml/min, Pi 34 mg/dL, iCa 1.06 mmole/L, PTH 32 pg/mL, uric acid 6.2 mg/dL, LDH 212 U/L, IgG 7888 mg/dL, total protein 13.2 g/dL, serum globulin 10.3 g/dL In the setting of normal renal function, normal PTH, no laboratory evidence of tumor lysis syndrome and discrepancy between serum phosphorus and calcium levels we suspected this was a case of pseudohyperphosphatemia.

Discussion: It has been stated that paraproteins interfere with spectroscopic measurement of phosphomolybdate which is the actually measured adduct in the routine laboratory phosphorous (P) assay. The inherent flaw in the design of this test is its dependence on light penetration into the sample, thus any condition that increases the turbidity of the sample would falsely elevate the reading. Also, the abnormal serum proteins may themselves bind phosphate which may spuriously increase the total serum

phosphate, but not the biologically active form of phosphate. The level of serum phosphate returns to normal when it is measured after deproteinization with sulfosalicylic acid or trichloroacetic acid. Instead of precipitating the proteins we performed a mixing study using normal serum with a Pi of 1.3 mg/d and performed serial dilutions. The patient's serum diluted fourfold only increased the Pi level of the mixture to 2.1 mg/dL indicating that the upper bound of our patient's true Pi level is around 4.5 mg/dL. We can also calculate the free Pi concentration from association constant of calcium and phosphorus, which is $2.3x10^{-7}$ $mole^2/L^2$. When the ionized calcium is 1 mmole/L the free serum Pi level has to be 0.23 mmol/L. Using an activity coefficient of Pi of 0.23, the patient's actual plasma Pi is about 1 mmole/L or ~ 3mg/dL. It is interesting that a falsely elevated Pi level does not occur in every patient with paraproteinemia thus it is likely that the type of paraprotein produced by the clone may have specific chemical attributes that leads to the spurious measurement.

FR-PO703

A Case of Spurious Hyponatremia in Hyperleukocytosis

Joshua Leisring, Tyler Gutkoski, Jason Prosek, Samir V. Parikh. *Ohio State University Medical Center, Columbus, OH.*

Introduction: Hyponatremia is commonly seen in the oncology population. Here we report a case of discordance between serum sodium and whole blood sodium measurements in the setting of severe leukocytosis.

Case Description: A 72-year-old male with blastoid variant mantle cell lymphoma presented with fatigue and nausea. He appeared hypovolemic on exam. Laboratory evaluation revealed a WBC count of 476 K/uL. Serum sodium (SNa) was 117 mmol/L, potassium > 10 mmol/L, BUN 27 mg/dL and creatinine 1.36 mg/dL. Whole blood potassium was 3.73 mmol/L. Glucose was 96 mg/dL and total protein was 5.2 g/dL. Urine chemistry showed sodium < 10 mmol/L, chloride < 15 mmol/L, potassium 66.0 mmol/L, osmolality 722 mosm/kg. SNa initially improved with normal saline hydration to 121, but did not improve further over the next 24 hours. No alternative causes for hyponatremia were identified. SNa at our institution is measured by the direct ion-specific electrode method which makes pseudohyponatremia from lipids or proteins unlikely. Whole blood sodium (WBNa) checked on day two was 131.7 mmol/L while concurrent SNa remained 121. With leukopheresis and R-CHOP the WBC count improved from 476 to 31.5 K/uL. Serial WBNa measurements remained stable (129.6 – 135) during treatment while SNa gradually increased from 117 to normal levels (Fig. 1). The gap between WBNa and SNa diminished as WBC burden was reduced and these measurements correlated well when WBC count decreased below 150 K/uL.

Discussion: This case identifies a disparity between SNa and WBNa measurements in the setting of severe leukocytosis. Psuedohyperkalemia has been previously described in this population and is thought to be due to leukocyte membrane fragility and mechanical stress during blood tube handling leading to cell lysis and leakage of intracellular contents into plasma. This case suggests that SNa measurements are also distorted by this mechanism. Whole blood sodium measurements may be more reliable than serum measurements in the setting of severe leukocytosis.

Mycobacterium Chimaera: An Unusual Cause of Hypercalcemia and Kidney Injury

Hanny Sawaf,[1] Georges Nakhoul,[3] Ali Mehdi.[2] *[1]Trihealth, Cincinnati, OH; [2]Cleveland Clinic, Mayfield Hts, OH; [3]Cleveland Clinic Foundation, Cleveland, OH.*

Introduction: Mycobacterium Chimaera is an indolent nontuberculous mycobacterium that has been recently associated with outbreaks of prosthetic valve endocarditis throughout Europe and the United States. Contaminated heater-cooler devices in the cardiothoracic operating rooms have been implicated as the cause of the outbreak. Hypercalcemia and kidney involvement have rarely been reported as part of the disease presentation. We hereby present a case of M. Chimaera prosthetic valve endocarditis presenting with hypercalcemia and kidney dysfunction.

Case Description: A 63-year-old male with a history of bicuspid aortic valve status post bioprosthetic AVR presented with generalized weakness, fatigue, and altered sensorium. MRI of the brain revealed small embolic events that prompted a TEE which was suspicious for vegetations on the bioprosthetic valve along with valve dehiscence and perivalvular abscess. He was thus transferred to our facility for evaluation of re-do surgery. On evaluation, he was found to have an AKI with a creatinine of 1.7 mg/dl (baseline around 1). He was also notably hypercalcemic at 12 mg/dl with an undetectable PTHrP level. Creatinine and calcium trended down slowly with hydration and the patient was eventually taken to the OR for AVR. While 25-OH vitamin D level was low (20.8 ng/ml), the 1,25-OH vitamin D level was elevated at 65.4 pg/ml. Microbiologic evaluation of the explanted valve revealed moderate acid-fast bacilli by Ziehl-Neelson stain and the cultures were positive for Mycobacterium Chimaera. The patient was also found to have multifocal choroiditis on ophthalmic evaluation, which was indicative of disseminated mycobacterial infection. He was thus treated with a prolonged course of rifampin, ethambutol, and azithromycin. The patient was eventually discharged home in good condition with complete normalization of creatinine and calcium levels.

Discussion: Mycobacteria are associated with elevated 1,25-OH Vitamin D levels due to production of 1-alpha-hydroxylase enzyme by activated macrophages. The ensuing hypercalcemia can certainly lead to kidney dysfunction but M. Chimaera has also been associated with granulomatous interstitial nephritis. Treatment focuses on antibiotic therapy and in the case of prosthetic valve endocarditis, surgical treatment whenever possible.

FR-PO705

Linezolid-Induced SIADH: A Rare Cause of Hyponatremia

Rebaika Chopra,[1] Shorya Bector,[2] Anjali Acharya.[3] *[1]James J Peters VA medical centre, Bronx, NY; [2]Jawanda hospital, Khanna, India; [3]Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

Introduction: Linezolid is a oxazolidinone antibiotic against gram-positive organisms that inhibits bacterial protein synthesis. Thrombocytopenia is common, but hyponatremia is rare after linezolid use.

Case Description: An 89-year old woman with MRSA wound infection after lumbar laminectomy required prolonged linezolid therapy. She was admitted to the hospital for acute anemia and hyponatremia, with a hemoglobin drop from 8gm/dl to 6.8gm/dl and a sodium level of 127meq/l on admission over a 3-week period. Patient was hypotensive with blood pressure of 90/50 mm Hg, but her sodium levels failed to improve with isotonic fluids. Labs showed serum sodium of 122meq/l, serum osmolality 255mOsm/kg, urine osmolarity 389mOsm/kg, urine sodium 125mmol/l and serum uric acid level of 2.6 mg/dl. Rest of the work-up including serum cortisol and TSH were normal. All labs were suggestive of SIADH and as further investigations towards finding the underlying etiology did not reveal any other cause, linezolid was considered to be the culprit. Linezolid was stopped, and patient was started on fluid restriction and salt tablets, her sodium improved from 122meq/l to 130meq/l over 4 days. Anemia was attributed to myelosuppression caused by linezolid, which is one of its serious side- effects.

Discussion: This case was given 6 points using Naranjo adverse drug reaction (ADR) probability score indicating an association between hyponatremia and Linezolid use. Linezolid has previously been reported to cause hyponatremia with a frequency of 18% in a retrospective cohort study. Exact mechanism remains unknown but could be secondary to ADH release due to the medication or from underlying inflammation. There are 3 other cases published to date reporting hyponatremia from linezolid use. Interestingly, most of these reports have been on Asian population, possibly hinting towards a higher incidence in this group. However, more research is needed to explore this hypothesis. It is important to increase awareness of this side-effect as new drug-resistant bacteria emerge and use of Linezolid increases. Close monitoring of serum sodium is important for those on prolonged treatment with Linezolid, since it also lowers the seizure threshold. The use of Linezolid can lead to neurologic side effects of hyponatremia, ranging from mild effects such as tremor, incoordination to severe such as seizures.

FR-PO706

Guess the "Glucose"

Nishanth Girija Kumar, David Sheikh-Hamad. *Baylor College of Medicine, Houston, TX.*

Introduction: Hyponatremia is the most common electrolyte abnormality encountered in clinical practice. Proper interpretation of the various laboratory tests helps to differentiate the various types of hyponatremia. Treatment varies with the nature of onset, acute or chronic, severity and symptoms.

Case Description: 39 year old male who recently immigrated from Guatemala 1 week ago was admitted for seizures witnessed by his family. Review of systems was positive for urinary incontinence and tongue biting. Vital signs showed Temperature 97.3F, BP126/97, HR 112, RR 16. Physical exam was notable for Tongue trauma, dry mucous membranes and decreased skin turgor. Laboratory data was significant for Sodium of 102, Glucose > 4000, BUN 50 and Serum Osmolality 350. A diagnosis of Hypertonic Hyponatremia due to Hyperglycemia was made. Patient was treated in the ICU for 2 days with Insulin and Isotonic Intravenous fluids and was discharged from the hospital on day 5.

Discussion: Scenario 1 - If the Glucose from the lab value were true at 4000, corrected sodium would be 164 meq/L, using the correction factor of 1.6 mEq per L decrease in serum sodium for every 100 mg per dL increase in glucose concentration. Scenario 2 - We calculated the estimated glucose using the formula for serum osmolality. Assuming an osmolal gap of 10, calculated osmolality was set at 340. This resulted in an estimated glucose of 2100. Based on the estimated glucose, the corrected sodium level was calculated at 134 meq/L. Take home teaching points - Extreme laboratory values should be cautiously examined. Corrected Sodium values in both the scenarios have very different managements with extremely improtant clinical implications. Fun fact - Guiness World Record for the highest blood glucose survived by a human being was 2656 mg/dL.

Characterization of ADPKD-Like Patients Monoallelic for ALG8 Mutations

Giancarlo Joli,[1,2] Sarah R. Senum,[2] Sonam Raj,[2] Iris B. Te paske,[2] Emilie Cornec-Le Gall,[3] Sravanthi Lavu,[2] Eliecer Coto,[4] Berenice Y. Gitomer,[5] Theodore I. Steinman,[6] Vicente E. Torres,[2] Peter C. Harris.[2] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]Mayo Clinic, Rochester, MN; [3]Centre Hospitalier Universitaire de Brest, Brest, France; [4]HUCA, Oviedo, Spain; [5]Div. Renal Diseases and Hypertension, Aurora, CO; [6]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Although *PKD1* and *PKD2* are the common ADPKD genes, recently monoallelic *GANAB* and *DNAJB11* mutations have been associated with an ADPKD-like phenotype. These studies showed genic overlap between ADPKD and the related disorder, autosomal dominant polycystic liver disease (ADPLD). Our aim was to further determine the etiology of genetically unresolved ADPKD-like patients.

Methods: Here we screened 723 ADPKD-like patients without mutations in the known ADPKD genes employing a 137 gene panel of described ADPKD, ARPKD, ADPLD, ADTKD and ciliopathy genes, plus candidate loci. Identified families were characterized by segregation, imaging and analysis of the clinical phenotype.

Results: One gene, *ALG8*, stood out due to a high number of truncating variants across multiple families. *ALG8* encodes a glucosyltransferase, and biallelic mutation have been associated with a congenital disorder of glycosylation, CDG1H, while monoallelic mutations have been described to cause ADPLD in 5 families. Nine families were identified with likely significant *ALG8* pathogenic variants: 2 missense and 7 truncating, with 14 mutation proven cases. The kidney involvement was mild with normal function and small to medium sized cysts, predominantly in the left kidney, and few liver cysts. The presentation was often sporadic, but in one family two sibs had similar asymmetric disease. The relatively high frequency of *ALG8* truncating changes in the normal population (gnomAD database) indicates that it may be a common cause of renal cysts, but additional modification may be required for clinically significant disease. Consistent with this, a patient with Stage 4 CKD also had a rare *PKD1* missense variant, while his sister with only the *ALG8* variant had just a few cysts. Further, in a described unlinked (PKD3) Spanish family, significantly affected individuals had splicing variants to one or two known ciliopathy genes segregating with the *ALG8* mutation.

Conclusions: *ALG8* is a gene associated with multiple cyst development in the kidney and screening will likely explain a significant number of mildly affected cases. Oligogenic inheritance with additional gene variants may be required to trigger clinically significant PKD.

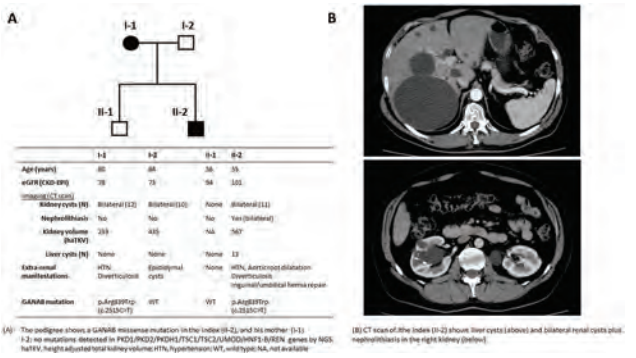
Expanding the Variability of the ADPKD-GANAB Clinical Phenotype: A New Family of Italian Ancestry

Claudia Izzi,[1] Elisa Delbarba,[2] Laura Econimo,[1] Barbara Gnutti,[3] Cinzia Mazza,[3] Francesco Scolari.[2] *[1]Spedali Civili di Brescia, Montichiari, Brescia, Italy; [2]University of Brescia, Montichiari (Brescia), Italy; [3]Spedali Civili di Brescia, Brescia, Italy.*

Introduction: Causative GANAB mutations have been described reported in only 12 families, 9 diagnosed with late-onset mild ADPKD and 3 with ADPLD. We describe a new family with mild, late-onset ADPKD due to p. R839W GANAB mutation, previously reported in an ADPLD patient requiring liver transplantation.

Case Description: Diagnosis of ADPKD was made in a 45-year old man during pre-surgical screening for umbilical and inguinal hernia repair. Hematuria, hypertension and aortic root dilatation were documented. At age 52, he experienced acute flank pain. Abdomen CT scan showed bilateral renal cysts (TKV 565 cc), nephrolithiasis, normal-sized liver with multiple cysts, and colonic diverticuli; renal function was normal. PKD1-PKD2 NGS and MLPA analyses were negative; analysis of additional PKD related genes showed a heterozygous p. R839W GANAB mutation. Familial study revealed p. R839W GANAB mutation in the mother. The elderly parents had normal renal function, normal-sized kidneys with multiple bilateral kidney cysts (mainly parapelvic in the father). The ADPKD-GANAB affected mother had no liver cysts on CT scan. The father has been studied for PKD related genes and no mutation was found.

Discussion: Since ADPKD-GANAB is a rare condition, we need further families to better characterize the phenotypic features of this new cystic disease. In our family, the p. R839W GANAB mutation, previously associated with severe ADPLD, was associated with a mild ADPKD, although showing several renal and extrarenal manifestations. The overlapping cystic phenotype and the plethora of renal and extrarenal manifestations are in agreement with the hypothesis that in GANAB disease, hepatic and renal cysto-genesis is the result of the common defective polycystin-1 pathway.



FR-PO709

ADPKD: Rare PKD1 and PKD2 Complex Genotypes May Explain Intrafamilial Phenotypic Variability

Claudia Izzi,[1] Elisa Delbarba,[3] Barbara Gnutti,[2] Gianfranco Savoldi,[2] Nadia Dallera,[1] Francesco Scolari.[3] *[1]Spedali Civili di Brescia, Montichiari, Brescia, Italy; [2]Spedali Civili di Brescia, Brescia, Italy; [3]University of Brescia, Montichiari (Brescia), Italy.*

Background: Discordant affected relative-pairs are seen in nearly 10% of ADPKD families. Complex genotypes may result in renal disease variability beyond that predicted by the sole effect of a PKD mutant allele, leading to the discovery of biallelic or digenic disease. Here we illustrate such complexity in 6 ADPKD pedigrees showing a marked intrafamilial phenotypic variability.

Methods: Among our single-center ADPKD cohort (186 patients), we selected pedigrees (P) in which marked phenotypic variability was investigated by NGS analysis of PKD1 and PKD2 genes.

Results: In P1 and P2, the index cases (IC), presented with very early onset (VEO) disease. In P1, with neonatal onset, the ADPKD affected father transmitted a PKD1 truncating (T) mutation, whereas the mother, without cystic phenotype, transmitted a PKD1 hypomorphic mutation. In P2, the ADPKD-PKD2 mother's pregnancy was complicated by Potter sequence. Parent's PKHD1 gene analysis was negative. Two non truncating (NT) mutations in PKD1/PKD2 genes were detected in the healthy father. Therefore, a complex PKD inheritance was suspected in the fetus. P3: early onset (EO) ADPKD in two monozygous twins was underpinned by a PKD1 NT mutation on their inherited paternal allele and by a de-novo PKD1 T mutation. In P4 a digenic ADPKD was diagnosed in the two most severely affected siblings: a PKD2 T mutation and a PKD1 NT mutation were detected. Elderly parents in P5 and P6 had few kidney cysts and preserved eGFR, whereas IC showed moderate/severe CKD due to ADPKD. In P5 the IC carried a homozygous PKD1 NT mutation; in P6 the IC harbored 2 PKD1 mutations (in trans).

Conclusions: Our study illustrates the genetic complexity in an otherwise "simple" Mendelian disorder, providing insights into the genetic basis of ADPKD intrafamilial disease variability.

FR-PO710

Clinical Variability in PKD2-Linked Families with the Same Germ-Line Mutation

Valentina Corradi,[1] Anna Giuliani,[1] Carlotta Caprara,[2] Fiorella Gastaldon,[1] Massimo de Cal,[1] Claudio Ronco.[3] *[1]San Bortolo Hospital, Vicenza, Italy; [2]IRRIV, Vicenza, Italy; [3]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common inherited renal cystic disease. It is genetically heterogeneous:72-75% of ADPKD cases are related to mutations in the PKD1, 15-18 % to PKD2 and the remaining 7–10% of affected are genetically unresolved (GUR). Both genes are characterized by high level of allelic heterogeneity. It is rare to identify the same germ-line mutation in different families, since mutations are "private". The age at disease onset, the severity, and the clinical outcome contribute to the intra and interfamilial variability. Aim of the study was to evaluate the clinical characteristics of PKD2 gene-linked families with the same germ-line mutation.

Methods: Patients (pts) with ADPKD were enrolled and followed prospectively. Diagnosis of ADPKD was made upon the revised Ravine's criteria. Complete clinical details were recorded, including family history and pedigree. We performed Sanger sequencing analysis to identify mutations. The eGFR was calculated CKD-EPI equation. The progression of CKD was determined by the change in eGFR per year. Data were shown as mean ± sd or median (min-max).

Results: Twenty-five pts (14male) were included in the analysis, belonging to 10 PKD2gene-linked families with the same germ-line nonsense mutation (c.2533C>T, p.Arg845Ter). 7/10 families had their origin from the same geographical area. The other three families originated from an area 100 km away. Four of them reached ESRD (61 ± 9 yrs) belonging to different families. In 3/4 families at least one relative of ESRD pts did not required RRT at the same age. Moreover, in one family 2 relatives are not even CKD. Nine patients (43 ± 14yrs) are still not affected by CKD; 6/9 pts have at least one ESRD relative. Eleven patients (61 ± 9.6 yrs) have CKD stage 2-3 and a progression rate estimated of 2.3 ml/min/year (0.73-5.1). One of them is a fast progressor and he is in treatment with Tolvaptan.

Conclusions: We found the same PKD2 germline mutation in 10 families maybe due to a founder effect in our region. High intra-interfamilial variability in ADPKD pedigrees was observed, despite the same germline mutation. This could be explained by other clinical or genetic factors (environmental, SNPs, modifier genes, etc) that may affect disease severity.

FR-PO711

Diagnostic Utility of Whole-Exome Sequencing in Autosomal Dominant Polycystic Kidney Disease

Alex R. Chang,[1] Yoosif Abdalla,[1] f m. Taher,[3] Jonathan Z. Luo,[3] Tooraj Mirshahi.[2] *[1]Geisinger Medical Center, Danville, PA; [2]Geisinger Clinic, Danville, PA; [3]Geisinger, Danville, PA.*

Background: Whole exome sequencing (WES) is increasingly being used to screen for certain genetic conditions, including some genetic forms of kidney disease. However, there are challenges in sequencing adult polycystic kidney disease (ADPKD) due to *PKD1* having 6 pseudogenes. Our goal was to examine WES accuracy in individuals with clinical diagnosis of ADPKD, as well as in an unselected cohort.

Methods: We examined data from 31,391 subjects in the Geisinger-MyCode population as part of the Regeneron-DiscovEHR collaboration. WES was performed using a modified version of the IDT xGen Exome Research Panel. Average depth of coverage for PKD1 and PKD2 were 27X and 33X, respectively. We identified subjects with *PKD1* or *PKD2* putative loss-of-function (pLoF) mutations (stop-gain, frameshift, canonical splice) as well as large deletions encompassing *PKD1*or *PKD2* detected in WES-based CNV analysis. ADPKD phenotyping was done by identification of individuals who had a diagnosis code for polycystic kidney disease, followed by confirmation by chart review.

Results: Out of the 31,391 subjects, we identified 22 (0.07%) patients with clinical diagnosis of ADPKD using a phenotype-first approach, and 26 (0.08%) pLOF mutation carriers using a genotype-first approach. With a phenotype-first approach, we found pLOF mutations in 21/22 (95.5%) patients with clinical diagnosis of ADPKD (13 *PKD1* and 8 *PKD2* carriers). Of the 26 pLoF carriers, there were 18 *PKD1* carriers and 8 *PKD2* carriers. All 8 *PKD2* carriers had clinical diagnosis of ADPKD by chart review. Of the 18 *PKD1* carriers, 12 had ADPKD by chart review although 2 of the remaining 6 patients without evidence of ADPKD were in their 30s and lacked adequate abdominal imaging.

Conclusions: When conducted with a sequencing platform that achieves sufficient depth of coverage of *PKD1*, WES provided 100% diagnostic accuracy in *PKD2* pLoF carriers and showed high sensitivity but limited specificity for *PKD1* pLoF carriers. WES may have diagnostic value in a genotype-first approach in identifying ADPKD patients, but additional confirmation of *PKD1* mutations may be needed.

Clinical Whole-Genome Sequencing Enables Diagnostic Certainty in Polycystic Kidney Disease

Amali Mallawaarachchi,[1,2] Yvonne Hort,[1] Nicole Schonrock,[11,3] Sarah R. Senum,[9] Andre E. Minoche,[10] Georgina E. Hollway,[11] Thomas Ohnesorg,[11] Chirag Patel,[15] Michel Tchan,[4,5] Andrew J. Mallett,[6,7] Marcel E. Dinger,[16] Gopi Rangan,[13,14] Mark J. Cowley,[8,3] Peter C. Harris,[9] Leslie Burnett,[10,11] John Shine,[1] Tim Furlong.[1,12] *[1]Division of Genomics and Epigenetics, Garvan Institute of Medical Research, Sydney, NSW, Australia; [2]Department of Medical Genomics, Royal Prince Alfred Hospital, Sydney, NSW, Australia; [3]Garvan Institute of Medical Research, Sydney, NSW, Australia; [4]Department of Genetic Medicine, Westmead Hospital, Sydney, NSW, Australia; [5]Sydney Medical School, The University of Sydney, Sydney, NSW, Australia; [6]Kidney Health Service & Conjoint Kidney Laboratory, Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [7]KidGen Collaborative, Melbourne, VIC, Australia; [8]Children's Cancer Institute, Randwick, NSW, Australia; [9]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [10]Kinghorn Centre for Clinical Genomics, Garvan Institute of Medical Research, Sydney, NSW, Australia; [11]Genome.One, Sydney, NSW, Australia; [12]Department of Renal Medicine, St Vincent's Hospital, Sydney, NSW, Australia; [13]Westmead Institute for Medical Research, The University of Sydney, Sydney, NSW, Australia; [14]Department of Renal Medicine, Westmead Hospital, Sydney, NSW, Australia; [15]Genetic Health Queensland, Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [16]School of Biotechnology and Biomolecular Sciences, University of New South Wales, Sydney, NSW, Australia.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is predominantly caused by pathogenic-variants in *PKD1* or *PKD2* and is the most common cause of Polycystic Kidney Disease (PKD). Diagnosis is usually by age-dependent ultrasound criteria, which is challenging in those without family history, with atypical clinical features or younger patients. ADPKD diagnosis has also become more complex with recent identification of additional genes that mimic the phenotype. However, new treatments require definitive diagnosis to appropriately prescribe. Whole Genome Sequencing (WGS) can diagnose PKD, including ADPKD and its gene mimics, and provide prognostic information, but has not been validated for clinical use.

Methods: In this study, we first validated WGS for ADPKD diagnostic testing using a blinded cross-over method. Forty-two adult ADPKD patients underwent sequencing of *PKD1* and *PKD2* by both WGS and Sanger sequencing. We then examined the first 85 samples referred to a clinically-accredited diagnostic laboratory for WGS, with variant analysis targeted to a PKD gene-panel (*PKD1, PKD2, GANAB, HNF1B, PKHD1, UMOD, TSC1, TSC2, OFD1).*

Results: WGS identified all *PKD1* and *PKD2* germline disease-causing variants in the validation study, without false-positive results (sensitivity and specificity 100%). In the unselected, real-world diagnostic cohort (42 males:43 females; median-age 39years (0-79years); 46% with family history of PKD), the overall diagnostic rate was 71%, with a 91% diagnostic rate in patients with typical clinical features of ADPKD (100% with *PKD1/PKD2* variants) and 56% in those with atypical clinical features (63% with *PKD1/PKD2* variants*;* 37% with *PKHD1, HNF1B, GANAB, TSC2* variants). Most patients with atypical PKD did not have clinical features that predicted likelihood of genetic diagnosis, highlighting the value of genomic testing in this group.

Conclusions: The high diagnostic rate in both typical and atypical PKD suggests clinicians should consider diagnostic genomics in their approach to PKD diagnosis.

FR-PO713

Prevalence of Diagnosed Polycystic Kidney Disease by Race/Ethnicity Among a Large Diverse United States Population, 1998-2018

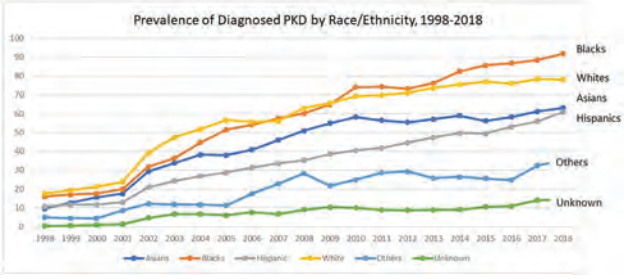
Thet T. Aung,[1] Qiaoling Chen,[1] Fatima T. Malik,[2] Kristi Reynolds,[1] Steven J. Jacobsen,[1] John J. Sim.[1] *[1]Nephrology, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [2]Nephrology, Kaiser Permanente Los Angeles, Los Angeles, CA.*

Background: While polycystic kidney disease (PKD) is considered a rare disease, it accounts for the 4th most common cause of ESRD in the United States (US). Estimates of PKD prevalence in Europe and the US are similar (30-50 per 100,000 persons) but whether differences exist across race/ethnicities is relatively unknown. We examined trends in the prevalence of diagnosed PKD overall and by race/ethnicity in a large, diverse healthcare delivery system with over 4.6 million members in the US.

Methods: Diagnosed PKD was identified among members aged ≥15 years in each calendar year from 1998 through 2018. PKD was defined as ≥2 separate encounter diagnoses for PKD (ICD9 codes 753.12, 753.13, 753.14, and ICD10 code Q61.2, Q61.19, Q61.3). Race/ethnicity was determined by self-report. Temporal trends in diagnosed PKD was examined overall and by race/ethnicity.

Results: A total of 7,580,947 members were included in the study period. Between 1998 and 2018, 3,524 members were identified as PKD with an overall prevalence of 46.5 cases per 100,000 people. The mean age of the PKD population was 49 years and comprised of 50% females with 10% Asians, 13% Blacks, 20% Hispanics, and 43% Whites. Prevalence (per 100,000) by race/ethnicity was 58.7, 84.5, 47.7, and 71.7 among Asians, blacks, Hispanics, and whites, respectively (p<0.001). Diagnosed prevalence of PKD increased among all racial/ethnic groups over the 20-years (Figure).

Conclusions: These data demonstrate sizeable differences in PKD prevalence by race/ethnicity. This information can help tailor strategies for identifying and managing this important population, based on the underlying population. Moreover, these data point to the potential to generate additional insights on the natural history/clinical course of this potentially modifiable genetic kidney disease.



FR-PO714

Tubular Basement Membrane Duplication and Cell Interposition Are Distinctive Histological Findings in the Adult Patients Genetically Diagnosed with Nephronophthisis-Related Ciliopathies

Takuya Fujimaru,[1] Takayasu Mori,[1] Michio Nagata,[2] Shintaro Mandai,[1] Motoko Chiga,[1] Hiroaki Kikuchi,[1] Fumiaki Ando,[1] Yutaro Mori,[1] Koichiro Susa,[1] Kiyoshi Isobe,[1] Soichiro Iimori,[1] Naohiro Nomura,[1] Shotaro Naito,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Shinichi Uchida,[1] Eisei Sohara.[1] *[1]Tokyo Medical and Dental University, Tokyo, Japan; [2]University of Tsukuba, Tsukuba, Japan.*

Background: Unlike pediatric patients, nephronophthisis-related ciliopathys (NPHP-RCs) are often suspected only after renal biopsy in adult patients, because they usually have no specific extra-renal complications of NPHP-RCs. However, histological findings of NPHP-RCs, such as microcyst and interstitial fibrosis, are also commonly seen in any chronic tubulointerstitial disorders in general. In addition, comprehensive genetic testing is not easily available. Therefore, identification of representative histopathologic pattern of NPHP-RCs is useful for precise diagnosis of adult patients.

Methods: We analyzed 16 adult patients who were suspected as NPHP-RCs by renal biopsy. All patients had no extrarenal findings (retinitis pigmentosa and liver function disorder) and no family history of NPHP-RCs. Comprehensive genetic testing was performed using capture-based next-generation sequencing for 69 genes that cause nine types of hereditary cystic kidney diseases, including NPHP-RCs.

Results: Through the analysis, six patients were genetically diagnosed with NPHP-RCs, including three patients with homozygous *NPHP1* mutations and three patients with a compound heterozygous mutation in *NPHP3*, *NPHP4*, or *CEP164*, respectively. At the time of renal biopsy, the patients diagnosed genetically as NPHP-RCs were significantly younger than those without mutations (median, 30 years old vs 69 years old, $P = 0.02$). Regarding the pathological findings, tubular basement membrane (TBM) duplication and cell interposition in TBM of intact tubules were significantly more common in the patients with NPHP-RCs (83% vs 20%, $P = 0.035$, 83% vs 10%, $P = 0.008$, respectively).

Conclusions: Our study revealed that disorders of TBM could be specific findings in the adult patients genetically diagnosed with NPHP-RCs. These findings are potentially beneficial for optimal diagnosis of adult NPHP-RCs and are suggestive of the pathogenesis of the diseases.

Therapeutic Targeting Strategies in Pkd1 Loss-of Function Mouse Model: Insights into Pkd1 Regulation

Almira Kurbegovic, Camila Parrot, Marie Trudel. *Institut de recherches cliniques de Montreal, Montreal, QC, Canada.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) causes renal and extrarenal phenotypes, mainly due to PKD1 mutations. As a therapeutic strategy, CRISPR-Cas is attractive but the high frequency of off-targets precludes clinical application. Because microscopic cysts are likely formed *in utero* in ADPKD kidneys, we targeted at early renal stage wild type *Pkd1/Pc1* protein from 3 series of transgenic (Tg) lines in *Pkd1*$^{-/-}$ mouse, to assess for long-term cure/improvement of severe renal and pancreatic cysts and neonatal death.

Methods: Re-expression of Pc1 was generated via three Tg matings: a) a systemic $Pkd1_{TAG}$ mouse (16 Tg copy) b) 2 renal-specific $SBPkd1_{TAG}$ mice (2 and 20 Tg copy) or c) a novel Tg line targeting Pkd1 cDNA with renal-specific elements, *SBP* (16 Tg copy). Longitudinal molecular and histologic analyses were performed on kidneys and pancreas.

Results: $Pkd1_{TAG}$;*Pkd1*$^{-/-}$ mice expressing 7-fold over the endogenous Pkd1 gene are totally rescued from renal or pancreatic phenotypes. From 8 mo onwards, $Pkd1_{TAG}$;*Pkd1*$^{-/-}$ mice, relative to parental Tg line, display later renal cysts consistent with gene-dosage increase pathogenic mechanism. $SBPkd1_{TAG}$;*Pkd1*$^{-/-}$ mice with mild ~0.64 or notable 7-fold renal Pc1 overexpression are rescued from neonatal death. In the mild expressor with Tg copies comparable to endogenous, renal and pancreatic cysts are detected at P5 and deaths occurs at P10-P15 whereas the high expressor display renal cysts later at P15 but no pancreatic cysts and survive up to ~3 mo. Renal cysts develop likely from differential tubular and temporal regulatory response to Pc1 either insufficient or over-expression. *SBP;Pkd1*$^{-/-}$ mice with 0.87-fold Pkd1 endogenous level exhibit very mild renal cyst formation at P0 and escape neonatal lethality. This targeting strategy required multiple SBP Tg copies to produce Pkd1 therapeutic levels similar to the $SBPkd1_{TAG}$ and provided evidence for regulatory region within the Pkd1 gene-body. Identification of cystic nephron segments will shed light on the mechanism.

Conclusions: Our results demonstrate that Tg foetal Pc1 expression can substantially delay cystogenesis and extend mouse lifespan. This study shows that Pc1 re-expression not only requires high spatiotemporal regulation by the Pkd1 upstream region but also by regulatory elements within the Pkd1 gene-body.

Betaine Supplementation Ameliorates Renal Disease Severity in Experimental ADPKD

Ali Y. Tug, Song Zhang, Ivan Vuckovic, Jennifer Arroyo, Alfonso Eirin, Lilach O. Lerman, Peter C. Harris, Vicente E. Torres, Maria V. Irazabal. *Mayo Clinic, Rochester, MN.*

Background: We have recently shown that kidney tissue levels of the methyl donor betaine and betaine dependent remethylation are lower in ADPKD, and correlate with disease severity. However, the effects of betaine supplementation have not been explored in ADPKD. We hypothesized that chronic betaine supplementation would increase renal betaine concentration and ameliorate disease progression in murine ADPKD.

Methods: One month old *Pkd1* $^{RC/RC}$ mice were divided into three groups and started treatment with regular water or regular water supplemented with 1 or 2% betaine for 5 months (n=16 per group). All mice were euthanized at 6 months of age, and kidneys were harvested. Cystic index was determined from histological sections. [1] H-NMR-based metabolomics analysis was performed from kidney tissue, urine and plasma samples.

Results: One and 2% betaine supplementation increased plasma and tissue betaine concentrations (p<0.001), reduced kidney/body weight to 1.82 and 1.85 vs 2.25 (p<0.01), and cystic index to 11.1 and 9.4 vs 21.1 (p<0.01) (Fig. 1). Tissue betaine concentrations correlated inversely with kidney/body weight (R^2=0.386, p<0.01). Metabolomics analysis from tissue and plasma identified significant differences in mitochondrial fatty acid oxidation and TCA cycle pathways among the groups.

Conclusions: Chronic betaine supplementation ameliorates disease severity in murine ADPKD possibly through improving mitochondrial function. These observations may represent a promising intervention from early stages of the disease.

Metformin Improves Relevant Disease Parameters in the Hypomorphic Pkd1$^{RC/RC}$ ADPKD Mouse Model

Kenneth R. Hallows, Hui Li, Pei-Yin Ho, Daniel Rivera, Biagio Saitta, Nuria M. Pastor-Soler. Department of Medicine, Division of Nephrology and Hypertension, USC/UKRO KIdney Research Center *University of Southern California, Los Angeles, CA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), caused by mutations in *PKD1* or *PKD2*, presents with progressive development of renal cysts and eventual end-stage kidney disease and has limited treatment options. Previous work showed that metformin treatment reduces cyst growth in two early, rapid ADPKD mouse models, potentially through inhibition of CFTR-mediated fluid secretion, mTOR signaling and cAMP production. Here we tested whether metformin treatment ameliorated ADPKD manifestations in a relevant, slowly progressive ADPKD mouse model.

Methods: Using the slowly developing ADPKD mouse model with an R3277C knock-in point mutation in both alleles of the *Pkd1* gene (*Pkd1$^{RC/RC}$* mice), male and female mice were treated ± metformin (300 mg/kg/day in drinking water) from 3 months through 9-12 months of age. During this treatment period, we periodically measured tail cuff blood pressures, glomerular filtration rates (GFR) by the FITC-sinistrin technique, and blood studies by i-Stat. At euthanasia, we assessed kidney histology (e.g., cystic index), total kidney weight/body weight ratio (TKW/BW), and mRNA and protein expression by qPCR and immunoblotting of key cell signaling, injury and inflammatory markers.

Results: As previously reported, *Pkd1$^{RC/RC}$* females had a more severe disease phenotype as compared with males. Metformin treatment reduced TKW/BW relative to age- and sex-matched controls at both 9 and 12 months of age. Metformin treatment also improved systolic blood pressures and increased GFR relative to controls at 9 months in both sexes. Moreover, metformin improved anemia (increased hematocrit) at both 9 and 12 months of age and generally lowered blood urea nitrogen (BUN) levels relative to controls in both sexes. Finally, metformin treatment also reduced the gene expression of key kidney injury markers, kidney injury molecule-1 (KIM-1) and neutrophil gelatinase-associated lipocalin (NGAL), and the inflammation markers tumor necrosis factor-α and interleukin-6 in these mice, along with KIM-1 protein expression.

Conclusions: Metformin improves various key ADPKD disease parameters in a relevant, slowly progressive ADPKD model. Additional studies to examine effects of metformin in PKD clinical trials and the potential additivity of these metformin effects with other mechanistically distinct ADPKD therapies are underway.

2-Deoxy-D-Glucose Effectively Retards Kidney and Liver Cysts Growth in the Mouse at a Plasma Concentration That Is Safe in Humans: A Bridge Study to Design a First Safety Trial in ADPKD Patients

Marco Chiaravalli,[1] Tamara P. Canu,[1] Andrea Armirotti,[2] Antonio Esposito,[3] Isabella Fermo,[1] Angelo M. Reggiani,[2] Alessandra Boletta.[1] *[1]San Raffaele Scientific Institute, Milano, Italy; [2]Istituto Italiano di Tecnologia, Genova, Italy; [3]IRCCS San Raffaele Hospital and Vita-Salute San Raffaele University, Milan, Italy.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a genetic disorder characterized by renal and liver cysts. The first therapy, tolvaptan, was recently approved. However, the presence of side effects and low tolerability calls for development of alternative approaches. We previously showed that inhibition of glycolysis by 2-deoxy-glucose (2DG) significantly retards disease progression (Rowe et al Nat Med, 2013; Chiaravalli et al, JASN, 2016). To translate the results for application in humans, we studied long term oral administration of 2DG and precise pharmacokinetic (PK) parameters.

Methods: We used a slowly progressive murine model by inactivating Pkd1 at P45 (Pkd1flox/-TmCre). Cohorts of 13 mice were treated for 4.5 months with oral administration of 2DG (100mg/kg) daily, for 5 days a week followed by 2 days of washout. Total kidney volume (TKV) was monitored by MRI, renal function by blood urea nitrogen and creatinine. At sacrifice kidney/body weight and histological analysis were performed. Liver cysts were identified by Cytokeratin-19 staining. Body weight, water and food intake as well as serum levels of ALT, AST, ALB and CK were detected for safety analysis. For the PK study of 2DG blood was collected after gavage at different time points (15, 30, 45, 60, 120, 180 min, 12 h, 24 h) and detected with HPLC pre-column fluorescent derivatization.

Results: 100mg/kg of 2DG significantly reduces TKV and restores renal function in the Pkd1flox/-TmCre mice. Biliary cysts were significantly reduced in number, length and area after 2DG treatment (n=8). Importantly, no sign of toxicity can be detected neither in Pkd1flox/- TmCre-nor in wt mice. PK analysis revealed that 100mg/kg 2DG oral administration in mice corresponds to/is slightly lower than the dose of 30mg/kg in humans based on published studies, a dosage extensively shown to be safe with no adverse events reported.

Conclusions: Our data show that 2DG is efficacious on renal and liver cysts, it improves renal function and shows no signs of toxicity at a dose that corresponds to a well tolerated dose in humans. Our data build a strong rationale for designing a first study with 2DG in ADPKD patients.

FR-PO719

Correcting the Trafficking of CFTR, NHE3, and ENaC in ADPKD Reduces Cysts and Improves Renal Function

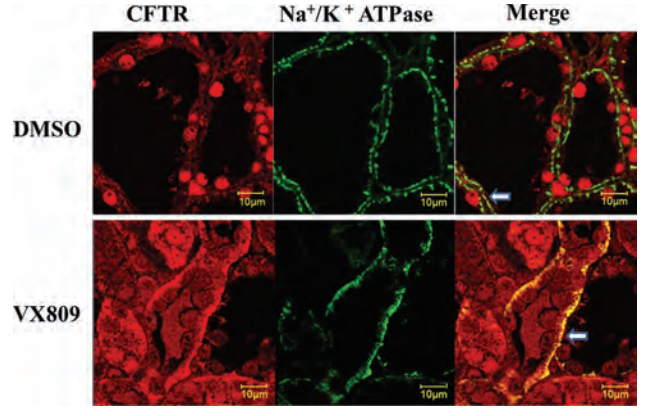
Murali K. Yanda, Liudmila Cebotaru. *Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), caused by malfunction of either PC1 or 2, is associated with progressive enlargement of cysts, leading to a decline in function and renal failure. We demonstrated previously that VX-809, a CFTR corrector, used to rescue CFTR trafficking, reduces cyst growth in mouse models.

Methods: To address the mechanism of how this occurs, we used proximal tubule-derived, cultured *Pkd1*-knockout cells and the *Pkd1$^{fl/fl}$; Pax8^{rtTA}; TetO-cre* mouse model. Treating the mice with doxycycline (doxy), ablates PC1 in renal tubular epithelial cells and causes the development of multiple large cysts which leads to a decline in renal function.

Results: We found that cysts are reduced when the mice are treated with VX-809 and renal function improved. VX-809 treatment of cultured *Pkd1*-knockout cells increased the activity of NHE3. We assessed the location of NHE3 and ENaC in the cystic kidneys using confocal microscopy. In the mice treated with doxy, NHE3 and ENaC were present in large cysts, but not at the apical membrane. NHE3 and ENaC primarily colocalized with Rab11, a marker of recycling endosomes. In the mice treated with doxy and VX-809, NHE3 and ENaC colocalized with a plasma membrane marker consistent with an increase in NHE3 and ENaC activity and protein expression. In the mice were treated with doxy large cysts developed and the CFTR was colocalized with the ER marker, and to a small amount with apical membrane marker. When mice were treated with doxy and VX-809, most of the CFTR was rescued from the ER and colocalized with the basolateral membrane (Fig.1) and total protein levels increased. Interestingly, basolateral localization of CFTR occurs in the sweat duct, a normally Cl^- absorbing epithelium.

Conclusions: The data suggest that VX-809 reduces cyst size in the PC1-null mice by promoting an absorptive phenotype. Given that administration of VX-809 is safe, this drug potentially offers a new way to treat patients with ADPKD.



FR-PO720

β$_3$-Adrenergic Receptor: Possible New Drug Targets for the Treatment of Autosomal Dominant Polycystic Kidney Disease

Giorgia Schena,[1] Andrea Gerbino,[2] Monica Carmosino,[3] Michael J. Caplan.[4] *[1]Yale University School of Medicine, New Haven, CT; [2]University of Bari "Aldo Moro", Bari, Italy; [3]University of Basilicata, Italy, Potenza, Italy; [4]Yale University School of Medicine, New Haven, CT.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a genetic condition caused by mutations in either Polycystin 1 or Polycystin 2 genes and characterized by the formation of fluid filled cysts in the renal parenchyma. Elevations of intracellular cAMP are a major driver of cyst growth. Inhibition of cAMP accumulation in vasopressin-sensitive nephron segments currently constitutes the only approved therapy for ADPKD. Interestingly, sympathetic nerve activity is elevated in patients with chronic kidney disease and this over-activity has been implicated in cystogenesis. Since β$_3$-adrenoreceptors (β$_3$-ARs) are expressed in multiple nephron segments we wished to characterize their signaling pathway in ADPKD and their potential role in its pathogenesis.

Methods: Murine cell lines heterozygous (Pkd1$^{+/-}$) or homozygous (Pkd1$^{-/-}$) for a deletion in Pkd1 gene were stably transfected with β$_3$-AR, then seeded in 3D matrix and stimulated with Mirabegron, a selective β$_3$-AR agonist. Cyst size and number were measured using ImageJ. cAMP levels in treated cells were measured via Fluorescence Resonance Energy Transfer (FRET). β$_3$-AR expression was studied via WB on total kidney lysates from an ADPKD mouse model (Pkd1$^{fl/fl}$; Pax8^{rtTA}; TetO-Cre). Mice were treated with either β$_3$-AR antagonist SR59230A (4mg/kg/day) for 4 weeks or saline. Finally animals were sacrificed and kidney parameters measured.

Results: We found that, upon treatment with Mirabegron, Pkd1$^{-/-}$+β$_3$-AR cells form larger and more numerous cysts than untransfected Pkd1$^{-/-}$ cells. FRET analysis confirmed that this effect is associated with a significant increase in cAMP levels elicited by β$_3$-AR activation. Using our ADPKD mouse model we found that renal β$_3$-AR expression is up-regulated in cystic animals *versus* healty littermates. Most importantly, treatment of

these mice with SR59230A leads to improved kidney/body weight ratios and Blood Urea Nitrogen levels in the treated animals *versus* controls.

Conclusions: Our *in vitro* data indicate that modulating the activity of β_3-AR has a direct effect on cystogenesis. Our *in vivo* data further suggest that β_3-ARs are potentially interesting therapeutic targets in the treatment of ADPKD in that antagonizing β_3-AR activity may reduce cAMP accumulation and thus cyst growth in both vasopressin-sensitive and insensitive nephron segments.

FR-PO721

Chronic Exercise Ameliorates the Progression of Renal Dysfunction in Polycystic Kidney Disease Model Rats

Jiahe Qiu,[1] Yoichi Sato,[1] Takahiro Miura,[1] Osamu Ito.[2] *[1]Tohoku University Graduate School of Medicine, Sendai-shi, Miyagi-ken, Japan; [2]Tohoku Medical Pharmacetical University Faculty of Medicine, Sendai, Japan.*

Background: Autosomal Dominant Polycystic Kidney Disease (PKD) is the most frequent hereditary renal disease, but the exact mechanisms of cystogenesis remain to be elucidated. PKD leads to renal dysfunction, and it is a major cause of ESRD. Several clinical studies have shown that chronic exercise (Ex) exerts beneficial effects in CKD patients. However, the beneficial effects of Ex on renal function have not been reported in PKD. The present study investigated the effects of Ex in polycystic kidney (PCK) rats with PKD.

Methods: Five-week-old male PCK rats were divided into the sedentary (Sed) group and Ex group. Ex underwent forced treadmill exercise (28m/min, 60 min/day, 5 days/week) for 12 weeks. Plasma and urinary parameters and renal histology were examined. Expression of Ki67, desmin, TGF-β and PGC-1α and phosphorylation of AMPK were assessed by immunohistochemistry and western blotting.

Results: Ex significantly decreased the body weight, kidney weight, urine volume, urinary protein excretion, plasma creatinine and ameliorated renal cystic formation and interstitial fibrosis. Ex significantly decreased the Ki67 and TGF-β expressions in tubulointerstitial cells and the desmin expression in glomeruli. Ex also increased the PGC-1α expression and stimulated the phosphorylation of AMPK in the kidney.

Conclusions: Chronic exercise ameliorates renal dysfunction with inhibition of cystic formation and podocyte injury via an AMPK-PGC-1α-mediated metabolic switch in PCK rats. Ex may be a novel therapeutic approach for the development of renal dysfunction in PKD patients.

FR-PO722

Pioglitazone and Tolvaptan in a Mouse Model of Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Anish A. Kanhai,[1] Hester Bange,[2] Leo S. Price,[2] Dorien J. Peters,[1] Wouter N. Leonhard.[1] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]OcellO, Leiden, Netherlands.*

Background: ADPKD is characterized by fluid-filled cyst formation and mainly caused by mutations in the *PKD1* gene. Currently, the only treatment option for ADPKD is the vasopressin V2 receptor antagonist tolvaptan (TVP). However, due to unfavourable side effects, the drug is not well tolerated by all patients, leaving a need for alternative approaches. We hypothesized that a combination treatment can result in a better therapy, as the complex intracellular signalling involved in ADPKD is then targeted from various angles simultaneously. We conducted a preclinical study in an adult onset ADPKD model to investigate the effects of a combination treatment of TVP and pioglitazone (PIO), a peroxisome proliferator-activated receptor gamma (PPARγ) agonist. This drug slows disease progression in two PKD rat models (Blazer-Yost et al., PPAR Res 2010 & Flaig et al., J Trans Int Med 2016), and is now tested in a clinical trial for ADPKD.

Methods: *In vitro*: PIO was tested in a 3D cyst model for PKD (mIMCD3-*Pkd1*$^{-/-}$ cells) to evaluate its efficacy on reducing cyst swelling. *In vivo:* An inducible adult onset model for ADPKD (P18Ksp*Pkd1*^{del} mice) was used. Following *Pkd1* inactivation by tamoxifen on postnatal day 18/19, mice (n = 20 males per group) were fed with food pellets containing 0.1% TVP and/or 0.1875% PIO. Mice were treated until 50% of the untreated group had renal failure (blood urea levels > 20 mmol/l).

Results: PIO was effective in reducing cyst swelling *in vitro*. TVP was able to improve renal survival in mice (86% vs. 41% in the untreated group, $p<0.01$) and reduced 2KW/BW% by 2-fold ($p<0.001$). Plasma adiponectin, a surrogate drug marker for PIO treatment, was higher in PIO-treated mice, to a similar extent as in humans after PIO treatment. However, PIO had no effect on renal survival and on downstream PPARγ signalling in the kidney. Also, *Pparg* gene and PPARγ protein expression was very low in wildtype, cystic and PIO-treated kidneys.

Conclusions: TVP improved renal survival and reduced cyst growth, confirming our model's relevance to ADPKD. Despite *in vitro* efficacy and using a clinically relevant dose, PIO had no therapeutic benefit *in vivo*, possibly due to low expression of PPARγ in mouse kidneys. Further research on the expression levels of the *Pparg* gene and the PPARγ protein in relevant rat models and patients are ongoing.

FR-PO723

Dual Targeting of the G Protein-Coupled Receptors CaSR and V2R for Treating Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Annarita Di Mise,[1] Xiaofang Wang,[2] Hong Ye,[2] Lorenzo Pellegrini,[3] Vicente E. Torres,[2] Giovanna Valenti.[1] *[1]University of Bari, Bari, Italy; [2]Mayo Clinic, Rochester, MN; [3]Palladio Biosciences, Newtown, PA.*

Background: ADPKD is the 4th leading cause of end stage renal disease in the US. It is caused by mutations in *PKD1* or *PKD2* genes, which lead to excessive cell proliferation and fluid secretion, and ultimately cyst formation and growth. Reduced resting cytosolic calcium (Ca^{2+}) and increased cAMP levels, associated with the tonic action of vasopressin, are two central biochemical defects in ADPKD. Currently there is no cure for the disease. The vasopressin V2 receptor (V2R) antagonist tolvaptan is the only drug approved to delay the progression of ADPKD, however it causes serious idiosyncratic hepatocellular toxicity. Simulations on a multiscale computational model of drug-induced liver injury indicate that the novel V2R antagonist lixivaptan has a safer liver profile. Here, we show that co-targeting two GPCRs, the Calcium Sensing Receptor (CaSR), which finely regulates Ca^{2+} homeostasis, and the V2R, using the calcimimetic R-568 in combination with lixivaptan, reduced cyst progression in two animal models of human PKD.

Methods: PCK rat and *Pkd1*$^{RC/RC}$ mouse littermates were fed ground rodent chow without or with lixivaptan (0.5%) and R-568 (0.025% for rats and 0.04% for mice), alone or in combination, for 7 (rats) or 13 (mice) weeks.

Results: In PCK rats, lixivaptan induced a significant reduction in kidney weight, cyst and fibrosis volumes by 20%, 31% and 60%, respectively, compared to animals fed with standard diet. The combined treatment strongly decreased the same parameters by 24%, 46% and 73%, respectively. R-568 alone induced a significant reduction only in kidney weight by 9% and fibrosis volume by 52%. Similar results were obtained in *Pkd1*$^{RC/RC}$ mice.

Conclusions: These data suggest an intriguing new application for two known drugs. The potential for synergy between these two compounds suggested in these animal studies warrants further investigation in clinical settings.

FR-PO724

New Therapeutic Approach Based in Inhibition of Metalloproteases in Polycystic Kidney Disease

Adrian Cordido,[1,2] Cándido D. Rodríguez,[4] Angel Carracedo,[3] Miguel A. Garcia-Gonzalez.[1,3] *[1]Instituto de Investigacion Sanitaria (IDIS) de Santiago de Compostela, Santiago de Compostela, Spain; [2]Grupo de Medicina Xenómica, Santiago de Compostela, Spain; [3]Fundación Publica Galega de Medicina Xenomica, Santiago de Compostela, Spain; [4]Complejo Hospitalario Universitario de Santiago de Compostela, Santiago de Compostela, Spain.*

Background: Polycystic Kidney Disease (PKD) is a group of genetic disorders characterized by the presence by multiple cysts in the renal parenchyma, as well as others extrarenal manifestations such as hepatic cysts (Polycystic Liver Disease or PLD). Mutations in genes PKD1 and PKD2 caused the dominant form called ADPKD, by other band mutation in PKHD1 caused the recessive form or ARPKD. To this day, it have been reported several altered molecular pathways in the PKD but the key mechanism of cystogenesis (process by which cysts are formed) remains unmask. In that studio, with the use of animal models we reported a study about metalloproteases or MMPs of Extracellular Matrix (ECM) in the renal and hepatic cystogenesis and its therapeutic potential.

Methods: We use the rodent models *Pkd1*$^{cond/cond}$ *TamCre* y *Pkdh1*$^{del3\text{-}4/del3\text{-}4}$, models of ADPKD and ARPKD respectively, as well as for the study at molecular level of the role of the MMPs, as models for the testing of a new therapeutic approach, called MTT. Furthermore, the understanding of the disease has been addressed by histological (immunofluorescent and immunohistochemical), pathophysiological (renal and/or hepatic function) and transcriptomic (RT-qPCR) techniques.

Results: We have realized a complete study of the MMPs present in kidney and liver of our animal models, as well as have studied different pro-fibrotic and inflammatory markers related to the enzymatic activity of MMPs. Our study indicates that in renal and hepatic cystogenesis the levels of these markers and genetic expression of MMPs are increased, and therefore that this molecular pathway may be a possibility of therapeutic approach. MTT is an inhibitor of the extracellular matrix metalloproteinases that our group wanted to test as a possible therapy for ADPKD and ARPKD. We have seen that MTT inhibits the gene expression of several MMPs, reduces renal and hepatic fibrosis, improves renal function and inhibits renal and hepatic cystogenesis.

Conclusions: In this work, we evaluate the role of matrix metalloproteases (MMPs) in the cystogenesis of PKD. In addition, the MMP inhibitor MTT was examined in two different rodent models reducing hepatic and renal cystogenesis, and offering a new possible approach.

FR-PO725

Development and Implantation of Novel Morphometric 3D Capsule Device to Constrain Structural Change of Polycystic Kidney: A Feasibility Study in a Rat Model

Kyongtae T. Bae,[1] Kanako Kumamoto,[2] Aya Yoshimura,[3] Masanori Kugita,[3] Shigeo Horie,[4] Tamio Yamaguchi,[5] Junu Bae,[6] Shizuko Nagao.[3] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Education and Research Center of Animal Models for Human Diseases, Fujita Health University, Toyoake, Aichi, Japan; [3]Fujita Health University, Toyoake, Aichi, Japan; [4]Juntendo University, Tokyo, Japan; [5]Department of Clinical Nutrition, Suzuka University of Medical Science, Suzuka, Mie, Japan; [6]Ohio State University, Columbus, OH.*

Background: Polycystic kidney disease is characterized by progressive enlargement of kidneys as a consequence of uninhibited formation and expansion of numerous kidney cysts. Current therapeutic options for polycystic kidney disease are limited in their effectiveness at halting disease progression. The objectives of the study were (1) to develop and implant a computed tomography (CT) image-derived morphometric 3D capsule device to encase a kidney and (2) to demonstrate experimental outcome of the device to constrain structural change of polycystic kidney in a rodent model.

Methods: Kidney capsule devices were designed from CT images of wild-type and Cy/+ rats. Capsule devices were surgically implanted on kidneys in six surgical sessions over a period of 14 months in 7 wild-type rats 6.5-8 weeks of age (3 sham operation, 2 right, 2 left) and 6 Cy/+ rats 6.5 weeks of age (2 sham, 3 left, 1 bilateral). After operation, rats were followed for 5.4-12.4 weeks to grow and sacrificed to retrieve kidneys. During the follow-up, serum creatinine was measured. Retrieved kidneys were weighed. Histological analysis including cystic area measurement and immunohistochemistry was performed.

Results: Morphometric capsule devices were configured and developed by image processing technique and produced using 3D printing technique. Encapsulated Cy/+ kidneys (n=5; mean weight 3.64g) were consistently smaller in size (by 21-36%; $p<0.001$) than unencapsulated Cy/+ kidneys (n=7; mean weight 5.52g). Encapsulated Cy/+ kidneys (mean %cyst area: 29.4%) showed smaller histologic cystic area (by 28-58%; $p<0.001$) than unencapsulated Cy/+ kidneys (mean %cyst area 48.6%). Cell proliferation and macrophages were also markedly reduced in encapsulated Cy/+ kidneys, compared to unencapsulated Cy/+ kidneys.

Conclusions: We developed a CT image-derived morphometric 3D capsule device to encase a kidney and demonstrated that the device constrained structural change of polycystic kidney in a rodent model as a feasibility study toward a novel potential therapeutic avenue for halting progression of polycystic kidney disease.

FR-PO726

Anti-Polyamine Therapy Restrains Polycystic Kidney Disease in Orthologous Mice

Timothy A. Fields,[1] Michael P. Vitek,[2,3] Katherine Swenson-Fields.[1] *[1]The Jared Grantham Kidney Institute, Univ of Kansas Med Ctr, Kansas City, KS; [2]Resilio Therapeutics LLC, Durham, NC; [3]Duke University Medical Center, Durham, NC.*

Background: Autosomal-dominant polycystic kidney disease (ADPKD) is caused by mutations in *PKD1* or *PKD2* and is characterized by cysts derived from renal tubules. Cysts slowly expand due to aberrant proliferation and secretion of cyst-lining epithelial cells, ultimately destroying the kidney by compression and resulting fibrosis. Only one FDA-approved drug is available for ADPKD, so there is a critical need for new therapies for this disease. The polyamines are metabolites of the amino acid ornithine and are produced by all cells. These metabolites are involved in a large number of cellular processes, including proliferation, for which they are essential. Polyamine production is often elevated in proliferative diseases, including multiple types of cancer, and inhibition of polyamine synthesis has been shown in some cases to restrain cancer progression. We hypothesized that polyamines promote cyst cell proliferation and disease progression in ADPKD. We tested this by treating an ADPKD-orthologous mouse model with DiFluoroMethylOrnithine (DFMO), an inhibitor of the rate-limiting enzyme (ornithine decarboxylase) responsible for polyamine biosynthesis.

Methods: *Pkd1*$^{RC/RC}$ mice ("RC"), which have a missense mutation [*Pkd1*(p.R3277C)] that matches an allele found in a human ADPKD family, were used. RC mice were given DFMO in the drinking water (665 mg/l) to achieve a dose of 133 mg/kg starting at PN28. Mice were sacrificed at 6 mo, and serum and kidneys were collected for assessment of 2 kidney/body weight (2K/BW), cystic index, fibrosis, proliferation, apoptosis, and BUN. RNA was collected from kidneys in control, DFMO-treated, and wild-type (C57Bl/6 at 6 month) mice for expression profiling by RNA-Seq.

Results: DFMO treatment had no effect on overall body weight but significantly lowered 2K/TBW and cystic index. There was no effect on BUN, which does not become elevated in RC mice until ~9 months. Assessments of other disease parameters are in progress. RNA-Seq analysis indicates inhibitory effects of DFMO on c-Myc and mTOR, as well as inflammatory pathways.

Conclusions: Inhibition of polyamine production by DFMO restrains kidney growth and cyst expansion in an orthologous model of ADPKD, potentially through effects on c-Myc and mTOR+1187 pathways. These data suggest that DFMO, which has been approved for use in humans, is a potential therapy for ADPKD.

Computational Drug Screening Identifies the Androgen Receptor Antagonist Flutamide as a Potential Treatment Option for Polycystic Kidney Disease

Paul Perco, Johannes Leierer, Michael Rudnicki, Gert J. Mayer. *Medical University Innsbruck, Innsbruck, Austria.*

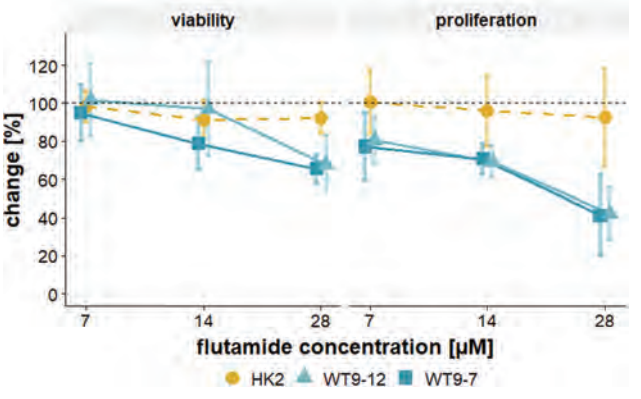
Background: Treatment options for patients with autosomal dominant polycystic kidney disease (ADPKD) are limited and novel therapies are needed. A key hallmark of ADPKD is enhanced tubular epithelial cell proliferation.

Methods: We constructed a network-based molecular model of ADPKD using ADPKD-associated molecular features from scientific literature, the OMIM database, clinical trials on ADPKD, and a human ADPKD transcriptomics dataset. We computationally screened compound libraries with the ADPKD molecular model using data from the Connectivity Map and a constructed library of literature-based drug mechanism of action molecular models. We finally evaluated the impact of top-ranked compounds on cell viability and proliferation in two ADPKD cell lines and HK2 cells.

Results: Five compounds - flutamide, mifepristone, spironolactone, troglitazone, and vorinostat - were identified in the computational drug screen being capable of inversing the ADPKD gene signature and showing significant positive overlap with the ADPKD molecular model. Four compounds had a significant negative impact on cell viability in ADPKD cell lines as compared to treated HK2 cells. Flutamide had the strongest impact on ADPKD cell viability (65.4% in WT9-7, 67.8% in WT9-12, 92.0% in HK2 cells). Flutamide on top significantly reduced cell proliferation in ADPKD cells (41.1% in WT9-7 and 41.9% in WT9-12) as compared to HK2 cells (92.8%).

Conclusions: Flutamide significantly hampers cell viability and cell proliferation of ADPKD cells and warrants follow-up studies to investigate its potential as novel treatment option for patients with ADPKD.

Funding: Government Support - Non-U.S.



The impact of flutamide on cell viability and cell proliferation in the two ADPKD cell lines WT9-7 and WT9-12 as well as in control human renal proximal tubular (HK2) cells is displayed. Data are presented as mean and standard deviation

Ciclopirox-Olamine Alters Ferritin Trafficking and Plays a Protective Role in Polycystic Kidney Disease

Priyanka Radadiya,[1,2] Dharmalingam Subramaniam,[3] Scott J. Weir,[4] James P. Calvet,[2] Darren P. Wallace,[2] Madhulika Sharma.[2] *[1]University of Kansas, Lawrence, KS; [2]Grantham Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [3]Kansas University Medical Center, Kansas City, KS; [4]University of Kansas Medical Center, Kansas City, KS.*

Background: The search for safer and better drugs for Polycystic kidney disease (PKD) continue despite successful lauch of Tolvaptan. We have recently shown that the Notch3 signaling pathway is activated in renal cyst epithelial cells. To determine *in vivo* role of Notch inhibition, we used Ciclopirox-olamine (CPX). CPX can inhibit Notch and other pathways by its property to chelate iron and thus inhibit the activity of iron dependent enzymes such as gamma secretase (involved in Notch pathway activation).

Methods: We used primary normal human kidney (NHK) cells of collecting duct origin and primary cells from cysts of ADPKD patients (ADPKD cells). The effect of CPX on cell viability, ability to form cAMP dependent 3D cysts *in vitro* and cellular ferritin status was evaluated by both Western blotting and immunocytochemistry. CPX was also injected into a mouse model of PKD (*PKD1*$^{RC/PC2}$) for 27 consecutive days and disease was analyzed and compared to the vehicle injected controls for Notch signaling and ferritin (another target of CPX).

Results: CPX (0.2micro molar) inhibited cyst formation in ADPKD cells and resulted in a 40% reduction in cyst area. *In vivo* use of CPX in an orthologous mouse model of PKD also resulted in amelioration of cyst progression. A significant reduction in cystic index and kidney to body weight ratio was observed. However, the disease rescue did not involve Notch3 inhibition. We then focused on iron metabolism, because CPX is an iron chelator. First, we found that ferritin levels were significantly elevated in the kidney lysates from PKD mice and CPX significantly down regulated that to the level of WT mice. Human ADPKD cells were highly enriched in ferritin and CPX reduced the ferritin

levels in a dose dependent manner. Since ferritinophagy is one of the known mechanisms of ferritin degradation, consistent with that we found that an autophagy marker (LC3B) and ferritinophagy marker (NCO4) dose dependently increased in ADPKD cells upon CPX treatment.

Conclusions: Our data suggest that CPX confers protection against ADPKD pathology and increased ferritinophagy is one of the mechanisms. These data also indicate that CPX, a drug used to treat skin infections and currently in clinical trials for cancer, may have the potential to treat ADPKD.

FR-PO729

Targeting Axoneme Polyglutamylation as a Potential Therapeutic Approach for ADPKD Treatment

Kai He.[1,2] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Translational PKD Center, Rochester, MN.*

Background: ADPKD is the most common inherited renal disorders mainly caused by mutations of *PKD1* or *PKD2*, which encodes Polycystin 1 (PC1) and Polycystin 2 (PC2) respectively. PC1 and PC2 co-localize to the primary cilium of kidney epithelial cells and have been proposed to form a receptor/channel complex to sense environmental cues. Recently, the structural mapping of ADPKD pathological mutations indicates that the pathogenic mechanism of *PKD* mutations are mainly associate with the incorrect folding or trafficking of PC1/PC2 complex. Thus, theoretically, correcting the proper cilia localization of PC1/PC2 complex could restore its functional dosage and holds strong potential for being developed as a therapeutic avenue to delay or even prevent the renal cystogenesis. However, perusing this strategy is impeded by the lack of understanding of how the ciliary targeting/maintenance of polycystins are controlled. Polyglutamylation is one of the tubulin posttranslational modifications (PTMs) that occur predominantly on cilia axoneme. We recently discovered a novel paradigm that axoneme polyglutamylation is essential for the ciliary anchoring of polycystins, indicative of its potential for being used as a drug target.

Methods: 1. Imaging-based drug screen. 2. Immunofluorescent. 3. 3D culture. 4. Embryonic kindney culture.

Results: Here, by implementing axoneme polyglutamylation as readout, we performed an imaging-based small molecule screen and discovered several hits that can increase PC2 dosage and restore the ciliary localization of PC2 in PKD cell model by promoting axoneme hyperglutamylation. Mechanistically, these drugs strongly promote the ciliary trafficking of TTLL5 and TTLL6, the key tubulin polyglutamylases that localize to primary cilia. We also have pinpointed the real molecular target of identified hits for inducing axoneme hyperglutamylation, which is overexpressed in ADPKD patients. Remarkably, inhibition of the identified molecular target by its selective inhibitor significantly suppressed the cyst growth in *in vitro* and *ex in vivo* models of renal cystogenesis, suggesting its strong potential for being developed as drug target for ADPKD treatment.

Conclusions: Targeting axoneme ploy glutamylation could be a effective way to restore the functional levels of polycystins and hold a strong potential for being developed as a therapeutic approach for ADPKD.

Early Cyst Initiation Transcriptional Changes in a Novel Porcine Model of Autosomal Dominant Polycystic Kidney Disease

Laurel K. Willig,[1] Christopher S. Rogers,[2] Jeffrey Johnston,[3] Tomi Pastinen,[4] Darren P. Wallace.[5] *[1]Children's Mercy Hospital, Kansas City, MO; [2]Exemplar Genetics, Coralville, IA; [3]Children's Mercy Hospital, Kansas CIty, MO; [4]Children's Mercy Kansas City, Kansas City, MO; [5]University of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), the most common genetic renal disease leading to renal failure in adulthood, starts in utero. However, most studies of transcriptional changes have been done either in late human disease or in mouse models that do not mimic the autosomal dominant pattern (AD) of genetic disease in humans. In this early study, we examine the feasibility of single cell RNA-seq (scRNA-seq) to identify transcriptional changes in specific cells types in an AD porcine PKD1 model.

Methods: We characterized 1928 cells from a wildtype littermate and 3702 cells from two PKD1 +/- littermates using unbiased scRNA-seq. We determined cell identity by performing differential gene expression analysis using the Seurat package, creating principle component analysis (PCA) and t-Distributed Stochastic Neighbor Embedding. Marker genes from PCA analysis were compared to previously reported renal marker genes for mouse. Differential gene expression between case and control was calculated using the Wilcoxon rank sum test in Seurat.

Results: Ten clusters were definitively identified as tubular in nature using marker genes. PKD1 was not differentially expressed between cases and controls, consistent with previous bulk RNA-seq studies. 85 genes were upregulated in PKD1 +/- cystic areas compared to controls, eleven of which were identified as part of the PKD signature in previous metaanalysis by Almeida, et al. Twenty-seven genes were upregulated in wildtype tissue, three of which were identified as part of the PKD signature in a previous metanalysis.

Conclusions: This study provides the first characterization of porcine PKD1 +/- population cell populations using scRNA-seq and provides a preliminary look at differential gene expression within the tubular component of cells between wildtype and PKD+/- tissue. Given the low power to detect change due to small sample size and lack of single cell transcription datasets for ADPKD comparison, we still identified differential expression of several genes previously reported to play a role in ADPKD. We are currently validating our findings on an additional 12 different pigs with up to 4 samples per animal.

miR-210-3p Inhibition Prevents Macrophage M2-Like Polarization and Decreases Fibrosis in Murine ADPKD

Ameya P. Patil,[1,2] William E. Sweeney,[1] Cynthia G. Pan,[1,2] Ellis D. Avner.[1,2] *[1]Medical College of Wisconsin, Wauwatosa, WI; [2]Children's Hospital of Wisconsin, Milwaukee, WI.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common life-threatening hereditary renal disease with an incidence of 1 in 400 to 1 in 1000 individuals. The decline in renal function in ADPKD correlates with the development of renal fibrosis in the peri-cystic local micro-environment (PLM) along withincreased expression of miR-210-3p. A large proportion of the cells in PLM are identified as macrophages (MØs). These MØs undergo a phenotypic switch from M1-like (INOS +) M2-like (arginase +) as fibrosis progresses.

Methods: LNA enhanced anti-miR's(Qiagen) is administered IP from PN14 to PN 28 or PN42 at a dose of 10 um/gm/ Q 4 days. At harvest (PN28 or PN42), one halves of each kidneyis formalin fixed paraffin embedded (FFPE) while the other halves are analyzed by flow cytometry. Serial FFPE sections are analyzed for fibrosis (trichrome staining) and proliferation (PCNA) by Image J software, macrophage phenotyped with IHC or IF.MØphenotypic changes areassessed by flow cytometry and IF or IHC of serial sections. Both wild-type and cystic kidneys are used to obtain MØs, WT-Mac, and C-Mac, respectively, as well as epithelial cells, WTEC and CEC, respectively that were co-cultured in transwells.

Results: *In vivo* targeting of miR-210-3p with an anti-miR reduces both fibrosis and proliferation in PLM areas and significantly improved renal function at PN42. MØ phenotype assessment of anti-miR-210-3p treated kidneys demonstrates a significant reduction in M2 (from 1900 cells to 1000, $p < 0.05$). Data from co-culture experimentsdemonstrate C-Macs show an increased change to M2, assessed by flow cytometry and express increased levels of Arg1, Mrc1, Egf, Retnla and decreased levels of Tnf transcripts when co-cultured with CEC in comparison to WTEC.

Conclusions: We demonstrate that *in vivo*miRNA inhibition of miR-210-3p significantly reduced fibrosis by reducing MØ phenotypic change to M2-like. In agreement with published studies miRNAs regulated transcription factors associated with MØ phenotype change to M2. Induction of MØphenotypic change to M2-like by the CEC via miRNA changes within the MØshas not been studied in depth and requires further investigation. miRNAs are an attractive target as these molecules are small in size and exogenously administered anti-miR concentrates in the kidney.

Urinary CD206+ Cells Correlate with Rate of Renal Function Loss in Autosomal Dominant Polycystic Kidney Disease

Zhang Li, Kurt Zimmerman, Teresa Chacana, James F. George, Bradley K. Yoder, Michal Mrug. *University of Alabama at Birmingham, Birmingham, AL.*

Background: We showed that tissue-resident macrophages promote renal cystic disease severity in mice; however, the relevance of this observation to ADPKD patients was unknown. While key markers that define these resident macrophages in mice cannot be used in humans (e.g., mouse marker F4/80 is encoded by gene *Emr1*; it is expressed exclusively by human eosinophils), we recently identified CD206 as a candidate marker of human resident macrophages.

Methods: We evaluated CD206+ immune cell populations in kidneys from ADPKD patients (vs non-ADPKD controls) using flow cytometry and confocal immunofluorescence microscopy approaches. We used similar analyses for analyses of CD206+ cells in urine samples from ADPKD patients.

Results: We found that CD206+ cells accumulated in regions adjacent to renal cysts. While the average number of intrarenal CD206 cells was higher in ADPKD kidneys (vs controls), the variability was high and this difference did not reach statistical significance (0.0252 vs. 0.006 percent of total renal cells; $p = 0.170$). Also, we found that the urinary CD206+ cell-based index (e.g., after adjustment for urine creatinine concentration) correlated moderately with a rate of GFR decline (over 5 years) in a small cohort of ADPKD patients (n=30). This effect was independent of kidney length (KL), recently described CKD stage 3B predictor in ADPKD with similar AUC 0.88 as height-adjusted total kidney volume. The correlation between average GFR decline rates and KL was comparably strong ($r = 0.400$; $p = 0.029$), the correlation between the eGFR decline rates and urine albumin to creatinine ratio was weaker (ACR; $r = 0.192$) in this cohort.

Conclusions: Together with studies on resident macrophages in animal models, these data suggest that resident renal macrophages participate in the disease pathogenesis in ADPKD patients. They also point to urinary CD206+ cells as a novel candidate marker of the disease activity in ADPKD.

Global MicroRNA Profiling in Human Urinary Exosomes Reveals Novel Disease Biomarkers and Cellular Pathways for ADPKD

Andrew J. Streets, Tajdida A. Magayr, Laura Vergoz, Albert C. Ong. Kidney Genetics Group *University of Sheffield, Sheffield, United Kingdom*.

Background: ADPKD is the most common genetic kidney disease and the fourth most common cause of end-stage renal disease (ESRD) world-wide. Although PKD1 and PKD2 patients present different phenotypes, a high intra-familial variability in disease progression has been observed, suggesting that other genetic or environmental factors have major influences on progression of ADPKD.

Methods: Spot urine specimens were collected from patients with ADPKD and healthy controls. Global miRNA-sequencing was conducted in urine exosome-derived miRNAs from healthy volunteers, ADPKD patients with early (eGFR > 60 mL/min) or late (eGFR < 60 mL/min) disease in a discovery cohort (n=22). TaqMan qPCR was carried out in a clinically phenotyped validation cohort (n=60) and in a *Pkd1* mouse model. In silico bioinformatic analyses identified altered miRNA target genes and disease pathways.

Results: Discovery phase RNA-seq identified a number of dysregulated miRNAs in ADPKD derived exosomes. Two candidate miRNA families identified (miR-192/miR-194-2 and miR-30) were selected for testing by qPCR in a validation cohort (n=60) and in an established mouse *Pkd1* model. We confirmed that miR-192-5p, miR-194-5p, miR-30a-5p, miR-30d-5p and miR-30e-5p were significantly downregulated in human urine exosomes and in *Pkd1* cystic kidneys. Expression levels of all five miRNAs showed significant correlations with baseline eGFR-EPI and ultrasound-mean kidney length (MKL) and improved the diagnostic performance (AUC) of MKL for the rate of disease progression. Finally, by analysing inverse correlations of these two miRNA families with the increased expression of their predicted target genes, we identified several dysregulated pathways and transcriptional networks. These included novel miR-194-5p interactions with the 3'UTR of *ANO1* and *PIK3R1*. Inhibition of these two candidate genes in human *PKD1* cystic cells significantly reduced cyst growth in vitro, confirming their functional significance.

Conclusions: Our results demonstrate that urine exosome global miRNA profiling can be a powerful tool to identify ADPKD patients with rapid disease progression who could benefit from disease modifying treatment. We have identified a subset of urinary exosomal miRNAs that could serve as novel biomarkers of disease progression and also suggest potential new therapeutic targets in ADPKD.

Exosomes Generated from Cystic Renal Epithelial Cells Regulate Cellular Communication and Cystogenesis in ADPKD

Hao Ding, Xiaoyan Li, Peter C. Harris, Xiaogang Li. *Mayo Clinic, Rochester, MN*.

Background: The exosomes have recently drawn considerable interest as they are implicated in many pathophysiological processes of human diseases, including ADPKD. Cells can use these vesicles to communicate with both adjacent cells via the molecules present on the surface of these vesicles and distant cells via the circulation. Urinary exosomes have been proposed as a potential diagnostic tool in ADPKD. However, the basic cell biological understanding of the exosomes in cellular communication and the role of circulating exosomes in ADPKD is lacking.

Methods: To investigate if exosomes regulate cell-to-cell communication and cystogenesis, we isolated exosomes from urine of ADPKD patients and normal individuals (control) as well as from culture media of $Pkd1^{+/+}$ and null renal epithelial cells. The isolated exosomes were used to treat $Pkd1^{+/+}$ renal epithelial cells for a cell proliferation assay and cystogenesis in 3D cultures. Circulating exosomes was isolated from blood to evaluate if exosomal PD-L1 is associated with disease progression of ADPKD and with response to treatment in PKD animals.

Results: We found that treatment with exosomes isolated from ADPKD patient urine and from media of cystic renal epithelial cells increased cell proliferation of NRK-52E cells and mIMCD cells compared to those cells treated with exosomes isolated from normal individuals and wild type renal cells in an exosome concentration dependent manner. In addition, we found that NRK-52E cells treated with ADPKD urinary exosomes developed cysts-like structures in collagen gels within 2 days, which continued to grow progressively up to day 8, whereas NRK-52E cells treated with normal urinary exosomes only developed tubule-like structures in collagen gel up to day 8. We further found that urinary ADPKD exosomes induced the activation of ERK and mTOR signaling in treated cells. The expression of PD-L1 was increased in cystic renal epithelial cells and we are now evaluating if the increase of PD-L1 in exosomes isolated from bloods of PKD animals and ADPKD patients can be used as a biomarker for ADPKD.

Conclusions: Urinary ADPKD exosomes and exosomes from cystic renal epithelial cells regulate renal epithelial cells proliferation and cystogenesis. The levels of PD-L1 in circulating exosomes may be a potential biomarker for ADPKD.

Diverse Receptor Tyrosine Kinase Phosphorylation in Urine-Derived Immortalized Tubular Epithelial Cells of ADPKD Patients

Kisho Ikeda,[1] Tetsuro Kusaba,[2] Keiichi Tamagaki,[2] Masahiro Uehara.[3] *[1]Department of Nephrology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan; [2]Kyoto Prefectural University of Medicine, Kyoto-city, Japan; [3]kyoto prefecture university of medicine, KYOTO, Japan*.

Background: Clinical features of autosomal dominant polycystic kidney disease (ADPKD), including responses to drugs, differ among patients even if they have the same gene mutation in PKD1 or PKD2. This suggests that there is diversity in the expression of other modifier genes or in the underlying molecular mechanisms of ADPKD, but these are not well understood. In this study, we analyzed the diversity in receptor tyrosine kinase (RTK) phosphorylation in tubular epithelial cells of ADPKD patients.

Methods: Urine-derived epithelial cells were primarily cultured, and immortalized cell lines were established by SV40 large T gene transfection. SLC12A3-positive colonies, which is a specific marker of distal tubules, were used for experiments. RTK phosphorylation and its downstream signaling were analyzed in established cell lines. Three-dimensional culture of MDCK cells was used as a cyst formation model of ADPKD.

Results: Comprehensive analysis of RTK phosphorylation in immortalized tubular epithelial cells from 8 ADPKD patients and 4 healthy controls revealed diversity in the activation of several molecules, such as Axl (Gas6 receptor) and Met (HGF receptor), and there were differences even among patients from the same family. Golvatinib, a selective Met inhibitor, or transduction of siRNA for Met suppressed cell proliferation as well as downstream signaling, such as phosphorylation of Akt, only in the cell lines in which hyperphosphorylation of Met was observed. In three-dimensional culture of MDCK cells, HGF activated Met and its downstream signaling, such as Akt or Erk, resulting in an increased total cyst number and total cyst volume. Golvatinib treatment inhibited these phenotypes in MDCK cells.

Conclusions: The analysis of urine-derived tubular epithelial cells demonstrated diverse RTK phosphorylation in ADPKD, and Met phosphorylation was noted in some patients. Given the difference in the effects of golvatinib on immortalized tubular epithelial cells among patients, this analysis may aid in determining suitable drugs for individual ADPKD patients as "precision medicine".

FR-PO736

3D In Vitro Cystogenesis Assays Utilizing Human Patient-Derived ADPKD Kidney Cells for Drug Screening

Matthew Redmann, Shaina Zarkin-Scott, Erik M. Schwiebert, Deborah Mai. *DiscoveryBioMed, Inc., Birmingham, AL*.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a slowly progressive genetic renal disorder that is caused by mutations in either the PKD1 gene (polycystin 1) or the PKD2 gene (polycystin 2). ADPKD is characterized by the formation of fluid filled cysts in both kidneys leading eventually to end-stage renal disease. Several *in vivo* and *in vitro* models of ADPKD exist, although many of them fall short of fully recapitulating the human disease phenotype, driving the failure of most therapeutic candidates in human clinical trials.

Methods: We have developed a unique 3D Biogel-based platform in 384-well tissue culture format utilizing cells isolated from individual cysts on human ADPKD donor kidneys. Cultures from each individual cyst are genotyped to determine the PKD1 or PKD2 mutation. Interestingly, from 9 human ADPKD donor tissues to date (8 with PKD1 mutations, 1 with a PKD2 mutation), we have discovered that only a subset of donors are prone to second somatic hits in single cyst-derived cultures, in addition to the germline mutation. These cells form cysts over days to weeks in culture that can be tracked by high-content imaging with cyst size and number being quantified through algorithm-based image analysis. This platform can be used for screening or validation of candidate drugs and provides significant advancement in throughput and pathophysiologic relevancy.

Results: Here, we show the effects of proprietary small molecules derived from a pre-clinical Cystic Fibrosis (CF) drug discovery program. In human bronchial epithelial cells, these compounds confer a dual effect of CFTR correction and ENaC inhibition. In our system, they are capable of reducing both the size and total number of cysts present after more than a week in culture.

Conclusions: The exact mechanism of action remains to be elucidated, but our data suggests two key findings. First, primary cultures of human cyst cells can be derived from individual cysts of ADPKD kidney tissues and can form cysts in 3D Biogel in a medium-throughput screening system to profile candidate PKD therapeutics. Second, treatments once reserved for CF and other genetic diseases might open new avenues for treatments of PKD. *DBM acknowledges the Mayo Clinic PKD Center Genotyping Core for genotyping services.*

Vascular Disease in PKD: A Novel Role for MLL1 in the Hedgehog-GLI1 Regulated Pro-Angiogenic Genes in Endothelial Cells

Federico Franchi, Karen M. Peterson, Ezequiel J. Tolosa, Peter C. Harris, Martin E. Fernandez-Zapico, Martin G. Rodriguez- Porcel. *Mayo Clinic, Rochester, MN.*

Background: We have previously reported that activation of the Hedgehog (Hh) pathway is severely impaired in Polycystic Kidney Disease Endothelial Cells (PKD-ECs), leading to endothelial dysfunction and development of vascular defects. Furthermore, the severity of vascular dysfunction cannot be completely accounted for by the genetic defects, suggesting that other factors play a role. Here, we hypothesized that epigenetic changes modulating PKD-ECs transcriptome are responsible for the abnormal endothelial phenotype.

Methods: We studied the expression and regulation of pro-angiogenic molecules, such as vascular endothelial growth factor A (VEGFA), Angiopoietin 1 (ANG1) and Angiopoietin 2 (ANG2) using Chromatin Immunoprecipitation (ChIP) and gene expression assays in ECs stimulated with Smoothened Agonist (SAG, 100 nM for 24 hrs).

Results: ChIP studies demonstrated that VEGFA, ANG1 and ANG2 are direct targets of the transcription factor GLI1, after activation of the Hh pathway. Furthermore, PKD-ECs displayed lower binding of GLI1 (Fig. 1A) and histone methyltransferase MLL1 (Fig. 1B) to the promoter region of those pro-angiogenic genes, compared to WT-ECs. Importantly, analysis of Histone 3 Lysine 4 methylation revealed a lower enrichment of methyl groups in PKD-ECs compared to WT (Fig. 1C).

Conclusions: Our data suggest that there is a specific epigenetic pathway affected in PKD controlling the ECs phenotype. These studies provide the base for the development of novel therapeutic strategies that, through modulation of epigenetic mechanisms, focus on the vascular aspects of PKD.

FR-PO738

Serum Global Metabolic Profiling Identifies Key Metabolic Networks Dysregulated in Autosomal Dominant Polycystic Kidney Disease

Tania M. Valencia,[1] Andrea N. Flaten,[2] Vishal Patel,[3] Darren P. Wallace,[4] Edmund Lee.[1] *[1]Regulus Therapeutics, San Diego, CA; [2]UT Southwestern Medical Center, Dallas, TX; [3]University of Texas Southwestern Medical Center, Dallas, TX; [4]University of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a monogenetic disorder, caused by mutations in either the *PKD1* or *PKD2* gene, that eventually leads to end-stage renal disease. Despite this prognosis, treatment options for ADPKD are limited. Total kidney volume has been qualified by both FDA and EMA as a prognostic enrichment biomarker for selecting patients at high risk for progressive decline in renal function for inclusion in interventional clinical trials for ADPKD. However, an ADPKD-specific, easily-accessible and reliable biofluid biomarker for identification, stratification and monitoring of disease progression is lacking.

Methods: As several signaling and metabolic pathways are known to be dysregulated during ADPKD progression, we examined the global metabolic profiles of serum samples from a *Pkd2*-KO mouse model of ADPKD (n=6) and WT normal (n=6) mice; as well as ADPKD patients (n=22) and healthy volunteers (n=15) to investigate whether a metabolic profile could be established to aid in assessing disease progression. Dysregulated metabolites were identified and interrogated for their correlation to BUN, eGFR or HtTKV.

Results: Global metabolic profiling carried out in mouse and human serum samples detected a total of 841 and 1156 metabolites, respectively. In human serum samples, principal component analysis showed a clear separation of serum global metabolic profiles between ADPKD and healthy populations. Sex and age were also contributing factors, accounting for 20% and 25% of the metabolite differences observed between the respective human populations. As anticipated, serum creatine and urea were among the dysregulated metabolites increased in ADPKD samples and were highly correlated to eGFR (R^2=0.949) and BUN (R^2=-0.078), respectively. Importantly, we have identified a targeted list of serum metabolites (including those involved in lipid metabolism) that showed differential abundance in both human and mouse ADPKD compared to their respective healthy cohorts.

Conclusions: Our comprehensive evaluation of the global metabolic profiles of serum samples from a mouse model of ADPKD as well as ADPKD patients have identified significant dysregulation in several key metabolic networks. Our results point to the potential use of serum metabolites as translational biomarkers for ADPKD.

Global DNA Hypomethylation in Autosomal Dominant Polycystic Kidney Disease

Wei Wang,[2] Jelena Klawitter,[3] Zhiying You,[4] Kristen L. Nowak,[5] Katharina Hopp,[6] Godela M. Brosnahan,[3] Michel Chonchol,[7] Berenice Y. Gitomer.[1] *[1]Div. Renal Diseases and Hypertension, Aurora, CO; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]University of Colorado Denver, Aurora, CO; [4]UC Denver, Aurora, CO; [5]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [6]University of Colorado Denver, AMC, Aurora, CO; [7]University of Colorado, Aurora, CO.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects an estimated 600,000 individuals in the United States. We have previously demonstrated that the serum level of s-adenosyl methionine (SAM): s-adenosyl homocysteine (SAH), an indicator of cellular methylation potential, is decreased in ADPKD patients with normal to mildly decreased kidney function. As the alteration in the methylation potential may influence DNA methylation, we hypothesized that global DNA hypomethylation may occur in ADPKD.

Methods: Global DNA methylation status was assessed in DNA extracted from whole blood and from kidney tissue by measurement of 5-methylcytosine content by ELISA (Epigentek, Farmingdale, NY). Blood samples were obtained from 17 subjects with ADPKD and normal or near normal kidney function and 12 age- and sex-matched healthy control subjects. Kidney tissue was available from 2 ADPKD patients and 2 control subjects.

Results: Global DNA methylation was significantly lower in the ADPKD subjects compared to healthy subjects (Table 1). Similarly, global DNA methylation was lower in the ADPKD kidney tissue (2.54% vs 5.80%). Renal blood flow decreases early in the course of disease and we show that SAM:SAH (methylation potential) is significantly correlated with renal blood flow ($r = 0.45$, $p = 0.02$). These findings suggests that decrease in methylation potential may be an early event in ADPKD.

Conclusions: Global DNA hypomethylation is present in ADPKD both in peripheral blood cells and in kidney tissue. As DNA hypomethylation might play a role in disease progression, agents that increase global DNA methylation might have therapeutic potential in ADPKD.

Identification of Cystogenic Signaling Pathways in a Newly Developed, Inducible-Kidney Epithelial Cell Model of Pkd2-Mediated Polycystic Kidney Disease

Hyun Jun Jung, Richard A. Coleman, Eryn E. Dixon, Patricia Outeda, Owen M. Woodward, Paul A. Welling. *Physiology Dept, U. of MD School of Medicine, Baltimore, MD.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disorder. Loss-of-function mutations of *Pkd1* and *Pkd2* genes cause the disease. However, initiating signaling events, most proximal to the polycystins, have not been precisely identified. Here, we developed in vitro inducible *Pkd2* gene knockout (KO) model to explore the immediate consequences of *Pkd2* KO and to identify the initiating factors that drive cystogenesis.

Methods: A doxycycline (Dox)-inducible *Pkd2* KO renal medulla epithelial cell line was established from Pkd2 $^{flox/flox}$/Pax8-rtTA/LC1 KO mice crossed with the SV-40 LTA "immorto mouse". For RNA-Seq, Dox treated cells were compared to isogenetic controls. 4 replicates from two different passages were analyzed. Libraries were constructed from mRNA and sequenced (2×75 bp, paired-end). Sequence reads were aligned on the mouse genome GRCm38p6, and downstream analyses were performed with R packages and multiple bioinformatics tools.

Results: The inner medulla epithelial cell line forms a polarized, electrically-tight, monolayer on filter supports, and as assessed by Western blot analysis, allows complete PC2 KO within 4 days of Dox treatment. Hierarchical clustering analysis of RNA-Seq corroborated renal medullary origin. Differential expression (DE) analysis of RNA-seq showed revealed 3243 genes changed significantly (FDR<0.05) in response to the rapid repression of *Pkd2*. Chief among them were other Cystic Disease genes, *Muc1*, *Ganab*, *Pkhd1*, *Dzip1l*, and *Dnajb11*, but not *Pkd1*. The other DE genes were significantly enriched in the sonic hedgehog (SHH) signaling pathway and cilia structure components. *Evc*, *Evc2*, *Gli3*, and *Prkacb* of the SHH signaling pathway were downregulated, implicating

suppression of SHH and alter cilia as cytogenetic drivers. In addition to *Gli3* of SHH, 108 other transcription factor (TF) genes were significantly changed, including TF associated with cilia (*Glis3* and *Pax8*), Wnt signaling and ER stress.

Conclusions: RNA-Seq analysis of our newly established inducible *Pkd2* KO kidney epithelial cell line identified gene networks that are rapidly changed in response to PKD2 repression, providing clues about the proximal cytogenetic signaling events in PKD.

A Human Organoid-on-a-Chip Model Reveals Effects of Flow on Polycystic Kidney Disease Cystogenesis

Sienna Li,[1,2] Ivan G. Gomez,[1,2] Nelly M. Cruz,[1,2] Jonathan Himmelfarb,[2] Benjamin S. Freedman.[1,2] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA.*

Background: Polycystic kidney disease (PKD) is caused by the loss of polycystin proteins that are posited to act as flow-sensitive mechanosensors on primary cilia, but the effects of flow on cystogenesis are difficult to study *in vivo*. Human kidney organoids differentiated from pluripotent stem cells provide a genetically specific model of PKD cystogenesis *in vitro*. We hypothesized that adding flow to this model would exacerbate cyst growth resulting from PKD mutations.

Methods: Kidney organoids were derived from stem cells with bi-allelic, truncating mutations in *PKD1* or *PKD2*, and subjected to fluid shear stress at physiological levels (0.2 dynes/cm^2) in microfluidic chips. A static culture condition in the same chips that allowed for simple diffusion of nutrients was used to control for the effects of flow. Fluorescence-labeled glucose was introduced and monitored in time-lapse videos over a 12 hour period, and absorption was quantified using image intensity analysis. Cyst polarity was determined by immunofluorescence for cilia and tight junctions. Cyst expansion was quantified in the presence or absence of transporter modulators such as SGLT2 inhibitors and mannitol.

Results: Cysts in PKD organoids were highly dynamic and increased in size rapidly under flow, compared to static controls. Flow could also be substituted by a diffusive static condition that exposed organoids to an equivalent volume of culture media to achieve a similar effect. PKD cysts in organoids polarized with the apical ciliated surface facing outwards towards the media and exposed to flow, modeling the interior of a tubule *in vivo*. Expansion of PKD cysts was coupled to glucose transport into epithelial structures and their lumens, while inhibition of glucose transport decreased cyst expansion in a dose-dependent manner.

Conclusions: Our findings suggest that flow, volume, and glucose transport are positive regulators of cyst expansion. Cystogenesis can be enhanced through mechanisms of tubular reabsorption in addition to secretion, and glucose transporters may be crucial to this effect. Collectively, our data support a role for polycystins in regulating the delicate balance of renal transporter function. Therapeutics that reduce flow through the kidney may therefore be beneficial in reducing cyst growth in PKD.

Microinjection-Based Analyses in a 3D Cyst Model

Andre Kraus,[1] Mario Schiffer,[2] Bjoern Buchholz.[3] *[1]Nephrology, University Hospital Erlangen, Erlangen, Germany; [2]University Hospital Erlangen, Erlangen, Germany; [3]University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: ADPKD is characterized by continuous cyst growth. Hereby fluid secretion into the cyst lumen plays a major role. We could show that in addition to cAMP-mediated chloride secretion also ATP- and Ca^{2+}-dependent chloride secretion contributes to cyst enlargement. Hereby the binding of luminal ATP to P2Y2-receptors leads to activation of the apical chloride channel Anoctamin 1. Functional studies in our established *in vitro* cyst model are partly restricted, since applied pharmaceuticals and substances only reach the basolateral side of the cysts. In addition, the quantification of the apical secretion rate of various molecules such as ATP is not possible. Our goal was to establish a micro puncture technique for *in vitro* cysts, which would allow us to inject or withdraw substances into or out of the cyst lumen.

Methods: In our *in vitro* 3D-cyst model, principal-like MDCK collecting duct cells (plMDCK) form cysts within a collagen matrix. Those cysts get punctured and substances injected utilizing a microinjector in combination with a micromanipulator and a high-resolution macroscope. Successful injection can be monitored by co-injection of a dye into the cyst's lumen. Injected cysts can then be tracked over time in a live cell imaging chamber.

Results: With this new technique we are able to puncture cysts and inject substances into *in vitro* cysts starting at a size of >100μM. Correct application can be visualized by applying a coloured dye in addition and visualizing the cyst thereafter in a live cell imaging chamber. Therefore, we are able to apply various substances of interest at the apical side of the cysts and analysing their direct effect on cyst growth. In addition, small amounts of fluid can be extracted from the cysts and further analysed. This technique will be used to test for luminal ATP concentrations under different culture conditions.

Conclusions: We have established a new method, allowing us to puncture *in vitro* cysts and applying substances luminally or measuring concentrations of different molecules in the cyst lumen such as ATP by extracting cyst's fluid. In addition, the punctured cysts can be imaged over time in our live cell imaging setup.

FR-PO743

A Novel CRISPR/Cas9 eGFP Knockin Mouse for Characterizing Endogenous Polycystin 1

Cheng-Chao Lin, Luis F. Menezes, Fang Zhou, Gregory G. Germino. *National Institutes of Health, Bethesda, MD.*

Background: Mutations in *Pkd1* are identified in the majority of cases of autosomal dominant polycystic kidney disease (ADPKD). This gene encodes a large trans-membrane protein, Polycystin 1 (PC1), which undergoes complex processing that results in multiple cleavage products. The complexity and low abundance of PC1 makes investigation into the functions of endogenous protein extremely challenging, and most of our knowledge of PC1 comes from study of recombinant protein over-expressed in heterologous systems. In order to investigate PC1 function under physiological conditions, we generated a knock-in mouse model that expresses a chimeric PC1-eGFP-3HA fusion protein under the control of its native promoter using the CRISPR/Cas9 method.

Methods: We characterized the expression of PC1-eGFP-3HA by immunoblot (IB), immunoprecipitation(IP), and immunofluorescence(IF) in mouse tissues and in Murine Embryonic Fibroblasts (MEFs) and Renal Epithelial Cells (REC) derived from the mouse line. The*Pkd1-eGFP-3HA/Pkd1* and *Pkd1/KO* mouse lines were intercrossed to test if the fusion protein was functional.

Results: Genomic PCR and sequencing results confirmed the successful insertion of eGFP and 3HA tag sequences into the *Pkd1* locus. Offspring of *Pkd1-eGFP-3HA/Pkd1* X *Pkd1/KO* crosses were obtained at mendelian ratios. Neither the kidneys nor livers of *Pkd1-eGFP-3HA homozygotes* were cystic at 1 year, and they remain healthy at >1.5 years without other apparent abnormality. The PC1-eGFP-3HA fusion protein can be reliably detected by IB and IP in various tissues and cell lines. Multiple previously reported PC1 cleavage products were detected in a variety of tissues. However, we have not yet been successful in detecting PC1-specific signal above background by IF in any tissues. Live cell imaging and IF in MEF cells using various antibody, fixation and microscopy methods failed to detect PC1. So far, we can only visualize the fusion protein unambiguously by IF in primary cilia of REC.

Conclusions: The PC1 fusion protein function appears to be as functional as untagged protein and could be detected more easily and reliably. Using GFP-nanobody magnetic beads, the affinity purification–mass spectrometry (AP-MS) for endogenous PC1 fusion protein is also more efficient. This model will be a helpful resource for studying endogenous PC1 trafficking in live cells and how it interacts with other proteins.

Primary Patient Material as Model for a High Content 3D In Vitro Screening Assay to Study ADPKD

Hester Bange,[1,3] Bob Van de water,[3] Dorien J. Peters,[2] Leo S. Price.[1] *[1]OcellO, Leiden, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands; [3]Leiden Academic Centre for Drug Research/LACDR, Leiden, Netherlands.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is characterized by the formation of fluid-filled cysts in the kidney. Currently only one drug is on the market for ADPKD, a vasopressin receptor 2 inhibitor Tolvaptan. However, Tolvaptan does not prevent cysts from forming but slows down cyst swelling. Identifying the mechanisms involved in cystogenesis and identification of treatments is hampered by the lack of pathophysiologically relevant *in vitro* models. Here, we report the development of an *ex vivo* 3D cyst screening assay that uses primary cells from resected kidneys from ADPKD patients to facilitate *in vitro* studies for ADPKD.

Methods: Patient tissue was harvested directly from resected kidneys and cultured in 3D in an optimized hydrogel and culture medium until cryopreservation. Short expansion culture was performed in similar culture conditions. Compound testing was done in 384 well plates. After 24h pre-culture, compounds were added for 48h. Plates were fixed and stained for nuclei and F-actin. Plates were imaged and using Ominer ™ high throughput image analysis software the entire z-stack of each well was recapitulated for 3D quantification and morphometric analysis.

Results: Cultures propagated from cryopreserved tissue developed a cystic phenotype that was stably maintained in 3D culture. Swelling of these cysts could be induced using forskolin, which activates adenylyl cyclase and using desmopressin, which activates the vasopressin 2 receptor. Effect of Metformin, Rapamycin, Roscovtine and Tolvaptan was examined in combination with desmopressin or forskolin. Compound effects were visualized with high content imaging. Using Ominer ™ images were analyzed. Measurement of phenotypic characteristics such as nucleus morphology and thickness of the cyst wall enabled discrimination of compounds that reduced cyst swelling and compounds that were cytotoxic. All reference compounds showed the expected decrease in cyst swelling.

Conclusions: We have developed a 3D screening assay that uses low-passage patient material as model of renal cysts. With this assay, we have successfully tested a panel of reference compounds. Using our image-based approach we are able to discriminate between efficacy or toxicity inducing compounds. This assay offers a powerful tool for future drug and target discovery as well as mechanistic studies for ADPKD.

Heterozygous Inactivation of PKD1 in Miniature Pigs Induces Embryonic Cyst Formation and Progressive Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Emily A. Daniel,[1] Archana Raman,[2] Christopher J. Ward,[3] Gail Reif,[1] Christopher S. Rogers,[4] Timothy A. Fields,[1] Peter S. Rowe,[1] James P. Calvet,[1] Darren P. Wallace.[1] *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of Pennsylvania, Philadelphia, PA; [3]KUMC, Kansas City, KS; [4]Exemplar Genetics, Coralville, IA.*

Background: Murine models do not faithfully recapitulate important features of human ADPKD or its dominant inheritance. Gene editing and somatic cell nuclear transfer in large animals have provided superior models for human genetic disorders that have improved our understanding of disease mechanisms and the translational value of pre-clinical studies for novel therapies. Porcine anatomy, development, physiology, genetics and body size are like those of humans. We generated a new ADPKD model in the Yucatan miniature pig to monitor renal cyst formation *in utero* and postnatal PKD progression.

Methods: Gene targeting methods were used to insert a blasticidin cassette into intron 30 of *PKD1*, which resulted in a null allele, and somatic cell nuclear transfer to generate *PKD1*$^{+/-}$ cloned pigs. Breeding colonies were established to generate *PKD1*$^{+/-}$ and wildtype littermates. Kidneys were collected at embryonic days 30, 60, 90, newborn (~120 embryonic days) and 3, 6, 9 and 12 months postnatal to evaluate cyst development. Embryonic kidneys were imaged by micro-CT and larger kidneys were sectioned using a tissue slicer for measurement of cystic index. Thin tissue sections were stained with antibodies to AQP-2 to identify collecting ducts and PCNA, a marker of cell proliferation.

Results: Embryonic *PKD1*$^{+/-}$ pig kidneys had sporadic cysts and cystic dilations that appeared to form in clusters, consistent with the proposed mechanism of early cyst development in human ADPKD. The number of cysts and total cystic area progressively increased after birth; however, changes in kidney weight relative to body weight were not significantly different between *PKD1*$^{+/-}$ and wildtype pigs. Many, but not all, cysts stained positive for AQP-2, indicating the involvement of multiple segments of the nephron. There were increased PCNA-positive cells in cystic epithelia compared to non-cystic tissue in embryonic and adult *PKD1*$^{+/-}$ kidneys.

Conclusions: Our results demonstrate that inactivation of one *PKD1* allele induces renal cyst formation *in utero* and progressive ADPKD in a new porcine model ADPKD.

FR-PO746

Kidney and Cystic Volume Imaging for Disease Presentation and Progression in the Cat ADPKD Large Animal Model

Leslie A. Lyons,[1] Kate Shumway,[1] Jodi S. Matheson,[1] Marie E. Edwards,[3] Timothy L. Kline,[3] Yoshihiko Yu.[2,1] *[1]College of Veterinary Medicine, University of Missouri, Columbia, MO; [2]Nippon Veterinary and Life Science University, Musashinoshi, Tokyo, Japan; [3]Mayo Clinic, Rochester, MN.*

Background: Persian cats have a variant in *polycystin – 1* (*PKD1*) causing autosomal dominant polycystic kidney disease (ADPKD). The variant (c.10063C>A) causes a protein truncation (p.C3284X) and is the only known variant in cats. As in humans, the variant is lethal *in utero* when in the homozygous state. Affected cats can have a wide range of progression and severity of disease. However, cats are an overlooked biomedical model and have not been used to test therapeutics and diets that may support human clinical trials. To reinvigorate the cat as a large animal model for ADPKD, the efficacy of imaging modalities in cats was demonstrated and supported robust estimates of kidney and fractional cystic volumes.

Methods: Three imaging modalities, ultrasound, computed tomography (CT), and magnetic resonance imaging, were used to examine variation in disease presentation and disease progression in 11 felines with *ADPKD*. Imaging was compared to well-known biomarkers for chronic kidney disease and glomerular filtration rate. Total kidney volume, total cystic volume, and fractional cystic volume (FCV) were determined for the first time in *ADPKD* cats. A few cats had follow-up examinations to evaluate progression.

Results: The size of the cat's kidney supported the determination of FCV measurements. CT was a rapid and efficient modality for evaluating therapeutic effects that cause alterations in kidney volume and/or FCV. Biomarkers, including glomerular filtration rate and creatinine, were not good indicators of kidney function. The wide variation in cystic presentation suggested genetic modifiers likely influence disease progression in cats. All imaging modalities had comparable resolutions to those acquired for humans, and software used for kidney and cystic volume estimates in humans can be used in cats.

Conclusions: Veterinary-based imaging protocols are as robust and efficient for evaluating *ADPKD* in cats as in humans. Cats can be identified as fast and slow progressors, thus, could assist with modifier discovery. Software to measure kidney and cystic volume in human ADPKD kidney studies is applicable and efficient in cats. The longer life span, similar genetics, disease presentation and progression, and the large kidney size suggest cats as an efficient biomedical model for evaluation of *ADPKD* therapeutics.

Angiomotin Knockout Causing Glomerulotubular Nephropathy May Be via an Activated Hippo Signalling Pathway

Yaochun Zhang,[1] Nurul Jannah Binti Ahmad,[1] Qingsong Lin,[1] Jerrold m. Ward,[3] Zi Jin Sun,[1] Hui Kim Yap,[2] Kar Hui Ng.[1] pae/imm *[1]National University of Singapore, Singapore, Singapore; [2]National University Hospital, Singapore, Singapore; [3]Global VetPathology, Montgomery Village, MD.*

Background: Angiomotin (Amot) is an angiostatin binding protein involved in endothelial cell migration. Using CRISPR/Cas9, we created Amot knockout (KO) rats that developed cysts from 1 month and proteinuria by 6 months. Histology revealed dilated tubules, podocyte hypertrophy, foot process effacement, thick glomerular and tubular basement membranes. We aimed to elucidate the pathomechanism of Amot KO with iTRAQ (isobaric tags for relative and absolute quantitation) based quantitative proteomics.

Methods: Kidney cortex from 1-mth rats were homogenized and labelled with iTRAQ. Quantitative proteomic analysis was performed using 2D-nLC-MS/MS. Peptide identification and quantification was carried out on ProteinPilot 5.0 software using Paragon database search algorithm (5.0.0.0.4767) and integrated false discovery rate(FDR) analysis function. Data were searched against UniProtKB protein sequence databases. Statistically significant differences were based on fold change ≥1.5 and p-value <0.05. Rat glomeruli were isolated for ex vivo podocyte culture or total RNA extraction. Immunofluorescence(IMF) and western blot(WB) were performed on podocytes for Yap (Yes-associated protein) nucleus translocation analysis. Real-time PCR were performed for Yap target genes.

Results: 5030 proteins were quantified with confidence corresponding to peptide and protein FDR <0.01 and with ≥2 unique peptides per protein. We identified 101 up-regulated and 209 down-regulated proteins in KO compared to WT rats. Expression of TEAD1, a major YAP target transcription factor, was significantly decreased. IMF and WB showed increased Yap nucleus deposition. Transcriptional expression of YAP target genes (Ankrd1, Cyr61, Diaph3, Anln and Ctgf) were increased.

Conclusions: *In vivo* Amot KO caused Yap nuclei translocation and activated the Hippo/Yap pathway.

FR-PO748

Notch Overexpression in a Mouse Model of Polycystic Kidney Disease

Brian C. Belyea, Maria Luisa S. Sequeira Lopez, Roberto Ariel Gomez. *University of Virginia, Charlottesville, VA.*

Background: Polycystic kidney disease (PKD) is a major cause of end stage renal disease and characterized by enlarged kidneys containing numerous fluid-filled cysts, hypertension, anemia, and progressive loss of kidney function. PKD is autosomal dominant (ADPKD), caused by mutations in the *PKD1* or *PKD2* genes, or autosomal recessive (ARPKD), caused by mutations in the *PKHD1* gene. While the genetic basis of PKD is known, the downstream molecular mechanisms which lead to deregulation of proliferation, apoptosis, and differentiation remain poorly understood. Previous work has demonstrated Notch activation in mouse models of ADPKD and ARPKD. In addition, we have shown that aberrant Notch signaling during kidney development leads to an alterations in cell fate. Thus, we hypothesize that Notch overexpression during kidney development may play an important role in PKD pathogenesis.

Methods: We generated transgenic mice with overexpression of *Notch1* in renin lineage cells using the Cre-lox system. Specifically, we crossed mice which express Cre recombinase under the control of the renin locus (*Ren1*$^{dcre/+}$) with transgenic mice containing a sequence encoding an intracellular portion of the mouse *Notch1* gene inserted into the ubiquitously expressed *Rosa26* locus (*Rosa*$^{Notch/+}$). Control mice (*Ren1*$^{d+/+}$;*Rosa*$^{Notch/Notch}$) and mutant mice (*Ren1*$^{dcre/+}$;*Rosa*$^{Notch/+}$) were studied at 3, 6, and 9 months of age.

Results: Mutant mice developed large kidneys with numerous cysts by 3 months of age and this phenotype worsened with advancing age. Histologic examination confirmed the presence of numerous cysts throughout the kidney cortex of mutant mice. Mutant animals had decreased *Renin* expression shown by PCR and decreased RENIN protein levels in the kidney and plasma as shown by immunohistochemistry and ELISA respectively. In addition, mutant animals developed anemia and worsening renal function with age. Finally, mutant animals did not live beyond 9 months of life, likely dying secondary to renal failure and/or anemia.

Conclusions: Mice with overexpression of *Notch1* in renin lineage cells develop numerous renal cysts, enlarged kidneys, anemia, progressive renal insufficiency and early death – recapitulating many features of human PKD. To our knowledge, this is the first model of PKD resulting from overexpression of Notch signaling, and this work highlights the importance of aberrant Notch signaling in PKD.

FR-PO749

Sprouty1 Regulates FGF Signaling-Mediated Nephron Progenitor Maintenance

Sung-Ho Huh. *University of Nebraska Medical Center, Omaha, NE.*

Background: Nephron progenitors maintain and differentiate with various signaling cascades. FGF9 and FGF20 play pivotal roles in generating and maintaining nephron progenitors during kidney development. However, molecules regulating FGF signaling during nephron progenitor development is not known. Sprouty (Spry) is an antagonist of receptor tyrosine kinases. In developing kidney, Spry1 is expressed in the ureteric buds

and regulates Ret-GDNF-dependent renal branch morphogenesis. Although Spry1 also expressed in the nephron progenitors, function of Spry1 in this population is still elusive.

Methods: To understand whether Spry1 antagonize function of FGF9/20 induced nephron progenitors, we generated Spry1, Fgf9, Fgf20 triple mutant animals and evaluated kidney phenotypes.

Results: Deletion of Spry1 rescues bilateral renal agenesis caused by deletion of both Fgf9 and Fgf20. In addition, deletion of Spry1 normalizes number of nephron progenitors in Fgf9 and Fgf20 hypomorphic kidneys. Nephron progenitor specific deletion of Spry1 also rescues loss of Fgf9 and Fgf20 induced bilateral renal agenesis. Further genetic analyses identified Fgf8 compensates loss of Fgf9 and Fgf20 at the background of Spry1 mutant.

Conclusions: This data demonstrate that Spry1 expressed in nephron progenitors antagonize FGF signaling to balance nephron progenitor maintenance.

Fibroblast Growth Factor Signaling Mediates Progenitor Cell Aggregation and Nephron Regeneration in the Adult Zebrafish Kidney

Thomas F. Gallegos, Caramai N. Kamei, Iain A. Drummond. *Massachusetts General Hospital, Boston, MA.*

Background: The zebrafish kidney regenerates after injury by development of new nephrons from resident adult kidney stem cells. Although adult kidney progenitor cells have been characterized by transplantation and single cell RNA seq, signals that stimulate new nephron formation are not known.

Methods: Adult wild type and Tg(*lhx1a:EGFP*) and Tg(*hsp70:dn-fgfr1*) transgenic zebrafish kidneys were injured by gentamicin injection. Regeneration was observed by in situ hybridization, immunofluorescence, and qPCR analyses.

Results: We demonstrate that fibroblast growth factors and FGF signaling is rapidly induced after kidney injury and that FGF signaling is required for recruitment of progenitor cells to sites of new nephron formation. Chemical or dominant negative blockade of Fgfr1 prevented formation of nephron progenitor cell aggregates after injury and during kidney development. Implantation of FGF soaked beads induced local aggregation of *lhx1a:EGFP+* kidney progenitor cells.

Conclusions: Our results reveal a previously unexplored role for FGF signaling in recruitment of renal progenitors to sites of new nephron formation and suggest a role for FGF signaling in maintaining cell adhesion and cell polarity in newly forming kidney epithelia.

SIX2+CITED1+ Cells: The Culprit of Wilms Tumor Development?

Laura Perin,[1] Astgik Petrosyan,[2] Valentina Villani,[3] Paola Aguiari,[4] Matthew E. Thornton,[5] Brendan Grubbs,[5] Roger E. De Filippo,[1] Stefano Da Sacco.[3] *[1]Childrens Hospital Los Angeles, Los Angeles, CA; [2]Saban Research Institute- Children's Hospital Los Angeles, Los Angeles, CA; [3]Children's Hospital Los Angeles, Los Angeles, CA; [4]Children's Hospital, Los Angeles, Los Angeles, CA; [5]University of Southern California, Los Angeles, CA.*

Background: Wilms tumor (WT) accounts for 95% of renal pediatric malignancies and is characterized by uncontrolled proliferation of nephron progenitors (NP) without generation of functional nephrons. Due to the inability of isolating these human NP, little is known about WT initiation and growth. In this study, we isolated NP expressing SIX2 and CITED1 (the master genes regulating nephrogenesis) from WT samples and from human fetal kidneys (hFK) and performed in vivo and in vitro experiments to study the regulation of self-renewal vs differentiation of NP.

Methods: WT and hFK samples were histologically analyzed, digested to single cell suspension, incubated with Smartflare-probe and SIX2+CITED1+ cells immediately sorted and processed for RNA-seq, single-cell RNA-seq and for other analysis. Xenografts of WT-NP and FK-NP were generated and tumor formation was assessed. Using a nephrogenic specific media, we established conditions for long-term culture of NPs and studied mechanisms that regulate self-renewal vs differentiation were performed.

Results: Histology confirmed a different pattern of expression for SIX2 and CITED1 across WT with different prognosis and stages compared to hFK. Our RNA-seq analysis confirmed of mechanisms overexpression of tumorigenic genes in WT-NP compared to WT-NP. When transplanted in vivo WT-NP demonstrated marked capacity of tumorigenesis, which in some instances induced metastasis, while hFK-NP did not. Single-cell RNA-seq after xenotransplantation of WT-NP defined precise cancer-associated cellular identities compared to WT-NP. In vitro experiments confirmed that modulation of integrin signaling leads to blockade of self-renewal in NP by decreasing CITED1 expression, activating b-catenin and inducing specification by stimulating the activation of LEF1.

Conclusions: This work evidenced that SIX2+CITED+ cells in WT represent a population of cancer stem cells with tumorigenic ability. Our characterization also highlights differences in self-renewal potential between favorable and unfavorable WT samples, with b-catenin playing a key role in regulating this biological process. These studies can help to increase our knowledge of human nephrogenesis and the development of new strategies aimed at halting tumor progression.

In Utero Exposure to Maternal Diabetes Impairs Nephron Progenitor Differentiation

Debora Malta C.S Santos,[1] Shelby L. Hemker,[2] Andrew J. Bodnar,[3] Daniella Ortiz,[5] Favour O. Oladipupo,[4] Elina Mukherjee,[2] Sunder Sims-Lucas,[1] Jacqueline Ho.[1] *[1]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh - Rangos Research Center, Pittsburgh, PA; [3]University of PIttsburgh, Pittsburgh, PA; [4]University of Pittsburgh School of Medicine, North Bethesda, MD; [5]University Michigan Medical School, Ann Arbor, MI.*

Background: The incidence of diabetes mellitus has significantly increased among women of childbearing age worldwide and infants exposed to maternal diabetes *in utero* are at increased risk of congenital renal anomalies. In this study, we utilized a genetic model of maternal type 1 diabetes, the *Akita* (*Ins2*$^{+/C96Y}$) mice, to evaluate its effect on kidney development.

Methods: Diabetic *Ins2*$^{+/C96Y}$ females were bred with wildtype *C57BL/6J* males and, wildtype offspring exposed to maternal diabetes *in utero* (DM_Exp) were assessed. Wildtype offspring from *C57BL/6J* dams were used as controls. Kidneys were collected at different postnatal days (P0, P2 and P34). Nephron numbers were estimated using the gold-standard physical dissector/fractionator method. The expression of nephron progenitor and developing nephron markers was analyzed by qPCR, immunohistochemistry and/or Western blot.

Results: Adult DM_Exp mice (P34) exhibited a nephron deficit of approximately 20% with no association with growth restriction. At P2, the rate of apoptosis and cell proliferation in nephron progenitors was unchanged. However, the expression of the nephron progenitor markers, *Six2* and *Cited1*, was increased in DM_Exp kidneys. In association with this, there was a significant reduction in the total number of early developing nephrons (i.e., renal vesicle, comma- and S-shaped body structures) in DM_Exp kidneys compared to control kidneys. This was associated with reduced expression of the intracellular domain of Notch 1 (NICD) and the canonical Wnt target lymphoid enhancer binding factor 1 (Lef1).

Conclusions: Together, these data suggest that the diabetic intrauterine environment impairs the differentiation of nephron progenitors into nephrons, which may be mediated by diminished Wnt/β-catenin and Notch signaling pathways.

FR-PO753

Development of a New Nephron Progenitor Cell Replacement System for Application in Human Induced Pluripotent Stem (iPS) Cell-Derived Nephron Progenitor Cells (NPCs)

Tsuyoshi Takamura,[1,2] Toshinari Fujimoto,[1,2] Susumu Tajiri,[1] Yatsumu Saito,[1] Shuichiro Yamanaka,[1] Kei Matsumoto,[1] Takashi Yokoo.[1] *[1]Division of nephrology and hypertension, Jikei University School of Medicine, Tokyo, Japan; [2]Division of regenerative medicine, Jikei University School of Medicine, Tokyo, Japan.*

Background: Previously, we generated a transgenic mouse model that enabled diphtheria toxin (DT)-induced ablation of Six2-positive NPC s (Six2-iDTR mouse). After eliminating host NPCs, we transplanted allogenic or xenogeneic NPCs into the metanephric mesenchyme. Donor NPCs were differentiated into neo-nephrons, which have the ability to filter and produce urine, and were connected to the host mouse ureteric bud. In the future, we aim to use this system in kidney regeneration using human iPS cell-derived NPCs. However, human cells permanently express diphtheria toxin receptors and can undergo apoptosis when treated with DT. Therefore, a new NPC elimination system is warranted. In this study, we developed a new transgenic mouse model to ablate NPCs without affecting human cells using tamoxifen instead of DT (six2 CreERT2-DTA mouse) for application in human cells.

Methods: Six2-CreERT2 mice were crossbred with Rosa26-floxed stop DTA mice to obtain Six2CreERT2-DTA mouse offsprings, which were used as hosts. We attempted regeneration from dissociated cells derived from E13 mice and E15 rats metanephros, and NPCs differentiated from human iPS cells. We injected these dissociated cells below the renal capsule of the E13 transgenic mice metanephros. The injected metanephros were isolated, and the organs were cultured for 7 days with 4OH-tamoxifen. After culturing, the metanephros were analyzed using immunofluorescent staining. To verify the blood-inducing ability of the regenerated nephrons in vivo, we additionally transplanted Six2CreERT2-DTA mice metanephros injected with dissociated cells derived from E13 mice into immunodeficient mice under tamoxifen administration and evaluated the results.

Results: We successfully eliminated Six2-positive NPCs from the cap mesenchyme by this system and regenerated nephrons derived from mouse or rat metanephros. In vivo, we successfully regenerated chimera kidneys that have blood-inducing ability from mouse metanephros. Human iPS cell-derived NPCs were engrafted in the Six2CreERT2-DTA mouse metanephros cap mesenchyme.

Conclusions: We developed a new nephron progenitor cell elimination and replacement system that can be utilized in human cells.

FR-PO754

ZEB2 Controls Ureteral Smooth Muscle Cell Fate

Sudhir Kumar, Brian D. Lara, Aneesha Pydi, Xueping Fan, Weining Lu. *Boston University, Boston, MA.*

Background: ZEB2 is a SMAD-interacting transcriptional factor and loss-of-function *ZEB2* mutations are associated with Mowat-Wilson Syndrome (MWS), a genetic disease with multiple congenital defects including hydroureter and hydronephrosis. Ureteral smooth muscle cells (SMCs) derive from TBX18^{+} mesenchymal progenitors and abnormal

development of ureteral SMCs can lead to hydroureter and hydronephrosis. However, the molecular role of ZEB2 in ureteral SMCs development from TBX18^{+} mesenchymal progenitors is not known.

Methods: We analyzed *Zeb2* ureteral mesenchyme-specific conditional knockout mice *Zeb2$^{flox/flox}$;Tbx18Cre^{+}* (*Zeb2* cKO) and their wild-type littermate controls for urinary tract phenotypes by gross and histological examination. Cell specific marker studies were carried out to determine abnormal ureteral cellular and molecular phenotypes and ureteral SMCs development.

Results: We found that at P0 and E16.5, *Zeb2* cKO mice developed hydroureter and hydronephrosis with dilated ureter devoid of ureteral smooth muscle cells as compared to wild-type littermate controls. Cell marker study showed that TAGLN^{+} ACTA2^{+} ureteral SMCs did not appear but there was an expanded layer of FOXD1^{+} POSTN^{+} ureteral tunica adventitia in *Zeb2* cKO mice during early ureter development. At E14.5-E15.5, there was an increase in SOX9 expression in ureteral mesenchymal cells but a decrease in TBX18 expression in *Zeb2* cKO mice, suggesting an early abnormal development of ureteral SMCs. We also found that both apoptosis and proliferation were increased in ureteral mesenchyme cells, and the SMAD signaling was disturbed in *Zeb2* cKO mice.

Conclusions: ZEB2 is expressed in ureteral mesenchymal cells. In the absence of ZEB2, ureteral inner mesenchymal cells differentiate into FOXD1^{+} POSTN^{+} ureteral tunica adventitia rather than ureteral SMCs. These data suggest that ZEB2 controls ureteral smooth muscle cell fate in ureteral mesenchymal cells. Loss of ZEB2 leads to depletion in the ureteral smooth muscle layer formation, which eventually causes hydroureter and hydronephrosis phenotype in *Zeb2* cKO mice.

FR-PO755

A Hedgehog (Hh)-TGFb Signaling Axis Controls Murine Stromal Cell Development and Ureteropelvic Junction Patency

Norman D. Rosenblum,[1,3] Katryna Stronks,[2,3] Sepideh Sheybani-Deloui,[2] Jaap Mulder,[1] Robert D'Cruz.[2,3] *[1]Paediatrics, Developmental and Stem Cell Biology, The Hospital for Sick Children, Toronto, ON, Canada; [2]Developmental and Stem Cell Biology, Hospital for Sick Children, Toronto, ON, Canada; [3]Laboratory Medicine and Pathobiology, U Toronto, Toronto, ON, Canada.*

Background: Signaling mechanisms that control stromal differentiation from *Osr1*+ progenitors during normal and malformed renal development are largely undefined. Hh proteins bind cell surface PTCH1, thereby disabling PTCH1-mediated inhibition of SMO and increasing Hh-mediated transcriptional activity. We showed that Cre-mediated *Ptch1* deletion in *Osr1*+ progenitor cells at mouse E9.5 increased Hh signaling and induced formation of an ectopic population of *Foxd1*+*Raldh2*+ cells that block the ureteropelvic junction (UPJ) and are present in obstructing tissue in human UPJO (Shebani-Deloui et al, 2018). Here, we investigated molecular mechanisms that function downstream of Hh in this developmental disease context.

Methods: Hh and TGFb signaling was investigated in mice with Tamoxifen (TM)-induced deficiency of either *Ptch1*, *Tgfbr2*, or both. *EGFP*+*Osr1*+ cells were isolated by flow sorting and analyzed by RNASeq. Kidney tissue was analyzed by histology, immunostaining, and light sheet fluorescence imaging. TGFbRII deficiency was induced with ITD-1, which causes proteosomal degradation of TGFbRII (Willems et al, 2012), at the stage of cell aggregation in human kidney organoid tissue.

Results: RNASeq of *Osr1*+ cells isolated from urogenital ridge of *Osr1-EGFP-Cre^{ERt2};Ptch1$^{loxP/-}$* mice at E11.5, 2 days post TM, demonstrated increased *Tgfb2* expression compared to controls (P=0.02). Yet, TM-dependent Cre-mediated *Tgfbr2* deficiency induced in *Osr1*+ cells at E9.5 revealed normal renal structural development and cell differentiation. In contrast, promotion of TGFbR2 degredation with ITD-1 in BiPS-derived human kidney organoid tissue treated from the stage of aggregation inhibited organoid growth, a finding consistent with nephron deficiency in mutant mice with *Tgfbr2* deficiency in both *Foxd1*+ and *Six2*+ cell (Rowan et al, Development, 2018). Analysis of mice at E18.5 with both *Tgfbr2* and *Ptch1*-deficiency (*Osr1-EGFP-Cre^{ERt2};Ptch1$^{loxP/-}$;Tgfbr2$^{loxP/-}$*), induced at E9.5, demonstrated a marked rescue of hydronephrosis (5/11 *Ptch1;Tgfbr2*-deficient vs. 13/15 *Ptch1*-deficient mice; P=0.02) and a major decrease in ectopic peri-ureteric RADH2-positive stromal cells.

Conclusions: Increased Hh signaling in *Osr1*+ cells increases TGFB signaling that controls formation of ectopic *Raldh1*+ stromal cells and obstruction of the UPJ.

FR-PO756

Loss of Dicer in the Peri-Wolffian Duct Stroma Leads to Aberrant Ureteric Budding and Increased Rates of Vesicoureteral Reflux

Melissa J. Anslow,[2,1] Andrew J. Bodnar,[1] Sunder Sims-Lucas,[2] Carlton M. Bates,[2] Jacqueline Ho.[2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Vesicoureteral reflux (VUR) is associated with urinary tract infections, hypertension, and reflux nephropathy, a leading cause of pediatric end-stage renal disease. Formation of the vesicoureteral junction is determined largely by the induction site of the ureteric bud from the Wolffian duct, which depends on signals from the surrounding stroma. VUR is heritable, but no single genetic mutation causes most known cases of VUR. miRNAs are small noncoding RNAs, processed by Dicer, that regulate gene expression post-transcriptionally. We hypothesize that miRNAs are necessary for vesicoureteral junction development and prevention of VUR.

Methods: We generated a transgenic mouse model with loss of Dicer in the peri-Wolffian duct stroma (mutant=Tbx18cre; Dicer$^{Fl/Fl}$). We performed euthanized cystograms and 3D reconstructions of the ureters and bladder on mutants and controls (control=Tbx18Cre negative littermates). We performed immunostaining and 3D reconstructions at E11.5 to assess ureteric bud induction, common nephric duct apoptosis, and metanephric mesenchyme positioning.

Results: Euthanized cystograms demonstrated higher rates of VUR in the mutant mice compared to control [44% (8/18) of mutants as opposed to 4.0% (3/77) of controls ($p < 0.01$)] at postnatal day 0 (P0). 3D reconstructions showed lower ureteral insertions into the bladder and shorter intravesicular tunnel lengths on the side of VUR in mutants compared to control and non-refluxing mutant ureters ($p < 0.05$) at P0. Calbindin immunostaining revealed that the ureteric bud induction site was cranially shifted in embryonic day 11.5 (E11.5) mutants compared to controls ($p < 0.05$). Cleaved caspase-3 and TUNEL staining at E11.5 showed no difference in apoptosis patterns between mutant and control.

Conclusions: These data suggest a requirement for miRNAs in peri-Wolffian duct stroma for normal ureteric bud induction, subsequent ureter insertion into the bladder, and prevention of VUR. This does not appear to be due to abnormal apoptosis. Current work is evaluating the metanephric mesenchyme position. Future work will elucidate which miRNAs and mRNAs in the peri-Wolffian duct stroma are critical for normal ureteric bud induction to prevent VUR.

Identification of TAZ as a Regulator of TGF-β Mediated Fibrosis in iPSC-Derived Organoids

Xiaoping Yang,[1] Parnaz Daneshpajouhnejad,[4] Marco Delsante,[2,1] Xiaoxin Wang,[3] Shogo Takahashi,[3] Kira Perzel mandell,[1] Marc Halushka,[4] Jeffrey B. Kopp,[5] Moshe Levi,[3] Avi Z. Rosenberg.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]University of Parma, Parma, Italy; [3]Georgetown University, Washington, DC; [4]Johns Hopkins University SOM, Baltimore, MD; [5]NIDDK, NIH, Bethesda, MD.*

Background: Chronic kidney disease (CKD) progresses by replacement of functional tissue compartments with fibrosis, a maladaptive repair process. Shifting kidney repair away from fibrosis is key to blocking CKD progression. Much research into the mechanisms of fibrosis is performed in rodent models, outside of the human genetic context and time consuming and expensive. By contrast, reductionist two-dimensional cell culture systems consist of single cell types and lack physiological context. Recently, human induced pluripotent stem cell (iPSC)-derived organoids have shown promise in avoiding some of these limitations. We used iPSC-derived organoids to study fibrogenesis and identify anti-fibrotic mechanisms of bile acid receptor agonists acting downstream of TGF-β1.

Methods: Renal organoids were derived from human iPSCs using a modified feeder-free Takasato protocol. Organoids showed glomeruloid (nephrin/podocalyxin-positive), tubular (E-cadherin/lotus lectin-positive), and vascular compartments. TGF-β1 treatments at 0, 5, 10, and 20 ng/mL were tested. FXR, TGFR5 and TAZ targets and extracellular matrix elements were assessed by qPCR, imunoblotting and confocal microscopy.

Results: TGF-β1 treatment of mature organoids induced extracellular matrix elaboration within 48-72 h in a dose-dependent manner with complete disruption of the organoids at the highest. Previously, we have shown that INT767, a dual TGR5/FXR bile acid receptor agonist, blocks TGF-β1-induced fibrogenesis. To understand the intersect between bile acid receptor agonism and TGF-β1-mediated fibrosis, we focused on transcription factors predicted to interact with the collagen 1 locus. TGF-β1 treatment increased tafazzin (TAZ) and TEA domain transcription factor 1 (TEAD1) expression in the organoids with TAZ and TEAD1 nuclear co-localization in tubules. INT767 decreased TAZ and TEAD1 expression and attenuated TGF-β1-induced fibrosis with preservation of mature nephron architecture.

Conclusions: Treatment of iPSC-derived renal organoids with TGF-β1 recapitulated important aspects of kidney fibrosis over a short period compared to traditional model systems. We demonstrated a mechanism downstream of TGF-β1, involving TAZ and TEAD1 transcription factors, with translational therapeutic potential.

Differentiated Expression of Biomarkers for Interstitial Cells During Kidney Development

Jia Xing, Jie Zhang, Kaiyue Wang, Si-Qi Deng, Kexin Song, Ling Gu, Xiao-Yue Zhai. Nephrology laboratory *Department of Histology and Embryology, Basic Medical College, China Medical University, Shenyang, China.*

Background: Recently, the development of renal fibrosis is thought to involve 3 more cell types in addition to renal epithelial and endothelial cells. They are pericytes, mesangial cells, and fibroblasts, which are all derived from mesenchymal cells and possess the potential to differentiate into ECM-secreting cells. According to literature, the biomarkers for them are PDGFR-β, α-SMA, and desmin, however they can not be specifically identified with alone immunostaining. Therefore, a systematic study of the relationship among three biomarkers for the differentiation of the mesenchymal cells is helpful for the cytological study of renal fibrosis.

Methods: In this study, we utilized serial kidney sections with multiple developmental timepoints (E12.5, E15.5, E17.5, P1, P3, P5, P7, P14, P21, P28, and P40) and localized PDGFR-β, α-SMA, and desmin combined with CD34 by immunostaining.

Results: 1. Druing the early development, PDGFR-β and α-SMA were expressed in reticular mesenchymal cells, which were perpendicular to scanty bundles of tubules and ureteric buds, while desmin was mainly expressed in cap-mesenchyme in early stage. 2. As more and more tubules extended into medulla, their expressions were decreased and confined to interstitial cells in the mature kidney, while peritubular vessels expressed CD34 instead. PDGFR-β was expressed at both fibroblast and pericyte, while α-SMA and desmin were respectively expressed at fibroblast and pericyte. 3. Through the kidney development, both PDGFR-β and α-SMA were expressed in the structure, closely associated with the artery and arteriole, with former in the outer layer (adventitia) while latter in smooth muscle cells of inner layer, next to CD34 positive endothelial cells. No co-localization was observed. 4. All of them were expressed in young glomeruli, while α-SMA vanished in the mature glomeruli.

Conclusions: Although the expressions of PDGFR-β and α-SMA are associated with renal vasculogenesis and angiogenesis, their expressions are related with different vascular structures, respectively participating in differentiation of endothelial and subendothelial smooth muscle cell, while desmin is related to the differentiation of renal progenitor cells. Among the three, PDGFR-β is the most reliable biological marker of grown renal interstitial cells, including pericytes.

Optimal Generation of Mesangial Cells and the Stromal Progenitor Cell Lineage from a Platelet-Derived Growth Factor Receptor Alpha Fraction of Fetus Cells

Yatsumu Saito, Shuichiro Yamanaka, Tsuyoshi Takamura, Toshinari Fujimoto, Susumu Tajiri, Kei Matsumoto, Takashi Yokoo. *The Jikei University School of Medicine, Tokyo, Japan.*

Background: We previously transplanted a cell population comprising several heterogenic types of renal progenitor cells (RPCs) from mouse metanephros into the nephrogenic zone of other mouse metanephros and regenerated nephrons derived from the transplanted RPCs. However, mesangial cells of the regenerated glomeruli comprised cells derived from the host. We could not confirm the regeneration of mesangial cells by the transplanted cells. Therefore, we optimized the RPC cell composition via cell sorting and examined the possibility of regenerating the mesangial cells.

Methods: Metanephros was harvested from GFP mice, and an enzymatic treatment extracted the dissociated single cells (DSCs) from the metanephros. Stromal progenitor cell components were extracted via cell sorting by targeting the platelet-derived growth factor receptor alpha (PDGFRa) fraction from the DSCs. Three groups of cells, i.e., the PDGFRa-sorted cells, non-sorted cells, and fibroblasts as controls, were transplanted into the nephrogenic zone of B6 mice metanephros. Then, these groups were transplanted under the retroperitoneum of the para-aortic region of adult B6 mice and harvested after 2 weeks. Specimens were assessed via immunofluorescence staining. Furthermore, the regenerative cells were counted to the extent to which the transplanted cells reached.

Results: In the fibroblast group, the cells transplanted to the nephrogenic zone did not colonized in the metanephros. In the non-sorted group, although some cells colonized, there was negligible regeneration of the mesangial cells. However, in the PDGFRa-fraction sorted group, we confirmed regeneration of the mesangial cells from the exogenous cells in 92% of glomeruli (n=13). Furthermore, the proportion of the exogenous mesangial cells with a single glomerulus unit was 67.5%. We also confirmed regeneration of other stromal progenitor cell lineages, such as interstitial fibroblasts, vascular pericytes, and juxtaglomerular cells.

Conclusions: When we increased the ratio of the stromal progenitor cells via cell sorting targeting the PDGFRa fraction from DSCs, we succeeded in efficiently regenerating the mesangial cells and other stromal progenitor cell lineages, such as interstitial fibroblasts, pericytes, and juxtaglomerular cells, in the kidney of the mouse embryos.

FR-PO760

Endothelial-Specific Phosphatase VEPTP/PTPRB Is Essential for the Development of the Renal Mesangium

Rizaldy P. Scott,[1,2] Antoine Tarjus,[1,2] Isabel A. Carota,[1,2] Yanyang Li,[1,2] Benjamin R. Thomson,[1,2] Tuncer Onay,[1,2] Susan E. Quaggin.[1,2] *[1]Feinberg Cardiovascular & Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Division of Nephrology & Hypertension, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: The angiopoietin-Tie2 signaling pathway plays an essential role in vascular development and homeostasis while its dysregulation is associated with a number of diseases including pathological neovascularization, glaucoma, diabetic nephropathy, and acute kidney injury. The endothelial-specific phosphatase VEPTP/PTPRB plays a major role in the negative regulation of Tie2 receptor phosphorylation. We genetically inactivated the *Ptprb* gene in mice in order to elucidate its significance in renal vascular development.

Methods: Global genetic inactivation of a conditional floxed allele of *Ptprb* was accomplished using a tetracycline-inducible Cre-based recombination system. Mouse kidney sections were processed for histology and immunostaining while glomerular ultrastructure was analyzed by transmission electron microscopy.

Results: Inactivation of *Ptprb* at E13.5 results in glomerular maldevelopment. *Ptprb* deficiency results in notable simplification of the glomerular tuft and glomerular aneurysms in neonatal (P0) kidneys due to the impaired establishment of the mesangium reminiscent of genetic loss of components of the PDGFB signaling system (*Pdgfb, Pdgfrb*, and *Nrp1*). Immunofluorescence for mesangial markers and ultrastructure analysis corroborate the absence of the renal mesangium in *Ptprb*-knockout mice. In contrast, postnatal (P0) deletion of *Ptprb* does not overtly affect mesangial cell recruitment but causes the development of renal capsule hemorrhages and sporadic thrombotic vascular anomalies in other organs of adult mutant animals which resemble hereditary venous malformations due to hyperactivating mutations of the Tie2 receptor in patients.

Conclusions: The renal mesangium is the *de facto* pericyte of the glomerular endothelium. Our findings indicate that *Ptprb* may play a pivotal and time-dependent role in pericyte recruitment and investment in different vascular beds. During gestation, *Ptprb* regulates the recruitment of mesangial cells into the glomerulus. Postnatally, *Ptprb* deficiency results in vascular anomalies reminiscent of venous malformations and poor pericyte investment caused by constitutive Tie2 activation.

Defining the Role of Vascular Endothelial Growth Factor 3 (VEGFR3) in the Fenestrated Microvasculature Beds of the Kidney

Michael D. Donnan,[1,2] Tuncer Onay,[1] Susan E. Quaggin.[1,2] *[1]Feinberg Cardiovascular & Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Nephrology & Hypertension, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: The vasculature of the mammalian kidney is heterogeneous due to the need to carry out highly specialized functions such as glomerular filtration, urinary concentration and electrolyte homeostasis. The vascular endothelial growth factor tyrosine kinase receptor 3 (VEGFR3) is best known for its essential role in lymphatic endothelial cell proliferation however it is also highly expressed in fenestrated microvascular beds in several tissues including the kidney. In contrast to VEGFR2, functions of VEGFR3 in kidney vasculature are poorly understood but have been implicated in a number of kidney pathologies including cystogenesis and renal fibrosis. We hypothesize that VEGFR3 is required for proper maturation of renal microvascular beds and that loss of VEGFR3 will accelerate progression of kidney disease.

Methods: We generated a new conditional transgenic mouse model to study *Vegfr3* function in the kidney vasculature (*Vegfr3*^{flox}). This model allows for endothelial-specific excision of the floxed *Vegfr3* allele using the vascular-specific Cre driver strain *Cdh5-Cre/ERT2*. We evaluated a *Vegfr3*-YFP reporter mouse to analyze expression of *Vegfr3* within the microvascular beds of the kidney. Mouse kidney sections were processed for histology and immunofluorescence.

Results: Analysis of *Vegfr3-YFP* reporter mice demonstrates that *Vegfr3* is expressed in multiple fenestrated microvascular beds of the kidney including the glomerulus, ascending vasa recta, and peritubular capillaries. Twenty percent of mice heterozygous for the intact neo-cassette-containing floxed *Vegfr3* allele (*Vegfr3*$^{+/neo}$) exhibit chylous ascites suggesting disruption of the neo-cassette containing VEGFR3 allele. These mice demonstrate reduced viability and exhibit several vascular pathologies including blood filled lymphatic capillaries and hemorrhage of intestinal Peyer's patches.

Conclusions: VEGFR3 is expressed in many specialized microvascular beds within the kidney and may play an important role in their development and maintenance. We have generated a novel conditional mouse model to comprehensively study the role of VEGFR3 in renal vasculature. Using this model to perform time dependent endothelial-specific knockout of *Vegfr3* through development will provide valuable insights into specialized functions of fenestrated microvascular beds in the kidney.

Modeling Vascular Diseases Using Organ-Specific Endothelial Cells

Tian Zhang,[1] Pin Li,[1] Jian hui Low,[2] Bingrui Zhou,[2] Yun Xia.[1] *[1]Nanyang Technological University, Singapore, Singapore; [2]Lee Kong Chian School of Medicine, Singapore, Singapore.*

Background: The establishment of vascular network initiates with the specification of endothelial cells and the formation of primitive vascular network. While primitive vascular network supplies nutrients to the developing embryo, postnatal vascular system mainly originates from aorta-gonad-mesonephros (AGM) that eventually gives rise to both endothelial and hematopoietic lineages. During development, homogeneous endothelial cells further differentiate to acquire organ-specific identities to accomplish diverse functions of different organs. Endothelial cells may also be derived from multipotent progenitor cells within certain mesodermal organs. Recent study has shown that renal progenitors could at least partially contribute to renal vasculature. We established a kidney organoid differentiation platform that can generate renal-specific endothelial cells from human pluripotent stem cells. This differentiation platform enables us to study vascular development and diseases in an organ-specific manner.

Methods: Kidney Organoid Differentiation Single Cell RNA Sequencing Disease Modelling

Results: We established a kidney organoid differentiation platform that can generate renal-specific endothelial cells from human pluripotent stem cells.

Conclusions: Recent study has shown that renal progenitors could at least partially contribute to renal vasculature. Vascularized Kidney Organoids for Modeling PKD

Ken Hiratsuka,[1,2] Tomoya Miyoshi,[1] Neil Lin,[2] Koen Van breugel,[2] Navin R. Gupta,[1] M. Todd Valerius,[1,3] Takuya Matsumoto,[1,2] Jennifer A. Lewis,[2,3] Ryuji Morizane.[1,3] *[1]Brigham and Women's Hospital/Harvard Medical School, Boston, MA; [2]Wyss Institute/Harvard University, Boston, MA; [3]Harvard Stem Cell Institute, Cambridge, MA.*

Background: Various models of 3D culture have been developed to model PKD cystogenesis. While recent studies demonstrated the utility of hPSC-derived kidney organoids for modeling ADPKD, even control organoids exhibited cyst formation when forskolin was administered. Moreover, those organoid models displayed cyst formation in both proximal and distal nephrons, which may not fully recapitulate cyst pathogenesis of PKD patients. We postulate that vascularized kidney organoids developed in vitro under flow may provide a better model for in vivo cystogenesis via activation of ciliary signals without the need for forskolin.

Methods: PKHD1-mutant hPSCs were generated by CRISPR/Cas9 genome editing. Hetero and homozygous mutants with frameshift mutations were selected with deep-seq. Kidney organoids were generated following our reported protocol and cultured in vitro under static or flow conditions. Forskolin was tested for cyst formation. cAMP activation was evaluated by ELISA. Control and cystic organoids were characterized by immunostaining and transcriptome analyses. To evaluate differential gene expression profiles, microarray (3D-Gene®) and Metacore™ were used.

Results: CRISPR-mutant kidney organoids (static culture) with homozygous mutations in PKHD1 exhibited cyst formation in both proximal and distal nephrons when treated with forskolin, while a heterozygous mutant did not form cysts. Forskolin significantly increased cell proliferation marked by Ki67 in both tubular cells and interstitial cells in homozygous mutant organoids. Further, microarray analysis revealed differential gene expression induced by forskolin and/or PKHD1 homozygous mutations, which was associated with >50 signal pathways. Some signal pathways have been implicated in PKD cystogenesis, yet others, apparently altered by forskolin, appeared to be non-specific to PKD cystogenesis. By contrast, CRISPR-mutant, vascularized kidney organoids cultured under flow exhibited cyst formation and Na, K-ATPase mislocalization solely in distal nephrons without addition of forskolin, which are consistent with clinical findings.

Conclusions: The fluidic chip model of PKD organoids demonstrated clinically relevant phenotypes of PKD patients, which would complement current PKD models to better understand PKD pathomechanisms for new therapeutic development.

Uremic Vasculopathy Modeling with Induced Pluripotent Stem Cells and Uremic Toxin Mixtures

Hye Ryoun Jang, Kyungho Lee, Hyo jin Boo, Suhyun Kim, Jung eun Lee, Wooseong Huh, Dae joong Kim, Yoon-Goo Kim. *Nephrology Division, Department of Medicine, Stem cells and Regenerative Research Institute, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Cardiovascular complications remain as major causes of morbidity and mortality in end-stage renal disease (ESRD) patients. Although uremic vasculopathy substantially contributes to the development of cardiovascular complications in ESRD, it is difficult to simulate uremic vasculopathy with current research methods like animal models or cell culture experiment. In this study, we aimed to develop a simplified uremic vasculopathy model using uremic toxin mixtures on endothelial cells differentiated from induced pluripotent stem cells (iPSCs-ECs).

Methods: Peripheral blood mononuclear cells from a normal control and an ESRD patient was reprogrammed to iPSCs using Sendai virus, then iPSC-ECs were differentiated from iPSCs. Uremic toxin mixtures comprised of diverse combination of urea, creatinine, uric acid, indoxyl sulfate, and advanced glycation end-product were tested in a cell culture model of iPSC-ECs. Reactive oxygen species (ROS), apoptosis, and tube formation or scratch migration assay were measured to evaluate dysfunction of iPSC-ECs. Media alone was used as a negative control and 15% serum from ESRD patients receiving hemodialysis was used as a positive control.

Results: Urea, uric acid, and indoxyl sulfate significantly suppressed the tube formation of iPSC-ECs, while creatinine alone did not affect ROS levels or the tube formation of iPSC-ECs. Uremic toxin mixtures comprised of high concentration of urea, creatinine, uric acid, and indoxyl sulfate increased ROS production and apoptosis, whereas decreased tube formation of iPSC-ECs similarly with ESRD patients' uremic serum. ESRD patient-specific iPSC-ECs showed impaired wound healing potential which was partially restored by losartan and TGF-β inhibitor.

Conclusions: We developed a simplified uremic vasculopathy model using uremic toxin mixtures comprised of urea, uric acid, and indoxyl sulfate and iPSC-ECs. This novel model may be used as a new research tool of uremic vasculopathy and drug screening system.

FR-PO765

Generation of Kidney Branching Ureteric Bud Organoid from Human Pluripotent Stem Cells

Zhongwei Li, Zipeng Zeng, Biao Huang. *University of Southern California, Los Angeles, CA.*

Background: The repetitive reciprocal interactions between metanephric mesenchyme (MM) and ureteric bud (UB) lay the basis for kidney organogenesis. Nephron progenitor cell (NPC) within the MM generates the nephrons, while UB branches to generate the collecting duct network. Human pluripotent stem cell (hPSC)-derived NPCs and nephron organoids have been well established. However, currently available hPSC-derived UB still lack their definitive features – they had very limited branching ability and did not interact with NPCs. Here we present a novel method to generate a branching UB organoid from hPSCs. Our platform will advance the kidney regeneration field and it will also provide a novel platform for modeling diseases in the collecting duct.

Methods: We first developed a robust culture medium, named UB culture medium (UBCM), to support the long-term expansion of mouse UB as three-dimensional (3D) branching organoid. Meanwhile, we employed *SOX9*-GFP reporter hPSC line to monitor and optimize our UB differentiation protocol. After differentiation, the *SOX9*-GFP+ UB progenitor-like cells were purified via flow cytometry. Aggregated *SOX9*-GFP+ cells branched out in UBCM and can be passaged as 3D organoid. The identity of the UB organoids were confirmed by gene expression, ability to interact with NPCs and the potential to generate mature collecting duct.

Results: The expandable mouse UB organoid cultured in UBCM showed homogenous expression of broad UB markers (Lhx1, Gata3, Pax2, Pax8) and UB progenitor markers (Ret, Etv5, Sox9). By qPCR, our hPSC-derived UB showed the expression of various UB markers at similar levels to that in the primary UB obtained from human fetal kidney. Immunostaining also confirmed the homogeneous expression of RET, GATA3, SOX9, PAX2, CDH1 and KRT8 in the hPSC-derived UB organoids. More importantly, when the hPSC-derived UB were reconstructed with hPSC-derived NPCs, kidney organogenesis was restored, generating nephrons from the NPCs and collecting duct from the UB.

Conclusions: 1. Novel UBCM supports the long-term expansion of mouse UB 2. Novel directed differentiation protocol generates UB progenitor-like cells from hPSCs 3. Aggregated hPSC-derived UB branches in UBCM and can be passaged as 3D organoids 4. Restored kidney organogenesis in vitro when hPSC-derived NPC and UB are reconstructed

Fibrotic Kidney Organoids and Human CKD Samples Demonstrate Loss of Homologous Recombination as a Critical Mediator of Maladaptive Repair

Navin R. Gupta,[1] Ken Hiratsuka,[1] Tomoya Miyoshi,[1] Koichiro Susa,[1] Narihito Tatsumoto,[2] Michifumi Yamashita,[2] Ryuji Morizane.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Myofibroblasts are a hallmark of maladaptive repair that have been demonstrated in injured kidney organoids and kidney tissue *in vivo*. Tubular epithelial DNA damage potentiates myofibroblast generation. Mechanisms for DNA repair include genome-conserving homologous recombination (HR) and mutation-generating non-homologous end joining (NHEJ). Here we hypothesize that DNA damage repair between HR and NHEJ in tubular epithelial cells governs maladaptive repair, which could be examined using kidney organoids and human kidney tissue.

Methods: Kidney organoids were generated from hPSCs by our established protocol. Organoids were treated with repetitive cisplatin to induce tubular epithelial DNA damage, ascertained by γH2AX positivity. Stromal cells were monitored for the advent of the myofibroblast marker, αSMA. DNA damage repair was modulated to inhibit either HR or NHEJ in cisplatin treated organoids. FANCD2, a crucial HR element, was used as a surrogate for HR activity. HR and NHEJ activities were evaluated by qPCR for multiple genes of DNA repair. Findings in organoids were confirmed in patient biopsy samples of CKD and minimal change disease (MCD) with tubular injury.

Results: Cisplatin treatment induced DNA damage to tubular epithelial cells. HR activity increased in injured tubules, yet repetitive cisplatin treatment downregulated HR-related genes wheras NHEJ activity persisted. Suppression of HR activity by RAD51 inhibition hastened nephron loss and the evolution of myofibroblasts, while inhibition of the critical NHEJ enzyme, DNA ligase IV, delayed maladaptive responses. Human CKD patient samples with moderate to severe parenchymal scarring demonstrated little HR activity in injured tubules, whereas non-fibrotic MCD patient samples with tubular injury displayed activation of HR.

Conclusions: Human kidney organoids model maladaptive repair upon recurrent DNA damage in tubular epithelial cells. Mechanistic analysis of maladaptive repair in kidney organoids revealed loss of HR as a pathologic process. As opposed to non-fibrotic human kidney tissue, CKD patient samples demonstrated little HR activity in DNA damaged tubular epithelial cells. Human kidney organoids represent a novel model to decipher pathophysiologic processes in human kidney injury and repair.

Development of Novel Real-Time Biosensor Kidney Organoids to Study AKI

Aneta J. Przepiorski,[1] Eugenel B. Espiritu,[1] Alan J. Davidson,[2] Neil A. Hukriede.[1]
[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Auckland, Auckland, New Zealand.

Background: Kidney disease is on the rise worldwide. Persistent acute kidney injury and chronic kidney disease inevitably both lead to tubular atrophy, kidney fibrosis and eventually end-stage renal disease. The exact mechanisms are poorly understood and there are currently no treatments. Recent advances in generating human kidney organoids *in vitro*, have provided an invaluable tool to study kidney disease and injury, and a new tool for small molecule screening. We utilize a recently developed human kidney organoid protocol from induced pluripotent stem cells (iPSCs) to generate a new kidney biosensor to deepen our understanding of acute kidney injury and fibrotic tissue development in this model.

Methods: As a real-time readout of acute injury and to test the efficacy of new compounds we developed an early apoptosis reporter, CytochromeC-GFP iPSC line. Healthy cells in the organoids express green GFP in the mitochondria, upon injury the GFP signal loses mitochondrial localization and becomes cytoplasmic before activating the Caspase 3 apoptotic pathway. We establish optimal dosage with known nephrotoxins and a real-time response using CytochromeC-GFP organoids to validate our biosensor.

Results: Using the CyochromeC-GFP biosensor iPSC line we show that the healthy iPSCs and organoids exhibit mitochondrial CytochromeC-GFP expression as shown by co-labelling with MitoTracker Red CMXRos. Upon injury with nephrotoxins the GFP signal in the injured cells loses localization to the mitochondria and becomes cytoplasmic. Co-labelling with apoptotic Caspase 3/7 stains showed that it co-localizes with the injured cells (cytoplasmic CytochromeC-GFP expression) in the tubules.

Conclusions: Using the CyochromeC-GFP biosensor iPSC line we show that the health of organoids can be monitored in real-time, and can be used to study cytotoxic response. It provides a new way to examine kidney health in a human based model that can be utilized in examining nephrotoxic effects during drug and small molecule compound screening.

Optimizing Human Kidney Organoids for Modeling Nephrotoxicity, Kidney Injury, and Kidney Diseases and for Screening to Identify Therapeutic Options

Nathan Lee,[1,2] Kyung hwa Choi,[1,3] Taja Zeleznik ramuta,[1,4] Joseph V. Bonventre.[5,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Broad Institute of MIT and Harvard, Cambridge, MA; [3]CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea; [4]Institute of Cell Biology, University of Ljubljana, Ljubljana, Slovenia; [5]Brigham and Women's Hospital, Boston, MA.*

Background: To optimize their potential in modeling nephrotoxicity and kidney disease, pluripotent stem cell-derived kidney organoid protocols are being optimized for enhancing reproducibility, differentiation, scalability and reducing costs.

Methods: Organoids were generated by modifications of our laboratory's prior published techniques. Importantly, organoids were generated without use of undefined matrices. Cell types and structures were identified by immunostaining for LTL, PODXL, NPHS1, CDH1, GATA3, PDGFR-β and CD31. Protocols were modified to generate organoids to contain different compositions of specific cell types and structures, and they were tested for nephrotoxicity and kidney injury response by exposure to stimuli including cisplatin and LPS. The degree of kidney injury was assessed by various markers including KIM-1, αSMA, $cPLA_2$, and γH_2AX. The protocols enable high throughput analyses.

Results: Our novel method to generate human kidney organoids without undefined matrices yields all major cell types including proximal and distal tubules, podocytes, collecting duct, stromal cells, and endothelial cells in anatomically juxtaposed contexts. Avoidance of undefined matrices facilitates potential use of these organoids for more clinically relevant applications. Variation on the simplified and cost-effective protocols results in variation in composition of cell types and structures along with varying connectivity among cell types. Immunostaining for markers including KIM-1, LTL, αSMA, $cPLA_2$, and γH2AX showed that kidney organoids containing multiple distinct structures present together were more sensitive to nephrotoxicants compared to organoids generated to have predominant amount of proximal tubules lacking other cell types.

Conclusions: Protocols have been developed to generate human kidney organoids without undefined matrices in a more streamlined cost effective manner with programmed relative amounts of distinct kidney component structures. Proximal tubule susceptibility to toxicity is altered by adjustments in the organoid generation that change the surrounding contextual environment of other kidney structures.

Modeling Renal Manifestations of Tuberous Sclerosis Complex with iPSC-Derived Kidney Organoids

Joel O. Hernández ramos,[2] Maria F. Sobral reyes,[3] Dario R. Lemos.[2,1]
Laboratory for Organ Regeneration and Tissue Engineering *[1]Harvard Medical School, Boston, MA; [2]Medicine, Brigham and Women's Hospital, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Renal manifestations are the second most common clinical finding in patients with TSC. Here we tested the ability of human induced pluripotent stem cell (iPSC) lines carrying heterozygous or homozygous mutations in the *TSC2* locus, to differentiate into human kidney cells and to model the cellular pathophysiology of TSC kidney lesions.

Methods: An iPSC cell line derived from a patient carrying a heterozygous microdeletion in the *TSC2* locus (*TSC2*$^{+/-}$), and a TALEN-engineered isogenic line carrying the microdeletion in both *TSC2* alleles (*TSC2*$^{-/-}$), were incubated with CHIR99021 (CHIR), Activin and FGF9, presented in a sequential fashion. The same concentration and stimulation duration for each growth factor were used for both iPSC lines.

Results: After modifications to the original chemically defined differentiation protocol developed by Morizane *et al.*, both iPSC lines successfully generated SIX2$^+$, PAX2$^+$ nephron progenitor cells with high efficiency by day 9 of differentiation. By day 14, self-organized renal vesicles had formed in the cultures of both cell lines, albeit visible cyst-like structures were observable in *TSC2*$^{-/-}$ vesicles but not in *TSC2*$^{+/-}$ vesicles. In low attachment 3D culture conditions, *TSC2*$^{-/-}$ organoids but not *TSC2*$^{+/-}$ organoids, presented expanding spheroidal cysts. Histological analysis of *TSC2*$^{-/-}$ and *TSC2*$^{+/-}$ organoids on day 21 of differentiation showed the presence of major kidney cell types including glomerular PDXL1-expressing podocytes, ECadherin-expressing distal tubules, and proximal tubules with brush borders. Cyst-like, dilated proximal and distal tubules with increased phosphorylation of p70-S6-kinase were observed in *TSC2*$^{-/-}$ organoids but not in heterozygous ones.

Conclusions: We have established a protocol for directed differentiation of TSC iPSCs into 3D organoids containing multi-segmented nephron structures that recapitulate TSC-specific cystic phenotypes. This novel bioengineering tool will provide valuable insight into the cellular and molecular mechanisms of renal abnormalities and set the basis for patient-specific phenotypic drug screens

FR-PO770

Kidney Organoid Model of Selective Podocyte Injury

Tomohiro Udagawa,[1,3] Keiko Tanaka,[1] Toshikazu Araoka,[2] Kenji Osafune,[2] Taiji Matsusaka.[1] *[1]Tokai University School of Medicine, Isehara, Japan; [2]Center for iPS Cell Research and Application (CiRA), Kyoto University, Kyoto, Japan; [3]Pediatric and Developmental Biology, Tokyo Medical and Dental University, Bunkyo-ku, Japan.*

Background: Podocyte injury triggers progressive loss of kidney function. Determining the mechanisms involved in the progression of podocyte damage is critical to developing renoprotective therapies. We previously generated a transgenic mouse line, NEP25, which expresses human (h) CD25 on podocytes. Selective podocyte injury can be induced by the hCD25-targeted immunotoxin, LMB2. In addition, we analyzed podocyte-specific gene expression profiles utilizing RiboTag mice, which selectively express hemagglutinin (HA)-tagged ribosomal protein in podocytes. In the present study, to efficiently investigate the function of altered genes during podocyte injury, we aimed to generate NEP25/RiboTag kidney organoids and establish an *in vitro* model of podocyte injury.

Methods: Nephron progenitor cells (NPCs) were established by culture-dependent purification (CDP) method from 12.5 dpc NEP25/RiboTag mouse kidneys (*Cell Stem Cell*. 2016, 19, 516-29). Kidney organoids were generated by transient stimulation with FGF2 and CHIR99021 of NPC aggregates and subsequent 6–8 day culture. Podocyte-specific polysomes were obtained via immunoprecipitation using an anti-HA antibody.

Results: We confirmed that the organoids show glomerulus-like and tubule-like structures. Immunostaining revealed that the former expressed nephrin, WT1, podcalyxin, and synaptopodin and the latter expressed LTL and megalin. Nephrin-positive podocytes also expressed hCD25 and HA. Q-PCR confirmed that *Nphs1* (33.3), *Nphs2* (21.2), *Wt1* (24.9), and *Dach*1 (6.2) were concentrated in HA-immunoprecipitated RNA by the indicated fold. When organoids were incubated with LMB2 (20 nM) for 4 days, podocalyxin and WT1 staining disappeared. *Nphs1* and *Nphs2* mRNAs became undetectable, *Wt1* (0.05 fold) and *Dach1* (0.37) decreased, and *Cxcl1* (4.2) and *Epha8* (55.6) increased, thus reproducing *in vivo* injured podocytes.

Conclusions: We established kidney organoids in which podocytes can be selectively injured and podocyte mRNA can be selectively obtained. This organoid system will be a powerful tool for investigating mechanisms underlying podocyte injury.

FR-PO771

A Drug-Specific Nephrotoxicity Prediction System Using Kidney Organoids

Koichiro Susa,[1,2] Akitoshi Tamura,[1] Pierre Galichon,[1,3] Navin R. Gupta,[4] Takuya Matsumoto,[5] Tomoya Miyoshi,[1] Venkata Sabbisetti,[1] Joseph V. Bonventre,[1] Ryuji Morizane.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; [3]Sorbonne Université, Paris, France; [4]Brigham & Women's Hospital/Massachusetts General Hospital, Brighton, MA; [5]Harvard medical school, Boston, MA.*

Background: Drug-induced nephrotoxicity is increasingly recognized as a serious clinical problem, leading to acute kidney injury (AKI) and chronic kidney disease. Lack of reliable models with physiological function of human kidneys results in the difficulty to predict nephrotoxicity of new drugs in preclinical trials. Here, we demonstrate kidney organoids containing multi-segmented nephron epithelial cells generated from human pluripotent stem cells (hPSCs) as a new technology for pre-clinical nephrotoxicity assessment.

Methods: We generated kidney organoids from hPSCs by a directed differentiation protocol and validated the maturation of organoids using immunostaining and transcriptome analyses. Organoids were treated with various nephrotoxicants which cause injury in a segment-specific manner via specific drug transporters. Injury responses were analyzed by immunostaining, qPCR, and biomarker assays. We also generated reporter organoids to evaluate the toxicity with a real-time biosensor of ATP/ADP ratio in 384-well culture plates.

Results: We confirmed increased expression of drug transporters including OAT1, OAT3, OCT2 and PMAT with matured gene expression profiles in kidney organoids during 5 to 7 weeks of differentiation. Organoids simulated various drug-induced injury such as biomarker upregulation, DNA damages, and morphological changes specifically in the tubules or in the glomeruli by low concentration of nephrotoxicants mediated by these transporters (OATs: tenofovir and aristolochic acid [AA], OCT: cisplatin, PMAT: puromycin aminonucleoside). The injuries induced by tenofovir and AA, or cisplatin were ameliorated by OATs inhibitor probenecid or OCT2 inhibitor cimetidine, respectively. On the other hand, high concentration of these nephrotoxicants resulted in widespread injury to all nephron compartments and interstitial cells. In addition, nephrotoxicants significantly reduced the ATP/ADP ratio within 24 hours of treatment.

Conclusions: Kidney organoids faithfully recapitulate drug-induced AKI by reflecting the toxicity characteristics of the drugs, allowing to distinguish between drug-specific and generalized toxicity responses. The reporter organoids may realize high-throughput and real-time nephrotoxicity screening, providing a new platform to evaluate nephrotoxicity as preclinical trials.

FR-PO772

Modeling a Recurring Wilms Tumor-Associated Mutation in Kidney Organoids

Matthew Stevenson, Marvin A. Meza Jarquín, Lori L. O'Brien. *University of North Carolina, Chapel Hill, NC.*

Background: Wilms tumor (WT) is the most common pediatric kidney cancer and blastemal-predominant tumors represent a more lethal, chemotherapy-resistant form of WT. This tumor subtype expresses markers found only in the nephrogenic niche of the fetal kidney, suggesting it arises from a malignant transformation of these cells. Sequencing of blastemal-predominant tumors has identified a recurring single amino acid mutation, Q177R, within the conserved DNA binding domains of the closely related transcription factors SIX1/SIX2. These factors are critical for the maintenance of nephron progenitors during mammalian kidney development. Therefore, we hypothesize that this recurring mutation disrupts the regulatory networks controlled by SIX1/SIX2 resulting in the malignant transformation of nephron progenitors. Efforts to model WT in mice have proven challenging and differences in gene expression dynamics between mouse and human nephrogenesis, specifically the temporal expression of SIX1, necessitates a novel system in which to investigate the tumorigenic potential of the Q177R mutation.

Methods: IPSC-derived kidney organoids recapitulate key stages of human kidney development *in vitro*, resulting in the formation of complex nephron-like structures. Building upon established protocols, we have developed a modified, minimal 3D protocol to reproducibly generate kidney organoids for use as a model system. To investigate the transformative potential of the SIX1-Q177R mutation within the context of our kidney organoid system, we generated an isogenic iPSC line expressing a FLAG-tagged, mutant SIX1-Q177R protein from the endogenous SIX1 locus.

Results: ChIP-qPCR revealed proper targeting of SIX1 to its canonical DNA targets by day 5 of differentiation with significantly increased binding by day 8, recapitulating the *in vivo* activities of SIX1 during human nephrogenesis. Analysis of gene expression changes over the course of differentiation also revealed proper temporal expression patterns of many canonical nephron progenitor markers in our kidney organoids.

Conclusions: By combining modern genome editing techniques with our defined kidney organoid differentiation system, we have enabled the in-depth characterization of the altered regulatory landscape brought about by the SIX1-Q177R mutation throughout the earliest stages of human kidney development in a relevant *in vitro* model system.

Comprehensive Gene Expression Analysis Using Renal Coloboma Syndrome Patient-Derived iPSCs

Yuta Yamamura,[2] Kengo Furuichi,[1] Keisuke Sako,[2] Yasunori Iwata,[2] Norihiko Sakai,[2] Takashi Wada.[2] *[1]Kanazawa Medical University, Kahoku-Gun, Japan; [2]Kanazawa University, Kanazawa, Japan.*

Background: Renal coloboma syndrome (RCS) is characterized by kidney hypoplasia or dysplasia and abnormality of the optic nerve. PAX2 mutation is one of the major genetic abnormalities of RCS. PAX2 is an essential transcription factor for kidney development. In mouse, Pax2 homozygous deficient mouse shows kidney agenesis and neonatal lethal. It is reported that Pax2 involved in ureteric bud branching via the regulation of Gdnf expression. However, the role of PAX2 gene during human kidney development is not clear. In this study, PAX2 regulated genes during human kidney development were evaluated using RCS patient derived induced pluripotent stem cells(iPSC)with PAX2 gene mutation.

Methods: Three RCS patient derived iPSCs with PAX2 gene mutation were established. Control iPSC and RCS patient derived iPSC were differentiated into kidney lineage cells with reported methods (Taguchi, et al. Cell Stem Cells 2014). The differentiated kidney organoid from iPSC were evaluated by immunocytochemistry and qPCR. Furthermore, to detect PAX2 regulated genes, comprehensive gene expression analysis was performed.

Results: Kidney lineage cells were inducible from both control and RCS patient derived iPSC. The expression patens of kidney lineage markers (such as WT1, SIX2, AQP1, PODXL) were almost similar among three RCS patient derived iPSC with PAX2 gene mutation and control iPSC. PAX2 gene expression in control iPSC was peaked on day 14 in our protocols. In immunocytochemical analysis and qPCR, PAX2 was highly expressed in INTEGRINα8+/PDGFRα- cells, which was known as the surface marker as nephron progenitor cells. These cells were collected by flow cytometry. By comprehensive gene expression analysis using control and RCS patient derived INTEGRINα8+/PDGFRα- cells, 189 upregulated genes were detected in control samples. Some upregulated genes were confirmed by qPCR in control iPSC derived INTEGRINα8+/PDGFRα- cells. The gene expression was also confirmed in mouse embryonic kidney. Additionally, *in silico* study using FANTOM database also indicate that some of our candidate genes were upregulated during the kidney development.

Conclusions: Comprehensive analysis using RCS patient derived iPSC with PAX2 gene mutationis is useful for identification of PAX2 regulated genes during human kidney development.

FR-PO774

Percutaneous Intrarenal Transplantation of Differentiated Induced Pluripotent Stem Cells into Newborn Mice

Ricky W. Lau,[1] Ali H. Al-Rubaie,[1] Pratibha Tripathi,[2] Sharon D. Ricardo.[1] *[1]Monash University, Clayton, VIC, Australia; [2]Monash University, Melbourne, NSW, Australia.*

Background: The reprogramming of adult cells to generate iPSCs may provide an unprecedented opportunity to elucidate disease mechanisms *in vitro*; for disease-modifying bioassays, and to advance cell-replacement therapy. The *in vivo* engraftment and survival of patient-derived iPSCs following allogenic transplantation into host kidneys remains a challenge. Here we investigate the survival and engraftment of human dermal derived iPSCs using a newborn mouse model, which represents a receptive immuno-privileged host environment.

Methods: iPSCs were generated from skin biopsies of patients using Sendai virus reprogramming. Differentiation of iPSCs to podocytes (iPSC-POD) was performed in *Nphs1* (Nephrin)-green fluorescent protein (GFP) iPSCs by the addition of activin A, bone morphogenetic protein 7 (BMP7) and retinoic acid over 15 days of culture. To assess *in vivo* integration, undifferentiated iPSCs and iPSC-POD differentiated for 10 or 15 days were labeled with either carboxyfluorescein succinimidyl ester (CFSE) or long term cell tracking Qtracker® 705 probe. Thereafter, 1 x 10^5 of differentiated iPSC-POD were resuspended and injected in 10 ul of phosphate buffered saline solution directly into the kidneys of mouse pups at postnatal day one (P1). A timecourse analysis of cell integration was assessed in differentiated iPSC-POD, compared to undifferentiated cells, using confocal fluorescence microscopy and the co-expression of glomerular and podocyte-specific markers.

Results: D10 differentiated iPSC-PODs, that were positive for podocyte markers including podocin, were detected following direct kidney injection in newborn mice after P3. Undifferentiated iPSC-PODs were not detected at the same timepoint. The transplanted cells were viable and located in the developing kidney cortex including the tubulointerstitium and localised adjacent to developing glomeruli in the outer nephrogenic zone where they were found to co-localise with glomerular-specific markers including podocin, synaptopodin and Wilms tumour 1 (WT1).

Conclusions: This study provides proof-of-principle that transplanted differentiated iPSC–POD can survive and integrate into recipient newborn mouse kidneys, and represents an ideal *in vivo* environment due to the immature and immunoprivileged nature of the developing postnatal kidneys.

FR-PO775

Low Nephron Number Resulting from SIRT3 Deficiency Increases Susceptibility to Renal Dysfunction Later in Life

Marina Morigi,[1] Anna Pezzotta,[1] Luca Perico,[1] Daniela Corna,[1] Valentina Benedetti,[1] Valerio Brizi,[1] Sara Conti,[1] Fabio Sangalli,[1] Daniela Rottoli,[1] Piera Trionfini,[1] Christodoulos Xinaris,[1] Norberto Perico,[1] Carlamaria Zoja,[1] Giuseppe Remuzzi,[1,2] Ariela Benigni,[1] Barbara Imberti.[1] *[1]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Bergamo, Italy; [2]L. Sacco Department of Biomedical and Clinical Sciences, University of Milan, Milan, Italy.*

Background: Low nephron endowment is a risk factor for chronic kidney diseases (CKD) in adulthood but no causal correlation has been formally proved. We have demonstrated that mice lacking the mitochondrial protein Sirtuin 3 (SIRT3) are more susceptible to acute kidney injury than wild type (WT) mice. Here, we explored whether *Sirt3*$^{-/-}$ mice can be used as a low nephron number model and are more susceptible to CKD.

Methods: Metanephroi were isolated from WT and *Sirt3*$^{-/-}$ mice to study nephrogenesis. The susceptibility of *Sirt3*$^{-/-}$ mice to CKD was studied in adriamycin (ADR)- or bovine serum albumin (BSA)- induced progressive nephropathies.

Results: We demonstrated that, at the embryonic day 12.5, *Sirt3*$^{-/-}$ mice had less ureteric bud branching and fewer metanephric SIX2^{+} progenitor cells. Impaired nephrogenesis in *Sirt3*$^{-/-}$ mice resulted in a nephron deficit compared to WT mice (40% reduction at post-natal day 7, P<0.001), due to altered mitochondrial dynamics, biogenesis, mitophagy and energetic metabolism. Notably, low nephron endowment at birth is not enough to cause renal disease in adulthood, but enhances the susceptibility of *Sirt3*$^{-/-}$ mice to renal damage. Specifically, when *Sirt3*$^{-/-}$ mice were exposed to ADR or BSA overload, they experienced more severe proteinuria, podocyte loss (% reduction in WT-1^{+} cell density: *Sirt3*$^{-/-}$, 68% vs WT, 30%, P<0.01) and vascular rarefaction than WT mice (% reduction in MECA-32^{+} cell density: *Sirt3*$^{-/-}$, 57% and WT, 43%, P<0.05). We also proved that nephron deficit can be corrected through prenatal SIRT3 boosting. Indeed, in a model of low nephron number and reduced renal SIRT3 levels – WT mice born to mothers fed a low protein diet – nephron number was restored through NAD^{+} precursor nicotinamide riboside (NR) treatment.

Conclusions: Our results provide evidence that low nephron endowment is a critical determinant of susceptibility to CKD when the kidney is challenged by additional hits, and support the use of SIRT3 boosting during nephrogenesis as a therapeutic option for increasing nephron number.

Loss of Hypoxia-Regulated MicroRNA-210 Results in Decreased Nephron Number

Shelby L. Hemker,[1] Andrew J. Bodnar,[2] Debora Malta C.S Santos,[3] Andrew S. Clugston,[2] Jacqueline Ho.[3] *[1]University of Pittsburgh - Rangos Research Center, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Low nephron number increases an individual's risk for developing hypertension and chronic kidney disease, which affect approximately 30% and 15% of American adults, respectively. Intrauterine growth restriction and fetal hypoxia are significant causes of low nephron number; however, the underlying molecular mechanisms that drive this are unknown. Nephron number, in turn, is determined prior to birth in humans. *microRNA-210* (*miR-210*) is the most consistently induced microRNA in hypoxia and regulates various processes including metabolism, cell cycle progression, and apoptosis. We hypothesize that loss of *miR-210* results in abnormal kidney development.

Methods: To test this hypothesis, we obtained a global *miR-210* knockout (KO) mouse. We used the "gold standard" physical dissector/fractionator combination method to estimate nephron number at postnatal day 30 (P30). We collected wildtype (WT) and KO littermates right before the burst in nephrogenesis at P0 and right before the end of nephrogenesis at P2. To measure changes in gene expression in nephron progenitors and their derivatives, we performed qPCR, immunofluorescent staining, and Western blot assays.

Results: We found an approximately 35% reduction in nephron number in *miR-210* KO male kidneys and a 28% reduction in both WT and KO female kidneys, compared to WT males. Analysis of nephron progenitor proliferation, apoptosis and differentiation markers showed no discernable difference in kidney development at P0. However, we observed decreased expression of the differentiation marker Jag1 by Western blot at P2, as well as fewer total Lef1-, Jag1, and Nicd1-positive differentiating nephron structures. We observed no difference in nephron progenitor proliferation nor apoptosis at P2. However, there was an approximately 35% increase in the total number of cleaved-Casp3-positive cells and its immunofluorescent staining suggests that there is an increase in apoptosis in differentiating nephron structures. Furthermore, we found increased mRNA expression of several pro-apoptotic *miR-210* target genes (*Casp8AP2/FLASH*, *Ptpn2*, and *Bnip3*).

Conclusions: *miR-210* KO kidneys have a nephron deficit, which is associated with decreased differentiating nephron structures and increased apoptosis within those structures.

FR-PO777

Caloric Restriction During Pregnancy Reduces Nephron Endowment and Impairs Adult Kidney Function by Inactivating mTOR and the Methionine Salvage Pathway

Oded Volovelsky,[1,2] Elad Resnick,[2] Liad Hinden,[3] Joseph Tam,[3] Raphael Kopan,[4] Morris Nechama.[2] *[1]Pediatric Nerphology Unit, Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Pediatric Nephrology Research Lab, Hadassah Medical Center, Jerusalem, Israel; [3]Obesity and Metabolism Laboratory, School of Pharmacy, The Hebrew University of Jerusalem, Jerusalem, Israel; [4]Division of Developmental Biology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Maternal malnutrition during pregnancy correlates with lower nephron numbers and higher risk of chronic kidney disease (CKD) in adulthood, but the underlying molecular mechanisms are still unknown. The nephron progenitor pool exhausts abruptly in third postpartum day in mice with no nephrogenesis at later stages. We used a mouse model to study the effects of maternal caloric restriction on kidney development and nephron progenitor cells (NPCs).

Methods: Pregnant CD1 mice were monitored in metabolic cages and their daily caloric intake was reduced by 30% compared to the average consumption of the control group at the same gestational age. The effect on kidney morphology and function was measured by immunostaining, kidney biomarkers analysis and nephron count. Six2^{+} GFP^{+} NPCs were extracted from Six2 Cre$^{tg/+}$ E18.5 embryos of calorically restricted pregnant dams or controls and isolated by FACS. mRNA expression and metabolomic activity in sorted NPCs were evaluated by bulk RNAseq and mass spectrometry, respectively. Key findings were validated using western blotting.

Results: Animals exposed to caloric restriction in utero had 50% fewer nephrons after birth and throughout adulthood as well as lower kidney function, as demonstrated by higher serum urea levels. Nephrogenesis was shorter by at least 24 hours. Calorically restricted E18.5 Six2^{+} NPCs had decreased expression of mTOR pathway genes, and lower overall mTOR activity, reflected in lower levels of phosphorylated ribosomal protein S6. Mass spectrometry of metabolites from isolated NPCs identified a strong reduction in the methionine salvage pathway.

Conclusions: Reduced mTOR signalling and methionine salvage activity in NPCs from fetuses carried by malnourished mothers led to a premature end of nephrogenesis, reduced nephron numbers, and the associated increased risk for CKD in adulthood.

Funding: Government Support - Non-U.S.

FR-PO778

Ontogeny and Phylogeny: Our Evolutionary History and Bioenergetics Explain High Variation in Nephron Number (NN) at Birth

Robert L. Chevalier. *University of Virginia, Charlottesville, VA.*

Background: Low NN at birth is recognized as a major lifetime risk factor for chronic kidney disease (CKD), but its origin is poorly understood. Recent studies based on the Barker hypothesis suggest that epigenetic downregulation of nephrogenesis modulated by maternal-fetal stressors (e.g. hypoxia, undernutrition) contributes to CKD in adulthood. Application of evolutionary biology to medicine has led to new approaches in cancer and infectious disease research, and shows promise in nephrology (Chevalier, Kidney Int Rep 2:302, 2017; J Am Soc Nephrol 29:705, 2018).

Methods: Data abstraction: Medline searches including the terms "kidney, evolution, physiology, genetics, bioenergetics, and development" 1970 to the present.

Results: The rapid evolution of hominids was a product of increased nutrient quality and availability ~2 million years ago, resulting from transition of the east African environment from forest to savannah. Natural selection favored doubling brain size from *Homo habilis* to *Homo sapiens* over a period of 1 million years. Our brain consumes 90% of basal metabolic rate (BMR) at birth, 50% at 1 year of age, and 20% in adulthood. Maternal energy consumption in pregnancy and during breastfeeding increases BMR by 20%, which must be balanced by high kidney oxygen consumption tied to BMR. Maternal protein restriction during pregnancy in mice resulted in 75% reduction in NN; offspring of mice lacking DNA methyltransferase 1 (Dmt1) in nephron progenitor cells developed 50% reduction in NN. Nutrients and oxygen signal energy metabolism to mitochondria through the hypoxia-inducible factor (HIF) pathway to regulate nephron morphogenesis. This epigenetic response is driven by metabolic reprogramming of nephron progenitor cells from glycolysis (maintenance of self-renewal) to differentiation (cessation of nephrogenesis) mediated by the Wnt pathway.

Conclusions: Energy, the currency of evolution, is constrained by the environment. Selection pressure favors allocation of available energy from kidney to brain growth in early development. Through epigenetic regulation of bioenergetics, reduction of nutrients available during pregnancy proportionately restricts nephrogenesis. Since only 18% of children with congenital kidney anomalies develop end-stage CKD before 15 years of age, this evolutionary strategy favors reproductive fitness in the majority of cases.

FR-PO779

Cell Turnover Dynamics in the Human Kidney Using Radiocarbon Dating

Christina Jones,[1] Keng-Yeh Fu,[1] Endre Kiss,[1] Kanar Alkass,[1] Anders Kjellman,[1] Jaakko Patrakka,[1] Samuel Bernard,[2] Henrik Druid,[1] Kirsty Spalding.[1] *[1]Karolinska Institutet, Huddinge, Sweden; [2]CNRS, Villeurbanne, France.*

Background: Kidney cell turnover is fundamental to maintain organ homeostasis and to replace lost cells in response to injury. This study aims to define regeneration in the human kidney and explore turnover kinetics in health and disease. Proximal tubular epithelial cells are known to turnover, however questions remain about the dynamics and source of replacement cells. Podocytes were traditionally considered irreplaceable, however reports of putative progenitors have sparked interest in podocyte regeneration. The novel method of radiocarbon dating DNA to determine human cell age (Spalding et al. 2005) has been used to answer fundamental questions about human regeneration in the brain, heart and adipose tissue. This study adapts the method to address these important questions in the kidney.

Methods: Human kidney nuclei sorting was developed for this study. The method is effective for whole kidney tissue and isolated glomerular fraction analyses, from either fresh or frozen tissue from both nephrectomy and postmortem sources. Podocyte, endothelial and proximal tubule nuclei were isolated, antibody-labeled and sorted by flow cytometry. This method yields over 10 million cell-type specific nuclei per sample with over 95% sort purity required for radiocarbon dating. DNA was extracted using carbon-clean methods and sent for carbon isotope analysis using accelerator mass spectrometry.

Results: Preliminary results from a cohort of 10 kidneys, collected from nephrectomy, indicates human proximal tubules have an average age of 13.3 years (±2.6), turning over at a rate of 7.7% per year. This was not impacted by patient age. Endothelial and podocyte dating is ongoing. DNA content analysis, via flow cytometric analysis of DAPI-labeled nuclei, indicates limited endoreduplication.

Conclusions: Radiocarbon dating has the potential to definitively answer questions regarding kidney regeneration in humans. Nuclei-based sorting provides an unbiased method to efficiently sort large numbers of cell-specific nuclei for a range of downstream analyses. Preliminary results of proximal tubules and ongoing successful sorts of podocytes and endothelial cells provides proof-of-principle that human kidney cell age can be determined. From physiological turnover, this study forms the basis for ongoing examination of kidney regeneration in pathology.

Using Next-Generation Imaging Technologies to Construct 3-D Multi-modal Molecular Atlases of the Human Kidney

Mark P. de Caestecker,[1] Haichun Yang,[1] Agnes B. Fogo,[1] Raymond C. Harris,[1] Raf Van de plas,[3] Jeffrey M. Spraggins.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN; [3]Delft University of Technology, Delft, Netherlands.*

Background: Little is known about the integration, interactions, and molecular cross-talk between the different cell types and cellular compartments in normal kidneys. As part of the Human BioMolecular Atlas Program (HuBMAP), we are developing an ultra-high content imaging mass spectrometry (IMS)-based 3-D imaging pipeline to characterize the molecular signatures of different cell types at high resolution in normal, intact human kidneys.

Methods: Fresh discarded human kidneys obtained from surgical nephrectomy specimens were frozen on dry ice/isopentane slurry. Sequential sections were obtained through tissue blocks, scanned for autofluorescence (AF), and alternate sections prepared for IMS and multiplexed immunofluorescence (MxIF). IMS data was collected using a prototype MALDI timsTOF Pro Mass Spectrometer. Two cycles of MxIF were performed using a panel of validated, fluorophore-conjugated antibodies, and image fusion used to integrate information from IMS-generated molecular maps with autofluorescence and MxIF images. Sequential 2-D IMS/AF/MxIF images were then registered and mapped to the 3-D coordinate system using data from sequential sections with in house tools.

Results: A preliminary lipidomics study of human kidney tissue has been performed using our custom 3-D multimodal molecular imaging platform. The data set consists of 32 serial sections collected from the cortex of the kidney. Each 2-D tissue section is ~4x8 mm and they were imaged using IMS at 20 μm spatial resolution, resulting in ~150,000 pixels per section. AF/IMS and MxIF image registration pipelines enabled the construction of high-spatial resolution ion volumes. The entire 3-D volume was ~4x8x0.32 mm and contains ~4.8 million voxels (20x20x10 μm). The fully constructed 3-D molecular atlas enabled the visualization of various lipids to specific substructures in the kidney, including the proximal and distal tubules and glomeruli. For example, C24 Sulfatide and PI-Cer(42:0) (putative identifications) were found to track with distal tubules throughout the 3-D volume.

Conclusions: We have developed a novel pipeline for 3-D biomolecular multimodal tissue imaging that will enable the construction of high-resolution molecular atlases of the human kidney.

FR-PO781

Phenotype Expansion of Heterozygous FOXC1 Mutations Towards Involvement of CAKUT

Chen-Han W. Wu,[1,2] Nina Mann,[1,2] Dervla M. Connaughton,[1,2] Makiko Nakayama,[1,2] Shirlee Shril,[1,2] Friedhelm Hildebrandt.[1,2] *[1]Medicine, Boston Children Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Heterozygous *FOXC1* mutations have been identified as the cause of Axenfeld-Rieger syndrome type 3 and anterior segment dysgenesis 3. Patients present with variable eye malformations. Syndromic cases may present with abnormalities in brain, heart, blood vessels, and hearing loss. Congenital anomalies of the kidney and urinary tract (CAKUT) have not been associated with mutations in *FOXC1*.

Methods: In order to identify novel monogenic causes of CAKUT we performed whole exome sequencing (WES) in 514 families with CAKUT.

Results: By WES analyses, we discovered 7 *FOXC1* heterozygous mutations in 8 CAKUT families. Five of the families have isolated CAKUT, while the other 3 families have syndromic CAKUT with anomalies in eyes, blood vessels, brain, bones, or facial dysmophologies. CAKUT phenotypes include renal agenesis, renal dysplasia, multicystic dysplastic kidney, ureteropelvic junction obstruction, hydronephrosis, vesicoureteral reflux, and posterior urethral valve. None of the 7 mutations were reported in patients with Axenfeld-Rieger syndrome or anterior segment dysgenesis before. Two of the mutations are absent, and the others are present in <5 individuals as heterozygote of 125,000 healthy controls in the gnomAD database. We thereby discovered CAKUT as a new phenotype of heterozygous *FOXC1* mutation. Interestingly, mouse models for *FOXC1* (Green, 1970; Kume et al., 1998; Kume et al., 2000; Motojima et al., 2016) show severe CAKUT with extra-renal malformations. The mode of inheritance is autosomal dominant with incomplete penetrance and variable expressivity. To evaluate whether the presence of CAKUT in heterozygous *FOXC1* mutation is due to allelism, we conducted genotype-phenotype correlations. There are 40 truncating and 34 missense mutations known in Axenfeld-Rieger syndrome or anterior segment dysgenesis. All 34 missense mutations are in the forkhead domain. In contrast, in the 8 CAKUT families, we did not find any truncating mutations and only 1 out of 4 missense mutation is in the forkhead domain.

Conclusions: We propose a phenotype expansion of *FOXC1* to include CAKUT, potentially explained by allelism.

PLXNB2 Mutations Are a Likely Cause of Congenital Anomalies of the Kidneys and Urinary Tract in Humans and Mice

Rufeng Dai,[1,2] Nina Mann,[1] Dervla M. Connaughton,[1] Shirlee Shril,[1] Chen-Han W. Wu,[3] Makiko Nakayama,[1] Franziska Kause,[3] Caroline M. Kolvenbach,[1] Thomas Worzfeld,[9] Carsten Höß,[7,8] Xuewu Zhang,[10] Julia Hoefele,[4] Korbinian M. Riedhammer,[5] Natasa Stajic,[6] Jia Rao,[2] Qian Shen,[2] Hong Xu,[2] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Children's Hospital of Fudan University, Shanghai, China; [3]Boston Children's Hospital/ Harvard Medical School, Boston, MA; [4]Klinikum rechts der Isar, Technical University of Munich, School of Medicine, Munich, Germany; [5]Technical University of Munich, Munich, Germany; [6]Institute for Mother and Child Health Care, Belgrade, Serbia, Belgrade, Serbia; [7]Institute of Pharmacology, BPC, University of Marburg, Marburg, Germany; [8]Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, Germany; [9]University of Marburg, Marburg, Germany; [10]University of Southwestern Medical Center, Dallas, TX.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) constitute the most common cause of end-stage renal disease in children, but the genetic causes of CAKUT remains largely elusive. Gene mutant mouse models are important research tools for human CAKUT, to date, 185 genes that if mutated causes murine CAKUT phenotypes is in the MGI database (http://www.informatics.jax.org). Most of them could also be a potential cause of CAKUT in humans.

Methods: To identify novel monogenic causes of CAKUT in humans, we performed whole exome sequencing (WES) in a worldwide cohort of 703 individuals with CAKUT. Based on the mode of inheritance in mice and pLI scores (Loss of function intolerant) in the ExAC database for the 185 murine CAKUT genes, we screened for variants in these genes in our CAKUT WES data to discover novel human candidate CAKUT genes. Functional studies were carried out to verify the pathogenesis of variants in these candidate genes.

Results: We identified 6 different heterozygous mutations in *PLXNB2* in 7 individuals from 6 unrelated families, one heterozygous mutation occurred *de novo*. Affected individuals exhibited a broad spectrum of CAKUT phenotypes, while, 77% of individuals exhibited syndromic features. With functional studies, we found mutations in *PLXNB2* destabilized the PLXNB2 protein, damaged the synthetic PLXNB2 protein transport, weakened the binding ability of the PLXNB2 protein to its receptor, Semaphorin 4, and influenced the cells migration and the activity of CDC42 and Ras in cells.

Conclusions: Our results support that mutations in *PLXNB2* are a novel cause of human syndromic CAKUT through defective cell migration via influencing the activity of CDC42-Ras or through defective Semaphorin-Plexin signaling.

FR-PO783

Mutations in UMOD Are Associated with FSGS and Can Be Mistaken for a Glomerular Disease

Justin Chun,[1,2] Minxian Wang,[3] Lihong Bu,[5] Martin R. Pollak.[4] *[1]University of Calgary, Calgary, AB, Canada; [2]BIDMC, Boston, MA; [3]Broad Institute, Cambridge, MA; [4]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [5]University of Minnesota, Minneapolis, MN.*

Background: Focal segmental glomerulosclerosis (FSGS) is a common histopathologically defined kidney lesion that can be observed with various underlying causes, including highly penetrant gene mutations. We recently identified pathogenic variants of *UMOD*, a gene encoding the tubular protein uromodulin, in seven families with suspected or biopsy proven FSGS.

Methods: We reviewed the clinical and pathology reports of seven families identified to have pathogenic variants of UMOD. Sanger sequencing of affected and unaffected to verify co-segregation with disease.

Results: Review of clinical records and pathology reports confirmed biopsy-proven cases of FSGS in 33% of patients with *UMOD* variants. The *UMOD* variants seen in these families were mutations previously reported in association with uromodulin associated kidney disease (UAKD). Consistent with the features for UAKD, most patients in our study presented with autosomal dominant inheritance, subnephrotic range proteinuria, minimal hematuria, and renal impairment. These patients with *UMOD* associated kidney disease did not have the classic clinical characteristics of gout, hyperuricemia, or presence of renal cysts on renal ultrasound. Kidney biopsies showed histologic features of glomerular injury consistent with secondary FSGS including focal sclerosis and podocyte foot process effacement.

Conclusions: Our study demonstrates that using our standard clinical testing using a kidney biopsy, patients with UAKD can be mistaken for FSGS since there are no specific histopathological features for UAKD. Genetic testing can clarify the diagnosis of UAKD with secondary FSGS. Genetic testing should be considered for families diagnosed as familial FSGS or hereditary glomerulonephritis of unclear etiology.

FR-PO784

Whole-Exome Sequencing Identifies Mutations in ARHGEF6 as a Potential Novel Monogenic Cause of Congenital Anomalies of the Kidney and Urinary Tract

Verena Klambt,[1] Youying Mao,[1] Florian Buerger,[1] Amar J. Majmundar,[1] Nina Mann,[1] Chen-Han W. Wu,[1] Mir Reza Bekheirnia,[2] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Baylor College of Medicine, Houston, TX.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are the most common cause of chronic kidney disease in the first 3 decades of life. Although over 40 monogenic genes have been implicated in human CAKUT so far, many causes remain elusive.

Methods: In order to identify novel monogenic causes of CAKUT we performed whole exome sequencing (WES) in 514 families with CAKUT.

Results: By WES, we discovered a missense mutation (p.I444N) in the X-linked gene *ARHGEF6* in 3 affected male subjects of family A5124 with CAKUT. Evaluation of our WES data of 514 unsolved CAKUT families revealed 3 further hemizygous *ARHGEF6* mutations in 3 families (family GM1: p.R191*; B1185: p.L387Afs*58; GM2: c.2135+4A>G, splice). Affected individuals exhibited a spectrum of CAKUT phenotypes that correlated in severity with the underlying mutation: renal agenesis, bladder exstrophy, VUR, PUV with hydronephrosis, renal hypoplasia and hypospadias. The 2 patients with loss-of-function mutations also had extrarenal features (cardiomyopathy; extra vertebra). No pathogenic variants in *ARHGEF6* were present in a control cohort of 100 NS and 258 NPHP cases. All variants, except p.I444N, were absent from gnomAD. *ARHGEF6* encodes a guanine nucleotide exchange factor for the small GTPases CDC42 and RAC1, and has been implicated in various biological functions including cell migration. Both small GTPases play a role in kidney development, such as the requirement of Cdc42 for normal tubulogenesis in ureteric bud and metanephric mesenchyme development (*J Cell Sci*; 128:4293, 2015). Overexpression in HEK293 cells of *ARHGEF6* wildtype cDNA, but not of patient mutants, activated CDC42 and RAC1, while *ARHGEF6* knockout cells reduced CDC42 activity.

Conclusions: We identified likely disease-causing mutations in *ARHGEF6* in 4 unrelated families with CAKUT. Our findings suggest that dysregulation of CDC42 or RAC1 via *ARHGEF6* dysfunction may cause CAKUT.

Recessive Mutations in TLN1, PAX, or ARHGEF17 Are Potential Novel Causes of Nephrotic Syndrome in Humans

Shazia Ashraf,[1] Makiko Nakayama,[1] Youying Mao,[1] Ronen Schneider,[1] Shirlee Shril,[1] Jameela A. Kari,[2] Neveen Soliman,[3] Friedhelm Hildebrandt.[1] *[1]Boston Childrens Hospital, Harvard Medical School, Boston, MA; [2]King abdulaziz University, Jeddah, Saudi Arabia; [3]Cairo University, Cairo, Egypt.*

Background: Steroid resistant nephrotic syndrome (SRNS) almost invariably progresses to end-stage kidney disease. Although more than 60 single-gene causes of SRNS are known, a large proportion remains unexplained. Recently, we identified mutations in *MAGI2*, *TNS2*, *DLC1* and *CDK20* genes as novel causes of NS (Ashraf *Nat Commun* 17:1960, 2018). Study of these proteins provided new insights into the pathogenesis of NS, linking into small GTPase 'RhoA' function.

Methods: We performed whole exome sequencing (WES) to identify novel monogenic causes of NS in >1,000 individuals with NS.

Results: We identified 4 different recessive mutations in 3 different genes *TLN1* (Talin1), *PAX* (Paxillin) and *ARHGEF17* (Tem4) in 4 unrelated families with NS. Specifically, in two individuals with NS, we identified a highly conserved homozygous *TLN1* mutation (family B3328, I1989del), or compound heterozygous mutations (family A3788, M79V and S1164W) in *TLN1*, which is known to interact with integrins and actin, and plays a role in activating integrins *via* its F3 N-terminal domain at focal adhesions. Knockout mice of *Tln1* have been previously shown to develop severe proteinuria, foot process effacement, and kidney failure. Additionally, we also discovered recessive homozygous mutations in *PAX* (family A3995, Y281H, conserved to *D. rerio*) and *ARHGEF17* (family A3658, V1883M, conserved to *C. elegans*). Interestingly, *TLN1*, *PAX* and *ARHGEF17* are highly expressed in podocytes and directly interact with *TNS2* and *DLC1*, which are both known to cause NS, if mutated. Talin1 and Tem4 are also known to specifically affect RhoA function *in vitro*.

Conclusions: We have identified mutations of *TLN1*, *PAX* and *ARHGEF17* as novel causes of NS. Our findings confirm that Rho-like small GTPase signaling is part of NS pathogenesis.

FR-PO786

Nos1ap-/- Mice Replicate the Human Nephrotic Syndrome Phenotype Potentially via a CDC42-Diaphanous-Related Mechanism

Florian Buerger,[1] Amar J. Majmundar,[1] Verena Klambt,[1] Ronen Schneider,[1] Konstantin Deutsch,[1] Ana C. Onuchic-Whitford,[1,2] Thomas M. Kitzler,[1] Youying Mao,[1] Shazia Ashraf,[1] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Department of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Steroid resistant nephrotic syndrome (SRNS) is the second leading cause of chronic kidney disease in the first three decades of life. We previously identified causative recessive mutations in *NOS1AP* in two SRNS families and demonstrated that *NOS1AP* mutations impaired CDC42 activation, podocyte migration rate (PMR) and filopodia formation (Majmundar, *JASN* 29:682, 2018). To further delineate the pathogenesis of SRNS due to *NOS1AP* loss-of-function, we generated a mouse model and performed additional cell culture studies.

Methods: Homozygous *Nos1ap*$^{ex3-/ex3-}$ C57Bl/6 mice, lacking *Nos1ap* exon 3 (*Int Heart J* 57:341, 2016), were screened monthly for proteinuria, and urine albumin-creatinine-ratios, BUN and serum creatinine levels were determined. We conducted live cell imaging in a human podocyte cell line under shRNA-mediated downregulation of *NOS1AP* and cDNA over-expression of *NOS1AP*, *CDC42* or *DIAPH3* as well as pharmacologic inhibition of DIAPH proteins (by SMIFH2).

Results: We examined *Nos1ap*$^{ex3-/ex3-}$ mice carrying biallelic *Nos1ap* Exon 3 deletion alleles for albuminuria. Mice developed albuminuria starting at the age of 5 months when compared to their wild-type and monoallelic littermates but had not developed renal failure by the age of 12 months. In a podocyte cell culture system we further studied the role of NOS1AP within the signaling pathway of CDC42 and its downstream effectors, the diaphanous proteins. Filopodia formation upon *NOS1AP* cDNA overexpression was assessed in the presence of the DIAPH protein inhibitor SMIFH2 and reduced in a dose-dependent manner similarly to prior CDC42 inhibiton by CASIN. Reversely, defective PMR, an established intermediate phenotype of SRNS, in *NOS1AP* shRNA-mediated knock-down podocytes was rescued by overexpression of *DIAPH3* cDNA and constitutively active CDC42.

Conclusions: We show that the human SRNS phenotype due to recessive *NOS1AP* mutations is replicated in *Nos1ap*$^{ex3-/ex3-}$ mice. We demonstrate that DIAPH function is part of the CDC42 mediated pathogenesis of SRNS due to *NOS1AP* loss-of-function.

FR-PO787

Mutations in the Diaphanous Related Formin DAAM2 as a Novel Cause of Nephrotic Syndrome

Ronen Schneider,[1] Konstantin Deutsch,[1] Gregory Hoeprich,[6] Daniela A. Braun,[2] Thomas M. Kitzler,[1] Youying Mao,[1] Amar J. Majmundar,[1] Florian Buerger,[3] Matias Wagner,[4] Korbinian M. Riedhammer,[4] Lutz Renders,[4] Shirlee Shril,[1] Julia Hoefele,[5] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]University Hospital of Muenster, Muenster, Germany; [3]Boston Children's Hospital, Harvard Medical School, Boston, MA; [4]Technical University of Munich, Munich, Germany; [5]Klinikum rechts der Isar, Technical University of Munich, School of Medicine, Munich, Germany; [6]Brandeis University, Waltham, MA.*

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is the second most frequent cause of end-stage renal disease in the first 3 decades of life. Identification of >55 monogenic causes of NS has rendered insights into disease mechanisms of NS (*Nat Rev Nephrol.* 12:133, 2016). Diaphanous related formins (DRF) regulate actin polymerization, filopodia and lamelipodia formation. The basal state interaction of the N-terminal DID domain with the C-terminal DAD domain is autoinhibitory and is relieved by conformational changes induced by GTPases. Accordingly, mutations in the DID domain of the formin gene, *INF2*, cause NS (*Nat Gen* 42:72, 2010).

Methods: To identify novel monogenic causes of NS we performed whole exome sequencing (WES) in a worldwide cohort of ~600 individuals with NS.

Results: In the three unrelated families (B1068, HN-F25, and HN-F627) with SRNS, we discovered three different homozygous mutations in the formin *DAAM2*: p.R335Q (located in the DID domain), p.S1027L (in the DAD domain), and p.R445* (terminating DAAM2 after the DID domain). All mutations are deemed disease causing by prediction programs and are absent homozygously and very rare heterozygously in the gnomAD database. We show that DAAM2 localizes to podocyte foot processes by immunofluorescence. In the podocyte migration rate assay (PMR), *DAAM2* knockdown by shRNA reduced PMR. PMR was rescued by overexpressing WT-DAAM2 cDNA but not by the cDNA representing the human missense mutations. In podocytes, filopodia formation was induced by overexpressing GFP-WT-DAAM2 cDNA but not by the cDNA representing the human missense mutations. Applying the formin activating small molecule IMM-01 caused filopodia formation in shRNA DAAM2-k.d. podocytes in a dose-dependent manner, and overcame the filopodia formation defect of mutant cDNA overexpression.

Conclusions: We here discovered mutations in the formin *DAAM2* as a novel monogenic cause of NS. We demonstrate that mutations of DAAM2 cause loss of filopodia formation and reduced PMR as intermediate phenotypes in NS, linking the pathomechanism to formin regulation. DAAM2 is likely a potential target for formin activating drugs.

FR-PO788

Recessive Mutations in Bassoon (BSN) Are a Potential New Cause of Nephrotic Syndrome

Ana C. Onuchic-Whitford,[1,2] Verena Klambt,[1] Florian Buerger,[1] Amar J. Majmundar,[1] Shazia Ashraf,[1] Ronen Schneider,[1] Konstantin Deutsch,[1] Youying Mao,[1] Tze Yin Lim,[3] Simone Sanna-Cherchi,[3] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Columbia University, New York, NY.*

Background: Steroid-resistant nephrotic syndrome (SRNS) is the second most frequent cause of chronic kidney disease in children and young adults. Major insights into its pathogenesis came from discovery of ~60 monogenic causes, contributing to ~12-30% of SRNS with onset <25 years of age. However, a significant proportion remains without a genetic diagnosis.

Methods: To identify novel pathogenic genetic variants, we performed whole-exome sequencing (WES) in a world-wide cohort of >800 individuals from different families with SRNS. We evaluated potential pathogenicity of genetic variants by in-silico prediction scores, evolutionary conservation and allele frequency in public genome sequencing databases.

Results: We identified 6 individuals from different families with recessive deleterious mutations in the *BSN* gene (bassoon). Two individuals harbored different homozygous mutations (p.S1481T and p.P3888L), while 4 had compound heterozygous mutations (p.R519W / p.T2829M; p.R3664Q / p.R1193H; p.P620L / p.K2697E; and p.P2503Afs*15 / p.H3716N). Age of SRNS onset was 7 months to >21 years old. Of 4 patients who underwent renal biopsies, 3 had focal segmental glomerulosclerosis, and 1 had minimal change disease. Four patients had extra-renal manifestations (microcephaly, atrial septal defect, short stature, seizures, and intellectual disability). Bassoon is a scaffolding protein found in the neuronal presynaptic plasma membrane, involved in priming of synaptic vesicles, assembly of active zones and localization of voltage-gated calcium channels (*Front Synaptic Neurosci* 7:19, 2015). Podocytes have been shown to contain structures resembling synaptic vesicles. Bassoon was previously identified in cultured podocytes and in kidney glomeruli by Western blot and immunohistochemistry (*FASEB J.* 20(7):976, 2006).

Conclusions: By WES, we here identify recessive mutations of *BSN* in 6 affected individuals, revealing a potential novel monogenic cause of SRNS.

Funding: NIDDK Support

FR-PO789

Recessive Mutations in TNS1 Are a Potential Novel Cause of Nephrotic Syndrome

Thomas M. Kitzler,[1] Ronen Schneider,[1] Konstantin Deutsch,[1] Youying Mao,[1] Shazia Ashraf,[1] Verena Klambt,[1] Amar J. Majmundar,[1] Florian Buerger,[1] Ana C. Onuchic-Whitford,[2] Iliana M. Cifuentes,[3] Randall M. Lou-Meda,[3] Angie L. Aguilar,[3] Neveen Soliman,[4] Arvind Bagga,[5] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Brigham and Women's Hospital / Boston Children's Hospital, Boston, MA; [3]Fundación para El Niño Enfermo Renal (FUNDANIER), Quetzaltenango, Guatemala; [4]Center of Pediatric Nephrology and Transplantation, Cairo University, Cairo, Egypt; [5]All India Institute of Medical Sciences, New Delhi, India.*

Background: Steroid resistant nephrotic syndrome (SRNS) is the second leading cause of chronic kidney disease in the first three decades of life. Using WES, we demonstrated that mutations in one of the 59 known SRNS genes can be identified in 25% of patients (*NDT*, 2019 doi: 10.1093/ndt/gfz028).

Methods: To discover additional monogenic causes of NS, we performed WES in a cohort of 600 families with childhood onset SRNS.

Results: We identified rare compound heterozygous missense mutations in the *TNS1* gene in five individuals from four unrelated families with NS: family **B2014:** p.R1198Q and p.R940Y; **A1226:** p.I224N and p.D66V; **A4619:** p.S1098R and S920C, **A4580:** p.T218I and p.A1685T. TNS1 is known to interact with actin, to bind to β1-integrin and serve as a scaffold for adhesion-related signaling. Specifically, it enhances RhoA activity in a DLC1-dependent manner through its multiple domains (*BBA* 1853:3258, 2015). We found that the p.T218I (PTEN_C2 domain) and p.A1685T (PTB domain) mutations are predicted to reduce overall protein domain stability, while the highly conserved p.D66V mutation is predicted to destabilize the PTEN_C2 domain (http://cupsat.tu-bs.de/). The two siblings in our index family (B2014) presented with a history of proteinuria. In addition, sibling B2014_21 had renal hypoplasia and lack of corticomedullary differentiation on renal ultrasound, while B2014_22 had increased renal echogenicity with prominence of the renal papillae. Notably, *tensin*$^{-/-}$ mice have renal failure, proximal tubule cysts with disrupted cell-matrix junctions in non-cystic areas, tubulointerstitial nephritis, glomerulosclerosis, and abnormal renal papillae (*JCB* 136:1349, 1997). Employing immunofluorescence in sections of healthy rat glomeruli, we demonstrated primarily mesangial localization of TNS1, which is corroborated by single-cell RNA expression data in mice glomeruli (*JASN* 29:2060, 2018).

Conclusions: We identified likely disease-causing mutations in *TNS1* in four unrelated families with NS, revealing a novel monogenic cause of human glomerular disease.

Recessive Mutations in SYNPO2 May Cause Nephrotic Syndrome via Mesangial Cell Dysfunction

Youying Mao,[1] Ronen Schneider,[1] Shazia Ashraf,[1] Amar J. Majmundar,[1] Verena Klambt,[1] Thomas M. Kitzler,[1] Makiko Nakayama,[1] Florian Buerger,[1] Konstantin Deutsch,[1] Ana C. Onuchic-Whitford,[3,1] Hanan E. Shamseldin,[4] Fowzan S. Alkuraya,[4] Hanan Fathy,[2] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]El Shatty Children's Hospital, Alexandria, Egypt; [3]Brigham and Women's Hospital / Boston Children's Hospital, Boston, MA; [4]King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia.*

Background: Steroid resistant nephrotic syndrome (SRNS) is the second leading cause of chronic kidney disease in the first three decades of life. So far mutations in 60 genes were identified to cause steroid resistant nephrotic syndrome (SRNS).

Methods: To identify novel monogenic causes of NS we performed whole exome sequencing (WES) in a cohort of 1,200 NS patients. To study the functional significance of mutations found, podocyte migration rate (PMR) and active Rac1 GLISA assay were performed in a human podocyte cell line.

Results: In 3 unrelated patients with childhood onset nephrotic syndrome (NS) we discovered 1 homozygous truncating and 2 homozygous missense mutations in *SYNPO2* (p.K1124*, p.G413S, and p.A1134T). From the 3 types of renal glomerular cells, the *SYNPO2* transcript is expressed 10 fold higher in mesangial cells than in podocytes or endothelial cells (*JASN* 29: 2060, 2018). Accordingly, by immunofluorescence (IF) in adult rat sections, SYNPO2 localized most strongly to mesangial cells. By IF, on the subcellular level, SYNPO2 colocalizes with F-actin. Upon overexpression in podocytes, SYNPO2 colocalizes also with ACTN4, a gene that is mutated in autosomal dominant SRNS in humans. *SYNPO2* shRNA knockdown reduced podocyte migration rate (PMR) in a human podocyte cell line. PMR was rescued by transfection of wild type mouse *SYNPO2* cDNA but not by cDNA representing any of the 3 mutations from patients with NS. *SYNPO2* shRNA knockdown in the podocyte cell line decreased active Rac1, which was rescued by transfection of wild type *SYNPO2* cDNA but not by cDNA representing any of the 3 mutations from patients with NS.

Conclusions: We here discovered recessive *SYNPO2* mutations as a novel monogenic cause of nephrotic syndrome, leading to mesangial cell dysfunction through Rac1-GTPase dysregulation.

FR-PO791

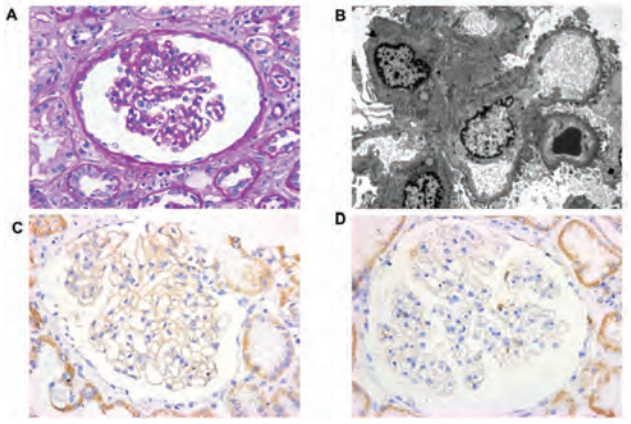
First Identification of a Rare PODXL Splice Site Mutation in a Case of Focal Segmental Glomerulosclerosis

Fujun Lin.[1,2] *[1]Renal Division, Department of Internal Medicine, Xin Hua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai, China; [2]Centre for Rare Diseases, Shanghai, Shanghai, China.*

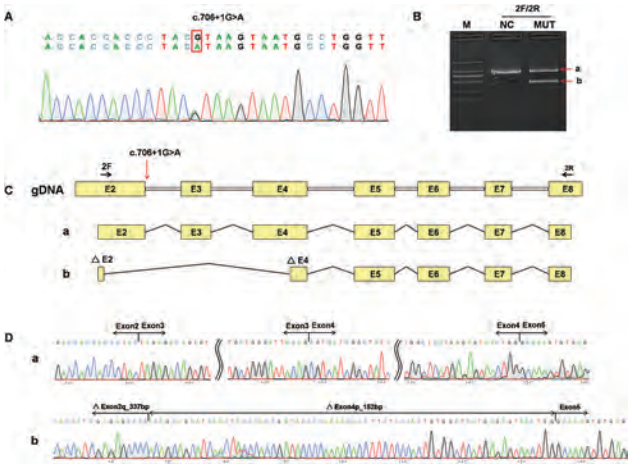
Introduction: Podocalyxin plays an important role in the regulation of podocyte morphogenesis and function. We recently identified heterozygous *PODXL* nonsense mutations linked to autosomal dominant focal segmental glomerulosclerosis (FSGS). Here, we reported the first heterozygous *PODXL* splice site mutation identified in FSGS.

Case Description: A 63-year-old Chinese female was admitted to the ward in December 2018 for persistent proteinuria (maximum 2500mg/24hr) and hypertension (140/90mmHg) for three months. Serum creatinine and albumin were within normal range and renal ultrasound revealed normal sized and echogenic kidneys. Renal biopsy suggested FSGS (Figure 1A-1B). Father of the patient was died of renal failure and no history of renal disease found in other close relatives. Whole exome sequencing performed on the patient revealed a *PODXL* heterozygous donor splice site variant (c.712+1G>A, rs137907090, allele frequency 0.0002) (Figure 2A), leading to the 585bp deletion including exon 3, the last 337 nucleotides on exon 2 and the first 152 nucleotides on exon 4 (Figure 2B-D). This mutation removed 195 amino acids in-frame in the sialomucin domain. Immunohistochemical showed decreased podocalyxin expression along glomerular capillary (Figure 1C) compared with that of normal control (Figure 1D). Losartan was started and at last follow up in May 2019, 24hr proteinuria was 1500mg and serum creatinine remained within normal range.

Discussion: This case expands the genetic spectrum of *PODXL*-associated FSGS and further supported that down-regulation of podocalyxin expression linked to FSGS.



Representative microscopic images of the patient.



Mutation and its consequences.

Nephrin Mutation in Childhood-Adult Onset Nephrotic Syndrome (NS)

Manish K. Saha,[1] Candace D. Henderson,[1] Keisha L. Gibson,[1] Dominic J. Ciavatta,[2] Vimal K. Derebail,[2] Ronald J. Falk.[1] *[1]UNC Kidney Center, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC.*

Background: Nephrin, a slit diaphragm protein, is essential to integrity of podocyte structure. Mutations in the nephrin gene, *NPHS1*, typically result in *congenital* NS. Variants causing similar disease in later childhood and adults are rare. We believe our family is the first case report in which all members of the family have this mutation. A 18-year-old Caucasian female was referred for steroid and calcineurin inhibitor resistant NS. Her first renal biopsy was at age 7 due to proteinuria with normal renal function and blood pressure. All 18 sampled glomeruli and interstitium appeared normal by light microscopy (LM), but electron microscopy (EM) showed partial foot process effacement. Repeat biopsy at age 18 when eGFR < 30 ml/min/1.73m^2 showed focal segmental glomerulosclerosis, not otherwise specified (FSGS-NOS). She received Rituximab as attempted salvage therapy. Renal function deteriorated further and she reached end-stage disease by age 19. Her brother, at age 16, was evaluated and had nephrotic range proteinuria with preserved renal function. His renal biopsy showed 37 normal glomeruli by LM, with global activation of foot processes and effacement by EM. With consent, both patients and their parents (without proteinuria) were tested for a podocyte mutation

Methods: Genomic DNA was extracted from peripheral blood cells and genotyped for coding sequence variants in the *NPHS1* gene in 9 healthy controls and the current family.

Results: No homozygous variants in *NPHS1* were detected in 9 healthy controls. The 2 children were homozygous for a pathogenic variant in *NPHS1* c.2928G>T [p.Arg976Ser]. Both parents were heterozygous for this variant, representing a possible carrier-state. This mutation, a missense single nucleotide variation in exon 22, may affect mRNA splicing in the fibronectin domain of nephrin

Conclusions: We report two cases of childhood-onset proteinuria due to a *NPHS1* missense mutation, with autosomal recessive inheritance. Renal pathology probably begins as a podocytopathy that slowly progresses to segmental glomerular sclerosis and renal impairment. NS due to genetic mutations may be resistant to conventional immunosuppressive therapy. Genetic testing may direct limitation of immunosuppression with minimal therapeutic benefit and inform counseling to future progeny

FR-PO793

Whole-Exome Sequencing in 33 Families with VACTERL or VACTERL-Like Phenotype Identifies Potential New Candidate Genes

Caroline M. Kolvenbach,[1,2] Amelie Van der ven,[1,3] Franziska Kause,[1,2] Shirlee Shril,[1] Dervla M. Connaughton,[1] Nina Mann,[1] Makiko Nakayama,[1] Rufeng Dai,[4] Gabriel C. Dworschak,[2,5] Alina Hilger,[2,5] Heiko M. Reutter,[2,5] Friedhelm Hildebrandt.[1] *[1]Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Department of Pediatrics, University of Bonn, Children's Hospital, Bonn, Germany; [3]UKE Hamburg-Eppendorf Germany, Hamburg, Germany; [4]Boston Children's Hospital/Children's Hospital of Fudan University, Boston, MA; [5]Institute of Human Genetics, University of Bonn, Bonn, Germany.*

Background: VACTERL association describes the combination of congenital anomalies including vertebral defects (V), anorectal malformations (A), cardiac defects (C), tracheoesophageal fistula with or without esophageal atresia (TE), renal malformations (R), and limb defects (L). Involvement of genetic factors in its pathogenesis is supported by reports of familial segregation, but only four likely monogenic causes have been suggested (*FOXF1, HOXD13, PTEN, ZIC3*).

Methods: We performed unbiased whole exome sequencing (WES) to identify monogenic or digenic causes in 33 families with VACTERL or VACTERL-like phenotype.

Results: We evaluated the WES data for causative mutations in 3 different groups of known or candidate VACTERL genes: i) mutations in the 4 known VACTERL genes *FOXF1*, *HOXD13, PTEN* and *ZIC3*, ii) in 108 VACTERL candidate genes of the Shh or Wnt pathway, and iii) in 58 syndromic human CAKUT genes. In addition, we evaluated WES data for mutations in potential novel VACTERL genes under 5 different monogenic hypotheses: iv) recessive, v) dominant, vi) *de novo*, vii) digenic dominant or viii) digenic recessive mutations. We detected no mutation in any of the 4 known VACTERL genes (above group i). In group ii we detected potential mutations in 11 different genes. In group iii we detected potential mutations in 13 genes. When evaluating for potential novel VACTERL genes, we identified recessive (group iv, n=4, *B9D1, CORO7, TTLL11, NKX2-3*), dominant (group v, n=5), *de novo* (group vi, n=1), digenic dominant (group vii, n=11) and digenic recessive mutations (group viii, n=3). Overall, we detected mutations in 25/33 families in 44 genes (17 had more than one potential gene). Interestingly, in 7 individuals at least one mutation in a known gene for syndromic CAKUT together with a second mutation in another syndromic CAKUT or VACTERL candidate gene could be found. Array-based molecular karyotyping revealed no copy number variants in any of the 33 families.

Conclusions: This study establishes that WES can identify mutations in potential candidate genes in 76% of families with VACTERL or VACTERL-like phenotype. Furthermore, WES shows a potential digenic mode of inheritance in 51% of our cohort.

FR-PO794

Variable Penetrance of the Therapy-Resistant Phenotype Among Children with the Genetic Form of Nephrotic Syndrome

Jennifer Lai Yee,[1] Jarcy Zee,[2] Damian Fermin,[1] Michelle Mcnulty,[1] V. Vega-Warner,[1] Matt G. Sampson.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Currently, genetic forms of nephrotic can be classified as highly penetrant, pathogenic variants in single genes ("monogenic") or common risk alleles contributing to the diseases pathogenesis such as *APOL1* high-risk (HR) genotypes. Monogenic NS is thought to be therapy-resistant, with an inability to achieve complete remission (CR) and *APOL1* NS has a lower odd of achieving CR. However, there have been reports that some patients with monogenic diseases may achieve CR. Factors associated with remission among genetic NS is still unclear. Therefore, this study used a large North American cohort of children with NS to (1) describe the prevalence of CR as a function of genetic profile and (2) identify factors potentially modifying the CR phenotype.

Methods: 70 genes implicated in monogenic forms of NS and the two *APOL1* risk alleles were analyzed in 215 children from the Nephrotic Syndrome Study Network (NEPTUNE) who had undergone whole genome sequencing. A variant pathogenicity pipeline was applied to identify patients with putative monogenic NS and *APOL1* HR genotypes. General characteristics and CR were compared among patients classified with putative monogenic NS, *APOL1*-attributed NS, and no know genetic form of NS.

Results: Monogenic NS was found in 15 patients (7%) and *APOL1* attributed NS was found in 28 patients (13%). Compared to no known genetic NS, monogenic and *APOL1* attributed NS had lower rate of ever achieving CR (83% vs 43% and 59%, p=0.002 and 0.01, respectively) and lower likelihood to achieve remission (Hazard ratio 0.4 for both, p = 0.02 and 0.009, respectively, at 6 months of follow up). Loss of function Mendelian variants and those co-existing with other Mendelian variants or *APOL1* HR genotype, tended to result in lack of CR.

Conclusions: Children with monogenic or *APOL1* attributed NS were significantly less likely to achieve CR. Despite this, a substantial proportion of children with genetic forms of NS still achieved CR. Mendelian variants and *APOL1* HR alleles in this North American, population-based NS cohort appear to increase risk of not achieving CR, rather than being fully penetrant for this phenotype. Further functional analysis is essential in increasing the accuracy of classifying patients with monogenic NS and making subsequent clinical correlations.

FR-PO795

Genotype-Phenotype Correlation for the COL4A3 2881+1 G>A Founder Mutation in the Croatian Population

Danica G. Ljubanovic,[1] Matija Horacek,[3] Tamara Nikuseva-Martic,[8] Petar Senjug,[6] Marija Senjug Perica,[7] Maja Oroz,[8] Dragan Klaric,[2] Marijan Saraga,[4] Danko Milosevic,[5] Kresimir Galesic.[9] *[1]University of Zagreb School of Medicine, Clinical Hospital Dubrava, Zagreb, Croatia; [2]General Hospital Zadar, Zadar, Croatia; [3]School of medicine, University of Zagreb, Karlovac, Croatia; [4]University Hospital in Split, Split, Croatia; [5]Zagreb School of Medicine, Clinical Hospital Centre Zagreb, Zagreb, Croatia; [6]University Hospital Dubrava, Zagreb, Croatia; [7]Children's Hospital Srebrnjak, Zagreb, Croatia; [8]School of Medicine, University of Zagreb, Zagreb, Croatia; [9]Dubrava University Hospital, Zagreb, Croatia*.

Background: Alport syndrome (AS) and thin glomerular basement membrane nephropathy (TBMN) are genetically heterogenic disorders caused by mutations in COL4A3, COL4A4 and COL4A5 genes. Genetic heterogeneity with various types and number of mutations with no mutational "hot spots" can make diagnostic process challenging. Some type of mutations increase the likelihood of a severe phenotype but recent studies also showed that same mutations can result in different clinical presentation.

Methods: Total of 26 patients from 10 unrelated families with heterozygous for COL4A3 splice donor 2881+1 G>A mutation detected by next generation sequencing (Illumina MiSeq platform) for COL4A3, COL4A4 and COL4A5 genes mutations was tested as part of a project "Genotype-Phenotype correlation in Alport's syndrome and Thin Glomerular Basement Membrane Nephropathy" founded by the Croatian Science Foundation. There were 11 females and 15 male patients, age range 5-72 years (median 44 years).

Results: According to available clinical data majority of patients (88,5%) presented with haematuria and 72,7% with proteinuria. Decline in kidney function was present in 65% of patients; 40% being mild, 15% severe and 10% suffered from end stage renal disease (2 transplanted patients). Three patients had sensorineural hearing impairment. Kidney biopsy was performed in 50% of cases. On light microscopy focal segmental sclerosis was present in 30% of specimens, whereas, electron microscopy showed TBMN in 40%, TBMN with focal lamellation in 20% and changes suggestive of AS (Figure 1) in 40% of patients.

Conclusions: Here we present genotype-phenotype correlation for COL4A3 2881+1 G>A founder mutation in Croatian population showing clinical and pathohistological heterogeneity. Therefore, identification of modifiers causing such heterogeneity is of grave importance for better understanding of collagen IV nephropathies.

FR-PO796

A Case of Autosomal Dominant Alport Syndrome with a Gene Variant of ESPN, a Hearing Loss-Causative Gene, That Was Diagnosed by Whole-Exome Analysis

Yu Nagayoshi, Yuichiro Izumi, Ami Hamaguchi, Rei Miura, Terumasa Nakagawa, Miyuki Nakagawa, Yutaka Kakizoe, Masashi Mukoyama. *Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan*.

Introduction: Alport syndrome (AS) is a rare hereditary disease that presents with chronic kidney disease and sensorineural hearing loss and is diagnosed by its clinical features, pathological features on renal tissue, and mode of inheritance. AS has three genetic modes of heredity: X-linked, autosomal recessive, and autosomal dominant. Because the clinical and pathological features of autosomal dominant AS are much milder than those of the other two modes of heredity, definitive diagnosis is difficult.

Case Description: We report a woman in her 20s who exhibited persistent haematuria with normal renal function and sensorineural hearing loss. Her family members exhibited the same clinical findings among three generations and were suspected of having autosomal dominant AS (ADAS). Renal biopsy showed minor glomerular abnormalities on light microscopy and extensive thinning of the glomerular basement membrane on electron microscopy. Whole-exome analysis revealed a missense variant on c. 2510 G > C (p. Gly837Ala) in COL4A4 (type IV collagen α4). Two cases with the same variant have been reported previously, one as ADAS and the other as autosomal recessive AS. However, these two cases exhibited no sensorineural hearing loss. The analysis in the present case revealed another missense variant in ESPN (Espin), an actin-bundling protein, which is a causative gene for sensorineural hearing loss. Although the pathophysiological significance of such missense variant needs to be clarified, computational analysis predicted that the variant creates a new phosphorylation site for protein kinase C.

Discussion: By applying whole-exome analysis, we confirmed the diagnosis of ADAS for the present case. Our case suggests a possible association of hereditary sensorineural hearing loss with ADAS. When a suspicious hereditary disease exists, direct sequencing of the gene is usually performed. Although direct sequencing of the specific gene is crucial for diagnosis, other possible mutations may be missed. Whole-exome analysis should be considered as a method to diagnose hereditary and multiple-organ disorders.

FR-PO797

Reassessing the Pathogenicity of p.G953V in COL4A5 Gene: Report of 19 Chinese Families

Yanqin Zhang, Fang Wang. *Peking University First Hospital, Beijing, China*.

Background: X-linked Alport syndrome (XLAS) is an inherited renal disease caused by mutations in *COL4A5* gene. The p.G953V variant in *COL4A5* gene is considered pathogenic previously. However, there is conflicting of its pathogenicity recently. Here we reported 19 Chinese families with the p.G953V in *COL4A5* to evaluate its pathogenicity.

Methods: Families were selected from the on-line registry database of hereditary kidney diseases in children in China, according to the following two criteria a) cases with gene mutations tested by targeted next generation sequencing (NGS); b) cases with the p.G953V in *COL4A5*. The clinical data and genetic findings were collected and analyzed.

Results: Fifty-one individuals from 19 families were enrolled, out of which 36 (18 probands and 18 family members) carried p.G953V. We found there were no clinical features of XLAS not only in the 6 probands with p.G953V and pathogenic variants in other genes (e.g. *WT1*, *ADCK4*, *NPHP1*, *TRPC6*, *COL4A4* and *PAX2*) but also in another 6 probands with only the p.G953V. The other 6 probands, with a combination of p.G953V and another pathogenic variant in *COL4A5* had XLAS. Eleven family members (11/18, 9 females and 2 males) who had the p.G953V variant only were asymptomatic. These two males had normal result of urine analysis (at age of 42 and 35 years) and no more clinical traits of Alport syndrome.

Conclusions: The p.G953V in *COL4A5* gene is not a pathogenic mutation for XLAS. Individuals should not be diagnosed as XLAS only based on the detection of p.G953V in *COL4A5* gene.

FR-PO798

β2 Adrenergic Signaling Regulates a New OPN-LDLR-βPix-Rac1 Multimolecular Complex in Alport Syndrome

Keyvan Yousefi,[1,2] Ahmed Chahdi,[3] Krista John-Williams,[3] Guerline Lambert,[3] Camila Irion,[3] Melina Ramic,[1] Nadja S. Andrade,[4] Zane Zeier,[4] Michael Freundlich,[5] Lina Shehadeh.[2,3] *[1]Department of Molecular and Cellular Pharmacology, University of Miami Miller School of Medicine, Miami, FL; [2]Interdisciplinary Stem Cell Institute, University of Miami Miller School of Medicine, Miami, FL; [3]Department of Medicine, University of Miami Miler School of Medicine, Miami, FL; [4]Department of Psychiatry and Behavioural Sciences, Center for Therapeutic Innovation, University of Miami Miller School of Medicine, Miami, FL; [5]Division of Pediatric Nephrology, University of Miami Miller School of Medicine, Miami, FL*.

Background: Alport syndrome is a rare hereditary renal disorder with no cure. Our group showed that Osteopontin (OPN) and low density lipoprotein receptor (LDLR) are highly expressed in the renal tubular epithelial cells (TECs) of the *Col4a3*$^{-/-}$ Alport mouse and play causative pathological roles. We showed that Alport kidneys had more epithelial to mesenchymal transition (EMT) and cholesterol accumulation in TECs, both phenotypes ameliorated by OPN deficiency. However, the molecular mechanisms involved are unknown.

Methods: Immunoprecipitation and cholesterol influx assays were used in human renal TEC line (HK2) with β_2AR agonism/antagonism. *Ksp*-Cre mosaic analysis with double marker (MADM) mice were used to track EMT in Alport mice. CD44 was measured by immunostaining in Alport Kidneys, and by western blot in HK2 cells treated with OPN monoclonal antibody (mAb) to quantify EMT. PBMCs from Alport patients and healthy donors were used to generate iPSCs which were differentiated into KSP+ve TECs.

Results: In HK2 cells, OPN interacts with LDLR and the Rac1 guanine exchange factor βPix to form a multi-molecular complex controlled by β_2AR signaling. Stimulating HK2 cells with adenylate cyclase activator forskolin or β_2AR selective agonist salbutamol, decreased cholesterol influx by 15.4% and 17.4%, respectively-p<.0001. Conversely, treating HK2 cells with Rac1 inhibitor NSC23766, PKA inhibitor H89, or selective β_2AR antagonist butoxamine significantly increased cholesterol influx -p<.05. OPN mAb blocked the Rac1 inhibitor effect, indicating the role of OPN in this complex. MADM mice showed that EMT in Alport kidneys is of tubular origin as was confirmed by excessive staining of interstitial CD44 (N=3 mice/group-p<.05). OPN mAb caused a 30% decrease in CD44 protein levels (N=3/group-p<.05). iPSC-TECs were functional in the cholesterol assay.

Conclusions: We conclude that elevated OPN in Alport TECs blocks cAMP production and reduces OPN binding to LDLR, thereby freeing LDLR to increase LDL cholesterol influx and drive EMT. OPN knockout or β2AR stimulation increases cAMP-mediated sequestration of LDLR by OPN-βPix complex that blocks LDLR function. Alport patient iPS-TECs may be a useful screening platform to identify β2AR stimulants regulating cholesterol influx.

FR-PO799

Antenatal Membranous Nephropathy and Axonal Charcot-Marie-Tooth Type 2 with c.466delC Mutation in the Metallo-Membrane Endopeptidase Gene: A Warning Signal About Long-Term Use of Neprilysin Inhibitors

Joelle L. Nortier,[1,2] Gauthier Remiche,[3,6] Michel Dupuis,[5] Hanna Debiec,[7] Pierre M. Ronco.[4] Agnès *[1]Hospital Erasme, Brussels, Belgium; [2]Laboratory of Experimental Nephrology, Erasme, Université Libre de Bruxelles, Brussels, Belgium; [3]Neurology, Erasme, Université Libre de Bruxelles, Brussels, Belgium; [4]INSERM UMR_S1155, Hospital Tenon, Paris, France; [5]Neurology, Sint Peter Clinic, Ottignies, Belgium; [6]Reference Center for Neuromuscular Disorders, Erasme, Université Libre de Bruxelles, Brussels, Belgium; [7]INSERM UMR_S1155, Tenon Hospital, Paris, France*.

Background: First cases of truncating mutations in the *neprilysin/metallo-membrane endopeptidase (MME)* gene were identified in 2002 as the cause of alloimmunization during pregnancy, resulting in moderate to severe forms of antenatal membranous nephropathy (MN). Ten years later, two sisters and one brother of the originally reported Moroccan family, found homozygous for the c.466delC mutation in the *MME* gene, developed rapid motor and sensory neurological disorders, leading to the diagnosis of axonal Charcot-Marie-Tooth (CMT2). We report here the description of clinical and electrophysiologic investigations.

Methods: Clinical features and ancillary test results were collected from laboratory database and patient charts. Electrodiagnostic tests were carried out by standard techniques with surface electrode recording.

Results: Patient 1 had experienced antenatal MN during her second pregnancy at the age of 23 years. She presented with vasomotor painful episodes and progressive muscle weakness of the lower limbs at the age of 33 years. Two years later, she developed progressive gait disturbances, distal lower limb weakness with foot drop and frequent falls. This was improved by foot orthotics. Neurological examination revealed moderate muscle atrophy of the 4 limbs associated with distal sensory loss. Patient 2, her sister, had a prior history of antenatal MN (at the age of 31 years) and autoimmune thrombocytopenic purpura with a long-term corticosteroid treatment. She presented with falls at the age of 44 years and subsequently broke her foot needing osteosynthesis. First neurologic manifestations of Patient 3, their brother, were painful nocturnal cramps at the age of 30 years. All these patients had normal kidney function parameters and exhibited a typical CMT2 phenotype being demonstrated by the clinical picture and electrodiagnostic test results.

Conclusions: This is the first family associating renal and neurological abnormalities linked to *MME* gene mutation. This observation confirms that neprilysin/*MME* is involved in peripheral nerve functioning. Neurological surveillance is recommended in prolonged treatment with neprilysin inhibitors.

FR-PO800

Renal Lesions Associated with MYH9 Disorder (5773delG Mutation): Clinical and Pathological Analyses

Kazuhiro Yoshikawa,[1] Shinji Kunishima,[3] Hidetake Kurihara,[2] Kei Takahashi,[4] Izaya Nakaya,[1] Jun Soma.[1] *[1]Iwate Prefectural Central Hospital, Morioka-city Iwate, Japan; [2]Aino University, Ibaraki, Japan; [3]Gifu University of Medical Science, Seki, Japan; [4]Toho University Ohashi Medical Center, Tokyo, Japan*.

Introduction: *MYH9* mutations at C-terminal, such as exon 40, have not been reported to cause renal injuries. This is the first report of renal phenotype with *MYH9* exon 40 5773delG mutation. Of note, focal segmental glomerulosclerosis (FSGS) could occur even in association with *MYH9* exon 40 5773delG mutation. Accumulation of abnormal Non-muscle myosin heavy chain IIA (NMMHC-IIA) in podocytes may lead to podocyte injuries and development of FSGS lesions.

Case Description: A 37-year-old Japanese man with persistent urine abnormalities and gradually progressive renal dysfunction was admitted to hospital; his mother and two sons had giant platelets. Renal biopsy was postponed 8 years ago because he had thrombocytopenia. Laboratory data showed serum creatinine, 2.45 mg/dL; urine protein, 6 g/gCr; urine red blood cells, 36 /high-power field; and platelets, 47,000 /μL. May–Hegglin anomaly was suspected owing to macrothrombocytopenia and cytoplasmic Döhle-like inclusion bodies in granulocytes; he had bilateral cataracts and hearing loss in the 4000-Hz range. On renal biopsy, 13 glomeruli were microscopically examined: 6 showed global sclerosis and others showed mild mesangial proliferation with segmental glomerulosclerosis. On immunofluorescence examination, IgG, IgA, IgM, C1q, and C3 deposits were observed in the mesangium; α2, 5 chain staining in basement membranes showed normal pattern. Foot process effacements and intense bleb-like morphological changes in podocytes were observed via electron microscopy. Electron dense deposits in certain mesangial areas and no Alport's basement membrane changes were found. NMMHC-IIA staining in spots pattern was observed via immunofluorescence examination of granulocytes. *MYH9* 5773delG (G1924fs) mutation was found via genomic DNA sequencing. These findings and ineffective steroid therapy led to the possible diagnosis of FSGS associated with MYH9 disorder.

Discussion: On further pathological analyses, double staining of vimentin and NMMHC-IIA showed decreased colocalization of NMMHC-IIA in cell bodies and primary processes of podocytes. Podocytes were significantly stained by an antibody specific to abnormal NMMHC-IIA produced by *MYH9* 5773delG mutation; this was not observed in glomeruli of patients without the mutation. We finally diagnosed the patient with FSGS associated with MYH9 disorder.

FR-PO801

Features of Glomerulopathy with Fibronectin Deposits

Jiwon M. Lee,[1] Yo Han Ahn,[2] Hee Gyung Kang,[3] Dae Eun Choi,[1] Beom Jin Lim,[5] Jung Tak Park.[4] *[1]Chungnam National University, Seoul, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [3]Seoul National University Children's Hospital, Seoul, Republic of Korea; [4]Yonsei University Health System, Seoul, Republic of Korea; [5]Yonsei University College of Medicine, Seoul, Republic of Korea*.

Background: Glomerulopathy with fibronectin deposits (GFND; OMIM: 601894) is a rare inherited kidney disorder characterized by massive fibronectin deposits, leading to end-stage renal disease (ESRD). Differential diagnosis of GFND from other immunotactoid glomerulopathy is important in treatment. We systematically reviewed and analyzed clinical features and genotypes of patients with GFND.

Methods: Electronic databases were searched using related terms (till May 30th, 2019). This report adhered to the Preferred Reporting Items for Systematic Reviews and Meta-analyses guidelines.

Results: From 1633 articles searched, there were 23 eligible studies with 86 patients with GFND from 44 families. Female patients were 40% (34/86) and most (70/83, 84%) patients had family history. 33 patients (38%) had hematuria and 38(47%) had nephrotic proteinuria. Median age at onset was 14.5 years for hematuria and 24 for proteinuria. Half of the patients had hypertension (18/35, 51%). ESRD was reported in 22 out of 68 patients (26%) at 34 median years. Of the 50 patients available for pathology reports, most patients showed negative immunofluorescence stains and fibrillary deposit in the electon-microscopy with the fibrils sized 9-14 nm in diameter. 42 patients underwent genetic tests for *FN1* and 3(8%) had no mutation. Of the 39 with *FN1* mutation, and 35 (35/39, 89%) had a missense mutation, 3 (8%) had deletion, and 1 had an intronic mutation. Mostly affected was the heparin-binding site where 92% (32/39) of the mutations occurred. c.2918A>G was the most commonly reported mutation. There was no genotype-phenotype correlation in this study.

Conclusions: GFND may proceed to ESRD at third decade of life. Hypertension and nephrotic syndrome are often accompanied. Some patients with GFND may present without family history and may be negative for *FN1* mutation.

Funding: Government Support - Non-U.S.

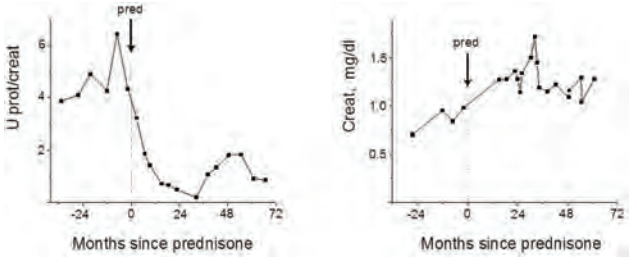
Prednisone Reduced Proteinuria and Stabilized Serum Creatinine in a Patient with Familial Fibronectin Glomerulopathy

Daniel A. Gray, Bruce Goldman, Matthew D. Gross. *University of Rochester, Rochester, NY.*

Introduction: Fibronectin Glomerulopathy (FNG) is a rare, autosomal dominant disease characterized by proteinuria, hematuria and progressive renal failure associated with glomerular deposition of fibronectin, typically leading to ESRD in the 2nd to 6th decade. There is no established treatment for this condition beyond conservative measures such as blood pressure control and use of ACE inhibitors. We present a case of FNG associated with progressive CKD and nephrotic range proteinuria showing a sustained response to prednisone treatment.

Case Description: A 27 year old G_2P_2 female presented with 3 g of proteinuria, serum creatinine 0.7 mg/dl, inactive urinary sediment and normotension without medication. She was part of a large family with glomerular disease, including 3 members who died of cerebral hemorrhage or stroke in their thirties. The patient's kidney biopsy showed mesangial deposition of fibronectin consistent with FNG. No interstitial fibrosis was seen. Genotyping revealed the Y973C fibronectin gene mutation. Despite maximal tolerable ACE inhibition, proteinuria increased to 4-6 g/g creat and serum creatinine increased to 1.0 mg/dl. Based on its use in IgA nephropathy, she was treated with prednisone 60 mg (~1 mg/Kg) for 2 mos, tapering by 20 mg every 2 mos. Proteinuria decreased to ~1 g/g creat for > 5 yrs and creatinine stabilized in the 1.2 mg/dl range with treatment. No significant side effects were encountered.

Discussion: Prednisone induced a sustained response in this patient. This is one of the first reports of effective treatment of FNG with immunosuppressive therapy. In conclusion, this protocol should be considered in FNG patients with nephrotic range proteinuria despite maximal ACE/ARB inhibition who have relatively preserved renal function.



Prednisone reduced proteinuria and stabilized serum creatinine

FR-PO803

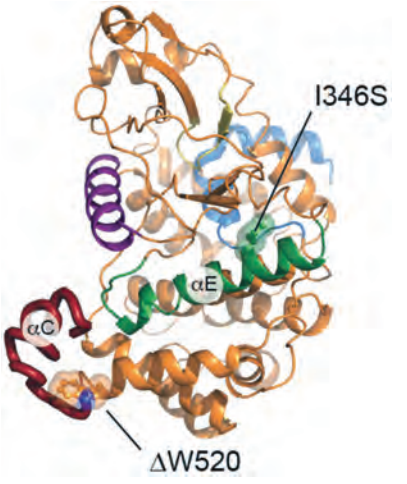
Mechanism of Mutation of AarF Domain-Containing-Kinase 4 (ADCK4) Glomerulopathy

Asmaa S. Abu-Maziad. Tomiask Lab *Department of Pediatrics, Tucson, AZ.*

Introduction: AarF domain-containing-kinase 4 (ADCK4) is a mitochondrial resident protein kinase belonging to the UbiB protein kinase-like family. ADCK4 is thought to facilitate the ATP dependent biosynthesis of coenzyme Q10 (CoQ10). Mutations in *ADCK4* cause early-onset proteinuria, focal segmental glomerulosclerosis/nephrotic syndrome, followed by end-stage renal disease (ESRD). The regulation of ADCK4 in CoQ10 biosynthesis is not well understood

Case Description: We report a patient who was discovered with proteinuria on routine screening at age of five-year-old. Renal biopsy showed FSGS. Renal functions and proteinuria continued to worsen over the years. Whole exome sequence revealed a novel compound heterozygous for two mutations in the aarF domain-containing-kinase 4 (ADCK4) gene. Her father has proteinuria related to fibrillary GN and bilateral duplicated collecting system, brother with right ureteropelvic junction obstruction and sister with unilateral duplicated collecting system. Genetic analysis using whole exome sequencing for this family with proteinuria and structural anomalies of the kidney and urinary tract revealed a novel compound heterozygous mutation in the *ADCK4*.

Discussion: We generated a computational model to understand the mechanism of action of 2 novel identified mutations: I346S in the C-lobe of the ADCK4 kinase domain, and a termination at W520 that leads to the truncation of the C-terminal a5 helix. The alterations of ADCK4 c.1560G>A and c.1037T>G are novel mutations. the model suggests potential mechanisms for alterations in protein function through either destabilization of important allosteric interactions necessary for kinase activation and/or conformational changes that facilitate enzyme activity (Figure 1).



FR-PO804

Sanger Sequencing Pitfall Exists in Hereditary Thrombotic Microangiopathy with Homozygous Mutation Identified in Only One Biological Parent

Fang Wang, Haiyue Deng, Yanqin Zhang, Yong Yao, Jie Ding. *Peking University First Hospital, Beijing, China*.

Background: The aim of this study was to elucidate the underlying etiology of a mutation appeared to be homozygous which was identified in only one of parents in one boy with hereditary thrombotic microangiopathy.

Methods: One boy was diagnosed as steroid-resistant nephrotic syndrome at 2.4 years old. Urinary protein recurrence occurred 1.5 years later, while serum creatinine (Scr) increased to 83 umol/L and platelet (PLT) decreased to 40×109/L. One point eight years later, hemoglobin (Hb) was 72 g/L, PLT 29×109/L, Scr 120 umol/L. Five point nine years later, his renal function was normal. Light microscopy, electron microscopy and immunofluorescence of renal biopsy indicated thrombotic microangiopathy. Genetic analysis revealed he had homozygous DGKE (NM_003647) missense variant c.1420G>A (p. Asp474Asn) which was identified in only his father. Six short tandem repeats (STR) were selected to confirm biological relationships between the boy and his parents. Quantitative PCR was performed to detect the deletion by Bio-Rad CFX real time PCR system using SYBR Green I qPCR SuperMix (TransGen Biotech, China, AQ131).

Results: Six loci alleles in different chromosomes demonstrated typical Mendelian inheritance with paternal and maternal alleles being detected in the patient, which indicated that biological relationship of the boy and his parents exist. The gDNA quantity in *DGKE* exon 11 of the boy was half of the normal control while normal in his parents. Further analysis showed the breakpoints in *DGKE* were exon 1 and exon 12. It may be a *de novo* heterozygous deletion.

Conclusions: The case was demonstrated to be homozygous due to a large deletion encompassing a missense/small deletion in DGKE gene.

Clinical and Genetic Characteristics of Pregnancy-Associated aHUS in Japan

Yoichiro Ikeda, Yoko Yoshida, Yuka Sugawara, Masaomi Nangaku. *The University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Complement dysregulations mostly by the genetic alterations of the complement related factors are involved in the pathogenesis of atypical hemolytic uremic syndrome (aHUS). Pregnancy can impact on the onset of aHUS. Clinical courses and pathogenesis of pregnancy-associated aHUS is not yet fully clarified.

Methods: Blood samples of aHUS patients were analyzed by hemolytic assay, anti-CFH antibody test and whole exome sequences. Pregnancy-associated aHUS was defined as aHUS that occurs during pregnancy or perinatal period. TMA cases with active underlying diseases were excluded.

Results: Out of 264 cases consulted to our division, 6 cases were associated to the pregnancy. All the cases developed TMA immediately after delivery within 12 hours, and no TMA events during pregnancy were observed. The ages of the patients ranged from 25 to 33 years old, and all the cases were primipara. 2 cases underwent Caesarean sections. 5 cases showed both liver and kidney dysfunctions, leading to the diagnoses of aHUS and HELLP syndrome. Hemolytic assays were negative to weak positive, and anti-CFH antibody tests were all negative. Whole exome sequencing detected diverse mutations in complement related factors (C3 V555I, C3 S562L, CFH R1215G, CFI R201S, CFB K533R, MCP S13F). Each mutation corresponds to each case, and there are no common mutations to them. 4 mutations are found in the idiopathic aHUS patients in our cohort, one (CFB K533R) is previously described as an aHUS causing mutation and one (C3 V555I) is novel. One case (CFI R201S) required temporary hemodialysis for severe acute kidney injury. 5 cases recovered the kidney function, while one case (CFB K533R) reached to the end stage kidney disease 1.5 years after the onset of the disease.

One case (CFH R1215G) continued eculizumab therapy every two weeks until now. All the cases were followed up for up to 5 years and one case had the second pregnancy with successful delivery. No recurrence of TMA was observed during follow-up period.

Conclusions: The clinical and genetic characteristics of pregnancy-associated aHUS in our cohort are; 1) postpartum TMA with HELLP syndrome is typical, 2) the recurrence rate of aHUS is low, 3) the recovery of kidney and liver functions is generally good, 4) diverse mutations in complement related factors were detected, but they might not be the sole factors responsible for the onset of the disease.

FR-PO806

Genotype and Phenotype Correlation in a Chinese Cohort with Autosomal Dominant Tubulointerstitial Kidney Disease

Kunjing Gong,[1] Min Xia,[2] Yuqing Chen.[1] *[1]Peking University First Hospital, Beijing, China; [2]Renal Division, Peking University First Hospital, Beijing, China.*

Background: Autosomal dominant tubulointerstitial kidney disease (ADTKD) characterized by tubulointerstitial damage and progressive chronic kidney injury might be an important cause of chronic kidney disease for patients with family aggregation of ESRD. *UMOD, HNF1B, MUC1, REN* and *SEC61A1* were reported to be the disease causing genes. In this study, we screened genetic variations and did a follow-up study in a Chinese suspected ADTKD cohort.

Methods: 80 individuals from 53 families suspected with ADTKD were enrolled. Demographic data, clinical data and family history of the 53 probands were obtained from clinical record. Genetic testing for *UMOD, HNF1B, REN, MUC1* and *SEC61A1* were performed with suitable method of direct sequence, multiple ligation-dependent probe amplification (MLPA) or next-generation sequencing (NGS). We performed a 1-5 years' flow-up study for the 53 probands.

Results: According to the genetic variants identified in the cohort, 11 persons were diagnosed as ADTKD-UMOD, 1 as ADTKD-REN and 1 as ADTKD-HNF1B. Pathogenic variant in *MUC1* and *SEC6lA1* genes were not confirmed. The mean age of diagnosis was 30±11years, and numbers of males and females were almost equal. Hyperuricemia and decreased kidney function were the common features. But clinical features were similar between patients with genetic variants and without variants (ADTKD-NOS). Flow-up study data from 35 probands were available while 18 probands lost. According to the flow-up study, ADTKD-NOS patients had better outcome than those patients identified genetic variants (p=0.011). Among the 11 variants in *UMOD*, 5 effected cysteine and 6 effected other amino acid. 80%ADTKD-UMOD patients with pathogenic variants lead to cysteine substitution did not develop to ESRD while 83.3% ADTKD-UMOD patients with other amino acid substitution developed ESRD.

Conclusions: 24.5% patients diagnosed ADTKD in a Chinese suspected ADTKD and *UMOD* was the mainly disease causing gene. Clinical features are not specific in patients carried pathogenic mutations compared to those without mutations. Renal survival of ADTKD-NOS is better than patients identified genetic variants. ADTKD-UMOD patients with pathogenic variants lead to cysteine substitution tend to have better outcome.

Quality of Life in Patients with Autosomal Dominant Tubulointerstitial Kidney Disease

Anthony J. Bleyer,[1,2] Kendrah O. Kidd,[1,2] Petr Vyletal,[2] Martina Zivna,[2] Stanislav Kmoch.[2,1] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Research Unit for Rare Diseases, First Faculty of Medicine, Charles University, Prague, Czechia.*

Background: The reaction to diagnosis and quality of life (QOL) in autosomal dominant tubulo-interstitial kidney disease (ADTKD) due to *UMOD* and *MUC1* mutations from the time of diagnosis until treatment for end-stage kidney disease (ESKD) has not been characterized. It is unclear how asymptomatic patients react to a positive genetic test result.

Methods: A cross-sectional survey concerning QOL and genetic testing was delivered to 622 individuals who had undergone genetic testing from families with known ADTKD.

Results: 286 of 622 individuals completed the survey, including 61(21%) genetically unaffected, 3(12%) with stage 1, 2 CKD, 51(18%) Stage 3, 41(14%) Stage 4 pre-dialysis, 50(17%) receiving dialysis, and 47(16%) s/p kidney transplantation. Of 55 respondents who thought they had normal kidney function at the time of testing and were found to have ADTKD, 51(93%) were happy testing was performed (Figure 1), 3(5%) neutral, and 1(2%) neutral/unhappy. Forty-two of 183(23%) affected individuals stated that ADTKD "has a substantial effect and I think about it daily," 47(26%) think about ADTKD weekly, 48(26%) monthly, and 48(26%) less than monthly. The mean PROMIS anxiety score was similar between unaffected and affected individuals and the general population. Depression was present in 41% of affected vs. 23% of unaffected individuals (p=0.01).

Conclusions: Genetic testing of presymptomatic patients for ADTKD is reasonable when requested. This study provides reassurance regarding the impact on QOL of the increased use of genetic testing to diagnose kidney disease. ADTKD has a significant impact on QOL, with depression, not anxiety, being more prevalent in affected individuals.

Funding: NIDDK Support

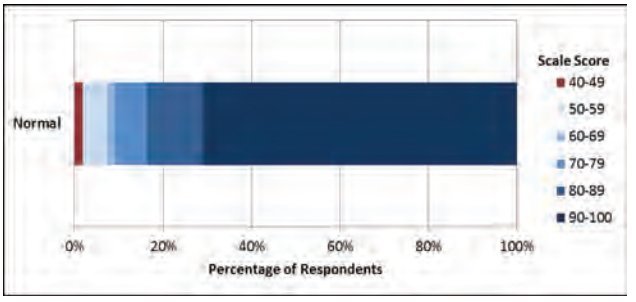

Figure 1. Response of 49 asymptomatic respondents who had undergone positive genetic testing for ADTKD to the question, "Are you happy that you underwent testing?" Patients responded on a scale with a score of 0=unhappy, 50=neutral, and 100=happy.

FR-PO808

Predictors of Age of ESRD in Autosomal Dominant Tubulointerstitial Kidney Disease due to UMOD Mutations

Anthony J. Bleyer,[1,2] Luca Rampoldi,[3] Olivier Devuyst,[4] Eric G. Olinger,[5] Kendrah O. Kidd,[1,2] Petr Vyletal,[2] Martina Zivna,[2] Celine Schaeffer,[3] Francesco Scolari,[6] Peter J. Conlon,[7] Jorge Reis Almeida,[8] Stanislav Kmoch.[2,1] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Research Unit for Rare Diseases, First Faculty of Medicine, Charles University, Prague, Czechia; [3]San Raffaele Scientific Institute, MILAN, Italy; [4]University of Zurich, Zurich, Switzerland; [5]University Hospital Bern, Bern, Switzerland; [6]University of Brescia, Montichiari (Brescia), Italy; [7]Beaumont Hospital, Dublin, Ireland; [8]Universidade Federal Fluminense, Niteroi, Brazil.*

Background: The aim of this work was to identify parameters that may explain the significant intra- and interfamilial variation in the age of onset of ESRD in patients with ADTKD-*UMOD*. The minor rs4293393 variant residing in the *UMOD* promoter has an allele frequency of 19% and decreases uromodulin synthesis by approximately 50%. It was postulated that if the minor variant was present in cis with the disease-causing mutation of *UMOD (mUMOD)*, it would result in decreased mUMOD production and improved survival. A Mendelian randomization experiment was therefore attempted.

Methods: The study included 983 individuals with 127 different *UMOD* mutations, with 722 undergoing genetic testing and 261 being historically affected. An *in vitro* score was created for 29 prevalent mutations based on transit time through the endoplasmic reticulum. Other parameters included in the evaluation were parental age of ESRD, median age of ESRD for the patient's family, BMI, history of gout, age of gout.

Results: The rs4293393 minor variant allele frequency was 16.4% when trans to *mUMOD* and 5.4% when cis to *mUMOD*, resulting in Hardy Weinberg equilibrium being present (p=0.03) and precluding a Mendelian randomization study. The following factors were found to be significantly associated with age of ESRD: age of gout (p<0.001), parental age of ESRD (p<0.001), body mass index (p=0.033), and median age of ESRD for the family (p=0.007). The *in vitro* score was also significant (p=0.03).

Conclusions: The minor variant was significantly less commonly linked to the *mUMOD*. The minor variant may lead to decreased mUMOD production and milder disease that was less frequently identified. An *in vitro* score was an excellent predictor of age of ESRD according to mutation. Parental age and age of gout were highly predictive of age of ESRD.

FR-PO809

Prevalence and Clinical Features of ADTKD-UMOD in Hemodialysis Patients in a Geo-Referenced Population in Southeastern Brazil: The REGENT Study

Jorge Reis Almeida,[1] Cinthia D. Abreu,[2] Cintia Souza,[3] Ludiana Lopes,[4] Ohanna Cavalcanti,[5] Fernanda Kehdy,[5] Petr Vyletal,[6] Stanislav Kmoch,[7] Kendrah O. Kidd,[8] Anthony J. Bleyer.[9] *[1]Federal Fluminense University, Niteroi, Brazil; [2]Federal Fluminense University, Niteroi, Brazil; [3]Federal Fluminense University, Niteroi, Brazil; [4]Federal Fluminense University, Niteroi, Brazil; [5]Instituto Oswaldo Cruz, Rio de Janeiro, Brazil; [6]1st Faculty of Medicine UK and VFN in Prague, Department of Pediatrics and Adolescent Medicine, Diagnostic and Research Unit for Rare Diseases, Prague, Czechia; [7]1st Faculty of Medicine UK and VFN in Prague, Department of Pediatrics and Adolescent Medicine, Diagnostic and Research Unit for Rare Diseases, Prague, Czechia; [8]Wake Forest University School of Medicine, Winston-Salem, NC; [9]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Autosomal dominant tubulointerstitial kidney disease due to *UMOD* mutations (ADTKD-*UMOD*) is a rare genetic kidney disease whose prevalence is not well known. We studied the prevalence and clinical aspects of ADTKD-*UMOD* in hemodialysis (HD) patients in a metropolitan health region of Southeastern Brazil (Metro-II).

Methods: The REGENT study (Familiar Renal Disease, Epidemiology and Genetics in Niteroi) was designed to study familial renal diseases in Metro-II (2 million inhabitants). Between 2017/2018, we evaluated HD patients geo-referenced in Metro-II. Each patient was asked whether any other family members had developed ESRD. If affirmative, after clinical exclusion of other known diseases (such as ADPKD, Fabry's, Alport's, Familial glomerulonephritis, etc.), blood was collected for *UMOD* genetic analysis.

Results: 209 of 1308 patients (16%) indicated a family history of kidney disease. After exclusions, 70 remained as index cases of an unknown familial disease (5.4% of the total). These patients reached ESRD at a younger age ($p < 0.05$), did outpatient treatment before dialysis ($p < 0.001$), and were on dialysis for more years ($p < 0.01$). Family pedigrees showed a dominant pattern in 35%. Three of the index cases were found to have unique *UMOD* variants, consisting of 3 heterozygous missense mutations (c.163 G>A; p.Gly55Ser) (c.667 T>G; p.Cis223Gly) and (c.263 G>A; p.Gly88Asp). The first family consisted of 3 HD, 1 CAPD, 1 transplant and 2 outpatients. Genotyping in the 3 families revealed a total of 18 UMOD affected individuals, regardless of HD, age or symptoms. Metro-II calculated prevalence was 10 ppm. Juvenile gout was not present, simple cysts were present in a few cases. There was no proteinuria or hematuria. Some cases showed hyperuricemia, episodes of urinary tract infection, anemia in childhood and a history of hypothyroidism without specific antibodies. Patients started HD on average between 51.7±9.4 years. A decline in eGFR first occurred between 32.7±4.4 years. Renal biopsy in 3 patients revealed interstitial nephritis.

Conclusions: Familial renal disease without diagnosis constitutes a significant proportion of ESRD patients in Brazil. ADTKD is rare, but frequently underdiagnosed.

Funding: Government Support - Non-U.S.

FR-PO810

Molecular Genetic Investigations Identify New Clinical Phenotypes Associated with BCSL1-Related Mitochondrial Disease

John A. Sayer. *Newcastle University, Newcastle, United Kingdom.*

Introduction: The human *BSC1L* gene encodes a homolog of the *Saccharomyces cerevisiae* bcs1 protein, which has a known role in the assembly of Complex III of the mitochondrial respiratory chain. Several human disease phenotypes have been reported in association with pathogenic *BCS1L* variants, including severe presentations with Growth Retardation, Aminoaciduria, Chloestasis, Iron overload, Lactic acidosis and Early death (GRACILE syndrome) and the relatively mild Björnstad syndrome, characterised by abnormal flattening and twisting of hair shafts (*pili torti*) and hearing problems.

Case Description: Here we describe a patient who presented as an adult with aminoaciduria, seizures, bilateral sensorineural deafness and learning difficulties. He also exhibited progressive chronic kidney disease and is approaching end stage renal disease age 49 years. The diagnosis was not obvious. Whole genome sequencing revealled bi-allelic variants in *BCS1L;* the first with a previously reported c.166C>T, p.(Arg56*) heterozygous variant together with a novel pathogenic heterozygous variant c.205C>T, p.(Arg69Cys). Characterisation of cellular consequences of *BCS1L* variants confirmed a decrease in BCS1L protein levels. Biochemical analysis of Complex III revealed normal respiratory chain enzyme activities in the muscle but a decrease in Complex III assembly was detected in cultured fibroblasts.

Discussion: Together, these data support the pathogenicity of the novel *BCS1L* variants identified in our patient and emphasise the importance of consideration of a mitochondrial disease in unexplained CKD with multisystem features.

FR-PO811

A Case of Hereditary Amyloidosis

Christine B. Vigneault,[1] Dominika Woch.[2] *[1]Greater Hartford Nephrology, Bloomfield, CT; [2]University of Connecticut, Plainville, CT.*

Introduction: Amyloidosis is a condition caused by improperly folded proteins causing end organ damage as the result of tissue deposition. The gold standard of diagnosis is by Congo red staining and fibril deposition on electron microscopy. Although both AL and AA amyloidosis are the most common presentations, inherited forms of the disease occur. A case of Fibrinogen A alpha type (Afib), a form of hereditary renal amyloidosis, is presented.

Case Description: A 72-year-old Spanish male with history of hypertension presented for evaluation of chronic kidney disease and proteinuria. At time of presentation he reported a family history of amyloidosis in his maternal cousin. Other family members affected by kidney failure included the patient's mother, maternal aunt and maternal uncle. Assessment for monoclonal protein was negative. A kidney biopsy revealed hypertensive arteriosclerosis and amyloid deposits. Staining for AA and Lect2 were negative. Fibrinogen A amyloid was suspected given predominant glomerular fibrinogen deposits. Testing by liquid chromatography tandem mass spectrometry confirmed presence of Fibrinogen A alpha-type amyloid. Single gene analysis of the FGA gene was positive for a variant of undetermined significance. The patient was referred for genetic counseling. Genetic testing of his maternal cousin in Spain is in process.

Discussion: Hereditary amyloidosis is a group of conditions inherited in an autosomal dominant fashion and includes Afib amyloidosis. Characterized as a renal disorder, systemic disease can be present. It may occur more commonly than previously thought, mischaracterized as AL disease and occurring in dialysis cohorts. The disease occurs as a result of hepatic production of the amyloid protein with renal deposition and progressive decline in renal function. Treatment options are limited but simultaneous liver and kidney transplant appear to be curative. Amyloidosis presents most commonly as AL or AA forms. Hereditary amyloidosis must be considered anytime a diagnosis of systemic amyloidosis is made, as systemic involvement does occur in this disease commonly identified as renal limited. Identification of hereditary amyloidosis is important for prognosis and treatment of the disease.

FR-PO812

A Novel ELISA Allows Exact PLA2R1 Domain-Specific Autoantibody Quantification in Sera from Patients with Membranous Nephropathy

Linda Reinhard, Gunther Zahner, Stephan Menzel, Friedrich Koch-nolte, Rolf A. Stahl, Elion Hoxha. *University Hospital Hamburg Eppendorf, Hamburg, Germany.*

Background: Phospholipase A2 Receptor 1 (PLA2R1) is the major antigen, which is recognized by autoantibodies in about 80% of patients with membranous nephropathy (MN). Total PLA2R1-antibody (PLA2R1-ab) levels are closely associated with disease prognosis and treatment response. The aim of the study was to investigate the clinical relevance of PLA2R1 domain-specific antibody levels in patients with PLA2R1-associated MN.

Methods: Individual CysR, CTLD1, CTLD7 and CTLD8 domains of the PLA2R1 were fused N-terminal to the rabbit Fc unit. The purified fusion proteins were used to establish novel PLA2R1 domain-specific ELISA. A prospective cohort of 149 untreated patients with newly-diagnosed PLA2R1-associated MN as well as a control cohort of 50 individuals (10 FSGS, 10 minimal change disease, 10 MPGN, 11 IgA nephropathy, 9 healthy donors) was analyzed. Results were validated using Western blot techniques.

Results: The ELISAs of the N-terminally located CysR and CTLD1 domains were highly sensitive and specific for the detection of domain-specific antibodies, as shown by the validation experiments using Western blot techniques. The CysR domain was recognized by 145 (97.3%) out of 149 MN patients, and the CysR-specific antibody level was highly correlated with the total PLA2R1-ab level (Spearmans rho = 0.949, $p<0.001$). In addition, CTLD1-ab were detected in 78 (52.3%) patients of the cohort. Again, a close correlation with the total PLA2R1-ab level was observed (Spearmans rho = 0.641, $p<0.001$). In contrast, the ELISA of the C-terminally located CTLD7 and CTLD8 domains exhibited a lower level of sensitivity compared to the Western blot technique. Precisely, all 149 MN patients of the cohort recognized the C-terminal CTLD7-8 domain in Western blot, while only 57 (38.2%) and 15 (10.1%) patients were tested positive in the CTLD7- and CTLD8-specific ELISA, respectively. A week correlation was observed between the CTLD7-ab level and the PLA2R1-ab level (Spearmans rho = 0.398, $p=0.002$). After adjustment for the total PLA2R1-ab levels, PLA2R1 domain-specific antibody levels could not predict the clinical outcome of patients in our cohort.

Conclusions: The total PLA2R1-ab levels, but not the PLA2R1 domain-specific antibody level, are predictive for the clinical outcome of patients with MN.

FR-PO813

Discrepancy of Serum Ant-PLA2R and Podocyte PLA2R Expression in Taiwan Patients with Membranous Nephropathy

Kun-Hua Tu,[1] Tsai-yi Wu,[2] Cheng-Lung Ku.[2] *[1]Chang gung memorial hospital, Taoyuan, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan.*

Background: Anti-phospholipase A2 receptor (PLA2R) autoantibodies could be found in 60~85% patients with idiopathic membranous nephropathy, first discovered in 2009. Enhanced expression of podocyte PLA2R protein in these patients was also postulated later. There are some patients, however, have serum anti-PLA2R antibodies only without enhanced expression of podocyte PLA2R protein, vice versa. Currently, patient with membranous nephropathy have one of each will be diagnosed as PLA2R-associated membranous nephropathy. The mechanism of this discrepancy existing is not clearly known yet. To date, there are few articles reporting prevalence of serum anti-PLA2R and podocyte PLA2R expression in Taiwan patient with membranous nephropathy. We conduct a study to investigate this issue.

Methods: This investigation was prospectively performed in a tertiary hospital. From 2016/8-2018/5 period, patients with biopsy-proved membranous nephropathy will received blood test of plasma anti-PLA2R ELISA (Euroimmune®) before initiation of glucocorticoid or immunosuppressants. In addition, pathologic slides of these patients are

proceeded to IHC stain for PLA2R (Atlas®). Clinical parameters and pathologic findings are collected for analyzed.

Results: During the study period, totally 60 patients were diagnosed with membranous nephropathy. 58 patients received blood test for plasma anti-PLA2R, and 55 patients' pathologic slide were successfully proceeded to IHC stain of podocyte PLA2R. Within patients receiving both evaluation (n=53), there are 24 patients with double positive results (45.3%), and 19 patients with double negative results (35.8%). 3 patients have plasma anti-PLA2R antibody but got negative results of podocyte PLA2R enhanced expression (5.7%). 7 patients have no plasma anti-PLA2R antibody but got positive results of podocyte PLA2R enhanced expression (13.2%). Discrepancy of serum ant-PLA2R and podocyte PLA2R expression account for totally 18.9% of enrolled patients.

Conclusions: The reason of discrepancy of serum ant-PLA2R and podocyte PLA2R expression is still not known yet. Further studies are still needed Currently, serum anti-PLA2R ELSIA assay and tissue IHC stain for PLA2R expression are both useful tools for diagnosis of PLA2R-associated membranous nephropathy.

FR-PO814

Complement in Membranous Nephropathy

Aikaterini K. Nikolopoulou,[1] H. Terence Cook,[2] Matthew C. Pickering,[1] Charles D. Pusey.[1] *[1]Imperial College London, London, United Kingdom; [2]Imperial College of London, London, United Kingdom.*

Background: Approximately 70% of patients with membranous nephropathy (MN) have autoantibodies against the PLA2 receptor and biopsy specimens generally show positivity for C3 and IgG4 in immune deposits. However the pathway of complement activation in MN remains unclear.

Methods: We examined a cohort of patients with PLA2R positive (n=10) and negative (n=9) idiopathic MN. Cases of secondary MN were excluded. Biopsies were stained for PLA2R, complement components (C3c, C3d, C4d, C5b9, FHR5) and IgG4. Staining intensities were graded categorically as 0, 1+, 2+ and 3+. Electron microscopy was performed and the presence of subepithelial electron dense deposits (EDD) was graded according to the percentage of stage 1 and 2 EDD present. More than 80% of stage 1 and 2 EDD was marked 3+, 50-80% was marked 2+, less than 50% was 1+ and absent stage 1 and 2 EDD was scored zero. Clinical and laboratory characteristics were reviewed.

Results: Both cohorts had similar clinical and laboratory characteristics. The PLA2R positive group had intense staining for all complement factors assessed. In contrast, complement staining in the PLA2R negative group was overall less intense. IgG4 staining was strong in PLA2R positive cases but varied in the PLA2R negative cases. In the PLA2R positive group the majority of the EDD were stage 1 and 2 and this was associated with intense staining particularly for C3c, C5b9, FHR5 and IgG4.

Conclusions: We have identified differences in the intensity of staining of complement factors C3c, C3d, C4d, C5b9 and FHR5 between PLA2R positive and negative patients possibly suggesting differences in disease mechanism that could affect prognosis and influence stratification for complement inhibiting therapies.

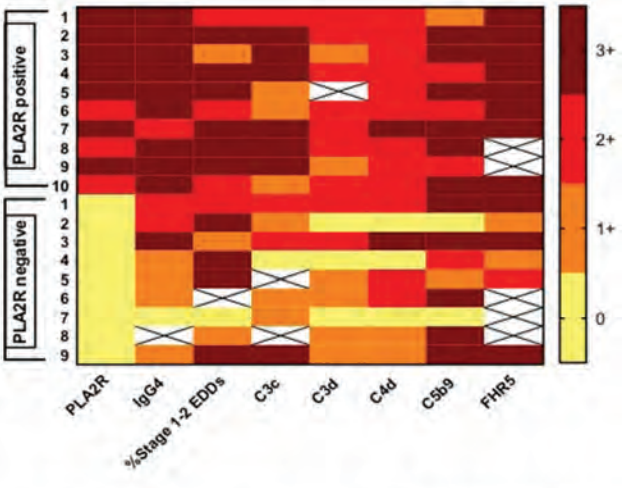

Figure 1. Heatmap of glomerular staining intensity of PLA2R, IgG4, % stage 1and 2 EDDs and complement factors in the two groups

FR-PO815

Clinical and Genetic Feature of Membranous Nephropathy in Patients with Primary Sjögren Syndrome

Linfeng Zou, Mengyu Zhou, Xiaoxiao Shi, Peng Xia, Yubing Wen, Chao Li, Hang Li, Xuemei Li, Xuewang Li, Limeng Chen. *Division of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China.*

Background: In our previous study, membranous nephropathy (MN) was the most common pathological patterns of glomerular involvement in patients with primary Sjögren's Syndrome. In this pilot study, we try to observe the clinical features and genetic background of MN patients with primary Sjögren's syndrome (pSS-MN).

Methods: Data from pSS-MN patients (n=73) confirmed by renal pathology were retrospectively collected from Peking Union Medical College Hospital, from Jan 30, 1993, to January 30, 2018. The serum anti-PLA2R antibody and renal tissue PLA2R antigen were tested by ELISA and immunofluorescence respectively. Idiopathic MN (iMN) patients were used as controls (n=150). Eight SNP sites, four high-risk sites for pSS and four high-risk sites for MN, as well as 3 HLA class II sites (HLA-DQA1, HLA-DQB1and HLA-DRB1) were typed by Sanger test in 23 pSS-MN patients. Genetic data of MN and normal people from Peking University First Hospital cohort and of pSS and normal people from Peking Union Medical Hospital cohort was used as control.

Results: pSS-MN patients were significantly older than iMN patients (mean age 53.3±14.1 vs 46.4±14.3, p<0.001) with predominantly female (78.1% vs 44.7%, p<0.001). Laboratory test showed significantly higher ESR (58.4±31.8 vs 35.0±26.5, p<0.001) but lower 24h urine protein (4.13±2.96 vs 6.02±5.71, p<0.001) in pSS-MN patients. There was no significant difference in eGFR and albumin level between the two groups when the biopsy was performed. pSS-MN and iMN patients had a similar positive rate of anti-PLA2R antibody (61.8% vs 74.0%, p=0.205). In pSS-MN patients, the mutation rates of 3 SNP (linked rs35771982- rs3749117 and rs9271588) were significance higher than normal control (30.1% vs 8.7%, p<0.001; 46.8% vs 21.7%, p=0.001, respectively), without significance when compared with iMN (p=0.30) or pSS patients (p=0.13). When compared with normal control, both HLA-DRB1*1501 (p=2.6×10^-5) and the haplotype (HLA-DRB1*1501-DQA1*0102DQB1*0602, 39.13% vs 9.00%, p=9.6×10^-8) in pSS-MN patients were identified as risk alleles, but the difference was not significant between the pSS-MN and iMN patients (p=0.09).

Conclusions: pSS-MN and iMN patients shared similar clinical and genetic feature, as well as PLA2R positive ratio. HLA-DRB1*1501 was the most significant HLA allele in pSS-MN patients.

FR-PO816

Can Multidrug Resistance-Associated Protein-1 and P-Glycoprotein Expression on Peripheral Blood Lymphocytes Be Used as Biomarkers to Predict Steroid Resistance in Idiopathic Nephrotic Syndrome?

Narayan Prasad,[1] Harshit Singh,[1] Akhilesh Jaiswal,[1] Saurabh Chaturvedi,[1] Vikas Agarwal.[2] *[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [2]Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.*

Background: Steroid remains mainstay therapy for Idiopathic Nephrotic Syndrome (INS). Other than histological changes, pharmacogenomic factors may also affect steroid response. Overexpression of P-glycoprotein (P-gp) and Multidrug resistance-associated protein 1 (MRP-1) modulate the pharmacokinetics of steroids and may contribute to steroid resistance.

Methods: P-gp, and MRP-1 expression were evaluated on whole blood and functional activity on PBMCs in steroid-sensitive nephrotic syndrome (SSNS) (n=170, M=103, age=8.54±4.3 yrs); steroid-resistant nephrotic syndrome (SRNS) (n=81, M=43, age=7.43±4.6 yrs) patients. The genetic variants G2677T/A of MDR-1 gene were genotyped by PCR-RFLP technique.

Results: Biochemical difference were found in 24hrs urinary protein/Creatinine ratio (SSNS=0.13±.0.06, SRNS=3.67±0.91, p<0.001), total cholesterol (SSNS=144.21±34.61, SRNS=460.52±201.09, p<0.001). Percentage expression of P-gp (9.80±3.44 and 4.36±2.05, p<0.001); and MRP-1 (13.46+4.80 and 7.75+3.22, p<0.001) was significantly higher in SRNS than SSNS. P-gp expression on CD4+ (6.08±2.06 v/s 4.34±1.97, p=0.008); and CD8+cells (8.65±2.19 v/s 3.99±1.72, p<0.001) was high in SRNS than SSNS respectively. MRP-1 expression on CD4+ and CD8+cells was higher in SRNS (12.06±2.91 v/s 3.35±1.83, p=0.043); (5.11±2.68 v/s 1.59±0.99, p<0.001) respectively. Functional activity of P-gp and MRP-1 was significantly increased in SRNS as compared to SSNS (66.26±+15.77 and 30. 82±9.87, p<0.001); (67.62+14.67 and 32.97+11.36, p<0.001) respectively. ROC curve predictive cut-off values percentage of P-gp (7.13%) and MRP-1 (9.62%) was found to be predictive of steroid resistance with a sensitivity of 90% and 80.7%, and specificity of 90% and 80%, respectively. Moreover, homozygous mutant allele TT+AA was significantly associated with a resistant population of nephrotic syndrome (p=0.025, OR = 2.86 CI=1.14-7.14). The expression of P-gp (9.68±4.99 v/s 5.88±3.38, p=0.002) was significantly higher in the patients of homozygous mutant alleles compared to wildtype GG.

Conclusions: Overexpression of P-gp and MRP-1 on peripheral blood lymphocytes may be used as biomarkers for SRNS with high sensitivity and specificity. Use of P-gp and MRP-1inhibitors may prevent steroid resistance.

FR-PO817

Preclinical Studies of N-Acetylmannosamine (ManNAc) for Glomerular Diseases

Marjan Huizing,[3] Jonathan P. Troost,[2] Petcharat Leoyklang,[3] Steven P. Bodine,[3] Matthias Kretzler,[2] William Gahl,[3] Jeffrey B. Kopp,[1] May christine Malicdan.[3] *[1]NIDDK, NIH, Bethesda, MD; [2]University of Michigan, Ann Arbor, MI; [3]NHGRI, NIH, Bethesda, MD.*

Background: Glomerular hyposialylation of glycoproteins and glycolipids has been implicated in human and experimental nephrotic syndromes. In this study we assessed the prevalence of glomerular hyposialylation in human nephrotic syndromes and explored

therapeutic potential of the sialic acid precursor *N*-acetylmannosamine (ManNAc) in three different nephrotic mouse models.

Methods: We created neuraminidase-induced and adriamycin-induced nephrotic mice and a nephrotic knock-in mouse model deficient in *Gne*, a central enzyme in sialic acid biosynthesis. ManNAc was administered in drinking water (~1 g/kg/d) to all three mouse models and clinical/biochemical parameters were assessed at different timepoints. Human glomerular sialylation was assessed by lectin histochemistry and confocal imaging in kidney biopsies of 123 well-phenotyped subjects with focal segmental glomerulosclerosis (FSGS; 69 subjects), minimal change disease (MCD; 29 subjects), or membranous nephropathy (MN; 25 subjects) supplied by the Nephrotic Syndrome Study Network (NEPTUNE).

Results: In all three mouse models, ManNAc administration increased glomerular sialylation and markedly reduced proteinuria and podocyte injury within a week of treatment. Hyposialylation was detected in an unexpectedly high percentage (>60%) of human kidney biopsies across all three disease entities, indicating that this condition may occur frequently, remains greatly unexplored and, importantly, may be treatable. Analysis of the association of sialylation status to clinical, pathological or other documented subject data showed a trend of correlation of severe glomerular hyposialylation with decreased eGFR, increased interstitial fibrosis and increased tubular atrophy, in particular in FSGS subjects.

Conclusions: These encouraging preclinical data, together with minimal toxicity of oral ManNAc therapy in humans (demonstrated in Phase 1 and 2 clinical trials for the rare hyposialylation disorder GNE myopathy) led to obtaining an Investigational New Drug approval to start a Phase 1 clinical trial to evaluate the safety, tolerability and pharmacokinetics of ManNAc in subjects with primary podocyte diseases (ClinicalTrials.gov NCT02639260). Preliminary results of this ongoing study are promising regarding safety and tolerability in subjects with glomerular disease.

Nuclear Magnetic Resonance Metabolomic Profiling in Distinguishing Primary from Secondary FSGS

Shane A. Bobart, Lisa E. Vaughan, Ivan Vuckovic, Sanjeev Sethi, Aleksandar Denic, Fernando C. Fervenza. *Mayo Clinic, Rochester, MN.*

Background: FSGS is a renal histologic lesion with diverse etiologies that cause podocyte injury and depletion. Subclasses of FSGS include primary, genetic, and secondary forms. These subclasses differ noticeably in management and prognosis. Without an accepted biomarker that discriminates among these FSGS types, classification of patients is often challenging. NMR-based urine metabolomics has shown potential in biomarker discovery. We hypothesized that urine metabolites can distinguish such patients.

Methods: We used high resolution NMR spectroscopy to study urines of 12 patients with primary FSGS and 14 patients with secondary or genetic FSGS. NMR spectra were binned and normalized by total spectrum area. Using non-specific feature selection, we analyzed the top 50% ranked bins in the dataset by partial least squares discriminant analysis (PLS-DA). Cross-validation was used to choose tuning parameters and to estimate predictive performance. The 95% confidence interval was estimated using the score test.

Results: PLS-DA score plot demonstrated considerable overlap within the secondary/genetic group relative to the primary group (Figure). When comparing these two groups, the top 5 spectra bins corresponding to highest variable importance included the following metabolites: choline, acetyl-carnitine, histidine, betaine, taurine *N*-phenylacetyglutamine and two unknown metabolites. Estimated predictive accuracy was 65.4% (95% CI 46.2-80.1%). Sensitivity was 58.3% (95% CI: 32.0-80.7%) and specificity was 71.4% (95% CI: 45.4-88.3%).

Conclusions: This study found that a panel of urine metabolites could potentially discriminate primary from secondary FSGS. Further studies are needed to identify the unknown compounds. Understanding the differential expression of these metabolites could shed new insights into the biology of FSGS.

Funding: Private Foundation Support

Tar Sequence (Double-Stranded-RNA)-PKR Activation Mediated Podocyte Injury with HIV-1 Infection

Koji Okamoto,[2,1] Teruhiko Yoshida,[2] Mariko Miyazaki,[3] Jeffrey B. Kopp.[2] *[1]Nephrology Endocrinology and Vascular Medicine, Tohoku Univesity Hospital, Sendai, Japan; [2]NIDDK, National Institutes of Health, Bethesda, MD; [3]Tohoku University Hospital, Sendai, Japan.*

Background: Podocyte damage by Human Immunodeficiency Virus (HIV-1) is critical to the pathogenesis of HIV-1 associated nephropathy (HIVAN). There is an evidence that viral RNA and proteins detected in podocytes, but there is no productive infection. While APOL1 risk genotypes for FSGS is also the risk for HIVAN. We reported that activated PKR (interferon-induced double-stranded RNA-activated protein kinase) by double-stranded-RNA (dsRNA) of APOL1 mediates APOL1 nephropathy (Figure). HIV-1 also has dsRNA structures called *tar sequence*. Our hypothesis is that activated PKR by *tar sequence* could be cause of podocute injury in HIVAN.

Methods: We prepared virus stocks were prepared by transfecting 293T cells with lymphocyte tropic pNL4-3 and Macrophage-Tropic pNL(AD8) tittered by p24 ELISA assay. Differentiated conditionally immortalized human podocytes were cultured a 6 well plate and infected with virus (p24 100 ng/6-well).

Results: After 6 hours incubation, activated PKR signal was observed and prominent in podocyte cell line from APOL1 risk genotype with pNL(AD8). WT-1 signal was decreased in Podocyte cell line after 96 hours incubation. Virus RNA (rev, vpu, env, and nef) was detected in podocytes by RNA sequence analysis, however, there is no productive infection. Next we generate *tar sequence* mutated virus (Figure). Activated PKR signal was not observed with mutated *tar sequence*. Specific PKR inhibitor demonstrated that PKR inhibitor reduced activated PKR and ameliorate WT-1 decline.

Conclusions: HIV-1 direct infection on podocyte cell line providing mechanism by which tar sequence of HIV-1 contributes to cell injury via PKR. Targeting *tar* sequence - PKR opens novel therapeutic approaches to treating HIVAN.

Akt Downregulation Induces Tubular Apoptosis via FoxO-1-Induced BIM Activation in Proteinuric States

Elif Erkan,[1] Meredith P. Schuh.[2] *[1]Children's Hospital of Cincinnati, CIncinnati, OH; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Proteinuria induces tubular apoptosis preceding tubular atrophy but the underlying molecular mechanism remains undetermined. We demonstrated that cell survival protein, protein kinase B(Akt) is downregulated in proximal tubule epithelial cells in response to albumin overload. We hypothesize that inhibition of Akt expression decreases phosporylation and activation of its downstream targets Forkhead box(FoxO) transcriptional factors leading to mitochondrial apoptosis in proteinuric states.

Methods: *In-vitro* albumin overload: Human kidney proximal tubule epithelial cells(HKC-8) were incubated with 10mg/ml endotoxin free human albumin for 6, 16 and 24 hours. Chromatin immunoprecipitation(CHIP) assay was used to probe protein-DNA interactions. *In-vivo* albumin overload: Wild type and Akt1/2 $^{lox/lox}$ SGLT2 cre+ mice underwent daily intraperitoneal albumin injections(10mg/g) for 6 weeks. Human kidney biopsies with minimal change disease and focal segmental glomerulosclerosis (FSGS) were investigated for Akt activation.

Results: Expression of phosphorylated Akt-Ser 473 and Akt-Thr 308 was downregulated in association with increased caspase-3 activity and BIM expression in HKC-8 cells with albumin overload. Treatment of HKC-8 cells with pan Akt inhibitor MK-2206 and constitutively active(CA-Akt) Akt resulted in down regulation and upregulation of apoptosis respectively with albumin overload. *In-vivo* albumin overload decreased active p-Akt expression in association with tubular apoptosis. Akt1/2 $^{lox/lox}$ SGLT2 cre+ mice displayed increased BIM/Bax expression in mitochondrial isolates in association with tubular apoptosis in response to albumin overload indicating a close causal link between inhibition of Akt and mitochondrial apoptosis in proximal tubule epithelial cells. Furthermore, patient kidney biopsies (n=5) with FSGS displayed decreased proximal tubule PSer473 Akt expression. Albumin overload caused decreased Akt phosphorylation of FoxO-1 and 3 and nuclear translocation of FoxO-1. CHIP assay revaled transcriptional activation of BIM by Foxo-1.

Conclusions: We concluded that Akt and its downstream targets play an important role in mediating mitochondrial apoptosis leading to tubular injury in glomerular diseases. We propose that discovery of novel treatment options targeted for activation of Akt can ameliorate tubulointerstitial injury and progression in proteinuric states.

FR-PO821

Network-Based Assessment of Minimal Change Disease Identifies Glomerular IL7 Pathway Activation as Potential Mechanism for Biomarker Discovery and Drug Testing

Bjørnar S. Lillefosse,[1] Philipp Strauss,[1] Oystein Eikrem,[1,4] Nicolas Delaleu,[2] Bjorn Egil Vikse,[1,5] Hanna Debiec,[3] Pierre M. Ronco,[3] Sabine Leh,[4] Hans-Peter Marti.[1,4] Renal Research Group Bergen *[1]University of Bergen, Bergen, Norway; [2]Institute of Oncology Research (IOR), Bellinzona, Switzerland; [3]INSERM UMRS 1155, Paris, France; [4]Haukeland University Hospital, Bergen, Norway; [5]Haugesund Hospital, Haugesund, Norway*.

Background: Minimal change disease (MCD) is a major cause of the nephrotic syndrome. With a substantial number of patients requiring long-term immunosuppression leading to significant morbidity, our study aim was to determine the glomerular transcriptome of MCD to serve as base for biomarker discovery and drug target identification. Respective animal work showed podocyte injury induced by IL7/IL7R signaling *(Zhai S, BBRC, 2018)*.

Methods: Renal biopsies from adult patients representing the following groups were selected from the Norwegian Kidney Biopsy Registry: MCD (n=14), as well as normal tissue (n=8) and primary membranous nephropathy (MN; n=12) as two reference groups. Glomerular RNA for 75 base-pair, paired-end RNA-seq was obtained via laser capture microdissection from archival FFPE cross-sections. Systematic delineation of condition-specific alteration in transcriptional landscapes was achieved by combining pathway-centered analyses with methodologies derived from network science and integrating multiple bioinformatics resources.

Results: Compared to normal glomeruli, glomeruli from MCD displayed an inflammatory signature that appeared to be predominantly governed by the IL1 and IL7 systems. While enrichment of IL1 production and secretion was a shared feature of MCD and MN compared to normal tissue, responses involving IL7 pathway activation were unique to MCD. Indeed, IL7R expressed by glomeruli was the most up-regulated gene of the interleukin-family in MCD vs normal controls. IL7 pathway activation was paralleled by significant enrichment in adaptive immune system processes and transcriptional regulation, and by depletion in pathways related to energy metabolism and transcription. Downregulation of these organ function-related themes again occurred predominantly in MDC and were significantly less pronounced in MN.

Conclusions: Our results demonstrate that archival renal biopsies can be used to generate glomeruli-specific gene expression profiles suitable for systematic delineation of kidney diseases. We provide a data-driven rationale to experimentally address the MCD-specific features as biomarkers and as novel drug targets. In this context, inhibiting the activation of IL7 pathway is particularly promising.

FR-PO822

Expression of Beta-3 Adrenergic Receptor (β3-AR) in Normal and Pathological Renal Tissue

Giorgia Schena,[2] Samantha Chiurlia,[3] Sharon N. Cox,[1] M. Rossini,[8] Saverio Capodiferro,[4] Mauro G. Mastropasqua,[5] Eugenio Maiorano,[6] Michael J. Caplan,[7] Francesco P. Schena.[1] *[1]University of Bari, Bari, Italy; [2]Yale University, New Haven, CT; [3]Schena Foundation, Valenzano-Bari, Italy; [4]university of bari, Bari, Italy; [5]Policlinico di Bari, Bari, Italy; [6]Università degli Studi di Bari, Bari, Italy; [7]Yale University School of Medicine, New Haven, CT; [8]University of Bari, Department of Emergency and Organ Transplantation, Nephrology Unit, Bari, Italy*.

Background: The β3-adrenoreceptor (β3-AR) is a G-protein coupled receptor whose expression has been reported in multiple nephron segments of the murine kidney, including thin ascending limb (tAL), thick ascending limb (TAL), distal convoluted tubule (DCT) and cortical collecting duct (CCD). However, no information is available regarding β3-AR presence in human kidney. The aim of our study was to investigate the presence of β3-AR at the glomerular and tubular level in normal and pathological human renal tissue.

Methods: β3-AR has been detected by immunohistochemistry in 10% formalin-fixed and paraffin-embedded kidney tissue sections of 6 glomerular diseases (GD), 6 autosomal dominant polycystic kidney disease (ADPKD) and 6 normal kidney donors (KD). We used three different β3-AR antibodies: rabbit polyclonal antibody (Biomatik), mouse polyclonal antibody (Abnova) and mouse monoclonal antibody (R&D System). Fluorescence co-localization analysis in combination with specific tubular markers was performed to characterize β3-AR expression in different tubular segments: LPR2 for staining in proximal tubule, AVPR2 for TAL, SLC12A3 for DCT and AQP-2 for CCD.

Results: β3-AR protein detected by polyclonal antibodies was present at the glomerular and tubular level in all renal samples with more intense staining in tubules from GD patients. β3-AR staining was also present in normal tubules from ADPKD samples but it was reduced in cystic tubules. Immunofluorescence studies performed using monoclonal antibodies showed β3-AR colocalization with tubular markers in TAL, DCT and CCD.

Conclusions: This is the first report on β3-AR localization in human kidney. Our data demonstrate that β3-AR is present in glomeruli and in nephron segments involved in water and solute reabsorption. The presence of this receptor in tissue from normal and diseased kidney suggests that further studies elucidating the physiology of β3-AR could lead to the identification of a new potential therapeutic targets in the treatment of renal diseases.

FR-PO823

Elucidating the Effects of Complement Stress in Neutrophil Extracellular Traps (NETs) Formation in C3 Glomerulopathy

Samuel E. Suntharalingham,[1,3] Carolina Ortiz,[3] Wouter J. Feitz,[3] Christoph Licht.[3,2] Licht Lab *[1]University of Toronto, Toronto, ON, Canada; [2]Cell Biology, University of Toronto, Toronto, ON, Canada; [3]The Hospital for Sick Children, Toronto, ON, Canada*.

Background: Neutrophil extracellular traps (NETs) have been recently implicated in several disease states, which is mostly attributed to their pro-inflammatory and prothrombotic properties. Neutrophils carry complement proteins, and when activated, release these complement proteins and contribute to their activation via NETs. By improving our understanding of the interaction of the complement system and neutrophils and their respective response to produce these NETs, we will be able to better understand how neutrophils and NETs play a role in complement-mediated diseases such as C3 glomerulopathy (C3G), in which both neutrophils and complement are expected to contribute to disease pathogenesis.

Methods: Neutrophils freshly isolated from healthy controls (HC) were used (male, ages 18-24 years old). Experiments were done at least threefold (N=3). We either applied our established protocol of complement activation via the use of a sensitizing antibody (monoclonal anti-human CD59 antibody) in combination with 50% NHS using healthy control (HC) neutrophils or investigated patient-derived neutrophils incubated in autologous serum or serum-free media. Complement deposition (C3b; C5b-9) on neutrophils was detected via IF and flow cytometry. NETosis was detected using SYTOXGreen assay and immunofluorescence (IF) imaging.

Results: We found that complement activation of neutrophils resulted in (i) surface deposition of C3b and C5b-9; (ii) appearance of citrullinated Histone 3 (cit-H3) and myeloperoxidase (MPO) release; (iii) the stepwise completion of NETosis after the transfer of neutrophils into serum-free media (SFM). In addition, we found that C3G patient-derived neutrophils (i) were positive for surface complement deposition; (ii) were positive for cit-H3; and (iii) completed NETosis after transfer from autologous serum into SFM. Finally, HC neutrophils (i) when incubated with C3G patient-derived serum showed cit-H3 formation, and (ii) NETosis when transferred into SFM.

Conclusions: Complement activation of neutrophils induces NETosis in a step-wise fashion with cit-H3 formation in serum ("priming") and full NETosis in SFM. These findings can be interpreted as resemblance of an intra- vs. an extra-vascular environment, suggesting that neutrophils are primed intra-vascularly and committed to full NETosis only extra-vascularly.

FR-PO824

Minimal Residual Autoimmunity After Rituximab in ANCA-Associated Vasculitis Patients

Laura S. van Dam, Jelle M. Oskam, Sylvia Kamerling, Eline J. Arends, Edwin Bredewold, Jacques J. Van dongen, Ton J. Rabelink, Cees van Kooten, Yoe Kie Onno Teng. Lupus, Vasculitis and Complement Center of Expertise (LUVACS) LUMC Leiden *LUMC, Leiden, Netherlands*.

Background: B-cell depletion with rituximab (RTX) is an effective treatment for ANCA-associated vasculitis (AAV) patients. Repeated RTX upon B-cell repopulation or return of ANCAs improved therapeutic efficacy, which indicates the presence of minimal residual autoimmunity (MRA) after RTX. Therefore, this study aimed to perform in-depth phenotypic and functional analyses of B and plasma cells after RTX in AAV.

Methods: EuroFlow-based highly sensitive flow cytometry (HSFC) was used during longitudinal follow-up of RTX-treated AAV patients (n=12). To investigate MRA in the memory B-cell compartment after RTX, peripheral blood mononuclear cells (PBMCs) were stimulated with CpG, IL-2 and IL-21 *in vitro* to induce plasma cells (PCs) and ANCA-IgG and -IgM were measured in these supernatants and in paired serum samples by ELISA.

Results: By employing HSFC we demonstrated that 12 weeks after RTX, low but significant numbers of circulating $CD19^+$ B cells (0.21^*10^6 cells/L) could still be detected (reduction of -99.7%). While naïve B-cells, memory B-cells and $CD20^+$ plasmablasts (PB) were rapidly depleted, $CD20^-$ PCs were reduced slower and depleted incompletely. Residual $CD20^-$ PCs were 0.05^*10^6 cells/L (-95.8% from baseline), whereof 57% were mature $CD138^+$ PCs. Early repopulation at 12 weeks was dominated by $CD20^-$ $CD138^-$ PCs, followed by $CD20^+$ PBs at 24 weeks while memory and naïve B cells remained suppressed. Simultaneously, serum ANCA IgG, IgM and IgA, produced by autoreactive PCs, decreased but did not disappear after RTX. Interestingly, 24 weeks after RTX, serum anti-MPO IgM increased in 3/4 patients, which associated with repopulating $CD20^+$ PBs. This suggested remaining autoreactive B cells despite RTX treatment, which was further studied by *in vitro* PBMC cultures. In these supernatants both anti-MPO-IgG and -IgM were detected at baseline, whereas anti-MPO IgG disappeared after RTX, in contrast to anti-MPO IgM, which was detected 24 weeks after RTX.

Conclusions: RTX results in a strong but not complete B cell depletion. In-depth analysis demonstrated that both ANCA-producing PCs and ANCA-memory B cells can be detected after RTX, indicating residual B-cell autoimmunity in AAV patients. Further identification of MRA could be worthwhile for guiding personalized treatment in AAV patients.

FR-PO825

Nonspecific Inflammatory Markers Can Be Predictors of Disease Activity in ANCA-Associated Vasculitis

Aleksandra Rymarz,[1] Magdalena Mosakowska,[1] Stanislaw Niemczyk.[2] *[1]Military Institute of Medicine, Warsaw, Poland; [2]Military Medical Institute of Warsaw, Warsaw, Poland.*

Background: The purpose of the study was to compare non-specific inflammatory markers such as high sensitivity C-reactive protein (hsCRP), erythrocyte sedimentation rate (ESR) and procalcitonin level (PCT) in clinically active ANCA associated vasculitis (AAV) before and after the induction therapy.

Methods: 28 patients with AAV diagnosed in the Nephrology Clinic between 2014 and 2017 were included. sCRP was measured using nephelometry assay (BNII Siemens) with a cutoff point 0.8 mg/dl and procalcitonin level using electrochemiluminescence method (*Elecsys BRAHMS PCT Cobas*, Roche) with the upper reference range of 0.046 ng/ml. Statistical analysis was performed using Mann-Whitney, Wilcoxon signed-rank and Kruskal-Wallis tests (SPSSv18).

Results: 28 patients with a median age 58 years (67.9% female) were included. Granulomatosis with polyangitis (GPA) was diagnosed in 16 (57%) patients, microscopic polyangitis (MPA) in 13 (43%). The most frequently affected organs were: lungs (83%), joints (83%) and kidneys (75%). Before the treatment the median BVAS/WG score was 7 points, the median hsCRP was 2 mg/dl, median ESR 56 mm and the median PCT was 0.17 ng/ml. Severe, systemic disease (EULAR) was diagnosed in 12 patients (42.8%). The these cases median hsCRP (10.3mg/dl), ESR (81.6 mm) and PCT (3.4 ng/ml) were significantly higher in comparison to the rest of the study group (p=0.006,0.007, <0.001 respectively). The mean serum creatinine concentration (SCr) was 3.4 ±2.2 mg/dl, eGFR 33.2 ±30,4 ml/min/1.7 m^2, 12 patients were treated with hemodialysis. The median ANCA level was 51 IU/ml. In all patients concomitant infections were excluded. After 6 months of treatment the whole group reached clinical remission. Median hsCRP was 0.2 mg/dl, ESR 17 mm, PCT 0.05 ng/ml and were significantly lower (p<0.001) in comparison to the levels before the treatment. The mean ANCA level was 4.5 IU/ml and were significantly lower after the induction treatment (p<0.001).

Conclusions: Non-specific inflammatory markers such as CRP, ESR, procalcitonin levels are associated with AAV activity and decreases after immunosuppressive, induction therapy.

FR-PO826

Difference Between Urinary Vesicle Fibroblast Specific Protein 1 and Urinary-Soluble CD163 as a Marker of Crescent Formation

Yukie Morikawa, Naoki Takahashi, Kazuko Kamiyama, Sho Nishikawa, Kazuhisa Nishimori, Yudai Nishikawa, Mamiko Kobayashi, Sachiko Fukushima, Seiji Yokoi, Daisuke Mikami, Hideki Kimura, Kenji Kasuno, Masayuki Iwano. *Nephrology, University of Fukui, Fukui, Japan.*

Background: Extracellular vesicles (EVs) are present in urine. We previously reported that fibroblast-specific protein 1 (FSP1) levels in urinary EVs (U-EVs) reflect active and ongoing glomerular injury, such as cellular crescent formation. However, it is unknown whether FSP1 in U-EVs is superior to urinary soluble CD163 (U-sCD163) which was established as a biomarker of crescentic glomerulonephritis.

Methods: To address that issue, we collected urine samples from 37 patients with various types of glomerular disease (6 with ANCA-associated nephritis, 11 with IgA nephropathy, 11 with membranous nephropathy, 6 with minimal-change disease and 3 with lupus nephritis), and purified U-EVs using total exosome isolation regent. We measured FSP1 levels in U-EVs and sCD163 levels in total urine using ELISAs and analyzed correlation between FSP1 or sCD163 levels and rates of biopsy-proven crescent formation. To determine whether FSP1 and sCD163 levels were associated with crescentic formation, we used receiver operating characteristic (ROC) curve analysis.

Results: FSP1 levels in U-EVs correlated positively with U-sCD163 levels (r=0.367, P<0.05). FSP1 levels in U-EVs also correlated positively with rates of biopsy-proven cellular crescent formation (r=0.562, P<0.001). Meanwhile, U-sCD163 levels correlated positively with rates of biopsy-proven cellular (r=0.595, P<0.001), fibrocellular (r=0.511, P<0.001), and fibrous (r=0.501, P<0.001) crescent formation. FSP1 levels in U-EVs and U-sCD163 levels for predicting cellular crescent formation affecting more than 20% of total glomeruli was 2.4 μg/gCr and 14.5 ng/mgCr, respectively, with an area under the ROC curve were 0.88 (95%CI, 0.693 to 1.070) and 0.82 (95%CI, 0.673 to 0.961) (P=0.58). Both U-sCD163 levels and FSP1 levels in U-EVs were significantly reduced after treatment (median: 4.90 to 0.35 ng/mgCr, mean: 2.72 to 0.14 μg/gCr).

Conclusions: These data suggest that both FSP1 in U-EVs and U-sCD163 are available biomarkers of active and ongoing glomerular injury, such as crescent formation. However, it was FSP1 level in U-EVs that specifically reflected cellular crescent formation requiring urgent treatment.

Patients with ANCA-Associated Vasculitis (AAV) Display Major Phenotypic Signs of T-Cell Dysfunction

Joaquin Manrique,[1] Susan Hartzell,[2] Emilie Chan,[3] Ioannis Tassiulas,[3] Andrea Angeletti,[4] Chiara Cantarelli,[5] Chiara Guglielmo,[2] Sofia Andrighetto,[2] Lisa Anderson,[2] Paolo Cravedi.[2] *[1]Complejo Hospital de Navarra, Pamplona, Spain; [2]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Mount Sinai Hospital, New York, NY; [4]Nephrology Dialysis and Renal Transplantation Unit, Sant'Orsola-Malpighi Hospital, Bologna, Italy; [5]Dipartimento di Medicina e Chirurgia, Università di Parma, Parma, Italy.*

Background: In chronic infection and tumors, persistent T cell stimulation results in functional T cell exhaustion and anergy but limited data are available on the association between chronic inflammation in AAV and T cell dysfunction.

Methods: We performed a comprehensive flow-cytometric analyses of major T cell markers of T cells dysfunction, including exhaustion ($KLRG1^+$ $PD1^+$ $CD57^-$), and anergy ($KLRG1^+$ $PD1^-$ $CD57^+$) in 20 patients with AAV with renal involvement (at clinical onset, before immunosuppressive therapy initiation) and 12 healthy controls (HC). We also measured $CD4^+$ $CD25^+$ $CD127^{low}$ regulatory T cells (Treg) and intracellular IFN-g, IL-4, and IL-17 production in the same study groups.

Results: We found a remarkable and statistically significant increase in $CD4^+$ and $C8^+$ T cells with exhausted and anergic phenotype in AAV patients compared to HC (**Fig. 1A-D**). AAV patients also displayed significantly higher levels of circulating Treg (**Fig. 1E**). Despite Treg increase, we did not record a significant difference in intracellular cytokine production.

Conclusions: Patients with AAV display a unique immune phenotype characterized by extensive T cell dysfunction, associated with increased Treg, suggesting the existence of chronic inflammation before clinical onset of the disease.

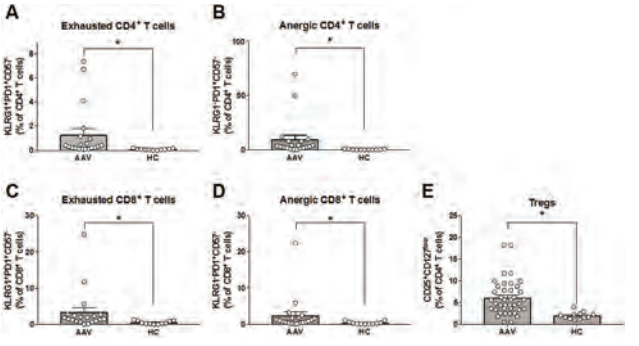

Fig. 1. Percentages of $CD4^+$ (**A-B**) and $CD8^+$ T (**C-D**) cells with exhausted or anergic phenotype and regulatory T cells (Treg) (**E**) according to disease group and in healty controls (HC). *P⟨0.05.

Antibodies to Plasminogen and a Pathogenic Myeloperoxidase (MPO) Epitope Precede MPO- and Proteinase 3-ANCA in Patients with ANCA Vasculitis

Carmen E. Mendoza,[1] Donna O. Bunch,[1] Kristin B. Kennedy,[1] Susan L. Hogan,[1] Yichun Hu,[1] Dustin J. Little,[2] Caroline J. Poulton,[1] Candace D. Henderson,[1] J. Charles Jennette,[3] Ronald J. Falk,[1] Stephen W. Olson.[4] *[1]UNC Kidney Center, Chapel Hill, NC; [2]AstraZeneca, Gaithersburg, MD; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Department of Defense, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: The preclinical immunopathogenesis of anti-neutrophil cytoplasmic autoantibody (ANCA) vasculitis has not been elucidated. Antibodies to plasminogen (anti-PLG) and a specific epitope of myeloperoxidase ($MPO^{447-459}$, anti-KIV) are associated with active disease. The presence of these antibodies has not been examined prior to diagnosis. We hypothesized that anti-PLG and anti-KIV precede detectable MPO-ANCA and proteinase 3 (PR3)-ANCA.

Methods: Up to 4 serum samples collected before clinical diagnosis were available from 64 patients with ANCA vasculitis (50 PR3, 12 MPO, 2 unknown) and 63 healthy controls (HC) matched for age, gender, ethnicity, and timing of sample through the Department of Defense Biorepository. Anti-PLG, anti-KIV, MPO- and PR3-ANCA were measured by ELISA. Analyses accounted for matched pairs using McNemar tests and odds ratios and 95% confidence intervals from stratified exact conditional logistic regression.

Results: Anti-PLG was detected in 17/64 (27%) of cases prior to diagnosis (median = -8.8 years [IQR -13.1, -2.0]). Anti-PLG was positive before ANCA in 76% (13/17) of cases where both were positive. Anti-KIV was detected in 21/64 (33%) of cases prior to diagnosis (-6.6 years [-15.0, -4.1]), was elevated before ANCA in 71% (15/21) cases, and elevated when MPO-ANCA was negative in 33% (4/12) of MPO-ANCA patients. ANCA patients were more likely to have elevated anti-PLG and anti-KIV than matched controls (Table). Limiting analysis to PR3-ANCA patients, the odds ratio for anti-PLG remained statistically significant; the odds ratio for anti-KIV was the same albeit not statistically significant.

Conclusions: Anti-KIV and anti-PLG antibodies are present years before diagnosis and prediagnostic ANCA seropositivity. Thus, anti-KIV and anti-PLG may participate in the initial genesis of the ANCA autoimmune response and be part of a multi-hit immunopathogenic mechanism. The views expressed are those of the author and do not reflect the official policy of the Department of Army, Department of Defense, or U.S. Government.

CD4⁺ T Cell Abnormalities in the Myeloperoxidase-ANCA Associated Vasculitis

Zhonghua Liao,[1] Jiale Tang,[1] Xinyue Hu,[4] Shuanglinzi Deng,[2] Juntao Feng,[3] Xiaozhao Li.[1] *[1]Nephrology, Xiangya Hospital, Central South University, Changsha, China; [2]Respiratory and Critical Care Medicine, Xiangya Hospital, Central South University, Changsha, China; [3]Department of Respiratory and Critical Care Medicine, Xiangya Hospital of Central South University, Changsha, China; [4]Department of Respiratory and Critical Care Medicine, Xiangya Hospital, Central South University, Changsha, China.*

Background: In ANCA-associated vasculitis, MPO-specific CD4 +T cells have been reported to involve in renal injury. Although in Granulomatosis with Polyangiitis (GPA), it has been found that lymphopenia is a common clinical feature, and the effect of treatment was excluded. However the pathogenesis of T cell recruitment is not fully elucidated. Thus, we dissect whether the microscopic polyangiitis patients have the similar symptoms and the underlying pathogenesis.

Methods: Clinical data from 143 newly diagnosed microscopic polyangiitis' patients (Collection time prior to use of Glucocorticoid and immunosuppressants) and 176 healthy controls was collected and analyzed. The phenotypic characterization of peripheral blood lymphocyte in 33 of MPA patients was measured by Flow cytometry. Meanwhile, disease activity of these patients according to the Birmingham Vasculitis Activity Score was marked. The cytokine produced by relevant CD4+T cells was detected. Chemokine and chemokine receptors axis concerning T cell recruitment was observed by immunohistochemistry in formaldehyde-fixed kidney nephridial tissue.

Results: MPA patients' lymphocyte count existing in peripheral blood was significantly decreased compared with healthy control. Besides, abnormal CD4+T cell subsets was found in MPA patients. Specifically, the proportion of Th1, Th9, Th17, Th22 was increased in these patients (BVAS≥15 points). In accordance with this, The concentration of IFN-γ, IL-9, IL-17A, IL-22 was observed to elevate. Moreover, both CXCL10+, CCL20+ cells and CCL27+cells, were adjacent to CXCR3+ cells, CCR6+cells, CCR10+ cells respectively in Paraffin section of kidney.

Conclusions: The activity of microscopic polyangiitis could lead to abnormalitis of absolute count and subsets in CD4⁺ T cells. CD4⁺ T cell is obviously activated and recruited to kidney to induce immunopathologic injury.

FR-PO830

Single-Cell RNA Sequencing Uncovers Distinct Clusters of T Helper 17 Cells In Renal Autoimmune Disease

Christoph Kilian, Alina Borchers, Patricia Bartsch, Yu Zhao, Ulf Panzer, Christian F. Krebs. *University Medical Center Hamburg-Eppendorf, Hamburg, Germany*.

Background: T cells play a pivotal role in the pathogenesis in various autoimmune diseases by their ability to differentiate into pathogenic effector Th1 and Th17 cells, this includes human and experimental glomerulonephritis. CD4⁺ T cells and Th17 cells in particular can have a high degree of plasticity in the brain and intestine but show limited spontaneous plasticity in the kidney. However, the mechanisms that control stability and transdifferentiation of Th17 cells into alternate subsets and the impact of T cell plasticity on autoimmunity are incompletely understood.

Methods: To address the heterogeneity and plasticity of renal Th17 cells in experimental glomerulonephritis in more detail in an unbiased approach, we established single cell RNA-sequencing of FACS-sorted T cells from the kidney in experimental crescentic glomerulonephritis (cGN, NTN).

Results: Here, we report data from 6,841 eYFP positive renal Th17 cells from IL-17A fate reporter mice (Il17aCre x R26reYFP). Our analysis unveiled a pronounced variety within this population. We discovered 10 clusters based on transcriptional similarities. Overall, in 25% of all cells we could detect IL-17A mRNA. These actively IL-17A-expressing cells are enriched in 3 clusters, which underscores the heterogeneity of our dataset. Interestingly, 25% of IL-17A negative cells (exTh17) display expression profiles of inactive states. Moreover, one cluster of cells with a Th1 profile emerged from Th17 cells and one cluster displays high Foxp3 expression indicating transdifferentiation of Th17 cells into Th1 cells and regulatory T cells, respectively.

Conclusions: In summary, our single cell atlas of renal Th17 cells shows a high degree of heterogeneity and expression profiles of the different clusters could build the basis for the analysis of potential cell-cell crosstalk that include resident kidney cells.

FR-PO831

Novel Assays to Distinguish Between Properdin-Dependent and Properdin-Independent C3 Nephritic Factors Provide Insight for Properdin-Inhibiting Therapy

Marloes Michels,[1] Nicole Van De Kar,[1] Ramon M. van den Bos,[3] Thea J. Van der velden,[1] Sanne van Kraaij,[2] Sebastian A. Sarlea,[1] Valentina Gracchi,[4] Michiel J. Oosterveld,[5] Elena Volokhina,[1,2] Lambertus P. Van den heuvel.[1,2] on behalf of the COMBAT consortium *[1]Pediatric Nephrology, Amalia Children's Hospital, Radboud university medical center, Nijmegen, Netherlands; [2]Laboratory Medicine, Radboud university medical center, Nijmegen, Netherlands; [3]Crystal and Structural Chemistry, Bijvoet Center for Biomolecular Research, Department of Chemistry, Utrecht University, Utrecht, Netherlands; [4]Pediatric Nephrology, University Medical Center Groningen, Groningen, Netherlands; [5]Pediatric Nephrology, Emma Children's Hospital, Amsterdam University Medical Center, Amsterdam, Netherlands*.

Background: C3 glomerulopathy (C3G) is a severe renal disorder caused by dysregulation of the alternative complement pathway and is characterized by depositions of C3 fragments in the glomeruli. C3 nephritic factors (C3NeFs) are found in the blood of more than half of C3G patients. These autoantibodies recognize the alternative pathway C3 convertase and prolong its activity. C3NeFs can be dependent or independent of the complement regulator properdin for their convertase-stabilizing function. However, studies to determine the properdin-dependency of C3NeFs are rare and not part of routine patient investigations. Until recently, only supportive treatments for C3G were available. Complement-directed therapies are now being investigated. We hypothesized that patients with properdin-dependent C3NeFs may benefit from properdin-inhibiting therapy to normalize convertase activity.

Methods: Therefore, we have validated two hemolytic assays to distinguish between properdin-dependent and properdin-independent C3NeFs by assessing the convertase activity and stability in absence of properdin. The first assay measures convertase stabilization by patient immunoglobulins in properdin-depleted serum. The second measures convertase stabilization directly in patient serum supplemented with the Salp20, a properdin-blocking agent.

Results: Blood samples from 13 pediatric C3G patients positive for C3NeF were tested for convertase stabilization in absence of properdin. Three patients presented with properdin-dependent C3NeFs as no C3NeF activity was observed in absence of properdin, whereas the C3NeF activity of the other 10 patients was independent of properdin. In the samples of the patients with properdin-dependent C3NeFs, addition of the properdin-blocking agent Salp20 normalized the convertase activity profile.

Conclusions: These results indicate that inhibition of properdin in patients with properdin-dependent C3NeFs can normalize alternative pathway convertase activity and could represent a novel therapy. Our assays provide a tool for identifying C3G patients who may benefit from properdin-inhibiting therapy and should be incorporated into standard C3G laboratory investigations.

FR-PO832

High Levels of Intestinal-Activated IgA⁺ B Lymphocytes Support the Pathogenic Role of Intestinal Mucosal Hyper-Responsiveness in IgA Nephropathy (IgAN) Patients

Fabio Sallustio,[1] Claudia Curci,[1] Nada Chaoul,[1] Gabriella Lauriero,[2] Chiara Divella,[1] Vincenzo Di leo,[1] Sanae Ben mkaddem,[4] Renato C. Monteiro,[3] Anna Gallone,[1] Francesco Pesce,[1] Loreto Gesualdo.[1] *[1]University of Bari, Bari, Italy; [2]University of Bari "Aldo Moro", Altamura, Italy; [3]Bichat Medical School, Paris, France; [4]Inserm U1149-, Paris, France*.

Background: In the last years, the role of mucosal immunity in IgAN, together with that of the gut microbiota in the activation of innate and adaptive immune cells, has gained importance. Particularly interesting is the role of the microbiota and intestinal immunity in IgAN, due to the activity of secretory IgA in the intestinal mucosa. Here we studied the intestinal-renal axis connections analyzing levels of BAFF, April and intestinal-activated B cells in patients and healthy subjects (HS).

Methods: Serum and fecal samples were collected from 44 IgAN patients and 23 HS. BAFF and APRIL serum levels were measured by ELISA assay. Metabolomic analysis of fecal microbiome was performed by mass spectrometry. B cell subsets were identified by FACS. We used anti-IgA, anti-Integrin β7 and anti-CCR9 antibodies to identify B cell subsets producing IgA and B cells from intestinal mucosa.

Results: IgAN patients had increased levels of Baff correlating to higher amounts of 5 specific microbiota metabolites (p=.012). We found also high April levels in IgAN patients. BAFF and APRIL can be produced by the intestinal epithelium, in response to signals triggered by TLRs activated by the commensal bacteria in the intestinal lumen. In addition, we found that IgAN patients have a higher proportion of circulating Breg activated at the intestinal level (CCR9⁺/INTB7⁺) compared to HS (p=0.02). Moreover, IgAN patients had also high levels of CCR9⁺/INTB7⁺ memory Bcells (p=.006) and of intestinal IgA-producing memory Bcells (CCR9⁺/INTB7⁺/IgA⁺ p=.03). Interestingly, they were significantly increased in IgAN patients but not in non-IgA glomerulonephritis. Finally, we found that IgAN patients had high levels both of total plasmablasts (p=.001) and of intestinal-activated plasmablasts (p=.01).

Conclusions: The results of our study showed for the first time an important difference in the amount of intestinal-activated B lymphocytes among patients with IgAN and HS, confirming the hypothesis of the pathogenic role of intestinal mucosal hyperresponsiveness in the IgAN patients. Therefore, this represents an important area of research for new targeted therapies aiming to stop the evolution towards end stage renal disease.

FR-PO833

B Cell and Monocyte Phenotyping in IGA Nephropathy: A Quick Asset to Investigate the Immune Status in Patients with IGA Nephropathy

Senka Sendic,[1,2] Ladan Mansouri,[1] Sigrid Lundberg,[2] Anna Nopp,[1] Stefan H. Jacobson,[2] Joachim Lundahl.[1] *[1]Karolinska Institutet, Stockholm, Sweden; [2]Danderyd Hospital, Stockholm, Sweden.*

Background: IgA nephropathy (IgAN) is the most common glomerulonephritis. Naive and adaptive immune cells play a major role in the development and progression of disease, therefore unraveling a correlation between changes in the immune status of the patient and clinical outcomes is of great value. We aimed to investigate B cell and monocyte phenotype, comparing the IgAN patients with disease controls (patients with polycystic kidney disease) and healthy individuals.

Methods: IgAN patients (n = 13) were recruited from Danderyd Hospital, Karolinska Institutet, Stockholm, Sweden. Patients (men 46%,) with median age of 45 years (IQR 38-60), median eGFR of 57 ml/min x1.73m^2 (IQR 42-84) and median urine albumin-to-creatinine ratio of 74 mg/mmol (IQR 18-116). Disease controls with polycystic kidney disease (n=13) were matched for eGFR, gender- and age (±10 years). Healthy controls (n = 13) were gender- and age-matched (±5 years) with patients. CD3+ cells were isolated from freshly separated peripheral blood mononuclear cells by positive selection using a magnetic cell sorting system. CD3+ and CD3- cells were then divided and stained for different subsets of B cells and analyzed by flowcytometry. Cytokines were analyzed by ELISA.

Results: We report an increase in the proportion of CD14+ CD16++ cells (non-classical monocytes) in patient with IgAN comparing to healthy individuals and disease controls. Decrease in the proportion of CD19+ CD27+ IgD+ cells (pre switched B), CD19+ CD27+ CD38+ cells (plasmablasts) in the peripheral circulation of IgAN patients. IgAN and disease control showed an increase in CD19- CD27hi CD38 hi (transitioned plasma cells). We report a higher proportion naïve/pre switched in IgAN patients compared to healthy- and disease controls. We report significantly higher IL-6 in IgAN compared to helathy controls.

Conclusions: The decrease in the number of circulatory pre-switched B cells and plasmablasts, but an increase of transitioned plasma cells in our study suggests trafficking of subsets of B cells in IgAN patients between peripheral blood and extravascular lymphoid tissues. The increase in the proportion of inflammatory monocytes in IgAN patients may play a role in the high inflammatory state and possible crosstalk between different sectors of the immune system through the IL-6 axis.

FR-PO834

Transglutaminase 2 (TGM2) and Lysozyme Significantly Upregulated in Staphylococcus Infection-Associated Glomerulonephritis (SAGN): A Mass Spectrometry Study

Anjali A. Satoskar,[2] John P. Shapiro,[2] Samir V. Parikh,[2] Michael Merchant,[1] Jon B. Klein,[3] Tibor Nadasdy,[2] Brad H. Rovin.[2] Ohio State University *[1]University of Louisville School of Medicine, Louisville, KY; [2]Ohio State University Wexner Medical Center, Columbus, OH; [3]University of Louisville Kidney Disease Program, Louisville, KY.*

Background: SAGN and primary IgA nephropathy (IgAN) are considered separate disease entities with different treatment approaches. However, overlapping histologic features and mesangial IgA deposits in both lead to diagnostic dilemma. A proteomic study on kidney biopsies was performed to identify potential distinguishing biomarkers.

Methods: Formalin fixed paraffin embedded (FFPE) tissue was used - SAGN (4), primary IgAN (8), baseline transplant biopsies (7), and acute tubular necrosis (ATN) (8) for laser capture and HPLC-MS/MS using the Oribtrap Elite instrument. Spectral counts were modeled as negative binomial distribution and compared. Immunohistochemistry (IHC) for lysozyme, S100 A9, CD68, TGM2 was performed (n=68).

Results: SAGN glomerular proteome showed remarkable similarities with IgAN, but significantly higher expression of monocyte/macrophage proteins - lysozyme and S1009 compared to primary IgAN (Oxford Classification E0 C0 and E1 C1), confirmed by IHC cell counts (Fig.1 p<0.0001, p<0.005 respectively). Tubulointerstitial proteomes differed widely. SAGN proteome resembled that of ATN, with marked downregulation of tubular metabolic pathways (including amino acid degradation, fatty acid oxidation, mitochondrial respiratory pathway) as compared to IgAN. Stress molecule TGM2 was highly expressed in SAGN (and ATN) along with other extracellular matrix proteins, and epithelial tight junction proteins.

Conclusions: SAGN may represent an inflammatory and rapidly progressive form of GN with marked tubular dysfunction, in contrast to primary IgAN. Prominent endocapillary proliferative glomerular lesions with significantly higher number of lysozyme positive cells, coupled with severe ATN and diffuse tubulointerstitial staining for TGM2 may favor SAGN over primary IgAN, in the appropriate clinical context.

Genome-Wide Association Study for Serum Galactose-Deficient IgA1 in IgA Nephropathy

Yanna Wang,[1,2] Xujie Zhou,[1,2] Hong Zhang.[1,2] *[1]Peking University First Hospital, Beijing, China; [2]Peking University Institute of Nephrology, Beijing, China.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. Galactose-deficient IgA1 (Gd-IgA1) plays a key role in the pathogenesis of IgAN. Although the heritability of serum Gd-IgA1 levels is high (ranging from 54% to 80%), the genetic association between Gd-IgA1 and IgAN has not yet been clearly determined. To further identify novel susceptibility loci, we carried out a genome wide association study (GWAS) for serum Gd-IgA1 levels in IgAN patients.

Methods: We performed a quantitative trait GWAS for serum Gd-IgA1 levels, with discovery and follow-up in 1,127 IgAN patients in a Chinese population. Gd-IgA1 levels were measured using a *Helix aspersa* lectin–based ELISA method. The mRNA levels of susceptibility genes in peripheral blood mononuclear cells (PBMCs) were evaluated by mRNA microarrays (Affymetrix PrimeView Human Gene Expression Array and Illumina HT-12 v4 Expression BeadChip).

Results: We identified two loci passing genome-wide significance, including *GALNT12* ($P = 1.67 \times 10^{-8}$, Beta = 0.68) and *C1GALT1* ($P = 3.10 \times 10^{-8}$, Beta = 0.24). Additionally, we confirmed reported association of *C1GALT1* with serum Gd-IgA1 levels, including rs1008897 ($P = 9.75 \times 10^{-3}$) and rs13226913 ($P = 3.89 \times 10^{-2}$), which are common variants in Europeans but rare in East Asians (MAF 34% vs. 5% and 58% vs. 7%). *C1GALT1* variant associated in our study is in partial linkage disequilibrium with rs1008897 (D' = 0.92, $r^2 = 0.07$) and rs13226913 (D' = 0.44, $r^2 = 0.02$). Compared with healthy controls (n = 61), *GALNT12* and *C1GALT1* showed lower mRNA expression in PBMCs from IgAN patients (n = 94) (0.86-fold change, $P = 1.00 \times 10^{-6}$ and 0.90-fold change, $P = 1.92 \times 10^{-4}$, respectively). Sub-phenotype analysis showed that the risk allele of *GALNT12* variant was associated with decreased serum C3 levels (P = 0.02, Beta = - 0.05).

Conclusions: Our study identifies two loci, which encode two enzymes (GALNT12 and C1GALT1) involved in O-linked glycosylation, are associated with serum levels of Gd-IgA1 in IgAN. Down-regulation of these two enzymes may contribute to the generation of aberrantly glycosylated IgA1 in IgAN.

FR-PO836

RNA Sequencing Identifies Novel Genes Implicated in the Pathogenesis of IgA Nephropathy

Ricong Xu. *The First Affiliated Hospital of Shenzhen University, The Shenzhen Second People's Hospital, Shenzhen, China.*

Background: IgA nephropathy (IgAN) is one of the most common form of glomerulonephritis throughout the world and also the leading cause of kidney failure among Asian populations. Previous genetic studies have identified several genetic factors predisposing to IgAN, however, the transcriptome changes of kidney tissue of IgAN are not thoroughly investigated yet, which was crucial for the exploration of the molecular pathogenesis of this disease.

Methods: We used RNA-sequencing to study the whole transcriptome of kidney biopsies of 8 IgAN patients and 5 control samples. Differentially expressed genes (DEG) were identified using DESeq2. GO and pathway enrichment analysis were applied to explore the biology relevance of these DEGs to IgAN.

Results: We identified 54 genes with differential expression between the IgAN patients and the healthy controls, with 41 genes were up-regulation and 13 were down-regulation in the IgAN patients (fold change >1.5 and FDR<0.1). Pathway enrichment analysis revealed that these DEGs were involved in cotranslational protein targeting to membrane, humoral and innate immune response and endothelium development. Among these, the top of six susceptible genes ($P<1\times10^{5}$) were MMP7, SERPINA3, SLPI, RPS27A, FLT1 and NES, which were related to renal fibrosis, innate mucosal defense,

angiotensin II production, and endothelial cell proliferation, indicating that they might participate in the pathogenesis of IgAN.

Conclusions: We found 54 genes were dysregulated in the kidney biopsies of IgAN patients, which provided new insights into the molecular pathogenesis of IgAN.

FR-PO837

Urine Biomarkers for Kidney Injury in IgA Nephropathy

Li Zhang,[2] Xiaolan Zhang,[1] Daniel J. Birmingham,[2] Anjali A. Satoskar,[2] Brad H. Rovin.[3] *[1]The Ohio State University, Columbus, OH; [2]Ohio State University, Columbus, OH; [3]Ohio State University Wexner Medical Center, Columbus, OH.*

Background: IgA nephropathy is the most common primary glomerular disease leading to chronic kidney disease. Clinical management and prognosis rely heavily on renal pathology; reliable biomarkers are needed for non-invasive evaluation of the kidney. The aim of this study was to investigate potential urine biomarkers of kidney injury severity in IgAN.

Methods: Spot urines were collected from 45 IgAN patients at the time of diagnostic kidney biopsy and 29 healthy volunteers (control). Biopsies were classified by the Oxford system and the degree of activity and chronic damage was recorded blindly as none, mild, moderate or severe by the renal pathologist. The candidate biomarkers of kidney injury we assessed were adiponectin, CD163, EGF, NGAL, ICAM1, VCAM1 and complement component C5a. These were measured in urine using R&D DuoSet ELISAs. ANOVA, nonparametric Wilcoxon test and multiple linear regression were done using JMP14 pro for data analysis.

Results: Urine adiponectin, CD163, C5a and VCAM-1 were significantly different than healthy controls with fold-increases of 7, 399, 28 and 7 respectively (all $p<0.0001$), while EGF decreased about 1.4-fold compared to control ($p=0.0015$). Urine EGF was inversely correlated with interstitial fibrosis and tubular atrophy (IFTA, $R^2=0.35$, $p < 0.0001$) and overall chronicity ($R^2=0.49$, $p<0.0001$), while C5a positively correlated with IFTA ($R^2=0.21$, $p=0.0018$). Adiponectin and C5a were both positively correlated with overall activity (based on biopsy MEST score) ($R^2=0.51$, $p=0.0008$ and $R^2= 0.38$, $p=0.008$, respectively). Using receiver operating characteristic analysis, the area under the curve for EGF to differentiate between mild and moderate-severe chronic injury is 0.91 ($p<0.0001$), and for adiponectin to detect the presence of active lesions is 0.96 ($p=0.0011$).

Conclusions: Urine EGF could serve as a biomarker for chronic kidney lesions in IgAN while adiponectin and complement 5a may be biomarkers for active kidney lesions. These biomarkers could be helpful in non-invasively evaluating the efficacy of therapies for IgAN.

FR-PO838

Aberrant Immune Response to Periodontopathic Microbiota in Patients with IgA Nephropathy

Hiroki Yamaguchi, Shin Goto, Masafumi Tsuchida, Hirofumi Watanabe, Suguru Yamamoto, Yoshikatsu Kaneko, Ichiei Narita. *Divsion of Clinical Nephrology and Rheumatology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Aberrant mucosal immune response is implicated in terms of the multi-hit theory of IgA nephropathy (IgAN) development, however, microbiota responsible for pathogenic IgA production in IgAN remained obscure. We have focused until now on roles of microbiome in tonsillar crypts, considering efficacy of tonsillectomy for the treatment of IgAN. To reveal distinct immune responses in IgAN patients, we studied the binding ability of serum IgA against anaerobic bacteria in tonsillar crypts and its relationship with galactose-deficient IgA1 (Gd-IgA1).

Methods: We enrolled 30 biopsy-proven IgAN patients treated with tonsillectomy. Seven recurrent tonsillitis patients who had no urine abnormalities as control. Serum of enrolled patients were fractionated with high-performance liquid chromatography, and the levels of Gd-IgA1 in each fraction were determined by ELISA using KM55 monoclonal antibody. Then, we quantified the binding of each fractionated IgA against bacteria anaerobically cultured from tissues of tonsillar crypts of IgAN patients (*Porphyromonas gingivalis, Prevotella intermedia, and Fusobacterium intermedia,* well known as periodontopathic bacteria, *and Escherichia coli* as control) using flowcytometry.

Results: The serum levels of Gd-IgA1 in IgAN patients were significantly higher than RT patients ($P < 0.01$). In fractionated serum, Gd-IgA1 levels in polymeric IgA fraction of IgAN patients were significantly higher than those of RT patients ($P < 0.05$), but not in monomeric IgA fraction. Polymeric IgA of IgAN patients were more bound to both *Porphyromonas gingivalis* and *Prevotella intermedia* than those of RT patients. The amounts of polymeric IgA bound to *Porphyromonas gingivalis* were significantly correlated with the levels of Gd-IgA1 in polymeric IgA fraction of IgAN patients ($P < 0.01$).

Conclusions: Patients with IgAN exhibit perturbed immune response against periodontopathic microbiota.

FR-PO839

Validation Study of KM55 ELISA Kit in IgA Nephropathy (IgAN) Patients for the Detection of Galactose-Deficient IgA1 (Gd-IgA1) and Corticosteroid Therapy Monitoring

Nikoletta-Maria Kouri,[4] Maria J. Stangou,[4] Samantha Chiurlia,[2] Sharon N. Cox,[3] Yukako Ohyama,[5] Kazuo Takahashi,[5] Aikaterini A. Papagianni,[4] Francesco P. Schena.[1,2] *[1]University of Bari, Bari, Italy; [2]Schena Foundation, Valenzano-Bari, Italy; [3]Schena Foundation, Valenzano-Bari, Italy; [4]Aristotle University of Thessaloniki, Hippokration Hospital, Thessaloniki, Greece; [5]Fujita Health University School of Medicine, Toyoake, Japan.*

Background: Serum levels of Gd-IgA1 may be considered the first biomarker of IgAN. In the past, Gd-IgA1 was detected by sophisticated methods such as mass spectrometry (MS) and lectin based assay. Recently, a monoclonal antibody KM55 that specifically binds Gd-IgA1 has become commercially available. Aim of our study has been i) to validate this tool, ii) to analyze relationships between serum Gd-IgA1 levels and the outcome of the disease and iii) to study the effect of corticosteroids (CS) on this non-invasive biomarker.

Methods: Serum levels of Gd-IgA1 were measured using ELISA Kit (Immune-Biological Lab. Co. LTD, Japan) in a cohort of 63 IgAN patients, 31 healthy blood donors (BD) and 31 primary non-IgAN (enrolled at the time of kidney biopsy in the Dept of Nephrology, Aristotle Univ of Thessaloniki, Greece). Fourteen IgAN patients were followed-up for a median time of 8.6±6.1 years. High resolution mass spectrometric (HRMS) analysis was used to study 2 IgAN patients with high serum level of Gd-IgA1, 2 IgAN patients with low serum Gd-IgA1 levels and 2 BD, to confirm the profile of IgA1 O-glycoforms.

Results: Patients with IgAN had higher values of Gd-IgA1 (1.53 ± 1.06 mg/dl) than controls (0.90 ± 0.65 mg/dl $p=0.002$) and patients with non-IgAN (0.89 ± 0.70 mg/dl $p=0.001$). HRMS analyses confirmed that less O-glycosylated glycoforms were predominantly presented in IgAN patients with high values of Gd-IgA1. A significant reduction of Gd-IgA1 serum levels was found during the follow-up compared to baseline values ($n=14$ $p<0.01$). This decline was more prominent in patients who received corticosteroids ($n=8$, $p=0.008$). The values of Gd-IgA1 did not influence the progression of renal damage (50% reduction of baseline eGFR).

Conclusions: High Gd-IgA1 serum levels characterize patients with IgAN at the time of kidney biopsy. During the clinical course of the disease Gd-IgA1 levels decline but this reduction is more prominent in patients receiving CS. This biomarker may be used for monitoring the effects of CS therapy

FR-PO840

Quantitative Determination of Human IgA Subclasses in Plasma and Their Fc-Glycosylation Patterns by Using Peptide Analogue Internal Standard and an UHPLC-Triple Quadrupole Mass Spectrometry

Chih-chin Kao,[1] Hsiao-Fan Chen,[2] Isabel I-Lin Tsai.[2] *[1]Taipei medical university hospital, Taipei, Taiwan; [2]Taipei Medical University, Taipei, Taiwan.*

Background: Glycosylation on the Fab and Fc regions of immunoglobulins is important for immune function. In this study, we developed and validated a method for the quantification of immunoglobulin A by using affinity purification and UHPLC (ultra-high-performance liquid chromatography)-MS/MS. Twenty-seven IgA-related Fc N-glycopeptides were also detected.

Methods: Peptide M was used to purify IgA, and a peptide analog was added as an internal standard. After on-bead digestion, samples were analyzed by UHPLC-MS/MS. After validation, the method was applied to plasma samples from 24 patients and 6 healthy controls, and the results were compared to those from ELISA assays.

Results: Correlation coefficients were greater than 0.999 for the IgA1 and IgA2 calibration curves and greater than 0.982 for glycopeptide regression curves. Intraday and interday precisions for IgA1 and IgA2 were <1.6% and <5.1% RSD, respectively. Intraday and interday accuracies ranged from 102.6-114.9% and 103.5-113.5% for IgA1 and IgA2, respectively. Recoveries for IgA1 and IgA2 in long-term and short-term stability ranged from 96.0-109.4%. Recoveries after three freeze-thaw cycles ranged from 93.2-113.2% for IgA1 and IgA2. The Pearson's correlation was 0.84 when comparing the quantification of the 30 clinical samples by ELISAs and the developed UHPLC-MS/MS method.

Conclusions: IgA1 and IgA2 were isolated by peptide M purification. An efficient on-bead digestion process was used prior to UHPLC-MS/MS analysis. The validated method was successfully applied to clinical samples which showed high correlation to the total IgA quantification ELISA results. This method has potential for investigating IgA profiles from human plasma.

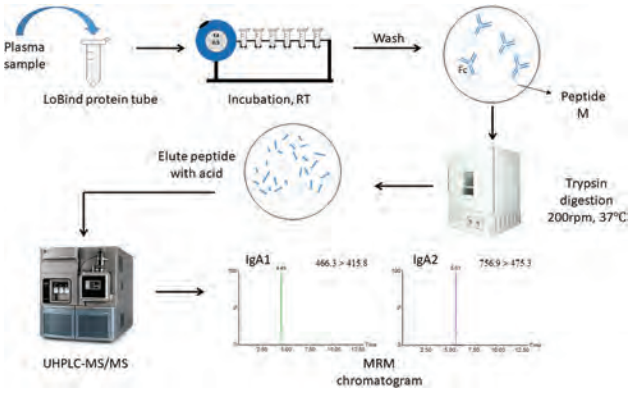

Figure 1. Workflow of IgA purification and UHPLC-MS/MS analysis.

FR-PO841

Prevalence of Periodontal Disease Bacteria in Tonsils of IgA Nephropathy Patients

Yasuyuki Nagasawa,[1] Ryota Nomura,[2] Taro Misaki,[3] Seigo Ito,[4] Shuhei Naka,[6] Kaoruko Wato,[2] Yukiko Hasuike,[1] Takahiro Kuragano,[5] Masaharu Ishihara,[1] Michiyo Matsumoto-Nakano,[6] Kazuhiko Nakano.[2] *[1]Hyogo College of Medicine, Nishinomiya, Japan; [2]Osaka University Graduate School of Dentistry, Suita, Japan; [3]Seirei Hamamatsu General Hospital, Hamamatsu, Shizuoka, Japan; [4]National defense medical college, Tokorozawa, Japan; [5]Internal Medicine Division of Kidney and Dialysis, Nishinomiya, Japan; [6]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: IgA nephropathy (IgAN) is one of most common primary glomerulonephritis, whose pathogenesis had remained unclear. We had reported that *C.rectus* and *T.denticola,* kinds of major periodontal disease bacteria, in tonsils with IgA nephropathy patients were specific to IgAN patients compared with chronic tonsillitis (Nagasawa-Y et al, Plos One, 2014). We also reported *C.rectus* and S.mutans increased proteinuria synergistically (Misaki-T et al, Nephron, 2018). *P.gingivalis* had not been evaluated in IgAN patients, although *P.gingivalis* is well known as one of most common periodontal disease bacteria. In this study, we evaluated the periodontal disease bacteria including *P.gingivalis* in tonsils of IgAN patients, and the relationship between these periodontal bacteria clinical features in IgAN patietns.

Methods: Tonsils were obtained from 23 IgAN patients and 63 chronic tonsillitis patients when the tonsillectomy was operated. mRNAs were extracted from tonsils and the prevalences of *C.rectus* and *T.denticola*, and *P.gingivalis* were evaluated by RT-PCR using bacteria specific primers. All patients gave the written informed consent which was approved by Hyogo College of medicine.

Results: Average age was 33+-14 in IgAN patients, and the age in control patients was 27+-7. The average proteinuria in IgAN patietns was 0.9+-1.1g/gcre, and average hematuria was (2+). The prevalence of *C.rectus* in IgA patients was 76%, while the prevalence in control patients was 62%. The prevalence of *T.denticola* was very low in both groups (0%, 1.6%). The prevalence of *P.gingivalis* in IgA patients was significantly higher than that in control patients (33% vs 3.2%, respectively, P=0.0001), which had not been reported. IgAN patients with *C.rectus* had greater proteinuria than those without *C.rectus* (1.2+-0.4 vs 0.5 +-0.3, respectively). IgAN patients with or without *P.gingivalis* had same levels of proteinuria (1.1+-0.4 vs 1.1 +-0.3, respectively). The types of cilia of *P.gingivalis* (fim A types) were also evaluated. Obviously untypeable of fim A, which is usually minor type, was dominant in IgAN patients.

Conclusions: Periodontal disease bacteria including *P.gingivalis* in tonsils were related with IgAN. The type of cilia of *P.gingivalis* might have some relationship with pathogenesis of IgAN

FR-PO842

TLR7-GalNAcT2 Axis Modulated IgA1 O-Glycosylation in Patients with IgA Nephropathy

Nuoyan Zheng,[1] Xueqing Yu.[2] *[1]The first affiliated hospital of Sun Yat-sen University, Guangzhou, China; [2]Department of Nephrology, Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: IgA nephropathy (IgAN) was featured with galactose deficient-IgA1 (Gd-IgA1) complex deposit in kidney of patients. O-glycosyltransferases were responsible for O-glycan synthesis, which made them crucial for the production of Gd-IgA1. Toll-like receptors (TLRs) were shown to be related with pathogenesis of IgAN. The underlying mechanism between TLRs and the production of Gd-IgA1 was not known yet.

Methods: Biopsy proven IgAN patients with clinical features of primary IgAN, MCD, MN, LN were enrolled in this study. Paraffin-embedded sections of kidney biopsies were subjected to immunofluorescence staining for analysis of TLR7 expression. Peripheral blood mononuclear cells (PBMCs) were prepared and used for real-time PCR analysis or cell-culture experiments.

Results: Here we found that TLR7 proteins were abundantly presented in infiltrated leukocytes in kidney of IgA patients (n=90), as compared with healthy donors and patients with MCD or MN. The mean fluorescence intensity of TLR7 was associated with renal function deterioration. Renal expression of TLR7 protein was evidently presented in CD19+ B cells. Moreover, mRNA levels of TLR7 were significantly correlated with those of GalNAcT2 in PBMCs and they were both increased in B cells of IgAN patients. After activation with TLR7 ligand-R848, PBMCs from IgAN patients secret more Gd-IgA1 molecules than controls and expression GalNAcT2 was increased in sorted B cells from IgAN patients. Over-expression of TLR7 led to up-regulated expression of GalNAcT2, whereas knockdown-expression of TLR7 led to down-regulated expression of GalNAcT2. Over-expression of GalNAcT2 in B cells resulted in augmented synthesis of Gd-IgA1 molecules, but not total IgA1 molecules.

Conclusions: Taken together, the abundant presence of TLR7 play important roles in pathogenesis of IgA nephropathy, by promoting GalNAcT2 expression in B cells and later the synthesis of Gd-IgA1 molecules.

FR-PO843

Novel Urine Metabolite in Human as a New Differential Diagnosis Biomarker for Lupus Nephritis

Shin'ichi Akiyama,[1] Akiyoshi Hirayama,[2] Asaka Hachiya,[3] Tomoyoshi Soga,[4] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Keio University, Tsuruoka, Japan; [3]Nagoya University, Nagoya, Japan; [4]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan.*

Background: Lupus nephritis (LN) is one of the major causes of mortality and disability in patients with systemic lupus erythematosus (SLE). LN shows many phenotypes so diagnosis is not easy and takes time and labor. Non-invasive biomarkers are required to accelerate diagnosis. The present study aimed to identify urine metabolites as new biomarkers for screening for LN from another nephritis.

Methods: Using capillary electrophoresis and mass spectrometry (MS), we analyzed low molecular weight metabolites in a total of 394 urine samples obtained from Japanese patients with biopsy-proven LN (n=27, n=13), membranous nephropathy (n=78, n=43), diabetic nephropathy (n=29, n=14), MCNS (n=74, n=22), FSGS (n=29, n=10), IgA-nephropathy (n=18, n=10), and rheumatoid arthritis (n=19, n=8), in discovery (n=274) and validation (n=120) cohorts, respectively. All urine samples were collected at the time of diagnosis. Multivariate analyses were used for the identification of marker candidates and development of discriminative models. Identification of chemical structure was made on the basis of NMR and liquid chromatography and MS/MS.

Results: We found that an initially unknown metabolite (peak ID: CU040) was present in the urine of LN patients and that measurement of its concentration could distinguish LN from another nephritis. Logistic regression models facilitated the discrimination between LN and other nephritis and yielded high areas under receiver-operating characteristic curves. The area under the curve values, sensitivity, and specificity were 0.8218, 0.7037 and 0.9717 in the discovery cohort, and 0.8698, 0.8462 and 0.9346 in the validation cohort, respectively. Based on the result of chemical structure analysis, the CU040 was identified as 3',4'-didehydro-3'-deoxycytidine ($C_9H_{11}N_3O_4$, MW 225.07). To the authors' knowledge, this metabolite has not been detected in humans, but it has been reported in 2013 as a novel biomarker for infection of *Plasmodium berghei* in the urine of malaria model mice(PMID: 24067624).

Conclusions: The 3',4'-didehydro-3'-deoxycytidine in urine was a novel and excellent differential diagnosis biomarker for LN. Our results may suggest the existence of a common molecular mechanism between malaria and SLE, and it is also very interesting from the viewpoint of understanding the pharmacological effect of Hydroxychloroquine.

CTLA4-ICOS Intergenic Variants Associated with Lupus Nephritis in Chinese Populations

Yuan-yuan Qi, Xinran Liu, Xiao-xue Zhang, Yaling Zhai, Pu Xinyu, Xiao-yang Wang, Yanna Dou, Jing Xiao, Zhan-zheng Zhao. *Institute of Nephrology , Nephrology Hospital, the First Affiliated Hospital of Zhengzhou University, Henan,China, Zhengzhou, China*.

Background: Lupus nephritis (LN) is one of the most prevalent and serious complications of systemic lupus erythematosus (SLE). *CTLA4* (cytotoxic T lymphocyte-associated protein 4) and *ICOS* (inducible T cell co-stimulator) are good candidate genes for SLE because of their role in regulating T cell activation. And the combination of CTLA-4Ig and cyclophosphamide therapy very effectively arrested the progression of murine lupus nephritis. Therefore, the aim of the present study was to identify susceptibility variants in *CTLA4-ICOS* intergenic region along with its functional significance.

Methods: In genetic association analysis, the discovery Beijing cohort (500 LN patients and 500 healthy controls) was adopted from previous reported GWAS data with the use of ImmunoChip arrays. The replication cohort was recruited from Henan population (508 LN patients and 812 healthy controls) and the genotyping was conducted by Sequenom Massarray. To identify functional significance, we analyzed publicly available Encyclopedia of DNA Elements data on transcription factor binding sites, blood expression quantitative trait locus data. The effect of SNP on expression was referred to GTEx2015_v6 and Westra2013 eQTL studies.

Results: In the discovery stage, a total of 136 single-nucleotide polymorphisms in a region spanning 113 kb encompassing *CTLA4-ICOS* were analyzed in 1000 individuals from Beijing cohort. Twenty four of them were significantly associated the susceptibility to LN ($p<0.05$). rs17268364 and rs13029135 were the top signals ($p = 1.41 \times 10^{-2}$, OR = 0.77, 95% CI 0.62 - 0.95) and were in high linkage disequilibrium (r-square = 0.99, D' = 1). This genetic association of rs17268364 was successfully replicated in an independent cohort with 508 LN patients and 812 healthy controls in Henan cohort ($p = 3.08 \times 10^{-4}$, OR 0.71, 95%CI 0.58 - 0.85). After combined analysis of Beijing cohort and Henan cohort, the association was further reinforced ($p = 1.31 \times 10^{-5}$, OR 0.73, 95%CI 0.64 - 0.84). Functional analysis predicted conservative and regulatory features of rs17268364. In eQTL analysis, rs17268364 was associated with the expression of CTLA4 ($p = 2.62\times10^{-6}$) and ICOS ($p = 3\times10^{-3}$).

Conclusions: Our results suggested genetic association between variants in the intergenic region of *CTLA4-ICOS* and LN risk in Chinese population.

FR-PO845

Angiotensin II Type 1 Receptor Agonist Antibodies Are Prevalent in Lupus Nephritis Patients and May Be Associated with Vascular Damage

Carlos A Carranza, Juan M. Mejia-Vilet, Cristinoc Cruz, Mariedel Trujeque, Luis E. Morales-Buenrostro. *Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de Mexico, Mexico*.

Background: Angiotensin type II receptor antibodies (AT1R-Ab) have been linked to hypertension, vascular inflammation and atherosclerosis in human diseases. The aim of this study was to determine the association between AT1R-Ab and intima-media thickness (IMT), microvascular damage and lupus nephritis (LN) activity.

Methods: Plasma AT1R-Ab were evaluated in 107 patients with biopsy proven LN. Then 80 patients were prospectively followed for one-year. Plasma AT1R-Ab, double-strand DNA antibodies (dsDNA-Ab), complement C3 and C4 were assayed in plasma samples obtained at 3, 6 and 12-months from the start of treatment. Morphometric analysis of the kidney biopsy vessels was performed to determine intimal fibrosis and medial layer thickness. Carotid IMT was evaluated by USG at the time of biopsy and then at one-year in 22 AT1R-Ab patients. The comparisons between AT1R-Ab+ and AT1R-Ab- patients were performed by Chi-square and Mann-Whitney's U. Association between the AT1R-Ab course and other parameters was evaluated by linear mixed models.

Results: AT1R-Ab were positive in 58 (54%) patients and higher than in inactive LN patients and kidney donors. AT1R-Ab+ patients had higher dsDNA-Ab (287 UI/ml [97-814] Vs. 26 UI/ml [26-182], p<0.001), lower complement C3 (62mg/dl [43-80] Vs. 74mg/dl [50-101], p=0.016), higher histologic activity index (5 [3-11] Vs. 2 [1-7], p=0.020), more segmental lesions (67% Vs. 43%, p=0.013) and more class III LN (43% Vs. 20%, p=0.019) than AT1R-Ab- patients. The prevalence of subintimal fibrosis >10% was 47% and the percentage of subintimal fibrosis was higher in AT1R-Ab+ patients (12% [6-20] Vs. 7% [3-16%], p=0.025). The area of medial layer hyperplasia was greater in AT1R+ patients ($72um^2$ [61-88] Vs. $55um^2$ [42-66]). On multivariate analysis, AT1R-Ab titers were independently associated with the degree of medial hyperplasia. The course of AT1R-Ab on follow-up was associated with the course of dsDNA-Ab (r=+0.454, p<0.001), complement C3 (r=-0.185, p=0.049) and C4 (r=-0.281, p=0.013). There were no significant changes in IMT after 12 months of follow-up between AT1R-Ab+ and AT1R-Ab- patients.

Conclusions: AT1R-Ab are associated with vascular medial hyperplasia and segmental glomerular damage in LN patients and are associated with serological biomarkers.

FR-PO846

Increased CaMK4 Expression in Podocytes from Renal Biopsies of Patients with lupus Nephritis Is Mirrored by Its Levels in Cultured Podocytes Exposed to Serum IgG and in Urine Podocytes

Rhea Bhargava,[1] Kayaho Maeda,[1] Maria Tsokos,[2] Abhigyan Satyam,[1] George C. Tsokos.[1] *[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Lupus nephritis (LN) is a devastating and potentially fatal disease that mainly affects women of child-bearing age. We previously demonstrated that Calcium/Calmodulin Kinase IV (CaMK4) inhibition in podocytes by cell targeted therapy prevents LN in mice. Here we explore the association of renal CAMK4 expression with the presence of LN in patients with SLE and describe novel noninvasive methods to identify patients prone to develop LN.

Methods: Expression of CaMK4 in frozen renal biopsy specimens from thirty individuals referred to rule out LN was evaluated by immunofluorescence. Logistic regression models were used to analyze the predictive value of CAMK4 in the development of LN. Immortalized human podocytes were examined for CaMK4 expression before and after exposure to IgG from ten SLE patients with and without LN and 5 healthy controls. We further devised a novel method to rapidly isolate urinary podocytes by using magnetic beads and successfully extract RNA.

Results: CaMK4 expression in podocytes is a strong predictor of active LN($p<.01$, β 2.36). Culture of podocytes in the presence of IgG from patients with active LN led to increased CaMK4 expression along with reduction in expression of nephrin while no changes were demonstrated in the presence of IgG from normal subjects or from individuals with SLE without nephritis. CaMK4 deficiency or pharmacologic inhibition preserved nephrin expression. CaMK4 inhibited GSK3beta by phosphorylating it at serine 9 which led to stabilization of transcription factor SNAIL and subsequent repression of nephrin transcription. Urinary podocytes from fresh urine were successfully and rapidly isolated by a novel magnetic bead method. Urinary podocytes from patients with active LN, but not from those without kidney disease, displayed increased expression of CaMK4 and CD80.

Conclusions: We conclude that CaMK4 expression in podocytes is a feature of patients with LN and more importantly, we present two novel assays to replace the need for kidney biopsy. We have shown that rapidly isolated urine podocytes from patients with LN, using a new protocol, and cultured podocytes exposed to IgG from patients with LN express CaMK4 which reflects the levels detected in the kidney biopsy material of patients with active LN.

Self-Clustering of Tissue Gene Expression to Classify Patients with Lupus Nephritis

Salem Almaani,[1] Lianbo Yu,[1] Huijuan Song,[1] Samir V. Parikh,[1] Isabelle Ayoub,[1] Juan M. Mejia-Vilet,[2] Ana Malvar,[3] Brad H. Rovin.[1] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; [3]Hospital Fernandez, Buenos Aires, Argentina*.

Background: Histologic classification of kidney biopsy in lupus nephritis (LN), while used for treatment decisions, is not sufficiently robust to account LN's molecular heterogeneity that affects treatment response and outcomes. We tested whether unsupervised clustering of LN biopsies based on tissue gene expression was feasible to classify LN. We postulated that such a classification of LN would reflect disease pathobiology and would be more relevant to managing LN with drugs targeting specific pathogenic pathways.

Methods: Transcript levels of >500 genes involved in autoimmunity were measured using NanoString in microdissected glomeruli from 57 LN patient biopsies, and then used for unsupervised hierarchical clustering. For each gene, mRNA abundance was compared between each cluster group (CG) and the mean abundance of the other groups to determine genes that were differentially expressed. Differentially-expressed genes from each CG were used for pathway analysis. Demographic, clinical and histopathologic data were also compared between CGs using ANOVA and Fisher's exact test as appropriate.

Results: Clustering resulted in 4 CGs. There were no significant differences in baseline creatinine, proteinuria, NIH activity or chronicity indices, or ISN/RPS class between CGs. Canonical pathway and upstream regulator analysis differentiated CGs (Table).

Conclusions: Transcript expression in the glomerular compartment of LN kidney biopsies identifies 4 subsets of patients. Inflammatory pathways expression appears to be highest in CG2 followed by CG4, and relatively suppressed in CG1 & 3. We suggest it may be feasible to tailor treatment to patients based on their CG classification of injury pathways that are differentially expressed.

Peripheral Blood RNA Signatures for Active Kidney Injury in Lupus Nephritis

Xiaolan Zhang,[1] Jessica M. Greco,[2] Li Zhang,[1] Tibor Nadasdy,[1] Paolo Fadda,[1] Brad H. Rovin.[2] *[1]Ohio State University, Columbus, OH; [2]Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Because lupus nephritis (LN) is a manifestation of a systemic process it is reasonable to ask whether circulating leukocytes can serve as a source of biomarkers of active kidney disease. To begin to examine this question we characterized the immune transcriptome of peripheral blood cells at the time of kidney biopsy and looked for associations with renal histology.

Methods: We studied 44 patients with SLE and kidney biopsies consistent with LN, 9 patients with IgAN as immune complex disease controls, and 5 healthy controls. Total RNA was extracted from buffy coats collected at the time of kidney biopsy and tested on a customized gene expression nCounter GX CodeSet. The Nano-String raw data were analyzed with nSolver™ 4.0 software and JMP 14 pro statistical program. Differential expression of significant transcripts was further confirmed by TaqMan gene expression real-time RT-PCR. The NIH activity (AI) and chronicity (CI) indices of the patients' kidney biopsies were scored by a renal pathologist.

Results: Compared to healthy and disease controls 57 out of 199 transcripts were overexpressed in LN patients. Of these, 25 genes were significantly increased 2-fold or more in active LN ($P<0.0001$). Over half of these 25 genes are involved in type I interferon signaling. Other differentially-activated pathways included cytokine-mediated responses, B-cell activation and apolipoprotein metabolism. The top overexpressed transcripts in LN were IFI27, CD169, LAMP3 and DNAPTP6 which were 49, 21, 18 and 12-fold higher than healthy and disease controls. PCR confirmed these RNA signatures with IFI 243-fold and CD169 24-fold higher than disease controls. AI correlated positively with APOEBC3A and IL-1A (both $R^2=0.19$) and negatively with TRADD ($R^2=0.31$), while MIP-1a ($R^2=0.2368$) positively correlated with CI (all, $P<0.01$).

Conclusions: Interferon-I signaling, cytokine response, B-cell activation and lipoprotein metabolism are the major differentially-activated in peripheral blood cells during LN flares. AI and CI correlates are mainly cytokines, mediators of innate immunity, and apoptosis.

Development of Novel Algorithms to Characterize Lupus Nephritis (LN) Renal Activity and Chronicity Using Urine Proteomics

Ahmad Akhgar,[1] Lingmin Zeng,[1] Alton B. Farris,[2] Binbing Yu,[1] Dominic Sinibaldi,[1] Jason Cobb,[3] Monica Battle,[2] Gabor Illei,[4] S. Sam Lim,[2] Wendy I. White.[1] *[1]AstraZeneca, Boyds, MD; [2]Emory University, Atlanta, GA; [3]Emory University School of Medicine, Atlanta, GA; [4]Viela Bio, Gaithersburg, MD.*

Background: We assessed the utilization of the widely available, high throughput platform for multiplex analysis of urine proteomics to define limited sets of baseline markers correlating with LN histopathology results assessed by the NIH Activity (NIH-AI) and Chronicity (NIH-CI) Indices. Novel algorithms were developed to characterize patients into high and low subgroups. Longitudinal urine sample were used as surrogates to monitor the disease indices over time.

Methods: Baseline urine samples were collected from 42 LN patients. Baseline LN biopsies were interpreted by an expert pathologist. Additional LN samples were collected over a year. Urine samples were tested on a large Luminex multiplex platform. Stepwise regression and single variable regression results were combined to limit the possible candidate urine biomarkers. A multivariate logistic regression model (MLRM) was applied to the remaining markers. Selection criteria for biomarkers were p values < 0.05, high area under the curve, and a low misclassification rate. Receiver operating characteristic curves based on cross-validations evaluated the predictiveness of selected biomarkers.

Results: Data from 288 markers were reduced to 177 by assessing assay robustness. Four markers (CD163, ferritin, KIM-1, and antileukoproteinase) were identified ($P<0.05$) in the MLRM, which predicted 93% of the NIH-AI high patients with a false positive rate (FPR) of 11%. The predicted probability of high activity patients decreased over time relative to baseline as serum albumin increased and proteinuria decreased, reflecting decreased activity. The markers identified for NIH-CI were hepatocyte growth factor, Eotaxin-2, IL-6R β, and ITAC. The model predicted 81% of patients with high NIH-CI with a FPR near 0%.

Conclusions: This study supports the continued evaluation of urine biomarkers with a multiplex immunoassay platform validated to clinical laboratory standards and could support wide distribution as a Luminex-based test. Novel combinations of markers were associated with renal histopathologic activity and chronicity (high and low categories) in LN. Treatment led to alterations in activity and chronicity longitudinally.

Study of T-Regulatory Cells and B-Regulatory Cells in Lupus Nephritis: A Prospective Observational Study

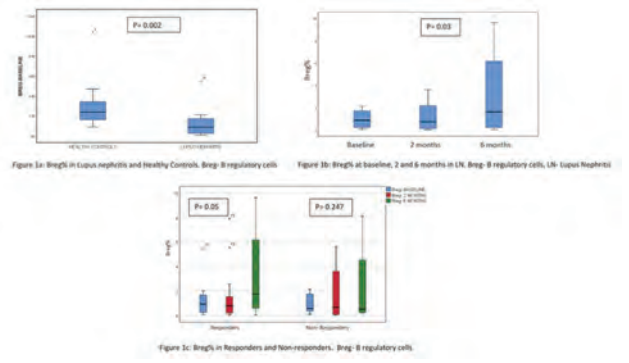
Niveditha Girimaji, Krishan Lal L. Gupta, Raja Ramachandran, Manish Rathi, Aruna Rakha, Aman Sharma, Ritambhra N. Duseja. *Post Graduate Institute of Medical Education and Research, Chandigarh, Chandigarh, India.*

Background: Studies in lupus nephritis(LN) have shown impairment in both T regulatory(Treg) number and function. The data on B regulatory (Breg) is limited in LN. We conducted a prospective observational study of Treg and Breg populations in LN and their trend after initiation of immunosuppression.

Methods: Study included 20 patients of treatment-naïve LN of ISN/RPS Class III(±V), IV(±V), V and 10 healthy controls(HC). Immunophenotyping was performed for peripheral blood mononuclear cell samples using flurochrome labelled monoclonal antibodies for identification of Tregs ($CD3^+$ $CD4^+$ $CD25^{hi}$ $CD127^{lo}$ $FoxP3^+$), Bregs ($CD19^+$ $CD5^+$ $CD1d^{hi}$ $IL\text{-}10^+$), Immature cells ($CD19^+$ $CD24^{hi}$ 38^{hi}) and B 10 cells ($CD19^+$ $CD24^{hi}$ $CD27^+$), each expressed as percentage of T and B cells. Each lymphocyte population was analysed at baseline, 2 and 6 months after initiation of immunosuppression. Regulatory cells between groups was analysed by Mann Whitney U test and within groups by Wilcoxon signed rank test and Freidman's test, as applicable.

Results: Bregs were significantly decreased compared to HC at baseline ($p=0.002$). With immunosuppression, Bregs showed significant increase at 2 and 6 months ($p=0.03$). Bregs in responders showed an increasing trend at 2 and 6 months ($p=0.05$), while they did not in non-responders ($p=0.247$). The increase in Bregs did not significantly differ between different immunosuppressive regimens given. At baseline, Bregs in responders and non- responders were not significantly different. Immature cells and B10 cells were significantly higher compared to HC ($p<0.001$). Tregs did not differ significantly from HC and did not show significant increase at 2 and 6 months, in both responders and non-responders.

Conclusions: We observed that Breg populations in treatment-naïve LN were significantly reduced compared to HC and increased significantly with immunosuppression. Responders had a trend toward increase in Bregs over time, whereas non-responders did not.



Bregs in HC and LN

FR-PO851

C1q A08 Is a Half-Cryptic Epitope of Anti-C1qA08 Antibodies in Lupus Nephritis and Important for the Activation of Classical Complement Pathway

Ying Tan, Ming Hui Zhao. Renal Division, Department of Medicine, Peking University First Hospital; Institute of Nephrology, Peking University *Peking University First Hospital, Beijing, China*.

Background: Anti-C1q antibody is one of the most important autoantibodies in lupus nephritis, while its role in pathogenesis of lupus nephritis is not so clear. Our previous study found that C1q A08 antibody correlated better with lupus nephritis relapse than antibody against intact C1q molecule in a large Chinese cohort, and could predict reanl prognosis in lupus nephritis. This study aims to verify the role of A08 by anti-C1q A08 antibodies in lupus nephritis

Methods: Anti-C1q A08 antibodies from ten patients with lupus nephritis were purified from plasmapheresis samples. Four monoclonal antibodies against C1q A08 is screened from mouse hybridoma cells to study the conformational change of C1q in different situation by ELISA and Biolayer Interferometry (BLI) method. The biofunction of anti-C1q A08 antibodies in activation of classical complement pathway was investigated by C3 activation assay.

Results: All C1qA08 antibodies isolated from ten lupus nephritis patients could not bind C1q coating on microtiter plate and the anti-C1q autoantibodies were not able to bind to resin coupled with C1q A08 peptide, which indicates that different epitopes of C1q were recognized by C1q antibodies and C1q A08 antibodies. One of the four C1q A08 mAb(32-4) binds to six amino acids of the N-terminal, while another C1q A08 mAb(17-9) could bind to eight or ten amino acids of the C-terminal. The third and fourth C1q A08 mAb(1A12 and 4B11) could bind to the whole sequence of C1qA08(Figure 1). 32-4 mAb could bind to C1q coating on ELISA plate, while 17-9 mAb, 1A12 mAb and 4B11 mAb could not. However, different result was shown by BLI method. That is, 17-9 mAb, 1A12 mAb and 4B11 mAb could bind to C1q but 32-4 mAb could not. 1A12 mAb and 4B11 mAb were able to prevent the activation of classical complement pathway, while 32-4 and 17-9 mAb could not.

Conclusions: C1q A08 is one important but half-cryptic epitope of C1q, only part of the six amino acids is cryptic. A08 is important in activation of classical complement pathway and some anti- A08 antibodies were able to prevent this process.

FR-PO852

Xenon Blunts NF-κB/NLRP3 Inflammasome Activation and Improves Acute Onset of Accelerated and Severe Lupus Nephritis in Mice

Shuk-Man Ka,[1] Ann Chen.[2] [1]*National Defense Medical Center, Taipei, Taiwan, Taipei, Taiwan;* [2]*Tri-Service General Hospital, National Defense Medical Center, Taipei, Taipei, Taiwan*.

Background: Accelerated and severe lupus nephritis (LN) might follow episodes of bacterial or viral infections as environmental triggers in patients with LN. Xenon (Xe), an anesthetic gas, is increasingly recognized to possess many desirable properties, including cytoprotective and anti-inflammatory effects.

Methods: The present study evaluated the effects of Xe on the progression of LN in a mouse model. A mixture of either 70% Xe or 70% N2 balanced with O2 was given daily to female NZB/W F1 mice with acute onset of progressive renal lesions and renal functional disturbance for 2 hrs for 5 weeks. Renal function and pathology and mechanistic studies were performed, including reactive oxygen species (ROS) production, activation of NF-κB/NLRP3 inflammasome and apoptosis-related pathway, proteomics-based NLRP3 inflammasome-mediated signaling.

Results: The mice that were induced of accelerated and severe LN were successfully treated with Xe in renal function and pathology, chemoattractants for neutrophils, and glomerular neutrophil infiltration, primarily through inhibiting ROS production, NF-κB/NLRP3 inflammasome activation, ICAM-1 expression, and apoptosis in the kidney. Moreover, Xe reduced the expression of p-NF-κB p65, ICAM-1 and p-p38 MAPK, and inhibited levels of total and mitochondrial ROS production as well as mitochondrial damage in activated primary mesangial cells. Proteomics analysis revealed that the Xe treatment downregulated renal NLRP3 inflammasome-mediated cellular signaling.

Conclusions: The results suggest that Xe may shed light of therapeutic value in treating such cases of LN although it might warrant further study.

Kidney Biopsy Proteome Reveals Novel Molecules and Pathways in Lupus Nephritis

Asmaa S. Abu-Maziad,[1,2] Ram R. Singh.[3] UCLA Autoimmunity and Tolerance Lab [1]*Department of Pediatrics, University of Arizona, Tucson, AZ;* [2]*Department of Pediatrics, University of California Los Angles, Los Angles, CA;* [3]*UCLA School of Medicine, Los Angeles, CA.*

Background: Lupus nephritis (LN) is a major cause of morbidity and mortality. Pathogenesis of LN is largely unclear. Identification of molecules that are differentially expressed between LN classes and normal control kidneys may help in elucidating mechanisms of LN and to help to identify potential new targets of treatment. Our objective in this study was to identify differences in specific proteins and molecular pathways between LN classes and normal kidneys. We hypothesized that morphologic changes that define the pathology of each class of lupus nephritis are characterized by specific protein expression.

Methods: Forty-eight formalin-fixed, paraffin embedded kidney biopsy specimens were obtained from UCLA Pathology repository. Kidney specimens included 10 histologically normal kidneys and 38 biopsy-proven LN by the 2003 International Society of Nephrology/Renal Pathology Society classification. These tissues were subjected to proteomics analysis using nano-scale liquid chromatography tandem mass spectroscopy (nLCMSMS) and tandom mass tag method for protein labeling. Quantitative relative expression data is extracted using Proteome Discoverer 2.2 Software. Ingenuity software was used for pathway analysis. Clinical and histological data were collected

Results: A total of 2190 peptides were identified in all 48 kidney specimens. Of the 2,190 peptides, 655 were differentially expressed between LN and normal control kidneys (FDR <0.05). Some of the top upregulated proteins included alpha-1-antichymotrypsin, keratin family proteins, immunoglobumins, alpha-1-antitrypsin, vimentin, and complements. The top downregulated proteins included apoptosis-inducing factor 1, glutathione S-transferase, V-type proton ATPase catalytic subunit A, transforming acidic coiled-coil-containing protein 3, and dipeptidase 1. Pathway analysis of differentially expressed peptides revealed a set of upregulated molecular pathways including immune cell communication, acute phase response signaling, glucocorticoid receptor signaling, and complement system, while pathways linked to oxidative phosphorylation, fatty acid oxidation, and amino acid degradation were reduced in LN compared to controls.

Conclusions: Using a relatively large cohort of LN kidney biopsies, we report a novel LN proteome using nLCMSMS. These data pave the way for defining molecular pathogenesis of LN and for identifying novel treatment targets

FR-PO854

Serum Biomarkers of Histologic Activity in Lupus Nephritis Kidney Biopsies

Xiaolan Zhang,[1] Huijuan Song,[2] John Sinclair,[1] Tibor Nadasdy,[2] Brad H. Rovin.[3] [1]*The Ohio State University, Columbus, OH;* [2]*Ohio State University, Columbus, OH;* [3]*Ohio State University Wexner Medical Center, Columbus, OH.*

Background: The kidney biopsy is the gold standard for diagnosing and managing lupus nephritis (LN) but it is not practical to repeat biopsies frequently to follow disease status. Because LN is part of a systemic disease we interrogated the serum of LN patients for biopsies that could non-invasively reflect biopsy findings.

Methods: Serum was collected at the time of biopsy from 50 LN patients and from 9 healthy controls. Fifteen pro-inflammatory cytokines and immune mediators were measured using the Luminex multiplexing platform. Data were analyzed by Milliplex Analyst Version 5.1. NIH activity (AI) and chronicity (CI) indices of the LN biopsies were scored by a renal pathologist. Mild, moderate and severe acute injury were defined as AI scores of 1-4, 5-9, and >10, respectively.

Results: IL-2R, CXCL16, M-CSF, TNFR1 and VCAM-1 were increased 2.7, 1.9, 2.6, 3.4 and 2.1-fold respectively in LN compared to healthy controls (all $p < 0.01$). Adiponectin, NGAL and M-CSF were significantly elevated in Class IV LN compared to other classes (all $p < 0.01$). M-CSF and pentraxin 3 (PTX) positively correlated with AI (R^2=0.46, p<0.0001; R^2=0.27, p=0.0006, respectively), but none correlated with CI. With respect to the individual elements of the AI, M-CSF was elevated significantly in endocapillary proliferation (R^2=0.43, p< 0.0001), wireloop formation (R^2=0.29, p 0.0045), PMN infiltration (R^2=0.37, p 0.0002), fibrinoid necrosis (R^2=0.28, p 0.0022), and cellular crescents (R^2=0.2883, p 0.0052). PTX only correlated with the fibrinoid necrosis component of AI (R^2=0.22, p 0.008). The area under the receiver operating characteristic curve (AUC) for M-CSF to differentiate between mild and moderate-severe crescentic injury was 0.89 (p=0.003) and for M-CSF to differentiate mild from moderate-severe AI was 0.87 (p<0.0001). PTX differentiated between mild and moderate-severe necrosis with an AUC of 0.90 (p=0.01).

Conclusions: Serum M-CSF and PTX appear to reflect severe intra-renal injury in LN. These biomarkers may be useful in managing LN if they can be shown to decrease as crescents and necrosis resolve.

Pediatric Patients with Membranous Glomerulopathy: A Single-Center Retrospective Study

Anne Kouri,[1] Carrie L. Phillips,[1] Michael T. Eadon,[2] Sharon P. Andreoli,[3] Myda Khalid.[3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University Division of Nephrology, Indianapolis, IN; [3]Indiana University, Indianapolis, IN.*

Background: Membranous nephropathy is a rare cause of pediatric nephrotic syndrome. The purpose of this study is to characterize the clinical presentation, treatment and outcomes of pediatric patients with membranous glomerulopathy in a single center over a 15 year period.

Methods: Patients with membranous nephropathy, age 18 years or less, were identified through an existing database of renal biopsy specimens at Indiana University and through billing records. Their charts were reviewed for clinical presentation, treatment and outcomes data.

Results: From 2002 to 2019, there were a total of 777 renal biopsy specimens interpreted at Indiana University with a diagnosis of membranous nephropathy. Of these, there were 14 patients, age 18 years or less, identified with primary membranous nephropathy and met inclusion criteria. An additional 4 patients were identified from billing data. Our cohort was primarily female (12/18) with a median age at presentation of 13 years (IQR 10.5--15.5). At presentation, nephrotic range proteinuria was present in 72%, hypoalbuminemia in 70%, edema in 62%, hematuria in 29%, and hypertension in 43% of patients. Renal function was normal in 17/18 patients at presentation. 3 patients had PLA2-R staining on biopsy and 2 were positive. 15 patients had treatment and/or outcomes data available. Median time to most recent follow-up was 20 months (IQR 7—35). 10/15 patients were treated with steroids; 12/15 had documented partial or complete remission at some point during their clinical course. Of the available data, 80%, 36%, and 15% had nephrotic range proteinuria at 3, 6, and 12 months, respectively. 27% and 38.5% of patients had entered complete remission at 6 and 12 months, respectively. One patient was steroid-dependent and relapsed when steroids were stopped. 14/15 patients were treated with an ACEi and/or ARB. One patient was treated with a steroid-sparing agent, mycophenolic acid, and did not enter remission. 14/15 patients had a creatinine less than 1.0 mg/dL at last follow-up. There were no documented complications of nephrotic syndrome such has thrombosis.

Conclusions: In our cohort, pediatric patients with membranous nephropathy presented with similar clinical characteristics as adult patients. Our patients had a good clinical response to steroids and/or ACEi/ARB with few documented adverse effects.

FR-PO856

Long-Term Exposure to Air Pollution and Increased Risk of Membranous Nephrology in China

Fan Fan Hou,[1] Xin Xu,[1] Liping Zhou,[1] Sheng Nie,[1] Guobao Wang,[1] Shuling Yue.[2] *[1]Renal Division, Nanfang Hospital, Southern Medical University; National Clinical Research Center for Kidney Disease, Guangzhou, China; [2]Guangzhou KingMed Diagnostics, Guangzhou, China.*

Background: We have previously shown that long-term exposure to $PM_{2.5}$ was associated with an increased risk of membranous nephrology(MN) in a large renal biopsy series in China, which partly accounted for the doubling of MN in patients with renal biopsy during the last decade. Due to limitation of the data, we were not able to assess the effect of the components of air pollution and to distinguish MN by presence and absence of PLA2R antigen in the tissue.

Methods: In the current study, we analyzed 94,388 renal biopsies conducted at 1,205 hospitals spanning 262 cities in China from 2015 to 2018, of which 31,481(33.35%) were diagnosed as primary MN. We obtained the daily air pollution data of each participating city from the Ministry of Ecology and Environment of China. We examined the association between the year-average exposure of each component of air pollution and the risk of MN in the biopsy series using a generalized additive model adjusting for age, gender, and biopsy indication.

Results: Higher exposure to each component was associated with increased risk of MN, thought the relationship appeared to be non-linear for $PM_{2.5}$ and linear for CO, NO_2, O_3, PM_{10}, and SO_2(Figure 1). Among the cases with primary MN, 7,947 had PLA2R test in the biopsy tissue, and the city-specific rate varied greatly, ranging from 73.68% to 88.26%.The overall PLA2R positive rate was 80.29%. Similarly, higher exposure to each component was associated with increased risk of PLA2R-related MN, thought the relationship appeared to be non-linear for CO, NO_2 and linear for PM_{10}, $PM_{2.5}$, O_3, and SO_2(Figure 2).

Conclusions: In conclusion, long-term exposure to $PM_{2.5}$,PM_{10},NO_2,SO_2,CO,O_3 in ambient air was associated with an increased risk of MN in patients with renal biopsy as well as with an increased presence of PLA2R antigen in patients with MN.

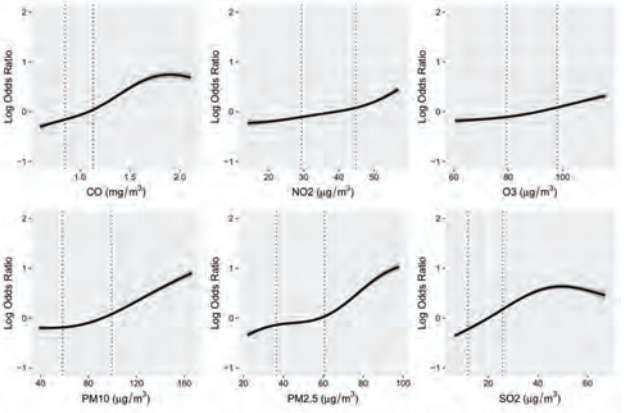

Figure 1. Smooth curves of the odds for MN along CO, NO_2, O_3, PM_{10}, $PM_{2.5}$, and SO_2 with adjustment for age, gender, and clinical indication.

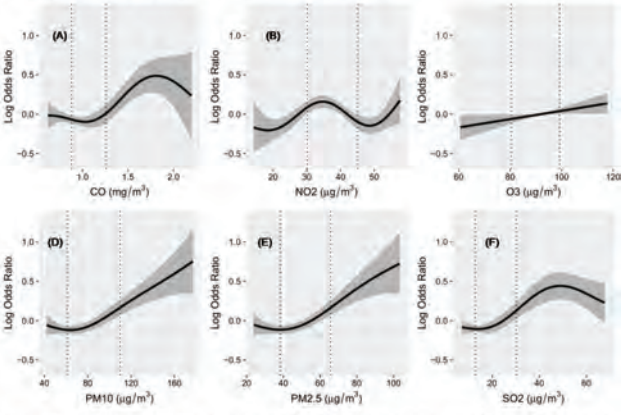

Figure 2. Smooth curves of the odds for PLA2R-related MN along CO, NO_2, O_3, PM_{10}, $PM_{2.5}$, and SO_2 with adjustment for age, gender, and clinical indication.

FR-PO857

Adoptive Transfer of Human Gingiva-Derived Mesenchymal Stem Cells Ameliorates Lupus Nephritis Depending upon CD39/CD73 Signals and the Induction of CD4+Helios-Foxp3+ Treg

Zhenjian Xu, Anping Xu. *Sun Yat-Sen Memorial Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Current approaches offer no cures for systemic lupus erythematosus (SLE)and lupus nephritis. Accumulating evidence has revealed that manipulation of bone-marrow mesenchymal stem cells (BMSCs) may have the potential to treat SLE. While BMSC-based therapy faces many challenges such as limited cell availability, BMSCs from patients with autoimmune diseases are dysfunctional, use of BMSCs with long term has a potential risk on tumorigenesis and reduced clinical feasibility, we herein demonstrate that substitution of gingival-derived mesenchymal stem cells (GMSCs) results in significantly improved therapeutic effects on lupus-like disease model.

Methods: Lupus-like disease has been induced with NZM2328 mice. In the study of prevention of lupus-like disease, GMSCs were injected i.v. into mice on age of 10 weeks. In some experiments, mice were injected with pre-treatment of GMSCs with CD39 or CD73 inhibitor. In the study of treatment of lupus-like disease, GMSCs were injected i.v. into mice on age of 20 weeks.

Results: In the study of prevention of lupus-like disease, infusion of GMSCs in NZM2328 mice significantly decreased the severity of lupus and kidney pathology scores, and down-regulated Th2, Tfh and Th17 cells. GMSCs significantly suppress activation and differentiation of B cells in vivo. Promotion of CD4+Helios-Foxp3+ Treg cells following treatment with GMSCs, these increased Tregs were noted in spleen, lymph nodes and kidney tissues. Pre-treatment of GMSCs with CD39 or CD73 inhibitor significantly reversed the protective effect of GMSCs on lupus-like disease model. In the study of treatment of lupus-like disease, GMSCs can also treat the established disease.

Conclusions: The role of GMSCs in controlling lupus-like disease mostly depends upon CD39/CD73 signals and upon the induction of CD4+Helios-Foxp3+ Treg cells. GMSCs provide a promising approach for the treatment of SLE and lupus nephritis.

FR-PO858

Clinical Predictors of Acute Tubular Necrosis in Membranous Nephropathy

Joshua Leisring, Shaili S. Kothari, Udayan Y. Bhatt, Anjali A. Satoskar, Brad H. Rovin, Samir V. Parikh. *Ohio State University Medical Center, Columbus, OH.*

Background: Acute tubular necrosis (ATN) is a common and important complication associated with membranous nephropathy (MN). Proteinuria magnitude is suggested as a cause for ATN in MN however clinical contributors to ATN in MN have not been previously evaluated. We queried the OSUWMC kidney biopsy repository to investigate predictors associated with ATN, and specifically explored the relationship between proteinuria magnitude and ATN in MN.

Methods: Ninety-five patients who underwent kidney biopsy from 2004 to 2017 were found to have MN. Pathology reports were reviewed for histologic findings including ATN. Patient demographics and clinical metrics collected at the time of biopsy were analyzed to determine their ability to predict ATN using univariate and multivariate testing. Metrics considered included age, gender, race, serum albumin, cholesterol, and proteinuria magnitude at diagnosis.

Results: A histologic diagnosis of ATN was identified in forty-three patients (45%) with MN. Serum creatinine at time of biopsy was higher in patients with ATN (1.39 mg/dL, IQR 1.06-2.3) compared to those without ATN (1.18 mg/dL, IQR 0.89-1.63), p=0.04. Proteinuria magnitude was the only clinical variable associated with ATN on multivariate testing (p=0.05). Proteinuria magnitude was then stratified into quartiles and ATN frequency was compared (Table 1). Overall, patients with > 4g/d proteinuria had a significantly higher rate of ATN on biopsy compared to those with 0-4g/d proteinuria (52.1% vs 22.3% respectively; OR: 3.7, 95% CI 1.23-11.07, p=0.03). The ATN rate did not differ at higher degrees of proteinuria above 4 g/d.

Conclusions: ATN commonly accompanies MN and is associated with a higher degree of renal impairment. Patients with MN and > 4 g/d proteinuria are at higher risk for ATN which may have both therapeutic and prognostic implications. Interestingly higher degrees of proteinuria did not further increase ATN rate suggesting additional factors may be involved and requires further study.

ATN Frequency According to Proteinuria Level

Magnitude of Proteinuria	Frequency of ATN
0-4 g/d	22.73%
4-6 g/d	50.00%
6-11 g/d	52.17%
> 11 g/d	53.57%

FR-PO859

Substitution of Oral for Intravenous Cyclophosphamide in Membranous Nephropathy

Leonella Luzardo,[1] Gabriela Ottati,[7] Jimena Cabrera,[8] Mariela Garau,[9] Maria C. Gonzalez-Bedat,[2] Ruben J. Coitiño rosa,[6] Maria Auchayna,[3] José Santiago,[1] Ricardo Silvariño,[1] Alejandro Ferreiro,[4] Liliana Gadola,[5] Hena M. Caorsi,[10] Oscar A. Noboa.[1] *[1]Nephrologhy, Hospital de Clínicas Facultad de Medicina UDELAR, Montevideo, Uruguay; [2]Uruguayan Dialysis Registry, Montevideo, Uruguay; [3]Pathology Department, Hospital de Clinicas, Universidad de la Republica, Montevideo, Uruguay; [4]School of Medicine, Montevideo, Uruguay; [5]Fisiopatología Hospital de Clínicas, Montevideo, Uruguay; [6]Hospital de Clinicas, Montevideo, Uruguay; [7]Universidad de la Republica, Montevideo, Uruguay; [8]Programa de Prevencion y tratamiento de las glomerulopatias, Montevideo, Uruguay; [9]Facultad de Medicina, UDELAR, Montevideo, Uruguay; [10]SUN, Montevideo, Uruguay.*

Background: Optimal treatment for idiopathic membranous nephropathy (MN) is s till a matter of controversy. Current guidelines recommend oral cyclophosphamide combined with steroids, but concerns about the cumulative toxicity of oral cyclophosphamide persist. During the last 30 years, MN has been treated with steroids plus a low-dose intravenous (IV) cyclophosphamide-based regimen in Uruguay. The aim of the study was to assess the efficacy of this regimen to induce remission in MN.

Methods: We performed a retrospective analysis of patients with membranous nephropathy, treated with a 6-month course of alternating monthly steroids (months 1, 3 and 5) plus IV cyclophosphamide (a single dose of 15 mg/kg IV the first day of months 2, 4, and 6).

Results: 55 patients treated between 1990 and 2017 were included; the median age was 53 years (IQR=38–64) and 69% of the patients were men. The follow-up was 7.1 years (3.2–13.9). Forty two (76.4%) patients achieved remission, 24 (43.6%) complete and 18 (32.7%) partial, respectively. Thirteen patients (23.6%) remained nephrotic. Time to achieve partial remission after treatment was 5.9 (4.6–16.0) and 11.5 (5.9–15.0) months to achieve complete remission (Table 1). During the follow up, six (10.9%) patients (one with partial and five with no remission) required chronic renal replacement treatment (Figure 1). The latency between diagnosis and end stage renal disease was 3.5 years (2.3–10.1).

Conclusions: Monthly IV cyclophosphamide plus steroids is an effective and safe treatment for membranous nephropathy and is worthwhile to be considered in prospective clinical trials.

FR-PO860

The Significance of Glomerular C1q Deposits in Primary Membranous Nephropathy

Kazuo Torikoshi. *Nishi-Kobe Medical Center, Kobe, Japan.*

Background: Unlike a previous report of no C1q deposition in idiopathic membranous nephropathy (iMN), recent studies have shown trace C1q deposition even in iMN due to improvements in the sensitivity of detection methods. The aim of study was to examine the clinical and pathological significance of glomerular C1q deposits in iMN.

Methods: 1) This single center retrospective study included 54 patients with MN who underwent renal biopsy from January 2005 to December 2017 (mean follow-up of 3.6±2.4 years). We evaluated remission of proteinuria (<1g/gCr) and other clinical examinations. 2) Next, after excluding patients with secondary MN (including hepatitis C virus infection, systemic lupus erythematosus, MCTD, malignancy and medication) (n=16), and those without immunofluorescence study (n=3), we selected 35 patients for further study. A variety of clinical parameters, outcomes and other serum and urine factors was compared in patients with and without significant glomerular capillary C1q deposits.

Results: 1) In 54 patients, 16 patients (29.6%) were diagnosed with secondary MN due to the detection of secondary causes including drugs, malignant tumors, autoimmune diseases and infectious diseases. A total of 40 patients (74.1%) achieved remission of proteinuria: 26 (48.2%) complete and 14 (25.9%) partial remission. 2) Glomerular C1q deposition was detected on capillary walls by immunofluorescence in 21/35 (60.0%) patients with iMN. In the group with glomerular C1q deposits, the remission of urinary protein was significantly delayed using a log rank test (log rank=0.019). In iMN, glomerular C1q deposition was an unfavorable predictor for remission of proteinuria (hazard ratio (HR) 2.41, 95%CI=1.13-5.14, P=0.022) in Cox proportional hazards analysis.

Conclusions: These results suggest that glomerular capillary C1q deposition was associated with poor renal outcome.

FR-PO861

Estimation of Nephron Number and Related Single Nephron Parameters in Patients with Idiopathic Membranous Nephropathy

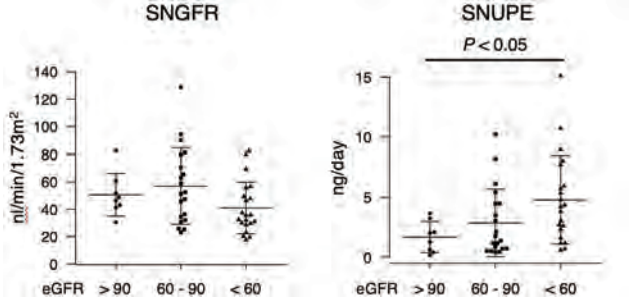
Yusuke Okabayashi,[1] Nobuo Tsuboi,[1] Hirokazu Marumoto,[1] Takaya Sasaki,[1] Kotaro Haruhara,[2] Go Kanzaki,[1] Kentaro Koike,[1] Takashi Yokoo.[1] *[1]The Jikei University School of Medicine, Tokyo, Japan; [2]The Jikei University School of Medcine, South Yarra, VIC, Australia.*

Background: Studies using animal models suggested that glomerular hyperfiltration as well as impaired hydraulic permeability play a crucial role in the progression of membranous nephropathy. To date, total nephron number and the related single nephron parameters have not been evaluated in patients with idiopathic membranous nephropathy (IMN) due to technical difficulties in counting nephrons in a clinical setting.

Methods: The total nephron number was calculated using a simplified method based on combined use of unenhanced computed tomography and stereology-based estimation of non-sclerotic glomerular density in biopsy specimens (Sasaki T et al. 2018, ASN). Single-nephron glomerular filtration rate (SNGFR) and single-nephron urinary protein excretion (SNUPE) were calculated by dividing eGFR or UPE by total nephron number, respectively.

Results: A total 49 IMN patients was included (age, 60 ± 14 years; 49 % male; UPE 4.1 ± 3.1 g/day). The total nephron number ranged from 197,561 to 1,824,272 per kidney. Compared to patients with CKD stage 1 or 2, the SNGFR showed a tendency to be low in patients with CKD stage 3 or higher. Patients with CKD stage 3 or higher were characterized by elevated SNUPE level (**Figure**). Nephron number and the related single nephron parameters were not associated with Ehrenreich-Churg stage of the glomerular basement membrane (GBM) lesions.

Conclusions: This study for the first time estimated total nephron number and the related single nephron parameters in IMN patients. Impaired single nephron functions may be involved in IMN patients with advanced-stage CKD regardless of severity of GBM lesions.



FR-PO862

Levels of Anti-Phospholipase A2 Receptor Antibodies (PLA2R) in Patients with Membranous Nephropathy in Argentina

Antonio R. Vilches, Biain Maria Elena, Gustavo Laham, Carlos H. Diaz. *CEMIC, Buenos Aires, Argentina.*

Background: Primary membranous glomerulopathy (NM) is the most common histological and immunohistochemical phenotype in adult non-diabetic nephrotic patients. 70% of untreated patients are positive for anti-PLA2R and this proportion is fairly constant We analyzed the experience of a single Center of the levels of AntiPLA2R in patients with MN or with a nephrotic syndrome without a renal biopsy and correlated with the histological and immunohistochemical phenotype and the clinical status at the time of the assay

Methods: We identified 169 adult patients who had anti-PLA2R antibody levels determined using ELISA between July 2015 and November 2018 in Argentina. We obtained relevant data on 101 patients

Results: The median time between the dosing and the biopsy was 12.1 (2.8-45) months. Levels were positive in 30.6%, doubtful in 4.7% and negative in 64.7%, with no significant differences between positive or negative groups in terms of age, sex, initial presentation, albuminemia, proteinuria and renal function. In patients whose first dosage was performed within 6 months of the biopsy (some had already started immunosuppressive treatment), the assay was positive in 45.5% and negative 54.3%. In the primary forms it was positive in 25, negative in 45 and doubtful in 4 patients. In secondary cases it was positive in only 1 patient and negative in 10 All patients with lupus MN were negative as were patients with other Glomerulopathies. Of four patients with a transplant who had a recurrence of MN in the graft 1 was positive, 1 had a doubtful result and 2 were negative All three pregnant women with a nephrotic syndrome were negative. In 12 patients the anti-PLA2 antibody titre decreased in response to immunosuppressive treatment (11) or spontaneous remission (1). Two patients who were negative in the course of a complete remission turned positive during a relapse

Conclusions: Our data show less positivity for anti-PLA2R than that reported in the literature in untreated patients with MN This is likely due to the fact that many patients were in complete or partial remission, and that treatments mostly consisted of Ponticelli regimens which induce a quicker reduction of antibody levels than other therapeutic options Our results are probably indicative of the wide spectrum of our sample in terms of clinical status and previous treatments

FR-PO863

Determination of Serum Anti-PLA2R and Anti-THSD7A Antibodies and Tissue Anti-PLA2R in Brazilian Patients with Primary and Lupus Membranous Nephropathy

Ligia C. Battaini. *HCFMUSP, São Paulo, Brazil.*

Background: Membranous Nephropathy (MN) is a common cause of nephrotic syndrome in adults. In Brazil, it is the second most frequent cause of glomerulopathies in biopsies registries. Incidence variations among the various studies may reflect patterns of biopsy indication in different countries, but it may also be related to socioeconomic, ethnic or environmental characteristics. In the past years, the role of anti-phospholipase A2 (anti-PLA2R) receptor autoantibodies and the antibody against THSD7A (thrombospondin type 1 domain-containing protein 7A) in the pathogenesis of idiopathic MN were described. The determination of these serum antibodies and renal tissue anti-PLA2R antibodies have not yet been performed in the Brazilian population.

Methods: Blood samples were collected from 28 patients diagnosed with MN, 17 patients with Lupus Membranous Nephropathy (LMN) and 8 patients with Focal and Segmental Glomerulosclerosis (FSGS), confirmed by renal tissue biopsy (OM and IF). The serum anti - PLA2R antibody was measured by the ELISA and IIFT techniques and antibodies against THSD7A by IIFT. In addition, immunohistochemistry was performed in paraffin blocks to identify the anti - PLA2R antibody in these patients.

Results: All 17 patients with LMN and the 8 patients with FSGS were negative for anti - PLA2R and anti - THSD7. A total of 28 patients with MN tested negative for anti - THSD7A. Among the patients with MN at admission, there was a positivity of 54% by IIFT and 39% by ELISA, considering VR of 20 RU/ml. When we reduced the ELISA reference value to 14 RU/ ml the sensitivity of the test equals the IIFT test. The specificity of both methods was 100% in this sample. Immunohistochemistry was performed in 24 of the 28 patients with NM, 15 (63%) presented positive labeling for the antibody in renal tissue. Of the 15 patients with tissue positivity, 13 tested positive for the antibody in the serum.

Conclusions: In this Brazilian population of MN patients, there was 54% positivity for anti - PLA2R. The IIFT and ELISA technique has the same sensitivity when considering the RV of 14 RU/ml for the ELISA. The sensitivity of immunohistochemistry in the tissue was greater than the serum antibody anti – PLA2R dosage.

Circulating Antibodies to Recombinant Exostosin 1 Are Detected in Patients with Primary and Secondary Membranous Nephropathy

Dawn J. Caster,[1] Shweta Tandon,[1] Kenneth R. McLeish,[2] David W. Powell.[2] *[1]University of Louiville, Louisville, KY; [2]University of Louisville, Louisville, KY.*

Background: Antibodies to phospholipase A2 receptor (PLA2R), a transmembrane podocyte protein, account for approximately 70% of cases of primary membranous nephropathy (MN). Antibodies to thrombospondin type-1 domain-containing 7A (THSD7A) account for approximately 10% of anti-PLA2R negative patients. Anti-PLA2R

and anti-THSD7A are rarely found in secondary MN, including class V lupus nephritis (LN). A recent report by Sethi and colleagues demonstrated glomerular deposition of exostosin 1/exostosin 2 (EXT1/EXT2) in about 10% of patients with anti-PLA2R negative MN, including 8 of 18 patients with pure class V LN. However, anti-exostosin antibodies were not detected in the 7 patients tested. This study tested the hypothesis that patients with class V LN have circulating antibodies to exostosin 1 (EXT1).

Methods: Recombinant full length human EXT1 (Abnova) was separated by SDS-PAGE and transferred onto a nitrocellulose membrane. Membranes were incubated overnight at 4°C with sera from patients (1:50-1:100) or rabbit polyclonal antibody to EXT1 (ABclonal; dilution 1:1000) followed by appropriate HRP conjugated secondary antibodies. 5 patients with class V LN (4 pure class V, 1 with class III/V) and 4 patients with primary MN (3 anti-PLA2R+) were evaluated. Secondary antibody controls were negative. All blots were run twice for validation.

Results: We found 3 of 5 patients with class V LN (including 1 patient with class III/V LN) had circulating antibodies to EXT1. We found 2 of 4 patients with primary MN (both anti-PLA2R+) had circulating antibodies to EXT1.

Conclusions: We conclude that circulating antibodies to EXT1 are found in patients with primary and secondary membranous nephropathy, including patients with circulating anti-PLA2R.

Anti PLA2R Antibody Titers and Disease Course in Primary Membranous Nephropathy

Jan A. van den Brand,[1] Anne-Els van de Logt,[1] Coralien Vink- van Setten,[2] Jack F. Wetzels.[3] *[1]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [2]Radboud UMC, Nijmegen, Netherlands; [3]Radboud University Medical Center, Nijmegen, Netherlands*.

Background: The natural course of primary membranous nephropathy (pMN) is highly variable. Up to half of the patients presenting with nephrotic syndrome will show progressive kidney function decrease. The remaining patients will show a spontaneous remission of proteinuria. Early prediction of prognosis is needed to personalize treatment.

Methods: We included 216 pMN patients referred to our hospital for urine analysis and followed these patients until renal progression, defined as an increase in serum creatinine of >50% from baseline, >25% to a level >1.5 mg/dl, or start of therapy due to severe nephrotic syndrome, or sponteaneous partial remission, defined as a reduction in proteinuria of >50% from baseline to a level <3.5 g/g creatinine with a stable serum creatinine. Anti-PLA2R antibody titers were determined using a EuroImmun ELISA assay. We created a multivariate prognostic model using cause-specific Cox regression that included baseline values for serum creatinine, urine protein creatinine ratio, anti-PLA2R antibody titer, α-1-microglobulin excretion rate.

Results: The table shows baseline characteristics for the study population. The prediction model showed good prognostic performance with a C-statistic of 0.78 (95%CI 0.71 to 0.84) for progression and 0.78 (0.70 to 0.85) for spontaneous remission at 24 months. The table shows baseline characteristics for the study population. The hazard ratio for progression was 1.07 (0.88 to 1.30) per doubling of aPLA2R titer. Conversely, the hazard ratio for partial remission was 0.68 (0.54 to 0.85). Discrimination was good with a C-statistic of 0.80 (95%CI 0.74 to 0.86) for progression and 0.76 (0.68 to 0.83) for spontaneous remission at 24 months. Predicted and observed risk of respectively progression and spontaneous remission were well calibrated.

Conclusions: Anti-PLA2R antibody titers appear to be predictive of spontaneous partial remission but not progression in primary MN.

Funding: Private Foundation Support

Waiting for Spontaneous Remission in Primary Membranous Nephropathy: Is It Safe?

Coralien Vink- van Setten, Anne-Els van de Logt, Jack F. Wetzels. *Radboud University Medical Center, Nijmegen, Netherlands*.

Background: We advocate a restrictive treatment strategy in patients with primary membranous nephropathy (pMN): immunosuppressive therapy(IS) is started late, while awaiting spontaneous remission. Many patients thus have persistent nephrotic syndrome for >12 months. Since proteinuria is associated with podocyte loss, delaying treatment might increase the risk of podocte depletion and secondary FSGS. We evaluated the outcome in patients with persistent proteinuria not receiving IS within 12 months after onset of disease.

Methods: We included patients with pMN, normal eGFR and nephrotic range proteinuria (urinary protein/creatinine ratio(uPCR) >3.0 g/10mmol) at presentation and followed for >2 years. We assume that in patients with podocyte loss and secondary FSGS, a complete remission(CR) will not occur. Therefore we selected patients with early and late spontaneous partial remission(SRem) and compared CR rate as outcome parameter. Partial remission(PR) was defined as uPCR <3.0g/10mmol and >50% decrease from baseline and stable kidney function. CR was defined als uPCR <0.2g/10mmol with stable kidney function.

Results: We included 254 patients. 12 months(m) after first presentation, 64(25%) patients were treated with IS and 47(19%) patients were in SRem. 94(37%) achieved SRem after 12 months, 33(13%) were eventually treated with IS, and 16(6%) had no IS nor remission. Baseline characteristics of the patients with SRem <12 months vs. SRem >12 months were comparable, except for number of aPLA2r positive patients. CR rate was comparable (47 vs. 40%). In patients who started with IS >12 months after diagnosis, PR was achieved in 27(82%) and CR in 17(51%).

Conclusions: Waiting for SRem in pMN is safe. Most patients with persisting proteinuria for more than 12 months develop a remission, even if immunosuppressive therapy is needed.

Comparison of early vs. late spontaneous remission in pMN

Early vs. Late Start of Immunosuppressive Therapy in Membranous Nephropathy

Anne-Els van de Logt,[2] Moniek W. Van de luijtgaarden,[2] Coralien Vink- van Setten,[2] Barbora Svobodova,[1] Vladimir Tesar,[1] Jack F. Wetzels.[2] *[1]General University Hospital, Prague, Czechia; [2]Radboud University Medical Center, Nijmegen, Netherlands*.

Background: Alkylating agents improve outcome in membranous nephropathy (MN). Guidelines advise restrictive treatment. Some centers wait beyond 6-12 months before start of immunosuppressive therapy. The risk of persisting proteinuria is podocyte loss, which may cause secondary focal glomerulosclerosis. This should reduce the likelihood of complete remissions. We evaluated the safety of delayed treatment.

Methods: We used data of two centers that participated in the MN registry (mnregistry.eu). In one center (Czech Republic (CZ)) treatment is started early after kidney biopsy, whereas in the Netherlands (NL) a restrictive treatment strategy is used[1]. For the current analysis we included incident patients, with proteinurie of > 2 grams/24 hours, treated with immunosuppressive therapy (ISRx) and available follow-up. To allow evaluation of late treatment, we included only patients from NL with an interval of more than six months from kidney biopsy. Partial and complete remissions were defined according to KDIGO criteria.

Results: In total 155 patients were included in the analysis. Baseline information and outcomes are presented in Table 1. Alkylating agents were mainly used, cyclophosphamide in NL (81 %) and chlorambucil in CZ (60 %). Overall remission rates (partial- and complete remission) calculated from start of therapy, were not different. Most importantly, also with delayed therapy complete remissions were observed frequently (Table 1).

Conclusions: The MN registry allows comparison of treatment protocols between centers. Our data support the safety of a delayed treatment strategy.

Clinical Analysis of Short-Term Therapeutic Response Factors in Membranous Nephropathy

Takatsugu Iwashita,[1] Kaori Takayanagi,[1] Maiko Yamasaki,[1] Takayuki Hamada,[1] Koki Ogawa,[1] Ryo Yamamoto,[1] Saeko Sato,[1] Toru Hida,[2] Hiroaki Hara,[1] Taisuke Shimizu,[1] Hajime Hasegawa.[3] *[1]Saitama Medical Center, Saitama Medical University, Kawagoe, Japan; [2]Saitama Medical Center, Kawagoe, Japan; [3]Saitama Medical University School of Medicine, Kawagoe, Japan*.

Background: Membranous nephropathy (MN) is known to affect frequently in elderly patients. Since the duration of MN treatment is likely to be prolonged, it is desirable that the treatment duration would be shortened by the concomitant use of immunosuppressant and prednisolone (PSL). Here, we examined clinical and histological parameters related to the rapid response to the therapy by the retrospective analysis.

Methods: Biopsy-proven 82 cases with MN, hospitalized between April 2009 and December 2017, were enrolled in this study. All cases were divided into three groups, 1st (high responder), 2nd (middle responder) and 3rd (low responder) quantiles, based on the proteinuria-reduction ratio at a month after the beginning of therapy including sole administration of PSL and concomitant use of immunosuppressants such as Cyclosporin or Mizoribine. Cases in 1st and 3rd quantile were comparatively studied. All biopsy specimens were stained by anti-phospholipase A2 receptor (PLA2R) and thrombospondin type 1 domain containing 7A (THSD7A) antibodies by standard protocol.

Results: Age of 1st (n=23) and 3rd (n=24) quantile groups were 66.7±2.16 vs 66.6±3.11, showing no difference. Estimated glomerular filtration rate (eGFR) and baseline urine protein-to-Cr ratio (PCR) in 1st quantile group were significantly higher than those in 3rd quantile group; eGFR: 72.7±2.78 vs 59.7±4.64 ml/min (p = 0.018), baseline PCR: 8.39±1.37 vs 5.09±1.11 (p = 0.039). There was no difference in intensity of immunofluorescent staining of IgG, A, M, C3 between 1st and 3rd quantile groups. We also studied the difference in immunofluorescent intensity of PLA2R, THSD7A and IgG subclass, however, we could not find out significant difference in the both groups.

Conclusions: Obtained results showed that higher eGFR and baseline PCR might be related to the rapid therapeutical response. Contrary to our expectation, staining intensity of PLA2R, THSD7A and IgG subclass might not be related the rapid response to the therapy.

FR-PO869

Calcineurin Inhibitors Treatment and Renal Function Decline in Patients with Idiopathic Membranous Nephropathy

Huaiya Xie,[1] Chao Li,[2] Yubing Wen,[2] Wei Ye,[2] Jianfang Cai,[2] Hang Li,[2] Xuemei Li,[2] Xuewang Li.[2] *[1]Chinese Academy of Medical Sciences, Peking Union Medical College Hospital, Beijing, China; [2]Division of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China*.

Background: Calcineurin inhibitors (CNIs), including cyclosporine A(CSA) and tacrolimus, is an established therapeutic option suggested for treatment in IMN patients. The major concern with CNIs remains its propensity to induce renal function impairment. This study was designed to assess the influence of CNIs on renal function compared with cyclophosphamide(CTX), and seek factors that can predict renal function impairment in patients receiving CSA.

Methods: In this study, we included 555 IMN patients treated with CTX or CNIs, with or without glucocorticoids and other immunosuppressant. Data on age, sex, body mass index, presence of hypertension and diabetes, laboratory tests, and therapeutic regimens were retrospectively retrieved from medical record. Cox regression was employed to analyze risk factors indicating a 30% decline in estimate glomerular filtration rate(eGFR) or end-stage renal disease (ESRD) in total patients or those treated with CSA.

Results: During a median follow up of 2.9(1.0-4.6) years, 59(10.6%) patients developed a 30% eGFR decline or ESRD, of whom over 90% had been treated with CNIs before. CNIs treatment was an independent risk factors associated with developing 30% decline in eGFR or ESRD (*HR*=5.7, *95%CI* 2.2-14.8, *P*<0.001), independently of age, sex, hypertension, baseline serum albumin, urine protein, and eGFR, and the dose of glucocorticoids. Further analysis restricted in patients receiving CSA showed age over 50 years old (*HR*=3.7, *95%CI* 1.8-7.3, *P*<0.001) and mean CSA dose over 2.2mg/kg/d (*HR*=1.8, *95%CI* 1.0-3.1, *P*=0.035) might indicate 30% decline in eGFR or ESRD.

Conclusions: CNIs treatment may associate with renal function decline independently in IMN patients, especially in patients over 50 years old or receiving CSA over 2.2mg/kg/d.

FR-PO870

Efficacy of Cyclophosphamide in Association with Low-Dose Cyclosporine for the Treatment of High-Risk Primary Membranous Nephropathy

Bogdan Obrisca, Roxana A. Jurubita, Bogdan M. Sorohan, Andreea G. Andronesi, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania*.

Background: Ponticelli regimen is associated with the highest remission rate in the treatment of primary membranous nephropathy (pMN), but corticosteroids are associated important side effects. As such, we tested the efficacy of the combination of cyclophosphamide and low-dose cyclosporine in the management of high-risk pMN.

Methods: We prospectively followed 8 patients with high-risk pMN, treated with cyclophosphamide (iv, 15 mg/kg/month, for 6 consecutive months) and cyclosporine 100 mg/d (for proteinuria control) (CF/Cyc regimen). We compared this cohort to 8 consecutive, prospectively followed patients with pMN treated with the Ponticelli regimen, with a similar risk. Clinical and laboratory data were collected at baseline and at 1, 3, 6, 12- and 15-months thereafter.

Results: The two cohorts had similar baseline characteristics, except for higher antibody titer and proteinuria for patients treated with CF/Cyc regimen. The Ponticelli cohort of patients had a mean age, serum albumin and eGFR of 50 ± 10 years, 2.7 ± 0.8 g/dl and 55 ± 26 ml/min/1.73m^2, respectively, while the median proteinuria and anti-PLA2R-ab titer were 6.25 (5.25-11) g/day and 122.5 (71.5-211) UI/ml, respectively. By comparison, the CF/Cyc cohort had a mean age, serum albumin and eGFR of 50 ± 9 years, 2.5 ± 0.5 g/dl and 69 ± 30 ml/min/1.73m^2, respectively (p=0.9, 0.4 and 0.3), while the median 24-hour proteinuria and anti-PLA2R-ab titer were 9.85 (7.15-13.15) g/day and 291.5 (100-571.75) UI/ml, respectively (p=0.1 and 0.06). CF/Cyc regimen was associated with a 70% and 90% decrease from baseline in mean proteinuria and anti-PLA2R-ab titer, as opposed to a 58% and 97% decrease from baseline following Ponticelli regimen (p=0.7 and 0.8, respectively). There was a 41% and 31% increase from baseline in mean serum albumin following CF/Cyc and Ponticelli regimen, respectively (p=0.9). Overall, the remission rate (CR and PR) was 62% and 50% in the CF/Cyc and Ponticelli cohort, respectively, while 50% of patients in both cohorts showed complete immunological remission by 6 months.

Conclusions: In our cohort of patients with high-risk pMN, treatment with cyclophosphamide and low-dose cyclosporine was as effective as the Ponticelli regimen in inducing disease remission and could represent an alternative to steroid-based regimens.

FR-PO871

Membranous Nephropathy: Efficacy of Low or Standard Rituximab-Based Protocols and Comparison to the Ponticelli Regimen

Roberta Fenoglio, Savino Sciascia, Dario Roccatello. *Nephrology and Dialysis Unit and Center of Research of Immunopathology and Rare Diseases (CMID), Giovanni Bosco Hospital and University of Turin, Italy, Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Turin, Italy*.

Background: About 80% of patients (pts) with primary Membranous nephropathy (PMN) have an autoimmune disease caused by autoantibodies and 75% of them have antibodies direct against the M-type phospholipase A2 receptor (PLA2R) present in podocytes. Immunosuppressive treatment is recommended in high-medium risk pts. Recently the use of rituximab (RTX), has emerged as an important therapeutic option in pts with PMN. The appropriate dose, the number of doses of RTX in MN pts is still uncertain. Few investigators have reported conflicting outcomes with low-dose of RTX. No randomized clinical trials have been performed so far to compare the efficacy and safety profiles of low-dose RTX (Protocol 1, one dose of RTX 375 mg/m^2) with standard dose RTX (Protocol 2, four weekly doses of Rituximab 375 mg/m^2) and Ponticelli regimen (PR). Waiting for the results of controlled trials that compare the efficacy of RTX with other therapeutic approaches in primary MN or different RTX regimens, we report our experience comparing 3 different treatment protocols. Our working hypothesis was that the efficacy of RTX was comparable to that of PR even at low dose.

Methods: 32 consecutive pts with PMN and nephrotic syndrome were included and received RTX (14 pts treated with Protocol 1; 17 with Protocol 2). All patients were followed for 24 months after RTX. 17 pts treated with PR were included as controls and matched with cases for age and baseline proteinuria. No statistical differences were observed among groups in baseline sCr and Proteinuria

Results: At 24 months, we observed a statistical significant improvement in terms of proteinuria levels in pts treated with Protocol 1 (7.5 +/- 4.8 at T0; 0.21 +/- 0.15 at T24, p<0.01) protocol 2 (5.1+/-1.41 g/24 at T0; 0.35 +/- 0.39 at T24 p<0.01) and in the controls (8.27 +/- 4.78 T0; 2.2 +/- 1.9 g/24h at T24, p<0.01). When comparing the 3 groups, we observed no differences in clinical response (p=0.53). No statistical significant change in sCr levels was observed, at baseline and during the follow-up.

Conclusions: Our data suggest that the RTX is a promising alternative to Ponticelli's protocol even at low-doses. RTX has the potential to be a cost-effective treatment in the short and medium terms despite the high single dose cost. The use of low dose can provide a further significant reduction in treatment.

FR-PO872

Remission and Relapse Rates for Primary Membranous Nephropathy Treated with Combination Rituximab, Cyclophosphamide, and Prednisone

Reza Zonozi, Karen A. Laliberte, Jillian Rosenthal, Noah Huizenga, Sarah Dowst, Frank B. Cortazar, John Niles. *Massachusetts General Hospital, Boston, MA.*

Background: We evaluated the efficacy of combination therapy with rituximab-induced continuous B cell depletion, a short course of low-dose, oral cyclophosphamide, and an accelerated prednisone taper (RCP) for the treatment of primary membranous nephropathy.

Methods: A retrospective analysis was conducted on 49 consecutive patients with primary membranous nephropathy treated with RCP at Massachusetts General Hospital. The co-primary outcomes were attainment of partial (PR) and complete remission (CR). PR was defined as a urinary protein to creatinine ratio (UPCR) < 3 g/g and a 50% reduction from baseline. CR was defined as a UPCR < 0.3 g/g. Secondary outcomes were SAEs and change in proteinuria, serum creatinine and albumin after 1 year of treatment. Relapse was defined as a UPCR > 3 g/g after having achieved CR or PR.

Results: Over a median follow-up of 36 (IQR 24 - 56) months, 100% of patients achieved PR and 82% of patients achieved CR at a median time of 3.4 and 13.1 months, respectively. After 1 year of treatment, median (IQR) UPCR declined from 8.2 (5.2 - 10.7) to 0.3 (0.2 - 0.7) g/g (P < 0.001). Fourteen SAEs occurred over 166 patient-years. One patient (2%) progressed to ESRD, and no patients died. Of those patients followed after B cell return (n = 25), only 1 patient relapsed over a median follow-up of 18 (IQR 6.2 - 37) months.

Conclusions: Treatment of primary membranous nephropathy with RCP resulted in high rates of complete remission and relapse-free survival.

Long-Term Outcomes of Rituximab Treatment in Membranous Nephropathy

Aikaterini K. Nikolopoulou,[1] Ana C. Teixeira,[4] Stephen P. McAdoo,[1] Jeremy B. Levy,[2] Frederick W. Tam,[3] Liz Lightstone,[1,5] Tom Cairns,[2] Charles D. Pusey,[1] Megan Griffith.[2] *[1]Imperial College London, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, London, United Kingdom; [3]Imperial College Kidney and Transplant Institute, London, United Kingdom; [4]Coimbra Hospital and Universitary Centre, Coimbra, Portugal; [5]Hammersmith Hospital, London, United Kingdom.*

Background: Rituximab is increasingly used for the treatment of membranous nephropathy (MN), both as first line & for relapsing disease, but there are few published data on long term outcomes.

Methods: In this retrospective, observational cohort study we report outcomes of 38 adult patients with biopsy proven MN treated with rituximab between Jan 2008 & Jan 2018. Follow up was for a mean of 4 years (range 1-10). Rituximab, 2 x 1 g doses, was administered at days 0 & 14.

Results: We identified 38 patients, 25 male, median age 57.5yrs (range 23-77). At administration of rituximab, patients were heavily nephrotic with median urinary protein creatinine ratio (uPCR) 851 mg/mmol (range 574-1420) & median eGFR 33 ml/min/1.73m^2 (23-59). B cell depletion occurred within 2 weeks of administration; however, 73% of patients were B cell replete at 3 months. By latest f/up, 27 (71%) patients achieved remission (CR & PR). Median time to PR was 12 mths but CR took longer to achieve, up to 36 mths in some cases. Relapses occurred in 5 (18.5%) responders, of whom 1 died & 1 progressed to ESRD. There were 11 (29%) non-responders of whom 7 progressed to ESKD. The eGFR was less than 30ml/min/1.73m^2 in 17 patients (44.7%) at the time of rituximab treatment. Whilst 7 of these patients progressed to ESKD, in 10 cases renal function improved or stabilised. 3 patients died during the follow up period one from intracerebral haemorrhage, one from lung malignancy & one from a cardiac event.

Conclusions: Rituximab is effective in treating MN though the time to remission can be prolonged. B cell repletion occurs early in MN however this is not necessarily associated with relapse. Importantly, response to rituximab can lead to preservation or improvement of renal function even when severely impaired. Such patients may benefit from treatment and should not necessarily be excluded from controlled trials.

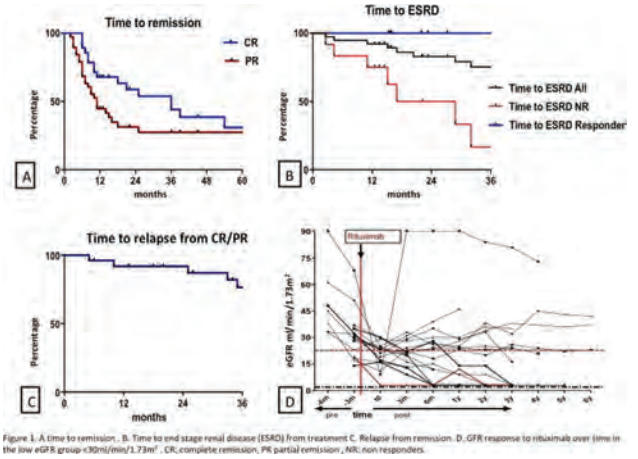

Figure 1. A time to remission , B. Time to end stage renal disease (ESRD) from treatment C. Relapse from remission. D. GFR response to rituximab over time in the low eGFR group <30ml/min/1.73m² . CR; complete remission, PR partial remission , NR; non responders.

FR-PO874

Long-Term Outcome of Treatment of Relapsing Primary Membranous Nephropathy with Rituximab

Ivan Margeta,[1] Ksenija Vucur,[1] Ana Kozmar,[2] Mladen Knotek.[1,3] *[1]Department of Nephrology, University Hospital Merkur, Zagreb, Croatia; [2]University Hospital Centre Zagreb, Zagreb, Croatia; [3]School of Medicine, University of Zagreb, Zagreb, Croatia.*

Background: Primary membranous nephropathy is often susceptible to relapse after treatment with usual immunosuppresive therapy constisting of cyclophosphamide and glucocorticoids, or a calcineurin-inhibitor with glucocorticoids. Patients with relapse may be treated with rituximab. However its dose, frequency of administration and effect on long-term outcome have been incompletely evaluated.

Methods: Fourteen patients from our hospital were included in this study. The data were retrospectively extracted. Primary membranous nephropathy was diagnosed after exclusion of secondary causes, with finding of subepithelial deposits on electron-microscopy ± anti PLA2R antibodies. The inclusion criterion was relapse of a primary membranous nephropathy following a calcineurin inhibitor- or cyclophosphamide-based treatment. Patients recieved a single dose of intravenous rituximab (500 or 1000 mg), with target B-cell count < 5/μL. Subsequent courses of rituximab were administered following a repeat relapse.

Results: Ten patients were male and 4 female. The median age at time of diagnosis was 49 years (IQR 39-57 months). Median time from diagnosis to rituximab treatment was 17 months (IQR 10-41). During the median follow-up period of 47 months (IQR 32-68 months) 8 patients recieved one course of rituximab, 4 patients two courses and 2 patients three courses. Median time between two courses of rituximab was 16 months (IQR 6-26). Relapses following rituximab treatment responded to a repeat course of rituximab. There was a significant reduction in proteinuria from date of first rituximab treatment to date last seen (4±2.2 vs 1.1±1.1 grams, p<0.001), while there was no significant difference in serum creatinine (124±45 vs 102±21 μmol/L). Two patients had severe infective complications after rituximab treatment.

Conclusions: Rituximab is a safe and effective option in long-term treatment of relapsing primary membranous nephropathy.

FR-PO875

Low-Dose Rituximab Monotherapy Alone or in Combination with Tacrolimus Is Effective in Primary Membranous Nephropathy

Vivek Pathak. *Nephrology, Kovai Medical Center and Hospital, Coimbatore, India.*

Background: Previous therapies though effective had more adverse events. Rituximab has been used to induce remission in doses of 2gms. It was therefore used in our patients with lower doses alone or in combination with Tacrolimus to achieve remmission. This is a retrospective study to evaluate the role of this treatment.

Methods: 15 patients aged 28 -72 years underwent treatment between since 2014 till 2018. Patients whose GFR was <40ml/min/1/73m2 were excluded from the study. Rituximab was given as a fixed dose of 500mg each. It was repeated if there was no response at 3 months. Rituximab was given as a monotherapy for 9 patients. Tacrolimus was added in 4/9 patients at the end of 3 months because of poor response. Rituximab and Tacrolimus were started together in 6 patients and out of these 2 were treated outside with modified Ponticelli regimen and had failed to show a response. Tacrolimus was given for 18 months. Complete remmission was defined as reduction in proteinuria of lessthan 0.3gms and partial remmission as less than 3gms or more than 50% reduction.

Results: Rituximab caused complete remmission in 4/ 9 patients and 1 patient attained partial remmission in the mean time of 8 months.2 patients attained remmission with the single dose of 500mg while another 2 required 2 doses of 500mg each. There was one relapse in this group who responded to one more dose of 500mg. Tacrolimus was added in 4 remaining patients at the end of 3 months.2 went into complete remmission after 3 months and one went into partial remmmission and one failed to respond. Tacrolimus was started along with first dose of Rituximab in 6 patients.2 patients received a single dose of 500mg, 2 received 500mg 2 doses and 1 received 3 doses of 500mg and 1 received 4 doses of 500mg. All went into complete remmission by mean time of 9 months.2 patients had relapses and both were sucessfully treated with 500mg of Rituximab. There was no fatal event in any group. There was only 1 patient who failed to respond to Rituximab and Tacrolimus combined therapy and subsequently responded to steroid and cyclophosphamide therapy.

Conclusions: Complete remmission was attained with a single dose of 500mg Rituximab monotherapy in 2 patients. This study showed complete or partial remmission in 14 /15 patients with this novel regimen with reduced side effects and cost by avoiding higher doses of Rituximab used in previous studies.

FR-PO876

Clinical Advantage of Mizoribine in Elderly Patients with Primary Membranous Nephropathy

Hajime Hasegawa,[1,2] Hitoshi Yokoyama,[1] Kunihiro Yamagata,[1] Masayuki Iwano,[1] Shin'ichi Akiyama,[1] Kaori Takayanagi,[1,2] Takatsugu Iwashita,[2] Taisuke Shimizu,[2] Tomonari Ogawa,[2] Koichi Kanozawa.[2] *[1]Study group for nephrotic syndrome in the elderly, Kawagoe, Japan; [2]Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Background: Membranous nephropathy (MN) is usually managed in Japan by sole administration of Prednisolone (PSL) of 1 mg/kg for 4 weeks, and concomitant use of immunosuppressant would be thereafter considered. Here, we show the clinical efficacy of concomitant use of lower doses of Mizoribine (MZB) and PSL in elderly patients with MN.

Methods: Thirty-six elderly patients (age≥65) diagnosed primary MN showing nephrotic syndrome were enrolled from 24 independent facilities. The patients were randomly assigned to two groups, solely administered PSL 30 mg (P group, n=18), or concomitantly administered MZB 150 mg (MP group, n=18), and observed for 12 months. In some cases, anti-phospholipase A2 receptor antibody (PLA2R-Ab) titer was measured.

Results: Percent-urine protein-to-Cr ratio (PCR) comparing to baseline of MP was better than P (50.0% vs 55.6% at 3 M, 31.4% vs 39.9% at 6 M). Logistic analysis showed that the odds ratio of high responder (PCR<1.0 g/gCr at 3 M) in MP group was 1.50 (1.00 in P group), suggesting that the concomitant use of MZB might accelerate the remission. Total amount of administered PSL in MP group seemed to be less than that in P group. Kaplan-Meier analysis showed that time-course of complete-remission (PCR<0.3 g/gCr) ratio in MP group was significantly higher than P group studied by log-rank test (p=0.01) and generalized Wilcoxon test (p<0.01). In additional logistic analysis, the odds ratio of the high responder was 2.67 (MP) and 1.00 (P) in cases showing negative PLA2R-Ab whereas the odds ratio was 0.33 (MP) and 0.40 (P) in cases showing positive PLA2R Ab, suggesting that concomitant use of MZB might be more effective in PLA2R-Ab negative cases. Kaplan-Meier analysis also showed that time-course of remission (PCR<1.0 g/gCr) ratio in PLA2R negative group was higher than PLA2R positive group.

Conclusions: Concomitant use of low dose MZB and PSL at the start-up might be beneficial for elderly patients with MN. Qualitative measurement of PLA2R-Ab might be useful for the prediction of therapeutical response.

FR-PO877

Characterization of Lupus Nephritis in a Predominantly Hispanic Population in the Western United States

Jim Nguyen,[2,1] Nina Petrosyan,[3] Gregory Stone,[3] Nora Bedrossian,[3] Melissa Mert,[4] Hui Yi Shan.[2,1] *[1]LAC-USC Medical Center, Los Angeles, CA; [2]Division of Nephrology and Hypertension, Keck School of Medicine of USC, Los Angeles, CA; [3]Keck School of Medicine of USC, Rolling Hills, CA; [4]University of Southern California, Los Angeles, CA.*

Background: Lupus Nephritis (LN) is a serious complication of systemic lupus erythematous (SLE). Both genetic and environmental factors play a role in disease manifestation and outcomes. Our study aims to characterize LN and its treatment in a predominantly Hispanic population residing in the Western US.

Methods: A retrospective chart review was conducted on all native kidney biopsies performed at Los Angeles County + USC Medical Center between 2008-2018. 124 patients with biopsy proven LN were identified.

Results: Among the total 124 patients, median age of diagnosis was 32 (26-42.5) years and the majority were female (87.8%) and self-reported as Hispanic (72.9%). The median serum creatinine and urine protein to creatinine ratio at baseline were 0.98 (0.71-1.92) mg/dl and 3.89 (1.47-6.32) mg/g, respectively. 72.6% had biopsies compatible with proliferative LN. Degree of tubular atrophy was significantly associated with remission status at 1-year (p=0.004). Subgroup analysis demonstrated better 1-year post induction partial (PR) and complete remission (CR) rates in patients who received mycophenolate (MMF) and steroid (29.7% PR, 51.4% CR) as compared to cyclophosphamide (CYC) and steroid (18.8% PR, 40.6% CR). Higher rate of relapse was observed in patients who received MMF and steroid compared to CYC and steroid (24.3% vs. 9.4%, respectively). A lower percentage of patients on MMF and steroid developed ESRD compared to patients treated with CYC and steroid (2.7% vs. 18.8%). A significantly higher proportion of patients who were not on hydroxychloroquine were diagnosed with ESRD compared with patients who were taking hydroxychloroquine (22.5% vs 6.5%, p=0.03).

Conclusions: Our study showed that this Hispanic cohort residing in the Western US presented early, with mildly elevated serum creatinine, minimal to no tubular atrophy, and primarily with proliferative LN. Of these treated patients, although it did not reach statistical significance, a noticeable trend was observed in achieving better remission rates at 1-year endpoint with MMF and steroid as induction therapy compared to CYC and steroid. Additionally, the use of hydroxychloroquine in this cohort is significantly associated with lower ESRD rate.

FR-PO878

Pregnancy Outcomes in Patients with Systemic Lupus Erythematosus with or Without Lupus Nephritis

Yuko Ohishi,[1] Hidekazu Ikeuchi,[2] Hiroko Hamatani,[1] Masao Nakasatomi,[1] Toru Sakairi,[2] Yoriaki Kaneko,[2] Akito Maeshima,[3] Keiju Hiromura.[2] *[1]Gunma University, Maebashi, Japan; [2]Gunma University Graduate School of Medicine, Maebashi, Japan; [3]Jichi Medical University, Shimotsuke, Japan.*

Background: Systemic lupus erythematosus (SLE) affects the pregnancy. Previous paper showed an increased risk of premature birth in patients who had a history of lupus nephritis. In the present study, we examined the outcomes of pregnancy in SLE patients with lupus nephritis (renal SLE) or without lupus nephritis (non-renal SLE).

Methods: We retrospectively examined 94 pregnancies in 53 SLE patients who treated in our department from January 1996 to March 2018.

Results: Mean patient age and serum creatinine at the beginning of pregnancy were not significantly different between renal and non-renal SLE patients: 29.4±5.8 vs 30.4±3.2 (years) and 0.48±0.11 vs 0.51±0.12 (mg/dL). Outcomes of pregnancy were shown in Table 1. Percentage of premature birth and low birth weight were more frequent in SLE patients in total, compared to the reported data of general population in Japan (19% vs 6% and 36% vs 10%, respectively). However, there were no significant differences between renal and non-renal SLE. Frequency of fetal loss was also not different between 2 groups, although natural abortion + stillbirth tended to be more in renal SLE than non-renal SLE (19% vs 4%, p=0.135). Among 43 renal SLE patients, 9 patients already had proteinuria at the beginning of pregnancy. Renal flare was observed in 5 patients (15%) out of 34 renal SLE patients without proteinuria at the beginning. In addition, pregnancy-induced hypertension was observed in 2 renal SLE patients (5%) and 3 non-renal SLE patients (6%).

Conclusions: In our study, frequencies of premature birth and fetal loss were not different between renal and non-renal SLE patients. However, both renal and non-renal SLE patients had higher rate of premature birth and low weight birth, compared to general population.

Table 1. Outcomes of pregnancy in SLE patients with or without lupus nephritis

	renal (n=43)	non-renal (n=51)	p-value
Delivery	30 (70%)	40 (78%)	0.354

FR-PO879

Venous Thromboembolism in Lupus Nephritis by ISN/RPS Biopsy Classification

Ian D. Cooley,[1] Keisha L. Gibson,[2] Vimal K. Derebail,[1] Carolina Alvarez,[1] Caroline J. Poulton,[2] Lauren N. Blazek,[2] Andrew Love,[1] Susan L. Hogan,[1] J. Charles Jennette,[1] Ronald J. Falk,[2] Saira Z. Sheikh.[1] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC.*

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease that can be associated with venous thromboembolism (VTE). Lupus nephritis (LN) has been shown to be an independent risk factor for VTE. To our knowledge the risk of VTE has not been studied by International Society of Nephrology/Renal Pathology Society (ISN/RPS) LN class.

Methods: A cross-sectional analysis was performed using data from the Glomerular Disease Collaborative Network (GDCN). Patients with class V LN were compared to those with class III or IV (but not associated class V) LN. Classes I, II and VI were excluded from analysis due to their low prevalence. The outcome of interest was image-confirmed VTE. Logistic regression was used to calculate odds ratios and 95% confidence intervals (OR, 95% CI), adjusted for age, sex, race, hormonal contraception use, serum albumin and use of hydroxychloroquine. Effect modification was assessed between the main effect and other covariates and considered if p<0.05.

Results: Our cohort consisted of 533 patients; mean±SD age of 30.9±15.0 years (range 6-79 years), with an overall incidence of image-confirmed VTE of 54/533 (10.1%). In adjusted analyses, the odds of VTE were not significantly different for those with class III/IV compared to class V LN (OR, 95% CI: 1.00, 0.54-1.84). There was evidence of effect modification of LN class on VTE by age at biopsy. Among patients with an average age at biopsy of 15 (-1SD), class III/IV was associated with higher odds of VTE (5.38, 1.42-20.34) while among patients with an average age at biopsy of 45 (+1SD), class III/IV was associated with lower odds of VTE (0.26, 0.09-0.78).

Conclusions: VTE was common in LN patients in the GDCN, occurring in ~10%, and was similar among patients with class III/IV LN and those with class V LN. These findings suggest that the association between LN and VTE is not limited to class V-related nephrotic syndrome. Interestingly, however, age-specific analysis demonstrated increased odds of VTE with class III/IV LN diagnosed at a younger age and decreased odds of VTE with class III/IV LN diagnosed at an older age. This may suggest the presence of an age-sensitive modulation of LN class-specific VTE risk.

FR-PO880

Wide Fluctuation in Serum Creatinine Is Observed in Patient with Lupus Nephritis in Remission

Salem Almaani,[1] Udayan Y. Bhatt,[3] Neil Solomons,[4] Brad H. Rovin.[2] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Ohio State University Wexner Medical Center, Columbus, OH; [3]The Ohio State University, Dublin, OH; [4]Aurinia Pharmaceuticals, Victoria, BC, Canada.*

Background: Clinical trials in lupus nephritis (LN) typically base remission on proteinuria and the relative change in serum creatinine (sCr) compared to baseline. These sCr cutoffs have been arbitrary, however we observe considerable fluctuation of sCr levels in clinical practice. This study was undertaken to assess the variability of sCr in stable, non-flaring LN patients.

Methods: Patient-level clinical data from patients enrolled in the ALMS, MAINTAIN, and ELNT trials who had ≥3 consecutive sCr measurements while in remission (uPCR ≤0.5g/mg) were used. Patients were split into a group having at least 1 sCr measurement >115% of baseline (fluctuators) and a group with no sCr measurements >115% of baseline (non-fluctuators). Disease characteristics and demographics were compared using ANOVA and logistic regression as appropriate.

Results: Changes in sCr over time are depicted in the figure. Group characteristics are described in the table. In the fluctuator group, 33%, 20%, and 12% of each patient's creatinine measurements were >115%, 120%, and 125% above their baseline respectively. There was no significance difference between the two groups according to sex, race, C3 levels, hematuria, or ISN/RPS class. Univariate analysis revealed that older age and lower sCr levels were associated with fluctuation (p=0.007 and <0.001 respectively). In a multivariable model only sCr remained significant (p<0.001).

Conclusions: Wide fluctuation in sCr is observed in non-flaring patients with LN. The typically used 115% cutoff is too restrictive, and a 125% cutoff might be more reasonable. The fluctuation tends to occur more in patients with low sCr, where small absolute changes in sCr represent large percentage point changes.

Group	Patients, n	Samples per patient, Median	Age, mean ±SD (yrs)	% Female	Race White, Black, Asian, Other (%)	ISN class III/IV, III + V/IV+V, V (%)	Baseline creatinine, mean ±SD (mg/dl)	Induction Drug* CYC, MMF, AZA (%)

FR-PO881

Lupus Patients with Low-Level Proteinuria: Time to Revisit the Guidelines

Alice Chedid,[1] Derek M. Fine,[2] Avi Z. Rosenberg,[3] Giovanni maria Rossi,[1] Steven Menez,[4] Lois J. Arend.[1] *[1]Johns Hopkins Hospital, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Johns Hopkins Medicine, Baltimore, MD.*

Background: Kidney biopsy is an important diagnostic tool in lupus nephritis. ACR guidelines recommend biopsy for proteinuria (>1000 mg), or proteinuria (≥500 mg) with hematuria, cellular casts or high creatinine. The presence of low level proteinuria (<1000 mg) alone doesn't qualify for a kidney biopsy.

Methods: We evaluated 150 SLE patients with low level proteinuria who underwent kidney biopsies between June 2003 to September 2018. 84 patients had only low level proteinuria.18 patients had low level proteinuria & hematuria. 48 patients had low level proteinuria & AKI

Results: Patients only with low level proteinuria: 67 of 84 patients (79.7%) had LN on kidney biopsy. 21 (25%) had proliferative LN; 16 (19%) had class III and 5 (6%) had class IV. 11(13.2%) had mixed classes (III or IV & V).17(20.2%) had LN class V. The remaining 17 (20.3%) had non-lupus diagnosis. When hematuria was present, 17 of 18 (94.4%) had LN: 9 (50%) had proliferative LN; 5 (27.8%) had class III & 4 (22.2%) had class IV. 3 (16.6%) had mixed classes. 4 (22.2%) had LN class V. Only one patient (5.6%) had non-lupus diagnosis. Adding AKI to low level proteinuria: 37 of 48 (77.1%) had LN on kidney biopsy. 11 (22.9%) had proliferative LN, 6(12.5%) had LN class III and 5 (10.4%) had LN class IV. 7(14.6%) had mixed classes. 8 (16.7%) had LN class V. The remaining 11(22.9%) had non-lupus diagnoses. Patients with AKI & low level proteinuria had a higher chronicity index (p-value 0.002) compared to patients with low level proteinuria alone.

Conclusions: SLE patients with low level proteinuria frequently have significant renal involvement on kidney biopsy including class III, IV, V and mixed class. This study, contrary to ACR guidelines, supports performance of kidney biopsy in those with isolated low level proteinuria

	Proteinuria <1 gm combined

Proteinuric Lupus-Related Kidney Disease: A Comparative Study of Pure Class V Lupus Nephritis vs. Lupus Podocytopathy

Nirav Parikh, Rima N. Pai, Muhannad Alqudsi, Jason Cobb. *Emory University School of Medicine, Atlanta, GA.*

Background: Lupus-related kidney disease research has focused on proliferative forms of lupus nephritis, and membranous (MLN) lupus nephritis is less studied. A newer clinical entity associated primarily with proteinuria is lupus podocytopathy (LP) which is

minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS) in patients with lupus without proliferative forms of lupus nephritis. The prognosis of patients with primarily proteinuric lupus-related kidney disease (pure class V lupus nephritis and lupus podocytopathy) isn't well studied and especially in a predominantly African-American patient population. This is the first comparative study of outcomes between pure class V lupus nephritis and lupus podocytopathy.

Methods: Retrospective chart review from single academic medical system with statistical analysis using single tail t-test.

Results: Average age 34 years (MLN) and 35 years (LP). The initial serum albumin (sAlb) 2.6 g/dL (MLN) vs. 2.01 g/dL (LP) p<.01, initial serum creatinine (sCr) 1.19 mg/dL (MLN) vs. 3.01 mg/dL (LP) p<.005, and initial urine protein-creatinine ratio (UPC) 4.23 g/g (MLN) vs. 5.73 g/g (LP) p<.09. Mean follow-up 3.3 years (MLN) vs. 5 years (LP), p <.05. Final sAlb 3.4 g/dL (MLN) vs. 3.35 g/dL (LP) p<.41, final sCr 1.16 mg/dL (MLN) vs. 1.20 mg/dL (LP) p<.44, final UPC 1.11 g/g (MLN) vs. 1.11 g/g (LP) p<0.50.

Conclusions: Both groups at initial presentation with similar age and nephrotic range proteinuria but statistically significant differences with a lower sAlb and higher sCr in lupus podocytopathy. Prognosis similar with no statistically significant differences at final presentation in final sAlb, sCr, or UPC despite lupus podocytopathy having a more severe initial presentation. A strength of this study is length of follow-up with 3.3-5 years in our patient population. Both groups at final presentation with acceptable renal function with final sCr of 1.2 mg/dL and non-nephrotic range proteinuria.

FR-PO883

Wire-Loop Lesion Is Associated with Serological Immune Abnormality but Not Renal Prognosis in Lupus Nephritis

Takeshi Zoshima,[1] Satoshi Hara,[2] Mitsuhiro Kawano.[3] *[1]Kanazawa university hospital, Kanazawa, Japan; [2]Kanazawa Graduate School of Medicine, Kanazawa, Japan; [3]Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan.*

Background: Revised ISN/RPS 2018 Classification of Lupus Nephritis (LN) includes wire-loop lesion (WL) as one of the activity indexes (AI). LN patients with WL are classified as class III or IV, both of which are associated with a poor prognosis and recommended to be treated by intense immunosuppressive therapy. However, few reports have focused on the clinicopathological impact of WL on serological immune abnormality and renal prognosis. We aimed to identify clinicopathological characteristics associated with WL, and to clarify whether WL predicts renal prognosis of LN.

Methods: We enrolled 126 Japanese LN patients subjected to renal biopsy in 11 hospitals from 2000 to 2018. We measured clinical findings at the time of renal biopsy, and determined the presence of comorbidities. We also measured Cr and eGFR at the last patient visit, and recorded medications prescribed for LN. Glomerular and tubulointerstitial lesions were expressed as the rate involved of all observed glomeruli or cortex, respectively. Chronic kidney disease (CKD) was defined as eGFR <60 ml/min/1.73m^2. In class III or IV patients, we retrospectively compared these clinicopathological findings between those with WL (WL+ group) and without WL (WL- group).

Results: Of 126 patients, 100 (79.4%) were classified as class III or IV (78 females; mean age 42.7 years; observational period 59.6 months). WL was found in 36 of them (36.0%). Although the renal function did not differ (eGFR; 83.1±33.7 vs 78.0±33.2 ml/min/1.73m^2, p=0.56), WL+ group had higher titer of serum anti-dsDNA Abs (median values; 184 vs 50 IU/ml, p=0.026) and lower level of C3 (42.6±19.4 vs 51.7±24.7 mg/dl, p=0.06) than WL- group. There were no significant differences in any other clinical findings. Linear regression analysis revealed associations between anti-dsDNA Abs and WL (β=0.36, p=0.01). There was no difference in the latest eGFR (78.1±24.5 vs 74.9±27.1 ml/min/1.73m^2, p=0.62) between the two groups. Cox regression analysis revealed significant associations of CKD at the last visit with age and hypertension, but not with WL.

Conclusions: WL was associated with serum anti-dsDNA Abs, but not with renal prognosis, suggesting that WL reflects immune abnormality, but is not an independent factor predictive of renal prognosis in LN.

FR-PO884

Renal Thrombotic Microangiopathy in Lupus Nephritis (LN)

Fernando L. Strufaldi,[1] Cristiane B. Dias,[2] Luis Yu,[3] Viktoria Woronik,[3] Denise M. Malheiros,[4] Livia B. Cavalcante,[6] Lectícia Jorge.[5] *[1]Hospital das clínicas - Faculdade de Medicina da USP, Sao Paulo, Brazil; [2]University of Sao Paulo, Brazil, São Paulo, Brazil; [3]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [4]University of Sao Paulo, Sao Paulo, Brazil; [5]University of São Paulo, São Paulo, Brazil; [6]Hospital das Clinicas da Faculdade de Medicina da USP, Sao Paulo, Brazil.*

Background: Renal thrombotic microangiopathy (rTMA) is one out of many vascular findings in LN. However, the influence of rTMA on prognosis and its related factors has not been well established. Therefore, the objective of this study was to evaluate the clinical and pathological aspects of patients with rTMA in kidney biopsy.

Methods: Analysis of medical reports database and kidney biopsy of 253 patients who had biopsy-proven LN, between January 2012 and December 2018 in our Hospital. We performed comparative analyses between groups with and without rTMA in kidney biopsy.

Results: Forty-three (17%) of 253 patients showed rTMA on kidney histology. This group had a significantly lower glomerular filtration rate (GFR) estimated by CKD-EPI formula (ml/min/1.73m2) at the time of biopsy (40.5±38.2 vs. 71.6±40.6, p<0.001), at 1 year of follow-up (50.7±48.7 vs. 83.5±40.4, p<0.001), and at the end of follow-up (47.7±50.5 vs. 80.3±38.3, p< 0.001). Significantly more patients in the rTMA group reached the composite end-point of hemodialysis, death or GFR < 15 (79.5% vs.31.8%, p < 0.001). Patients with histological findings of microangiopathy had a lower mean of Hb, platelets and haptoglobin (10.3± 1.6 vs.11.1±1.5 p=0.0018, 194±88 vs. 253±92 p=0.0001 and 119±86 vs 160±104 p=0.02 respectively) and a higher LDH (391± 209 vs 303±147 p=0.008). However, if the classical diagnostic criteria for microangiopathic anemia (Hb <12, hapto <10 high DHL and platelet <150) were applied, no patient fulfilled the entire criterion. As expected, TMA group showed higher blood pressure (SBP 131±10.5 vs 124±17.3 p=0.01). There was no difference between groups concerning C3, C4, ANA, anti-Ro, and anti-La. Concerning histopathological features, rTMA group had significantly higher activity (9.0±4.8 vs. 6.0±4.5, p=0.001) and chronicity (4.4±2.9 vs. 2.7±2.2, p =0.001) scores. On the other hand, there was no difference in immunofluorescence.

Conclusions: The classical criterion of microangiopathic hemolytic anemia was not able to predict rTMA. For NL patients, these criteria could be more flexible. Serological data were also not predictors. Renal biopsy remains the critical method for diagnosis and rTMA was a frequent and serious finding. RTMA was an important risk factor for renal outcome, as demonstrated by lower GFR and higher hemodialysis rates in this group.

FR-PO885

A Urine Biomarker of Renal Prognosis in Lupus Nephritis

Juan M. Mejia-Vilet,[1] John P. Shapiro,[2] Huijuan Song,[2] Cristinoc Cruz,[1] Samir V. Parikh,[2] Mayra L. Cano verduzco,[1] Brad H. Rovin.[2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; [2]Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Urine epidermal growth factor (uEGF) has been described as a biomarker of progressive kidney failure in adults with glomerular diseases. Through an agnostic proteomic approach, we found decreased urinary pro-epidermal growth factor (EGF) levels in LN patients. Here we verified and evaluated uEGF as a biomarker of chronic kidney damage in lupus nephritis (LN).

Methods: Pro-uEGF was detected by urine proteomics in LN patients from the Ohio SLE Study. Then uEGF was measured by ELISA in two independent cohorts (US [n=29] and Mexican [n=120]) of LN patients. Serial uEGF measurements and renal outcomes were available from 92 patients of the Mexican cohort with long-term (>12 months) follow-up, and their association assessed by linear mixed modeling.

Results: The LC-MS/MS showed decreased pro-EGF peptides in active LN patients compared to normal controls. Western blot analysis corroborated decreased pro-EGF urine levels in LN. Measurement of urinary pro-EGF by ELISA closely correlated with mature uEGF levels. uEGF were decreased in active LN patients compared to LN in remission and healthy kidney donors from both cohorts. uEGF levels correlated with the percentage of glomerular sclerosis (r=-0.539, p<0.001), interstitial fibrosis (r=-0.665, p<0.001), tubular atrophy (r=-0.665, p<0.001) and overall histologic chronicity index (r=-0.669, p<0.001) of the kidney biopsies. uEGF levels at LN flare were independently associated with the combined outcome of doubling of serum creatinine/ progression to ESRD (HR=0.58, 95% CI 0.34-0.98, p=0.043). The slope of uEGF over time correlated with eGFR slope. Patients who developed the combined outcome had significant and progressive decreases in uEGF compared to those who did not (Figure).

Conclusions: uEGF correlates with LN kidney biopsy findings of chronic damage. uEGF at flare and during follow-up is associated with progressive kidney disease.

FR-PO886

The Value of Repeated Kidney Biopsies in Patients with Lupus Nephritis

Teresa Bada Bosch, Marina Alonso riaño, Elena Gutierrez-solis, Hernando Trujillo Cuellar, Beatriz Redondo navarro, María Fernández vidal, Elizabeth Canllavi fiel, Lucia Aubert, Justo Sandino Perez, Enrique Morales. *Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: The indication to repeat renal biopsy in lupus nephritis (LN) flare is controversial. Studies with protocol biopsies had shown a mismatch between clinical and pathological remission, giving even more importance to repeated biopsies. The aim of our study was to evaluate the pathological changes in patients with LN with a repeated biopsy

Methods: We analyzed 107 patients with LN biopsied between 1990-2018, we selected 26 patients who had had 2 renal biopsies

Results: Mean age at the diagnosis of LN was 29.6±3 years, 73.1% female and 73.1% caucasic. At 1 biopsy 30.7% of the patients were class II, 7.7% class III, 38.5% class IV, 11.5% class V and 11.5% mixed class. Cyclophosphamide was the induction treatment in 53.8% of patients and mycophenolate in 23.1%. Time between biopsies was 71.5±10.7 months. Proteinuria was the most common reason to repeat biopsy (73.1%). At 2 biopsy, patients had lower SLEDAI (12 vs 16, p 0.00) and less number of patients had anti-dsDNA antibodies (46.2 vs 73.1%, p 0.03). There were no differences in creatinine (SCr), proteinuria or complement. 73.1% of patients change of class at 2 biopsy; 38.4% to a higher and 34.6% to a lower class. There were no differences in analytical data between patients who changed class and those who didn't. Most patients 75% with class II changed to a proliferative class, while only 16.6% of patients with proliferative classes change to non-proliferative and 16.6% to a mixed class. There was an increased in chronicity index (CI) between biopsies (1 vs 3, p<0.001) and no difference in activity index. At the end of follow up (163.6 months), 38.5% patients had chronic kidney disease (CKD) and 19.2% end stage renal disease. Patients with CKD had more percentage of glomerulosclerosis (%GE) at first biopsy (8.7% vs 1.2%, p 0.02) and higher CI at second(4 vs 2, p 0.006). They also had less rate of complete remission (CR) at 12 months (0% vs 37.5%, p 0.02) and higher SCr (1.7 vs 0.9 mg/dl, p 0.004) and proteinuria (3.1 vs 4.5g/24h, p 0.02) at second biopsy

Conclusions: Our study suggests the utility of repeated renal biopsies as 38.4% of patients changed to a higher class without relevant clinical expression. The percentage of CR at 12 month, %GE and CI were the main prognosis factors for CKD

FR-PO887

A Fingerprint of Response to Treatment in Lupus Nephritis: Identification of a Panel of Eight Proteins from Baseline Renal Biopsies That Predict Response

Hannah R. Wilson,[1] Bethany Geary,[2] Alyssa C. Gilmore,[1] Reyna Gutierrez Rivera,[2] H. Terence Cook,[1] Anthony Whetton,[2] Liz Lightstone.[1] *[1]Imperial College London, London, United Kingdom; [2]University of Manchester, Manchester, United Kingdom.*

Background: Lupus nephritis (LN) carries significant morbidity & mortality risk. Only ~50% of patients respond satisfactorily to current standard of care. Likelihood of response & long term prognosis are unclear at the outset with no reliable predictors identified. We set out to establish if proteomic analysis of baseline kidney biopsies by relative quantification SWATH mass spectrometry (MS) could reveal biomarkers associated with subsequent response to treatment or mechanisms of disease in non-responders.

Methods: 32 FFPE renal biopsy tissue blocks were identified for analysis: LN class IV: 8 complete responders (CR) & 8 non responders (NR); class V: 5 CR & 4 NR; Controls: 7 thin basement membrane disease. Protein was extracted & trypsin digested using pressure-cycling technology. SWATH-MS analysis was performed using a 6600 TripleTOF mass spectrometer coupled to a Dionex Ultimate 3000 HPLC. Data analysis was performed using openSWATH plus, pyProphet & MSproteomicstools. The false discovery rate was 1%. Proteomic data was submitted for machine learning (1000 iterations) using the RandomForest R package (version 4.6-14) in which the dataset was split randomly 70:30 into a training & testing set.

Results: Of the 5139 proteins identified, 57 were significantly up-regulated in CR compared to NR and included Th17 cell differentiation, metabolic & RNA degradation pathways. Downregulation in CR compared to NR was noted in 106 proteins which included HIF-1 & MAPK signalling & melanogenesis. Further analysis revealed that a panel of 8 proteins separated CR from NR including moesin, a key protein in immunity, & eukaryotic translation elongation factor 1 epsilon-1, a negative regulator of cell proliferation, each downregulated in CR compared to NR. A validation study in a separate set of biopsies is underway.

Conclusions: Whilst the protein yields from FFPE blocks are extremely small (4-8ug protein), we demonstrate these can be successfully analysed by SWATH MS. Importantly, this approach allows us to use baseline biopsies to identify CR from NR using a panel of just 8 proteins and provides novel insights into the intra-cellular mechanisms governing response to treatment in LN, biomarkers of response to therapy as well as potential targets for new therapeutics.

Histologic Findings from Paired Renal Biopsies: Single-Site Results from the ALLURE Study of Abatacept for Lupus Nephritis

Ana Malvar,[1] Valeria G. Alberton,[1] Cecilia Recalde,[1] Sheng Gao,[2] Michael Maldonado.[2] *[1]Hospital Fernandez, Buenos Aires, Argentina; [2]Bristol-Myers Squibb, Princeton, NJ.*

Background: The optimal method for determining length of therapy for proliferative lupus nephritis (LN) is challenging. Discrepancies between clinical parameters and renal biopsies (Bx) remain. This is a *post hoc* analysis of repeat Bx and clinical outcomes from a single site in a study comparing abatacept (ABA) with placebo (PBO).

Methods: ALLURE (NCT01714817) is a PBO-controlled study in patients (pts) with active Class III or IV LN on mycophenolate mofetil/corticosteroids. We evaluated pts from a single site with repeat kidney Bx, which were classified by ISN/RPS and scored using National Institutes of Health activity index (AI) and chronicity index (CI). Findings were correlated with clinical outcomes.

Results: 20/25 pts at the site had pre- and post-treatment (tx) Bx. Clinical characteristics and AI/CI scores were similar at baseline (Table). Four pts discontinued tx due to lack of efficacy (ABA n=1; PBO n=3). Most pts achieved urine protein to creatinine ratio (UPCR) ≤0.5 at least once during therapy (ABA 6/8; PBO 8/12); mean UPCR at Year 1 was lower in ABA arm (0.56 vs PBO 1.53). ABA group had lower 2nd Bx mean AI score (0.8 vs PBO 2.9). 6/8 from ABA group had an AI of 0 in 2nd Bx vs 5/12 in PBO group (Figure). Two PBO pts had UPCR ≤0.5 but had activity on 2nd Bx; two ABA pts without activity on 2nd Bx had UPCR >0.5 (0.6 and 0.8).

Conclusions: Repeat Bx in pts with LN after therapy can reveal tx-dependent discrepancies between clinical and histologic responses. Most patients treated with abatacept showed lack of activity. Better methodologies are needed to assess LN activity and improve clinical tx in pts with LN. Writing assistance: Caudex.

Characteristics and Treatment Patterns of a Real-World Lupus Nephritis Cohort Based on Primary Physician Specialty

Kerry Gairy,[2] Ben Hoskin,[1] David Bell,[1] Olivia Massey,[1] Justyna Amelio,[3] Alexander Liakos,[4] Roger Abramino levy.[5] *[1]Adelphi Group, Macclesfield, Cheshire, United Kingdom; [2]Value Evidence & Outcomes, GSK, Brentford, Middlesex, United Kingdom; [3]Real World Evidence & Epidemiology, GSK, Stevenage, Hertfordshire, United Kingdom; [4]Immuno-inflammation and Future Pipeline, GSK, Brentford, Middlesex, United Kingdom; [5]Immunology and Specialty Medicine, GSK, Collegeville, PA.*

Background: Real-world data describing clinical characteristics and treatments of patients with lupus nephritis (LN) are limited. We describe characteristics and treatment patterns of patients with LN managed by rheumatologists and nephrologists.

Methods: This secondary analysis (GSK study 208683) used survey data of physicians and their patients with LN, enrolled in the 2015 Adelphi Real World Disease Specific Programme (GSK study 205086). Patients (≥18 years) with an LN diagnosis and their treating rheumatologists/nephrologists completed survey forms. Data relating to

characteristics, treatment patterns, and disease burden were extracted and compared using Mann-Whitney, Pearson's chi-squared and Fisher's exact tests.

Results: Overall, 38 rheumatologists and 113 nephrologists provided data for 819 patients with LN; 26.9% were provided by a rheumatologist and 73.1% by a nephrologist. Most patients were primarily managed by the responding physician (85.2%), although input was obtained from a range of healthcare practitioners (HCPs). Care for nephrologist-managed patients was shared by more HCPs from other specialties compared with rheumatologist-managed patients. Nephrologists saw significantly more patients with moderate to severe LN than rheumatologists ($p<0.01$) although LN histological class distribution was similar. Significant differences ($p<0.001$) were observed between rheumatologist- and nephrologist-managed patients respectively, for current kidney dysfunction (48.2% vs 69.9%), mean (standard deviation [SD]) time since diagnosis (364.6 [347.0] vs 296.8 [345.9] weeks), mean (SD) number of prior treatment lines (2.6 [1.1] vs 2.3 [1.1]), and associated systemic lupus erythematosus systemic features (93.2% vs 46.1%). Patient-reported activity impairment and fatigue were similar regardless of treating physician.

Conclusions: In a real-world setting, patients with LN managed primarily by nephrologists had more severe disease and involvement from more specialties than those managed by rheumatologists. Patient-reported experience was similar, reflecting a high overall disease burden regardless of treating physician specialty. Editorial assistance (GSK-funded): Gosia Carless, PhD, Fishawack Indicia Ltd, UK. **Funding:** Commercial support – GSK.

FR-PO890

Efficacy of Cyclophosphamide and Mycophenolate Mofetil as Induction Immunosuppression in Proliferative Lupus Nephritis in Ethnic Minorities

Qiyu O. Wang,[1] Alfred T. Solomon,[1] Jing Xu,[2] Amit J. Joshi,[1] Ambarish Athavale,[1] Peter D. Hart.[1] [1]*John Stroger Jr. Hospital of Cook County, Chicago, IL;* [2]*John H. Stroger Jr. Hospital, Chicago, IL*.

Background: Among patient with lupus nephritis, proliferative glomerulonephritis has the worst prognosis. Cyclophosphamide (CTX) and Mycophenolate mofetil (MMF) remain the preferred agents for induction immunosuppression in these patients. Some studies have suggested that MMF may be a superior induction agent among African American and Hispanics. We reviewed our experience in a predominant minority population.

Methods: A retrospective review of renal biopsy database from Jan 2011-March 2018 identified 50 patients with biopsy-proven class 3 or class 4 (±class 5) lupus nephritis with at least 6 months of follow-up. Baseline characteristics between the 2 treatment groups were compared using independent sample t-test for continuous variables, and Chi-square test for categorical variables. The KDIGO 2012 definition of remission criteria in lupus nephritis was used in assessing treatment response.

Results: The overall remission rate was similar between CTX and MMF group (64.2% vs 68.2%, p=0.773). There was a trend to use CTX in patients with class 4 lupus nephritis. African American patients were more likely to have crescents on kidney biopsy (65% vs 41%) and a lower response rate (52% vs 78%, P=NS). Tubular atrophy and interstitial fibrosis >25% was significantly associated with a lower response rate (OR= 3.01). Although 8 patients had positive antiphospholipid antibodies, thrombotic microangiopathy on kidney biopsy was noted in only one case. The response rate was lower in patients with positive antiphospholipid antibodies (37.5% vs 68.8%, P=NS). Table 1: Demographic and clinical characteristics:

Conclusions: CTX and MMF are equally effective in inducing clinical remission in ethnic minorities with proliferative lupus nephritis. African American ethnicity, presence of crescents and higher tubular atrophy and interstitial fibrosis on renal biopsy was associated with lower response rate.

Table 1: Demographic and clinical characteristics:

		CTX	MMF	P-value
Age (years): 36.2 ±12.5	Class 3	N=8	N=16	
M:F 7:43	Class 4	N=20	N=6	
Ethnicity: African American: 23, Hispanic: 15, Others:12	S. Cr mg/dL (baseline)	1.7±1.3	1.1±0.7	0.046
	S. Cr (6 mo)	1.4±1.3	1.1±0.6	0.268
	Proteinuria g/g Cr (baseline)	4.6±3.3	2.8±3.0	0.571
	Proteinuria g/g Cr (6 mo)	2.4±2.9	1.3±2.0	0.158

FR-PO891

Ten-Year Outcome Differences in Lupus Nephritis Patients Treated with Cyclophosphamide and Mycophenolate-Based Treatment Regimen

Narayan Prasad, Jithu Kurian, Vikas Agarwal, Amit Gupta, Dharmendra Bhadauria. *Sanja Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India*.

Background: Lupus nephritis(LN) poses a considerable impact on the morbidity and mortality of SLE patients. Long term comparative outcome data with cyclophosphamide (CP) and mycophenolate mofetil (MMF) based regimen from the Indian subcontinent is sparse.

Methods: In the study, between July 2008 to June 2018, We analyzed outcomes of 100 LN patients (26 class III, 25 class IV, 6 class III+V, and 10 class IV+V)) treated with CYP (euro lupus-40 and NIH-27) and MMF-33 based regimen with the steroid. Class distribution of the patients in the two groups was similar. The renal survival and patients survival at the end of follow-up between two groups were compared.

Results: The clinical characteristics were similar in both groups, except activity index was high in CP patients (6.13 ±4.48 Vs 4.61 ± 2.80), however, chronicity index was similar. The overall remission was 70% at end of induction, CR, PR, and NR in the CP group was 46.2%, 23.9 %, 29.9% respectively; and in MMF group was 57.6%, 12.1%, and 30.3% respectively. In CP 14.9% and in MMF 9.1 % of patients died. The 1-, 2-, 3-, 4-, 5- and 10-years patient survival in the CP induction was 89.5%, 86.2%, 86.2%,83.8%, 83.8% and 83.8%; and in MMF was 93.9%, 93.9%, 89%, 89%, 89% and 89% respectively. The most common cause of death was sepsis 9/13(69.2%) followed by uremia. The high serum creatinine, low Hb, male, thrombocytopenia, microscopic haematuria, leucocyturia, nephrotic proteinuria, lack of remission at 12 months, dialysis, doubling of creatinine on follow-up were significant predictors of mortality. The 1-, 2- 3-, 4-, 5- and 10- years renal survival(event death-censored, but dialysis dependency) in CP group was 98.5%, 96.7%, 94.7%, 92.4%, 92.4% and 84 % respectively; and in the MMF was 96.8 %, 96.8%, 91.9%, 91.9%, 91.9%, and 78.8% respectively. At the end of the study, dialysis dependency in the MMF group and CYP group was 7.5% and 12.1 % respectively(NS). In the maintenance therapy, 3/56(5.3%) had doubling of creatinine in MMF, and 7/34 (20.5%) in the AZA group(p=0.03).

Conclusions: Long term outcomes in terms of patient and renal survival of LN patients treated with CP and MMF based induction is similar. Serum creatinine doubling was more with MMF than AZA based maintenance. Majority of death occurred during induction and sepsis was the most common cause of death.

FR-PO892

Calcineurin Inhibitors May Prevent Diffuse Membranous Lesions In Lupus Nephritis

Daisuke Ikuma, Hiroki Mizuno, Masayuki Yamanouchi, Junichi Hoshino, Kenmei Takaichi, Yoshifumi Ubara. *Nephrology center, Toranomon Hospital Kajigaya, Kawasaki, Japan*.

Background: Lupus nephritis (LN) is a relapsing disease. The pathologic features of LN may change with relapse, and such changes cannot definitely be predicted clinically. Current guidelines recommend selecting treatment for LN according to the 2003 ISN/RPS classification, which states that glucocorticoids (GC) are the key drugs. Little is known about whether or not other immunosuppressants are effective for LN, including cyclophosphamide, mycophenolate mofetil, azathioprine, and calcineurin inhibitors (CNI). In class V LN, accumulation of subepithelial immune complexes leads to glomerular inflammation. CNI have been reported to show a podocyte-protecting effect that is independent of their immunosuppressive activity. Accordingly, we examined the effect of CNI on class V lesions in patients with relapsing LN.

Methods: Forty-six Japanese patients with LN, who underwent one or more repeat renal biopsies at our hospital between May 1995 and May 2017, were analyzed retrospectively. Patients who received continuous administration of CNI were assigned to the CNI group and other patients were assigned to the non-CNI group.

Results: There were 25 patients in the CNI group and 21 patients in the non-CNI group. No significant differences of baseline characteristics were noted between the two groups. In the CNI group, the number of patients with class V lesions decreased from 13/25 (52%) at baseline to 9/25 (36%) at the time of re-biopsy. On the other hand, the number of patients with class V lesions increased from 6/19 (31.6%) at baseline to 14/21 (66.7%) at re-biopsy in the non-CNI group. We investigated risk factors for relapse of LN with class V lesions by performing multiple logistic regression analysis, and found that CNI use was a negative risk factor with an odds ratio (95% confidence interval) of 0.211 (0.0531-0.839).

Conclusions: CNI may prevent the relapse of LN with class V lesions.

FR-PO893

Tacrolimus Combined with Short-Term Corticosteroids for Inducing Remission in Membranous Lupus Nephritis: A Retrospective Study

Yaomin Wang, Fei Han. *First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*.

Background: We retrospectively analyzed the efficacy of Tacrolimus combined with short-term corticosteroids for inducing remission in membranous lupus nephritis.

Methods: We retrospectively reviewed purely class V LN patients that were followed up in our center between January 2012 and December 2017. They were divided into 2 groups: IVC group received intravenous cyclophosphamide (0.75g/m2,once monthly) combining with prednisone (0.6-0.8mg/kg/d) and the dose of prednisone was gradually tapered after 8 weeks. Tacrolimus group received tacrolimus (trough serum concentration 6-8ng/ml) combining with a course of methylprednisolone impulse (8-10mg/kg/d, maximum 500mg/d, for 3 days), with or without following methylprednisolone 40mg/d; the total duration of corticosteroids was less than 2 weeks.

Results: Totally 65 patients with class V LN were analyzed, including 26 patients in IVC group and 39 patients in tacrolimus group. There were no significant differences on serum albumin, proteinuria, blood cells and immunological index at baseline between IVC and Tacrolimus group. Also, there were no significant differences on the severity of pathological changes such as glomerular sclerosis, crescent formation, mesangial proliferation, segmental necrosis and interstitial infiltrates between two groups. At 6 months, there were no significant differences on the remission rates between IVC group and tacrolimus group (80.8% vs 64.1%). The median follow-up time was 15.0 (10.5, 36.0) months in IVC group and 12.0 (6.0, 24.0) months in tacrolimus group (P=0.119). At the end of follow up, the remission rate (CR and PR) was significantly higher in IVC group than that in Tacrolimus group (92.3% vs 66.7%, P=0.045). There were 10 relapses including 3 (11.5%) relapses in IVC group and 7 (17.9%) relapses in tacrolimus group

(P=0.369) at the end of follow up. Patients experienced less acne vulgaris in Tacrolimus group (10,25.6%) than IVC group (15,57.7%, P=0.010) and less Cushing syndrome in Tacrolimus group (5, 12.8%) than IVC group (13,50%, P=0.001).

Conclusions: Tacrolimus combined with short-term corticosteroids was as effective in short term but not as good in long term as intravenous cyclophosphamide combining with prednisone for inducing remission in membranous lupus nephritis, but with a tendency of fewer adverse effects.

FR-PO894

The Level of Proteinuria After 6 and 12 Months of Treatment Predicts Long-Term Renal Outcomes in Lupus Nephritis: Data from a Nationwide Cohort Study in Japan

Hidekazu Ikeuchi,[1] Keiju Hiromura,[1] Hitoshi Sugiyama,[3] Hiroshi Sato,[2] Hitoshi Yokoyama,[4] Yoshihisa Nojima.[5] On Behalf of the JSN Lupus Nephritis Study Group *[1]Gunma University, Maebashi, Japan; [2]Tohoku University, Sendai, Japan; [3]Okayama University, Okayama, Japan; [4]Kanazawa Medical University, Uchinada, Japan; [5]Inoue Hospital, Takasaki, Japan*.

Background: Recent studies of lupus nephritis in European countries (the Euro-Lupus Nephritis Trial and the MAINTAIN study) showed the level of proteinuria at 12 months is the best predictor for long-term renal outcome. The aim of this study is to evaluate urinary protein levels after treatment as a predictor of long-term renal outcomes, by analyzing data of a recent nationwide cohort study of lupus nephritis in Japan.

Methods: Among 498 lupus nephritis patients who received renal biopsy between 2007 and 2012 at 27 institutions and were registered in Japan Renal Biopsy Registry, data of 282 patients were analyzed who were treated with immunosuppressive therapies after renal biopsy and were observed more than 5 years. Poor renal outcome was defined as doubling serum creatinine (S-Cr) or end-stage renal disease (ESRD). Deterioration of renal function was defined as 1.5 times increase in S-Cr from baseline. Clinical data at the time of biopsy, 6 and 12 months after treatment were analyzed.

Results: During the median observation period of 5.3 years, 32 patient reached poor renal outcome and 68 patients showed deterioration of renal function. ROC analysis revealed that levels of urinary protein/Cr (UP/U-Cr) predicting poor renal outcomes were as follows: 1.64 g/gCr at 6 months (sensitivity 83.0%, specificity 72.7%, AUC 0.828) and 0.87 g/gCr at 12 months (sensitivity 80.0%, specificity 81.8%, AUC 0.862). Levels of UP/U-Cr predicting deterioration of renal function were as follows: 1.10 g/gCr at 6 months (sensitivity 79.5%, specificity 63.3%, AUC 0.753) and 0.49 g/gCr at 12 months (sensitivity 73.4%, specificity 71.0%, AUC 0.745).

Conclusions: Levels of proteinuria at 6 months and 12 months after the treatment are good predictors for long-term renal outcomes in a recent nationwide cohort study of lupus nephritis in Japan.

FR-PO895

Relapse Risk of Lupus Nephritis After Discontinuing Maintenance Mycophenolate

Gabriel Contreras,[1] Naveen Punchayil narayanankutty,[2] Bianca Madrid,[1] Gayathri Devi,[3] Juan C. Duque,[1] Jair Munoz Mendoza,[1] Marie A. Sosa,[1] Zain Mithani,[1] Catarina Regis,[2] Ragi Philips,[2] Saul N. Gonzalez Montalvo,[2] Luis A. Vazquez Zubillaga.[2] *[1]University of Miami, Miami, FL; [2]Jackson Memorial Hospital, Miami, FL; [3]Providence Hospital, Miami, FL*.

Background: Patients who achieved remission of lupus nephritis (LN) after induction immunosuppressive therapy are recommended to continue maintenance mycophenolate or azathioprine for at least three years.

Methods: In this study, we assessed the relapse risk of discontinuing mycophenolate after remission in 59 biopsy-proven LN patients on maintenance mycophenolate. Partial remission was defined as decreased urine protein/creatinine ratio (UPCR) <3 with prior nephrotic proteinuria or decreased UPCR ≤ 50% with sub-nephrotic proteinuria accompanied by improvement in or stabilization of creatinine (±25%). Complete remission was defined as UPCR <0.3 with creatinine <1.3 (in women) or <1.4 mg/dl (in men) and improved in the urine sediment. Relapse was defined as doubling of proteinuria (proteinuric) to UPCR > 1 from complete remission or > 2 from partial remission) or ≥50% increased creatinine.

Results: Patients who discontinued maintenance mycophenolate in <3 years compared with ≥3 years had similar baseline characteristics except for lower hematocrit (34 vs. 36%, p=0.026) and higher biopsy chronicity index (4 vs. 1 points, p=0.001). Discontinuing mycophenolate in <3 years compared with ≥3 years was significantly associated with relapse (adjusted hazard ratio of 3.56 [95% CL 1.33-9.54]) and shorter relapse free half-live of 3 years compared with 12 years.

Conclusions: Discontinuing maintenance mycophenolate prior to 3 years after remission of LN is significantly associated with relapse risk.

FR-PO896

Risk Factors for Poor Long-Term Renal Outcome and Death in Lupus Nephritis: Analysis on a Nationwide Cohort Study in Japan

Hidekazu Ikeuchi,[1] Keiju Hiromura,[1] Hitoshi Sugiyama,[2] Hiroshi Sato,[3] Hitoshi Yokoyama,[4] Yoshihisa Nojima.[5] On Behalf of the JSN Lupus Nephritis Study Group. *[1]Gunma University, Maebashi, Japan; [2]Okayama University, Okayama, Japan; [3]Tohoku University, Sendai, Japan; [4]Kanazawa Medical University, Uchinada, Japan; [5]Inoue Hospital, Takasaki, Japan*.

Background: We previously reported the outcomes of adult lupus nephritis (LN) in a recent nationwide retrospective cohort study in Japan (ASN 2018). Here we aimed to determine risk factors for poor long-term renal outcome and death.

Methods: Adult patients who received renal biopsy between 2007 and 2012 at 27 institutions and were registered in the Japan Renal Biopsy Registry as LN were analyzed. Poor renal outcome was defined as doubling serum creatinine (S-Cr) or end-stage renal disease (ESRD).

Results: 498 patients (88 male), median age 39 (IQR, 30-52) years-old were evaluated. Clinical data at the renal biopsy and the frequency of ISN/RPS Class were as follows: median eGFR 78.3 (IQR, 56.3-100.8) ml/min/1.73m^2, median urinary protein 2.04 (IQR, 0.87-4.30) g/gCr, Class I, 1.6%; II, 5.8%; III, 26.9%; IV, 46.6%; V, 18.5%; VI, 0.6%. Among 498 patients, 36 patients (7.0%) reached doubling S-Cr or ESRD, during the median observation period of 63 months (IQR, 49-82). Death was observed in 28 patients (infection, 14 pts; cardiovascular disease, 6 pts; malignant tumor, 4 pts; others, 4 pts). Univariate analysis revealed age, body mass index (BMI), systolic BP, serum albumin, urinary protein, eGFR and Class IV LN were significant risk factors for poor renal outcome (P <0.05). Multivariate analysis revealed BMI (HR, 1.11; 95%CI, 1.02-1.21; P=0.012) and eGFR (HR, 0.98; 95%CI 0.96-1.00; P=0.019) were independent risk factors. As risk factors for death, age, systolic blood pressure, serum albumin, eGFR and urinary protein were identified by univariate analysis (P <0.05). Multivariate analysis revealed age (HR, 1.04; 95%CI, 1.01-1.07; P=0.008) and eGFR (HR, 0.97; 95%CI, 0.95-0.99, P<0.001). Among 348 patients who received renal biopsy for the first time, 22 patients reached doubling S-Cr or ESRD and 28 patients died. Multivariate analysis also identified BMI (HR, 1.13; 95%CI 1.01-1.27; P=0.032) and eGFR (HR, 0.98; 95%CI 0.96-1.00; P=0.028) for poor renal outcome and age (HR, 1.04; 95%CI 1.01-1.07; P<0.010) and eGFR (HR, 0.97; 95%CI 0.95-0.99; P=0.003) for death.

Conclusions: Using recent data of the real-world clinical practice of LN in Japan, we identified BMI and eGFR at the time of renal biopsy as risk factors for poor long-term renal outcome and age and eGFR as risk factors for death.

FR-PO897

Influence of Therapeutic Drugs on Different Manifestations of Renal Involvement in 907 Chinese Patients with Ankylosing Spondylitis

Qin Xue,[1] Yan Wu.[2] *[1]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China; [2]Shanghai University of Medicine & Health Sciences Affiliated East Branch of Sixth People's Hospital, Shanghai, China*.

Background: Studies on renal involvement in AS are at the initial stage, and hardly we see systematic and large-scale study on the relationship between therapeutic drugs and renal involvement in AS patients. Moreover, the drug sensitivity of kidney varies significantly from races and regions. Therefore, the aim of this study is to investigate the impacts of therapeutic drugs on renal involvement in Chinese AS patients.

Methods: The clinical characteristics and biochemical data of the patients were collected and analyzed. The differences in clinical and laboratory characteristics between the drug and drug-free patients were calculated by Inter-group comparison to screen out confounding factors. Then the multivariate logistic regression analysis with correcting confounding factors was carried out to explore the impacts of the drugs on the renal involvement according to clinical manifestations.

Results: A total of 907 patients were enrolled in the study, 232(26%) patients suffered from renal involvement. Among them, there were 149/232(64%) hematuria, 55/232 (24%) proteinuria, and 27/232 (12%) patients with multiple clinical manifestations. 21/232 underwent a renal biopsy to determine renal pathology. 363/907 (40%) of the patients received therapy: 92(25%) NSAIDs monotherapy, 88(24%) csDMARDs monotherapy, 27(8%) TNF-α inhibitor monotherapy, and 156(43%) combination of the drugs. The probability of renal involvement in Chinese AS patients increased significantly in NSAIDS or csDMARDs monotherapy, and combination therapy of NSAIDs, csDMARDs and TNF-α inhibitor. For AS patients, NSAIDs monotherapy increased the probability of hematuria by 2.4 times, and the probability of mixed manifestations of renal involvement by 3.0 times; csDMARDs monotherapy increased the probability of proteinuria by 2.4 times; combination therapy of NSAIDs, csDMARDs and TNF-α inhibitor increased the probability of hematuria by 4.1 times. In addition, the study found that TNF-α inhibitor monotherapy and its combination therapy with NSAIDs or csDMARDs had no obvious impact on renal involvement in AS patients.

Conclusions: NSAIDs or csDMARDs monotherapy may significantly increase renal involvement in AS patients. The combination therapy of TNF-α inhibitor with NSAIDS and csDMARDs should be used prudently. Renal involvement should be closely observed during the treatment.

Clinical Value of Complement Biomarkers in Autoimmune Glomerulonephritis

Myriam Khalili,[1] Arnaud Bonnefoy,[2] Jérémy Quadri,[3] Jean-Philippe Rioux,[1] Stephan Troyanov.[1] *[1]Hopital du Sacre-Coeur de Montreal, Town of Mount Royal, QC, Canada; [2]CHU Ste-Justine - Université de Montréal, Montréal, QC, Canada; [3]CHU Ste-Justine, Montréal, QC, Canada*.

Background: Complement activation plays a central role in the mechanisms of injury of autoimmune glomerular diseases. Urinary excretion of different complement biomarkers could indicate relevant activated pathogenic pathways (classical, lectin, alternate), parallel disease activity and add clinical value beyond proteinuria.

Methods: We performed a prospective observational cohort study of 81 patients including focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), IgA nephropathy (IgAN), lupus nephritis (LN) and ANCA-associated vasculitis (AAV). Urinary samples were collected at different time points. We measured proteinuria, C4a (classical and lectin pathway), Bb (alternative pathway), and sC5b-9 (terminal cascade), expressed as creatinine ratios. We assessed remission status (partial or complete) as currently defined for each disease. For AAV, we assessed the renal BVAS score after 6 months of treatment.

Results: At baseline, urinary excretion of sC5b-9 was present in each individual (4.28, IQR 0.84-21.96 µg/mmol creatinine) and correlated with the initial proteinuria ($p<0.05$ for each disease). Urinary C4a and Bb were mostly absent. In those who obtained clinical remission, we observed a 92% reduction in urinary sC5b-9 levels, which was greater than the 69% reduction observed in proteinuria (p=0.02 by Wilcoxon signed-rank test), suggesting earlier and more precise variations in urinary sC5b-9. This same pattern occurred with each disease group (table), and reached statistical significance for MN (p=0.05) and AAV (p=0.03). When no clinical remission was obtained, there was a greater increase in sC5b-9 levels (43%) than for proteinuria (21%), although not statistically significant (n=12, p=0.68).

Conclusions: In active autoimmune glomerular diseases, urinary sC5b-9 is measurable in all individuals. In those who obtained a clinical remission, the urinary sC5b-9 reduction was greater than the decline observed with proteinuria. This pattern was seen in each disease suggesting that C5b9 is a more sensitive marker of remission.

Funding: Government Support - Non-U.S.

FR-PO899

Outcome of Membranoproliferative Glomerulonephritis and Postinfectious Glomerulonephritis Stratified by New Classification

Sewon Oh,[1,2] Young-Bin Son,[3] Ho Jun Chin,[4,2] Kyungmi Lee,[1] Kijoon Lim,[1] Jihyun Yang,[5] Myung-Gyu Kim,[1] Sang-Kyung Jo.[6] Korea University Anam Hospital, Korea University College of Medicine *[1]Korea University Anam Hospital, Korea University College of Medicine, Seoul, Republic of Korea; [2]Korean GlomeruloNephritis Study Group, Seoul, Republic of Korea; [3]Korea university, Seoul, Republic of Korea; [4]Seoul National University Bundang Hospital, Seong nam, Republic of Korea; [5]Korea university medical college, Seoul, South Africa; [6]Korea University Hospital, Seoul, Republic of Korea*.

Background: The new classification of membranoproliferative glomerulonephritis (MPGN) has been suggested based on the immunofluorescence (IF) staining: Immune complex (IC)-MPGN and C3 glomerulopathy. In addition, the possibility of overlap between C3 glomerulopathy and postinfectious glomerulonephritis (PIGN) has been raised because of high proportion of C3 dominancy and poor renal outcome in PIGN. However, little is known about clinical features and outcomes of C3 glomerulopathy compared to IC mediated GN (IC-GN).

Methods: A total of 4,431 patients who underwent kidney biopsy and had IF data were identified in six university hospitals during 1980-2018. We included 280 subjects with MPGN and 69 with PIGN. C3 dominant glomerulonephritis (C3DG) was defined as C3 staining stronger than immunoglobulins in patients with MPGN or PIGN.

Results: Among patients with MPGN and PIGN, 39 (14%) and 36 (52%) were classified as C3DG. C3DG had higher proportion of women, lower C3, nephrotic range proteinuria and serum cholesterol, and higher serum albumin although renal function was not different at the time of biopsy ($P<0.05$). In addition, C3DG had almost no association with viral hepatitis B (3.1 vs. 29.2%, $P<0.001$), and lower tendency of ANA ($P=0.085$). After 6 months of biopsy, C3DG had significantly lower proteinuria and high rate for remission of proteinuria ($P<0.05$). The incidence of 40% decline in eGFR was significantly lower in C3DG compared than IC-mediated GN (16.3% vs. 31.5%, $P=0.031$). The incidence of end stage renal disease (ESRD) was the highest in IC-MPGN and the lowest in C3-PIGN during 107 [28-247] months of median follow up (IC-MPGN, 37.4%; C3-MPGN; 26.3%, IC-PIGN; 22.2%, C3-PIGN, 9.1%; P=0.036). Together with MPGN and PIGN, C3DG was associated with better renal survival (P=0.016). Multivariate analysis showed that C3DG demonstrated 0.396-fold increase of ESRD (95% CI, 0.192-0.814) compared than IC-GN. Mortality was not significant between groups.

Conclusions: C3DG had lower rate of moderate proteinuria and less likely to be associated with chronic infection and autoimmune disease at presentation. The 13.7% of C3DG progressed to ESRD in although it showed favorable renal survival compared to IC-MPGN.

FR-PO900

Clinicopathological Study of Mixed Cryoglobulinemic Glomerulonephritis Caused by Non-Hepatitis C Virus Infection

Chao Li, Hang Li, Xuemei Li, Xuewang Li. *Peking Union Medical College Hospital, Beijing, China*.

Background: To describe the clinical features, renal pathology findings and renal prognosis in patients with mixed cryoglobulinemic glomerulonephritis caused by non-hepatitis C virus infection.

Methods: This was a retrospective study including seven Chinese patients with non-HCV infection associated mixed cryoglobulinemic glomerulonephritis in a tertiary referral hospital from 2015 to 2018. The demographic, clinical, pathological characteristics, treatment and follow-up data were analyzed.

Results: Age at renal biopsy was 51±13 years, including five females and two males. 24hUP was 5.0±3.5g/d and three cases presented with nephrotic syndrome. The median baseline eGFR(CKD-EPI) was 40.5±15.8ml/min per 1.73m^2. The extrarenal manifestations were: purpura (n=6), arthralgia (n=2, 28.6%), peripheral neuropathy (n=1), cardiomyopathy (n=1). The etiologies of cryoglobulinemia were: HBV infection (n=4), Sjögren syndrome(n=2), essential(n=1). The median cryocrit was 4.9% (range4.0-5.0), rheumatoid factor was 567±153 IU/ml, C3 was 0.47g/L(range0.32-0.57), C4 was 0.003g/L(range0.001-0.013). Renal pathologic findings on light microscopy: endocapillary proliferative glomerulonephritis(n=4), membranoproliferative glomerulonephritis(n=3). Ultrastructural studies showed granular subendothelial electron-dense deposits in all patients and organized microtubules or fibrils were seen in three cases. Four patients with HBsAg positive receive antiviral medication. All patients were given corticosteroid, alone or combined with cyclophosphamide(n=5) or mycophenolate mofetil(n=1). One patient received plasmapheresis. The median follow-up time was 16 months (range 6-41). All patients survived, and no one progressed to ESRD. At endpoint of follow-up, 24hUP was 0.89g/d (range 0.17-2.0), and eGFR(CKD-EPI) was 72.6±21.2 ml/min per 1.73m^2.

Conclusions: Mixed cryoglobulinemic glomerulonephritis should be screened for non-HCV etiologies, especially in HBV-endemic country. Endocapillary proliferative glomerulonephritis was the common pathologic feature, as well as membranoproliferative glomerulonephritis. Early diagnosis and management of mixed cryoglobulinemic glomerulonephritis could benefit patients'renal outcome. Long-term prognosis should be investigated in further studies.

FR-PO901

DNAJB9 Protein Accumulation in Fibrillary GN Is Not due to Local RNA Upregulation

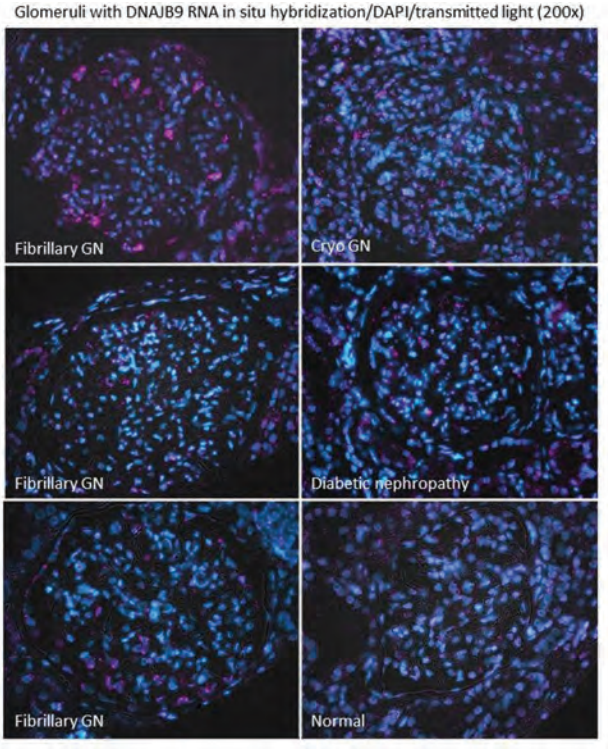
Jonathan W. Nelson,[1] Bridget A. Robinson,[1] Timothy J. Nice,[1] Randall Woltjer,[1] Philipp W. Raess,[1] Susan B. Gurley,[1] Kelly D. Smith,[2] Nicole K. Andeen.[1] *[1]Oregon Health & Science University, Portland, OR; [2]University of Washington, Seattle, WA.*

Background: Fibrillary glomerulonephritis (FGN) is characterized by glomerular accumulations of haphazardly arranged fibrils and deposition of IgG with DNAJB9, a protein in the ER stress/unfolded protein response pathway (UPR). In this study, we sought to determine source of glomerular abundance of DNAJB9.

Methods: We evaluated formalin-fixed paraffin embedded kidney biopsies from patients with FGN (n=6), non-fibrillary glomerular disease (n=2 amyloidosis, n=3 cryoglobululinemic gn, n=3 diabetic nephropathy) and normal controls (n=2). Confocal microscopy was performed on slides stained with a DNAJB9 RNA in situ hybridization probe and DAPI. Automated image analysis was performed and corroborated with DNAJB9 immunohistochemistry.

Results: By immunohistochemistry, FGN cases were DNAJB9-positive and non-FGN cases were DNAJB9-negative. DNAJB9 RNA signals were present in FGN, non-FGN glomerular disease, and normal controls; signals were identified in podocytes and mesangial regions as well as tubular, interstitial, and vascular tissue. There were no significant differences in glomerular DNAJB9 RNA signals (313 vs. 379, p=0.3), DNAJB9/DAPI ratios (2.25 vs. 3.3, p=0.3), or DNAJB9 signal intensity between FGN and non-FGN cases.

Conclusions: DNAJB9 RNA expression does not predict protein accumulation in FGN, suggesting that the pathogenesis of FGN is not dependent on local activation of the UPR. Our findings corroborate prior proteomic studies in which other components of the UPR pathway were not locally upregulated (PMID: 29097624), and provide contextual data to studies which identified increased levels of DNAJB9 protein in serum from patients with FGN (PMID: 31010480). This supports an alternate mechanism or circulating source for DNAJB9 accumulation in fibrillary GN.



FR-PO902

Proliferative Glomerulonephritis with Non-Organised Monoclonal Immunoglobulin Deposits (PGNMID): A Single-Centre Retrospective Study

Sarah Blakey,[3] Neill D. Duncan,[1] Frederick W. Tam,[2] Tom Cairns,[3] Jeremy B. Levy,[3] H. Terence Cook,[4] Aristeidis Chaidos,[4] Candice A. Roufosse,[4] Andreas Kousios.[3] *[1]Hammersmith Hospital, London, United Kingdom; [2]Imperial College Kidney and Transplant Institute, London, United Kingdom; [3]Imperial College Healthcare NHS Trust, London, United Kingdom; [4]Imperial College London, London, United Kingdom.*

Background: PGNMID is a rare glomerular disease, most often seen in the context of MGRS. At present, optimal treatment is not established.

Methods: All native renal biopsies performed at the Hammersmith Hospital between 2006 and 2017 were analysed. 15 cases of PGNMID were identified. Baseline characteristics and clinical outcomes during follow-up to January 2019 are summarised in the Table.

Results: Mean age was 61, 31% were men, mean eGFR was 49 mL/min/1.73m2 and mean uPCR 384 mmol/mol. A circulating paraprotein was detectable in 5 (33%) of 15 patients. Most (73%) underwent bone marrow aspiration and trephine (BMAT), with a clone identified in two of 11. One had a plasma cell clone and was not immunosuppressed, having presented at end stage with an eGFR of 7mL/min/1.73m2 and 50% IFTA. The second patient had a B cell clone, with an eGFR of 83 mL/min/1.73m2 and 0% IFTA, and achieved remission of proteinuria and stabilisation of eGFR with prednisolone and rituximab. Three (20%) patients had a detectable paraprotein but no clone on BMAT, and all received treatment. Two progressed to ESRD despite steroids, rituximab and cyclophosphamide. One patient initially responded to steroids, MMF, rituximab and bortezomib, but relapsed following cessation of bortezomib due to peripheral neuropathy. 10 of 15 (67%) patients had no detectable paraprotein at diagnosis. Of these, 89% had partial or complete renal remission. Treatment of this group was variable; none had clone-directed therapy. One case was lost to follow-up post renal biopsy.

Conclusions: Our cohort of PGNMID patients corroborates the previously-described low rate of detection of circulating paraprotein and pathogenic clones on BMAT. Further collaborative studies are required to establish the safety and efficacy of clone-directed therapy, and to guide optimal management in patients with PGNMID.

Study of Anti-Complement Factor H Mediated Disease at a Tertiary Care Centre

Umesh Lingaraj. *Nephrolgy, Institute of NeohroUrology, Bangalore, India.*

Background: Complement dysregulation is an important aetiology for glomerular diseases. Antibody against complement factor H which regulates the alternate complement pathway can cause atypical HUS and C3 glomerulopathy[1]. **Aim of the study :** To study the clinical profile and outcome of patients with anti complement factor H mediated disease at our centre.

Methods: Materials and methods : We studied the clinical profile and outcome of patients with anti complement factor H mediated disease at a tertiary care centre over 24 months (August 2016 to July 2018). We had a total of 18 cases during the study period. All patients were followed up to assess their response to therapy.

Results: A total of 28 cases of atypical HUS were seen during the study period of which anti factor H antibody was elevated in 18 (64.2%). Mean age of the patients was 26.6 +/- 3.2 yrs with 10 patients in the paediatric age group. There were 13 males (72.2%). 10 patients had a febrile prodrome (55.5%). All patients presented with hypertension with active urinary sediments and rapidly progressive renal failure. Mean serum creatinine at presentation was 6.8 +/- 1.2 mg/dl and all patients were oliguric at presentation and required haemodialysis. Serum C3 was low in all patients with a mean of 68 +/- 12.2 mg/dl with normal C4 levels. LDH was elevated in all patients with a mean of 2878 +/- 211.4 IU/ml. All patients had schistocytes in peripheral smear. Anti complement factor H antibody was elevated in all patients with a mean of 549 +/- 90 AU/ml. (normal - 0 to 100 AU/ml). Renal biopsy showed thrombotic microangiopathy in 12 patients (66.6%) while features were suggestive of C3 glomerulopathy in 6 patients (33.3%).

Conclusions: Our study shows that anti complement factor H mediated disease shows good response to plasmapheresis followed by immunosuppression with B cell targeted therapy. Anti CFH mediated disease should be ruled out in all patients with atypical HUS. It is more common in the paediatric age group with excellent response to plasmapheresis and immunosuppression in the form of oral steroids and cyclophosphamide. Also patients presenting with TMA have better prognosis compared to C3 glomerulopathy. Identification of the pathological clone of cells producing the anti factor H antibody would provide more insight into the nature of the disease. We also hypothesise that the clones producing antibody to the N and C terminals might be different.

FR-PO904

Outcome of First Relapse After Eculizumab Withdrawal in Atypical Hemolytic Uremic Syndrome: The CUREiHUS Study

Caroline Duineveld, Romy N. Bouwmeester, Kioa L. Wijnsma, Nicole Van De Kar, Jack F. Wetzels. CUREiHUS study group *Radboudumc, Nijmegen, Netherlands.*

Background: Eculizumab was introduced as lifelong therapy for patients with aHUS. However, the costs of therapy and potential side effects have stimulated early drug withdrawal. The safety of an early withdrawal strategy is debated, since relapses may cause chronic kidney injury. In the Netherlands eculizumab is used according a restrictive treatment regime, with a preference to withdraw or taper the drug three months after start of therapy. Here, we present an interim analysis of the outcome of patients with a first relapse.

Methods: We evaluated outcome in all aHUS patients in whom eculizumab was tapered or withdrawn, and developed a (suspected) relapse necessitating renewed eculizumab therapy. Serum creatinine, eGFR (CKD-epi) and protein-creatinine ratio's at 6 and 9 months after relapse and last follow-up were compared with baseline.

Results: We evaluated 34 patients (20 F, 14 M; median age 35 years, IQR 34) with aHUS, in whom eculizumab was tapered or withdrawn. Fourteen patients (41%), including 3 children, had a relapse. Of these, 93% were known with a genetic variant in complement genes. Eight patients had a kidney transplant. Restart of eculizumab was effective in most patients, with no significant difference between eGFR at baseline (median 42.6 ml/min/1.73m^2, IQR 40) at 6 months (40.5 ml/min/1.73m^2, IQR 48), 9 months (36.6 ml/min/1.73m^2, IQR 42) after relapse, and at the end of follow-up (35.6 ml/min/1.73m^2, IQR 53). At the end of follow-up (18 months, range 2-31), one patient with multiple relapses had developed ESRD, with notable and unexplained cystic malformation in both kidneys. In four other patients eGFR had decreased ≥20% compared to baseline. All

four had received a kidney transplant, had moderate-severe CKD at baseline, with eGFR affected by viral infections and rejection episodes.

Conclusions: Eculizumab withdrawal was successful in 53% (18/34) of the patients. In 41% of the patients a relapse occurred. Overall, there was no safety signal. Still, the number of patients is limited. Patients with a kidney transplant, and/or moderate-severe CKD may be at risk for sustained kidney injury.

FR-PO905

Mechanistic and Potency Evaluation of Complement Factor D and Factor B Inhibitors

Jane A. Thanassi, Dharaben Patel, Yongsen Zhao, Venkat R. Gadhachanda, Jason Wiles, Mingjun Huang, Steven D. Podos. *Achillion Pharmaceuticals, Inc., New Haven, CT.*

Background: Complement factor D (FD) and complement factor B (FB) are serine proteases essential for complement alternative pathway (AP) activity. FD and FB are present in normal human serum (NHS) at approximately 0.07 μM and 2 μM, respectively. Small molecule inhibitors of FD and FB have been discovered and a few, including ACH-4471 (FD inhibitor) and LPN023 (FB inhibitor), are in clinical development for multiple indications of AP dysregulation including the rare renal disease C3 glomerulopathy (C3G). In this study, we evaluated FD and FB inhibitors for potency and mechanism of action. We also examined their effect on ex vivo C3 consumption in serum from C3G patients.

Methods: FD and FB inhibitor potencies were profiled by AP hemolysis with rabbit erythrocytes and NHS. Mechanism of action (MOA) and potency of inhibitors were assessed in soluble and bound C3 convertase studies with purified components, including FB titrations and order-of-addition tests; convertase activity was assessed from C3 cleavage product generation measured by ELISA. Compound inhibition in C3G patient sera mixed equally with NHS was assessed in fluid phase, with convertase activity assessed by monitoring C3 cleavage products.

Results: ACH-4471 and next generation FD inhibitors were more potent than LNP023 in AP hemolysis with 4.0-fold to 32-fold lower IC_{50} values. A reference FD inhibitor (Schubart et al, PNAS 2019) was less potent, with a 1.2-fold lower IC_{50} than LNP023. LNP023 potency was comparable to input serum FB concentration, suggesting a stoichiometric limit for FB inhibition and a relative advantage for FD inhibitors. MOA studies with C3 convertase revealed that LNP023 binds free intact FB, and that it inhibits AP convertase activity but not proconvertase assembly or its activation to convertase. Inhibitor assessments in C3G patient sera also showed a potency advantage for FD inhibitors over LNP023; ACH-4471 and next-generation inhibitors showed comparable inhibition to LNP023 at 1 μM but all FD inhibitors were more inhibitory than LNP023 at 0.1 μM.

Conclusions: ACH-4471 and next generation FD inhibitors demonstrated greater achievable potencies than the FB inhibitor LNP023 in serum from healthy donors and C3G patients, likely due to the molar difference in systemic FD and FB concentrations.

C3 Inhibition with APL-2 Targets the Underlying Disease Process of C3G Complement Hyperactivity and Improves Proteinuria

Bradley P. Dixon,[1] Larry A. Greenbaum,[2] Liwei Huang,[3] James C. Mccabe,[4] Sandeep K. Rajan,[5] Nick Robertson,[7] Hetal S. Kocinsky,[7] Marvin R. Garovoy,[6] Carl Di casoli,[7] Pascal Deschatelets,[7] Cedric G. Francois,[7] Federico Grossi.[7] *[1]Children's Hospital of Colorado, Aurora, CO; [2]Emory University, Atlanta, GA; [3]Tidewater Kidney Specialists, Inc., Chesapake, VA; [4]Southeastern Nephrology Associates, Wilmington, NC; [5]University of Tennessee Health Science Center, Memphis, TN; [6]Independent Consultant, Ex-Equals, LLC, Sausalito, CA; [7]Apellis Pharmaceuticals, Inc., Waltham, MA.*

Background: C3G is a rare disease of complement dysregulation in which inappropriate C3 activation leads to excessive production of C3 breakdown products. The prognosis is poor with 30 – 50% of patients reaching end-stage renal disease within 10 years of diagnosis. APL-2, a cyclic peptide that inhibits C3 activation, has the potential to address the underlying pathophysiology of C3G. The study aims to assess whether APL-2 inhibits C3 activation, and improves proteinuria, in patients with C3G.

Methods: Adult and adolescent patients with primary C3G, proteinuria > 0.75 mg protein/mg creatinine and eGFR ≥ 30 ml/min/1.73 m^2, were eligible for this Phase 2 open-label study to assess the safety and biological activity of APL-2 over 48 weeks. Eight C3G patients were recruited. Biological activity was assessed by changes from baseline in serum C3 and proteinuria. Proteinuria was quantitated by urine protein-to-creatinine ratio (uPCR) from a 24-hour urine, or as the mean from triplicate first-morning urine samples. Data are reported through Study Day 84 (12 weeks) for the first three patients. Data for all eight patients through Study Day 84 are planned for November, 2019.

Results: Patient 1 was non-compliant with APL-2 dosing, and so data from this patient is not presented. In Patients 2 and 3, baseline serum C3 was low (≤ 13 mg/dL; normal range 90 – 180 mg/dL) and increased to > 130 mg/dL by Day 14 of APL-2 treatment. Both patients also had substantial improvements in proteinuria by Day 84, as evidenced by improvements in uPCR and serum albumin. In Patient 2, uPCR decreased from a baseline of 6.6 to 0.36 mg/mg on Day 84, with an increase in serum albumin from 2.4 to 4.4 g/dL. Patient 3 had a decrease in uPCR from a baseline of 3.2 to 1.6 mg/mg on Day 84, with a corresponding increase in serum albumin from 2.3 to 3.1 g/dL. APL-2 appears well-tolerated with no serious adverse events reported in C3G patients.

Conclusions: These data provide strong preliminary evidence that APL-2 targets the complement dysregulation of C3G with an increase in serum C3 levels and a reduction in proteinuria.

Accelerated suPAR-Mediated Kidney Disease in the Solitary Functioning Kidney

Xuexiang Wang,[1] Jing Li,[3] Ke Zhu,[1] Beata Samelko,[1] Michael R. Garrett,[2] David C. Wei,[3] Jochen Reiser.[1] *[1]Rush University Medical Center, Chicago, IL; [2]University of Mississippi Medical Center, Jackson, MS; [3]Rush University, Chicago, IL.*

Background: Kidney mass and number of functioning nephrons are determinants of renal long-term health. Single functioning kidney (SFK) is a rare disease (1:1500 at birth) resulting in early onset chronic kidney disease (CKD) in over 50% of those affected. Similarly, kidney donors may have an increased risk for future CKD. The underlying mechanisms are not clear. The soluble urokinase receptor (suPAR) is an immune-derived circulating factor implicated in pathogenesis and prediction of CKD incidence and progression. We hypothesized that SFK condition could be more sensitive to increased suPAR levels and examined 3 different rodent models of SFK.

Methods: Uninephrectomy and sham surgeries were performed on C57B/6 mice, suPAR transgenic/knockout models or littermate controls. The minipumps with different concentrations of LPS were implanted subcutaneously. Proteinuria and suPAR were followed for 4 weeks. In congenital SKF rat model (HSRA), the recombinant human suPAR protein was injected intravenously into HSRA single kidney rats (HSRA-S) and two-kidney controls (HSRA-C). Proteinuria and beta3 integrin activity were assessed.

Results: Urinary protein slowly increased in nephrectomized suPAR transgenic mice, while the littermate controls with nephrectomy showed no change. LPS infusion resulted in increased level of serum and urine suPAR in C57B/6 mice. Interestingly, SFK models had a higher serum suPAR and substantially higher proteinuria, compared to the sham two-kidney groups. In contrast, uPAR deficient SFK mice were protected from LPS induced proteinuria. HSRA-S rats revealed an increase of proteinuria compared to HSRA-C after the recombinant human suPAR injection. The activity of the suPAR receptor beta3 integrin was increased in the kidney of HSRA-S rats following administration of suPAR.

Conclusions: Increased circulating suPAR levels, either induced by LPS, or from suPAR transgenic models or extrinsically injected, induce proteinuria in uninephrectomized mice or congenital SFK rats, when compared to their two-kidney controls. These findings suggest the importance of suPAR in SFK, possibly in kidney donors and support findings that suPAR cause declined renal function. Monitoring circulating suPAR levels might be important in understanding the pathogenesis and risk-control for patients who are born with or remain having only one functional kidney.

FR-PO908

Mechanism of CLIC5A Action in Podocytes

Md. M. Rahman, Laiji Li, Barbara J. Ballermann. *University of Alberta, Edmonton, AB, Canada.*

Background: CLIC5A is a major podocyte protein essential for assembly of the Ezrin/NHERF2/Podocalyxin complex that shapes the apical domain of foot processes. CLIC5A *does not* function as an ion channel, but it stimulates apical plasma membrane phosphatidylinositol 4,5-bisphosphate (PI(4,5)P2) generation by PI4P5 kinases (PI4P5Ks) through localized Rac1 activation. Docking on PI(4,5)P2 then changes the Ezrin conformation causing Ezrin to link Podocalyxin to actin. CLIC5A deletion in vivo abrogates podocyte Ezrin activation and heightens hypertension-induced glomerular injury.

Methods: We defined the relationship between CLIC5A, Rac1 and Ezrin by pull-down of Rac-GTP with Pak Binding Domain (PBD) beads, GST-CLIC5A pull-down, and Yeast-two-Hybrid (Y2H) assay, in which direct protein-protein interactions generate blue colonies by α-gal LacZ activity and growth on "DDO media" (Figure).

Results: CLIC5A overexpression in cultured podocytes and HEK293 cells increased Rac1-GTP levels 5-10 fold, and CLIC5A, Ezrin and PI4P5Kiα, PI5P4Kα, and PI4P5Kγ isoforms were all co-precipitated from cell lysates with GTP-Rac1 by PBD beads. Notably, Pak-PBD pulled the PI4P5Kα3 isoform from kidney cortex lysates of $CLIC5A^{+/+}$ but not $CLIC5A^{-/-}$ mice. GST-CLIC5A pulled Rac1-GTP and -GDP from cell lysates, but failed to interact directly with purified, recombinant Rac1-GDP or -GTP. Domain-based Y2H screening and mapping showed that CLIC5A interacts directly with the ezrin C-terminus (lys516-leu586; Figure) and the βPix/ARHGEF7 interacting protein Shank2. The CLIC5A/Ezrin interaction required the active conformation of Ezrin, and siRNA knockdown of Ezrin reduced CLIC5A-induced Rac1 activation in cultured podocytes.

Conclusions: Thus, CLIC5A, Rac1-GTP, Ezrin and PI4P5K exist in a protein complex. In which CLIC5A interacts directly with Ezrin. CLIC5A-dependent Rac1 activation requires the direct interaction with Ezrin, and probably Shank2, leading to the formation of the CLIC5A/Ezrin/ Rac1-GTP/PI4P5Kα3 complex that generates PI(4,5)P2 clusters at the apical plasma membrane.

Anti-Apoptotic Role of Phosphatidylinositol-3 Kinase (PI3-Kinase) in Angiotensin II-Induced Podocyte Injury

Tae-Sun Ha. *Chungbuk National University College of Medicine, Cheongju-si, Republic of Korea.*

Background: PI3-kinase has distinct roles in cellular processes spanning from metabolism to cell motility and survival. Angiotensin II (Ang II) promotes the development and progression of proteinuria and renal diseases and induces podocyte apoptosis. Phosphatidylinositol-3 kinase (PI3-K), connected to CD2-associated protein (CD2AP) in podocytes, is known to send signaling through nephrin-CD2AP-PI3-kinase/Akt pathway and promote cell survival. Autophagy and apoptosis constitute the two processes through which injured/aged cells or organelles are eliminated. We investigated the role of PI3-kinase in angiotensin II-induced podocyte injury.

Methods: Mouse podocytes were incubated in media containing various concentrations of Ang II and at different incubation times. Cell survival/death-modifying reagents and siRNA targeting SHIP2, a negative regulator of the PI3-kinase/Akt signaling pathway, and Atg5 were applied. The changes of podocyte autophagy and apoptosis were observed by confocal imaging, western blotting, realtime PCR, FACS and TUNEL assay according to the presence of Ang II.

Results: Ang II-treated podocytes showed an increase in autophagosomes compared with control cells at early phase in a dose-dependent manner. This pro-autophagic effect of Ang II was inhibited by pretreatment with 3-methyladenine (3-MA), an inhibitor of PI3-kinase class III. Atg5 siRNA reduced LC3 puncta levels and increased the number of apoptotic podocytes over that observed with Ang II treatment at 12 hours. Thereafter, Ang II reduced the expression of autophagy-related genes, such as, *Atg3*, *Atg5*, *Atg7*, and *bcl-2* at 24 hours and induced podocyte apoptosis at later stages, 12 and 24 hours in concentration- and time-dependent manners in FACS and TUNEL assays. Thereafter, Ang II induced podocyte apoptosis significantly in concentration- and time-dependent manners in FACS and TUNEL assays. PI3-kinase inhibitors, 3-MA and LY294002, and Atg5 siRNA further increased Ang II-induced podocyte apoptosis. On the other hand, SHIP2 siRNA suppressed Ang II-induced podocyte apoptosis and the expression of apoptotic proteins. Therefore, PI3-kinase protect podocyte from apoptosis in angiotensin II-induced podocyte injury.

Conclusions: Our findings suggest that Ang II induces podocyte apoptosis, which could be prevented by PI3-kinase activation through the inhibition of SHIP2 and promoting autophagy.

Synaptopodin Deficiency Exacerbates Renal Disease in a Mouse Model of Alport Syndrome

Liang Ning,[2] Hani Suleiman,[2] Jeffrey H. Miner.[1] [1]*Washington University School of Medicine, St. Louis, MO;* [2]*Washington University, Saint Louis, MO.*

Background: Synaptopodin (Synpo) is a proline-rich actin-associated protein found in podocyte foot processes and dendritic spines. It has been reported (Asanuma et al., J Clin Invest 2005) that *Synpo*$^{-/-}$ mice lack Synpo-short and Synpo-long isoforms but show an upregulation of Synpo-T (truncated) in podocytes. *Synpo*$^{-/-}$ mice show an overtly abnormal phenotype in the brain but not in the kidney, demonstrating that Synpo-T may serve as a backup for Synpo-long in *Synpo*$^{-/-}$ podocytes. X-linked Alport syndrome is caused by mutations in *COL4A5*, which encodes the collagen IV α5 chain, resulting in structural and functional abnormalities of the glomerular basement membrane and leading to ESRD. It has been reported that expression of synaptopodin was decreased in Alport syndrome patients. We predicted that the deletion of *Synpo* in mice would exacerbate the effects of a *Col4a5* mutation.

Methods: To directly investigate the role that Synpo plays in Alport syndrome, we crossed mutant mice carrying null mutations in *Synpo* and *Col4a5* to produce mice deficient in one, both, or neither of these genes. Urine and tissues were taken at select time points to evaluate albuminuria, histopathology, and glomerular capillary wall ultrastructure.

Results: We generated novel *Synpo*$^{-/-}$ mice that should completely lack all known Synpo isoforms, but we did not observe obvious abnormalities in the kidneys. We found that the ablation of *Synpo* in *Col4a5*$^{-/-}$ or *Col4a5*$^{-/Y}$ mice led to shortened life span and acceleration of disease progression, such as more severe proteinuria and glomerulosclerosis. We obtained the same results except for decreased life span in *Col4a5*$^{+/-}$ females; surprisingly, most *Col4a5*$^{+/-}$ mice could live 5 months regardless of the presence or absence of Synpo. Immunostaining showed that the expression of COL4A345 was upregulated in these mosaic female mice in the absence of Synpo.

Conclusions: We conclude that *Synpo* deletion exacerbates the Alport syndrome disease phenotype in Alport mice, revealing the podocyte actin cytoskeleton as a target for therapy.

β2-Adrenergic (β2-AR) Agonist Protects Mice from Glomerular Injury Through the Activation of β2-AR Receptor in Podocytes

Ehtesham Arif,[1] Ashish K. Solanki,[1] Pankaj Srivastava,[1] Bushra Rahman,[1] Rick G. Schnellmann,[2] Deepak Nihalani.[1] [1]*Medical University of South Carolina, Charleston, SC;* [2]*University of Arizona, Tucson, AZ.*

Background: Podocytes have a remarkable ability to recover from injury, however, little is known about the recovery mechanisms involved in this process. In this report, we demonstrate that pharmacological activation of β_2-AR dependent MB (mitochondrial biogenesis) is involved in the recovery of podocytes from injury in a PGC-1α dependent manner. We further demonstrate that the drug-induced podocyte recovery was significantly attenuated in podocyte-specific β_2-AR knockout mice.

Methods: The β_2-AR knockdown human podocytes were generated using specific shRNA, and the podocyte specific β_2-AR knockout mice were generated by crossing β_2-AR flox mice with podocin cre (B6.Cg-Tg(NPHS2-cre)295Lbh/J) mice to remove β_2-AR protein specifically in podocytes. The effect of a potent, specific, and long-acting β_2-AR agonist formoterol on MB was analyzed in control and β_2-AR knockdown podocytes by evaluating mtDNA (mitochondrial-DNA) copy number. Formoterol-induced (1mg/kg body weight/day) recovery of renal function was analyzed in wild-type and β_2-AR knockout mice by analyzing UACR, histological, ultrastructural and immunostaining analyses.

Results: β_2-AR knockdown in cultured human podocytes reduced mtDNA copy number indicating β_2-AR role in MB. While the podocyte-specific β_2-AR knockout mice developed normally, interestingly, when these mice were injured by treatment with adriamycin or nephrotoxic serum, unlike their WT (wild type) littermates, they failed to recover in response to treatment with formoterol and showed diseased glomerular morphology with consistent albuminuria.

Conclusions: Overall, these results confirmed that β_2-AR plays a critical role in podocytes recovery from injury and genetic deletion of β_2-AR affects the ability of mice to recover from injury. Overall these results suggest β_2-AR as a novel therapeutic target for treating podocytopathies.

FR-PO912

Melanocortin 5 Receptor (MC5R) Signaling Protects Against Podocyte Injury and Proteinuria

Mingyang Chang, Lance D. Dworkin, Rujun Gong. *University of Toledo Medical Center, Toledo, OH.*

Background: Melanocortin therapeutics represented by ACTH has a demonstrable steroidogenic-independent antiproteinuric and glomerular protective effect. It remains unclear which melanocortin receptors (MCR) mediate this renoprotective activity. MC5R was the last MCR to be characterized and has been involved in both biophysiology and pathology. However, the role of MC5R in glomerular disease is unknown and was examined here.

Methods: Adriamycin(ADR) nephropathy was induced in MC5R knockout (KO) and wild-type (WT) mice. Proteinuria and glomerular injury were evaluated. *In vitro*, ADR-insulted murine podocytes were treated with a highly selective MC5R agonist and cellular injury assessed.

Results: Under physiological condition, KO were no different from WT mice and had normal kidney physiology and histology. Upon ADR injury, KO mice demonstrated an exacerbated glomerular injury, featured by heavier albuminuria and worsened glomerular pathology, including glomerulosclerosis, podocyte apoptosis, loss of podocyte markers and ultrastructural lesions in podocytes like foot process effacement and microvillous transformation. Mechanistically, GSK3β, a transducer downstream of MC5R signaling and key regulator of podocyte injury, was more active in glomeruli of KO mice after ADR injury. This was concomitant with a potentiated activation of NFκB RelA/p65, a cognate substrate of GSK3β, in glomeruli in KO mice, and reinforced *de novo* expression of NFκB-dependent podocytopathic mediators, including B7-1, cathepsin L and MCP-1, in podocytes. Moreover, paxillin, a focal adhesion-associated adaptor protein and GSK3β substrate, was more activated in glomeruli of KO mice after ADR injury, associated with more disruption of podocyte cytoskeleton, shown by filamentous actin staining. In consistency, *in vitro* in ADR-insulted podocytes, treatment with a MC5R agonist rectified GSK3β overactivity, suppressed NFκB activation and the consequent *de novo* expression of B7-1, cathepsin L and MCP-1, and inhibited paxillin phosphorylation, resulting in a protection against podocyte injury, marked by cell shrinkage, hypermotility, cytoskeleton disorganization and apoptosis. This protective activity was blunted by ectopic expression of a constitutively active GSK3β mutant, signifying the mediating role of GSK3β.

Conclusions: MC5R-mediated melanocortinergic signaling protects against podocyte injury and proteinuria.

Proteasomal Dysfunction Enhances the Glomerular Accumulation of the Membranous Nephropathy Antigen THSD7A Following Autoantibody Binding

Wiebke Sachs, Johanna Herwig, Karen Neitzel, Sinah Skuza, Uta Wedekind, Nicola M. Tomas, Catherine Meyer-Schwesinger. AG Meyer-Schwesinger *University Medical Center Hamburg-Eppendorf, Hamburg, Germany*.

Background: Membranous nephropathy (MN) is the most common cause of nephrotic syndrome in Caucasian adults. In MN, podocyte membrane antigens such as the thrombospondin domain-like containing 7A (THSD7A) serve as targets to immunity. Diagnostic for MN is an enhanced antigen reactivity and antigen/antibody deposition in the subepithelial podocyte space and podocyte cytoplasm, for which the underlying mechanisms are unknown. The aim of this project is to investigate the mode of THSD7A degradation under homeostatic conditions and upon autoantibody binding, and whether alterations of THSD7A degradation relate to the pathological glomerular THSD7A accumulation in MN.

Methods: THSD7A half-life and homeostatic THSD7A degradation pathways were investigated in kidney slice cultures, cultured podocytes, and naïve Balb/C mice treated with either vehicle, proteasomal or lysosomal inhibitors. Furthermore, mice with genetic lysosomal dysfunction were used. To assess the involvement of protein turnover for the subepithelial accumulation of THSD7A following autoantibody binding, cultured podocytes were treated with rabbit anti-THSD7A IgG, and the model of rabbit anti-THSD7A MN was induced in Balb/C mice in the absence or presence of proteasomal or lysosomal inhibitors. Cells and mice were analyzed by Western blot, qPCR and high-resolution confocal microscopy.

Results: Under homeostatic conditions THSD7A has a long half-life in vitro and in vivo, and its protein content is regulated by the lysosomal system in naïve cultured podocytes and mice. Upon autoantibody binding, THSD7A is cross-linked at the plasma membrane and internalized through the endosomal system into multivesicular bodies. Internalized autoantibody-THSD7A complexes are degraded by both the lysosomal and proteasomal system. Impairment of the proteasomal system results in the (for MN typical) glomerular deposition of THSD7A in the subepithelial space and podocyte cytoplasm.

Conclusions: Homeostatic THSD7A levels are regulated by lysosomal degradation. Upon autoantibody binding, pathological glomerular THSD7A accumulation additionally strongly depends on the proteasomal system.

FR-PO914

ApoL1-DNA Cross-Talk with Cytosolic DNA Sensing Pathways in Podocytes

Alok Jha,[2] Vinod Kumar,[2] Kamesh R. Ayasolla,[2] Himanshu Vashistha,[3] Xiqian Lan,[2] Ashwani Malhotra,[4] Karl Skorecki,[5] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Feinstein Institute for Medical Research, Manhasset, NY; [3]Ochsner Health System, New Orleans, LA; [4]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [5]Rambam Health Care Campus, Haifa, Israel*.

Background: Viruses such as HIV are known to release double stranded DNA in cytosol and also known to induce activation of inflammasome Nod-like receptor (NLR) protein (P) 3 in podocytes. APOL1 renal risk variants have also been shown to activate NLRP3 pathway. The NLR family protein NLRC3 is a negative regulator of cytosolic DNA sensing pathway mediated innate immune response. We hypothesize that sensors of the NLR family, including NLRP3 inflammasomes, detect a variety of cytosolic nucleotides and trigger signaling that leads to pyroptosis and the maturation of interleukins.

Methods: Human podocyte stably expressing vector, APOL1G0/G1/G2 were activated with HIV (NL4-3) and evaluated for protein and mRNA expression of NLRP3, IL-1β, and Caspase-1. DNA binding site on ApoL1 variants was identified using DNABIND tool and by analyzing different DNA binding motifs on ApoL1 protein. Helix-turn-Helix motif and Leucine Zipper motif were analyzed using Prabi, iDNA-Prot, GYM2.0, 2Zip tools, and DNABINDPROT for the identification of DNA binding residues on ApoL1 variants protein. Models of ApoL1G0 and its variants ApoL1G1, ApoL1G2, NLRC3, and STING were generated using ITasser and protein-DNA and protein-protein complexes (docking approach); additionally, protein-protein interaction (PPI) interfaces and the thermodynamic properties of the protein-protein complexes were analyzed.

Results: HIV accelerated NLRP3 inflammasomes activation in APOL1RRVs milieu. ApoL1 variants displayed DNA binding sites, and the DNA binding residues provide ensemble for DNA-protein interactions. The ApoL1 and its variants showed potential to form protein-protein interaction (PPI) complexes individually with NLRC3 and STING, and also with the NLRC3-STING complex. Additionally, ApoL1G1 and ApoL1G2 could form thermodynamically favorable complexes with NLRC3 and stable complexes with STING individually. Since the interaction of ApoL1 and its variants seem to be weaker and transient with the NLRC3-STING complex, it indicates that ApoL1 variants and double-stranded cytosolic DNA could sequester NLRC3 and diminish NLRC3 interaction with STING and prevent inhibitory interaction of NLRC3 with STING.

Conclusions: ApoL1 variants provide a feed-forward response to STING pathway mediated inflammasome activation through cross-talk with cytosolic DNA sensing pathway.

Alterations in Plasma Membrane Ion Channel Structures Stimulate NLRP3 Inflammasome Activation in APOL1 Risk Milieu

Alok Jha,[2] Vinod Kumar,[2] Ashwani Malhotra,[3] Karl Skorecki,[4] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Feinstein Institute for Medical Research, Manhasset, NY; [3]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [4]Rambam Health Care Campus, Haifa, Israel*.

Background: APOL1 has been demonstrated to act as ion transporter in cellular lipid membranes. APOL1 risk proteins have been shown to enhance K^+ -efflux and inflammasome activation. However, the involved mechanism is not clear. We evaluated the role of basic configurations of APOL1 pores on K^+-efflux and the activation of NLRP3 inflammasomes in APOL1 risk milieu.

Methods: Immortalized human podocytes were transduced with vector (V-PD) APOL1G0 (G0-PD), APOL1G1 (G1-PD), and APOL1G2 (G2-PD) employing lentivirus expression system and incubated with either vehicle or Glyburide (100 μM, a K^+- efflux inhibitor) for 48 hours (n=4). Protein blots and cDNAs were probed for NLRP3, IL-1β, and cleaved Caspase-1. Bioinformatics studies were conducted to evaluate alterations in plasma membrane ion channel structures in G0-, G1-, and G2-podocytes, including pore domain and structures, membrane integration and orientation, electrostatic properties and pKa calculation, binding with phosphatidic acid, and grid formation and docking of Glyburide in podocytes expressing APOL1G0 and variants.

Results: G1- and G2-podocytes enhanced the transcription of NLRP3. However, Glyburide inhibited this effect of APOL1G1 and APOL1G2. Superimposition of bioinformatic reconstructions of APOL1G0, G1, and G2 showed several aligned regions. The analysis of pore-lining residues revealed that Ser342 and Tyr389 are involved in APOL1G0 pore formation, however, conformations resulting from the Ser 384Met mutation in the case of G1 and deletion of the Tyr389 residue in the case of G2 are expected to alter pore characteristics, including K+ ion selectivity. Analysis of multiple membrane (lipid bilayer) models of interaction with the peripheral protein, integral membrane protein, and multimer protein revealed that for an APOL1 multimer model, G0 is not energetically favorable while the APOL1G1 and APOL1G2 moieties favor the insertion of multiple ion channels into the lipid bilayer. Protein-substrate/ligand interaction between Glyburide (a K^+- efflux inhibitor) and APOL1G0/APOL1G1/APOL1G2 revealed that a relatively lower concentration of Glyburide could bind to APOL1G1 and APOL1G2 multimer.

Conclusions: The altered pore configurations carry the potential to facilitate K^+ ion transport in APOL1 risk milieu.

Disruption of APOL1-mIR193a Axis (AMA) Facilitates the Development of Collapsing Phenotype in HIV-Associated Nephropathy

Vinod Kumar,[1] Himanshu Vashistha,[2] Kamesh R. Ayasolla,[3] Xiqian Lan,[3] Sushma Chinnapaka,[5] Maleeha Qayyum,[5] Ashwani Malhotra,[4] Pravin C. Singhal.[1] *[1]Medicine, Zucker School of Medicine at Hofstra-Northwell, Great Neck, NY; [2]Ochsner Health System, New Orleans, LA; [3]Feinstein Institute for Medical Research, Manhasset, NY; [4]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [5]Northwell health, Hicksville, NY*.

Background: A recent discovery of APOL1-mIR193a axis (AMA) highlighted the role of parietal epithelial cells (PECs) in podocytes' (PDs) renewal both under normal physiological and pathological states. APOL1 and miR193a inversely regulate the expression of each other. PECs do not express APOL1. However, APOL1's induction stimulates PECs transition to podocyte molecular phenotype. We hypothesize that disruption of AMA in HIV-induced proliferating PECs expressing either APOL1G1/G2 or lacking APOL1G0 compromises PECs transition result in their accumulation in the Bowman's space (collapsing phenotype). We have validated this hypothesis in HIV transgenic mice experssing APOL1G0/G1/G2.

Methods: To aim transition (differentiation) to PDs, immortalized human PECs were incubated in special media for 14 days. PECs- transduced with either vector or HIV (NL4-3) were assayed for APOL1 expression. Differentiated PECs were transduced with vector, APOL1G0, APOL1G1, or APOL1G2 lentivirus. After 48 hours, cellular lysates were probed for PEC (PAX2 and Claudin 1) and PD (CD2AP, WT1, and podocalyxin) markers. Cellular lysates of above-mentioned transduced cells were assayed for miR193a expression and PEC, and PD markers. PECs' accumulation in Bowman's space was scored in renal cortical sections of 4-week and 8-week old HIV transgenic mice (Tg26) expressing APOL1G0, APOL1G1, and APOL1G2. Three-week old TG26 mice expressing APOL1G0 were administered Adriamycin (10 mg/Kg, IV) to induce APOL1G0 deficit.

Results: HIV induced APOL1 and PD markers, however downregulated miR193a expression in PECs. Differentiated- PECs and PDs expressing APOL1G1 and APOL1G2 displayed an attenuated expression of PD markers (protein as well as mRNA) but enhanced levels of miR193a expression. Renal cortical sections of Tg26 mice expressing APOL1G1 and G2 showed higher miR193a levels and abundance of PECs in Bowman's space. Tg26 mice expressing APOL1G0 displayed attenuated miR193a levels as well as minimal PECs accumulation in Bowman's space; in contrast, Adriamycin-treated Tg26 mice expressing APOL1G0 showed attenuated APOL1, increased miR193a expression, and abundance of PECs in Bowman's space.

Conclusions: Loss of APOL1's potential modulates miR193a expression and induces the collapsing phenotype in HIVAN.

FR-PO917

Podocytes Expressing APOL1 Non-Risk and Renal Risk Variants Carry Potential to Secrete APOL1 Through Exosomal Pathway

Vinod Kumar,[4] Harsha Adnani,[4] Xiqian Lan,[2] Maleeha Qayyum,[5] Sushma Chinnapaka,[5] Ashwani Malhotra,[3] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Feinstein Institute for Medical Research, Manhasset, NY; [3]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [4]Medicine, Feinstein Institute of Research, Manhasset, NY; [5]Northwell health, Hicksville, NY.*

Background: Recent reports indicate a vital role of APOL1-miR193a axis in the development of focal segmental glomerulosclerosis. Circulatory APOL1 is bound to HDL complex and unlikely to pass through glomerular filtration barrier. Although APOL1 has been considered to be a secretory protein but its secretion by podocytes remains controversial. However, the realese of APOL1 from podocytes throuhg the exosomal pathway has not been studied to date. We asked whether cultured podocytes have potential to release APOL1 in exosomes. To confirm exosomal secretion, we validated this hypothesis in human embryonic kidney cells (HEKs) expressing vector, APOL1G0, APOL1G1, and APOL1G2. Additionally, we evaluated exosomal contents in the urine of the APOL1G0, APOLG1, and APOL1G2 transgenic mice.

Methods: Immortalized human podocytes and HEKs stably expressing vector (V), APOL1G0 (G0), APOL1G1 (G1), APOL1G2 (G2) were incubated with exosome-free media for 48 hours (n=6). Subsequently, media were collected and ultra-centrifuged for exosome isolation; Western blotting and FACS analysis were carried out for the expression of exosomal markers (CD81, HSP70), and cytosolic marker (Calnexin). The isolated exosomes were analyzed for their size by using Nano site system. To determine the presence of other relevant proteins, the single exo RNAseq and proteomic analysis was carried out. To validate these findings in vivo, the exosomes were harvested from the urine of the APOL1G0, APOLG1, and APOL1G2 transgenic mice.

Results: Exosomes harvested from both podocytes and HEKs expressing APOL1G0 and G1/G2 displayed the presence of APOL1. Nano Site analysis characterized the isolated exosomes in the range from 90-125 nM in size. Western blotting and FACS analysis displayed the exosomal expression of CD81 and HSP70 but Calnexin was not expressed. Release of exosome amounts differed in incubation med harvested from G0-, G1-, and G2-podocytes and HEKs. However, exosomes harvested from podocytes and HEKs expressing APOL1 risk variants showed a decrease in APOL1 expression. Data from urinary exosomes from APOL1 transgenic mice were consistent with *in vitro* findings.

Conclusions: Podocytes expressing APOL1G0, APOL1G1, and APOL1G2 carry potential to secrete APOL1 through the exosomal pathway.

APOL1 Renal Risk Variants (RRVs)-Induced Translocation of miR193a and Podocyte mRNAs to P-Bodies Prevents Their Degradation and Facilitates Translation

Vinod Kumar,[3] Himanshu Vashistha,[2] Xiqian Lan,[3] Maleeha Qayyum,[5] Sushma Chinnapaka,[5] Kamesh R. Ayasolla,[3] Ashwani Malhotra,[4] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Ochsner Health System, New Orleans, LA; [3]Feinstein Institute for Medical Research, Manhasset, NY; [4]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [5]Northwell health, Jamaica, NY.*

Background: A disruption of APOL1-miR193a axis (AMA) has been reported in podocytes expressing APOL1 renal risk variants (RRVs, G1, and G2). However, the involved mechanism of disruption of AMA is not understood. We hypothesize that miR193a binding with APOL1G0 mRNA directs it for degradation, whereas, non-complementary binding with APOL1RRV mRNAs would facilitate their translocation to P-bodies to prevent their degradation as well as facilitate translation. To validate this hypothesis, we have evaluated the binding of APOL1G0 and APOL1RRVs mRNAs with miR193a and PKR in cultured podocytes. Additionally, we have examined the role of miR193a and involved mechanism of PKR activation in dual transgenic mice expressing miR193a and APOL1G0/APOL1RRVs.

Methods: RNAs of podocytes stably expressing G0s, G1s, and G2s were immunoprecipitated with anti-PKR antibody, and IP fractions were evaluated for PKR and downstream signaling (total and phospho--PKR, total and phospho-eIF2a, and GAPDH) and assayed for miR193a (n=6). Co-labeling of PKR and LSM14A/HEDLs (to localize PKR in P-bodies) were conducted. Protein blots of renal tissues of 10-weeks old control, single and dual transgenic (APOL1G0/G1/G2 and miR193a transgenic) mice (n=6; started on doxycycline [to induce miR193a and APOL1] feed at age 4 weeks) were probed for total and phospho--PKR, total and phospho-eIF2a and GAPDH. RNAs from renal tissues of single and dual transgenics were immunoprecipitated with anti-PKR antibody, and IP fractions were evaluated for PKR activation.

Results: PKR IP fractions from G1- and G2-podocytes displayed enhanced binding of APOL1mRNA; similarly, PKR IP fractions of renal tissues of dual G1- and G2 as well as single G1- and G2 transgenic mice displayed enhanced expression of miR193a. Immunolabeling studies showed enhanced translocation of PKR into P-bodies in G1- and G2-podocytes vs. G0 podocytes. Cellular lysates of G1- and G2-podocytes, renal tissues of both single and dual G1- and G2- transgenic mice, and miR193a mice displayed activation of PKR and associated downstream signaling.

Conclusions: APOL1RRVs facilitates translocation of miR193a and other podocyte mRNAs to P-bodies. It prevents their degradation and facilitates their translation.

APOL1 Kidney Disease-Associated Variants Induce Differential Glomerular Expression of Immune Sensory Proteins in FSGS

Sethu M. Madhavan, John P. Shapiro, Clarissa A. Cassol, Samir V. Parikh, Brad H. Rovin. *Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Variants in *APOL1* (G1 and G2) associate with increased risk of CKD including hypertension-related CKD and focal segmental glomerulosclerosis (FSGS) in individuals with West African ancestry. Mechanisms by which the APOL1 variants contribute to the pathogenesis of CKD is not well understood. We hypothesized that variant APOL1 proteins mediate kidney disease through pathways independent from reference APOL1 protein. We aimed at characterizing differentially regulated protein networks in glomeruli of FSGS patients in presence of APOL1 variants.

Methods: Formalin-fixed paraffin-embedded kidney biopsies with a diagnosis of primary FSGS with (n=3) and without (n=3) homozygous *APOL1* risk variants and normal donor kidney biopsies (n=5) were identified. Glomeruli were isolated from the biopsies using laser capture microdissection followed by protein recovery, trypsin digestion and HPLC MS/MS using an Orbitrap fusion mass spectrometer. Label-free quantification in combination with global normalization of spectral count data was performed to determine changes in protein expression. Comparison of protein expression levels and upstream regulatory pathways were performed using Ingenuity Pathway Analysis software.

Results: In patients with FSGS, HLA-DQB1, HLA-DQA1 and ICAM-1 were significantly upregulated in the glomeruli in the presence of homozygous *APOL1* variants. Interferon-gamma regulated pathways were upregulated in glomeruli of FSGS patients in the presence of homozygous *APOL1* variants compared to FSGS with no *APOL1* variants and normal donor kidney.

Conclusions: Upregulation of immune sensory proteins in glomeruli in presence of APOL1 variants suggests that a differential cellular immune response mediated by the variants could contribute to the pathogenesis of FSGS. A larger cohort of patient samples needs to be interrogated to validate the observation.

Nuclear Magnetic Resonance Studies Reveal Structural Differences Between APOL1 G0 and G1 C-Terminus

Sethu M. Madhavan,[1] Alexandar L. Hansen,[1] Shufen Cao,[2] John R. Sedor.[3] *[1]The Ohio State University, Columbus, OH; [2]Case Western Reserve University, Cleveland, OH; [3]Cleveland Clinic, Cleveland, OH.*

Background: Common variants (G1: S342G and I384M, G2: N388del and Y389del) located in the C-terminus of APOL1 associate with high risk of progression to end stage kidney disease. Our previous studies using molecular modeling suggested that APOL1 C-terminus adopts an alpha-helical structure and G1 and G2 variants disrupt the structural integrity of the C-terminus leading to impaired intracellular protein interactions. We used nuclear magnetic resonance (NMR) spectroscopy to experimentally characterize the structural consequence of kidney disease-associated variants.

Methods: ^{15}N and ^{13}C isotope labeled C-terminus of APOL1-G0 and -G1 (aa 305-398) recombinant protein was generated using bacterial expression followed by metal affinity and size exclusion chromatography. The chemical shifts of backbone atoms in dodecylphosphocholine (DPC) micelles were determined by solution nuclear magnetic resonance (NMR).

Results: Two-dimensional solution NMR studies (^{1}H-^{15}N-HSQC spectra) demonstrated significant differences between reference protein G0 and G1 variant chemical shits suggesting variation in protein structure. The secondary structure determined using chemical shifts of backbone atoms demonstrated helical properties of APOL1 G0 and G1 C-terminus. G1 variant interrupted the alpha-helix of APOL1 C-terminus.

Conclusions: The changes in the structure of APOL1 C-terminus induced by kidney disease associated variants could disrupt protein interactions and underlie the intracellular mechanisms that mediate the pathogenesis of chronic kidney disease. Further characterization of the three-dimensional protein structure and dynamics using NMR and Molecular Dynamics simulations will refine the time-dependent behavior of APOL1 variants.

Mitochondrial Programming of Metabolic Signaling in Glomerular Podocytes

Cem Oezel,[1] Thomas Schömig,[1] Mahsa Matin,[1] Johanna Odenthal,[1] Bernhard Schermer,[1] Richard Coward,[2] Thomas Benzing,[1] Paul T. Brinkkoetter.[1] Nephrolab Cologne *[1]University Hospital Cologne, Cologne, Germany; [2]University of Bristol, Bristol, United Kingdom.*

Background: Metabolic signaling events are critical regulators of podocyte function. We have recently established a metabolic link between mitochondrial dysfunction and enhanced insulin signaling in podocytes. In this study, we interfered with OPA1 cleavage, a central regulatory hub that determines mitochondrial morphology under stress and in disease by conditional ablation of *Oma1* gene expression.

Methods: Conventional Oma1 KO animals and conditional Phb2$^{fl/fl}$;pod-cre mice were held in a pure C57/Bl6 background. Mice were characterized by observing survival and proteinuria while insulin-signaling activation was measured using histology and MS/MS. Oma 1 KO podocytes and Phb2 knockdown cells were utilized to further delineate the down-stream effects on MAPK, mTOR and GSK activation as well as MS/MS and seahorse measurements to assess glycolytic function and the metabolic status of the cells.

Results: An impaired OPA1 degradation by depletion of either Oma1 or Phb2, both, led to an increased insulin sensitivity as evidenced by increased Akt and mTOR-activation in vitro and in vivo. However, only loss of Phb2 resulted in a disrupted slit-membrane, proteinuria and premature death as previously published while Oma1 KO animals presented with normal glomerular function. Oma1/Phb2 double KO podocytes presented with an improved mitochrondrial cristae formation and prolonged animal survival. On a functional level, aerobic glycolysis was disrupted in both cases. Proteome analysis of Oma1 knockout mice glomeruli revealed elevated translation of proteins associated with fatty-acid metabolism and Acetyl-CoA synthesis and an increase in ribosomal protein s6 phosphorylation.

Conclusions: Here, we identified OMA1 as a critical regulator of podocyte metabolism in vitro and in vivo and demonstrate that a stress-induced OPA1 processing by OMA1 promotes a metabolic switch in glomerular podocytes. However, this metabolic switch alone was not sufficient to cause podocyte injury. Using mice lacking prohibitin membrane scaffols as a model of mitochondrial dysfunction, we demonstrate that additional ablation of OMA1 protects mitochondrial cristae formation from degradation leading to a significantly prolonged survival as compared to prohibitin deficient mice.

FR-PO922

Role of IRE1α in Podocyte Proteostasis

José R. Navarro-Betancourt,[1] Joan Papillon,[1] Julie Guillemette,[1] Takao Iwawaki,[2] Andrey V. Cybulsky.[1] *[1]Medicine, McGill University, Montreal, QC, Canada; [2]Life Science, Kanazawa Medical University, Ishikawa, Japan.*

Background: Podocyte (glomerular epithelial cell; GEC) proteostasis is disrupted in glomerular diseases. To maintain proteostasis, the endoplasmic reticulum (ER) orchestrates the unfolded protein response (UPR), which includes upregulation of chaperones. Proteostasis also involves clearance of misfolded proteins via autophagy. Inositol requiring enzyme-1α (IRE1α) resides in the ER membrane and is a transducer of the UPR. In mice, podocyte-specific deletion of IRE1α leads to age-related podocyte injury, autophagy impairment, and disruption of glomerular permselectivity. This study characterizes mechanisms by which IRE1α regulates proteostasis in GECs.

Methods: GECs were isolated from transgenic mice with loxP sites flanking the ribonuclease domain of the IRE1α gene. IRE1α was deleted by transduction of Cre recombinase (IRE1α KO). GECs expressing full-length IRE1α served as control (IRE1α WT). GECs were exposed to tunicamycin (TM), rapamycin (R), and glutamine starvation (GS) during 24 h. ER chaperones and LC3 were monitored by immunoblotting. Mitochondria were visualized using MitoTracker Red CMXRos.

Results: IRE1α KO and WT GECs exhibited comparable proliferation rates and protein content, implying that IRE1α is not involved in cell cycle progression. Stimulation of GECs with the ER stressor TM upregulated total IRE1α in WT, but not IRE1α KO GECs. After TM treatment, the chaperones BiP, GRP94, and mesencephalic astrocyte-derived neurotrophic factor increased in WT GECs. Deletion of IRE1α, or chemical inhibition of the IRE1α RNase with 4μ8C, significantly attenuated upregulation of chaperones and enhanced ER stress-induced apoptosis (evidenced by caspase-3 cleavage). Neither R nor GS enhanced expression of ER chaperones. Compared with WT GECs, IRE1α KO and 4μ8C-treated WT GECs showed similar basal autophagy, but reduced LC3 lipidation after stimulation with TM, R, and GS, indicating deficient autophagosome formation. Under basal conditions and after exposure to TM, the percentage of cell area occupied by active mitochondria in IRE1α KO and 4μ8C-treated GECs was significantly lower than in WT GECs, suggesting collapse of the mitochondrial network.

Conclusions: Stress-induced chaperone production, autophagy and mitochondrial distribution are compromised by deletion of IRE1α. The IRE1α pathway may play an important protective role in glomerular diseases associated with podocyte ER stress.

Angiotensin II Receptor Blocker Blocks Spreading Podocyte Damage in a Partial Podocytectomy Model

Masahiro Okabe,[2,1] Kazuyoshi Yamamoto,[2,1] Yoichi Miyazaki,[1] Takashi Yokoo,[1] Taiji Matsusaka.[2] *[1]The Jikei University School of Medicine, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: We established a new mosaic mouse model in which approximately 50% of podocytes express hCD25 and tdTomato whereas the other podocytes express EGFP but not hCD25. After the injection with hCD25-targeting immunotoxin, LMB2, not only hCD25-positive but also hCD25-negative podocytes were injured, and the mice developed global sclerosis. These indicated that injury incurred in a fraction of podocyte population causes secondary damage in other initially intact podocytes. This phenomenon may underlie progressive deterioration of chronic kidney diseases. In the present study, we tested whether this new mosaic 'partial podocytectomy' model can be used to evaluate renal protective effects of candidate drugs. As a proof of concept, we investigated the effect of angiotensin II receptor blocker (ARB), a well-established reno-protector, in this model.

Methods: Twelve female mosaic mice from 28 to 35 weeks of age were injected with LMB2. One day later, they were treated with losartan (0.5g/L in drinking water) (ARB group, n=6) or with 5% sucrose (Control, n=6). Fourteen days after LMB2 injection, kidneys were harvested and analyzed.

Results: Control mosaic mice developed severe glomerular damage with early sclerosis, adhesion, and hyalinosis, and dilated tubules with protein casts. These were markedly ameliorated in the ARB group. Glomerular injury index (in 0 (normal)-4 scales) was 3.3±0.30 (SE) in the Control group, which was improved to 0.13±0.083 in the ARB group ($p<0.01$). In addition, nephrin staining was more preserved (7.7±0.2 vs 3.0±1.0 in 0-8 (normal) scales, $p<0.01$) and desmin-positive podocytes were less observed (29±7% vs 74±11%, $p=0.026$) in the ARB group than the Control group. Importantly, EGFP-labeled podocytes, which do not carry hCD25 gene therefore are not directly injured by LMB2, were also secondarily injured, and the number decreased from 3.8±0.14 to 1.4±0.23 per a glomerulus after LMB2 injection in the Control group. The EGFP-positive podocytes were significantly more preserved in the ARB group (from 3.9±0.3 to 2.9±0.2, $p<0.01$).

Conclusions: Thus, our mosaic mouse model can visualize and evaluate secondary podocyte injury, and we have herein demonstrated that ARB attenuates the secondary podocyte injury.

Angiotensin II Impairs Podocyte Motility via Sirtuin-Mediated Zyxin Deacetylation and Cytoskeleton Rearrangement

Dian Bao, Fang-Fang He, Chun Zhang. *Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Zyxin, as an adaptor protein primarily located at the adhesion plaque complex, has been implicated in the regulation of cytoskeletal dynamics and nuclear-cytoplasmic communication. However, the particular role of zyxin in regulating podocyte cytoskeleton assembly in kidney diseases remains obscure. In this study, we aimed to explore the role and mechanism of zyxin in SHR rats and AngII-treated podocytes.

Methods: The expression of zyxin and SIRT2, a mammalian homologue of NAD^+-dependent deacetylase sirtuin family, were detected by western blotting, immunohistochemistry, and immunofluorescence in glomeruli of SHR rats and AngII-treated conditional immortalized human podocytes (HPCs). Co-IP was performed to assess the level of acetylated-zyxin in AngII-treated HPCs and explore the interaction between zyxin and SIRT2. AGK2, the chemical inhibitor of SIRT2, was utilized to inhibit the activity of deacetylation. Finally, the podocyte motility was assessed by migration assay.

Results: Zyxin was widely expressed in kidney tissues and HPCs. Compared with the control group, the expression of zyxin in SHR rats was unchanged, which was in line with the results in vitro. Intriguingly, podocytes exposed to AngII showed a redistribution of zyxin, which was characterized by accumulation at adhesion plaques rather than along with actins in the cytoplasm, accompanied by F-actin disarrangement. Meanwhile, we found that zyxin was deacetylated in AngII-treated podocytes. On the other hand, SIRT2 level was upregulated in glomeruli of SHR rats and dual immunofluorescence staining revealed co-localization of zyxin and SIRT2. Co-IP also suggested that SIRT2 could interact with zyxin and modulate its function through deacetylation. Finally, we found that inhibition of SIRT2 activity ameliorated podocyte motility.

Conclusions: Zyxin participated in the actin rearrangement and podocyte injury induced by AngII exposure. Our results raise the possibility that SIRT2 regulates podocyte cytoskeleton dynamics and cell motility by modulating the function of zyxin via deacetylation.

FR-PO925

Injured Podocytes Show an Increased Responsiveness to Angiotensin II-Mediated Calcium Transients

Julia Binz, Lioba Ester, Bernhard Schermer, Thomas Benzing, Matthias Hackl. *University Hospital Cologne, Cologne, Germany.*

Background: Angiotensin II (AngII) signaling has been shown to play a role in regulating glomerular perfusion and progression in kidney disease. The treatment of patients with ACE inhibitors is well established. Furthermore, AngII has shown to be able to trigger calcium signals podocytes *ex vivo*. In this study we aimed at unravelling AngII induced calcium signaling in healthy and diseased podocytes *in vivo*.

Methods: Kidney disease was induced in 4 week old mice expressing the calcium indicator GCaMP3 in podocytes (Pod:cre) by injecting 25 mg/kg Adriamycin. 4 days after injection the mice underwent 2-photon in vivo imaging. Mice were anaesthetized, a vascular access generated and the left kidney exteriorized. The vasculature was labelled with a 70 kDa dextrane (Texas Red). Untreated GCaMP3 Pod:cre animals were used as controls. AngII was infused with 100 ng/g/min. As inhibitors Losartan (10 mg/kg) and PD123319 (10 mg/kg) were used. The induced calcium transients were recorded as time lapse videos with 1 frame/second. The percentage of podocyte area showing an increase in calcium levels was calculated using ImageJ.

Results: The data shows that in 21 % of healthy glomeruli and in a mean of 2 podocytes a calcium signal can be triggered by AngII. The probability of inducing a calcium transient in a glomerulus by AngII stimulation increased by two-fold (41 %) in diseased (ADR) podocytes. Furthermore, the number of podocytes showing calcium transients is significantly increased. These findings correlate with a rise in the percentage of podocyte area showing a calcium signal from 12 to 26 %. The AngII induced calcium transient can be completely blocked by using Losartan, but not by PD123319.

Conclusions: Our study shows that calcium signaling in podocytes is highly regulated and the response to AngII increases upon injury. Additionally, we observed that not all podocytes react to AngII which points to heterogeneity in the podocyte population during health and disease. We can show that AngII mediates its calcium effects through the AT1R since Losartan completely blocked the calcium signal in podoyctes. Therefore our results

strongly support the need of a RAAS blockade in glomerular disease to protect podocytes from high calcium levels induced by AngII.

FR-PO926

Genetic Ablation of Calcium-Independent Phospholipase $A_2\gamma$ Exacerbates Glomerular Injury in Adriamycin Nephrosis in Mice

Hanan Elimam,[1,2] Julie Guillemette,[1] Joan Papillon,[1] Andrey V. Cybulsky.[1]
[1]Medicine, McGill University, Montreal, QC, Canada; [2]Pharmacy, University of Sadat City, Sadat City, Egypt.

Background: Genetic ablation of calcium-independent phospholipase $A_2\gamma$ (iPLA$_2\gamma$) in mice resulted in marked damage of mitochondria and enhanced autophagy in glomerular visceral epithelial cells (GECs) or podocytes. iPLA$_2\gamma$ knockout (KO) GECs in culture show mitochondrial dysfunction and enhanced autophagy. The present study addresses the role of iPLA$_2\gamma$ in glomerular injury, focusing on mitochondrial function and autophagy.

Methods: Adriamycin nephrosis was induced in wild type (WT) or iPLA$_2\gamma$ KO mice (age 3.5-4.5 months) by a single intravenous injection of adriamycin (12 mg/kg). Cultured WT or iPLA$_2\gamma$ KO GECs were transfected with mito-YFP (to label mitochondria), RFP-LC3 (to label autophagosomes) and RFP-LAMP1 (to label lysosomes). Colocalization of fluorescent signals was measured by the Pearson correlation coefficient.

Results: In adriamycin nephrosis, deletion of iPLA$_2\gamma$ exacerbated albuminuria and reduced podocyte number (WT1 counts). Glomerular LC3-II increased and p62 decreased in adriamycin-treated iPLA$_2\gamma$ KO mice, compared with treated control. In cultured iPLA$_2\gamma$ KO GECs, LC3-II was increased, compared with WT cells (by immunoblotting). After transfection of WT and KO GECs with RFP-LC3, RFP-LC3-II puncta and puncta area were enhanced in KO cells, consistent with greater autophagy. iPLA$_2\gamma$ KO GECs showed increased phosphorylation of AMP kinase (pAMPK), in keeping with mitochondrial dysfunction and lower cell ATP levels. Adriamycin further stimulated pAMPK and LC3-II. For comparison, induction of mitochondrial dysfunction with carbonyl cyanide m-chlorophenylhydrazone (CCCP) also increased pAMPK and LC3-II. There was greater colocalization of mito-YFP with RFP-LC3 and with RFP-LAMP1 in iPLA$_2\gamma$ KO GECs, compared with WT, indicating enhanced mitophagy in KO. Adriamycin and CCCP increased colocalization of mito-YFP with RFP-LC3 and with RFP-LAMP1.

Conclusions: iPLA$_2\gamma$ has a cytoprotective function in the normal glomerulus and in glomerulopathy, as deletion of iPLA$_2\gamma$ leads to mitochondrial damage and impaired ATP production. Deletion of iPLA$_2\gamma$ induces autophagy and mitophagy. Understanding how iPLA$_2\gamma$ maintains mitochondrial integrity and attenuates mitochondrial damage in glomerular diseases is essential for development of novel therapeutic approaches to glomerular injury and proteinuria.

FR-PO927

A Role for the Developmental Gene Pax2 in the Adult Kidney After Glomerular Injury

Bedra U. Sharif,[1] Khalil Udwan,[1] Rohan John,[1] Moumita Barua.[1,2] *[1]University Health Network, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada.*

Background: Pax2 is a member of the Pax family of highly conserved transcription factors that play important roles during development. Pax2 is essential for mammalian kidney organogenesis, without which the kidneys fail to form. We have previously reported that heterozygous missense mutations in Pax2 lead to focal and segmental glomerulosclerosis (FSGS) in ~5% of adults with the disorder. FSGS is a clinico-pathologic entity characterized by proteinuria and podocyte foot process effacement. We have obtained a mouse model with a Pax2 missense mutation to further investigate the mechanism by which the glomerular defect occurs.

Methods: We employed immunohistochemistry, electron microscopy, and Western blotting to examine kidneys from wild type and Pax2 mutant mice that were subjected to Adriamycin (ADR) administered through tail vein injections.

Results: Mice homozygous for Pax2 A220G (Pax2$^{A220G/A220G}$) develop dysplastic kidneys and are not viable though they survive to late gestation (E18.5). As expected, heterozygous Pax2$^{A220G/+}$ mice display smaller kidneys and reduced nephron number with no other obvious glomerular defects. Surprisingly, we find that Pax2 expression still persists widely in the adult kidney, both in the glomerular and tubular compartments. Challenging Pax2$^{A220G/+}$ mice with Adriamycin (ADR) recapitulated human FSGS with mutant mice more susceptible to injury compared to wildtype. Ki-67 staining revealed increased glomerular cell proliferation, that was not due to infiltrating immune cells, and caspase-3 staining demonstrated increased parietal epithelial cell (PEC) apoptosis that was observed in mutant but not wildtype mice.

Conclusions: We have demonstrated that a Pax2 heterozygous missense mutation renders the adult mouse kidney more susceptible to podocyte injury, approximating FSGS observed in humans. We postulate a role for Pax2 in the repair of injured glomeruli that may involve parietal epithelial cells.

Osteocrin Ameliorates Adriamycin-Induced Glomerular Injury

Takaya Handa,[4] Keita P. Mori,[2] Akira Ishii,[4] Yugo Kanai,[1] Akihiro Yasoda,[1,5] Takashige Kuwabara,[3] Masashi Mukoyama,[3] Motoko Yanagita,[4] Hideki Yokoi.[4]
[1]Department of Diabetes, Endocrinology and Nutrition, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]TMK Project, Medical Innovation Center, Graduate School of Medicine, Kyoto University, Kyoto City, Japan; [3]Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Kumamoto, Japan; [4]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [5]Clinical Research Center, Kyoto Medical Center, Kyoto, Japan.

Background: Natriuretic peptides including atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP) and C-type natriuretic peptide (CNP) have cardioprotective effects through binding to natriuretic peptide (NP) receptors: Npr1 and Npr2. ANP or BNP exhibits potent renal effects in patients and animal models with heart failure. Recently a peptide, OSTN (osteocrin) is reported to bind to Npr3 which is a clearance receptor for NPs, and to prevent the worsening of congestive heart failure by increasing NPs with inhibition of degradation. However, the effect of OSTN on kidney function has not been elucidated yet. We hypothesized that OSTN has a renoprotective role by binding Npr3 to suppress clearance of NPs. We examined the role of OSTN in adriamycin (ADR) nephropathy, since podocytes are reported to express Npr3 in single-cell transcriptomics of the mouse kidney.

Methods: ADR was administered to wild-type and serum amyloid P (SAP) promoter-driven OSTN-transgenic (Tg) mice which showed plasma OSTN elevation, at dose of 8 mg/kg body weight via tail-vein injection. Mice were sacrificed at 4 weeks after ADR injection.

Results: There were no significant differences between wild-type mice and OSTN-Tg mice in systemic blood pressure, urinary volume, serum creatinine nor BUN. The body weight and body length of wild-type mice were significantly lower than those of OSTN-Tg mice (26.0 ± 1.0 g vs. 29.7 ± 0.6 g, $p < 0.01$; 9.5 ± 0.1 cm vs. 10.4 ± 0.1 cm, $p < 0.0001$, respectively). Increase of urinary albumin creatinine ratio of wild-type mice induced by ADR administration peaked at 2 weeks (165.6 ± 41.4μg/mgCr vs. 86.7 ± 7.6μg/mgCr, $p < 0.05$) and was significantly suppressed in that of OSTN-Tg mice at 4 weeks (91.5 ± 11.9μg/mgCr vs. 61.9 ± 3.0μg/mgCr, $p < 0.05$). Footprocess effacement observed in ADR-injected wild-type mice was ameliorated in ADR-administered OSTN-Tg mice, and thickness of glomerular basement membrane were significantly mitigated in OSTN-Tg mice in electron microscope (wild-type mice, 209 ± 12 nm vs. OSTN-Tg mice, 141 ± 3 nm, $p < 0.0001$).

Conclusions: These findings indicate that circulating OSTN has a reno- and podocyte-protective role in ADR nephropathy, probably through increase of natriuretic peptides on podocytes, and suggest that administration of OSTN could be a therapeutic option against podocyte injury.

FR-PO929

Shroom3-Fyn Interaction Regulates Podometrics via Activation of AMP-Kinase (AMPK)

Khadija Banu,[1] John M. Basgen,[2] Felipe Garzon,[1] Chengguo Wei,[1] Marina Planoutene,[1] John C. He,[1] Barbara T. Murphy,[1] Madhav C. Menon.[1]
[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Charles Drew University, Minnetonka, MN.

Background: We recently showed that Shroom3 interacts with Fyn, an Src kinase in podocytes, regulating Fyn activation. Intriguingly Shroom3 knockdown reduced podocyte and glomerular volume (Vglom).

Methods: To investigate mechanism of this phenotype, we examined Shroom3-(S3KD) & Fyn-knockdown (FynKD) human podocytes, and inducible Shroom3 knockdown mice (s3kd).

Results: FynKD podocytes also had reduced cell volume vs controls, suggesting that Fyn mediated the effect of S3KD on podocyte morphology. To investigate whether glomerular Shroom3 regulated Vglom hypertrophy, we performed unilateral nephrectomy in control and s3kd mice and examined Vglom in remnant kidneys. At day 7, s3kd mice showed restricted Vglom hypertrophy vs controls, (n=5; 8% vs 19%; $P<0.05$) and reduced expansion of podocyte fraction of Vglom. To investigate whether reductions of cell size were due to reduced protein content we measured protein:DNA ratio. S3KD & FynKD podocytes had reduced Protein:DNA ratios (n=5; $P<0.01$). Since MTOR is a key pathway regulating protein biosynthesis, we examined MTOR signaling. Phospho AMPK, a negative regulator of MTORC1 was significantly increased with S3KD/FynKD cells as well as in glomeruli of s3kd (Fig 1- immunofluoresence). Ribosomal biogenesis (18S RNA), downstream of MTORC1, was inhibited by qPCR in S3KD/FynKD cells (n=3) and s3kd kidney lysates. Since Fyn activation causes nuclear retention of LKB1, an AMPK-kinase, we examined ratio of cytoplasmic:nuclear LKB1, which was increased in S3KD and FynKD cells explaining AMPK activation.

Conclusions: In summary we show regulation of Vglom and podometrics by Shroom3-Fyn interaction that regulates protective AMPK-signaling. These findings have implications to loss of nephron mass and minimal change disease where podocyte Fyn-inactivation has been specifically observed.

Regulation of Cytoskeletal Assembly by YAP (Yes-Associated-Protein) Mediates Podocyte Repair During the Response to Glomerular Injury

Evelyne Huynh Cong,[2] Astrid Weins,[1] Valerie A. Schumacher,[2] Mary E. Taglienti,[2] Jordan A. Kreidberg.[2] *[1]Pathology, Brigham and Women's Hospital, Boston, MA; [2]Boston Children's Hospital, Boston, MA.*

Background: The HIPPO signaling pathway regulates the YAP/TAZ-Tead transcription factor complex involved in cell growth to determine organ size. Published studies have suggested that YAP is required for podocyte survival.

Methods: *Yap* was conditionally inactivated in podocytes of adult mice using an inducible Cre recombinase. *In vitro*, immortalized differentiated mouse podocytes were treated with *Yap* siRNAs. Podocyte injury was induced by treatment with adriamycin or trypsinization, *in vivo* or *in vitro* respectively. Electron microscopy, histology, molecular and cellular biology studies were conducted to characterize the phenotype of either *Yap* knockout mice or *Yap* knockdown cells.

Results: Electron microscopy analysis eight weeks after *Yap* inactivation in mouse revealed that *Yap* knockout led to mild foot process effacement. However, there was no evidence of proteinuria or glomerulosclerosis in *Yap* knockout mice, suggesting that there may be a redundant function of TAZ in uninjured podocytes. Treatment of *Yap* mutant mice with Adriamycin led to microalbuminuria and an increased frequency of histological lesions resembling Focal Segmental Glomerulosclerosis. *Yap* knockdown in immortalized differentiated mouse podocytes led to a reduction in focal adhesion area per cell and decreased area per cell. *Yap* siRNA treatment also led to a dramatic inability to spread and to organize actin stress fibers after trypsinization and reseeding. Consistent with the inability to spread, levels of pY397 FAK and phospho-cofilin, a downstream target of RhoA GTPase, were reduced in *Yap* knockdown podocytes. *Yap* knockdown also led to decreased inactivation of Rac1, a member of the Rho GTPAse family.

Conclusions: Our studies demonstrate that YAP has a crucial role in the assembly of the actin cytoskeleton during recovery from injury, affecting the polymerization of actin mediated by Rho family GTPases. In vivo, YAP appears to have a greater role in recovery from injury than in maintaining the cytoskeleton in uninjured podocytes.

Insights from Genome-Wide MicroRNA Target Identification In Podocytes Using Argonaute PAR-CLIP

Devorah Gur-Wahnon,[2] Royi Navon,[3] Iddo Z. Ben-Dov.[1] Laboratory of Medical Transcriptomics *[1]Nephrology and Hypertension, Hadassah - Hebrew University Medical Center, Jerusalem, Israel; [2]Nephrology and Hypertension, Hadassah Medical Center, Jerusalem, Israel; [3]Hebrew University, Maale adumim, Israel.*

Background: MicroRNAs (miRNA) are a class of small non-coding RNAs that regulate gene expression through inhibition of translation or stability of target mRNAs. While several studies have shown the crucial role played by miRNAs in podocyte development and homeostasis, the specific miRNA and miRNA targets remain under-explored. Quantitative miRNA profiling is essential, but has a limitation: the inhibitory activity of a miRNA depends not only on its absolute expression level in the cell, but also on its loading onto the RISC complex and the availability of its target binding sites.

Methods: We have therefore applied argonaute-2 (AGO2) PAR-CLIP (Photoactivatable Ribonucleoside-Enhanced Crosslinking and Immunoprecipitation) to provide us with the miRNA target principles in podocytes. We searched for enriched miRNA seed-complimentary regions within PAR-CLIP output clusters using an in-house algorithm as well as Sylamer.

Results: The most enriched 6-8-mer sequences complimentary to the seed of miRNA that are expressed in podocytes, show extensive overlap between human and mouse. Surprisingly, the top enriched sequences were complementary to the seed of miR-27a and miR-27b, which are not among the most abundant miRNAs in podocytes, and thus might have been overlooked based on miRNA profiling alone. Subsequently, knocking down miR-27 expression in podocytes resulted in their reduced survival as well as an altered actin cytoskeleton pattern.

Conclusions: These results suggest a central role for miR-27 in podocyte maintenance. Furthermore our work implies that researchers interested in miRNA research may apply similar methods when choosing miRNA and miRNA targets suitable for their research.

Studying the Role of MiRNA in Podocyte Maintenance, Inspired by a Nephrotic Syndrome-Related Point Mutation in XPO5

Royi Navon, Iddo Z. Ben-Dov, Devorah Gur-Wahnon. Laboratory of Medical Transcriptomics *Nephrology and Hypertension, Hadassah - Hebrew University Medical Center, Jerusalem, Israel.*

Background: MicroRNA (miRNA) are small noncoding RNA molecules that regulate gene expression, and are crucial for the development and homeostasis of podocytes. Biogenesis of miRNA requires a multistage process of which Exportin5 (*XPO5*) plays a rate limiting step by exporting miRNA precursors from the nucleus to the cytoplasm. Recently, steroid-resistant nephrotic syndrome (SRNS) in a child was attributed to a point mutation in *XPO5* (Braun DA 2016). However, whether or not the mutation affects the miRNA related function of Exportin-5 is not known. We hypothesized that the V552I mutation impedes miRNA maturation and that the association with SRNS may shed light on the roles of specific miRNA in podocytes.

Methods: We have successfully generated the p.V552I Exportin-5 ($XPO5^{V552I}$) homozygous mutation in HEK293 cells via CRISPR-Cas9. In addition we have generated human podocyte clones with a heterozygous mutation.

Results: Small RNA sequencing of our HEK293 cells shows a significant decrease in global miRNA content in $XPO5^{V552I}$ compared to parental cells. Principal component analysis (Figure) also revealed population separation between wildtype HEK293 and $XPO5^{V552I}$ cells, indicating miRNA expression segregated by genotype. Moreover, Small RNA sequencing of the podocyte clones revealed distinct changes in miRNA profiles.

Conclusions: These results strongly suggest the involvement of the $XPO5^{V552I}$ mutation in the dysregulation seen in the miRNA. Further investigation will lead us to the discovery of the specific miRNA involved in maturation and maintenance of podocytes.

Funding: Government Support - Non-U.S.

Podocyte-Specific Deletion of Early B Cell Factor 1 Minimizes Sclerotic Damage After Glomerular Injury

Shaymah H. Alruwaili,[3,1] Tracy Nelson,[2] Jackie A. Fretz.[1] *[1]Yale School of Medicine, New Haven, CT; [2]Yale university School of Medicine, New Haven, CT; [3]Quinnipiac University, Hamden, CT.*

Background: It is now understood that podocyte loss, through sloughing and/or apoptosis, is the precipitating factor driving glomerulosclerosis. We also had previously reported that podocytes express the transcription factor Early B Cell Factor 1 (EBF1), although the function of this protein in these cells was unclear.

Methods: Utilizing a floxed version of *Ebf1* and podocin-cre we eliminated EBF1 specifically from podocytes, and injured glomeruli directly with either hypertensive

L-NAME injury or glomerular nephritis induced by anti-GBM serum. To identify the signaling pathways altered by EBF1 following its deletion alterations in RNA levels were compared to the chromosomal occupancy of EBF1 through ChIP-Seq.

Results: In both models of injury, EBF1 deletion from the podocytes was reno-protective. Fibrosis was reduced folowing anti-GBM serum at the at 7 and 10 days post injection. GFR decline and glomerular injury were found to be equivalent during the 20-week L-NAME hypertensive duration, however, recovery of the kidney for an additional ten-week period was dramatically accelerated when EBF1 was absent. This was reflected in the histologically as well as functionally through GFR measurement with the conditional knockout mice recovering almost half of their lost GFR within 3 weeks (no change in WT mice) and fully restoring kidney function by 10 weeks. Controls, by contrast, were not improved at the three-week mark, and only partially recovered by ten weeks. Less fibrotic injury was reflected in the RNA analysis of both models where markers of collagen formation, inflammation, and compliment and coagulation are all increased in controls. Conversely, pathway analysis performed with Metascape revealed EBF1 loss protects the integrity of the slit diaphragm components and that this is partially mediated by blunted calcium signaling, NFAT activation in the absence of EBF1. These changes were vified though clacineuin activity assay, reporter assays and western blots.

Conclusions: These results indicate that EBF1 normally promotes injury signals detrimental to the health of the podocyte through cell-intrinsic gene regulation. Deletion of this transcription factor from podocytes protects from glomerular injury at the initial stages of podocyte injury and these beneficial actions are mediated in part through minimizing NFAT signaling early in the injury process.

Calcineurin Inhibitors Activate WNK1 Kinase to Preserve Glomerular and Podocyte Structure and Mechanics

Zhenan Liu,[2,1] Joonho Yoon,[2,1] Audrey N. Chang,[2] R. Tyler Miller.[1] *[1]University of Texas Southwestern Medical School, Dallas, TX; [2]University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Tacrolimus (FK-506) and cyclosporin A (CsA), both calcineurin inhibitors (CNIs), are immunosuppressants used to treat organ transplant rejection and auto-immune diseases. Although use of these drugs can be limited by side effects including hypertension, hyperkalemia, and vasculopathy with glomerulopathy, they can also protect podocytes and glomerular capillaries from injury by preserving podocyte cytoskeletal structure. Activation of WNK kinases by CNIs causes volume-dependent hypertension and hyperkalemia, but the mechanism of CNIs' vascular and glomerular effects is not understood.

Methods: Fresh, isolated mouse glomeruli were used for measurement of WNK1 activity (measured as pOSR1), glomerular elasticity using microindentation, F/G actin ratios, and confocal imaging for glomerular structure and pOSR1. Conditionally-immortalized podocytes were used for WNK1 activity measurements (pOSR1), confocal microscopy imaging, F/G-actin ratios, pOSR1, collagen gel contraction, and migration.

Results: We found that CNIs activate WNK1 in renal glomeruli and cultured podocytes increasing pOSR1 and F-actin. Treatment of glomeruli with CNIs increases the elastic modulus (E) of glomeruli (2.4 kPa vs control 2 kPa), an effect blocked by WNK463. FK-506 increases pOSR1, F/G Actin ratios and traction by podocytes in 3-dimensional collagen gels, increases lamellipodium formation, pOSR1 localization in leading edges, and migration of cultured podocytes, effects blocked by WNK463. In glomerular capillaries, CNIs increase pOSR1, while WNK463 reduces pOSR1and disrupts capillary structure.

Conclusions: The CNI-induced increase in glomerular F-actin and E, and modifications in podocyte cytoskeletal structure, provide mechanisms by which CNIs can protect glomeruli and podocytes against injury, and illustrate a novel mechanism involving WNK1 kinase and vascular tissue. This is the first report of a function for WNK1 in glomeruli.

TLR4-Myd88-NF-κβ and Calcineurin/NFAT Signaling Pathway Cooperatively Regulate Lipopolysaccharide-Induced Angptl4 in Podocyte

Xiujin Shen. *Kidney Disease Center, The First Affiliated Hospitial, Zhejiang University, Hangzhou, China.*

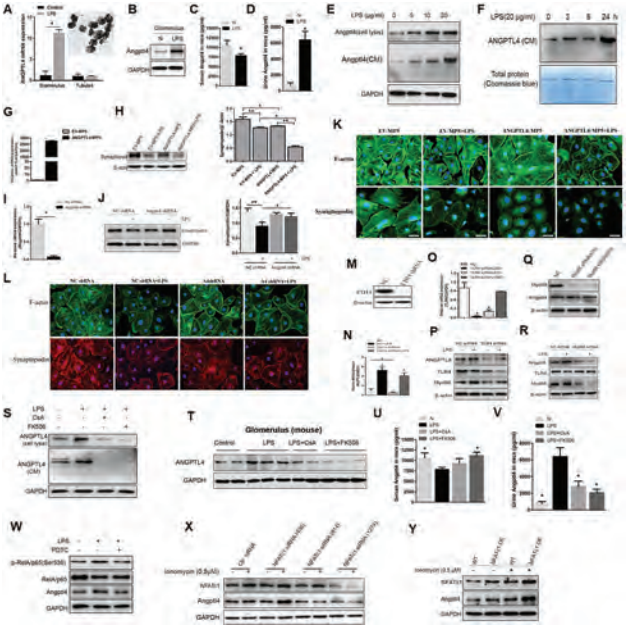
Background: Inflammation and immunological abnormalities damage podocytes and induce proteinuria. Angptl4 is a member of the angiopoietin-like protein family, which is involved in lipid metabolism, wound repair, tumor metastasis. Podocyte Angptl4 is involved in proteinuria formation, but its upstream regulation mechanism is still unclear. This study aims to clarify the molecular mechanisms involved in Angptl4 expression

Methods: LPS induced podocyte injury model was used to clarify the effect of LPS on Angptl4 in podocytes. Then, the effect of TLR4-Myd88- NF-κβ signaling pathway on Angptl4 expression was detected. In addition, Calcineurin inhibitors were used to detect Angptl4 expression in LPS-induced MCD model. Podocytes was transfected with Angptl4 to investigate the role of Angptl4 on podocyte injury.

Results: Angptl4 was promoted after LPS induction. Angptl4 overexpression disordered podocyte cytoskeleton, reduced synaptopodin, which was further decreased by LPS induction, while Angptl4 knockdown partially restored synaptoodin and podocyte cytoskeleton in LPS induced podocytes. In addition, TLR4, Myd88 siRNA and NF-κβ inhibitor PDTC effectively inhibited Angptl4 after LPS induction, while CD14 siRNA had no effect on Angptl4 expression, implying that Angptl4 was regulated by TLR4-Myd88-NF-κβ pathway. Furthermore, Calcineurin inhibitors significantly inhibited Angptl4, reduced the nuclear translocation of NFATc1, and restored podocyte cytoskeleton, which suggested that CaN inhibitors affected the expression of Angptl4 also through Calcineurin-NFAT signaling pathway.

Conclusions: LPS induced Angptl4 was regulated by Calcineurin-NFAT and TLR4-Myd88-NF-KB signaling pathway in podocytes

Funding: Government Support - Non-U.S.



TLR4-Myd88-NF-κβ and Calcineurin/NFAT signaling pathway cooperatively regulate LPS induced Angptl4 in podocyte

FR-PO936

NHERF2 Interacts with Ephrin-B1 at the Slit Diaphragm: NHERF2 Bridges Podocalyxin and Slit Diaphragm Components

Yoshiyasu Fukusumi,[1] Ying Zhang,[1] Hidenori Yasuda,[2] Hiroshi Kawachi.[3] *[1]Department of Cell Biology, Kidney Research Center, Niigata University, Niigata, Japan; [2]Kidney Research Center, Niigata University, Niigata, Japan; [3]Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: We have reported ephrin-B1 is a novel component of the slit diaphragm (SD). Ephrin-B1 interacts with nephrin via their extracellular domains and plays an essential role in maintaining the barrier function of SD (JASN 29, 2018). We reported NHERF2, a scaffold protein possessing two PDZ domains, was downregulated in the glomeruli of the podocyte-specific ephrin-B1 KO mice, which suggesting NHERF2 is associated with ephrin-B1 (ASN 2018). It is reported that NHERF2 binds to podocalyxin at the second PDZ domain and plays the pivotal role in maintaining actin cytoskeleton by phosphorylating ezrin in podocytes. However, the precise localization of NHERF2 and its interaction with ephrin-B1 are unclear.

Methods: The interaction of NHERF2 with ephrin-B1 and nephrin was analyzed by the immunoprecipitation (IP) analyses with glomerular lysates and HEK293 transfected cells. The expressions of these molecules in glomeruli of normal rat and rat with nephropathy induced by the anti-nephrin antibody were analyzed by immunofluorescence.

Results: NHERF2 band was detected in the precipitates with anti-nephrin antibody by IP assay with normal rat glomerular lysate, which indicating NHERF2 is a member of the SD complex. The IP assay with the HEK cell expression system showed NHERF2 directly interacted with ephrin-B1 at the first PDZ domain and did not interacted with nephrin. The analyses with the HEK cells triple transfected with NHERF2, ephrin-B1 and nephrin showed that the anti-nephrin antibody binding phosphorylated not only nephrin but also ephrin-B1, and that the phosphorylated ephrin-B1 did not interacted with NHERF2. Dual-labeling analyses showed NHERF2 was detected not only apical area but also SD area, and a portion of NHERF2 was colocalized with ephrin-B1 in normal glomeruli. Ephrin-B1 was phosphorylated and dissociated from NHERF2 in the nephrotic state caused by the anti-nephrin antibody injection. The immunostaining of NHERF2 and ezrin as well as ephrin-B1 and nephrin were clearly decreased.

Conclusions: NHERF2 interacts with ephrin-B1 via its first PDZ domain and with podocalyxin via its second PDZ domain, and bridges podocalyxin, an apical surface protein and ephrin-B1, an SD component. The bridging structure was disrupted by the nephrin-mediated signal. The disruption is one of the critical mechanisms of podocyte injury.

Membrane-Associated Guanylate Kinase Inverted 2 Stabilizes Glomerular Filtration Barrier via the PDZ Domain

Hiroyuki Yamada,[1,2] Shinichi Makino,[1,2] Motoko Yanagita,[2,3] Katsuhiko Asanuma.[1,2] *[1]Department of Nephrology, Chiba University Graduate School of Medicine, Chiba, Japan; [2]The Laboratory for Kidney Research (TMK project), Medical Innovation Center, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Slit-diaphragm (SD) of podocytes plays a crucial role as a final barrier of glomerular filtration. The main components of SD, such as Nephrin and Neph1, are indispensable in preventing progression of glomerulosclerosis. However, it remains unknown what is important for protecting these main components. Here, we demonstrate that Membrane-associated guanylate kinase inverted 2 (MAGI-2) functions as a critical scaffold protein for maintaining the SD components.

Methods: We examined the immunofluorescence intensity of MAGI-2 in human biopsy sample. We analyzed the phenotype of podocyte specific MAGI-2 knock out (KO) mice. Additionally, using *piggy-Bac* transposon and CRISPR-Cas9 system, we analyzed the function of MAGI-2 in cultured MAGI-2 overexpression podocytes and ZO-1 KO podocytes. Next, using biochemical assay, we investigated which domain of MAGI-2 is necessary for the binding among these molecules.

Results: In the immunofluorescence of human biopsy sample, MAGI-2 is downregulated in glomerular diseases such as focal segmental global sclerosis or IgA nephropathy. Actually, podocyte specific MAGI-2 KO mice also significantly exhibited glomerulosclerosis and the reduced expression of Nephrin and Neph1. Cultured MAGI-2 overexpression podocytes showed the colocalization of MAGI-2 and Nephrin in cell-cell contact, while Nephrin was not expressed in cellular edge of cultured control podocytes. Additionally, although ZO-1 deletion undermines the Neph1 expression in cultured podocytes, the transfection of MAGI-2 in the ZO-1 deleted cells could retrieve the reduced Neph1 expression. Biochemical assay demonstrated that MAGI-2 binds to Nephrin and Neph1 through different PDZ binding domains.

Conclusions: These results showed that MAGI-2 is crucial for maintaining the key components of SD such as Nephrin and Neph1. Moreover, they also showed that MAGI-2 could localize these main components to intracellular compartments through different PDZ domains. Therefore, the MAGI-2 protection strategy could be a new route to the new drug development against glomerular diseases.

FR-PO938

Fabry Disease and Renal Transplant

Maria F. Toniolo. *Centro de Diagnostico Patologico, Buenos Aires, Argentina.*

Introduction: Fabry disease is a rare, X linked, multisystemic, multiorgan disorder in wich globotriaosylceramide (GL3) and other glycosphingolipids accumulate within lysosomes due to deficient activity of alpha-galactosidase A. The accumulation of GL3 in multiple cell types is associated with severe complications including cardiac events, stroke and renal failure. Fabry Nephropathy can lead to end stage renal disease requiring renal transplantation. Little is know about this outcomes and the overall patient survival after kidney transplantation.

Case Description: Here we report two Fabry patients (1 male and 1 female) who received kidney transplant and their treatment and follow-up with kidney biopsy at 5 and 10 years. Patients are 42 and 43 years old and received kidneys from deceased donors. We performed renal biopsies in both cases and GL3 levels in each patient.

Discussion: Over 874 kidney transplants perfomed at our Center, 3 patients had pre-transplant, Fabry Disease diagnosis. One patient died, 10 years post transplantation. Two more patients had excellent outcome with serum creatinine between 1,23 and 1,57 md/dl and Lyso GL3 between 14,9 and 52. In spite of good renal function, we decide to performed renal biopsies. Both patients show abnormalities: podocytes deposits of GLB3, in arteries and also found deposits in mesangial cells. Electron-dense lamellar inclusions were found in podocytes, and vascular endothelial cells.

FR-PO939

The Role of SOAT1 in Renal Disease Associated with Alport Syndrome

Xiaochen Liu,[1] Gloria Michelle Ducasa,[1] Sandra M. Merscher,[2] Alessia Fornoni.[2] *[1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Miami, Miami, FL.*

Background: Defective cholesterol metabolism is closely associated with the progression of renal disease in Alport syndrome(AS), an inherited disease associated with progressive kidney failure, hearing loss and eye abnormalities. We recently demonstrated that accumulation of cholesterol esters occurs in experimental models of AS. SOAT1 is an enzyme that converts free cholesterol to cholesteryl esters at the endoplasmic reticulum, and plays an important role in cellular cholesterol homeostasis. Recent studies indicate that inhibition of SOAT1 may have beneficial effects in Alzheimer's disease and in cancer where SOAT1 inhibition reduced cancer proliferation and suppressed tumor growth. However, whether the accumulation of free or of esterified cholesterol contributes to progression of renal disease in AS remains unclear. With this study, we aimed at investigating the role of SOAT1 in the progression of renal disease in AS.

Methods: Normal human podocytes were treated with SOAT1 inhibitor (SI) or DMSO for 48h. Podocytes were stained with Bodipy and Cell Mask Blue. The Opera High Content screening system and Image Analysis software were used to quantify the density of lipid droplets. Cholesterol and triglyceride content was assessed using the Amplex Red Cholesterol kit and Triglyceride Colorimetric kit. Urinary albumin-to creatinine ratios were determined by mouse albumin ELISA and creatinine Companion kits.

Results: We observed a significant reduction of cholesterol esters in SI-treated human podocytes when compared to vehicle-treated podocytes in association with a decrease in lipid droplet density and triglyceride content. To assess the effect of SOAT1 deficiency in the kidney, the renal phenotype of *Soat1* knockout (SKO) mice was investigated. SKO mice did not develop albuminuria or mesangial expansion at 10 months of age. Analysis of SOAT1 expression in kidney cortexes of AS mice demonstrated increased SOAT1 mRNA when compared to WT mice, while expression levels of several other genes important in cholesterol homeostasis remained unchanged.

Conclusions: Our data suggest that increased SOAT1 expression in the kidney cortex of AS mice contributes to progression of renal disease in AS. We conclude that preventing cholesterol ester accumulation in kidney cortex of AS mice by SOAT1 inhibition may represent a new therapeutic strategy to treat renal disease in AS patient.

FR-PO940

Plasma Circulating Factors in Recurrent Nephrotic Syndrome Increases Podocyte Motility via Signalling Pathways That Mimic PAR-1 Activation

Musleeha Chesor, Carl J. May, Bryony Hayes, Gavin I. Welsh, Moin Saleem. *University of Bristol, Bristol, United Kingdom.*

Background: Post-transplantation recurrence steroid resistant nephrotic syndrome (SRNS) is thought to be due to the presence of an unknown "circulating factor" the identity of which has so far remained elusive. Our previous work suggests that an unknown circulating protease in recurrent SRNS plasma signals to podocytes through protease activated receptor-1 (PAR-1), a G-protein-coupled-receptor and alters the actin cytoskeleton leading to increased podocyte motility via phosphorylation of vasodilator-stimulated phosphoprotein (VASP) a known actin cytoskeleton regulator. We have now further elaborated this signalling pathway in podocytes with the hypothesis that the circulating factor(s) in FSGS relapse plasma will initiate specific signalling pathways via PAR-1 receptor to the podocyte cytoskeleton and this consequently leads to increased podocyte motility and proteinuria.

Methods: Conditionally immortalised human podocytes (ciPods) were treated with 1) PAR-1 agonist; 2) Relapse and paired-remission plasma from FSGS patients, along with three different PAR-1 inhibitors, Vorapaxar, SCH 79797, and FR17113. A scratch assay was performed to determine the motility of ciPods after treatment with FSGS plasma. A mouse model of podocyte specific constitutively active PAR-1 was generated.

Results: We found that PAR-1 agonist and patient relapse disease plasma but not remission plasma from the same patient induced phosphorylation of VASP and JNK, a member of the mitogen-activated protein kinases (MAPK) superfamily in human podocytes, and increased motility compared to relevant controls. These changes were blocked by co-incubation of cells with certain PAR-1 inhibitors. These three PAR-1 inhibitors demonstrate distinct antagonistic properties and among 3 inhibitors, only FR17113 was effective, suggesting a non-canonical agonism of PAR-1 by disease plasma. The $PAR1_{active}$ mouse developed FSGS and upregulation of VASP, MAPK and JNK in podocytes by D8.

Conclusions: We reveal a consistent signalling pathway in 'circulating factor' SRNS that leads to increased podocyte motility and proteinuria and suggests direct therapeutic targets.

Towards Clinical Assays for Evaluating Circulating Permeability Factors in Nephrotic Syndrome

Susan Veissi,[1] Bart Smeets,[2] Joanna Van Wijk,[3] Annelies Jeronimus-Klaasen,[1] Lambertus P. Van den heuvel,[1,4] Michiel F. Schreuder.[1] *[1]Department of Pediatric Nephrology, Amalia Children's Hospital, Radboud university medical center, Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands; [2]Department of Pathology, Radboud University Medical Center, Nijmegen, Netherlands; [3]Department of Pediatrics, Vrije Universiteit University Hospital Amsterdam, Amsterdam, Netherlands; [4]Department of Development and Regeneration, University Hospital Leuven, Leuven, Belgium.*

Background: Circulating permeability factors (CPFs) have been implicated as one of the causes of nephrotic syndrome (NS). Evidence for CPFs comes mainly from clinical observations and animal studies, since reliable *in vitro* assays are lacking. Therefore, we aim to study the presence and pathogenic relevance of CPFs in plasma of NS patients during active disease and remission using conditionally immortalized human podocytes (ciHPOD) and primary human glomerular microvascular endothelial cells (GMVECs) *in vitro*.

Methods: Podocytes (ciHPOD) and primary endothelial cells (GMVECs) were incubated with plasma from NS patients in relapse and remission as well as from a non-renal control patient. Cell viability, podocyte motility, podocyte actin cytoskeleton architecture, and reactive oxygen species (ROS) formation at the presence or absence of ROS scavenger, dimethylthiourea, were investigated by CCK-8 assay, scratch-assay, immunofluorescence stainings, and CM-H2DCFDA probing, respectively.

Results: Plasma from active NS patients, but not from remission or control patients, caused excessive ROS formation in podocytes, but not in endothelial cells. Immunofluorescence microscopy revealed severe derangement of the podocyte's actin cystoskeleton in response to active NS plasma. Moreover, the motility of podocytes seemed to be reduced in the presence of active NS plasma, but not in the presence of remission or control plasma. Prolonged incubation of podocytes, but not endothelial cells,

led to cell death only when active NS plasma was present. Furthermore, the ROS scavenger dimethylthiourea abolished the ROS formation and the podocyte's actin cytoskeleton dearangement and cell death in response to active NS plasma, suggesting that ROS plays an important role in podocyte injury in NS.

Conclusions: We provide a high-throughput and sensitive assay to measure ROS in response to NS plasma, providing a new framework for monitoring *in vivo* CPF activity that could be used for diagnostics or disease monitoring purposes. Moreover, our findings suggest that the inhibition of ROS formation or facilitating rapid ROS scavenging might exert beneficial effects in patients with NS.

FR-PO942

Analysis of Urinary Extracellular Vesicle Autofluorescence by Imaging Flow Cytometry and Spectral Flow Cytometry

Luca Musante,[1] Sabrina La salvia,[1] Joanne Lannigan,[1] Uta Erdbruegger.[2] *[1]University of Virginia, Charlottesville, VA; [2]University of Virginia Health System, Charlottesville, VA.*

Background: Urinary extracellular vesicles (uEVs) provide a source of valuable biomarkers for kidney and urogenital diseases. Analysis of uEVs in imaging flow cytometry is challenging for its intrinsic auto fluorescence emission across the whole electromagnetic spectrum. To date it is not known what the rate of the autofluorescence interference is with respect to the detection of specific uEVs markers

Methods: First morning void urine and citrate blood from the same donor were centrifuged at relative centrifugation force RCF of 4,600 g for 30 and 15 minutes respectively. The supernatant was further centrifuge at relative centrifugation force of 20,000g to collect urinary (uEVs) and plasma (pEVs) which were stained with the same commercial clone antibody (3D3) anti podocalyxin (PODXL) conjugated with 3 different fluorescent dyes: Alexa Fluor® 405 (AF405), Alexa Fluor® 488 (AF488) and Alexa Fluor® 647 (AF647). Stained EVs were acquired with both imaging flow cytometry and spectral flow cytometry. Gate strategy was based on the low scatter of the unstained uEVs and the negative control was the fluorescent probe alone in buffer.

Results: Acquisition of uEVs alone showed auto-fluorescence emission in channel 2 (λ_{ex} 488 nm; λ_{em} 480-560 nm) camera 1 and channel 11 (λ_{ex}658 nm; λ_{em} 660-740 nm) but not channel 7 (λ_{ex}405 nm; λ_{em} 420-505 nm) for camera 2 for the imaging flow cytometry meanwhile the spectral flow cytometry revealed a spectral fingerprint spanning from the violet to the red emission. Autofluorescence was detected for uEVs but not pEVs. Podocalyxin-AF405 conjugated stained both uEVs and pEVs with a double staining for the autofluorescence and PODXL on the same uEV. While PODXL-AF488 and AF647 stained better pEVs than uEVs as per PODXL-AF405. Same results were obtained for both flow cytometry instruments.

Conclusions: Our results showed an unexpected additional complication of the analysis of uEVs in flow cytometry originated from the auto-fluorescence of the uEVs fraction. In fact, the autofluorescence quenched the emission of PODXL-AF488 and AF647 but not AF405. Moreover, uEVs auto-fluorescence needs to be taken into account especially when simultaneous co-detection of uEVs markers of podocyte origin is planned with particular emphasis on the critical selection of the antibody conjugated fluorescent dye.

FR-PO943

C-Type Lectin-Like Receptor (CLEC)-2, the Ligand of Podoplanin, Facilitates Motility of Podocytes

Keiko Tanaka, Taiji Matsusaka. *Tokai University School of Medicine, Isehara, Japan.*

Background: Podoplanin is strongly expressed on podocyte membrane in an evolutionally conserved manner. Podoplanin binds to phosphorylated (p)ezrin, which binds and maintains filamentous (F-) actin. The endogenous ligand of podoplanin is C-type lectin-like receptor (CLEC)-2, which is highly expressed in platelets. Normally, podocytes are sequestered from platelets, but when the GBM barrier is injured, podocytes may have access to platelets or CLEC-2. In addition, soluble CLEC-2 was reported to exist in human serum. In the present study, we aimed to investigate the impact of CLEC-2 on podocytes.

Methods: Recombinant Fc-CLEC-2, a fusion of human Fc and CLEC-2 (51-229) proteins, which was reported to bind to mouse podoplanin, was generated in HEK293 cells and purified by Protein A affinity chromatography. Primary mouse cultured podocytes were incubated with the Fc-CLEC-2 or Fc protein (each 10 ug/mL) for 1 hour. Cell morphology, F-actin (Phalloidin staining), p-ezrin (immunostaining), cell adhesion to collagen-1 coated dish, and migration (Wound scratch test) were evaluated. To assess whether Fc-CLEC-2 has an impact on reversal from injury, podocytes were pretreated with protamine sulfate (PS) followed by heparin sulfate (HS), and then the effect of Fc-CLEC-2 or Fc on cell form, F-actin and p-ezrin were evaluated.

Results: No obvious change was observed in cell form and F-actin after the stimulation with Fc-CLEC-2. However, podocytes treated with Fc-CLEC-2 showed less adhesion to collagen-1 coated plate within 1 hour than the Fc control (86.7% vs. 100%). In migration assay, podocytes with Fc-CLEC-2 showed faster movement than control (11.1 vs. 9.2 mm/24hr) and faster wound closure (18.6 vs. 21.0 hours). After incubation with PS and HS, Fc-CLEC-2 retarded recovery of F-Actin formation compared to control (54.4% vs. 77.0%). Treatment with PS and HS increased p-ezrin, which was further enhanced by Fc. In contrast, Fc-CLEC-2 reduced cytosolic p-ezrin, suggesting that CLEC-2 inhibits F-actin formation by decreasing p-ezrin which binds to podoplanin.

Conclusions: These results indicate that CLEC-2 facilitates motility of podocytes and retards the reconstruction of F-actin during recovery from injury. Activation of motility of podocytes may be beneficial to wound healing, but the biological significance of these phenomena needs to be clarified in in vivo studies.

FR-PO944

Studying the Role of Fibronectin in Mechanically Stressed Podocytes

Felix Kliewe,[1] Sören Kaling,[1] Henriette Lötzsch,[1] Nadine Artelt,[1] Maximilian Schindler,[1] Henrik Rogge,[1] Sindy Schröder,[1] Christian Scharf,[1] Kerstin U. Amann,[3] Christoph Daniel,[3] Maja Lindenmeyer,[2] Clemens D. Cohen,[4] Karlhans Endlich,[1] Nicole Endlich.[1] *[1]University Medicine Greifswald, Greifswald, Germany; [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]University Hospital Erlangen, Erlangen, Germany; [4]Klinikum Munchen, Munchen, Germany.*

Background: Glomerular hypertension induces mechanical load to podocytes *in situ*, often resulting in podocyte detachment and the development of glomerulosclerosis. Although it is well known that podocytes are mechanosensitive, the mechanosensor and mechanotransducer, respectively, are still unknown. Extracellular matrix proteins could function as such a mechanosensor. The objective was to clarify the potential significance of the extracellular matrix protein fibronectin which became up-regulated in cultured podocytes 2-fold after the exposure to mechanical strain. Furthermore, biopsies of patients suffering from diabetic nephropathy were used to study the expression of fibronectin.

Methods: Mouse podocytes were cultured on silicone membranes that were connected to the stretch apparatus for three days (0.5 Hz and 5% extension). To study the role of fibronectin in cultured podocytes under mechanical stretch, fibronectin was knocked down (Fn1 KD) by specific siRNAs. Additionally, we established a fibronectin knockout podocyte cell line (Fn1 KO) by CRISPR/Cas9. LC-MS as well as qRT-PCR were performed from mechanically stretched podocytes.

Results: Here, we demonstrate that the extracellular matrix protein fibronectin is essential for the attachment of podocytes during mechanical stress. By qRT-PCR as well as by LC-MS, we found a significant up-regulation of fibronectin in cultured podocytes after three days of mechanical stretch. Additionally, we observed a significant loss of Fn1 KD as well as Fn1 KO podocytes (> 80%) compared to controls in the presence of mechanical strain. Beside this, a significant down-regulation of the focal adhesion proteins talin, vinculin and paxillin and a reduced cell spreading was observed in Fn1 KO podocytes indicating an important role of fibronectin for the adhesion of cultured podocytes. Analyzing kidney biopsies of patients suffering from diabetic nephropathy, we found a significant up-regulation of fibronectin especially in podocytes in contrast to control biopsies.

Conclusions: Fibronectin plays an important role in the adaptation and adhesion of cultured podocytes in the presence of mechanical stretch and could serve as a mechanosensor in podocytes.

FR-PO945

Targetable Biomarker in Glomerular Disease: Determining the Role of Plasminogen in Podocyte Injury

Marc Egerman,[1] Jenny Wong,[2] Steven G. Coca,[1] Evren U. Azeloglu,[1] Kirk N. Campbell,[1] Leopoldo Raij.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai School of Medicine, New York, NY; [3]University of Miami Miller School of Medicine, Miami, FL.*

Background: Recent studies have shown significant quantities of plasminogen/plasmin, or plasmin(ogen)uria, in the urine of proteinuric patients and that exposure of cultured podocytes to plasminogen can result in injury via up-regulation of endothelin-1 (ET1) and oxidative stress pathways. However, a causative role for plasminogen as a "second hit" in disease progression has yet to be demonstrated *in vivo*, and the associations between plasmin(ogen)uria and kidney function in glomerular diseases remains unclear.

Methods: We performed comparative studies in a puromycin aminonucleoside (PAN) nephropathy rat model treated with amiloride, which has off-target effects inhibiting plasminogen activation, and measured changes in plasmin(ogen)uria and urinary ET1 by ELISA. Western blotting, proteomics, and IF were conducted to investigate changes in ET1 and plasmin(ogen) in isolated glomeruli as well as markers of oxidative stress and podocyte homeostasis. We used a biorepository at Mount Sinai hospital to identify patients with glomerular diseases (n=128). Urine samples were measured for time-of-biopsy albuminuria and plasmin(ogen)uria to assess for correlations with kidney function outcomes by logistic and linear regression.

Results: Plasmin(ogen) was found—for the first time to our knowledge—to be strongly bound within glomeruli in PAN rats, which was later confirmed in FSGS patients. PAN-treatment was associated with increases in plasmin(ogen)uria and urinary ET1, which was rescued by amiloride. Similarly, amiloride was protective against PAN-induced glomerular injury and oxidative stress. In the patient cohort, associations were shown between plasmin(ogen)uria and edema status as well as with eGFR, independent of age and gender.

Conclusions: Here, we (i) present strong supportive evidence for a causative role of the plasmin(ogen)-system in podocyte injury, with amiloride having reno-protective properties *in vivo*, and (ii) advance clinical correlations of plasmin(ogen)uria as a biomarker of glomerular injury in proteinuric patients. Plasmin(ogen) may thus aggravate renal disease through direct injury to podocytes during its trans-glomerular passage in the setting of proteinuria. Given such a function, plasmin(ogen) represents an attractive target for the development of mechanistically-based novel therapeutic interventions.

FR-PO946

Upregulated LRRC55 Aggravates Podocyte Injury Through Activating the BK Channel

Shuai Hu,[2] Runhong Han,[1] Long Chen,[3] Hao Bao,[1] Zhihong Liu.[1] *[1]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [2]Nanjing University School of Medicine, Nanjing, China; [3]National Standard Laboratory of Pharmacology for Chinese Materia Medica, School of Pharmacy, Nanjing University of Chinese Medicine, Nanjing, China.*

Background: Focal segmental glomerulosclerosis (FSGS) is a common podocytopathy, accounting for 40% of cases of nephrotic syndrome in adults, andits pathogenesis has not been fully elucidated. LRRC55 is a γ subunit of the BK channel, and the role of LRRC55 in podocyte injury has not been studied.

Methods: Glomerular tissues of FSGS patients and controls were isolated and subjected to transcriptome analysis. Cell biology techniques were used to analyze LRRC55 expression, BK channel current, intracellular potassium level, caspase-3 activation, DNA fragmentation and podocyte apoptosis in human podocytes and Ang II-treated mice.

Results: Based on transcriptome analysis and confirmation study, the level of LRRC55 was significantly increased in glomerular podocytes in FSGS patients. *In vitro*, treatment with Ang II induced NFATc nuclear translocation and promoted LRRC55 upregulation in podocytes. The upregulated LRRC55 and increased intracellular calcium led to BK channel activation and the loss of intracellular potassium, which caused caspase-3 activation and DNA fragmentation in Ang II-treated podocytes. In contrast, silencing of LRRC55 reversed the intracellular potassium loss, caspase-3 activation and DNA fragmentation in the Ang II-treated podocytes. *In vivo*, Ang II-infusion caused an obvious increase in LRRC55 expression, BK channel activation, intracellular potassium decrease, podocyte apoptosis and focal segmental sclerosisin mice. Knockout of BK channel or silencing of LRRC55 prevented intracellular potassium decrease and ameliorated podocyte injury and focal segmental sclerosis in Ang II-treated mice.

Conclusions: The results suggest that the upregulated LRRC55 aggravates podocyte injury through activating BK channel. Inhibition of LRRC55 attenuates podocyte injury, may representing a new therapeutic approach for FSGS patients.

FR-PO947

Loss of Robo2 in Mature Podocytes Is Protective from Injury by Enhancing Podocyte Adhesion That Helps Maintain Foot Process Structure

Anna Pisarek-Horowitz,[2] Xueping Fan,[1] Sudhir Kumar,[3] Hila Milo Rasouly,[4] Richa Sharma,[2] Hui Chen,[5] Laurence H. Beck,[2] Joel M. Henderson,[2] David J. Salant,[2] Weining Lu.[2] *[1]Medicine, Boston University School of Medicine, Boston, MA; [2]Boston University Medical Center, Boston, MA; [3]Boston University, Boston, MA; [4]Columbia University, New York, NY; [5]BMC, Boston, MA.*

Background: Repulsive guidance cue receptor ROBO2 plays an important role during early kidney development. ROBO2 is expressed in podocytes, inhibits nephrin-induced actin polymerization, down-regulates nonmuscle myosin IIA activity, and destabilizes kidney podocyte adhesion. However, the role of ROBO2 during kidney injury, particularly in mature podocytes, is not known.

Methods: In this study, we compared phenotypes between adult *Robo*2 podocyte specific knockout mice (*Robo2* cKO) and wildtype controls under two different glomerular injury conditions induced by protamine sulfate (PS) perfusion or nephrotoxic serum (NTS) injection. We also analyzed ROBO2 expressions in the glomeruli of NTS injured mice, passive Heymann nephritis (PHN) rat, and membranous nephropathy patients.

Results: Ultrastructural analysis reveals that *Robo2* cKO mice display less foot process effacement and better preserved slit-diaphragm density compared to wild-type littermates injured by either protamine sulfate (PS) or nephrotoxic serum (NTS). The *Robo2* cKO mice also develop less proteinuria after NTS injury. Further studies reveal that ROBO2 expression in podocytes is upregulated after glomerular injury since its expression levels are higher in the glomeruli of NTS injured mice and passive Heymann membranous nephropathy rats. Moreover, the amount of ROBO2 in the glomeruli is also elevated in patients with membranous nephropathy. Finally, overexpression of ROBO2 in cultured mouse podocytes compromises cell adhesion.

Conclusions: These findings suggest that kidney injury increases glomerular ROBO2 expression that might compromise podocyte adhesion and thus loss of *Robo2* in podocytes could be protective from glomerular injury by enhancing podocyte adhesion that helps maintain foot process structure. Our findings also suggest that ROBO2 is a therapeutic target for podocyte injury and podocytopathy.

FR-PO948

Role of Sphingomyelin Phosphodiesterase Acid-Like 3B (SMPDL3b) in Fatty Acid Uptake and in Progression of Podocyte Damage

Shamroop Kumar Mallela,[1] Lorenza Macrina,[3] Devang M. Patel,[2] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Medicine, Katz Family Division of Nephrology and Hypertension, Peggy and Harold Katz Family Drug Discovery Center, Miami, FL; [2]Monash University, Mill park, NSW, Australia; [3]Katz Family Division of Nephrology and Hypertension Peggy and Harold Katz Family Drug Discovery Center, Miami, FL.*

Background: LD play an important role in many biological processes and LD size and number have been linked to several diseases such obesity, insulin resistance and type 2 diabetes, heart disease, and non-alcoholic fatty liver disease. LD are mainly composed of triglycerides and cholesterol. We previously demonstrated that the accumulation of LDs occurs in glomeruli of experimental models of focal segmental glomerulosclerosis (FSGS) and Alport syndrome and that lipid accumulation in podocytes is one of the factors contributing to the pathogenesis of kidney disease. We furthermore demonstrated that glomerular expression of sphingomyelinase phosphodiesterase like 3b (SMPDL3b), a glycosylphosphatidylinositol (GPI) anchored protein primarily localized at plasma membrane (PM), affects the function of podocytes in FSGS and diabetic kidney disease (DKD). With this study, we aimed at exploring a possible role of SMPDL3b in fatty acid uptake and in the formation of LDs ultimately contributing to podocyte damage.

Methods: Fatty acid uptake in podocytes was determined using the fatty acid uptake kit from Sigma (#MAK156). LDs were isolated using a kit from Cell Biolabs (#MET-5011) and proteins present in LDs were analyzed by Western blotting. Triglyceride (TAG) and esterified cholesterol (CE) content were measured using enzymatic and mass spectrometric methods. Lipolysis was measured using a lipolysis colorimetric assay kit from Sigma (#MAK211).

Results: Decreased SMPDL3b expression (siSMPDL3b) was associated with an increase in fatty acid uptake and an increased number of LDs, the number of LD was decreased in podocytes with increased SMPDL3b expression (SMPDL3b OE). Similarly, triglyceride and cholesterol ester content were increased in siSMPDL3b when compared to control podocytes. Finally, we demonstrate for the first time that SMPDL3b is present in isolated LDs suggesting a possible role for SMPDL3b in the formation of LDs.

Conclusions: Our results identify a new role of SMPDL3b in the uptake of fatty acids, the accumulation of TAG and the formation of LDs. Further experiments to understand the exact mechanism by which SMPDL3b controls the uptake of fatty acids thus contributing to podocyte damage are underway.

FR-PO949

Podocyte Cell Cycle Manipulation as a Potential Tool in Treating Glomerular Disease

Laura Perin,[1] Camille H. Nicolas frank,[2] Kevin V. Lemley,[1] Roger E. De Filippo.[1] *[1]Childrens Hospital Los Angeles, Los Angeles, CA; [2]The Saban Research Institute, Los Angeles, CA.*

Background: Loss of podocytes is a hallmark of most progressive kidney disease. Podocytes do not replicate in situ; hence, hypertrophy is the only mechanism they have to compensate for cell loss by allowing a smaller number of podocytes to effectively cover the glomerular tuft. To undergo hypertrophy, podocytes re-enter the cell cycle, moving from quiescent G0 to G1. Regulation of the G1/S checkpoint is critical. If podocytes exit G1 and continue toward mitosis, they detach from the GBM during cytokinesis and are lost in the urine. Understanding cell cycle regulation may be pivotal in developing novel therapies to prevent podocyte loss.

Methods: To the study the podocyte cell cycle, we established colonies of FUCCI2aR mice. These mice have ubiquitylation-mediated fluorescent protein expression, which reflects the cell cycle in vivo: red in G1/S, green in S/G2, yellow for S phase, no fluorescence in G0. These FUCCI mice were bred with our model of glomerular injury (Alport Syndrome, AS) and with a podocyte-specific Cre-mouse, yielding a model that allows real-time studies of the cell cycle specifically in podocytes.

Results: Podocytes isolated from glomeruli of wild type FUCCI2aR mice were 23% of total glomerular cells: 93% were in G0, 6% in G1 and none in S/G2. In late-stage proteinuric AS FUCCI2aR mice, 95% of the podocytes were in G1. We found that rapamycin (an mTOR inhibitor) was protective by supporting podocyte survival in vitro. Podocytes isolated from cultured glomeruli exposed to rapamycin for 3 days had increased survival (16%-20%) compared to podocytes not exposed to rapamycin (7%-9%). Furthermore, in PAN-exposed podocytes in vitro rapamycin increased the number of podocytes in G1 [from 4% to 13.5%]. The G1 podocytes were also larger by 41.5% ($p<0.05$) than those in G0 as assessed by flow cytometry forward scatter, confirming that the G1 podocytes are in a hypertrophic state.

Conclusions: Interventions that support podocyte hypertrophy, while limiting progression to mitosis or cytokinesis, may stabilize glomeruli against sclerosis following a loss of podocytes. Rapamycin presents a potential novel therapy in glomerular diseases such as AS by enhancing stable hypertrophy of podocytes in G1, while preventing progression through the cell cycle to S and mitosis.

ZNF277-Induced Podocyte Injury by Regulating the Expression of ITGAV and ITGB5

Yuqiu Lu, Chen Yu. *Shanghai Tongji Hospital, Shanghai, China*.

Background: ZNF277, a newly discovered zinc finger protein, is highly conserved in evolution. Previously, by single-cell RNA sequencing, we found that ZNF277 was specifically expressed in mouse glomerular podocyte. Then, by searching Nephroseq database, the expression level of ZNF277 in glomerular of FSGS patients was significantly down-regulated. Therefore, we speculated that ZNF277 might be involved in podocyte injury.

Methods: Firstly, we detected the mRNA level of ZNF277 in human podocyte lines (HPCs) by Q-PCR. Then, ZNF277 was specifically knocked down by siRNA in HPCs, and the changes of podocyte-specific genes were detected by Q-PCR. Finally, by bioinformatics analysis of podocyte-specific genes down-regulated when ZNF277 was knocked down, we speculated the possible mechanism of ZNF277 involved in podocyte injury.

Results: In vitro, the expression level of ZNF277 in PAN-induced podocyte injury model was down-regulated (0.50 ±0.13). 92 podocyte-specific genes were detected in HPCs in which ZNF277 was knocked down by siRNA. Among them, 18 genes were down-regulated, including ITGB5, ITGAV, IFT80, MYOM2, HAUS8, RAB3B, CDKN1C, DTNB, CYB5R4, SDC4, ARPC1A, WT1, PODXL, ILDR2, SYNPO, ALCAM, SEPT10, TMOD3. Then, the 18 genes were analyzed by Bioinformatics analysis, including GO and KEGG analysis, The results suggested that they were mainly involved in biological processes such as cytoskeleton and cell adhesion,and ITGB5 and ITGAV were the main genes involved in the biological process.

Conclusions: the mechanism of ZNF277 participates in podocyte injury may be regulating the expression of ITGAV and ITGB5.

FR-PO951

Protective Effect of Hydroxychloroquine on Cultured Mouse Podocytes Expressing the HIV Accessory Protein Vpr

Hiroshi Kajiyama,[1] Jeffrey B. Kopp,[2] Toshihide Mimura.[1] *[1]Department of Rheumatology and Applied Immunology, Saitama Medical University, Iruma, Japan; [2]NIDDK, NIH, Bethesda, MD.*

Background: Studies in HIV-transgenic mice have implicated the HIV accessory protein R (Vpr) in podocyte injury, culminating in HIV-associated nephropathy. Clinical studies indicate that hydroxychloroquine reduces kidney damage in lupus. In this study, we tested protective effects of hydroxychloroquine on cultured mouse podocytes expressing Vpr.

Methods: Stably-transfected mouse podocytes bearing three transgenes, expressing Vpr (thermosensitive SV40 T antigen, podocin-promoter-rtTA and tet-responsive element-Vpr) or control AI podocytes expressing two transgenes (thermosensitive SV40 T and podocin-promoter-rtTA) were grown at 33°C and differentiated at 37°C. Differentiated podocytes were plated on day 1, hydroxychloroquine at concentrations ranging from 0.63 to 80 μg/mL was added to podocyte cultures on day 3, and 1 μg/mL doxycycline (DOX) was added day 4). Cell death was observed by phase-contrast microscopy on day 6 and 9, and total cell number and dead cell number were counted in each condition to obtain the percentage of dead cells.

Results: AI control and Vpr-expressing podocytes tolerated hydroxychloroquine concentrations of 10 μg/mL of hydroxychloroquine or less but died at higher concentrations. Vpr podocytes died 48 h after 1 μg/mL DOX was added, likely due to induced expression of Vpr. DOX-treated Vpr podocytes were protected from cell death with 24 h pretreatment of 0.63, 1.25, 2.5, 5 and 10 μg/mL hydroxychloroquine (H), in a dose-dependent manner (H0: 30.2%, H0.63: 25.0%, H1.25: 20.8%, H2.5: 4.3%, H5: 0%, H10: 0%). DOX-untreated Vpr podocytes without hydroxychloroquine also underwent cell death on day 9 of 37°C culture due to leaky expression of Vpr, which was partly inhibited by 5 and 10 μg/mL of hydroxychloroquine pretreatment (H0: 56.3%, H5: 32.0%, H10: 2.6%).

Conclusions: In cultured mouse podocytes expressing Vpr, hydroxychloroquine showed protective effects at up to 10 μg/mL. Hydroxychloroquine has diverse effects on mammalian cells, including increasing lysosomal pH, which in turn alters protein processing such as glycosylation. Hydroxychloroquine also alters Toll-like receptor signaling. The effects of hydroxychloroquine on Vpr-induced podocyte injury deserve further study.

FR-PO952

Regulation of Podocyte Senescence by GSK3β: A Novel Senostatic Target for Delaying Glomerular Aging

Yudong Fang, Lance D. Dworkin, Rujun Gong. *University of Toledo Medical Center, Toledo, OH*.

Background: Along with worldwide population aging, nephrology practice is challenged by renal aging, which is associated with progression of age-related glomerulosclerosis centrally involving podocyte senescence. Compelling evidence suggests that microdoses of lithium, an inhibitor of GSK3β, alleviated aging in *Drosophila* and *C. elegans*. As a multitasking kinase, GSK3β has also lately been implicated in podocyte pathobiology. However, it remains unknown if GSK3β regulates renal aging.

Methods: Renal aging was examined in mice with doxycycline-induced podocyte-specific ablation of GSK3β (KO) or in control littermates at 2, 12 or 24 months. Cultured podocytes were tested for senescence.

Results: Accompanying aging, control mice exhibited evident renal aging, featured by a decline in renal function, persistent albuminuria and typical pathologic changes, including glomerular hypertrophy, focal global glomerulosclerosis, hyaline arteriolosclerosis and renal fibrosis on light microscopy, associated with ultrastructural lesions in podocytes like foot process effacement and deposits of protein aggregates, podocytopenia, and loss of podocyte markers like synaptopodin and podocin. In parallel, senescence-associated β-galactosidase activity and expression of senescence-related $p16^{INK4A}$, p53 and p21 were progressively increased in glomeruli, correlated with concomitant GSK3β overactivity, as evidenced by linear regression analysis. In the aged KO mice, GSK3β was selectively ablated in podocytes, resulting in a blunted induction of $p16^{INK4A}$, p53, p21 and β-galactosidase activity in glomeruli, and alleviation of glomerulosclerosis and other signs of glomerular aging. Mechanistically, *in silico* analysis revealed that $p16^{INK4A}$, p53 and p21 are cognate substrates of GSK3β and contain the GSK3β consensus motifs. *In vitro*, ectopic expression of a constitutively active GSK3β mutant in podocytes promoted phosphorylation of $p16^{INK4A}$, p53 and p21, incurring a potentiated cellular senescence, marked by an elevated β-galactosidase activity and loss of podocyte differentiation markers like synaptopodin. Conversely, GSK3β knockdown attenuated phosphorylation of $p16^{INK4A}$, p53 and p21, leading to a diminished cellular senescence.

Conclusions: GSK3β plays a key role in glomerular aging by regulating podocyte senescence, and thus is likely an actionable senostatic target for delaying glomerular aging.

FR-PO953

APOL1 Renal Risk Variants Induce Disruption in APOL1-miR193a Axis Through Downregulation of Vitamin D Receptor

Vinod Kumar,[1] Alok Jha,[1] Xiqian Lan,[1] Harsha Adnani,[2] Maleeha Qayyum,[4] Sushma Chinnapaka,[4] Ashwani Malhotra,[3] Pravin C. Singhal.[1] *[1]Feinstein Institute for Medical Research, Manhasset, NY; [2]Medicine, Feinstein Institute of Research, Manhasset, NY; [3]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [4]Northwell health, Hicksville, NY.*

Background: APOL1-miR193a Axis has been demonstrated to play a vital role in the maintenance of podocyte molecular phenotype. Both APOL1G0 (wild-type) and miR193a inversely regulate each other. However, APOL1 renal risk variants ([RRVs], G1 and G2) upregulated instead of downregulation of miR193a expression in podocytes. Recent reports indicate that Vitamin D Receptor agonist (VDA) downregulates miR193a expression in podocytes. We hypothesize that APOL1RRVs enhance degradation of Vitamin D Receptor (VDR) and that would enhance the expression of miR193a in podocytes. VDR heterodimerizes with RXR and VDR-RXR binds on the gene promoter.

Methods: Immortalized human podocytes stably expressing vector (V-podocytes), APOL1G0 (G0-podocytes), APOL1G1 (G1-podocytes), and APOL1G2 (G2-podocytes) were differentiated. Proteins and RNAs were extracted. Protein blots of V-podocytes, G0-, G1-, G2-podocytes were probed for APOL1, VDR, and GAPDH (n=6); cDNAs were amplified for VDR; RNAs were assayed for miR193a. Bioinformatics studies suggested that VDR binds at miR193a gene. To validate the binding of VDR and RXR on miR193 promoter, ChiP assay was carried out. To determine the role of proteasomal degradation, V-, G0-, G1-, and G2-podocytes were incubated in media containing either vehicle or MG132 (10 nM) for 48 hours (n=4); protein blots were probed for APOL1, VDR, and GAPDH. Podocytes were transfected with either scrambled or VDR siRNA; protein blots were probed for VDR and GAPDH; RNAs were assayed for miR193a.

Results: G0-podocytes displayed enhanced ($P<0.05$) APOL1 and VDR but attenuated ($P<0.05$) expression of miR193 when compared to V-podocytes. In contrasts, G1- and G2-podocytes showed decreased ($P<0.05$) VDR but enhanced ($P<0.01$) expression of miR193a when compared to V- and G0 podocytes. MG132-treated G1- and G2-podocytes showed an increased expression of VDR vs. only vehicle treated G1-and G2-podocytes. Podocytes silenced for VDR displayed enhanced miR193a expression. ChiP assay revealed binding of VDR and RXR at miR193a promoter.

Conclusions: APOL1RRVs enhance miR193a expression in podocytes through downregulation VDR.

Molecular Mechanisms Underlying the GRK4 65L-Mediated Hypertension in Mice

Selim Rozyyev,[1] Prasad Konkalmatt,[1] Van Anthony M. Villar,[1] Laureano D. Asico,[2] Megha Kumar,[1] Pedro A. Jose,[2] Ines Armando.[1] *[1]George Washington University, Washington, DC; [2]George Washington University School of Medicine and Health Sciences, Washington, DC.*

Background: The genetic causes of salt sensitivity and hypertension in humans are not completely understood. The kidney plays a preeminent regulatory role in water and electrolyte balance and blood pressure (BP) homeostasis. The renal dopamine receptors, D_1R and D_3R, engender natriuresis via the inhibition of renal Na^+ transport, whereas the angiotensin II type 1 receptor (AT_1R) does the opposite. The renal paracrine inhibition of Na^+ transport by dopamine is impaired in salt-sensitive rats, mice, and humans. Agonist activation promotes the phosphorylation of D_1R and D_3R by the G protein-coupled receptor kinase type 4 (GRK4), whose gene variants impair D_1R and D_3R activity.

Methods: To demonstrate the specific renal causal mechanisms in GRK4 65R>L-mediated hypertension, we heterologously expressed the *GRK4 65R>L vs. GRK4 wild-type* (WT) transgenes in the kidneys of *Grk4* knockout mice on normal salt diet. The transgenes were delivered selectively into the renal tubules by the bilateral retrograde ureteral infusion of AAV-9 vectors.

Results: The renal tubule-restricted expression of *GRK4 65R>L* increased the BP (117±4 *vs*. 93±1 mm Hg, P<0.05, n=4), while that of the *GRK4 WT* only tended to increase the BP (105±6 *vs*. 96±2 mm Hg, n=5), indicating that the presence of the GRK4 variant in the kidney caused the increase in BP. We next evaluated the renal expression profiles of select genes. We found that the expressions of the pro-natriuretic D_1R (0.81±0.01 *vs*. 1.28±0.04, P<0.01) and D_3R (0.44±0.02 *vs*. 1.27±0.07, P<0.01) were decreased. By contrast the expressions of the anti-natriuretic Na^+/K^+-ATPase (1.14±0.024 *vs*. 1.0 ±0.007, P<0.05) and a-ENaC (1.4±0.14 *vs*. 1.0±0.11, P<0.05) were increased, demonstrating the mechanistic changes that underlie the hypertension in these mice. Interestingly, we also observed that the expressions the AT_1R (0.82±0.02 vs. 1.02±0.02) and the proximal tubule Na^+ transporters NaPi2 (0.81±0.02 *vs*. 1.04±0.02), SGLT2 (0.89±0.03 *vs*. 1.07±0.05), and NBCe2 (0.50±0.07 *vs*. 1.15±0.03), were decreased, which may represent insufficient compensatory mechanisms against the increase in BP

Conclusions: Our results highlight the underlying and compensatory renal mechanisms for the hypertension that developed in mice with either kidney-restricted or globally expressed *GRK4 65R>L*.

FR-PO955

The Differential Expression Research of Circular RNAs in Exosomes from Serum and Urine in Systemic Lupus Erythematosus Patients

Hualin Ma. *Shenzhen People's Hospital, Shenzhen, China.*

Background: To further explore the pathogenesis of SLE, the technique of gene-sequencing was used to analyze the differentially expressed circular RNAs (circRNAs) in exosomes both from serum and urine of patients with SLE, which may lay the foundation for the research of circRNAs as a new class of exosome-based SLE diagnosis biomarkers.

Methods: Ten patients with SLE (SLE group) and ten normal controls (NC group) were recruited as experimental subjects in our research. The serum and urine were separated from each participant's peripheral venous blood and early morning urine, which the exosomes were extracted from the collected serum and urine by the ExoQuick Exosome Precipitation Solution and ultracentrifugation. Then the pure circRNAs were extracted from the exosomes with a series of enzymatic reactions. And then, the significantly differentially expressed circRNAs were picked out by the method of gene-sequencing to analyze the function of corresponding target genes.

Results: Compared with normal controls, the species of circRNAs were reduced in the exosomes from serum of patients with SLE, which were mostly originated from intron gene regions; Meanwhile, a total of 121 circRNAs were significantly differentially expressed, which were also mostly derived from intron gene regions, including 54 up-regulated and 67 down-regulaed. But the species were increased in the exosomes from urine of patients with SLE compared with normal controls, and which were mainly originated from intron gene regions; Simultaneously, a total of 14 circRNAs were significantly differentially expressed, which were primarily belonged to intron gene regions, including 7 up-regulated and 7 down-regulaed. Compared with the circRNAs detected from urinary exosomes, a total of 52 circRNAs were significantly differentially expressed in the exosomes from serum of patients with SLE, which were also mostly originated from intron gene regions, including 45 up-regulated and 7 down-regulaed.

Conclusions: The significantly differential and specific expression of circRNAs in the exosomes from serum and urine of patients with SLE were found. Such as gene snoU13, SNORA31 and SNORA51 could be regarded as potential diagnostic biomarkers of SLE. Furthermore,these figures suggested that the significantly differentially expressed circRNAs can be used as a reference or a supplement in the research of the pathogenesis of SLE.

FR-PO956

Proteomics of Human Glomerulonephritis by Laser Microdissection and Liquid Chromatograph-Tandem Mass Spectrometry (LMD-LC MS/MS)

Naoto Kawata,[1] Dedong Kang,[3] Kiyoko Inui,[1] Takanori Shibata,[3] Ashio Yoshimura,[2] Kazuho Honda.[4] *[1]Showa University Fujigaoka Hospital, Yokohama, Japan; [2]Shinyokohama Daiichi Clinic, Yokohama, Japan; [3]Showa University, Tokyo, Japan; [4]Showa University, Tokyo, Japan.*

Background: Laser microdissection and liquid chromatograph tandem mass spectrometry (LMD-LC MS/MS) methods enable us to analyze the proteins from the tissue sections. In nephrology, they are preferentially applied in the diagnosis of abnormal protein deposition diseases, such as amyloidosis. In this study, we applied this method to the renal biopsy specimens obtained from the patients with IgA nephropathy(IgAN) and idiopatic membranous nephropathy(MN) to investigate its usefulness for the diagnosis and pathophysiological understanding of human glomerular diseases.

Methods: The 0.3mm^2 of glomerular tissue were dissected by LMD from 10μm-thick sections of renal biopsy specimens obtained from five patients with IgA nephropathy, membranous nephropathy and kidney transplant donor, respectively. The samples were analyzed by LC-MS/MS and the results were investigated to clinical and histological findings.

Results: From the control glomeruli, more than 300 types of proteins such as cytoskeleton proteins, nuclear related proteins, Extracellular Matrix(ECM) related proteins and enzymes were identified. In addition to IgA1 and C3, IgAN showed significant increases in the factors related to oxidative stress and cell proliferation, such as heat shock protein 70/71/90, peroxiredoxin, and elongation factor 1α, as compared to controls. In MN, the proteins such as IgG1, IgG4, C3, C4a, and phospholipase-A2-Receptor(PLA2R) were significantly elevated compared to controls.

Conclusions: By applying LMD-LC MS/MS method to renal biopsy specimens, it was possible to identify the pathognomonic proteins for the diagnosis of IgAN and MN as well as immunohistochemistry. Furthermore, we identified the several factors involved in the pathogenesis of glomerular diseases. Although further investigation is necessary, it seems that the proteomics of glomerular proteins analyzed by LMD-LC MS/MS is a promising method for the diagnosis and pathophysiological understanding of human glomerulonephritis.

FR-PO957

JNK-Associated Leucine Zipper Protein (Jlp) Protects Against Renal Fibrosis by Counteracting TGF-Beta1-Induced Profibrotic Effects and Autophagy on Renal Tubular Epithelial Cells

Huiming Wang. *Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, China.*

Background: Renal fibrosis is a process involving a wide range of cells and molecules and is controlled by both profibrotic and antifibrotic forces. TGF-β1 has been identified as the primary driver of renal fibrosis, but direct targeting TGF-β1 in clinical trials has yielded no promising therapeutic effects. In this study, we identified the JNK-associated leucine zipper protein (Jlp) as a novel endogenous antifibrotic factor.

Methods: We studied the role of JLP in regulating the progress of renal fibrosis in vivo using the UUO mice model with jlp wildtype, jlp deficient, as well as jlp overexpression genotype, and explore the molecular mechanism in vitro on the tubular epithelial cells.

Results: We found that Jlp was predominantly expressed in renal tubular epithelial cells (TECs) in human or mouse kidneys in normal conditions, whereas Jlp was downregulated in fibrotic kidneys, including in kidneys of unilateral ureteral obstruction (UUO) mouse model and in kidneys of advanced CKD patients. In UUO mouse model, global or TECs-specific deletion of Jlp resulted in more severe lesion of kidney fibrosis, whereas TECs-specific transgenic expression of Jlp brought about the beneficial effects of fibrosis resistance. The protective role of Jlp in renal fibrosis could be ascribed to its potentials of overall counteracting the profibrotic effects induced by TGF-β1 through negatively regulating TGF-β1 expression, counteracting TGF-β1 induced ECM production, epithelial-to-mesenchymal transition (EMT), apoptosis, cell cycle arrest, and autophagy in TECs. The protective effects of Jlp could be compromised by its downregulation mediated by TGF-β1 and FGF-2 but not the inflammatory factor TNFα, implying that kidney fibrosis is a consequence of unbalanced forces of profibrotic factor TGF-β1 and FGF-2 and antifibrotic factor Jlp.

Conclusions: JLP is a novel endogenous antifibrotic molecule in renal fibrosis.

FR-PO958

A Novel Conductive Polymer-Based Biosensor for Ultrasensitive Detection of Biomarkers in Lupus Nephritis

Tianfu Wu. *University of Houston, Houston, TX.*

Background: Lupus is a systemic autoimmune disease that immune system can attack the organs and tissues, partiuclarly kidney causing highly mortality and co-morbidity. Unfortunately there is not a non-invasive diagnostic tool for lupus nephritis (LN). Recent studies have shown that urinary biomarkers are promising in LN diagnosis. However, since the concentration of biomarkers in urine sample is low, most the current assays are not optimial in detecting specific urinary biomarkers for LN due to their low sensitivity.

Methods: In this study, we developed a novel biosensor based on human thrombin aptamer-functionalized conductive gel-nanoparticle with poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) nanowires which could capture and concentrate low-abudant biomarkers, causing a binding-induced shrinkage of the gel nanoparticles, which could lead to a conductance change of the biosensor and subsequent signal amplification.

Results: By using Atomic-force microscopy (AFM), the topography and height profiles of the polymeric sensor were recorded and to analyze polymeric network shrinkage in response to PBS or Thrombin. Urinary thrombin levels were quantitatively analyzed through monitoring the conductance change caused by polymeric network shrinkage upon the aptamer-thrombin binding. A significant shrinkage of 18.14% of the biosensor was observed after biomarker recognition. The limit of detection (LOD) of the conductive gel-nanoparticle biosensor for human urine thrombin sample could reach 4.82×10^{-16} M. This thrombin-specific biosensor and a commercial human thrombin enzyme linked immunosorbent assay (ELISA) kit were used to perform side-by-side measurement of urinary thrombin in LN samples. The result obtained from the same patient using sensor or ELISA were used for pair test of correlation, and a strong correlation with a R^2 value of 0.97 was found between the sensor and ELISA. The results indicate that this conductive gel-nanoparticle biosensor is highly sensitive and selective in accurately differentiate LN from healthy controls using urinary thrombin as a biomarker ($P < 0.001$).

Conclusions: Collectively, this novel ultrasensitive conductive gel-nanoparticle biosensor may hold promise in biomarker detection and diagnosis of LN.

Deficiency of the Atypical Chemokine Receptor 2 (ACKR2) Accelerates Progression of Nephrocalcinosis-Related CKD

Alexander Blaut, Nuru Eltrich, Hans J. Anders, Shrikant R. Mulay, Volker Vielhauer. *Nephrologisches Zentrum, Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Ludwig-Maximilians-University Munich, Munich, Germany.*

Background: Primary and secondary hyperoxaluria lead to deposition of calcium oxalate crystals in the kidney, i.e. nephrocalcinosis. Calcium oxalate-induced necroinflammation is an important mechanism of kidney injury in nephrocalcinosis. The atypical chemokine receptor 2 (ACKR2) is a chemokine decoy receptor expressed in the tubulointerstitium, which scavenges inflammatory CC-chemokines and reduces renal inflammation in chronic kidney disease models. We therefore hypothesized that ACKR2 limits renal inflammation and fibrotic tissue remodeling in nephrocalcinosis-related chronic kidney disease and slows progression to end-stage renal failure.

Methods: Chronic oxalate nephropathy was induced in wild-type and Ackr2-deficient (Ackr2-/-) mice by feeding an oxalate-rich and calcium-depleted diet. Renal functional decline was monitored by measurement of glomerular filtration rates in weekly intervals until day 14. Renal injury, inflammation and fibrosis were assessed at day 14.

Results: Compared to wild-type, Ackr2-/- mice showed increased mortality following induction of oxalate nephropathy. Renal function declined more rapidly in Ackr2-/- mice, leading to end-stage renal failure until day 14. Tubular injury was worse in Ackr2-/- mice. Tubulointerstitial infiltrates of granulocytes and mononuclear phagocytes, but not T cells increased in Ackr2-/- kidneys. Moreover, Ackr2 deficiency aggravated renal inflammation, with increased expression of the inflammatory chemokine CCL2 and enhanced accumulation of CCR2+ inflammatory macrophages. Renal expression of annexin II and CD44, which mediate adhesion of calcium oxalate crystals to tubular epithelial cells, was increased in Ackr2-/- mice. This may contribute to more extensive crystal deposition present in Ackr2-/- kidneys despite comparable calciuria and oxalate levels to wild-type. More severe renal injury and inflammation in Ackr2-/- mice was paralleled by aggravated renal fibrosis, as revealed by increased expression of extracellular matrix molecules, renal accumulation of myofibroblasts and enhanced infiltration of bone marrow-derived fibrocytes.

Conclusions: This data suggest that ACKR2 limits renal inflammation, calcium oxalate deposition, tubular injury and renal fibrosis in nephrocalcinosis, and thus slows progression to end-stage kidney disease.

Assessment of Urinary Microparticles in Aristolochic Acid-Induced Nephropathy in Wild-Type and GPR40 Receptor Knockout Mice

Thalia Medeiros,[2,1] Jean-Francois Thibodeau,[2,3] Amélie Blais,[2] Chet E. Holterman,[2] Andréa A. Silva,[1] Jorge Reis Almeida,[1] Vera A. Tang,[4] Marc-Andre Langlois,[4] Chris R. Kennedy,[2,4] Lyne Gagnon,[3] Dylan Burger.[2,4] *[1]Faculty of Medicine, Universidade Federal Fluminense, Niteroi, Brazil; [2]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada; [3]ProMetic BioSciences Inc., Laval, QC, Canada; [4]University of Ottawa, Ottawa, ON, Canada.*

Background: Urinary microparticles (MP) are novel non-invasive biomarkers of renal injury. However, the dynamics of MP release in AKI/CKD are not well understood. We questioned whether urine MPs are generated early in disease and how their levels change as disease progresses. Lastly, we determined whether urine MP levels are altered in mice with deletion of the protective, anti-fibrotic Gpr40 receptor.

Methods: 8 week-old male [wild type (WT) or Gpr40$^{-/-}$] mice were subjected to aristolochic acid nephropathy (AAN) via four consecutive daily injections (3.5mg/kg, ip). Renal function was assessed by plasma creatinine measured (HPLC) at days -4, 4, 11 and 28 days post-AAN. At endpoint, tubulointerstitial injury was assessed histologically. Total urine MPs were measured using nanoparticle tracking analysis (NTA) and nanoscale flow cytometry. Podocyte derived MPs (Annexin V^{+}/Podoplanin^{+}) were quantified by flow cytometry. Finally, mouse proximal tubule epithelial cells (PTECs) were treated with aristolochic acid (50 μM) and formation of MPs was quantified by NTA.

Results: AAN was associated with albuminuria, decline in renal function and anemia. NTA and flow cytometry revealed that both total and podocyte-derived MPs were increased at day 4 and progressively decreased until day 28. The drop in MP levels were associated with tubular interstitial fibrosis, tubular dilatation and inflammatory cell infiltration. At endpoint, plasma creatinine was significantly increased in Gpr40$^{-/-}$ vs. WT mice and this was associated with higher levels of total MPs (P<0.05 at day 4). Finally, PTECs treated with AA exhibited a ~3-fold increase in MP formation at 24h (P=0.01).

Conclusions: Taken together, our data suggest that the dynamics of MP release by glomerular and tubular cells changes according to the progression of kidney disease. Gpr40 deletion is associated with increased early MP levels and impaired function at endpoint. The increased early MP levels may be indicative of greater injury compared with WT leading to increased functional decline.

RNA Sequencing in Proximal Tubule Cells Reveals Lack of Expression of Proximal Tubule Markers

Syed J. Khundmiri,[1] Lihe Chen,[2] Eleanor D. Lederer,[3] Mark A. Knepper.[4] *[1]Howard University College of Medicine, Washington, DC; [2]NIH, Bethesda, MD; [3]University of Louisville; Robley Rex VA Medical Center, Louisville, KY; [4]National Heart Lung and Blood Institute, Kensington, MD.*

Background: There are close to 12 different immortalized cell lines available commercially or from other sources that are being used as models of renal proximal tubule cells. There is strong need to characterize these cells so as to establish their lineage and help the scientific community at large to make decisions regarding their suitability in experiments. Our goal is to characterize the cell lines using RNA-Seq.

Methods: To accomplish this goal, we grew 5 different human cell lines, one mouse, three rat, and 2 opossum kidney cell lines on Transwell filters using the recommended culture media. RNA-Seq was performed using Illumina kits following the manufacturer's protocol. The RNA-Seq was compared to a mouse S1 proximal tubule data. The data are presented as expression rank with the rank above 8000 as negative expression. To validate the data a native S1 proximal tubule cell line was used as a positive control.

Results: Results are shown in the Table.

Conclusions: Our data suggest that the available human and rat kidney tubule cells are epithelial cells (express occludin and claudins) but not of proximal tubule origin (lack sodium-dependent transporters, megalin and PTH receptor). Although, LLC-PK1 cells express the proximal tubule specific proteins, they also express markers of cortical tubule cells. These are therefore a mixed population and not specific proximal tubule cells. The opossum kidney cells express all the markers of proximal tubule cells and thus are the only cell of proximal tubule origin.

Funding: Other NIH Support - NHLBI, AHA, Private Foundation Support

Tacrolimus Ameliorates Podocyte Injury by Restoring FK506 Binding Protein 12 (FKBP12) at Actin Cytoskeleton in Injured Podocyte

Hidenori Yasuda,[1] Yoshiyasu Fukusumi,[2] Ying Zhang,[3] Hiroshi Kawachi.[4] *[1]Kidney Research Center, Niigata University, Niigata, Japan; [2]Dept. Cell Biology, Kidney Research Center, Niigata University, Niigata, Japan; [3]Niigata University, Japan, Niigata, Japan; [4]Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: FKBP12 was identified as a binding protein of Tacrolimus (Tac). Tac binds to FKBP12 and exhibits immunosuppressive effect through inhibition of calcineurin (CN) activity in T cells. It is reported that Tac treatment directly ameliorates the dysfunction of podocyte by inhibiting the activation of NFAT, a substrate of CN in nephrotic syndrome. We reported that FKBP12 is expressed in glomerular podocyte and the altered expression of FKBP12 is involved in the development of podocyte injury. However, the precise pharmacological mechanism of Tac in podocyte injury was not well understood yet.

Methods: The protein expression of FKBP12 was investigated with western blot and the localization was analyzed with dual label immunostaining in human cultured podocytes. The localization of NFATC3 was also investigated.

Results: FKBP12 was detected both in cytoplasm and along actin cytoskeleton in normal human cultured podocytes. These FKBP12 stainings were decreased in the cultured podocytes treated with Adriamycin (ADR). Tac treatment restored the FKBP12 at actin cytoskeleton. The expression of FKBP12 at the actin cytoskeleton was increased by the Tac treatment to normal cultured podocytes. The western blot analysis showed the protein expression of FKBP12 was decreased in the podocytes with ADR (43.9% to normal, P<0.005). Tac treatment suppressed the decrease (80.5%). The FKBP12 expression of the cells treated with Tac only was 78.7%. NFATC3 staining in nucleus was increased in the podocytes with ADR. Tac treatment partially reduced the nuclear accumulation of NFATC3 in the ADR-treated cells. 27.5% of the cells showed multiple processes with positive actin staining in normal cultured podocytes. The proportion of the cells forming the processes to total cells was decreased in the podocytes treated with ADR (17.5%, P<0.05 vs. normal). Tac treatment suppressed the decrease in ADR (38.1%, P<0.05 vs. no treatment). Tac treatment to normal cells increased the proportion of the cells forming processes (55.7%, P<0.005 vs. normal).

Conclusions: The proper localization of FKBP12 at the actin cytoskeleton participates in the maintenance of process formation. Tac treatment ameliorates podocyte injury by restoring FKBP12 at actin cytoskeleton in injured podocyte.

Funding: Government Support - Non-U.S.

FR-PO963

Expression of Acsm2, a Kidney Specific Gene, Parallels the Structural and Functional Maturity of Proximal Tubular Cells

Hirofumi Watanabe, Robert L. Paxton, Maria Luisa S. Sequeira Lopez, Roberto Ariel Gomez. *Department of Pediatrics, Child Health Research Center, University of Virginia School of Medicine, Charlottesville, VA.*

Background: Acyl-CoA synthetase medium-chain family member 2 (Acsm2) gene was first identified and cloned by our group as a kidney specific "KS" gene. Acms2 may participate in fatty acid metabolism and glycine conjugation pathways. However, little has been reported on *Acsm2*, and the expression pattern and function of it remain to be clarified.

Methods: The expression pattern of *Acsm2* was investigated with RT-PCR using RNA extracted from multiple organs of adult C57BL/6 mice and kidneys at multiple age. Immunohistochemistry for Acsm2 was performed in kidney or liver tissue sections. *In situ* hybridization was performed using digoxigenin-labeled RNA probes for mRNA of *Acsm2*. We also investigated the kidneys from mice subjected to partial unilateral ureteral obstructions (pUUO) and chronic kidney disease (CKD) with total renin gene knockout or conditional knockout of integrin beta 1 gene in cells from the renin progeny using aforementioned methods. Data from the Encyclopedia of DNA Elements (ENCODE) project was analyzed to examine the epigenetic state at *Acsm2* locus in each organ of mice.

Results: We found that *Acsm2* was expressed in the kidney samples at high level. The expression of *Acsm2* in the liver was less than 1/10,000 of the expression in the kidney. No other organs tested expressed *Acsm2*. Immunohistochemistry and *in situ* hybridization revealed that *Acsm2* was highly expressed in the proximal tubular cells in normal adult mice. In contrast, Acsm2 was not detected in liver. The expression level of *Acsm2* in kidneys was at a low level in newborn mice, increased with development, and reached a plateau by 2 months of age. With pUUO and CKD, the expression of *Acsm2* in the proximal tubules was significantly decreased according to the severity of the renal impairment. Analysis using ENCODE database revealed that *Acsm2* locus in mice has specific histone modifications that are related to the active enhancer and promoter and transcription only in kidney cells.

Conclusions: The Acsm2 gene is specifically expressed in proximal tubules, and not in other tissues. The expression of *Acsm2* parallels the structural and functional maturation of proximal tubular cells. Downregulation of its expression in several models of kidney disease suggests that *Acms2* may serve as a novel marker of proximal tubular injury and/or dysfunction.

Total Extracts of Single Chinese Medicine Herb Attenuates Renal Tubule Injury via Suppression of ERK1/2-Mediated NLRP3 Inflammasome Activation

Wei Li,[2,1] Ping Xia,[2,1] Yao Zhou,[3] Wei Sun,[1] Kun Gao.[1] *[1]Nephrology Division, Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, China; [2]Nanjing University of Chinese Medicine, Nanjing, China; [3]Xuzhou Medical University, Xuzhou, China.*

Background: *Abelmoschus Manihot* (Linnaeus) Medik. is an herb used in traditional Chinese medicine to treat some kidney diseases. The chemical constituents in the plant are mainly flavonoids, organic acids, steroids and volatile compounds. Five flavonoids, hyperoside, myricetin, quercetin, isoquercitrin, and rutin, have been determined to be the major pharmacologically bioactive components via high-performance liquid chromatography (HPLC) that simultaneously quantifies the flavonoid compounds of *Abelmoschus Manihot* L. flower. To date, the detailed mechanisms by which *Abelmoschus Manihot* L. improves some kinds of renal disease are not fully understood. Our previous study showed that *Abelmoschus Manihot* L protects podocyte and reduce proteinuria *in vivo*.

Methods: In this study, we established Adriamycin-induced NRK-52E cells, the normal rat kidney epithelial cell line, and Sprague-Dawley rats with Adriamycin-induced nephropathy to evaluate the role and mechanisms of total extracts of *Abelmoschus Manihot* L. flower (TEA) on tubular cell both *in vitro* and *in vivo*.

Results: In Adriamycin-induced nephropathy rat model, TEA decreased proteinuria and attenuated renal tubule lesions. Interestingly, NLRP3 was increased mostly in tubule not in glomeruli and TEA inhibited the expression of NLRP3 in tubules. In vitro study, TEA ameliorated Adriamycin-induced cellular morphological changes, cell viability, and apoptosis through the suppression of protein oxidation and ERK1/2 signaling. However, this anti-oxidative stress role of TEA was independent of ROS inhibition. Adriamycin activated ERK1/2 signaling followed by activation of NLRP3 inflammasomes. TEA suppressed NLRP3 inflammasomes via inhibition of ERK1/2 signal transduction.

Conclusions: TEA protects renal tubular cells against toxity of Adriamycin via inhibition of ERK1/2-NLRP3 inflammasomes.

High-Throughput Determination of Aminoglycoside Antimicrobials in Human Plasma by Hydrophilic Interaction Liquid Chromatography Mass Spectrometry

Shinya Omiya,[4,1] Xiao-Pen Lee,[1] Takeshi Kumazawa,[3,1] Naoto Kawata,[4] Tomoaki Miyazaki,[4] Kiyoko Inui,[4] Yoshihiko Inoue,[4] Ashio Yoshimura,[2,4] Fumihiko Koiwa.[4] *[1]Showa University Department of Legal medicine, Tokyo, Japan; [2]Shinyokohama Daiichi Clinic, Yokohama, Japan; [3]Seirei Christopher University, Shizuoka-ken, Japan; [4]Division of Nephrology, Department of Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan.*

Background: Aminoglycoside antibiotics can cause acute kidney injury (AKI) due to tubular necrosis in a dose-dependent manner. Therefore, a qualitative and quantitative method for determining AG antibiotics in blood must be useful in prevention of AKI.

Methods: We developed a simple and rapid method for the analysis of six AG antibiotics, such as streptomycin, ribostamycin, kanamycin, amikacin, dibekacin, and arbekacin, in human plasma samples by hydrophilic interaction liquid chromatography (HILIC)-tandem mass spectrometry (MS/MS). Each sample was 50μl of plasma.

Results: All drugs showed base peaks due to [M+H]+ ions by HILIC-MS with positive ion electrospray ionization, and the product ions were produced from each [M+H]+ ion by HILIC-MS/MS. Quantitation was performed by selective reaction monitoring using each base peak of product ions of HILIC-MS/MS. Good peak shapes of the six drugs were achieved within an analysis time of 1.4 min. All drugs spiked into plasma showed recoveries of 23-77% and extraction efficiencies of 72-105%. The regression equations for the antibiotics showed excellent linearity with the limits of quantitation of 3.9-16 μg/ml. The intra- and inter-day relative standard deviations for all drugs were not greater than 19%. The accuracies of quantitation were 80-114%. Streptomycin and kanamycin in human plasma after intramuscular administration of the drugs could actually be determined.

Conclusions: A simple and rapid method was developed for the analysis of six AG antibiotics in human plasma by HILIC-MS/MS. This method seem to be useful for determining AG antibiotic residues in the edible tissues of livestock in addition to human plasma. therefore, it will be widely used in patients with kidney dysfunction *who need administration of AG.*

FR-PO966

A Modified Ellipsoid Formula for Estimating Total Kidney Volume

Kristen Chao,[1] Kimberly Liao,[1] Maheen Khan,[1] Itzhak D. Goldberg,[2] Prakash Narayan.[2] *[1]Angion, Uniondale, NY; [2]Angion Biomedica Corp., Uniondale, NY.*

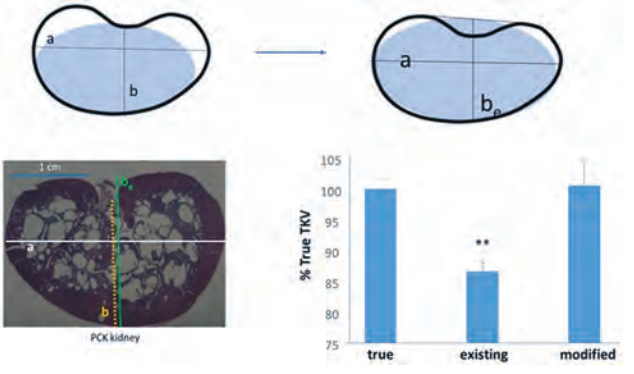
Background: Total kidney volume (TKV) informs progression of polycystic kidney disease, enables matching of donor organ to recipient, and surgical management of kidney tumors. The existing ellipse-based formula underestimates TKV by as much as 30%. We have reported (https://doi.org/10.1371/journal.pone.0190815) a modified ellipse-based formula to better estimate renal parenchymal area by extending the minor axis to the renal hilum. We sought to determine whether this modified formula better informs TKV.

Methods: PKC and Sprague-Dawley rats were used as kidney donors. True TKV was determined by the formalin displacement method. Renal thickness (t) was measured by a pair of Vernier calipers. Kidneys were then cut coronally and photographed. Treating the coronal section as an ellipse, the major axis (a), the minor axis (b) and the extender minor axis (b_e) were measured. TKV was calculated by entering t, a and b or b_e into an ellipsoid formula.

Results: Compared to true TKV, use of the existing formula underestimated calculated TKV by 14% (n=6, **, p<0.01). By contrast, there was no difference between true TKV and TKV calculated using the modified formula.

Conclusions: Use of a modified ellipsoid formula more accurately estimates TKV and has important ramifications for clinical management of polycystic kidney disease, kidney transplant, and surgical resection of renal tumors.

Funding: Private Foundation Support



Treating the kidney as an ellipse and extending the minor axis into the hilum provides a better estimate of renal dimensions. The existing formula underestimated TKV significantly in healthy and PKC rats whereas use of the modified formula provided an estimate of TKV no different than true or measured TKV.

FR-PO967

Kidney Injury Enhances Renal Granulocyte-Colony Stimulating Factor Expression, Granulopoiesis, and Human Neutrophilic Granulocyte Proteinase 3 Receptor CD177 Expression

Julia Volkmann,[1] Jessica Schmitz,[1] Alexandra Helmke,[1] Payel Sen,[2] Jan H. Braesen,[2] Wanja Bernhardt,[4] Stephan Immenschuh,[1] Wilfried Gwinner,[3] Roland Schmitt,[2] Hermann G. Haller,[1] Sibylle Von Vietinghoff.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Medizinische Hochschule Hannover, Hannover, Germany; [3]Medical School Hanover, Hannover, Germany; [4]Heidering Dialysis clinic, Hannover, Germany*.

Background: Acute kidney injury causes significant systemic adverse events beyond retention of uremic waste and volume expansion, mechanisms of which are incompletely understood. Neutrophilic granulocytes, the most abundant human blood leukocytes, are characterized by a high turnover rate. They are chiefly controlled by granulocyte colony stimulating factor (G-CSF), which can be produced by diverse cell types. The impact of kidney injury on G-CSF production and granulopoiesis has not been determined.

Methods: Renal G-CSF expression in murine experimental kidney injury and after human kidney transplantation was assessed by immunostaining and qPCR. Neutrophils were characterized by flow cytometry in mice with experimental kidney injury, patients with chronic kidney disease, before and after kidney transplantation and in healthy controls. Human cell culture was employed for mechanistic experiments.

Results: In murine experimental ischemia reperfusion injury and unilateral ureteral obstruction, renal G-CSF mRNA and protein increased and characteristics of emergency granulopoiesis developed in bone marrow and blood. In humans, G-CSF and kidney transplantation similarly transiently elevated human neutrophil expression of CD177, a highly G-CSF responsive neutrophil gene. In kidney graft recipients, the rise in CD177 correlated with renal tubular G-CSF expression. In contrast, CD177 was unaltered in patients with chronic renal impairment independent of renal replacement therapy. As possible underlying mechanisms, hypoxia and proinflammatory cytokine interleukin 17A enhanced G-CSF expression in human renal tubular epithelial cells, while complement activation promoted G-CSF in endothelium.

Conclusions: Our data demonstrate induction of renal G-CSF and modulation of granulopoiesis after kidney injury. They delineate differential G-CSF regulation in renal epithelium and endothelium. Altered granulopoiesis may contribute to the distant effects and possibly prognostic role of kidney injury.

Integration of Spatial Metabolomics to Single-Nucleus Droplet-Based Sequencing Data Identifies New Glomerulus-Specific Gene Markers

Guanshi Zhang,[1] Dusan Velickovic,[2] Annapurna Pamreddy,[1] Blue Lake,[3] Viktor Drel,[1] Dharam Kaushik,[1] Shweta Bansal,[1] Manjeri A. Venkatachalam,[1] Ljiljana Pasa-Tolic,[2] Theodore Alexandrov,[4] Christopher R. Anderton,[2] Kumar Sharma.[1] for the KPMP Consortium *[1]University of Texas Health San Antonio, San Antonio, TX; [2]Pacific Northwest National Laboratory, Richland, WA; [3]University of California San Diego, La Jolla, CA; [4]European Molecular Biology Laboratory, Heidelberg, Germany*.

Background: The current study is a part of the NIDDK Kidney Precision Medicine Project (KPMP). We recently cross-validated that a sphingomyelin (SM(d18:1/16:0)) was a glomerulus-enriched marker, as visualized by two independent sites using matrix-assisted laser desorption/ionization-mass spectrometry imaging (MALDI-MSI). To establish integration of data with other Tissue Interrogation Sites (TIS) and technologies, we provided a tabulated list of 48 SM/ceramide metabolism-related gene/enzymes (from KEGG Ontology Database) to results from other TIS sites.

Methods: Two MALDI-MSI platforms (QE-HFX at UTHSA and FTICR at PNNL) were employed to spatially characterize the lipid profile in normal human kidney tissues (n = 6; U. Michigan) at 20-30 μm spatial resolution. 30 different cell types were identified using the single-nucleus droplet-based sequencing (snDrop-Seq) analysis developed by the UCSD-WashU TIS and the SM/ceramide genes were queried across the database. Enrichr software and the Database of Genotypes and Phenotypes (dbGaP) were used for enrichment analysis.

Results: *PLPP3*was identified as one of the few glomerular endothelial cell specific genes and can be added as a gene marker to KPMP Atlas. Furthermore, *PLPP1*was found to be localized to the glomerular endothelial cells and to endothelial cells of AEA and descending vasa recta. Fluorescence microscopy analysis showed that PLPP3 protein is localized within glomeruli but separated from synaptopodin (a podocyte marker). Further enrichment analysis using Enrichr and dbGaP showed that the identified glomerular specific genes are associated with carotid stenosis, diabetic nephropathies, and other phenotypes.

Conclusions: This highlights the value of the untargeted mass spectrometry imaging for linking the spatial metabolomic data to different kidney cells types, and an avenue connect metabolic information to gene expression. Integrated MALDI-MSI and snDrop-Seq data could help identify novel glomerular-specific gene markers.

Protein Phosphatase Mg^{2+}/Mn^{2+}-Dependent 1A (PPM1A) and PTEN Deregulation in Kidney Fibrosis: Novel Mechanisms and Co-Dependency of Expression

Jiaqi Tang,[1] Roel Goldschmeding,[2] Rohan Samarakoon,[1] Paul J. Higgins.[1] *[1]Albany Medical College, Watervliet, NY; [2]University Medical Center Utrecht, Utrecht, Netherlands*.

Background: PPM1A and PTEN emerged as novel suppressors of the TGF-β1 pathway during renal disease. Loss of PPM1A and PTEN, following obstructive renal injury, promoted tubular dysfunction as evident by fibrotic factor deposition, epithelial dedifferentiation and cell cycle arrest. However, the molecular mechanism of PPM1A deregulation in renal fibrosis is unknown. We hypothesize that TGF-β1 orchestrates PPM1A loss of expression and that there is functional collaboration between PPM1A and PTEN during progressive fibrosis.

Methods: A double transgenic mouse model of conditional TGF-β1 renal tubular upregulation (created by crossing Pax8-rtTA with Tet-O-TGF-β1 mice and subsequent doxycycline administration) and the TGF-β1-driven aristolochic acid nephropathy (AAN)-induced renal fibrosis system were employed to determine the role of TGF-β1 in PPM1A deregulation. Human renal epithelial cells (HK-2) and primary kidney fibroblasts (HKFs) with stable PPM1A and PTEN expression or depletion were created to investigate the potential functional interplay among TGF-β1, PPM1A and PTEN.

Results: Renal tubular-specific upregulation of TGF-β1 resulted in tubulointerstitial loss of PPM1A expression 2-3 days post-doxycycline administration in mice. TGF-β1 dramatically attenuated PPM1A and PTEN expression in both HK-2 cells and HKFs via mechanisms involving protein degradation. TGF-β1 promotes ubiquitination of PTEN and PPM1A. A proteasomal inhibitor, MG132 rescued PTEN and PPM1A expression, even in the presence of TGF-β1, along with decreased fibrogenesis. Concurrent loss of PPM1A and PTEN expression in a mouse model of AAN further suggests crosstalk between these repressors. PPM1A stable silencing in HKFs, in fact, resulted in PTEN loss, while PTEN stable depletion decreased PPM1A expression, resulting in a fibro-proliferative response in each case. Transient expression of PPM1A, conversely, increased PTEN protein levels, while PTEN transient induction led to elevated PPM1A expression.

Conclusions: TGF-β1 promotes loss of PPM1A and PTEN expression *in vitro* and *in vivo*. We are the first to uncover the pathological functional cooperation between PPM1A and PTEN as they co-regulate each other's relative abundance, identifying previously unknown links between TGF-β1-repressors in progressive renal injury and CKD.

FR-PO970

The Spectrum of Renal Involvement in Four Murine Models of Multiple Myeloma

Dao-Fu Dai. *University of Iowa, Coralville, IA.*

Background: Approximately 20-50% of multiple myeloma involves kidneys, and additional ~38% of monoclonal gammopathy involves kidney (MGRS). The renal manifestations range from tubulopathies to a spectrum of glomerular diseases that can present with varying degrees of proteinuria and renal dysfunction, to amyloidosis and myeloma cast nephropathy. Although several mouse models of multiple myeloma have been reported, the studies of murine models of myeloma-associated kidney diseases are rather limited.

Methods: We examined renal pathology of four murine models of multiple myeloma (MM): First, mice carrying a human IL-6 Tg driven by the major histocompatibility complex H2-Ld promoter (IL-6), Second, IL6-Tg with concomitant Tg of i-Myc with deregulated expression of the Myc oncogene and enhancers in the IgH locus (designated i-Myc/IL6), Third, IL6-Tg with concomitant Tg of pro-survival oncoprotein Bcl2 (designated Bcl2/IL6), Fourth, xenograft model with mouse myeloma cells injected into KaLwRij strain mice.

Results: All four models of MM demonstrated M-spike paraproteinemia. The presence of second transgene in the IL6-Tg background significantly accelerated and aggravated the tumor burden and progression of MM, which developed at 3-6 months, characterized by paraproteinemia, marked splenomegaly and bone involvement. Light-chain restricted casts with variable acute tubular injury resembling cast nephropathy was present in 50-75% of IL6, i-Myc/IL6 and in Bcl2/IL6 mice. Features suggestive of light chain tubulopathy were present in ~25-50% of these three models. Various glomerular deposits were identified in ~50% of Bcl2/IL6 and ~80% of i-Myc/IL6, but not in the IL6 mice. The spectrum of glomerular involvement ranged from light chain deposition disease to intracapillary paraprotein plugs resembling cryoglobulin or crystalglobulin glomerulopathy. Surprisingly, the xenograft model did not show any significant paraprotein nephropathy, however, myeloma cells infiltration of renal tissue was observed in ~30% of xenograft model. Amyloidosis is not identified in any of the mouse models.

Conclusions: Transgenic IL6 mice develop various paraprotein-associated nephropathies and may serve as good preclinical models of myeloma-associated kidney diseases, to study the molecular pathogenesis and to develop nephroprotective strategies for myeloma-associated kidney diseases.

The Mechanisms of Gadolinium-Based Contrast Agent-Induced Nephrotoxicity

Brent Wagner.[1,2] Kidney Institute of New Mexico [1]*Kidney Institute of New Mexico, Albuquerque, NM;* [2]*Research Service, New Mexico Veterans Administration Health Care System, Albuquerque, NM.*

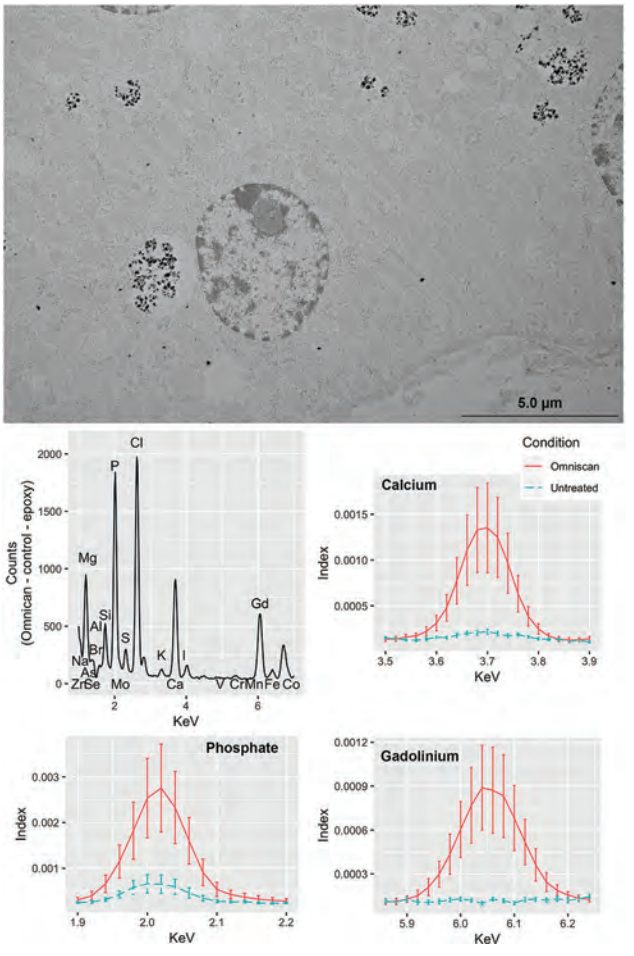
Background: *All classes of gadolinium-based contrast agent* (GBCA) *are nephrotoxic*. This is well accepted from case reports, prospective studies, and prescriber information sheets.

Methods: Generation of chimeric transgenic mice provided a means of tracing myeloid-derived cellularity in the target organs. Groups were randomized to GBCA treatment versus none. Kidney sections were examined with a Hitachi HT7700 with an AMT 16 megapixel camera *and* a Jeol JEM 2010F field emission electron microscope at 200 kV with a GATAN Orius camera and Oxford Analytical ISIS energy-dispersive spectrometer (EDS).

Results: GBCA exposure caused significant renal fibrosis and podocyte injury associated with elevations in plasma creatinine *and* metabolic disorders as evidenced by dyslipidemia. Metabolomic analysis of flash-frozen renal cortex demonstrated that GBCA treatment—*far from being inert*—resulted in glycolytic switching—the Warburg effect—where glycolysis and lactate accumulation *increased* with suppression of the tricarboxylic acid cycle. In the treated group, the electron-dense deposits riddled the glomeruli and vacuoles of proximal tubular cells. By EDS, these contained high quantities of gadolinium ($P < 0.01$), calcium ($P < 0.01$), and phosphate ($P < 0.05$).

Conclusions: We provide the first evidence that GBCAs cause significant metabolic disorders and kidney injury in mice without pre-existent renal insufficiency. Accumulation of non-physiologic lanthanide heavy metals may be leaching phosphorous from lysosomal membranes, catalyzing the formation of calcium phosphates, and thwarting cellular energetics in this manner.

Funding: NIDDK Support, Veterans Affairs Support, Private Foundation Support



Transmission electron microscopy of proximal tubule (top) laden with electron-dense material. Energy-dispersive x-ray spectroscopy of the electron densities minus control and normalized counts in regions for gadolinium, calcium, and phosphate.

CTGF/CCN2 Knockdown Prevents AKI-Induced Cellular Senescence and Subsequent Fibrosis

Floris Valentijn,[2] Laura Marquez-Exposito,[1] Sebastiaan Knoppert,[2] Raúl R. Rodrigues díez,[3] Roel Broekhuizen,[2] Andrew Leask,[4] Roel Goldschmeding,[2] Tri Q. Nguyen,[2] Marta Ruiz-Ortega,[3] Lucas Falke.[2] Renal Pathology UMCU [1]*IIS Fundacion Jimenez Diaz, Madrid, Spain;* [2]*University Medical Center Utrecht, Utrecht, Netherlands;* [3]*Universidad Autonoma, Madrid, Spain;* [4]*University of Western Ontario, London, ON, Canada.*

Background: Acute kidney injury (AKI) involves damage to the tubular epithelium with subsequent accumulation of senescent cells and can progress to fibrosis and chronic kidney disease (CKD). Cellular senescence is characterized by anti-apoptotic and DNA Damage Response (DDR) features, and expression of a Senescence Associated Secretory Phenotype (SASP). Connective Tissue Growth Factor (CTGF/CCN2) is a constituent of the SASP and has been implicated in fibrosis as well as in (paracrine) senescence induction. Therefore we explored the involvement of CTGF and cellular senescence in two models of AKI and subsequent CKD development.

Methods: We subjected wild type (WT) and conditional tamoxifen inducible CTGF-KO mice (CTGF-cKO) to bilateral ischemia reperfusion injury (IRI) and to folic acid (FA) renal injury and studied damage parameters in relation to anti-apoptotic signaling and cellular senescence in the acute and chronic phase of both models.

Results: In WT mice, both IRI and FA induced AKI resulted in upregulation of DDR and anti-apoptosis markers, including yH2Ax, $p21^{CIP1}$ (p21) and the BCL-2 family members BCL-xL and MCL-1. This effect persisted largely in the chronic phase, during which also the expression of $p16^{INK4a}$ together with CTGF and other SASP factors like PAI-1, IL-1β, and IL-6 became markedly upregulated. Furthermore, CTGF expression levels correlated with senescence phenotype, including anti-apoptotic BCL-xL and MCL-1 in the acute phase, SASP factors like PAI-1, IL-1β and IL-6 in the chronic phase, and p21 in both phases. CTGF knockdown protected against acute tubular injury and functional decline in the initial phase of both injury models. Furthermore, DDR- and anti-apoptotic marker expression (p21 and MCL-1) were lower in CTGF cKO than in WT mice. Likewise, in both models tubular atrophy, interstitial fibrosis and functional decline in the chronic phase were less severe in CTGF cKO mice, together with reduced expression of senescence (p21 and MCL-1) and SASP markers (PAI-1, IL-1β and IL-6).

Conclusions: CTGF/CCN2, beyond its known profibrotic role in CKD, is also involved in AKI, possibly by modulating apoptotic and cellular senescence associated pathways. We propose that inhibition of CTGF might be beneficial in AKI and diminish AKI to CKD progression.

FR-PO973

Detection of Urinary MicroRNA Biomarkers Using Diazo Sulfonamide-Modified Screen Printed Carbon Electrodes

Timothy Bowen, Daniel A. Smith, Kate A. Simpson, Lucy J. Newbury, Donald Fraser, James E. Redman. *Cardiff University, Cardiff, United Kingdom.*

Background: We have established RT-qPCR-based protocols for urinary microRNA (miRNA) quantification to determine expression profiles for diabetic kidney disease (DKD) and predict graft function following renal transplantation. In parallel we are developing electrochemical quantification methods, and have demonstrated that urinary miRNA detection by glassy carbon electrode-based biosensors is more sensitive than RT-qPCR. Here we describe development of disposable screen printed carbon electrode (SPCE)-based miRNA sensors that can discriminate between urine samples from DKD patients and controls with similar sensitivity.

Methods: Screen-printed SPCEs were modified by deposition of a diazotised naphthalene sulfonic acid derivative, 4-amino-3-hydroxy-1-napthalene sulfonic acid (ANSA). The ANSA was then transformed into a sulfonyl chloride, before a 5'-amine-tagged DNA oligonucleotide with complementary sequence to the target miRNA was attached via a sulfonamide linkage to complete the biosensor. Analysis of biosensor output was carried out via reductive and oxidative chronocoulometry, obtained by measuring negative and positive potential sweeps using a ferri/ferrocyanide electrolyte, respectively. Selected miRNA readings were compared before and after hybridization in exogenous control miRNA dilution series, and between urine samples from DKD patients and controls.

Results: We demonstrated a linear response for our SPCE sensors across physiologically relevant concentrations of exogenous miR-21, replicating the femtomolar limit of detection from our previous glassy carbon electrode-biosensor studies. Subsequently, our SPCE sensors successfully detected a DKD-associated decrease in miR-192 that we reported previously following RT-qPCR analysis. Using histochemistry and atomic force microscopy analyses throughout the biosensor fabrication process, we observed sequential deposition of sensor components at the electrode surface which demonstrated the desired biosensor composition.

Conclusions: Our disposable electrode-based biosensors have strong potential for use in rapid, highly sensitive miRNA biomarker quantification in urine and other body fluids. In parallel studies we have identified urinary miRNA expression profiles associated with renal pathologies, and are now adapting our technology for clinical testing purposes.

Automated Podocyte Foot Process Width Measurement Using Deep Learning

Behzad Najafian,[1] Forough Sargolzaeiaval,[1] Michael Mauer.[2] *[1]University of Washington, Seattle, WA; [2]University of Minnesota, Minneapolis, MN.*

Background: Increased foot processes (FP) width (FPW) is an important measure of podocyte injury. There is no consensus on how to estimate average FPW. The current gold standard (unbiased stereology) is time consuming and not widely available. We aimed to automate average FPW estimation using deep learning (DL).

Methods: A custom multi-layered deep learning model was trained on a normalized electron-microscopy (EM) dataset of 800 images (augmented 10000+) obtained at ~40,000X. Images were captured using systematic uniform random sampling. Testing was done on 29 new kidney biopsies (30-157 images per biopsy) from patients with Fabry disease and variable proteinuria and pathology severity and a compiles set of images from kidney donors as normal controls. DL FPW measurements were compared with measurements done by an experienced technician using unbiased stereology. Measurements were correlated with available clinical and structural parameters.

Results: The automated report utility substantially reduced the time needed for average FPW measurement per biopsy (<1 min DL vs. 6-8 hours human). The DL model accuracy based on human segmentation as the ground truth on a scale of 0-1 (1=perfect) accuracy was 0.8 for glomerular basement membrane and 0.6 for slits. DL measurements (737±151nm) were ~6.5% smaller (p=0.03) than human measurements (788±194nm), but these two were correlated (r=0.77; p<0.0001). Bland-Altman plot showed that ~94% of DL vs. human differences fell within mean ± 1.96 SD of the differences. Both human and DL showed increased FPW in Fabry patients compared with controls and similar correlations between age and FPW in Fabry patients. Globotriaosylceramide inclusion density in podocytes correlated with DL-measured FPW (r=0.33, p=0.04), but human measurements did not. DL-measured FPW showed a trend with urine protein excretion rate (r=0.31, p=0.058), but human measurements did not. DL showed substantial variability in individual FPW in Fabry patients but not in controls.

Conclusions: DL algorithms while substantially reduced time needed for FPW measurement, provided reasonably accurate data correlating with human stereology measurements and with relevant clinical correlations. In addition, DL readily provided additional information on individual FPW variability which may be useful in podocyte injury assessment in secondary podocytopathies.

Loss of Glomerular Thrombomodulin Precedes Diabetic Nephropathy in Diabetic Patients

Cleopatra C. Van Aanhold, Manon Bos, Ingeborg M. Bajema, Jan A. Bruijn, Hans J. Baelde. *Leiden University Medical Center, Leiden, Netherlands.*

Background: Thrombomodulin (TM) is an endothelial transmembrane protein which regulates vascular homeostasis. Previously, it was demonstrated that TM-mediated protein C activation ameliorates glomerular apoptosis and inflammation in a DN mouse model (Nat Med 2007), indicating that diminished TM levels may contribute to DN. Cleavage of TM is a well-established feature of endothelial cell dysfunction, and serum levels of cleaved TM are increased in DN. Here, we investigate TM expression in glomeruli of patients with DN and in a DN mouse model.

Methods: We measured staining of glomerular TM in an autopsy cohort, including 94 DN patients, 57 diabetic patients without DN and 38 healthy controls. Additionally, TM mRNA expression was measured in microdissected glomeruli from renal biopsies of 24 patients with DN and 13 controls. Furthermore, we studied glomerular TM expression in a STZ-induced DN mouse model, including 20 STZ and 10 WT mice, at 5 and 15 weeks after diabetes induction – reflecting acute and chronic DN.

Results: TM expression was 1.7x lower in patients with diabetes compared to non-diabetic controls (p=0.004), but no differences were observed between diabetic patients with and without DN. TM mRNA levels of DN cases were 2.3x higher compared to control cases (p=0.017). In STZ mice, TM expression was 1.2x lower than in WT mice (p<0.001), but no difference in TM expression was observed between acute and chronic DN mice. TM expression correlated negatively with glomerular number of macrophages and TNF-α protein in these mice.

Conclusions: Glomerular TM expression is decreased on protein level, but increased on mRNA level in patients with DN. TM may be cleaved under diabetic conditions, which is compensated by increased production. Furthermore, a loss of TM is associated with increased glomerular inflammation in DN. Interestingly, no differences in TM levels were observed between diabetic patients with and without DN, nor between mice with acute and chronic DN. We speculate that TM loss is an early feature of the diabetic glomerulus, and contributes to glomerular inflammation and DN development. Restoration of TM levels may be a promising treatment to prevent DN in diabetic patients.

FR-PO976

Exploring Origins of Autoimmune Nephritis Using HLA DR+ CD34+ Humanized Immune System Mice

Mary H. Foster,[1,2] Amy G. Clark,[1] Jeffrey R. Ord,[1] Alexa Lavergne,[1] Anastasiya Birukova,[1] Jeffrey I. Everitt,[1] Robert M. Tighe,[1] Lanette Fee.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]VAMC, Durham, NC.*

Background: Autoimmunity causes most glomerulonephritis (GN) and must be controlled to limit nephron destruction. Understanding the origins of the autoimmune response can guide development of targeted intervention. We generated a human immune system (HIS) model to examine interactions of two potent disease susceptibility factors: autoimmune-linked HLA Class II receptor DR4 and inhalation of crystalline silica (Si), an environmental exposure linked to lupus and ANCA vasculitis.

Methods: NOD-scid-gamma mice lacking mouse MHC Class II and transgenic (Tg) for HLA DR4 were infused with T-depleted DR4+ CD34+ human hematopoietic stem cells (HSC) from 1 of 4 cord blood donors. The Tg DR4 is expressed in host thymus to educate human CD4+ T cells, and DR4 is expressed on HSC-derived B cells. 3 mon later mice were exposed by aspiration to Si, vehicle (V), or neither, followed in 0 to 10 wks by adjuvant±PR3 or foreign antigen injection. Organs were harvested 4-8.5 mon post-engraftment.

Results: Among 19 surviving engrafted DR4+/moCIIKO/CD34+HIS mice, mean spleen chimerism was 72.2±27%. Low levels of human anti-PR3 Ig were detected in bronchoalveolar lavage fluid (BALF) from 69% (9 of 13) of immunized HIS mice, representing all 4 HSC donors and each exposure group. Low levels of human anti-DNA Ig were detected in BALF of 3 immunized (1 Si/2V) HIS mice, derived from the same HSC donor; 2 had lung perivascular infiltrates. Among Si-exposed mice, 5 deteriorated clinically 5-9 wks post-exposure, precluding immunization. All 5 had severe lung injury, including findings typical of chronic silicosis with extensive fibrosis and/or alveolar proteinosis in 4 mice. These 5 Si-exposed HIS mice (derived from 3 HSC donors) with 77%-85% spleen chimerism had no detectable serum or BALF anti-DNA & anti-PR3 Ig.

Conclusions: DR+ CD34+ HIS mice provide a useful translational platform to study susceptibility factors and gene-environment interactions that promote human nephritogenic autoimmunity. Our findings suggest that immunization and/or adjuvant, but not silicosis alone, facilitates induction of humoral autoimmunity in the context of HLA DR4. Future models can test the impact on autoimmune control of alternative risk alleles, modifiable host factors, and environmental co-exposures.

Sex-Dependent Modulation of Systolic Blood Pressure and Glucosuria in Tubule-Specific Heterogeneous Nuclear Ribonucleoprotein F Knockout Mice

Chao-Sheng Lo,[1] Kana N. Miyata,[1] Shuiling Zhao,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montréal, QC, Canada; [2]Maisonneuve-Rosemont Hospital, Montreal, QC, Canada; [3]The New England Journal of Medicine, Boston, MA.*

Background: We previously reported that mice with selective tubular deficiency of heterogeneous nuclear ribonucleoprotein F (hnRNP F) exhibit elevated systolic blood pressure (SBP) and glucosuria associated with up-regulation of renal angiotensinogen (Agt) and down-regulation of sodium-glucose co-transporter-2 (Sglt2) (2018 ASN TH-OR073). Here, we compared the impact of sex hormones on glucosuria and expression of Agt and Sglt2 in hnRNP F knockout (KO) mice and control littermates (Ctrls).

Methods: HnRNP F KO mice were generated by crossbreeding Pax8-Cre mice with floxed hnRNP F mice on a C57BL/6 background. Male KO mice and Ctrls were subjected to either sham-operation or bilateral castration at 12 weeks (wks) of age and followed until 20 wks of age. Female KO mice and Ctrls underwent either sham-operation or bilateral ovariectomy at the age of 8 wks and then followed until the age of 24 wks. Testosterone were implanted in female KO and Ctrls mice at the age of 8 wks and followed an extra 4 wks. Body weight (BW), SBP, blood glucose (BG), urinary glucose (UG) were monitored. Western blotting and real-time qPCR were used to quantify Agt and Sglt2 expression in renal proximal tubules (RPTs). Human RPTCs (HK-2) ± KO of HNRNP F by CRISPR/Cas9 method were also studied.

Results: Both male and female KO mice exhibited elevated SBP and glucosuria with up-regulation of Agt and down-regulation of Sglt2 expression in RPTs as compared to Ctrls. However, glucosuria disappeared in male KO mice at 12 wks of age whereas female KO mice had persistent glucosuria. Castration restored glucosuria in male KO mice; no change was seen in ovariectomized female mice. Gonadectomy had no effect on UG in Ctrls. Testosterone treatment prevented glucosuria in female KO mice. In vitro, HK-2 cells with HNRNP F KO displayed up- and down-regulation of AGT and SGLT2 expression, respectively. Finally, testosterone but not estrogen stimulated SGLT2 promoter activity in HK-2 cells but not in HK-2 with HNRNPF KO.

Conclusions: Our results indicate that hnRNP F may play an important role in the development of hypertension and glucosuria in mice in a sex-dependent manner through modulation of renal Agt and Sglt2 expression, respectively.

Role of ApoL1-miR193a Axis in Sox2-Mediated Reprogramming of Differentiated Podocytes

Alok Jha,[2] Kamesh R. Ayasolla,[2] Vinod Kumar,[2] Himanshu Vashistha,[3] Xiqian Lan,[2] Maleeha Qayyum,[4] Sushma Chinnapaka,[4] Harsha Adnani,[5] Ashwani Malhotra,[6] Karl Skorecki,[7] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Feinstein Institute for Medical Research, Manhasset, NY; [3]Ochsner Health System, New Orleans, LA; [4]Northwell health, Jamaica, NY; [5]Medicine, Feinstein Institute of Research, Glen Oaks, NY; [6]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [7]Rambam Health Care Campus, Haifa, Israel.*

Background: Enhanced autophagy maintains molecular phenotype in differentiated podocytes. The Sox2 is known to initiate autophagy by repressing Mammalin Target of Rapamycin (mTOR) expression; however, Sox2-induced autophagy induction carries negative feedback on reprogramming of differentiation. Since miR193a suppresses Sox2 expression, it would modulate the Sox2-induced transient autophagy during an early step in reprogramming to pluripotency/differentiation. Because APOL1 inversely regulates miR193a, it would de-repress Sox2 and accelerate autophagy in differentiated podocytes

Methods: Human podocytes expressing vector, APOL1G0/G1/G2 were differentiated; protein blots were probed for Sox2, APOL1, nephrin, CD2AP, and GAPDH. RNAs were assayed for miR193a and cDNA amplified for APOL1, and Sox2. The silico method was used to analyze motifs on ApoL1 and its variants mRNA. MEME suite for motif identification, JASPARv2010 and STAMP tool for alignment, and database matching for identified motifs were used. 3D models of ApoL1 and its variants mRNA segments (with mutations and deletions) were generated. Structural model of Sox2 (template-based method Itasser) docking approach was used to form the ApoL1 and its variants RNA and Sox2 complexes. The thermodynamic properties of ApoL1G0, G1, and G2 mRNAs and Sox2 were analyzed.

Results: Differentiated G0-podocytes displayed enhanced Sox2 but decreased expression of miR193a; in contrast, G1- and G2-podocytes showed the opposite outcome. The MEME suite identified motifs on ApoL1, and its variants and the JASPARv2010 and STAMP database for motif matching suggested that Sox2 can bind on ApoL1G2 mRNA. The thermodynamic properties of RNA-protein interaction interface suggested that the ApoL1G2 mRNA and Sox2 form a very strong and stable complex with surface area 4443.8 Å2, solvation free energy gain upon the formation of the interface (ΔiG) -93.8 kcal/mol and free energy of assembly dissociation (ΔGdiss) 95.6 kcal/mol. The ApoL1G2 mRNA-Sox2 complex has 38 hydrogen bonding interactions.

Conclusions: The Sox2 binding with ApoL1 and its variants mRNA suggests that Sox2 has an RNA binding property. This interaction carries the potential to modulate Apol1-miR193a-induced downstream signaling.

Intracellular Trafficking Pathway of Albumin in Glomerular Epithelial Cells

Takahito Moriyama, Kosaku Nitta. *Tokyo Women's Medical University, Tokyo, Japan.*

Background: Recently, intracellular trafficking pathway of albumin through caveolae in glomerular epithelial cells (podocytes) has been suspected to new etiological hypothesis of albuminuria in addition to pathway through gap between foot processes. In this analysis, we analyzed albumin endocytosis, subsequent transcytosis in cytoplasm and exocytosis.

Methods: Alexa flour 488 labeled bovine serum albumin (AF488-BSA) were incubated with Podocytes for 30, 60, and 120 minutes, and analyzed co-localization with caveolin-1(which was main structural component of caveolae), clathrin, and FC receptors (FcRn) as endocytosis, with several organelles, such as early endosome, Golgi apparatus (GA), endoplasmic reticulum (ER), lysosome, and proteasome, and with cytoskeletons such as microtubules and actins as transcytosis by immunofluorescence analysis (IF). In western blotting (WB) and IF, methyl beta cyclodextrin (MBCD) were preincubated with podocytes, then incubated with AF488-BSA or human serum albumin (HSA), and the amount of intracellular albumin through caveolae was analyzed. HAS were incubated with full confluent podocytes on transwells plate with or without MBCD, and concentration of HAS in inside and outside medium between transwells plate were evaluated to analyze exocytosis.

Results: At first, AF488-BSA were colocalized with Cav-1 and FcRn, but not with clathrin. Then AF488-BSA were colocalized with actin cytoskeleton, but not with microtubules, and colocalized with early endosome, lysosome, and proteasome, but not with ER and GA. MBCD treatment significantly decrease the Cav-1 and decreased the 488-BSA in IF and HAS in WB. The amount of HAS were gradually decreased in inside medium over podocytes on transwells plate and gradually increased in outside medium under transwells plate, and MBCD interfered that phenomenon. All these results indicated that albumin entered into Podocytes through Caveolae or FcRn but not clathrin, moved along with actin but not with microtunules, and reached to early endosome. At endosome, some of them were sorted to be degraded in lysosome or proteasome, and others were bypassed GA and ER and transported to the other side of cells as exocytosis.

Conclusions: In this study, we have shown intracellular trafficking pathway of albumin, and this pathway may be a new etiological hypotheis of urinay albumin excretion.

Defective ATP Synthase Mediates Renal Fibrosis and Tubular Epithelial-Mesenchymal Transition

Junne-Ming Sung. *National Cheng-Kung University Hoispital, Tainan, Taiwan.*

Background: Reduced mitochondrial function is a feature of chronic kidney disease (CKD). However, there is limited understanding of various aspect of mitochondrial biology in the renal injury.

Methods: This study aims to explore the role of mitochondrion dysfunction on TGFβ1–induced tubular cell epithelio-mesenchyamal transition (EMT) in vitro and renal fibrosis in vivo and clinical renal biopsy samples from patients with various stage of CKD.

Results: We observed TGFβ1-induced EMT in cultured renal tubular HK2 cells, and found that TGFβ1-treated cells have a decrease of oxygen consumption and an increase in use of non-oxidative phosphorylation glycolysis pathway as their energy source (by seahorse assay) while undergoing EMT, which was accompanied by increased mitochondrial membrane potential (MMP) and lower complex V activity (The activities of complex 1-IV were normal). Adding a mitochondrial complex V inhibitors (oligomycin) may induce EMT and further enhances TGF-β1-induced EMT. Blue native (BN)-PAGE studies showed a defective assembly of complex V (ATP synthase) in the mitochondria of EMT cells, which was possibly attributed by attenuation of its assembly factor ATPAF1. In HK2 cells, ATPAF1 knockdown caused EMT, and restoration of ATPAF1 protects renal tubule cells from TGFβ-induced mitochondrial dysfunction and EMT. Consistently, the animal model of tubulointerstitial fibrosis caused by unilateral ureteral obstruction (UUO) demonstrated attenuations in ATPAF1 level and complex V formation, accompanied by increased MMP. Overexpression of Atpaf1 in vivo attenuated mitochondrial dysfunction of tubular cells and interstitial fibrosis in UUO animal model. Thus, restoration of ATPAF1 in the kidney is protective against injury during the progression of renal fibrosis. In clinical renal biopsy samples, we performed immunostaining for ATPAF1, MMP and α-smooth muscle actin(α-SMA, a marker of fibrosis) and found that the severity of interstitial fibrosis (α-SMA staining intensity) negatively correlated with tubular ATPAF1 and positively with MMP. In addition, tubular ATPAF1 intensity also negatively correlated with MMP staining.

Conclusions: Our study underscores ATPAF1 is an important factor in maintaining mitochondrial energy capacity in tubule cells, and is vulnerability to injury and mediates the development of renal fibrosis.

Loss of Endothelial Klf4 Leads to Severe Glomerular Endothelial Injury in Aged Mice

Chelsea C. Estrada,[1] Stephanie Cardona,[1] Monica P. Revelo Penafiel,[2] Sandeep K. Mallipattu.[1] *[1]Stony Brook Medicine, Stony Brook, NY; [2]University of Utah, Murray, UT.*

Background: Renal-specific thrombotic microangiopathy (TMA) represents the most severe form of renal microvascular injury, and is associated with activation of complement and dysregulation of key endothelial genes. To investigate transcriptional mediators involved in renal-TMA, we reviewed expression arrays of global and single cell RNA-seq from human kidney biopsies with complement mediated renal microvascular injury and observed that Krüppel-Like Factor 4 (KLF4), a zinc finger transcription factor, is both differentially expressed in endothelial cells (ECs) and predicted to regulate other differentially expressed genes. Although previous reports show that *KLF4* coordinates an anti-thrombotic, anti-inflammatory phenotype in systemic vascular beds, its role in renal microvascular injury remains to be investigated.

Methods: Endothelial-specific *Klf4* knockout mice ($Klf4^{\Delta EC}$) were generated by crossing $Klf4^{fl/fl}$ with *Cdh5-Cre* mice. Mice were aged to 1 year as a model of endothelial dysfunction. Periodic acid-Schiff, electron microscopy, immunofluorescence (IF), ELISA and RT-PCR were performed to investigate the effects of endothelial *Klf4* in the renal microvasculature. Renal histology and ultrastructure were evaluated, blinded, by renal pathology (MPR).

Results: We demonstrated 80% knockdown of endothelial KLF4 by RT-PCR and IF. At 12 weeks of age, while we did not observe any histologic changes, $Klf4^{\Delta EC}$ mice exhibited increased glomerular *Pai-1, Vcam-1* and decreased *Nos3*, as compared with $Klf4^{fl/fl}$. Increased complement activation in glomerular capillaries was also noted in $Klf4^{\Delta EC}$ mice (complement factor 3 and C5b-9 fragments by IF). In addition to an exacerbation of these findings, at 1 year, $Klf4^{\Delta EC}$ mice exhibited histologic and ultrastructural changes observed across many TMA subtypes, including glomerular capillary dilation and congestion, EC swelling with loss of fenestrations, subendothelial expansion and mesangiolysis, as compared with aged matched controls. Furthermore, in line with this pathologic TMA signature, 1 year $Klf4^{\Delta EC}$ mice also demonstrated increased glomerular von Willebrand factor and albuminuria, compared with age-matched controls.

Conclusions: Loss of endothelial *Klf4* in aged mice recapitulates many pathologic features of renal-TMA, including complement activation and dysregulation of thrombotic and inflammatory genes.

Fibrillin 1-Enriched Tissue Microenvironment Plays a Key Role in Mediating Vascular Rarefaction in CKD

Li Li,[1] Haiyan Fu,[1] Youhua Liu.[2] *[1]Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Vascular rarefaction, characterized by reduced capillary density due to the loss of endothelial cells, is a common pathologic feature in a wide variety of CKD. However, how endothelial cells are lost in CKD remains elusive. In this study, we report that Fibrillin-1, an extracellular matrix glycoprotein, plays a critical role for mediating vascular rarefaction after kidney injury.

Methods: Unilateral ureteral obstruction (UUO) and unilateral ischemic-reperfusion (UIRI) were used as models of kidney fibrosis. Decellularized kidney tissue scaffold (KTS) was prepared. The differential expression of KTS proteins was analyzed by mass spectrometry proteomics. The role of fibrillin-1 in endothelial cell survival and proliferation was investigated in vitro. The expression of fibrillin-1 was knocked down by shRNA approach in vivo.

Results: Compared to sham controls, KTS from fibrotic kidney induced human umbilical vein endothelial cells (HUVEC) to undergo apoptosis, characterized by an increased expression of cleaved caspase-3, PARP-1, Fas and p53. KTS from fibrotic kidney also promoted endothelin-1 expression, and inhibited c-fos and cyclin D1 expression in response to mitogen stimulation. Mass spectrometry proteomics analyses identified 414 proteins that were differentially expressed in the KTS of control and fibrotic kidney. Fibrillin-1 was one of the most upregulated. In vitro, recombinant fibrillin-1 protein inhibited HUVEC proliferation and the expression of proliferation-related genes. Fibrillin-1 also induced the expression of Fas, FADD and p53 in HUVEC. Fibrillin-1 expression was markedly upregulated in multiple models of kidney fibrosis. Knockdown of renal fibrillin-1 expression by shRNA approach ameliorated kidney vascular rarefaction and reduced renal fibrosis after UIRI.

Conclusions: These studies demonstrate that fibrillin-1-enriched KTS is a hostile environment for endothelial cells, leading to vascular rarefaction in CKD. Targeted inhibition of fibrillin-1 could be a novel therapeutic strategy for protecting kidney integrity against vascular rarefaction in CKD.

FR-PO983

Spironolactone Ameliorates Endothelial Dysfunction Through Inhibition of the AGE/RAGE Axis in a Chronic Renal Failure Mouse Model

Chiz-Tzung Chang,[1,2] Ming-Yi Shen,[2] Chun-Cheng Wang.[1] *[1]China Medical University Hospital, Taichung, Taiwan; [2]China Medical University, Taichung, Taiwan.*

Background: Spironolactone can improve endothelial dysfunction in the setting of heart failure and diabetes models. However, its beneficial effect in the cardiovascular system is not clear in the setting of non-diabetic renal failure. We conducted this study to investigate whether spironolactone can ameliorate endothelial dysfunction in a 5/6 nephrectomy model, and to determine the underlying mechanism.

Methods: Twenty-four Sprague-Dawley rats were divided into four groups. A renal failure model was created using the 5/6 nephrectomy method. The four groups included: Sham-operation group (Group1), chronic kidney disease (CKD; Group2), CKD + ALT-711 (advanced glycation end products [AGEs] breaker; Group 3), and CKD + spironolactone group (Group4). Acetylcholine (Ach)-mediated vasodilatation responses were compared between the four groups. To investigate the underlying mechanism, we cultured human aortic endothelial cells (HAECs) for in-vitro assays. Differences between two groups were determined with the student's t test. Differences between three or more groups were determined through one-way analysis of variance (ANOVA) with post-hoc analysis with LSD method.

Results: Compared with Group 1, Group 2 has a significantly impaired Ach-mediated vasodilatation response. Group 3 and 4 exhibited improved vasoreactivity responses. To determine the underlying mechanism, we performed an in-vitro study using cultured HAECs. We noted significant sirtuin-3 (SIRT3) protein downregulation, reduced phosphorylation of endothelial nitric oxide synthase at serine 1177 (p-eNOS), and increased intracellular oxidative stress in cultured HAECs treated with AGEs (200μg/mL). These effects were counter-regulated when cultured HAECs were pretreated with spironolactone (10μM). Furthermore, the increased p-eNOS production by spironolactone was abrogated when the HAECs were pretreated with tenolvin (1μM), a SIRT3 inhibitor.

Conclusions: Spironolactone could ameliorate endothelial dysfunction in a 5/6 nephrectomy renal failure model through AGEs/Receptor for AGEs (RAGEs) axis inhibition, SIRT3 upregulation, and nicotinamide adenine dinucleotide phosphate oxidase-2 (NOX-2) and its associated intracellular oxidative stress attenuation.

FR-PO984

Fibroblast p90RSK Induces Epithelial-to-Mesenchymal Transition Through Oxidative Stress-Mediated β-Catenin Pathway

Ling Lin, Kebin Hu. *Penn State University College of Medicine, Hershey, PA.*

Background: Healthy kidney structure and environment rely on epithelial integrity and interactions between epithelial cells and other kidney cells. p90RSK, a serine/threonine kinase, is recently shown to promote obstruction-induced kidney fibrosis, however, the underlying mechanism remains largely unknown.

Methods: We generated a novel fibroblast-specific p90RSK transgenic mouse (RSK-Tg) and established a fibroblast-epithelial coculture system using primary kidney fibroblasts from RSK-Tg and RSK-wt mice and human proximal tubular epithelial cells (HKC-8) to investigate the role of p90RSK in fibroblast-epithelial interactions and kidney fibrosis.

Results: It was found that RSK-Tg mouse has similar phenotype as the littermate control (RSK-wt). However, after UUO injury, RSK-Tg mice display significantly increased fibrosis, as demonstrated by renal collagen content and FSP-1 abundance, in comparison with their littermates. We further found that RSK-Tg mice display decreased E-cadherin, increased MMP-9, and de novo activation of alpha-SMA, indicating enhanced epithelial-to-mesenchymal transition (EMT), which was also visualized by double fluorescence staining of FSP-1 and lectin. Moreover, it was found, in our in vitro fibroblast-epithelial coculture system, that RSK-Tg fibroblasts consistently produce excessive H2O2 causing epithelial oxidative stress and inducing β-catenin nuclear translocation. Of note, blockade of reactive oxygen species (ROS) or β-catenin abolished fibroblast p90RSK-mediated EMT.

Conclusions: Thus, it is clear that fibroblast p90RSK induces EMT through oxidative stress-mediated β-catenin pathway.

Evaluation of CB1 Receptor Expression in Human Diabetic Kidney Disease and Rodent CKD Models

Li-Jun Ma,[1] Matthew M. Rankin,[1] Jing ying Ma,[2] Nathaniel H. Wallace,[1] Brian Rady,[1] Jingjun Li,[1] Bindu Bennet,[2] Vinicius S. Carreira,[2] Joseph Tam,[3] Alessandro Pocai,[1] Andrea R. Nawrocki.[1] *[1]Cardiovascular & Metabolism, Janssen R&D, Johnson & Johnson, Spring House, PA; [2]Pathology, Nonclinical Safety, Janssen R & D, Johnson & Johnson, Spring House, PA; [3]Obesity and Metabolism Laboratory, Institute for Drug Research, School of Pharmacy, faculty of Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel.*

Background: Published data suggest that cannabinoid receptor 1 (CB1R) is an attractive target for metabolic complications, including renal fibrosis and diabetic kidney disease (DKD). CB1R protein, detected by immunohistochemistry, was reported to be expressed at low level in normal kidneys from human and rodents, and increased in renal biopsy samples from patients with DKD and fibrotic kidneys in rodents. Elevated expression of CB1R is postulated to be implicated in DKD leading to metabolic derangement, inflammation and fibrosis. We aimed to characterize CB1R protein expression in human DKD and three rodent chronic kidney disease (CKD) models.

Methods: Histological sections of renal biopsies from DKD patients and autopsy samples from normal human subjects were analyzed by immunohistochemistry to assess CB1R protein expression. Rodent CKD models included subtotal nephrectomy (STNx, on 129/Sv), unilateral ureteral obstruction (UUO, on C57BL/6) and folic acid nephropathy (FAN, on C57BL/6). Paraffin sections of kidney from normal control and diseased groups from each model (12 weeks after surgery for STNx, 10 days after surgery for UUO, 6 weeks after folic acid injection for FAN) were evaluated. Anti-CB1R polyclonal antibody from ImmunoGenes (Hungary) was used for all immunohistochemistry. Sections from human brain and mouse tissues (brain, kidney) from CB1R wild type (WT) and knockout (KO) were used as positive or negative control.

Results: Specific CB1R protein expression was observed in the presynaptic axons in the human and mouse brains without non-specific background. CB1R labeling was absent in the CB1R KO brain and kidneys. No specific CB1R positive labeling was observed in the normal mouse kidneys, normal human kidneys, or renal biopsy samples from human DKD. Only minimal and focal (less than 5% of total kidney area) CB1R protein expression was observed in tubular epithelial cells in the kidneys from STNx, UUO, and FAN models.

Conclusions: CB1R protein expression was absent from normal and human DKD, and very low and only minimally and focally increased in diseased kidneys from rodent CKD models. These observations suggest challenges for validation of this target in renal fibrosis and diabetic kidney disease.

FR-PO986

Melanocortin 1 Receptor (MC1R) Deficiency Exacerbates Glomerular Injury and Proteinuria in the Autologous Phase of Nephrotoxic Serum (NTS) Nephritis

Xuejing Guan,[1,2] Rong Zhou,[2] Lance D. Dworkin,[1] Rujun Gong.[1] *[1]University of Toledo Medical Center, Toledo, OH; [2]Yangpu Hospital, Tongji University, Shanghai, China.*

Background: The clinical effectiveness of melanocortin therapy with adrenocorticotropin in inducing remission of steroid-resistant nephrotic syndrome points to a steroidogenic-independent anti-proteinuric activity of melanocortins. However, which melanocortin receptor conveys this beneficial effect is controversial. A growing body of evidence suggests that activation of podocytic MC1R may convey a podocyte protective and anti-proteinuric effect. However, this paradigm seems inconclusive because MC1R agonist was seemingly ineffective in such nephrotoxic glomerulopathies as Adriamycin nephropathy. Moreover, how MC1R signaling is involved in immune-mediated glomerular diseases is unknown.

Methods: NTS nephritis was induced in mice with nonfunctional mutation of MC1R(e/e) and in wild-type (WT) mice by injection of rabbit NTS. Kidney function and renal injury were evaluated.

Results: Seven or 14 days after NTS injection during the autologous phase, e/e as compared with WT mice demonstrated an exacerbated kidney dysfunction and injury, as evidenced by higher serum creatinine levels, heavier proteinuria, and aggravated renal pathology, featured by glomerular hypercellularity, crescent formation, mesangial expansion, protein casts, and renal inflammation and fibrosis. Consistent with the worsened proteinuria, e/e mice displayed more severe podocyte injury, characterized by podocytopenia, marked by diminished WT-1 staining, and loss of podocyte markers like synaptopodin and podocin. Mechanistically, the aggravated renal disease in e/e mice was unlikely due to a sensitized response of the e/e kidney to injury, because 1 day after NTS insult during the heterologous phase, e/e mice developed albuminuria, podocytopathy and glomerular damage to a comparable extent as WT mice. Rather, deficiency of an MC1R-mediated non-kidney-autonomous or extra-renal mechanism may contribute. In support of this, e/e mice exhibited much more glomerular deposition of autologous anti-rabbit IgG together with the terminal complement complex C5b-9 along glomerular capillary loops than WT mice, despite the same degree of deposition of glomerular basement membrane-reactive rabbit IgG.

Conclusions: MC1R signaling protects against glomerular injury and proteinuria in immune-mediated glomerular disease *via*, at least in part, an immune modulatory effect.

Deletion of the Non-Canonical NOTCH Ligand DLK1 Promotes an Overactivation of the NOTCH Signaling Pathway and the Th17 Immune Response in the Unilateral Ureteral Obstruction Model

Laura Marquez-Exposito,[2,1] Raúl R. Rodrigues díez,[2] Sandra Rayego-Mateos,[2] Marta Fierro-Fernández,[3] Raquel Rodrigues-Diez,[2] Macarena Orejudo del río,[1] Jorge Laborda,[5] Sergio A. Mezzano,[4] Santiago Lamas,[3] Carolina Lavoz,[4] Marta Ruiz-Ortega.[4] *[1]Instituto de Investigación Sanitaria de la Fundación Jiménez Díaz, Madrid, Spain; [2]Universidad Autónoma de Madrid, Madrid, Spain; [3]Centro de Biología Molecular Severo Ochoa, Madrid, Spain; [4]Universidad Austral de Chile, Valdivia, Chile; [5]Universidad de Castilla-La Mancha, Albacete, Spain.*

Background: The NOTCH signaling pathway is activated in embryonic development, silenced in adult tissues, and reactivated in human kidney diseases. The non-canonical ligand DLK1 has been described as a Notch inhibitor in Drosophila and in mammal cells, but there are no data in renal injury. In renal pathologies, Th17 response has been involved in immune and nonimmune diseases, including diabetic nephropathy.

Methods: 129/SvJ mice with an embrionary deletion in the *Dlk1* gene were used. The Unilateral Ureteral Obstruction (UUO) model was performed in both the transgenic and the WT mice, and data studied at 2, 5, 10 and 14 days after the injury. C57BL/6 mice were treated daily with 0.1 mg/day of the γ-secretase inhibitor DAPT, starting one day before the UUO procedure and sacrificing the animals 5 days after.

Results: Non-canonical ligands DLK1 and DLK2 were studied at each point, showing increased gene expression levels from day 5 to 14 in the WT animals. The inflammatory infiltrate was scored by PAS staining in the obstructed kidneys and it was significantly increased in the *Dlk1*-null mice vs WT from 5 days and continued at 10 and 14 days. Remarkably, at 14 days these knockout obstructed kidneys showed a huge inflammatory infiltrate as aggregates, not found in the WT animals. These inflammatory aggregates were positive for the NICD, as well as some tubules, demonstrating that the *Dlk1*-null mice have an overactivation of the NOTCH pathway in the obstructed kidneys. They were also associated to a significant increase of CD3+, CD4+, F4/80+ infiltrating cells and neutrophils. At 14 days, the increase of the Th17 response in the *Dlk1*-null obstructed kidneys was very remarkable, as shown by the elevation of the transcription factors RORγt and STAT3 and the effector cytokine, IL17A. These factors were also increased at 5 days in the C57BL/6 mice and clearly diminished with the tratment of the γ-secretase inhibitor DAPT.

Conclusions: Deletion of DLK1 overactivates the Notch pathway in the UUO model, and this triggers an increase in the inflammation of the tissue as well as an induction of the Th17 response. Therefore, DLK1 can be suggested as a Notch inhibitor in this context.

FR-PO988

A Novel Klotho-Derived Peptide KP1 Attenuates Renal Fibrosis by Blocking TGF-Beta Signaling

Qian Yuan,[1] Lili Zhou,[1] Youhua Liu.[2] *[1]Department of Pathology, Nanfang hospital, Guangzhou City, China; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Renal fibrosis, characterized by excessive extracellular matrix (ECM) deposition, is a common feature of a variety of CKD. Klotho is an antiaging protein with remarkable reno-protective potential. Because Klotho is a large transmembrane protein, making it difficult to be used clinically, we hypothesized that a small Klotho-derived peptide may mimic the reno-protective action of Klotho.

Methods: A peptide mini-library was established, which encompassed the extracellular region of Klotho. The anti-fibrotic activity of the Klotho-derived peptide was screened in normal kidney fibroblast cells (NRK-49F) stimulated with TGF-β1. The effect of the identified peptide on renal fibrosis was tested in mouse models of fibrosis including unilateral ureteral obstruction (UUO) and unilateral ischemia reperfusion injury (UIRI).

Results: After screening the klotho peptide mini-library, one peptide with potent anti-fibrotic potential, designated as klotho-derived peptide 1 (KP-1), was identified. KP-1 was effective in blocking the upregulation of fibronectin and α-smooth muscle actin (α-SMA) in NRK-49F cells induced by TGF-β1. Mechanistically, we found that KP-1 bound to the TGF-β receptor type II (TβR-II), which competitively inhibited TGF-β1/TβR-II engagement. As such, KP1 was able to block Smad2/3 phosphorylation and activation induced by TGF-β1. KP-1 also inhibited TGF-β1-mediated mitogen-activated protein kinase (MAPK) activation in NRK-49F cells. In vivo, KP-1 blocked renal Smad2/3 and MAPK activation, inhibited myofibroblast activation and matrix production, ameliorated renal interstitial fibrosis and restored the expression of endogenous klotho protein in two models of renal fibrosis induced UUO and IRI.

Conclusions: We have identified KP-1 is a novel Klotho-derived peptide that specifically inhibits TGF-β signaling via binding to TβR-II. KP-1 could be used as a therapeutic agent for treating fibrotic kidney disease.

A Deep Learning-Based Approach for Glomeruli Object Extraction from Multistained Renal Biopsy Pathologic Images

Lei Jiang,[1] Ke Mei,[2] Chuang Zhu,[2] Jun Liu,[2] Yu Yan,[3] Bao Dong,[3] Gongwei Wang,[4] Hongxia Shi.[1] *[1]Electron Microscope Lab, Peking University People's Hospital, Beijing, China; [2]School of Information and Communication Engineering, Beijing University of Posts and Telecommunications, Beijing, China; [3]Department of Nephrology, Peking university people's hospital, Beijing, China; [4]Department of Pathology, Peking University People's Hospital, Beijing, China.*

Background: Glomeruli extraction from pathologic images is a key step in automatic analysis of renal biopsy. We present a deep learning-based approach for the object extraction of three types of glomeruli with various pathological lesions in multi-stained images.

Methods: Sources of images: 1.1947 glomeruli from images captured at 10x, 20x, and 40x, including 33 pathological types of kidney diseases; 2. 601 glomeruli from 44 whole slide images (WSI) scanned at 40x using Precice 500B scanner (UNIC Technologies Inc, China). Slides were stained with Periodic acid-Schiff (PAS), Periodic Acid-silver Methenamine (PASM), and Masson's trichrome stains. Glomeruli were divided into training and testing sets. Mask R-CNN architecture based on convolutional neural networks (CNN) was trained by using glomeruli training set. The adopted mask R-CNN, which is built by extending Faster R-CNN by adding a branch for predicting an object mask, can detect, classify, and segment three types of glomeruli: 1. glomerulus with basically normal structure (gn), 2.global sclerosis (gs), and 3.glomerulus with other abnormal structure (gl) at the same time.

Results: The detection and pixel level segmentation results was graded via average precision, average recall, and F-score (true positives were defined by >50% overlap of the predicted region).

Conclusions: We present a robust network using relatively limited sample size, which can detect normal and abnormal glomeruli stained with PAS, Masson and PASM.

Deep Learning-Based Segmentation of Normal Histologic Kidney Primitives on Whole Slide Images from NEPTUNE Digital Renal Biopsies

Catherine P. Jayapandian,[6] Yijiang Chen,[6] Andrew Janowczyk,[6] Matthew Palmer,[1] Jarcy Zee,[2] Clarissa A. Cassol,[7] Miroslav Sekulic,[6,3] Jeffrey B. Hodgin,[8] Stephen M. Hewitt,[9] John F. O'Toole,[4,6] John R. Sedor,[4,6] Laura Barisoni,[5] Anant Madabhushi.[6,10] *[1]University of Pennsylvania, Philadelphia, PA; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]UH Cleveland Medical Center, Cleveland, OH; [4]Cleveland Clinic, Cleveland, OH; [5]Duke University, Durham, NC; [6]Case Western Reserve University, Cleveland, OH; [7]The Ohio State University, Columbus, OH; [8]The University of Michigan, Ann Arbor, MI; [9]National Cancer Institute, Bethesda, MD; [10]Louis Stokes Cleveland Veterans Affair Medical Center, Cleveland, OH.*

Background: The establishment of digital pathology repositories, such as Nephrotic Syndrome Study Network (NEPTUNE), enables large scale analyses of renal biopsies by sophisticated computational imaging approaches and machine-human interactive protocols. Here we evaluate the performance of U-Net deep learning algorithm for identification of normal histologic primitives in whole slide images (WSIs) across multiple stains.

Methods: Eighteen U-Nets were trained to segment: (i) normal glomerular tufts, (ii) normal glomerular unit (tuft + Bowman's space and capsule), (iii) normal proximal tubular segments (PT), (iv) normal distal tubular segments (DT), (v) interstitial capillaries, and (vi) arteries. Regions were extracted from 419 WSIs, including 103 H&E, 112 PAS, 100 Silver, 103 Trichrome) from 125 NEPTUNE digital renal biopsies with a diagnosis of Minimal Change Disease. The renal biopsies were randomly sampled into training, validation and testing sets in the ratio 6:1:3. Five pathologists provided the manual segmentation (ground truth). Detection and segmentation results were evaluated using F-Score, True Positive Rate (TPR), Positive Predictive Value (PPV) and Dice Similarity Coefficient (DSC), respectively.

Results: PAS stained WSIs yielded the best performance for all primitives with F-Score (i) 0.93, (ii) 0.94, (iii) 0.91, (iv) 0.93, (v) 0.93 and (vi) 0.85.

Conclusions: This work represents a solid foundation towards enlisting machine learning classifiers to aid large scale tissue quantification efforts. Ongoing effort is devoted to segment abnormal histologic primitives for the development of image-based predictors of disease prognosis.

Deep Learning-Based Histopathological Assessment of Renal Tissue

Meyke Hermsen,[1] Marjolijn Den boer,[1] Thomas de Bel,[1] Jesper Kers,[2] Joris J. Roelofs,[2] Mark D. Stegall,[3] Mariam P. Alexander,[3] Byron H. Smith,[3] Bart Smeets,[1] Luuk Hilbrands,[1] Jeroen A. van der Laak.[1,4] *[1]Radboudumc, Nijmegen, Netherlands; [2]Academic Medical Center, Amsterdam, Netherlands; [3]Mayo Clinic, Rochester, MN; [4]Center for Medical Image Science and Visualization, Linköping University, Linköping, Sweden.*

Background: Quantitative measures are often used for histopathological assessment of renal tissue. We trained a convolutional neural network (CNN) for multi-class segmentation of digitized periodic acid-Schiff(PAS)-stained renal tissue sections.

Methods: The CNN was trained using annotations of 40 whole-slide images of PAS-stained renal transplant biopsies. Multi-class segmentation performance was assessed by calculating Dice coefficients (DCs) for 10 tissue classes on 10 transplant biopsies from Radboudumc and on 10 transplant biopsies from the Mayo clinic. Additionally, we fully segmented 15 nephrectomy samples and assessed the CNN's glomerular detection rates. Lastly, CNN-based measures were compared with visually scored histological (Banff) components in 82 transplant biopsies.

Results: The weighted mean DCs were 0.80 and 0.84 in 10 transplant biopsies from Radboudumc and the Mayo Clinic, respectively. The 'glomeruli' class was best segmented in both data sets (DC 0.95 and 0.94), followed by 'tubuli combined' and 'interstitium'. An example of the CNN's visual output is shown in Figure 1. The CNN detected 92.7% of all glomeruli in nephrectomy samples, with 10.4% false positives. In whole transplant biopsies, the mean intraclass correlation coefficient for glomerular counting performed by pathologists and the CNN was 0.94. Moderate to strong correlations were observed between components of the Banff scoring system and CNN-based measures (Table 1).

Conclusions: This study presents the first CNN for multi-class segmentation of PAS-stained nephrectomy samples and transplant biopsies. Our CNN can be of aid for quantitative studies concerning renal histopathology across centers and provides opportunities for deep learning applications in routine diagnostics.

Deep Learning-Based Segmentation Enables an Efficient Assessment of Glomerulosclerosis That Is Predictive of Progressive Kidney Disease

Matthew Palmer,[1] Catherine P. Jayapandian,[2] Jarcy Zee,[3] Miroslav Sekulic,[5] Clarissa A. Cassol,[6] Andrew D. Rule,[4] Andrew Janowczyk,[2] Yijiang Chen,[2] John R. Sedor,[8] Stephen M. Hewitt,[9] Anant Madabhushi,[2] Laura Barisoni.[7] *[1]University of Pennsylvania, Philadelphia, PA; [2]Case Western Reserve University, Cleveland, OH; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Mayo Clinic, Rochester, MN; [5]UH Cleveland Medical Center, Cleveland, OH; [6]The Ohio State University, Columbus, OH; [7]Duke University, Durham, NC; [8]Cleveland Clinic, Cleveland, OH; [9]National Cancer Institute, Bethesda, MD.*

Background: The percentage of globally sclerotic glomeruli (GSG) adjusted by age is a clinically relevant parameter that has been shown to be associated with outcome across diseases. While annotation of glomeruli on whole slide images (WSI) using the NEPTUNE Digital Pathology Protocol has improved overall accuracy, manual counting remains time consuming. The aim of this study is to develop deep learning (DL) networks for automated annotation of GSG and test whether the DL-generated % GSG associates with clinical outcome.

Methods: 126 WSI (PAS) from 107 minimal change and 19 FSGS patients from the NEPTUNE dataset were used to train and test a DL network to identify normal glomeruli and GSG. The %GSG was calculated on 1 level and compared with %GSG visually assessed on the same level by 1 of 4 pathologists. Outcome data (ESRD or 40% eGFR decline) were available in 125 cases. Cases were divided into 3 groups: no GSG (95), GSG appropriate for age (14), and GSG excessive for age (16). Hazard ratios for clinical outcomes were compared across the 3 groups.

Results: The DL classifier's sensitivity as compared with visual assessment for detecting non-GSG was 0.85 and for GSG was 0.75. Compared with no GSG, GSG normal for age was associated with 1.06 (0.13-8.62) times the hazards of composite progression outcome and GSG abnormal for age was associated with 4.43 (1.14-17.26) times the hazards of composite progression outcome.

Conclusions: Our DL classifier is able to detect normal glomeruli and GSG with high sensitivity. The DL-generated %GSG correlates with clinical outcome in a manner similar to previously reported manual assessments. This work represents a foundation towards enlisting robust machine learning classifiers for evaluating clinically relevant pathologic parameters.

The Use of Quantitative Morphometrics in Nephrectomy Specimens to Understand Focal Segmental Glomerulosclerosis

Christopher L. O'Connor,[1] Jennifer A. Schaub,[1] Jeffrey B. Hodgin,[2] Roger C. Wiggins,[3] Markus Bitzer.[1] *[1]University of Michigan, Ann Arbor, MI; [2]The University of Michigan, Ann Arbor, MI; [3]University of Michigan Health System, Ann Arbor, MI.*

Background: Detection of a single segmentally sclerosed glomerulus is sufficient to establish the diagnosis of focal segmental glomerulosclerosis (FSGS), which guides management and prognosis of kidney function decline. Because 10-15 glomeruli are available for examination of standard kidney biopsies, glomerular lesions present in low frequency such as segmental glomerulosclerosis (SGS) may be missed. To determine the probability of detection of SGS and whether morphometric parameters in normal appearing glomeruli are associated with SGS, we evaluated larger kidney tissue samples from nephrectomy specimens.

Methods: We obtained specimens from 79 patients who underwent nephrectomy and abstracted clinical data from the patient's electronic medical records. We analyzed PAS-stained kidney sections for global and segmental glomerulosclerosis, and quantified glomerular morphometrics using chemical and immunohistochemical stains. We estimated the probability that a biopsy would identify FSGS using the geometric distribution with varying frequencies of SGS lesions and number of glomeruli obtained in a kidney biopsy.

Results: The median number of glomeruli per specimen was 227. 44% of patients were classified as having FSGS as defined by the presence of at least one glomerulus with SGS. Of those, 18 (39.1%) had less than 1% of their glomeruli with an SGS lesion. Patients with FSGS were more likely to be diabetic (37.5% vs. 8.1%, p=0.003), hypertensive (48.3% vs. 29.7%, p=0.006) and have a lower baseline eGFR prior to nephrectomy (69.6 vs. 86.7 - ml/min/1.73m^2, p=0.002). Patients with FSGS had increased glomerular volume (4.1 vs. 3.6 - 10^{6}μm^3, p=0.04), decreased podocyte density (106.4 vs.129.3 - podocytes/10^{6}μm^3, p=0.001), and increased podocyte volume (4885 vs 4100 - μm^3, p=0.005). For low frequency SGS lesions (<1% of glomeruli), a kidney biopsy could miss a FSGS diagnosis more than 74% of the time.

Conclusions: Qualitative and quantitative morphometric analysis of nephrectomy specimens identify low frequency SGS lesions. Kidney biopsy can frequently miss an FSGS diagnosis if there is a low frequency of SGS lesions. Future directions involve examining the possibility of using computer aided quantitative morphometry in order to impute the existence of rare glomerular features unlikely to be captured during routine biopsy.

Classification of Cell Types with Neural Networks in Reference and Diseased Human and Mouse Kidney Tissue Using Nuclear Morphology

Andre Woloshuk,[2] Dawson F. Dean,[3] Andrew Mcnutt,[1] Michael T. Eadon,[3] Pierre C. Dagher,[1] Seth Winfree,[2] Tarek M. El-Achkar.[1] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University Division of Nephrology, Indianapolis, IN.*

Background: Despite improvements in non-invasive analysis of kidney function, kidney biopsy remains the gold standard for diagnosing renal pathology. This field relies heavily on subjective interpretation and semi-quantitative image analysis of 2-dimentional (2D) images of stained tissue thin-sections. Advances in 3D confocal fluorescence imaging and machine learning approaches such as neural networks provide the opportunity for an automated and quantitative approach, and the potential for extracting new data from the 3-dimentional (3D) space. Neural networks have wide applications in image classification of natural images and medical imaging. Recent applications of neural networks in pathology are starting to explore segmentation and classification of histologically stained samples. The same approach has not been fully exploited in kidney tissue labeled with multiple fluorescent probes and imaged in 3D.

Methods: We identify individual cells in human and mouse kidney tissue and assigning each cell a ground truth classification based on validated cell markers. Images of the nuclei as 2D projections and 3D volumes from tissue are extracted and classified based on these markers using volumetric tissue exploration and analysis cytometry. Different neural network architectures are trained and evaluated using this image database. The efficacy of different architectures is assessed by their ability to distinguish different cell types within the biopsy.

Results: In this work, we create an image database of fluorescently stained nuclei collected from human and mouse renal tissue that can be used to identify and classify different cell types solely on their nuclear features. Furthermore, we begin to demonstrate the efficacy of identifying pathologies in either a mouse model of acute kidney injury or in human diabetes.

Conclusions: This work lays the groundwork for quantifying the types of cells present in biopsies, and the automatic classification of pathological cell states in a biopsy that may have otherwise gone unnoticed. Ultimately, machine learning-augmented image analysis has the potential not only to describe novel and distinct disease features, but also define a standardized approach to quantifying pathology in a kidney biopsy.

Unsupervised Machine-Learning Cytometry of High-Dimensional Image Data from Fluorescently Labeled Mesoscale Kidney Tissue Automates Quantitation and Uncovers Unique Cellular Populations

Seth Winfree,[2] Andrew Mcnutt,[1] Michael J. Ferkowicz,[1] Tarek M. El-Achkar.[1] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: The cytometric analysis of fluorescent mesoscale kidney imaging datasets presents unique challenges in segmentation, measurement and analysis. To address these challenges, we developed the tissue cytometry tool, Volumetric Tissue Exploration and Analysis (VTEA). VTEA streamlines nuclei segmentation, measurements and enables flow cytometry-like analysis in mesoscale 3D images of kidney tissue. However, as we add 1) additional fluorescent markers with novel imaging modalities and 2) imaging metrics, including texture and spatial characteristics, flow cytometry-like approaches become inadequate under the strain of these higher dimensional data. Here our goal was to implement and demonstrate the need and utility of unsupervised analysis of higher dimensional tissue cytometry data.

Methods: Imaging datasets were collected from fluorescently labeled mouse and human kidney tissue with confocal fluorescence microscopy and up to 8 independent

fluorophores. Image processing and analysis was performed with the recent version of VTEA that incorporates Java based libraries for clustering of datasets (e.g. K-mean, Gaussian-mixtures) and dimensionality reduction tools (e.g. PCA and tSNEs).

Results: We extended our cytometry tool, VTEA, incorporating unsupervised machine learning approaches with publicly available Java libraries. Using clustering, we identify cellular population of cells not readily identified with manual gating. The mapping of high dimensional cytometry data to lower dimensions facilitates rapid visual identification of cell sub-population not readily apparent. Lastly, we demonstrate the advantage of looking at our imaging data with both dimensionality reduction and clustering-an approach that has been exploited by the omics fields.

Conclusions: Our work demonstrates the need and utility for high dimensional analysis of mesoscale kidney imaging data and suggests we gain insight with the application of unsupervised machine learning approaches to image analytics, especially in the framework of the interactive exploratory platform VTEA. Lastly, our work underlines the importance of reusable software and the power of an open software community found in the NIH supported ImageJ community.

Gene-Environment Interactions Modulate Anti-DNA and Anti-Myeloperoxidase. Autoimmunity in Lupus

Lanette Fee,[1,2] Jeffrey R. Ord,[1] Amy G. Clark,[1] Anastasiya Birukova,[1] Robert M. Tighe,[1] Mary H. Foster.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]VAMC, Durham, NC.*

Background: Autoantibody (autoAb)-mediated glomerulonephritis develops in 60-85% of patients with lupus and ANCA vasculitis. Nephron preservation requires control of the systemic autoimmune response. To better understand factors driving autoimmunity, we used a mouse model system to study interaction of lupus genetic susceptibility and inhalation of crystalline silica (Si), an environmental exposure linked to human lupus. We previously showed that Si induces lung injury, lymphoid aggregates, and autoAbs in mice of genetically diverse backgrounds. Herein we report strain differences in Si-induced autoAb specificity, production site, and co-exposure requirements.

Methods: Wildtype (WT) and autoAb transgenic (Tg) B6, BXSB, MRL, and NZB mice were exposed to Si (Si+) or vehicle (V+) by aspiration; tissues were harvested for immunophenotyping 1 to 3 months later.

Results: Among WT lupus mice exposed to Si, anti-DNA IgG levels are significantly higher in bronchoalveolar lavage fluid (BALF) from Si+ MRL compared to other Si+ strains (mean OD405 1.35 vs 0.07, 0.49, & 0.36 for B6, BXSB & NZB, $p<0.05$). TLR7/TLR9 ligands induce significantly more anti-DNA IgG from cultured lung cells of Si+ vs V+ MRL (OD405 0.49±0.43 vs 0.11±0.21, n=6-9/grp, $p<0.05$), and vs lung cells of Si+ B6 and Si+ NZB (OD405 0.02±0.02 & 0.01±0.01). Anti-myeloperoxidase (MPO) Ig are detected only in BALF of Si+ BXSB, and are not found in BALF from V+ BXSB ($p<0.05$, n=7/grp) or from Si+ B6, MRL, & NZB. To probe the in vivo fate of autoAb-producing lymphocytes after Si exposure, we studied mice of each strain expressing an autoAb Tg. Results suggest that central deletion and anergy are intact: mean spleen B cell numbers (5.7±3.4 mil, n=25) are markedly lower than that for non-Tg counterparts (35±2 mil, n=53) and do not differ for Si+ vs V+ mice in any of the 4 Tg strains; and, the residual autoAb Tg B cells produce little Tg autoAb. However, TLR7/TLR9 stimulation induces Tg autoAb production by splenocytes from Si+ Tg B6 mice.

Conclusions: These results suggest that silica exposure can disrupt local and systemic autoimmune control in a strain-dependent manner, consistent with gene-environment interaction in modulation of the autoimmune response. The results further suggest that Si-induced subtle alterations in autoreactive lymphocyte regulation are unmasked by environmental co-exposure.

Imaging Renal Inflammation and Fibrosis After Ischemia-Reperfusion Injury by Novel Diffusion MRI

Chun-Fu Lai,[1] Hsin-Chieh Yang,[2] Sheng-Kwei Song,[2,3] Tsen-Hsuan Lin.[2] *[1]Renal Division, Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [2]Radiology, Washington University in St. Louis, St. Louis, MO; [3]Biomedical Engineering, Washington University in St. Louis, St. Louis, MO.*

Background: Conventional MRI provides noninvasive assessment for disease progression but lacks the pathological specificity. Previously, we successfully developed diffusion basis spectrum imaging (DBSI) to assess coexisting axonal injury, demyelination, and inflammation. This study aims to test whether DBSI can noninvasively detect kidney pathologies after ischemia reperfusion injury (IRI).

Methods: Six 10-week-old female C57BL/6 mice received unilateral left kidney IRI for 30 minutes. Mice were euthanized and perfusion fixed with 4% PFA at 4-7 days after surgery. IRI and contralateral control (CTL) kidneys were harvested for *ex vivo* DBSI scans. The DBSI scan was performed on a 4.7-T scanner: TR = 1.5 s, TE = 33 ms, maximal b-value = 1,500 s/mm^2, image slice thickness = 0.5 mm, in-plane resolution = 156 × 156 μm^2. DBSI-assessed restricted (putative cellularity), hindered (putative cytotoxic edema) and fiber (putative interstitial fibrosis) were derived using a novel lab-developed software. H&E and Masson's trichrome (MT) stains were performed to validate DBSI findings.

Results: Representative H&E and MT images of IRI kidneys demonstrated obvious tubular injury, interstitial edema, inflammation (b) and fibrosis (c). The region of interest (ROI)s were defined on T2W anatomy image (D). The corresponding DBSI metrics suggested significant increased cellularity (higher restricted fraction, E) and reduced interstitial space (reduced hindered fraction, F) in outer medulla. Higher anisotropic fiber fraction in outer stripes of outer medulla of IRI group (G) indicated increased fibrosis at that region.

Conclusions: DBSI MRI could detect coexisting pathologies in kidneys after injury. It has potential to noninvasively follow kidney disease progress, monitor treatment efficacy, and translate to clinical application.

The Solute Carrier SLC16A12 Is Critical for Creatine and Guanidinoacetate Handling in the Kidney

Sofia N. Verouti,[1,2] Delphine Lambert,[1,2] Escher Geneviève,[1,2] Bruno Vogt,[1,2] Daniel G. Fuster.[1,2] *[1]Department of Biomedical Research, University of Bern, Bern, Switzerland; [2]Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, Bern, Switzerland.*

Background: A heterozygous mutation (c.643C.A; p.Q215X) in the creatine transporter *SLC16A12* was proposed to cause a syndrome with juvenile cataracts, microcornea and glucosuria in one Swiss family. However, we previously discovered a digenic syndrome in the index family and demonstrated that the glucosuria was due to a concomitant *SCL5A2* mutation. In localization studies, we found SLC16A12 expression at the basolateral membrane of proximal tubular cells (PCT), and patients with the heterozygous *SLC16A12* mutation displayed significantly reduced plasma levels and increased fractional excretion rates of guanidinoacetate (GAA).

Methods: To further explore the role of SLC16A12 in renal physiology and decipher the mechanism underlying the heterozygous *SLC16A12* mutation in humans, we studied SLC16A12 deficient rats.

Results: SLC16A12 KO rats had lower plasma levels and increased 24 h urinary excretion rates of creatine and GAA compared to WT littermates. SLC16A12 KO rats also displayed lower plasma creatinine levels, but urinary creatinine excretion rates were reduced in parallel compared to WT rats. The phenotype of heterozygous rats was indistinguishable from WT rats. Metabolic cage experiments revealed no additional signs of tubular dysfunction in SLC16A12 KO rats. In addition, glomerular filtration rate, measured by FITC-sinistrin, was unaltered in SLC16A12 KO rats. Selective renal artery and vein sampling showed similar A-V differences in GAA concentrations between WT and SLC16A12 KO rats, indicating incomplete compensation of urinary GAA losses by renal synthesis in SLC16A12 KO rats. In support of this finding, mRNA expression of L-arginine:glycine amidinotransferase (AGAT), the rate limiting enzyme in GAA synthesis, was significantly reduced in kidneys of SLC16A12 KO rats.

Conclusions: Our results reveal that SLC16A12 is critical for tubular reabsorption of creatine and its precursor GAA from the glomerular filtrate. In the absence of SLC16A12, ongoing urinary losses of GAA are not adequately compensated by increased intrarenal synthesis, possibly caused by AGAT feedback inhibition due to impaired basolateral exit of creatine from the PCT. Furthermore, the lack of a phenotype in SLC16A12 heterozygous rats suggests a dominant-negative mechanism underlying the phenotype observed in humans with heterozygous c.643C.A; p.Q215X *SLC16A12* mutation.

Tubular Epithelial Cell-Derived Exosomal MiRNA-19b-3p Promotes M1 Macrophage Activation in Kidney Injury

Ye Feng. *Zhongda Hospital, Southeast university, Nanjing, China*.

Background: Tubulointerstitial inflammation is a common characteristic for acute and chronic kidney injury. However, the mechanism by which the initial injury on tubular epithelial cells (TECs) drives interstitial inflammation remains unclear. Here we set out to characterize the miRNA profile of kidney exosomes and aim to explore the role of exosomal miRNAs derived from TECs in the development of tubulointerstitial inflammation.

Methods: Exosomes were isolated from kidney and characterized via electron microscopy (EM) and nanoparticle analysis(NTA). We examined profiles of miRNAs in kidney exosomes from LPS-induced kidney injury model by Exiqon microarray. Putative targets of miRNA were predicted by TargetScan. Chronic proteinuric kidney disease model was induced by adriamycin(ADR) injection. Exosomes purified from TECs were added to macrophages or intrarenal injected to mice to determine its effects both in vitro and in vivo.

Results: Serum creatinine and urine albumin to creatinine ratios were significantly increased in LPS treated mice compared with controls. Histologically, the tubular epithelial cell injury, protein cast and CD68+ macrophage infiltration was found in LPS injected mice. EM and NTA confirmed the typical characteristic of exosomes. Global miRNA expression profiling on renal exosomes was examined in LPS-induced AKI model and miR-19b-3p was identified as the most remarkable miRNA increased in TEC-derived exosomes compared with controls. Similar results were found in ADR-induced chronic proteinuric kidney disease model in which exosomal miR-19b-3p was markedly released. Interestingly, once released, TEC-derived exosomal miR-19b-3p was internalized by macrophages, leading to M1 phenotype polarization through targeting NF-κB/SOCS-1. Importantly, the pathogenic role of exosomal miR-19b-3p in initiating renal inflammation was revealed by the ability of adoptive transfer of purified TEC-derived exosomes to cause tubulointerstitial inflammation in mice, which was reversed by inhibition of miR-19b-3p. Clinically, high levels of miR-19b-3p were found in urinary exosomes and correlated with the severity of tubulointerstitial inflammation in patients with diabetic nephropathy.

Conclusions: Exosome/miR-19b-3p/SOCS1 axis played a critical pathologic role in tubulointerstitial inflammation that might represent a new therapeutic target for kidney disease.

FR-PO1000

Impact of Nephron Number on Renal Uric Acid Excretion in Patients with IgA Nephropathy

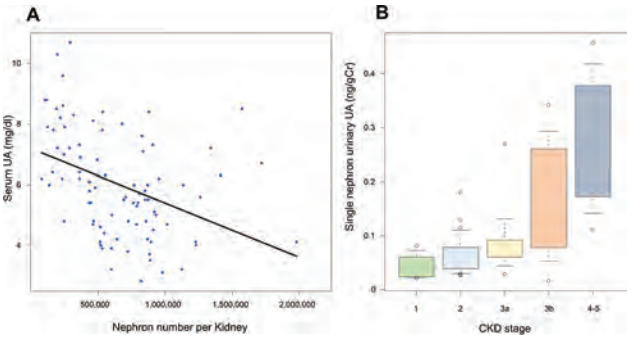
Hirokazu Marumoto,[1] Nobuo Tsuboi,[1] Takaya Sasaki,[1] Yusuke Okabayashi,[1] Kotaro Haruhara,[1] Go Kanzaki,[1] Kentaro Koike,[1] Kimiyoshi Ichida,[2] Takashi Yokoo.[1] *[1]Division of Nephrology and Hypertension, The Jikei University School of Medicine, Tokyo, Japan; [2]Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan.*

Background: Hyperuricemia is a risk factor for the progression of chronic kidney disease (CKD), which is characterized by a progressive loss of functioning nephrons. Uric acid (UA) induces renal tubular cell injury. To date, renal UA handling has not been examined in relation to nephron number in patients with CKD due to technical difficulties in counting nephrons in a clinical setting.

Methods: The relationships between parameters related to UA handling and clinically relevant factors, including total nephron number, were examined in patients with biopsy-proven IgA nephropathy (IgAN). The total nephron number was estimated by the combined use of unenhanced computed tomography and stereology-based estimation of non-sclerotic glomerular density in biopsy specimens (Sasaki T et al. 2018 ASN).

Results: A total 87 patients were included in the study (mean age, 39.7 years; 47.1% male; estimated glomerular filtration rate [eGFR], 67.1 ± 22.1 ml/min/1.73 m^2). The total nephron number in the patients ranged from 78,000 to 1,989,000 per kidney. The serum UA level and total nephron number showed a significant inverse correlation ($r = –0.395$, $p < 0.01$) (**Figure A**). Multivariate analysis showed that the association between the serum UA and nephron number was independent of gender, BMI, and renal function. The single-nephron excretion of urinary UA (urinary UA/urinary creatinine per total nephron number) was markedly increased in patients with advanced CKD at stage 3b or higher (**Figure B**).

Conclusions: The results of this study suggest that the total number of nephrons is an important determinant of the serum UA level in patients with IgAN. Abnormally concentrated UA in renal tubules due to compensatory failure may play additional roles in the progression of renal injury in patients with advanced-stage CKD.



FR-PO1001

Total Nephron Number and Renal Histopathological Lesions in IgA Nephropathy

Hirokazu Marumoto, Nobuo Tsuboi, Takaya Sasaki, Yusuke Okabayashi, Kotaro Haruhara, Go Kanzaki, Kentaro Koike, Tetsuya Kawamura, Takashi Yokoo. *Division of Nephrology and Hypertension, The Jikei University School of Medicine, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is the most frequently occurring primary glomerulonephritis. It is histopathologically characterized by various degrees of glomerulosclerosis together with a series of active proliferative lesions, which represent a process of progressive loss of functional nephrons. To date, total nephron number has not been evaluated in relation to the histopathological findings of IgAN due to the technical difficulties in counting nephrons in a clinical setting.

Methods: The histopathological findings in diagnostic biopsies of IgAN patients were evaluated based on the Oxford international classification and the Japanese histological grade. The latter is a lamped scoring system of glomerular lesions exhibiting cellular or fibrocellular crescents, segmental sclerosis, and global sclerosis. Total nephron number was calculated using a simplified method based on the combined use of unenhanced computed tomography and stereology-based estimation of non-sclerotic glomerular density on renal biopsy (Sasaki T et al. 2018, ASN).

Results: A total of 107 cases (age 43, male 54%, estimated glomerular filtration rate 61.5 ± 24.2 ml/min/1.73 m^2, urinary protein excretion 1.4 ± 1.6 g/day) were included. The frequencies of the Oxford classifications were as follows: M (0, 51%; 1, 49%), E (0, 88%; 1, 12%), S (0, 10%; 1, 90%), T (0, 74%; 1, 20%; 2, 6%) and C (0, 64%; 1, 36%), respectively. The frequencies of the Japanese histological grades were as follows: H-I, 56.1%; H-II, 28.0%; H-III, 13.1%; and H-IV, 2.8%. Among all patients, the total nephron number ranged from 78,000 to 1,989,000. Total nephron number was significantly associated with the S score ($p < 0.042$) and the T score ($p < 0.001$), but was not associated with the M, E and C scores of the Oxford classification. Moreover, total nephron number significantly decreased in parallel with increasing Japanese histological grade ($p < 0.001$). Multivariate analyses showed that the associations between total nephron number and the T score or H-grade were independent of age, amount of urinary protein excretion, and renal function at the time of biopsy.

Conclusions: These results suggest that the total nephron number may be associated with certain histopathological lesions and thus may be involved in the progression of renal injuries in IgAN.

ChromA-ExM: A New Application of Expansion Microscopy for Optical Imaging of Chromatin Architecture in Renal Tubular Epithelial Cells with Nanoscale Resolution

Kirolous Soliman,[2,1] Nicole D. Santos,[2] Maria F. Sobral reyes,[2] Joel O. Hernández ramos,[2,1] Dario R. Lemos.[2,1] Laboratory for Organ Regeneration and Tissue Engineering *[1]Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: In the eukaryotic cell nucleus, chromatin is physically organized into euchromatin and heterochromatin domains. Those domains regulate transcriptional accessibility to DNA, ultimately determining cell phenotype and function. Currently, high-resolution visualization of chromatin domain architecture can be achieved only with either electron microscopy or super-resolution microscopy. Both techniques have practical limitations, a major one being that they are not easily accessible to most laboratories. Here we introduced a modification to the original Expansion Microscopy (ExM) protocol developed at MIT that allows nanoscale resolution for visualization of high-order chromatin structures using regular confocal microscopes. The new procedure is called Chromatin Architecture Expansion Microscopy (ChromA-ExM)

Methods: Using conventional immunofluorescence techniques we labeled histone decorations in either cell or tissue specimens. The immunostained tissue specimens are subsequently embedded in a swellable polymer network, and digested with protease K. The combination of both treatments allows for ~4.5 isotropic expansion of the sample, which constitutes a magnification factor multiplied by the magnification of the microscope objective used. In ChromA-ExM we introduced steps of selective enzymatic digestion with DNAses allowing further expansion of chromatin domains

Results: Analysis of H3K9me3 chromatin domains in kidney PTECs indicated that, compared to regular ExM, the ChromA-ExM protocol results in increased resolution for visualization of high-order chromatin domains, including chromocenters associated with active cell phenotype, and senescence associated heterochromatin foci. Further, we can interrogate spatial interactions between $H3K9me3^{+}$ (silent chromatin) and $H3K4me3^{+}$ (open chromatin) domains in kidney tubular epithelial cells with exquisite detail, to detect architectural chromatin arrangements associated with kidney disease

Conclusions: ChromA-ExM is a new tool to study chromatin spatial configuration and chromatin status. The technique is useful for ultrastructural analysis of chromatin changes in PTEC senescence and tubular pathologies

Deletion of Proximal Tubular Cell VEGF Production Promotes Renal Fibrosis: Implications for VEGF-Based Cancer Therapy

Jamie Lin,[1] Hikaru Sugimoto,[1] Gangadhar Taduri,[2] Farhad R. Danesh,[1] Valerie Lebleu,[3] Raghu Kalluri.[1] *[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]Nizams Institute of Medical Sciences, Hyderabad, India; [3]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Targeting tumor angiogenesis by blocking VEGF (vascular endothelial growth factor) inhibits tumor development and growth, and is a common strategy in cancer therapeutics. Human and animal observations have shown that subtle changes in VEGF levels can result in hypertension, proteinuria, and glomerulopathies. VEGF deletion in all renal tubular epithelial cells has been reported to disrupt peritubular microvascularization. Since proximal tubular (PT) cells are arguably the primary target cells during kidney injury we hypothesized that loss of PT-VEGF production might provoke the development of renal fibrosis following injury.

Methods: We crossed GGT-$Cre^{+/-}$ mice with $VEGF^{f/f}$ mice to generate PT-specific VEGF knockout (GGT^{Cre+};$VEGF^{f/f}$) and control (GGT^{Cre-};$VEGF^{f/f}$) mice. Mice were challenged with unilateral ureteral obstruction (UUO) kidney injury model.

Results: PT-VEGF is dispensable for kidney development and health. No obvious histological differences including peritubular capillary assessment using CD31, an endothelial cell marker, was observed. To determine whether PT-secreted VEGF might contribute to the development of injury-induced interstitial fibrosis, both groups underwent UUO x Day 7. Increased tubular damage and interstitial fibrosis was observed in the PT-VEGF KO group compared to the control group. While there were no differences in peritubular capillary distribution in non-injured animals, segmental loss of peritubular capillaries with increased hypoxic areas was detected by carbonic anhydrase IX (hypoxia marker) staining in the PT-VEGF KO group. Furthermore, increased myofibroblasts was also observed in these animals.

Conclusions: PT-VEGF is necessary for the maintenance of the peritubular capillary network following kidney injury; preventing hypoxia, subsequent myofibroblast recruitment, and indirectly limiting renal fibrosis. Cancer patients are at high risk for developing acute kidney injury, and those on pharmacological inhibition of VEGF are even more vulnerable. These two factors alone warrant increased attention and diligence to our cancer patients who are at highest risk for progressive kidney disease and emphasize the growing importance of onco-nephrology.

FR-PO1004

Jade-1 in Double-Strand Break Repair in Kidney Cancer

Delia Lopez,[1,2] Kun-Lin Ho,[3] Leili Niu,[1,2] Ajit K. Bharti,[1,2] Herbert T. Cohen.[1,2] *[1]Boston University School of Medicine, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]University of Georgia, Athens, GA.*

Background: Like many solid tumors, kidney cancer is characterized by chromosomal breaks and instability, which arise from defects in DNA double-strand break (DSB) repair. We have established that Jade-1 is a renal tumor suppressor that induces apoptosis, inhibits proliferation, and inhibits oncoproteins Akt and β-catenin. Jade-1 also functions on DNA, through gene transcription, histone acetylation and DNA replication. As an unbiased approach to identify new Jade-1 tumor suppressor functions, Jade-1 was immunoprecipitated with Flag antibody in kidney cells to discover novel interactors via mass spectrometry. Surprisingly, many DNA repair proteins were found associated with Jade-1, including those involved in DSB repair, such as DNA-dependent protein kinase catalytic subunit (DNA-PKcs) and Ku70 and Ku80.

Methods: Kidney and kidney cancer cells were treated with a variety of agents that induce DSBs, including neocarzinostatin (NCS), a radiomimetic agent that induces DSBs. Immunofluorescence (IF) studies were done to visualize Jade-1 and DNA damage indicator γH2AX. Additionally, sensitivity assays were performed to assess for *Jade-1* dose-dependent survival differences in kidney proximal tubule-derived HK-2 cells, which serve as a model of renal cancer precursor cells.

Results: Interaction of endogenous Jade-1 and DNA-PKcs was confirmed in coimmunoprecipitations. Jade-1 was found to be inducible in kidney and kidney cancer cells in response to DSBs. IF studies demonstrated colocalization of Jade-1, γH2AX, and phospho-DNA-PKcs following DNA damage. Moreover, silencing of *Jade-1* in HK-2 cells offered protection against DNA damage in cell survival assays, supporting a direct role for Jade-1 in the DNA repair process.

Conclusions: We hypothesize that Jade-1 directly promotes DSB repair in part by binding and regulating DNA-PKcs, thereby favoring homologous recombination over error-prone repair through non-homologous end-joining. Our findings indicate that Jade-1 helps maintain genomic stability and further underscore its importance as a renal tumor suppressor. In short, understanding the molecular underpinnings of DNA repair may be critical for developing strategies for deterring progression of renal cancer and other solid tumors as well.

FR-PO1005

The Role of the Inflammatory Chemokine CCL20 in Renal Injury in Multiple Myeloma

Hong Dong Huang,[1] Sha Liu,[2] Wenhu Liu.[2] *[1]Department of Nephrology, Capital Medical University, Beijing, China; [2]Capital Medical University, Beijing, China.*

Background: The pathogenesis of the occurrence and development of renal injury in myeloma is unclear. In this study to investigate the role of inflammatory chemokine CCL20 in multiple myeloma with kidney injury.

Methods: To detect the expression of CCL20 in renal tissue and bone marrow of multiple myeloma patients with kidney damage by Immunohistochemical technique. Using flow cytometry to analysis proliferation of myeloma cells with overexpression or lowexpression of CCL20. By qRT PCR and flow cytometry method to detect expression of myeloma cells infiltrating organize related receptor CXCR4 and ROBO4 with overexpression or knockdown CCL20. Establish myeloma cells transplantation model. Vitro imaging techniques were used to observe myeloma cells implanted into the bone marrow and kidney tissue. By flow cytometry, to analysis the graft rate(%) of myeloma cells and expression of CXCR4 and ROBO4 in bone marrow cell population and renal tissue on mice with overexpression or knockdown CCL20. Morbidity and survival situation were dynamically observed for mice with overexpression or knockdown CCL20.

Results: The expression of CCL20 in myeloma and renal tissue was obviously higher than control group, and found that the myeloma cells with strong invasion ability had higher expression of CCL20 that suggested CCL20 were related with myeloma invasion ability. Showed that there was a difference in the ratio of immature cells in myeloma cells at different expression levels. The overexpression of CCL20 myeloma cell had significantly proliferated compared with the low expression of CCL20 myeloma cell. The CCL20 promoted the expression of CXCR4 and ROBO4 of myeloma cell. We had successfully established myeloma transplanted model. Animal experiments showed: After transplanting myeloma cells with knockdown CCL20 to immunodeficiency mice, myeloma cells badly survived and slightly damaged kidney. After transplanting overexpression of CCL20 myeloma cells to immunodeficiency mice, myeloma cell could survival well and damage kidney. The above thought that CCL20 in maintaining the survival of myeloma cells in bone marrow and renal tissue was necessary.

Conclusions: CCL20 plays an important role in the occurrence and development of renal injury in myeloma. Antagonistic CCL20 might be a new target for the prevention and treatment of renal injury in myeloma.

AKI Promotes the Development of Papillary Renal Carcinoma from Tubular Progenitors

Anna J. Peired,[1] Marco Allinovi,[3] Maria Lucia Angelotti,[2] Giulia Antonelli,[4] Francesco Guzzi,[4] Paola Romagnani.[4] *[1]Department of Biomedical, Experimental and Clinical Sciences "Mario Serio", University of Florence, Florence, Italy; [2]Excellence Center for Research, Transfer and High Education Denothe, University of Florence, Florence, Italy; [3]Meyer Children's Hospital, Firenze, Italy; [4]University of Florence, Firenze, Italy.*

Background: Renal cell carcinoma (RCC) accounts for about 2% of all cancers. Risk factors for RCC include obesity, diabetes, hypertension and genetic factors, but the majority of cancers occur in apparent absence of clear risk factors. As tissue injury is an important cofactor for many types of cancers, we propose to verify if acute kidney injury (AKI) plays a role in RCC development, and to identify the cellular origin of RCC.

Methods: We used the following techniques: 1. Experimental AKI induction in wild-type mice to study tumor development over 36 weeks. 2. Analysis of TCGA Research Network dataset on human papillary RCC (pRCC) molecular characterization, focusing on AKI-driven pathways. 3. Development of mouse models in which the intracellular domain of Notch 1 (NICD1) a molecule modulated during AKI, is expressed constitutively by all Pax8+ tubular epithelial cells (Pax8/NICD1) or only by Pax2+ renal progenitors (Pax2/NICD1) upon induction in adult mice. The mice were sacrificed at 36 weeks or 4 weeks after AKI. 4. Clonal analysis of tumoral lesions with Confetti reporter. 5. Examination of single cell RNA sequencing (RNAseq) data from pRCC patients.

Results: Wild-type mice subjected to AKI developed type 2 papillary adenomas and pRCCs over time. Among AKI-related pathways, Notch1 overexpression in human pRCC associated with worse outcome, prompting us to generate NICD1-overexpressing mice. At 36 weeks or at 4 weeks following AKI, Pax8/NICD1 mice presented a significant decline of renal function as well as type 2 pRCCs. Confetti lineage tracing showed that most of the pRCCs were mono- or biclonal, suggesting a local stem cell/progenitor cell origin. Pax2/NICD1 mice presented type 2 pRCCs, and lineage tracing identified single Pax2+ tubular progenitors as the source of pRCCs. RNAseq analysis confirmed that PT1 signature of pRCC cell of origin matched human tubular progenitor molecular characteristics.

Conclusions: AKI promotes long-term development of type 2 papillary tumors in mice by activating AKI-associated pathway Notch1. This study establishes Pax2+ renal progenitors as the cellular origin of the tumor in mice, and identifies renal progenitors as pRCC PT1 signature cells in humans.

Light Chain Endocytosis in Renal Proximal Tubular Cells Lead to Impaired Autophagy and Mitophagy

Avital Angel-Korman,[1] Brian Spencer,[2] Chinaemere Igwebuike,[3] Tatiana Prokaeva,[4] Zhiyong Wang,[1] Steven C. Borkan,[1] Lawreen H. Connors,[2] Andrea Havasi.[5] *[1]Boston Medical Center, Boston, MA; [2]Amyloidosis Center, Boston University, Boston, MA; [3]Boston University School of Medicine, Boston, MA; [4]Boston University, Boston, MA; [5]Boston University Medical Center, Boston, MA.*

Background: AL amyloidosis is the result of clonal production of amyloidogenic immunoglobulin light chain (LC) proteins, often resulting in renal failure. Although amyloid fibril deposition of LC proteins is a major cause of renal damage in AL amyloidosis, amyloid precursor proteins might also directly impair renal tubular function at the cellular level, independent of fibril formation. Light chains are actively reabsorbed in the proximal tubular epithelial cells (PTECs) by endocytosis and degraded in lysosomes. Lysosomes are also essential for functional autophagy, a process responsible for the removal of damaged mitochondria (mitophagy) and denatured proteins. We hypothesize that LC endocytosis causes PTEC injury by inhibiting autophagy, including mitophagy, resulting in accumulation of dysfunctional mitochondria, that mediates PTEC injury.

Methods: Cultured primary PTECs extracted from kidneys of Balb/C mice were exposed *in vitro* to 6 different LCs purified from patients' urine. Light chains were derived either from AL amyloid patients with associated nephropathy or from a non-amyloid myeloma patient, as control. Autophagic flux was estimated by immunoblot using the autophagy marker LC3-II, in both bafilomycin treated and untreated cells. Autophagosomes were quantified in live cells using fluorescent microscopy as well as a microplate reader. Mitochondrial respiration and reactive oxygen species production were measured in live cells. Mitochondrial morphology was also assessed using confocal microscopy.

Results: Patient derived LCs caused autophagy inhibition at various levels. Amyloid LC exposed cells accumulated damaged mitochondria with altered mitochondrial function and morphology resulting in increased ROS production.

Conclusions: Dysfunctional autophagy and mitophagy caused by direct cellular toxicity of LCs likely contribute to tubular cell toxicity in AL amyloidosis.

Repurposing Tolvaptan, a Drug for Polycystic Kidney Disease, for Renal Cell Carcinoma Therapy

Nidhi Dwivedi, Sonali Sinha, Abeda Jamadar, James P. Calvet, Reena Rao. *University of Kansas Medical Center, Kansas City, KS.*

Background: The vasopressin type-2 receptor (V2R) plays an essential role in the regulation of salt and water homeostasis by the kidneys. Based on a serendipitous finding that V2R is ectopically expressed in human clear cell renal cell carcinoma (ccRCC) tumors, the current studies examined if V2R plays a pathogenic role in ccRCC tumor growth. The effect of Tolvaptan, an FDA approved drug for hyponatremia and polycystic kidney disease was also tested.

Methods: V2R expression was examined using the cancer genome atlas database, and analysis of human RCC tumor tissue microarrays, cDNA arrays and tumor biopsy samples. *In vitro* and *in vivo* mouse tumor xenograft studies were performed to determine V2R's role in ccRCC tumor growth and test therapeutic interventions.

Results: V2R expression and activity, suggested by high intracellular cAMP and phosphorylated ERK1/2 (pERK1/2), levels were detected in human ccRCC tumors. The V2R antagonists OPC31260 and Tolvaptan, as well as V2R gene silencing reduced *in vitro* clonogenicity, wound closure and cell viability of 786-O and Caki-1 human ccRCC cell lines. V2R antagonists reduced pERK1/2 levels, while V2R agonist increased cAMP and pERK1/2 levels. Tolvaptan and OPC31260 also decreased RCC tumor growth in mouse xenograft models by reducing cell proliferation and angiogenesis, while increasing apoptosis. In contrast, the V2R agonist dDAVP significantly increased tumor growth.

Conclusions: These results provide novel evidence for the pathogenic role of V2R signaling in ccRCC and suggest that V2R antagonists, including the FDA approved drug Tolvaptan, could be utilized as novel therapeutics for ccRCC.

TIMAP Drives Tumor Angiogenesis

Salah A. Aburahes, Parnian Alavi, Md. M. Rahman, Laiji Li, Barbara J. Ballermann. *University of Alberta, Edmonton, AB, Canada.*

Background: TIMAP (TGFβ inhibited membrane associated protein) is an endothelial cell (EC)-predominant inhibitor of myosin phosphatase, which we first identified in glomerular EC. It is abundant in EC of developing, but not mature kidneys. Glomerular EC proliferation and sprouting angiogenesis *in vitro* require TIMAP. This study utilized the murine breast cancer model to determine whether *in vivo* angiogenesis also requires TIMAP.

Methods: Mouse mammary adenocarcinoma cells (E0771, syngeneic for C57BL/6 mice) were injected into mammary glands of 5 pairs of 8-week-old female TIMAP$^{+/+}$ and TIMAP$^{-/-}$ mice (C57BL/6 background). Each pair was euthanized on the day the tumor diameter, determined by externally applied calipers, in one mouse of the pair exceeded 1.5 cm. The tumors were excised, their weight and mean diameter measured. Vascular density was quantified using fluorescence microscopy for the EC marker PECAM1.

Results: Tumor size was similar in TIMAP$^{+/+}$ and TIMAP$^{-/-}$ mice through day 8-10. In 4 of 5 TIMAP$^{-/-}$, but not TIMAP$^{+/+}$ mice, the tumors then began to erode through the skin, bleed spontaneously and then regressed gradually. At the time of euthanasia (day 20-34 after injection) tumor size, weight and blood vessel density were significantly lower in TIMAP$^{-/-}$ compared to TIMAP$^{+/+}$ mice (Table).

Conclusions: The data are interpreted to indicate that mammary tumors in TIMAP$^{-/-}$ become necrotic and then involute due to insufficient hypoxia-driven angiogenesis. The data furthermore indicate that TIMAP provides a critical pro-angiogenic signal in EC, at least during tumor angiogenesis. Further work is required to determine whether TIMAP could be targeted in the treatment of highly vascular tumors, including renal cell carcinoma.

Funding: Private Foundation Support, Government Support - Non-U.S.

Tumor Parameters

	TIMAP+/+ (n=5)	TIMAP-/-(n=5)	p (Student t-test)
Mean Diameter (mm ± SD)	18.24 ± 3.56	10.85 ± 2.73	0.006
Mean Weight (g ± SD)	2.59 ± 0.92	0.55 ± 0.43	0.002
Vascular Density (arbitrary units ± SD)	32.05 ± 6.82	20.65 ± 8.52	0.048

FR-PO1010

Molecular Analysis of Urothelial Carcinoma After Kidney Transplantation

Lee-Moay Lim,[1,2] Daw-yang Hwang,[1] Hung-Tien Kuo.[1,3] *[1]Kaohsiung Medical University Hospital Division of Nephrology, Kaohsiung City, Taiwan; [2]Faculty of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan; [3]Faculty of Renal care, College of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan.*

Background: In Taiwan, urothelial carcinoma(UC) is the most common de novo cancer after kidney transplantation(KT). UC has high degree of molecular heterogeneity compared with other solid tumor. Mutational profiles as revealed by whole exome sequencing (WES) could help in identifying disease-specific genes and also novel genes for therapeutic target and outcomes. In this study, we perform WES of UC developed after KT in an effort to discover the molecular genetics of UC post KT.

Methods: Formalin-fixed paraffin-embedded tumor samples of UC and blood samples from 6 KT patients from our medical center were obtained. KT patients with UC diagnosed before the transplant surgery were excluded. All of the patients were sporadic, without any family history of UC. 5 hemodialysis patients with UC diagnosed after dialysis treatment were selected as control. DNA from tumor sample was extracted for WES analysis. Genomic DNA from blood sample was confirmed by Sanger sequencing as mutation validation.

Results: Our WES data was matched with the Catalogue of Somatic Mutations In Cancer (Cosmic), Intogen, and The Cancer Genome Atlas (TCGA) database for onco-driver genes. 8 genes were identified, including *GNAQ, MLLT10, SEPT6, SLC34A2, NTRK3, IKZF1, SH3GL1,* and *HOXD13.* After validation from genomic DNA, 6 genes were identified as uniquely found in tumor sample: *MLLT10, SH3GL1, SEPT6, IKZF1, GNAQ and NTRK3*.

Conclusions: This preliminary data provides clues for understanding the mutational landscape of UC developed after KT. In future, functional study regarding these 6 genes will be developed in an effort to investigate the mutational environment of UC after KT.

Funding: Private Foundation Support

Kidney Involvement in Primary Myelofibrosis and Possible Role of the JAK-STAT Pathway

Miguel Gil,[1] Harini Bejjanki,[1] Shahab Bozorgmehri,[1] Peter Sayeski,[1] Rajesh Mohandas.[1,2] *[1]University of Florida, Gainesville, FL; [2]Renal Section, Malcolm Randall VA Medical Center, Gainesville, FL.*

Background: Isolated case reports have described a connection between primary myelofibrosis (PMF) and kidney disease. Activation of JAK-STAT pathways, commonly seen in PMF, leads to worsening kidney function in rodent models. Hence, we hypothesized that JAK-STAT activation in PMF may be associated with kidney disease.

Methods: We used the integrated data repository to identify all adult patients with PMF evaluated at an academic hospital between 1/1/2007 and 11/20/2017. We recruited a control group matched for age, sex, and presence or absence of diabetes mellitus. Chronic kidney disease (CKD) was defined as estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73m^2. Paired t-test was used to compare continuous variables and McNemar's test for categorical variables. Change in renal function over time was compared using mixed-effects model. A p-value < 0.05 was considered significant.

Results: Most patients with PMF(n=46) were Caucasian (93%), male (57%) and older (mean age of 66 ± 11 years). 70% had hypertension and 18% diabetes. Cytogenetic analysis showed more than half had a Jak2 mutation (67%). There were no differences in baseline renal function or prevalence of CKD between patients with PMF and matched controls. Proteinuria on dipstick was more common in PMF than controls (50 % vs. 18%, p=0.03). Patients with PMF and Jak 2 mutation were more likely to have proteinuria at baseline (73%) compared without Jak 2 mutations (22%) or controls (18%) Overall p<0.005. A mixed effects model showed no changes in eGFR over time. However, patients with PMF had higher blood urea nitrogen (BUN) levels at follow-up than matched controls (22±9 vs. 18±12 mg/dl, p=0.001) and a significant increase in BUN (3.3±9.8 vs. 0.5±8.2 mg/dl, p=0.03) from baseline.

Conclusions: Patients with PMF were more likely to have proteinuria, higher BUN at follow-up and a significant increase in BUN compared to controls matched for age, gender, and diabetes. Proteinuria was more likely in those with Jak2 mutations. Our results suggest that PMF is associated with kidney dysfunction and highlights the need for more thorough assessment of renal function in these patients. Identifying the molecular basis of these clinical observations could help improve outcomes in PMF and give us novel insights into the pathogenesis of kidney disease.

FR-PO1012

Urinary mRNA Signature of Graft vs. Kidney Disease in Hematopoietic Stem Cell Transplant Recipients Mirror Acute Rejection of Kidney Allograft

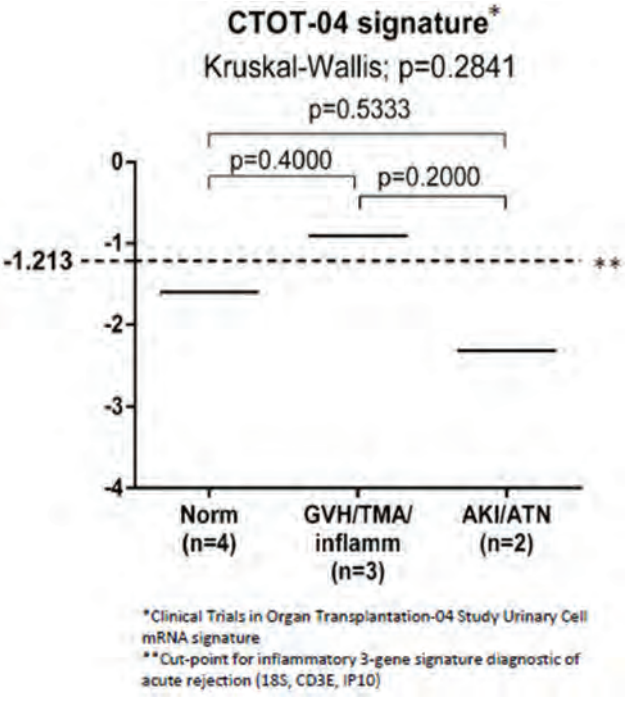
Michelle L. Lubetzky, Michael F. Cassidy, Catherine Snopkowski, Koen Van besien, Thangamani Muthukumar. *Weill Medical College of Cornell University, New York, NY.*

Background: Acute kidney injury (AKI) is a complication of hematopoietic stem cell transplants (HSCT). GVKD can resemble acute rejection (AR) of kidney allograft, with inflammation in the intersititium and tubules. In GVKD, the graft inflammatory cells attack the host kidney (compared to host versus graft disease in AR). HSCT recipients have multiple comorbid conditions and performing kidney biopsies in patients with AKI can be challenging. Development of urinary mRNA profiles as noninvasive biomarkers has been validated as a robust tool for the noninvasive assessment of kidney allograft status. We hypothesized that urinary mRNA cells in patients with GVKD would mirror AR in kidney allograft and could serve as a tool for the noninvasive diagnosis of AKI.

Methods: We obtained urine specimens from 9 HSCT recipients; 3 with AKI and biopsy diagnosis of GVKD; 2 with AKI that resolved spontaneously; and 4 with normal kidney function. We isolated RNA from urinary cells and quantified the CTOT-04 three-gene molecular signature for AR (urinary cell mRNA levels of 18S, CD3e and IP10, Suthanthiran et al, N Engl J Med 2013) by RT-qPCR assay.

Results: Of the 3 patients with AKI who received kidney biopsy, 2 had significant interstitial inflammation that stained positive for CD3 and/or Granzyme B in the interstitium and tubules. Figure 1 demonstrates the mRNA levels and 3 gene signature of the 3 patients with GVKD as compared to 2 HSCT patients with AKI that resolved and 4 HSCT patients with normal kidney function. The cell signature of GVKD most clearly resembles that found in AR.

Conclusions: Our results demonstrate an immune inflammatory signature in the urine of patients with HSCT who have GVKD. Our pilot study further advances urinary cell mRNA profiling as a noninvasive tool for the differential diagnosis of AKI in HSCT recipients.



FR-PO1013

Mesoscale Nanoparticles Treat Cisplatin-Induced AKI and Avoid Tumor Accumulation

Edgar A. Jaimes, Ryan M. Williams, Janki Shah, Daniel A. Heller. *Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Acute kidney injury (AKI) develops in ~ 30% of patients who receive cisplatin-based chemotherapy. In this setting, AKI can result in delays in completion of treatment or the need to switch to other therapeutic regimens. Despite its high incidence there is no effective pharmacologic intervention for AKI. In cisplatin-induced AKI, it is imperative that any intervention effective for AKI will not interfere with the chemotherapeutic effects of cisplatin. In prior work (Nano Letters 2015) we developed mesoscale nanoparticles (MNPs) that localize to the kidneys with high affinity, primarily to the proximal tubules.

Methods: We synthesized nanoparticles from PLGA-PEG and encapsulated the small molecule reactive oxygen species scavenger edaravone. Experiments were performed in C57 mice with cisplatin-induced AKI (25 mg/kg IP). To assess therapeutic efficacy, IV injections of 50 mg/kg edaravone-containing MNPs, control MNPs, or 30 mg/kg free edaravone were performed 24 hours after cisplatin. Mice were euthanized at 72 hours post-cisplatin. In a separate group of mice bearing metastatic small cell lung cancer, fluorescent MNPs were injected to determine whether MNPs localization.

Results: Compared to mice receiving cisplatin alone, mice receiving edaravone-containing MNPs had normal sCr and normal renal histology. Neither free edaravone nor empty MNPs improved sCr or histology. In mice with metastatic lung tumors, we determined that MNPs maintain their specific renal distribution and do not localize to tumors as has been described with smaller nanoparticle systems.

Conclusions: These studies confirm the likelihood of successful AKI therapy in the context of cisplatin-induced AKI, while avoiding the possible therapeutic abatement associated with tumor deposition of ROS scavengers. We anticipate that these studies will constitute the basis for the development of novel strategies for the treatment and prevention of cisplatin induced AKI in humans.

Association of Systolic Blood Pressure with Cardiovascular and Renal Outcomes in CKD: A Nationwide Cohort Study

Shin-Wook Kang,[2] Chan-Young Jung,[2] Byounghwi Ko,[2] Wonji Jo,[2] Tae ik Chang.[1] *[1]Department of Internal Medicine, National Health Insurance Service Medical Center, Ilsan Hospital, Gyunggi-do, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea.*

Background: Blood pressure (BP) is associated with a linearly incremental risk for cardiovascular disease and death in the general population. However, the ideal BP to decrease cardiovascular and renal risk in patients with non-dialysis-dependent chronic kidney disease (CKD) is unclear.

Methods: We studied the associations of baseline systolic BP (SBP) with the risk of composite outcomes (all-cause death, acute myocardial infarction, heart failure, stroke, and end-stage renal disease) in 1.5 million adults who participated in the NHIS National Health Checkup Program between 2009 and 2012 and had an estimated glomerular filtration rate (eGFR) 15–59 mL/min/1.73m^2 at study entry using Cox proportional hazard models.

Results: During 8,223,922 person-years of follow-up, the composite outcomes occurred in 305,851 (20.5%) subjects with a crude event rate of 37.2 (95% CI, 37.1-37.3) per 1,000 person-years. In fully-adjusted Cox models, there was a U-shaped association between SBP and composite outcomes, such that SBP <120 mmHg and SBP ≥130 mmHg were each associated with higher risk of cardiovascular and renal outcomes (reference: 120-129 mmHg): the HRs (95% CIs) were 1.20 (1.18-1.22), 1.08 (1.07-1.09), 1.03 (1.02-1.04), and 1.10 (1.09-1.11) for SBP <110, 110-119, 130-139, and ≥140 mmHg, respectively. These associations remained consistent and significant across all eGFR strata.

Conclusions: In a large national cohort of Korean adult population with CKD, the association of SBP levels with cardiovascular and renal risks was U-shaped, with both lower and higher SBP levels showing a substantial and significant increase in death, major cardiovascular events, and end-stage renal disease.

The Influence of Baseline Diastolic Blood Pressure on the Effects of Intensive Blood Pressure Lowering on Cardiovascular Outcomes in Type 2 Diabetes Mellitus

Olesya Ilkun,[1] Tom Greene,[1] Guo Wei,[1] Robert E. Boucher,[1] Alfred K. Cheung,[1] Glenn M. Chertow,[3,4] Walter T. Ambrosius,[5] Paul K. Whelton,[2] Srinivasan Beddhu.[1,4] *[1]University of Utah School of Medicine, Salt Lake City, UT; [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [3]Stanford University School of Medicine, Palo Alto, CA; [4]VA SLC Healthcare System, Salt Lake City, UT; [5]Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Intensive (INT) compared to standard (STD) systolic blood pressure (SBP) control might be harmful in persons with low baseline diastolic blood pressure (DBP) and type 2 diabetes mellitus (T2DM).

Methods: ACCORD BP was a 2X2 factorial design RCT that examined the effects of SBP control (<120mmHg vs. <140 mmHg) and glycemia (GLY) control (HbA1C goal < 6% vs. 7.0–7.9%) on a primary cardiovascular disease (CVD) composite outcome in T2DM (N = 4714). We examined whether the effects of INT SBP lowering on CVD was modified by baseline DBP stratified by the GLY arm.

Results: There were 689 CVD events/ 21,389 years of follow-up. Lower baseline DBP was associated with increased risk of CVD composite (Fig 1). INT SBP lowering decreased the risk of the CVD composite in the STD GLY arm (HR 0.76, 95% CI 0.62 to 0.93) but not in INT GLY arm (HR 1.05, 95% CI 0.85 to 1.31). Linear interaction p-values for SBP intervention and baseline DBP were not significant in the STD (p = 0.58) or INT (p=0.78) GLY arms. The effects of INT SBP lowering on CVD composite in those with DBP ≤70 mmHg compared to those with DBP > 70 mmHg were similar within the STD or INT GLY arms (Fig 2).

Conclusions: Low baseline DBP was associated with increased risk of CVD composite in T2DM. However, there was no evidence that the beneficial effects of INT SBP lowering on CVD events in STD GLY arm was modified by low baseline DBP.

FR-PO1016

Association of Pulse Pressure and Double Product with Cardiovascular and All-Cause Mortality in the LURIC Study

Bernhard K. Krämer,[1] Winfried März,[2,1] Babak Yazdani.[1] LURIC Study Group *[1]5th Department of Medicine, University Hospital Mannheim, Medical Faculty Mannheim of the University of Heidelberg, Mannheim, Germany; [2]Synlab Holding Deutschland GmbH, Mannheim, Germany.*

Background: Systolic (SBP) and diastolic blood pressure (DBP) as well as mean arterial pressure (MAP) are already known as important predictors respectively risk factors for cardiovascular mortality. Pulse pressure (PP) is considered as an easily available marker of vascular stiffness and the double product (DP; SBP x heart rate (HR)) as a marker of cardiac workload. Therefore, we extended our analysis of outcome parameters by use of PP and DP.

Methods: We retrospectively analysed data from the Ludwigshafen Risk and Cardiovascular Health (LURIC) study, in which 3316 patients underwent coronary angiography.

Results: Long-term data from 3316 patients undergoing coronary angiography showed that by increasing SBP by 1mmHg the risk of both cardiovascular and all-cause mortality rose by 0.9 %. However, there was no significant relationship between DBP and mortality. A higher PP of 1 mmHg resulted in a higher cardiovascular mortality risk of 1.6 % and an all-cause mortality risk of 1.7 %. Increasing DP by 100 mmHg/min was associated with a 1.0 % higher risk of cardiovascular mortality and 0.9 % higher risk of all-cause mortality.

Conclusions: We provide evidence that not only the classic standard blood pressure parameters SPB and MAP predict cardiovascular mortality, but also that PP and DP are powerful predictors of cardiovascular and all-cause mortality in a cardiovascular risk population. PP and DP are superior predictors of a higher cardiovascular mortality in heart failure patients.

FR-PO1017

Systolic Blood Pressure and Risk of Incident CKD: A Nationwide Cohort Study of 10 Million Adults in South Korea

Hyung Woo Kim,[2] Chan-Young Jung,[2] Byounghwi Ko,[2] Wonji Jo,[2] Shin-Wook Kang,[2] Tae ik Chang.[1] *[1]Department of Internal Medicine, National Health Insurance Service Medical Center, Ilsan Hospital, Gyunggi-do, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea*.

Background: In the general population, guidelines recommend a target blood pressure (BP) <120/80 mmHg in order to reduce cardiovascular risk. However, the optimal BP to prevent chronic kidney disease (CKD) is unknown.

Methods: In a national population-based cohort of 10.5 million adults who underwent National Health Insurance Service health examination between 2009 and 2015 and had an estimated glomerular filtration rate (eGFR) ≥60 mL/min/1.73m^2 at baseline, we studied the association of time-updated and baseline systolic BP (SBP) with risk of incident CKD using marginal structural models (MSMs) and Cox models. Incident CKD was defined as *de novo* development of eGFR <60 mL/min per 1.73m^2 for at least two consecutive measurements.

Results: During 49,169,311 person-years of follow-up, incident CKD developed in 172,423 (1.64%) subjects with a crude event rate of 3.51 (95% CI, 3.49-3.52) per 1,000 person-years. Using MSMs, we found a graded association between incrementally higher time-updated SBP levels ≥130 mmHg and risk of incident CKD, whereas SBP levels <120 mmHg were associated with lower risk (reference: 120-129 mmHg): HRs (95% CIs) were 0.57 (0.55-0.58), 0.81 (0.80-0.82), 1.41 (1.39-1.43), and 2.16 (2.12-2.19) for SBP <110, 110-119, 130-139, and ≥140 mmHg, respectively. Using Cox models, the corresponding HRs for the noted SBP range were 0.84 (0.82-0.85), 0.92 (0.91-0.94), 1.11 (1.09-1.12), and 1.30 (1.28-1.32), respectively. Among subjects receiving antihypertensive medications, time-updated SBP of <110 mmHg was associated with higher risk of CKD: HR (95% CI) 1.07 (1.00-1.15).

Conclusions: In healthy people without kidney disease, higher SBP ≥130 mmHg was associated with higher risk of incident CKD. However, among those receiving antihypertensive therapy, low SBP <110 mmHg was also associated with incident CKD risk, suggesting that excessive BP control may contribute to adverse renal outcomes.

FR-PO1018

The Influence of Blood Pressure Patterns on Renal Outcomes in Patients with CKD: The Long-Term Follow-Up Result of the APrODiTe-2 Study

Ran-hui Cha,[1] Hajeong Lee,[2] Jung Pyo Lee,[3] Sung gyun Kim.[4] *[1]National Medical Center, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Hallym University, Anyang, Republic of Korea*.

Background: Blood pressure (BP) control is the most established practice for preventing the progression and complications of chronic kidney disease (CKD). We examined the influence of BP patterns on target organ damage in hypertensive patients with CKD by using long-term follow-up data of the APrODiTe-2 study.

Methods: We collected 5 years of data of APrODiTe-2 study participants (n=378).

Results: Initially, the BP control and the dipping states were as follows: true controlled (16.5%), white-coat (2.9%), masked (50.0%), and sustained uncontrolled (30.6%); extreme-dipping (11.4%), dipping (22.2%), nondipping (31.3%), and reverse-dipping (35.0%). Only 18.8% and 20.8% of participants showed a better change in BP control patterns (to true controlled and white-coat) and a dipping pattern change to dippers over 1 year, respectively. Twenty-two patients (5.8%) died. Composite of new cerebro-cardiovascular (CCV) accidents occurred in 43 patients (11.4%), and no BP patterns were associated with the occurrence of new CCV accidents. A worse change in BP control categories over 1 year was associated with increased occurrence of composite of doubling of serum creatinine, a 50% decrease in the estimated glomerular filtration rate (eGFR), the initiation of dialysis, and kidney transplantation after adjustment for age, sex, and the cause of CKD. Patients with a worse initial BP control category, a worse change in BP control categories over 1 year, and higher clinic systolic BP and pulse pressure (PP) (> median level) were more likely to have faster eGFR progression (absolute eGFR and eGFR ratio).

Conclusions: Higher BP burden (a worse change in BP control categories, higher initial clinic systolic BP and PP) was associated with faster eGFR progression and increased occurrence of renal outcomes.

FR-PO1019

Outcomes in Adults with Systolic Blood Pressure Between 130 and 139 mm Hg in ACCORD BP and SPRINT

Gabriel Contreras,[1] Lingyi Lu,[2] Leonardo Tamariz,[1] Michael V. Rocco,[2] Vasilios Papademetriou,[5] John B. Kostis,[8] Roberto Pisoni,[3] Stephen P. Glasser,[6] Mary Ellen T. Sweeney,[11] Jan N. Basile,[9] Lisa H. Gren,[7] Sara Zamanian,[10] William C. Cushman.[4] The SPRINT Research Group. *[1]University of Miami, Miami, FL; [2]Wake Forest School of Medicine, Winston-Salem, NC; [3]Medical University of South Carolina, Charleston, SC; [4]Memphis VA Medical Center, Memphis, TN; [5]Georgetown University, Potomac, MD; [6]UAB, Nicholasville, KY; [7]University of Utah, Salt Lake City, UT; [8]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [9]MUSC, Charleston, SC; [10]Geisinger Medical Center, Danville, PA; [11]Emory University School of Medicine, Atlanta, GA*.

Background: Patients with stage 1 systolic hypertension (130-139 mmHg) have increased risk of cardiovascular disease (CVD) events compared to those with normal blood pressure.

Methods: In this post-hoc analysis, we assess the effect of targeting an intensive systolic blood pressure (SBP) goal of less than 120 mmHg compared with standard SBP goal of less than 140 mmHg on the risk of CVD events in adults with stage 1 systolic hypertension enrolled in the Action to Control Cardiovascular Risk in Diabetes (ACCORD) Blood Pressure (BP) Trial (n=1,901) and the Systolic Blood Pressure Intervention Trial (SPRINT) (n=3,484) using adjusted Cox models. In ACCORD, the primary composite CVD outcome was the first occurrence of myocardial infarction (MI), stroke or CVD mortality. In SPRINT, the primary composite CVD outcome was the first occurrence of MI, other acute coronary syndrome, stroke, heart failure or CVD mortality.

Results: In SPRINT, targeting an intensive SBP goal significantly reduced the risk of the primary CVD outcome (hazard ratio [HR] 0.75, 95% confidence interval [95% CI] 0.57-0.98; 1.78 vs. 2.37 % per year). In ACCORD BP, the relationships of SBP goal with the primary CVD outcome was modified by the glycemia goal intervention (interaction P = 0.039). In the standard glycemia subgroup (A1c target 7-7.9%), intensive SBP goal significantly reduced the risk of the primary CVD outcome (HR 0.61 [0.40-0.94]; event rates 1.63 vs. 2.56 % per year). In the intensive glycemia subgroup (A1c target <6%), the risk of the primary CVD outcome was not significantly different between SBP goal groups (HR 1.20 [0.76-1.89]; event rates 1.91 vs. 1.60 % per year).

Conclusions: Targeting a SBP goal of less than 120 mmHg significantly reduced the risk of CVD events in patients with stage 1 systolic hypertension without diabetes and with diabetes on standard glycemia goal.

Funding: NIDDK Support, Other NIH Support - ACCORD BP and SPRINT were supported by the National Heart, Lung, and Blood Institute, the National Institute of Diabetes and Digestive and Kidney Disease, the National Institute on Aging, the National Institute of Neurological Disorders and Stroke, and the Department of Veterans Affairs. The study was approved by the SPRINT research group. Authors analyzed and interpreted the data for this abstract, with support from the Department of Biostatistical Sciences, Wake Forest School of Medicine, Winston-Salem, NC. All aspects of the abstract writing and revision were initially carried out by the authors, with subsequent revisions made according to the SPRINT research group recommendations. FR-PO1020

The Influence of Baseline Diastolic Blood Pressure on the Effects of Intensive Blood Pressure Lowering on All-Cause Mortality in Type 2 Diabetes Mellitus

Olesya Ilkun,[1] Tom Greene,[1] Guo Wei,[1] Robert E. Boucher,[1] Alfred K. Cheung,[1,4] Glenn M. Chertow,[2] Walter T. Ambrosius,[5] Paul K. Whelton,[3] Srinivasan Beddhu.[1,4] *[1]University of Utah School of Medicine, Salt Lake City, UT; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [4]VA SLC Healthcare System, Salt Lake City, UT; [5]Wake Forest School of Medicine, Winston-Salem, NC*.

Background: Intensive (INT) compared to standard (STD) systolic blood pressure (SBP) control might be harmful in persons with low baseline diastolic blood pressure (DBP) and type 2 diabetes mellitus (T2DM).

Methods: The Action to Control Cardiovascular Risk in Diabetes Blood Pressure trial (ACCORD BP) was a 2X2 factorial design RCT that examined the effects of SBP control (<120mmHg vs. <140 mmHg) and glycemia (GLY) control (HbA1C goal < 6% vs. 7.0–7.9%) on cardiovascular events and all-cause mortality (ACM) in T2DM (N = 4714). We examined whether the effects of INT SBP lowering on ACM was modified by baseline DBP stratified by the GLY arm.

Results: There were 292 ACM events/ 23,326 years of follow-up. Lower baseline DBP was associated with increased risk of ACM (Fig 1). Hazard ratios for INT SBP lowering in the STD and INT GLY arms were 0.84 (95% CI 0.60 to 1.17) and 1.34 (95% CI 0.97 to 1.84), respectively. Linear interaction p-value for SBP intervention and baseline DBP was not significant in the STD GLY arm (p = 0.40) but significant in INT GLY arm (p=0.01). In those with DBP ≤70 mmHg, INT SBP lowering appeared not harmful in the STD GLY arm but deleterious in the INT GLY arm (Fig 2).

Conclusions: Low baseline DBP was associated with increased risk of ACM in T2DM. In persons with baseline DBP ≤70 mm Hg, INT SBP lowering increased ACM in the setting of INT GLY but not STD GLY.

FR-PO1021

Heart Failure Risk with Intensive Systolic Blood Pressure (SBP) Lowering Does Not Differ by Albuminuria Status in Diabetes

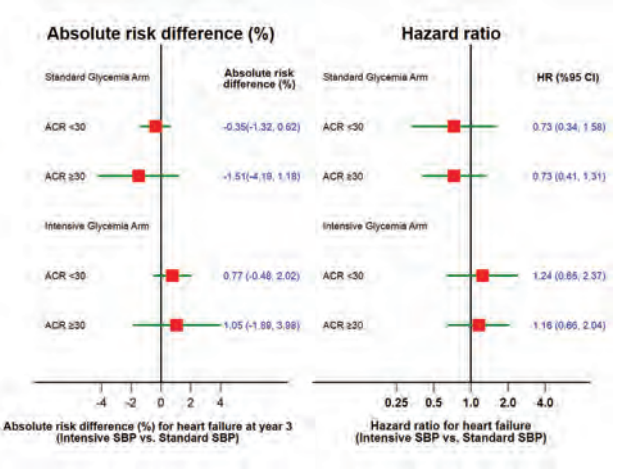
Chandra Kanth Chaturvedula,[1] Holly J. Kramer,[1] Guo Wei,[2] Robert E. Boucher,[3] Sri Mahathi P. Kalipatnapu,[4] Srinivasan Beddhu.[3] *[1]Loyola University Medical Center, Maywood, IL; [2]University of Utah, Salt Lake City, UT; [3]University of Utah School of Medicine, Sandy, UT; [4]Macneal Hospital, Berwyn, IL.*

Background: Albuminuria is associated with heightened risk for heart failure (HF) in persons with diabetes mellitus (DM) but optimal SBP goals for reducing HF risk remain controversial. We examined the effects of intensive vs. standard SBP lowering on HF risk by baseline albuminuria status among adults with DM.

Methods: Using data from the Action to Control Cardiovascular Disease (ACCORD) trial. Kaplan Meier curves were used to examine time to acute decompensated HF events by intensive vs. standard SBP lowering and by baseline albuminuria status (albumin-to-creatinine ratio < 30 mg/g vs. ≥ 30 mg/g) after stratifying by intensive vs. standard glucose control. Interaction terms of albuminuria x intensive SBP lowering on HF risk were fitted into Cox proportional hazard models while adjusting for demographics, estimated glomerular filtration rate, blood pressure, and heart disease.

Results: A total of 4524 patients (2257 in standard SBP arm, mean age 62.5 (6.5) years and baseline SBP (142.9 (15.8) mmHg and 2267 in intensive SBP arm, mean age 63.2 years and baseline SBP 137.1 (14.6) mmHg), were followed for a mean of 4.78 years. Within the standard glycemia arm, the absolute risk difference of HF (intensive vs. standard SBP) was -0.35(-1.32, 0.62) in ACR<30 and -1.5(-4.19,1.18) in ACR >30, whereas in the intensive glycemia arm, it was 0.77 (-0.48,1.18) in ACR<30 and 1.05(-1.89,3.98) in ACR >30. Hazard Ratio(95% CI) in the standard arm was 0.73(0.34,1.58) and 0.73(0.41,1.31) in the ACR <30 and ACR>30 respectively, and in the intensive arm 1.24(0.65, 2.37) and 1.16(0.66, 2.04) in the ACR <30 and >30 respectively.

Conclusions: The effects of intensive SBP lowering on HF rates does not appear to be modified by albuminuria status in adults with DM.



Absolute risk difference and Hazard ratio in both the groups

FR-PO1022

Association Between eGFR Variability and Risk of Cardiovascular Events and Mortality: The SPRINT Trial

Rakesh Malhotra,[1] Ronit Katz,[2] Vasantha Jotwani,[15] Adhish Agarwal,[3] Debbie L. Cohen,[4] William C. Cushman,[5] Anthony A. Killeen,[14] Vasilios Papademetriou,[6] Chirag R. Parikh,[7] Kalani L. Raphael,[8] Michael V. Rocco,[9] Leonardo Tamariz,[10] Jackson T. Wright,[11] Michael Shlipak,[12] Joachim H. Ix.[13] *[1]University of California San Diego, San Diego, CA; [2]University of Washington, Seattle, WA; [3]University of Utah, Salt Lake City, UT; [4]University of Pennsylvania School of Medicine, Philadelphia, PA; [5]Memphis VA Medical Center, Memphis, TN; [6]Georgetown University, Potomac, MD; [7]Johns Hopkins University, Baltimore, MD; [8]VA Salt Lake City Health Care System, Salt Lake City, UT; [9]Wake Forest School of Medicine, Winston-Salem, NC; [10]University of Miami, Doral, FL; [11]Case Western Research University, Cleveland, OH; [12]San Francisco VA Medical Center, San Francisco, CA; [13]UCSD, San Diego, CA; [14]University of Minnesota, Minneapolis, MN; [15]UCSF, San Francisco, CA.*

Background: In clinical practice, there is considerable visit-to-visit variability in estimated glomerular filtration rate (eGFR). While low eGFR is an established cardiovascular disease (CVD) risk factor, less is known about the clinical significance of eGFR variability over time.

Methods: Among 7520 SPRINT participants, we used proportional hazards models to estimate associations between eGFR variability (measured by coefficient of variation, CV) and subsequent CVD events and all-cause mortality. The CV (SD/mean) was calculated from eGFR values measured at 6-, 12-, and 18-month study visits. CVD events were defined as the composite of MI, ACS, stroke, heart failure, or CVD death. The final model was adjusted for demographics, randomization, prior CVD, heart failure, current smoking, body mass index, serum lipids, baseline systolic BP, albuminuria, eGFR at month 6, medications (ACEI/ARB or diuretics at month 6) and fasting status.

Results: The mean age was 68±9 years, 65% were men, and 58% were white. The mean eGFR was 73±21 ml/min/1.73m^2 at 6 months. There were 370 CVD events and 154 deaths during a median follow-up of 2.4 years. In adjusted model, greater eGFR variability was associated with all-cause mortality (hazard ratio (HR) per SD increase in eGFR-CV (0.06), 1.28; 95% CI 1.14 - 1.44). Associations were somewhat weaker for CVD events (HR 1.06; 0.96 -1.17) (Figure 1). When variability was evaluated by quartiles, the highest compared with the lowest quartile was associated with both all-cause mortality (HR 1.57; 0.99 - 2.47) and CVD events (HR 1.35; 0.99 - 1.84). Associations were similar when stratified by treatment arm and baseline CKD status.

Conclusions: Greater eGFR variability was associated with higher risk for all-cause mortality in SPRINT trial participants, independent of baseline eGFR. Future studies should evaluate mechanisms underlying these associations.

FR-PO1023

Association of Pulse Wave Velocity with Renal Outcomes in Pre-Dialysis CKD: Results from the Korean Cohort Study for Outcomes in Patients with CKD (KNOW-CKD)

Yongjin Yi, Kipyo Kim, Jong Cheol Jeong, Sejoong Kim, Ho Jun Chin, Ki Young Na, Dong-Wan Chae. *Seoul National University Bundang Hospital, Seongnam-si, GyeonGgi-Do, Republic of Korea.*

Background: Vascular stiffness, a common complication of CKD, would inhibit the capacity of arteries to dampen systolic blood pressure, which would lead to increased barotrauma to glomerular capillary. Therefore, we assessed the effect of brachial-ankle pulse wave velocity (baPWV) on renal outcomes in pre-dialysis CKD.

Methods: KNOW-CKD is a currently on-going prospective cohort study of CKD in Korea in which nine major tertiary hospitals are participating (NCT01630486). A total of 1,903 subjects who performed baPWV test and have ankle-brachial index>0.9 was selected. Mean value of right and left baPWV (mbaPWV) was used for analysis. Renal event (RE) was defined by the doubling of serum creatinine or 50% decrease in CKD-EPI eGFR from the baseline values, or the initiation of renal replacement treatment. The subjects were grouped according to quartile value of mbaPWV. The values of mbaPWV in each quartile group were Q1: 857.5–1,292.5 cm/sec, Q2: 1,293.0–1,458.5 cm/sec, Q3: 1,459.0-1,701.5 cm/sec, Q4: 1,702.3-4,632.5 cm/sec respectively.

Results: Of 1,903 subjects, a total of 507 subjects (26.6%) developed RE during the mean follow up period of 3.6 years. Cox regression analysis adjusted by sex, age, CKD-EPI eGFR, urine albumin creatinine ratio (UACR), medical history of diabetes, hypertension, coronary diseases, hypercholesterolemia, smoking and alcohol revealed that each unit increase of ln (mbaPWV) was associated with 91.7% increase in risk for RE (HR=1.92 95% CI; 1.11-3.32, p=0.021). Time dependent Cox regression adjusted by the same variables revealed that RE increased along with mbaPWV quartile groups (Q1: reference, Q2: HR=2.13; 95% CI 1.07-4.23; p=0.032, Q3: HR=2.37; 95% CI 1.12-4.56; p=0.011, Q4: HR=3.43; 95% CI 1.77-6.65; p=0.000, respectively). While unfavorable effect of mbaPWV on RE was consistent in subject with UACR≤ 300 mg/g, this effect disappeared in subject with UACR> 300 mg/g. Unfavorable effect of mbaPWV on RE was more prominent in subjects with CKD-EPI eGFR≥ 45 ml/min/1.73m^2 than those with CKD-EPI eGFR< 45 ml/min/1.73m^2.

Conclusions: Vascular stiffness was associated the unfavorable renal outcomes in pre-dialysis CKD, particularly in non-proteinuric and early stage CKD.

FR-PO1024

Modification of Effect of Intensive Blood Pressure Lowering on Cardiovascular (CV) Outcomes by Baseline Body Mass Index (BMI)

Adhish Agarwal,[1] Guo Wei,[1] Robert E. Boucher,[2] Tom Greene,[1] Srinivasan Beddhu.[2] [1]*University of Utah, Salt Lake City, UT;* [2]*University of Utah School of Medicine, Salt Lake City, UT.*

Background: It is unknown whether clinicians should consider body weight when determining the optimal blood pressure (BP) goal for a hypertensive patient. Obesity is independently associated with hypertension (HTN), CV outcomes and mortality; thus may modify the effects of BP control. We conducted a post hoc analysis of the SPRINT to assess whether baseline BMI modifies the effects of intensive (INT) systolic blood pressure (SBP) control.

Methods: SPRINT randomized 9361 high-risk non-diabetic participants with a SBP of 130 mm Hg or higher to either INT SBP target of < 120 mm Hg or standard SBP target of < 140 mm Hg. After excluding participants with a baseline BMI of <18.5 or > 50 Kg/m^2 (N= 9191) from SPRINT BioLINCC data, we evaluated the effects of INT SBP control on SPRINT composite outcome (composite of myocardial infarction (MI), acute coronary syndrome (ACS), stroke, acute decompensated heart failure, or CV death) and all-cause death during the mean 4.1 years follow-up in four strata defined by baseline BMI of < 25, 25 to <30, 30 to < 35, and >35 Kg/m^2 using Cox proportional hazards models. We also tested the interaction effect between treatment group and baseline BMI as a continuous variable.

Results: The mean age was 67.9 ± 9.4 years, 35.3 % were female, and mean baseline BMI was 29.8 ± 5.4 Kg/m^2. There were 1682, 3599, 2413, and 1497 participants respectively in the four baseline BMI strata. The effect of INT SBP control on CV outcome or all-cause mortality did not differ significantly between different baseline BMI levels (*P*- linear/categorical interactions 0.24/0.31 and 0.12/0.15 respectively).

Conclusions: In the majority of participants in the baseline BMI range of 22 to 35 Kg/m^2, INT SBP lowering was beneficial. However, in the extremes of BMI, there was not enough power to draw firm conclusions.

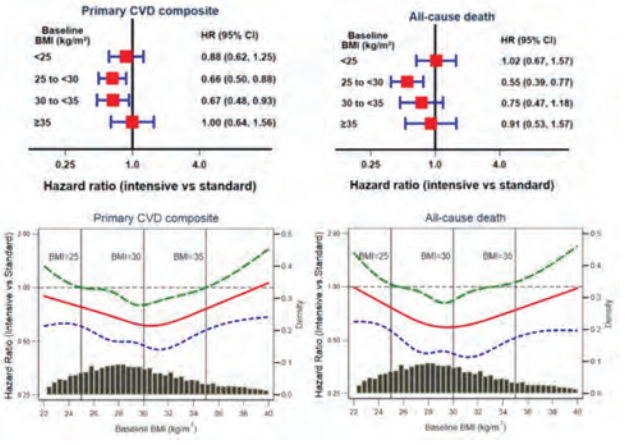

Figure: Forest Plots and Spline Curves with hazard ratios for risk of outcome with INT SBP control

Global Longitudinal Strain on Cardiac MRI Is Superior to Conventional Cardiac Parameters at Predicting Mortality in Patients with ESRD

Luke Y. Zhu,[1] Kenneth Mangion,[1,2] Elaine Rutherford,[1,2] Keith Gillis,[1,2] Jennifer S. Lees,[1,2] Rajan Patel,[1,2] Giles Roditi,[1,2] Patrick B. Mark,[1,2] Alastair J. Rankin.[1,2] [1]*University of Glasgow, Glasgow, United Kingdom;* [2]*NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Left Ventricular Global Longitudinal Strain (LV-GLS) by Feature Tracking Cardiac Magnetic Resonance (FT-CMR) is a non-contrast, post-processing technique that has shown promise as a sensitive predictor of cardiovascular mortality. We aim to assess the ability of LV-GLS to predict death in patients with end-stage renal disease (ESRD).

Methods: We retrospectively analysed research cardiac MRIs (CMR) performed at a major renal transplant centre between 2002-2016. Included patients were receiving, or within 6-months of receiving, renal replacement therapy for ESRD. CMR parameters were derived, including left ventricular mass index (LVMI), LV ejection fraction (LVEF), left atrial ejection fraction (LAEF), and LV-GLS. Cox proportional hazards regression analyses were used to identify potential predictors of all-cause death. Model fit was assessed using the C-statistic.

Results: Among 237 patients (mean age: 53.7, 61% male), mortality was 50.6% over 4.6-year median follow up. LV-GLS quartiles were significantly correlated with mortality (Figure 1). While 89.7% of patients had preserved LVEF (>55%), 24% of patients had abnormal LV-GLS. On multivariable Cox regression, age (HR: 1.04, 95% CI: 1.020-1.057), LAEF (HR: 0.98, 95% CI: 0.963-0.997) and LV-GLS (HR: 1.08, 95% CI: 1.011-1.044) were independent predictors of mortality. The C-statistic of this model for predicting ACM at 1-year was 0.955 (95% CI: 0.920-0.991). Traditional CMR parameters such as LVEF and LVMI were not correlated with mortality.

Conclusions: In this cohort of patients with ESRD, LV-GLS and LAEF as measured on FT-CMR demonstrate independent predictive utility for all-cause death, whilst conventional imaging biomarkers such as LVEF did not. The effect was present even with normal LVEF. LVGLS has a potential role in the prognostication and pre-transplant assessment of patients with ESRD.

Magnetic Resonance Imaging Evaluation of Mineralocorticoid Receptor Antagonism in Diabetic Atherosclerosis (MAGMA) Trial: Baseline Characteristics

Anuja Sarode,[2] Anas Fares,[3] Heather L. Conger,[2] Kim Connelly,[8] Ann M. Dever,[4] Juan Gaztanaga,[7] Laleh Razavi nematollahi,[5] Armando Vergara-Martel,[3] Matthew R. Weir,[6] Sanjay Rajagopalan,[2] Mirela A. Dobre.[1] *[1]Case Western Reserve University, Cleveland, OH; [2]University Hospitals, Kent, OH; [3]University Hospitals Cleveland Medical Center, Cleveland, OH; [4]University Hospitals Cleveland, Cleveland, OH; [5]University Hospitals of Cleveland, Orange, Islamic Republic of Iran; [6]University of Maryland School of Medicine, Baltimore, MD; [7]NYU Winthrop Hospital, Mineola, NY; [8]St Michael's Hospital, Toronto, ON, Canada.*

Background: MAGMA is a multicenter double-blind, randomized controlled trial that aims to assess the effect of spironolactone on atherosclerosis progression and left ventricular (LV) mass regression in type 2 diabetic patients with CKD.

Methods: 46 adult diabetic patients with eGFR<90 ml/min/1.73m^2 and albuminuria>30 mg/g or eGFR<60 ml/min/1.73m^2 regardless of albuminuria, on ACEi/ARB were enrolled at 4 sites and randomly assigned to spironolactone (12.5mg with eventual escalation to 25mg daily) *vs.* placebo. 24hr ambulatory blood pressure monitoring (ABPM) and cardiac MRI and aortic plaque imaging were performed at baseline and will be repeated at 1 year. We examined baseline characteristics and achieved systolic blood pressure (SBP) at 6 weeks follow-up.

Results: The mean age(SD) was 63(8.3) years; 46% were women, and 52% were African-American. Baseline characteristics showed no significant differences between the groups(Table). Native myocardial T1 times, a marker of myocardial fibrosis, were high normal across groups. At 6 weeks, treatment A group had an increase in average 24hr overall and nocturnal SBP by 3.9(20.8) mmHg and 5.7(25.2) mmHg respectively. Treatment B group had an average decrease in 24hr overall and nocturnal SBP of –6.0(11.7) mmHg, and – 8.3(9.8) mmHg respectively.

Conclusions: MAGMA trial enrolled individuals with high atherosclerotic disease burden. Long-term follow-up will provide critical insights into the role of mineralocorticoid antagonism on LV mass and atherosclerosis reduction in high-risk patients.

Funding: Other NIH Support - NHLBI

Association of Masked and Sustained Hypertension with Cardiac Magnetic Resonance Imaging Measures of Left Ventricular Structure and Function in Patients with Diabetes and CKD

Mirela A. Dobre,[1] Heather L. Conger,[2] Anuja Sarode,[2] Anas Fares,[3] Kim Connelly,[4] Juan Gaztanaga,[5] Chris Longenecker,[6] Armando Vergara-Martel,[3] Matthew R. Weir,[7] Sanjay Rajagopalan.[2] *[1]Case Western Reserve University, Cleveland, OH; [2]University Hospitals, Cleveland, OH; [3]University Hospitals Cleveland Medical Center, Cleveland, OH; [4]St Michael's Hospital, Toronto, ON, Canada; [5]NYU Winthrop Hospital, Mineola, NY; [6]Case Western Reserve University School of Medicine, Cleveland, OH; [7]University of Maryland School of Medicine, Baltimore, MD.*

Background: Diabetes and chronic kidney disease (CKD) are risk factors for hypertension phenotypes, such as masked and sustained hypertension which lead to increased cardiovascular risk. We aimed to describe the association of masked and sustained hypertension with structural and functional left ventricular measurements as assessed by cardiac magnetic resonance imaging (MRI) in type 2 diabetic patients with CKD.

Methods: A total of 38 adult patients enrolled in a prospective randomized controlled trial of mineralocorticoid receptor antagonism in patients with CKD (MAGMA) who had 24hr ambulatory blood pressure monitoring (ABPM) and cardiac MRI performed at study baseline were included. Masked hypertension was defined as SBP<130 mmHg in the office, and >125 by mmHg 24hr ABPM and resistant hypertension was defined as SBP>130 mmHg in the office and >125 mmHg by 24hr ABPM. Analysis of Variance was performed to assess the difference in mean MRI measures of cardiac structure and function for various hypertension phenotypes.

Results: The mean age (SD) was 62.5(8.9) years; 61% were women, and mean eGFR was 48.6 (20.3)ml/min/1.73m^2. Compared to participants with controlled SBP (n=7), participants with masked (n=12) and sustained (n=17) hypertension had a higher left ventricular mass index (66.5±9 and 64.7±8.9 vs 58.6±7.7 g/m^2 respectively (Figure). In adjusted models we found no association between hypertension phenotypes and T1 times, cardiac output, LVEF, LVEDV and LVESV.

Conclusions: Masked and sustained hypertension are associated with a high left ventricular mass index in individuals with CKD and diabetes. Larger trials are needed to better characterize MRI cardiac structural abnormalities in individuals at high cardiovascular risk.

FR-PO1028

Reproducibility and Clinical Determinants of Stress T1-Mapping in Patients on Haemodialysis: A Feasibility Study

Federica E. Poli,[1] Daniel S. March,[1] Gaurav S. Gulsin,[1] Gerry P. Mccann,[1] James Burton,[1,2] Matthew P. Graham-Brown.[1,2] *[1]Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom; [2]John Walls Renal Unit, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.*

Background: Identification of coronary artery disease (CAD) in patients with end stage renal disease (ESRD) is challenging. Adenosine stress non-contrast native T1 mapping on cardiac MRI has been proposed as a method to assess myocardial blood volume changes. It has been shown to accurately detect obstructive CAD and microvascular dysfunction in the general population. However, it has never been tested in patients with ESRD, who have higher resting native T1 times compared to control subjects. This study assesses the potential of stress T1 mapping to identify myocardial ischaemia in patients on haemodialysis (HD).

Methods: 124 patients underwent rest T1 mapping. 58 of them had stress scans. 10 patients had identical reproducibility scans within two weeks. Myocardial stress T1 reactivity was calculated as ΔT1=[(stress T1−rest T1)/rest T1]×100. Interstudy reproducibility, inter-observer and intra-observer variability were assessed using intraclass correlation coefficient (ICC), coefficient of variability (CoV) and Bland-Altman analyses.

Differences between groups and correlations between T1 and clinical variables were assessed. Independent predictors of ΔT1 were examined on multivariate linear regression.

Results: There were no clinically relevant differences between baseline characteristics of patients undergoing rest only or rest and stress scans. Of the 58 patients who had stress scans, only one had an inadequate haemodynamic response to adenosine. All patients tolerated and completed the scan, with no adverse effects. Inter- and intra-observer variability of rest T1, stress T1 and ΔT1 were excellent (ICC >0.9). Interstudy reproducibility for rest and stress T1 was good (CoV 1.2% and 1.5%; ICC 0.79 and 0.69, respectively), but average for ΔT1 (CoV 27.4%, ICC 0.55). On multivariate analysis, CAD, diabetes and rest native T1 time were independent predictors of ΔT1 (β= -0.244, p=0.038; β= -0.326, p=0.008; β= -0.458; p<0.001, respectively).

Conclusions: Stress T1 mapping is a feasible, reproducible and well-tolerated technique in patients on HD. It has the potential to evaluate myocardial ischaemia secondary to obstructive epicardial CAD or microvascular dysfunction despite the elevated resting native T1 values in this population. However, the reproducibility of ΔT1 is sub-optimal.

FR-PO1029

Comparability and Tolerability of Ambulatory and Home Blood Pressure Monitoring in Hemodialysis Patients

Jordana B. Cohen,[1] Chi-yuan Hsu,[2] David V. Glidden,[2] Lori Linke,[3] Farshad Palad,[2] Hanna L. Larson,[4] Rajnish Mehrotra,[4] Raymond R. Townsend,[1] Nisha Bansal.[3] *[1]University of Pennsylvania, Philadelphia, PA; [2]University of California San Francisco, San Francisco, CA; [3]Kidney Research Institute, Seattle, WA; [4]University of Washington, Des Moines, IA.*

Background: 44-hour (hr) ambulatory blood pressure monitoring (ABPM) in hemodialysis (HD) patients provides valuable prognostic information, but is often impractical in clinical practice. Home BP monitoring (HBPM) may be better suited for longitudinal BP management. However, limited evidence exists regarding the comparability and tolerability of ABPM and HBPM in this high risk population.

Methods: In a post-hoc analysis, we studied pre-randomization data from participants who agreed to 44-hr ABPM in a randomized controlled trial targeting a home vs. pre-HD systolic BP (SBP) <140 mmHg (NCT03459807).

Results: Of the 50 in-center HD patients enrolled, 31 (62%) agreed to ABPM. The mean age was 56 (SD 14) years, 13 (42%) were black. Mean pre-HD SBP was 146 (19) mmHg, ABPM SBP 140 (21) mmHg, daytime SBP 141 (20) mmHg, and nighttime SBP 134 (25) mmHg; 24 (77%) participants were non-dippers, including 7 (23%) reverse dippers. Home SBP was correlated with ABPM SBP (Figure); the strongest correlation was with daytime SBP in the initial 24-hrs post-HD (r=0.76, 95% CI 0.43-0.91). Using ABPM instead of HBPM, 2 participants were reclassified from controlled to masked hypertension (HTN), 1 from white coat to uncontrolled HTN, and 1 from masked to controlled HTN. Most patients described their ABPM experience as neutral (e.g. “No problem”); however, some expressed substantial discomfort (e.g. “the pressure was way too high and unbearable”). Participants described HBPM more positively (“It was fun and gave me knowledge of my own BP’s”), with no reported discomfort.

Conclusions: Among HD patients, HBPM correlated with ABPM, particularly daytime post-HD ABPM readings. Given greater tolerability and feasibility for repeated measurements, HBPM seems to be a practical option for longitudinal monitoring and management of HTN among HD patients.

The Accuracy of Clinic and Home Blood Pressure Recordings in Diagnosing Hypertension Among Patients on Peritoneal Dialysis

Vassilios Liakopoulos,[1] Vasileios Vaios,[1] Panagiotis I. Georgianos,[1] Georgia Vareta,[1] Evangelia Dounousi,[2] Aikaterini A. Papagianni,[3] Pantelis Zebekakis.[1] *[1]Peritoneal Dialysis Unit, 1st Department of Medicine, AHEPA Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Department of Nephrology, University Hospital of Ioannina, Ioannina, Greece; [3]Department of Nephrology, Hipokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece.*

Background: Earlier studies testing the diagnostic accuracy of blood pressure (BP) measurement techniques among patients on peritoneal dialysis (PD) have shown that home BP recordings overestimate daytime ambulatory BP and are inferior to standardized automated clinic BP measurements in diagnosing hypertension. The aim of this study is to elucidate this paradoxical observation that contradicts evidence from the general hypertensive population and may be attributable to methodological limitations of earlier studies.

Methods: In a cohort of 81 stable PD patients with unmodified antihypertensive therapy or dialysis regimen for at least 2 weeks prior to study enrollment, BP was recorded using 3 different methodologies: (i) triplicate automated clinic BP recordings after a 5-min seated rest with the self-inflating monitor HEM 705 CP (Omron Healthcare); (ii) 1-week averaged morning and evening home BP recordings taken by the patients themselves with validated automated BP monitors; (iii) 24-hour ambulatory BP monitoring with the oscillometric device Mobil-O-Graph (IEM, Germany).

Results: In Bland-Altman analysis, clinic systolic BP (SBP) overestimated daytime ambulatory SBP by 5.02 mmHg with 95% limits of agreement ranging from -17.92 to 27.96 mmHg. Similarly, home SBP overestimated daytime ambulatory SBP by 4.23 mmHg, again with wide 95% limits of agreement (-16.05 to 24.51 mmHg). The area under the curve of receiver operating characteristic (ROC) curve for clinic and home SBP to detect a daytime ambulatory SBP ≥135 mmHg was 0.859 (95% CI: 0.776-0.941) and 0.895 (95% CI: 0.815-0.976), respectively. Home SBP of ≥138.5 mmHg had the best combination of sensitivity (80.6%) and specificity (84%) in diagnosing ambulatory systolic hypertension.

Conclusions: 1-week averaged home BP recordings are at least similar with a standardized BP measurement at clinic in detecting ambulatory hypertension among patients on PD.

FR-PO1031

Patterns of Nocturnal Blood Pressure Changes in Patients on Ambulatory Blood Pressure Monitoring (ABPM) in Patients with Complex Hypertension

Neil K. Agarwal, Tarig Elraiyah, Siddique Akbar, Ziauddin Ahmed, Ellie Kelepouris, Sandeep Aggarwal. *Drexel University College of Medicine, Rose Valley, PA.*

Background: Nocturnal blood pressure changes are associated with patient centered outcomes. We attempted to investigate the patterns of blood pressure changes in complex hypertensive patients with concomitant cardiovascular comorbidities.

Methods: We retrospectively reviewed 35 charts of patients who received ABPM from a single outpatient nephrology office. Of the 35, 3 were excluded due to incomplete data. We collected demographic information: Age, Gender, Ethnicity, Diabetic status, CKD stage, Indication for ABPM. ABPM data Including: Average daytime pressures, Average nighttime pressures, total average pressures, nocturnal dipping, hypertensive load. IBM SPSS® v22 was used for statistical analysis – t-tests.

Results: Of the 32 patients (22 Female, 10 Male), 20 were African American, 6 were diabetic, 17 had CKD stage 3 or greater, and mean age was 56±19 years. Among CKD patients, the mean nocturnal systolic dip was 3.4±9.8mmHg, mean diastolic nocturnal dip 8.2±8.3mmHg, mean MAP nocturnal dip 5.9±9.2mmHg. Among non-CKD patients, the mean systolic nocturnal dip was 6.9±5.8mmHg, mean diastolic nocturnal dip 11.9±6.5mmHg, mean MAP nocturnal dip 9.6±6.2mmHg. The mean difference between systolic nocturnal dip was 3.5±2.9 mmHg (p=0.2433), mean difference between diastolic nocturnal dip was 3.7±2.7mmHg (p=0.1708), mean difference between MAP nocturnal dip was 3.6±2.8 mmHg (p=0.2034). Among diabetic patients, the mean systolic nocturnal dip was 5.8±8.9mmHg, mean diastolic nocturnal dip 11.2±7.6mmHg, mean MAP nocturnal dip 8.8±8.2mmHg. The mean difference between systolic nocturnal dip was 3.8±3.7 mmHg (p=0.3148), mean difference between diastolic nocturnal dip was 7.1±3.3mmHg (p=0.0376), mean difference between MAP nocturnal dip was 6.2±3.5 mmHg (p=0.0864).

Conclusions: In our study, there was no difference in nocturnal blood pressure changes in patients with or without cardiovascular co-morbidities, except for nocturnal diastolic blood pressure in diabetic patients. Additional, larger scale trials are required to look for additional or synergistic risk of nocturnal blood pressure variability in patients with high cardiovascular risk.

FR-PO1032

A Pilot Trial Targeting Home vs. Pre-Dialysis BP in Hemodialysis (HD) Patients

Nisha Bansal,[4] David V. Glidden,[2] Rajnish Mehrotra,[4] Raymond R. Townsend,[5] Hanna L. Larson,[3] Lori Linke,[1] Farshad Palad,[2] Chi-yuan Hsu.[2] *[1]Kidney Research Institute, Seattle, WA; [2]UCSF, San Francisco, CA; [3]University of Washington, Seattle, WA; [4]UW, Seattle, WA; [5]UPenn, Philadelphia, PA.*

Background: Guidelines recommend treatment of pre-dialysis blood pressure (BP) among HD patients. However, there is a U-shaped association between pre-dialysis BP and death. We hypothesize that home BP may be a better target for treatment since there is a linear relationship between out-of-dialysis unit BP and death in observational studies. To test the feasibility of this approach, we conducted a trial of treating home vs. pre-dialysis BP in HD patients.

Methods: We conducted a 4-month randomized controlled trial of 50 HD patients at two centers, targeting home systolic BP (SBP) vs. pre-dialysis SBP 140-100 mmHg. Home and pre-dialysis SBPs were obtrained every 2 weeks and adjustments in dry weight and medications were made to reach the target SBP in each group. The primary outcomes were feasibility, adherence, tolerability and safety.

Results: One in four potentially eligible patients enrolled in the study. We had enthusiastic buy-in from 10 nephrologists from 8 different dialysis units (operated by 3 dialysis providers). The mean age of participants was 56 years, 40% were women, and 74% were non-white. All enrollees successfully completed the study except one who got a kidney transplant. Adherence to obtaining home BP was 97%. In the home BP group, there was no increased frequency of high or low pre-HD BP; lower frequency of intradialytic hypotension and falls; but more fatigue and syncope(**Table**).

Conclusions: This pilot study shows that HD patients can successfully participate in and adhere to home BP measurement. Given that there is a U-shaped association of pre-dialysis BP (but not out-of-dialysis-unit BP) with risk of death, targeting home BP may be a promising intervention to improve outcomes in this population and should be tested in larger clinical trials.

Funding: NIDDK Support, Private Foundation Support

Tolerability and safety over 4 months in HD participants randomized to home vs. pre-dialysis BP <140 mmHg

FR-PO1033

Awareness and Monitoring Behavior of Home Blood Pressure Among Patients with CKD in Guangzhou, China

Jing Zheng,[1] Yamin Wang,[2] Hui-qun Li,[3] Yan-ru Chen,[3] Wenbo Zhao.[3] *[1]School of Nursing, Guangdong Pharmaceutical University, Guangzhou, China; [2]School of Nursing, Sun Yat-Sen University, Guangzhou, China; [3]Department of Nephrology, the Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Home blood pressure monitoring (HBPM) has been proved superior to office measurements to predict cardiovascular outcomes and target organ damage in patients with chronic kidney disease(CKD). However, the awareness and monitoring behavior of home BP in CKD patients are still not explored in depth in China. The aim of this study was to investigate the awareness and monitoring behavior of home BP among patients with CKD and to compare the difference of control rate of BP between patients with and without HBPM.

Methods: This was a cross-sectional, descriptive study conducted in a hospital in Guangzhou, a city in southern China. The CKD patients complicated with hypertension (office systolic blood pressure(SBP)≥140mmHg and/or diastolic blood pressure(DBP)≥90mmHg) were recruited in 2019 by convenience sampling and were surveyed with the awareness and behavior model of HBPM questionnaire.

Results: A total of 114 patients with CKD stage 2-5, aged 52.8±14.2 years were enrolled. The mean values of office SBP and DBP were 145.8±20.2mmHg and 93.0±12.7mmHg respectively, while only 3.5%(4/114) patients correctly answered the upper limit of normal BP and 44.7% (51/114) of them reached the target of BP control (office BP<140/90mmHg). Although the BP monitors were owned by 91.2% (104/114) patients, in which 96.2% (100/104) were electronic device and 94% (94/100) were upper-arm BP monitors, 75% (78/104) of CKD patients didn't know that the monitor needed to be calibrated regularly. Regarding the monitoring frequency of home BP, 15.8% (18/114) didn't measure their BP at home, and 35.1% (40/114) measured only when they felt uncomfortable (e.g. headache, dizziness). 41.7% (40/96) never recorded the measurements, and 49% (47/96) never communicated the monitored data with their health professionals. The control rate of BP (office BP<140/90mmHg) in patients undergoing HBPM was 46.9%, which was higher than the one in patients without HBPM(33.3%, $p<0.05$).

Conclusions: CKD patients have poor BP control in Guangzhou, China. Although most of them have a HBPM device, the awareness of HBPM are still insufficient,and the utilizing rate of HBPM are undesirable. Given patients undergoing HBPM have a higher control rate of BP than those without HBPM, education and supervision should be strengthened to promote the application of HBPM on CKD patients.

Survival of Patients with Percutaneous Coronary Intervention of Acute Coronary Syndrome in Left Main Coronary Artery Disease: The Role of Kidney Function

Igor Balevski,[1] Vigor Arva,[1] Sandra Burja,[4] Tadej Petreski,[1] Nejc Piko,[2] Vojko Kanic,[1] Sebastjan Bevc.[3] *[1]University Medical Centre Maribor, Maribor, Slovenia; [2]University Clinical Centre Maribor, Maribor, Slovenia; [3]UKC Maribor, Maribor, Slovenia; [4]Faculty of Medicine, University of Maribor, Maribor, Slovenia.*

Background: Chronic kidney disease (CKD) is associated with a high burden of stable coronary artery disease and an increased incidence of acute coronary syndromes (ACS). Left-main coronary artery disease (LMCAD) is the highest-risk lesion of ischemic heart disease, where revascularization with either percutaneous coronary intervention (PCI) or coronary artery bypass grafting (CABG) is needed. Presence of CKD may increase the risk of complications and mortality connected with revascularization procedures. The aim of our study was to determine the role of CKD in the survival of patients after undergoing PCI for ACS in LMCAD.

Methods: In our retrospective study, 211 patients (142 male (67.3%)) were included. All patients underwent primary PCI because of LMCAD between January 1st, 2008 and December 31st, 2016. The patients were observed from PCI until their death or December 20st, 2018 (average time of observation was 5.3 years). Mean age of included patients was 69.2±11.3 years (minimum 38 years, maximum 91 years). CKD was defined as estimated glomerular filtration rate (eGFR)≤60 ml/min/1.73m^2 by using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation. Comorbidities, such as arterial hypertension (AH), diabetes mellitus (DM), and dyslipidemia were recorded. Survival rates were analyzed using Kaplan-Meier survival curves. The Cox regression model was used to assess the influence of CKD, AH, DM and dyslipidemia.

Results: 82.5% of patients had AH, 28% had DM and 64.4% had dyslipidemia. 24.2% of patients had eGFR≤60 ml/min/1.73 m^2 (CKD group). Mean survival time of patients in the CKD group was 1294±1402 days and in the non-CKD group 2122±1246 days. 32 (62.73%) CKD and 53 (33.1%) non-CKD patients died. Kaplan-Meier survival analysis showed a higher risk of death for CKD patients (log-rank test; p<0.001). In Cox multivariable regression model, CKD remained a predictor of all-cause mortality in our patients (HR was 1.623 (95% CI 1.414-1.757; P=0.0001)). The impact of dyslipidemia on patient survival was statistically significant (p=0.0001), while AH (p=0.671) and DM (p=0.136) showed no impact on patient survival.

Conclusions: The results indicate an association between CKD and all-cause mortality in patients after undergoing PCI for ACS in LMCAD.

FR-PO1035

Number of Right Coronary Artery Lesions Increases as CKD Progresses

Shiko Gen. *Saitama Sekishinkai Hospital, Sayama city, Japan.*

Background: Chronic kidney disease is a risk factor for cardiovascular disease, and low glomerular filtration rate (GFR) is known to be associated with a higher risk of developing cardiovascular disease. However, there is currently no report on the association between the stage of chronic kidney disease and coronary artery lesion parameters such as site and number.

Methods: We examined variations in the site and number of coronary artery lesions in relation to the presence or absence of diabetes and dyslipidemia, and differences in laboratory parameter values such as serum blood urea nitrogen (BUN), creatinine (Cr), and estimated glomerular filtration rate (eGFR) in 2885 cases (average age: 68.96±10.32 years; 2140 men, 745 women) who underwent coronary angiography in our hospital from January 2009 to November 2011.

Results: Although there was no significant variation in coronary artery lesion sites in relation to differences in age or the presence or absence of diabetes or dyslipidemia, there was a significant increase in the number of right coronary artery lesions as the stage of chronic kidney disease progressed (P=0.001, Kruskal Wallis test).

Conclusions: Our results suggest that the progression of renal dysfunction may cause an increase in the number of right coronary artery lesions.

FR-PO1036

Association of Coronary Artery Calcification Density, Coronary Artery Calcification Score, and Cardiovascular Risk in Maintenance Hemodialysis Patients

Yoshiko Nishizawa,[1] Sonoo Mizuiri,[2] Kazuomi Yamashita,[2] Kenichiro Shigemoto,[2] Takao Masaki.[3] *[1]Division of Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Ichiyokai Harada Hospital, Hiroshima, Japan; [3]Division of Nephrology, Hiroshima University, Hiroshima, Japan.*

Background: Agatston's coronary artery calcification score (CACS) is a composite of coronary artery calcification (CAC) volume and CAC density (CACD). In general population, CAC volume is positively and CACD is inversely associated with cardiovascular disease (CVD) events. This study aimed to evaluate the association of CACD, CACS and cardiovascular disease (CVD) in MHD patients.

Methods: The subjects were Japanese MHD patients. CACD, CACS, laboratory parameters were assessed at baseline. The subjects were stratified into CACD and CACS level tertiles (T1–T3), respectively and assessed by Kruskal-Wallis test. Regression analyses for CACD were examined in MHD patients with and without CVD, respectively. Independent variables were age, sex, dialysis vintage, diabetes, current smoker, systolic blood pressure (SBP), serum magnesium, phosphate, uric acid, C-reactive protein (CRP), β2-microglobulin, albumin adjusted-serum calcium, and geriatric nutritional risk index (GNRI).

Results: Among all 291 patients (diabetes: 37.8%, past or present CVD: 39.9%), the mean age and dialysis vintage were 66±13 years, and 104±90 months. The CACD values for T1 (n=97), T2 (n=98), and T3 (n=96), were <3.67, 3.67-3.92, and >3.92. The CACS values for T1, T2, T3, were T1 (n=95), T2 (n=98), and T3 (n=98), were <380.0, 380.0-1931.0, and>1931.0. Multivariate regression analysis for CACD showed that age [β 0.30, 95% CI (0.02-0.03)], diabetes [β 0.31, 95% CI (0.39-0.80)], dialysis vintage [β 0.24, 95% CI (0.00-0.01)], β2-microglobulin [β 0.12, 95% CI (0.01-0.03)] and albumin adjusted-serum calcium [β 0.16, 95% CI (0.08-0.42)] were significantly related factors (P<0.001), but not CVD. Multivariate logistic regression for CVD showed that the highest CACS group [OR 1.9, 95% CI (0.94-3.98)], current smoker [OR2.19, 95% CI (1.22-3.99)], SBP [OR1.03, 95% CI (1.01-1.04)], and serum magnesium [OR 2.91, 95% CI (1.16-7.63)], CRP [OR0.73, 95% CI (0.53-0.95)], β2-microglobulin [OR0.97, 95% CI (0.93-1.02)] and GNRI [OR1.07, 95% CI (1.02-1.13)] were significantly related factors (P<0.05), but not CACD.

Conclusions: In MHD patients, presence of CVD is positively associated with CACS and hypomagnesemia, but not with CACD.

FR-PO1037

Blood Pressure and Renal Outcomes in Patients Undergoing Percutaneous Coronary Intervention

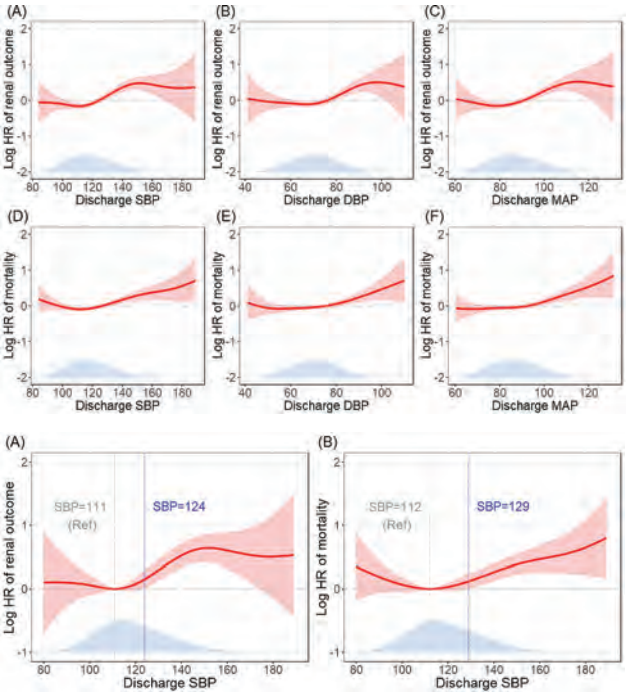
Dong hwan Yun,[1] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[2] Seung Seok Han.[2] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Patients undergoing percutaneous coronary intervention (PCI) require strict control of blood pressure (BP) because abnormal control is related with worse cardiovascular and other organ outcomes. However, discharge BP-dependent renal outcome after PCI has not been thoroughly evaluated.

Methods: A total of 8204 adult patients undergoing PCI were reviewed at Seoul National University Hospital from 2006 to 2016. Renal outcome was defined when either a doubling of serum creatinine, ≥ 50% decrease of estimated glomerular filtration rate, or end-stage renal disease developed. The risks of renal outcome and all-cause mortality were evaluated according to BPs between 8:00 AM and 10:00 AM at discharge day using multivariable Cox proportional hazard regression and additive Cox regression with penalized splines.

Results: 9.5% (766 patients) of total patients reached renal outcomes during the median follow-up period of 6.5 years (maximum 13.0 years). Admission BP and discharge BP had poor correlation, and BP parameters at discharge including systolic BP (SBP), diastolic BP (DBP) and mean arterial pressure (MAP) mainly showed J-shaped relationship on renal outcome and all-cause mortality. Among BP parameters at admission and discharge, discharge SBP was the best predictor of both mortality and renal outcome. In additive Cox regression with reference BP which had minimal hazard ratios of study outcomes, there seemed to be threshold values for renal outcome (124 mmHg of SBP) and mortality (129 mmHg of SBP).

Conclusions: BP of patients undergoing PCI had J-shaped association on renal outcome and all-cause mortality. This non-linear relationship implies there could be a possible threshold of BP for renal outcome after PCI.



FR-PO1038

Cardiovascular and Renal Outcomes with Percutaneous Coronary Intervention Compared with Medical Therapy in Patients with CKD: A Meta-Analysis

Lauriane Poli,[5] Stéphanie Zbinden,[5] Alexandre Leszek,[3] Lucas C. Godoy,[4] Michael E. Farkouh,[4] Thomas Mavrakanas.[1,2] *[1]Department of Medicine, Geneva University Hospitals, Geneva, Switzerland; [2]Department of Medicine, McGill University Health Centre, Montreal, QC, Canada; [3]Hopital Neuchatelois Pourtalès, Neuchatel, Switzerland; [4]University of Toronto, Toronto, ON, Canada; [5]Geneva University Hospitals, Geneva, Switzerland.*

Background: The optimal management of coronary artery disease (CAD) in patients with chronic kidney disease (CKD) remains a matter of debate because these patients have been excluded from most randomized controlled trials (RCTs). The purpose of this meta-analysis was to examine whether percutaneous coronary intervention (PCI) among patients with CKD is associated with lower incidence of cardiovascular and renal outcomes compared with standard medical therapy.

Methods: A Medline literature research was conducted in PubMed for RCTs or cohort studies that compared different treatment strategies in adult patients with CAD and CKD. The primary outcome was the incidence of major adverse cardiovascular events. The secondary outcomes were progression of CKD and death from any cause. CKD was defined as an estimated glomerular filtration rate < 60ml/min/1.73m^2. The risk ratio (RR) was estimated using a random effects model.

Results: Four cohort studies and one RCT were included in this meta-analysis (839 CKD patients) for the primary outcome. Compared with optimal medical therapy, PCI was not associated with lower incidence of major adverse cardiovascular events: RR 0.91, 95% confidence interval (CI) 0.70-1.18 (**Figure**). In addition, PCI was not associated with lower incidence of CKD progression: RR 1.20, 95% CI (0.92-1.56). However, PCI was associated with lower all-cause mortality: RR 0.70, 95% CI (0.51-0.97), compared with medical therapy.

Conclusions: PCI may be superior to medical therapy in patients with CKD and CAD. Because of high inconsistency and risk of bias of the included studies, no definite conclusions can be drawn until ongoing RCTs report.

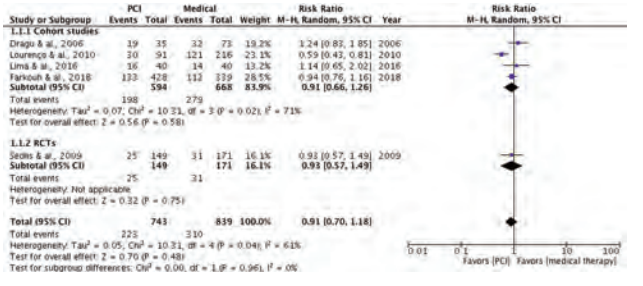


Figure Forest plot for major adverse cardiovascular events in patients with CAD and CKD

FR-PO1039

Prasugrel and Ticagrelor in Patients with Drug-Eluting Stents and ESRD

Thomas Mavrakanas,[2,3] David M. Charytan.[1] *[1]New York University School of Medicine, Bronx, NY; [2]Renal Division, Brigham & Women's Hospital, Harvard Medical School, Boston, MA; [3]Department of Medicine, Geneva University Hospitals, Geneva, Switzerland.*

Background: Prasugrel and ticagrelor have superior efficacy compared with clopidogrel in patients with preserved renal function. No randomized or cohort data exist with respect to their efficacy or safety in patients with end-stage renal disease (ESRD).

Methods: This retrospective cohort study used United States Renal Data System data from 2012 to 2015. We identified all dialysis patients who received a drug-eluting stent (DES) and were alive at 90 days after DES insertion. Prasugrel or ticagrelor users were matched 1:3 to patients treated with clopidogrel according to a propensity score. Outcomes were ascertained at 12 months. Competing risk survival models were used.

Results: Compared with clopidogrel, prasugrel or ticagrelor use was not associated with reduced risk of the composite outcome of cardiovascular mortality, myocardial infarction, or stroke: adjusted hazard ratio (HR) 0.91, 95% confidence interval (CI) 0.80-1.02 for prasugrel and HR 0.93, 95% CI 0.82-1.07 for ticagrelor. Ticagrelor use was associated with lower all-cause mortality and prasugrel use was associated with lower incidence of stroke, compared with clopidogrel. There was no difference in the incidence of fatal/intracranial or clinically-significant bleeding with either of the newer antiplatelet agents, compared with clopidogrel (**Table**). Shorter duration of the antiplatelet agent and acute coronary syndrome at presentation were independently associated with worse prognosis.

Conclusions: This is the first study examining clinical outcomes with prasugrel or ticagrelor in ESRD. Although no major efficacy benefit was detected, both prasugrel and ticagrelor were well-tolerated in patients with ESRD and may be considered in selected cases. Disclaimer The interpretation and reporting of these data are the responsibility of the authors and in no way should be seen as official policy or interpretation of the US government.

Clinical outcomes with prasugrel and ticagrelor, compared with clopidogrel in patients with DES and ESRD

Outcome	Prasugrel vs. clopidogrel		Ticagrelor vs. clopidogrel	
	HR (95% CI)	p	HR (95% CI)	p
CV death, MI, stroke	0.91 (0.80-1.02)	0.12	0.93 (0.82-1.07)	0.31
CV death	1.01 (0.81-1.27)	0.91	0.88 (0.69-1.12)	0.30
MI	0.98 (0.83-1.14)	0.75	1.03 (0.87-1.22)	0.74
Stroke	0.76 (0.64-0.91)	0.003	1.03 (0.86-1.23)	0.74
All-cause mortality	0.86 (0.72-1.03)	0.10	0.84 (0.70-0.99)	0.047
Fatal-intracranial bleeding	1.01 (0.59-1.72)	0.97	0.82 (0.43-1.57)	0.55
Clinically-significant bleeding	1.10 (0.94-1.28)	0.24	1.10 (0.93-1.30)	0.27

FR-PO1040

Thirty-Day Refill Gap in Prescription for P2Y12 Inhibitor Predicts Death in Dialysis Patients

Rajendra Mandalapu,[1] Junqiang Dai,[3] Suzanne L. Hunt,[3] Milind A. Phadnis,[3] Rafia Rasu,[2] Nishank Jain.[4] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]University of North Texas Health Science Center, Fort Worth, TX; [3]University of Kansas Medical Center, Kansas City, KS; [4]Little Rock VA Hospital, Little Rock, AR.*

Background: It remains unclear whether gaps in refill of prescriptions for oral P2Y12 inhibitors (P2Y12-I) is associated with mortality in patients on chronic dialysis (ESRD).

Methods: USRDS registry from 2011 to 2015 was used to capture new P2Y12-I prescriptions for ESRD patients. The cohort was followed until death, kidney transplantation, switching between P2Y12-I, or lost to follow-up. After flagging and censoring key variables, all-cause death was counted and prescription refill pattern was ascertained for the first 6 months from the index date. Two major patterns were recognized: continuous users with no gaps in refills of 30 days and users with ≥30 days' gap in refills. Cox proportional regression (CPR) model analyzed association between all-cause death and ≥30 days' gap in prescription refills compared to continuous users with no such gaps in refill.

Results: Of the 32,886 patients in the cohort, median age of the cohort 64 years (IQR: 55 years, 72 years). 54% were male, 41% Caucasians, 36% African American and 18% Hispanic. 93% on hemodialysis, 7% on peritoneal dialysis, and average time on dialysis 3.8 years. Median modified Liu Index was 7 (IQR: 4, 10), and median number of baseline medications were 7 (IQR: 5, 10). During the first 6 months from the index date, there were 14,907 patients who filled prescriptions continuously without 30 days gap while 16,810 patients had ≥30 days' gap in refill. Compared to continuous refill pattern, ≥ 30 days' gap in refill of P2Y12-I prescription was associated with all-cause death, unadjusted hazard ratio (HR) 1.10 (95%CI: 1.06, 1.15) and adjusted HR 1.16 (95%CI: 1.11, 1.20).

Conclusions: Gaps in P2Y12-I prescription refills of ≥30 days among ESRD patients is independently associated with short term all-cause death.

FR-PO1041

All Types of Aortic Valve Replacement (AVR) May Not Be Equal in ESRD: Survival After Bioprosthetic, Mechanical, and Transcatheter AVR (bAVR, mAVR, and TAVR)

Nagaraju Sarabu,[1] David K. Ngendahimana,[2] Krista L. Lentine,[3] Salil Deo.[2] *[1]University Hospitals Cleveland Medical Center, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH; [3]Saint Louis University, St. Louis, MO.*

Background: Guidelines have no preference for bAVR or mAVR or TAVR in patients with ESRD. Their outcomes among those who subsequently get transplants is unclear.

Methods: All adult ESRD patients who were underwent AVR, between 1992 and 2015, were identified from the United States Renal Data System (USRDS) using ICD-9 codes. Baseline comorbidities were also identified using ICD-9 codes. Time to death was compared among the three groups (bAVR, mAVR, and TAVR) using Kaplan-Meier survival curves and with aHR (adjusted HR) using Cox proportional hazards model. These statistical procedures were performed separately for entire ESRD cohort and exclusively for those who subsequently underwent kidney transplant. TAVR group was excluded from latter analysis due to low numbers.

Results: There were a total of 9865 patients who underwent AVR (bAVR=4292, mAVR=4951, TAVR=622). Patients who underwent mAVR were the youngest and had the least comorbidity profile. Patients who underwent TAVR were the oldest and had the highest comorbidity profile (Fig 1). For the entire cohort, compared to bAVR, mAVR had better survival (aHR: $_{0.8}0.9_{0.96}$) but TAVR had worse survival (aHR: $_{1.14}1.27_{1.42}$). Among those who subsequently got kidney transplant, there was no difference in survival for the mAVR group compared to bAVR (aHR: $_{0.8}1.09_{1.53}$) (Fig 2).

Conclusions: Mechanical AVR is the preferred choice in ESRD. TAVR may be associated with worse survival but it may be due to higher baseline comorbidity.

FR-PO1042

Transcatheter vs. Surgical Aortic Valve Replacement in US Dialysis Patients

David T. Gilbertson,[1,2] James B. Wetmore,[2,1] Nicholas S. Roetker,[1,2] Mario Goessl,[3] Kirsten L. Johansen,[2,1] Charles A. Herzog.[2,1] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Hennepin Healthcare, Minneapolis, MN; [3]Minneapolis Heart Institute, Minneapolis, MN.*

Background: The benefits of transcatheter aortic valve replacement (TAVR) vs. surgical (SAVR) valve replacement are uncertain among patients receiving maintenance dialysis with aortic stenosis. We compared inpatient and 1-year mortality in dialysis patients with aortic stenosis receiving TAVR vs. SAVR.

Methods: We used the CMS 100% ESRD files from 2013-2015 to compare characteristics and outcomes among patients receiving TAVR or SAVR. The cohort comprised patients receiving an AVR between January 1, 2013 and December 31, 2014. Outcomes of interest were inpatient and 1-year mortality. We used the six-month period prior to the procedure to assess comorbidity using claims. We used Cox proportional hazards models to compare 1-year mortality, adjusting for patient characteristics and comorbidity.

Results: Of the 1867 patients who received an AVR, 66.1% received SAVR and 33.9% TAVR. TAVR patients were more likely to be older, female, white, and have a higher comorbidity burden. Although TAVR patients experienced less inpatient mortality (4.6% vs. 7.8% for SAVR), there was no difference in 1-year mortality among those discharged alive (HR 1.1, 95% CI 0.9-1.4).

Conclusions: Although TAVR is an increasingly attractive option compared to SAVR in the general population, there is less evidence supporting its use in dialysis patients. Short term outcomes appeared to be better among dialysis patients receiving TAVR despite their older age and greater comorbidity burden, and 1-year mortality was not significantly different than for SAVR.

TAVR vs. SAVR, Dialysis Patients

Health-Related Quality of Life After Ligation of Arteriovenous Fistula for Pulmonary Hypertension

Vinayak Rohan, Patrick B. Dennis, Katie M. Flower, Karim M. Soliman, Prabhakar Baliga, David J. Taber. *Medical University of South Carolina, Charleston, SC.*

Background: AV fistulas (AVF) are the access method of choice in patients on long-term hemodialysis. Due to their high blood flow, AVFs are also a potentially reversible cause of secondary pulmonary hypertension. There are multiple small case series describing change in the hemodynamics and improvement in the symptoms after ligation of AVF for pulmonary hypertension. There is very little data regarding health related quality of life changes (HRQOL) after ligation AV fistula for Pulmonary HTN

Methods: Patients undergoing ligation of AVF for Pulmonary Hypertension (PHT) were identified from our AVF database from January 2017 to December2018. All patients were specifically referred from the PHT clinic with the diagnosis of moderate or severe PHT. Detailed demographics, postoperative clinical variables and recipient's outcomes were abstracted from electronic health records. We used ***emPHasis10***, a validated PHT HRQOL questionnaire developed by the Pulmonary Hypertension Association, United Kingdom and freely available over for use. Patients were asked to respond to the questionnaire before and after ligating the fistula. Statistical comparisons were made using the Wilcoxon signed-rank test.

Results: We identified 9 patients who underwent ligation of AV fistula for PHT. One patient died during the follow up period and one patient was lost to follow up hence 7 patients were included in the study. The mean age was 47.7 years (range 33-58), 5 patients were male and 2 females. All the patients presented with an upper arm arteriovenous fistula. **The mean pre-ligation emPH asis-10 score was 29.0±15.1 and post-ligation this significantly decreased to 6.1±5.2(p<0.01), indicating significant improvements in HRQOL surrounding PHT**

Conclusions: Ligation of AV fistula for secondary pulmonary HTN may potentially lead to significant improvement in pulmonary hypertension indices and health-related quality of life

Patient Number	Age	Sex	Race	Pre-Procedure emphasis 10 score	Post- Procedure emphasis 10 Score	Duration of follow Up in months

Impact of Electrocardiographic Finding on Cardiac Mortality in Hemodialysis Patients: Ten-Year Outcomes of the Q-Cohort Study

Hiroto Hiyamuta,[1] Shigeru Tanaka,[1] Masatomo Taniguchi,[2] Toshiaki Nakano,[1] Kazuhiko Tsuruya,[3] Takanari Kitazono.[4] *[1]Kyushu University, Fukuoka, Japan; [2]Fukuoka Renal Clinic, Fukuoka, Japan; [3]Nara Medical University, Kashihara, Japan; [4]Department of Medicine and Clinical Science, Fukuoka, Japan.*

Background: Electrocardiography is a noninvasive and inexpensive test and regularly performed in dialysis clinic. However, its clinical predictive value in hemodialysis patients is unclear. We investigated electrocardiographic finding associated cardiac-related mortality in Japanese hemodialysis patients.

Methods: A total of 1087 Japanese HD patients aged ≥18 years who underwent electrocardiography within 1 year from baseline were followed for 10 years. Multivariate-adjusted odds ratios (OR) with 95% confidence intervals (95% CI) for electrocardiographic finding of cardiac death were calculated using logistic regression analysis. To assess the additional predictive value of electrocardiographic finding in risk assessment, we compared the c-statistics between clinical model included electrocardiographic finding and basic model.

Results: During the follow-up period, 492 patients died totally, and 119 patients died of cardiac disease. After adjusting for confounding risk factors, heart rate (odds ratio [OR] for all cause moratality.1.46, 95% CI 1.28-1.67 for every 10/min increase), QT prolongation (OR 2.23, 95% CI 1.46-3.42), and left ventricular hypertrophy by Sokolow-Lyon voltage criteria (OR 1.81, 95% CI 1.15-2.86) was an independent predictor of cardiac-related mortality. The c-statistics of the traditional risk factors with the elcectrocardiographic findings in cardiac mortality were significantly increased compared to those of the traditional risk factors without the elcectrocardiographic findings (0.713 vs.0.753, p = 0.02).

Conclusions: We demonstrated electrocardiographic finding associated with all-cause and cardiac-related mortality in hemodialysis patients. Moreover, addition of the electrocardiographic finding to models with standard risk factors significantly improves the predictive ability of cardiac-related mortality.

FR-PO1045

The Ankle-Brachial Index Is Linked to the Subendocardial Viability Ratio: A Correlation Between Peripheral and Myocardial Perfusion

Nejc Piko,[1] Radovan Hojs,[1,2] Sebastjan Bevc,[1,2] Nina Vodošek Hojs,[1] Tadej Petreski,[1] Robert Ekart.[1,2] *[1]University Clinical Centre Maribor, Maribor, Slovenia; [2]University of Maribor, Faculty of Medicine, Maribor, Slovenia.*

Background: Subendocardial viability ratio (SEVR), non-invasively calculated through pulse wave analysis (PWA), is an index of myocardial oxygen supply and demand. Lower SEVR values are linked with advanced coronary artery disease (CAD) and higher mortality, especially in patients with chronic kidney disease (CKD). Peripheral artery disease (PAD) can be assessed by the ankle-brachial index (ABI) and is also associated with increased cardiovascular mortality. Both PAD and CAD are the result of advanced athersclerosis and increased arterial stiffness, but the direct correlation between these two entities is still not fully understood. The aim of our study was to determine the correlation between PAD and CAD by using ABI and SEVR.

Methods: 86 clinically stable patients with ishemic CAD (56 male, 65.1%), who were hospitalized due to elective coronary angiography, were included in the study. Kidney function was determined by the estimation of glomerular filtration rate (eGFR) using the CKD-EPI Creatinine equation. SEVR was determined with PWA (SphygmocorÒ, Atcor Medical, Australia) and ABI index was measured using an automated, non-invasive, waveform analysis device (MESIÒ, Slovenia). All the data were obtained prior to coronary angiography.

Results: Mean age of patients was 64.6±9.6 years (minimum 27, maximum 82 years). 23 patients had diabetes mellitus (26.7%) and 52 patients were smokers (60.5%). Mean eGFR was 74.5±18.4 ml/min/1.73 m^2. Mean ABI values were 1.0±0.1 (0.76-1.31), mean SEVR values were 163.1±34.7% (92-260%). Pearson's correlation test showed a statistically significant correlation between ABI and SEVR (r=0.251, p=0.02). Multiple regression analysis with SEVR as dependent variable has shown statistically significant association with ABI (p=0.032, beta coefficient=0.245) as independent variable, but not with age, diabetes, smoking, eGFR and cholesterol.

Conclusions: ABI is independently associated with SEVR in patients with stable CAD, suggesting a direct connection between peripheral and myocardial perfusion, independent of traditional atherosclerosis risk factors and kidney function.

FR-PO1046

Lipid Metabolic Profiling of Primary Sjögren Syndrome with Kidney Function Deficiency

Shijia Liu,[1] Jiawei Lu,[2] Dong Zhou.[3] *[1]Department of Clinical Pharmacology, the Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, China; [2]China Pharmaceutical University, Nanjing, China; [3]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Primary Sjögren Syndrome (pSS) is characterized by lymphocytic infiltration of the exocrine glands occurs primarily from age 50 onward, with a female to male ratio of 9:1. In the clinic, a severely affected pSS patient not only has the salivary and lacrimal glands damages, but also manifests other extraglandular diseases. Earlier research reported that lipid metabolism disorder linked to pSS caused renal disease. However, the overall lipid metabolic profile of pSS remains unknown. The aim of this study is to analyze lipid metabolic signature of the pSS patients with declined estimation of glomerular filtration rate (eGFR) by which to provide a new angle to underlying the pathogenesis of pSS associated renal diseases.

Methods: Dionex UltiMate 300 Ultra-high performance liquid chromatography system coupled online via electrospray ionization source with an Q Extractive Orbitrap MS instrument was used to evaluate lipid metabolites in 210 female patients with pSS, compared with 396 healthy subjects. We conducted analysis of covariance with potential confounders as covariates. Receiver operating characteristic (ROC) curves were plotted to explore the significance of multiple biomarkers for renal function in pSS.

Results: We identified 1001 differentially expressed lipid metabolites between healthy adults and the pSS patients. Subtype comparisons also revealed significantly differentially expressed lipid metabolites between the pSS patients with eGFR<90ml/min/1.73m2 and eGFR>90ml/min/1.73m2. Changes in triacylglycerol (50:4/14:0-18:2) and Phosphatidyl cholines (40:8/20:4) were the most distinctive lipids between the pSS patients eGFR<90ml/min/1.73m2 and eGFR>90ml/min/1.73m2. Particularly, the diagnostic outcomes are shown *via* the ROC curves for comparison between healthy adults vs pSS (eGFR>90ml/min/1.73m2), healthy adults vs pSS (eGFR<90ml/min/1.73m2), and pSS patients eGFR>90ml/min/1.73m2 vs eGFR<90ml/min/1.73m2. Consistent with the eGFR levels, specific lipidomics-based biomarkers provided AUC of 0.975 to 0.986 in different stage of kidney disease, compared with the healthy controls. The AUC is 0.690 if directly compare the pSS patients with eGFR>90ml/min/1.73m2 or eGFR<90ml/min/1.73m2.

Conclusions: pSS patients are characterized by a distinct lipid metabolic profile providing new insights into the pathogenesis of pSS renal damages.

FR-PO1047

Risk of Ischemic Heart Disease Is Increased in Patients with ANCA-Associated Vasculitis

Chinar Rahmattulla,[1] Andreas Kronbichler,[3] Ron Wolterbeek,[1] Jan A. Bruijn,[1] Ingeborg M. Bajema,[1] David R. Jayne.[2] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]University of Cambridge, Cambridge, United Kingdom; [3]Medical University Innsbruck, Innsbruck, Austria.*

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a chronic autoimmune disease characterized by inflammation of the small to medium-sized blood vessels. A well-established long-term complication of many inflammatory diseases is the occurrence of cardiovascular events. In AAV, the results of experimental studies indicate the occurrence of accelerated atherosclerosis. However, the risk of ischemic heart disease (IHD) in patients with AAV remains poorly quantified. The aim of this study is to investigate the IHD risk in patients with AAV and to examine the effect of immunosuppressive therapy on the IHD risk.

Methods: The study included patients with AAV treated at the Vasculitis and Lupus Clinic in Addenbrooke's Hospital (Cambridge, United Kingdom) between 1990 and 2015. The occurrence of IHD (defined as angina pectoris or myocardial infarction) in these patients was compared with the incidence in the general population by calculating standardized incidence ratios (SIRs), adjusted for sex, age, and calendar year.

Results: Of the 529 included patients, 51 patients developed a total of 57 ischemic heart events during a mean follow-up of 6.3 years. This represented a 2.0-fold increased (95%CI 1.53-2.58, p<0.001) IHD risk in AAV patients compared to the sex-, age-, and calendar year matched general population. There was no significant difference in follow-up duration of patients with and without IHD (mean follow-up of 6.3 year and 5.4 year, respectively) IHD risk was higher in patients with MPO-ANCA (SIR 2.31; 95%CI 1.55-3.44; P <0.001) than in patients with PR3-ANCA (SIR 1.63; 95%CI 1.01-2.61; p=0.043). Moreover, IHD was increased in patients treated with cyclophosphamide (SIR 1.78; 95%1.22-2.60; p=0.003), but not in patients treated with rituximab (SIR 1.03; 95%CI 0.26-4.10; p=0.971).

Conclusions: The result of this large study demonstrate that patients with AAV have an increased IHD risk as compared to the sex-, age-, and calendar year matched general population. IHD risk was higher in patients with MPO-ANCA. Importantly, IHD risk was not increased in patients treated with rituximab but was increased in patients treated with cyclophosphamide. The results of this study demonstrate a need for the active monitoring and treatment of cardiovascular risk factors in patients with AAV.

FR-PO1048

Apabetalone Lowers Serum Alkaline Phosphatase in CVD Patients with and Without CKD and Improves Cardiovascular Risk

Mathias Haarhaus,[1,2] Jan O. Johansson,[3] Michael Sweeney,[3] Ewelina Kulikowski,[4] Norman C. Wong,[4] Christopher Halliday,[4] Aziz Khan,[4] Kenneth E. Lebioda,[4] Vincent Brandenburg,[5] Srinivasan Beddhu,[6] Marcello Tonelli,[7] Carmine Zoccali,[8] Kamyar Kalantar-Zadeh.[9,10] *[1]Division of Renal Medicine and Baxter Novum, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [2]Diaverum Sweden, Stockholm, Sweden; [3]Resverlogix Inc., San Francisco, CA; [4]Resverlogix Corp., Calgary, AB, Canada; [5]Department of Cardiology and Nephrology, Rhein-Maas-Klinikum, Würselen, Germany; [6]Division of Nephrology and Hypertension and Medical Service, Veterans Affairs Salt Lake City Healthcare System, Salt Lake City, UT; [7]Department of Medicine, University of Calgary, Calgary, AB, Canada; [8]CNR IFC, Clinical Epidemiology of Renal Diseases and Hypertension, Reggio Calabria, Italy; [9]Division of Nephrology and Hypertension, Harold Simmons Center for Kidney Disease Research and Epidemiology, University of California Irvine, School of Medicine, Orange, CA; [10]Nephrology Section, Tibor Rubin Veterans Affairs Medical Center, Long Beach, CA.*

Background: Patients with cardiovascular disease (CVD) with or without chronic kidney disease (CKD) have considerable residual risk despite optimal standard of care. Alkaline phosphatase (ALP) has been suggested as a modifiable CVD risk factor. Apabetalone, a bromodomain and extraterminal (BET) inhibitor selective for bromodomain 2 (BD2) lowers ALP in a dose-response fashion. In phase 2 studies apabetalone treatment was associate with a significant 44% reduction in CVD events. We sought to determine whether this CVD risk reduction by apabetalone is associated with the concomitant lowering of serum ALP.

Methods: In a pooled phase 2 post-hoc analysis of 795 CVD patients on standard of care treatment including statins, of which 11.8% had CKD as defined by eGFR <60 m/min/1.73m^2 (n=94; 71=apabetalone; 23=placebo) we assessed the effect of apabetalone vs. placebo treatment for up to 24 weeks on the incidence of CVD events and serum ALP.

Results: Apabetalone treatment decreased serum ALP in CKD and non-CKD CVD patients by 10.2% and 6.5%, respectively (12 weeks), and 7.7% and 7.2%, respectively (24 weeks) (all $p<0.01$). Further analysis on the whole population showed that baseline ALP (median 72 U/L) predicted MACE (death, non-fatal myocardial infarction, coronary revascularization, or hospitalization for cardiovascular causes), independent of high-sensitivity C-reactive protein (hsCRP), sex, age, study, established CVD risk factors, CKD, and treatment allocation (hazard ratio [HR] per standard deviation [SD] 1.6, 95% CI 1.2-2.1, $p<0.001$). In the apabetalone group, a 1 SD reduction in ALP was associated with a HR for MACE of 0.58 (95% CI 0.43-0.78, $p<0.001$).

Conclusions: Serum ALP predicts strongly the residual cardiovascular risk, independent of hsCRP, established cardiovascular risk factors and CKD, in patients with cardiovascular disease on statin treatment. Apabetalone lowers serum ALP and may prevent the incidence of new cardiovascular events. The phase 3 BETonMACE CVD outcomes study reporting H2 2019, will provide further insights about apabetalone's ALP reduction and potential causality for CVD events.

FR-PO1049

Use of Bisphosphonates in CKD Is Associated with Incident Cardiovascular Disease (CVD)

Kathleen Borghoff,[1] Yunshu Zhou,[3] Agnes Ounda,[1] Melissa L. Swee,[1] Patrick Ten eyck,[1] Diana I. Jalal,[1] Anna J. Jovanovich.[2] *[1]University of Iowa, Coralville, IA; [2]Denver VA / University of Colorado, Denver, CO; [3]The University of Iowa, Iowa City, IA.*

Background: CKD-mineral bone disorder, including vascular calcification, is associated with increased CVD risk. Studies suggest that bisphosphonates, the preferred therapy for osteoporosis, are safe in CKD patients. In animal models, bisphosphonates inhibit vascular calcification. We hypothesized that use of bisphosphonates in CKD is associated with lower incident CVD, CVD mortality, and all-cause mortality.

Methods: 2593 Framingham OFFSPRING participants were included. We used propensity score-adjusted Cox regression models to determine the relationship between bisphosphonate use and the following outcomes: time to incident CVD, time to CVD mortality, and time to all-cause mortality. The data were stratified by presence or absence of CKD, defined as eGFR <60 mL/min/1.73m2. The propensity score model included age, sex, hypertension, smoking status, diabetes, total cholesterol, and HDL.

Results: Mean age was 70±9 years and 10% were male. Of the 371 participants using bisphosphonates, 31 had CKD. In the unadjusted analysis, those with CKD who used bisphosphonates had a significant increase in incident CVD [HR 2.061 (95% CI, 0.99-4.29; p=0.05)] compared to those with CKD who did not use bisphosphonates. After adjusting for the propensity score, the HR for incident CVD in participants with CKD who used bisphosphonates increased [HR 2.76 (95% CI, 1.24-6.18; p=0.01)]. There was no significant association between bisphosphonate use and mortality from CVD or all-causes in participants with CKD. In participants without CKD who used bisphosphonates, there was a trend showing a decrease in time to CVD mortality [HR 0.28 (95% CI, 0.07-1.14; p=0.08)] compared to those who did not use bisphosphonates. However, after propensity score adjustment, the HR was attenuated [HR 0.39 (95% CI 0.09-1.67; p=0.21)]. There was no significant association between bisphosphonate use and incident CVD or all-cause mortality in those without CKD.

Conclusions: Contrary to our hypothesis, we show, for the first time, that bisphosphonate use is associated with increased incident CVD in CKD patients. Our analysis was limited by a small sample size. However, future studies in larger cohorts are necessary to confirm these findings and to better understand the mechanisms underlying this association.

Effects of Vitamin D on Cardiovascular and Renal Outcomes in Adults with CKD: A Systematic Review with Meta-Analysis of Randomized Controlled Trials

Wing Chi G. Yeung,[1,2] Ben Talbot,[2] Nasir A. Shah,[1] Suetonia Palmer,[3] Nigel D. Toussaint,[4] Sunil Badve.[1,2] *[1]Department of Nephrology, St George Hospital, Sydney, NSW, Australia; [2]The George Institute for Global Health, University of New South Wales, Sydney, NSW, Australia; [3]University of Otago, Christchurch, New Zealand; [4]Department of Nephrology, The Royal Melbourne Hospital, Melbourne, VIC, Australia.*

Background: Cardiovascular disease is the leading cause of mortality in patients with chronic kidney disease (CKD). The excess risk has been attributed to increased vascular calcification and higher prevalence of left ventricular hypertrophy. Vitamin D therapy plays an important role in management of secondary hyperparathyroidism but may also have cardioprotective effects. This systematic review was performed to study the effects of vitamin D therapy on cardiovascular and renal outcomes.

Methods: MEDLINE, EMBASE and Cochrane databases were searched for randomised controlled trials involving CKD patients stages 3-5D with ≥3 months follow-up that compared a vitamin D compound (nutritional or active) with placebo, no study medication, or an active medication. For continuous variables, the change between the baseline value and end-of-treatment value was calculated. Summary estimates were obtained by a random-effects model and expressed as weighted mean differences (WMD) or relative risks (RR) with 95% confidence intervals (CI).

Results: One hundred and thirteen trials (9973 participants) were included (mean age 60.5 years, median follow-up 6 months). Of these, 71 trials were conducted in 6036 dialysis patients, and 42 trials were conducted in 3937 non-dialysis CKD patients. Trials were generally at high or unclear risk of bias. There was no significant difference in risk of major adverse cardiovascular outcomes when comparing vitamin D and placebo (11 trials, RR 0.98, 95%CI 0.65-1.48), or active and nutritional vitamin D (2 trials, RR 0.85, 95%CI 0.32-2.31). Compared to placebo, vitamin D did not significantly change systolic blood pressure (7 trials, WMD 0.43 mmHg, 95% CI -3.43 to 4.29), diastolic blood pressure (5 trials, WMD 0.58 mmHg, 95%CI -2.16 to 3.32), pulse wave velocity (4 trials, WMD -0.75 m/sec, 95%CI -1.56 to 0.07), left ventricular mass (4 trials, WMD 2.17 g/m^2, 95%CI -8.01 to 12.36) or glomerular filtration rate (11 trials, WMD -0.25 mL/min/1.73m^2, 95%CI -0.78 to 0.29). Data for B-natriuretic peptide levels and urine albumin/creatinine ratio were insufficient for meta-analysis.

Conclusions: The effects of vitamin D compounds on cardiovascular and renal outcomes in CKD are uncertain. Further research with adequately powered trials is required.

FR-PO1051

Effect of Renin-Angiotensin System Blockade on Stroke in Kidney Transplant Recipients: Retrospective Multicenter Study in Japan

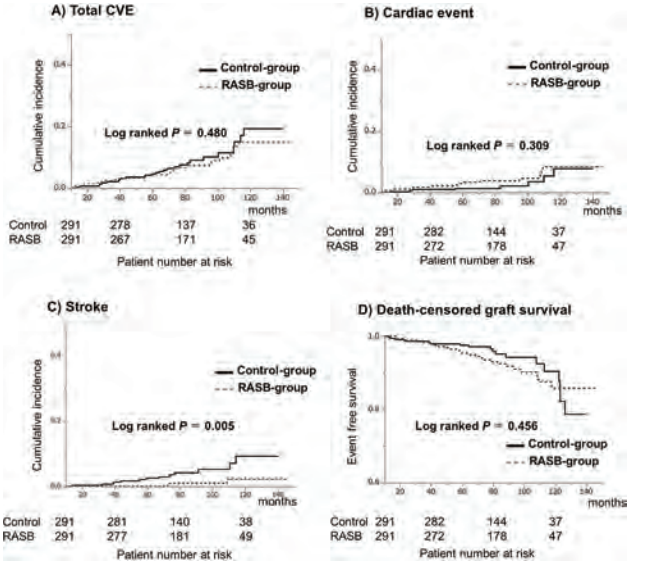
Akihiro Tsuchimoto,[1] Kosuke Masutani,[3] Kenji Ueki,[2] Kaneyasu Nakagawa,[1] Yuta Matsukuma,[1] Shigeru Tanaka,[1] Yoichi Kakuta,[4] Masayoshi Okumi,[5] Yasuhiro Okabe,[6] Toshiaki Nakano,[1] Takanari Kitazono,[7] Kazunari Tanabe.[5] *[1]Kyushu University, Fukuoka, Japan; [2]Kyushu University, Fukuoka, Japan; [3]Fukuoka University, Fukuoka, Japan; [4]Tokyo Women's Medical University, Tokyo, Japan; [5]Tokyo Women's Medical University, Shinjuku, Japan; [6]Kyushu University Hospital, Higashi-ku, Japan; [7]Department of Medicine and Clinical Science, Fukuoka, Japan.*

Background: Renin–angiotensin system blockers (RASBs) reduce end-stage kidney disease and cardiovascular event (CVE) development in chronic kidney disease. However, whether RASBs improve long-term prognosis in kidney transplant (KT) recipients remains unknown.

Methods: We investigated 900 kidney transplant patients in a multicenter retrospective cohort study in Japan and compared death-censored graft-survival and CVE (total, cardiac events, stroke) based on RASB use within 12 months after KT. The associations were examined using a Cox hazard model and propensity score-matching analysis.

Results: The cohort comprised 375 patients treated with RASBs (RASB group) and 525 patients without RASBs (control group). The median observational period was 82 months, with 68 patients reaching graft loss: 79 total CVE, 36 cardiac events, 26 stroke. In a matching cohort comprising 582 patients, graft survival, total CVE, and cardiac events were not different between the two groups. Only stroke incidence rate was significantly lower in the RASB group compared with the control group (1.4 vs. 6.4 per 1000 patients/year, log-ranked P=0.005). In a multivariable analysis, stroke events were also significantly lower in the RASB group compared with the control group (Hazard ratio and 95% confidence interval, 0.20 [0.04–0.62]).

Conclusions: RASBs potentially reduce stroke events in KT recipients.



The cumulative incidence for each endpoint was compared between the RASB and control groups: (A) Total CVE, consisting of cardiac event, stroke, and peripheral artery disease; (B) Cardiac event; (C) Stroke; (D) Death-censored graft-survival

FR-PO1052

Postural Blood Pressure Control Is Decreased in Diabetic Patients After Successful Renal Transplantation

Dvora Rubinger, Michal Dranitzki Elhalel, Dan Sapoznikov. *Hadassah Hebrew University Medical Center, Jerusalem, Israel.*

Background: The postural control of blood pressure (BP) under othostatic challenges, a measure of the robustness of the autonomic nervous system, is reduced in both renal insufficiency and diabetes mellitus (DM). The present study was undertaken to assess the effect of normalization of kidney function by renal transplantation (TX) on postural changes of BP and autonomic indices in uremic patients, without [DM(-)] and with [DM(+)].

Methods: Continuous interbeat interval (IBI), systolic (SBP) and diastolic (DBP) BP and their variabilities in the low (LF) and high (HF) frequency ranges were recorded during sitting and standing in 48 TX DM(-), in 14 TX DM(+) patients and in 37 control (C) individuals of similar age range. α index, a measure of baroreflex function was obtained from the square roots of the ratio of average IBI and SBP powers. LF IBI/HF IBI was considered a measure of the sympatho-vagal balance.

Results: Plasma creatinine was 116±31 and 113±43 μmol/l in TX DM(-) and TX DM(+) respectively (pNS). Differences (Δ) in BP and variability measures between sitting and standing positions (median and interquartile ranges) are shown in Table1. In C, moving from sitting to standing was associated with increased BP, decreased IBI, decreased α indices and increased sympatho-vagal balance. These changes were partly maintained in TX DM (-) but markedly suppressed in TX DM (+).

Conclusions: Our data show that in C, BP during postural changes is maintained by sympathetic activation, which is partialy attenuated in TX DM (-) and almost abolished in TX DM(+), despite the reversal of renal failure. These alterations, arguably the consequence of long standing DM autonomic neuropathy, may be responsible for frailty, gait instability and falls in these patients.

Table 1.

	C	TX DM (-)	p vs.C	TX DM (+)	p vs. C
Δ SBP (mmHg)	9.7 (16.2)	8.9 (18.1)	0.818	-1.6 (32.4)	0.045

The Relationship Between Retinal Artery Wall-to-Lumen Ratio and Kidney Pathology Findings in Accelerated Hypertension

Tristan De nattes,[2] Charles Verney,[4] Yosu Luque,[3] David Buob,[6] Michel Paques,[5] Cedric Rafat.[1] *[1]Hôpital Tenon, AP-HP, PARIS 20, France; [2]Hôpital Tenon, APHP, Paris, France, Paris, France; [3]Assistance Publique - Hopitaux de Paris, Paris, France; [4]APHP paris, Saint Ouen, France; [5]Quinze-Vingts Hospital, PAris, France; [6]Tenon Hospital and Sorbonne University, Paris, France.*

Background: Accelerated hypertension is characterized by macrovascular and microvascular endothelial damage. In this study we analyze the relationship between retinal artery wall-to-lumen ratio (WLR) and renal histology.

Methods: All patients hospitalized into Kidney Intensive Care Unit for malignant hypertension with acute kidney injury had measurement of retinal wall-to-lumen ratio (WLR) using SPECTRALIS retina imaging. Renal clinical and pathology findings were collected as well as details pertaining to heart echography. Data were presented as median [25th-75th], correlation were calculated according to Spearman's test.

Results: Twenty-seven patients were hospitalized for accelerated hypertension in our center between September 2016 and April 2019. Median age was 39.4 years old [30.7-45.3]. Initial systolic, diastolic and mean arterial pressure were 218 [185-239], 128 [113-162] and 153 [137-187] mmHg, respectively. Ten (37.0%) patients underwent haemodialysis during their stay, 8 (29.6%) patients underwent chronic haemodialysis, 4 (14.8%) had myocardial microvasculature involvement, 4 (14.8%) had posterior-reversible encephalopathy syndrome. Seventeen patients (63.0%) had kidney biopsy. Retinal WLR was correlated with systolic and mean arterial pressure, respectively r=0.56 (p=0.003) and r=0.46 (p=0.02), but did not reach significance for tubulo-interstitial fibrosis (r=-0.45, p=0.09) or glomerulosclerosis (r=-0.38, p=0.15). Retinal WLR was not correlated with renal WLR (r=0.13, p=0.6). Retinal WLR did not correlate with left ventricular mass estimation (r=0.10, p=0.6)

Conclusions: Retinal WLR was found to be closely correlated to initial systolic and mean arterial pressure. Perhaps due to the cohort size, we failed to demonstrate an association between retinal WLR and kidney pathology findings.

FR-PO1054

Role of Endothelial Function Determined by Asymmetric Dimethylarginine in the Prediction of Resistant Hypertension: A Subanalysis of the ReHot Trial

Daniel Beraldo,[1] Cassio J. Rodrigues,[1] Beata M. Quinto,[1] Marcelo C. Batista.[1,2] *[1]Universidade Federal de São Paulo, São Paulo, Brazil; [2]Hospital Israelita Albert Einstein, São Paulo, Brazil.*

Background: Endothelial dysfunction has been conceived as the basis of cardiovascular disease. Brought in core of global epidemic of obesity and the increased life expectancy, resistant hypertension (ReHy) represents a growing public health issue. We conducted a subanalysis of the Resistant Hypertension Optimal Treatment (ReHOT) study to evaluate the association between endothelial dysfunction and resistant hypertension in a population of patients treated in a staged fashion for hypertension.

Methods: ReHOT was a prospective, multicenter, randomized trial comprising 26 sites in Brazil. One hundred and three hypertensive patients of one site were included for this 6 months study in 7 visits (V0-V6), 28 days apart. There was a first phase (V0-V3) of antihypertensive adjustment with 3 drugs to detect ReHy. A second randomized phase (V3-V6) of treatment with a fourth drug (clonidine or spironolactone) in the hypertensive patients characterized as resistant. Serum asymmetric dimethylarginine (ADMA) was determined by high performance liquid chromatography (HPLC) on Visits 1 and 7.

Results: Of the 103 patients included, 86 (83.5%) underwent the randomization visit (V3), 71 were characterized as non-resistant hypertensives (82.5%) and 15 as resistant hypertensives (17.5%). Patients from the upper tercile of serum ADMA had a higher V1 blood pressure, higher total cholesterol values as well as higher prevalence of cardiovascular disease. There was a parallel reduction in blood pressure levels and ADMA values during follow-up with a positive correlation in both groups and a greater reduction among those with ReHy. Serum ADMA was shown to be an independent predictor of resistant hypertension after adjustment for multiple variables (OR: 11.42, 95% CI: 1.02 - 127.71, p = 0.048).

Conclusions: We demonstrated that ADMA was an independent predictor of resistant hypertension, and we observed that the improvement in blood pressure levels obtained with the treatment was proportional to the reduction in ADMA values, suggesting a complementary role of ADMA not only as a stratification tool for the occurrence of resistant hypertension, but also as a potential therapeutic target in this population.

Impedance Cardiography-Guided Individualized Hypertension Treatment

Yossi Chait,[1] Brian H. Nathanson,[2] Barbara A. Greco,[3] Michael J. Germain.[3] *[1]University of Massachusetts, Amherst, MA; [2]OptiStatim, LLC, Longmeadow, MA; [3]Renal and Transplant Associates of New England, Springfield, MA.*

Background: Current guidelines for management of hypertension (HTN) allow considerable leeway in selection of antihypertensive medications to achieve new lower blood pressure (BP) targets. Success in achieving target BP remains suboptimal. We observed BP outcomes under standard (standard) and individualized (modified) HTN treatment protocols.

Methods: We instituted a practice improvement project comparing standard to modified treatment protocols for the management of patients referred for resistant HTN with or without chronic kidney disease. The modified protocol, managed by two nephrologists, was centered around hemodynamic status: vasconstricted, hyperdynamic, or mixed state. Hemodynamic status was defined by impedance cardiography (central BP and pulse wave velocity were measured in a subset of patients). Antihypertensive medications were adjusted to treat the hemodynamic state. During an initial 6-month run-in, patients not in target BP were assigned to study groups. We compared BP outcomes using paired and unpaired t-tests at the study end.

Results: Of 169 patients at baseline, 88 continued with standard care and 81 were managed with the modified protocol. Demographics were similar in both groups. The modified group had significant reductions in both systolic BP and diastolic BP baseline to study end but the standard care group had little to no change (see Figure 1). At study end, 45.7% and 11.4% were in target BP in the modified and standard groups, respectively (p<0.001). This correlated with increased use of calcium channel blockers and beta-blockers in the modified group compared to standard care.

Conclusions: Impedance cardiography is a simple, noninvasive method for evaluating underlying hemodynamic drivers of HTN. Hypertension management is more effective when guided by hemodynamic parameters.

Determination of Adherence to Antihypertensive Medications by Urine Testing In Patients with Advanced CKD

Se ri Bae, Mariel Lerma, Elizabeth A. Black, Raymond K. Hsu, Elaine Ku. *University of California, San Francisco, CA.*

Background: Our objective was to assess blood pressure (BP) medication adherence and its predictors in adults with advanced CKD using KardiAssure, a commercially available urine test that detects a comprehensive battery of BP medications. We also aimed to compare assessments of medication adherence by providers and study coordinators compared to KardiAssure testing in the clinical and research setting.

Methods: Participants with advanced CKD (stage 4-5) in a randomized pilot trial were included. Urine specimens were collected at baseline and 4-month follow up visits. Adherence was defined as agreement between patient-reported BP medications and medications detected by KardiAssure. Providers and study coordinators were surveyed regarding their perceptions of patient BP medication adherence. Logistic models were used to examine predictors of adherence.

Results: We included 57 patients at baseline and 40 patients at the 4-month follow-up for study. Mean age was 54±17 years; 58% were male; mean baseline eGFR was 22 mL/min/1.73m^2. Diuretics and beta blockers were the the most common agents that patients were non-adherent to by KardiAssure testing (27% and 23%, respectively). Providers and coordinators identified adherence accurately but significantly under-estimated non-adherence (Figure). Factors predictive of adherence included provider perceptions of adherence and female sex.

Conclusions: Non-adherence is common in patients with advanced CKD, especially to diuretics and beta-blockers. Further studies are needed to understand how to best assess adherence in clinical practice and research studies and identify reasons for selective adherence to different classes of BP agents.

Management of Resistant Hypertension due to Renal Artery Stenosis

Jinhua Zhao. *Cleveland VA Medical Center, Cleveland, OH.*

Introduction: Medical management of secondary hypertension caused by renal artery stenosis (RAS) remains mainstream especially after the publication of Coral Study. Coral Study suggested no difference in blood pressure (Bp) control between medical management alone and medical management plus percutaneous intervention. Some patients' clinical picture does not fit in the inclusion criteria of Coral Study, the management should be individualized.

Case Description: A 68-year-old white male with uncontrolled HTN on 5 antihypertensives, HLD, T2DM, CKD Stage 3-4. His antihypertensive medications include: amlodipine 10mg daily, Chlorthalidone 25mg daily, hydralazine 50mg 3 times a day, terazosin 5mg daily at bedtime, and clonidine 0.3mg twice a day. Patient was briefly on lisinopril which was stopped after patient developed acute renal failure with hyperkalemia. His Bp had been 180-210's/80-90's for most time. Our work-up was significant for renin activity 27.36 ng/ml/h, serum aldosterone 5.9 ng/DL. Renal US showed right kidney 10.2cm, left kidney 7.4cm. Angiography showed severe narrowing at the right renal artery orifice which has early bifurcation, involving the upper and lower branches. Left renal arteriogram: A small accessory lower pole left renal artery is visualized with complete occlusion of the main left renal artery. Renal vein sampling was done 3 days later. Renin activity of left renal vein was 30.62, whereas that of the right renal vein was 117.05, that of inferior vena cava was 41.85. Thus the decision was to re-vasculize the right renal artery in 1 week to avoid repeated iv contrast exposure in very short time. Placement of 6 mm x 18 mm balloon expandable stent in the dominant branch of the right renal artery was done. Patient's systolic Bp was 140-160's mmHg one month later on only lisinopril 2.5mg daily. His Bp were ~ 130/70 mmHg one year later on lisinopril 10mg daily.

Discussion: The management of resistent hypertension due to renal artery stenosis needs to be individualized.

FR-PO1058

Chronotherapy of Renin-Angiotensin System (RAS) Inhibitor Ameliorates Renal Damage via Suppression of Intrarenal RAS Activity

Taro Aoki, Naro Ohashi, Shinsuke Isobe, Sayaka Ishigaki, Takashi Matsuyama, Tomoyuki Fujikura, Akihiko Kato, Hideo Yasuda. *Hamamatsu University School of Medicine, Hamamatsu, Japan.*

Background: We have shown that intrarenal RAS with chronic kidney disease (CKD) patients is activated and that intrarenal RAS activity contributes to blood pressure (BP) elevation, abnormal circadian rhythm of BP and renal damage. Moreover, changing the administration time of RAS inhibitors from morning to evening, namely chronotherapy, decreases BP and ameliorates renal damage during nighttime. However, it has not been clarified whether chronotherapy changes intrarenal RAS activity and the change of intrarenal RAS activity by chronotherapy reflects the change of BP and renal damage.

Methods: We recruited 34 CKD patients who took RAS inhibitors in the morning (sex: 22 males / 12 females, age: 60.2±19.4 years, estimated glomerular filtration rate (eGFR): 34.8±30.8 ml/min/1.73 m^2). We collected urine during daytime and nighttime, respectively, and evaluated urinary albumin (U–Alb) and urinary angiotensinogen (U–AGT), a surrogate marker for intrarenal RAS activity. Ambulatory BP monitoring was conducted at 30–min intervals during the daytime and nighttime. Thereafter, the same experiments were made after 4.1±0.5 days from change of the administration time. The ratios of clinical parameters morning dosing against evening dosing were defined as M/E ratio.

Results: The excretion levels of U–Alb and U–AGT during daytime and nighttime were significantly decreased by chronotherapy in all CKD patients. M/E ratio of U–Alb had significant and positive relationships with M/E ratio of U–AGT. Moreover, there were significant and positive relationships between M/E ratio of U–Alb and U–AGT during nighttime (β=0.73 and p=0.005), but not daytime (β=0.39 and p=0.098) in the CKD patients whose eGFR is less than 45 ml/min/1.73m^2. In addition, significant and positive relationships were found between M/E ratio of U–Alb and U–AGT during nighttime (β=1.04 and p <0.001), but not daytime (β=0.52 and p=0.074) in the CKD patients who have nondipper or riser patterns when the night–to–day ratio of systolic BP is 0.90–1.00 or >1.00, respectively.

Conclusions: The present study indicated that chronotherapy of RAS inhibitor improved renal damage via intrarenal RAS suppression in CKD patients. This effect was more remarkable in patients with highly impaired renal function and nocturnal hypertension.

FR-PO1059

RNF213 p.Arg4810Lys Variant Screening in Renovascular Hypertension in Korean Children

Heeyeon Cho, Jeong yeon Kim. *Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Moyamoya disease (MMD) -a steno-occlussive disease of the distal cerebral arteries- is often accompanied by renovascular hypertension (RVH), and a variant of *RNF213* p.Arg4810Lys is known as a susceptibility gene of MMD. There is a report for a *RNF213* variant-associated vasculopathy with peripheral pulmonary arterial stenosis and homozygous variant for *RNF213* p.Arg4810Lys without the presence of MMD. The purpose of this study was to evaluate clinical manifestations and gene test for the *RNF213* variant in Korean pediatric patients with initially presenting with isolated RVH.

Methods: A retrospective analysis of medical records in pediatric patients with isolated RVH from January 2001 to October 2017 were performed. The presence of renovascular hypertension was confirmed by computer tomography (CT) angiography or renal doppler ultrasonography. The genetic test for *RNF213* variant was performed in the pediatric patients with RVH.

Results: The gene test for *RNF213* was performed in 11 patients with isolated RVH. The molecular testing revealed homozygosity of *RNF213* p.Arg4810Lys in 5 patients, and heterozygosity in 2 patients. Among 7 patients with *RNF213* variant, on CT angiography, it revealed bilateral renal artery stenosis of ostial lesions in 3 of the patients and unilateral stenosis of ostial to proximal lesions in 4 of the patients. Among 7 patients with *RNF213* variant, MMD developed in 4 patients during follow-up. In one patient with homozygosity of *RNF213* p.Arg4810Lys, he showed the isolated RVH, and his mother with heterozygosity of *RNF213* p.Arg4810Lys presented with MMD and no evidence of RVH.

Conclusions: Our study suggests that *RNF213* may be the causative gene in RVH in Korean children. The screening for MMD and other organ involvement might be helpful in children and family members with RVH and *RNF213* variant.

Case	sex	RNF213	Brain image	Time interval RVHT →MMD	Family History

Dual Renin-Angiotensin System Blockade: A Meta-Analysis of Cardiovascular and Renal Outcomes

Satyanarayana R. Vaidya,[1] Waleed Ali,[2] Ajai S. Rajabalan,[1] James L. Bailey.[1] *[1]Emory University School of Medicine, Decatur, GA; [2]University of chicago, Chicago, IL.*

Background: Dual renin-angiotensin (RAS) blockade has shown to decrease blood pressure, proteinuria and hospitalization due to heart failure (HF). We intended to evaluate its efficacy and safety in HF, diabetes mellitus (DM), hypertension (HTN), and chronic kidney disease (CKD).

Methods: All randomized trials comparing dual RAS blockade with monotherapy in HF, CKD, DM, and HTN as of January 31, 2019, were identified after searching the PubMed, EMBASE, and CENTRAL databases. Those which compared the dual RAS blockade [Angiotensin converting enzyme inhibitor+ Angiotensin receptor blocker] (ACEI + ARB) or [Direct Renin inhibitor (DRI), aliskiren combined with ACEI or ARB] with monotherapy (ACEI or ARB) were selected. Major outcomes were all-cause and cardiovascular mortality, progression to end-stage renal disease (ESRD), and

hospitalization due to HF. Minor outcomes were proteinuria, BP change, renal failure, hyperkalemia, hypotension, and withdrawal due to adverse events.

Results: Eighty-one studies fulfilled the inclusion criteria, yielding 76,866 patients. When compared to monotherapy, the dual RAS blockade reduced blood pressure and proteinuria. In HF subgroup, dual RAS blockade reduced hospitalizations due to HF [relative risk (RR)=0.82, 95% CI0.71-0.94; P=0.004], [number needed to treat (NNT=15)], but had no effect on all-cause mortality (RR=0.98, 95% CI=0.88-1.09; P=0.72) and cardiovascular mortality (RR=0.92, 95% CI=0.79-1.06; P=0.25). Despite a decrease in blood pressure of 11.7 / 7.5 mm Hg in the HTN subgroup and a decrease in proteinuria, dual RAS blockade failed to slow progression to ESRD and was associated with increased rates of renal failure, hyperkalemia, hypotension, and withdrawal due to adverse effects. Neither in DM or CKD were there any outcome benefits.

Conclusions: When compared to monotherapy, dual RAS blockade failed to improve morbidity and mortality in HF, CKD, DM, and hypertension but reduced hospitalizations due to HF. Dual RAS blockade failed to slow progression to ESRD and led to higher withdrawal rates because of adverse effects.

Outcome	Dual RAS blockade Events	Dual RAS blockade Patients	Mono RAS blockade Events	Mono RAS blockade Patients	RR (95% CI)	RR (95% CI)
All-cause mortality	453	5203	434	5220	1.05 (0.92 - 1.19)	
Progression to ESRD	76	999	83	996	0.92 (0.70 - 1.22)	
HF hospitalizations	220	4505	238	4523	0.93 (0.77 - 1.11)	
Renal failure	357	5601	315	5616	1.07 (0.78 - 1.48)	
Hyperkalemia	1537	5485	1123	5447	1.45 (1.08 - 1.94)	
Withdrawal due to adverse events	651	4894	509	4887	1.28 (1.15 - 1.43)

Uremic Pericarditis in CKD: National Estimates of Hospitalizations, Procedures, and Outcomes (2006-2015)

Carl P. Walther, Sankar D. Navaneethan, Jingbo Niu, Wolfgang C. Winkelmayer.
Baylor College of Medicine, Houston, TX.

Background: Uremic pericarditis and pericardial effusions are well-known and potentially deadly complications of chronic kidney disease (CKD). These complications can often be managed with intensive hemodialysis, but sometimes invasive procedures are indicated, for cardiac tamponade, diagnosis, or definitive management. We investigated national trends in uremic pericardial disease hospitalizations, procedures, and mortality.

Methods: We used the National Inpatient Sample, a 20% sample of US hospital discharges, from 2006-2015. We applied appropriate survey methods to obtain national estimates. We identified any CKD using ICD discharge codes, and pericarditis or pericardial effusion using the first 10 discharge codes. We excluded patients with possible non-uremic causes of pericardial disease (e.g., malignancy, myocardial infarction, myocarditis, non-pericardial cardiac surgery). We identified pericardiocentesis and pericardial window procedures using procedure codes.

Results: There were an estimated 24,508 (95%CI 23,647-25,369) hospitalizations for pericarditis in CKD that met the inclusion criteria. Age was 61±18 years. 43% of patients were female. An estimated 9.1% underwent pericardiocentesis alone, 8.8% underwent pericardiotomy alone, and 1.5% underwent both procedures. In-hospital mortality was 2.8% (2.5%, 6.4%, 2.7% and 2.8%, respectively, among those who underwent neither procedure, pericardiocentesis alone, pericardiotomy alone, and both procedures; p>0.05). Median (IQR) length of stay was 5 (3-8) days.

Conclusions: Uremic pericarditis and pericardial effusions remain an important complications of CKD, with approximately 1 in 5 hospitalizations involving an invasive pericardial intervention. In-hospital mortality is relatively low, but we were not able to assess post-hospital outcomes. Further investigations can target improved causal understanding and management.

Relationship Between 24-Hour Blood Pressure (BP) Load and Renal or Cardiac Outcomes in Children with CKD

Jason T. Lee,[1] Divya Seth,[1] Joseph T. Flynn,[3] Joshua A. Samuels,[4] Charles E. McCulloch,[1] Mark Mitsnefes,[2] Elaine Ku.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Cincinnati Children's Hospital, Cincinnati, OH; [3]Seattle Children's Hospital, Seattle, WA; [4]University of Texas, Houston, TX.*

Background: Blood pressure (BP) load, the proportion of elevated BPs detected by 24h ambulatory blood pressure monitoring (ABPM), is not a uniform criteria for diagnosing hypertension in all BP guidelines. We aimed to determine whether systolic BP load on ABPM was associated with adverse renal or cardiac outcomes in children with chronic kidney disease (CKD).

Methods: We analyzed data from 533 children with CKD. We categorized the BP status of participants as normotensive (normal mean awake/sleep BP and normal BPL), isolated BPL elevation (normal mean awake/sleep BP, elevated BPL >25%), or hypertensive (elevated mean awake/sleep BP, regardless of BP load). We examined the association between BP status and left ventricular hypertrophy (LVH) in logistic models and ESRD in Cox models. We also examined the value of considering BPL (as a continuous variable) independently and in conjunction with mean BP in predicting outcomes. We tested for differences in risk discrimination in our models (using c-statistics).

Results: One-third of the cohort met criteria for ambulatory hypertension and an additional 25% of participants had isolated BPL elevation. In both unadjusted and adjusted analyses, isolated BPL elevation was not statistically significantly associated with LVH or ESRD compared to those with normotension, whereas hypertension was (figure). Although BPL was independently associated with risk of ESRD, when used in conjunction with mean BPs, BPL was no longer associated with outcomes [table]. BPL also provided poor risk discrimination for LVH and ESRD [table].

Conclusions: BPL may not provide additive prognostic information over and beyond mean BP, and isolated BPL elevations were not associated with risk of LVH or ESRD in children with CKD.

Funding: NIDDK Support

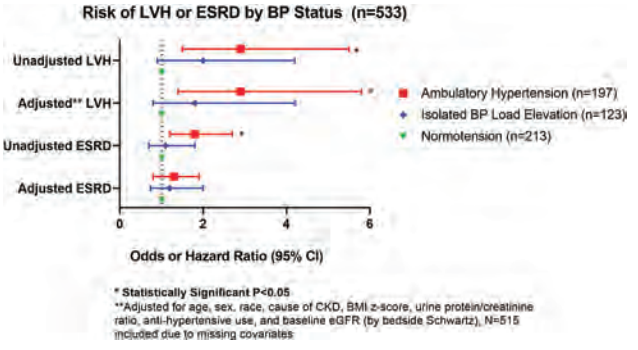

Table. N=533	LVH Unadjusted OR‡ (95% CI)	LVH C-statistic (95% CI)	ESRD Unadjusted HR‡ (95% CI)	ESRD C-statistic (95% CI)
Awake SBP load (every 10% increase)	1.2 (1.0-1.3)	0.61 (0.53-0.68)	1.2 (1.1-1.2)	0.60 (0.55-0.67)
Awake mean SBP* (per 0.1 increase)	1.7 (1.2-2.3)	0.62 (0.55-0.69)	1.6 (1.3-1.9)	0.60 (0.56-0.68
Awake SBP load + Awake mean SBP*	0.9 (0.7-1.2) 2.4 (1.0-5.6)	0.63 (0.55-0.69)	1.1 (1.0-1.3) 1.2 (0.7-1.9)	0.60 (0.56-0.68)

*Mean SBP is represented as an index (ratio of the patient's mean BP to the 95th percentile for age/height, such that a ratio of 1 represents a 95th percentile BP)
OR = odds ratio; HR = hazard ratio; LVH = left ventricular hypertrophy

FR-PO1063

Ambulatory Hypertension Disproportionately Affects African American Children with Non-Glomerular CKD Independent of Socioeconomic Factors

Kl Sgambat,[1] Jennifer Roem,[2] Joshua A. Samuels,[3] Susan L. Furth,[4] Bradley A. Warady,[5] Asha Moudgil.[1] *[1]Children's National Health System, DC, DC; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]University of Texas, Houston, TX; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]Children's Mercy Kansas City, Kansas City, MO.*

Background: Although hypertension is common in children with chronic kidney disease (CKD), particularly among African Americans (AA), the extent to which that association is explained by socioeconomic factors (SES) is not well known. The objective of this study was to contrast racial differences in ambulatory hypertension among children with CKD before and after adjustment for putative confounding SES factors.

Methods: This cross-sectional analysis comprised 1021 repeated measures from 475 children enrolled in the CKiD study, stratified by glomerular and non-glomerular diagnosis. Children (1-16 years, eGFR 30-90 ml/min/1.73m^2 at study entry) with at least 1 ambulatory blood pressure monitor (ABPM) measurement were included. Logistic regression models were used to estimate odds ratios (OR) of ABPM hypertension (systolic

or diastolic wake/sleep blood pressure ≥95th or load>25th percentile) associated with AA race. Inverse probability weighting was used to account for potential confounding of SES (public insurance, food insecurity, household income, maternal education), abnormal birth history, demographics (age, sex), obesity (BMI>95th percentile) and disease severity (eGFR<45 mL/min|1.73m²) at study entry.

Results: Overall prevalence of ambulatory hypertension was 54%. AA children with both glomerular and non-glomerular CKD were disproportionately affected by SES variables by univariate analysis. In unadjusted models, AA children with non-glomerular disease had higher odds of ambulatory hypertension (OR=2.93; 95%CI:1.57, 5.47, p=0.001). Multivariable analysis adjusted for demographics, SES, birth history, obesity, and disease severity showed that among the non-glomerular group, AA children had 3.08-fold odds (95%CI:1.58, 6.00, p=0.001) of ambulatory hypertension. However, there was no difference in ambulatory hypertension between AA and Caucasian children with glomerular CKD, either unadjusted (OR=1.54; 95%CI:0.73, 3.26, p=0.262) or adjusted (OR=1.26; 95%CI:0.40, 4.00, p=0.694).

Conclusions: AA children with non-glomerular CKD are disproportionately affected by ambulatory hypertension, independent of SES. Glomerular injury is a driving force of hypertension, thus minimizing racial differences in ambulatory hypertension after adjustment for SES in children with glomerular CKD.

FR-PO1064

Discordances Between Pediatric and Adult Thresholds in the Diagnosis of Ambulatory Hypertension in Adolescents with CKD

Jason T. Lee,[1] Elizabeth A. Black,[1] Divya Seth,[1] Joseph T. Flynn,[3] Joshua A. Samuels,[4] Mark Mitsnefes,[2] Elaine Ku.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Cincinnati Children's Hospital, Cincinnati, OH; [3]Seattle Children's Hospital, Seattle, WA; [4]University of Texas, Houston, TX.*

Background: The diagnostic threshold for hypertension (HTN) by 24-hour ambulatory blood pressure (ABP) monitoring in adults was changed in the updated American Heart Association (AHA) 2017 guidelines. Our objective was to compare the prevalence, sensitivity/specificity, and predictive value of a diagnosis of HTN by pediatric versus adult ambulatory thresholds in children with CKD.

Methods: We included 371 children with CKD ages 13 or older. We used normative pediatric cutoffs (sex/height-based), prior adult cutoffs (awake SBP>135 mmHg, sleep>120), and updated AHA 2017 cutoffs (awake>130mmHg, sleep>110) to define HTN and determine its prevalence. We then compared the sensitivity, specificity, positive (PPV) and negative predictive values (NPV) of each threshold for development of left ventricular hypertrophy (LVH) and progression to end-stage renal disease (ESRD).

Results: 27% of the cohort met criteria for HTN using pediatric ABP normative thresholds, versus 44% by the updated AHA 2017 adult threshold and 16% by prior adult guidelines (Table). For LVH, the sensitivity of all thresholds was poor with the prior adult criteria being the least sensitive but most specific (Figure). For ESRD, the updated AHA 2017 adult threshold had the greatest sensitivity but lowest specificity (Figure). Overall, the PPV and NPV were similar across all thresholds for LVH and ESRD.

Conclusions: In adolescents with CKD, the updated AHA 2017 adult threshold leads to the highest prevalence of ambulatory HTN and has variable sensitivity and specificity for LVH versus ESRD. The pediatric thresholds had lower sensitivity but higher specificity vs. the AHA 2017 criteria. Further research is needed to optimally define ambulatory HTN as adolescents transition to adulthood.

Funding: NIDDK Support

Table: Prevalence of HTN by different SBP cutoffs from 24-hour ABP monitoring (n=371)

	Pediatric Age/Sex-based Threshold	Prior Adult Guideline Threshold	AHA 2017 Updated Adult Threshold
Ambulatory Hypertension by SBP N (%)	102 (27)	61 (17)	163 (44)
Awake Hypertension N (%)	72 (19)	37 (10)	81 (22)
Sleep Hypertension N (%)	77 (21)	48 (13)	152 (41)

FR-PO1065

Hypertension and Obesity in High School Students: Genetic and Environmental Factors in the HYGEF Study

Simone Fontana,[1] Chiara Maggioni,[2] Chiara Lanzani,[2] Laura Zagato,[4] Marco Simonini,[2] Elena Brioni,[4] Lorena Citterio,[3] Simona Delli carpini,[1] Paolo Manunta.[1] *[1]HSR-Nefrologia, Milano, Italy; [2]San Raffaele Scientific Institute, Milan, Italy; [3]Università Vita-Salute - Ospedale San Raffaele, Milano, Italy; [4]Ospedale San Raffaele, Milan, Italy.*

Background: The clinical outcomes associated to hypertension and obesity in the young population are major risk factors for renal and cardiovascular events in the adult age. Objectives of the study are: to assess the associations among genetic and environmental factors and blood pressure (BP) in a high school population before developing hypertension and to study the transition from normotension to hypertension.

Methods: This observational cohort study obtained data from 3057 high school students in three different regions of Italy. Participants underwent anthropometric, BP measurement and saliva and urine sample collection. Selected genetic variants were determined.

Results: Our results confirmed the link between body weight, salt intake and BP in adolescents (p<0.005; R square 30%). Analysis of BP values (adjusted for BMI, waist circumference, age, sex, region) and genetic polymorphisms evidenced associations with Lanosterol Synthase (LSS), an enzyme involved in Endogenous Ouabain synthesis. The A allele of a missense variant in LSS gene was associated to higher diastolic and systolic BP levels (DBP: LSS AA+AC 69.7±0.32 mmHg, LSS CC 68.8±0.3, p=0.004; SBP: LSS AA+AC 120.3±0.5, CC 119.3±0.4, p=0.008). Furthermore, a Klotho (KL) missense genetic variant resulted strongly associated to 24h-urinary Na excretion (p=0.017, recessive model). The urinary proteomic study showed an augmented excretion of IL1 in both ADD1 T subjects and LSS C subjects, suggesting an increased inflammatory activity.

Conclusions: In this young Italian population we detected specific environmental factors (such as high salt intake) and gene polymorphisms linked to higher BP values. This help to create the basis for future interventions in educational, clinical and/or pharmacological studies

FR-PO1066

Persistence of Hypertension from 5-7 Years After Pediatric Cardiac Surgery

Jason H. Greenberg,[1] Michael Zappitelli,[2] Heather Thiessen Philbrook,[3] Yaqi Jia,[3] Prasad Devarajan,[4] Chirag R. Parikh.[3] TRIBE-AKI Consortium *[1]Yale University, Woodbridge, CT; [2]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; [3]Johns Hopkins University, Newton, MA; [4]Cincinnati Children's Hospital, Cincinnati, OH.*

Background: We have determined that children who require surgery for congenital heart disease (CHD) are at an increased risk for hypertension 5 years after cardiac surgery. The goal of this study is to assess the long-term risk of hypertension after cardiac surgery and if hypertension improves or is sustained.

Methods: We prospectively enrolled children from 1 month to 18 years old, undergoing cardiopulmonary bypass. Children who survived their surgical hospitalization had blood pressure measured at two in-person follow-up visits (median 5.4 years and 7.4 years after surgery). Elevated blood pressure and hypertension was defined using the American Academy of Pediatrics 2017 Hypertension guidelines. We compared the risk of hypertension status at the 5 and 7-year visits using the McNemar test.

Results: Of the 131 children with a follow-up visit 5 years after cardiac surgery, 88 (67%) children participated in the 7-year follow-up visit. Baseline characteristics were not significantly different between children that participated in both the 5 and 7-year visit vs those who only participated in the 5-year visit. The median age of the cohort at the 7-year follow-up was 10.6 [IQR: 7.6 – 15.2] years and 47% were female. 32 children had previously had a septal defect repair, 15 an inflow/outflow tract or valve procedure, 34 had a combined procedure, and 7 were not defined. Elevated BP was present in 16 (18%) and 13 (15%) children at the 5-year and 7-year visit, respectively. Hypertension was present in 13 (15%) and 15 (17%) children at the 5-year and 7-year visit, respectively, with no statistically significant change in risk at the two visits (p=0.56). Between the 5-year and 7-year visits, hypertension was sustained in 8 (62%) patients.

Conclusions: The long-term risk of elevated blood pressure and hypertension was common at both the 5 and 7-year visits and hypertension was sustained in the majority of children after cardiac surgery. The risk factors for sustained hypertension should be studied in children with congenital heart disease.

Funding: NIDDK Support

FR-PO1067

Hypertension as a Modifiable Risk Factor in Children with Immune Complex MPGN and C3 Glomerulopathy

Amrit Kirpalani,[1,3] Natasha Jawa,[1] Larry A. Greenbaum,[2] William E. Smoyer,[4] Christoph Licht.[1,3] *[1]Nephrology, The Hospital for Sick Children, Toronto, ON, Canada; [2]Emory University, Atlanta, GA; [3]University of Toronto, Toronto, ON, Canada; [4]Nationwide Children's Hospital, Columbus, OH.*

Background: Hypertension is a known complication of complement-mediated renal disease and carries prognostic significance. Hypertension is associated with reduced GFR in children with immune-complex membranoproliferative glomerulonephritis (IC-MPGN). Similarly, hypertension has been associated with poor renal function and

long-term outcome in patients with C3 glomerulopathy (C3G). This study explored the prevalence of hypertension in a IC-MPGN/C3G cohort.

Methods: Renal biopsy reports of 45 patients <18 years of age (originally diagnosed as MPGN between 2003 and 2012) across three centers were reviewed. Patients were re-classified as either IC-MPGN or C3G in 2019 based on consensus criteria. Demographic, clinical, and biochemical results were collected at enrollment and retrospectively at disease onset. Data were analyzed using Fisher's exact test. Hypertension was defined as blood pressure > 95th percentile for age, sex, and height.

Results: 19 of 45 (42%) of patients were diagnosed with hypertension at disease onset; only 2 of 19 (10%) resolved by the time of enrollment (mean 4 years later). 27 of 45 (60%) required antihypertensive medication at disease onset (mean 2.3 medications per patient); the same number (60%) required ongoing antihypertensive support at enrollment (mean 1.7 medications per patient). 9 of 27 (33%) required multiple antihypertensive medications. Baseline demographics, clinical and biochemical parameters, incidence of hypertension, and antihypertensive use were similar between C3G and IC-MPGN patients (P>0.05). Specifically, the use of angiotensin-converting enzyme inhibitors (86% vs. 76%, P=0.66) was the same in both groups, and though proteinuria improved significantly from disease onset to the time of study enrollment, hypertension continued to require treatment.

Conclusions: The incidence of hypertension in both pediatric C3G and IC-MPGN is similar to previously reported data. Interestingly, resolution of hypertension was low in this cohort (10%), and many patients (33%) required multiple antihypertensive medications. These data suggest that more aggressive hypertension management may be required and may potentially help to improve the long-term outcomes of children with C3G and IC-MPGN. The prognostic relevance of persistent hypertension in these diseases should be further studied.

FR-PO1068

Recategorization of Adolescent Hypertension (HTN) by Ambulatory Blood Pressure (ABPM) Using Adult Norms Compared with Pediatric Norms

Fallon Campbell, Shweta S. Shah, Poyyapakkam Srivaths, Alisa A. Acosta. *Texas Children's Hospital, Houston, TX.*

Background: 2017 guidelines for pediatric blood pressure (BP) applied adult BP norms to define clinic HTN in patients (pts) ≥ 13 yrs. The 2014 pediatric ABPM guidelines recommend age and sex specific percentile norms for pts < 18 yrs. Data applying adult ABPM norms to define ABPM HTN in adolescents is scarce. We aimed to evaluate the re-categorization of HTN by ABPM alone when applying adult ABPM norms in pts ≥ 13 yrs. We then assessed the association of left ventricular hypertrophy (LVH) with HTN.

Methods: Retrospectively, pts 13-17 yrs who wore an ABPM between 9/2018 and 5/2019 were reviewed to collect gender, age, BP med status, ABPM systolic and diastolic BP mean and load for 24hr, day, and night, and left ventricular mass index (LVMI). The ABPM adult norms applied were based on American Heart Association (AHA) 2005 (AHA2005), AHA 2017 (AHA2017), and European Society of Hypertension 2018 (ESH) guidelines and were compared to 2014 AHA pediatric norms (pABPM). HTN was defined according to the respective guidelines using only ABPM. LVH was defined as LVMI > 51 g/m$^{2.7}$.

Results: 357 pts (243 male) had ABPM data. 172 had LVMI data; 33 pts on BP meds with controlled HTN were excluded (final n=139). LVMI correlated significantly with systolic BP (24h, day, night mean and load) but not diastolic BP. All adult norms resulted in significant differences in the re-categorization of HTN (Table). The odds of a pt with HTN having LVH was significant only when defined by AHA2005 and ESH norms [OR 3.86 (1.55, 9.61), p=0.004 and OR 2.63 (1.05, 6.57), p=0.04 respectively].

Conclusions: There is significant difference in the categorization of HTN depending on the norms applied. HTN is significantly associated with LVH when AHA2005 and ESH norms are applied. Application of adult norms to define ABPM HTN in adolescents should take into account these differences with thoughtful evaluation of outcomes.

Categorization of HTN by adult norms (%)

		AHA2005		AHA2017		ESH	
		no HTN	HTN	no HTN	HTN	no HTN	HTN
pABPM	no HTN	44	2	31	15	43	3
	HTN	35	19	7	47	20	35
p by X^2		<0.001		<0.001		<0.001	

FR-PO1069

Relationship of Blood Pressure to Sleep in High School Students

Neena R. Gupta,[1] Rakesh Gupta.[2] *[1]UMass Memorial Children's Medical Center, Worcester, MA; [2]PrimaCARE Sleep Center, PrimaCARE, Somerset, MA.*

Background: Childhood hypertension is a risk factor for adult hypertension and target organ damage. Emerging data suggests a role of inadequate sleep in hypertension. In our previous study, newly diagnosed primary hypertensive children had less weekend catch up sleep than age and sex matched normotensives. The usual sleep pattern of adolescents shows less sleep on school days with catch up sleep on the weekends, but it is not known if blood pressure (BP) tracks the changes in sleep over the course of the week. The aim of this study is to compare the BP of high school students at the beginning of the week with that at the end of the week. We also studied the relationship of self-reported weekday and weekend sleep duration to the BP.

Methods: Students from a public high school (11 and 12th grade) were asked to participate. Interested students completed a questionnaire. BP, height and weight were measured on Monday and Thursday morning of the same week. Average of 3 consecutive BP was taken using automated Omron BP 786 monitor. Weekday and weekend total sleep time (WDTST and WETST) was estimated from the questionnaire responses for usual getting in and getting out of bed time. T-test and multivariate linear regression were used for analysis.

Results: Of the 32 students recruited, 24 were female. Systolic BP on Monday and Thursday was 114.8 ± 16.5 and 110.9 ± 13.1 mm Hg respectively. Diastolic BP on Monday and Thursday was 72.7 ± 7.4 and 70.9 ± 13.7 mm Hg respectively. BMI was 25.7 ± 5.5 Kg/M^2. WDTST was 418.6 ± 80.1 and WETST was 566.9 ± 132.3 minutes. Paired T-test showed no significant difference between SBP and DBP for Monday and Thursday. However, multiple regression analysis showed significant inverse relationship of SBP-Monday (adjusting for BMI) with WDTST (p= 0.016) and WETST (p=0.017). Similar results were seen for DBP-Monday (adjusting for BMI) with WDTST (p= 0.049) and WETST (p=0.038).

Conclusions: Our results show that shorter sleep time is associated with higher BP in high school students. Previous studies in children and adults have also shown higher BP in subjects with short sleep durations. Beneficial effect of sleep extension has also been observed in prior studies. In our subjects, weekend sleep duration was about 2.5 hours longer, but BP-Monday was not different from that on Thursday. Lack of information on Sunday night sleep time and a small sample size are main limitations.

FR-PO1070

Clinical Features of Pediatric Patients with Severe Hypertension (HTN) Requiring Infusions in the Pediatric Intensive Care Unit (PICU)

Yonique P. Petgrave,[1,2] Jennifer L. Morris,[2] Ayse Akcan Arikan,[1,2] Alisa A. Acosta.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: Data regarding PICU management of severe HTN, defined as receiving continuous antihypertensive infusions (antiHTN), are scarce. We aimed to describe the clinical characteristics of this population.

Methods: A medication order report from January 2017-July 2018 identified pts 2-22 years receiving antiHTN infusions in the PICU. Vasopressors 6 hrs prior to antiHTN, cardiac surgery, neurosurgery, or ECMO were reasons for exclusion. For comparison among age groups, we defined systolic and diastolic blood pressure index (sBPI,dBPI) as the ratio of absolute BP to the threshold for stage 2 HTN [95th percentile +12 mmHg for age, sex, and height (< 13 yrs) or 140/90 mmHg (≥ 13 yrs)] based on 2017 guidelines. Acute kidney injury (AKI) was defined by KDIGO guidelines. Left ventricular hypertrophy (LVH) was defined as left ventricular mass index (LVMI) > 51 g/m$^{2.7}$.

Results: All 78 pts (11.7 +/- 5.3 yrs, 56% male) had sBPI ≥ 1 and 85% had dBPI ≥ 1 at antiHTN initiation. Nicardipine was the most common antiHTN (90%). The most common symptoms (64.1%) were neurologic (headache, altered mental status, seizure); 22% were asymptomatic. Neuroimaging was performed in 49 pts of which 68% (33/49) were abnormal. 45% (35/78) had AKI. Only 21 pts had eye exams; 19% (4/21) had retinopathy. 68% (53/78) had echocardiograms of which 53% (28/53) had LVH. There was no association between LVH and sBPI (95% CI 0.7 to 565.3, p=0.08) or dBPI (95% CI 0.2 to 100.9, p=0.3). Pts with chronic HTN had a higher odds of having LVH (OR 3.98, 95% CI 1.1-15.0, p 0.04).

Conclusions: A significant number of children who present with severe HTN have evidence of end organ damage on assessment. Neurologic findings are most common and frequently accompanied by abnormal neuroimaging. LVH is common and more likely present in patients with chronic HTN.

Baseline Characteristics, reported as mean +/- SD or median (IQR)

BMI centile (%)	87.5 (40.6-98.4)
ICU LOS (days)	10.5 (5-27)
Length of antiHTN (hr)	57.7 (32.6-105.9)
eGFR at antiHTN start (ml/min/1.73m2)	84.5 (31.7-98.4)
LVMI2.7 (g/m)	52.1 +17.5
LV Mass (g/m2)	81.7 +31.3
sBPI	1.32 +0.17
dBPI	1.16 +0.19

FR-PO1071

Family History as a Risk Factor for Blood Pressure Control in Pediatric Hypertension

Laura Betcherman,[1,2] Jessica Fitzpatrick,[1] Natasha Jawa,[1] Mina Matsuda-Abedini,[1] Valerie Langlois,[1] Rulan S. Parekh.[1] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Faculty of Medicine, University of Toronto, Toronto, ON, Canada.*

Background: Hypertension (HTN) in adults is aa leading cause of death worldwide. Pediatirc HTN often persists into adulthood. We investigated whether a family history of HTN influences blood pressure (BP) control in hypertensive children.

Methods: A retrospective chart review was done on patients aged 0-18 at a HTN clinic between 2002-2014. HTN was defined as a systolic or diastolic BP greater than the 95th % for age and gender. Patients with chronic kidney disease and those without HTN were excluded. We included children with both primary and secondary HTN. Linear mixed effects regression models were used to compare BP z scores over time. Cox proportional hazards regression was used to assess time to achieve BP control, defined as a systolic and diastolic BP less than the 90th %. Models were adjusted for age, gender and presence of antihypertensive medications.

Results: 410 patients were included in the analysis. Mean age at diagnosis was 9.17 years and 268 (65%) were male. 233 (57%) had a positive family history of HTN. There was no significant difference in systolic BP Z scores over time between the two groups

(*p>0.5*). Diastolic Z scores were significantly lower in those with family history compared to those without (*p<0.01*) [Figure]. There was no significant difference in achieving BP control between both groups (*p>0.5*).

Conclusions: There was a known family history of HTN in over 50% of children with HTN. Family history did not significantly affect longitudinal BP control nor the time it took to achieve good BP control. Future research should be directed at evaluating short and long-term outcomes in these children.

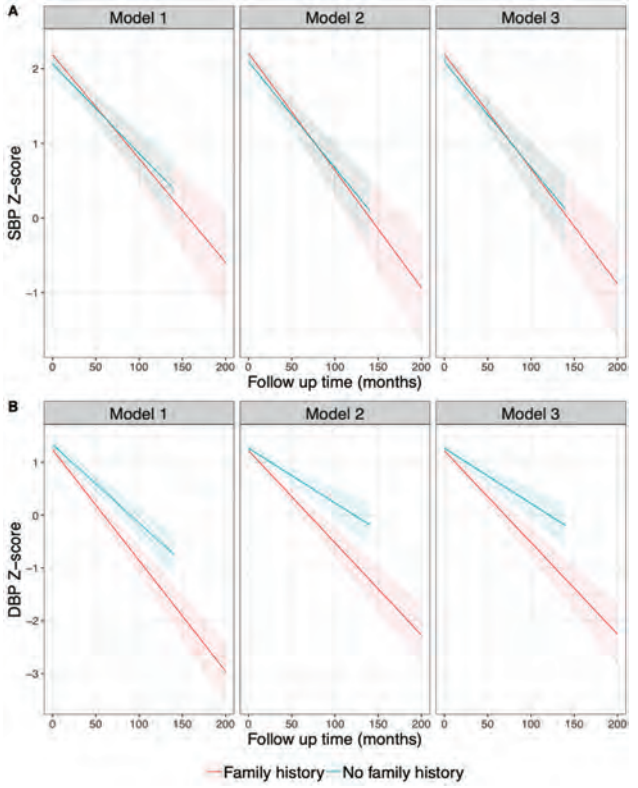

Figure 1 SBP and DBP z-scores over time. Model 1 unadjusted; Model 2 adjusted for age and gender; Model 3 adjusted for age, gender, number of antihypertensives

FR-PO1072

Abnormal Blood Pressure Patterns on Ambulatory Blood Pressure Monitoring Prior to Pediatric Hematopoietic Cell Transplantation (HCT): False Alarm or Cause for Concern?

Yonique P. Petgrave,[1] Ivory L. White,[1] Tami John,[2] Poyyapakkam Srivaths,[2] Joseph R. Angelo.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: Hypertension (HTN) influences morbidity and predicts renal and cardiovascular (CV) outcomes following HCT. Systematic misclassification of HTN may occur with the use of casual blood pressure (BP) measurements; therefore, ambulatory blood pressure monitoring (ABPM) is recommended in children and adolescents with high-risk conditions. Diagnosis of HTN by ABPM strongly correlates with risk of target organ damage. We conducted a pilot prospective observational study using ABPM to determine BP risk profile of patients (pts) undergoing first allogeneic HCT.

Methods: Pts age 5-21 yrs at Texas Children's Hospital were recruited prior to HCT from November 2018 to May 2019. Of 22 pts recruited, 16 had APBMs placed and 14 were adequate for analysis.

Results: Mean age was 14.3 yrs (6.7-19), 7 pts were male. Mean baseline GFR was 113 ml/min/1.73m2, (SD 19.1) mean baseline LVMI [2.7] was 42.4 g/m (SD 7.8) and spot urine protein/creatinine ratio (UPC) was 0.3 (SD 0.28). Two pts had severe ambulatory HTN based on elevated daytime, nighttime, and 24hr mean recordings and elevated BP load in all categories. Of the 12 remaining pts, 25% had elevated nighttime load, and 33% had attenuated nocturnal dipping despite normal office BP and normal average BP. There was no association with baseline LVMI[2.7] or UPC for pts with HTN by casual BP or ABPM, elevated daytime/nocturnal load, or attenuated dipping when univariate analysis was performed.

Conclusions: Elevated BP load and abnormal nocturnal dipping were seen in our pts prior to HCT despite normal mean ABPM and office BP. According to the 2017 guidelines for pediatric HTN, this group is termed 'unclassified', but may have increased risk for end organ effects and may require closer supervision. Screening with APBM can be beneficial in this high risk population.

ABPM Results

Prior HTN	Yes 2 (14.3) No 12 (85.7)
Office BP	N 10 (71.4) Ab 4 (28.6)

Adverse Childhood Experiences in Adolescents with Hypertension in an Inner-City Population in the Bronx, New York

Kaye E. Brathwaite,[1] Roberto A. Valdovinos,[2,5] Tamar Rubinstein,[3] Kimberly J. Reidy.[4] *[1]Montefiore Medical Center, Bronx, NY; [2]Children's Hospital of Philadelphia, Philadelphia, PA; [3]Children's Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY; [4]Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronxville, NY; [5]Albert Einstein College of Medicine, Bronx, NY.*

Background: Adverse Childhood Experiences (ACEs) are associated with hypertension (HTN) and increased risk of cardiovascular (CV) disease in adults, however less is known of risk factors in adolescence. The prevalence of HTN in adolescents is 3.5% and leads to increased CV risk in adulthood. We hypothesized: ACEs in adolescents are associated with increased CV risk factors, particularly HTN and end organ damage.

Methods: ACE survey was administered in both general pediatric and subspecialty clinics including 10 questions [max score 10 ACEs]. A retrospective study was used to assess whether ACE scores are associated with uncontrolled HTN and left ventricular hypertrophy (LVH) in adolescents. Using Clinical Looking Glass (a software to extract information from the electronic health record), data on ACE screenings at Montefiore Medical Center, latest blood pressures (BP) and echocardiograms were obtained. Adolescents ages >/=13 or <25 years old with a ICD10 diagnosis of HTN and a recorded ACE score were included. BP control was assessed with BP cutoff of 130/80mmHg and end organ damage was based on presence of LVH on echocardiograms.

Results: In 302 hypertensive patients, 38.7% were female and 61.3% male. 40.4% were African American, 10.9% Caucasian, 1.7% Asian, and 36.4% other/unknown race; 39.7% were Spanish/Hispanic/Latino. The median ACE score was 0 [IQR 0-1] adverse experiences. At least one ACE was reported in 44.4% of children and 20.8% had 2 or more ACEs. There was no difference in the age of completion of the ACE screen (16.6 ± 2.5 years with-ACE & 15.95 ± 2.3 years without-ACE), or in the average BP (128/76mmHg ± 13.6/8.8 with-ACE & 126/76mmHg ± 12.4/8.1 without-ACE). Using a cutoff of 130/80mmHg there was a trend toward worse BP control with ACE exposure: Uncontrolled BP was noted in 53% with an ACE vs. 43% without an ACE (p=0.09). Echocardiograms were present in 35.8% of patients and there was no difference in LVH (4.3% with-ACE and 4.8% without-ACE).

Conclusions: 20.8% of adolescents with HTN in the Bronx report an ACE score of 2 or more, comparable to national data. Our findings suggest that BP control may be worse with ACEs present, however the data was limited by a small sample size. Additional study is needed to assess the impact of ACEs and resilience factors on BP control and end-organ damage in adolescents with HTN.

FR-PO1074

Immune Cell Profiles in Children with Essential Hypertension (EH)

Howard Trachtman,[1] Laura Jane Pehrson,[2] Laura Malaga-Dieguez,[2] Jason M. Alexandre,[1] Pratip K. Chattopadhyay.[1] *[1]NYU Langone Health, New York, NY; [2]New York University School of Medicine, New York, NY.*

Background: There is growing evidence that sodium is stored in a non-osmotic form in the interstitial compartment of skin and muscle. In these sites, sodium may contribute to the development of EH by altering the immune system. These effects may be reflected in peripheral blood (PB). We tested PB of children with EH to examine the diversity of immunophenotypes, and to test whether disease treatment changed circulating cells. We deployed high parameter flow cytometry, which allowed detailed characterization of T-cell subsets.

Methods: Eight pediatric patients with EH were enrolled. PB was collected at baseline for all patients, and after 4 and 16 weeks of anti-hypertensive treatment for 3 patients. We designed a 24-parameter flow cytometry panel to enumerate various T-cell subsets, including naïve, memory, dividing, exhausted, regulatory, and suppressive cells. We analyzed data using t-sne, a dimension reduction algorithm that provides a broad overview of the landscape of T-cell immunophenotypes, and applied bivariate difference gating to identify the cell populations uniquely altered with treatment.

Results: At baseline, 7 of 8 patients showed the expected diversity in T-cells subsets. There were dominant populations that differed by patient, suggesting heterogeneity that might be linked to clinical outcome. The 8th patient had a striking polarization in T-cell phenotype at baseline, with two major subpopulations and very few other cells. Her "skewed" T-cell landscape resolved with treatment, and we could precisely identify the cells lost. Cells were uniformly CD4+CD45RA+CD127+CD25-CD38+CCR4-Ki67-LAG3+CTLA4-CD39-IDO-HELIOS-FoxP3-CXCR3-GITR+. This phenotype represents

a class of naïve, non-classical regulatory (i.e., suppressive) T-cells. Subsets also expressed other suppressive markers like LAP, GARP, and CD73. Interestingly, the other two patients also showed loss of cells expressing LAG3, CD73, LAP, and/or GARP with treatment.

Conclusions: Children with EH have heterogeneous regulatory T-cell subsets. Successful control of blood pressure with anti-hypertensive drugs re-shapes the T-cell landscape in PB, reducing the number of suppressive T-cells. Our approach – to precisely identify specific cell types altered with disease – is well-suited to identifying biomarkers, and can provide detailed mechanistic information that informs treatment approaches.

An Evaluation of Renin-Angiotensin System Markers in Youth with Type 2 Diabetes and Associations with Renal Outcomes

Allison Dart,[1,3] Brandy Wicklow,[2,3] James W. Scholey,[4,3] Elizabeth A. Sellers,[2] Farid H. Mahmud,[5,3] Etienne B. Sochett,[6,3] Jill Hamilton,[9] Tom D. Blydt-Hansen,[7] Kevin D. Burns.[8,3] Diabetes Research Envisioned and Accomplished in Manitoba (DREAM) *[1]Pediatrics and Child Health, University of Manitoba, Winnipeg, MB, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]Can-SOLVE network, Vancouver, BC, Canada; [4]University of Toronto, Toronto, ON, Canada; [5]Hospital for Sick Children, Toronto, ON, Canada; [6]Hospital for Sick Children, Toronto, Toronto, ON, Canada; [7]University of British Columbia, Vancouver, BC, Canada; [8]The Ottawa Hospital - Riverside Campus, Ottawa, ON, Canada; [9]Hospital for Sick children, Toronto, ON, Canada.*

Background: Activation of the renin-angiotensin system (RAS) is associated with diabetic kidney disease in adults, and may also have prognostic significance in youth. We evaluated serum and urine RAS markers in youth with T2D and associations with albuminuria status, glycemic control, eGFR and blood pressure.

Methods: This is a cross sectional analysis of 183 youth with T2D and 100 controls from the iCARE cohort. Youth further stratified by albuminuria status (ACR < or ≥2mg/mmol (Alb)) and ACEi/ARB excluded. RAS levels measured with ELISA and enzyme activities measured by synthetic substrates. Differences in levels between groups were evaluated. For T2D group, levels log transformed and Tobit regressions evaluated for associations with ACR, HbA1c, eGFR and 24 BP loads (correcting for age, sex, BMIz-score and duration of diabetes).

Results: Mean age 14.7 yrs, duration of diabetes 1.7 years and 21.3% with Alb. Serum PRA (p=0.0006), aldosterone (p=0.004) and sACE activity (p=0.005) were higher in T2D than controls (C). uACE (0.1 (C), 1.2 (T2D) and 2.0 (Alb) ng/mgCr; p<0.001) and uACE2 activity (6.0 (C), 160.8 (T2D), 505.2 (Alb) ng/mgCr; p<0.001) also increased. In mulitvariable regressions, higher aldosterone (p=0.02), urinary AGT (p<0.0001), and ACE2 activity (p=0.009) associated with albuminuria. Higher AGT and urinary ACE2 protein and activity associated with higher HbA1c. No associations seen between RAS marker and eGFR or BP loads.

Conclusions: RAS activation is present in youth with T2D. The prognostic and therapeutic significance of the combined effect of glycemia and RAS activation on renal outcomes requires additional investigation.

Improving Recognition and Reporting of AKI in the Neonatal Intensive Care Unit

Michelle C. Starr,[2,1] Alexander J. Kula,[1] Joshua Lieberman,[3] Teresa Lam,[4] Shilpi Chabra,[4] Sangeeta R. Hingorani.[1] *[1]Seattle Children's Hospital, Seattle, WA; [2]Department of Pediatrics, Division of Pediatric Nephrology, Indiana University School of Medicine, Indinapolis, IN; [3]University of Washington Medical Center, Seattle, WA; [4]University of Washington, Seattle, WA.*

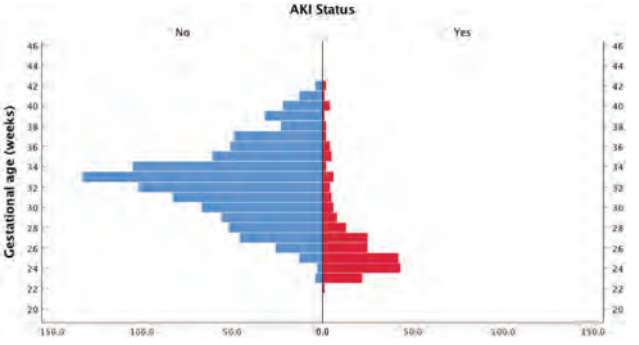
Background: Neonatal AKI leads to increased short and long-term morbidity and mortality. Recognition of AKI is essential as monitoring can lead to earlier detection of kidney dysfunction, particularly in neonates who are at high risk of CKD. This study determined prevalence of AKI among infants admitted to a NICU, and evaluated the frequency of AKI recognition/reporting over time.

Methods: Records of all infants admitted to a level 3 neonatal intensive care unit from 2012 to 2017 were reviewed. During this time period, several interventions were instituted including AKI education, a dedicated AKI followup clinic, and NICU nephrology rounds. AKI was classified using the Kidney Disease: Improving Global Outcomes definition modified to include only serum creatinine. Continuous variables were compared using t-test, and categorical variables with chi-square or Fisher exact test.

Results: AKI occurred in 19.1% of 1168 infants. AKI varied by gestational age, occurring in 171 (54.3%) of 315 of patients born at 22 weeks to <29 weeks, 36 (5.6%) of 643 patients born from 29 weeks to <36 weeks, and 16 (7.6%) of 210 patients born at 36 weeks or older (Figure 1). Infants with AKI were more likely to die than those without AKI (p<0.001). While AKI was recorded in the discharge summary for only 17.0% of AKI survivors, recognition improved during this study (p=0.03). No infants were referred to a nephrologist for AKI follow-up.

Conclusions: AKI occurred in 1 in 5 NICU patients and in over half of the most premature infants. While AKI was rarely noted in the discharge summary, recognition improved during this study. This may be in part due to dedicated AKI follow-up clinics, AKI specific education, and multidisciplinary rounding which began during this study. Nephrology AKI followup did not occur, highlighting areas for ongoing improvement.

Funding: NIDDK Support



AKI occurance by gestational age among infants; 77% of infants who experenced AKI were born at <29 weeks gestationa age; whereas 85% of infants who did not experience AKI were born at ≥29 weeks

FR-PO1077

Association of Pediatric Cardiac Surgery-Associated AKI with 1- and 5-Year Healthcare Utilization and Kidney Outcomes

Sophia Nunes,[4] Erin Hessey,[1] Marc Dorais,[2] Michael Zappitelli.[3] *[1]University of Alberta Faculty of Medicine, Montreal, AB, Canada; [2]StatSciences Inc., Notre-Dame-de-l'Île-Perrot, QC, Canada; [3]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; [4]Toronto Hospital for Sick Children, Toronto, ON, Canada.*

Background: AKI in children undergoing cardiac surgery (CS) is strongly associated with hospital morbidity. Post-discharge CS AKI outcomes are less clear. Hypotheses: Pediatric CS AKI is associated with a) increased hospitalizations, emergency room (ER) visits and physician visits within 1 and 5 yrs post-discharge and b) increased risk for chronic kidney disease (CKD), hypertension (HTN) or death within 5 yrs post-discharge.

Methods: Retrospective 2-centre cohort study (children surviving to hospital discharge after CS, 2003-2005). Exposure: post-CS AKI (KDIGO serum creatinine and urine output definition). Outcomes: Number of hospitalizations, ER visits, and physician visits within 1 and 5 yrs of CS discharge; composite of CKD, HTN or death within 5 yrs of discharge. Multivariable Poisson regression: evaluate association of AKI with health care utilization; multivariable Cox-proportional hazards analysis: evaluate association of AKI with composite patient outcomes. Models adjusted for age and RACHS-1 score (surgical severity) ≥3.

Results: N=350 (age 3.1 ± 4.5 years; 180 [49%] AKI; 60 [17%] ≥Stage 2 AKI). See Table for detailed results: In adjusted analyses, AKI was associated with increased risk for 1-yr physician visits and 5-yr hospitalizations, ER visits and physician visits. 12.03% and 11.54% of AKI *vs.* non-AKI developed the composite patient outcome within 5 yrs of discharge. In adjusted analyses, AKI was not associated with CKD, HTN or death by 5 yrs post-discharge (Table).

Conclusions: Post-CS AKI is associated with higher 5-yr healthcare utilization, but not the composite outcome of CKD, HTN or death. Studies should aim to better understand post-CS surgery healthcare utilization patterns and non-AKI risk factors for CKD and HTN, to develop cost-effective strategies to reduce long-term CKD and HTN after CS.

Funding: Government Support - Non-U.S.

Table. Association of post-cardiac surgery AKI with risk for A) hospitalizations, emergency room (ER) visits and physician visits and B) chronic kidney disease (CKD), hypertension (HTN) or death within 1 and 5 years after hospital discharge.

Outcome	1-yr post-discharge	5-yrs post-discharge
A) Healthcare utilization outcomes		
Stage 1 or worse AKI (*vs.* no AKI) association with outcomes Poisson regression-derived adjusted Relative Risk (aRR, 95% CI), adjusted for age and RACHS-1≥3		
Hospitalizations	1.16 [95% CI 0.93 - 1.44]	**1.17 [95% CI 1.01 - 1.35]**
ER visits	0.98 [95% CI 0.82 - 1.16]	**1.14 [95% CI 1.03 - 1.26]**
Physician visits	**1.13 [95% CI 1.06 - 1.20]**	**1.09 [95% CI 1.05 - 1.13]**
Stage 2 or worse AKI (*vs.* no AKI or Stage 1) association with outcomes Poisson regression-derived adjusted Relative Risk (aRR, 95% CI), adjusted for age and RACHS-1≥3		
Hospitalizations	1.04 [95% CI 0.80 - 1.35]	**1.12 [95%CI 0.95 - 1.33]**
ER visits	1.06 [95% CI 0.85 - 1.32]	**1.13 [95% CI 1.01 - 1.27]**

Point-of-Care Urinary Neutrophil Gelatinase-Associated Lipocalin Readings Are Highly Predictive of Formal Laboratory Levels

Hailey E. Woollen, Kelli A. Krallman, Stuart Goldstein. *Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Since the discovery and validation of urinary neutrophil gelatinase-associated lipocalin (NGAL) as an early, non-invasive marker of kidney injury, clinicians are able to more rapidly, and reliably, predict the development of acute kidney injury (AKI.) Urinary NGAL has been validated on various clinical lab platforms, but has yet to be assessed using point of care (POC) techniques. A reliable POC urinary NGAL test would offer a rapid and inexpensive screening test for AKI that could be clinically valuable in both inpatient and outpatient settings.

Methods: Hospitalized patients from 2 different pediatric hospitals who were exposed to 3 or more nephrotoxic medications simultaneously or 3 or more consecutive days of either IV vancomycin or an IV aminoglycoside had a daily urine collection for 7 consecutive days. Discrete laboratory urinary NGAL results were obtained using The NGAL Test™ (Bioporto, Denmark) and stratified corresponding to a colorimetric NGAL test (Bioporto) with ranges of: 25ng/mL, 50ng/mL, 100ng/mL, 150ng/mL, 300ng/mL and 600ng/mL. Different urinary NGAL cutoffs were then used to determine sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV), with the laboratory NGAL Test™ serving as the reference standard.

Results: In total, 86 individual patients (55% male, median age 13.2 years, range 4 months to 34 years) had 521 paired laboratory and POC urinary NGAL assessment. Of the 521 urine samples, 94 were analyzed using fresh urine and 427 using frozen urine samples. The POC performance data are depicted in the table.

Conclusions: A POC urinary NGAL assessment of <300ng/mL was highly predictive of an NGAL Test™ value <300ng/mL. We suggest this colorimetric POC assay is useful as a surrogate to the laboratory NGAL Test™ and to rule out risk for AKI. Patients with a POC test >300 ng/ml should have a confirmatory NGAL Test™ assessed.

Results

NGAL Test™ threshold	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value
<50ng/mL	93.90% (89.01-97.04%)	66.11% (60.94-71.01%)	56.00% (52.28-59.66%)	95.93% (92.8-97.74%)
<150ng/mL	97.14% (85.08-99.93%)	81.48% (77.74-84.84%)	27.42% (23.71-31.46%)	99.75% (98.29-99.96%)
<300ng/mL	100.00% (85.75-100%)	89.34% (86.28-91.91%)	31.17% (25.99-36.87%)	100.00%

Cell Cycle Arrest Biomarkers and Kidney Injury Molecule 1 (KIM-1) in Pediatric Aminoglycoside-Induced AKI

Hayton Chui,[1] Vedran Cockovski,[1] Prasad Devarajan,[2] Stuart Goldstein,[2] Qing Ma,[2] Michael Zappitelli.[1,3] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]University of Toronto, Toronto, ON, Canada.*

Background: AKI is common in children treated with aminoglycosides (AG). We evaluated urine KIM1 and cell cycle arrest biomarkers (tissue inhibitor of metalloproteinase 2 [TIMP2]; insulin-like growth factor-binding protein 7 [IGFBP7]) for AG-AKI diagnosis.

Methods: Nested-case control study from a prospective 2-center (Montreal, Cincinnati) cohort (non-critically ill children starting AG's; 3 months-18 years old; no known kidney condition; AG treatment ≥3 days; recruited within 48 hours of AG start; ≥1 SCr's/5 AG days). Urine was collected daily, measured for KIM1 (pg/ml), TIMP2 (ng/ml) and IGFBP7 (ng/ml) (expressed as TIMP2*IGFBP7). AKI: KDIGO SCr definition. Non-AKI *vs.* AKI biomarkers were compared on a) AG treatment day 2 and 3, and b) 3, 2 and 1 day before and the day of AKI onset (Mann-Whitney). Area under the receiver operating characteristic curve (AUC, 95% CI) to detect AKI was calculated.

Results: 104 AG episodes (48% male, age 8.0 ± 4.9 years; AG treatment days 8.1 ± 7.7); 41% developed AKI. *Results in Table*: KIM1 ~3-fold higher in AKI *vs.* non-AKI, on day of AKI onset (AUC 0.87 [0.72-1.00]); no statistically significant AKI association on other days. TIMP2*IGFBP7 ~6-fold higher in AKI *vs.* non-AKI on AG treatment day 2 (AUC 0.72 [0.57-0.87]); on day of AKI onset (AUC 0.75 [0.54-0.97]) to detect AKI. *Results not in Table*: KIM1 combined with TIMP2*IGFBP7 on the day of AKI onset detected AKI with AUC 0.90 (0.78 – 1.00, p<0.05).

Conclusions: KIM1 and TIMP2*IGFBP7 are diagnostic of AG-AKI only the day of AKI onset. Future research should validate our findings and investigate these biomarkers to predict AKI severity and recovery.

Cell Cycle Arrest Biomarkers to Diagnose Pediatric AKI due to Cisplatin

Hayton Chui,[1] Kelly McMahon,[2] Mariya Yordanova,[8] Louis Huynh,[3] Frédérik Crépeau-Hubert,[9] Jasmine Lee,[1] Tom D. Blydt-Hansen,[4] Maury N. Pinsk,[5] Cherry Mammen,[7] Shahrad R. Rassekh,[7] Kirk R. Schultz,[7] Prasad Devarajan,[6] Qing Ma,[6] Michael Zappitelli.[1] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Research Institute, McGill University Health Centre, Montreal, QC, Canada; [3]Queen's University School of Medicine, Kingston, ON, Canada; [4]University of British Columbia, Vancouver, BC, Canada; [5]University of Manitoba, Winnipeg, MB, Canada; [6]Cincinnati Children's Hospital, Cincinnati, OH; [7]British Columbia Children's Hospital, Vancouver, BC, Canada; [8]Montreal Children's Hospital, Montreal, QC, Canada; [9]McGill University, Montreal, QC, Canada.*

Background: Cisplatin (CisP) causes AKI and electrolyte abnormalities. Urine tissue inhibitor of metalloproteinase 2 (TIMP2) and insulin-like growth factor-binding protein 7 (IGFBP7) may be early AKI biomarkers.

Methods: 12-site, prospective cohort study of children treated for cancer with >=1 CisP cycle. Excluded: >18 years, kidney transplant, GFR<30ml/min/1.73m². Blood and urine collected at pre and 24-hrs post CisP during 1st or 2nd CisP cycle (Early Visit [EV]) and during 2nd to last or last CisP cycle (Late Visit[LV]). Urine measured for TIMP2(ng/ml), IGFBP7(ng/ml) (expressed as TIMP2*IGFBP7). AKI Outcomes: 1) **KDIGO SCr** definition; 2) Combined KDIGO SCr and electrolyte abnormality-based definition (from National Cancer Institute [NCI] criteria) - **KDIGO+NCI**. AKI *vs.* non-AKI TIMP2*IGFBP7 were compared pre and post CisP (Mann Whitney); within-subject pre *vs.* post CisP were compared (Wilcoxon signed-rank). Area under the curve (AUC, 95% CI) to detect AKI was calculated. Clinical model comparison for AKI prediction: neuroblastoma (yes/no) + age<3 years; assessed added benefit of TIMP2*IGFBP7 to increase AUC (DeLong).

Results: n=159, median [IQR] age 5.4 [9.4] years, 50% male. KDIGO AKI: EV 30%; LV 16%. KDIGO+NCI AKI: EV 20%; LV 11%. Table: AKI *vs.* non-AKI: EV Pre TIMP2*IGFBP7 is 5-7 fold lower in AKI, p<0.05; LV Post TIMP2*IGFBP7 is 4-6 fold higher in AKI, p<0.05. Non-AKI pre *vs.* post: TIMP2*IGFBP7 drops after CisP, p<0.05. Highest AUC: LV post (0.70-0.73). Clinical model: AUC 0.70 (0.58-0.81); addition of TIMP2*IGFBP7 increased LV Post AUC (0.77 [0.66-0.87]), p<0.05.

Conclusions: TIMP2*IGFBP7 is a modest predictor of CisP-AKI. Drop in TIMP2*IGFBP7 might be protective of CisP induced injury, but results must be validated in another cohort.

Outpatient Follow-Up After AKI in the Pediatric Intensive Care Unit (PICU)

Cal Robinson,[2] Erin Hessey,[3] Sophia Nunes,[1] Marc Dorais,[4] Rahul Chanchlani,[2] Michael Zappitelli.[1] *[1]Pediatric Nephrology, The Hospital for Sick Children, Toronto, ON, Canada; [2]Pediatric Nephrology, McMaster Children's Hospital, Hamilton, ON, Canada; [3]University of Alberta Faculty of Medicine, Montreal, AB, Canada; [4]StatSciences Inc., Montreal, QC, Canada.*

Background: Although KDIGO AKI guidelines recommend re-evaluation at 3 months, few studies have characterized pediatric AKI follow-up. This information is needed to target knowledge translation to enhance post-AKI care. Aims: 1) Describe outpatient follow-up of children with PICU-AKI; 2) Determine factors associated with nephrology follow-up in AKI patients.

Methods: Two-center retrospective cohort study (PICU admissions ≥2 days from 2003-2005; children 0-18 years old surviving hospitalization; non-cardiac surgery; no baseline kidney disease). Provincial administrative databases used to determine outcomes (until 2010). Exposure: AKI (KDIGO serum creatinine and urine output definition). Primary outcome: outpatient nephrology (Neph) visit by 1 yr post-discharge. Secondary outcomes: a) family physician (FP) or pediatrician (Ped), b) FP, Ped or non-Neph specialist (Spec) visits. Univariable analyses used to compare outcomes by AKI stage and evaluate patient factors associated with 1-yr Neph follow-up.

Results: Of n=2041, 355 (17%) had AKI: 64/355 (18%), 198 (56%) and 338 (95%) had Neph, FP or Ped and FP, Ped or Spec follow-up by 1 yr post-discharge. Figure: Children with AKI were more likely to have Neph follow-up (p<0.0001). There was no AKI *vs.* non-AKI difference in follow-up for other physicians (p>0.05). 44/142 (31%) stage 2-3 AKI patients had Neph follow-up by 1 yr. Factors associated with 1-yr Neph follow-up in AKI patients were: longer hospital stay; AKI stage 2-3; dialysis receipt; discharge SCr >1.5x baseline (all p<0.0001).

Conclusions: Children with PICU-AKI are more likely to receive Neph follow-up, though follow-up is suboptimal for severe AKI. Non-Neph physician follow-up is very high, suggesting AKI follow-up knowledge translation strategies for non-Neph providers should be a priority.

Efficacy of Rasburicase in Children with AKI from Diarrhea-Associated Hemolytic Uremic Syndrome

Yo Han Ahn,[1] Myung hyun Cho,[2] Jiwon M. Lee,[3] IL-Soo Ha,[2] Hae Il Cheong,[2] Hee Gyung Kang.[2] *[1]Department of Pediatrics, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [3]Department of Pediatrics, Chungnam National University Children's Hospital, Daejeon, Republic of Korea.*

Background: Diarrhea associated hemolytic uremic syndrome (D+HUS) is a common etiology of acute kidney injury (AKI) in children. Hyperuricemia during acute phase is a typical finding of D+HUS. Recently we have used rasburicase to manage hyperuricemia, thereby ameliorate AKI and accelerate their recovery. Here we assessed the efficacy of rasburicase in D+HUS.

Methods: We retrospectively analyzed the medical records of pediatric D+HUS patients who were admitted to Seoul National University Children's Hospital between January 2001 and July 2017. We compared the clinical outcomes between those treated with rasburicase (rasburicase group) and the rest (control group).

Results: A total of 72 patients were analyzed. Their median age was 3.2 years old. Median values of the lowest hemoglobin, the lowest platelet, and the highest uric acid were 6.3g/dL, 24,000/uL, and 12.6mg/dL, respectively. Twelve (16.7%) were treated with rasburicase. It was administered once at a median dose of 0.10 (range 0.05–0.20) mg/kg during the first day of admission. There was no difference in age, sex, the lowest hemoglobin, the lowest estimated glomerular filtration rate (eGFR), and the highest uric acid between the rasburicase group and the control group. The lowest platelet in rasburicase group was lower than that in the control group (14,000 vs. 25,000/uL; *P*=0.002). In the rasburicase group, hyperuricemia was rapidly reversed (2.4 vs. 6.5 days; *P*<0.001). There was no statistical difference in requirement of dialysis (66.7% vs. 55.0%; *P*= 0.456) and the duration of dialysis (5.5 vs. 8.6 days; *P*=0.262) between the two groups. However, median hospital length of stay was shorter in the rasburicase group than in the control group (12.9 vs. 18.2 days; *P*=0.043), and median eGFR at 1 year follow up was lower in the control group than in the rasburicase group (81.2 vs. 111.0 mL/min/1.73m², *P*=0.002).

Conclusions: Although rasburicase treatment in patients with D+HUS did not lower the requirement of dialysis, patients who were treated with rasburicase during the acute phase were discharged earlier from the hospital and had better renal function at 1 year follow-up. Since there are no known effective therapies for AKI induced by D+HUS, we may consider rasburicase to improve their long-term renal outcome.

FR-PO1083

HIP/PAP and BD-1 Indicate Successful Surgical Intervention in Pediatric Patients with Ureteropelvic Junction Obstruction

Sudipti Gupta,[2,1] Lauren Nicassio,[2] Guillermo J. Yepes,[2] Ashley R. Jackson,[2,1] Daryl J. Mcleod,[2] Brian Becknell,[2,1] Christina B. Ching.[2,1] *[1]Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH.*

Background: We have previously found a panel of antimicrobial peptides (AMPs) to be significantly elevated in ureteropelvic junction obstruction (UPJO). We sought to see if these same AMPs decreased after surgical correction of UPJO to further test their ability to identify obstruction.

Methods: Bladder urine was collected from pediatric patients (≤18 years old) immediately prior to surgical correction of an UPJO and then at least 6 months after surgery according to an IRB-approved protocol. Patients were included only if they did not have signs of active urinary tract infection at time of collection. Based on a prior study demonstrating that the AMPs beta defensin 1 (BD-1), hepatocarcinoma-intestine-pancreas/pancreatitis-associated protein (HIP/PAP), LL-37, and neutrophil gelatinase-associated lipocalin (NGAL) were significantly elevated in patients with UPJO as compared to patients without, we performed enzyme-linked immunosorbent assays on these four AMPs to compare their expression before and after surgical intervention. AMP levels were normalized to urine creatinine. Results were analyzed with paired t test or Wilcoxon test using Graphpad software. A p-value of <0.05 was considered significant.

Results: Follow-up samples were obtained a median of 27.4 months (average 27.4; range 7.8-45.3 months) after surgery and removal of all drainage tubes on 13 patients on whom we also had urine samples collected immediately prior to pyeloplasty for their UPJO. Nine of the patients were male. Their age at urine collection at time of surgery was a median of 4.3 years (average 6.1; range 0.4-18.4 years). All 13 patients showed clinical improvement from before surgery and/or signs of improved hydronephrosis on post-operative imaging. We found that HIP/PAP and BD-1 were significantly decreased in post-surgical samples compared to pre-surgical samples (p=0.0215 and 0.0052, respectively); NGAL and LL-37 did not significantly change. The sensitivity/specificity of HIP/PAP to show correction of an obstruction was 77% and 85%, respectively, while for BD-1 it was 75% and 67%, respectively.

Conclusions: HIP/PAP and BD-1 are significantly elevated in upper urinary tract obstruction and significantly decrease with correction. These AMPs could serve as markers of successful surgical intervention.

FR-PO1085

Associations of Plasma Neutrophil Gelatinase-Associated Lipocalin, Anemia, and Renal Scarring in Children with Febrile Urinary Tract Infections

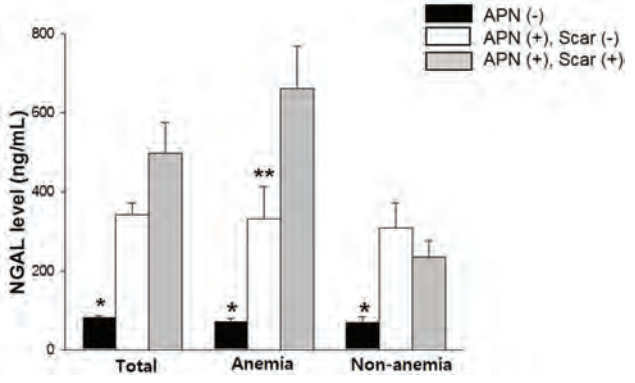
Hyung Eun Yim, Kee Hwan Yoo. *Pediatrics, Korea University, Ansan-Si, Republic of Korea.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL), a bacteriostatic agent, is known to inhibit erythropoiesis leading to anemia. We aimed to investigate the relationships of NGAL, anemia, and renal scarring in children with febrile urinary tract infections (UTIs).

Methods: We retrospectively reviewed the medical records of 261 children with first febrile UTIs. The associations between plasma NGAL levels and indices of anemia were studied. NGAL performance in comparison with serum C-reactive protein (CRP) at admission and after 72 hours of antibiotic treatment was also evaluated for the prediction of renal scarring.

Results: Plasma NGAL levels were considerably elevated in patients with anemia compared with those without anemia ($P < 0.001$). NGAL concentrations were inversely correlated with levels of hemoglobin and hematocrit and red blood cell count (all $P < 0.001$). Increased NGAL, but not CRP, was independently associated with the presence of anemia in a multivariable logistic analysis [OR 2.37 (95% CI 1.07-5.27), $P < 0.05$]. Receiver operating curve analyses showed good diagnostic profiles of NGAL at admission and after treatment for identifying renal scarring (all $P < 0.05$). Plasma NGAL after treatment showed a higher area under the curve (AUC) (0.730; 95% CI 0.591–0.843) than that of CRP after treatment (AUC 0.520; 95% CI 0.395–0.643) ($P < 0.05$). In a multivariable analysis, elevated plasma NGAL level at admission and the presence of anemia were independently associated with the presence of renal scarring in children with febrile UTIs (all $P < 0.05$). In the presence of anemia, NGAL concentration increased consecutively in febrile UTI, APN, and renal scar ($P < 0.05$).

Conclusions: Increased plasma NGAL levels may be associated with the presence of anemia and renal scarring in children with febrile UTIs.



Plasma NGAL levels at admission in febrile UTI, APN, and renal scar (*$P < 0.05$, febrile UTI vs. APN & scar, **$P < 0.05$, APN vs. renal scar)

FR-PO1086

Long-Term Renal Outcomes in Children with AKI Post Cardiac Surgery

Yeshwanter Radhakrishnan,[1] Rupesh Raina,[2] Sidharth K. Sethi.[3] *[1]Cleveland Clinic Akron General, Akron, OH; [2]Nephrology, Cleveland Clinic Akron General, Akron, OH; [3]Medanta, The Medicity Hospital, Gurgaon, India.*

Background: Acute Kidney Injury (AKI) is associated with poor short-term outcomes such as mortality, longer ICU and hospital length of stay and duration of mechanical ventilation as demonstrated by numerous studies. Our objective was to study the long-term renal outcomes and markers of kidney injury in pediatric patients with congenital heart disease who did and did not develop AKI following cardiac bypass surgery.

Methods: This was a prospective case-control observational study in which all infants and children who underwent cardiac bypass surgery from 2010-2017 and who had a long term follow up were included. Patients with CKD, Hypertension, AKI from primary kidney disease and previous history of AKI were excluded. 44 Patients who developed AKI were matched to 49 consecutive controls who did not develop AKI postoperatively. GFR was estimated by Schwartz formula and cystatin C. Kidney injury biomarkers that were used are NGAL, L-FABO, KIM-1, IL18.

Results: Age, Gender, weight, height, aortic cross-clamp (ACC) time and cardiopulmonary bypass (CPB) time were not statistically significant among cases and controls. Patients with AKI had a higher baseline serum creatinine (0.43±0.22, p<0.001) and longer ICU length of stay (days, 5.7±3.0, p<0.001) than the control group. On the long term follow up, patients with AKI had a higher serum creatinine level, the trend towards higher urinary KIM-1 levels and lower estimated GFR but were not statistically significant. When backward linear regression analysis was performed, CPB time (Odds Ratio: -0.550, p<0.05) and AKI (OR: 10.913, p>0.05) were the only risk factors associated with lower GFR at follow-up. CPB time (OR: 0.010, p<0.05), baseline serum creatinine (OR: -0.643, p>0.050) and AKI (OR: -0.381, p<0.05) were the only risk factors associated with higher KIM-1 at follow up.

Conclusions: Cardiopulmonary bypass time (CPB) is significantly associated with a decrease in GFR and a rise in kidney injury biomarker KIM-1 level several months post postoperatively independent of postoperative AKI.

FR-PO1087

Perioperative AKI in Pediatric Liver Transplant Patients

Naile Tufan pekkucuksen,[1,2] Ryan Himes,[5] Justin Young,[3] Poyyapakkam Srivaths,[4] Moreshwar Desai,[3] Ayse Akcan Arikan.[3] *[1]Pediatrics, Division of Pediatric Nephrology, University of FLorida, Gainesville, FL; [2]Pediatrics, Renal Division, Baylor College, Houston, TX; [3]Baylor College of Medicine, Houston, TX; [4]Texas Children's Hospital, Houston, TX; [5]Ochsner Hospital for Children, New Orleans, LA.*

Background: Acute kidney Injury (AKI) is a common complication in children in the post- orthotopic liver transplant (OLT) period. However, data regarding pre OLT AKI are scarce. We examined the incidence of perioperative AKI (7 days pre OLT- 7 days post OLR) in pediatric OLT population. AKI was defined using KDIGO criteria and HRS was defined using revised consensus recommendations of the International Club of Ascites, 2015 publication.

Methods: This is a single center retrospective chart review.

Results: A total hundred twenty-two pediatric patients (pts) underwent OLT between 11/2011- 3/2017. One patient who had known chronic kidney disease (CKD), was excluded. The median age was 2.5 years (IQR:0.83-10) and 71 were female (59%). Most common etiologies of liver disease were biliary atresia (BA) (68/121, 56%) and autoimmune idiopathic hepatitis (AIH) (25/121, 20%). Forty pts (33%) had perioperative AKI: 15% stage 1, 30% stage 2 and 55% stage 3. Of those, 15 (38%) pts had AKI pre-OLT, with hepatorenal syndrome (HRS) diagnosed in 11(73%). Twenty-five (62%) pts experienced post-OLT AKI. Most common etiologies for post OLT AKI were abdominal compartment syndrome (ACS), acute tubular necrosis (ATN) due to hypotension or bleeding, or nephrotoxin exposure. 29 pts (24%) received continuous renal replacement therapy (CRRT), 24 of those were started pre OLT due to AKI, fluid overload (FO) or hyperammonemia without AKI and 3 of those were discontinued after OLT. Five pts needed CRRT only post-OLT. Unfortunately, 7 AKI pts were never recognized by the clinical team.

Conclusions: AKI is common in perioperative period in children receiving OLT. HRS was the most common etiology for pre OLT. Post OLT, operative complications with ascites leading to ACS and hypotension leading ATN predominated. Majority of AKI pts were stage 3 and needed RRT. Unless monitored in a systemic fashion with structured diagnostic criteria, AKI can be missed by the clinical team. Short- and long-term outcomes of this population need to be elucidated through further studies.

FR-PO1088

The Long-Term Kidney Outcomes of Prune Belly Syndrome in Australia

Erin Jose,[1] Lee Skeat,[2] Jennifer C. English,[2] Lisa S. Jeffs,[2] Matthew D. Jose.[3,4] *[1]Royal Adelaide Hospital, Adelaide, SA, Australia; [2]Royal Hobart Hospital, Hobart, TAS, Australia; [3]University of Tasmania, Hobart, TAS, Australia; [4]Australia and New Zealand Dialysis and Transplant Registry (ANZDATA), Adelaide, SA, Australia.*

Background: Prune Belly Syndrome (PBS) a rare congenital disorder consisting of the triad of: absence or incomplete abdominal wall muscle development, bilateral cryptorchidism and urinary tract anomalies including hydronephrosis, kidney dysplasia and dilated ureters, urethra or bladder. PBS varies considerably in clinical severity, with prognosis primarily being influenced by the degree of chronic kidney disease. The aim of this study was to describe the long-term kidney outcomes of people with Prune Belly Syndrome in Australia.

Methods: We identified all Australians treated with renal replacement therapy (RRT) who had a diagnosis of PBS (as determined by the treating unit) from the Australia and New Zealand Dialysis and Transplant Registry (ANZDATA). ANZDATA is a clinical quality registry containing information on all people receiving dialysis or a kidney transplant since 1977.

Results: We identified 37 males (no females) with a diagnosis of PBS who received RRT in Australia and were recorded in ANZDATA. Commencement of RRT was at a median age of 17yrs (mean 19yrs, range 1-45yrs) when median creatinine was 720umol/L. RRT at first treatment was haemodialysis in 54%, peritoneal dialysis 30% and pre-emptive kidney transplant in 16%. Twenty percent of patients were late referrals to the dialysis unit (referral <3 months prior to starting dialysis). Comorbidities of diabetes, heart disease or vascular disease were not present at commencement of RRT. One man had chronic lung disease. Forty-five kidney transplants (including 33 first, 10 second and 2 third grafts) occurred, of which 47% were from deceased donors. Mean age at first transplant was 21yrs (range 2-47yrs). Graft survival at 1, 5 & 10 years for first grafts was 94%, 67% and 48% respectively (range 6 days to 36 years). Parenthood was reported for 3 men at a median age of 35yrs. There were 10 deaths reported at a median age of 37yrs (range 17-49yrs) due to cardiac death (50%), malignancy (20%), dialysis cessation (10%) and uncertain cause (20%).

Conclusions: Prune Belly Syndrome has marked variation in the severity of kidney disease. For those who receive RRT, kidney transplant is the predominant treatment, but peritoneal dialysis has been used successfully. Infertility is not universal. There is early cardiovascular mortality associated with this syndrome.

FR-PO1089

Aptamer-Based Proteomics Analysis Reveals a Urine Protein Signature That Differentiates UTIs from Culture-Negative Pyuria and Normal Urine

Andrew L. Schwaderer, David S. Hains. *Indiana University, Zionsville, IN.*

Background: UTIs account for 7% of pediatric emergency department antibiotic prescriptions. UTI diagnosis is typically made at the point-of-care by symptoms and the identification of nitrites and/or leukocyte esterase (LE) on urinalysis (UA). Growth of ≥ 50,000 colony forming bacterial units on culture is used to confirm a UTI. However accurate urine culture results can be dependent on collection methodology and take 24-72 hours to complete. UAs have limitations as well. The sensitivity/specificity for LE to detect childhood UTIs is 83%/78%.

Methods: An aliquot of urine was obtained from pediatric Emergency Department patients who had a sample collected for clinical urine culture. Included samples consisted of 16 with urinary tract infection (UTI), 8 culture negative (CN) pyuria, and 8 with normal UAs. The levels of 1,310 proteins were quantified as relative fluorescent units/ml using the SOMAscan platform (Somalogic Inc, Boulder, CO) and the normalized to urine creatinine (mg/dl). The results were filtered for proteins that were (a) significantly higher in the UTI vs CN pyuria samples and in the UTI vs normal urine samples with a p value of < 0.01 and that had an area under the curve (AUC) of > 0.9 which is used to define an "excellent" biomarker.

Results: Eight candidate biomarkers met this stringent filtering criteria and are presented along with the threshold urine biomarker to creatinine ratio with the highest likelihood ratio to differentiate UTI from non UTI samples in Figure 1.

Conclusions: A biomarker panel containing some of the candidates identified via this study has the potential to improve the timeliness and accuracy of UTI detection. Prospective studies evaluating levels measured by ELISA and conversion to a point of care testing modality are the next investigative steps.

Incidence of Early Dysnatremia in the Assessment of Neonatal Acute Kidney and Epidemiology (AWAKEN) Cohort

Abby M. Basalely,[1] David J. Askenazi,[2] Jennifer R. Charlton,[3] Mamta Fuloria,[1] Ronnie Guillet,[7] Frederick J. Kaskel,[5] Linzi Li,[2] David T. Selewski,[4] Kimberly J. Reidy.[6] *[1]The Children's Hospital at Montefiore, Bronx, NY; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Virginia, Charlottesville, VA; [4]Medical University of South Carolina, Mount Pleasant, SC; [5]Children's Hospital at Montefiore, Bronx, NY; [6]Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronxville, NY; [7]University of Rochester, Rochester, NY.*

Background: Incidence of dysnatremia during the first postnatal week in the neonatal intensive care unit (NICU) and its association with mortality has not been well described. We hypothesized that incidence of dysnatremia would vary with gestational age (GA) and that early dysnatremia predicts mortality.

Methods: We studied neonates in the AWAKEN cohort, a 24-center retrospective study of NICU admissions on IV fluids ≥ 48 hrs, with ≥ 1 serum sodium (sNA) recording during postnatal days 2-7. sNA values were compared in 3 GA cohorts (24-<29 weeks(wk), ≥29-<36wk, ≥36wk). Hypernatremia was defined as sNa >145meq/L (moderate=146-155, severe=≥156); hyponatremia was defined as sNa <135meq/mL (mild=130-134; moderate=125-129; severe<125). Survival was considered reaching 36 wk post-GA or hospital discharge. Kruskal Wallis, Chi^2 tests, and multivariable logistic regression were used as appropriate.

Results: The cohort included 1,972 infants with 15,302 sNa values (Table 1). Of these, 23% developed hypernatremia and 35% developed hyponatremia. The incidence and severity of hypernatremia differed by GA (Figure 1). Infants <29 wk GA were most likely to develop severe hypernatremia (OR 8.8 95%CI 6.1-12.6, p<0.01). The incidence and severity of hyponatremia also differed across GA groups (Figure 2). Over 40% of infants in the 24-<29 wk and ≥36 wk cohorts developed hyponatremia, compared to 26.8% of the ≥29-<36 wk group (p< 0.001). Both hyponatremia (adjusted (a)OR 2.7 95%CI 1.6-4.5, p<0.001) and hypernatremia (aOR 2.2 95%CI 1.3-3.8, p=0.005) in models adjusted for GA predicted increased odds of mortality.

Conclusions: This is the largest and most inclusive cohort to describe the incidence and impact of dysnatremias in critically ill neonates. The incidence and severity of hypernatremia differed by GA category and was most substantial in very premature infants. However, infants 24-<29 wk and ≥36 wk GA developed hyponatremia at similar rates, which may reflect oliguria and/or fluid provision strategies. Further evaluations of this cohort will evaluate whether hyponatremia and hypernatremia are independently associated with mortality after adjusting for other important cofounders.

Delta Bilirubin: A Lesser-Known Bilirubin Fraction and Its Impact on Interpretation of Single-Pass Albumin Dialysis (SPAD) Efficacy

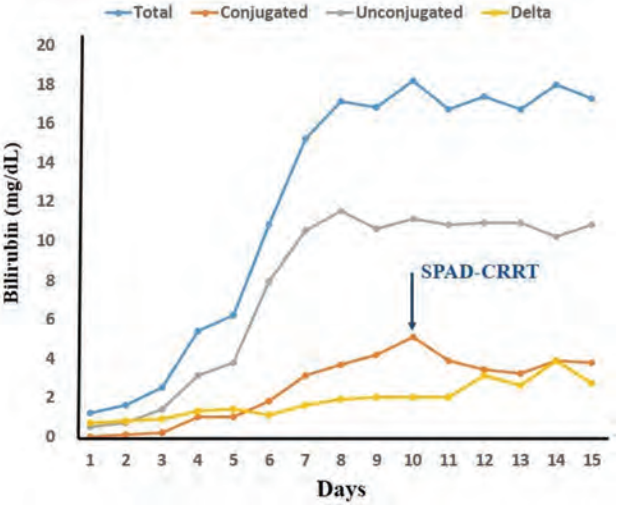
Vimal Chadha,[1] Amy Wiebold,[1] Angela M. Ferguson,[1] Uttam Garg.[2] *[1]Children's Mercy Hospital, Kansas City, MO; [2]Children's Mercy Hospitals and Clinics, Knasas City, MO.*

Background: Acute liver failure (ALF) is a rapidly progressive disease that leads to multiple organ failure with high mortality. Combination of supportive therapies are utilized to stabilize these patients until recovery, or as a bridge to liver transplant. As MARS is not readily available in all pediatric centers, modification of continuous renal replacement therapy (CRRT) with SPAD is an equally efficacious alternative. During SPAD, bilirubin clearance is used as a surrogate marker for clearance of protein bound-toxins. We have previously shown >10 fold increase in bilirubin clearance with SPAD as compared to CRRT alone. However, we failed to observe increased bilirubin clearance in a group of ALF patients who received SPAD.

Methods: We studied 3 patients with ALF who failed to show increased bilirubin clearance. These patients had significant unconjugated hyperbilirubinemia which is not cleared by SPAD as it is tightly albumin-bound. However, we also found significantly decreased clearance of conjugated-bilirubin in these patients. We thus studied the bilirubin fractions in the serum and the effluent by using Vitros 5600 chemistry analyzer, a unique method that uses two slides to measure total, unconjugated and conjugated-bilirubin fractions, and calculates delta bilirubin, a form of conjugated-bilirubin that is covalently bound to albumin.

Results: Review of our raw data showed that these 3 patients had significant proportion of their conjugated bilirubin in the form of delta-bilirubin (Figure), which is not cleared by SPAD due to its tight albumin binding. Delta bilirubin is known to accumulate in patients with prolonged liver failure and biliary atresia.

Conclusions: Decreased bilirubin clearance in this subset of ALF patients was found to be due to increased serum delta-bilirubin. Since most laboratories do not measure or report delta-bilirubin, increased delta-bilirubin may lead to the perception that SPAD is not working efficiently, and may lead to unnecessary and expensive work-up.



Bilirubin fractions

Undetected Sexual Transmitted Infection in Adolescents with Sterile Pyuria

Yee-Hsuan Chiou,[1] Yu-shan Huang,[2] Nai-Wen Fang.[2] *[1]Department of Pediatrics, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan; [2]Kaohsiung Veterans General Hospital, Taiwan, Taiwan.*

Background: The percentage of sexual transmitted infection(STI) in adolescents had been underestimated and misdiagnosed as urinary tract infection(UTI), which may lead to unnecessary treatment and public health issue. We aimed to distinguish STIs through symptoms, laboratory and urinary analysis. We emphasize on the correlation of STIs and child maltreatment.

Methods: We performed a retrospective study of adolescents aged from 15-18 years old, who visited a tertiary center from January 1, 2015 through July 30, 2018, with diagnosis of urinary tract infection, acute cystitis, acute pyelonephritis, dysuria, urinary frequency, or renal colic. We compared clinical characters, symptoms, serum laboratory data, urine analysis, percentage of been reported to Social Affair Bureau between STIs and UTIs groups.

Results: Of the 45 adolescents, there was a significant difference in pyuria count(p=0.036), with 44.7% of UTI group reached the highest pyuria level (WBC>100/HPF) and none in STI group had pyuria >100/HPF. 71.4% of STIs had only mild pyuria with 5~49/HPF. No significant difference in clinical symptoms, including fever, dysuria, hematuria, abdominal pain, flank pain, serum white cell count, or CRP level between UTIs and STIs groups. We found 71% of adolescents with STIs had been reported as in need of child protection.

Conclusions: The clinical features and serum laboratory data were overlapping in STIs and UTIs, and both of them cause pyuria, which may lead to over-diagnosis of UTIs. Adolescents with lower degree of pyuria had higher possibility of STIs. The incidence of family dysfunction in STI is extremely high.

FR-PO1093

Renal Abnormalities in HIV-Exposed Children: A Guatemalan Retrospective Cohort Study

Guerthy S. Lizama,[3] Julio W. Juarez,[4] Angie L. Aguilar,[1] Randall M. Lou-Meda.[2] *[1]FUNDANIER, Guatemala, Guatemala; [2]Fundanier, Guatemala, Guatemala; [3]Roosevelt Hospital, Guatemala, Guatemala; [4]Pediatric. Infectious Diseases, Roosevelt Hospital, Guatemala, Guatemala.*

Background: Among the various organs involved with the progression of HIV infection, the kidneys have had a significant impact Studies have highlighted the importance of early detection of kidney disease in HIV-infected patients in order to reduce the progression of CKD We identify the renal abnormalities in HIVexposed children in a tertiary hospital in Guatemala

Methods: After ethics approval, we retrospectively evaluated a cohort of patients perinatally exposed to HIV during the period 2015-2016 Patients attending the outpatient clinic for at least 6 months were captured in the study. eGFR, pr/cr, ca/cr ratio were obtained at the time of inclusion and at least 6 months after enrollment. Renal abnormality was outlined if lasting more than 6 months Clinical and immunologic status, viral load, time in which the patient was without antiretroviral treatment since HIV perinatal exposure and time of antiretroviral exposure were determined

Results: From 102 patients enrolled, 52 were HIV positive and 50 were HIV negative. The mean age was 12.2yr(SD, 4.9) and 40% of the patients were male. 56%(29/52) of the infected patients had a C clinical status, 62%(32/52) had a severe immunosuppression status and 39%(20/52) had a viral load<50 thousand The mean pretreatment time was 2.82yr(SD, 2.5) and the mean time of antiretroviral exposure was 8yr(SD,3). Regarding renal function marker, 42%(22/52) of the infected patients had an eGFR abnormality (20 patients had eGFR>140 and 2 patients had eGFR<90ml/min/1.73m2), compared to 10%(5/50) of the uninfected patients (all the patients had eGFR>140ml/min/1.73m2). Infected patients had 4 times higher risk to present abnormalities in eGFR compared to uninfected patients. IC-95%(1.73-10.30) The mean eGFR values at 0-2, 2-4, 4-6 and >6yr of pretreatment time were 177.73(SD,91.12), 171.59(SD,91.12) and 171.27ml/min/1.73m2(SD,94.16). The 0-2yr of pretreatment time group had the highest frequency of abnormalities in eGFR and pr/cr ratio, compared to the rest of the groups. 48%(25/52) of the patients during the antiretroviral exposure, 50%(26/52) with C clinical status, 52%(27/52) with 3 immunologic status and 21%(11/52) with ≤50thousand load had at least 1 renal abnormality

Conclusions: Hyperfiltration was the predominant renal abnormality in HIV infected patients The early screening for renal function is mandatory in all HIV exposed patients

FR-PO1094

Use of an Artificial Neural Network for the Prediction of Urine Culture Positivity from Urine Dipstick in Children

Janusz Feber,[1] Ivan Blasutig.[2] *[1]Division of Nephrology, Department of Pediatrics, Children's Hospital of East Ontario, Ottawa, ON, Canada; [2]Division of Biochemistry, Department of Pathology and Laboratory Medicine, CHEO, Eastern Ontario Regional Laboratory Association, Ottawa, ON, Canada.*

Background: Urine dipstick results are important for clinical decision making regarding the presence or absence of urinary tract infections. The aim of the study was to analyse the performance of artificial neural network (ANN) in the prediction of positive urine culture from an automated urine dipstick test.

Methods: We retrospectively analysed all available automated urine dipstick (UD) and urine cultures (UCULT) tests performed at our institution over 2-year period (2015-2017). The final dataset (after merging and cleaning) consisted of 5912 complete UD and UCULT performed on the same date and time. Predictors of UCULT included: age, gender, and all UD results: glucose, ketones, specific gravity, blood, pH, protein, nitrates and leukocytes. ANN model (sequential, feedforward with backpropagation) consisted of 30 neurons in 2 hidden layers (Tensorflow Keras). Data samples (n=5912) were randomly divided into training (70%) and validation set (30%). ANN prediction probabilities thresholds for positive UCULT results were set to 0.5 (ANN05) and 0.3 (ANN03). The performance of both ANN models was assessed by accuracy scores, sensitivity, specificity, positive and negative predictive value (PPV, NPV).

Results: Out of 1773 children (aged 4.3 ±5.3 years) in the validation set, 449 had a positive UCULT. ANN05 correctly predicted 1272 negative + 254 positive UCULT; with ANN03 the prediction was: 1229 negative + 289 positive UCULT. The mean accuracy of both ANN05 and ANN03 models was 86% (95% CI = 84-88%). Sensitivity and specificity of ANN05 was 0.57 and 0.96 with PPV of 0.83 and NPV of 0.87. The corresponding numbers for the ANN03 model were: 0.64, 0.93, 0.75, and 0.89. The four most important UD variables for prediction of UCULT were: leukocytes, blood, nitrates and protein.

Conclusions: ANN predicted positive urine cultures from a simple urine dipstick (without urine microscopy) with 84-88% accuracy, PPV of 75-83% and NPV of 87-89%. ANN-powered automated urine dipstick lab prediction of positive urine cultures can be considered to facilitate clinical decision making.

FR-PO1095

Which Grading System Is More Useful to Estimate the Time to Resolution of Isolated Hydronephrosis Between SFU and APPD Grades? A Single-Center Study

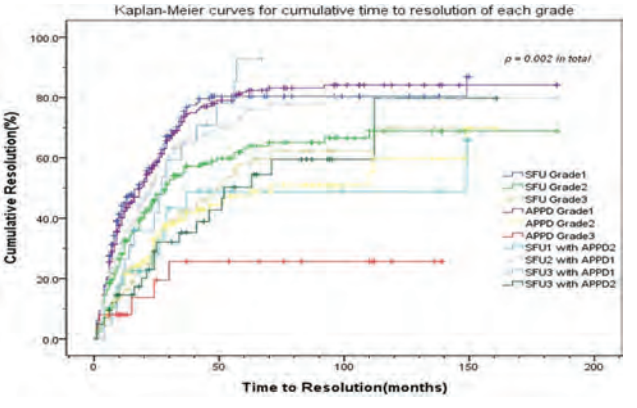
Jiwon Jung, Joo Hoon Lee, Young seo Park. *Department of pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: Predicting the time to resolution of isolated hydronephrosis is an important topic for both clinicians and families. Because the Society for Fetal Urology(SFU) classification and Anterior-Posterior Pelvic Diameter(APPD) are the two most commonly used grading tools of hydronephrosis, we aimed to compare the ability of two systems in estimating resolution rate.

Methods: We retrospectively reviewed medical records of patients with isolated hydronephrosis prenatally detected and postnatally diagnosed between 1990-2018, and excluded patients with pyeloplasty, vesicoureteral reflux or other anomalies. SFU grade and APPD at first USG were collected and APPD ranges of 5–9mm, 10–14mm, 15–19mm, and above 20mm were classified as grade 1, 2, 3 and 4. Resolution was defined as APPD below 5mm with SFU grade 1. Log rank test and Kaplan-Meier curves were used to analyze time to resolution of each SFU and APPD grades.

Results: Of 432 patients(544 renal units), 382(88.4%) were male, and 398(73.2%) renal units were left sided. 217(39.9%) units reached resolution at a mean follow-up of 51±44 months. SFU grades 1 through 4 showed resolution rate of 80.0%, 60.2%, 48.0%, 20.0% respectively, and APPD grades showed resolution rate of 78.0%, 44.3%, 25.7%, 6.7% respectively at 48 months. There was discrepancy between SFU and APPD grades in 253(46.5%) units. In each disproportional case, resolution rate approximated to the rate of APPD grade without significant difference. In proportional cases, the cumulative resolution rate of each pair of grade 1 and 2(84.5%, 52.7%) approached the rate of each APPD grade(84.1%, 59.7%), while SFU grade 3 with APPD grade 3 showed a value of resolution rate(48.1%) between the resolution rate of each SFU(69.8%) and APPD(25.7%) grade.

Conclusions: APPD grade is more useful than SFU grade in predicting time to resolution when there is discrepancy between two grades. In the low grade concordant cases, prediction of time to resolution can be resonably based on APPD.



FR-PO1096

The Ribonuclease 6 Antimicrobial Peptide Limits Bacterial Burden During Experimental Pyelonephritis

Hanna H. Cortado,[1] Ashley R. Jackson,[1] Birong Li,[1] Christina B. Ching,[3] John D. Spencer,[2] Brian Becknell.[1] Nephrology and Urology Research Affinity Group *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Research Institute at Nationwide Children's, Columbus, OH; [3]Nationwide Children's Hospital, Columbus, OH.*

Background: Ribonuclease 6 (RNase 6) is an evolutionarily-conserved antimicrobial peptide that kills uropathogenic bacteria at low micromolar concentrations *in vitro*. Here, we investigated the hypothesis that RNase 6 limits urinary tract colonization by uropathogenic *Escherichia coli* (UPEC) *in vivo*.

Methods: We generated mice with a *Rnase6*^{EGFP} knock-in allele on a C57BL/6J genetic background. We identified cellular sources of RNase6 based on flow cytometry, epifluorescence, and immunofluorescence microscopy. We transurethrally inoculated *Rnase6*$^{EGFP/EGFP}$ and control female mice with UPEC strain CFT073 and enumerated bacterial burden in urinary tract tissues by homogenization and serial plating.

Results: Flow cytometry in *Rnase6*$^{EGFP/+}$ mice identified EGFP expression by circulating Ly6C^{hi} monocytes which were recruited to the infected bladder by 6 hours post inoculation (hpi). In addition, EGFP was expressed by two discrete resident macrophage populations within the kidney. We confirmed *Rnase6* deletion in *Rnase6*$^{EGFP/EGFP}$ mice, which displayed normal urinary tract development, fertility, and hematopoiesis. *Rnase6* deficiency led to increased renal and ureteral UPEC burden at 6 and 12 hpi, compared to control mice.

Conclusions: In the infected urinary tract, RNase6 is primarily expressed by resident macrophages and recruited monocytes. We have demonstrated a critical role for RNase 6 in UPEC clearance from the upper urinary tract during ascending UTI *in vivo.*

FR-PO1097

Urinary Klotho Abnormalities in Pediatric Sickle Cell Disease (SCD)

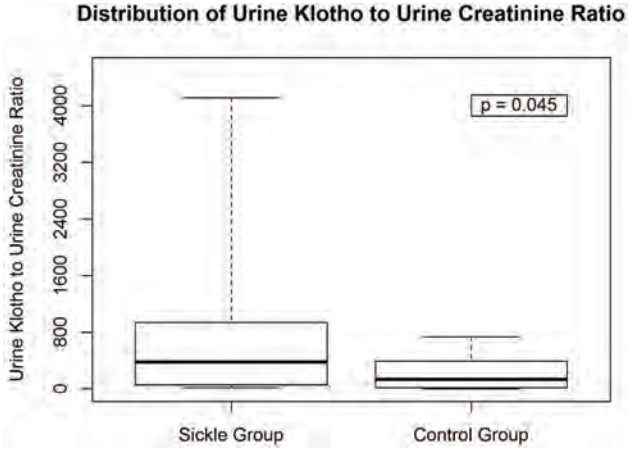
Vimal Master sankar raj,[1] Diana L. Warnecke.[2] *[1]Pediatric Nephrology, UICOMP, Peoria, IL; [2]Univ of Illinois College of Medicine, Peoria, IL.*

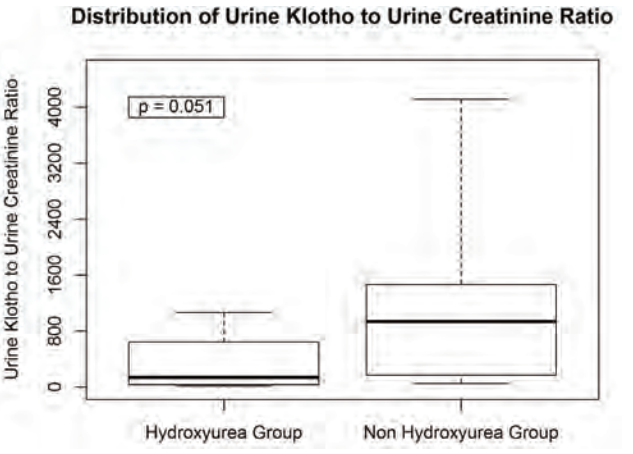
Background: Klotho is a transmembrane protein expressed in the renal tubules and serves as an obligatory co-receptor for FGF23 to aid in phosphorus excretion. Prior studies have shown FGF23 resistance in SCD. The purpose of the study is to investigate urinary klotho/creatinine (Ur Kl/Cr) in pediatric SCD and no markers of ongoing renal damage (eGFR > 90 ml/min and no microalbuminuria) and to compare it with healthy control population.

Methods: Cross sectional observational study to compare Ur Kl/Cr in pediatric SCD and controls. To do a sub group analysis among the study population to assess the effect of hydroxyurea(HU) on Ur Kl/Cr

Results: 20 control and 22 pediatric SCD were enrolled. In SCD group, 13 were on HU. The baseline characteristic of the study and control group were same. Wilcoxon rank-sum test was used to compare the levels of Ur Kl/Cr ratio between SCD and control. For P value of 0.05, the levels of Ur Kl/Cr were statistically significantly higher in the sickle cell group (752.7 ± 1101.0) over the control group (216.8 ± 225.3). Subgroup analysis in the SCD group showed high Urinary Kl excretion in the non HU group(1346.7 ± 1523.4) vs non HU group (341.4 ± 355.3) but not statistically significant.(Fig 1 & 2)

Conclusions: Children with SCD tend to have increased secretion of Ur Kl/Cr compared to control likely due to tubular receptor resistance. HU tends to reverse this phenomenon by it's effect on preventing tubular damage.





FR-PO1098

Genetic Background of Infants with Urinary Tract Infection and Transient Pseudohypoaldosteronism

Min-hua Tseng,[2] Shih-Hua P. Lin.[1] *[1]Tri-Service General Hospital, Neihu, Taiwan; [2]Chang Gung Momorial Hospital, Taipei City, Taiwan.*

Background: Transient pseudohypoaldosteronism type 1 (PHA1) is a rare but severe complication of urinary tract infection (UTI) in infants. A detailed clinical and molecular analysis for this patient cohort is still lacking.

Methods: Transient pseudohypoaldosteronism type 1 (PHA1) is a rare but severe complication of urinary tract infection (UTI) in infants. A detailed clinical and molecular analysis for this patient cohort is still lacking.

Results: They included twelve infants (9 male) with an age of 1-8 months. All of them exhibited hypovolemic hyponatremia (125.3 ± 3.3 mmol/L), hyperkalemia (6.4 ± 0.2 mmol/L), metabolic acidosis (HCO_3^- 15.1 ± 1.5 mmol/L), low TTKG (3.3 ± 0.5), and relatively elevated FENa (2.4 ± 0.2 %), high plasma renin (476.2 ± 295.2 pg/ml) and aldosterone levels (869.8± 280.3 pg/ml). The time from onset of UTI to occurrence of PHA1 was 2.4 days. Vomiting and poor feeding were the most common symptoms. Seven had hyperkalemia-related arrhythmia and two of them developed life-threatening ventricular tachycardia. With prompt therapy for PHA1 and UTI, clinical manifestations and biochemical abnormalities were all resolved. Despite vesicoureteral reflux as the most common urinary tract anomalies, five patients had normal urinary tract and one of them harbored a novel mutation at phosphorylation site (heterozygous S544A) of *NR3C2*. During follow-up, none of them had recurrence of PHA1 and 4 of them developed renal scaring.

Conclusions: The development of PHAI from UTI is rapid and may exhibit severe features. Besides the well-known urinary tract anomalies, genetic mutation on *NR3C2* may contribute to PHA1 in UTI infants without identifiable risk factors.

FR-PO1099

Context-Specific Cellular Mechanisms of Urothelial Development and Repair in the Kidney

Ashley R. Jackson,[1] Monica L. Hoff,[5] Birong Li,[1] Christina B. Ching,[4,1] Kirk M. McHugh,[3,1] Brian Becknell.[2,1] *[1]Center for Clinical and Translational Research, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Division of Nephrology, Nationwide Children's Hospital, Columbus, OH; [3]Department of Anatomy, The Ohio State University College of Medicine, Columbus, OH; [4]Division of Pediatric Urology, Department of Surgery, Nationwide Children's Hospital, Columbus, OH; [5]Department of Pediatrics, The Ohio State University College of Medicine, Columbus, OH.*

Background: Congenital urinary tract obstruction (UTO) is a leading cause of pediatric chronic kidney disease and end stage renal disease. The renal urothelium is the kidney's anatomic front line of defense during UTO, and represents an understudied but novel therapeutic target. Renal urothelium contains two mutually exclusive, Krt5+ and Upk+ renal urothelial cell (RUC) populations. UTO triggers an iterative RUC remodeling sequence that culminates in the formation of bladder-like Upk+ apical plaque producing RUCs, which attenuate UTO injury. The ontology of Upk+ RUCs is unknown, stalling efforts to therapeutically promote protective renal urothelial remodeling.

Methods: In this study, we performed genetic fate mapping to determine whether Upk+ RUC arise through self-renewal or via differentiation from Krt5+ RUC. We mapped the fate of Upk+ and Krt5+ RUC lineages in *Upk2*$^{CreERT2/+}$*;R26*$^{tdT/+}$ and *Krt5*$^{CreERT2/+}$*;R26*$^{tdT/+}$ mice, and performed immunofluorescent assays to mark Krt5, Krt14, p63, foxa1, Upk, Krt20, tdT-expressing and proliferating cells across development. Unilateral ureteral obstruction was used to trigger UTO.

Results: Renal urothelium develops at embryonic day 17, and temporal waves of Upk and Krt5 expression are observed through adulthood. Krt5+ RUCs commonly express Krt14 and p63 and are the primary proliferative RUC. Adult Upk+ RUCs derive from

embryonic and neonatal Krt5+ RUCs. Paralleling a proliferative decline, Krt5+ RUCs lose progenitor capacity by postnatal day 14. In a temporally restricted manner, UTO triggers formerly lineage restricted Krt5+ RUCs to regain progenitor capacity and form bladder-like Upk+ RUCs. In addition, adult Upk+ RUCs possess the ability to lose Upk protein expression, proliferate, and give rise to daughter Upk+ RUCs that reacquire Upk protein synthesis.

Conclusions: This study is the first to establish the temporal manner in which the embryonic and postnatal renal urothelium is patterned, and demonstrates the contexts during which Upk+ RUCs arise via self-renewal versus differentiation from Krt5+ progenitors. Identification of the context-specific mechanisms governing progenitor plasticity or restriction have broad implications for urothelial development, repair and therapeutic manipulation.

Mercaptoacetyltriglycine Scan vs. Functional Magnetic Resonance Urography: A Comparison and Long-Term Follow-Up of Clinical Outcomes

Bernarda Viteri, Dmitry Khrichenko, Juan S. Calle-Toro, Hansel J. Otero. *Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) are the leading cause of End Stage Renal Disease in children. Obstructive uropathy (OU) presenting with urinary tract dilation (UTD) is one of the most common forms of CAKUT. While there is no gold standard for OU evaluation or clear cutoffs for surgical intervention, functional imaging evaluation is recommended to help the decision making process. In children, functional Magnetic Resonance Urography (fMRU) is increasingly used because of its superior anatomic detail when compared to the most widely used MAG3 nuclear medicine renal scan (RS). However, there is not enough data to assure that fMRU-based differential renal function is equivalent to RS results. Here we compare the functional results of fMRU and RS in a pediatric cohort presenting with UTD.

Methods: This is an IRB-approved retrospective review of 37 out of 988 (3.75%) fMRUs performed in 735 children (0-21 yrs) at our institution between 2007 and 2017, which had an accompanying RS within 6-months and with no interval surgical intervention.

Results: The 37 unique patients (15 F, 25 M) had a median age: 6 months (range: 2mo-19y) and; 24% were caucasian. The majority (26/37, 70.3%) presented with UTD P3. Main diagnoses included uretero-pelvic junction obstruction (UPJO) in 21/37, megaureter (5/37) and duplex kidney (4/37). Differential renal function (DRF) was obtained from each test and 14 fMRU and 12 RS patients were grouped as normal but there was no significant agreement between tests in the dilated groups ($p = 0.135$). Only 7/33 (21%) patients had concordant (<5% DRF difference) DRF from fMRU and RS. Upon evaluating obstruction determinants fMRU was found to be 88.24% specific and 38.10% sensitive with 69.09% accuracy (95% CI 55.19-80.86). 2/19 patients who had follow up for a mean of 3 years (range 6mo-9 years) had elevated BP. eGFR was found to be >100mL/min/1.73m2 consistent with normal renal function at follow-up in 15 patients.

Conclusions: The differential renal function determined by RS and fMRU in children is discordant in a majority of cases with significant agreement limited to those deemed normal in both modalities. Using RS as the gold standard, fMRU was found to be 88.24% specific though average sensitivity in determining obstruction. Overall cohort did not present adverse outcomes after a mean 3 years follow up.

Pre-Transplant Elevated Chemokines CXCL9, CXCL10, and CXCL11 Influence Kidney Graft Status in Mexican Mestizos

Pedro Alejandro V. Galván,[1] Caridad L. Cortes,[1] Eliseo P. De buen,[1] Miguel Medina Perez,[1] Luis N. Barajas Gutierrez,[1] Aracely E. Ruiz,[1] Isis G. Vázquez,[1] Monserrat G. Navarro,[1] Claudia A. Mendoza Cerpa,[1,2] Benjamin Gomez-Navarro.[1,2] *[1]Instituto Mexicano del Seguro Social, Guadalajara, Mexico; [2]Hospital de Especialidades Centro Médico Nacional de Occidente, Guadalajara, Mexico*.

Background: A high incidence of CKD in Mexico, affects a significant number of young patients. Chemokines CXCL9, CXCL10 and CXCL11 may be sensitive markers of rejection or infection. Variability in the genetic background of populations is relevant. The clinical implications of these differences suggest the need to study other traits, including the influence of inflammatory processes in CKD Mestizos. Here, we explore how pre-transplant serum levels of CXCL9, CXCL10 and CXCL11 influence kidney grafts at 3 months after transplantation.

Methods: Retrospective study; 57 kidney receptors and 19 donors. Serum base levels of CXCL9, CXCL10 and CXCL11 were measured (Luminex 200). Other data were obtained from clinical charts. Correlations and mean comparisons were used to identify possible associations of chemokine levels with several conditions at 3 months.

Results: All chemokine levels were different between receptors and donors (CXCL9: 992.04 pg/mL vs 301.78 pg mL; CXCL10: 37.83 pg/mL vs 30.54 pg/mL; CXCL11: 333.98 pg/ml vs 23.78 pg/mL, respectively; $p< 0.05$). A negative correlation was identified between base creatinine and CXCL11 (r=-0.268, p=0.043), CXCL10 (r=-0.257, p=0.054), as well as time on dyalisis (r=0.329, p=0.019). CXCL9 was different between sexes (969.22 pg/ml male vs 433.57 pg/ml female; p=0.045). Receptors younger than 25 years had higher CXCL9 values (1282.91 pg/ml <25 y, vs 660.36 pg/ml ≥25 y, p=0.044). Other differences included pre-transplant type of dialysis (CXCL9 1643.95 pg/ml PD, vs 563.16 pg/ml HD, p=0.048). Preemptive patients had lower CXCL10 (23.41 pg/ml no dialysis vs 37 pg/ml peritoneal vs 41.29 pg/ml hemodyalisis; p=0.009). No associations were found between chemokines and infections at 3 months, but were found with calcineurin inhibitor toxicity (CXCL9: 1842.79 pg/ml toxicity vs 892.45 pg/ml no toxicity; p=0.049).

Conclusions: CKD patients have elevated chemokine serum levels, which associate with age, are reduced after transplantation, and correlate with creatinine. Type and time on dialysis may contribute to high chemokine levels, which may influence graft dysfunctions. Young Mexicans had a predisposition for higher chemokine production.

FR-PO1102

Everolimus Suppresses the BK Virus Replication in Human Embryo Cells In Vitro

Noriaki Sato,[1] Keita P. Mori,[1] Kaoru Sakai,[1] Kazunari Tanabe,[3] Motoko Yanagita,[1] Kimiyasu Shiraki.[2] *[1]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Senri Kinran University, Suita, Japan; [3]Tokyo Women's Medical University, Shinjuku-ku, Japan.*

Background: BK virus causes BKV-associated nephropathy in about 8% of kidney transplant patients and allograft loss occurs in 10-50% of the affected individuals. There is currently no effective treatment for BKV and it is mainly treated by reducing immunosuppression or changing the treatment regimen. Therefore, the search for effective treatments and mechanisms for BK virus infection is important. To date, various immunosuppressants were reported to suppress the replication of BKV *in vitro*. However, there are few reports that showed the effects of everolimus. We report the in vitro study of the effects of everolimus on BKV proliferation.

Methods: Confluent human embryo lung cells were infected with BKV isolated from a renal transplant recipient. We first determined the replication time and viral infectivity in this system. BKV DNA replication was evaluated by the increase in the DNA copy numbers in infected cells and the tissue culture infectious dose ($TCID_{50}$) and viral copy number were determined in three viral stocks. Effects of immunosuppressants on BKV replication were examined in this system. Cells were infected and treated with everolimus, cyclosporine, and tacrolimus at various concentrations attained in the recipients for 72 hours and the amounts of the replicated viral DNA were determined by a real-time quantitative PCR with primers targeting the large T-antigen.

Results: BKV growth curve showed that BKV DNA increased at 48 hours and further at 88 hours after infection, indicating one replication cycle was 48 hours. Viral infectivity was attained at 10^8 to 10^9 $TCID_{50}$/mL and particle per infectivity ratio was 2.12 $TCID_{50}$/1,000 DNA copies (n=3) in this system. BKV replication was not affected by treatment with tacrolimus and cyclosporine at concentrations from 1 to 30 ng/mL and from 0.01 to 1 μg/mL, respectively. Everolimus at concentrations from 0.1 to 300 ng/ml significantly suppressed BKV replication to 20 to 40% of untreated cells.

Conclusions: Everolimus has been reported to alleviate BKV infection in the TRANSFORM study. Everolimus suppressed BKV replication at the concentrations attained in the serum of renal transplant recipients and this results support the alleviation of BKV infection with everolimus.

FR-PO1103

B Cell and T Cell Subset Changes in a Rat Kidney Transplant Model of Chronic Antibody-Mediated Rejection

Nancy A. Wilson, Shannon Reese, Lucille D. Ptak, Robert R. Redfield, Sarah E. Panzer. *University of Wisconsin Madison, Madison, WI.*

Background: Chronic antibody mediated rejection (cAMR) is a leading cause of kidney graft loss. In many instances, mixed chronic AMR and cellular rejection are observed. We examined B and T cell populations in the lymphoid organs of a sensitized rat kidney transplant model. We hypothesized that sensitized recipients would have increased populations of memory and proinflammatory B and T cells in lymphoid tissues.

Methods: Minor mismatch kidney transplantation was performed to generate cAMR. The cAMR model had 3 groups: 1) syngeneic (Syn, Lewis donor to Lewis recipient), 2) allogeneic (Allo, Fisher donor to Lewis recipient), and 3) sensitized (Sens Allo, Fisher donor to Lewis recipient that received blood transfusion 21 days pre-transplant). Animals were harvested at 6 months post-transplant and lymphoid cells were analyzed by flow cytometry.

Results: Sensitized recipients demonstrated increased numbers of nonswitched and memory B cells in the bone marrow compared to allogeneic recipients (Figure 1). Sensitized recipients demonstrated increased numbers of splenic CD4+ T cells compared to allogeneic recipients. However, splenic CD8+ T cells and T regulatory cell numbers were similar between sensitized and allogeneic recipients. Additionally, splenic T follicular helper (Tfh) cells were elevated in sensitized recipients compared to allogeneic recipients.

Conclusions: We show sensitized kidney transplant recipients with cAMR develop increased populations of memory B cells and CD4+ T cells, including Tfh cells. The interactions of CD4+ T cells, including Tfh cells, with B cells promote the generation of memory B cells and antibody production and support a role for T and B cells in chronic rejection.

Funding: Other NIH Support - KL2 award

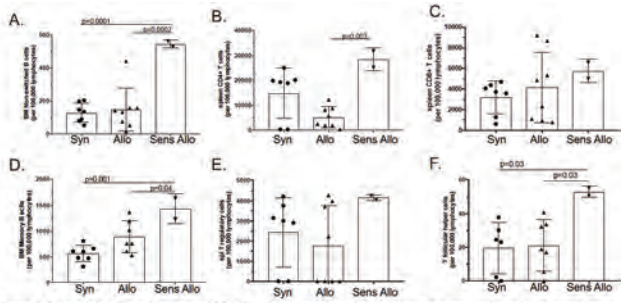

Figure 1. B cells in the Bone Marrow and CD4+ T cells in the spleen are increased by sensitization prior to transplant. Both early A) non-switched B cells and late D) Memory B cells in the bone marrow were expanded in sensitized animals B) CD4+ T cells in the spleen were elevated in sensitized animals. In contrast, C) splenic CD8+ T cells were not different between groups. E) Tregs were not significantly increased with sensitization, but F) T follicular helper cells were expanded in animals

FR-PO1104

Ex Vivo Exposure to IL-6 and TNFa Improves Proliferation of Regulatory T Cells Without Impairing Their Function and Lineage Stability

Nikolaos Skartsis,[1] Yani Peng,[1] Yannick Muller,[1] Leonardo M. Ferreira,[1] Flavio Vincenti,[1] Qizhi Tang.[2] *[1]University of California, San Francisco, CA; [2]School of Medicine, University of California, San Francisco, CA.*

Background: Clinical trials testing the efficacy of regulatory T cell (Treg) therapy in kidney and liver transplantation are underway. The survival and function of the infused Tregs in the inflammatory environment of the recipient are key determinants of the safety and efficiency of Treg therapy. We sought to investigate the impact of ex vivo exposure to IL-6 and TNFa on Treg proliferation, phenotype, and function.

Methods: First, we isolated $CD4^+$ $CD25^+$ $CD62L^+$ Tregs from C57BL/6J mice lymph nodes using fluorescence activated cell sorting (FACS). We stimulated the Tregs with anti-CD3/CD28 beads in the presence of IL-2, with or without IL-6 and TNFa and monitored Treg proliferation over a 10-day period. In addition, we adoptively transferred IL-6 and TNFa exposed NOD.BDC2.5 TCR transgenic Tregs into NOD.CD28KO mice. Similarly, we setup ex-vivo cultures of human $CD4+CD25^{hi}$ $CD127^{lo}$ Tregs isolated from peripheral blood mononuclear cells of healthy donors. Finally, we profiled both murine and human Tregs using flow cytometry, luminex, bisulfite conversion and pyrosequencing.

Results: We observed that C57BL/6J mouse Tregs exposed to IL-6 and TNFa have increased proliferation (136+/-28 versus 1106+/-505 fold; n=3; p=0.02), expressed Foxp3 and Helios and remained demethylated at the Treg specific demethylated region (TSDR). Adoptive transfer of IL-6 and TNFa exposed NOD.BDC2.5 TCR transgenic Tregs protected NOD.CD28KO recipients from diabetes. Similarly, ex-vivo exposure to IL-6 and TNFa increased proliferation of human $CD4^+$ $CD25^+$ $CD127^{lo/-}$ Tregs (24+/-13 versus 53+/-19 fold; n=4; p=0.04). IL-6 and TNFa exposed human Tregs remained $FOXP3^{hi}$ $HELIOS^{hi}$, did not produce pro-inflammatory cytokines such as IL-2, IL-4, IFNg or IL-17, and maintained demethylated TSDR. Finally, IL-6 and TNFa exposed human Tregs maintained their suppressive function against pre-activated $CD4^+$ Teff cells, similar to their non-exposed Treg counterparts.

Conclusions: Our results demonstrate that Treg exposure to IL-6 and TNFa enhances their proliferation without negatively impacting their lineage stability and suggests that Tregs positively respond to these cytokines by increasing their proliferation as a way to scale to inflammation. This property may be exploited to improve therapeutic Treg manufacturing for transplantation.

Association of the Insertion/Deletion Polymorphism of the ACE Gene with Acute Rejection and Chronic Dysfunction of Kidney Allografts

Andres Inzunza,[1,2] Jorge fernando Topete reyes,[3,1] Mario Salazar-Paramo,[3] Maria cristina Morán moguel,[3] Carlos alberto López lozano,[3] Leonardo Pazarin-Villaseñor,[5] Mario A. García Cárdenas,[6,4] Renato Parra Michel.[6,4] *[1]Escuela de Medicina y Ciencias de la Salud, Tecnológico de Monterrey, Guadalajara, Mexico; [2]GI & Hepatology, Mayo Clinic, Rochester, MN; [3]Universidad de Guadalajara, Guadalajara, Mexico; [4]Hospital General Regional No. 46, Instituto Mexicano del Seguro Social, Guadalajara, Mexico; [5]Instituto Mexicano del Seguro Social, Guadalajara, Mexico; [6]Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Mexico.*

Background: There are several factors influencing the outcomes of kidney trasnplantion. It should be noted, that several individual genes are suspected to have a role in the clinical outcome of rejection. One of these candidates, is the insertion/deletion polymorphism, of the angiotensin converting enzyme (*ACE*) gene.

Methods: This work focuses on the role of the insertion/deletion polymorphism of ACE, in the clinical rejection of kidney allografts. We performed an analysis of 166 patients, and looked for a possible association between alleles and genotypes of (I/D) polymorphisms of the *ACE* gene, with episodes of acute rejection and CAN, in patients with kidney transplantation.

Results: In the 166 patients included in the study, the genotype frequencies were heterogenous. We found that 35 patients (21%) were homozygous for the insertion genotype, 80 patients (48%) were heterozygous, and 51 patients (31%) had a homozygous genotype for deletion. Another statistical analysis was performed, in which the control group was considered independently from the four sub-groups of adverse events. We could observe statistically significant differences in the comparison amongst all of the groups (p 0.003) and in the analysis for the generalized additive models (I+ p <0.0001, D+ p 0.029).

Conclusions: No particular allele or genotype of the I/D polymorphism of the ACE can be associated with episodes of acute rejection, or with chronic allograft nephropathy, in patients with kidney allograft transplant. We can also conclude that the Homozygous Deletion allele of the I/D polymorphism, can be associated with toxicity by calcineurin inhibitors, at least in the population studied in this present work.

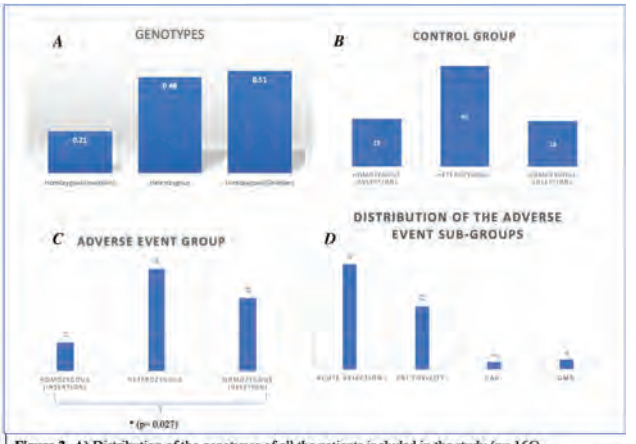

Figure 2- A) Distribution of the genotypes of all the patients included in the study (n= 166) **B)** Distribution of the genotypes of the patients in the control group **C)** Distribution of the genotypes of the patients in adverse event group **D)** Distribution of the sub-groups included in the adverse event group

FR-PO1106

Angiotensin-(1–7) Attenuates Tacrolimus-Induced Apoptosis in Human Renal Proximal Tubular Epithelial Cells

Chang Seong Kim,[1] Hong sang Choi,[2] Eun Hui Bae,[2] Seong Kwon Ma,[1] Soo Wan Kim.[1] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Republic of Korea.*

Background: Tacrolimus (FK-506) is used clinically to reduce the rejection rate in patients with kidney transplantation; however, the nephrotoxicity induced by tacrolimus remains serious clinical problem. Although tacrolimus-induced nephrotoxicity might be involved renin-angiotensin system, but the role of angiotensin-(1–7) [Ang-(1–7)] has not been completely understood. The present study was aimed to investigate the renoprotective effects of Ang-(1–7) in tacrolimus-induced renal tubular injury.

Methods: To investigate the molecular mechanisms underlying tacrolimus-induced renal tubular cell injury, human proximal tubular epithelial (HK-2) cells were treated with tacrolimus (75 μM) in the presence or absence of Ang-(1–7) (1 μM) and Mas receptor antagonist A779 (1 μM). Cell viability was examined using WST-1 assay. Cell cycle arrest was assessed by the protein expression of cyclin B1, phospho-Cdc2 (Tyr 15) and phospho-Histone H3 (Ser 10).

Results: Treatment of tacrolimus decreased cell viability in a dose or time-dependent manner in HK-2 cells. In addition, treatment of tacrolimus decreased the protein expression of cyclin B1, phospho-cdc2 and phospho-Histone H3 in cytosol and nuclear fraction compared with control, indicating that cells arrested at G_0/G_1 phase. Moreover, tacrolimus induced the expression of nuclear factor-κB (NF-κB) signaling, pro-apoptotic markers Bax and cleaved caspase-3 and necrotic cell death marker cleaved PARP1, as well as attenuated the anti-apoptotic marker Bcl-2 in HK-2 cells. However, these changes were attenuated by pretreatment with Ang-(1–7), while co-treatment with A779 abolished the effect of Ang-(1–7). In addition, tacrolimus increased tumor necrosis factor-α converting enzyme (TACE) and decreased angiotensin-converting enzyme 2 (ACE2) expression in HK-2 cells, while pretreatment with Ang-(1–7) or A779 significantly inhibited or enhanced these effects, respectively.

Conclusions: NF-κB signaling and cell cycle arrest at G_0/G_1 phase might be mediated in tacrolimus-induced apoptosis. Also, tacrolimus increased TACE expression, which could mediate the vicious cycle of decreasing ACE2. However, Ang-(1–7) protects the cell viability by suppressing apoptosis and necrosis via Mas receptor in tacrolimus-induced HK-2 cells.

FR-PO1107

Whole Blood vs. Packed Red Blood Cell-Based Perfusate in Normothermic Machine Perfusion of Kidneys

Yilun Wu, Darren Freed, Xiuhua (sue) Wang. *University of Alberta, Edmonton, AB, Canada.*

Background: With a rapidly growing gap between supply and demand for donor kidneys, transplant centres look to utilize extended criteria donors to meet the demand. Normothermic machine perfusion (NMP) is a novel preservation method that offers opportunities for graft evaluation and therapeutic interventions not possible with traditional

hypothermic methods. With higher metabolic demand, NMP requires an oxygen carrier for efficient tissue oxygenation, and the most common choice is packed red blood cells or leukocyte depleted blood. We aim to investigate the effects of whole blood compared to packed red blood cell-based NMP perfusate on graft perfusion and inflammation.

Methods: Porcine kidneys were recovered and perfused with our pressure controlled NMP system for 12 hours. The NMP system is primed with a modified plasmalyte (crystalloid) solution and either whole donor blood or washed donor packed red blood cell. Perfusate is supplemented with heparin, glucose, and insulin over time through infusions. Perfusate and urine samples are collected for analysis throughout perfusion.

Results: Both groups experienced comparable mean renal blood flow consistently over 12 hours of perfusion, with a trend showing increased renal blood flow in whole blood perfusates (whole blood: 719±27.5ml/min; packed red blood cell: 639±28.8ml/min). No significant differences in perfusate pH were detected. Pro-inflammatory cytokines TNF-alpha and IL-6 were significantly increased in whole blood compared against packed red blood cell-based perfusate. Anti-inflammatory cytokine IL-10 was also significantly increased in whole blood compared to packed red blood cell-based perfusate.

Conclusions: Both whole blood and packed red blood cell-based perfusates demonstrated equivalent perfusion resistance and perfusate biochemistry in a porcine model of kidney normothermic machine perfusion. With the presence of leukocytes in whole blood-based perfusates, there was a significant increase in perfusate cytokines, including both pro-inflammatory cytokines TNF-alpha and IL-6 and anti-inflammatory cytokine IL-10. However, the physiological significance of perfusate cytokine presence still requires further study through histological evaluation and a transplant model with long term follow up.

Downregulation of Allograft 25-Hydroxyvitamin D3 1 Alpha-Hydroxylase Is an Early Biomarker for Rejection in Kidney Transplantation

Youli Wang,[1] Andrew Harner,[1] Xuexiu Fang,[1] Todd D. Merchen,[1] Chak-Sum Ho,[2] Daniel T. Kleven,[1] Thomas Z. Thompson,[1] N. Stanley Nahman.[1]
[1]Augusta University, Augusta, GA; [2]Gift of Hope Organ & Tissue Donor Network, Itasca, IL.

Background: 1a, 25(OH)2 vitaminD3 (1a,25VitD3) results from both renal and extrarenal 25-Hydroxyvitamin D3 1 alpha-Hydroxylase (1a-HOase) activity. Renal 1a-HOase is classically associated with mineral metabolism whereas extrarenal 1a-HOase exhibits immunomodulatory effects. Vitamin D deficiency may also be prevalent in the immediate post-transplant period. In the present study, we investigated the relationship between cytokine secretion, graft 1a-HOase expression, renal cortical epithelial cell injury (RCEC), and allograft rejection in a pig model of kidney transplantation and in cultured human RCEC.

Methods: Outbred Yorkshire pigs underwent autotransplants or mismatched allogeneic kidney transplants as we described (Transplant Immunol 42:40). No immunosuppression was used. The vitamin D axis was assessed 72 hours post transplant. The effect of 1a,25VitD3 and 25VitD3 on T cell proliferation and epithelial-mesenchymal transformation (EMT) were investigated using cultured RCEC.

Results: Circulating levels of 1a,25VitD3 and 25VitD3VitD were increased and decreased, respectively, in 30 pigs following auto (n=5) or allotransplantation (n=25). Allograft 1a-HOase was decreased in rejection showing a negative correlation with the extent of rejection (Banff) (r=-0.712 ($p<0.01$), and renal function (BUN (r=-0.706 ($p<0.01$); creatinine (r=-0.673 ($p<0.05$)). Additionally, IL17 and FGF23 were upregulated, and 1, 25-hydroxyvitamin D3 24-hydroxylase was downregulated in rejecting grafts. 1a-HOase was mainly expressed in RCEC. Activating cultured RCEC with cytokines gave a rapid, 10x reduction of 1a-HOase, associated with dramatic decreases of protective E-cadherin (E-cad) and tight junction protein-1 (TJP1), whereas 1a,25VitD3 attenuated cytokine induction of EMT, as well as normalized expression of E-cad and TJP1. When compared to 25VitD3, 1a,25VitD3 exhibited a 50-fold greater suppression of T cell proliferation.

Conclusions: Allograft 1a-HOase expression may predict allograft rejection, not the circulating 1a,25VitD3. Allograft 1a-HOase may play a key role in the prevention of allograft rejection.

Inhibition of Spleen Tyrosine Kinase Decreases Donor-Specific Antibody Levels in a Rat Model of Presensitization

Shenzhen M. Tempest-Roe,[1] Stephen P. McAdoo,[1] Candice Clarke,[1] Maria Prendecki,[1] Esteban S. Masuda,[2] Candice A. Roufosse,[1] H. Terence Cook,[1] David Taube,[1] Charles D. Pusey,[1] Frederick W. Tam.[1]
[1]Imperial College London, London, United Kingdom; [2]Rigel Pharmaceuticals, Inc, South San Francisco, CA.

Background: Antibody mediated rejection (ABMR) is the leading cause of allograft failure post transplantation and there is currently no available effective treatment. Orthotopic kidney allographs from Fischer F344 DU (F344) to Lewis RT1[l] (LEW) rats is a model for chronic allograft nephropathy. The aim of this study was to determine if LEW pre-sensitized with F344 whole blood produced donor specific antibodies (DSA); and whether inhibition of SYK with Fostamatinib had efficacy in reduction of circulating DSA levels.

Methods: Male LEW rats were transfused with whole blood from male F344 rats. Transfused LEW rats were treated with 40mg/kg of Fostamatinib or vehicle by oral gavage twice daily for 14 days from 7 days (early treatment), or 11 days (late treatment) post transfusion. Serum MFI levels for IgG DSA levels were determined on a BD LSRFortessa™ X- 20.

Results: This is the first time F344 to LEW whole blood transfusion has been described as a pre-sensitization model. Transfused LEW rats developed IgG DSA. Early treatment was implemented at onset of IgG antibody production (day 7), and late treatment where IgG antibody production was established and nearing peak levels (day 11) (Fig1a). In our experiments, early treatment with Fostamatinib significantly decreased circulating IgG levels (Fig1b), late treatment, when antibody levels were established was not effective (Fig1c).

Conclusions: In conclusion, we have shown that treatment of pre-sensitized LEW rats with selective SYK inhibitor Fostamatinib at the start of IgG antibody production significantly reduced levels of circulating IgG DSA. Cytotoxic IgG antibodies have a well-established role in ABMR. This indicates a potential use of Fostamatinib as a treatment option for pre-sensitized patients requiring renal transplant or following development of a de novo DSA.

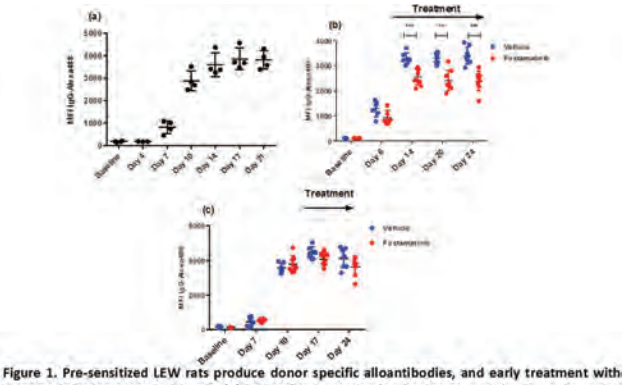

Figure 1. Pre-sensitized LEW rats produce donor specific alloantibodies, and early treatment with Fostamatinib decreases IgG levels. (a) IgG antibody production begins around day 7, peaks at day 17, remaining high at day 21 (n=4). Pre-sensitized LEW rats treated with 40mg/kg Fostamatinib twice daily for 14 days, commencing 7 days post transfusion (b) had significantly decreased IgG levels at days 14, 20 and 24. Late treatment, commencing 14 days post-transfusion did not affect IgG levels (c). Both (b,c) n=7 per group. Error bars represent SD. Results were analysed by the Mann-Whitney U test. (P ** ≤ 0.01, *** P ≤ 0.001).

FR-PO1110

Calcineurin Inhibitors Induce Endoplasmic Reticulum Stress in Kidney Epithelial Cells via PERK- and ATF6-Dependent Mechanisms

Duygu E. Yilmaz, Karin M. Kirschner, Martin N. Thomson, Sebastian Bachmann, Kerim Mutig. *Charité - Universitätsmedizin Berlin, Berlin, Germany.*

Background: Calcineurin inhibitors such as cyclosporine A (CsA) or tacrolimus (Tac) form the core of immunosuppressive regimens in organ transplant recipients but may cause substantial nephrotoxicity with induction of endoplasmic reticulum (ER) stress and maladaptive unfolded protein response (UPR) in kidney epithelia. Calcineurin stimulates the activity of PKR-like ER kinase (PERK), which is an ER stress sensor suppressing protein translation. Calcineurin may also promote ATF6-induced autophagy to alleviate ER stress. We hypothesized that calcineurin inhibition interferes with functions of PERK and ATF6, thereby inducing ER stress and UPR.

Methods: To test this hypothesis, we generated PERK-deficient and ATF6-deficient human embryonic kidney (HEK293) cell lines using CRISPR/Cas9-mediated gene editing. Effects of CsA on expression and cellular distribution of two critical UPR transcription factors, CHOP and spliced XBP1, were monitored using quantitative PCR, immunoblotting and immunofluorescence.

Results: Treatment of control HEK293 cells with CsA (10 μM for 6h) induced a two-fold increase of CHOP abundance and a 70-fold increase of spliced XBP1 abundance in cell lysates. Parallel immunofluorescence analysis showed CsA-induced nuclear translocation of CHOP. In contrast, PERK-deficient and ATF6-deficient cells showed no significant CsA-induced increases of CHOP expression. Stimulation of spliced XBP1 was weaker in PERK-deficient (five-fold increase) and ATF6-deficient HEK293 cells (30-fold increase) compared to control cells. To extend these results, we evaluated effects of Tac in cultured murine distal convoluted tubule (DCT) cells. In this model, treatment with Tac (10 μM for 6h) increased CHOP expression by two-fold but did not affected spliced XBP1.

Conclusions: In sum, these results suggest that calcineurin inhibitors cause ER stress and UPR in kidney epithelial cells, which may in part depend on suppression of PERK or ATF6 functions.

Funding: Government Support - Non-U.S.

FR-PO1111

Blockade of PKCδ in Donor Kidneys Protects Against Cold Ischemia-Reperfusion Injury in Kidney Transplantation

Jiefu Zhu,[2,1] Zheng Dong.[2,1] *[1]Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha, China; [2]Department of Cellular Biology and Anatomy, Medical College of Georgia at Augusta University, Augusta, GA.*

Background: Ischemia-reperfusion injury (IRI) is an inevitable consequence of kidney transplantation. PKCδ has been reported to contribute to mitochondrial pathway of apoptosis during cell stress, but role of PKCδ in kidney IRI remains unknown. This study aims to evaluate the role and regulation of PKCδ in cold storage with renal transplantation.

Methods: C57BL/6 mice kidneys were preserved in an ice bath for 0.5, 4, 8, 10 or 14 hours in University of Wisconsin solution (UWS) and transplanted into syngeneic recipients. Renal injury and regeneration were examined at 24 hours or day 6 after transplantation. The responses of kidneys from wild-type and PKCδ-null mice were examined and compared. Rat proximal tubular cells (RPTC) were exposed to hypothermia at 4°C with UWS incubation and then changed with complete medium in 37°C. Mitochondria morphology was examined under confocal microscopy and mitochondria dysfunction was evaluated by Cytochrome C release and Bax translocation. Active and kinase-dead PKCδ were transfected to determine the role of PKCδ in RPTC cells.

Results: Post-transplant injury in WT kidneys was mild when cold storage time was shorter than 4 hours, but the injury increased notably with 8 hours and longer cold storage. Ki-67+ tubules peaked at 8 hours of cold storage, while longer cold storage suppressed post-transplant tubular proliferation. PKCδ was activated during cold storage as indicated by its phosphorylation at Y-311 and proteolysis. WT kidneys with 10 hours cold preservation showed remarkable damage and tubular apoptosis at 24 hours after transplantation. In comparison, PKCδ-KO kidneys had significant less injury and better tubular proliferation. Furthermore, PKCδ-KO kidneys had improved kidney repair and function as life-supporting kidney at day 6 when native kidneys were removed from recipient. Consistently, pharmacological inhibitors of PKCδ also prevented early post-transplant injury at day 1. In RPTC cells, mitochondrial fragmentation and leakage were involved in cold storage injury. Mitochondrial injury and cell death were inhibited by PKCδ kinase-dead mutant but were aggravated by active PKCδ fragment.

Conclusions: PKCδ is activated during cold storage of donor kidneys and mediates subsequent renal IRI during kidney transplantation. Inhibition of PKCδ may alleviate kidney injury during cold storage and benefit subsequent renal transplantation.

Developing an Imaging Mass Cytometry-Based Injury Panel to Define the Pathogenesis of Delayed Graft Function

Zachary Avigan, Nikhil Singh, Judith Kliegel, Marlene Weiss, Gilbert W. Moeckel, Lloyd G. Cantley. *Yale University School of Medicine, New Haven, CT.*

Background: Delayed Graft Function (DGF) is a significant source of morbidity in transplant patients and is associated with decreased graft survival and increased mortality; however, treatment is restricted by limited mechanistic understanding of its pathogenesis. To better define the cellular architecture of the human kidney, we developed an imaging analysis pipeline using Imaging Mass Cytometry, a novel approach for simultaneous mass spectrometry-based analysis of up to 42 protein targets on formalin-fixed tissue. While antibodies to resident and infiltrating cell populations are in our panel, antibodies to identify cell injury are needed.

Methods: In vitro models were developed for inducing programmed cell death (apoptosis—TNFa, ATP depletion; necroptosis—TNFa, ATP depletion, zVAD) and cell stress (autophagy—serum starvation, TGFb; ER stress—serum starvation, tunicamycin) pathway activation in human proximal tubule HK-2 cells. Antibodies showing specificity by IF were conjugated to heavy metals to be used for IMC.

Results: HK-2 cells showed reduced viability under cell death conditions (control 95.0+/-0.9%; apoptosis 46.3 +/- 5.9%; necroptosis 66.6 +/- 5.9%). Validated antibodies showed significant differences under injury vs control conditions, including: apoptosis (anti-cPARP: 9.5 +/- 2.5% vs 0.8 +/- 0.3%); necroptosis (anti-pMLKL: 17.9 +/- 5.1% vs 2.8 +/- 0.7%); autophagy (anti-P62: 29.8 +/- 7.4% vs 7.1 +/- 1.9%); and ER stress (anti-GRP94: 21.0 +/- 0.6% vs 2.0 +/- 0.7%). All 4 antibodies retained staining by IMC in a tumor-associated interstitial nephritis kidney biopsy.

Conclusions: We now have 35 validated antibodies, including the 4 described above, to simultaneously quantify injured tubular and vascular cell populations and their frequency of interaction with immune subtypes. We will perform IMC with this expanded panel using our cohort of pre-implantation transplant biopsies from 16 deceased donors (7 with subsequent DGF) and 15 living donors as healthy controls.

Funding: NIDDK Support

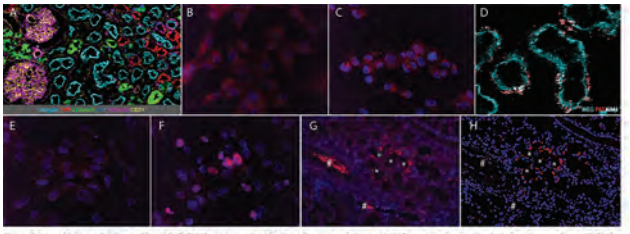

Figure 1. Injury Marker validation by IF and IMC. (A) Illustrative region of a Living Donor sample imaged in IMC, pseudocolored with selected markers as shown. (B-C) IF validation in HK-2 cells of anti-P62 antibody under control (B) and autophagy (C) conditions. (D) IMC image of kidney with tumor-associated interstitial nephritis showing proximal tubule cells co-expressing P62 (red) and KIM1 (white). P62 positive cells also co-expressed LC3B (not shown). (E-F) In vitro IF staining for pMLKL in control (E) and necroptosis-treated (F) cells. (G-H) Human kidney tissue with tumor-associated interstitial nephritis was stained by IF with anti-pMLKL-175Lu (G), followed by IMC ablation of the same region (H), pseudocolored for pMLKL (red) and DNA intercalator (blue). Note corresponding tubules show pMLKL positivity (*), with absence of RBC autofluorescence by IMC (#). Meg – Megalin; THP – Tamm Horsfall Protein.

FR-PO1113

Differential Control of COX-2 Expression in Macula Densa Cells Under Calcineurin Inhibition by Cyclosporine A

Junda Hu, Yan Xu, Kerim Mutig, Sebastian Bachmann. Institut fuer Vegetative Anatomie *Charité-Universitätsmedizin Berlin, Berlin, Germany.*

Background: Calcineurin inhibitors such as cyclosporine A (CsA) are in use as immunosuppressive drugs to prevent rejection of transplanted organs. Despite positive outcomes, side effects such as decreased GFR and overall functional and structural deterioration may affect the kidney. Among the causes, interactions of vasoactive systems have been considered. We therefore studied how CsA may cause dysregulation of key juxtagomerular signaling components.

Methods: Wistar rats received vehicle or 25mg CsA/kg b.w./d for 14d. Organs were perfusion-fixed and embedded for morphology. Cultured macula densa (MD) cells were treated with CsA (5 μM) and angiotensin II (AngII; 1 μM) for 6 or 24h. Tissues or cells were immunohistochemically studied for renin, COX-2, NFAT subtypes 1 to 4, p38 MAPK, CREB, NF-kB, and activating p38 MAPK and CREB phosphorylation. Inhibitors to p38 MAPK (SB203580; 10 μM) and NF-kB (Bay 11-7082; 5 μM) were applied in cells. Cells were also analyzed by PCR and Western blot.

Results: CsA caused the known upregulation of renin and complete downregulation of COX-2. An assumed link between NFAT and COX-2 within MD could not be established. In MD cells, CsA caused a rise in COX-2 abundance at 6 and 24 h (2-fold each); p38 MAPK phosphorylation was increased in parallel (1.9-fold). Inhibition of p38 MAPK attenuated CsA-induced COX-2 upregulation by 50%. Under the same conditions, NF-kB showed nuclear translocation (+50%). Inhibitor to NF-kB (6h) blunted COX-2 stimulation by 35%. CREB phosphorylation was increased 2- to 4-fold with COX-2 stimulation (6h). AngII substantially decreased expression of baseline COX-2 by 40% (6h) and blunted CsA-induced COX-2 stimulation by 30% (6h). All data were significant (min. $p<0.05$).

Conclusions: In sum, calcineurin inhibition by CsA *in vivo* suppressed juxtaglomerular COX-2 independently of NFAT signaling. Contrastingly, cultured MD cells show substantial stimulation of COX-2 upon CsA, involving MAPK, NF-kB, and CREB. Dominant, antagonistic AngII is likely to act on the same signaling cascade. This novel, MD cell-specific regulatory synergism of calcineurin and angiotensin, governing COX-2 biosynthesis, may serve to address juxtaglomerular dysregulation under CsA treatment.

Non-Cultured Adipose-Derived Regenerative Cells Limit Early Inflammation and Fibrosis in Renal Ischemia-Reperfusion Injury

Rashida Lathan,[1] Patrick B. Mark.[1,2] *[1]University of Glasgow, Glasgow, United Kingdom; [2]Queen Elizabeth University Hospital, NHS, Glasgow, United Kingdom.*

Background: Studies in our rat model of ischemic reperfusion injury (IRI) demonstrate improved kidney function post injection of adipose-derived regenerative cells (ADRC). The mechanism on how these cells induce reparative effects during IRI remains elusive. We investigated ADRC-derived effects within the injured kidney at early timepoints.

Methods: Inguinal rat ADRC or vehicle control were injected via the renal artery of the IRI rat model. At 48 hours and 1-week post-ischemia injury, kidney was evaluated for fibrotic and inflammatory markers through qPCR and western blotting of (n=6-8). Leukocyte quantity was assessed by flow cytometry (n=4-5). Histology was used to measure infiltrative lesions and Masson Trichrome stained collagen accumulation (n=8-20).

Results: ADRC-treated kidneys expressed lower levels of inflammatory gene CXCL12 and significantly lower protein levels of granulocyte macrophage colony-stimulating factor (both $p<0.05$). In addition, a consistent increase in cytotoxic T-lymphocyte-associated protein 4 transcript was characteristic of ADRC treated kidneys. At 48 hours post-IRI, half of vehicle controls contained higher levels of CD45+ leukocytes. Assessment of leukocyte infiltrate indicated a trend of higher infiltrate in vehicle control kidneys compared to ADRC kidneys at 48 hours with significant apparent differences by 1-week post IRI ($p<0.05$). Early accumulation of interstitial factors: tissue inhibitor of metalloproteinase-1 ($p<0.05$) and collagen type 1, alpha 2 ($p<0.001$) in vehicle control kidneys indicated early fibrotic development. This was mirrored by significantly high levels of collagen staining in control compared to ADRC treated kidneys at 1-week post IRI ($p<0.001$).

Conclusions: Collectively, gene, protein expression and histological evidence suggest that ADRC treated IRI kidneys experience early anti-inflammatory changes conducive to the inhibition of fibrogenesis.

Alternative M2 Macrophages Activation and TGF-β1 Production Are Induced by TNF-α Through the Adenosine A2A Receptor Pathway

Montserrat M. Diaz Encarnacion,[1] Elena Guillen-gomez,[1] Irene Silva,[1] Nuria Serra,[1] Jose Ballarin,[1] Francisco Caballero,[2] Lluis Guirado.[1] *[1]Fundación Puigvert, Barcelona, Spain; [2]Hospital Santa Creu i Sant Pau, Barcelona, Spain.*

Background: Kidney transplants from deceased donors have a worse prognosis than those from living donors. Early and persistent inflammation may contribute to the development of fibrosis and impact transplant outcome. We showed previously that, in renal tissue from deceased donors, increased expression of A2A adenosine receptor, that could be involved in anti-inflammatory activity and M2 macrophage activation, correlated with inflammatory and anti-inflammatory mediators such as TNF-α and TGF-β1. The aim of this research is to study the association between TNF-α and A2A in macrophage phenotype differentiation.

Methods: THP-1 cells were seeded in the presence of TNF-α at different time-points (3, 6, 18 and 24 hours) and concentrations (5, 10 and 20 ng/ml). Cells were pretreated for 30 minutes with 1 μM of the A2AR antagonist ZM241385 before TNF-α was added and samples were analyzed by Real-time PCR.

Results: TNF-alpha significantly augmented the expression of A2A but not A2B at all points analyzed, reaching the maximum increase at a concentration of 10 ng/ml at 3 hours of treatment ($p<0.001$). TNF-α also induced the expression of TGF-β1 and the M2 marker CD163 at 18 and 24 hours (figure 1A). Interestingly, the expression the M1 macrophage marker CD86 decreased with TNF-α treatment. Pretreatment with ZM241385 abolished the effect of TNF-α over CD163 (figure 1B) and TGF-β1, providing evidence that A_{2A} receptor is involved in M2 macrophage activation by TNF-α. In fact, induction of CD163 expression by IL-10 ($p=0.0006$) was partially but significantly blocked by ZM241385 (31.4% increase blocked, $p=0.018$). We did not detect any effect of IL-10 on TGF-β. The decrease in CD86 does not seem to involve the A2A purinergic pathway.

Conclusions: Our results suggest TNF-alpha induces macrophage M2 switching and TGF-β1 expression through A2a receptor activation.

Funding: Government Support - Non-U.S.

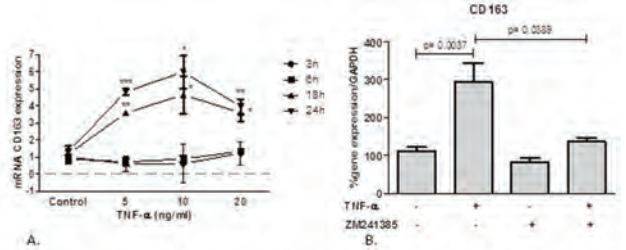

Figure 1. Expression of the M2 macrophage marker CD163 in THP-1 cells. (A) CD163 was increased by TNF-α at time-points and concentrations indicated. (B) Induction of CD163 by TNF-α was blocked by A2A receptor antagonist ZM 241385.

Dual Treatment of CD40 Silencing or Mesenchymal Stem Cells Infusion with Sub-Therapeutic Doses of Cyclosporine Effectively Prevents Acute Rejection in an Allogenic Model of Renal Transplantation

Jordi Guiteras,[1] Laura De ramon,[1] Nuria Bolanos,[1] Marcela Franquesa,[3] Montse Goma,[2] Nuria Lloberas,[1] Oriol Bestard,[2] Josep maria Grinyó,[2] Juan Torras.[2] *[1]IDIBELL, Hospitalet de Llobregat, Spain; [2]Bellvitge Hospital, Barcelona, Spain; [3]Hospital Germans Trias i Pujol, Badalona, Spain*.

Background: Previous studies in our group, showed partial protective effect of costimulatory silencing with a siRNA-CD40 or MSC infusion in life sustaining model of rat renal allograft transplant. This study was designed to investigate the combination of CD40 silencing or MSC infusion with suboptimal doses of Cyclosporine in this renal allograft model.

Methods: In this model, rats were randomly allocated into different groups: Non-Treated (n=10); Scrambled siRNA (n=10); Cyclosporine (control full dose, 5 mg/kg/day) (n=9); CsA1/2 (sub-therapeutic, 2.5 mg/kg), (n=5); MSC, group treated with two MSC doses at day -7 and day 0 (n=8); siRNA-CD40 (500 ug), (n=5); CsA1/2+siRNA-CD40 group (n=5) and CsA1/2+MSC group (n=8). Heterotopic renal transplantation was performed from Wistar to Lewis rats, with 21 days of follow up. Survival, renal function, conventional histology and immunohistochemistry (CD68 cells, CD3 cells, glomerular and peritubular capillary C4d) were analyzed in all groups.

Results: Monotherapy either with CsA1/2, siRNA-CD40 or MSC showed slight improvement in all the studied parameters compared with Non-treated or Scrambled groups. The combined therapy using CsA1/2+MSC or CsA1/2+siRNA-CD40 displayed significant amelioration of these parameters compared to monotherapy groups. Interestingly, the CsA1/2+siRNA-CD40 group presented a clear reduction of glomerular and peritubular C4d deposition and the degree of CD3 infiltrate, reaching similar values to Cyclosporine full dose group.

Conclusions: In conclusion, siRNA or MSC combined with sub-therapeutic doses of Cyclosporine offered better prevention in allograft rejection and survival than monotherapy groups. But was the CsA1/2+siRNA-CD40 group that gave the greatest prevention both in the cellular and humoral arms, perhaps by an additive effect.

Contrasting Effects of Conventional Immunosuppressants in Establishing Murine Transplantation Tolerance

Haruki Katsumata,[2,1] Satoshi Miyairi,[2] Toshihito Hirai,[3] Kan Saiga,[3] Masayoshi Okumi,[4] Yasuyuki Ishii,[5] Takashi Yokoo,[1] Kazunari Tanabe.[4] *[1]The Jikei University School of Medicine, Minato-ku, Japan, Japan; [2]Urology, Tokyo Women's Medical University, Tokyo, Japan; [3]Tokyo Women's Medical University, Menlo Park, CA; [4]Tokyo Women's Medical University, Shinjuku, Japan; [5]REGiMMUNE Corporation, Tokyo, Japan*.

Background: Tacrolimus (TAC) is one of the most commonly used calcineurin inhibitors (CNIs) for immunosuppression maintenance after kidney transplantation. It inhibits immune responses by suppressing T-cell receptor signaling and downstream expression of interleukin-2. An inhibitor of the mammalian target of rapamycin (mTOR-I) such as everolimus (EVL) shows immunosuppressive activity by inhibiting other pathways. Since, regulatory t cells (Treg) function depends on interleukin-2 signaling, CNIs could affect their suppressive potentials. However, mTOR-I has a weaker effect on Treg proliferation. We previously reported an approach to induce mixed chimerism by stimulating invariant natural killer T cells with liposomal formation of alpha-galactosylceramide (RGI-2001) and CD40 ligand (CD40L) blockade. We evaluated the impact of TAC or EVL on chimerism establishment and Treg in this regimen.

Methods: Recipient mice were treated with either TAC or EVL from day 1 to day 14 after bone marrow transplantation from donor mice, in addition to the regimen using sublethal irradiation, and a single injection of RGI-2001 and anti-CD40L antibodies. Then, we analyzed the proportion of donor cells and Treg in peripheral blood mononuclear cells. Isolated Treg were co-cultured with the mixture of host T cells and T-activator CD3/CD28 beads. After 4-day culture, the proliferation of responder cells was analyzed.

Results: In immunosuppressive drug-dosing phase, chimerism was comparably enhanced by TAC and EVL. Following drug discontinuation, TAC-treated mice exhibited a gradual decrease in the donor cell proportion. In contrast, EVL-treated mice sustained long-term robust chimerism. Treg of TAC-treated mice showed lower prolifration and low suppressive activity than EVL-treated mice.

Conclusions: TAC negatively impacted the regimen by interfering with Treg proliferation and activation.

Anti-CD40 (Iscalimab) Treatment Results in Preserved Allograft Histology in Non-Human Kidney Transplantation Compared with Calcineurin Inhibitors

James Rush,[1] Grazyna Wieczorek,[1] Michael J. Mihatsch,[3] Melanie Ceci,[1] Ulrike Naumann,[1] Enrico Ferrero,[1] Boerje Haraldsson.[2] *[1]Novartis Institutes for Biomedical Research, Basel, Switzerland; [2]Novartis Pharma AG, Basel, Switzerland; [3]University Hospital Basel, Basel, Switzerland*.

Background: The CD40-CD154 costimulatory pathway has been implicated in the pathology of transplant rejection, and blockade of this interaction using anti-CD40 antibodies significantly prolongs renal allograft survival in non-human primates (NHPs). Further, recent clinical data indicated that the anti-CD40 mAb Iscalimab (CFZ533) demonstrated comparable efficacy and superior renal function versus tacrolimus in de novo calcineruin inhibitor (CNI)-free kidney transplantation. One possible explanation for superior renal function was that Iscalimab treatment may have resulted in improved graft quality compared to CNIs, a notion supported by data from a small number of patients from the aforementioned clinical study.

Methods: To further examine this notion, allograft histology from baseline and up to one hundred days post-transplanted NHP kidney allografts from transplanted animals treated with Iscalimab, anti-CD154 mAb, Cyclosporine A, PKC inhibitors or FTY720 were reviewed and scored in a blinded fashion by a pathologist according to the Banff classification.

Results: In addition, we performed molecular analyses of these samples. Our analyses indicated that the quality of allografts as defined using total, inflammatory and fibrotic BANFF scores, from Iscalimab treated animals were superior to that observed in animals dosed with all other immunomodulatory and immunosuppressive agents. This was also reflected in the molecular analyses of allograft biopsies showing that CFZ533 was more likely to preserve the gene expression profile of baseline tissue following transplantation compared to other drugs.

Conclusions: Collectively our data indicated that prevention of allograft rejection by Iscalimab appears to be associated with higher graft quality compared to other drugs, including CNIs.

T Cell-Specific miR-17-92 Knockout Improved Skin Graft Tolerance by Modulating T Follicular Helper Cell Development and Regulatory T Cell Activity

Huang-Yu Yang. *Chang Gung Memorial Hospital, Taoyuan, Taiwan*.

Background: T follicular helper (T_{FH}) cell provide crucial growth signals to germinal center (GC) B cells supporting antibody production. Tight control of T_{FH} numbers maintains self-tolerance. Regulatory T (Treg) cells play a critical role in maintaining self-tolerance and controlling the magnitude of physiologic immune response. The Treg transcription factor forkhead box P3 (Foxp3) works in concert with other co-regulator molecules to determine suppressive phenotype of Treg. MicroRNA-17-92 (MiR-17-92) has been shown in our previous study to regulate the suppressive effect of Treg on mice EAE models. The knockout of Mir-17-92 increase the immunosuppressive activity of Treg.

Methods: We generated T cell specific miR-17-92 knockout (miR-17-92-/-) mice, followed by skin transplantation. B6 miR-17-92 -/- and B6 wild type littermates were used as recipients of *BALB/c* skin grafts. By bioinformatics study, possible targets of mir-17-92, related to Treg function was evaluated. In addition, we performed a MLR (mixed lymphoid reaction) by co-culture donor APC with recipient derived T cells.

Results: The sirolimus-treated, miR-17-92 -/- mice showed less TFH cells, less GC B cells and the less plasma cells as compared with those in the sirolimus-treated, wild type mice. Consistent with the reduction germinal center response, skin histological analysis revealed a lower mean histopathology score. Moreover, miR17-92 knockout enhance the suppression function of Tregs. Th1 and Th17 are decreased in the miR-17-92 -/- mice.

Moreover, T cells from miR-17-92 -/- mice demonstrated a donor antigen-specific hyporesponsiveness in vitro MLR.

Conclusions: We found that the skin graft survival was significantly better in the sirolimus-treated, miR-17-92 -/- mice, unveiling the future therapeutic potential of microRNA manipulation in transplantation.

Examination of a Novel Emerging Immune Checkpoint in Kidney Transplant Recipients

George J. Kavalam, Amar D. Desai, Anil K. Chandraker, Sudipta Tripathi. *Brigham and Women's Hospital, Boston, MA.*

Background: The balance between T-cell immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domain (TIGIT) and its co-receptor CD226 function as an 'immune checkpoint' with immunomodulatory functions in both T and NK cells. Immunomodulation is mediated through the balance of TIGIT/CD226 binding with the ligands CD155/CD112. Interaction of CD226 with the ligands CD155 and CD112 co-stimulates T cell, whereas TIGIT exerts the opposite effect and inhibits T cell response. This ligand/receptor network plays an important role in various autoimmune diseases and cancer, but its role in transplantation remains unclear. We examined the expression levels of TIGIT, CD226 and their ligands CD155 and CD112 in kidney transplant recipients (KTR) and healthy controls (HC) to understand the relevance of TIGIT/CD226 co-signaling in transplantation.

Methods: Blood samples were collected from 23 HC and 68 KTR and cell surface expression of CD226, TIGIT, CD155 and CD112 and other cell markers on peripheral T and NK cells were determined by flow cytometry.

Results: We observed that in the KTR group both T and NK cell populations showed a significant decrease in TIGIT and an increase in CD226 expression compared to HC. Interestingly, in the KTR $CD4^+$ T cells showed a significant increase in CD226 expression whereas $CD8^+$ T cells showed a significant decrease in TIGIT expression. Both these changes lead to an increase in IFN-γ production and a pro-inflammatory environment. The predominant peripheral $CD16^+$ NK cells also showed an inflammatory phenotype with both increased CD226 expression and decreased TIGIT expression and also showed a significant increase in the expression of both the ligands CD155 and CD112 in comparison to HC.

Conclusions: Increased expression of CD226 in both T and NK cells and increased expression of its ligands CD155 and CD112 on NK cell populations were observed in KTR, suggesting a pro-inflammatory phenotype and a pluasible NK-T cell-cell interaction in the periphery. The TIGIT/CD226 axis members are potential targets for reducing the alloimmune response mediated by T and NK cells.

Dissecting the Role of Adipocyte Na-K-ATPase Signaling in Attenuating Experimental Uremic Cardiomyopathy by Adipose Tissue Transplantation

Komal Sodhi. *Marshall University Joan C. Edwards School of Medicine, Huntington, WV.*

Background: Adipocytes contribution to systemic disease has become an important topic. We have recently demonstrated that administration of NaKtide, antagonist of Na/K-ATPase (NKA) signaling, coupled to adipocyte specific promoter adiponectin can improve adipocyte phenotype. In experimental uremic cardiomyopathy, uremic toxin exposure of adipocyte will generate ROS, subsequently activating adipocyte NKA signaling and causing adipocyte dysfunction, cytokine production, and systemic oxidative stress. Studies have shown that transplanting brown adipose tissue from C57BL6 mice reduced obesity and improved whole energy metabolism. Based on these observations, we hypothesize that the transplantation of NaKtide transfected subcutaneous fat tissues into mice with partial nephrectomy (PNx) will improve adipocyte phenotype and attenuate uremic cardiomyopathy.

Methods: Following 4 weeks of PNx or Sham surgery and lenti-adiponectin-Naktide treatment, 300mg of fat pads (Sham, Sham+NaKtide, and PNx+NaKtide groups) were subcutaneously transplanted into strain- and age- matched donor littermates in the dorsal interscapular region of PNx mice. Following 4 weeks after transplantation, tissues were harvested for morphological and molecular analyses.

Results: Histological analysis of cardiac tissue shows increased fibrosis with PNx, which was decreased with transplantation of adipose tissue from mice treated with NaKtide ($p \leq 0.01$). PNx mice developed cardiomyopathy characterized by increased heart weight and decreased cardiac function, assessed by echocardiography measurements, as compared to Sham operated mice ($p<0.01$). These alterations were reversed in PNx mice, by the transplantation of NaKtide transfected adipose tissues from PNx+NaKtide donor mice ($p<0.01$). Our results also showed that NaKtide transfected adipose tissue from PNx+NaKtide mice, transplanted to PNx recipient mice improved glucose tolerance, hematocrit levels and levels of plasma inflammatory cytokines, including TNFα, IL-6 and MCP-1.

Conclusions: Our study demonstrates that adipocytes contribute to the oxidant stress associated with uremic cardiomyopathy by activation of NKA signaling, which is improved by the subcutaneous fat transplantation transfected with NaKtide. These data suggest that the adipocyte NKA signaling may be a viable clinical target for the prevention or treatment of uremic cardiomyopathy.

Human Donor-Specific Regulatory T-Cell Line Function Is Mediated Through the Adenosinergic Pathway

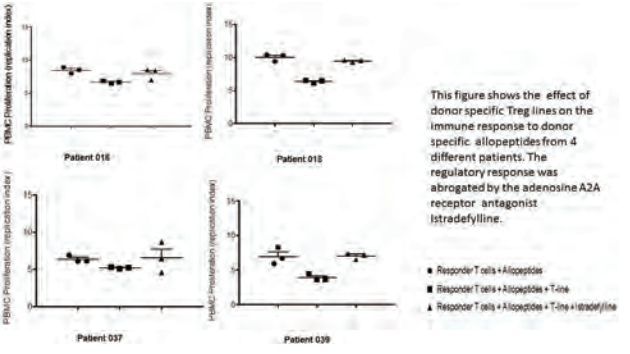
Paloma L. Martin Moreno,[1,2] Sudipta Tripathi,[1] Prof. dr. ana maria Waaga-Gasser,[1] Anil K. Chandraker.[1] *[1]Transplantation Research Center, Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Nephrology Department, Clinica Universidad de Navarra, Instituto de Investigación Sanitaria de Navarra (IdiSNA), Pamplona, Spain.*

Background: We have previously shown that regulatory T cell lines generated and expanded from transplanted individuals have the capacity to induce longterm allograft survival in an animal model and suppress human donor specific effector T cell responses *in vitro*. In murine models targeting the CD39/73 adenosinergic pathway is associated with long-term graft function and reduced graft versus host disease severity. Little is known about the role of this pathway in human regulatory T cells.

Methods: 45 Kidney transplant recipients were included in the study and 19 T-cell lines were generated from 17 patients by stimulating PBMCs with mismatched donor-derived HLA-DR allopeptides. T-cell lines were immunophenotyped with fluorphore conjugated human anti-CD39 and anti-CD73 and analyzed using Flowjo. Involvement of the adenosinergic pathway by using Adenosine A2A receptor (A2Ar) antagonist.

Results: The functional characterization of the *ex vivo* expanded T-cell lines was determined by assessing their immunosuppressive function to inhibit antigen specific and non specific T cell proliferation. We observed that all *ex vivo* expanded T-cell lines were able to substantially inhibit donor antigen specific T cell proliferation. Expression of both CD39 and CD73 in our T-cell lines, both related to the adenosinergic pathway. Inhibition using the A2Ar antagonist Istradefylline resulted in abrogation of suppression and increase in antigen specific T cell proliferation (Figure).

Conclusions: Our results suggest that the CD39/CD73 adenosinergic pathway is important in the function of regulatory T cells and therapies targeting CD39 and CD73 may enhance human regulatory T cell function.



FR-PO1123

Increased Mitochondrial Metabolic Enzymes Are Associated with Superior Kidney Function After Normothermic Ex Vivo Kidney Perfusion: A Proteomics Study

Caitriona M. McEvoy,[1] Sergi Clotet Freixas,[1] Tomas Tokar,[6] Ihor Batruch,[7] Shelby Reid,[5] Chiara Pastrello,[1] Peter Urbanellis,[2] Lisa Robinson,[3] Markus Selzner,[4] Ana Konvalinka.[1,2] *[1]University Health Network, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]The Hospital for Sick Children, Toronto, ON, Canada; [4]Toronto General Hospital, Toronto, ON, Canada; [5]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [6]Princess Margaret Cancer Centre, Toronto, ON, Canada; [7]Mount Sinai Hospital, Toronto, ON, Canada.*

Background: Normothermic ex-vivo kidney perfusion (NEVKP) is associated with significantly improved graft function following transplantation in comparison to static cold storage (SCS). We hypothesized that NEVKP would induce key alterations in the kidney proteome compared to SCS, and provide insights into the molecular mechanisms central to superior graft function.

Methods: Porcine kidneys were removed following 30 minutes of warm ischemia, and then subjected to either SCS or NEVKP (n=5 each) for 8 hours prior to auto-transplantation. Kidney biopsies were collected at time zero, upon reperfusion, and at POD3. We conducted an unbiased proteomics analysis by LC-MS/MS on Q-Exactive-Plus mass spectrometer. Subsequent analyses were performed using MaxQuant, Perseus, R, pathDIP, mirDIP, and NaVIGATOR.

Results: Kidney function was significantly improved with NEVKP compared to SCS with higher creatinine clearance on POD3 (F-test, $p < 2.2 \times 10^{-15}$). We identified 6354 proteins in total (FDR<0.01), with 70 proteins significantly differentially expressed between experimental groups and time points (2-way ANOVA, $p<0.05$). Gene ontology and pathway enrichment analyses revealed that the proteins increased in NEVKP were significantly associated with the preservation of metabolic processes such as fatty acid ß-oxidation, the TCA cycle and oxidative phosphorylation (e.g. CPT2, MPC2, ETFB, COX4I1). Additionally, proteins associated with the maintenance of adherens junctions and the actin cytoskeleton (e.g. CGNL1, PDLIM4) were enhanced in NEVKP in contrast to SCS. Proteins increased in SCS were associated with RNA binding and protein translation.

Comparison with external datasets of ischemia reperfusion injury, and datasets relating to other models of acute and chronic kidney injury confirmed that many of the molecular changes observed in these datasets are expected to be reversed or attenuated by NEVKP.

Conclusions: The proteome-level changes associated with NEVKP demonstrate that the preservation of major metabolic pathways, and of cell polarity and integrity may be pivotal mechanisms by which NEVKP results in improved graft function.

FR-PO1124

Role of Interferon-γ Associated Chemokines and FOXP3+ T Cells in BK Virus Nephropathy

Sneha Shrestha,[1] Essa Abuhelaiqa,[3] Catherine Snopkowski,[1] John R. Lee,[3] Steven Salvatore,[1] Michelle L. Lubetzky,[2] Thangamani Muthukumar,[1] Surya V. Seshan,[3] Manikkam Suthanthiran,[1] Darshana Dadhania.[1] *[1]Weill Cornell Medical College, New York, NY; [2]Division of Nephrology and Hypertension, New York, NY; [3]Weill Cornell Medical Center, New York, NY.*

Background: BKV reactivation has been associated with increased expression of interferon-γ (IFNγ) induced chemokines and increased levels of granzyme B, cytotoxic T cell molecule. Histological findings of BK virus nephropathy (BKVN) have been compared to those with acute cellular rejection (ACR) but the role of FOXP3 has not been studied. We hypothesized that heightened expression of IFNγ associated chemokines and lower expression of FOXP3 would be prognostic of 3-year outcomes in BKVN.

Methods: To address this hypothesis, we studied absolute mRNA copies of MIG, IP-10, CD3, granzyme B, FOXP3 and 18SrRNA in biopsy matched urine cell pellets of 53 BKVN and 33 ACR patients using a standard curve method in real-time quantitative PCR assay. Continuous variables were compared using Mann-Whitney test and logistic regression was used to determine if urine mRNAs were predictive of graft loss in BKVN patients.

Results: We found that urinary cell mRNA for interferon-γ inducible chemokines IP-10 was higher and mRNAs for CD3, GB and FOXP3 were lower in BKVN cohort compared to ACR cohort. Ratio of IP-10/CD3 mRNA in urinary cells was significantly higher in BKVN cohort versus ACR cohort. Urinary cell mRNA for IP-10, MIG and GB were associated with increased risk of 3 year graft loss.

Conclusions: We conclude that BKVN is associated with increased levels of IP-10 and lower levels of CD3 as compared to ACR and the ratio of IP10/CD3 mRNA can be used to distinguish inflammation associated with BKVN from that of ACR. Urinary cell mRNA levels of IFNγ associated chemokines are associated with 3-year graft loss.

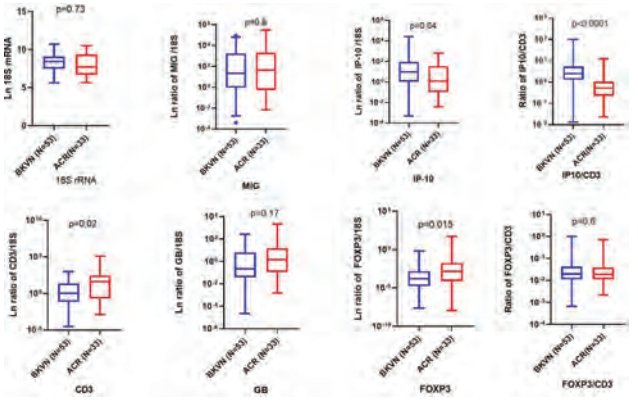


Table 1: Association of urine mRNA profiles with graft loss at 3 years following BKVN

	Odds Ratio	95% CI	P-value
Ln (IP10/18S)	1.55	1.0-2.43	0.04
Ln (MIG/18S)	1.32	1.0-1.81	0.05
Ln (CD3/18S)	1.21	0.84-1.76	0.28
Ln (GB/18S)	1.65	0.94-2.04	0.08
Ln (FOXP3/18S)	1.23	0.81-1.8	0.3

FR-PO1125

Proteomics of Laser-Captured Microdissected Glomeruli and Tubulointerstitium Reveals Extracellular Matrix Remodelling of Kidney Allografts with Antibody-Mediated Rejection

Sergi Clotet Freixas,[1] Caitriona M. McEvoy,[1] Ihor Batruch,[1] Max Kotlyar,[1] Chiara Pastrello,[1] Julie Anh Dung Van,[1] Andrea Bozovic,[1] Vathany Kulasingam,[1] Pei Xuan Chen,[1,2] Andrzej Chruscinski,[1] Rohan John,[1] Ana Konvalinka.[1] *[1]University Health Network, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada.*

Background: Kidney transplantation is the optimal treatment for end-stage kidney disease, but most grafts fail prematurely. Antibody-mediated rejection (AMR) accounts for >50% of graft loss. AMR is caused by antibodies against HLA and non-HLA antigens in two main renal compartments: glomeruli and tubulointerstitium. We hypothesized that compartment-specific proteome alterations may uncover the mechanisms of early antibody-mediated injury.

Methods: We performed laser-capture/microdissection to isolate glomeruli and tubulointerstitium from FFPE kidney biopsies, and subjected samples to proteome analysis. We compared 7 biopsies with AMR with 23 matched 'non-AMR' biopsies with T-cell rejection or acute tubular necrosis. Primary human glomerular microvascular endothelial cells (HGMEC) were studied *in vitro*.

Results: We identified 2026 proteins in glomeruli and 2399 in tubulointerstitium (FDR=0.01). 120 proteins were differentially expressed ($p<0.05$) in AMR vs. non-AMR glomeruli and 180 in the tubulointerstitium. Proteins involved in HLA-mediated antigen presentation were increased in AMR. Proteins decreased in AMR were basement membrane components, and belonged to processes such as extracellular matrix (ECM) and cytoskeleton. Reduced glomerular protein levels of LAMC1, NPHS1, and PTPRO in AMR was verified by immunostaining. Levels of ECM proteins correlated directly and significantly ($R>0.7$; $p<0.05$), suggesting co-regulation in AMR. Protein expression of CCT8 (cytoskeleton dynamics) and CALU (protein folding) significantly and directly correlated with histological features of AMR, namely glomerulitis and peritubular capillaritis ($q=0.017$). Protein-protein interaction and pathway analysis of our glomerular protein signature revealed enrichment of inflammatory pathways, such as IL-8 signaling. Stimulation of HGMECs with anti-HLA class I antibody increased the secretion of IL-8 and MCP-1 cytokines.

Conclusions: Basement membranes are often remodeled in late chronic AMR and are the targets of non-HLA antibodies, suggesting that our findings may represent early, important alterations in AMR. Targeting early ECM changes in AMR may represent a new therapeutic opportunity.

FR-PO1126

A Proteomic Atlas Depicting the Changes in Small Urinary Extracellular Vesicles Throughout Kidney Transplantation

Fabian Braun,[1,3] Markus M. Rinschen,[2,3] Denise Buchner,[3] Katrin Bohl,[3] Ingo Plagmann,[3] Bernhard Schermer,[3] Andreas Beyer,[3] Thomas Benzing,[3] Roger Wahba,[3] Dirk L. Stippel,[3] Christine E. Kurschat,[3] Roman-Ulrich Mueller.[3] *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]The Scripps Research Institute, La Jolla, CA; [3]University of Cologne, Cologne, Germany.*

Background: Extracellular vesicles (EVs) have come into the research focus of many life sciences. Urinary EVs, specifically since they can be collected noninvasively, hold the prospect of harboring valuable biomarkers to complement renal biopsies. We aimed to establish a concise atlas of the urinary EV protein content and its changes during living donor transplantation as a resource for the investigation of biological processes and biomarker identification.

Methods: We employed a protocol of differential highspeed- and ultracentrifugation for the separation of small urinary EVs (suEVs) of 22 recipient-donor pairs collected on day -1 (donor sample), 0, 1 as well as 3 and 12 months after transplantation (recipient samples). Quantitative mass spectrometry was used to detect the suEV proteome with subsequent GO analysis to define the involved and changing biological processes. We used linear regression models to correlate the proteomic data set with transplant function 6 and 12 months after transplantation. The resulting candidate proteins were validated in a targeted proteomic analysis of additional 22 recipient-donor pairs sets.

Results: More than 1700 unique proteins were identified in ≥50% of the initial sample set. The single samples depicted a clear clustering by time point of urine collection with specific proteomic time course patterns apparent over the course of transplantation when analyzing the mean protein intensities per time point. Specifically, we detected a decrease in membrane trafficking and increased complement components directly after transplantation. Linear regression models identified a list of 64 candidate proteins with a correlative potential for renal function (eGFR) 6 and 12 months after transplantation. The performed validation experiments showed the abundance of one protein - PEPCK – to be a potential predictor of allograft eGFR after 12 months.

Conclusions: We present the first concise atlas of the changes in the human suEV proteome throughout living donor kidney transplantation. This data set serves as a valuable resource for the investigation of both the biological processes affected by renal transplantation and the identification of potential biomarkers as indicated by our first correlation analyses.

FR-PO1127

DNA Methylation Profiling Reveals Epigenetic Differences Before and After Acute Rejection-Induced Allograft Dysfunction

Chaohong Zhu, Hong Jiang, Jianghua Chen. *Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*.

Background: The incidence of acute rejection (AR) has declined to <15% in the first year after renal transplantation but remains a risk factor for allograft nephropathy and determination of allograft fate. DNA methylation regulates gene expression and persists after removal of the stimulus. Here, we analyzed dynamic changes in the methylation landscapebefore and after AR-induced allograft dysfunction.

Methods: In this two-cohort study, we followed-up with identical patients who successively experienced end-stage renal disease, renal transplantation with allograft function or dysfunction, and final hemodialysis. Peripheral blood mononuclear cells from the same patients were collected at different time points and used for mircoarray analysis of changes in DNA-methylation status.

Results: In contrast to the allograft-stable cohort, AR accelerated changes in DNA-methylation patterns. Pathway analysis revealed that hypermethylated areas associated with genes were related to T cell receptor, nuclear factor-kappa B, and mammalian target of rapamycin signaling in the AR-induced allograft-dysfunction group, which differed from pathways associated with hypomethylated areas. Moreover, AR altered the methylation status of genes related to epigenetic modification, and in a mouse model of AR, the DNA-methyltransferase inhibitor decitabine ameliorated renal allograft-related inflammatory injuries by enhancing regulatory T cell activities through inhibiting DNMT1 and suppressing T helper 1/2/17.

Conclusions: These results revealed that AR after renal transplantation reshapes the DNA-methylation landscape, with hypermethylated genes associated with AR, and suggested inhibition of DNA methylation as a potential therapeutic approach for AR after organ transplantation to improve allograft survival.

FR-PO1128

Calcium Release-Activated Calcium (CRAC) Channel Inhibitor BTP2 Blocks IL2 and CD25 Expression in Human Peripheral Blood Mononuclear Cells

Divya Shankaranarayanan,[1] Milagros T. Lagman,[1] Vijay K. Sharma,[1] Carol Y. Li,[1] Michael F. Cassidy,[1] Brittany Botticelli,[1] Catherine Snopkowski,[1] Hua Yang,[2] Thangamani Muthukumar,[1] Khaled Machaca,[3] Manikkam Suthanthiran.[1] Weill Cornell Medicine, New York City *[1]Weill Cornell Medicine, New York, NY; [2]Weill-Cornell, New York, NY; [3]Weill Cornell Medicine, Doha, Qatar*.

Background: CRAC channels are essential for the signaling of cells via calcineurin. BTP2, a tri-fluoro methyl pyrazole has been found to be a selective blocker of CRAC channels, prevents calcineurin activation and subsequent import of dephosphorylated NFAT into the nucleus in cell lines. In a search for a new type of calcineurin inhibitor, we investigated whether BTP2 inhibits calcineurin activation dependent expression of IL-2 and IL-2R alpha (CD25) by normal human peripheral blood mononuclear cells (PBMC).

Methods: PBMC isolated from healthy volunteers (N=4), were incubated alone, with 2ug/ml phytohemagglutinin (PHA) or with PHA + 1000nM BTP2 for 16 hours at 37C in 5% CO2. The cells were retrieved and analyzed by two methods: (i) Single cell Flow cytometry by labelling the cells with CD3-PE and CD25-FITC antibodies and (ii) Pre-amplification enhanced real time quantitative PCR (RT qPCR) to quantify the absolute copy numbers of mRNA encoding IL2 and CD25.

Results: BTP2 was a potent inhibitor of PHA induced expression of IL2 mRNA (Figure 1) and CD25 mRNA (Figure 2). In accord with its effect on CD25 mRNA, BTP2 inhibited the induced expression of CD25 protein as assessed at the single cell level by flow cytometry (Figure 3A & 3B).

Conclusions: To date, the effect of CRAC channel blockade with BTP2 has been studied in rat models and cell lines. We established normal human PBMC cell culture to investigate the effect of BTP2 and demonstrate that BTP2 reduced IL2 and CD25 expression in human PBMC. These inhibitory effects would effectively block T cell clonal expansion, a prerequisite for allograft rejection. CRAC channel blockade represents a novel strategy for immunosuppression.

AKI in Renal Transplant Recipients Undergoing Cardiac Surgery

Gregory L. Hundemer,[1] Anand Srivastava,[2] Shreyak Sharma,[4] John A. Kellum,[3] Leonardo V. Riella,[4] David E. Leaf.[4] *[1]The Ottawa Hospital, Ottawa, ON, Canada; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]University of Pittsburgh, Pittsburgh, PA; [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA*.

Background: Acute kidney injury (AKI) is a key risk factor for chronic kidney disease in the general population, but few studies have assessed AKI among renal transplant recipients (RTRs). Moreover, most studies of AKI among RTRs focused on AKI occurring in the immediate peri-transplant period, included heterogenous (or unknown) causes of AKI, and relied on diagnostic/billing codes rather than granular patient-level data. We conducted a detailed investigation into the incidence, severity, and risk factors for AKI following cardiac surgery among RTRs.

Methods: We queried electronic medical records of >20,000 cardiac surgeries at two major academic medical centers in Boston, MA, from 2005-2018. We identified 83 RTRs and matched them 1:1 to non-RTRs by age, preoperative eGFR, and type of surgery. We used multivariable logistic regression to adjust for potential confounders. AKI and its severity were defined according to KDIGO criteria.

Results: RTRs had a higher rate of AKI following cardiac surgery compared to non-RTRs (46% vs. 28%; adjusted OR 2.77 [95% CI, 1.36 to 5.64]). Among RTRs, deceased donor (DD) vs. living donor (LD) status, as well as higher vs. lower preoperative calcineurin inhibitor (CNI) trough levels, were associated with higher rates of AKI (57% vs. 33% for DD-RTRs vs. LD-RTRs, P=0.03; 73% vs. 36% for RTRs with higher vs. lower CNI trough levels, P=0.02). The combination of both risk factors (DD status and higher

CNI trough level) had an additive effect (88% AKI incidence among patients with both risk factors vs. 25% incidence among RTRs with neither risk factor, P=0.004).

Conclusions: RTRs have a higher risk of AKI following cardiac surgery compared with non-RTRs with otherwise similar characteristics. Among RTRs, DD-RTRs and those with higher preoperative CNI trough levels are at highest risk.

Transcatheter vs. Surgical Aortic Valve Replacement in US Renal Transplant Patients

Charles A. Herzog,[1,2] James B. Wetmore,[1,2] David T. Gilbertson.[1,2] Chronic Disease Research Group [1]*Chronic Disease Research Group, Minneapolis, MN;* [2]*Hennepin Healthcare /University of Minnesota, Minneapolis, MN.*

Background: Renal Transplant (RT) patients are a high risk group for surgical aortic valve replacement. Few data exist on the comparative outcome of renal transplant patients with aortic stenosis receiving transcatheter (TAVR) vs. surgical (SAVR) aortic valve replacement.

Methods: The CMS 100% ESRD files from 2013-2015 were used to find RT patients receiving TAVR or SAVR, and to compare inpatient death and adjusted 1-year mortality. The cohort comprised patients receiving TAVR or SAVR 1/1/2013-12/31/2014. Patients with endocarditis or multivalve SAVR were excluded. A six-month period prior to the valve replacement procedure was used to assess comorbidity from claims. Post-discharge mortality rates were estimated and Cox proportional hazards models were used to compare post-discharge 1-year mortality, adjusting for patient characteristics and comorbidity.

Results: (Table 1) Of the 303 RT patients receiving aortic valve replacement, 73.3% received SAVR and 26.7% TAVR. TAVR patients were more likely to be older, male, with a higher comorbidity burden. TAVR patients experienced lower inpatient mortality (3.7% vs. 5.4% for SAVR). The post-discharge one year mortality rate was 30.2/100 pt-yrs for TAVR and 12.4/100pt-yrs for SAVR. For those patients discharged alive, the adjusted hazard ratio for one year mortality (TAVR vs SAVR) was 1.1(95% CI, 0.5-2.2).

Conclusions: RT patients undergoing TAVR have lower in-hospital mortality compared to SAVR, but higher post-discharge mortality rate. After adjustment for comorbidity, the hazard ratio for one year mortality is similar for TAVR vs SAVR in RT patients undergoing TAVR and SAVR in 2013-2014. Future studies comparing TAVR to SAVR in the more recent treatment era are warranted.

Development and Validation of a Risk Score for the Prediction of Cardiovascular Disease in Kidney Transplant Recipients

Kenji Ueki,[1] Akihiro Tsuchimoto,[1] Yuta Matsukuma,[1] Kaneyasu Nakagawa,[1] Hiroaki Tsujikawa,[1] Kosuke Masutani,[2] Shigeru Tanaka,[1] Yasuhiro Okabe,[1] Kohei Unagami,[3] Yoichi Kakuta,[3] Masayoshi Okumi,[3] Toshiaki Nakano,[1] Kazunari Tanabe,[3] Takanari Kitazono.[1] Japan Academic Consortium of Kidney Transplantation investigators [1]*Kyushu University, Fukuoka, Japan;* [2]*Fukuoka University, Fukuoka, Japan;* [3]*Tokyo Women's Medical University, Shinjuku, Japan.*

Background: Cardiovascular disease (CVD) is a major cause of death in kidney transplant (KT) recipients. It is clinically important to estimate the risk of CVD after a KT.

Methods: A derivation cohort contained 387 KT recipients underwent KT at Kyushu University Hospital from January 2006 to December 2012. A prediction model was retrospectively developed and risk scores for CVD were investigated via multivariable logistic regression. The internal validation of the prediction model was estimated via the c-static and the external validation was calibrated via the Hosmer-Lemeshow goodness of fit test using a validation cohort containing 332 KT recipients underwent KT at Tokyo Women's Medical University Hospital.

Results: In derivation cohort 34 patients (8.8%) had CVD events during the observation period. Age, CVD history, diabetic nephropathy, dialysis vintage, and serum albumin at 12 months after KT were significant predictors of CVD. A prediction model consisting of integer risk scores demonstrated good discrimination (c-statistic 0.80) and goodness of fit (Hosmer-Lemeshow test P = 0.78). In a validation cohort containing 332 KT recipients the model demonstrated moderate discrimination (c-statistic 0.70) and goodness of fit (Hosmer-Lemeshow test P = 0.94), suggesting external validity.

Conclusions: This simple model for predicting CVD after kidney transplantation was moderately accurate and useful in clinical situations. In also suggested that nutritional status was an influential risk factor for CVD in KT recipients.

FR-PO1132

Cardiovascular Disease After Kidney Transplantation: A Nationwide Study in South Korea

Ji Eun Kim,[1] Sehoon Park,[4] Yong Chul Kim,[2] Mi-yeon Yu,[3] Yon Su Kim,[4] Hajeong Lee.[4] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]SNUH, Seoul, Republic of Korea; [3]Hanyang University Guri Hospital, Gyeonggi, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Cardiovascular disease (CVD) is the most common cause of death in end-stage renal disease (ESRD). Kidney transplantation (KT) is an effective treatment for ESRD, and is known as lowering risk for CVD compared to the ESRD patients on the transplantation waiting list. However, there is a lack of large-population studies especially for Asians.

Methods: We analyzed the nationwide health insurance database of South Korea and identified patients who received kidney transplantation from the year of 2007 to 2015. Patients who were under 20 years of age, had previous CVD identified, or had multiorgan transplantation were excluded from the study. As controls, ESRD and GP groups were extracted after same exclusion and matching with KT recipients by age, sex, and inclusion year. CVD was defined as major cardiovascular events (MACEs) consisted of myocardial infarction, ischemic stroke, and all-cause mortality.

Results: During the study period, a total of 13,179 patients received KT. After exclusion, 4,156 KT recipients were selected. The same number of ESRD and GP control were extracted after matching. Mean age was 41.3 ± 10.2 years and 55.2% were men in all 3 groups. KT recipients had similar proportions of diabetes and hypertension and a lower proportion of dyslipidemia compared with ESRD controls, although significantly higher co-morbidities than GP controls. The total number of MACEs was 76 (3.7 per 1000 person-year) in KT recipients, 377 (21.7 per 1000 person-year) in ESRD, 51 (2.5 per 1000 person-year) in GP, respectively. KT recipients showed a significantly lower MACE risk (adjusted HR 0.16, 95% CI 0.12-0.20, p <0.001) than ESRD controls. And the MACE risk were not significantly different between KT recipients and matched GP controls (adjusted HR 0.81, 95% CI 0.52-1.27, p=0.365). When subgroup analysis of age, sex, diabetes and hypertension was performed, similar trends were observed regardless of subgroups.

Conclusions: In this study, we found that the KT recipients had a lower risk of newly onset MACE after transplantation compared to patients maintaining dialysis in Korea, and showed a similar MACE risk compared to the general population.

FR-PO1133

Pre-Transplant Body Mass Index as a Risk for Late Post-Kidney Transplant Hypertension: A Propensity Score Weighting

Ekamol Tantisattamo,[1,2] Samapon Duangkham,[3] Pitchaya Worapongsatitaya,[4] Nessa Tantivit,[5] Natchaya Polpichai,[6] Natnicha Leelaviwat,[7] Possawat Vutthikraivit.[8] *[1]Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; [2]Multi-Organ Transplant Center, Division of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; [3]Faculty of Medicine Burapha University, Saraburi, Thailand; [4]Faculty of Medicine Vajira Hospital, Navamindradhiraj University, Bangkok, Thailand; [5]Faculty of Medicine Siriraj Hispital, Mahidol University, Bangkok, Thailand; [6]Prince of Songkla University, Songkla, Thailand; [7]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [8]Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand.*

Background: Body mass index (BMI) at the time of kidney transplantation (KT) is associated with post-transplant hypertension (HTN). However, imbalance between comparison groups can distort the result.

Methods: Kidney transplant recipients from a single center were divided into obesity and non-obesity with BMI < or≥30 kg/m^2, respectively. Baseline pre-transplant characteristics of both groups were balanced by propensity scores (PS) with weighting method leading to new study populations. Association between BMI and post-transplant systolic (SHTN) and diastolic HTN (DHTN) defines as systolic (SBP) and diastolic blood pressure (DBP) of ≥130 and 80 mmHg, respectively at 1.5 year among this new study population was examined by multiple logistic regression.

Results: Of all 70 patients, mean age±SD was 52.7±11 years old, 58.6% were male, and 31% were obese. Mean BMI was significantly higher in obese than non-obese groups (34.1±3.8 vs 24.7±3.4, mean difference 9.4, 95% CI 7.5, 11.3). Several baseline characteristics between 2 groups are different. After using PS weights with generalized boosted modeling to balance covariates (Figure 1), obese group has 7.09 and 9.21 times higher the odds of having SHTN and DHTN, respectively compared to non-obese group (SHTN: OR 7.09; 95% CI 1.19, 42.17; DHTN: OR 9.21; 95% CI 2.13, 39.77). After adjusted for race, age, gender, type of induction immunosuppression, type of KTx, the association remains (SHTN: OR 5.53; 95% CI 4.12, 741.02; DHTN: OR 12.32; 95% CI 2.23, 68.15).

Conclusions: With PS as a balancing method to examine inference, pre-transplant obesity remains one of the risks for post-transplant HTN. Pre-transplant weight should be controlled to mitigate poorer transplant outcomes.

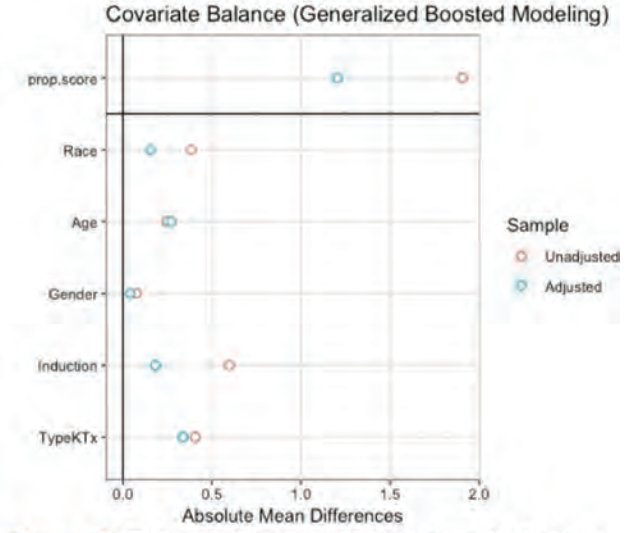

Figure 1: Estimated propensity score weights using generalized boosted modeling

FR-PO1134

Renal Graft Resistivity Index Utility in Cardiovascular Risk (CVR) Evaluation in Long-Term Kidney Transplant Recipients (KTR)

Secundino Cigarran,[1] Naiara N. Azcarate,[1] Lourdes Gonzalez tabares,[1] Ana maria Sanjurjo amado,[1] Nicolas Menendez,[2] Jesus Calvino.[1] *[1]Nephrology, Eoxi Lugo Cervo Monforte, Burela, Spain; [2]Nephrology Research Unit, Nephrology Service, Hospital da Costa, Burela, Spain.*

Background: Intra-renal graft resistivity index (RI) is an echographic measure widely used as early dysfunction marker in renal transplant (RTs). Associated factors with this index as a prognostic, outcome and patient survival are controversial. Our aim is to analyse the relationship between the RI with renal outcomes, clinical variables and cardiovascular risk (CV).

Methods: This observational study enrolled 220 stable RTs were (134 M & 86 W; Mean age 56±13.1 yo, 34% DM, 15% previous CV events), CKD stages 1-4 & more than 12 months after transplantation. Immunosuppression (IS) included anticalcineurin/mTOR with Mycophenolate Mofetil, besides steroid therapy. Variables studied: Diabetes Mellitus (DM), CV diseases history, ankle-brachial index, 24h-ABPM, anthropometric & nutritional measurements (including handgrip); as well as biochemistry parameters: hemoglobin, albumin, transferrin, creatinine, GFR estimated by CKD-EPI formula, urinary albumin/creatinine ratio (UACR), calcium, phosphorus, PTHi, vitamin D & C reactive protein. Cardiovascular risk was assessed by REGICOR equation. RI was measured by Echo-Doppler US following the standard of care technique being RI ≥0.8 as pathologic

Results: 28% showed a pathologic RI. The univariable analysis showed a significant correlation IR with age (r=0.40, p<0.01) Higher in diabetic population (0.81±0.09 vs 0.73±0.10) without influenced by IS treatment. A significative negative correlation was evidenced with diastolic arterial pressure, as well as daytime (r=-0.35) as nocturnal (r=-0.23). A positive significant with a number of antihypertensive drugs (r=0.23). Also, GFR-EPI (r= -0.27) and UACR (r= 0.21) were significant as well. Bone mineral markers PTHi (r=0.18) & P (r=0.28) were positively related to RI, meanwhile Hb (r=-0.22), albumin (r=-0.16), transferrin (r=-0.15) and dynamometry (r=-0.21) shown negative correlation. Ankle-brachial index (ABI) and REGICOR equation (r=0.18) showed also significance. Multivariable adjustments, only age and DM hold a significant relationship with RI

Conclusions: Although RI is related to functional graft factors, factors depending on RTs as age and diabetic status appear more relevant. RI may express the subclinical atheromatosis status, related to CV risk in RTs, that with the renal function itself.

FR-PO1135

Detection of BK Virus in Renal Allograft Biopsies by RNA In Situ Hybridization RNAscope® Assay

Francesca Costigliolo,[1] Kara A. Lombardo,[2] Lois J. Arend,[3] Avi Z. Rosenberg,[4] Andres Matoso,[5] Naima Carter-Monroe,[6] S.M. Bagnasco.[7] *[1]Pathology, Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins Medical Institutions, Baltimore, MD; [3]Johns Hopkins Hospital, Baltimore, MD; [4]Johns Hopkins University, Baltimore, MD; [5]Johns Hopkins, Baltimore, MD; [6]Veterans Administration Maryland Health Care System, Baltimore, MD; [7]The Johns Hopkins School of Medicine, Baltimore, MD.*

Background: BK polyomavirus associated nephropathy (BKpyVAN) remains a cause of graft loss in kidney transplant recipients on immunosuppressive therapy, and its diagnosis relies on identification of BK virus in the renal allograft biopsy based on positive immunohistochemical stain for the viral SV40 large-T antigen. Real time PCR (qPCR) and in situ hybridization (ISH) for BKv DNA can also be used to identify BKv in kidney tissue. Aim of this study was to evaluate RNAscope®, a novel-next generation technique for in situ hybridization with probes designed to increase the signal-to noise ratio to visualize RNA transcripts, for the detection of BKv RNA in allograft biopsies.

Methods: SV40 IHC stain (Santa Cruz, Ventana System) and RNAscope® ISH (following Advanced Cell Diagnostics manufacturer protocol), were performed on serial paraffin embedded tissue sections of kidney allograft biopsies. The number of tubules showing positive SV40 nuclear staining was compared to the number of tubules showing positive RNAscope® ISH signal in each biopsy (paired, 2 sides t-test, linear regression, Pearson).

Results: From 2010 to 2018, a diagnosis of BKpyVAN was made on 32 allograft biopsies from 30 renal transplant recipients (66% Caucasian, 58% male, average age at biopsy 54 ± 13 years). Median time of diagnosis post-transplant was 366 days (range 21-1577), median serum creatinine at diagnosis was 1.6 mg/dl (range 0.84-3.48 mg/dl), range BKv viremia levels: <201 – 1,270,000 DNA copies. We excluded 3 biopsies with equivocal SV40 stain, low BKv viremia (296 and 2830 DNA copies) and negative RNAscope® ISH. Three biopsies from 2 patients with high BKv viremia (>100,000 DNA copies), basophilic inclusion, negative SV40, showed positive staining by RNAscope® ISH in more than 50 tubules. In the remaining 26 biopsies with BKpyVAN there was no significant difference (P=0.207) in the average number of BKv-positive tubules detected by SV40 (26 ± 33) or RNAscope® ISH (21 ± 44), with good correlation between the two methods (r^2=0.798, P<0001). Weak correlation was seen between the level of BK viremia and the number of positive tubules detected by either SV40 (r^2=0.250, P=0.012) or RNAscope® ISH (r^2=0.255, P=0.014).

Conclusions: Our data suggest that RNAscope® ISH may be comparable to SV40 for detection of BKv in renal allograft biopsies.

FR-PO1136

Assessment of the Banff Working Group Classification of Definitive BK Polyomavirus Nephropathy

Jolanta Kowalewska,[1] Alamgir Mirza,[1] Jaclyn Simpkins,[1] Dean Troyer,[1] Agnieszka Perkowska-Ptasinska,[4] Mercury Y. Lin,[5] Meghan E. Kapp,[2] Agnes B. Fogo,[2] Magdalena Durlik,[4] Michal Ciszek,[6] Dominika Deborska-Materkowska,[4] Daniel Kuczynski,[4] Thomas R. McCune.[3,1] *[1]Eastern Virginia Medical School, Norfolk, VA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Nephrology Associates of Tidewater, LTD, Norfolk, VA; [4]Medical University of Warszaw, Warsaw, Poland; [5]Cedars Sinai Medical Center, Los Angeles, CA; [6]Medical University of Warsaw, Warsaw, Poland.*

Background: The Banff Working Group on Polyomavirus Nephropathy (PVN) proposed a classification of definitive PVN based on polyomavirus replication/load level and the extent of interstitial fibrosis. This study is to test the classification using independent cohorts of patients with PVN in renal allograft biopsies, and to analyze the significance of other variables that may play a role in the outcome of PVN, namely presence of tubular basement membrane deposits (TBMD) and peak level of plasma BK particles by PCR.

Methods: Four institutions participated in this study. Patients with kidney allograft biopsy-proven PVN with at least 24 months follow up were identified. Clinical data was captured and biopsies were scored according to the Banff PVN classification. Statistical analysis was performed using multivariable logistic regression and analysis of covariance (ANCOVA) to assess dichotomous and continuous outcomes, respectively.

Results: 145 patients met the criteria for the study. 25 (17%) biopsies were classified as Class 1; 97 (68%) as Class 2; and 20 (14%) as Class 3. Baseline serum creatinine (Scr) levels were elevated and similar regardless of class, with Class 1 mean 1.78 mg/dl, Class 2 1.62 mg/dL, and Class 3 1.78 mg/dL. At the time of diagnostic biopsy the median change in Scr was parallel across classes of PVN (increase in Scr 0.60, 0.52, and 0.60 respectively, p=0.57). At 24 months, median Scr change from baseline increased numerically, as also seen in previous reports (increases 0.45, 0.75 and 1.2, p=0.29). In this cohort overall graft failure was 22% (compared to 30% previously reported), and was equally distributed amongst classes (25%, 20% and 25%). TBMD were found in a subset of all PVN classes (10%, 10% and 20%), and were associated with a trend toward worse outcomes (p=0.15). The highest mean number of plasma BK particles was seen in PVN Class 3, but was not statistically different from other classes.

Conclusions: The proposed classification of PVN is promising for evaluation of allograft biopsies; however, the classes do not stratify and identify patients at increased risk of allograft loss. Additional parameters need to be identified to determine risk for adverse allograft outcome.

FR-PO1137

The Incidence of BK Viremia Among Recipients Who Received Kidney Transplants (KT) from Hepatitis C-Infected and Uninfected Donors

Masahiko Yazawa,[1,2] Orsolya Cseprekál,[4,1] Manish Talwar,[1,3] Vasanthi Balaraman,[1,3] James D. Eason,[1,3] Miklos Z. Molnar.[1,3] METEOR (MEthodist Transplant EpidemiOlogy Research) Group *[1]Division of Transplant Surgery, Department of Surgery, University of Tennessee Health Science Center, Memphis, TN; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [3]James D. Eason Transplant Institute, Methodist University Hospital, Memphis, TN; [4]Department of Transplantation and Surgery, Semmelweis University, Budapest, Hungary.*

Background: Our previous data showed KT from hepatitis C virus(HCV) infected donor to non-infected recipients might be associated with higher incidence of BK viremia.

Methods: One hundred and ninety-two deceased KT recipients (74 HCV infected(D+/R-) and 55 HCV negative (D-/R-) donor) to HCV negative recipients were included. Outcome was defined as time to incidence BK viremia which 1)was detectable in blood specimen by PCR (BK viremia;n=21), 2)was greater than 10,000 copies/mL (high BK viremia;n=9). We performed time to event analysis from KT to 120 days after KT with unadjusted and thymoglobulin dose adjusted Cox regression model.

Results: The mean age at KT was 52±11 years old and 80% were African-American. Table shows the baseline characteristics of HCV D+/R- and D-/R- groups. The median number of the highest viral copies was tended to be 5-fold higher in HCV D+/R- group (median:19,632; interquartile range (IQR):2,329-303,823 copies/mL) than D-/R- group (median:4,356; IQR:2,931-15,219 copies/mL,p=0.45). Figure shows the probability of the (high) BK viremia over the follow-up time. Compared to D-/R-, HCV D+/R- group reported similar probability of BK viremia in unadjusted (Hazard Ratio(HR):1.32, 95% Confidence Interval(CI):0.54-3.19) and adjusted (HR:1.28, 95%CI:0.52-3.13) model, a trend for higher risk for high BK viremia unadjusted (HR:2.87, 95%CI:0.60-13.8) and adjusted (HR:2.68, 95% CI:0.56-12.9) Cox regression model.

Conclusions: HCV D+/R- KT was not associated with higher incidence of BK viremia and showed trend for higher incidence of BK viremia.

Nocardiosis in Renal Transplant Patients

Maya Gibson,[1] Nianlan Yang,[1] Jennifer L. Waller,[1] N. Stanley Nahman,[1,2] Kathryn M. Martin,[1] Mufaddal Kheda,[3] Azeem Mohammed,[1] Lufei Young,[1] Wendy B. Bollag,[1] Stephanie L. Baer.[2] *[1]Medical College of Georgia at Augusta University, Augusta, GA; [2]Augusta VA Medical Center, Augusta, GA; [3]Auburn University, Leesburg, GA.*

Background: Kidney transplant (Tx) patients are chronically immunosuppressed and are at increased risk for opportunistic infections, including the gram positive rod *Nocardia*. Nocardiosis is rare, with an incidence of 0.4%-3.6% in solid organ Tx recipients. The disease is difficult to diagnose, and targeted therapy is required for treatment. In kidney Tx patients specifically, information on the incidence and risk factors for *Nocardia* infection

is limited. To address this issue in a large at-risk population, we utilized the United States Renal Data System (USRDS) to investigate the incidence and risk factors for *Nocardia* in over 200,000 kidney Tx patients. Sequelae of allograft failure or rejection after infection was also examined.

Methods: Demographics, clinical risk factors, *Nocardia* diagnosis, and allograft failure following *Nocardia* infection were queried in kidney Tx patients from the USRDS using ICD-9 codes and CMS Form 2728. Generalized linear models incorporating the number of person years at risk were used to examine risk factors for *Nocardia* and the adjusted relative risks (aRR) and 95% confidence intervals were determined.

Results: We queried 203,233 kidney Tx patients and 657 (0.32%) were diagnosed with *Nocardia.* Pneumonia was the most frequent presentation (15.2%) followed by brain abscess (8.4%). Factors that increased the risk for *Nocardia* included granulomatous disease (aRR=7.65), history of allograft rejection (4.82), tacrolimus use (2.45), and age > 65 years (2.11). Azathioprine use (0.73), hepatitis C (0.56) and tobacco use (0.74) were associated with decreased risk. Patients with nocardiosis had associated high percentages of graft failure (67.28%) and kidney rejection (60.58%).

Conclusions: In this large kidney Tx population, nocardiosis affected 0.3% of patients and presented most often as pneumonia or brain abscess. A history of granulomatous disease, allograft rejection, and tacrolimus use increased the risk for infection, presumably due to higher rates of immunosuppression associated with these comorbid events. This study may improve early recognition of nocardiosis in kidney Tx patients.

Cytomegalovirus Prevention Strategies and the Risk of BK Polyomavirus Viremia and Nephropathy

Tomas Reischig,[1] Martin Kacer,[1] Ondrej Hes,[2] Daniel Lysak,[5] Jana Machová,[4] Mirko Bouda.[3] *[1]Charles University Medical School and Teaching Hospital, Plzen, Czechia; [2]Charles University, Plzen, Czechia; [3]Faculty Hospital Pilsen, Charles University, Plzen, Czechia; [4]Biomedical Centre, Faculty of Medicine in Pilsen, Pilsen, Czechia; [5]University Hospital Pilsen, Pilsen, Czechia.*

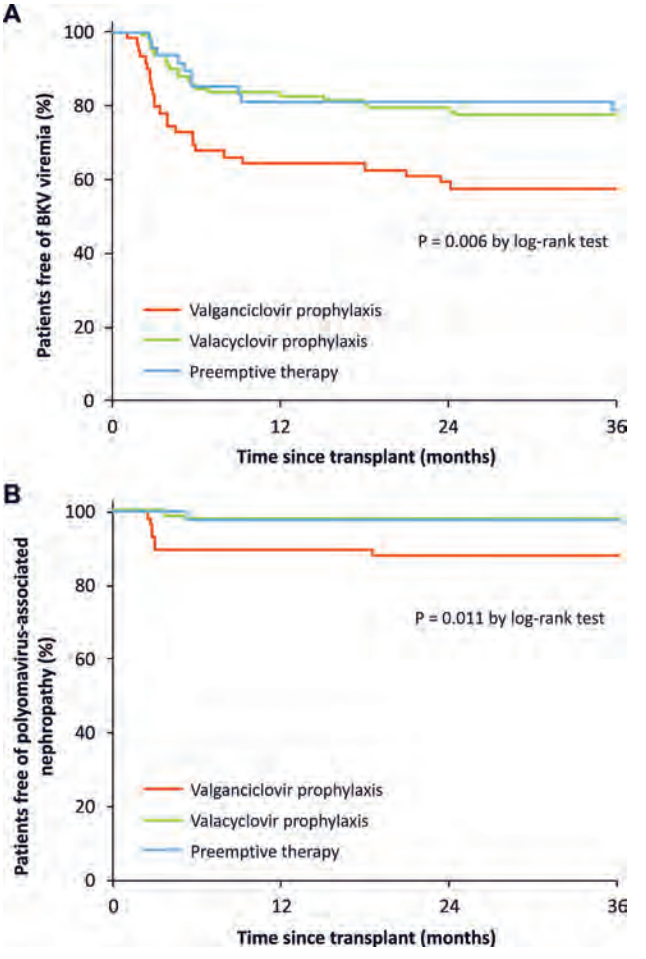
Background: Polyomavirus BK (BKV) is the cause of polyomavirus-associated nephropathy resulting in premature graft loss. There are limited data regarding the role of cytomegalovirus (CMV) infection and its prevention in developing BKV viremia and PVAN.

Methods: In a prospective study, we analyzed 207 consecutive renal transplant recipients previously enrolled to 2 randomized trials evaluating different CMV prevention regimens with routine screening for BKV and CMV. Of these, 59 received valganciclovir and 100 valacyclovir prophylaxis, 48 patients were managed by preemptive therapy.

Results: At 3 years, the incidence of BKV viremia and PVAN was 28% and 5%, respectively. CMV DNAemia developed in 55% and CMV disease in 6%. Both BKV viremia (42% vs. 23% vs. 21%, P=0.006) and PVAN (12% vs. 2% vs. 2%, P=0.011) were increased in patients treated with valganciclovir prophylaxis compared to valacyclovir and preemptive therapy. Using multivariate Cox proportional hazard regression, valganciclovir prophylaxis was independent predictor of BKV viremia (hazard ratio [HR]=2.38, P=0.002) and PVAN (HR=4.73, P=0.026). In contrast, the risk of subsequent BKV viremia was lower in patients with antecedent CMV DNAemia (HR=0.50, P=0.018).

Conclusions: These data suggest that valganciclovir prophylaxis is associated with increased risk of BKV viremia and PVAN. CMV DNAemia did not represent a risk for BKV.

Funding: Government Support - Non-U.S.



Kaplan-Meier curves for the cumulative probability of freedom from (A) polyoma BKV viremia, and (B) polyomavirus-associated nephropathy based on cytomegalovirus prevention strategy. BKV, polyomavirus BK.

Serum Albumin Levels Prior to Kidney Transplant Predicts Post-Transplant BK and Cytomegalovirus Infections

Aniruddha Srivastava,[1] Josh Bodnar,[1] Brad C. Astor,[2] Didier A. Mandelbrot,[3] Sandesh Parajuli.[3] *[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]University of Wisconsin-Madison, Madison, WI; [3]UW Health, Madison, WI.*

Background: Post-transplant Infections are a common cause of morbidity and mortality in kidney transplant recipients (KTRs). Prior studies have shown that pre- and post-transplant hypoalbuminemia are associated with graft failure and all-cause mortality. Others suggested that low post-transplant albumin is linked to cytomegalovirus (CMV) infections. These studies suggest serum albumin levels could indicate post-transplant infection risks. Our study evaluated the association between pre-transplant serum albumin and post-transplant BK Virus (BKV) and Cytomegalovirus (CMV) infections in KTRs.

Methods: We used our university database to identify adult KTRs transplanted between 01/01/2005 and 12/31/2015. All subjects had serum albumin measured within 45 days before the transplant. We categorized all KTRs into three pre-transplant albumin levels: Group 1: normal serum albumin ≥ 4.0 g/dL, Group 2: moderate hypoalbuminemia 2.5-3.9 g/dL, and Group 3: severe hypoalbuminemia < 2.5 g/dL. We used incidence models per 100 person-years and Cox proportional hazards to compare outcomes between groups.

Results: 1717 patients were included in the study. Of those, 36.2% (n=622) were identified as group 1, 62.3% (n=1070) as group 2, and 1.4% (n=25) as group 3. Albumin groups differed by age, cause of end-stage renal disease, BMI, induction immunosuppression and maintenance immunosuppression with tacrolimus vs other, all with a p-value less than 0.001. Incidence of BK viremia for group 1 was 2.2 per 100 person-year which was lower, compared with group 2: 4.6/100 person-year and group 3: 9.9/100 person-year; as well as for CMV viremia, group 1: 1.75/100 person-year, group 2: 2.7/100 person-year and group 3: 3.6/100 person-year. The adjusted relative hazard for BK was also higher for group 2 (HR=1.25, 95% CI[0.95 -1.6]) and group 3 (HR=2.3, 95% CI[1.0-4.9]) compared to group 1. A similar trend was found for CMV for group 2 (HR=1.1, 95% CI[0.77-1.53]) and group 3 (HR=1.4, 95% CI (0.43-4.5])

Conclusions: Our results suggest that the degree of hypoalbuminemia pre-transplant is directly correlated with the risk of BKV and CMV post-transplant. Proper screening and management of hypoalbuminemia may be helpful in reducing the future risk of these infections.

FR-PO1141

BK Virus Surveillance and Outcomes

Aju Jose,[1] Wendy I. McCallum,[1] Daniel R. Migliozzi,[1] Apaar Dadlani,[3] Ronald D. Perrone,[1] Anshul Bhalla,[2] Nitender Goyal.[1] *[1]Tufts Medical Center, North Attleboro, MA; [2]Johns Hopkins Hospital, Baltimore, MD; [3]University of Louisville School of Medicine, Lexington, KY.*

Background: Polyoma virus associated nephropathy (PyVAN) caused by BK virus (BKV) occurs in 1-10% of kidney transplant recipients (KTR). Due to lack of effective treatment options, early screening for BKV replication is the most important tool to improve outcomes. Proposed screening strategies are based on consensus guidelines but protocols vary across centers. We report the outcomes in a single center with an intensive BKV screening protocol.

Methods: We performed a retrospective analysis of KTR between Jan 2014 and Nov 2017. We obtained monthly plasma BKV DNA PCR in the first year and every other month in the 2nd year after transplant. A BKV load of >1000 copies/mL was considered positive. Information regarding incidence, treatment and outcomes of patients with BKV, rejection episodes and graft and patient survival was collected.

Results: Among 144 KTR, data were available for 138. There were 34 (25%) patients who developed BKV during a median 2.6-year follow-up period. Baseline characteristics of patients with BKV and no BKV were similar except that more patients in BKV group were on maintenance steroids (62% vs 32%, P 0.004). Median time from transplant to detection of BK viremia was 139 days (range 34-743). Of those who developed viremia, 30 (88%) developed BKV in 1st year. Median initial and peak viral loads were 7762 copies/ml (Range, 1044-862,198) and 26200 copies/ml (Range 1145-5,000,000) respectively. Six patients developed biopsy proven PyVAN. Almost all patients (32/34) were managed with reduction in immunosuppression (IS). The initial IS reduction was MMF in 16 patients, CNI in 8 patients and 7 patients required reduction in both CNI and MMF. IVIG was used in 6 (18%) of patients in whom viremia persisted despite decrease in IS. Over our follow-up period, 27 (79%) patients had resolution of BK viremia (<1000 copies/ml), another 4 patients had >75% reduction in viral load and only one patient developed biopsy proven rejection. No grafts were lost as a result of BKV or rejection as result of reduction in IS for BKV.

Conclusions: Intensive BKV screening in the 1st year post kidney transplant allows for early detection to guide IS management with excellent graft outcomes. Few patients develop BK viremia in the 2nd year and a less intense monitoring can be considered in 2nd year. Larger trials are needed to determine the optimum frequency of BKV monitoring.

FR-PO1142

Efficacy and Safety According to Dose of Valganciclovir for Cytomegalovirus (CMV) Prophylaxis in Transplantation: Network Meta-Analysis Using Recent Data

Seon Deok Hwang,[1,2] Seoung woo Lee.[2,1] *[1]Inha University College of Medicine, Incheon, Republic of Korea; [2]Inha University Hospital, Incheon, Republic of Korea.*

Background: Valgancivlovir is importantly used to prevent post-transplant CMV infection among kidney transplantation patients. However, the dose of such drug being used still remains controversial since the continuous use of such drug decrease kidney functions and induces leukopenia in some of the cases. Accordingly, the purpose is to measure the appropriate dose of the drug required for preventing CMV using network Meta analysis.

Methods: We searched the Cochrane Central Register, OVID MEDLINE and Pubmed until April 15, 2019. Studies evaluating among valganciclovir 900 mg, 450 mg and controls were evaluated. We performed direct and indirect network meta-analysis using Bayesian models and generated rankings of the different dose of valgaciclovir agents by generation mixed treatment comparison (GeMTC).

Results: Twenty-three studies involving 3,478 participants were eligible. As a result of analyzing among three groups, following completion of the research, the analysis revealed that the glomerular filtration rate, graft loss, tacrolimus level, antibody mediated rejection, fungal, and *Candida* infection rates were not different among groups. Compared with control, there was no difference between low dose 0.79 [95% Crl, 0.50-1.40] and standard dose 1.0 [95% Crl, 0.61-1.60] groups when CMV incidence was compared. In the Rank probabilities table, the best order for lowering the CMV event was as high as dose of 450mg (71.1%). Incidence of leukopenia showed a significant difference, but there was no statistical significance in the low dose group 1.5 [95% Crl, 0.99-2.20] compared with the control group, but 4.3 times higher in the high dose group [95% Crl, 2.69-7.10], which was 2.9 times higher in the high dose group compare with low dose group [95% Crl, 1.88 -4.67].

Conclusions: The use of valganciclovir did not show any difference in other side effects, but the use of low doses of leukopenia significantly reduced side effects. The incidence of CMV was not different among the three groups, but the tendency was also decreased at low dose.

FR-PO1143

Incident Cancer After Kidney Transplantation in South Korea: A Nationwide-Population Based Study

Mi-yeon Yu,[3] Sehoon Park,[1] Ji Eun Kim,[2] Yong Chul Kim,[2] Yon Su Kim,[1] Hajeong Lee.[1] *[1]Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Hanyang University Guri Hospital, Gyeonggido, Republic of Korea.*

Background: Cancer is one of the most common cause of death with functioning graft in kidney transplantation (KT) patients. In this study, we aimed to investigate post-KT cancer incidence using a nationwide data compared with end-stage renal disease (ESRD) control and general population (GP).

Methods: We included incident KT recipients aged over 20 years without previous cancer history using a Nationwide Health Insurance Database of South Korea from January 1, 2007, to December 31, 2015. We analyzed the incidence rate (IR) per 1000 patient-year of cancer in KT recipients compared with ESRD and GP cohorts which were extracted after matching by age, sex, and inclusion year.

Results: A total of 10,203 KT recipients were analyzed with matched ESRD and GP controls. Their mean age was 45.2±10.7 years and 60.3% were men. Economic status of KT recipients was lower than GP but better than ESRD control. Combined diabetes or hypertension of KT recipients was similar to ESRD control but higher than GP. Incident cancer IR in KT recipients (8.63/1000 patient-year) was higher than that of GP (5.28/1000 patient-year), but lower than ESRD controls (12.27/1000 patient-year). In overall, KT recipients had 65.3% higher risk of incident cancer, whereas ESRD patients were at 2.4-fold higher risk of cancer development than GP. Among various cancer types, KT recipients showed higher risk of urinary tract cancer (HR 3.01, 95% CI 1.45-6.22), non-Hodgkin lymphoma (HR 3.97, 95% CI 1.14-13.79), and skin cancer (HR 4.33, 95% CI 1.46-12.83), whereas ESRD patients revealed higher risk of urinary tract cancer, and leukemia compared with GP. We can show a similar trend of cancer IR according cancer type within 5 years after KT, but after then, only stomach cancer IR in KT patients (0.88/1000 patient-year), was higher than that of GP (0.25/1000 patient-year).

Conclusions: In this study, we found that KT recipients had higher risk of incident cancer than GP, although this did not exceed that of ESRD patients. It is suggested that KT recipients should be monitored on the occurrence of urinary tract cancer, skin cancer and non-Hodgkin lymphoma more meticulously than GP, especially, within 5 years after KT. Gastroscopy should be recommended for all KT recipients regardless of the post KT duration.

FR-PO1144

Graft Survival and Characteristics of Kidney Transplant Recipients with Renal Cell Carcinoma

Rushad Machhi,[1] Brad C. Astor,[2] Didier A. Mandelbrot,[3] Sandesh Parajuli.[4] *[1]University of Wisconsin School of Medicine and Public Health, Mequon, WI; [2]University of Wisconsin, Madison, WI; [3]U of Wisconsin Hospital, Madison, WI; [4]UW Health, Madison, WI.*

Background: The risk of acquiring renal cell carcinoma (RCC) is the greatest among all solid tumors in kidney transplant recipients (KTRs). While most RCCs are caught in the localized stage incidentally, leading to low cancer-specific mortality, there is limited information on how to properly screen for RCC in KTRs based on risk stratification, and how RCC impacts graft survival down the line.

Methods: We analyzed risk factors and determined patient and graft survival of all KTRs with RCC in both native and grafted kidneys compared to those without RCC in our institution between 01/01/1994 and 12/31/2014. Risk factors analyzed were race, age, mean time on dialysis prior to transplantation, causes of ESRD, re-transplant, type of graft, and type of induction agent.

Results: 48 cases of RCC were found among the 4,837 KTR's performed at our institution. The mean interval from transplant to RCC was 8.0±6.3 years. Glomerulonephritis was the most common cause of ESRD in KTRs with RCC at our institution (n=17), but this was not found to be a signficfant risk factor for acquiring RCC (p=0.54 in univariate analysis, p=0.42 in multivariate analysis). None of the risk factors analyzed were associated with a statistically significant higher risk for RCC. Graft survival at 10 years was significantly lower in KTRs with RCC compared to those without (Figure 1, p<0.001). However, the trend toward shorter 10 year patient survival did not reach statistical significance (p=0.13).

Conclusions: Although no factor was identified in our sample population that specifically was associated with increased risk for RCC in KTRs, KTRs with RCC were found to have significantly lower graft survival. Identifying specific risk factors in patients with graft failure following RCC can lead to better screening, treatment, and immunosuppression strategies to bolster graft survival in KTRs with RCC.

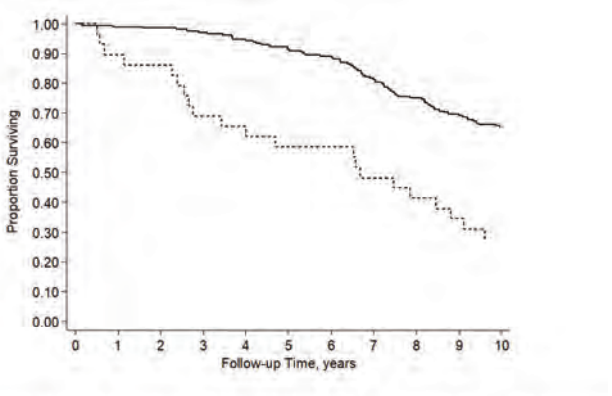

Figure 1: Mean graft survival in all post-transplant patients (solid line) vs patients with post-transplant RCC (dashed line). P<0.001.

FR-PO1145

Immunosuppression Management in Kidney Transplant Recipients with Malignancy/Mortality and Renal Graft Outcome

Natanong Thamcharoen,[1] Danwen Yang,[1] Francesca Cardarelli.[2] *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Kidney transplant recipients(KTR) are at high risk of cancer compared to general population. Prognosis is poor and the data of how to manage immunosuppression(IS) after cancer diagnosis is scarce. We aims to assess the impact of IS dose reduction on graft survival and mortality outcome in KTR diagnosed with cancer.

Methods: We retrospectively reviewed and collected the data of KTR with cancer diagnosis after kidney transplant. Early stage non-melanoma skin cancer was excluded. We divided our study population in 2 groups, IS reduction and no reduction. Study outcomes were mortality and graft failure. Follow-up time was 10 years. Data were calculated as percentages for categorical variables and mean or median for continuous variables. Patient survivals and graft survivals were analyzed using Kaplan-Meier survival curves with log-rank test. Competing risk analysis was used for graft failure outcome and Cox proportional hazards was used for mortality analysis.

Results: There were 110 patients in total. The mean age at cancer diagnosis was 60.2 years. IS was changed in 74%. Solid organ tumor was 79.1%. Mortality rate was 46.4 % with median survival time of 1.8 years after cancer diagnosis. Graft failure rate was 16.4%. Median graft survival was 2.97 years. Kaplan-Meier curves showed that IS reduction was associated with higher mortality risk and graft failure. However, from multivariable models, history of chemotherapy was the only factor associated with increased mortality(image1). Creatinine at cancer diagnosis and history of rejection were significant predictors of graft failure(image2).

Conclusions: Reduction of IS after cancer diagnosis was not significantly associated with patient mortality, nor with increased risk of kidney allograft failure.

	Univariable model		Multivariable Model

FR-PO1146

Characteristics of Malignancy in Kidney Transplant Recipients at the Keck Hospital of USC in Year 2006 Through 2009 Compared to Year 2000 Through 2004

Roshanak Azimi, Osun Kwon. *Medicine/Nephrology, Keck School of Medicine of USC, Los Angeles, CA.*

Background: Recent national kidney transplant registry data reported that 17 % reported causes of death are due to malignancy after transplant, which suggests higher incidence of malignancy as a cause of death compared to 13% about a decade ago.

Methods: The study has been conducted by reviewing medical records of kidney transplant recipients who had been followed by the transplant team at Keck Hospital of USC in 2000 through 2019. The findings have been compared in 200 patients who had received a kidney transplant in two time periods; 100 patients each in 2000 through 2004 (group 1) and 2006 through 2009 (group 2) and had at least 10 years of follow-up.

Results: Subjects (83 female, 116 male) were 134 recipients of a kidney transplant from a deceased donor and 66 from a living donor. Mean age of patients at the time of the first kidney transplant was 48 (range 17-77) and 48 (range 23-75) in group 1 and group 2. Hispanic is the majority followed by Caucasian, Asian, African American; 56, 22, 13, 3% in group 1 and 52, 19, 21, 7%, respectively in group 2. In group 1, 14 patients developed malignancy after kidney transplant; 8 within 10 years post-transplant. In group 2, 12 patients were diagnosed with malignancy; 11 within 10 years. In group 1, 32 patients died and in group 2, 25 patients died. Seven died with functioning graft in group 1 (22% of mortality) and 5 died with functioning graft in group 2 (20% of mortality). Types of cancers were variable; adenocarcinoma of lung, GI and prostate, squamous cell carcinoma of the skin, lymphoma, and thyroid cancer. In group 2, HCC was in 4 among 12 reported malignancies. HCC was diagnosed in 3 recipients of combined liver and kidney transplant. In group 1, 15 patients received induction immunosuppression (OKT3, Thymoglobulin, Basiliximab/Daclizumab), while in group 2, 69 patients received Thymoglobulin or Basiliximab. Duration until the time of cancer diagnosis after transplant seems shortened considerably; median and mean time, 4 and 6.9 years in group 1 vs. 2.4 and 2.7 years in group 2, respectively.

Conclusions: In kidney transplant recipients who received a kidney transplant in 2006-2009, incidence of cancer seems increased during 10 year follow-up and duration until the time of cancer diagnosis seems shortened, compared to those in 2000 through 2004, in the patient population studied.

FR-PO1147

Plasma Citrulline and Mycophenolate Mofetil-Induced Enterocyte Toxicity in Renal Transplant Recipients

Rianne M. Douwes,[1] Mohammad Y. Said,[1] J.c. Swarte,[1] Antonio W. Gomes Neto,[1] Dimitrios Tsikas,[2] Gerjan Navis,[1] H. Blokzijl,[1] Stephan J. Bakker.[1] *[1]University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands; [2]Hannover Medical School, Hannover, Germany.*

Background: Citrulline is a non-protein amino acid mainly produced by enterocytes of the small intestine which can be used as a biomarker of functional enterocyte mass. Plasma citrulline is reduced in diseases characterized by enterocyte damage. Diarrhea is a well-known side effect of Mycophenolate Mofetil (MMF), as a consequence of MMF induced gastrointestinal mucosal injury. To prevent complications from severe diarrhea, clinicians often lower MMF dosages or change to other immunosuppressive regimens. We aimed to investigate whether citrulline levels are associated with MMF use in a large cohort of stable renal transplant recipients (RTR).

Methods: Plasma citrulline concentrations were measured in 567 stable RTR with a ≥ 1 year functioning graft, from the TransplantLines Biobank and Cohort study (Clinicaltrial.gov NCT03272841). Citrulline was measured using a validated UHPLC-MS/MS method. MMF through levels were available in 234 RTR and were natural log transformed to obtain a normal distribution. Associations between MMF use, MMF through levels and plasma citrulline concentrations were analyzed using linear regression analyses.

Results: Mean age was 55.5±13.2 years and 392 RTR (69.1%) used MMF. Mean plasma citrulline concentration was 42.1±14.2 μmol/L. In univariable linear regression analyses, MMF use was inversely associated with plasma citrulline (β: -6.8, P<0.001). After adjustment for age, sex and eGFR, MMF use remained significantly associated with lower citrulline levels (β: -4.6, P<0.001). Moreover, among MMF users, through

levels were inversely associated with citrulline levels, independent of age, sex and eGFR (β: -2.8, *P*=0.02).

Conclusions: This study demonstrates that MMF use is associated with lower citrulline levels in RTR potentially related to MMF induced enterocyte toxicity, which may lower systemic citrulline levels. More research is warranted to validate whether citrulline can be used as biomarker of MMF induced enterocyte toxicity in RTR.

FR-PO1148

Diagnostic Yield of Multiplex Polymerase Chain Reaction for Diagnosis of Acute Gastroenteritis in Renal Transplant Recipient: A Single-Center Study from India

Anurag Gupta,[1] Vaibhav Tiwari,[2] Yogeshman Anand,[3] Devinder S. Rana,[2] Anil Bhalla,[2] Ashwani Gupta,[2] Vinant Bhargava.[2] *[1]Nephrology, Sir Ganga Ram Hospital, New Delhi, India; [2]Sir Ganga Ram Hospital, New Delhi, India; [3]nephrology, Ganga Ram Hospital, New Delhi, India.*

Background: Acute gastroenteritis is an unwelcome and harmful yet unavoidable complication in the renal transplant patient. Standard methods of staining and culture have poor sensitivity as well as require significant time for the reports. Stool Polymerase Chain Reaction is a quick, sensitive and hassle-free method which diagnose more than 20 organisms within 1 hour.

Methods: We retrospectively analyzed all renal transplant patients admitted between 2015 to 2018 with diarrhea. The sample was tested for conventional microbiological methods including stool routine for microscopy and culture. A stool sample was also sent for Multiplex PCR which was analyzed by Bio Fire FilmArray GI Panel which identifies 22 enteropathogens.

Results: 110 diarrheal events were recorded in 82 patients with 181 organisms isolated in all samples. 85% sample yielded a positive result. The conventional method yielded a positive result in only 32.3% as compared to stool PCR. Coinfections were common as 71.2% events were associated with 2 or more organisms. Norovirus(20%) was the most common organism isolated from stool followed by Giardia (17%) and Enteropathogenic E.Coli (16%). Giardia Lambia with Norovirus was the most common co-infection in 19% of patients.

Conclusions: Stool PCR significantly improves the diagnostic yield in diagnosing enteric pathogens. Stool PCR is especially sensitive in detecting multiple organisms. Norovirus is the most common enteropathogen. Giardia with Norovirus was the most common co-infection among post-transplant patient.

Frequency of Enteropathogens diagnosed by stool PCR

Enteropathogens	No. of Positive cases (%)
Norovirus	37 (20%)
Giardia	30 (17%)
Enteropathogenic E.Coli	29 (16%)
Cryptosporidium	21(12%)
Shigella/Enteroinvasive E.Coli	20 (11%)
Others	44 (34%)

FR-PO1149

Incident Dementia in Kidney Transplantation Recipients: A Nationwide Population-Based Cohort Study in Korea

Seon Ha Baek,[1] Ji Eun Kim,[2] Yong Chul Kim,[2] Dong Ki Kim,[2] Hajeong Lee.[3] *[1]Hallym University Dongtan Sacred Heart Hospital, Hwaseong-si, GyeongGi-do, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Recent studies have shown that patients with end stage renal disease (ESRD) are at elevated risk of dementia. However, whether kidney transplantation lower the risk of dementia development or not remains unclear. In this study, we aimed to estimate the risk of incident dementia in KT recipients compared with ESRD patients and healthy controls (HCs).

Methods: From the Korean National Health Insurance Service database, we identified KT recipients aged ≥ 20 years without any history of dementia between 2007 and 2015. We also established two control cohorts without a history of dementia: 1) incident ESRD cohort, 2) HC cohort of insured subjects without a history of kidney disease with frequency matched for age, sex, and inclusion year. All-cause dementia (F00-F03), Alzheimer' disease (AD, F00), and vascular dementia (VD, F01) were diagnosed on the code of the International Classification of Disease, 10th Revision.

Results: We followed 11,385 KT recipients, ESRD patients, HCs for 54,454, 46,260, and 56,020 patient-years, respectively (mean age: 45.7 years, 6754 male/4631 female). Over observation periods, 44, 231, and 44 dementias occurred in KT recipients, ESRD patients and HCs. AD/VD was found in 21/14 KT recipients, 144/58 ESRD patients, and 26/13 HCs. KT recipients showed lower risk of all types of dementia (hazard ratio [HR] 0.15, P<0.001), AD (HR 0.11, P<0.001), and VD (HR 0.20, P<0.001) compared with ESRD patients even after adjustment. These findings were reproduced even when KT recipients were compared with HCs. The strongest predictors for dementia in KT recipients were older recipient age, diabetes and numbers of Charlson's comorbidity index.

Conclusions: These findings suggest that KT recipients had a lower risk of incident dementia, AD, and VD than those of ESRD patients. Furthermore, their dementia development risk was lower than even HCs in spite of long-standing kidney disease and/or use of neurotoxic immunosuppressants.

FR-PO1150

Health-Related Quality of Life Among Kidney Transplant Patients Using the PROMIS Global Health Scale

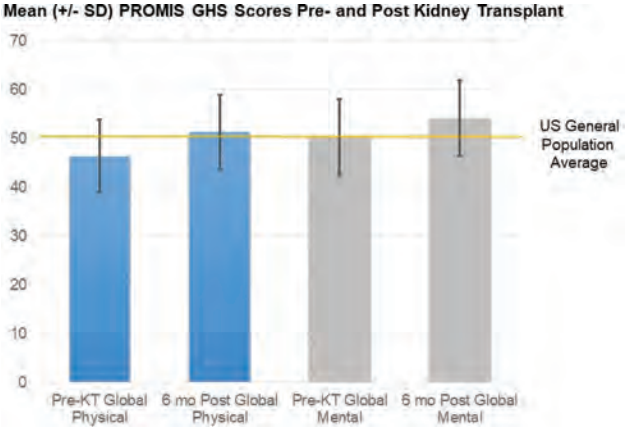
John D. Peipert,[1] Farrukh M. Koraishy,[2] Amy D. Waterman,[4] Mark Schnitzler,[3] Krista L. Lentine.[2] *[1]Northwestern University, Chicago, IL; [2]Saint Louis University, Saint Louis, MO; [3]Saint Louis Univ, Shiloh, IL; [4]UCLA Transplant Research and Education Center, Los Angeles, CA.*

Background: Survival after kidney transplant (KT) is increasing, turning attention to health-related quality of life (HRQOL). Brief but valid measures are needed to screen HRQOL among KT patients. We examined the 10-item PROMIS Global Health Scale (GHS) pre- and post-transplant among KT patients. We also examined GHS scores among a cohort of liver transplant (LT) patients for comparison.

Methods: Data were from KT and LT patients at a transplant center in the United States. PROMIS GHS was assessed pre-transplant (KT, n=189; LT, n=88) and 6 months post-transplant (KT, n=43; LT, n=16). We estimated global physical health (GPH) and global mental health (GMH) summary scores from the GHS. We compared KT and LT to the US general population normative mean value of 50. We then estimated associations between PROMIS GPH and GMH scores with clinician-rated functional status sourced from the Scientific Registry for Transplant Recipients.

Results: Among KT patients, the mean GPH and GMH scores at pre-transplant were 46.3 and 50.2, respectively, which increased to 51.1 and 54.1 at 6 months post-transplant. As expected, LT patients had lower physical and mental HRQOL than KT patients. Among LT patients, mean GPH and GMH scores at pre-transplant were 42.1 and 46.3, respectively, which increased to 44.7 and 50.1 at 6 months post-transplant. Pre-transplant differences in functional status were not statistically significant for KT patients. However, in comparison to LT patients with normal function, LT recipients unable to carry-on normal activities had significantly lower mean GPH (39.9 vs. 47.4, p<0.001) and GMH (44.5 vs. 50.3, p=0.01) scores.

Conclusions: The PROMIS GHS is a brief, clinically-feasible, and patient-centered approach to tracking changes in patients' health over time for KT and LT patients. Inclusion of patient-reported outcomes like the GHS can enhance the standard health metrics collected for transplant patients.



FR-PO1151

A Modified Charlson Comorbidity Index (CCI) for Predicting Kidney Transplant Outcomes in the Elderly

Adam N. Sholi, Mohamed K. Kamel, Jim Kim, Samuel Sultan, Anthony Watkins. *Kidney Transplantation, Weill Cornell Medicine, New York, NY.*

Background: Contemporary kidney transplant recipients are older and tend to have significant comorbidities. However, the impact of comorbidities in elderly kidney recipients is unclear. This study used a modified Charlson comorbidity index (CCI) to compare the clinical features of elderly patients surviving ≤ 3 years versus those with post-transplant survival > 3 years.

Methods: A prospective database was reviewed for patients aged ≥70 years undergoing deceased donor renal transplantation from 2007 – 2016. A modified CCI score was used designating 3 points for history of myocardial infarction and heart failure, traditional comorbidities as 1 point, and excluded renal disease. Multivariable analysis identified predictors of 3-year mortality.

Results: Among 114 elderly patients undergoing transplantation, 43 (38%) had 1 comorbidity and 39 (34%) had ≥2 comorbidities. The most common comorbidities were diabetes (45%), heart disease (39%), and peripheral vascular disease (18%). Patients were stratified based on 3-year post-transplant survival (Table). Male gender, heart disease, and an unweighted and modified CCI scores were significantly greater among patients surviving ≤3 years post-transplant. Multivariable analysis identified the unweighted CCI (OR= 1.47, CI: 1.02-2.13) and modified CCI (OR= 1.35, CI: 1.08-1.69) as significant predictors of 3-year mortality, but not age, gender or time on waitlist. However,

after adjusting for age and gender, only the modified CCI was predictive (OR= 1.30, CI: 1.03-1.64).

Conclusions: A modified CCI is a simple and effective tool for predicting 3-year mortality following transplantation in elderly patients. This scoring system should be considered as an adjunct in determining transplant candidacy in this population.

Elderly kidney recipients (N= 114)	Survival ≤ 3 years (N= 22)	Survival > 3 years (N= 92)	P value
Age, years (SD)	74 ± 4	75 ± 4	0.29
Male gender	19 (86%)	58 (63%)	0.04
Waitlist duration, months (SD)	28.5 ± 19.9	25.2 ± 20.0	0.50
Heart disease	14 (64%)	31 (35%)	0.015
CCI unweighted	1.82 ± 1.26	1.20 ± 1.18	0.03
CCI modified	3.00 ± 2.39	1.65 ± 1.80	0.004

FR-PO1152

A Cross-Sectional Prospective Study of High Serum Adipocyte Fatty Acid Binding Protein Level Associated with Low Handgrip Strength in Renal Transplant Recipients

Lin Lin,[1] Liang-Te Chiu,[3] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan; [3]Buddhist Tzu Chi General Hospital, Hualien, Taiwan.*

Background: Adipocyte fatty acid-binding protein (A-FABP) involved in lipid metabolism and metabolic and inflammatory responses and can accelerate cardiovascular disease. Low muscle strength is related to functional limitations and physical disability and is associated with all-cause mortality. The present study evaluated the relationship between fasting serum A-FABP level and handgrip strength (HGS) in renal transplant recipients.

Methods: Fasting blood samples were collected from 80 renal transplant recipients. HGS was measured using a Jamar Plus Digital Hand Dynamometer for assessment of muscle strength. Low muscle strength was defined as HGS less than 26 Kg for men and 18 Kg for women, according to the Asian Working Group for Sarcopenia (AWGS) criteria. Serum A-FABP levels were determined using a commercially available enzyme immunoassay.

Results: Thirty-one renal transplant recipients (38.8%) had low HGS, and they included a higher percentage of patients with diabetes (P = 0.025), serum triglyceride (P = 0.003), fasting glucose (P = 0.009), blood urea nitrogen (P = 0.003), creatinine (P = 0.005), and A-FABP level (P < 0.002), while lower estimated glomerular filtration rate (P = 0.008) compared with renal transplant recipients with normal HGS. After adjusting for factors significantly associated with low HGS in these patients by multivariate logistic regression analysis, serum A-FABP level (Odds ratio (OR): 1.037, 95% confidence interval (CI): 1.012–1.064, P = 0.004) was independently associated with low HGS in renal transplant recipients. The serum A-FABP level is also statistically significant in male renal transplant recipients (OR: 1.052, 95% CI: 1.000–1.107, P = 0.049) and female renal transplant recipients (OR: 1.132, 95% CI: 1.008–1.272, P = 0.037) after multivariate logistic regression analysis.

Conclusions: The serum fasting A-FABP level is positively associated with low HGS in renal transplant patients.

FR-PO1153

Impact of Delayed Graft Function (DGF) on Length of Stay After a Deceased Donor Kidney Transplant

Kristen L. King,[3] Syed A. Husain,[3] Tracy J. Mayne,[1] Sumit Mohan.[2] *[1]Angion BioMedica, San Francisco, CA; [2]Columbia University, New York, NY; [3]Columbia University Medical Center, New York, NY.*

Background: The goal of the Medicare Diagnosis Related Group bundled payment system was to increase efficiency and decrease cost of hospital care. We examined trends over the past decade on the length of the index hospitalization (LOS) for deceased donor kidney transplant (DDKT) recipients and the impact of the increasing incidence of DGF.

Methods: We identified a cohort of 118,865 patients receiving a DDKT between 1/1/2009 and 12/31/2018, excluding those with LOS >180 days (0.3% of sample). We compared the LOS for patients with and without DGF (defined as the need for dialysis in the first 7 days post-transplant) and estimated the excess LOS attributable to DGF.

Results: From 2009-2018, the incidence of DGF for DDKT rose from 23.9% to 28.3%. Median(IQR) LOS decreased from 8(6-13) to 6(5-10) days for DDKT with DGF but remained significantly higher than LOS for DDKT without DGF, which was unchanged at 5(4-7) days (p<0.001). Despite decreasing LOS for DDKT DGF, patients with DGF accounted for an increasing share of the total LOS for all DDKT, from 32.9% in 2009 to 36.3% in 2018 and the excess LOS attributable to DGF rose by 13% from a total of 10,025 days in 2009 to 11,314 days in 2018. [Fig1]

Conclusions: Although the LOS in DDKT with DGF is decreasing, the increasing incidence of DGF is has led to an absolute increase in the number of hospital days that are attributable to DGF after DDKT.

FR-PO1154

Histopathological Findings on Biopsy Among Kidney Transplant Recipients Needing Dialysis Within 2 Weeks Post-Transplant

Stacey Rolak,[1] Brenda L. Muth,[2] Didier A. Mandelbrot,[3] Arjang Djamali,[4] Brad C. Astor,[4] Sandesh Parajuli.[5] *[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]University of Wisconsin, Department of Medicine, Madison, WI; [3]U of Wisconsin Hospital, Madison, WI; [4]University of Wisconsin, Madison, WI; [5]UW Health, Madison, WI.*

Background: The need for dialysis acutely after transplant is associated with an increased risk of graft loss. No studies have characterized post-transplant graft and mortality outcomes based on biopsy-proven causes of early need for dialysis, to our knowledge. Our study reports the incidence and outcomes of histopathological cause-specific need for dialysis within two weeks following kidney transplantation at our university.

Methods: We examined kidney transplant recipients transplanted at our center between 2000-2015 who required dialysis within the first two weeks of transplant and received a biopsy during this time. Subjects were categorized into one of five categories based on their biopsy results: acute rejection (AR), acute tubular necrosis (ATN), both acute rejection and ATN (Both), other findings including tubular injury (Other), and no findings on biopsy (None). Outcomes examined included baseline characteristics, graft failure, death-censored graft failure (DCGF), and death after biopsy.

Results: Of a total of 291 patients, 111(38.1%) had Other pathology, 86 (29.6%) had ATN, 67 (23%) had AR, 22 (7.6%) had Both, and 5 (1.7%) had None. Mean time to biopsy was 8 ± 2.83 days. Of those with a diagnosis of AR, the incidence of graft failure was 36.2 per 100 person-years within the first year post-biopsy, compared to 25.1 per 100 person-years for those with ATN, and 18.9 per 100 person-years for those with Other pathology. A similar trend was seen for DCGF within the first year (32.4 for AR, 18.1 for ATN, and 12.6 for Other pathology). AR was associated with greater risk for DCGF compared to other categories, as illustrated in the K-M curve in Figure 1.

Conclusions: AR is associated with a greater risk for graft failure and DCGF than other causes of dialysis within the first two weeks post-transplant. Identification of cause of graft failure may help inform prognostic information.

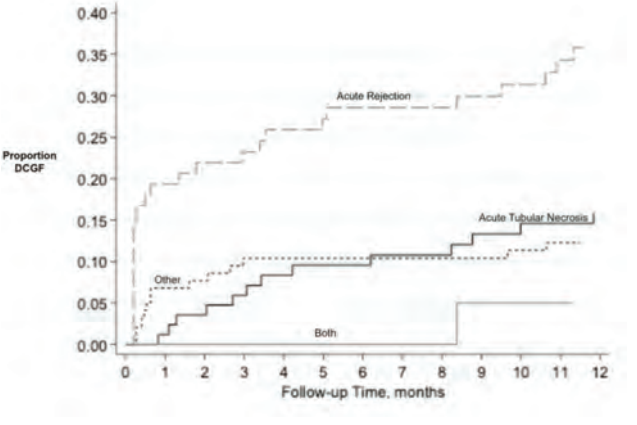

Figure 1. DCGF between study groups.

FR-PO1155

Delayed Graft Function (DGF) in Kidney Transplantation Patients: An Analysis of Disease Burden

Tracy J. Mayne,[1] Frank A. Corvino,[2] Allison L. Dillon,[2] Weiying Wang,[2] Sumit Mohan.[3] *[1]Angion BioMedica, San Francisco, CA; [2]Genesis Research, Hoboken, NJ; [3]Columbia University, New York, NY.*

Background: Kidney transplantation patients with DGF are at greater risk of graft failure and mortality, as well as additional disease burden. Hospitals are sensitive to both short- and medium-term costs as they are reimbursed through a 90-day Diagnosis Related Group (DRG) code and must manage all related expenses within the bundled payment. This study aims to assess patient characteristics, Health Resource Use (HRU) and costs associated in post-transplant patients with and without DGF in the hospital setting.

Methods: A retrospective analysis of the Premier Hospital Database (PHD) was performed on adult kidney transplant patients from January 2014 to December 2018. Kidney transplant patients were identified via ICD9/10 procedure codes and charge codes. DGF status was defined as the presence of a dialysis charge code within 7 days following a transplant. Patient and admission characteristics, HRU and costs were calculated for patients with and without DGF.

Results: Of the 12,097 kidney transplant patients, 3,087 (25.5%) had DGF. The majority of transplants (79.2%) were performed at large 500+ bed facilities and in urban areas (95.5%); males represented 61.1% of all transplant patients with a slightly higher proportion (64.2%) in the DGF group. The primary insurer (67.9%) of all patients was Medicare. Black patients (36.5%) had a higher incidence DGF compared to other races. DGF patients were also older (median 55 vs 53 years). The incidence proportion of DGF increased from 22.6% to 26.7% from 2014 to 2018. Patients with DGF had longer mean and median hospital stays of 11.5 and 8 days, compared to 7.3 and 6 days ($p<0.01$) in non-DGF patients. A significantly higher proportion of DGF patients (59.1% vs 56.0%, $p<0.01$) were admitted to the ICU and had a longer length of stay (mean days: 4.8 vs 2.5, $p<0.01$. The mean total admission costs for the Medicare patients were higher in DGF patients ($113,628.9 vs $105,962.4, $p<0.01$). The same trend was observed for ICU costs during admission ($5,815.0 vs $3,901.4, $p<0.01$).

Conclusions: DGF leads to longer hospital stay, significantly higher admission costs and a higher percentage of patients being admitted to the ICU compared to patients without DGF.

FR-PO1156

Potential Prognostic Value of Immediate Postoperative Proteinuria Predicting Early Renal Outcome After Kidney Transplantation

Kyungho Park, Mee yeon Park, Hyo jin Boo, Junseok Jeon, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae joong Kim, Hye Ryoun Jang. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Proteinuria in kidney transplant recipients (KTRs) is associated with poor patient and allograft survival. However, the relationship between urinary protein to creatinine ratio (uPCR) or urinary albumin to creatinine ratio (uACR) during the immediate postoperative period and renal outcome of KTRs is yet to be determined.

Methods: This single center retrospective cohort study included 474 KTRs who underwent kidney transplantation (KT) from January 2014 to December 2017 and followed up for ≥ 1 year. After excluding patients without urine PCR and ACR within 7 days after KT and those without serum creatinine at 1 year after KT, a total of 353 KTRs were finally analyzed: living donor KT in 186 KTRs and, deceased donor KT (DDKT) in 167 KTRs. Immediate postoperative uPCR and uACR were measured within postoperative day 7. The primary outcome was estimated glomerular filtration rate (eGFR) at 1 year after KT. The secondary outcome was the incidence of delayed graft function (DGF) in DDKT recipients.

Results: Patients with higher eGFR (≥ 60 mL/min/1.73 m^2) at 1 year after KT had lower uPCR (patients with ≥ 60 mL/min/1.73 m^2 vs. those with < 60 mL/min/1.73 m^2, median 810 ug/mgCr [IQR 500 - 1780] vs. median 1220 ug/mgCr [IQR 632 – 3905]; p = 0.007) and lower uACR (median 342 ug/mgCr [IQR 165 - 976] vs. median 613 ug/mgCr [IQR 284 - 2562]; p = 0.002) during the immediate postoperative period than those with lower eGFR. DDKT recipients with uPCR ≥ 3 mg/mgCr during the immediate postoperative period is associated with the higher incidence of DGF (DDKT recipients with uPCR ≥ 3 mg/mgCr vs. those with uPCR < 3 mg/mgCr, 30% vs. 13% [odds ratio 2.87]; p = 0.007), and lower eGFR before discharge (60 mL/min/1.73 m^2 [IQR 41 – 84] vs. 75 mL/min/1.73 m^2 [56 – 92]; p = 0.001) than those with uPCR < 3 mg/mgCr.

Conclusions: Our results suggest immediate postoperative uPCR as a potential predictor of early renal outcome in KTRs.

FR-PO1157

Preventable 30-Day Readmission After Kidney Transplantation: Classification System and Risk Association

Fawaz Al Ammary,[1] Deidra C. Crews,[1] Daniel C. Brennan,[2,1] Alexander C. Wiseman,[3] Allan Massie,[4] Dorry L. Segev,[1] Daniel J. Brotman.[1] Johns Hopkins Epic Faculty Scholar Program *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins, Baltimore, MD; [3]University of Colorado at Denver and Health Sciences Center, Denver, CO; [4]Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Preventable readmissions post kidney transplantation (KT) may reflect cost inefficiencies and gaps in quality of care. There is no practical tool to identify preventable 30-day readmissions post KT, and it is not known whether socioeconomic status (SES) influences risk of preventable readmissions.

Methods: A single-center cohort of 756 adult first-time kidney-only transplant recipients from 2013-2017 was followed for 30 days post-discharge. We merged electronic health records with national databases to develop a classification system assignment of 30-day readmission (preventable vs. non-preventable) using All-Patient Refined Diagnosis Related Group and International Classification of Diseases, ninth and tenth revisions, Clinical Modification and assessed its performance and discrimination against clinical assignment (chart review). We used multivariable logistic regression to assess the independent association of patients' SES and preventable readmissions.

Results: Recipient median age was 57 years (IQR, 45-66); 51% were white, 45% black, and 4% Hispanic. The sensitivity and specificity of the classification system were 92% and 96%, respectively, with area under the receiver-operating-characteristic curve (AUC) 0.94 (95%CI 0.89-0.97). Residents within the lowest ZIP code level neighborhood household income had the highest odds of preventable readmissions (adjusted odds ratio [OR] 2.16; 95%CI: 1.25-3.72).

Conclusions: Our classification system had a comparable discriminating ability to the gold standard of chart review identifying preventable vs. non-preventable 30-day readmission; however, our new tool requires prospective validation. Low income recipients had greater risk of preventable readmission.

Funding: Other NIH Support - Johns Hopkins Institute for Clinical and Translational Research (ICTR) which is funded in part by UL1 TR001079 from the National Center for Advancing Translational Sciences (NCATS)

Preventable Readmission	Clinically Observed	Clinically Observed

+	67	4	71
-	6	99	105
Total	73	103	176

Sensitivity: 91.78%; Specificity: 96.12%. Area under ROC: 0.9395

FR-PO1158

Perioperative Antibiotics for Preventing Post-Surgical Site Infections in Solid Organ Transplant Recipients

Samuel S. Chan,[1] Samantha Ng,[9] Carmel Hawley,[2] Elaine Pascoe,[6] Hooi peng Chan,[5] Geoffrey Playford,[7] Germaine Wong,[3] Jeremy R. Chapman,[8] Wai H. Lim,[4] Ross S. Francis,[2] Nicole Isbel,[2] Scott B. Campbell,[2] David W. Johnson.[2] Australasian Kidney Trials Network *[1]Department of Nephrology, Princess Alexandra Hospital, Metro South Hospital and Health Service, Woollongabba, QLD, Australia; [2]Princess Alexandra Hospital, Brisbane, QLD, Australia; [3]School of Public Health, The University of Sydney, Sydney, NSW, Australia; [4]Sir Charles Gairdner Hospital, Nedlands, WA, Australia; [5]General Practice, Brisbane, NSW, Australia; [6]The University of Queensland, New Farm, NSW, Australia; [7]Princess Alexaandra Hospital, Woolloongabba, NSW, Australia; [8]Westmead Hospital, Westmead, NSW, Australia; [9]C/o, Spring Hill, QLD, Australia.*

Background: No consensus exists on the role of antibiotics for preventing surgical site infections (SSIs) in solid organ transplant recipients (SOTRs). Objectives: To assess the benefits and harms of prophylactic antibiotics for preventing SSIs in SOTRs.

Methods: The Cochrane Kidney and Transplant Register was searched up to 8 Dec 2018. Studies were identified through searches of CENTRAL, MEDLINE, EMBASE, conference proceedings, International Clinical Trials Register (ICTRP) Search Portal, and ClinicalTrials.gov. All randomized controlled trials (RCTs) and quasi RCTs in any language assessing prophylactic antibiotics for preventing SSIs in SOTRs at any time point after transplantation. Two authors independently determined study eligibility, assessed quality and extracted data. The primary outcome was SSI incidence. Summary effect estimates were obtained using a random-effects model and results were expressed as risk ratios (RR) and 95% confidence intervals (CI) for categorical variables, and mean differences (MD) or standardized mean differences (SMD) and 95% CI for continuous variables.

Results: This review included 9 eligible studies (803 participants). Six studies (416 participants) compared antibiotics versus no antibiotics and 3 studies (387 participants) compared extended duration antibiotics versus short duration antibiotics. Risk of bias was assessed as high for performance (9 studies), detection (9 studies), attrition (2 studies) and selective outcome reporting (1 study). Antibiotics had an uncertain effect on SSI incidence (RR 0.63, 95%CI 0.37-1.06; 6 studies, 416 participants, I^2=61%, very low certainty evidence). Most RCTs occurred prior to 200 (RR 2.17, 95%CI 0.84-5.66; 1 study, 188 participants, very low certainty evidence) with only 1 RCT in the last 2 decades (RR 0.30, 95%CI 0.15-0.60; 5 studies, 228 participants, I^2=33%, very low certainty evidence).

Conclusions: There is very low certainty evidence to support perioperative antibiotics for preventing SSIs in SOTRs. Further high quality, adequately powered RCTs would better inform practice.

FR-PO1159

Serum Phosphate Levels Modify the Impact of Intact PTH Levels on Renal Outcomes in Kidney Transplant Recipients

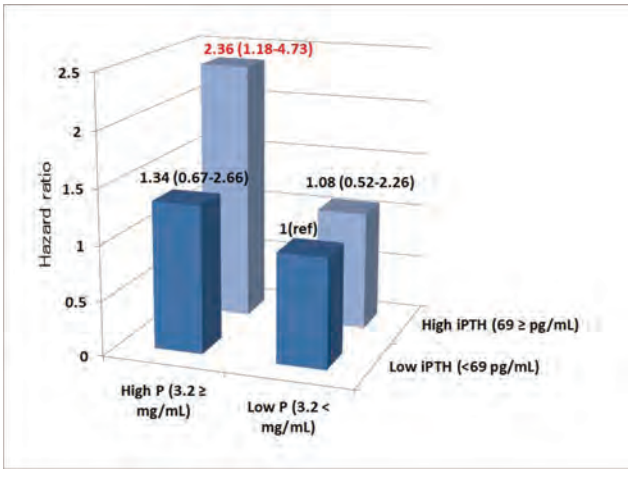
Yohei Doi, Takayuki Hamano, Satoshi Yamaguchi, Tatsufumi Oka, Yusuke Sakaguchi, Isao Matsui, Yoshitaka Isaka. *Osaka University Graduate School of Medicine, Suita Osaka, Japan.*

Background: Mineral bone disorder (MBD) parameters including parathyroid hormone (PTH), fibroblast growth factor 23 (FGF23), calcium, phosphate (P), 1,25-dihydroxyvitamin D (1,25D), and 25-hydroxyvitamin D predict renal outcomes, when assessed separately, in kidney transplant recipients (KTRs). However, data evaluating those parameters simultaneously and interwoven relationships on renal outcomes are scarce.

Methods: In this single-center prospective cohort study, we included 263 KTRs with grafts functioning at least 1 year after transplantation. The renal outcome was a composite of estimated GFR (eGFR) halving and graft loss. We performed Cox regression analyses to assess associations of MBD parameters with the renal outcome.

Results: Median eGFR was 38 ml/min/1.73m^2. The renal outcome occurred in 98 KTRs during a median follow-up of 10.7 years. In a multivariable Cox model, intact PTH (iPTH), P, and 1,25D, but not intact FGF23 levels, were associated with the renal outcome (HR 1.60 per log scale; 95%CI 1.19-2.14, 1.60 per mg/dL; 1.14-2.23, 0.98 per pg/mL; 0.96-1.00, and 0.99 per log scale; 0.74-1.34, respectively). A competing risk analysis with death as a competing event yielded a similar result. After stratification into 4 groups by the median values of iPTH and P (Pinteraction<0.1), however, high iPTH levels (69 ≥ pg/mL) were not associated with worse renal outcomes when serum P levels were less than median (3.2 mg/dL) (Figure). Only in KTRs not receiving oral active vitamin D, 1,25D levels predicted the renal outcome (Pinteraction<0.1).

Conclusions: High iPTH, P, and low 1,25D levels predicted poor renal outcomes in KTRs. Given that PTH promotes phosphaturesis and enhances 1α-hydroxylase activity in proximal tubules (PT), low P and high 1,25D levels may reflect viable PT function.



Hazard ratios for renal outcomes stratified by the median values of serum iPTH and phosphate levels

FR-PO1160

Bone Turnover Markers Are Associated with Hypocalcemia Immediately After Renal Transplantation

Weiwei Kong,[2] Jianghua Chen,[1] Hongfeng Huang.[3] *[1]Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [2]Kidney center, First hospital of Zhejiang University, Hangzhou, China; [3]Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China, Hangzhou, China.*

Background: Bone and mineral disorders occur commonly after renal transplantation (RTX). Serum calcium levels decreased after RTX and gradually reach calcium homeostasis. Hypocalcemia immediately after RTX may influence QTc interval and myocardial contractility, thus it is a life-threatening phenomenon after RTX. Bone turnover markers (BTMs) are markers reflect the bone turnover stage and bone and mineral disorders. Whether BTMs can predict the occurrence of hypocalcemia after RTX has not been reported.

Methods: A total of 101 patients receiving ABO compatible living donor renal transplantation were assessed. General patient information, kidney function and calcium metabolism indexes were measured before transplantation. Calcium metabolism indexes included calcium, phosphorus, parathyroid hormone (PTH), 25-dihydroxyvitamin D (25(OH)D3) and BTMs. BTMs included procollagen type I N-terminal propeptide (PINP), N-terminal mid-molecule fragment osteocalcin (N-MID) and β-C-telopeptide of type I collagen (β-CTX). The patients were divided into two groups dependent on post-transplantation calcium levels, non-hypocalcemia group and hypocalcemia group. The prediction value for hypocalcemia were evaluated by concordance index (c-index), akaike information criterion (AIC) and cayesian information criterion (BIC) methods.

Results: General patient information, kidney function and calcium metabolism indexes were compared between non-hypocalcemia group and hypocalcemia group. Age, dialysis type, serum calcium levels, PTH, 25(OH)D3 and BTM levels showed differences between non-hypocalcemia group and hypocalcemia group. Then correlation analysis showed calcium levels after RTX showed positive correlations with serum PTH, 25(OH) D3, PINP, N-MID and β-CTX amounts. Further utilizing multi-regression selected risk factors to established basic model equation (AIC=126.85 and BIC=134.69; c-index 0.78). Then we added PTH, 25(OH)D3, N-MID and PINP to basic model respectively and found no influence on predictive ability. Final inclusion of β-CTX, one of BTMs, to basic model improved the predictive performance significantly (AIC=113.44 and BIC=123.9; c-index 0.83).

Conclusions: Low levels of BTMs were associated with hypercalcemia after RTX. To predict the occurrence of hypocalcemia, β-CTX, one of BTMs, could improve the predictive ability.

FR-PO1161

Vitamin D Status in a Cohort of Renal Transplanted Patients: Factors Related and Impact on Rejection Occurrence and Long-Term Graft Outcome

Anna Regalia,[1] Carlo M. Alfieri,[1,2] Oksana Ruzhytska,[3] Maria Teresa Gandolfo,[1] Donata C. Cresseri,[1] Mariarosaria Campise,[1] Piergiorgio Messa.[1,2] *[1]Fondazione IRCCS Ca Granda- Ospedale Maggiore Policlinico Milano, Milano, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [3]I. Horbachevsky Ternopil National Medical University, Ternopil, Ukraine.*

Background: Immunomodulatory properties in renal transplant (RTx) have been hypothesized for vitamin D (VD). We evaluated retrospectively, in a cohort of renal transplanted patients (RTxp): a) VD status at 1 (T1) and 12 (T12) months after RTx; b) the factors related to VD status; c) the impact of VD status on rejection rate and long term graft outcome.

Methods: The study includes 438 (M=265;age 49[40-50]years), out of 670 patients (pts) transplanted between April 2004 and November 2017, where VD status parameters were available both at T1 and T12. Included and not included pts did not differ in general features. VD status, based on 25OH-VD levels, was categorized as: insufficient (iVD) or sufficient (sVD), if 25OH-VD was < or ≥30 ng/mL, respectively. Patients were followed-up for 65[33-97] months and evaluated for rejection rate, diagnosed on renal biopsy (RBx) performed for clinical indication, and for achieving combined major adverse clinical events (MACE: death or graft failure, considered as either return to dialysis or eGFR halving).

Results: A) 25OH-VD levels increased from 14[8-18] ng/mL at T1 to 17[10-23] ng/mL at T12 (p<0.0001), with iVD being present in 425 (97%) pts at T1 and in 380 (87%) pts at T12. VD status normalized spontaneously or after VD supplementation in 19 and 35 pts, respectively; 9 sVD pts at T1 were iVD at T12. b) 25OH-VD levels were negatively related with PTH both at T1 and T12, while they were positively related with Ca levels at T12. c) Rejection (REJ+) was diagnosed in 38 (36%) out of the 105 RTxp submitted to RBx. No difference was found in 25OH-VD levels between REJ+ and REJ- pts, both at T1 and T12. MACE occurred in 66 (15%) pts (MACE+). 25OH-VD levels at T12 were significantly lower in MACE+ pts and were the only variable significantly associated with MACE+ at multivariate analysis (OR=0.96, p= 0.01).

Conclusions: With the limitations of the retrospective design and the relatively low number of pts, we found that: a) iVD was highly prevalent in RTx patients both at T1 and T12; b) VD levels were inversely related with PTH levels; c) no association was found between VD status and REJ occurrence, while 25OH-VD levels at T12 were inversely and independently related to MACE+.

FR-PO1162

The Risk of Hypercalcemia After the Kidney Transplantation? Analysis of Cinacalcet Therapy with 10 Years of Follow-Up in a Single Center

Francesca K. Martino,[1] Ilaria Tantillo,[1] Fiorella Gastaldon,[1] Claudio Ronco.[2] *[1]San Bortolo Hospital, Vicenza, Italy; [2]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy.*

Background: The persistence of secondary hyperparathyroidism after kidney transplantation (KT) occasionally manifests itself by hypercalcemia and hypophosphatemia. In patients with KT, Cinacalcet is an off label treatment for hypercalcemia related to hyperparathyroidism. The aim of our study is to evaluate which factors are predictive of hypercalcemia that requires the use of Cinacalcet.

Methods: We retrospectively examined all the patients who received a KT from 2008 and 2018. In each patient we evaluated demographic characteristics and the following parameters: creatinine, hemoglobin, albumin, Calcium, Phosphate, PTH, vitD25OH, and the linked therapies. T Student, Kruskal Wallis, and Pearson's chi-square tests were used, as appropriate. The regression model was used to evaluate the predictive variables for the use of Cinacalcet.

Results: In a 10-year period 459 KT were performed. Only 9.2% of the patients needed Cinacalcet therapy. Table 1 shows the comparison of the characteristics of those

patients who needed Cinacalcet therapy and those who did not. Dead donor transplantation (OR 4.3 p = 0.023), number of KT received (OR 6.8 p <0.0001), PTH levels (OR 1.01 p <0.001), and phosphate levels (OR 0.44.6 p = 0.01) were all independent predictors for Cinacalcet use in multivariable analysis.

Conclusions: Our data show that dead donor transplantation, presence of previous KT, and both PTH and phosphate levels were able to predict Cinacalcet therapy. In these cases we suggest a more careful monitoring of the calcium levels.

Funding: Government Support - Non-U.S.

	No Cinacalcet	Cinacalcet	p value
Age (years)	55.8±12.9	55.2±12.4	0.753

FR-PO1163

The Impact of Periodontitis on Recipient Outcomes After Kidney Transplantation

Myung-Gyu Kim, Hyeonjin Min, Sewon Oh, Sang-Kyung Jo. *Korea University Anam Hospital, Seoul, Seoul, Republic of Korea*.

Background: Periodontitis has a high prevalence in patients with chronic kidney disease and has been reported to increase systemic inflammations and cardiovascular risks. Although dental care is usually recommended prior to transplantation due to potential for serious infection, little is known about impact of periodontitis on transplant outcomes. The purpose of this study was to examine whether periodontitis before KT affects post-KT recipient outcomes.

Methods: This was a single center, retrospective study including KT recipients from April 2008 to October 2018. The panoramic radiographs at pre-KT work up were analyzed by a dentist with severity of periodontitis graded according to new classification system developed in 2017.

Results: One hundred and sixty-six recipients who received pre-KT dental examination were divided into 3 groups according to 1st, 2nd, 3rd and 4th-stage periodontitis; group1 (1st and 2nd stage, 28.9%), group2 (3rd stage, 35.8%), and group3 (4th-stage, 22.6%) respectively. Seventy-seven patients (46.4%) with periodontitis received treatments such as scaling or surgical extraction before KT. Advanced stage periodontitis patients were more likely to be older, obese, smoker and had higher prevalence of diabetes. However, pre-transplant immunological variables or immunosuppression were not different according to periodontitis grades. The mean follow-up period is 4.16 years. Advanced stage periodontitis without treatment was associated with significantly increased risk of CMV and BKV infection. However, rate of acute T cell mediated rejection was significantly lower in patients with advanced stage periodontitis. eGFR measured at 36 months after KT was significantly higher in patients with advanced periodontitis (p=0.016) and this association was evident only in younger (<50yrs), male and non-diabetic patients. Multivariate logistic regression analysis showed that low stage of periodontitis and the use of cyclosporine were independent predictors for lower eGFR at 36 months.

Conclusions: These results suggest that pre-transplant periodontitis could be a manifestation of systemic inflammation and altered immune function in patients with end-stage renal disease and may affect long-term post-transplant outcomes. Impact of periodontitis or its treatment on transplant outcomes needs to be further clarified.

FR-PO1164

Effect of a Good Oral and Dental Care on Inflammation and Oral Lesions in Renal Transplant Patients

Raj K. Sharma,[2] Lokesh Sharma,[1] Sonia Mehrotra,[2] Devina Pradhan.[3] *[1]Sardar Patel Post Graduate Institute of Dental and Medical Sciences, Lucknow, India; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [3]Rama Dental College Hospital & Research Centre, Lucknow, India*.

Background: Inflammation plays an important role in causing complications in CKD and transplant patients. C-reactive protein and pro-inflammatory cytokines could predict outcomes in transplant patient. Poor oral health results in inflammation and cytokine production. There is need to evaluate the benefit of good oral hygiene on renal transplant outcome.

Methods: A randomized controlled trial was carried out amongst CKD patients going for renal transplantation. All patients had dental and oral examination (Type III clinical examination as per American Dental Association specifications and WHO oral health proforma, 2013) Group I (Non interventional group) 50 patients. Group II (Intervention group) - 50 patients of chronic kidney disease going for transplantation. Group III (Control group) comprised of 50 healthy age, sex matched subjects. Intervention group followed regular tooth brushing, use of dental floss along with use of mouth wash twice every day and counseling sessions for good oral and dental care for a period of 3 months after transplant. Non-intervention group continued usual oral and dental care. The oral and dental findings specially the periodontitis score was compared between groups I and II and with the healthy controls. CRP (C- reactive protein) values were assayed at baseline and after 3 months.

Results: Comparison of CRP values between Interventional and non-interventional groups at baseline and at 3months showed that periodontitis score and CRP significantly came down at 3 months in intervention group as compared to non- intervention group. CRP values in the interventional and non-intervention groups were analyzed in relation to presence of donor specific antibodies (DSA) and HLA mismatch scores in the two groups. Our data shows that after aggressive dental and mouth hygiene routine, intervention group patients showed significant decline in CRP values as compared to the non intervention group. It almost reached close to values in normal controls.

Conclusions: The present study concludes that the oral hygiene of the patients with chronic kidney disease going for transplant is deteriorated. Good oral and dental care in transplant recipients can improve inflammation which could have beneficial effect on post transplant outcomes ”

FR-PO1165

Safety and Effectiveness of Ferric-Carboxymaltose in Kidney Transplant Patients

Luca Apicella, Vincenzo Bellizzi, Carmine Secondulfo, Giuseppe Palladino, Giancarlo Bilancio. *Nephrology, Dialysis and Renal Transplantation Division, University Hospital “San Giovanni di Dio e Ruggi d’Aragona” of Salerno - Italy, Salerno, Italy*.

Background: In kidney transplant patients (KTx), the post-transplant anemia (PTA) is associated with worst graft outcome and increased cardiovascular/all causes mortality. With common available iron treatments, iron deficiency (ID) in KTx is highly prevalent and represents one of the major causes of PTA. This prospective study evaluates the safety and effectiveness of ferric-carboxymaltose (FCM) in KTx patients with iron deficiency anemia (IDA) and no/low response to other previous iron treatment.

Methods: Consecutive, stable (tx age > 1-y), CKD-3/5 stages, anemic (Hb <11g/dl and/or ESA treatment), iron deficiency (TSAT <20% and/or ferritin <100 ng/ml), previous iron intolerance or low-responce, KTx were prospectively enrolled. Each patient was administered FCM, 500 mg, in standardized conditions at baseline, and eventually a second dose 500 mg dose one month later. Patients were evaluated for clinical conditions, iron status, anemia and renal function every month during a 6-months follow-up (irrespective of iron administration). Clinical and lab side-effects FCM related (nausea, vomiting, diarrhea, headache, fever, rush, erythema, itching, myalgia, bronchospasm, anaphylaxis) were monitored during the study.

Results: 32 KTx (M15-F17); Diabetes: 19%; Age: 55.8±11.7years; BMI: 26.3±4.5 kg/m^2; transplant age: 104±92 months; eGFR: 38.2±11.9 ml/min; SBP:135±21, DBP:81±12 mmHg; ACEi/ARB:28.1%; previous iron: naïve, n=7 (reported intolerance during dialysis), os, n=20 (16 ongoing), i.v., n=4 (0 ongoing). At 34±4 days after FMC infusion, ferritin increased from 44±53 to 149±136 ng/mL (p<0.001), TSAT from 10±6 to 18±10% (p<0.001), Hb from 10.2±1.0 to 11.3±1.4 g/dl (p<0.01); at 160±71 days, ferritin was 93±110 ng/mL, TSAT 19±9% and Hb 12.0±1.7 g/dl (all p<0.05 *vs* Baseline and NS *vs* 34days). At baseline, 81% of pts were on ESA at a mean dose of 9.960±6.620; during the follow-up, pts on ESA reduced to 75% and 44% and ESA dose to 10.480±9.670 and 6.760±11.220 IU/week, respectively. No changes of clinical parameters, renal function or electrolytes occurred; no side effect was detected.

Conclusions: In stable KTx patients with iron deficiency related anemia, the treatment with FCM is safe and effective, even in subjects resistant to previous iron treatment, allowing an optimal and stable correction of both iron deficiency or anemia, while reducing the ESA dose.

FR-PO1166

Impact of Peritransplant Red Blood Cell Transfusion on Long-Term Renal Outcome After Kidney Transplantation

Kyungho Lee,[1] Mee yeon Park,[1] Seungmin Song,[1] Hyo jin Boo,[1] Junseok Jeon,[1] Jung eun Lee,[1] Wooseong Huh,[1] Yoon-Goo Kim,[1] Dae joong Kim,[1] Ho geol Ryu,[2] Hye Ryoun Jang.[1] *[1]Division of Nephrology, Department of Internal Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Department of Anesthesiology and Pain Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Republic of Korea*.

Background: Patients undergoing kidney transplantation (KT) frequently receive red blood cell (RBC) transfusion perioperatively. Transfusion of blood products may induce allosensitization in KT recipients. The effects of peri-transplant transfusion on graft survival were investigated using a nationwide database.

Methods: Data were collected from the National Healthcare Insurance Service database in Korea. 13,872 patients who received KT in Korea between 2007 and 2015 were analyzed. The outcome measures were graft failure rate at 5 years from KT and overall patient survival depending on the amount of RBC transfusion. Diabetes mellitus, hypertension, coronary artery disease, cerebrovascular disease, transplantation period, and Elixhauser comorbidity index were adjusted as covariates.

Results: The 5-year graft failure rates were 17% in the no transfusion group, 17% in 1-2 units group (OR 0.98 [95% CI 0.84–1.16]), 26% in 3-5 units group (OR 1.51 [95% CI 1.19–1.91]), and 38% in 6 units or more group (OR 2.13 [95% CI 1.39–3.27]) (P < .001, 3-5 units or 6 units or more vs. no transfusion group). The 10-year survival rates were 97% in no transfusion group, 96% in 1-2 units group (OR 1.44 [95% CI 1.19-1.75]),

92% in 3-5 units group (OR 2.38 [95% CI 1.86-3.05]), and 67% in 6 units or more group (OR 10.78 [95% CI 8.47-13.71]) (*P* <.001, 1-2 units, 3-5 units or 6 or more units group vs no transfusion group).

Conclusions: Peri-transplant RBC transfusions in KT recipients were independently associated with increased risk of renal allograft failure and death. Further studies are required to confirm the risk of allosensitization following blood transfusion and to search for alternative ways to reduce sensitization with blood products.

FR-PO1167

Changes in Blood Pressure, Graft Function, and Proteinuria After Dialysis Arteriovenous Fistula Closure in Kidney Transplant Recipients

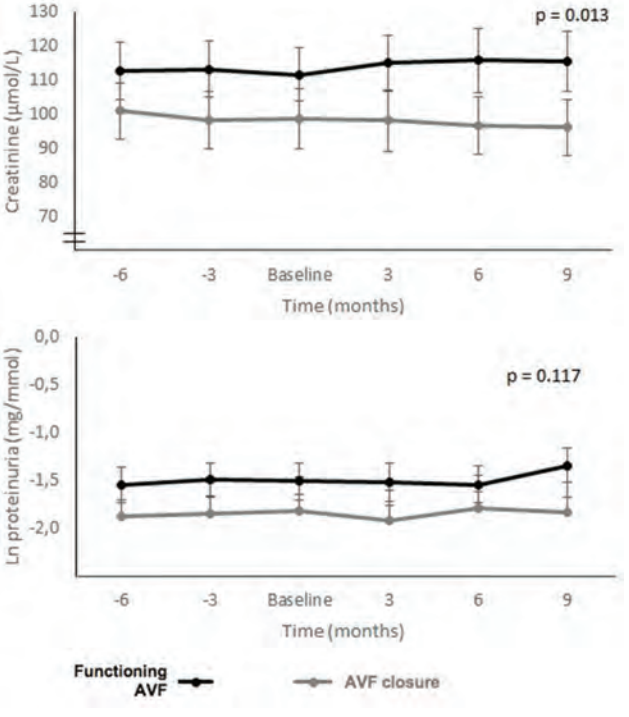
Barbara Vajdic trampuz, Miha Arnol, Jadranka Buturovic-Ponikvar. *University Medical Centre Ljubljana, Ljubljana, Slovenia*.

Background: The aim of our observational historic cohort study was to evaluate the impact of dialysis arteriovenous fistula (AVF) closure on systolic and diastolic blood pressure (SBP, DBP), graft function and proteinuria in kidney transplant recipients.

Methods: The study group included 111 kidney transplant recipients with an AVF closure after a median 34 months' post-transplant. Controls included 53 recipients with a functioning AVF after a median 33 months of follow-up. Graft function was assessed by serum creatinine and estimated glomerular filtration rate (eGFR) using CKD-EPI formula, and proteinuria was assessed by spot urine protein/creatinine ratio. SBP and DBP was measured at each visit. We used linear mixed models to calculate the slope of serum creatinine, eGFR and proteinuria change versus time.

Results: Baseline mean SBP and DBP were comparable between groups (134±16 *vs.* 138±16 mmHg; P=0.150, and 79±10 *vs.* 77±13 mmHg; P=0.472). Following AVF closure, SBP increased from 134±16 to 138±15 mmHg (P=0.001), and DBP increased from 79±10 to 84±10 mmHg (P<0.001). In the control group with functioning AVF SBP decreased (138±16 to 135±15 mmHg; P=0.038), while DBP did not change (77±13 to 76±11 mmHg; P=0.122). The course of serum creatinine and proteinuria and 95% confidence intervals are shown in Figure 1. The mean eGFR slope improved before (0.224 mL/min/1.73m^2 per month) and deteriorated after AVF closure (-0.023 mL/min/1.73m^2 per month) (P=0.044). The groups were significantly different with respect to serum creatinine slope (primary study end point; P=0.013) but not with respect to proteinuria slope (P=0.117).

Conclusions: The closure of a dialysis AVF may affect blood pressure and kidney graft function, but it does not impact proteinuria.



FR-PO1168

Kidney Recipients with Allograft Failure, Transition of Care (KRAFT): Practice Survey

Tarek Alhamad,[2] Michelle L. Lubetzky,[1] Emmanuel Y. Edusei,[14] Christopher D. Blosser,[5] Neeraj Singh,[3] Beatrice P. Concepcion,[13] Leonardo V. Riella,[12] Gaurav Gupta,[8] Krista L. Lentine,[10] Miklos Z. Molnar,[9] Ekamol Tantisattamo,[11] Deborah B. Adey,[4] John J. Friedewald,[6] Alexander C. Wiseman,[7] Martha Pavlakis,[15] Ronald Parsons,[16] Kenneth J. Woodside,[17] James C. Rice,[18] Edward S. Kraus,[19] Darshana Dadhania.[14]
[1]Division of Nephrology and Hypertension, New York, NY; [2]Washington University in St. Louis, St. Louis, MO; [3]LSU Health Sciences Center, Shreveport, LA; [4]University of California, San Francisco, San Francisco, CA; [5]University of Washington, Seattle, WA; [6]Northwestern University, Chicago, IL; [7]University of Colorado at Denver and Health Sciences Center, Denver, CO; [8]Virginia Commonwealth University Health System, Richmond, VA; [9]University of Tennessee Health Science Center, Memphis, TN; [10]Saint Louis University, St. Louis, MO; [11]University of California, Irvine School of Medicine, Irvine, CA; [12]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [13]Vanderbilt University Medical Center, Nashville, TN; [14]Weill Cornell Medicine, New York, NY; [15]Beth Israel Deaconess Medical Center, Boston, MA; [16]Emory University School of Medicine, Atlanta, GA; [17]University of Michigan, Ann Arbor, MI; [18]University of San Diego, San Diego, CA; [19]Johns Hopkins University, Baltimore, MD.

Background: Sensitization after failed allograft in the setting of withdrawal of immunouspression makes re-transplantation increasingly difficult. We sought to understand how different centers and clinical care providers approach withdrawal of immunosuppression in a failing kidney allograft through a survey of US kidney transplant centers.

Methods: After approval from IRB and the AST Education Committee, a survey about practices related to withdrawal of immunosupression was distributed electronically to members of the AST members between Nov 2018 and May 2019.

Results: There were 101 responders with a response rate of 31%. Most survey respondents were Transplant Nephrologists (80.4%) at academic medical centers (90.2%). The most common approach to withdrawal of immunosuppression was withdrawal of the anti-metabolite first; with 64.2 % respodning they would withdraw antimetabolite first, 24% with no unified protocol, and 9.4% responding they would stop CNI first. Most providers would stop immunosupression over a time frame of 2-6 months (38.9%), although 24.1% responded they would keep a low dose of prednisone, and 20.4% had no unified protocol. Approach to tapering of immunosuppression did differ based upon whether or not practitioners felt the patient would be re-transplanted shortly. While most practitioners, 96.6% felt development of sensitization was of intermediate or most importance in the decision to taper immunosuppression there were many concerns of risk of infections, malignancy and patient age which were factors in the decision to taper or continue immunosuppression. Overall, 57.4% providers felt there was a need for standardized approach to taper immunosuppression in the failing allograft.

Conclusions: In a sample of US Kidney Transplant centers, we found a wide range of approaches to withdrawal of immunosuppression in a failed kidney transplant with no unified protocols in quarter of the respondents. Efforts to standardize clinical practice are warranted to tailor immunosuppression withdrawal according to the availability of a second kidney transplant and patient comorbidities.

FR-PO1169

Safety and Efficacy of a Kidney Graft Biopsy Program by Nephrologists with Short Post-Biopsy Surveillance Times

Mauricio Arvizu-Hernandez, Lluvia A. Marino-Vazquez, María F. Mejia, Dheni Fernandez, Brenda Rendon, Mariel Estrada, Ricardo Correa-Rotter, Luis E. Morales-Buenrostro. *Department of Nephrology and Mineral Metabolism, National Medical Science and Nutrition Institute Salvador Zubirán, Mexico, Mexico*.

Background: Kidney graft biopsies (KGB) are the gold standard for diagnosis of kidney graft dysfunction. Since Jan/2015 we have increased the KGB, reducing wait times and costs, due to the implementation of a ambulatory program (intrahospital surveillance <6 hrs), in charge of the fellows of the transplant nephrology program, supervised and guided by an interventional nephrologist.

Methods: Prospective, observational and descriptive study.

Results: 1091 KGB were made (jan/15-dec/18). Indications: protocol 463 (43.8%), de *novo* or increase of DSA 231 (21.2%), post-rejection control 149 (13.7%), graft dysfunction 146 (13.4%) and others 87 (7.9%). A total of 33 (3.0%) complications were reported; 5 (0.5%) were serious (persistent hematuria and hospitalization requirement). 11 (1%) were hematuria; 21 (1.9%) peri-graft hematomas. No infections, graft loss, or other procedures were required. In 1070 KGB (98.1%) the sample was adequate. Protocolized KGB at 3 and 12 mo post-KT and surveillance KGB for new pts from other centers carried out in 463 cases; 236 at 3 mo, 187 at 12 mo and 40 of newly admitted pts. Spite of not having clinical/laboratories alterations, the result of the KGB was abnormal in 58% of the total; 50% at 3 mo, 63% at 12 mo and 67% in new pts. Findings were: borderline alterations 158 (34%), humoral rejection 44 (9.5%), cellular rejection 24 (5%) and other alterations 36 (7.7%). In 161 (14%) pts we evaluated the relationship between the angle of incidence of the needle on the renal graft and the quality of sample and complications. The firing angle was 33.1±8.8 degrees, with a median of 12 (8-16 glom). There were no relation between angle of incidence and the quality of sample, or in the probability of

complications. We observed a saving of 75% in each KGB ($680 before 2015 vs $172 after 2015); total savings of $553,855, and a reduction 1091 hospital beds in the 4 yrs.

Conclusions: The implementation of a KGB program by nephrologists reduced costs and hospital stay. It was effective (adequate sample in 98%) and safe (3% complications). In our study there were no serious complications that required invasive procedures, transfusions or graft loss. The angle of shot does not impact on the frequency of complications or the quality of the sample.

FR-PO1170

Renal Transplant Complications in Patients with and Without Gout

Megan Francis-Sedlak, Brian LaMoreaux, Robert J. Holt. *Horizon Therapeutics plc, Lake Forest, IL.*

Background: Graft-related complications are among the most serious issues solid-organ transplant recipients and their healthcare teams face post-operatively. Gout is a known frequent co-morbidity in transplant patients. Whether renal transplant patients with gout suffer from higher rates of transplant-related complications, as compared to transplant patients without gout, has not been investigated. We analyzed a large US population database to determine the overall transplant complication rate in patients having a renal transplant with and without gout.

Methods: A retrospective review of Humana Research Database claims (2007-2017) was undertaken to identify kidney transplant patients with ≥6 months in plan before and after transplant. Diagnostic gout codes (ICD9/10) were used to categorize patients into gout and non-gout groups. Additionally patients were classified as having gout pre- or post-transplant based on first gout code occurrance. Transplant complications were determined using codes for complications of transplanted kidney, unspecified and other complications of kidney transplant, kidney transplant rejection, failure, and infection.

Results: The database contained 6085 patients with a kidney transplant and ≥6 months in plan both pre and post-transplant. Of these, 1504 patients had ≥1 gout codes (the first code occurred in 909 patients pre-transplant and 595 post-transplant), and 4581 patients never had a gout code. The renal transplant complication rate in the overall cohort was 36.0%. Patients with gout had a higher complication rate (40.4%) than those without gout (34.6%, OR: 1.28, 95%CI: 1.136–1.443, p<0.001). The higher complication rate in gout patients was driven by those who developed gout post-transplant.(**Table 1**)

Conclusions: Our analysis indicates that patients with gout, especially those with gout arising post-transplant, suffered from higher rates of overall transplant-related complications. In addition to more research on this topic, an increased focus on awareness and screening of renal transplant patients for gout is warranted.

Funding: Commercial Support - Horizon Therapeutics plc

Table 1. Renal transplant-related complications

Group	Number of Patients	Number with Complications	% with Complications
Enrolled Patients	6085	2191	36.0%
Gout and Transplant	1504	607	40.4%
Gout Pre-Transplant	909	304	33.4%
Gout Post-Transplant	595	303	50.9%
No Gout	4581	1584	34.6%

FR-PO1171

Assessing the Relationship Between Gout and Return to Hemodialysis Among Renal Transplant Patients

Justin W. Li,[1] Zheng Wang,[1] David Yin,[1] Mark D. Brigham,[1] Brian LaMoreaux,[2] Jeffrey Kent,[2] Megan Francis-Sedlak,[2] Richard J. Johnson,[3] Nandini Hadker,[1] Gavin Miyasato.[1] *[1]Trinity Partners, Waltham, MA; [2]Horizon Therapeutics plc, Lake Forest, IL; [3]University of Colorado Denver, Aurora, CO.*

Background: Although gout has been shown to be associated with poor renal outcomes among chronic kidney disease populations, this relationship is not well understood among renal transplant recipients. This analysis compared rates of return to maintenance hemodialysis, a negative transplant outcome, across three primary renal transplant patient cohorts based on gout status: non-gout, pre-existing gout, and new-onset gout.

Methods: This retrospective study of the United States Renal Data System examined Medicare beneficiaries that received a primary renal transplant between 2008-2013. Patients' Medicare claims data were used to identify pre-existing gout in the 2 years prior to transplant and new-onset gout in the 3 years post-transplant. To mitigate the effect of complications associated with acute allograft rejection/ failure, recipients who died, returned to dialysis, or received re-transplantation within 3 years after primary renal transplantation were excluded. Patients' return to hemodialysis was observed in the period between 3-5 years post-transplantation. The association between gout status (non-gout, pre-existing, and new-onset) and 5-year return to dialysis was evaluated via chi-squared tests.

Results: 39,780 patients received a primary renal transplant between 2008-2013 with Medicare as their primary payer after exclusions. Of these patients, 33,105 (83.2%) were non-gout, 4,747 (11.9%) had pre-existing gout, and 1,928 (4.8%) developed new onset gout post-transplant. 2,211 (5.6%) primary renal transplant recipients returned to hemodialysis 3 to 5 years post-transplantation. The rate of return to hemodialysis 3 to 5 years after transplantation for non-gout, pre-existing gout, and new onset gout was 5.6, 4.6, and 7.5%, respectively (all pairwise comparisons yielded p<0.05).

Conclusions: Compared to non-gout and pre-existing gout patients who received a primary renal transplant, patients who developed new-onset gout after transplantation were more likely to require maintenance hemodialysis, a negative renal transplant outcome. Further investigation is needed to determine if the presence, timing, and duration of gout relative to renal transplantation are independent predictors for return to dialysis.

Funding: Commercial Support - Horizon Therapeutics plc

FR-PO1172

Can Uric Acid Blood Levels in Renal Transplant Recipients Predict Allograft Outcome?

Ofer Isakov, Doron Schwartz, Tamar Hod. *Souraski Medical Center, Tel Aviv, Israel.*

Background: Hyperuricemia is common after renal transplantation, especially in those receiving calcineurin inhibitors (CNI). Increased uric acid (UA) levels were found predictive of kidney disease and end-stage renal disease in those with normal renal function and disease progression in individuals with kidney disease. Little, however, is known about the relationship between UA levels and allograft outcome.

Methods: We conducted a retrospective single-center analysis (N=368) in order to assess UA blood levels posttransplant association with allograft outcome.

Results: Patients were divided into 2 groups based on the mean UA level measured between 1-12 months posttransplant. Those with mean UA level ≥ 7 and 6.5 mg/dL (N = 164) versus mean UA level< 7 and 6.5 mg/dL for men and women respectively (N=204) had lower GFR values at 1, 3 and 5 years posttransplant. In a multivariate analysis adjusted for age, gender, race, transplant type, mean CNI levels, presence of slow graft function (SGF) and baseline allograft function (GFR at 3 months posttransplant) the association of UA levels to allograft function were not significantly associated with differences in GFR at 1, 3 and 5 years posttransplant.

Conclusions: Hyperuricemia is a surrogate for a worse allograft function. After adjustment for baseline allograft function increased UA levels were not found to be an independent predictor of long-term allograft function despite the known association of hyperuricemia with progression of cardiovascular and renal disease.

Baseline Characteristics of the High versus low UA groups

	High UA (N=164)	Low UA (N=204)	P Value
Age (years)	52.24 (13.76)	51.38 (13.92)	0.553
Males	84 (51.2)	124 (60.8)	0.083
Whites	99 (60.4)	134 (65.7)	0.462
Blacks	40 (24.4)	38 (18.6)	
LD	70(42.7)	138(67.6)	<0.001
DCD-ECD	57(34.8)	35(17.2)	
SCD	37(22.6)	31(15.2)	
SGF	86 (52.4)	61 (29.9)	<0.001
GFR 3M (ml/min)	43.33 (15.06)	58.37 (17.84)	<0.001
GFR 1Y (ml/min)	45.92 (17.30)	60.77 (19.70)	<0.001
GFR 3Y (ml/min)	43.42 (20.64)	58.02 (19.87)	<0.001
GFR 5Y (ml/min)	41.81 (21.38)	53.59 (23.12)	0.009

Continuous variables are presented as means (and standard deviations), categorical variables are presented as number of patients (and % of the entire group).

Longitudinal Kidney Function After Liver Transplantation in Patients with Acute-on-Chronic Liver Failure

Masahiko Yazawa,[1,2] Saradasri Karri,[7] Pradeep S. Podila,[5,6] Uchenna Agbim,[1,3] Daniel Maluf,[1,3] James D. Eason,[1,3] Sanjaya K. Satapathy,[4] Miklos Z. Molnar.[1,3] METEOR (MEthodist Transplant EpidemiOlogy Research) Group *[1]Division of Transplant Surgery, Department of Surgery, University of Tennessee Health Science Center, Memphis, TN; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [3]James D. Eason Transplant Institute, Methodist University Hospital, Memphis, TN; [4]Sandra Atlas Bass Center for Liver Diseases & Transplantation, Department of Medicine, Northshore University Hospital/ Northwell Health, Manhasset, NY; [5]Faith & Health Division, Methodist Le Bonheur Healthcare, Memphis, TN; [6]Division of Health Systems Management & Policy, School of Public Health, The University of Memphis, Memphis, TN; [7]Department of Medicine, University of Tennessee Health Science Center, Memphis, TN.*

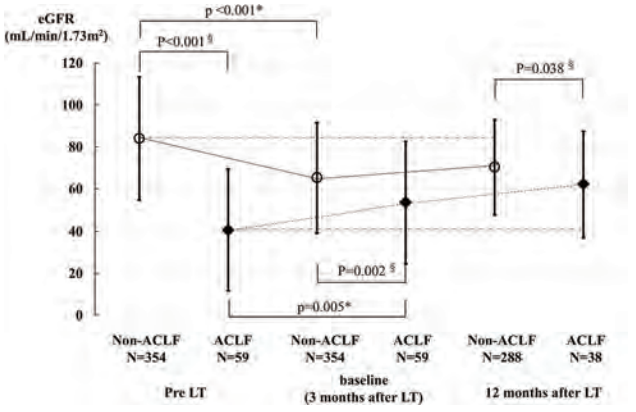
Background: Acute on Chronic Liver Failure (ACLF) is a syndrome defined as acute decompensation on pre-existing chronic liver disease (cirrhosis) caused by hepatic or extra-hepatic insights with several organ failures including acute kidney injury and associated with worse prognosis unless undergoing liver transplantation (LT). However, it has not been well known whether ACLF affects mid- and long-term kidney function after transplantation.

Methods: From 687 eligible LT recipients, 413 patients who had the data of serum creatinine at 3 months after LT (baseline) has been included, in this single-center, retrospective cohort study. Association of ACLF and estimated glomerular filtration rate (eGFR) at baseline and 12 months, also eGFR slope after baseline assessed by mixed effect model has been assessed.

Results: Fifty-nine patients (14.3%) was assigned to ACLF group. ACLF group was significantly younger, higher prevalence of alcoholic hepatitis, higher MELD score, and lower mean eGFR at the time of LT compared to non-ACLF group. The eGFR recovered toward to baseline then stabilized through 12 months after LT in ACLF group and eGFR decreased toward to baseline then stabilized through 12 months after LT in non-ACLF

group. However, eGFR at baseline and 12 months in ACLF group was still significantly lower than that in non-ACLF group (53.6±29.1 and 62.3±25.2 ml/min/1.73m^2 in ACLF group and 65.4±26.2 and 70.5±22.6 ml/min/1.73m^2 in non-ACLF group) (Figure). The eGFR slope in non-ACLF group was decreasing (-2.58 ml/min/1.73m^2/year, 95%CI: -4.79 to -0.38); however, the eGFR slope in ACLF group did not have significant trajectory (0.93 ml/min/1.73m^2/year, 95%CI: -6.08 to 7.94) during observational period. These slopes were not statistically different between two groups (p=0.431).

Conclusions: The mid- and long-term eGFR in ACLF group would be corresponded to deteriorated eGFR before LT and would not recover to the same level of non-ACLF group.



FR-PO1174

Sex Differences in Multimorbidity Clusters in Kidney Transplant Patients: Data from a Multicentre Trial

Courtney J. Lightfoot, Thomas J. Wilkinson, Alice C. Smith. *University of Leicester, Leicester, United Kingdom.*

Background: Multimorbidity is a complex phenomenon which is highly prevalent in patients with chronic kidney disease (CKD). Comorbidities can create a 'treatment burden' and specific combinations of conditions may have greater effects on functional status, quality of life, and mortality than others. Before determining the impact of multiple chronic conditions on kidney transplant recipients, the patterns of multimorbidity disease need to be identified.

Methods: Data was derived from a cross-sectional multicentre survey study. Principal Components Analysis (PCA) (orthogonal (varimax) rotation with a minimum factor loading of .40) was used to identify multimorbidity clusters for both sexes. The number of components ('clusters') was determined by the Eigenvalue of >1 or visual interpretation of the scree plot.

Results: Data from 2240 transplant patients [age: 52.6 (13.6) years; males: 1289 (58%); white: 1503 (67%); total number of additional (to CKD) comorbidities: 1.35 (1.1); cadaver donor grafts: 1077 (48%); months with transplant: 71.0 (85.2)] were collected from 17 geographically diverse transplant centres. Five multimorbidity clusters were identified for males, and three for females, which are displayed in Figure 1. For males, one cluster included cardiopulmonary diseases; in females this cluster also included musculoskeletal conditions. In females, hypertension clustered with diabetes, whereas in males it was a standalone condition.

Conclusions: Patterns of comorbidities are different between male and female transplant patients, and include concordant (i.e. sharing common pathophysiological pathway with CKD (e.g. diabetes)) and discordant conditions (i.e. not sharing common pathway with CKD (e.g. depression)). Recognition of multimorbidity clusters may help identify patients at risk of co-occurring diseases. This may favour a more patient-orientated management strategy to reduce treatment burden and improve quality of life. Further research is needed to enhance the understanding of the identified clusters to improve the management of multimorbid kidney transplant recipients.

FR-PO1175

Long-Term Changes in Sleep Disordered Breathing in Renal Transplant Patients

Francesca Mallamaci, Rocco Tripepi, Graziella D'Arrigo, Gaetana Porto, Carmela Marino, Maria cristina Sanguedolce, Giovanni Tripepi, Carmine Zoccali. *IFC-CNR, Reggio Calabria, Italy.*

Background: Sleep Disordered Breathing (SDB) triggers sympathetic over-activity, hypertension and cardiovascular (CV) events in the dialysis population. SDB improves after renal transplantation but long term changes in SDB in renal transplant patients have not been studied.

Methods: We studied long term changes in SDB in a series of 221 renal transplant patients (age: 46.9±11 years; M: 70.1%). Over a median follow up of 52.1 months (Interquartile range: 36.8-67.3 months) we performed 404 polysomnographic recordings (on average 2 studies per patient). Data analysis was performed by Generalized Estimating Equations (GEE).

Results: At baseline, the median value of the apnea-hypopnea index (AHI) was 1.8 episodes/h [interquartile range (IQR): 0.6-5.0]. One-hundred and sixty-six patients (75%) had a normal AHI (<5). Thirty-seven patients (17%) had mild to moderate SDB (AHI 5 to 14.9) and a minority (18 patients, 8%) had severe SDB (AHI >15). At baseline, AHI was directly related with age (rho=0.24, P<0.001), BMI (rho=0.27, P<0.001), fibrinogen (rho=0.16, P=0.027) and glucose (rho=0.14, P=0.035). The median values of minimum ($MinSaO_2$) and average nocturnal O_2 saturation were 89% and 95.6%. On longitudinal observation, the median AHI rose from 1.8 (IQR: 0.6-5.0) to 2.9 (IQR: 1.0-6.6) and to 3.6 (IQR: 1.7-10.4) at the second and the third longitudinal visit, respectively (P for trend=0.009) and the proportion of patients with mild to moderate and severe SDB rose to 22.7% and 20.5%, respectively. Longitudinal changes in MinSaO2 paralleled those in the AHI. In adjusted analyses BMI (P<0.001) and C-reactive protein (P=0.001) emerged as the sole independent longitudinal correlates of AHI and $MinSaO_2$.

Conclusions: Sleep Disordered Breathing worsens over time in renal transplanted patients. The post-transplantation rise in BMI, a potentially modifiable risk factor, is an important factor underlying the risk for SDB worsening in this population.

FR-PO1176

Prevalence of Depression in Kidney Transplant Recipients: A Long-Term Population-Based Study

Semin Cho,[1] Sehoon Park,[2] Ji Eun Kim,[1] Mi-yeon Yu,[1] Seon Ha Baek,[3] Hajeong Lee,[2] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[2] Yong Chul Kim.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Hallym University Dongtan Sacred Heart Hospital, Hwaseong-si, Republic of Korea.*

Background: Depression is associated with impaired quality of life and increased morbidity and mortality in patients with end-stage renal disease (ESRD) and kidney transplant (KT) recipients. Few data is known about the prevalence of depression in KT recipients. In this study, we aimed to explore the prevalence of depression in KT recipients compared with ESRD patients and healthy controls (HCs) in a long-term population-based cohort.

Methods: We analyzed a Nationwide Health Insurance Database of South Korea and identified patients who received KT from the year of 2007 to 2015. KT recipients were selected and matched with ESRD patients and HCs considering age, sex, and inclusion year. KT and ESRD patients were further matched with diabetes and hypertension. The prevalence (prevalence ratio, PR per 1000) of depression in KT recipients was compared with ESRD patients and HCs, respectively.

Results: A total of 7,971 patients were analyzed in all three groups, respectively. Both KT recipients and ESRD patients were poorer, having more co-morbidities than matched HCs. KT recipients revealed markedly a lower prevalence of depression than in ESRD patients (IR, 66.1 vs 23.5 per 1000 patient-year; Hazard ratio [HR], 0.36; 95% confidence interval [CI], 0.33-0.39), although they showed only slightly higher prevalence of depression than in HCs (IR, 19.4 vs 23.5; HR, 1.21; 95% CI, 1.09-1.35). Interestingly, after adjusting the comorbidity status with Charlson Comorbidity Index (CCI), KT recipients showed a lower risk of depression compared with HCs (adjusted HR 0.64; 95% CI, 0.54-0.75, P<0.001), whereas ESRD patients remained at higher risk of depression development than HCs (adjusted HR 1.80; 95% CI, 1.55-2.10, P<0.001). Among KT recipients, older age, female sex, lower socioeconomic status, and more co-morbidities represented by CCI score were associated with increased risk of depression.

Conclusions: KT recipients showed a markedly lower risk or depression than ESRD patients and even than matched HCs after adjustment of co-morbidities. Our data suggest a broader role of KT than previously appreciated in terms of improving quality of life by reducing the risk of depression.

The Potential for Improved Medication Adherence with a Complete Once Daily Immunosuppression Regimen in Kidney Transplant: Results of a Randomized Controlled Study

David J. Taber, Maria Aurora C. Posadas, Vinaya Rao, John Mcgillicuddy, Vinayak Rohan, Satish N. Nadig, Derek Dubay, James Fleming. *Medical University of South Carolina, Charleston, SC.*

Background: Medication non-adherence is common after transplant and a major contributor to rejection and graft loss. The objective of this study was to obtain preliminary

safety, tolerability and efficacy data of a complete once daily immunosuppression regimen of LCP-Tac (Envarsus XR), everolimus and pred, compared to LCP-Tac, mycophenolate BID and pred.

Methods: This was a randomized, controlled pilot study with the primary aim of assessing self-reported medication adherence and comparing this between a once and twice daily immunosuppressant regimen. At 3±2 months post-transplant, patients were randomized to receive LCP-Tac and everolimus once daily or LCP-Tacand mycophenolate BID (control arm) for 6-months.

Results: 354 were screened, 80 met eligibility, and 40 were randomized. The mean age was 51±14 years, 33% were female, 45% African-American, and 55% had a cPRA >20%. Baseline characteristics were similar between study arms. Tac exposure was lower in the intervention arm (left side of Figure). Self-reported high medication adherence was higher at baseline in the control group (80% vs. 45%, p=0.049), which equilibrated at study end (59% vs. 47%, p=0.525; right side of Figure). Medication side effect burden tended to be less severe in the intervention group, with both regimens being well tolerated. For QOL, role limitations improved in the entire study group similarly across arms while social functioning trended towards improving to a greater degree in the intervention arm (net change: +8.8 intervention arm, -4.1 control arm; p=0.0898). There were no acute rejections, graft loss or death in either arm during the study.

Conclusions: These results provide preliminary evidence of the safety, efficacy, tolerability and potential benefit of sustaining high medication adherence with a novel once daily immunosuppression regimen.

Can Pretransplant Psychosocial Factors Predict Racial Difference in Post-Transplant Adherence?

Yue-Harn Ng,[1] Igor Litvinovich,[1] Christopher G. Ford,[1] Yiliang Zhu,[1] Mary amanda Dew,[2] Chethan M. Puttarajappa,[2] Ron Shapiro,[3] Mark L. Unruh,[1] Larissa Myaskovsky.[1] *[1]University of New Mexico, Albuquerque, NM; [2]University of Pittsburgh, Pittsburgh, PA; [3]Recanati/Miller Transplantation Institute, New York, NY.*

Background: The success of a kidney transplant (KT) relies on patients' ability to adhere to a complex medical regimen and routine follow up post-transplant. Non-adherence is common post-transplant and is a leading cause of allograft loss. In this study, we aimed to *identify non-medical factors at the time of initial KT evaluation that predicted racial difference in non-adherence post-transplant.*

Methods: We performed a prospective cohort study of patients who underwent initial KT evaluation, received a KT and were interviewed at 6 months post-transplant. We collected data on baseline demographics, medical, cultural, psychosocial and transplant related factors. We quantified adherence to each medication within the first 6 months post KT (immunosuppressants and anti-hypertensives) with a Likert scale ranging from never to daily missing of medications and used the average of the individual scores as a continuous outcome variable. We then built multiple linear regression models using variables with effect estimates ≥0.2 and p-values <0.1 in bivariate analyses to identify factors that predicted adherence.

Results: 1152 patients were enrolled in the initial study, 149 patients underwent KT and had ≥6 months follow up; 123(82.55%) were White, 84(56.38%) were male and 103(69.13%) were age >45; adherence scores ranged from 1-7 [mean(SD)=6.8(0.78)]. African American race predicted lower adherence, even after accounting for cultural, psychosocial and transplant factors. Age > 45 and having public insurance predicted greater adherence(Table 1).

Conclusions: African American race was a significant risk factor for post-transplant non-adherence. Data from this study showed that cultural and psychosocial factors did not affect this association.

FR-PO1179

Noncompliance: A Significant Contributor for Renal Allograft Loss

Kartik Kalra, Srijan Tandukar, Dana R. Jorgensen, Rajil B. Mehta, Puneet Sood, Christine Wu, Chethan M. Puttarajappa, Nirav A. Shah, Sundaram Hariharan. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: United network for organ sharing (UNOS) implemented the new kidney allocation system (KAS) in 2014 to reduce inequity and improve life-years gained from kidney transplantation (KT). KAS allowed matching of high quality kidneys to younger recipients and allowed backdating of waitlist date to account for dialysis vintage. Additionally, transplant centers have aimed to increase access to KT by streamlining evaluation process and reducing barriers to wait listing. Potential unintended consequences of these policies may be selection of patients with higher disease burden and lower social support. We investigated this by examining causes of allograft loss within the first 5 years at our center.

Methods: Single center study of kidney transplant recipients between 2013- 2017. Causes of death-censored allograft loss was examined using the following 7 categories: 1. Non Compliance (medication, follow up, blood work), 2. Donor Related (High KDPI), 3. Rejection (Acute/Chronic T- Cell and Antibody Mediated Rejection), 4. Recurrence of primary kidney disease, 5. Surgical/Technical, 6. Infection Related (BK Virus, Pyelonephritis), 7. Others. Differences in baseline characteristics for patients with and without noncompliance were examined.

Results: 18 of 63 (29%) graft losses were attributed to noncompliance. Noncompliance group had younger patients (mean age 38 y vs 55 y; p=0.0001) and higher proportion of African American race (47% vs 22%;p=0.055)

Conclusions: Early allograft loss due to noncompliance is high and is more common among African Americans and young patients. This might offset the potential benefits arising from the new KAS. This data should be used to further investigate specific reasons for non-adherence that can be targeted for intervention.

Clinical Outcomes of HLA-Identical Transplants in the Tacrolimus Era

Matthew R. D'Costa, Massini Merzkani, Walter Park, Mariam P. Alexander, Byron H. Smith, Manish Gandhi, Carrie A. Schinstock, Andrew J. Bentall, Mark D. Stegall. *Mayo Clinic, Rochester, MN*.

Background: HLA identical living donor transplants (LDKT) have excellent graft survival. It remains unclear if causes of death/graft loss, histology or complications associated with tacrolimus-era immunosuppression are different when compared to non-HLA identical recipients.

Methods: We performed a nested case control study of HLA identical full sibling LDKT recipients (cases) and non-HLA identical LDKT recipients (controls) matched for age, sex and year of transplant from 1999 to 2018. Baseline characteristics, overall survival and death censored graft survival (DCGS), histology, and complications were compared.

Results: 184 recipients were in each cohort with similar baseline characteristics except for induction regimens: cases were more likely to receive anti-CD25 and alemtuzumab and less likely to receive thymoglobulin (p=<0.01). Cases had longer median follow-up [7.6 (3.7-11.9) vs 5.7 (2.8-10.1) years, p=0.01], better overall survival (81% vs. 71%, p<0.001) and better DCGS (94% vs. 77%, p<0.001). Protocol biopsies at 1, 2, 5, and 10 years showed more tubulitis, peritubular capillaritis and glomerulitis in controls. Acute cellular rejection, chronic antibody-mediated rejection, and BK nephropathy were more common in controls (Table 1). Causes of DCGS and death were similar between groups (Table 1). Time to DCGS from alloimmune injury was shorter in controls (p=0.01); all events in cases (n=3) occurred in the absence of immunosuppression (two were non-adherent and one had PTLD). Rates of leukopenia, proteinuria, and urinary tract infections were similar.

Conclusions: HLA identical LDKT recipients had better patient survival and DCGS when compared to a non-HLA identical cohort. Causes of DCGS and death were similar. Time to DCGS from alloimmune injury was shorter in controls. Controls had higher rates of both cellular and antibody-mediated injury and BK nephropathy. These results suggest a potential role for reducing immunosuppression in HLA identical sibling LDKT.

Outcomes	Cases	Controls	p-value

FR-PO1181

Impact of 1-Year Post-Transplant Tacrolimus Trough Levels on Long-Term Renal and Cardiovascular Outcomes in Stable Kidney Transplant Recipients

Hee-Yeon Jung,[1,2] Ji-Young Choi,[1,2] Jang-Hee Cho,[1,2] Sun-Hee Park,[1,2] Yong-Lim Kim,[1,2] Chan-Duck Kim.[1,2] *[1]Kyungpook National University Hospital, Daegu, Republic of Korea; [2]School of Medicine, Kyungpook National University, Daegu, Republic of Korea*.

Background: This study aimed to investigate the impact of 1-year post-transplant tacrolimus (TAC) trough levels on renal and cardiovascular outcomes in stable kidney transplant recipients (KTRs).

Methods: KTRs receiving TAC and mycophenolate-based immunosuppression who have never experienced renal or cardiovascular events within 1-year post-transplant were included from a multicenter observational cohort study. Renal outcome was defined as a composite of biopsy-proven acute rejection, interstitial fibrosis and tubular atrophy, and death censored graft loss. Cardiovascular outcome was defined as a composite of de novo cardiomegaly, left ventricular hypertrophy, and cardiovascular events.

Results: A total of 603 eligible KTRs were divided into low-level (LL) and high-level (HL) TAC based on the median TAC level at 1-year post-transplant of 5.9 ng/mL (range 1.3-14.3). During the mean follow-up of 38.2 ± 13.0 months, 27 and 166 episodes of renal and cardiovascular outcomes occurred, respectively. In multivariate Cox regression analysis, LL-TAC and HL-TAC were not independent risk factors for renal and cardiovascular outcomes, respectively. Instead, deceased donor KT (adjusted hazard ratio [AHR], 2.52; 95% confidence interval [CI], 1.10–6.01; P = 0.037) and male (AHR, 1.62; 95% CI, 1.06–2.47; P = 0.025) were independent risk factors for renal and cardiovascular outcomes, respectively. No significant differences in estimated glomerular filtration rate at 2- and 3-year post-transplant were observed between two groups.

Conclusions: TAC trough levels after 1-year post-transplant were not directly related to long-term renal and cardiovascular events in stable KTRs. There might be no need to insist higher TAC trough levels after 1-year post-transplant in KTRs with stable post-transplant clinical course.

FR-PO1182

Induction Therapies in the Tacrolimus-Based Immunosuppression Era: A Meta-Analysis

Karim M. Soliman,[1] Hatem Ali,[2] Ahmed Daoud,[5] Tibor Fulop,[3] Ahmed Halawa.[4] *[1]Medical University of South Carolina, Charleston, SC; [2]Heartlands hospital, Birmingham, United Kingdom; [3]Medical University of South Carolina, Charleston, SC; [4]Liverpool university, Liverpool, United Kingdom; [5]Cairo University, Cairo, Egypt*.

Background: Induction therapy with rabbit Anti-thymocyte Globulin (rATG) and IL-2 Receptor Antagonist (IL-2RA) resulted in marked reduction of acute allograft rejection rate. However, the relative value of these agents in the era tacrolimus-based maintenance immunosuppression remains uncertain.

Methods: A systematic review of Pubmed, Medline, Embase and Cochrane databases was conducted to identify outcomes in terms of graft and patient survival, rejection, infection and malignancy rates in renal transplant recipients (RTRs) (Figure 1). Based on received induction therapy, RTRs were divided into 2 groups (IL2-RA versus rATG). All subjects were on tacrolimus-based immunosuppression. The meta-analysis included 6 randomized case-control studies with total of 1017 subjects and follow-up period ranged from 12 months to 36 months. Random effects model (REM) was used to identify risk difference. Confidence interval excluding the value 1 was used as evidence for statistically significant risk difference. Heterogeneity was assessed using Der Simonian analysis (P value<0.1).

Results: The REM showed no significant differences in acute rejection rates, graft survival and patient survival between IL2-A and rATG induction therapies with confidence interval ranges (CIR) from 0.94 to 1.64, 0.57 to 1.42 [relative risk (RR): 0.9], and 0.6 to 2.35, RR:1.19 respectively (Figure 2, 3). REM for CMV infection showed a lesser tendency for CMV infection and higher rate of acute rejection in high-risk transplants of

the IL2-RA group compared to ATG group with CIR from 0.52 to 1.05 (RR: 0.73) and 1.05 to 2.51 (RR: 1.55) respectively. In standard risk transplants, there were no significant differences between acute rejection rates (CIR from 0.71 and 1.47, RR: 1.02).

Conclusions: This meta-analysis revealed no significant difference in patient and graft survival when using IL-2RA vs rATG with the tacrolimus-based maintenance immunosuppression. Subgroup analysis noted a trend for reduced rejection in high-risk recipients receiving rATG compared to IL-2RA.

Renal Transplant Patients Under Calcineurin Inhibitor Therapy Rapidly Acquire an Aberrant Lysosomal Lesion in Proximal Tubular Cells

Benjamin A. Vervaet,[1] Nika Kojc,[2] Cynthia C. Nast,[3] Gerd Schreurs,[4] Patrick C. D'Haese,[1] Marc E. De Broe.[4] *[1]University Antwerp, Antwerp, Belgium; [2]Medical faculty Ljubljana, Ljubljana, Slovenia; [3]Cedars-Sinai Medical Center, Los Angeles, CA; [4]University of Antwerp, Antwerp, Belgium.*

Background: Calcineurin inhibitor therapy has changed the field of (renal) transplantation by considerably prolonging graft survival. Yet, all immunosuppressive calcineurin inhibitors are nephrotoxic that eventually contribute to complete scarring of the renal allograft. In renal biopsies, many histopathological features have been considered indicative of CNI nephrotoxicity, i.e. striped fibrosis, vascular hyalinosis, isometric tubular vacuolization, glomerulosclerosis, cellular infiltration and tubular atrophy, however, all are rather aspecific and can be secondary to many other causes. During the course of evaluating the specificity of a recently discovered proximal epithelial lysosomal lesion (i.e. multiple enlarged (>1,2µm) dysmorphic lysosomes containing electron dense non-membrane bound aggregates) in patients with Chronic Interstitial Nephropathy in Agricultural Communities (CINAC), we observed this lesion in renal transplant patients treated with cyclosporine or tacrolimus. Here, we test the hypothesis whether this lysosomal lesion is acquired during CNI therapy.

Methods: A retrospective transmission electron microscopic analysis was performed to evaluate the presence of the typical lysosomal lesion on the following biopsies from renal transplant patients: 20 deceased donor implantation biopsies; 5 living donor implantation biopsies. For another 10 additional deceased donor renal allograft recipients, we evaluated implantation as well as protocol biopsies taken after 6 and 12 months of CNI treatment that started immediately after transplantation. Also included were 24 indication biopsies of CNI treated renal transplants.

Results: Of the total set of implantation biopsies (n=35), 2 (6%) were positive for the aberrant lysosomal phenotype on EM, whereas in the protocol and indication biopsies prevalence of the lesion was considerably higher ranging between 56% (protocol) and 80% (indication) of cases.

Conclusions: CNI therapy is associated with the fairly rapid appearance of a particular proximal tubular lysosomal phenotype observable on EM, that was not (or rarely) present at implantation. Whether this lesion is related to CNI toxicity and indicative for the outcome for the graft and/or patient survival after renal transplantation has to be investigated in a prospective trial.

Drug Formulation Associates with Patterns of Serum Trough Tacrolimus Levels: Experience at a Single Irish Centre

Ted J. Fitzgerald, Laura M. Slattery, Sean F. Leavey. *University Hospital Waterford, Dublin 4, Ireland.*

Background: Consistently maintaining serum trough tacrolimus levels in the desired therapeutic range is critical to optimise outcomes in kidney transplant recipients. Patients are typically prescribed twice-daily (BD) or once-daily (OD) tacrolimus formulations (e.g. Prograf ® or Advagraf ®). Not uncommonly, patients switch formulation in the course of their follow-up. This study examines associations between BD and OD tacrolimus formulations and achieved serum trough levels (TL) in a cohort of kidney transplant recipients.

Methods: Data pertaining to tacrolimus prescription (date, dose, formulation) and serum TL in kidney transplant recipients was extracted from eMedRenal for a 3-year period (January 2016 to December 2018). Descriptive and inferential analyses were first performed on all TLs in the study population. Mean TL and standard deviations by formulation type were then calculated for each patient. Comparisons of mean TL and standard deviations within subjects who switched formulation during the study period were made by paired samples t-test. The potential for time post-transplant influencing observations was recognised and all analyses were performed in stratified datasets of TL within and after the first post-transplant year.

Results: 2870 serum TL were analysed for 142 patients; 67.6% male and 32.4% female with a mean age of 57 (±14) years. The mean allograft vintage in our study population was 8.1 (± 5.7) years. In the 47 patients who switched formulation during the study period, fluctuation in within-patient TL levels was reduced ($p<.001$), but overall mean serum TL per patient was 1.6ng/mL lower (95% CI,1.18 to 2.04, $p<0.001$), on OD versus BD tacrolimus.

Conclusions: The differences in serum TL noted by formulation beyond 1-year post-transplant in this cohort were very significant. Furthermore, switching to OD formulations while associated with less fluctuation in levels is associated with lower mean TL. The data emphasises the importance of attending to tacrolimus trough levels, and by implication drug dosing, beyond the first transplant year and especially after switches in formulation.

	<1 year post-transplant	>1 year post-transplant

FR-PO1185

Prevalence of CYP3A Haplotype and Its Relation to Calcineurin Inhibitors Toxicity in Patients with Renal Transplantation Greater Than a Year in Western Mexico

Omar H. Sanchez Vazquez,[1] Alejandro Garcia Rivera,[1] Renato Parra Michel,[2] Caridad Leal,[1] Ana L. Garcia-Vera,[1] Marlene D. Cisneros-Carbajal,[1] Antonio M. Murga,[1] Carlos F. Fonseca cerda,[1] Jorge fernando Topete reyes,[2] Silvia Flores,[1] Francisco Mendoza,[1] Carlos D. Jimenez Mejia.[1] *[1]Instituto Mexicano del Seguro Social, Guadalajara, Mexico; [2]Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Hospital General Regional No.46, Instituto Mexicano del Seguro Social., Zapopan, Mexico.*

Background: ESRD is a public worldwide health problem and kidney transplantation is the RRT of choice. Immunosuppressive treatment with tacrolimus has significantly improved short-term graft survival. It has a narrow therapeutic index and a pharmacokinetic variability that may predispose to nephrotoxicity. Polymorphisms of cP450 (CYP3A4 and CYP3A5) have been related to variability in tacrolimus metabolism.

Methods: Retrospective study in 338 patients with renal transplant over a year being cared in our hospital, in treatment with tacrolimus, January 2017 - January 2018. Genotyping of the variants CYP3A5*3, CYP3A5*1, CYP3A4*1, and CYP3A4*1b was performed and frequency of nephrotoxicity and blood tacrolimus levels were associated with each of the genotypes.

Results: The most frequent polymorphisms were CYP3A5*3/*3 in 53% and CYP3A4*1/*1 in 84%. The most frequent haplotype was CYP3A5*3/*3 + CYP3A4*1/*1 in 50.59%, followed by CYP3A5*1/*3 + CYP3A4*1/*1. Figure 1 shows the behavior of the CYP3A polymorphisms. CYP3A4*1b/*1b and CYP3A5*1/*1 required the highest tacrolimus weight dose and had the lowest blood tacrolimus levels, statistically different from CYP3A*1/*1 and CYP3A5*3/*3, respectively. The comparison between different haplotypes showed a significant difference only in the weight dose, not in the tacrolimus blood levels. There was no significant statistical difference in CNI toxicity.

Conclusions: In the western Mexican population, CYP3A4*1/*1 and CYP3A5*3/*3 are the most prevalent polymorphisms, with a slow metabolizer profile. Recipients with CYP3A4*1b/*1b or CYP3A5*1/*1 polymorphisms require higher tacrolimus dosage and show a tendency to have higher rates of CNI toxicity despite having low tacrolimus blood levels.

FR-PO1186

Safety and Efficacy of LCP-Tacrolimus (LCPT) in Hispanic De Novo Kidney Transplant Recipients (KTR)

Rafael Villicana,[3] Giselle Guerra,[4] Misbah A. Moten,[1] Samir J. Patel,[1] Daniel R. Stevens,[1] Ulf Meier-Kriesche,[1] Suphamai Bunnapradist.[2] *[1]Veloxis Pharmaceuticals, Cary, NC; [2]University of California Los Angeles, Los Angeles, CA; [3]Loma Linda University, Loma Linda, CA; [4]University of Miami/ Miller School of Medicine, Miami, FL.*

Background: Safety and efficacy of once daily, LCPT have been established among various subgroups of KTR, however outcomes in Hispanic patients have yet to be analyzed. The purpose of this analysis was to investigate treatment failure and safety outcomes in Hispanic de novo KTR on LCPT or twice daily, immediate-release tacrolimus (IR-TAC).

Methods: A post hoc, subgroup analysis of patients identifying as Hispanic/Latino from a phase III randomized controlled trial was conducted. Patients were dosed at 0.17 mg/kg/day LCPT and 0.1 mg/kg/day IR-TAC on day 1, with target tacrolimus trough concentrations of 6-11ng/mL for the first month, then 4-11ng/mL. Treatment failure was defined as a composite of biopsy-proven rejection (BPAR), graft loss, death, and loss-to-follow up. Concomitant immunosuppressants included basiliximab induction, mycophenolate, and steroids.

Results: Seventy-four LCPT and 79 IR-TAC patients were included in the analysis. Demographics were similar between the two groups. Overall, fewer treatment failures occurred in Hispanic LCPT recipients compared to those on IR-TAC at 12 months (12.2% vs. 25.3%, p=0.04). BPAR largely accounted for the difference in efficacy (Table 1). Mean tacrolimus trough levels were higher with LCPT during the first 2 weeks post-transplant and similar thereafter. Renal function remained stable from 1 month to 12 months for LCPT patients, however the incidence of NODAT at 12 months in at-risk patients was 18.8% in LCPT patients and 3.8% in IR-tac patients (p=0.057). Remaining adverse events and opportunistic infections were similar between groups.

Conclusions: Hispanic de novo KTR on LCPT experienced fewer treatment failures at 12 months, however a trend towards increased NODAT was noted. These findings may support the approved, lower recommended initial dose (0.14 mg/kg) in this population.

Weight-Based Dosing for Tacrolimus: A Single-Center Experience

Goni Katz-Greenberg, Peter Burke, Pooja Singh. *Thomas Jefferson University Hospital, Philadelphia, PA.*

Background: Tacrolimus (FK) remains the mainstay of maintenance immunosuppression for kidney transplant (KT) recipients. A therapeutic trough (TT) is maintained by dose adjustments within an acceptable narrow range. Low TTs are associated with acute rejection (AR) episodes. In order to address a wide variability in the initial prescribed dose, as well as issues with delayed time to TT, we implemented weight-based dosing (WBD) for FK in our center. Herein we present the results following this change.

Methods: For WBD, patients received FK at 0.1mg/kg/day on first post operation day (POD), with dose adjustments thereafter per standard protocol, for target TTs of 8-11ng/mL. Patients who underwent KT in the 6 months pre and post implementation of WBD were included in the analysis. We looked at baseline demographics, as well as donor and recipient characteristics. Rates of AR (per Banff 2017 criteria) at 90 days, serum creatinine (SCr) at 30 days, time to TT, and delayed graft function (DGF) were reviewed. Multi-organ txps, except kidney-pancreas were excluded.

Results: Following KT, 70 patients in the WBD cohort, and 68 patients in the cohort prior to the implementation [non WBD (nWBD)] were included. AR was seen in 7/65 of the WBD group, and in 3/56 of the nWBD group; p=0.281. On POD 3, the median FK TT was 8.5ng/mL in the WBD, versus 5.9ng/mL in the nWBD (figure 1). To avoid confounding, 38 live donor KT recipients were excluded from DGF analysis. In patients with deceased donor KT (DDKT), DGF rate was significantly higher in nWBD versus WBD group (19/41 [46.3%] vs 9/42 [21.4%], respectively; p<0.05). No difference in median SCr was noted.

Conclusions: FK levels are expected to reach a steady state after 3-4 doses. The WBD group achieved TTs earlier than the nWBD group. Significantly higher DGF rate was noted in the nWBD group, with similar rates of rejection in both groups. Further large-scale studies are needed to examine the role of WBD on DGF, AR and its effect on graft function, as well as costs in the immediate post txp period.

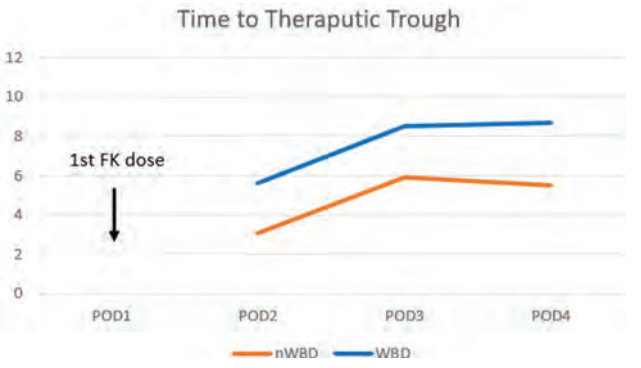

Figure 1

FR-PO1188

Safety and Efficacy of Conversion from Immediate-Release Tacrolimus (IR-TAC) to LCP-Tacrolimus (LCPT) in Hispanic Kidney Transplant Patients (KTR)

Suphamai Bunnapradist,[3] Giselle Guerra,[4] Samir J. Patel,[1] Misbah A. Moten,[1] Daniel R. Stevens,[1] Ulf Meier-Kriesche,[1] Rafael Villicana.[2] *[1]Veloxis Pharmaceuticals, Cary, NC; [2]Loma Linda University, Loma Linda, CA; [3]University of California Los Angeles, Los Angeles, CA; [4]University of Miami/ Miller School of Medicine, Miami, FL.*

Background: A large phase III study demonstrated safety and efficacy of once daily, LCPT in stable KTR converted from twice daily IR-TAC. Hispanic patients comprise a substantial proportion of KTR, however analyses within this cohort had yet to be conducted. The purpose of this subgroup analysis was to investigate treatment failure and safety outcomes of Hispanic KTR converted from IR-TAC to LCPT.

Methods: A post hoc, subgroup analysis from a phase III randomized controlled trial was conducted. Hispanic/Latino patients at least 3 months post-transplant on a stable IR-TAC dose were converted using a multiplier of 0.85 for non-Black recipients and 0.7 for Black recipients to maintain target tacrolimus trough concentrations of 4-15 ng/mL. Treatment failure was defined as a composite of for cause biopsy-proven acute rejection (BPAR), graft loss, death, and loss-to-follow up.

Results: 55 patients were included in this analysis. LCPT and IR-TAC groups were similar with respect to age, gender, donor type, and sensitization. Overall, treatment failure was low for both LCPT and IR-TAC groups at 12 months post-conversion (3.85% vs. 3.45%, p=1.00) (Table 1). Tacrolimus trough levels remained similar in between groups throughout the study renal function was stable at 12 months post-conversion. Adverse events related to study drug occurred in 27% of LCPT patients and 14% of IR-TAC patients (p=0.32), with no significant differences seen in any specific AE. Rates of new-onset diabetes and opportunistic infections were similar for both groups.

Conclusions: This analysis demonstrates safe and effective conversion from IR-TAC to LCPT in a subgroup of Hispanic KTR.

Outcomes of Kidney Allograft Function in a Patient with Thrombotic Microangiopathy Switched to Co-Stimulation Blocking Agent (Belatacept)

Khalid M. Elharrif,[1] Ann Kathleen N. Gamilla-Crudo,[1] Syed A. Hussain,[1] Regina L. Ramirez,[2] Farah Abifaraj,[1] Muhammad A. Mujtaba.[1] *[1]University of Texas Medical Branch, Galveston, TX; [2]UTMB Health, Galveston, TX.*

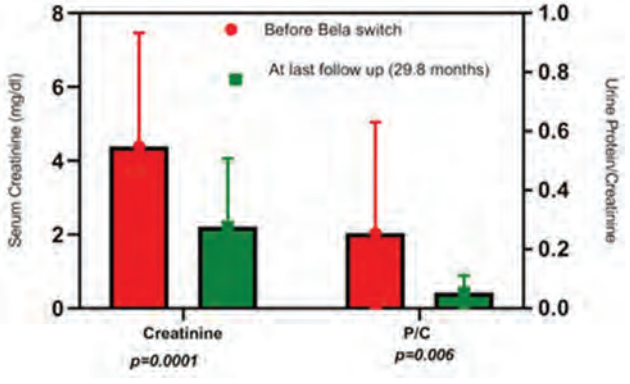
Background: Thrombotic microangiopathy (TMA) is a severe complication of kidney transplantation. TMA may occur de novo or as recurrent disease post transplantation. De novo disease is usually associated with immunosuppressive drugs [calcineurin inhibitors (CNI's) and sirolimus] or can be seen as a part of endothelial damage that accompanies antibody-mediated rejection (AMR). Treatment for de novo TMA is limited to plasma exchange and change in immunosuppression. Belatacept a co-stimulation blocking agent

is considered least nephrotoxic, and may provide an immunosuppression option in patients with TMA.

Methods: A retrospective review of prospectively collected data was conducted on kidney transplant from 2013 to 2019, 45 kidney transplant patients were switched from CNI's to a Belatacept due to concerns of TMA. Seventy percent of the patients had kidney biopsy proven changes of TMA. Continuous variables are being reported as mean with SD. A paired t-test was used and P value of <0.05 was considered to be significant.

Results: Majority of patients were Hispanic with age 54Y± 11.9, 55% were females. Post belatacept switch follow up on these patients was 29.8±15 months. Significant improvement in pre and post switch serum creatinine (p=0.0001) and urine protein/creatinine (0.006) was observed (Graph). Fourteen patients had detectable DSA at the time of switch, out of these 4 patients were still positive at last follow up, where as 2 new patients developed DSAs. Four (8%) patients developed acute cellular rejection, and one (2%) patient had AMR.

Conclusions: Belatacept appears to be useful alternative immunosuppressive agent in kidney transplant patients with TMA without increasing the risk of rejection. Switching maintenance immunosuppression to Belatacept will likely result in significant improvement in renal outcome.



FR-PO1190

Surveillance Biopsy-Driven Steroid Withdrawal

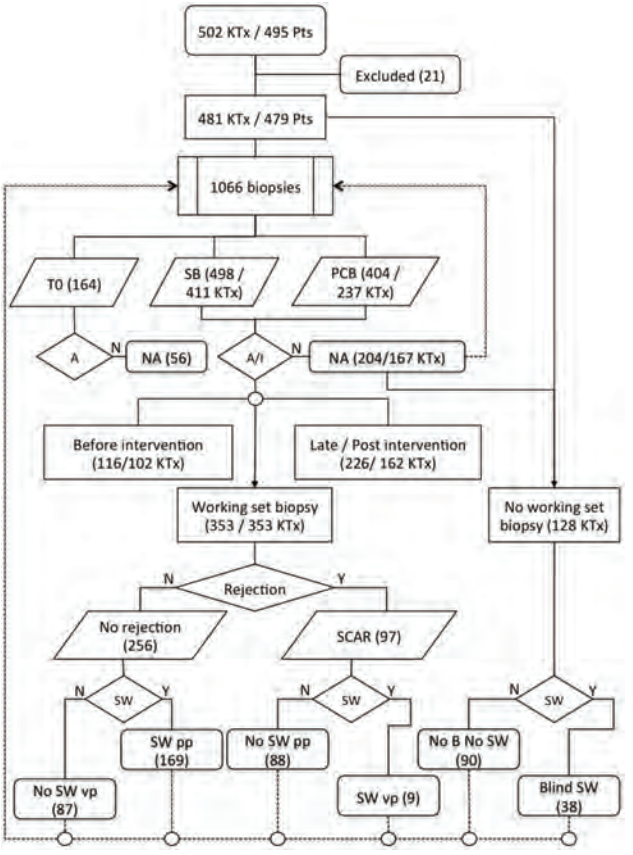
Laurent E. Weekers,[1] Hans Pottel,[2] Catherine Bonvoisin,[1] Francois Jouret.[3]
[1]CHU ULg, Esneux, Belgium; [2]KULeuven, Kortrijk, Belgium; [3]University of Liege Hospital (ULg CHU), Liege, Belgium.

Background: Steroids withdrawal (SW) is the most frequently used IS minimizing-strategy, but it increases the risk of AR. We reasoned that surveillance biopsy (SB) could help individualized selection of patients with low risk of AR after SW. We implemented a systematic SB-driven SW protocol since 2007. We present a critical appraisal of the safety, efficiency and utility of this procedure.

Methods: Mono-centric analysis of all KTx performed from 2007 to 2015 and followed until March 2019. SB was performed at a prednisolone dose of 5 mg. SW was only allowed in kidney transplant (KT) with no sign of rejection (including borderline). Combining the two possible interventions (SB and SW) and adherence to the clinical protocol, we defined 6 groups as depicted in the study flow-chart. The safety and efficiency analysis are purely descriptive. The primary end-point for the utility analysis is the prevalence of late (occurring after the intervention) AR and the secondary is time-to-event analysis (Cox model) of a combination of graft lost or eGFR decline>30% from 1 to 3 years post-KTx.

Results: The complication rate after SB was 2,5%: 1,8 % requiring non- or minimally-invasive intervention and 0,3% necessitating an embolization. No graft lost or procedure-related death was encountered. Out of the 481 KTx analyzed, 169 (35%) were withdrawn from steroids after SB and 97 (20%) showed some degree of SCAR. Rate of late AR were distributed as follow: [SW pp] 6%, [No SW vp] 8%, [No SW pp] 14% and [SW vp] 22% (Chi-2 for trend 0.008). Breakdown of the population according to pre-specified groups was associated to the secondary end-point in both total (p=0.0002) and death-censored (p=0.019) in univariate analysis with [SW pp] being among the best survival groups.

Conclusions: SB-driven SW was safe and associated with good long term outcome.



FR-PO1191

Center-Level Variation in the Association of Clinical Factors with Use of an Early Steroid Withdrawal Regimen in Kidney Transplant Recipients

Sunjae Bae,[1] Mara McAdams-DeMarco,[2] Jacqueline Garonzik wang,[2] Allan Massie,[4] Josef Coresh,[3] Dorry L. Segev.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins, Baltimore, MD; [3]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [4]Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Early steroid withdrawal (ESW) may confer net benefit to low-risk kidney transplant (KT) recipients. However, there is limited evidence on what clinical factors constitute the "low-risk" status that favors ESW, possibly resulting in heterogeneous, and even contradicting, practices across KT centers. Quantifying this heterogeneity using real-world data is also crucial for making unbiased inferences on ESW. We aimed to characterize the center-level variation in how clinical factors influence the selection of ESW.

Methods: Using SRTR data, we studied 210,133 KT recipients in 2002-2017, after excluding who did not receive tacrolimus and mycophenolate for maintenance immunosuppression (n=47,756). ESW was defined as withdrawal of steroid by the time of discharge from KT admission. We quantified the center-level variation in the associations of 74 variables with ESW, via the standard deviation (SD) of the random slope terms in multilevel logistic models.

Results: We identified 10 variables with greater variation (Figure). Factors such as recipient hypertension and pulsatile perfusion were associated with ESW in opposing directions at different centers. For example, the center-specific odds ratio (OR) of ESW for recipient hypertension was <0.8 at 110 (39.6%) centers, but >1.25 at 63 (22.7%) centers. On the other hand, factors such as increased PRA and longer cold ischemic time were associated with lower odds of ESW at most centers, but to substantially varying degrees. For example, while high PRA (80-100 vs 0-9) was associated with lower odds of ESW in the entire population ($OR=_{0.44}0.50_{0.58}$), this association was particularly stronger at some centers [eg, OR<0.2 at 29 (10.4%) centers].

Conclusions: Our findings suggest a substantial discordance among KT centers on what clinical factors indicate ESW and how important each factor is.

FR-PO1192

The Graft and Patient Survival Rate According to Ethnicity in US Kidney Transplant Recipients

Sunmin Kim,[2] Ye na Kim,[3] Ho Sik Shin,[1] Yeonsoon Jung,[2] Hark Rim.[4] *[1]Harvard Medical School, Brigham & Women's Hospital, Brookline, MA; [2]Kosin University Gospel Hospital, Busan, Republic of Korea; [3]Kosin University College of Medicine, Gospel Hospital, Busan, Republic of Korea; [4]Kosin University College of Medicine, Busan, Republic of Korea.*

Background: African American(AA) kidney transplant recipients experience disproportionately high rates of graft loss. The aim of this analysis was to use a UNOS data set that contains detailed baseline and longitudinal clinical data to establish and quantify the impact of the current overall graft loss definition on suppressing the true disparity magnitude in US AA kidney transplant outcomes.

Methods: Longitudinal cohort study of kidney transplant recipients using a data set created by United Network for Organ Sharing (UNOS), including 266,128 (African American 70,215, Non-African American 195,913) transplant patient between 1987 and December 2016. Multivariable analysis was conducted using 2-stage joint modeling of random and fixed effects of longitudinal data (linear mixed model) with time to event outcomes (Cox regression).

Results: 195,913 non-African American (AA) (73.6%) were compared with 70,215 AA (26.4%) recipients. 10-year-graft survival of AA in all era is lower than that of non-AA (31% in deceased kidney transplants (DKT) AA recipient and 42% in living kidney transplantation (LKT) non-AA recipient). 10-year-patient survival of AA with functioning graft in all era is similar that of non-AA. Multivariate Cox regression of factors associated with patient survival with functioning graft are acute rejection within 6 months, DM, hypertension and etc. Pre-transplant recipient BMI in AA show the trend as a protective factor in patient survival with functioning graft although not significantly in statistics

Conclusions: African American kidney transplant recipients experience a substantial disparity in graft loss, but not patient death with functioning graft.

Association of Race and Risk of Graft Loss Among Kidney Transplant Recipients in the Military Health System

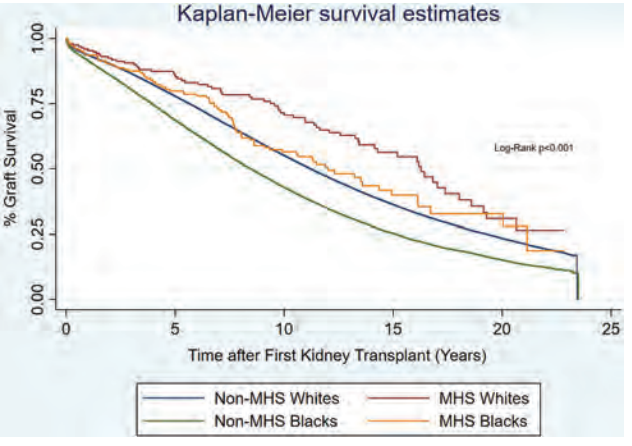
Crystal Forman,[4] Christina M. Yuan,[1,2] Rahul M. Jindal,[2] Lawrence Agodoa,[3] Kevin C. Abbott,[3] Robert Nee.[1,2] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Uniformed Services University of Health Sciences, Bethesda, MD; [3]The National Institutes of Health, NIDDK, Bethesda, MD; [4]San Antonio Uniformed Services Health Education Consortium, San Antonio, TX.*

Background: Racial disparities in transplant outcomes are well documented, attributed to both immunologic and non-immunologic risk factors that include social determinants of health. We assessed differences in graft survival between Black and White kidney transplant recipients in the Military Health System (MHS), a model of universal health care and free lifelong access to immunosuppressive medications.

Methods: Using the United States Renal Data System database, we identified 449 (0.16%) MHS patients first transplanted from January 1, 1995 to January 1, 2018, out of a total of 276,564 patients in the US. We examined the time to first graft loss using Kaplan-Meier and Cox regression analyses, adjusted for demographic, clinical and socioeconomic factors (health insurance, employment, education level, ZIP code-level median household income).

Results: In the MHS, 43% of Black recipients experienced graft loss compared with 35% of Whites (p=0.11). Death-censored graft loss for Blacks was 28% vs. 19% in Whites (p=0.05). MHS Blacks had an adjusted hazard ratio (aHR) of 0.88 (95% CI 0.39-1.98, p=0.75) for overall graft loss compared to their White counterparts. In the wider non-MHS cohort, Black recipients had an increased risk of overall graft loss compared to Whites (aHR 1.11, 95% CI 1.08-1.14, p<0.001). Estimated graft survival was similar between MHS Blacks and non-MHS Whites (Figure).

Conclusions: In the MHS, Black transplant recipients did not have a statistically significant higher risk of overall graft loss compared to their White counterparts, a finding that differs from the broader transplant population. {The views expressed in this abstract are those of the authors and do not reflect the official policy of the National Institutes of Health, the Department of Army/Navy/Air Force, Department of Defense, or U.S. Government}.



First graft loss in kidney transplant recipients, stratified by racial/MHS groups

FR-PO1194

Impact of First Kidney Transplant Type on the Outcomes of a Subsequent Transplant

Kalathil K. Sureshkumar,[2] Rita L. McGill,[1] Pratik B. Shah,[1] Bhavna Chopra,[2] Patrick Cunningham,[1] Michelle A. Josephson.[1] *[1]University of Chicago, Chicago, IL; [2]Allegheny Health Network, Pittsburgh, PA.*

Background: Many patients with kidney failure will require more than one kidney transplant during their life time. It will be useful to know the impact of the type of (living vs. deceased donor) first transplant on the outcomes of a subsequent transplant as well as cumulative graft survivals between first (G1) and second (G2) espeically in patients with limited living donor options.

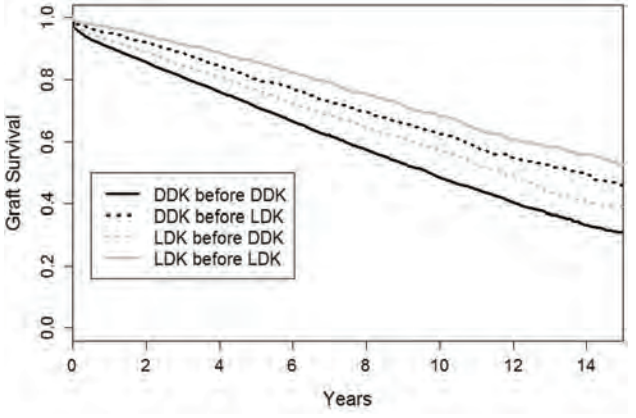
Methods: Using OPTN/UNOS database, we identified patients who underwent a second kidney transplantation between 1996 and 2016. Patients were then stratified into 4 groups based on the sequence of the transplant type as follows: living donor (LD) first, LD second (n=4402); deceased donor (DD) first, LD second (n=2460); LD first, DD second (n=5723); DD first, DD second (n=11411). Using a Cox model, graft outcomes were compared for the second transplant (G2) in all 4 transplant sequences. Subsequently a cumulative combined allograft failure risk (G1 + G2) was also calculated.

Results: Survival plots for G2 are shown in figure 1. Adjusted graft failure risks for G2 along with G1+G2 are shown in the table.

Conclusions: We observed reduced cumulative graft failure risk associated with DD followed by LD sequence compared to LD followed by DD sequence. This interesting observation could be related to the disproportionately negative impact of second DD transplant on overall outcomes.

Graft Failure by Donor Type Sequence

1st - 2nd	Graft 2 Failure	G1 + G2 Failure
LD - LD	Ref	Ref
DD - LD	1.25 (1.13, 1.38)	1.43 (1.30, 1.58)
LD - DD	1.64 (1.51, 1.78)	2.10 (1.94, 2.28)
DD - DD	1.91 (1.77, 2.05)	2.54 (2.36, 2.73)



FR-PO1195

Non-Preemptive vs. Preemptive "Second" Kidney Transplant with Graft Failure Risk Among Pediatric Kidney Transplant Recipients

Yusuke Okuda,[1,2] Connie Rhee,[1] Ekamol Tantisattamo,[1] Marciana Laster,[4] Ying Tang,[7] Deepak K. Rajpoot,[6] Miklos Z. Molnar,[5] Hirohito Ichii,[3] Yoshitsugu Obi,[1] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Kitasato University School of Medicine, Minato, Japan; [3]University of California Irvine, Huntington Beach, CA; [4]University of California Los Angeles, Los Angeles, CA; [5]University of Tennessee Health Science Center, Memphis, TN; [6]Pediatric Renal Medical Corp, Irvine, CA; [7]Shengjing Hospital of China Medical University, Shenyang, China*.

Background: Preemptive kidney transplant may have a graft survival benefit for the first kidney transplant among children. However, its benefit is less clear for subsequent transplantation after allograft failure. This study aimed to evaluate the graft failure risk associated with nonpreemptive (vs. preemptive) second kidney transplant among pediatric recipients.

Methods: In a cohort of pediatric kidney transplant recipients who underwent a second kidney transplant by the age of 21 years old between 1987 and 2016 from the United States Renal Data System, we examined the association of nonpreemptive (vs. preemptive) second transplant with risk for second graft failure, using a Cox proportional hazards regression in case mix, transplant data, and fully (transplant data plus preemptive first transplant, first graft survival time and total duration of receiving renal replacement therapy) adjusted models.

Results: Among 2,860 included patients, the median age at the second transplant was 16 (interquartile range: 12–19) years old, and 481 (17%) underwent a preemptive transplant. A total of 1,351 graft failures were observed during a total follow-up of 14,960 patient-years (median 4.8 years). Nonpreemptive had higher graft failure risk [Figure A]. In the fully adjusted Cox model, hazard ratio (HR) for the nonpreemptive group was 1.43 (95%CI, 1.18–1.72). In subgroup analysis by the first graft survival time, the fully adjusted HRs (95%CIs) for the nonpreemptive group were 4.04 (1.38–11.80), 1.15 (0.80–1.66), 1.23 (0.88–1.71), and 1.38 (0.99–1.94) in first graft survival time 0–<1, 1–<12, 12–<60, and ≥60 months, respectively [Figure B].

Conclusions: Nonpreemptive second transplant was associated with higher graft failure risk compared to preemptive transplant. Our results demonstrate the benefit of preemptive second transplant among pediatric kidney transplant recipients.

Pre-Transplant Dialysis Modality and Long-Term Patient and Kidney Allograft Outcome: A 15-Year Retrospective Cohort Study

Michael S. Balzer,[1] Stephanie Pankow,[1] Robert Claus,[1] Stephan Ruben,[2] Hermann G. Haller,[1] Gunilla Einecke.[1] *[1]Dpt. of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Dpt. of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany*.

Background: Among factors determining long-term kidney allograft outcome, pre-transplant renal replacement therapy (RRT) is the most easily modifiable. Previous studies analyzing the impact of RRT modality on patient and graft survival are conflicting. Studies on allograft function are scarce and lack sufficient size, follow-up time or generalizability.

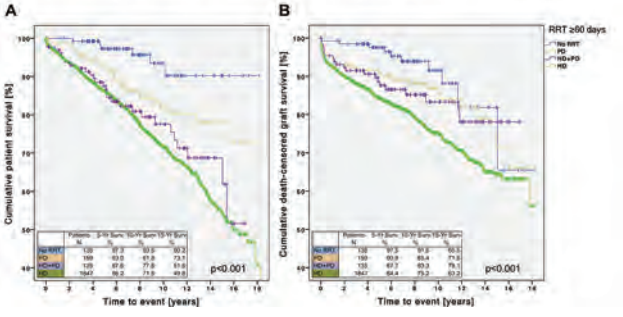
Methods: We retrospectively studied patient and allograft survival as well as allograft function and its decline in 2277 allograft recipients who received a kidney transplant at our tertiary care center during 2000-2014. Pre-transplant RRT modality ≥60 days as grouped into 'no RRT' (n=136), 'hemodialysis (HD)' (n=1847), peritoneal dialysis (PD)' (n=159), and 'HD+PD' (n=135) was evaluated.

Results: Unadjusted (Kaplan-Meier) primary outcomes demonstrated superior 5-, 10-, and 15-yr patient and death-censored graft survival in PD vs. HD patients (p<0.001 and p=0.016, respectively). Adjusted Cox regression revealed 35.6% lower hazards of death (p=0.038), whereas hazards for death-censored graft loss were similar (p=0.204). Secondary outcomes of allograft function showed significantly lower 1-, 3-, and 5-yr serum creatinine in 'PD' vs. 'HD' groups (p=0.007, p=0.048, and p=0.012, respectively). Living donation benefit for allograft function was most pronounced in groups 'no RRT' and 'PD'. Although not statistically significant, functional allograft decline measured by estimated glomerular filtration rate (eGFR) slope was lowest in PD patients. Recipients on pre-transplant PD with living donation grafts even demonstrated eGFR gain during post-transplant years 1-5.

Conclusions: Allograft recipients on pre-transplant PD vs. HD demonstrated superior all-cause and similar graft survival. Allograft function was better in PD vs. HD patients, although the trajectory of functional decline was similar.

Funding: Private Foundation Support

Figure 2. Unadjusted (Kaplan-Meier) primary outcomes comparing allograft recipients according to pre-transplant RRT modality. Shown are patient survival (A) and death-censored graft failure (B). Maximum follow-up was 18.3 years, log rank (Mantel-Cox) p<0.001 for (A) and (B); HD, hemodialysis; PD, peritoneal dialysis; RRT, renal replacement therapy.



FR-PO1197

CKD Progression Rate from Stage 4 to 5 Is Faster in Kidney Allograft Recipients

Sahin Eyupoglu,[1] Gizem Kumru,[1] Damla Örs Şendoğan,[1] Rezzan Eren Sadioglu,[1] Sim Kutlay,[1] Gokhan Nergizoglu,[1] Sehsuvar Erturk,[2] Kenan Keven.[1] *[1]Nephrology, Ankara University School of Medicine, Ankara, Turkey; [2]Ankara University School of Medicine, Ankara, Turkey*.

Background: In kidney transplant recipients (KTR), average glomerular filtration rate (GFR) is around 55-70 ml/min in early period after transplantation. Although, chronic kidney disease progression (CKD) rates have been extensively studied in non-transplanted CKD patients, there are limited comparative studies in KTR. In this study, we aimed to evaluate whether CKD progression from stage 4 to 5 is different in KTR than those of CKD patients.

Methods: The study included 76 stable CKD patients and 34 stable RTR (24 living donor, 10 deceased donor) with stage 4 CKD who reached stage 5 during their follow-up between May 2017 and December 2018 in our hospital. Patients with graft loss due to early acute rejection, early graft loss due to surgical complications, immunosupressive non-compliant patients were excluded in KTR. In control, patients with rapidly progressive glomerulonephritis, acute kidney injury on chronic were excluded. CKD stage was determined according to Kidney/Disease Outcomes Quality Initiative staging system. The progression rate from stage 4 CKD to 5 was calculated retrospectively and compared through Kaplan-Meier analysis between groups. Also, clinical features which could contribute to disease progression were assessed and Cox regression analysis was performed for adjustment.

Results: The KTR were under triple immunosuppressive treatment including prednisolone, mycophenolate mofetil (azathioprine) and tacrolimus (cyclosporine). The average follow-up were 89±77 months in KTR. Median progression time in RTR patients was significantly shorter than CKD patients 18 (95% CI: 13.5-22.6) vs 38 (95% CI: 33.25-42.75) months, p= 0.017. GFR levels were 28.2 ml/min and 29.5 ml/min in KTR and CKD patients on stage 4, respectively. At the end GFR levels were 7.43 ml/min and

7.4 ml/min in KTR and CKD groups on stage 5. Male patients had shorter progression time than women (25 [%95CI: 22.1-27.8] vs 42 [95% CI:37.2-46.7] months p=0.01). After Cox regression analysis gender (p=0.016) and transplant status (p=0.015) remained their significance.

Conclusions: Progression time from stage 4 to 5 is shorter in RTR than native CKD patients. Gender and age also can contribute disease progression.

FR-PO1198

Reporting and Handling of Missing Outcome Data in Systemic Reviews of Kidney Transplant Studies

Pooja Budhiraja,[1] Mohamad A. Kalot,[1] Abdallah El alayli,[2] Ahmad B. Dimassi,[2] Amna Ilahe,[1] Reem Mustafa.[1] *[1]University of Kansas, Kansas city, KS; [2]Lebanese American University Medical Center, Beirut, Lebanon.*

Background: Missing outcome data (MOD) can be absent not at random but due to side effects or in effectivity of interventions and can have implications on the validity, reproducibility and generalizability of the results. Hence, before concluding the effectiveness of the intervention in clinical setting it is important for the systematic reviews (SRs) to collect information about MOD and perform appropriate analysis to assess the robustness of the results.

Methods: We conducted a methodological survey of reporting and handling of MOD in SRs published in past 5 years. We included meta-analyses of randomized controlled trials performed in adult kidney transplant recipients that provided pooled estimate of an intervention on at least one dichotomous outcome. We used a standardized pilot tested forms with detailed instructions for each step of the review process. Title, abstract, full text screening and data abstraction all are done in duplicates. We studied how SRs collected, reported and handled MOD in the primary analysis.

Results: Seventy-one SRs (14 Cochrane and 57 Non-Cochrane reviews) met the inclusion criteria. Drugs were the most common intervention studied (84%) and average follow up was 12 months. Intention to Treat (ITT) or modified ITT was reported in 50% Cochrane and 9% non-Cochrane reviews. Ninety one percent of SRs did not collect information for number or reasons for participants with MOD. Only 5% handled and justified the analytical method(s) used to handle MOD. Furthermore, only 4% performed sensitivity analysis to account for MOD and considered the uncertainty associated with imputing outcomes in the analysis. The Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach for evaluation of the confidence in estimates of effect was used in 21% of the SRs.

Conclusions: Missing outcome data can introduce bias due to systematic differences between the observed and unobserved data, which can compromise the certainty in the evidence. SRs in kidney transplant recipients do not adequately report, handle or discuss the risk of bias associated with the MOD before concluding the results.

FR-PO1199

Clinical Trials in Nephrology: An Updated Systematic Review of ClinicalTrials.gov

Reem Mustafa,[1] Nedaa Husainat,[1] Mohamad A. Kalot,[1] Abdallah El alayli,[2] Adnan Shaaban,[3] Laith Numan,[4] Mohammed N. Alkhatib,[1] Nigar Sekercioglu,[5] Raabia Nizamuddin,[1] Julie H. Ishida,[6] Melissa West,[7] Sheri Tibbs,[8] Uptal D. Patel,[9] Jula K. Inrig.[10] *[1]University of Kansas, Kansas City, KS; [2]Lebanese American University, Beirut, Lebanon; [3]University of Minnesota, St. Paul, MN; [4]University of Missouri, Kansas City, MO; [5]McMaster University, Hamilton, ON, Canada; [6]Gilead Sciences, San Francisco, CA; [7]American Society of Nephrology, Washington, DC; [8]Duke University, Durham, NC; [9]Gilead Sciences, Inc., Foster City, CA; [10]IQVIA; UC Irvine; Duke University, Yorba Linda, CA.*

Background: Previously published reviews have highlighted low rates and poor quality of clinical trials in nephrology compared to other specialties. In this review, we assessed temporal trends in the quantity and quality of nephrology trials.

Methods: We conducted a systematic review among nephrology trials registered on ClinicalTrials.gov from inception to November 2018. Two independent reviewers assessed every trial and extracted data.

Results: A database of 288,515 registered interventional trials was restricted to studies that included one of 154 nephrology terms. We screened 5412 studies and included 4943 in the analysis. Figure 1 summarizes the number of registered nephrology trials over time. Trials were grouped into 3 Eras [Table 1]. Compared to Era 1, Era 3 had more randomized, blinded, and large trials. Fewer studies were NIH and industry-funded. Drug trials decreased while device and behavioral interventions increased. While there was a decrease in transplant trials, there was an increase in living donor recipient and in glomerular disease trials.

Conclusions: There has been an increase in the number of nephrology trials conducted over time with some improvement in quality and an increase in trials for devices, behavioral interventions, and rare kidney diseases.

Table 1	Era 1: 09/30/1982 - 08/31/2010	Era 2: 09/01/2010 - 08/31/2014	Era 3: 09/01/2014 - 11/31/2018

Plasmapheresis Reduces Mycophenolic Acid Concentration: A Study of Full AUC_{0-12}

Sudarat Piyasiridej,[1] Natavudh Townamchai,[2] Suwasin Udomkarnjananun,[1] Somchai Eiam-Ong,[1] Kriang Tungsanga,[3] Kearkiat Praditpornsilpa.[1] *[1]Chulalongkorn University, Bangkok, Thailand; [2]Division of Nephrology, Bangkok, Thailand; [3]King Chulalong Memorial lHospital, Bangkok, Thailand.*

Background: Mycophenolic acid (MPA), which is a crucial immunosuppressive drug, and plasmapheresis, which is an effective immune reduction method, are simultaneously used for the management of various immune-related diseases, including kidney transplantation. While plasmapheresis has been proven for removing many substances from the blood, its evidence on MPA levels remains unestablished.

Methods: A cross-sectional study was conducted in kidney transplantation recipients who were taking a twice-daily oral dose of mycophenolate mofetil (MMF, Cellcept®) and undergoing plasmapheresis at King Chulalongkorn Memorial Hospital, Bangkok, Thailand, during January 2018 and January 2019. The MPA levels were measured by enzymatic method (Roche diagnostic®) at 0, 1/2, 1, 2, 3, 4, 6, 8 and, 12 hours for AUC_{0-12} calculation on the day with and the day without plasmapheresis sessions. Plasmapheresis was started within 4 hours after the oral morning dose of MMF. Our primary outcome was the difference of AUC_{0-12} between the day with and without plasmapheresis.

Results: Forty complete AUC measurements included 20 measurements on the plasmapheresis day and the other 20 measurements on the day without plasmapheresis of six kidney transplant patients. The mean age of patients was 56.2 ±20.7 years. All patients had received MMF 1,000 mg/day for at least 72 hours before undergoing 3.5±1.2 plasmapheresis sessions. Mean AUC on the day with plasmapheresis was lower than the day without plasmapheresis sessions (28.22 ±8.21 vs 36.79 ±10.29 mg x hour/L, p=0.001) and the percentage of AUC reduction was 19.49 ±24.83 %. This was mainly the result of a decrease in AUC_{0-4} of MPA (23.96 ±28.12% reduction).

Conclusions: Plasmapheresis significantly reduces the level of full AUC_{0-12} of MPA. The present study is the first to measure the full AUC_{0-12} in MPA-treated patients undergoing plasmapheresis. Our study suggests that a supplementary dose of MPA in patients undergoing plasmapheresis is necessary.

Funding: Private Foundation Support

AUC0-12 on PP and non-PP day

Parameters	Day without PP	PP day	p-value
AUC0-12	36.79 ±10.29	28.22 ±8.21	p=001
AUC0-12 reduction (%)	19.49 ±24.83

Outcome Implications of Benzodiazepine and Opioid Co-Prescription in Kidney Transplant Recipients: A Pharmacoepidemiologic Analysis

Ngan Lam,[2] Mark Schnitzler,[4] Mara McAdams-DeMarco,[3] Gregory P. Hess,[5] Krista L. Lentine.[1] *[1]Saint Louis University, St. Louis, MO; [2]University of Alberta, Edmonton, AB, Canada; [3]Johns Hopkins, Baltimore, MD; [4]Saint Louis Univ, Shiloh, IL; [5]LDI University of Pennsylvania/Symphony Health, Wayne, PA.*

Background: Recent studies identify coprescription of benzodiazepines and opioids as a risk factor for adverse outcomes in the general population, but relationships have not been described among kidney transplant (KTx) recipients.

Methods: We examined a novel linkages of national registry data with records from a pharmaceutical claims warehouse (2008 to 2017) to characterize benzodiazepine and opioid use in the year after KTx and associations (adjusted hazard ratio, 95% $_{LCL}$aHR95%$_{UCL}$) with death >1 to 5 years post-KTx.

Results: Among 103,969 KTx recipients 15% filled benzodiazepines in the year after transplant: 6.3% long-acting, 7.5% short-acting, 1.8% both. Considered alone, benzodiazepine use in the first year posttransplant was associated with increased (P<0.05) mortality >1 to 5 yrs after KTx: aHR long-acting, $_{1.14}$1.25$_{1.36}$; aHR short-acting, $_{1.33}$1.44$_{1.56}$; aHR both, $_{1.41}$1.64$_{1.91}$. Opioid use was higher in those who also filled benzodiazepines, especially both long- and short-acting (**Fig A**). Use of both medications was more common among recipients who were white, unemployed, and received prior KTx. There was also graded association of higher level opioid use with mortality that appeared additive with benzodiazepine coprescription (**Fig. B**). Patients who filled both classes of benzodiazepines and high-level opioids had 2.6-times mortality risk, compared to no use.

Conclusions: Benzodiazepines use is correlated with opioid fills after KTx, and these agents have additive associations on post-KTx mortality. Future work is needed to examine mechanisms of these associations and impact of reducing coprescription on improving outcomes after KTx.

Opioid Use by Benzodiazepine Use, and Associated Outcomes

FR-PO1202

Correcting Anemia and Native Vitamin D Supplementation in Kidney Transplant Recipients: A Randomized Clinical Trial

Yoshitsugu Obi,[1,2] Naotsugu Ichimaru,[3] Yusuke Sakaguchi,[3] Takayuki Hamano.[3] CANDLE-KIT Trial Study Group *[1]University of California Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN; [3]Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Higher levels of hemoglobin (Hb) and serum 25(OH)D have been associated with better allograft survival among kidney transplant recipients (KTRs). Therefore, aggressive anemia correction and cholecalciferol (VD_3) supplementation may preserve allograft kidney function.

Methods: This is a multicenter, open-label, randomized clinical trial with a 2-by-2 factorial design. KTRs with anemia and >1-year history of transplantation from 23 facilities were randomly assigned to either the high or low Hb target group (>12.5 vs. <10.5 g/dL) and to either the VD_3 (1000 IU/day) or control group. The primary outcome was the 2-year change in eGFR from baseline.

Results: This trial was stopped early after a planned interim analyses using a Pocock type α-spending function (α=0.036). At that time, 153 patients had undergone randomization, and 133 were available for the intention-to-treat analysis. Mean Hb levels at Year 2 were 11.6±1.7 g/dL and 10.7±1.3 g/dL in the high and low Hb group, respectively (**Figure A**). The high Hb group showed a smaller decline in eGFR than the low Hb group (i.e., -1.9±5.4 vs. -4.2±6.9 ml/min/1.73 m^2; *P*=0.032) (**Figure B**), which was consistent in the per-protocol analysis. Mean serum 25(OH)D levels at Year 1 were 31.9±9.1 g/dL and 14.9±6.6 ng/mL in the VD_3 and control group, respectively (**Figure C**). The difference in 2-year change of eGFR did not reach statistical significance between the VD_3 and control groups (i.e., -4.0±6.1 vs. -2.2±6.3 ml/min/1.73 m^2, respectively; *P*=0.10) (**Figure D**), but the VD_3 group showed a greater decline in the per-protocol analysis (*P*=0.033). VD_3 supplementation did not modify the effect of the high Hb target strategy on eGFR ($P_{interaction}$=0.74).

Conclusions: Aggressive anemia correction preserves allograft kidney function while VD_3 supplementation may accelerate the decline rate among KTRs (ClinicalTrials.gov Identifier: NCT01817699).

Application of the IBox Clinical Trial Simulation Tool to Project Long-Term Kidney Allograft Outcome in the TRANSFORM Study

Gillian Divard,[1] Olivier Aubert,[1] Marc Raynaud,[1] Julio Pascual,[2] Peter Bernhardt,[4] Christophe M. Legendre,[1,3] Alexandre Loupy.[1] Paris Transplant Group *[1]Paris Transplant Group, INSERM U970, Paris, France; [2]Hospital del Mar, Parc de Salut Mar, Barcelona, Spain; [3]Hôpital Necker, Paris, France; [4]Novartis Pharma AG, Basel, Switzerland.*

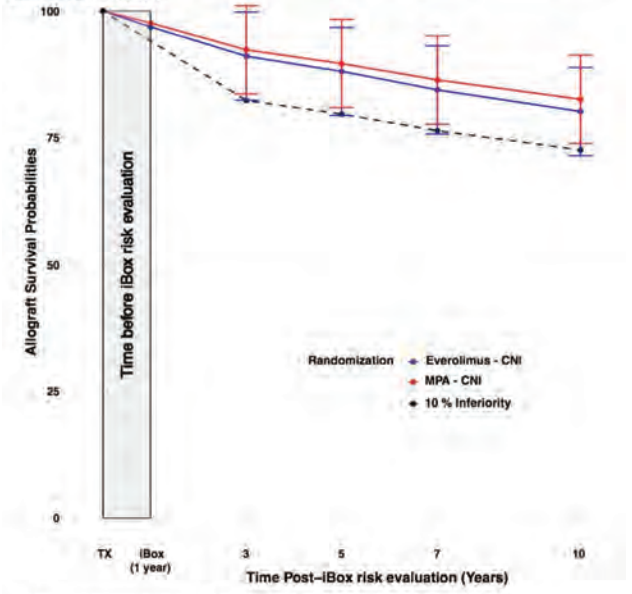
Background: Development of pharmaceutical agents in transplant is currently limited by long waits for hard endpoints. We sought to use a risk stratification system in a randomized control trial (RCT) and determine individual patient long-term graft survival.

Methods: We used validated data from TRANSFORM trial (NCT01950819), a RCT that compares KTR to receive everolimus with low-exposure CNI or mycophenolic acid (MPA) with standard-exposure CNI. We applied the iBox (NCT03474003), an integrative and validated risk score which used parameters measured at 1 year after randomization and projected patients individual long-term allograft survival.

Results: A total of 1855 patients (930 with everolimus and 925 with MPA) reached the 1 year after transplant primary endpoint. Mean eGFR was 55.9±19.7 mL/min/1.73m^2 with everolimus vs 56.1±19.1 with MPA. Mean protein/creatinin ratio was 0.32±0.67 g/g vs 0.26±0.63 with MPA. The incidence of BPAR was of 2.5% with everolimus *vs* 3.6% with MPA. The rate of DSA was 13.7% with everolimus *vs* 15.9% with MPA. These immunological, functional and histological parameters were entered into the iBox, which translated to an overall patient graft survival at 3, 5 and 10 years after randomization of 94.2% *vs* 94.7%, 91.2% *vs* 92.0% and 83.3% *vs* 84.9% in the everolimus and MPA arms respectively (95%CI -3.1% to 0.2% below the non-inferiority margin of 10%) **Figure.**

Conclusions: The iBox system confirms the non-inferiority of everolimus vs MPA 10 years after patient's randomization in the RCT. Given the unmet need for surrogate endpoint for clinical trials, this study shows the potential of a clinical trial simulation tool to fast track the development and approval of pharmaceutical agents.

Figure: Projected long term allograft graft survival between the everolimus and MPA groups using the iBox clinical trial simulation tool.



Mean projected allograft survival

Everolimus - CNI	94.2%	91.2%	87.6%	83.3%
MPA - CNI	94.7%	92.0%	88.7%	84.9%

FR-PO1204

Association Between Post-Transplant Opioid Use and Immunosuppressant Therapy Adherence Among Renal Transplant Recipients

Marie Chisholm-Burns,[2] Christina A. Spivey,[1] Praveen Kumar Potukuchi,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy,[1] Miklos Z. Molnar.[1]
[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of Tennessee Health Science Center College of Pharmacy, Memphis, TN; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA.

Background: Little is known about the effect of post-renal transplant opioid use on adherence to immunosuppressant therapy (IST).

Methods: Longitudinal data were analyzed from a retrospective cohort study examining US veterans undergoing renal transplant from October 1, 2007 through March 31, 2015. Opioid prescriptions dosages were collected and divided based on annual morphine milligram equivalent (AMME) within a year of transplant. Proportion of days covered of at least 80% indicated adherence to tacrolimus. We used logistic regression analyses to examine the association between posttransplant opioid use and adherence to IST.

Results: Compared to renal transplant recipients (RTRs) without opioid usage, RTRs with opioid usage had lower probability of being adherent to tacrolimus in unadjusted and multivariable adjusted models (model 2-5) [Figure]. In the adjusted Model 5, RTRs with AMME opioid dose of 1-30 [OR (95% CI): 0.17 (0.05-0.56)], 31-60 [OR (95% CI): 0.21 (0.06-0.74)], and >60 [OR (95% CI): 0.18 (0.05-0.61)] had lower probability of tacrolimus nonadherence compared to RTRs without opioid usage.

Conclusions: RTRs who use prescription opioids during the first year posttransplant are less likely to be adherent to tacrolimus. Future studies are needed to better understand underlying causes of the association between opioid use and tacrolimus nonadherence.

Funding: NIDDK Support

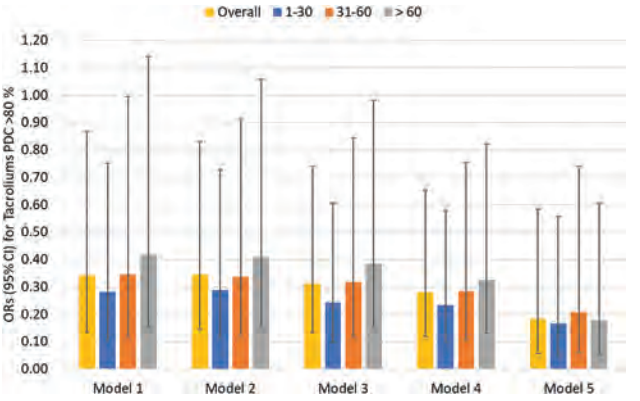


Figure: Association of one-year posttransplant opioid AMME dose with tacrolimus adherence in unadjusted models (Model 1) in 1,229 RTRs and adjusted models (Models 2-5) in 1,068 RTRs. Overall, Any opioid use; AMME dose categories, 1-30, 31-60, >60; Reference, No opioid use.

Model 1: unadjusted; Model 2: demographic characteristics; Model 3: model 2 variables plus comorbidities and smoking status; Model 4: model 3 variables plus medications; Model 5: model 4 variables and systolic/diastolic blood pressure and body mass index.

Trends in Causes of Death in Australian and New Zealand Kidney Transplant Recipients: A Registry Analysis by Era and Time Post Transplant

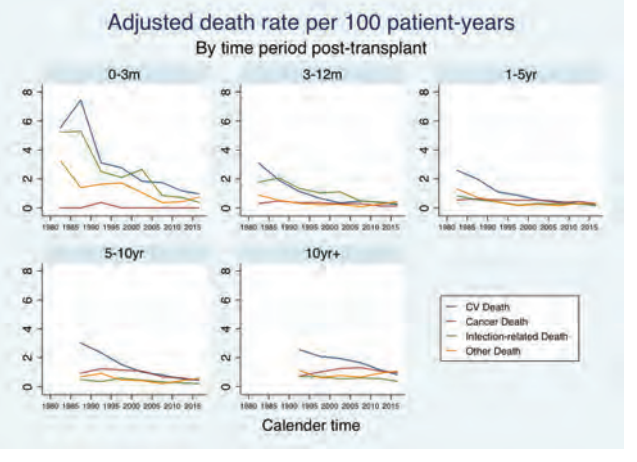
Tracey Ying,[1,2] Bree Shi,[2] Patrick Kelly,[3] Philip A. Clayton,[4] Steven J. Chadban.[1,2]
[1]Royal prince Alfred hospital, Camperdown, NSW, Australia; [2]Kidney Node Charles Perkins Centre, University of Sydney, Camperdown, NSW, Australia; [3]The University of Sydney, Camperdown, NSW, Australia; [4]Royal Adelaide Hospital, Adelaide, SA, Australia.

Background: Donor and recipient characteristics in kidney transplantation (KT) have changed dramatically since the 1980s. Along with an increase in marginal donors and older recipients, incremental improvements have ensued in immunosuppression, surgical techniques and cardiovascular (CV) disease management. A contemporary assessment of the risks and determinants of deaths in KT recipients is required to better inform our patients.

Methods: Using the ANZDATA registry, we included all kidney-only transplant recipients between 1980 to 2017. We censored patients at graft loss or date of last follow-up. We calculated crude death rates by dividing the number of deaths by the total patient-years at risk. Adjusted death rates per 5-year intervals were compared using a piecewise exponential model, stratified by time period post-transplant.

Results: 22,078 incident KT recipients accumulated 183,964 person-years of follow-up. The adjusted all-cause death rate was 2% per annum, remaining stable since 2005. Compared with 1995-1999, KT recipients in 2015-2017 were older (mean age 47 vs. 41) and had more comorbidities (CVD 25% vs. 13%, diabetes 24% vs. 10%). Since 1980, there has been a significant reduction in CV and infection-related deaths at all periods post-transplant (Figure-1). Recipients in the current era had a 56% reduction in CV deaths (adjusted HR=0.44, 95%CI 0.36-0.52) and 53% reduction in infection-related deaths (adjusted HR=0.47, 95%CI 0.36-0.61), compared with recipients in 2000-2004. Short-term cancer-deaths have remained stable over time, with a marginal fall in long-term cancer-deaths since 2005.

Conclusions: The risk of death after KT has reduced significantly since the 1980s, driven by a reduction in CV death at all time points and a decline in infection-related deaths. Contrary to previous studies, cancer-deaths have remained stable over time after adjusting for time post-transplant.



FR-PO1206

Improvement in Long-Term Graft Survival of Post-1-Year Survivor Kidney Transplant Recipients in the United States

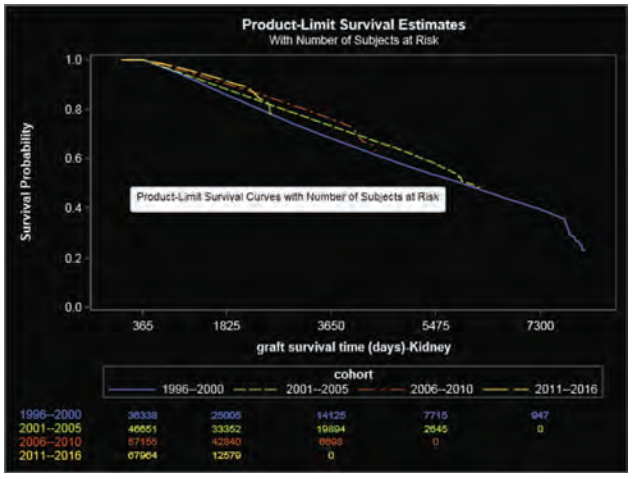
Catherine Wu, Abbas Rana, John A. Goss, Samaya J. Anumudu, Bhamidipati V. Murthy. *Baylor College of Medicine, Houston, TX.*

Background: Advances in prevention and treatment of acute rejection of kidney transplants significantly improved the short-term allograft survival. However, these successes have not been translated to long term outcomes of kidney transplants. We re-evaluated long-term graft survival for recipients whose survived one year after kidney transplantation such that the short-term adverse outcomes do not cloud the long term outcomes.

Methods: We retrospectively analyzed 219,645 recipients from 1995 to 2017 using data from the United Network for Organ Sharing. Patients undergoing re-transplants, multiorgan transplants, and recipients <18 years age at transplantation were excluded. Patients who died within 1 year of transplantation were excluded. Multivariable Cox regression was employed to estimate graft survival.

Results: Compared with patients transplanted during the period 1996-2000, on multivariate analysis, the hazard ratio (HR) for graft loss for 2001-2005 was 0.88, 2006-2010 was 0.73, and 2011-2016 was 0.63. The HR for graft loss for males was 1.12, age >60 years (vs 18-40) was 1.39, Blacks (vs Whites) was 1.34, BMI >30 (vs 18.6-25) was 1.13, dialysis prior to transplant (vs pre-emptive) was 1.40, diabetes was 1.52, and deceased donor (vs living donor) was 1.38. Compared to patients with PRA 0-79%, the HR for graft loss for PRA 80-89% was 1.15, and for 90-100% was 1.22. Compared to donor age 18-29 years, HR with donors 30-39 yrs was 1.10, 40-50 years was 1.26, and >50 years was 1.50. All these were statistically signicant with p<0.0001.

Conclusions: Long-term graft survival among kidney transplant recipients in the US has improved steadily over time. While advances in maintenance immunosuppression, and prevention and treatment of antibody-mediated rejection may have contributed, further research is needed to better understand other causes behind this improvement in kidney graft survival over the past 30 years.



FR-PO1207

Outcomes of Deceased Donor Kidney Transplant Recipients Based on Age and Kidney Donor Profile Index

Josh Bodnar,[1] Aniruddha Srivastava,[1] Sandesh Parajuli,[1,2] Brad C. Astor,[1] Brenda L. Muth.[1] *[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]UW Health, Madison, WI.*

Background: The Kidney Donor Profile Index (KDPI) is a score used to estimate the overall quality of a deceased-donor kidney prior to transplant. This study sought to determine the outcomes of receiving KDPI >85% Kidneys relative to KDPI ≤85% kidneys based on graft survival and patient survival at two different age groups.

Methods: This was an observational study of all deceased-donor kidney transplant recipients >40 years of age at the time of transplant between 2011 and 2015 at our University hospital (n=837). Patients were divided into two groups, group 1 included patients between >40 and 59 years of age at the time of transplant (n=176) who received a KDPI >85% (n=15) or KDPI ≤85% (n=161). Group 2 included patients ≥60 years of age (n=121) who received a KDPI >85% (n=11) or KDPI ≤85% (n=110).

Results: Most of the baseline characteristics were similar across groups. Around 25-27% of ESRD was due to Diabetes (DM) in both groups, Recipients were on dialysis for a longer time in group 1 compared to group 2. In the univariate analysis, KDPI >85% or presence of delayed graft function (DGF) in either group were not associated with patient or graft survival. However, DM as a cause of ESRD was significantly associated with increased risk of graft failure and patient death in group 2 but not in group 1. Similarly, the use of depleting induction immunosuppressive compared to the non-depleting agent was significantly associated with increased risk of graft failure and patient death in both groups. After adjustment in multivariate analysis, in group 1, DM was associated with increased risk of graft failure [HR: 1.4, CI: 1.0-1.9, p=0.03] and death [HR: 1.44, CI: 1.1-1.9, p=0.03], along with in group 2 for graft failure [HR: 1.76, CI: 1.2-2.6, p=0.003] and death [HR: 1.75, CI: 1.2-2.5, p=0.002]. The similar, association was found for the use of depleting immunosuppressive medications in both groups for graft and patient survival.

Conclusions: In our observation, elevated KDPI >85% and delayed graft function were not associated with patient or graft survival regardless of age. The provider should consider these factors during transplant.

FR-PO1208

Reverse Epidemiology and the Obesity Paradox for Patients with CKD

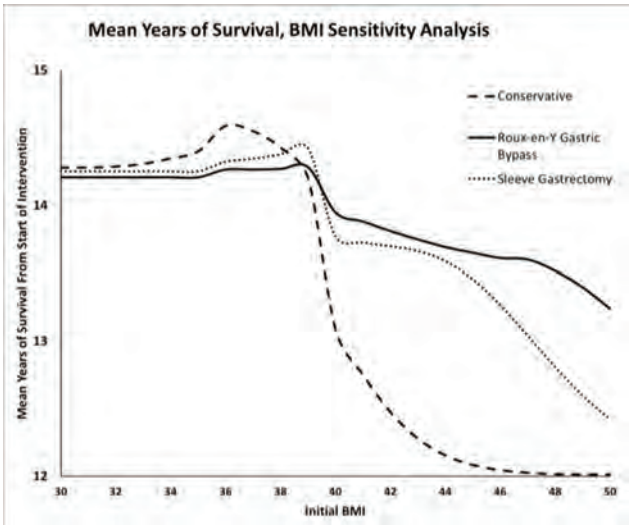
Rashikh A. Choudhury,[1] Dor Yoeli,[1] Hunter B. Moore,[1] Gerard Hoeltzel,[2] Kristoffel R. Dumon,[2] Peter L. Abt,[2] Kendra D. Conzen,[1] Trevor Nydam.[1] *[1]University of Colorado Hospital, Denver, CO; [2]University of Pennsylvania Hospital, Philadelphia, PA.*

Background: Obesity has been associated with both increased progression of chronic kidney disease as well as with a paradoxical improvement in survival among ESRD patients undergoing hemodialysis. As such, the optimal weight management strategy for obese CKD patients remains unclear.

Methods: A decision analytic Markov state transition model was created to simulate the life of 30,000 obese patients with CKD stage 3b, as they progressed to ESRD, transplantation, and death. Life expectancy following conservative medical weight management (observation), Roux-en-Y Gastric Bypass (RYGB) and Sleeve Gastrectomy (SG) were estimated. Base case patients were defined as being 55 years old and having a pre-intervention BMI of 40 kg/m^2. Sensitivity analysis of initial BMI was performed. All Markov parameters were extracted from literature review.

Results: RYGB and SG were associated with improved survival for patients with pre-intervention BMI of > 39.6 kg/m^2. Compared to conservative weight management, base case patients who underwent RYGB gained 10.3 months of life, and gained 8.2 months of life following SG.

Conclusions: Balancing progression of CKD with improved survival on ESRD for obese patients requires selective use of weight management strategies. RYGB and SG improved survival for CKD patients with Class III obesity, but not for patients with Class I and Class II obesity. As such aggressive weight loss interventions should be reserved for patients with Class III obesity, while more conservative methods should be offered to those with Class I and II obesity.



FR-PO1209

One-Year Outcome of Deceased Donor Kidney Transplantation in the Elderly Using High Kidney Donor Profile Index Kidneys

Wei Xiang Wong, Nicole Low, Wina Yousman, Pablo Loarte, Angelo M. De Mattos, Lavanya Kodali. *University of Arizona, Banner Medical University Tucson, Tucson, AZ.*

Background: Elderly patients with end stage renal disease account for 22.5% of the adults on kidney transplant waiting list in 2016, a significant rise from 15.3% in 2006. At our institute, deceased donor kidney transplant (DDKT) rate for elderly patients (defined as ≥ 65 years of age) was 33.8% between 2016-2017, much higher than the national rate of 19.2%. The use of kidneys with Kidney Donor Profile Index (KDPI) higher than 85 has facilitated shorter waiting time for this target population. Our objective is to see the outcome of the elderly patients who received high KDPI>85% DDKT.

Methods: Retrospective chart review was done on patients who received deceased kidney transplants from July 2016 to August 2017 at Banner University Medical Center in Tucson, Arizona. Primary outcomes were glomerular filtration fraction (GFR) 1-year post transplant, rejection rate (RR) and delayed graft function (DGF) rate in the elderly who received high KDPI deceased donor kidneys. Data was analyzed using SPSS. GFR is calculated using MDRD.

Results: Among 154 patients who received kidney transplantation at our institute, 52 (33.8%) patients were elderly and 34.6% of them received high KDPI kidneys.

Characteristics of our cohort were represented in table 1. The elderly who received high KDPI kidneys have similar rate of DGF, RR, and GFR 1 year post transplant compared to the rest of the cohort (50.0% vs 48.6%, 11.1% vs 18.9%, 47 vs 58 ml/min/1.73m^2, all p>0.05). Elderly patients had significantly higher cold ischemic time (CIT) compared to the rest of the cohort (32.4±9.7 vs 27.2±12.5h).

Conclusions: Elderly patients at our institute who received high KDPI kidneys have similar rate of DGF, RR and GFR 1-year post transplant compared to the rest of the cohort. Compared to the national rate, elderly high KDPI recipients in our study have prolonged CIT (32.4±9.7 vs 17.0±8.7) and higher DGF (50% vs 23.8%) but comparable rejection rate (9.5% vs 11.1%) and GFR 1-year post transplant was 47 vs 58 ml/min/1.73m2.

Variables		Age ≥ 65 (n=52)	Age < 65 (n=102)	p value
KDPI, N (%)	> 85	18 (34.6%)	9 (8.8%)	<0.01*
	≤ 85	34 (65.4%)	93 (91.2%)	
EPTS, N (%)	> 70	37 (71.2%)	19 (18.6%)	<0.01*
	≤ 70	15 (28.8%)	83 (81.4%)	
PRA, N (%)	> 40	10 (19.2%)	26 (25.5%)	0.43
	≤ 40	42 (80.8%)	76 (74.5%)	
Induction, N (%)	Basiliximab	42 (80.8%)	69 (67.6%)	0.09
	rATG	10 (19.2%)	33 (32.4)	
DGF, N (%)	Yes	25 (48.1%)	50 (49%)	1
	No	27 (51.9%)	52 (51%)	
Rejection, N (%)	Yes	7 (13.5%)	18 (17.6%)	0.65
	No	45 (86.5%)	84 (82.4%)	
CIT, mean		31.9 ± 11.5	25.5 ± 12.1	0.01*
GFR 1-year post transplant, ml/min/1.73m^2		56	58	0.75

Table 1: Elderly vs non-elderly 1-year outcomes in our cohort

FR-PO1210

Single Cell RNA-Seq profiling of renal endothelial cells in experimental diabetic nephropathy model reveals transcriptomic changes in separate endothelial subpopulations

Alex X. Zhou,[1] Pernille B. Laerkegaard Hansen,[2] Christer Betsholtz,[3] Marie Jeansson,[4] Liqun He,[3] Martin Uhrbom,[5] Jianping Liu,[4] Anna Granqvist,[5] Pernilla Tonelius.[6] *[1]AstraZeneca Gothenburg, Mölndal, Sweden; [2]Imed CVMD, Mölndal, Sweden; [3]Uppsala University, Uppsala, Sweden; [4]Karolinska Institutet, Huddinge, Sweden; [5]AstraZeneca, Mölndal, Sweden; [6]AstraZeneca R&D Gothenburg, Sweden, Mölndal, Sweden.*

Background: Endothelial dysfunction and vascular rarefaction are hallmarks of chronic kidney disease, while little is known about the transcriptomic changes of renal endothelial cells (ECs) during disease progression. Moreover, kidney contains heterogenous EC subpopulations that are structurally and functionally distinguishable. This study aims to determine and compare transcriptome profiles in separate renal EC subpopulations between healthy mice and mice of diabetic nephropathy (DN) using single cell RNA-seq (scRNA-Seq).

Methods: Kidneys of BTBR lean and *ob/ob* mice at 6, 11 and 20 weeks of age were enzymatically dissociated with Liberase™. After incubation with Pecam1 antibody and Calcein-AM, Pecam1$^+$ and Calcein-AM$^+$ single live cells were FACS sorted into 384-well plates. Single EC cDNA library was generated by Smart-seq2 technique and the sequencing was performed on Illumina HiSeq 3000. Unsupervised clustering of EC subpopulations was performed with Pagoda2 analysis.

Results: BTBR *ob/ob* mice develop vascular rarefaction with age. Compared to the lean mice, the proportion of renal single live ECs in the *ob/ob* mice showed no difference at 6 weeks of age, a 25% reduction at 11 weeks of age, and a 32% reduction at 20 weeks of age (P=0.01). The current Pagoda2 analysis on the 11-week-old lean and *ob/ob* mice revealed twelve EC subpopulations and 142 genes with significantly altered expression in *ob/ob* mice. Among differentially expressed genes (DEGs), certain redox genes were ubiquitously regulated. However, majority of the DEGs were altered in distinct EC subpopulations, likely owing to either the different sample sizes or the heterogeneity on gene expression/regulation in various EC subpopulations. The data of 6- and 20-week-old BTBR mice is under analysis to explore the time course of the transcriptomic changes.

Conclusions: The full length scRNA-seq on FACS sorted renal ECs provides a feasible approach to a high-resolution transcriptomic profiling of heterogenous EC populations in kidney and importantly the heterogenous transcriptomic changes in an experimental DN model.

ASN Communities: A Growing Thriving Online Educational Asset

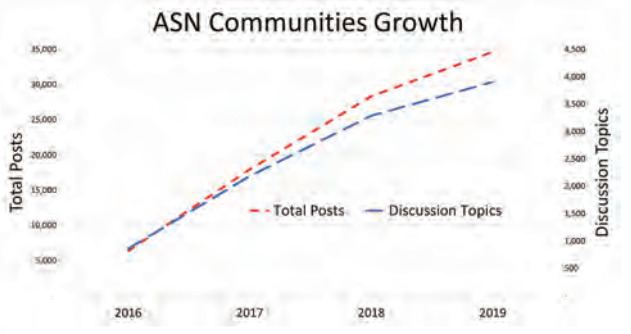
Roger A. Rodby,[1] Susan Willner.[2] *[1]Rush University Medical Center, Chicago, IL; [2]American Society of Nephrology, Washington, DC.*

Background: Doctors are turning to social media (SoMe) and internet-based venues to teach, improve patient care, and to bolster knowledge. In 2016**,** the American Society of Nephrology launched "ASN Communities" ("Comms") an online collaboration platform designed to provide ASN members with a dynamic international peer to peer venue to discuss challenging clinical cases, as well as other professional education activities. The clinically oriented Comms include: Open Forum, Patient Care Q&A, AKI, Kidney Transplantation, Onco-Nephrology and Nephrologists Transforming Dialysis Safety. Other Communities include Public Policy and Public Health, Renal Educators, Women's Health and Research, Basic Science Research, Career Advancement, Fellows Connect, and Renal Educators.

Methods: ASN members are automatically enrolled in the Open Forum Comm while the other Comms require a one-click join process. Members can opt to receive email alerts for each Comm in which they are a member. ASN Comms combines the best of all SoMe platforms into a professional, iterative, educational experience for the mundane to the most complex questions of health care workers around the world, and by design not limited to academia. Each Comm has "Community Leaders" (topic experts that help lead the discussions) who are chosen by the ASN's Media and Communication Committee which also oversees the activities of all Comms.

Results: ASN members from throughout the world regularly leverage the expertise and knowledge of the greater community as evidenced by 25% of logins and 30% of posts originating from outside of the U.S. To date there have been 3,902 Discussions generating 27,871 replies (see Figure) from 180 countries and over 4,800 cities, with 330,149 logins representing 13,300 ASN Members. Each month approximately 3,000 ASN members access Comms. Comms are accessible on any computer as well as smart phones via a dedicated Comms app and on Twitter at @ASNCommunities.

Conclusions: ASN Communities should serve as a template for other medical subspecialties interested in the education and growth of their members.



SA-PO002

Survey-Based Evaluation of Home Dialysis Education During Nephrology Fellowship in United States

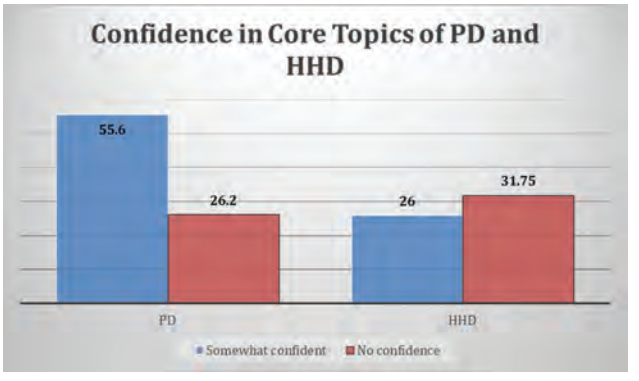
Nupur Gupta,[1] Elizabeth Taber-Hight,[1] Brent W. Miller.[2] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Carmel, IN.*

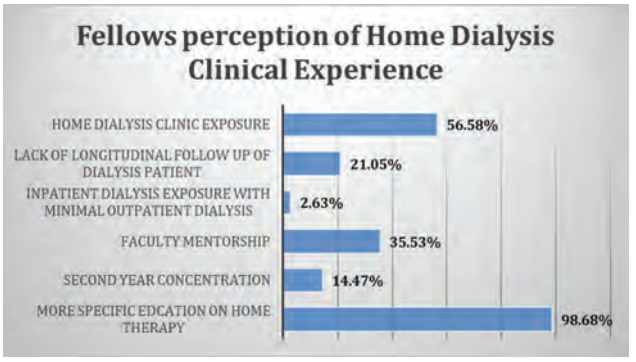
Background: Home Dialysis seems to be an underutilized modality for many reasons, one of which includes physician unfamiliarity with the practical aspects in both Peritoneal Dialysis (PD) and Home Hemodialysis (HHD). Previous surveys have suggested suboptimal exposure and confidence amongst fellows. The goal was to identify gaps in knowledge and evaluate possible areas of improvement in Home Dialysis

Methods: A 23 question survey on education during fellowship training was developed and distributed at 3 Home Dialysis University Symposia in 2019. Survey assessed core competencies, clinical experience and overall preparedness of Home based renal therapies amongst graduating fellows.

Results: 76 out of 250(30%) graduating fellows completed the survey. Nearly all the respondents (98.7%) desired more teaching focused on both Home Therapies. Assessing the core competencies of PD, majority (55.6%) of them were "somewhat confident" and 26.2 % selected "no confidence". A larger portion of respondents (31.8%) felt "Not at all confident" regarding HHD key competencies. Most of the participants believed fewer than national average (< 10%) patient population were on Home Therapies in their Academic practice. A large number of fellows (71.7%) reported that patients followed in Home Continuity clinic were on PD but fewer on HHD. Approximately half the fellows have opportunity of continuity clinic with Faculty mentorship.

Conclusions: Nephrology fellows felt significantly more prepared for PD than HHD but moderate overall preparedness. Implementation of well-structured curriculum integrated with robust clinical experience would improve utilization of Home Therapies with preparedness of fellows.





SA-PO003

Comparing Author Gender and Publications in Two Medical Subspecialties

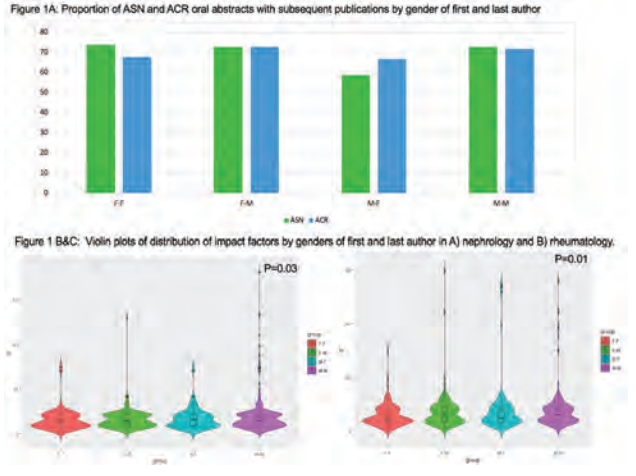
Niralee Patel, Yumeng Wen, Nidhi Naik, Benjamin O. Adegbite, Steven G. Coca, Girish N. Nadkarni, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: A gender gap exists in scientific publications, with women being underrepresented. We assessed the proportion of oral presentations that are subsequently published in peer-reviewed journals and their impact factor (IF) by gender in nephrology (40% female fellow trainees) and rheumatology (60% female fellow trainees).

Methods: We reviewed oral abstracts presented at American Society of Nephrology (ASN) Kidney Weeks 2011-2013 and American College of Rheumatology (ACR) annual conferences 2011-2013. Proportions of gender combinations for first and last author (Female-Female (FF), Female-Male (FM), Male-Female (MF), and Male-Male (MM)) were compared utilizing Chi^2 and IFs using ANOVA.

Results: Of 1,262 ASN oral abstracts, 39% had female first authors and 21% had female last authors. MF had the lowest proportion (59%) of abstracts published compared to FF, FM, and MM authors (74 vs. 73 vs. 73%, P=0.005) (Figure 1A). MM papers were published in journals with higher IF (Figure 1B). In contrast, of 1,191 ACR oral abstracts, females comprised of 52% of first authors and 41% of last authors. There were no significant differences seen in the combinations of authorship (FF 68%, FM 73%, MF 67%, vs. MM 72% p=0.35) (Figure 1A). MM papers were published in journals with higher IF (Figure 1C).

Conclusions: Author gender differences seen in the proportion of oral abstracts that were later published were inconsistent between nephrology and rheumatology. However, MM abstracts were published in higher impact journals in both fields. Whether these findings hold true in other medical subspecialties with varying proportions of female trainees should be further explored.



SA-PO004

Kidney Disease Screening and Awareness Program Is an Effective Model to Expand the Recruitment Pipeline by Capturing Undergraduates for Nephrology

Rui Song,[4] Rebecca P. Chen,[2] Min Zhuo,[1] Sirine Bellou,[3] Andrew Cho,[6] Jiahua Li,[4] Li-Li Hsiao.[5] Kidney Disease Screening and Awareness Program (KDSAP) Clinical Research Team *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]University of California, Los Angeles, San Diego, CA; [3]Brigham & Women's Hospital, Brookline, MA; [4]Brigham and Women's Hospital, Chestnut Hill, MA; [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [6]Harvard University, Cambridge, MA.*

Background: Physician shortage in nephrology is causing an impending workforce crisis. The Kidney Disease Screening and Awareness Program (KDSAP) is a national student-led organization targeting college students via community health screening and mentorship. This longitudinal study aims to assess the impact of KDSAP on career choice of its alumni in nephrology.

Methods: KDSAP alumni were defined as college graduates from 2009 to April 2019, who have attended at least one KDSAP health screening or KDSAP academic event. There are 173 alumni who met the criteria and with valid contact information. An online survey evaluating demographics, career choice impact, perspectives on nephrology was sent by email. To gain in-depth knowledge of KDSAP's impact, one-on-one interviews were conducted with those who are currently practicing medicine; and focus group discussions were conducted with medical students and health-related graduate students. This study was conducted via a mixed-method study approach.

Results: Our study enrolled 112 alumni who completed the survey. Among them, 75 (67%) reported "very" or "extremely" invested in KDSAP activities. The community screening is the most meaningful (97%) and influential (69%) to their career choices. Out of 112 respondents, 94 (84%) are in the field of medicine in various stages, including 3 nephrologists. While 40 (36%) consider doing kidney-related research or patient care, impressively 8 (24%) of those attending medical school (n=34) consider Nephrology as their career choice. Our results also revealed favorable perceptions of Nephrology among KDSAP alumni: Nephrology is exciting compared to other specialties (79%), Nephrologists are important to community health (97%), Nephrology is a well-respected practice (91%), Nephrology is a rewarding field for a career option (88%) and considering a kidney-related profession for the further career (31%). Qualitative analysis (n=8) revealed four main categories in the impact of KDSAP on alumni: career choice, mentorship, career development, and community health services.

Conclusions: In fighting the Nephrology workforce crisis, KDSAP is an effective model to expand the recruitment pipeline by capturing undergraduates entering the field of Nephrology.

SA-PO005

What Do Internal Medicine Residents Consider When Choosing Careers? An Exploratory Q Sort Study with a Focus on Nephrology Interest

John K. Roberts, Charles Hargett, Myles Wolf. *Duke University, Durham, NC.*

Background: Interest in nephrology among internal medicine (IM) residents has been low in recent years. A better understanding of contemporary attitudes about career choice decisions in IM residents could help nephrology recruiting efforts. Therefore, we used a Q sort survey to better understand IM resident attitudes surrounding career choice decisions in the modern era.

Methods: We invited IM residents (post-graduate year 2/3) at an academic medical center to take a Q sort survey in the late fall of the training year. Residents prioritized 50 statements that reflected issues affecting career choice: scope of practice, patient continuity, procedures, consultant care, general care, family responsibilities, debt, remuneration, length of training, interest in physiology, and lifestyle concerns. To find statistically significant perspectives, we performed by-person factor analysis using the Centroid method. At the conclusion of the Q sort, we collected the residents' top three career interests.

Results: Out of 47 sorts, we identified four viewpoints that accounted for 43% of the variance in the sample. Figure 1 shows the viewpoints. Across all four groups, all agreed that positive interactions with a faculty role model and control over future practice are important for career decisions. Among residents considering nephrology, two loaded onto the Academic Proceduralist viewpoint, five loaded onto the Lifestyle-Family viewpoint, and one loaded onto the Lifestyle-Salary group.

Conclusions: The Q-sort survey identified the dominant career choice viewpoints of contemporary IM residents. Two of the viewpoints were centered on lifestyle considerations: one focused on family responsibilities and the other focused on remuneration, educational debt, and burnout. To make nephrology more attractive to the current generation, changes to the profession are needed. Interventions that support an attractive lifestyle, control of practice, while accommodating to family responsibilities and educational debt may impact interest more than other factors.

SA-PO006

A Unique Hybrid Nephrology Training-Hospitalist Medicine Track: The University of Kentucky Experience

Faris Khasawneh,[1] Jon C. Webb,[2] B. Peter E. Sawaya.[2] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY.*

Background: There has been a declining interest in nephrology training as evidenced by a decline in the number of applicants and increased number of unfilled positions through the Match. On the other hand, hospitalists are a growing group of physicians with some gaining mature interest in nephrology. However, salary disparity has been an obstacle to translate this interest into pursuing nephrology training. The creation of a hybrid program combining nephrology training and hospitalist work is a possible pathway that would be of value to Nephrology programs and interested hospitalists.

Methods: In 2016, the nephrology program at the university of Kentucky embarked in a systematic creation of a hybrid program combining nephrology training and hospitalist practice. A curriculum expanding over 4 years with alternating 6-month blocks was developed. The salary of the candidates alternates between PGY-4 or 5 remuneration and those of a full time hospitalist faculty. The curriculum was approved by the university graduate medical education (GME) and by the ACGME. ABIM recognizes this fellowship under the "interrupted" training track. A major obstacle is the alignment of the offices of human resources, hospital administration and GME. An effective communication system is necessary to signal the switching between the different status. A geographic separation where the training is in one hospital, while the faculty hospitalist practice is in another proved to be a practical mechanism to circumvent potential confusion. Once the program is approved, advertisement in prominent hospitalists journals was necessary.

Results: After 1 month of advertisement in two hospitalists journals at a cost of $2500, we identified 9 interested candidates after the match. We offered the position to two. The average yearly salary for the hospitalist-fellow trainee is $138,250/year. Moonlighting is allowed as a supplementation to their salary, provided that it does not interfere with the duty hours regulation. Currently, the two hybrid trainees have completed two years in this program with 1 year of accredited training toward nephrology. Their feedback has been very positive.

Conclusions: Nephrology Fellowship-hospitalist track appears to be a valid approach to ameliorate the negative impact of declining interest in nephrology fellowship on the manpower and overall training programs.

SA-PO007

The Nephrology Immersion Classroom: Using Digital Videos to Boost Knowledge in Nephrology

John K. Roberts, Myles Wolf. *Duke University, Durham, NC.*

Background: Improving residents' nephrology knowledge is one way to stimulate interest and self-efficacy in nephrology. Newer methods of resident education should be sought to better personalize the learning process and meet resident needs. One way to foster self-directed, asynchronous learning is through digital chalk talk videos. We hypothesized that adding a nephrology video curriculum to a nephrology rotation would improve medical knowledge in internal medicine residents.

Methods: Internal medicine residents (post-graduate year 2/3+) on the nephrology consult rotation were invited to participate in the study. In both a control and intervention year (access to the videos), we surveyed and tested residents' knowledge using 15 case-based multiple-choice questions (MCQs) before and after their nephrology rotation. We created a library of 32 short, digital blackboard videos that covered high-yield topics in nephrology. We hosted the video curriculum on Google Classroom, so that access could be restricted to study participants and they could view content using the Google Classroom smartphone app. In the post-rotation survey, we measured satisfaction and usability of the nephrology classroom.

Results: 39 residents completed the nephrology rotation in the control group and 26 (66%) participated in the study. In the intervention group, 33 residents completed the nephrology rotation, 25 (75%) enrolled in the Google classroom, and 30 (90%) participated in the study. Performance on nephrology MCQs improved between the pre and post-tests in both years, but the difference was not statistically different. During the study period, videos were viewed on average 5.6 times and the classroom was considered very easy to use. Other usability metrics suggest high levels of satisfaction with the video curriculum.

Conclusions: Adding a digital chalk talk curriculum did not improve short-term medical knowledge, but hosting videos on a mobile classroom platform resulted in modest usage with high resident satisfaction. Efforts to boost video views may improve both short and long term learning outcomes.

Nephrology Medical Knowledge in Control and Intervention Years

Study Condition	Control		Intervention	
	Pre-Test	Post-Test	Pre-Test	Post-Test
Number	18	21	29	22
Median time to complete (min)	30	33	38	40
Mean Number of Correct Questions (%)	8.7 (58%)	10 (68%)	8.3 (56%)	9.5 (63%)

Interim analysis, full data will be available by Oct 2019

SA-PO008

Internal Medicine Residents' Perception of the Nephrology Specialty

Georges Nakhoul,[1] Ali Mehdi,[2] Jonathan J. Taliercio,[3] Andrei Brateanu,[1] Amit Diwakar,[2] Remy Daou,[4] John R. Sedor,[2] John F. O'Toole,[2] Joseph V. Nally,[2] S. beth Bierer.[2] *[1]Cleveland Clinic Foundation, Cleveland, OH; [2]Cleveland Clinic, Mayfield Hts, OH; [3]Glickman Urological and Kidney Institute, Cleveland, OH; [4]Saint Joseph University, Beirut, Lebanon.*

Background: Interest in nephrology as a specialty has been declining among US medical graduates As a result, more than half of the fellowship programs remain unfilled. To better understand this phenomenon, we intended to qualitatively explore the nephrology perceptions among Internal Medicine (IM) residents and to identify factors influencing their choice of a subspecialty career.

Methods: A qualitative study was designed using the grounded theory methodology. Ten semi-structured interviews were conducted with randomly selected internal medicine residents (Postgraduate Year (PGY) 1 and 2). The interview questions were guided by the Professional Identity (PI) Formation Framework, which captures key elements of the socialization processes contributing to the development of the PI. Interviews were recorded and transcribed verbatim. Coding was performed by 2 independent reviewers who met to reach consensus on emerging themes. Data saturation was reached after the 8th interview. Decision to stop interviewing was made after the 10th interview.

Results: Several recurring themes emerged in our analysis (Table 1). The negative factor that recurred most commonly was the lack of exposure to nephrology rotations both in the clinical and pre-clinical years. This was mentioned by 9 out of 10 residents. Other frequently recurring themes were: patient population (mentioned by 5/10 residents), lack of innovation in the field (4/10) and inability to make a difference (4/10). Factors positively influencing residents' decision included: breadth (5/10) and complexity of pathology (7/10) and perception of nephrology as a highly intellectual specialty (7/10).

Conclusions: Lack of exposure to nephrology rotations in preclinical and clinical years appears to be the most important factor dissuading residents from pursuing a career in nephrology.

Factors Influencing Residents Career Decision-Making

Georges Nakhoul,[1] Ali Mehdi,[2] Jonathan J. Taliercio,[3] Andrei Brateanu,[1] Amit Diwakar,[2] Remy Daou,[4] John R. Sedor,[2] Joseph V. Nally,[2] John F. O'Toole,[2] S. beth Bierer.[2] *[1]Cleveland Clinic Foundation, Cleveland, OH; [2]Cleveland Clinic, Mayfield Hts, OH; [3]Glickman Urological and Kidney Institute, Cleveland, OH; [4]Saint Joseph University, Beirut, Lebanon.*

Background: Interest in nephrology as a specialty has been declining among US medical graduates and more than half of the nephrology fellowship programs remain unfilled. To better understand this phenomenon, we aimed to identify factors influencing residents' choice of a "subspecialty career".

Methods: A qualitative study was designed using the grounded theory methodology., Ten semi-structured interviews were conducted with randomly selected internal medicine residents (Postgraduate Year (PGY) 1 and 2 PGY2). The questions were guided by the Professional Identity (PI) Formation Framework, which captures key elements of the socialization processes contributing to the development of the PI. The residents' answers were recorded and transcribed verbatim. Coding was performed by 2 independent reviewers who met to reach consensus on emerging themes. Data saturation was reached after the 8th interview. Decision to stop interviewing was made after the 10th interview.

Results: Several recurring themes emerged in our analysis and were classified into three general categories: personal attributes (personality, family tradition, experiences and values), social factors (Mentors, transformative events, exposure, quality of instruction, performance and autonomy) and specialty-specific factors (Field, lifestyle and job-related

factors) (Table 1). Among those themes, the role of role models/mentor stood out as the most important as it was mentioned by 100% of the residents. This adds new information to the factors that were previously identified by the ASN workforce.

Conclusions: We identified the factors influencing career decision-making in internal medicine residents and the key role of mentorship in this process. Understanding these factors could help the nephrology community understand the declining interest in the field and formulate interventions to potentially remedy the current situation.

PERSONAL ATTRIBUTES	SOCIAL FACTORS	SUBSPECIALTY SPECIFIC FACTORS
Personality	**Role models / mentors**	**Field-related factors:** - Innovation in the field - Social aspect (teamwork) - Breadth of pathology
Family Tradition	**Transformative events**	**Lifestyle-related factors** - Work-life balance - Stress level / Acuity - Work load
Experiences	**Formal learning (pre-clinical)** - Exposure - Topic Difficulty - Intellectual challenge - Quality of instruction - Experience / performance on block	**Job-related factors** - Prestige / Influence - Compensation - Job Market - Academic prospects - Opportunity for procedures
Values	**Clinical years** - Exposure - Environment - Quality of instruction - Experience / performance on rotation - Autonomy on rotation	**Patient-related factors** - Patient population - Longitudinal care / continuity - Inpatient vs. outpatient focus - Practice focus: narrow vs. wide - Ability to make a difference

SA-PO010

An Innovative Night Float System in Nephrology: A Mixed-Methods Evaluation

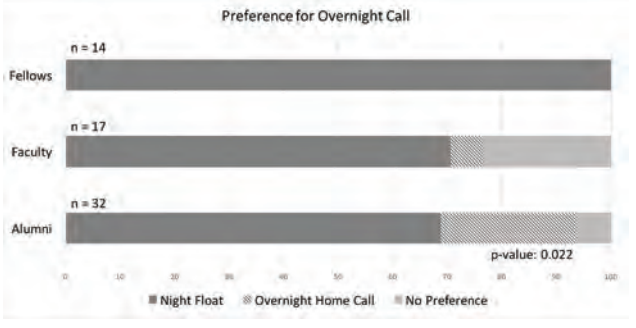
Jennifer B. Plotkin,[1] Eric Jia Yi Xu,[2] Derek M. Fine,[2] Daphne H. Knicely,[2] John Sperati,[2] Stephen M. Sozio.[2] *[1]Department of Medicine, UCLA, Los Angeles, CA; [2]Division of Nephrology, Johns Hopkins University, Baltimore, MD.*

Background: Johns Hopkins was early to adopt an in-house nephrology fellowship night float to improve work-life balance. The aim of our study was to elucidate attitudes about night float to guide fellowship structuring.

Methods: We conducted a mixed-methods study. We surveyed current fellows, program alumni, and current faculty and conducted a focus group of current fellows. Surveys were developed through literature review, queried on a 5-point Likert scale, and analyzed with unpaired t and ANOVA tests. The focus group transcript was iteratively analyzed by two independent reviewers to identify major themes.

Results: Survey response rates were 14 (100%) fellows, 32 (91%) alumni and 17 (94%) faculty. All groups felt quality of patient care was good to excellent with no significant differences among groups (mean (SD) range 4.12 (0.70) - 4.57 (0.65), p=0.12), but we found a statistically significantly more positive view on autonomy rated by fellows compared to faculty (4.57 (0.51) vs. 4.12 (0.33), p=0.006). Exploring the impact on the day team experience, fellows indicated a statistically significant improvement across domains (range 4.21 (0.80) - 4.64 (0.63), p<0.001 compared to neutral effect). Focus group themes included wellness, professional development, patient care, continuity of care, and structural components. Says one fellow, "…my bias is that every program would switch to a night float system if they could." All groups were satisfied with night float with 4.71 (0.47), 4.18 (0.81) and 4.03 (0.86) for fellows, faculty, and alumni respectively; fellows were more enthusiastic (p=0.028). Overall, all three groups preferred night float; fellows did so unanimously.

Conclusions: Night float was well-liked by fellows and improved the experience of the daytime fellow. Alumni and faculty were also positive about night float; however, they were less enthusiastic than fellows possibly because alumni and faculty have concerns about career preparation. Implementation of night float at other nephrology programs should be considered.



SA-PO011

Non-Tunneled Hemodialysis Catheter Placement Experience and Perception of Graduating US Adult Nephrology Fellows

Hitesh H. Shah,[1] Fatima Sheikh,[3] Kenar D. Jhaveri.[2] *[1]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]Northwell Health Sys, Great Neck, NY; [3]Northwell, New Hyde Park, NY.*

Background: Nephrology fellows are required to acquire skills and demonstrate competency in the placement of non-tunneled hemodialysis catheter (NT-HDC) during fellowship. To gain a greater insight in the NT-HDC placement experience and perception of US adult nephrology fellows, we carried out a national survey.

Methods: An on-line survey was created and sent to US adult nephrology fellows in May 2018. Data was further analyzed for fellows graduating in 2018.

Results: 254 fellows responded to our survey (31.4% response rate). 128 (50.4%) were graduating in 2018. Most NT-HDCs were placed in the hospital and 17.3% reported having a dedicated rotation for NT-HDC placement. 33.9% received simulation based training, 14.2% received bedside training, 20.5% received both simulation and bedside training, while 29.1% did not receive any formal training in NT-HDC placement. 45.3% did not receive any formal didactic session on NT-HDC placement during fellowship. Of the 128 graduating nephrology fellows (G-NFs), 27.3% had not placed any femoral NT-HDC during fellowship while 25.8% had placed ≤3 and 27.3% had placed >10. While 35.1% of G-NFs had placed >10 internal jugular NT-HDCs during fellowship, 21% had placed ≤3 and 23.4% had placed none. 14.8% of G-NFs had not placed any NT-HDC. 41.4% of G-NFs needed to place at least 5 NT-HDCs before independently performing this procedure during fellowship, while 11.7% required ≥10. While 64.8% of the G-NFs reported having received adequate training in NT-HDC placement, only 37.5% planned to place NT-HDCs after graduation. Majority (57%) of G-NFs felt that nephrologists should not place NT-HDC in clinical practice. Reasons cited for those who had inadequate or no training in NT-HDC placement included: lack of opportunities to place NT-HDCs (53.9%), lack of formal training (41.4%), lack of nephrology faculty interest (42.97%) and expertise (32.8%).

Conclusions: While majority reported adequate training in NT-HDC placement, a significant percentage of graduating fellows had not placed either a femoral or internal jugular NT-HDC or both during fellowship. Majority received simulation based training, however a significant percentage did not receive any didactic session or formal training in NT-HDC placement during fellowship. Fellowship programs should take measures to ensure that all fellows receive adequate training in NT-HDC placement.

SA-PO012

A Program of Renal Biopsy Training Using Low-Cost Realistic Models

Guilherme P. Santa Catharina, Igor Smolentzov, Roberto Zatz, Lectícia Jorge. *Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Renal biopsy is a necessary procedure in Nephrology practice, but adequate training is necessary to minimize its inherent risks.

Methods: We developed a method for the training of residents and professional nephrologists in percutaneous renal biopsy, utilizing homemade simulators that imitate a lumbar torso and contain a dummy kidney made of colored forensic gelatin. The "kidneys" exhibit realistic physical appearance, consistency and ultrasound properties, yielding equally real looking fragments when "biopsied". The models were manufactured locally with a cost of less than 20 USD.

Results: Two workshops were carried out involving 61 nephrologists and Nephrology residents. The procedure consisted of the presentation of archived glomerulopathy cases, followed by an explanation of the biopsy procedure, after which hands-on ultrasound guided obtainment of "kidney" fragments (Figure), available to all participants, was performed. Afterwards, the possible complications, and the measures to avoid or limit them, were discussed. As a final step, the "results" were presented and discussed in the form of digitized renal slides corresponding to each case studied, along with the response to treatment and outcomes. When invited to evaluate the course, 98% of the respondents declared that they would recommend the course to others, whereas 100% considered the workshop "excellent" or "very good", and 92% assigned these same attributes to the hands-on training procedure. This method is currently being applied in the training of Nephrology Residents in our Division.

Conclusions: The use of these inexpensive dummies is a useful and well-received tool that can improve the efficiency of training in renal biopsy and increase the safety of the procedure.

Funding: Government Support - Non-U.S.

SA-PO013

Exploring Nephrologists' Attitudes Towards Kidney Biopsies for Research

Afolarin A. Amodu,[1] Gearoid M. McMahon,[2] Ragnar Palsson,[3] Suraj Sarvode Mothi,[4] Sushrut S. Waikar.[5] *[1]Brigham and Women's/ Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Brookline, MA; [3]Harvard, Belmont, MA; [4]Brigham and Women's, Boston, MA; [5]Harvard Medical School, Boston, MA.*

Background: Recent interest in kidney biopsies for research purposes raises the question of safety versus benefit of the procedure. Physician perspectives on indications for kidney biopsy and perceived safety of the procedure have not been studied in detail

Methods: We sent an IRB-approved, anonymous, online survey to 98 nephrologists at three Boston academic hospitals. Participants were asked about their clinical experience, their perception of the risk of kidney biopsies, and the likelihood that they would support biopsies being obtained from their patients for research purposes. We scored responses using a Likert Scale (1 = "absolutely not"; 5 = "definitely yes"). We compared scores using independent sample t-test

Results: Response rate was 58%. The Table shows mean scores according to whether nephrologists were primarily clinicians (n=12) or clinician-researchers (n=43). There were no differences between the respondents' assessment of renal biopsy risk when comparing researchers vs. clinicians or stratifying by years of experience or number of biopsies performed. Overall, nephrologists who were primarily clinicians scored lower than researchers on the scale for willingness to allow research kidney biopsies

Conclusions: Substantial variability exists among nephrologists regarding the indications for kidney biopsy and their comfort with kidney biopsies for research purposes

Funding: Other NIH Support - T32

Willingness of nephrologists to allow patients to be approached for research kidney biopsies. Results are reported as mean (SD) on a 1 through 5 scale (higher number suggests higher likelihood

Association of Nephrology Inpatient Service Size on Medication Safety Recommendations

Huiwen Chen,[1] Syeda B. Ahmad,[2] James R. Johnston,[1] Ranil N. DeSilva.[3] *[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Providing quality and safety care are the highest goals for most medical institutions. Quality care is difficult to define but has been linked with adequate staff to patient rato, timely care, and medical error reduction. Emergency department and intensive care units have studies that have identified safe and optimal nurse-to-patient ratios and physician-to-patient ratios respectively. The nephrology field lacks data in this area.

Methods: Retrospective chart review of general nephrology consults placed from Jan 1st 2018 to Dec 31st 2018. Daily service size and physician work schedules were reviewed with distribution analyzed. High patient census defined as greater than 40 (top 10%), low patient census defied as less than 26 (bottom 10%). Four types of renal related medications were assessed: electrolyte related, antibiotics related, nephrotoxic agents and central nervous system related. Medication errors were exressed as percentage and coordinated with daily service size. Clinical adverse outcomes associated with medication erros were also reviewed.

Results: 11.2% of the medication errors were experienced by our patients during the high census days vs 19.4% during the low census days. P= 0.225 Potential confounders include: higher census days were more prevalent in the winter months, and more experienced fellows and house staff worked during the winter months. Also there was low awareness of nephrologists responsibility to commend of renal dosed medication as standard consult recommendations amongst nephrology fellows.

Conclusions: The number of overloaded medication errors did not differ based on renal service size. However, patients expereinced greater than 10% of the medication errors in 2018. A pharmacist might be needed in the nephrology consult service to reduce the errors of renally excreted medication experienced by our patients. Awareness of nephrologists' role in medication safety recommendation shall be heightened by nephrology training programs.

Timing and Type of Nephrology Consults in an Academic Medical Center: A Springboard for Quality Improvement

Graham T. Gipson, Faisal R. Radwi, Benjamin Schwartz, Niraj R. Kothari, Jason M. Kidd. *Virginia Commonwealth University School of Medicine, Richmond, VA.*

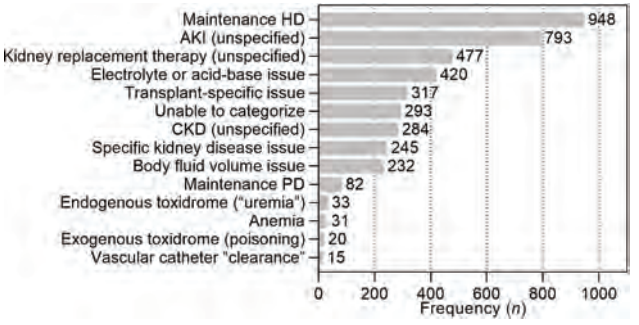
Background: Inpatient consultation is a common part of nephrology practice. Give our decreased work force and increasing clinical demand, knowing the type and timing of consult requests can improve the quality of care that we provide.

Methods: VCU Health is a large tertiary-care hospital with a clinical nephrology fellowship and 15 faculty members. An electronic consult request process was implemented in 2017. For nephrology, inpatient consult requests were submitted to 1 of 4 services: Floor (non-ICU), ICU, Chronic Dialysis, or Transplant. We used a health care informatics platform to abstract data for 3087 consults over a 12-mo period. Data included time of consult request and free-text reasons for consult (RFC); the latter were categorized using 1 or more of 16 prespecified categories.

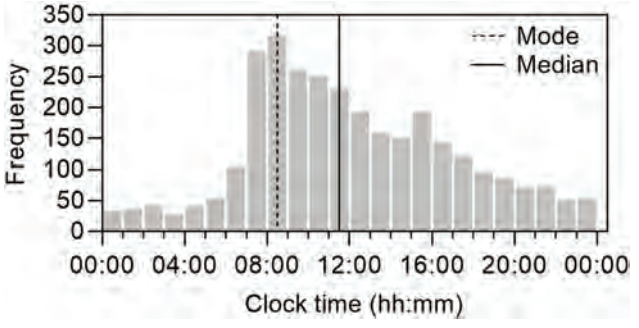
Results: The most common RFC was maintenance HD, followed by AKI (Figure 1). The maximum frequency (mode) of nephrology consultation occurred between 08:00 and

09:00, though a second mode arose between 15:00 and 16:00 (Figure 2). The frequency distribution of consultation was not different between the 4 consult services. Limitations include subjectivity and interrater variability in RFC categorization, and inability to capture consult requests that were not submitted electronically.

Conclusions: We identified the timing and type of consults requested over a 12-mo period. Our hope is to identify consultation patterns that place workload strain on the available nephrology staff. From that, we seek to undertake quality improvement initiatives to alter these patterns in order to maximize the quality of care rendered by our limited workforce.



Consult frequency by reason-for-consult.



Consult frequency by time of day

SA-PO016

The Impact of the Electronic Medical Record (EMR) on Nephrology Fellowship Training

Christina M. Yuan,[1] Dustin J. Little,[3] Rajeev Raghavan,[2] Robert Nee.[1] Nephrology Education Research and Development Consortium (NERDC) *[1]Walter Reed National Military Medical Center, Laurel, MD; [2]Baylor College of Medicine, Houston, TX; 3AstraZeneca, Gaithersburg, MD.*

Background: A potential unintended consequence of EMR use is the impact on physician training. We surveyed U.S. Nephrology fellows to assess perceived burdens and benefits of the EMR on fellow education.

Methods: Using the ACGME 2018-2019 public list of nephrology programs, we contacted 148 program directors (PDs) by email requesting completion of an anonymous on-line survey on EMR impact on fellow education. PDs were asked to forward an anonymous survey link to their clinical fellows, and indicate to how many they forwarded the link. Surveys were open for 2 months, with reminders sent to PDs every 2 weeks.

Results: PD response rate was 34% (51/148 programs). 22% (33 PDs) forwarded the link to their fellows (n=216; 26% of U.S. nephrology fellows). Median fellows/program was 6 (range 2-20). 72 fellows (33%) responded. 39 were 1st year; 33 were 2nd/3rd year fellows. 42% indicated that their institution's EMR functionality was "slowed, disrupted, or completely lost" monthly or more. 51% of fellows agreed/strongly agreed that the EMR contributed positively to their education. The 3 most frequently cited positive effects were: access to EMR from home/mobile device (81%); efficient laboratory result trending (70%); and efficient determination of patient medications (47%). The 3 most frequently cited negative effects were: more time spent with the EMR than the patient (75%); excessive/irrelevant documentation (67%); and preventing fellows from learning the minimal essential evaluation for a given disease (42%). More than 50% of fellows agreed/strongly agreed they were "often reluctant" to do procedures (52%), participate in conferences (57%), prolong patient interactions (74%), and do independent case-directed literature review (55%), because of the competing time demands of EMR completion. 65% "sometimes" or "often" exceeded work hours limits because of time spent on EMR documentation. 54% "sometimes" or "often" made mistakes in the EMR due to the use of "copy forward".

Conclusions: Although the nephrology fellows surveyed indicated that the EMR had positive impacts on their education, the time demands of data entry appear to interfere with educational opportunities and may contribute to work hours violations. *The views expressed are those of the authors and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense, or the US Government.*

SA-PO017

Evaluation of an Online Conservative Care Curriculum for Nephrology Fellows

Jane O. Schell,[1] Alexandra E. Bursic,[1] Emily Chan,[1] Robert A. Cohen.[2] *[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Older patients with advanced kidney disease experience increased mortality and morbidity despite life prolonging treatments such as dialysis. Conservative care (CC) without dialysis may provide better symptom management and quality of life. Yet nephrologists rarely offer CC, and most patients initiate dialysis without knowing about CC as a treatment option. We developed an online CC curriculum for nephrology fellows to increase knowledge and preparedness in CC skills.

Methods: ACGME accredited nephrology programs were invited to participate in the curriculum and designate a nephrology educator to serve as local champion of the curriculum. Participating programs received the multimodal curriculum including: 1) four online content modules; 2) online communication skills demonstrations; 3) worksheet activities; and 4) a post-curriculum session at each participating program facilitated by local champion to augment the online learning. Using RedCap data management, pre- and post- surveys measured fellow experience, preparedness, and knowledge in CC before and after undergoing the curriculum.

Results: Nineteen nephrology programs participated in the online CC curriculum. 150 of 176 participating fellows (85%) completed the CC pre-survey. Fifty-nine (49%) of fellows were female and almost all were first or second year fellows. Over 75% reported no or limited (1-2 times) teaching in how to define CC, identify who would benefit from CC, and use a values-based communication framework for treatment decisions for CC or time-limited trial (TLT). Using a 5-point Likert scale, most fellows felt 'not very' or 'somewhat' prepared to use a communication framework for treatment decisions for CC or TLT. Almost all fellows who completed the curriculum (46 at time of submission) felt 'very' and 'extremely' prepared to do the following: define conservative care; identify patients who will do poorly on dialysis; how to respond when a patient is emotional; and how to incorporate values-based communication framework for CC and TLT. Almost all fellows were 'very' to 'extremely' satisfied with the curriculum.

Conclusions: Fellows report little to no preparedness in CC or how to discuss CC with patients. An online conservative care curriculum led to increased perceived preparedness in core CC skills. Future research can track CC curriculum impact on patient outcomes and treatment decisions.

SA-PO018

Teaching Renal Physiology and Pathophysiology to Second- and Third-Year Medical Students by Combining Lecturing and Hands-on Computer Simulation

Roberto Zatz, Luis C. Arcon, Antonio C. Seguro, Rosa M. Moyses, Giovana C. Boer, Patricia Z. Tempski. *Univ of Sao Paulo, Sao Paulo, Brazil.*

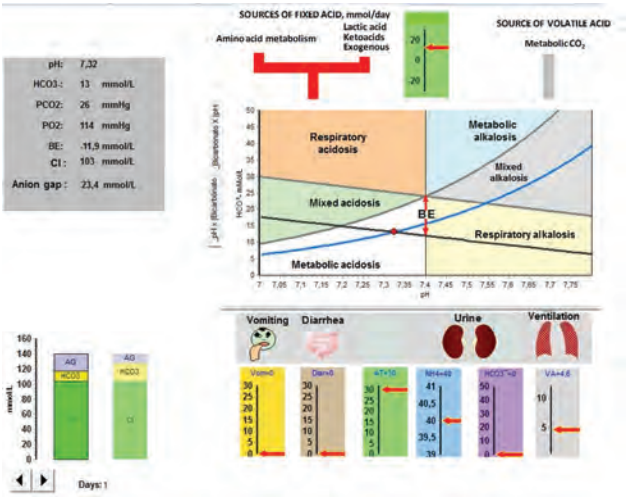
Background: Teaching of Renal Physiology and Pathophysiology (RPP) is one of the most challenging tasks in medical training, given the complexity of concepts and the number of interacting variables.

Methods: We devised a method to teach RPP to second and third-year medical students, consisting of one-hour lectures, followed by one-hour hands-on computer simulation during which students utilize mathematical models that we developed in Visual Basic® and Delphi®, presented through a friendly graphic interface (example in figure). Complex events such as glomerular ultrafiltration and acid-base disorders are simulated by changing variables through ordinary tools such as scrolling bars and sliding arrows. In a final step, students undergo a quick exam consisting of multiple-choice tests, which are discussed afterwards. At the end of each class, students are invited to fill in a self evaluation form about their perception as to whether preestablished learning outcomes were achieved.

Results: Evaluation made by third-year students in 2018/19 showed a high degree of perceived learning, with 79,1% reporting complete, and 18,5% partial, goal fulfillment in subjects such as Dehydration, Acute Kidney Injury, Chronic Kidney Disease and Acid-Base Disorders. In a more objective evaluation, 92 students who attended computer simulation scored 7.8±0.2 SE (on a 0-10 scale) in a test involving the pathophysiology of Edema and Hypertension, as compared to 7.1±0.1 obtained by 87 who just watched the presentation of a computer model ($p<0.05$).

Conclusions: These observations indicate that computer technology associated with classical methods can strongly improve the teaching of RPP, and confirm the concept that hands-on activity can be a more efficient learning method than passive transmission of knowledge.

Funding: Government Support - Non-U.S.



Acid-base equilibrium: dynamic Davenport nomogram.

Application of a Virtual Patient (VP) Program in a Medical School Nephrology Curriculum

Georges Nakhoul,[1] Jonathan J. Taliercio,[2] Shreya Louis,[3] Raoul Wadhwa,[3] Cecile M. Foshee,[3] S. beth Bierer,[3] Neil Mehta,[4] Michael Lioudis,[3] Joseph V. Nally.[3] *[1]Cleveland Clinic Foundation, Cleveland, OH; [2]Glickman Urological and Kidney Institute, Cleveland, OH; [3]Cleveland Clinic, Cleveland Heights, OH; [4]Cleveland Clinic Lerner College of Medicine, Cleveland, OH.*

Background: Immersive simulations have been shown to motivate students and promote learning in a fun and safe environment. Body Interact (BI) is among the most successful VP programs and has been used as a teaching adjunct by medical schools in the United States and Europe.

Methods: We identified 2 nephrology cases that would be appropriate for virtual simulation. We solicited the help of experts in order to build them in a VP platform. The VP cases were piloted then used during class in groups of 8 students accompanied by 1 teaching faculty. The VP allows direct interaction with the students including history gathering, physical examination, testing and live reaction to proposed treatments. At the end of each class, students were asked to fill a survey/feedback form that consisted of a 4-point Likert scale questionnaire rating student agreement [(SA) strongly agree, (A) agree, (D) Disagree and (SD) Strongly Disagree]. The questionnaire focused on 6 parameters: program interface, user engagement, perceived educational value, likability, need for improvement and interest in dissemination.

Results: All 32 CCLCM students used the VP platform for the 2 designed cases. The survey response rate was 73%. Ninety two percent of answers related to the program interface fell into positive categories (55% A and 37% SA), 90% of answers related to user engagement fell into positive categories (50% A and 40% SA), 85% of answers related to educational value fell into positive categories (55% A and 30% SA), 90% of answers related to the likability/need for improvement fell into positive categories (61% A and 29% SA) and 90% of answers related to the interest in dissemination fell into positive categories (60% A and 30% SA). Despite generally favorable feedback by the students, 68% thought that the program could be improved. Most of the desired improvements related to the speed of the program and to the presence of technical glitches on library computers.

Conclusions: We successfully incorporated a VP platform into the nephrology educational curriculum. The BI program was well received and was found to be a useful educational adjunct. Our experience taught us that the use of gaming engines may require considerable computer processing power and this will need to be taken into account in future virtual endeavors.

SA-PO020

The Renal Biopsy Trainer: A Cheaper and More Practical Approach to Procedure Simulation

Elias Nassar,[1] Neil B. Horsley,[1] B. Peter E. Sawaya.[2] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY.*

Background: Current kidney biopsy simulators are scarcely available, expensive and hard to maintain. We developed a Renal Biopsy Trainer (RBT) based on 3D printing technology. This RBT is a life size recreation of the abdominal cavity and the anatomy of the kidney and lumbar region with use of 3D volume visualization of CT images of the abdomen. From the CT the kidney was reconstructed and ported into a CAD program and to create a mold. Silicone molds of the various anatomical structures (e.g. cortex, medulla, calices) were printed so that these structures can be visually distinguished upon taking a biopsy core. The "Renal Biopsy Trainer (RBT)" intends to teach both the anatomy of the kidney as well as serve as an introductory tool to performing kidney biopsy, which can allow a learner to train on a more accurate model obtain immediate feedback on core sample that was taken.

Methods: The RBT is a life-size recreation of the abdominal cavity, kidney and lumbar region with the use of 3D volume visualization of CT images of the abdomen. The kidney was reconstructed into a 3D object which was exported into a computer assisted design (CAD) program. We created silicone molds of the various anatomical structures of the kidney (e.g. cortex, medulla, calices). Each structure was color coded and can be visually distinguished upon inspection.

Results: We created a life-size RBT at a cost of $20. It allows more than 20 passes. The replacement parts (lower pole of the kidney) cost less than $10. The RBT is ultrasound compatible and allows real-time performance of the kidney biopsy. The varied density of each layer allows the operator to "feel" when penetrating the cortex. The color coded sections of the kidney permits immediate feedback about the section from which the biopsy was obtained.

Conclusions: In contrast to commercially available simulators, which are prohibitively expensive, and their use is limited to only a few large medical education centers with a high cost of operation. The RBT is a practical and cheap introductory tool to teach both the anatomy of the kidney and the performance of a renal biopsy with all its intricacies. It can be easily located in the trainees' room for practicing frequently and gaining confidence in performing this critical procedure in Nephrology training.

SA-PO021

NephroPro v2: A New Smartphone App for Medical Students and Residents

George Vasquez-Rios,[1] Neil Evans,[1] Helbert Rondon Berrios,[2] Stephanie C. Shieh.[3] *[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]St. Louis VA Medical Center, Saint Louis, MO.*

Background: There has been a marked decline in applicants to US Nephrology programs. According to some studies, one-third of the medical residents would have considered Nephrology as a career path if topics would have been explained in a manner that facilitated improved understanding.

Methods: We formed a committee of IM residents and Nephrology faculty at Saint Louis University and the University of Pittsburgh Medical Center with the aim to design an educational tool that would help trainees to engage in nephrology. A list of high yield topics was created and ranked. Selection criteria included relevance for medical education and complexity. We then generated short case-scenarios based on real-world problems. Questions were added to help solidify the educational points.

Results: We created *NephroPro*; an interactive app that includes medical scenarios designed around high yield knowledge useful for inpatient rounds, and shelf examinations. In the exploration of the case, students touch on relevant aspects of renal physiology/pathophysiology. An immediate feedback system helps to efficiently educate users on diagnostic tests/management. Each case has a set of 5 questions. Correct/incorrect alternatives are followed by a short explanation, summary tables/graphics. *NephroPro* was developed in partnership with professional developers and is available through Android/iPhone with no registration fee. The maintenance cost of the app is very low. New cases can be upload via our software (*Mobincube*). This app is not financially supported by any private or public institution.

Conclusions: *NephroPro* offers an innovative teaching tool to learn Nephrology. By expanding its use in the medical community, *NephroPro* could serve to generate a dynamic and fun environment to promote renal education.

SA-PO022

Role Play Simulation to Improve Empathy in Nephrology Trainees

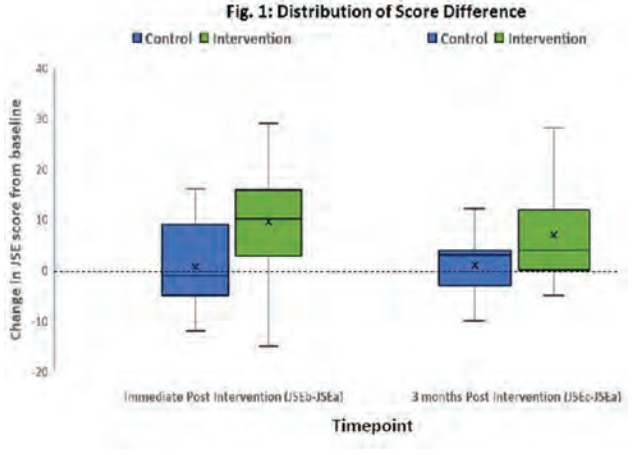
Tushar S. Malavade,[1,5] Jeffrey Schiff,[4] Sarbjit V. Jassal,[2] Gemini Tanna.[3] *[1]Division of Nephrology, University of Toronto, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada; [3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [4]Toronto General Hospital, Toronto, ON, Canada; [5]Department of Medicine, University of Toronto, Toronto, ON, Canada*.

Background: Empathy enables one to identify with another's situation, thoughts, or condition. Empathizing with patients is believed to enhance patient satisfaction & treatment adherence. Simulation is increasingly used to teach empathy to health professionals. Using a randomized controlled trial design we assessed whether role play simulation improves empathy in nephrology trainees (NT).

Methods: All NT at the University of Toronto were eligible to participate. Participants were randomized to either Intervention or Control. The intervention comprised participation in medication intake (7-day dosette with QID placebo pills) & a clinical encounter (either ½ day outpatient clinic (MCKC) or a mock dialysis visit. Both involved clinical assessment by a physician, dietician, social worker & pharmacist. Control group was not exposed to any interventions. Empathy was assessed using the questionnaire for empathy (Jefferson Scale of Empathy for Health Professionals – JSE) at baseline (JSEa), within 24h of interventions (JSEb), & again at 3 months (JSEc). A difference in empathy scores was analyzed, between JSEa & JSEb, and JSEa & JSEc, using the paired T-test.

Results: All 36 NT were approached, 29 consented & randomized (Intervention n=16; Control n=13). Participants were mostly male (69%) & aged 31-40 yrs. In the Intervention group, 16 completed all JSE questionnaires & medication intake, 5 completed a dialysis session, & 5 completed MCKC session. Incomplete questionnaires were given by 2 Control group NT. At baseline, no differences were found between Intervention & Control groups (JSEa 108 ± 14 & 113 ± 8 respectively, NS). An increase in empathy was seen in the intervention group, but not the control group (JSEb 117 vs.113, P=0.03, Fig 1). A trend to persistent improved scores was seen (115 vs 113, P 0.09 at JSEc).

Conclusions: This small study suggests that role play simulation can increase empathy in NT at least over the short term. Larger studies, with longer time period follow up are required.



SA-PO023

NephSim: An Innovative, Mobile-Friendly Nephrology Education Tool

Samira S. Farouk,[1] Rachel Hilburg.[2] *[1]Icahn School of Medicine at Mt. Sinai, New York, NY; [2]University of Pennsylvania, Philadelphia, PA.*

Background: The evolving landscape of technology in medicine has created the need for new approaches to medical education in nephrology. Free open-access medical education (FOAMed) tools provide educational growth at no cost to the user. NephSim is a FOAMed tool that teaches pathophysiology and diagnostic approach to interactive nephrology cases through history and physical, diagnostic tests, and pathology. Cases provide real-time, iterative feedback and allow users to learn from mistakes. Tutorials and infographics illustrate nephrology concepts. NephSim, recipient of the 2018 ASN Innovation in Kidney Education Award, was created as an innovative tool for educators and trainees.

Methods: Built in WordPress, new content is published on NephSim.com every 2-4 weeks and can be accessed using mobile devices or computers. HIPAA compliant, peer reviewed content is distributed via social media and an email subscriber list. To evaluate the scope, effectiveness, and reach of NephSim, we assessed the website usage via WordPress analytics and administered an anonymous survey to evaluate user demographics and experience.

Results: To date, 31 cases have been published on NephSim (29% glomerular, 23% acid-base/electrolyte, 19% dialysis, 19% AKI/other, 6% transplant). 94,000 pageviews represent 100 countries. 17% (76/445) of email subscribers completed the survey. Most users were between 31-45 years (52%). 32% of users were nephrology fellows, 25% nephrology attendings, 9% internal medicine residents, and 1.4% medical students. The majority of users agreed or somewhat agreed that they use NephSim for individual learning (68%) or to teach others (75%). 96% agreed or somewhat agreed that NephSim was easy to use. Nearly all users either agreed or somewhat agreed that they enjoyed using NephSim (96%) and planned to continue using it in the future (99%). Anecdotally, NephSim has been used by educators to guide case-based lectures, teach medical students on nephrology electives, and foster independent learning for trainees at all levels.

Conclusions: NephSim has successfully deployed a mobile-friendly, cased-based approach to teaching nephrology. In just 1 year, usage continues to grow with global participation. Feedback has been positive. We aim to incorporate NephSim in medical school, internal medicine, and nephrology training program curricula while diversifying content and contributors.

SA-PO024

CME Effectively Improves the Clinical Performance of Nephrologists, Nurses, and Nurse Practitioners Related to Comprehensive, Chronic Hyperkalemia Management

Amy Larkin,[1] David R. Anderson,[2] George Boutsalis.[3] *[1]Medscape Education, Nicholasville, KY; [2]Medscape LLC, New York, NY; [3]Medscape, New York, NY.*

Background: Chronic hyperkalemia requires comprehensive management. We sought to determine if online continuing medical education (CME) could improve the clinical performance of nephrologists and nurses/nurse practitioners related to chronic management of hyperkalemia.

Methods: The CME activity was a 15-minute interactive case study with patient-physician vignettes featuring a patient with uncontrolled T2D, HF, and CKD for whom chronic hyperkalemia management was required. A repeated pairs pre-/post-assessment study design was used and chi-square test (P <.05 is considered significant) assessed educational effect for each activity. Cramer's V was used to calculate the effect size (0.06-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activity launched September 21, 2018 and data were collected through November 30, 2018.

Results: In total, 88 nephrologists and 1,504 nurses were included in the study. Upon patient presenting with increasing serum creatinine levels, proteinuria, and mild hyperkalemia, 52% (P <.001; V=.473) of nephrologists and 41% of nurses (P <.0001; V=.364) improved at recommending a low-potassium diet in addition to dose reduction of a potassium-lowering drug One month later, upon recognition of chronic potassium elevation, 36% of nephrologists (P <.001; V=.357) and 29% of nurses (P <.001; V=.214) improved at adding a potassium binding agent Three months post potassium binder initiation, patient returns with normal serum potassium levels, 42% of nephrologists (P <.001; V=.388) and 36% of nurses (P <.001; V=.370) improved at managing continued elevated blood pressure 32% of nephrologists and 44% of nurses reported increased confidence in adding a potassium binding agent in a patients taking multiple drugs that can induce hyperkalemia Continued educational gaps: 36% of nephrologists and 53% of nurses failed to effectively manage the patients' blood pressure 23% of nephrologists and 39% of nurses failed to initiate a potassium binding agent when indicated

Conclusions: This study demonstrates the success of online, CME-accredited, interactive case study with patient-physician vignettes on significantly improving clinical performance of nephrologists and nurses related to chronic management of hyperkalemia. Continued gaps were identified for future educational targets.

Funding: Commercial Support - independent educational grant from AstraZeneca

SA-PO025

Online Quizzes Based on Nephrology Social Media Coverage: A Novel Enduring Educational Material

Divya P. Bajpai,[1] Arvind Conjeevaram,[2] Tejas Desai.[3] *[1]Nephrology, Seth G.S.M.C. & K.E.M.Hospital, MUMBAI, India; [2]The Bangalore Hospital, Bangalore, India; [3]East Carolina University - Brody School of Medicine, Greenville, NC.*

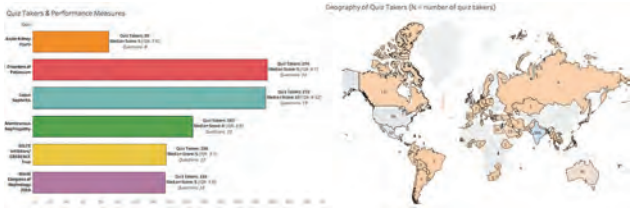
Background: The ACGME defines an **enduring educational material** as one that can be repeatedly utilized for learning purposes. Social media education, however, poses a challenge in creating enduring materials. Learning from tweets is difficult because of a large number of tweets posted rapidly and poor Twitter search engine. A quiz employs active learning which helps develop critical thinking and enhances interest in knowledge acquisition. The ISNeducation team created **online quizzes** to package **scientific tweets** into a readily useable enduring educational material. This is a pilot study to evaluate them as a tool to disseminate knowledge and **improve social media learning.**

Methods: Each monthly quiz is untimed **MCQ based learning activity**, consisting of 10-20 questions. Questions are derived from the **most informative tweets** on a concept covered in a **recent nephrology conference**. Answers, scores, and global ranking are revealed in real-time. Each question also has an explanation with a link to the original supportive evidence-based tweet. Learner details and scores are recorded. The quizzes can be freely shared via a link on Twitter, Facebook, WhatsApp and the top scorers for each quiz are acknowledged at the end of the month.

Results: 6 quizzes were analyzed on the following topics: Glomerular diseases, AKI, Potassium disorders, Advances in membranous nephropathy, SGLT2 inhibitors, and WCN 2019 twitter coverage. **2,237** users visited the quiz page and **1,133** completed the quiz. Maximum participation was seen from Asia (35%) followed by North America (15.5%). The median score was 5 (for 10 questions quiz) and 9.5 (for 19 questions quiz). https://twitter.com/i/moments/1132700081767890944 is the link for a running collection of quizzes URL.

Conclusions: Online quizzes highlight informative evidence-based tweets from which learning can occur at any time and location, fulfilling ACGME criteria as an enduring

educational material. They have the potential for augmenting **active learning** and also to improve the **reach of conferences** globally. With free access and minimum time required they also enhance the interest of medical graduates in the field of nephrology.



Quiz Analytics

SA-PO026

Online Anemia: An Online Educational Approach to the Management of Outpatient Renal Anemia

Georges Nakhoul,[1] Jonathan J. Taliercio,[2] Tushar J. Vachharajani,[3] Remy Daou,[5] Wendy M. Green,[4] Cecile M. Foshee.[6] *[1]Cleveland Clinic Foundation, Cleveland, OH; [2]Glickman Urological and Kidney Institute, Cleveland, OH; [3]Glickman Urological & Nephrology Institute, Cleveland, OH; [4]Cleveland State University, Cleveland, OH; [5]Saint Joseph University, Beirut, Lebanon; [6]Cleveland Clinic, Cleveland Heights, OH.*

Background: Nephrology trainees spend the majority of clinical training in the acute inpatient setting. Unfortunately, the lack of ambulatory experience results in the inexperience of new graduates to manage patients with chronic disease longitudinally. One area of weakness is the management of renal anemia, which is further exacerbated by the mainstream use of anemia protocols. We decided to address this educational gap by creating a comprehensive online module.

Methods: Using the Cleveland Clinic "MyLearning" platform, we constructed an interactive online module that focuses on renal anemia, and we focused particularly on the landmark trials. The module incorporated several tools such as infographics and embedded videos. The module also included problem-based case discussions that gave the opportunity for teacher feedback. Prior to its implementation, the module was piloted by faculty and students. Eight nephrology fellows received a 30-minute orientation course discussing the goals and objectives along with the expectations and assignments. They filled out an anonymous 10- question pre-test to assess their baseline renal anemia knowledge. The time allotted for completion of the module was 1 month. Upon module completion, fellows were required to complete a 10-question post-test and a 4 point Likert-scale questionnaire/feedback survey addressing six parameters: program interface, user engagement, education value, course feedback, interest in dissemination and need for improvement. Six months after module completion, fellows completed the same 10-question post-test in order to assess long-term retention.

Results: All 8 fellows completed all the surveys. Fellows scored an average of 49% on the 10-question pretest vs. an average of 79% on the 10-question post-test. At 6 months, the average post-test score was 65%. The overall impression of the online module was positive with 100% of fellows favoring the modules, finding them useful and asking to duplicate the approach in other topics. Fifty percent of the fellows preferred less content. Twenty-five percent of fellows found that the module could use technical improvement with the interface.

Conclusions: Online modules can be used with success in training programs as an adjunct to traditional education. Our experience shows improvement in both short-term and long-term retention.

SA-PO027

Gender Disparities in Social Media and Medical Education

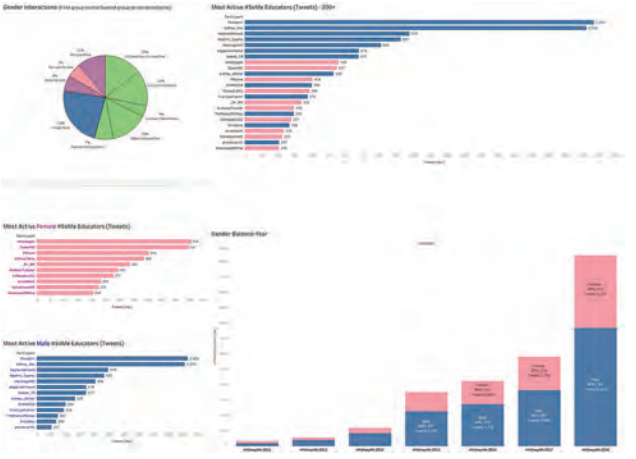
Hector M. Madariaga,[1] Edgar V. Lerma,[2] Tejas Desai.[3] *[1]Good Samaritan Medical Center, Brockton, MA; [2]Associates in Nephrology, SC, Berwyn, IL; [3]NOD Analytics, Charlotte, NC.*

Background: Gender inequality is a pervasive societal issue and medicine is not immune. The American Society of Nephrology (ASN) has prioritized initiatives to promote diversity, including addressing gender equality. In order to understand gender disparities in nephrology social media (#SoMe) education, we report data that measures the magnitude of the imbalance.

Methods: We examined the official #KidneyWk, the social media education platform of the annual ASN Meeting from 2011-13 and 2015-18 using NOD Analytics (@nephondemand). We measured the differences in tweets authored by and the interactions between men and women.

Results: As of 2019, the ASN had 18,041 current members; 11,179 males, 5,386 females, and 1,476 no gender selected. Since 2012, the number of female and male #SoMe educators has been increasing but the proportion of each has remained unchanged since 2015. Additionally, we also found that 64% of the 48,852 tweets included invitations for #SoMe educators to opine and join the online discourse during #KidneyWk; however, only 6% of these invitations were male #SoMe educators inviting a female #SoMe educator to join the conversation.

Conclusions: The number of female #SoMe educators and their tweeting activity are increasing but continues to be under-represented; both are needed prerequisites to restore gender balance in the online medical education community. Unfortunately, there is a gender imbalance and the percentage of invitations that females receive from their male counterparts to join various online discussions, particularly during #KidneyWk remains low. Indeed cross-gender invitations (either M-F and F-M) are low and can promote "educational islands" where knowledge of female perspectives are not adequately represented. Having gender diversity in #SoMe would not only mean a high number of female educators tweeting, but an equal exchange of ideas between females and males.



SA-PO028

KIDNEYcon: An Innovative Conference for Nephrologists and Trainees

Samira S. Farouk,[1] Matthew A. Sparks,[3] Kelly W. Bulloch,[2] Shree G. Sharma,[4] John M. Arthur.[2] *[1]Icahn School of Medicine at Mt. Sinai, New York, NY; [2]University of Arkansas for Medical Sciences, Little Rock, AR; [3]Duke University and Durham VA Medical Centers, Durham, NC; [4]Arkana Laboratories, Little Rock, AR.*

Background: KIDNEYcon is an annual conference geared towards trainees and practicing nephrologists established in 2016 with a goal to fill important educational, career development, and practice gaps in nephrology. KIDNEYcon features unique interactive workshops, hands-on educational experiences, clinical sessions, and mentoring opportunities provide to provide rich opportunities for learning, fostering research careers, networking, and enhance collaboration. In addition, KIDNEYcon provides a venue to foster enthusiasm and interest in nephrology among medical students and residents.

Methods: KIDNEYcon is a 3-day conference held each April in Little Rock, AR. We evaluated the content of interactive workshops, assessed attendee demographics over the last 4 years, and sent an anonymous survey to trainee attendees to evaluate the experience and impact of KIDNEYcon.

Results: Attendance to KIDNEYcon grew from 35 in 2016 to 109 in 2019. In 2019, 38% (42/109) of the attendees were trainees (20% from the Northeast, 7% Midwest, 51% Southeast, 10% Southwest, 12% West). Of the 42 trainees, 59% were fellows (13 programs), 24% residents (9 IM residency programs), and 17% medical students (3 medical schools). 57% of trainee attendees responded to the survey. 100% rated their experience at KIDNEYcon as 4 or 5 out of 5, with 5 being the highest. 92% learned either "a great amount" or "quite a bit." 92% strongly agreed or agreed that KIDNEYcon contributed to their overall knowledge base. 50% reported increased interest in a research career. 88% and 92% strongly agreed or agreed that they would maintain relationships with nephrologists and other trainees, respectively. Topics for the interactive workshops (4 hrs) vary each year, though several high interest workshops have been repeated including the Kidney Biopsy Academy, Pathology Workshop, Acid-Base & Electrolytes workshop.

Conclusions: KIDNEYcon is a unique opportunity for trainees and practicing nephrologist to learn hands-on skills, network with colleagues, while increasing interest in nephrology and research careers. Response from trainees has been overwhelmingly positive. Goals for future conferences are to continue to expand workshop and didactic offerings, including direct solicitation of workshops from the community, and to further develop trainee engagement.

SA-PO029

Effect of Renal Replacement Therapy Options Education Class on Patient Outcomes

Leonid Pravoverov,[1] Sijie Zheng.[2] *[1]Kaiser Permanente, Walnut Creek, CA; [2]The Permanente Medical Group, Oakland, CA.*

Background: Transition from CKD into ESRD is a traumatic and often uncoordinated process. Many patients "crash landing" into hemodialysis with a central venous catheter. Structured CKD care can better prepare patients for transition to ESRD. Yet, it has not been systematically implemented nationally due to fragmented care outside of integrated health care systems, lack of patient awareness or engagement regarding CKD issues. Kaiser Permanente East Bay Nephrology Group implemented patient education program delivered by renal RN's to provide patients and family education on RRT modalities with the goal of providing smoother transition into ESRD.

Methods: KP East Bay implemented a standardized RRT option class for patients with CKD stage 4 and 5. It was highly recommended to be completed when a patient's

eGFR reaches 20ml/min or below. It was taught by a renal nurse. The class last average 1-2 hours. It was attended by a patient and family members. The nurse discussed different type of RRT options, including: conservative management without dialysis (CMWD), kidney transplant, in-center hemodialysis (HD) and home dialysis (PD and HHD).

Results: Since the initiation of new Options Class in 2016, 460 patients have attended it. The average creatinine at the time of referral was 3.58 mg/dl and average eGFR was 18.71 ml/min. After the option class, 43.3% patients chose home therapy: 37.3% chose PD and 5.4% chose HHD. 26.5% chose ICHD, 3% chose CMWD. 31% remained undecided on their care plan after attending option class. As of 2019, 86 (11.7%) patients who attended Options education initiated dialysis. Among them 53.2% on home dialysis (50% with PD; 2.3% with HHD); 47.6% with ICHD, 2.3% received a pre-emptive transplant. 29% expired before dialysis initiation and 59.3% remained dialysis independent.

Conclusions: A structured RRT option class resulted in a smoother transition into RRT with higher percentage of patients chose home modality. Further work needs to be done to improve targeted interventions to guide patients who have difficulties to formulate decision or ESKD Life Plan. Comparison of characteristics of patients who attended the classes versus those who did not, as well as details of outcomes of patients remaining with CKD and those who died before reaching RRT need to be studies to confirm and quantitate benefits of this educational program.

SA-PO030

Nephrology Fellow Performance on a Formative Peritoneal Dialysis Objective Structured Clinical Examination

Christina M. Yuan,[1] Brian C. Y'Barbo,[2] Gregory L. Braden,[6] Alice Ching,[8] Scott D. Cohen,[9] Sarah L. Elfering,[10] Yiming Lit,[11] Varun Malhotra,[5] Sharon E. Maynard,[7] Rajeev Raghavan,[4] Maura A. Watson,[1] Lisa K. Prince.[3] Nephrology Education Research and Development Consortium (NERDC) *[1]Walter Reed National Military Medical Center, Laurel, MD; [2]Brooke Army Medical Center, San Antonio, TX; [3]Colorado Kidney Care, Denver, CO; [4]Baylor College of Medicine, Houston, TX; [5]Nephrology Associates of Tidewater, LTD, Virginia Beach, VA; [6]Kidney Care and Transplant Services of New England, Springfield, MA; [7]Lehigh Valley Health Network, Emmaus, PA; [8]Medical College of Wisconsin, Milwaukee, WI; [9]George Washington University School of Medicine, Washington, DC; [10]University of Minnesota School of Medicine, Minneapolis, MN; [11]Stanford University/PAVA, Palo Alto, CA.*

Background: Less than 10% of prevalent ESRD patients are treated with peritoneal dialysis (PD), and nephrology fellows may not have sufficient PD exposure to be comfortable with the procedure. We previously developed and initially validated a formative objective structured clinical examination (OSCE) assessing management of PD-associated peritonitis (based on the International Society for Peritoneal Dialysis practice guideline). We now report the preliminary results of fellow testing.

Methods: The OSCE test committee set the passing threshold at 16/22 points (Ebel's method), with median relevance essential/important for all questions (content validity index 91%). Validators (16 board-certified practicing nephrologists) had a mean score of 19 (SD 2) points, with 94% passing. Cronbach's alpha was 0.70. Score agreement between investigators was very good (Kappa =0.85). The OSCE is being prospectively administered by 19 U.S. nephrology fellowship programs. Fellows are anonymous, and have 1 hour to take the test (using local institutional order sets at the program director's discretion).

Results: 9 programs have submitted OSCE results. 48 fellows were tested (25 1st year and 23 2nd year). Mean time to take the test was 34 (SD 8) minutes. Mean score was 17 (SD 3), with 71% passing. 19% correctly indicated the 3 diagnostic criteria for peritonitis (vs. 44% of validators); 72% recognized peritonitis-associated ultrafiltration failure (vs. 100% of validators); and 22% correctly prescribed a 21 day course of antibiotics for gram negative peritonitis (vs. 63% of validators). Some programs used the OSCE to introduced a didactic session on PD-associated peritonitis management.

Conclusions: The OSCE is an opportunity for program directors to assess local curriculum effectiveness, and for fellows to ascertain their familiarity with PD-associated peritonitis management practice guidelines. *The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense, or the US Government.*

SA-PO031

A Novel Smartphone-Based Self-Management System for Hemodialysis Patients

Laith Al-Rabadi, Pamela Giahi, Yuanrui Sang, Sherry Liao, Flory Nkoy. Kidney Tracker *University of Utah, Salt Lake, UT.*

Background: Dialysis patients are commonly disengaged from hemodialysis their care. Evidence suggests that the care of patients with advanced CKD and ESRD does not optimize patient engagement. Lack of self-participation in dialysis care may worsen clinical cardiovascular outcomes and warrants the need to educate and engage patients. In particular, patient engagement is essential to achieve optimal fluid balance and avoid excessive fluid intake. Increasing patient active participation in their dialysis care through a digital health application can potentially improve the clinical outcomes and patient satisfaction. Mobile app use among healthcare professional is still limited. Smartphone apps are deemed "useful tools at the point of care and in mobile clinical communication, as well as in remote patient monitoring and self-management of disease." Utilization of digital health application in hemodialysis patients has not been explored yet. There is a lack of readily available and validated mobile apps for the HD population.

Methods: We performed 200 interviews with hemodialysis patients. Dedoose software was used for cording and conducting this qualitative research. Smartphone app (herein referred to as Kidney Tracker) was developed through feedback loops.

Results: The smartphone dialysis application proposed (Kidney Tracker) offers four main functions. The first function of the smartphone dialysis application is the dialysis tracking function. Data from the patient's dialysis treatments will automatically be migrated to the fluid tracking function. The second function of the smartphone dialysis application, the fluid, and activity-tracking page, features intuitive fluid tracking that streamlines the tracking process. The third function of the smartphone dialysis application, the game function, offers awards and challenges that use game-design concepts to keep the patient engaged. The fourth function of the dialysis application is the direct patient to care provider contact function.

Conclusions: This is an innovative project that specifically targets HD patients and resulted in developing a smartphone app for use in this patient population. This digital health technology can be a very helpful tool in the dialysis setting.

SA-PO032

Establishing Inpatient Dialysis Education Program Using an iPad

Syeda B. Ahmad,[2] Huiwen Chen,[2] Filitsa H. Bender,[1] Ranil N. DeSilva.[3] *[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: It is well known that providing chronic kidney disease education to patients will result in better planning for dialysis. However, there are patients who are admitted to hospitals with advanced kidney diease and require dialysis either during hospitalization or shortly after discharge. Many of these patients are started on hemodialysis (HD) rather than home dialysis despite dialysis modalities such as peritoneal dialysis (PD) and home hemodialysis (HHD) offering better quality of life. To address this gap, we established a quality improvement initiative to educate hospitalized patients near dialysis about kidney disease and dialysis modalities. The primary aim is to improve patient understanding of dialysis modalities and chronic kidney disease. Secondary aim is to refine educational material and determine what dialysis modality patients chose in long term and if there is an increase in number of peritoneal dialysis patients.

Methods: Enrollment criteria was patients admitted to UPMC Magee-Women's and Presbyterian-Montefiore hospitals who are advanced CKD (stage 4/5) and planning to start dialysis on their admission or within several weeks of discharge as identified by nephrologist. The dialysis education was provided on iPad by a physician. Patient response to dialysis education was recorded using a survey.

Results: The project was initiated in January 2019 with enrollment of 10 patients. The average age was 57.5 years and 70% female with 70% of patients having previously seen a nephrologist. The average time required for education was 45 minutes. Patient reported post education understanding of dialysis and kidney disease as 4.6 (scale of 1 to 5). Post education, 50% of patients were leaning towards home dialysis.

Conclusions: Our preliminary results show that providing education increases awareness of home dialysis modalities with 50% choosing to do so. Interestingly, majority of our patients had previously seen a nephrologist but had required re-education highlighting that CKD patients require significant re-enforcement of their disease process. The patient response is overall positive (rating 4.6 out of 5). Results of a follow up survey to patients who did and did not receive education are pending and will help in determining the secondary aim. For furture improvement, we aim to incorporate tele-health nurse and patient advocate as educators.

SA-PO033

Effect of an Audiovisual Educational Program on Nutritional Knowledge and Adherence to Dietary Treatment in CKD Patients Undergoing Hemodialysis

Ximena Atilano carsi,[1] Estefanía Veles mariscal,[1] Ricardo Velázquez garcía,[2] Celene V. Arce santander,[3] Paola V. Miranda,[1] Angeles Espinosa-Cuevas,[1] Ricardo Correa-Rotter.[1] *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de México, Mexico; [2]Universidad Mexiquense del Bicentenario, Estado de Mexico, Mexico; [3]Lapi Unidad de Hemodiálisis, Ciudad de México, Mexico.*

Background: Multiple complications of advanced chronic kidney disease require specialized treatment and nutritional education. In Mexico, there are no formal education programs in hemodialysis (HD) units that allow improvement in the patient's self-care. The aim of this study was to assess the effect of an audiovisual nutritional education program on the nutriological knowledge and adherence to dietary treatment in patients of two different hemodialysis units

Methods: Three videos, with dietary phosphorus, potassium and sodium topics, were created and projected during the HD sessions of all shifts during 9 weeks. Nutritional knowledge was measured with a questionnaire and adherence to diet was evaluated with a 3-day food record, before and after the educational intervention. Level of knowledge was classified according to the percentage of correct answers, being bad with <60%, regular between 60 and 79.9% and good > 80%

Results: One hundred and thirty eight patients from both units were included. Average age was 38.9 ± 14.3 years. Nutritional knowledge changed significantly after the intervention: from 30.4% to 6.6% for the bad level, from 57.2% to 30.4% for the regular level, while the level of adequate knowledge increased from 12.4% to 63%. Increase of knowledge was greater in potassium topic followed by phosphorus. After the intervention, the percentage of correct answers for sodium, potassium and phosphorus knowledge

were significantly higher; 75.5 ± 17 vs 87.6 ± 9.0 (p <0.001), 57.3 ± 20.4 vs 78.3 ± 12.8 (p <0.001) and 64.4 ± 18.3 vs 81.9 ± 15.7 (p <0.001) respectively. A significant correlation was found between educational level, dialysis vintage and nutritional knowledge; r = 0.41, p <0.05 and r = 0.43, p <0.05, respectively. Regardless of the increase in nutritional knowledge, no improvement in adherence to the dietary plan was found

Conclusions: The audiovisual educational program had a positive impact on the nutritional knowledge of the patients, however nutritional education alone did not improve adherence to diet

SA-PO034

Respectful Engagement of Indigenous Peoples in a Pan-Canadian Kidney Research Network

Helen Robinson-Settee, Craig Settee, Kevin Settee, Catherine Turner, Cathy Woods. Can-SOLVE CKD Network *Can-SOLVE CKD Network, Vancouver, BC, Canada*.

Background: Kidney disease has a disproportionate impact on the health of Indigenous communities in Canada. A national strategy to improve kidney health must include meaningful, culturally appropriate engagement with Indigenous peoples. Can-SOLVE CKD Network is a pan-Canadian patient-oriented kidney research initiative that is working to improve the health of all Canadians and bring Indigenous ways of knowing into health research.

Methods: As part of the Can-SOLVE CKD Network, Indigenous patients, caregivers, researchers, and community leaders created an Indigenous Peoples' Engagement and Research Council (IPERC). IPERC supports collaboration grounded in traditional values and partnerships with Indigenous peoples and communities. IPERC guides Can-SOLVE CKD research projects in respectful engagement of Indigenous communities. The network has created a training pathway, *Wabishki Bizhiko Skaanj* ("White Horse" in Anishinaabe), helping researchers and patient partners build respectful partnerships with Indigenous peoples in health research. Participants are encouraged to look, listen, learn, and lead their way along the pathway by examining racial identities, privileges, and biases, as well as participating in interactive learning exercises, facilitated online modules and webinars. The *Wabishki Bizhiko Skaanj* learning pathway includes a focus on Indigenous Elders in research. This training aims to create a culturally safe space for researchers, patients, and Elders to come together to gain understanding of a holistic context for scientific observations.

Results: Can-SOLVE CKD and IPERC has created a culturally safe space for Indigenous individuals to participate in all aspects of patient-oriented kidney research. *Wabishki Bizhiko Skaanj* represents a novel learning platform for Indigenous cultural safety in Canadian health research. By enhancing knowledge, self-awareness and strengthening cultural competency, this learning pathway is enabling all partners in health research to close the gaps in kidney health outcomes between Indigenous and non-Indigenous communities.

Conclusions: The Can-SOLVE CKD Network offers a model for respectful engagement of Indigenous communities in health research. By adopting Indigenous ways and fostering cultural competency, kidney health outcomes and overall wellness for and with Indigenous peoples across Canada will be enhanced.

SA-PO035

Patient and Caregiver Views on the Definitions and Impact of Terms Used to Describe Kidney Health

Allison Tong,[1] Andrew S. Levey,[2] Kai-Uwe Eckardt,[3] Wolfgang C. Winkelmayer.[4] KDIGO Nomenclature Initiative *[1]The University of Sydney, Seven Hills, NSW, Australia; [2]Tufts Medical Center, Boston, MA; [3]Charité – Universitätsmedizin Berlin, Berlin, Germany; [4]Baylor College of Medicine, Houston, TX*.

Background: The terminology for kidney health is inconsistent, inaccessible, and may be conceptualized differently between patients and health professionals. These problems can impair the quality of communication, care and patient outcomes. As part of the Kidney Disease: Improving Global Outcomes (KDIGO) Nomenclature Initiative, we aimed to describe patient perspectives on the definitions and impact of terms for kidney health.

Methods: 54 patients and 13 caregivers from the United States, United Kingdom and Australia participated in 10 focus groups to discuss terms and concepts used for kidney health (e.g. kidney, renal, CKD, end-stage kidney disease, kidney failure, and descriptors and measures for kidney function i.e. CKD stages). Transcripts were analyzed thematically.

Results: We identified four themes: ***frustrated by ambiguity*** (with subthemes of: confused by medicalized language, lacking relevance to personal circumstances, baffled by imprecision in meaning, uncertainty of what can be controlled, opposed to obsolete terms); ***making sense of the prognostic enigma*** (conceptualizing level of kidney function, characterizing function based on symptoms and life impact, predicting progression and need for intervention); ***provoking and exacerbating undue trauma*** (fear of the unknown, denoting impending death, losing hope in having no treatment options, premature labeling and assumptions, judgment and failure of personhood); and ***mobilizing self-management*** (needing to accept the harsh reality, prompting and motivating behavior change, learning medical terms for self-advocacy). (Fig 1)

Conclusions: The obscurity and imprecision of terms in CKD can be unduly distressing and traumatic for patients. Consistent and meaningful patient-centered terminology may improve patient autonomy, satisfaction and outcomes.

Theme	Selections quotations
Frustrated by ambiguity	
Confused by medicalized language	*What is renal? Just say kidney and I'll understand that more. What's renal failure?* *I used to get confused about kidney failure and my nephrologist would say "you're not in kidney failure yet, you've got kidney disease." He was using it as the end point. I was thinking my kidneys are failing.*
Lacking relevance to personal circumstances	*Pre-kidney; replacement, it is not luxury that everybody has.* *Even when they're putting the GFR out there for you to read and understand they have in parenthesis that if you're African American it's a different number, but they didn't explain why it's a different number.*
Baffled by imprecision in meaning	*A disease is something you've caught or something that you have. I don't think that reflux is a disease. It's an abnormality.* *I never thought of myself as having end-stage renal failure because I was on renal replacement therapy.* *I feel end stage refers to palliative care. My husband was on dialysis for 20 years. That's hardly end stage.*
Uncertainty of what can be controlled	*The language doesn't give a sense, that's used, doesn't give a sense of control or that it's controllable.*
Opposed to obsolete terms	*The more technology develops, the less appropriate that word end becomes. For the majority of people there are life sustaining treatments: dialysis and transplant.*
Making sense of the prognostic enigma	
Conceptualizing level of kidney function	*The percentage, this is where I'm confused. If it has to be over an eGFR of 60 do you consider 60 100%? I mean what percentage is the hundred percent because it could up to 115?* *But when they say now you're at stage three, now you're at stage four kidney disease, you think, what is that? What is stage three, what is stage four?*
Characterizing function based on symptoms and life impact	*I was in stage five and I still didn't have any symptoms.* *My kids would say, "kidney disease means you're sick, tired, or vomiting." To them kidney disease impacts how I was rather than anything to do with what treatment or what was required to keep me well.*
Predicting progression and need for intervention	*Stage1 It's good in terms of qualifying where you're at in that. Is it one of those things that you put a time onto though? How long are you going to be stage one for, how long before stage two?* *Stage one is your kidneys are not working, full stop. Stage two is getting bad. stage three is getting to the fistula stage, stage four, dialysis, stage five is not working.*
Provoking and exacerbating undue trauma	
Fear of the unknown	*It was quite upsetting the first time it was mentioned. It's just basically, denial, what does it actually mean?* *It scared me because no one was telling me anything. All that you hear, the whispering going on about the GFR. I was lying there. I felt like a cattle being led into slaughter.*
Denoting impending death	*When they told me end-stage I thought I was dying. I accepted the fact that it was just a matter of weeks.* *The problem is that end stage in other areas is referred to as those last few months of life, you're at the end. Whereas with this it's really saying this is the end of my kidney. It could be the start of a transplant or dialysis.* *You're on the cliff, about to fall off. It was quite traumatic and scary.* *You're watching the creatinine go up and the kidney function come down and you're watching this guillotine, but terms don't help. This wicked term, end-stage.*
Losing hope in having no treatment options	*Once they say 'end-stage,' it's kind of like, why not let nature run its course?* *Chronic kidney disease. It's very terminal and final and nothing you can do about it.*
Premature labeling and assumptions	*I would rather you educate me as to what stage I'm at then using a word that doesn't apply to me such as pre-dialysis. Dialysis doesn't apply to me now, why do I need to even use the word?* *Pre-dialysis, that just alludes to you will be doing that, because some people don't ever have to have dialysis.*
Judgment and failure of personhood	*The connotation of end-stage, isn't helpful. Your kidneys fail and so will you. By association, your physical existence is failing. Separate it from the person.* *Other people said to me 'you've got kidney failure' and it was like I had done something wrong.* *Pre-dialysis is derogatory: if I'm in Stage 3 I don't want someone telling me I'm pre dialysis because I could change my lifestyle.*
Mobilizing self-management	
Needing to accept the harsh reality	*The words are kind of damaging and painful to the patient, but they're a necessary damage, because you have to understand it. End-stage is a really harsh term, but I feel it's a good term, because you have to drill it home that that really is the last stage of whatever you're going through. If you'd been told that you're a stage V, I would have been like, oh, it's just stage V, I can still reverse it.*
Prompting and motivating behavior change	*When people say you're prediabetic, okay that means that you're headed for diabetes, but if you make these changes then you, you can either not get the disease or control the effects of the disease on you? If you're saying pre dialysis in my mind that says I'm about to go on dialysis. I'm going to wonder is there something I can do to keep me from going on dialysis.*
Learning medical terms for self-advocacy	*Understanding the big words; although it can be intimidating, this is your life.* *That's the kind of things that you need to know. Every profession wants to use their language, you can't stop it. But we need to know what it is.*

SA-PO036

Computational Fluid Dynamics Modeling (CFD) of Wall Strain in a Murine Glomerular Capillary Segment

William H. Fissell,[1] John B. Davenport,[3] Mark S. Goodin,[2] Rachel Lennon.[3] *[1]Vanderbilt University, Nashville, TN; [2]SimuTech Group, Hudson, OH; [3]University of Manchester, Manchester, United Kingdom*.

Background: Mechanical forces such as pressure and stress in the glomerular capillary tuft have been proposed to mediate hyperfiltration and podocyte injury and detachment, leading to irreversible glomerular disease. However, the actual forces imposed by blood flow in the tuft are incompletely defined. Simple tube models poorly capture the complex anatomy of the tuft. We undertook to model fluid flow through an actual capillary tuft to understand the feasibility of applying CFD to glomerukar physiology.

Methods: Mouse kidneys were cut into 1 mm cubes and fixed wiht glutaraldehyde and prepared for electron microscopy with osmium. Tissue was mounted onto an aluminim cryo pin using cyanoacrylate and all block surfaces trimmed. A gold coating was applied to the block to create a conductive surface. The block was placed in the Quanta 250 FEG/Gatan 3view system and a 41 x 41 field of view was imaged at an approximate pixel size of 10 nm and section thickness of 50 nm. MIMICS (Materialise, Ann Arbor, MI) image reconstruction software was used to create a 3D surface representation of the capillary segment. The flow through the capillary segment was then modeled using ANSYS-Fluent (ANSYS, Canonsburg, PA) CFD software. Steady-state, laminar flow conditions were modeled and a pressure differential across the section was applied to provide the desired velocities within the capillary lumen. Estimates of desired fluid velocity in the capillary were drawn from 2-photon intravital microscopy experiments.

Results: The CFD solution predicted values of fluid shear stress, fluid streamlines, and wall strain along the glomerular capillary segment.

Conclusions: End-to-end estimation of physical forces at the glomerular capillary wall is possible by computational modling of flow through structures imaged via serial block section EM. Further work is needed to capture unsteady flow and the influence of blood cells on local wall strain.

Prolonged In Vivo Perfusion of a Re-Endothelialized Human-Scale Tissue Engineered Kidney Graft

Joseph S. Uzarski,[1] Emily Russell,[1] Emily C. Beck,[1] Matthew L. Holzner,[2] Vikram Wadhera,[2] Ron Shapiro,[2] Dylan Adamson,[2] Sander Florman,[3] Dominique Davidow,[1] Jeff Ross.[1] *[1]Miromatrix Medical, Inc., Eden Prairie, MN; [2]Recanati/Miller Transplantation Institute, New York, NY; [3]Mount Sinai Medical Center, New York, NY.*

Background: Advances are desperately needed to increase the supply of transplantable kidneys for the 100,000 patients on the waiting list. Whole organ engineering is one approach that holds tremendous promise and to date, the most successful approach utilizes perfusion decellularization to provide the ideal kidney extracellular matrix scaffold that maintains the organ's native vasculature and architecture, and allows recellularization with human cells. A critical component and the focus of the current study is to demonstrate the ability to functionally revascularize clinically relevant whole kidney matrix with human endothelial cells and provide sustained in vivo perfusion following orthotopic implantation.

Methods: Kidneys recovered from adult pigs were decellularized via detergent perfusion through the vasculature. The porcine matrix was seeded with human umbilical vein endothelial cells (HUVECs) and cultured using a custom perfusion recellularization bioreactor until sufficient cellular coverage of the vasculature was obtained. Functional testing of the renal vascular bed was performed using an ex vivo porcine blood flow model. Re-endothelialized kidney grafts were transplanted orthotopically in a pig model and evaluated with angiography at days 3, 7, 10, and 14 days before explantation.

Results: A minimum glucose consumption rate of 20 mg/hr was determined to represent sufficient endothelialization to sustain continuous blood flow (>100 mL/min) ex vivo, and was predictive of early patency in orthotopic transplants. At 7 days after transplantation in pigs, 83.3% (n=5/6 pigs) of grafts in surviving animals maintained renal perfusion during follow-up angiography. One kidney graft remained patent through post-operative day 14.

Conclusions: As 14 days is the longest reported continuous perfusion of a revascularized kidney graft to date, these results lay the foundation for the long-term success of human-scale recellularized kidney grafts and move the field closer to increasing the supply of transplantable kidneys.

SA-PO038

Tunable Stiffness Polyacrylamide Hydrogels with Functionalized Matrigel for Renal Tissue Culture

William H. Fissell,[1] Kuniko Hunter,[1] Rachel C. Evans,[3] Harold D. Love,[3] Shuvo Roy.[2] *[1]Vanderbilt University, Nashville, TN; [2]UCSF, San Francisco, CA; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: Tunable stiffness polyacrylamide (PA) based hydrogels are commonly used for mechanotransduction studies. PA gels must be functionalized with protein for cell attachment. This is commonly accomplished using sulfo-SANPAH or acrylic acid NHS ester to bind protein to the gel surface. However, these methods do not produce reliably uniform surface protein concentrations. In order to produce PA gels with highly reproducible surfaces, we modified methods used for producing methacylated gelatin (GelMA), to produce methacrylated Matrigel. The "MatrigelMA" can be added into the polymerization mix prior to casting gels, where it is covalently linked to the gel network.

Methods: 5 ml of Matrigel (10 mg/ml) with phenol red, was mixed with 5 ml of ice cold 50mM HEPES pH 8.5 while stirring at 4° C. 25 ul of methacrylic anhydride was added dropwise. 1N Sodium hydroxide was added as needed to maintain an alkaline pH. After 30 minutes, this was repeated with an additional 25 ul of methacrylic anhydride. The reaction was continued overnight, then the mix was dialyzed against sterile deionized water for 5 days at 4° C, with daily changes of water. The resulting solution was aliquoted and stored at -20° C. MatrigelMA was added to PA mixes designed to produce gels with expected stiffnesses of 4.5 kPa or 40 kPa. The elastic modulus was measured using an Electroforce 3100 mechanical analyzer.

Results: Gel stiffnesses were not significantly altered by the addition of up to 100 ug/ml of MatrigelMA. Immunohistochemical staining for laminin was highly uniform wihtin and between gels. RPTEC/TERT1 cells were found to attach exceptionally well when seeded on both soft and stiff gels containing 100 ug/ml MatrigelMA. However, the cells tended to become round and detach from the soft gels after 6-8 days in culture, but persisted for several weeks on stiffer gels.

Conclusions: Extracellular basement membrane (Matrigel) was functionalized with methacrylate groups to facilitate crosslinking to polyacrylamide. The addition of 100 ug/ml to PA gels resulted in surfaces with the expected stiffnesses that promoted excellent attachment of RPTEC/TERT1 cells. However, cells tend to detach from the softer gels. We are continuing to determine if this results from degradation of matrix or if this is due to a cellular response to soft matrices.

SA-PO039

A High-Throughput Oxygen Biosensing Platform for a Microfluidic In Vitro Kidney Models

Samuel H. Kann,[1,2] Hesham Azizgolshani,[2] Jonathan Coppeta,[2] Xin Zhang,[1] Else M. Vedula,[2] Joseph L. Charest.[2] *[1]Boston University, Boston, MA; [2]Draper Laboratory, Cambridge, MA.*

Background: Oxygen concentration and dynamics directly influence renal cell function *in vivo.* For example, low oxygen tension plays a significant role in both acute and chronic kidney disease. In addition, decreased cellular oxygen consumption in the kidney has been linked to mitochondrial and metabolic dysfunction. Therefore, monitoring oxygen levels within *in vitro* kidney models will enable physiologically accurate oxygen conditions for the models and allow assessment of metabolic function for normal tissue or metabolic changes due to toxic insults, disease states, or therapy administration. Current microfluidic *in vitro* kidney models control flow to generate tissue with kidney-specific functionality, however, such systems lack high-throughput oxygen sensing capabilities.

Methods: We integrated optical luminescence based oxygen sensors into a high-throughput microfluidic *in vitro* kidney model platform (PREDICT-96), previously developed at Draper, for real-time and non-destructive monitoring of dissolved oxygen in the tissue microenvironment. PREDICT-96 supports renal co-cultures under flow in a 96 tissue replicate device. The oxygen sensor probes, deposited in each microfluidic channel, are excited by red-light transmitted via a fiber optic cable resulting in near infrared emission with an oxygen dependent phase-shift. The O_2 measurement system was adapted to fit a standard microscope stage. High-throughput readings are accomplished by programming the stage to align the optic fiber with each sensor probe and to cycle through all 96 devices.

Results: Oxygen consumption rates for co-cultured human renal proximal tubule epithelial and human microvascular endothelial cells under flow and static conditions were quantified. A COMSOL-based computational model indicates the ability to regulate oxygen concentration via controlling flow of the PREDICT-96 pumps. In this way, oxygen levels will be characterized for varying *in vitro* model parameters, resulting in both physiologically accurate renal co-culture conditions of normal tissue and hypoxic or ischemic injury tissue.

Conclusions: The PREDICT-96 oxygen biosensing platform will enhance *in vitro* renal tissue function and provide a high-throughput respirometric platform for studying renal metabolic dynamics in response to nephrotoxic drugs or disease progression.

SA-PO040

Screening of Drugs for Nephrotoxicity Using a Microfluidic Proximal Tubule on-a-Chip

Leslie Donoghue, Palaniappan Sethu. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Off target effects of pharmaceutical drugs account for approximately 20% of all patients diagnosed with acute renal failure. To avoid such scenarios and prevent drugs that have nephrotoxic effects from advancing past pre-clinical testing to late-stage clinical trials, it may be necessary to evaluate drug induced nephrotoxicity early during the drug discovery cycle to ensure safety and minimize costs associated with drug failure in late-stage clinical trials.

Methods: We engineered a scaffold that enables co-culture of human proximal tubule epithelial cells (RPTEC) with renal microvascular endothelial cells (MVEC) on either side of a porous polycarbonate membrane which enables cell-cell and soluble factor communication and facilitate reabsorption. The surface was coated with Collagen IV for cell attachment and approximately $1x10^6$ cells of each RPTECs and MVECs were seeded on each side of the membrane. The device was then integrated into a microfluidic flow loop assembly to match physiological and biomechanical conditions associated with tubular flow and resorption to accurately recreate the proximal tubule.

Results: We evaluated the cells integrated within a flow loop to determine the effects of fluid shear associated with tubular flow. Our results indicate that the cells can be grown to confluence and can be maintained in culture under fluid flow at physiological levels of shear (approximately 0.1 dynes/cm^2). We used immunofluorescence to determine confluency using phalloidin for actin skeleton, LIVE/DEAD® for cell viability, and occuldin for the establishment of barrier function. These stains provided insight of cell-cell tight junction formation, monolayer integrity, and paracellular permeability in polarized and transporting RPTECs.

Conclusions: In this project, we were able to recreate the architecture of the proximal tubule using the bilayer scaffold within the microfluidic flow loop to reproduce the fluid flow associated with both tubular flow and resorption ensuring a physiologically accurate model of the tubule. This model was evaluated for cell viability, resorption and establishment of barrier function to further validate the physiological function. Finally, we expect to be able to reproduce effects of drugs known to have low, intermediate and high levels of toxicity using our model and will confirm that this model can be used for pre-clinical evaluation of new drugs.

Culturing of Murine Podocytes via a 3D Suspension Culture System Using the Microcarrier

Chih-Chuan Yu,[2] Daw-yang Hwang,[1,3] Jer-Ming Chang.[1] *[1]Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung, Taiwan; [2]Kaohsiung Medical University, Kaohsiung, Taiwan; [3]National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan.*

Background: Cell culture in two dimensions has been well established in the worldwide for the past decades. However, the culture of cells in two dimensions is unable to representative of real cell environments, lack of predictively to anatomy or physiology *in vivo*. Creating a third dimension for cell culture is clearly a better way of representing physiological relevant then 2D culture.

Methods: Murine poodcytes were determined that stirred suspension bioreactors utilizing Cytodex-3 microcarrier beads represent a viable platform for the differentiation of podocytes. 1 gram microcarrier beads were loaded, an inoculation ratio of 2 x 10^7 cells per 1 gram beads, and discontinuous agitation in a medium with 10% serum resulted in high cell attachment efficiencies.

Results: At the end of incubation, the expression levels of nephrin and synaptopodin were examined after various microcarriers beads culture time periods. Compared to static tissue culture dishes, a bioreactor-based bioprocess requires fewer handling steps, lower operating cost of culture consumable, less differentiation time needed when compared to 2D culture.

Conclusions: stirred suspension bioreactors incorporating microcarrier technology represent a viable and more efficient platform than tissue culture flasks for the generation of differentiated podocytes in culture.

Protocol to Make Renal Tubuloids from Human Kidneys

Yutaro Mori,[1] Takaharu Ichimura,[1] Ankit B. Patel,[1] Andrew M. Siedlecki,[1] Joseph V. Bonventre.[1,2] *[1]Division of Renal Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Division of Engineering in Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Kidney organoids derived from human induced pluripotent stem (hiPS) cells can be used to simulate a response to drugs in human kidneys. We have developed an alternative way to make more homogeneous epithelial-like structures from kidney tissue derived from multiple patients in a short period of time.

Methods: Human primary epithelial cell cultures were obtained from the non-tumor kidney tissue removed from patients with renal cell carcinoma. Human renal cortex was diced and then digested with collagenase. Tubules were seeded on matrigel-coated plates with serum-free media containing epidermal growth factor. After passage, primary cells and immortalized LLC-PK1 cells, for comparison, were cultured on ultra-low attachment plates for several days. Then cells were transferred into media containing matrigel, hepatocyte growth factor, fibroblast growth factor-2 and 5% fetal bovine serum.

Results: Primary human renal tubular epithelial cells (hRTECs) tubuloids were generated from dissected patients' kidneys using epidermal growth factor, serum-free media and matrigel. We have generated a library of hRTECs derived from 15 patients. hRTECs showed phenotypes reflecting age and renal function of each original patient, especially in growth rate and in γH2AX expression, a marker for DNA damage response. We also generated tubuloids using a 3D culture technique both with hRTECs and with LLC-PK1 cells. Tubuloids had polarized expression of cell surface markers, LTL, KIM-1 (apical) and Na-K-ATPase (basolateral). The tubuloids endocytosed labeled oxidized LDL, which is observed in 2D KIM-1-expressing epithelial cell culture. It took only a week to establish hRTECs from patient kidneys and four weeks to form tubuloids from hRTECs.

Conclusions: We succeeded in making renal tubuloids using hRTECs derived from multiple patients. This strategy is potentially an excellent way to simulate pathological conditions and response of epithelial cells to toxins and therapeutic agents in a personalized fashion.

SA-PO043

Activation of AMPK and Inhibition of TGFß Stimulate In Vitro Transport in Human Renal Epithelial Cells

William H. Fissell,[2] Shuvo Roy,[3] Raymond C. Harris,[4] Roy Zent,[6] Matthew H. Wilson,[1] Rachel C. Evans,[4] Harold D. Love.[5] *[1]Vanderbilt University, Nashville, TN; [2]Medicine, Vanderbilt University Medical Center, Nashville, TN; [3]UCSF, San Francisco, CA; [4]Vanderbilt University Medical Center, Nashville, TN; [5]Vanderbilt Univ Med Ctr, Nashville, TN; [6]Vanderbilt Medical Center, Nashville, TN.*

Background: Qualitative and quantitative fidelity of a cultured cell to its *in vivo* counterpart is critical to a wide variety of organs-on-a-chip applications including drug discovery, physiology-based pharmacokinetics, toxicity screens, as well as therapeutic applications for *ex vivo* or implanted engineered organs. Investigators have shown several differentiated functions of renal tubule cells *in vitro* including Vitamin D hydroxylation, ammoniagenesis, and specific drug uptake and excretion, but the tubule cells' primary role in the kidney, electrolyte and water transport, has been elusive.

Methods: Primary human renal tubule epithelial cells (RPTEC) harvested from transplant discards were seeded at passage 1-3 onto Costar permeable supports and cultured at 37 on an orbital shaker. 3 weeks post-confluence a TGF-b inhibitor, SB431542, and metformin were added to hormonally-defined media. Apicobasal transport was measured by weighing apical volumes before and after culture, and by measuring the change in apical inulin concentration.

Results: RPTEC in hormonally defined media showed negligible transport (14 μL/cm^2/day), but addition of SB431542 increased transport 5.2-fold; addition of metformin increased transport 5.6-fold; addition of both increased transport 10-fold. Addition of 10nM ouabain reduced transport by about 45% in all groups. Inulin leak rate did not increase.

Conclusions: Using simple modifications to cell culture protocols, we were able to attain inhibitable apicobasal transport, a key attribute of differentiated RPTEC.

Whole-Slide Podocyte Quantification in Renal Tissue via p57 Immunohistochemistry

Briana A. Santo,[2] Avi Z. Rosenberg,[1] Parnaz Daneshpajouhnejad,[1] Pinaki Sarder.[3] *[1]Johns Hopkins University, Baltimore, MD; [2]University at Buffalo, Buffalo, NY; [3]SUNY Buffalo, Buffalo, NY.*

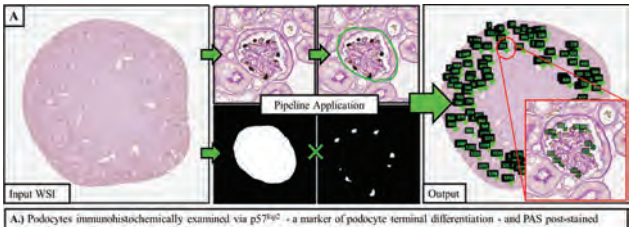
Background: Podocyte injury and podocytopathy drive the progression of Diabetic Nephropathy (DN). Histologic examination of podocytes in disease sections is challenging due to the lack of podocyte specific markers, as well as the limited resolution of podocytes, from all glomerular cells, in traditional stains. Based on our unique podocyte staining protocol, we have developed a whole slide podocyte computational pipeline.

Methods: Murine kidney sections (n = 66) were IHC stained for p57^{kip2}, and PAS post-stained. Whole slide images (WSIs) were acquired, and a neural network segmented glomeruli. WSIs entered our MATLAB pipeline, which applies color deconvolution and morphological processing to segment and quantify podocytes (Fig A). We derived 28 features from segmented podocytes and glomeruli. Pathologist estimated podocyte count per glomerulus was compared with computational results for pipeline evaluation.

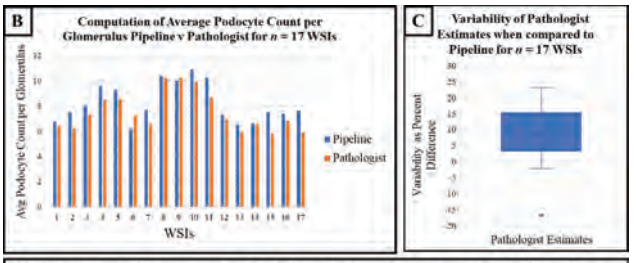
Results: For a subset of WSIs, pathologist and pipeline counts were comparable (Fig B). In practice, pathologist estimates are based on small, random samples of glomeruli from WSIs. Our computational pipeline analyzes all glomeruli, thus producing more accurate results. Pathologist assessments were found to be highly variable with estimates ranging ±23% (Fig C). Our pipeline averages 0.04 seconds per glomerulus, while the pathologist averages 36. Therefore, our computational approach achieves higher precision at a conservative estimate of 900x faster rate than a pathologist.

Conclusions: Our unique staining protocol and pipeline enable rapid quantification of podocyte populations in renal tissue specimens, which will expedite disease-specific evaluation of podocytes, and inform on the contribution of podocyte structural and functional integrity to disease progression.

Funding: NIDDK Support



A.) Podocytes immunohistochemically examined via p57^{kip2} - a marker of podocyte terminal differentiation - and PAS post-stained without hematoxylin counterstain. Pipeline output includes podocyte and glomerular segmentation, as well as 28 derived features. Podocyte quantification viewed here in Aperio Imagescope.



B.) Comparing pipeline computed and pathologist estimated podocyte count per glomerulus on WSI basis for $n = 17$ WSIs. **C.)** Variability of pathologist's estimates when compared to pipeline results, expressed as percent difference. When compared to pipeline results, pathologist assessments were highly variable. . The pathologist overestimated up to 23%, depicted as positive percent difference, and underestimated down to 18%, depicted as negative percent difference.

Machine Learning and Glomerular Remodeling

Anthony Pellicano, Itzhak D. Goldberg, Prakash Narayan. *Angion Biomedica Corp., Uniondale, NY.*

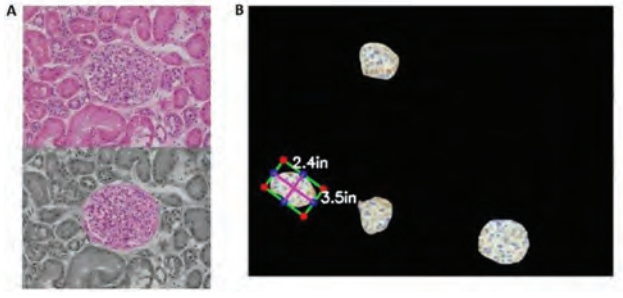
Background: Glomerular hypertrophy is an early biomarker of ongoing renal disease and informs glomerulosclerosis and proteinuria. Using machine learning we trained a computer to first identify glomeruli and then measure glomerular dimensions.

Methods: The training set comprised ~100 images (varying magnification) of hematoxylin-eosin (H-E) or periodic acid Schiff (PAS)-stained kidney tissue sourced from published literature. An open-source git-hub implementation of the mask region-convolutional neural network was used to generate a model and Keras HDF5 data used to identify, count, and measure areas of glomeruli present in the renal tissue on a Raspberry Pi 3 server. The test set comprised images (40X and 10X, n=16) of stained kidney tissue from rats sacrificed 14 days after puromycin aminonucleoside (167 mg/kg, intraperitoneal, n=3) administration, and a sham cohort of animals (n=3). Kidney sections comprising the test set had been stained with H-E or hematoxylin alone.

Results: The Raspberry Pi 3 machine was able to correctly identify glomeruli (A) while excluding non-glomerular structures in all test cases. Having correctly identified glomeruli, the machine was able to measure (B) glomerular area using a precalibrated tool.

Conclusions: Machine learning has enabled both recognition of glomeruli within renal sections and measurement of their dimensions, reducing time and labor while eliminating operator bias. This technology can be used in images from renal biopsies to diagnose ongoing glomerular kidney disease.

Funding: Private Foundation Support



A glomerulus (A) amidist in a renal section was identified by the machine, greying out the surrounding nephrons. The machine was able to isolate several glomeruli and start quantifying their area (B).

SA-PO046

Unsupervised Modeling of Glomeruli for Diabetic Nephropathy Staging in Renal Biopsies

Brendon Lutnick,[1] Brandon Ginley,[1] Kuang-Yu Jen,[2] Sanjay Jain,[3] Pinaki Sarder.[1] *[1]SUNY Buffalo, Buffalo, NY; [2]University of California, Davis, Sacramento, CA; [3]Washington University School of Medicine, St. Louis, MO.*

Background: As biological science pushes for computational analysis, the success of deep learning has obliged its adoption. However, biological datasets are different from the well-annotated standardized data used to develop such algorithms. Due to availability of unlabeled biological data, we have tested a variational autoencoder (VAE) for unsupervised modeling of glomeruli images (without labels). We show that encoded features allow interpolation between image states and are predictive of biopsy-level Tervaert classing of diabetic nephropathy (DN).

Methods: A VAE was trained using 87K 256x256 PAS and H&E stained glomeruli images, segmented from whole-slide kidney biopsies. The VAE encodes the images into a code of 200 numbers able to be decoded back to the input image. This technique automatically clusters similar images together in the code space. To show the relevance of our trained VAE, we model Tervaert DN class for expert staged human biopsies using the image codes as sequential input for a recurrent neural network (RNN). Namely a network model which predicts DN class from sequencial reading of glomeruli codes, similar to how experts read biopsies.

Results: While our decoded (simulated) glomeruli images lack detail, exploration of the image code space shows smooth interpolation between holdout images, verifying the continuity of the encoded data distribution. Figure 1 shows simulated samples between class I and IV DN glomeruli generated by our VAE. Despite having only 54 staged biopsies, an RNN model using our image codes for biopsy level DN class prediction predicts <1 class off with a mean square error of 0.971 and linear weighted Cohen's kappa of 0.402 with 10-fold cross validation.

Conclusions: Further refinement of the VAE architecture is needed to produce sharp images, but current image codes are predictive of Tervaert DN class using supervised regression modeling. In the future, this promises powerful ways to incorporate unlabeled biological data to augment machine learning training sets of medical images.

Funding: NIDDK Support

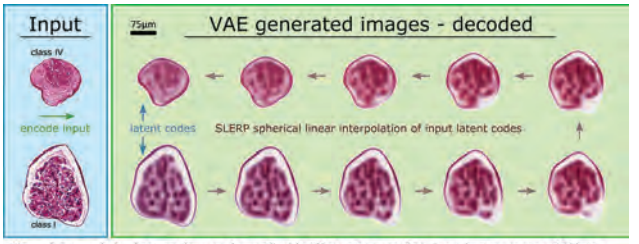


Figure 1. Interpolation between human glomeruli with different Tervaert class. Input images are encoded into a code of 200 numbers which is representative of the input image. These codes are interpolated and decoded back into intermediate images. The VAE network was trained using the input images alone - without data labels.

SA-PO047

Analyzing the Influence of Glomerulus Structural Features Using Minimum Spanning Trees

Samuel P. Border,[1] Kuang-Yu Jen,[2] Sanjay Jain,[3] Agnes B. Fogo,[4] John E. Tomaszewski,[1] Pinaki Sarder.[1] *[1]SUNY Buffalo, Buffalo, NY; [2]University of California, Davis, Sacramento, CA; [3]Washington University School of Medicine, St. Louis, MO; [4]Vanderbilt University Medical Center, Nashville, TN.*

Background: Patients with Type 1 or Type 2 Diabetes mellitus are at an increased risk for extensive vascular dysfunction which leads to Diabetic Nephropathy (DN) in close to 40% of cases. Structural changes within the glomerulus resulting from the diabetic phenotype are used to classify glomeruli into different stages of DN. Using Minimum Spanning Trees (MST's) we are able to quantitatively define these structural abnormalities and assess their contribution to DN stage of that glomerulus. We employed Bayesian Networks (BN) to visualize and assess the relationships between different MST features and the glomerulus's DN stage.

Methods: We used stain deconvolution to isolate nuclear regions in 799 H&E stained glomerulus images. The centroids of glomerular nuclei were used as nodes to create a MST in Matlab. Features calculated from these MST's quantified spread, connectedness, and fraction of terminal "leaf" nodes present as a representation of degree of glomerular expansion, cellularity, and sclerosis. Using these features, a BN was generated in R using the Hill-Climbing structure learning method. The resulting network was thresholded so that only the most significant relationships were included.

Results: Graph features calculated from the glomerular MST had a significant influence on the DN Stage. From this network, we are able to generate conditional probability distributions for each of the feature values that can be used to predict the DN classification.

Conclusions: By analyzing glomeruli using MST's we can impose repeatable, robust measures of nuclei distribution and derive further information as to what biological factors contribute to DN progression. Incorporation of BN and other probabilistic graphical models in medicine allows for more informed diagnosis and research.

Funding: NIDDK Support

SA-PO048

Contribution of Glomerular Phenotype to Digital Classification of Diabetic Nephropathy

Brandon Ginley,[1] Brendon Lutnick,[1] Kuang-Yu Jen,[2] Agnes B. Fogo,[3] Sanjay Jain,[4] Avi Z. Rosenberg,[5] Vighnesh Walavalkar,[6] John E. Tomaszewski,[1] Giovanni maria Rossi,[5] Pinaki Sarder.[1] *[1]SUNY Buffalo, Buffalo, NY; [2]University of California, Davis, Sacramento, CA; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Washington University School of Medicine, St. Louis, MO; [5]Johns Hopkins University, Baltimore, MD; [6]UC San Francisco Medical Center, San Francisco, CA.*

Background: Diabetic nephropathy (DN) is a leading cause of kidney disease; renal pathologists assess its pathology via visual interpretation of biopsied tissue in the form of a digitized whole slide image (WSI). Inter-rater agreement increases with consensus classifications like the Tervaert approach, but reproducibility could still be improved. Computation can unify interpretation of image structure. We engineered a complete start-to-finish glomerular detection and classification pipeline for digitized biopsies of DN. Further, we investigated the glomerular phenotypes and features that it relies on to make decisions.

Methods: We studied 54 patients. Glomeruli were detected from WSIs using our previously published method for WSI segmentation. Glomerular structure was condensed to a three-component system that facilitates detection in widely varying phenotypes. Handcrafted features (n = 232) were used to quantify glomerular structures. Glomerular features from a single biopsy were fed as a sequence to a recurrent neural network (RNN) which yields a continuous number representing Tervaert class. Glomeruli and features were dropped from the network one-by-one; the resultant shift in predicted class was used as a proxy to investigate how much each glomerulus and feature contributed to the overall output. We trained our method by taking one renal pathologist as ground truth, and compared its performance against two other renal pathologists.

Results: Digital classification agreed with the ground truth renal pathologist with linear weighted Cohen kappa κ = 0.55, 95% confidence interval (CI) [0.5, 0.6]. The other two other renal pathologists agreed with the first with κ_1 = 0.48, 95% CI [0.32, 0.64], and κ_2 = 0.68, [0.5, 0.86]. The features that hurt network performance the most when dropped out included features quantifying color of glomerular structures as well as those quantifying mesangial width. The network was most sensitive to dropped glomeruli when there were fewer total glomeruli contained in the biopsy.

Conclusions: Our digital classification reaches agreement similar to renal pathologists and makes decisions intuitively. Digital quantification of renal tissue can enhance clinical workflow by improving precision used to describe disease state.

Neutrophil Extracellular Trap (NET) Quantification in Lupus Nephritis Potentiates NETs as a Prognostic Biomarker

Briana A. Santo,[1] Brandon Ginley,[1] Brendon Lutnick,[1] Sanjay Jain,[2] Brahm Segal,[4] John E. Tomaszewski,[3] Pinaki Sarder.[1] *[1]SUNY Buffalo, Buffalo, NY; [2]Washington University School of Medicine, St. Louis, MO; [3]University at Buffalo, Buffalo, NY; [4]Roswell Park Comprehensive Cancer Center, Buffalo, NY.*

Background: Lupus Nephritis (LN) is a major risk factor for morbidity and mortality in Systemic Lupus Erythematosus (SLE), with 10% of patients developing ESRD. LN classification, which involves pathologist visual scoring of active and chronic lesions in renal biopsies, is limited due to lesion complexity. NETs have been implicated in SLE as immunogenic structures which contribute to lesion manifestation. Glomerular NET density may function as a predictive biomarker in LN, defining active to chronic lesion transition. We have developed a whole slide image (WSI) NET segmentation pipeline which enables computation of NET glomerular density in renal biopsies.

Methods: LN biopsies (n = 21) were labeled according to accepted immunofluorescence (IF) NET staining protocols, post-stained with H&E, and imaged. Our WSI NET segmentation pipeline, as well as a convolutional neural network for glomerular boundary segmentation, were applied. NET+ regions were identified and lesions were hand annotated in glomerulus images.

Results: A two-sampled t-test confirmed that glomerular NET density, for all active and chronic lesion affected glomeruli, is significantly different with p = 0.0002. Therefore, NET glomerular density co-occurrence with active lesion manifestation is statistically significant. NETs may serve as a prognostic biomarker in LN, and may functionally contribute to glomerular injury.

Conclusions: Our pipeline enables evaluation of glomerular NET density as a prognostic biomarker of LN progression, which could improve the clinical interpretation and treatment of LN in SLE. This pipeline may be used to compute NET density in other diseases featuring NET effected tissues, thus potentiating NET density as a universal prognostic biomarker. In addition, NET quantification will enable implementation of supervised classification for classifying NET structures in histology WSIs.

SA-PO050

Measuring Nephron Endowment by Positron Emission Tomography

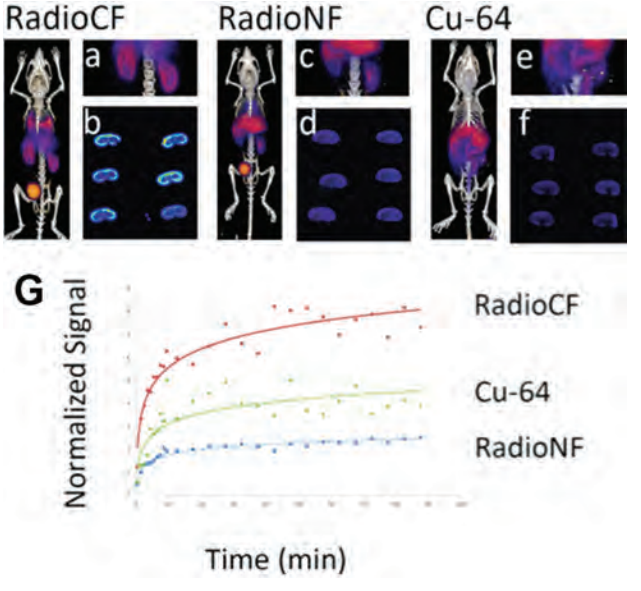
Kevin M. Bennett,[1] David E. Reichert,[2] Scott Beeman,[2] Jennifer R. Charlton,[3] Kooresh I. Shoghi,[2] Edwin Baldelomar.[4] *[1]Washington University in St. Louis, St. Louis, MO; [2]Washington University School of Medicine, St Louis, MO; [3]University of Virginia, Charlottesville, VA; [4]University of Hawaii at Manoa, Honolulu, HI.*

Background: Nephron loss is a primary feature of kidney disease. Recent MRI tools using cationic ferritin (CF) offer a unique view of nephron mass in the intact kidney *in vivo*. We propose a novel contrast agent (RadioCF) based on CF for positron emission tomography (PET). Because RadioCF is detected in trace (<100 ug) doses in humans, RadioCF-PET may enable rapid translation of nephron endowment as a clinical marker.

Methods: Cationic ferritin was filled with Cu-64 created by cyclotron. Radiochemical purity was assessed by radioTLC. 24 mice were anesthetized and administered intravenous injections of radioCF (n = 8), radioNF (uncationized native ferritin, n = 8), or Cu-64 alone (n=8). Mice were injected with 50-80 μCi of radioCF. In four animals of each cohort, a single 3D image series was acquired post-injection.

Results: RadioCF accumulated specifically in the cortical glomeruli, while radioNF and Cu-64 did not. Binding of radioCF was confirmed by phosphorimaging. RadioNF and Cu-64 did not bind. Dynamic imaging and timecourse from renal cortex showed continuous radioCF accumulation in cortex over 90 minutes compared to radioNF or CU-64. Selective accumulation of RadioCF in cortex was confirmed by biodistribution.

Conclusions: RadioCF is a new, translatable molecular imaging tool. Because it binds selectively to the glomerulus, RadioCF accumulation should directly reflect the number of perfused nephrons.



PET imaging in mice after RadioCF injection. RadioCF accumulated in the renal cortex (a, RadioCF in red), while radioNF and Cu-64 do not (c,e). Binding of radioCF, blue, was confirmed by phosphorimaging (b). radioNF and Cu-64 were absent (d,f). Dynamic whole body imaging and timecourse from the renal cortex (G) showed continuous radioCF accumulation in cortex over 90 minutes compared to radioNF or CU-64.

SA-PO051

Renal PET/CT-Rubidium-82 (Rb-82) Is a Precise and Reliable Method for Determination of Renal Blood Flow (RBF)

Stine Langaa,[1] Thomas G. Lauridsen,[1] Claire A. Fynbo,[2] Jorn Theil,[2] Jesper N. Bech.[1] *[1]University Clinic of Nephrology and Hypertension, Holstebro Hospital, Holstebro, Denmark; [2]Department of Nuclear Medicine, Herning Hospital, Herning, Denmark.*

Background: Changes in RBF may play a pathophysiological role in hypertension and kidney disease; however, RBF determination in humans has proven difficult. In a previous study, we demonstrated that RBF estimation based on PET/CT and Rb-82 is feasible and established that RBF can be determined based on a single PET/CT-Rb-82 scan, hereby minimizing radiation exposure associated with the method. We also found an intra-assay coefficient of variation of approximately 5.5% for both kidneys which indicates that the method is precise. The aim of this study is to test the reliability of renal PET/CT-Rb-82 for RBF estimation.

Methods: Ten healthy subjects underwent three dynamic PET/CT-Rb-82 scans spread over two days. Rb-82 was given as bolus injections. On day 1, a single 8 min dynamic scan was performed. On day 2, an 8 min dynamic scan was performed before and after RBF was stimulated by a two-hour long infusion of an amino acid-solution. Time activity curves of arterial activity and renal uptake were recorded, and a 1-tissue compartment model was used for Rb-82 renal clearance estimation using PMOD® software. The clearance constant K1 in the model represents RBF. The day-to-day variation was calculated as the difference between the unstimulated K1-values on day 1 and day 2. K1-values determined before and after RBF stimulation on day 2 were compared.

Results: The mean unstimulated K1 value was 1.80 ± 0.17 ml/min/g for the right kidney and 1.78 ± 0.19 ml/min/g for the left kidney. The mean stimulated K1 value was 1.97 ± 0.17 ml/min/g for the right kidney and 1.95 ± 0.19 ml/min/g for the left kidney. There was no significant difference between the right and the left kidney for either the unstimulated or the stimulated K1 values. The day-to-day variation was 5.2% for the right kidney and 5.3% for the left kidney. For both kidneys, K1-values determined after RBF stimulation were significantly higher than K1-values determined before stimulation.

Conclusions: The approximate 5% day-to-day variation was acceptably low. For both kidneys, a significant increase in RBF was detected after application of a well-documented RBF stimulus. In conclusion, our preliminary results indicate that renal PET/CT-Rb-82 is a precise and reliable method for RBF determination.

Diffusion-Weighted Magnetic Resonance Imaging (DWI) Correlates with Renal Injury in Patients with Renovascular Disease (RVD)

Christopher M. Ferguson,[2] Alfonso Eirin,[2] Abdelrhman Abumoawad,[2] Kai Jiang,[2] Ahmad F. Hedayat,[3] Amir Lerman,[2] Stephen C. Textor,[2] Lilach O. Lerman.[1] *[1]Mayo Clinic College of Medicine, Rochester, MN; [2]Mayo Clinic, Rochester, MN; [3]University of Mississipi Medical Center, Ridgeland, MS.*

Background: There is pressing need to identify novel markers that can predict response to therapy in patients with RVD. DWI is a useful tool for the assessment of renal microstructure and DWI-derived apparent diffusion coefficient (ADC) reflects unobstructed water diffusion. We hypothesized that lower values of ADC (index of fibrosis) can be used as an index of renal injury and response to therapy.

Methods: ADC and renal hypoxia (R2*; blood oxygen level dependent-MRI) were studied before and 3 months after treatment in 20 patients (23 stenotic kidneys) with hemodynamically significant RVD under constant sodium intake. Patients were treated with medical therapy (n=9) or medical therapy plus renal revascularization (n=11, n=14 kidneys). Serum creatinine (Scr), eGFR (CKD-EPI), blood pressure (BP), and systemic levels of pro-inflammatory marker tumor necrosis factor (TNF)-α, were measured at each time-point. Baseline ADC values were correlated with change in renal hypoxia and systolic BP (SBP), as well as TNF-α levels at 3 months.

Results: BP and Scr decreased and eGFR increased 3 months after therapy (Table), but renal hypoxia and TNF-α levels remained unchanged. Overall, ADC values increased 3 months after therapy (Fig. A), although not in medical therapy or renal revascularization considered separately. Baseline ADC values modestly and inversely correlated with changes in hypoxia and SBP, and with TNF-α levels at 3 months (Fig. B), but not with levels of or changes in renal function.

Conclusions: Lower levels of ADC may potentially reflect kidney injury, but do not predict changes in renal function after therapy over 3 months in patients with RVD. Future studies need to identify indices of renal recovery potential.

Detection of Acute Change in Renal Perfusion Using Arterial Spin Labeling MRI

Dennis Kannenkeril,[1] Rolf Janka,[2] Susanne Jung,[1,3] Kristina Striepe,[1] Christian Ott,[1] Michael Uder,[2] Roland E. Schmieder.[1] *[1]Department of Nephrology and Hypertension, University Hospital Erlangen, Erlangen, Germany; [2]Institute of Radiology, University Hospital Erlangen, Erlangen, Germany; [3]Department of Cardiology, University Hospital Erlangen, Erlangen, Germany.*

Background: Magnetic resonance imaging(MRI) with arterial spin labeling(ASL) is a noninvasive promising approach to measure renal blow flow without the use of contrast dye. The purpose of this study was to evaluate change in renal perfusion following a physiological stress(Experiment 1), by ASL kidney perfusion measurements. We also compared the renal perfusion in 3 different study populations(healthy controls(C), patients with hypertension(HT) and chronic renal failure(CRF)- Experiment 2).

Methods: MRI with ASL was performed with a 1.5 Tesla MRI(Magnetom Aera, Siemens Healthineers, Erlangen, Germany) using a FAIR True-FISP sequence. Cortical, medullary, and whole kidney parenchymal perfusion were determined separately. After initial MRI measurement in C and HT, the measurement was repeated after both feet were covered with 1 degree C ice packs, which trigger a systemic sympathetic activation leading to vasoconstriction(cold pressor test).

Results: The group of C subjects(11 males, aged 35.2 ± 12 years) was compared to HT(11 males, aged 39.2 ± 10.3 years) and CRF patients(8 males, 2 females, aged 68.3 ± 7.8 years). The renal perfusion of both kidneys in HT(309.5 ± 17.3 mL/100 g/min) and CRF patients(260.4 ± 29.0 mL/100 g/min) were significantly lower compared to C subjects(338.7 ± 30.0 mL/100 g/min)(C vs. HT- age adjusted p=0.014, C vs. CRF- age- and gender adjusted p=0.004). Renal perfusion was also significantly different between patients with HT and patients with CRF (age- and gender-adjusted p=0.047). In the first experiment blood pressure and heart rate increased significantly in response to the sympathetic trigger. Significant reduction in renal cortical perfusion also has been found. A trend has been noticed in the whole renal perfusion.

Conclusions: With Experiment 1, we could demonstrate that acute changes in renal blood flow could be detected using ASL-MRI. Experiment 2 documented that this technology is able to detect differences in renal perfusion between heathy subjects and diseased subjects by needing only few subjects per group. This offers an advantage in conducting clinical trials in humans compared to other technologies.

Renal perfusion (mL/100 g/min)	before cold stimulus (n=22)	during cold stimulus (n=22)	p-value
Whole renal perfusion	324.1 ± 28.2	318.7 ± 27.8	0.053
Cortical perfusion	368.3 ± 41.5	357.6 ± 38.5	0.042
Medullary perfusion	301.7 ± 32.4	297.5 ± 32.6	0.592

SA-PO054

Fluid Dynamics Analysis by CT Imaging Technique of Hollow Fiber Dialyzer with Medium Cut-Off Membrane

Anna Lorenzin,[1] Ilaria Godi,[3] Gaia Mari,[1] Massimo de Cal,[4] Claudio Ronco.[2] *[1]IRRIV, Vicenza, Italy; [2]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy; [3]Universitá degli studi di Padova, Padova, Italy; [4]San Bortolo Hospital, Vicenza, Italy.*

Background: Inadequate removal of molecules between 5and50KDa, due to their restriction in diffusibility, may cause long-term complication in chronic hemodialysis patients. Medium Cut-off(MCO) is a new class of membranes with enhanced sieving properties and negligible albumin loss, thanks to its high molecular weight(MW) retention onset and MW cut-off value lower than albumin MW. MCO membrane used in HD allows to perform expanded hemodialysis (HDx), a technique based on high internal filtration(IF). Our previous study quantified the IF of Theranova dialyzer leveraging a nuclear imaging technique. In order to characterize the local distribution of the IF, an *in vitro* study assessing the fluid dynamics inside Theranova dialyzer was conducted through CT imaging technique.

Methods: Dialyzer Theranova400(Baxter, Deerfield, USA) was placed in vertical position in the CT gantry. Blood and dialysate compartments were analyzed separately. Dye solution was circulated through blood compartment at 300ml/min and through dialysate one at 500ml/min. Longitudinal sections, 0.5cm thick, were recorded for 60seconds.

Results: In blood compartment, dye solution immediately after its entrance in the dialyzer demonstrates homogeneous progression, while different velocity profiles were observed among the fibers proceeding to the outlet port (Fig b). In dialysate compartment, dye solution is distributed in the periphery first (Fig d), then seeps in the fibers bundle and reaches the complete compartment filling.

Conclusions: The homogeneous dye profile immediately after its entrance in blood compartment demonstrated a good design of the inlet port; the optimal dye distribution reached in both blood and dialysate compartments ensure that IF phenomenon is equally achieved in both central and peripheral regions of the dialyzer.

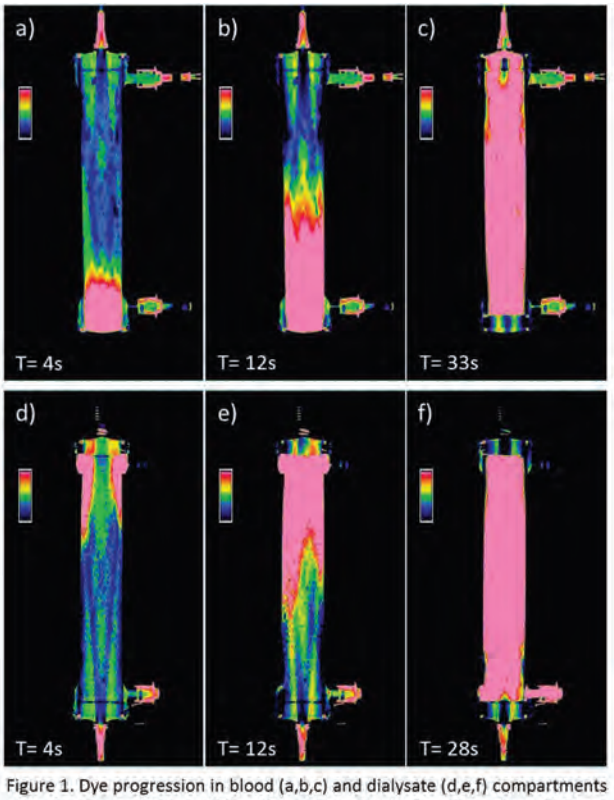

Figure 1. Dye progression in blood (a,b,c) and dialysate (d,e,f) compartments after 4s, 12s, and at total filling. Central longitudinal sections show different profiles in the two compartments: in blood, initial progression is homogeneous, at 12s different velocity profiles emerge along the fiber bundle; in dialysate, dye solution proceeds faster along the dialyzer wall than within the fiber bundle, at the end the whole compartment is reached by the dye solution.

SA-PO055

Feasibility and Effectiveness of 6-Week Plantar Electrical Stimulation Therapy During Routine Hemodialysis Sessions to Improve Gait and Balance: A Randomized Controlled Trial

Fadwa M. Al-Ali,[1] He Zhou,[2] Abdullah I. Hamad,[1] Rania A. Ibrahim,[1] Mincy M. Mathew,[1] Heba M. Ateya,[1] Bijan Najafi.[2] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Baylor College of Medicine, Houston, TX.*

Background: Poor gait and balance are serious problems for people with diabetes undergoing hemodialysis (HD). These patients visit their clinic three times weekly to receive HD which provides an optimal opportunity for intervention. This study aims to examine the feasibility and effectiveness of plantar electrical stimulation therapy (PEST) during routine HD sessions to improve gait and balance.

Methods: Twenty-six participants with diabetes receiving HD were recruited and randomized into an intervention group (IG: n=13, age=59.5±10.4years, BMI=29.7±6.0kg/m^2, female=39%) or a control group (CG: n=13, age=63.2±6.1years, BMI=30.9±6.0kg/m^2, female=54%). The IG received 1-hour PEST during routine HD process (3 sessions/week) for 12 weeks. The CG was provided with an identical but non-functional device for the same period. Participants were blinded to the group allocation. Gait and balance were examined at baseline, midline (6-week), and conclusion of the program. This study however focused on changes in gait and balance at 6-week.

Results: All participants in the IG tolerated the PEST and completed all sessions of the therapy indicating the feasibility. None of the gait or balance parameter showed noticeable differences in the CG group (p>0.050). However, improvement trends were observed in the IG with the largest effect observed in double support for gait parameters (13% improvement, Cohen's effect size d=0.66) and eyes-open center of mass sway for balance parameters (27% improvement, d=0.31).

Conclusions: This pilot study provides earlier results on the feasibility and effectiveness of PEST during routine hemodialysis. The study is still ongoing and is expected to recruit 100 eligible participants for sufficient power. If results can hold in a larger sample size, it may recommend the use of routine plantar electrical stimulation therapy to improve mobility and potentially prevent falls in this highly vulnerable population, who are highly prevalent with frailty, depression, and falls caused by decline in motor function associated with hemodialysis.

Size and Charge Effects of Nanoparticles for Renal Targeting in Polycystic Kidney Disease

Yi Huang, Eun ji Chung. *University of Southern California, Los Angeles, CA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by renal cyst formation and leads to ESRD. Tolvaptan, the only FDA approved treatment for ADPKD, has low bioavailability and results in non-specific uptake and liver toxicity. Our group has recently developed a novel nanoparticle system based on peptide amphiphile micelles (PAM) with the kidney-targeting peptide, $(KKEEE)_2K$ (K3) (Wischnjow, 2016 and Wang, 2018). To improve the nanoparticle targeting efficiency, we incorporated and tested a variety of peptide sequences: $(EEKKK)_2E$ (E3), $(KKEEE)_2K$ (K2), $(EEKKK)_2E$ (E2), (KKEEE)K (K1), and (EEKKK)E (E1). K2, E2, K1, and E1 are shorter amino acid sequences that result in smaller nanoparticles to cross the filtration barrier easily and E3, E2, and E1 are positively-charged sequences to allow for binding to the negatively-charged glomerular basement membrane.

Methods: All peptides were synthesized on an automated peptide synthesizer, conjugated to DSPE-PEG2000, and purified and characterized by HPLC and mass spectrometry. Size and charge of nanoparticles were measured by dynamic light scattering and zeta potential. The *in vivo* renal targeting ability of Cy7-labeled nanoparticles was assessed by tail vein injection of kidney-targeting PAMs, non-targeting PAMs, or PBS in C57BL/6 mice models. Organs were excised and imaged for Cy7 and the fluorescence signal was quantified using the AMI imaging system.

Results: K3 micelles had the largest diameter of 15.4 nm with a negative charge of -17.04 mV, while E1 had the smallest size of 10.6 nm with a near-neutral charge of 0.1 mV. *Ex vivo* imaging results demonstrated all micelles accumulated in the kidneys to a greater extent than other organs, and K3 and E3 demonstrated the highest uptake although not statistically significant (Figure 1).

Conclusions: Our approach demonstrated that our library of kidney-targeting PAMs can accumulate in the kidney. Future studies will further optimize charge and size to understand nanoparticle structure-function relationships in the context of kidney uptake.

Next-Generation Renal Replacement Therapies (RRT): How Do Patients Weigh the Risks and Benefits?

Leslie Wilson,[1] Lynda A. Frassetto,[1] Harini Sarathy,[1] William H. Fissell,[2] Shuvo Roy.[1] *[1]University of California, San Francisco, CA; [2]Vanderbilt University, Nashville, TN.*

Background: Device developers are increasingly asking patients for input on product developments, and the FDA now uses patients' risk-benefit preferences in approving new devices. Implantable/wearable devices under development may revolutionize patient lives by providing more frequent/prolonged RRT, releasing them from in-center/home dialysis (ICHD). Our objective was to determine key risks/benefit considerations that would drive ESRD patient choices.

Methods: We developed a choice-based conjoint discrete choice instrument (CBCDCI) and surveyed by computer 498 ESRD patients. The CBCDCI consists of 9 attributes of risk and benefit derived from literature reviews, patient/clinician interviews, and pilot testing. Attributes include risk of: serious infection, death within 5 years, permanent rejection, surgical requirements, diet restrictions, flexibility in mobility (no ICHD), follow-up requirements, pill burden, and fatigue reduction. We used a random, full profile, balanced overlap design from Sawtooth Software with 12 choice pairs and 2 fixed tasks to test validity. We used a mixed effects regression with attribute levels as independent predictor variables and choice decisions as dependent variables.

Results: In univariate and multivariate analyses, all variables were significantly important to choice preferences except follow-up requirements. For each 1% increase in risk of death within 5 years, preference utility across factors decreased by 2.2, while for each 1% increase in infection, utility decreased by 1.4. Avoiding a 1% risk of infection or death was 1 and 1.5 times preferred over no ICHD, respectively. Pill burden and diet restrictions were less important.

Conclusions: ESRD patients had a strong aversion to even a 1% increase in death within 5 years, infection risk or permanent device rejection, but were willing to trade-off these risks for the benefit of moving to complete mobility. These results will inform device developers on acceptable benefit-risk thresholds for next generation RRT.

Funding: Other NIH Support - NIBIB, Private Foundation Support

Attributes	Beta (preference utilities)	p value
avoiding death in 5 yrs	-2.217	<0.01
no ICHD	1.520	<0.01
avoiding infection	-1.384	<0.01
risk of rejection	-1.066	<0.01
70% fatigue decrease	0.977	<0.01
only 1 implant surgery	0.844	<0.01

Diagnosticator: A Time-Sparing Web-Based Tool for Easy Clinical Annotation of Genetic Data

Enrico Cocchi,[1,2] Hila Milo Rasouly,[2] Lucrezia Carlassara,[3,2] Dina Ahram,[4] Krzysztof Kiryluk,[2] Simone Sanna-Cherchi,[2] Ali G. Gharavi.[2] Ali Gharavi Lab *[1]University of Turin, Torino, Italy; [2]Columbia University, New York, NY; [3]Universita' degli Studi di Brescia, Vicenza, Italy; [4]Columbia University Medical Center, New York, NY.*

Background: Genetic testing is increasingly used in clinical medicine and has been shown to impact clinical care in Nephrology. The American College of Medical Genetics and Genomics (ACMG) has provided standardized guidelines for clinical interpretation of variants, but the large quantity of data generated from genome-wide testing pose a challenge for seamless clinical interpretation of results. We developed a web-based tool that allows users to upload genetic data, analyze them with customizable filters and easily navigate results.

Methods: The analysis algorithm prioritizes results based on customizable parameters: allele frequency from several publicly available databases (GnomAD, ExAC, EVS and 1000Genome), prior reports of disease association (Clinvar and HGMD) and proximity with hot-spot regions, functional and pathogenicity prediction (VEP, pLI, SIFT, PolyPhen, REVEL, dbNSFP, dbscSNV), and ACMG interpretation. Both Dominant and Recessive models are analyzed based on the OMIM-known (or selected) disease inheritance mode for each gene. The final results are presented as an easily interacting and customizable patient-, genelist- or gene-centered interface. Aggregated variant information is presented on a single page, facilitating decision-making about its pathogenicity. Once accepted/rejected, the variant is flagged, to avoid needless re-interpretation of the same variant on other patients or by other users. Moreover, the platform offers a feature that will alert users about a change in status of variants based on interpretation from available databases or other users in the group.

Results: We tested our algorithm on a cohort of 3315 patients with nephropathy with known and validated genetic results (Groopman et al. NEJM, 2019) and we could replicate all of the significant findings (n: 343). The average time required for upload and generation of candidate genes was only 27'. Moreover, causative variants were proposed as the top 10 candidates in 97.8% of the time, significantly speed up annotation. Diagnosticator also flagged 87 new possibly pathogenic variants that we are currently validating.

Conclusions: In summary, we developed an easy to use interface for prioritization and annotation sequencing results, which facilitates clinical interpretation of results and keep users updated about their findings.

SA-PO059

Outcomes of Using Telemedicine to Provide Nephrology Care in Rural Hospitals

Janice P. Lea,[1] Jason Cobb,[2] Jose E. Navarrete,[1] Tahsin Masud,[1] Jerome S. Tannenbaum.[3] Emory University *[1]Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Sanderling Healthcare, LLC, Nashville, TN.*

Background: Telemedicine has recently permeated into the nephrology space allowing patients in rural underserved areas to be treated in their local hospitals without transfer to larger healthcare systems miles away. We report our two year experience providing telenephrology consult services to both ESRD and non- ESRD patients in rural hospitals.

Methods: A retrospective, descriptive study of patients receiving tele-nephrology consultation and chronic dialysis services between September 2017 and May 2019 in three South Georgia (GA) rural hospitals. Consultations were requested by the on-site physicians and were performed by Emory University Tele-nephrologists based in Atlanta, GA by reviewing the patient's hospital electronic medical record (EMR) and performing a real-time history and physical exam with audio-video technology and Littman electronic stethoscope. Nephrologists documented treatment plan in the hospital's EMR on each follow-up visit and provided orders for dialysis when indicated using portable dialysis machines that captured electronic data on each HD session.

Results: In three rural hospitals we provided care to 128 unique patients (pts) with a total of 525 patient encounters. Average age for ESRD pts - 59 and for non-ESRD-66. 60% of the consults were in dialysis patients with congestive heart failure being the major admitting diagnosis in 42%, while 88% of ESRD pts were discharged to home. For the non-ESRD consults: 24.6% were acute kidney injury who had 71% renal recovery at discharge; and 15.6% were electrolyte disorders- mainly hyponatremia. 34% of overall renal consult patients were treated in the ICU with 8.3% requiring pressor support. See Table for other outcomes including length of stay (LOS), mortality rate, and discharge status (DC) for both the ESRD and non-ESRD patients.

Conclusions: Both ESRD and non-ESRD patients in rural hospitals who received nephrology care via telemedicine were effectively managed in their local hospitals, had low mortality rates, and had similar LOS to larger healthcare systems. Telemedicine is an innovative and feasible option to provide specialty care in rural hospitals.

Clinical Outcomes of Rural Hospital Patients Managed by Telenephrology Sevices

	LOS (days)	Mortality	Transfer to higher level of care	DC to skilled nursing/LTAC
ESRD (n=76)	4.3	0	5.7%	3.8%
non-ESRD (n=52)	7.1	5.7%	11.4%	14.3%

SA-PO060

Identification of Very Early Response Genes and Sex-Dependent Response Genes for Ischemia-Reperfusion Injury in Human Transplant Patients

Nathan Lee,[1,2] Hannes Olauson,[1,3] Shun-Yang Cheng,[1] Kyung hwa Choi,[1,4] Taja Zeleznik ramuta,[1,5] Joseph V. Bonventre.[6,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Broad Institute of MIT and Harvard, Cambridge, MA; [3]Department of Clinical Science, Intervention, and Technology, Karolinska Institutet, Stockholm, Sweden; [4]CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea; [5]Institute of Cell Biology, University of Ljubljana, Ljubljana, Slovenia; [6]Brigham and Women's Hospital, Boston, MA.*

Background: Ischemia-reperfusion injury (IRI) is highly implicated in various kidney conditions leading to acute (AKI) and chronic kidney disease (CKD). IRI during renal transplantation often initiates responses that can result in poor outcome and the loss of kidney graft viability. It is important to identify very early response programs that can be utilized to better characterize the pathobiology and identify therapeutic targets to minimize the injury. Furthermore, it has been shown that sex influences susceptibility to kidney IRI. However, such early response programs for IRI and sex-dependent response programs are poorly understood with most of our knowledge derived from animal studies or tissue analyses after longer times post-ischemia in the transplant population.

Methods: Twenty paired biopsies from the cortical region of the human kidney were obtained before and after ischemia-reperfusion during living donor transplantation, with minimal cold ischemia time (1-2 hours) compared to other studies. Glomeruli were

removed and the tubulointerstitial fraction was subjected to RNA sequencing (RNA-seq). Genes were identified that were differentially regulated early in response to IRI.

Results: There was a robust and novel early response program to IRI. When compared to published datasets of both human and rodents, there was a significant overlap of the post-ischemic transcriptional profiles. Interestingly, however, our results identified a unique set of highly upregulated early response genes that have not been identified previously for their roles in kidney IRI. Furthermore, we identified sex-dependent genes that were differentially upregulated in males and females.

Conclusions: Within 1-2 hr of cold ischemic time in transplanted human kidneys there is a unique set of genes which reflect a very early response. There was a different early response to IRI between males and females. Findings from this study can be utilized to further investigate mechanisms and potential therapeutic options for IRI and AKI.

Circular RNA Expression Profiles in Cisplatin-Induced AKI in Mice

Canming Li, Ming Li, Zengchun Ye, Hui Peng, Tan-qi Lou. *The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*.

Background: Cisplatin is an effective chemotherapeutic agent whose nephrotoxicity is a serious clinical problem. However, the molecular mechanisms underlying cisplatin-induced acute kidney injury (Cis-AKI) remain unknown. Circular RNAs (circRNAs), a novel class of noncoding RNAs, have been reported to be involved in a variety of diseases. However, the roles of circRNAs in AKI are poorly understood.

Methods: In this study, an AKI model was established in cisplatin-treated mice, and the expression of circRNAs was profiled by next-generation sequencing. The differential expression levels of selected circRNAs were determined by qRT-PCR. Bioinformatics analysis was conducted to predict the functions.

Results: In total, 368 circRNAs were detected to be differentially expressed in response to cisplatin treatment. The qRT-PCR analysis showed that the expression of six selected circRNAs was consistent with that determined by RNA sequencing. The GO and KEGG pathway analyses indicated that the parental genes of the differentially expressed circRNAs were predominantly implicated in the cell part and organelle, cellular process, metabolic process and cancer pathways.

Conclusions: Our study yielded a comprehensive expression profile of differentially expressed circRNAs associated with AKI, indicating the possible involvement of these dysregulated circRNAs in the pathophysiology of cisplatin-induced nephrotoxicity.

Mitochondrial Fission and Apoptosis-Related CircRNA Plays an Important Role in Ischemia-Reperfusion-Induced AKI by Sponging miR-652-3p

Mengping Ran, Junjun Luan, Hua Zhou. *Department of Nephrology, The Affiliated Shengjing Hospital of China Medical University, Shenyang, China*.

Background: Circular RNAs (circRNAs) can serve as sponges of microRNAs (miRs) to participate in the pathogenesis of various diseases. A study reports that mitochondrial fission and apoptosis-related circRNA (*MFACR*) mediates cardiomyocyte apoptosis by sponging miR-652-3p to regulate mitochondrial fission process 1 (MTFP1) pathway. However, the role of *MFACR* in acute kidney injury (AKI) remains unclear. We aim to investigate whether *MFACR* is involved in ischemia and reperfusion (I/R)- induced AKI and its corresponding mechanisms.

Methods: Male Balb/c mice were subjected to 35 mins of bilateral renal ischemia and then reperfusion. We evaluated AKI by examining blood urea nitrogen (BUN), tubular necrosis with PAS and spoptosis by TUNEL staining, and renal inflammation by measuring interleukin-6 (*Il6*) and tumor necrosis factor-α (*Tnfα*) 48h after the reperfusion. Meanwhile, we examined the expression of mitochondria related mRNAs and proteins including optic atrophy 1 (OPA1), peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1a), and mitochondrial transcription factor A (TFAM). Finally, we measured the levels of *MFACR*, *miR-652-3p*, and *Mtfp1*. *We* analyzed the match seeds between *MFACR* and *miR-652-3p as well as miR-652-3p* and *Mtfp1* with TargetScan and miRanda.

Results: We found that kidney function declined with elevated BUN levels, increased renal tubular necrosis scores on PAS and positive apoptosis on TUNEL staining in kidneys 48h after I/R in mice compared to the shamed control mice. *Il6* elevated 14-folds and *Tnfα* elevated about 5-folds in I/R mice compared to shamed mice. Renal mitochondrial damage biomarkers including OPA1, PGC-1α, TFAM statistically decreased in I/R mice on the levels of their mRNAs and proteins. Importantly, renal *MFACR* was downregulated, *miR-652-3p was* upregulated, and *Mtfp1* was downregulated in I/R-induced mice compared to the shamed mice. Finally, we found perfect match seeds between *MFACR* and *miR-652-3p* as well as between *miR-652-3p* and *Mtfp1* on TargetScan and miRanda analysis.

Conclusions: Our findings suggested that MFACR played an important role in I/R induced AKI. The mechanism might be that MFACR regulates renal mitochondrial functions by sponging miR-652-3p and consequently increasing MTFP1. Regulating MFACR-miR-652-3p-MTFP1 pathway may open a novel therapeutic avenue for AKI.

Sex Transcriptomic Signatures in Pig Kidneys After Ischemia-Reperfusion Injury and Recovery

Anna Meseguer,[1] Stéphane Nemours,[1] Didac Ribatallada,[2] Miguel Aranda,[2] Luis Castro.[2] Renal Physiopathology Group. VHIR *[1]Vall d'Hebron Institut de Recerca, Barcelona, Spain; [2]Renal Physiopathology, VHIR, Barcelon, Spain*.

Background: Renal ischemia/reperfusion injury (IRI) is a major cause of acute kidney injury (AKI). Men are more prone to AKI and to CKD than women and it is accepted that androgens have a role in these processes. The mechanisms involved in injury/regeneration and the impact of gender remain to be fully elucidated. We propose that the identification of differentially expressed genes in male and female pig kidneys in basal, after injury and upon renal function might unravel genes and pathways useful to understand the different outcomes observed in men and women.

Methods: IRI was performed in single-kidney female and male pigs by clamping the renal artery for 30 minutes. Pre-ischemic, ischemic and post-ischemic kidney tissues (one week later) were collected for microarray assays. Pathway enrichment analysis and visualization of -omics data was done by GSEA, cytoescape and enrichment map. Systems biology-based mathematical models were also conducted to identify injury/recovery pathways and networks modulated in a sex-dependent manner.

Results: The numbers of genes differentially expressed in males versus females (adj P value 0.25) were 100 in pre-ischemic conditions, 858 at 5 min post-ischemia and 2 at one week pos-ischemia, indicating that although males were exhibiting differences in gene expression in basal situation and after injury, the general pattern of expression was similar to that of the females after one-week post-injury. Enriched pathways containing different gene sets down-regulated in males after one-week post-injury, but activated in basal situation and injury included, among others, immnune cell regulation, ion transpost transmembrane, steroid hormone response, type inteferon interleukins and intrinsic and extrinsic apoptosis. Contrarily, males after one-week have activated responses to growth factors such as the TGF-beta family members and extracellular matrix organization and collagen formation. Anaxomics systems biology patented technology has also pointed to STAT-1 and STAT-3 as crucial effectors of androgen mediated injury in kidney.

Conclusions: The targets identified in female and male pig samples together with the extensive bioinformatic analyses we have performed shall provide with novel mechanistic insights into the role of sex hormones in the kidney injury and regeneration processes.

Funding: Government Support - Non-U.S.

SA-PO064

Drug Repurposing for the Prophylaxis of Renal Ischaemia Reperfusion Injury

David A. Foxwell,[1] Usman Khalid,[2] Gilda Pino-Chavez,[3] Rafael E. Chavez,[4] Timothy Bowen,[3] Donald Fraser.[3] *[1]Wales Kidney Research Unit (WKRU), Cardiff, United Kingdom; [2]Cardiff Transplant Unit, Cardiff, United Kingdom; [3]Cardiff University, Cardiff, United Kingdom; [4]University Hospital of Wales, Cardiff, United Kingdom*.

Background: Ischaemic Preconditioning applied to the kidney (direct IPC) or to distant sites (indirect IPC) confers protection from subsequent ischemic Acute Kidney Injury (AKI). However, IPC has not proven effective in clinical trials enrolling individuals at high AKI risk. The purpose of this study was to employ a drug repurposing approach, in an attempt to translate the experimental benefit of IPC into candidate agents for clinical testing.

Methods: IPC regimens were tested iteratively in a rat model of bilateral IRI. Optimised direct and indirect IPC approaches were transcriptomically profiled by RNA sequencing, and a shared protective signature identified. Computational prediction of drug repurposing candidates was performed by Ingenuity Pathway Analysis. Effects of predicted candidates were evaluated *in vivo*, by renal histology and serum creatinine.

Results: Optimum benefit was observed with direct and indirect pulsatile IPC employing two minutes of ischaemia followed by five minutes of reperfusion, repeated for 3 cycles. Whole kidney transcriptomic profiling performed across sham, IRI, and direct- and indirect-IPC/IRI groups (n=6 per group) mapped to 16,780 unique genes, of which 2,193 genes were differentially expressed between IRI and sham, which IPA attributed to a phenotype of Acute Renal Failure ($p = 1.32 \times 10^{-27}$) and Renal Proximal Tubular Toxicity ($p = 5.06 \times 10^{-15}$). A core set of master regulators and pathways were identified within inflammatory response, oxidative stress and cell cycle, that were diminished by direct and indirect IPC. Comparison with transcriptomic information available for 23,686 biological drugs and chemicals (compounds) contained within the IPA knowledge base was employed to identify repurposing candidates for benefit in IRI prophylaxis. Six compounds exhibiting favourable characteristics for progression to clinical testing were further evaluated *in vivo*, and all exhibited functional benefits when administered as a single dose prophylaxis pre-IRI.

Conclusions: Our data identify a common protective gene expression signature between direct and indirect IPC. These findings provide novel insights into the pathology of IRI injury and protection afforded by IPC. Computational transcriptional analysis using this dataset has identified candidate drugs for repurposing.

SA-PO065

Neuro-Immune Cross-Talk in Pathophysiology of AKI

Sanjeev Puri, Veena Puri, Aprajita Gupta. *Panjab University, Chandigarh, India*.

Background: Acute kidney injury is a heterogeneous syndrome characterized by inflammation, decrease in glomerular filtration rate, vascular modulation, oliguria and swing in nervous system. Its progression is mediated by cytokines production, neuro-molecules and infiltration of immune cells into kidneys and other organs including brain. Lead molecule, TNF-α aids in the recruitment & activation of immune response. The neuropeptide calcitonin gene-related peptide (CGRP) has been significantly observed in pain pathways, hemodynamic and nerve signal modulation in AKI. The interdependent mediation of immune molecules and neuropeptide during AKI further point to the progression of pain pathways that still remains unexplored in AKI.

Methods: A systems biology approach was used to find neuro-inflammatory molecules of AKI by employing *in-silico* retrieval of AKI genes and investigation of their role in mouse model. The neuro-inflammatory genes in AKI and the respective signalling pathways were searched by PANTHER, GENOMATIX and Target Explorer. Common interactors between TNF and CGRP were expedited by STRING and CYTOSCAPE. The AKI was induced in male Balb/c mice through an intraperitoneal injection of folic acid (250 mg/kg). Kidneys and brains were harvested and expression of CGRP and TNF-alpha, TRPV1, PTGER4 and CGRP receptor genes were analyzed by quantitative real-time PCR analysis. Immuno-histology of kidney and brain and Serum ELISA were employed to study the CGRP and TNFα protein expression. The changes in BBB were evaluated by Evan's blue estimation.

Results: The in-silico search retrieved a list of 49 genes which participate in neuro-immune axis of AKI. KEGG pathway analysis revealed that most of these communicators converse through the calcium signalling pathways. With progression of injury mRNA expression of CGRP, TNF- α and other genes was found modulated. The variation in expression was also reflected by immuno-histology in kidney and brain. The serum CGRP and TNF were also modulated in similar fashion as estimated by ELISA. The changes in the cell architecture of brain and the changes in BBB evidence the kidney cross talk with brain.

Conclusions: The study unveils the route of the communication between CGRP and TNF on neuro-immune axis. Most of the mediators signal through calcium mediated pathways leading to pain and pointing towards one of the pilot routes between them.

SA-PO066

Kidney-Targeting Nanoplatform for the Specific Delivery of Triptolide to Treat Renal Ischemia-Reperfusion Injury

Zeng Tao,[1,2] Aiqing Li,[3] Jiawen Li.[3] [1]*State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Guangzhou, China;* [2]*Department of Chemistry, College of Chemistry and Chemical Engineering, South China University of Technology, Guangzhou, China;* [3]*Nanfang Hospital, Southern Medical University, Guangzhou, China*.

Background: Triptolide (TP) has been proved with a therapeutic effect on a few kinds of kidney diseases. However, its clinical application is limited due to high toxicity and low specificity. Herein, we report a novel kidney-targeting, safe nanoplatform for the specific delivery of TP.

Methods: TP was wrapped in a kind of meso-scale nanoparticles (MNPs) with promising kidney-targeting ability to synthesize the nano-polymer MNPs-TP. TP and then it was administrated to mice through tail vein to evaluate its toxicity to organs and immune system. The targets of MNPs-TP and its mechanism were explored by organ imaging, Transwell and other experimental methods. Finally, a mouse model of renal ischemia/reperfusion injury (IRI) was applied to explore the protective effects and mechanism of different concentrations of TP and MNPs-TP on renal tubules.

Results: The toxicity test showed serious pathological changes in liver and the proportion of CD4+/cd8+ also decreased in TP group, suggesting immune function was damaged. However, MNPs-TP showed no obvious toxic effect on organs and immune system. The pharmacokinetic experiments showed that free TP had no specificity in the distribution in various organs, while the MNPs-TP showed longer metabolic cycle and clear kidney targeting. Transwell experiments showed that renal tubular epithelial cells could ingest MNPs-TP from the basal medium and transport it to the apical side, suggesting that the uptake of MNPs-TP is related to their endocytosis and exocytosis. After administration of TP at the dose of 0.1mg/kg body weight to the IRI mice, the renal function assessed by BUN and SCr was alleviated. The lower score of renal tubular injury, and the down-regulation of p-ERK and NGAL further verified the therapeutic effect of TP. However, free TP at the dose of 0.01mg/kg lacked these protective effects, and surprisingly, MNPs-TP still showed protection, which demonstrated that the effective therapeutic dose of MNPs-TP was significantly lower relative to free TP.

Conclusions: MNPs-TP showed superior therapeutic effect on renal ischemia-reperfusion injury (IRI) model in comparison with TP. Furthermore, MNPs-TP conjugate presented much lower hepatotoxicity and no adverse effect on the immune and genital system. The kidney-targeting MNPs may provide a promising drug delivery platform of hydrophobic drugs for treatment of renal diseases.

Transcriptomic Mapping of Early Cellular Responses to Renal Ischemia-Reperfusion at Single-Cell Resolution

Shintaro Ide, Yoshihiko Kobayashi, Sarah A. Strausser, Anisha Watwe, Purushothama rao Tata, Tomokazu Souma. *Duke University, Durham, NC*.

Background: Therapeutic options for treating acute kidney injury (AKI) and the subsequent development of chronic kidney disease (CKD) are limited. The lack of a clear molecular understanding of its pathogenesis and renal reparative pathways contributes to this scarcity of targeted therapeutics. Recent technological advancements in single-cell RNA sequencing have revolutionized our understanding of complex and dynamic tissues such as the kidney. However, optimization is still required to successfully apply this technology to rodent AKI models. Understanding cellular events in AKI at single-cell resolution will guide us to develop new therapeutic strategies.

Methods: We have optimized the kidney digestion protocol to achieve high viability (>95%) and very few doublet formations to avoid flow-cytometry-based cell isolation. We used our unilateral ischemia-reperfusion injury (uIRI) mouse model, which causes severe renal atrophy at 21 days after IRI. Droplet-based single-cell RNA-seq libraries were created and sequenced from a total of 10,000 cells from both injured (IRI) and contralateral kidneys (CLK) using a Drop-Seq platform. Single-cell transcriptome profiles were clustered and annotated based on the expression patterns of known marker genes.

Results: Our tSNE analyses identified at least 25 clusters in our combined dataset of IRI and CLK. We captured podocytes in 1.97% of total cells, which is close to the published single-nucleus RNA-seq dataset (2.4%; Wu et al., JASN 2019). There was clear separation among epithelial cells between IRI and CLK kidneys. We successfully mapped the known expression pattern of epithelial injury marker genes such as Havcr1 (encoding kidney injury molecule1), Lcn2 (encoding neutrophil gelatinase-associated lipocalin), and cytokeratins. Gene ontology analyses identified unique cell-type specific signaling such as oxidative stress responses in the KIM1-expressing proximal tubular segment.

Conclusions: We have developed an optimized platform for generating and analyzing the single-cell transcriptome of mouse kidneys which underwent IRI. Future studies using this platform will inform us as to how the cell-type specific and shared gene signatures change during the course of the disease and guide us to identify novel therapeutic approaches for AKI and its transition to CKD.

Whole-Genome Chromatin Immunoprecipitation Sequencing Identifies a Role of CtBP2 in Renal Cell Dysfunction and AKI

Ji Young Kim, Yuntao Bai, Laura A. Jayne, Navjotsingh P. Pabla. *The Ohio State University, Columbus, OH*.

Background: Acute kidney injury (AKI) is a clinical syndrome characterized by rapid decline in renal function that results in 2 million deaths annually worldwide and pays for billions of dollars in US healthcare costs. In a pathophysiologic manner, renal tubular cell dysfunction and cell death is the hallmark and the underlying cause of AKI. However, the transcriptional regulators that control alteration in epithelial cell gene expression that triggers renal tubular cell dysfunction and death remain underexplored. The application of deep transcriptional sequencing has provided the new insights of AKI. Here we have examined the role of transcription regulator C-terminal binding protein 2 (CtBP2) in the pathogenesis of AKI through global profiling.

Methods: The mRNA and protein expression of CtBP2 were determined in multiple AKI-associated mouse models, namely rhabdomyolysis, ischemia reperfusion injury, and cisplatin nephrotoxicity. To define the role of CtBP2 in vivo, a pharmacological inhibitor (MTOB) and CtBP2-specific siRNA knockdown (hydrodynamic intravenous injection) were examined in ischemia- and cisplatin- associated AKI. Finally, to directly determine the molecular targets of CtBP2, we carried out chromatin immunoprecipitation followed by sequencing (ChIP-Seq) in rhabdomyolysis-induced AKI and associated changes of the target gene expression of CtBP2 in multiple AKI-associated mouse models with RNA-sequencing (RNA-Seq) data.

Results: During the early phase of rhabdomyolysis, ischemia, and cisplatin induced AKI, there is a remarkable increase in CtBP2 protein expression in renal epithelial cells. Functional *in vivo* studies showed that inhibition of CtBP2 function significantly improves renal impairment in ischemia and cisplatin-associated kidney injury. Global analysis of CtBP2 in rhabdomyolysis-induced AKI revealed that it drives DNA damage, cell cycle, cell proliferation/differentiation pathway, and carbohydrate/lipid metabolism. These target genes of CtBP2 were validated by RNA-Seq and qPCR analysis in all three AKI-associated murine kidneys.

Conclusions: Here we first have identified broad roles for CtBP2 as a transcriptional repressor during acute kidney injury. We propose that development of CtBP2 targeting small molecules could provide a therapeutic strategy for the treatment of AKI.

Erythropoietin-Derived HBSP Binding to Tubular Epithelia In Vitro Reduces Apoptosis and Synergistically Protects Kidneys with Caspase-3 siRNA Against 2-Week Ischemia-Reperfusion Injury in the Mouse

Yuanyuan Wu,[2,1] Yu Liu,[4] Yufang Zhang,[2] Wenting Li,[5] Joanna M. Barker,[3] Mark P. Lowe,[3] Nigel J. Brunskill,[1,4] Bin Yang.[1,4] *[1]Department of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom; [2]Basic Medical Research Centre, Nantong University, Nantong, China; [3]Department of Chemistry, University of Leicester, Leicester, United Kingdom; [4]Nantong-Leicester Joint Kidney Science Institute, Affiliated Hospital of Nantong University, Nantong, China; [5]Nantong University, Nantong, China*.

Background: Ischemia-reperfusion injury (IRI) induced acute kidney injury has high morbidity and mortality, but no specific treatment. Renoprotection by caspase-3 siRNA (C3siRNA), erythropoietin (EPO) derived peptide HBSP, or cyclic HBSP ± C3siRNA, has been previously demonstrated against IRI at 24 or 48 h. HBSP only recognizes tissue protective heterodimer receptor (EPOR/βcR) and highly expresses in early IRI kidneys. This study further explored the synergistic long-term effect and mechanism of these agents administrated at the onset of injury.

Methods: Bilateral occlusion and sham operation of renal pedicles for 30 min were performed on adult male C57BL/6 mice, followed by reperfusion for 2 w, with or without the treatment of HBSP ± C3siRNA/negative control siRNA (NCsiRNA, n=5-9). Twenty-four nmol/kg BW of HBSP was administrated at the onset of occlusion and 15 min after reperfusion, while 30 μg/kg BW of C3siRNA or NCsiRNA was injected via tail vein 2 h before surgery. Moreover, the localization of fluorescent iridium labeled HBSP (HBSP-Ir) at 25 μM was detected at 1 h post incubation with TCMK-1 cells (mouse kidney tubular epithelial cell line, TECs) ± H_2O_2 at 200 μM post 24 h. Apoptosis was assessed when HBSP-Ir at 5, 10, 20 or 40 ng/ml was added together with H_2O_2 for 24 h.

Results: The typical impairment of renal structure and function was observed in the IRI kidneys, with increased apoptotic cells. However, this injury was reversed by HBSP or C3siRNA, which decreased serum creatinine, tubulointerstitial damage and apoptosis. Furthermore, co-treatment with both agents resulted in greater preservation of kidney structure and apoptosis compared with single administration. In addition, HBSP-Ir bound to TCMK-1 cells only treated by H_2O_2. HBSP-Ir also significantly reduced cell apoptosis at all dosages.

Conclusions: HBSP binds to TECs and induces anti-apoptosis. HBSP administrated at the early stage of injury has long-term and synergistic effects with C3siRNA on renal IRI. These data indicate a feasibility that HBSP might be a guide for cell-specific delivery of siRNA, if both are conjugated, targeting caspase-3 in specific cells highly-expressed EPOR/βcR in IRI kidneys.

Phenotype of Ksp-Cadherin Deficient Mice: Enhanced Recovery from AKI

Robert B. Thomson,[1] Diane W. Dynia,[1] Benjamin R. Thomson,[2] Carmen J. Booth,[1] Vijayakumar R. Kakade,[1] Arnaud Marlier,[1] Felix Knauf,[3] Lea Jagels,[4] Anja Lück,[5] Lloyd G. Cantley,[1] Peter S. Aronson.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]University Hospital Charite Berlin, Berlin, Germany; [4]Friedrich-Alexander-Universität Erlangen-Nürnberg, Hamburg, Germany; [5]Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany*.

Background: We have generated a mouse line that is deficient in Ksp-cadherin (Ksp-null), a member of the cadherin superfamily of cell adhesion molecules that is primarily expressed on the basolateral membrane of renal tubular epithelial cells (Thomson *et al.* ASN 2019). To further elucidate the phenotype of this null-mutation, we exposed Ksp-null and wild-type (WT) mice to an aristolochic acid (AA)-based model of AKI.

Methods: A single application of AA (2 mg/kg body weight) or vehicle alone was administered by i.p. injection to 10 week-old Ksp-null and WT male mice.

Results: At one week post AA exposure both cohorts showed similar levels of renal injury by histological evaluation. BUN values rose to 74 and 79 mg/dL for Ksp-null and WT animals respectively and serum creatinine values rose to 0.473 and 0.632 mg/dL respectively. Three weeks post AA treatment, WT animals had persistently elevated BUN and serum creatinine values of 80 and 0.462 mg/dL respectively and substantial evidence of unresolved tubular injury. In contrast, the Ksp-null animals had significantly lower BUN and serum creatinine values (35 and 0.206 mg/dL respectively) and histological evaluation revealed that their tubular injury had largely resolved. To gain insight into the nature of this accelerated recovery, we performed a comparative evaluation of kidneys from Ksp-null and WT animals specifically looking for differences in cell proliferation indices, inflammatory cytokine expression levels, immune cell response, and Klotho expression levels. No differences were observed between Ksp-null and WT animals at 1 week post AA injection. At 3 weeks post AA injection, however, Ksp-null animals exhibited significantly lower levels of expression of CD68, TGF-β, $p16^{INK4a}$, IL-6, and Arg1. Furthermore, Ksp-null kidneys demonstrated significantly higher levels of Ki67 staining and significantly enhanced recovery of Klotho expression.

Conclusions: In conclusion, despite sustaining similar levels of initial injury in response to AA exposure, Ksp-null animals exhibited an accelerated recovery relative to WT controls that was characterized by enhanced cell proliferation, elevated levels of Klotho, lack of persistent expression of immune cells, and decreased expression of inflammatory cytokines.

SA-PO071

GSK3-Beta Inhibits Tubular Regeneration in AKI by a FoxM1-Dependent Mechanism

Abeda Jamadar, Sonali Sinha, Nidhi Dwivedi, Reena Rao. *University of Kansas Medical Center, Kansas City, KS*.

Background: Acute kidney injury (AKI) is characterized by injury to the tubular epithelium. Although renal tubules are capable of regeneration, inadequate repair and fibrosis can lead to chronic kidney diease. FoxM1 is a forkhead box family member transcription factor which regulates cell division, survival and oxidative stress. FoxM1 is also a substrate for glycogen synthase kinase 3beta (GSK3-beta), a known inhibitor of renal tubular regeneration in AKI. The current study tested the hypothesis that GSK3-beta suppresses tubular repair after AKI by inhibiting FoxM1.

Methods: To determine the role of FoxM1 in tubular repair, the effect of FoxM1 inhibition was examined in renal ischemia/reperfusion (I/R) induced AKI in C57BL/6J mice and HK2 proximal tubular cells *in vitro*.

Results: Renal FoxM1 expression increased after I/R induced AKI in mice and was accompanied by increased cell proliferation. Treatment with Thiostrepton, a FoxM1 inhibitor reduced renal tubular cell proliferation and kidney tubular repair. To test if GSK3-beta regulates FoxM1, the effect of FoxM1 inhibitor on tubule-specific GSK3-beta knockout mouse was determined. In GSK3-beta knockout mice, FoxM1 expression, cell proliferation and tubular repair were significantly high, leading to improved renal function. Significant increase in p21, a cell cycle inhibitor and reduction in pro-proliferative factors were found in cells and kidneys where GSK3-beta was inhibited. Thiostrepton treatment abolished the improved tubular repair in GSK3-beta knockout mice.

Conclusions: These studies demonstrate that FoxM1 is an important factor for renal tubular regeneration following AKI, and that GSK3-beta suppresses tubular repair by inhibiting FoxM1

Loss of Gsα Impairs Renal Tubular Epithelial Cell Regeneration via the Raf-MEK-ERK Dependent Inhibition of CDK2/Cyclin E Mechanism

Lele Liu,[1] Min Han,[2] Gang Xu.[1] *[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [2]Tongji Hospital, Tongji Medical College, Wuhan, China*.

Background: The alpha subunit of the heterotrimeric G stimulatory protein (Gsa), encoded by the guanine nucleotide binding protein, alpha stimulating gene (Gnas), is expressed ubiquitously and mediates receptor-stimulated production of cyclic adenosine monophosphate (cAMP) and activation of the protein kinase A signaling pathway. We investigated the roles of Gsa in renal tubular epithelial cell regeneration.

Methods: We generated a distal tubule epithelial-specific Gsa deletion ($Gsa^{flox/flox}$ Ksp-Cre) mouse to demonstrate the essential role of Gsa in renal tubular epithelial cell regeneration in two AKI models: acute aristolochic acid toxic nephropathy (AAN) and unilateral ischemia reperfusion injury (UIRI). To further explore the effect of Gsa on cell proliferation, we next knocked down Gsa in cultured human HK-2 cells using a specific small interfering RNA.

Results: $Gsa^{flox/flox}$ Ksp-Cre mouse developed more severe renal impairment including higher levels of serum creatinine and massive tubular necrosis after AAN and UIRI. Gsa inactivation dramatically impaired renal tubular epithelial cell regeneration and blocked proliferating tubular cells in G1/S transition due to the reduction in the number of BrdU+ cells and the depression of cyclin-dependent kinase2 (CDK2)/ cyclinE1 activities. In vitro, treatment of renal tubular epithelial cells with Gsa-targeting small interfering RNA inhibited tubular epithelial cells proliferation by preventing cell cycle progression from G1 to S phase. Down-regulation of Gsa inhibited the activity of CDK2/cyclinE1 and inhibited the Raf-MEK-ERK signaling pathway before and after aristolochic acid stimulates HK-2 cells.

Conclusions: Gsa is required for tubular epithelial cell regeneration in the kidney repair stage after AKI. Loss of Gsa could dramatically impair the regeneration of renal tubular epithelial cells by blocking Raf-MEK-ERK pathway.

SA-PO073

FGF9 Signaling Is a Crucial Regulator of AKI

Yuntao Bai, Ji Young Kim, Laura A. Jayne, Navjotsingh P. Pabla. *The Ohio State University, Columbus, OH*.

Background: Acute kidney injury (AKI), a clinical syndrome characterized by rapid loss of renal function, is associated with significant mortality and morbidity in hospitalized patients. Currently, there is no effective treatment or prophylactic approaches available for AKI. Our overarching goal is to dissect the molecular pathways underlying renal tubular cell dysfunction, and to identify drug-able targets that can be therapeutically exploited and translated into patients. Over the past decades, significant advances have been made in understanding the pathogenesis of AKI, mainly through the study of small animal models. Compelling evidence supports that renal cell death and dysfunction are the major hallmarks of AKI. However, clinical translation of these findings remains a significant barrier, in part due to the lack of drug-able targets.

Methods: An unbiased drug-able genome siRNA screen for regulators of renal epithelial cells was carried out in murine and human tubular epithelial cells. Primary screening and validation studies revealed fibroblast growth factor 9 (FGF9) as a novel regulator of renal cell death. To directly define the role of FGF9 in vivo, kidney tubule specific FGF9 knockout mice were generated. In addition, FGF9 targeted therapies

(anti-FGF9 antibody or FGFR kinase inhibitor) were evaluated in multiple mouse models, namely cisplatin-, ischemia-, and rhabdomyolysis-associated AKI. Proteomic approaches were used to identify the downstream targets.

Results: Genetic ablation of FGF9 in kidney tubules ameliorated the severity of AKI in multiple mouse models. Moreover, FGF9 targeted treatment, e.g. anti-FGF9 antibody or FGF9 receptor inhibitor, significantly reduced the kidney damage and improved renal function in these models. We also found that Glutathione peroxidase 4 (GPx4) is the downstream target of FGF9-FGFR signaling during AKI.

Conclusions: Together these studies have identified a previously unknown pathway responsible for AKI pathogenesis. More importantly, our data provides strong preclinical evidence to further evaluate the use of FGF9 targeted therapy in AKI treatment.

Epithelial STAT5 Confers Protection Against Glomerular and Tubular Injury

Aïssata Niasse,[3] Kevin Louis,[3] Aymeric Couturier,[3] Sophie Vandermeersch,[3] Placier Sandrine,[3] Eric Rondeau,[2,1] Laurent Mesnard,[2,1] Yosu Luque.[2,1] *[1]Sorbonne Université / Inserm UMRS1155, Paris, France; [2]Urgences Néphrologiques et Transplantation rénale, Tenon Hospital. Assistance Publique Hôpitaux de Paris, Paris, France; [3]Inserm UMR_S1155, Paris, France.*

Background: Recent data support Janus Kinase/signal transducers and activators of transcription (JAK/STAT) signaling, a pathway described in immune cells, as relevant to the kidney's tissue-specific response to injury. Studies have shown a deleterious role of podocyte STAT3 in glomerular diseases and the involvement of tubular STAT3 in renal fibrosis. Recently, we showed a protective role for the podocyte gamma chain, a potential activator of STAT5, during experimental glomerulonephritis. Here, we hypothesized that STAT5 may protect the kidney epithelium.

Methods: Mice with a podocyte-specific deletion of STAT5 and their littermate controls were challenged with nephrotoxic serum or with adriamycin. Mice with an inducible tubular-specific deletion of STAT5 and their littermate controls were challenged with a cisplatin nephrotoxicity model. All mice were derived on a C57BL6/J genetic background. We also investigated epithelial STAT5 activation by immunohistochemistry in different clinical nephropathies.

Results: Podocyte STAT5 deficiency exacerbated proteinuria in both nephrotoxic nephritis and adriamycin nephropathy. In addition, loss of STAT5 in podocytes associated with a loss of epithelial markers, such as nephrin, and exaggerated foot process effacement. Furthermore, podocytic STAT5 is activated in vitro by interleukin 15. Tubular STAT5 deficiency aggravated renal dysfunction and tubular injury in cisplatin nephropathy. In man, we observed STAT5 activation in injured podocytes in focal and segmental glomerulosclerosis, and in tubular cells in those with acute tubular injury.

Conclusions: Our results suggest a novel protective role of the STAT5 transcription factor in podocytes and tubular epithelium in experimental nephropathy. Our clinical data suggest a similar cellular activation of STAT5 as seen pre-clinically. Epithelial STAT5 activation could represent a potential therapeutic target in AKI.

SA-PO075

Regulation of Epidermal Growth Factor Induced Rac1 Activity by the Adapter Protein Dok-4

Serge Lemay,[2,3] Victoria Roodman,[2,1] Cindy Baldwin,[2,1] Agnieszka Masztalerz,[2] Yoon Namkung,[2] Stephane A. Laporte,[2,1] Tomoko Takano.[2,3] *[1]McGill University, Montreal, QC, Canada; [2]Metabolic Diseases and Complications Program, Research Institute of the McGill University Health Centre, Montreal, QC, Canada; [3]Dept. of Medicine, Div. of Nephrology, McGill University Health Centre, Montreal, QC, Canada.*

Background: Following renal ischemia-reperfusion injury (IRI), locally produced or exogenously administered growth factors such as EGF promote tubular repair. To better understand the intracellular signaling events that may regulate this response, we explored the role of Dok-4, a highly conserved member of the Dok family of adapter proteins most abundantly expressed in epithelial cells and thought to mediate inhibitory signaling through largely undefined molecular interactions.

Methods: We screened a kidney cDNA library by yeast two-hybrid using Dok-4 as bait, with co-expression of the tyrosine kinase Lyn in order to detect phspho-Tyr (pY)-dependent interactions. Interactions were validated and their structural basis mapped by mutagenesis, co-IP and pull-down in transfected 293 cells. Expression of relevant proteins was confirmed in mouse kidneys subjected to 30 min. of unilateral ischemia and in sham controls. A novel bioluminescence resonance energy transfer (BRET)-based Rac1 assay was used to study the impact of Dok-4/Chn2 interaction in on EGF-induced Rac1 activity.

Results: The Rac1 GTPase activating protein (GAP) β2-chimerin (Chn2) was identified as a Dok-4 partner. This interaction involved binding of the Dok-4 PTB domain to phosphorylated Y153 of Chn2. Notably, Chn2 Y153 is contained within a canonical PTB-binding motif (NPXY) that is conserved in the highly homologous Rac-GAP α2-chimerin (Chn1), where pY143 can also mediate binding to Dok-4. While Dok-4 protein is expressed in kidney tissue and all cultured tubular cells examined to date, Chn2 protein was undetectable except in cerebellum. However, 24h after renal IRI, Chn2 was strongly expressed. BRET-based quantification of GTPase activity in 293 cells showed a rapid activation of Rac1 by EGF. Chn2 attenuated this activation in the presence of Dok-4 WT, but not mutant Dok-4 lacking the membrane-targeting PH domain. Retargeting of mutant Dok-4 to the membrane by a myristoylation signal rescued the cooperative inhibition of Rac1 by Dok-4 and Chn2.

Conclusions: The Rac-GAP Chn2 is a novel pY-dependent Dok-4 partner and effector expressed in the injured kidney. Dok-4 facilitates inhibition of Rac1 by promoting recruitment of Chn2 at the membrane. This cooperative inhibition of Rac1 may regulate key downstream events in renal IRI, including proliferation, migration and tubular repair.

SA-PO076

Induction of Hnf-1β Transcription Factor Protects Against Epithelial Hypoxia During Renal Ischemia-Reperfusion Injury

Mengna Ruan,[2] Jielu Hao,[1] Zhenhua Wang,[2] Sixiu Chen,[4] Jie Zhou,[3] Changlin Mei.[4] *[1]Mayo Clinic, Rochester, MN; [2]Changzheng Hospital, Second Military Medical University, Shanghai, China; [3]Shuguang Hospital, Shanghai, China; [4]Changzheng Hospital, Shanghai, China.*

Background: Ischemia-reperfusion injury is the crucial cause of acute kidney injury (AKI) in clinical settings. Proximal tubular cells are highly sensitive to ischemic injury and the following repair capability. Hnf-1β transcription factor drives the normal nephrogenesis and epithelial homeostasis. In the present study, we investigated the role of Hnf-1β regulation against hypoxic damage of proximal tubular cells in renal ischemia-reperfusion injury.

Methods: Renal ischemia-reperfusion was induced by bilateral clamping renal pedicles, the clamps were released for reperfusion. Kidney function was measured by BUN and serum creatinine, pathological damage was evaluated by HE and TUNEL stain. In vitro, cells were treated with hypoxia (1% oxygen) to represent ischemic condition, to test the effect of Hnf-1β, the editing-proficient Cas9 cell line was generated before hypoxia. The expression of Hnf-1β was tested by western blot and IHC. Flow cytometry and Hoechst stain were used to detect apoptosis. To explore the further effect of GJB1, the down-regulated stable cell line was created, and the expression was tested by realtime PCR. ChIP analysis was used to confirm the binding of NF-κB and Hnf-1β.

Results: Using western blot, we identified expression of Hnf-1β are significantly increased in kidney after 30 minutes of bilateral renal ischemia and reperfusion 12h, while the IHC staining showed the signal mainly in cortex. In vitro, hypoxia can also induce Hnf-1β in rat kidney epithelial cells (RPTC) as early as 4h and lasted to 12h. Interestingly, CRISPR/Cas9-mediated Hnf-1β knockout cells exacerbated apoptosis induced by hypoxic condition and caspase activity, whereas overexpression of Hnf-1β revealed more resistant to apoptotic responses in hypoxic cells. We further indicated these protective effects of Hnf-1β were mediated by *NF-κB,* which were confirmed by ChIP analysis, and its specific inactivator TPCA-1. Moreover, we also show that gap junction gene GJB1 could serve as downstream target of Hnf-1β as evidenced inhibition of GJB1 rescued Hnf-1β anti-apoptotic effect.

Conclusions: The study indicates the protective role of Hnf-1β against ischemic/hypoxic conditions in kidney. Hnf-1β performs anti-apoptotic factor mediated by NF-κB, and the renal protective effect may carry out via regulating its downstream gene GJB1.

SA-PO077

Inhibition of Ataxia-Telangiectasia Mutated Exacerbates AKI by Activating p53 Signaling in Mice

Masahiro Uehara, Tetsuro Kusaba, Noriyuki Yamashita, Keiichi Tamagaki. *Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: The DNA damage response (DDR) after kidney injury induces cell cycle arrest in renal tubular epithelial cells. Cell cycle-arrested tubular epithelia secrete pro-fibrotic cytokines, thereby promoting interstitial fibrosis in a paracrine manner. Phosphorylation of ataxia-telangiectasia mutated (ATM) is the initial step in DDR and subsequent cell cycle arrest. ATM inhibitors are emerging cancer drug candidates; however, the effects of ATM inhibition on the injured kidney have not been explored.

Methods: We administered KU55933, a selective ATM inhibitor, to cisplatin-treated mice and UUO mouse model. In order to specifically investigate the underlying mechanism in tubular epithelia, we isolated the proximal tubular epithelia by FACS from bigenic SLC34a1-CreERt2; R26tdTomato proximal tubular-specific reporter mice.

Results: ATM inhibition did not ameliorate but rather exacerbated cisplatin-induced DNA damage and tubular injury, thereby increasing mortality. Numerous tubules with denuded tubular basement membrane where the tubular epithelia had completely detached were observed in the kidneys of mice that received KU55933 and cisplatin. Analysis of isolated tubular epithelia revealed that KU55933 upregulated p53 and subsequent pro-apoptotic signaling, such as PUMA and Bax expression, in tubular epithelia of cisplatin-treated mice, leading to marked mitochondrial injury and apoptosis. In addition, ATM inhibition did not increase the nuclear expression of MutL homologue 1 in tubular epithelia of cisplatin-treated mice, suggesting that DNA mismatch repair after tubular injury was not sufficient to prevent cisplatin-induced tubular injury. Lastly, we investigated the effect of ATM inhibition on UUO kidney and found that KU55933 did not ameliorate the kidney fibrosis.

Conclusions: Our study suggested that ATM inhibition does not increase DNA repair after cisplatin-induced DNA damage and exacerbates tubular injury through the upregulation of p53-dependent pro-apoptotic signaling. Acute kidney injury must be carefully monitored when ATM inhibitors become available in clinical practice in the future.

SA-PO078

PTIP Deletion in Renal Proximal Tubules May Cause Epigenetic Change and Prevent Recovery After AKI

Abdul A. Soofi, Greg R. Dressler. *University of Michigan, Ann Arbor, MI.*

Background: Paxip1gene encodes a PTIP nuclear protein that is expressed in most cells and is implicated in a variety of nuclear processes, including DNA repair, and transcription activation. Consequent to acute kidney injury (AKI), surviving proximal tubule cells re-enter mitosis and will form cysts if disease associated genes are mutated. Thus, epigenetic information that maintain a stable phenotype must be reset during regeneration. PTIP is part of an Mll3/4 histone H3K4 methyltransferase complex that is essential for development. To test whether such epigenetic imprints are dependent on histone H3K4 methylation, we generated a mouse model with deletion of PTIP (PTIP-) in the terminally differentiated renal proximal tubular cells.

Methods: We used Cre-loxP system, standard genetic and biochemical techniques to generate and study the deletion of PTIP- specifically in renal proximal tubular cells. Also mice carried the mT/mG; Pepck-cre. Mice were age-matched and injected i.p with a single dose of folic acid.

Results: The kidneys of mice carrying the PTIP- appeared normal with little evidence of loss of kidney function or other abnormalities. Upon AKI, such mice failed to regenerate damaged tubules leading to scarring and interstitial fibrosis. The inability to repair damage was likely due to a failure to re-enter mitosis and reactivate regulatory genes such as Sox9. PTIP- reduced histone H3K4M3 in uninjured kidneys but had no effect on H3K4M2. A transient decrease in trimethylation was also observed in controls after AKI but returned to normal after repair. Strikingly, cell lineage tracing revealed that surviving PTIP mutant cells could alter their phenotype and lose epithelial markers. These data demonstrate that PTIP is needed for regenerating proximal tubules and to maintain or reestablish the cellular phenotype

Conclusions: The process of regeneration must require changes in gene expression of surviving epithelial cells, which may involve the reactivation of genes controlling development and proliferation. Despite PTIP-, mice had no gross morphological phenotypes, suggesting that PTIP- at this stage of differentiation had little apparent effect on kidney function. However, when such mice were subjected to AKI, the ability to repair and repopulate damaged tubules was severely compromised.

SA-PO079

HDAC3 Contributes to Necrotic Tubular Damage in Ischemic AKI

Guie Dong,[1,2] Zheng Dong.[1,2] *[1]Department of Cellular Biology and Anatomy, Medical College of Georgia at Augusta University, Augusta, GA; [2]Charlie Norwood VA Medical Center Augusta Georgia, Augusta, GA.*

Background: Histone deacetylases (HDAC) are group of enzymes that remove acetyl groups from lysine residues of histone and nonhistone proteins. The action of histone deacetylation condenses chromatin and DNA structure, resulting in the repression of gene transcription and expression. We reported that HDAC inhibitors attenuate apoptosis of renal proximal tubular cells during cisplatin treatment. This study was designed to determine the specific role of HDAC3 in acute kidney injury (AKI).

Methods: In vivo, we generated proximal tubule-specific HDAC3 knockout (PT-HDAC3-ko) mice, which were subjected to 30mins of ischemia with 48hrs of reperfusion. We also tested the effect of RGFP966, a specific pharmacological inhibitor of HDAC3. Serum sample was collected to check blood urea nitrogen (BUN) and serum creatinine. Kidney tissue was collected for histology, immunohistochemistry and immunoblot analysis. In vitro, rat proximal tubular cells (RPTC) were treated with azide for 4.5hrs followed by 2hr reperfusion to induce necrotic cell death to examine the effects of RGFP966. Necrosis was indicated by propidium iodide staining and LDH release. In addition, the effect of HDAC3 knockdown was examined.

Results: HDAC3 was localized in the nucleus and cytoplasm of proximal tubular cells in kidneys. After ischemic AKI, HDAC3 was induced. Compared to wild-type mice, PT-HDAC3-ko mice showed less ischemic AKI as indicated by less necrotic damage in proximal tubules and improved renal function with lower levels of BUN and serum creatinine. Consistently, RGFP 966 protected against ischemic AKI in mice. In immunoblot analysis, acetylation of histone H3, H2B and H4 was better preserved in kidney tissues of PT-HDAC3-ko mice. In RPTC cells, HDAC3 was induced during azide treatment and significantly increased during subsequent recovery. Both RGFP966 and HDAC3 knockdown suppressed HDAC3 induction and preserved the acetylation of histone H3, H2B and H4. Notably, both RGFP966 and HDAC3 knockdown suppressed necrosis following azide treatment.

Conclusions: HDAC3 is induced during ischemic AKI and plays an important role in necrotic damage in proximal tubules. Specific blockade of HDAC3 may have therapeutic potential in AKI.

Hdac8 Knockout Results in Amelioration of AKI in Zebrafish

Hwa I. Han,[1] Amanda Crunk,[1] Christine M. Crana,[2,1] Michael D. McDaniels,[1] Neil A. Hukriede.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA.*

Background: Despite the prevalence of AKI, the need for therapeutics is currently unmet. One candidate for a small molecule therapeutic is 4-(phenylthio) butanoic acid (PTBA), which had previously shown increased RTEC productive repair and functional recovery by enhancing dedifferentiation and decreasing injury in both murine and zebrafish models of AKI. Here, we show that histone deacetylase 8 (HDAC8) is potential target of PTBA. HDAC8 is known to interact with cell cycle regulators, such as SMC3 and p53, to acetylate and modulate cell cycle activity. We further investigate the role of Hdac8 in affecting the cell cycle using a larval zebrafish model of AKI.

Methods: Cellular thermal shift assay (CETSA) was used to evaluate the target engagement of PTBA with HDACs. *hdac8*$^{sa14948/-}$and *hdac8* $^{sa14948/+}$mutant zebrafish were injected with gentamicin to induce AKI and observed for post-injury survival from 1-7dpi. Cells harvested from whole larvae were stained with propidium iodide and analyzed with flow cytometry for variation in the cell cycle phase. Using cell cycle specific antibodies, EdU and pH3, larval pronephros were stained for S and G2/M phases at various timepoints following AKI.

Results: PTBA was shown to stabilize HDAC8 at higher temperatures compared to control, consistent with PTBA binding to HDAC8. *hdac8* $^{sa14948/-}$ fish showed significantly increased survival when compared with wildtype and *hdac8* $^{sa14948/+}$. Analysis of whole larvae cell cycle showed increased G1/S population with injury at 1dpi. Immunohistochemistry showed increased EdU during an early injury timepoint (1dpi) while showing delayed G2/M entrance in a later injury timepoint (4dpi).

Conclusions: Absence of Hdac8 in larval zebrafish model of AKI improved survival. The survival correlated with increased G1/S cell cycle phase during earlier timepoints of injury, as well as delayed entrance to G2/M. Here, we demonstrate the role of Hdac8 in increasing repair by delaying proliferation after injury. Furthermore, we have identified PTBA as an HDAC8 inhibitor. Taken together these data suggest a potential mechanism to induce productive repair after an AKI event.

SA-PO081

Removal of Apoptotic Cells During AKI

Sho Morioka, Shinji Tanaka, Nataliya Skrypnyk, Mark D. Okusa, Kodi S. Ravichandran. *University of Virginia, Charlottesville, VA.*

Background: The incidence of acute kidney injury (AKI) is increasing worldwide, however, effective treatment for AKI remains elusive and no approved pharmacological agents exist. Tubular cell apoptosis has been shown to be present in preclinical models and also in some clinical samples from patients with AKI. The human body removes over 200 billion dead cells every day. This process, i.e. clearance of apoptotic cells or 'efferocytosis', occurs in nearly every major organ (Morioka et al., Nature 2018). Clearance machinery can often become overwhelmed by massive induction of apoptosis such as occurs with ischemia reperfusion injury (IRI). While it has been shown that defective clearance leads to exacerbation of AKI, whether promoting efferocytosis leads to amelioration of AKI has not been explored.

Methods: In order to delinate whether apoptotic cell clearance could be boosted for beneficial effects during AKI, we established a way to boost apoptotic cell clearance by modulating the protein structure of a previously characterized phosphatidylserine (PtdSer) receptor, BAI1. Previous studies have shown that while BAI1 interacts PtdSer via its extracellular region, BAI1 also binds via its cytoplasmic tail to ELMO1 and in turn, a second protein Dock180, which together serve as a guanine nucleotide exchange factor complex for the GTPase Rac1. Activation of Rac1 induces a conformational change of the actin filament to initiate the uptake of target cells. We generated a chimeric version of BAI1 where we deleted the natural ELMO1 binding site and directly fused ELMO1 to the BAI1 cytoplasmic tail (denoted BELMO).

Results: Strikingly, we found that expression of this chimeric BELMO receptor strongly boosted apoptotic cell engulfment. This chimeric receptor still behaved faithfully as it was dependent on PtdSer recognition, and an intact ELMO1 that can engage the downstream Dock180 and Rac1 signaling machinery. We have also generated transgenic mouse expressing BELMO receptor. We demonstrate that BELMO expression in tubular epithelial cells significantly improved the survival rate of the mice underwent AKI induced by renal IRI surgery.

Conclusions: Here we open up new avenue for targeting cell clearance in AKI therapy. In addition, BELMO transgenic mice allow us to explore the effect of boosting apoptotic cell clearance on variety of other disease models involving accumulation of dead cells.

SA-PO082

Quantifying Autophagic Flux in Kidney Tissue with Super-Resolution Structured Illumination Microscopy Imaging

Bertha C. Elias,[1] Kensei Taguchi,[1] Craig R. Brooks.[1,2] *[1]Vanderbilt University Medical Center, Division of Nephrology & Hypertension, Nashville, TN; [2]Vanderbilt University School of Medicine, Cell and Developmental Biology, Nashville, TN.*

Background: Autophagy, a key homeostatic catabolic pathway in eukaryotic cells, is linked to pathological conditions in most organs as well as cancer and aging. In the kidney, autophagy has been shown to modulate both acute and chronic injury. Despite the importance of autophagy, few methods are available to monitor autophagic flux, i.e. clearance of autophagosomes by the lysosome. Autophagy is usually evaluated by presence of autophagosomes, LC3 II levels or EM but not autophagic flux. We combined the RFP-GFP-LC3 reporter mice with super-resolution structured illumination microscopy (SIM) to measure autophagic flux at an individual autophagosome level in response to kidney ischemia.

Methods: Kidneys of RFP-GFP-LC3 reporter mice were injured by unilateral ischemic reperfusion injury. The GFP of the reporter is sensitive to low pH, quenching the fluorescent signal upon autophagosome/lysosome fusion, leaving only RFP signal. At 48 hours the kidneys were harvested, fixed and paraffin imbedded. The tissue was sectioned at 4-6μm and mounted on silanized coverslips. Immunofluorescence staining was done using

antibodies against GFP and RFP and stained with DAPI. The tissue was imaged using an N-SIM microscope to obtain Z stacks. These images were reconstructed using Bitplane's Imaris software. Colocalization of RFP and GFP was quantified using NIS elements.

Results: SIM imaging captured LC3 positive structures ranging in size from <0.3 μm to >4 μm. LC3 positive autophagosomes were present in larger numbers and size in injured kidneys compared to contralateral. Analysis of the colocalization of RFP with GFP, to quantify flux, in the control kidney showed the presence of many small RFP only positive organelles, indicating that these were autolysosomes, i.e. autophagosomes fused with lysosomes. In the injured kidney the organelles were larger and positive for both RFP and GFP, thus indicating more autophagosomes but a lower autophagic flux.

Conclusions: Combining the RFP-GFP-LC3 reporter mouse with SIM imaging allows for the quantification of individual autophagosomes in kidney tissue and measurement of the dynamic flux of the process. In unilateral IRI injury, we found the autophagic flux to be higher in the contralateral kidney than the injured kidney at 48 hours despite the presence of very large autophagosomes. These data suggest autophagic clearance is overwhelmed following ischemic injury.

SA-PO083

Mapping and Functional Characterization of Proteolytic Cleavage of Murine Kidney Injury Molecule 1

Saranga Sriranganathan,[1] Ji yun Lee,[1] Lakshman Gunaratnam.[1,2] [1]*Schulich School of Medicine and Dentistry, Western University, London, ON, Canada;* [2]*Medicine, London Health Sciences Centre, London, ON, Canada*.

Background: Kidney injury molecule-1 (KIM-1) is a type I transmembrane glycoprotein expressed apically on proximal tubule epithelial cells. KIM-1, absent in healthy kidneys, is upregulated transiently during acute kidney injury (AKI). KIM-1 as a phagocytic receptor plays a protective role during AKI facilitating the clearance of apoptotic cells (efferocytosis) from the tubular lumen, thereby reducing inflammation and promoting repair. Human KIM-1 undergoes spontaneous and accelerated ectodomain shedding (into urine and blood) via metalloproteases including TACE/ADAM17 and ADAM10. Both blood and urine KIM-1 are clinically relevant biomarkers for AKI, however, the biological role of KIM-1 shedding is not known. In order to study significance of KIM-1 shedding *in vivo* in mice, we first aimed to identify the murine KIM-1 cleavage site and study its functional relevance *in vitro*.

Methods: Based on common structural motifs involved in TACE and ADAM10 recognition of substrates, we mapped out a potential cleavage site between A201 and I202 within the predicted cleavage region T194 to I202. Site-directed mutagenesis was used to generate various substitution mutants (I202Q and I202A) at the P1' position of the potential cleavage site. We generated HEK293 cells stably expressing expression vectors encoding either *wild type* (WT), I202Q or I202A (murine) KIM-1. Expression of KIM-1 was verified by Western blot. Phorbol 12-myristate 13-acetate (PMA) and ionomycin were used to induce general metalloprotease- or ADAM10-mediated shedding, respectively, with or without GI254023X (ADAM10-specific inhibitor). Transfected cells were fed pHrodo stained apoptotic thymocytes and percent efferocytosis was quantified using flow cytometry. ADAM10 siRNA was used to study effect of ADAM10 silencing on KIM-1 shedding and efferocytosis.

Results: Both PMA and ionomycin accelerated shedding were drastically reduced in both (I202Q and I202A) mutants compared to WT. Efferocytosis was significantly reduced with the two mutants compared to WT KIM-1. Cells treated with ADAM10 inhibitor or ADAM10 siRNA exhibited significantly reduced efferocytosis compared to their respective controls.

Conclusions: ADAM10 is involved with both *baseline* and *accelerated* shedding of murine KIM-1. ADAM10-mediated KIM-1 shedding is required for efficient efferocytosis.

The Protective Effects of Novel HIF-Hydroxylase Inhibitors in Renal Tubules

Steffen Grampp, Victoria Lauer, Johannes Schödel. *Universitätsklinikum Erlangen, Erlangen, Germany*.

Background: Acute kidney injury (AKI) has an increasing incidence. To date there are no specific pharmacological treatment options for AKI. Results from multiple rodent models of AKI suggest that the pre-conditional stabilization of hypoxia-inducible factors (HIFs) in renal tubular epithelial cells leads to improved kidney function. However, so far it is unclear whether these effects can be translated into human disease, and the underlying molecular mechanisms are poorly understood. HIF protein stability is regulated by prolyl hydroxylases (PHD) and HIF transcriptional activity is regulated by the Factor Inhibiting HIF (FIH). Novel inhibitors of PHDs (PHDi) have been developed to treat the anemia in chronic kidney disease by increasing EPO levels. Here we evaluate the effects of some of the novel selective PHDi on the HIF-response in human primary renal tubular cells and contrast them with effects of pan-hydroxylase inhibition.

Methods: Human primary renal tubular cells (hPTC) were isolated from kidney of patients undergoing tumour nephrectomy. hPTC were exposed to different hydroxylase inhibitors and HIF levels, HIF DNA-interactions as well as target gene induction were measured by western blotting, ChIP experiments and RNA analyses, respectively. We employed an in vitro model of cisplatin induced apoptosis to screen for protective effects of HIF stabilization in hPTC.

Results: PHDi stabilize HIF-1α protein to levels comparable to pan-hydroxylase inhibition by dimethyl oxalylglycine (DMOG) in hPTC. ChIP analyses confirmed comparable HIF-binding to selected gene loci under PHDi and DMOG. In contrast to equal protein levels and DNA-binding, transcriptional activation of selected HIF targets (CA9, EGLN3) was more pronounced in cells treated with DMOG suggesting that the additional inhibition of FIH increases the HIF response. PHDi led to reduced apoptosis in the cisplatin AKI in vitro model. However, combined inhibition of PHDs and FIH either by siRNA mediated knock-down or with a selective FIH-inhibition further increased target gene expression and cell protection.

Conclusions: Novel PHDi lead to a remarkable HIF-response in hPTC and have protective effects upon toxic stimuli. Additional inhibition of FIH which regulates HIF activity further improves cell survival. Therefore, pan-HIF hydroxylase inhibition is protective in tubular cells and might open a novel route into AKI treatment.

Deciphering the Molecular Mechanisms Underlying Nephroprotection by Hypoxia-Signalling: A Comparative Analysis of Prolyl Hydroxylase Inhibition and Hypoxic Preconditioning

Martin R. Späth,[1] Karla J. Hoyer-Allo,[1,2] Katrin Bohl,[1,2] Ingo Flamme,[3] Felix C. Koehler,[1,2] Franziska Grundmann,[1] Cedric Debes,[2] Andreas Beyer,[2] Bernhard Schermer,[1,2] Thomas Benzing,[1,2] Volker R. Burst,[1] Roman-Ulrich Mueller.[1,2] [1]*Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Germany, Cologne, Germany;* [2]*CECAD, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany;* [3]*Bayer Pharma AG, Wuppertal, Germany*.

Background: Acute kidney injury (AKI) is one of the most common kidney diseases leading to increased morbidity and mortality. However, preventive or therapeutic strategies in the clinical setting are still missing. In animal models, AKI can be effectively prevented by preconditioning strategies – e.g. activating hypoxia signalling – that increase cellular stress resistance. Since translation of this approach by exposure to hypoxia (HP) is not feasible in the clinical setting, pharmacological strategies would be a favourable alternative. Therefore, inhibition of prolyl-hydroxylases (PHDi) and consecutive activation of hypoxia inducible factors (HIF) is an attractive strategy. Our aim was to confirm the protection by HP and PHDi in renal ischemia-reperfusion injury (IRI) and to characterize shared molecular patterns to identify novel therapeutic targets.

Methods: Male 14-week-old C57Bl6 wildtype mice were either treated with a PHD-inhibitor or by incremental exposure to hypoxia on three following days aiming for a similar induction of the HIF-target gene EPO to increase the comparability of both approaches. Afterwards all mice underwent a right nephrectomy and 40 min of contralateral renal IRI. In the following they were characterized functionally (e.g. by creatinine), histologically and by a transcriptomic and proteomic analysis of the right and left kidneys to unravel the molecular key players.

Results: Hypoxia and PHD-inhibition significantly ameliorated AKI 24 h after reperfusion. Histological analysis confirmed the protective effect of both strategies. The omics-analyses of the right kidneys revealed only little influence of HP and PHDi before damage. After damage, kidneys from HP and PHDi treated animals differed strongly from controls. There was only a limited overlap between both approaches which will allow for narrowing down the pathways and genes causally involved in organ protection.

Conclusions: Here, we confirmed the protective effect of HP and PHDi and performed the first comparative molecular phenotyping of kidneys treated with these strategies. Future studies will answer the question whether the genes and pathways identified can be modulated to prevent AKI.

Identification of Small Molecule Inducers of Heme Oxygenase-1 (HO-1) in Renal Epithelial Cells

Amie Traylor,[1] Bini Mathew,[3] James R. Bostwick,[3] Ntsang M. Nebane-Ngwa,[3] James F. George,[1] Stephanie Esman,[1] Ling Zhai,[3] Mark J. Suto,[3] Anupam Agarwal.[1,2] [1]*University of Alabama at Birmingham, Mountain Brk, AL;* [2]*Birmingham VA Medical Center, Birmingham, AL;* [3]*Southern Research, Birmingham, AL*.

Background: Acute kidney injury (AKI) is a major public health concern that is associated with increased morbidity and mortality in hospitalized patients. Furthermore, the rising cost of care for these patients presents an increasing economic burden. While several promising biomarkers are emerging to aid in the early identification of AKI, no new therapies have succeeded in clinical trials. Currently, the only FDA approved treatment for AKI is dialysis. Recent studies from our laboratory and others have demonstrated the beneficial effects of HO-1, an enzyme that catalyzes heme breakdown into biliverdin, carbon monoxide and iron, in animal models of AKI.

Methods: We designed an assay suitable for high throughput screening to assist in the identification of novel small molecule targets that both induce HO-1 and have desirable pharmacologic characteristics. We created a stable HEK293 cell line that contains portions of the human HO-1 promoter and a unique 220 bp enhancer sequence in a luciferase reporter vector to screen a library of >150,000 compounds.

Results: We identified 2240 candidate compounds in the initial screen. Based on chemical structure, we pared these down to 800. Compounds exhibiting $E_{max} \geq 70\%$ of 5uM hemin and $EC_{50} < 10mM$ were assayed for endogenous HO-1 expression in HEK293 cells. The screen was repeated on a library of >4,000 FDA approved compounds and several additional candidates were identified, including broxaldine, an antiprotozoal drug. At low micromolar concentrations (1-5uM), broxaldine induced markedly high expression of HO-1 mRNA, protein and enzyme activity. Using RNA seq, the transcription factor,

Nrf2 was identified as a target for broxaldine induced HO-1 expression, which was confirmed using siRNA experiments. We further assessed the potential for broxaldine to inhibit cisplatin-induced cytotoxicity in HEK293 cells. Pretreatment with broxaldine preserved cell viability and reduced cleaved caspase-3 expression.

Conclusions: These studies provide a methodology for the identification of compounds that are clinically relevant and efficacious in inducing HO-1, and therefore confer protection against a variety of pathologies, including AKI.

SA-PO087

The Effects of PARP Inhibitor Treatment on Early Renal Injury in a Murine Ischemic AKI Model

Kyungho Lee, Hye Ryoun Jang, Seungmin Song, Song in Baeg, Junseok Jeon, Jung eun Lee, Yoon-Goo Kim, Dae joong Kim, Wooseong Huh. *Nephrology Division, Department of Medicine, Samsung Medical Center, Samsung Biomedical Research Institute, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Intrarenal robust inflammatory responses following ischemia-reperfusion injury are major factors in the pathogenesis of renal injury in ischemic AKI. Although numerous studies have investigated various agents to modulate immune responses in ischemic AKI, few have demonstrated reproducible effects in animals and humans. We hypothesized that poly(ADP-Ribose) polymerase(PARP) inhibitor may change the post-ischemic intrarenal immunologic micromilieu favorably by reducing DAMP signal and protect the kidneys from further damage after ischemic injury. The effects of JPI-289 (PARP inhibitor) on early renal injury in a murine ischemia-reperfusion injury model were investigated.

Methods: Bilateral ischemic-reperfusion injury (BIRI) was induced in three groups of 9-week male C57BL/6 mice (control, JPI-289 50mg/kg, and JPI-289 100mg/kg; n=9-10 in each group) by laparotomy approach. Intraperitoneal injection of saline or JPI-289 were performed immediately before reperfusion and at 24 hours after IRI. Serial changes in renal function were assessed up to day 3 following BIRI. The effects of JPI-289 on HK-2 cells after a hypoxic insult were investigated.

Results: Deterioration of renal function was significantly attenuated in the JPI-289 treatment groups in a dose-dependent manner. The expression of proinflammatory cytokines such as IFN-γ, IL-2, and MCP-1 was reduced by the JPI-289 treatment, while intrarenal VEGF expression was higher after IRI in the JPI-289 groups. Intrarenal T cell infiltration following IRI was comparable between control and JPI-289 groups, but intrarenal B cell infiltration was increased by JPI-289 treatment. Low dose (0.5 μg/mL) JPI-289 treatment facilitated proliferation of hypoxic HK-2 cells, but very low dose or high dose treatment did not show favorable effects on hypoxic HK-2 cells.

Conclusions: JPI-289 treatment attenuated early renal injury in a murine ischemic AKI model and facilitated proliferation of hypoxic HK-2 cells. Further studies are needed to identify optimal dosage and administration timing of JPI-289 treatment.

SA-PO088

JNK Signalling Mediates Oxidant-Induced Tubular Epithelial Cell Death

Keren Grynberg,[1,2] Gregory H. Tesch,[1,2] Elyce Ozols,[1,2] William R. Mulley,[1,2] David J. Nikolic-Paterson,[1,2] Frank Y. Ma.[1,2] *[1]Department of Nephrology, Monash Medical Centre, Monash, VIC, Australia; [2]Centre for inflammatory diseases, monash univeristy, Melbourne, VIC, Australia.*

Background: The reactive oxygen species-inducible JNK signaling pathway is activated in tubular cells within 20min of renal ischaemia/reperfusion (I/R) injury. Tubular cell death following I/R injury is reduced by systemic JNK inhibitor treatment, but whether this is a direct or indirect effect and the contribution of JNK1 versus JNK2 isoforms are unclear. We aimed to define the role of JNK1 versus JNK2 signaling in oxidant-induced tubular cell death and whether this mechanism also operates in diabetes.

Methods: Bilateral renal I/R injury was induced in groups (n=8 to 10) of male wild type (WT), Jnk1-/-, Jnk2-/-, and Jnk1f/f γGT-Cre mice (all C57BL/6J) which were killed 24hr later. Diabetes was induced in WT mice by 5 low dose streptozotocin (STZ) injections.

Results: Compared to renal I/R injury in WT mice, Jnk1-/- but not Jnk2-/- mice were significantly protected from tubular cell death (PAS and cleaved caspase 3 staining) and renal failure (serum creatinine) (both P<0.01). Furthermore, conditional deletion of Jnk1 in proximal tubular cells (Jnk1f/f γGT-Cre mice) also showed a significant reduction in tubular cell death and renal failure (both P<0.01 vs WT I/R). H2O2 (0.25 to 1mM) induced dose-dependent cell death in primary cultures of WT tubular epithelial cells (TEC); however, Jnk1-/- TEC showed 50%↓ cell death (P<0.001), whereas Jnk2-/- TEC showed no protection. A JNK inhibitor reduced H2O2-induced cell death in WT and Jnk2-/- TEC by 50%, but did not affect cell death in Jnk1-/- TEC. In a further study, renal I/R injury was induced in WT mice 8 weeks after STZ-induced diabetes. Compared to non-diabetic controls, I/R injury caused increased JNK signalling, greater tubular cell death and more severe renal failure (all P<0.01 vs non-diabetic I/R). Culture of WT TEC in high glucose for 48hr increased H2O2-induced cell death. However, a JNK inhibitor reduced H2O2-induced cell death under high glucose by 38 to 45% (P<0.001).

Conclusions: JNK1 but not JNK2 direct contributes to oxidant-induced tubular cell death in vivo and in vitro. JNK signalling may also promote the enhanced tubular cell death and renal failure seen in renal I/R injury in established diabetes.

SA-PO089

Greater High-Mobility Group Box 1 (HMGB1) in Male Spontaneously Hypertensive Rats (SHR) Enhances Renal Ischemia-Reperfusion (IR) Injury Compared with Females

Riyaz Mohamed,[1] Olga Rafikova,[2] Paul O'Connor,[1] Jennifer C. Sullivan.[1] *[1]Augusta University, Medical College of Georgia, Augusta, GA; [2]University of Arizona, Tucson, AZ.*

Background: Renal IR injury is a major cause of acute kidney injury, which carries a high mortality rate and increases the risk of later developing hypertension and CKD. There are sex differences in renal IR injury, with males exhibiting greater injury following an ischemic insult than females. The mechanisms that are responsible for observed sex differences in IR injury are unknown. Recent studies have reported that increased HMGB1 after renal IR in males contributes to renal damage. The contribution of HMGB1 to renal IR injury in females is unknown. We hypothesis that greater HMGB1 in males promotes enhanced renal IR injury compared to females.

Methods: 13wk old male and female SHR were subjected to sham or 45-min warm bilateral ischemia followed by 24hr reperfusion. A separate set of SHR were pre-treated with control (IgG) or neutralizing anti-HMGB1 antibody (300 μg/rat) 1hr prior to renal IR (n=4-6). Blood was collected for biochemical analysis; kidneys were harvested for histological and WB analysis.

Results: IR significantly increased renal HMGB1 levels in both sexes compared to sham (P_{IR}<0.001). Renal HMGB1 levels were greater in males vs. females, although the effect of IR to increase HMGB1 levels was comparable between the sexes (P_{sex}= 0.009, $P_{sex*IR=}$0.3). Treatment with anti-HMGB1 ab prior to IR attenuated IR-induced increases in plasma creatinine ($P_{anti-HMGB1}$=0.02), tubular damage ($P_{anti-HMGB1=}$0.04), and tubular cell death ($P_{anti-HMGB1=}$0.04) compared to rats receiving control IgG. However, effect of anti-HMGB1 ab was only observed in males; treatment with anti-HMGB1 did not alter plasma creatinine (P_{sex}=0.1; $P_{sex*anti-HMGB1}$=0.0039), tubular damage (P_{sex}=0.99; $P_{sex*anti-HMGB1}$<0.003) and tubular cell death (P_{sex}=0.07; $P_{sex*anti-HMGB1=}$0.05) following IR in females. In addition, HMGB1 neutralization attenuated IR-induced activation of pro-inflammatory signaling molecules downstream of HMGB1 only in male SHR, including decreased renal Toll-like receptor (TLR) 4 phosphorylation ($P_{anti-HMGB1}$=0.08; $P_{sex * anti-HMGB1}$=0.004), IL1β mRNA ($P_{anti-HMGB1}$=0.04; $P_{sex * anti-HMGB1}$=0.05) and plasma TNFα ($P_{anti-HMGB1}$=0.61; $P_{sex * anti-HMGB1}$=0.03).

Conclusions: In conclusion, greater levels of HMGB1 in males compared to females results in enhanced pro-inflammatory signaling and exacerbation of IR-induced injury.

Cyclo(His-Pro) Prevents Against Oxidative Stress-Induced Renal Apoptosis and Fibrosis Through Activating the Nrf2-Mediated Pathway

Ji Eun Kim,[1] Yong Chul Kim,[1] Jong joo Moon,[1] Jinseon Jeong,[1] Sunhwa Lee,[1] Dong Ki Kim,[1] Yon Su Kim,[2] Seung Hee Yang.[3] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea.*

Background: Apoptosis is a key feature of the pathogenicity associated with glomerular and tubulo-interstitial injury of acute kidney injury (AKI) and chronic kidney disease (CKD). Cyclo(His-Pro) (CHP) is an endogenous cyclic dipeptide that exerts cellular protective effects against oxidative damages. Here, we show that treatment with exogenous (recombinant) CHP prevented renal structural and functional injury triggered by experimental ischemia-reperfusion injury (IRI) model in mice as well as 5/6 nephrectomy (Nx) model in rat.

Methods: In this study, to investigate the effect of CHP on AKI, we used IRI mice model and hypoxia-induced in vitro models with cultured human tubular epithelial cells (TECs). In addition, 5/6 nephrectomy rat model and TGFβ- and hydrogen peroxide (H2O2)-induced apoptosis models with cultured human podocytes were employed.

Results: Exogenous CHP pre-treatment prevented kidney function and accompanied by a significant reduction in ischemia-induced tubular injury, apoptosis, and inflammatory cell infiltration on renal IRI model. In vitro stimulation of TECs with hypoxia, CHP-mediated renal protection was associated with reduced IL-11, IL-18, reactive oxygen species (ROS) and the proportion of dead cells. Compared with control-treated 5/6 Nx rat, CHP-treated 5/6 Nx rat also restored kidney function and decreased proteinuria and pathologically decreased glomerulosclerosis, tubule-interstitial fibrosis in the remnant kidney of 5/6 nephrectomized rat. The administration of exogenous CHP significantly reduced not only ROS production via Nrf2-dependent pathway, but also the resultant apoptosis induced by H2O2 in cultured human podocytes. Microarray analysis highlights a cascade of specific gene expression patterns related to kidney injury, repair, and innate immunity. Notably, tubular epithelial cell and podocytes cell cycle arrest in G2/M mediates oxidative stress after injury.

Conclusions: This study has uncovered a major protective role of CHP in renal IRI and 5/6 nephrectomy through TECs and podocytes regeneration that could be potentiated as a therapeutic strategy.

SA-PO091

Tonsil-Derived Mesenchymal Stem Cells Protect the Kidney from Nephrotoxin-Induced AKI by an Amelioration of Oxidative Stress via Incorporation into Damaged Renal Tubules

Duk-Hee Kang, Eun sun Ryu, Sung min Jung, Dal-ah Kim. *Ewha University College of Medicine, Seoul, Republic of Korea.*

Background: The therapeutic effect of mesenchymal stem cells (MSCs) in repairing damaged renal cells in AKI has been demonstrated. Tonsil-derived MSCs (T-MSCs) derived from tonsillar tissues are reported to be effective in acute liver injury. The aim of this study is to investigate the therapeutic potential of T-MSCs in gentamicin-induced AKI

Methods: Twenty male Sprague-Dawley rats were divided into four groups: Control, GM (140 mg/kg/day, intraperitoneal injection for 10 days for 10 days), GM+T-MSCs ($1x10^7$ cells, intravenous injection at 1 day after the 1st GM injection), and T-MSC group. To examine the intra-renal localization of T-MSCs, T-MSCs were labeled with PKH-26 red fluorescence before infusion. Measurement of BUN, Cr, proteinuria and histologic analysis including TUNEL staining were performed on 16 days of GM injection. Effect of T-MSC on renal tubular cells was also evaluated using a transwell co-culture system of NRK cells and T-MSC. Intracellular ROS was analyzed by measuring NOX activity, H_2O_2 generation, NOX mRNA expressions with DCF-DA staining

Results: The infusion of T-MSCs in animal model of GM-induced AKI preserved renal function with a decrease in proteinuria. T-MSCs also ameliorated renal tubular dilatation and reduced apoptosis of renal tubular cells, which was associated with decreased number of apoptotic cells, down-regulating apoptotic genes and up-regulating anti-apoptotic gene. In addition, T-MSCs resulted in suppression of oxidative stress as reflected by a decrease in the level of urinary 8-OHdG with an increase in antioxidant enzymes (GPx and catalase) in the renal tissue. PKH-26-labeled T-MSCs were identified within the renal cortex and localized primarily in the renal tubules. The in-vitro study revealed that T-MSC and/or T-MSC-conditioned media ameliorated GM-induced NOX-1 expression, H_2O_2 generation, and apoptosis of NRK cells.

Conclusions: Our study demonstrated that T-MSCs ameliorated GM-induced AKI by directly incorporating into the damaged renal tubules, exerting anti-apoptotic and anti-oxidative effects

SA-PO092

Overexpression of MIOX Accentuates Gentamycin-Induced Acute Tubular Injury via ALOX12-12HETE-GPR31 Signaling

Isha Sharma,[1] Fei Deng,[1,3] Yingjun Liao,[1,2] Yashpal S. Kanwar.[1] *[1]Northwestern University Medical School, Chicago, IL; [2]Nephrology, Second Xiangya Hospital, Central South University, Changsha, China; [3]Urology, Third Xiangya Hospital, Central South University, Changsha, China.*

Background: Myo-inositiol oxygenase (MIOX), a renal tubular enzyme, has been implicated in the pathogenesis of high glucose and cisplatin induced tubular injury. Gentamycin is an aminoglycoside antibiotic used clinically, and it is known for its nephrotoxic effects. The mechanism(s) for its nephrotoxicity are somewhat elusive

Methods: In the present investigation, we identified a novel signaling pathway, i.e., arachidonate 12-lipoxygenase (ALOX12)–12-hydroxyeicosatetraenoic acid (12-HETE) G-protein-coupled receptor 31 (GPR31) axis, relevant to gentamycin induced tubular injury. Wild type (WT), MIOX overexpressing (MIOX-TG) and MIOX knockout (MIOX-KO) mice received daily intraperitoneal injections of gentamycin (100 mg/kg) for seven days. The following day animals were sacrificed, and their urine, blood and kidney samples were collected for various studies

Results: We observed that gentamycin-treated MIOX-TG mice had relatively high serum creatinine levels and increased albuminuria compared to WT mice, whereas MIOX-KO mice had minimal increase in serum creatinine and no detectable albuminuria. Interestingly, the increased ROS generation induced by gentamycin promoted the expression of MIOX via ROS modulation, leading to accentuated lipid peroxidation. Arachidonic acid, a fatty acid present abundantly in renal tubules, which is metabolized into 12-HETE by ALOX-12, leading to acute inflammatory response under various pathologic conditions. We observed significant increase in ALOX-12 expression and 12-HETE production in gentamycin-treated MIOX-TG and WT mice. These perturbations were minimally seen in gentamycin-treated MIOX-KO mice. MIOX gene disruption in HK-2 cells abolished gentamycin induced cascade of inflammatory signaling events (p-p44/42, p-pERK, p-p38, p-pJNK, p-Nf-kB). Of note, the gentamycin-induced up-regulated 12-HETE binds with GPR-31 to accentuate the inflammatory response in renal tubules, which was attenuated by ML-355 (inhibitor of ALOX-12).

Conclusions: Collectively, these studies highlight a novel mechanism, i.e., ALOX12-12-HETE-GPR31 signaling axis, in the pathogenesis of gentamycin-induced nephrotoxicity modulated by MIOX.

SA-PO093

3-Deazaneplanocin A Protects Against Cisplatin-Induced Tubular Cell Apoptosis and AKI by Restoration of E-Cadherin Expression

Jun Ni,[2] Hou X. Ying,[2] Xueqiao Wang,[3] Yingfeng Shi,[4] Liuqing Xu,[3] Na Liu,[5] Andong Qiu,[3] Shougang Zhuang.[1] *[1]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China; [3]Tongji University, Shanghai, China; [4]Nephrology, Shanghai Dongfang Hospital, Shanghai, China; [5]Shanghai East Hospital, Shanghai, China.*

Background: 3-deazaneplanocin A (DZNeP) has been used as an inhibitor of enhancer of zeste homolog 2 (EZH2). Here, we explore the role and underlying mechanisms of 3-DZNeP in cisplatin nephrotoxicity.

Methods: Cultured mouse renal proximal tubular epithelial cells (mTECs) were exposed to cisplatin in the presence or absence of EZH2 inhibitors (3-DZNeP, miRNA). A murine model of cisplatin-induced acute kidney injury was used to examine the effect of 3-DZNeP on cisplatin nephrotoxicity.

Results: Exposure of cultured mTECs to cisplatin resulted in dose and time-dependent cleavage of caspase-3, decrease of cell viability and increase of histone H3 lysine 27 trimethylation (H3K27me3), whereas expression levels of EZH2, a major methyltransferase of H3K27me3, were not affected. Treatment with 3-DZNeP significantly inhibited cisplatin-induced activation of caspase-3, apoptosis, loss of cell viability but did not alter EZH2 expression and H3K27me3 levels. Similarly, administration of 3-DZNeP also attenuated cisplatin-induced renal dysfunction, morphological damage and renal tubular cell death in a mouse model. Mechanistically, 3-DZNeP treatment did not affect activation of extracellular signal-regulated kinase 1/2, p38 or c-Jun N-terminal kinases 1/2, which contribute to renal epithelial cell death, but caused dose-dependent restoration of E-cadherin in mTECs exposed to cisplatin. Silencing of E-cadherin expression by siRNA abolished the cytoprotective effects 3-DZNeP. In contrast, 3-DZNeP treatment potentiated the cytotoxic effect of cisplatin in H1299, a non-small *cell* lung cancer cell line that expresses lower E-cadherin level.

Conclusions: These data indicate that 3-DZNeP can suppress cisplatin-induced tubular epithelial cell apoptosis and acute kidney injury via an E-cadherin dependent mechanism and suggest that combined application of 3-DZNeP with cisplatin is a novel chemotherapeutic strategy that enhances the anti-tumor effect of cisplatin and reduces its nephrotoxicity.

Renoprotective Effect of IL-34 Inhibition on Cisplatin-Induced Nephrotoxicity in Mouse

Yukihiro Wada,[1] Masayuki Iyoda,[2] Kei Matsumoto,[2] Taihei Suzuki,[2] Shohei Tachibana,[2] Nobuhiro Kanazawa,[2] Takanori Shibata.[2] *[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [2]Showa University School of Medicine, Tokyo, Japan.*

Background: Interleukin (IL)-34 is reported to mediate macrophage (Mø) proliferation and to be associated with kidney disease progression. However, the physiological properties of IL-34 on tubular epithelial cell (TEC) injury remain unclear. Thus, we investigated the effect of IL-34 on TEC damage caused by cisplatin nephrotoxicity (CP-N).

Methods: 7-week-old male C57BL/6 (B6) mice (n=16) were fasted for 8 hours and then induced CP-N by intraperitoneal injection (IP) of CP (25 mg/kg) on day 0. Groups of animals were given either anti mouse IL-34 antibody (CP+anti-IL-34 Ab, 400 ng/kg, n=8) or vehicle (CP+V, n=8) daily by IP from day -1 to day 2. Three age-matched male B6 mice were used as normal control (NC). All mice were sacrificed on day 3. In addition, mouse renal proximal TECs (MRTEpiC) were cultured to analyze the inhibitory effects of IL-34 on CP-induced TEC apoptosis. Cells were stimulated with CP (2 μg/mL), then treated with or without anti-IL-34 Ab (1000 pg/mL).

Results: Compared to the NC, CP+V mice exhibited marked acute kidney injury (AKI) and upregulated expression of IL-34 and its receptors, C-FMS and PTP-ζ. Compared to the vehicle treatment, anti-IL-34 Ab treatment significantly suppressed the protein levels of IL-34 and its receptors in CP-N mice; it also significantly improved serum Cr levels, ameliorated the numbers of casts/HPF, and suppressed the increased numbers of F4/80+, TUNEL+, and caspase-3+ cells in CP-N mice. The renal transcript levels of Kim-1, MIP-1/CCL3, TNF-α, and Bax were significantly lower in the CP+anti-IL-34 Ab mice than in the CP+V mice. Furthermore, CP+anti-IL-34 Ab mice showed significantly less renal infiltration of CD11b+F4/80+TNF-α+ cells. *In vitro*, stimulation with CP induced the expression of IL-34 and its receptors in MRTEpiC. Treatment with anti-IL-34 Ab significantly suppressed CP-induced caspase-3 and Bax expression with degradation of ERK1/2 phosphorylation in the damaged MRTEpiC.

Conclusions: These results indicated that IL-34 secreted from damaged TEC binds to its receptors and aggravates CP-N. Treatment with anti-IL-34 Ab directly prevented CP-induced TEC apoptosis by inhibiting the phosphorylation of ERK1/2, and the blocking of IL-34 might have indirectly attenuated CP-N via the suppression of cytotoxic Mø proliferation. Thus, IL-34 may be a therapeutic target for AKI.

SA-PO095

MeCP2 Promotes Cisplatin-Induced AKI Through Epigenetic Regulation of Irf8

Hui Tang, Hua Su, Chun Zhang. *Nephrology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*.

Background: Emerging evidence suggests that epigenetic regulation like DNA methylation plays an important part in the process of acute kidney injury (AKI), but the mechanism remains largely elusive. Methyl-CpG binding protein 2 (MeCP2) is an epigenetic regulator which binds to methylated cytosines and functions as gene transcriptional inhibitor or activator. The role of MeCP2 was examined most notably in brain development, while the involvement of MeCP2 in renal disease remains unknown.

Methods: Twenty male C57 mice were randomly grouped into control, cisplatin-1d, cisplatin-2d, and cisplatin-4d according to the time of execution after cisplatin intraperitoneal injection. HK-2 cells were exposed to cisplatin at 20uM for variable incubation time. HK-2 cells were transfected by siRNA to knockdown MeCP2 expression. Apoptosis was detected with the TUNEL method. Chromatin immunoprecipitation assay (CHIP) was used to analyze the binding of MeCP2 to the interferon regulatory factor 8 (Irf8) gene.

Results: We found consistent expression of MeCP2 in renal cortical tubules of SD rat, WKY rat, and C57 mouse. Compared with the sham group, cisplatin-treated mice kidney showed significant upregulation of MeCP2 in proximal tubules in both protein and mRNA level, accompanied by severe renal histology changes and the upregulation of NGAL and KIM-1. In vitro, MeCP2 was also induced in cultured proximal tubular cells by cisplatin treatment. Interestingly, knocking down MeCP2 alleviated caspase-3-dependent tubular cell apoptosis but enhanced cell autophagy induced by cisplatin. Furthermore, a pro-apoptotic gene interferon regulatory factor 8 (Irf8) was found upregulated in tubular cells by cisplatin in vivo and in vitro. Importantly, we demonstrated that MeCP2 upregulated Irf8 expression by directly binding to its gene.

Conclusions: Elevated expression of MeCP2 was found in cisplatin-treated renal proximal tubules in vivo and in vitro. MeCP2 promoted cisplatin-induced renal tubular damage by facilitating apoptotic process and inhibiting autophagy activity. The epigenetic regulation of pro-apoptotic gene Irf8 by MeCP2 may be the possible mechanism implicated in the pathophysiological process of cisplatin-induced AKI.

SA-PO096

The mRNA Editing via Apobec-1 Is Necessary to Repair Kidneys from Cisplatin (CP)-Induced Renal Injury

Xiaojia Guo,[1] Heino Velazquez,[2] Tian-Min Chen,[1] Zhongshan Cheng,[1] Gilbert W. Moeckel,[3] Valerie Blanc,[4] Nicholas Davidson,[4] Robert L. Safirstein,[2] Gary V. Desir.[2] *[1]Yale University, West Haven, CT; [2]Yale and VAMC, West Haven, CT; [3]Yale University School of Medicine, New Haven, CT; [4]Washington University School of Medicine, ST Louis, MO*.

Background: Cisplatin (CP) induces AKI as the proximal tubules (PT) undergo regulated necrosis. Repair is almost complete following such a single dose. Repeated doses of CP, however, leads to unresolved injury and progresses to chronic kidney disease (CKD). Interrogation of the renal transcriptome throughout the process of AKI to CKD progression identified Apobec1 protein, a cytosine deaminase that binds to and edits mRNAs that regulate mitochondrial metabolism, cell fate and proliferation pathways, which in liver, small intestine and brain play a crucial role in recovery from stress. We therefore examined the role of apobec1 in kidney nephrotoxicity.

Methods: Apobec1 knockout (ko) mice were given CP 15 mg/kg i.p. and renal function, histology, mRNA and protein expression were analyzed and compared to wild type (WT) mice of similar genetic background. We also overexpressed Apobec-1 in PT cells, after CP treatment, and assessed cell viability histologically and by WST-1 assay.

Results: Apobec-1 gene knockout resulted in more severe AKI, plasma creatinine 2.069 mg/dL ± 0.591, n=13) versus 0.228 mg/dL ± 0.087, n=8) 3d ($p < 0.01$) in WT. Remarkably all apobec1 ko mice died after 6 days, while WT animals all survived. The kidney showed greater necrosis and neutrophil invasion, but no change was noted in TUNEL or ki67 staining. mRNA and protein levels of RIPK3, MLKL, TLR2, and TLR4 were 3.76-, 3.54-, 6.26-, and 40.07-fold higher, respectively (p,001), in Apobec-1 kos than WT kidneys. Overexpression of Apobec-1 in mouse PT cells protected cells from CP-induced cytotoxicity: the CP-induced cell death was 2.35-fold lower in cells transduced with Apobec-1 than in cells transduced with vector alone ($n = 4$, $p < 0.05$). Such overexpression of Apobec-1 increased the activities of kinases associated with survival (ERK, STAT3, and AKT) and inhibited those inducing cell death (TLR4, IRF4, and JNK).

Conclusions: We have identified Apobec1 as a crucial gene regulating the necrotic response to CP-induced nephrotoxicity. The studies show that mRNA editing is a key survival response to CP-induced AKI and that increasing Apobec-1 activity could be an effective strategy to reduce or prevent CP-induced AKI.

Proteomic Studies of Cisplatinated DNA Binding Proteins Identifies RtcB, a Novel RNA Ligase, as an Essential Regulator of Epithelial Cell Death and DNA Damage Response

Laura A. Jayne,[1,2] Ji Young Kim,[1] Yuntao Bai,[1] Navjotsingh P. Pabla.[1] *[1]The Ohio State University, Columbus, OH; [2]University of Toledo, Toledo, OH*.

Background: Cisplatin is one of the most widely used and effective anti-cancer drugs. The therapeutic efficacy and side-effects of cisplatin are largely dependent on its ability to cause DNA damage in both normal and cancer cells. However, the molecular mechanisms involved in cisplatin-mediated DNA damage response and repair remains incompletely understood. In order to uncover novel proteins involved in the cisplatin-associated DNA damage response, we carried out immunoprecipitation of cisplatin-DNA adducts followed by mass spectrometric analysis of associated proteins. These studies revealed that RNA ligase RtcB is associated with cisplatinated DNA under in vitro and in vivo conditions.

Methods: In order to identify novel proteins associated with cisplatin-mediated DNA damage response, we used a cisplatin-DNA adduct antibody to pull down chromatin-associated proteins in murine kidneys after cisplatin treatment. Mass spectrometric analysis was then carried out to identify the proteins associated with cisplatinated-DNA. In vivo and in vitro siRNA approaches were then used to decipher the functional relevance of identified proteins in cisplatin-mediated renal epithelial cell death and DNA damage signaling. Western blot and immunofluorescence experiments were carried out in epithelial cells and renal tissues to measure the extent of DNA damage as well as the activation of DNA damage response.

Results: Initial pulldown studies followed by mass spectrometric analysis identified RtcB as a previously unknown sensor of cisplatin-associated DNA damage. Functional studies in murine renal epithelial cels showed that RtcB knockdown impairs DNA repair, increases DNA damage response and sensitizes cells to cisplatin-mediated cell death. In vivo siRNA mediated RtcB knockdown resulted in augmented AKI and higher renal epithelial cell death. While RtcB is known to play a role in tRNA splicing and unfolded protein response, our work has identified RtcB as a novel player involved in the DNA damage response and repair.

Conclusions: Together, these results suggest an important role for RtcB in the therapeutic efficacy and toxicities associated with the anti-cancer drug cisplatin.

Role of AMPK and KLF4 in Determining the Survival of Cisplatin-Treated Human Umbilical Vein Endothelial Cells

Wilfred Lieberthal,[2,1] Meiyi Tang,[2] Qin Liu,[2] Evgenii Boriushkin,[2] Sandeep K. Mallipattu.[2] *[1]Nephrology, Northport Veterans Administration Hospital, Northport, NY; [2]Nephrology, Stony Brook Medicine, Stony Brook, NY*.

Background: We have reported that preconditioning renal tubular cells with A-769662, a specific pharmacologic activator of AMPK, increased the survival of these cells when subjected to hypoxic stress. We have also shown that preconditioning mice A-769662 ameliorates the severity of ischemic AKI in mice *in vivo*. In these studies we examined the role of AMPK and the Kruppel-like transcription factor-4 (KLF4) in determining the fate of human umbilical epithelial cells (HUVECs) exposed to cisplatin

Methods: The phosphorylation (activity) of AMPK was determined by immunoblotting and expressed as % of total AMPK. The expression of KLF4 was knocked down (by >85%) using a specific siRNA ("KD cells"). "Control cells" were transfected with a scrambled siRNA. The response of HUVECVs to cisplatin induced-injury was determined by first pretreating the cells with either A-769662 (250uM) or its vehicle for 24 h., followed by incubation with either cisplatin (100uM) or its vehicle) for an additional 18h. Then cell survival was determined by flow cytometry and expressed as a % of vehicle-treated cells.

Results: A-769662 increased the phosphorylation (activity) of AMPK to a comparable extent in control and KD cells (by 6.3±.24 and by 5.9±2.2 fold respectively). In control cells, the activation of AMPK induced by A-76962 (250mM), increased the expression of KLF4 mRNA (by 4±2.3 fold), and of KLF4 protein (by 3.9±2.2 fold). As expected, A-769662 had no effect on the expression of KLF4 in KD cells. In the absence of preconditioning with A-769662, the survival after cisplatin treatment was substantially higher in control cells (55.4%±4.2) than in KD cells (15.5±3.4%). These data show that KLF4 has pro-survival effects that are independent of AMPK. Furthermore, preconditioning HUVECs with A-769662, increased the survival of both control cells to 84.4±6.5%, and of KD cells to 57.9±7.6%. These data demonstrate, that the pro-survival effect of KLF4 is increased by the activation of AMPK.

Conclusions: i) AMPK induces the expression of KLF4; ii) AMPK and KLF4 both promote the survival of cisplatin-treated cells; iii) the pro-survival effects of AMPK and KLF4 are mediated by different pathways; iv) the activation of AMPK augments the pro-survival effect of KLF4 by increasing its expression.

Activation of Renal AMP-Activated Protein Kinase (AMPK) Is an Adaptive Response to Sepsis/Inflammation That Can Be Pharmacologically Harnessed to Improve Survival

Carlos L. Manrique-Caballero,[1] Alicia Frank,[1] Catherine J. Baty,[2] John A. Kellum,[1] Hernando Gomez Danies.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: To determine the role of renal AMPK activation and inhibition in the renal tubular epithelial cells (TEC) metabolic response to sepsis, and to investigate the effects of AMPK signaling on sepsis-induced TEC injury, clinical status and survival

Methods: Animals: Ten-twelve week old C57BL/6 (n=6-10/group) mice were randomized to vehicle, 5-Aminoimidazole-4-carboxamide ribonucleotide (AICAR) or compound C (CC), and underwent cecal ligation and puncture (CLP). Outcome: Survival at 7 days. Cells: Human kidney 2 (HK2) cells were cultured in serum-containing media at 21% O_2 and were assigned to control, AICAR and CC, and then exposed to inflammatory mix (IM=LPS+HMGB1). Using the Seahorse metabolic analyzer, we measured oxygen consumption rate (OCR) as a surrogate of OXPHOS (mitochondrial respiration) and extracellular acidification rate (ECAR) as a surrogate of glycolysis at 24 hours. Spare respiratory capacity defined as the capacity of the cell to increase ATP production in conditions of increased energetic demands was assessed by comparing OCR at baseline and after uncoupling mitochondria.

Results: Pharmacologic activation of AMPK with AICAR before or after sepsis improves mice survival at 7 days (AICAR+CLP vs CLP; 70% vs 19%; $p<0.05$), and inhibition with CC before sepsis increases mortality at 7 days (CC+CLP vs CLP; 100% vs 81%; $p<0.05$). Cells exposed to IM and CC showed a decrease in OCR and spare respiratory capacity at 24 hours by 26% and 90.3% respectively when compared to IM (Fig 1B, C), and limited the recruitment of glycolysis upon blockade of the mitochondrial electron transport chain (Fig 1D).

Conclusions: Enhancement of AMPK with AICAR increases survival, whereas inhibition with CC increases mortality. AMPK inhibition limited the capacity of tubular epithelial cells to recruit OXPHOS and glycolysis, thereby limiting metabolic flexibility. These findings suggest that TEC metabolic response to sepsis is an adaptive mechanism and that maintenance of metabolic flexibility may be key to survival from sepsis

Funding: Other NIH Support - 1K12HL109068-02, 1K08GM117310-01A1

Figure 1

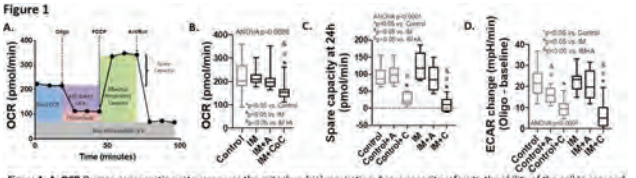

Figure 1: A: OCR Oxygen consumption rate measures the mitochondrial respiration. Spare capacity refers to the ability of the cell to respond to an energetic demand, and constitutes an indicator of how close the cell is respiring at its theoretical maximum respiration. **B: OCR 24h:** Inhibition of AMPK with compound C significantly decreases OCR at 24 hours when compared to control and IM. **C: Spare Respiratory Capacity:** Inhibition of AMPK during with compound C significantly decreases the spare respiratory capacity of the cell at 24 hours in the control and in the IM group. **D: ECAR change (Oligo-baseline):** Glycolytic metabolism recruitment is impaired in the compound C group after inhibition of OXPHOS with oligomycin.

Alpha-7 Nicotinic Receptor Agonist GTS-21 Ameliorates Contrast-Induced Nephropathy in Rats

Seckin Akcay,[1] Zarife Ozdemir,[4] Ozlem T. Cilingir-Kaya,[2] Irem Peker,[3] Mustafa Akkiprik,[3] Berrak Yegen,[4] Mehmet Koc.[1,4] *[1]Department of Internal Medicine, Marmara University Medical Faculty, Istanbul, Turkey; [2]Department of Histology, Marmara University Medical Faculty, Istanbul, Turkey; [3]Department of Medical Biology and Genetics, Marmara University Medical Faculty, Istanbul, Turkey; [4]Department of Physiology, Marmara University Medical Faculty, Istanbul, Turkey.*

Background: Despite the extensive use of contrasts in medicine, no proven pharmacological therapies exist to prevent contrast-induced nephropathy (CIN), which causes renal damage by renal vasoconstriction, medullary hypoxia, oxidative stress and direct tubular toxicity of the contrast agent. In an experimental CIN model, we aimed to evaluate the possible therapeutic effects of GTS-21, a selective alpha-7 nicotinic receptor agonist with anti-apoptotic, anti-inflammatory and anti-oxidative properties.

Methods: In male Sprague-Dawley rats, CIN was induced by intravenous injection of indomethacin (10 mg/kg), L-NAME (10 mg/kg) and a high-osmolar contrast agent (Urografin 76%, 6 ml/kg). Starting at 24 h before CIN induction, every 12 hours, rats were injected intraperitoneally with saline (contrast, n=14) or GTS-21 (GTS-21-contrast, 4 mg/kg, n=10), while the control groups with no CIN induction were treated with saline (control, n=8) or GTS-21 (GTS-21-control, n=8). At the 48th h of CIN, blood and kidney samples were obtained for the determination of cytokine expression (RT-PCR), oxidative stress parameters and histopathological analysis. Data were analyzed using ANOVA and Student's t-test.

Results: When compared to control and GTS-21-control groups, serum creatinine and BUN levels in the contrast group were elevated ($p<0.05$), while these measurements in GTS-21-contrast group were not different than controls. Increased histopathological damage score in contrast group ($p<0.01$) with respect to both control groups was significantly decreased in GTS-21-contrast group ($p<0.001$). Elevated malondialdehyde level in contrast group ($p<0.001$) was partially lowered by GTS-21 treatment, while antioxidant glutathione level was increased ($p<0.05$). In both contrast groups, an increase in IL-6 expression and a reduction in TGF-β expression were observed ($p<0.05$), but GTS-21 treatment increased TGF-β expression ($p<0.05$) and slightly depressed IL-6 expression.

Conclusions: GTS-21 improves renal dysfunction and provides a significant protection against contrast nephropathy via anti-oxidant and anti-inflammatory mechanisms.

SA-PO101

Molecular Pathways Driving Omeprazole Nephrotoxicity

Miguel Fontecha, Diego Martin-Sanchez, Julio M. Martínez Moreno, Alberto Ortiz, Ana B. Sanz. *Instituto de Investigación Sanitaria de la Fundación Jiménez Díaz, Madrid, Spain.*

Background: Omeprazole, a proton pump inhibitor used to treat peptic ulcer and gastroesophageal reflux disease, has been associated to chronic kidney disease and acute interstitial nephritis. However, whether omeprazole is toxic to renal cells is unknown. Omeprazole has a lethal effect over some cancer cells, and cell death is a key process in kidney disease.

Methods: Thus, we evaluated the potential lethal effect of omeprazole over cultured tubular proximal cells.

Results: Omeprazole induces dose-dependent cell death in human and murine proximal tubular cell lines and in human primary proximal tubular cell cultures. Increased cell death was observed at the high doses used in cancer cell studies and also at lower concentrations similar to those in peptic ulcer patient serum. Cell death induced by omeprazole has features of necrosis such as annexinV/7-AAD staining and irregular chromatin condensation. Weak activation of caspase-3 was observed but inhibitors of caspases (carbobenzoxy-valyl-alanyl-aspartyl-[O-methyl]-fluoromethylketone,zVAD), necroptosis (necrostatin-1) or ferroptosis (ferrostatin-1) did not prevent omeprazole-induced death. However, omeprazole induced a dose-dependent and early increase in ROS production as assessed by CM-H2DCFDA staining and flow cytometry. ROS production increased in mitochondria, as assessed by MitoSOX staining, and by NADPH activity role, determined by lucigenin assay. Moreover, the antioxidant molecule N-Acetylcysteine (NAC) partially prevented omeprazole-induced ROS production and cell death as assessed by the MTT assay and by annexin-V/7AAD staining. Omeprazole also induced lysosomal stress, evidenced by an increase in lysosomal pH and this was also prevented by NAC. Autophagy activation was also observed but blockade of autophagosome formation by 3-methyladenine did not decrease omeprazole-induced death. An adaptive increase in the expression of the antiapoptotic protein BclxL failed to protect the cells. In mice, parenteral omeprazole increased tubular cell death and the expression of NGAL, a marker of renal injury.

Conclusions: In conclusion, omeprazole nephrotoxicity may be related to induction of oxidative stress and renal tubular cell death, supporting the biological plausibility for the epidemiological association of chronic proton pump inhibitor use to kidney disease.

SA-PO102

Mechanistic Modelling of the Linkage Between Proximal Tubule Cell Sublethal Injury and Tubular Sodium Reabsorption Impairment

Nader Hamzavi, Yeshitila Gebremichael, Jeffrey L. Woodhead, Shailendra Tallapaka, Scott Q. Siler, Brett A. Howell. *DILIsym Services Inc., a Simulation Plus Company, Research Triangle Park, NC.*

Background: Renal epithelial cell injury, a prominent feature of drug-induced acute kidney injury (AKI), is characterized by loss of brush border and cellular polarity of proximal tubular cells (PTCs). The key alterations caused by sublethal injury involve impaired energetics and associated disruptions in cytoskeletal structure and sodium transporters activity. A mechanistic model relating AKI mediated cellular injury with renal tubular dysfunction is needed to address the complexity of renal physiology.

Methods: We developed a model of sublethal PTCs injury and sodium reabsorption impairment within the framework of RENAsym, a quantitative systems toxicology (QST) model of drug-induced AKI under development. The mathematical model represents major components of renal sublethal injury in a system of equations accounting for ATP decline, microfilament redistribution, and Na+/K+ ATPase activity reduction. The model equations were parametrized with an experimental study in which induced sublethal injury in rats, by selectively inhibiting cortical ATP production using maleic acid, was investigated and the effect of dose-dependent ATP decrement on apical F-actin networks and tubular sodium reabsorption was measured [1].

Results: Microfilament disruption was quantified with ATP decrement and then related to translocation-based loss of Na+/K+-ATPase, while a decline in the molecular activity of a sodium pump was directly related to ATP decrement. The model recapitulated the link between ATP decrement and sodium reabsorption impairment through the intermediate pathological pathways of microfilament redistribution and Na+/K+ ATPase activity reduction. Simulations of varying ATP decrement reveals a sharp decline in sodium reabsorption as the relative ATP decrement exceeds 40%, in accord with observations [1].

Conclusions: A mechanistic model of subcellular injury is developed to link cellular ATP decrement and tubular sodium reabsorption impairment. The model serves as a bridge between cellular toxicity and renal tubular functional impairment, allowing mechanistic prediction of AKI induced renal hemodynamics.

SA-PO103

Evaluating the Nephrotoxicity of Exemplar Compounds Using a Mechanistic Model of Drug-Induced AKI

Yeshitila Gebremichael, Jeffrey L. Woodhead, Nader Hamzavi, Shailendra Tallapaka, Scott Q. Siler, Brett A. Howell. *DILIsym Services, Inc., Research Triangle Park, NC.*

Background: Drug-induced nephrotoxicity is a common source of acute kidney injury (AKI) and brings clinical complexities. Drugs cause nephrotoxicity by various mechanisms, including mitochondrial dysfunction and oxidative stress. Predicting the AKI potential and toxicity mechanisms of drugs remains a challenge. We utilized a quantitative systems toxicology (QST) model to evaluate the nephrotoxicity and underlying mechanisms of two positive (cisplatin, gentamicin) and one negative (acetaminophen) control exemplar compounds.

Methods: We employed RENAsym, a QST model of drug-induced AKI that is currently under development, to evaluate the toxicity and injury mechanisms of the exemplar compounds. RENAsym represents aspects of renal proximal tubule cells (PTCs) including cell life cycle, bioenergetics, drug-induced cell death pathways, and biomarker (αGST) responses. *In vitro* data from literature were utilized to parameterize the oxidative stress production and clearance of the compounds. To determine the effects of drugs on mitochondrial dysfunction, electron transport chain (ETC) inhibition mechanism was parameterized using literature *in vitro* data.

Results: Drug nephrotoxicity was predicted by performing simulations using a virtual human model. In the simulations, a single dose of 533 mg/m^2 cisplatin resulted in 17% decline of PTC viability in 2 days. The simulations also showed a significant rise in urine aGST, a biomarker that marks PTC death. Similarly, a single dose of 3 mg/kg gentamicin showed 40% cell viability decline and high αGST elevations in 1 day. In contrast, no cell viability loss or aGST elevations were observed after multiple doses of 1 g QID (a maximum recommended dose for human) acetaminophen for over a week. In terms of injury mechanisms, simulations showed oxidative stress as the dominant mechanism for both cisplatin and gentamicin-induced toxicities.

Conclusions: Simulations predicted toxicity for two positive control compounds and no toxic response to the negative control compound, in qualitative agreement with the expected behaviors. RENAsym shows promise in providing a unique tool for drug-induced AKI prediction.

Intravital Imaging of Single Collecting Ducts Micro-Perfused with Uropathogenic Escherichia coli Demonstrates Phagocytosis by Intercalated Cells

Andrew L. Schwaderer,[1] Takashi Hato,[1] David S. Hains,[1] Vijay Saxena,[1] Sam W. Arregui.[2] [1]*Indiana University, Zionsville, IN;* [2]*IU School of Medicine, Indianapolis, IN.*

Background: Renal epithelial cells have a different lineage and historically were considered to have different functions than myeloid derived macrophages. However some epithelial cells, such as renal intercalated cells have been recently demonstrated to have distinct immune functions.

Methods: VATPaseB1-cre transgenic mice were crossed to tdTomato-loxp homozygous mice which results in red fluorescence of intercalated cells. Under isoflurane anesthesia a kidney was surgically exposed and a single collecting duct was cannulated with a 5 micron needle. The tubule was perfused with green fluorescent protein (GFP) expressing uropathogenic E.coli (UPEC) strain CFT 073 or E.coli coated bioparticles and imaged with Leica TCS SP8 (upright high-speed multiphoton and confocal imaging system).

Results: Single collecting ducts could be cannulated (Figure 1A). Micro-perfusion with UPEC could be confirmed by visualization GFP expressing bacteria flowing through a tubular structure (Figure 1B). Bacteria were internalized selectively in red fluorescent expressing intercalated cells (Figure 1C-D). Ecoli coated bioparticles were also selectively internalized by intercalated indicating an intercalated cell activated process not just bacterial invasion.

Conclusions: We demonstrate that micro-perfusion of single collecting ducts can be accomplished in vivo and imaged using intravital microscopy. Renal intercalated cells phagocytize bacteria similar to myeloid immune cells such as macrophages even though intercalated cells are renal epithelial cells.

In Vitro and Ex Vivo Exploration of the Expression of MicroRNAs to Assess the Progression of AKI

Annie Masih,[1] Su wei Ng,[1] Patrick T. Murray,[2] Peter P. Doran.[1] [1]*University College Dublin, Dublin, Ireland;* [2]*UCD School of Medicine and Medical Science, Dublin 7, Ireland.*

Background: MicroRNAs are endogenous short, non-protein coding RNAs that post-transcriptionally/translationally control protein expression by binding to target mRNA. There is increasing interest in miRNAs in disease research because of their ability to coordinate the regulation of protein expression by influencing multiple signalling pathways. Some miRNAs have previously been shown to be responsive to AKI, suggesting they may be mediators of the damage and repair processes and potential markers. To build on this work, we have sought to determine miRNA expression in AKI using a combination of *in vitro* and *ex vivo* models.

Methods: We first sought to categorise the urinary expression of selected miRNAs to determine their biological importance in AKI. Recognising the challenges of recovering low abundance transcripts in urine, we sought to firstly validate our experimental approach. We found that RNA recovery was similar in urine before centrifugation and after centrifugation. We further compared the RNA recovery rates between normal sample and exosome enriched samples, demonstrating that whilst exosome enrichment did not increase the overall yield of miRNAs, it did result in improved amplification profiles. Having demonstrated experimental validity, miRNA was assessed in urine samples obtained from patients with KDIGO Stage 2 and 3 and samples from non-AKI donors. Expression of miR-30a-e, miR-192, miR-101-3p was reduced in KDIGO 3 and KDIGO 2 compared to healthy control samples.

Results: Having shown that these miRNAs are differentially regulated in AKI *ex vivo*, we next sought to categorise *in vitro*. For these investigations, HK2 tubule epithelial cells were cultured with 10 µg/ml, 1 mg/ml and 0.1 mg/ml of LPS for 2, 4, 6, 12 and 24 hours. Following stimulation, RNA was extracted, cDNA prepared, and RT-PCR conducted to determine the expression of miR-30c, miR-101-3p and miR-192.

Conclusions: These investigations demonstrated LPS dysregulation of these target miRNAs in a time and concentration dependent manner. These data suggest these mediators respond to tubule injury and thus may be useful as early markers of AKI, as well as contributing to the changes in transcription which underpin the initiation, progression and outcome of AKI. Further investigations will focus on delineating the functional importance of MiRNAs as molecular drivers of AKI.

SA-PO106

Administration of miR-486-5p Protects Against Kidney Ischemic Injury and Alters the Transcriptome in Male and Female Mice

Jose L. Vinas,[1] Matthew Spence,[1] Joe A. Zimpelmann,[1] Adrianna Douvris,[1] Alex Gutsol,[1] Pearl A. Campbell,[2] Christopher J. Porter,[2] Kevin D. Burns.[1] [1]*Kidney Research Centre, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada;* [2]*Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Ischemia-reperfusion is a common cause of acute kidney injury (AKI), and no treatments exist to restore function. We showed that cord blood endothelial colony forming cells (ECFCs) release exosomes (enriched in miR-486-5p) that are protective against ischemic AKI in male mice. This response involves inhibition of *phosphatase and tensin homolog* (PTEN, a target of miR-486-5p) and Akt activation. Here, we studied effects of direct administration of miR-486-5p to mice with AKI, and defined sex differences.

Methods: Kidney injury was induced in mice by 30-minute bilateral renal vascular clamping followed by reperfusion and sacrifice at 24 or 48 hrs. ECFC exosomes, miR-486-5p mimic (in cationic lipid), or scrambled miR were injected i.v. at the start of reperfusion. Kidney endothelial cells and proximal tubules were isolated for transcriptomic analyses.

Results: Male and female mice treated with miR-486-5p mimic at the time of reperfusion had increased miR-486-5p levels in kidney endothelial cells and proximal tubules, liver and spleen ($P<0.01$, n=8), but not in lung, heart or brain. In male or female mice with kidney ischemia-reperfusion, miR-486-5p mimic or exosomes significantly

decreased serum Cr and urea, histologic injury, apoptosis, and neutrophil infiltration (n=8). Delivery of miR-486-5p reduced kidney PTEN protein expression, and increased Akt phosphorylation (P<0.05, n=6). Female mice were resistant to kidney injury compared to males, by all parameters (P<0.05 vs male), showed fewer differentially expressed genes compared to males, and had less gene variation with treatments. Kidney ischemia induced higher numbers of differentially expressed genes in tubules compared to endothelial cells. In male mice treated with miR-486-5p mimic, the expression of most tubular genes that were significantly changed with ischemia-reperfusion alone returned to levels close to sham.

Conclusions: Systemic delivery of miR-486-5p to male and female mice with AKI increases miR-486-5p levels in kidney endothelial cells and proximal tubules, and prevents ischemic injury. Female mice are resistant to AKI compared to males, and exhibit fewer differentially expressed genes. Changes in the kidney transcriptome with miR-486-5p may define pathways relevant to prevention of AKI in humans.

Association of Altered Urinary miR-141 and miR-192 Expression with AKI Outcome

Timothy Bowen,[1] Lucy J. Newbury,[1] Usman Khalid,[2] Kate A. Simpson,[1] Robert H. Jenkins,[1] Donald Fraser.[1] *[1]Cardiff University, Cardiff, United Kingdom; [2]Cardiff Transplant Unit, Cardiff, United Kingdom.*

Background: Acute Kidney Injury (AKI) is characterised by a sudden decline in kidney function and affects over 20% of US hospitalisations, resulting in a greater than 4-fold increased mortality. The mechanisms underlying AKI recovery versus non-recovery remain poorly understood, and current biomarkers have limited capacity to predict outcome. These factors limit the development of new therapies. Here we evaluated the potential of urinary microRNAs (miRNAs) as biomarkers in patients with severe AKI.

Methods: Daily consecutive urine samples were collected from 30 patients with AKI stage III by KDIGO criteria. 377 miRNAs were profiled by RT-qPCR screening in pooled samples from recovery (n = 6) and non-recovery (n = 5) groups, with validation using individual assays. MiRNAs exhibiting altered expression in the urine of patients subsequently recovering vs. not recovering renal function were evaluated in *in vivo* (ischemia reperfusion injury (IRI) in the rat) and *in vitro* (proximal tubular epithelial cells (PTCs) exposed to hypoxia or oxidative stress) models by RNA sequencing and RT-qPCR. To identify miRNA targets, selected miRNAs were manipulated using transfection-based gain- and loss-of-function approaches *in vitro*.

Results: An extensive pattern of miRNA changes was observed, notably decreased miR-192 and increased miR-141 expression that predicted non-recovery. Alterations in miRNA expression were validated and linked to changes in our rat IRI model and in PTC miRNA expression *in vitro*. Network analysis of predicted miRNA targets converged on protein tyrosine phosphatase type G (PTPRG) and dysregulated PTPRG expression was confirmed.

Conclusions: These data identify quantifiable urinary miRNAs that predict outcome following AKI, and link these miRNAs to potential mechanisms of injury and recovery following AKI.

SA-PO108

miR-214 Promotes Mitochondrial Fragmentation and Cellular Apoptosis by Targeting MFN2 in ATP-Depleted Renal Proximal Tubular Cells

Yu Yan,[1] Zheng Dong.[2] *[1]Augusta University, Augusta, GA; [2]Medical College of Georgia, Augusta, GA.*

Background: Mitochondria injury is a pathological factor for AKI by promoting cell apoptosis. microRNAs have been reported to play important regulatory roles in AKI. However, microRNA associated with mitochondrial injuries are poorly understood.

Methods: Azide-induced ATP-depletion model to study AKI in renal proximal tubular cells (RPTCs) in vitro. The mRNA expressions of miR-214 were detected by RT-qPCR. The protein levels of MFN2,β-actin and cleaved-caspase3 were determined by western blot, then analysis by image J. The mitochondria morphology was detected by confocal microscope.

Results: We found that miR-214 level was upregulated after azide treatment and reperfusion in RPTCs, while MFN2 protein level was reduced. Overexpression of miR-214 by transfection decreased MFN2 protein level. The inhibition of miR-214 by anti-miR-214 LNA reduced the decrease in MFN2 and induced by ATP depletion, and the percentage of RPTCs with fragmented mitochondria were decreased as well. The number of apoptotic cells and the increase in cleaved-caspase 3 expression induced by azide treatment in RPTCs were reduced by anti-miR-214 LNA transfection. On the contrary, overexpression of miR-214 increased apoptosis and cleaved-caspase 3 expression in ATP-depleted RPTCs.

Conclusions: These results suggest that miR-214 upregulation promotes mitochondrial fragmentation and cellular apoptosis by downregulating MFN2 expression and inhibition of miR-214 ameliorates mitochondrial fragmentation and reduces cellular apoptosis by upregulating MFN expression in ATP-depleted RPTCs. Targeting miR-214 could show potentially therapeutic effect in AKI.

Endothelial-Derived miR-17~92 Protects Against Renal Ischemia-Reperfusion Injury

Takuto Chiba,[1] Andrew J. Bodnar,[1] Shelby L. Hemker,[2] Elina Mukherjee,[5] Yu Leng Phua,[5] Kai J. Shaikh,[3] Brandon T. Sanders,[4] Jacqueline Ho,[5] Sunder Sims-Lucas.[5] *[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh - Rangos Research Center, Pittsburgh, PA; [3]University of California, Berkeley, CA; [4]Claflin University, Orangeburg, SC; [5]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury (AKI), resulting from renal ischemia reperfusion injury (IRI) among others, is an independent predictor of morbidity and mortality, and is identified in as many as 50% of ICU patients. Damage to the renal microvasculature is a hallmark of renal IRI. *miR-17~92* encodes 6 polycistronic microRNAs that show potent pro-angiogenic capacity by targeting anti-angiogenic factors. The function of miR-17~92 in renal microvasculature after renal IRI remains unknown. We hypothesized that endothelial-specific *miR-17~92* mediates endothelial repair and kidney recovery after renal IRI.

Methods: Endothelial-specific *miR-17~92* knockout (*miR-17~92$^{endo-/-}$*) transgenic mice were generated and a renal IRI model was performed. Mice were monitored for the development of AKI using serum chemistries, histology, and markers of renal tubular injury. The renal vasculature and infiltrating macrophages post-injury were evaluated using multiple markers.

Results: We demonstrate that miR-17, *miR-18a, miR-19b* and *miR-20a* in the *miR-17~92* cluster are up-regulated in CD31+ renal endothelial cells following renal IRI. Loss of *miR-17~92* in endothelial cells does not affect renal vascular development and renal function in adult mice. Following renal IRI, *miR-17~92$^{endo-/-}$* mice had worse renal dysfunction and epithelial damage, and exhibited up-regulation of the injury marker NGAL in proximal tubules compared to the controls. *miR-17~92$^{endo-/-}$* kidneys had decreased Endomucin-positive renal microvasculature post renal IRI. *miR-17~92$^{endo-/-}$* kidneys upregulated the potent anti-angiogenic factor Thrombospondin-1 (TSP1) in a subset of Endomucin-positive renal microvasculature. *miR-17~92$^{endo-/-}$* kidneys also had increased F4/80-positive infiltrating macrophages post renal IRI along with up-regulation of multiple macrophage markers in its kidneys.

Conclusions: These data suggest that *miR-17~92* in renal endothelial cells confers protection from damage in the renal microvasculature during renal IR mediated AKI by targeting an anti-angiogenic factor TSP1. This, in turn, mitigates hypoxic damage in tubular epithelial cells and down-regulates inflammatory activation following injury.

Proteomics Reveals the Principle of Transition from AKI to CKD

Haiyan Fu,[1] Silvia Liu,[2] Xianke Zhou,[1] Dong Zhou.[2] *[1]Renal Division, State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Chronic kidney disease (CKD) compromises renal function and occurs as a potential long-term outcome in response to acute kidney injury (AKI). Currently, lack of mechanistic understanding prevents the progression from AKI to CKD. As we enter the 'big data' era, multiple OMICS analyses provide a platform not only assist the field to further understand kidney disease transition, but also significantly enhance the possibility to translate novel findings from basic research into the clinic. The present study aims to systemically analyze the proteomes profiles from the onset of kidney injury to end stage renal disease and identify dynamic network biomarkers during disease progression.

Methods: We constructed renal ischemia reperfusion injury (IRI) mouse model for time series courses. Quantitative proteomics (isobaric peptide tags for relative and absolute quantification, iTRAQ) was applied in revealing the proteomes profiles in kidney tissues. Dynamic network biomarker (DNB) analysis was performed to clearly identify the critical state or tipping point during the transition of kidney disease.

Results: We identified 6146 proteins in the disease kidneys. Pearson correlation analysis indicated that the transitional process from AKI to CKD could be divided into 4 periods in mice, initiate phase (0-12h), switching phase (1d), repair phase (3-5d), and irreversible phase (after 5d). Impressively, protein signatures were completely different in the above 4 phases. Among these phases, two time points (4h and 3d) were critical in determining the prognosis of kidney disease. We then analyzed time-series protein expression data with the DNB method, and identified NCBP1 as a core DNB member. At a network level, the biological role of NCBP1 was prominent in kidney repair and regeneration.

Conclusions: Establishing disease monitoring system at appropriate time points will be greatly beneficial in understanding the pathogenesis of kidney disease transition.

Proteomic Analysis of the Tubulointerstitium Characterizes Extracellular Matrix Changes in Acute Tubular Necrosis

Anjali A. Satoskar,[1] John P. Shapiro,[1] Michael Merchant,[2] Jon B. Klein,[2] Tibor Nadasdy,[1] Brad H. Rovin,[1] Samir V. Parikh.[1] *[1]Ohio State University Medical Center, Columbus, OH; [2]University of Louisville School of Medicine, Louisville, KY.*

Background: Acute tubular necrosis (ATN) is the most common form of acute kidney injury (AKI) in the hospital setting. Urine proteomic analyses have been extensively performed in AKI, but the kidney proteome has largely been unexplored. Here, we performed unbiased proteomics on the tubuloniterstitium (TI) from kidney biopsies with ATN to identify kidney specific proteomic signatures that characterize ATN.

Methods: Laser microdissection was performed on FFPE kidney biopsy tissue from 8 ATN and 8 living transplant donor kidney biopsy controls (LTx). The TI was isolated and total protein was extracted and submitted for HPLC-MS/MS analysis using the Oribtrap Elite. Label free quantification followed by global normalization of spectral count data was performed. Proteomic expression of ATN was compared to LTx. Statistical significance was considered if 2-fold change and P<0.01.

Results: All patients had biopsy proven ATN. The average serum creatinine in ATN was 5.7mg/dl (SD: ± 2.7). Overall, 86 proteins were upregulated and 44 downregulated in ATN compared to LTx. The top upregulated markers included extracellular matrix (ECM) proteins implicated in AKI to CKD transition, ER stress proteins, and wound repair proteins (Figure 1). Meanwhile, transport, metabolism, and mitochondrial markers were suppressed. Pathway analysis revealed activation of remodeling of epithelial adheren junctions, acute phase response signaling, and coagulation and suppression of metabolic pathways.

Conclusions: Kidney proteomic evaluation demonstrates overexpression of ECM proteins in ATN that previously have been implicated in CKD progression and may reflect AKI to CKD transition. These markers could serve as novel therapeutic targets to arrest injury early and prevent progression to chronic kidney disease.

Long-Term Outcomes in Mouse Models of Ischemia-Reperfusion-Induced AKI

Lauren N. Scarfe, Anna Menshikh, Haichun Yang, Mark P. de Caestecker. *Vanderbilt University Medical Center, Nashville, TN.*

Background: AKI is a risk factor for CKD, but no therapies have improved outcomes. Therapies that are effective in models that mimic features in patients, and evaluate long-term outcomes, are more likely to be predictive of success in the clinic. Here, we evaluated susceptibility to CKD after unilateral ischemia reperfusion injury (uIRI) with a delayed contralateral nephrectomy (DN-IRI) in mice. We define the conditions to induce renal dysfunction and fibrosis without increased mortality, and evaluate effect of mouse strains, sexes, and pre-existing diabetes.

Methods: Studies were performed in different strains and sexes of mice, and in mice with streptozotocin (STZ)-induced diabetes mellitus (DM). DN-IRI with different renal pedicle clamp times was performed along with contralateral nephrectomy (Nx) 8 days after injury to identify conditions associated with reduced GFR 4 weeks after injury. After optimizing IRI clamp time, we evaluated renal function with serial BUN, creatinine and transdermal GFR. Renal fibrosis: QRT-PCR for fibrosis markers, picro-sirius red (PSR) quantification. Peritubular capillary density (PTCD) by quantifying CD31 immunostaining. Results expressed as means (SD).

Results: Male and female BALB/c mice had >90% survival after uIRI clamp times of 30 and 40 minutes, respectively. C57BL/6 mice from Charles River and Jackson labs had >90% survival with 28 and 21 mins uIRI, respectively, and male DBA2j mice with DM had >90% survival after 22 mins uIRI. These were all associated with reduced GFR and increased renal PSR staining 4 weeks after IRI. Long term studies in male BALB/c mice showed reduced GFR 6 weeks after ND IRI 229.1 (50.1) vs. 296.7 (44.1) microL/min in Nx only mice (p<0.05), but GFR recovered by 12 weeks. This was associated with increased PSR staining at 12 weeks, but PTCD, which was reduced at 4 weeks after IRI 0.67 (0.12) vs. 1 (0.21) FC (p<0.01), was the same as Nx control by 12 weeks.

Conclusions: These data define renal pedicle clamp times for the DN-IRI model in different mouse strains, sexes, and in the presence of DM. Long-term studies showed renal functional recovery at 12 weeks, and showed that peritubular capillary rarefaction is more closely associated with changes in GFR than fibrosis. This provides insight into the role of capillary rarefaction as the driver of AKI to CKD progression.

SA-PO113

Super-Resolution Ultrasound to Monitor Microvascular Rarefaction After AKI in Mice

Brittney M. Rush, Qiyang Chen, Sean D. Stocker, Kang Kim, Roderick J. Tan. *University of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury is associated with an increased incidence of chronic kidney disease. One mechanism to explain this is the loss of vascular density in the kidney post-AKI, leading to chronic hypoxia. Current techniques to evaluate the vasculature are limited by a lack of resolution, technique causing harm to the subject, or inability to perform in live subjects. Super-resolution ultrasound (SRU) is an emerging technology to achieve high spatial resolution to identify microvessels in live animals.

Methods: C57BL/6 mice were subjected to unilateral ischemia-reperfusion injury (IRI) survival surgery. At 21 and 42 days after injury, mice were injected with clinical ultrasound contrast agent (Definity) and both the injured and contralateral control kidneys were evaluated *in vivo* under anesthesia. Using B-mode imaging the kidneys were imaged in the maximal longitudinal plane. Imaging data of 1000 effective frames were acquired using multi-angle ultrasound plane wave imaging at an effective frame rate of 250 Hz. Off-line signal processing was performed in MATLAB with radio-frequency data processed through beamforming, motion compensation, singular value decomposition filter, Richardson-Lucy deconvolution, and frame summation. After imaging, mice were euthanized, kidneys were recovered and subjected to immunohistochemistry to identify CD31 positive blood vessels. Fibrosis was assessed with trichrome and picrosirius red stains. Collagen and vascular endothelial growth factor (VEGF) levels were also assessed.

Results: SRU was capable of the accurate identification of microvessels with a resolution of 32 microns. Using SRU, a clear reduction in vascular density was identified in the IRI kidneys compared to control. SRU measurements correlated favorably with traditional CD31 immunohistochemical staining (R^2=0.8). This was accompanied by a reduction in renal blood volume and kidney size. As expected, there was an increase in renal fibrosis that appeared to peak at 21 days. VEGF levels were also decreased after IRI.

Conclusions: SRU was capable of identifying the decrease in microvascular density after IRI in mice at late timepoints after injury. This correlated favorably with traditional immunohistochemistry and could be a method to monitor the progression of kidney disease after AKI.

Capillary Rarefaction Is Associated with CKD Progression in Cisplatin and Rhabdomyolysis AKI

Anna Menshikh, Lauren N. Scarfe, Haichun Yang, Mark P. de Caestecker. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Incomplete recovery of renal function after AKI results in progressive CKD, but no therapies improve long-term outcomes in patients with AKI. For this reason there has been interest in pre-clinical models of AKI to CKD transition that mimic the pathophysiology of human AKI. One end point for pre-clinical interventions is renal fibrosis. However, reduced peritubular capillary density (PTCD) is also associated with CKD after ischemia-reperfusion AKI, and it is unknown whether PTCD is an independent predictor of CKD in models of AKI. Many studies have evaluated therapy in short term studies after cisplatin (CP), and glycerol-induced rhabdomyolysis (Rhabdo-AKI), but there are limited published data on long-term outcomes. In these studies we evaluated long-term renal outcomes, renal fibrosis and PTCD in mouse models repeat dose CP (RDCP) and Rhabdo-AKI.

Methods: RDCP was induced in male FVB/N mice with 7mg/kg CP weekly for four weeks, tissues harvested at 28 days. Rhabdo-AKI was induced by injecting 5.8ml/kg 50% glycerol IM in male BALB/c mice, tissues harvested at 36 and 66 days. Renal function: serial BUN, serum creatinine and transdermal GFR. Renal fibrosis: QRT-PCR for fibrosis markers, picro-sirius red (PSR) quantification. PTCD by quantifying CD31 immunostaining.

Results: There was a progressive decline in renal function with reduced GFR 110.69 (65.3) vs. 330.6 (36.8) microL/min (p<0.0001, T-test) and increased creatinine 28 days after RDCP-AKI. This was associated with increased expression of renal fibrosis markers, *LoxL2*, *Col1a1* and *Col1a3* mRNAs, but not PSR staining. In contrast, while mice treated with IM glycerol developed severe AKI, with peak BUN 161.6 (15.8) mg/dl at day 1, there was complete recovery of GFR at 36 and 66 days. This was associated with increased PSR staining, but unlike RDCP mice in which there was a reduction PTCD, PTCD was not reduced after Rhabdo-AKI.

Conclusions: These data demonstrate a dissociation between renal fibrosis and changes in GFR over time in different models of AKI to CKD transition, and that peritubular capillary rarefaction is more closely associated with changes in GFR than fibrosis. This provides insight into the potential role of capillary rarefaction as being the principal driver and candidate cellular target to prevent AKI to CKD progression, rather than renal fibrosis.

Transplanted Senescent Renal Tubular-Like Cells Induce Renal Microvascular Injury

Seo Rin Kim,[1,2] Kai Jiang,[1] Christopher M. Ferguson,[1] Hui Tang,[1] Xiaojun Chen,[1] Xiang yang Zhu,[1] LaTonya J. Hickson,[1] Tamara Tchkonia,[3] James L. Kirkland,[3] Lilach O. Lerman.[1] *[1]Nephrology and Hypertension, Mayo clinic, Rochester, MN; [2]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; [3]Robert and Arlene Kogod Center on Aging, Mayo Clinic, Rochester, MN.*

Background: Cellular senescence is characterized by a senescence-associated secretory phenotype (SASP), which reinforces senescence and exerts noxious effects on adjacent cells. Recent studies suggest that transplanting small numbers of senescent cells suffices to provoke tissue inflammation. Several models of kidney disease show increased prevalence of senescent renal cells. We hypothesized that senescent cells can directly augment renal injury.

Methods: Cellular senescence was induced in primary tubular-like cells acquired from pig kidneys by 10Gy of cesium radiation, and 3 weeks later cells were characterized for senescence and SASP markers. Control (CON) or senescent (SEN) renal tubular-like cells were pre-labeled and injected intra-aorta to C57BL/6J mice. Four weeks later, renal oxygenation was studied using magnetic resonance imaging, and function by plasma creatinine level. Renal markers of SASP, fibrosis, and microvascular density were evaluated.

Results: Per flow cytometry, 80-99% renal tubular-like cells were senescent after irradiation. They showed increased mRNA of senescence and SASP markers, SA-ß-gal staining, and cytokines levels secreted in conditioned-medium. Four weeks after injection, cells were detected engrafted in the kidneys with no evidence for rejection. Plasma creatinine and renal tissue hypoxia tended to increase in SEN compared to CON. SEN kidneys were more fibrotic, with fewer CD31+ endothelial cells, and showed upregulation of IL-6 gene expression.

Conclusions: Senescent renal tubular-like cells directly induce renal inflammation, fibrosis, microvascular loss, and hypoxia. These observations suggest a role for cellular senescence in the pathogenesis of kidney injury, and support development of senolytic therapy.

IKKα Aggravates Renal Fibrosis by Positively Regulating the Wnt/β-Catenin Pathway

Zhang Hao. *Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI) with maladaptive repair is a major contribution to renal fibrosis characterized by tubulointerstitial fibrosis. Previously, we have revealed that IKKα was involved in inhibiting inflammation and kidney regeneration.

Methods: By mating IKKα-floxed mice with Kap-Cre transgenic mice, mice with IKKα gene specifically ablated in renal tubular cells were created. After dorsal incision, the left renal pedicle was clamped with a micro vascular clamp for 45 min, while the sham-operated mice underwent the same treatment except clamping renal pedicle. We added TGF-β1 to the culture medium to establish the cell fibrosis model in human tubular epithelial cells.

Results: The expression of IKKα was up-regulated in kidney tubular epithelium in mice models of unilateral ureteral obstruction and ischemic reperfusion injury. In addition, immunohistochemical staining showed IKKα renal expression positively correlated with the kidney fibrosis in chronic kidney diseases (CKD) patients. Futhermore, we generated a knockout mouse model with IKKα gene specifically deleted in renal tubules. These knockout mice were phenotypically normal at birth and had no significant defects in kidney morphology and function. Compared with controls, Kap-IKKα$^{-/-}$ mice decreased Wnt/β-catenin activation, serum creatinine and attenuated interstitial fibrosis at 14 days after ischemic reperfusion injury. In vitro, IKKα blocked the interaction of GSK-3β with β-catenin in TGF-β1-stimulated human tubular epithelial cells resulting in β-catenin nuclear translocation. Additionally, blocking IKKα by siRNA specifically suppressed β-catenin activation and profibrotic gene expression such as fibronectin and α-smooth muscle actin.

Conclusions: IKKα aggravates renal fibrogenesis by amplifying regulation of the Wnt/β-catenin signaling pathway which may provide a potential anti-fibrosis therapy target for chronic kidney diseases.

SA-PO117

β-Catenin/Foxo Promotes Epithelial Healing in Kidney Injury

Padmashree Rao,[1] Xi Qiao,[1,2] Hong Yu,[1] Titi Chen,[1] Qi Cao,[1] Yiping Wang,[1] Vincent W. Lee,[1] Yuan Min Wang,[3] Stephen I. Alexander,[3] Guoping Zheng,[1] David Harris.[1] *[1]The University of Sydney at The Westmead Institute for Medical Research, Westmead, NSW, Australia; [2]Second Hospital of Shanxi Medical University, Taiyuan, China; [3]Children's Hospital at Westmead. The University of Sydney, Westmead, NSW, Australia.*

Background: Transforming growth factor (TGF-β) is known to promote healing after tissue injury, but also drives a maladaptive fibrotic response that leads to fibrosis and organ failure. β-catenin/TCF is central to TGF-β's profibrotic signaling pathways. β-catenin also binds to Foxo in competition with TCF and promote cell survival under oxidative stress. We propose that targeting TGF-β signaling by using an inhibitor of β-catenin/TCF will promote β-catenin/Foxo which results in physiological healing with epithelial rather than mesenchymal cells.

Methods: Scratch assay was used as an in vitro model of healing in murine proximal tubule-like epithelial C1.1 cells treated with TGF-β1 (3ng/ml) with or without β-catenin/TCF inhibitor ICG-001 (5μM). CRISPR/Cas9 was used to knockout Foxo1. Wound closure was measured as the percentage area of wound closure at 48 h (%). In vivo kidney injury healing was evaluated in murine unilateral ischemia reperfusion injury (UIR) by Gomori trichrome staining. Epithelial (E-cadherin) or mesenchymal (α-SMA) healing was examined by immunofluorescence staining and measured as percentage area of positive staining (%). β-catenin/Foxo or β-catenin/TCF interactions were examined by proximity ligation assay (PLA).

Results: The combined treatment of TGF-β1 and ICG-001 in C1.1 cells and UIR caused increased β-catenin/Foxo interaction as demonstrated by PLA. The combined treatment inhibited TGF-β-induced α-SMA expression and showed dominant E-cadherin expression to a greater extent than seen with TGF-β alone; α-SMA, 5±1% vs 40±3%, P<0.01 in vitro, and 18±1% vs 42±3%, P<0.01 in vivo; E-cadherin, 29±4% vs 2±3%, P<0.05 in vitro, and 22±5% vs 11±2%, P<0.05 in vivo. Foxo1 KO in C1.1 cells showed significant reduction in closure of the wound gap compared to WT cells (75±3% vs 95±3%; P<0.05). Foxo1 KO C1.1 cells slowed wound closure under combined treatment compared to that of WT cells (70±3% vs 98±2%, P<0.01) which could be explained by absence of β-catenin/Foxo in Foxo1 KO C1.1 cells. In UIR mice, combined treatment with rhTGF-β and ICG-001 significantly attenuated kidney fibrosis compared with TGF-β alone (42±5% vs 73±5%, P<0.01).

Conclusions: These results indicate that β-catenin/Foxo may serve as a therapeutic target to prevent pathological fibrotic healing and fibrosis in the treatment of kidney diseases.

SA-PO118

Endothelial Nitric Oxide Synthase/Nitric Oxide Pathway Underlies the Mechanisms of AKI to CKD Transition via Prolonged Activation of the Wnt/β-Catenin Pathway

Megumi Kondo, Hajime Nagasu, Yuji Sogawa, Hiroyuki Kadoya, Kengo Kidokoro, Minoru Satoh, Naoki Kashihara. *Kawasaki Medical School, Kurashiki, Japan.*

Background: Acute kidney injury (AKI) is not always reversible, but often promotes to chronic kidney disease (CKD), known as "AKI to CKD transition." Aging and disease conditions such as hypertension and diabetes are recognized as risk factors for AKI to CKD transition. These conditions are also closely associated with endothelial dysfunction (ED). Therefore, we hypothesized that AKI to CKD transition is promoted by ED characterized by deterioration in eNOS/Nitric Oxide (NO) /sGC/PKG pathway.

Methods: Wild-type mice (C57B6/J: WT) and eNOS deficient mice (eNOSKO) were used. WT and eNOSKO mice were divided into 4 groups: WT-sham, WT-IRI, eNOSKO-sham and eNOSKO-IRI. Mice were sacrificed on day 28 (D28) after ischemic reperfusion injury(IRI) (WT-IRI-D28 and eNOSKO-IRI-D28). To evaluate the therapeutic potential of sGC activation on the AKI to CKD transition, eNOSKO-IRI mice treated with PDE5 inhibitor (PDE5i, Sildenafil citrate, 5mg/kg/day, drinking water) from day 7 (D7) to day28 (D28) after IRI.

Results: Acute kidney damages of IRI were fully recovered in WT-IRI-D28 group. However, tubulointerstitial injuries, tubular cell damage, interstitial fibrosis and infiltration of inflammatory cells remained in eNOSKO-IRI-D28 group. These results indicate that deficient eNOS/NO/sGC/PKG signaling pathway promotes AKI to CKD transition after IRI. Next, the kidney damages in the early phase, day 1 and day 7, after IRI were examined in both groups. Histological examinations of kidney tissues failed to detect alterations in both groups at day 1 and day 7. However, RNA-seq analysis revealed significant increased expressions of Wnt/βcatenin-related genes and M2 macrophage (MΦ) related genes in eNOSKO-IRI-D7 group compared with WT-IRI-D7 group. In addition infiltration of M2 MΦ, evaluated by flow cytometric analysis, were increased in eNOSKO-IRI-D7 but not WT-IRI-D7. Furthermore, PDE5i treatment significantly ameliorated the kidney injuries compared with non-treated group.

Conclusions: Endothelial dysfunction, characterized by deterioration of eNOS/NO/sGC/PKG signaling pathway underlies prolonged activation of Wnt/βcatenin pathway and infiltration of M2 MΦ, thereby plays a pivotal role in AKI to CKD transition.

SA-PO119

Cyclin G1-Mediated Dedifferentiation of Proximal Tubular Cells Drives Fibrosis

Kensei Taguchi,[1] Bertha C. Elias,[1] Seiji Kishi,[2] Guillaume Canaud,[3] Joseph V. Bonventre,[4] Craig R. Brooks.[1] *[1]Vanderbilt University Medical Center/Division of Nephrology & Hpertension, Nashville, TN; [2]Kawasaki Medical School, Kurashiki, Japan; [3]Université Paris Descartes, INSERM U845, Hopital Necker, Paris, France; [4]Brigham and Women's Hospital, Boston, MA.*

Background: Over 13% of the world's population have chronic kidney disease (CKD). Severe acute kidney injury can lead to chronic kidney disease (CKD) through maladaptive repair of proximal tubular cells (PTC) and cycle arrest in the G2/M transition. Recently, we identified an atypical cyclin, cyclin G1 (CG1), as a key mediator of G2/M arrest, maladaptive repair and fibrosis; however, the underlying mechanism how CG1 regulates G2/M arrest and fibrosis remains to be resolved. The aim of the current study is to ascertain whether CG1-induced dedifferentiation drives PTC profibrotic signaling and kidney fibrosis.

Methods: Protocol 1; 8-week-old male BL57Bl/6 (WT) and CG1 knockout mice (CG1KO) received unilateral ureteral obstruction (UUO). Kidneys were taken at day 9 and fibrosis was assessed by picrosirius red staining and polarized microscopy. PTC dedifferentiation was defined by upregulated kidney injury molecule1 (KIM-1) and staining and PCR for differentiation/dedifferentiation marker expression. Protocol 2; Primary PTCs isolated from WT and CG1KO mice were treated with aristolochic acid (AA) and gene expression was analyzed by PCR and western blot.

Results: In response to UUO, kidney fibrosis was dramatically reduced in CG1KO compared with WT. Upregulation of KIM-1 in WT-UUO was ameliorated in CG1KO and markers of differentiation were preserved at both protein and mRNA levels in CG1KO. Compatible with our animal data, connective tissue growth factor (CTGF) and fibronectin were upregulated by AA treatment in WT PTC and attenuated in CG1KO PTC. Further, AA-induced cell enlargement was restored by deletion of CG1. Na-K-ATPase and AQP1 mRNA were also maintained in CG1KO PTC. Importantly, inhibition of dedifferentiation reduced levels of G2/M arrested cells, marked by phosphorylated Histone 3 (pH3), in CG1KO-UUO kidneys compared to WT-UUO.

Conclusions: Cyclin G1 drives a maladaptive dedifferentiation of proximal tubular cells after kidney injury, resulting in increased secretion of profibrotic cytokines and progression of fibrosis. Cyclin G1-induced dedifferentiation facilitates G2/M arrest and subsequent maladaptive responses. As cyclin G1 is only expressed in chronically injured cells, it represents a potential therapeutic target for prevention of kidney fibrosis.

SA-PO120

The Role of Glycolysis in Progression of Renal Fibrosis

Geoffrey Harley,[1] Mardiana Lee,[1] Marina Katerelos,[1] Kurt Gleich,[1] Mitchell A. Sullivan,[2] Peter F. Mount,[1] David A. Power.[1] *[1]Austin Health, Melbourne, VIC, Australia; [2]Mater Research Institute - The University of Queensland, Brisbane, NSW, Australia.*

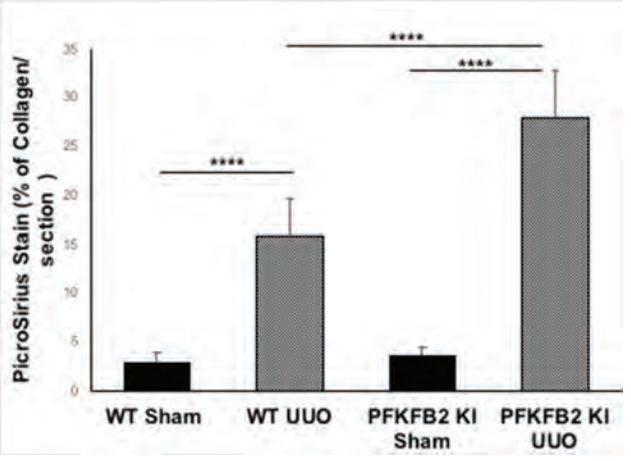
Background: Fatty acid oxidation is reduced in renal fibrosis and drugs that increase it improve fibrosis. The role of glycolysis, however, is unclear. We mutated a key controller of glycolysis in mice to determine its effect on renal fibrosis.

Methods: 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase (PFKFB) is a key regulator of glycolysis. Mice with inactivating S466A and S483A mutations of the phosphorylation sites in PFKFB2 (PFKFB2 KI mice) were generated. The mutations are predicted to reduce the ability to increase the rate of glycolysis following stimulation. The unilateral ureteric obstruction (UUO) and folic acid nephropathy (FAN) models were used.

Results: In both UUO ($p<0.01$) and FAN ($p<0.05$) models, there was reduced expression of PFKFB2 in WT mice compared with controls. PFKFB2 KI mice showed no obvious phenotype and had normal plasma glucose. Serum creatinine and urea were similar to wild type (WT). Western blots confirmed unchanged levels of PFKFB2 expression in kidneys from PFKFB2 KI mice. In the UUO model, there were significant increases in renal fibrosis in PFKFB2 KI mice when assessed by picrosirius red staining ($p<0.001$), RT-PCR and Western blots for a-SMA ($p<0.05$) and fibronectin ($p<0.05$) compared to WT. Glycogen increased similarly in both KI and WT mice following UUO but lipid accumulation, measured by oil red O ($p<0.005$), was greater in PFKFB2 KI mice. In contrast, similar studies with the FAN model showed no significant increase in fibrosis, greater glycogen content in the PFKFB2 KI mice compared to WT ($p<0.05$) and no difference in lipid accumulation.

Conclusions: These data show that inhibition of the regulation of glycolysis by PFKFB2 increases fibrosis in the UUO but not the FAN model. Increased fibrosis in the UUO model may reflect a greater effect on distal tubules compared with the FAN model, with the well-known reliance of distal tubules on glycolysis leading to energy shortage and fibrosis.

Funding: Government Support - Non-U.S.



SA-PO121

Pyruvate Kinase M2 Mediates Fibroblasts Activation Alleviates AKI

Yinyin Ye, Lei Jiang, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI) is a devastating condition with high morbidity and mortality. The pathologic features of AKI are characterized by tubular injury, infiltration of inflammation cells and vascular integrity impairment. Pyruvate kinase is the last rate-limiting enzyme in the glycolysis pathway, We have previously shown that Pyruvate kinase M2 (PKM2) plays an important role in regulating the glycolytic recombination of fibroblasts in chronic kidney disease. But the role of PKM2 in fibroblasts in the pathogenesis of AKI is unknown.

Methods: Lentivirus was used to down-regulate PKM2 expression in NRK-49F cells, and then analyzed the expression of the key enzymes of glycolysis and the ability of cell proliferation. *In vivo*, we generated fibroblast specific PKM2 knockout mice (Fibroblast-PKM2-/- mice) by crossbreeding PKM2-flox mice with S00A4-Cre mice. Then we compared renal function, expression of urinary KIM-1 and NGAL, pathological damage and renal tubular cell apoptosis between Fibroblast-PKM2-/- mice and control mice after ischemia-reperfusion injury(I/R) or folic acid (FA) injection. Reno-protective factors secreted by fibroblasts such as HGF and EPO were determined by RT-PCR and Elisa. Co-culture of NRK-52E cells and NRK-49F cells under oxygen deprivation condition was used to investigate the interaction between fibroblasts and renal tubular cells.

Results: Down-regulation of PKM2 can reduce glycolysis level and decrease the ability of proliferation of NRK-49F cells. Compared with control mice, Fibroblast-PKM2-/- mice had less fibroblast activation, more kidney injury indicated by increased BUN, KIM-1 and NGAL levels and more apoptosis of tubular epithelial cells after AKI induced by I/R or FA injury. Furthermore, Fibroblast-PKM2-/- mice secreted lower renal protective factors such as HGF and EPO. Additionally, Fibroblast-PKM2-/- mice showed suppressed of HGF-cmet signaling and decreased expression of p-ERK and p-bad. Co-culture experiment in oxygen deprivation condition revealed that down-regulation of PKM2 in NRK-49Fcells could decrease the expression of HGF and EPO in NRK-49F cells and inhibit fibroblast activation, and increase apoptosis in NRK-52E cells.

Conclusions: Collectively, these results suggest that PKM2 mediated fibroblasts activation plays a critical role in the pathogenesis of AKI.

Altered Citrate Metabolism Leads to Maladaptive Repair After Tubular Injury and Facilitates Kidney Fibrosis in Diabetic Nephropathy

Jiahua Li,[1] Jae Hyung Chang,[2] Tomohisa Suzuki,[3] Chen Yang,[4] Yutaro Mori,[1] Michifumi Yamashita,[5] Venkata Sabbisetti,[1] Takaharu Ichimura,[1] Joseph V. Bonventre.[1] *[1]Internal Medicine, Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Columbia University Medical Center, New York, NY; [3]Otsuka Pharmaceuticals, Naruto, Japan; [4]Pathology, Yale University School of Medicine, New Havens, CT; [5]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Dysregulated lipid metabolism is a primary feature of DKD. Citrate is a tricarboxylic acid cycle metabolite and a regulator of lipid metabolism via ATP-citrate lyase (ACLY) and acetyl-CoA carboxylase (ACC). Citrate accumulates in the renal

parenchyma after AKI. We hypothesized that altered citrate metabolism contributes to maladaptive tubular repair after AKI and progression of diabetic nephropathy.

Methods: We generated C57B/6 Akita^{DTR} mice expressing the simian diphtheria toxin receptor (DTR) in the renal tubule in a non-obese diabetic background. Animals on a high-fat diet (HFD) were administered one dose of DT to induce tubular injury, and the kidney tissue damage was evaluated at four months. In a cisplatin toxicity model in vitro, LLC-PK$_1$ kidney epithelial cells were exposed to high glucose or high palmitic acid concentrations, and analyzed for cell cycle arrest, DNA damage response, and alteration in citrate metabolism.

Results: DT-treated Akita^{DTR} mice on HFD developed overt proteinuria, severe tubulointerstitial fibrosis, secondary glomerular sclerosis, interstitial inflammation, capillary rarefaction, and podocyte dropout, while the control littermates without tubular injury, or without diabetes, or without HFD did not. The Akita^{DTR} mice on HFD had increased inhibitory phosphorylation of ACC (p-ACC). In cisplatin-treated cells in high glucose, G2/M arrest was associated with increased citrate concentration, and compensatory decreased p-ACC and increased ACLY. Co-treatment with palmitic acid and cisplatin increased p-ACC and enhanced DNA damage and G2/M arrest. When compared with cisplatin treatment alone, co-treatment with a small molecule inhibitor of ACC and cisplatin also increased DNA damage, G2/M arrest, and the conditioned media from the kidney epithelial cells enhanced a-SMA production by 10T$^{1/2}$ pericyte-like cells.

Conclusions: Citrate-derived acetyl-CoA facilitates tubular repair. Inhibitory phosphorylation of ACC by exogenous lipid or pharmacological inhibition of ACC resulted in more DNA damage, G2/M arrest, and production of pro-fibrotic agents by renal epithelial cells after AKI.

COUP-TFII Enhances TGFβ-Induced Metabolic Reprogramming in Stromal Cells and Contributes to Kidney Fibrosis

Li Li,[1] Ana C. Figueroa Ramirez,[1] Diana Tamayo,[1] Kyle Mccracken,[2] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Boston Children's Hospital, Boston, MA.*

Background: Metabolic perturbation is implicated in the pathogenesis of kidney fibrosis, but the molecular mechanisms that couple myofibroblast metabolism and differentiation are unknown. COUP-TFII is an orphan nuclear receptor involved in metabolic regulation, but its role in the kidney has not been investigated. We hypothesized that TGFβ-induced metabolic reprogramming in stromal cells is regulated by COUP-TFII.

Methods: Unilateral ureter obstruction (UUO) surgery was used for *in vivo* modeling of kidney injury and fibrosis. *In vitro*, we used CRISPR and an inducible lentiviral construct to generate COUP-TFII loss- and gain-of-function models in C3H/10T1/2 cells. For metabolic assays, we used the Seahorse XF24 flux analyzer and JC-1 staining to estimate glycolysis and the mitochondrial membrane potential. We generated conditional COUP-TFII deficient (cKO) mice by crossing floxed alleles with an inducible Cre driver.

Results: We first examined gene expression in fibrotic kidneys and found that key glycolytic enzymes were upregulated while *PGC1α* was suppressed seven days after UUO. This expression pattern was conserved in TGFβ-treated C3H/10T1/2 cells. Accordingly, TGFβ treatment *in vitro* led to increased cellular lactate production and decreased mitochondrial membrane potential. Interestingly, we found that COUP-TFII was required for the TGFβ-induced shift toward glycolysis, and COUP-TFII KO cells exhibited an attenuated profibrotic phenotype. In contrast, overexpression of COUP-TFII was sufficient to enhance glycolysis and increase αSMA and collagen 1 levels. This pathway was further interrogated *in vivo*, where cKO mice were protected from kidney fibrosis.

Conclusions: TGFβ induces a shift in cellular metabolism from oxidative respiration to aerobic glycolysis, and this effect is dependent on COUP-TFII activation. Loss of COUP-TFII ameliorates fibrotic phenotypes both *in vitro* and *in vivo*. These findings provide new mechanistic insights into TGFβ-induced myofibroblast differentiation pathways, and targeting COUP-TFII may thus serve as a novel treatment approach for mitigating kidney fibrosis in chronic kidney disease.

Cellular G2/M Arrest Induced by VPR in Kidney Promotes AKI or AKI-CKD Transition and Can Be Partially Rescued by Specific Small Molecule Inhibitors

Yuqiang Chen,[1,2] Wenzhen Xiao,[2] Jing E,[3] Niansong Wang,[1] Kyung Lee,[2] John C. He.[2] *[1]Sixth People's Hospital Affiliated to Shanghai Jiaotong University, Shanghai, China; [2]Mount Sinai School of Medicine, New York, NY; [3]Ningxia People's Hospital, New York, NY.*

Background: HIV-1 encodes an accessory protein named vpr that will damage renal cells. Podocyte damage and tubular epithelial cell injury may lead to proteinuria, impaired renal function and acute kidney injury (AKI). AKI can contribute critically to chronic kidney disease (CKD). Studies show that vpr plays an important role in cell injury and leads to AKI or AKI-CKD transition. Developing the strategies for AKI-CKD transition is urgently needed. But the cellular and molecular basis of AKI-CKD transition by vpr is very complex and largely unclear.

Methods: Pax8-rtta; TRE-vpr double transgenic mice were fed with DOX to overexpress vpr in tubular cells. Similarly, podocin-rtta; TRE-vpr were generated to overexpress vpr in podocyte. DOX induction were started at the age of 4 weeks and the induction periods were 8wks, 18wks, 23wks and 28wks, respectively. To alleviate or reverse vpr related lesion,P53 inhibitor PFT- α or PLK 1 inhibitor BI 2536 was administrated by Peritoneal Injection for 4 weeks. Renal function and proteinuria were monitored. After sacrifice the mice, the renal cortex genes, proteins and histology are screened.

Results: Vpr in tubular cells led to proximal tubular cells injury, G2/M arrested cell, AKI and impaired renal function without proteinuria. Histopathological analysis indicated PTC injury and apoptosis, even interstitial fibrosis and secondary cyst formation and kidney enlargement in long-term induced mice, which indicated AKI-CKD transition. Vpr overexpression in podocyte led to massive podocyte injury, proteinuria and secondary reduced renal function. Dox withdrawal led to relative mild lesions and less AKI-CKD transition, which indicated vpr overexpression was responsible for those kidney lesions. P53 and PLK 1 activation were involved in vpr overexpression related G2/M arrest. Both inhibitors reduced P53 and PLK 1 level in vivo, and partially rescued tubular cell injury, proteinuria and renal function impairment, as well as AKI-CKD transition.

Conclusions: Our study demonstrates that vpr plays an important role in the pathogenesis of tubular epithelial cell and podocyte damage and subsequent AKI or AKI-CKD transition. P53 and PLK 1 inhibition are useful to relieve or rescue tubular cell injury, proteinuria and AKI-CKD transition in vpr induced damages.

SA-PO125

ATG5-Mediated G2/M Arrest Through ATR-Chk1 Signaling Contributes to Renal Fibrosis After Injury Induced by Aristolochic Acid I

Meiju Wu,[2] Xuan Huang,[2] Yuan Peng,[2] Xi Xiao,[2] Xueqing Yu,[3] Xiao Yang.[1] *[1]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]The First Affiliated Hospital, Sun Yat-sen University, Guang Zhou, China; [3]Department of Nephrology, Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Recent studies have shown that autophagy is involved in the regulation of G2/M arrest and plays a renoprotective role after kidney injury. However, its role in aristolochic acid (AA)-induced AKI transition CKD remains largely unclarified.

Methods: Here, we investigated whether autophagy-related gene 5 (ATG5) modulation of Chk1 phosphate expression during AKI contributes to the progression to CKD. We tested this hypothesis by administration of aristolochic acid-I (AAI) in vitro.

Results: (1) CCK-8 showed that the viability of HK-2 cells treated with different concentrations of AAI (0, 2.5, 5, 10, 20, 40 μM) for 48 hours decrease in a concentration-dependent manner. The cell viability decreased in a time-dependent manner when HK-2 were stimulated with 5 μM AAI for different durations (0, 3, 6, 12, 24, 48 hours). (2) Western blot showed that the expression of LC3-II/I, DNA double-stranded damage marker γH2AX and FN in concentration-dependent, time-dependent increase after AAI stimulation. Phosphorylation level of Chk1(s345) and its upstream regulatory protein ATR(t1989) showed parabolic trends at 48 h after AAI stimulation. Chk1(345) and ATR(t1989) phosphorylation level increased in a time-dependent manner when AAI stimulation concentration was 5 μM. (3) Flow cytometry: After AAI treat of HK-2 cells for 48 h, the cell cycle G2/M arrest rate increased most at AA-I concentrations of 5 μM and 10 μM and the proportion of G2/M arrest was 39.12±9.1% and 40.88±10.1% respectively; the difference was statistically significant compared with 0μM (8.09±1.5%) ($p<0.05$, 0.05). While stimulation with AAI concentration of 5 μM for different times. The proportion of G2/M arrest gradually increased with time, and it was 41.57±16.6%at 48h; the difference was statistically significant compared with 0h (6.94±0.7%) ($p<0.05$). (3) ATG5 deletion led to enhanced G2/M cell-cycle arrest and increased expression of the Chk1 and of profibrotic factors (Fibronectin(FN), Connective Tissue Growth Factor (CTGF)). Autophagy activator (rapamycin) down-regulated phosphorylation level of chk1 and aggravated fibrosis (CTGF). Treatment with a Chk1 inhibitor reduced mRNA expression of fibrosis gene (FN).

Conclusions: Taken together,these findings indicated that ATG5 mediated G2/M arrest through Chk1 contributes to renal fibrosis after injury induced by AAI.

SA-PO126

The Progression of AKI to Chronic Tubulointerstitial Fibrosis Was Ameliorated in IL-18 Knockout Mice After Folic Acid Induction

Junjun Luan,[1] Jingqi Fu,[2] Jingbo Pi,[2] Detian Li,[1] Hua Zhou.[1] *[1]The Affiliated Shengjing Hospital of China Medical School, Shenyang/China, China; [2]Chinese Medical University, Shenyang, China.*

Background: Folic acid (FA)-induced acute kidney injury (AKI) can proceed to chronic tubulointerstitial fibrosis (TIF) in mice. This is clinical relevant animal model of AKI to latent TIF. The mechanisms of the progression still remain unclear. We aim to investigate the role of interleukin (IL)-18, a cytokine secreted by macrophages and T cells, in the progression from AKI to TIF induced by FA and its corresponding mechanisms.

Methods: We first explored time course of renal injury and IL-18 expression in *Il18*$^{+/+}$ mice at day 2, 14, and 30 after 250mg/ kg of FA intraperitoneal injection. Then we compared the acute necroptosis indicated by receptor-interacting serine/threonine-protein kinase1 (RIPK1), RIPK3, and phosphorylation of mixed lineage kinase domain like pseudokinase (p-MLKL); transdifferentiation marked by IL-11, transforming growth factor β1, vimentin, and connective tissue growth factor; renal fibrosis expressed with α-smooth muscle activating protein and collagen type I as well as inflammatory response including cytokines, M1 and M2 macrophages, and T lymphocytes infiltration in *Il18*$^{+/+}$ and *Il18*$^{-/-}$ mice after FA administration at each experimental time point.

Results: In *Il18*$^{+/+}$mice following FA injection, renal IL-18 and serum interferon-γ progressively increased accompanied with the progression from AKI to TIF. In addition, biomarkers of necroptosis on day 2, transdifferentiation on day 14, and tubulointerstitial fibrosis on day 30, M1 macrophages on day 14, and M2 macrophages on day 30 were peaked respectively at the different time points after FA injection. In *Il18*$^{-/-}$ mice, traditional acute and chronic renal damage, necroptosis, transdifferentiation, and renal fibrosis were all attenuated. Importantly, IL-18 deficiency decreased infiltration of M1 macrophages and its secreted cytokines on day 2 and day 14, reduced the infiltrated M2 macrophages and T cells as well as their related inflammatory responses at each time points from day 2 to 30 after FA.

Conclusions: IL-18 deficiency suppressed renal tubular damage, necroptosis, transdifferentiation, and fibrosis in FA-induced AKI to TIF. The renal protective role of IL-18 deletion in this progression might be mediated by inhibition of cytokines and the infiltrated M1, M2 macrophages, and T cells as well as the macrophage transformation from M1 to M2 types.

Soluble fms-Like Tyrosine Kinase-1 Promotes AKI and CKD After Renal Ischemia-Reperfusion Injury

Hideo Tsushima,[1] Masahiro Eriguchi,[1] Masaru Matsui,[2] Takaaki Kosugi,[1] Masatoshi Nishimoto,[1] Kaori Tanabe,[1] Miho Tagawa,[1] Ken-ichi Samejima,[1] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Kasihara-city, Japan; [2]Nara Prefecture General Medical Center, Nara, Japan.*

Background: Soluble fms-like tyrosine kinase-1 (sFlt-1), which is extracellular domains of Flt-1, acts as an antagonist of both placental growth factor (PlGF) and vascular endothelial growth factor A (VEGF-A). We previously reported that kidney is a main source of circulating sFlt-1 (about 50%). Generally, VEGF signaling is associated with angiogenesis and macrophage migration. Angiogenesis has a protective effect against renal ischemia, however macrophage migration contributes renal injury. The objective of this study is to examine the role of sFlt-1 in acute and chronic kidney injury after renal ischemia.

Methods: Unilateral or bilateral 30-minute renal ischemia were performed using sFlt-1 knockout (KO) and wild-type (WT) mice. For evaluation of acute kidney injury (AKI), plasma urea nitrogen levels and macrophage infiltration in the kidney were measured on day 1 and 7 after bilateral renal ischemia. Kidneys two weeks after unilateral renal ischemia were used for chronic kidney disease (CKD) model. Ischemic/non-ischemic kidney weight ratios (ischemic kidney weight divided by non-ischemic kidney weight) and renal fibrosis of the unilateral ischemic kidneys (Sirius red staining) were examined.

Results: After bilateral renal ischemia, plasma urea nitrogen levels from sFlt-1 KO mice were significantly lower than those from WT mice (130.5 ± 5.0 vs 164.0 ± 10.2 mg/dL, p=0.009 on day 1; 56.2 ± 2.9 vs 76.3 ± 4.1 mg/dL, p=0.001 on day 7). However, there was no difference in macrophage infiltration in the kidneys between sFlt-1 KO and WT mice on day 1 (49 ± 8 vs 59 ± 5/field, p=0.30). Two weeks after unilateral renal ischemia, ischemic/non-ischemic kidney weight ratios from sFlt-1 KO mice were significantly larger than those from WT mice (76.5 ± 7.6 vs 60.4 ± 1.9%; P=0.046). Finally, renal fibrosis from sFlt-1 KO mice was significantly reduced by 21.0% compared to WT mice (p=0.032).

Conclusions: sFlt-1, which is mainly secreted from kidneys, promotes AKI and following CKD after renal ischemia-reperfusion injury in a paracrine manner.

SA-PO128

Grhl2-Deficient Mice Are Protected from Renal Fibrosis After Ischemic AKI

Felix Boivin,[1] Dominik Müller,[3] Kai M. Schmidt-Ott.[2] *[1]Max Delbrück Center, Berlin, Germany; [2]Charite - Universitaetsmedizin Berlin, Berlin, Germany; [3]Charité, Berlin, Germany.*

Background: Ischemic acute kidney injury disrupts epithelial tight junctions and induces a loss of epithelial cell polarity in the tubules of the nephron and collecting duct, leading to increased urine output and decreased urine osmolality. While the kidney can re-establish epithelial barrier integrity following injury, it is at an increased risk of developing fibrosis during recovery due to the activation of maladaptive repair mechanisms. Our group recently demonstrated that a transcription factor termed Grhl2 controls epithelial barrier formation of the collecting duct and is critical for renal osmoregulation. We showed that mice deficient for Grhl2 fail to properly concentrate urine and as a result exhibit reduced urine osmolality and develop diabetes insipidus. The relationship between the collecting duct barrier integrity and recovery post-injury is unclear.

Methods: To test this, we generated mice deficient for Grhl2 specifically in the collecting duct epithelium (Grhl2 $^{CD-/-}$). We subjected these mice, along with their control littermates, to kidney injury via unilateral ischemia of the left kidney for 25 minutes. Subsequently, we investigated renal injury and regeneration by allowing the mice to recover for reperfusion periods of 1, 3, 7, or 21 days.

Results: Semi-quantitative scoring of tubular damage in the initial phase of injury, at 1 and 3 days, did not reveal any significant differences between Grhl2$^{CD-/-}$ mice and controls. During the late recovery phase, 7 days post-ischemia, however, we observed a 38,52% decrease in tubular damage in Grhl2$^{CD-/-}$ mice (45.48% vs 27.96%, p<0.05). Additionally, we observed a 62.59% reduction in overall interstitial fibrosis 21 days post-ischemia in Grhl2$^{CD-/-}$ compared to control littermates (10.43% vs 6.53%, p<0.05). Further analysis of extracellular matrix components fibronectin and collagen IV, and the myofibroblast marker a-Smooth Muscle Actin, revealed marked reductions in Grhl2$^{CD-/-}$ mice. Additionally, we observed a significant reduction in mRNA expression of pro-inflammatory cytokines TNF-a (1.019 vs 0.4917, p<0.05) and IL-6 (1.027 vs 0.511, p<0.05) in Grhl2$^{CD-/-}$ mice 21 days post-ischemia.

Conclusions: Grhl2-deficient mice display an improved renal recovery following injury, raising the possibility that collecting duct epithelial barrier function and/or the intrarenal osmotic gradient contribute to renal recovery.

SA-PO129

Ischemia-Reperfusion-Induced AKI (IR-AKI) Associated with Renal Fibrosis Is Attenuated Through Suppressing Indoxyl Sulfate Accumulation in Sulfotransferase (Sult) 1a1-Deficient Mice

Keisuke Matsushita,[1] Nao Gunda,[1] Rika Fujino,[2] Aina Nishigaki,[1] Yuya Hayashi,[2] Kazuhiko Nishi,[3] Hirofumi Jono,[2,1] Hideyuki Saito.[2,1] *[1]Clinical Pharmaceutical Sciences, Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan; [2]Pharmacy, Kumamoto University Hospital, Kumamoto, Japan; [3]Hemodialysis and Apheresis, Kumamoto University Hospital, Kumamoto, Japan.*

Background: IR-AKI is a high risk factor in the progression towards chronic kidney disease (CKD), which is featured by renal fibrosis. Indoxyl sulfate (IS), a typical uremic solute, is accumulated in the various organs of CKD patients, whereas the relationship of IS levels and AKI-to-CKD transition associated with renal fibrosis has not been clarified. IS is produced predominantly in the liver by CYP2A6/2E1-mediated oxidative metabolism of gut microflora-derived indole to indoxyl, followed by Sult1a1-mediated sulfate transfer to indoxyl. We established the Sult1a1 gene-deficient mice (Sult1a1$^{-/-}$), and explored the toxicological roles of IS in IR-induced AKI-to-CKD process associated with renal fibrosis.

Methods: C57BL/6 mice (WT) and Sult1a1$^{-/-}$ (9wks) were subjected to 30 min of renal IR, and sacrificed at 28 days after surgery. Serum creatinine (sCr) and BUN were evaluated as renal function markers. IS accumulation in serum and renal tissue was determined by LC-MS/MS. Renal fibrosis was assessed by Sirius red staining, and mRNA expression of fibrosis-related genes including Col1a1 and PAI-1 were determined by qRT-PCR.

Results: Sult1a1$^{-/-}$ mice subjected to IR showed partial prevention of renal damage compared to WT mice with IR treatment: sCr, 0.80 mg/dl in WT vs 0.33 mg/dl in Sult1a1$^{-/-}$, p<0.01; BUN, 75.0 mg/dl in WT vs 45.8 mg/dl in Sult1a1$^{-/-}$. Renal dysfunction was associated with the suppression of serum and renal tissue IS levels in Sult1a1$^{-/-}$ mice: serum, 23.1 μM in WT vs 1.8 μM in Sult1a1$^{-/-}$, p<0.01; renal tissue, 15.0 nmol/g tissue in WT vs 0.06 nmol/g tissue in Sult1a1$^{-/-}$, p<0.01). IR treatment caused marked renal interstitial fibrosis in both WT and Sult1a1$^{-/-}$ mice, whereas fibrosis formation in the cortex of the kidney showed a tendency to be reduced in Sult1a1$^{-/-}$ mice, compared to WT mice. mRNA expression of Col1a1 and PAI-1 in the kidney were markedly increased in both WT and Sult1a1$^{-/-}$ mice treated with IR, however, these gene levels were suppressed in Sult1a1$^{-/-}$ mice compared with WT mice.

Conclusions: Sult1a1 appeared to be the key hepatic enzyme responsible for deriving IS in IR-AKI. IS could be one of the exacerbation factors in IR-induced AKI-to-CKD transition by promoting renal fibrosis.

SA-PO130

Low-Dose Verteporfin Attenuates Tubule Interstitial Fibrosis from AKI via Inhibition of YAP-MCP1-Associated Inflammation

Zhihuang Zheng,[1,2] Chuanlei Li,[1] Yili Fang,[2] Chenyang Qi,[2,3] Zhigang Zhang,[2] Huijuan Wu,[2] Jun Liu.[1] *[1]Department of Nephrology, Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Department of Pathology, School of Basic Medical Sciences, Fudan University, Shanghai, China; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: Incomplete recovery of AKI leads to an increased risk for CKD. Tubule-interstitial fibrosis (TIF) is the main pathological features of the AKI–CKD transition. Increasing evidence indicates that YAP, downstream of Hippo pathway, might be the key regulator of renal regeneration and fibrogenesis, but its role in the renal TIF after Ischemia-reperfusion (IR)-induced AKI remained unclear.

Methods: We established bilateral renal 30min-IR-induced AKI mice model and YAP expression was examined. Then different doses of Verteporfin (VP) were injected into AKI mice intraperitoneally (every other day) for 2 weeks. Hypoxia-reoxygenation (HR) was used to mimic IR in vitro.

Results: Renal interstitial inflammation and fibrosis were gradually aggravated from 1-to-12 weeks after IR. YAP was significantly activated in the epithelium of tubules, which usually surrounded by focal inflammation and fibrosis. Two weeks injection of VP into post-IR mice with a dose of 100 mg/kg caused 100% of death (n=10), 50 mg/kg caused 85% of death (n=10) and 25mg/kg only caused 25% of death (n=10). By using Low-dose of Verteporfin (LDVP, 25mg/kg) for 2 weeks, there was no significant change in levels of SCr and BUN, but the concentration of urine electrolytes including sodium, potassium and chlorine increased. Moreover, levels of serum IL-1β,TNF-α,and MCP1 and renal positive staining for CD3 or F4/80 were reduced, compared to vehicle treated post-IR mice. Masson trichrome and Sirius red staining showed a significant reduction of collagen deposition indicating inhibited fibrogenesis. Interestingly, we found LDVP down-regulated the expression of inflammatory factor MCP1 *in vitro*. And hyperactivate YAP via knocking down the Lats1 could up-regulated MCP1. While IR mice treated by bindarit, a MCP1 inhibitor, levels of serum IL-1β,TNF-α,and MCP1 and renal positive staining of CD3 and F4/80 decreased as well. In addition, LDVP did not attenuate oxidative stress *in vitro* and tubular damage *in vivo*.

Conclusions: This study indicates inhibition of YAP by low-dose of Verteporfin has an anti-fibrotic effects in the progression of IR-caused AKI, which might via inhibition

of YAP-MCP1 associated inflammation, whereas the higher-doses of Verteporfin has increased mortality.

15-Lipoxygenase Alters Inflammation, Metabolism, and Fibrosis in a Model of Renal Injury

John R. Montford,[1,2] Colin D. Bauer,[1] Sarah Faubel,[1,2] Raphael A. Nemenoff,[1] Seth B. Furgeson.[1,3] *[1]University of Colorado Health Science Center, Aurora, CO; [2]Rocky Mountain Regional VAMC, Aurora, CO; [3]Denver Health and Hospitals, Denver, CO.*

Background: 15-Lipoxygenase (15-LO, ALOX15) is implicated in the pathogenesis of a growing number of inflammatory and fibrotic diseases such as asthma, heart failure, and stroke but its role in renal injury is unexplored. We sought to examine if manipulating 15-LO would influence renal inflammation and fibrosis using a rodent model of unilateral ureteral obstruction (UUO).

Methods: Wild Type (WT) mice (N=18), mice lacking 15-LO (*Alox15-/-*) (N=11), and mice with transgenic overexpression of 15-LO (N=9) were subjected to UUO and kidneys were collected at 3 and 10 days postoperatively for histology, qRT-PCR, hydroxyproline assessment, and metabolomic and lipidomic analysis of over 200 unique compounds.

Results: At 3 days after UUO, as compared to WT controls, *Alox15-/-* kidneys had decreased mRNA levels of pro-inflammatory cytokines tumor necrosis factor alpha (TNFα) and fractalkine (CX3CL1) (0.84 vs 1.71 mean fold decrease, p<0.05; and 0.41 vs 1.04 mean fold decrease, p<0.01, respectively). Similar results were obtained 10 days after UUO (0.93 vs 1.39 mean fold decrease, p<0.01, and 2.79 vs 5.32 mean fold decrease, p<0.01, respectively). At 3 days after UUO, injured Alox15-/- mice had reduced levels of toxic reactive eicosanoids including 12(13)- and 9(10)-DiHOMEs, 9- and 13-OxoODEs, and 5(S)-HETE compared with WT specimens. At 10 days after UUO, *Alox15-/-* mice had evidence of marked oxidative phosphorylation vs. WT mice, which demonstrated a shift towards glycolysis. Also at 10 days after UUO, there was a trend towards reduced fibrosis in the Alox15-/- vs. WT by Picrosirius red staining (p=0.09), but not by mRNA for transforming growth factor beta (TGF-β) and smooth muscle alpha actin (αSMA). Next, we determined if overexpressing 15-LO would promote inflammation and fibrosis 10 days after UUO. As compared with WT mice, 15-LO transgenic mice had increase message for CX3CL1 (4.89 vs 1.69 mean fold increase, p<0.001), TGF-β (6.22 vs 2.35 mean fold increase, p<0.001), and αSMA (4.34 vs 2.52 mean fold increase, p<0.01). Fibrosis was significantly worse among the 15LOTG mice as compared to WT controls by Picrosirius red staining (7.52 vs 4.03 % fibrosis, p<0.05) and cortical hydroxyproline content (4.09 vs 1.99 mcg/mg total protein, p<0.01).

Conclusions: 15-Lipoxygenase contributes to inflammation, metabolic changes, and fibrosis in mice undergoing UUO.

SA-PO132

Increased HIPK2 Expression in Tubular Epithelial Cells Aggravates Kidney Fibrosis

Wenzhen Xiao,[1] Jing E,[1,4] Kyung Lee,[2] John C. He.[3] *[1]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Mount Sinai School of Medicine, New York, NY; [4]Ningxia People's Hospital, New York, NY.*

Background: Irrespective of etiology, kidney fibrosis is a final common pathogenic process for the progression of chronic kidney disease (CKD) to end-stage renal disease. Therefore, there is an urgent need to develop effective anti-fibrosis therapy for CKD. We previously demonstrated that homeodomain interacting protein kinase 2 (HIPK2) is a critical protein kinase regulating multiple pro-fibrotic and pro-inflammatory pathways in the diseased kidney. The global knockout of HIPK2 attenuates kidney fibrosis in several animal models of kidney disease. However, the direct effects of HIPK2 in renal tubular cells have not been confirmed. Therefore, we used several conditional knockout or expressing mouse models to further investigate the role of HIPK2 in renal tubular epithelial cells in kidney fibrosis.

Methods: We generated tetracycline-inducible, tubule-specific HIPK2 knockout mice ($Hipk2^{fl/fl}$; pax8-rtTA; TRE-Cre). We also generated tetracycline-inducible tubule-specific HIPK2 wildtype overexpression mice ($Hipk2^{WT}$; pax8-rtTA), as well as kinase-dead HIPK2 mutant mice ($Hipk2^{MT}$; pax8-rtTA) as a control. Tetracycline analog doxycycline was administered for 3 weeks prior to unilateral ureter obstruction (UUO) and at the age of five-week-old Tg26 mice. Extent of fibrosis was assessed after 14 days of UUO and at the age of 10-week-old Tg26 mice by histopathological scoring and by assessment of fibrosis markers using quantitative PCR and western blot.

Results: We observed that the loss of tubular HIPK2 resulted in significant attenuation of kidney fibrosis, while tubular overexpression of wildtype HIPK2 resulted in marked augmentation of kidney fibrosis in UUO mice. Furthermore, the overexpression of kinase-dead HIPK2 mutant significantly diminished kidney fibrosis in UUO mice and Tg26 mice, suggesting that the kinase activity of HIPK2 is required for its pro-fibrosis effect.

Conclusions: Our results clearly demonstrate that increased HIPK2 expression in renal tubular cells aggravates kidney fibrosis progression. Therefore, the inhibitors of HIPK2 could be developed as a potential anti-fibrotic therapy for CKD.

Urinary EGF and ICAM-1 Predict Glomerular Number Using Cationic Ferritin Enhanced-MRI in a Murine Model Folic Acid Nephropathy

Jennifer R. Charlton,[1] Kimberly Deronde,[1] Yanzhe Xu,[2] Teresa Wu,[2] Kevin M. Bennett.[3] *[1]University of Virginia, Charlottesville, VA; [2]Arizona State University, Tempe, AZ; [3]Washington University in St. Louis, St. Louis, MO.*

Background: Chronic kidney disease (CKD) is difficult to detect in the earliest stages. Cationic ferritin enhanced-MRI (CFE-MRI) has been used to measure glomerular number (N_{glom}) in the entire kidney in 3D in animals and human kidneys. Although urinary biomarkers are used as early and sensitive predictors of acute kidney injury (AKI), there is little data correlating urinary biomarkers to nephron number following AKI. We hypothesize that urinary biomarkers can predict microstructural changes detected by CFE-MRI in the transition from AKI to CKD.

Methods: To induce CKD, male mice were injected with intraperitoneal folic acid (125 mg/kg, n=5); controls received $NaHCO_3$ (n=5). Urine was collected on day 4 after folic acid and at 12 wks following AKI. The mice received horse spleen cationic ferritin 12 wks after injury. Kidneys were imaged *ex vivo* using a 7T Bruker ClinScan MRI (3D T2*-weighted, TE:20, TR:80, 60 μm, 640x640). MRI-derived biomarkers included N_{glom} and cluster size (volume where glomeruli were detectable but lacked tubules). Forty urinary biomarkers (inflammation and growth factors) were analyzed using Mouse Cytokine Array Q1000 (RayBiotech).

Results: By CFE-MRI, the CKD group had 28% fewer glomeruli (8008 ± 2880) as compared to the controls (11105 ± 818, p=0.04). In the CKD cohort, nearly 9% of the kidney had labeled glomeruli with a lack of surrounding tubules designated as "clusters" (CKD: 8.8±2.4% vs. controls: 2.3±0.59%, p=0.03). Urinary EGF was higher 4 days after injury (AKI:11538 vs controls: 5087 pg/ml, 0.0004) and ICAM-1 was lower at 12 weeks (CKD: 2621 vs controls: 6629 pg/ml, p=0.007). Four days after injury urinary EGF correlated to N_{glom} at 12 weeks after injury (r=-0.71, 0.02) and cluster size (r=0.78, p=0.008). At 12 weeks after injury, urinary ICAM-1 correlated to N_{glom} (r=0.76, p=0.01) and cluster size (r=-0.80, p=0.005).

Conclusions: In this murine model of AKI transitioning to CKD, urinary EGF at the time of AKI correlate with both a lower N_{glom} and larger cluster size. At CKD, 12 weeks after injury, ICAM-1 strongly correlated with glomerular number and cluster size. Further work to define the pathophysiology of these biomarkers in AKI and CKD is needed, however this work highlights the utility of urinary biomarkers and CFE-MRI to noninvasively detect early nephron injury and track progression of CKD.

MiR-874/ADAM19 Mediates Macrophage Activation and Renal Fibrosis After AKI

Junni Wang, Wanyun Nie, Xishao Xie, Fei Han. *First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: The pathogenesis of CKD following AKI is not fully investigated.

Methods: We established a mouse AC (AKI to CKD) model caused by ischemia/reperfusion(I/R), and identified miR-874 downregulated in fibrotic kidneys of both AC model and UUO model by RNA-Seq. Then we used human patient samples as well as animal and cell models to investigate how miR-874 regulates renal fibrosis after I/R injury.

Results: MiR-874 was reduced at different time point after I/R and UUO. In vitro, miR-874 was downregulated in HK2 cells treated with TGF-β1. Moreover, miR-874 level of peripheral mononuclear cells was lower in IgA nephropathy (IgAN) patients with proliferative sclerosing glomerulonephritis than those in pathological stage M0E0S0T0(p<0.01). In vitro, transient transfection of miR-874 inhibitor in HK2 cells induced the increase of mesenchymal makers, and transfection of miR-874 mimic in HK2 cells treated with TGF-β1 could alleviate EMT compared with negative control. Overexpression of human miR-874 into AC and UUO mice led to alleviated renal fibrosis with decreased expression level of Acta2, Col1a1, Fn1, chemokines including CCL2/CCL5, and ADAM19, a target gene of miR-874 verified by luciferase microRNA target reporter assay. F4/80 staining was also junior in miR-874 mice compared with negative control. In vitro, transfection of miR-874 mimic in mouse macrophage cell line Raw264.7 stimulated with LPS downregulated the expression of CCL2/CCL5. Then we focused on the biological function of ADAM19 expression towards renal fibrosis. ADAM19 was induced in both UUO mice and AC mice at different time point. Transfection of adenovirus carrying human ADAM19 into HK2 cells, ADAM19 could induce the increase of mesenchymal makers and inflammatory factors and decrease of epithelial markers. Overexpression of ADAM19 directly induced fibrotic changes in vivo. The expression of CCL2/CCL5 and F4/80 staining were also upregulated in ADAM19 mice compared with negative control. In vitro, transfection of adenovirus carrying human ADAM19 into Raw264.7 cells increased nitric oxide synthase 2 (NOS2), chemokines and proinflammatory cytokines such as interleukin-1β (IL-1β) at both mRNA and protein levels.

Conclusions: Our results suggest miR-874/ADAM19 could mediate renal fibrosis through regulating renal tubular epithelial cell injury and macrophage activation.

A Selective USP30 Inhibitor Attenuates Progressive Fibrosis in Ischemia-Induced CKD

David C. Bedford,[1] Jamie A. Wright,[1] Charlotte Knights,[1] Song Rong,[2] Nelli Shushakova,[2] Sonja Schmidt,[2] Faikah Gueler,[2] Judit Molnar.[1] *[1]Mission Therapeutics Ltd, Cambridge, United Kingdom; [2]Phenos GmbH, Hannover, Germany.*

Background: Much literature evidence points towards an essential role of mitochondrial quality control mechanisms in acute kidney injury progression. Ischemic-reperfusion injury (IRI) results in metabolic adaptation of Proximal Tubule Epithelial Cells (PTECs), a site of high mitochondrial turnover (1). Moreover, exacerbation of renal injury has been demonstrated following IRI in both PINK1 KO and PARK2 KO mice (2). USP30 is a mitochondrial associated deubiquitylating enzyme and represses PINK1/PARKIN-mediated mitophagy (3). Within the kidney, USP30 expression is predominantly tubular and accordingly, USP30 inhibition may provide a mechanism to protect against IR-induced tubular injury. Here we present data on MTX008, a selective small molecule inhibitor of USP30 in a mouse model of IRI induced kidney fibrosis.

Methods: MTX008 was administered to C57BL/6 mice 15 mg/kg (p.o.) and compared to vehicle treatment from Day -1 through to Day +21. On Day 0, mice were anaesthetized, and their left renal pedicle clamped for 45 min, then released to induce IRI. Mice were monitored and urinary kidney injury biomarkers (KIM-1 and NGAL) were measured on Day +1 and +7. On Day +14 and Day +21 kidneys were harvested. Morphology, fibrosis and immune cell infiltration were assessed.

Results: Body weight was similar between groups and remained constant throughout the observation periods. MTX008 appeared to limit urinary kidney injury biomarkers, KIM1 and NGAL on Day +1. There were large interindividual variations and the differences did not reach significance. Macrophage infiltration was significantly reduced on Day +21. Masson trichome stain revealed significantly less tubular atrophy in MTX008 treated animals on Day +14 and Day +21. Fibronectin expression in the cortex was significantly reduced in MTX008 treated mice on Day +14 and +21.

Conclusions: MTX008, a novel selective small molecule inhibitor of USP30 has shown efficacy in a model of IR-induced CKD. Daily treatment has shown significant benefits towards attenuated tubular atrophy and reduced cortical fibrosis. Mission Therapeutics is investigating MTX008 in a variety of preclinical renal injury models with a view to developing this novel molecule towards the clinic. 1 McWilliams, *et al.* 2017 2 Tang, *et al.* 2018 3 Bingol, *et al.* 2014

Tubulointerstitial Injury in Renal Congestion Was Suppressed by Inhibiting Platelet-Derived Growth Factor Pathway

Takuma Matsuki,[2] Takuo Hirose,[1] Chika Takahashi,[1] Takefumi Mori.[1] *[1]Tohoku Medical and Pharmaceutical University, Sendai, Japan; [2]Pediatrics, Tohoku Univeristy, Sendai, Japan.*

Background: Increased central venous pressure in congestive heart failure is responsible for renal dysfunction. We created a novel rat renal congestion model, resulting high renal interstitial hydrostatic pressure, tubulointerstitial injury and pericyte-myofibroblast transition (PMT). In this model, platelet-derived growth factor receptors (PDGFRs), PMT indicators, were also upregulated, especially in outer medulla. Thus we examined the effect of imatinib, a PDGFR inhibitor, for renal injury.

Methods: The inferior vena cava (IVC) between the renal veins was ligated by suture in male Sprague-Dawly rats to increase upstream IVC pressure and induce congestion in the left kidney only. Imatinib mesylate (20 mg/kg) or saline were injected intraperitoneally every day from one day of the operation. Both control right kidney and congesitve left kidney were obtained after 3 days of the surgery and were weighted. The expression of renal injury marker and PDGFRs were assessed by quantitative reverse transcription-polymerase chain reaction, western blot and immunohistochemistry.

Results: Kidney weight was significantly increased in left congestive kidney, and ameliorated by imatinib administration. Staining intensity and mRNA expression levels of Tagln, Pdgfra, Pdgfrb were higher in the control kidneys, especially in the cortex. Imatinib attenuated the intensity and mRNA expression levels. Fibronectin and Kim1 expression was higher in the control kidneys and were attenuated by imatinib.

Conclusions: Imatinib attenuates the elevation of kidney weight and PMT markers. These results suggest that imatinib has potentiality against renal fibrosis in renal congestion.

The Role of Akt1 in a Murine Model of AKI to CKD Progression

Byung Min Ye,[1] Il Young Kim,[1] Dong Won Lee,[1] Soo Bong Lee,[1] Miyeun Han,[2] Harin Rhee,[2] Eun Young Seong,[2] Sang Heon Song.[2] *[1]Pusan National University Yangsan Hospital, Yangsan-si, Republic of Korea; [2]Pusan National University Hospital, Busan, Republic of Korea.*

Background: Acute kidney injury (AKI) is an underestimated, yet important risk factor for development of chronic kidney disease (CKD). However, underlying mechanism of AKI to CKD progression are poorly understood. Akt has been reported to be involved in renal ischemic reperfusion injury (IRI). In this study, we investigated the role of Akt1, one of the three Akt isoforms, in murine model of IRI-induced AKI to CKD progression

Methods: We subjected the wild type and *Akt1*$^{-/-}$ mice to renal IRI. Renal IRI was induced by clamping the left renal artery for 30 min followed by reperfusion. After 6 weeks of IRI, the renal fibrosis was assessed by histologic grading and Masson's-trichrome staining. Fibrosis/apoptosis markers and MAPKs were also assessed by western blot.

Results: After 6 weeks after IRI, IRI kidneys in wild type mice showed the typical features of progressive CKD: widespread interstitial fibrosis/tubular atrophy, as indicated by collagen deposition assessed by Masson's-trichrome staining. These fibrotic changes were significantly alleviated in *Akt1*$^{-/-}$ mice compared with the wild type mice. In addition, western blot analysis showed that *Akt1*$^{-/-}$ had attenuated expressions of fibrosis marker (vimentin and α-SMA) and phosphorylated-p44/42 MAPK (Erk1/2) compared with the wild type mice. Western blot analysis and TUNEL assay showed that the apoptosis was attenuated in *Akt1*$^{-/-}$ mice compared with wild type mice.

Conclusions: Our findings demonstrate that Akt1 contributes to IRI-induced AKI to CKD progression, suggesting that inhibition of this signaling pathway may provide a therapeutic approach of preventing IRI-induced AKI to CKD progression.

Cholesterol Lipid Rafts When Blocked Prevent Epithelial-Mesenchymal Transition in Cisplatin-Induced Renal Injury

Maria Angeles Gonzalez-Nicolas Gonzalez,[3,1] Blanca Humanes Sanchez,[1] Sonia Camaño paez,[1] Veronica Astrid Perez Fernandez,[1] Alberto Tejedor jorge,[3,1] Alberto Lazaro Fernandez.[2,1] *[1]Renal Physiopathology Lab, Instituto de Investigación Sanitaria Gregorio Marañón (Hospital G.U. Gregorio Marañón), Madrid, Spain; [2]Physiology, School of Medicine, Universidad Complutense, Madrid, Spain; [3]Medicine, School of Medicine, Universidad Complutense, Madrid, Spain.*

Background: Cisplatin is a potent cytostatic, but its nephrotoxicity is a major complication and a dose limiting factor for anticancer therapy. Some evidences have shown that epithelial-mesenchymal transititon (EMT) contributes to the progression from acute renal failure to chronic renal failure. We have found that binding of cilastatin to renal dehydropeptidase-I inhibits transport and signalling of brush border lipid rafts in proximal tubule, thus providing protection.

Methods: In this study we investigated whether the protective effects of cilastatin are related to the prevention of the EMT-induced by cisplatin. Male Wistar rats were divided into 4 groups: control rats, cilastatin-control rats, cisplatin-injected rats, cilastatin-treated cisplatin-injected rats. Nephrotoxicity was assessed 5 days after cisplatin treatment, by measuring serum creatinine, blood urea nitrogen (BUN), glomerular filtration ratio (GFR), proteinuria and renal morphology. Some typical markers of EMT and cell-cell adhesion were measured by western blot and immunohistochemical studies.

Results: Cisplatin-treated rats showed significant elevations in BUN, creatinine, and proteinuria and decreased the GFR when compared with control rats. Cisplatin rats also exhibited severe morphological changes such as vacuolization and hyaline cast in the tubular lumen. Cilastatin significantly prevented partial or totally these changes in renal function and ameliorated histological damage in cisplatin-treated animals. On the other hand, cisplatin increased transforming growth factor beta, connective tissue growth factor (inducers of EMT and profibrotic markers), and vimentin (mesenchymal cell marker) levels while decreased significantly β-catenin and zonula occludens-1 levels, both proteins involved in cell adhesion. Cilastatin treatment reversed these changes.

Conclusions: This study provides evidence that the protection offered by cilastatin to acute renal failure-induced by cisplatin, is associated to the prevention of the EMT by decreasing the signaling pathways that cause it and avoiding the loss of cell junctions. EMT signals seem to be triggered during the renal injudy-induced by cisplatin.

SA-PO139

A Furosemide Excretion Stress Test (FEST) Predicts Mortality After Sepsis Independent of Vasopressin Administration

Jonathan Street, Tiffany R. Bellomo, Erik H. Koritzinsky, Hiroshi Kojima, Peter S. Yuen, Robert A. Star. *National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: The furosemide stress test (FST) has been shown to be a sensitive and specific predictor of progression to AKIN stage III in the ICU. FST measures the volume of urine produced after a furosemide bolus. Furosemide is actively excreted by the proximal tubules into the lumen where it inhibits NKCC2 in the thick ascending limb. Vasopressin is used as a vasopressor in some hypotensive sepsis patients and can markedly reduce urine production. We hypothesize that furosemide excretion (FEST) will be a more direct measure of tubule health than diuresis (FST) and may be insensitive to the effects of vasopressin on urine volume. We developed a protocol for FST and FEST in mice and tested this hypothesis in a murine model of septic-AKI.

Methods: Sepsis was induced in male and female CD-1 mice by cecal ligation and puncture (CLP). A subgroup of mice received 0.00114 U/(kg.min) vasopressin i.p. to simulate vasopressor support. The FST/FEST started at 42 hours post-CLP. 1 mg/kg furosemide s.c. was given and urine collected for 12 hours. The mice were monitored until 7 days post-CLP. Furosemide concentration was determined by a reverse phase HPLC assay.

Results: From 139 mice (79M/60F), 55 survived to 42 hours and underwent FST/FEST with 33 mice surviving to 7 days. Both FST and FEST predicted time of death (R^2 = 0.26 and 0.74) and mortality [AUC ROC values of 0.92 for FST in males, 0.95 for FST in females, 0.87 for FEST for males, and 1.00 for FEST in females]. Optimal performance was 91% sensitivity and 82% specificity for FST and 90%/79% for FEST

with cutoffs of 0.94 ml and 44%, respectively. In the subgroup receiving vasopressin, urine production was reduced by 0.6 ml (p = 0.03) without altering furosemide excretion (p = n.s.). Therefore, when we used the optimal cutoffs from septic mice not treated with vasopressin for vasopressin-treated septic mice, the specificity of FST was eliminated (0%, p < 0.01) but specificity of FEST was preserved.

Conclusions: The FST and FEST perform similarly in predicting mortality in untreated animals. Only the furosemide excretion stress test also predicted time to death and was insensitive to vasopressin treatment. In order to use FST in conjunction with vasopressin, cutoff values must be adjusted, but such adjustment is not needed for FEST.

SA-PO140

Lysozyme-Induced AKI: A Case Series

Larry Nicholas Cossey, Christopher P. Larsen. *Arkana Laboratories, Little Rock, AR.*

Background: Only rare case reports exist describing increased serum lysozyme with acute kidney injury. This study represents the first case series to describe the clinical and laboratory findings associated with this disease.

Methods: 17 kidney biopsy samples displaying lysozyme-induced acute kidney injury and associated clinical histories were prospectively collected from 2012-2019. 40 additional kidney biopsies were utilized as controls to compare morphologic findings. Light microscopy, immunofluorescence, electron microscopy, thioflavin T, Congo red, and lysozyme IHC were performed. Laser microdissection coupled with mass spectrometry was performed on our initial two patients.

Results: 82% of patients were male with an average age of 66 years. 94% presented with acute kidney injury and average serum creatinine of 2.95 mg/dL. All patients had proteinuria with an average protein:creatinine ratio of 2.2. Hematuria was present in 42%, however where available, all urine sediments were bland. Serum lysozyme results were available in 10 patients all showing elevated levels. Hematologic disease was present in 71% of patients with chronic myelomonocytic leukemia affecting 31%. Outcome data was limited but showed recovery to near baseline serum creatinine in 4/4 (13 months f/u) who were treated for their underlying disease. Progressive CKD/ESKD was seen in 3/3 (3 months f/u), who did not undergo treatment of their underlying disease. The most helpful histologic features in identifying this disease were the pattern and intensity of lysozyme staining, Congo red reactivity without birefringence, weak Thioflavin T staining, extent of proximal tubule protein resorption droplets, and refractile protein resorption droplets in proximal tubules. Laser microdissection of proximal tubules followed by mass spectrometry showed lysozyme as the most frequent protein hit identified and a >20 fold increase in lysozyme hits compared to controls.

Conclusions: Lysozyme-induced acute kidney injury occurs in the setting of increased serum lysozyme leading to increased lysozyme in the proximal tubules. It is most commonly seen in the context of hematologic malignancy. While subtle, a constellation of morphologic and immunohistochemical findings exist that allow for accurate diagnosis. In our limited outcome data, treatment of the patient's underlying disease is critical for recovery of kidney function and favorable prognosis.

Assessment of Renal Angina Index for the Prediction of Severe AKI in Critically Ill Adults

Javier A. Neyra,[2] Victor M. Ortiz-Soriano,[1] Shaowli Kabir,[1] Rolando Claure-Del Granado,[3] Arnold J. Stromberg,[1] Stuart Goldstein.[4] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY; [3]Hospital Obrero #2 - C.N.S.; Universidad Mayor de San Simon, School of Medicine, Cochabamba, Bolivia, Plurinational State of; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Risk-stratification tools of incident AKI in critically ill adults are needed. The renal angina index (RAI) was developed and validated in the pediatric population. We evaluated the performance of the RAI for the prediction of severe AKI in critically ill adults.

Methods: A cohort of 12,084 patients admitted to the ICU at the University of Kentucky (2009-2017) was utilized. Inclusion criteria consisted of age ≥18, ICU stay ≥3 days, at least 2 serum creatinine (SCr) measures in the first 2 days of ICU stay and one measure at 3-7 days of stay. Exclusion criteria consisted of ESKD, kidney transplant or baseline eGFR <15. A modified RAI (mRAI) included risk level criteria 1) mechanical ventilation or vasoactive drug support, 2) sepsis, and 3) diabetes and injury level criteria of 1) SCr increments (<25%, 25-49%, 50-99%, ≥100) and 2) fluid overload (FO%, <5%, 5-10%, 11-19%, ≥20%). Performance metrics were used for evaluation of components of the mRAI in reference to isolated changes in SCr.

Results: Mean (SD) age was 57.3 (16.5), 42% were women and 90% white. Mean (SD) SOFA score was 5.2 (3.0). The incidence of AKI (KDIGO-SCr) stage ≥2 at 3-7 days of ICU stay was 15.7%. Median [IQR] mRAI (determined in the first 2 days of ICU stay) was 24 [8-40] vs 10 [5-40], p<0.001 for those with vs without AKI stage ≥2 at 3-7 days. Performance metrics are reported in **Table**. Similar performance was observed when the cohort was restricted to patients without AKI or AKI stage ≤1 in the first 2 days of ICU stay.

Conclusions: When compared with examination of isolated changes in SCr, components of the mRAI exhibited better performance for the prediction of severe AKI in critically ill adults, particularly when measured baseline SCr was not available. The mRAI is a feasible risk-stratification tool that needs validation in the adult population.

Performance metrics (95%CI) of components of the mRAI for the prediction of AKI stage ≥2 in critically ill adults

	ΔSCr first 2 days of ICU stay	mRAI using ΔSCr first 2 days of ICU stay	ΔSCr first 2 days of ICU stay (ref: measured baseline)	mRAI using ΔSCr first 2 days of ICU stay (ref: measured baseline)

SA-PO142

Clinical Characteristics and Prognosis of Patients with Community-Acquired AKI Compared with Hospital-Acquired AKI: A Meta-Analysis

Linxi Huang,[1] Cheng Xue,[2] Jing Xu,[2] Zhiguo Mao.[3] *[1]Division of Nephrology, Kidney Institute of CPLA, Changzheng Hospital, Second Military Medical University, Shanghai, China; [2]Shanghai Changzheng Hospital, Shanghai, China; [3]Changzheng Hospital, Shanghai, China.*

Background: The difference between hospital-acquired acute kidney injury (HA-AKI) and community-acquired AKI (CA-AKI) was inconclusive. We conducted a meta-analysis to summarize and quantify the meaningful diversities between CA-AKI and HA-AKI.

Methods: We identified observational studies reporting clinical characteristics and prognosis between HA-AKI and CA-AKI. Odds ratios (ORs) and mean differences (MD) were extracted for outcomes as mortality, oliguria, ICU risk, dialysis risk, hospital stay and renal recovery.

Results: Fourteen eligible studies were finally included, involving 43,949 patients: 21,418 CA-AKI patients and 22,531 HA-AKI patients. The mortality was significantly lower in CA-AKI patients than HA-AKI: 13.45%vs. 16.17% (OR 0.41, 95%CI 0.34-0.49). Oliguria incidence was lower in CA-AKI patients (OR 0.58, 95%CI 0.38-0.88). ICU was less required in CA-AKI patients (OR 0.24, 95%CI 0.14-0.40). CA-AKI patients were associated with a shorter hospital time (MD -10.08, 95%CI -15.44- -4.73). The renal recovery rate of the two groups' patients did not show a significant difference (OR 1.26, 95%CI 0.46-3.48). Dialysis need between the two groups was similar (OR 0.99, 95%CI 0.75-1.30).

Conclusions: CA-AKI showed better clinical manifestations with lower oliguria incidence, shorter hospital time and less risk of ICU treatment. The mortality of CA-AKI was lower compared to HA-AKI, indicating a better prognosis; whereas the renal recovery denoted no significant difference between the two groups. Further studies should be conducted to provide more evidence on the time, dose and prognosis for dialysis.

Funding: Government Support - Non-U.S.

Outcomes	No. of studies	No. of patients	Mean Difference [95%CI]	P value	I^2(%)

AKI Risk Stratification in Cardiac Surgery Patients: Is SPARK Index an Option?

Abhilash Koratala,[2,1] Harini Bejjanki,[1] Kawther F. Alquadan,[1] A. A. Ejaz.[3,1] *[1]University of Florida, Gainesville, FL; [2]University of Texas Health science center, San Antonio, TX; [3]Centra Medical Group Nephrology Center, Farmville, VA.*

Background: The Simple Postoperative AKI Risk (SPARK) index has been proposed as a preoperative AKI risk score for patients undergoing "non" cardiac surgery, which is a summation of the integer scores of the following variables: age, sex, expected surgery duration, emergency operation, diabetes mellitus, use of renin-angiotensin-aldosterone inhibitors, baseline eGFR, albuminuria hypoalbuminemia, anemia, and hyponatremia. Based on the score, 4 SPARK classes were defined, A, B, C and D in the order of increasing score/AKI risk. Since the index incorporates many of the risk factors common to cardiac surgery (CS) patient, albeit with major differences, we investigated its usefulness in this cohort.

Methods: We utilized data from a previously published study where we reported that serum uric acid (SUA) is an independent risk factor for AKI in patients undergoing CS. SPARK scores were calculated for all patients (N=190). Odds ratio (OR) for AKI was calculated and AUC of SPARK scores, preoperative SUA, creatinine (SCR) and eGFR were compared.

Results: SPARK class A (score <20), B (≥20 to <40), C (≥40 to <60) and D (≥60) consisted of 18, 98, 45 and 9 patients, respectively. OR with $CI_{95\%}$ and p-value for AKI

were: raw SPARK score, 1.0 (1.0-1.0, 0.603); class A, 1.1 (0.8-1.4, 0.286); class B, 1.1 (2.0-1.2, 0.878); class C, 1.0 (0.9-1.1. 0.788); class D, unable to calculate due to small sample size. Pair-wise comparison of AUCs revealed significant differences between SUA and SCR (Z=3.6, <0.0003), GFR (Z=4.1, <0.0003) and SPARK score (Z=3.8, <0.0001). SPARK score did not demonstrate significant differences with GFR (Z=0.7=6, 0.552) or SCR (Z=1.2, 0.229). Receiver Operating Characteristics (ROC) curves shown in Figure 1.

Conclusions: Our data suggests that the SPARK Index is not a good predictor of AKI in CS where SCR, eGFR and SUA outperform its discriminatory capabilities and require only a single, cost-effective laboratory test.

SA-PO144

Impact of Clinical Variables at Dialysis Initiation for AKI in the ICU on In-Hospital Mortality

Anirban Ganguli, Shreedhar Adhikari, Vatsal Shah, Michael J. Sherman, Judith H. Veis, Jack Moore. *Division of Nephrology, Department of Medicine, Medstar Washington Hospital Center, Washington, DC.*

Background: Current research on timing of dialysis in critically ill AKI has focused on analyzing survival outcome with arbitrary definitions of "early" or "late" start. However, the competing effects of other variables such as clinical comorbidities, dialysis indication, or acuity of illness at dialysis start are unknown.

Methods: We analyzed new adult AKI patients initiated on renal replacement therapy (RRT) while in our 5 intensive care units (ICU) from 1/1/2010 through 12/31/2015, to identify clinical variables associated with survival to hospital discharge.

Results: Of the 235 patients initiated on RRT in medical and surgical ICUs, the mean age was 61.8+/- 14.3 yrs; 60 % were male, 47 % were Afro-American with a Charlson Comorbidity Score (CCS) of 5.5 +/- 3.1 and acuity scores of 29.6 +/-7.6 (APACHE-II) and 12.0 +/- 4.4 (SOFA) at dialysis start. The most common modality of RRT was continuous (67.2%). Logistic regression identified independent association of survival with low serum lactate, low SOFA scores, elevated serum creatinine at RRT initiation and hyperkalemia but not with CCS and time from KDIGO Stage 3 AKI to dialysis initiation (as a surrogate for timing). Serum lactate{odd ratio (O.R.) 0.74- 0.91} at initiation also correlated inversely with survival beyond 48 hours. Stratifying patients by SOFA scores at RRT initiation (<10=low-risk, ≥10= high-risk) identified severity of volume overload or hyperkalemia (low-risk group) and RRT modality type or serum lactate (high-risk group), as being associated with survival. Receiver-Operator Characteristics (ROC) of biochemical variables at dialysis initiation showed that only serum lactate had a moderate c-statistic of 0.759 in discriminating survivors from non-survivors.

Conclusions: Data from critically ill AKI patients initiated on RRT in the ICU primarily showed acuity of illness at the start of RRT affecting survival. Since time from KDIGO Stage 3 AKI to dialysis initiation was not associated with survival, the validity of definitions such as "early" or "late" RRT initiation remains uncertain. Triaging clinical decision based on acuity scores may optimize clinical outcomes. Finally, the absence of any association between hospital survival and co-morbid scores has great implications for prognostication and palliative care.

SA-PO145

Simplified Acute Physiology Score II Predicts 4-Year Outcomes in Critically Ill Elderly Patients with AKI

Linpei Jia,[1] Hongliang Zhang,[2] Rufu Jia.[3] *[1]Xuanwu Hospital of Capital Medical University, Beijing, China; [2]the National Natural Science Foundation of China, Beijing, China; [3]Cangzhou Central Hospital, Cangzhou, China.*

Background: Acute kidney injury (AKI) is a serious complication of critically ill elderlies. Several severity scoring systems have been used to predict the prognosis. However, which severity score has the better predictive efficiency in elderlies with AKI is unknown.

Methods: Data of AKI elderlies was extracted from Medical Information Mart for Intensive Care III database. Subjects were divided into three groups, according to 65-75 years, 75 - 85 years and ≥ 85 years. SAPS II, OASIS, MLODS, SIRS and SOFA were compared. The Kaplan-Meier and receiver operating characteristic (ROC) curves were performed to assess the prognostic values.

Results: Totally 10472 AKI elderlies were enrolled. Older patients had higher death rates (**Figure A**) and shorter survival time (**Figure B**). SAPS II had the best prognostic value ($P < 0.01$, **Figure C**). The AUC of SAPS II (95% CI, 0.676 to 0.694) was significantly the highest ($P < 0.01$, **Table**). The cut-off value of SAPS II was 40. Patients with SAPS II < 40 would have a better prognosis than those with SAPS II ≥ 40 (**Figure D**).

Conclusions: SAPS II could better predict the long-term prognosis of elderly patients with AKI.

Area under receiver operating curve (AUC) of mortality and different severity scores.

	All subjects (N = 10472)		AKI stage 1 (N = 3039)		AKI stage 2 (N = 4045)		AKI stage 3 (N = 3388)

Atrial Fibrillation Chronicity in Patients with AKI on Continuous Renal Replacement Therapy

Khaled Shawwa, Panagiotis Kompotiatis, Shane A. Bobart, Brandon M. Wiley, Jacob Jentzer, Kianoush Kashani. *Mayo Clinic, Rochester, MN.*

Background: Atrial fibrillation (AF) has been reported in 44% of patients with acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT), but the chronicity of AF remains unclear. We aim to assess the epidemiology and outcomes of AF among AKI patients receiving CRRT, including predictors of new-onset AF (NOAF) on CRRT.

Methods: This is a retrospective analysis of a cohort of patients admitted to the ICUs at a tertiary care hospital from 12/2006 through 11/2015 who had AKI and received CRRT. The primary outcome was mortality at three years, which was assessed using a Cox proportional hazard model. Secondary outcomes included in-hospital mortality. AF was ascertained by manually reviewing the chart. A random sample of 10% of cohort was independently reviewed by another investigator and agreement was reported using kappa coefficient.

Results: Out of 1,394 CRRT patients who had AKI, 582 patients did not have any arrhythmia. There were 419 (30%) patients who were known to have AF prior to starting CRRT. NOAF occurring while on CRRT developed in 193 (14%) patients. Another 160 patients (11.5%) developed NOAF during their index ICU admission prior to initiation of CRRT. Kappa was 0.95 (95% CI: 0.87-1, p<.001). A known history of AF (HR: 1.19, 95%CI: 1.01-1.41, p=0.04) and NOAF occurring on CRRT (HR: 1.27, 95% CI: 1.04-1.56, p=0.02) were independently associated with an increased hazard of death at 3 years, compared to the group who did not have any arrhythmia. There was no difference in in-hospital mortality between the AF groups. The models were adjusted for age, sex, BMI, SOFA score at CRRT initiation, baseline serum creatinine, Charlson comorbidity index, number of vasopressors used in the ICU, use of invasive ventilation. In multivariate analysis, using time-dependent covariates, higher potassium (HR 1.24, 95%CI: 1.01- 1.54, p=0.043) and bicarbonate (HR 0.95, 95%CI: 0.92-0.98, p=0.003) were associated with increased and decreased risk of NOAF on CRRT, respectively.

Conclusions: Incident NOAF in critically ill patients with AKI receiving CRRT is common and carries an unfavorable prognosis similar to patients with prevalent AF. Further studies are required to elucidate modifiable risk factors for NOAF occurring on CRRT and the mechanisms driving the observed association with adverse outcomes.

SA-PO147

Hypoalbuminemia Is Related with Short-Term and Long-Term Mortality in Patients Undergoing Continuous Renal Replacement Therapy

Jong joo Moon,[1] Yaerim Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[2] Seung Seok Han.[2] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Hypoalbuminemia reflects several pathologic conditions such as nutritional deficiency and chronic inflammation. However, its relationship with short-term and long-term mortality in patients undergoing continuous renal replacement therapy (CRRT) remains unresolved.

Methods: A total of 1,581 patients who underwent CRRT due to acute kidney injury between 2010 and 2016 were retrospectively reviewed. Patients were categorized by the tertiles of albumin levels at the time of starting CRRT. Odds ratio (OR) and hazard ratio (HR) for the risk of all-cause mortality were calculated before and after adjustment of multiple covariates.

Results: Mean albumin level was 2.7 ± 0.6 g/dL. During the median follow-up period of 14 days (maximum 4 years), 1,040 patients (65.8%) died. The 1st tertile had a higher risk of mortality than the 3rd tertile with an HR of 1.9 (1.63–2.21). Although the mortality rate was stratified by the timeframe, the 1st tertile had a higher risk than the 3rd tertile as following ORs: 3.0 (2.34–3.87) in 2-week mortality; 2.7 (2.12–3.52) in 1-month mortality; 2.7 (2.08–3.53) in 6-month mortality; and 2.8 (2.11–3.62) in 1-year mortality. The 1st

tertile group had also higher rates of intensive care unit- and in-hospital mortalities than the 3rd tertile group.

Conclusions: Because hypoalbuminemia is associated with short-term and long-term mortality after CRRT, serum albumin levels should be monitored during the period of CRRT.

SA-PO148

Using Standardised Monitoring of Physiological Parameters (National Early Warning Score) to Predict AKI

Alexandra Riding, Kate Berresford, Clare Morlidge, Suresh Mathavakkannan, Andrew Findlay. *Renal Medicine, East and North Herts NHS Trust, Stevenage, United Kingdom.*

Background: Acute kidney injury (AKI) affects approximately 16% of inpatients, particularly the elderly and confers an increased length of hospital stay, medical intervention and mortality (Holmes et al, CJASN, 2016 and Kerr et al, NDT, 2014). Risk factors are well established and yet we cannot reliably identify susceptible patients before abnormal serum creatinine results, though this forms the basis of national AKI e-alert systems. In 2012, The Royal College of Physicians endorsed a National Early Warning Score (NEWS) to identify deteriorating and acutely unwell patients. The score is based on the physiological parameters of respiratory rate, oxygen saturation, systolic blood pressure, pulse rate, conscious level and temperature, with higher scores triggering urgent or immediate medical escalation. The utility of clinical early warning scores in predicting AKI severity and patient outcome has been variable (Kovacs et al, BJS, 2016; Potter et al, JICS, 2017 and Faisal et al, Clin Med, 2018). We predicted that those with high NEWS (>4) might correlate to AKI stage and form a useful pathway to highlight and appropriately escalate this patient group.

Methods: Retrospective data were collected on hospitalized patients (Jan-March 2019), identified by elevated serum creatinine results (as per national AKI reporting guidance). Highest NEWS within 5 days of AKI alert was recorded. Data sources were patient records and computerized reporting systems.

Results: 140 patients were identified (complete data for 138). NEWS is shown according to AKI stage in the table. Higher NEWS (>4) was unaffected by AKI stage (p= 0.75, 2-way ANOVA).

Conclusions: Those with stage 2 and 3 AKI did not trigger significantly higher NEWS. Whilst NEWS remains an important discriminator in escalating acutely unwell patients, it did not predict AKI or its severity. Biomarkers of AKI are in development, but clinically relevant discriminators remain elusive. Further parameters are urgently required to refine AKI alert algorithms for clinical use.

NEWS according to AKI stage

AKI stage (n=patients)	NEWS 0-4 (%)	NEWS 5-6 (%)	NEWS 7+ (%)
1 (63)	38 (60)	11 (17)	14 (22)
2 (52)	24 (46)	10 (19)	18 (35)
3 (23)	10 (43)	8 (35)	5 (22)

SA-PO149

The Development of AKI After Acute Nephrons Loss: An Unexpected Journey

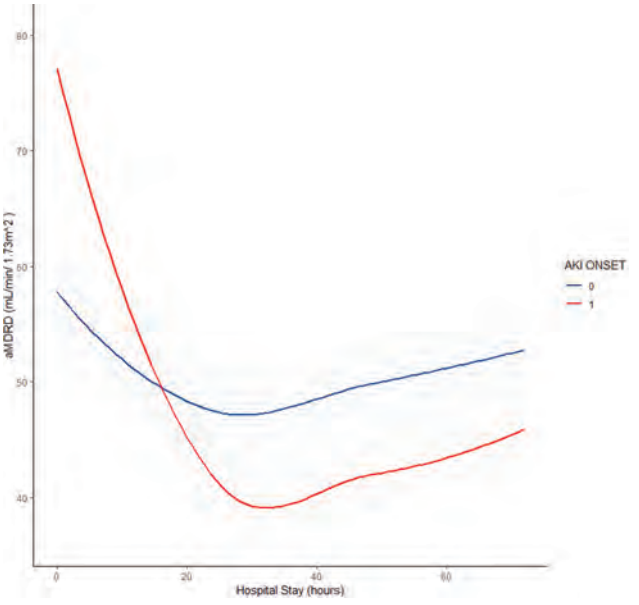
Francesco Trevisani,[1] Federico Di marco,[1] Giacomo Dell'Antonio,[3] Antonello Pani,[2] Alessandro Larcher,[1] Umberto Capitanio,[1] Arianna Bettiga,[1] Esteban Porrini,[4] Andrea Salonia,[1] Alberto Briganti,[1] Francesco Montorsi.[1] *[1]Urological Research Institute, IRCCS San Raffaele Scientific Institute, Milan, Italy; [2]AziendaOspedalieraG. Brotzu, Cagliari, Italy; [3]IRCCS San Raffaele Scientific Institute, Milan, Italy; [4]University Hospital of the Canary Island, La Laguna, Spain.*

Background: Acute Kidney Injury (AKI) following radical nephrectomy (RN) is associated with an increased risk of morbidity and mortality. Up to know it is impossible to understand the major predictor for AKI developement.

Methods: We collected prospectively clinical data of a group of 195 patients who underwent RN for renal masses. To evaluate the risk of AKI after surgery, serum-creatinine (sCr) values were collected before surgery (t0), 24h and 48h after the operation (t1 and t2), and at dismissal (tf). We calculated eGFR with aMDRD formula. According to RIFLE criteria, we defined the AKI onset with a ratio of sCr/sCr(t0) higher than 1.5. A pathological evaluation using the Remuzzi Score was carried out on the healthy renal parenchima based on glomerular global sclerosis, tubular atrophy, interstitial fibrosis and arterial narrowing.

Results: In our study a strong significative correlation (p <0.001) was found with the basal eGFR at t0. In fact, the lower was the basal sCr, the higher was the risk of AKI development. A lower variation of eGFR from t0 to tf was related with the presence of tubular atrophy (p<0.01) or interstitial fibrosis (p<0.05)

Conclusions: An eGFR higher than 70 ml/min could represent an unexpected predictive cutoff of AKI development after RN. There are two possible explanation: a better medical treatment of the CKD patients; a "non adequate compensatory function mechanisms" after acute nephron loss. In fact, in healthy pts, the hyperfiltration mechanism is not yet well established (as in CKD pts) so that RN results in an unexpected trauma for the remnant kidney who will take time to restore the renal function.



Temporal pattern of renal function according AKI onset

SA-PO150

Factors Associated with AKI in Mexican Patients with Acute Coronary Syndromes

Diana Ramirez-Flores,[1,3] Adriana Banda Lopez,[1] Milagros M. Flores Fonseca,[2] Rodolfo Parra-Michel,[5] Victoria G. Maldonado Gomez,[1] Benjamin Gomez-Navarro.[4] *[1]Nephrology and Trasplant Unit HE, IMSS, Zapopan, Mexico; [2]Centro Medico Nacional de Occidente, Guadalajara, Mexico; [3]Universidad de Guadalajara, Guadalajara, Mexico; [4]IMSS, HECMNO, Zapopan, Jalisco, Mexico; [5]Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Background: AKI is a leading cause of morbidity and mortality in hospitalized patients with ACS. The aim of this study was to identify potential risk factors and patient characteristics associated in patients with ACS.

Methods: We analyze a single center retrospective review of 77 patients with ACS. The sCr at hospital and daily during the coronary unit was available for analyzed patients to diagnose AKI. Demographics, clinical and biochemical profiles, risk factors for AKI and RRT prescription was assessed and reported during diagnosis and discharge. Outcome measures were renal recovery, mortality and causes of death. Statistical analysis was done with SPSS version 26.0. The categorical variables were analyzed using chi-square test or Fisher's exact probability test, as appropriate. The continuous variables were analyzed using the Student's t test. A value of $p < 0.05$ was regarded as statistically significant.

Results: Mean age was 65.45 ± 10.84 years and 70% were male. AKI was diagnosed in 50% of ACS cases. The mortality rate was 31% due to cardiovascular complications. Pre-existing comorbidities and other factors found to have increased association with AKI presence were: CKD (p < 0.0001), diabetes with complications (p=0.031), bacteremia (p=0.028), history of surgery complications (p<0.0001), nephrotoxic use (p=0.004) and biochemical alterations as anemia, hyperbilirubinemia, hyperglycemia, hyperlactatemia, metabolic acidosis, and elevated cardiac biomarkers (p<0.05).

Conclusions: This study shows that AKI is a frequent complication of ACS and its association with predictive factors. Further studies are needed to stablish early strategies aimed to preventing AKI or at reducing its severity might provide significant clinical benefit in patients with ACS.

Comparison of AKI presence in ACS patients

	AKI N = 39	Non AKI N = 38	p
Age (years)	67.41 ± 11.22	63.45 ± 10.19	0.818
Body mass index (kg/m2)	28.47 ± 3.97	27.98 ± 4.96	0.066
Procalcitonin (ng/ml)	26.36 ± 60.78	0.58 ± 0.93	0.001
Lactate dehydrogenase (U/L)	5522.47 ± 7329.03	742.58 ± 627.69	<0.001
Troponin I (mcg/L)	1719.92 ± 7038.70	15752.55 ± 16133.56	<0.001
B type natriuretic peptide (pg/ml)	1719.92 ± 7038.70	3039.23 ± 4928.30	<0.001
Serum creatinine (mg/dl)	15208.67 ± 9787.68	0.90 ± 0.31	<0.001

SA-PO151

Predicting Major Adverse Kidney Events in the First Year After AKI

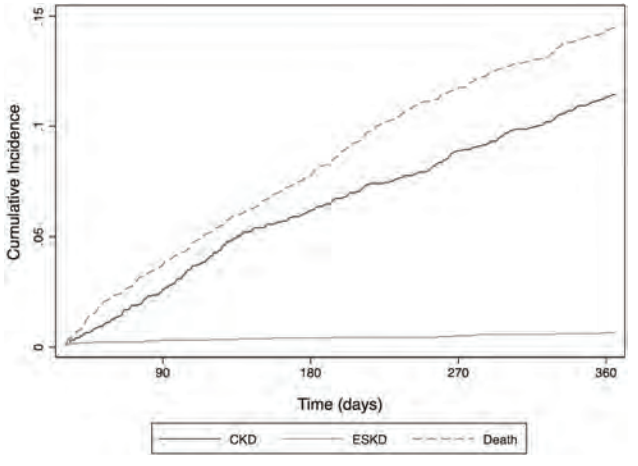
Emily J. See,[1] Kevan Polkinghorne,[2] David W. Johnson,[3] Nigel D. Toussaint.[4] *[1]Austin Health, Melbourne, VIC, Australia; [2]Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [3]Princess Alexandra Hospital, Greenslopes, QLD, Australia; [4]The Royal Melbourne Hospital, Parkville, VIC, Australia*.

Background: Acute kidney injury (AKI) is a common complication of hospital admission, and survivors are at increased future risk of major adverse kidney events (MAKE), including chronic kidney disease (CKD), end-stage kidney disease (ESKD) and death. High-risk patients may benefit from specialist follow-up; however, the factors associated with increased risk have not been reported.

Methods: We conducted a retrospective study of all adult patients admitted with AKI to a single centre between 1 January 2012 and 31 December 2016. Cox regression models were performed to examine the primary outcome, which was the development of a MAKE in the first year following hospital discharge. The secondary outcomes (CKD, ESKD, and death) were studied using Cox and competing risk regression analyses. Candidate predictor variables included patient demographics, comorbidities, and laboratory values available at the time of hospital discharge.

Results: Of 2,101 patients included in the study, 767 patients (37%) developed a MAKE within the first year. MAKE occurred more frequently in patients who were older (HR 1.02 95% CI 1.01-1.02) and in those with a history of chronic heart failure (HR 1.41 95% CI 1.19-1.67), liver disease (HR 1.68 95% CI 1.39-2.03), and either non-metastatic (HR 1.44 95%CI 1.14-1.82) or metastatic (HR 2.26 95% CI 1.80-2.83) malignancy. They were also more common in patients with a greater severity of AKI (stage 2 HR 1.38 95% CI 1.16-1.64; stage 3 HR 1.62 95% CI 1.31-2.01) and in those with a higher serum creatinine level at discharge (HR 1.01 95% CI 1.00-1.01). Female sex (SHR 1.54 95% CI 1.27-1.88) and hypertension (SHR 1.28 95% CI 1.04-1.58) were additional risk factors for the development of CKD.

Conclusions: A significant number of patients with AKI will develop a MAKE within the first year. Clinical variables available at the time of discharge could be used to stratify risk and identify patients who may benefit from specialist follow up.



SA-PO152

AKI: A Risk Factor for Sepsis in Critically Ill Children

Cassandra L. Formeck,[1,2] Emily L. Joyce,[1,2] John A. Kellum.[2] *[1]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) affects up to 56% of pediatric patients admitted to pediatric intensive care units (ICUs) worldwide, and is now recognized as a systemic disease with numerous short and long-term complications that independently increase morbidity and mortality. Evolving evidence suggests that AKI alters innate immune function, which may place patients at increased risk for subsequent infection. We hypothesized that that critically ill children with AKI will be at higher risk of developing hospital-acquired infections compared to critically ill children without AKI. Our objective was to compare the rates of sepsis manifesting in critically ill children with and without AKI at ICU admission, while controlling for severity of illness.

Methods: Using a pediatric ICU database of 8,733 admissions, we included patients who had sufficient information to categorize AKI status, and excluded patients if they had sepsis prior to or within the first 48 hours of ICU admission. Using logistic regression analysis we evaluated the association between exposure to stage 2 or 3 AKI during the first 48 hours of ICU admission, on the development of sepsis during the 7 days following the 48 hour exposure window (days 3-9), adjusting for severity of illness and other known risk factors for sepsis. The covariates included in the final model were age, race, sex, Pediatric Index of Mortality 2 score, vasopressor use, mechanical ventilation, elective admission to the ICU, recovery from surgery and a history of heart failure, liver failure, chronic kidney disease or malignancy.

Results: A total of 5,590 patient admissions (male 58%, mean age 6.9 years) were included in the analysis. 5.2% of patients had stage 2 or 3 AKI during the first 48 hours of admission and 6.0% of patients developed sepsis on days 3 through 9 of ICU admission. The incidence of sepsis was 16.9% in patients with stage 2 or 3 AKI, as compared to 5.4% in patients without AKI. In the adjusted analysis, patients with AKI were more likely to develop sepsis (OR 2.04, P <0.001).

Conclusions: Stage 2 or 3 AKI is a significant risk factor for development of sepsis in critically ill children.

SA-PO153

The Association Between Kinetic Estimated Glomerular Filtration Rate and Clinical Outcomes: A Systematic Review

Cairina E. Frank,[3] Thomas Mavrakanas,[2,1] Ahsan Alam.[1] *[1]McGill University Health Centre, Montreal, QC, Canada; [2]Geneva University Hospital, Geneva, Switzerland; [3]McGill University, Montrel, QC, Canada*.

Background: Accurate assessment of kidney function is an essential aspect of clinical care. In acute kidney injury or renal function recovery, serum creatinine lags behind true kidney function, and GFR estimation using conventional formulae is problematic when serum creatinine is not at steady state. The kinetic estimated glomerular filtration rate (KeGFR) was proposed an alternative as it takes into account changing creatinine over a period of time. The objective of this systematic review was to examine the association between KeGFR and clinical outcomes.

Methods: We conducted a systematic review of studies examining the association between KeGFR and clinical outcomes. The databases searched were PubMed, EMBASE, CINAHL, Scopus and Web of Science, searching for articles in French and English and published from 2013 until 2019. Quality of each study was assessed using the Newcastle-Ottawa scale.

Results: Of 488 articles identified, there were 19 that met inclusion criteria (12 full articles, 7 supplements/abstracts). Ten articles examined the association between KeGFR and acute kidney injury (AKI). KeGFR was not only associated with AKI, but all but one study found that that it better discriminated risk or injury in certain populations. KeGFR could also detect AKI earlier than other commonly used formulae. Four of the five studies that examined mortality found that KeGFR was associated with an increased risk of death and performed better than other biomarkers. KeGFR was also found to accurately predict delayed graft function (n=3) and discontinuation of renal replacement therapy (n=4). Two studies examining the use of KeGFR in therapeutic drug monitoring found it to be a poor predictor.

Conclusions: KeGFR has been shown to be an accurate method of predicting adverse outcomes including acute kidney injury, mortality and renal recovery, however, it appears to not be as effective when used for therapeutic drug monitoring. Prospective studies to validate its use in clinical practice are warranted.

SA-PO154

Severity of Sepsis-Associated Acute Kidney Disease and 90-Day Survival

Priyanka Priyanka,[1] David Wilfret,[2] Anat Shirvan,[2] Wayne M. Dankner,[2] John A. Kellum.[1] *[1]The University of Pittsburgh, Pittsburgh, PA; [2]Atox Bio, Ltd, Ness Ziona, Israel*.

Background: Current evidence suggests that survival following sepsis with AKI (S-AKI) is strongly associated with recovery of renal function by hospital discharge. Acute Disease Quality Initiative (ADQI) consensus classifies persistent renal dysfunction for >7 days as acute kidney disease (AKD) with staging as per AKI using serum creatinine or dialysis. However, the relationship between AKD stage and the risks of death, chronic dialysis or persistent renal dysfunction over the following three months are unknown. Further, it is unknown if 14 or 28 day AKD status reflects 90 day status. Here, we examined the relationship between AKD at days 14, 28 and outcomes at 90 day in patients with sepsis.

Methods: We conducted a retrospective cohort study of patients admitted to any of 16 hospitals with in the University of Pittsburgh Medical Center between October 2008 and May 2014. We included critically ill adult patients who had s-AKI (stage 2-3 as per KDIGO criteria occurring after sepsis). Sepsis was identified using Sepsis-3 criteria plus an ICD9 code. We staged AKD at day 14 and 28 from first max AKI stage. Our primary outcome was survival at 90 day. We also assessed rates of dialysis and persistent renal dysfunction (>150% of baseline creatinine) as well as the composite of all three—major adverse kidney events (MAKE) at 90 day.

Results: Of 121,817 patients, 10,999 met our definition of s-AKI. Median age was 67 (IQR, 56-79) years., 50.2% were male, estimated baseline glomerular filtration rate was 70.12 (IQR, 47.19 – 93.44) mL/min/1.73m^2, APACHE III score was 61 (IQR, 46 – 78). Among the 2,402 (27.6%) patients known to have AKD on day 14, 1,897 (79%) met MAKE criteria by day 90. However, of the 2,354 (26.8%) patients known to have AKD on day 28, 2,031 (86.3%) met MAKE criteria by day 90. Overall, 182 patients (7.6%) recovered renal function between day 14 and day 28.

Conclusions: Permanent loss of renal function is more accurately assessed at day 28 compared to day 14 as well as risks for dialysis and persistent renal dysfunction in patients with s-AKI. However, day 14 evaluation may allow an early opportunity to focus attention on those patients who have not yet demonstrated evidence of renal function recovery.

SA-PO155

Fluid Overload Is a Major Predictor for Mortality in Critically Ill Patients with Cirrhosis and AKI

Mohit Gupta,[2] Russell E. Rosenblatt,[2] Brett E. Fortune,[1] Michelle L. Lubetzky.[3] *[1]Weill Cornell Medical College, New York, NY; [2]Weill Cornell Medicine, New York, NY; [3]Division of Nephrology and Hypertension, New York, NY.*

Background: Fluid overload is associated with poor outcomes in critically ill patients with acute kidney injury (AKI), but data on whether this applies to patients with cirrhosis are limited. In the setting of portal hypertension, management of AKI can be challenging due to systemic vasodilatation and ineffective renal arterial blood flow. This study aims to determine whether fluid overload had a detrimental effect on critically ill patients with cirrhosis and AKI.

Methods: Clinical and demographic data from 81 hospitalized patients with cirrhosis transferred to the ICU with AKI were collected from a single academic medical center from 2012-2018. Fluid overload was defined as >10% weight gain after the first 3 days in ICU. The primary endpoint was 14-day survival after hospital admission. Kaplan-Meier survival and adjusted Cox hazards analyses were performed.

Results: There were no significant differences between the two groups in terms of age, sex, or etiology of cirrhosis. Non-survivors had a higher MELD-Na when compared to survivors (30 vs 22.5, p=0.001) at the time of transfer to ICU. Fluid overload in the first 3 days of ICU stay, oliguria, and the use of renal replacement therapy (RRT) were highly associated with mortality (p=0.04, 0.0004 and 0.01 respectively). Unadjusted Kaplan-Meier survival analysis demonstrated inferior 14-day survival for patients who developed fluid overload (36% vs 73%)while in ICU (log-rank p=0.006; Figure 1). A multivariable Cox Hazards model, adjusting for age, MELD-Na, and RRT, demonstrated that fluid overload after 3 days following ICU transfer was associated with a 2.45-fold increased risk of mortality (p=0.02).

Conclusions: Our data demonstrate that fluid overload in critically ill patients with cirrhosis and AKI is major predictor for short-term mortality. Prospective studies that focus on restrictive fluid management are warranted to improve care for this high-risk population.

Table 1

Variables	Survivors (n=46)	Non-survivors (n=41)	p-value
Demographics			
Age (years)	64.5 (58.5 – 70)	64 (58 – 73)	0.52
Gender (male)	65%	83%	0.08
Race (AA)	30%	37%	0.36
Weight at Admission to ICU (kg)	74.7 (63.2-84.5)	82.45 (69-95.25)	0.19
Etiology of Cirrhosis			
Alcohol (%)	27.5	24.4	0.74
Hepatitis C (%)	27.5	41.4	0.19
Laboratory Values prior/at admission			
Baseline Creatinine (mg/dL)	0.98 (0.79-1.36)	0.98 (0.82-1.53)	0.31
Admission Creatinine (mg/dL)	1.65 (1.27-2.57)	1.745 (1.36-3.51)	0.07
Admission Sodium (meq/L)	137 (131-139)	132 (130-138.5)	0.52
Admission MELD-Na	22 (16-28)	26 (20-30.5)	0.07
Laboratory Values at ICU Transfer			
Sodium (meq/L)	137 (134-139)	135 (132-139)	0.19
Creatinine (mg/dL)	1.69 (1.23 – 2.93)	1.63 (1.07-4.2)	0.008
MELD-Na	22.5 (19.5-29.5)	30 (22-36)	0.001
Net Fluid Volume Balance after ICU Transfer			
Day 1 (Liters)	+0.66 (-0.24 – +3.51)	+0.83 (+0.06 – +2.24)	0.29
Days 1 and 2 (Liters)	+0.87 (-0.15 – +2.69)	+2.28 (+0.83 – +4.05)	0.10
Days 1,2 and 3 (Liters)	+0.84 (-0.43 – +2.90)	+3.43 (+0.62 – +6.51)	0.04
Average I/O change	+0.77 (-0.7 – +2.35)	+3.33 (+0.86 – +6.31)	0.02
% Weight Change	+1.8 (-0.4 – +4.8)	+3.5% (+0.8 – +8.9)	0.07
Oliguric Urine Output	74.4%	52.3%	0.0004
RRT			
Use of SLED	7.5%	29.2%	0.01
Days to RRT from ICU Transfer	1 (0 – 9)	2.5 (2 – 5.5)	0.62

Similarity of Outcomes in Hepatorenal Syndrome and Other Forms of AKI in Cirrhosis

Maria Soledad Rivera,[2,1] Juan Carlos Q. Velez.[2,1] *[1]Ochsner Clinical School, The University of Queensland, New Orleans, LA; [2]Ochsner Clinic Foundation, New Orleans, LA.*

Background: Recent data suggests that severe AKI from either hepatorenal syndrome type-1 (HRS-1) or acute tubular injury (ATI) may carry similar mortality, challenging the previous notion of a more ominous prognosis in HRS-1. However, those studies are confounded by uncertainties in adjudication of diagnosis imposed by retrospective designs and by the inherent limitations of the International Club of Ascites (ICA) criteria. Thus, we aimed to examine outcomes of AKI in cirrhosis via a prospective design.

Methods: We established prospective data collection in cirrhotics with AKI stage ≥ 2 (AKIN) over 1.5-years. To reduce uncertainty in diagnosis, we supplemented the standard ICA criteria for HRS-1 with supportive phenotypic criteria: urine Na <20 mEq/L, urine volume <500 ml, mean arterial pressure <80 mmHg, serum Na <135 mEq/L and absence of evidence of ATI by urine sediment microscopy (MicrExUrSed) using the Chawla score (CS). "Definite HRS-1" (Def-HRS) was assigned to those who met all ICA and supportive criteria. "No HRS-1" (No-HRS) was assigned to those with ≥1 unmet ICA criteria or CS for ATI. "Possible HRS-1" (Poss-HRS) was assigned to those who met the ICA criteria but either did not meet all supportive criteria, lacked MicrExUrSed or had a CS equivocal for ATI. Outcomes chosen: need for dialysis (RRT), discharge to hospice (Hosp), liver transplant (LT) and death at 1, 3- and 6-months post-AKI.

Results: We included 133 patients [40% women, age 58 (25-87)] in our cohort. MicrExUrSed was done in 88 (66%) patients. We categorized 29 (22%) patients as Def-HRS, 24 (18%) as Poss-HRS and 80 (60%) as No-HRS. Baseline serum creatinine [2.6 (2-4.1), 2.4 (2-3) and 2.8 (2.3-3.6) mg/dL] and bilirubin [5.6 (2.3-15.6), 5.4 (2.1-14.6) and 5.6 (2.3-14.5) mg/dL] were comparable for the 3 groups. At 30 days, need for RRT was 38%, 21% and 36% and for Hosp 41%, 33% and 28%, for Def-HRS, Poss-HRS and No-HRS, respectively. Mortality rates at 1, 3 and 6 months were: Def-HRS: 21%, 21% and 24%; Poss-HRS: 29%, 33% and 42%; and No-HRS: 35%, 43% and 44%, respectively. At 6 months, LT occurred in 15%, 17%, and 24% for each of the 3 groups, respectively.

Conclusions: Our prospective cohort with stringent adjudication of diagnosis indicates that HRS-1 is not associated with more ominous clinical outcomes compared to other forms of AKI in cirrhosis.

SA-PO157

A Decision Tree to Predict Renal Replacement Therapy Requirement in Rhabdomyolysis-Induced AKI

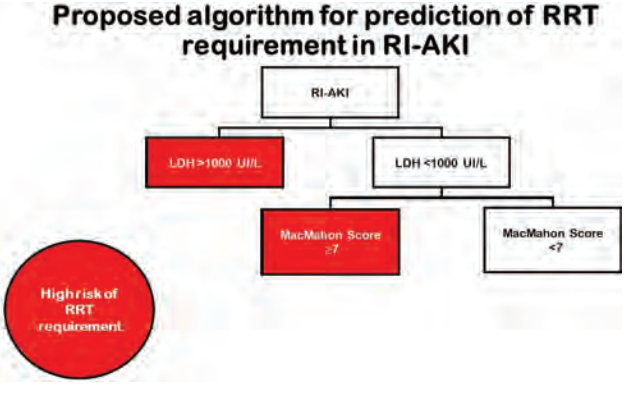
Ismael A. Gómez Ruiz,[1] Ricardo Correa-Rotter,[3] Luis E. Morales-Buenrostro,[2] Juan M. Mejia-Vilet.[2] *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [3]Institutor Nacional de la Nutricion, Mexico City, Mexico.*

Background: Rhabdomyolysis Induced Acute Kidney Injury (RI-AKI) develops in 10-40% of patients who present rhabdomyolysis. When damage is severe enough to develop complications such as life-threatening hyperkalemia or anuria, up to 85% of patients will require renal replacement therapy (RRT). The aim of the present study was to study admission variables that predict RRT requirement.

Methods: Retrospective cohort study. All patients hospitalized for RI-AKI between 2007-2017 were included. Patients were divided according to RRT requirement and their admission parameters compared with Mann-Whitney's U test. Using ROC curves, we determined the best cut-off for lactate dehydrogenase (LDH), creatine kinase (CK) and the MacMahon score to predict RRT requirement and a decision tree was generated.

Results: We identified 42 RI-AKI hospitalizations. All patients had CK>5000 U/L. The main etiologies were drug-induced (41%) and excessive physical activity (21%). Nine patients (21%) developed stage 1 AKI, 5 (12%) stage 2 AKI and 28 (67%) stage 3 AKI. Twenty-two patients (52%) required RST. The most frequent indications for RRT initiation were anuria (64%) and hyperkalemia (32%). Intermittent hemodialysis was used in 52% of cases. The median time on RRT was 17.5 days (range 4-59). Five patients (12%) died during hospitalization due to infectious causes. On follow-up, 6 patients (14%) developed CKD. Patients with RRT requirement presented with higher serum phosphorus (6.2mg/dl [5.5-7.6] Vs. 3.3mg/dl [3.0-3.9], p<0.001), potassium (5.5mEq/l [4.8-6.3] Vs. 4.3mEq/l [3.6-4.8], p<0.001) and LDH (2124 U/l [1067-3193] Vs. 553 U/l [322-744], p<0.001). The AUC of LDH, MacMahon score and CK to predict RRT requirement were 0.873, 0.900 and 0.620 respectively. A decision tree was generated and shown in Figure 1.

Conclusions: A simple decision tree based on LDH levels and the MacMahon score at presentation can predict RRT requirement in RI-AKI



SA-PO158

Dyschloremia and Prognosis in Patients with AKI Requiring Continuous Renal Replacement Therapy

Dong Ho Shin. *College of Medicine, Hallym University, Seoul, Republic of Korea.*

Background: Dyschloremia is common in critically ill patients. There has been some interest in the low or high serum chloride levels as poor prognostic factor of them. However, litter is known about the impact of dyschloremia in patients with acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT).

Methods: A total of 980 patients who received CRRT for AKI between 2009 and 2018 were collected and divided into 3 groups according to the serum chloride levels at the timing of CRRT. Thirty-day all-cause mortality and continued dialysis dependence after hospital discharge was compared among groups.

Results: The hypochloremia group (serum chloride < 98mEq/L, n = 190), normochloremia group (98 ≤ serum chloride ≤ 110 mEq/L, n = 647), and hyperchloremia groups (serum chloride > 110 mEq/L, n = 143) were divided based on the reference values of serum chloride. Compared to normochloremia group, simplified acute physiology III score were higher in hyperchloremia and hypochloremia group. On multivariate logistic regression, hypochloremia group (odd ratio, 1.38; 95% confidence interval, 1.12 - 1.69; p = 0.02) and hyperchloremia group (odd ratio, 1.57; 95% confidence interval, 1.32 - 2.54; p = 0.04) were significantly associated with mortality. In continued dialysis dependence after hospital discharge, similar trends were observed. Moreover, Kaplan-Meier analysis

revealed that mortality was significantly higher in hypochloremia and hyperchloremia groups than normochloremia group.

Conclusions: This study showed that dyschloremia was a predictor for poor prognosis in patients with acute kidney injury requiring CRRT.

SA-PO159

A Non-Steady State Adaptation of the CKD-EPI Equation

Florian Buchkremer, Andreas H. Bock, Stephan Segerer. *Kantonsspital Aarau, Aarau, Switzerland.*

Background: The CKD-EPI equation is one of the most widely used estimates of kidney function. It is commonly calculated whenever a plasma creatinine (pcr) is measured, although only valid when pcr is stable. Chen proposed a "kinetic eGFR" (JASN 24, 877-888 (2013)) for non-steady state conditions. Despite its name it essentially estimates a creatinine clearance (crcl). The goal of our calculations was to develop a true kinetic eGFR estimation and to improve the underlying kinetic clearance formula by explicitly including creatinine generation rate (cgr), the creatinine distribution volume (vd), and accounting for possible changes in distribution volume (deltavd).

Methods: The pharmacokinetics of creatinine are comprehensively described by equation A. To solve it for crcl requires an iterative process, so a simplified form has been used, which we modified to allow for corrections of deltavd (equation B). In steady state crcl is creatinine excretion rate (which equals cgr) divided by the pcr. To convert our kinetically determined crcl into CKD-EPI based eGFRs, we divided cgr by crcl and calculated a virtual steady state pcr. We then inserted this term into CKD-EPI. Cgr and vd were estimated with published formulas (incorporating age, gender, race, weight and height). We integrated all modifications into four final kinetic CKD-EPI formulations for female and male, as well as black and non-black, respectively.

Results: The comparison of crcl values obtained by equation B and the "gold standard" equation A demonstrated excellent agreement across physiologically plausible ranges of their variables pcr1, pcr2, vd, deltavd, time interval (t) and cgr. The final kinetic CKD-EPI equations were tested for sensitivity to deviations of cgr and vd from their estimated values. We show that differences within clinically meaningful ranges can have significant effects on the kinetic eGFR. Therefore, cgr and vd need to be checked for plausibility and adjusted (e.g. according to muscle mass, volume status) in individual patients.

Conclusions: We have developed a non-steady state adaptation of the CKD-EPI equation.

Funding: Private Foundation Support

Equation A:

$$pcr2 = pcr1\left(\frac{deltavd-vd}{vd}\right)^{-1\frac{crclt}{deltavd}} + \frac{cgr\left[1-\left(\frac{deltavd-vd}{vd}\right)^{-1\frac{crclt}{deltavd}}\right]}{crcl=\frac{deltavd}{t}}$$

Equation B:

$$crcl = -\frac{deltavd}{t} + \frac{2\left[cgr-\frac{(-pcr1-pcr2)\,vd}{t}\right]}{pcr1+pcr2}$$

SA-PO160

How to Estimate Kidney Function in AKI via the Basic Clearance: Role of the True Average (Creatinine)

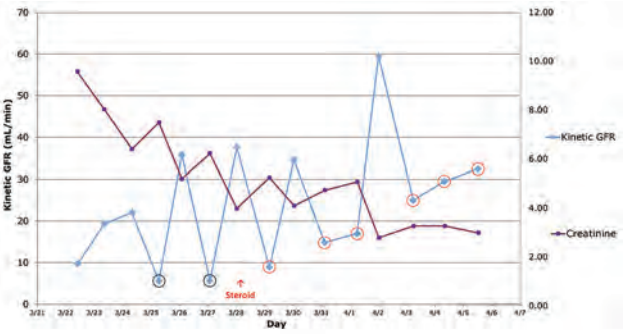
Sheldon Chen. *Section of Nephrology, MD Anderson Cancer Center, Houston, TX.*

Background: The basic clearance formula U×V/**P** has a single **P**lasma creatinine ([Cr]), so it seems to apply only in the steady state. Can U×V/P be used in the non-steady state when there are multiple values of P? We postulate that if all the P's in a [Cr] trajectory are represented by a "true average" [Cr], then dividing by this one P will recreate the kinetic GFR.

Methods: Working from *any* differential equation that models creatinine kinetics, we can take the novel step of using the fundamental theorem of calculus at the start. This produces a definite integral that calculates the average (not the simple mean) of a [Cr] vs. time function, our candidate true average [Cr]. It ends up in the denominator after solving for kinetic GFR, fitting the template of U×V/P.

Results: To use the true average [Cr] to compute kinetic GFR, we present two techniques, a graphical one and a numerical one—Newton's method. Both yielded identical answers for kinetic GFR, verifiable by a gold standard technique. But the true average method arrived at the answer faster than the gold standard and without any false solutions. In analyzing a recent case, the kinetic GFR aided clinical decision-making on a 74-year-old man whose creatinine rose subacutely from 1.10 to 9.57 mg/dL. Intermittent dialysis was done, giving the [Cr] plot a sawtooth pattern (Fig., in purple). Despite an overall decline in [Cr] at first, the kinetic GFR (in blue) showed no improvement in his kidney function, since the "valleys" in between dialyses sank down to the same low level. Later, a renal biopsy (3/26) revealed acute interstitial nephritis, and prednisone was started (3/28). The next kinetic GFR valley (3/29) was slightly higher, hinting at an early renal recovery. The valleys kept increasing (3/31-4/5), telling us that the steroid was working and so dialysis was stopped.

Conclusions: The clearance paradigm applies to the non-steady state as well if the true average [Cr] is the divisor, providing a fundamental strategy to deduce the kinetic GFR from the plasma [Cr] trends occurring in real-life acute kidney injury or renal recovery.



SA-PO161

Kidney Recovery in Patients Discharged with AKI Requiring Hemodialysis to Outpatient Centers

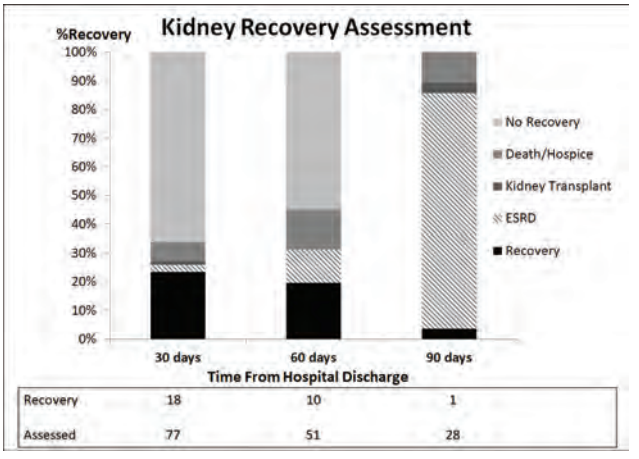
Melissa R. Jordan,[1] Victor M. Ortiz-Soriano,[1] Lauren Chism,[1] Aaron Pruitt,[1] B. Peter E. Sawaya,[2] Hartmut H. Malluche,[1] Javier A. Neyra.[2] [1]*University of Kentucky, Lexington, KY;* [2]*University of Kentucky Medical Center, Lexington, KY.*

Background: As of January 2017, patients with acute kidney injury requiring dialysis (AKI-D) can be discharged to outpatient centers for continued hemodialysis (HD) support. We aimed to examine kidney recovery and time-to-recovery in these patients.

Methods: Single-center, prospective cohort study of 118 adult patients who were admitted to the University of Kentucky Hospital (7/2017-2/2019), suffered from AKI-D and were discharged to non-academic affiliated outpatient HD centers. Kidney recovery was defined as the patient being alive and no longer requiring HD and was assessed at 30-day intervals up to 90 days post discharge.

Results: Of the 118 patients diagnosed with AKI-D during the index hospitalization, 15 patients were declared ESKD prior to discharge. We excluded patients that were prisoners (n=2) or were lost to follow-up (n=19). There were 5 patients that were misclassified as ESKD at their HD center despite being discharged as AKI-D. Among the remaining 77 patients, mean (SD) age was 54.4 (16.0) years; 61% were male and 88.3% white. Overall 29 (37.6%) patients recovered kidney function, about two-thirds of them within the first 30 days of hospital discharge [**Figure**].

Conclusions: At least 1 out of 3 AKI-D patients discharged to outpatient HD units with continued HD need recovered kidney function within 90 days of hospital discharge. The majority of patients recovered kidney function within 30 days of discharge, illustrating a critical window for surveillance and intervention. Future studies should focus on identifying best practices to promote recovery in this susceptible population.



Kidney recovery assessment in patients discharged with AKI requiring hemodialysis to outpatient centers

SA-PO162

The Value of Body Composition Analysis in Predicting the Prognosis of Patients with AKI Undergoing Continuous Renal Replacement Therapy

Huijuan Mao,[1] Buyun Wu.[2] [1]*First Affiliated Hospital of Nanjing Medical University, Nanjing, China;* [2]*Nanjing medical University, Nanjing City, China.*

Background: To investigate the value of nutritional and fluid status measured by bioelectrical impedance methods in predicting the prognosis of AKI patients undergoing continuous renal replacement therapy (CRRT).

Methods: Patients with severe AKI treated with CRRT in the first affiliated hospital of Nanjing medical university from Sep.2016 to Sep.2018 were prospectively enrolled, and divided into death group and survival group according to 28-day survival. Cox regression was used to analyze the association between 28-day survival and lean Tissue Index(LTI), fat Tissue Index(FTI), the ratio of extracellular water(ECW) and body cell mass (BCM) (ECW/BCM), and overhydration (OH), respectively.

Results: A total of 156 patients were included, including 101 males and 55 females. The average age was 62.7±15.4 years, with an average SOFA score of 9.9±3.9. The 28-day mortality rate was 46.2%. The pre-CRRT OH values and ECW/BCM values of the 28-day survival group and death group were 3.0(1.8, 5.5) L vs. 4.2(3.0, 5.7) L (P=0.016), 1.00(0.76, 1.18) vs. 1.07(0.88, 1.25) (P=0.033), respectively. Pre-CRRT high OH values (HR=0.83,95%CI=0.72-0.95,P=0.008) and high ECW/BCM values (HR=6.79,95%CI=1.72-26.82,P=0.006) were associated with 28-day death, while LTI and FTI were uncorrelated with 28-day death. The changes of OH values (HR=0.83,95% CI=0.72~0.95, P=0.008), ECW/BCM values (HR=6.79,95% CI=1.72~26.82, P=0.006) and FTI values (HR=1.12,95% CI=1.02~1.22, P=0.023) between pre-CRRT and the 7th day after CRRT initiation were significantly associated with 28-day mortality in patients survived 7 days after CRRT initiation. After adjusting for age, gender, and SOFA scores, the high OH value before CRRT, the changes of OH values, ECW/BCM values and FTI values between pre-CRRT and the 7th day after CRRT initiation, were independently associated with 28-day death.

Conclusions: In bioelectrical impedance analysis, the OH value and ECW/BCM value before CRRT is associated with 28-day mortality in patients with AKI, while the nutritional indicator LTI is not significantly related. The correction of fluid overload by CRRT within 7 days may reduce the 28-day risk of death.

SA-PO163

Preoperative Low Urine Specific Gravity Levels Predict AKI After Cardiac Surgery

Wonji Jo, Byounghwi Ko, Chan-Young Jung, Youngu su Joo, Sangmi Lee, Shinchan Kang, Jung Tak Park. *Yonsei University College of Medicine, Seoul, Republic of Korea*.

Background: Acute kidney injury (AKI) is a common and serious complication following cardiac surgery. However, strategies that could effectively stratify AKI risk before cardiac surgery are scarce. Recent investigations identified urinary osmolality to be associated with non-glomerular kidney damage in patients who are at higher risk for CKD progression. Patients with underlying kidney damage, although clinically insignificant, may be prone to cardiac surgery associated AKI. Hypothesizing that urine specific gravity (SG) could reflect kidney damage, the clinical implication of preoperative urine specific gravity on AKI occurrence after cardiac surgery was investigated in subjects with normal kidney function.

Methods: A total of 4135 patients who underwent coronary artery bypass or valve surgery at Yonsei University Health System from were enrolled. Patients whose eGFR was lower than 60mL/min/1.73m^2 were excluded. Fasting urinary specific gravity was measured from the morning first void a day before the surgery. The patients were divided into tertiles based on urine specific gravity. The primary outcome was the incidence of AKI within 48hours of cardiac surgery. AKI was defined according to Acute Kidney Injury Network criteria.

Results: The mean age of the patients was 60 years and 60% were male. Diabetes consisted of 25.6% of the patients and 54.5% were hypertensive. The mean eGFR and urine SG was 98.8mL/min/1.73m^2 and 1.020, respectively. AKI developed in 1,089 (26.3%) patients. The incidence of AKI was highest in the lowest urine SG tertile group (410, 29.0%) and lowest in the highest tertile group (304, 23.5%) (P < 0.001). Multivariable logistic regression analysis revealed that being included in the lowest preoperative urine SG tertile group was significantly related with higher post cardiac surgery AKI incidence risk (odd ratio (OR), 1.33; CI, 1.12-1.57; P =0.001). This association was significant even after adjustments were made for confounding factors.

Conclusions: Low urine SG was associated with increased risk of cardiac surgery associated AKI in patient with normal renal function. Evaluating preoperative urine SG may be useful in stratifying post cardiac surgery AKI risk.

SA-PO164

External Validation of an Electronic Health Record (EHR)-Based Machine Learning Risk Score for Hospital-Based AKI

Jay L. Koyner,[1] Majid Afshar,[2] Emily R. Gilbert,[3] Kyle Carey,[4] Matthew M. Churpek.[1] *[1]University of Chicago, Chicago, IL; [2]Loyola University Chicago, Chicago, IL; [3]Loyola University Medical Center, Maywood, IL; [4]University of Chicago, Chicago, IL*.

Background: We seek to externally validate our previously published EHR-based machine learning AKI risk score in data from a new hospital system.

Methods: All hospitalized patients who had SCr measured at Loyola University Medical Center (LUMC) from 2008 to 2016 were eligible. Patients with a first serum creatinine (SCr)>3.0mg/dl, those who had an ICD codes for CKD Stage 4 or higher, or received renal replacement therapy(RRT) within 48 hours(hrs) of admission were excluded. Demographics, vital signs, laboratory results, and nursing scores were utilized in the previously published gradient boosted machine learning algorithm based on data from the University of Chicago (UofC) to predict SCr-based KDIGO AKI. Areas under the curve (AUC) were calculated in the LUMC cohort, and subgroup analyses were conducted across admission SCr, AKI severity, and hospital location.

Results: Among the 194,930 included LUMC patients, 27,374 (14.0%) developed KDIGO AKI with 7,364 (3.8%) developing Stage 2 and 3,393 (1.7%) requiring RRT. These rates were similar compared to the UofC cohort (14.4% AKI, 3.5% Stage 2). The AUC (95%CI) of the model in the LUMC cohort was 0.80(0.80-0.80) for predicting Stage 2 AKI within 48 hrs compared to 0.86(0.86-0.86) in the UofC cohort. The AUC was 0.80(0.80-0.80) for Stage 3 in 48 hrs in the LUMC cohort. AUCs for subgroups (patient location and admitting SCr) at LUMC (24 and 48 hr predictions) can be found in the table.

Conclusions: We report the first externally validated machine learning EHR-based AKI risk algorithm. EHR data can be used to predict impending AKI prior to significant changes in SCr across different patient locations and baseline SCr values. We are using this validated EHR model in real-time in an active clinical trial seeking to improve AKI outcomes.

Funding: NIDDK Support

Validation of EHR Risk Score in Subgroups Based on Patient Location and Admission SCr

	AUC (95%CI) for Predicting Stage 2 AKI within 24 hrs in LUMC cohort	AUC (95%CI) for Predicting Stage 2 AKI within 48 hrs in LUMC
Patient Location		
Ward	0.80 (0.80 - 0.80)	0.75 (0.75 - 0.75)

Identification and Performance Evaluation of AKI Trajectory Subtypes Associated with Mortality and Kidney Recovery in Critically Ill Patients

Javier A. Neyra,[2] Taylor D. Smith,[1] Victor M. Ortiz-Soriano,[1] Xilong Li,[3] Donglu Xie,[3] Beverley Adams-Huet,[3] Orson W. Moe,[3] Robert D. Toto,[3] Jin Chen.[1] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY; [3]University of Texas Southwestern Medical Center, Dallas, TX*.

Background: Few risk-prediction models focus on outcomes specific to critically ill patients with AKI. We developed and evaluated the performance of a novel machine learning model called Trajectory of Acute Kidney Injury (TAKI) for the prediction of mortality and kidney recovery.

Methods: Independent cohorts from two academic institutions were used: UK (discovery, n=37,095) and UTSW (validation, n=10,590). Exclusion criteria consisted of age <18, eGFR <15 or ESKD, kidney transplant, absence of ≥2 serum creatinine (SCr) measures, absence of SCr-criteria of AKI in the first 7 ICU days or ICU stay <48 h. First, a trajectory based on KDIGO-AKI SCr-severity classification was composed for every patient using repeated SCr measures up to 7 days. Second, for trajectories with different length, population-based dynamic time-warping was developed for alignment. Third, the distance between any two aligned trajectories was computed and then adjusted using AKI severity. Fourth, hierarchical clustering was adopted with a dynamic merging process to determine the final trajectory subtypes, which were used as features for predicting hospital mortality and major adverse kidney events (MAKE) at 90 days following discharge (composite of death, RRT dependence or inability to recover 50% of baseline eGFR).

Results: The incidence of AKI was 33.4% (UK) and 27.0% (UTSW). Hospital mortality rates were 24.4% and 13.7% and MAKE rates 38.3% and 36.2% in UK and UTSW cohorts, respectively. TAKI identified improving, stationary and worsening AKI subtypes associated with outcomes beyond severity classification. TAKI improved prediction of mortality and MAKE when added to severity classification of AKI or multiorgan failure scores in both cohorts [**Table**].

Conclusions: TAKI is a feasible method of AKI subtyping that informs risk-stratification of mortality and kidney recovery in critically ill adults with AKI beyond current AKI severity classification. Further validation is needed.

Performance metrics (95%CI) of TAKI for the prediction of mortality and MAKE (UK cohort)

	SOFA Mortality	SOFA+TAKI Mortality	KDIGO Mortality	KDIGO+TAKI Mortality	KDIGO MAKE	KDIGO+TAKI MAKE
AUC	0.66 (0.65-0.68)	0.76 (0.74-0.77)*	0.63 (0.61-0.64)	0.73 (0.71-0.73)*	0.64 (0.62-0.65)	0.77 (0.76-0.78)*

SA-PO166

Recovery Patterns After AKI Differentiate Risk of Long-Term Adverse Kidney Outcomes

Pavan K. Bhatraju,[1,2] Leila R. Zelnick,[3] Vernon M. Chinchilli,[4] Dennis G. Moledina,[5] Steven G. Coca,[6] Chirag R. Parikh,[7] Amit X. Garg,[8] Chi-yuan Hsu,[9] Alan S. Go,[10] Kathleen D. Liu,[11] Edward D. Siew,[12] James S. Kaufman,[13] Paul L. Kimmel,[14] Jonathan Himmelfarb,[3] Mark M. Wurfel.[1] *[1]University of Washington, Seattle, WA; [2]Medicine, Division of Nephrology, Kidney Research Institute, Seattle, WA; [3]Kidney Research Institute, Seattle, WA; [4]Penn State College of Medicine, Hershey, PA; [5]Yale School of Medicine, New Haven, CT; [6]Icahn School of Medicine at Mount Sinai, New York, NY; [7]Johns Hopkins University, Baltimore, MD; [8]London Health Sciences Centre, London, ON, Canada; [9]University of California San Francisco, San Francisco, CA; [10]Kaiser Permanente Northern California, Oakland, CA; [11]University of California at San Francisco School of Medicine, San Francisco, CA; [12]Vanderbilt University School of Medicine, Nashville, TN; [13]VA New York Harbor Healthcare System, New York, NY; [14]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD.*

Background: Whether the trajectory of kidney function 72 hours after AKI informs long-term clinical outcomes, including CKD, dialysis and death, is unknown.

Methods: We prospectively enrolled patients who survived 90 days after hospitalization with or without AKI in ASSESS-AKI. Resolving AKI was defined as a decrease in SCr of 0.3 mg/dL or 25% from maximum in the first 72 hours after AKI diagnosis. Non-resolving AKI was defined as all AKI cases not meeting the 'resolving' definition. The primary outcome was a composite of major adverse kidney events (MAKE), defined as incident or progressive CKD, incident dialysis or death. Time to event analyses were completed conditioning on: demographics, comorbidites and KDIGO stage of AKI.

Results: We evaluated 772 participants with AKI and 831 participants without AKI over a median of 4.8 years. Among the AKI group, 479 (62%) had a resolving AKI pattern and 294 (38%) had a non-resolving pattern. The unadjusted incidence rate for MAKE was 5.5 events per 100 patient years in participants without AKI, 11.1 events in resolving AKI and 15.4 events in non-resolving AKI **(Figure 1)**. The adjusted hazard ratio (aHR) for MAKE was higher for both resolving (aHR, 1.76; 95% CI, 1.17 to 2.63; p=0.006) and non-resolving (aHR 2.54; 95% CI, 1.69 to 3.81; p<0.001) AKI compared to participants without AKI. Within the AKI population, non-resolving AKI was associated with a 45% greater risk of MAKE (95% CI, 17% to 78% greater; p<0.001) compared to resolving AKI. The higher risk of MAKE in non-resolving AKI was due to a higher risk of incident and progressive CKD.

Conclusions: The 72-hour time period post AKI diagnosis distinguishes the risk of MAKE. The identification of AKI recovery patterns may improve patient risk stratification, facilitate prognostic enrichment in AKI clinical trials, and recognize patients who may benefit from nephrology consultation.

Funding: NIDDK Support

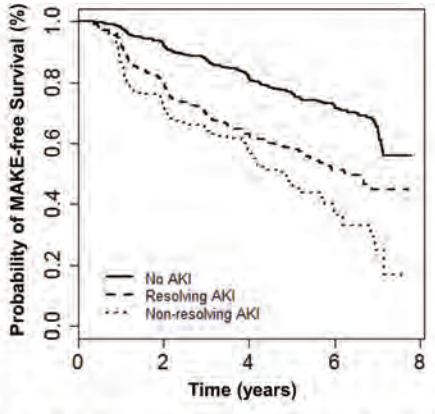

Figure 1. Kaplan-Meier plot demonstrates the highest risk for major adverse kidney events (MAKE) among participants in the non-resolving AKI recovery group with a step-wise decrease in risk for MAKE in the resolving AKI group and then in participants without AKI. MAKE is defined as the composite of death, dialysis, CKD incidence, or CKD progression during study follow-up.

SA-PO167

Crizotinib-Induced Pseudo-AKI: A Case Report

Laura Cosmai,[1] Meri Pedone,[2] Nicole Gri,[3] Mimma Rizzo,[4] Marina Foramitti,[6] Camillo Porta,[5] Mario Cozzolino.[7] *[1]San Carlo Borromeo Hospital, Milano, Italy; [2]ASST Santi Paolo e Carlo Borromeo - Ospedale San Carlo Borromeo, Milan, Italy; [3]I.R.C.C.S. Istituti Cllinici Scientifici Maugeri, Pavia, Italy; [4]ICS Maugeri, Viggianello, Italy; [5]University of Pavia, Pavia, Italy; [6]ASST Cremona, Cremona, Italy; [7]Department of Health Sciences, University of Milan, Milan, Italy.*

Introduction: The appearance of treatment-related Acute Kidney Injury (AKI) or the worsening of a pre-existing Chronic Kidney Disease (CKD) often limit the correct administration of many potentially life prolonging Oncological treatments. Crizotinib is a multikinase inhibitor, used to treat ALK-traslocated non-small cell lung cancers (NSCLC). Chronic and acute (mainly due to competitive inhibition of creatinine at renal proximal tubule) kidney failure possibly related to Crizotinib treatment have been described

Case Description: A 59 year old male came to onconephrological evaluation with stage 5 CKD (creatinine 6.1 mg/dl, urea 76 mg/dl, no clinical signs of uremia); he had a solitary kidney after a previous right nephrectomy for urothelial carcinoma, and carried a left ureteral stent for concomitant nephrolithiasis. More importantly, he had a metastatic ALK-traslocated NSCLC previously treated with Cisplatin-based chemotherapy (CT), which lead to a first episode of AKI and then to CKD, presently treated with Crizotinib 250 mg b.i.d. with optimal disease control. Creatinine levels worsened from 1.6 mg/dl post nephrectomy, to 2.2 post CT, to 4 mg/dl after Crizotinib. The oncological treatment was thus stopped. When referred to us, a kidney sequential scintigraphy with Tc 99mDTPA was performed, which showed a glomerular clearance of 26 ml/min (vs a CKD-EPI of 9.2 ml/min and a Cockroft Gault of 13.2 ml/min). We thus postulated that CKD worsening could be due to the inhibition of creatinine tubular secretion by Crizotinib. We thus recommended to restart Crizotinib treatment at the reduced dose of 250 mg o.d., suggesting to perform more frequent urotelial stent changes. Two years after restarting Crizotinib, the patient is still on treatment, with stable oncological disease, as well as renal function

Discussion: Crizotinib may induce inhibition of creatinine tubular secretion together with creatinine increase, thus mimicking AKI on CKD. This case highlights the importance of renal scintigraphy in assessing these patients, as well as the role of Onco-Nephrologist

De Novo Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits After Allogeneic Stem Cell Transplant

Lynn M. St.pierre, Regan M. Seipp, Maxwell L. Smith, Leslie F. Thomas, Musab S. Hommos. *Mayo Clinic, Scottsdale, AZ.*

Introduction: Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits (PGNMID) is a rare form of monoclonal gammopathy of renal significance (MGRS). Here we describe an unusual presentation of de novo PGNMID occurring in patient who underwent allogeneic stem cell transplant two years prior to the diagnosis.

Case Description: A 71-year-old male underwent matched related allogeneic stem cell transplant (SCT) for acute myelogenous leukemia (AML). The donor was the patient's brother. The patient's relevant medical problems at the time of transplant included enlarged prostate, status post prostatectomy, and previous acute kidney injury events attributed to sepsis and hypotension in the setting of chemotherapy administered for AML. At the time of transplant, serum creatinine was 1.5 mg/dL (eGFR 47 ml/min). Urinalysis was devoid of hematuria and proteinuria. Post SCT, he developed graft vs host disease involving the gastrointestinal tract which was treated with steroids. Subsequent restaging bone marrow biopsies showed no residual AML. Two years post SCT, he developed nephrotic syndrome associated with a rapid rise in serum creatinine to 4.5 mg/dL (eGFR 12 ml/min), and hematuria. Serum testing showed a new monoclonal IgG kappa, and kappa free light chain of 4.8 mg/dL (kappa/lambda ratio of 2). Kidney biopsy revealed a diffuse mesangial and endocapillary proliferative glomerulonephritis with immunofluorescence microscopy revealing capillary loop pseudolinear reactivity for IgG (2+), kappa (2+), and C3 (3+), with no reactivity for lambda. A subsequent bone marrow biopsy was negative for plasma cell neoplasm or lymphoma as was the flow cytometric analysis.

Discussion: To our knowledge, this is the first reported case of PGNMID following allogenic SCT. Similar to many other reported cases, a plasma cell clone was not identified via histologic examination of the bone marrow. Given the time of PGNMID diagnosis post SCT, transfer of plasma cell disorder from the donor is one consideration to explore by testing the donor for monoclonal dysproteinemia. This case illustrates the importance of considering MGRS in the differential diagnosis of kidney disease and proteinuria in patients with history of stem cell transplant.

Ibrutinib-Induced Acute Tubular Injury: A Case Series and Review of the Literature

Anip Bansal,[1] Sandhya Manohar,[2] Vipulbhai Sakhiya,[4] Rimda Wanchoo,[3] Kenar D. Jhaveri.[3] *[1]University of Colorado, Aurora, CO; [2]Mayo Clinic, Rochester, MN; [3]Zucker School of Medicine at Hofstra Northwell, Great Neck, NY; [4]Northwell Health, Great Neck, NY.*

Introduction: CLL is the most prevalent form of leukemia in adults. Treatment with Bruton tyrosine kinase pathway inhibitor, ibrutinib has revolutionized its treatment. HTN and tumor lysis syndrome (TLS) with ibrutinib are known but acute tubular injury (ATI)

has not been reported. Here, we describe 2 cases of biopsy proven ATI associated with ibrutinib and review its nephrotoxicity.

Case Description: Case 1: 63 year old man with CLL was started on ibrutinib with excellent disease control for the past 3.5 years. His baseline creatinine was 1.4 mg/dl but since starting therapy had slowly increased to 2.0 mg/dl. Non-invasive workup was unremarkable and hence underwent a kidney biopsy. This showed mild ATI on a background of mild chronicity. There was suspicion for low grade vascular injury on light microscopy but no endothelial injury was noted on electron microscopy. Clinically he had no HTN nor any lab evidence of microangiopathic hemolysis. Considering the unfavorable cytogenetics of his CLL and good disease control decision was made to continue ibrutinib and at 6 month follow up his creatinine continues to be stable. Case 2: 59 year old man with CLL was started on ibrutinib 6 months before nephrology consultation. His baseline creatinine was 1.1 mg/dL but with treatment slowly increased to a peak of 2.71 mg/dL. His BP was normal. Non-invasive workup was unremarkable and hence underwent a kidney biopsy which showed ATI alone. Based on absence of any other etiology of his kidney injury a diagnosis of ibrutinib associated ATI was made and ibrutinib was discontinued. One month later his serum creatinine had improved to 2.37mg/dL.

Discussion: We reviewed the FAERS quarterly legacy data file for ibrutinib associated adverse events (third quarter of 2014 to fourth quarter of 2018) and overall >600 events were reported of which >25% were for AKI. Conclusion: In addition to TLS and HTN, ATI can be seen with ibrutinib. Hematologists and nephrologists need to be aware of this rare but important toxicity of ibrutinib.

Severe Placental Insufficiency 3 Years After Treatment with Bevacizumab: An Epigenetic Effect?

Dominique C. Pagniez. *Nephrology, Centre Hospitalier Universitaire, Lille, France.*

Introduction: We report on a patient whose second pregnancy was complicated by severe intra uterine growth retardation and early preeclampsia with the HELLP syndrome, three years after she had been treated with Bevacizumab for breast cancer.

Case Description: A 26-year-old patient had had an uneventful first pregnancy in 1998. Ten years later, she was diagnosed with grade I intra ductal triple negative breast carcinoma, and treated with partial mastectomy, chemotherapy associated with Bevacizumab, and radiotherapy. Three years later, bilateral ovariectomy was about to be performed, when an unexpected pregnancy was found at echography. The patient elected to pursue this pregnancy. Severe intra uterine growth retardation occurred, and cesarean section had to be performed at 29 weeks of amenorrhea, because of preeclampsia with the HELLP syndrome. Four months later, blood pressure and renal function were normal, and there was no proteinuria. No congenital or acquired thrombophilia was found.

Discussion: Our patient had severe placental insufficiency during her second pregnancy, three years after treatment with conventional chemotherapy and Bevacizumab for breast cancer. Conventional chemotherapy, even if used during pregnancy, is not associated with an increased risk of preeclampsia (1). In non-pregnant patients, Bevacizumab may induce a preeclampsia-like syndrome, which disappears when treatment is stopped (2). In our patient, one may speculate that former bevacizumab treatment caused a long-lasting alteration of the balance of angiogenic and antiangiogenic factors, which was later revealed during pregnancy, a distinctly unusual event in that context. Antiangiogenic drugs can alter the transcription profile of acetylation genes in retinal cells (3). This very unusual observation supports the hypothesis that Bevacizumab may have long-lasting endothelial effects through epigenetic pathways. Monoclonal Immunoglobulin Tubulointerstitial Deposits in Kidney in Sjogren Syndrome with MALT Lymphoma: Occam's Razor or Hickam's Dictum

Purva D. Sharma,[1] Hugo Andrade paz,[2] Vanesa Bijol.[3] *[1]Nephrology and Hypertension, Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]Northwell Health, Great Neck, NY; [3]Northwell Health Hofstra University, Lake Success, NY.*

Introduction: Monoclonal gammopathy is a common phenomenon in patients with MALT (Mucosa Associated Lymphoid Tissue) lymphoma likely due to clonal production of paraproteins by lymphoplasmacytic cells, which responds to B cell directed therapy. We report a case of Sjogren's disease and MALT lymphoma with rearranged kappa light chain, serum monoclonal gammopathy, and monoclonal IgM-kappa tubulointerstitial deposits in the kidney, that presented with a challenging therapeutic dilemma

Case Description: 60 yo woman with Sjogren's disease presented with a subacute rise in creatinine from 1.4 to 1.8 mg/dl and 1 gm proteinuria. Work up was positive for low C3, undetectable C4, positive RF. SIFE showed weak IgM-kappa band, urine immunofixation showed kappa bence jones protein. Kappa/Lambda free light chain ratio was 23. She had a h/o parotid mass 2 years ago, diagnosed on excisional biopsy to be extra-nodal marginal zone lymphoma with IHC positive for CD20 and PCR showing rearranged kappa light chain. Repeat CT showed persistent low level + FDG activity in left eye and parotids that was decided to be monitored. A kidney biopsy was obtained that showed IgM kappa tubulointerstitial deposition disease with polytypic chronic active interstitial nephritis. Immunohistochemistry analysis revealed polytypic T cell predominant immunophenotype with no evidence of lymphoma. A subsequent work up included a bone marrow biopsy that showed a polytypic plasma cell population (0.6% of the cells) with a K/L ratio of 3:1. Immunohistochemistry showed polyclonal plasma cells. There was no evidence of myeloma or lymphoma. Considering the above, it was concluded that the low level lymphoma was likely the source of monoclonal protein and a decision was made to treat with B cell directed therapy only.

Discussion: Monoclonal gammopathy has been reported with MALT lymphomas but this is the first case in literature with associated monoclonal IgM-kappa tubulointerstitial deposition disease in the kidney. It is important to work up these patients for another clone producing site since it impacts decision making about immunosuppression. Close follow up is needed for monitoring renal and hematologic recovery.

SA-PO172

Rituximab Administration Unveils Monoclonal Gammopathy of Renal Significance (MGRS)

Itamar Sagiv, Karen Meir, Dvora Rubinger, Moshe E. Gatt. *Hadassah Hebrew University Medical Center, Jerusalem, Israel.*

Introduction: Cryoglobulinemic renal disease occurs in the presence or the absence of serological markers. In this case type I cryogobulinemia-associated MGRS was diagnosed after rituximab (Rx) administration.

Case Description: A 52 yr old man was evaluated for moderate proteinuria with no extrarenal manifestations. Laboratory evaluation disclosed low C3 and increased antistreptolysin titer. Ramipril treatment did not affect urinary protein excretion. On kidney biopsy, there were PAS positive proteinaceous thrombi obliterating capillary lumens in a focal segmental pattern. These findings were suggestive of cryoglobulinema. Immunofluorescence revealed intramembranous deposits positive for C3 and IgM κ chains (Figure1). Cryocrit increased from traces to 2% (Table 1). Anti HCV antibodies, rheumatoid factor, ANA, ANCA were negative. No paraprotein was detected. Treatment with Prednisone and subsequently with Rx had no effect. After Rx, the patient developed severe nephrotic syndrome and renal dysfunction. Cryocrit rose to 3% and IgM κ paraprotein appeared for the first time on immunofixation. A bone marrow biopsy showed 4-8% monoclonal plasma cells positive for IgM κ. Treatment with Bortezomib, Cyclophosphamide and Dexamethasone resulted in resolution of nephrotic syndrome and normalization of renal function.

Discussion: B cell suppression after Rx exposed the serum IgM/κ originating from a small clone of plasma cell and responsible for MGRS. A Bortezomib based protocol induced complete clinical and serological remission.

Table 1. Clinical course and response to treatment.

Year	2014	2015	2016	2017	2019
Urinary protein excretion (mg/24 hr)	945	1680	4600	11900	127
Serum creatinine (μmol/L)	70	79	79	203	88
Serum albumin (g/L)	42	39	36	23	43
Cryocrit	Trace	1%	2%	3%	Trace
Free kappa/lambda (κ/λ) light chains ratio*	NA	2.1	1.8	2.7	1.4
IgM κ**	NA	Negative	Negative	Positive	Negative
Treatment	ACE Inhibitors	Prednisone	Rituximab	Bortezomide, Cyclophosphamide. Dexamethasone	ACE Inhibitors

NA:not available; ACE: angiotensin converting enzyme

*Normal range: 0.26-1.65; ** Immunofixation.

SA-PO173

Amyloidosis Returns

Purva D. Sharma,[1] Vanesa Bijol,[2] Bessy Suyin Flores Chang,[3] Kenar D. Jhaveri.[4] *[1]Nephrology and Hypertension, Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]Northwell Health Hofstra University, Lake Success, NY; [3]Zucker School of Medicine at Hofstra/Northwell, Kew Gardens, NY; [4]Northwell Health Sys, Great Neck, NY.*

Introduction: AL Amyloidosis is the most common type of systemic amyloidosis and frequently involves the kidney. Renal outcomes in renal AL Amyloid post autologous stem cell transplant (ASCT) depend on hematologic remission, initial organ injury and depth of organ response. We describe a case of renal AL amyloid who developed worsening kidney function and nephrotic range proteinuria 3 years post ASCT and presented a challenging diagnostic and therapeutic dilemma.

Case Description: A 71 yo male presented with nephrotic syndrome with 5 gms proteinuria and had a renal biopsy revealing renal amyloidosis with lambda restriction. There was 50% interstitial fibrosis and tubular atrophy. Workup showed IgG Lambda monoclonal protein in serum and urine, normal troponin and mildly elevated NT-pro-BNP.

Skeletal survey was negative. ECHO showed EF of >70% with normal wall thickness. Bone marrow (BM) showed 70% cellularity with 15-25% plasma cells cytoplasmic lambda, and CD 38 and 138 were positive. Patient received cyclophosphamide, bortezomib and dexamethasone followed by ASCT. Following transplant, he developed acute kidney injury requiring short term dialysis with creatinine stabilizing at 1.6-1.8 g/dl and a proteinuria of 1-2 gms. BM biopsy post ASCT was negative. Serum immunofixation (SIFE) was negative. 3 years later, he presented with subacute rise in proteinuria to 8 gms and a serum creatinine of 2.5-3 mg/dl. He had a second kidney biopsy that showed lambda light chain restricted AL amyloidosis, with global sclerosis or obliteration by amyloid in 42% of glomeruli, tubular atrophy (70% of cortex), diffuse interstitial fibrosis and amyloid deposition. SIFE remained negative and Kappa/Lambda ratio was 1.3. A repeat BM biopsy was negative. Minimal residual disease testing on BM was also negative. There was no evidence of cardiac or hepatic amyloid. Considering the above, this was ascertained to be progression of the original amyloid disease and no further treatment was considered.

Discussion: We present a case of AL amyloidosis treated with chemotherapy and ASCT and remained in complete hematologic remission, but three years later presented with worsening renal failure and proteinuria with repeat kidney biopsy showing extensive amyloid deposits. This case highlights the importance of distinguishing between recurrence and progression of renal amyloidosis post ASCT by detailed hematologic work up and ruling out extra-renal disease.

SA-PO174

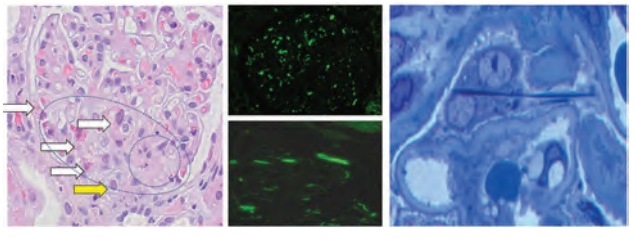
Autologous Stem Cell Transplant for the Treatment of Masked Crystalline Light Chain Tubulopathy and Podocytopathy Causing FSGS in the Context of Monoclonal Gammopathy of Renal Significance

Andreas Kousios,[1] Stephen P. McAdoo,[1,2] Sarah Blakey,[1] Maria Atta,[3] Neill D. Duncan,[1] Frederick W. Tam,[1,2] H. Terence Cook,[4,2] Candice A. Roufosse,[4,2] Aristeidis Chaidos.[3,2] Imperial College Healthcare NHS Trust *[1]Renal and Transplant centre, Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]Centre for Haematology, Imperial College Healthcare NHS Trust, London, United Kingdom; [4]Centre for Cellular Pathology, North West London Pathology, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Introduction: MGRS encompasses a wide spectrum of renal histopathology. Light chain (LC) crystalline podocytopahty causing secondary FSGS has rarely been described. We present a case with masked crystalline tubulopathy and podocytopathy associated with MGRS which was treated with myeloma induction therapy followed by autologous stem cell transplantation (ASCT).

Case Description: A 47 year old male presented with nephrotic proteinuria (uPCR 760 mg/mmol), microscopic haematuria and renal impairment (Creatinine 146umol/l, eGFR 49ml/min). Autoimmune, virology screen, Complement were normal. Protein electrophoresis (SPEP) showed IgG kappa paraprotein 11g/l. Serum free light chain (SFLC) ratio was 9.5 (kappa level 91.3mg/l, lambda 9.6mg/l). No cryoglobulin was detected. Renal biopsy showed features of secondary FSGS. Immunofluorescence (IF) was negative for IgG, IgM, IgA, c3, c1q and equal kappa/lambda staining. We performed IF on paraffin sections after protease digestion unmasking crystalline inclusions in podocytes and tubules showing kappa LC restriction. Bone marrow biopsy (BMAT) showed 10-12% plasma cells. Normal skeletal survey. In conjunction, BMAT and renal biopsy results were in keeping with MGRS with an unusual histology of masked FLC-crystalline in tubules and podocytes causing FSGS. Treatment included VCD chemotherapy with partial response followed by melphalan conditioned ASCT. One month post ASCT renal function and proteinuria improved(Creatinine 120 umol/l, eGFR 60 ml/min).

Discussion: MGRS must be suspected in all patients with kidney disease and paraprotein regardless of the tumour burden. Protease digestion may be needed to unmask FLC restriction and should be considered in selected cases. Effective haematological treatment improved renal outcome.



SA-PO175

Minimal Change Nephropathy as a First Manifestation of Waldenstrom Macroglobulinemia

Kamolwan Pakchotanon,[1] Noppanit Pattanachaiwit,[1] Pongsathorn Gojaseni,[1] Suchin Worawichawong,[2] Kolasorn Pakchotanon.[1] Bhumibol Adulyadej Hospital *[1]Bhumibol Adulyadej hospital, Bangkok, Thailand; [2]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.*

Introduction: Waldenstrom's macroglobulinemia (WM) is an uncommon disease, with rare renal presentation. We report a case of nephrotic syndrome (NS) resulting from minimal change nephropathy (MCN) as a first presentation of WM.

Case Description: A 60-year-old woman presented with progressive generalized edema over 3 months. Her physical examination showed severe edema in both legs and mildly pale conjunctiva. Urinalysis revealed 3+ protein with bland sediment. Urine protein creatinine ratio (UPCR) was 7.28. Blood tests were hemoglobin (Hb) 9.3 g/dL, Cr 1.48 mg/dL and serum albumin 1.7 g/dL. Serum protein electrophoresis had no signs of monoclonal gammopathy. Serum kappa/lambda ratio was 5.51. Bence-Jones proteinuria was negative. Renal biopsy revealed unremarkable glomerular capillaries and mesangium on light microscopy. An immunofluorescent study unveiled trace kappa and IgM. Electron microscopy showed diffuse foot process effacement without electron-dense deposits. This patient was given a diagnosis of MCN, and prednisolone was started. After 6 weeks of corticosteroid treatment, her clinical outcomes did not improve, with her anemia worsening. The results of further investigations showed immunofixation: IgM kappa monoclonal gammopathy. The bone marrow biopsy had 85% dense atypical small lymphoid cell infiltration. The WM diagnosis was rendered, and treatment instituted with rituximab, cyclophosphamide, vincristine, prednisolone (R-CVP). WM went into partial remission, and MCN was in complete remission (UPCR 0.22, Cr 0.7 mg/dL) after 5 courses of R-CVP.

Discussion: MCN's good response to chemotherapy suggests a relationship between MCN and WM. However, the pathogenesis of MCN in WM remains unclear. It was suggested in cases of MCN associated with classic Hodgkin lymphoma that excessive production of inflammatory cytokines could alter the glomerular filtration barrier. An imbalance in T cell subpopulations, a significantly low ratio of CD4:CD8 and the decrease of T regulatory cells (Tregs), may be associated with the occurrence of MCN. More recently, clinical evidence of the effectiveness of B cell depletion via rituximab, an anti-CD20 monoclonal antibody, in different forms of NS has theorized a role for B cells as drivers of MCN. Moreover, targeting B cells may affect the cross-talk between T and B cells.

SA-PO176

Combination of Immune Checkpoint Inhibitor and Antiangiogenic Therapy for the First-Line Treatment of Advanced Renal Cell Carcinoma: A Combined Analysis of Three Phase 3 Randomized Controlled Trials

Anita Sultan,[1] Vaqar Ahmed,[2] Sriman Swarup,[1] Rachana Yendala,[1] Wut yi Hninn,[5] Maung htain K. Lin,[7] Thura W. Htut,[4] Dia R. Waguespack,[6] Kyaw Z. Thein.[3] *[1]Texas Tech University Health Sciences Center, Lubbock, TX; [2]Dallas Nephrology Associates, Dallas, TX; [3]The University of Texas MD Anderson Cancer Center, Lubbock, TX; [4]Aberdeen Royal Infirmary, Colchester, Essex, United Kingdom; [5]UTHealth, Houston, TX; [6]McGovern Medical School - UTHealth - Houston, Houston, TX; [7]Charles Wilson VA outpatient clinic, Houston, TX.*

Background: Management of advanced renal cell carcinoma (RCC) is an area in dire need of therapeutic innovation. Sunitinib, a tyrosine kinase inhibitor targeting vascular endothelial growth factor (VEGF), has been the standard first-line treatment of advanced RCC for the past decade. Recently, combination of immune checkpoint inhibitor (ICI) and antiangiogenic agent has shown survival benefits. The purpose of our study is to stratify the efficacy of combination of ICI and antiangiogenic therapy for the first-line treatment of advanced RCC, according to international metastatic RCC database consortium (IMDC) risk groups and PD-L1 status.

Methods: PUBMED, MEDLINE, EMBASE databases and meeting abstracts from inception through May 2019 were queried. RCTs utilizing upfront combination of ICI and antiangiogenic therapy in patients with advanced RCC were incorporated. A generic inverse variance method was used to calculate the estimated pooled hazard ratio (HR) for progression-free survival (PFS) with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q -statistic.

Results: A total of 2662 patients from 3 phase III RCTs were included. The study arm used pembrolizumab+ axitinib, avelumab+ axitinib or atezolizumab+ bevacizumab while control arm utilized sunitinib. The randomization ratio was 1:1 in all studies. The I2 statistic for heterogeneity was 0%, suggesting homogeneity among RCTs. The PFS benefit was observed in all IMDC risk groups, including favorable group (HR, 0.70; 95% CI: 0.52- 0.96; P = 0.02), intermediate group (HR, 0.71; 95% CI: 0.60- 0.84; P < 0.0001) and poor group (HR, 0.58; 95% CI: 0.42- 0.80; P = 0.0009). The PFS benefit was only noted in PD-L1 positive (≥1%) cohort with HR of 0.66 (95% CI: 0.57- 0.77; P < 0.0001).

Conclusions: Our study showed that combination of immune checkpoint inhibitor and antiangiogenic therapy significantly improved PFS compared to standard sunitinib in patients with advanced RCC, regardless of IMDC risk categories. However, PFS benefit was only noted in PD-L1 positive cohort and further strategies are warranted in PD-L1 negative subset.

SA-PO177

Incidence of AKI in Melanoma Patients Treated with Immune Checkpoint Inhibitors

Ala Abudayyeh,[3] Yan Heather Lin,[3] Jamie Lin,[3] Omar Mamlouk,[1] Umut Selamet,[4] Maen Abdelrahim.[2] *[1]University of Texas Health Science Center, Houston, TX; [2]Houston Methodist Cancer Center, Houston, TX; [3]University of Texas MD Anderson Cancer Center, Houston, TX; [4]UCLA, Marina Del Rey, CA.*

Background: Immune checkpoint inhibition (ICI) had a major clinical success in clinical oncology. Immune related adverse events (irAEs) are well described toxicities. Unlike other common irAEs, the incidence of renal toxicity is reported 3.8% with varied definitions of AKI. In this study we sought to retrospectively review a single center 10 year experience of patients diagnosed with Melanoma and treated with CPI and evaluate incidence of AKI and overall survival.

Methods: We performed a retrospective chart review from 2008-2018 and extracted all patients treated with ICI. We identified 1691 unique melanoma patients and extracted

all available creatinine. We have defined AKI based on KDIGO guidelines. 1st definition: as an absolute increase in serum creatinine of 0.3 mg/dl within 48 hours and 2nd as 50% relative increase in serum creatinine within 7 days. Time to first AKI was defined as time from treatment initiation to time of AKI. Cumulative incidence rate of AKI after initiation of ICIs were calculated in the presence of death as a competing risk. The effects of covariates on the cumulative incidence function of AKI were evaluated in the univariate setting using Gray's test. Validity of the proportional cause-specific hazards and sub-distribution hazards assumptions were assessed using the proportionality test on time-varying covariates.

Results: Ipilimumab was the most commonly used ICI (27.63%). Incidence of AKI at median time of duration of treatment of 110 days using 1st definition was at 2.76% and using 2nd definition was at 3.25%. Patients older than 60 years of age (median) had a higher experiencing AKI than the younger patients. Compared to the patients treated with pembrolizumab, the patients treated with ipilimumab (HR3.68), ipilimumab /nivolumab (HR 5.271) Ipiliumab/Nivolumab/pembrolizumab (HR 4.284), ipiliumab/pembrolizumab (HR 7.285), nivolumab/pembrolizumab(HR 6.639) had significantly higher risk of experiencing AKI using both definitions.

Conclusions: With such a large population of melanoma patients treated with ICI we have the first accurate documentation of AKI in setting of ICI use and confirmation of incidence that has been reported. In addition, it's an expansive look at predictors of AKI and the use of ipiliumuab and combinations of ICI more associated with AKI. Impact of AKI on survival is underway.

Incidence of Nephrotoxicity Secondary to PD-1/PD-L1 Inhibition: A Single Health Center Experience

Ping L. Zhang, Hassan D. Kanaan, Wei Li. *Anatomic Pathology, Beaumont Health System, Royal Oak Campus, Royal Oak, MI.*

Background: Immuno-check point inhibitors (CPI) such as PD-1/PD-L1 inhibitors alone or in combination with other chemotherapeutic medications have been used to treat variety of metastatic neoplasms with amazing effects in recent years. However, cases of their associated nephrotoxicity become more often seen. Here we present a single health center experience of identifying CPI associated nephrotoxicities in renal biopsies and their follow-up data.

Methods: Over past 17 months (till April 2019), we have had approximately 620 cases of renal biopsies from our eight-hospital system (4000 beds in total) in Southeast Michigan. Seven indicated native renal biopsies were performed to evaluate renal pathology in patietns who were treated with CPI for various metastatic neoplasms, but developed acute kidney injury. Conventional light microscopy, immunofluorescent stains and electromicroscopy wrere used to assess renal pathology and clinical correlations were conducted.

Results: The cases are summarized in Table below. The identified cases represent 1.1 % of our renal biopsies. Typical acute interstitial nephritis (AIN) (composed of dominant CD3 positive T lymphocytes) was seen in five of seven patients (Table below) but remaining two patients' biopsies without AIN had either chromic thrombotic microangiopathy (TMA) or acute tubular injury (ATI). Three out the five patients with CPI induced AIN had significant recovery of renal function after steroid treatment, while other two AIN cases had limited renal functional recovery.

Conclusions: Since our first cases seen at the end of 2017, there have been increased incidence of nephrotoxcitiy cases due to CPI treatment, most characterized by T lymphocytes mediated AIN. Some patients had a good renal function recovery in response to steroid treatment.

Clinical and Pathologic Indices, and Follow-up Renal Function

Age/Gender/Tumors	CPI	Pre-sCr (mg/dl)	Biopsy diagnosis	Follow-up sCr (mg/dl)
68M, renal cell carcinoma	Opdivo	8.3	AIN, moderate	2.47
62M, lung cancer	Keytruda	2.0	AIN, moderate	1.93
66M, lung cancer	Keytruda	4.0	AIN, moderate	1.01
84F, lung adenocarcinoma	Opdivo	2.7	AIN, mild	0.95
82M, melanoma	Opdivo	2.9	TMA	1.77
38M, bladder cancer	Keytruda	2.0	AIN, mild	1.89
77M, lung cancer	Keytruda	1.9	ATI, mild	1.15

M - male; F - female

A Single-Institution Study of Renal Outcomes in Patients Receiving Checkpoint Inhibitors

Savan Shah, Daniel A. Kerr, Sarah Mushtaq, Abu-Sayeef Mirza, Hatem Hassanein, Kayla Shirley, Jung-hoon Lee, Claude Bassil. *University of South Florida, Tampa, FL.*

Background: Checkpoint inhibitors (CPI) are becoming more widely used for various malignancies. The reported incidence of renal toxicities has varied, with a lower incidence reported in clinical trials but significantly higher in follow-up retrospective cohorts. Here, we present a single-institution retrospective study monitoring renal function in patients receiving CPI treatment.

Methods: An IRB-approved retrospective analysis was performed using patients seen at Moffitt Cancer Center between 1/1/2015 and 1/1/2016 who were receiving CPI therapy (ipilimumab, nivolumab, pembrolizumab or any combination). Selected patients had up to 12 months follow-up including laboratory analysis of renal function. If available, serum electrolytes and urine studies were also collected. Primary endpoint was acute kidney injury (AKI), defined as increase in serum creatinine by > 0.3 mg/dL or ≥ 50% from baseline.
