Conclusions: A clear fast progressing cluster was identified with an average eGFR decline of ≥5 ml/min/1.73m^2 per year with a higher risk of all-cause mortality compared to other clusters. Whilst Bayesian and unsupervised machine learning methods can detect non-linear patterns, we found broadly linear trajectories.

Using Autoencoders for Imputing Missing Data in eGFR Decline Trajectories of Patients with CKD

Davina J. Zamanzadeh,[1] Panayiotis Petousis,[1] Tyler A. Davis,[1] Anders O. Garlid,[1] Xiaoyan Wang,[1] Keith C. Norris,[1] Obidiugwu Duru,[1] Katherine R. Tuttle,[2] Alex Bui,[1] Susanne B. Nicholas.[1] CURE-CKD Registry Study Team *[1]University of California Los Angeles, Los Angeles, CA; [2]Providence St Joseph Health, Spokane, WA.*

Background: Using machine learning (ML) approaches to impute missing data has not been explored in CKD progression. We investigated the utility of a data-driven imputation to improve downstream classifier prediction of rapid eGFR decline in the CURE-CKD registry.

Methods: We analyzed CKD patients at UCLA (N=13,206) over a 2-year period. We used: 1) the dataset with missing data; and 2) a censored subset with no missing data. We introduced 33% and 66% missingness by removing values by removing values either missing completely at random (MCAR); missing at random (MAR); or missing not at random (MNAR). We included: eGFR, hemoglobin (HbA1c), systolic blood pressure (SBP), number of ambulatory and inpatient visits, age, sex, ethnicity, rurality status, diagnosis of hypertension, diabetes mellitus (DM), pre-DM, and use of renin angiotensin aldosterone system inhibitors. We introduced missingness on SBP and HbA1c to mirror the original dataset. We imputed missing values using an autoencoder ML model. To predict a 40% eGFR decline over 2 years, we developed random forest models using the full and resultant imputed datasets.

Results: On the full subset, the MNAR imputation method achieved a root mean squared error (RMSE) of 0. The MAR method achieved RMSE of 3.8 at 33% missingness and 5.4 at 66%. MCAR achieved RMSE of 38.5 at 33% missingness and 56.4 at 66%. Using the random forest model to predict rapid decline on the fully observed subset without removing and imputing data achieved a receiver operating characteristic (ROC) area under the curve (AUC) mean of 80.8%±1.1 and precision/recall (PR)-AUC mean of 23.9%±1.5; the same as our methodology on MNAR, which is explained by the RMSE of 0, shown in Table 1.

Conclusions: Our method accurately imputes clinical data values while accounting for uncertainty caused by missing values.

Machine Learning Prediction of ESKD and Death in CKD Patients: Electronic Medical Record-Based Cohort Study

Eiichiro Kanda, Atsuyuki Tokuyama, Seiji Itano, Hajime Nagasu, Naoki Kashihara. *Kawasaki Medical School, Kurashiki, Japan.*

Background: Chronic kidney disease (CKD) is a risk factor for end-stage kidney disease (ESKD) and death. An accurate prediction of these risks is required to improve their prognosis. We developed the new machine learning models for the prediction of CKD progression and death using the electronic-medical-record-based CKD-patient big database in Japan (n=3,714, 66,981 claim data).

Methods: We developed 20 risk prediction models with 45 variables for the classification of the patients on the basis of their outcomes (ESKD and death) over 1 to 3 years using random forest (RF), Gradient Boosting Decision Tree (GB), eXtreme Gradient Boosting (XG), support vector machine, and multivariate logistic regression models using validation datasets including baseline or time-series datasets. The performance characteristics of the models were compared with those of the laboratory indices, and the kidney failure risk equation (KFRE) using the area under the prediction curves (AUCs) by bootstrapping 1000 times.

Results: 53.1% were male: age, 60.1±17.6 years; eGFR, 54.2±30.7 ml/min/1.73 m2; diabetes mellitus, 23.1%. In the validation dataset, 14 models showed statistically significantly higher AUCs for the prediction of outcomes than KFRE 0.782 (0.682, 0.881), and the RF, GB, and XG models based on time-series data showed the highest AUCs: 0.924 (95% CI 0.895, 0.953) (Fig. A). These three models also demonstrated the highest performance in the subgroup analysis that considers eGFR, DM, gender, and age. Moreover, the models' sensitivities were 0.971 (95% CI 0.914, 1.0). Cox proportional hazards models revealed that the probabilities predicted by these models represented the risk of the outcome ($p<0.0001$) (Fig. B).

Conclusions: The machine learning models exhibit better performance than pre-existing models in identifying patients at an increased risk of CKD progression and death. Thy will enable us to implement effective measures to improve patient's prognosis.

Funding: Government Support - Non-U.S.

Predicting Rapid eGFR Decline Using Electronic Health Record (EHR) Data Despite High Missingness in the CURE-CKD Registry

Tyler A. Davis,[1] Panayiotis Petousis,[1] Davina J. Zamanzadeh,[1] Xiaoyan Wang,[1] Keith C. Norris,[1] Obidiugwu Duru,[1] Katherine R. Tuttle,[2] Alex Bui,[1] Susanne B. Nicholas.[1] CURE-CKD Registry Study Team *[1]University of California Los Angeles, Los Angeles, CA; [2]Providence St Joseph Health, Spokane, WA.*

Background: Patients with rapid eGFR decline tend to progress to kidney failure. Automated tools can identify individuals at risk of severe renal function decline and facilitate disease mitigation. We describe a deep neural network (DNN) for predicting the risk of rapid eGFR decline (>40% decrease in eGFR over 2 years) and identified populations at higher risk of rapid decline using the CURE-CKD Registry.

Methods: Variables include: age, sex, race/ethnicity, ACE inhibitor/ARB use, eGFR, systolic blood pressure (SBP), hemoglobin A1C, and the diagnosis of hypertension, type 2 diabetes (DM), pre-DM or chronic kidney disease (CKD) based on EHR coding from patients with CKD (N=93,567) and at-risk for CKD (N=913,289) with eGFR ≥15ml/min/1.73m^2 over 2 years. We trained and validated a 5-layer DNN, a logistic regression (LR) model, and a gradient boosted tree (GBT) model using a 60/20/20 train/test/validation split. We computed the risk distribution of all 25,475 subpopulations, based on all possible expert defined combinations of the above variables, and compared this risk distribution against the whole population's risk distribution using the Kolmogorov-Smirnov (KS) test. Subgroups with the highest risk of decline were identified using the KS test ($p<0.05$) on our highest performing model.

Results: The DNN achieved an area under the receiver operating curve (AUC-ROC) of 0.75 on the test set. The LR and GBT achieved an AUC-ROC of 0.72 and 0.73, respectively. The subpopulations with significantly highest average predicted risk across training, validation, and testing were 17,734. We identified the most frequent predictors of rapid eGFR decline across the highest risk populations. Of the top 100 significantly higher risk subpopulations the following variables were the most frequent: CKD (100%), SBP > 140 mmHg (72%), age 45-66 years (56%), DM (52%), and A1C > 8 (50%).

Conclusions: We developed a methodology that uses a risk model for rapid eGFR decline using big data and used its predictions, along with the KS test, to identify subpopulations with significantly high risk for rapid eGFR decline.

PO0529

A Machine Learning-Based Prediction Model for Trajectory of GFR in CKD Patients with Rapid Decline of GFR by Using a Big Database

Daijo Inaguma,[1] Akimitsu Kitagawa,[3] Ryosuke Yanagiya,[4] Akira Koseki,[2] Toshiya Iwamori,[2] Michiharu Kudo,[2] Shingo Fukuma,[5] Naotake Tsuboi,[1] Yukio Yuzawa.[1] *[1]Fujita Health University School of Medicine, Department of Nephrology, Toyoake, Japan; [2]IBM Research, Tokyo, Japan; [3]Fujita Health University Bantane Hospital, Department of Nephrology, Nagoya, Japan; [4]Fujita Health University, Division of Medical Information System, Toyoake, Japan; [5]Kyoto University Graduate School of Medicine, Human Health Sciences, Kyoto, Japan.*

Background: There are various patterns of GFR trajectories in patients with chronic kidney disease (CKD), even among those with rapid declines in GFR. We sought to create a machine learning-based predictive model for extremely rapid decline of GFR in patients with CKD using a single hospital database.

Methods: We used a database, which included the electronic medical records of 286,494 patients. We selected patients with CKD and rapid decline in kidney function, which was defined as an estimated GFR (eGFR) decline of 30% or more within two years. We used longitudinal statistics using data extracted from baseline, 90-, 180-, and 360-day windows prior to baseline and exponentially weighted averages (ESAs) where the weight was calculated as 0.9*(days/decay parameter). The random forest algorithm and python code with the scikit-learn library (https://scikit-learn.org/) were used for model creation.

Results: Patients were automatically classified, using machine learning, into three groups according to eGFR at baseline (G1; high GFR, G2; intermediate GFR, G3; low GFR) and nine subgroups according to the slope of eGFR decline. The subgroup with the

fastest GFR decline exhibited the steepest slope (Figure 1). The area under the curves for predicting the steepest (fastest) GFR decline by random forest model among the G1, G2, and G3 were 0.68, 0.72 and 0.81, respectively. Regarding feature importance, in the G1 group, hemoglobin of the 7-day ESAs and measures obtained 90 days prior to baseline ranked within the top five. Meanwhile, serum albumin and CRP at baseline ranked within the top seven in the G3 group.

Conclusions: The random forest model identified patients with extremely rapid GFR decline. Anemia in patients with higher eGFR, and nutritional status in patients with lower eGFR, emerged as strong risk factors.

Automation of Renal Blood Flow Analysis from Dynamic Phase-Contrast MRI with Deep Learning

Andrés Martínez Mora,[1,3] Dag Lindgren,[1] Camilla Englund,[1] Lars Johansson,[1] Paul Hockings,[1] Joel Kullberg.[1,2] *[1]Antaros Medical, Mölndal, Sweden; [2]Uppsala University, Department of Surgical Sciences, Radiology, Uppsala, Sweden; [3]Kungliga Tekniska Hogskolan Skolan for kemi bioteknologi och halsa, Stockholm, Sweden.*

Background: Phase-contrast magnetic resonance imaging (PC-MRI) allows to assess renal blood flow (RBF), an important parameter in the development of chronic kidney disease (CKD). RBF assessments require time-consuming and observer-dependent delineations of the renal arteries. Thus, we have developed and evaluated a fully-automated deep learning model for renal artery segmentation.

Methods: PC-MRI data came from 131 subjects, four studies, three MRI vendors and a range of velocity encodings. The deep learning model (DL) was a deeply-supervised attention U-Net with residuals with the result re-introduced in a second iteration. Flow was estimated by integrating the flow values in the segmentations. Segmentation and flow results were compared for cross-validation (CV, 73 subjects) against manual delineations and reference flow measurements from external software. The remaining data (Extra) only had reference flow measurements, being only evaluated for flow.

Results: In 4-fold CV, a segmentation accuracy of Dice 0.71 ± 0.21 was obtained. Although most segmentations were relatively accurate, the model failed in ten out of 144 arteries. Flow measurements were relatively highly correlated in CV with no significant deviation from the reference: (r=0.84, DL: 5.8±3.0 ml/s vs Ref: 5.8±3.0 ml/s, p=0.98). The Extra set provided a high correlation and no significant deviation (r=0.94, DL: 6.4±2.8 ml/s vs Ref: 6.7±2.9 ml/s, p=0.11).

Conclusions: The method shows promise to support RBF measurements from PC-MRI. It may save analysis time and increase objectivity in the future. More high quality and representative training data are likely to improve accuracy and generalizability.

Funding: Government Support - Non-U.S.

PO0531

Healthcare Engineering to Predict Time and Resource Impact of Integrating a CKD Education Intervention into Primary Care Practice

Julie A. Wright Nunes,[1] Tammy Ellies,[1] Emily P. Chen,[1] Audrey Fan,[1] Pamela G. Rockwell,[1] Angela Fagerlin,[2] Luis M. Garcia-Guzman.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Utah Health, Salt Lake City, UT.*

Background: This study describes the novel use and application of healthcare engineering and Discrete Event Simulation (DES) to study the impact of adding a physician-led chronic kidney disease (CKD) education review for patients in two primary care settings.

Methods: We developed a computer model to simulate a General Internal Medicine and Family Medicine practice and used it to examine the impact of adding a physician-led CKD education review into routine primary care appointments. To create the computer models we gathered data using real-time process mapping and information from the electronic health record (EHR). The physician-led education review included physicians reviewing a one-page education information sheet, tailored to individual patients. Computer models of each clinic were developed to test the effect on patient flow and time through clinic appointments using different proportions of patients with CKD for which a physician would review the CKD education. We also tested varying amounts of time it would take for physicians to review CKD education within the model.

Results: Adding the physician-led review of CKD education into clinic visits did not significantly increase patient flow or time through clinic. Incrementally increasing potential times for the CKD education review, up to 10 minutes with 50% of all patients, did not reduce patient flow or significantly increase overall time of patients going through clinic from check-in to check-out. For General Internal Medicine, the 95% baseline Confidence Interval for patient time through clinic was between 53.4 min and 65.03 min whereas the 95% Confidence Interval when CKD education was reviewed with 50% of patients resulted in an estimated visit time between 57.54 min and 69.17 min. The estimated resource utilization of physicians increased by about 5%. Similar results were found for Family Medicine.

Conclusions: This research allowed us to perform a "what-if" analysis on the effect of introducing physician-led CKD patient education into routine primary care practice. Results show that it is possible to introduce patient education and support without major disruptions in clinic flow nor patient time through clinic.

Kidney Outcomes Associated with Fibrosis and Inflammation on Kidney Wedge Sections

Luisa M. Ricaurte Archila, Aleksandar Denic, Aidan F. Mullan, Marija Bogojevic, Bradley Leibovich, R. houston Thompson, Walter K. Kremers, Mariam P. Alexander, John C. Lieske, Andrew D. Rule. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Interstitial fibrosis and tubular atrophy (IFTA) and inflammation are prognostically important but crudely assessed in biopsy reports. We used manual morphometry to characterize different patterns of IFTA and inflammation on large biopsy sections and their associations with CKD progression.

Methods: We studied 936 patients who had a radical nephrectomy due to renal cancer and no severe renal disease. A wedge section distal to tumor was used for morphometry. All areas of cortex, glomeruli, IFTA and inflammation were annotated. We calculated glomerular volume, % globally sclerotic glomeruli (GSG), overall %IFTA, mean area of each contiguous focus of IFTA (focus area), number of IFTA stripes (from capsule toward medulla) per cortex area, % subcapsular cortex with IFTA (%SC IFTA), % total inflammation (%TI), % inflammation outside (%I-non IFTA) and within foci of IFTA (%I-IFTA). We followed patients for progressive CKD censoring at cancer recurrence

or death. Progressive CKD was defined as kidney failure or 40% decline in eGFR from the baseline (4 months after surgery). Models were unadjusted, adjusted for %IFTA, and adjusted for %TI.

Results: At surgery mean age was 64 years, 64% male, 66% hypertensive, and 13% diabetic. Samples contained a mean of 349 glomeruli and mean baseline eGFR was 48 ml/min/1.73m^2. After a mean follow-up of 6.4 years there were 117 CKD progression events and 299 deaths. %IFTA and %TI predicted progressive CKD independent of each other (**Table**). %I-non IFTA (not %I-IFTA) contributed to this risk. After %IFTA adjustment, smaller mean IFTA focus area associated with a higher risk of CKD progression. These findings persisted with adjustment for clinical characteristics including eGFR and proteinuria.

Conclusions: Both total %IFTA and %TI (particularly %I-non IFTA) are important predictors of progressive CKD. At the same %IFTA, a greater number of small IFTA foci are more predictive of progressive CKD than fewer large foci of IFTA.

Table. Tubulointerstitial predictors of progressive CKD

	Mean (SD)	Unadjusted (p-value)	Adjusted for %IFTA (p-value)	Adjusted for % Total inflammation (p-value)	Adjusted for % GSG (p-value)

Modification of the Association Between Dipstick Hematuria and Decline in Kidney Function by Proteinuria: Results from a Longitudinal Nationwide Survey

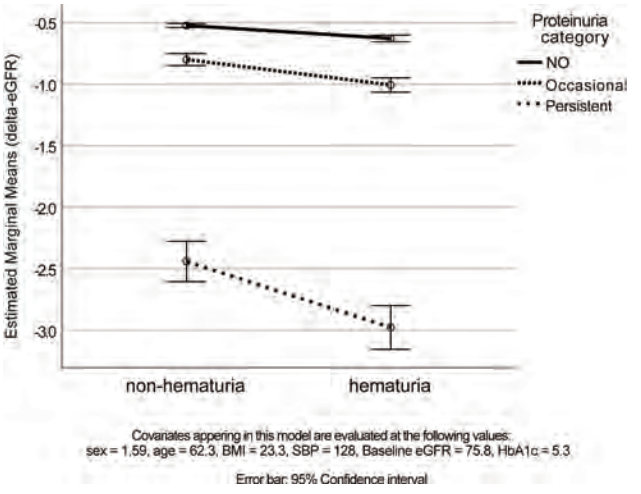
Hikari Tasaki,[1] Masahiro Eriguchi,[1] Hisako Yoshida,[3] Masatoshi Nishimoto,[1] Takaaki Kosugi,[1] Masato Kasahara,[1] Kunitoshi Iseki,[4] Koichi Asahi,[5] Kunihiro Yamagata,[12] Tsuneo Konta,[6] Shouichi Fujimoto,[8] Ichiei Narita,[9] Yugo Shibagaki,[2] Toshiki Moriyama,[10] Masahide Kondo,[7] Tsuyoshi Watanabe,[11] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Kashiwara, Japan; [2]Saint Marianna University School of Medicine, Kawasaki, Japan; [3]Osaka City University Graduate School of Medicine, Osaka, Japan; [4]Nakamura clinic, Urazoe city, Japan; [5]Iwate Medical University, Morioka, Japan; [6]Yamagata University Faculty of Medicine Graduate School, Yamagata, Japan; [7]University of Tsukuba, Tsukuba, Japan; [8]Miyazaki University, Miyazaki, Japan; [9]Niigata University, Niigata, Japan; [10]Osaka University Health Care Center, Suita, Japan; [11]Fukushima Medical University School of Medicine, Fukushima, Japan; [12]University of Tsukuba, Tsukuba, Japan.*

Background: We hypothesize that proteinuria has a modification effect on the association of hematuria with decline in kidney function.

Methods: Participants were recruited who have undergone multiple nationwide specific health checks between 2008 and 2014 and have been observed for ≥2 years. We divided the participants into two and three categories according to hematuria and proteinuria, respectively. Using analysis of covariance, changes in eGFR over time (delta-eGFR) adjusted for clinically relevant factors were examined among hematuria category stratified by proteinuria category.

Results: Among 253,679 participants, median delta-eGFR was -0.36 mL/min/1.73m^2 per year (IQR: -2.25-0.54) during a median observation period of 4.0 years (IQR: 3.1-5.0), with a median age of 65 years (IQR: 60-68) and median baseline eGFR of 75 mL/min/1.73m^2 (IQR: 65-87). Compared to non-hematuria group, hematuria group had a greater eGFR decline rate even after adjusting confounders including proteinuria category. When stratified by proteinuria category, hematuria-related eGFR decline rate gradually increased as the proteinuria category progressed (P for interaction <0.001).

Conclusions: Among general population, delta-eGFR levels with and without hematuria were comparable in the absence of proteinuria, but proteinuria levels had a synergistic effect on eGFR decline rate associated with hematuria.



PO0534

Mortality Following New Onset of CKD Among Veterans by Comorbid Conditions: Results from a US Large Incident CKD Population

Nilka Rios Burrows,[1] Devasmita Choudhury,[2,3] Wei Yu,[3] Meda E. Pavkov,[1] Robert Nee,[4] Alfred K. Cheung,[5,7] Keith C. Norris,[6] Guofen Yan.[3] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]Salem VA Medical Center, Salem, VA; [3]University of Virginia, Charlottesville, VA; [4]Walter Reed National Military Medical Center, Bethesda, MD; [5]University of Utah Health, Salt Lake City, UT; [6]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [7]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Data on mortality rates after CKD onset are scarce. Using a recently constructed national incident CKD cohort, we examined mortality rates following new-onset CKD for various subgroups with or without comorbidities.

Methods: We identified 1,074,238 individuals with new-onset CKD between 2002 and 2017 in the US Veterans Health Administration (VHA). CKD onset was defined as the first time when estimated GFR (eGFR; CKD-EPI equation) decreased to <60 mL/min/1.73 m^2 for >3 months. Individuals excluded were those in the VHA for <2 years prior to first eGFR <60, or had CKD stage 4 or 5, or end-stage kidney disease when first identified. Thus, the first time identified was close to the onset of CKD stage 3. Comorbidities at CKD onset were ascertained from ICD-9/ICD-10 codes during any time before onset and through 6 months after onset. All individuals were followed for death status from onset through June 30, 2018.

Results: CKD patients with and without comorbidities had similar mean eGFRs at onset (51 ml/min/1.73m^2). Most (97%) were male and mean age at onset was 72 years. Hypertension (HTN) (90%), cardiovascular disease (CVD) (75%), and diabetes (46%) were the three most common comorbidities. For each comorbidity, mortality rate was substantially greater among those with compared to those without (Table). After adjustment for age, sex, race, ethnicity, and onset eGFR, mortality risks remained substantially greater among those with than those without the comorbidities, ranging from 12% greater with HTN to 100% greater with liver disease.

Conclusions: At time of CKD onset, mortality risk is greater in veterans with the presence of comorbidities. Intervention trials to examine the management and treatment of comorbidities on mortality in an incident CKD population might be warranted.

Funding: NIDDK Support, Other U.S. Government Support

Mortality by comorbid conditions

Comorbidity	Prevalence (%)	Death rate (per 1000 patient-years)		Adjusted hazard ratio (95% CI)	P value
		With the comorbidity	Without the comorbidity		
HTN	90	75.5	67.5	1.12 (1.11-1.13)	<0.001
CVD	75	86.4	46.0	1.75 (1.73-1.76)	<0.001
Diabetes	46	79.9	70.6	1.33 (1.32-1.34)	<0.001
Chronic obstructive pulmonary disorder	30	102.4	65.2	1.75 (1.74-1.76)	<0.001

Impact of Variability in Estimated Glomerular Filtration Rate on Major Clinical Outcomes: A Nationwide Population-Based Study

Soojin Lee,[1] Yeonhee Lee,[1] Sehoon Park,[1] Yaerim Kim,[2] Min woo Kang,[1] Semin Cho,[1] Yong Chul Kim,[1] Kwon Wook Joo,[1] Chun Soo Lim,[3] Yon Su Kim,[1] Dong Ki Kim.[1] *[1]Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Keimyung University, Daegu, Republic of Korea; [3]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

Background: The estimated glomerular filtration rate (eGFR), commonly estimated using the serum creatinine value, often fluctuates throughout the serial measurement. The clinical significance of GFR variation among the general population with normal renal function has not yet been demonstrated. Thus, we explored the impact of GFR variability on adverse clinical outcomes.

Methods: A nationwide retrospective cohort study using the Korean National Health Insurance System database was performed. National health screening examinees who underwent creatinine measurement ≥3 times between 2012 and 2016 were considered. Those with eGFR under 60 mL/min/m² were excluded. The fluctuation of eGFR was represented with variability independent of the mean (VIM) index; which was calculated by the standard deviation divided by the exponent of the regression coefficient of the mean. Then, the risks of myocardial infarction (MI), stroke and death were assessed according to the quartiles of the VIM.

Results: Of total 3,538,500 participants, 0.29% of myocardial infarction (MI), 0.14% of stroke, 0.36% of deaths were observed during the median follow up of 3.27 years. Participants with the highest VIM index, which represents the highest eGFR variability, were significantly associated with an increased risk of MI (hazard ratio [HR]; 1.10, 95% confidence interval [95% CI]; 1.04-1.16), stroke (HR: 1.16; 95% CI 1.09-1.23), and death (HR: 1.18; 95% CI 1.12-1.24). (Figure 1)

Conclusions: Increased eGFR variability exhibited an association with major clinical outcomes, indicating that monitoring eGFR variability might be a useful parameter for predicting the adverse outcomes.

PO0536

Development and Internal Validation of a Mortality Risk Prediction Model in Older Adults with Advanced Non-Dialysis-Dependent (NDD) CKD

David Y. Li,[1] Heather L. Prigmore,[2] Thomas G. Stewart,[2] Khaled Abdel-Kader.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: Older adults with CKD expect practitioners to share prognostic estimates to inform decision-making regarding future care. The availability of useful mortality prediction models in NDD-CKD could reduce prognostic uncertainty and aid in identifying patients who would benefit from advance care planning (independent of dialysis initiation).

Methods: 699 patients with NDD-CKD stages 4-5 and age ≥60 were enrolled and followed between 2014 and 2019. Cox proportional hazards regression was used to model the risk of 1-year mortality. Candidate predictor variables included age, gender, race, Charlson Comorbidity Index (CCI), common labs and the provider's response to the Surprise Question ("Would you be surprised if this patient died in the next 12 months?", SQ, recorded using binary and 5-point Likert response scales). Optimism-corrected measures of model performance were calculated with bootstrap resampling. Model calibration was assessed visually.

Results: In the derivation cohort, age, CCI, hemoglobin values and the provider's Likert scale response to the SQ were predictive of 1-year mortality (Table 1). The C-statistic in the derivation sample was 0.76 and the optimism corrected C-statistic obtained by bootstrap resampling was 0.73. Visual examination of model calibration demonstrated good calibration.

Conclusions: A 1-year mortality risk prediction model in older adults with advanced NDD-CKD performed reasonably well and was well calibrated. Studies are needed to understand how to best leverage information on mortality risk to enhance patient-provider communication and ensure that future care delivered to patients is aligned with their priorities.

1-year Mortality Hazard Ratios

	Hazard Ratio (95% CI)
Age (per 12 yr increase)	1.57 (1.18 - 2.09)
CCI (per 2-point increase)	1.37 (1.12 - 1.67)
Hemoglobin (per 2.3 g/dl increase)	0.80 (0.65 - 0.99)
SQ - not at all surprised: neutral	2.06 (1.27 - 3.33)
Not surprised: neutral	1.12 (0.71 - 1.75)
Surprised: neutral	0.55 (0.33 - 0.92)
Very surprised: neutral	0.48 (0.28 - 0.82)

PO0537

Validation and Comparison of the Kidney Failure Risk Equation and a Novel Risk Calculator in Advanced CKD

Susan J. Thanabalasingam,[1] Patrick A. Norman,[1] Andrew G. Day,[1] Ayub Akbari,[2] Eduard A. Iliescu,[1] Christine A. White.[1] *[1]Kingston Health Sciences Centre, Kingston, ON, Canada; [2]Ottawa Hospital, Ottawa, ON, Canada.*

Background: The Kidney Failure Risk Equation (KFRE) is a widely used clinical tool for predicting risk of CKD G3-5 progressing to end-stage kidney disease (ESKD). A novel calculator (Grams) was developed for G4+ patients to predict ESKD, CVD events and death. The Grams model has not been externally validated. We aimed to assess this new tool in a cohort of advanced CKD patients for ESKD prediction and compare it to the KFRE.

Methods: This retrospective cohort study included 444 adult CKD G4+ patients (mean age 73 ± SD 12; mean eGFR 19.6 ± 6.1). The 2- and 5-year KFRE and 2 and 4-year Grams scores were compared in terms of discrimination and calibration (4 ESKD risk intervals <10%,10-20%, 20-40% and >40%). Sensitivity, specificity, positive (PPV) and negative predictive values (NPV) of KFRE-2 and Grams-2 were reported using 10% and 20% thresholds.

Results: Both models had similar discrimination for ESKD risk at the 2-(KFRE-2 AUC 0.82, 95% CI 0.80–0.87, Grams-2 AUC 0.80, 95% CI 0.75–0.86), 4-(Grams-4 AUC 0.81, 95% CI 0.77–0.86) and 5-year (KFRE-5 AUC 0.80, 95% CI 0.76–0.84) timepoints. Both were well calibrated with observed risk at predicted intervals of <10% and 10-20% at 2 years and <10%, 10-20% and 20-40% intervals at 4 and 5 years (Figure 1). Grams-2 under-predicted while KFRE-2 over-predicted risk at higher intervals (20-40% and >40%). KFRE-2 and Grams-2 had adequate sensitivity, performing similarly at ESKD risk thresholds of 10% (p=0.71) and 20% (p=0.48) (Table 1). Both had poor specificity and low PPVs at both thresholds.

Conclusions: The KFRE and Grams models perform similarly at lower ranges of risk in CKD G4+. The KFRE and Grams models however overestimate and underestimate risk respectively at higher risk intervals.

Association of eGFR Index Category and Annual Slope with Adverse Clinical Outcomes in Japan

Ling Zhang,[1] Moe H. Kyaw,[1] Yasuhisa Ono,[2] Sibylle J. Hauske.[3,4] *[1]Boehringer Ingelheim USA, Ridgefiled, CT; [2]NIppon Boehringer Ingelheim, Tokyo, Japan; [3]Boehringer Ingelheim Germany, Ingelheim, Germany; [4]5th Medical Center Mannheim, University of Heidelberg, Germany, Heidelberg, Germany.*

Background: The relationship between the slope of eGFR with adverse clinical events has not been evaluated extensively. The objective of the study was to assess the association between eGFR and clinical outcomes.

Methods: The study population included persons with 3 or more eGFR values in the MDV database between January 1, 2014 and September 31, 2019. Patients were stratified into 5 index eGFR categories (TABLE). Least square regression model was used to examine the association between eGFR and its slope vs. study outcomes. Patients were stratified into 5 index eGFR categories (TABLE). Least square regression model was used to calculate the annual rate of eGFR change to stratify into 6 categories. Cox proportional hazard model was applied to examine the association between eGFR and its slope vs. study outcomes.

Results: 57,692 patients met the study criteria, and were grouped by index eGFR and its slope (TABLE). The mean age ranged from 56.69 to 74.21 in the index eGFR and from 65.3 to 67.2 in the slope categories. The risk of all-cause mortality or hospitalization, CV death, and any CV or renal outcomes were higher among the low and high index eGFR compared to the reference groups (grade 3 eGFR and -1~+1 slope), as well as those with rrapidly declining or increasing eGFR.

Conclusions: Our study showed that those with the highest or lowest categories in index eGFR and eGFR slope had a higher risk for adverse clinical outcomes. Further studies are needed to confirm the findings and explore potential reasons why high eGFR and rapid increase are associated with mortality, CV and renal events.

Funding: Private Foundation Support

Sex-Specific Differences in Clinical Outcomes Among Patients with CKD: Results from CKDopps

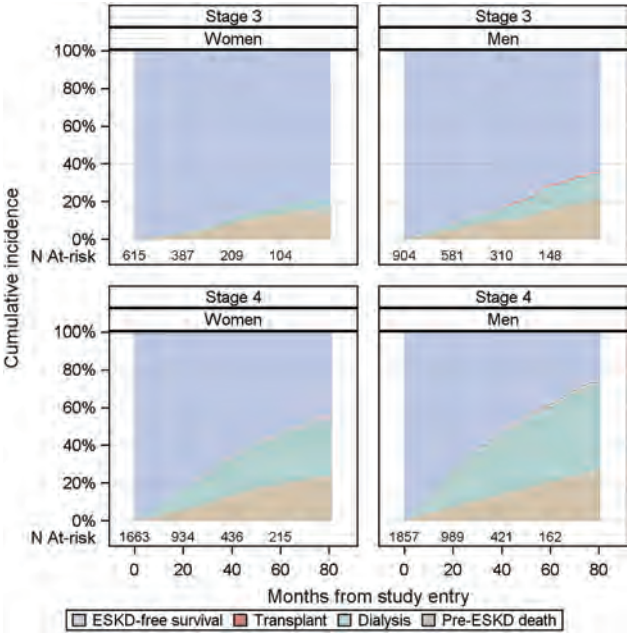
Manfred Hecking,[1] Charlotte Tu,[2] Jarcy Zee,[2] Brian Bieber,[2] Sebastian Hödlmoser,[3] Benedicte Stengel,[4] Helmut Reichel,[5] Kunihiro Yamagata,[6] Ricardo Sesso,[7] Friedrich K. Port,[2] Bruce M. Robinson,[2] Roberto Pecoits-Filho.[2] on behalf of CKDopps and CKD REIN investigators *[1]Medical University of Vienna, Nephrology & Dialysis, Vienna, Austria; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Medical University of Vienna, Department of Epidemiology, Vienna, Austria; [4]CESP, Inserm U1018, Kidney and Heart Team, Villejuif, France; [5]Nephrologisches Zentrum Villingen-Schwenningen, Villingen-Schwenningen, Germany; [6]University of Tsukuba, Ibaraki, Japan; [7]Escola Paulista De Medicina, Unifesp, Sao Paulo, Brazil.*

Background: Women have more chronic kidney disease (CKD) than men, but are under-represented in the dialysis population. We aimed to assess sex-specific differences in clinical outcomes among CKD Outcomes and Practice Patterns Study (CKDopps) participants.

Methods: Using data of 5682 CKDopps stage 3-5 patients from Brazil, Germany and the US, we reported cumulative incidence of pre-dialysis death, dialysis, and transplantation, by sex and CKD stage at CKDopps entry. We used Fine & Gray models to assess the effect of sex on the time to events, stratified by CKD stage. Models were adjusted for age and race, and then for eGFR slope in the first 6 months after enrolment, but not for case mix variables as men and women are biologically different.

Results: There were more men than women at baseline (54 vs 46%). Men were more likely on the transplant waitlist (13 vs 10%) and had higher median eGFR at dialysis initiation (11.2 vs 10.6 mL/min/1.73m^2). Over a median follow-up of 1.75 years, the crude cumulative incidence of dialysis was higher in men while that of death was similar (Figure). The age- and race-adjusted hazard ratio (HR) (95% CI) between men vs women was 1.59 (1.40-1.82) for dialysis, 1.24 (1.04-1.49) for death and 1.80 (0.85-3.80) for transplantation. After adjustment for eGFR slope, the HR for dialysis was 1.72 (1.46-2.01), but the HR for the other two outcomes remained similar.

Conclusions: Despite higher CKD prevalence in women, more men received treatment at nephrologist-run clinics in our study. Men had a higher chance of commencing dialysis before death, unexplained by CKD progression. This finding helps interpret the preponderance of men in the dialysis population.



PO0540

Predictive Value of Urine Osmolal Gap and Urine Anion Gap in CKD Progression

Hyung Duk Kim, Cheol Whee Park. *Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.*

Background: Metabolic acidosis is the major complication of chronic kidney disease (CKD) and associated with poor clinical outcome. Impaired renal ammonium excretion in CKD lead to metabolic acidosis. The urinary anion gap (UAG) and urinary osmolal gap (UOG) have been used to estimate urinary ammonium excretion because of the limitation of clinical application of direct ammonium measurement. We sought to determine whether UAG and UOG predict progression of CKD.

Methods: 185 patients with Stage II-V CKD were prospectively followed up at Catholic Medical College Multicenter Native Kidney Biopsy Cohort. 24-hour urine chemistry was measured at baseline. Routine laboratory test results were obtained at baseline and 1 year after enrollment. UAG and UOG were calculated using 24-hour urine chemistry results. Estimated GFR was calculated with CKD-EPI equation.

Results: Baseline characteristics are shown in Table 1. Positive association between UOG and decline of renal function was observed (Figure 1). The line indicates the regression line for the relation between decline of renal function and urine osmolal gap; $R = 0.035$, $\beta = 0.003$ ($P = 0.011$).

Conclusions: UAG and UOG predict decline in renal function in CKD patients. Further studies are required to determine the direct correlation between UAG and UOG and urinary ammonium excretion.

Figure1. Association between urinary osmolal gap and decline of renal function. The line indicates the regression line for the relation between decline of renal function and urine osmolal gap; $R = 0.035$, $\beta = 0.003$ ($P = 0.011$).

Risk Factors for Hemorrhage After Renal Biopsies: Analysis of Data from the National Inpatient Sample Database

Yi Zhang, Harley Friedman. *Dartmouth-Hitchcock Medical Center, Lebanon, NH.*

Background: Prior studies examining risk factors associated with bleeding from renal biopsy have demonstrated conflicting results. The purpose of this study is to utilize the large sample size of the National Inpatient Sample (NIS) Database to explore risk factors associated with post procedure hemorrhage.

Methods: Data were gathered from the NIS Database (2012-2013). Records with a closed percutaneous needle biopsy of the kidney (procedure code 5523) were selected, excluding patients under age 18. Bleeding was defined by a diagnosis of hemorrhage/hematoma complicating a procedure (ICD-9 codes 99811, 99812). Binary logistic regression was performed to explore associations between hemorrhage and age, sex, and comorbidities defined in the NIS severity elements.

Results: The data set included 13260 renal biopsies, with 626 instances of bleeding related to procedure. The overall model fit was excellent ($X^2 = 119.6$, $p < 0.000$). Seven comorbidities were significantly associated with bleeding. Obesity, age, hypertension were not significantly associated with bleeding.

Conclusions: Our results indicate that renal failure, female gender, coagulopathy, and anemia are risk factors for bleeding after renal biopsy, whereas obesity and hypertension are not. A strength of this study is the large sample size. It also suggests that peripheral vascular disease, collagen vascular disease, and weight loss increase bleeding risk. Limitations include lack of specific clinical details (e.g. creatinine levels) and risk for confounders. Also, though several individual risk factors were significant, the overall predictive value of the model was limited. In conclusion, this study supports previously thought of risk factors for hemorrhage after renal biopsy and introduces several factors that are of potential clinical significance.

Risk of Bleeding after Renal Biopsy By Comorbidity

	Relative Risk	Lower Limit CI	Upper Limit CI	p-value	Standard Error
Chronic Blood Loss Anemia	2.012	1.327	3.051	.0010	.212
Renal Failure	1.667	1.407	1.976	.0000	.087

Evaluation of Thromboelastometry and Multiple Electrode Aggregometry in ESRD

Alyaa Abdelmaguid,[1,2] Lara N. Roberts,[3] Jennifer R. Joslin,[1] Beverley Hunt,[4] Kiran H. Parmar,[4] Kate Bramham.[1,5] *[1]King's Kidney Care, King's College Hospital, London, United Kingdom; [2]Alexandria University, Medical Research Institute, Alexandria, Egypt; [3]King's Thrombosis Centre, Department of Haematological Medicine, King's College Hospital NHS Foundation Trust, London, United Kingdom; [4]Thrombosis and Haemostasis Centre, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [5]Department of Women and Children's Health, King's College London, London, United Kingdom.*

Background: Bleeding and thrombosis rates are paradoxically increased in chronic kidney disease (CKD), but risk assessment for both is not possible with routine laboratory tests. We aimed to evaluate haemostatic changes in CKD stage 5 patients with modern techniques; using thromboelastometry (TEM), multiple electrode aggregometry (MEA), markers of thrombogenesis, fibrinolysis and endothelial activation.

Methods: TEM, MEA, thrombin antithrombin (TAT), alpha-2 antiplasmin, d-dimer and Intercellular Adhesion Molecule-1 (ICAM-1) were quantified in 50 CKD Stage 5 patients (including 20 haemodialysis patients) and 30 healthy controls. Patients taking antiplatelet agents were excluded from MEA analysis.

Results: TEM parameters showed hypercoagulability, with increased maximal clot firmness (MCF) & shorter clot formation time (CFT); and D-dimer, TAT and ICAM-concentrations were also increased in CKD Stage 5 patients compared to HC (Table 1). Platelet dysfunction was evident in CKD Stage 5 with lower aggregation in ADPtest and TRAPtest compared to HC.

Conclusions: Our study shows that the prothrombotic changes in CKD Stage 5 are due to increased coagulation and endothelial activation. Bleeding tendency may relate to platelet dysfunction and possibly increased fibrinolytic activation.

Table (1): Comparison of TEM, MEA, Alpha-2 Antiplasmin, D-dimer, Thrombin Antithrombin and ICAM-1 between Healthy Controls and CKD Stage 5 (Median and Interquartile Range (IQR))

PO0543

During $P2Y_{12}$ Antiplatelet Therapy, Treatment of Anemia Was More Frequent Among Peripheral Artery Disease Patients with Lower eGFR: The EUCLID Trial

Judith Hsia,[1,3] Sarah T. Kavanagh,[1] Charles W. Hopley,[2] Marc P. Bonaca,[1,3] William R. Hiatt.[1,3] *[1]CPC Clinical Research, Aurora, CO; [2]Dartmouth College, Hanover, NH; [3]University of Colorado School of Medicine, Aurora, CO.*

Background: Anemia independently predicts amputation and mortality among patients with peripheral artery disease (PAD). In the EUCLID trial, minor bleeding was more frequent among PAD patients with baseline eGFR<60 vs ≥60 ml/min/1.73m² (adjusted HR 1.51, 95% CI 1.07-2.15; p=0.02 for TIMI minor bleeding; HR 1.21, 95% CI 0.89-1.64; p=0.22 for TIMI major bleeding). We evaluated the impact of eGFR on hemoglobin (Hb) levels and anemia treatment.

Methods: EUCLID (NCT01732822) randomized symptomatic PAD patients to monotherapy with ticagrelor or clopidogrel for 30 months (median); treatment groups were combined for analysis. Independent predictors of Hb change from baseline were evaluated in a multivariable model including baseline Hb and eGFR, sex, age, and post-randomization revascularization procedures, myocardial infarction and anemia treatment.

Results: At baseline, 9025, 1870 and 1000 patients had eGFR ≥60, 45-59 and <45 ml/min/1.73m^2, respectively. Patients with lower eGFR were older, more often male and had higher prevalence of diabetes and hypertension. Mean Hb at baseline was 14.2, 13.5 and 12.7 g/dL for the 3 eGFR categories. Mean fall in Hb during the trial was 0.5±1.7 g/dL and did not differ by baseline eGFR category. On-study treatment with iron, erythropoietin and/or red blood cell transfusion was reported for 479 (5.3%), 165 (8.8%) and 129 (12.9%) patients, respectively (Figure, p<0.0001 across eGFR categories). In multivariable analysis, even after adjustment for baseline and post-randomization effects, baseline Hb was a significant independent predictor of Hb fall; anemia treatment was a significant independent predictor of Hb rise.

Conclusions: Among patients with PAD taking antiplatelet therapy in the EUCLID trial, those with lower eGFR were more often treated for anemia.

PO0544

The Ratio and Difference of Urine Protein-to-Creatinine Ratio and Albumin-to-Creatinine Ratio Facilitate Risk Prediction of All-Cause Mortality: A Retrospective Cohort Study

David R. Chang,[1] Hung chieh Yeh,[1] Pei-Lun Chu,[2] Chin-Chi Kuo.[1] *[1]China Medical University Hospital, Taichung, Taiwan; [2]Fu Jen Catholic University Hospital, New Taipei City, Taiwan.*

Background: The difference and ratio of albuminuria (defined by urine albumin-to-creatinine ratio, uACR) and proteinuria (defined by urine protein-to-creatinine ratio, uPCR) has not been systematically evaluated with relevant clinical outcomes. We aimed to assess the prognostic performance between the difference and ratio of uACR and uPCR with all-cause mortality.

Methods: This retrospective cohort study identified 2904 adult patients with concurrently measured uACR and uPCR from the same urine specimen in a tertiary medical center in Central Taiwan between January 2003 and June 2017. Urinary albumin-to-protein ratio (uAPR) was derived by dividing uACR by uPCR. Urinary non-albumin protein (uNAP) was calculated by subtracting uACR from uPCR. Conventional severity categories of uACR and uPCR were used to develop a risk matrix. We evaluated all-cause mortality based on uAPR and uNAP on a continuous scale using the multivariable Cox proportional hazards model.

Results: For each doubling increase in uPCR, uACR, and uNAP, the adjusted hazard ratios (aHRs) of all-cause mortality were 1.29 (95% confidence interval [CI]:1.24-1.35), 1.12 (1.09-1.16), and 1.41 (1.34-1.49), respectively. Linear dose-response association with all-cause mortality was only observed with uPCR and uNAP. The 3 × 3 risk matrices revealed that patients with severe proteinuria and minimal albuminuria had the highest risk of all-cause mortality (aHR 5.25, 95% CI: 1.88, 14.63). uNAP significantly improved the discriminative performance compared to that of uPCR (c-statistics: 0.834 vs. 0.828, *p*=0.03).

Conclusions: uNAP provides better mortality prognostic assessment than uPCR and uACR.

Funding: Private Foundation Support, Government Support - Non-U.S.

PO0545

Metformin and the Risk of Lactic Acidosis in Patients with CKD Stage 3

Melis Sahinoz,[1] Everly Ramos,[1] Carlos O. Pena,[2] Elvis A. Akwo,[1,3] Zhihong Yu,[1] Edward D. Siew,[3,1] Christianne Roumie,[3,1] Talat Alp Ikizler,[1,3] Adriana Hung.[3,1] *[1]VUMC, Nashville, TN; [2]Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of; [3]Nashville VAMC, Nashville, TN.*

Background: Metformin has become the first-line therapy for the treatment of diabetes in patients with CKD stage 3. The use of metformin in CKD has been debated due to safety concerns related to lactic acidosis.

Methods: We assessed the safety of metformin in a double-blinded trial (NCT02252081). Fifty patients with CKD Stage 3 and metabolic syndrome and/or prediabetes were randomized to either metformin or placebo for 16 weeks. Metformin was started at 500 mg and titrated in 1-2 weeks up to 1500 mg/day in CKD 3a and 1000 mg/day in CKD 3b. Lactic acid (LA) levels were measured at weeks 2, 4, 8, 12, and 16. We compared the effect of metformin on LA between groups and over time using a mixed model and on plasma $HCO3^-$ and anion GAP (AG) using ANCOVA of change analysis.

Results: The mean age was 65±10 years old, 80% were male, BMI was 31.4±5.1 kg/m^2, 16% of patients were CKD Stage 3b. LA levels slightly increased with metformin, but in most patients remained within normal limits (≤2.5 mEq/L) [Figure 1 **;**p=0.054]. The association of metformin and LA remained non-significant in the multivariable-adjusted mixed model (β= 0.15, p=0.07) and remained steady over time (β= -0.003, p=0.54). Baseline eGFR had no effect on LA levels (β= 0.01, p=0.35), whereas higher BMI was associated with higher LA levels (β=0.02, p=0.03). Only 3 patients developed LA levels >3 mEq/L: 2 at week 2 which led to drug discontinuation and 1 at week 12 which was transient. The changes in $HCO3^-$ levels and AG were not statistically significant [($HCO3^-$: Metformin baseline 27±2.1 mEq/L, week 16 26.2 ± 2.8 mEq/L; placebo baseline 26.2±2.1 mEq/L, week 16 26.7±2.8 Eq/L; p=0.21) (AG: Metformin baseline 10.1±2.2 mEq/L, week 16 10.4±2.1 mEq/L; placebo baseline AG 10.4±2.2 mEq/L, week 16 9.9±2.3 mEq/L, p=0.42)].

Conclusions: Metformin use in patients with CKD stage 3 appears to be safe. LA levels mildly increased with metformin, but remained within normal limits and stable after week 2. Patients did not develop clinical or laboratory manifestations of acidosis based on $HCO3^-$ levels and AG.

PO0546

Magnetic Resonance Imaging-Based Renal Function Estimation Using a Machine Learning Approach

Daichi Fukaya,[1] Tsutomu Inoue,[1] Eito Kozawa,[2] Masahiro Ishikawa,[3] Yusuke Watanabe,[4] Hiroaki Amano,[1] Naoki Kobayashi,[3] Mamoru Niitsu,[2] Hirokazu Okada.[1] *[1]Department of Nephrology, Faculty of Medicine, Saitama Medical University, Iruma-gun, Japan; [2]Department of Radiology, Faculty of Medicine, Saitama Medical University, Iruma-gun, Japan; [3]School of Clinical Engineering, Faculty of Health and Medical Care, Saitama Medical University, Hidaka-shi, Japan; [4]Division of Dialysis Center and Department of Nephrology, Saitama Medical University International Medical Center, Hidaka-shi, Japan.*

Background: In patients with deterioration of GFR with an unknown clinical course, it is quite difficult to determine whether the renal dysfunction is caused by a hemodynamic alteration or changes in the renal parenchyma, even when using kidney imaging. Therefore, to estimate renal function quantitatively based on the morphology of the renal parenchyma, we performed an advanced image analysis of renal magnetic resonance imaging (MRI) using machine learning (ML).

Methods: We used coronal DIXON water-dominant images obtained on a 3.0T MR device and a deep ML convolutional neural network (CNN) to evaluate renal function (eGFRcre). K-fold cross-validation (k = 5) was performed for the assessment of accuracy and generalization performance. The study protocol was approved by the IRB of our institute.

Results: A total of 196 patients (age, 57.9 ± 16.9 years; 128 males; CKD stage, G1 (n = 18), G2 (39), G3a (43), G3b (45), G4 (35), and G5 (16)) were included. After optimization of the CNN model, the accuracy, precision, recall, and f1-score of the confusion matrix, as well as the AUC of the ROC curve at thresholds of eGFRcre of 60, 45, and 30 were 0.80, 0.83, 0.90, 0.87, 0.86; 0.75, 0.71, 0.84, 0.77, 0.83; and 0.76, 0.80, 0.90. 0.85, 0.83, respectively. The output value of the CNN also showed a significant positive correlation with the normalized eGFRcre of the subjects (R^2 = 0.46, P < 0.01). When the difference in signal intensity between the renal cortex and medulla, as measured based on the region of interest method, was used as a diagnostic index, the accuracy was the same as that of ML if the threshold was eGFRcre 30 (AUC of the ROC curve, 0.84). Conversely, when the threshold was set at eGFRcre 45 or 60, the accuracy deteriorated gradually (AUC, 0.80 and 0.73, respectively).

Conclusions: Compared with the classical method, in which only the signal intensity is used, the ML approach was able to quantitatively evaluate differences in renal morphology regarding a wide range of renal functions. Our results may have clinical applications for assessing the cause of changes in kidney function in the conditions in which renal function and morphology diverge, e.g., in the early stages of acute kidney injury, renovascular hypertension, and therapeutic interventions that cause hemodynamic alterations.

Inflammation Mediates the Association of Depression Severity with Selective Serotonin Reuptake Inhibitor Treatment Response in Patients with CKD

Stephanie Torres Rodriguez,[1] L Parker Gregg,[1,2] Thomas Carmody,[1] Madhukar Trivedi,[1] Susan Hedayati.[1] *[1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX.*

Background: Patients with chronic kidney disease (CKD) are at high risk for depression, which is associated with inflammation in patients with chronic diseases. We investigated whether depression severity is associated with response to treatment with sertraline and whether inflammation mediates this relationship in CKD patients with major depression (MDD).

Methods: We conducted the CKD Antidepressant Sertraline Trial (CAST), a randomized double-blind trial of 193 participants with stage 3-5 CKD and MDD randomized to sertraline or placebo for 12 weeks. Depressive symptoms were assessed using the Quick Inventory of Depressive Symptomatology (QIDS). High sensitivity C-reactive protein (hsCRP) was measured at baseline. Logistic regression determined associations of QIDS and hsCRP with treatment response (≥50% decrease) or improvement (≥3-point decrease) in QIDS. Interaction P<0.10 was considered significant.

Results: Fifty-five (28.5%) participants achieved treatment response. Baseline depression severity by QIDS correlated positively with hsCRP, rho=0.162, P<0.05. Median (IQR) hsCRP was 5.0 (2.0, 14.6) mg/L in sertraline responders and 2.7 (0.8, 6.0) mg/L in non-responders, P=0.03. Higher baseline QIDS was associated with increased odds of response in the sertraline group, OR (95% CI) per 1-point increase 1.26 (1.04-1.53), but lower odds in the placebo group, 0.77 (0.61-0.97), interaction P=0.002 **(Figure)**. Higher baseline hsCRP was associated with higher odds of response, OR per log-unit increase 1.52 (1.06-2.19), and improvement, 1.66 (1.11-2.48), in the sertraline group, but not in the placebo group, interaction P=0.08 for response and 0.03 for improvement, even after controlling for baseline depression severity by QIDS score **(Figure)**.

Conclusions: Higher depression severity was associated with improvement in depressive symptoms and response to treatment with sertraline in CKD patients. This may be explained by elevated baseline inflammation. Future studies should test whether sertraline is more effective than placebo in CKD individuals with higher plasma hsCRP.

Prospective Study of Patient-Reported Outcomes After Endovascular Renal Ablation in Individuals with Chronic Kidney Pain and Opiate Use

Victor A. Lopez,[1] Abhishek Deshmukh,[4] Rajiv Gulati,[4] Paul Novotny,[3] Marie C. Hogan.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic Dpt of Neph & HTN Research, Rochester, MN; [3]Mayo Clinic Biomedical Statistics and Informatics, Rochester, MN; [4]Mayo Clinic Dpt of Cardiovascular Medicine, Rochester, MN.*

Background: Endovascular renal ablation (ERA) may be useful for palliating and in some instances relieving refractory kidney pain (RKP) but is not widely available. We report our experience of ERA in 20 patients with RKP.

Methods: We conducted a prospective study of patient-reported outcomes pre and post ERA for RKP. Baseline & subsequent pain questionnaires (McGill Pain (MPQ), Brief Pain Inventory (BPI), Opioid oral morphine milligrams equivalent (MME)) & QOL (LASA-6, PHQ-9 & SF-8) were obtained. The Wilcoxon test was used. ERA using an open irrigated ablation catheter was performed in a spiral manner distal to proximal upto the renal artery ostium. Power was titrated between 5-30 watts guided by change in impedance.

Results: We performed 24 ERA (3 bilateral, 21 unilateral; 4 redos) in 20 patients, female:male; 14:6; median age 40yr. 12 patients (60%) had Loin Pain Hematuria Syndrome(LPHS), 4 (20%) ADPKD, and others 4 (20%). 17 of 20 have completed the baseline questionnaires & 9 of 17 patients have 6mo data. All nine experienced variable or complete reductions in pain & QOL from baseline to 6mo (**Table1**). A median of 8mo pain relief was reported. After their first ERA, responders (pain relief >6mo) median 8.5mo (n=12/20;60%) while 4 (20%) reported pain relief <6mo (non-responders) median 2mo. 3 (15%) had no relief, and 1 was lost to FU. In the redo ERA, there was no relief in 2; in 1 pain relief lasted 4mo (non-responder), and in the other, relief was 8mo (responder). Following the first ERA, MME decreased by ≥30% in 6, increased in 7 (≥30% in 6;15% in 1), was unchanged in 3, and no data was available in 4. **There were** 3 access site hematomas, one acute renal artery dissection (procedure related) requiring stents & one renal artery stenosis (5mo later) treated by percutaneous transluminal angioplasty but subsequent reduced kidney function.

Conclusions: Among patients with RKP undergoing ERA, half achieved objective improvement in pain & QOL at 6 mo. Prospective randomized studies with careful patient selection are required to assess the role of ERA for palliation of pain.

Assessments of Pain & QOL

PO0549

Clinical Impact of Body Muscle Mass for Kidney Function Evaluation: New eGFR Formula Based on Serum Creatinine and Body Muscle Mass

Kazunori Goto, Yoshinari Yasuda, Sawako Kato, Shoichi Maruyama. *Nagoya University, Nagoya, Japan.*

Background: Kidney function is globally evaluated by estimated glomerular filtration ratio (eGFR) based on serum creatinine (Cre). Since Cre is influenced by body muscle mass, there is serious concern of overestimation of eGFR among elderly people with less muscle volume due to frailty. In this study, eGFR based on Cre (eGFRcreat) and CysC (eGFRcys) were analyzed in association with psoas muscle mass index (PMI) by CT image among CKD patients whose kidney function was accurately evaluated by measured GFR (mGFR) computed from inulin clearance (Cin).

Methods: Study design was single-center cross-sectional retrospective study. Study subjects were consecutive 184 CKD patients (123 males) at Nagoya university hospital whose Cin and abdominal CT were examined within 1 year between 2009 and 2013. New eGFR formula based on Cre and PMI (eGFRcreat-PMI) were developed in 122 patients and validated in 62 patients, which were randomly determined to each cohort. 20%

accuracy for Cin was analyzed by eGFRcreat and eGFRcys calculated by eGFR formulae for Japanese. The performance of eGFRcreat-PMI was assessed by means of bias (eGFR-mGFR), accuracy (percentage of estimates within 20% of mGFR), root mean squared error, and correlation coefficient. In PMI tertile subgroups and GFR(Cin) subgroups (<30, 30-60, 60<), the performance of each formulae was assessed.

Results: Patients' characteristics (n=184, mean(SD) or median[IQR]) were age: 62 [50, 70], eGFRcreat: 58.5 (25.5), eGFRcys: 59.4 (25.9), Cin: 55.0 (25.0) and PMI: 7.29 [6.18, 9.11]. Log-PMI was significantly associated with age, gender, log-BMI, log-Cre and uCre in univariate analyses, and with age, gender and log-BMI in multivariate analysis. New GFR formula (eGFRcreat-PMI) was well correlated with Cin. 20% accuracies for Cin was the highest in eGFRcreat-PMI (74.5%), compared to eGFRcys (67.9%) and eGFRcreat (68.5%), which was more prominent among low PMI tertile group (77.4% in eGFRcreat-PMI, 67.7% in eGFRcys, and 71.0% in eGFRcreat) and high PMI tertile group (73.8% in eGFRcreat-PMI, 59.0% in eGFRcys, and 60.7% in eGFRcreat).

Conclusions: Body muscle mass seriously influences accuracy of kidney function evaluation, and new GFR formula based on PMI and Cre would be useful for accurate evaluation of kidney function, especially among patients with low and high body muscle mass.

PO0550

Incidence and Predictors of Non-Alcoholic Fatty Liver Disease in CKD

Sankar D. Navaneethan,[1,2] L Parker Gregg,[3] Peter Richardson.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX; [3]The University of Texas Southwestern Medical Center, Dallas, TX*.

Background: The prevalence of non-alcoholic fatty liver disease (NAFLD) is increasing due to the global epidemics of obesity and diabetes mellitus, which are commonly seen in CKD. We studied the incidence and predictors of NAFLD in those with CKD.

Methods: We conducted a retrospective cohort study of patients with incident CKD (eGFR <60 mL/min/1.73 m2 for ≥90 days) in the Veterans Health Administration from 2005-2016. Patients with no NAFLD at the time of CKD diagnosis were followed for a primary outcome of NAFLD, defined as development of sustained elevated alanine aminotransferase levels in the absence of hepatitis B or C virus infection or alcoholic liver disease, identified by laboratory values and diagnosis codes. We calculated incidence rates for NAFLD for the entire study population and by CKD stage. Predictors of NAFLD were evaluated using Cox proportional hazards regression, considering death and ESKD as competing risks.

Results: Of 1,155,901 veterans with CKD but no NAFLD, 51,584 (4.4%) developed NAFLD at a rate of 0.86 (0.85-0.87) per 100 person-years during 4.74 years follow-up. A total of 3.9% developed ESKD at a rate of 0.76 (0.75-0.77) per 100 person-years, and 33% died at a rate of 6.5 (6.5-6.5) per 100 person-years during the same time period. In a multivariable model, age >50 (vs. 40-49 years) (HR 0.72, 95% CI 0.67, 0.77), women, blacks and veterans with advanced CKD were less likely to develop NAFLD; however, presence of diabetes, higher BMI, anemia, CHF, and hypertension were associated with higher risk of developing NAFLD (Table).

Conclusions: Patients with CKD have a high incidence of NAFLD, which was associated with diabetes, BMI, and CHF. Future studies should determine if interventions targeting these factors may reduce NAFLD risk.

Factors associated with incident NAFLD in CKD

Variable	Level	HR (95% CI)
Sex	Female	0.88 (0.83, 0.92)
Race	Blacks (vs. Whites)	0.66 (0.64, 0.68)
CKD Stage (Ref: Stage 3A)	Stage 3B	0.89 (0.87, 0.91)
	Stage 4	0.77 (0.74, 0.81)
	Stage 5	0.60 (0.50, 0.74)
Comorbid condition	Diabetes	1.18 (1.15, 1.20)
	BMI >25	1.24 (1.20, 1.28)
	BMI >30	1.43 (1.39, 1.48)
	CHF	1.03 (1.00, 1.07)
	Coronary heart disease	1.18 (1.13, 1.24)
	Hypertension	1.04 (1.02, 1.07)

PO0551

Alterations of Gray Matter Volumes and Connectivity in Patients with CKD

Changmin Heo, Yang Wook Kim, Yoo jin Lee, Sihyung Park, Bongsoo Park, Eunjae Yoon. *Haeundae Paik Hospital, Inje University College of Medicine, Busan, Republic of Korea*.

Background: Our previous study demonstrated that patients in End stage renal disease had decreased structural and functional brain connectivity, and there was significant association between brain connectivity and cognitive function. The aim of this study was to evaluate the alterations of structural and functional connectivity using graph theoretical analysis in the neurologically asymptomatic patients with relatively early stage chronic kidney disease (CKD).

Methods: We prospectively enrolled neurologically asymptomatic 20 patients with CKD stage 3 and 20 healthy controls, and all of the subjects underwent diffusion tensor imaging (DTI) and resting state functional MRI (rs-fMRI). Using data from the structural and functional connectivity matrix based on DTI and rs-fMRI, we calculated network measures, including global efficiency, local efficiency, mean clustering coefficient, characteristic path length, and small-worldness index, and investigated the differences between the patients with CKD and healthy controls.

Results: The patients with CKD had altered global structural connectivity and preserved functional connectivity compared to healthy controls. The all of the measures of global structural connectivity were significantly different between the patients with CKD and healthy controls. However, all of the measures of global functional connectivity in the CKD patients were not different from those in healthy participants. In the CKD patients, the functional betweenness centrality of the right insular cortex, right occipital pole, and right thalamus was significantly different from that in healthy subjects. The structural betweenness centrality of the left calcarine, right posterior cingulum was significantly different from that in healthy subjects.

Conclusions: There were significant alterations of global structural connectivity between patients with CKD and control. However, functional connectivity of brain network was preserved in contrast to ESRD patients.

PO0552

CKD and Metabolic Risk Factors: A Cross-Sectional Study Based on 398,120 Adults in China

Lingling Xu, Jin Liu, Yang Zhou, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China*.

Background: Chronic kidney disease (CKD) has become a worldwide health problem. The prevalence of CKD varied within countries by different socio-demographic characteristics and economic status. Olderly people are particularly susceptible to kidney damage from age-related decline in glomerular filtration and chronic disease states, such as diabetes mellitus (DM) and hypertension (HTN). It is necessary to understand the epidemiological features and the association risk factors of CKD in adults, especially in these elderly population.

Methods: We did a cross-sectional survey based on the records of universal health examinations of the residents in Binhai county of China in 2018. A total of 398,120 participants aged ≥ 18 years in this study had underwent blood test, body measurements and general demographic characteristics registration. Then 31.6% of subjects who aged ≥ 65 years (n=37,533) were randomly selected to complete the routine urinalysis. Chronic renal insufficient (CRI) was defined by eGFR < 60 mL/min.1.73 m^2(CKD-EPI), while CKD was defined by CRI or presence of proteinuria. We analyzed the epidemiological features and the association between CKD and relevant covariates by logistic regression models in the general and elderly population.

Results: The age- and gender- standardized prevalence of CRI was estimated to be 1.10% (95% CI, 1.07%-1.13%) in Chinese adult population. It was 0.86% among men (95% CI, 0.82%-0.90%) and 1.34% among women (95% CI, 1.29%-1.39%). Female, aging, central obesity, elevated triglycerides, systolic blood pressure, fasting blood glucose (FBG) and heart rate were independent risk factors for CRI in the general adults. Rates of CRI increased significantly by age, especially when people aged ≥ 60 years. Furthermore, the prevalence of CKD was 17.7% (95% CI, 17.3%-18.1%) in the elderly. Aging, HTN, elevated triglyceride and FBG were still found to be independent risk factors for CKD in this subgroup. Elevated FBG had the strongest correlation with CKD, gender was no longer association with CKD in the elderly.

Conclusions: Aging, HTN, elevated triglyceride and FBG were all independent metabolic-related risk factors associated with CKD in Chinese adults. More attention should be paid to metabolic diseases such as DM, HTN and hyperlipidemia to prevent CKD in adults, especially in the elderly.

PO0553

Are There Any Further Modalities for Prediction of Subclinical Volume Overload in Advanced Stages of CKD?

Aber H. Baki, Hazem Mansour. *Ain Shams University Faculty of Medicine, Cairo, Egypt*.

Background: Subclinical volume overload is commonly seen in our daily practice which represents a debatable issue. These patients respond favorably to diuretics despite lacking clinical signs of volume overload. Therefore a proper assessment of the volume status in Chronic Kidney Disease (CKD) patients leads to a better control of their medical condition and prevents further deterioration of their clinical situation into the well-known sequelae. Although many tools were used to detect volume overload in such patients as biomarkers, ultrasonography, bio-impedance, echo, and blood viscosity, many non-specific results were due to presence of concomitant comorbidities. The use of Bio Impedance Spectroscopy (BIS) is a recent tool increasingly used due to its appealing features as being non-invasive. BIS is an objective fluid status assessment method, which is shown superior to classical methods such as BP monitoring and weight control in many studies. Combining some of these tools may improve their accuracy and specificity. Inferior vena cava collapsibility index (IVCCI) with Brain Natriuretic Peptide (BNP) can be combined for more specific volume status assessment.

Methods: To assess the usage of combined IVCCI and BNP level in CKD patients to predict subclinical volume overload, 110 patients with CKD (stage 4&5) & not on dialysis and having normal LV systolic function were included with exclusion of the following: 1) Patients with other causes of raised BNP than volume overload (i.e. anemia and heart failure). 2) Patients on diuretics. Complete history, clinical examination and basic laboratory were done for all included patients. IVCCI, BNP serum level were evaluated. By using BIS, we estimated Fluid overload (FO) and extracellular water (ECW). The patients who exhibited a FO/ECW ratio >15% were considered to have volume overload.

Results: Among the 110 cases, we found that 26 patients (23.6%) had subclinical hypervolemia as diagnosed by FO/ECW ratio >15. IVCCI ≤ 38% had higher diagnostic

performance than BNP ≥24 pg/ml. Combining both IVCCI ≤38% and BNP ≥24pg/ml increased the specificity and negative predictive value for detection of subclinical hypervolemia.

Conclusions: Combined elevated BNP level and decreased IVCCI could be more precise tools for subclinical volume overload detection in CKD patients.

PO0554

Sensitivity of Urinary N-Terminal Osteopontin-to-Creatinine Ratio in Predicting Renal Function Loss

Ling Sun,[2] Satyesh K. Sinha,[1] Aldons J. Lusis,[1] Susanne B. Nicholas.[1] Metabolic Syndrome In Men (METSIM) *[1]UCLA, University of California Los Angeles, Los Angeles, CA; [2]Xuzhou City Centre Hospital, Xuzhou, China.*

Background: Osteopontin (OPN) is a multifunctional protein that gets cleaved to create N- terminal OPN (ntOPN). ntOPN has been reported in urine in kidney diseases but little is known about the sensitivity of ntOPN to creatinine ratio (ntOCR) as a urinary biomarker compared to the urinary albumin-to-creatinine ratio (UACR). This study is aimed to explore the prognostic value of ntOCR regarding renal function loss in a subset of the metabolic syndrome in men (METSIM) study with a high incidence of diabetes mellitus.

Methods: The METSIM study recruited 10,197 Finnish men between 2005 and 2010 and reexamined participants at two 5-year follow-ups. We performed a prospective observational study of a METSIM cohort of 137 participants, 45-72 years old at entry, with available urine at baseline and the first follow-up period, after 3.8±1.4 years. Serum and urinary levels of the ntOPN were quantified by ELISA. Using estimated glomerular filtration rate (eGFR), UACR and urine albumin excretion (UAE) of progressors and non-progressors, data were analyzed by paired t-test and Wilcoxon matched-pairs signed-rank test. The area under the receiver-operating characteristics (ROC) curve (AUC) was used to assess the sensitivity/specificity of variables in predicting the progression of CKD. Pearson correlation coefficient was performed to detect the relationships between the values of variables.

Results: Compared to the CKD non-progressors, the progressors had significantly higher eGFR at baseline (96.95 vs. 87.75 mL/min/1.73 m^2, p<0.00) and lower eGFR at follow-up (86.11 vs. 91.40 mL/min/1.73 m^2, p=0.01). The baseline urine levels of ntOCR were higher in progressors than non-progressors (6.83 vs 3.68 pmol/mg, p=0.05). There were no differences in the UAE, UACR, or serum ntOPN between the two groups. However, baseline urinary ntOCR predicted renal function loss with an AUC of 0.60 (p=0.05), and the change between baseline and follow-up had a higher AUC value of 0.63 (p=0.01).

Conclusions: Our study suggests that urinary ntOCR might be a promising predictive biomarker for renal function loss in a population with high rates of metabolic syndrome and diabetes. Measurements at the second METSIM follow-up may confirm this observation. Further studies are needed in females, larger size populations, and long-term follow up.

PO0555

Effect of Renin-Angiotensin System Blockade in Immunoglobulin A Nephropathy Only with Persistent Hematuria

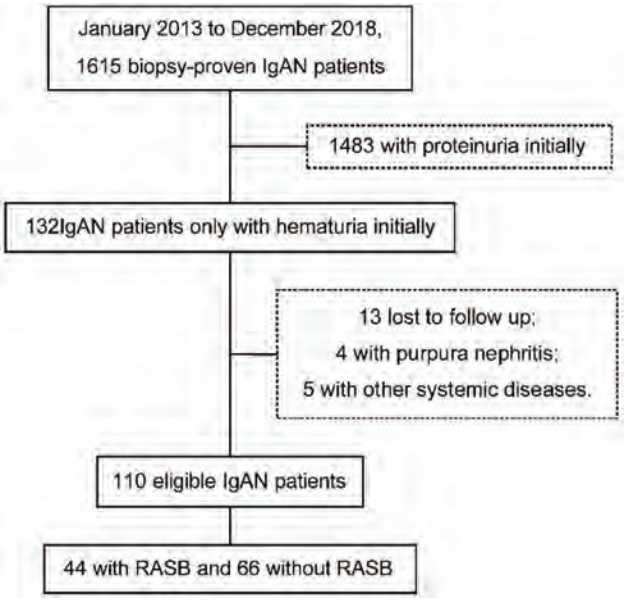
Hui Xu. *Department of Nephrology, Xiangya Hospital, Central South University, Changsha, China.*

Background: Recent guideline recommended that long-term renin–angiotensin system blockade (RASB) should be used in immunoglobulin A nephropathy (IgAN) when proteinuria > 1g/d. If proteinuria is 0.5–1g/d, RASB is also suggested. We tried to investigate whether IgAN patients only with persistent hematuria and without proteinuria can benefit from RASB.

Methods: IgAN patients only with persistent hematuria initially from January 2013 to December 2018 from four centers were included. We divided patients into treatment and untreated group according to the use of RASB. The primary outcome was the appearance of proteinuria, the secondary outcome was the decreased percentage of hematuria and the rate of estimated glomerular filtration rate (eGFR) decline. Effect of RASB on the outcomes was assessed by multivariate Cox regression models and a propensity score matching.

Results: 110 eligible patients were included and 44 (41.0%) received RASB. Patients in the treatment groups had higher diastolic pressure. The unadjusted primary outcome of RASB treated patients was better than the untreated individuals. The multivariate Cox regression revealed that RASB lowered the risk of primary outcome, besides, RASB decreased more percentage of hematuria. No obvious difference was found in the rate of eGFR decline between two groups.

Conclusions: RASB decreased the risk of proteinuria appearance and increased the remission of hematuria in IgAN only with persistent hematuria initially, but it did not obviously impact the blood pressure of patients without hypertension and the rate of eGFR decline.



PO0556

Fibrates and CKD Patients: A Controversial Issue

Aber H. Baki, John Zarif. *Ain Shams University Faculty of Medicine, Cairo, Egypt.*

Background: Fenofibrates were not previously known to affect renal function tests until some reports indicated that these drugs may lead to a decrease in renal function. Likewise, the nephrotoxic effect of fibrates remains to be vague and unclear.Fenofibrate's safety in patients with renal insufficiency is an issue because it may increase plasma creatinine. Furthermore, guidelines regarding fenofibrate dosing in renal impairment vary internationally. We investigated fenofibrates' effects on cardiovascular and on advanced CKD, according to eGFR. The multiple incidents of elevated kidney function tests for patients on fibrates have led us to make this study to review our experience as well as literature on this matter.

Methods: A prospective cohort study over 6 months with a total of 80 patients on fibrates divided into 2 groups, 40 of which received statins and the other 40 continued on fibrates. All our patients were subjected to full history, clinical examination and complete baseline labs. The kidney function tests including serum creatinine and eGFR were measured at 0,1, 2 and 6 months' intervals and lipid profile at 0,3,6 months serially in both groups.

Results: Out of the baseline values of the kidney function tests that were recorded on previous fibrate therapy, the statin group (n=40) showed a significant decrease in all kidney function values including serum creatinine by (0.9mg/dL P=0.001) and an increase in eGFR (8.9 mL/min/1.73 m2, P<0.001). Whilst in the other 40 patients who continued to receive fibrates the kidney function tests continued to rise as serum creatinine showed a significant increase in their mean serum Cr levels (by 0.9 mg/dL or 20%, P=0.001), and a significant decrease in their mean eGFR values (by 8.2 mL/min/1.73 m2 or 20.55%, P<0.001). On the other hand total and LDL Cholesterol were significantly lower in Statin group at all follow up intervals. Also triglycerides were significantly higher in Statin group at the end of month-6 from baseline.

Conclusions: In our study fibrates administration showed a short term state of renal insufficiency. The long term effects of fibrates versus variable renal derangement are yet to be identified. As to lipid profile, shifting from fibrates to statins led to a stastically significant rise in triglycerides but it's clinical impact is yet to be investigated, so established guidelines might need a revision regarding clinical benefits of fibrates versus it's renal injury.

PO0557

Calciphylaxis: An Uncommon Skin Manifestation in Non-Dialysis CKD Patients

Rabia Sarwar,[1] Ujala Zubair,[2] Wanwarat Ananthapanyasut.[1] *[1]Skagit Regional Health, Mount Vernon, WA; [2]Jinnah Sindh Medical University, Karachi, Pakistan.*

Introduction: Calciphylaxis is a rare but fatal skin disorder seen in 1-4% of dialysis patients. It is characterized by ischemia and necrosis of the skin tissue due to the deposition of calcium in the arterioles and subcutaneous tissues. The risk of infection is increased, and once ulceration develops, the mortality rate can be above 80%. Risk factors include diabetes, warfarin, vitamin D, obesity, female, white race and mineral-bone disorder. The skin findings ranging from livedo reticularis to nodules, plaques, or deep ulcerations. The treatment is focused on supportive care. To date, there is no strong studies to suggest that sodium thiosulfate (STS), bisphosphonates, or calcimimetics are curative. However, STS is commonly used despite the lack of strong supporting data.

Case Description: We report a case of a 76-year-old Caucasian woman with a history of stage G4/A3 chronic kidney disease, insulin-dependent diabetes, hypertension, secondary hyperparathyroidism, and obesity, who presented with severe pain and redness on both legs. The skin lesions had progressed to the painful ulcerations and eschars on both shins one month after the initial visit. A skin biopsy was performed and histopathology was consistent with calciphylaxis. She was started on STS 25 mg intravenously (IV) twice a week and cinacalcet 30 mg by oral route (PO) thrice a week. The patient showed improvement within one month of the treatment.

Discussion: Calciphylaxis in non-dialysis patients is uncommon; however, it should be considered in those with predilection factors. The skin biopsy is crucial for the diagnosis, which can lead to proper management of such a rare yet lethal disease. STS is the most common drug used to treat calciphylaxis. It acts as a calcium chelator with some antioxidative and vasodilation properties leading to recovery.

PO0558

Calciphylaxis: Clinical Features, Therapeutic Options, and Outcomes

José Agapito Fonseca, Maria Sanches, Inês C. Duarte, Joana Gameiro, Cristina B. Outerelo, Hugo Silva, Sofia C. Jorge, Jose A. Lopes, Estela Nogueira. *Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisboa, Portugal.*

Background: Calciphylaxis is characterized by microvascular disease with calcification of the middle layer of the arterioles, intimal hyperplasia and thrombotic occlusion, conditioning areas of ischemia and skin necrosis. Given the rarity of this pathology, there is a lack in literature regarding clinical presentation, diagnostic approach and therapeutic management. We performed a descriptive analysis of clinical, epidemiologic, laboratory characteristics, treatment options and outcomes in a population of patients with calciphylaxis.

Methods: Retrospective analysis of all calciphylaxis diagnosed in a single-center between January 2003 and December 2019.

Results: The diagnosis of calciphylaxis was made in 9 patients, 7 of whom were female, with a mean age of 63.4±10.9 years. Eight patients were on renal replacement therapy (all hemodialysis) at the time of diagnosis, with a dialysis vintage of 66.4±82.4 months and one patient had no chronic kidney disease. Six patients were taking warfarin, with an average of 46 months on anticoagulation. The mean pre-diagnostic serum calcium value was 9.4 mg/dL, with an average phosphorus level of 4.5 mg/dL, phosphocalcic product was 42 mg^2/dL^2 and the average PTH was 1078 pg/mL. The onset or increase in calcium-containing phosphorus binders was recorded in 6 patients, with cinacalcet being used in only 4 patients. Five patients underwent bisphosphonate therapy, 1 undewent sodium thiosulfate, 3 were submitted to hyperbaric chamber sessions, 2 underwent dialysis intensification and 3 patients were submitted parathyroidectomy. Three patients died within 12 months of diagnosis. Mean follow-up time was 28.8±24.5 months.

Conclusions: More than 60% of patients were under warfarin, reinforcing the role of vitamin K antagonists in the pathogenesis. Mean time on dialysis was highly variable, from the 1st to the 216th month since the beginning of the technique. The standard of treatment varied according to the drugs available and the clinical evidence that supported its use at the time of diagnosis. The registered deaths corresponded to patients diagnosed later in the course of the disease, reinforcing the importance of a high clinical suspicion regarding the appearance of trophic skin lesions in this population as a form of early diagnosis to prevent mortality.

PO0559

Role of Adipose Tissue-Derived Mesenchymal Stem Cells in CKD: A Phase 1 Study Assessing Safety and Clinical Feasibility

Zheng Cai-Mei. *Taipei Medical University College of Medicine, Taipei, Taiwan.*

Background: Chronic kidney disease (CKD) is a most common progressive disorder associated with high mortality and huge socio-economic burden globally. We hypothesize that allogeneic adipose tissue mesenchymal stromal cells (hASCs) are renotropic and may retard CKD progression through anti-apoptotic, anti-fibrotic, and anti-inflammatory effects. In this study, we will assess the safety and tolerability of a hASCs infusion in CKD patients with various underlying etiologies.

Methods: We performed a single-arm phase I clinical trial with a 6-month follow-up. This study enrolled 12 eligible CKD patients with an estimated glomerular filtration rate (eGFR) of 15-44 mL/min/1.73m^2 (mL/min). Patients were allocated to receive low, moderate, or high dose of allogeneic cultured hASCs infusion. We investigated the safety issues and kidney function during the follow-up visits.

Results: There was no patient lost to follow-up. We observed two treatment related adverse events (AE) in high dose group. One subject experienced grade 1 slow speech immediately after hASCs infusion, which was resolved on the next day and completely normal afterwards. The AE was considered possibly related to study treatment and met dose-limiting toxicity (DLT). Another subject experienced grade 1 bradyphrenia after the infusion, and the situation was resolved during the following 9 days, however, this AE was not considered as DLT. One SAE was reported in moderate dose group, who was hospitalized for persistent heavy proteinuria, and later proved as diabetic nephropathy stage 4 by renal biopsy. No significant reduction in eGFR was noted among all treated patients, and specifically an improvement in eGFR was noted among those with baseline eGFR>30mL/min. No significant reduction in proteinuria was noted.

Conclusions: This trial demonstrated the safety and tolerability of allogenic hASCs infusion in stages 3b and 4 CKD patients. Patients with reserved renal function (e.g. eGFR>30mL/min) could be more beneficial from hASCs compared to those without. hASCs efficacy and dosing interval in various CKD stages should be investigated in future randomized placebo-controlled trial among various CKD population.

PO0560

Pegunigalsidase Alfa, Novel Pegylated Enzyme Replacement Therapy, Evaluated in Fabry Patients with Progressing Kidney Disease: A Randomized Clinical Trial Study Design

David G. Warnock,[1] Derralynn Hughes,[2] Sari Alon,[3] Raul Chertkoff,[3] Einat Almon,[3] Raphael Schiffmann.[4] *[1]UAB Medicine, Birmingham, AL; [2]LSDU, Institute of Immunity and Transplantation, Royal Free London NHS Foundation Trust, London, United Kingdom; [3]Protalix Biotherapeutics, Carmiel, Israel; [4]Baylor Institute of Metabolic Diseases, Baylor University Medical Center, Dallas, TX.*

Background: Fabry disease (FD) is an X-linked multisystem lysosomal storage disorder, affecting males and females caused by the deficient of α-galactosidase-A (α-Gal-A) activity. Long-term disease manifestations include progressive renal failure, hypertrophic cardiomyopathy, cardiac rhythm disturbances, stroke, and death. Two enzyme replacement therapies (ERT) and oral chaperon therapy are commercially available. The clinical benefit of available treatments may not be as robust as anticipated, especially in the subset of males with 'classic' Fabry disease. In the context of ERT, a combination of factors including dose, dosing interval, presence of anti-drug antibodies, estimated glomerular filtration rate (eGFR), and age at the time of ERT initiation, and proteinuria could explain the less than optimal responses achieved by the currently available ERT. Pegunigalsidase alfa is a novel PEGylated homo-dimer ERT which is more stable, has a favorable safety profile, potentially less development of anti-drug antibodies, and enhanced pharmacokinetic profile (~80 hours half-life and higher AUC) compared to other available ERT.

Methods: Adult FD patients (males and females) deteriorating in kidney function with annualized eGFR ≤ -2 mL/min/1.73 m^2/year while on agalsidase beta have been enrolled into BALANCE, a phase-III double-blind active control study (NCT02795676), and were randomized (2:1 ratio) to pegunigalsidase alfa or continue agalsidase beta for 2 years at 1 mg/kg every other week. The primary outcome is the difference in the mean annualized slope of eGFR during the study between the two groups.

Results: Description of the baseline characteristics for approximately 75 patients enrolled at 29 US and European study sites by: age, sex, enzymatic activity, genetic mutations, FD symptoms, previous FD treatment length, kidney function (eGFR, eGFR slope and UPCR), Lyso-Gb3, and anti-drug antibodies pre-treatment status.

Conclusions: The current work describes the design and methods of the study protocol and the baseline characteristics for approximately 75 enrolled patients in the study.

PO0561

Pegunigalsidase Alfa, PEGylated α-Galactosidase-A Enzyme in Development for the Treatment of Fabry Disease, Shows a Correlation Between Renal Gb3 Inclusion Clearance and Reduction of Plasma Lyso-Gb3

Ahmad M. Tuffaha,[1] Derralynn Hughes,[2] Simeon Boyd,[14] Pilar Giraldo,[3] Myrl D. Holida,[4] Mohamed G. Atta,[5] Ozlem Goker-Alpan,[13] Kathleen M. Nicholls,[6] Raphael Schiffmann,[7] Gustavo Maegawa,[12] Laura Barisoni,[8] Robert B. Colvin,[9] J. Charles Jennette,[10] Sari Alon,[11] Mali Szlaifer,[11] Einat Almon,[11] Raul Chertkoff.[11] *[1]Kansas University Medical Center, Kansas City, KS; [2]LSDU, Institute of Immunity and Transplantation, Royal Free London NHS Foundation Trust, London, United Kingdom; [3]Hospital de Dia Quiron, Zaragoza, Spain; [4]University of Iowa Hospitals and Clinics, Iowa City, IA; [5]Department of Medicine, Division of Nephrology, Johns Hopkins, Johns Hopkins University School of Medicine, Baltimore, MD; [6]Nephrology Department, the Royal Melbourne Hospital, Melbourne, VIC, Australia; [7]Baylor Institute of Metabolic Diseases, Baylor University Medical Center, Dallas, TX; [8]Duke University, Durham, NC; [9]Massachusetts General Hospital, Harvard Medical School, Department of Pathology, Boston, MA; [10]University of North Carolina, Department of Pathology, Chapel Hill, NC; [11]Protalix Biotherapeutics, Carmiel, Israel; [12]University of Florida, Department of Pediatrics/Genetics & Metabolism, Gainesville, FL; [13]O&O Alpan LLC, Fairfax, VA; [14]Department of Pediatrics, Section of Genetics, MIND Institute, UC Davis Medical Center, Sacramento, CA.*

Background: Fabry disease (FD) is caused by the loss of function of the lysosomal enzyme α-Galactosidase-A leading to the accumulation of globotriaosylceramide (Gb3). Reduction in histological Gb3 burden in renal peritubular capillaries (PTC) is considered an appropriate and objective surrogate endpoint, likely to predict the clinical benefit of treatment in FD. Pegunigalsidase-alfa is a novel PEGylated enzyme in development for the treatment of FD with enhanced pharmacokinetics.

Methods: The phase I/II (NCT01678898) dose-ranging studies (0.2mg/kg; 1 mg/kg; 2mg/kg) were designed to evaluate the safety (primary objective), pharmacokinetics and efficacy (secondary objective) of pegunigalsidase-alfa administered IV every 2 weeks in adult symptomatic FD treatment naïve male and female patients. The Barisoni Lipid Inclusion Scoring System (BLISS) was adopted to quantitively assess patients' renal biopsies taken at baseline and at 6 months of treatment. BLISS methodology consists of counting the number of Gb3 inclusions per peritubular capillary; a decrease in the score is indicative of clinical improvement.

Results: Renal biopsies were available and evaluated in 13 out of 16 patients allocated in the three dose groups. Mean BLISS score at baseline was 4.23, proving an important renal involvement, and was reduced to a mean of 0.83 after 6 months (-67.8% ± 3.3 %) with an 86.5% reduction in the 1 mg/kg dose cohort. From the totality of the available biopsies (14, including one subject with an FD cardiac variant), 78.6% of patients reached ≥50% reduction in BLISS score.

Conclusions: These results show a profound reduction in Gb3 inclusion in PTC after 6 months of pegunigalsidase-alfa treatment. A high correlation (r=0.800) between the reduction in plasma Lyso Gb3 and the reduction of kidney Gb3 inclusions in the kidney biopsies was observed, giving additional support to the potential effectiveness of pegunigalsidase alfa in treating FD.

PO0562

Switching from Agalsidase Alfa to Pegunigalsidase Alfa for Treating Fabry Disease: One Year of Treatment Data from Bridge, a Phase 3 Open-Label Study

Camilla Tøndel,[1] Ales Linhart,[2] Gabriela Dostálová,[2] Kathleen M. Nicholls,[3] Michael L. West,[4] Ana Jovanovic,[9] Pilar Giraldo,[5] Bojan Vujkovac,[6] Einat Almon,[7] Sari Alon,[7] Mali Szlaifer,[7] Raul Chertkoff,[7] Derralynn Hughes.[8] *[1]Haukeland University Hospital, Bergen, Norway; [2]Charles University, Praha, Czechia; [3]The Royal Melbourne Hospital, Melbourne, VIC, Australia; [4]Dalhousie University, Halifax, NS, Canada; [5]Hospital de Dia Quiron, Zaragoza, Spain; [6]General Hospital Slovenj Gradec, Slovenj Gradec, Slovenia; [7]Protalix Biotherapeutics, Carmiel, Israel; [8]LSDU, Institute of Immunity and Transplantation, Royal Free London NHS Foundation Trust, London, United Kingdom; [9]Salford Royal, Dept of Inherited Metabolic Disease, Salford, United Kingdom.*

Background: Pegunigalsidase-alfa is a novel, PEGylated α-Galactosidase-A enzyme in development for the treatment of Fabry disease (FD).

Methods: Bridge (PB-102-F30, NCT03018730) is a phase III, open-label, switch-over study, designed to assess the safety and efficacy of pegunigalsidase-alfa (1 mg/Kg EOW) in adult FD patients previously treated with agalsidase alfa for at least 2 years.

Results: This is an interim report of 12-months on-treatment data generated from the first 16 patients (9 males and 7 females) out of the 22 adult patients enrolled. Baseline characteristics: age 24-60 years, the mean estimated Glomerular Filtration Rate (eGFR) 75.45 in males and 85.78 mL/min/1.73m² in females, annualized eGFR slope was -5.04 and -5.18 mL/min/1.73m²/year, respectively, mean residual leucocytes enzymatic activity 5.9% of lab normal mean in males and 27.9% in females, and plasma lyso-Gb3 53.6 and 13.8 nM, respectively. After one year the mean annualized eGFR slope improved from -5.10 mL/min/1.73m²/year while on agalsidase alfa, to -0.23 mL/min/1.73m²/year on pegunigalsidase-alfa. According to Wanner et al. 2018, FD patients with eGFR slope between ≥ -5 and < -3 mL/min/1.73 m²/year are defined as kidney disease progressing and with eGFR slope < -5 mL/min/1.73 m²/year are defined fast progressing. The therapeutic goal is to reach eGFR slope ≥ -3 mL/min/1.73 m²/year for the progressing, and ≥ -5 mL/min/1.73m²/year or more than 50% decrease in progression for the fast progressing. In this interim analysis, 100% of the progressing patients and 66.7% in the fast progressing group achieved the proposed therapeutic goals after switching to pegunigalsidase-alfa. The switch to pegunigalsidase-alfa was safe and well-tolerated. The majority of the patients who completed the study rolled over to a long-term extension study, continuing receiving pegunigalsidase-alfa.

Conclusions: These results suggest a potential benefit of pegunigalsidase-alfa on renal function for FD patients currently treated with agalsidase alfa, to be confirmed by long-term data.

PO0563

Tolerance for Potassium Supplementation in Patients with CKD

Martin Gritter,[1] Stanley M. Yeung,[2] Rosa D. Wouda,[3] Liffert Vogt,[3] Martin H. De Borst,[2] Joris I. Rotmans,[4] Ewout J. Hoorn.[1] *[1]Erasmus MC, Rotterdam, Netherlands; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [3]Amsterdam Universitair Medische Centra, Amsterdam, Netherlands; [4]Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Recent studies have shown an association between higher potassium (K^+) intake and better kidney outcomes in patients with chronic kidney disease (CKD). However, K^+ supplementation in CKD may be limited by the risk of hyperkalemia (>5.5 mEq/L). In this study in patients with CKD our aims were to (1) analyze the effect of K^+ supplementation on whole-blood K^+ (WBK^+), (2) identify factors associated with a rise in WBK^+, and (3) identify risk factors for hyperkalemia.

Methods: To do so, we analyzed the results of the 2-week open-label run-in phase of a randomized clinical trial studying the renoprotective effect of long-term K^+ supplementation in patients with progressive CKD and hypertension.

Results: In 151 patients (67±11 years, 74% males, eGFR 32±9 ml/min/1.73 m², 83% on renin-angiotensin inhibitors), K^+ supplementation (40 mEq/day) increased urinary K^+ excretion from 73±24 to 106±28 mEq/day, WBK^+ from 4.3±0.5 to 4.7±0.5 mEq/L, and plasma aldosterone from 294 (210-447) to 366 (271-504) pg/mL (P<0.001 for all). The majority of patients (n=138, 91%) remained normokalemic. K^+ supplementation had no significant effect on urinary sodium excretion (158±62 to 155±68 mEq/day), systolic blood pressure (132±15 to 132±15 mmHg), or eGFR (32±9 to 32±8 mL/min/1.73 m²). Multivariable linear regression identified that age (β 0.008, 95%CI 0.001 to 0.02), female sex (β 0.2, 95%CI 0.001 to 0.3), renin-angiotensin inhibitor use (β 0.2, 95%CI 0.05 to 0.4), diuretic use (β -0.1, 95%CI -0.3 to 0.0), baseline WBK^+ (β -0.3, 95%CI -0.5 to -0.2), and baseline bicarbonate (β -0.03, 95%CI -0.06 to -0.01) are independently associated with a change in WBK^+ after K^+ supplementation. The 13 patients who developed hyperkalemia (WBK^+ 5.8±0.2 mEq/L) were older (74±7 vs. 66±11 years), more often had diabetes (69 vs. 36%), had lower eGFR (26±8 vs. 33±8 ml/min/1.73 m²), lower baseline bicarbonate (22.5±3.8 vs. 24.8±3.4 mEq/L), and higher baseline WBK^+ (4.8±0.4 vs. 4.2±0.4 mEq/L, P<0.05 for all).

Conclusions: In conclusion, the majority of patients with advanced CKD remains normokalemic upon K^+ supplementation, despite the use of renin-angiotensin inhibitors. This short-term study illustrates the feasibility of investigating the renoprotective potential of K^+ supplementation in patients with CKD and provides the characteristics of patients in whom this is safe.

PO0564

The Effect of Amiloride and Triamterene on Proteinuria in Patients with Proteinuric Kidney Diseases

Mohammed Alshehri,[1] Wen Shen,[1] Sameer Y. Desale.[2] *[1]MedStar Georgetown University Hospital, Washington, DC; [2]Medstar Health Research Institute, Hyattsville, MD.*

Background: Proteinuric kidney diseases are associated with a significant risk of developing end-stage renal disease. Treatment options after maximizing the renin-angiotensin-aldosterone system (RAAS) inhibition are limited. Amiloride, a diuretic inhibiting epithelial sodium channel (ENaC), has been reported to have antiproteinuric effects in animal studies independent of its action on ENaC. This study was designed to specifically examine the effect of Amiloride and triamterene in patients with significant proteinuria.

Methods: It is a cross-over pilot trial where each patient acted as his/her own control. Patients with proteinuria more than 1.0g/day, eGFR >30ml/min/1.73m2, and on the highest tolerable dose of angiotensin-converting enzyme inhibitor (ACEI) or angiotensin receptor blocker (ARB) for at least 8 weeks were recruited. They received amiloride 5 mg twice daily or triamterene 50 mg twice daily for 8 weeks. All the patients then entered a washout phase for 4 weeks, followed by a crossover to the other trial drug for 8 weeks. Weight, blood pressure, metabolic panel, urine studies, and 24-hour urine protein excretion were frequently monitored. Patients with serum potassium >5.5 or an increase in serum Cr >30% one week after the treatment were withdrawn.

Results: A total of 12 patients were enrolled and completed the study. Amiloride reduced 24-hour urine protein by 25.4% (P=0.0435), UPCR by 31.6% (P=0.0104), UACR

by 39.4% (P=0.0049). Triamterene reduced 24-hour urine protein by 33.7% (P=0.0153), UPCR by 29.4% (P=0.0130), UACR by 28.6% (P=0.0294). The effect on the 24-hour urine protein is not significantly different between the two drugs. The average change on the eGFR is -2 and -9 ml/min/1.73m2 in the amiloride and triamterene groups, respectively. Average systolic blood pressure reduction is 11 and 3 in amiloride and triamterene groups, respectively. The average change in the weight is -0.5 and -0.7 kg in amiloride and triamterene groups, respectively. Three patients exited the study due to hyperkalemia.

Conclusions: Both amiloride and triamterene showed the effect of proteinuria reduction regardless of the underlying pathology. This effect appears to be independent of the RAAS, given that patients were all on RAAS blockade. Large scale trials are needed to evaluate the antiproteinuric and renoprotection effects of ENaC inhibitors.

PO0565

Comparison of Extended-Release Calcifediol (ERC), Immediate-Release Calcifediol, Cholecalciferol, and Paricalcitol for Treating Secondary Hyperparathyroidism (SHPT) in CKD

Stephen A. Strugnell,[1] David M. Spiegel,[2] Philipp Csomor,[2] Akhtar Ashfaq,[1] Charles W. Bishop.[1] *[1]OPKO Health Inc., Miami, FL; [2]Vifor Pharma Ltd, Zurich, Switzerland.*

Background: Serum total 25-hydroxyvitamin D (25D) levels above 50.8 ng/mL are required to produce meaningful and progressive reductions in plasma intact parathyroid hormone (iPTH) in patients with stages 3 or 4 CKD [Strugnell et al 2019]. The current study compared the abilities of four treatment regimens to increase serum 25D to this level and to reduce iPTH in this population.

Methods: Subjects with stage 3 or 4 CKD, SHPT (iPTH ≥85 and <500 pg/mL) and vitamin D insufficiency (25D <30 ng/mL) underwent an 8-week washout from previous vitamin D therapies and were randomized to 60 days of open-label treatment with: 1) ERC 60 mcg/day; 2) immediate-release calcifediol (IRC) 266 mcg/month; 3) high-dose cholecalciferol (HDC) 300,000 IU/month; or 4) paricalcitol plus low-dose cholecalciferol (PLDC) 1 mcg and 800 IU/day. Paricalcitol was increased to 2 mcg/day after 30 days if iPTH was not reduced by 30% and safety parameters allowed. Subjects were monitored for changes in serum 25D, calcium (Ca) and phosphorus (P), and plasma iPTH.

Results: Mean (SD) post-washout/pre-treatment baseline levels for 25D and iPTH in the per-protocol population were 20.6 (6.6) ng/mL and 145 (90) pg/mL, respectively. No differences were observed at baseline between treatment groups (14-17 subjects each). At the end of treatment, mean 25D (ng/mL) increased to 82.9 (17.0) with ERC (P<0.05), 30.8 (11.6) with HDC (P<0.05), 26.3 (6.8) with IRC and 24.2 (7.3) with PLDC. All subjects treated with ERC attained 25D levels ≥30 ng/mL vs. only 44% with HDC (P<0.001), 20% with IRC and 14% with PLDC. Most ERC subjects (94%) attained 25D levels >50.8 ng/mL. The proportion of subjects who achieved at least a 20% reduction in iPTH were 71% with ERC, 38% with HDC, 20% with IRC and 79% with PLDC. No changes from baseline were observed in mean Ca or P in any treatment group, but one instance of hypercalcemia (>10.3 mg/dL) was observed with PLDC treatment.

Conclusions: ERC was safe and more effective at increasing serum 25D and decreasing plasma iPTH than IRC, HDC or PLDC in patients with SHPT, vitamin D insufficiency, and stage 3 or 4 CKD.

PO0566

Renoprotective Effects of Febuxostat and Allopurinol in Patients with Hyperuricemia and CKD: A Meta-Analysis

Sherida N. Edding, Monica Therese Cating-Cabral, Brian Michael I. Cabral. *St. Luke's Medical Center - Global City, Taguig City, Philippines.*

Background: Hyperuricemia is associated with rapid deterioration of renal function in patients with chronic kidney disease (CKD). The two most common urate-lowering drugs available are allopurinol and febuxostat. Randomized controlled trials and observational studies have shown that the individual drugs have potential to slow down deterioration of renal function in CKD patients. However, it is unclear which drug is more effective because of insufficient direct comparison between the two. Hence our study aims to perform a meta-analysis to assess the renoprotective and urate-lowering effects between the two drugs in patients with CKD and hyperuricemia.

Methods: A comprehensive literature search using PubMed was performed with the following search terms: febuxostat, allopurinol, chronic kidney disease, renoprotection. Five relevant studies were selected and analyzed using Cochrane Revman v5.3. Outcomes assessed were changes in estimated glomerular filtration rate, serum creatinine, level of proteinuria and/or albuminuria and change in serum uric acid levels.

Results: Five studies comprising 606 patients were selected – 304 treated with febuxostat and 302 with allopurinol. No significant differences were found in the changes in serum creatinine (mean difference (MD) -0.02; CI -0.07, 0.03; P = 0.39) and eGFR (MD 2.09; CI -0.67, 4.84; P = 0.14) from baseline to 3 months between the two group. Significant difference in the change in eGFR, favoring Febuxostat, was observed after 6 months (MD 4.94; CI 2.25, 7.64, P = 0.003). Significant decrease in proteinuria (MD -0.24; CI -0.42, -0.07, P = 0.007) and albuminuria (MD -80.47, CI -149.29, -11.64, P = 0.02) were observed more in the febuxostat group after 3 months; however these changes were not significant after 6 months. Serum uric acid levels were significantly more reduced in the febuxostat group both after 3 (MD -0.90; CI -1.14, -0.67, P < 0.00001) and 6-months (MD -1.50; CI -1.70, -1.30, P < 0.00001).

Conclusions: Our study showed that febuxostat might be more renoprotective (as measured by eGFR change in 6 months) and offers a better anti-proteinuric and urate-lowering effect. However, more studies are needed to assess its efficacy across the spectrum of CKD, including those requiring hemodialysis and post-transplant patients.

PO0567

CKD Is Associated with Attenuated Plasma Metabolome Response to Oral Glucose Tolerance Testing

Armin Ahmadi,[1] Brian J. Bennett,[1,6] Jorge Gamboa,[4] Leila R. Zelnick,[2] Daniel Raftery,[3] Ian H. de Boer,[4,5] Baback Roshanravan.[1] *[1]Department of Medicine, Division of Nephrology. University of California Davis, Davis, CA; [2]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [3]Anesthesiology and Pain Medicine, University of Washington, Seattle, WA; [4]Vanderbilt University School of Medicine, Nashville, TN; [5]Puget Sound Health Care System, Seattle, WA; [6]Obesity and Metabolism Research Unit, Western Human Nutrition Research Center, USDA, ARS, Davis, CA.*

Background: Chronic kidney disease (CKD) is associated with decreased anabolic response to insulin contributing to protein-energy wasting. Targeted metabolic profiling of the response to oral glucose tolerance testing (OGTT) may help identify metabolic pathways contributing to disruption in incretin response.

Methods: Using targeted metabolic profiling, we examined the plasma metabolome in 58 moderate to severe non-diabetic CKD patients with estimated glomerular filtration rate (eGFR)<60ml/min per 1.73m^2 and 37 healthy controls with normal eGFR before and after 2h of 75g oral glucose challenge. We used linear mixed effect models adjusting for potential confounders of age, sex, race, and body weight to determine the interaction of eGFR and change in metabolites in response to OGTT by CKD status. Pathway analyses were performed using Metaboanalyst.

Results: CKD patients had lower eGFR compared to healthy control (37.3 ± 12.5 Vs. 89.3 ± 17.1 ml/min per 1.73m^2). Oral glucose challenge was associated with a marked reduction in a wide array of metabolites, predominantly amino acids, TCA cycle intermediates, and bile acids. CKD status was associated with attenuated OGTT induced prominent changes in pathways of taurine metabolism, phenylalanine, tyrosine and tryptophan biosynthesis, nicotinamide metabolism, and TCA cycle (Figure 1).

Conclusions: Targeted plasma metabolic profiling in response to OGTT suggests a broad disruption of amino acid and mitochondrial energy metabolism in CKD patients. These findings motivate further investigation into the incretin response in patients with CKD and the impact of incretin mimetics such as GLP-1 receptor agonist.

Funding: NIDDK Support

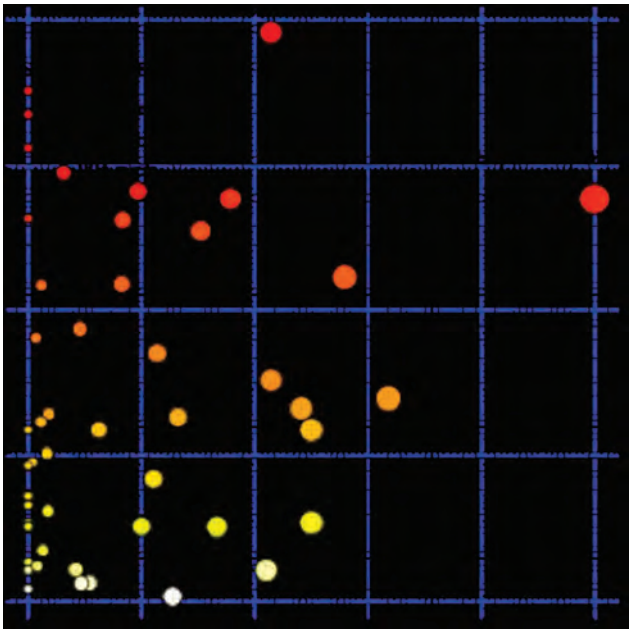

Figure 1: Pathway analysis of OGTT challenege in CKD vs control subjects.

The Effects of Allopurinol on the Progression of CKD According to Baseline Serum Urate Level: Results from Post Hoc Analyses of the CKD-FIX Trial

Anushree Tiku,[1] Elaine Pascoe,[2] Neil Boudville,[3] Alan Cass,[4] Nicola Dalbeth,[5] Richard O. Day,[6] Janak de Zoysa,[5] Bettina Douglas,[2] Randall Faull,[7] David Harris,[8] Carmel Hawley,[2] Graham R. Jones,[9] John Kanellis,[10] Suetonia Palmer,[11] Vlado Perkovic,[1] Gopi Rangan,[12] Donna Reidlinger,[2] Laura Robison,[2] Robert J. Walker,[11] Giles Walters,[13] David W. Johnson,[2] Sunil Badve.[1] *[1]George Institute for Global Health, Sydney, NSW, Australia; [2]The University of Queensland, Saint Lucia, QLD, Australia; [3]The University of Western Australia, Perth, WA, Australia; [4]Menzies School of Health Research, Casuarina, NT, Australia; [5]The University of Auckland, Auckland, New Zealand; [6]St Vincent's Health Australia Ltd, Bondi Junction, NSW, Australia; [7]The University of Adelaide, Adelaide, SA, Australia; [8]The University of Sydney, Sydney, NSW, Australia; [9]University of New South Wales, Sydney, NSW, Australia; [10]Monash University, Clayton, VIC, Australia; [11]University of Otago, Dunedin, New Zealand; [12]Westmead Hospital, Westmead, NSW, Australia; [13]Australian National University, Canberra, ACT, Australia.*

Background: Allopurinol did not slow decline in estimated glomerular filtration rate (eGFR) over 2 years in patients with chronic kidney disease (CKD) at risk of progression in the CKD-FIX trial. We assessed the effect of allopurinol on eGFR slope by baseline serum urate level.

Methods: In this trial, 369 adults with stage 3 or 4 CKD, without history of gout, and either urinary albumin-to-creatinine ratio ≥265 mg/g or eGFR decrease ≥3.0 mL/min/1.73 m^2 in the preceding year, were randomized to allopurinol or placebo. The primary outcome was change in eGFR up to 104 weeks using the CKD-EPI creatinine equation. This post hoc subgroup analysis describes outcomes in 352 participants according to baseline serum urate level (normouricemic and hyperuricemic [serum urate >6 mg/dL in women and >7 mg/dL in men], and tertiles of baseline serum urate level).

Results: At baseline, 65 (18.5%) and 287 (81.5%) participants had normouricemia and hyperuricemia, respectively. The mean serum urate level in the normouricemic group was 5.9 mg/dL (4.8 mg/dL for women, 6.1 mg/dL for men), and mean serum urate in the hyperuricaemic group was 8.7 mg/dL (8.3 mg/dL for women and 8.9 mg/dL for men). There were no significant differences in change in eGFR between allopurinol and placebo in normouricemic (mean difference [MD] 0.35, 95%CI -2.72 to 3.42 mL/min/1.73 m^2/year) and hyperuricemic (MD -0.06, 95%CI -1.20 to 1.08 mL/min/1.73 m^2/year) participants (interaction P value = 0.84). The mean serum urate levels in the lowest, middle and highest tertiles were 6.3 mg/dL, 8.0 mg/dL and 10.0 mg/dL, respectively. The result for the primary outcome was consistent across all tertiles of baseline serum urate level (interaction P value for subgroup analysis = 0.49).

Conclusions: In CKD patients at risk of progression, the effect of allopurinol on eGFR decline was not modified by baseline serum urate.

PO0569

CKD Progression End Points as Potential Surrogates for Kidney Failure: Findings from the CKDopps

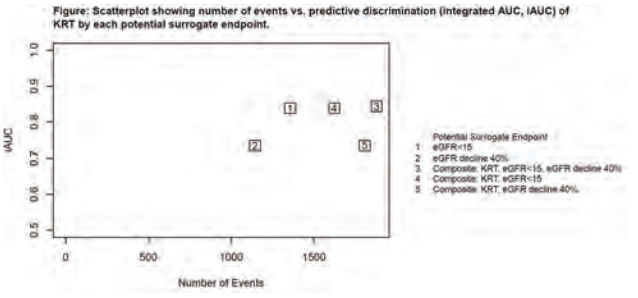
Jarcy Zee,[1] Daniel G. Muenz,[1] Keith McCullough,[1] Brian Bieber,[1] Marie Metzger,[2] Natalia Alencar de Pinho,[2] Antonio A. Lopes,[3] Danilo Fliser,[4] Bruce M. Robinson,[1] Eric W. Young,[1] Ronald L. Pisoni,[1] Benedicte Stengel,[2] Roberto Pecoits-Filho.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]French Institute of Health and Medical Research (INSERM), Villejuif, France; [3]Department of Internal Medicine, Federal University of Bahia, Salvador, Brazil; [4]Universitatsklinikum des Saarlandes und Medizinische Fakultat der Universitat des Saarlandes, Homburg, Germany.*

Background: Many potential surrogate endpoints for kidney failure (KF) have been used in clinical trials and observational studies of chronic kidney disease (CKD). Individual and composite surrogate endpoints must be compared to ensure accurate research that maximizes power and facilitates harmonization across studies, particularly among an international sample of advanced CKD patients.

Methods: Using data from CKD stage 3-5 patients from Brazil, France, Germany, and the US enrolled in the CKD Outcomes and Practice Patterns Study (CKDopps), we defined potential individual surrogate KF endpoints based on reaching (1) eGFR<15 mL/min/1.73m^2 and (2) eGFR decline of ≥40%, and composite surrogate endpoints that combine (1) and (2) with and without kidney replacement therapy (KRT, dialysis or transplant). We used each individual and composite endpoint as a time-varying indicator in an unadjusted Cox model to predict time from study entry to the hard outcome of KRT. Potential surrogate endpoints were compared by number of events and prediction accuracy (integrated area under the time-varying receiver operating curve [iAUC]).

Results: N=5242 patients had median (IQR) baseline eGFR of 26.8 (20.7-35.5) and 1448 KRT events over a median (IQR) follow-up time of 2.7 (1.2-3.0) years. Potential surrogate endpoints that included eGFR<15 had higher prediction discrimination compared with those that only included 40% eGFR decline (Figure, iAUCs of 0.83-0.84 vs. 0.73-0.73). Composite endpoints had higher event counts than non-composite endpoints (Ns of 1622-1878 vs. 1144-1356, see Figure x-axis).

Conclusions: A composite KF endpoint defined by the earliest occurrence of either KRT, eGFR<15, or eGFR decline of 40% had the highest prediction discrimination for KRT and the highest number of events among a cohort enrolled at low eGFR. This endpoint should be further evaluated and considered for clinical research studies to optimize power while sufficiently capturing KF.



PO0570

Treatment for CKD: A Systematic Literature Review and Population Comparison

Juan Jose Garcia Sanchez,[1] Juliette C. Thompson,[2] David A. Scott,[2] Naveen Rao,[1] Elisabeth SOrstadius,[3] Glen James,[1] Stephen Nolan,[1] Eric T. Wittbrodt,[4] Alyshah Abdul Sultan,[1] Bergur V. Stefansson,[3] Dan Jackson,[1] Neil S. Hawkins,[2] Keith R. Abrams.[2] *[1]BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom; [2]Visible Analytics, Oxford, United Kingdom; [3]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [4]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD.*

Background: DAPA-CKD is the first renal outcomes trial assessing the efficacy and safety of a sodium–glucose cotransporter-2 inhibitor, dapagliflozin, vs placebo, added to standard of care in patients with chronic kidney disease (CKD) with/without type 2 diabetes (T2D). Several other agents have been or are currently under investigation for their effect on renal and cardiovascular outcomes in CKD; however, comparisons of efficacy are challenging, due to differences in study design, duration, patients and endpoint definitions. We conducted a systematic literature review of randomized controlled trials (RCTs) in CKD, with the aim of assessing inter-study comparability.

Methods: Searches of MEDLINE, Embase, the Cochrane Central Register of Controlled Trials and grey literature sources were conducted to identify phase 3–4 RCTs of adults (≥18 years) with albuminuric CKD with/without T2D, published in English between 1990 and March 25, 2020. Studies of ≥12 weeks duration that reported clinical outcomes, adverse events, quality of life or patient-reported outcomes for pharmacologic CKD treatments were eligible for inclusion.

Results: Preliminarily, 13,451 unique citations were identified, and 204 full-text manuscripts were included after abstract screening **(Figure)**. Data from 81 RCTs were included: 24, 39 and 18 in patients with CKD with/without T2D, CKD with T2D and CKD without T2D, respectively.

Conclusions: As anticipated, differences in the inclusion of patients with/without T2D between studies make comparisons difficult. Future work will compare additional relevant study characteristics, with further insights available in October 2020.

A New Vision for Nephrology Trials in Canada

Alicia Murdoch,[2] Francois Madore,[1] Dwight Sparkes,[2] Karthik K. Tennankore,[3] Arris H. Vorster,[2] Rita Suri.[4] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Can-SOLVE CKD Network, Vancouver, BC, Canada; [3]Dalhousie University, Halifax, NS, Canada; [4]McGill University, Montreal, QC, Canada.*

Background: The Canadian Nephrology Trials Network (CNTN) was established in 2014 to improve the quantity and quality of clinical trials in nephrology in Canada. With inception of the Canadians Seeking Solutions and Innovations to Overcome Chronic Kidney Disease (Can-SOLVE CKD) Network in 2016, CNTN received additional funding to expand its mandate. We surveyed and assembled a broad cross-section of Canadian kidney patients, nephrology researchers, and other relevant stakeholders in order to establish an expanded new vision for CNTN.

Methods: In July-August 2018, we administered two separate surveys – one to patient members of Can-SOLVE CKD and the second to members of CNTN and other Canadian nephrology investigators. We then conducted a two-day visioning workshop in September 2018 to discuss how best to support nephrology research in Canada. Over 40 stakeholders participated, including 10 patients, 22 researchers, and members of the Can-SOLVE CKD Operations Team.

Results: Through the survey, we identified two issues that were at least moderately challenging: inability to facilitate multi-site trials (81%) and lack of engagement with community sites (74%). Three key themes emerged from the visioning exercise: peer review, training, and engagement. A summary report captured workshop discussions and was used to inform revisions to CNTN's structure and governance. Three new working committees were created: Capacity Building, Communication and Engagement, and Scientific Operations; as well as a governing Executive Committee. Each committee is co-chaired by a nephrologist and patient, who take turns leading the Executive Committee.

Conclusions: With its new vision and committee structure, CNTN aims to promote a culture of collaboration within the Canadian kidney community and integrate patients into research. The network offers resources to enhance nephrology researchers' ability to conduct clinical trials, directly involve patients in designing studies, and motivate change in patient care based on patient priorities through increased peer review, engagement, and training.

PO0572

Implementation of Surprise Question Assessments Using the Electronic Health Record in Older Adults with Advanced CKD

Natalie C. Ernecoff,[1] Khaled Abdel-Kader,[2] Manqi Cai,[1] Jonathan Yabes,[1] Jane O. Schell,[1] Manisha Jhamb.[1] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Vanderbilt University, Nashville, TN.*

Background: The Surprise Question (SQ; "Would you be surprised if this patient died in the next 12 months?") is a validated prognostication tool for mortality and hospitalization among patients with advanced CKD. Yet, barriers in clinical workflow have slowed SQ implementation into practice. We sought (1) To evaluate implementation outcomes following use of electronic health record (EHR) decision support to automate collection of the SQ, and (2) To assess the prognostic utility of the SQ for mortality and hospitalization/emergency room (ER) visit.

Methods: We developed and implemented a synchronous decision support [best practice alert (BPA)] algorithm in the electronic health record (EHR) to identify patients attending an outpatient nephrology follow-up visit who were ≥ 60 years of age with an eGFR<30. At the time of the visit, a 'pop-up' BPA was triggered, prompting the physician to answer the SQ (dichotomized). To evaluate implementation, we assessed provider response rate, and efficiency of responses. We assessed the SQ's prognostic utility in survival and time-to-hospital encounter (hospitalization/ER visit) analyses. We abstracted EHR data on patient sociodemographics and clinical characteristics. Physicians provided their demographic and clinical practice characteristics.

Results: Among 510 unique patients for whom the BPA triggered, 95 had the SQ completed (18.6%) by 16 unique providers. Among those patients with completed SQ, nearly all providers (97.9%) completed the SQ on the clinic appointment day, and 61 (64.2%) the first time the BPA fired. Providers answered "No" for 27 (28.4%) and "Yes" for 68 (71.6%) patients. By 12 months, 6 (6.3%) "No" patients died; 3 (3.2%) "Yes" patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]). About 40% of "No" patients and 25% of "Yes" patients had a hospital encounter by 12 months (HR 1.85, CI[0.927, 3.689]).

Conclusions: We successfully integrated the SQ into the EHR for routine collection to aid in clinical practice. Our response rate indicates additional implementation efforts are needed to encourage further integration of the SQ in clinical practice. Consistent with prior research, the SQ has reasonable prognostic utility for mortality and future hospital encounters.

Telehealth for Adults with CKD: A Systematic Review and Meta-Analysis

Li Luo,[1] Min Zhang,[1] Dingjun Zhang,[1] Huifen Chen,[1] La Zhang,[3] Bingqing Xia,[1] Jiaowang Tan,[2] Chendi Dong,[1] Yanmin Xu,[1] Xusheng Liu,[3] Yifan Wu.[3] *[1]The Second Clinical College, Guangzhou University of Chinese Medicine, Guangzhou, China; [2]Renal Division, Bejing University of Chinese Medicine Shenzhen Hospital, Guangzhou, China; [3]Renal Division, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine (Guangdong Provincial Hospital of Chinese Medicine), Guangzhou, China.*

Background: Evidence has supported improved quality of CKD care when assisted with telehealth, while these results were predominantly based on cohort observation or small-scale randomized controlled trials(RCTs). Moreover, robust findings regarding its effects on endpoints were still limited. This study thus aimed to evaluate impacts of telehealth on non-dialysis CKD patients.

Methods: This study was conducted and reported according to PRISMA statement. We searched databases including MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), Chinese Biomedicine Database (CBM), Chinese National Knowledge Infrastructure (CNKI), Wanfang Database and VIP Database until 2019 April. Relevant studies regarding telehealth for non-dialysis CKD population were screened, reviewed, selected and assessed of quality for systematic review and meta-analysis. The protocol was registered at PROSPERO(CRD42017073665).

Results: Eighteen trials involving 4749 patients were included for systematic review and 4 for further meta-analysis. The qualitative study summarized different study population, telehealth intervention type(consultation, education, monitoring) and variable results of outcomes measured(endpoints, surrogate values, patient-centered outcomes). The quantitative analysis comparing the telehealth and control group detected no significant difference in systolic blood pressure(SBP), diastolic blood pressure(DBP) and serum creatinine(SCr) at 12 months, but found significantly lower SCr level at 6 months, preserved estimated glomerular filtration rate(eGFR) at 6 months and at 12 months in telehealth group.

Conclusions: This study detected advantages of telehealth on delaying CKD progression but uncertain impacts on decreasing endpoint incidence.

Funding: Government Support - Non-U.S.

PO0574

Telenephrology Care for Veterans in the COVID-19 Pandemic

Juan D. Salcedo Betancourt,[1] Carlos A. Torres,[1] Yanetsy Olivera Arencibia,[1] Vasuki N. Venkat,[1,2] Daniel J. Soberon,[1,2] Marco A. LadinoAvellaneda.[1,2] *[1]University of Miami School of Medicine, Miami, FL; [2]Miami VA Healthcare System, Miami, FL.*

Background: Chronic kidney disease (CKD) affects 37 million adults in the United States. Since 2013 our Nephrology section has carried out a telenephrology clinic and implemented electronic consults (E-consults). During the COVID-19 pandemic, we implemented changes to evaluate patients with kidney disease. The aim of this study is to report our experience.

Methods: This is a single-center, retrospective chart review study, which evaluated the effect of our telenephrology clinic (video-on-demand and telemedicine clinic visits), as well as E-consults. Between January 2013 and 2020, 410 patients were seen at telemedicine clinic visits, and 1020 E-consults were evaluated. During the COVID-19 pandemic, between March 2020 and May 2020, 40 patients were assessed through video-on-demand.

Results: For telemedicine, a total of 169 patients were included, 99.4% were males, and 87% were white. The mean age was 66 ± 10 years, 92% had hypertension, and 41% diabetes mellitus. The baseline eGFR was 45 ± 14 ml/min/1.73m2. A one-way analysis of variance was conducted showing a statistically significant reduction on the systolic (SBP) and diastolic (DBP) blood pressure (p-value = 0.000), and improvement in potassium and bicarbonate levels (p-value = 0.000). Phosphorus levels did not show a significant difference (p-value 0.37). There was a significant association between attendance to >3 telenephrology visits and SBP control (p-value=0.027), DBP control (p-value=0.002) and potassium improvement (p-value=0.013). The overall decrease in GFR was 1.2 ± 11.1 ml/min/1.73 m2 (95% CI -0.41 to 2.95), lower than the reported natural progression of CKD (1.03 ml/min/1.73 m2/year). A survey for the video-on-demand patients showed 100% satisfaction, reflecting that patients felt their renal care needs were fulfilled. E-consults were answered in less than 24 hours, with 100% satisfaction from primary care physicians.

Conclusions: This is the first study evaluating the use of telenephrology in patients with kidney disease during the COVID-19 pandemic. In our cohort, telenephrology interventions improved SBP, DBP, bicarbonate, and potassium control. All three options improved health outcomes and guaranteed safety during the COVID-19 pandemic, at a reduced cost for the patient and the institution.

PO0575

Telenephrology: A Feasible Option for Inmates

Maxwell Butler, Laura J. Maursetter. *University of Wisconsin-Madison, Madison, WI.*

Background: Socioeconomic and racial disparities are factors that contribute to the disproportionately high burden of chronic disease amongst the incarcerated population in the United States. Access to care can be compromised because of the burden of cost to a facility, lack of staff to transport patients and physical distance from specialists. Telenephrology has been shown to be a feasible option in the correctional setting for specialties such as mental health, infectious disease, cardiology, and primary care, but has not been studied in nephrology. In this quality improvement study, we showed telenephrology is a feasible option that can be implemented for CKD and hypertension management.

Methods: Using quality improvement methodology, data was collected from the electronic medical record for all telenephrology appointments from January 2015 to June 2019. Demographic data, comorbidities, appointment compliance, and clinical data including eGFR and blood pressure were tracked for analysis. Data for patients seen over a period of at least 3 years were included in the CKD progression portion and those seen at least 4 times for the blood pressure management.

Results: There were 871 appointments schedule over the 4.5 year period with 86% completed. Technology limited 3.5% of the cancelled appointments. The population was predominantly men (96%) of black race (51.9%) with hypertension (78%) and CKD (75.2%) being the most common comorbidities. There were 214 patients included in the analysis for management of CKD that showed an average annual change in eGFR of -1.57 mL/min/1.73 m^2 (95% CI: -2.87 to -0.27). There were 79 included in the hypertension analysis with 19.0% achieving a goal BP of ≤130/80 mm Hg and 63.3% achieving a BP of ≤140/90 mm Hg.

Conclusions: Telenephrology can be successfully carried out in the correctional facility population with a low number of cancellations due to technology. The study sample showed mild-to-moderate CKD progression consistent with previously reported population rates of eGFR decline suggesting comparable management. The smaller subset in hypertension showed control that was less than the rates achieved in a nationally representative sample of CKD patients (52% and 75%). This marks an area that requires improvement. Continued rising referrals to telenephrology suggest provider acceptance but it is important to study and adjust management to provide at least equal care as in person visits.

PO0576

Nephrology eConsultation: The "Curb Side" Consult for the 21st Century

David Levy, Rickinder Grewal, Scott E. Liebman, Thu H. Le. *University of Rochester School of Medicine and Dentistry, Rochester, NY.*

Background: The Nephrology Division at the University of Rochester receives on average 120 new outpatient referrals per month. While every effort is made to see new referrals promptly, this demand exceeds the capacity to evaluate these patients in a timely manner. To decrease waiting time and increase efficiency, we developed a Nephrology eConsultation program. Here we report our experience with time and value-based metrics as well as primary care provider (PCP) satisfaction.

Methods: After a year-long pilot phase, in September 2019 we expanded the eConsult program to provide electronic nephrology consultation to PCPs across the University health system for renal-related issues such as mild to moderate acute kidney injury, CKD, electrolyte disturbances, and proteinuria.

Results: Within the first 8 months of the expanded program, 110 eConsult requests were received. Of these, 62 were deemed medically appropriate and completed, with 46 (74.2%) related to acute kidney injury, CKD, or azotemia, 6 (9.7%) related to electrolyte imbalances, and 4 (6.5%) related to proteinuria. The mean time for a nephrologist to complete an eConsult was 18.3 minutes (Table 1). Of the 48 deemed inappropriate for eConsults, 36 (75%) were converted to in-person visits due to complexity (Table 2). All eConsults were completed within 67 hours (mean time 15.5 hours). Survey of PCP satisfaction showed that 68% of PCPs were very satisfied and 32% were satisfied with the nephrology eConsult program.

Conclusions: eConsultation in Nephrology has the potential to provide timely, cost effective, and remote guidance to PCPs for more straightforward questions, while prioritizing the limited resource of face-to-face nephrology consultation for patients with more complex diseases. This also offers financial advantages, as the work relative value units (wRVUs) for eConsult is 0.7, or up to 2.8 wRVUs per hour in our model. eConsultation in Nephrology could also be integrated with the rapidly evolving field of telemedicine to improve delivery of care remotely and increase provider and potentially patient satisfaction.

Funding: Clinical Revenue Support

Table 1: Accepted eConsults

eConsult Diagnosis	Number of eConsults	Percentage of total completed eConsults (%)	Mean time to complete eConsult (minutes)
CKD, AKI and Azotemia	46	74.2	18.2
CKD Stage 1-4	36	58.1	18.0
CKD Stage 1-3	34	54.8	17.6
CKD Stage 4	2	3.2	25.0
Acute Kidney Injury	2	3.2	25.0
Proteinuria	4	6.5	17.8
Electrolyte imbalance	6	9.7	18.5
Azotemia (not CKD or AKI)	8	12.9	18.2
Other	6	9.7	18.0
Total	62	100.0	18.3

Table 2: Rejected eConsults

eConsult Diagnosis	Number of eConsults	Percentage of total rejected eConsults (%)	Reason for rejection
Acute Kidney Injury	2	4.2	Case complexity - face-to-face visit required
CKD Stage 3	6	12.5	Patient following with another nephrologist
CKD Stage 3	5	10.4	Case complexity - face-to-face visit required
CKD Stage 4	8	16.7	Patient following with another nephrologist
CKD Stage 4	3	6.3	Case complexity - face-to-face visit required
CKD Stage 5	1	2.1	
Hyperkalemia	3	6.3	
Hyponatremia	3	6.3	
Proteinuria	5	10.4	
Other	8	16.7	Condition not managed by nephrology
Other	3	6.3	PCP asking general question, not formal eConsult
Other	1	2.1	
Total	48	100.0

PO0577

Development of a Global CKD Personal Impact Index (CKD-PII) Assessing the Reality of Living with CKD

Mary F. James,[1] Corey Windett,[2] Jillian K. Guiglotto.[1] *[1]W2O, San Francisco, CA; [2]AstraZeneca, Wilmington, DE.*

Background: CKD affects >700M people globally, but its full burden and personal impact attributes (PIA)—impact on instrumental activities of daily living—are under-recognized. Quality of life (QoL) measures fail to show the full patient experience. A Global CKD-PII uncovering the direct and indirect daily impact of CKD on patients may improve understanding of disease burden and secondary complications. The development of the CKD-PII using a geographically diverse cohort of CKD patient-reported aggregate data is described.

Methods: A multiphase approach was used to develop CKD-PII. In Phase 1, social media landscape audit and qualitative interviews determined PIA to understand disease burden. Patient conversations within online communities gauged the social, economic and physical impact of CKD. Each attribute was assigned as high, medium or low impact based on the lexicon, overall sentiment and self-reported effect on patient's QoL. Qualitative, moderated phone interviews followed an engagement model, whereby key PIA and language and characterization of attributes were further explored. Findings of Phase 1 informed Phase 2, a quantitative survey. Data from both phases will culminate in the development of CKD-PII.

Results: Phase 1: Social media landscape analysis leveraged 12 months of relevant patient dialogues (n=156) and shortlisted 11 key PIA from >200M internet sources. Among the key PIAs identified, dietary impacts (19%), time lost to appointments/dialysis (45%) and mental health implications (44%) were rated as high impact. Qualitative interviews (n=15) uncovered key PIA identified consistently. Phase 2: An online survey questionnaire was administered to quantify the extent of patients' experience of PIA. The CKD-PII synthesizes data from all research phases into an insights and perspectives report evaluating global perspectives.

Conclusions: Uniquely, CKD-PII will use metrics to showcase the real-life impact of CKD, beyond QoL, providing insights into the patient experience that other studies do not typically address. The social media data facilitates understanding of critical issues and patient needs in an organic environment. This cohort of global patient-reported data will raise awareness of the deeper impact of CKD and develop tangible and realistic solutions for both patients and doctors to solve the challenges uncovered.

PO0578

Lowering Mortality in CKD Stage 3B and CKD Stage 4 with Increased Outpatient Nephrology Visits

Stephanie S. Cheung,[3] Michael Shen,[4] Hui Xue.[1,2] *[1]Kaiser Permanente San Diego Medical Center, San Diego, CA; [2]Kaiser Permanente Department of Research and Evaluation, Pasadena, CA; [3]Kaiser Permanente Orange County, Anaheim, CA; [4]Kaiser Permanente Orange County, Business Intelligence & Transformation, Santa Ana, CA.*

Background: Management of Chronic Kidney Disease(CKD) is complex requiring comprehensive evaluation of multiple organ systems. We hypothesized that more frequent outpatient nephrology visits is associated with lower mortality in advanced CKD patients.

Methods: CKD3B & CKD4 patients at Kaiser Permanente Southern California Orange County were followed from 2012 to 2018. Patients were divided into 4 groups based on initial eGFR per MDRD equation; eGFR 30-44, 25-29, 20-24, and 15-19. Each eGFR group was further divided by the number of annual nephrology visits(0, 1, 2, 3, and 4+). Patients who transitioned to dialysis, kidney transplant, or lost to follow up during the 7 years were excluded. Annual all-cause mortality was analyzed based on the number of nephrology visit in each eGFR category using ANOVA.

Results: The cohort consisted of 2943 individuals, 59% female, 41% male, mean age 77.4. 42% of patients were diabetic and 89% had hypertension. Lower starting eGFR had increased mortality over time while renal function stayed fairly stable. Increased outpatient visit was seen with lower eGFR during the follow up period, Figure 1. All CKD3B and CKD4 patients gained a statistically significant reduction in mortality when seen at least twice in nephrology clinic annually, $p<0.04$, in Figure 2. For eGFR ≤24, the mortality benefit was observed with 1 or more nephrology visit, $p<0.005$.

Conclusions: CKD stage 3B and 4 patients seen in nephrology clinic at least twice a year had improved survival. More frequent follow up was associated with lower eGFR. The relationship between the lower eGFR and the improved survival warrants further investigation.

PO0579

Uptake of Evidence-Based Recommendations to Improve Care for CKD Patients in the Kidney Coordinated Health Management Partnership (Kidney CHAMP) Study

Melanie R. Weltman,[1] Huiwen Chen,[2] Jonathan Yabes,[3,4] Manqi Cai,[4] Khaled Abdel-Kader,[5] Manisha Jhamb,[2] Thomas D. Nolin.[1,2] *[1]University of Pittsburgh School of Pharmacy, Pittsburgh, PA; [2]University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA; [3]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [4]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; [5]Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN.*

Background: Medication therapy in patients with chronic kidney disease (CKD) is focused on slowing CKD progression, managing causes of CKD, and preventing cardiovascular morbidity and mortality. The aim of this project was to assess the uptake of evidence-based medication recommendations (recs) provided to primary care providers (PCP) of patients with high-risk CKD by an interdisciplinary nephrology team.

Methods: This project is part of Kidney CHAMP, an ongoing NIH funded, pragmatic randomized controlled trial testing an electronic health record (EHR)-based population health management (PHM) approach to improve CKD care. Eligible patients are 18-85 years with CKD who have a high risk of progression to ESKD and are not being followed by a nephrologist. Patients in the intervention arm receive a nephrologist-led electronic consult and pharmacist-led telephonic medication therapy management (MTM). Recs are provided in the EHR for the PCP to review and order at the upcoming office visit. We focused on medication recs related to the progression of CKD and prevention of cardiovascular disease, which included use of RAAS inhibitors, SGLT2 inhibitors, GLP-1 receptor agonists, and HMG-CoA reductase inhibitors (statins).

Results: From July 1, 2019 to January 31, 2020, 125 patients received an e-consult and 121 patients received MTM. A total of 83 recs were provided to PCPs. Uptake of recs for initiation or dose escalation of RAAS inhibitors was the highest, with 19 of 46 recs (41%) being implemented. Two of eight recs regarding GLP-1 receptor agonists were implemented (25%) and two of 24 recs for SGLT-2 inhibitor initiation were implemented (8%). Five recs for statin initiation were made and none were implemented; however, baseline statin use was high at >75%.

Conclusions: Many patients with high risk CKD receive suboptimal care, which can be effectively identified by interdisciplinary nephrology teams using an EHR-based PHM platform. Uptake of RAAS inhibitor recs was highest. However, initiation of medications with recent FDA approved indications for CKD management remained poor. Future research is needed to identify barriers and strategies to increase uptake of evidence-based CKD recs and thereby improve patient care.

Interdisciplinary Care Improves Patient Preparedness for ESRD in a High-Risk Patient Population with CKD

Kalyan Prudhvi,[1,2] Kaltrina Sedaliu,[1,2] Michelle M. Estrella,[3] L. Ebony Boulware,[4] Michal L. Melamed,[1,2] Tanya S. Johns.[1,2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, Bronx, NY; [3]San Francisco VA Medical Center, San Francisco, CA; [4]Duke University School of Medicine, Durham, NC.*

Background: The Kidney Care Choice initiative has made improving the quality of care for patients with late-stage CKD a national priority. Interdisciplinary care (IDC), including nurse practitioner (NP) driven care coordination, is an intervention that may improve health outcomes in patients with CKD. Few studies have evaluated this model of healthcare delivery in racial-ethnic minorities.

Methods: We compared incident ESRD patients who received NP care coordination as part of our IDC clinic (n=84) to a contemporaneous cohort of incident ESRD patients (n=245) who received usual nephrology care alone at Montefiore Medical Center from 10/1/2013—10/31/2017. Clinical data were extracted using Clinical Looking Glass®, and chart reviews were done for validation. Patients included in our study had established care for CKD stage 4/5 and had at least one nephrology clinic visit within 3 months preceding their progression to ESRD. All patients were eligible for IDC, but receipt of IDC was limited by resource availability.

Results: Of the 329 incident ESRD patients included in our study, the mean age was 59.6 years (SD 13.8), 47% were female, and 86% were African American or Hispanic. The baseline characteristics were similar between the groups, except the IDC group had a lower prevalence of hypertension (60% vs 77%). The mean eGFR was 8 ml/min/1.73m^2 at dialysis initiation. Fifty percent of patients had an arteriovenous (AV) access prior to developing ESRD. However, compared to the usual care group, patients in IDC group were more likely to have a mature AV access at HD initiation (41% vs 33%); start HD as an outpatient (30% vs 19%); receive a preemptive transplant (4% vs 2%); do peritoneal dialysis (7% vs 4%); and be listed for kidney transplant (44% vs 15%) prior to developing ESRD. Receipt of IDC was associated with a higher odds (OR 3.9 [95% CI 2.0 - 7.8]; $P< 0.001$) of kidney transplant listing compared to usual care alone after adjusting for sociodemographic and clinical factors. Other outcomes also favored IDC but were not statistically significant.

Conclusions: Interdisciplinary care is associated with better ESRD preparedness compared to usual nephrology care alone in racial-ethnic minorities. Larger multicenter randomized studies are needed to determine the effectiveness of IDC among patients with advanced CKD.

Patient Outcomes Following Discharge from a CKD Clinic

Michael Che, Susan J. Thanabalasingam, Eduard A. Iliescu, Christine A. White. *Queen's University Department of Medicine, Kingston, ON, Canada.*

Background: In Ontario, Canada multidisciplinary care for patients with advanced chronic kidney disease (CKD) is delivered in Multi-Care-Kidney-Clinic (MCKC) operated by Regional Programs funded through a provincial network based on the number of eligible patients. These eligibility criteria were progressively revised between 2016 and 2018 from an absolute estimated glomerular filtration rate (eGFR) less than 30 ml/min/1.73m^2 to less than 15 ml/min/1.73m^2 or a two-year risk of end-stage kidney disease, calculated by the Kidney Failure Risk Equation (KFRE), greater than 10%. The objective of this study was to ascertain the outcomes of existing MCKC patients who were discharged as these criteria were implemented.

Methods: This is a retrospective cohort study of prevalent CKD patients in MCKC in 2013 in the region of South Eastern Ontario, followed to January 2020. The outcomes were discharge from MCKC, re-referral, initiation of kidney replacement therapy (KRT), and death. Data were extracted from electronic medical record. Death was ascertained through Ontario's Office of the Registrar General. Patients' 2 and 5-year KFRE scores were calculated using the 4-variable KFRE.

Results: Of the 643 MCKC patients in 2013 with available data, 470 (73%) continued follow-up in MCKC, while 142 (22%) and 31 (5%) were discharged to primary care and general nephrology respectively. Of those discharged to primary care, 52 (37%) died, while 15 (11%) were re-referred to nephrology, and 8 (6%) initiated KRT within median (IQR) times of 982 (560) and 850 (1411) days from discharge respectively. Five (63%) of the 8 discharged patients who required KRT did so for unforeseen acute illness rather than progressive CKD.

Conclusions: The results of this study suggest that gradually moving MCKC funding eligibility criteria from absolute eGFR level to one based on both eGFR and the KFRE prediction model resulted in the discharge of a significant number of patients. Notably, few of the discharged patients ultimately required KRT that could have been prevented. This study offers a regional perspective with low loss to follow-up as there is only one Renal Program in the region. The results may not be generalizable to different populations, health care systems, or predictive models. Further research is needed to establish the optimal KFRE criterion upon which MCKC funding eligibility can be based.

PO0582

Association of CKD with Early Heart Failure Readmissions in Adults

Si Li, Yichen Wang, Nasha Elavia, Bojana Milekic. *The Wright Center for Graduate Medical Education, Scranton, PA.*

Background: Heart failure is a complex chronic disease with multiple comorbidities that contribute to frequent hospitalization. We aimed to examine the impact of chronic kidney disease on the 30-day readmission rate among patients hospitalized with heart failure.

Methods: We performed a retrospective analysis of the National Readmission Database (NRD) 2016- 2017. We identified adult patients with a primary hospital diagnosis of heart failure. We compared baseline demographics and calculated all-cause 30-day readmission rates. Multivariate survey logistic regression was used to identify predictors of readmission.

Results: We identified a total of 865,328 patients admitted with heart failure. 839,625 patients were discharged alive. Among which 181,130 (21.5%) had at least one readmission within 30 days. The in-hospital mortality of index admissions and readmissions was 2.9% and 6.5%, respectively. The 30-day inpatient mortality was 4.0%. The mean length of stay of index admission and readmissions were 5.3 days and 6.4 days, respectively. The most common reasons for all-cause readmissions were acute on chronic heart failure (systolic, diastolic, combined), hypertensive heart and chronic kidney disease with heart failure, sepsis, acute kidney failure. After adjusting for multiple covariates, 30-day readmission was independently associated with chronic kidney disease [adjusted odds ratio (aOR) 1.2, 95% confidence interval (CI) 1.17- 1.23, p<0.001], coronary artery disease (aOR 1.01, 95% CI 1.07- 1.11), chronic obstructive pulmonary disease (COPD) (aOR 1.20, 95% CI 1.18- 1.22). Younger age, lower-income, discharge from larger hospitals were also predictive.

Conclusions: Further prospective studies with focus on multilevel interventions are needed to help reduce early readmission associated significant morbidity and resource utilization for this high-risk population.

Table 1. Independent predictors of heart failure readmission

Machine Learning (ML) Driven CKD Care Navigation Confers Robust Value Through Adoption of Home Dialysis and Transplantation

Titte Srinivas,[1,2] Ray Morales,[2] Suji Lee,[2] Michael Phillips.[2] *[1]University Hospitals, Cleveland, OH; [2]Intermountain Health Care Inc, Salt Lake City, UT.*

Background: The ESRD patient journey is an abyss of lost opportunity for home dialysis or transplantation (Tx). Despite known value of home dialysis (Home hemodialysis (HHD), Peritoneal Dialysis (PD)) and Tx, CKD patients default to in center hemodialysis (IC-HD) after crashing into ESRD. This picture exists absent upstream navigation with management of comorbidity and misaligned fee for service economic forces incenting IC-HD. We report early results of ML directed care navigation upstream of CKD and multidisciplinary co management (Primary care (PCPs) and Nephrology) driving greater adoption of Tx and HHD/PD in a large integrated health system in the intermountain West.

Methods: A custom-built ML algorithm identified chronic kidney disease (CKD) patients using synthetic data from multiple Electronic Health Record sources. Features used to identify CKD included but were not limited to eGFR, other laboratory values, ICD-10 codes, comorbidity clusters, CKD risk factors (DM, HTN etc.), scheduling data, DRG data, biopsy and imaging data. ML output triggered workflows of Kidney Care Navigators (KCNS) who, using a customer relationship management utility (CRM) co-managed comorbidity of CKD with PCPs and navigated patients to nephrology consultation aiming improved HHD/PD/Tx adoption rates

Results: Over 6 mo, among 12000 CKD records, the ML algorithm identified 1898 patients not seen by a nephrologist. KCNs interfaced with PCPs co-managing ESRD and CKD patients using CRM;1169 unique patients generated 1873 workflows (Fig, A); 58 PC of ESRD pts. adopted HHD/PD and pre emptive Tx vs. historic averages of 12 percent. Fig, B.; 7 year Net Present Value, $ 28,000,000 vs. Capital outlay of $2,00,000 (Fig., C).

Conclusions: 1) ML-Driven CKD Care Navigation conferred robust value through five-fold increased home dialysis/transplant adoption in a large integrated health system. 2) Our approach is generalizable across EHRs and with synthetic data ML, allows multi-institutional collaboration or consortia to deliver value in CKD at scale.

A Medication Use Evaluation of Patiromer in a Clinical Practice Setting at a Veteran's Affairs Medical Center

Danielle N. Cooney,[2] Emily M. Fox,[2] Mary Beth Low,[2] Niraj Desai.[1,2] *[1]Case Western Reserve University, Cleveland, OH; [2]Louis Stokes VA Medical Center, Cleveland, OH.*

Background: Patiromer is cation exchange polymer approved for treatment of hyperkalemia. There is limited data regarding the utility, adverse effects, frequency of laboratory monitoring and discontinuation rate of Patiromer in a clinical practice setting.

Methods: We performed a retrospective, observational review of veterans prescribed one or more doses of patiromer between 10/2015 and 11/2019 at the Veterans Affairs Northeast Ohio Hospital System (VANEOHS), to evaluate changes to RAAS inhibitor therapy, adverse effects resulting in patiromer discontinuation, and monitoring of serum potassium level. Patiromer prescription characteristics, concomitant medications, laboratory characteristics and adverse effects were collected for each veteran over the study time period. Baseline characteristics are reported as means; relative frequency of outcomes are reported as percentages.

Results: 69 Veterans with hyperkalemia were included for analysis. Mean age was 70 years, African-American race 29%, diabetes 90%, chronic kidney disease 91%, 17% ESRD on dialysis, and heart failure 36%. The most common patiromer dose was 8.4 g daily (78%), prescribed for a mean 274 (SD 3-1250) days. 21% of patients had repeat labs within 2 weeks and 54% within 4 weeks of patiromer initiation. 77% of patients achieved normokalemia (K< 5.0 meq/L) by the first follow up lab draw. Amongst 52 veterans with chronic, continuous patiromer use, 22 (41%) were taking RAAS inhibitors at baseline; 15 (29%) veterans either maintained or increased RAAS inhibitor dose over the study period. 28 (54%) discontinued patiromer with 7 (25%) veterans doing so due to GI complaints.

Conclusions: In a clinical setting at a Veteran's Affairs hospital, patiromer therapy preserved RAAS inhibitor use and improved serum potassium levels, but was discontinued at a high rate due to adverse effects

PO0585

The Practical Patterns of Medication and the Association Between CKD Stage and Polypharmacy: The Fukuoka Kidney Disease Registry Study

Masatoshi Hara,[1] Shigeru Tanaka,[2] Kumiko Torisu,[2] Masanori Tokumoto,[1] Kazuhiko Tsuruya,[3] Hiroaki Ooboshi,[1] Toshiaki Nakano,[2] Takanari Kitazono.[2] *[1]Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [3]Department of Nephrology, Nara Medical University, Kashihara, Japan.*

Background: Polypharmacy has emerged as one of the important medical and socioeconomic problems in an aging society. Chronic kidney disease (CKD) is also one of the important medical problems for older people. However, the extent to which CKD is involved in polypharmacy still has not been fully explored yet.

Methods: We examined 3,968 Japanese CKD patients using baseline data from a multicenter prospective cohort study in a cross-sectional manner. We used the baseline data of prescribed medicines on medical records. We evaluated the association between CKD stage and polypharmacy (defined as ≥6 medicines/day; Kojima T, et al. Geriatr Gerontol Int, 2012) using logistic regression analyses with adjustment for potential confounding factors.

Results: At baseline, the prescribed medicines varied between 0 and 17, and the median (interquartile range) was 5 (3–7). Among 3,968 CKD patients, 1,540 (38.8 %) patients showed polypharmacy. The multivariable-adjusted odds ratios for polypharmacy were 1.42 [95% confidence interval, 0.77–2.61] for G2, 1.44 [0.78–2.65] for G3a, 2.44 [1.34–4.49] for G3b, 4.00 [2.17–7.37] for G4 and 8.64 [4.53–16.5] for G5, respectively, compared with patients in the lowest category (G1) as the reference value. In the higher glomerular filtration rate (GFR) category (>G3b), many drugs, including angiotensin-2 receptor blockers, calcium channel blockers, uric acid synthesis inhibitors, proton pump inhibitors, aspirins, loop diuretics, and cation exchange resins were prescribed more frequently than the lower GFR category (≦G3a). In addition, aldosterone blockers, biguanides, fibrates, non-steroidal anti-inflammatory drugs, and sulfonylureas were continuously prescribed despite decreased GFR.

Conclusions: The higher GFR categories were independently associated with higher odds of polypharmacy. This might reflect the increasing prescription for managing to control symptoms caused by decreased GFR. We also have to pay more attention to prescribe medicines according to renal function.

PO0586

A Pilot and Feasibility Randomized Clinical Trial Targeting Sedentary Behavior in CKD: Sit Less, Interact and Move More (SLIMM) Study

Robert E. Boucher,[1] Guo Wei,[1,3] Tom Greene,[3] Srinivasan Beddhu.[1,2] *[1]Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; [2]Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT; [3]Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT.*

Background: Sedentary behavior (engaging in activities in the seated/ lying position) is highly prevalent and associated with mortality in CKD.

Methods: In a 24-week pilot and feasibility RCT, we tested the feasibility of a 'Sit Less, Interact, Move More (SLIMM)' intervention to replace sedentary activities with casual stepping activities in CKD. Participants wore an accelerometer for 7 days before randomization to measure baseline sedentary and stepping durations. In the SLIMM group (N=54), these data were used to develop individualized plans targeting sedentary behavior; accelerometry was repeated every 4 weeks to monitor adherence and to provide personalized feedback. The standard of care (SOC) group (N=52) were provided physical activity guidelines and underwent followup accelerometry at weeks 8, 16 and 24.

Results: Mean age was 69 ±13 yrs, 42% were women. 5%, 38%, 43% and 14% had CKD stages 2, 3A, 3B/4 and ESKD, respectively. Sedentary and stepping durations did not change in the SOC group. In the SLIMM group, the maximum decrease in sedentary duration, increase in stepping duration, and the number of steps/day, were seen at week 20 but attenuated at week 24 (Fig1). In separate linear mixed effects models (Table 1), overall treatment effects of the intervention on sedentary duration, stepping duration and the number of steps were not significant. The SLIMM intervention significantly reduced BMI and body fat%.

Conclusions: It is feasible to reduce sedentary duration and increase stepping duration in CKD but additional measures along with SLIMM intervention may be needed to sustain its effect on sedentary behavior.

Funding: NIDDK Support

Mixed effects models of treatment effects in SLIMM vs. Stand of Care groups

	Mean change (95% CI)	p-value
Sedentary duration, min/d	-15.6 (-41.0, 9.6)	0.22
Stepping duration, min/d	6.5 (-2.7, 15.6)	0.16
Number of steps/d	631 (-166, 1429)	0.12

PO0587

The Effects of Allopurinol on the Progression of CKD According to Baseline Kidney Function: Prespecified Analyses of the CKD-FIX Trial

Anushree Tiku,[1] Elaine Pascoe,[2] Neil Boudville,[3] Alan Cass,[4] Nicola Dalbeth,[5] Richard O. Day,[6] Janak de Zoysa,[5] Bettina Douglas,[2] Randall Faull,[7] David Harris,[8] Carmel Hawley,[2] Graham R. Jones,[9] John Kanellis,[10] Suetonia Palmer,[11] Vlado Perkovic,[1] Gopi Rangan,[12] Donna Reidlinger,[2] Laura Robison,[2] Robert J. Walker,[11] Giles Walters,[13] David W. Johnson,[2] Sunil Badve.[1] *[1]George Institute for Global Health, Sydney, NSW, Australia; [2]The University of Queensland, Saint Lucia, QLD, Australia; [3]The University of Western Australia, Perth, WA, Australia; [4]Menzies School of Health Research, Casuarina, NT, Australia; [5]The University of Auckland Faculty of Medical and Health Sciences, Auckland, New Zealand; [6]St Vincent's Health Australia Ltd, Bondi Junction, NSW, Australia; [7]The University of Adelaide Faculty of Health and Medical Sciences, Adelaide, SA, Australia; [8]The University of Sydney, Sydney, NSW, Australia; [9]University of New South Wales, Sydney, NSW, Australia; [10]Monash University, Clayton, VIC, Australia; [11]University of Otago, Dunedin, New Zealand; [12]Westmead Hospital, Westmead, NSW, Australia; [13]Australian National University, Canberra, ACT, Australia.*

Background: The CKD-FIX trial showed that allopurinol did not slow the decline of estimated glomerular filtration rate (eGFR) over 104 weeks in patients with chronic kidney disease (CKD) and risk of progression. In this study, we assessed the effect of allopurinol on change in eGFR according to CKD stage at baseline.

Methods: Three hundred and sixty nine adults with CKD stage 3 or 4, no history of gout, and who were at risk of progression (identified by either urinary albumin-to-creatinine ratio ≥265 mg/g or eGFR decrease ≥3.0 mL/min/1.73 m^2 in the preceding year) were randomized to receive allopurinol or placebo. Primary outcome was rate of change in eGFR up to 104 weeks using the CKD-EPI creatinine equation. This pre-specified subgroup analysis describes outcomes in patients with CKD stage 3 and stage 4.

Results: At baseline, 178 (49%) patients had CKD stage 3 (mean eGFR 41 mL/min/1.73 m^2, mean serum urate 7.9 mg/dL) and 185 (51%) patients had CKD stage 4 (mean eGFR 23.1 mL/min/1.73 m^2, mean serum urate 8.4 mg/dL). In patients with CKD stage 3, change in eGFR did not differ between the allopurinol (-3.67 mL/min/1.73 m^2/year, 95% CI -4.97 to -2.38) and placebo (-3.34 mL/min/1.73 m^2/year, 95% CI -4.59 to -2.09) groups (mean difference [MD], -0.33 mL/min/1.73 m^2/year, 95% CI -2.13 to 1.47). In patients with CKD stage 4, there was no difference in change in eGFR between the allopurinol (-2.89 mL/min/1.73 m^2/year, 95% CI -3.74 to -2.03) and placebo (-2.89 mL/min/1.73 m^2/year, 95% CI -3.73 to -2.04) groups (MD, 0.00 mL/min/1.73 m^2/year, 95% CI -1.18 to 1.17). The interaction P value for subgroup analysis was 0.87.

Conclusions: In CKD patients at risk of progression, the effect of allopurinol on eGFR decline was not modified by baseline kidney function.

Funding: Government Support - Non-U.S.

PO0588

Effects of the SGLT2 Inhibitor Dapagliflozin on Proteinuria in Non-Diabetic Patients with CKD (DIAMOND): A Randomized Double-Blind Cross-Over Trial

Hiddo J. L Heerspink,[1] Claire Dekkers,[1] David Cherney.[2] *[1]Department of Clinical Pharmacy and Pharmacology, University Medical Centre Groningen, Groningen, Netherlands; [2]Department of Medicine, Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada.*

Background: Sodium glucose co-transporter 2 (SGLT2) inhibition decreases albuminuria and reduces the risk of kidney disease progression in patients with type 2 diabetes. These benefits are unlikely mediated by improvements in glycemic control alone. We therefore examined the renal effects of the SGLT2 inhibitor dapagliflozin in patients with proteinuric kidney disease without diabetes.

Methods: A multicenter double-blind placebo controlled 6-week crossover study was performed in six hospitals in the Netherlands, Canada, and Malaysia. Patients (18-75 years old), without diagnosis of diabetes, 24-h urinary protein excretion >500 and ≤3500 mg/24h and estimated glomerular filtration rate (eGFR) ≥25 ml/min/1.73m^2 on stable renin angiotensin system blockade were included. Participants were randomly assigned to one of the two consecutive treatment periods of first placebo and then dapagliflozin 10 mg/day or vice versa. The primary outcome was percentage change from baseline in 24-h proteinuria. The main secondary outcome was change in iohexol measured GFR (mGFR).

Results: Fifty-eight patients were screened of whom 53 patients were randomized. Median baseline proteinuria was 1110 mg/24h (IQR 730, 1560) mg/24h; mean mGFR was 58.3 ml/min/1.73m^2 (SD 23). The difference in mean proteinuria change from baseline between dapagliflozin and placebo was 0.9% (95% CI: -16.6, 22.1; p=0.93). Compared to placebo, mGFR changed with dapagliflozin treatment by -6.6 ml/min/1.73m^2 (95% CI: -9.0, -4.2; p<0.0001) at week 6, which was completely reversible within 6 weeks after dapagliflozin discontinuation. Differences between dapagliflozin and placebo in body weight, systolic blood pressure and hematocrit were -1.5 kg (95% CI: -3.0, -0.03; p=0.0455), -3.6 mmHg (95% CI: -7.6, 0.4; p=0.0775) and 0.02 L/L (95% CI: 0.01, 0.03; p<0.0001). HbA1c did not change. The number of patients with adverse events during dapagliflozin treatment (n=17; 32.1%) and during placebo treatment (n=13; 25.0%) was similar. No hypoglycemic events were reported.

Conclusions: Six week treatment with dapagliflozin does not affect proteinuria in patients with chronic kidney disease without diabetes, but did induce acute and reversible decline in mGFR, body weight reduction, and increased hemoconcentration.

PO0589

The Impact of Decline in Renal Function on the Clinical and Economic Burden of CKD: An Application of the DAPA-CKD Cost-Effectiveness Model

Philip McEwan,[3] Juan Jose Garcia Sanchez,[1] Klas Bergenheim,[5] Oliver T. Darlington,[3] David C. Wheeler,[4] Hiddo J. L Heerspink.[2] *[1]AstraZeneca, Cambridge, United Kingdom; [2]University of Groningen, Groningen, Netherlands; [3]Health Economics and Outcomes Research Ltd., Cardiff, United Kingdom; [4]University College London, London, United Kingdom; [5]AstraZeneca, Gothenburg, Sweden.*

Background: The efficacy of dapagliflozin for the treatment of chronic kidney disease (CKD) was assessed in DAPA-CKD, which was stopped early for overwhelming efficacy. Cost-effectiveness analysis of new treatments plays an important role in the effective allocation of healthcare resources. The objective of this study was to develop a model for evaluating the cost-effectiveness of dapagliflozin based on the pending results of DAPA-CKD, and to demonstrate its functionality by characterizing the health economic burden of CKD progression from a UK payer perspective.

Methods: A lifetime microsimulation model was developed to estimate health economic outcomes in patients with CKD. Disease progression was modelled based on a linear decline in estimated glomerular filtration (eGFR) rate. Patients were eligible for renal replacement therapy (RRT) at end-stage renal disease. Life expectancy was estimated using a published risk equation of 10-year mortality in CKD patients. Incidence of cardiovascular (CV) events was linked to CKD stage based on published data. Outcomes were evaluated in two hypothetical patient cohorts with stage 3a CKD; one with standard eGFR decline (-0.65mL/min/1.73m^2 annually) and one with rapid eGFR decline (-4.20). Published cost and utility estimates were applied and discounted at 3.5%.

Results: CKD patients with rapid eGFR decline had a reduced life expectancy of 9.1 years compared with 6.4 years in those with standard rates of eGFR decline. Patients with rapid eGFR decline experienced an additional 326 CV events per 1,000 patients and spent an additional 0.4 years receiving RRT. Reduced life expectancy, increased rates of CKD progression and CV event incidence translated to 2.4 fewer quality adjusted life years gained in patients with rapid eGFR decline (5.5 versus 7.9) and an additional £937 of direct healthcare expenditure.

Conclusions: The DAPA-CKD cost-effectiveness model is capable of estimating health economic outcomes in patients with CKD, projecting health benefits and costs consistent with previously published estimates. This study shows that improved diagnosis and management of CKD may reduce the burden imposed by CKD on both patients and healthcare systems.

Development of a CKD Model in Cynomolgus Monkeys and Its Application to Test Zampilimab, a Monoclonal Antibody (mAb) Specific for Human Transglutaminase 2 (TG2)

Linghong Huang,[1] James Z. Song,[2] Timothy S. Johnson.[1] *[1]UCB Pharma, Slough, United Kingdom; [2]Prisys Biotechnology, Shanghai, China.*

Background: TG2, a crosslinking enzyme involved in wound healing, is linked to the development of renal fibrosis. TG2 irreversibly crosslinks proteins via ε(γ-glutamyl) lysine dipeptide bonds, including extracellular matrix (ECM) proteins. TG2 accelerates ECM deposition and renders the matrix resistant to ECM proteases, forcing ECM homeostasis towards accumulation. TG2 also crosslinks large latent TGFβ1 into the ECM, releasing the active pro-fibrotic TGFβ1 dimer. Zampilimab (IC50 0.2nM, K_d 120pm), a humanized mAb specific for human TG2, is under investigation for the treatment of fibrosis. Application of zampilimab in a primary human cell model of renal fibrosis had positive results; however due to human specificity, zampilimab efficacy cannot be tested in rodent *in vivo* models.

Methods: A unilateral ureteric obstruction model of CKD was developed in aged cynomolgus monkeys. Zampilimab was applied prophylactically immediately following model induction. TG2 activity was measured using an *in-situ* activity assay, and zampilimab target occupancy determined by competitive immunofluorescence. Renal fibrosis was measured by computerized image analysis and histopathological scoring of Masson's trichrome, Picosirius red and H&E stained slides with hydroxyproline measured by amino acid analysis.

Results: Ligation of the left ureter led to development of severe tubulointerstitial fibrosis with elevated TG2 antigen levels and activity, leading to end-stage histology by 6 weeks. This primate model has a greater expansion of the tubular basement membrane than similar rodent models, with histology more closely resembling obstructive disease in man. Following zampilimab intervention in a 4-week study, 7 days post final dose, TG2 activity remained completely inhibited at a high dose, whereas 70% of activity returned at a low dose. However, both zampilimab doses ameliorated the level of renal fibrosis by pathology score, computerized determination of fibrotic index and hydroxyproline.

Conclusions: Our primate model of CKD demonstrated that zampilimab can effectively block TG2 activity and prevent renal fibrosis. A Phase 1/2 study of zampilimab for the treatment of post-renal transplant fibrosis is ongoing (NCT04335578).

Conditional Deletion of Myeloid-Specific Mitofusin 2 Promotes Kidney Fibrosis

Divya Bhatia, Allyson M. Capili, Kiichi Nakahira, Thangamani Muthukumar, Augustine M. Choi, Oleh M. Akchurin, Mary E. Choi. *Weill Cornell Medicine, New York, NY.*

Background: Mitochondrial dysfunction is implicated in the pathogenesis of CKD. Mitochondrial dynamics regulate macrophage mitochondrial stress responses; we hypothesize that their impairment leads to kidney fibrosis. We determined the role of myeloid-specific mitochondrial fusion proteins (MFN)1 and MFN2 in PINK1-mediated mitophagy in experimental and human kidney fibrosis.

Methods: *Pink1*$^{-/-}$, myeloid-specific *Mfn1* (*LysM-Cre*$^{+/-}$*Mfn1fl/fl*), *Mfn2* (*LysM-Cre*$^{+/-}$*Mfn2fl/fl*) null mice and corresponding controls were subjected to unilateral ureteral obstruction (UUO,7-days) or adenine diet (AD,28-days). Kidneys, renal macrophages (RMs), bone marrow-derived macrophages (BMDMs), PBMCs, and plasma were analyzed by western blot, qPCR, Mito stress test, ELISA, immunohistochemistry, flow cytometry, confocal and electron microscopy. Patients with renal biopsy-proven interstitial fibrosis & tubular atrophy (IFTA,*n*=6) and severe-CKD (GFR<30 ml/min,*n*=15) were compared to controls (no IFTA,*n*=9) and mild/moderate-CKD (GFR≥30 ml/min,*n*=8).

Results: MFN1 and MFN2 expression decreased in kidneys after UUO or AD, and BMDMs after TGF-β1 treatment. AD-fed *LysM-Cre*$^{+/-}$*Mfn2fl/fl* but not *LysM-Cre*$^{+/-}$*Mfn1fl/fl* mice displayed increased renal expression of CD11b+F4/80+ macrophages than AD-fed controls. Increases in fibronectin, CD206, galectin-3, and TGF-β1 expression in the kidneys and RMs were higher in AD-fed *LysM-Cre*$^{+/-}$*Mfn2fl/fl* mice than AD-fed controls. TGF-β1-induced inhibition of mitophagy and increases in mitochondrial mass, size, and superoxide levels were greater in *LysM-Cre*$^{+/-}$*Mfn2fl/fl* RMs and BMDMs than *LysM-Cre*$^{+/-}$*Mfn1fl/fl* and controls. The reduction in colocalization of MFN2 but not MFN1 with renal mitochondria after UUO was higher in *Pink1*$^{-/-}$ mice. PBMCs from patients with severe-CKD showed higher superoxide levels and lower MFN2 expression than mild/moderate-CKD. IFTA was associated with lower renal expression of MFN1 and MFN2 and higher circulating CCL2 levels than controls. Decreased MFN2 and PINK1 expression in TGF-β1-treated human RMs was associated with increased fibrotic response.

Conclusions: This study is the first to suggest that myeloid-specific MFN2 but not MFN1 by regulating renal macrophage mitochondrial biogenesis and mitophagy prevents fibrosis. Mitophagy inducers may attenuate macrophage superoxide production and progression of kidney fibrosis.

PO0592

EZH2 Mediates Renal Fibrosis and Links Activation of Notch Signaling and Suppression of Klotho and BMP-7 Expression

Shougang Zhuang.[1,2] Shanghai East Hospital, Shanghai, China [1]*Rhode Isand Hospital, Brown University, Providence, RI;* [2]*Shanghai East Hospital, Shanghai Tongji University, Shanghai, China*.

Background: Our previous studies have shown that pharmacological blocking EZH2 (Enhancer of Zeste Homolog 2), a histone H3 lysine 27 methyltranferse, attenuates renal fibrosis in a murine model of renal fibrosis, but the underlying mechanism in this process remain undefined.

Methods: In this study, we used two highly selective EZH2 inhibitors and conditional knockout mice to evaluate the effect of EZH2 inhibition on renal fibrosis and activation of profibrotic signaling pathways and expression of renoprotective proteins in two murine models of chronic kidney disease (CKD) induced by UUO and 5/6 nephrectomy (SNx).

Results: Global inhibition of EZH2 by administration of gambogic acid or GSK-126 and conditional depletion of EZH2 in pericytes suppressed renal fibroblast activation and fibrogenesis in the kidney with UUO and SNx. Treatment with these inhibitors or EZH2 siRNA also inhibited serum- and TGF-β1-induced activation of renal fibroblasts in culture. Moreover, pharmacological and genetic inhibition of EZH2 suppressed expression of Notch-1, Notch-3, Jagged-1 and HES-1 and HEY-2 in vivo and in vitro. Similarly, inhibition of EZH2 was effective in inhibiting phosphorylation of extracellular signal-regulated kinase 1/2, AKT and NF-kB as well as expression of multiple profibrogenic cytokines/chemokines and renal macrophage infiltration. In contrast, EZH2 inhibitors prevented injury-induced downregulation of Klotho and BMP-7, two anti-fibrotic proteins in the kidney.

Conclusions: These results revealed that EZH2 may promote renal fibrosis and activation of renal fibroblasts by activation of Notch signaling, downregulation of Klotho and BMP-7 and induction of inflammation in the injured kidney. Targeting EZH2 may be a novel therapeutic strategy to treat CKD.

Kidney Targeted Renalase Agonist Peptide Rescues Severe Model of Cisplatin-Induced AKI and CKD

Xiaojia Guo,[1] Leyuan Xu,[1] Heino Velazquez,[1,2] Tian-Min Chen,[1] Ryan Williams,[3,4] Daniel A. Heller,[3] Robert L. Safirstein,[1,2] Gary V. Desir.[1,2] [1]*Yale University School of Medicine, New Haven, CT;* [2]*VAMC, West Haven, CT;* [3]*Sloan-Kettering Institute, New York, NY;* [4]*The City College of New York Division of Science, New York, NY*.

Background: Cisplatin (CP) causes Chronic Kidney Disease (CKD) upon repeated doses and limits its chemotherapeutic use. Renalase (RNLS) is a protein that activates kinases linked to survival and attenuates acute ischemic and CP-induced kidney injury. We now seek to target delivery of RNLS specifically to kidney to prevent CP-induced CKD.

Methods: CKD was induced in RNLS knockout (KO) (severe) and wild type (WT) mice by 2 doses of CP 15 mg/kg 2 weeks apart. The RNLS agonist peptide RP81 was synthesized and encapsulated in mesoscale nanoparticles (MNP) that target the kidney. Its cytoprotective activity was tested *in vitro* using TKPTS proximal tubule cells and *in vivo* using RNLS KO mice. RP81MNP or empty MNP was administered weekly for 4 weeks. Renal injury and function was evaluated by immunohistochemistry and plasma creatinine (Cr). The mechanism of action of RP81MNP was investigated using single cell RNA sequencing (scRNAseq) of whole kidney cells.

Results: MNP were retained intracellularly by TKPTS cells and were localized to proximal tubules *in vivo*. RP81MNP protected TKPTS cells from CP-induced cytotoxicity: cell viability was enhanced 3.5-fold, n=6, p<.05, compared to empty MNP. Naked RP81 increased cell viability 1.72-fold, n=6, p<.05 over BSA control. Compared to WT, CP in KO caused more severe AKI (Cr: 0.61 mg/dL ± 0.05 vs. 0.13±0.03 in WT, n=3, $p<0.05$), higher mortality (45% death at 4 weeks n=20, p<0.005), and more severe CKD (Cr 0.16 ± 0.02 mg/dl, vs 0.12 ± 0.01, n=5, p<0.05;). In KO given CP, RP81MNP ameliorated AKI (Cr 0.30 ± 0.05 mg/dL vs 0.64 ± 0.14 in control, n=5, p<0.05;) and CKD (increased kidney weight: 176mg ± 7.0, vs 145.4± 4.5, decreased plasma Cr: 0.10± 0.01 vs 0.16± 0.02, and KIM-1: 124.3±15.1 pg/ml vs 227±28.4). RP81MMP significantly reduced plasma cytokines IL-1β, IL-2, IL-6, KC, and TNFα and inhibited regulated necrosis. ScRNAseq revealed that RP81MNP preserved tubule and vasculature cell mass and decreased infiltrated immune cells caused by CP.

Conclusions: We conclude that RP81MNP attenuates CP-induced CKD by diminishing cell death pathways and inflammation activated by CP. These data suggest that RP81MNP may be an effective therapeutic agent to prevent CKD in patients treated with repeated doses of cisplatin.

Pyruvate Kinase M2 in Renal Tubular Cells Is a Key Regulator of Kidney Repair After Ischemic Injury

Qingqing Wei,[1] Zheng Dong.[1,2] [1]*Augusta University, Augusta, GA;* [2]*Augusta VA Medical Center, Augusta, GA*.

Background: Tissue injury and repair is associated with changes of metabolism. In kidneys, metabolic changes including mitochondrial dysfunction and induction of glycolysis have been reported in renal fibrosis and chronic kidney disease. It remains unclear whether and how the metabolic changes contribute to kidney injury and repair. We have examined the effects of glycolysis inhibitors and the ablation of pyruvate kinase M2 (PKM2, an enzyme in glycolysis) in kidney tubules. Glycolysis inhibitors (including PKM2 inhibitor shikonin) suppressed renal fibrosis in the mouse model of unilateral ureter obstruction (UUO). Interestingly, in vitro the inhibitors suppressed fibrotic gene expression (e.g. fibronectin and a-SMA) in fibroblasts, but not in cultured renal tubular cells.

Methods: To further understand the role of glycolysis in renal tubular cells in vivo, we established a mouse model in which PKM2 ablation in renal tubule cells can be induced by doxycycline. To this end, PKM2-floxed mice were bred with Pax8-rtTA/LC1 CRE recombinase mice to create an inducible renal tubule-specific PKM2 knockout (iRT-PKM2-KO) mouse model. Exposure to doxycycline for 5-7 days induced PKM2 ablation in all renal tubules in iRT-PKM2-KO mice, but not in wild-type littermates. These mice were subjected to 30 minutes of unilateral renal ischemia-reperfusion one day after initial doxycycline treatment, and kidneys were collected at 2 weeks later for histology, immunoblot analysis, and fibrosis staining.

Results: Wild-type mice showed increased expression of collagen I, collagen IV, vimentin and a-SMA in kidney tissues. The increase of collagen I was significantly attenuated in iRT-PKM2-KO mice, while collagen IV and vimentin induction was marginally inhibited and no inhibition for fibronectin and a-SMA in these mice. Wild-type and iRT-PKM2-KO kidney tissues had similar levels of Sirius red staining of collagen fibrils. We further examined Lotus Tetragonolobus lectin (LTL) staining of proximal tubules, which detected obviously more intact proximal tubules in iRT-PKM2-KO mice than in wild-type littermates.

Conclusions: Together, these results indicate a pathogenic role of glycolysis in maladaptive kidney repair. Importantly, PKM2 and associated metabolism contribute to the degeneration of renal tubules after acute kidney injury.

Proximal Tubule-Specific DPP4 Deletion Slows Kidney Disease Progression in Obese Mice

Ravi Nistala,[1] Jing Ren,[1] Jianzhong An,[2] Tammy L. Strawn,[1] Suryanshi Rawat,[1] Priyanka Patel,[1] Adam Whaley-Connell.[1] [1]*University of Missouri, Columbia, MO;* [2]*Suzhou Municipal Hospital, Suzhou, China*.

Background: Obesity is a major risk factor for Chronic Kidney Disease progression to End Stage Renal Disease and/or Dialysis. Increased absorption of fats and/or sugars from Western Diet (WD) likely leads to kidney tubular injury in obesity. We observed that whole body dipeptidyl peptidase 4 (DPP4) deletion as well as inhibition in WD-fed mice results in decreased kidney injury which, in turn was associated with a decrease in proximal tubule DPP4. Therefore, we **hypothesized** that proximal tubule (PT) DPP4 activation leads to injury and progression of kidney disease.

Methods: PT-KO and WT littermates were fed a WD starting 4-6 wks of age and continued for 2 years. GFR and albuminuria were monitored periodically. Tissue histology was performed at select intervals. GeLC-MS was used to separate kidney peptides and Scaffold 4/iPathwayguide used to analyze the Proteomics data.

Results: WD-fed WT mice gained 150-200% weight of chow-fed [CD] mice and had a greater decline in GFR than CD-fed animals over 2 years (50% vs. 20%, p<0.05). WD-fed PT-KO mice had a lesser decline (~35%) when compared to WT mice. This was true for both male and female mice. Concomitantly, there was an increase in albuminuria in WD-fed WT mice that was mitigated in PT-KO mice. PAS/PSR stained sections showed worsening fibrosis, tubular dilatation and glomerulomegaly, tubular vacuolization in WD-fed WT mice that was mitigated in PT-KO mice. Oil Red O staining showed increased fat accumulation in glomeruli and tubules of WD-fed WT mice that was mitigated in KO mice. Proteomics analysis followed by immunoblots showed that WD-feeding led to an increase in cell adhesion proteins and ribosomal machinery that was significantly suppressed by KO. In addition, there was a shift towards reduction in gluconeogenesis and improved fatty acid oxidation in KO mice.

Conclusions: Obesity without diabetes can lead to rapid decline in GFR in both male and female mice. DPP4 inhibition may slow decline if started early in the course of developing obesity and/or insulin resistance.

The PAR-1 Antagonist Vorapaxar Protects Against AKI to CKD Transition

Sarah W.Y. Lok,[1] Wai Han Yiu,[1] Loretta Y.Y. Chan,[1] Joseph C K Leung,[1] Kar Neng Lai,[2] Sydney C. Tang.[1] *[1]The University of Hong Kong, Queen Mary Hospital, Hong Kong, Hong Kong; [2]The University of Hong Kong, Hong Kong, Hong Kong.*

Background: Protease-activated receptor-1 (PAR-1) has been reported as a coagulation regulator in the pathophysiology of AKI. Beyond its normal function in haemostasis, aberrant PAR-1 signaling may lead to the development of tubulointersitial fibrosis, and subsequently CKD.

Methods: We investigated whether the administration of PAR-1 antagonist vorapaxar, an FDA-approved drug for reducing thrombotic cardiovascular events, has any renoprotective effect in a robust kidney fibrosis murine CKD model following unilateral ischemia reperfusion injury (UIRI), as well as in hypoxia-induced cultured rat proximal tubular epithelial cells (NRK-52E).

Results: Vorapaxar reduced morphological abnormalities and the expression of tubular injury marker KIM-1 in UIRI kidneys. Mice treated with vorapaxar showed less intrarenal accumulation of ECM proteins including fibronectin, α-smooth muscle actin and collagen 1 via TGF-β/Smad signaling after UIRI. IR-induced endothelial dysfunction and macrophage infiltration were also decreased by vorapaxar treatment. In NRK-52E cells, PAR-1 expression was activated under a hypoxic milieu associated with upregulation of TGF-β-induced ECM protein accumulation.

Conclusions: Vorapaxar diminishes renal fibrosis through TGF-β/Smad signaling in UIRI model, and protects against tubular injury during AKI to CKD transition. A PAR-1 targeted strategy by vorapaxar as a therapeutic approach in human CKD warrants further. **Funding:** Health and Medical Research Fund (HMRF) of Hong Kong (grant no. 05163596), Research Grants Council of Hong Kong (Collaborative Research Fund, grant no. C7018-16G), and Hong Kong Society of Nephrology/HK Kidney Foundation Research Grant 2018.

PO0597

Sphingosine Kinase 2 in Kidney Perivascular Cells Promotes Inflammation and Fibrosis Through S1PR1 Signaling

Shinji Tanaka,[1] Yugesh Kharel,[2] Shuqiu Zheng,[1] Jonathan E. Lipsey,[1] Diane L. Rosin,[2] Kevin Lynch,[2] Mark D. Okusa.[1] *[1]Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacology, University of Virginia, Charlottesville, VA.*

Background: Sphingosine 1-phosphate (S1P) is a sphingolipid, which is produced by two different kinases, sphingosine kinase (SphK) 1 and 2. S1P is exported through Spns2 or Mfsd2b, and then reacts with S1P receptors (S1PR1-5) to affect myriad cell functions. We recently showed that *Sphk2*$^{-/-}$ mice were protected from renal fibrosis when compared to wild type or *Sphk1*$^{-/-}$ mice (PMID: 27799486). We hypothesized that *Sphk2* deletion in renal perivascular cells confers the protection from progressive kidney fibrosis.

Methods: Male *Foxd1Cre*$^{+}$ *Sphk2*$^{fl/fl}$ and *Foxd1Cre*$^{-}$ *Sphk2*$^{fl/fl}$ (control) mice were used. For unilateral ischemia-reperfusion injury (IRI), left kidney was clamped for 30 min; right nephrectomy was performed at day 13. For bilateral IRI, both kidneys were clamped for 30 min. Mice were euthanized at day 14 to evaluate kidney fibrosis (unilateral IRI) and at day 1 to evaluate the extent of acute kidney injury (bilateral IRI). Primary kidney perivascular cells were isolated from kidneys of *Foxd1Cre*$^{+}$ *Sphk2*$^{fl/fl}$ and control mice.

Results: In the unilateral IRI model, *Foxd1Cre*$^{+}$ *Sphk2*$^{fl/fl}$ mice demonstrated better kidney function (plasma creatinine), less kidney fibrosis (histology) with less macrophage infiltration, and suppressed expression of fibrosis-related genes (*Acta2, Col1a1, Col3a1*) in the kidneys compared with control mice but there was no difference in plasma S1P between the groups. In contrast, in the bilateral IRI model, there was no difference between the groups in kidney function, kidney *Havcr1/Lcn2* expression, and histology at day 1. In *in vitro* studies, *Sphk2*-deficient perivascular cells expressed less inflammatory cytokines, such as *Ccl2, Il6, Cxcl1*, after LPS stimulation compared with control perivascular cells. *Sphk2*-deficient and control perivascular cells robustly expressed *Spns2*, but not *Mfsd2b*, and *S1pr1-3* among the five S1P receptor subtypes. Among *S1pr1-3*, only knockdown of *S1pr1* resulted in suppressed expression of inflammatory cytokines after LPS stimulation.

Conclusions: *Sphk2* deletion in renal perivascular cells was protective against kidney fibrosis. *In vitro* studies suggested that S1P produced by Sphk2 is exported through Spns2 and reacts with S1PR1 to enhance the inflammatory signal in these cells, leading to immune cell infiltration and subsequent fibrosis in the kidneys.

Histone Demethylase JMJD3 Protects Against Renal Fibrosis by Suppressing TGF-β and Notch Signaling

Chao Yu,[2] Shougang Zhuang.[1,2] Shanghai East Hospital, Shanghai Tongji University *[1]Rhode Island Hospital, Brown University, Providence, RI; [2]Shanghai East Hospital, Shanghai TongJi University, Shanghai, China.*

Background: The Jumonji domain containing-3 (JMJD3), a specific histone demethylase for trimethylation on histone H3 lysine 27 (H3K27me3), is associated with the pathogenesis of many diseases, but its role in renal fibrosis remains unexplored. Here, we examined the role of JMJD3 and mechanisms involved in the activation of renal fibroblasts and development of renal fibrosis.

Methods: Murine models of 5/6 nephrectomy (SNx) and ureteral unilateral obstruction (UUO) were used to assess the effect of a specific JMJD3 inhibitor, GSKJ4, and genetic deletion of JMJD3 from FOXD1 stroma-derived renal interstitial cells on the development of renal fibrosis and activation of renal interstitial fibroblasts. Cultured rat renal interstitial fibroblasts (NRK-49F) and mouse renal epithelial (mTECs) cells were also used to examine JMJD3-mediated activation of profibrotic signaling.

Results: JMJD3 and H3K27me3 expression levels were upregulated in the kidney of mice subjected to SNx 5/6 and UUO. Pharmacological inhibition of JMJD3 with GSK J4 or genetic deletion of JMJD3 led to worsening of renal dysfunction as well as increased deposition of extracellular matrix proteins and activation of renal interstitial fibroblasts in the injured kidney. This was coincident with decreased expression of Smad7 and enhanced expression of H3K27me3, transforming growth factor β1 (TGFβ1), Smad3, Notch1, Notch3 and Jagged1. Inhibition of JMJD3 by GSK J4 or its specific siRNA also resulted in the similar responses in cultured NRK-49F and mTECs exposed to serum or TGFβ1. Moreover, JMJD3 inhibition augmented phosphorylation of AKT and ERK1/2 in vivo and in vitro.

Conclusions: These results indicate that JMJD3 confers anti-fibrotic effects by limiting activation of multiple profibrotic signaling pathways and suggest that JMJD3 modulation may have therapeutic effects for chronic kidney disease.

Funding: NIDDK Support

PO0599

Induction of CKD by Gene Deletion of Canonical Transient Receptor Potential 1 (TRPC1) Channels Independent of Hypertension and Nephromegaly Despite Diabetes and Metabolic Syndrome

Muhammad Mubeen Anwar, Usman A. Khan, Bonnie Eby, Kai Lau. *The University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: TRPC1 gene on chromosome 3q22-24 is in the linkage region for diabetic nephropathy. Despite reduced expression in diabetes, no causal relationship has been shown. Since null mice are obese, hypertriglyceridemic and diabetic with fatty liver, we evaluated potential renal phenotypes, testing the hypothesis of impaired Ca signaling, as we found reduced cell free Ca in bone, renal, and parathyroid cells.

Methods: From 3rd to 22nd mon, metabolic, cardiac & abdominal ultrasound (US) & clearance (Cl) studies were done in age- & sex-matched littermates of TRPC1 +/+, +/-, & -/- mice. Creatinine (Cr) was analyzed by creatininase or HPLC; glomerular filtration rate (GFR) by inulin Cl. Systolic (S) & diastolic (D) BP was measured by arterial (A) cannulation.

Results: Null mice were hyperglycemic from the 3rd mon & developed diabetes from 6 to 22 mon by standard IP glucose tolerance test. Nephromegaly was absent in null mice since kidney volume by US (0.38 vs. 0.46 at 7 mon & 0.4 vs 0.5 cc at 11-20 mon) was 16% smaller & kidney (K) to body (B) weight (W) (1.2 vs.1.5 % at 7 mon & 1.1 vs.1.5 % at 11-20 mon) was lighter by 17-28 %. Chronic injury & scarring were suggested by 37% increase in echogenicity at 20 mon, though normal at 7 or 11 mon. Urine albumin/Cr ratio in null mice rose barely (64-71%). But at 17 mon, CrCl fell by 30% ($p<0.01$) in null ♀ & by 46% ($p<0.01$) in null ♂. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 45-48%, whether expressed per mouse, per g KW, or per 100 g BW. Haploid TRPC1 deletion reduced CrCl by in 40% ($p<0.05$) at 16 mon vs 44% by diploid deletion ($p<0.02$). TRPC1 deletion significantly reduced, not raised, mean SBP (113 vs 131 torr), DBP (77 vs 86 torr), & MABP (89 vs 98 torr). Since TRPC1 was implicated in cardiac hypertrophic signaling, smooth muscle proliferation & mesangial cell contraction, we did cardiac US & found 33% reduced cardiac output in -/- mice (14 vs 21 ml/min) & 14% smaller heart mass, corroborated by 20% lower weights measured at 22 mon.

Conclusions: 1. TRPC1 deficiency impairs Ca signaling, retards renal & heart development, compromizes hemodynamics and produces hypoplastic nephropathy. 2. Null mice provide an excellent model to study progressive CKD independent of hypertension and heavy proteinuria.

The Novel Soluble Guanylyl Cyclase (sGC) Activator Runcaciguat Induced Renal Vasodilation and Reduced Kidney Damage in a Rat CKD Model

Agnes M. Benardeau,[1] Michael G. Hahn,[1] Michael Gerisch,[1] Michaela Meyer,[1] Dzianis Menshykau,[1] Terence Hetzel,[1] Jan Schlender,[1] Elke Hartmann,[1] Tibor Schomber,[1] Andreas Patzak,[3] Frank Schweda,[2] Jan R. Kraehling,[1] Peter Sandner,[1] Frank Eitner.[1] *[1]Bayer AG, Leverkusen, Germany; [2]Universitat Regensburg, Regensburg, Germany; [3]Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: CKD progression is associated with impaired NO/sGC/cGMP-signaling, low cGMP production and increased oxidative stress. Oxidative stress modifies the native sGC to oxidized, heme-free apo-sGC which cannot be activated by NO anymore. Runcaciguat is a novel potent and selective sGC activator that binds and activates heme-free sGC independently of NO and restores NO/sGC/cGMP signaling. We investigated the effects of Runcaciguat on intrarenal hemodynamics and in a rat model of T2D-associated CKD.

Methods: Hemodynamic effects were analyzed *ex vivo* in isolated renal afferent/efferent arterioles and in perfused kidneys. Effect of Runcaciguat on kidney protection was evaluated in diabetic and proteinuric rats. ZSF1 rats (12w, male, n=6/gp) were implanted with telemetry systems and treated daily orally for up to 12 weeks with Runcaciguat, Enalapril or placebo. Key parameters included proteinuria, kidney structural changes, biomarkers, kidney gene expression, systemic hemodynamics, and substance plasma exposures.

Results: Runcaciguat dilated renal afferent/efferent arterioles under NO depletion and increased blood flow, GFR and cGMP production in NO-depleted, isolated perfused kidneys. In ZSF1 rats, Runcaciguat dose-dependently reduced proteinuria (-17%, -50%, -85% @ 1, 3, 10 mg/kg/bid) without changing mean arterial pressure at steady-state. The reduction of proteinuria was significantly higher than with Enalapril (-39%, -63% @ 20, 60 mg/kg/d) at doses significantly reducing systemic blood pressure. Runcaciguat reduced kidney structural damages and kidney and liver weight. Runcaciguat reduced glycosylated hemoglobin and plasma triglycerides while Enalapril did not. Metabolic improvement was accompanied by gene expression changes suggesting improvement of vascular and endothelial functions independently of interaction with the Renin-Angiotensin-Aldosterone system. Runcaciguat plasma concentration was dose-proportional after acute and chronic dosing.

Conclusions: Runcaciguat prevented further decline in kidney function and structure independent of blood pressure in CKD rats. Our data suggest that the novel sGC activator Runcaciguat represents a promising treatment option for CKD patients.

Inhibition of KIM-1-Mediated Fatty Acid Uptake by a Novel Inhibitor Attenuates Pro-Fibrotic Responses in Multiple Models of Human Primary Kidney Epithelial Cells Including Kidney Tubuloids

Yutaro Mori,[1] Amrendra K. Ajay,[1] Ankit B. Patel,[1] Andrew M. Siedlecki,[1] Seiji Kishi,[2] Takaharu Ichimura,[1] Joseph V. Bonventre.[1] *[1]Division of Renal Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Department of Nephrology, Tokushima University Hospital, Tokushima, Japan.*

Background: Tubulointerstitial damage is strongly associated with many forms of kidney injury including diabetic kidney disease. Kidney Injury Molecule-1 (KIM-1), a scavenger receptor, is the most upregulated proximal tubule protein with kidney injury. We hypothesized that KIM-1-mediated uptake of fatty acids (FAs) contributes to tubulointerstitial damage.

Methods: Human DKD renal biopsy samples were analyzed. Human primary epithelial cell cultures were established from the non-tumor kidney tissue removed from patients with a renal mass. To grow human renal tubuloids, primary cells were cultured on ultra-low attachment plates for several days. Cells were transferred into media containing multiple growth factors and 5% fetal bovine serum. Cells and tubuloids were treated with palmitate acid with certain groups having siRNA knockdown of KIM-1. Conditioned media from FA-treated human primary cells and tubuloids were applied to mouse primary kidney fibroblasts. An inhibitor for KIM-1-mediated FA-uptake was identified from >14,400 compounds and tested for its anti-fibrotic ability.

Results: KIM-1 expression in DKD patients was positively correlated with tubulointerstitial inflammation and fibrosis. FA-BSA uptake was markedly reduced in cells depleted of KIM-1 indicating the relative importance of KIM-1 to proximal tubule FA uptake. High-dose FA treatment increased cell death. FA treatment increasedγH2AX expression, a marker for DNA damage response. FA also increased the number of cells in the G2/M phase without an increase of those in S phase by cell cycle analysis, indicating that cells are likely arrested in G2/M phase. Our newly identified inhibitor for KIM-1, JB1, prevented FA uptake at least in part by inhibiting the direct binding of FA to KIM-1. JB1 reduced the pro-fibrotic effect of conditioned media from FA-treated human primary cells and tubuloids.

Conclusions: KIM-1 enhances the proximal tubular uptake of FA, leading to proximal tubule damage, pro-fibrotic responses and increase in cell death. Our findings support the role of KIM-1 as a target for chronic kidney disease including DKD and our work introduces a new candidate therapeutic agent.

Histone Deacetylase 6 Inhibition Mitigates Renal Fibrosis by Suppressing TGF-β/SMAD3 and eGFR Signaling Pathways

Xingying Chen,[1] Shougang Zhuang.[2,1] Shanghai East Hospital *[1]Shanghai East Hospital, Shanghai Tongji University, Shanghai, China; [2]Rhode Island Hospital, Brown University, Providence, RI.*

Background: We have recently shown that histone deacetylase 6 (HDAC6) is critically involved in the pathogenesis of acute kidney injury, however, its role in renal fibrosis remains unclear.

Methods: In this study, we examined the effect of ricolinostat (ACY-1215), a selective inhibitor of HDAC6, on the development of renal fibrosis in a murine model induced by unilateral ureteral obstruction (UUO).

Results: HDAC6 was highly expressed in the kidney following UUO injury, which was coincident with deposition of collagen fibrils and expression of α–smooth muscle actin, fibronectin, and collagen III. Administration of ACY-1215 reduced these fibrotic changes and inhibited UUO-induced expression of transforming growth factor β1 and phosphorylation of Smad3, but increased expression of Smad7. ACY-1215 treatment also suppressed phosphorylation of epidermal growth factor receptor and several signaling molecules associated with renal fibrogenesis, including AKT, signal transducer and activator of transcription 3 and NF-κB in the injured kidney. Furthermore, ACY-1215 was effective in inhibiting dedifferentiation of renal fibroblasts to myofibroblasts in cultured renal interstitial fibroblasts.

Conclusions: Collectively, these results indicate that HDAC6 inhibition can attenuate renal fibrosis development by suppression of TGFβ1 and EGFR signaling.

Crucial Role of STAT6 Signaling in Renal Fibrosis

Baihai Jiao,[1] Changlong An,[1] Yanlin Wang.[1,2] *[1]University of Connecticut School of Medicine, Farmington, CT; [2]VA Connecticut Health System, West Haven, CT.*

Background: Kidney fibrosis is a pathologic characteristic of chronic kidney disease, resulting in progressive loss of kidney function to end-stage kidney failure. We have recently demonstrated that bone marrow-derived fibroblasts contribute to the pathogenesis of kidney fibrosis. In this study, we investigated the role of STAT6 in activation of bone marrow-derived fibroblasts and development of renal fibrosis in folic acid nephropathy.

Methods: To investigate the role of STAT6 in myeloid fibroblast activation and kidney fibrosis, we used STAT6 knockout mice or treated wild-type mice with AS1517499, a STAT6 inhibitor. Wild-type mice treated with vehicle were used as controls. Folic acid was administered at 250 mg/kg intraperitoneally to induce kidney fibrosis. Kidneys were harvested 2 weeks after folic acid injection.

Results: Folic acid injury led to activation of STAT6 in the interstitial cells of the kidney, which was abolished by treatment with AS1517499. Wild-type mice treated with AS1517499 accumulated fewer bone marrow-derived fibroblasts in the kidneys following folic acid injury compared with vehicle-treated mice. AS1517499 treatment significantly inhibited myofibroblast activation, reduced total collagen deposition, and suppressed expression of extracellular matrix proteins after folic acid injury. Compared with wild-type mice, mice with STAT6 deficiency exhibited fewer myeloid fibroblasts and myofibroblasts and expressed less α-SMA protein in the kidneys following folic acid injury. Furthermore, genetic deletion of STAT6 significantly reduced total collagen deposition and ECM protein production in the kidneys with folic acid nephropathy.

Conclusions: Our results demonstrate that STAT6 signaling plays an important role in the activation of bone marrow-derived fibroblasts during the development of renal fibrosis in folic acid nephropathy. AS1517499 may serve as a novel therapeutic agent for the treatment of chronic kidney disease.

The Role of HNF4α in CKD Progression

Marta Martinez-Calle, Guillaume Courbon, Xueyan Wang, Bridget Hunt-Tobey, Jadeah J. Spindler, Emily P. Lynch, Aline Martin, Valentin David. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Acquired kidney mitochondrial dysfunction is a prominent feature of Chronic Kidney Disease (CKD), and is associated with onset and progression of CKD. HNF4α is a transcription factor highly expressed in proximal tubules which controls the expression of genes involved in critical metabolic pathways. As a result, mutations in *Hnf4α* are associated with mitochondrial defects. We previously found that *Hnf4α* is reduced in the kidneys of Col4a3^{KO} mice with progressive CKD and it correlates with hyperphosphatemia. Here we tested the hypothesis that kidney *Hnf4α* is reduced in response to hyperphosphatemia and that *Hnf4α* decline in CKD contributes to mitochondrial dysfunction and CKD progression.

Methods: We fed WT mice a control (Ctr) and a high phosphate diet (HPi) for 6 weeks. We confirmed that *Hnf4α* expression was reduced in the kidneys Col4a3^{KO} mice by RT-PCR and next performed RNA sequencing (RNAseq) to identify genes and molecular pathways affected by HNF4α reduction in CKD. Finally, to further evaluate the causal role of *Hnf4α* reduction in CKD progression, we treated Col4a3^{KO} mice with a daily dose of 30μg/g of HNF4α antagonist (BI-6015) for 5 days.

Results: WT mice fed a HPi diet showed a significant 70% reduction in kidney HNF4α mRNA and protein expression, suggesting that hyperphosphatemia, a hallmark of progressive CKD, contributes to HNF4α downregulation in the kidney. Kidney molecular profiling by RNAseq of Col4a3^{KO} mice showed increased acquired mitochondrial dysfunction and reduced oxidative phosphorylation, suggesting that impaired mitochondrial function strongly contributes to CKD progression. Downstream pathway analyzes showed that the vast majority of these genes (~80 %) are regulated by HNF4α. Pharmacological inhibition or HNF4α in Col4a3^{KO} mice led to an accelerated decline in kidney function (200% increase in BUN), demonstrating the crucial role of HNF4α in CKD progression.

Conclusions: These results suggest that HNF4α is a master regulator of mitochondrial function in kidney and might represent a novel therapeutic target to improve outcomes in CKD.

An In Vitro Model to Elucidate the Synthesis of Extracellular Matrix Proteins Involved in Renal Interstitial Fibrosis

Alexandra L. Møller,[1,2] Alexander L. Reese-Petersen,[1] Daniel Guldager Kring Rasmussen,[1] Federica Genovese,[1] Morten A. Karsdal.[1] Fibrosis, Renal and Cardiovascular Research *[1]Nordic Bioscience, Herlev, Denmark; [2]Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark.*

Background: Accumulation of extracellular matrix (ECM) proteins is a hallmark of renal fibrosis, which can lead to altered tissue homeostasis, kidney failure, and ultimately death. Many different cell types are involved in this process, but fibroblasts are the main source of ECM proteins such as fibronectin, collagen type I (COL I), III (COL III), and VI (COL VI). Recently it was suggested that a fragment of COL VI released during collagen maturation is, in fact, a bioactive molecule (endotrophin; ETP) with signaling potential, indicating that collagens are not just passive structural proteins. In this study, we investigated the effect of transforming growth factor (TGF)-β and ETP on the synthesis of different ECM proteins by human renal fibroblasts in the scar-in-a-jar (SiaJ) cell model.

Methods: Cells were seeded in 48-well plates at 30.000 cells/well and incubated for 24h in DMEM + 10% FBS for adherence. Cells were starved by incubating them for further 24h in DMEM + 0.4% FBS. Fresh medium was added at day 0 with 225/150 mg/mL Ficoll 70/400 and 1% ascorbic acid, containing 0.02 nM TGF-β or either 12 or 30 nM ETP. Medium was changed and collected on days 3, 6, 10, and 13. Biomarkers of COL I (PRO-C1), III (PRO-C3), VI (PRO-C6), and fibronectin (FBN-C) formation were assessed in the medium by enzyme-linked immunosorbent assays developed at Nordic Bioscience.

Results: Stimulating renal fibroblasts with 0.02 nM TGF-β significantly increased the formation of COL I ($P<0.0001$), III ($P<0.0001$), and fibronectin ($P<0.0001$) compared to unstimulated cells. Interestingly, TGF-β treatment suppressed the formation of COL VI compared to untreated cells. Stimulating with 30 nM ETP significantly increased the formation of COL I ($P<0.0001$) and III ($P<0.0001$) compared to unstimulated cells. 12 nM ETP significantly increased the synthesis of fibronectin compared to unstimulated cells ($P<0.0001$).

Conclusions: Different growth factors induce different protein expression profiles in fibroblasts. Interestingly, ETP, which originates from the ECM, drives renal fibrosis through increasing COL I and III as well as fibronectin. This SiaJ model, combined with the investigated biomarkers of ECM formation, could be used to elucidate the mechanisms behind acute and sustained matrix production profiles.

PO0606

FoxM1 Inhibition Ameliorates Renal Interstitial Fibrosis (RIF) by Decreasing Extracellular Matrix and Epithelial-to-Mesenchymal Transition

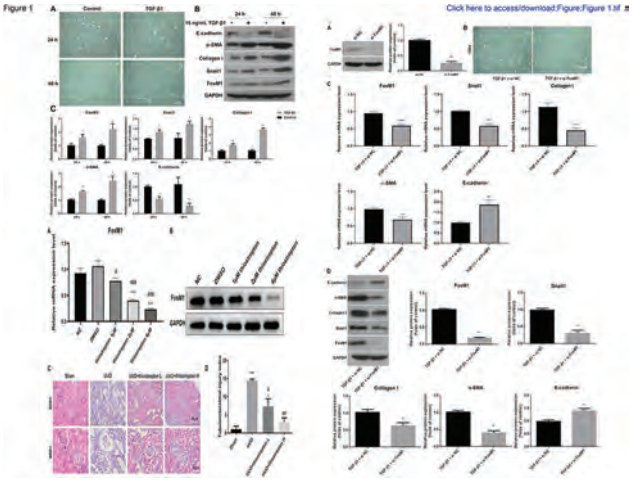
Wang Y. Hui,[1,2] Qiaoling Zhou.[1] *[1]Xiangya Hospital, Central South University, Changsha, China; [2]Department of Geriatrics, Guangzhou First People's Hospital, School of Medicine, South China University of Technology, Guangzhou, China.*

Background: FoxM1 is a transcriptional regulator involved in tumor development, pulmonary fibrosis, and cardiac fibrosis. However, its role in RIF has yet to be elucidated.

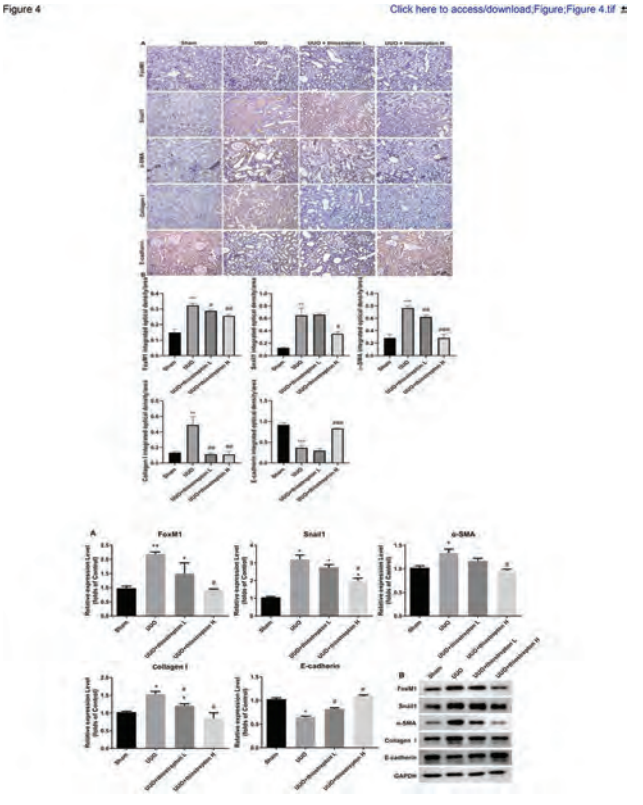
Methods: We established a TGF-β1-stimulated human proximal tubular epithelial cell (HK-2) model *in vitro* and a unilateral ureteral obstruction (UUO)-induced rat RIF model *in vivo*. FoxM1 inhibition was achieved by siRNA interference *in vitro* and by injecting thiostrepton into UUO-induced RIF rats *in vivo*. The degree of renal damage and fibrosis were determined by histological assessment via hematoxylin and eosin staining. Immunohistochemistry, western blots, and qPCR were used to determine the expression levels of FoxM1, Collagen I, E-cadherin, α-SMA, and Snail1

Results: FoxM1 inhibition could ameliorate RIF and reduce the deposition of Collagen I. H&E staining revealed that renal structural damage, inflammatory cell infiltration, and ECM deposition were significantly attenuated by thiostrepton treatment in the UUO rats. FoxM1 downregulation significantly suppressed EMT, as evidenced by decreased protein and mRNA expression levels of α-SMA and Snail1 and a significant increase in protein and mRNA expression levels of E-cadherin.

Conclusions: FoxM1 inhibition could be a novel therapeutic strategy for the treatment of RIF.



Protein levels in TGF-β1-induced HK-2 cells.FoxM1 downregulation inhibited TGF-β1-induced EMT



PO0607

The Macrophage Recruitment in the Unilateral Ureteral Obstruction Is Associated with the Raise of MCP-1 and Is Dependent of Lipocalin 2 Expression

Stefanny M. Figueroa, Mauricio A. Lozano, Carolina A. Lobos, Javier I. Reyes Osorio, Patricio A. Araos, Cristián A. Amador. Laboratory of Renal Physiopathology *Universidad Autonoma de Chile - Campus El Llano Subercaseaux, Santiago, Chile.*

Background: The persistent renal inflammation has been proposed as a crucial mechanism at the early stages of renal disease. The macrophages recruitment, as part of the pathogenic events, depends of the monocyte chemoattractant protein-1 (MCP-1) raise. In addition, studies in patients have demonstrated that neutrophil gelatinase-associated lipocalin (NGAL, also called Lipocalin-2), it is overexpressed during early stages of renal lesion. However, whether NGAL is relevant for macrophages recruitment at renal level, and if this is related to the increase of MCP-1, remains unknown. Our objective was to determine whether NGAL promotes the pro-inflammatory status during the unilateral ureteral obstruction (UUO), characterized by the macrophage recruitment and the increase of MCP-1.

Methods: Male C57BL/6 Wild type (WT) y NGAL-KO mice (8-12 weeks) were underwent to UUO and to Sham surgery (control group) during 3 and 7 days (n=8), in order to determine the associated damage at kidney level and the raise of MCP-1 in peripheral blood mononuclear cells (PBMC).

Results: In WT mice, the UUO induced luminal tubular dilation starting at 3 days (P<0.001 vs. Sham), and an induction of plasma urea (76.36 ± 5.37 mg/dL. P<0.01 vs. Sham). In addition, UUO increased NGAL levels in PBMC, plasma and urine (24.1 μg/L in Sham vs. 103.8 μg/L and 134.5 μg/L in UUO, at 3 and 7 days, respectively). This was in accordance with the renal induction of NGAL (mRNA and protein, P<0.001 vs. Sham), and with the increase of mRNA for the following pro-inflammatory mediators: TGF-β1, CCL5 (RANTES) and MCP-1, with a *peak* at 7-days. The genetic abalation of NGAL prevented tubular dilation (34.24 ± 6.55 μm. P<0.01 vs. UUO WT) and the rise of MCP-1 induced by UUO in kidney and PBMC (P<0.001 vs. WT). This was accompanied with a low grade of macrophage infiltration in kidney of NGAL-KO mice underwent to UUO (15.2% in WT vs. 7.3% in NGAL-KO).

Conclusions: The renal overexpression of MCP-1 and the macrophage recruitment induced by UUO is dependent of NGAL presence. Our results suggest that NGAL, by a regulation on MCP-1, may be crucial for macrophage chemoattraction during the early stages of renal disease. **Acknowledgments.** Fondecyt #1201251 and Fondecyt #3201016

PO0608

Enabled ICOS$^+$-RTE-Tresp Proliferation Is Involved in the Pathogenesis of Active Systemic Lupus Erythematosus (SLE)

Florian Kälble,[1] Christian Nusshag,[1] Christian Morath,[1] Martin G. Zeier,[1] Matthias Schaier,[1] Andrea Steinborn-Kroehl.[2] *[1]Department of Medicine I (Nephrology), University of Heidelberg, Heidelberg, Germany; [2]Department of Obstetrics and Gynecology, University of Heidelberg, Heidelberg, Germany.*

Background: Dysfunction of CD4$^+$-regulatory-T-cells (Tregs) and CD4$^+$-responder-T-cells (Tresps) is an important trigger in the development of active systemic lupus erythematosus. By now, underlying mechanisms are not fully understood.

Methods: To determine differences in the differentiation of inducible costimulatory molecule (ICOS)$^+$- and ICOS$^-$-Tregs/Tresps, their percentages of CD45RA$^+$CD31$^+$-recent thymic emigrant (RTE)-Treg/Tresps and CD45RA$^+$CD31$^-$ mature naïve (MN)-Treg/Tresps as well as CD45RA$^-$CD31$^+$ and CD45RA$^-$CD31$^-$-memory-Treg/Tresps (CD31$^+$- and CD31$^-$-memory Treg/Tresps) within total Tregs/Tresps were calculated. Additionally, subsets were stained for the proliferation marker Ki67. 124 healthy control patients and 117 with a preexisting lupus erythematosus (102 patients in remission, 15 patients with a flare) were measured.

Results: SLE patients in remission show an increased differentiation of ICOS$^+$-RTE-Tregs and ICOS$^-$-RTE-Tregs via resting MN-Tregs into CD31$^-$-memory-Tregs compared to healthy control patients. In contrast, proliferation of ICOS$^+$-RTE-Tresps into ICOS$^+$CD31$^-$-memory-Tresps is inhibited. Similarly, active SLE patients show an increased differentiation of ICOS$^+$-RTE-Tregs and ICOS$^-$-RTE-Tregs via resting MN-Tregs. Moreover, proliferation ability of ICOS$^+$-RTE-Tresps is not inhibited but enabled in these patients. Both SLE patients in remission and active SLE patients show an impaired ICOS$^-$-RTE-Tresp differentiation compared to healthy control patients. Hence, the ratio of ICOS$^-$-Tregs/ICOS$^-$-Tresps within CD4$^+$-T-cells is significantly increased in both SLE remission and active SLE patients compared to healthy control patients. In contrast, the ratio of ICOS$^+$-Tregs/ICOS$^+$-Tresps is significantly increased in SLE remission patients, but decreased in active SLE patients compared to healthy control patients.

Conclusions: Proliferation of ICOS$^+$-RTE-Tresps is medically inhibited in SLE remission patients. In active SLE patients, proliferation is enabled decreasing the ICOS$^+$-Treg/ICOS$^+$-Tresp ratio.

PO0609

Involvement of Calcium-Sensing Receptor in the Development of Interstitial Fibrosis

Akira Kurosawa, Kaori Takayanagi, Taisuke Shimizu, Masaaki Terao, Hiroaki Hara, Takatsugu Iwashita, Hajime Hasegawa. *Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Background: Physiological and pathophysiological role of renal Ca sensing receptor (CaSR) have not been well understood. We have reported the down regulation of CaSR in the process of renal interstitial fibrogenesis along with the down regulation of Mg transporting molecules, suggesting that CaSR plays an important role in the development of renal damage associated with Mg deficiency. We report here an analysis of the effects of calcimimetics administration on renal fibrosis models.

Methods: The left ureters of 8-week-old SD rat were ligated to create unilateral ureter obstruction (UUO) models and studied after 7 days. Cinacalcet 1.0 mg/day, a calcimimetics, was administered to a part of UUO animals. Experiments were performed in three groups of sham group, UUO group and UUO+Cinacalcet group (n=5). Fibrosis was evaluated by Azan staining and analysis of mRNAs of fibrosis-related molecules. We also studied on mRNA expression of Mg-transporting molecules.

Results: It was confirmed from immunohistochemistry and gene expression that CaSR expression was remarkably decreased by UUO (RT-PCR: sham 1.01±0.09 vs UUO 0.04±0.00, n=5). Cinacalcet treatment partially restored the expression by approximately 50% compared to UUO group. In Azan staining, an increase in the fibrosis area and a recrease in the non-damaged tubules were apparent in UUO, however, Cinacalcet treatment partially rescued. mRNA expression of TGF-beta and MCP-1 was not significantly decreased by Cinacalcet treatment as compared to UUO group. mRNA expression of claudin-14, 16 and 19, Mg transpirting molecules, seemed to be increased by Cinacalcet treatment, however, it was not statistically significant. However, Cinacalcet partially, but significantly increased the mRNA expression of TRPM6 comparing to UUO group (sham: 1.01±0.07, UUO: 0.35±0.01, Cinacalcet: 0.41±0.02).

Conclusions: The expression of claudin-16 and TRPM6 was significantly decreased with the development of fibrosis in UUO. The effect of CaSR activation and upregulation by Cinacalcet was limited, however, it restored the progression of fibrosis and impairment of Mg reabsorption. CaSR may play a key role for the Mg loss-relating renal fibrogenesis.

PO0610

Fibroblast-Specific LRP-1 Promotes Renal Fibrosis

Ling Lin, Kebin Hu. *Penn State University College of Medicine, Hershey, PA.*

Background: LRP-1, a scavenger receptor up-regulated during obstructive nephropathy, has been shown to mediate the actions of multiple profibrotic factors including tPA, TGF-β1, and CTGF. However, the in vivo role of LRP-1 in kidney fibrosis remains largely unknown.

Methods: We generated a novel fibroblast-specific LRP-1 knockout mouse (LRP-1-/-) and induced the unilateral ureteral obstruction (UUO), a classic model of chronic kidney disease (CKD), in these mice to investigate the in vivo role of LRP-1 in kidney fibrosis.

Results: It was found that LRP-1-/- mice had similar phenotype as their littermate controls (LRP-1+/+). However, after UUO injury, LRP-1-/- mice displayed significantly decreased fibrosis, as demonstrated by reduced renal collagen content and FSP-1 abundance, in comparison with their littermates. We further found that obstruction-induced epithelial damage was alleviated in LRP-1-/- mice. After UUO, LRP-1+/+ mice displayed decreased E-cadherin and increased vimentin expression, suggesting that epithelial-to-mesenchymal transition (EMT) was induced in the obstructed kidneys. Intriguingly, LRP-1-/- mice showed significantly reduced EMT as demonstrated by restoration of E-cadherin and elimination of vimentin induction.

Conclusions: Thus, it is clear that fibroblast LRP-1 promotes kidney fibrosis through EMT.

Essential Renal Tubular Proteins Are Lost by Excretion Within Novel Large Extracellular Vesicles During Chronic Renal Insufficiency

Ryan J. Adam, Mark Paterson, Brian R. Hoffmann, Alison J. Kriegel. *Medical College of Wisconsin, Milwaukee, WI.*

Background: Within weeks of surgery, the 5/6 nephrectomy (5/6Nx) rat spontaneously develops renal disease including tubular damage, brush border loss, and the production of very large extracellular vesicles present in the tubule lumen. These large renal tubule extracellular vesicles (LRT-EVs) are too large to be microsomes or exosomes, and lack markers of apoptotic bodies, and thus may represent an undescribed vesicle. We hypothesized that formation and excretion of these vesicles represents a pathological mechanism by which important tubule proteins are lost in chronic renal insufficiency.

Methods: We performed a longitudinal, histologic examination for the presence of LRT-EVs in renal tubules of 5/6Nx and sham-operated rats, and a proteomic analysis of LRT-EVs isolated from 5/6Nx rat urine 10 weeks following surgery.

Results: Histologic examination revealed virtually no LRT-EVs in sham-operated rat tubules at any time point. LRT-EVs were present in 5/6Nx rat tubules at all measured time points including 2, 4, 5, 7, and 10 weeks post-surgery, and exhibited a marked increase in percentage of tubule presence between week 5 (7.0 ± 2.7%) and week 7 (51.1 ± 6.5%). This increase temporally corresponds to a time of rapid progression of renal disease. Median LRT-EV diameter upon microscopic image analysis was 2.5 μm. Proteomic analysis of isolated LRT-EVs revealed them to contain a wide array of functionally essential tubule proteins including but not limited to basolateral Na^+/K^+ ATPase subunits, sodium-glucose co-transporters, aquaporin 1, megalin, cubilin, and mitochondrial VDAC.

Conclusions: Loss of important tubule proteins through production and urine-excretion of previously unreported LRT-EVs may represent a hitherto unappreciated aspect of chronic renal insufficiency.

Indoleamine-2, 3-Dioxygenase Activates Wnt/β-Catenin to Induce Kidney Fibrosis

Binbin Pan,[2] Changchun Cao,[1] Xin Wan.[2] *[1]Nanjing Medical University, Sir Run Run Hospital, Nangjing, China; [2]Nanjing First Hospital, Nanjing Medical University, Nangjing, China.*

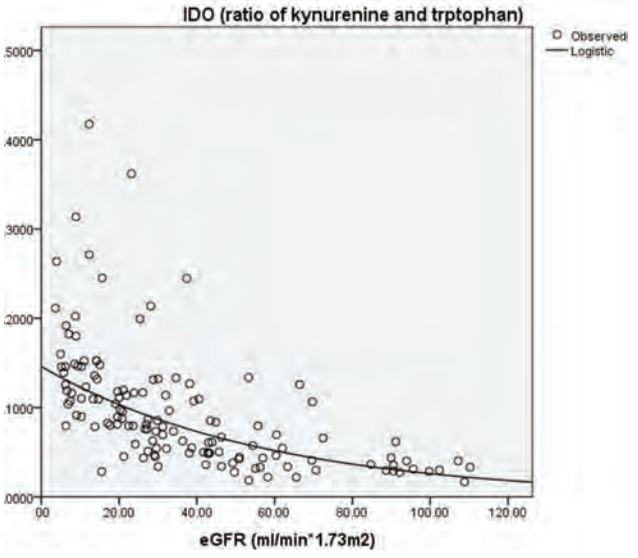
Background: Dysorder of tryptophan metabolism catalyzed by indoleamine-2, 3-dioxygenase (IDO) is common in chronic kidney disease which manifests as increased kidney fibrosis. IDO is also reported to be involved in fibrosis of other organs while little is known about correlations of IDO and fibrosis in kidney disease.

Methods: Wild type (WT) mice and IDO$^{-/-}$ mice were employed. Mice in Sham group underwent exposure of renal artery while mice in AKI group received unique renal artery ischemia-reperfusion injury (IRI) and the contralateral kidney was removed at day 13 after IRI. Samples were collected at day 14. Kidney function, morphology and fibrosis markers were analyzed. Prostaglandin E2 (PGE2) was administrated to WT AKI mice. Clinically, a total of 115 CKD patients and 30 non-CKD patients were recruited. IDO was

calculated by the ratio of kynurenine and tryptophan. Correlations between indicators were analyzed. The ROC curve was also performed.

Results: WT AKI mice revealed elevated expression of IDO and worse kidney function. PAS staining exhibited less loss of tubular epithelial cells and atrophy tubules in $IDO^{-/-}$ AKI mice. Additionally, fibrosis markers, including α-SMA, fibronectin and vimentin, were more severer in WT AKI mice. GSK-3β and β-catenin were significantly decline in $IDO^{-/-}$ AKI mice. On top of that, PGE2 administration revealed reduced IDO expression and decreased levels of GSK-3β and β-catenin resulting in lower expressions of α-SMA, fibronectin and vimentin in WT AKI mice. In patients, IDO had negative correlations with eGFR (r=-0.742, p<0.001). Further, the linear regression showed IDO was an independent influence factor of eGFR. ROC curve showed the area under the ROC curve was 0.825 for IDO.

Conclusions: IDO could activate Wnt/β-catenin pathway to induce kidney fibrosis. PGE2 could ameliorate kidney fibrosis via inhibiting IDO expression.



Scatter plot of IDO associated with eGFR

PO0613

Human Induced Pluripotent Stem Cell-Derived Kidney Micro-Organoids for High Throughput Disease Modeling in Drug Discovery

Santhosh V Kumar,[1] Anna Jonebring,[2] Pernille B. Laerkegaard Hansen,[3] Ryan Hicks,[2] Kevin Woollard.[1] AZ Kidney-organoids *[1]Bioscience Renal, Research and Early Development Cardiovascular, Renal and Metabolism (CVRM) BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [2]Translational Genomics, Discovery Sciences, R&D, AstraZeneca, Gothenburg, Sweden; [3]Bioscience Renal, Research and Early Development Cardiovascular, Renal and Metabolism (CVRM) BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden.*

Background: Human kidney contains around 1 million nephrons, more than 2 dozen different cell types. Reproducing physiological kidney cell types in-vitro is limited. Recent advancements in human iPSCs differentiation provide an opportunity to culture and utilize multicellular kidney structures "kidney-organoids". We have employed a kidney micro-organoid in suspension culture this method eventually accelerates kidney organoids to the industrial scale and differentiates from traditional low throughput transwell organoids. This method involves differentiation of iPSCs to intermediate mesoderm using CHIR and FGF9 and spontaneous aggregation in the swirler culture leads to mature to kidney organoids, this can be used to study kidney disease in a high-throughput manner.

Methods: We aimed to model human kidney inflammatory and genetic disease in-vitro using kidney micro-organoids, treatment with different insults to reproduce CKD microenvironment eg. IL-1b, TGFb, Angiotensin-II and protamine sulphate.

Results: After 24h of stimulation, we noted significant upregulation of kidney injury biomarkers including KIM1 and inflammatory cytokines. Reproducing genetic diseases like PKD is very challenging in-vitro, we show treatment of cultured micro-organoids with forskolin (to elevate intracellular cAMP) altered the transportation of ciliary proteins and promoted cyst formation, resembling human PKD. These observations clearly demonstrate the use of micro-kidney organoids to study renal diseases in-vitro for drug discovery applications with human translatable functional biomarkers.

Conclusions: Impact statement: Kidney micro-organoids provide a platform for high throughput modeling of human kidney diseases related fibrosis, inflammation and genetic disease like polycystic kidney disease with human translatable biomarkers in drug discovery.

PO0614

CKD of Unknown Origin (CKDuo): Is the Problem Dehydration, Water Contamination, or Both?

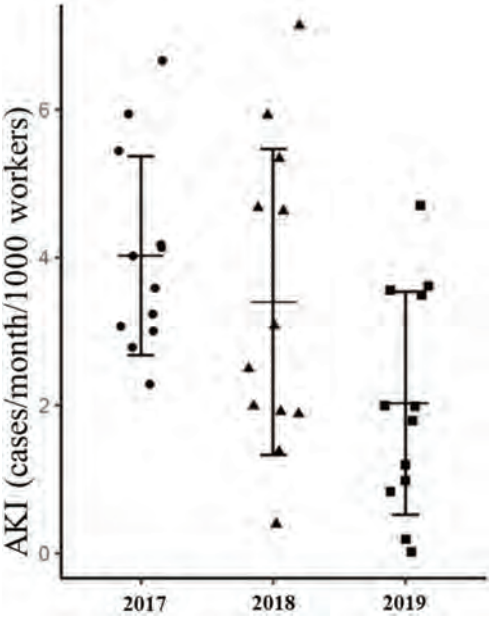
Vito M. Campese,[1] Alessia Fornoni,[2] Yan Zhong.[1] *[1]Keck School of Medicine of USC, Los Angeles, CA; [2]University of Miami, Miami, FL.*

Background: An increasing number of people of Central America develop CKDuo. The disease is characterized by chronic tubulo-interstitial nephritis. Occasionally, it presents as an acute kidney injury (AKIuo). The cause(s) remain unknown. Some sustain that dehydration is responsible. Others believe the disease is caused by water contaminated with heavy minerals or agrochemicals. To prevent dehydration, workers in these regions ingest 8-12L of water/day. Hence, even if concentrations of toxins are in "acceptable range", the cumulative intake may reach toxic levels. If this hypothesis is correct, purified water should reduce the incidence of the disease. In 2017 a Nicaraguan sugarcane factory (SER) adhered to the Adelante initiative, consisting of reducing working hours, exposure to heat and dehydration. In 2017-18, these measures had no impact on the incidence of AKIuo.

Methods: During the 2019 season, SER adopted the policy of providing highly purified drinking water to > 6000 workers (1L/hour during working hours). The effects on AKIuo were monitored. Comparisons were made of the monthly incidence of AKIuo during years 2017, 2018 and 2019, by One-way ANOVA.

Results: With the introduction of purified water, the incidence of AKI decreased from 4.0±1.3 cases in 2017 and 3.4±2.1 in 2018 to 2.0±1.5 cases/1000 workers/month in 2019 (P< 0.02).(Fig.1)

Conclusions: Although preliminary, these data support the hypothesis that contaminated water may play a major role in AKIuo. This raises enormous public health issues. If dehydration is responsible, the remedies are hydration and less heat exposure. If toxins and agrochemical are responsible, the remedy is providing highly purified water to those at risk. The potential impact of these measures on CKDuo remains to be determined.



PO0615

Effects of Chronic Intermittent Hypoxia on umod-/- Rats' Model Link to Alterations of Gut Microbiota

Na Wang, Yuqing Chen. *Renal division, Peking University First Hospital, Beijing, China.*

Background: Previous studies showed that both obstructive sleep apnea and uromodulin (UMOD) were associated with gut microbiota regulation. Here we explored the interaction effects of chronic intermittent hypoxia (CIH) and UOMD expression on variation of gut microbiota and association with phenotype.

Methods: umod-/- and wild type (WT) Sprague Dawley rats were attributed into 4 groups (N=10 in each group), umod-/- and WT under CIH, umod-/- and WT under normal air. All four groups were fed with same chaw for 10 weeks. All rats were anesthetized to collect fecal samples from large intestine directly and blood at the end of 10 weeks feeding. The bacterial composition was analyzed based on 16S ribosomal DNA pyrosequencing. Bioinformatics tools, including sequence alignment, abundance, and taxonomic diversity, were used in microbiome data analyses. Correlation analysis between differential genera and changed biochemical indicators were measured.

Results: Under normoxia, the serum phosphorus(P*) tend to be lower in umod$^{-/-}$ group compared with WT group (1.9±0.2 vs 2.1±0.2mmol/L, P=0.064). Under normoxia environment, the α-diversity of gut microbiota decreased in umod$^{-/-}$ group compared with WT group (Chao1 index, 301.8±30.2 vs 374.3±55.3,P=0.005), and the composition of microbiota was clearly separated between two groups (PCoA, P<0.001). The abundance of g-Lactobacillus (P=0.002) and g-Phascolarctobacterium (P=0.026) increased and g-Ruminococcus (P=0.023) decreased in umod$^{-/-}$ group compared with WT group. g-Ruminococcus showed positive relationship with serum phosphorus (R=0.511, P=0.043). When CIH was added as an environment condition, the serum phosphorus(P*) increased in umod$^{-/-}$ group obviously (2.3±0.3 vs 1.8±0.2 mmol/L,P=0.002). Gut composition in umod$^{-/-}$ were still clearly separated from WT (PCoA, P<0.001). The abundance of g-Lactobacillus, g-Phascolarctobacterium and g-Ruminococcus showed no difference. The abundance of g-Blautia (P=0.008), g-Sutterella (P=0.008), g-Anaerostipes (P=0.008) increased and g-Flavonifractor (P=0.008) and g-Anaerotruncus (P=0.008) decreased in umod$^{-/-}$ CIH group compared with wild type CIH group. G-Sutterella showed positive relationship with Phosphorus (R=0.831, P<0.001).

Conclusions: Chronic intermittent hypoxia can interact with uromodulin to affect serum phosphorous in umod$^{-/-}$ rats. These changes were strongly linked to the alterations in gut microbiota.

PO0616

Influence of Colonic Dialysis on the Distribution of Gut Microbiome in CKD Stage 3-5 Patients

Hui Xu. *Department of Nephrology, Xiangya Hospital, Central South University, Changsha, China.*

Background: Chronic kidney disease (CKD) becomes a major public health challenge given high incidence rates in the world. colonic dialysis (CD) has been used in pre-dialysis CKD patients (CKD3-5) in many hospitals of China because of its advantages of simple operation, low price and few complications. The gut microbiome is a potential cause of CKD progression and serve as a promising therapeutic target. We raise the question that whether CD improve renal function by affecting intestinal microbiome in CKD3-5 patients. Improving the imbalance of intestinal microbiome is considered a potential therapeutic target to decline chronic kidney disease(CKD) progression. We amied to investigate the influence of colonic dialysis(CD) on the distribution of gut microbiome in CKD3-5 patients.

Methods: We studied gut microbiota in 50 patients with CKD, 25 CD patients, 25 outpatients(OP), and compared to 34 healthy subjects(HS). The gut microbiome composition was analyzed by a 16S ribosomalRNA(16S rRNA) gene-based sequencing protocol.

Results: we found that there was no significant difference in the richness of intestinal microbiota between CD and HS, but the richness of bacterial in OP decreased significally (HS VS. OP p = 0.002). CD can increase the abundance of some short chain fatty acid(SCFA) producing bacteria and decrease the abundance of some uremic toxin producing bacteria. CD also can increase the abundance of some anaerobic bacteria in intestine. Compared with OP, the profile of intestinal microbiota in CD group and HS group was more similarity.

Conclusions: Our study reveals CD treatment alterings microbiome profile and increases microbiome richnessll in CKD3-5.

Asymptomatic Hyperuricemia, a Regulator of Innate Immunity in CKD

Stefanie Steiger,[1] Qiuyue Ma,[1] Paola Romagnani,[2] Hans J. Anders.[1] [1]*Division of Nephrology, Department of Medicine IV, LMU Hospital, Munich, Germany;* [2]*Department of Biomedical Experimental and Clinical Sciences Maria Serio, Univerisity of Florence, Florence, Italy.*

Background: Asymptomatic hyperuricemia (HU) is common in patients with chronic kidney disease (CKD) but the causative role of HU on CKD progression remains controversial. Two large multi-center randomized controlled trials, CKD-FIX and PERL study, have now disproven a causal relation. On the other hand, a causative role of HU exists with gout but a rapid correction of HU with urate lowering therapy can also elicit acute gout attacks. This suggests a more complex role of HU in this context. Hence, we hypothesized that soluble uric acid (sUA) has immunomodulatory effects on neutrophil function during the immune response to monosodium urate (MSU) crystals.

Methods: Alb-creERT2;*Glut9*$^{lox/lox}$ and *Glut9*$^{lox/lox}$ control mice were injected with tamoxifen and placed either on a chow or acidogenic diet with inosine to induce HU with or without CKD. After 3 weeks, MSU crystals or vehicle were injected into air pouches or postcapillary venules in the cremaster muscle of transgenic mice. Leukocyte infiltration and the extent of inflammation were assessed by flow cytometry, intravital microscopy, and ELISA. Blood neutrophils were isolated from CKD stage G2-4 and G5D patients or healthy individuals and neutrophil transwell migration assays performed.

Results: We found that HU impaired leukocyte recruitment into MSU crystal-injected air pouches of mice with or without CKD. Intravital microscopy revealed that HU specifically reduced leukocyte adhesion, extravasation, and tissue inflammation. The CKD-mediated attenuation of MSU crystal-induced inflammation was fully reversible by treating HU with urate lowering therapy. In neutrophils isolated from healthy individuals, sUA diminished β2 integrin activation and expression, and hence impaired neutrophil migration *ex vivo*. This process was dependent on the intracellular uptake of sUA via the urate transporter SLC2A9/GLUT9. An impaired migratory capability was also observed in neutrophils from CKD patients.

Conclusions: We identify sUA as an endogenous modulator of innate immunity. HU modulates neutrophil migration by altering efficient β2 integrin activation via SLC2A9 in gouty arthritis related or unrelated to CKD. This process provides a molecular explanation for several previously unexplained clinical phenomena in the context of gout and renal failure.

Serum Lysyl Oxidase Is a Potential Diagnostic Biomarker for Kidney Fibrosis

Xiaoqin Zhang, Chen Yu. *Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China, Shanghai, China.*

Background: Kidney fibrosis is the ultimate consequence of advanced stages of chronic kidney disease (CKD); however, there are currently no reliable biomarkers or noninvasive diagnostic tests available for the detection of kidney fibrosis. Lysyl oxidase (LOX) promotes collagen crosslinking, and serum LOX levels have been shown to be elevated in patients with fibrosis of the heart, lungs and liver. However, serum LOX levels have not been reported in patients with kidney fibrosis. We explored whether serum LOX levels are associated with kidney fibrosis.

Methods: Overall, 202 patients with kidney disease underwent renal biopsy, scoring of kidney fibrosis and determination of the area of kidney fibrosis. LOX levels were measured in serum and in kidney tissues. We analyzed the association of circulating LOX and tissue LOX levels with the scores and areas of kidney fibrosis. LOX expression was also investigated with *in vitro* and *in vivo* kidney fibrosis models.

Results: Serum LOX levels were higher in patients with kidney fibrosis than in those without kidney fibrosis ($p<0.001$) and higher in patients with moderate-severe kidney fibrosis than in patients with mild kidney fibrosis ($p<0.001$). Both serum LOX and renal tissue LOX levels correlated with the area of kidney fibrosis ($r=0.748$, $p<0.001$; $r=0.899$, $p<0.001$, respectively). ROC curve analysis of serum LOX levels showed an AUC of 0.80 (95% CI: 0.74 to 0.86). The optimal serum LOX level cutoff point was 253.34 ρg/ml for the prediction of kidney fibrosis and 306.56 ρg/ml for the prediction of moderate-severe renal fibrosis. LOX expression levels were significantly upregulated (2.3-2.6-fold and 6-fold, respectively) in *in vitro* and *in vivo* interstitial fibrosis models.

Conclusions: Both serum LOX and tissue LOX levels correlated with the presence and degree of kidney fibrosis in patients with CKD. These results suggest that serum LOX levels could potentially serve as a noninvasive diagnostic biomarker for kidney fibrosis and may further potentially serve as a stratified biomarker for the identification of mild and moderate-severe kidney fibrosis.

PO0619

Tubulointerstitial Fibrosis and Markers of Kidney Tubule Secretion

Pranav S. Garimella,[1] Ronit Katz,[2] Sushrut S. Waikar,[3] Anand Srivastava,[4] Insa M. Schmidt,[3] Andrew N. Hoofnagle,[2] Isaac E. Stillman,[5] Ragnar Palsson,[6] Helmut G. Rennke,[7] Ke Wang,[2] Bryan R. Kestenbaum,[2] Joachim H. Ix.[2] *[1]University of California San Diego, La Jolla, CA; [2]University of Washington, Seattle, WA; [3]Boston Medical Center, Boston, MA; [4]Northwestern University, Evanston, IL; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]Landspitali, Reykjavik, Iceland; [7]Brigham and Women's Hospital, Boston, MA.*

Background: Tubular secretion plays an important role in the efficient elimination of endogenous solutes and medications, and lower secretory clearance is associated with risk of kidney function decline. We evaluated whether the biopsy measurement of tubular damage atrophy and interstitial fibrosis was associated with lower tubular secretory clearance in persons undergoing kidney biopsy.

Methods: The Boston Kidney Biopsy Cohort is a prospective cohort study of persons undergoing native kidney biopsies for clinical indications. Trained pathologists scored interstitial fibrosis and tubular atrophy (IFTA) on a semi-quantitative scale. We measured plasma and urine concentrations of nine endogenous secretory solutes using a targeted liquid chromatography mass-spectroscopy assay. We used linear regression to test associations of urine to plasma ratios (UPR) of these solutes with IFTA score after controlling for estimated GFR (eGFR) and albuminuria.

Results: Among 418 persons, the mean age was 53 years, 51% were women, 64% were White and 18% were African American. The mean eGFR was 50 ml/min/1.73m^2 and median albumin/creatinine ratio was 890 mg/g. Compared to individuals with no IFTA, those with >50% IFTA had 27 to 76% lower UPR for the all 9 secretory markers. After adjusting for age, sex and race, these associations remained essentially unchanged. After further adjusting for eGFR and albuminuria this association were attenuated [Image] but the trend across groups remained statistically significant (p for trend <0.05) for all 9 solutes. For example, persons with >50% IFTA had, on average, 44% lower (95% CI 12% - 65% lower) UPR of p-cresol sulfate, a highly protein bound secretory solute, compared to persons with no IFTA. A composite secretory index incorporating UPR for all 9 secretory solutes using the min-max method showed similar results.

Conclusions: Greater IFTA severity is associated with lower tubular clearance of endogenous solutes clearance even after adjusting for eGFR and albuminuria.

Funding: NIDDK Support

Proximal Tubule Albumin Uptake: Potential Role for Endothelin System in Sickle Cell Disease Mice

Malgorzata Kasztan, David M. Pollock. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Elevated plasma endothelin-1 (ET-1) reported in sickle cell disease (SCD) patients correlate with microalbuminuria, a major mortality risk factor in SCD. ET-1 contributes to glomerular and tubular injury in SCD, as evidenced by increased glomerular permeability to albumin and urinary excretion of tubular injury markers. Although selective ET_A receptor antagonism reduces albuminuria in humanized sickle cell (HbSS) mice, the mechanism of this action remains unclear. The aim of the study was to determine whether selective ET_A receptor antagonism prevents albuminuria by preserving the expression of tubular albumin-associated transporters in proximal tubule (PT) cells.

Methods: Male C57BL/6 or HbSS and genetic control (HbAA) mice were used to determine the effect of ET-1 on the expression of proximal tubule albumin trafficking mediators, such as megalin and NHE-3.

Results: Exposure of primary mouse PT cells to ET-1 (50nM) for 8h decreased megalin (53% reduction) and doubled NHE-3 expression. Pre-treatment with the ET_A antagonist, BQ123 (1 μM), preserved megalin expression and had no effect on NHE-3. Moreover, selective ET_B receptor blockade (BQ788, 1 μM) prevented ET-1-mediated increase in NHE-3 expression. Primary PT cells isolated from HbSS mice showed decreased megalin mRNA expression as well as protein abundance relative to HbAA PT controls. Ten-week treatment with selective ET_A receptor antagonist (10mg/kg/day) preserved expression of megalin at control levels. There were no differences in NHE-3 mRNA expression in HbSS PT cells regardless the treatment. Interestingly, PT cells from HbSS cultured with HbSS plasma and ET-1 (10nM) had decreased NHE-3 protein abundance compared to non-treated cells.

Conclusions: These results potentially uncover a novel role for ET-1 in PT albumin handling and suggest that PT ET-1 receptor signaling contributes to albuminuria in SCD.

PO0621

Phosphate and Fibroblast Growth Factor 23 Are Mediators of Lung Injury in CKD

Seth Bollenbecker,[1] Brian A. Czaya,[2] Molly Easter,[1] Dominik Kentrup,[2] Jarrod W. Barnes,[1] Christian Faul,[2] Stefanie Krick.[1] *[1]University of Alabama at Birmingham, Division of Pulmonary, Allergy, and Critical Care Medicine, Birmingham, AL; [2]University of Alabama at Birmingham, Division of Nephrology, Birmingham, AL.*

Background: Although well-documented in chronic kidney disease (CKD), the role of phosphate in pulmonary pathology is not widely known. Phosphorus, or phosphate in its oxidized circulating form, is normally removed from the body by healthy kidneys. CKD disrupts this process, leading to hyperphosphatemia in later stages. We have shown that fibroblast growth factor 23 (FGF23), a key regulator of phosphate metabolism, is elevated in inflammatory lung diseases; that increase in FGF23 contributes to unfavorable clinical outcomes. To improve outcomes for patients with concomitant CKD and pulmonary disease, we wanted to examine direct actions of phosphate and FGF23 and their potential underlying mechanisms.

Methods: For *in vitro* experiments, human lung fibroblasts were treated with 0 to 5 mM sodium phosphate. Expression levels of interleukin (IL)-8 and collagen (COL)1A1 were analyzed by qPCR. Cell counts and viability were quantified with trypan blue staining. *In vivo*, we placed C57Bl/6 mice on a high phosphate (3%) diet to elevate serum phosphate levels in absence of kidney injury and administered bleomycin via oropharyngeal aspiration to generate an acute pulmonary inflammatory response. Serum FGF23 levels were measured by ELISA and serum analysis for phosphate and renal function were obtained. Expression of FGF23 pathway and inflammatory markers were analyzed in murine lung and kidney tissue using qPCR and western blotting.

Results: Augmented phosphate concentrations increased IL-8 and COL1A1 expression from human lung fibroblasts with a concomitant reduction in overall cell number. Serum FGF23 levels were significantly upregulated in mice on a high phosphate diet and further increased in these mice when exposed to bleomycin. Serum phosphate and creatinine levels were significantly elevated. High phosphate and bleomycin increased local FGF23 expression in murine lung tissue.

Conclusions: Upregulation of FGF23 in response to bleomycin during a high phosphate diet suggests that inflammation induced by primary lung injury is worsened by systemic elevation of serum phosphate levels. Our data suggest that in CKD, high serum phosphate levels may increase susceptibility and progression of lung injury. Our results indicate that the existence of a pulmo-renal crosstalk is exaggerating pulmonary injury.

PO0622

APOL1 Risk Variants Mediate Increased Oxidative Phosphorylation Complexes Biogenesis and Mitochondrial Dysfunction

Mengyuan Ge,[1] Gloria Michelle Ducasa,[1] Shamroop Kumar Mallela,[1] Shaoyi Liu,[2] Hazel H. Szeto,[2] Jeffrey B. Kopp,[3] Flavia Fontanesi,[4] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Katz Family Division of Nephrology and Hypertension/ Drug Discovery Center, University of Miami, Miami, FL; [2]Social Profit Network Research Lab, Alexandria LaunchLabs, New York, NY; [3]Kidney Disease Section, NIDDK, NIH, Bethesda, MD; [4]Department of Biochemistry and Molecular Biology, University of Miami, Miami, FL.*

Background: Susceptibility to focal segmental glomerulosclerosis (FSGS) in African Americans is associated with genetic variants of the Apolipoprotein L1 gene (*APOL1*) named G1 and G2. APOL1 risk variants (RV) are a major driver of mitochondrial dysfunction. The mitochondrial specific lipid cardiolipin (CL) interacts with oxidative phosphorylation (OXPHOS) complexes and plays an important role in the biogenesis of OXPHOS complexes. While APOL1 function was assessed in tagged and overexpressed systems, studies evaluating the functions of endogenous APOL1 protein are missing.

Methods: We studied mitochondrial function using human urinary podocyte-like epithelial cells (HUPECs) established from patients with FSGS carrying different APOL1 alleles. Protein and mRNA levels were measured by WB and quantitative PCR respectively. TEM was performed to study mitochondrial morphology. OXPHOS complexes were studied by BN-PAGE analysis followed by WB. To study how APOL1 RV contributes to mitochondrial dysfunction, we purified APOL1-6xHis protein using HeLa cells infected with lentivirus carrying the APOL1 G0, G1 under the CMV promoter, followed by protein-lipid overlay assay.

Results: The expression of endogenous APOL1 was decreased in HUPECs carrying RVs (G1/G2 HUPECs) when compared to G0/G0 carrying HUPECs. We observed reduced mitochondrial function in the presence of increased OXPHOS complexes in G1/G2 HUPECs. Using TEM, reduced mitochondrial matrix density and increased mitochondrial area were detected in G1/G2 HUPECs. Hyperbranched mitochondria in G1/G2 HUPECs were accompanied by a significant increase in the mRNA levels of mitochondrial fission and fusion proteins FIS1 and MFN1. The affinity of APOL1 G1 to CL was significantly higher than the affinity of APOL1 G0 to CL, when normalized to 6xHis tagged APOL1 expression. We found the mRNA level of cardiolipin synthase (CRLS1) was significantly increased in G1/G2 HUPECs, which is consistent with the overexpression of OXPHOS complexes in G1/G2 HUPECs.

Conclusions: Our findings indicate that endogenous APOL1 RV expression in human podocytes is associated with mitochondrial dysfunction in the presence of increased OXPHOS complexes, and that APOL1 RVs interact with CL thus interfering with CL function in mitochondria.

Uncovering Genomic Alterations in DOCA-Salt Nephropathy Rats Treated with Finerenone

Junnan Wu,[1] Ziyuan Ma,[1] Hana Cernecka,[2] Ralf Lesche,[2] Peter Kolkhof,[2] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Bayer AG, Leverkusen, Germany.*

Background: The aldosterone antagonist spironolactone has antifibrotic effects but its clinical use is limited due hyperkalemia, especially in patients with kidney disease. The novel nonsteroidal and selective mineralocorticoid antagonist finerenone has recently been developed with pronounced antifibrotic activity at doses which have only limited effect on the potassium homeostasis. The exact molecular transcriptional targets of spironolactone and finerenone, however, remain unknown. Since there are more than 20 different cell types in the kidney, single cell RNA and single cell epigenome (ATAC) analysis can help to define transcriptional targets.

Methods: We treated uninephrectomized, Sprague-Dawley rats injected with DOCA and salt with a high dose of finerenone (10mg/kg/d), spironolactone (50mg/kg/d), or vehicle. Outcome parameters included blood pressure, serum and urine electrolytes, albuminuria, renal and cardiac histology. Single nuclei suspension was prepared from kidneys and hearts for single nuclear RNA and single nuclear open chromatin (ATAC) profiling using the 10X Genomics Chromium platform as well as bulk RNA sequencing.

Results: Finerenone and spironolactone resulted the same degree of blood pressure reduction. DOCA treated rats developed severe myocardial hypertrophy and focal vasculopathy, glomerulosclerosis and tubulointerstitial fibrosis. Finerenone significantly attenuated cardiac and renal histological damage. DOCA-salt rats developed marked albuminuria which was significantly attenuated by spironolactone and finerenone. Serum potassium was elevated in the spironolactone group at weeks 6, but it was unchanged compared to controls in the finerenone group. Bulk RNA-seq results revealed the reduced enrichment of immune response related transcripts in finerenone group compared with DOCA and spironolactone group. Single-nuclei open chromatin and gene expression profiling uncovered genomic alterations in different cell types in finerenone-treated kidneys.

Conclusions: Taken together, these findings demonstrated that treatment with finerenone protected from DOCA salt induced cardiac hypertrophy, glomerulosclerosis and kidney fibrosis without a significant increase in serum potassium. Single cell epigenome analysis highlighted transcriptional targets of aldosterone, spironolactone and finerenone.

Cell Type-Specific Chromatin Architecture Reveals Target Genes for Kidney Disease Risk Variants

Jingping Yang,[1,2] Aiping Duan,[1] Zhihong Liu.[1] *[1]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing, China; [2]Nanjing University, Nanjing, China.*

Background: Although GWAS studies have identified hundreds of genetic variants associated with kidney diseases, the identification of causal variants and their target genes are rather limited. Most of disease-associated variants locate in non-coding elements. The roles of these elements are cell type-specific. Additionally, due to the non-linear regulation of the elements, the identification of causal variants as well as their target genes is even more challenging.

Methods: In order to understand the genetic risk of kidney diseases, we generated a cell type-specific set of epigenetic landscape including transcription-centered 3D chromatin organization, histone modifications distribution and transcriptome with HiChIP, ChIP-seq and RNA-seq respectively, in kidney tubule cells. We integrated the epigenetic annotation to identify causal variants and target genes which were further tested by CRISP techniques in zebrafish.

Results: We identified genome-wide functional elements and thousands of interactions between the distal elements and target genes. The results revealed that risk variants for renal tumor and chronic kidney disease were enriched in kidney tubule cells. We further pinpointed the target genes for the variants and validated two target genes by CRISP techniques in zebrafish, demonstrating that SLC24A1 and MTX1 were indispensable genes to maintain kidney function.

Conclusions: Our results produce valuable multi-omic resource and establish a bioinformatic pipeline in dissecting functions of kidney diseases-associated variants based on cell type-specific epigenetic landscape.

PO0625

A Comprehensive Transcriptome Profiling of Adipocyte Na-K-ATPase Signaling in Uremic Cardiomyopathy by RNA Sequencing Analysis

Komal Sodhi. *Joan C Edwards School of Medicine at Marshall University, Huntington, WV.*

Background: Oxidant stress plays a key role in the development and progression of uremic cardiomyopathy. We have recently demonstrated that adipocyte dysfunction and uremic cardiomyopathy developed in partial nephrectomy mice model, were significantly ameliorated by adipocyte-specific expression of NaKtide, an antagonist of Na/K-ATPase signaling. Hence, to better characterize the cellular transcriptome that are involved in various biological pathways associated with adipocyte function, we aim to explore the genomic approach in the present study, through RNAseq analysis.

Methods: For invitro studies, mouse adipocytes were subjected to oxidized LDL (oxLDL) or indoxyl sulfate (IS) with or without pNaKtide treatments. Partial nephrectomy was performed in C57Bl6 mice in order to produce experimental uremic cardiomyopathy. Specific expression of NaKtide in adipocytes was achieved using a lentivirus construct driven by an adiponectin promoter. A complete RNAseq analysis was performed using DESeq2 R package in combination with packages to perform over-representation analysis (ORA) and gene set enrichment analysis (GSEA).

Results: Several gene subsets corresponding to various biological processes and molecular phenotype were differentially expressed in adipocytes with in vitro oxLDL/IS treatments and in vivo PNx model. These genes, compared using GSEA analysis, showed that more than 75% of the Kegg pathways were similar among the in vitro treatments and in vivo model. The pathways that were common between in vitro and in vivo treatments, including adipogenesis, ROS signaling, inflammatory response and oxidative phosphorylation pathways, have profound impact on the pathogenesis of uremic cardiomyopathy. The overall analysis showed a widespread normalization of gene expression by pNaKtide/adipose specific NaKtide treatments that were altered in uremic cardiomyopathy.

Conclusions: The study provides a detailed genome-wide molecular information about adipocyte function in relation to uremic cardiomyopathy pathogenesis. These data provide deeper insight into the activation of pathways associated with adipocyte Na/K-ATPase signaling, which may be a viable clinical target for the prevention and treatment of uremic cardiomyopathy.

PO0626

Transcriptomic Profiling Identifies Potential Mediators of Tubular Injury Sensitization of Glomeruli to Subsequent Second Hits

Janka Babickova,[1,2] Xin Li,[3] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Universitetet i Bergen, Bergen, Norway; [3]Shanghai Jiao Tong University, Shanghai, China.*

Background: Previous studies have shown that even isolated mild tubular injury leads to more severe glomerular damage in response to subsequent injury. The responsible mediators for this sensitization are unknown.

Methods: Double transgenic male mice, Nep25/DTR^{+} (expressing human CD25 receptor on podocytes and Diphtheria toxin receptor on proximal tubular cells) and Nep25/DTR^{-} (n=5 per group) were used. Tubular injury was induced by injecting diphtheria toxin, followed by uninephrectomy (Nx) 4 weeks later and induction of glomerular injury

by LMB2 toxin (CD25 ligand) one week after Nx. Mice were sacrificed 4 weeks after LMB2. Glomeruli and tubules from Nx were separated by sieving technique, RNA was isolated from tubules and next generation RNA sequencing was performed.

Results: Histopathological analysis and urinary Kim-1 at Nx and sacrifice confirmed mild tubulointerstitial fibrosis at Nx in Nep25/DTR+ but not Nep25/DTR- mice, and more severe glomerulosclerosis and albuminuria at sacrifice after LMB2 in Nep25/DTR$^+$ vs Nep25/DTR$^-$ mice. RNA sequencing revealed 283 differentially expressed genes between the groups, with 93 over-represented and 190 under-represented in Nep25/DTR$^+$ vs Nep25/DTR$^-$. GO of biological processes showed involvement in 13 processes, with the highest amount of genes involved in cellular processes, biological regulation and metabolic processes. STRING analysis of protein-protein interactions (PPI) based on cellular processes detected interactions between the Serpin family members: plasminogen activator inhibitor PAI-1 (*Serpine1)*, alpha-1-antitrypsin 1-2 (*Serpina1b)*, protein Z-dependent protease inhibitor (*Serpina10*) and complement C4b (*C4b*). In addition, members of the non-canonical Wnt signalling pathway Wnt-9a (*Wnt9a)* and Wnt-10a *(Wnt10a)* and their interactors latent transforming growth factor beta binding protein 2 (*Ltbp2*) and VANGL planar cell polarity protein 2 (*Vangl2*) were over-represented and PPI of these genes was found. Quantitative real-time PCR confirmed numerically higher expression of all above-mentioned genes in Nep25/DTR$^+$.

Conclusions: High-throughput RNA sequencing of isolated tubules with mild injury revealed potential novel mediators of glomerular sensitization to a subsequent injury. Further experimental validation of the effects of the identified molecules on glomerular injury are warranted.

A Novel Short ACE2 Variant Causes ACE Suppression and Fosters Ang 1-7 Formation in a Murine Model of CKD

Gvantca Gulua,[1,2] Jan Wysocki,[1] Arndt Schulze,[1,2] Minghao Ye,[1] Chad R. Haney,[1] Ming Zhao,[1] Zheng J. Zhang,[1] Daniel Batlle.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: ACE2 is a monocarboxypeptidase that cleaves Ang II to form Ang-(1-7). It is a large molecule the administration of which leads to increased enzyme activity in plasma, but not in the urine or kidney tissue. We have developed a truncated form of ACE2 that has a longer half-life by fusing it with an Albumin-binding domain (ABD) and is still short enough to be filtered by the kidney. In this study we examined the impact of this novel variant of ACE2 on kidney RAS in a model of CKD.

Methods: We used a 5/6 Nephrectomy model in CD-1 mice. The ACE2-ABD was given 3 days post-ablation surgery and thereafter every 3-4 days (3 ug/g BW) for 5 weeks. Afterwards, mice were euthanized and kidneys collected for analyses of RAS components.

Results: Administration of ACE2-ABD resulted in increased plasma ACE2 activity (768 vs. 12 RFU/ul/hr, p<0.0001). In kidney lysates there was also an increase in ACE2 activity (32 vs. 22 RFU/ug protein/hr, p=0.03) and a decrease in ACE activity (7187 vs. 4006 RFU/ug protein/hr, p=0.0001). These changes in enzymatic activities were accompanied by a significant increase in kidney Ang-(1-7) (90 vs. 37 fmol/mg protein, p=0.0014) without a significant change in Ang II levels (272 vs. 299 fmol/mg protein). To verify the kidney uptake of our ACE2 variant SPECT/Micro-CT imaging was performed. After the injection of radiolabeled ACE2-ABD kidney uptake was clearly seen (red) (Figure).

Conclusions: A long-acting form of a short ACE2 variant fused with ABD given every 3-4 days resulted in sustained plasma ACE2 activity and an increase in kidney ACE2 activity associated with suppressed kidney ACE activity. These enzymatic changes provide a favorable kidney RAS profile with increased Ang-(1-7), which overall should be renoprotective.

Disruption of the H3K4 Methyltransferase MLL-1/Menin Complex Attenuates Renal Fibrosis Development by Inhibiting Epithelial-Mesenchymal Transition and Fibroblast Activation

Jianan Zou, Shougang Zhuang. Rhode Island Hospital, Brown University *Rnode Island Hospital, Brown University, Providence, China.*

Background: The MLL-1/menin was disrupted by MI-503 and/or siRNA in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO), cultured mouse proximal tubular cells and fibroblasts exposed to serum and transforming growth factor β1 (TGFβ1). Protein expression or activation was determined by immunofluorescent microscopy and immunoblot analysis.

Methods: The MLL-1/menin was disrupted by MI-503 and/or siRNA in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO), cultured mouse proximal tubular cells and fibroblasts exposed to serum and transforming growth factor β1 (TGFβ1). Protein expression or activation was determined by immunofluorescent microscopy and immunoblot analysis.

Results: Injury to the kidney increased MLL1 and menin expression and H3K4 monomethylation (H3K4me1) in renal tubular epithelial cells and fibroblasts. Administration of MI-503, a highly selective inhibitor of the MLL1/menin complex, attenuated renal fibrosis and expression of α-smooth muscle actin, fibronectin and collagen I. Treatment with MI-503, MLL1 siRNA or menin siRNA also inhibited TGFβ1 and serum-induced activation of epithelial-mesenchymal transition (EMT) in vitro. Moreover, UUO injury induced epithelial expression of phospho-histone 3 at Serine 10 and expression of profibrotic factors, TGFβ1 and connective tissue growth factor; and blocking the MLL1/menin complex with MI-503 inhibited these responses. Finally, MLL1 inhibition reduced expression of snail and twist, two transcription factors involved in the development of EMT and renal fibrosis and the expression of *proliferating cell nuclear antigen,* cyclin D1 and p27 in fibroblasts.

Conclusions: Our data suggest that targeting disruption of the MLL1/menin complex can attenuate renal fibrosis through inhibition of EMT and fibroblast activation/proliferation.

Transcriptomic Profiling of Thick Ascending Limb Cells In Vivo Reveals the Complex Network of Genes Regulated by Uromodulin

Kaice A. LaFavers, Shehnaz Khan, Nida A. Khan, Laura Apple, Radmila Micanovic, Tarek M. El-Achkar. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Tamm-Horsfall Protein (THP or Uromodulin, gene: *Umod*) is a protein uniquely made in the kidney by cells of the thick ascending limbs (TAL) of the loop of Henle. We previously established that THP has protective biological functions. Furthermore, THP production is decreased with chronic kidney disease (CKD). It was suggested that the promoter region of the *Umod* can regulate other genes. THP deficiency itself could alter the expression of other genes. Here, we used an unbiased approach to study the effect of a deletion in the *Umod* promoter/gene and the resultant THP deficiency on the transcriptomic profile of TAL cells in vivo.

Methods: THP$^{-/-}$ mice resultant from deletion of exons 1-4 and part of the *Umod* promoter were used, along with THP$^{+/+}$ controls. Immuno-fluorescence guided laser microdissection was performed to isolate TAL cells from the medulla of kidneys of THP$^{-/-}$ and THP$^{+/+}$ mice. After RNA extraction, next generation RNA sequencing and transcriptomic analysis was performed.

Results: The transcriptomic profile of medullary TAL cells was comprehensively defined *in vivo*. 85% of the top 250 expressed genes were common between THP$^{+/+}$ and THP$^{-/-}$ TAL cells. Overall, 33 protein-coding genes, including *Umod*, were differentially expressed (FDR<0.05). These encompassed genes with a variety of functions such as immunomodulation (*Erdr1*, *Gp2*), cytoskeletal/extracellular matrix fibers (*Lama1*, *Cttnbp2*) and signal transduction (*Camk2b*, *Ptprn2*). One down-regulated gene was a direct neighbor to the Umod locus (*Gp2*) on chromosome 7. However, many other affected genes were on different chromosomes. Bioinformatic analysis revealed that THP deficiency is associated with significant clustering of genes involved in connective tissue formation and activation or dysfunction of molecular mechanisms that could lead to fibrosis.

Conclusions: We delineated a comprehensive transcriptomic profile of TAL cells *in vivo* from mouse kidneys. Although highly expressed genes in TAL may not be altered by THP deficiency, many close and distant genes are regulated by the *Umod* locus or altered by the absence of THP. The absence of THP may also prime the TALs cells towards a fibrosis program. These findings may contribute to understanding the pathogenesis of CKD progression.

Lipid Metabolic Profiling of Ex Vivo Isolated Glomeruli as a Screening Platform for Modelling Glomerular Metabolic Dysfunction During Renal Disease

Simone Romoli,[1] Fynn N. Krause,[2] Julian L. Griffin,[2] Pernille B. Laerkegaard Hansen,[1] Kevin Woollard.[1] Renal Bioscience ex-vivo glomerular team [1]*Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom;* [2]*University of Cambridge Department of Biochemistry, Cambridge, United Kingdom.*

Background: Dysregulated renal metabolism is a hallmark of loss of function in CKD. It is established that changes in tubular metabolism impact tubular functionality during progression of CKD. However, lipid metabolism in the glomerulus during CKD remain poorly described. Here, we use Isolated Glomeruli (IRG) to study lipid metabolism for metabolic drug discovery in kidney diseases.

Methods: Sprague Dawley rat glomeruli were isolated by differential sieving. We used disease inducers: Adriamycin 1uM (ADR) and AngiotensinII 100nM (AngII) for 24h. To probe metabolic activity, we used an LC-MS approach to quantify uptake and excretion rates of relevant metabolites in culture media, and to measure intracellular metabolites and lipids.

Results: We developed a new cultivation protocol for IRG, using organoids media and shaking platform to maximizing the biological activity. Metabolic and lipidomic profiles of IRG were monitored up to 150h. We saw significant metabolic activity for a wide range of metabolites: Uptake and excretion rates rapidly changed during the first 24h of culture, after which they declined. Metabolic rates for glutamine, glutamate and alanine were comparatively stable. Following treatment with AngII or ADR glomeruli exhibited metabolic changes after 24h: AngII reduced asparagine uptake, and induced trends towards lower substrate uptake consistent with reduced metabolic activity. Both ADR and AngII perturbated intracellular metabolite levels: nucleosides adenosine (-159%) and inosine (-171%), increases in 1,3-BPG (+194%), and changes in NAD (+209%), which suggest alterations in pentose phosphate pathway. Multivariate analysis revealed differentially responding lipid clusters: specifically, significant abundance and saturation ratio increases of intracellular FFA, including stearate (+34%), oleate (+102%) and arachidonate (+107%), as well as the depletion of several phosphatidylcholine and phosphoethanolamine species following AngII, which have been implicated as renal injury markers and/or relevant to renal injury protection.

Conclusions: Our results show alterations in lipid metabolism after IRG stimulation with AngII and ADR after 24h. We propose IRG/lipid metabolome as a novel platform/tool for understanding lipid signalling and improving CKD drug discovery.

Study on the Mechanism of Microinflammation with Uremia Caused by Lactobacillus Activation of Intestinal Macrophages by Mincle

Lingshuang Sun, Hongli Jiang. *First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: My previous studies have found that Intestinal macrophages in the uremic rats are polarized towards a proinflammatory phenotype and assist bacterial translocation resulting in microinflammation. However, it is still unclear what kind of mechanism activates intestinal macrophages in uremia.

Methods: Male Sprague-Dawley rats were randomly divided into two groups: sham, uremia. Immunochemistry was used to analyze the expression of macrophage-inducible C-type lectin (Mincle). RT-PCR and western blot were employed to assess the mRNA and protein expression of toll-like receptor 4 (TLR4).

Results: Our RCT study found that the number of Lactobacilli in the intestines of patients with end-stage diabetic nephropathy was significantly higher than that in non-diabetic patients. The plasma levels of endotoxin, CRP, IL-6, and TNF-a in the uremia group were greater than those in the sham group (p>0.05)(Table 1). Compared with the sham group, the uremia group exhibited macrophages with higher staining intensities for Mincle and higher mRNA and protein expression of TLR4(Figure1-2).

Conclusions: The solution to this scientific problem will not only clarify the molecular mechanism of intestinal bacteria in controlling the activation of intestinal macrophages, but also to clarify the micro-inflammation state of uremia.

Angiotensin II Type 1a Receptor Loss Ameliorates Chronic Tubulointerstitial Damage After Renal Ischemia Reperfusion

Yoko Fujita,[1] Takeshi Sugaya,[1] Daisuke Ichikawa,[1] Jun Tanabe,[1] Kenjiro Kimura,[2] Yugo Shibagaki,[1] Atsuko Ikemori.[1,3] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [2]JCHO Tokyo Takanawa Hospital, Tokyo, Japan; [3]Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.*

Background: Although angiotensin II (Ang II) type 1 receptor blocker was reported to attenuate chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR), its effect is limited. The aim of this study is to reveal whether suppressed activation of angiotensin II type 1a receptor (AT1a) ameliorates severe chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR).

Methods: To induce severe chronic TID after renal IR, unilateral renal ischemia for 45 min was performed via clamping of right renal pedicle using cerebral aneurysm clip in AT1a knockout homo ($AT1a^{-/-}$) male mice and wild type ($AT1a^{+/+}$) male mice. Right and left kidneys were removed at 3, 28 and 70 days postischemia. Left kidneys were used as control. Furthermore, another $AT1a^{+/+}$ mice were administered hydralazine to maintain the same levels of systolic blood pressure (SBP) as the $AT1a^{-/-}$ mice because the SBP levels of the $AT1a^{-/-}$ mice were significantly lower compared to the $AT1a^{+/+}$ mice.

Results: Acute tubular necrosis in IR-kidneys of both $AT1a^{-/-}$ mice and $AT1a^{+/+}$ mice was observed at 3 days postischemia, and the degree was significantly more severe in the IR-kidneys of $AT1a^{-/-}$ mice than in the IR-kidneys of $AT1a^{+/+}$ mice. Conversely, the degrees of both interstitial fibrosis at 28 and 70 days postischemia and proximal tubular loss at 70 days postischemia were significantly attenuated in the IR-kidneys of $AT1a^{-/-}$ mice compared to the $AT1a^{+/+}$ mice. While marked renal atrophy at 70 days postischemia was induced in the $AT1a^{+/+}$ mice, such a development was not provoked in the$AT1a^{-/-}$ mice. Although the administration of hydralazine in the $AT1a^{+/+}$ mice mildly attenuated the degree of TID at 70 days postischemia, the degree of the $AT1a^{+/+}$ mice was significantly greater compared to the $AT1a^{-/-}$ mice. Because renal expression levels of angiotensin-(1-7) protein at 28 days postischemia was significantly higher in the $AT1a^{-/-}$ mice compared to the$AT1a^{+/+}$ mice, renala ngiotensin-(1-7) may contribute to amelioration of chronic TID after IR in the $AT1a^{-/-}$ mice.

Conclusions: Early administration of Ang II type 1 receptor blocker in recovery phase after AKI may be useful for prevention of AKI-to-CKD transition.

Anti-Interleukin 22 Antibody Relieves Angiotensin II-Induced Renal Injury in Mice Through Inhibiting NLRP3 Inflammasome Activation

Rong Tang. *Xiangya Hospital Central South University, Changsha, China.*

Background: Interleukin-22 (IL-22) is considered as a proinflammatory cytokine and participates in the pathogenesis of inflammatory and autoimmune diseases. Previously, we found that serum IL-22 increased significantly in hypertensive renal damage patients, and IL-22 were positively correlated with renal damage. The aim of this study was to investigate whether anti-IL-22 antibody exerts renoprotective effect via inhibiting NLRP3 inflammasome activation in angiotensin II (Ang II) induced hypertensive renal damage in mice.

Methods: Ang II was infused subcutaneously at a rate of 1.5 mg/kg/d to C57BL/6 mice for 28 days to establish the hypertensive model. One day after modeling, mice were injected intraperitoneally every other day with saline, recombinant mouse IL-22 (rIL-22; 20 ug/kg), mouse anti-IL-22 monoclonal antibody (anti-IL-22 mAb; 1.25 ug/mouse) or isotype IgG. So mice were divided into 5 groups: control, Ang II, Ang II+rIL-22, Ang II+anti-IL-22, Ang II+IgG. 28 d after Ang II infusion, all mice were euthanized. Blood pressure, urinary albumin/creatinine ratio, serum creatinine (Scr) and renal histopathology were measured. NLRP3, cleaved caspase-1 and IL-1β in kidney were detected by western blot. Renal inflammatory factors were detected by ELISA, IL-22 and IL-22R1 in kidney were detected by immunohistochemistry, fibrotic related factors expression in kidney were evaluated by western blot.

Results: IL-22 and IL-22R1 Levels were elevated in kidney of Ang II-induced mice. Anti-IL-22 mAb therapy ameliorated proteinuria excretion, Scr and renal pathological damage in mice with established hypertensive renal injury. Blood pressure in Ang II-infused mice was also decreased after the treatment of anti-IL-22 mAb. In addition, anti-IL-22 mAb reduced NLRP3, cleaved caspase-1, IL-1β, TNF-α and IL-6 expression in kidney, along with inhibition of renal fibrotic related factors expression.

Conclusions: Anti-IL-22 antibody can reduce renal inflammation and fibrosis in Ang II-induced hypertensive mice, which may be through suppression of NLRP3/caspase-1/IL-1β pathway, suggesting it might exert therapeutic potential for the treatment of hypertensive renal injury.

PD-1 Regulates Group 3 Innate Lymphoid Cells in Renal Fibrosis

Zhou Liang,[1] Hao-Jie Zhong,[2] Chang-Jian Zhu,[1] Yi Zhou.[1] *[1]The first Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Guangdong Medical University, Guangzhou, China.*

Background: Group 3 Innate Lymphoid Cells (ILC3) belong to a new family of innate effectors, participating in lots of inflammatory and fibrotic diseases. However, limited information exists on the molecular mechanisms regulating these cells. Here, we investigated the expression and function of the immune checkpoint programmed cell death-1(PD-1) in ILC3 during renal fibrosis.

Methods: Unilateral ureteral obstruction (UUO)-induced renal injury tested subsets of ILC3 activities in immune responses and tissue fibrosis. Kidney and intestine were collected to define the frequency, localization and characterization of $PD\text{-}1^{+}$ILC3. Loss/gain-of-ILC3s in UUO mice were designed to investigate their roles in renal fibrosis progression. And the fibrogenic effects of ILC3s and the regulatory activity of PD-1 were determined by *in vitro* co-culture experiments.

Results: ILC3 were accumulated rapidly in fibrotic kidneys, with surrounding by increasing number of active myofibroblasts, and more interestingly, coincided with a robust depletion from the intestines of mouse models, suggesting a functional recruitment of ILC3 after kidney injury. Moreover, fibrosis was associated with an increase of PD-1 expression in ILCs, and up-expression of PD-1 ligand, PD-L1 was also detected in fibrotic kidney, suggesting a possible involvement of PD-1/PD-L1 pathway. Adoptive transfer of purified intestinal ILC3 into UUO mice significantly enhanced renal fibrosis than those with PBS, whereas PD-1-deficent ILC3 protects kidney from fibrosis. Notably, mice that lacked ILC3s exhibited reduced inflammatory infiltration and decreased fibroblast activation. *In vitro* studies, direct co-culture of WT-ILC3 with primary renal fibroblasts exacerbates inflammatory response and extracellular matrix production (ECM), which could be blocked by the treatment with neutralizing anti-IL-17A and anti-IL-22 antibodies. Yet co-cultured with PD-1-deficent ILC3 displayed reduced fibrotic activity.

Conclusions: Our findings provided the first evidence that during renal fibrosis, PD-1/PD-L1 axis might play a regulatory role in ILC3 migration and fibrogenesis via producing pro-fibrotic cytokines IL-17A and IL-22.

PO0635

Interaction Between the Na-K-ATPase and CD40 Signaling in Proximal Tubule Epithelial Cells (PTECs) Contributes to Renal Inflammation and Fibrosis

Steven T. Haller,[1] Shungang Zhang,[1] Ying Nie,[2] Joseph I. Shapiro,[2] Jiang Liu.[2] *[1]Department of Medicine University of Toledo College of Medicine and Life Sciences, Toledo, OH; [2]Marshall University Joan C. Edward School of Medicine, Huntington, WV.*

Background: We have demonstrated that signaling through the Na/K-ATPase-α1 subunit/c-Src kinase (NKA-α1/c-Src) complex and activation of the pro-inflammatory receptor, CD40 induce renal inflammation and fibrosis in both clinical and experimental models of ischemic and chronic kidney disease (CKD). Circulating cardiotonic steroids (specific ligands of Na/K-ATPase) are significantly elevated in CKD that not only stimulate NKA-α1/c-Src signaling, but also regulate CD40 signaling by upregulation of CD40 expression in PTECs. Furthermore, soluble CD40 ligand (sCD40L)-stimulated CD40 signaling in PTECs is dependent on NKA-α1/c-Src signaling. However, the interplay between Na/K-ATPase and CD40 signaling-induced renal inflammation and fibrosis has not been thoroughly investigated.

Methods: RNA sequencing was performed on pig PTECs with and without a functional NKA-α1/c-Src signaling complex (Ly-α2 cells and Lx-α2 cells, respectively) following treatment with sCD40L (100ng/mL) for 24hrs. In pig PTECs LLC-PK1 cells treated with the cardiotonic steroid telocinobufagin (TCB), immunoprecipitation was performed to detect protein-protein interaction.

Results: Treatment with sCD40L in Ly-α2 cells demonstrated a significant increase in gene expression of pro-inflammatory and pro-fibrotic mediators [CXCL9, CXCL10, IL1R1, complement C3, and COL1A2 (all > 5-fold increase)] compared to Lx-α2 cells. In LLC-PK1 cells, short-term TCB treatments (up to 1 hr) stimulates interaction between NKA-α1 and CD40 that presents under resting conditions. Long-term TCB treatment (24 hr) still shows the NKA-α1 and CD40 interaction, but reduced NKA-α1 and CD40 interaction was also observed in comparison to control, suggesting a possible endocytosis of NKA-α1 (by the cardiotonic steroid) and CD40.

Conclusions: In renal proximal tubular cells, CD40-induced pro-inflammatory and pro-fibrotic signaling is dependent on the NKA-α1/c-Src complex, and there is an

interaction between NKA-α1 and CD40 that was enhanced by activation of the NKA-α1/c-Src signaling. A regulation through expression level and/or endocytosis of NKA-α1 and CD40 might be involved to control signaling strength.

Soluble Uric Acid, a Negative Regulator of Monocyte Activation in Innate Immunity

Stefanie Steiger,[1] Qiuyue Ma,[1] Maja Lindenmeyer,[2] Paola Romagnani,[3] Hans J. Anders.[1] *[1]Division of Nephrology, Department of Medicine IV, LMU Hospital, Munchen, Germany; [2]Department of Medicine III, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Department of Biomedical Experimental and Clinical Sciences Maria Serio, Univerisity of Florence, Florence, Italy.*

Background: While monosodium urate (MSU) crystals are known to trigger acute inflammation in gouty arthritis, published data on soluble uric acid (sUA) in this context are discrepant. We hypothesized that diverse sUA preparation methods account for this discrepancy and that a novel animal model with clinically relevant levels of asymptomatic hyperuricemia (HU) and gouty arthritis can ultimately clarify this issue.

Methods: Soluble UA was prepared either by pre-warming or solubilized with NaOH. THP-1 cells or CD14+ monocytes from patients with HU and healthy individuals were pre-incubated with sUA prior to stimulation with MSU crystals or LPS. Intracellular sUA uptake via urate transporters was quantified using siRNA technology. *In vivo*, Alb-creERT2;*Glut9*$^{lox/lox}$ and *Glut9*$^{lox/lox}$ control mice were injected with tamoxifen and placed on a chow diet with inosine to induce HU. After 3 weeks, MSU crystals or vehicle were injected into air pouches, and leukocyte infiltration and the extent of inflammation were assessed by flow cytometry, RT-PCR, ELISA.

Results: We found that pre-warmed UA created erroneous results because of microcrystal contaminants triggering IL-1β release. Solubilizing UA with NaOH avoided such artifact. This microcrystal-free preparation suppressed LPS- or MSU crystal-induced monocyte activation, a process dependent on the intracellular uptake of sUA via the urate transporter SLC2A9/GLUT9. CD14+ monocytes isolated from HU patients were less responsive to inflammatory stimuli compared to monocytes from healthy individuals. Treatment with plasma from HU patients impaired the inflammatory function of CD14+ monocytes, an effect fully reversible by removing sUA from HU plasma with rasburicase. Moreover, Alb-creERT2;*Glut9*$^{lox/lox}$ mice with HU (serum UA of 9-11mg/dL) showed a suppressed inflammatory response to MSU crystals compared to *Glut9*$^{lox/lox}$ controls without HU.

Conclusions: We unravel a technical explanation for discrepancies in the published literature on immune effects of sUA and identify HU as an intrinsic suppressor of innate immunity, where sUA modulates the capacity of monocytes to respond to danger signals. Thus, sUA is not only a substrate for the formation of MSU crystals but also an inhibitor of sterile inflammation and may explain several clinical observations in the context of gout and CKD.

PP2Acα Promotes Macrophage Accumulation and Activation to Accelerate Tubular Cell Death and Kidney Fibrosis Through Regulating Rap1 and TNFα Production

Yan Liang, Chunsun Dai. *Nanjing Medical University, Nanjing, China.*

Background: Macrophage accumulation and activation play an essential role for kidney fibrosis, the underlying mechanisms remain to be explored.

Methods: Analyzing the kidneys of patients and animal models with kidney fibrosis. Generating the mice with macrophage PP2Acα ablation.

Results: We observed a significantly increased induction of PP2Acα in macrophages. We then generated mice with macrophage-specific deletion of PP2Acα. These mice developed less renal fibrosis as indicated by less macrophage accumulation, tubular atrophy or extracellular matrix deposition. In cultured cells, the deficiency of PP2Acα in macrophages resulted in decreased cell motility by inhibiting the activity of Rap1. Furthermore, TNFa production was downregulated in macrophages with PP2Acα-deficiency and co-culture of PP2Acα-deficient macrophages and renal tubular cells resulted in less tubular cell death, which was due to decreased TNFα production via phosphorylation of STAT6 in macrophages.

Conclusions: This study shows that PP2A promotes macrophage accumulation and activation, hence accelerating tubular cell death and kidney fibrosis through regulating Rap1 and TNFa production.

PO0638

Investigating LOX and Its Role in AT1R/β-Arrestin Biased Signaling Pathway-Induced Renal Interstitial Fibrosis

Xiaoqin Zhang, Chen Yu. Tongji University, Shanghai, China *Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China, Shanghai, China.*

Background: We studied the downstream and mechanism of β-arrestins signaling in renal fibrosis process and the role of lysyl oxidase (LOX) in the AT1R-β-arrestin pathway

Methods: The mechanism of β-arrestins signaling was studied in normal rat kidney tubule epithelial cells (NRK-52E) treated with SII in vitro. BAPN or placebo was administered during ischemia reperfusion (IR)-induced fibrosis progression. Collagen crosslinking and fibrosis progression were assessed histologically and biochemically.

Results: The mRNA and protein levels of β-arrestin-1 and β-arrestin-2 were significantly upregulated in renal fibrosis model both in vitro and in vivo. SII activated the ERK-STAT3 PY705 but not STAT3-Try727 in nucleus of NRK-52E cells, which effects were abolished when transfection of siRNA targeting β-arrestin-1 and β-arrestin-2 or pretreated with PD98059 (MEK inhibitor). LOX was strongly induced in fibrotic kidney and NRK-52E cells treated with SII. Active LOX significantly increased collagen crosslinking. In established IR-28d renal fibrosis, LOX inhibition promoted fibrosis reversal and with a 25% decrease insoluble collagen. Gene silencing of β-arrestin-1+2 or STAT3 apparently inhibited SII-induced LOX expression in vitro. Besides, chromatin immunoprecipitation (ChIP) assay clearly demonstrating the interaction between STAT3 and the LOX promoter, which indicated LOX is a direct target gene of SII-β-arrestins-STAT3 signaling.

Conclusions: The ERK/STAT3 was downstream of AT1R-β-arrestins, ERK entered the nucleus and activated STAT3-PY705. LOX mediates collagen crosslinking and fibrotic matrix stabilization during renal fibrosis via the AT1R-β-arrestins-ERK-STAT3-PY705 signaling. By blocking this profibrotic pathway, therapeutic LOX inhibition attenuates the fibrosis and suggesting target the LOX has significant potency for the treatment of patients with fibrotic kidney disorders.

Downregulated Endothelial JMJD3 Accelerates Neointimal Hyperplasia of Arteriovenous Fistula in CKD

Shaozhen Feng,[1] Qunying Guo,[1] Eric K. Peden,[2] William E. Mitch,[1] Luan D. Truong,[3] Jizhong Cheng.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Houston Methodist Hospital DeBakey Cardiology Associates, Houston, TX; [3]Houston Methodist Hospital, Houston, TX.*

Background: Epigenetic changes are involved in vascular remodeling. The histone demethylase, Jmjd3, is a transcriptional co-activator that promotes endothelial regeneration. Despite the importance of Jmjd3 in maintaining endothelial function, its role in neointima formation in AVF remains unknown.

Methods: Mice with JMJD3 specific knockout (KO) in ECs was generated. CKD and AVF models were created in Wild type and Jmjd3 EC-specific KO mice. Evans blue, immunostaining assays were used to characterize JMJD3 expression and vascular pathology. Mouse primary ECs and VSMCs were isolated to study the signaling pathways that regulate Jmjd3 expression and endothelial mesenchymal transition (EndMT). The changes found in mouse AVFs were assessed in AVFs from ESRD patients.

Results: JMJD3 expression was downregulated in endothelium of CKD mice. Specific KO of JMJD3 in EC stimulated endothelial barrier dysfunction, EndMT, and inflammatory cells infiltration in AVFs. There were more VSMC proliferation and collagen deposition in AVFs created in Jjmd3 KO mice vs. that of in WT mice. Specific KO of JMJD3 in EC accelerated neointimal hyperplasia of AVF in CKD mice. *In vitro*, inhibition of JMJD3 activity reduced EC proliferation and migration. Suppression of Jmjd3 enhanced the level of histone H3K27me3 promoting its binding to the promoter of EC markers (VE-cadherin and eNOS). These responses resulted in EnMT and VSMC proliferation. Moreover, the expression of JMJD3 is reduced through TGFβ1/Hes1 signaling pathway. In AVFs from ESRD patients, the decreased expression of JMJD3 in ECs was associated with endothelial dysfunction, EndMT, and ECM deposition plus neointimal hyperplasia. Remarkably, endothelial expression of Hes1 in AVFs from ESRD patients was correlated with the decreased JMJD3 level.

Conclusions: These findings demonstrate that TGFβ1-Hes1-JMJD3 signaling exist in ECs which epigenetically regulates EC differentiation and barrier function leading to neointimal hyperplasia of AVF in CKD.

Renal Macrophage Infiltration Precedes Macrophage to Myofibroblast Transition and T-Cell Recruitment Following Repeated Low-Dose Cisplatin Treatment

Sophia M. Sears, Mark A. Doll, Levi J. Beverly, Leah J. Siskind. *University of Louisville School of Medicine, Louisville, KY.*

Background: Cisplatin is a commonly used chemotherapeutic agent with dose-limiting nephrotoxicity. 30% of patients who receive cisplatin develop acute kidney injury (AKI), which significantly increases the risk of developing renal fibrosis and chronic kidney disease (CKD). There are currently no therapies approved to prevent or treat cisplatin-induced kidney injury (CDDP-KI) and fibrosis. Other models of renal fibrosis have demonstrated that macrophages can play a pro-fibrogenic role by differentiating into myofibroblasts, the main effector of fibrotic development. Macrophage to myofibroblast transition (MMT) is proposed to occur when bone marrow derived M2 macrophages undergo chronic TGFβ stimulation. We hypothesize that cisplatin promotes fibrosis and CKD development through stimulating chronic macrophage activity and MMT in the kidney.

Methods: We used a clinically relevant, repeated low dose model of CDDP-KI to characterize the immune response and MMT in the kidney following cisplatin treatment.

Results: Flow cytometric analysis revealed significantly increased numbers of renal infiltration of Ly6C hi inflammatory monocytes and F4/80 lo infiltrating macrophages after four doses of cisplatin. These populations remained elevated above vehicle treated controls after a 6-month age out. At the four dose timepoint, we observed an increase in CD206+ F4/80+ cells and *Arg-1* mRNA, indicating M2 polarization. We also identified a population of F4/80+ CD206+ αSMA+ cells present in the kidney, suggesting MMT is occurring. Interestingly, at the 6-month timepoint renal CD4+ and CD8+ T cell populations remained significantly elevated in cisplatin-treated mice compared to vehicle treated controls.

Conclusions: These studies provide insight on how the immune response to CDDP-KI can promote CKD via infiltration of bone marrow derived macrophages and subsequent M2 polarization and MMT. These early events orchestrate an immune response that continues up to 6-months after cisplatin treatment. Therefore, targeting macrophages could be a potential strategy for preventing the AKI to CKD transition triggered by cisplatin.

Microvascular Loss and Remodeling in Human Kidneys Distal to Severe Atherosclerotic Renovascular Disease

Nattawat Klomjit,[1] Alfonso Eirin,[1] Xiang yang Zhu,[1] Aditya S. Pawar,[1] Amrutesh S. Puranik,[2] Christopher M. Ferguson,[1] Seo Rin Kim,[1] Kyra L. Jordan,[1] Hui Tang,[1] Amir Lerman,[3] Stephen C. Textor,[1] Lilach O. Lerman.[1] *[1]Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; [2]Langone Health, New York University, New York, NY; [3]Department of Cardiovascular Disease, Mayo Clinic, Rochester, MN.*

Background: Renovascular disease (RVD) may induce hypertension and kidney injury, but its effect on the microcirculation of the post-stenotic human kidney remains unclear.

Methods: Kidneys were collected from patients with RVD undergoing unilateral nephrectomy due to refractory hypertension (n=5) and deceased donor kidneys (DK) discarded due to incompatibility (n=7). Renal microvasculature (MV) was studied *in vitro* using micro CT after infusing contrast agent into the renal artery. Kidneys were also compared for angiogenic gene and protein expression.

Results: Age and sex were comparable between RVD and DK. RVD had reduced density of medium-sized (0.2-0.3mm) MV vs. donor kidneys (Fig. A-B, p=0.04), whereas density of small (0.02-0.2mm) and large (0.3-0.5 mm) MV was similar. Vascular tortuosity ratio was higher in RVD vs DK (Fig. C, p=0.05). The number/tubule of peritubular capillaries (PTC) was significantly lower in RVD, as was CD31+ area, whereas numbers of new angiogenic vessels (β3 integrin+, Fig. D) and pericytes were higher. Renal fibrosis and MV remodeling (media/lumen) were greater in RVD, as were oxidative stress and angiopoietin-1 expression, whereas VEGF (p=0.9) and FLK-1 (p=0.2) protein or gene expression were unchanged.

Conclusions: Human RVD kidneys develop marked MV remodeling and loss, particularly of PTC and medium-size MV. Angiopoietin-1 upregulation may promote new PTC formation, but fails to offset overwhelming MV loss distal to severe RVD. These findings underscore the major component of microvascular injury in the development of ischemic kidney disease.

PO0642

Combined Efficacy of the Novel Nonsteroidal and Selective Mineralocorticoid Receptor Antagonist Finerenone and the SGLT2 Inhibitor Empagliflozin in a Non-Diabetic Cardiorenal Rat Model

Peter Kolkhof,[1] Mira Pavkovic,[2] Elke Hartmann,[3] Peter Sandner,[1] Ilka Mathar,[1] Jörg Hüser,[1] Frank Eitner.[1] *[1]BAYER AG, Pharmaceuticals, Research & Development, Cardiovascular Research, Wuppertal, Germany; [2]BAYER AG, Pharmaceuticals, Research & Development, Biomarker Research, Wuppertal, Germany; [3]BAYER AG, Pharmaceuticals, Research & Developent, Research Pathology, Wuppertal, Germany.*

Background: Finerenone and SGLT2 inhibitors have demonstrated clinical benefits in CKD patients with T2D. Efficacy of finerenone and SGLT2i, especially in combination, is unknown in non-diabetic kidney disease.

Methods: Cardiorenal morbidity and mortality was studied in hypertensive and proteinuric L-NAME (20 mg/L) treated renin-transgenic (mRen2)27 rats. Rats (10-11 weeks old female, n=13-17/group) were treated once daily orally for up to 7 weeks with placebo, finerenone (1 and 3 mg/kg), empagliflozin (3 and 10 mg/kg), or a combination of the respective low doses. Key outcome parameters included mortality, blood pressure, proteinuria, kidney histology and gene expression.

Results: Placebo-treated rats demonstrated a 50% mortality rate over the course of 7 weeks (figure). Drug treatment resulted in variable degrees of survival benefit, most prominent and statistically significant in the low dose combination group (figure). Low dose combination revealed an early, sustained and efficacious proteinuria reduction (-86%, p<0.05) and was highly efficient on renal histology parameters. Monotherapies of finerenone (-27% @ 1 mg/kg, p = n.s.; -87% @ 3 mg/kg, p<0.05) and empagliflozin (-38% @ 3 mg/kg, p = n.s.; -64% @ 10 mg/kg, p = n.s.) dose-dependently reduced proteinuria with a comparable protection from renal lesions at higher dosages. Treatment with finerenone and the combination significantly decreased systolic blood pressure while empagliflozin alone and in combination acted strongly glucosoric.

Conclusions: Both, MRA by finerenone and SGLT2i by empagliflozin confer renal protection in preclinical non-diabetic, hypertensive kidney disease. Combination of these two modes of action at low dosages revealed efficacious reduction in proteinuria and mortality indicating a strong potential for combined clinical use in respective cardiorenal patient populations.

Novel Small Molecule Inducers of ABCA1-Dependent Cholesterol Efflux Preserve Renal Function in Mouse Models of FSGS and Alport Syndrome

Javier T. Varona Santos,[1,2] Matthew B. Wright,[4] Christian Kemmer,[4] Cyrille Maugeais,[4] Jean-Philippe Carralot,[4] Stephan Roever,[4] Judith T. Molina David,[1,2] Gloria Michelle Ducasa,[1,2] Alla Mitrofanova,[1,2] Alexis J. Sloan,[1,2] Jeffrey D. Pressly,[1,2] Christopher Pedigo,[1,2] Laura Barisoni,[5] Armando Mendez,[6] Jacopo Sgrignani,[7] Andrea Cavalli,[7,8] Sandra M. Merscher,[4,1] Marco Prunotto,[4,3] Alessia Fornoni.[1,2] *[1]University of Miami, Katz Family Division of Nephrology and Hypertension, Miami, FL; [2]University of Miami, Peggy and Harold Katz Family Drug Discovery Center, Miller School of Medicine, Miami, FL; [3]University of Geneva, School of Pharmaceutical Sciences, Geneva, Switzerland; [4]Pharma Research and Early Development (pRED), Roche Innovation Center Basel, F. Hoffmann-La Roche Ltd., Basel, Switzerland; [5]University of Miami Department of Pathology, Miller School of Medicine, Miami, FL; [6]University of Miami, Miller School of Medicine, Diabetes Research Institute, Miami, FL; [7]Institute for Research in Biomedicine, Università della Svizzera Italiana, Bellinzona, Switzerland; [8]Swiss Institute of Bioinformatics, Lausanne, Switzerland.*

Background: Pathological accumulation of cholesterol in podocytes is associated with the progression of kidney disease. Depletion of podocyte cholesterol by non-specific means, with agents such as cyclodextrin, or by specific upregulation of ABCA1- mediated cholesterol efflux, have shown promise in renal disease models, but have not progressed in clinical development.

Methods: The effects of novel compounds (Cpds A and G) that induce ABCA1-mediated cholesterol efflux were evaluated in comparison to LXR agonists in differentiated human podocytes *in vitro*. *In vivo* efficacy studies of Cpds A & G were conducted in mouse models of proteinuric kidney disease (Adriamycin-induced nephropathy and Alport Syndrome).

Results: ABCA1-mediated cholesterol efflux was significantly increased in podocytes by all agents. While an LXR agonist resulted in accumulation of ABCA1 at the plasma membrane, it also induced significant accumulation in microsomal fractions. In contrast, Cpds A & G induced the redistribution of ABCA1 from intracellular sites to the plasma membrane. In ADR challenged mice, Cpd A and Cpd G reduced ACR by 8 and 30-fold, respectively, compared to controls. In Col4A3 knockout mice, Cpd G significantly reduced ACR, serum creatinine and blood urea nitrogen, as well as prevented weight loss and mortality vs. control mice. We found that increased accumulation of cholesterol esters in the kidney cortex of ADR challenged mice strongly correlated with albuminuria. In both the FSGS and Alport models, Cpd G significantly reduced lipid droplet formation and cholesterol ester content in kidney cortex.

Conclusions: In summary, our studies describe the effects of novel small molecule drugs in renal disease models that induce ABCA1-mediated cholesterol efflux independently of LXR. This may represent a promising new therapeutic strategy for the treatment of kidney diseases and disorders of cellular cholesterol homeostasis.

PO0644

Metformin Therapy Is Able to Halt the Progression of Established CKD in Rats

Raphaëlle Corremans, Ellen Neven, Patrick D'Haese, Benjamin A. Vervaet, Anja Verhulst. *Universiteit Antwerpen, Antwerpen, Belgium.*

Background: Metformin, first-line drug for type-2 diabetes, exerts benign pleiotropic actions beyond its prescribed use and emerging data show protective effects against the development/progression of renal impairment. Current treatment strategies for chronic kidney disease (CKD) mainly focus on controlling important risk factors, while effective treatment directly targeting the kidney is lacking. However, in 2019, the FDA approved the use of the sodium-glucose co-transporter-2 (SGLT2) inhibitor, canagliflozin, to treat diabetic nephropathy. Here, the ability of metformin to attenuate the progression of established, non-diabetic CKD was investigated and compared to canagliflozin.

Methods: Adenine-induced CKD rats (n=86) were assigned to different treatment groups to receive 200 mg/kg metformin, 4 or 5 weeks after the start of the adenine diet (0.25%), *i.e.* after CKD had developed, or 25 mg/kg canagliflozin 4 weeks after the start of the diet, by daily oral gavage, during 4 weeks. Each treatment group was compared to a vehicle (1% carboxymethylcellulose) group.

Results: Serum creatinine levels dramatically rose in vehicle-treated CKD rats: from 0.7 ± 0.1 mg/dL (week 0) to 1.5 ± 0.1 mg/dL (week 4), 2.6 ± 1.2 mg/dL (week 5) and further to 6.2 ± 0.3 mg/dL (week 8) and 4.8 ± 1.1 mg/dL (week 9). Canagliflozin treatment did not alter the increase in serum creatinine as indicated by serum creatinine levels at week 8 (5.8 ± 0.4 mg/dL). In contrast, metformin treatment almost completely prevented the increase from week 4 or 5 on, as indicated by the serum creatinine levels after 8 (2.0 ± 0.5 mg/dL) and 9 (2.9 ± 0.5 mg/dL) weeks ($p<0.05$ vs. vehicle). Canagliflozin treatment did not alter the tubulointerstitial area percentage, while this parameter was 33% lower at week 8 and 23% lower at week 9 in metformin-treated CKD rats compared to vehicle treatment ($p<0.05$ vs. vehicle). Further histological examination revealed more tubular proliferation (PCNA positive cells) and less interstitial inflammation (CD45 positive cells) in metformin-treated rats compared to vehicle-treated animals.

Conclusions: In conclusion, metformin is able to attenuate the progression of pre-existing adenine-induced CKD in rats. Our data do not present evidence for a beneficial effect of canagliflozin on progression of non-diabetic CKD.

PO0645

The Novel Soluble Guanylyl Cyclase (sGC) Activator Runcaciguat Attenuates Hypertensive Cardiorenal Rat Diseases

Agnes M. Benardeau, Johannes-Peter Stasch, Michael G. Hahn, Jutta Meyer, Jan R. Kraehling, Frank Eitner, Peter Sandner. *Bayer AG, Leverkusen, Germany.*

Background: Chronic kidney disease (CKD) is often associated with arterial hypertension, leading to the development of hypertensive nephropathy and ultimately kidney failure that is poorly prevented by current treatment options. Hypertension and nephropathy are associated with impaired NO/sGC/cGMP signaling, low cGMP production and increased oxidative stress. Runcaciguat is a novel potent and selective, NO- and heme-independent sGC activator. Here we investigated the therapeutic potential of Runcaciguat in rat models of hypertension associated chronic kidney disease.

Methods: Hypertensive rats (Sprague Dawley, 12-13 weeks old male, n=13/ group, angiotensin II (ANG) minipumps, 450ng/kg/min) were treated orally twice daily for 2 weeks with Runcaciguat (0.3, 1 or 3 mg/kg), losartan (30 mg/kg) or placebo. In a second study, male Renin-transgenic rats (mRen2/27, 8 weeks old, L-NAME 30-50 mg/L, n=18-24/group) were treated twice daily orally for up to 8 weeks with Runcaciguat (1, 3 or 10 mg/kg) or placebo. Key outcome parameters included mortality, blood pressure (BP), proteinuria, kidney histology, kidney and heart biomarkers and kidney gene expression.

Results: In the 2-week-treated ANG-rats, Runcaciguat dose-dependently and significantly reduced proteinuria without changing BP. Losartan significantly decreased BP and proteinuria. Runcaciguat reduced kidney LCN2 (NGAL) expression. In the 8-week-treated Renin-transgenic rats, Runcaciguat significantly and dose-dependently improved mortality from 58% (placebo) to 56%, 39% and 28% (@ 1, 3, 10 mg/kg). At all tested doses, Runcaciguat significantly reduced kidney and heart hypertrophy and increased creatinine clearance. At the highest dose, Runcaciguat also significantly reduced BP and proteinuria.

Conclusions: The novel oral sGC activator Runcaciguat exhibits cardiorenal protection and improved survival in hypertensive rat models. Our data strongly suggest that Runcaciguat represents a promising treatment option for hypertensive kidney disease patients.

The Novel Nonsteroidal and Selective Mineralocorticoid Receptor Antagonist Finerenone Differentiates from SGLT2 Inhibitor Empagliflozin by Anti-Fibrotic Effects in a Progressive Mouse Kidney Fibrosis Model

Karoline Droebner, Mira Pavkovic, Manuel Grundmann, Elke Hartmann, Laura Goea, Johannes Nordlohne, Frank Eitner, Peter Kolkhof. *Bayer AG, Wuppertal, Germany.*

Background: Finerenone and SGLT2 inhibitors have demonstrated clinical benefits in CKD patients with T2D. Cellular and molecular mechanisms responsible for these benefits are incompletely understood. MR-signaling has been linked to fibrosis *in vitro* via plasminogen activator inhibitor-1 (PAI-1) modulation. Here we investigated potential effects and mechanisms in a relevant preclinical mouse kidney fibrosis model.

Methods: Kidney fibrosis was induced in mice via unilateral ureteral obstruction. In a series of experiments, mice (C57/Bl6J, 8 weeks old male, n=10-12/group) were treated orally for 10 days with the MR antagonist finerenone (3 and 10 mg/kg), the SGLT2 inhibitor empagliflozin (10 and 30 mg/kg), or in a direct comparison of both drugs. Interstitial myofibroblast accumulation was quantified via alpha-smooth muscle actin (αSMA) and interstitial collagen deposition via Sirius red fast green staining. Secondary analyses included kidney mRNA expression of inflammatory and fibrotic markers and pathways.

Results: Myofibroblast accumulation was dose-dependently reduced in finerenone-treated mice (-22% @ 3 mg/kg, p=0.1; -41% @ 10 mg/kg, p=0.002) as well as collagen deposition (-22% @ 3 mg/kg, p=0.1; -44% @ 10 mg/kg, p=0.001). These antifibrotic effects of finerenone on protein level were matched on mRNA expression level (including collagens type III and IV). In contrast, treatment with SGLT2 inhibitor strongly increased urinary glucose excretion but had neither significant effects on kidney myofibroblasts (0% @ 10 mg/kg, p=0.7; -10% @ 30 mg/kg, p>0.99) nor on collagen deposition (-6% @ 10 mg/kg, p=0.9; -9% @ 30 mg/kg, p=0.8). In finerenone-treated mice reduced kidney fibrosis was paralleled by reduced kidney PAI-1 expression (-19% @ 3mg/kg, p=0.3; -41% @ 10 mg/kg, p=0.002).

Conclusions: Finerenone has direct anti-fibrotic properties resulting in reduced myofibroblast and collagen deposition in a mouse model of progressive kidney fibrosis.

The Novel Potent and Selective Vasopressin V1a Antagonist BAY2327949 Blocks Arginine Vasopressin-Mediated Decline of Renal Blood Flow and Tissue Oxygenation

Hana Cernecka, Karoline Droebner, Hanna Tinel, Eisabeth Pook, Chantal Fuerstner, Marie-Pierre L. Collin, Peter Hein, Frank Eitner, Peter Kolkhof. *Bayer AG, Research & Development, Pharmaceuticals, Wuppertal, Germany*.

Background: Hypoxia is a major contributor to kidney disease progression. Arginine vasopressin (AVP) potently induces renal medullary vasoconstriction via vascular V1 receptors resulting in reduced renal blood flow (RBF). Here we characterized the kidney-protective properties of a recently identified, potent and selective V1a receptor antagonist.

Methods: BAY 2327949 was characterized in Chinese hamster ovary cells expressing recombinant human and rat V1a and V2 receptors. Vasodilatory effects were investigated on isolated *A. renalis* rings from male Wistar rats (n=10). RBF and intrarenal tissue oxygenation were studied in isolated perfused rat kidneys and in anesthetized rats (n= 5-8 per group) via Laser Doppler Flowmetry.

Results: *In vitro* receptor profiling showed high potency and selectivity of BAY 2327949 for human V1a receptor (IC50 hV1a: 1.2 nM, IC50 hV2: 170 nM). BAY 2327949 mediated dose-dependent relaxation (IC_{50}= 3.1 nM) of isolated rat *A. renalis* vessel rings precontracted by AVP. BAY 2327949 improved the AVP-mediated reduction of perfusate and venous flow (figure) without affecting urinary volume. *In vivo*, infusion of AVP significantly increased mean arterial pressure (CON: 97±1, AVP: 135±12; mean±SD) which was normalized by BAY 2327949 in a dose-dependent manner (90±5; p<0.0001). Infusion of AVP reduced both renal perfusion (CON: 1060±8, AVP: 758±107) and tissue oxygenation (CON: 27±1, AVP: 17±4). BAY 2327949 dose-dependently restored RBF (960±30; p<0.0001) and increased pO_2 (25±0.4; p<0.0001).

Conclusions: BAY 2327949 is a novel potent and selective vasopressin V1a receptor antagonist blocking the detrimental effects of elevated vasopressin levels on renal perfusion and oxygenation in rats, suggesting potential benefit for patients with cardiorenal diseases.

PO0648

Apabetalone, an Inhibitor of BET Proteins, Downregulates Alkaline Phosphatase and Improves Cardiovascular Risk

Dean Gilham,[1] Laura Tsujikawa,[1] Li Fu,[1] Sylwia Wasiak,[1] Christopher Halliday,[1] Chris Sarsons,[1] Phoebe S. Ho,[1] Stephanie Stotz,[1] Brooke D. Rakai,[1] Kenneth E. Lebioda,[1] Ravi Jahagirdar,[1] Michael Sweeney,[2] Jan O. Johansson,[2] Norman C. Wong,[1] Kamyar Kalantar-Zadeh,[3] Mathias Haarhaus,[4] Ewelina Kulikowski.[1] *[1]Resverlogix, Calgary, AB, Canada; [2]Resverlogix, San Francisco, CA; [3]University of California Irvine, Irvine, CA; [4]Karolinska University Hospital, Stockholm, Sweden.*

Background: Elevated serum alkaline phosphatase (ALP) predicts major adverse cardiac events (MACE). ALP is associated with vascular calcification (VC), inflammation & endothelial dysfunction in patients with cardiovascular disease (CVD) &/or chronic kidney disease (CKD). Apabetalone is an inhibitor of BET proteins - epigenetic readers modulating gene expression in pathological VC & inflammation. We studied apabetalone's impact on tissue non-specific ALP (TNALP) expression in cell culture, then analyzed serum ALP in phase 2 trials.

Methods: Expression of TNALP (gene symbol *ALPL*) was measured in primary hepatocytes, HepaRG, HepG2, primary mesangial cells (MC), vascular smooth muscle cells (VSMC) & vascular endothelial cells by q-PCR. TNALP was assessed by immunoblot & flow cytometry, ALP activity by enzymatic assays. Serum ALP was measured in CVD patients in phase 2 trials (ASSERT, SUSTAIN & ASSURE). Subpopulations had CKD (eGFR<60).

Results: Apabetalone downregulated *ALPL* expression in liver cells by 60-80%. HepG2s had lower TNALP protein >55%, enzyme activity >40% & TNALP positive cells 15-30%; renal MCs had >90% decreases in *ALPL* expression & TNALP enzyme activity (p<0.001). *ALPL* was suppressed 50-70% in 3 vascular endothelial cell types with apabetalone. In VSMCs, apabetalone lowered *ALPL* expression, TNALP protein, enzyme activity & extracellular calcium deposition. In ASSERT, apabetalone dose dependently reduced serum ALP (p<0.001). In combined phase 2 analysis, apabetalone lowered ALP (p<0.001), including patients in the CKD subgroup (p=0.008). Notably, the apabetalone-mediated decreases in serum ALP in phase 2 correlated with reduced MACE at 12-14 weeks (HR 0.64 per 1-SD in ALP, 95% CI 0.46–0.90 p=0.009 1-SD=13U/L); similar associations were observed at 24–26 weeks (HR 0.66 per 1-SD ALP 95% CI 0.43–0.99 p=0.045; 1-SD=14U/L).

Conclusions: Apabetalone lowers serum ALP, consistent with reduced hepatic, renal & vascular TNALP production. Modulation of ALP by apabetalone may affect pathogenetic processes to lower cardiovascular risk. This study provides insight to MACE reductions in phase 2 clinical trials.

Renal Expression of L-Type Fatty Acid Binding Protein in Addition to Angiotensin II Type 1a Receptor Loss Ameliorates Chronic Tubulointerstitial Damage After Renal Ischemia Reperfusion

Yoko Fujita,[1] Takeshi Sugaya,[1] Daisuke Ichikawa,[1] Jun Tanabe,[1] Kenjiro Kimura,[2] Yugo Shibagaki,[1] Atsuko Ikemori.[1,3] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [2]JCHO Tokyo Takanawa Hospital, Tokyo, Japan; [3]Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.*

Background: Although angiotensin II (Ang II) type 1 receptor blocker was reported to attenuate chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR), its effect is limited. We had revealed the importance of renal L-type fatty acid binding protein (L-FABP) with antioxidative effect in various renal disease models. Therefore, the aim of this study is to elucidate the renoprotective effect of renal L-FABP and Ang II type 1a receptor (AT1a) loss against chronic TID after renal IR.

Methods: To induce severe chronic TID after renal IR, unilateral renal ischemia for 60 min was performed via clamping of right renal pedicle using four types of male mice; wild type mice (hL-FABP$^{-/-}$AT1a$^{+/+}$), human L-FABP chromosomal transgenic mice (hL-FABP$^{+/-}$AT1a$^{+/+}$), AT1a knockdown homo mice (hL-FABP$^{-/-}$AT1a$^{-/-}$), and generated hL-FABP$^{+/-}$AT1a$^{-/-}$ mice. Right and left kidneys were removed at 10 weeks after IR.

Results: While marked renal atrophy and progressive TID were found in each IR-kidney of hL-FABP$^{-/-}$AT1a$^{+/+}$, hL-FABP$^{+/-}$AT1a$^{+/+}$ and hL-FABP$^{-/-}$AT1a$^{-/-}$ mice, the degrees of both atrophy and TID were significantly ameliorated in the IR-kidneys of the hL-FABP$^{+/-}$AT1a$^{-/-}$ mice. Systolic blood pressure levels in the hL-FABP$^{+/-}$AT1a$^{-/-}$ mice were similar to the hL-FABP$^{-/-}$AT1a$^{-/-}$ mice. These results suggested that antioxidative effect of L-FABP in addition to AT1a loss may be related to suppression of chronic TID after IR.

Conclusions: Increased expression of renal L-FABP in addition to suppressed activity of AT1a may be a useful strategy for prevention of AKI-to-CKD transition.

Development of a Synthetic Biotic, SYNB8802, for the Treatment of Enteric Hyperoxaluria

Lauren Renaud, David Lubkowicz, Pip Reeder, Chris Bergeron, Zhibin C. Chen, Michael J. James, Pasquale Cantarella, Mark Charbonneau, Ron Shmueli, Jr Gao, Vincent Isabella, Mylene Perreault. *Synlogic, Cambridge, MA.*

Background: Enteric hyperoxaluria (EH) is a metabolic disease that results from excessive absorption of oxalate from dietary sources. Increased oxalate levels can lead to the formation of kidney stones and, ultimately, to kidney failure. EH occurs most frequently in patients with underlying gastrointestinal disorders, including inflammatory bowel disease, short bowel syndrome, or individuals who have undergone bariatric surgery. There is a high unmet need for new EH therapies, as a low oxalate diet is the only option currently available to patients. Synlogic is developing a novel Synthetic Biotic™ medicine for the treatment of EH, designated as SYNB8802.

Methods: SYNB8802 is an engineered bacterium derived from *Escherichia coli* Nissle 1917 (*EcN*) that has been engineered to metabolize oxalate to formate and CO_2 in the gastrointestinal tract.

Results: Inoculation of SYNB8802 into minimal media showed significant consumption of oxalate and production of formate as compared to un-engineered (EcN) bacterial strain. When administered concomitantly with ^{13}C-oxalate to healthy mice, SYNB8802 decreased the urinary recovery of ^{13}C-oxalate, indicative of its ability to consume oxalate *in vivo*. In healthy non-human primates (NHP) administered approximately 400 mg of dietary oxalate, SYNB8802 lowered the urinary recovery of oxalate and ^{13}C-oxalate in a dose dependent manner by up to 75% as compared to vehicle. In addition, Synlogic has developed a mathematical model that predicts clinically meaningful reductions in urinary oxalate in EH patients.

Conclusions: Overall, SYNB8802 represents a promising new approach for the treatment of enteric hyperoxaluria.

PO0651

A Novel Small Molecule Modulating the Mitochondrial NEET Proteins Improves Inflammation and Fibrosis in Kidneys of Nonalcoholic Steatohepatitis Mice

Fabiola Terzi,[2] Stéphanie Le Corre,[1] Florence Vasseur,[2] Diane Sampson,[1] Pauline Radreau,[1] Benoit De Chassey,[1] Jacky Vonderscher,[1] Raphael Darteil,[1] Eric Meldrum.[1] *[1]ENYO Pharma SA, Lyon, France; [2]Institut Necker-Enfants Malades, Paris, France.*

Background: Non-alcoholic steatohepatitis (NASH) is a disease characterized by excessive fat accumulation, inflammation, and ballooning degeneration of hepatocytes, with or without fibrosis in the liver. It is now reported that NASH not only affects the liver but is also associated with chronic kidney disease (CKD). However, the morphological appearance of NASH kidneys has been poorly characterized. These observations highlight the need for a treatment that targets both conditions. Here, we assessed the effect of a novel chemistry that regulates the function of 3 mitochondrial proteins called the NEET proteins, previously reported to be important in metabolic diseases, on a diet-induced NASH model in mice.

Methods: Mice were fed with a high fat diet for 30 weeks prior treatment with ENYO's molecule for 8 weeks. The kidneys and livers were collected at sacrifice and sections were stained with H&E, PAS and picrosirius red staining to analyze their morphology. Specific immunostainings and qRT-PCR were performed to quantify the extent of inflammation (CD3, MAC1 and F4/80) and fibrosis (Col1a1, Col3a1, fibronectin).

Results: NASH mice displayed severe renal lesions such as glomerulosclerosis, tubular casts, tubular lipid accumulation and interstitial fibrosis. Mononuclear cell infiltration was also massively increased, in particular in the perivascular areas. Quantitative RT-PCR revealed a significant increase of the expression of several fibrosis and inflammation markers. Therapeutic administration of ENYO's molecule was shown to resolve these lesions with a return back to normal regarding fibrosis, and a 50% and 35% decrease in lymphocyte and macrophage accumulation, respectively. In the liver, inflammation and fibrosis were also attenuated, specifically in the periportal zone that has been shown to be correlated with the severity of the disease. Interestingly, the most significant responders in the liver were also the best responders in the kidneys.

Conclusions: We have shown that NASH mice developed CKD, recapitulating the phenotypes observed in humans. Moreover, we have identified a new treatment, that by targeting NEET proteins, protects mice from the development of both liver and renal lesions.

PO0652

SIRT3 Deacetylates PDHE1α to Regulated Mitochondria Metabolism in Tubular Epithelial Cells During Renal Fibrosis

Yu Zhang, Yang Zhou, Lei Jiang, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Abnormal energy metabolism is considered to be related to renal interstitial fibrosis. Pyruvate dehydrogenase α (PDHE1α) is the main catalytic enzyme of pyruvate dehydrogenase complex (PDHC) linking glycolysis to the TCA cycle. N-lysine acetylation is an important post-translational modification involves in energy metabolism. SIRT3 is a mitochondrial deacetylase that mediates the activity many metabolic enzymes.

Methods: Unilateral ureteral obstruction (UUO) or ischemia-reperfusion (I/R) were used to induce renal fibrosis in C57BL/6J mice or SIRT3 knockout mice. Primary tubular epithelial cells (PTCs) were stimulated by TGF-β1. Protein array and the acetylation array by LC-MS/MS were performed on tubules separated from sham or UUO-operated mice. K149R, K267R, K385R mutations in PDHE1a were transfected into PTCs.

Results: Acetylome showed that the majority of proteins were hyper-acetylation after UUO. GO enrichment analysis revealed that PDH was the most obviously enriched GO term. Immunoprecipitation analysis confirmed that PDHE1α acetylation was enhanced after UUO or I/R operation. Activation of SIRT3 by HKL could block the hyper-acetylation of PDHE1α, restored PDH enzyme activity, and inhibited the phosphorylation of PDHE1α in mice with UUO or I/R. On the contrary, Sirt3 KO mice had more acetylated PDHE1α, more phosphorylated PDHE1α and defective PDH enzyme activity. In vitro, increased PDHE1 acetylation was accompanied by reduced PDH enzyme activity and increased PDHE1α phosphorylation in PTCs after TGF-β1 stimulation. Activation of SIRT3 by HKL repressed the effect of TGF-β1. Inhibition SIRT3 activity by 3-TYP or SIRT3 siRNA transfection have the same effect as TGF-β1. K149, K267, K385 were identified as the main potentially lysine acetylated sites in PDHE1α. Acetylation of PDHE1α, the activity of PDH and PDHE1α phosphorylation remained unchanged in PTCs with the K385R mutation stimulated with TGF-β1 or SIRT3 siRNA transfection.

Conclusions: In summary, our data showed that mitochondrial proteins involved in regulating energy metabolism were acetylated and targeted by SIRT3 in PTCs. The deacetylation of PDHE1α at lysine 385 by SIRT3 plays a key role in metabolic reprogramming in renal fibrosis.

Empagliflozin Restores CKD-Induced Impairment of Endothelial Regulation of Cardiomyocyte Relaxation and Contraction

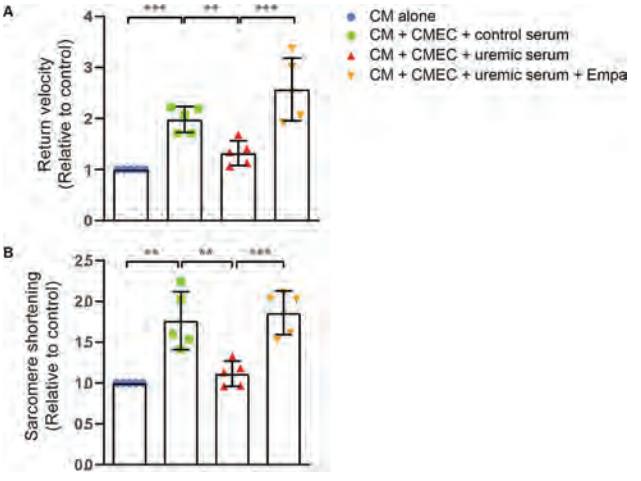
Rio P. Juni, Rushd Al-Shama, Diederik W. Kuster, Jolanda Van der velden, Henrike M. Hamer, Marc G. Vervloet, Etto C. Eringa, Pieter Koolwijk, Victor van Hinsbergh. *Amsterdam University Medical Centres, Amsterdam Universitair Medische Centra, Amsterdam, Netherlands.*

Background: Chronic kidney disease (CKD) promotes development of cardiac abnormalities and is highly prevalent in patients with heart failure (HF), particularly HF with preserved ejection fraction (HFpEF). CKD and HF are associated with endothelial dysfunction and have been shown to benefit from a sodium-glucose co-transporter 2 inhibitor, empagliflozin. We hypothesized that uremic serum from CKD patients impairs cardiomyocyte (CM) relaxation and contraction by inducing endothelial cell dysfunction and that empagliflozin protects against this effect.

Methods: Co-culture system of human cardiac microvascular endothelial cells (CMECs) with adult rat ventricular cardiomyocytes (CMs).

Results: We showed that CMECs promote CM relaxation (return velocity, Fig. A) and contraction (sarcomere shortening, Fig. B). Serum from CKD patients impaired endothelial enhancement of CM function which was rescued by empagliflozin (Fig. A-B). Exposure to uremic serum reduced nitric oxide (NO) bioavailability in CMECs and increased mitochondrial reactive oxygen species (ROS) and 3-nitrotyrosine level, indicating NO scavenging by ROS. Empagliflozin restored endothelial enhancement of NO level in CMs by restoring endothelial NO bioavailability and reducing endothelial mitochondrial ROS, an effect that was largely independent of sodium-hydrogen exchanger-1.

Conclusions: Serum from CKD patients impairs CM relaxation and contraction through induction of endothelial dysfunction driven by an increase in mitochondrial ROS production. Empagliflozin restores the enhancement effect of CMECs on CM function by reducing mitochondrial oxidative damage, leading to reduced ROS accumulation and increased endothelial NO bioavailability.



PO0654

Genetic Ablation of CD148 Increases Renal Macrophage Inflammation and Fibrosis in Ureteral Obstructed Kidney

Tadashi Otsuka,[1] Keiko Takahashi,[1] Chikage Narui,[1] Raymond C. Harris,[1] Manuel Grundmann,[2] Takamune Takahashi,[1] Lejla Pasic.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Bayer AG, Leverkusen, Germany.*

Background: CD148 is a transmembrane protein tyrosine phosphatase expressed in several cell types including epithelial, endothelial, and hematopoietic cells. Macrophages express high level of CD148, and its expression is up-regulated by lipopolysaccharide (LPS) which activates innate immune response through toll-like receptor 4. Recently the innate immune system has been recognized as an important modulator of the inflammatory response during infection and tissue injury/repair. However relatively little is known about CD148 function in this cell type and kidney disease model. Here we showed influences of CD148 depletion on unilateral ureteral obstruction (UUO) model and macrophage polarization.

Methods: UUO surgeries were performed in CD148 KO and wild-type (WT) mice on DBA2/J background. Histological and gene expression analysis were performed 3 days and 10 days after UUO to investigate inflammation and fibrosis. Flowcytometry was used to analyze macrophage polarization using CD38/Egr2 method. Primary culture of peritoneal macrophages isolated from these mice were used for *in vitro* study. After LPS stimulation, inflammatory response (TNFα, IL-1b, IL-6) was quantified by qPCR and ELISA.

Results: CD148KO mice developed more severe renal fibrosis than WT mice at day10. They showed more severe tubular damage compared to WT mice at day3. F4/80 staining revealed increased infiltrated macrophages in outer medulla lesion and flowcytometry showed increased population of inflammatory subtype (M1; CD11b+F4/80+CD38+Egr2-) in CD148KO mice. Although there were no significant

differences in whole kidney analysis of inflammatory cytokine qPCR between them, renal macrophages isolated from CD148KO mice showed higher expression of inflammatory cytokine expression (TNFα, IL-1b, IL-6). Peritoneal macrophages derived from CD148KO mice showed higher inflammatory cytokine expression (TNFα, IL-1b, IL-6) to LPS, accompanied by higher phosphorylation of Erk. In addition, Erk inhibitor, U0126 diminished the difference between WT and CD148KO macrophages.

Conclusions: Our data suggests that CD148 negatively regulates macrophage M1 polarization through Erk and its deficiency accelerates macrophage inflammation in UUO kidneys, leading to advanced tubular injury and renal fibrosis.

LRG1 Promotes Renal Fibrosis by Enhancing TGF-β-Induced Smad3 Pathway

Quan Hong,[1,2] Hong Cai,[1,3] Lu Zhang,[1,5] Zhaohui Ni,[3] Guangyan Cai,[2] Xiangmei Chen,[2] John C. He,[1,4] Kyung Lee.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Chinese PLA General Hospital, Beijing, China; [3]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [4]James J Peters VA Medical Center, Bronx, NY; [5]The First Affiliated Hospital of Xiamen University, Xiamen, China.*

Background: Renal fibrosis is a final convergent pathway for CKD progression, but effective fibrosis therapy is lacking. We recently showed that leucine-rich alpha-2 glycoprotein-1 (LRG1), a secreted glycoprotein, is highly upregulated in diabetic kidneys and potentiated the endothelial TGF-β signaling, mediated by ALK1 receptor and Smad1/5 activation, to increase angiogenesis and worsen DKD progression. However, increased LRG1 expression was not limited to the endothelial cells in the diabetic kidneys, but also found in the renal tubular epithelial cells (RTECs). Therefore, we examined whether LRG1 contributes to the TGF-β signaling in RTECs leading to renal fibrosis progression.

Methods: We examined the expression of LRG1 in the tubulointerstitium RNAseq datasets of human CKD. We explored the potential mechanism in LRG1 upregulation in cultured RTECs and examined the specific TGF-β/Smad signaling pathway mediated by LRG1 using shRNA-knockdown. We examined the effects of global *Lrg1* ablation in unilateral ureteral obstruction (UUO) and aristolochic acid nephropathy (AAN) models of renal fibrosis. We also examined the effects of RTEC-specific overexpression of LRG1 in renal fibrosis in vivo. We further compared the activation of Smad proteins in the RTECs of control, $Lrg1^{-/-}$, and Pax8-$LRG1^{OE}$ mice with UUO.

Results: We found that the *LRG1* mRNA transcript was markedly increased in the microdissected tubulointerstitium of human CKD. In cultured RTECs, LRG1 expression was upregulated by a pro-inflammatory cytokine TNF-α, and chromatin IP assay confirmed the binding of p65 subunit NF-κB to the LRG1 promoter region. Importantly, LRG1 enhanced the TGF-β-induced Smad3 activation, but not of Smad1/5, and the expression of pro-fibrotic genes in RTECs. The global knockout of *Lrg1* attenuated renal fibrosis in mice with UUO or AAN. In AAN mice, *Lrg1* ablation also improved renal function. In contrast, the RTEC-specific overexpression of LRG1 markedly heightened the renal fibrosis in vivo. The level of Smad3 phosphorylation in RTECs in the obstructed kidneys was directly associated with the loss or gain of LRG1 expression.

Conclusions: Our current study attributes a previously undescribed role of LRG1 as a key modulator of the canonical TGF-β/Smad3 signal transduction in RTECs and suggests that the targeting of LRG1 may be an effective approach against renal fibrosis.

Single-Nucleus RNA Sequencing Identifies New Classes of Renal Proximal Tubular Epithelial Cell in Kidney Fibrosis

Yuehan Lu,[1,2] Chia-te Liao,[1] Rachel Raybould,[1] Bnar Talabani,[1] Barbara Szomolay,[1] Timothy Bowen,[1] Robert Andrews,[1] Philip R. Taylor,[1] Donald Fraser.[1] Wales Kidney Research Unit *[1]Cardiff University, Cardiff, United Kingdom; [2]Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

Background: Proximal tubular cells (PTC) play a central role in nephron recovery versus fibrosis following renal injury. PTC heterogeneity is well-documented but poorly-characterized in extant single-cell sequencing data. Here we have determined PTC phenotype in renal fibrosis by single-nucleus RNA sequencing (snRNA-seq).

Methods: Kidneys were harvested from naïve mice and mice with renal fibrosis induced by chronic aristolochic acid administration. Nuclei were isolated using Nuclei EZ Lysis buffer. Libraries were prepared on the 10X platform and snRNA-seq completed using Illumina NextSeq 550. Downstream bioinformatics analyses used Seurat.

Results: A total of 23,885 nuclei were analyzed. PTC's were found in five abundant clusters, mapping to S1, S1-2, S2-cortical S3, and medullary S3 segments. Additional cell clusters were present ("new PTC clusters") at low abundance in normal kidney and in increased number in kidneys undergoing regeneration/fibrosis following injury. These clusters exhibited clear molecular phenotypes, permitting labeling as, proliferating, dedifferentiated-intermediate, dedifferentiated-regenerating, and (present only following injury) dedifferentiated-senescence. Each of these clusters exhibited a unique gene expression signature, including multiple genes associated with renal injury response and fibrosis progression. Comprehensive pathway analyses revealed metabolic reprogramming, enrichment of cellular communication and cell motility, and various immune activations in new PTC clusters. In ligand-receptor analysis, new PTC clusters promoted fibrotic signaling to fibroblasts and inflammatory activation to macrophages.

Conclusions: SnRNA-seq permits the dissection of cell-type and cell-subtype-specific responses. We identified previously unknown, injury-associated PTC clusters. These exhibit highly specific and restricted gene signatures, including canonical PTC injury genes previously assumed to be expressed at low level throughout injured PTC, on the basis of bulk expression analyses.

Artificial Intelligence-Driven Target Identification in CKD

Chanchal Kumar,[1] Lisa Buvall,[2] Maria Ryaboshapkina,[1] Kevin Woollard,[9] Julie Williams,[2] Natalie Kurbatova,[4] Anna Reznichenko,[1] Iain MacPhee,[3] Mohammad Bohlooly,[5] Dirk S. Paul,[6] James Dunbar,[7] Andrea Taddei,[7] Mark Davies,[7] Siobhan McMahon,[7] Andres Mori,[7] Regina Fritsche-Danielson,[8] Claus Bendtsen,[4] Pernille B. Laerkegaard Hansen.[2] *[1]Translational Science and Experimental Medicine, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [2]Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [3]Early Clinical Development, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [4]Quantitative Biology, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [5]Translational Genomics, Research and Early Development, Discovery Biology, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [6]Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [7]BenevolentAI, London, United Kingdom; [8]Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [9]Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom.*

Background: Involvement of multiple pathways and complex pathophysiology are few of the hallmarks of Chronic Kidney Disease (CKD). These reasons contribute to the challenge for drug discovery in CKD, which is a major contributor to global disease burden. Availability of a wealth of CKD omics data has opened avenues for novel insight generation through unbiased integrative analysis. In a pioneering effort AstraZeneca and BenevolentAI initiated a collaboration to leverage the potential of artificial intelligence (AI) to generate novel hypotheses for drug targets in CKD.

Methods: We have created a CKD knowledge graph (CKD-KG) - a knowledge base of biological and chemical entities (genes, small molecules, etc) and their relationships (gene-disease associations, therapeutic drugs, biological processes, etc) and augmented with CKD specific information derived from both public and AstraZeneca proprietary data sets. The CKD-KG was constructed by aggregating information from structured biomedical databases, machine learning (ML)-based extraction from unstructured sources, and patient-centric omics datasets (i)unstructured: 140M documents, 1B relationships, (ii) structured: 30M relationships, 3B omics data points, (iii) 35 licensed data sources, and (iv) 53 CKD omics datasets. The CKD-KG was used as input to BenevolentAI's relational inference and causal reasoning ML models to produce target hypotheses for CKD.

Results: The fleet of models identified 295 potential targets that were triaged down to 69 targets. These 69 targets have been further prioritized based on an in-house human target validation pipeline, and additional criteria such as safety and druggability, in line with AstraZeneca's 5R framework. We are undertaking *in vitro* studies via genetic modification in selected cell types to generate target-specific CKD-linked readouts. Subsequently, we will employ *in vivo* studies to confirm the mechanism of action for targets that had shown successful *in vitro* readouts. Eventually, we will progress targets with compelling novel biology within our renal portfolio.

Conclusions: CKD-KG enables a transformative approach to generating novel target hypotheses with the potential of improving health outcomes for CKD patients.

PO0658

Twist1 in T Lymphocytes Exaggerates Kidney Fibrosis After Ureteral Obstruction

Jiafa Ren, Jamie Privratsky, Steven D. Crowley. *Duke University School of Medicine, Durham, NC.*

Background: T cells play a critical role in directing kidney fibrogenesis. The transcription factor Twist1 limits pro-inflammatory cytokine production in T cells, but the role of T cell-derived cytokine mediators regulated by Twist1 in kidney damage has not been fully elucidated. To explore the role of T cell Twist1 in kidney scar formation, we subjected mice with T lymphocyte-specific deletion ("TKO") of Twist1 and controls to the UUO.

Methods: 129/SvEv mice with a floxed allele for the gene encoding Twist1 or TNFα were bred with CD4-Cre mice to yield Twist1 TKO or TNFα TKO mice with robust but selective deletion of Twist1 mRNA [>90% vs. WTs in $CD4^+$ T cells, and >85% vs. WTs in $CD8^+$ T cells; p<0.0001] or TNFα mRNA in T cells (published), respectively. Twist1 TKO, TNFα TKO, and WT controls underwent UUO with assessment of kidney fibrosis and T cell phenotype at 14 days.

Results: 2 weeks after UUO, Twist1 TKO mice developed less kidney fibrosis compared to WTs as quantitated by western blot for Col1 (0.75±0.06 vs 1.0±0.05 au; p=0.02) and αSMA (0.65±0.01 vs 1.0±0.08 au; p=0.001) and by RT-PCR for Col1 (0.69±0.08 vs 1.0±0.10 au; p=0.048), fibronectin (0.76±0.07 vs 1.0±0.06 au; p=0.03), TGFβ1 (0.73±0.08 vs 1.0±0.04 au; p=0.004) and PAI-1 (0.47±0.05 vs 1.0±0.09 au; p=0.001). Twist1 TKO mice also showed attenuated kidney injury as indicated by NGAL mRNA expression (0.53±0.06 vs 1.0±0.16 au; p=0.04). Twist1 can suppress proinflammatory mediators such as TNFα and IL17A in T cells. At 14d, flow cytometry revealed similar T cell and macrophage numbers in the obstructed WT and Twist1 TKO kidneys. We then used fluorescent cell sorting to isolate $CD4^+$ and $CD8^+$ T cells from obstructed WT and Twist1 TKO kidneys. Sorted $CD4^+$ T cells from Twist1 TKO kidneys expressed similar mRNA levels for TNFα and IL17A. Sorted $CD8^+$ T cells from obstructed Twist1 TKO kidneys expressed higher mRNA levels for TNFα (1.8±0.39 vs 1.0±0.19 au; p=0.03), but not IL17A than WT controls. To further explore the role of TNFα in T cells during fibrogenesis, we subjected TNFα TKO and WT mice to UUO. We found TNFα deletion in T cells exaggerated kidney fibrosis and injury as quantitated by real time PCR for fibronectin (1.4±0.09 vs 1.0±0.13 au; p=0.03) and NGAL (1.3±0.10 vs 1.0±0.05 au; p=0.01) mRNA expression, respectively.

Conclusions: Twist1 in T cells drives fibrosis in the injured kidney, possibly by limiting TNFα production.

Evaluation of the Effects of a Resistant Starch Diet and Metaproteomics Study of Microbiome-Host Interactions in a 5/6 Nephrectomy Murine Model of CKD

Oleg K. Karaduta,[1] Galina V. Glazko,[1] Zeljko Dvanajscak,[2] Yasir Rahmatallah,[1] Samuel G. Mackintosh,[1] John M. Arthur,[1] Boris Zybailov.[1] *[1]University of Arkansas System, Little Rock, AR; [2]Arkana Laboratories, Little Rock, AR.*

Background: Chronic kidney disease (CKD), a progressive decline in kidney function, is a growing health problem: 13% of adults in the US have CKD. In 40% of cases, CKD leads to irreversible loss of kidney function, end-stage renal disease. Prebiotic Resistant Starch (RS) changes gut flora and alleviates CKD. However, mechanisms of RS action remain unclear.

Methods: Male mice (n=8) were used to reduce renal mass and to induce CKD. 8 mice served as healthy controls. Each of the two groups was further split in two subgroups (n=4, each), either supplemented with RS or regular diet. PEAKS was used to identify peptides via de novo sequencing in cecal content. To better understand the differences between CKD, CKDRS, HRS and H phenotypes we combined all bacteria that were differentially abundant in six comparisons to infer bacterial co-abundance (BCoA) network. Histopathological evaluation was used for kidney damage comparison.

Results: Histopathological evaluation showed that CKDRS mice had less kidney damage compared to CKD group. Using metaproteomics we found that the most abundant bacterium in HRS phenotype is indole-producing Oscillibacter sp. 1-3, confirming the result of Blast2GO that indole metabolism is upregulated in HRS phenotype as compared to CKDRS and CKD. The most connected network' hub Firmicutes bacterium ASF500 is significantly overrepresented in CKDRS as compared to CKD and is not significantly different between HRS and H. Firmicutes bacterium ASF500 belongs to 20 bacterial strains from human intestine that can induce Th17 cells in the mouse and rat intestine and have immunostimulatory effects. Experiments to validate effect of butyrate on host epithelial cells in germ-free mice are underway.

Conclusions: Resistant starch slows down the progression of chronic kidney disease in 5/6 nephrectomy model. For the first time we demonstrate decrease in kidney fibrosis during RS supplementation. Metaproteomics allows to discover molecular mechanisms and bacterial species responsible for beneficial effects of RS. MST2 analysis allows for clear visualization of the most important connections within the bacterial co-abundance network.

Sex Differences in Renal Mitochondrial Function of Young Healthy Rats

Ryan Schibalski,[1] Regina F. Sultanova,[1,2] Mark Domondon,[1] Allison N. Mccrimmon,[3] Krisztian Stadler,[3] Daria Ilatovskaya.[1] *[1]Medical University of South Carolina, Charleston, SC, US, Charleston, SC; [2]St. Petersburg Chemical Pharmaceutical University, St. Petersburg, Russian Federation; [3]Pennington Biomedical Research Center, Baton Rouge, LA, US, Baton Rouge, LA.*

Background: Sex differences in mitochondrial performance have been linked to many pathologies. Premenopausal females are typically less prone to cardiorenal damage than males. Differences in the ability to manage oxidative stress, calcium uptake, fission/fusion cycles, and respiratory performance in mitochondria can affect the onset and progression of the diseases. While characteristic sex-related dissimilarities have been reported in renal function, nothing is known with regards to how sex may affect the performance of renal mitochondria. The goal of this study was to compare renal mitochondrial function in young healthy male vs female rats.

Methods: Mitochondria were isolated from the kidneys from Sprague Dawley (SD) rats (10-11 weeks). Mitochondrial membrane potential, superoxide and H_2O_2 levels were measured with luminescent (MCLA) or fluorescent (TMRM, Amplex Red) dyes, and seahorse analysis was performed. Antioxidant capacity was measured with a Trolox-based assay. Lipid peroxide radicals were detected using with spin resonance spectroscopy (ESR) with *in vivo* spin trapping.

Results: Kidneys from SD male (SD^M) and female rats (SD^F) were divided into cortex ($SD^{MC, FC}$) and medulla ($SD^{MM, FM}$). First, we report significantly higher membrane potential in SD^{FM} compared to SD^{MM} (p<0.001). H_2O_2 levels were elevated in both the SD^{FC} and SD^{FM} mitochondria compared to SD^M (p<0.01). Interestingly, mitochondrial superoxide production was increased in the medulla compared to the cortex for both SD^M and SD^F, while SOD2 expression was lower (p<0.001). Antioxidant capacity was lower in SD^{FM} tissues compared to all other groups, which is consistent with higher H_2O_2 level (p<0.05). Female mitochondria had significantly lower basal and ATP-linked respiration, as well as reserve and maximal capacity compared to males. In addition, we report that these parameters were lower in medullary vs cortical mitochondria, independent of sex. ESR analysis showed similar lipid peroxide radical levels in males and females, but detected a different radical adduct – an amine or amino acid-centered radical – in the medulla.

Conclusions: We report sex-related differences in mitochondrial function in the kidneys of young healthy rats. Further studies are needed to establish the mechanisms that they may affect the predisposition to kidney disease development later in life.

Renal Involvement in Coronavirus Disease 2019 (RECORD): A Systematic Review and Meta-Analysis

Kam wa Chan,[1] Kam Yan Yu,[1] Pak Wing Lee,[2] Sydney C. Tang.[1] *[1]Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [2]London School of Hygiene and Tropical Medicine Faculty of Epidemiology and Population Health, London, United Kingdom.*

Background: COVID-19 caused substantial casualty worldwide. As the reported renal involvement varied across regions, we sought to review the global prevalence of renal manifestations among COVID-19 patients and determine the risk factors associated with AKI.

Methods: We systematically searched 6 databases for peer-reviewed reports and 7 data portals for grey literature for all trials, cohorts, case-control studies and case-series that reported the prevalence of renal manifestations including AKI, RRT, proteinuria and hematuria, and their associated risk factors. All papers were screened, assessed and extracted by at least 2 researchers independently. Quality was assessed according to NIH assessment tools. To avoid duplicate of patient data, we matched the location, institution and time period, and only included the largest data source if studies overlapped. Prevalence of renal manifestations was pooled from studies that consecutively recruited patients from the general population, and with clear definition of outcome. This review was prospectively registered at PROSPERO (CRD42020184621).

Results: 36 studies from 8 countries and over 50 cities with a total of 14,712 patients were identified. 34 and 2 were cohorts and case-control studies respectively. 24, 7 and 5 studies reported COVID-19 patients from the general population, severe / critical patients and patients with history of RRT. AKI occurred in 14.3% of all COVID-19 cases and was highest in New York City. 4.7% of hospitalized COVID-19 patients underwent RRT. Proteinuria and hematuria were present in 42.5% and 26.7% of all COVID-19 cases. The odds of mortality among COVID-19 patients who developed AKI was 15 times higher than non-AKI COVID-19 patients (pooled OR=16.85, 95% CI: 10.06 to 28.23, 2 cities, 6 studies, 9,297 patients) and was higher in Hubei. Such effect was not observed among kidney transplant patients (pooled OR=0.95, 95% CI: 0.12 to 7.22, 2 studies, 30 patients). Higher C-reactive protein, leukocyte count, serum lactate dehydrogenase and creatinine levels on admission were associated with AKI.

Conclusions: AKI was prevalent among COVID-19 patients and significantly associated with mortality. The odds of mortality among AKI patients varied significantly between cities, which could be associated with differences in healthcare infrastructure and delayed hospitalization and treatment initiation.

PO0662

Forecasting Continuous Renal Replacement Therapy Shortages During the COVID-19 Pandemic in the United States

Yuvaram N. Reddy,[1,2] Rochelle P. Walensky,[3,2] Krishna P. Reddy.[4,2] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Medical Practice Evaluation Center, Massachusetts General Hospital, Boston, MA; [3]Division of Infectious Diseases, Massachusetts General Hospital, Boston, MA; [4]Division of Pulmonary and Critical Care Medicine, Massachusetts General Hospital, Boston, MA.*

Background: The coronavirus disease 2019 (COVID-19) pandemic has increased continuous renal replacement therapy (CRRT) demand in the US, however total CRRT demand and capacity remain unclear. Our objective was to project national and statewide CRRT demand and capacity during the COVID-19 pandemic.

Methods: We projected CRRT demand using a model in which 4% of patients admitted with COVID-19 develop acute kidney injury (AKI) requiring CRRT for 12 days. To estimate non-COVID-19 CRRT demand, we applied the prevalence of AKI requiring CRRT among other ICU patients of 8.8%. We assumed capacity would be double this demand and that this demand would decrease to 25% during the pandemic. We compared CRRT demand and capacity to estimate shortage. In sensitivity analysis, we varied parameters influencing CRRT demand and capacity.

Results: We estimated a national CRRT shortage of 1529 (95% uncertainty interval:1264-3837) machines with a capacity of 9375 machines, and shortages in 8 states during the COVID-19 pandemic (Table 1 and Figure 1).

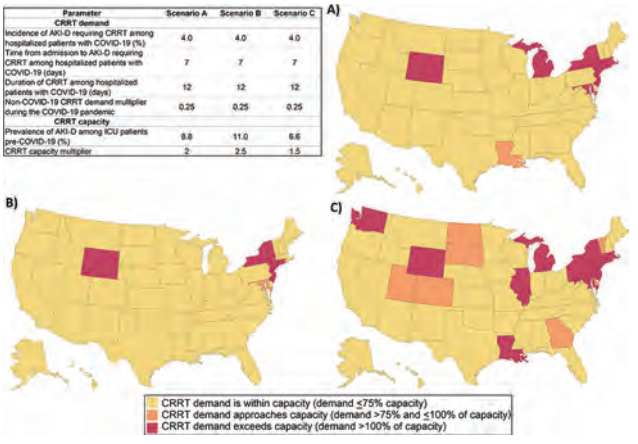
Conclusions: Several US states are projected to have CRRT shortages during the COVID-19 pandemic. A national strategy, such as the creation of a federal stockpile, is needed to mitigate CRRT shortages during this pandemic and future healthcare crises.

Funding: NIDDK Support

Model-generated results for 8 states with CRRT shortages

State	Total ICU beds	Occupied ICU beds	Pre-COVID-19 CRRT demand	CRRT capacity	CRRT demand at peak resource utilization (95% uncertainty interval)	CRRT shortage at peak resource utilization (95% uncertainty interval)
Connecticut	731	446	39	78	224 (171-503)	146 (92-425)
Maryland	1227	805	71	142	174 (128-391)	32 (0-249)
Massachusetts	1555	984	87	173	193 (143-464)	20 (0-291)
Michigan	2749	1773	156	312	313 (293-429)	1 (0-117)
New Jersey	1891	1045	92	184	575 (514-1011)	391 (330-827)
New York	4420	2750	242	484	1391 (1325-1565)	907 (841-1081)
Rhode Island	279	202	18	36	51 (24-207)	15 (0-171)
Wyoming	102	37	3	7	25 (2-114)	17 (0-107)

As noted, 8 US states are projected to encounter CRRT shortages with a total shortage of 1529 (95% uncertainty interval: 1264-3837) machines during the COVID-19 pandemic. Minor discrepancies in this table are due to rounding.



Heat maps demonstrating states with CRRT shortages during the COVID-19 pandemic under scenarios: A) base case, B) highest CRRT capacity estimate and C) lowest CRRT capacity estimate

PO0663

Acute Tubular Injury in Patients with Severe COVID-19 Infection

Yusuke Fukao, Hajime Nagasawa, Yoshihito Nihei, Seiji Ueda, Masao Kihara, Tomohito Gohda, Yusuke Suzuki. *Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Novel coronavirus, severe acute syndrome coronavirus 2 (SARS-CoV-2), has rapidly spread all over the world. SARS-CoV-2 enters host target via angiotensin-converting enzyme-2 which are ubiquitously expressed in many organs including proximal tubules in kidney. Indeed, autopsy cases with coronavirus disease-2019 (COVID-19) revealed the existence of coronavirus particles in the renal tubular epithelium. Several reports have shown COVID-19-associated acute kidney injury (AKI), however involvements of SARS-CoV2 in tubular injury has not been fully understood. Here, we evaluated tubular injury in patients with severe and non-severe COVID19.

Methods: We investigated the relationship between urinary levels of tubule markers (NAG, β2-MG, α1MG, and L-FABP) and laboratory markers in 17 COVID-19 patients without chronic kidney disease on admission. We also analyzed the relationship between the laboratory markers and respiratory status in severe (n=7) or non-severe (n=10) COVID-19 patients which were defined by requirements of supplemental oxygen.

Results: Although only 2 patients developed AKI in severe cases, serum Interleukin-6 (IL-6) level significantly increased in all of severe patients and correlated with levels of proteinuria (R2=0.37, p=0.01), NAG (R2=0.41, p=0.006), α1MG (R2=0.47, p=0.007), L-FABP (R2=0.57, p=0.001) on admission. In addition, severe patients had significantly higher levels of proteinuria (severe: 0.67 vs non-severe: 0.14g/gCr), NAG (33.3 vs 10.1U/L), β2MG (17134.4 vs 1168.5μg/L), α1MG (63.6 vs 12.4mg/L), L-FABP (57.9 vs 7.5μg/gCr) as compared to non-severe cases. Proteinuria and elevated tubular markers were observed only in 2 and 6 cases respectively in non-severe patients, despite those were found in all severe cases.

Conclusions: We found that acute tubular injury was associated with the severity of COVID-19 infection. Since the pathophysiological hallmark of COVID-19 is severe systemic inflammation, it remains obscure whether progressive damage of tubules in SARS-CoV-2 is the result of direct viral infection, ischemic injury, or exposure of any humoral factors. Further large scaled studies focusing on tubular damage should be needed to elucidate underlying mechanisms of renal complication in COVID-19 infection.

PO0664

Incidence of AKI and Its Association with Mortality in Coronavirus Disease 2019 (COVID-19) Patients: A Meta-Analysis

Panupong Hansrivijit,[1] Boonphiphop Boonpheng,[5] Charat Thongprayoon,[2] Wisit Cheungpasitporn,[3] Nasrollah Ghahramani.[4] *[1]UPMC Pinnacle, Harrisburg, PA; [2]Mayo Clinic Minnesota, Rochester, MN; [3]University of Mississippi Medical Center, Jackson, MS; [4]Penn State College of Medicine, Hershey, PA; [5]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Acute kidney injury (AKI) is a common complication in medical practice accounting from 8-18% of hospitalized patients. However, although it has been well-established that AKI is linked to increased mortality in hospitalized patients, whether this knowledge would extend to Coronavirus Disease 2019 (COVID-19) patients remained unanswered. Thus, this study aimed to determine the incidence of AKI and its association with mortality in COVID-19 patients from available literatures using a systematic review and meta-analysis.

Methods: We search Ovid MEDLINE, EMBASE, and the Cochrane Library for eligible publications reporting the clinical characteristics of confirmed COVID-19 patients without language restriction. Incidence of AKI and mortality were reported. Because COVID-19 is an emerging pandemic, a large number of studies were published within a short period of time. Valid Institutional Review Board (IRB) number or approval by the National Health Commission of that country were screened to avoid studies with duplicated patients' population.

Results: From 26 studies (n = 5,497), the pooled incidence of AKI in COVID-19 patients was 8.4% (95% CI, 6.0-11.7) with a pooled incidence of renal replacement therapy of 3.6% (95% CI, 1.8-7.1). The incidence of AKI was higher in critically ill patients (19.9%) compared to hospitalized patients (7.3%). Critically ill patients had higher mortality than hospitalized patients. (33% vs. 16.1%, respectively). The pooled estimated unadjusted odds ratio for mortality from AKI was 13.33 (95% CI, 4.05-43.91). By using meta-regression analyses, the incidence of AKI was positively associated with mortality in an adjusted model (Q 26.18; p = 0.02). Moreover, our adjusted model showed that age (p < 0.01), diabetes (p = 0.02), hypertension (p < 0.01) and baseline serum creatinine levels (p = 0.04) were positively associated with the incidence of AKI.

Conclusions: AKI is present in 8.3% of overall COVID-19 patients and in 19.9% of critically ill COVID-19 patients. Presence of AKI is associated with 13-fold increased risk of mortality. Age, diabetes, hypertension, and baseline serum creatinine levels are associated with increased AKI incidence. More studies, including the ones from multi-national databases, are encouraged to confirm our findings.

PO0665

Prolonged Intermittent Renal Replacement Therapy for AKI in COVID-19 Patients with Acute Respiratory Distress Syndrome

Juan Carlos Ramirez-Sandoval, Jorge Gaytan, Mauricio Arvizu-Hernandez, Juan M. Mejia-Vilet, Pedro Xolalpa Chavez, Ricardo Correa-Rotter, Olynka Vega. *Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico.*

Background: Patients with COVID-19 associated acute respiratory distress syndrome (ARDS) frequently develop severe AKI. Although continuous renal replacement therapy (CRRT) is standard of care for critically ill patients, prolonged intermittent renal replacement therapy (PIRRT) is a feasible option.

Methods: Prospective analysis of 101 PIRRT treatments in a COVID-19 reference hospital in Mexico City (Mar-May 2020).

Results: Of 142 severe COVID-19 patients, 91 (64%) developed AKI, 42 (29%) Stage 3, and 14 (7%) initiated PIRRT; median age 51 y [IQR 51-59, range 40-73], male 11 [78%], diabetes 5 [36%], median BMI 31 kg/m² [27-51], SOFA score 10 [IQR 9-11], ferritin 888 [510-1374 ng/mL], and D-dimer 3076 [1929-5858 ng/mL]. In 81/101 (81%) PIRRT sessions, ultrafiltration (UF) goal was achieved. Duration of PIRRT was 6-8 h in 65/101 (64%) yet in 16/101, procedure was extended 2-4 additional h, to reach UF goal. In subjects with vasopressors, there was a mean norepinephrine dose increase of

0.067 mcg/kg/min (95% CI 0.047-0.101). Intradialytic hypotension (SBP decrease ≥20 mmHg) occurred in 39 (39%) of PIRRT procedures, and 13/101 (13%) PIRRT were discontinued due to severe hypotensive episodes, with 2 patients switched to CRRT. System clotting was a frequent event during the first weeks of March (7 events in the first 30 PIRRT procedures) until concomitant enoxaparin (0.5 mg/kg/day) and regional anticoagulation (unfractionated heparin 500 U/h) were employed. During follow-up, 5 patients (36%) recovered from AKI and respiratory failure, 3 (21%) died, and 6 (43%) are still hospitalized at the time of this report. In those who recovered renal function (9/14), the median number of PIRRT sessions was 6 [IQR 5-8]. Table shows changes in our PIRRT protocol during the COVID-19 outbreak.

Conclusions: PIRRT therapy was feasible and appropriate in most patients who exhibited an exuberant inflammatory response, severe hemodynamic instability, and hypercoagulability.

Recommendation	
"Early" placement of vascular access	Place CVC before adopting prone position in high risk patients for RRT
Timing for initiation of PIRRT	Do not reduce net positive fluid balance until complete fluid resuscitation is confirmed (consider high insensible losses due fever)
Limit COVID-19 exposure	Limit HD staff exposure (place patients close in the ICU to simultaneously deliver PIRRT and limit time of nursing staff to max 4-6 h per person)
Prothrombotic complications	Use of systemic and regional anticoagulation
Severe mixed acidemia	Increased dialysate base yet avoid sudden pH normalization

PO0666

COVID-19 AKI: Risk Factors and Markers of Disease from a Large UK Cohort

Thomas Phillips,[1] Gary Leggatt,[1] Matt Stammers,[1] Kirsty Armstrong,[1] Simon D. Fraser,[2] Becky Bonfield,[1] Kristin Veighey.[1] *[1]University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; [2]University of Southampton, Southampton, United Kingdom.*

Background: Acute kidney injury (AKI) is a significant complication of COVID-19 infection. UK NICE guidelines have been developed. Aim: to examine our local patient-level COVID-19 Hospitalisation in England Surveillance System (CHESS) database to elucidate potential risk factors for AKI vs guidelines.

Methods: 564 COVID positive admissions between 7 March-24 May 2020 at University Hospital Southampton were examined using Python (Anacondas distribution) and SPSS™. AKI was staged by RIFLE and AKIN criteria consistent with NICE guidance. X^2, t-test, Mann-Whitney U test and logistic regression were used to analyse the data.

Results: AKI was present in 177 patients (31%). At peak, 108 (61%) stage 1; 42 (24%) stage 2; 27 (15%) stage 3. There were no significant differences in cohorts with respect to white vs non-white ethnicity, gender, obesity or anti-COVID-19 treatment. 44% of patients with AKI died vs 19% in the non-AKI group ($p<0.001$). AKI was associated with ICU admission (27% vs 10% $p<0.001$), requirement of non-invasive (13% vs 4%) and invasive ventilation (14% vs 4%) (both $p<0.001$). Prior diabetes (18% vs 8%), hypertension (47% vs 34%), chronic respiratory and cardiac disease (both 25% vs 15%) were more common in the AKI group ($p<0.004$). Increased age was associated with AKI ($p=0.02$) and length of stay (LOS) positively correlated to AKI stage($p<0.001$). Peak levels of biomarkers: ferritin, D-dimer, C-reactive protein, high sensitivity troponin-I, neutrophil count and total white cell count, were all significantly raised ($p<0.001$) in the AKI group, increasing with stage of AKI ($p<0.001$). However, in multivariable analysis first clinical observations, neutrophil count, haemoglobin, D-Dimer and albumin came out as the most significant predictors of AKI: Specificity 88.7%, Sensitivity 43.6%.

Conclusions: AKI is a frequent complication of COVID-19 and we identified similar risk factors to those in the NICE guidelines. In addition, we found hypertension and chronic respiratory disease to increase risk of AKI whilst ethnicity, gender, obesity and COVID-19 treatments did not. Furthermore, AKI was associated with increased mortality, ICU admissions and LOS, concordant with previous studies. This data also points to several biomarkers as possible predictors of AKI development and severity. Further analysis of this data is ongoing.

PO0667

High C-Reactive Protein and D-Dimer on Admission Predict the Development of AKI in Patients Hospitalized with COVID-19

Sandheep Venkataraman, Zhiying You, Jessica B. Kendrick. *University of Colorado Denver School of Medicine, Aurora, CO.*

Background: COVID-19 infection is characterized by an acute respiratory syndrome that causes severe symptoms in some patients including a high incidence of acute kidney injury (AKI), which is associated with poor prognosis. COVID-19 infection results in a complex host response including a cytokine storm and severe inflammation. We aimed to identify whether high inflammatory markers on admission predict the development of AKI.

Methods: We performed a cohort study utilizing data from 430 patients admitted with COVID-19 to the University of Colorado Hospital. We excluded patients with a known diagnosis of end stage kidney disease or chronic kidney disease or with missing data. A total of 203 patients were included in this analysis. The primary predictors were initial serum C-reactive protein (hsCRP) >100 mg/L and D-dimer >1000 ng/mL FEU on admission to the hospital. The primary outcome was AKI, defined by KDIGO definition of AKI based on serum creatinine levels. AKI diagnosis was confirmed by chart review. Multivariate logistic regression analysis was used to examine the association between CRP and D-dimer on admission and development of AKI.

Results: The mean age and body mass index of patients was 53.7 (16.9) years and 31.5 (8.4) kg/m2. Fifty-nine percent of patients were male, 40% were Hispanic and 22.7% were Black. 44.3% had hypertension, 35.0% had diabetes and 23% had underlying respiratory disease. Twenty-seven (13.3%) patients developed AKI. After adjustment for age, gender, race/ethnicity, diabetes, hypertension, respiratory disease, cardiovascular disease and ACEi/ARB use, admission CRP level >100 mg/L was associated with nearly a 4-fold increased odds of developing AKI (OR 3.8, 95% CI 1.4-9.8). After full adjustment, admission D-dimer level greater than 1000 ng/mL FEU was associated with a 5-fold increased odds of AKI (OR 5.0, 95% CI 1.8 to 13.5).

Conclusions: High CRP and D-dimer levels on admission were associated with a significantly higher risk of developing AKI, independent of underlying comorbidities. Thus, high CRP and D-dimer on admission should trigger due deliberation and avoidance of nephrotoxic medications and close monitoring for the development of AKI.

PO0668

Hematuria and Elevated Lactate Dehydrogenase Are Associated with AKI in Hospitalized COVID-19 Patients

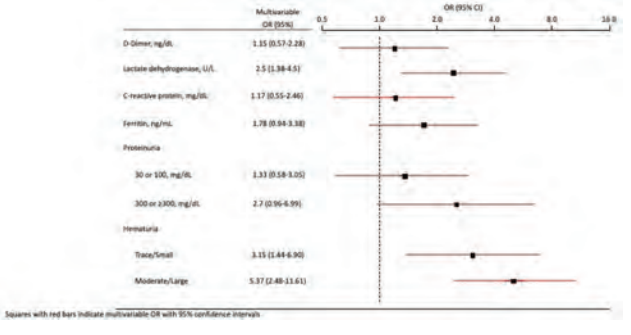
George Thomas, Georges Nakhoul, Jonathan J. Taliercio, Tushar J. Vachharajani, Sevag Demirjian. *Cleveland Clinic, Cleveland, OH.*

Background: Acute kidney injury (AKI) can be a severe complication of COVID-19, particularly in those who require intensive care. Its relationship to the incidence of proteinuria, hematuria, and elevated inflammatory markers has not been well characterized. Our objective is to describe the incidence of AKI in COVID-19, and its association with inflammatory markers.

Methods: Retrospective cohort study of adult patients hospitalized at the Cleveland Clinic with COVID-19. SARS-CoV-2 infection was confirmed by virus detection in respiratory specimens using RT-PCR. AKI was diagnosed per KDIGO serum creatinine-based classification. We selected stage 2 and higher as our primary endpoint for the study. Baseline creatinine was defined as the most recent pre-admission level available within 3 months of presentation. Acute lung injury was defined by the need for mechanical ventilation.

Results: The incidence of AKI was 14% in 621 hospitalized COVID-19 patients, with half requiring kidney replacement therapy (KRT). The incidence of proteinuria and microscopic hematuria were high in these patients (83% and 77% respectively). Seventy five percent of patients with AKI needed mechanical ventilation, and timing of KRT overlapped with time of mechanical ventilation. Inflammatory markers and acute phase reactants, including LDH, ferritin, and C reactive protein were significantly higher in patients with AKI compared to those with no AKI. On adjusted analysis, hematuria and elevated LDH levels were significantly associated with AKI (Figure).

Conclusions: Elevated lactate dehydrogenase levels and microscopic hematuria on presentation are independently associated with 50% probability of moderate to severe AKI. Our findings suggest a possible pathogenetic mechanism of endothelial cell injury and thrombotic microangiopathy as a cause of AKI in COVID-19 patients. Additional studies are needed to explore this potential mechanism of AKI in COVID-19.



Association of hematuria and LDH with AKI in COVID-19

PO0669

Renal Recovery in COVID-19 with AKI Managed on Peritoneal Dialysis

Elly Varma,[1] Divya Shankaranarayanan,[1] Sanjay P. Neupane,[1] Daniil Shimonov,[1] Supriya Gerardine,[1] Perola Lamba,[1] Lorenz Leuprecht,[1] Thalia Salinas,[1] Aarti Bhasin,[1] Vesh Srivatana.[1,2] *[1]Weill Cornell Medicine, New York, NY; [2]The Rogosin Institute, New York City, NY.*

Background: Acute peritoneal dialysis (AKI-PD) used to manage about 20% of our COVID-19 AKI patients requiring renal replacement therapy (RRT) of whom 45% had renal recovery.

Methods: Retrospective chart review of 11 consecutive patients undegoing bedside PD catheter placement from 4/1/2020 to 4/30/2020

Results: Median time from admission to the development of AKI was 1 day (IQR 0-3) (Table 1). In 73% of the patients, CRRT or intermittent HD was used as the initial RRT modality; CRRT circuit clotting was the primary reason for switching to PD in 2 patients. Median time from diagnosis of AKI to PD catheter insertion was 5 days (IQR 2-14). At one week, 10 catheters (91%) were functional with no leaks or bleeding detected. Only one patient was switched to CRRT due to primary PD catheter non-function; this

patient had BMI greater than 35 kg/m² and a history of appendectomy. Median duration of follow up from time of PD catheter placement was 37 days (IQR 32-37.5), death-censored median follow up was 35 days (IQR 30-37.5). The median time from AKI to death was 17 days (IQR 14-22). Median time from AKI to renal recovery was 34 days (IQR 21- 40).

Conclusions: In our AKI-PD cohort, the mortality rate was noted to be 36% and 45% had renal recovery during the follow up period. We hypothesize that preservation of residual renal function utilizing PD may have contributed to the high rate of renal recovery observed. Two of our patients converted from CRRT to PD due to repeated filter clotting. We did not observe any bleeding complications in our cohort. We hypothesize that hypercoagulable COVID-19 patients may be excellent candidates for PD potentially due to lower risk of bleeding complications.

Acute Peritoneal Dialysis in Patients with COVID-19 and AKI: A Single-Center Experience in a Time of Crisis in the United States

Maryanne Sourial,[1,2] Mina Sourial,[1,2] Rochelle Dalsan,[1,2] Jay A. Graham,[1,2] Michael J. Ross,[1,2] Wei Chen,[1,2] Ladan Golestaneh.[1,2] *[1]Montefiore Medical Center, Bronx, NY; [2]Yeshiva University Albert Einstein College of Medicine, Bronx, NY.*

Introduction: In developed countries such as the United States, intermittent hemodialysis (iHD) or continuous renal replacement therapy (CRRT) are the primary mode of renal replacement therapy (RRT) for the management of AKI. However, during the COVID-19 pandemic, the ability to provide HD in our hospital system was overwhelmed due to the surge in the number of patients with AKI requiring RRT combined with severe personnel shortages related to illness. Studies have shown no difference in clinical outcomes between HD and PD for AKI. We describe our rapid adoption of an acute PD program during the COVID-19 surge.

Case Description: At Montefiore Medical Center (MMC), in Bronx, NY, the first patient with COVID-19 was admitted on March 11, 2020. As the number of patients with AKI rose, we initiated an acute PD program starting on March 25th. As of April 13th, there were 2,015 patients with COVID-19 admitted to MMC. From April 1st to April 22nd, 30 patients were initiated on PD with the help of surgery and interventional radiology who placed Tenckhoff catheters at bedside and under fluoroscopy, respectively. Of those 30 patients, 14 died, 8 were discharged, and 8 were still hospitalized as of May 14, 2020. Of the 8 patients discharged, 3 were still on PD and 5 had renal recovery (all were able to stop dialysis and 4 returned to baseline creatinine). Of the 8 patients still hospitalized, 4 patients were switched to iHD (3 due to fluid retention and 1 due to PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Challenges to this program included lack of nurse training, difficulty securing supplies and irregular therapy provision and underdosing due to staffing shortages. Patients on medical wards received more frequent exchanges and did not have significant volume overload and metabolic derangements like those patients requiring intensive care.

Discussion: Despite challenges, we demonstrate the feasibility of acute PD as an alternative to HD in patients with COVID-19-associated AKI. In this single-center experience, we found that acute PD was more effective for stable patients on the wards than for patients with severe illness requiring intensive care.

PO0671

Fluid Balance on CRRT and Association with Respiratory Status in Patients with COVID-19 and AKI

John T. Ludwig, Ryann Sohaney, Salma Shaikhouni, Markus Bitzer, Lenar T. Yessayan, Anca Tilea, Michael Heung. *University of Michigan, Ann Arbor, MI.*

Background: Acute kidney injury is common among critically ill patients with COVID-19 (CoV-AKI), complicating the primary syndrome of ARDS. We report our single center experience with fluid management on CRRT in relation to respiratory parameters.

Methods: Retrospective chart review of 32 consecutive patients with CoV-AKI requiring CRRT admitted to the ICU at the University of Michigan between 3/23 and 4/26, with follow-up through 5/12/2020. All patients received post-filter continuous venovenous hemodiafiltration with regional citrate anticoagulation per institutional protocol. Daily cumulative fluid balance and respiratory parameters (P/F and PEEP) were recorded for the first 7 days of CRRT. We assess the relationship between cumulative fluid balance on CRRT and respiratory parameters (P/F and PEEP) with repeated measures modeling adjusted for fluid accumulation at CRRT start, height, weight, and age.

Results: Mean age 54.8, majority black (75%), and comorbidities included hypertension (90.6%), diabetes (56.2%), CKD (53.1%), and organ transplantation (18.8%). Median length of mechanical ventilation was 15.0 (12-25) days. Median cumulative fluid balance from admission to CRRT start was +3.3 (2.0- 5.6) liters. There was a trend toward increasingly negative fluid balance on CRRT (figure). When adjusting for age, weight, height and cumulative fluid balance at CRRT start, there was no association between cumulative fluid balance on CRRT and P/F (p=0.21) or PEEP (p=0.47). At end of data collection, 9 (28.1%) patients remained in the hospital, 10 (31.3%) survived to hospital discharge and 13 (40.6%) had died.

Conclusions: Cumulative fluid balance on CRRT did not correlate with change in P/F or PEEP, even after accounting for baseline fluid balance. Nevertheless, it is possible that more aggressive fluid removal is required to demonstrated an effect.

Mean Daily Fluid Balance

PO0672

Effect of Early Initiation of Blood Purification in ICU Adults with Severe COVID-19

Jing Qian, Mengjing Wang, Li Ni, Weichen Zhang, Kangjie Wang, Li Yuan, Jing Chen. *Huashan Hospital Fudan University, Shanghai, China.*

Background: Cytokine storm induced by SARS-CoV-2 was considered as one of the main mechanisms of multiple organs dysfunction in Covid-19. Blood purification could remove excess cytokines or other harmful substances and then attenuate target organs injury. In this prospective single-center cohort study, we aimed to assess the efficacy of early initiation of blood purification in ICU adults with severe Covid-19.

Methods: Sixty-two patients in early stage of severe Covid-19 in ICU(Tongji Hospital, Wuhan, China) from Feb.9.2020 to Mar.24.2020 were recruited and divided into two subgroups: 20 patients initiated blood purification including CVVH(/HP) after ICU admission, and the other 42 patients who had not received RRT unless reached traditional RRT indication, were served as control. The primary outcome was in-hospital all-cause mortality.

Results: The 20 patients initiated early RRT after 6.4±3.6 days from ICU admission. The mean cumulative treatment time was 50.0±42.2 hours, the net ultrafiltration rate was 65.5±65.2ml/h. One patient in control group also received RRT after ICU admission due to AKI. No statistic difference was found in the two subgroups in baseline. 61.3% patients died during hospitalization. The median survival time was 12 days and the average observation time was 19 days. Kaplan-Meier analysis showed that the in-hospital all-cause mortality of early RRT patients was lower than control group(50.5% vs 66.7%, *p*=0.040). Univariate analysis and Cox proportional hazard regression also confirmed that early initiation of RRT was an independent protective factor(HR 0.21, 95%CI 0.06-0.74, *p*=0.014) for in-hospital all-cause death of severe Covid-19 after adjusting by SpO_2, lymphocyte proportion, albumin, LogNT-proBNP, LogInterleukin-6, mechanical ventilation and use of glucocorticoid. A figure that shows the course of disease indicates that early initiation of blood purification may decrease the death without multiple organs injuries(39% vs 0%, *p*=0.037).

Conclusions: Early initiation of blood purification could probably reduce the mortality of severe Covid-19. It was implied that it could delay occurs and reduce degrees of target organs injuries by cutting the peak load of cytokine storm. Further research in basic and clinical were needed to clarify the mechanism of blood purification in cytokine storm-related diseases.

PO0673

Incidence of New-Onset Proteinuria in AKI Associated with COVID-19 Is Not Greater Than It Is in AKI from Other Causes

Vipin Varghese,[1] Muner Mohamed,[2] Juan Carlos Q. Velez.[1,2] Ochsner Nephrology *[1]Ochsner Clinical School - University of Queensland, New Orleans, LA; [2]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Early reports of acute kidney injury (AKI) associated with COVID-19 have claimed high incidence of proteinuria. If so, it may suggest an AKI pathogenesis not solely related to ischemic acute tubular injury (ATI). We hypothesized that those claims result from observation bias. Therefore, we sought to investigate the rate of *de novo* proteinuria in AKI associated with COVID-19 (CoV-AKI) compared to that of AKI in the pre-COVID-19 era (non-CoV-AKI).

Methods: Hospitalized patients with CoV-AKI entered the cohort (n=161). As a control non-CoV-AKI group (n=186), we accessed a database of patients with AKI who underwent urinary sediment microscopy due to suspicion of an intrinsic cause of AKI (Sedi-AKI cohort, 2017-2019). We examined the incidence of proteinuria of any degree (1+ dipstick), significant [urine protein-to-creatinine ratio (UPCR) ≥ 0.5–3.0 g/g or 2+ dipstick] or overt [UPCR ≥ 3.0 g/g + 3+ dipstick].

Results: Median age were similar: 65 (34-95) and 60 (20-88) years for CoV-AKI and non-CoV-AKI, respectively. Women were 62% and 63% (p=0.86). Black race was more common in CoV-AKI (75% vs. 35%; p=<0.0001). ATI (ischemic and/or toxic) was the presumed cause of AKI in 75% and 71% of CoV-AKI and non-CoV-AKI, respectively. Incidence of any, significant or overt proteinuria were 123/148 (83%) vs. 127/184 (69%) (p=0.003), 98/148 (66%) vs. 81/184 (44%) (p=0.0001) and 14/148 (10%) vs. 23/184 (13%) (p=0.39), for CoV-AKI and non-CoV-AKI, respectively. Among those with significant proteinuria, no difference in median UPCR was found [0.69 vs. 0.69 g/g (p=0.23)]. Using baseline UPCR when available, rates of *de novo* significant and overt proteinuria were similar [57/124 (46%) vs 57/123 (46%) (p=1.00) and 6/124 (5%) vs 7/123 (7%) (p=0.75)]. Among overt cases who underwent kidney biopsy, collapsing glomerulopathy was found in 3/4 (75%) in the CoV-AKI group compared to 0/11 (0%) in the control (p=0.002).

Conclusions: The incidence rate of new onset proteinuria was not found to be increased in CoV-AKI and is consistent with that of other forms of ATI. An observed overall greater incidence in significant proteinuria in CoV-AKI may be driven by preexisting proteinuria. While the rate of overt proteinuria is not greater in CoV-AKI, the primary cause of *de novo* glomerular disease may vary.

PO0674

AKI Perspectives and Practices in Latin America (LA) During COVID-19: Analysis from GlomCon Latin America Working Group

Javier Soto-Vargas,[1] Desiree Garcia Anton,[2] Diana Aguirre,[3] Denisse Arellano-Mendez,[4] Franco H. Cabeza Rivera,[2] Julio A. Gutierrez-Prieto,[5] Blanca Martinez-Chagolla,[6] Sonia Rodriguez Ramirez,[7] Carmen Avila-Casado.[8] GlomCon Latin America Working Group *[1]Especialidad de Nefrología, Hospital General Regional 46, Guadalajara, Mexico; [2]University of Mississippi Medical Center, Jackson, MS; [3]Hospital General de Mexicali, Mexicali, Mexico; [4]Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; [5]Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; [6]Hospital General "Dr. Miguel Silva", Morelia, Mexico; [7]Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; [8]Pathology Department, University Health Network, Toronto, ON, Canada.*

Background: The epidemiology, clinical presentation, management and outcomes of COVID-19 comes from early reports from China and Europe with AKI prevalence ranging widely from 0.5% to 29%. However, knowledge about this pandemic is still emerging. With the epicenter now in the western hemisphere, we aim to determine the behavior and possible differences in presentation of AKI in COVID-19 patients in Latin America. To our knowledge, this is the first of such study.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases between May 20-27, 2020 from sixteen Spanish speaking Latin American countries divided into 6 categories. We present the results for the AKI category.

Results: 430 responses were obtained of which 360 (84%) were considered for analysis. 86% of the participants were nephrologists. 35% of the respondents reported the prevalence of AKI to be <5%, while 32% estimated it at 6-10%. The majority of AKI in these patients was stage 3 according to 31% of the respondents. Roughly half of the nephrologists witnessed new onset proteinuria which was almost exclusively (96%) sub-nephrotic. The majority (64%) reported no hematuria. Half of the participants (50.2%) reported that renal replacement therapy (RRT) was never or rarely required. Intermittent hemodialysis was the main RRT used reported by 88% of those surveyed followed by continuous renal replacement therapy (33%), peritoneal dialysis (24%) and prolonged intermittent RRT (19%). The most common complications during RRT were hypotension (60.3%) and circuit clotting (36.6%). Over one third of the participants (35%) estimated the mortality of patients with AKI and COVID to be <20%.

Conclusions: Our survey highlights potential differences in the presentation, management and outcomes of AKI in patients with COVID-19 in LA; among those, a lower prevalence, higher need for RRT and lower mortality. More studies are warranted to better understand AKI in hispanic COVID-19 patients as well as its distinct characteristics compared to the rest of the world.

PO0675

AKI due to COVID-19 in the Intensive Care Unit: Analysis of a Brazilian Center

Precil D. Neves, Victor Sato, Sara Mohrbacher, Bernadete Ferreira, Leonardo V. Pereira, Erico S. Oliveira, Alessandra M. Bales, Luciana L. Nardotto, Jéssica Ferreira, David Machado, Estevao Bassi, Amilton Silva-Junior, Pedro Chocair, Americo L. Cuvello neto. *Hospital Alemão Oswaldo Cruz, Sao Paulo, Brazil.*

Background: The kidney may be affected by coronavirus (COVID) in the setting of acute kidney injury (AKI) or glomerular diseases. Data about AKI in Intensive Care Unit (ICU) patients of Latin-America are scarce. The aim of this study is evaluate the risk of AKI, dialysis (HD) and death in ICU patients diagnosed with COVID pneumonia in a brazilian center.

Methods: Analysis from medical records of ICU patients with diagnosis of COVID pneumonia in a brazilian single-center. AKI was defined according to KDIGO criteria.

Results: During the period of February 2nd to May 4th, 95 ICU patients diagnosed with COVID were analyzed. There was predominance of male (64.2%), median age of 64.9 years, previous diagnosis of hypertension, diabetes and obesity in 51.6%, 27.4 and 30.5% respectively. AKI was diagnosed in 54 (56.8%) patients and 32 (59.2%) of them required HD. Mortality rate was 17.9%. Patients with AKI, compared to no-AKI were statisticaly significant more frequently hypertensive and diabetic, worse SAPS3 and SOFA scores and need for organ support therapies. Laboratory tests depicted more anemia, lymphopenia, and higher levels of inflamatory markers as well as longer lenght of stay in ICU, hospital and death. Similar findings were seen in those ones who required HD compared to those with conservador treatment. Comparing patients who undergone death to survivors, they were older, more frequently diabetic, worse SAPS3 and SOFA scores and need for organ support therapies, AKI and dialysis. Multinomial logistic regression predicted that hypertension (p=0.01), mechanical ventilation (p=0.01) and use of hydroxychloroquine (p=0.009) were independent risks factors for AKI; hypertension (p=0.002), mechanical ventilation (p=0.03), use of vasopressor (p=0.04), and use of hydroxychloroquine (p=0.009) for HD patients; and age >65 years (p=0.03) and AKI (p=0.04) for death.

Conclusions: In our study, AKI was a common complication of ICU COVID patients, it was associated to hypertension, organ support therapies and use of hydroxichloroquine. As well as age >65 years, AKI was an independent risk fator to death.

PO0676

AKI in Patients with COVID-19 Infection: Preliminary Data from AKI COVID-19 Registry of the Spanish Society of Nephrology

Maria Jose Soler,[1] Esteban Poch,[2] Raquel Diaz Mancebo,[4] Rocío E. Echarri,[5] Nuria Areste,[3] Mercedes Salgueira Lazo.[3] AKI COVID-19 Registry of the Spanish Society of Nephrology. *[1]Hospital Vall d Hebron, Barcelona, Spain; [2]Hospital Clínic de Barcelona., Barcelona, Spain; [3]Hospital Universitario Virgen Macarena., Sevilla, Spain; [4]Hospital de la Paz, Madrid, Spain; [5]Hospital Universitario Infanta Sofia., San Sebastian de los Reyes, Spain.*

Background: SARS-CoV-2 coronavirus pandemic has significant impact on the general population, and chronic hemodialysis patients presented a poor prognosis with a mortality rate around 25%. Data from severe acute kidney injury(AKI) and acute renal replacement therapy(RRT) is scarce. We present the preliminary results of AKI COVID-19 Registry of the Spanish Society of Nephrology.

Methods: The online Registry began operating on May 21th. It collects epidemiological variables, contagion and diagnosis data, signs and symptoms, treatments and outcomes. Patients were diagnosed with SARS-Cov-2 infection based on PCR of the virus.

Results: One week after the AKI COVID registry started, 54 patients with AKI with RRT and COVID-19 from 11 Hospitals. Age was 64+9years and 55% men. 65% hypertension, 31% diabetes mellitus, 14% cardiovascular disease, 26% chronic kidney disease, 6% neoplasm, 29% obesity, 8% chronic obstructive pulmonary disease, and

6% smokers. Previous treatment: 10% immunosuppressive, 20% ACEi, 25% ARBs, 14% antiplatelets, and 10% anticoagulants. Clinical characteristics: 92% common respiratory symptoms, 96% pneumonia, 90% required intensive care unit(ICU) and 87% mechanic ventilation. 32% albuminuria, 18% hematuria, and 50% AKI with preserved urine output. Time from COVID-19 symptoms start to AKI 12.3+8days, time ICU 19.8+5days. APACHE at UCI admission 15+7. 81% lymphopenia. RRT was needed in 91% 13.4+12days: 55% received continuous RRT, and 72% anticoagulation. Kidney biopsy was not performed. Mortality 46.3% (60% males), and 4% remained under RRT. Time from AKI to renal function recovery 25+14 days. 65.2% death patients had hypertension. No differences were observed in comorbidities, chronic treatments, renal clinical characteristics, dialysis modality and mortality. Decreased lymphocyte count was associated with worse patient prognosis (dead 495±260 vs. survivors 789±460,p=0.023).

Conclusions: The mortality in AKI with RRT and COVID-19 is alarming high. Severe AKI associated with COVID-19 disease is more frequent in males. Interestingly, half of the patients preserved urine output. Severe lymphopenia was associated with mortality. More data from the AKI COVID-19 registry will help us to enlighten the prognosis and risk factors associated to mortality.

AKI in People Living with HIV Hospitalized with COVID-19

Molly Fisher,[1,2] Melissa Fazzari,[2] David B. Hanna,[2] Viraj V. Patel,[1,2] Uriel R. Felsen,[1,2] Mindy Ginsberg,[2] Kathryn Anastos,[1,2] Michael J. Ross.[2,1] *[1]Montefiore Medical Center, Bronx, NY; [2]Yeshiva University Albert Einstein College of Medicine, Bronx, NY.*

Background: People living with HIV (PLWH) have an increased burden of kidney disease and unique factors that may place them at increased risk for acute kidney injury (AKI) in the setting of COVID-19. The aim of our study was to characterize the incidence, risk factors and outcomes of AKI among hospitalized PLWH with COVID-19.

Methods: We performed a retrospective study of adult PLWH hospitalized with laboratory-confirmed COVID-19 in a large healthcare system in Bronx, New York from March 10-May 11, 2020. Data collected included demographics, comorbidities, antiretroviral therapy (ART), initial laboratory data, and preadmission CD4 count and HIV viral load. AKI was defined and staged using KDIGO criteria. Fisher and Wilcoxon tests compared differences in those with and without AKI.

Results: During the study period, 77 PLWH were hospitalized with COVID-19. The majority were Black or Hispanic, 50% were men, 53% had hypertension, 31% diabetes mellitus, 22% chronic kidney disease (CKD) and 14% end-stage kidney disease (ESKD). Mean CD4 count was 470 cells/uL and 83% had a suppressed HIV viral load (<40 copies/mL). After excluding 11 with ESKD, AKI incidence was 50%. Those with AKI were older [63 (SD 9) vs 55 (SD 13) years, p=0.005], more were black (56% vs 37%, p=0.01) and more had CKD (42% vs 9%, p<0.0001) compared to those without AKI. There were no significant differences in CD4 count, HIV viral load, or use of tenofovir-containing ART between those with and without AKI. By AKI severity, 11/33 (33%) were stage 1, 4/33 (12%) stage 2 and 18/33 (55%) stage 3. Mechanical ventilation (33% vs 0%, p=0.0004) and in-hospital mortality (42% vs 3%, p=0.0002) were more common in those with AKI. Of 6 patients who required renal replacement therapy, 4 died and 2 remained RRT dependent. Admission white blood cell count, neutrophil/lymphocyte ratio, D-dimer, ferritin, C-reactive protein and lactate dehydrogenase levels were significantly higher in those with AKI.

Conclusions: The incidence of AKI in PLWH hospitalized with COVID-19 was high and associated with poor outcomes. We did not identify HIV-specific risk factors for AKI in the setting of COVID-19. Admission inflammatory markers may be predictive of AKI in PLWH with COVID-19.

PO0678

AKI Is Related to Mortality in COVID-19 Patients Without Underlying Kidney Disease

Yue Yu, Huipeng Ge, Xiufen Wang, Lijian Tao, Zhangzhe Peng, Xiangcheng Xiao. *Xiangya Hospital Central South University, Changsha, China.*

Background: Due to its high infectivity and mortality, coronavirus disease 2019 (COVID-19) has become a global public health issue. The kidneys act as critical metabolic organs, therefore, whether COVID-19 can induce renal damage is of utmost importance but remains controversial, and the prognosis of COVID-19 encountering acute kidney injury (AKI) is unknown. Moreover, the efficacy of different treatments that COVID-19 patients undergo needs to be explored. In this study, we aimed to explore these questions.

Methods: A single-centered, retrospective study was conducted in which 96 patients with COVID-19 were enrolled. Epidemiological, clinical, and laboratory characteristics, as well as treatments and patient outcomes were described. Characteristics were compared between severe cases and critical cases. Relevant factors of AKI were filtrated, and the treatment efficacy was also evaluated.

Results: A total of 6 patients (6.3%) died during hospitalization. Four patients (4.2%) developed AKI, among which 3 patients (75%) died. Statistical analysis indicated that AKI was not common in COVID-19 patients without underlying kidney disease, but was related to mortality. Age, severity of disease, procalcitonin, C-reactive protein and interleukin-6 were correlated with AKI onset in COVID-19 patients, while lymphocyte count and estimated glomerular filtration rate at admission were inversely related to the development of AKI.

Conclusions: In conclusion, AKI is not common in COVID-19 patients without underlying kidney disease but related to mortality.

Acute Peritoneal Dialysis with Percutaneous Catheter Insertion for COVID-19-Associated AKI in Intensive Care: Experience from a UK Tertiary Centre

Dandisonba B. Braide-Azikiwe, Elaine Bowes, Kate Bramham, Caroline Tulley, Eirini Lioudaki, Hugh Cairns, Claire C. Sharpe. *King's College Hospital, London, United Kingdom.*

Background: During the COVID-19 pandemic in 2020, high rates of acute kidney injury (AKI) in critically unwell patients are being reported, leading to increased demand for renal replacement therapy (RRT). There are considerable challenges providing RRT for large numbers of patients with COVID-19 and alternatives to continuous veno-venous hemodiafiltration therapies (CVVHDF) in intensive care units (ICU) are needed in both high and low-resource settings. Peritoneal dialysis (PD) can be initiated immediately after percutaneous insertion of the catheter, but there are concerns about impact on ventilation and RRT efficacy. We describe our recent experience of percutaneous catheter insertion and peritoneal dialysis in patients in ICU with COVID-19 infection.

Methods: Patients were selected according to local protocol and catheters inserted percutaneously using Seldinger technique by two experienced operators. Sequential Organ Failure Assessment score (SOFA) and ventilation requirements were recorded at time of insertion, and at 24 hours after insertion. Procedure complications, proportion of RRT provided by PD, renal recovery and RRT parameters during PD were assessed.

Results: Percutaneous PD catheters were successfully inserted in 32/39 (82.1%) patients after median of 10.0 (IQR 13.0, 19.0) days on ICU. No adverse events following insertion were reported, SOFA scores and ventilation requirements were comparable before and after insertion and adequate RRT parameters were achieved. Median proportion of RRT provided by PD following catheter insertion was 90.2% (IQR 77.5, 100).

Conclusions: PD provides a safe and effective alternative to CVVHDF in selected patients with AKI and COVID-19 infection requiring ventilation on intensive care.

Clinical Parameters of Patients Prior to and after Peritoneal Dialysis Catheter Insertion

Parameter, Median (IQR) N=31(1 Missing)	24 hours Prior to PD Catheter Insertion	24 hours After PD Catheter Insertion
Lowest PaO2: FiO2 Ratio	22.0 (18.3, 30.0)	22.5 (18.5, 31.0)
SOFA Score	16.0 (15.0, 16.0)	16.0 (15.0, 17.0)
Requirement for vasopressor support (N (%)) Median maximal dose of norepinephrine (μg/kg/min)	18 (46.2%) 0.13 (0.08, 0.22)	16 (41.0%) 0.17 (0.07, 0.32)

IQR: interquartile range; PD: Peritoneal Dialysis; PaO2 : FiO2 ratio (arterial oxygen partial pressure (PaO2 in mmHg) to fractional inspired oxygen (FiO2 expressed as a fraction)); SOFA: Sequential Organ Failure Assessment

PO0680

Adding Heparin to Citrate in Continuous Renal Replacement Therapy May Extend Filter Lifespan in COVID-Related AKI

Eduardo d. Valle, Claudia C. Albuquerque, Carla P. Sandoval Cabrera, Giovanio V. da Silva, Igor Smolentzov, Bernardo V. Reichert, Lucia Andrade, Paulo R. Lins, Victor F. Seabra, Camila E. Rodrigues. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: COVID may predispose patients to thrombosis and lower filter lifespan. Association between D-dimer level (DD) and filter clotting in Continuous Renal Replacement Therapy (CRRT) has not been described.

Methods: All patients who needed CRRT in Hospital das Clínicas (Brazil) during March to May 2020 (COVID related-AKI (COV+), n=37) and August to September 2019 (COVID unrelated-AKI (COV-), n=18) were studied. Anticoagulation in CRRT in COV+ was done with citrate 3mmol/L (ACD, n=19), or citrate 4mmol/L plus non-fractioned heparin 10U/Kg/h (ACD/Hep, n=18), while in COV- with citrate 3mmol/L only. Data are expressed in median [IQR]. We performed Spearman's correlation between DD and time-free of filter clotting (TFC), and Kaplan-Meier curve to study filter survival by anticoagulation method and DD.

Results: ACD/Hep group presented lower filter clotting in 72h when compared to other groups (ACD/Hep: 35% vs ACD: 100% vs COV-: 80%, p< 0.05). Analyzing

filter clotting per patient-day, ACD/Hep also presented less clotting than ACD group (ACD/Hep: 41% vs ACD: 100%, p< 0.05). In COVID patients, median TFC was 33.5 h [17.0;72.0] (ACD: 29.0 h [13.0;68.5], ACD/Hep: 40.0 h [17.0;62.0], p: NS). Clotting time from obese patients did not differ from non obese patients (obese: 31.0 h [18.5;57.2] vs non-obese: 56.0 h [16.8;72.0], p: ns). Median DD in all COVID patients was 3,519 [1420-13,883]. Patients with DD below median (<3,500) had higher TFC (ACD high DD: 19.0 h [9.00;27.5], ACD/Hep high DD: 34.0 [17.0;62.0], ACD low DD: 57.0 h [27.2;66.8], ACD/Hep low DD: 67.0 h [26.0;72.0]; Figure 1). There was statistically significance in correlation between DD and TFC in ACD patients, but not in ACD/Hep group.

Conclusions: Heparin may extend filter lifespan in CRRT, and this benefit seem to be greater in high DD patients.

PO0681

A Retrospective Observational Study Comparing the Frequency of CRRT Clotting in COVID-19 Positive vs. Negative Patients

Aulio E. Bustos, Michael Connery, Viviam I. Becerra rivera, Savneek S. Chugh, Sanjeev Gupta, Hay Me Me, Neha Deval, Firas Jafri, Vrunda Mangaroliya, Shruti Kore, Anant Jain. *Westchester Medical Center Health Network, Valhalla, NY.*

Background: Coronavirus disease 2019 (COVID-19) emerged from China in late 2019 as a respiratory disease of unknown cause. A novel coronavirus 2019-CoV was implicated as the cause. A high proportion of patients goes into septic shock from COVID-19infection and develop acute kidney injury (AKI) which often requiring continuous renal replacement therapy (CRRT). Clinical experience has suggested that these patients are hypercoagulable with studies showing increased rates of thrombosis. This complicates the administration of CRRT as this leads to more frequent clotting of the dialysis catheter and sequelae of blood loss, time off dialysis, and increased use of resources

Methods: We retrospectively audited all patients admitted at our center from February to April 2020 who developed severe AKI requiring CRRT and compared the number of CRRT clotted in the first 7 days in COVID-19 negative (N = 49) and positive (N = 55) patients. Pediatric patients were excluded from this analysis. We also collected data on other variables which may influence rate frequency such as location of catheter, INR, and presence of systemic anticoagulation

Results: We found that patients who tested positive for COVID-19 had a higher number of clotting events in the first 7 days of CRRT (3.51 vs 1.63, p < 0.00008). This population had higher incidence of AKI vs ESRD, number of pressor, and PEEP. Also, COVID 19 patients on anticoagulation has decreased clotting frequency compare to COVID 19 positive patients not on anticoagulation (2.7 vs 4.3, P <0.05)

Conclusions: This data confirms our clinical experience that coagulopathy in COVID-19 positive patients lead to a greater incidence of CRRT clotting and the use of systemic anticoagulation was effective in reducing the number of clotting events

PO0682

A Retrospective Study of Critically Ill Patients with COVID-19 and Anticoagulation Used Throughout CRRT

Ryan Mocerino, Kaltrina Sedaliu, Yogita Rochlani, Nicholas Quinn, Sasa Vukelic, Michal L. Melamed, Maureen E. Brogan. *Montefiore Medical Center, Bronx, NY.*

Background: Studies indicate that 5% of patients with COVID-19 develop critical illness, warranting ICU level of care. Up to 15% of these critically ill patients develop acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT). COVID-19 also appears to generate a pro-thrombotic state in some patients and thrombosis during CRRT could prevent life sustaining clearance and fluid removal.

Methods: In this single center study, we performed a retrospective chart review of patients admitted to Montefiore Medical Center, with a confirmed diagnosis of COVID19 in an ICU requiring CRRT between 3/10/2020 — 4/28/2020. Subsequently, we categorized the different anticoagulation (AC) types that were used for each CRRT treatment: no AC, heparin, bivalirudin, apixiban. The primary outcome was to determine the percent of achieved versus prescribed CRRT in patients treated without AC, heparin, or bivalirudin (dosing > 0.25 mg/kg/hr, versus < 0.25 mg/kg/hr). The secondary outcome was to determine the percent reduction in BUN and potassium within 10 hours of CRRT.

Results: We excluded patients with renal failure requiring renal replacement therapy (RRT) that did not have a confirmed diagnosis of COVID19, as well as patients with a previous history of thrombosis. We were left with 69 patients, whom we analyzed the first three RRT treatments of each patient. The average age was 59.48 years, 81.2% male, 18.8% female. 15% of patients were African American, 5% Caucasian, 31% Hispanic, and 17% identified as other. The average BMI was 30.2. 40% of patients had diabetes mellitus, 49% hypertension, and 14% CKD or ESRD. We analyzed a total of 162 RRT treatments. Of these 162 treatments, 49% of patients received bivalirudin, 27% heparin, and 23.4% did not receive AC. We found that 84.5% of patients receiving bivalirudin completed their CRRT treatment, 77.7% receiving heparin completed treatment, and 59.3% of patients not on AC completed treatment.

Conclusions: Patients with a confirmed diagnosis of COVID 19 that are critically ill and receive CRRT are more likely to finish their CRRT treatment, and therefore achieved improved clearance, if they were given some form of AC to prevent clotting.

PO0683

Association of Ventilatory Time and AKI in a Bronx Cohort of COVID-19 Patients

Abby M. Basalely,[1] Diane Liu,[1] Molly Fisher,[2] Ladan Golestaneh,[2] Eran Y. Bellin,[2] Kimberly J. Reidy.[1] *[1]Children's Hospital at Montefiore, Bronx, NY; [2]Montefiore Medical Center, Bronx, NY.*

Background: The relationship of lung-kidney interactions in COVID19 has not been well described. AKI has been associated with increased mechanical ventilation times. Recent publications have shown a strong association of COVID19-AKI with mortality and a high incidence of AKI occurring peri-intubation. We hypothesized that mechanical ventilation (MV) time would be increased in patients with COVID19-AKI and longer in those with severe AKI.

Methods: We analyzed a cohort of incident COVID19 patients who required MV. Patients with end stage renal disease were excluded. AKI was defined using KDIGO criteria (0.3 mg/dL increase or greater than a 50% increase from the baseline Cr) between the maximum Cr and baseline Cr. AKI stage was defined by KDIGO criteria. Days of total MV was measured in days from date of initial intubation, including subsequent intubation/extubation events, until successful extubation or death. Censored data was not included. Linear regression models were utilized to evaluate associations.

Results: We analyzed 318 patients. 62% were male, 37% were black/African American and 33% were Hispanic/Latino. Hypertension was prevalent in the cohort (N=212) and over 50% were obese. Median MV time was 4.67 days (IQR 1.76, 9.95). AKI occurred in 89% (N=283) of the cohort. Stage 3 AKI developed in over 50% (N=161) of patients. In models adjusted for age, hypertension, diabetes and disease related group weight, patients with AKI had 3.46 more days of MV, however this finding did not reach statistical significance (95%CI 0.92-6.00). This association however was significant and increased linearly with stage of AKI (p for trend <0.001).

Conclusions: This is one of the first studies to evaluate the association of COVID19-AKI and MV time. Even after adjusting for severity of illness, patients with increased stage of AKI had longer MV times. This may be due to pathophysiologic kidney-lung interactions seen in non-COVID19 disease and/or direct effect of COVID19 on the kidneys. As few patients in our cohort were spared from kidney injury, inferences comparing those with and without AKI are difficult to discern. We plan to explore this question in a larger cohort to determine whether COVID19-AKI alone is associated with ventilatory time.

Funding: NIDDK Support

PO0684

Can the AKI Alert Staging Tool Help Manage Patients Admitted During the COVID Pandemic?

Barian Mohidin, Devnandan A. Chatterjee, Gurminder S. Khamba, Georgia Winnett. Kidney Medicine, Basildon & Thurrock University Hospital *Mid and South Essex University Hospitals Group, Basildon, United Kingdom.*

Background: Basildon & Thurrock University Hospital has the second highest rate of hospital admissions with AKI stage 3 in the United Kingdom based on Renal Registry Hospital Episode Submission Data. Acute kidney injury (AKI) is common in hospitalized patients and carries a higher risk of mortality. Given the limitations of resources both personnel and equipment, a retrospective study was done to see if the AKI alert staging tool could help predict and direct resources to those patients who would benefit most from specialist intervention.

Methods: Data was reviewed from January - May 2020. This corresponded to the peak of admissions and by the end of the period, the hospital was on course to returning to pre pandemic activity. Relevant data including admission laboratory tests and imaging was collected. The admission stay was analysed for duration, the need for transfer to an intensive care environment to receive ventilator support and/or renal replacement therapy. Discharge destination was reviewed and whether the patient was discharged home, to another facility or did not survive the admission. For comparison we looked at the same period in the preceding year as this would represent the most matched population.

Results: Over 5000 AKI alerts were generated for this period for 4390 unique admissions. This compares to 3910 AKI alerts for 1098 unique admissions for the identical period in the previous year. The vast majority were for AKI stage one alerts none of which were in COVID positive patients. A significant proportion of patients with AKI Stage 2 and 3 alerts were positive for COVID. Those that were admitted to Intensive Care with Stage 3 AKI almost always required intubation and renal replacement therapy. Mortality was higher in this group.

Conclusions: The AKI alert system helps identify patients who are unwell and can benefit from Nephrologist input at an early stage. The Alert algorithm excludes haemodialysis patients, therefore this population was excluded. During the COVID pandemic there was a clear increase in AKI admissions and alerts creating a substantial demand on renal services. Specialist intervention should be directed to AKI alert stage 2 patients where intervention can help prevent progression into AKI stage 3 and subsequent ICU admission. AKI stage 1 patients who are COVID negative can be managed without specialist input.

PO0685

Characteristics and Outcome of AKI Needing Dialysis with COVID-19 Infection

Suresh Sankarasubbaiyan, Mallikarjuna Gowda B. Gowda, Venkatraman Ganapathi Subraman, Mohammad S. Husain, Vikram A. Sonawane, Satyanarayana R. Puvvada, Kaparaboina K. Kumar, Guruvulu Venkata, Kamal D. Shah. *Nephroplus, Hyerabad, India*.

Background: COVID-19 infection has varying grades of mortality worldwide. Multi-organ injury, not uncommonly associated with AKI, portends a poor outcome. We studied AKI needing hemodialysis (HD) in the context of COVID-19 infection

Methods: From March 15th to May 25th 2020, for consecutive COVID-19 infections AKI needing HD in a large dialysis network age, gender, payer type, days:admission to HD start, urine output, S. Cr, comorbidities, other organ injuries, length of stay & outcome, dialysis session details: blood flow rate(BFR), dialysis flow rate(DFR), ultafiltration volume were reviewed. We compared survivors and non survivors using Mann Whitney/ Wilcoxon 2 sample test for medians and Fisher exact 2 tailed for association

Results: n = 20. Mean age: 56. 7 + 3.93 years. M:F 17:3, 9 survived, 11 expired. HD sessions=51; CRRT: 4, duration: 29.2 ± 25.4 hours. 47 sessions: Duration: 4.87 ± 1.11 hours, BFR: 195 ± 43 ml/min, DFR: 389 ±99 ml/mn, UF: 437ml/hour. No clotting reported.

Conclusions: AKI needing HD in COVID-19 infection is associated with significant multiorgan injury and high mortality; middle aged male predominate. No significant clinical characteristics were predictive of survival in a sample size

Comparison of survivors and non survivors of COVID-AKI needing HD

	Survivors (n= 9)	Non survivors (n=11)	p value
Age (yrs)	56	55	0.68

PO0686

Circuit Clotting on Continuous Venovenous Hemofiltration in COVID-19 Patients at New England's Largest Health Safety-Net Hospital

Claire Avillach, Megan E. Feeney, Mohamed T. Hassan Kamel, Hassan Mahmoud, Aileen W. Zhen, Natasha Awais, Sandeep Ghai. *Boston Medical Center, Boston, MA.*

Background: The pandemic of COVID19 led to a surge in critically ill patients with severe kidney failure requiring continuous renal replacement therapy (CRRT). Primary reports rapidly showed a hypercoagulable state associated with cytokine storm representing a challenge to conduct CRRT. We report our experience to face clotting on continuous venovenous hemofiltration (CVVH) with COVID19 patients.

Methods: We reviewed data on all admitted patients with COVID19 diagnosis and requiring CVVH at Boston Medical Center between March, 15th and May 7th, 2020. The study was approved by the institutional IRB.

Results: Twenty six patients were admitted to ICU with COVID19 disease and developed acute kidney injury requiring CRRT. The majority of patients were males (73%), and mean age was 64.3 (+/ 9.4) years. At dialysis initiation, patients showed marked inflammatory state with a median CRP of 239mg/dl (IQR 123-391.5), fibrinogen 609mg/dl (431-693), d-dimer 4,036 ng/ml (1,777-15,558). CVVH was conducted in predilution mode, with a median therapy rate of 3L/h (2.5-3.1) and a mean blood flow of 280 mL/min. The median cartridge half-life from CVVH initiation was 11.8 hours (3.5-20). Twelve patients (46%) experienced CVVH circuit clotting within the first 24 hours, including 6 patients (23%) with severe recurring clotting. Curative systemic anticoagulation by heparin was used in 12 patients (46%) based on hospital protocol. Its use was associated with mild improvement in cartridge half-life: 15h with curative heparin dosing compare to 11.25h with no/ low dose preventive anticoagulation (non-significant). Of note, heparin was held prior to CRRT initiation for dialysis catheter placement and was reinitiated without bolus, which could lead to early coagulation of the filter in patients with hypercoagulable state. The fatality rate was 76.9% with a median time from CVVH initiation to death of 2.5 days (1 - 8.75).

Conclusions: Conducting CRRT in patients with multiorgan failure secondary to COVID19 is challenging. Our experience suggests only a mild non significant improvement of clotting prevention with heparin anticoagulation at the time of cvvh initiation. Further studies are warrantied to determine the optimal anticoagulation regimen.

PO0687

Clinical Characteristics and Short-Term Outcomes of Severe AKI in COVID-19 in Bronx, New York

Milagros Yunes,[1] Emad Alahiri,[1] Ryan Mocerino,[1] Kalyan Prudhvi,[1] Ladan Golestaneh,[1,2] Molly Fisher.[1,2] *[1]Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: After the first reported case of COVID-19 in the U.S., New York City quickly became the epicenter of the pandemic. AKI has been reported in patients with severe COVID-19. The Bronx consists of a predominantly minority population with a high burden of comorbidities that may be at increased risk for AKI in the setting of COVID-19. We aimed to characterize risk factors and short term outcomes in patients hospitalized with COVID-19 and severe AKI.

Methods: We performed a retrospective study of 113 adults hospitalized with COVID-19 in a large healthcare system in the Bronx who required nephrology consultation for AKI from March 11-March 30, 2020. We extracted data on demographics, comorbidities, admission vital signs and labs, need for mechanical ventilation, renal replacement therapy (RRT), in-hospital death and discharge. AKI was defined by KDIGO criteria. Chi-square analyses and Wilcoxon tests were used. Data was censored on April 12, 2020. All patients had ≥ 14 days of follow up.

Results: Mean age was 63 (SD 12) years old; 69% were men and 33% were Black and 23% were Hispanic. Forty-five patients (39.8%) had chronic kidney disease, 58(51%) had diabetes mellitus and 87(77%) had hypertension. The majority presented with AKI within 24 hours of admission and 75% had Stage 3 AKI. Ninety-two (81%) patients had proteinuria and 53(47%) had hematuria. Intensive care unit (ICU) was required in 62(55%), 64(57%) required mechanical ventilation, 56(49.5%) required RRT and 18(16%) were not candidates for RRT. In-hospital death occurred in 68(60%) and 22% were discharged. Of those who required RRT, in-hospital death occurred in 35(62.5%) and only 6 patients were discharged, 5 of whom remained RRT dependent. Heavy proteinuria (3-4+ on urinalysis) and initial C-reactive protein (CRP) were higher in those with AKI who died [21.1 (IQR 14.3-29.6) versus 6.6 (3.2-16.3), p<0.001].

Conclusions: Severe AKI in the setting of COVID-19 is associated with increased utilization of ICU, mechanical ventilation, and RRT. Outcomes are poor in those with Stage 3 AKI, underscoring the need for palliative care involvement and early goals of care discussions. Elevated initial CRP and heavy proteinuria may be useful to risk stratify patients with COVID-19 and severe AKI at increased risk for mortality.

PO0688

Clinical Factors Associated with AKI in Patients with COVID-19 from a University Hospital in Brazil

Daniela M. Chiloff,[1] Isabela S. Maltoni,[1] Felipe F. Sanches,[1] Mariana R. Coletti,[1] Caio C. Delfino,[1] Isabela G. Almeida,[1] Letícia C. Albeny,[1] Gabriel N. Araujo,[2] Renata G. Roizman,[1] Giovanna M. Zavadzki,[1] Miguel Angelo Goes.[1] *[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]Unisa, São Paulo, Brazil.*

Background: Critically ill patients with COVID-19 frequently presents Acute kidney Injury (AKI) associated with increased mortality. However, there is paucity of data from Brazil. So, we analyzed factors in associated with AKI patients in a university hospital.

Methods: We conducted an observation with frequencies and association with binary logistic regression study in patients with COVID-19 hospitalized at Hospital Sao Paulo-Federal University of Sao Paulo. Diagnosis and classification of acute kidney injury (AKI) were by KDIGO. We examined the rates of renal function, mechanical ventilation (MV), renal replacement therapy (RRT), medications and in-hospital mortality.

Results: We observed a total of 172 in-patients with COVID-19. Patients were predominantly male (61,5%). We observed hypertension in 55%, diabetes 34%, smokers 27%, obesity (19%). Eighty-nine (52%) patients needed intensive care unit (ICU)], 70 (79%) cases of AKI were in ICU (31% of general ward admissions; p<0,001). In the ICU there were 78% needed mechanical ventilation, 36% in RRT, amine vasoactive 65% and mortality in 48%. AKI patients were older (61±15, 55±15; p=0.01), higher creatinine in admission (2.6±1.6, 1.3±0.7; p=002), higher RDW (14.7±1.5, 13.3±1.6; p=0.08), needed of MV (88%) and vasoactive amine (90%), RRT (88%) and higher mortality (87%). We used serum creatinine, age, RDW, mechanical ventilation and vasoactive amine in model of regression. We observed that MV (OR 1026 [CI95%, 1009-1038; p<0.001) and age (OR 1030 [CI95%, 1004-1056; p=0.002) were independently associated with AKI.

Conclusions: AKI is associated with high rates of RRT and death. Higher age and need of mechanical ventilation were associated with AKI in COVID-19 patients.

PO0689

Community and Hospital-Acquired AKI in COVID-19

Armando Jezael Martinez-Rueda, Juan M. Mejia, Mauricio Arvizu-Hernandez, Rigoberto D. Alvarez, Nathan Berman, Jorge Gaytan, Rossa A. Méndez, Dheni Fernandez, Areli A. Flores Camargo, Ricardo Correa-Rotter, Olynka Vega. *Department of Nephrology and Mineral Metabolism, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, Tlalpan, Mexico.*

Background: AKI is a frequent complication of COVID-19. We describe characteristics of patients with COVID-19 who developed both, community-acquired AKI (CA-AKI) and hospital-acquired AKI (HA-AKI) in a Mexico City reference COVID-19 center.

Methods: We included data from all consecutive patients hospitalized between March 16th - May 29th 2020, with pneumonia and positive SARS-CoV-2 by RT-PCR test. Only data from patients who finished follow-up (n=636) was analyzed. AKI was defined according to KDIGO and ESKD patients (n=6) were excluded. Clinical and demographic characteristics of those with CA-AKI, HA-AKI, and non-AKI were compared by non-parametric ANOVA.

Results: Of 630 COVID-19, AKI was detected in 164 (26%), 81 (49%) CA-AKI, and 83 (51%) HA-AKI. Among AKI, 84 (51%) were Stage 1, 38 (23%) Stage 2, and 42 (26%) Stage 3. Stage 3 was more frequently observed in HA-AKI (p<0.001). RRT was provided to 15 (9.1%) at a median 3 days from diagnosis. Fluid overload was the main indication for RRT initiation. In general, AKI was associated with higher severity of COVID-19 evidenced by several risk scores, ICU admission, mechanical ventilation, and vasopressor therapy. Recovery from AKI was more frequent in the CA-AKI group 66% vs 44 % (p<0.001), and often associated to volume depletion reverted with fluid management. Among patients with AKI, 92 (56%) died, 49% in the CA-AKI vs. 63% in the HA-AKI group (p<0.001). There were no differences in RAAS inhibitor use between groups.

Conclusions: CA-AKI and HA-AKI are frequent renal manifestations in COVID-19. AKI is associated with more severe COVID-19 and significantly higher mortality. Although more comorbidities were present in CA-AKI, outcomes were better for CA-AKI vs. HA-AKI, in spite the latter group being younger, as it represents ICU patients with severe COVID-19 disease and associated multiorgan failure.

Table 1. Characteristics and In-hospital outcomes for CA-AKI versus HA-AKI.

	Non-AKI (N=466)	CA-AKI (N=83)	HA-AKI (N=81)	*P* value
Age (yr), median (IQR)	51 (41-61)	61 (47-68)	51 (45-62)	<0.001
Male, n (%)	292 (63)	59 (71)	57 (70)	0.176
Comorbidities, n (%)				
Diabetes mellitus	116 (25)	33 (40)	28 (35)	0.008
Hypertension	117 (25)	37 (45)	24 (30)	<0.001
Chronic kidney disease	13 (3)	12 (15)	6 (7)	<0.001
BMI (kg/m²), median (IQR)	29.1 (26.4-31.8)	29.6 (25.9-33.3)	29.4 (27.2-32.9)	0.293
C-reactive protein (mg/dL)	13.1 (5.5-20.1)	18.8 (13.7-28.2)	20.0 (13.3-28.1)	<0.001
CPK (mg/dL)	97 (55-207)	120 (69-273)	180 (96-386)	<0.001
LDH (mg/dL)	348 (265-455)	477 (342-624)	468 (368-585)	<0.001
D-Dimer (ng/mL)	703 (426-1158)	978 (549-2042)	825 (566-1712)	<0.001
Days admission to AKI, median (IQR)	-	-	3 (2 -6)	<0.001
Renal replacement therapy, n (%)	-	2 (3)	13 (16)	<0.001
SLED	-	-	11 (85)	
CRRT	-	1 (50)	2 (15)	
IHD	-	1 (50)	-	
Need for ICU admission, n (%)	122 (26)	49 (59)	74 (91)	<0.001
Mechanical ventilation, n (%)	38 (8)	12 (15)	68 (84)	<0.001
Vasopressor, n (%)	37 (8)	9 (11)	64 (79)	<0.001
ICU length of stay (d), median (IQR)	3 (1-9)	3 (1-6)	11 (5-20)	<0.001

Mortality, n (%)	92 (20)	41 (49)	51 (63)	<0.001

PO0690

Is AKI in COVID-19 Patients Associated with Increased Mortality?

Vasantha M. Muthuppalaniappan, Jennifer Ng, Phoebe Sharratt, Kristi Sun, Mark Harber. *Whittington Hospital, London, United Kingdom.*

Background: Acute kidney injury(AKI) affects 22% of hospitalised patients and is associated with a 21.9% increased risk of mortality in non COVID-19 admissions. Based on reports from China the rate of AKI in patients hospitalised with COVID-19 is 3-9%. The study's objective was to identify AKI prevalence in COVID-19 patients and associated adverse outcomes.

Methods: This is a retrospective observational cohort study of patients admitted to hospital with positive COVID-19 PCR testing from 14th February to 7th May 2020. Demographic data, past medical history and blood results were obtained from health records. AKI was defined according to KDIGO criteria.

Results: 383 patients (220 Male) were included in the final analysis, with an age range of 18-99 yrs(median 69 yrs). AKI occurred in 153(39.9%) patients (103 male), with a median age of 74 years. 111(72.5%) patients had AKI on admission, 42(27.5%) developed AKI while hospitalised. Average clinical frailty score (CFS) in the AKI group was 4. Median creatinine kinase in the AKI group was 213iu/L(IQR 149-1260). Of all 153 AKI patients;100(65.4%) were in Stage 1, 29(19%) in Stage 2 and 24(15.7%) in Stage 3. 14(9.2%) patients required renal replacement therapy (RRT) with 7(50%) becoming dialysis independent. 3 patients died and 4 transferred to specialist units for treatment whilst on RRT. Mean peak serum creatinine of 246umol/L was observed on Day 5 of admission and Day 11 of symptoms on average. 90/153(58.5%) patients had recovery of renal function. 40/76(53%) patients who required CPAP or mechanical ventilation respiratory support had evidence of AKI compared to 113/304(37%) of non-ventilated patients. Of all 153 AKI patients, 61(39%) deaths occurred compared to 43/228(19%) in the non-AKI group. This difference was significant, p<0.01, OR= 2.89 (95% CI: 1.81, 4.58) suggesting that patients with AKI had a 74% chance of increased death. Univariate analysis showed that age, males, baseline eGFR, albumin, CFS and Charlson comorbidity index were predictors of AKI. Multivariate analysis showed that independent predictors of AKI included males, Black and Asian race, baseline eGFR and albumin. An increase in baseline eGFR by 1ml/min in COVID-19 patients was associated with a 2.4% risk reduction in death, p<0.01, OR= 0.976 (95% CI: 1.02, 1.03).

Conclusions: AKI is a common finding and a poor prognosticator in patients with COVID-19.

PO0691

Kidney Injury in ICU Adults with Severe COVID-19

Jing Qian, Li Ni, Mengjing Wang, Weichen Zhang, Kangjie Wang, Li Yuan, Jing Chen. *Huashan Hospital Fudan University, Shanghai, China.*

Background: The SARS-CoV-2 infected humans through the angiotensin converting enzyme (ACE-2) receptor. Kidney, which highly expressed ACE-2, became one of the main target organs attacked by SARS-CoV-2. In this cross-sectional study, we aimed to explore renal injury in ICU adults with severe coronavirus disease 2019 (Covid-19).

Methods: Fifty-three severe Covid-19 adults, admitted into ICU (Tongji Hospital, Wuhan, China) from Feb.9.2020 to Mar.24.2020, were finally included in analysis. Baseline demographic, clinical characteristics, laboratory examination data and prognosis were all recorded.

Results: Mean age of 53 patients was 67.5±15.2 yrs, including 34 men and 19 women. The predominant comorbid conditions were as follows: hypertension in 26 patients (50.0%), diabetes mellitus in 11 patients (21.2%), cardiovascular diseases in 5 patients (9.6%) and chronic kidney disease in 2 patients (3.8%). The mean serum creatinine at baseline was 67.2±26.7 μmol/L, while the baseline urine routine before hospitalization was uninformed. In the period of whole ICU stay, most patients presented abnormal urine routine: 93.2% of patients had proteinuria (+/- 9.1%, 1+ 40.9%, 2+ 31.8% and 3+ 11.4%, respectively) and 97.7% had hematuria. 20 of 53 patients (37.7%) with mean age of 72.2±9.9 yrs diagnosed as hospital-acquired acute kidney injury, according to KDIGO 2012 AKI diagnosis creatinine criteria. In those AKI patients, 5(25%), 7(35.0%) and 8(40%) reached AKI stage I, II and III, respectively. AKI was diagnosed after 25.0±12.8 days since onset of Covid-19 and after 7.8±5.6 days since ICU admission. The mean duration of AKI course was 7.9±7.1 days. Finally, 16 of 20 patients with AKI (80.0%) died in ICU. The survival time of AKI patients was 32.9±14.6 days since onset of Covid-19 and 15.7±9.4 days since ICU admission. The in-hospital all-cause mortality of AKI patients was higher than non-AKI patients (80.0% vs 29.4%, *p*=0.004). Only one (5.0%) patient recovered from AKI during ICU stay (serum creatinine reduced ≥50%).

Conclusions: Kidney injury including abnormal urine routine and increased serum creatinine presented in almost all severe Covid-19 patients. AKI event could predict poor prognosis with severe Covid-19. We should increase awareness of kidney injury in patients with severe COVID-19.

PO0692

Association of Antiplatelet and Anticoagulation Therapy with Dialysis-Requiring AKI in Critically Ill Patients with COVID-19

Andrew A. Moses, Amer Assal, Paul Asadourian, Anson G. Bautista, Rebekah Boyd, Lyle Dershowitz, Aaron Gans, Catherine Ha, Hannah L. Mcmullen, Mary Nattakom, Olivia D. Perez, Connor Stonesifer, William S. Stringer, Yuqing Xiong, Shayan Shirazian. *Columbia University Irving Medical Center, New York, NY.*

Background: Critically ill patients with COVID-19 have a high incidence of thrombotic complications and dialysis-requiring acute kidney injury (AKI-D). COVID-19 hypercoagulability has been implicated as a possible contributor to AKI-D. Our hypothesis is that pre-existing antiplatelet (APT) or anticoagulation therapy (ACT) is associated with a lower incidence of AKI-D in critically ill patients with COVID-19.

Methods: Records of patients with COVID-19 admitted to the ICU from March 13th -April 1st 2020 were reviewed. Exclusion criteria included ESRD status, and ICU discharge or death prior to 14 days of follow-up. Groups were divided based on APT or ACT prior to ICU admission. AKI-D was defined as initiation of renal replacement therapy (RRT) of any kind during the 14 days. Groups were compared using 2-tailed Fisher's exact test and unpaired t tests.

Results: A total of 149 records were reviewed, and 98 patients were included (47 died and 4 discharged). Twenty-three patients (23.5%) were on APT or ACT and 39 (40%) required RRT. Table 1 compares characteristics by study group. Hypertension and cardiac conditions were significantly different between groups. Twelve (52%) of patients on APT or ACT required RRT and 27 (36%) not on either required RRT (p=0.22).

Conclusions: Pre-existing APT or ACT was not associated with AKI-D in critically ill patients with COVID-19 and 2 weeks of follow up. Our study confirmed a high incidence of AKI-D but was limited by significant differences in cardiac conditions between study groups. Future larger studies examining this association in groups with comparable cardiac conditions are needed.

Table 1: Demographic and Clinical Characteristics

Characteristic	On AP or AC (n=23)	Off AP or AC (n=75)
Age, mean (SD), years	62 (12)	58 (13)
Males, n (%)	12 (52%)	50 (67%)
Cr, mean (SD), mg/dL	1.8 (1.4)	1.6 (1.9)
Diabetes, n (%)	10 (43%)	23 (31%)
Hypertension, n (%)	17 (74%)	38 (50%)*
Cardiac condition	16 (70%)	4 (5%)**
Lung condition	3 (13%)	13 (17%)
BMI, mean (SD), kg/m^2	35 (12)	31 (8)
RRT requiring AKI, n (%)	12 (52%)	27 (36%)

AP, antiplatelet; AC, anticoagulation; Cr, admission creatinine; Cardiac condition = coronary artery disease, congestive heart failure and/or atrial fibrillation; Lung condition = chronic obstructive pulmonary disease or asthma; RRT, renal replacement therapy; AKI, acute kidney injury; * = p-value = 0.06; ** = *p*-value <0.01

PO0693

COVID-Related AKI Recovery Courses with Negative Fluid Balance and Related Electrolyte Disorders

Ana Gabriela J. T. Melo, Rayra G. Ribeiro, Géssica S. Braga Barbosa, Daniela Via Reque Cortes, Carla P. Sandoval Cabrera, Camila E. Rodrigues. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil*.

Background: Acute Kidney Injury (AKI) occurs in 3-37% of COVID patients; recovery is poorly described.

Methods: All patients who recovered from AKI in Clinics Hospital (São Paulo, Brazil) during April 2020 (COVID related-AKI (COV+), n=35) and September 2019 (COVID unrelated-AKI (COV-), n=25) were studied for 1.5 month each. Recovery was represented by spontaneous serum creatinine (sCr) drop in patients not submitted to dialysis, or by withdrawal of dialysis in those who needed the therapy. Serum creatinine, urea (sU), sodium (sNa), bicarbonate (bic), and fluid balance (FB) were analyzed during the first five days of recovery (5-Dr). Data are expressed in mean ± SD. Repeated mesaures ANOVA was used to compare different days on each parameter, and t test was used to compare groups. Categorical data were analyzed using Fisher's test.

Results: Among 88 COV- patients, 25 recovered from AKI, while 35 in 102 COV+ patients recovered during the time studied (86% COV+ were in KDIGO 3 classification). In COV+ group, COVID-AKI time was predictive of AKI duration: earlier AKI (≤ 7 days from COVID symptoms) lasted 5.6 ± 4.0 days (vs 11.9 ± 9.2 days in later AKI presentation, p< 0.05). Both COV+ and COV- patients coursed with sCr and sU drop during 5-Dr, except for diuretic users, who presented sCr drop without sU drop. COV+ patients presented negative overall FB during 5-Dr, while COV- patients presented positive FB (-516.2 ± 2730 vs 225.5 ± 5686 ml/24h). In COV+, sNa rose through 5-Dr (p< 0.05), and in COV- it did not. Among diuretic users, the same patern of FB was seen between groups (-194.9 ± 3163 in COV+ vs 163.5 ± 1080 ml/24h in COV-), and COV+ showed increased sNa through 5-Dr (p< 0.05), while COV- reduced sNa through 5-Dr (p< 0.05). Diuretic users had bicarbonate increase in COV+ (from 24.3 ± 3.6 to 27.0 ± 4.9 mmol/L, p<0.05), but not in COV-. In diuretic non-users, both groups have risen sNa through 5-Dr, but only COV+ reached statistical significance. Diuretic use at AKI-recovery was higher in COV+ patients (57% vs 28%, p< 0.05).

Conclusions: Later-onset COVID-related AKI seems to be more prolonged. Diuretics should be carefully used in AKI-recovering COV+ patients, once hypernatremia and metabolic alcalosis are more common than in other AKI etiologies.

PO0694

CRRT Circuit Patency in Patients with COVID-19 and AKI

Salma Shaikhouni, Ryann Sohaney, John T. Ludwig, Anca Tilea, Markus Bitzer, Lenar T. Yessayan, Michael Heung. *University of Michigan, Ann Arbor, MI*.

Background: COVID-19 is associated with AKI and hypercoagulable state, which may present challenges in delivering CRRT. We present our center's experience with CVVHDF with regional citrate anticoagulation (RCA) in COVID-19, with special attention to circuit life.

Methods: We performed a retrospective review of 32 consecutive patients with COVID-19 and AKI managed with CVVHDF-RCA at the University of Michigan. CVVHDF was prescribed according to institutional protocol consisting of a fixed blood flow to citrate ratio with target post-filter ionized calcium 0.2-0.4mmol/L. Replacement fluid was delivered post-filter. Primary outcome was mean circuit life per patient during the first 7 days of CRRT. We used Wilcoxon rank sum to examine whether systemic anticoagulation use associated with circuit life. We used univariate linear regression to assess the relationship between baseline inflammatory markers and circuit life.

Results: Prior to CRRT start, the median ferritin was 1587 (IQR 933-2219) ng/ml, d-dimer 6.0 (IQR 3.0-9.5) mg/ml and CRP 20.0 (IQR 8.6-33.0) mg/dl. The mean patient circuit life was 56.9 (SD 28.8) hours. Mean circuit life was 54.3 (SD 23.1) hours for those on systemic anticoagulation (n=23) and 63.6 (SD 29.1) hours for those without (n=9), p=0.39. There was no association between circuit life and inflammatory makers (ferritin p=0.92, CRP p=0.29, d-dimer p=0.24).

Conclusions: The circuit life in COVID-19 patients on CVVHDF-RCA at our institution was similar to our experience with non-COVID-19 patients, and longer than what has been reported in randomized controlled trials assessing anticoagulation protocols in CRRT. We found no association between systemic anticoagulation use or inflammatory markers and circuit life, further supporting that a standardized CVVHDF-RCA protocol with fixed blood flow to citrate rate provides an effective means of maintaining CRRT circuit patency in patients with COVID-19 infection at increased risk of clotting.

PO0695

Filter Clotting, Anticoagulation, and Duration of Sustained Low-Efficiency Dialysis in Patients with COVID-19 and AKI

Yuang Wen,[1] Jason R. Ledoux,[1] Akanksh Ramanand,[1,2] Kevin Scharwath,[1] Destiney A. Mundy,[1] Muner Mohamed,[1] Ivo Lukitsch,[1] Juan Carlos Q. Velez.[1] Ochsner Nephrology [1]*Department of Nephrology, Ochsner Health System, New Orleans, LA;* [2]*Ochsner Clinical School- The University of Queensland, New Orleans, LA.*

Background: There have been anecdotal accounts of shortened duration of renal replacement therapy (RRT) due to filter clotting in patients with COVID-19 and acute kidney injury (AKI) (CoV-AKI) requiring RRT (AKI-RRT). Thus, we examined the duration of runs of RRT in patients with CoV-AKI as well as in patients with AKI-RRT in the pre-COVID-19 era.

Methods: Among 161 patients with CoV-AKI, we identified patients with CoV-AKI who underwent RRT by sustained low efficiency dialysis (SLED) for ≥ 2 days (n = 52) (March-April 2020). As a control, we included patients with AKI without COVID-19 diagnosis who underwent SLED (n = 24) (non-CoV-AKI) in December of 2019, pre-COVID-19 era. We quantified the duration of RRT under various protocols of anticoagulation (AC) [no AC, citrate (CIT), regional heparin (rH), minimally intensive heparin (mIH), systemic low intensity heparin (sLH), systemic high intensity heparin (sHH) and sHH plus CIT (sHH+CIT)] by computing the duration (hours) of each SLED session (hrs of SLED/start) and the percentage of short SLED runs (< 6 hours).

Results: In CoV-AKI, the median hrs of SLED/start under each AC protocol were 6.1 for no AC, 5.4 for CIT, 10.6 for rH, 11.6 for mIH, 11.4 for sLH, 12.4 for sHH and 14.6 for sHH+CIT. As the AC intensified, the duration of SLED increased (chi-square for trend, p = 0.014). Pre-COVID-19, standard AC for non-CoV-AKI were no AC or CIT and had a longer median RRT duration compared to CoV-AKI under either no AC or CIT (10.2 vs 5.5 hrs of SLED/start, for non-CoV-AKI vs CoV-AKI, respectively, p = 0.021). Similarly, the proportion of patients with short runs was greater in CoV-AKI (under no AC or CIT) vs non-CoV-AKI (55% vs 19%, p = 0.01). When comparing the 3 more aggressive AC protocols (sLH, sHH and sHH+CIT) in CoV-AKI with non-CoV-AKI, the duration of RRT was similar (12.2 vs 10.2 hrs of SLED/start, p = 0.11) and the percentage of short SLED runs were also similar (10% vs 19%, p = 0.25).

Conclusions: RRT in CoV-AKI was associated with shorter duration of SLED compared to non-CoV-AKI, likely driven by increased filter and/or catheter clotting. Aggressive AC protocols with sHH with or without CIT in CoV-AKI were successful in restoring the duration of RRT back to that observed in patients with AKI-RRT in the pre-COVID-19 era.

PO0696

Impact of Renal Replacement Therapy Modality on Prognosis of SARS-CoV2 Infection

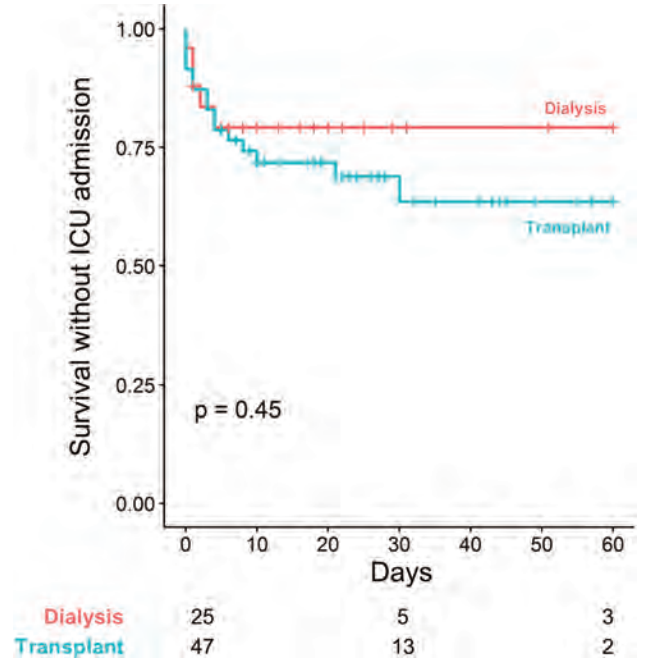
Yannis Lombardi,[1,2] Hafedh Fessi,[1,2] Hélène François,[1,2] Pierre A. Michel,[1,2] Camille Petit-Hoang,[1,2] Eric Rondeau.[1,2] *[1]Hopital Tenon, Paris, France; [2]Sorbonne Universite, Paris, France.*

Background: Prognosis of SARS-CoV2 infection among patients with Chronic Kidney Disease (CKD) is poorly known. In particular, the impact of renal replacement therapy (RRT) modality on prognosis is undetermined. Patients with kidney transplant exhibit treatment-induced immunodepression, while patients on dialysis are usually older and exhibit higher frailty. We aim to determine the impact of RRT modality on the prognosis of SARS-CoV2 infection among patient with advanced CKD.

Methods: We conducted a retrospective cohort study using our institution's Clinical Data Warehouse. Health records of all patients with at least one hozpitalization or consultation in our nephrology department were screened based on ICD-10 codes. Inclusion criteria were: hospitalization in any of our institution's hospitals for SARS-CoV2 infection (national Public Health agency criteria). Patients were divided into two groups: «active kidney transplant» and «dialysis». A Cox model stratifying on age and medical history of coronary artery disease was used to determine adjusted Hazard Ratio (HR) for death or intensive care unit (ICU) admission.

Results: We included 72 patients: 47 in the «transplant» group and 25 in the «dialysis» group. First hospitalization was on 20/02/28 and last hospitalization on 20/05/19. Median follow-up was 21.5 days. Death or ICU admission occurred in 21 (29%) patients («transplant» group: 15 (32%), «dialysis» group: 6 (24%), p=0.45). In multivariate analysis, adjusted HR for death or ICU admission was 1.70 [95%CI:0.59–4.86] for transplant vs. dialysis (p=0.32).

Conclusions: In our study, among patients hospitalized for SARS-CoV2 infection, no significant difference in risk for ICU hospitalization or death was found between CKD patients on dialysis or with active kidney transplant. A trend for higher risk was noted among patients with active kidney transplant. Further studies are required to confirm those findings.



PO0697

Lower Continuous Venovenous Hemodialysis Replacement Rate and Its Effect on Patient Outcome in the COVID Crisis Time

John K. Guirguis, Priya Yenebere, S. J. Sher, Katherine J. Kelly. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Acute kidney injury (AKI) is a common problem encountered in COVID positive patients with incidence close to 23% and mortality close to 60% in this cohort of patients. Continuous Veno-Venous Hemodialysis (CVVH) plays a primary role in management of these patients. Nephrologists nationwide have been facing a compelling supply/demand mismatch dilemma. Lowering the rate of replacement fluid flow rate (RFFR) is one strategy that was used by our practice to mitigate this issue in selected patients. We hypothesize there is no difference in clinical outcome between the patients receiving high RFFR vs low RFFR.

Methods: This is a retrospective observational study from a single center experience. We analyzed data from March 2020 till the end of May 2020. We included patients with confirmed coronavirus disease 2019 (COVID-19) who required CVVH during their hospitalization. Patients were divided into two groups i.e Group 1 (> 20ml/kg/hr RFFR) vs Group 2 (< 20ml/kg/hr RFFR). Patients 18 years or older with at least 3 days of CVVH during their hospital stay were included. We compared percentage drop of blood urea nitrogen (BUN) and phosphorus as well as hospital stay and mortality between the 2 groups. We used ANOVA, t-test and Chi square for analysis, as appropriate.

Results: We enrolled 36 patients in the study, 20 in group 1 and 16 in group 2. Eighty percent of the patients enrolled were men. Mean weight was 100 ± 8kg in group 1 vs 107 ± 8 in group 2. There was no statistically significant difference in percentage reduction of blood urea nitrogen (BUN) or phosphorus (Po4) *P*= 0.2& 0.5 respectively (Means 25.4 vs 21.7 & 18.4 vs 17.1). Mean filtration fraction was similar between the two groups (17.9% vs 17%). Frequency of line clotting events was compared in the two groups using Chi square with *P* value 0.8. Mortality was not significantly different between groups, although it was actually lower in the groups treated with the lower RFFR.

Conclusions: Although our data analysis is still evolving, we found no difference in mortality, toxin clearance and frequency of line clotting between the two studied groups. No randomized control trial has assessed using a lower than 20ml/kg/hr RFFR in CVVH. Our study, thus far, showed no difference between the two groups. This finding needs to be further validated in a randomized control study.

PO0698

Low-Molecular-Weight Heparin Is a Superior Anticoagulant to Unfractionated Heparin for Renal Replacement Therapy in Patients with AKI due to Coronavirus Disease 2019

Neeharik Mareedu, Benjamin German, Casey N. Gashti, Payal K. Gurnani, Roger A. Rodby, William L. Whittier. *Rush University Medical Center, Chicago, IL.*

Background: Severe coronavirus disease 2019 (COVID-19) not only causes acute pulmonary pathology leading to acute respiratory distress syndrome needing intubation, but also leads to acute kidney injury (AKI) requiring renal replacement therapy (RRT). Due to hemodynamic instability, these patients (pts) often need either continuous RRT (CRRT) or prolonged intermittent RRT (PIRRT). Accelerated Veno-Venous Hemodialysis (AVVHD), a form of PIRRT with typically 40-50 liter of dialysate used over 8-10 hours has been successfully used to treat hemodynamically unstable pts. In the past, we have published extracorporeal circuit clotting (ECC) to be low (5%) even without anticoagulation. However as hypercoagulability is extreme with COVID-19, we noticed a marked increase in ECC. Unfractionated heparin (UFH) was the initial anticoagulation of choice during the early phase of the pandemic but was ineffective in preventing ECC, prompting a trial of low molecular weight heparin (LMWH).

Methods: We conducted a single-center retrospective study to evaluate the efficacy and safety of LMWH vs UFH in preventing ECC in pts with AKI due to COVID-19 who received AVVHD from 3/25/20 through 4/30/20 at a large academic medical center. Data collected included pt demographics, type of anticoagulation and thrombolytic use, treatment characteristics including clotting frequency as well as bleeding complications. ECC was defined as any event that required an unexpected interruption in treatment or the use of thrombolytics.

Results: A total of 58 pts received 408 AVVHD treatments. The average pt age was 58 years, 65% were male, 66% were black and 69% were obese with body mass index >30 kg/m^2. 188/408 (46%) of AVVHD treatments received anticoagulation with UFH while 165/408 (40%) of treatments received LMWH. ECC occurred in 30% of AVVHD treatments who received UFH vs 15% in the LMWH group, a relative risk reduction of 50% (P = 0.001). 47.1% pts who were on UFH had ECC on the first RRT treatment compared to 13.6% on LMWH (P = 0.01). Only 1 pt experienced a major bleeding event in the UFH group and none with LMWH.

Conclusions: Anticoagulation with LMWH is superior to UFH in reducing ECC in pts receiving AVVHD for AKI due to COVID-19 without an increased risk of bleeding.

PO0699

Markers of Inflammation and Risk for AKI and Need for Dialysis in Patients with COVID-19

Aldo E. Torres Ortiz,[1] Joseph B. Walker,[2] Alaa E. Mohammed,[3] Muner Mohamed,[1] Ivo Lukitsch,[1] Juan Carlos Q. Velez.[1] Ochsner Nephrology *[1]Department of Nephrology, Ochsner Health System, New Orleans, LA; [2]Ochsner Clinical School, The University of Queensland, New Orleans, LA; [3]Department of Research, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Acute kidney injury (AKI) is a reported manifestation of COVID-19 (CoV-AKI). Release of inflammatory cytokines has been recognized as a characteristic feature of COVID-19 and is linked to severity of illness. However, it has not been clearly determined if levels of serum markers of inflammation are associated with risk for development of AKI or its severity.

Methods: We conducted an observational study in patients hospitalized at Ochsner Medical Center over 1-month period with COVID-19 and diagnosis of AKI. We examined the relationship between the blood level of ferritin, C-reactive protein (CRP), procalcitonin (proCal), D-dimer and lactate dehydrogenase (LDH) and the incidence of AKI, as well as AKI requiring renal replacement therapy (AKI-RRT), by assessing comparison of means and proportions and by logistic regression analysis.

Results: Among 644 patients with COVID-19, we compared 161 (26%) with AKI vs 414 (64%) without AKI. Median serum creatinine on admission was higher in the AKI group (1.8 vs 1.1 mg/dL, p<0.0001). Preexisting chronic kidney disease rates were comparable (35% vs 28%, for AKI and no AKI groups). The median value of inflammatory markers on admission were higher in the AKI group [ferritin 1016 (516-2534) vs 680 (315-1416) ng/mL, p<0.0001; CRP 163 (93-243) vs 93 (46-165) mg/L, p<0.0001; proCal 0.37 (0.2-1.6) vs 0.12 (0.06-0.32) ng/mL, p<0.0001; D-dimer 1.57 (0.96-5.14) vs 1.13

(0.68-2.57) mcg/mL, p=0.0004; and LDH 532 (365-804) vs 428 (309-548), p=0.0004]. On multivariate logistic regression analysis, CRP (p=0.003) and ferritin (p<0.035) were associated with greater risk for AKI. In addition, ferritin ≥ 1200 ng/mL and CRP ≥ 300 mg/L were independently associated with AKI [adjusted odds ratio: 2.3 (1.3-4), p=0.003, and 2.5 (1.0-6.3), p=0.05; respectively]. Furthermore, ferritin, CRP, proCal and LDH levels were significantly higher in those with AKI-RRT compared to those not requiring RRT (p=0.022 to p=0.009).

Conclusions: Higher level of inflammatory markers were associated with CoV-AKI, and levels were even higher for those with CoV-AKI-RRT. In patients with COVID-19, magnitude of ferritin and CRP on admission could be used for AKI risk stratification.

PO0700

Morbid Obesity, Hypertension, and Male Sex Are Associated with Greater Risk for AKI in Patients with COVID-19

Ivo Lukitsch,[1] Aldo E. Torres Ortiz,[1] Alaa E. Mohammed,[3] Joseph B. Walker,[2] Muner Mohamed,[1] Juan Carlos Q. Velez.[1] Ochsner Nephrology *[1]Department of Nephrology, Ochsner Health System, New Orleans, LA; [2]Ochsner Clinical School, The University of Queensland, New Orleans, LA; [3]Department of Research, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Acute kidney injury (AKI) is a reported manifestation of COVID-19 (CoV-AKI). However, there is paucity of data regarding risk factors for CoV-AKI. We examined the association of demographics and comorbidities with CoV-AKI risk and its severity at an academic hospital in New Orleans.

Methods: We conducted an observational study in patients hospitalized at Ochsner Medical Center over 1-month period with COVID-19 and diagnosis of AKI. We assessed the relationship between baseline demographic and clinical characteristics and the incidence of AKI, as well as AKI requiring renal replacement therapy (AKI-RRT), by assessing comparison of means and proportions and by logistic regression analysis.

Results: Among 644 patients with COVID-19, we compared 161 (26%) with AKI vs 414 (64%) without AKI. Male sex (62% vs 51%, p=0.02) and essential hypertension (HTN) (83% vs 70%, p=0.002) were more common in the AKI group. Median body mass index (BMI) was higher among those with AKI (34 vs 31 kg/m^2, p<0.0001). No difference was found in age, race, presence of diabetes, chronic kidney disease or heart disease respect to AKI rate. On multivariate logistic regression analysis, HTN was strongly associated with greater risk for AKI [OR 1.96 (CI 1.2-3.2), p=0.009]. Male sex [OR 1.72 (CI 1.1-1.9), p=0.005] and higher BMI [OR 1.04 (CI 1.02-1.07), p<0.001] were also associated with AKI. RRT was required in 89 (55%) of the patients with AKI. Those with AKI requiring RRT (AKI-RRT) had higher median BMI (35 vs 33 kg/m^2, p=0.048) and younger age (61 vs. 68, p=0.0003) compared to those with AKI not requiring RRT. Of note, higher BMI correlated with younger age (R=-0.53, p<0.0001).

Conclusions: HTN, male sex and higher BMI were associated with greater incidence of AKI in patients hospitalized with COVID-19. Higher BMI was further associated with AKI-RRT. Hypertensive, male and obese patients are at higher risk for CoV-AKI and should be more closely monitored during the COVID-19 pandemic.

PO0701

Mortality of AKI in Human Immunodeficiency Virus with and Without Co-Infection with COVID-19

Jie Ouyang,[1,2] Siddhartha D. Bajracharya,[1,2] Ernie Yap,[1,2] Mary C. Mallappallil.[1,2] *[1]Kings County Hospital Center, Brooklyn, NY; [2]SUNY Downstate Medical Center College of Medicine, Brooklyn, NY.*

Background: Since the start of COVID-19 pandemic, concerns have been raised about specific populations being at potential higher risk for developing more severe diseases, and patients living with HIV (PLWH) are among them. SARS-CoV-2, a newly isolated virus from the Corona Virus family, is enveloped, positive-sense single-stranded RNA virus that causes multi-organ failure, especially acute kidney injury (AKI) which is proved to be associated with significantly elevated mortality rate. It dysregulates human immunity especially on T lymphocytes which is shared by HIV as the mechanism of causing related diseases. We reviewed our hospital data to examine if HIV infection resulted in worse outcomes in COVID-19 patients who developed AKI.

Methods: Retrospective chart review of all admitted patients to Kings County Hospital (KCH), a municipal hospital in Brooklyn, New York City between 3/1 to 5/15, 2020, from the electronic medical record. Patients were reviewed in groups of COVID infection without history of HIV, HIV patients admitted without COVID infection and patients with history of HIV who were admitted because of COVID infection. The rate of AKI and mortality were extracted and analyzed suing Chi-squared test in SPSS.

Results: A total of 1092 patients with confirmed COVID-19 diagnosis were admitted in the above time period, out of which 22 were diagnosed with COVID-19 and HIV. In the COIVD-19 without HIV diagnosis group, 450 patients developed AKI and 213 patients died, with a mortality rate of 47.3%; in the COVID-19 with HIV group, 9 patients developed AKI and 4 expired, mortality rate is 44.4%. There's no significant difference between these two groups (p=0.86). Compared to these two groups, 21 out of 93 PLWH without COVID infection had AKI during hospitalization with 2 patients deceased, and a mortality rate of 9.5% which is significantly lower (p=0.03).

Conclusions: Data from our hospital bewtween 3/1 and 5/15/2020 shows the mortality rates of patients with HIV and COVID-19 co-infection with AKI and COVID patients without HIV who developed AKI are not statiscally different, but significantly higher than patients with HIV who developed AKI.

Patients admitted to KCH from 3/1 to 5/152020

	COVID-19 without HIV	COVID-19 with HIV	HIV without COVID-19
Total N (& Mortality %)	1070 (29.6%)	22 (27.3%)	93 (3.2%)
Patients developed AKI (& Mortality %)	450 (47.3%)	9 (44.4%)	21 (9.5%)

PO0702

Phenotype and Outcomes of AKI Associated with COVID-19 in Urban New Orleans

Muner Mohamed,[1] Ivo Lukitsch,[1] Aldo E. Torres Ortiz,[1] Joseph B. Walker,[1] Cesar F. Hernandez-Arroyo,[1] Muhannad Alqudsi,[1] Juan Carlos Q. Velez.[1,2] *[1]Department of Nephrology, Ochsner Health System, New Orleans, LA; [2]Ochsner Clinical School, The University of Queensland, Brisbane, QLD, Australia.*

Background: Acute kidney injury (AKI) is a manifestation of COVID-19 (CoV-AKI). However, there is paucity of data from United States, particularly in a predominantly African American (AA) population. We report the phenotype and outcomes of AKI at an academic hospital in New Orleans.

Methods: We conducted an observational study in patients hospitalized at Ochsner Medical Center over 1-month period with COVID-19 and diagnosis of AKI by KDIGO. We examined the rates of renal replacement therapy (RRT) and in-hospital mortality as outcome measures. Adjudication of cause of AKI was independently performed via manual chart review by 3 study team members.

Results: Of 644 admissions with COVID-19, 69 were excluded due to ESRD or kidney transplant. Thus, 575 patients entered the cohort [173 (28%) to an intensive care unit (ICU)]. Patients were predominantly AA (71%). AKI was diagnosed in 161 patients (28% overall, 61% of ICU admissions), median age 65 (34 – 96), predominantly male (62%) and hypertensive (83%). Median follow up was 25 (1 – 45) days. Vasopressors and/or mechanical ventilation was required in 105 (65%) of them. In-hospital mortality rate for those with AKI was 50% (80/181). *De novo* AKI was diagnosed in 65%, whereas AKI over preexisting chronic kidney disease occurred in 35% of the cohort. Ninety-one (57%) patients arrived with AKI, whereas the remaining 43% acquired AKI during the hospitalization [median hospital day of AKI onset: 4 (2 – 10)]. RRT was required in 89/161 (55%) and 77/105 (73%) patients for all AKI cases and the ICU subset, respectively. The mortality rate for those with AKI-RRT was 72% (64/89). Hemodynamic instability leading to ischemic acute tubular injury (ATI) and rhabdomyolysis accounted for 66% and 7% of the etiology, respectively. Reversible prerenal azotemia occurred in 9%. In 13%, no obvious cause of AKI was identified aside from the COVID-19 diagnosis. Three (1.8%) patients had *de novo* collapsing glomerulopathy.

Conclusions: CoV-AKI is associated with high rates of RRT, ICU care and death. Hemodynamic instability leading to ischemic ATI is the predominant cause of AKI in this setting, but other etiologies contribute to the overall AKI burden.

PO0703

Presentation on Admission and Outcomes in COVID Patients Admitted with AKI

Richard J. Durrance,[1] Payal Ram,[1] Paul Catella,[1] Demetrios Papademetriou,[2] George N. Coritsidis.[1,2] *[1]Icahn School of Medicine at Mount Sinai, Elmhurst Hospital, Elmhurst, NY; [2]Elmhurst Hospital Center Department of Nephrology, Elmhurst, NY.*

Background: COVID-19 infection secondary to the SARS-CoV2 virus was defined by the WHO as a global pandemic. While the disease initially affects the respiratory system, a multi-systemic organ dysfunction of varying degrees has been described. Renal failure has been recognized as a significant part of the pathophysiology. Elmhurst Hospital Center (EHC) was described as the "epicenter of the epicenter" in New York City.

Methods: A retrospective chart review was undertaken of COVID positive adult patients (polymerase chain reaction testing of a nasopharyngeal sample) admitted to EHC from 3/7/20 - 4/7/20. Demographics, clinical characteristics, biomarkers, and outcomes were examined. AKI was determined by the KDIGO definition. Exclusion criteria: <18 years old, pregnant, ESRD, patients expired within first 5 days

Results: The average age was 59 years, 77.95% were Male; 55% had hypertension (HTN), 40% had diabetes (DM). Hispanics made up the most significant portion of the demographic with 62.05%, followed by Asians (24.1%). AKI occurred in 44.1% of patients and was associated with HTN ((p=0.011) but not DM (p=0.289). AKI was associated with an increased use of mechanical ventilation (p<0.001), and increased mortality (p<0.001). Hypertension (p=0.007), older age (p=0.003), and DM (p=0.018) were significantly associated with mortality. Ethinicity was not associated with mortality (p=0.231). Admission CPK did not have a significant association with AKI (0.065) or death (p=0.19).

Conclusions: Both HTN and DM are associated with increased mortality. AKI is significantly associated with increased respiratory failure requiring mechanical ventilation and mortality. Diabetes and admission CPK were not associated with AKI.

Demographics of patients admitted to EHC.

Demographics	n=195				
	Median	Interquartile range			
Age (years)	59	48 - 69

PO0704

Refractoriness of Hyperkalemia and Hyperphosphatemia in Dialysis-Dependent AKI Associated with COVID-19

Akanksh Ramanand,[1] Vipin Varghese,[1] Yuang Wen,[2] Muner Mohamed,[2] Juan Carlos Q. Velez.[1,2] Ochsner Nephrology *[1]Ochsner Clinical School- The University of Queensland, New Orleans, LA; [2]Department of Nephrology, Ochsner Health System, New Orleans, LA.*

Background: There have been anecdotal accounts of an unusual incidence of persistent hyperkalemia (hyperK) and hyperphosphatemia (hyperP) in patients with COVID-19 and acute kidney injury (AKI) (CoV-AKI) despite renal replacement therapy (RRT). However, an observation bias could not be discarded. Thus, we examined the rate and severity of hyperK and hyperP in patients with CoV-AKI actively treated with RRT.

Methods: Among 161 patients with CoV-AKI, we selected those who underwent RRT by sustained low efficiency dialysis (SLED) for ≥2 days (n=64). A database of patients with AKI on SLED who underwent urinary sediment microscopy (Sedi-AKI cohort, 2017-2019, n=60) served as control (non-CoV-AKI). We examined the rate of hyperK [serum potassium (sK) ≥ 5.5 mEq/L], severe hyperK [sK ≥ 6.5 mEq/L], hyperP [serum phosphate (sP) ≥ 4.5 mg/dL], moderate hyperP [sP ≥ 7.0-10.0 mg/dL] and severe hyperP [sP > 10.0 mg/dL] as % SLED-days with an event.

Results: Median age were similar: 60 (39-84) and 58 (22-88) years for CoV-AKI and non-CoV-AKI, respectively. Black race (77% vs. 30%; p<0.0001) and male sex (78% vs. 61%; p=0.04) were more common in CoV-AKI. Ischemic ATI was the presumed cause of AKI in 85% and 82% of the CoV-AKI and non-CoV-AKI, respectively. Along the duration of SLED, the incidence of hyperK was greater in CoV-AKI [mean 19 ± 2% vs. 14 ± 3% SLED-days, p=0.002]. The proportion of patients with ≥1 event of severe hyperK was greater in CoV-AKI [33% vs. 7%, p=0.0004]. The incidence of hyperP were similar between groups [mean 56 ± 4% vs. 53 ± 5% SLED-days, p=0.49]. However, the proportion of patients with ≥1 event of moderate and severe hyperP were greater in CoV-AKI [86% vs. 60% (p=0.001) and 50% vs. 18%, (p=0.0002)]. In CoV-AKI, sK and sP correlated with lactate dehydrogenase (LDH) [R=0.305 (p=0.044) and R=0.307 (p=0.043), respectively] but not with creatine kinase; and hyperP events correlated with shorter SLED runs (hours/run) (R=-0.268, p=0.055).

Conclusions: HyperK and hyperP refractory to RRT (by SLED) were more frequent in CoV-AKI compared to other forms of AKI in the pre-COVID-19 era. Because of the correlation of sK and sP with higher LDH and shorter SLED runs, intracellular ion release from cell injury due to cytokine "storm" and RRT interruptions may play a role.

PO0705

Risk Factors for AKI in Patients Hospitalized with COVID-19

Mridula Nadamuni, Yu-Lun Liu, Sadaf S. Khan, Shani Shastri, Duwayne L. Willett, Nilum Rajora, Catherine Chen, Susan Hedayati. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: We evaluated risk factors and prevalence associated with AKI in our early experiences with patients hospitalized with COVID-19, 32% of whom required ICU level care, at the University of Texas Southwestern and Parkland Hospitals in Dallas, Texas from 3/13/20-5/07/20.

Methods: Patients admitted with COVID-19 confirmed by SARS-CoV2 PCR test were screened for AKI. Univariate and multivariate logistic regression using backward selection identified factors associated with AKI.

Results: COVID-19 was confirmed in 145 patients, of whom 62 (43%) had AKI. Patients with AKI were older, mean (SD) age 60 (17) vs. 54 (15) years without AKI, p=0.03, and were more likely to have hypertension, 74% vs. 47%, p=0.002, and diabetes mellitus, 61% vs. 31%, p<0.001. CKD was present in 42% of those with AKI vs. 7% of those without, p<0.001. Race, ethnicity, and ACEI/ARB use did not differ between groups. Patients with AKI had higher CRP, median (IQR) 102 (44-161) vs. 59 (21-116) mg/L, p=0.009, and LDH on presentation, 365 (265-493) vs. 317 (228-385) U/L, p=0.04. Ferritin, IL-6, and D-dimer was similar between groups. A higher percent with AKI received steroids, 42% vs. 16%, p<0.001. Tocilizumab was administered in 15% of AKI vs. 5% of non-AKI groups, p=0.08 while rates of hydroxychloroquine and remdesivir use did not differ. Renal replacement therapy was required in 8 patients with AKI, of whom 7 received CVVHDF and 1 HD. There were 8 (13%) deaths in those with AKI vs. 5 (6%) in those without. Factors associated with AKI are listed (**Table**).

Conclusions: During the first weeks of COVID-19 outbreak at our hospitals, 43% of patients had AKI. Underlying CKD, diabetes, steroid use and illness severity were independently associated with AKI. Follow-up is needed to determine the long-term impact on kidney function and recovery.

PO0706

The Impact of COVID on CRRT Filter Lifespan

Lewis Mann, Mony Fraer, Sarat C. Kuppachi, Lama A. Noureddine, Lisa M. Antes, Sreedevi koppisetti Jenigiri, Maria T. Story, Meenakshi Sambharia, Jayesh B. Patel, Kandi O'Connor, Benjamin R. Griffin. *University of Iowa, Iowa City, IA.*

Background: Patients with COVID are more likely to have systemic thrombotic events. Although it has been theorized that those on CRRT also have an increased rate of filter loss due to clotting. If COVID-positive patients are more likely to clot their filter than other patients on CRRT, a more aggressive anticoagulation strategy may be worthwhile. This could result in longer filter lifespan, less circuit down time, which would result in improved clearance, lower costs, less risk of iatrogenic blood loss, and less wasted nursing time. If there is no difference in filter lifespan between COVID positive and negative patients, then more aggressive anticoagulation would result only in added risk without a clear benefit.

Methods: We analyzed COVID data on patients in a related unblinded prospective randomized trial, in which patients are assigned to either pre-filter CVVH or CVVHD. The standard treatment protocol at the University of Iowa is to use citrate anticoagulation with a blood flow rate of 200 mL/min and a dose of 25 mL/kg/hr. The primary outcome is average filter life, and secondary outcomes are mortality, intensive care unit LOS, hospital LOS, and renal recovery.

Results: A total 30 patients using a total of 90 filters from March 25 to May 20, 2020 were evaluated (Table 1). The average filter life in COVID-positive patients was 37.4 +/- 35.8 compared to 33.1 +/- 26.7 in COVID-negative patients (p = 0.55). However, COVID-19 patients were more likely to receive heparin anticoagulation in addition to citrate.

Conclusions: Contrary to other reports, in this retrospective, unadjusted analysis of CRRT patients, the presence of COVID-19 did not decrease average filter life. Further research is needed regarding the appropriate anticoagulation strategy in COVID-19 positive patients.

Table 1: Patient characteristics

	COVID-positive (n = 8)	COVID-negative (n = 16)	p value
Age	53.6 +/- 13.9	59.2 +/- 16.0	0.41
Male (%)	8 (100%)	7 (44%)	0.0089
Caucasian (%)	1 (13%)	14 (88%)	< 0.01
Hispanic (%)	7 (88%)	0 (0%)	< 0.01
Black (%)	0 (0%)	1 (6.3%)	< 0.01
SOFA	9.25 +/- 1.98	10.4 +/- 2.85	0.32
CVVH (%)	5 (63%)	8 (53%)	0.65
Diabetes (%)	4 (50%)	11 (69%)	0.37
CAD / HF (%)	0 (0%)	5 (31%)	0.084

PO0707

Single-Center Experience of AKI in COVID-19-Infected Patients in West Kent Hospital, United Kingdom

Matthew James, Tord H. Hogsand, Kieran Jankowski, Jeetendra R. Rathod, Nihil Chitalia, Jonathan Kwan. *Darent Valley Hospital, Dartford, United Kingdom.*

Background: The outcome of renal function and in COVID-19 positive patients is unclear. We studied the epidemiology of acute kidney injury (AKI) in the COVID-19 positive patients

Methods: Between 9th March 2020 and 26th April 2020 data was prospectively collected on 253 adult COVID-19 positive inpatients about co-morbidity, s. creatinine, demographics and AKI from digital records at our secondary care hospital. AKI stages were defined as per KDIGO Criteria

Results: Of the 253 patients, 58.9% were male with (mean ± stdev) age 71.9 ± 16.4 years. Common co-morbidities were Hypertension (54.1%), Cardiovascular Disease (34%), Diabetes Mellitus (28.3%), Chronic lung disease (23.3%), Dementia (20.5%), CKD (stage 3 - 5) 19.8% & 2 (0.8%) renal transplant. 2.8% (7) Patients on regular dialysis were excluded. 42.6% (105) patients had AKI. Of these 53.3% (56) had AKI 1, 20.9% (22) AKI 2 and 25.7% (25) had AKI 3. 2.4% (6) patient's needed acute haemofiltrated. The mean systolic BP at admission in non-AKI patients was 136 ± 22 mmHg (109 of 147 available) whilst in those with AKI it was 124 ± 25 mmHg (78 of 105 available). Thes, creatinine (median and range) in AKI patient at admission, peak and discharge or death was 126 (Range 30 - 1339), 173 (57 - 1339) and 113 (28 - 761) umol/L respectively. 52.4% (55) patients had recovered from AKI. The overall mortality rate in COVID-19 infected patient was 36.4% with mean age of 77.5 ± 12.4 years. Mortality in patients without AKI was 22% (31) & with AKI was 56.2% (59) with mean age of 77.7 ± 11.7 Years. The stage

wise AKI mortality was AKI1 25.7% (27), AKI2 10.4% (11) and AKI3 20% (21). 66.6% haemofiltration patients. 23% (25) AKI patients died with normal creatinine. Mortality in CKD patients as co-morbidity was 64%. All renal transplant patients survived without having AKI. 7.7% {19} patients required continuous positive airway pressure, 42.1% (8) patients developed AKI of these 75% (6) patients with CPAP died. A further 24 (9.75%) required mechanical ventilation with 62.5% (15) of these developed AKI with mortality of 80% (12).

Conclusions: Elderly patients were most commonly infected with COVID-19 infection. AKI was seen in 42.6% patients with COVID-19 infection. More than 60% COVID-19 infected patients died if they had AKI and were on any form of mechanical ventilatory support or had CKD as co-morbidity.

PO0708

Severe AKI in SARS-COVID-19 Patients from a Tertiary Hospital in Rhode Island

Harshitha Kota,[1] Kevin Mitchell,[1] Jie Tang.[1,2] [1]*Brown University, Providence, RI;* [2]*University Medicine Foundation Inc, Providence, RI.*

Background: The clinical features & outcomes of COVID-19 patients who developed severe AKI are still being elucidated.

Methods: 42 patients with COVID-19 infection who developed KDOGI stage 3 AKI were identified from March 1 to May 15, 2020, at Rhode Island Hospital, a large tertiary teaching hospital. Their clinical presentations and outcomes are presented. The data in table 1 were presented as mean (± SD), median (IQR), or # (%).

Results: The baseline characteristics are outlined in table 1. Among them, 88% were admitted to ICU, 83% were intubated and needed pressor support. 71% received renal replacement therapy (RRT)(56% on CVVHDF). The mean duration of RRT and ICU stay were 6 and 14 days, respectively. 33 participants received treatment for COVID-19, among them 14 (33%) received Remdesivir(RDV), 6 (14%) received convalescent plasma(CP), 4 (10%) received hydroxychloroquine(HCQ), and 25 (60%) also received azithromycin. The mortality rates were 15% in the RDV group, 67% in the CP group, and 75% in the HCQ group. The mortality was 67% in those without any treatment. At the 60-day follow-up, 11 (26%) were discharged alive, 21 (50%) died. Those who died were older (mean age 71 vs. 61), having higher Charlson Comorbidity Index (4.7 vs 3.0), more likely to have diabetes (71% vs. 61%) and coronary artery disease (38% vs. 24%).

Conclusions: The mortality rate of SARS-COVID patients who developed severe AKI is high in our cohort. Future larger scale studies are needed to elucidate the causes of this high mortality.

The Clinical Presentation of AKI Complicating COVID-19: Observations from Elmhurst Hospital, New York City

Nasser M. Alnazari, Demetrios Papademetriou, George N. Coritsidis, Payal Ram, Ellena A. Linden, Aaron S. Stern. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Early in March, NYC Hospitals became inundated, especially safety net public hospitals, The physicians at Elmhurst Hospital Center (EHC) encountered countless cases of respiratory failure often accompanied by AKI. Autopsy studies from China described an interstitial nephritis, with macrophage infiltrates and complement deposition along with fibrotic changes. We report our experience with COVID-19 and AKI.

Methods: We reviewed the charts of 137 SARS-CoV-2 positive patients (PCR of a nasopharyngeal sample) admitted to EHC 3/7/2020 - 4/7/2020. We categorized patients as having KDIGO defined AKI vs no AKI within the first seven days of admission. Co-morbidities, renal associated markers and inflammatory markers were anlayzed. Clinical outcomes were assessed. Exclusion criteria: <18 years old, pregnant, ESRD, mortality prior to day 7 of hospitalization. Welch T test and Chi square were used for AKI vs non-AKI

Results: Age was similar in both groups as was gender (male 74% vs 79%) and incidence of diabetes. Early AKI developed in 35% of whom 55% needed RRT; 85% of the AKI patients required mechanical ventilation vs 11.2% of the non-AKI group. Inflammatory markers (WBC, CRP, LDH); urine protein and urine white cells (but not CPK) were significantly higher in the AKI group. Procalcitonin and D-dimers as maximum levels became significant. We found that 20% of those not with early AKI developed late-onset AKI. Mortality was 76.7% in the AKI and 17.9% in the non-AKI group.

Conclusions: Early AKI developing in the first week of hospitalization was associated with overwhelming respiratory failure. The accompanying higher inflammatory markers, elevated urine WBCs and protein could implicate interstitial nephritis as an underlying pathology as described earlier.

Incidence of AKI in Hospitalized Patients with COVID-19

Lili Chan, Kumardeep Chaudhary, Aparna Saha, Kinsuk Chauhan, Akhil Vaid, Barbara T. Murphy, John C. He, Girish N. Nadkarni, Steven G. Coca. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Preliminary reports indicate that acute kidney injury (AKI) is common in coronavirus disease (COVID-19) patients and is associated with worse outcomes. AKI in hospitalized COVID-19 patients in the United States is not well-described.

Methods: This is a retrospective observational study of patients aged ≥18 years with laboratory confirmed COVID-19 admitted to the Mount Sinai Health System between February 27 and April 15, 2020. We describe the frequency of AKI and dialysis requirement, AKI recovery, and adjusted odds ratios (aOR) for mortality while adjusting for age, gender, race, comorbidities, and admission labs and vital signs.

Results: Of 3,235 hospitalized patients with COVID-19, AKI occurred in 1406 (46%) patients and 280 (20%) with AKI required dialysis. The proportion with stages 1, 2, and 3 AKI overall was 35%, 20%, 45%, and 20% received dialysis (Figure 1A). In the 815 patients admitted to the intensive care unit (ICU), 553 (68%) had AKI and 34% required dialysis. The median peak serum creatinine was 2.2 (IQR 1.6-3.7) mg/dL in those that did not receive dialysis and was 8.6 (IQR 6.5-11.4) mg/dL in those that did receive dialysis. Urine studies were available for 581 (18%) patients of whom 338 (60%) patients had AKI. 558 (96%) of all patients had any urinary abnormalities of proteinuria, hematuria, or leukocyturia. Independent predictors of severe AKI were chronic kidney disease, systolic blood pressure, and potassium at baseline. In-hospital mortality in patients with AKI was 41%. The aOR for mortality for AKI was 9.6 (95% CI 7.4-12.3). 56% of patients with AKI who were discharged recovered kidney function back to baseline (Figure 1B).

Conclusions: AKI is common in patients hospitalized with COVID-19, associated with worse mortality, and nearly half of patients do not recover kidney function.

Figure 1A: Acute kidney injury stages overall and stratified by intensive care unit admission

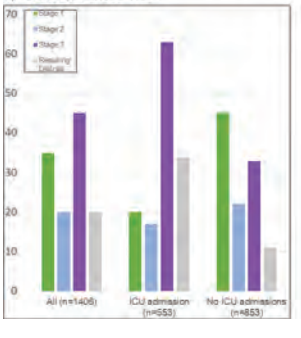

Figure 1B: Recovery and acute kidney disease overall, by need for dialysis, and by mortality status

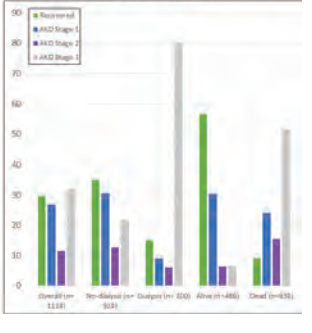

PO0711

SARS-CoV-2 Infection and Outcomes in Chronic Dialysis Patients

Eduardo K. Lacson,[1,2] Gideon N. Aweh,[1] Vladimir Ladik,[1] Harold J. Manley,[1] Carol Stewart,[1] Doug Johnson.[1] [1]*Dialysis Clinic Inc, Nashville, TN;* [2]*Tufts University School of Medicine, Boston, MA.*

Background: The SARS-COV-2 pandemic (COVID) impacted ESRD patients on dialysis, categorized by the CDC as immunocompromised. We describe the characteristics and outcomes in patients treated by a non-profit dialysis provider.

Methods: From 2/17 to 5/29, 2020, Dialysis Clinic Inc. had identified 422 COVID+ patients from 90 clinics in 20 states. We compared their characteristics relative to the uninfected source clinic population (N=6,993) and tracked outcomes over the 15-week period.

Results: Comparative characteristics are shown in the table (*p<0.05). Hospitalization occurred in 295 (70%) with 75 deaths, 159 discharges and 61 still hospitalized. Ten patients died <30 days post-discharge. Another 11 deaths occurred in 116 non-hospitalized patients. Overall, 96 of 422 died (22.7%). While more black patients were infected, death rates were higher in white than black dialysis patients (31.5% vs. 18.8%, p=0.008).

Conclusions: Chronic dialysis patients with COVID have higher death rates than the general population. Infected patients tended to be older, with more comorbidity, particularly DM/CVD, and utilized respiratory inhalers/assistance. Group home residents were overrepresented with COVID while home dialysis patients were disproportionately spared.

ESKD Patients Hospitalized with COVID-19: Early Outcomes in Bronx, New York

Molly Fisher,[1,2] Milagros Yunes,[1] Michele H. Mokrzycki,[1,2] Ladan Golestaneh,[1,2] Maria Coco.[1,2] *[1]Montefiore Medical Center, Bronx, NY; [2]Yeshiva University Albert Einstein College of Medicine, Bronx, NY.*

Background: It is unclear whether end-stage kidney disease (ESKD) patients with COVID-19 are at increased risk for adverse outcomes due to impaired immune responses attributable to uremia. Alternatively, a weakened immune state could mitigate the cytokine surge observed in non-ESKD patients with COVID-19. The aim of our study is to describe the clinical characteristics and short term outcomes in ESKD patients requiring hospitalization for COVID-19.

Methods: We performed a retrospective study of 114 consecutive ESKD patients hospitalized at two major hospitals in the Bronx with COVID-19 from March 9, 2020 to April 12, 2020 in the midst of the coronavirus surge in New York City. Clinical and laboratory data were extracted from the medical record and short term outcomes were reported.

Results: The mean age was 63 years (range 30-87); 61.4% were men and 88.6% were Black or Hispanic. Most had hypertension (89.5%) and diabetes mellitus 66% and 30.7% were nursing home residents. Intensive care unit admission was required in 13(11.4%) patients and 17(14.9%) required mechanical ventilation. In-hospital mortality occurred in 23(20%) patients and was similar to mortality observed in non-ESKD patients. Mortality was 59% in those who required mechanical ventilation. At the time of data censoring, 47% had been discharged and 32% remained hospitalized. Initial procalcitonin, ferritin, lactate dehydrogenase and lymphocyte percentage were significantly higher in those who died.

Conclusions: Short term mortality in Bronx ESKD patients hospitalized with COVID-19 was similar to non-ESKD patients. Mechanical ventilation was associated with high mortality. Initial elevated inflammatory markers may be predictors of mortality in ESKD patients with COVID-19. To date, this is one of the largest studies describing outcomes in hospitalized ESKD patients with COVID-19. Further studies describing long-term outcomes in this population following COVID-19 are needed.

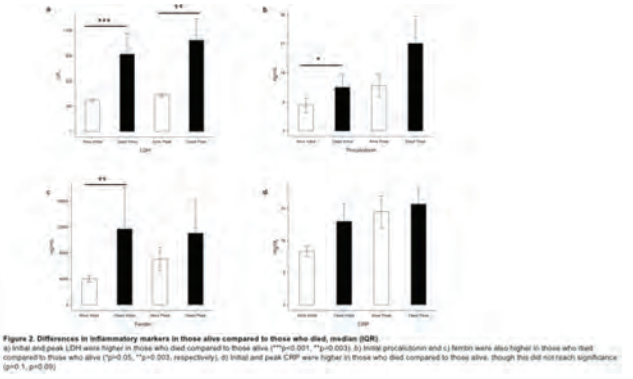

Figure 2. Differences in inflammatory markers in those alive compared to those who died, median (IQR):
a) Initial and peak LDH were higher in those who died compared to those alive (***p<0.001, **p=0.003). b) Initial procalcitonin and c) ferritin were also higher in those who died compared to those who alive (*p=0.05, **p=0.003, respectively). d) Initial and peak CRP were higher in those who died compared to those alive, though this did not reach significance (p=0.1, p=0.09)

PO0713

Trends in Fever and Respiratory Illness in Hemodialysis Patients During the COVID-19 Pandemic

Sheetal Chaudhuri,[1] Hao Han,[1] John W. Larkin,[1] Len A. Usvyat,[1] Dinesh K. Chatoth,[2] Jeffrey L. Hymes,[2] Michael A. Kraus,[2] Allan J. Collins,[2] Franklin W. Maddux.[3] *[1]Fresenius Medical Care, Global Medical Office, Waltham, MA; [2]Fresenius Medical Care, North America, Waltham, MA; [3]Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany.*

Background: Hemodialysis (HD) patients are vulnerable to the 2019 coronavirus disease (COVID-19) due to older age and common coexistence of comorbidities. Fever and respiratory illness (RI) are common symptoms of COVID-19. In order to create a disease surveillance tool and anticipate areas of COVID-19 outbreak, we aimed to assess the trends in fever and RI symptoms in HD patients treated at a national dialysis provider network in the United States during the pandemic.

Methods: We used data from HD patients actively treated between Jan 1 2018 ad May 16 2020 at a national dialysis provider network of large integrated health care company. If the body temperature of the patient either before or after the treatment was greater than 100 degrees Fahrenheit, then the patient was identified as exhibiting the symptom of fever. If the patient complained of shortness of breath, wheezing, runny nose, bloody cough, dry cough or purulent cough, then in this analysis the patient was identified as exhibiting the symptom of RI.

Results: The total patients count ranged from 196,774 to 209,475 per week while the total count of HD treatments ranged from 413,477 to 454,215. For the year 2020, a clear increase in trend for number of patients was observed after week 11 (03/08-03/14/2020) for RI symptoms (Figure 1A) and week 12 (3/15-3/21/2020) for fever symptom (Figure 1B). Both increasing trends spike at the week 15 (04/05-04/11/2020) and decline thereafter.

Conclusions: HD patients appear to exhibit a different trend in RI and fever symptoms during the year 2020 compared to concurrent periods in 2018 and 2019. which coincides with COVID-19 outbreak. Routine surveillance of dialysis patients may allow for early identification of COVID-19 outbreaks.

PO0714

Implementation of Strategies for Prevention and Control of SARS-CoV-2 Infection at Dialysis Units in Latin America: Analysis from GlomCon Latin America Working Group (LGlomCon)

Denisse Arellano-Mendez,[1] Julio A. Gutierrez-Prieto,[2] Javier Soto-Vargas,[3] Blanca Martinez-Chagolla,[4] Franco H. Cabeza Rivera,[5] Desiree Garcia Anton,[5] Diana Aguirre,[6] Sonia Rodriguez Ramirez,[7] Carmen Avila-Casado.[8] GlomCon Latin America Working Group *[1]Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; [2]Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; [3]Hospital General Regional 46, IMSS, Guadalajara, Mexico; [4]Hospital General "Dr. Miguel Silva", Morelia, Mexico; [5]University of Mississippi Medical Center, Jackson, MS; [6]Hospital General de Mexicali, Mexicali, Mexico; [7]Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; [8]Pathology Department, University Health Network, Toronto, ON, Canada*.

Background: Patients on dialysis belong to the high-risk group to develop severe COVID-19 infection due to their multiple comorbidities. International societies have issued recommendations for the control and prevention of SARS-CoV-2 infection at dialysis units but implementing them may not always be feasible as many healthcare systems in Latin America (LA) have limited resources. This study aims to reflect the experience of nephrologists in LA at taking care of these patients and if the recommendations were adopted in their practices.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases between May 20-27, 2020 from sixteen Spanish speaking LA countries divided into 6 categories. We present the results for the ESRD category.

Results: 430 responses were obtained, 360 were considered for analysis. 276 (86.5%) of the participants were nephrologists and 178 (64%) of them practiced in dialysis units. 163 (92.6%) already implemented strategies to control and prevent COVID-19 in their units. 125 (71%) received training on it and 128 (72.7%) reported personal protective equipment availability. The most common implemented strategies were: education sessions about COVID-19 for patients and caregivers (68.5%), designated isolation areas (77.8%) or shifts (68.75%) for patients with suspected or confirmed COVID-19 and a 7-feet separation between hemodialysis (HD) machines (61.9%). 49 (28%) of the nephrologists reported an outbreak among patients and 60 (34.2%) among medical staff. Patient absenteeism to their HD sessions due to fear of infection, a decrease in the frequency and a shortening of the time of the sessions was reported in 41.7%, 30.2% and 36%, respectively. 29 (16.5%) of the respondents considered that those practices were associated with patient mortality.

Conclusions: Most dialysis units in LA are partially implementing the recommended strategies for control and prevention of COVID-19 but this seems to be insufficient since at least one third of them already faced outbreaks among patients and medical staff.

PO0715

Implementing COVID-19 Infection Control Procedures in Outpatient Dialysis in an Urban US Population

Ibironke W. Apata, Jason Cobb, Jose E. Navarrete, Janice P. Lea. *Emory University School of Medicine, Atlanta, GA.*

Background: Emerging data reveal disparities in the burden and severity of disease among racial and ethnic minorities in the US. Emory Dialysis consists of 4 outpatient dialysis facilities, serving an older, urban and predominantly African-American population. These facilities are in counties with the highest number of COVID-19 cases in Georgia. We describe infection control measures implemented to prevent COVID-19 transmission, and the clinical characteristics of patients with COVID-19 in the facilities.

Methods: Based on CDC's recommended guidance, we implemented the following infection control procedure between February and April 2020: 1) screening; triaging all patients, and separating patients with symptoms of COVID-19; 2) monitoring staff for COVID-19 symptoms; 3) limiting healthcare personnel in the facilities; 4) universal masking in the dialysis units; 5) conducting PPE re-trainings; 6) assessing facility preparedness; 7) separating high risk patients (nursing home residents); and 8) cohorting patients with COVID-19 to a dedicated dialysis shift.

Results: Of the 745 patients followed at the Emory dialysis facilities, 18 (2.4%) were diagnosed COVID-19 between March 25—May 7, 2020. Among the 18 patients, 17 were receiving in-center hemodialysis and 1 was on peritoneal dialysis. The median age was 66.8 years (range 43–84) and 11 (61.1%) were female. Nine (50%) were residents of a skilled nursing facility. Sixteen (88.9%) patients had a diagnosis of hypertension, 10 (55.6%) had diabetes, and 10 (55.6%) had cardiac disease. Eight patients (44.4%) required hospitalization and 4 patients (22.2%) died from COVID-19 related complications. Two patients with COVID-19 were dialyzing at adjacent dialysis stations and the timing of their symptoms suggested possible transmission in the dialysis facility. In response, education, infection control audits and PPE re-trainings were conducted to bolster infection control practices.

Conclusions: In a high-risk patient dialysis population, we successfully implemented recommended infection control measures to mitigate the spread of SARS-COV-2 in our facilities. Dialysis facilities must stay vigilant and monitor for possible transmission of COVID-19. Regular audits of infection control practices remains critical.

PO0716

Canaries in the Coal Mine: Nursing Home Dialysis Patients as Sentinels During COVID-19

Allen Kaufman, Alice Hellebrand, Steven M. Kaplan, Jordan Ledvina, Nathan W. Levin, Eran Y. Bellin. *Dialyze Direct, Brooklyn, NY.*

Background: At least one-third of USA COVID-19 deaths are skilled nursing facility (SNF) residents. Since 2016, Dialyze Direct has brought staff-assisted home hemodialysis (HD) on-site to more than 7,000 patients in SNFs. HD is performed 5x per week in a den setting. Since 3/9/20, Dialyze Direct has screened patients for COVID signs or symptoms before every HD. Infection controls include, but are not limited to, patient masks, staff PPE, physical distancing, and cohorting by COVID symptoms or status. The penetrance of likely COVID in SNF HD patients in NY vs FL is presented.

Methods: A symptom diagnostic hierarchy tracked presumptive COVID infection and augmented the limited available COVID testing. At every HD, patient symptoms were recorded in an Electronic Health Record. Prevalent infection is defined as the proportion of patients with any of the symptoms during the pandemic living in the SNF during the week of interest. We report on weekly proportion from 3/9/20-5/16/20.

Results: Once COVID symptoms appeared among the HD population, penetrance increased over time. In NY, penetrance in week 1,5 (4/5/20), and 10 was 8, 52, and 64%. In FL, comparable data was 13, 15, and 25%. Prevalence differences (5/10/20) for NY (29/45) vs FL (23/92) (RR 2.6, CI 1.7-3.9; p=.000).

Conclusions: COVID symptom penetrance in SNF HD patients differed between NY and FL, likely attributable to differences in community disease prevalence, SNF's infection controls, their relationships to referring hospitals, and state health regulatory environment. On 3/25/20, NY mandated SNFs to accept COVID hospital returns and forbade SNFs to demand proof of negative test before accepting the return of suspected patients. COVID symptoms in SNF HD residents can serve as sentinel for COVID for the general SNF population as they are the most intensively monitored patients there. The more frequent 5x per week HD model in the SNF provides intense and relevant local surveillance compared to less frequent conventional off-site HD. This sentinel strategy can inform an urgent pivot of infection containment efforts by the SNF and larger regulatory agents so that lessons learned from successful containment strategies can be implemented early.

PO0717

Chronic Dialysis Access Management in the COVID-19 Era: The Need for Raising Awareness

Anita Vincent-Johnson,[1] Lakshmi Kannan,[1] Ashkan Karimi,[2] Tushar Chopra,[1] Negiin Pourafshar.[1] *[1]University of Virginia, Charlottesville, VA; [2]Augusta Health, Fishersville, VA.*

Background: Coronavirus Disease 2019 (COVID-19), an acute respiratory disease caused by novel coronavirus SARS-CoV-2, is particularly ominous to chronic dialysis patients as they are likely to experience more severe illness. However, these patients continue to require renal replacement therapy (RRT) during this time. To inform best practices for hemodialysis (HD) patients, we sought to determine the challenges regarding access placement during the pandemic era.

Methods: This is a retrospective single-center study of adult patients who received chronic dialysis at one of the University of Virginia dialysis units. Prevalence of central venous catheter (CVC) use were assessed in patients receiving chronic HD between the months of February-April 2020 (during the pandemic in our area) and compared to the three months prior (October-December 2019). The patients' relevant clinical and laboratory information were reviewed and recorded monthly. All patients who received RRT on HD were included.

Results: A total of 58 patients were evaluated, among whom 33 were male and 25 were female. The age range is 18-90 with a median age of 65. The number of patients using catheters in the pandemic months was 18 (31%), 19 (33%) and 22 (37%). The numbers pre-pandemic were 14 (25%), 19 (33%) and 17 (30%). The number of patients with central venous catheter for more than 90 days during the pandemic was 14 (24%), 16 (30%) and 16 (30%). The numbers pre-pandemic were 12 (22%), 15 (27%) and 15 (27%).

Conclusions: This single-center study reveals the impact of the pandemic on HD catheter use in our area. There is a large population of ESRD patients in the United States on HD that require vascular access. An AVF is the desired access type as it has the most extended access survival, the best patient survival outcomes, the lowest cost, and requires the fewest interventions. Early referral for AVF is important; however, during the Covid-19 pandemic era patients and providers are hesitant to refer patients, wanting to avoid any exposure to the virus while resources remain scarce. This study identifies the inherent difficulty for access placement in this high-risk population of patients during times like this and raises questions in the literature on the best choice of access for these patients along with the optimal timing of fistula placement to provide safe care for the patients.

PO0718

Clinical Characteristics and Outcomes in ESKD Patients with COVID-19 Infection in an Urban Community Hospital in Brooklyn, New York, During the Global Pandemic

Carlos M. Zapata, Yariana E. Rodriguez, Olawale Akande, Laurie Ward, Premila Bhat. *Wyckoff Heights Medical Center, Brooklyn, NY.*

Background: The impact of coronavirus disease 2019 (COVID-19) on individuals with End Stage Kidney Disease (ESKD) receiving maintenance hemodialysis (MHD) is unknown. This study aims to describe clinical characteristics and outcomes in a cohort of patients with ESKD receiving MHD hospitalized with confirmed COVID-19 infection in an urban community hospital during the New York City peak of the global COVID19 pandemic.

Methods: Cases with a diagnosis of ESKD and COVID-19 based on positive PCR testing results were identified from retrospective review of electronic health records for patients hospitalized between March 4, 2020 and April 30, 2020. Electronic health records were reviewed in order to obtain demographic data, presenting symptoms, laboratory values, medical management, and outcomes.

Results: 29 patients with ESKD on MHD with confirmed COVID-19 infection were identified. 16/29 (55%) were over age 60 years, 20 (69%) were male and 14 (48%) were Hispanic. 18 (62%) had Diabetes and 26 (89%) were overweight or obese (BMI >25). All had hypertension. 68% were on Statin and 40% on ACE inhibitor or ARB at the time of admission. 25/29 (86%) were dialyzed via arteriovenous fistula or graft. The most common presenting symptoms were dyspnea (85%), cough (60%) and fever (28%). All initial chest radiographs showed abnormalities, with diffuse infiltrates on 21 (72.4%) and focal infiltrates on the remainder. All patients who required renal replacement therapy during hospitalization received conventional HD. 10 patients required mechanical ventilation during hospitalization (34%); all of these patients died. Overall, 13 patients (45%) died and 16 patients (55%) were discharged after a median of 6 and 7 days hospitalization, respectively. Three patients (10%) were readmitted during the period of observation. No significant associations were found between age, sex, race, or diabetes and mortality. Mechanical ventilation was the most consistent predictor of death.

Conclusions: 45% mortality was observed in a small cohort of patients with ESKD on MHD with confirmed COVID-19 infection hospitalized during the peak of the global COVID-19 infection. This high mortality rate reinforces the need for social distancing and infection control measures to reduce transmission in this high risk population.

PO0719

Clinical Outcomes of Patients with ESKD Hospitalized with COVID-19

Aldo E. Torres Ortiz, Muner Mohamed, Vernelle T. Mitchell, Juan Carlos Q. Velez. Ochsner Nephrology *Ochsner Health System, New Orleans, LA.*

Background: Patients with end-stage kidney disease (ESKD) comprise a vulnerable population to infections. COVID-19 has been responsible for high mortality worldwide. To-date, there is limited data regarding the impact of COVID-19 in the ESKD population. We report clinical outcomes of ESKD patients with COVID-19 admitted to an academic hospital in New Orleans.

Methods: We conducted an observational study in patients with ESKD and COVID-19 hospitalized at Ochsner Medical Center over a 7-week period. We compared rates of need for mechanical ventilation, shock, need for intensive care (ICU) and in-hospital mortality as outcome measures between patients with and without ESKD.

Results: Among 851 admissions (67% black) with COVID-19, 49 (6%) patients had diagnosis of ESKD. Patients with ESKD were mostly male [61% vs 49% in non-ESKD (n = 806), p = 0.10] with a median age of 64 (38 – 90) years. Median body mass index (BMI) were 32 vs 27 kg/m^2 (p = 0.11) for those admitted to ICU vs wards, respectively. Thirteen of them (27%) vs 293 (37%) in the non-ESKD group, p=0.16) were admitted to an intensive care unit (ICU). In-hospital mortality rate for the ESKD cohort was 32% compared to 24% for non-ESKD (p = 0.21). Compared to a subset with 161 patients with acute kidney injury (AKI) with 50% mortality, the 32% mortality rate in ESKD was significantly lower (p = 0.027). Shock and/or mechanical ventilation requirement were comparable between groups [12 (24%) of those with ESKD vs 213 (26%) of non-ESKD, p = 0.65]. Median serum ferritin level was significantly more elevated in ESKD compared to non-ESKD [2125 vs 633 ng/mL, p = 0.0019).

Conclusions: Clinical outcomes in individuals with ESKD with COVID19 appear to be grossly similar to that of non-ESKD population with COVID19. The similar mortality rate was seen despite higher levels of ferritin, suggesting that the interpretation of the significance of serum ferritin in ESKD has to be done with caution. Furthermore, the mortality in ESKD patients with COVID19 is lower than that observed in AKI. The observed lack of increased mortality in ESKD does not align with the outcomes of this patient population in other critical illnesses. The ability to mount and exaggerated inflammatory response in COVID19 might be somewhat restricted in ESKD.

PO0720

Clinical Symptoms in 44 Hemodialysis Patients Who Survived and Recovered from a Confirmed SARS-CoV-2 Infection and COVID-19 in Relation to Age and Hospitalization: An International Experience

Mauricio Ruiz,[1] Szymon Brzosko,[2] Marta Serwanska-Swietek,[2] Werner Kleophas,[3] Thilo Krueger,[3] Joao M. Frazao,[4] Fatima F. Silva,[4] Wisam H. Al-Badr,[5] Atef Z. Altaher,[5] Rosnawati Yahya,[6] Maciej Drozdz,[7] Partha Das,[7] Claudio A. Monteiro,[8] Stefan H. Jacobson.[9] *[1]DaVita Colombia, Bogota, Colombia; [2]DaVita Poland, Wroclaw, Poland; [3]DaVita Germany, Dusseldorf, Germany; [4]DaVita Portugal, Lisbon, Portugal; [5]DaVita Saudi Arabia, Riyadh, Saudi Arabia; [6]DaVita Malaysia, Kuala Lumpur, Malaysia; [7]DaVita International, London, United Kingdom; [8]DaVita Kidney Care Brazil, Brasilia, Brazil; [9]Karolinska Institutet, Stockholm, Sweden.*

Background: A novel coronavirus (SARS-CoV-2) is now rapidly spreading throughout the world. Patients undergoing long-term in-center hemodialysis (HD) are highly vulnerable given kidney failure, comorbidities, and the need for frequent visits to a dialysis facility.

Methods: A total of 610 patients on maintenance HD at DaVita clinics in 6 countries were tested for presence of infection with SARS-CoV-2 using polymerase chain reaction (PCR) between March 28 and May 18. Of these, 115 HD patients (19%) were positive. Information up to May 25, 2020, show that 44 patients have recovered. Clinical symptoms during infection with SARS-CoV-2 are reported from these 44 recovering survivors (Germany 13 patients, Poland 12, Portugal 12, Colombia 2, Saudi Arabia 3, and Malaysia 2) and classified into 4 categories: no symptoms, mild, moderate, or severe symptoms. Hospitalizations and time to recovery were also analyzed. Statistical comparisons were made using Chi-2 analysis and Kruskal-Wallis tests.

Results: Of the 44 patients recovering from COVID-19, 22 patients were ≥70 years and 9 patients were >80 years. Symptoms in relation to age, hospitalization, and time to recovery are shown below.

Conclusions: The majority of HD patients (66%) who recovered from COVID-19 had no or mild clinical symptoms during the infection. There were no significant differences in the occurrence of symptoms from SARS-CoV-2 in relation to age, hospitalization, or time to recovery. Additionally, old and frail HD patients with confirmed COVID-19 may have mild symptoms of the disease.

Percentage of HD Patients Who Recovered From Clinical Symptoms During Infection With SARS-CoV-2

	No symptoms	Mild symptoms	Moderate symptoms	Severe symptoms
All patients	27.3	38.6	31.8	2.3
<70 years	36.4	40.9	22.7	0
>= 70 years	18.2	36.4	40.9	4.5
Hospitalized	36.1	36.1	25	2.8
Time to recovery (days)	27	25	30	41

PO0721

Comparison of Psychological Distress and Demand Induced by COVID-19 During the Lockdown Period in Patients Undergoing Peritoneal Dialysis and Hemodialysis: A Cross-Section Study in a Tertiary Hospital

Zhiyun Zang, Zi Li, Xiaoxiao Xia, Xiaofang Wu. *Department of Nephrology, West China Hospital, Sichuan University, Chengdu, China.*

Background: Since the outbreak of COVID-19 in December 2019, it has spread rapidly and widely, bringing great psychological pressure to the public. In order to prevent the epidemic, lockdown was required in many areas of China, which led to inconvenience of treatment for dialysis patients. However, there are few studies on the mental health of dialysis patients with ESRD after health emergencies and the comparison between HD and PD is less. To explore the psychological distress and the psychological demand induced by COVID-19 in the patients undergoing dialysis and compare the difference between hemodialysis (HD) and peritoneal (PD) patients during the lockdown period.

Methods: Questionnaires were given to the dialysis patients in West China Hospital of Sichuan University. The Impact of Event Scale (IES) was used to investigate the patients' trauma-related distress in response to COVID-19. We investigated the patient characteristics, the impact of COVID-19 to the severity of illness and daily life, the IES scores and the psychological support during the epidemic period of COVID-19.

Results: 232 eligible respondents were enrolled in this cross-section study, consisting of 156 PD patients and 76 HD patients. The median IES score for all the enrolled patients was 8.00 (2.00-19.00), which belonged to the subclinical dimension of post-traumatic stress symptoms. HD patients had a significant higher IES score than PD patients (11.50 vs 8.00) (p<0.05). HD patients already got more psychological support from the medical staff. There was no significant difference on further demand of psychological support between the two groups. In the multivariate regression analysis, we found that dialysis vintage, the impact of COVID-19 on the severity of illness and daily life, and confidence in overcoming the disease contributed to IES score (p<0.05).

Conclusions: HD patients had more severe trauma-related stress symptoms than PD patients. When major public healthy events occurred, careful psychological estimate and sufficient psychological support should be provided to the dialysis patients, especially to the HD patients.

PO0722

COVID-19 Incidence and Outcomes in Hemodialysis Patients in Mexico

Juan M. Ardavin Ituarte, Alicia Pineirua, Juan Carlos Rodriguez. Medica Santa Carmen Staff Nephrologists *Medica Santa Carmen, Mexico, Mexico.*

Background: HD pts are at high risk for COVID-19. High incidence and death rate were reported in China and Europe with more than 20% of asymptomatics. We report incidence, features and outcomes of COVID-19 in HD patients in a network of 8 clinics in Mexico. A protocol was started on Mar 15 with hygiene measures; symptoms triage; separation by age; use of PPE and isolation of suspected cases. We use a more inclusive case definition, different from Mexico Health Ministry's(SSA). All cases are referred for PCR but most aren't tested.

Methods: Retrospective analysis of cases (suspect or PCR(+)) from mar 15 to may 22 2020 compared to controls. T-test and Chi² were used. Hospitalization, IMV and deaths were registered. Overall mortality from mar - may 2020 compared to same period of 2019. We compared the number of cases using our case definition with that using the SSA's. Incidence of COVID-19 in staff was also analyzed.

Results: Total 1276 pts; Of 102 suspects 25 (24%) had PCR and 16 (64%) were(-). 13 (12%) non-tested were discarded based on alternative dx. 2 pts with (-) PCR were cases based on CT. Total 75 cases (10 (+)PCR, 65 w/o test) were analyzed and compared to controls. No differences in HD vintage, DM, CVD, HD session length, VA, BUN or Kt/V. Less age, fem gender, HTN, more sessions/wk, ACEi/ARB and lower Hb were found in the cases. 7 (9%) hospitalized and 2 (3%) required IMV. There were 6 (8%) deaths, only 1 (1.3%) attributed to COVID-19. Overall mortality minimally higher than that of the same period of 2019 (1.35% vs 1.30%). 31% of cases had only 1 symptom. Only 1 PCR(+) and 14 PCR(-) cases fulfilled SSA's definition. Among 231 staff members, 31 cases (13.8%), 11 (35%) PCR(+) and 20 non tested.

Conclusions: Incidence of probable or confirmed COVID-19 was 5.9%; probably overestimated suggested by scarce testing and low mortality. ACEi/ARB use more frequent in cases, adjusted for HTN and age. Our protocol helps prevent in-clinic contagion. A more comprehensive probable case definition appears more useful for HD patients.

	COVID-19 (Susp / Conf) n 75 (5.7%)	Non - COVID-19 n 1,201	Total n 1,276	p
Mean age (S.E.)	44.7 (18.8)	49.7 (17.7)	49.4 (17.8)	0.019
Female (%)	45 (60)	471 (39.2)	516 (40.4)	<0.001
Hypertension (%)	67 (91.8)	804 (66.9)	871 (68.4)	<0.001

PO0723

COVID-19 Infection in Patients with ESRD Requiring Hemodialysis

Anna Anisimova,[1] Valeria Ripa,[2] Biruk Almaz,[2] Nirav Mistry,[2] Fariborz Rezai.[2] *[1]St. George's University School of Medicine, True Blue, Grenada; [2]Saint Barnabas Medical Center, Livingston, NJ.*

Background: This case series assesses characteristics and outcomes of patients with confirmed novel coronavirus (SARS-CoV-2, COVID-19) infection and end stage renal disease (ESRD) requiring hemodialysis during the COVID-19 pandemic.

Methods: This is a single center retrospective study of 24 ESRD patients on hemodialysis who were admitted to Saint Barnabas Medical Center, a 597-bed acute care hospital in Livingston, New Jersey, and with a confirmed COVID-19 diagnosis between February 1st to April 5th, 2020. The characteristics, clinical course, and outcome were assessed and compared. In addition, a subgroup analysis was made between patients who expired (n=8) versus those who lived (n=16).

Results: The overall mortality rate was 33.3% vs. 21% in the general population with COVID-19. Among the 4 (16%) patients who required ICU admission and prolonged pressor support and invasive mechanical ventilation, 2 (50%) patients were successfully extubated and discharged from the hospital while the other 2 (50%) patients died. There were no statistical differences in laboratory values between patients who survived versus patients who died except C-reactive protein (CRP), p=0.002.

Conclusions: We report a mortality rate of 33.3% in our case series of 24 patients with ESRD on dialysis with concurrent COVID-19 infection. There was a statistical difference in CRP value between patients who died versus survived. Fifty percent of intubated patients were successfully extubated and discharged.

PO0724

COVID-19 Infection Patterns in an Academic Inner City Dialysis Unit

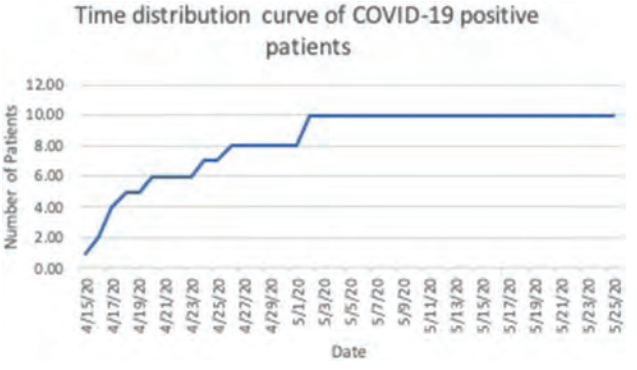
Vinay Srinivasan, Sarah M. Ahmad, Sandeep Aggarwal, Ihab M. Wahba, Yonghong Huan. *University of Pennsylvania, Philadelphia, PA.*

Background: COVID-19 remains a major public health emergency and in-center dialysis provides multiple opportunities for its spread. Elderly immunocompromised hosts pose a significant risk for infection as well as poor outcomes. We present a retrospective analysis of COVID-19 cases in our dialysis unit.

Methods: Retrospective analysis was done as a part of a quality improvement project using unidentified patient data including: demographics, distribution of dialysis shift, patient zip code, transportation mode (self, ride share or public transport), residence type (home, long term care facility or homeless shelter), etiology of ESRD and dialysis vintage. T-test and multivariate analysis (including logistic regression for binary and categorical data) were conducted using SPSS v23.

Results: There were 70 patients in the unit and 10 became positive for COVID-19. 65/70 (92%) of all patients were African American. Between COVID-19 positive and negative patients, there was no significant difference in age (62±15 vs 63±14 years p=0.2), dialysis vintage (7.6±8.7 vs 5.2±4.7 years p=0.31), male gender (7/10 (70%) vs 40/70 (58%) p=0.31). 5/10 (50%) of the positive patients were MWF 2nd shift. On multivariate analysis, this effect approached significance (p=0.051); however, there was no interaction of COVID-19 positive status with demographic characteristics, dialysis vintage, residence type, zip code distribution, or transportation modality. Of note, universal masking and temperature screening were implemented on March 5, 2020 in this unit and no new cases were noted after May 2, 2020.

Conclusions: Our analysis did not show any clear factor associated with COVID-19 infection among our dialysis patients although clustering approached statistical significance. Small sample size and demographic distribution are shortcomings of our study; larger scale epidemiological studies and data analysis are required for better understanding the risk of COVID-19 infection amongst in-center dialysis patients.



Chronological Distrubtion of COVID-19 Cases

PO0725

COVID-19 Infections in a Small Dialysis Organization in New York City

Jeffrey I. Silberzweig,[1,2] Tarek Barbar,[2] Yao Liu,[1] Kwan Kim,[1] Thomas Parker,[1,2] Daniel M. Levine.[1,2] *[1]The Rogosin Institute, New York, NY; [2]Weill Cornell Medicine, New York, NY.*

Background: COVID-19 infected more than 1.6 million Americans (0.48%) and more than 15,000 of the 500,000 (3%) Americans with chronic kidney disease treated by dialysis. The Rogosin Institute operates nine dialysis centers in New York City (NYC), the epicenter of the COVID-19 US Public Health Emergency (PHE). We followed guidance from the Centers for Disease Control and Prevention and the New York State Department of Health throughout the PHE. We screened all patients and staff for signs and symptoms of COVID-19 by measuring temperature and inquiring about symptoms on presentation to our dialysis centers. Infected patients who did not require hospitalization were treated in our centers on a dedicated shift by dedicated staff. We used a symptom-based approach to discontinuing isolation.

Methods: We created a COVID-19 tool in REDCap to track the spread of Coronavirus. We surveyed our Electronic Health Record weekly using a direct data connection and automated scripting to identify patients infected with COVID-19. We reviewed demographic and clinical data for each infected patient. We used descriptive statistics to analyze our population of infected patients.

Results: On February 28, 2020, 1,559 patients received dialysis at our centers. By May 11, 241 (15.5%) had been infected. Our mortality rate was 22.8% compared to general populations in NYC (10-12%), US (6.0%) and worldwide (6.5%) and rates for dialysis patients reported between 7-20%. We had a disproportionate occurrence of COVID-19 among residents of Brooklyn (49% of infections, 44% of patients) and Queens (29%; 25%). Most of the infected patients were male (53%) and Black (51%). Common co-morbidities included hypertension (98%), diabetes mellitus (60%), heart failure (25%) and coronary artery disease (25%). Common outpatient medications included statins (64%) ACE inhibitors/ARBs (80%) and calcium channel blockers (63%). Fever was the only common presenting symptom (94% of patients). A significant proportion (12%) of patients were in the hospital within 14 days prior to diagnosis of COVID-19 infection.

Conclusions: COVID-19 infection was common and associated with high mortality rate in our NYC population of dialysis patients despite adherence to governmental guidelines for control of disease spread. We hypothesize community spread was common in our patients residing in the epicenter of the US COVID-19 PHE.

PO0726

COVID-19 Outbreak and Experience in a Dialysis Unit in the Philippines

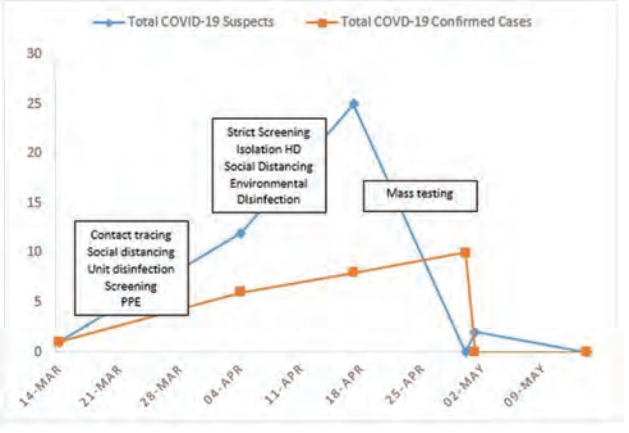
Ma. Anna Angelica S. Cruzado, Filoteo Ferrer. *Makati Medical Center, Makati City, Philippines.*

Background: Patients on regular dialysis are at an increased risk to COVID-19 due to their multiple comorbidities and exposure in the health care setting. The risk for virus transmission within a dialysis unit is also high emphasizing the importance of implementing infection control measures. The objective of this report is to describe the COVID-19 outbreak in a dialysis unit including interventions done.

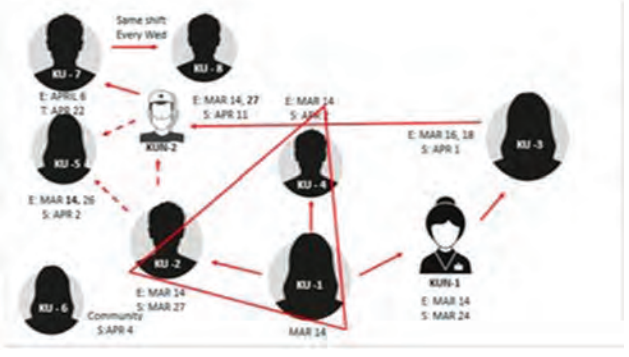
Methods: Review of the epidemic course with contact tracing was done from March 14 to May 14, 2020 in the dialysis unit of a tertiary hospital in the Philippines

Results: Of 167 patients, 20 became COVID-19 suspects. Eight were positive - 3 were exposed from the first confirmed case, 2 were handled by a COVID-19 infected healthcare worker (HCW) who was asymptomatic at time of contact while 2 asymptomatic patients tested positive during mass testing. Two of 67 HCWs tested positive were exposed to patients. Key interventions are (a) enhanced screening by mass testing using NPS/OPS RT-PCR of patients and HCWs after identifying 6 patients and 2 HCWs infected with COVID-19 (b) instead of cohort, dialysis of COVID-19 confirmed and suspected cases was done in isolation rooms separate from the dialysis unit (d) adequate personal protective equipment for HCWs and masks for all patients and (e) environmental disinfection especially in the waiting area with strict social distancing and daily screening.

Conclusions: The infection control and preventive actions done halted the increase in cases. Maintaining these strategies for the duration of the pandemic allowed further decline in the rate of infection.



COVID-19 Suspects, Cases and Interventions



Contact Tracing in the Unit

PO0727

Demographic and Clinical Characteristics of Patients with CKD and SARS-CoV2 Undergoing Hemodialysis Treatment

Laura C Fuentes-Mendez, Angela M. Cordoba Hurtado, L. M. Perez-Navarro, Rafael Valdez-Ortiz, Maribel Merino. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: Patients on HD or PD are likely to be at increased risk of COVID-19 and its complications because they have multiple comorbid conditions. There is a lack of evidence about the optimal management and even clinical manifestations because clinical presentation is highly variable. The delayed diagnosis is because it's not recognized by the treating centers and the confusion with patients with fluid overload or uremic syndrome can be fatal in this population.

Methods: Retrospective, observational, single-center study in Mexico. We analyzed the clinical manifestations and outcomes of all maintenance HD patients hospitalized with COVID-19 from April 9th to May 31st, 2020 as confirmed by real-time polymerase chain reaction

Results: 20 patients followed in our hospital with median age of 45.2±13.8 years, 50% were men. All the patients have HTA (100%), DM (50%), the most common symptoms at admission were asthenia (75%), dyspnea (65%), cough (55%) followed by myalgias (50%) and fever (45%). Poor oxygen saturation (<95%) breathing room air was observed in 18 patients (90%) with mean oxygen saturation of 77± 9%. Lung abnormalities on initial chest X-ray were observed in all patients. Peripheral ground-glassopacities, the typical radiologic pattern, were bilateral in 13 patients and unilateral in 7. Laboratory studies with lymphopenia in 85% of patients with a mean of 0.7+0.38. There were no differences baseline leukocyte or lymphocyte from patients who survived vs from those who died. The mortality rate (40%) was much higher than that observed in the general population (8%). Mortality was higher in women.

Conclusions: The impact of this virus on patients with CKD is poorly understood. The evaluation of the nephrologist must be very detailed, most of the patients had mild dyspnea, however on physical examination, desaturation and radiological images were suggestive of infection by SARS-CoV2. The current situation provides a unique opportunity to gather vital information to process and learn from the experience worldwide. These results will allow us to treat them in a timely manner and reduce lethality in dialysis patients.

PO0728

Effect of COVID-19 on Dialysis Practices on the Ground: Early Results from an International DOPPS Program Survey

Murilo H. Guedes,[1,2] Brian Bieber,[2] Patricia De Sequera,[3] Pablo A. Urena Torres,[4] Giuliano Brunori,[5] Xinling Liang,[6] Li Zuo,[7] Michel Y. Jadoul,[8] Roberto Pecoits-Filho,[2] Jeffrey Perl,[9] Ronald L. Pisoni,[2] Bruce M. Robinson.[2] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University Hospital Infanta Leonor, Madrid, Spain; [4]AURA Nord Saint Ouen, Paris, France; [5]Ospedale S. Chiara, Trento, Italy; [6]Guangdong Provincial People's Hospital, Guangzhou, China; [7]Peking University People's Hospital, Beijing, China; [8]Cliniques Saint-Luc, University of Louvain Medical School, Brussels, Belgium; [9]St. Michael's Hospital, University of Toronto, Toronto, ON, Canada.*

Background: The COVID-19 pandemic caused unprecedented disruption to dialysis patients care globally. Facility surveys were distributed to assess the impact of COVID-19 pandemic on hemodialysis (HD) and peritoneal dialysis (PD) practices.

Methods: Medical Director (MD) and Nurse Manager (NM) Surveys (MDS, NMS) are being distributed in May/June 2020 to 723 clinics enrolled in the Dialysis (in-center HD, DOPPS) or Peritoneal (PDOPPS) Dialysis Outcomes and Practice Patterns Study in Canada, China, Japan, the United States, 7 European countries, 5 Gulf Cooperative Council countries, and China metropolitan areas (Beijing, Guangzhou, Shanghai). Surveys content includes the number of COVID-19 cases, testing, and clinical management, screening, infection control, staffing, patient transportation, and psychological support.

Results: As of 27 May 2020, we have 80 MDS (China, Europe, US = 33, 38, 5) and 101 NMS (45, 46, 9) responses from DOPPS sites. The following percentages are presented sequentially for China, Europe, and US. Among MDs, 0%, 67%, 67% reported at least one confirmed COVID-19 case among dialysis patients, and 85%, 70%, 66% reported being on the late phase of the COVID-19 curve. 40%, 23%, 100% of MDs were more likely to recommend home dialysis; 19%, 5%, 29% reported an increase in missed dialysis treatments; 30%, 24%, 50% were more likely to prescribe potassium binders; and 75%, 68%, 43% had greater challenges obtaining vascular access interventions. Among NMs, 30%, 9%, 40% reported current limitations in access to COVID-19 testing; and 61%, 51%, 29% reported having, or risk of, shortage in staffing.

Conclusions: Early results indicate many clinics in Europe and US have had COVID-19 cases, but sites in the three DOPPS-China cities have avoided COVID-19 to date. In all regions, shortages of human and medical resources were common, as were changes to dialysis delivery/practice including more skipped sessions, greater use of potassium binders, and preferentially recommending home dialysis. Over the next month, we expect hundreds more responses, and will compare approaches in PD and HD clinics. These data will inform guidance for dialysis care as the COVID-19 pandemic ensues.

Funding: NIDDK Support, Commercial Support - Support for the DOPPS Program (including CKDopps, DOPPS, and PDOPPS) is provided by Amgen (founding sponsor, since 1996), Kyowa Kirin Co. (since 1999, in Japan), and Baxter Healthcare (since 2011). Additional support is provided for specific projects and/or countries by Akebia Therapeutics, AstraZeneca, Bard Peripheral Vascular, Bayer Yakuhin, Chugai Pharmaceutical, DialyzeDirect, Japanese Society for PD, JMS Co., Kidney Research UK, Kidney Foundation Japan, Kissei Pharmaceutical Co., Medice, Nikkiso Co., ONO Pharmaceutical Co., Sanofi-Aventis Deutschland GmbH, Terumo Corporation, Torii Pharmaceutical Co., and Vifor Fresenius Renal Pharma.

PO0729

Factors Associated with SARS-CoV-2 Infection (COVID) Severity and Mortality in Chronic Dialysis Patients

Eduardo K. Lacson,[1,2] Gideon N. Aweh,[1] Vladimir Ladik,[1] Harold J. Manley,[1] Carol Stewart,[1] Doug Johnson.[1] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts University School of Medicine, Boston, MA.*

Background: From 2/17 to 5/29, 2020, Dialysis Clinic Inc. had 422 maintenance dialysis patients diagnosed with COVID from 90 clinics in 20 states. While prognostic factors in the general population have been reported, there is limited information regarding the US dialysis population.

Methods: Over a 15 week period of observation, 96 patients died (22.7%) and 116 (27.5%) were not hospitalized (for up to 30 days post-COVID diagnosis), likely with milder illness. We compiled univariable associations with p<0.1 into stepwise logistic regression models (forcing in age, sex. race) to determine factors associated with 1) Death from COVID; and 2) Moderate/severe illness (hospitalized or died without hospitalization <30 days post-COVID diagnosis).

Results: Candidate variables are listed in the table, with retained significant factors marked (a or b at p<0.05). Notably, 42% of all deaths occurred at age >75 years, increasing to 74% of all deaths at age >65 years. Wheelchair use also associated with higher death risk.

Conclusions: Dialysis patients with low albumin and vintage ≧1 year associated with increased illness severity. It was surprising that a history of pneumonia vaccine associated with more severe illness - whether this reflects "treatment by indication" bias vs. pulmonary immune activation by vaccination vs. chance finding is unclear. PVD also tended to increase illness severity but more importantly, was significantly associated with risk of death, independent of older age.

Each Model Total N=422	COVID Severity		COVID Death	
Model Entry Variables	Mod/Severe (N=306)	Mild Disease (N=116)	Died (N=96)	Alive (N=326)
Mean Age (years)	65.5	64.1	71.1[a]	63.4

Fighting COVID-19: Experience from a Chinese Hemodialysis Center

Qian Zhang, Mengjing Wang, Jing Chen. *Huashan Hospital Fudan University, Shanghai, China.*

Background: COVID-19 has ravaged China and spread throughout the rest of the world. Since there is no effective treatment available at present time, patients with ESRD feel anxious and uncomfortable to come to dialysis center and receive dialysis treatments.

Methods: To help the patients deal with their anxiety without interrupting their treatments, we developed emergency response plans and offered following instructions during the pandemic of COVID-19.

Results: 1) We have immediately adopted a comprehensive epidemiological screening and symptom evaluation for all hemodialysis patients, family members and medical staff. Confirmed and suspected COVID-19 patients will be quarantined in the designated places for 14 days after they are cured and discharged from hospitals. 2) We emphasize scientific education and teach our patients about the scientific evidence-based protection measures. 3) Patients shall wear masks throughout the treatment and avoid gathering and talking. They are trained how to wash hands in the correct way. They are required to wash their hands before entering the hemodialysis center and after returning home. 4) Before entering the hemodialysis center, everyone shall scan the QR code and register his or her health information. Medical staff will screen patients and perform the risk stratifications as seen in **figure 1.** Medical staff will check the patients' temperature before, during and after dialysis treatment. 5) The environmental cleaning and disinfection measures will be strengthened for hemodialysis facility. The spaces between dialysis stations will be increased and the isolation curtains will be installed to keep social distance. Isolation treatment area will be set up to reserve for suspected COVID-19 hemodialysis patients.

Conclusions: Since we adopted above-mentioned instructions, we have zero infection case during the pandemic of COVID-19.

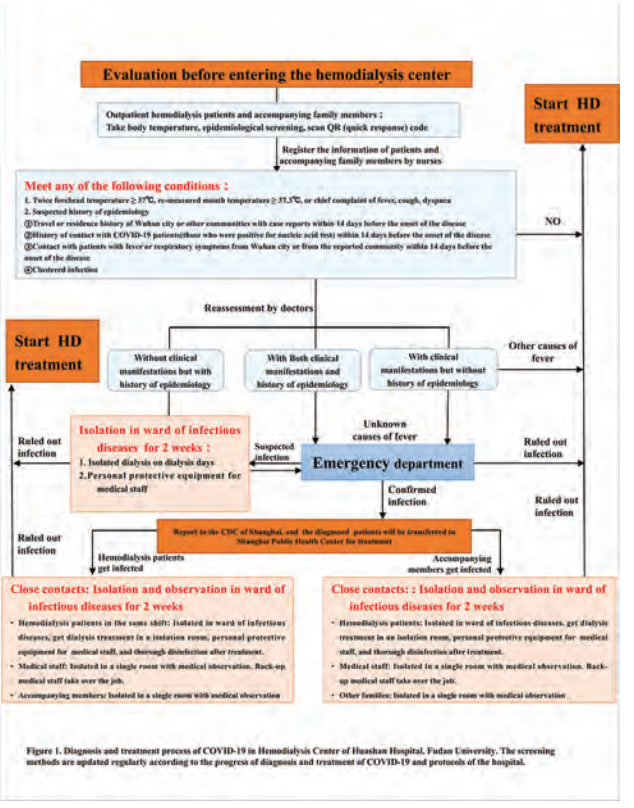

Figure 1. Diagnosis and treatment process of COVID-19 in Hemodialysis Center of Huashan Hospital, Fudan University. The screening methods are updated regularly according to the progress of diagnosis and treatment of COVID-19 and protocols of the hospital.

PO0731

Ferritin and Lymphopaenia as Markers of COVID-19 in a Haemodialysis Population

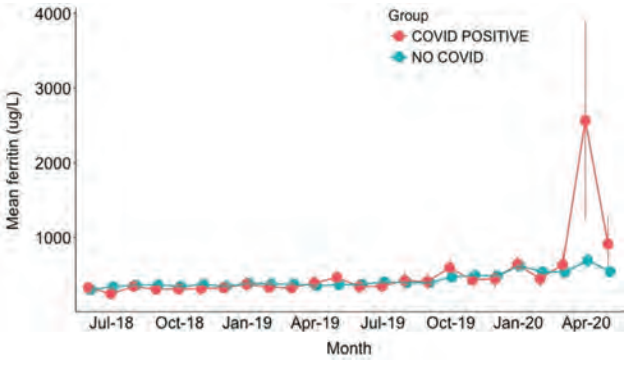
David Makanjuola, Rajit W. Shail, Nicholas I. Cole. *St. Helier hospital, Surrey, United Kingdom.*

Background: The COVID-19 PCR swab test has low sensitivity and some infected people are asymptomatic, which makes it possible for inadvertent spread of the virus to occur. We reviewed laboratory data in haemodialysis (HD) patients to investigate the utility of routine blood tests as surrogate markers of COVID-19 infection.

Methods: Retrospective cohort study of data in prevalent patients on HD from 1st March 2020. Blood test results from June 2018 to May 2020 were analysed.

Results: There were 708 patients. 473 were on HD since June 2018. 150 had ≥1 PCR test for COVID-19: 69 were positive. 268 (37.9%) were female and 282 (39.8%) were of non-white race. Median age was 69 years (IQR 56-78). *Lymphocytes* Mean lymphocyte count at baseline was 1.5 (SD 4.3). Prior to March 2020, the mean monthly prevalence of lymphopaenia was stable at 32 %, but rose to 67 % in COVID +ve patients and 36 % in COVID -ve patients (p<0.001) during the peak of the COVID crisis in April. *Ferritin* Mean monthly ferritin at baseline was 395μg/L. Prior to March 2020, only 3% of patients each month had a ferritin of > 1000μg/L. In April, 68 % of COVID +ve individuals had a ferritin of >1000μg/L compared to 18 % of COVID –ve patients (p<0.001). No significant differences were noted in platelet count, neutrophils and CRP over the study period.

Conclusions: Our data show a high prevalence of lymphopaenia which was more pronounced in COVID +ve patients. There was no similar rise over the previous 2 winter periods, so we feel this was a COVID specific, rather than just a viral phenomenon. A low lymphocyte count has recently been associated with adverse prognosis in our patients with COVID-19. Our data support reports which suggest that ferritin could aid screening for COVID-19 in HD patients. The degree of elevation of ferritin during the 'COVID months' in our COVID +ve group suggests that the disease was contributing to this. This may be due to a cytokine storm and multi-organ involvement and ferritin may prove to be a prognostic factor for COVID-19.



PO0732

Impact of Undertaking Safeguards to Limit Exposure and Prevent COVID-19 Infection in Ambulatory Dialysis: A Single-Center Experience

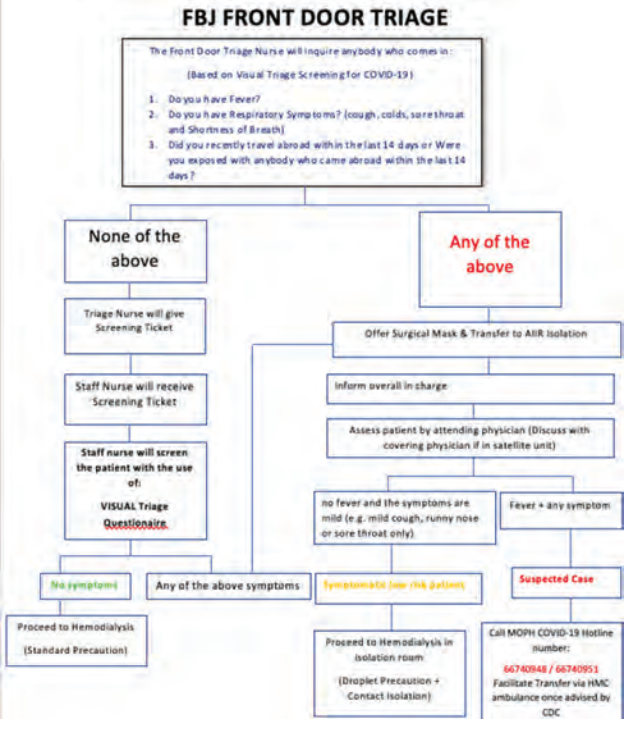
Abdullah I. Hamad, Musab Elgaali, Essa Abuhelaiqa, Mohamad M. Alkadi, Muftah Othman, Mohamed A. Elesnawi, Tarek A. Ghonimi, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar*.

Background: Dialysis patients are considered at high risk to develop serious COVID19 complications. Taking extreme measures are necessary to prevent COVID19 transmission at the dialysis center. We are presenting outcomes of our COVID19 prevention project from our largest dialysis center in Qatar.

Methods: Our project was done at FBJKC (largest dialysis center in Qatar with about 60% of all hemodialysis (HD) and 90% of all peritoneal dialysis (PD) patients in Qatar)) between March 1st and May 25th 2020. We gradually implemented a bundle of measures and algorithm (attached) to properly triage and limit COVID19 exposure inside the center. New infection control protocol with specifications to COVID19 were implemented, including a new policy for reusing N95 masks in high risk areas. We tracked number of patients and staff who were infected during that period and source of infection.

Results: Our dialysis census during that period was 480 HD and 170 PD patients. Only 6 HD patients turned positive for COVID19 (0.9%) and 2 PD patients (1.2%) (compared to 1.3% general population in Qatar by May 25th). We had 3 dialysis staff infected out of 114 (2.6%). Our investigation showed that all cases of COVID19 (both in patients and staff) were likely contracted outside the center. All staff and patients exposed to positive cases of COVID19 inside the center turned out negative. Our infection control classified most exposures at low risk, especially after we fully implemented our precautions.

Conclusions: Preventive actions implemented inside a large dialysis center led to prevention of COVID19 transmission. Increase positive COVID19 cases (in staff and patients) were related to countrywide growth of infection.



PO0733

Outcomes of COVID-19 in ESRD Patients on Hemodialysis

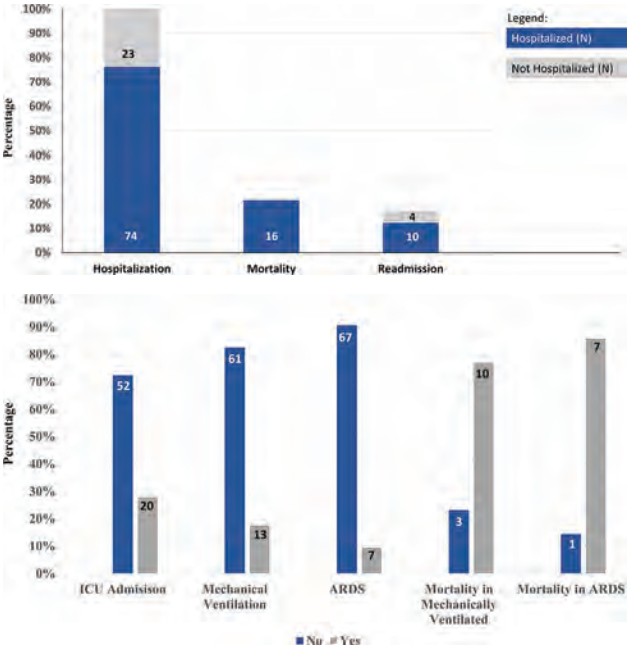
Chantale Daifi, Junior Uduman, Jerry Yee. *Henry Ford Health System, Detroit, MI.*

Background: The presentation, natural course, outcomes, and markers of COVID-19 among end stage renal disease (ESRD) have not been well defined. The objective of this study is to evaluate the outcomes of COVID-19 hospitalized and nonhospitalized outpatient ESRD patients. The secondary objectives are to evaluate mortality rate, hospital readmission rates, treatment methods, lengths of hospital stay, mechanical ventilation requirement, and acute respiratory distress syndrome (ARDS) between hospitalized and non-hospitalized patients.

Methods: This is a prospective, observational study evaluating the outcomes of hemodialysis patients who test positive for COVID-19 between March 10 to May 8, 2020 at a large regional health system in Southeast Michigan. Incenter hemodialysis patients, 18 years or older who tested positive for COVID-19 were included. Descriptive statistics are used, and continuous variables are presented as medians with interquartile ranges, and categorical variables are presented as percentages. Two-sided t-tests were used for exploratory analysis.

Results: 97 of 192 patients tested positive for SARS-CoV-2. Hospitalization rate among COVID-19 positive patients were 76.3%. The most common presenting symptom was fever (63%). Overall mortality and readmission were 16.5% and 14.4%. Median length of hospital and intensive care unit stay was 7.6 and 8 days. Of the hospitalized patients, 17.6% required mechanical ventilation, and 53.9% developed ARDS, with a mortality of 85.7% in this group of patients. Leucopenia, C-reactive protein, peak ferritin and D-dimer corelated with mortality among hospitalized patients.

Conclusions: ESRD pose a higher risk for hospitalization, overall mortality was acceptable, although survival among patients requiring mechanical ventilation was low.



PO0734

Outcomes of ESKD Patients Hospitalized with COVID-19

Jia Hwei Ng, Jamie S. Hirsch, Rimda Wanchoo, Mala Sachdeva, Susana Hong, Vipulbhai Sakhiya, Kenar D. Jhaveri, Steven Fishbane. on Behalf of Northwell Nephrology Covid-19 Research Consortium *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: Patients with ESKD have a dysregulated immune system and a higher annual mortality rate compared with the general population. We aimed to describe the clinical characteristics and compare the outcomes of patients with and without ESKD, among those hospitalized with COVID-19 disease.

Methods: We reviewed the health records for all patients hospitalized with Covid-19 between March 1, 2020 and April 27, 2020 from 13 hospitals in New York. Patients < 18 years or admitted to inpatient obstetrics service were excluded. ESKD diagnosis was defined using ICD-10 code and manual adjudication. Patients were followed up through May 27, 2020.

Results: Of 10,482 patients admitted with COVID-19, 419 (4.0%) had ESKD. Among patients with ESKD, 408 (97.4%) were on hemodialysis and 11 (2.6%) were on peritoneal dialysis. When comparing baseline characteristics of the two groups, patients with ESKD were older, were predominately of Black race, and had greater proportions of comorbid conditions. The primary outcome was that patients with ESKD had a higher odds of in-hospital death than those without ESKD (rates, 31.7% vs 25.4%; OR 1.4, 95% CI 1.1 - 1.7). After adjusting for age, sex, race/ethnicity, the odds of

in-hospital death remained higher in the ESKD group (adjusted OR 1.5, 95% CI 1.2 - 1.8). The ESKD group did not have a significantly higher odds of needing mechanical ventilation than the non-ESKD group in both the crude analysis and after adjustment for age, sex, race/ ethnicity. The odds of having a length of stay of >7 days was higher in the ESKD group compared to the non-ESKD group, in both the crude analysis and the adjusted analysis (OR 1.62, 95% CI 1.3 - 2.1; adjusted OR 1.6, 95% CI 1.3 - 2.1). The independent predictors for death for non ESKD patients were age, male gender, cancer, CHF, elevated BUN, low albumin and being on a ventilator. The independent predictors of death for ESKD patients were age, lymphopenia, low albumin and being on a ventilator. Black race was associated with lower risk of death..

Conclusions: ESKD patients had a higher rate of mortality compared to non-ESKD patients hospitalized with COVID-19. Black race was associated with a lower risk of death among ESKD patients compared to white patients.

PO0735

Outcome of Hospitalized ESRD-COVID-19 (C19) Infected Patients

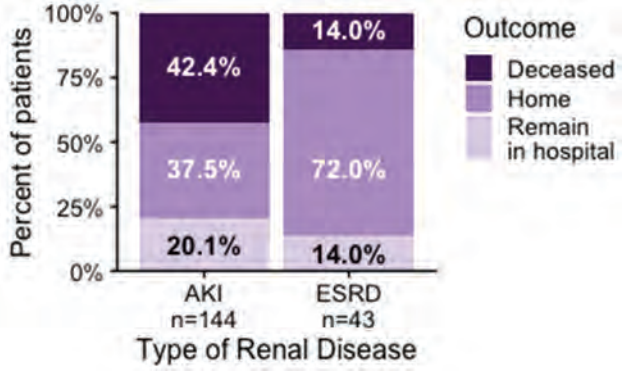
Jose E. Navarrete, Darya Hosein, Harold A. Franch, Frederic F. Rahbari-Oskoui, Michael J. Connor, Janice P. Lea. *Emory University, Atlanta, GA.*

Background: Emory University affiliated hospitals serve the metro Atlanta area, where a significant number of C19 cases have ocurred. In this report we describe the outcomes of AKI and ESRD patients with confirmed C19 admitted to our health-system.

Methods: All patients seen by Emory Nephrology at 2 tertiary referral and one county hospital were categorized as **ESRD** if they required dialysis prior to C19 infection, or **AKI** if they developed acute kidney injury as a result of C19 infection. Outcomes of interest included patient survival and discharge from the hospital. Admission to Intensive care unit and use of mechanical ventilation were recorded. Comorbid conditions and outpatient use of medications were analyzed.

Results: From 3/1/20 to 5/26/20, 474 consecutive patients were seen in COVID-19 related consultation. 287 patients were considered PUI and eventually tested negative for C19. The remaining 187 patients were C19 positive by nasopharyngeal swab or tracheal aspirate and represent the study population for this report. There were 43 ESRD (23%) and 144 AKI (77%) patients. Age (64 vs 63 years), gender (63 vs 66% males) ethnicity (86 vs 82% African-americans) and comorbid conditions were similar in AKI and ESRD patients. AKI patients were more likely to be admitted to ICU (83 vs 35%) and to require mechanical ventilation (73 vs 20%) compared to ESRD patients ($p<0.05$). Figure 1 presents the outcomes based on the type of renal disease at presentation. The eGFR of AKI patients at time of admission was 50±34 ml/kg/m^2. 84 AKI patients required dialysis during their hospitalization (52.5%).

Conclusions: Patients with ESRD C19+ were less likely to require ICU admission or mechanical ventilation. Mortality of ESRD patients was 14% compared with 42% of AKI patients, ($p<0.002$). ESRD patients with C19 were also more likely to be discharged from the hospital compared to those with AKI. Despite similar demographics and co-morbidities, hospitalized C19 AKI patients had worse mortality than those receiving chronic dialysis.



PO0736

Non-Hospitalized Maintenance Hemodialysis Patients with COVID-19 Have Elevated Inflammatory Markers

Akhil Hegde,[1] Jennifer E. Flythe,[1] Cynthia J. Denu-Ciocca,[1] Kawan A. Swain,[1] Raven A. Voora,[1] Heather J. Ansede,[2] Gerald A. Hladik,[1] Peter Kotanko,[2] Prabir Roy-Chaudhury,[1] Abhijit V. Kshirsagar.[1] *[1]UNC Kidney Center, Chapel Hill, NC; [2]Renal Research Institute, New York, NY.*

Background: In addition to an aggressive pneumonia, patients hospitalized with COVID-19 have marked inflammatory and hypercoagulable states, with downstream cardiovascular and thrombotic events. Hemodialysis patients have baseline increases in inflammation and hypercoagulability. However, to our knowledge, little is known about the level of inflammation and hypercoagulability among non-hospitalized in-center hemodialysis patients with COVID-19. We collected inflammatory and coagulation markers among hemodialysis patients with COVID-19 who were managed as outpatients.

Methods: Patients in our dialysis program with one positive nasopharyngeal swab PCR for SARS-CoV-2 were consecutively admitted to an outpatient COVID-19 hemodialysis shift. While receiving their usual dialysis prescription, the patients also had weekly measurements of D-Dimer, Fibrinogen, C-reactive protein (CRP), and Serum Ferritin, until they tested negative x 2 for SARS-CoV-2.

Results: 16 consecutive patients were admitted to the COVID-19 isolation shift over 30 days. Their average age was 60 yr, 56% were Black, 25% Hispanic, and 44% female. Causes of ESKD included diabetes (75%), glomerular diseases (19%), and hypertension (6%). No patients received intravenous iron supplementation while on the isolation shift. Table 1 displays the inflammatory marker levels in this group. Note, the 4-fold (D-Dimer), 6-fold (Ferritin) and 21-fold (CRP) increase in these biomarkers from normal levels.

Conclusions: Our initial, unique data show an increase in inflammatory markers in a cohort of non-hospitalized COVID-19 hemodialysis patients. Such an increase may be from the pro-inflammatory impact of COVID-19 in a group with pre-existing high levels of inflammation from uremia and oxidative stress. Additional investigation as to whether these elevated markers associate with cardiovascular and thrombotic events (dialysis circuit and vascular access clotting, sudden cardiac death) is needed.

Funding: NIDDK Support, Clinical Revenue Support

Inflammatory Markers among Non-Hospitalized HD Patients with COVID-19

	Mean ± S.D.	Observed Range	Normal Range(non-ESKD)
D-Dimer mcg/mL	2.0±1.0	0.4 - >4.0	0.0-0.5
Fibrinogen mg/dL	527.4±122.7	273-960	217-480
C-reactive protein mg/L	50.4±54.4	0.9-477	0.0-2.4
Serum Ferritin ng/mL	1954.6±1697.0	419-11066	22-322

PO0737

Network Analysis of In-Center Spread of COVID-19: A Single Dialysis Center Experience

Lemuel Rivera Fuentes,[1] Hanjie Zhang,[1] Alhaji Cherif,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The need to continue in-center hemodialysis (HD) during COVID-19 pandemic presents a risk of transmission for patients and staff members. The present study aimed to determine if the periodic interactions among patients and staff resulted in spread of COVID-19 in a HD center during a period of 2 months

Methods: This is a retrospective analysis on a HD center in New York City (172 patients, 32 staff members, 26 chairs, MWF and TTS schedules, and 4 shifts/day). From March 2nd to April 24th we recorded every HD treatment (chair, patient, and staff member involved in care). We kept dated records for positive COVID-19 cases (patients and staff). To estimate the patient-to-patient interaction, we obtained the location coordinates of each dialysis chair, calculated the Euclidian distance between them and weighted the interaction by proximity between chairs. We conducted network analysis to assess these interactions

Results: During the study period, 16 patients and 2 staff members became COVID-19 positive. As shown in Figure 1(a), there were 3 chairs (2, 24, and 25) that had more than 1 positive patient. Clusters in chairs 2 and 25 were ruled out based on a lack of direct contact between the involved patients (at least 2 shifts separating them at all times; no in-between patients became positive); chair 2 had a nonviable temporal direction of transmission. Based on schedule, shift, and a 14-day incubation period, the cluster in chair 24 was dismissed. This was corroborated by network analysis [Fig. 1(b)] where the purple dots represent the COVID-19 positive patients, the blue dots represent negative patients (same shift/schedule), and the edges represent the weighted patient-to-patient interaction. We reasoned that more exposed patients would have had a higher chance of becoming infected. Similar information was found for staff-to-patient interaction

Conclusions: Based on our analysis we consider that for patient-to-patient, staff-to-patient, and staff-to-staff interactions, in-center spread of COVID-19 was unlikely

Funding: Private Foundation Support

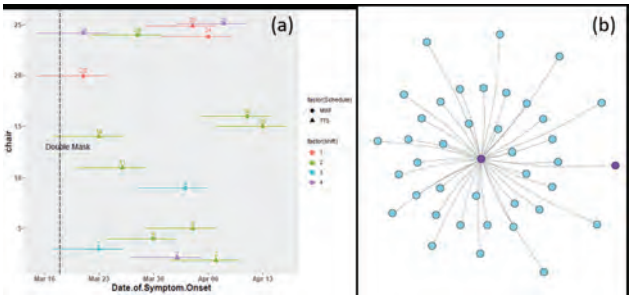


Figure 1(a)infection history;(b)network analysis patient interaction

PO0738

Outcomes of Patients on Chronic Dialysis Hospitalized with COVID-19

Lili Chan, Suraj K. Jaladanki, Lewis Kaufman, Shuchita Sharma, Staci A. Leisman, John C. He, Barbara T. Murphy, Steven G. Coca, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Preliminary reports find that patients with end stage renal disease (ESRD) on dialysis who test positive for SARS-CoV-2 have fewer symptoms and require less intensive care than expected. However, there are no reports regarding the outcomes of ESRD patients who are hospitalized with coronavirus disease 2019 (COVID-19).

Methods: This is a retrospective observational study of patients aged ≥18 years with laboratory confirmed COVID-19 admitted to the Mount Sinai Health System between February 27 and May 20, 2020. ESRD patients were identified by International Classification of Disease codes for ESRD. ESRD patients were propensity matched (5:1) to non-ESRD patients by age, gender, race/ethnicity, comorbidities, body mass index, and facility and week of hospital admission. Multivariate analysis was performed to test the association of ESRD with mortality after adjustment for age, diabetes, hypertension, stroke, coronary artery disease, and congestive heart failure.

Results: 122 ESRD patients were admitted during the study period and matched to 610 non-ESRD patients from the same study period. Patients with ESRD were well matched on age, sex, race/ethnicity and most comorbidities except ESRD patients had a higher prevalence of diabetes (55% vs 43%, P=0.02) and hypertension (66% vs. 55%, P=0.03). ESRD patients had higher inflammatory markers of ferritin and procalcitonin. There was no significant differences in d-dimer, fibrinogen, C reactive protein, or interleukin-6 (Figure 1A). ESRD patients were significantly less likely to receive mechanical ventilation (3% vs. 10%, P=0.01) or be admitted to the intensive care unit (9% vs. 21%), and had similar in-hospital mortality (9% vs 13%, P=0.5). ESRD status was associated with lower odds of intubation and intensive care admission, but not significantly associated with mortality after adjustments for age and comorbidities (Figure 1B).

Conclusions: While ESRD patients had higher prevalence of comorbidities and higher inflammatory markers, they had similar in-hospital mortality as matched non-ESRD patients.

Figure 1A: Boxplot for maximum inflammatory markers between ESRD and non-ESRD patients

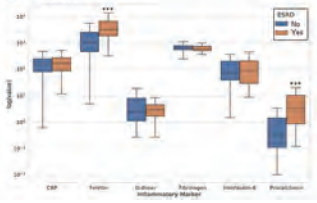

Figure 1B: Forest Plot for association of ESRD with intubation, ICU admission, and in-hospital mortality*

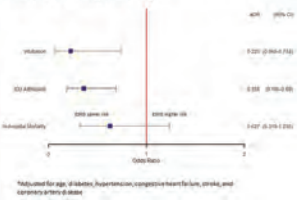

PO0739

Outpatient Hemodialysis Unit Preparedness During COVID-19 Pandemic in Several Dialysis Units in New York State

Errol Carter, Duarxy R. Sainvilien, Ibrahim A. Mohamed, Jamrose K. Durrani, John D. Wagner, Angelika C. Gruessner, Subodh J. Saggi. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: HD units are clustered close contact environments where prolonged and repeated exposure to blood borne pathogens occurs. Weeks into the CoVID-19 pandemic, wide disparities in rates of death and exposure of staff and patients amongst HD units in the same zip code of an epicenter in New York regions emerged.

Methods: Random HD units surveyed as to when and what infection control measures they implemented. Direct input into RedCap and SAS 9.0 analysis of the data conducted.

Results: 15 HD units (average census 18-240) responded. Survey compiled exposure rates from 3/1/20 - 4/30/20. The 1st reported case of CoVID-19 by a facility was 3/2/20. Most facilities reported outbreaks (4-30 cases per facility) by 3/21/20. Missed HD sessions due to CoVID varied from 2-100, hospital stays for such patients varied from 2-20 days and death rates from 0-15 per facility. 4 of 15 facilities reported deaths of family members of exposed patients and impediments in logistics of single person transportation forcing carpooling. Home dialysis programs reported minimal deaths and exposures. 20% of facilities had no infection preventionist and 26% no patient educator. Reported waiting area cleaning and hand sanitizer refill rates ranged from 1-5 times per day. 20% of the facilities have < 6 feet distance between patients. Implementation of infection control practices such as wearing of masks by patients varied widely amongst units. Some started March 1st-March 16th, some later due to mixed messages of its importance. Lack of personal protective equipment (PPE)(in 13% of facilities), staff, and housekeeping shortages (6.7-13.3%) compounded the problems. Positive CoVID results had 1-10 staff members infected per facility with sick call rates from 7-30 days, and no staff death. 46% of the HD units don't belong to the CDC coalition.

Conclusions: Maintenance of strict hand hygiene, proper air flow, repeated environmental surface cleansing, availability of PPE, and patient and staff education remain the corner stone in preventing infections from spreading. Lack of leadership support and failing to share best practices between dialysis units in the US remains prohibitive but must be encouraged and standardized.

PO0740

Outpatient Initiation of Dialysis for AKI Requiring Dialysis Following Diagnosis of COVID-19

Kristine Kubisiak, Lorien S. Dalrymple, Norma J. Ofsthun, Yuping Sun, Franklin W. Maddux, Robert J. Kossmann, Jeffrey L. Hymes. *Fresenius Medical Care, Waltham, MA.*

Background: COVID-19 has been associated with the development of AKI, and the incidence of AKI-D may be as high as 3-5% in patients hospitalized with COVID-19. We examined the initiation of outpatient (OP) dialysis for AKI-D following a diagnosis of COVID-19.

Methods: We identified patients who were diagnosed with COVID-19 prior to initiating OP dialysis for AKI-D in a Fresenius Medical Care North America (FMCNA) dialysis facility between March 30, 2020 and May 22, 2020. COVID-19 diagnosis was based on information provided at the time of referral or data collected within FMCNA. We assessed demographics, geographic location, and select initial outpatient lab values. We followed patients from initiation of OP dialysis until the earliest of recovery of kidney function, transition to ESKD, death, loss to follow-up (typically, transfer to another dialysis provider), or May 24, 2020, and estimated the cumulative incidence of these outcomes.

Results: The cohort comprised 127 patients who were diagnosed with COVID-19 prior to initiating OP dialysis for AKI-D. Mean age was 56.3 ± 14.7 years and 64% were male. Initiation of OP dialysis for AKI-D was observed in regions with a known high incidence of COVID-19 disease (Figure). The median hemoglobin, platelet count and albumin at dialysis initiation were 8.9 g/dL, 271,000 per microliter, and 3.2 g/dL, respectively. During a median follow-up period of 19 days, 18 (14.2%) patients recovered kidney function, 2 (1.6%) transitioned to ESKD, and 2 (1.6%) died.

Conclusions: In an approximate 7-week period, 127 adults started OP dialysis for AKI-D following a diagnosis of COVID-19. Unfortunately, information regarding the clinical course of COVID-19 preceding OP initiation of dialysis was not available and using information at the time of referral may have resulted in misclassification of COVID-19 disease. Nevertheless, these are important findings and warrant further study, especially with respect to long-term outcomes in this population.

PO0741

Impact of the COVID-19 Pandemic on In-Center Intermittent Hemodialysis Treatment Adherence

Jasmeet Gill,[1] Stevan A. Gonzalez,[2] Michael R. Wiederkehr,[3] Harold M. Szerlip,[1] Richard C. Fuquay.[3] *[1]Baylor University Medical Center at Dallas, Dallas, TX; [2]Baylor Simmons Transplant Institute, Fortworth, TX; [3]Dallas nephrology associates, Dallas, TX.*

Background: Studies have shown that 7.9% of patients miss one to two hemodialysis session per month and 35% miss hemodialysis at least once every three months.[1] During current COVID-19 pandemic there has been a decrease in utilization of emergency medical services due to fear of contagion. We hypothesized that patients undergoing in-center hemodialysis might have increased compliance with their dialysis prescription to avoid emergency department visits or hospitalizations. We therefore evaluated the effects of the COVID-19 pandemic on patient adherence to their dialysis prescription.

Methods: This is a retrospective analysis of in-center hemodialysis patients treated in the seven American Renal Associates (ARA) dialysis facilities in Dallas, Texas. COVID-19 was declared a pandemic on March 11, 2020 and pandemic related changes were mandated in ARA hemodialysis facilities on March 13, 2020. We used existing clinical data and examined patient compliance with their dialysis prescription between January 1 to March 14, 2020 (pre-COVID) and March 15 to May 18, 2020 (COVID).

Results: The study enrolled 754 eligible patients. Significantly fewer patients missed a single treatment in the COVID vs pre-COVID periods (35.5% vs 49.9%; p<0.001). The percentage of patients who were hospitalized was lower during COVID vs pre-COVID (12.5% vs. 19.6%; p<0.001). The percentage of patients who shortened hemodialysis time was lower during COVID vs pre-COVID (36.2% vs. 40.9%; p=0.06) although not statistically significant. Finally, significantly more patients achieved a weight within1 kg of their estimated dry weight at the end of the dialysis sessions COVID vs. pre-COVID (28.5% vs. 34.5%, p=0.01).

Conclusions: These data suggest that during current COVID-19 pandemic, hemodialysis patients have become more adherent to their dialysis prescription. Retrospective studies have suggested that patients are avoiding seeking medical care due to fear of contacting the SARS-CoV-2 virus[1]. Our data suggest that similarly, hemodialysis patients have significantly increased their adherence to hemodialysis prescription in order to avoid hospital visits. Additional studies are ongoing to determine the causes for the observed improved compliance.

PO0742

Accuracy of Lower Temperature Thresholds in Detecting COVID-19 in Hemodialysis Patients

Remi Goupil,[1] Annie-Claire Nadeau-Fredette,[2] William Beaubien-Souligny,[3] Francois Madore,[1] Rita Suri.[4] for the Réseau Rénal Québécois *[1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [2]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [3]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [4]McGill University, Montreal, QC, Canada*.

Background: Patients receiving in-center hemodialysis (HD) are uniquely vulnerable to COVID-19 yet identifying infected individuals may be challenging. They may not present with typical symptoms and low basal body temperature may impair detection of fever. We studied the accuracy of temperature thresholds in detecting COVID-19 in HD patients.

Methods: We retrospectively studied all patients between March 24-May 14, 2020 from a single HD unit (Hôpital du Sacré-Coeur) in Montreal, Canada, where COVID-19 is highly prevalent. All patients who presented with symptoms or contact exposure were tested by nasopharyngeal swab. Prompted by an outbreak, systematic testing of all HD patients was started on April 18th. Basal temperature was defined as the average pre-dialysis temperature from weeks -1 to -3 before testing. Diagnostic performance was determined for various temperature thresholds defined *a priori*.

Results: Of 205 in-center HD patients, 34 developed COVID-19 during the study period. Of these, 21 (61%) were hospitalised, 4 (11%) required intensive care and 9 (26%) died. Baseline characteristics are presented in Table 1. Less than a third had typical symptoms. Thresholds of ≥ 37.3 °C and "basal temperature +0.5 °C" had similar moderate sensitivity and high specificity in predicting COVID-19 (Table 2). Combining symptoms and either of these thresholds improved sensitivity to 85%.

Conclusions: Less than one third of HD patients have typical symptoms of COVID-19 or fever >38.0°C. Pre-dialysis temperature >37.3°C or 0.5°C above basal temperature markedly improves sensitivity for detection of COVID-19 in asymptomatic HD patients. A screening strategy combining symptom questionnaires and pre-dialysis temperature monitoring should be used in HD units in regions of high COVID-19 prevalence.

Table 1: Baseline characteristics in HD patients without and with COVID-19

Characteristics	COVID-19 negative (n=171)	COVID-19 positive (n=34)	p-value
Male sex	59%	56%	0.7
Age	71 (60, 81)	76 (68, 85)	0.03
Black race	20%	38%	0.02
Living in long-term care facilities	11%	32%	0.001
Primary kidney disease			0.5
Diabetic	47%	32%	
Hypertensive	22%	47%	
Glomerulonephritis	14%	9%	
Diabetes	54%	47%	0.4
Ischemic heart disease	37%	32%	0.6
Heart failure	9%	24%	0.01
Indication for screening			<0.001
Symptoms without fever	2%	24%	
Fever (at home, or >37.5 in HD)	1%	47%	
Contact with positive case	4%	9%	
Systematic screening	94%	21%	
Temperature at screening (°C)	36.5 (36.3, 37.0)	37.5 (37.0, 38.0)	<0.001
Basal temperature (°C)	36.5 (36.3, 36.7)	36.6 (36.4, 36.9)	0.1
Change from basal (°C)	0.1 (-0.3, 0.5)	0.9 (0.3, 1.5)	<0.001
Above 37 °C	28%	77%	<0.001
Above 37.3 °C	8%	65%	<0.001
Above 37.5 °C	4%	59%	<0.001
Above 38 °C	0%	27%	<0.001
Above basal	56%	87%	0.001
Above basal + 0.5 °C	25%	70%	<0.001
Above basal + 1 °C	1%	43%	<0.001

Presented as Percent and median (25th-75th percentiles)

Table 2: Diagnostic performance of various thresholds

Pre-dialysis temperature	Sensitivity	Specificity	Positive predictive value	Negative predictive value	Positive likelihood ratio	Negative likelihood ratio
Above 37 °C	77%	72%	35%	94%	2.7	0.33
Above 37.3 °C	65%	92%	61%	93%	7.9	0.38
Above 37.5 °C	59%	96%	74%	92%	14.3	0.43
Above 38 °C	27%	100%	100%	87%	∞	0
Above basal + 0.5 °C	70%	93%	33%	93%	10.7	0.32
Above basal + 1 °C	43%	91%	93%	91%	4.7	0.62

PO0743

Assessment of a Laboratory-Based SARS-CoV-2 Antibody Test Among Hemodialysis Patients: A Quality Improvement Initiative

Dena E. Cohen,[1] Gilbert Marlowe,[1] Gabriel Contreras,[2] Marie A. Sosa,[2] Jair Munoz Mendoza,[2] Oliver Lenz,[2] Zain Mithani,[2] Jorge L. Posada,[3] Julio A. Fernandez-Bombino,[4] Luis Garcia-Mayol,[3] Michael T. Lemont,[5] Anne Marie V. Miles,[5] Steven Zeig,[6] Pura M. Teixeiro,[2] Nery Queija,[2] Jean S. Jeanty,[2] Katie Swanzy,[7] Misha J. Palecek,[7] Mahesh Krishnan,[7] Jeffrey A. Giullian,[7] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]University of Miami, Coral Gables, FL; [3]Kendall Regional Medical Center, Miami, FL; [4]Hialeah Hospital, Hialeah, FL; [5]Kidney and Hypertension Specialists, Miami, FL; [6]Memorial Healthcare System, Hollywood, FL; [7]DaVita Inc, Denver, CO*.

Background: The coronavirus disease 2019 (COVID-19) pandemic is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection. Assessment of newly developed anti-SARS-CoV-2 antibody tests in hemodialysis patients is needed.

Methods: As part of a quality improvement (QI) initiative, nasopharyngeal swabs and predialysis blood samples were collected on the same day from adults receiving routine dialysis care at clinics managed by a large dialysis organization in the Miami, Florida, region (April 23-30, 2020). Polymerase chain reaction (PCR) tests for SARS-CoV-2 (Fulgent Genetics, Temple City, California) and chemiluminescence immunoassays (Diazyme Laboratories, Inc, Poway, California) were performed according to manufacturer protocols. For antibody tests (IgM and IgG), a reading of >1 arbitrary unit/mL was scored as positive.

Results: Of 715 participants in the QI initiative, 38 had symptoms consistent with COVID-19 prior to or during the initiative. Among these, COVID-19 was confirmed in 14 and ruled out in 20, with 4 being inconclusive. Among the 34 patients with known COVID-19 status, the sensitivity and specificity of the antibody test were 57.1% and 85.0%, respectively, when both IgM and IgG were considered. The remaining 677 patients had no record of symptoms consistent with COVID-19 or any known exposure. Of these, 38 (5.6%) tested positive for anti-SARS-CoV-2 antibodies; none of the antibody-positive patients with available PCR results (N=33) tested positive for SARS-CoV-2.

Conclusions: The operational characteristics of the laboratory-based antibody test make it sufficient to rule in, but not rule out, SARS-CoV-2 infection in the appropriate clinical circumstance. A substantial proportion of dialysis patients may have had asymptomatic SARS-CoV-2 infection.

PO0744

Clinical and Psychosocial Impact in Mexican Hemodiafiltration Population During the COVID-19 Pandemic, Twice Weekly Sessions: Is This Safe?

Jose S. Lopez Gil, Hector Alejandro P. Garza, Magdalena Madero, Daniela Xavier. Division of Nephrology *Instituto Nacional de Cardiologia Dr Ignacio Chavez, Mexico City, Mexico*.

Background: There is evidence that in patients with residual kidney function (RKF) could benefit switch thrice to twice weekly sessions. In patients without RKF, the evidence is limited. We evaluate the clinical and psychosocial impact of the Covid-19 pandemic in Mexico City.

Methods: At the beginning of the Covid-19 pandemic, the on-line posdilutional hemodiafiltration (OL-HDF) sessions were adjusted from 3 to 2 times per week. 2 months later, we determine hemoglobin, urea, serum creatinine, sodium, potassium, calcium, phosphate, albumin, ferritin and C reactive protein. Likewise psychological evaluation using Hamilton test were carried out and characteristic of sessions were collected. We divide in two groups according to thrice versus twice weekly schedule

Results: 25 patients were evaluated, 16 (64%) were female, mean age was 42.04±18.02 years, 21 (84%) did not have RKF. The length session between thrice vs twice were 181.74± 9.94 vs 196 ± 9.19 **(p<0.001)**. When we analyzed the anuric patients we found a significant difference in post-session systolic and diastolic blood pressure when compared between groups **(p = 0.014).** We did not find difference in dry weight **(p = 0.5)**. We found significance difference between total substitution volume between groups (24.43±10.9 L vs 26.5± 12.48 L, **p =0.042**) and no difference in Kt/V (1.67 ± 0.25 VS 1.73 ± 0.34, p = 0.35). We found significance difference between groups in serum creatinine (8.68±3.55 vs 10.04±2.94, **p=0.03**) in the rest of molecules we did not find difference. 32 and 44% of the patients developed depression and anxiety, respectively. 36% of patients lost their jobs and 80% use public transport. There was a moderate correlation between anxiety episodes and economic limitation due to Covid-19 (**r = 0.40 p = 0.04**). There was no significant inverse correlation between pharmacological adherence and economic limitation (r = -0.29 p = 0.29).

Conclusions: Change of the schedule in patients without RFK did not show significant differences in terms of biochemical parameters, on the other hand, improvement in replacement volumes. We considered a safe strategy to reduce the risk of transmission among our population. Pharmacological and attending adherence to sessions was not modified despite the psychological findings due to the Covid-19 pandemic.

PO0745

Clotting of Hemodialysis Catheters in Patients with Renal Failure with COVID-19

Mary C. Mallappallil,[1,2] Jie Ouyang,[1,2] Sabu John,[1,2] John D. Wagner,[1] Mariah W. Thaxton,[1] Ernie Yap,[1,2] Siddhartha D. Bajracharya.[1,2] *[1]Health and hospital corporation New York City - Kings County Hospital, New York, NY; [2]State University of New York at Downstate Medical Center, Brooklyn, NY.*

Background: We are an inner-city hospital in New York that had a surge of patients diagnosed with COVID-19. Many of these patients had acute kidney injury (AKI) and required renal replacement therapy (RRT). NYC Health + Hospitals/Kings County has 40 adult intensive care unit (ICU) beds. ICU capacity expanded to a potential of 150 beds during the COVID-19 surge. The surge included patients transferred from other NY inner-city hospitals for critical care and RRT. Sequential obstacles were faced in providing hemodialysis (HD) to this expanded pool of AKI patients. Additional machines, supplies, staffing and organization were helpful. Clinicians noted that COVID-19 complications included hypercoaguability and we observed an increased frequency of clotting of hemodialysis catheters (HDC).

Methods: We examined the percentage COVID-19 tested renal failure patients with clotting of HDC access during the period March 1, 2020 to May 15, 2020. We collected data on 146 patients during the above period who had HD. We then compared those who were COVID-19+ positive confirmed by testing to those who were not COVID-19+ by testing. HDC clotting was identified by the use of alteplase. We compared our findings of the two groups to historical controls during a similar time period prior to the COVID-19 surge, between January 1 to February 29, 2020.

Results: We had 3,665 admissions between March 1 and May 15, 2020, of which 1,075 patients had a confirmed COVID + test during the admission. Of these, 773 patients were noted to have AKI from diagnosis codes in the electronic medical record. Of the146 patients who needed HD (including patients with AKI and CKD) 97 were COVID-19+ and 49 were negative. HDC clotting identified by the use of alteplase was noted in 27% of those who were COVID-19 + compared to 10% of those who were COVID-19 negative. (P value= 0.02 by Chi-square using SPSS Version 24). The percentage of patients with clotting of catheters in the non-COVID-19 group was comparable to historical controls.

Conclusions: Significantly more COVID-19+ patients had HD catheter clotting compared to non-COVID-19 patients. Increased clotting was noted as a barrier to providing optimal HD therapy. For this and other reasons, we initiated an urgent start acute peritoneal dialysis program to mitigate the challenges in delivering HD to COVID-19 patients.

PO0746

Contingency Planning for COVID-19: Feasibility of Twice Weekly Hemodialysis in a Large Canadian Cohort

David Clark, Kenneth A. West, Karthik K. Tennankore. *Dalhousie University Faculty of Medicine, Halifax, NS, Canada.*

Background: Reducing hemodialysis treatments from three times weekly to twice weekly is a potential strategy to lessen potential exposure/transmission of COVID-19 while allowing hemodialysis units to operate with fixed/reduced resources. As part of contingency planning at a large Canadian center, all facility-based hemodialysis patients were reviewed in advance for candidacy of a reduced "twice weekly" schedule.

Methods: All prevalent patients receiving at least thrice weekly, facility-based hemodialysis - affiliated with the QEII Halifax, Nova Scotia, Canada - were systematically reviewed in a stepwise manner, using accepted criteria for implementing twice weekly hemodialysis (Fig. 1).

Results: Of 473 patients assessed, only 18 (4%) fulfilled criteria for twice weekly hemodialysis (Fig 1.) Of these patients, average age was 63 ± 12 (SD) years, 61% were diabetic, 95% Caucasian; and at least 67% receiving dialysis for 6+ months prior to assessment. 83% of qualifying patients missed 0 treatments in the preceding month, and none missed >1 treatment. Average for serum albumin was 36 ± 4 g/L, Urea reduction ratio, 72.7, and residual urea clearance, 5.7 ± 2.7 mL/min/1.73m^2.

Conclusions: Although feasible, a twice weekly hemodialysis strategy applied to a small proportion of our patient population, potentially reflecting an 'intention to defer' strategy for initiating dialysis.

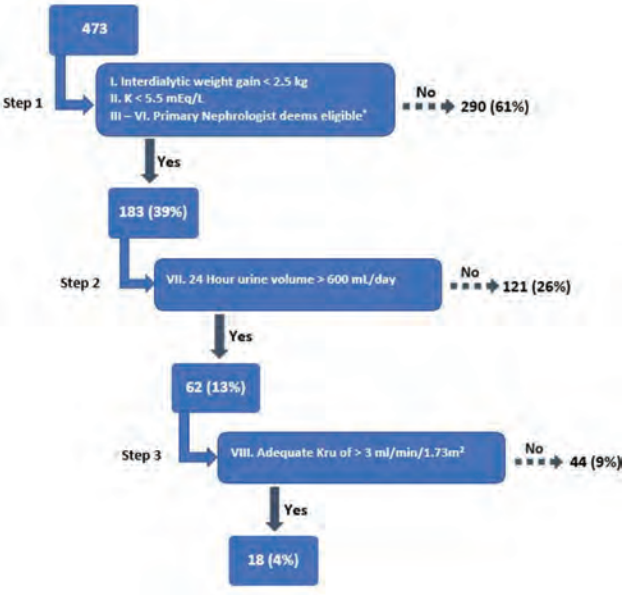

Figure 1. Stepwise approach and selection criteria to review all facility-based hemodialysis patients for candidacy of twice weekly hemodialysis (N=473). *Patients who fulfilled interdialytic fluid gain and serum potassium criteria were assessed by primary nephrologist for eligibility using each of: III. good nutritional status, IV. no clinical evidence of fluid overload, and VI. infrequent hospitalization/easily manageable co-morbid conditions (cardiovascular and pulmonary).

PO0747

Impact of the COVID-19 Pandemic on Virtual Care in Home Dialysis

Martin J. Schreiber, Adam J. Weinstein, Mahesh Krishnan, Brooke Bowlby, Mike Gonzales, Liz Mooney, Michelle Cassin. *DaVita Inc, Denver, CO.*

Background: While almost every provider and the majority of patients in the United States (US) possess the technology needed to conduct a telemedicine visit, prior to the current pandemic utilization in home dialysis was relatively low. The current study examined trends in telehealth utilization before and during the COVID-19 pandemic in US home dialysis patients treated by a large dialysis organization in the US.

Methods: Telehealth was delivered using a proprietary multiparty, video, secure messaging (HIPAA compliant), scheduling, and educational resource telehealth platform DaVita Care Connect™ (DCC™) application. IT systems data were utilized to develop ongoing reports depicting patient, facility, and physician adoption rates across 1750 home dialysis programs. Data were segmented by geographic areas (9) and by time of COVID-19 dissemination within locales.

Results: A meaningful increase in telehealth utilization was observed since the start of the pandemic (prior to March 2020). Among 28,500 home dialysis patients treated, the DCC™ application was installed on 18,300 patient cell phones (65.3%). Overall, 16,000 peritoneal dialysis (PD) patients and 2,200 home hemodialysis (HHD) patients participated in a telehealth visit. Fifteen thousand visits were performed in April 2020. There were 18,000 messages sent between the care team and patient and 6000 educational resources viewed by patients at home since the COVID-19 pandemic (mid-March). The numbers of social worker and dietician visits and interdisciplinary team rounds also increased over time. There was significant variation DCC™ app download and utilization across geographic regions.

Conclusions: The COVID-19 pandemic has dramatically increased the use of telehealth management for home dialysis patients in the US. Examining the impact of virtual visits on patient outcomes going forward will be critical in designing post-COVID care. Balancing the integration of telehealth visits and face-to-face visits to optimize care will necessitate advancing a new care model for patients with end-stage kidney disease.

Abstract Withdrawn

PO0749

Mental Health Status During the COVID-19 Pandemic of Hemodialysis Patients

Ernesto Sabath,[1,2] Edgar Morales-Montes.[1] *[1]Servicios de Salud del Estado de Queretaro, Santiago de Queretaro, Mexico; [2]Universidad Autonoma de Queretaro Facultad de Ciencias Naturales, Queretaro, Mexico.*

Background: Patients receiving hemodialysis (HD) treatment are a particularly vulnerable population as previous studies have shown that they are at higher risk to develop anxiety, depression, and diminished health-related quality of life. During the COVID-19 pandemic patients and health professionals are under insurmountable psychological pressure which may lead to various psychological problems. The aim of this study was to assess the effect of this pandemic on mental health and quality of life in low-income HD patients.

Methods: Observational, cross-sectional study done in low-income HD patients and matched healthy controls from March-April 2020. The survey collected basic demographic and laboratory data. To assess mental status 3 different scales were used: Generalized Anxiety Disorder (GAD-7), Insomnia Severity Index (ISI), and the Kidney Disease Quality of Life (KDQOL-36). An evaluation of media interest was added.

Results: 152 HD patients and 33 control subjects were included. The median age was similar in both groups (HD 51±17 vs 48±10 yrs p=NS). Literacy was significantly higher in the control group. The control group showed significantly higher interest media (p=0.03); 60.5% of HD patients showed none or low emotional impact with this pandemic (42% in control group p=0.02). Severe anxiety was more prevalent in the control group (22.6 vs 0% p= 0.01). The ISI scale showed also significantly higher sleep impairment in control subjects (42.6 vs 20.5% p=0.04). In the HD group, the prevalence of GAD symptoms was higher in females than men (p=0.005), and one of the most influential factors associated with GAD symptoms was to live in a rented home. Patients ≤50 years had significantly higher GAD symptoms (0.01). Unemployed HD patients showed the lowest K-DQOL scores.

Conclusions: HD patients had less emotional impact, lower GAD-7 and ISI scores symptoms than healthy controls. To live in a rented home and unemployment were important risk factors associated with a higher prevalence of anxiety and sleep disorders.

PO0750

Monitoring Trends of COVID-19 Among ESKD Patients in a Large Dialysis Organization

Kristine Kubisiak,[1] Eric D. Weinhandl,[1,2] Norma J. Ofsthun,[1] Jeffrey L. Hymes,[1] Robert J. Kossmann,[1] Lorien S. Dalrymple.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Chronic Disease Research Group, Minneapolis, MN.*

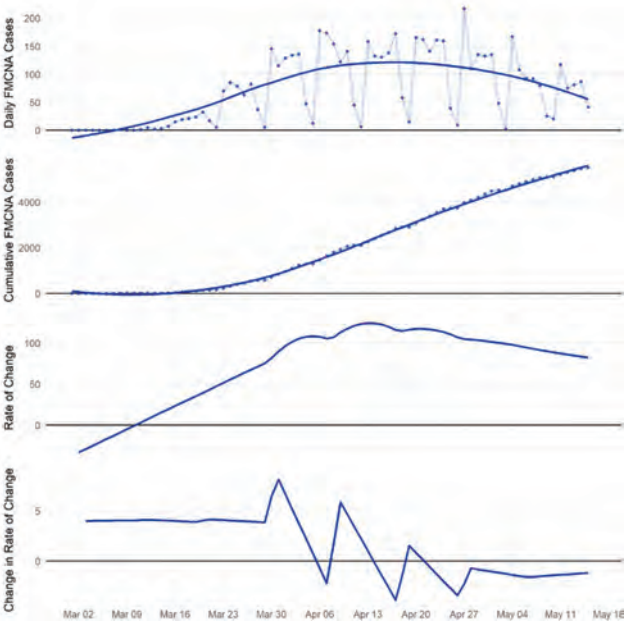
Background: Monitoring real-time acceleration, plateaus, and deceleration of infection rates is important for healthcare planning during a pandemic. We implemented methodology to continuously monitor daily cases and changes of COVID-19 case rates among individuals with ESKD receiving care in a large dialysis organization.

Methods: We identified patients with ESKD receiving dialysis in a Fresenius Medical Care North America (FMCNA) dialysis facility who tested positive for COVID-19. We fit a loess curve to the daily cumulative number of identified cases and computed the first and second derivative of the fitted curve to assess rate of change and change in rate of change, respectively, over time. We used these visualization techniques to monitor trends in case rates at the national and state levels.

Results: By May 15, 2020, there were 5,513 confirmed COVID-19 cases among patients receiving dialysis in an FMCNA facility. Mean age was 63.6 years, 57% were male, and 71% of confirmed cases had diabetes. Nationally, during the peak infection period in early April, new cases routinely exceeded 150 per day and there was a steady acceleration in growth of cases until the second week of April. As of May 15, 2020, among states with sufficient data, 2 states demonstrated continued acceleration, 10 demonstrated deceleration, and 13 plateaued in rate of growth.

Conclusions: The timing of the acceleration in growth of COVID-19 cases among individuals with ESKD followed national trends in the general population. Varying patterns of plateauing and deceleration of cases at the state level were observed in the ESKD population. Real-time monitoring of disease rates in high-risk populations, such as individuals with ESKD, is needed to plan for continuously changing healthcare demands during a pandemic.

Funding: Commercial Support - Fresenius Medical Care



PO0751

Psychological Impact of COVID-19 and Implementability of Prevention and Control Measures in Hemodialysis Centers: A Provincial Questionnaire Survey in China

Xinling Liang,[1] Yuanhan Chen,[1] Yanhua Wu,[2] Penghua Hu.[1] *[1]Guangdong Provincial People's Hospital,Guangdong Academy of Medical Sciences, Guanghzou, China; [2]Guangdong Provincial People's Hospital,Guangdong Academy of Medical Sciences, Guangdong Provincial Geriatrics Institute, Guangzhou, China.*

Background: This study investigated the psychological status of patients and staff and implementabilty of prevention measures in hemodialysis centers in Guangdong Province of China during the Coronavirus disease 2019 (COVID-19) pandemic.

Methods: An electronic questionnaire survey was performed in an anonymous manner between March 28 and April 3, 2020. Two questionnaires were designed to investigate the psychological status for hemodialysis patients and general staff (doctors, nurses, technicians, and other staff), respectively. And an additional questionnaire for administrators (directors or head nurses) of hemodialysis centers was designed to address the implementabilty of prevention measures, including strengthened patient triage management, restricting caregiver visits to patients during dialysis, strengthened prevention amongst staff, and improved patient education and protection. All the 516 hemodialysis centers registered in Guangdong Province were voluntarily invited to join the survey.

Results: Total 1,782 patients, 3,400 staff, and 420 administrators responded for this survey. Patients living in rural areas reported a higher incidence of severe anxiety compared to those living in other areas. Medical staff reported better mental health than non-medical staff. With respect to implementabilty of prevention measures, hemodialysis centers in general hospitals outperformed independent blood purification centers, and tertiary hospitals outperformed other level hospitals. However, restricting acceptance of non-resident patients was lower in tertiary hospitals than that in other hospitals. Under this condition, only one patient imported from Hubei Province was diagnosed with COVID-19.

Conclusions: The outbreak did not significantly affect the psychological status of most patients and medical staff. Due to the successful implementation of comprehensive prevention measures, the COVID-19 epidemic was controlled effectively. This provincial survey may provide experience for other countries and regions with similar epidemic.

PO0752

Persistent Viral Shedding and Antibody Response to the SARS-CoV-2 Virus in Chronic Hemodialysis Patients

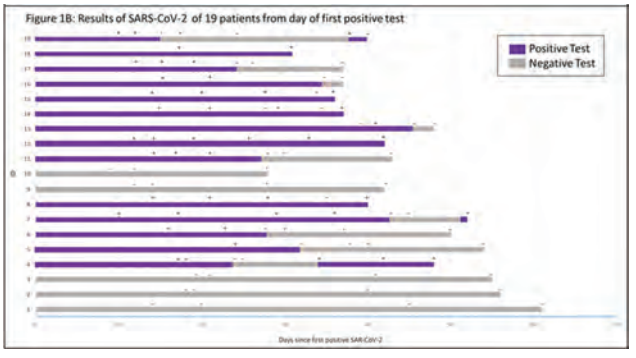
Aisha Shaikh,[1,2] Etti Zeldis,[1] Kirk N. Campbell,[2] Lili Chan.[2] *[1]James J. Peters VA Medical Center, Bronx, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The duration of SARS-CoV-2 viral RNA shedding and antibody response of chronic HD patients to the SARS-CoV-2 virus is currently unknown

Methods: This is a retrospective case series of chronic HD patients who tested positive for severe acute respiratory syndrome corona virus 2 (SARS-CoV-2 RNA) on nasal or nasopharyngeal specimen between March 20 and May 28, 2020 at the James J. Peters VA Hospital. Patients were tested at varying intervals to document clearance of virus or for surveillance purposes. SARS-CoV-2 Virus IgG Antibody (Ab) testing was performed on all HD patients with COVID-19 (using the Abbot IgG nucleocapsid antibody test and i2000SR machine, Ref. range of the Ab titer: >1.39 positive)

Results: Of 84 chronic HD patients, 26% (22) were diagnosed with COVID-19. Mean age of those with COVID-19 was 72±9 years old, 86% were Black, 77% had diabetes and all had hypertension. Of these patients, 59% (13/22) required hospitalization and 18% (4/22) died. IgG Ab testing was performed on 19 out of 22 COVID-19 patients. All 19 patients tested positive for IgG Ab with an average Ab titer of 7±1.2. 20 days after the first SARS-CoV-2 RNA positive test, 68% (13/19) patients remained positive on repeat RNA testing. 3 patients tested positive for SARS-CoV-2 RNA on repeat surveillance testing, despite testing negative on 2 prior consecutive nasal or nasopharyngeal specimens (Fig. 1). None of these 3 patients were symptomatic at the time their repeat swabs were positive for SARS-CoV-2 RNA

Conclusions: All HD patients with a confirmed diagnosis of COVID-19 developed IgG Ab to the SARS-CoV-2 virus, but the SARS-Cov-2 RNA was detectable in the swab specimen for a prolonged duration of time. In a few cases, the SARS-CoV-2 RNA became detectable after 2 consecutive negative RNA specimens. It is unknown if the IgG antibodies confer immunity against the SARS-CoV-2 virus. Additionally, the significance of persistent viral RNA shedding in patients who have recovered from COVID-19 remains to be elucidated



PO0753

Screen for Initial assessment of COVID-19 Infection Using Lung CT and Lymphocyte Count in Patients Under Hemodialysis

Cuifang Li, Xiangning Yuan, Hui Xu. *Xiangya Hospital, Central South University, Changsha, China.*

Background: The maintenance hemodialysis (MHD) patients with elder age and more comorbidities are more susceptible to SARS-CoV-2 than the general population. There is a clear need to effective assessment of COVID-19 infection status in these patients in hemodialysis center in order to prevent virus spread and decrease mortality in MHD patients.

Methods: MHD patients in the hemodialysis center and patients screening for COVID-19 in the fever clinic were enrolled from February,21 2020 to February,29 2020. Baseline characteristics, lung CT, blood routine and COVID-19 nucleic acid test results were collected.

Results: 276 MHD patients and 313 patients screening for COVID-19 in the fever clinic were collected. After matching for age and gender, 136 MHD patients and 136 patients in fever clinic were included. Compared with patients screening for COVID-19 in fever clinic, more MHD patients showed decreased white blood cell count and lymphocyte count (18.4% VS 5.9%, P<0.001; 59.6% VS 36.8%,P<0.001; respectively). 48.5% of the MHD patients and 41.2%of patients in the fever clinic with positive CT findings. Compared with the MHD patients, patients screening for COVID-19 in fever clinic showed more ground glass opacity (GGO) (80.3%VS 98.2%,P=0.002), more consolidation (16.7% VS 67.9%, P<0.001), and less pleural effusion (40.9% and 19.6%, P=0.01). Among them, centrally distributed GGO was more common in MHD patients than patients in the fever clinic (42.4% vs 23.2%,P=0.03), while diffuse GGO was more common in patients with pulmonary infection in the fever clinic than MHD patients (37.5% vs 4.5%; P<0.001). There was no significant difference in the proportion of peripheral GGO distribution between the two groups (33.3% vs 39.3%,P=0.5). Thirteen patients in the fever clinic and none of the MHD patient were positive for SARS-CoV-2 by RT-PCR analysis. 109 pairs of MHD patients underwent CT examination before and after dialysis were analyzed, results showed no significant difference between the CT lesion detection rate pre- and post-dialysis (48.6% vs 47.7%, P=0.89).

Conclusions: Lymphocyte count decrease is common in MHD patients, and pulmonary CT of MHD patients may show signs similar to that of COVIP at some time. RT-PCR is of great significance for the differential diagnosis, while pulmonary CT are conducive.

PO0754

Rates of Asymptomatic Carriage and Antibody Positivity for SARS-CoV-2 in a Large Haemodialysis Cohort

Kieran Mccafferty, Maria Davari, Katherine Price, Ravindra Rajakariar, Andrea Cove-smith, Suzanne H. Forbes. *Barts Health NHS Trust, London, United Kingdom.*

Background: Haemodialysis patients represent a unique challenge in the COVID-19 pandemic, balancing infection risk while safely providing life-sustaining haemodialysis. Asymptomatic infection rates in haemodialysis patients are unknown. **Aims:** 1 - To define rates of asymptomatic swab positivity in a cohort of prevalent haemodialysis patients 2 - To define rates of antibody positivity in patients known to have been historically swab positive 3 - To define rates of antibody positivity in patients without prior symptoms or clinical suspicion of COVID-19

Methods: A programme of COVID-19 screening using a validated nasopharyngeal PCR analysis was carried out across a prevalent cohort of 1253 haemodialysis patients. Concurrently all patients were offered antibody testing for Anti-SARS-CoV-2 IgG/IgM (Roche) and a total of 848 tests were completed.

Results: 1 – Routine screening over a 4 week period from 4/5/20 to 1/6/20 confirmed 7 cases of asymptomatic swab positivity (0.6%). 2 – In our cohort there were 197 confirmed swab positive cases of COVID, and of the 153 survivors 124 were antibody positive (81%). 10 patients were highly clinically suspicious of COVID and managed as such; of those 3 were antibody positive (30%). 3 – Of the remaining swab negative patients who had antibody testing (n=710) 82 were antibody positive (11.5%).

Conclusions: In a large inner-city London haemodialysis where the population prevalence of COVID has been high, we demonstrate 1 – low asymptomatic rates of virus carriage at this later stage in the pandemic 2 – significant proportions of swab positive patients seroconverting to be antibody positive 2 – suggestion that 11.5% of patients had previous been asymptomatic carriers and had seroconverted to be antibody positive

PO0755

Providing Multidisciplinary Renal Care in the Time of COVID-19

Ollie Fielding,[1] Jung Hoon Son,[1] Tia Y. Yu,[1] Andrew Bohmart,[2] Frank Liu,[2] Jeffrey I. Silberzweig.[2] The PEAK team *[1]pulseData, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: New York City (NYC)-based Rogosin Institute has provided a specialty case management to patients via its Program for Education in Advanced Kidney Disease (PEAK) since 2015. PEAK aims to educate patients about options for renal replacement therapy and encourages adoption of home dialysis modalities and transplantation. The global pandemic due to the novel coronavirus SARS-CoV-2 (COVID-19) hit NYC at the beginning of March 2020 and has resulted in over 40,000 hospital admissions and claimed the lives of 15,000 NYC residents.

Methods: A city-wide requirement to adopt social distancing caused us to adapt our approach so we could continue our patient management and delay dialysis starts where possible. Our multidisciplinary team continued to provide regular consults via a telehealth platform. pulseData built a query to look at the standard deviation of lab results for creatinine and potassium over the prior six months leading to decreased need for patients to leave their homes for venipuncture. We also built a query to identify those patients at high risk of poor COVID-19 outcomes (those over age 65, with COPD or other respiratory conditions, and other comorbid risk factors). These high risk patients were discussed in a weekly care plan meeting.

Results: The Rogosin team delivered 481 telehealth appointments between January 1 and May 1 2020. We identified 17 of 189 patients seen in PEAK over the last 12 months as high risk for poor COVID-19 outcomes. The standard deviation (SD) of the last six months of serum creatinine measurements for PEAK patients was 0.24 (IQR 0.16-0.44), patients with an SD in the top quintile were considered to be in need of repeat lab tests and home-based venipuncture was used where possible. Only 12 PEAK patients began dialysis treatment between January 1 and May 1 2020 compared with 28 patients in the same period in 2019. Most of these patients (67%) began dialysis optimally (as an outpatient and with venous access) in Jan-May 2020 vs. only 43% in the same period 2019 (a 56% increase).

Conclusions: Responding to the challenges of the COVID-19 crisis were acutely felt in NYC and represented a major disruption to our ability to deliver nephrology care. Adopting a coordinated, data driven approach we were able to continue to deliver multidisciplinary care to patients and improve renal replacement therapy outcomes.

Enhanced Sentinel Surveillance System for COVID-19 Outbreak Prediction in a European Dialysis Clinics Network

Francesco Bellocchio,[3] Paola Carioni,[3] Mario Garbelli,[3] Francisco Martínez-Martínez,[1] John W. Larkin,[2] Len A. Usvyat,[2] Franklin W. Maddux,[2] Stefano Stuard,[1] Luca Neri.[3] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care North America, Waltham, MA; [3]Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy*.

Background: Accurate predictions of epidemic dynamics may enable timely organizational interventions in high risk regions. We exploited the interconnection of the EMEA Fresenius Medical Care (FMC) dialysis clinic network to establish a sentinel surveillance system where the occurrence of new cases in a clinic propagates distance-weighted risk estimates to proximal dialysis units. The surveillance system is embedded in an artificial intelligence model which predicts COVID-19 outbreak occurrence in HD clinics from trends in clinical practice patterns and regional COVID-19 epidemic metrics. The system stratifies clinics by their risk of new local outbreak.

Methods: The risk prediction model is computed considering a cohort of 640 clinics belonging to the FMC network. We trained a model to predict outbreak in each clinic in a 2-week prediction horizon (i.e. two or more COVID-19 cases). In addition to sentinel distance-weighted risk estimates, the model included 73 variables (i.e. regional-level epidemic data from open source datasets and clinical practice data from the EuCliD® database). We generated the training set on data available on 04/01/2020 and tested prediction accuracy at 4/15/2020 and 4/20/2020.

Results: In the training set there were 58 (9.1%) clinics with two or more patients with COVID-19 infection in the two-week prediction window. In the validation samples there were 27 (4.2%) and 12 (1.9%) clinics with two or more patients with COVID-19 infection during the two-week prediction window. The performance of the model was suitable in both testing windows (AUC=0.86 and 0.80 respectively). The model is used to construct risk maps highlighting geographical clusters of clinics at risk (figure).

Conclusions: A sentinel surveillance system together with the wealth of information collected in EuCliD® and state of the art modeling strategies allows prompt risk assessment and timely response to COVID-19 epidemic challenges throughout networked European clinics.

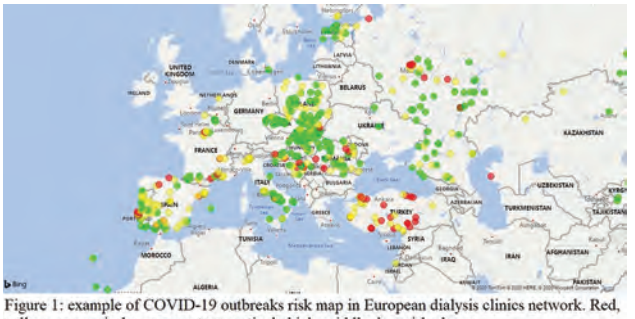

Figure 1: example of COVID-19 outbreaks risk map in European dialysis clinics network. Red, yellow, green circles represent respectively high, middle, low risk classes

PO0757

Trajectories of Clinical and Laboratory Characteristics Before COVID-19 Diagnosis in Hemodialysis Patients

Yue Jiao,[1] John W. Larkin,[1] Caitlin Monaghan,[1] Anke Winter,[3] Jochen G. Raimann,[2] Luca Neri,[3] Peter Kotanko,[2] Jeffrey L. Hymes,[4] Sangho Lee,[5] Len A. Usvyat,[1] Franklin W. Maddux.[6] *[1]Fresenius Medical Care, Global Medical Office, Waltham, MA; [2]Renal Research Institute, New York, NY; [3]Fresenius Medical Care Deutschland GmbH, EMEA Medical Office, Bad Homburg, Germany; [4]Fresenius Medical Care North America, Waltham, MA; [5]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [6]Fresenius Medical Care AG & Co. KGaA, Global Medical Office, Bad Homburg, Germany*.

Background: The frequency of evaluations in hemodialysis (HD) care affords opportunities to assess profiles that may characterize onset of the 2019 coronavirus disease (COVID-19). We aimed to characterize the trajectories of clinical/laboratory assessments before COVID-19 diagnosis in HD patients.

Methods: We assessed data from HD patients with known COVID-19 dialyzed at Fresenius Kidney Care in the United States between 02 Mar and 09 Apr 2020. We computed mean daily values for 40 variables 90 days before a positive rRT-PCR test (COVID-19+). Nonparametric smoothing splines were used to fit data of individual trajectories and estimate the mean change over time.

Results: There were 1294 HD patients with COVID-19 (mean age 64±14 years, 60% male, 47% white race, 69% had diabetes, and 24% had coronary artery disease). Mean pre-HD body temperature (primarily oral) increased by about 1° Fahrenheit (F) over 10 days before COVID-19+ test and approached 99° F at diagnosis (**Fig 1A**). Mean interdialytic weight gain decreased by about 0.75 kg (**Fig 1B**) over 14 days before COVID-19+ test; concurrent decreases of about 20 minutes were seen in HD treatment time. Mean neutrophil-to-lymphocyte ratio had mild increases (**Fig 1C**), while mean platelet counts decreased by about 40×10^9/L over 14 days before COVID-19+ test (**Fig 1D**). Trajectories of many variables (vitals, heparin, hematology, nutrition, bone, anemia) were observed to change before COVID-19+ test, yet alternations were generally minor.

Conclusions: The trajectories of several clinical/laboratory parameters appeared to change before COVID-19 diagnosis in HD patients. Many changes were small and may not be independently useful in identifying onset of COVID-19. Mean pre-HD body temperature before SARS-CoV-2 infection was 97.4° F and should be considered in screening. Findings may have utility in prediction model development. Further comparisons to patients without COVID-19 are needed.

PO0758

Distribution of SARS-CoV-2 Positive Tests, Dialysis Stations, and Household Poverty Within Cook County, Illinois

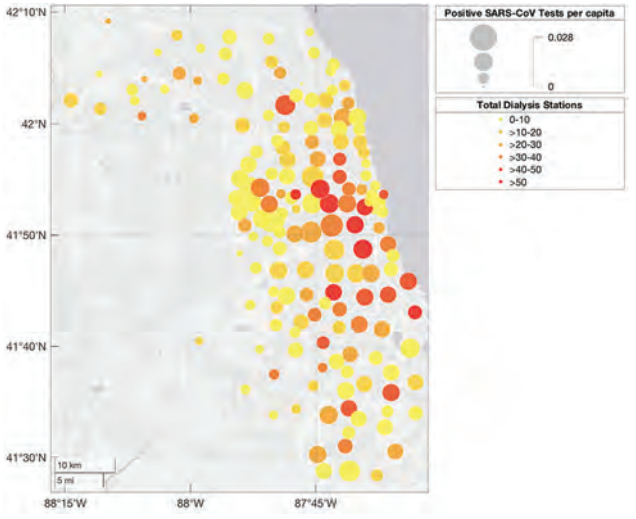
Siddharth Bhayani,[1] Ranit Sengupta,[2] Talar Markossian,[2] Mohammad samie Tootooni,[2] Amy Luke,[2] David A. Shoham,[2] Richard Cooper,[2] Holly J. Kramer.[3] *[1]Loyola University Chicago Stritch School of Medicine, Maywood, IL; [2]Loyola University Chicago, Chicago, IL; [3]Loyola University Medical Center, Maywood, IL*.

Background: End stage renal disease (ESRD) shows higher prevalence in poor urban communities, areas with high SARS-CoV-2 exposure risk. This ecological analysis examined the correlation of SARS-CoV-2 positive tests per capita with number of dialysis stations, demographics and income data of the residents within ZIP codes (n=163) in Cook County, Illinois.

Methods: Data on SARS-CoV-2 positive tests per capita within a ZIP code were merged with ZIP code data on number of dialysis stations (sum of dialysis stations per dialysis center), demographics and household income, during a period from January 21-May 16, 2020 in Cook County (5,231,852 residents). Spearman's rank correlation coefficients were calculated to examine the linear correlation of SARS-CoV-2 positive tests per capita with dialysis stations, demographics and household poverty. We mapped SARS-CoV-2 positive tests per capita and total dialysis stations by ZIP code in Cook County.

Results: Positive tests per capita correlated significantly with number of dialysis stations ($r = 0.23$; 95% CI 0.18, 0.28; $P < 0.005$), number of households living in poverty ($r= 0.58$; 95% CI 0.54, 0.61; $P < 0.005$) and percentage of residents reporting Black race ($r = 0.34$ $p < 0.005$, CI = 0.30, 0.39) or Hispanic ethnicity ($r = 0.60$ $p < 0.001$, CI: 0.57-0.63). Figure 1 show several areas within Cook County with both high number of SARS-CoV-2 tests per capita and number of dialysis stations.

Conclusions: SARS-CoV-2 tests per capita correlates positively with number of dialysis stations, and poverty status of that ZIP code. These findings highlight the high risk of SARS-CoV-2 exposure for patients with ESRD living in poor urban areas.



PO0759

Kidney Patient Mortality due to COVID-19 in Ecuador: The Experience in Guayas Province

Fabian A. Ortiz-Herbener.[1,2] *[1]Instituto Ecuatoriano de Dialisis y Trasplantes [IEDYT], Guayaquil, Ecuador; [2]Unidad de Cuidado Renal Avanzado [UCRA], Guayaquil, Ecuador.*

Background: Ecuador is a country of seventeen million population located in the west coast of South America. In late February 2020, Ecuador had its first Covid-19 case in the city of Guayaquil, followed by massive growth of infections in Guayas Province (14000 of 39000 cases), the current epicenter. Due to the lack of official information in this population, and the significant impact in mortality saw in other countries, a need for data is warrant.

Methods: There are approximately 15000 patients on renal replacement therapy in Ecuador, 94% of them on hemodialysis. At Guayas Province, the estimation of 5200 people on hemodialysis accounts for the 34% of the country's patients. A simple telephone-based questionnaire was performed at the first week of May, directed to the owner, medical director, or head of nurses of each center in the Guayas Province.

Results: From the 35 centers in Guayas, it was possible to collect data from 29 locations (82.5%) -mostly private centers-, that represents approximately 4719 patients, 89.8% from the total of patients in Guayas Province. Just 2 / 8 public centers provide information. Results are summarized in Table 1.

Conclusions: The 11.91% Covid-19 mortality in Guayas Province was high, especially if the expected monthly mortality is around 0.8-1.1%; the lethality was very high, and this could be explained by the fact that renal patients are considered as high-risk patients in this disease. The low mortality in PD patients could be attributable to the lockdown and stay-in-home measures. It is necessary to implement specific protocols in order to avoid high mortality, if a second peak of Covid-19 is expected.

Results from Guayas Province in Covid-19 pandemic.

	Global Results	N	Range
Mortality (HD)	11.91%	(n= 562/4719)	5-35%
Lethality	55%		43-62%
Mortality (PD)	2.88%	(n= 6/208)	
Mortality (TX)	2.06%	(n= 9/436)

PO0760

Clinical Characteristics, Management, and Outcomes in COVID-19-Positive Dialysis Patients from Three London Renal Centres, United Kingdom

Dalvir Kular,[1] Irina Chis Ster,[4] Dandisonba B. Braide-Azikiwe,[2] Alexander Sarnowski,[3] Eirini Lioudaki,[2] Martin L. Ford,[2] David Makanjuola,[1] Alexandra C. Rankin,[2] Hugh Cairns,[2] Joyce Popoola,[3] Nicholas I. Cole,[1] Mysore K. Phanish,[1] Richard Hull,[3] Pauline A. Swift,[1] Debasish Banerjee.[3,4] *[1]St Helier Hospital, London, United Kingdom; [2]King's College Hospital, London, United Kingdom; [3]St George's University Hospitals NHS Foundation Trust, London, United Kingdom; [4]St George's University of London, London, United Kingdom.*

Background: Dialysis patients, with frequent co-morbidities, advanced age and frailty, visiting treatment facilities frequently are perhaps more prone to SARS-Cov-2 infection and related death - the risk-factors and dynamics of which are unknown. The aim of this study was to investigate the hospital outcomes in SARS-CoV-2 infected dialysis patients.

Methods: This prospective, observational, multi-centre study collected data on SARS-CoV-2 infected HD patients between 29/02/2020 and 15/05/2020. Data was collected on demographics, comorbidities, WHO performance status, clinical symptoms, laboratory parameters, hospital management and outcomes. Treatment was predominantly supportive, unless patients were part of an approved clinical trial. The study was approved by NHS Research Ethics Committee 20/SW/0077 and Heath Research Authority IRAS 283130.

Results: Of 1737 HD patients at the 3 renal centres, 224 (13%) were COVID-19 positive over the study period. The characteristics of the COVID-19 HD patients were: mean age 65.8; 59% male; 38% Caucasian; 81% hypertension; 54% diabetes; 25% chronic lung disease; 29% ischaemic heart disease and 22% cerebrovascular disease. The most common symptoms at presentation were fever (62%) and cough (53%). About 143 (64%) patients were managed as an inpatient and 81 (36%) as an outpatient. Of 9 patients that required mechanical ventilation: 6 died, 1 patient was discharged and 2 are still under clinical care. Overall 51 patients died (23%), 154 (69%) were discharged alive and 19 (8%) were still under clinical care as of 15/05/2020. Preliminary analyses suggested that those that died were significantly older (p=0.0028), more likely to have ischaemic heart disease (p=0.003), cerebrovascular disease (p=0.019), smoking history (p=0.006), WHO performance status 3-4 (p=0.004), higher neutrophil: lymphocyte ratio at presentation (p=0.0001) and higher CRP at presentation (p=0.0021).

Conclusions: This large cohort of COVID-19 positive haemodialysis demonstrates a high case fatality ratio, which increased significantly with age, cardiovascular disease, smoking history, frailty and markers of inflammation.

PO0761

COVID-19 Infection in Kidney Transplant Recipients: A Single-Center Experience

Tyler Andrea, Bhavna Chopra, Sabiha M. Hussain, Kalathil K. Sureshkumar. *Allegheny Health Network, Pittsburgh, PA.*

Introduction: The SARS-CoV-2 (COVID-19) pandemic presents significant challenges to kidney transplant recipients (KTRs) with risk for higher mortality yet sparse available data. We present our single center experience of COVID-19 infection in KTRs.

Case Description: Methods We reviewed the electronic health records of KTRs with confirmed COVID-19 infection using rt-PCR testing via nasopharyngeal swabs, at our transplant center. Results We identified four KTRs with diagnosed COVID-19 infection in our institution. Details of individual cases are summarized in table 1. Patient A died of complications while patients B, C and D fully recovered. Patient A initially recovered from COVID-19 pneumonia but then was readmitted three weeks later and developed features closely resembling macrophage activation syndrome (MAS) and hemophagocytic lymphohistiocytosis (HLH) leading to death despite treatment with dexamethasone, IV immunoglobulin and anakinra. Patient C had minimal symptoms without cytokine storm possibly related to complement blockade from revulizumab, a C5 inhibitor, which was being used for treatment of aHUS.

Discussion: Our single center case series of COVID-19 infections in KTRs is small but highlights two important aspects: 1) development of MAS/HLH like features in patient A which to our knowledge has not been described in the setting of COVID-19 infection in KTRs; 2) development of minimal symptoms without cytokine storm in patient C likely related to use of C5 blocking agent revulizumab. Further studies are needed to shed light on these phenomenon.

Case series of varied clinical manifestation of COVID 19 infection at our center

aHUS – atypical hemolytic uremic syndrome; DCD – donation after cardiac death; LURD – living unrelated donor; MMF – Mycofenolate Mofetil; THYMO – rabbit antithymocyte globulin, Cr- Creatinine

PO0762

Incidence of COVID-19 Disease in Pediatric Kidney Transplant Recipients: A Report of the Improving Renal Outcomes Collaborative

Charles D. Varnell,[1,2] Samhar I. Al-Akash,[4] Craig W. Belsha,[23,24] Abanti Chaudhuri,[6,5] Rachel M. Engen,[25,26] Paul Fadakar,[27,28] Rouba Garro,[9,7] Caroline A. Gluck,[10,11] Jens W. Seifert.[8,3] Improving Renal Outcomes Collaborative *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Cincinnati, Cincinnati, OH; [3]The University of Alabama at Birmingham, Birmingham, AL; [4]Driscoll Children's Hospital, Corpus Christi, TX; [5]Stanford University School of Medicine, Stanford, CA; [6]Lucile Salter Packard Children's Hospital at Stanford, Palo Alto, CA; [7]Emory University School of Medicine, Atlanta, GA; [8]Benjamin Russell Hospital for Children, Birmingham, AL; [9]Children's Healthcare of Atlanta Inc, Atlanta, GA; [10]Alfred I DuPont Hospital for Children, Wilmington, DE; [11]Nemours Children's Health System, The Nemours Foundation, Jacksonville, FL; [12]Children's Hospital Colorado, Aurora, CO; [13]University of Colorado Denver School of Medicine, Aurora, CO; [14]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [15]Indiana University School of Medicine, Indianapolis, IN; [16]Nationwide Children's Hospital, Columbus, OH; [17]The Ohio State University College of Medicine, Columbus, OH; [18]Johns Hopkins University School of Medicine, Baltimore, MD; [19]Seattle Children's Hospital, Seattle, WA; [20]University of Washington School of Medicine, Seattle, WA; [21]Mattel Children's Hospital UCLA, Los Angeles, CA; [22]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [23]SSM Health Cardinal Glennon Children's Hospital, Saint Louis, MO; [24]Saint Louis University School of Medicine, Saint Louis, MO; [25]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [26]Northwestern University Feinberg School of Medicine, Chicago, IL; [27]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [28]University of Pittsburgh School of Medicine, Pittsburgh, PA; [29]Boston Children's Hospital, Boston, MA; [30]Harvard Medical School, Boston, MA; [31]Children's Mercy Hospitals and Clinics, Kansas City, MO; [32]University of Missouri Kansas City, Kansas City, MO; [33]The University of Iowa Stead Family Children's Hospital, Iowa City, IA; [34]The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA.*

Background: The impact of COVID-19 disease on previously healthy children has been minimal, yet there is limited data on the impact of COVID-19 on children and adolescents with kidney transplants.

Methods: We used the existing infrastructure of the Improving Renal Outcomes Collaborative (IROC) learning health system to develop and rapidly implement a web-based registry for collecting clinical and outcomes data about COVID-19 disease in pediatric transplant recipients. We distributed the registry to 32 U.S. pediatric kidney transplant centers and requested clinical and outcomes data from all recipients suspected of having COVID-19 disease. Here, we present an interim analysis of the first 6 weeks of registry data.

Results: Between April 6 and May 27, 2020, 18 IROC centers entered data on 99 pediatric kidney transplant recipients who had PCR based testing for COVID-19. 54 patients were tested due to symptoms of COVID-19 (most commonly fever and cough), 7 asymptomatic patients had a known COVID exposure. 34 patients were tested per hospital policy (e.g. pre-anesthesia), and 4 did not have a reported testing indication. Overall, 10/99 (10%) tested positive for COVID-19, 6 of whom had any symptoms, 3 had a known exposure with a COVID+ individual, and 1 was diagosed by a pre-anesthesia screen. Thus far, the clinical course and outcomes are known in 8/10 COVID-19+ patients: 5 received outpatient supportive care alone, 2 were admitted to intensive care and 1 was admitted to a non-intensive care inpatient unit. Transplant outcomes were excellent in all COVID-19+ patients. There were no cases with respiratory failure, acute kidney injury, or allograft rejection/failure. There were no deaths due to COVID-19 disease.

Conclusions: In this interim analysis of the IROC learning health system, pediatric kidney transplant recipients had a relatively low incidence of COVID-19 disease and excellent short-term outcomes.

PO0763

Living Organ Donor Perspectives on Organ Donation During the COVID-19 Pandemic

Meera N. Harhay,[1] Ann C. Klassen,[1] Janet Fleetwood,[1] Peter P. Reese,[2] Krista L. Lentine,[3] Michael Mittelman,[4] Rebecca L. Bertha.[4] *[1]Drexel University, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]St. Louis University, St. Louis, MO; [4]American Living Organ Donor Fund, Philadelphia, PA.*

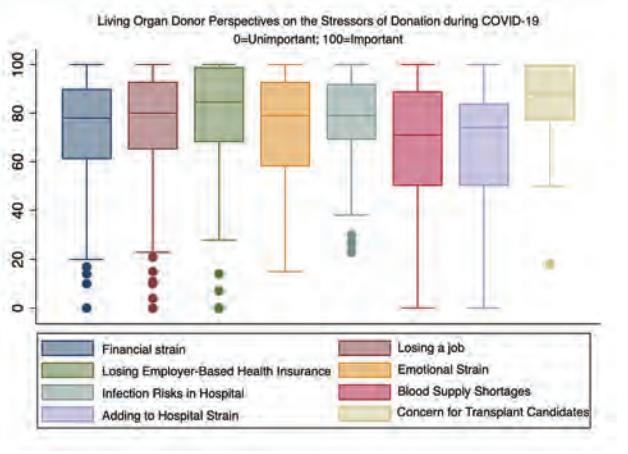
Background: Due to the COVID-19 pandemic, transplant programs across the U.S. postponed living donor surgeries and transplants. We examined perspectives of former and prospective living organ donors on the risks and excess burdens of organ donation during the COVID-19 pandemic.

Methods: In late April 2020, we disseminated an IRB-approved survey to a national online forum of over 1300 living donors and those in workup for donation. Using visual analog scales, respondents rated sources of information about COVID-19, burdens on donors due to the pandemic, and what factors should determine whether living donation should proceed during the pandemic (0=unimportant, 100=very important).

Results: After 4 weeks, there were 101 respondents from 35 U.S. states; 63% were between 31-50 years old, 95% were non-Hispanic white, and 90% were female. Respondents included 68 living donors (72% kidney) and 33 people in work-up to donate (73% kidney). The most and least important sources of information about COVID-19 were personal doctors (median importance 88, IQR 73-100) and social media (median 26, IQR 12-54), respectively. Nearly half (41%) were unsure of their transplant program's policy for living donation during the pandemic, and 58% reported that the decision to donate during COVID-19 should depend on factors such as transplant candidate health (median 100, IQR 90-100) and availability of COVID-19 tests (median 84, IQR 70-95). Respondents rated concern for transplant candidates and loss of employer-based health insurance as the most important pandemic-related stressors for donors (Figure).

Conclusions: Many living organ donors were uncertain about their transplant program's approach for donation during the pandemic. Donors were concerned about the health of transplant candidates and financial stressors, and prioritized availability of COVID-19 testing to determine when living donation should proceed during the pandemic.

Funding: NIDDK Support



PO0764

Clinical Outcomes of Hospitalized Kidney Transplant Recipients with COVID-19 in a Predominantly Minority Population

Yorg Al Azzi, Maria Ajaimy, Luz E. Liriano-Ward, Cindy T. Pynadath, Pablo Loarte Campos, Purna Bindu Nandigam, Enver Akalin, Omar Alani, Michael K. Parides. *Montefiore Medical Center, Bronx, NY.*

Background: COVID-19 has been associated with increased morbidity in kidney transplant recipients. We aimed to identify risk factors for mortality in hospitalized kidney transplant recipients with COVID-19

Methods: We retrospectively reviewed the medical records of 75 kidney transplant recipients admitted for COVID-19 at our institution.

Results: Among the 75 patients, 28 (37%) died at a median 8 days (range, 1-36) after admission to the hospital. The Table summarizes the demographics and initial labs values of both groups. Most of our patients were Hispanic (54%) and African American (32%) and 97% had hypertension and 65% had diabetes mellitus. There was no difference between the two groups in terms of sex, type of transplant, time from transplant, immunosuppressive medications, medical comorbidities, presenting symptoms, temperature, or pulse oximetry values on admission. Non-survivors were older and had higher BMI. On admission most patients were lymphopenic, had low CD3/CD4/CD8 counts and had higher inflammatory markers (ferritin, d-dimer, CRP, procalcitonin, interleukine-6 levels). Non-survivors had statistically significant higher procalcitonin, IL-6 and pro-BNP levels on admission. More non-survivors required ICU stay (64% vs. 13%, $p < 0.001$), intubation (57% vs. 11%, $p < 0,001$) and renal replacement therapy (32% vs. 17%, $p=0.17$) compared to survivors. There was no difference in secondary bacterial infections, CMV viremia, DVT or stroke between the two groups. In a multivariate analysis, BMI (OR 1.15, CI 1.04-1.30, $p= 0.017$ per unit increase), higher procalcitonin (OR 4.16, 1.09-18.87, $p=0.046$) and proBNP levels (OR 1.017, 1.002-1.034, $p=0.039$, per 100 unit increase) on admission were associated with increased mortality.

Conclusions: COVID-19 is associated with increased mortality (37%) in our kidney transplant recipients and higher BMI, procalcitonin and proBNP levels at admission are associated with mortality.

	Hospitalized N =75	Survivors N = 47	Non-survivors N = 28	P-value

PO0765

COVID-19 and Kidney Transplantation: Results from the TANGO International Transplant Consortium

Leonardo V. Riella,[1] Suraj Sarvode mothi,[4] Enver Akalin,[2] Paolo Cravedi.[3] TANGO Consortium *[1]Massachusetts General Hospital, Boston, MA; [2]Montefiore Medical Center, Bronx, NY; [3]Mount Sinai Health System, New York, NY; [4]Brigham and Women's Hospital, Boston, MA.*

Background: Chronic immunosuppression and comorbidities may expose kidney transplant recipients to an increased risk of developing critical coronavirus disease 2019 (COVID-19), but data in transplantation have been limited so far to single centers. To determine the clinical presentation, outcomes, and mortality risk factors in transplant patients with COVID-19, we analyzed retrospective data from a large international transplant consortium (TANGO Study).

Methods: Retrospective cohort study included kidney transplant recipients admitted with COVID-19 in 11 centers participating in the international TANGO consortium. We included all adult (≥18 yeas) kidney transplant recipients with a functioning kidney allograft who were admitted to a hospital between March-April, 2020. Epidemiological, demographic, clinical, laboratory, treatment, and outcome data were extracted from electronic medical records using an ad hoc designed data collection form.

Results: Among 9,697 kidney transplant recipients followed at 11 transplant centers, 145 (1.5%) were hospitalized due to COVID-19. 65% were male and more than half were over 60 years old (55%). Median time since transplant was 5 years (2-10) and only 16% were transplanted less than one year from the presentation. Prevalent comorbidities included hypertension (95%), obesity (41%), heart disease (25%) and lung disease (19%). Common symptoms at the onset of illness were fever and dyspnea (71%), followed by myalgia (54%) and diarrhea (35%). Management of anti-rejection therapy varied across centers: antimetabolites were withdrawn in 69% of patients and calcineurin inhibitor in 26%. Other treatments used during hospitalization included hydroxychloroquine (83%), antibiotics (76%), tocilizumab (13%) and antivirals (10%). During a median follow-up of 13 days (IQR: 7 - 21) after diagnosis of COVID-19, mortality was 30% and occurred at a median 10 (5-16) days after admission. Acute kidney injury (AKI) occurred in 46% and respiratory failure requiring intubation in 29% of cases. No rejection events were observed.

Conclusions: Our large international consortium indicates that kidney transplant recipients with COVID-19 have increased mortality (30%) upon hospitalization compared to the general population with a high rate of AKI (46%) and significant respiratory failure (29%).

PO0766

Atypical Clinical Presentation of COVID-19 in a Kidney Transplant Recipient with Tacrolimus Toxicity

Michael J. Chau,[1] Ismail K. Almokyad,[1] Ping Li.[2] *[1]The George Washington University Milken Institute of Public Health, Washington, DC; [2]US Department of Veterans Affairs, Washington, DC.*

Introduction: Kidney transplant recipients represent a unique challenge to manage amidst the Coronavirus disease 2019 (COVID-19) pandemic as they have reduced innate ability to fight the viral infection due to immunosuppression. However, calcineurin inhibitors such as tacrolimus, may offer an advantage in reducing the effects of cytokine storms in transplant patients with viral pneumonia. We present an atypical case of COVID-19 in a kidney transplant recipient with toxic levels of tacrolimus that presented with mainly fever and diarrhea.

Case Description: A 76-year old African American male kidney transplant recipient presented to the Emergency Department (ED) after five days of fever (temperature of 101.8°F), nausea, vomiting, diarrhea and urinary frequency on March 27, 2020. His vitals were noted with a temperature of 96.9°F, respiratory rate of 40/min, and heart rate of 166 beats/min, blood pressure of 110/75 mmHg and pulse oxygen situation was 85% at ambient air. Admission labs were significant for a rise of serum creatinine to 3.1 mg/dL from a baseline of 1.5 mg/dL, lactic acid of 4.4 mmol/L, and a tacrolimus level of 26.9 mcg/L. He was transferred to the ICU following increased oxygen demands and elective intubation for impending respiratory failure on hospital day 2. His blood pressure transiently improved with a decrease in lactic acid to 1.4 mmol/L and serum creatinine down to 1.6 mg/dL following IV fluid resuscitation. On hospital day 4, he continued to require high ventilator support and initiated on vasoconstricting agents for hemodynamic support. His serum tacrolimus level continued to increase to 32.9 mcg/L with concordant increase of serum creatinine to 2.1 mg/dL with oliguria. Tacrolimus levels sustained super therapeutic levels >8 mcg/L despite cessation of the drug.

Discussion: It is possible that Severe Acute Respiratory Syndrome coronavirus 2 (SARS-CoV-2) infection may cause hepatic dysfunction and diarrhea, which reduced drug metabolism and lead to toxic levels of tacrolimus—perpetuating cytokine storm. It is important that in this particular transplant patient population to closely monitor drug levels due to SARS-CoV-2 infection on its metabolism, as well as preventing toxic levels, which further reduces the body's innate immunity and may indirectly worsen cytokine storm.

PO0767

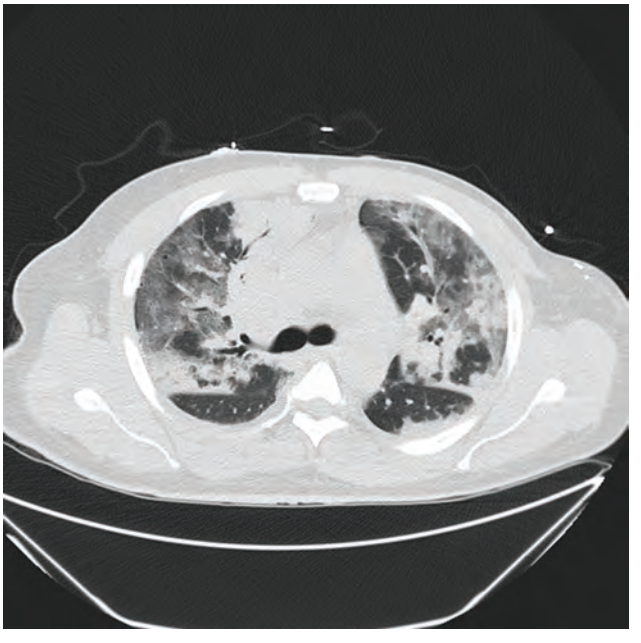
Late Rejection of Failed Renal Allograft Precipitated by COVID-19 in a Hemodialysis Patient (HD)

Ali Arif, Iris J. Lee, Dina Abdelwahab. *Temple University, Philadelphia, PA.*

Introduction: We present a case report of an HD patient with a failed allograft that had been stable off immunosuppression who presented with acute allograft rejection in the setting of COVID-19 infection.

Case Description: 50 y/o male with a history of hypertension, living-related kidney transplant in 2005 E.S.R.D after his allograft failed in 2018. The patient's allograft remained stable off immunosuppression on HD until 3/2020, when the patient presented with severe allograft tenderness with no fever or evidence of urinary tract infection. An abdominal CT was consistent with allograft rejection. Abdominal pain resolved after IV steroids and initiation of low dose tacrolimus. He was discharged but returned 4 days later, with recurrent abdominal pain, fever and shortness of breath. CT chest was consistent with COVID19 pneumonia with a positive swab. His condition was complicated by acute respiratory failure and cytokine storm. Despite receiving Ankinra for COVID-19, our patient died.

Discussion: Failed allograft rejection for patients who initiate HD usually occurs within the first 6-12 months. Unless allograft failure occurs within a year of transplantation, many nephrologists complete withdrawal of immunosuppression in failed grafts after 4 months to decrease the risk of infections. In our case, the development of allograft rejection after stable long-term HD, is very unusual. We propose that the cytokine storm from COVID-19 in our patient provided the appropriate "danger signals" that triggered innate inflammation and augmented effector responses against the allograft. COVID-19 infection triggers a pro-inflammatory immune response, with IL-6 being a key cytokine that potentially drives T-cell effector responses and inhibits T-regulatory responses to donor allograft.



PO0768

Risk Factors for Mortality in Kidney Transplant Recipients with COVID-19

Vinay Nair, Nicholas Jandovitz, Mersema Abate, Gayatri D. Nair, Madhu C. Bhaskaran, Ernesto P. Molmenti. *Northwell Health, Great Neck, NY.*

Background: There is limited information on the presentation and risk factors for poor outcome in kidney transplant recipients with COVID-19.

Methods: We reviewed data of admitted kidney transplant recipients at 12 system hospitals with COVID-19 between March 1, 2020, and April 30th, 2020. We analyzed risk factors for mortality.

Results: 31 patients were identified, 30 were admitted. Median age was 58 (IQR 53-68), 61% male, 32% Caucasian, 29% African American, 29% multiracial and 6% Asian. Median time from transplant to COVID-19 testing was 1178 days (IQR 252-2897). The most common symptom was cough, followed by fever, shortness of breath and fatigue. Chest X-ray/CT revealed multifocal patchy opacities. Ten patients required mechanical ventilation. Laboratory markers can be seen in the table. Acute kidney injury occurred in 39% of patients. The majority of patients were on triple immunosuppression (94% on tacrolimus, 90% on mycophenolate, and 74% on prednisone). During the hospital course 87% had the antimetabolite stopped while 35% had CNI stopped. Treatments utilized included hydroxychloroquine (93%), azithromycin (50%), convalescent plasma (14%), IL-6 inhibitor (10%) and 1 received remdesivir. At a median follow up of 19 days (IQR 8 – 26) 10 patients died. Risk of death was greater if the patient was admitted to a non-transplant hospital (80% vs 23%, p=0.027), lymphopenic at presentation (47% vs 8%, p=0.013 or had O2 saturation less than 94% upon admission (100% vs 57%, p=0.03). During hospitalization mortality was also higher in patients with higher peak serum creatinine (3.2 mg/dl vs 1.5 mg/dl, p=0.013), or if requiring intubated (70% vs 14%, p<0.001). Increase in inflammatory markers including peak D-dimer, peak CRP, ferritin and procalcitonin were also predictive of mortality.

Conclusions: Kidney transplant recipients with COVID-19 should be monitored closely in a transplant center. Mortality is high, particularly in patients presenting with lymphopenia and hypoxemia.

	Total	Survived	Died	p-value

Living Donor Kidney Transplant Practice in the COVID-19 Era: A Survey of US Transplant Programs

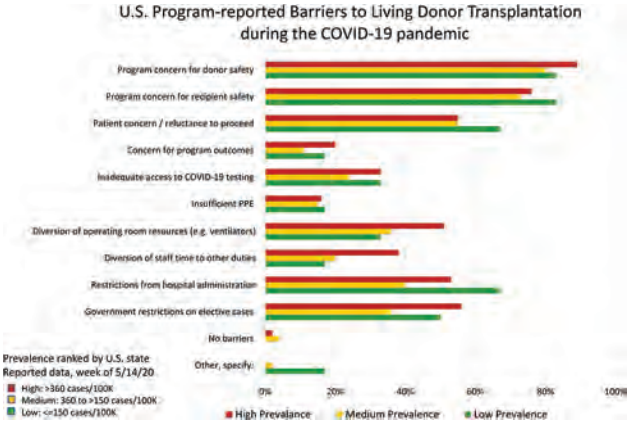
Krista L. Lentine,[1] Luke S. Vest,[1] Mark Schnitzler,[1] Roslyn B. Mannon,[2] Vineeta Kumar,[3] Mona D. Doshi,[4] Matthew Cooper,[5] Didier A. Mandelbrot,[6] Meera N. Harhay,[7] Michelle A. Josephson,[8] Bertram L. Kasiske,[9] Yasar Caliskan,[1] David Axelrod.[10] *[1]Saint Louis University, Saint Louis, MO; [2]University of Nebraska Omaha, Omaha, NE; [3]The University of Alabama at Birmingham, Birmingham, AL; [4]University of Michigan, Ann Arbor, MI; [5]MedStar Georgetown University Hospital, Washington, DC; [6]University of Wisconsin-Madison, Madison, WI; [7]Drexel University, Philadelphia, PA; [8]University of Chicago, Chicago, IL; [9]Hennepin County, Minneapolis, MN; [10]University of Iowa, Iowa City, IA.*

Background: We surveyed U.S. transplant programs to assess practices, strategies and barriers related to living donor kidney transplantation (LDKT) in the context of the COVID-19 pandemic.

Methods: After IRB approval, the survey was launched 5/9/20 by email and postings to professional society list-servs, using the Qualtrics platform. Data are reported through 5/27/20, and examined by state COVID-19 prevalence.

Results: Staff at 117 unique centers responded, representing 58% of U.S. living donor recovery centers and 75% of LKDT volume in the year before pandemic declaration. Overall, 66% reported LDKT surgery was on hold (82% in high vs. 50% in low prevalence states). 36% reported that evaluation of new donor candidates had paused, 27% reported evaluations were very decreased (>0% to <25% typical) and 23% reported evaluations were moderately decreased (25% to <50% typical). Barriers to LDKT surgery included program concerns for donor (84%) and recipient (75%) safety, patients concerns (54%), restrictions on elective cases (47%) and hospital administrative restrictions (47%). Programs with higher local COVID-19 prevalence reported more barriers related to staff and resource diversion (**Figure**). Most centers continuing donor evaluations used remote strategies (video 82%; telephone 43%). 61% of centers plan to continue more telehealth after the pandemic. 32% plan to resume some LDKT within 2 wks and 27% within 1 month. When surgery resumes, all will screen for COVID-19 before donation surgery, although timeframe and modalities vary.

Conclusions: COVID-19 has created many barriers to LDKT, especially in areas of highest prevalence. Transplant centers are planning to restart LKDT cautiously. Consensus-building is needed to reduce barriers, guide optimal practice, and facilitate safe restoration of LDKT across centers.



Barriers to LDKT during COVID-19 pandemic

PO0770

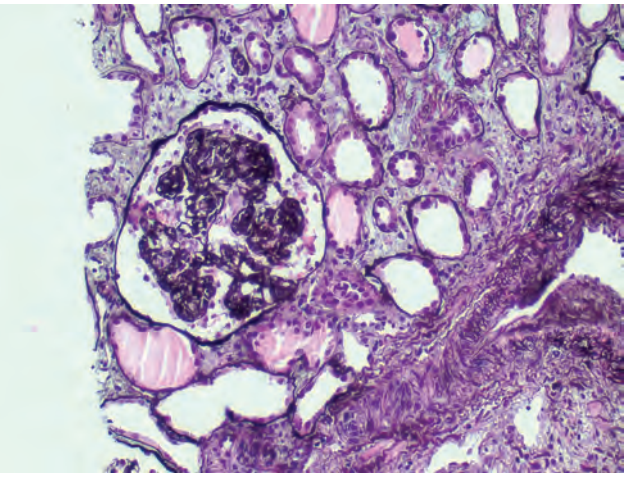
Collapsing/Sclerosing Glomerulopathy (CSG) and Acute Tubular Injury (ATI) in Patients with COVID-19

Sunil Sherchan, Mohamed Kahila, Jamrose K. Durrani, Isha Puri, Ibrahim A. Mohamed, Yohannes Melaku, Ernie Yap, Robert F. Leonardo, Subodh J. Saggi, Moro O. Salifu, Anthony D. Nicastri. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

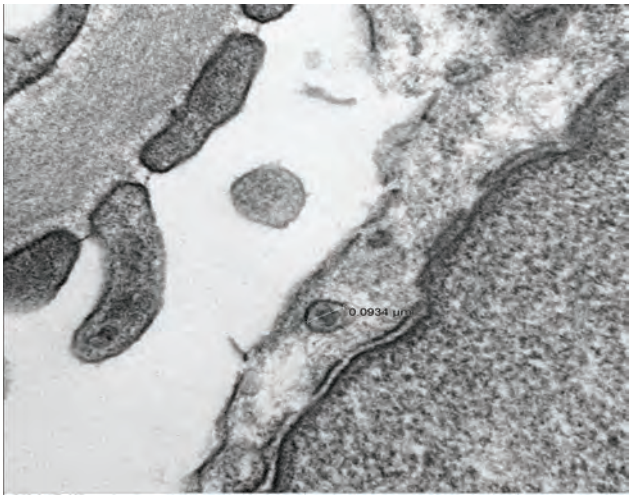
Introduction: AKI in patients with COVID-19 may be due to ATI from hemodynamic instability or inflammatory responses. We present two cases of CSG and ATI in patients admitted for COVID-19

Case Description: Case 1 25-year-old black obese female admitted with fever, cough, dyspnea and serum creatinine of 1.4 mg/dL, discharged next day with home quarantine. Re-admitted 26 days later due to nausea, fatigue, and bilateral foot swelling. Serum creatinine 28 mg/dl and urine protein to creatinine ratio (uPCR) of 10.4 g/g Case 2 42-year-old black female with hypertension, diabetes mellitus admitted with fever, dyspnea, cough, and diarrhea. Patient found to have diabetic ketoacidosis, serum creatinine 12.7 mg/dl. She developed deep vein thrombosis and pulmonary embolism and uPCR 15.4 g/g. She was started on hemodialysis Kidney biopsy showed global and segmental capillary collapse with a variable degree of sclerosis and severe renal tubules injury. Electron microscopy showed spherical structures in the podocytes, endothelial cells, and tubular epithelium similar to Coronavirus particles

Discussion: Our experience above is part of a growing literature describing the direct visualization of SARS-CoV-2 in causing ATI and CSG. Pathogenetic pathways remain to be elucidated



Capillary collapse.



Viral particles with preserved foot processes

PO0771

What Do Data Tell Us About Patients Receiving Calcineurin Inhibitors (CNIs) and Contracting a Coronavirus

Jung Hoon Son,[1] Ollie Fielding,[1] Xiaoyan Wang,[1] Chris Kipers,[1] Jeffrey I. Silberzweig,[2] Frank Liu.[2] The PEAK team *[1]pulseData, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: We hypothesized that patients taking CNIs, cyclosporine and tacrolimus would be less susceptible to coronavirus infections because of antiviral and anti-cytokine-storm effects and compared the occurrence of positive coronavirus test rates in a population receiving a CNI and non-CNI treatment population. This is of high importance as CNIs are being trialed as a treatment for severe acute respiratory syndrome coronavirus 2 (COVID-19) immune response (NCT04341038). Transplant nephrologists recommend continuing CNIs through the COVID-19 pandemic.

Methods: We analyzed longitudinal EHR system data from the Rogosin Institute's nephrology clinic to identify a population of 5,144 patients with a record of respiratory viral panel (RVP) testing for any coronavirus strain between December 2012 and May 2020. We identified 1,195 patients receiving cyclosporine or tacrolimus and compared positive test rates of any coronavirus stain in those receiving CNIs to those not receiving CNIs.

Results: A total of 51 patients tested positive (1.05%) Of the 1,195 CNI recipients, 21 tested positive (1.76%); of 3,949 patients with no record of CNI treatment, 33 tested positive (0.84%). Given an age distribution difference between the two cohorts (CNI cohort median 58; non-CNI cohort median 68). We therefore calculated an age-adjusted positive test rate for both populations, with results of 1.76% for the CNI cohort and 0.83% for the non-CNI cohort. A z-test comparing the population proportions testing positive had a z-value of 2.71 (p-value 0.003), indicating significant difference. 8.47% of positive tests on an RVP for any of coronavirus, rhinovirus or respiratory syncytial were for a coronavirus in the CNI group vs. 6.48% in the non-CNI group (z 2.37, p 0.009). Using a logistic regression model to examine the probability of testing positive for a coronavirus (features for age, gender, whether the test was conducted in flu season (Dec-Feb) and whether the patient was receiving CNIs) we found that CNIs were statistically significant (p 0.007).

Conclusions: Based on the data, as far as we can tell being on a CNI does not offer protection from a symptomatic coronavirus infection. It remains to be seen if it decreases severity of the illness because of the potential for cytokine storm effects.

PO0772

ESKD Patients with COVID-19 vs. Kidney Transplant Recipients with COVID-19

Thalia Salinas, Michelle L. Lubetzky, Rebecca Craig-Schapiro, Meredith J. Aull, John R. Lee, Jun B. Lee, Samuel Sultan, Choli Hartono, Thangamani Muthukumar, Sandip Kapur, Manikkam Suthanthiran, Darshana M. Dadhania. *NYP-Weill Cornell, New York, NY.*

Background: The Covid-19 pandemic has had significant impact on the ESKD population with reduction in kidney transplantation due to decreased organ availability and temporary cessation of transplant procedures. To better understand the impact on patients with ESKD, we compared the outcomes of Covid-19 positive patients on the Waitlist with those with a functioning kidney transplant.

Methods: Our center developed a dashboard and active surveillance of Waitlisted and Kidney transplant recipients tested for SARS-CoV-2. From 3/13/20 to 5/20/20, we identified 55 Waitlisted patients who tested positive for SARS-CoV-2, and compared their clinical characteristics and outcomes with those post kidney transplant. Primary outcomes included hospitalization and mortality rates.

Results: Presenting symptoms and hospitalization rates were similar in waitlisted ESKD and kidney transplant patients with Covid -19. Azithromycin and doxycycline use was similar in both groups. Hydroxychloroquine use was more frequent in kidney transplant patients (62% vs 36%), as were other experimental therapies. Mortality was greater in waitlisted ESKD compared to kidney transplant patients (29% vs 13). Of the waitlisted ESKD patients who died, most were males, Black or Hispanic, and 81% had T2DM and/or HTN as the cause of their ESKD. None of the non-hospitalized patients died in either group.

Conclusions: Waitlisted ESKD patients on dialysis with Covid-19 are comparatively at higher risk for mortality compared to kidney transplant recipients with Covid-19 despite similar demographics and similar burden of comorbidities. Whether the ability of immunosuppressive therapy to prevent the cytokine storm contributed to better survival among kidney transplant recipients remains to be determined.

Kidney Transplant Practices in Latin America During the COVID-19 Pandemic: Analysis from GlomCon Latin America Working Group (LGlomCon)

Sonia Rodriguez Ramirez,[1] Franco H. Cabeza Rivera,[2] Julio A. Gutierrez-Prieto,[3] Javier Soto-Vargas,[4] Blanca Martinez-Chagolla,[5] Denisse Arellano-Mendez,[6] Diana Aguirre,[7] Desiree Garcia Anton,[2] Carmen Avila-Casado.[1] GlomCon Latin America Working Group (LGlomCon) *[1]University Health Network, Toronto, ON, Canada; [2]University of Mississippi Medical Center, Jackson, MS; [3]Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; [4]Hospital General Regional 46, Guadalajara, Mexico; [5]Hospital General "Dr. Miguel Silva", Morelia, Mexico; [6]Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; [7]Hospital General de Mexicali, Mexicali, Mexico.*

Background: Latin America (LA) is the current epicenter of a global pandemic that has never been seen in the era of transplantation and immunotherapy. We aimed to describe their nephrologists' practices and experiences regarding kidney transplant (KT) management in the context of COVID-19 pandemic.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases between May 20-27, 2020 from sixteen Spanish speaking LA countries divided into 6 categories. We present the results for the kidney transplant category.

Results: 430 responses were obtained of which 360 (84%) were considered for analysis. 139 (49%) respondents routinely participate in the care of transplant patients at centers that perform up to 50 KT per year (70% of them). The transplant activity was suspended in 90% of the centers at the time of the survey. Bigger centers continued their activity but not at full capacity. For transplant recipients who developed COVID-19, 52% of physicians continued the same maintenance immunosuppression for the ones with mild disease (outpatient). For moderate cases (inpatient but not requiring mechanical ventilation or vasopressors), 72% decreased maintenance therapy starting with the antiproliferative drug. For severe cases (ICU admission for mechanical ventilation or vasopressors), 74% stopped all the immunotherapy with the exception of steroids. ICU admission and need for renal replacement therapy were reported in less than 20% of their cases. Nephrologists from centers that continued their transplant activity during the pandemic reported that only 32% performed routine COVID-19 tests to donors and 51% to recipients before KT surgery.

Conclusions: Kidney transplants programs are almost closed throughout LA during the COVID-19 pandemic. The disproportionate resource allocation to COVID-19 will have unintended consequences for those already carrying the burden of health inequality with the potential to disadvantage marginalized patients further. Reported immunosuppression management is in line with transplant societies' recommendations.

A Machine Learning-Based Predictive Model for Outcome of COVID-19 in Kidney Transplant Recipients

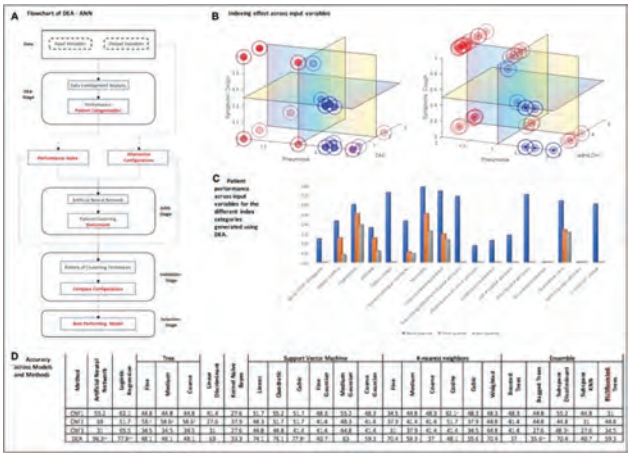
Ignacio Revuelta,[1,2] Francisco-Javier Santos-Arteaga,[3] Enrique Montagud-Marrahi,[1] Pedro Ventura-Aguiar,[1,2] Debora Di Caprio,[4] David Cucchiari,[1,2] Beatriu Bayès,[1] Esteban Poch,[1] Federico Oppenheimer,[1] Fritz Diekmann.[1,2]
[1]Department of Nephrology and Kindey Transplant. Hospital Clinic, Barcelona, Spain; [2]Institut d'Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain; [3]Faculty of Economics and Management. Free University of Bolzano, Bolzano, Italy; [4]Department of Economics and Management. University of Trento, Trento, Italy.

Background: Health systems need tools to deal with COVID-19, especially for high-risk population, such as transplant recipients. Predictive models are necessary to improve management of patients and optimize resources.

Methods: A retrospective study of hospitalized transplant patients due to COVID-19 was evaluated(March 3-April 24,2020). Admission data were integrated to develop a prediction model to evaluate a composite-event defined as Intensive Care Unit admission or intensification treatment with antiinflamatory agents. Predictions were made using a Data Envelopment Analysis(DEA)-Artificial Neural Network(ANN) hybrid, whose accuracy relative to several alternative configurations has been validated through a battery of clustering techniques.

Results: Of 1006 recipients with a planned or an unscheduled visit during the observation period, thirty-eight were admitted due to COVID-19. Twenty-five patients(63.2%) exhibited poor clinical course(mortality rate:13.2%), within a mean of 12 days of admission stay. Cough as a presenting symptom(P=0.000), pneumonia(P=0.011), and levels of LDH(P=0.031) were admission factors associated with poor outcomes. The prediction hybrid model working with a set of 17 input variables displays an accuracy of 96.3%, outperforming any competing model, such as logistic regression(65.5%) and Random forest(denoted by Bagged Trees, 44.8%). Moreover, the prediction model allows us to categorize the evolution of patients through the values at hospital admission.

Conclusions: The prediction model based in Data Envelopment Analysis-Artificial Neural Network hybrid forecasts the progression towards severe COVID-19 disease with an accuracy of 96.3%, and may help to guide COVID-19 management by identification of key predictors that permit a sustainable distribution of resources in a patient-centered model.



PO0775

Outcomes of COVID-19-Positive Kidney Transplant Recipients

Goni Katz-Greenberg, Anju Yadav, Rakesh Gulati, Pooja Singh. *Thomas Jefferson University, Philadelphia, PA.*

Background: Kidney transplant recipients (KTR) are at increased risk of infections due to immunosuppression (IS). COVID-19 has posed unique challenges due to its evolving symptomatology and lack of effective treatment options. Current data published about the impact of COVID-19 in KTR comes from severely impacted areas. The aim of our study was to review course and outcomes of KTR at our center.

Methods: Retrospective chart review of KTR diagnosed with COVID-19. Descriptive statistics were summarized as absolute numbers for categorical data and as median with interquartile range (IQR) for skewed distribution.

Results: We had 20 KTR diagnosed with COVID-19. Median age of 53.5 years(47-63), 10 males, and 12 blacks. Median time from KT to presentation was 70.7 months(17.25-158.75), with 1 pt in 1st year post KT. Thirteen (65%) pts were obese with BMI≥30kg/m^2, 2 pts had chronic obstructive pulmonary disease, and 5 had cardiac disease. Most common presenting symptom was cough in 14 pts, followed by fever-13 pts, shortness of breath-9, and diarrhea-6pts. During the study, 15 pts were hospitalized, and 9 of them had chest x-ray findings of bilateral opacities consistent with pneumonia. Inflammatory markers were elevated in all pts but did not correlate with disease outcome. Acute kidney injury was seen in 9 pts, with 3 requiring continuous renal replacement therapy. Four pts required mechanical ventilation. Ten pts had reduction of their IS. Hydroxychloroquine was used in 11 pts, and azithromycin in 4. Four hospitalized pts received convalescent plasma as part of an ongoing COVID-19 trial in our center. Donors were 4-6 weeks post recovery from confirmed severe acute respiratory syndrome coronavirus 2 infection. Enrollment was offered to pts at high risk of progression to severe disease. We had 3 deaths, 2 pts remain hospitalized, and the remaining 15 were either discharged or managed as outpatients. Median follow up time from presentation was 25 days(13-38) for the entire cohort.

Conclusions: In our cohort, 45% of patients presented with acute allograft dysfunction highlighting impact of SARS-CoV-2 infection on kidney function. Our center utilized investigational convalescent plasma in 4 pts successfully while the clinical trial outcomes are awaited. Ultimately, the development of a safe and efficacious vaccine targeting SARS-CoV-2 may better equip us to fight this pandemic.

PO0776

COVID-19 in Kidney Transplant Recipients at New England's Largest Safety-Net Hospital

Hassan Mahmoud, Sandeep Ghai, Jean M. Francis. *Boston University, Boston, MA.*

Background: The coronavirus disease 2019 (COVID-19) has led to a global pandemic as announced by the World Health Organization. Kidney transplant patients are thought to constitute a unique high risk group for severe COVID19 infection. Furthermore, disparities in health care have led to COVID-19 disproportionately affecting minority groups including African Americans and Hispanics.

Methods: We identified adult kidney transplant recipients who were admitted with COVID-19 between March, 15th and May 1st, 2020. We evaluated the demographic, clinical and laboratory data of all admitted patients. We also evaluated the presence of co-infections as well as decisions regarding immunosuppressant management.

Results: 23 kidney transplant recipients who were hospitalized for COVID-19 were evaluated. 91% of our patients were of minority groups. 35% of patients required ICU admission, and 30% required mechanical ventilation. 40% of patients had associated coinfections in addition to COVID19. 87% of patients had variable degrees of AKI, 26% of patients with AKI required renal replacement therapy. Mortality rate in our population was 22%. Upon admission to the hospital, our immunosuppressant therapeutic approach included stopping the antimetabolites and continuing with the calcineurin inhibitors (targeting trough level of 4 to 6 ng/dl for tacrolimus and 50 ng/dl for cyclosporine), and prednisone if patients were on steroids.

Conclusions: This report demonstrates higher rate of AKI, coinfection and mortality in kidney transplant patients in the setting of COVID19 as compared to general population.

Baseline Characteristics	Patients (N= 23)
Admissions	23
Mean age - year (range)	51 (24-68)
Sex – no (%)	
Male	19 (83 %)
Female	4 (17 %)
Body-mass index	26.1 (18.6-41)
Ethnicity/Ancestry	
African	9 (39%)
Hispanic	12 (52%)
Caucasian	1 (4%)
Arabic	1 (4%)
Co-existing disorder – no (%)	
Asthma	1 (4%)
Current or former smoker	3 (13 %)
Coronary Artery Disease	2 (9 %)
Congestive Heart Failure	11 (48 %)
Diabetes mellitus	10 (43 %)
Hepatitis B	1 (4 %)
Hypertension	21 (91 %)
Obstructive sleep apnea	3 (13%)
Type of transplant	
Cadaveric	20 (87 %)
Living	3 (13%)

Table 2 – Hospital Data	
Systemic symptoms at admission	
Fever	19 (83%)
Headache	2 (9%)
Diarrhea	8 (35%)
Nausea/Vomiting	3 (13%)
Respiratory symptoms at admission	
Cough	13 (57%)
Shortness of breath	10 (43%)
Requiring oxygen	15 (65%)
Requiring Intensive Care	8 (35%)
Requiring intubation	7 (30%)
Requiring Renal Replacement Therapy	6 (26%)
Survival	20 (87%)
Chronic Immunosuppressive therapy	
Calcineurin inhibitor	23 (100%)
Antimetabolite	23 (100%)
Prednisone	12 (52%)

Identifying Scenarios of Benefit or Harm from Kidney Transplantation During the COVID-19 Pandemic: A Simulation Study

Allan Massie,[1] Brian J. Boyarsky,[1] William A. Werbel,[1] Sunjae Bae,[1] Eric Chow,[2] Robin K. Avery,[1] Daniel C. Brennan,[1] Jacqueline Garonzik wang,[1] Dorry L. Segev.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, IL.*

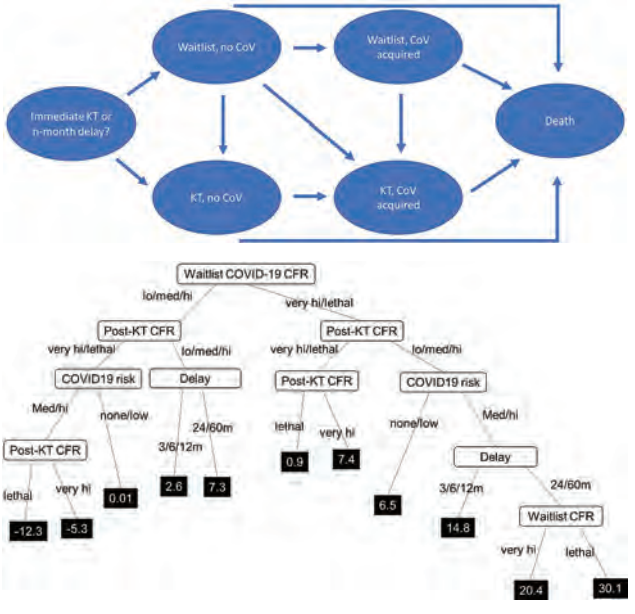
Background: Clinical decision-making in kidney transplantation (KT) during the COVID-19 pandemic is a challenge: both candidates and recipients may face increased acquisition risks and case fatality rates (CFRs). Given our poor understanding of these risks, many centers have paused or reduced KT activity, yet data to inform such decisions are lacking.

Methods: To quantify the benefit/harm of KT in this context, we conducted a Markov simulation study of immediate-KT vs delay-until-after-pandemic for different patient phenotypes under a variety of potential COVID-19 scenarios (Figure 1), simulating expected life-months gained from transplant over 5 years. A calculator was implemented (http://www.transplantmodels.com/covid_sim), and machine learning approaches were used to evaluate the important aspects of our modeling.

Results: Characteristics of the pandemic (acquisition risk, CFR) and length of delay (length of pandemic, waitlist priority for DDKT) had greatest influence on benefit/harm (Figure 2). In most scenarios of COVID-19 dynamics and patient characteristics, immediate-KT provided survival benefit; KT only began showing evidence of harm in scenarios where CFRs were substantially higher for KT recipients (e.g. ≥50% fatality) than for waitlist registrants.

Conclusions: Our simulations suggest that KT remains beneficial under COVID-19 in many scenarios. Our calculator can help identify patients who would benefit most. As the pandemic evolves, our calculator can update these predictions.

Funding: NIDDK Support



Partial summary of simulation output. Black boxes denote life-months gained from transplant; a negative value denotes harm from transplantation.

PO0778

COVID-19 in Patients with CKD in New York City

Oleh M. Akchurin,[1,2] Sharmi Biswas,[1] Michaela Greenbaum,[1,2] Alexandra Licona,[1,2] Justin J. Choi,[1,2] Mary E. Choi.[1,2] *[1]Weill Cornell Medicine, New York, NY; [2]NewYork-Presbyterian Healthcare System Inc, New York, NY.*

Background: Coronavirus disease 2019 (COVID-19) has affected millions of people, and several chronic medical conditions appeared to increase the risk of severe COVID-19. However, limited data are available about the outcomes of COVID-19 in patients with chronic kidney disease (CKD).

Methods: This was an observational study of patients with CKD at three affiliated hospitals in New York City who were diagnosed with COVID-19 by reverse-transcriptase polymerase chain reaction of nasopharyngeal swab specimens collected in the emergency departments between March 3rd and April 21st, 2020. We stratified patients into three groups: pre-dialysis CKD, dialysis, and transplant. Data are shown as median (interquartile range). Logistic regression was used to identify CKD characteristics associated with non-survival.

Results: Of the 372 confirmed COVID-19 patients with CKD, 182 were pre-dialysis, 149 were on dialysis, and 41 had functional kidney transplant. The median age of the pre-dialysis group was 75 (63-85) years, dialysis group 66 (58-74) years, and transplant group 63 (48-71) years. Men comprised 62.4% of the cohort. Baseline serum creatinine was 1.5 (1.2-2.2) mg/dL in the pre-dialysis group. By the end of the observation period, 78.5% of patients were discharged or had died. Of these patients, mortality was highest in the pre-dialysis group (26.9%), followed by dialysis (24.2%), then transplant (9.8%) groups. Almost half of the cohort was receiving ACE-inhibitors or ARBs pre-COVID-19, which was not associated with non-survival. In the pre-dialysis group, baseline serum phosphorus was associated with non-survival (OR 1.5 per each 1.0 mg/dL of increase in serum phosphorus). Anemia, defined as hemoglobin <10 g/dL, was also associated with non-survival (OR 3.1) in that group. Body mass index (BMI)<25 kg/m^2 was paradoxically associated with non-survival (OR 2.7) in patients with pre-dialysis CKD.

Conclusions: Our data demonstrate that mortality in this cohort, particularly in patients with pre-dialysis CKD, was substantially higher than in the general population in New York City. Poorly controlled CKD complications, including CKD-mineral and bone disorder and anemia, as well as low BMI were associated with mortality. Ongoing control of CKD complications may serve as an opportunity to improve outcomes of COVID-19 in patients with CKD.

PO0779

COVID-19 in CKD: Retrospective, Propensity Score-Matched Cohort Study

Ahmet B. Dirim ,[1] Erol Demir, [1] Serap Yadigar,[2] Seda Safak, [1] Ergün Parmaksız,[2] Nurana Guller,[1] Alpay Medetalibeyoglu, [1] Ozgur A. Oto,[1] Kubra Aydin Bahat,[2] Meric Oruc,[2] Seniha Basaran,[1] Günseli Orhun,[1] Halil Yazici,[1] Aydin Turkmen.[1] *[1]Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey; [2]Dr Lufti Kirdar Kartal Egitim ve Arastirma Hastanesi, Istanbul, Turkey.*

Background: The prognostic factors for COVID-19 in patients with chronic kidney disease (CKD) are uncertain. We conducted a propensity score-matched study to compare clinical and prognostic features between hospitalized COVID-19 patients with and without CKD.

Methods: Patients with estimated creatinine clearance below 60 ml/min/1.73 m^2 for more than three months, were included in the CKD group. Fifty-six patients and the propensity score-matched fifty-six control patients were followed-up at least 15 days or until death after diagnosis of COVID-19. All demographic data and diagnostic and therapeutic methods were evaluated. The endpoints were all-cause mortality and acute kidney injury (AKI).

Results: Patient and control groups were reviewed retrospectively over a median follow-up of 44 days (IQR, 36-52 days) after diagnosis of COVID-19. Patients in the CKD group had higher intensive care unit follow-up and mortality rates than the other group, but these results did not reach statistical significance (16 [28.6%] vs. 19 [33.9%]; p=0.54 and 11 [19.6%] vs. 16 [28.6%], p=0.269, respectively). The frequency of AKI was significantly higher in predialysis patients with CKD compared to the other group (8 [14.3%] vs. 5 [45.5%]; p<0.001), but there was no significant difference between the groups in terms of cytokine release syndrome and respiratory failure (13 [23.2%] vs. 8 [14.2%]; p=0.226, 25 [44.6%] vs. 22 [39.3%], p=0.566, respectively). Multivariate logistic regression analysis revealed that respiratory failure (39.283 [95% CI, 7.296 to 211.519; P<0.001] and AKI (10.961 [95% CI, 1.688 to 71.186; P=0.012] were independent risk factors for the mortality.

Conclusions: The prognosis of COVID-19 in patients with CKD is worse than non-uremic patients. Also, AKI and respiratory failure are independent risk factors for mortality.

Table 1. The laboratory results, treatment regimen, and outcomes of the patients

		Control group (n=56)	Patients with CKD (n=56)	p-value
Laboratory results at admission (Median-IQR 25-75)	Lymphocyte count (/mm3)	1150 (758-1478)	940 (520-1355)	0.055
	Serum CRP levels (mg/L)	39 (17-93)	55 (18-154)	0.027
	Serum Ferritin levels (ng/ml)	247 (149-580)	731 (723-2860)	<0.0001
Anti-viral treatment (N, %)	Favipiravir	26 (46.4%)	15 (27.3%)	0.037
Anti-cytokine agents (N, %)	Tocilizumab	5 (8.9%)	1 (1.8%)	0.324
	Anakinra	3 (5.4%)	4 (7.3%)	
	Tocilizumab+Anakinra	5 (8.9%)	3 (5.5%)	
Outcomes (N%)	Number of died patients	11 (19.6%)	16 (28.6%)	0.269

Abbreviations; CKD, chronic kidney disease; CRP, C-reactive protein.

Kidney and Clinical Outcomes of COVID-19 in the Mexican Population

Luz Y. Villegas, Alejandro Garcia Rivera, Ríos C. Katia yuritzi, Arantxa K. Aguilar, Marcos Adrian E. Lopez, Jesús A. Rico sánchez, Carlos A. Villavicencio López, Ernesto Ojeda, Carolina R. Alvarez, Jesús A. Vega López de Nava, Rafael A. Ayala cortés, Luis A. Salazar Soltero, Omar H. Sanchez Vazquez, Jorge fernando Topete reyes. *Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Hospital General Regional No.46, Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Background: Coronavirus Disease 2019 (COVID-19) is a new disease of pandemic proportions. Currently, there are no reports about kidney involvement and the association with mortality in Mexico. Our aim was to describe the characteristics in our population, clinical and renal outcomes.

Methods: Prospective, descriptive, single-center study in patients diagnosed with COVID-19 (positive RT-PCR tests), admitted to our hospital from April 2020 to date.

Results: 48 patients (60.41% men) with an average age of 54.33 years were included. 23 (47.9%) had a previous diagnosis of HTN and DM, 11 (22.9%) had obesity, 5 (10.4%) had neurological diseases, 4 (6.3%) had heart disease, 3 (6.3%) had malignancies and 1 (2.1%) had liver disease. 9 (18.8%) patients with a history of smoking. At admission, the mean oxygen saturation was 85.76%. The main reason for consultation was dyspnea in 35 patients (72.9%). Regarding symptoms, 81.3% (39) had dyspnea, 87.5% (42) fever, 54.2% (26) headache, 72.9% (35) cough and, to a lesser extent, odynophagia, myalgia and malaise in 33.3% (16), 45.8% (22) and 41.7% (20) respectively. The mean creatinine, urea and bicarbonate was 1.34 mg/dl, 56.69 mg/dl, and 18.49 mmol/l respectively. 25% of the patients required ICU admission and 27.1% mechanical ventilation. During the study period, 19 patients (39.6%) developed AKI, 20.8% classified as KDIGO stage 1 and 18.8% as stage 3. At the end of this study, 56.3% (27) had a complete recovery, 35.4% (16) died and 8.3% (5) are still admitted. Regarding the patients that had an AKI, 6 (31.57%) had a complete recovery, 3 (15.7%) required intermittent HD but eventually died, for a total of 13 death patients (68.4%). There was a statistically significant difference in mortality between patients with AKI vs patients with normal kidney function (p=0.002), with a RR of 3.47.

Conclusions: This study showed a higher prevalence of AKI in the Mexican population compared to reports from other countries, with a significantly higher risk for death. Special attention should be paid to this outcome and as nephrologists, we must take an active role in the care of these patients.

PO0781

Association Between Kidney Dysfunction at Admission and Outcomes in Hospitalized Patients with COVID-19

Imran Chaudhri,[1] Farrukh M. Koraishy,[1] Olena Bolotova,[1] Jeanwoo Yoo,[1] Simrat Dhaliwal,[2] Raji Reddy Annadi,[3] Minh Hoai Nguyen,[3] Sandeep K. Mallipattu.[1,4] *[1]Stony Brook University Hospital, Stony Brook, NY; [2]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [3]Stony Brook University, Stony Brook, NY; [4]Northport VA Medical Center, Northport, NY.*

Background: AKI is a major predictor of mortality in patients with coronavirus disease 2019 (COVID-19). Data regarding association of renal dysfunction (AKI, hematuria and proteinuria) at the time of admission with hospital outcomes is limited.

Methods: In this retrospective single-center study, we analyzed electronic medical record data on 300 patients admitted with COVID-19. Data collection included history of comorbidities, medications, vital signs, and admission and peak laboratory values. Outcomes included inflammatory burden (calculated using composite scores for multiple markers of inflammation), AKI during hospitalization, admission to the intensive care unit (ICU), need for invasive mechanical ventilation, mortality and length of stay. For multivariate analyses, generalized linear model (continuous outcomes) and logistic regression (dichotomous outcomes) were used. Machine learning algorithms (XGBoost classifier with 3-fold cross-validation) were performed to develop a predictive model for in-hospital AKI.

Results: No significant associations between admission AKI and hospital outcomes were observed. Admission proteinuria was associated with increases in in-hospital AKI, ICU admission, death, peak inflammation score, and length of stay on descriptive analysis; however, on multivariate analysis (after adjusting for multiple covariates), only in-hospital AKI remained statistically significant (OR=4.71, 1.28–17.38, p=0.02). Admission hematuria was associated with increases in in-hospital AKI, ICU admission, invasive mechanical ventilation, and death on descriptive analysis; and on multivariate analysis it still predicted increased rates of ICU admissions (OR=4.56, 1.12-18.64, p=0.03), invasive mechanical ventilation (OR=8.79, 2.09-37.00, p=0.003), and death (OR=18.03, 2.84-114.57, p=0.002). Using machine learning algorithms, an area under the receiver operating curve (AUROC) of 87.4% with an accuracy of 87.6% was obtained for predicting in-hospital AKI using only admission data.

Conclusions: In patients with COVID-19, admission hematuria and proteinuria are associated with adverse hospital outcomes, and admission data can be used to predict AKI during hospitalization.

PO0782

COVID-19 in CKD Patients: Lessons from 553 CKD Patients with Biopsy-Proven Kidney Disease

Juan León Román, Clara García-Carro, Nestor Toapanta, Irina Torres, Roxana Bury, Cinthia Baldallo, Daniel Serón, Maria Jose Soler. *Hospital Vall d'Hebron. Nephrology Department, Barcelona, Spain.*

Background: COVID-19 is a novel coronavirus currently at the centre of a global pandemic, and patients with cardiovascular risk factors such as hypertension and diabetes are at risk of a serious complication such as hospitalization and death. Chronic kidney disease (CKD) increased cardiovascular risk and >90% of CKD patients presented hypertension. The prognosis and lethality of COVID-19 in patients with biopsy-proven kidney disease has not been previously studied.

Methods: Data included patients who underwent a kidney biopsy at the Vall d'Hebron Hospital between January 2013 and February 2020 with diagnostic confirmation and those with high clinical suspicion of SARS-CoV-2 infection during the period from March to May 2020.

Results: Of 553 patients, 39(7%) were diagnosed with SARS-CoV2 infection. The mean age was 63.4±15 years. 48.7% were male, 31 hypertension, 19 diabetic, 12 obese and 18 patients had lung disease. The renal histological diagnosis of glomerulonephritis with extracapillary proliferation in 10.3%, allergic interstitial nephritis in 10.3 %, secondary GSFS in 8.5% and diabetic nephropathy in 10.3%. 4 patients were on hemodialysis and 6 had a kidney transplant. Creatinine before infection was 1.52mg/dL±0,66. 17 patients were under immunosuppressive treatment (14 with prednisone, 8 mycophenolate, 6 tacrolimus, 1 rituximab). 26 patients had confirmation of SARS-CoV2 infection with RT PCR obtained from nasopharyngeal swab. 22 patients required hospital admission [average hospital stay was 16 days±11], of which 4 in the ICU and 6 (15%) died. 15 patients received lopinavir/ritornavir; 23 patients, azithromycin; 20 patients, hydroxychloroquine; 6 patients, tocilizumab; 9 patients, intravenous corticosteroids. 11 patients presented impaired renal function, of which 3 were transplanted and 8 with CKD. CKD patients under RAS blockade had less mortality than patients without RAS blockade treatment (29% vs 0%, p=0.014).

Conclusions: COVID-19 was diagnosed in 7% of our CKD patients with kidney biopsy. The mortality was 15%, lower than the reported in hemodialysis patients. RAS blockade is not exerting a deleterious effect in our CKD patients with COVID-19 infection, suggesting that they should not be withdrawn.

PO0783

Renal Dysfunction, COVID-19 Infection, and Mortality

Yanetsy Olivera Arencibia,[1,2] Oscar A. Garcia Valencia,[1,2] Juan D. Salcedo Betancourt,[1,2] Gabriel Contreras,[1,2] Alessia Fornoni,[1,2] Sabrina N. Taldone,[1,2] Sayari Patel,[2] Alexander R. Sands,[2] Marie C. Desir,[2] Samantha Spring,[2] Staci J. Marbin,[2] Anna K. Shah,[2] Angela M. Mcgaugh,[2] Ciara G. Sanon,[2] Jay-Shing Wang,[2] Camille C. Baumrucker,[2] Nidhi Patel,[2] Samantha R. Greissman,[2] Matthew J. Gulau,[2] Carlos A. Dallera,[2] Sohil S. Desai,[2] Marie A. Sosa.[1,2] *[1]Jackson Memorial Hospital, Miami, FL; [2]University of Miami, Coral Gables, FL.*

Background: Critically ill patients with the SARS-CoV-2 virus (COVID-19) infection have diverse clinical manifestations including renal dysfunction which can determine their short-term outcomes. We assess if renal dysfunction on day one of hospital admission is associated with increased mortality risk of patients with severe COVID-19 infection.

Methods: We conducted a retrospective review of records of patients with severe COVID-19 infection admitted to the Intensive Care Unit between March 4 and April 11, 2020. Patients were divided into two groups based on serum creatinine level on day one of hospital admission. Group 1 included patients with normal serum creatinine (SCr) 1.10 mg/dl while group 2 included patients with high SCr > 1.10 mg/dl. The primary outcome was mortality. Secondary outcomes were the need for renal replacement therapy (RRT), duration of RRT, development of adult respiratory distress syndrome (ARDS) and need for mechanical ventilation. Comparisons between groups were done using Mann-Whitney U-tests for continuous variables and chi-square tests for categorical variables. Mortality was evaluated with a Kaplan-Meier Survival Analysis.

Results: A total of 47 patients were included: 27 in group 1 and 20 in group 2. Patients in group 2 compared to group 1 were older (67 vs. 56, p=0.04), more frequently African Americans (11% vs 45%, p=0.02), hypertensives (80% vs 52%, p=0.05) with chronic kidney disease (25% vs 0%, p=0.01), without significant differences sex, diabetes mellitus, smoking status or use of renin-angiotensin antagonists. 8 patients in group 2 and 3 patients in group 1 died, with significant difference in cumulative survival (Figure 1). Need for RRT (55% vs 41%, p=0.33), duration of RRT (6 vs 3 days, p=0.08), development of ARDS (85% vs 81%, p=0.75) and need for mechanical ventilation (65% vs 61%, p=0.89) were not significantly different between groups 2 and 1.

Conclusions: The presence of renal dysfunction on the day of hospital admission is associated with increased hospital mortality in patients with severe COVID-19 infection.

PO0784

Kidney Involvement and Outcome of COVID-19 Patients Admitted from a Federal Medical Facility

Yahya R. Ahmad,[1] Matthew Shea,[1] Mohamed M. Abdalbary,[2] Elijah Kakani,[1] Javier A. Neyra,[1] Amr E. Mohamed.[1] *[1]University of Kentucky Medical Center, Lexington, KY; [2]Mansoura University, Mansoura, Egypt.*

Background: Correctional facilities face unique challenges with the COVID-19 pandemic. A COVID-19 outbreak was reported in the Federal Medical Center (FMC) in Lexington, Kentucky, a prison for inmates requiring medical and/or mental health care. We aimed to compare clinical characteristics and kidney related outcomes in inmates from this FMC to other COVID-19 hospitalized patients.

Methods: A total of 86 COVID-19 patients were admitted to our hospital between March 1st and June 1st, 2020. Among those, 37 patients were from the same FMC. We examined demographics, clinical and laboratory characteristics, along with the outcomes of this cohort and compared it to other COVID-19 non-prisoners. AKI was determined by KDIGO criteria.

Results: All inmates were men and their mean age was 59.8±10.6 years. The majority of them were white (60%) and required ICU admission (54%), while 39% of patients required mechanical ventilation. The prevalent comorbidities were hypertension (81%), obesity (62%), diabetes (41%) and coronary artery disease (CAD) (38%). Stage 3 CKD was present in 22% of inmates. The mean eGFR was 68±26 ml/min/1.73m^2 at time of admission. Significant hematuria and proteinuria were found in 17% and 25% of patients, respectively. Hypertension, heart failure, CAD, COPD, hepatitis C infection, and AKI were more prevalent in the FMC cohort (P= 0.030, 0.001, 0.024, 0.001, 0.017, and 0.011, respectively). The difference in mortality rates was not statistically significant between groups (12% for inmates vs.17% for non-inmates, p=0.520). Incident AKI was higher in inmates vs. non-inmates (68% vs. 38%, p=0.006) and there was no difference in acute dialysis need (14% vs 12%, respectively). The overall mortality rates were higher in patients that required dialysis (80% vs. 6% for those who did not, p<0.001). The need for acute dialysis was independently associated with mortality in multivariable models.

Conclusions: Incidence of AKI was higher in hospitalized inmates with COVID-19 vs. non-inmates. The need for acute dialysis was strongly associated with mortality in overall COVID-19 hospitalized patients.

PO0785

Can Urine Biomarkers Predict Severity of COVID-19? A Preliminary Study

Daisuke Katagiri, Eisei Noiri, Masahiro Ishikane, Yusuke Asai, Noriko Kinoshita, Norio Ohmagari, Fumihiko Hinoshita. *National Center for Global Health and Medicine, Shinjuku-ku, Japan.*

Background: Early detection of coronavirus disease (COVID-19) in patients likely to develop severe manifestations enables appropriate interventions, including rapid intensive care unit admission. This study was conducted to determine whether non-invasive urine biomarkers can predict the clinical severity of COVID-19.

Methods: Design A retrospective case series. **Setting** Single-center study, national center hospital designated for infectious disease. **Patients** Fifty-eight patients who tested positive for SARS-CoV-2 in respiratory specimens through real-time reverse transcription-polymerase chain reaction (RT-PCR) were retrospectively studied. **Measurements and main results** Urinary β2-microglobulin (β2MG), liver-type fatty acid-binding protein (L-FABP) were serially measured. Serum interferon γ and monocyte chemotactic protein-1 were also evaluated.

Results: The 58 patients were assigned into three groups. Patients requiring intensive care were assigned to the severe group (N = 12). Patients treated with oxygen were assigned to the moderate group (N = 13). Other patients were assigned to the mild group (N = 33). Urine tests revealed that low β2MG and L-FABP levels on admission were associated with mild disease, whereas high levels were associated with severe disease. In severe cases, L-FABP tended to be persistently high. The resulting cutoff values were β2MG; Severe vs. Moderate+Mild: 2457 μg/dL (Specificity 76.9% and Sensitivity 90.0%, AUC 85.9%), L-FABP; Severe vs. Moderate+Mild: 22.0 μg/gCre (Specificity 84.6% and Sensitivity 90%, AUC 91.8%). Urinary β2MG and serum IFN-γ/MCP-1 showed a similar trend.

Conclusions: Evaluating urinary biomarkers such as β2MG and L-FABP may allow determination of COVID-19 patients with active cytokines and recognition of patients likely to become critically ill and requiring careful observation and early intervention.

Funding: Government Support - Non-U.S.

PO0786

Urinary Sediment Microscopy in COVID-19-Associated AKI

Cesar F. Hernandez-Arroyo,[1] Vipin Varghese,[2] Muner Mohamed,[1] Juan Carlos Q. Velez.[1,2] Ochsner Nephrology *[1]Department of Nephrology, Ochsner Health System, New Orleans, LA; [2]Ochsner Clinical School, The University of Queensland, Brisbane, QLD, Australia.*

Background: Acute kidney injury (AKI) is a complication of COVID-19 that is not fully understood. Microscopic examination of the urinary sediment (MicrExUrSed) is a valuable diagnostic tool in AKI. Thus far, there has been scarcity of data about MicrExUrSed in COVID-19-associated AKI (CoV-AKI). We hypothesized that MicrExUrSed provides diagnostic clues in CoV-AKI.

Methods: We conducted a prospective observational study in patients seen for inpatient nephrology consultation with KDIGO AKI stage ≥ 1 and COVID-19 over a 1-month period. Urine specimens were collected with personal protective equipment to perform MicrExUrSed. Slides were assessed for presence of white blood cells (WBC) [≥ 2+ dipstick, ≥ 6 per low power field (LPF)], red blood cells (RBC) (≥ 2+ dipstick, ≥ 8 per LPF), acanthocytes, granular casts (GC), renal tubular epithelial cell casts (RTECC) and waxy casts (WxC). Slides were assigned to a category of acute tubular injury (ATI) based on either a Perazella cast score ≥ 2 or a Chawla cast score ≥ 3.

Results: Among 161 cases of AKI, MicrExUrSed was performed in 20 (12.4%). Anuria and contact precautions were barriers to obtain specimens. GC were found in 17 (85%) of which 16 (80%) had "muddy" brown GC (MBGC). A median 5 MBGC per LPF (1-20) were found in a median 40% (10-95%) of LPFs. WxC were found in 10 (50%) cases with a median 2 (1-5) per LPF, all of whom had MBGC also present. RTECC were found in 3 (15%) cases with a median 1 (1-4) per LPF. Altogether, ATI score was assigned to 17 (85%) patients, of which 12 (60%) had AKI either after a hemodynamic/ischemic insult (9) or after a toxic insult (3) (rhabdomyolysis, vancomycin, contrast) and 3 (15%) had biopsy-proven ATI along with collapsing glomerulopathy; for a total of 15 (75%) patients with either clinical or histological evidence on ATI matching the MicrExUrSed findings. Ten (50%) and 5 (25%) had WBCs and RBCs, respectively. Acanthocytes were found in 1 (5%) patient with presumptive proliferative endocapillary glomerulonephritis.

Conclusions: MicrExUrSed in most patients with CoV-AKI showed overt evidence of ATI with an abundance of MBGC and WxC, including in cases of coexisting glomerulopathy. Pyuria was observed in half. The diagnostic utility of MicrExUrSed in CoV-AKI was comparable to that demonstrated in other forms of AKI.

PO0787

COVID-19 Infection in Kidney Transplant Recipients: A Multicenter Experience in Istanbul

Erol Demir,[1] Murathan Uyar,[5] Ergün Parmaksız,[4] A. Sinangil,[2] Berna Yelken,[3] Ahmet B. Dirim,[1] Ozgur Merhametsiz,[5] Serap Yadigar,[4] Zuhal Atan ucar,[2] A. Ucar,[1] Mehmet E. Demir,[5] M. Mese,[4] Emin Baris Akin,[2] Nurana Guller,[1] Seda Safak,[1] Ozgur A. Oto,[1] Halil Yazici,[1] Aydin Turkmen.[1,3] *[1]Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey; [2]Istanbul Bilim Universitesi Tip Fakultesi, Istanbul, Turkey; [3]Koc Universitesi, Istanbul, Turkey; [4]Dr Lufti Kirdar Kartal Egitim ve Arastirma Hastanesi, Istanbul, Turkey; [5]Yeni Yuzyil Universitesi, Istanbul, Turkey.*

Background: Management of COVID-19 in kidney transplant recipients (KTR) should include treatment of infection and regulation of immunosuppression but there is no consensus on this issue yet. In this study, we aimed to describe our experience in KTR with COVID-19.

Methods: In this retrospective cohort study, we included KTR who diagnosed with COVID-19 from five centers. The patients were categorized into two groups for the analysis. Patients had respiratory failure and multiple organ dysfunctions were defined as severe pneumonia. All other cases were classified as moderate pneumonia. The primary endpoint was all-cause mortality.

Results: 40 patients (20 female) were reviewed over a median follow-up of 32 days (IQR, 14-51 days) after COVID-19. 5 patients died during the follow-up. The frequency of graft dysfunction was similar between groups (n=12 and n=2; p=0.615, respectively). The frequency of previous induction (n=18 and n=7; p=0.016, respectively) and rejection therapy (n=4 and n=3; p=0.023, respectively) was significantly increased in the group with severe pneumonia compared to the moderate pneumonia group. None of the patients using cyclosporine A developed severe pneumonia. Also, multivariate logistic regression analysis revealed that previous anti-rejection therapy (9.75 [95% CI, 1.223 to 77.724; P=0.032]) was the independent predictor for mortality.

Conclusions: COVID-19 more commonly causes moderate or severe pneumonia in KTR. Immunosuppression should be carefully reduced in KTR. Induction therapy with lymphocyte depleting agents should be carefully avoided in KTR during the pandemic period.

The demographic characteristics, treatment regimen, and outcomes of the patients

		All patients (n=40)	Moderate pneumonia (n=33)	Severe pneumonia (n=7)	p-value
	Age (Mean±SD, year)	44.9±14.8	43.3±14.9	49.3±14.8	0.388

Abbreviations; ALT, alanine aminotransferase; LDH, lactate dehydrogenase. P-values compared moderate pneumonia and severe pneumonia.

PO0788

COVID-19 and Kidney Transplant Outcomes

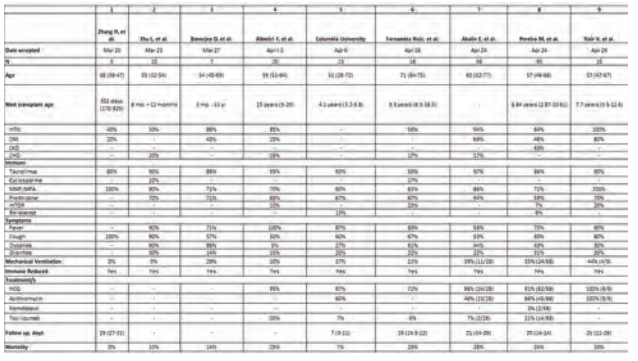
Vinay Nair, Nicholas Jandovitz, Mersema Abate, Madhu C. Bhaskaran, Gayatri D. Nair, Ernesto P. Molmenti. *Northwell Health, Great Neck, NY.*

Background: Recent publications report great variations in the clinical course and mortality of COVID-19 in solid organ transplant (SOT) recipients. It is unclear whether these differences are related to study methods, treatment choices, or variables associated with patient populations.

Methods: We reviewed and summarized 9 published articles of COVID-19 in solid organ transplant recipients. We contrasted difference between study design and compared outcomes.

Results: All studies included kidney transplant recipients while study 6 and 8 included non-renal SOT. Four come from the United States. Results can be seen in the attached table. Most studies had a median age in the 50's, with hypertension and diabetes being common comorbidities. Tacrolimus, mycophenolate analogs and prednisone was the most common immunosuppression regimen. Presenting symptoms were usually fever, cough, dyspnea, and diarrhea. Immunosuppression was either reduced or discontinued in all studies. The majority of patients received hydroxychloroquine. Azithromycin, remdesevir, leronlimab, lopinavir/ritonavir, darunavir, oseltamivir, and tocilizumab were also used. Mortality ranged from 0% to 30%. All studies described hospitalized patients. A third of reports also included outpatients. The median follow up was approximately 3 weeks for most studies (range of 7 to 29 days). All but one series with reported patient deaths under 20% either did not include or had follow-up periods of less than 10 days.

Conclusions: Presentation of COVID-19 and immunosuppression strategies are similar among transplant centers. Differing outcomes may be related to small number of cases, potentially varying acuities of illness and follow up periods. Given that cytokine storm occurs late in the course of COVID-19, it is plausible that mortality may increase in studies with short follow up. When excluding short or missing follow up, mortality appears to be between 20-30%, which suggests that transplant recipients have a higher mortality than their non-immunocompromised peers.



PO0789

Thrombotic Microangiopathy (TMA) in a Patient with COVID-19

Bessy Suyin Flores Chang, Rushang Parikh, Rimda Wanchoo, Vanesa Bijol, Kenar D. Jhaveri. *Donald and Barbara Zucker School of Medicine at Hofstra/ Northwell, Hempstead, NY.*

Introduction: We describe a patient with COVID-19 and clinically significant kidney biopsy proven TMA

Case Description: 69-year-old Caucasian female with medical history of asthma came to the ED with productive cough, fever and dyspnea for 2 weeks. She was afebrile, tachypneic and hypoxic. Initial laboratories showed a normal WBC, hemoglobin level and platelet count. Inflammatory markers were elevated. SARS-CoV-2 infection was confirmed by PCR assay. CXR showed bilateral diffuse patchy opacities. Treated with hydroxychloroquine, enoxaparin and oxygen was started. Patient received anakinra and tocilizumab. On day 12, the patient developed thrombocytopenia, anemia and worsening kidney function concerning for microangiopathic hemolytic anemia. Due to worsening hypoxemia, patient received convalescent plasma. On day 17, she was intubated due to worsening respiratory failure. Findings suggestive of hemolysis were present. Urinalysis showed hematuria and proteinuria. Patient's kidney function worsened requiring initiation of CRRT. On day 20, the patient underwent a kidney biopsy that revealed severe acute TMA with cortical necrosis. Beta 2 glycoprotein-1 IgM levels were elevated, anti-phospholipid antibodies were absent. A disintegrin and ADAMTS13 level were not low. C3,C4 were in normal range. Heparin induced antibody testing was negative. Coagulation parameters were normal. Kidney doppler was unremarkable. No other systemic findings of macro thrombi were found. Low factor H complement antigen, elevated plasma CBb complement and plasma SC5b-9 complement levels suggesting an activation of the alternative complement pathway were found. Genetic testing was not done. Plasma exchange was not performed, but received a single dose of eculizumab on day 21. Unfortunately, she died on day 23.

Discussion: Coagulopathy associated with SARS-CoV-2 has been widely reported. Profound hypoxia, inflammation, disseminated intravascular coagulation(DIC) have all been implicated as potential causes, but were not present in our patient. To the best of our knowledge, we report the first case of TMA associated with SARS-CoV-2 with presence of diffuse cortical necrosis and widespread microthrombi in kidney biopsy. It is not clear if the virus played a direct pathogenic role or unmasked a latent complement defect leading to widespread endothelial damage and micro thrombi

PO0790

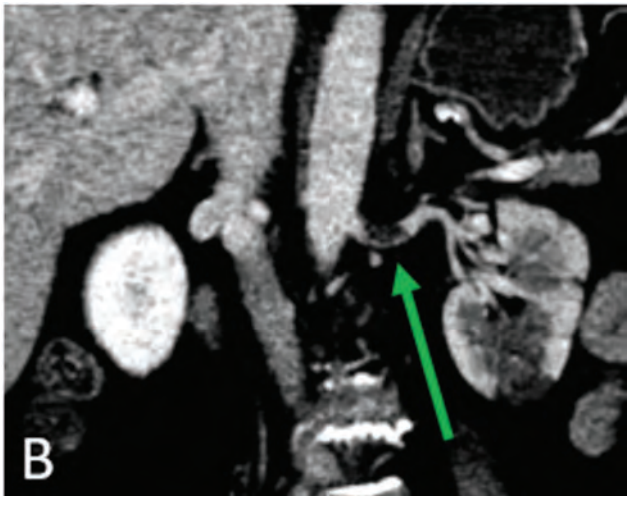
Renal Artery Thrombosis with Infarction in a Patient with Mild COVID-19

Ryan Mocerino, Neelja D. Kumar. *Montefiore Medical Center, Bronx, NY.*

Introduction: There has been increased focus on the microvascular and macrovascular complications of COVID-19. Here we present a case of renal arterial thrombosis in a woman with mild symptoms of COVID-19.

Case Description: A 69 year old female with diabetes, hypertension, coronary artery disease, and acute embolic cerebrovascular event post cardiac catheterization in 2016 presented to the emergency department with acute diffuse intermittent abdominal pain and nonbloody emesis. Prior to this, she had been evaluated for cough, shortness of breath and myalgias which were conservatively managed with improvement. Her medications included aspirin, clopidogrel, furosemide, and insulin. Examination was significant for diffuse nonspecific abdominal tenderness without rebound or guarding. Laboratory assessment revealed preserved renal function with creatinine of 1.10 mg/dL and PCR positive for SARS-CoV-2. A computed tomography of the abdomen and pelvis with intravenous contrast revealed a non-occlusive thrombus in the left renal artery with several large wedge-shaped areas of decreased enhancement consistent with multiple left renal infarctions. On interdisciplinary discussion, the patient was managed conservatively with anticoagulation without acute intervention and was discharged home on apixaban.

Discussion: To our knowledge, this is the first description of renal artery thrombosis with renal infarction in the setting of COVID-19 infection. Patients who present with a COVID-19 infection, regardless of disease severity, should be evaluated for coagulopathy and development of thrombi as these may potentially contribute to infarction and end-organ damage. Although it requires a high index of suspicion, renal infarction should be considered part of the differential when evaluating a patient with COVID-19 infection presenting with abdominal pain or acute kidney injury. Initiation of anticoagulation should be considered with consideration of risks involved.



PO0791

A Case of Severe Thrombocytopenia in a Patient with COVID-19 Receiving Continuous Venovenous Hemodialysis

Hay Me Me, Zhong Zheng, Jennifer Griffiths, Anjani K. Dubey, Savneek S. Chugh. Westchester Medical Center *Westchester Medical Center, Valhalla, NY.*

Introduction: Thrombocytopenia is a rare complication of renal replacement therapy with most of the cases reported in intermittent hemodialysis patients. There is limited data regarding the incidence of thrombocytopenia caused by continuous renal replacement therapy (CRRT). We report a case of thrombocytopenia in patient treated with CRRT for severe AKI from COVID-19 sepsis unrelated to heparin.

Case Description: A 73-year female with history of type 2 diabetes mellitus was admitted for Coronavirus Disease 2019 (COVID-19) pneumonia. Patient developed acute hypoxic respiratory failure requiring mechanical ventilation despite treatment with hydroxychloroquine, azithromycin and convalescent plasma. Hospital course was complicated by septic shock and acute kidney injury with serum creatinine rising from a baseline of 0.8 mg/dl. Continuous veno-venous hemodialysis (CVVHD) without any anticoagulation was initiated due to severe fluid overload. Significant thrombocytopenia below 50,000/mm3 was noted 2 days after CVVHD treatment. Patient received multiple antibiotics and heparin drip before CVVHD and platelet counts were above 150,000/mm3. Heparin induced thrombocytopenia (HIT) was ruled out with negative serotonin release assay and platelet counts remain low despite the discontinuation of all potential agents. Disseminated intravascular coagulopathy was excluded based on coagulation tests. Platelet counts finally went up to 160,000/mm3 on subsequent CVVHD holidays and again dropped to 70,000/mm3 after CVVHD was resumed.

Discussion: The rate of rise in platelet count more than 150,000/mm3 in 2 days after cessation of CVVHD supports the diagnosis of thrombocytopenia caused by CVVHD. Although the exact mechanisms remain unclear, previous studies suggested that the mechanical destruction of platelets by the hemofilter or allergic reaction to dialyzer membrane as some of the reasons. Some studies have found that severe decline (more than 50%) in platelet count was associated with increased mortality and decreased rate of renal recovery. Thrombocytopenia on CVVHD unrelated to HIT is an under-acknowledged complication. Understanding the multiple etiologies of thrombocytopenia will help prevent the excessive use of blood products, fluid overload state and the potential clotting issue of CVVHD due to transfusion.

PO0792

Case Study: Kidney Transplant Patient with COVID-19: Impact of Viral Infection on Background Cell-Free DNA in a Donor-Derived Cell-Free DNA Rejection Assay

Suphamai Bunnapradist,[1] Joanna Schaenman,[1] Erik L. Lum,[1] Philippe M. Gauthier,[2] Ebad Ahmed,[2] Paul R. Billings.[2] *[1]University of California Los Angeles, Los Angeles, CA; [2]Natera, In, San Carlos, CA.*

Introduction: Donor-derived cell-free DNA (dd-cfDNA) assays are clinically validated to detect kidney transplant injury, reporting the donor fraction as a percentage of the total, or background, cfDNA. Various clinical factors can cause a significant increase in recipient cfDNA, contributing to higher background cfDNA and lower donor fraction, which may result in a false negative test result.

Case Description: A 50+ year old woman with end-stage renal disease secondary to polycystic kidney disease presented with 4 days (d) of diffuse muscle pain at 11 months post-kidney transplant. In the emergency department she had a fever to 101°F, bilateral infiltrates on chest x-ray, and a positive COVID-19 (SARS-CoV-2) test. She remained febrile for 3d before developing acute respiratory distress requiring oxygen supplementation; her creatinine level was 3 mg/dL. Due to worsening of her respiratory status, she was intubated and started empirically on vancomycin, meropenem, and azithromycin; mycophenolate mofetil was discontinued. She rapidly progressed to septic shock requiring vasopressor therapy. Her renal function deteriorated, and she was started on continuous renal replacement therapy on hospital d7. She received leronlimab on hospital d7 and d14 and convalescent plasma on hospital d11. Tacrolimus was discontinued on hospital d10 and she continued prednisone at 5 mg/d. Dd-cfDNA testing to assess allograft injury and to rule out active rejection was performed. At hospital d20, her dd-cfDNA was 0.07% with an elevated background cfDNA of 28,569 arbitrary units (AU, ~57X median value). At the second blood draw at hospital d25, her dd-cfDNA was 0.25% with a background cfDNA level reduced to 7,503 AU (~15X median value).

Discussion: In this case, infection with the SARS-CoV-2 virus was associated with a very elevated background cfDNA level, likely due to cellular apoptosis due to the immune process and/or tissue ischemia due to sepsis-associated hypoperfusion. Although this patient was not known to have active rejection of her allograft, the very high background levels complicate the interpretation of results, especially when donor fraction were reported.

PO0793

COVID-19 AKI to ESRD: A New Cohort of Dialysis-Dependent Patients

Eric J. Chacko,[1] Jason Cummings,[1] Marc Richards.[2] *[1]Florida Atlantic University, Boca Raton, FL; [2]Florida Atlantic University, Boca Raton, FL.*

Introduction: The Covid-19 pandemic has resulted in a massive number of hospitalizations with widespread effects on the global healthcare system. More research is needed to understand the implications of the disease, particularly its effects on renal function. Although initial studies from China suggested otherwise, there is growing evidence for an association between Covid-19 and AKI.

Case Description: A 66-year old man with history of CKD IIIb presented to the ED with fever and dry cough for several days. On admission the patient was febrile and tachypneic. Labs were showed elevations in BUN, SCr and inflammatory markers. Chest CT revealed bilateral ground glass opacities and NP swab was positive for SARS-CoV-2. The patient was initially treated with hydroxychloroquine, levofloxacin, and IV fluids. Clinical status worsened, eventually requiring intubation and vasopressors. Renal function progressed to anuria. Bicarbonate, potassium binders and loop diuretics were attempted to treat renal failure. On hospital day 4 the patient was placed on CRRT however he remained anuric. CRRT was complicated by clotting episodes managed with circuit anticoagulation with unfractionated heparin. The patient slowly improved, was extubated 17 days later, and transitioned to IHD. The patient underwent tunneled catheter placement and was discharged 30 days after admission and remains on IHD.

Discussion: It is theorized that renal impairment in Covid-19 is due to virus entry into host cells via the ACE-2 receptor present in lungs and kidneys. Post-mortem kidney biopsies suggest that renal damage in Covid-19 is mediated through multiple mechanisms including direct cytotoxicity, immunologic deposition, and microthrombi-related tubular damage. Although our patient recovered after a prolonged hospital course, he remained anuric requiring IHD far sooner than anticipated with natural progression of CKD, illustrating the unforeseen consequences of Covid-19 on healthcare resource utilization. Early use of CRRT may have a role as a therapeutic modality via inflammatory cytokine removal, however consideration must be made for future resource utilization including alternative RRT measures such as acute PD for critically ill patients as supplies dwindle. As the cases of Covid-19 increases, a higher number of patients may not see a return of renal function despite recovery and RRT resource management will need to be prioritized.

PO0794

Rhabdomyolysis as a Complication of COVID-19: A Report of Five Cases

Miguel Maza Moreno,[1,2] Vanessa C. García Macas,[1,2] Jose L. Herrera,[1] Gandhy T. Fonseca,[1] Jose H. Cano,[1] Juvenal Torres Pastrana.[1] CMN 20 de Noviembre *[1]Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico; [2]Nephrology and Extracorporeal Membrane Therapy Department, Mexico City, Mexico.*

Introduction: COVID-19virus pandemia has caused more than 5million infected and 330thousand deaths worldwide. The incidence of acute kidney injury (AKI) is variable, from 0.5%to29.8%. Rhabdomyolysis(Rb) is a life-threatening emergency, usually manifesting as myalgia, fatigue, pigmenturia, and AKI. One of its leading non-traumatic causes are viral infections. We report 5cases of Rb associated with COVID-19.

Case Description: Of a total of 460 positive cases of COVID-19infection (real-timePCR), at the NationalMedicalCenter20deNoviembre in MexicoCity, 5were diagnosed with Rb and associated AKI(Ck>5,000U/l and KDIGO AKIcriteria). Characteristics of patients are presented in(Fig.1). Age range was from 29to64 years, only one female, all withBMI>25 kg/m2, time from admission-diagnosis of Rb was on average oneweek. Most common symptoms were fever, cough, and dyspnea(5/5), as well as abdominal pain(4/5). Only(1/5) was oliguric at diagnosis. Average Ck at diagnosis was7845 (18-165µg/L) and all cases had high levels of interleukin-6. They were managed with aggressive hydration, 2of them required renal replacement. At the time of this report, 2 had been discharged, 2 remain hospitalized(one still on RRT), and one died.

Discussion: COVID-19patients can develop AKIprimarily due to low oral intake, sepsis, andcytokine storm. Patients with COVID-19have multiple risk factors for Rb development: viral muscle cytotoxicity, continuous hyperthermia, andcytokine storm among others. This results in a high risk ofAKI via 3mechanisms: renal vasoconstriction, tubular obstruction and direct tubular toxicity. Of note, in the described cases, abdominal pain was a common symptom and only one was oliguric. Early identification allowed timely fluid resuscitation, which underscores the importance of having a high index of suspicion. Further observations will be needed to understand the full spectrum of association between COVID-19and Rb, but is clear that these patients are at highrisk for developing AKI by these mechanisms.

Corticosteroid Treatment in a Case of COVID-19-Associated Collapsing FSGS

Anna M. Zemke,[1] Pravir V. Baxi,[2] Roger A. Rodby.[2] *[1]Department of Internal Medicine, Rush University Medical Center, Chicago, IL; [2]Division of Nephrology, Department of Internal Medicine, Rush University Medical Center, Chicago, IL.*

Introduction: Collapsing FSGS (cFSGS) is associated with viral infections including HIV, parvovirus B19 and CMV. Recent reports describe cFSGS in patients infected with coronavirus (COVID-19). While reports on idiopathic cFSGS suggest early institution of steroids improves renal outcomes, there are little data to guide treatment of cFSGS associated with infection. We present a case of AKI with severe abrupt nephrotic syndrome in a COVID-19 patient with cFSGS on biopsy and a rapid response to steroids.

Case Description: A 51 y/o black woman with no known medical history presented with 8 days of fever and SOB. COVID-19 testing was positive. Admission serum creatinine (sCr) was 3.2 mg/dL with an albumin of 2.6 g/dL. A urinalysis showed moderate blood and 3+ protein on dipstick along with granular casts. A urine albumin:Cr (UAC) ratio was 0.19 g/g. Despite volume resuscitation, her sCr continued to rise. Workup included negative HIV, hepatitis panel, and parvovirus B19. ANA, ANCA, anti-dsDNA, C3, and C4 were neg/nl. On day 5, she was afebrile with resolution of her symptoms, but sCr was further elevated at 5.3 mg/dL and albumin was 1.1 g/dL. Repeat UAC ratio was elevated over lab measurable range. A biopsy showed cFSGS and ATN. She was started on 60mg of prednisone/day. Two weeks later, her sCr was 2.9 mg/dL, albumin 2.4 g/dL and her UAC ratio was 3.0 g/g (Fig 1).

Discussion: The optimal treatment for viral related cFSGS is unknown. Because diffuse foot process effacement typically accompanies this lesion, it is tempting to give steroids. However, there is concern that this may exacerbate the infection, and cFSGS may improve along with clearance of the virus. Still, steroids may hasten recovery and reduce morbidity associated with the nephrotic syndrome. The rapid improvement in

proteinuria despite an increase in GFR suggests that steroids played a role in the recovery. A randomized trial would be necessary to determine the safety and efficacy of steroids for COVID-19 related cFSGS.

PO0796

Remote Peritoneal Dialysis Training in a COVID-19-Positive Patient

Aditya V. Jain, Tina S. Samuel, Leslie A. Jansto, Erwin E. Morales, Cybele Ghossein. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Training patients in peritoneal dialysis (PD) traditionally requires up to fourteen in-person clinic visits to cover all aspects of care. The COVID-19 crisis has created an unprecedented challenge in educating patients to perform PD safely while minimizing exposure to staff. Telemedicine has been well-received by staff and patients in other aspects of PD care. We present a case of a COVID-19 positive patient who was fully trained in PD using telemedicine.

Case Description: The patient is a 21-year-old man with VATER Syndrome who progressed to ESRD with uremic symptoms. He chose PD as his dialysis modality while awaiting a kidney transplant. Prior to his PD catheter insertion, he tested positive for COVID-19. He was deemed an ideal candidate for PD training via telemedicine and agreed to proceed. For the first two training sessions, he presented to the PD clinic and was placed in a designated isolation room with his personal computer. His PD nurse was in an adjoining room and trained him via video conferencing with the option to enter his room if needed. The patient quickly mastered the procedure in this monitored environment. He completed the remainder of the required education remotely in his home via telemedicine. Currently, he is fully trained and has initiated his full PD prescription.

Discussion: There are several advantages of telehealth in COVID-19 patients. The risk of viral exposure to healthcare staff and other patients is reduced by limiting trips to the PD clinic. Additionally, reducing the burden of travel saves time and expense for the patient. Patient selection for telehealth learning is critical: the ideal patient must be motivated and technologically savvy. The patient, PD nurse, and nephrologist must jointly determine whether proceeding with tele-learning is feasible and safe. Although remote videoconferencing is not the conventional or optimal method for PD education, it can be used successfully to train patients while minimizing exposure of COVID-19 to staff.

PO0797

Calciphylaxis and COVID-19-Associated Thrombotic Retiform Purpura in a Peritoneal Dialysis Patient

Elly Varma,[1] Cynthia M. Magro,[1] Jerry Nuovo,[1] Frank Liu,[2] Vesh Srivatana.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Rogosin Institute, New York, NY.*

Introduction: The Coronavirus disease (COVID-19) pandemic has posed diagnostic and management challenges for nephrologists. We report an atypical manifestation of COVID-19 presenting as a case of Calciphylaxis and COVID-19 Associated Thrombotic Retiform Purpura in a peritoneal dialysis patient.

Case Description: A 62-year-old female presented to the emergency room with leg pain and edema for 4 weeks. She had recently been started on peritoneal dialysis. Examination revealed tender, indurated retiform dusky plaques on thighs and bilateral lower legs (Figure 1). Laboratory findings are summarised in Table1. Her SARS-COV-2-RT-PCR was positive. Imaging revealed no evidence of thrombosis. Skin biopsy showed severe ischemic dermopathy syndrome consistent with an overlap of COVID-associated thrombotic retiform purpura and calciphylaxis (Figure 2). The SARS-CoV-2 envelope protein was seen in endothelial cells within dermal blood vessels. The patient was transitioned to intermittent hemodialysis and started on intravenous sodium thiosulfate 25 grams three times weekly.

Discussion: In COVID-19 era, coagulation abnormalities are becoming increasingly evident. Management of calciphylaxis in PD patients is difficult under current circumstances due to limitations in the ability to provide regular infusions and multi-interventional care. We hypothesize that our patient had an underlying predisposition for calciphylaxis given risk factors of secondary hyperparathyroidism and an additional insult (COVID-19) caused a so-called "second hit" resulting in clinically apparent disease. Atypical presentations of COVID-19 due to a combination of procoagulant state, as well as any preexisting risk factors for calciphylaxis, must be kept in mind.

Table 1. Laboratory investigations

Sodium	122mmol/L
Potassium	2.9mmol/L
Chloride	79mmol/L
Blood urea nitrogen (BUN)	38 mg/dL
Creatinine	8.32mg/dL
Calcium, corrected	10.7mg/dL
Phosphorus	4.2mg/dL
Hemoglobin	10.7mg/dL
Hematocrit	32.3%
Platelets	217 x 103/uL
Alkaline phosphatase	140U/L
Parathyroid hormone (PTH)	1554pg/mL
Vitamin D 25 hydroxy (OH)	68.5ng/mL
Vitamin D 1,25 dihydroxy	79.7pg/mL
C-reactive protein	19mg/dL
Erythrocyte sedimentation rate	122
Creatine kinase	516 U/L

Lactate dehydrogenase	529U/L
Complements, C3 and C4	133mg/dL and 40.3mg/dL
HIV, Hepatitis B and C serologies	Negative

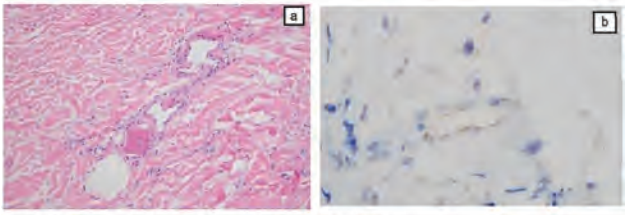

Figure 2. Skin biopsy showing severe ischemic dermopathy syndrome
(a): Illustrated is a dilated venule occluded with fibrin unaccompanied by a significant mural inflammatory cell infiltrate. A few background neutrophils secondary to ischemia are observed. (200X, hematoxylin and eosin).
(b): There is evidence of endocytosis of viral particles within the microvasculature of the dermis and subcutaneous fat. Illustrated is the SARS-CoV-2 envelope protein decorating the endothelium. There is, however, no evidence of active viral replication as revealed by the negative SARS-CoV-2 viral RNA studies(not illustrated). (1000X, Diaminobenzidine).

PO0798

Successful Recovery of COVID-19 Pneumonia in a Kidney Transplant Recipient with a Regimen Consisting of Favipiravir, Azithromycin, Nafamostat Mesylate (NM), and Intravenous Immunoglobulin (IVIg)

Sumi Hidaka, Kunihiro Ishioka, Hidekazu Moriya, Yasuhiro Mochida, Hiroyuki Suzuki, Takayasu Ohtake, Shuzo Kobayashi. *Kidney Disease and Transplant Center, Shonan Kamakura General Hospital, Kamakura, Japan.*

Introduction: The SARS-CoV-2 virus has caused a worldwide pandemic of coronavirus disease 2019 (COVID-19) since end of 2019. Although COVID-19 has been widely reported, little is known about its impact on transplant recipients. We report a case of an interstitial pneumonia due to SARS-CoV-2 viral infection in a kidney transplant recipient. We also investigated how treatment of COVID-19 influenced the changes of lymphocyte subset and the number and activity of NK cells.

Case Description: This is a 49-year-old man who received kidney transplantation 13 months ago. His first clinical symptoms were of high fever, general fatigue, and myalgia. He had no complaints of cough nor shortness of breath, but his chest CT revealed interstitial pneumonia with SpO2 90 - 92 mmHg. Nasopharyngeal swab for SARS-CoV-2 RT-PCR assay was reported positive. He also showed acute kidney injury (AKI), whose serum creatinine level got elevated from 1.33 mg/dL to 1.67 mg/dL. We stopped tacrolimus and mycophenolate mofetil and continued low dose of methylprednisolone. The COVID-19 pneumonia and AKI were successfully treated with the regimen consisting of favipiravil, azithromycin, NM, and IVIg. On the 14th hospital day, the SARS-CoV-2 RT-PCR had become negative and simultaneously had acquired IgG antibody against SARS-CoV-2 virus. Regarding lymphocyte subset, the percentage of CD19^{+} B lymphocytes has been extremely low level because of administration of rituximab 13 months ago due to ABO-incompatible living related-donor kidney transplantation. On the day of admission, the total number of lymphocytes was only 482/μL and most of them were CD4^{+} lymphocytes and the number of NK cells were very few (6.8%). As the symptoms improved, the number and activity of NK cells increased and the proportion of CD4^{+} lymphocytes decreased.

Discussion: We successfully treated the patients with 4 off-label drugs against COVID-19, consisting of favipiravil, azithromycin, NM, and IVIg. Our current regimen seems to be successful, in particular, NM seems to block cytokine storm, thus preventing from serious illness, but a larger cohort of patients is required. Activation and expansion of NK cells are important in the treatment of COVID-19.

PO0799

Severe Hypernatremia as an Unintended Consequence of COVID-19-Related Social Distancing

Mahmoud M. Mohamed,[1] Stacy A. Johnson,[1] Barry M. Wall.[1,2] [1]*The University of Tennessee Health Science Center, Memphis, TN;* [2]*Memphis VA Medical Center, Memphis, TN.*

Introduction: COVID-19 is primarily a respiratory infection which can have adverse effects on multiple organ systems. There is limited information concerning the harmful effects of social distancing in patients with chronic illnesses who avoid seeking medical attention due to fear of contracting the novel COVID-19 disease.

Case Description: A 64-year-old African American female with a past history of HIV- related dementia and seizure disorder was residing with family members, requiring assistance with activities of daily living. She was ambulatory but needed assistance with hygiene and meals. The family reported that over the past 7-10 days, she had become less interactive, remaining bedbound and resisting oral intake. There was an initial reluctance to bring her to the Medical Center due to the fear of contracting COVID-19 infection, given her immune-suppressed status. Despite family efforts to provide social distancing and home care, mental status progressively worsened, prompting presentation to the emergency department. The patient had a GCS of 10. The patient was nonresponsive, did not follow commands, and only withdrew from noxious stimuli. Vital signs were prominent for fever 37.7° C and blood pressure was 94/64 mmHg. Pertinent laboratory results included: serum sodium, 201 mEq/L, plasma osmolality, 431 mOsm/kg, BUN 107 mg/dl, and creatinine of 4.8 mg/dL. CT head showed no acute intracranial pathology. Her condition required ICU care, including mechanical ventilation. COVID-19 screening was negative, while culture of lower respiratory secretions was positive for Staphylococcus aureus. With treatment of the respiratory infection and gradual hydration with 0.9 % sodium chloride solution which was shifted to Dextrose 5% after 3 days, the serum sodium concentration decreased to167 mEq/L. The patient was extubated and mental status gradually improved toward her baseline level. Serum sodium improved to 140 mEq/L and serum creatinine improved to 0.7 mg/dL over a 10 day period. The patient was subsequently transferred to a rehabilitation unit.

Discussion: Despite the pivotal role of social distancing in preventing the spread of the novel Coronavirus, reluctance in seeking medical attention can lead to serious and even life threatening consequences.

PO0800

Bilateral Renal Artery Thrombosis in a COVID-19 Patient with Anuric AKI

Nitzy N. Munoz Casablanca, Osama El Shamy, Steven G. Coca, Jaime Uribarri, Shuchita Sharma. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: AKI is common in COVID-19. Hypercoagulability has been described. We present the case of a COVID-19 patient with anuric AKI who was found to have bilateral renal artery thrombosis (RAT) while on systemic anticoagulation.

Case Description: A 66-year-old woman with a past medical history of paroxysmal atrial fibrillation on apixaban (continued on admission), hypertension, and heart failure presented with 2 days of shortness of breath and a productive cough. She was found to be in hypoxic respiratory failure in the setting of COVID-19 pneumonia. Admission laboratory evaluation was significant for a white blood cell count of 36.8 x 10^3/mL, creatinine 6.04mg/dL, blood urea nitrogen 53mg/dL, lactate dehydrogenase 2,600U/L, and urine protein ≥ 500mg/dL. A renal ultrasound showed bilateral echogenic kidneys. She required initiation of hemodialysis then transitioned to peritoneal dialysis. Dialysis accesses and peritoneal fluid were complicated by bleeding with a subsequent drop in hemoglobin to 5.5g/dL (from 13.6g/dL, 48 hours prior). A contrast-enhanced CT angiogram of the abdomen and pelvis showed bilateral RAT, and thrombosis of the proximal celiac artery, with no evidence of acute arterial extravasation. She underwent bilateral renal artery aspiration thrombectomy and thrombolysis with stent placement in the right renal artery. Restoration of blood flow was achieved but she remained dialysis-dependent - her hemodynamic instability with continued blood loss may have played a role in this. A hypercoagulable work-up showed elevated prothrombin time, activated partial thromboplastin time, and INR. Fibrinogen was normal with an elevated fibrin degradation dimer, and low antithrombin III antigen, Protein C and S. These results are difficult to interpret in the setting of active anticoagulation and AKI

Discussion: We present a case of anuric AKI with bilateral RAT in a COVID-19 patient necessitating initiation of dialysis. Although her history of atrial fibrillation increases the risk of thromboembolic events, renal arteries are affected in only 2% of the cases. Complete occlusion and bilateral involvement is even rarer, moreover, our patient was on anticoagulation before and during the event. Given that COVID-19 can result in vascular injury and thromboembolic complications, assessing renal perfusion in oligoanuric COVID-19 patients with AKI may have merit.

PO0801

Severe Rhabdomyolysis in the Time of Coronavirus

Sergio E. Alvarez Torres, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Coronavirus disease 2019 (COVID-19), caused by SARS-CoV-2, has become a global pandemic with alarming numbers of morbidity and mortality. COVID-19 primarily presents as a lung infection, with symptoms of fever, cough, myalgia, and fatigue. The severity of the disease may range from a mild upper respiratory infection to severe pneumonia, ARDS, and death. This novel disease can also present with involvement of multiple organ systems including the kidneys. Acute kidney injury (AKI) has been reported in up to 37 % of cases. Here we report a case of a woman with COVID-19 presenting with rhabdomyolysis and AKI.

Case Description: A 48 y/o Hispanic woman with history of HTN, hyperlipidemia and DM type 2 who presented to the ED complaining of shortness of breath, fever, cough, and myalgias. Four days before presentation she had been diagnosed with COVID-19 and was self-isolating at home. Her symptoms worsened prompting her visit to the ED. Vital signs showed fever of 103.1 F, pulse 86, respirations 37, blood pressure 106/58 and O2 Sat 85% at room air, 95% with nasal canula at 4 L. PE was normal except for tachypnea and coarse breath sounds bilaterally on lung auscultation. Admission labs were remarkable for AKI and rhabdomyolysis. Serum creatinine was 3.61, BUN 83, and total CK 106,193. U/A with blood, 5-10 RBC, 5-10 WBC and many bacteria. FeNA was 0.3%. Toxicology panel was negative. Respiratory viral panel was negative. Influenza A and B are negative. She initially received 2 L bolus of IV NS and then continued with balanced crystalloid solutions for volume expansion over the next 3 days. She received treatment with hydroxychloroquine, azithromycin and ceftriaxone for COVID-19 pneumonia. Her symptoms improved and serum creatinine and CK gradually decreased until back to normal levels.

Discussion: Rhabdomyolysis can be seen associated with viral infections. We presented a patient with COVID-19 and rhabdomyolysis. There are no studies establishing a mechanism for COVID-19 induced rhabdomyolysis. Patients with COVID-19 pneumonia are generally kept with negative fluid balance to avoid overload and worsening of ARDS. On the other hand, volume expansion is mainstay management for rhabdomyolysis. Clinicians should have a high suspicion for rhabdomyolysis in patients with COVID-19 presenting with myalgias and AKI. Early recognition of and appropriate treatment is crucial to improve outcomes.

PO0802

Plasma Exchange in Critically Ill COVID-19 Patients

Christian Morath, Markus A. Weigand, Martin G. Zeier, Claudius Speer, Theresa Hippchen, Shilpa Tiwari-Heckler, Uta Merle. *Ruprecht Karls Universitat Heidelberg, Heidelberg, Germany.*

Introduction: The spectrum of coronavirus disease 2019 (COVID-19) ranges from asymptomatic infection to respiratory failure and death of patients. Severely affected patients may develop a cytokine storm-like clinical syndrome with multi-organ failure and a mortality rate of up to 90%.

Case Description: Here we report on five COVID-19 patients with a median age of 67 years who were treated at the intensive care unit due to respiratory failure. Prophylactic antibiotic, antimycotic, and antiviral/immunomodulatory therapy was initiated in all patients upon admission. During the course of the disease, patients developed circulatory shock and persistent fever together with increased interleukin 6-levels compatible with the cytokine storm-like clinical syndrome. In addition, all patients had multi-organ failure with acute respiratory-distress syndrome (ARDS, 4 severe, 1 moderate) and acute kidney injury of at least KDIGO stage 2. A single PE with a median of 3.39 L of fresh frozen plasma was initiated in all patients followed by one additional treatment in patients 1, 3, and 5. During the PE, striking reduction of inflammatory markers C-reactive protein (-47%, P=0.0078) and interleukin 6 (-74%, P=0.0078), as well as significant reduction of ferritin (-49%, P=0.0078), LDH (-41%, P=0.0078), and D-Dimer (-47%, P=0.016) were observed. Due to circulatory shock, four patients received vasopressor treatment at the start of the PE that could be substantially reduced during treatment (-71%, P=0.031). Biochemical and clinical improvement continued over the following days together with an increase in the oxygenation index in 4 out of 5 patients. These improvements were achieved with only 1 to 2 PE, which might be a possible indication of a direct pathophysiological influence of PE on the COVID-19-associated cytokine storm-like clinical syndrome. Three of the 5 most critically ill patients are alive, while a 71-year-old male and a 76-year-old female patient died after the therapy was limited due to persistent severe ARDS.

Discussion: PE improved inflammation, microcirculatory clot formation, and hypotension, thereby improving clinical outcomes. Further studies to test whether (repeated) PE can alter the course of critically ill COVID-19 patients are clearly indicated.

PO0803

A Case of Severe Hyponatremia in a Patient with COVID-19

Nupur N. Uppal, Bessy Suyin Flores Chang, Hugo Andrade paz, Mala Sachdeva. *Northwell Health, Manhasset, NY.*

Introduction: Hyponatremia is a common electrolyte disturbance seen in association with conditions such as malignancy and infections. In the recent literature, hyponatremia has been linked to SARS-CoV2 infection. To date, the most likely reported etiology of hyponatremia in setting of COVID-19 has been SIADH. We describe a severe case of hyponatremia, not due to SIADH, seen in a patient with COVID-19

Case Description: 49-year-old male with history of hypertension, hyperlipidemia, positive novel coronavirus nasopharyngeal swab done as outpatient, presented to the emergency department with fever, cough and dyspnea for a week. On admission, he was afebrile with respiratory rate of 18 and oxygen saturation of 84% on ambient air. His BP was not low, and heart rate ranged from 95-105 beats per minute. Pulmonary examination revealed rales bilaterally. Initial laboratory test showed serum sodium of 104 mEq/L and serum creatinine 0.58 mg/dL. Additionally, C-reactive protein was elevated to 7.19, serum ferritin elevated at 1798 and D-dimer was 158. CXR showed bilateral infiltrates. Serum osmolality was low at 217, and urine studies showed elevated urine osmolality (328) and low urine sodium (< 35), suggestive for diagnosis of hypotonic hyponatremia from volume depletion. He received treatment with 3% hypertonic saline with a subsequent

decrease in urine osmolality to 83. Serum sodium rapidly corrected to 118 requiring hypotonic fluids to manage overcorrection. Subsequently, serum sodium improved to a level of 133 mEq/L in the next 5 days after admission

Discussion: As the COVID-19 pandemic continues to evolve, cases of related hyponatremia in this setting are being reported, mostly SIADH being the underlying etiology. Various mechanisms for SIADH development, including cytokine storm, and hypoxic pulmonary vasoconstriction have been postulated, however, the common aspect of volume depleted state in setting of viral infection, leading to appropriate ADH release should not be forgotten

PO0804

Extracorporeal Cytokine Reduction Using Oxiris Blood Purification in COVID-19

Spencer Hodgins,[1] Marat Abdullin,[2] Mark A. Tidswell,[1] Daniel L. Landry.[1]
[1]Baystate Medical Center, Springfield, MA; [2]Kidney Care and Transplant Services of New England, Springfield, MA.

Introduction: Severe COVID-19 infection can cause "cytokine storm" and end-organ dysfunction. OXIRIS, a blood-purification filter, was recently approved by the FDA under emergency use authorization for this indication due to its ability to remove cytokines and endotoxin through its AN-69ST membrane. We describe our experience with the first two cases treated at our institution.

Case Description: Case 1: 58 year-old female patient with a baseline creatinine of 0.8 mg/dL & history of hemoglobin SC disease was admitted with respiratory failure due to COVID-19 infection. She deteriorated on hospital day (HD) 6 and was intubated. She received broad-spectrum antibiotics and convalescent plasma. On HD 15 she had increasing vasopressor requirement, anuric AKI and was started on continuous renal replacement therapy (CRRT). Due to worsening clinical status on HD18 she was started on the OXIRIS hemofilter through the CRRT circuit for 48 hours. Oxygenation improved and there was some improvement in inflammatory markers (IM) (table 1), however, the family withdrew care on HD 20. Case 2: 29-year-old male with no prior past medical history apart from morbid obesity presented with fever and dry cough in the setting of recent COVID-19 exposure. He was found to be COVID-19 positive and rapidly deteriorated with resultant intubation on HD4. He received hydroxychloroquine, doxycycline, remdesivir and convalescent plasma. OXIRIS hemoperfusion was initiated on HD8 due to worsening hypoxia despite high FiO2. Oxygenation improved by HD10 (table 1) and he was successfully extubated on HD16.

Discussion: We present our first 2 cases using the OXIRIS hemofilter. We treated the patients for 48 hours with a scheduled filter exchange at 24 hours. We used a blood flow of 250 ml/min and dialysate flow of 25 ml/kg/hour with either systemic heparin or regional citrate anticoagulation along with 1L/hr of pre-filter saline. For hemoperfusion we used the same parameters without dialysate. We observed rapid improvements in oxygenation (Figure 1). The findings are hypothesis generating though more data is needed to determine optimal timing and efficacy of this filter.

Table 1. Inflammatory and Respiratory Parameters.

	Case 1			Case 2

PO0805

Rhabdomyolysis as a Late Complication of COVID-19 Infection

Benjamin Lidgard, Ann M. O'Hare, Sarah F. Sanghavi, Bessie A. Young.
University of Washington, Seattle, WA.

Introduction: The 2019 novel Coronavirus (COVID-19) is a betacoronavirus which typically presents with fever, cough, myalgia, and fatigue and can be associated with acute kidney injury (AKI). Recently, several cases of rhabdomyolysis (with and without AKI) have been reported with COVID-19 infection. We present a case of a patient with COVID-19 infection who developed rhabdomyolysis on hospital day 22.

Case Description: A 74-year-old man presented with several weeks of progressive malaise, dyspnea, fatigue, and nausea. He was hypoxic to 87%, febrile (38.8 C) and had diffuse bilateral infiltrates on chest x-ray [Figure 1]. He was intubated on hospital day 1. Testing for COVID-19 by PCR was positive. Creatinine improved from 1.6 to 0.9 mg/dL with 2L of IV fluids. He did not require vasopressors. On hospital day 22, while still intubated, his creatinine increased from 1.4 to 3.8 mg/dL. The level of creatinine phosphokinase (CPK) had was 7393 U/L from 118U/L on admission, and his plasma free myoglobin was 34,640 mcg/L. Urinalysis was positive for 3+ occult blood, few red blood cells, and many granular casts. His serum creatinine peaked at 6.67 mg/dL on hospital day 26 and subsequently declined to 1.6 by hospital day 33.

Discussion: Rhabdomyolysis is an infrequent complication of COVID-19 infection. When observed, rhabdomyolysis is typically present on admission. This is, to our knowledge, the latest that rhabdoymyolysis has been observed in COVID infection. The patient's inflammatory markers were not re-checked at the time of this event, though worsening inflammation may have provoked this event. Their troponin was mildly elevated; a TTE was not performed. No bed sores were observed, and the patient had no access to illicit substances. No medications known to cause rhabdomyolysis were given prior to this development. This case report suggests that rhabdomyolysis-related AKI may be a late complication of COVID-19 infection.

PO0806

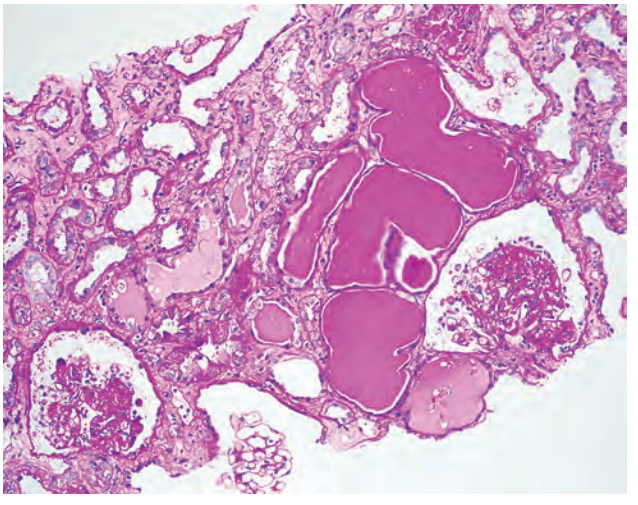
Collapsing FSGS in COVID-19

Muna Hale,[1] Elise J. Barney,[2,3] Yveline D. Jean-Claude,[2] Christine A. Vanbeek.[4]
[1]The University of Oklahoma - Tulsa, Tulsa, OK; [2]Phoebe Putney Memorial Hospital, Albany, GA; [3]The University of Arizona College of Medicine Phoenix, Phoenix, AZ; [4]Quest Diagnostics Inc, Secaucus, NJ.

Introduction: The pandemic of novel coronavirus disease (COVID-19) has been complicated by high incidences of acute kidney injury (AKI). A virus-associated focal segmental glomerulosclerosis (FSGS) has been reported. We present a case of collapsing FSGS in a patient with severe acute respiratory syndrome coronavirus 2.

Case Description: A 56-year-old African-American (AA) man with hyperlipidemia and new diagnosis of COVID-19 the week prior, was admitted for vomiting, abdominal pain, and non-oliguric AKI with creatinine (Cr) of 4.97 mg/dL. Labs done within the year showed Cr of 1.1 mg/dL and microalbuminuria of 44 mcg/mg. An ER visit 3 days prior for fever and cough revealed a serum Cr of 1.47 mg/dL. CT abdomen/pelvis with IV contrast showed no obstruction. Urinalysis showed +2 protein and 2 RBCs/hpf. A 24-hour urine protein showed proteinuria of 15 grams. HIV and drug screen was negative. Renal biopsy showed FSGS with collapsing features, no cellular crescents, and severe acute tubular injury. Electron microscopy did not show viral particles. Two months later, the patient remained on hemodialysis.

Discussion: A challenge facing this pandemic is lack of knowledge of the pathology of COVID-19. Reports from post-mortem renal biopsies in China showed the majority were due to acute tubular injury with only 2 of 26 cases due to FSGS, none of the collapsing variant. However, there are at least 5 reports in the literature of COVID-19 complicated by de novo collapsing FSGS in patients of African descent, of which 2 tested positive for the *APOL1* genotype. The collapsing variant of FSGS is known to occur more commonly in AA patients, who are high risk for *APOL1* genotype. In viral infections, this genotype can be upregulated and promote development of FSGS. Although not directly tested, it cannot be excluded as a predisposing factor in our patient. In patients with COVID-19 and proteinuric AKI, especially in African-Americans, collapsing FSGS should be considered.



Renal Biopsy

PO0807

Attenuation of Circuit Longevity in COVID-19 Critical Illness with AKI on Continuous Venovenous Hemodiafiltration Despite the Use of Regional Citrate Anticoagulation (RCA) and Heparin-Bonded AN 69 (Oxiris®) Filter

Tung Lin Lee, Zhong Hong Liew, Manish Kaushik, Li Choo Michelle Ng, Jiunn Wong, Hui-Lin Choong, Han K. Tan. *Singapore General Hospital, Singapore, Singapore*.

Introduction: Critical illness in SARS-CoV-2 (COVID-19) infection can result in acute kidney injury (AKI). Continuous renal replacement therapy (CRRT) is part of the overall supportive ICU management.

Case Description: CRRT was delivered as Continuous Veno-venous Haemodiafiltration (CVVHDF) using the Prismaflex (Baxter Inc.) system with heparin-bonded AN69 filter (oXiris®). The filters were electively changed every 12 hours for first 5 days to augment cytokine adsorptive capacity. Regional citrate anticoagulation (RCA) was used to ensure filter longevity. Initial citrate dose was prescribed at 3.0 mmol/L. All 3 consecutive patients were male aged 66.7 ± 6.02 years. APACHE II score was 32.7 ± 6.51 and predicted mortality was 71%. Mean initial creatinine was 264.7 µmol/L, and urine output was 6.7 mL/hour. All patients were on vasopressor support, broad spectrum antimicrobials and mechanical ventilation. 30 oXiris filters were studied in the 3 patients. 6/30 (20%) filters clotted spontaneously before scheduled change. Mean filter lifespan (24/30) was 689.6 ± 42.3 min before elective change. For the filters that clotted, mean circuit longevity was 515.7 ± 126.2 min. The observed difference was significant, p = 0.002. Importantly, filter clotting occurred despite adequate citrate dose of 3.0 mmol/L and mean post-filter ionized calcium of 0.34 ± 0.06 mmol/L. Vascular access issues were excluded by review of access, return pressures. Citrate dose was increased to 3.2 mmol/ L for all patients and this reduced the frequency of filter clotting subsequently. Two patients were extubated and had full renal recovery - mean duration of CRRT dependence was 9.5 days. However, the third patient remained CRRT dependent until demise on the 28th day of ICU stay.

Discussion: Attenuation of circuit lifespan was observed despite adequately dosed RCA and heparin bonded oXiris filters. We theorize that this could be due to a pro-coagulant state induced by the SARS-CoV-2 infection. Possibly, higher citrate dose to target even lower post-filter ionized calcium may be required to optimise anticoagulation and filter lifespan, thereby ensuring optimal effluent dose and solute clearance, for critically ill COVID-19 patients.

PO0808

SARS-CoV-2 Infection in the Early Post-Transplant Period After a Living Donor Kidney Transplant

Ashay Shingare, Madan Bahadur, Chandan L. Chaudhari, Pankaj G. Ganvir, Sharad A. Garudkar, Shaurya Mehta, Harsh P. Shah, Irawati R. Waghmare, Neville Colaco. *Jaslok Hospital and Research Centre, Mumbai, India*.

Introduction: Coronavirus disease 2019 (COVID-19) pandemic presented multiple challenges for living and deceased donor kidney transplant programs with the likelihood of exposure to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We report the course of COVID-19 and immunosuppression within 3 months of living donor kidney transplant (LDKT) which has not been described previously.

Case Description: Three LDKT recipients developed COVID-19 in the early post-transplant period and were detected positive for SARS-CoV-2 at day 7, day 19 and 2 months post-transplant. Patients 1 and 2 had received 1 mg/kg of anti-thymocyte globulin (ATG) as induction and patient 3 had received no induction at the time of transplant. Patients 1 and 2 had minimal symptoms at diagnosis, whereas patient 3 had high grade fever, cough and shortness of breath. All 3 patients had lymphopenia at diagnosis and none required supplemental oxygen or intensive care unit monitoring. All 3 patients received azithromycin and hydroxychloroquine. Mycophenolate mofetil dose was reduced in patient 1 and was stopped in patients 2 and 3. Patient 3 developed acute kidney injury with a peak serum creatinine of 2.4 mg/dL, whereas other 2 patients did not develop kidney allograft dysfunction. All 3 patients recovered from SARS-CoV-2 infection with normal renal function at discharge.

Discussion: Limited experience of SARS-CoV-2 infection in early post-transplant period is available in deceased donor kidney transplant (DDKT) with serious morbidity and mortality implications. Lymphopenia described in patients with severe illness due to SARS-CoV-2 can be aggravated by recently used higher dose of lymphocyte depleting agent, especially to cover for delayed graft function in DDKT. As compared to previously reported cases of DDKT, our relatively young recipients of LDKT had a milder course, minimal complications and recovered from SARS-CoV-2 infection. We suggest consideration of recipient age, pretransplant isolation and using induction agent basiliximab or lower dose of ATG for a LDKT program during COVID-19 pandemic.

PO0809

COVID-19-Related Collapsing Focal Segmental Glomerulosclerosis and Apolipoprotein L1: A Report of Two Cases

Sandeep Magoon,[1] Varun Malhotra,[1] Prasad B. Bichu.[2] [1]*Eastern Virginia Medical School, Norfolk, VA;* [2]*Nephrology Associates of Tidewater, Norfolk, VA*.

Introduction: Acute kidney injury has been seen in approximately 15% of the patient with COVID-19 infection. Acute tubular injury was presumed to be the most common cause of AKI, but it did not explain significant proteinuria and hematuria. We present the case report of 2 patients with collapsing focal segmental glomerulopathy with COVID-19.

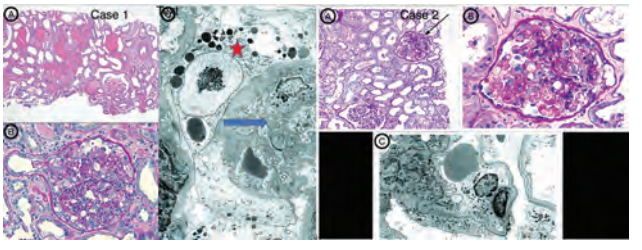
Case Description: Case 1, a 28 years old African American female and Case 2, a 58 years old African American male with baseline CKD III, admiited with COVID-19 infection and had acute kidney injury with significant proteinuria with hypoalbuminemia. Patients had kidney biopsies. Please see table for all the details.

Discussion: Possible etiologies of acute kidney injury in COVID 19 are tubular injury due to cytokine storm, direct cytopathic effect and immune mediated glomerulonephritis. Both the patients had collapsing FSGS in addition to tubular injury suggesting injury to the podocytes. Viral particles were not seen on both the biopsies, and hence direct cytopathic effect was not considered to be the mechanism of renal injury, although viral level below the detection threshold could not be excluded. Collapsing FSGS has been seen with other viral infections including Parvo-virus infection, Cytomegalovirus infection and HIV. Variant of apolipoprotein L1 (APOL1) gene in African Americans have been shown to be associated with FSGS. These two patients had genetic susceptibility due to APOL1 and COVID infection caused interferon surge leading to a second hit. Teaching Points: Renal biopsy should be consedered in patients with COVID-19 and Nephrotic range proteinuria. APOL1 testing should be done in patients with African American descent.

Demographic, clinical, laboratory, biopsy findings and follow up.

Patient No.	Age/Sex/Race	Onset of AKI	Risk Factors	Urinary findings	Chemistry	serology	Renal biopsy	APOL1	50 day follow up
1	28 Years Female AAa	7 days after the onset of fever	Asthma, Obesity	Proteinuria 2 grams on spot UPCRb No hematuria No eosinophils No casts	Cr: 0.9 to 8.05 mg/dl Albumin 3.3 to 1.3 g/dl Mild transaminitis Mild Rhabdomyolysis CRPd 15.7 mg/dl	Complements normal. Hepatitis B/C serologies negative. HIVe PCR negative.	LMf: Tubular injury ++. Collapsing FSGS. Mild IFTA IFg: No IF pattern EMh: No immune deposits Global podocyte foot process effacement.	Homozygous for G1 allele	Patient is off dialysis, but renal functions are not at baseline
2	56 years Male AA	7-10 days after the onset of fever	CKD 3 HTN, Obesity	Proteinuria 20 grams on UPCR, No hematuria No eosinophils No casts	Cr: 3.37 to 7.72 mg/dl Albumin 2 to 0.8 g/dl Mild transaminitis Mild Rhabdomyolysis CRP 9.0 mg/dl	Complements normal. Hepatitis B/C semologies negative. HIV PCR negative.	LM: Tubular injury ++. Collapsing FSGS. Mild IFTA IF: No IF pattern EM: No immune deposits Global podocyte foot process effacement.	Heterozygous for G1 and G2 alleles	Patient is off dialysis, but renal functions are not at baseline

a. AA: African American; b. UPCR: urine protein to creatinine ratio; c. Cr: Creatinine; d. CRP: C-reactive protein; e. HIV: Human immunodeficiency virus; f. LM: Light microscopy; g. IF: Immunofluorescence; h. EM: Electron microscopy.



PO0810

Diagnosing Vasculitis in the Era of COVID-19: A Diagnostic Dilemma for House Staff Officers

Kalyani L. Avva, Roberto L. Collazo-Maldonado, Christopher Farmakis. *Methodist Health System, Dallas, TX*.

Introduction: During our current pandemic, physicians must exclude COVID-19 in every patient presenting to the hospital with a febrile illness. However, every patient should have a complete work-up done to not miss other disease processes. Here we describe a case of microscopic polyangiitis with symptoms mimicking COVID-19.

Case Description: The patient is a 69 yo female with history of HTN who presented with four weeks of polyarthralgia and fevers; this was accompanied by a dry cough and morning stiffness in her shoulders and hips, for which she heavily used ibuprofen. Vital signs were within normal limits. Physical exam showed clear breath sounds with 2+ pitting edema in the lower legs and no rashes. Labs reveled a WBC of 20,000 cells/ microliter, with creatinine of 2.29 mg/dL, bicarbonate of 17 mmol/L, and C-reactive peptide of 204 mg/L. UA showed moderate leukocyte esterase, trace protein, and large blood. Serum C3 and C4 levels were normal, and a spot urine/protein ratio was 600 mg. Urine microscopy had several non-dysmorphic RBCs with occasional RBC and WBC casts. Infectious work-up via COVID-19 screening, blood cultures, hepatitis, and HIV was negative. The patient's creatinine trended up, peaking at 2.8 mg/dL. She was started on empiric solumedrol at a dose of 60 mg TID for possibilities of polymyalgia rheumatica or vasculitis or NSAID-induced acute interstitial nephritis. She had a positive MPO ANCA with titer of 1:320. Kidney biopsy confirmed pauci-immune crescentic glomerulonephritis, with clinical diagnosis of microscopic polyangiitis. She was placed on prednisone 40 mg daily and rituximab 375 mg/m 2 weekly for four weeks and was discharged home in stable condition.

Discussion: Systemic vasculitis remains to be a diagnostic challenge, especially in the era of COVID-19, given the overlap in symptoms. The diagnosis is made via clinical history and histopathological findings coupled with positive ANCA. Despite treatment, almost a quarter of these patients will progress to ESRD. In the era of COVID-19, great care must be taken to diagnose the kidney manifestations of systemic vasculitis.

PO0811

Low-Sodium Disorders and the 2019 Novel Coronavirus Disease (COVID-19)

Jasmeet Gill,[1] Xunxi S. Guo,[2] Akinwande A. Akinfolarin,[2] Ankit Mehta.[1] *[1]Baylor University Medical Center at Dallas, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: COVID-19 have been well characterized with hallmarks of pneumonia and respiratory failure. Hyponatremia is a well reported finding in patients with pneumonia. However only few reports of sodium disorders have been directly attributable to the disease. We report three different presentations of hyponatremia in COVID19 patients.

Case Description: 1. 70 year old man with hypertension, diabetes presented with dyspnea. He was clinically euvolemic. Chest X-ray (CXR) showed bilateral interstitial and airspace opacities. Laboratory data revealed, serum sodium 122 meq/L, serum osmolality 264 mosm/kg, urine osmolality 579 mosm/kg and urine sodium 153 mmol/L. A diagnosis of hyponatremia secondary to the Syndrome of inappropriate Antidiuretic Hormone (SIADH) was made and the patient was treated with oral urea and fluid restriction. 2. 50 year old man with chronic alcohol abuse presented with bilateral calf soreness. CXR revealed increased interstitial markings. Laboratory data showed serum sodium 113 meq/L, serum osmolality 251 mosm/kg, urine osmolality 426 mosm/kg and urine sodium 14 mmol/L. Hyponatremia was attributed to a low solute state. Serum sodium improved with normal saline infusion. 3. 69 year old female with hypertension admitted with vomiting and diarrhea. CXR showed diffuse pulmonary infiltrates. Initial laboratory data revealed serum sodium of 126 meq/L, serum osmolality 260 mosm/kg. Serum sodium recovered as diarrhea resolved. However, eight days after starting therapy with Selinexor, a nuclear transport inhibitor, serum Na declined to 128 meq/L, serum osmolality 275 mosm/kg, urine sodium 29 mmol/L, urine osmolality 372 mosm/Kg. SIADH was attributed to Selinexor therapy. Sodium improved with oral sodium chloride therapy and fluid restriction

Discussion: Incidence of Hyponatremia due to SIADH in community acquired penumonia is 8-31% in adult patients. To the best of our knowledge, there have only been two case reports of SIADH in COVID-19 disease from Switzerland. Hence, it is unclear if SIADH is the predominant presentation of hyponatremia with COVID-19. The etiology of hyponatremia could be multifactorial as seen in the cases above. Clinical assessment of volume status and urine studies including osmolality and sodium with a thorough review of medications is the key to differentiate causes of hyponatremia and determining adequate management.

PO0812

COVID-19 Short-Term Outcomes of AKI and Chronic Hemodialysis

Jessica Smolander,[1] Annette Bruchfeld.[2,3] *[1]Danderyds Sjukhus AB, Stockholm, Sweden; [2]Karolinska Universitetssjukhuset, Stockholm, Sweden; [3]Linkopings universitet, Linkoping, Sweden.*

Introduction: Acute kidney injury (AKI), albuminuria and hematuria are common and increase mortality in Covid-19 in addition to viral pneumonia, hypercoagulability and hyperinflammation. We present short-term outcomes of 21 Covid-19 patients with AKI and CRRT and the clinical course of 40 chronic hemodialysis (HD) patients with Covid-19.

Case Description: Twenty-one non-CKD Covid-19 infected patients with AKI required mechanical ventilation and CRRT at the ICU, 20 were males, average age was 59.7 years (y), average BMI 29 kg/m2, 33 % had diabetes. The typical scenario was a normal/slightly elevated creatinine level at admission, normalizing after iv fluids, but rising creatinine from day 3-4 and start of CRRT on day 8 (median). Urine analysis was available in eight patients, of which seven had albuminuria and/or hematuria. So far eight patients (38 %) have died. Dialysis has been discontinued in nine patients (43 %), median time 17 days in dialysis (range 1-35 days), follow up of 1-4 weeks. Patients 3-4 weeks after CRRT discontinuation have a creatinine level of 50-161 μmol/L (ref < 90-100 μmol/L). Four patients are still dialysis dependent (median time in dialysis 7-22 days). Forty out of 520 patients on chronic HD in Stockholm had symptomatic Covid-19 in March-April 2020, of these 24 patients (60 %) required hospitalization, 16 patients (40%) did not. Nine patients died (22,5 %), of whom eight were men. The average age (78 y) was significantly higher (p = 0.003) and median time in dialysis (11.5 y) was longer (p = 0.01) in the non-survivors compared to the survivors. CRP at admission was significantly higher in the non-survivors (p=0.0003), but there were no differences regarding prior cardiovascular disease or diabetes (56 vs 55 %). Only three patients had a BMI > 30 kg/m2. Among survivors, the number of patients with ACE inhibitor/ARB treatment did not differ from non-survivors (p = 0.08), 13 out of 15 patients continued their treatment, without more serious disease.

Discussion: The AKI mortality in Covid-19 with CRRT is high, but a substantial number of patients have survived and recovered kidney function although follow-up for long-term CKD prognosis is important. Fewer chronic HD patients than expected suffered severe disease, however patients older than 70 y in combination with longer time (> 10 y) in HD and high CRP at admission were at a higher risk of dying from symptomatic Covid-19.

PO0813

ANCA-Associated Vasculitis Under a COVID-19 Mask

Rui Song, Srikanth Thiruvarudsothy, Jared Hassler, Ziauddin Ahmed, Serban Constantinescu, Avrum Gillespie. *Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Introduction: Ground glass opacities (GGO) on CT scan are the hallmark of COVID-19. GGO can also be seen in ANCA-associated lung injury. Additionally, both can present with kidney injury. We report a case of presumed COVID-19 with AKI which was actually severe ANCA-associated vasculitis.

Case Description: A 74-year old female with a history of hypertension and diabetes, who presented with a week of chills, cough, dyspnea, and watery diarrhea, and a creatinine of 10.2 mg/dl (baseline creatinine 1.02 mg/dl). A month prior to admission, she was treated for presumed bacterial conjunctivitis, followed by otitis media, and then bacterial sinusitis with oral ciprofloxacin. Despite a negative swab, she was admitted with suspicion of COVID-19 given GGO seen on CT scan and an exposure history at her senior home. She was treated per the COVID-19 protocol: IV methylprednisolone 125mg, azithromycin, and ceftriaxone. She had microscopic hematuria and 4 grams of proteinuria. ATN was suspected as urine microscopy showed granular casts and no dysmorphic RBC or cellular/WBC/RBC casts. After a repeat negative swab and improvement in respiratory symptoms yet worsening renal function requiring hemodialysis, a full serologic workup was performed. Positive results include p-ANCA (1:320), MPO (49), and ANA (1:160 homogeneous) without hypocomplementemia. Other autoimmune markers including anti-GBM antibody were negative. A kidney biopsy was performed and showed pauci-immune crescentic glomerulonephritis (GN) with cellular crescents in more than 80% of the glomeruli with minimal interstitial fibrosis and tubular atrophy. Given the frailty of this patient, she was treated with oral prednisone and rituximab instead of cyclophosphamide. She remained on intermittent hemodialysis and tolerated the treatment well.

Discussion: This case emphasizes the importance of detecting pulmonary-renal syndrome in the time of COVID-19. Given the current global pandemic and a high volume of infected patients coupled with the lack of sensitivity of the SARS-CoV-2 assays, it is possible to miss this relatively rare ANCA-associated vasculitis. Patient with rapid proliferative GN feature and lung symptoms should be further worked up to avoid missing an ANCA-associated vasculitis. COVID-19 may actually provoke ANCA-associated vasculitis and further testing is underway.

PO0814

Antineutrophil Cytoplasmic Antibody (ANCA) Vasculitis with Glomerulonephritis in COVID-19

Yuriy Khanin, Vanesa Bijol, Kenar D. Jhaveri, Nupur N. Uppal. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and the disease it inflicts, coronavirus disease 2019 (COVID-19), has become a global pandemic in 2020. To date, only one case of ANCA associated vasculitis (AAV) with COVID-19 has been reported from Iran. We describe the first two cases of AAV and glomerulonephritis in the United States.

Case Description: Case one: 64 year old African American male with a distant (> 10years) history of cryptogenic organizing pneumonia presented to the hospital with hypoxic respiratory failure secondary to COVID19. He had an acute kidney injury(AKI) with elevated creatinine(Cr) of 7.87mg/dL. Urinalysis revealed active sediment with 55 RBC/hpf, 65 WBC/hpf, and nephrotic range proteinuria: 5 gm/gm of creatinine. He was initiated on renal replacement therapy and received convalescent plasma along with Tocilizumab for the treatment of COVID-19. Serologic testing revealed a positive perinuclear (p)-ANCA (1:320), myeloperoxidase (32.5). Kidney biopsy was consistent with a pauci immune glomerulonephritis; cellular crescent present in 40% of glomeruli. He received pulse dose steroids and Rituximab. The patient had a good clinical response and was able to discontinue hemodialysis and serum Cr decreased to 3.5mg/dL. Case Two: 46 year old South Asian male presented with rash from leukocytoclastic vasculitis and was diagnosed with COVID-19. He had an AKI, serum Cr peaked at 4.0mg/dL with proteinuria, leukocyturia, and microhematuria on urinalysis. Cytoplasmic(c)-ANCA and proteinase-3(PR-3) were positive. A kidney biopsy was performed which revealed a necrotizing glomerulonephritis. He was treated with steroids and Rituximab with a positive response, Cr decreased to 2.0mg/dL.

Discussion: It is now well known that SARS-CoV-2 affects organs outside of the respiratory system, with the kidneys being a usual target. The most commonly reported presentation of COVID-19 and the kidneys is AKI, the etiology of which is predominantly acute tubular necrosis (ATN). Collapsing GN is by far the most described glomerular lesion. Clinicians should be aware of AAV with GN as another potential pathology, and concurrent use of immunosuppression with treatment of infection, can lead to favorable clinical outcomes.

PO0815

Hemodialysis Refractory Hyperkalemia in a Case of SARS-CoV-2 Infection

Siddharth Mehta,[1] Rohan Parikh,[1] Shantanu Solanki,[2] Jagmeet Singh,[2] Rajvee Patel.[1] *[1]Trumbull Regional Medical Center, Warren, OH; [2]Geisinger Commonwealth School of Medicine, Scranton, PA.*

Introduction: Severe acute respiratory syndrome coronavirus- 2 (SARS-CoV-2) is a newly identified virus that affects respiratory tract with varying severity. Renal disease is not uncommon, but the etiology is multifactorial and still not well understood. We present a case of hemodialysis refractory hyperkalemia in a patient with SARS-CoV-2 infection.

Case Description: 56-year-old African American male with past medical history of hypertension presented with cough, dyspnea and fever. On admission, he had a temperature of 104F, BP of 149/90 mmHg, HR of 104 bpm, and oxygen saturation of 92%. Physical examination was remarkable for diminished and diffuse coarse breath sounds. Lab work-up showed serum creatinine of 2.99 mg/dl (baseline 1.19 mg/dl) with an estimated GFR of 26 ml/min. Urinalysis revealed protein > 500 mg/dl, RBC 25, and presence of coarse granular casts. Urine protein-creatinine ratio was 3.2. Serology was negative for ANA, ANCA, and anti-proteinase antibodies, as well as hepatitis and HIV panels. Serum C3 and C4 levels were within normal limits. Viral PCR of nasopharyngeal aspirate was positive for SARS- CoV-2. Home medications lisinopril and hydrochlorothiazide were held on admission, and he was started on intravenous fluids, azithromycin, and hydroxychloroquine. On day 4, serum creatinine trended up to 3.29 mg/dl and potassium was 4 mmol/L but since the patient was oliguric, hemodialysis (HD) was started. Serum creatinine then trended to a high of 15 mg/dl, urea nitrogen to 102 mg/dl and serum potassium level to 6.9 mmol/L despite multiple HD sessions. Meanwhile, his oxygen requirement also increased to 15L. After 10 days of daily HD sessions, serum potassium came down to 4.3 mmol/L but he ultimately required HD post discharge.

Discussion: Previous literature has discussed SARS-CoV-2 association with effects on ACE2 of RAS and proximal tubular cells causing hypokalemia. To the best of our knowledge this would be the first documented case of hemodialysis refractory hyperkalemia seen with SARS-CoV-2 infection. One of the mechanisms for kidney injury is a direct viral induced cytopathic effect, which we believe held true for our patient. As viremia cleared, the kidney function improved though it did not return to baseline. In our case, development of hyperkalemia despite hemodialysis makes it more interesting, but it remains unclear how.

PO0816

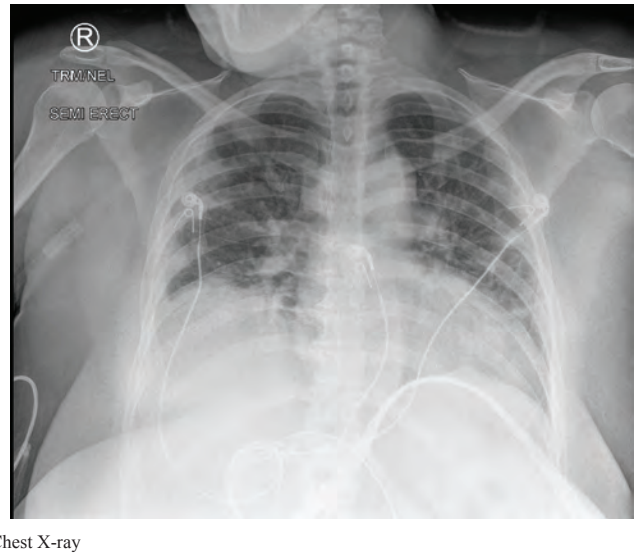
Rhabdomyolysis in COVID-19 Patient Requiring RRT

Muhammad usama shah Hamdani, Jeremy Carlson, Hasan Zahid. *University of Florida College of Medicine, Gainesville, FL.*

Introduction: Rhabdomyolysis is characterized by the release of intracellular muscle contents into the circulation. Of the 1099 patients affected by Covid-19 in China, only 0.2% had rhabdomyolysis.

Case Description: A 52 year old African American female with past medical history of Diabetes and hypertension presented to the ER with 7 days of worsening fever, chills, myalgias, nausea, vomiting, dyspnea, loss of sense of taste and smell. Her home medications included metformin and Candesartan-HCTZ, however, she had been off these medications for the last seven days. She was not on statins. She was a healthcare worker at a nursing home that had a recent outbreak of the novel Coronavirus with 51 positive cases. In ER, she was febrile, tachypneic with WBCs of 11.8 thousands/mm3, Creatinine of 6.68 mg/dl, BUN 76mg/dl, and creatinine kinase (CK) of 167,770 U/L. Urinalysis showed large amount of blood with 17 RBCs. Chest X-ray significant for mild patchy airspace opacity in the Lingula. She also tested positive for Covid-19. She was adequately volume resuscitated and alkalinized. Due to her severe AKI, she did not meet criteria for Hydroxychloroquine and Azithromycin. Sarilumab was contraindicated due to transaminitis. Patient was started on hemodialysis on day 3 of admission as her creatinine continued to rise. On the 10th day after admission, her transaminitis improved and Sarilumab was administered. Repeat Covid-19 test before administering Sarilumab was positive. Her IL-6 levels checked before initiating the drug were <5 pg/mL. Her CK levels had started to trend down and were at 4880 U/L the day before starting Sarilumab. She remained oliguric and on hemodialysis with no signs of renal recovery at the time of discharge.

Discussion: Coronavirus has a huge range of presentation from asymptomatic to severe ARDS. Our goal is to highlight one of the complications of the novel corona virus leading to acute renal failure requiring hemodialysis.



Chest X-ray

PO0817

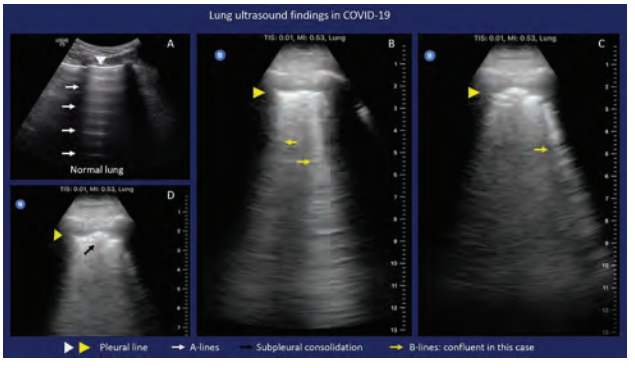
The Role of Point-of-Care Ultrasound in the Management of Dialysis Patients with COVID-19

Nathaniel C. Reisinger,[2] Abhilash Koratala.[1] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]University of Pennsylvania, Philadelphia, PA.*

Introduction: Much of the burden for management of outpatient dialysis patients with suspected or confirmed Coronavirus Disease 2019 (COVID-19) has fallen to the dialysis units. Symptom recognition is not straightforward as these patients often have multiple putative etiologies for dyspnea especially given concomitant pulmonary congestion due to fluid overload. In this context, point-of-care ultrasonography (POCUS), particularly lung ultrasound (LUS) is a valuable diagnostic tool for nephrologists taking care of these patients. POCUS is free of ionizing radiation, can be performed at the bedside, and has comparable diagnostic accuracy to chest CT scan for most lung pathologies. We present a case study to illustrate the role of POCUS in dialysis patients.

Case Description: A 79-year-old woman with a history of ESKD on maintenance hemodialysis was found to be hypoxemic with an oxygen saturation of 90% on room air. Bedside LUS demonstrated patchy areas of pleural thickening and irregularity as well as confluent B-lines and scattered consolidations consistent with viral pneumonia [Figure]. Focused cardiac US did not reveal any overt signs of fluid overload. She tested positive for COVID-19 and improved with supportive care. She continued to receive dialysis on a separate shift for COVID-19 positive patients.

Discussion: In addition to aiding in diagnosis, POCUS limits staff exposure to the virus during transportation and avoids the downtime for radiology room decontamination unlike CT. Most handheld US devices can be completely encased in a standard plastic transducer cover that can be discarded after each use. We propose that dialysis units adopt LUS as a bedside tool to diagnose and monitor the extent of pulmonary involvement in patients with COVID-19 and differentiate from other causes of dyspnea. CT scan can be reserved for those with equivocal LUS findings or underlying chronic lung disease that interferes with interpretation.



PO0818

Severe AKI from Thrombotic Microangiopathy and Acute Tubular Necrosis in a Patient with COVID-19 and Gemcitabine Chemotherapy Use

Varun Madireddy, Deepa A. Malieckal, Vanesa Bijol, Hitesh H. Shah. *Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY, Great Neck, NY.*

Introduction: Thrombotic microangiopathy (TMA) is a known but rare complication of gemcitabine therapy. However, gemcitabine-associated TMA has not been reported in a patient with concurrent COVID-19. Here, we present an interesting patient with COVID-19 who developed severe acute kidney injury (AKI) from acute TMA and acute tubular necrosis (ATN) following gemcitabine therapy.

Case Description: 45-year-old AA female with history of recurrent metastatic cervical cancer, peritoneal carcinomatosis, small bowel resection, colo-vesical fistula, colostomy and bilateral nephrostomy tubes was hospitalized for severe symptomatic anemia, fever and AKI. A week prior to hospitalization, patient had received her third outpatient dose of gemcitabine. Four weeks prior to presentation, serum creatinine (Scr) was 0.77. On admission labs, Scr was elevated at 7.36 and hemoglobin was low at 4.8. Patient also tested positive for COVID-19 on admission labs. There was no evidence of hydronephrosis on CT scan. Patient found to have clinical and labs findings of TMA (hypertension, thrombocytopenia, elevated lactate dehydrogenase and low haptoglobin) during hospital stay. Peripheral smear showed multiple schistocytes. Urinalysis was significant for microscopic hematuria and proteinuria. Spot urine total protein to creatinine ratio was 4.6. Complement C3 and C4 were not low. Patient was Coombs IgG positive and was initiated on high dose intravenous corticosteroids. Our patient also received one dose of rituximab therapy as per inpatient oncology team. Patient was initiated on hemodialysis for uremic symptoms. Kidney biopsy subsequently performed during hospital stay showed acute TMA and acute tubular injury with focal tubular necrosis.

Discussion: Our patient developed severe AKI in the setting of gemcitabine chemotherapy use and COVID-19. Kidney biopsy showed findings of both TMA and ATN. While the kidney biopsy findings are very interesting, it is unknown if either gemcitabine or COVID-19 or both were responsible for the severe AKI seen in our patient. Our patient remains oliguric and dialysis dependent.

PO0819

First US Case Series: Continuous Renal Replacement Therapy with Adsorbent Oxiris Filter in the Setting of COVID-19 Infection

Aireen Kate M. Kuan, Bessy Suyin Flores Chang, Mala Sachdeva, Deepa A. Malieckal, Richard L. Barnett. *Northwell Health, Great Neck, NY.*

Introduction: Many COVID-19 hospitalized patients sustain acute kidney injury (AKI) requiring CRRT. Multisystem hyperinflammatory response plays a large role in their infection leading to enhanced morbidity and filter clotting. Oxiris filters have been used for years in Europe in septic patients due to their properties of reducing cytokines and inflammatory mediators but have not been available in the United States until late April 2020. Use of these filters in COVID-19 patients has been very limited, and has not yet been reported. We report the first U.S. experience in 3 COVID-19 patients requiring mechanical ventilation for their respiratory failure and continuous venous to venous hemodiafiltration (CVVHDF) using oXiris dialyzers for their (AKI).

Case Description: Case 1: A 73 year old male with laboratory tests revealing: creatinine 1.79mg/dl, C-Reactive Protein 1.01mg/dl, D-dimer 597, ferritin 13,000 ng/ml and Interleukin-6 (IL-6) 96 pg/mL. He was started on CVVHDF with M150 filter and then switched to oXiris filter. He remained on oXiris CVVHDF for 9 days with no reported clotting events, a decline in ferritin by 90% to 1437ng/mL and a decline in IL-6 levels to 73 pg/mL. Case 2: A 55 year old male on CVVHDF with the M150 filter had a serum ferritin level progressively increasing to 2377 ng/ml and multiple clotting events. The dialyzer was switched to oXiris. He had no clotting events while on CVVHDF for six days and his serum ferritin level decreased to 1759 ng/ml. Case 3: A 40 year old male on extracorporeal membrane oxygenation (ECMO). He was initiated on CVVHDF to the ECMO circuit using a M150 filter for 7 days and was switched to oXiris filter with no reported clotting events thereafter.

Discussion: The COVID-19 cytokine storm leads to activation of pro-inflammatory mediators leading to severe morbidity including coagulopathic events. Optimal treatment is still unknown. ECMO and CVVHDF with oXiris dialyzer in critical COVID-19 infection may play a role in decreasing inflammatory markers, which confers overall clinical improvement. Once switched to oXiris, our patients showed improvement in inflammatory markers and had no clotting of their dialyzers. In these patients, convective clearances (CVVHDF) may be more beneficial than diffusive therapies (CVVHD).

PO0820

Pre-Filter Argatroban for Coronavirus Disease 2019

Pablo Villanueva-Meyer,[1] Sandhya S. Thomas.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX.*

Introduction: Coronavirus disease – 2019 (Covid-19) has been implicated in a pro-thrombotic state. This has been well documented in numerous articles and has posed to be a difficult obstacle for those caring for Covid-19 positive patients. This has been particularly challenging for Nephrologist managing patients on continuous renal replacement therapies (CRRT). Amongst other things, filter clotting has been associated with an increased number of transfusions and interruptions in sustained therapy, as well as increased costs to the healthcare systems and patients.

Case Description: We present the case of a 73-year old African American male with a past medical history of underlying chronic kidney disease, hypertension, diabetes mellitus, heart failure, and atrial fibrillation who was admitted from his nursing facility after being found to be altered. Upon presentation to the hospital, the patient was screened for SARS-CoV-2 and found to be positive. He was transferred to the intensive care unit due to septic shock requiring vasopressors. Given oliguria, worsening acidosis, and metabolic derangements the patient was started on CRRT. Hospitalization was complicated by acute lower limb ischemic. Direct thrombolysis was unable to be performed due to thrombocytopenia and the patient subsequently underwent a guillotine amputation of the right lower extremity. CRRT was continued however multiple issues with filter clotting were noted despite systemic anticoagulation with heparin. The patient was transitioned to Argatroban as thrombocytopenia worsened and there was a concern for heparin-induced thrombocytopenia. Following the transition to Argatroban, the patient's filter life was exponentially increased and only replaced per hospital protocol. No further issues with clotting were reported with the dialysis circuit.

Discussion: The pathogenesis of hypercoagulability associated with Covid-19 is not fully understood. Techniques utilized to minimize the risk of clotting include increasing the blood flow rate, regional and systemic anticoagulation, and running replacement fluids pre-filter. The role of Argatroban, a direct thrombin inhibitor, in treating Covid-19 patients has not been well documented. We report the case of a patient who was successfully anti-coagulated with Argatroban being run pre-filter. Pertinent outcomes included prolonging filter life, elimination of filter clotting events, and fewer interruptions in CRRT.

PO0821

Efficacy of Acute Continuous High-Volume Peritoneal Dialysis on the Respiratory Mechanics of a Mechanically Ventilated Patient with Acute Respiratory Distress Syndrome due to COVID-19

Thanh Cao, Viktoriya Yanchuk, Neeraj Sharma. University of Southern California *University of Southern California, Los Angeles, CA.*

Introduction: Acute renal failure (ARF) is a common issue in mechanically ventilated patients diagnosed with acute respiratory distress syndrome (ARDS) due to COVID-19. Renal replacement therapy (RRT) is often required for volume overload. Such patients may not tolerate hemodynamic shifts induced by hemodialysis (HD). Continuous renal replacement therapy (CRRT) while better tolerated is a limited resource. Acute peritoneal dialysis (PD) remains a feasible RRT modality in patients on mechanical ventilation. Some hesitate to use PD for fear of increasing intra-abdominal pressure (IAP) with dwells leading to altered respiratory mechanics. Our case demonstrates that acute PD has no adverse respiratory outcomes in a COVID-19 patient.

Case Description: A 42 year-old Hispanic male with end stage renal disease newly initiated on urgent start PD for 1 week presents with acute hypoxemic respiratory failure secondary to ARDS from COVID-19. Upon presentation, he was intubated and initiated on lung protective ventilator strategies. Due to high ventilatory requirements (PEEP 15, FiO2 100%) with severe volume overload HD was selected in lieu of PD. He underwent daily HD but remained overloaded due to high daily intake. Due to limited availability of CRRT, he was transitioned to acute continuous PD via cycler (fill volume 2L, every 4hr). FiO2 reduced to 40%, peak and plateau pressures did not change, and he was able to maintain adequate ventilation with unchanged tidal volumes while on PD. He eventually received a tracheostomy.

Discussion: COVID-19 has challenged providers with managing critically ill patients in the setting of limited resources. In our case of ARDS with ARF, we transitioned from HD to acute PD in order to facilitate fluid removal in lieu of CRRT. The ICU team feared increased IAP from PD would worsen lung compliance and hypoxemia from atelectasis. A prospective study by Almeida et al showed that acute PD in mechanically ventilated patients was associated with increased IAP, but lung compliance, oxygenation, and PaO2/FiO2 increased. Our case noted similar observations without adverse event. Acute PD was able to meet the demands on his daily intake without any compromise to ARDS lung protective ventilator strategies.

PO0822

Methemoglobinemia and AKI in Patients with COVID-19: Don't Forget G6PD Deficiency

Samraiz Nafees, Rouvick Gama, David Makanjuola, Virginia A. Quan. *St Helier Hospital, London, United Kingdom.*

Introduction: Patients with COVID-19 can be asymptomatic or have severe illness. Oxidative stress may be a cause of increased severity and mortality in COVID-19 patients. Methaemoglobinaemia (MetHb) and haemolysis can occur as a result of oxidative stress. MetHb is associated with sepsis, exposure to drugs and inborn errors of metabolism. Glucose-6-phosphate dehydrogenase (G6PD) deficiency may also manifest with MetHb and severe haemolysis.

Case Description: A 31-year old man, originally from West Africa, with no co-morbidities, presented with dyspnoea, cough, anosmia and oligo-anuria. He had type 1 respiratory failure and stage 3 AKI, which led to critical care admission for intubation, ventilation and haemofiltration. COVID-19 pneumonia was confirmed by nasopharyngeal swab and radiological imaging. He developed haemolytic anaemia. The MetHb was 3.5% (normal <1.5%). It rose to a peak of 10.7% with persisting anaemia and further investigations showed G6PD deficiency. He had no exposure to medications known to trigger haemolytic crises, such as Hydroxychloroquine. He was treated with supportive management including red cell transfusions and also with Tocilizumab for COVID-19. He was extubated after 15 days and recovered renal function. Data on 9 other patients admitted during this period to the ITU with COVID-19 and AKI showed 7 had normal MetHb levels and 2 had modest elevations (<3%).

Discussion: Triggers of G6PD deficiency include stress from infections, fava beans, or drugs e.g Hydroxychloroquine. It typically presents as haemolytic anaemia, jaundice and AKI. Although MetHb is linked to severe illness including sepsis, little is known about a possible association with COVID-19. Our report highlights the importance of considering alternative diagnoses of very high MetHb levels such as G6PD deficiency in COVID-19 patients. This is of particular relevance as Hydroxychloroquine has been used as experimental treatment for COVID-19 and in the current climate, G6PD deficiency should be suspected in COVID-19 patients with AKI, acute haemolytic anaemia and signikficantly elevated MetHb, particularly in those from regions of high prevalence and those treated with known triggers such as Hydroxychloroquine.

PO0823

Rhabdomyolysis and High Catabolic State in Patients with COVID-19 Who Develop Dialysis-Requiring AKI

Viviam I. Becerra rivera, Aulio E. Bustos, Sanjeev Gupta, Aromma Kapoor. Westchester Medical Center *Westchester Medical Center, Valhalla, NY.*

Introduction: Covid-19–associated rhabdomyolysis has not been clearly established; therefore, clinicians might have low clinical suspicion for rhabdomyolysis

Case Description: We are presenting five cases where Covid-19 patients became very catabolic and developed rhabdomyolysis associated with acute kidney injury (AKI). Symptoms were shortness of breath, fever, generalized malaise one week before the presentation. At the time of admission all patients had fever, tachycardia, tachypnea and were hypoxemic. One day later they were intubated for tachypnea and worsening oxygen saturation. They were admitted to the intensive care units and were treated with intravenous hydration. All the patients eventually required pressor support. AKI developed 10 days after onset of the symptoms and it was attributed to cytokine storm, ischemic acute tubular necrosis, and rhabdomyolysis. Intravenous furosemide was attempted with poor responses. Renal replacement therapy (RRT) was needed approximately three days after development of AKI. Continues renal replacement therapy (CRRT) was the modality used. After 3 days of interrupted therapy due to clotting, there was not improvement and overall high mortality.

Discussion: Rhabdomyolysis has been associated with many infectious diseases, including viral infections. The direct viral invasion and circulating viral toxins may directly destroy muscle cell membranes leading to rhabdomyolysis. However the

excessive immune response and cytokine storms which often seen in COVID-19 can promote to high catabolic state and rhabdomyolysis and therefore it will contribute to rapid worsening on renal function. Early detection and promptly supportive treatment with RRT may help to improve the vital prognosis of COVID-19.

Characteristic	1	2	3	4	5

Severe Hypertriglyceridemia Leading to CRRT Malfunction in a COVID-19 Patient

Rushang Parikh, Richard L. Barnett. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Continuous renal replacement therapy (CRRT) is a therapy used in critically ill patients and is of particular importance with COVID-19. We present a patient with COVID-19 on propofol for sedation with persistent filter clotting issues found to have severe hypertriglyceridemia (SHT) corrected with lipopheresis. This case highlights the importance of managing all aspects of CRRT, the highly inflammatory state of COVID-19 and supply chain management during high utilization periods.

Case Description: A 41-year-old male with severe obesity and T2DM presented to the hospital with shortness of breath and fevers found to have COVID-19. The patient was intubated on presentation due to hypoxemic respiratory failure and admitted to the ICU. The patient was placed on Propofol for sedation. The patient presented with normal kidney function but peri-intubation had a rapid rise in creatinine to 4.00 mg/dL and was started on CRRT. It was noted that the CRRT circuit was continuously clotting within 30 minutes of initiation. The patient was also noted to have rising CPK levels and a concern for Propofol Infusion Syndrome (PRIS) was raised. A triglyceride level was checked and found to be 3286 mg/dL. The patient was initiated on insulin and heparin drips however due to CRRT issues and inadequate clearance a decision was made to perform lipopheresis to rapidly correct SHT. Patient underwent lipopheresis and the triglycerides dropped to 426 mg/dL. The heparin drip was continued and filter life greatly improved. The patient was continued on CRRT and adequate clearance was achieved.

Discussion: This case highlights important points for CRRT, COVID-19 and supply chain management. This patient was found to have PRIS however COVID-19 is a highly inflammatory state with a particularly robust response in patients with higher central adiposity. In this patient with metabolic syndrome, the addition of Propofol was a particular risk for SHT. With respect to the CRRT, a big indication to check triglycerides was the clotting of filters. Lipopheresis was indicated not only for the SHT but in order to help correct issues with CRRT and to achieve adequate clearance. Finally, during the COVID-19 crisis supply chain management was important with a shortage of CRRT machines, fluids and filters. In order to achieve optimal use of CRRT supply, adequate clearance, and correct SHT, lipopheresis was indicated.

PO0825

COVAN, COVID-Associated Nephropathy: An Evolving Epidemic of Kidney Disease

Aneesha A. Shetty, Ibrahim Tawhari, Maria L. Safar-Boueri, Nay Seif, Ameen S. Alahmadi, Vikram Aggarwal, Richard Gargiulo, Yashpal S. Kanwar, Susan E. Quaggin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: We highlight COVID-19 related renal characteristics in 6 African American patients with positive nasopharyngeal RT-PCR for SARS-COV-2 infection, presenting without severe respiratory symptoms but with acute kidney injury and nephrotic range proteinuria.

Case Description: One of the patients was a transplant recipient. None required mechanical ventilation and no COVID-19 specific therapy was prescribed. All underwent a renal biopsy that showed varying combinations of collapsing glomerulopathy, podocytopathy and protein overload tubulopathy (Fig 1A). Additionally, tubulo-reticular inclusions and virions (suspected to be SARS-COV-2 virions) were seen in electron micrographs (Fig 1B). *APOL1* genotype was tested in 3 patients who were all found to carry high-risk genotypes, suggesting possible susceptibility of patients with high-risk *APOL1* alleles to kidney involvement in SARS-Cov-2 (Fig 1C)

Discussion: There was discordance between the high risk G1/G1 genotype of the transplant recipient and the low risk G1/G0 donor kidney genotype, suggesting the important possibility of a systemic APOL1-related mechanism in kidney injury. In conclusion, these 6 cases draw attention to proteinuric kidney disease in COVID-19 infection, possibly associated with a milder form of respiratory disease and high risk *APOL1* genotype, emphasizing the need for ongoing vigilance and further investigation into this phenomenon

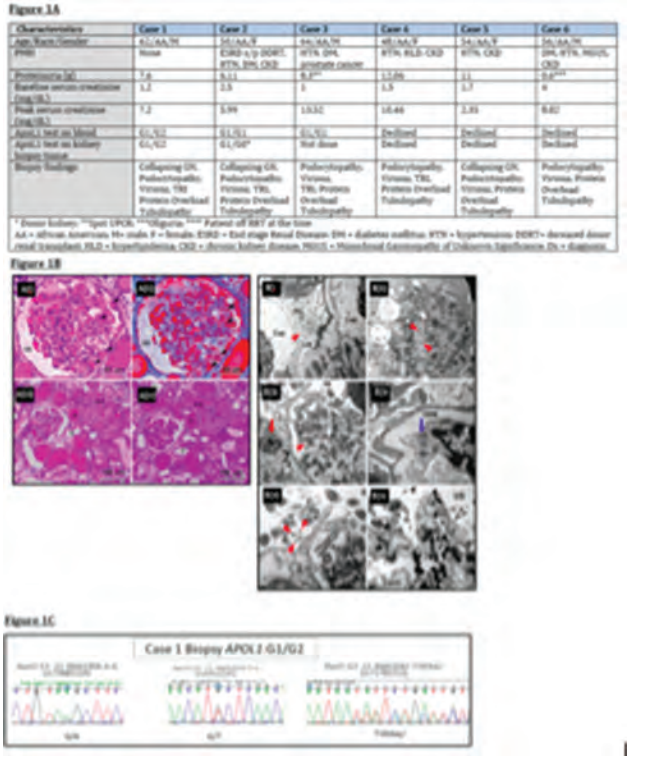

Figure 1: 1A: Demographic and Clinical features of the Six Cases. 1B:Biopsy findings. 1C: ApoL1 genotyping for Case 1

PO0826

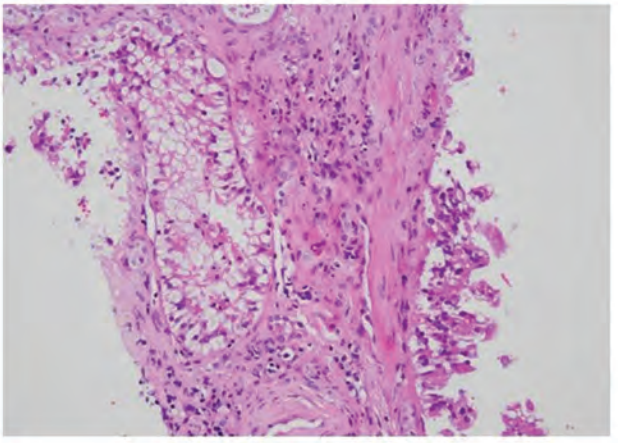
AKI and Purpuric Rash in a COVID Patient

Zakir Shaik, Rui Song, Jared Hassler, Iris J. Lee, Dina Abdelwahab, Avrum Gillespie. *Temple University, Philadelphia, PA.*

Introduction: AKI in COVID-19 patients are reported in several studies with an incidence of 23%. We report a case of COVID-19 pneumonia with AKI and purpuric rash.

Case Description: A 54 y/o female with hypertension, CKD stage 3, with a COVID+ swab, presented with CT chest findings consistent with COVID-19 pneumonia, purpura of the lower limbs concerning for leukocytoclastic vasculitis and non-oliguric AKI. Creatinine on admission was 8.5mg/dl, (baseline of 1.6mg/dL), CBC showed a wbc 26.9, Hb 6.9, platelets 196 and eosinophilia. Serologies were notable for elevated direct coomb, low haptoglobin, low C3/C4, and rheumatoid factor of 26. UA had no hematuria, UPCR 0.75 mg/mg. Home medication, naproxen was stopped one month ago. Renal biopsy showed severe acute tubular injury (ATI), coarse vacuolization of tubular epithelial cells, severe leukocytic infiltration of lymphocytes, neutrophils, eosinophils, severe vascular hyalinosis, global glomerular sclerosis (11 out of 30 glomeruli), severe (60%) interstitial fibrosis & tubular atrophy. Per institutional protocol, Immunofluorescence could not be performed in COVID+ patients. Renal function improved significantly after a 5 day course with IV steroids alone and patient remained stable with a creatinine of 3.4 mg/dL.

Discussion: This case features multiple potential mechanisms for AKI in a COVID-19 patient. Viral effects include, acute interstitial nephritis (AIN), severe ATI, and endothelial inflammation leading to vasculitis and purpuric rash. Recently, vasculitis similar to Kawasaki disease has been described in COVID-19 patients. Our case suggests that immune dysregulation from COVID infection may result in autoimmune findings such as elevated RF and hemolytic anemia. AKI improved in our patient after steroids, suggesting that a biopsy with features of AIN should be treated and could change the course of the disease.



PO0827

Unforeseen Complications of Delayed Vascular Access Intervention: A Case Report in the Wake of the COVID-19 Pandemic

Kevin S. Hsu, Rasha Alawieh, Khaled Boubes. *The Ohio State University, Columbus, OH.*

Introduction: Well-functioning dialysis access is of utmost importance as the lifeline of those with end stage kidney disease (ESKD). With the evolvement of COVID-19 pandemic, elective procedures were placed on hold. The American Society of Diagnostic and Interventional Nephrology (ASDIN) and Vascular Access Society of the Americas (VASA) issued a joint position statement on March 24, 2020, designating dialysis vascular access procedures to be "essential". We present a case with a series of complications that could have been prevented had the patient undergone a timely thrombectomy procedure.

Case Description: A 62 year old woman with ESKD undergoing hemodialysis through an upper arm arteriovenous fistula (AVF) presented with a thrombosed AVF in early March 2020 (before the ASDIN statement was issued). She was evaluated by the surgical team; however, due to restrictions to surgical procedures at the time, she did not undergo a thrombectomy and had a right internal jugular tunneled dialysis catheter (TDC) inserted instead. This was complicated by a superior vena cava thrombosis a few weeks later. The TDC was then removed and she had a right femoral TDC placed. She was started on anticoagulation. Her right femoral TDC was complicated by tunnel infection, necessitating its removal and subsequent placement of a left femoral TDC.

Discussion: This case illustrates the complexity of dialysis vascular access and some of the potential complications that are associated with it. It also highlights the importance of timely action to rescue any failed access. As outlined by the statement of ASDIN and VASA, dialysis vascular access should always be treated as a priority, and procedures to salvage it ought to be considered essential. This should also be the case in any future unforeseen restrictions to surgical procedures, such as pandemics or natural disasters.

PO0828

Does Cyclophosphamide Exposure in Patients with Vasculitides Lead to Better COVID-19 Outcomes?

Syed mohammed faizaan M. Zabiullah,[1,2] Arie Gunarso,[1] Ashok P. Chaudhari.[1] *[1]Metropolitan Hospital Center, New York, NY; [2]New York Medical College, Valhalla, NY.*

Introduction: COVID 19 is a pandemic disease caused by novel coronavirus called SARS-CoV- 2. End Stage Renal Disease patients are at high risk for developing severe manifestations of the disease often associated with high morbidity and mortality. Excessive and uncontrolled immune response is thought to be one of the important underlying mechanism for severity of the disease. We present 3 ESRD patients with underlying vasculitides who were admitted with respiratory distress due to COVID 19.

Case Description: All 3 patients presented with shortness of breath and had typical features of COVID 19 including hypoxia, fever; extensive bilateral interstitial infiltrates on Chest X rays, lymphocytopenia, elevated LDH; and ferritin. The first patient is a 37-year-old Hispanic male with ANCA -PR3 related vasculitis resulting in ESRD, on hemodialysis. He had been treated with Cyclophosphamide and prednisone induction therapy and is on maintenance prednisone. The second patient is a 40-year-old male with ESRD secondary to crescentic IgA nephropathy. He had been treated with cyclophosphamide and prednisone induction. The third patient is a 43-year-old female with SLE; ESRD secondary to lupus nephritis. She had been treated with cyclophosphamide and prednisone induction and is on maintenance prednisone. All 3 patients recovered in the hospital with oxygen supplementation and did not require NIV or intubation.

Discussion: We hypothesize that due to residual immunosuppressive action of cyclophosphamide, the inflammatory response in these patients was probably blunted. And this could have led to better outcome in these patients. Due to lots of unknowns related to COVID 19, further prospective/retrospective studies should be done looking at outcomes of COVID 19 in patients who had received cyclophosmide previously.

PO0829

Renal Biopsy Findings in Patients with COVID-19 Infection

Tuyet Hong T. Tran, Ming Wu. *NYU Langone Health, New York, NY.*

Introduction: COVID-19 infection is caused by severe acute respiratory syndrome-2 (SARS-CoV-2). SARS-CoV-2, using its Spike protein, interacts with angiotensin converting enzyme-II (ACE2) protein expressed in human kidneys. Upon internalization, host cells may go through pyroptosis, a process characterized by membranous pore formation, cytokine storm and cell death. We report light microscopy (LM), immunofluorescence microscopy (IF), and electron microscopy (EM) findings in renal biopsies of patients with COVID-19 to further understand the pathological process.

Case Description: 10 patients were biopsied, age range 25-63 years. 7 were confirmed by polymerase chain reaction (PCR) via nasopharyngeal swab. 3 patients were suspected, but PCR-negative. Common comorbidities include hypertension, hyperlipidemia, and obesity. Patients had AKI with elevated creatinine, range 1.2 to 13.48 mg/dL. Kidney ultrasound showed enlargement and increased echogenicity. Biopsies were performed 9 to 71 days from symptom onset of such as fever, cough, and diarrhea. Tissue was fixed in formalin and processed for LM. Fresh frozen tissue was utilized for IF. Tissue was fixed in paraformaldehyde and processed for EM. All had acute tubular injury and viral particles on EM (Figure). Patients received supportive care. None required ventilation, but 4 required hemodialysis. Survival rate is 100% (8-12 weeks).

Discussion: Renal biopsies were evaluated in 7 confirmed and 3 suspected COVID-19 patients. Although PCR is the gold standard, it is known to have a 15% false negative rate. This may be due to low viral loads and antibody testing may be warranted in suspected PCR-negative patients. Coronavirus particles are reported to measure 50-200 nm, and SARS-CoV-2 50-140 nm. Viral particles were seen in all 10 patients. The particles are contained in vesicles or sacs, and can be found in podocytes, endothelial, and tubular epithelial cells. This may contribute to intrinsic injury resulting in AKI seen in patients.

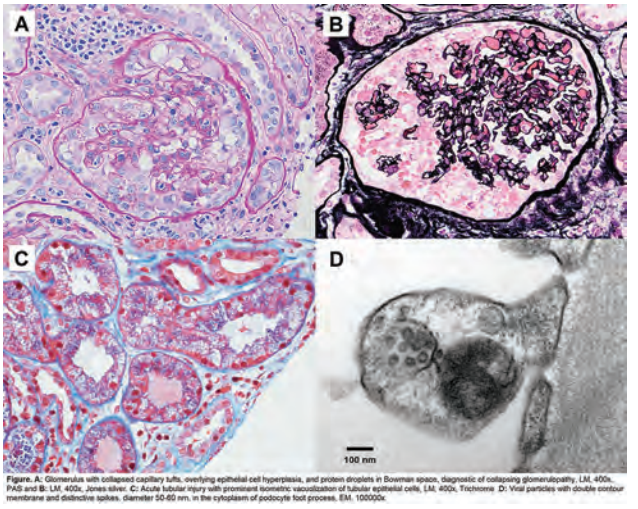


Figure. A: Glomerulus with collapsed capillary tufts, overlying epithelial cell hyperplasia, and protein droplets in Bowman space, diagnostic of collapsing glomerulopathy, LM, 400x, PAS and B: LM, 400x, Jones silver. C: Acute tubular injury with prominent isometric vacuolization of tubular epithelial cells, LM, 400x, Trichrome. D: Viral particles with double contour membrane and distinctive spikes, diameter 50-80 nm, in the cytoplasm of podocyte foot process, EM, 100000x.

PO0830

AKI in the Setting of COVID-19: Histopathologic and Ultrastructural Findings in Postmortem Kidney Biopsy

Pouneh Golmai,[1] Christopher P. Larsen,[2] Maria V. DeVita,[1] Samuel J. Wahl,[1] Astrid Weins,[3] Helmut G. Rennke,[3] Vanesa Bijol,[4] Jordan L. Rosenstock.[1] *[1]Lenox Hill Hospital, New York, NY; [2]Arkana Laboratories, Little Rock, Arkansas, USA., Little Rock, AR; [3]Brigham and Women's Hospital, Boston, MA; [4]Hofstra Northwell School of Medicine at Hofstra University, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: COVID-19 has been associated with a very high risk of AKI. The pathophysiology of the AKI is unclear with conflicting reports regarding the presence of direct infection of the kidney with SARS-CoV2.

Methods: Postmortem kidney biopsy was performed in adult patients with confirmed COVID-19 and stage 2 /3 AKI. Biopsies were examined using light and electron microscopy. Immunohistochemistry and RNA in situ hybridization were performed for SARS-CoV2.

Results: 12 patients (83% male) with mean age of 70±13 years underwent biopsy. Mean baseline and peak creatinine were 1.0 and 5.3 mg/dL, respectively. Renal replacement therapy was required in 8 (67%) patients (Table 1). All 12 patients had a pathologic diagnosis of acute tubular injury with focal acute tubular necrosis (Table 2). There was no glomerulitis, vasculitis, or thrombotic microangiopathy. There were no characteristic viral particles on electron microscopy and there was no evidence of SARS-CoV-2 on Immunohistochemistry or in situ RNA hybridization.

Conclusions: AKI in patients with COVID-19 infection was associated with acute tubular injury and focal epithelial necrosis in all patients. There was no evidence of direct viral infection. It appears unlikely that SARS-CoV-2 causes renal injury by direct infection.

Serum Induces Major Transcriptional and Epigenetic Changes at COVID-19-Associated Gene Loci in Primary Renal Epithelial Cells

Kevin Lidberg, Selvaraj Muthusamy, Mohamed Adil, Jonathan Reichel, Jonathan Himmelfarb, Edward J. Kelly, Shreeram Akilesh. *University of Washington, Seattle, WA.*

Background: Tubular epithelial cells express high levels of COVID-19 entry receptors ACE2 and the accessory protease TMPRSS2. High systemic levels of IL-6 and IL-8 may contribute to the "cytokine storm" associated with poor outcome with COVID-19 infection. We sought to understand the regulation of these key genes in a 3D microphysiological system (MPS) containing primary human tubular epithelial cells treated with human serum, a surrogate for a disease-state ultrafiltrate.

Methods: Primary human tubular epithelial cells cultured in the 3D MPS were exposed to 0.5 and 2% serum for 48 hours and their transcriptional responses were evaluated by RNA-seq. Observed changes in transcription of secreted proteins were validated by ELISA on MPS effluents. We also orthogonally validated our MPS findings against gene expression and chromatin accessibility (ATAC-seq) data generated from intact human renal cortex and primary tubular epithelial cells cultured in 2D in the presence of 10% serum.

Results: Serum exposure of tubular MPS elicited 535 up and 285 downregulated genes with upregulation of pro-inflammatory and chemotactic cytokines *IL6* and *IL8* consistently seen across multiple donors. This was associated with increased IL6 and HAVCR1 (KIM-1) protein secretion in MPS effluents. Tubular epithelial cells cultured in 2D with 10% serum expressed higher levels of *HAVCR1* (up 4.5x), *LCN2* (*NGAL,* up 6x), *IL6* (up 11.2x) and *CXCL8* (*IL8,* up 7.6x) compared to renal cortex. In contrast, *ACE2* (down 8.6x) and *TMPRSS2* (down 4.4x) were significantly downregulated. Analysis of open chromatin regions revealed a stress response signature at these gene loci, indicating active regulation in response to injury.

Conclusions: Proteinuria is common in COVID-19 infected patients and we studied serum-exposure, as a model of glomerular dysfunction and subsequent proximal tubule responses in our kidney MPS. Serum induces the expression and secretion of IL6 and IL8, suggesting a localized, pro-inflammatory tubule response. Our epigenetic analysis revealed that COVID-19 associated genes have a stress response signature with implications for inter-individual variability in expression. Our kidney MPS model and data represent a powerful system for studying the complex effects that COVID-19 infection exerts on the kidney.

PO0832

Kidney Injury Molecule 1 Is a Receptor for SARS-CoV-2

Takaharu Ichimura,[1,2] Mahmoud L. Nasr,[1,2] Samuel Mon-Wei Yu,[1,2] Yutaro Mori,[1,2] Joseph V. Bonventre.[1,2] *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Acute kidney injury (AKI) is a common feature of Coronavirus disease 2019 (COVID-19) caused by SARS-CoV-2. **K**idney **I**njury **M**olecule-**1** (**KIM-1**) has been reported to be a receptor for Hepatitis A virus. KIM-1 is a scavenger receptor in kidney epithelial cells. We hypothesized that KIM-1 is a receptor for SARS-CoV-2 and may play an important role in COVID-19-associated AKI.

Methods: Liposomal nanoparticles displaying the SARS-CoV-2 spike protein trimer (S1 and S2) on their surface (virosomes) were generated. We evaluated spike protein and virosome uptake by human KIM-1 expressing kidney epithelial cells and human kidney tubuloids, 3D structures of kidney epithelial cells. KIM-1-mediated uptake was compared to uptake by ACE2, a well-known receptor for SARS-CoV-2. Our recently discovered specific KIM-1 uptake inhibitor, JB-1 was tested for its ability to block virosomes uptake by KIM-1 expressing cells. KIM-1 expression was augmented in the tubuloids by infection with adenovirus vector carrying human KIM-1 cDNA to examine if the virosome uptake was enhanced. Protein-protein interaction characteristics between purified SARS-CoV-2 spike protein and S1 binding domain and purified KIM-1 were determined using microscale thermopheresis.

Results: KIM-1 expression on kidney epithelial cells markedly enhanced virosome uptake, despite no change in ACE2 expression. This KIM-1 specific uptake was inhibited by JB-1. Human kidney tubuloids also endocytosed virosomes, and tubuloids with enhanced KIM-1 expression secondary to infection of KIM-1-adenovirus had increased uptake of virosomes. Using microscale thermopheresis the Kd for interaction between KIM-1 and SARS-CoV-2 spike protein and the receptor binding domain were 56.2+/-28.8 nM and 9.95+/-3.10 nM respectively.

Conclusions: KIM-1 is a receptor for SARS-CoV-2. KIM-1 specific uptake of the SARS-CoV-2- virosomes suggests that KIM-1 confers efficient SARS-CoV-2 binding in kidney epithelial cells when these cells are expressing KIM-1. The KIM-1 dependent virosome uptake by 3D tubuloids indicates that this can be a valuable human cell model for studying SARS-CoV-2 interactions and testing for inhibitors. KIM-1 inhibitors, such as JB-1, can be potential therapeutics SARS-CoV-2 for COVID-19. Kidney tubular intraluminal and systemic circulating levels of KIM-1 ectodomain may be protective by acting as decoy receptor for the virus.

PO0833

Morphological Evidence Suggests That Kidney Injury Molecule 1 May Serve as a Proximal Tubule Receptor for SARS-CoV-2

Ping L. Zhang,[1] Mustafa M. Deebajah,[1] Joseph Fullmer,[1] Takaharu Ichimura,[2] Mitual B. Amin,[1] Joseph V. Bonventre.[2] *[1]Beaumont Health System, Royal Oak, MI; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Kidney injury molecule-1 (KIM-1), a type-1 transmembrane glycoprotein, has been well studied as a specific injury marker for proximal tubules (PT). KIM-1 functions as a receptor for apoptotic fragments through a phagocytic process. KIM-1 (also called TIM-1) serves as a receptor for hepatitis A virus and Ebola virus, and possibly for severe respiratory syndrome-coronavirus (SARS-CoV-1). During the pandemic spread of coronavirus disease 2019 (COVID-19), many patients have suffered from acute kidney injury (AKI) as well as lung damage, Viral upkake has been attributed to interactions with ACE2, a receptor for the virus. The goal of this study was to investigate whether there is kidney histological data that KIM-1 may also serve as a receptor for SARS-CoV-2 to infect the PT.

Methods: Two patients (one adult and one child) who died of COVID19 and 10 patients with AKI but no COVID19 (control group) were included in the study. All kidney tissue sections were stained for KIM-1 (monoclonal AKG7 antibody) and scored from 0 to 3+. Electron microscopy was conducted using kidney tissue of the COVID19+ patients.

Results: Both COVID19+ patients had normal pre-mortem levels of serum creatinine (sCr) (adult 0.63 and child 0.17 mg/dl), whereas the control cases all had elevated sCr (1.9 to 10.7 mg/dl). Control renal biopsies revealed positive KIM-1 staining ranging from 1+ to 3+ along the surface of PT in a patchy pattern involving 20 to 80% of the cortex; no cytoplasmic granular materials were identified. By contrast, the KIM-1 staining in COVID19+ kidneys revealed spotty granular staining in the cytoplasm and diffuse surface 2+ to 3+ staining in most PTs, while glomeruli stained negatively for KIM-1 as internal negative controls. In the two COVID19+ patients, SARS-CoV-2 particles showed spiking-crown appearances with sizes ranging from 70 to 110 nm in the PT cytoplasm by ultrastructural studies.

Conclusions: Our initial evidence suggests there is an atypical staining pattern of KIM-1 in the PT of COVID19+ patients, raising a possibility that KIM-1 may serve as a receptor for SARS-CoV-2. KIM-1 may also serve to internalize the virus into the PT. In addition the two COVID+ patients had normal sCr levels but positive KIM-1 staining, indicating that sCr underestimates renal injury caused by SAR-CoV-2 infection.

PO0834

Kidney and Lung ACE2 Expression After an ACE Inhibitor or an Angiotensin II Receptor Blocker: Implications for COVID-19

Enrique Lores,[1] Jan Wysocki,[1] Minghao Ye,[1] Maria Jose Soler,[2,1] Daniel Batlle.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Hospital Universitari Vall d'Hebron, Hospital Vall d'Hebron, Barcelona, Spain.*

Background: There have been concerns that ACE inhibitors and Ang II receptor blockers may cause an increase in full length (FL) membrane bound ACE2, the main receptor for SARs-CoV-2, that could enhance the risk and worsen the clinical course of COVID -19. Information on the impact of ACE deficiency and AT1 blockade on ACE2 expression at target sites is required to understand this issue.

Methods: Kidneys from two genetic models of kidney ACE ablation and mice treated with captopril or telmisartan were used to examine ACE2 in isolated kidney and lung membranes.

Results: In global ACE KO mice, ACE2 protein abundance in kidney membranes was reduced to 42 % of wild type, $p < 0.05$. In ACE 8/8 mice that over-express cardiac ACE protein but has no kidney ACE expression, ACE2 protein in kidney membranes was

also decreased (38 % of the WT, p<0.01). In kidney membranes from mice that received captopril or telmisartan for 2 weeks there was a reduction in ACE2 protein to the level of 37%, p<0.01 and 76%, p <0.05 of that of vehicle control mice, respectively. In lung membranes the expression of ACE2 was very low and not detected by western blotting but no significant differences in terms of ACE2 activity could be detected in mice treated with captopril (118% of control) or telmisartan (93% of control).

Conclusions: Genetic kidney ACE deficiency, suppressed ACE enzyme activity by Captopril or blockade of the AT1 receptor with telmisartan are all associated with a decrease in ACE2 expression in kidney membranes. These findings altogether suggest that ACE2 protein abundance at two potential target sites for SARS-CoV-2 infection is decreased or unaffected by RAS blockers. Since these medications do not increase ACE2 expression in lung or kidney epithelia, we conclude that they likely would not pose a risk for increased susceptibility to COVID -19.

Noninvasive Mapping of the Cellular Response to COVID-19 via Urine Single-Cell RNA Sequencing (scRNAseq)

Jennifer A. Schaub, Ryann Sohaney, Abhijit S. Naik, Rajasree Menon, Edgar A. Otto, Laura H. Mariani, Celine C. Berthier, Matthias Kretzler. *University of Michigan Health System, Ann Arbor, MI.*

Background: COVID-19 is associated with a high incidence of AKI. Mapping the transcriptional profiles of kidney and urinary track derived single cell populations can establish a framework to assess renal molecular response to COVID-19 and emerging treatment strategies.

Methods: Patients throughout the COVID-19 disease course were recruited to the study. A modification of our protocol (Arazi et al. Nat Immunol) allowed for immediate isolation of urinary cell pellets followed by 10X Genomics Chromium based scRNAseq.

Results: Urine scRNAseq data sets were generated from 13 COVID patients: age 50+/-17; 7 males; 7 African Americans; urine sampling 11 days post SARS-CoV-2 diagnosis (IQR 5-29) with 8 in AKI at time of sampling. 25,954 single cell profiles passed QC with a median of 433 cells per sample [IQR 271 to 718]). Cellular clusters were annotated to immune (9780 cells, Fig: cluster 3.-7.), renal epithelial (4364, cluster 1.) and bladder cells (4151, cluster 2.). The SARS-CoV2 receptor ACE2 was found in epithelial cells and co-expressed with CTPSL. The COVID-19 therapeutic target IL-6 was robustly detected in both myeloid and epithelial cells with co-expression networks linking IL6 expression in proximal tubular epithelial cells to HMGB1, VEGF and HIF signaling and to viral response networks in myeloid cells.

Conclusions: COVID-19 patients urine cells contain a spectrum of epithelial and immune cells expressing viral receptors of SARS-CoV-2 and therapeutic targets of emerging COVID-19 therapies offering a window to monitor renal cellular responses in COVID-19 trials.

Stimulus and Cell-Specific Responses to Volume Depletion, Ischemia, and COVID-19

Katherine Xu, Tian Shen, Jacob Stauber, Krzysztof Kiryluk, Vivette D. D'Agati, Jonathan M. Barasch. *Columbia University Irving Medical Center, New York, NY.*

Background: A stimulus-response map of the injured kidney might reflect a common stereotyped "final common pathway" or alternatively, a set of "stimulus-specific", "cell-specific", and "time-specific" read outs.

Methods: We expressed uracil phosphoribosyl transferase (Uprt) in specific segments of the kidney (Rosa-*Uprt$^{fl/+}$;Hoxb7Cre* and Rosa-*Uprt$^{fl/+}$;Atpase6v1b1Cre*) and identified nascent RNA by 4-thiouracil pulse labeling after initiating two clinically relevant stimuli. Thio-RNA was isolated from intact kidneys with thio-biotin beads. We examined human biopsies with RNAScope to confirm patterns of gene expression.

Results: Hierarchical clustering of z-score transformed normalized counts (padj<0.05 and $\log_2$ fold changes ≥1) demonstrated that 3180 genes distinguished volume depletion from arterial ischemia in Hoxb7Cre purified genes and 1405 genes in AtpaseCre purified genes, respectively. The vast majority of these stimulus specific genes (96% ischemia and 83% volume depletion) constituted cell specific responses as well (exclusive to Hoxb7Cre or AtpaseCre purified RNA). Pathway analyses demonstrated immune regulation, complement and the coagulation pathways in ischemic disease, whereas volume depletion activated inhibitors of inflammatory pathways and metabolic Foxo signaling, clock genes, and lipid metabolism. Timed evaluation demonstrated distinct early and late responses. To confirm the unique responses to clinical injury, we examined the most prominent mouse genes responding to ischemia, *LCN2* (NGAL) and *HAVCR1* (KIM1) in human ATN kidneys (associated with NSAIA (1), hypotension (1), DGF (1), nephrectomy (2), COVID-19 (8), unknown etiology (1)), together with segment specific anchor genes (*LRP2*, *AQP2*). *LCN2* and *HAVCR1* expression was cell specific (*HAVCR1*: proximal tubule, *LCN2* : Loop of Henle and Collecting Ducts > Proximal Tubules) in the majority of biopsies. *LCN2* and *HAVCR1* overlapped in the proximal tubule in a minority of severely affected kidneys.

Conclusions: KDIGO criteria for AKI imply that any elevation of serum creatinine marks injury to the nephron. Yet, without resorting to destructive methods of dissection or cell isolation, we identify snapshots of genes induced by different stimuli, expressed by different cells, specific in timing, constituting different sets of unrelated molecular responses.

AKI and Collapsing Glomerulopathy Associated with COVID-19 and APOL1 High-Risk Genotype

Juan Carlos Q. Velez,[1,8] Christopher P. Larsen,[2] Huijuan Wu,[3] Tiffany Caza,[2] Cesar F. Hernandez-Arroyo,[1] Muner Mohamed,[1] Asim Chughtai,[6] Moh'd Sharshir,[4] Liping Xie,[7] Ellen Acheampong,[5] Ivy Rosales,[5] Robert B. Colvin,[5] Agnes B. Fogo.[3] Ochsner Nephrology - Arkana - Vanderbilt *[1]Department of Nephrology, Ochsner Health System, New Orleans, LA; [2]Arkana Laboratories, Little Rock, AR; [3]Department of Pathology, Microbiology and Immunology, Vanderbilt University Medical Center, Nashville, TN; [4]Division of Nephrology, Tulane University School of Medicine, New Orleans, LA; [5]Department of Pathology, Massachusetts General Hospital, Boston, MA; [6]Northwest Indiana Nephrology, Munster, IN; [7]Ascension All Saints Hospital - Spring Street Campus, Racine, WI; [8]Ochsner Clinical School, The University of Queensland, Brisbane, QLD, Australia.*

Background: Acute kidney injury (AKI), with or without proteinuria, has been described in patients with Coronavirus disease 2019 (COVID-19). Kidney involvement in COVID-19 has been reported to be of greater severity in African Americans (AA). Herein, we report genetic, histopathological and molecular findings in 6 AA patients with COVID-19 presenting with AKI and *de novo* nephrotic-range proteinuria.

Methods: Percutaneous kidney biopsies were performed in 6 patients with COVID-19 with respiratory manifestations and proteinuric AKI. Peripheral blood was obtained for apolipoprotein L1 (APOL1) risk allele assessment. Kidney tissue was also examined by *in situ* hybridization (ISH) for viral detection and by NanoString for COVID-19 associated genes and genes related to tubular injury.

Results: Six AA patients with COVID-19 (4 men, 2 women), mean age 55 years (37-65) were included in the series. At biopsy day, the mean serum creatinine was 6.5 mg/dL (2.9 – 11.4) and the mean urine protein-to-creatinine ratio was 11.5 g (3.6 – 25.0). Kidney biopsy specimen showed collapsing glomerulopathy, extensive foot process effacement, microcystic tubular dilation and focal or diffuse acute tubular injury. Three patients had reticular endothelial aggregates. No viral particles were identified. ISH and NanoString showed absence of SARS-CoV-2 RNA. NanoString analysis showed changes in genes related to acute tubular injury and an increase in chemokine gene expression. All 6 patients tested positive for 2 APOL1 risk alleles. Two patients died, 1 remained dialysis dependent, 2 partially recovered after transient need for dialysis and 1 partially recovered without needing dialysis.

Conclusions: Collapsing glomerulopathy in AA patients with COVID-19 was associated with high risk variants of APOL1. Direct viral infection in the kidneys was not observed, suggesting a possible "two-hit" phenomenon of genetic predisposition and cytokine-mediated host response to infection. Given the resemblance with HIV-associated nephropathy, we propose the term COVID-19-associated nephropathy (COVAN) to this new entity.

PO0838

COVID-19-Associated Kidney Injury: A Case Series of Kidney Biopsy Findings

Purva D. Sharma, Hitesh H. Shah, Kenar D. Jhaveri, Vanesa Bijol. On behalf of the Northwell Renal COVID 19 Consortium *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.*

Background: Acute kidney injury (AKI) has been recognized as a common complication of severe COVID-19 in hospitalized patients. Proteinuria and microscopic hematuria have also been observed. While a recent autopsy series of patients who died with severe COVID-19 in China found acute tubular necrosis (ATN) in the kidney, few case reports of collapsing glomerulopathy in COVID-19 have also been reported

Methods: To better understand the clinical and histopathologic findings, we looked at 10 kidney biopsy cases in patients with COVID-19 along with clinical features of AKI with or without proteinuria or hematuria in our institution. We described their clinical features, pathologic findings and outcomes.

Results: The mean age of the patients who underwent kidney biopsy was 65 years. Five patients were African American, three patients were Hispanic, and two were Caucasian. Nine patients had varying degree of proteinuria. Eight patients had severe

AKI necessitating renal replacement therapy. On kidney biopsy, all patients had varying degree of ATN, with one patient having associated widespread myoglobin casts. In addition, two patients had findings of thrombotic microangiopathy (TMA), one patient had pauci-immune crescentic glomerulonephritis and another patient had global as well as segmental glomerulosclerosis with features of healed collapsing glomerulopathy. Interestingly, all patients had negative immunohistochemistry staining for SARS-CoV-2 on their kidney biopsy material.

Conclusions: This biopsy series reveals ATN as the most common kidney biopsy finding with AKI in COVID-19 infection with no evidence of significant viral presence in the kidney tissue

PO0839

Kidney Pathology Findings in Patients Dying with COVID-19

Meghan E. Kapp,[1] Jose E. Najul,[2] Michael H. Hines,[2] Brian P. Strollo,[2] Jonathan L. Babin,[2] Paisit Paueksakon,[1] Mark Lusco,[1] Agnes B. Fogo,[1] Juan Carlos Q. Velez.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Ochsner Health System, New Orleans, LA.*

Background: The global pandemic caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) leading to coronavirus disease 2019 (COVID-19) has predominantly resulted in a profound hypoxic respiratory disease with a significant subset of patients demonstrating abnormalities in renal function. Acute kidney injury (AKI) in these patients is an independent risk factor for mortality; however, the mechanism for injury is unknown and our understanding of the pathologic findings is limited.

Methods: Kidney tissue from nine patients who died with COVID-19 was obtained at autopsy and evaluated by light, immunofluorescence, and electron microscopy. RNAScope technology was used to perform RNA in situ hybridization (RNA ISH) with probes to the SARS-CoV-2 virus (sense) and for human gene *ACE2*.

Results: The cohort was comprised of 6 men and 3 women, 78% black, median age of 65 years (37 - 78) and median body mass index 29 (26 – 48) kg/m^2, of which 6 (67%) had hypertension and 4 (44%) had diabetes. AKI was present in 7 of 9 (78%), 5 (55%) of them needed dialysis. One patient had creatine kinase about 5000 U/L suggestive of rhabdomyolysis. All but one expired while on mechanical ventilation. The predominant morphologic finding on postmortem biopsy was acute tubular injury. Three cases (33%) demonstrated endocapillary platelet aggregates with one demonstrating fibrin tactoids and loss of endothelial fenestrations by EM, consistent with early TMA; however, no overt thrombotic microangiopathy was present. Immunofluorescence in one case demonstrated mesangial C3 staining without deposits by EM. Background mild-to-moderate arterionephrosclerosis was present in 6 of 9 (67%) cases. In one patient with AKI at time of death, RNA-ISH detected SARS-CoV-2 in tubular epithelial cells which also express *ACE2*, the receptor for coronavirus cell entry.

Conclusions: Among a cohort of 9 patients dying with COVID-19, postmortem evaluation of kidney samples predominantly revealed ATI without overt evidence of hypercoaguloability, complement dysregulation, or immune complex deposition. While the mechanism for AKI in most cases is not immediately apparent, this series suggests, but does not prove, direct renal infection with SARS-CoV-2 as the presence of viral RNA does not prove active viral infection.

PO0840

Renal Histopathological Post-Mortem Findings of 17 Patients with COVID-19 in New York City

Nitzy N. Munoz Casablanca, Mohamed Rizwan Haroon Al Rasheed, Judy Hindi, Lili Chan, Steven G. Coca, Fadi Salem, John C. He. *Icahn School of Medicine at Mount Sinai, New York, NY.*

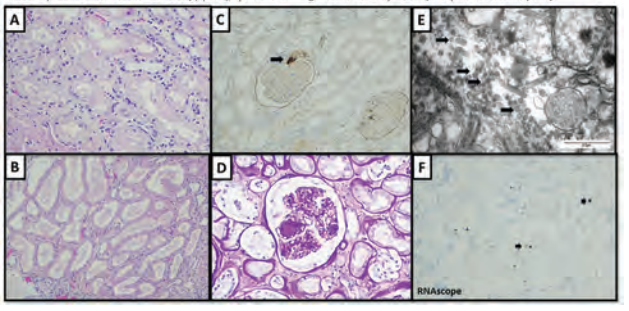
Background: While acute kidney injury (AKI) is a common and serious complication of patients with COVID-19, the mechanisms are unclear. Histopathologic reports of kidney tissue in COVID-19 are limited.

Methods: This was a retrospective case series of autopsy cases with confirmed SAR-CoV-2 infection performed at the Mount Sinai Hospital in patients who died between 3/21/2020 to 4/23/2020. Patients who had a kidney transplant, were on dialysis, if severe autolysis was present, or had no clinical data were excluded. To identify SARS-CoV-2, sections were examined by Transmission Electron Microscopy (TEM) and stained by In Situ Hybridization (RNAscope) in kidney sections.

Results: 32 patients had autopsies done, of which 17 patients fulfilled our inclusion criteria. The median age was 64 (interquartile range (IQR) 50, 79), 70% were male, 18% were black, 42% had diabetes and 59% had hypertension. Of the 17 patients, clinical evidence of AKI was present in 12 (71%) patients; 4/12 (33%) had Stage 1 AKI, 6/12 (50%) had Stage 2 AKI, and 2/12 (17%) had stage 3 AKI. Median peak creatinine was 0.96 mg/dL IQR 0.92-1.23 in those without AKI and 2.98 mg/dL IQR 2.11 – 5.99 in those with AKI. 3 patients had urine studies performed, only one of them had AKI and had hematuria, proteinuria, and leukocyturia. On histopathology, 9/17(53%) had acute tubular injury (ATI) only (Fig 1A & B) and 1/17 (5%) had TMA and ATI (Fig 1C). ATI was present in 4/5 (80%) of patients without AKI. There was no TMA found in patients without AKI. Glomerular pathology included nodular sclerosis in diabetic nephropathy (Fig 1D) and glomerulosclerosis secondary to ischemic hypertension. Virus was found in 4 samples (Fig 1E & F).

Conclusions: There is direct involvement of kidney by SARS-CoV-2 supported by identification of viral particles by TEM, and by ISH RNAscope. The most common histopathologic finding in patients that died with COVID-19 was ATI, which was also present in patients who did not have AKI by serum creatinine criteria.

Figure 1: Representative histopathologic findings of A) Vacuolization (isometric) of proximal tubules (H&E x200), B) Proximal tubules show diffuse attenuation of epithelial cells consistent with acute tubular injury (H&E x100), C) Mesangial sclerosis in a case of diabetic nephropathy (PASx200), D Platelets aggregates in the hilum of one glomerulus highlighted by CD61 immunoperoxidase (x100), E) Viral particles in proximal tubules by Transmission Electron Microscopy (x25k), F) Positive staining of SARS-CoV-2 by RNAscope in proximal tubules (x100)



PO0841

COVID-19-Associated Nephropathy (COVAN): An Emerging Entity of Severe Viral Podocyte Injury and Collapsing Glomerulopathy in Kidney Biopsies

Surya V. Seshan,[1] Steven Salvatore,[1] Billie S. Fyfe-Kirschner,[2] Ronald Miick,[3] Aqeel A. Siddiqui,[7] Mohamed Kahila,[4] Ramya Ramakrishnan,[5] Richard E. Freundlich,[6] Anthony D. Nicastri.[4] *[1]Weill Cornell Medicine, New York, NY; [2]Rutgers The State University of New Jersey, New Brunswick, NJ; [3]Albert Einstein Healthcare Network, Philadelphia, PA; [4]SUNY Downstate Health Sciences University, Brooklyn, NY; [5]NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY; [6]Newark Beth Israel Medical Center, Newark, NJ; [7]Lankenau Medical Center, Wynnewood, PA.*

Background: COVID19 caused by novel Coronavirus SARS-COV-2 initially presenting primarily as a respiratory illness, is now known to affect several organ systems as part of multiorgan failure including acute kidny injury (AKI), some cases also manifesting nephrotic range proteinuria or syndrome.

Methods: 10 renal biopsies from 6 institutions (1 transplant) performed in April-May 2020 were processed for light microscopy, immunostaining (IS) and electron microscopy (EM) for clinco-pathologic analysis.

Results: The 10 patients ranged from 25-73 years (Mean 43), male:female 5:5, 8 African American, 1 Hispanic, 1 Asian Indian, having pre-existing co-morbidities of hypertension (7), Diabetes mellitus (5), obesity (9), presenting with AKI (10), nephrotic syndrome (9), proteinuria ranging from 1.5-25g/24hrs, lung symptoms or pneumonia (7), fever (5). SARS-COV-2 RT-PCR positive (7), IgG antibody positive (2), both negative (1). All kidney biopsies showed widespread acute tubular injury with focal necrosis, 9 with typical features of segmental/global collapsing glomerulopathy in 10-53% of glomeruli, global glomerulosclerosis (0-35%), focal tubular microcystic changes (8), patchy (7) or diffuse (2) active tubulointerstitial inflammation and scarring (10-40%), focal & diffuse peritubular capillary inflammation, moderate vascular sclerosis and

diabetic kidney disease in 2. No immune deposits were localized by IS. By EM, varied glomerular capillary wall wrinkling and collapse with segmental or global loss of patency (7), total foot process effacement (7), with hyperplastic and vacuolated epithelial cells having protein droplets are noted. The endothelial cells are variably swollen, with tubuloreticular inclusions in 2. Viral particles are identified within cells of glomeruli and tubulointerstitium, scattered or in clustesr in the cytoplasm and endoplasmic reticulum vesicles, confirmed by IS.

Conclusions: The constellation of typical glomerular collapsing features with tubulointerstitial findings and localization of virus by EM, suggests a distinct viral associated nephropathy, reminicent of HIV associated nephropathy. A role for viral cytopathic effect, cytokines and underlying APOL1 gene variants could be considered.

PO0842

COVID-19 Renal Pathology Protocols and Pathology Practice in Latin America: Analysis from GlomCon Latin America Working Group (LGlomCon)

Blanca Martinez-Chagolla,[2] Denisse Arellano-Mendez,[3] Diana Aguirre,[4] Desiree Garcia Anton,[5] Julio A. Gutierrez-Prieto,[6] Sonia Rodriguez Ramirez,[7] Javier Soto-Vargas,[8] Franco H. Cabeza Rivera,[9] Carmen Avila-Casado.[1] GlonCon Latin America Working Group *[1]Pathology Department, University Health Network, Toronto, ON, Canada; [2]Hospital General de Morelia Miguel Silva, Morelia, Mexico; [3]Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; [4]Hospital General de Mexicali, Mexicali, Mexico; [5]University of Mississippi Medical Center, Jackson, MS; [6]Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; [7]Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; [8]Hospital General Regional 46 IMSS, Guadalajara, Mexico; [9]University of Mississippi Medical Center, Jackson, MS.*

Background: A significant fraction of patients with COVID-19 display renal involvement (60%); however, the histological findings and pathology practice in Latin America (LA) have not been reported. The aim is to know how COVID-19 pandemic has affected the protocols for renal pathology and the main pathology findings in the kidney.

Methods: An online survey with 75 questions in 6 sections, directed to pathologists, nephrologists and other specialists from 16 Spanish speaking LA countries treating COVID patients with kidney involvement. We are analyzing the impact of COVID-19 in renal pathology and pathology practice in LA.

Results: From 430 responses, 360 (84%) were considered for analysis. Only13 participants from 16 countries were renal pathologists but the rest of responders also contributed with the pathology section. Only 10% is performing renal biopsies (RBx) of COVID-19 patients. Acute kidney injury (AKI) (85%) was the most frequent indication for RBx, hematuria-proteinuria (42%), nephrotic syndrome (28%) and subnephrotic proteinuria (21%). Combination of AKI and other syndrome was seen. Handling fresh tissue for immunofluorescence (IF) is a regular practice in the centers that perform IF (66%). No ultrastructural examination in 90% due to the lack of EM equipment. Postmortem studies only in 3% of the centers. Autopsy and biopsies shiwed thrombotic microangiopathy (TMA), with acute tubular injury (ATI). Pathology redeployment to clinical areas, ICU and inpatient care is seen in 12%. Only 70% of those received guidance or updating clinical courses.

Conclusions: The survey has highlighted the deep shortage of renal pathologists and the lack of equipment (EM) compromising the best practice of renal pathology in LA. Protocols for tissue handling for COVID have not been established in any center, adding a burden to the practice. Most frequent indication for renal biopsy is AKI while the presence of TMA and ATI is found in autopsy and renal samples. Collapsing glomerulopathy (CG) has a high prevalence in hispanics and has been described in COVID patients, however CG was not seen. Outbreaks had forzed pathology redeployment to clinical care without proper preparation.

PO0843

Oxidative Stress, the Final Common Pathway in Lung-Kidney Pathophysiological Cross-Talk in an Experimental Model of COVID-19: Clinical Implications

Firoozeh Farahmand. *Saint Louis University, Saint Louis, MO.*

Background: AKI occurs frequently in patients with COVID-19 disease early in the course, in temporal association with respiratory failure and is associated with a poor prognosis. AKI is primarily seen in Covid-19 patients with respiratory failure, with 90% of patients on mechanical ventilation developing AKI compared to 22% of non-ventilated patients. To develop experimental models investigating pathophysiological mechanism of Lung- kidney inetarctions is an essential part of understanding the mechanisms of organs cross talk, i.e., the complex biological communication and feedback between distant organs mediated via cellular and molecular pathways.

Methods: In a novel experimental model similar to human COVID-19, ARDS followed by AKI developed by single injection of a Toxoid.(TOX). Two days post injection lungs and kidney were analyzed for antioxidant enzyme activities including superoxide dismutase, glutathione peroxidase, catalase and oxidative stress. Lungs wet/dry weight ratios were measured to evaluate edema. After sacrificing the animals, kidney and the lung were removed for histology.

Results: At 2 days post-TOX injection there was acute lung injury with cytotoxin influx, lung edema, neutrophil infiltration, hypoxemia and pulmonary artery thrombosis. In the kidney there was acute tubular necrosis with inflammatory infiltration. Oxidative stress was increased in the lung and the kidney. Antioxidant enzymes activities of SOD and GSHPx were decreased in the lung and the kidney.

Conclusions: In this experimental model mimicking COVID-19 organ failure, AKI and ARDS in rats correlates with a decrease in antioxidant and increase in oxidative stress in the lung & the kidney. This suggest the role of antioxidant as the potential adjunct therapeutic agents in COVID-19 related organ failure.

PO0844

Renal Pathology of 34 Consecutive COVID Autopsies: A Single-Institution Experience

Steven Salvatore, Alain C. Borczuk, Surya V. Seshan. *Weill Cornell Medicine, New York, NY.*

Background: Patients infected with the novel coronavirus 2019 (COVID19) have a wide spectrum of symptoms ranging from asymptomatic carriers to multisystem organ failure and death. While 20-40% of critically ill patients develop acute kidney injury (AKI) during the course of the disease, only few are biopsied. The most severely affected patients, frequently with multiple co-morbidities, provide insight into renal disease at autopsy.

Methods: 30 of 34 autopsies performed on COVID patients had kidneys available for routine evaluation. Clinicopathologic features are presented.

Results: The 34 patients range in age from 30-100 years (mean 68.5), 24 males and 10 females, 13 Caucasian, 10 Hispanic, 5 African American, 3 Indian, 3 Asian. All cases were positive by RT PCR nasal swab for SARS-CoV-2 except 3 (presumed false negative). All had on average 3.4 comorbidities (range: 0-7, hypertension (HTN), diabetes (DM), obesity, COPD, asthma, stroke, dementia, cancer), frequently HTN (20) and DM (20), 11 required intubation. 18 patients had AKI (53%), 2 previously ESRD, and 5 required renal replacement therapy. Presenting Cr ranged from 0.7-9.6 mg/dl (mean 1.7). Renal pathology included diabetic nephropathy (14, 47%), with tubulointerstitial scarring ranging from <25% (60%), 25-50% (23%), to >50% (17%), and moderate (40%) or severe (40%) chronic vascular sclerosis. Other findings: obesity related glomerulopathy (2), atheroemboli (1), bilateral infarction (1), papillary necrosis (2), and thrombotic microangiopathy (2). No collapsing glomerulopathy was seen. Tubular autolysis prevents complete assessment of ATN. Platelet thrombi were seen by CD61 staining in 43% of cases to involve >20% of glomeruli and peritubular capillaries. C5b-9 staining was strong, 2-3+ arteriolar in 67% and glomeruli in 20%, suggesting localized complement activation. By electron microscopy, viral particles were identified within cells of glomeruli and tubulo-interstitium.

Conclusions: Pathology in autopsy kidneys from 30 patients with COVID display pre-existing chronic disease correlating with co-morbidities, presenting with AKI or ESRD (59%). Despite varied tissue autolysis and the absence of significant proteinuria, the majority of AKI is presumed to be acute tubular injury due to ischemia and other causes. The viral particles in the renal glomerular and tubular cells may play a role in renal cytopathic injury.

PO0845

RAAS Inhibition, Mortality, and Severity in COVID-19 Patients: A Systematic Review and Meta-Analysis

Hatem Ali,[2] Mahmoud M. Mohamed,[1] Ahmed Daoud,[3] Tibor Fulop,[4,5] Maria Aurora C. Posadas,[4] Michael Casey,[4] Vinaya Rao,[4] Karim M. Soliman.[4] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University Hospitals of Birmingham, Birmingham, UK, Birmingham, United Kingdom; [3]Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt; [4]Medical University of South Carolina, Charleston, SC; [5]Ralph H. Johnson VA Medical Center, Charleston, SC, USA, Charleston, SC.*

Background: The effect of angiotensin-receptor blockers (ARBs) and angiotensin-converting enzyme inhibitors (ACEi) on outcome and severity in COVID-19 patients has been postulated.

Methods: We performed a systematic review in different databases to identify studies and research work that assessed the association of ACEi/ARBs on the severity of illness and mortality in COVID-19 subjects. Inclusion criteria for our meta-analysis were all studies that included human subjects with COVID-19 infection, reported mortality and severity of the disease, and described ACEi/ARB treatment. The data collected were the name of the first author, journal title, the country of the study, sample size, relative risk and confidence intervals for association of ACEi/ARB treatment and mortality and severity. We used the random-effects model for the meta-analysis and the funnel plot analysis to assess potential publication bias.

Results: Out of 4,702 records reviewed in different databases, 11 papers were included in our meta-analysis. Altogether, 8,643 patients were included in the final analysis. Random effects model (REM) for the relationship between ACEi/ARB and survival showed that ACEi/ARB does not affect survival (relative risk [RR]=0.81, confidence interval ranges [CIR] from 0.53 to 1.23). There was no evidence of heterogeneity with I-squared =25.5% and p<0.235. By applying Egger's test, there was no evidence of small studies effect with P=0.64. REM for the relationship between ACEi/ARB and disease severity showed that ACEi/ARB are not related to disease severity (RR=0.90, CIR from 0.70 to 1.15). There was evidence of heterogeneity with I-squared =56.2% and p=0.01. By applying Egger's test, there was no evidence of small studies effect with P=0.93.

Conclusions: Based on the results of this meta-analysis, ACEi/ARB are not associated with increased mortality or severity in COVID-19 subjects.

PO0846

The Use of ACE Inhibitors and ARBs in Patients Admitted for COVID-19

Hay Me Me, Aditi A. Sen, Zhong Zheng, Jennifer Griffiths, Viviam I. Becerra rivera, Sanjeev Gupta, Savneek S. Chugh, Shruti Kore, Vrunda Mangaroliya, Aulio E. Bustos. *Westchester Medical Center, Valhalla, NY.*

Background: Angiotensin converting enzyme (ACE 2) receptor has been implicated as an entry point for severe acute respiratory syndrome coronavirus 2 (SARS-COV-2) causing pandemic coronavirus disease 2019 (COVID-19). Experts have postulated the potential benefits of using ACEI/ARB to reduce the severity of acute lung injury and as the treatment of hypertension in COVID-19. However, there is limited data in showing the renal outcomes after the use of angiotensin converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs) in COVID-19 patients.

Methods: This is a retrospective, single center study of 300 patients diagnosed with COVID-19 confirmed by real-time reverse transcription polymerase chain reaction. Four groups were divided based on ACEI/ARB exposure. Group 1 (n=51 patients; 17%) were initiated on ACEIs/ARBs during hospitalization, group 2 (n=58 patients; 19%) were on ACEIs/ARBS at home and discontinued, group 3 (n=76 patients; 25%) were on ACES/ARBS at home and continued during hospitalization and group 4 (n=116 patients; 38%) were never treated with ACEIs/ARBS. The primary end points including the incidence of AKI using KDIGO definition, hyperkalemia, the necessity of dialysis and the secondary end points being the length of total hospital stays, the recovery rate, mortality rate were compared between group 1,2,3 with 4 using adjusted odd ratios (ORs).

Results: In group 1, the use of ACEI/ARB has 4 times higher risk of developing AKI than the control group 4 (P= 0.001, 95% CI of 1.70-9.59). and is 4.6 times for stage 2 or above AKI (P= 0.001; 95% CI of 1.8-11.5). OR for hyperkalemia is 5.7 (P= 0.001, 95% CI of 2.09-15.5) and for hemodialysis is 3.7 (P= 0.02, 95% CI of 1.2-11.2). Their mortality rate is increased 2.9 times (P=0.026, 95% CI of 1.23-7.44). In group 2, the incidence of AKI is 7.5 times higher (P= <0.001, 95% CI of 3.3-17) and 3.5 times (P=0.001, 95% CI of 1.6-7.7) for stage 2 above AKI. OR for the initiation of hemodialysis and the mortality rate are not statistically significant after adjusted with variables. In group 3, no statistically significant data were found.

Conclusions: Our findings suggest that the initiation of ACEI/ARB in COVID 19 patients have increased risk of AKI, hyperkalemia, necessity of dialysis and mortality rate.

PO0847

Prospective Feasibility Study with the Use of Losartan in COVID-19

Jeanwoo Yoo, Olena Bolotova, Imran Chaudhri, Nisha Nataraj, Haseena Sahib, Farrukh M. Koraishy, Sahar Ahmad, Michelle E. Bloom, Sandeep K. Mallipattu. *Stony Brook University Hospital, Stony Brook, NY.*

Background: The risks of administering Angiotensin II Receptor Blockers for hypertension in hospitalized patients infected with SARS-CoV-2 remains debated. To date, there are no prospective studies evaluating outcomes with the use of ARBs in patients with hypertension and COVID 19.

Methods: We conducted a single-center prospective feasibility study to ascertain the safety and efficacy of losartan in patients with COVID-19 and HTN. Inclusion criteria are patients with age ≥ 18yr, PCR confirmed SARS-CoV-2, BP>130/80, and required FiO2 ≥ 0.25 to maintain SpO2 > 92%. These patients were started and titrated on losartan 25mg daily to reach BP goal of <130/80. The vital signs, FiO2 requirements, LFTs, inflammatory markers, serum creatinine and K+ were monitored until discharge, with weekly evaluation of symptoms post-discharge.

Results: 250 patients were screened from April 22 to May 18, 2020, and 16 patients enrolled. Average time to enrollment was 5.5 days, with varying degrees of acuity. 6 patients were removed from the study (see Table 1). Eight patients completed the minimum 7 days of losartan while in the hospital 6/8 patients demonstrated no deterioration of SaO2/FiO2 ratio, SaO2/FiO2 compared on day 1 (201.1 ± 108.1) and day 7 (252.3 ± 148.4), and 2/8 patients improved to room air on day 7. Among all patients, inflammatory markers were not significantly changed from admission to peak values (Table 1).

Conclusions: This study has demonstrated that patients admitted with COVID 19 and hypertension who completed 7 days of Losartan showed no significant deterioration in oxygenation/worsening of inflammatory markers, thereby providing the rationale for a RCT with the use of losartan versus nonRAAS blockade in COVID-19.

Medications and Treatments		
Average Duration Losartan, days	7.0 ± 6.6	
Average Daily Losartan dose in mg	30. 2 ± 17.4	
Average Total Losartan dose in mg	233.3 ± 223.5

Renin-Angiotensin-Aldosterone System Blocking Drugs in Patients with SARS-CoV-2: Systematic Review and Meta-Analysis

Chang Chu,[1,3] Shufei Zeng,[1,3] Ahmed A. Hasan,[2,3] Carl-Friedrich Hocher,[3] Bernhard K. Krämer,[3] Berthold Hocher.[3] *[1]Charité – Universitätsmedizin Berlin, Berlin, Germany; [2]Department of Nutritional Toxicology, Institute of Nutritional Science, University of Potsdam, Potsdam, Germany; [3]Fifth Department of Medicine (Nephrology/Endocrinology/Rheumatology), University Medical Centre Mannheim, University of Heidelberg, Mannheim, Germany.*

Background: COVID-19 patients requiring treatment with blockers of the renin-angiotensin-aldosterone system (RAAS) are at highest risk of developing pneumonia and dying. ACE2 is the functional receptor for SARS-CoV-2. Animal studies suggest that RAAS blocking agents might increase the expression of ACE2 and hence potentially increase the risk of SARS-Cov-2 infection.

Methods: We conducted a systematic review and meta-analysis of published studies on the association of RASS blocking agents with lung disease related outcomes.

Results: The effect of ACE inhibitor treatment on the incidence of pneumonia in non-COVID-19 patients was analyzed in 25 studies (330,780 patients). ACE inhibitor use was associated with a 27% reduction of pneumonia risk (OR: 0.73, p<0.001). Pneumonia related death cases in ACE inhibitor treated non-COVID-19 patients were reduced by 27% (OR: 0.73, p=0.004). ARB treatment was analyzed in 10 studies (275,621 non-COVID-19 patients). The risk of pneumonia was not different between patients who did or did not use ARBs. Pooled result from 13 studies (27,704 COVID-19 patients) showed that COVID-19 related severe adverse clinical outcomes were not different between patients who did or did not use RAAS blocking agents (OR: 0.87, p=0.28). All-cause mortality risk in COVID-19 patients was reduced by 27% (p=0.04).

Conclusions: Given the weak evidence coming from animal studies and the clear beneficial data of ACE inhibition in non-COVID-19 patients and the limited but promising data in COVID-19 patients, the use of RAAS blocking agents in patients with SARS-CoV-2 infection is justified. Further clinical studies analysing ARBs and ACE inhibitors separately in COVID-19 patients are needed.

PO0849

Association of Prehospital RAAS Inhibitor Use with AKI and Death in a Cohort of Hospitalized COVID-19-Infected Patients

Ryan Mocerino, Emad Alahiri, Matthew K. Abramowitz, Ladan Golestaneh. *Montefiore Medical Center, Bronx, NY.*

Background: The relationship of RAAS inhibitors (RAASi) and their purported role in increasing COVID-19 viral attachment and worse outcomes is controversial. In this study we examined the association of RAASi use with Acute Kidney Injury (AKI) and in-hospital death.

Methods: We assembled a cohort of all patients admitted to the 3 main Montefiore hospitals and diagnosed with COVID-19. RAASi use was defined by a prescription within 365 days prior to hospitalization. The association of RAASi use with COVID associated AKI incidence and mortality was evaluated using logistic regression models. Propensity score matching was then used to derive the odds ratio (OR) of AKI and death in those using RAASi compared with controls.

Results: Of 3345 hospitalized patients, 9.3% were prescribed a RAASi prior to hospitalization. Those prescribed RAASi were older (71.9 vs 63.6 years, p<0.001), more commonly Black or Hispanic (RAASi users 41.3% Black and 41.0% Hispanic vs non-RAASi 35.4% Black and 36.9% Hispanic) and had higher Charlson co-morbidity scores (median 4 (IQR 3-7) for RAASi users vs 2(1-3) for non-RAASi users). In unadjusted analysis, RAASi use was associated with a higher OR for AKI (OR 1.32(95% CI 1.04-1.68)) and a higher OR for death (OR 1.53 (95% CI 1.18-1.98). Multivariate adjustment for age, demographics, and clinical comorbidity attenuated associations of AKI and death towards the null (AKI: OR 1.00 (95% CI 0.76-1.31); Death: OR 0.92 (95% CI 0.68-1.24)). Similarly, in propensity score analysis there was no association between RAASi use and either AKI (OR 0.96 (95%CI 0.88-1.04)) or death (OR: 0.96 (95%CI 0.89-1.05).

Conclusions: RAASi use prior to hospitalization was not associated with AKI or in-hospital mortality in a cohort of patients hospitalized with COVID-19.

Outcomes Associated with the Use of Angiotensin-Converting Enzyme Inhibitors and Angiotensin II Receptor Blockers in Hospitalized Patients with SARS-CoV-2 Infection

Imran Chaudhri,[1] Farrukh M. Koraishy,[1] Olena Bolotova,[1] Jeanwoo Yoo,[1] Sandeep K. Mallipattu.[1,2] *[1]Stony Brook University Hospital, Stony Brook, NY; [2]Northport VA Medical Center, Northport, NY.*

Background: SARS-CoV-2 uses the angiotensin converting enzyme (ACE) receptor for cell entry leading to COVID-19. The use of ACE Inhibitors (ACEIs) and Angiotensin II Receptor Blockers (ARBs) in hypertensive COVID-19 patients remains unclear. Since hypertension is a major comorbidity in COVID19, evaluating the efficacy versus adverse outcomes with the use of ACEI or ARB in patients with COVID-19 is essential.

Methods: In this retrospective single-center study, we analyzed electronic medical record data on 300 patients admitted with COVID-19 disease. Data collection included comorbidities, medications, vital signs, and laboratory values (on admission and during hospitalization). Outcomes included inflammatory burden (calculated using composite scores for multiple markers of inflammation), AKI, admission to the intensive care unit (ICU), need for mechanical ventilation, and mortality. For multivariate analyses, generalized linear model (continuous outcomes) and logistic regression (dichotomous outcomes) were used.

Results: Of the 300 patients, 80 patients (26.7%) had history of ACEI or ARB use prior to admission, with 61.3% (49/80) of these patients continuing the medications during hospitalization. Outpatient users of ACEI or ARB had a higher burden of comorbid disease and increased rates of admission and in-hospital AKI in the descriptive analysis, but not on multivariate analysis (after adjusting for multiple covariates). Continuation of ACEI or ARB inpatient was associated with lower peak C-reactive protein (CRP) levels, peak inflammation score, ICU admission and mortality in the univariate analysis. On multivariate analysis, continuation of these agents during hospitalization predicted lower ICU admissions (OR=0.25, 0.08-0.81, p=0.02), peak CRP (-6.9 ± 3.1 mg/dl, p=0.03) and peak inflammatory score (-2.3 ± 1.1, p=0.04) as compared to their discontinuation.

Conclusions: In hospitalized patients with COVID-19, the use of ACEI or ARBs as an outpatient was not associated with adverse outcomes despite greater comorbid illness in users. The continued use of these medications during hospitalization was also not associated with adverse events, rather it predicted fewer ICU admissions and decreased inflammatory burden.

PO0851

Glomerular Diseases and Immunosuppression Practices in Latin America During the COVID-19 Pandemic: Analysis from GlomCon Latin America Working Group (LGlomCon)

Julio A. Gutierrez-Prieto,[1] Franco H. Cabeza Rivera,[6] Sonia Rodriguez Ramirez,[7] Javier Soto-Vargas,[2] Denisse Arellano-Mendez,[3] Desiree Garcia Anton,[6] Diana Aguirre,[5] Blanca Martinez-Chagolla,[4] Carmen Avila-Casado.[8] GlomCon Latin America Working Group *[1]Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; [2]Hospital General Regional 46, IMSS., Guadalajara, Mexico; [3]Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; [4]Hospital General de Morelia "Dr. Miguel Silva", Morelia, Mexico; [5]Hospital General de Mexicali, Mexicali, Mexico; [6]University of Mississippi Medical Center, Jackson, MS; [7]Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; [8]Pathology Department, University Health Network, Toronto, ON, Canada.*

Background: As COVID-19 spreads across the world, nephrologists are facing difficult decisions regarding the management of active glomerular diseases (GD). We aimed to report how COVID-19 pandemic may have changed the use of immunotherapies among nephrologists In Latin America (LA) for the treatment of glomerulopathies.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases between May 20-27, 2020 from sixteen Spanish speaking LA countries divided into 6 categories. We present the results for the GD and immunosuppression category.

Results: 430 responses were obtained of which 360 (84%) were considered for analysis. The participants were mainly nephrologists 276 (86%), renal pathologists 13 (4%) and physicians in training 11 (3%). 213 (59%) of the respondents treat patients with GD. For patients at risk but without COVID-19 infection, the induction immunosuppression for GD treatment was not changed by 54.1% of the respondents while 24.2% gave only a fraction of it and 21.7% deferred the induction treatment. For maintenance immunosuppression, the same regimen was maintained by 74.2% of the respondents, 24.3% decreased it and 1.5% suspended it completely. In case of relapse or flare, 53.6% used standard increase of immunosuppression, 39.7% increased it but at lower levels than usual and 6.7% continued the maintenance regimen. For patients already on immunosuppression diagnosed with COVID-19 infection, 42% would decrease immunosuppressive regimens for mild disease, 62.3% in case of moderate disease and 70.8% would consider completely discontinuing immunosuppression in case of severe disease.

Conclusions: Over 40% of the respondents in LA are already prescribing lower than recommended doses of immunosuppression for induction, relapses or flares as a preventive strategy in the context of COVID-19 pandemic. How this change in practice would affect the renal outcomes remains to be seen. The experience in the treatment of GD in patients with concurrent COVID-19 infection remains limited.

PO0852

Ramipril Decreases Lung and Kidney Angiotensin Converting Enzyme 2 (ACE2) in Diabetic Mice: Lessons for COVID-19 Infection

Ander Vergara,[1,2] Conxita Jacobs Cachá,[2] Pamela Domínguez Báez,[2] Mireia Molina Van den Bosch,[2] Anna Giralt-López,[2] Clara García-Carro,[1,2] Daniel Serón,[1,2] Maria Jose Soler.[1,2] Nephrology Research Group *[1]Hospital Vall d'Hebron, Barcelona, Spain; [2]Vall d'Hebron Institut de Recerca, Barcelona, Spain.*

Background: ACE2 is a component of the renin-angiotensin system(RAS) that mainly degrades angiotensin II to angiotensin(1-7). It is expressed in renal tubular cells. Lung type 2 alveolar cells also express ACE2 where it acts as a receptor for SARS-CoV-2, which is responsible for the current coronavirus disease 2019(COVID-19) pandemic. A controversy raised regarding the use of RAS blockers in COVID-19 patients despite its demonstrated efficacy in cardiovascular disease. We studied the effect of ramipril on ACE2 expression in experimental diabetes.

Methods: 12 weeks old diabetic db/db mice were given ramipril(8 mg/Kg/day) or vehicle during 8 weeks. db/m mice were used as controls. ACE2 expression and enzymatic activity were studied in kidney, heart and lung.

Results: In non-treated db/db, ACE2 mRNA expression was increased in kidney($p<0.0001$) and ramipril treatment reversed this effect. In heart, ACE2 expression decreased in db/db when compared to db/m($p=0.028$) and ramipril had no effect. We found no differences in lung. ACE2 enzymatic activity was increased 23% in kidney and 22% in lung of db/db mice when compared to db/m. Ramipril treatment decreased ACE2 activity 25% in the lung and 13% in the kidney when compared to untreated db/db. In the heart, ACE2 activity tended to decrease in db/db mice when compared to db/m, and increased with ramipril, but did not exceed the cardiac ACE2 activity of the db/m.

Conclusions: ACE2 is increased in the kidney and in the lung, and decreased in the heart of diabetic mice. Ramipril treatment restores ACE2. Our results suggest that diabetes and hypertension may *per se* be risk factors for COVID-19 and not the treatment with ACE inhibitors, which may exert a protective effect on COVID-19 infection.

Funding: Government Support - Non-U.S.

Caring for Patients with Kidney Disease in the COVID-19 Era: The Kaiser Permanente Northern California Experience

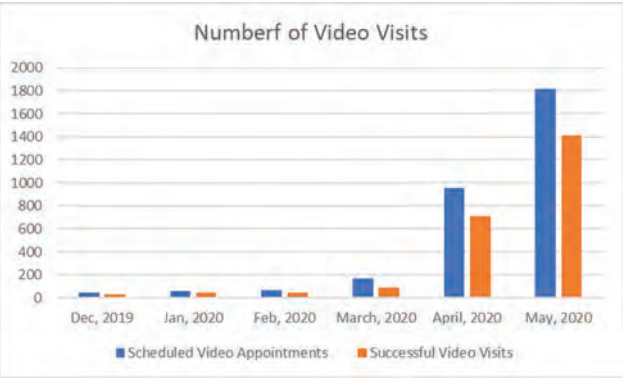
Sijie Zheng,[1,2] Ali Poyan-Mehr,[1] Leonid Pravoverov,[1] Sharina Belani.[1] *[1]The Permanente Medical Groups, Oakland, CA; [2]Kaiser Permanente, Oakland, CA.*

Background: The COVID-19 pandemic has presented health care system in the United States with unprecedented challenges. Kaiser Permanente Northern California is an integrated health care system with 4.5 million members, who are cared for by The Permanente Medical Group (TPMG), a multiple specialty medical group of 10,000 physicians. Utilizing coordinated care, sophisticated Electric Medical Record system. KPNC Nephrology service line has developed several strategies to mitigate the effect of COVID-19, including rapidly increased video visit appointments for members with CKD.

Methods: After the "Shelter in place" order in March 2020, KP nephrologists started weekly virtual townhall meetings to coordinate care among 85 nephrologists in 19 hospitals covering patients with chronic kidney disease, receiving dialysis, and post kidney transplant. TPMG nephrologists have developed guidelines on: 1. Tier testing for Person Under Investigation (PUI) members; 2. Management of patients with Glomerulonephritis; 3. Post-kidney transplant care; 4. Expand advance care planning; 5. Converting direct patient visits to video visits; 6. Coordinating care with contracted dialysis providers for members on outpatient dialysis.

Results: The video visits have increased 780% from March to April and 1968% from March to May of 2020 (Figure). The top three diagnosis for video visits were: CKD3, CKD4, and post kidney transplant. Since April 8, 2020, average 0.038% of Dialysis patients were tested positive for COVID-19 and average 1.6% are PUI.

Conclusions: As an integrated health care system, KPNC has developed a systematic, collaborative and rapid crisis management of patients with CKD in COVID era. Further studies are needed to evaluate the long-term outcomes of these approaches.



PO0854

Benefits of Telephonic Case Management: Increased Home Dialysis and Decreased Hospitalizations

Rahul Dhawan, Wade M. Bannister, Cindy Gong, Jiang Tao, Kevin Plosser. KRS Team *Optum Inc, Eden Prairie, MN.*

Background: Home dialysis has been noted to improve quality of life in patients receiving dialysis. Patients at risk for COVID-19 include those on dialysis. The pandemic has resulted in additional focus on social distancing and home dialysis offers this distinct advantage compared to in center hemodialysis. The ASN also similarly has supported advancing education around home dialysis, and COVID is being noted as a true catalyst to home dialysis care. Our study on a commerical poppulation analyzed cost of care with regards to home versus in center dialysis.

Methods: The KRS Case Management program identified and educated commerical patients with this case management benefit regarding the options for home versus in center hemodialysis. Patients were enrolled in the program and educated on the benefits of home dialysis, the benefits of permanent access, and the benefits of transplantation. Cost of care analysis was conduted using claims paid until February 2020, and variables studied included in-patient cost, skilled nursing facility cost, professional cost for dialysis service, facility cost for dialysis service, non dialysis outpatient cost and professional cost for physician visits. Patients were educated telephonically of the benefits of home dialysis and permanent access placment, and demographics including age and gender were also calculated.

Results: A total of 6692 members were analyzed. Of these patients 1793 members were attributed to home based dialysis. It as noted that when adjusting for per diseased member per month, there was a 62% decrease in cost of care for in-patient hospitalizations in the home dialysis group. In addition, there was a striking reduction of 247% in skilled nursing facility costs for the home dialysis group as well. After adjusting for all variables, there as a 5% cost savings in the home dialysis group as compared to in-center.

Conclusions: There are cost of care benefits to home dialysis. Further studies are needed to help identify barriers to home dialysis, and given the advent of COVID-19, it is important to consider home dialysis for all patients more now than ever before.

PO0855

Bridging Office-Based Care with the Virtual Practice Care Model: Evolving Care for CKD Patients in the COVID-19 Pandemic—and Beyond

Bingbin Zhao,[3] Lei Zhang,[3] Peili Ji,[3] Jianfeng Lin,[3] Jianfang Han,[1] Jiaying Li,[3] Zijuan Zhou,[3] Haiyun Wang,[3] Xia Hong,[4] Winfred W. Williams,[2] Limeng Chen.[3] *[1]Department of Nephrology, Qinghai Provincial People's Hospital, Xining, China; [2]Department of Nephrology, Massachusetts General Hospital, Boston, MA; [3]Department of Nephrology, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China; [4]Department of Psychological Medicine, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China.*

Background: Since the outbreak of the coronavirus epidemic, the "virtual" telemedicine has become a critical substitute for patient-provider interactions. However, virtual encounters often face challenges in care for high-risk patients such as chronic kidney disease (CKD) patients. In this study, we explore the patient's satisfaction and practical effects of a newly established telemedicine program in CKD patients' care during the pandemic.

Methods: We established an online CKD patient care program, including triage strategy, medical care delivery, and psychological support, based on a smartphone application. A total of 278 CKD patients were invited, at least 3 months before the pandemic or during the pandemic. A pilot survey interrogating medical and psychological

conditions was conducted. The feedback to the program and the psychological assessment repeated after one month.

Results: Totally, 181 patients showed active responses to the program, with 289 person-time medical consultations occurred during the study. The virtual care program provided a rapid triage, with 17% patients provided a timely referral to in-patient medical encounters. Nearly all patients (97.4%) believed the program was helpful. The number of symptoms (OR 1.309, 95%CI 1.113-1.541; *P*=0.001) and being enrolled during pandemic (OR 3.939, 95% CI 1.174-13.221; *P*=0.026) were associated with high stress. After the follow-up, the high-stress CKD group at baseline showed a significant decrease in avoidance score (6.9±4.7 vs. 9.8±1.9, *P*=0.015).

Conclusions: During the pandemic, we established an online telemedicine care program for CKD patients that provides a rapid triage function, effective CKD disease management, and essential psychological support.

PO0856

How the COVID-19 Pandemic Sparked Change: What Will Be the "New Normal" in Physician Practices and Patient Care?

Jennifer Robinson. Spherix Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: The COVID-19 pandemic and resulting social distancing and stay-at-home orders significantly impacted physician practices across the board. The objective of this study was to evaluate the COVID-19 impacts and responses across different specialists as they unfolded and to understand how the model of patient care delivery will change moving forward.

Methods: Survey data was collected weekly or bi-weekly between March 20th and May 8th, to provide rapid responses on the quickly evolving COVID-19 outbreak. Approximately 50 nephrologists participated in each each wave, along with 200 neurologists, dermatologists, rheumatologists and gastroenterologists.

Results: The impact of the COVID-19 outbreak on physician practices was swift and monumental, as of early April office visits were down more than 70% across specialties. As of early May, nephrologists remained one of the hardest hit groups and continued to report 85% fewer patients compared to a typical, pre-COVID week. Nephrology was somewhat buffered from overall declines due to their dialysis patient responsibilities. Not only did these significant drops in patient office visits impact patient access to medical care, physician practices also suffered drastic financial impacts. More than half of the specialists reported a "substantial" impact on the financial health of their practice by early May. Practices responded swiftly with telemedicine adoption, and by early April more than 90% of most specialties had adopted some telemedicine capabilities. By the final wave, 78% reported that the COVID-19 experience will have a lasting impact on how their practice operates from the way physicians interact and see patients to long-term staffing structure and variations in the way they interact with the pharmaceutical industry.

Conclusions: The delivery of patient care, which has remained largely unchanged for decades and relied primarily upon direct, in-person care, has had to evolve to meet the demands of a world in pandemic. As a result, significant changes have occurred with the adoption of telemedicine, and given physicians and patients a new way to interact. Additionally, as practices try to rebuild from significant lost revenues, staffing structures and typical in-office activities, such as meeting with pharmaceutical representatives, along with conference attendance, will likely never return to their pre-pandemic levels.

PO0857

Resource Utilization and Provision of In-Hospital Dialysis in an Academic Hospital in New Orleans During the COVID-19 Pandemic

Jason R. Ledoux, Kenneth Chauvin, Vernelle T. Mitchell, Juan Carlos Q. Velez. Ochsner Nephrology *Department of Nephrology, Ochsner Health System, New Orleans, LA.*

Background: COVID-19 has caused an ominous healthcare toll in the United States. New Orleans rated among the top affected cities. Acute kidney injury (AKI) requiring renal replacement therapy (RRT) affected 16% of COVID-19-related hospitalizations, resulting in an exponential upsurge in resource utilization related to RRT. We report our single center experience providing metrics of overall utilization and workforce expansion.

Methods: We conducted a prospective collection of data of daily census of hospitalized patients with COVID-19 and AKI or ESKD for 7 weeks (3/8-4/30, 2020) quantifying usage of RRT equipment and allocation of personnel. Two independent electronic health record databases were simultaneously used to track the data.

Results: Within 1 month, in-hospital COVID-19 census peaked at 377 patients, with 97 (26%) of them receiving RRT at peak day. Starting from a mean of 65 patients on RRT per day in pre-COVID-19 era, the estimated RRT growth peaked at 49%. Four out of 10 newly purchased Fresenius K2 SLED machines (FKs) were utilized by week 5 (after delivery, assembly and negative culture). Starting from an average 80% usage of baseline capacity (31 of 38 FKs), usage of 42 K2s at peak revealed 35% growth. Four new reverse osmosis devices were obtained (growth: 25 to 29, 16%) by week 5. For CVVHDF, 4 PrismaFlex machines (PFs) were rented and 10 new PrisMax were bought. Starting from an average 33% usage of baseline capacity (2 of 6 FKs), use of 6 PFs at peak meant 400% growth. Up to 30 nurses were trained virtually on RRT. Eight agency nurses and 6 perfusionists were recruited, to increase the operator number from 21 to 35 (67% growth). Five of 21 (24%) RRT nurses were out of work at peak due to COVID19+ status. One attending physician, 1 nurse practitioner and 2 subspecialty residents were added to the inpatient service, increasing the number of providers from 9 to 13 (44% growth).

Conclusions: The pandemic of COVID-19 resulted in substantial increase in in-hospital RRT demand and resource utilization. Our experience may provide other centers a guide to optimize preparedness in the event of facing a "second wave" of COVID-19 in the near future. Delay in implementation has to be accounted for during strategic planning.

PO0858

Telemedicine for Nephrology Outpatient Care in a Large Integrated Health System During the COVID-19 Pandemic

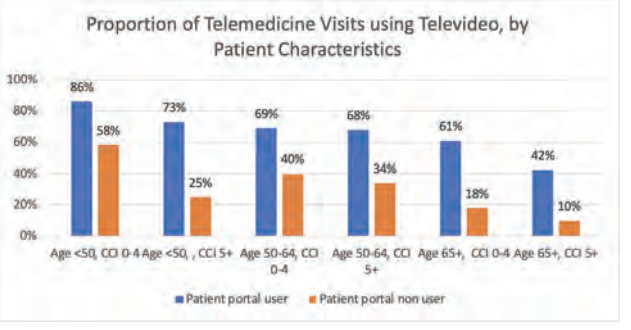
Waleed Zafar, Prince Mohan, Evan Norfolk, Jamie A. Green, Alex R. Chang. *Geisinger Health, Danville, PA.*

Background: The COVID-19 pandemic has necessitated increased use of telemedicine for outpatient care. Understanding factors impacting access to telemedicine is important to optimize care delivery during the pandemic.

Methods: We examined trends in telemedicine use during the COVID-19 pandemic using data from Geisinger, a large, integrated, predominantly rural health system in central and northeast Pennsylvania. We also examined the association between patient characteristics (age, sex, patient portal status, Charlson Comorbidity Index [CCI]) and use of televideo nephrology visits.

Results: From 3/15/20-5/29/20, nephrology was the top adult specialty using telemedicine at Geisinger in terms of proportion of office visits using telemedicine (televideo or telephone) with 1911 (94% of all outpatient visits). The proportion of nephrology visits using telemedicine increased rapidly from <1% pre-COVID-19 crisis to 21% (week of 3/15/20) to consistently ≥95% each week from (3/22/20-5/29/20). Visit completion rate during this time was 84% with 8% same-day cancellations and 8% no-shows/left prior to being seen. The majority of nephrology clinic patients were ≥65 years old (63%), had severe CCI score 5+ (70%), and had active patient portal status (65%). The proportion of telemedicine visits using televideo was 42% overall with large differences by age, CCI score, and patient portal status **(Figure)**. For example, the proportion of telemedicine visits using televideo was as low as 10% (65+ year old patients, CCI 5+, non-user of patient portal) and as high as 86% (<50 year old patients, CCI score 0-4, active patient portal users).

Conclusions: Telemedicine may serve an important role in providing nephrology care to elderly patients with many comorbidities who are particularly susceptible to ill effects from COVID-19. Patient portal users were much more likely to use televideo for telemedicine visits. Further investigation into the digital divide (e.g. broadband internet access) is needed to optimize care delivery during the COVID-19 crisis.



PO0859

Telemedicine Heightens Healthcare Disparities in Nephrology Ambulatory Care After COVID-19

Florence Lima, Jay Christian, Clay Larkin, Yahya R. Ahmad, Katherine M. Donaldson, Ashami Athukorala, Hana Kebede, Madison Ginn, Madhumathi Rao. *University of Kentucky Medical Center, Lexington, KY.*

Background: The COVID-19 pandemic paused in- person clinic visits and introduced telehealth (TH) creating a paradigm shift in ambulatory practice. TH remains out of reach for many patients, highlighting healthcare (HC) disparities.

Methods: We studied Nephrology ambulatory clinic schedules during the transition to TH (April 1 to May 15 2020) at the University of Kentucky (UK), Lexington KY. We estimated the proportion of patients who could perform TH visits, trends over time, compared TH use in Nephrology vs other clinics (cardiology, pulmonology, Infectious disease, women's health), evaluated causes for non-use, and studied the geographic variation of TH use/non-use across the regions served by the hospital.

Results: TH was successfully adopted by 43.5% of the clinic population, without significant change across weeks (wk) 1 to 5. Wk 6 increased when reimbursement was allowed for telephone visits (p<0.01) (Figure 1). The % of patients unable to do TH dipped from 72% in wk 1 and remained steady at ~56.5% thereafter. Lack of internet access and/or smart device was the most frequent reason. The Nephrology clinic trend did not differ from other clinics. By spatial analysis, TH non-use rates clustered in geographic areas of Eastern and Southern KY with the lowest socioeconomic indices (Figure 2).

Conclusions: The Nephrology clinic at UK, serves the Eastern half of KY, that includes poorer and largely rural regions. While TH provides a remarkably useful tool to reach patients, over 50% did not benefit, and use-rates reached saturation rapidly. TH further highlights HC disparities and the need to mitigate them.

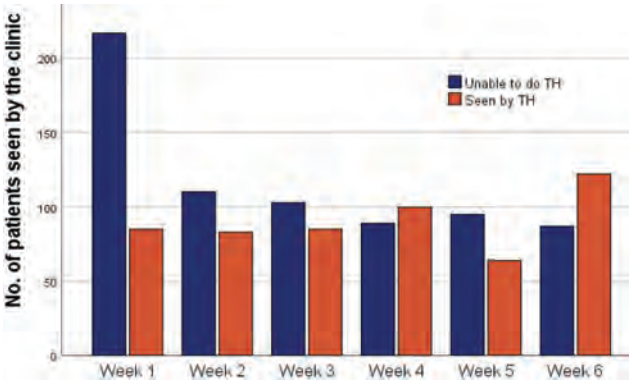


Figure 1: TH trend by week

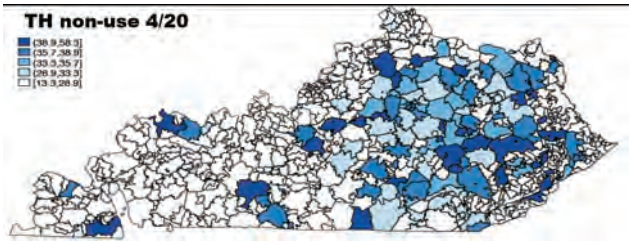

Figure 2: Distribution of TH non-use by zip-code

PO0860

Urgent Training with the Tablo Hemodialysis System in Response to COVID-19

Michael A. Aragon, Michelle L. Gilliland, Marc Maynard. *Outset Medical, Inc., San Jose, CA.*

Background: During the COVID-19 pandemic, many facilities experienced dialysis resource shortages of specialized dialysis staff, sterile dialysate, dialysis systems, and treatment locations. The Tablo® Hemodialysis System was deployed in numerous hospitals to help meet the increased need for dialysis delivery. Tablo is an all-in-one, easy-to-learn system indicated for clinic, hospital and home settings. Features include integrated water purification, on demand dialysate production, simplified user interface and two-way wireless connectivity. Tablo's clinical versatility and simplicity allow for broad prescribing and treatment location options. The objective is to report on Tablo training effectiveness during urgent deployment to facilities amidst the COVID-19 pandemic.

Methods: Standard training with Tablo (< 4 hours) was performed during the peak COVID months of March through May at 51 facilities. Information regarding nursing experience and current role was recorded. Nursing staff trained on Tablo in May completed an electronic survey post-training. Based on a Likert scale ranging from Strongly Agree to Strongly Disagree, respondents rated their satisfaction with training, system ease of use, and confidence performing dialysis independently post training.

Results: Of 926 clinicians trained, 854 were registered nurses (RNs). 136 RNs completed the survey and were representative of the entire group (49% vs 47% ICU, 35% vs 34% HD, 11% vs 16% Non ICU/Non HD). Responses of Strongly Agree or Agree are presented in Table 1 by experience and current role.

Conclusions: Nurses of varied experience and areas of focus trained on Tablo during the pandemic reported: high levels of satisfaction with training, the device was easy to use, and confidence in providing treatment to patients. The Tablo Hemodialysis System can allow training of existing staff to efficiently expand a facility's renal replacement capabilities.

Funding: Commercial Support - Outset Medical, Inc.

Table 1 - Tablo Training Survey Responses

RN	EXP	I am Satisfied with Tablo Training	I Found Tablo Easy to Learn and Use	I am confident Treating with Tablo Independently
HD	≤ 5yrs	100% (8/8)	100% (8/8)	100% (8/8)
	> 5yrs	100% (39/39)	97.4% (38/39)	82.1% (32/39)
ICU	≤ 5yrs	100% (24/24)	95.8% (23/24)	75% (18/24)
	> 5yrs	93% (40/43)	93% (40/43)	76.7% (33/43)
Neither	≤ 5yrs	100% (7/7)	100% (7/7)	100% (7/7)

PO0861

Use of Tablo Hemodialysis Systems to Extend Dialytic Capabilities for the COVID-19-Associated Surge of AKI

David S. Goldfarb,[1,3] Jessica M. Yan,[3] Matthew A. Gross,[3] Clay A. Block.[2] *[1]NYU Langone Health, New York, NY; [2]Dartmouth College Geisel School of Medicine, Hanover, NH; [3]VA New York Harbor Healthcare System, New York, NY, NY.*

Background: The COVID-19 pandemic was associated with a greater incidence of AKI than expected. At the NY Harbor VA we faced an overwhelming number of AKI patients who were critically ill with multi-organ failure. We needed to invoke new mechanisms of providing kidney replacement therapy (KRT).

Methods: We obtained 3 Tablo systems in late March, 2019. The machines have self-contained reverse osmosis capabilities and so do not require other equipment to operate. They can make dialysate from concentrate and tap water and so do not require special plumbing adaptation. Their self-contained step-by-step procedures are relatively simple to follow and allow rapid training of previously unskilled personnel. Tablo generates 300 ml dialysate per minute, and blood flow was increased to up to 400 ml/min as tolerated.

Results: Training was completed by 2 nephrologists and 2 RNs without previous dialysis experience. We used the Tablo Hemodialysis System to provide KRT to critically ill patients. In the first week we demonstrated that water cultures and endotoxin testing were negative, and that AAMI water tests were acceptable. We used the machines to provide KRT for ICU patients with double-lumen dialysis catheters. In addition we used the machines on hospital wards where KRT had not been provided before because of a lack of the plumbing needs of conventional HD machines. We provided multiple treatments 3-6 times per week for 15 AKI patients, mean age 65 years. The mean of the best urea reduction ratio achieved in the first 1-4 treatments, if available, was 41% (often limited by hypotension and fulfillment of ultrafiltration, UF, needs). Most treatments were successful and were slowed for hypotension or tachycardia. Some were aborted because of water pressure alarms if sediment filters needed replacement, or lines clotted due to hypercoagulability associated with COVID-19. Personnel availability dictated that most treatments were 3-4 hours (and up to 8h), and generally achieved UF goals. Later HD nurses cannulated arteriovenous fistulas in ESKD patients and left treatment to non-HD nurses to complete.

Conclusions: By incorporating a user-friendly platform and an accelerated training program including nephrologists and RNs without previous dialysis experience, we were able to nearly *double* our capacity to deliver KRT during the surge.

PO0862

The Introduction of Quanta SC+ to Critical Care for Haemodialysis During the COVID-19 Pandemic

Ian Rechner,[1] Ria D. Mcmullen,[1] Angela M. Clarke,[2] Bernice G. Boore,[2] Emma C. Vaux.[2] *[1]Royal Berkshire NHS Foundation Trust, Reading, United Kingdom; [2]Berkshire Kidney Unit, Royal Berkshire NHS Foundation Trust, Reading, United Kingdom.*

Background: Of 800 patients treated annually in 19 ICU beds (catchment 500,000) 120 require renal replacement therapy (RRT) delivered by Baxter Prismaflex® (continuous veno-veno haemodiafiltration (CVVHDF)). With the onset of the COVID19 pandemic significant increased incidence of acute kidney injury (AKI) requiring RRT & existing intermittent haemodialysis (IHD) patients contracting COVID19 requiring ICU support raised concerns regarding RRT ICU capacity. Additionally a worrying national shortage of CVVHF/HDF consumables & new machines to deliver this requirement; all critical drivers to seek local solutions for RRT provision beyond usual capability

Methods: A kidney unit neighbour described their successful experience trialling SC+ in home IHD patients. Translation of SC+ from home use to safe IHD treatment in ICU was quickly apparent alongside ease of supporting technical infrastructure set up & minimal training requirements. Immediate availability & fiscal acceptability of purchasing 4 Quanta SC+ and 2 supporting RO machines were critical determinants in making IHD a realistic & sustainable solution to desperate RRT shortages. Provision of expert technical support and clinical nurse specialist facilitation expedited training of ICU workforce & enabled swift implementation

Results: 27 ICU nurses were trained in 3 weeks (23 in 14 days). Between 22/4/20 & 17/5/20 8 patients (range 37-63 yrs, median 53.5; 7/8 known IHD, 1/8 AKI; 7/8 COVID19 positive) received 20 treatments (1-5/patient) using SC+ in ICU. An agreed ICU IHD protocol was co-designed gaining consensus in an unfamiliar territory of provision of IHD in ICU & differing clinical perspectives in IHD prescription in a critical care setting

Conclusions: At a time of unprecedented national shortage of dialysis machines & increased RRT need associated with COVID19, Quanta provided an effective solution for safe provision of IHD in ICU. Ease of use with training delivered in <6 hours enabled ICU nurses to effectively treat patients independent of dialysis nurses allowing continuity of the chronic HD programme. Learnings identified the importance of training, enabling rapid growth of a critical mass of expertise & confidence. Critical elements included mastering unfamiliar technique, establishing infrastructure, procurement & team communication enabled by online & face-to-face troubleshooting support

Funding: Commercial Support - Quanta Dialysis Technologies

PO0863

Design of PREVENT: A Phase 2 Study of the Effect of RBT-9 on Progression of COVID-19 Infection in High-Risk Individuals, Including Those with Advanced CKD

Stacey Ruiz,[1] Philip T. Lavin,[5] Donald J. Keyser,[1] Alvaro F. Guillem,[1] Richard A. Zager,[2,3] Bhupinder Singh.[4,1] *[1]Renibus Therapeutics, Southlake, TX; [2]Fred Hutchinson Cancer Research Center, Seattle, WA; [3]University of Washington Department of Medicine, Seattle, WA; [4]University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA; [5]Boston Biostatistics Research Foundation, Framingham, MA.*

Background: Coronavirus 2019 (COVID-19) has infected millions of people worldwide, with the US reporting the most deaths. Many individuals are at high risk of disease progression, which may result in multi-organ failure and death. Risk factors include advanced age, cardiovascular disease (CVD), and chronic kidney disease (CKD). In addition, more than 40% of hospitalized patients develop acute kidney injury (AKI), with 20% of those requiring dialysis. Several therapeutic agents are in development, but patients with advanced CKD or those requiring immunosuppressive therapy are frequently excluded from participation in clinical trials. RBT-9, a proprietary formulation of stannous protoporphyrin, has organ protective effects, as demonstrated in animal models of kidney, liver, and lung injury. RBT-9 also has antiviral effects, as demonstrated in several enveloped viruses, including influenza, HCV, dengue, and yellow fever. A Phase 2, randomized, placebo-controlled study was designed to evaluate the effect of RBT-9 on progression of COVID-19 infection in high-risk individuals.

Methods: This study will enroll up to 252 subjects with documented SARS-CoV-2 infection who are at risk of progression based on age (≥70 years) or comorbidities, including CKD (all stages, not on dialysis), CVD, chronic lung disease, diabetes mellitus, obesity, and mild hypoxemia. Subjects will be randomized 2:1 to receive a single dose of RBT-9 or placebo and will be followed for 56 days.

Results: Study Objectives The primary objective is to evaluate the effect of RBT-9 versus placebo on clinical status measured using the 8-point World Health Organization (WHO) Ordinal Clinical Scale at Day 28. Secondary objectives include time to first occurrence of death from any cause or new/worsened organ dysfunction, survival, AKI incidence, new or worsening heart failure, hospitalization status and duration, ICU status, days on ventilator, vasopressor utilization or ventricular arrythmias.

Conclusions: The organ protective and antiviral effects of RBT-9 warrant conduct of this clinical study, which is aimed at preventing progression to severe COVID-19 and organ failure. The first patient is expected to be enrolled in June 2020.

Funding: Commercial Support - Renibus Therapeutics

PO0864

The COVID-19 Infodemic

Tejas Desai,[1] Arvind Conjeevaram.[2] *[1]NOD Analytics, Harrisburg, NC; [2]The Bangalore Hospital, Bangalore, India.*

Background: In Situation Report #13 by the World Health Organization and 39 days before declaring COVID-19 a pandemic, the WHO declared a "COVID-19 infodemic". The volume of coronavirus tweets was far too great for one to find accurate or reliable information. Healthcare workers were flooded with "noise" which drowned the "signal" of valuable COVID-19 information. To combat the infodemic, physicians created healthcare-specific micro-communities to share scientific information with other providers.

Methods: We analyzed the content of six physician-created communities and categorized each message in one of five domains (Symptoms, Diagnostics, Therapeutics, Prevention, Pathophysiology). We programmed 1) an application programming interface to download tweets and their metadata in JavaScript Object Notation beginning 11 March and 2) a reading algorithm using visual basic application in Excel to categorize the content. We superimposed the publication date of each tweet into a timeline of pandemic events. Finally, TD created a free repository of the dataset in the #NephTwitter Archives (https://bit.ly/2M6HJQ2) to help healthcare workers find quality information when treating patients.

Results: From 11 March to 27 April, 45% of the 19270 tweets in the dataset were categorized (signal). Tweets about Therapeutics (34%) and Prevention (32%) were the most prevalent. Tweets about Therapeutics spiked six times; the first coming 4 days after the WHO declared COVID-19 a pandemic. The largest spike came on day 8: 5 days after the US President suggested hydroxychloroquine as a potential treatment. Tweets about antimalarial therapy comprised 15% of tweets in this category. Tweets about Prevention spiked five times; the largest coming 21 days after the pandemic declaration when 1 million global cases were reported. Protective equipment comprised 13% of tweets in this category. There were 2210 searches performed of the signal tweets in the #NephTwitter Archives. Evidence-based tweets comprised 1 in every 8 tweets in the categorized corpus. That ratio was better for tweets about antimalarials (1 in 3) and vaccines (2 in 3), the same for protective equipment, and worse for mechanical ventilation (1 in 31).

Conclusions: Algorithmic coding can 1) mitigate the COVID-19 infodemic and 2) identify & elevate illuminating evidence-based tweets. Both outcomes help healthcare workers find higher-quality information to combat the pandemic.

PO0865

The Impact of the COVID-19 Pandemic on the Mental Health of Health Workers Treating Patients with Kidney Diseases in Latin America (LA): Analysis from GlomCon Latin America Working Group (LGlomCon)

Sonia Rodriguez Ramirez,[1] Franco H. Cabeza Rivera,[2] Julio A. Gutierrez-Prieto,[3] Javier Soto-Vargas,[4] Blanca Martinez-Chagolla,[5] Denisse Arellano-Mendez,[6] Diana Aguirre,[7] Desiree Garcia Anton,[2] Carmen Avila-Casado.[1] GlomCon Latin America Working Group (LGlomCon) *[1]University Health Network, Toronto, ON, Canada; [2]University of Mississippi Medical Center, Jackson, MS; [3]Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; [4]Hospital General Regional 46, Guadalajara, Mexico; [5]Hospital General "Dr. Miguel Silva", Morelia, Mexico; [6]Unidad Medica de Atencion Ambulatoria 254, Morelia, Mexico; [7]Hospital General de Mexicali, Mexicali, Mexico.*

Background: The rapid spread of the COVID-19 pandemic into LA countries where health systems were already facing major limitations might further challenge their physician's emotional and mental wellbeing. We aimed to describe the perception of health workers managing kidney diseases in the context of the COVID-19 pandemic.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists, and other health workers treating kidney diseases between May 20-27, 2020 from sixteen Spanish speaking Latin American countries divided into 6 categories. We present the results for the mental health category.

Results: 430 responses were obtained of which 360 (84%) were considered for analysis. The participants were mainly nephrologists 276 (86%), renal pathologists 13 (4%), and physicians in training 11 (3%). Ages ranged between 30-49 years old in 271 (75%), mostly working on tertiary centers 258 (71%). 329 (90%) participated in inpatient care. 277 (86%) considered that the COVID-19 pandemic has impacted their mental health. Prevailing symptoms were anxiety, insomnia, and depression, with 75.2%, 42.5%, and 18.2%, respectively. Physical or verbal violence from the community was reported by 18 (5%) of the participants because they were seen as a source of viral transmission. 179 (55%) considered personal protective equipment (PPE) was sufficiently provided and 275 (79%) had to invest up to 20% of their income to obtain PPE. In addition, 144 (44%) of the respondents reported a shortage of COVID-19 tests and only 99 (30%) felt their hospital was well equipped to care for COVID-19 patients. 126 (39%) of the health workers responded that they received adequate training, while 105 (32%) endorsed they did not feel prepared in the management of patients with COVID-19.

Conclusions: This survey reveals the considerable impact that the COVID-19 pandemic is generating among physicians treating patients with kidney diseases in LA. Possible aggravating factors also found in our survey included lack of testing, PPE availability, and overall hospital preparedness.

Funding: Private Foundation Support

PO0866

Developing a COVID-19 Screening Program for an Emergency-Only Dialysis Cohort Within a Large Public Safety-Net Hospital

Ravi D. Bhatia,[1,2] Lauren Kasper,[1,2] Sarah A. Johnson.[1,2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Grady Health System, Atlanta, GA.*

Background: As the prevalence of coronavirus disease 2019 (COVID-19) worsens, one patient population that warrants further inquiry are those receiving emergency-only hemodialysis (EoHD). This cohort specifically at Grady Health System (GHS) in Atlanta, consisting largely of undocumented immigrants, receives 1-3 times weekly hemodialysis (HD) via emergency departments due to legislative restrictions on Medicaid funding. GHS has one of the largest populations of EoHD patients in the nation. The cohort of 91 patients is 89% Hispanic with a mean age of 51. The majority of patients, 69%, reside in Fulton or DeKalb counties, the intended service region for GHS. The remaining patients reside in more distant counties, potentially increasing risk of transmission to a larger area. Prior to our screening program, 6 patients in the cohort had positive diagnostic tests and 4 of these patients required hospitalization (67%). Notably, 3 out of those 4 patients were admitted due to hypertensive emergency with pulmonary edema, so symptomatic COVID disease is debatable. Due to the frequency of hospital visits and requirement of isolation HD treatments if COVID+, a screening of the cohort was conducted. Our aim was to establish a baseline prevalence rate to direct an ongoing screening program in this vulnerable population.

Methods: Over 5 days, we conducted 84 COVID PCR screening tests via nasopharyngeal swab. One patient was excluded due to missed sessions. Patients were asked about symptoms prior to swabs. Swabs were obtained by a single operator in a consistent fashion. Data was collected and stratified by patient demographics.

Results: A total of 84 patients were screened for COVID. Notably, 3 asymptomatic patients had positive results, a rate of 3.6%, and 6 patients had positive diagnostic tests prior to screening, resulting in a rate of 9.9% positive COVID tests. 6 patients were DeKalb/Fulton residents (67%).

Conclusions: The risk of COVID-19 in EoHD patients is an issue that will require a coordinated effort to prevent the spread of disease. A collaboration between nephrology and infectious diseases has led to the implementation of a bimonthly screening program. Future directions include antibody screens and contact-tracing to understand more fully the spread of disease as well as elucidating the asymptomatic positive rate vs. actual disease prevalence.

PO0867

SARS CoV-2 Continuous Quality Improvement Program: Initiation of a Standardized Protocol for AKI Prevention

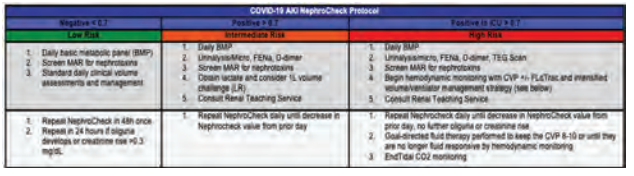
Adam Dossaji, Asad H. Khan, Spencer Hodgins, Daniel L. Landry, Daniel Engelman, Jonathan Slater, Bill Mcgee, Michael J. Germain. *Baystate Medical Center, Springfield, MA*.

Background: During the initial phase of the SARS CoV-2 pandemic our institution had high rates of acute kidney injury (AKI) requiring renal replacement therapy (RRT). Nephrocheck (NC), a renal biomarker, indicating renal stress was the basis of a continuous quality improvement (CQI) program to identify patients at risk for AKI & RRT.

Methods: Patients admitted from 4/17-5/15/2020 were all tested for SARS CoV-2. All positive patients ≥ 18 years old & with a creatinine <2.0 mg were tested with NC. Values ≥ 0.7 led to nephrology consults & utilization of a renal-protective strategy including monitoring volume status, scrutinizing nephrotoxic medications & urine studies. A "Plan-Do-Study-Act" approach was used to increase utilization of NC and the resulting protocol for positive results. Intervention was biphasic with a follow up maintenance phase, each lasting 10 days. Phase 1 was adding NC to the SARS CoV2 admission order set & Phase 2 was educating hospitalist providers about using and interpreting NC to increase appropriate nephrology consults. Education was reinforced with protocol cards & reminders via encrypted text services. Additionally, intervention team members reviewed charts daily & reminded providers in real time.

Results: In Phase 1, 58% of the SARS CoV-2 positive patients had a NC but only 48% of NC positive patients had a renal consult. In Phase 2, 79% of SARS CoV-2 positive patients had a NC with 80% of positive patients getting a renal consult. In the maintenance phase, 67% of SARS CoV-2 positive patients had NC with 59% of NC positive patients getting a renal consult.

Conclusions: During our CQI project, efforts to mitigate severe AKI by using a biomarker-based alert for nephrology consultation saw the number of SARS CoV2 positive patients screened with NC & the number of positive NC patients seen by nephrologists rise significantly. Barriers to implementation included the weekly turn-over of house staff & a reliable alert system to ensure adequate screening. The multidisciplinary team reviewing charts and reminding hospitalists of the protocol also helped significantly but was difficult to sustain.



COVID-19 AKI NephroCheck Protocol

Negative < 0.7	Positive > 0.7	Positive in ICU > 0.7
Low Risk	Intermediate Risk	High Risk
1. Daily basic metabolic panel (BMP) 2. Screen MAR for nephrotoxins 3. Standard daily clinical volume assessments and management	1. Daily BMP 2. Urinalysis/Micro, FENa, D-dimer 3. Screen MAR for nephrotoxins 4. Obtain lactate and consider 1L volume challenge (LR) 5. Consult Renal Teaching Service	1. Daily BMP 2. Urinalysis/micro, FENa, D-dimer, TEG Scan 3. Screen MAR for nephrotoxins 4. Begin hemodynamic monitoring with CVP +/- FLoTrac and intensified volume/ventilator management strategy (see below) 5. Consult Renal Teaching Service
1. Repeat NephroCheck in 48h once 2. Repeat in 24 hours if oliguria develops or creatinine rise >0.3 mg/dL	1. Repeat NephroCheck daily until decrease in Nephrocheck value from prior day	1. Repeat Nephrocheck daily until decrease in NephroCheck value from prior day, no further oliguria or creatinine rise 2. Goal-directed fluid therapy performed to keep the CVP 8-10 or until they are no longer fluid responsive by hemodynamic monitoring 3. EndTidal CO2 monitoring

PO0868

Renal Critical Care Project Management of COVID-19 Pandemic Surge

Richard L. Barnett, Steven Fishbane, Mark A. Finger. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: The COVID-19 surge for the NY area severely stretched hospitall resources as critical care areas expanded 2-3 fold. In addition to well chronicled ventilator management of respiratory failure, 37% sustained some degree of AKI with many requiring continuous renal replacement therapy (CRRT). The challenge of providing optimal renal critical care given unprecedented demand was met with a defined project plan which required close integration of physician, nursing, pharmacy and materials management resources over multiple hospital sites

Methods: The Renal Critical Care Project Management Team (T) initially met on 3/11 and identified likely shortfalls in the quantity of Baxter Prisma machines for Long Island Jewish and contiguous Cohen Children's Hospital (LIJ 7), Southside Hospital(SSH 3) and NorthShore University Hospital (NSUH 18). 10 PrisMax and an additional 5 Prismaflex were delivered to NSUH and redeployed as required. Alternative CRRT fluid supplies were defined as T precluded acute PD. Spot shortages of machines, fluids and filter sets by 3/26 finalized the creation of multisite T with project manager selected from Central Procurement. Detailed communication plan kept all components and sites informed of daily changes.

Results: During the Pandemic Peak 4/3-5/1 T met daily. From 445-845 am Director of Renal Critical Care examined the electronic records from 74-92 COVID+ patients receiving CRRT, HD OR deemed likely to require RRT in the near future, and reviewed with each renal provider. At 9am T examined supplies of machines, fluids and filter sets, requiring daily shift of resources among each site 4/3-4/24. Machines were redeployed SSH(6), LIJ(13) and NSUH(24) with 36 peak total daily usage. Each patient averaged 13 five L/bags fluid daily which could be reduced by SCUF or other methods. Pre COVID filter life of 22 hours declined by half in these hypercoagulable patients only partially offset by step wise anticoagulation strategy. Fluid supplies during these 3 weeks averaged 1-2 days with low 0.25 on 4/22. A SLED program was initiated 4/21. FIVE day fluid and filter supplies were delivered 4/24.

Conclusions: The magnitude of the COVID-19 surge required tight project management to ensure adequate renal critical care. The ability to shift resources among multiple sites using CRRT was a major key to success. This integrated approach may have application for future pandemic surges.

PO0869

Electrolyte Abnormalities in Hospitalized Patients with COVID-19

Diane Liu,[1] Molly Fisher,[2] Abby M. Basalely,[1] Neelja D. Kumar,[2] Jyotsana Thakkar,[2] Ladan Golestaneh,[2] Kimberly J. Reidy,[1] Wei Chen.[2] *[1]Children's Hospital at Montefiore, Bronx, NY; [2]Montefiore Medical Center, Bronx, NY.*

Background: Electrolyte abnormalities have been observed in hospitalized patients with COVID-19. Whether the prevalence of electrolyte disturbances differ between hospitalized patients with and without COVID-19 is unknown.

Methods: We performed a retrospective observational study of adult patients hospitalized in a large tertiary healthcare system in the Bronx between March 11-April 26, 2020. We compared the prevalence of the disturbances in sodium, potassium, calcium and magnesium between patients with and without COVID-19 using Chi-square. Electrolyte disturbances were defined as the following: hypernatremia (>145 mEq/L), hyponatremia (<135 mEq/L), hyperkalemia (>5 mmol/L), hypokalemia (<3.5 mmol/L), hypermagnesemia (>2.5 mEq/L), hypomagnesemia (<1.5 mEq/L), hypocalcemia (<8.5 mg/dL) and hypoalbuminemia (<3.5 g/dL).

Results: Of 4579 patients, 51.8% were male. Median age was 65 years, IQR (52-76). 3313 (72.3%) were positive for the COVID-19. Hypernatremia, hyponatremia, hyperkalemia, hypermagnesemia, hypocalcemia, and hypoalbuminemia were significantly more common in hospitalized patients with COVID-19 (p<0.0001).

Conclusions: Dysnatremias, hyperkalemia, and hypermagnesemia were more common in patients with COVID-19. Hypocalcemia was more common in patients with COVID-19 but this may be due to a higher prevalence of hypoalbuminemia. Further studies are needed looking at adjusted models to describe the association between electrolyte abnormalities and clinical outcomes.

PO0870

Quality Improvement Project: Examining Urine Sediment and Microscopic Findings in COVID-19 AKI Patients

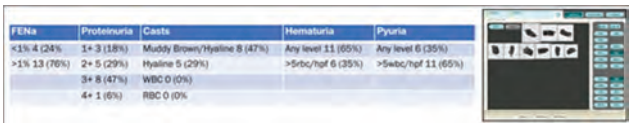
Abdulhadi T. Gelaidan, Ajai S. Rajabalan, Janice P. Lea, Jose E. Navarrete, Jason Cobb. *Emory University School of Medicine, Atlanta, GA.*

Background: The examination of the urine microscopy manually is common in the work-up of AKI. SARS-CoV-2 has been detected in urine samples of infected patients. There have been safety concerns about the handling of urine samples in patient under investigation and COVID-19 confirmed cases. Limitations in personal protective equipment have provided challenges. There has been limited reports of urine microscopic findings during the COVID-19 pandemic. We developed a QI project examining the urine sediment of COVID-19 AKI patients from digital pictures provided by the IRIS IQ200 Microscopy System.

Methods: This QI project took place at Emory University Hospital Midtown. We retrospectively evaluated baseline characteristics, labs, and urine volume. The urinalysis and urine sediment were evaluated for each patient by digital images produced by the IRIS IQ200 Microscopy System.

Results: A total of 17 African American patients with a mean age of 71±12.5 years (range, 55 to 98); 64.7 % were female. Comorbidities included hypertension (94.1%), diabetes (58.8%), CAD (11.9%) and CKD (52.9%). Average serum creatinine was 3.1 mg/dL. 8 patients (47%) were oliguric; 4 patients had FENa < 1%. 8 patients (47%) had 2+ proteinuria. 9 patients (52.9%) had a positive leukocyte esterase and all were nitrate negative. 8 patients (47%) had ATN with visible muddy brown casts. 6 patients (35%) had ≥ 5 rbc/hpf and 11 patients (65%) had ≥ 5 wbc/hpf. 8 patients (47%) had shock requiring vasopressor support, 8 patients (47%) required dialysis and 13 patients (76.5%) required mechanical ventilation.

Conclusions: Urinalysis and urine microscopy are important in evaluation of AKI, and there is a paucity of data about findings in COVID-19 AKI patients. Without conclusive evidence of the infective potential of urine samples, it is much needed at this time to device a safe alternative to manual urine microscopic examination. Almost half of our patients had ATN and we were able to arrive at the diagnosis using digital images from this automated urine microscopy system. Use of such technology will help nephrologists safely examine urine sediments and minimize exposure to COVID-19.



FENa	Proteinuria	Casts	Hematuria	Pyuria
<1% 4 (24%	1+ 3 (18%)	Muddy Brown/Hyaline 8 (47%)	Any level 11 (65%)	Any level 6 (35%)
>1% 13 (76%)	2+ 5 (29%)	Hyaline 5 (29%)	>5rbc/hpf 6 (35%)	>5wbc/hpf 11 (65%)
	3+ 8 (47%)	WBC 0 (0%)		
	4+ 1 (6%)	RBC 0 (0%		

PO0871

Clinical Relevance of AKI Trial Data for Severe COVID-19 Patients

Rita N. Barcia, Brian O'Rourke, Sunny H. Nguyen, Arno W. Tilles, Payal Garg, Christopher V. Gemmiti, Brian Miller. Sentien Biotechnologies *Sentien Biotechnologies, Lexington, MA.*

Background: Coronavirus disease 19 (COVID-19), caused by SARS-CoV-2 was declared a pandemic in March 2020 and remains without any approved treatments. After entering the cells, the virus begins to replicate and viral antigen is presented to antigen presenting cells (APCs), the cells that stimulate the body's normal anti-viral immune response. In severe cases however, this immune reaction becomes dysregulated as evidence by high levels of certain cytokines and chemokines in the blood, a reaction known as cytokine storm. This results in a systemic uncontrolled inflammatory state that triggers a violent attack by the immune system to the body, causes acute respiratory distress syndrome (ARDS) and multiple organ failure, leading to death.

Methods: Mesenchymal stromal cells (MSCs) are a unique source of secreted factors that modulate an inflammatory response and enhance the repair of injured tissue. MSCs have been extensively studied in ARDS and other acute organ injuries. Sentien has created a novel delivery approach to enable sustained exposure to MSCs and their secreted factors, overcoming limits of cell transplantation/infusion while preserving their broad acting and dynamically responsive properties. Our lead product, SBI-101, contains allogeneic human MSCs inoculated into a hollow-fiber hemofilter, which enables communication with patient blood via the semi-permeable membrane, while maintaining MSC viability. Through this interplay, SBI-101 aims to restore balance to the immune system by reprogramming the molecular and cellular components of blood in patients with severe inflammation and organ injury.

Results: Sentien's Phase I/II clinical study of SBI-101 in critically ill patients with Dialysis-Requiring Acute Kidney Injury (AKI-D) has produced data to support the therapeutic hypothesis of SBI-101. Consistent with MSC biology, inflammatory markers, such TNFa and IFNg, were shown to be modulated, suggestive of a shift from a pro- to an anti- inflammatory state in treated patients.

Conclusions: Data obtained in our AKI-D trial showed modulation of many biological molecules and immune populations that may be correlated with severe COVID-19 immunopathology. Here we make the case, using our existing AKI-D trial data, that SBI-101 may be of therapeutic benefit to severe cases of COVID-19.

PO0872

Point-of-Care Ultrasound Findings in Patients with COVID-19 and AKI

Forrest F. Lindsay-McGinn, Vishnu S. Potluri, Sadichhya Lohani, Claire A. Centeno, Jennifer Morganroth, Christy Moore, Felipe Teran, Nathaniel C. Reisinger. *University of Pennsylvania, Philadelphia, PA.*

Background: More than one third of patients presenting with COVID-19 in the United States develop acute kidney injury (AKI) and many require dialysis. AKI portends a poor prognosis particularly if dialysis is required. Point-of-care ultrasound (POCUS) is a valuable tool for the evaluation of AKI particularly for assessment of volume status. Here we describe clinical and ultrasonographic characteristics of COVID-19 patients with AKI.

Methods: This cohort includes prospectively enrolled adult patients with confirmed COVID-19 who developed AKI as part of their hospital encounter in April and May of 2020. Ultrasounds were performed using a published 12-point lung and limited 5-view cardiac protocol. The diagnosis of AKI was determined by a nephrologist. The institutional review board at the University of Pennsylvania approved this study.

Results: 33 patients were included. 79% were African-American. 56% were female. Median age was 65 and average BMI 30±9. 29% had CKD, 47% had diabetes, 68% had hypertension and 24% had heart failure. 12 experienced stage 1 AKI, 4 had stage 2 AKI, 17 had stage 3 AKI, and 10 required dialysis. 16 patients (52%) had a diagnosis of acute tubular injury. 18 (53%) had significant proteinuria, 24 (71%) had hematuria, and 20 (59%) had pyuria. 73% required ICU admission, 15 were discharged and 5 died. 25 of 33 had a left ventricular ejection fraction (EF) assessment, 22 had an EF >55%, 4 had an EF 30-55% and 1 had an EF <30%. 23 had an assessment of their inferior vena cava (IVC). 8 had a normal IVC, while 6 had a full, non-collapsing IVC and 9 had a flat IVC. 5 had pericardial effusion. 2 had right-ventricular dysfunction. The lung US assessments included an average of 10 of the 12 specified zones, favoring the anterior zones. An average of 3.8 zones per scan showed scattered b-lines, 3.1 zones showed confluent b-lines and 1.0 zone showed consolidations. 3 patients had pleural effusion.

Conclusions: Our study describes cardiac and lung US findings in patients who experience AKI during their COVID-19 course. Most patients had multifocal b-line findings. Most had normal ejection fractions but there was wide variation in IVC distension. More studies are needed to determine if ultrasound can guide fluid management or identify reversible causes of AKI.

PO0873

Constitutive Activation of Hedgehog Signaling Disrupts Nephrogenic and Stromal Differentiation

Robert D'Cruz,[1,2] Yun-Kyo Kim,[1,2] Jaap Mulder,[1] Norman D. Rosenblum.[1,2] *[1]Hospital for Sick Children, Toronto, ON, Canada; [2]U Toronto, Toronto, ON, Canada.*

Background: Nephron progenitors (NPs) and stromal cells differentiate from a common *Osr1+* progenitor. While maldifferentiation of nephrogenic and stromal tissue is a hallmark feature of renal dysplasia, signaling mechanisms regulating the genesis of stroma relative to NPs are largely undefined. We have shown that increased Hedgehog (Hh) signaling in murine *Osr1+* cells *in vivo* causes urinary tract obstruction through abnormal stromal cell localization (Sheybani-Deloui et al., 2018). Here, we investigated mechanisms that function downstream of Hh to control NP and stromal cell differentiation using human induced pluripotent stem cell (hiPSC) kidney organoids and genetic mouse models.

Methods: Agonists of the Hh receptor, SMO, were added to hiPSCs differentiated into kidney organoids at the stage of cell aggregation. Mature organoids were analyzed by histology, light sheet fluorescence microscopy, and RNA microarray. Processes downstream of Hh signaling were investigated in mouse kidneys with deficiency of *Ptch1* specific to FOXD1(+) stromal cells (*FoxD1Cre;Ptch1*$^{loxP/-}$) using histology, RNAseq, and scRNAseq.

Results: Stimulation of Hh activity in kidney organoids with SAG (120 nM) or Purmorphamine (10 μM) resulted in a 26% increase in surface area compared to controls. Volumetric analysis using light sheet fluorescent imaging of WT1+ nephrogenic structures and CDH1+ tubular structures in SAG-treated organoids demonstrated an 88% (n=3, $p<0.01$) and 67% (n=3, $p<0.05$) reduction, respectively. In contrast, the mass of non-epithelial cells was increased by 79% (n=2, $p<0.05$). RNA microarray analysis of SAG-treated organoids (n=3) revealed elevated expression of medullary stromal markers *TnC* (2.60 fold-change [FC], $p<0.01$) and *Pdgfrb* (1.60 FC, $p<0.01$), and decreased expression of nephron markers *Nphs1* (0.23 FC, $p<0.01$), *Slc3a1* (0.32 FC, $p<0.01$), and *Slc12a1* (0.08 FC, $p<0.001$). Mice with constitutive Hh activity in FOXD1+ stromal cells showed a 41% reduction in nephrons at E18.5 (n=4, $p<0.05$) and a 19.5% decrease in nephron intermediate structures at E15.5 (n=4, $p<0.01$). In contrast, RNAseq of E13.5 mutant kidney tissue demonstrated increased expression of medullary stroma genes *TnC* and *Pdgfrb*.

Conclusions: Increased Hh signaling in human and mouse increases differentiation of stroma compared to NPs, providing new insights into mechanisms that may underlie kidney dysplasia.

PO0874

Caspase Inhibition in a Mouse Model of Prenatal Ureteropelvic Obstruction Rescues Normal Ureter Development

Ross Villiger, Malia H. Harrison-Chau, Michael Ortega, Ben Fogelgren. *University of Hawaii at Manoa, Honolulu, HI.*

Background: The most common cause of congenital obstructive nephropathy is ureteropelvic junction obstruction (UPJO). We previously described a unique mouse model of *in utero* UPJOs through urothelial knockout of Exoc5, a central subunit of the exocyst trafficking complex. In this neonatal-lethal model, UPJO formation is preceded by urothelial cell death in the ureter between E16.5 and E17.5. Here, we investigated if normal ureter development could be restored in this mouse model by blocking cell death pathways, and conversely, if we could induce UPJOs by simply activating urothelial cell death during ureter development.

Methods: We utilized the Cre-lox system to achieve either targeted gene knockout or activation during mouse embryonic development. For inhibition of cell death pathways in Exoc5$^{FL/FL}$;Ksp-Cre ureters, we performed IP injections of caspase inhibitors into pregnant mice at gestational day E16.5. Also, diphtheria toxin A (DTA) mice crossed with Ksp-Cre^{ERT2} mice were used to investigate the effect of inducing urothelial cell death with tamoxifen administration at E16.5.

Results: Morphologically, dying Exoc5-KO urothelial cells appeared more necrotic than apoptotic, and they were negative for cleaved PARP and active caspase-3. However, a single IP injection of pan-caspase inhibitor z-VAD-FMK at E16.5 rescued ureter development in all Exoc5$^{FL/FL}$;Ksp-Cre mice analyzed. At E18.5, all z-VAD-FMK treated embryos displayed patent ureters with no hydronephrosis (n=9 from multiple litters). If followed past birth, z-VAD-FMK treated Exoc5$^{FL/FL}$;Ksp-Cre mice survived to adulthood. Interestingly, caspase-1 inhibitor Ac-YVAD-cmk also rescued ureter development when injected at E16.5, supporting the hypothesis that a non-apoptotic pathway is responsible for urothelial cell death in this mouse model. Conversely, DTA-induced urothelial cell death in E16.5 ureters showed evidence of UPJO formation by E18.5.

Conclusions: Based on these findings, we have shown that urothelial cell death is a critical event leading to UPJO pathogenesis and lethality in our mouse model. The data suggest inflammasome-associated caspase-1 may play a role in activating cell death in urothelial cells with disrupted exocyst trafficking.

PO0875

Exocyst Inactivation in Urothelial Cells Disrupts Autophagy and Upregulates the Fibroblast Growth Factor-Inducible 14 (Fn14) Receptor

Michael Ortega, Ross Villiger, Malia H. Harrison-Chau, Suzanna K. Lieu, Kadee-Kalia Tamashiro, Amanda J. Lee, Geetika Y. Patwardhan, Ben Fogelgren. *University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI.*

Background: Despite their prevalence, the etiology of congenital ureter obstructions in infants is poorly understood, with little evidence identifying genetic or environmental causes. We previously reported a unique mouse model of *in utero* ureteropelvic junction obstruction (UPJO) in which ureter urothelial cells with deleted Exoc5 gene failed to differentiate into a stratified epithelium and underwent cell death. This resulted in bilateral UPJOs, hydronephrosis, and neonatal lethality. Here, we investigated the urothelial cells prior to cell death to identify the disrupted cell processes necessary for urothelial differentiation and ureter development.

Methods: Gene expression profiling was performed on E16.5 ureters of $Exoc5^{FL/FL}$;Ksp-Cre mice and control littermates, with validation using real time qPCR and immunohistochemistry. Follow up investigations utilized an *ex vivo* ureter explant organ culture model, where mouse embryonic ureters were isolated at E15.5 and maintained in culture for 72 hours. Additionally, we used primary human urothelial cells (pHUCs) and immortalized SV-HUC1 cells for advanced studies on exocyst regulation of autophagy, which was measured through immunoblotting and immunostaining of p62, LC3I/II, and autophagy-related genes (ATGs).

Results: Analysis of gene profiling data from E16.5 $Exoc5^{FL/FL}$;Ksp-Cre ureters revealed that metabolic pathways were significantly downregulated and NF-kB signaling was significantly upregulated, indicating cell stress. The highest upregulated gene was Fn14 (>30-fold), a member of the TNF receptor subfamily that binds the ligand TWEAK. Fn14 is upregulated in damaged tissues and can activate non-canonical NF-kB signaling and cell death via multiple pathways. Using ureter explants and cell line models, we found exocyst is critical for urothelial autophagy, which when disrupted, led to a high Fn14 increase and cell death.

Conclusions: From our data, we propose that autophagy is necessary for urothelial differentiation during ureter development, and irregular autophagy may trigger urothelial cell death through Fn14 signaling. This disruption of autophagy during a critical stage in ureter development may contribute to UPJOs in humans.

PO0876

Transcription Factor 21 Regulates Nephron Progenitor Cells Self-Renewal/Induction and Podocyte Development

Gal Finer,[1] Tomoko Hayashida,[1] Tomokazu Souma,[2] Xiangmin Zhao,[1] Xiaoyan Liang,[1] Tuncer Onay,[1] Yoshiro Maezawa,[3] Susan E. Quaggin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Duke University, Durham, NC; [3]Chiba-ken, Chiba, Japan.*

Background: Most forms of CAKUT arise from mutations in genes of kidney development. We previously showed that Transcription Factor 21 (Tcf21) regulates branching morphogenesis by downregulating GDNF. We now aim to study Tcf21 in nephron progenitor cells (NPC). During nephrogenesis, WNT9b signals to NPC through the canonical Wnt/β-catenin pathway, which promotes both self-renewal at a state of low β-catenin level, and induction at a state of high β-catenin. Following induction, β-catenin level must decrease for MET to progress. Additionally, optimal intensity of β-catenin is essential for NPC differentiation to podocytes. Hence, discrete levels of β-catenin promote disparate cell fates. It remains unclear however what drives this change and direct NPC to exit/maintain self-renewal.

Methods: Kidneys from $Six2CreTcf21^{f/f}$ mice were extracted for qPCR and immunohistochemistry. MK3 cells were used to study Tcf21 signaling. Recombinant Tcf21 was used for over-expression.

Results: $Six2CreTcf21^{f/f}$ kidneys show marked decrease in Cited1 expression from E12.5 through P0 compared to control, while still expressing normal levels of Six2, indicating decreased self-renewing NPC population. $Six2CreTcf21^{f/f}$ kidneys also demonstrated low Lef1 expression suggesting decreased NPC epithelialization. However, Wnt4, a marker of the pretubular aggregate, was persistently elevated in the developing nephrons of $Six2CreTcf21^{f/f}$. This state of $Cited1^{low}Wnt4^{high}Lef1^{low}$ in the mutants suggests arrested MET and persistently elevated β-catenin levels in the differentiating progenitors. In uninduced mesenchymal cell culture (MK3), over-expression of wild-type Tcf21 led to enhancement of genes that mark renewing NPC: Cited1, Tafa5, and Pla2g7, while over-expression of mutated-Tcf21 abrogated that enhancement, again supporting Tcf21 involvement in NPC dynamics. As to podocyte differentiation, lineage tracing of Tcf21Cre showed its expression in a subset of NPC in the cap-mesenchyme and then in developing and mature podocytes. At P0, $Six2CreTcf21^{f/f}$ kidneys showed very low podocin expression. This suggests that Tcf21 is required for NPC differentiation to podocytes.

Conclusions: Together, these data suggest that Tcf21 modulates Wnt/β-catenin signal intensity spatially and temporally to direct NPC toward self-renewal or differentiation.

PO0877

A Novel ADPKD Model Using Kidney Organoids Derived from Disease-Specific Human Induced Pluripotent Stem Cells

Tatsuya Shimizu,[1,2] Shin-ichi Mae,[1] Toshikazu Araoka,[1] Kunihiro Yamagata,[2] Kenji Osafune.[1] *[1]Center for iPS Cell Research and Application (CiRA), Kyoto University, Kyoto, Japan; [2]Department of Nephrology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most prevalent hereditary diseases, accounting for up to 10% of end-stage kidney disease worldwide. Although many disease models have been proposed for ADPKD, the pre-symptomatic pathology of the human disease remains unknown and no definitive therapies are currently available. To elucidate the mechanisms of early cytogenesis, robust and genetically relevant human models are needed.

Methods: Using a stepwise differentiation protocol that we have recently reported (Tsujimoto H. et al., 2020), we generated kidney organoids from two kinds of disease-specific human induced pluripotent stem cells (hiPSCs), *PKD1* gene-edited hiPSCs and ADPKD patient-derived hiPSCs. We applied chemical treatment to reproduce cystic phenotypes within kidney organoids, quantitatively analyzed macroscopic cystic lesions, and performed immunofluorescence analyses. ADPKD patient-derived kidney organoids were further utilized to examine the effects of known inhibitors of cystogenesis.

Results: Although wild-type organoids developed cystic lesions under forskolin, *PKD1*-mutant organoids exhibited significantly larger cystic areas depending on the *PKD1* genotype. Importantly, ADPKD patient-derived kidney organoids as well as gene-edited heterozygous *PKD1*-mutant ones also recapitulated cystogenesis *in vitro*. Immunofluorescence analyses confirmed that the cyst epithelia predominantly originate from LTL-positive cells. Furthermore, inhibitor experiments suggested the predictive validity of patient-derived kidney organoids as a disease model.

Conclusions: We established a novel model for ADPKD using kidney organoids differentiated from gene-edited *PKD1*-mutant and ADPKD patient-derived hiPSCs. Further, we demonstrated the possibility of ADPKD kidney organoids serving as drug screening platforms. This newly developed model will contribute to identifying novel therapeutic targets, extending the field of ADPKD research.

Kidney Organoids Represent a Novel Platform to Study Adaptive and Innate Immunity

Samuel Mon-Wei Yu,[1] John Y. Choi,[1] Takaharu Ichimura,[1] Mahmoud L. Nasr,[1] Paolo Cravedi,[2] Michael Brehm,[3] Jamil R. Azzi,[1] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Mount Sinai Health System, New York, NY; [3]University of Massachusetts System, Boston, MA.*

Background: Human kidney organoids have been utilized as a model to study genetic kidney diseases and kidney development. Innate or adaptive immune responses in organoids are currently poorly defined. Kidney transplant rejection and activation of complement pathways are two common renal immune phenomena. SARS-CoV-2 virus, the pathogen of the recent pandemic, leads to complement pathway activation in human kidneys and can infect kidney organoids. Here, we investigated (i) the alloimmunogenicity of kidney organoids in a humanized mice model, and (ii) the responses to exogenous complement C5a and spike protein (S1) of SARS-CoV-2 in kidney organoids.

Methods: Kidney organoids were generated from human embryonic stem cells using protocols developed in our laboratory, and transplanted under the kidney capsule in humanized (BLT) mice. Immunophenotype, mixed lymphocyte reaction, and intracellular cytokine staining were analyzed from grafts and mouse splenocytes collected after 30 days of transplantation. In other experiments organoids were treated with S1 protein and human recombinant C5a for 24 hours or 3 days respectively, followed by qPCR and immunofluorescence analysis.

Results: Transplanted organoids were extensively infiltrated by lymphocytes. Graft $CD8^+$ T cells demonstrated a switch from naïve to memory T cells. Splenocytes isolated from transplanted BLT mice showed increased IFN-γ and TNF-α. Splenocytes proliferated after exposure to 2D kidney organoids (MLR) for 72 hours ex vivo, and organoids were markedly injured as reflected by DNA damage (γ-H2AX) and cleaved caspase 3. Reflecting innate responses, robust interstitial fibrosis was found in non-transplanted organoids after direct activation of C5aR by exogenous C5a. We confirmed ACE2 expression on proximal tubules and parietal epithelium of glomeruli, consistent with human autopsy results. Non-transplanted organoids treated with S1 protein showed transcriptionally upregulated C5a1 receptors.

Conclusions: Our results indicate the alloimmunogenicity of kidney organoids and the deleterious effects of C5a in kidney organoids. Human kidney organoids represent a novel platform to study renal immunology including adaptive and innate immunity and the inflammatory responses to coronavirus disease (COVID-19).

Kidney Organoids Derived from a Pediatric Patient with Type 1 Diabetes and Steroid-Dependent Nephrotic Syndrome Show Losses of Podocyte Podocalyxin and Increased Proximal Tubule Injury

Nathan Lee,[1] Kyung hwa Choi,[1,2] Shun-Yang Cheng,[1,3] Leonardo V. Riella,[1] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [3]University of Southern California, Los Angeles, CA.*

Background: Whole exome sequencing of a pediatric patient, who at age 3 developed Type 1 diabetes mellitus and steroid-dependent nephrotic syndrome, revealed a de novo heterozygous mutation of the *GREM1* gene. Gremlin is a BMP antagonist crucial for kidney development and also implicated later in life in diabetic kidney disease. Specifically, gremlin has been associated with kidney inflammation, Notch activation and fibrosis, and proposed to be a mediator of diabetic nephropathy and other progressive kidney diseases. 3D kidney organoids differentiated from induced pluripotent stem cells (hiPSCs) provide a platform technology to explore the effects of genetic changes on pathobiology of human tissue.

Methods: An induced pluripotent stem cell (iPSC) line was created from the patient. Organoids were generated from iPSCs by modifications of our laboratory's prior published techniques without use of undefined matrices. Structures of kidney organoids were imaged by immunostaining for LTL, CDH1, GATA3, PODXL, NPHS1, NPHS2, and CD31. Organoids were also stained for gremlin, SGLT2, and KIM-1 to investigate phenotypes.

Results: A de novo heterozygous mutation of the *GREM1* gene was identified. The *GREM1* mutation specifically eliminates one of the three known *GREM1* splicing isoforms while leaving the other two intact. When compared to organoids generated from embryonic stem cells or BJFF iPSCs the patient-derived organoids had several kidney disease phenotypes including decreased expression of podocalyxin, aberrant expression of SGLT2, and pronounced expression of KIM-1, an indicator of proximal tubule injury. The phenotypes could be rescued by treatment of the kidney organoids with recombinant GREM1 protein, altering the balance of long and short forms of gremlin.

Conclusions: Organoids derived from a patient with a *GREM1* heterozygous mutation demonstrated decreased podocalyxin, aberrant SGLT2 staining, and increased proximal tubule injury. Better understanding of the relative roles for *GREM1* isoforms could lead to better understanding of diabetic progressive kidney disease and organoids can be used to find potential therapies.

PO0880

CD133^{+} Progenitor Cells in Proximal Tubules Are Most Likely the First Responding Cells to Acute Tubular Injury in Human Kidneys

Wenqing Yin,[2] Ping L. Zhang.[1] *[1]Beaumont Health, Royal Oak, MI; [2]Boston Medical Center, Boston, MA.*

Background: Proximal tubules (PT) are mainly used for the reabsorption of electrolytes and fluid. Recent studies reveal CD133+ progenitor cells scattered along the PT, and CD133 wrapped in extracellular vesicles (EV) of urine can be used as an injury biomarker. The main goal of the study was to investigate how CD133+ progenitor cells are distributed along the convulated PT and whether CD133+ progenitor cells are related to initial repairing of PT.

Methods: Ten early metanephrons, 10 control adult renal sections and 40 renal biopsies with various degrees of acute tubular injury (ATI) were stained CD133 for highlighting progenitor cells of PT, followed by special Periodic Acid Schiff (PAS) staining for identifying brush borders. The dual stains sections fo evaluate surface CD133 expression and PAS positive brush borders were evaluated by light microscopy.

Results: CD133 staining was positive in the renal S shape body, parietal epithelium of primordial glomeruli, distal tubules and focally positive in PT of early metanephros. The control adult nephron revealed single CD133+ progenitor cells at the U turn niches of convoluted PT, which were stained negatively for PAS, indicating that CD133+ progenitor cells may watch turning segments (convoluted loops) of PT and do not have reabsorption capacity. At the early stage of ATI, there were side-by-side and nearby dual or triple CD133+ cells in each cross section of PT, which were negative for PAS staining as well. Surface CD133+ micro-granules of proximal tubules were identified in the early injured PT.

Conclusions: Our data indicate that CD133 in parietal epithelium and renal tubules are most likely derived from the condensing mesenchymal cells/S-shaped body after the induction of ureteric bud in the metanephros. There are two types of cells in proximal tubules – classic PT cells with brush borders for reabsorption and scattered CD133+ progenitor cells that are lack of brush borders and may serve as " injury watchdog" at each turning segment of convoluted PT. During early ATI, dual or triple CD133+ cells were present, implying that CD133+ progenitor cells may represent the first responding cells to acute tubular injury for tubular repairing. CD133+ micro-particles were present at the surface of injured PT imply that CD133+ progenitor cells may pass the CD133+ EV to signal surrounding cells for the injury insult.

PO0881

Renal Endothelial Cells After Injury Were Dominantly Regenerated by an Adult Renal Endothelial Cell Pool

Jan Sradnick, Nicole Bunk, Anika Wirth, Vladimir T. Todorov, Christian Hugo. *Division of Nephrology, Department of Internal Medicine III, University Hospital CGC, Dresden, Germany.*

Background: Previously we demonstrated that endothelial repair in murine kidneys exclusively depends on local renal mechanisms. This is related to the question whether a renal non-endothelial (precursor) cell pool/niche exists parallel to local endothelial cell proliferation.

Methods: Inducible Cdh5(PAC)-ERT2 tdTomato (tdT) reporter mice were used to assess the proportion of renal endothelial cells regenerating exclusively from labelled endothelial cells, which persisted after selective endothelial cell injury (ECI) in individualized animals. ECI was induced by renal arterial perfusion of the left kidney with ConcanavalinA (ConA)/anti-ConA. The recombination efficiency of tamoxifen-induced mice was determined 24h prior to ECI by flow cytometric analysis. 24h after ECI, a biopsy of the previously damaged kidney was taken to determine the degree of endothelial damage. One week after ECI the mice were sacrificed and all kidneys were examined by flow cytometry (CD105+CD31+CD45-) and histology (CD31+ERG+ cell/glomeruli). Sham operated mice (SHAM) and the intact contralateral kidney (CL) served as controls.

Results: More than 85% of all renal endothelial cells expressed tdT in 19 of 27 induced mice, which were selected for further experiments. The mean labelling efficiency with tdT was 94.1% of all endothelial cells. Seven mice served as sham. 24h after ECI (n=12), and a 28.6±9% reduction of glomerular ERG+ endothelial cells (8.7±1.1 cells) vs. sham control mice (13.5±0.9 cells) was observed ($p<0.02$). Seven days after ECI, the number of ERG+ glomerular cells was not significantly different compared to the non-damaged kidney or sham (d7 ECI:12.4±1.9 cells vs CL:13.1±0.8 cells; SHAM:13.5±0.9 cells) demonstrating complete repair. Hereby, the proportion of tdT positive cells did not significantly differ between any of the groups, neither at different time points (24h: 92.8%; d7 ECI: 91.2%) nor between sham and injured kidneys one week following ECI (ECI: 91.2%; CL: 93.6%; SHAM 94.2%).

Conclusions: In individualized inducible Cdh5(PAC)-ERT2 tdT reporter mice, the percentage of tdTomato positive versus total endothelial cells does not change during/after endothelial regeneration. This experimental study suggests that the renal endothelium regenerates from an existing intrarenal endothelial cell pool and not from a non-endothelial precursor cell pool.

Single-Cell RNA Sequencing Reveals Subpopulation of PDGFRβ^{β} Pericytes as Fibroblast Precursor in Interstitial Kidney Fibrosis, and Smad Anchor for Receptor Activation Overexpression Modifies Their Fates

Xiaoyan Liang,[2] Vidhi Dalal,[2] H. William Schnaper,[1,2] Tomoko Hayashida.[1,2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: In last several ASN meetings, we showed that SARA plays a critical role for fibroblast precursor activation, and that overexpressing SARA in PDGFRβ^{+} pericytes prevents chemically-induced kidney fibrosis in interstitium. Here, we present our findings from single cell RNAseq analyses of PDGFRβ^{+} pericytes with or without fibrosis.

Methods: PDGFRβ-Cre; Z/EG; SARA^{Tg} or ^{WT} mice that express GFP and SARA (in SARA^{Tg} line) only in PDGFRβ^{+} cells were given aristolochic acid (AA, 10 mg/kg, i.p., 3x week for 3 weeks). After 3 more weeks, kidneys were harvested and digested with Liberase/DNAse I. GFP^{+} cells were flow sorted and subjected to scRNAseq. 2-3 samples from a group (WT or SARA^{Tg,} and AA or control) were analyzed altogether by Seurat clustering, and subsequent inter-cluster analyses.

Results: Unsupervised analyses with Surat identified 30 clusters. Clusters characterized with differential expression of Apoe1 and C1a1 were dominant in cells isolated from healthy WT kidney, whereas clusters differentially expressing Kap and Cd74 became dominant in WT kidney treated with AA. This shift was abrogated in cells isolated from fibrotic SARA^{Tg} kidney. RNA velocity analyses to reveal specific clusters that transition to fibroblasts are being analyzed.

Conclusions: These results implicate a sub-population of PDGFRβ^{+} pericytes are progenitors for fibroblasts in fibrosing kidney and genes identified that are differentially expressed could have therapeutic implication in treating kidney fibrosis.

Successful Introduction of Renovascular Units into the Mammalian Kidney

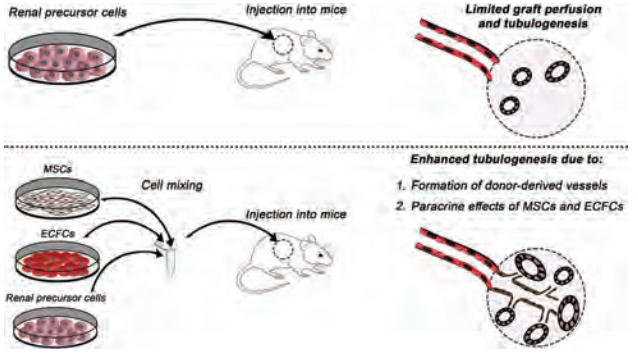
Oren Pleniceanu,[1,2] Yehudit Gnatek,[1] Barak Rosenzweig,[2] Alon Eisner,[5] Zohar A. Dotan,[2] Leon G. Fine,[3] Shoshana Greenberger,[4] Benjamin Dekel.[1,2]
[1]Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel; [2]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel; [3]Cedars-Sinai Medical Center, Los Angeles, CA; [4]Sheba Medical Center at Tel Hashomer, Tel Hashomer, Israel; [5]Assuta Ashdod Hospital, Ashdod, Israel.

Background: Various cell-based therapies, aimed at replenishing renal parenchyma, have been proposed as means to treat chronic kidney disease (CKD). However, a key limitation to the applicability of these strategies is the failure of in-vivo administered cell types to develop donor-derived vessels, resulting in poor graft survival. Similarly, such strategies do not address renal hypoxia, a key factor in CKD progression. We hypothesized that administering self-organizing human renal tubule-forming cells (RTFCs) derived from adult and fetal kidneys, previously shown to exert a functional effect in CKD mice, alongside mesenchymal stromal cells (MSCs) and endothelial colony-forming cells (ECFCs), would result in generation of both vessels and tubules with potential interaction.

Methods: NOD-SCID mice were injected with either RTFCs or a mix of RTFCs, MSCs and ECFCs in Matrigel into the sub-cutis (SC), under the renal capsule or into the renal parenchyma. The resulting grafts were analyzed after 2 weeks.

Results: While RTFC-derived grafts harbored few host-derived vessels, injection of MSC, ECFCs and RTFCs into the SC, sub-renal capsular space, or renal parenchyma, resulted in robust formation of donor-derived reno-vascular units. These consisted of both well-developed renal tubules tubular epithelia of different nephron segments, and human vascular networks, which connect to host vasculature. The latter demonstrated the presence of both $CD31^+$ endothelium and αSMA^+ pericytes, originating from administered ECFCs and MSCs, respectively. Notably, MSC/ECFC-derived vessels augmented *in-vivo* tubulogenesis by RTFCs while *in vitro* co-culture experiments showed MSC/ECFCs to induce self-renewal and mesenchymal-epithelial transition-associated genes in RTFCs, disclosing paracrine effects.

Conclusions: Combined cell therapy of vessel-forming cells and RTFCs aimed at enhancing tubulogenesis and potentially alleviating renal hypoxia may serve as the basis for new renal regenerative therapies.



PO0884

Elastin-Microfibril Axis Proteins Form Transient 3D Structures During Murine Nephrogenesis

Sarah N. Lipp,[1,2] Andrew L. Schwaderer,[2] David S. Hains,[2] Sarah Calve.[3,1]
[1]Purdue University System, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]University of Colorado at Boulder, University of Colorado Boulder, Boulder, CO.

Background: Dynamic changes in the composition and structure of the extracellular matrix (ECM) are understudied but critical during renal development. Our recent proteomic study indicated proteins in the *elastin-microfibril* axis were upregulated with development; however, structural changes during maturation are unclear.

Methods: Kidneys were decellularized, stained for *elastin-microfibril* axis protein (EMILIN1), FREM2, and proteoglycans (WGA), imaged using confocal microscopy, and rendered in 3D using FIJI. For comparison, E18.5 cryosections were stained for additional members of the e*lastin-microfibril* axis (COL26A1, FBN2).

Results: At perinatal timepoints, *elastin-microfibril* axis proteins were organized in the interstitium surrounding developing tubular and glomerular elements, including vertical fibers connecting to the capsule and medullary ray sheath fibers. Patterning was lost in the adult (Fig. 1). Different *elastin-microfibril* axis proteins displayed similar staining patterns perinatally (Fig. 2).

Conclusions: The 3D corticomedullary junction structures for *elastin-microfibril* axis proteins at the perinatal timepoint were consistent with the proteomic trends. We hypothesize the structures are important for nephrogenesis through mechanical support and growth factor modulation.

Funding: Other NIH Support - National Institutes of Health [DP2 AT009833 to S.C.]

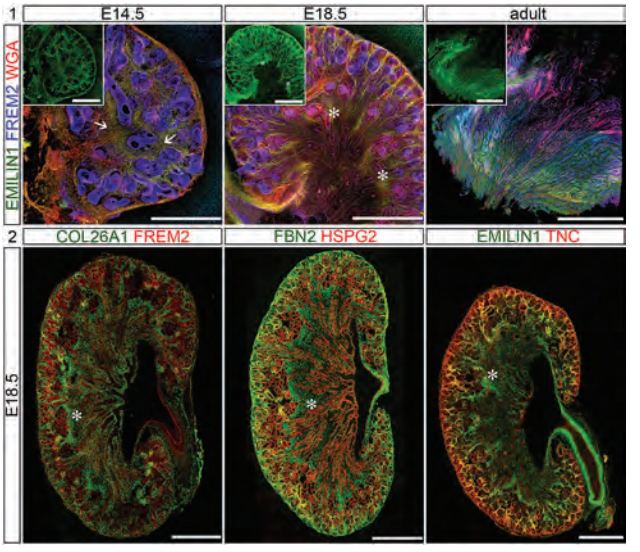


Figure 1 (top): 3D visualization of EMILIN1 showed medullary ray sheath fibers transiently formed at E18.5. EMILIN1 was localized to the corticomedullary junction (green, white arrow) fibers surrounding tubules at E14.5 that grouped into medullary ray sheath fibers (*) at E18.5 but regressed in the adult murine kidney. Insets are visualization of the EMILIN1 channel. scale bar=500 μm**Figure 2 (bottom): *Elastin-microfibril* axis proteins displayed similar staining patterns at E18.5.** *Elastin-microfibril* axis proteins (green) were co-stained for ECM (red). medullary ray sheath fibers (*), scale bar=500 μm

PO0885

Development of Noninvasive Clinically Applicable In Vivo Tracking of Extracellular Vesicles Using Magnetic Resonance Imaging (MRI)

Sargis Sedrakyan,[1] Johnny C. Akers,[2] Paola Aguiari,[1] Hasmik Soloyan,[1] Seda Mkhitaryan,[2] Gevorg Karapetyan,[1] Roger E. De Filippo,[1] Mya S. Thu,[2] Laura Perin.[1] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]Visicell Medical Inc, San Diego, CA.*

Background: Extracellular vesicles (EVs) derived from amniotic fluid stem cells (AFSC) hold great potential for the treatment of chronic kidney diseases (CKD). We have already shown that AFSC-EVs are renoprotective in a mouse model of CKD, Alport syndrome. However, there is an important unmet need for real-time *in vivo* monitoring of these therapeutic EVs after they are injected into a subject to understand their safety, targeting, and effectiveness. While current optical imaging solutions like bioluminescence and fluorescence are useful for EV tracking studies in animal models, there is limited utility in clinical applications. Here we present a novel *in vivo* tracking solution for our therapeutic EVs in Alport mice, utilizing clinically applicable MRI technology.

Methods: To generate trackable EVs, AFSC were labeled with a novel magnetic agent (VSCM). EVs secreted by the labeled AFSC were isolated by ultracentrifugation. The viability and morphology of labeled-cells were evaluated, and the *in vitro* MR properties of EVs were analyzed by magnetometer. Purity, potency and identity of labeled EV was compared to non-labeled EVs. *In vivo* biodistribution of labeled EVs was evaluated in WT and Alport mice by MRI at 10 min and 3 hr post injection, and retro-orbital and intra-cardiac routes of delivery were compared.

Results: The magnetic label did not affect the physiological characteristics of the cells and did not change identity, purity and potency (therapeutic effect in vivo) of EVs. MRI phantom studies confirmed the in *vitro/ex vivo* detectability of labeled-EVs. Importantly, as expected MRI studies showed that EV homing to the kidney injected intra-cardiacally into Alport mice was more efficient vs the retro-orbital route, and Prussian blue staining of sections confirmed EV homing to the kidney.

Conclusions: We have developed a clinically applicable novel magnetic nanoparticle agent that can be used to label and track the biodistribution of EVs in the kidney and other organs using non-invasive, safe, and effective MRI technology that's widely available. This technology is highly adaptable and can be deployed in both preclinical and clinical settings.

Obesity Blunts the Reparative Function of Human Adipose Tissue-Derived Mesenchymal Stem Cells in Ischemic Murine Kidneys

Nattawat Klomjit,[1] James Krier,[1] Sabena Conley,[1] Xiang yang Zhu,[1] Christopher M. Ferguson,[1] Kyra L. Jordan,[1] Hui Tang,[1] Amir Lerman,[2] Lilach O. Lerman.[1] *[1]Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; [2]Department of Cardiovascular Medicine, Mayo Clinic, Rochester, MN.*

Background: Obesity is a health burden that can affect cellular processes. Mesenchymal stromal/stem cells (MSC) ameliorate renal injury in several diseases. Obesity impairs MSC function *in vitro*, but its effect on *in vivo* reparative function of human MSC remains unknown.

Methods: MSC were harvested from non-obese ('lean') (body mass index [BMI] <30 kg/m^2) and obese (BMI≥30) human subjects during kidney donation or bariatric surgery, respectively. To test their function *in vivo*, MSC (5x10^5/200 μL) or vehicle were injected into 129S1 mice 2 weeks after renal artery stenosis (RAS) or sham surgery (n=6-8/group). Two weeks later, mice underwent magnetic resonance imaging to assess renal perfusion and oxygenation, and kidneys then harvested.

Results: A similar number of lean and obese human MSC engrafted in stenotic mouse kidneys. Vehicle-treated RAS mice had reduced cortical and medullary perfusion. Lean (but not obese) MSC normalized cortical perfusion (p=0.2 vs sham+vehicle) (Figure A&B), whereas both effectively mitigated renal hypoxia. Serum creatinine and blood pressure were elevated in all RAS mice, and lowered only by lean MSC (p=0.4 vs sham+vehicle). Both alleviated renal fibrosis in RAS, but lean more effectively than obese MSC (p=0.02). Tubular and glomerular injury was improved similarly by both.

Conclusions: Lean MSC are superior to obese MSC in repairing ischemic kidney injury and blood pressure in murine RAS, implying dysfunction of the endogenous MSC repair system in obese patients. This should also be considered during autologous cell-based approaches.

Single-Cell Transcriptional and Chromatin Accessibility Profiling Redefines Cellular Heterogeneity in the Adult Human Proximal Tubules

Yoshiharu Muto,[1] Parker C. Wilson,[1] Sushrut S. Waikar,[2] Benjamin D. Humphreys.[1] *[1]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [2]Boston Medical Center, Boston, MA.*

Background: Single nucleus RNA sequencing (snRNA-seq) has improved our understanding of cell-specific genes and pathways, however, relatively less is known about how chromatin accessibility contributes to cell identity. We hypothesized that an integrated analysis by snRNA and ATAC sequencing (snATAC-seq) would enhance our ability to detect unique cell types and states in the kidney, uncovering previously unrecognized cellular heterogeneity.

Methods: We performed snRNA-seq and snATAC-seq on 5 healthy adult kidney samples (3M and 2F, mean age = 55.8y, mean sCr = 1.07 mg/dl). Nuclear preparations were processed using 10x Genomics 5' v2 (snRNA) and Single Cell ATAC (snATAC) Chromium kits, sequenced and counted with Cell Ranger. Seurat was used to integrate snRNA and snATAC datasets with label transfer. Chromatin interactions were predicted with Cicero and pseudotemporal ordering was performed with Monocle.

Results: We analyzed a total of 52,097 nuclei by snRNA-seq (n=19,985) and snATAC-seq (n=32,112), identifying 214,890 accessible chromatin regions that confer kidney cell type identity. This multi-modal analysis highlighted a unique subpopulation of proximal tubule (PT) cells characterized by increased chromatin accessibility in *VCAM1* and a pro-inflammatory gene expression signature. Immunofluorescence studies showed that these cells are present in a scattered distribution in the kidney cortex. Transcription factor motif analysis implicated NFkB signaling in the transition between healthy PT and the *VCAM1*-positive subpopulation. We identified candidate regulatory regions that are predicted to interact with the *VCAM1* promoter via cis-coaccessibility networks. Inter-species snRNA-seq data integration suggests this subpopulation exists in the post-IRI mouse kidney and bulk RNA-seq deconvolution implicates a potential role in CKD and kidney aging.

Conclusions: Our multi-omics approach improves the ability to detect unique cell states within the kidney and reveals a previously unrecognized subpopulation of proximal tubule cells with a pro-inflammatory signature.

Vegfr3 Is Expressed in Fenestrated Microvascular Beds of the Kidney and Is Required for Glomerular Development

Michael D. Donnan,[1] Tuncer Onay,[1] Rizaldy P. Scott,[1] Jean-Leon Thomas,[2] Susan E. Quaggin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Yale University School of Medicine, New Haven, CT.*

Background: Chronic Kidney Disease is associated with pathological changes to the kidney vasculature which contribute to disease progression. Despite the recognized importance of vascular dysfunction in kidney disease, the mechanisms by which these changes occur are poorly understood, limiting therapeutic design. Dysregulation of Vascular Endothelial Growth Factor Receptor 3 (VEGFR3), known for its role in lymphangiogenesis, is causally linked to the development of kidney diseases, including renal fibrosis and cystogenesis. How VEGFR3 signaling influences kidney disease progression and the specific vascular beds involved remains unclear.

Methods: We performed a detailed expression analysis of *Vegfr3* in the kidney using a *Vegfr3-YFP* reporter mouse line. We generated a new transgenic mouse model to investigate the role of *Vegfr3* in the kidney vasculature (*Vegfr3^{flox}*). Conditional and cell-specific excision of the floxed allele was performed using the *Rosa-rtTA-TetOCre, Cdh5-Cre/ERT2, and PDPN-GFPCre* driver strains to evaluate global, pan-endothelial, and lymphatic endothelial cell deletion of *Vegfr3* respectively. Mice underwent a detailed phenotypic evaluation and kidney sections were processed for histology.

Results: *Vegfr3* undergoes dynamic expression through development in several fenestrated blood microvascular beds of the kidney including the peritubular capillaries, the ascending vasa recta, and the glomerular capillaries. Constitutive deletion of *Vegfr3* results in early embryonic lethality while induced deletion at later embryonic stages results in lymphatic pathologies including chylous ascites, blood-filled lymphatic vessels, and reduced viability. Both global and endothelial-cell specific deletion of *Vegfr3* at embryonic day 11.5 resulted in marked disruption of glomerular development with cavernous capillary malformations. Immunofluorescence and electron microscopy revealed endothelial cell lined structures surrounded by immature podocytes with disrupted basement membrane development.

Conclusions: VEGFR3, while typically associated with lymphatic vessels, is expressed in fenestrated microvascular beds of the kidney and is required for glomerular development. These findings have important implications for the development of therapeutics targeting this pathway for the treatment of kidney disease.

Malnutrition During Pregnancy Impairs Nephrogenesis by Interrupting Methionine Metabolism

Oded Volovelsky,[1] Yaniv Makayes,[1] Elad Resnick,[1] Raphael Kopan,[2] Morris Nechama.[1] *[1]Pediatric Nephrology Unit, Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Division of Developmental Biology, Cincinati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Poor nutritional status during pregnancy has long term effects on kidney health by impairing nephron endowment in an unknown mechanism. Nephron progenitor cells are dependent on constant nutrient supply for maintaining high metabolic activity. We aimed to study the effect of malnutrition during pregnancy on the metabolic profile of nephron progenitor cells.

Methods: Six2 Cre$^{tg/+}$ males were mated with wild type females. Pregnant mice were fed with 70% of the daily chaw intake in individual cages. Six2$^+$ NPC's cells were FACS sorted and the metabolites were extracted and measured using mass spectrometry. For kidney organ cultures, kidneys were dissected and immediately incubated in well plates containing media either with or without L-methionine. By the end of the incubation period, the kidneys were fixed and whole-mount immunostained for Six2 and cytokeratin (ureteric bud marker). The nephron number was measured by acid maceration.

Results: The metabolomic analysis showed significant impairment in methionine metabolism in E15.5 NPCs. Methionine deprivation in organ culture reduced nephron progenitors' density in metanephric mesenchyme of cultured embryonic kidneys. The effect was reversible by supplementation of the media without L-methionine, with metabolites that promote methionine recycling. Supplementation of methionine-enriched drinking water to caloric restricted pregnant mice prevented the reduction in nephron number in offspring.

Conclusions: Impairment of methionine metabolism plays a major role in mediating the effect of caloric restriction on kidney development. Replenishing methionine may revert the effect of malnutrition on the future risk of developing chronic kidney disease in offspring.

PO0890

Generation of Branching Ureteric Bud Organoids from Human Pluripotent Stem Cells

Kyle Mccracken,[1,2] Min Shi,[2] Weitao Zhang,[2] Lioba Ester,[2] Joseph V. Bonventre.[2] *[1]Boston Children's Hospital, Division of Nephrology, Boston, MA; [2]Brigham and Women's Hospital Department of Renal Medicine, Boston, MA.*

Background: Directed differentiation of human pluripotent stem cells (hPSCs) to kidney organoids has been well established; however, the generation of hPSC-derived ureteric bud (UB), which undergoes branching morphogenesis to generate collecting duct (CD) epithelia, has remained a significant challenge. Here we describe a highly efficient method for deriving UB/CD organoids from hPSCs, which form unprecedented branching structures. This method provides a new platform for studying human CD development, physiology, and disease modeling. Moreover, this will provide the opportunity to markedly enhance existing kidney organoids by providing a collecting system and importantly, introducing an iterative branching component that is essential to driving metanephric kidney development.

Methods: First, we modified existing methods to efficiently direct hPSCs into anterior intermediate mesoderm cells in monolayer format. From that point, we optimized a process of 3-D development that included forced aggregation followed by spontaneous budding and then branching of the UB epithelia.

Results: We generated GATA3/PAX2 AIM with >80% efficiency within 5 days of induction, which was then aggregated into 3-D spheres. Over the subsequent days, the cells underwent a spontaneous process of organization and maturation that parallels normal development of the embryonic nephric duct (ND). Nearly synchronously, each aggregate then formed a single epithelial outgrowth that exhibited expression of UB markers PAX2, GATA3, RET, SOX9 and CALB1. Next, we embedded the UB-like buds into a hydrogel matrix, and they underwent a complex branching morphogenetic program driven by growth factor signals. At later stages, we identified culture conditions to stimulate differentiation of the ureteric epithelia into CD principal cells, identified by expression of AQP2 and SCNN1A/B. Additionally, GATA3+ UB progenitor cells were maintained and expanded over several passages in our 3-D culture system.

Conclusions: We have developed a novel strategy to generate branching UB tissues from hPSCs, which are also competent to differentiate into CD epithelia. Efforts are ongoing to investigate the functional and physiologic properties of these tissues, as well as to model genetic diseases that impact morphologic development of the collecting system.

PO0891

Modeling Damage-Associated Molecular Pattern Injury and Fibrosis Using Human Kidney Organoids

Aneta J. Przepiorski,[1] Eugenel B. Espiritu,[1] Alan J. Davidson,[2] Neil A. Hukriede.[1] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]The University of Auckland Faculty of Medical and Health Sciences, Auckland, New Zealand.*

Background: Recent developments in generating human kidney organoids *in vitro*, have provided an invaluable tool to study human renal diseases, injury, and screening new therapeutics. In order to study acute kidney injury (AKI) we have developed a human kidney organoid model of injury with the damage associated molecular pattern molecule (DAMP), hemin, which is released during hemolysis, often occurring after ischemia/reperfusion and rhabdomyolysis. To spatially and temporally characterize tubule injury in the hemin AKI model, we generated transgenic iPSC lines that carry an early apoptosis biosensor, CytochromeC-GFP. Healthy cells within organoids will localize CytochromeC to the mitochondria but, upon injury, will diffuse into the cytoplasm before activating the apoptotic pathway. This approach provides a real-time readout of injury progression in the kidney organoids.

Methods: Kidney organoids at day 14 of culture were treated for 48 hours with varying concentrations of hemin to determine the optimal dose for measurable injury at day 26. CytochromeC-GFP iPSC lines were generated using AAVS1 Safe Harbor targeting approach. CytochromeC-GFP response in the organoid was validated using menadione (mitochondrial toxin) and tested with hemin to determine the extent of injury. To test efficacy of new therapeutic compounds, hemin injured organoids were treated with varying concentrations of 4-(phenylthio)butanoic acid (PTBA) analogs for 10 days and analyzed to determine changes in fibrotic, and oxidative stress markers.

Results: We show injury in the organoids with optimal hemin dose leading to a reproducible increase in fibrotic, and oxidative stress response. CyochromeC-GFP biosensor iPSC lines allowed us to monitor organoids under hemin insult. Organoids treated with nephrotoxin or hemin exhibit cytoplasmic GFP signal in the injured cells and morphological changes of the mitochondria. Hemin injured organoids treated with PTBA analogs showed a reduction in fibrotic markers at day 26 suggesting a reduction in fibrotic scar tissue development.

Conclusions: We have developed a reliable injury model using hemin, and together with CytochromeC-GFP as a biosensor, these tools can be exploited to test nephrotoxicity, study acute kidney injury, and new therapeutic compounds in a human based *in vitro* model.

PO0892

Delaying Nephrogenesis In Vitro Results in Enhanced Proximal Tubule Alignment and Maturity in Kidney Organoids

Jessica M. Vanslambrouck,[1] Ker sin Tan,[1] Sean Wilson,[1] Sara E. Howden,[1,2] Kynan T. Lawlor,[1] Michelle Scurr,[1] Melissa H. Little.[1,2] Kidney Development, Disease and Regeneration *[1]Murdoch Children's Research Institute, Parkville, VIC, Australia; [2]The University of Melbourne, Department of Paediatrics, Parkville, VIC, Australia.*

Background: Stem cell-derived organoids represent a promising model for complex organs such as the kidney, with studies of disease, physiology and drug interactions relying mostly on simplistic cell cultures or animals that do not completely recapitulate the complex human environment. However, kidney organoids are still less mature than the *in vivo* organ, a limitation arguably most apparent in the proximal tubule (PT) compartment. The critical role of the PT in performing the bulk of solute reabsorption makes it a key requirement for drug screening and bioengineering. By inhibiting promiscuous epithelialisation, we report the development of PT-enhanced kidney organoids with improved PT alignment, maturity, functionality and suitability for therapeutic applications.

Methods: Standard and fluorescent reporter iPSC lines were subjected to prolonged monolayer differentiations, with 4 - 5 day initial CHIR exposure durations (modified from: Howden *et al*, *EMBO Rep*, 2019; Vanslambrouck *et al.* JASN, 2019) and precisely-timed modifications to signalling pathways such as canonical WNT, BMP and NOTCH. Organoids were generated as previously published (Takasato *et al*, *Nat Protoc*, 2016) and analysed using confocal immunofluorescence, live imaging of fluorescent reporters, transcriptional profiling (single cell RNAseq) and functional transport assays.

Results: PT-enriched organoid could be generated in a highly reproducible manner from multiple cell lines. Proximal tubules showed mature protein and gene expression, as well as transport capacity in multiple assays. Nephron spatial arrangement/directionality, as well as shifts in proximo-distal nephron patterning, were influenced by these modified conditions.

Conclusions: Here, we describe PT-enhanced kidney organoids with improved PT maturity and functionality, with this approach providing a more stringent control over the spatial arrangement of nephrons. Such findings have significant implications for downstream applications including drug screening, toxicology assays and bioengineering of functional replacement cells or tissues.

PO0893

Glomerular Endothelial Glycocalyx Damage Occurs in Human Diabetic Nephropathy and Could Be Prevented by Early Mineralocorticoid Receptor Inhibition

Michael Crompton, Matthew J. Butler, Karen L. Onions, Anna S. Ogier, Gavin I. Welsh, Rebecca R. Foster, Simon C. Satchell. Bristol Renal *University of Bristol, Bristol, United Kingdom.*

Background: The glomerular endothelial glycocalyx (GEnGlx) forms the first part of the filtration barrier. In rodent models, damage to the GEnGlx occurs early in the pathogenesis of diabetic nephropathy (DN). Until now no techniques have been available to quantify GEnGlx damage in human disease. Mineralocorticoid receptor (MR) antagonists slow disease progression, but side effects limit their clinical use. We aimed to develop a method to study GEnGlx changes in human disease and investigate whether MR inhibition could preserve the GEnGlx in a rat DN model.

Methods: Human renal biopsies from patients with DN and thin basement membrane disease (TBMD) were analysed using our novel peak-to-peak confocal imaging method (UEA-I lectin) to assess GEnGlx depth. Male Wistar rats injected with streptozotocin (50mg/kg I.P.) were used to study if spironolactone (50mg/kg daily S.C.), an MR inhibitor, could preserve the GEnGlx and limit the development of DN. Our glomerular permeability assay was used to directly measure the albumin permeability (Ps'alb), in isolation from haemodynamic changes. Peak-to-peak (WGA lectin) was validated against electron microscopy GEnGlx depth measurements. MMP2 activity was quantified using a specific activity assay and ELISAs were used to measure urine albumin levels.

Results: In human DN, GEnGlx depth was reduced compared to patients with TBMD (p=0.013). Diabetic rats developed albuminuria and the Ps'alb increased 1.6-fold (p<0.001). Again, GEnGlx depth was reduced in DN compared to controls (p<0.001). Plasma and urinary active MMP2 were increased (p=0.017 and p<0.001). MR blockade preserved the GEnGlx, restored Ps'alb to control values and prevented albuminuria progression. Reduced urinary active MMP2 (p=0.012) and glomerular *Mmp2* mRNA expression (p=0.002) were seen following MR blockade in DN. GEnGlx enzymatic degradation, with hyaluronidase, reversed the effect of MR blockade in DN confirming the importance of GEnGlx preservation in this model.

Conclusions: MR blockade in DN preserves the GEnGlx, reduces Ps'alb and retards the development of albuminuria. Alternative approaches to block MR-induced GEnGlx damage represent a novel potential therapeutic strategy, to reproduce the benefit of MR antagonists without adverse side effects.

PO0894

Targeting αvβ8 Integrin Improves Renal Function Through Local Inhibition of TGF-β Activation

Elena Liarte Marin,[1] Lihuan Liang,[1] Asha Seth,[1] Stephanie C. Heasman,[2] Viknesh Selvarajah,[3] Iain MacPhee,[3] Xiaozhen Wang,[4] Judith Hartleib-Geschwindner,[5] Carol P. Moreno Quinn,[1] David J. Baker,[6] Denis Feliers.[1] *[1]Renal Bioscience, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [2]Imaging & Artificial Intelligence, Clinical Pharmacology & Safety Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [3]Clinical Development, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [4]Translational Science and Experimental Medicine, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD; [5]Projects, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [6]Metabolism Bioscience, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom.*

Background: TGFβ signalling plays a central role in the development and progression of renal interstitial fibrosis in chronic kidney disease (CKD), which predicts time to dialysis. Systemic blockade of TGFβ has shown serious adverse effects (progression of premalignant lesions) and limited efficacy at doses that were safe for patients, highlighting the need for a targeted inhibition of TGFβ in the kidney. αvβ integrins have a unique ability to activate latent TGFβ through the binding of latency-associated peptide (LAP) to release active TGFβ and therefore can modulate fibrotic processes. Consequently, they have emerged as promising therapeutic targets.

Methods: We generated MEDI8367, an antibody that specifically binds human integrin β8 and works allosterically reducing its affinity for the LAP domain, hence preventing β8-mediated TGFβ activation but not its cell adhesion function. We confirmed its neutralising activity using a reporter cell *in vitro* assay that detects TGFβ bioactivity.

Results: To assess its therapeutic effect ITGB8 humanized mice were subjected to unilateral ureteral obstruction to induce fibrosis. Obstructed kidneys showed strong up-regulation of integrin β8 in the tubular compartment and MEDI8367 significantly improved fibrosis without affecting integrin β8 expression. This was accompanied by inhibition of TGFβ activation, which mimicked the effect of a pan-TGFβ neutralizing antibody, suggesting that MEDI8367 reduces renal fibrosis by blocking local TGFβ activation. We next tested the effect of targeting integrin β8 in a mouse model of diabetic nephropathy, the db/db-uninephrectomy model. Mice underwent uni-nephrectomy at 8 weeks of age and were randomized to receive either an anti integrin β6/β8 or an anti integrin β6 antibody at 12 weeks of age for 3 weeks. Blocking integrin β6 did not affect albuminuria in these mice while blocking integrins β6/β8 stopped the progression of albuminuria in all the mice tested (n=9). These data suggest that it is the blockade of integrin β8 that has a beneficial effect on albuminuria.

Conclusions: We conclude that targeting integrin β8 in CKD ameliorates kidney dysfunction and reduces fibrosis, an effect that is mediated by inhibition of local TGFβ activation.

PO0895

Integrated Single Nucleus RNA and ATAC-Seq Implicate Cis-Regulatory Chromatin Interactions That Promote Gluconeogenesis in the Human Diabetic Proximal Tubule

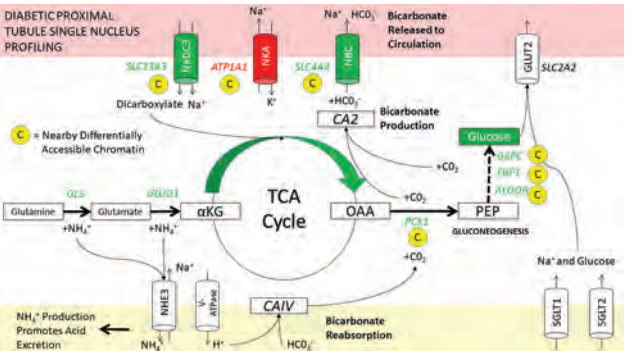
Parker C. Wilson,[1] Yoshiharu Muto,[2] Sushrut S. Waikar,[4] Benjamin D. Humphreys.[2,3] *[1]Division of Anatomic and Molecular Pathology, Department of Pathology and Immunology, Washington University in Saint Louis School of Medicine, Saint Louis, MO, USA, Saint Louis, MO; [2]Division of Nephrology, Department of Medicine, Washington University in Saint Louis School of Medicine, Saint Louis, MO, USA, Saint Louis, MO; [3]Department of Genetics, Washington University in Saint Louis, Saint Louis, MO, USA, Saint Louis, MO; [4]Division of Nephrology, Department of Medicine, Boston University School of Medicine, Boston, MA, USA, Boston, MA.*

Background: Type 2 diabetes is characterized by impaired glucose metabolism, but relatively little is known about cell-specific changes in the kidney. We hypothesized that single nucleus ATAC (snATAC) and RNA (snRNA) sequencing of kidney tissue from patients with early diabetes would reveal cis-regulatory chromatin interactions that promote expression of genes that lead to glucose intolerance.

Methods: We analyzed five kidney samples from patients with early diabetes and five healthy controls. Diabetic patients had elevated A1c and two of five had proteinuria. Serum creatinine (mean = 1.01 mg/dl) was not different between groups. Nuclear preparations were processed with 10x Genomics 5' v2 or Single Cell ATAC kits, sequenced and counted with Cell Ranger. Analysis was performed with Seurat. snATAC peaks were called with MACS2 using SnapATAC. Chromatin interactions were predicted with Cicero.

Results: A total of 80,576 nuclei were analyzed by snATAC (n=46,564) or snRNA (n=34,012) sequencing and included all cell types. In the diabetic proximal tubule, we observed increased expression of gluconeogenic genes *PCK1*, *ALDOB*, *FBP1*, and *G6PC* and the sodium bicarbonate exchanger, *SLC4A4* (Figure 1; green=upregulated, red=downregulated). Increased expression of *GLS* and *GLUD1* implicate glutamine as a gluconeogenic substrate. Transcriptional changes were accompanied by cell-specific differential chromatin accessibility in regulatory regions that were linked to their respective promoters via predicted chromatin interactions. Differentially accessible regions in the proximal tubule were enriched for NFkB binding motifs, suggesting it may regulate chromatin accessibility in diabetes.

Conclusions: This is the first single cell multi-omic analysis of early human diabetic kidney injury. Our analysis reveals that early diabetes induces changes in chromatin accessibility that promote gluconeogenesis and ammoniagenesis in the proximal tubule, and suggests utility for single cell multi-omic analyses.



PO0896

Mapping the Response of Murine Diabetic Nephropathy to Therapy at Single-Cell Resolution

Haojia Wu,[2] Romer A. Gonzalez-Villalobos,[1] Xiang Yao,[3] Dermot F. Reilly,[1] Matthew M. Rankin,[1] Maria chiara Magnone,[1] Eugene Myshkin,[1] Matthew D. Breyer,[1] Benjamin D. Humphreys.[2] *[1]CVM Janssen Research & Development, LLC, Boston, MA; [2]Division of Nephrology, Washington University in Saint Louis, St. Louis, MO; [3]Tox LJ Janssen Research & Development, LLC, La Jolla, CA.*

Background: Diabetic Kidney Disease (DKD) is the major cause of kidney failure in the USA. Angiotensin blockers (ACEi/ARBs) and SGLT2 inhibitors (Canagliflozin) are only two approved therapies demonstrated to slow the progression of DKD.

Methods: We treated 40 diabetic db/db hypertensive (reninAAV) mice either with ACE inhibitor (lisinopril), an SGLT2 inhibitor (JNJ-39933673), a PPARg agonist (Rosiglitazone), or vehicle control (n=10/group). Each group received either 2 days or 2 weeks of treatment. We measured BP, glucose and UACR and collected kidneys for snRNA-seq.

Results: Drug treatment at 2d and 2 wks significantly reduced BP (lisinopril), glucose (Rosi and JNJ'3673), and Uacr (lisinopril, Rosi and JNJ'3673) from baseline demonstrating that either BP or glucose control independently impact Uacr in this model. We generated 1,324,051 single nucleus transcriptomes, detecting 2,028 unique genes/cell on average. Unbiased clustering identified 19 cell clusters representing all major cell types, including rare ones such as the JGA (3,614 cells), podocytes (8,851 cells) and macula densa (MD, 4,239 cells), with differential expression of hundreds of genes across all clusters. These expression changes included JGA renin expression which was strongly downregulated by exogenous renin in ReninAAV db/db mice compared to WT. SGLT2 expression was restricted to the S1 segment of the PT, and SGLT2 inhibition acutely downregulated S1 glucose transporter Slc2a5 (Glut5) perhaps reflecting compensation. Sglt1 expression was strongly downregulated in db/db reninAAV MD, and Sglt2 inhibition partially restored this expression. MD Sglt1 has been shown to act as a glucose sensor and, inhibit tubuloglomerular feedback, so increased expression would increase GFR.

Conclusions: This is the first comprehensive single cell transcriptional atlas of the effects of diabetic nephropathy treatments in a mouse model. Drug specific and overlapping gene expression patterns were identified and should help elucidate cell-specific mechanisms of therapeutic benefit.

PO0897

The β_2-Adrenergic Receptor Agonist Formoterol Restores Mitochondrial Dynamics and Energy Production in the Diabetic Renal Proximal Tubule

Kristan H. Cleveland, Frank C. Brosius, Rick G. Schnellmann. *University of Arizona, Tucson, AZ.*

Background: While diabetic kidney disease (DKD) is the leading cause of end stage renal disease, the early pathophysiology of this disease remains poorly understood. In type 2 diabetes mitochondrial dysfunction and changes in energy metabolism occurs in proximal tubules. We examined the effects of formoterol, a β_2-adrenergic receptor (AR) agonist previously demonstrated to induce mitochondrial biogenesis and promote recovery from acute kidney injury, on renal mitochondrial homeostasis and energy production in diabetic db/db mice and in renal proximal tubule cells (RPTC) treated with high glucose.

Methods: RPTC from rabbits were isolated using the iron oxide perfusion method and grown in 0 glucose, 17mM glucose or 17mM mannitol as an osmotic control for 96 hr. ATP, uncoupled oxygen consumption rate (OCR) and mitochondrial dynamics and energetics proteins were measured. Db/db and nondiabetic db/m control mice were treated with either vehicle or formoterol (1mg/kg, i.p.) daily for three weeks beginning at 10 weeks of age. At 13 weeks, kidneys were harvested and changes in mitochondrial proteins were measured.

Results: RPTC treated with glucose for 96 hr exhibited a decrease in ATP, uncoupled OCR and the mitochondrial fusion protein Mfn1. In contrast, the fission protein pDrp1 and electron transport chain (ETC) complexes I-V increased. Treatment with formoterol (30nM) restored ATP, Mfn1, pDrp1 and ETC complex proteins to control levels. Similarly, vehicle treated db/db mice exhibited increases in ETC protein complexes I, II, III and V, and pDrp1 in renal cortex. Diabetic mice showed a decrease in Mfn1 in renal cortex. Formoterol restored complexes I, II, III and V, pDrp1 and Mfn1 to control levels in db/db mice. ATP was decreased in db/db mice and was restored to control levels with formoterol treatment.

Conclusions: Together, these in vivo and in vitro results suggest that increased glucose alters mitochondria dynamics (increase fission/decrease fusion) and decreases ATP in spite of increased ETC proteins. Formoterol reverses these glucose-induced effects and may be used as a potential therapy to prevent early disease progression of DKD.

UCP2 Activates Autophagy to Protect Against Albuminuria and Podocyte Injury in Diabetes

Qianqian Yang, Qi Sun, Junwei Yang. *Second Affiliate Hospital of Nanjing Medical Univerity, Nanjing, China.*

Background: Podocytes injury and albuminuria are leading features of glomerular damage in diabetic kidney disease. Autophagy plays an important role in maintaining podocyte homeostasis. However, the underlying mechanism remains unknown. In this study, we reported a critical role of mitochondrial uncoupling protein 2 (UCP2) in maintaining autophagic activity and protecting podocyte from hyperglycemia-induced injury.

Methods: First, to elucidate the role of UCP2 in podocyte homeostasis and injury in vivo, we generated conditional knockout mice in which UCP2 is specifically ablated in podocytes by using Cre–LoxP recombination system. Second, autophagosome was detected by transmission electron microscopy. Dual-fluorescence lentiviral mRFP-GFP-LC3 was transfected into podocyte to detect the autophagic flux. Autophagy marker, LC3II, p62 and Beclin1, were tested by quantitative real-time PCR and western blot. At last, AMPK activator and mTORC1 inhibitor were used to identify the signaling pathway UCP2-mediated to regulate autophagy.

Results: UCP2 was upregulated synchronously with autophagy marker during glomerular development. Loss of UCP2 in podocytes led to a decrease of autophagic activity and an increase of podocyte injury. Podocyte-specific knockout of UCP2 aggravated age-related proteinuria and increased podocyte susceptibility to hyperglycemia in streptozotocin (STZ) -induced DKD mice. UCP2 promotes podocyte autophagy through activation of AMPK/mTOR signaling pathway.

Conclusions: Our findings demonstrates a critical protective role of UCP2 in podocyte survival via maintaining autophagic activity through AMPK/mTOR signaling pathway.

PO0899

Darunavir Protects Mice with Type 1 Diabetes Against Kidney Injury

Xiaobo Gao, Buadi K. Tandoh, Heidi Karttunen, Michael J. Ross. *Albert Einstein College of Medicine, Bronx, NY.*

Background: Despite the success of antiretroviral therapy (ART) in improving mortality, HIV-positive persons still have increased risk of death and kidney disease and diabetes mellitus are important contributors to this excess mortality. Data from our laboratory demonstrate that the HIV protease inhibitor darunavir (DRV) prevents kidney disease in HIV-transgenic mice via mechanisms independent of HIV protease. Since diabetic kidney disease (DKD) is the most common cause of chronic kidney disease (CKD) in the general population and HIV infection predisposes persons with diabetes to more rapid progression of CKD, we studied the efficacy of DRV in a non-HIV animal model of DKD.

Methods: eNOS-/- 9 week-old C57BL/6 mice underwent induction of diabetes by administration of 5 daily 50mg/kg doses of streptozotocin (STZ) injection. Blood glucose was measured before and after DRV treatment. 14 weeks after STZ induction, mice were treated with either DRV (100mg/kg) or control by daily oral gavage for 4 weeks. Albumin-to-creatinine ratio (ACR) assay, immunocytochemistry, western blotting and real-Time PCR were performed with routine protocols. Mouse blood pressure (BP) was measured with CODA mouse tail-cuff system.

Results: STZ induced severe sustained hyperglycemia in eNOS-/- mice, which resulted in marked increase urine ACR. DRV-treated mice had a 60% decrease in UACR compared to control-treated mice but blood glucose levels did not change. DRV also reduced renal fibrosis as detected by tubulointerstitial type 1 collagen and fibronectin and prevented loss of synaptopodin expression in podocytes. Since the renin-angiotensin system (RAS) is an important contributor to DKD pathogenesis, we studied whether DRV affected expression of RAS genes. Unexpectedly, DRV increased renin expression and ACE expression in kidneys of diabetic eNOS -/- mice to levels similar to non-diabetic mice. DRV also increased endothelial CD31 and VEGFR2 expression in glomeruli, but did not change renal VEGF expression in diabetic eNOS-/- mice. Surprisingly, DRV treatment reduced mean BP in diabetic eNOS-/- mice.

Conclusions: These data demonstrate that DRV protects mice against type I diabetic renal injury. Further studies are needed to determine whether changes to renal gene expression are due to direct effects of DRV or secondary to reduced renal injury, resulting in normalization of gene expression suppression and BP.

Proteasome Mediated NF-E2 Degradation Occurs Upstream of JNK Activation-Mediated CTGF Expression in Renal Tubules and Diabetic Kidneys

Madhavi J. Rane, Jia Li, Shunying Jin, Michelle T. Barati. *University of Louisville, Louisville, KY.*

Background: TGF-β is a critical mediator of diabetes-induced renal fibrosis. We recently demonstrated that TGF-b and diabetes (Type 1 and type 2) decreased NF-E2 expression and promoted pro-fibrotic signaling in renal cells and kidneys. P38 MAPK and ERK MAPK pathways contributed to proteasome activation and NF-E2 degradation. As JNK pathway is known to induce CTGF expression, current studies examined the contribution of JNK pathway in mediating NF-E2 degradation in TGF-β treated renal tubule cells.

Methods: HK-11 cells were pre-treated with/without JNK inhibitor SP600125, p38 inhibitor SB203580, or p38 and MEK/ERK inhibitor PD98059, or proteasome inhibitor MG132, for an hour prior to treatment with TGF-b for 24 h. Cell lysates were immunoblotted with appropriate antibodies. Kidney homogenates from FVB and OVE26 diabetic mice treated with 10 μg/Kg MG132 daily for 3 mo starting at 3 mo of age when OVE26 mice already displayed significant albuminuria.were immunoblotted with appropriate antibodies. MG132 were injected intraperitoneally at a dose of 10 μg/kg daily for 3 mo starting at 3 mo of age when OVE26 mice already displayed significant albuminuria.

Results: Inhibition of p38 MAPK partially preserved NF-E2 expression but induced CTGF expression, as p38 blockade induced ERK phosphorylation. Blockade of both p38/ERK, prevented NF-E2 degradation and inhibited CTGF expression. Blockade of JNK pathway, inhibited CTGF expression without preserving NF-E2 expression. Interestingly, proteasome inhibition in renal cells and OVE26 mice preserved NF-E2 expression and inhibited JNK activation and CTGF expression suggesting JNK activation occurs downstream of proteasome activation.

Conclusions: Our studies have demonstrated that p38 and ERK MAPK pathways promote proteasome activation and NF-E2 degradation while proteasome activation promotes JNK activation and CTGF expression in renal cells and diabetic kidneys. We have recently demonstrated that NF-E2 over-expression inhibited CTGF expression however; future studies will examine effects of NF-E2 over-expression on TGF-b-induced and diabetes-induced JNK activation in renal cells.

PO0901

Single-Cell Immune Landscape of Mouse Diabetic Kidney Disease

Jia Fu, Xuan Wang, Zeguo Sun, Weijia Zhang, Kyung Lee, John C. He. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Diabetic kidney disease (DKD) is historically been considered as a non-inflammatory glomerular disease that is induced by metabolic and haemodynamic derangement. Increasing evidence suggests that renal inflammation contributes to the pathogenesis and progression of DKD. However, specific characteristics of dysregulated immune cells under diabetic conditions are poorly understood. We hypothesized that single cell RNA-seq could provide insight into the cellular mechanisms of diabetic nephropathy.

Methods: We collected kidney samples from control(n=9) and OVE26 (n=9) mice at 16 weeks. CD45+ innate immune cells were harvested by flow cytometry cell sorting and processed using 10x Genomics Chromium platform.

Results: 18000 immune cells (avg=1400 unique genes detected/cel) from control and diabetic mice were included in the integrated analysis. 17 immune cell clusters were identified and included all major immune cell types, with differential expression of hundreds of genes across all clusters. Increased expression of inflammatory cytokines was detected in particular immune cell clusters. Resident macrophages which took the majority of macrophage subtypes in the kidney are decreased after injury. Trem2high, IFN signature high, Stmn1high macrophage, and Chemokinehigh dendritic cells, which exhibited inflammatory response activation and strong ability of proliferation was observed with higher infiltration in diabetes. By Macspectrum analysis, we found a spectrum of diabetic macrophage activation states with greater complexity than traditional M1/M2 definitions. We generated a detailed diabetic immune cell intercellular communication map between macrophage, NK cell, T cell and Neutrophil. We observed restricted expression for kidney risk inflammatory signature (KRIS) in specific cell types, with macrophage showing the highest enrichment suggesting multiple unique functionalities may contribute to dysfunctional kidney physiology in diabetes.

Conclusions: This is the first comprehensive immune single cell landscape of a mouse model of DN. We demonstrate that (1) activated macrophage subtype recruitment, (2) spectrum of macrophage activation; (3) detailed diabetic immune cell intercellular communication, (3) Macrophage-specific expression of KRIS that associated with progression of ESRD in T1DM and T2DM patients.

Rab27b Repression by Foxo1 Leads to Decreased Exosome Production in Diabetic Kidneys

Mengru Zeng,[1,2] Jin Wen,[3,4] Zheng Dong.[2] *[1]Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha, China; [2]Department of Cellular Biology and Anatomy, Medical College of Georgia at Augusta University, Augusta, Georgia; [3]Yongchuan Hospital of Chongqing Medical University, Chongqing, China; [4]West China Hospital of Sichuan University, Chengdu, China.*

Background: Diabetic kidney disease (DKD) is associated with changes in exosomes. However, it is unclear whether the production or secretion of exosomes is affected in DKD. This study aims to investigate whether and how the secretion of exosomes is affected in DKD using in vivo and in vitro diabetic models.

Methods: In vivo, exosomes were isolated from kidney cortical tissues of Akita and streptozotocin-induced diabetic mice for analysis. In vitro, mouse kidney proximal tubular BUMPT cells were incubated with high glucose (30mM, HG) or mannitol (control) for 8 days to collect exosomes in culture medium. Exosomes were examined by electron microscopy (EM), nanoparticle tracking analysis (NTA), and immunoblotting. Knockdown and overexpression were used to study the roles of Rab27b and Foxo1 on exosome secretion.

Results: In vivo, diabetic mice had a reduced number of exosomes in renal cortical tissues compared with non-diabetic mice. In vitro, HG treatment led to a significant decrease in exosome secretion in BUMPT cells, which was associated with the specific downregulation of Rab27b, a key GTPase for exosome secretion. Overexpression of Rab27b restored exosome secretion in HG-treated cells, suggesting a role of Rab27b downregulation in decreased exosome secretion in DKD. For the mechanism of Rab27b downregulation, bioinformatic analysis predicted Foxo1-binding sites at Rab27b gene promoter. We demonstrated the phosphorylation of Foxo1 in HG-treated cells, accompanied by less Foxo1 accumulation in the nucleus. Overexpression of Foxo1 increased Rab27b expression, whereas Knockdown of Foxo1 had opposite effects. Moreover, expression of non-phosphorylatable (constitutively active) Foxo1 led to the upregulation of Rab27b and increases in exosome secretion in HG treated cells.

Conclusions: In diabetic kidney cells and tissues, Foxo1 is phosphorylated and inactivated, leading to decreases in Rab27b expression and consequential secretion of exosomes.

Disruption of Long Non-Coding RNA MIAT Induces Mitotic Catastrophe of Podocyte in Diabetic Nephropathy

Ziyang Wang,[1] Jinxiu Hu,[1] Qun Yu,[1] Zhimei Lv,[2,1] Rong Wang.[2,1] *[1]Department of Nephrology, Shandong Provincial Hospital, Cheeloo College of Medicine, Shandong University, Jinan, China; [2]Department of Nephrology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China.*

Background: Diabetic nephropathy (DN) is becoming the principal inducement of end-stage renal disease (ESRD) worldwide. Importantly, mitotic catastrophe (MC) is characterized as impeded mitosis-linked cell death, which plays an essential role in expediting podocyte loss and detaching from glomerular basement membrane (GBM). The concrete mechanism of MC in podocyte injury and proteinuria, however, remains inadequately elucidated. In the current study, we demonstrated the biological function and underlying mechanism of a long noncoding RNA myocardial infarction-associated transcript (Lnc MIAT) in podocytes MC.

Methods: The role of MIAT was investigated by resorting to cultured podocytes, CRISPR/Cas9 MIAT knockout mice and human samples. Immunofluorescence, western bolt, Transwell assay, TEM and histology staining including PAS and Masson staining were performed to assess the lesion of podocytes. RNA-FISH, RIP and luciferase reporter assays were utilized for mechanistic study of the interaction between MIAT, miR-130b and Sox4 further. Moreover, apoptosis and cell cycle of podocytes were detected by flow cytometry and the expression of G_2/M transition-related proteins ($p21^{cip1/waf1}$, cyclin B and cdc2).

Results: MIAT is noticeably upregulated in HG-stimulated podocytes, STZ-induced mice and serum of DN patients, accompanied by higher creatinine production and significantly lower eGFRs values in clinical. And MIAT contributes to the proliferation, apoptosis, migration and G_2/M arrest of podocytes, while depletion of MIAT significantly meliorates podocytes injury and albuminuria by restoring slit diaphragms (SD) integrity, attenuating foot processes effacement (FPE) and suppressing cyclin B/cdc2-mediated G_2/M arrest. Mechanistic investigation reveals that MIAT not only elevates Sox4 protein expression and subsequently manipulates the ubiquitination and acetylation of p53, thereby stifling downstream factors cyclin B/cdc2 via enhancing $p21^{cip1/waf1}$ activity, but also participates in crosstalk with Sox4 mRNA through competition for miR-130b binding.

Conclusions: Our findings provide plausible insight in the interplay between LncRNA MIAT, miR-130b and Sox4 which consequently lead to podocyte mitotic dysfunction involved in the progression of DN, indicating MIAT may act as a promising biomarker and therapeutic target for DN patients.

PO0904

The Decrease in Renal Cystathionine β-Synthase/Hydrogen Sulfide Was Involved in the Pathogenesis of Diabetic Nephropathy

Yanting Yu,[1,2] Zhiyun Ren,[2] Gangyi Zhu,[2] Weiwan Wang,[2] Yutao Jia,[1] Xiaoyan Wang.[2,3] The Affiliated BenQ hospital of Nanjing Medical University *[1]Department of Nephrology, BenQ Medical Center, The Affiliated BenQ hospital of Nanjing Medical University, Nanjing, China; [2]The Core Laboratory for Clinical Research, BenQ Medical Center, The Affiliated BenQ hospital of Nanjing Medical University, Nanjing, China; [3]Department of Medicine, The George Washington University, Washington DC, WA.*

Background: Hydrogen sulfide (H_2S) and its producing enzymes are associated with human diseases including coronary heart disease, Alzheimer's disease, diabetic retinopathy and obstructive kidney disease, etc.

Methods: In order to determine their roles in pathogenesis of diabetic nephropathy, we examined plasma H_2S levels in diabetic nephropathy patients and mice, renal H_2S production & H_2S producing enzymes in the mouse model, and the effects of glucose on H_2S producing enzymes, mainly Cystathionine β-synthase(CBS), in cultured mouse proximal convoluted tubule cells (mPTC).

Results: Plasma H_2S levels were decreased in patients (17.8±0.5 vs 24.8±0.8 umol/l, $p<0.05$, n=18/group) and mice(18.7±1.6 vs 40.7±1.8 umol/l,$p<0.05$,n=6/group). The renal H_2S production in mice was decreased (vs 52.1±2.9 vs 81.5±5.8 umol/l, $p<0.01$) along with the reduction of renal protein expression of CBS (52.1±13.4,% of control). A similar protein decrease of CBS(52.5±12.2, $p<0.01$) was found in cultured mPTC sitimulating by high glucose (25mmol/l D-glucose), but not CSE or MST. CBS protein expression was correlated negatively with glucose concentration (0,5,10,15,20,25,mM) ($p<0.01$). The significant decrease of CBS by glucose occurred at 1, 2, 24 and 48 hrs. Ubiquitination of CBS was increased remarkably (588.7± 140, $p<0.05$) within 1 hr of high glucose stimulation. CBS immunostaining became less strong with high glucose at the time points of 1hr & 2hr while the co-staining of CBS and LAMP2, a lysosome marker, reached the maximum at 30 min. The decrease of CBS mRNA expression was also found at points of 6 hr, 12hr. High glucose increased nitrotyrosine(NT) (170.6±22.9, $p<0.05$) in mPTC, which was restored by GYY4137, a slow-releasing H_2S donor. The expression of NT was increased by inhibition of CBS protein with its siRNA but was reversed by GYY4137 in normal glucose medium. Furthermore, in diabetic nephropathy mice, the urine albumin(58.6±6.6 vs 117.6±8.6 ug/d, $p<0.01$),mesangial matrix proliferation and glomerular basement membrane thickening were ameliorated by exogenous supplement GYY4137 at 20mg/kg for 8 weeks.

Conclusions: These findings suggest that high glucose may decrease renal CBS protein by increasing its ubiquitination / degradation and inhibiting its mRNA, eventually induce proximal tubular cell injury due to loss of protective mechanism of H_2S.

Funding: Government Support - Non-U.S.

PO0905

Lysophospholipids Predict Fast Decliners with Diabetic Kidney Disease

Kentaro Yoshioka,[2,1] Yosuke Hirakawa,[2] Kensuke Kojima,[1] Masaomi Nangaku,[2] Reiko Inagi.[3] *[1]Kyowa Kirin Kabushiki Kaisha Kenkyu Kaihatsu, Chiyoda-ku, Japan; [2]University of Tokyo School of Medicine, Bunkyo-ku, Japan; [3]University of Tokyo Graduate School of Medicine School of Medicine, Bunkyo-ku, Japan.*

Background: In type 2 diabetes, lipid metabolism disorder is frequently complicated due to insufficient insulin secretion and cytokines by visceral fat and regarded as one of the most important risk factors for renal dysfunction. However, specific lipid metabolites that have critical effects on renal dysfunction are not fully understood.

Methods: We performed the metabolomic analysis for patients with diabetic kidney disease (DKD) to identify novel metabolites related to renal prognosis. Plasma and urine biosamples in stage G3 DKD patients (n=135) are collected, and the whole metabolites of them were quantified by capillary electrophoresis mass spectrometry (CE-MS). Significantly fluctuating metabolites in patients with rapidly impaired renal function within 3 years (called "fast decliners"; about 10% in total) were statistically extracted. We also validated the metabolomic candidates with animal DKD model of SDT-fatty rats, or *in vitro* study using renal proximal tubular cells (HK-2).

Results: In the clinical metabolomic analysis of the biosamples, over 250 metabolites, including lipids, glycates, and amino acids were identified by CE-MS. Among them, specific urinary lysophospholipids (named as $LPLs_X$) in the fast decliners of DKD were significantly increased. The $LPLs_X$ were moderately correlated with eGFR decline after 3 years (r=0.42, $p<0.01$). In animal experiments, the level of $LPLs_X$ was also increased in both the urine and the kidney in the subnephrectomized SDT-fatty rats, while we did not see these damages in normal SD rats. *In vitro* experiments: the exposure of $LPLs_X$ to HK-2 induced apoptosis within 24 h and upregulated pro-apoptotic gene expressions. More physiological changes were investigated in refence to transcriptomic analysis, and we could find that $LPLs_X$ also deranged the lipid metabolism, estimated by intracellular lipid droplet accumulation, and increased the level of mitochondrial reactive oxygen species.

Conclusions: $LPLs_X$ predict "fast decliners" in DKD patients or DKD rats and may have crucial roles in renal tubular damage and dyslipidemia. Our findings provide new insights into the pathophysiological understanding of the relationship between lipid metabolism disorder and DKD progression.

PO0906

Podocyte-Specific Induction of KLF6 Attenuates Diabetic Kidney Disease in Mice

Bismark Owusu Frimpong, Nehaben A. Gujarati, Sandeep K. Mallipattu. *Division of Nephrology, Department of Medicine, Stony Brook University, Stony Brook, NY.*

Background: Krüppel-Like Factor 6 (KLF6), a zinc finger transcription factor, is a key regulator of cytochrome c oxidase assembly in the podocytes. Podocyte-specific *Klf6* knockdown increases the susceptibility to streptozotocin (STZ) induced-diabetic kidney disease (DKD). However, salutary effects of podocyte-specific *KLF6* induction in DKD remain to be explored.

Methods: Podocyte-specific inducible human KLF6 (*hKLF6*) was generated in mice using the "Tet-on" system, by breeding *NPHS2-rtTA* mice with newly generated *TRE-hKLF6* to generate *hKLF6^{PODTA}* mice. *TRE-KLF6* transgene were generated using the (TetO)7/CMV regulatory element driving the full-length human *KLF6* coding sequence (CCDS 7060.1). Transgene was purified from plasmid vector sequences and microinjected into the pronucleus of *FVB/N* single-celled embryos. Founder mice were selected based on the level of *hKLF6* induction after doxycycline (DOX) treatment. STZ + Unilateral nephrectomy (STZ-UNX) was utilized to induce DKD in mice. First, DOX diet was administered at 8 weeks of age in all mice. UNX or Sham was performed at 10 weeks of age followed by low-dose STZ or vehicle (VEH) treatment respectively, at 12 weeks for 5 consecutive days. DOX-STZ-UNX treated *NPHS2-rtTA,* DOX-VEH-Sham treated *NPHS2-rtTA* and *hKLF6^{PODTA}* mice served as controls. All mice were euthanized at 20 weeks of age and assessed for functional and histological changes in the kidney.

Results: DOX-STZ-UNX treated *hKLF6^{PODTA}* mice exhibited significantly lower albuminuria, focal and global glomerulosclerosis, mesangial expansion, and improved mice survival as compared to age and gender-matched DOX-STZ-UNX treated *NPHS2-rtTA* mice. DOX-STZ-UNX treated *hKLF6^{PODTA}* mice also exhibited less tubulointerstitial fibrosis and inflammation (pathology scoring) as compared to age- and gender-matched DOX-STZ-UNX treated *NPHS2-rtTA* mice.

Conclusions: These data suggest that podocyte-specific induction of human *KLF6* attenuates podocyte injury and DKD, and improves overall survival in mice.

nPOD-Kidney, a New Tool for Investigating Diabetic Kidney Disease

Florence Anquetil,[1] Vivek Das,[1] Heather H. Ward,[1] Charles E. Alpers,[2] Xu Zeng,[3] Johnna D. Wesley,[1] Anil K. Karihaloo.[1] *[1]Novo Nordisk Research Center Seattle, Inc., Seattle, WA; [2]University of Washington School of Medicine, Seattle, WA; [3]University of Florida Health Pathology Laboratories, University of Florida Health, Gainesville, FL.*

Background: Diabetic kidney disease (DKD) is a common complication of diabetes, yet it remains poorly understood. The network for Pancreatic Organ donors with Diabetes - Kidney (nPOD-K) project was initiated to assess the feasibility of evaluating human kidneys from organ donors with long-standing diabetes (>8 years), with the long-term goal of improving our understanding of DKD pathogenesis.

Methods: Formalin-fixed paraffin-embedded sections from nPOD-K were stained for specific renal cell and disease markers by multiplex immunofluorescence, followed by periodic acid-Schiff (PAS) staining. Whole sections were imaged using an Axioscan Z1 scanner (20X objective) and quantitative image analyses were performed using Visiopharm software

Results: Tissue integrity and histological stage were independently assessed by two renal pathologists. The majority of cases presented a moderate or severe diagnosis, and 20% of the cohort displayed no overt sign of kidney disease despite long-standing diabetes. Algorithms for automatic segmentation of kidney compartments (e.g. glomeruli, tubules) in the PAS layer were then developed using deep convolution neural network DeepLabV3+. We achieved a DICE coefficient of 0.95 for glomeruli and 0.89 for tubules. Quantification of renal markers was performed using machine learning classification methods. In accordance with published studies, our quantitation demonstrated loss of podocyte marker WT1, endothelial marker CD31, and tubular marker *Lotus tetragonolobus* lectin correlating with the progression of DKD, concomitantly with increased tubular atrophy and expression of fibrotic markers.

Conclusions: In conclusion, kidneys obtained from organ donors are viable and display all expected features of human DKD at the level of light microscopy. This cohort provides a unique opportunity to better understand DKD pathophysiology through analysis of large, CKD stage-specific regions. Similar to the results from the nPOD pancreas cohort, all histological stages of disease can be detected in affected kidneys, providing a pseudo-timeline of the evolution of DKD and supporting the potential to identify novel therapeutic targets.

Nerve Growth Factor Protects Podocyte Apoptosis by Regulating Sirt1 Expression

Jing E, Yali Zheng. Ningxia People' Hospital *Ningxia People's Hospital, Yinchuan, China.*

Background: Podocyte injury contributes to the progression of diabetic kidney disease (DKD). In the previous studies, we demonstrate that expression of Cdk5/p35 play an important role in the diabetic kidney and associated with the progression of DKD in human. As know, podocyte can secret NGF and Sirt1 is one substrate of CDK5, so the objective of this article is to investigate the mechanism of NGF protecting podocyte apoptosis by regulating Sirt1 expression and to provid a new biological target for clinical treatment.

Methods: The immortalized mouse podocyte was cultured in vitro, then were transfected with control siRNA or siNGF vector to detect protein level of Sirt1 and apoptosis associated protein Cleaved caspase3 through western blot. In addition, podoctyes were also given different concentration of NGF to detect the expression of Sirt1 and Cleaved caspase 3 in order to find the relationship of NGF and Sirt1, and the role of NGF on podocytes.

Results: To understand the role of NGF on podocyte, we stimulated immortalized mouse podocytes with NGF in different concentration, the protein level of Sirt1 was positive associated with NGF expression. 2. Podocytes were transfected with control siRNA or siNGF vector by using ViaFect™ Kit, the effect of siNGF was verified by western blot. knockdown of NGF decreased the expression of Sirt1 and Cleaved caspase. 3. When gave NGF stimulation, the protein lelvel of Cleaved caspase3 was deceaed.

Conclusions: NGF plays a key role in protection podocyte by regulating the expression of Sirt1, NGF/SIRT1 axis may be a new biological target for preventing podocyte injury.

Integrin aVb8/TGF-b Activation in Kidney Is Associated with Renal Function Deterioration and Can Be Monitored in Urine

Xiaozhen Wang,[1] James Conway,[1] Kristina Kovacina,[3] Stephanie C. Heasman,[4] Elena Liarte Marin,[4] Sonja Hess,[1] Chelsea Boo,[1] Denis Feliers,[4] David J. Baker,[4] Marvin V. Sinsakul,[1] Iain MacPhee,[4] Viknesh Selvarajah,[4] Sven M. Moosmang,[5] Judith Hsia,[2] Judith Hartleib-Geschwindner.[5] *[1]AstraZeneca, Gaithersburg, MD; [2]University of Colorado, Aurora, CO; [3]Astrazeneca, South San Francisco, CA; [4]AstraZeneca UK Ltd, Cambridge, United Kingdom; [5]AstraZeneca, Gothernburg, Sweden.*

Background: Integrin-TGFb activation plays a central role in fibrosis. The specificity of TGFb activation is regulated by the expression of integrin isoforms in tissues. We set out to study molecular signatures associated with various aetiologies in CKD, the specific integrins that modulate TGFb activation and fibrotic initiation in the kidney and the potential for non-invasive monitoring of renal TGFb activation.

Methods: Kidney biopsies were obtained from CKD cohorts of diverse aetiologies and living donor (LD) controls. Gene profiling data (Microarray) were obtained from glomeruli and tubulointerstitium. Renal integrin expression was evaluated and the correlation with TGFb activation as well as eGFR was assessed.

Results: In the Gene Set Variation analysis (GSVA), fibrosis signatures including collagen signature increased with CKD severity compared to LD. This was more prominent in diabetic nephropathy (DN) in both glomeruli (N=12, p=1.09e-04) and tubulointerstitium (N=17, 2.31e-04). Further analysis showed that renal integrin b8 (ITGB8) was enriched and elevated at CKD stage 2, maintained at the similar level at

stage 3 and 4. ITGB8 was higher in DN tubolointerstitium (FC=1.23, p=5.56e-04, N=17) vs LD. Consistent with this, immune-histochemistry showed that ITGB8 protein was increased in tubular tissues in kidney biopsies from DN patients and co-localized with areas of fibrosis. Moreover, TGFb activation signature of 30 genes was significantly correlated with ITGB8 expression (R=0.58, p=2.39e-16, N=169) and inversely correlated with eGFR (p<0.01). Active TGFb was detectable in urine by a Simoa immunoassay. The active TGFb/creatinine ratio was increased by 4.4 fold (p=0.0003) in CKD subjects (median: 7.5 ug/g, N=20) compared to non-CKD controls (1.4 ug/g, N=20). The level of active TGFb in urine can potentially identify patients at risk for fibrosis and progression of renal dysfunction.

Conclusions: In conclusion, fibrosis is associated with CKD severity, most prominent in DN. Integrin b8 is enriched in DN and correlates with TGFb activation. The fibrosis status may be monitored via measuring active TGFb in urine.

PO0910

Omentin 1 and Histone 1 Variants as Remote Candidate Prognostic Biomarkers of CKD Among People with Type 1 Diabetes Mellitus (T1DM)

Michael Merchant,[1] Jian Cai,[1] Adam E. Gaweda,[1] Michelle T. Barati,[1] Michael E. Brier,[1] Ming Li,[1] Minghao Ye,[4] Jan Wysocki,[4] Brad H. Rovin,[3] Mark E. Molitch,[4] Daniel Batlle,[4] Jon B. Klein.[1,2] *[1]University of Louisville Health Sciences Center, Louisville, KY; [2]Robley Rex VA Medical Center, Louisville, KY; [3]The Ohio State University Wexner Medical Center, Columbus, OH; [4]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: It has been difficult to identify biomarkers that antedate the development of CKD. In a previous study we identified omentin-1 and histone H1 (HISTH1) variants as candidate surrogate prognostic biomarkers associated with future CKD development in T1DM Diabetes Control and Complications Trial (DCCT) study participants. Work presented here extends these findings into the follow-up samples from the Epidemiology of Diabetes Interventions and Complications (EDIC) study.

Methods: Paired-serum samples from 23 controls (defined as participants with stable renal function) and 23 cases (defined as participants who went on to develop CKD stage 3 (GFR<60ml/min/1.73m2) were examined prior to and following the development of CKD. HISTH1 variant proteins were quantified using a parallel reaction monitoring (PRM) LCMS method to quantify HISTH1-variant specific peptides unique to H1.1, H1.2, H1.3, and H1.4. Omentin-1 was quantified using a commercial ELISA kit for omentin-1 (BioVendor; Asheville, NC). Protein abundance data were analyzed using Kruskal-Wallis rank sum tests with an unadjusted p-value 0.05 considered significant.

Results: HISTH1 peptides did not differentiate (p>0.05) DCCT cases and controls. HISTH1.3 was significantly increased in EDIC cases over controls. A multivariate logistic regression analyses of histone peptides identified HISTH1.4 as best able classify case or control DCCT-to-EDIC progression (p<0.05). Omentin-1 quantification confirmed discovery findings (DCC control >case, fold-change 1.2, p<0.05). Additionally, in cases, omentin-1 increased significantly (p<0.0001) from the DCCT to the EDIC (1.4) whereas it did not (p=0.06) in controls (fold-change 1.1).

Conclusions: Plasma HISTH1 variants levels did not predict future CKD3 status but did predict DCCT versus EDIC cohorts. Increased plasma omentin-1 levels in DCCT cohort were associated with stable renal function but in EDIC cohort were associated with CKD stage 3. These data suggest a role for omentin-1 or pathways regulating omentin-1 expression are associated with progression of kidney function loss in T1DM.

Investigations on Urinary Exosomal MiRNA Biomarkers That Reflect Pathologic Features of Patients with Diabetic Kidney Diseases

Seo Jung-Woo,[1,2] Yu ho Lee,[3] Miji Kim,[1] Yang gyun Kim,[1,4] Sangho Lee,[1,4] Jin sug Kim,[4] Hyeon Seok Hwang,[4] Kyung hwan Jeong,[4] Hye yun Jeong,[3] So-young Lee,[3] Dong Ho Yang,[3] Ju young Moon.[1,4] *[1]Division of Nephrology, Department of Internal Medicine, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [2]Department of Core Research Laboratory, Medical Science Institute, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea; [4]Division of Nephrology, Department of Internal Medicine, Kyung Hee University Medical Center, Seoul, Republic of Korea.*

Background: Diabetic kidney disease (DKD) is a leading cause of end-stage renal disease worldwide. Although histological severity of DKD is a well-established predictor of adverse renal outcomes, investigations on the identification of non-invasive biomarkers that can reflect intrarenal status are scarce. The aim of this study was to discover urinary exosomal miRNA biomarkers of DKD and to examine their associations with the degree of various pathologic injury scores.

Methods: We collected and analyzed urinary samples obtained from 95 patients with biopsy-proven DKD and 32 healthy controls. The candidate microRNAs of DKD were selected based on the analysis of GEO dataset (GPL22945 and GPL24120) and public microRNA databases (miRTarBase, TargetScan, microRNA). Urinary exosomes were extracted by column-based isolation kit, and the levels of selected candidate microRNAs were measured by quantitative real-time polymerase chain reaction.

Results: Mean estimated glomerular filtration rate and urinary protein-to-creatinine ratio of enrolled DKD patients were 46.0 mL/min/1.73 m^2 and 6.8 g/g creatinine, respectively. Upon the analysis of public dataset, we identified 11 candidate microRNAs for DKD, whose expression in urinary exosomes were all significantly higher in patients with DKD compared to controls. In particular, urinary exosomal miR-30a-5p and miR-335-3p levels showed positive correlation with the degree of interstitial inflammation and arterial hyalinosis, respectively. There was no significant association between the remaining microRNAs and the degree of glomerular injury, tubulointerstitial fibrosis, or arteriosclerosis. Finally, we found significant correlation between urinary protein-to-creatinine ratio and the levels of urinary exosomal miR-98-5p.

Conclusions: Urinary exosomal microRNAs could reflect the degree of intrarenal pathologic status in patients with diabetic kidney disease.

PO0912

Urine Biomarkers of Tubulointerstitial Injury in Diabetic Kidney Disease

Xiaolan Zhang, Li Zhang, Clarissa A. Cassol, Brad H. Rovin. The Ohio State Univeristy *The Ohio State University, Columbus, OH.*

Background: Diabetic kidney disease (DKD) is a serious complication of diabetes. Chronic damage to the tubulointerstitium often predicts loss of kidney function, but kidney biopsies are seldom obtained during the routine clinical care of patients with presumed DKD. This study was done to identify non-invasive urine biomarkers that reflect kidney histology in DKD.

Methods: Urine and serum were collected from 34 diabetic patients at the time of kidney biopsy, and from 30 healthy volunteers who served as controls. Biopsies were read by a nephropathologist. The severity of interstitial fibrosis/tubular atrophy (IFTA) was reported semi-quantitatively using Tervaert's Score. Epidermal growth factor (EGF), NGAL, and complement component C5a were measured in urine and serum by ELISA. Analyte levels were compared between patients and controls and correlated to histologic lesions using ANOVA, the Wilcoxon test, linear regression, and logistic model fitting.

Results: Compared to controls, urine (u)C5a and uNGAL levels were about 359 and 20-fold higher, and uEGF levels were 4-fold lower in the DKD cohort (all p<0.0001). Serum and urine C5a and EGF were not correlated, but there was a modest correlation between serum and urine NGAL (r2 0.41, p 0.0024). uEGF was negatively correlated with IFTA (r2 0.41, p < 0.0001) while uC5a, uNGAL, and serum (s)NGAL were positively correlated (r2 0.21, p=0.009; r2 0.17, p=0.02; r2 0.46, p=0.0007). Receiver operating characteristic (ROC) curves were modeled to determine the best combination of biomarkers to distinguish between mild, moderate, and severe IFTA in DKD. The model with a combination of uEGF+sNGAL yielded an area under the ROC curve (AUC) of 1.00 to differentiate mild from moderate IFTA, an AUC of 0.86 to differentiate mild from severe IFTA. The model with uEGF+uNGAL+uC5a gave an AUC of 0.94 to differentiate moderate from severe IFTA. These composite biomarkers outperformed serum creatinine (AUC 0.9 mild-moderate; AUC 0.82 mild-severe; AUC 0.74 moderate-severe) and proteinuria (AUC 0.76 mild-moderate; AUC 0.67 mild-severe; AUC 0.60 moderate-severe).

Conclusions: Urine EGF, C5a and serum and urine NGAL reflect chronic tubulointerstitial damage in patients with DKD. These biomarkers may be useful for monitoring the effectiveness of treatment to slow progression of DKD.

PO0913

Renoprotective Effect of a GLP-1 Receptor Agonist, Liraglutide, in an Early Phase of Diabetic Kidney Disease in Spontaneously Diabetic Tori Fatty Rats

Shohei Yamada,[1] Jun Tanabe,[1] Takeshi Sugaya,[1] Daisuke Ichikawa,[1] Kenjiro Kimura,[2] Yugo Shibagaki,[1] Atsuko Ikemori.[3] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [2]JCHO Tokyo Takanawa Hospital, Shinagawa, Japan; [3]Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.*

Background: Early intervention is extremely needed for preventing the progression of diabetic kidney disease (DKD) to end stage renal disease. The aim of this study is to investigate the renoprotective effect of GLP-1 receptor agonist, liraglutide, in early phase of DKD and to determine the mechanisms underlying its effects using an animal model of type 2 diabetes with various metabolic disorders.

Methods: Male spontaneously diabetic torii (SDT) fatty rats (n = 30) at 8 weeks of age were randomly assigned to three groups; the liraglutidegroup (n = 11) was subcutaneous injected liraglutide. Another treatment group(n = 6) was subcutaneous administered insulin against hyperglycemia and was given hydralazine against hypertension for matching both levels of blood glucose and blood pressure with the liraglutidegroup. A control group (n = 13) was injected only a vehicle. Urinary tubular marker, L-type fatty acid-binding protein (L-FABP), was measured to evaluate the effect of liraglutide against tubulointerstitial damage.

Results: Control group of SDT fatty rats exhibited hyperglycemia, obesity, hypertension, glomerular sclerosis and tubulointerstitial injury with high levels of urinary albumin and L-FABP, whereas treatment with liraglutide reduced body weight, food intake, both blood glucose and blood pressure levels, as well as, amelioration of renal pathological findings with lower levels of both urinary albumin and L-FABP. Liraglutide increased in expressions of both phosphorylated (p)-eNOS and p-AMPK in glomeruli. It also down-regulated renal expression of p-mTOR, and up-regulated renal expressions of LC-3 II, suggesting activation of autophagy. However, these effects were not brought

by the treatments of both insulin and hydralazine, despite comparable levels of both hyperglycemia and hypertension to those of liraglutide.

Conclusions: Liraglutide may exert a renoprotective effect via prevention of glomerular endothelial dysfunction and acceleration of autophagy in the early phase of DKD, independently of both blood glucose and blood pressure levels. Furthermore, urinary L-FABP may be a useful marker reflecting the therapeutic efficacy of liraglutide.

PO0914

PLVAP as a Novel Marker for Endothelial Injury in Diabetic Nephropathy

Elena E. Wolf,[1] Anne Steglich,[1] Friederike Kessel,[1] Florian Gembardt,[1] Jan Sradnick,[1] Simone Reichelt-Wurm,[2] Kathrin Eidenschink,[2] Miriam C. Banas,[2] Christian Hugo,[1] Vladimir T. Todorov.[1] *[1]Division of Nephrology, Department of Internal Medicine III, University Hospital Carl Gustav Carus, TU Dresden, Dresden, Germany; [2]Department of Nephrology, University Hospital Regensburg, Regensburg, Germany*.

Background: Diabetic nephropathy (DN) is associated with endothelial cell dysfunction and progressive loss of kidney function. The plasmalemma vesicle associated protein (PLVAP) has been found to be necessary for the formation of endothelial diaphragms in fenestrae, caveolae, and transendothelial channels. In the adult kidney, glomerular endothelial cells lack diaphragms in the fenestrae. Previous studies reported glomerular expression of PLVAP in transplant glomerulopathy, in mesangioproliferative glomerulonephritis model and in mice developing renal thrombotic microangiopathy as a consequence of defective Gsα/cAMP signaling in renin cells. Therefore, we investigated whether PLVAP expression in glomerular capillaries is induced in different models of DN.

Methods: To induce a model of type 1 diabetes, one dose of streptozotocin (STZ, 180 mg/kg) was administered by intraperitoneal injection in 6-8 weeks old mice. 16-week-old black and tan brachyuric (BTBR) ob/ob mice, with spontaneous mutation in the leptin gene were used as a model of type 2 diabetes. Immunohistochemical staining and analysis was performed to examine the expression of PLVAP. We co-stained the Intercellular Adhesion Molecule 2 (ICAM2) as a marker for endothelial cells.

Results: Glomerular hypertrophy was found in STZ mice and BTBR ob/ob mice, which was interpreted as evidence for successful induction of DN (STZ: 2750 μm^2, control: 2527 μm^2; BTBR ob/ob: 4471 μm^2, control: 2295 μm^2). Using immunohistochemical analysis, the BTBR ob/ob mice and the STZ mice revealed induced PLVAP expression in their glomeruli, as compared with non-diabetic controls ($p<0.05$ respectively). ICAM2 expression in glomeruli of STZ mice tended to be lower than in control mice, but the difference was not statistically significant. In BTBR ob/ob mice, the expression of ICAM2 was significantly decreased compared to control mice ($p<0.05$).

Conclusions: Our results indicate that the glomerular expression of PLVAP is induced in diabetic nephropathy. The protein PLVAP represents a potential novel marker for endothelial injury in diabetic nephropathy.

PO0915

MTORC1/STAT1 Signaling Stimulates CFB Expression and Alternative Complement Pathway Activation to Induce Podocyte Dysfunction and Diabetic Kidney Disease

Qingmiao Lu, Chunsunb Dai. *Nanjing Medical University, Nanjing, China*.

Background: Alternative complement pathway activation has been reported in diabetic kidney disease (DKD). However, the role and mechanisms for regulating alternative complement pathway activation in podocyte dysfunction and DKD are not understood.

Methods: STZ-induced DKD mice, db/db mice, Podocyte-specific TSC1 deletion mice were used.

Results: The analysis of GSE30528 data and the immunohistochemical staining results showed that mTORC1 signaling, STAT1, complement factor B (CFB) and complement alternative pathway were activated in podocytes from patients and animal models with DKD. Knocking down CFB remarkably alleviated podocyte loss, glomerular basement membrane thickening, mesangial expansion, and proteinuria in DKD mice. In addition, ablation of Tsc1 in podocytes led to mTORC1 and STAT1 signaling activation, CFB induction, and alternative complement pathway activation in the glomeruli. In cultured podocytes, high glucose culture could activate mTORC1 signaling, stimulate STAT1 phosphorylation and upregulate CFB expression. Blockade of mTORC1 or STAT1 signaling could abolish high glucose upregulated CFB expression in podocytes.

Conclusions: This study uncovers that mTORC1/STAT1 activation in podocytes may promote DKD progression through activating complement alternative pathway.

Loss of Nrf2 Exacerbates Diabetic Kidney Disease in Akita Mice

Yexin Liu,[1,2] Akira Uruno,[1,3] Masayuki Yamamoto.[1,3] *[1]Department of Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Department of Nephrology, The Second Xiangya Hopital, Central South University, Changsha, China; [3]Department of Integrative Genomics, Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan*.

Background: Diabetic kidney disease (DKD) is a devastating microvascular complication with considerable mortality in patients with diabetes mellitus. Excessive reactive oxygen species and inflammation have been identified as major components in the progression of this microvascular complication. Transcription factor Nrf2 (NF-E2-related factor-2), which plays essential roles in protection against oxidative/xenobiotic stresses, is known to alleviate inflammation and oxidative tissue damage. We hypothesized that keeping Nrf2 activated is beneficial for the treatment of DKD.

Methods: To clarify roles Nrf2 plays in the pathogenesis of DKD, we generated *Nrf2*-knockout Akita mice (Akita::Nrf2$^{-/-}$) by crossing *Ins2*$^{Akita/+}$ (Akita) mice (C57BL/6J) with *Nrf2* knockout (Nrf2$^{-/-}$) mice (C57BL/6J). Phenotypic parameters of male mice were measured, and samples were harvested from the mice at 4 months.

Results: We found that Akita::Nrf2$^{-/-}$ mice displayed more pronounced hyperglycemia and diabetes symptoms than Akita mice did. While expression of Nrf2-tageted genes *Nqo1* and *Hmox1* was induced in Akita mouse kidneys; the expression was significantly reduced in kidneys of Akita::Nrf2$^{-/-}$ mice. Histologically, Akita mice showed modest mesangial expansion, but Akita::Nrf2$^{-/-}$ mouse glomeruli showed marked distended capillary loops suggesting enhanced mesangiolysis. Akita::Nrf2$^{-/-}$ mice exhibited dilated distal tubules mainly within cortex, which might be associated with osmotic polyuria and oxidative stress-mediated injury; this notion was supported by increased tubular staining of oxidative stress marker 8-OHdG. Nrf2-deficiency in Akita mice contributed to the decrease of glutathione (GSH), which was assessed by *in situ* matrix-assisted laser-desorption/ionization mass-spectrometry imaging (MALDI-MSI) and lowered expression of GSH-synthesis related genes. Kidneys of Akita::Nrf2$^{-/-}$ mice suffered from severe inflammation, which was evidenced by increased infiltrated monocytes/macrophages and elevated pro-inflammatory cytokine expression. Interstitial fibrosis was developed in the Akita::Nrf2$^{-/-}$ mouse kidneys along with increased expression of fibrogenic genes.

Conclusions: These results demonstrate that Nrf2-deficiency exacerbated inflammatory response, oxidative stress and interstitial fibrosis in the Akita mouse kidneys, indicating that Nrf2 plays important roles in the protection of DKD kidneys.

The Novel Soluble Guanylyl Cyclase (sGC) Activator Runcaciguat Improves Cardiorenal Morbidity in a Diabetic Rat Model of CKD

Agnes M. Benardeau, Johannes-Peter Stasch, Michael G. Hahn, Mira Pavkovic, Ilka Mathar, Jan R. Kraehling, Frank Eitner, Peter Sandner. *Bayer AG, Leverkusen, Germany*.

Background: Patients with chronic kidney disease (CKD) and Type-2-Diabetes (T2D) have a high risk of kidney failure and cardiovascular events. CKD and T2D are associated with oxidative stress impairing NO/sGC signaling thus driving CKD progression. Runcaciguat is a novel potent and selective, sGC activator able to restore sGC signaling by activating the oxidized and heme-free sGC. Here we investigated the therapeutic potential of Runcaciguat in a rat model of T2D associated CKD.

Methods: Cardiorenal morbidity was studied in diabetic and proteinuric rats. Rats (ZDF/Crl-Lebr-fa/fa, 22 weeks old male, n=20/group) were treated orally for up to 42 weeks with Runcaciguat (3 mg/kg) or placebo. Key outcome parameters included mortality, blood pressure, proteinuria, kidney histology, biomarkers of kidney and heart damages, and gene expression.

Results: Proteinuria steadily increased over time in the placebo arm (uPCR (g/mmol) 0.9±0.1 @ baseline, 1.8±0.1 @12 wk, 5.9±0.7 @42 wk)) and was significantly reduced in the Runcaciguat arm (0.8±0.1 @ 12 wk, 3.0±0.5 @ 42 wk). Improved proteinuria was paralleled by significantly improved glomerular filtration rates @ 42 wk (55±5 ml/min vs. 36±9 in the placebo arm). Histological examination of kidney revealed that Runcaciguat strongly reduced tubular dilation, glomerulopathy and accumulation of protein cylinders. Runcaciguat significantly improved left ventricular heart weight as well as several kidney and heart injury markers in urine and in plasma.

Conclusions: The novel sGC activator Runcaciguat improved kidney and heart function and structure in a preclinical diabetic and hypertensive rat model and may become an effective treatment option for diabetic and chronic kidney disease patients.

PO0918

RNA-Binding Proteins Tristetraprolin and Human Antigen R Are Novel Modulators of Podocyte Injury in Diabetic Kidney Disease

Jia Guo,[1] Rujun Gong,[2] Zhangsuo Liu.[1] *[1]Zhengzhou University First Affiliated Hospital, Zhengzhou, China; [2]The University of Toledo, Toledo, OH*.

Background: Diabetic kidney disease (DKD) is one of the most common complications of diabetes and the most common cause of end-stage renal disease, with no definitive therapy yet available to halt its progression. As key RNA-binding proteins (RBP) that play a pivotal role in epigenetic regulation, Tristetraprolin (TTP) and human antigen R (HuR) competitively bind to mRNAs of myriad cytokines, exert opposite effects on RNA stability, and dictate overall inflammatory states. However, the roles of these RBP in diabetes-related glomerulopathy is poorly understood. Herein, we investigated whether and how TTP and HuR are involved in the posttranscriptional regulation of podocytopathic molecules and inflammatory cytokines in DKD.

Methods: Kidney tissues were procured from diabetic patients and from db/db mice. Quantitative RT-PCR was performed to measure mRNA expression levels of *IL-17* and *claudin-1*. Lentivirus vector transduction was employed to overexpress or silence target proteins. RNA immunoprecipitation (RIP) and co-immunoprecipitation assays were used to identify RNA-protein and protein-protein interactions.

Results: In DKD patients and db/db mice, TTP expression was significantly decreased and HuR expression was increased in glomerular podocytes, concurrent with podocyte injury, histological signs of DKD, and augmented glomerular expression of interleukin (IL)-17 and claudin-1, which are targets of TTP and HuR, as evidenced by RNA

immunoprecipitation. In cultured podocytes, exposure to high ambient glucose amplified HuR expression and repressed TTP expression, upregulated IL-17 and claudin-1, and promoted podocyte injury. Thus, TTP hypoactivity or HuR hyperactivity is sufficient and essential to diabetic podocytopathy. Moreover, in silico analysis revealed that several kinases govern phosphorylation and activation of TTP and HuR, and glycogen synthase kinase (GSK)-3β activated both TTP and HuR, which harbor putative GSK-3β consensus phosphorylation motifs.

Conclusions: TTP and HuR are dysregulated in DKD via a GSK3b-mediated mechanism and play crucial roles in podocyte injury via posttranscriptional regulation of diverse molecules implicated in inflammation and podocytopathy. Our findings provide novel insights into the mechanism of and identify therapeutic targets for diabetic kidney disease.

Nogo-B and Soluble Nogo-B Modulate VEGFA/VEGFR2 Signalling in Glomerular Endothelial Cells

Carlo Alberto Ricciardi,[1] Ivan Hernandez,[1] David A. Long,[2] Luigi Gnudi.[1] *[1]King's College London Faculty of Life Sciences and Medicine, London, United Kingdom; [2]University College London, London, United Kingdom.*

Background: Nogo-B is an endoplasmic reticulum protein present either as a full-length or circulating soluble isoform (sNogo-B) corresponding to the first ~200aa of the N-terminus. Nogo-B is expressed in the vasculature and in glomerular endothelial cells (GECs) and downregulated in diabetic glomeruli. Overexpression of sNogo-B ameliorates diabetic glomerulopathy, but the biological mechanisms are unknown. We hypothesise that, in GECs, Nogo-B and/or sNogo-B modulate VEGFA/VEGFR2 signalling and vascular remodelling.

Methods: Nogo-B deficient human GECs were generated with CRISPR/CAS9 technology. VEGFA signalling was studied in differentiated, serum starved (5 h, FBS 2%) GECs exposed to VEGFA (50 ng/ml) for 5, 10 and 15 min. VEGFR2 phosphorylation (Tyr1175) was assessed with western immunoblotting. Experiments were conducted in GECs transfected with adenoviral vector expressing sNogo-B or control vector. To investigate the role of Nogo-B on GECs survival, Caspase-3/7 activity was utilised as marker of apoptosis in WT and Nogo-B deficient GECs after 5 h incubation in 2% FBS. *In vivo* Matrigel-angiogenesis assay in wild-type (WT) and Nogo-A/B deficient mice were conducted in parallel.

Results: When compared to WT GECs, Nogo-B deficient cells appeared more elongated with a peripheral distribution of F-actin but maintained expression of endothelial markers such as eNOS and CD31. Phosphorylated VEGFR2/total VEGFR2 ratio was similar in baseline condition in WT and Nogo-B deficient GECs. VEGFA-mediated VEGFR2 phosphorylation (15 min) was observed in WT GECs but not in Nogo-B deficient GECs ($p<0.01$). In the presence of sNogo-B, there was significant reduction in VEGFA-mediated VEGFR2 phosphorylation in WT GECs ($p<0.05$). There was no significant effect of sNogo-B on VEGFR2 phosphorylation in Nogo-B deficient GECs. Apoptosis was higher in Nogo-B deficient GECs when compared to WT ones ($p<0.04$). Preliminary work in *in vivo* Matrigel angiogenesis showed that Nogo-B deficient ECs were unable to form vascular structure when compared to wild-type cells ($P<0.05$). Presence of sNogo-B blunted the angiogenesis in WT mice.

Conclusions: Nogo-B is required for VEGFA-mediated VEGFR2 phosphorylation and for vascular remodelling (angiogenesis). Overexpression of sNogo-B blunts VEGFA-mediated VEGFR2 phosphorylation. sNogo-B could represent a tool to modulate VEGFA signalling in diseases.

PO0920

Cytosine Methylation Changes in Early Diabetic Kidney Disease (DKD) in a Pima Indian Cohort

Katie Sullivan,[1] Chengxiang Qiu,[2] Hongbo Liu,[1] Robert G. Nelson,[3] Robert L. Hanson,[3] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]University of Washington, Seattle, WA; [3]National Institutes of Health, Bethesda, MD.*

Background: Pima Indians of Arizona have an extremely high prevalence of type 2 diabetes and DKD. Genetically related Pima Indians living in Mexico, whose lifestyle remains traditional, have a much lower prevalence of these morbidities. The differences in lifestyle indicate that environmental factors play an important role in disease origins and suggest involvement of epigenetic programming. We analyzed cytosine methylation (5mC) changes in Pima Indians from Arizona.

Methods: 327 Pima Indians (205 women, 122 men) were selected from a longitudinal cohort, all had an eGFR greater than 60ml/min and ACR <300mg/g at baseline. DNA methylation from peripheral blood leukocytes was analyzed on an Illumina Infinium HumanMethylation 450 Beadchip. Preprocessing and Quality Control were performed using Minfi Package, normalization was performed using BMIQ. Methylation changes were expressed transformed to M values. Covariates included age, sex, duration of diabetes, mean blood pressure, HbA1c, genotype, batch, cell count and conversion efficiency. P-values were corrected for multiple comparisons.

Results: Mean age was 42.4±11.9 years, diabetes duration 7.8±7.5 years, HbA1c 8.8±2.4%, GFR 107±16 ml/min and median albuminuria was 20.2[48.2]mg/g. Subjects were followed for a median of 10 years (range 3-17 years) and had a mean GFR decline of 2.0±2.8 ml/min/year. Ranked regression, adjusted for key variables, identified 20 probes that passed the corrected significance threshold for kidney function decline. Most significant probes were enriched on gene regulatory regions such as promoters and enhancers. The top identified probe was cg05711886 around the Maternally expressed gene 3 (MEG3)on chromosome 14, ($p=2.66E-10$). MEG3 is a non-coding RNA previously associated with diabetic microvascular complications. Other probes included cg11306628 ($p=1.62E-5$) in Platelet Derived Growth Factor Alpha (PDGFA) on chromosome 7, a known type 2 diabetes risk gene, as well as cg06392169 ($p=3.14E-5$) in Interferon Related Factor 4 (IRF4) on chromosome 6 and cg12577105 ($p=4.11E-5$) in Corticotrophin Releasing Hormone Receptor 1 (CRHR1) on chromosome 17 involved in the HPA axis.

Conclusions: We identified cytosine methylation changes that correlated with early kidney function decline in Pima Indians with type 2 diabetes.

PO0921

Pathogenic Impact of Altered Leptin in Diabetes Induced by Genetic Deletion of the Canonical Transient Receptor Potential Channel 1 (TRPC1): Role of Insulin, Body Weights, Calcium-Sensing Receptor, and Intracellular Calcium

Bonnie Eby,[1] Usman A. Khan,[1,2] Muhammad Mubeen Anwar,[1] Kai Lau.[1,2] *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Oklahoma Veteran Administration Hospital & Medical Center, Oklahoma City, OK.*

Background: We recently reported diabetic phenotypes in TRPC1 mutatioon. The role of the elevated serum leptin & reduced adiponectin is unclear. Like CaSR, TRPC1 participates in cell Ca homeostasis & its deficiency impairs Ca entry & induces hyperparathyroidism (JCI Apr 2020). We tested if by raising serum Ca by 4-5 mg%, we would raise cell Ca in adipocytes to lower lepin & elevate adiponectin, based on published in vitro data.

Methods: In age- & sex-matched TRPC1 +/+, +/- & -/- mice, we did metabolic studies, IP glucose toleranace tests, & measured serum cytokines & PTH by ELISA. At 10 m, we injected IP Ca to cause hypercalcemia (~15 mg%) to raise cell Ca enough to lower PTH, & by inference, similar rises in adipocytes & beta cells to alter leptin & insulin. At 16 m, we injected calcimimetic (Parsabiv) IP x 2 wks to evaluate if glucose tolerance is improved by chronically raising cell Ca.

Results: Serum leptin increase in -/- mice vs +/+ by 17% at 4.5 m, 75% ($p<0.05$) at 6.5 m, & 130% ($p<0.001$) at 9.5 m. It is directly related to body weight (BW) at 4.5 mon regardless of genotypes or gender ($N=80$; $p<0.05$). The relationship holds true at 17 m ($p<0.05$ for +/+ & $p<0.05$ for -/-). High fat diet x 3 m stimulates leptin 3 to 5 fold for all 3 genotypes, but linkage to BW holds. Serum leptin after fast ($r=0.93$) & 30 min post IP glucose ($r=0.75$) are highly correlated with simultaneous insulin. Leptin rose from 6.6 to 10.6 ng/ml 2 h after IP glucose ($p<0.01$). With induced hypercalcemia, PTH, elevated in null (288 vs 119 pg/ml), fell 75% (vs. 48% in +/+), but the elevated leptin (15.1 vs. 6.6 ng/ml) did not fall; insulin, similar between +/+ & -/-, fell comparably in both genotypes. GTT did not improve in +/+ or -/- mice after 2 wk of calcimimetics.

Conclusions: 1. Leptin is upregulated by anabolism, high fat diet, weight gain, & correlated with body weight & insulin in normal & TRPC1 null mice. 2. It is however increased in TRPC1 deficiency, uncorrected by raising intracellular Ca by hypercalcemia (sufficient to inhibit PTH by 50 to 75%) 3. Like insulin-resistant diabetes in mice with leptin receptor deficiency, we postulate the lack of TRPC1 impairs leptin signaling in neurons inhibiting hyperphagia. The elevated leptin reflects inadequate compensation to combat obesity.

The Significance of Renal TSPAN9 Overexpression in Diabetic Nephropathy

Xi Tang,[1,2] Desiree Leverette,[3] Raymond C. Harris,[1] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]West China Hospital of Sichuan University, Chengdu, China; [3]Meharry Medical College, Nashville, TN.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease. We performed proteomic analysis in isolated human glomeruli (DN vs. normal control) and RNAseq in glomeruli from a murine model of DN (db/db/eNOS$^{-/-}$) vs. nondiabetic controls (eNOS$^{-/-}$). We identified differentially expressed molecules with potential impact in DN, including tetraspanin 9 (TSPAN9), which mediates transduction signaling and regulates cell development, growth and motility. We investigated the potential contribution of TSPAN9 in DN.

Methods: Human kidney biopsies from DN (class II, III and IV, total n=30) were studied, and compared to control (non-cancer regions of human nephrectomy (Nx), n=10). TSPAN9 immunostaining was assessed and correlated with morphologic lesions and clinical data. Human mesangial cells (HMC) were cultured in normal glucose, mannitol or high glucose medium. TSPAN9 expression in HMC was determined by qPCR, western blot and immunofluorescence. HMC viability and migration were assessed by MTT assay and transwell experiments. Collagen IV protein in the cellular supernatant was detected by ELISA. Apoptosis regulating molecules Bax and BCL-2 were assessed by qPCR and western blot.

Results: TSPAN9 was expressed weakly in normal human kidney control, in glomerular mesangial areas and luminal side of tubules. Immunostaining intensity was gradually increased in class II, III and IV DN. TSPAN9 translocated from the luminal to apical side in tubular epithelial cells, and extended to more extracellular expression in mesangial areas. In DN samples, glomerular TSPAN-9 expression correlated with extent of glomerulosclerosis, hyalinosis, mesangial expansion and proteinuria, while tubular

TSPAN-9 correlated with extent of interstitial fibrosis, proteinuria and serum creatinine. In vitro, TSPAN9 in HMC was significantly upregulated by mannitol and high glucose, accompanied by decreased cell viability, migration and increased apoptosis.

Conclusions: DN was associated with increased TSPAN9 overexpression and translocation in mesangial and tubular epithelial cells, respectively, and was associated with worse renal function and more severe structural injury.

PO0923

Loxl4 Deacetylates OPA1 to Regulate Mitochondrial Dynamics During Diabetes

Qingqing Ke, Lei Jiang, Yang Zhou, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Mitochondrial morphology is regulated by the balance between two counteracting mitochondrial processes of fusion and fission. There is significant evidence suggesting a stringent association between morphology and bioenergetics of mitochondria. Morphological alterations in mitochondria are linked to several pathological disorders, including diabetic kidney disease. The consequences of high glucose-induced acetylation of mitochondrial proteins on the organelle morphology and function remain largely unexplored.

Methods: Here, we examined the kidneys of mice with streptozotocin-induced diabetes and primary tubular epithelial cells exposed to high glucose.

Results: Using high-resolution mass spectrometry, we identified 152 hyperacetylated and 19 hypoacetylated proteins in the mitochondria from kidney tubule of diabetic mice compared with control mice. OPA1, a mitochondrial fusion protein was hyperacetylated at lysine 228, 792 and 847 residuals under high glucose-induced pathological stress and this posttranslational modification increased mitochondrial fragmentation. Overexpression of a deacetylation-mimetic version of OPA1 recovered the mitochondrial functions of OPA1-null cells, thus demonstrating the functional significance of K228/792/847 acetylation in regulating OPA1 activity. The newly discovered deacetylase lysyl oxidase like 4 (Loxl4) interacts with OPA1 in mitochondria. Overexpression of Loxl4 prevents high glucose-induced acetylation, preserved mitochondrial networking and protected the high glucose-induced decrease of oxygen consumption rate.

Conclusions: In summary, these data indicated that hyperacetylation of OPA1 regulates mitochondrial fusion and fission under diabetes conditions. Loxl4 promotes mitochondrial function by regulating mitochondrial dynamics by targeting OPA1.

Discovery of a Small-Molecule Drug for Treating Diabetic Kidney Disease

Hassan Al-Ali, Javier T. Varona Santos, Alexis J. Sloan, Sandra M. Merscher, Alessia Fornoni. *University of Miami School of Medicine, Miami, FL.*

Background: Diabetic Kidney Disease (DKD) is the leading cause of chronic kidney disease and one of the fastest growing epidemics worldwide. Podocyte injury is a hallmark of DKD. As such, preventing podocyte injury is necessary for effectively treating DKD. Our prior studies demonstrated that the accumulation of lipid droplets (LDs) in podocytes is associated with increased susceptibility to apoptosis in the context of DKD. Conversely, reducing LD accumulation in podocytes prevented renal disease in a mouse model of DKD (BTBR ob/ob). Thus, compounds that reduce LD accumulation may protect podocytes from injury and prevent the progression of DKD. The goal of this study is to identify compounds that reduce LD accumulation *in vivo* and lead to the identification of therapeutic candidates for DKD.

Methods: Advances in high throughput synthetic chemistry have enabled the design of combinatorial libraries for efficient screening and identification of novel bioactive compounds. The approach is particularly powerful when combined with a phenotypic screening assay that recapitulates disease biology. We have developed a high content screening assay to quantify LD accumulation in human podocytes in response to stress stimuli. The assay is highly suitable for screening with a Z factor consistently > 0.5.

Results: We performed a pilot screen using 100 compound mixtures, each containing thousands of compounds, obtained from the Torrey Pines Institute for Molecular Studies (TPIMS). We identified one compound mixture (2275) that consistently reduces LD accumulation in a dose-dependent manner. 2275 significantly reduces LD accumulation induced by TNF, a pro-inflammatory cytokine associated with DKD, and induced by sera from patients with DKD. The TPIMS hit deconvolution method will be used to identify the active compound(s) within the 2275 mixture.

Conclusions: We identified compounds that significantly reduce LD accumulation in cultured human podocytes in response to stress stimuli, including sera from DKD patients. Further studies to deconvolve and validate those compounds, and test them in an animal model of DKD, are underway.

PO0925

Altered Protein Translation in the Kidney Precedes the Development of Diabetic Kidney Disease

Timothy A. Sutton,[1] Bernhard Maier,[1] Takashi Hato,[1] Pierre C. Dagher.[1,2] *[1]Indiana University School of Medicine, Division of Nephrology, Indianapolis, IN; [2]Roudebush VA Medical Center, Indianapolis, IN.*

Background: Diabetic kidney disease (DKD) is one of the most serious complications of diabetes. Diabetes is characterized by a variety of physiologic derangements and maladaptive pathways that contribute to cell stress and the development of DKD. There is mounting evidence in a variety of disease models demonstrating that altered protein translation, a fundamental step in gene expression, is important in both responding and contributing to cell stress. The hypothesis of this study is that altered protein translation precedes the development of overt DKD. It was the aim of this study to undertake a detailed examination of protein translation in the kidney early in the course of diabetes.

Methods: Ribosome footprint profiling (Ribo-seq) was employed to unbiasedly examine translational processes in the kidney at nucleotide level resolution across the whole genome during the develpment of diabetes in db/db mice. RNA-seq was done in parallel to examine transcriptional pathways of translation and augment findings from the translatome.

Results: Ribo-seq in 12 week-old db/db mice and age-matched, background C57BL/6J control mice (BC) demonstrated a marked (50%) global increase in translation in kidneys from db/db mice as compared to BC mice. This findings of increased translation was further supported by polyribosomal profiling and pathway analysis of RNA-seq done in parallel. Increase of global translation was also observed as the vintage of diabetes increased from 9 weeks to 12 weeks in db/db mice. Increased translation in the kidney of important pathgenic mediators were observed in pathways that contribute to alterations in cell cycling (p21), fibrogenesis (fibronectin), inflammation (osteopontin), glucose transport (SGLT2), and oxidative stress (NOX4). Although overall transcription and translation of p53 was not observed early in diabetes, translation of ΔNp53 (Δ40p53), a stress-induced, translationally-regulated isoform of p53 important for development of the diabetic phenotype was found to be increased by Ribo-seq. These findings underscore the importance of examining the translatome in the kidney as a missing omics layer in DKD.

Conclusions: Generalized protein translation is increased in the kidney early in the course of DKD. Pharmacological manipulation of translation may represent a novel therapeutic approach to the development and progression of DKD.

Esculin Restores Kidneys Mitochondrial Function in the Early Stage of Experimental Diabetic Nephropathy

Robson S. Serralha, Inri Rodrigues, Angela Bertolini, Deyse Lima, Moises Nascimento, Margaret G. Mouro, Giovana Punaro, Iria Visoná, Adelson Rodrigues, Elisa M. Higa. Laboratory of Nitric Oxide and Oxidative Stress *Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

Background: Diabetes mellitus (DM) is a chronic disease which progresses with many complications such as diabetic nephropathy (DN). Mitochondria are the main producer of reactive oxygen species (ROS) in a hyperglycemic condition, consuming oxygen without providing ATP to the cell. In turn, ROS act as a trigger to activation of inflammatory processes. Coumarin derivatives, as esculin, reduced oxidative damage seen in intestinal inflammation, arthritis and cognitive impairment related to diabetes. The aim of this study was to evaluate the effects of esculin on mitochondrial function and on the kidneys cortex in the DN development in rats.

Methods: DM was induced in 7-week-old male Wistar rats, using a single dose of streptozocin (60 mg/kg; i.v) and confirmed with blood glucose ≥ 200mg/dL. The animals received daily doses of esculin (50 mg/kg, p.o.) or its vehicle, during 8 weeks. After this period they were euthanized under anesthesia and the kidneys cortex were collected for histology and mitochondria isolation, to be analyzed by high resolution respirometry. Statistical analysis was performed in GraphPad Prism 6. The results are described as mean ± SEM, significance defined for $p < 0.05$.

Results: Esculin reduced 24 hs proteinuria in DM rats. The histological analysis of kidneys cortex showed the presence of intense inflammatory lymphomononuclear infiltrate, mild fibrosis and interstitial atrophy characterized by collagen IV deposition in diabetic animals, that were not observed in any of those treated with esculin. In addition, esculin restored mitochondrial function in the kidneys cortex of diabetic rats as analyzed by glycolysis (3.08 ± 0.17 *vs* 2.39 ± 0.08; $p < 0.05$) and β-oxidation substrates (4.75 ± 0.08 *vs* 3.68 ± 0.20; $p < 0.05$).

Conclusions: Esculin restored mitochondrial function in DM rats and probably through ROS control, reduced the kidney lesions. We suggest the use of esculin as an adjuvant therapy to control the development of DN.

PO0927

Selonsertib Reduces TNFα-Induced Markers of Injury and Inflammation in an Organ-on-a-Chip Model of Proximal Tubular Injury

Shawn S. Badal, Maile Velasquez, John T. Liles. *Gilead Sciences Inc, Foster City, CA.*

Background: Increased Circulating levels of TNF Superfamily Receptors 1 and 2 (TNFRSF1A and TNFRSF1B) in patients are associated with rapid declines in eGFR and proposed as biomarkers of DKD progression. In a phase 2 DKD trial which evaluated

safety and efficacy of the ASK1 inhibitor Selonsertib (SEL), higher serum sTNFR1 levels associated with progression to End Stage Renal Disease (ESRD). In vitro, mono-culture studies have demonstrated that ASK1 signaling is required for TNFα induced apoptosis in kidney and other organ systems. Current studies with a microfluidic organ-on-a-chip system to investigate the effects of TNFα in a kidney co-culture system and determine effect of SEL treatment on kidney proximal tubular injury.

Methods: After populating cells in a co-culture, microfluidic device (Emulate Bio) containing either Lonza RPTEC (top channel) or kidney microvascular endothelial cells (bottom channel), TNFa (2ng/ml) was added at Day 0 along with SEL (10μM) to inlet flow of each channel. After 7 days, RNA was isolated from each channel and gene expression analyzed by qPCR. Outlet supernatant from each channel was analyzed for kidney injury and inflammation markers on Mesoscale Discovery device (MSD). Data shown as fold-of-change or mean ± standard error of the mean (s.e.m.)

Results: TNFα significantly increased expression of both TNFRSF1A and1B in the RPTEC channel (1.4 and 2.6-fold, respectively vs. control), and SEL decreased TNFRSF1A expression by 108% (p=0.0058) and lowered TNFRSF1B expression by 64% (p=0.1549). SEL decreased TNFα-induced expression of IP-10 (6.4 vs. 37.3-fold, p=0.0083) and IL-18 expression (0.67-fold vs 1.6-fold, p<0.0001) in proximal tubules. Osteoactivin and Clusterin, biomarkers used to assess proximal tubule injury were significantly increased in RPTEC supernatant following TNFα stimulation channel (2.1 and 3.7-fold, respectively, p<0.0001 for each). SEL significantly reduced levels of osteoactivin (139.6 ± 33.74 vs 778.2 ± 44.24 pg/ml, p<0.0001) and clusterin (28.9 ± 1.8 vs. 108.5 ± 1.7 ng/ml, p<0.0001).

Conclusions: In a microfluidic, RPTEC/Endothelial co-culture model, treatment with the ASK1 inhibitor Selonsertib reduced several markers of kidney injury. Efficacy to reduce inflammatory gene expression and biomarkers of proximal tubular damage indicate SEL treatment may have potential to impact DKD progression.

The Usefulness of Antisense Oligonucleotide Modified with Serinol Nucleic Acid for Kidney Disease

Toshiki Tsuboi,[1] Takuji Ishimoto,[2] Kentaro Imai,[1] Tomohito Doke,[3] Noritoshi Kato,[2] Yukiko Kamiya,[2] Hiroyuki Asanuma,[2] Shoichi Maruyama.[2] *[1]Nagoya University Graduate School of Medicine Faculty of Medicine, Nagoya, Japan; [2]Nagoya Daigaku, Nagoya, Japan; [3]University of Pennsylvania Department of Medicine, Philadelphia, PA.*

Background: The use of nucleic acid drugs such as antisense oligonucleotides (ASOs) and siRNA has received a lot of attentions as next-generation drugs. However, the nucleic acid drugs for kidney diseases have not been put to practical use. Recently, we have newly developed the serinol nucleic acid (SNA) modified ASO which had strong nuclease resistance. In this study, we investigated the *in vivo* efficacy of SNA-modified ASO in mouse kidney.

Methods: Various types of PS-modified gapmer ASOs with or without SNA targeting both human and murine SGLT2 (sodium glucose cotransporter 2) were tested in the immortalized human proximal tubule epithelial cell (HK-2), and subcutaneously administered into mice. Urinary and blood glucose levels, renal function, liver function and renal SGLT2 expression were analyzed.

Results: First, we confirmed that SGLT2 ASO had enough inhibitory effects of SGLT2 expression in HK-2 cells. Next, we synthesized various types of SNA gapmer SGLT2-ASOs (SGLT2-SNA-ASO). Subcutaneous administration of SGLT2-SNA-ASO significantly suppressed renal SGLT2 mRNA and protein expressions and increased urine glucose in dose dependent manner. Those inhibitory effects of SGLT2-SNA-ASO were high and long-lasting compared with ASOs without SNA (SGLT2-ASO). No apparent kidney disfunction was observed. Mild and similar liver damages were found in both SGLT2-ASO and SGLT2-SNA-ASO groups. After subcutaneous administration of Cy5-labeled SGLT2-SNA-ASO, we observed the SGLT2-SNA-ASO accumulation in kidney, especially in renal proximal tubules, by in vivo imaging system (IVIS) and fluorescent microscope.

Conclusions: Systemic administration of SGLT2-ASO modified with novel artificial nucleic acid SNA well suppressed renal SGLT2 expression and induced urinary sugar excretion. These results indicated that ASOs modified with SNA might be applied to the development of neucleic acid drugs.

PO0929

Empagliflozin Inhibits Basal and IL1-β-Mediated CCL2 and Endothelin1 Expression in Human Proximal Tubular Cells

Markus Pirklbauer, Maximilian Bernd, Lisa Fuchs, Petra Staudinger, Ulrike Corazza, Johannes Leierer, Gert J. Mayer, Herbert Schramek. *Medical University Innsbruck - Department of Internal Medicine IV (Nephrology and Hypertension), Innsbruck, Austria.*

Background: SGLT2 inhibitiors (SGLT2i) slow the progression of type II diabetic kidney disease, however, evidence for underlying molecular mechanisms is scarce. As reno-protection is observed promptly after starting SGLT2i, we aimed at investigating pathways involved in early disease pathogenesis.

Methods: human proximal tubular cell (HPTC) culture (HK-2 and RPTEC), microarray hybridization, real-time PCR, ELISA.

Results: Microarray hybridization identified 1263 genes that presented a uniform expression pattern 24h after ligand stimulation: IL1-β-mediated up- and Empagliflozin (Empa) mediated down-regulation in two HPTC lines (n=2, each). Functional annotation of these genes using DAVID enrichment analysis identified 33 pathway clusters. Based on their established involvement in early pathogenesis of diabetic kidney disease, 2 genes of interest, namely CCL2 and endothelin1, that were represented in the two top ranked clusters, have been selected for verification on the mRNA level: Basal CCL2 mRNA expression was upregulated by IL1-β (10 ng/ml) (15-fold, p<0,01 and 19-fold, p<0,01) but downregulated by Empa (500nM) (0,6-fold, p<0,01 and 0,5-fold, p<0,001) as early as 1h and at least for 24h after ligand stimulation in HK-2 and RPTEC cells, respectively. Coadministration of Empa inhibited IL1-β-mediated CCL2 mRNA expression after 1h (0,2-fold, p<0,01 and 0,2-fold, p<0,01) and 24h (0,2-fold, p<0,001 and 0,6-fold, p<0,01) in HK-2 and RPTEC cells, respectively. Basal endothelin1 mRNA expression was upregulated by IL1-β (3-fold, p<0,001 and 8-fold, p<0,001) but downregulated by Empa (0,3-fold and 0,2-fold, p<0,001 each) as early as 1h and at least for 24h after ligand stimulation in HK-2 and RPTEC cells, respectively. Coadministration of Empa inhibited IL1-β-mediated endothelin1 mRNA expression after 1h (0,2-fold and 0,2-fold, p<0,001 each) and 24h (0,1-fold, p<0,001 and 0,7-fold, ns.) in HK-2 and RPTEC cells, respectively. In HK-2 cells, Empa inhibited both IL1-β-induced CCL2 (0,24-fold, p<0,001) and basal endothelin1 (0,4-fold, p<0,001) protein expression.

Conclusions: By demonstrating an inhibitory effect of Empa on basal and IL1-β-mediated CCL2 and endothelin1 expression in two independent HPTCs, we present novel evidence for early non-hemodynamic, nephro-protective effects of SGLT2i.

PO0930

Comparison of the Effect of Calorie-Matched High Saturated Fat and High Unsaturated Fat Diets on Lysosomal Renal Injury in Non-Obese, Streptozotocin-Injected CD-1 Mice

Tamio Yamaguchi,[1] Aya Yoshimura,[2] Masanori Kugita,[2] Kanako Kumamoto,[2] Kazuya Shiogama,[3] Kyongtae T. Bae,[4] Shizuko Nagao.[2] *[1]Department of Clinical Nutrition, Faculty of Health Science, Suzuka University of Medical Science, Suzuka, Japan; [2]Education and Research Center of Animal Models for Human Diseases, Fujita Health University, Toyoake, Japan; [3]Division of Morphology and Cell Function, Faculty of Medical Technology, Fujita Health University, Toyoake, Japan; [4]Department of Radiology, University of Pittsburgh, Pittsburgh, Pittsburgh, PA.*

Background: Type 2 diabetes mellitus often causes renal injury characterized by autophagic vacuoles. Although many studies with comparisons of high fat versus a normal balanced diet have been reported in diabetic models, there are few studies that equalized calorie intake and body weights. We reported that a high fat diet induced renal injury with impaired lysosome-mediated autophagic degradation in streptozotocin (STZ) injected mice (ASN Kidney Week 2019). However, the effect of fat type, saturated- or unsaturated-fat, was not determined. In the current study, an AIN93M diet (CONT group) was compared to energy-matched lard derived high saturated fat (LARD group) and soybean oil derived high unsaturated fat (SOY OIL group) diets to compare their effects on biochemical markers and renal morphology with lysosome-associated membrane protein 1 (LAMP1) expression.

Methods: Male CD1 mice were randomly divided into three pair-fed groups with 380 kilocalorie/100g energy from 7 to 20 weeks of age. CONT group: AIN93M diet with 62% (w/w) cornstarch, 10% sucrose, 4% soybean oil and 5% cellulose; LARD group: Diet with 31% cornstarch, no sucrose, 22% lard oil and 28% cellulose; SOY OIL group: Diet identical to the LARD diet, except that soybean oil replaced lard oil. At 17 and 18 weeks of age, STZ (100mg/kg body wt) was injected. At 20 weeks of age, blood was taken for measurements of insulin, triglyceride, total cholesterol, ALT, AST, creatinine and SUN. Kidneys were prepared for H&E staining and immunohistochemical staining to detect LAMP1.

Results: Final body weight, total intake of water, food and energy were not different between all groups. No statistical differences in all blood biochemical markers were detected as well. In kidneys, the number of LAMP1-positive renal tubular lipid vacuoles was higher in LARD compared with SOY OIL and CONT groups, whereas no difference was shown between SOY OIL and CONT groups.

Conclusions: The results suggest that high intake of saturated-fat may aggravate lysosomal renal injury in a non-obese, streptozotocin-induced diabetes mellitus model.

Overexpression of ACE in Macrophages Accelerates Diabetic Kidney Disease

Keigo Tomita,[1] Masahiro Eriguchi,[2] Kumiko Torisu,[1] Jorge F. Giani,[3] Kenneth E. Bernstein,[3,4] Kazuhiko Tsuruya,[2] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Science, Fukuoka, Japan; [2]Department of Nephrology, Nara Medical University, Kashihara, Japan; [3]Cedars-Sinai Medical Center, Departments of Biomedical Sciences, Los Angeles, CA; [4]Cedars-Sinai Medical Center, Pathology and Laboratory Medicine, Los Angeles, CA.*

Background: We previously reported that renal tubular angiotensin-converting enzyme (ACE) is mainly involved in the pathological progression in diabetic kidney disease (DKD). Although ACE in macrophages has been shown to be important in controlling inflammation, the expression and function of ACE in macrophages in DKD are still unknown.

Methods: Diabetes was induced by five consecutive daily intraperitoneal injections of streptozotocin (55 mg/kg) using C57Bl6/J male mice. Primary peritoneal macrophages

were harvested after intraperitoneal injection with 2 mL of 4% thioglycolate solution into mice. Mouse-ACE overexpressing plasmid was electroporated into Raw 264.7 to evaluate cytokine release and migration ability. ACE 10/10 mice was deficient of ACE in the whole body but overexpressed only in monocytes/macrophages. We induced diabetes in ACE 10/10 and wild-type mice and analyzed albuminuria or pathological changes of kidney after six months of diabetes.

Results: ACE mRNA was increased in peripheral blood monocytes and peritoneal macrophages from diabetic mice. LPS-induced release of IL-6 and nitric oxide was increased in macrophages overexpressing ACE. The migration ability of macrophages overexpressing ACE was higher than that of control vector-expressing cells. In diabetic ACE 10/10 mice, glomerular hypertrophy and glomerular hyperfiltration were not evident as in diabetic wild-type mice. Although ACE 10/10 mice lacks ACE in vascular endothelial cells and tubular cells, mesangial expansion and interstitial fibrosis in the kidney, and albuminuria from diabetic ACE 10/10 mice were similar to those from diabetic wild-type mice.

Conclusions: In diabetes, the expression of ACE in macrophage is enhanced. As a result, dysregulation of macrophage function occurred, and it may be involved in the development of diabetic kidney disease.

PO0932

Transgenic Mechano-Growth Factor Overexpression in Mice Induces Glomerular PKCα and Type I Collagen with Glomerulosclerosis

Yongxin Gao,[1] Irtiza Hasan,[1] Zaiyara A. Rivera,[1] Hongwei Li,[2] Charles W. Heilig.[1] *[1]University of Florida College of Medicine - Jacksonville, Jacksonville, FL; [2]Southern Medical University, Guangzhou, China.*

Background: Mechano-Growth Factor (MGF), a normally expressed component of several positive feedback loops in the renal glomerular mesangial cells (MC), was implicated by us in the control of glomerulosclerosis. Transgenic mice overexpressing MGF (LK440-mMGF) were produced to determine the role of MGF in glomerulosclerosis (GS).

Methods: Our previous studies demonstrated that MGF was induced in the glomeruli of diabetic mice with subsequent induction of several factors responsible for diabetic GS. In the current study, immunohistochemistry using specific antibodies was performed to compare the expression of select glomerular proteins involved in GS, in MGF–overexpressing transgenic mice (MGF Tg) vs. non-transgenic control mice (NT). DAB staining with 0-4^{+} scoring in glomeruli was performed, and $p < 0.05$ between groups was considered significant. PAS staining was performed to assess development of overall GS. The effects of transgenic MGF overexpression on mouse body weights and kidney weights was also assessed.

Results: A 2.5-fold higher expression of MGF was found in glomeruli of MGF Tg as compared to NT mice. This resulted in 2.1-fold increased expression of active PKC α, a potential mediator of the 2.2-fold increased GLUT1 expression observed. These changes appeared to drive the 2.2-fold increased Collagen Type I (Col-I) in glomeruli. All these prosclerotic factors likely contributed to the resultant GS, evidenced by 2.2-fold increased PAS positive material in MGF Tg glomeruli. All the above results were found to be significant with a P value <0.0001. Adult body weight in MGF Tg tended to be 8% higher in both males and females (NS). Mean kidney weights were 14% larger in MGF Tg vs same gender NT mice (NS).

Conclusions: 1. MGF Tg displayed increased glomerular PKC α activation, Col-I protein, and PAS-positive extracellular matrix similar to diabetic GS with increased MGF. 2. Future studies of glomerular MGF inhibition in diabetic mice may help define the potential value of this maneuver in blocking GS.

Severe Diabetic Glomerulosclerosis by Chronic Hypoxic Housing of db/db Mice: The Role of Mesangiolysis and Podocyte Injury

Naoki Takahashi,[1] Haruyoshi Yoshida,[2] Hideki Kimura,[1] Kazuko Kamiyama,[1] Seiji Yokoi,[1] Kenji Kasuno,[1] Hiroyuki Kurosawa,[3] Yoshiaki Hirayama,[3] Masanori Hara,[4] Masayuki Iwano.[1] *[1]Fukui Daigaku Igakubu, Yoshida-gun, Japan; [2]Sugita Genpaku Kinen Koritsu Obama Byoin, Obama, Japan; [3]Denka Seiken Kabushiki Kaisha Niigata Kojo, Gosen, Japan; [4]Iwamuro Health Promotion Center, Niigata, Japan.*

Background: Chronic hypoxia may play a pivotal role in the development of diabetic nephropathy (DN). However, the precise mechanisms underlying progressive hypoxia-induced glomerular injury remain unclear.

Methods: We housed db/db mice in a hypoxia chamber (12% O_2) for up to 16 weeks beginning at 8 weeks of age. Various urine, serum and kidney abnormalities and glomerular mRNA expression were compared with those in age-matched db/db mice housed under normoxia.

Results: Levels of urinary albumin and podocalyxin (PCX) were significantly higher in hypoxic mice early during hypoxia. Ultracentrifugation of urine samples revealed that podocytes in the hypoxic mice shed PCX-positive microparticles into the urine. After 16 weeks of hypoxia, the mice also had higher hematocrits with lower serum glucose and various degrees of mesangiolytic glomerulosclerosis with microaneurysms and the infrequent occurrence of nodular lesions. Immunohistologically, hypoxic mice showed significantly decreased endothelial cell densities early during hypoxia and decreased podocyte densities later. In both hypoxic and normoxic mice, glomerular macrophage and transforming growth factor-β1 (TGF-β1) staining significantly increased with aging, without changes in vascular endothelial growth factor or endothelial nitric oxide synthase (eNOS). Glomerular mRNA expression of monocyte chemoattractant protein-1, eNOS, and TGF-β1 was significantly enhanced in the hypoxic mice.

Conclusions: These results indicate that chronic hypoxia induces advanced glomerulosclerosis with accelerated albuminuria triggered by mesangiolysis and podocyte injury in a murine model of DN.

Summary of the glomerular changes in db/db mice exposed to chronic hypoxia.

PO0934

Overexpression of Nrf2 Increases Sglt2 Gene Expression and Exacerbates Dysglycemia and Nephropathy Progression in Diabetic Transgenic Mice

Shuiling Zhao,[1] Kana N. Miyata,[1] Chao-Sheng Lo,[1] Anindya Ghosh,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]Centre Hospitalier de l'Universite de Montreal Centre de Recherche, Montreal, QC, Canada; [2]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [3]Massachusetts General Hospital, Boston, MA.*

Background: Nuclear factor erythroid-2 related factor 2 (Nrf2), a transcription factor abundantly expressed in renal proximal tubule cells (RPTCs), possesses cytoprotective effects. However, clinical trial with Nrf2 activator (bardoxolone methyl) in T2D patients increased mortality, heart failure rates, heightened hypertension and albuminuria without favorable effect on end-stage kidney disease (ESKD), though the underlying mechanism(s) remain unknown. We reported previously that Nrf2 deficiency ameliorates hyperglycemia and kidney injury in diabetic Akita (T1D) mice, and we identified putative NRF2-binding sites in the promoter of SGLT2. We here hypothesized that overexpression of Nrf2 may upregulate Sglt2 expression and contribute to nephropathy progression in diabetes.

Methods: We generated Akita Nrf2$^{-/-}$/Nrf2^{RPTC}-Tg mice by cross-breeding Akita Nrf2 knockout mice (Akita Nrf2$^{-/-}$) with Nrf2 transgenic mice (Nrf2^{RPTC}-Tg) overexpressing Nrf2 in RPTCs, studying them until age 20 weeks. Immortalized human RPTC (HK2) stably transfected with plasmid containing *SGLT2* gene promoter were also used.

Results: Akita Nrf2$^{-/-}$/Nrf2^{RPTC} Tg mice had increased blood glucose, glomerular filtration rate, urinary albumin-creatinine ratio, tubulointerstitial fibrosis and *Sglt2* expression as compared to their Akita Nrf2$^{-/-}$ littermates. *In vitro*, addition of oltipraz (a Nrf2 activator) or transfection of *NRF2* cDNA increased *SGLT2* mRNA expression and promoter activity in HK2; these effects were blocked by small interference (si) RNA of *NRF2*. Deletion of NRF2-*responsive elements (*NRF2-*REs)* in the *SGLT2* promoter abolished the stimulatory effect of oltipraz on *SGLT2* promoter activity. NRF2 bound to NRF2-*RE*s of *SGLT2* promoter was seen on gel mobility shift and chromatin immunoprecipitation assays.

Conclusions: Our results identify a novel mechanism by which NRF2 mediates hyperglycemia (oxidative stress)-stimulation of SGLT2 expression and exacerbates dysglycemia and kidney injury in diabetes.

Durable Euglycemia by Intraperitoneal Administration of Allogeneic Neo-Islets, 3D Organoids of Pancreatic Islet and Mesenchymal Stem Cells, Effectively Reduces Diabetic Nephropathy in Immune-Component Non-Obese Diabetic Mice

Christof Westenfelder,[1,2] Anna Gooch,[1] Sabiha Sultana Chowdhury,[1] Ping Zhang,[1] Zhuma Hu.[1] *[1]SymbioCellTech, LLC, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: We demonstrated that the i.p. administration of allogeneic "Neo-Islets" (NIs), 3-D organoids of culture expanded Pancreatic Islet (PI) and Mesenchymal Stem Cells (MSC), induces permanent euglycemia without the need for anti-rejection drugs in NOD mice with auto-immune Type I Diabetes mellitus (T1DM). The NIs engraft in the omentum and physiologically deliver insulin and other islet hormones into the hepatic portal system, while providing auto- and allo-immune isolation, up regulate T-regs, stimulate angiogenesis, prevent apoptosis and inflammation. As a significant percentage of patients with T1DM develop diabetic nephropathy (DNP) and other end organ damage, we tested whether the induction of stable euglycemia in NOD mice would prevent or ameliorate DNP.

Methods: Three Groups of adult mice (n=7 each; ~25 g b.wt.; age 12 weeks) were examined: (1) Non-diabetic, age and sex matched C57/Bl6 mice; (2) Vehicle treated NOD mice with fully developed auto-immune T1DM; (3) NI treated NOD mice with normal blood glucose levels. Animals were followed for 21 weeks post treatment (blood glucose levels, body weights, blood pressures, proteinuria, renal function).

Results: At the termination of the study, kidneys from all groups were examined for glomerulosclerosis and interstitial fibrosis (Trichrome staining). The vehicle treated NOD mice (Group 2) had blood glucose levels of 400-600 mg/dL, lost weight, had systolic hypertension and showed extensive interstitial fibrosis, glomerulosclerosis, proteinuria, hypertension and elevated SCr and BUN levels, while NI treated, euglycemic NOD mice (Group 3) showed significantly lower degrees of glomerulosclerosis, interstitial fibrosis, proteinuria, hypertension and better preserved renal function. All tested variables remained normal in non-diabetic Group 1 control mice.

Conclusions: The presented data demonstrate that NI therapy-induced normalization of glycemia significantly improves the manifestations of DNP without fully correcting them when compared to non-diabetic controls. Modifications in NI treatment protocols are expected to further improve the development of DNP, which, if successful, would further strengthen the translational relevance of this novel therapy. PO0936

IL-17A Deficiency Attenuates Autophagosome Formation in Streptozotocin-Induced Rat Diabetic Nephropathy

Geum-Lan Hong, Kyung-hyun Kim, Ju young Jung. *Department of Veterinary Medicine & Institute of Veterinary Science, Chungnam National University, Daejeon, Republic of Korea.*

Background: Diabetic nephropathy (DN) is one of the most important medical complications in diabetes mellitus. Autophagy is an important mediator of pathological responses and plays critical roles in inflammation during the progression of diabetic nephropathy. The Th-17 effector cytokine interleukin (IL)-17A can favorably modulate inflammatory disorders including DN. In this study, we examined whether IL-17A deficiency affects the autophagy process in streptozotocin (STZ)-induced DN in kidney.

Methods: The autophagic response for IL-17A in the nephrotoxicity of STZ was evaluated by observing STZ-induced functional and histological renal injury in *IL-17a*$^{-/-}$mice.

Results: IL-17A KO STZ-treated mice were developed more severe nephropathy, exhibiting increased albuminuria, glomerular damage and renal interstitial fibrosis at 12 weeks. IL-17A deficiency also increase the up-regulation of proinflammatory cytokine and fibrotic genes expression after STZ treatment. Meanwhile, autophagy-associated proteins were induced in STZ wild type mice however, IL-17A KO STZ-treated mice displayed a significant decrease in these protein expression. Especially, LC3 and ATG7, which play crucial role for autophagosome formation, is notably decreased in IL-17A KO STZ-treated mice compared with their wild type counterparts.

Conclusions: These results suggested that autophagy is closely related to the increased cellular stress due to IL-17A deficiency. Our study demonstrate an important role of IL17A for autophagosome formation during the progression of DN and provide a potential therapeutic target for DN

NQO1 Deficiency Aggravates Renal Fibrosis Downregulating Through PI3-Complex Formation in Diabetic Nephropathy

Geum-Lan Hong, Kyung-hyun Kim, Ju young Jung. *Chungnam National University, Daejeon, Daejeon, Republic of Korea.*

Background: Diabetic nephropathy (DN) is one of cause leading to end-stage renal failure and the main pathological feature is renal fibrosis. An autophagy is a vital for cellular remodeling and intracellular homeostatsis and negatively regulate and limit renal fibrosis. NAD(P)H: quinone oxidoreductase 1 (NQO1) modulates the ratios of reduced/oxidaized nicotinamide nucleotide pools acting cytoprotective function. In this study, we examined the relationship between NQO1 and autophagy, and furthermore renal fibrosis alteration in NQO1$^{-/-}$ streptozotocin (STZ)-induced DN.

Methods: STZ (50 mg/kg) was injected to C57BL/6 (Wile type) and NQO1$^{-/-}$ mice to induce DN. After 12 weeks of STZ injection, renal pathology and the markers of autophagy and fibrosis were examined. To confirm the effects of NQO1 genes in DN progression *in vitro*, autophagy proteins and pro-fibrotic markers were assessed in silencing or overexpression of NQO1 on human proximal tubular cells (HK2) and human renal mesangial cells (HRMC).

Results: The STZ administration induced phenotypes of hyperglycemia and aggravated renal fibrosis in NQO1-/- mice. Futhermore, NQO1 deficiency reduced the autophagy down-regulating hVps34 and ATG14L of PI3-complex and induced pro-fibrotic genes including TGF-β1, Smad3, and MMP9, *in vitro* and *in vivo*. The fluorescence intensity of both hVps34 and ATG14L was reduced in siNQO1. However, NQO1-overexpression increased the expression of hVps35 and ATG14L but, reduced the expression of TGF-β1, Smad3 and MMP9.

Conclusions: NQO1 deficiency aggravated renal fibrosis mediating autophagy induction and phagophore formation. This results suggested that NQO1 may have a potential role for DN amelioration.

Cell Sex and Sex Hormones Modulate Glucose and Glutamine Kidney Metabolism: Implications for Diabetic Kidney Disease

Sergi Clotet Freixas,[4] Julie Anh Dung Van,[4,1] Caitriona M. McEvoy,[4,3] Sofia Farkona,[4] Aman Mehrotra,[4,2] Adam J. Gehring,[4,2] Minna Woo,[4] Ana Konvalinka.[4,3] *[1]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [2]Department of Immunology, University of Toronto, Toronto, ON, Canada; [3]Department of Medicine, Division of Nephrology, University Health Network, Toronto, ON, Canada; [4]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada.*

Background: Male sex predisposes to diabetic kidney disease (DKD). We uncovered androgen-induced perturbations in kidney metabolic proteins that may drive faster DKD progression in men. Our goal is to characterize cell sex- and sex hormone-specific alterations in the kidney cell metabolism.

Methods: Human primary proximal tubule epithelial cells (PTEC) from 3 male and 3 female donors were stimulated with control, dihydrotestosterone (DHT), or estradiol (EST). We assessed glycolysis (extracellular acidification rate, ECAR) and oxygen consumption rate (OCR) in a Seahorse analyzer. We also studied sex differences in 16-week-old diabetic Akita mice.

Results: Male PTEC showed significantly higher ECAR, OCR, superoxide levels and apoptosis, compared to female PTEC ($p<0.05$). Higher OCR in male PTEC was further enhanced in the presence of glutamine as a unique susbstrate. In male PTEC, ECAR was increased by DHT, whereas OCR was increased by DHT and EST. Further, glucose levels in the media were reduced by DHT. DHT-induced metabolic changes were prevented by androgen receptor (AR) inhibitors. ATP, superoxide and apoptosis were increased by DHT, especially in male PTEC. Under hyperglycemia (25mM glucose), male cells showed a more rapid decline in OCR, and DHT increased superoxide and ATP levels. Transcriptional regulator analysis predicted that PTBP1, MCM4, and KDM5D (Y-linked) regulate proteins increased by DHT. Targets of PTBP1 and MCM4 include enzymes involved in glucose and glutamine metabolism (TKT, GLUD1). *In vivo*, diabetes increased kidney gene expression of *Tkt, Glud1,* and glutamine transporter *Slc38a3* in males, but not females.

Conclusions: PTEC metabolism is influenced by cell sex and sex hormones. Male PTEC show higher glycolysis, oxygen consumption, and respiratory capacity than female PTEC, and a higher propensity to oxidize glutamine in the mitochondria. Importantly, glutamine plays a key role as anaplerotic substrate for the TCA cycle in diabetes. Our *in vivo* data support the link between male sex and regulation of glutamine metabolism, and suggests that kidney utilization of glutamine in DKD is sex-specific. By understanding and monitoring how these metabolic changes occur in male and female patients, our findings may contribute to a more personalized management of DKD.

PO0939

Effects of Dapagliflozin-Induced Glucosuria on Urinary Tract Infection Susceptibility

Kristin Bender, Laura Schwartz, John D. Spencer. *Nationwide Children's Hospital, Columbus, OH.*

Background: Individuals with diabetes mellitus (DM) have a higher risk for urinary tract infection (UTI). The infection is more likely to cause acute kidney injury leading to an increased risk for chronic and end-stage kidney disease. Glucosuria is one of the proposed mechanisms by which people with DM have increased UTI risk, but this association is understudied and uncertain. In order to study the relationship between glucosuria and UTI susceptibly *in vivo*, mice were treated with an SGLT-2 inhibitor Dapagliflozin (Dapa) and subjected to experimental UTI.

Methods: Non-diabetic C57BL/6 female mice were treated via oral gavage with vehicle or Dapa at 0.1, 1, or 10 mg/kg/dose. One group received a 2-dose regimen: 6 hours before and 3 hours post infection. Another group was treated daily for 7 days. Mice were transurethrally infected with uropathogenic *E. coli* (UPEC). 24 hours post infection (hpi) bacterial burden was enumerated in the urine and bladder. Serum glucose, urine glucose, and urinary output was monitored over the course of treatment.

Results: Compared to controls, Dapa-treated mice developed glucosuria while maintaining normoglycemia and comparable weights. After UTI with the 2-dose regimen, control and Dapa-treated mice had comparable bladder and urine UPEC titers. Mice treated over a longer time course had no significant differences in CFUs in the bladder and urine at 24 hpi – suggesting that glucosuria may not be a primary UTI risk factor. Urine output was increased in mice treated with Dapa which could impact infection susceptibility.

Conclusions: These data suggest that there is no direct relationship between glucosuria, SGLT2 inhibitors, and UTI susceptibility. Also, glucosuria alone doesn't explain the increase in DM-associated UTI risk. More studies are needed to understand the mechanisms that increase UTI susceptibility in individuals with DM.

Systemic Therapies Targeted to Ischemia in a Model of Diabetic AKI

Jeffrey Cleland,[1] Rishi Sharma,[1] Santiago Appiani La Rosa,[1] Jinglei Zhang,[2] Audrey Q. Chang,[2] Sujatha Kannan,[3] Kannan Rangaramanujam.[1] *[1]Ashvattha Therapeutics, Inc, Redwood City, CA; [2]Creative Biolabs, Shirley, NY; [3]Johns Hopkins Medicine, Baltimore, MD.*

Background: In acute kidney injury (AKI) and chronic kidney disease (CKD), ischemia in the kidney results in inflammation and tissue damage. The initial response to injury is the infiltration of reactive macrophages into the kidney with subsequent pro-inflammatory cytokine expression. Upon systemic administration, hydroxyl dendrimers selectively target reactive macrophages in the ischemic kidney with renal clearance maximizing kidney exposure.

Methods: Diabetes was induced in Wistar rats by administration of streptozotocin (70 mg/kg) as a single intraperitoneal (IP) injection. Rats with a blood glucose of >16.7 mM were allocated to 4 groups (G1-4; n=3/group). After 6 weeks, ischemia reperfusion injury (IRI) was conducted with 60 min ischemia(I)/6 hr reperfusion (R) (G2), or 45 min I/24 hr R (G3 & G4). A sham surgery was performed as a control (G1). Hydroxyl dendrimer labeled with Cy5 (D-Cy5) was administered IP 1 hr after IRI in G1, G2 and G3 and 12 hr after IRI in G4. Renal function was assessed by clinical chemistry, glomerular filtration rate (GFR), and kidney injury biomarkers. Rats were euthanized 6 (G2) or 24 hr (G1, G3, G4) after surgery. Kidneys were evaluated for tubular damage and tubular epithelial cell necrosis and stained by DAPI and anti-CD68 antibody (macrophage).

Results: Glucose levels increased to ~30 mM prior to IRI. GFR was significantly reduced from 1.8 mL/min (sham) to <0.1 mL/min in IRI rats. Serum creatinine and blood urea nitrogen were significantly elevated in IRI groups (G4>G3>G2). The degree of kidney damage increased with the longer reperfusion time prior to sacrifice (G4, G3 > G2). In all IRI groups, renal tubular necrosis was moderate to severe and proximal tubule damage was severe. Maximal uptake of the D-Cy5 was observed in renal tubules in reactive macrophages in G2.

Conclusions: A diabetic model of AKI was successfully established to evaluate targeting of hydroxyl dendrimers to reactive macrophages. Prolonged ischemia followed by rapid reperfusion increased reactive macrophages and subsequent uptake of hydroxyl dendrimers. Given the high incidence of diabetic nephropathy and higher risk for AKI in these patients, these results provided a model and treatment strategy to evaluate targeted therapies with hydroxyl dendrimer drug conjugates to treat AKI and CKD.

PO0941

Novel Analysis Approach for Intravital Single Nephron GFR Measurement in Mice

Hannah Kroeger,[1] Friederike Kessel,[1] Jan Sradnick,[1] Michael Gerlach,[2] Vladimir T. Todorov,[1] Christian Hugo.[1] *[1]University Hospital Dresden Center of Internal Medicine - Nephrology, Universitatsklinikum Carl Gustav Carus, Dresden, Dresden, Germany; [2]University Hospital Dresden, Core Facility Cellular Imaging, Universitatsklinikum Carl Gustav Carus, Dresden, Dresden, Germany*.

Background: Intravital microscopy in animals is an emerging technique with advanced applications in kidney research. Particularly, the measurement of single nephron (SN) GFR in mice comprises a method to assess a key parameter of kidney disease. Filtration in single glomeruli is measured by two-photon microsopy in a time series after intravenous injection of a freely filtered fluorescent dye. From the intraglomerular capillaries to the connected proximal tubulus (PT) the glomerular filtration is observed and the intratubular dye intensity shift is measured. However, existing methods for the analysis of the image data in rats (Kang et al. 2006) had limited robustness in mice, due to smaller size, higher tubular curvature and therefore smaller acquisition distances.

Methods: By continuous, rather than punctual measurement of signal intensity along the PT in the time series we extended the published workflow. To further increase reliability and objectivity, we replaced the inaccurate estimation of the tubular volume by additional modelling in a 3D dataset. After normalizing the shift of the intensity position along the PT over time against the exact tubular volume, the filtrated volume per second is calculated by linear regression.

Results: With the method published by Kang the results were highly variable in our hands. After repeated analysis of image material (10 glomeruli in 5 animals, analyzed 5 times by one person), the GFR varied by a mean relative SD of 41%. By reducing overall user interaction with our method, this SD could be decreased to 14%. When applying the analysis to image data acquired in healthy and diabetic C57BL/6J mice, we detected a 4-fold increase in SN GFR in diabetic mice. Administration of the ACE inhibitor enalapril for three days ameliorated this effect in diabetic mice by 50%.

Conclusions: To increase the reliabilty of SN GFR measurements by intravital microscopy in mice, we extended an existing workflow by continuous measurement, 3D-modelling and sophisticated data analysis while reducing manual interaction. Application to microscopy data acquired in diabetic and healthy mice prove the general applicability and high reliability of this novel analysis approach. The clinical relevance is apparant in the context of monitoring disease progression as well as effects of medical intervention.

PO0942

A Hyaluronan Synthesis Inhibitor Delays the Progression of Diabetic Kidney Disease in a Mouse Experimental Model

Loay H. Salman,[1] Guillermo Selman,[1] Andrea R. Lightle,[1] Alejandra E. Aguilar,[1,3] Daniel R. Woltmann,[1] Laisel Martinez,[2] Roberto I. Vazquez-Padron.[2] *[1]Albany Medical College, Albany, NY; [2]University of Miami School of Medicine, Miami, FL; [3]Massachusetts Institute of Technology, Cambridge, MA.*

Background: There is a paucity of options to treat Diabetic Kidney Disease (DKD) in the clinical practice. Hyalinosis is an important morphological feature of DKD. However, the role of hyaluronan (HA) in the development and progression of DKD as well as the precise mechanisms and consequences of HA involvement in this pathology are still to be clarified.

Methods: In this study, we assayed the effects of hyaluronan synthesis inhibitor 4-Methylumbelliferone (4-MU) on the development of DKD. As a model, we used the diabetic and moderately hypertensive endothelial nitric oxide synthase/leptin receptor deficient (eNOS$^-$ C57BLKS/J^{db}) double mutant mice.

Results: At 9 weeks old, the diabetic model mice were separated into two similar groups regarding sex, body weight, non-fasting plasma glucose concentrations, and consanguinity; then, experimental animals were fed *ad libitum* identical artificial diets formulated by Envigo-Teklad, containing or not 5% of 4-MU sodium salt for 9 weeks. Our measures of daily food consumption show that treated animals had a dose of 270±50mg per day of 4-MU (about 6.2g/Kg body weight/day). At the end of the experimental period, we found that 4-MU-treated diabetic animals: **1)** kept their average GFR, while a significant reduction of GFR was observed in diabetic controls (P=0.042, n=9/8 per group); **2)** kept the average urine ACR and plasma cystatin-c values significantly lower than controls (P=0.049 (n=12 per group) and P=0.043 (n=11/10 per group) respectively); **3)** had lower average kidney weight (P=0.041, n=6), and 36% less hyaluronans in kidneys (P=0.095; Effect size=1.32, n=5); and **4)** 4-MU treated animals kept their body weight (final weight/maximum weight relationship) much higher than diabetic controls (P=0.002, n=16/15 per group) as well as their median survival was 6.4 weeks longer (P=0.048, n=6/5 per group). Moreover, after the treatment, an independent histopathology study showed a significant lower glomerular injury score in kidneys of 4-MU-fed animals (P=0.039, n=5/7 per group).

Conclusions: These results showed that the hyaluronan synthesis inhibitor 4-MU effectively slowed the progression of DKD. 4-MU provides a potential new therapeutic approach to treat DKD.

PO0943

Therapeutic Benefit of CCR2 Antagonism in a Model of Diabetic Nephropathy Suggests a Mechanism of Action Distinct from Nrf2 Activation

Zhenhua Miao, Bin N. Zhao, Linda Ertl, Vicky Chhina, Alice L. Kumamoto, Ton H. Dang, Simon K. Yau, Kenken Luong, Penglie Zhang, Kathleen M. Sullivan, Israel Charo, Thomas J. Schall. *ChemoCentryx, Inc, Mountain View, CA.*

Background: Diabetic nephropathy (DN) affects nearly half of the patients with type 2 diabetes and is characterized by albuminuria and/or a relentless decline in renal function that may lead to ESRD. We have recently shown that a CCR2 antagonist improved renal structure and reduced proteinuria in the db/db murine model of DN, as well as in the Adriamycin and 5/6 nephrectomy models of CKD. To understand the mechanism we compared CCX872, a small molecule antagonist of CCR2, with Bardoxolone methyl, an investigational drug targeting Nrf2 pathway in the db/db murine model of DN.

Methods: The [KS1] CCR2 specific inhibitor CCX872 and Nrf2 activator Bardoxolone methyl were formulated in 1 % HPMC and dosed for 2 weeks. Proteinuria (urinary albumin excretion rate- UAER) and glomerular filtration rate (GFR) were assessed by measuring murine albumin ELISA and FITC-insulin, respectively. The kidneys were disrupted non-enzymatically, and preparations enriched in glomerular cells were obtained by filtration. Activated parietal epithelial cells (PECs) were analyzed in these preparations by flow cytometry.

Results: UAER was rapidly and significantly reduced after treatment with CCX872: 59% (p=0.004) and 76% (p<0.0001), versus vehicle by week 1 and 2 respectively. In contrast, Bardoxolone did not improve UAER. The db/db mice had kidney hyperfiltration, which measured 943 µl/min at 8 weeks. Bardoxolone reduced hyperfiltration in db/db mice by 36% versus vehicle at week 2, while CCX872 had no effect on GFR. Furthermore, CCX872 significantly reduced the number of CD44 positive activated PECs in the glomerular cell preparations(p=0.04), while Bardoxolone had no effect on the number of these cells.

Conclusions: Treatment with CCR2 antagonist provides rapid renal protection in the db/db mice, as measured by improved UAER. The reduction in UAER was associated with reduction of activated PECs, which are known to contribute to kidney disease. Although Bardoxolone was able to improve GFP, it did not improve UAER or reduce the number of activated PECs. Thus, CCR2 blockade and Nrf2 activation appear to afford renal protection by different mechanisms in the db/db model of DN.

PO0944

Can Nrf2 Inducers Cause Renal Proximal Tubule Epithelial Cell De-Differentiation?

Jessica Eskridge, Susan M. Isaacs, Madhavi J. Rane, Michelle T. Barati. *University of Louisville, Louisville, KY.*

Background: Nrf2 is a transcription factor serving as a master regulator of cytoprotective responses and Nrf2-inducing agents have been shown to attenuate renal injury in animal models of kidney disease. However, use of these agents in the clinical setting are limited and defining/comparing mechanisms of action of different agents remains to be defined. Previous lab studies showed two Nrf2 inducers (Protandim [nutritional supplement] and DMF [Dimethyl fumarate]) caused differing effects on proximal tubule cell shape, actin and tubulin cytoskeleton, junction proteins, and extracellular matrix (ECM) secretion. Some of these responses were similar to tubule cell changes during epithelial to mesenchymal transition (EMT) and diabetes. This study tested the hypothesis that the combined effect of high glucose and DMF or Protandim may cause tubule cell de-differentiation.

Methods: Human proximal tubule cells (HK-11 cells) were cultured in high glucose (HG; 25mM) or normal glucose concentrations (NG; 5mM) for 24h, followed by additional treatment with 5μg/ml Protandim or 10μM DMF for another 24h. To test markers of EMT and cytoskeleton, cells were immuno-stained for vimentin and fibronectin, and actin filaments stained with FITC-phalloidin. Cell extracts were immunoblotted for E-cadherin and vimentin.

Results: Protandim and DMF increased vimentin filaments by image analysis of immunostained cells, and HG+DMF conditions led to a further increase. Treatment with Protandim following culture in both HG and NG caused collapse of actin filaments (as previously observed) and vimentin encapsulated and co-localized with the collapsed actin. The cell-cell junction protein E-cadherin was downregulated by DMF and culture in HG prior to DMF was not additive to this effect. Protandim did not alter E-Cadherin expression. Extracellularly deposited fibronectin increased with HG and this effect was augmented by additional treatment with DMF.

Conclusions: Protandim and DMF distinctively regulate the cell cytoskeleton. Increased vimentin filament formation with Protandim may be a compensatory mechanism due to collapse of actin filaments. DMF decreases E-Cadherin and increases vimentin and ECM deposition, suggestive of tubule cell de-differentiation. The disparate effects of these two Nrf2 inducers may lead to varying outcomes if used for treatment of diabetic or other types of kidney disease.

Beneficial Effect of Chloroquine and Amodiaquine on Diabetic Tubulopathy by Attenuating Mitochondrial Nox4 and Endoplasmic Reticulum Stress

So-young Lee,[1] Dong Ho Yang,[1] Hye yun Jeong,[1] Yu ho Lee,[1] Hyeyeon Lee,[1] Taeyoung Yang,[1] Sangho Lee.[2] *[1]Department of Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea; [2]Department of Internal Medicine, Kyung Hee University Hospital at Gangdong, Kyung Hee University, Seoul, Republic of Korea.*

Background: Oxidative stress induced by chronic hyperglycemia is recognized as a significant mechanistic contributor to the development of diabetic kidney disease (DKD). Nonphagocytic nicotinamide adenine dinucleotide phosphate oxidase 4 (Nox4) is a major source of reactive oxygen species (ROS) in many cell types and in the kidney tissue of diabetic animals. We designed this study to explore the therapeutic potential of chloroquine and amodiaquine for inhibiting mitochondrial Nox4 and diabetic tubular injury.

Methods: Human renal proximal tubular epithelial cells (hRPTCs) were cultured in high-glucose media (30 mM D-glucose), and diabetes was induced with streptozotocin (STZ, 50 mg/kg i.p. for 5 days) in male C57/BL6J mice. Chloroquine and amodiaquine were administered to the mice via intraperitoneal injection for 14 weeks.

Results: Chloroquine and amodiaquine inhibited mitochondrial Nox4 and increased mitochondrial mass in hRPTCs under high-glucose conditions. Reduced mitochondrial ROS production after treatment with the drugs resulted in decreased endoplasmic reticulum (ER) stress, suppressed inflammatory protein expression and reduced cell apoptosis in hRPTCs under high-glucose conditions. Notably, chloroquine and amodiaquine treatment diminished Nox4 activation and ER stress in the kidneys of STZ-induced diabetic mice. In addition, we observed attenuated inflammatory protein expression and albuminuria in STZ-induced diabetic mice after chloroquine and amodiaquine treatment.

Conclusions: We substantiated the protective actions of chloroquine and amodiaquine in diabetic tubulopathy associated with reduced mitochondrial Nox4 activation and ER stress alleviation. Further studies exploring the roles of mitochondrial Nox4 in the pathogenesis of DKD could suggest new therapeutic targets for patients with DKD.

In Vitro Evaluation of [^{18}F]Canagliflozin, a Potential PET Tracer for Imaging Tissue Distribution of the SGLT2 Inhibitor Canagliflozin in Type 2 Diabetes Patients In Vivo

Sjoukje van der Hoek, Inês F. Antunes, Harry Van goor, Hiddo J. L Heerspink, Philip Elsinga, Jasper Stevens. *University Medical Center Groningen, Groningen, Netherlands.*

Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitors are guideline recommended for prevention of kidney and cardiovascular outcomes in patients with diabetic kidney disease. But not all patients benefit from these agents, possibly due to differences in SGLT2 inhibitor tissue distribution. Imaging studies can assist to quantify *in vivo* tissue drug distribution and SGLT2 density in patients in order to unravel the underlying determinants of this response variability. The objective of this study was firstly to synthesize [^{18}F]canagliflozin ([^{18}F]CANA) for human use, and secondly, to confirm its affinity for SGLT2.

Methods: [^{18}F]CANA was synthesized by GMP compliant automated substitution of a boronic ester precursor with [^{18}F]fluoride. Its *in vitro* binding with SGLT2 was tested by incubating human kidney slices with [^{18}F]CANA alone or together with canagliflozin or glucose and analyzing them with autoradiography. [^{18}F]CANA binding sites were compared with SGLT2 distribution using immunohistochemistry on consecutive slices.

Results: [^{18}F]CANA radiochemical yield was 2.0% ± 1.9% within 80 min, molar activity 5-20 GBq/μmol and radiochemical purity >99%. Autoradiography shows [^{18}F] CANA binding in kidney slices with a significant reduction in binding in presence of canagliflozin and a clear trend in reduced binding in presence of glucose (Fig 1A and B). The pattern of [^{18}F]CANA binding on autoradiography corresponds with the distribution of SGLT2 in the apical membrane of proximal tubules as shown with immunohistochemistry (Fig 1C).

Conclusions: We showed the successful automated synthesis of the SGLT2 inhibitor [^{18}F]CANA and its specificity to the SGLT2. Given its unchanged structure compared to the marketed compound, canagliflozin tissue distribution and SGLT2 density can now be studied *in vivo* in human as determinants of between-patient response variability.

Funding: Private Foundation Support, Government Support - Non-U.S.

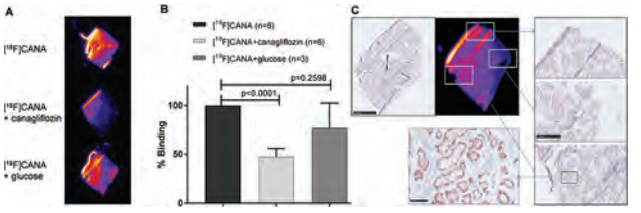

Figure 1. A and B: [^{18}F]CANA binding in kidney sections with autoradiography. C: [^{18}F]CANA binding using autoradiography compared with SGLT2 distribution using immunohistochemistry.

PO0947

Exploring New Targets of Diabetic Nephropathy by Bioinformatics Analysis

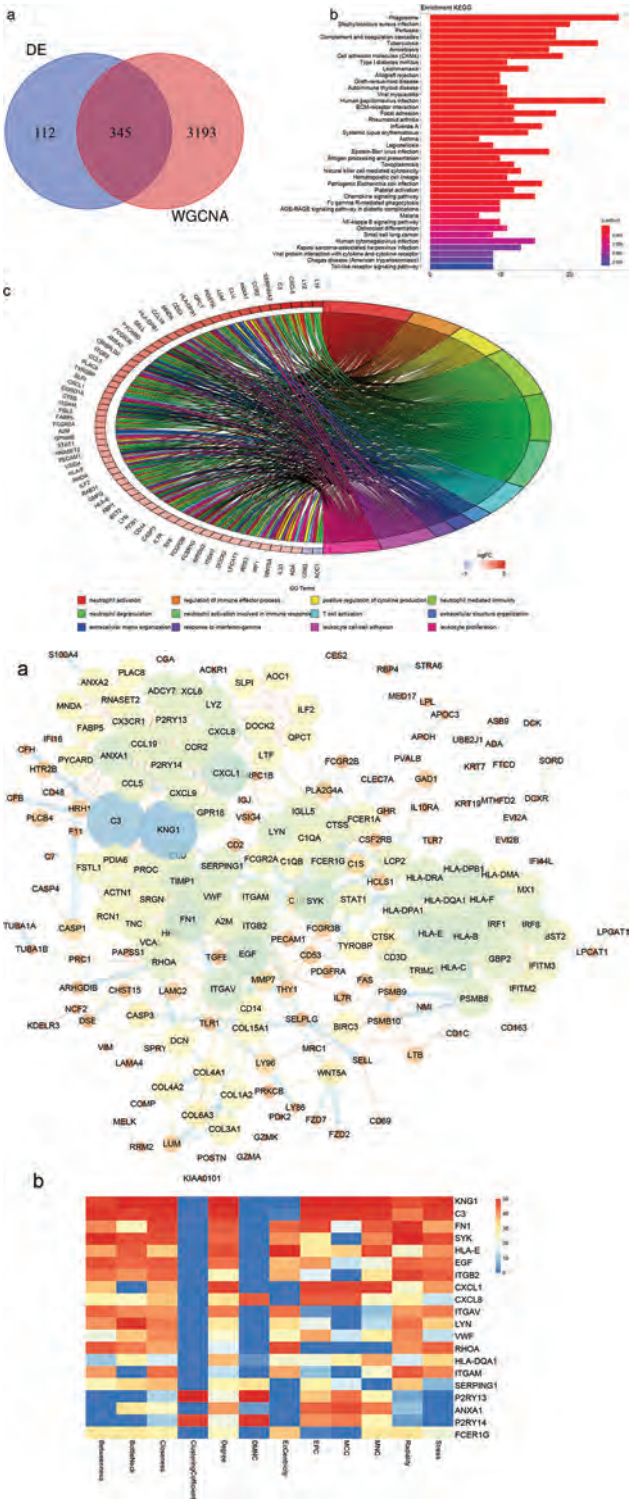
Shumei Tang, Xiangcheng Xiao. *Xiangya Hospital Central South University, Changsha, China.*

Background: The pathogenesis of diabetic nephropathy has not been fully understood and the public platform contains mass data for bioinformatics analysis.

Methods: Difference analysis and weighted gene coexpression network analysis were carried out on GSE30529 to obtain target genes and perform functional enrichment analysis. Non-coding RNA analysis was studied to understand the potential mechanism of differential expression of target genes. Using STRING database to build protein-protein interaction network. Nephroseq v5 database can access gene expression characteristics and clinical characteristics.

Results: From the GSE30529, 345 genes were identified through bioinformatics analysis. GO annotations of them included neutrophil activation, regulation of immune effector process and positive regulation of cytokine production. KEGG pathways included phagosome, complement and coagulation cascades and cell adhesion molecules. From miRNA profile, miR-1237-3p/SH2B3, miR-1238-5p/ZNF652 and miR-766-3p/TGFBI axis may be involved in diabetic nephropathy. C3 is located at the center of PPI network. Correlation analysis with GFR showed *SYK, CXCL1, LYN, VWF, ANXA1, C3, HLA-E, RHOA, SERPING1, EGF and KNG1* may be related to diabetic nephropathy.

Conclusions: C3 may serve as a therapeutic target for diabetic nephropathy



PO0948

Apolipoprotein C3 Inhibition Reduces Diabetic Kidney Disease and Atherosclerosis in a Mouse Model

Cheng-Chieh Hsu,[1] Farah Kramer,[1] Charles E. Alpers,[1] Rosanne M. Crooke,[2] Jenny E. Kanter.[1] *[1]University of Washington School of Medicine, Seattle, WA; [2]Ionis Pharmaceuticals Inc, Carlsbad, CA.*

Background: Diabetes increases the risk of cardiovascular disease and kidney disease. Importantly, the majority of the excess cardiovascular risk in people with diabetes is observed in those who also have kidney disease. Apolipoprotein C3 (APOC3) is a small lipoprotein that is elevated by insulin-insufficiency and regulates plasma triglyceride levels.

Methods: To test if APOC3, and the dyslipidemia it represents, play a role in diabetic kidney disease (DKD) we treated BTBR wildtype (WT) and leptin-deficient (OB; diabetic) mice with an antisense oligonucleotide (ASO) to APOC3 or a control ASO (cASO), all in the setting of human-like dyslipidemia (accomplished by administration of an LDLR ASO).

Results: APOC3 ASO treatment reduced triglycerides, triglyceride-rich lipoproteins, and prevented diabetes-accelerated atherosclerosis in the brachiocephalic artery and the aorta (aortic lesion was 9.3 ± 1.5 mm^2 lesion in cASO-treated OB mice compared to 4.7 ± 0.93 mm^2 in APOC3 ASO-treated OB mice, $p<0.001$, n=7-10). Intriguingly, APOC3-ASO treatment reduced diabetes-associated urinary albumin excretion but had no effect on non-diabetic mice (WT mice: 108 ± 24.0 mg urinary albumin/day, OB cASO mice: 1076 ± 219 mg/day and OB mice with APOC3 ASO: 435 ± 63 mg/day, $p<0.001$, n=7-14). Diabetes resulted in a dramatic increase in glomerular neutral lipid and APOC3-accumulation, which was attenuated by APOC3 ASO-treatment. Diabetes led to a doubling of glomerular volume (45126 ± 1908 μm^3 glomerular volume in OB mice vs. 21775 ± 1041μm^3 in WT mice, $p<0.001$, n=7-14), increased glomerular PAS-staining indicative of mesangial expansion (2494 ± 332 μm^2 PAS-positive matrix in OB mice and 822 ± 40 μm^2 in WT mice, $p<0.001$; or from 21% in WT to 28% in diabetes, $p<0.01$), and a significant loss of podocytes (80 ± 8 podocytes/10^6 μm^3 glomerular volume in OB mice and 230 podocytes/10^6 μm^3 glomerular volume in WT mice, $p<0.001$), all of which were in part reversed by APOC3 inhibition (glomerular volume in OB mice treated with APOC3 ASO 36331 ± 2240 μm^3, $p<0.05$; PAS area 1761 ± 131 μm^2, $p<0.01$; and podocyte density 114 ± 9 podocytes/10^6 μm^3 glomerular volume, $p=0.07$, all compared to OB mice treated with cASO).

Conclusions: Together, this suggests that targeting APOC3 and diabetic dyslipidemia might be beneficial for both diabetes-accelerated atherosclerosis and DKD.

PO0949

Shen-Qi-Yan-Shen Formula Attenuates Diabetic Renal Lipid Deposition by Down-Regulating Proteoglycan Expression

Ying Li, Weijian Xiong. *Chongqing Traditional Chinese Medicine Hospital, Chongqing, China.*

Background: Renal lipid deposition is a crucial factor in the pathophysiology of diabetic nephropathy (DN). Proteoglycan (PG) is an important component of the extracellular matrix. Shen-Qi-Yan-Shen Formula (SQYSF) is a clinical empirical formula in treating DN. In this study, db/db mice are used to explore the potential mechanism of SQYSF by down-regulating PG expression.

Methods: We divide the mice into db/m normal control group, db/db model group, SQYSF treated group, captopril treated group, and SQYSF + captopril treated group. The groups of mice are given continuous administration of saline, SQYSF, captopril or SQYSF + captopril for 12 weeks, respectively.

Results: We have revealed that treating db/db mice with SQYSF protects them against renal injury. Our finding is supported by lower blood urea nitrogen and serum creatinine and less urinary albumin in the treated mice compared with the saline-treated db/db controls. Mice treated with SQYSF have significantly reduced protein levels of fasting blood glucose (FBG), HbA1c, TG, LDL-c and HDL-c. SQYSF markedly down-regulates protein expression of proteoglycan (PG), apoB and LDL- receptor in the db/db mice. In addition, captopril exhibits a partial inhibitory effect on PG and other proteins, which can be enhanced by SQYSF.

Conclusions: SQYSF may protect db/db mice by relieving lipid deposition through the down-regulation of PG. These encouraging results corroborate SQYSF's potential of becoming a novel therapeutic strategy for diabetic nephropathy.

Circulating MicroRNAs Associated with Hyperglycemia and Their Effects on Renal Function Decline in Type 2 Diabetes: Global miRNome Analysis

Hiroki Kobayashi, Eiichiro Satake, Zaipul I Md Dom, Andrzej S. Krolewski. *Joslin Diabetes Center, Boston, MA.*

Background: It has been reported that microRNAs (miRNAs) play an important role in the pathogenesis of diabetic complications. We aimed to search for circulating miRNAs that were associated with hyperglycemia in type 2 diabetes (T2D) and examine their effects on renal function decline.

Methods: Using the next-generation sequencing-based HTG EdgeSeq miRNA platform, a total of 2,083 miRNAs were measured in baseline plasma specimens obtained from 73 subjects with T2D and normal renal function (discovery panel), and 136 subjects with T2D and impaired renal function (replication panel). Subjects in both panels were followed for 6-12 years to determine eGFR decline.

Results: We identified 11 candidate miRNAs that were strongly associated with elevated levels of glycated hemoglobin (HbA1c) in both screening and replication panels. Using bioinformatics analyses, we found that the candidate miRNAs targeted proteins of 6 pathways (the Ras signaling pathway, Signaling pathways regulating pluripotency of stem cells, the MAPK pathway, Glutamatergic synapse, the Rap 1 signaling pathway, and the AMPK signaling pathway). Importantly, 4 of these 11 miRNAs were significantly associated with risk of renal function decline.

Conclusions: There were few previous reports about the association between circulating miRNAs, hyperglycemia, and diabetic kidney disease in T2D. The present study comprehensively examined and identified hyperglycemia-regulated miRNAs in human samples. Our findings are novel in that circulating miRNAs regulated by hyperglycemia are associated with risk of eGFR decline in T2D.

Longitudinal Changes in Plasma Biomarkers and Diabetic Kidney Disease Progression in VA NEPHRON-D

Teresa K. Chen,[1] Heather Thiessen Philbrook,[1] Wassim Obeid,[1] Linda F. Fried,[3] Hiddo J. L Heerspink,[4] Chirag R. Parikh,[1] Steven G. Coca.[2] CKD BioCon
[1]*Johns Hopkins University, Baltimore, MD;* [2]*Mount Sinai, New York, NY;* [3]*VA Pittsburgh Healthcare System, Pittsburgh, PA;* [4]*UMCG, Groningen, Netherlands.*

Background: Pathways of inflammation are central to the pathogenesis of diabetic kidney disease (DKD). We previously reported in VA NEPHRON-D that higher baseline levels of soluble tumor necrosis factor receptors 1 and 2 [sTNFR1, sTNFR2] and kidney injury molecule-1 [KIM-1] were associated with DKD progression. Whether longitudinal changes in these and other promising biomarkers are also associated with subsequent kidney function decline is unclear.

Methods: We measured 6 plasma biomarkers (sTNFR1, sTNFR2, KIM-1, interleukin-18 [IL-18], monocyte chemoattractant protein-1 [MCP-1], chitinase-3-like protein-1 [YKL-40]) at baseline and 12 mths. Using Cox models, we studied associations of each biomarker (at baseline, at 12 mths, and relative change from baseline to 12 mths) with kidney function decline (first occurrence of eGFR decrease ≥30 ml/min/1.73 m^2 or >50% if randomization eGFR ≥60 and <60, respectively, or ESRD), adjusting for biomarker, sex, race, treatment arm, BMI, HgbA1c, eGFR, UACR at baseline and age, systolic BP, eGFR, UACR at 12 mths. We excluded events before 12 mths (n=5).

Results: Of 754 VA NEPHRON-D participants with baseline and 12-mth plasma samples, mean eGFR=57 ml/min/1.73 m^2 and median UACR=0.8 g/g. Over a median follow-up of 2.5 yrs, 118 (16%) had kidney function decline. Compared to quartiles 2&3, the highest quartile of delta sTNFR1, sTNFR2, KIM-1, and YKL-40 had 1.7 to 2.0-fold greater risks and the lowest quartile of delta MCP-1 had 52% lower risk of kidney function decline. Higher baseline and 12-mth biomarker levels were also associated with DKD progression [**Figure**].

Conclusions: Repeated measures of several plasma biomarkers in patients with DKD provided additional prognostic information even after adjusting for baseline biomarker levels, clinical variables, and time-updated eGFR and UACR.

A Polyubiquitinated Form of PTEN Predicts Declining Kidney Function and ESKD in Type 2 Diabetes

Helen C. Looker,[1] Chunru Lin,[2] Viji Nair,[3] Matthias Kretzler,[3] Michael Mauer,[4] Behzad Najafian,[5] Robert G. Nelson.[1] [1]*National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ;* [2]*University of Texas MD Anderson Cancer Center, Houston, TX;* [3]*University of Michigan, Ann Arbor, MI;* [4]*University of Minnesota, Minneapolis, MN;* [5]*University of Washington, Seattle, WA.*

Background: Fibrosis is a major driver of chronic kidney disease and epithelial-mesenchymal transformation (EMT) may contribute to its development. A polyubiquitinated form of phosphatase and tensin homolog (PTEN ^{K27polyUb}) promotes EMT *in vitro* and may be a useful biomarker of progressive kidney fibrosis.

Methods: PTEN^{K27polyUb} was measured in 234 serum samples from American Indians (80 men, 154 women) with early diabetic kidney disease (DKD). Quartiles of serum PTEN^{K27polyUb} were assessed as risk factors for DKD progression (≥40% loss of GFR) or onset of end-stage kidney disease (ESKD) using Cox proportional hazards models adjusted for age, sex, diabetes duration, HbA1c, blood pressure, measured GFR and albuminuria.

Results: Baseline, mean age was 42.8 years (SD 10.5), diabetes duration 11.5 years (7.1), mean arterial pressure 90.5 mmHg (9.5), HbA1c 9.3% (2.4), GFR 151 ml/min (45) and median albumin:creatinine ratio 38 mg/g (interquartile range 14-217). 168 subjects had a ≥40% loss of GFR and 74 (64 with prior ≥40% GFR loss) developed ESKD during median follow-up of 6.3 and 15.8 years, respectively. In univariate analysis, serum PTEN^{K27polyUb} was associated with risk of ≥40% GFR decline and of ESKD (Figure). After adjustment for clinical covariates higher PTEN^{K27polyUb} was associated with greater risk of ≥40% GFR decline [Hazard ratio (HR) for the 4th vs. 1st quartile = 3.67, 95% CI 1.98-6.78, p<0.001] and with ESKD [HR quartile 4 vs. 1 = 5.00, 95% CI 1.77-14.11, p=0.002]. Adding serum PTEN^{K27polyUb} increased the model c-statistics from 0.696 to 0.725 for DKD progression and from 0.738 to 0.766 for ESKD.

Conclusions: Higher serum PTEN^{K27polyUb} is associated with increased risk for GFR decline and ESKD in type 2 diabetes and improves prediction over standard clinical measures.

Funding: NIDDK Support

Mahaffey,[14] Vlado Perkovic.[1,15] *[1]Department of Medicine, University of Chicago Medicine, Chicago, IL; [2]The George Institute for Global Health, Sydney, NSW, Australia; [3]Concord Repatriation General Hospital, Sydney, NSW, Australia; [4]Department of Radiology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [5]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [6]Indiana University School of Medicine and VA Medical Center, Indianapolis, IN; [7]Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, New York, NY; [8]Baim Institute for Clinical Research, Boston, MA; [9]Janssen Research & Development, LLC, Raritan, NJ; [10]Kolling Institute of Medical Research, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia; [11]Department of Renal Medicine, UCL Medical School, London, United Kingdom; [12]Renal Division of Peking University First Hospital, Beijing, China; [13]Lunenfeld-Tanenbaum Research Institute, Mt Sinai Hospital, University of Toronto, Toronto, ON, Canada; [14]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [15]The Royal North Shore Hospital, Sydney, NSW, Australia.*

Background: Albuminuria is a risk factor for kidney disease progression and CV disease. We examined the relative and absolute effects of CANA by baseline albuminuria among CREDENCE participants.

Methods: CREDENCE was a double-blind, randomized study of 4401 participants with eGFR 30-<90mL/min/1.73m^2 and uACR >300-5000mg/g who demonstrated that CANA significantly reduced renal and CV outcomes, including the primary composite of end-stage kidney disease, doubling serum creatinine, or renal or CV death. We analyzed the effect of CANA on renal, CV, and safety outcomes by baseline uACR.

Results: At baseline, 2348 (53.4%), 1547 (35.2%), and 506 (11.5%) participants had uACR ≤1000, >1000-<3000, ≥3000mg/g. Higher uACR was associated with higher event rates (Figure). CANA reduced renal and CV endpoints, with no statistical variation by uACR (all p heterogeneity >0.17). CANA led to a greater absolute reduction in renal events in those with higher uACR (number needed to treat to prevent 1 episode of the primary composite: 22 and 8 for uACR >1000-<3000 and ≥3000mg/g). Rates of renal-related adverse events were lower with CANA, and the relative reduction was greater with higher uACR (p heterogeneity=0.003). CANA had no significant effect on acute kidney injury, volume depletion, hyperkalemia, urinary tract infections or hypoglycemia, with no differences by uACR (all p heterogeneity >0.12).

Conclusions: CANA safely reduces renal and CV events in people with type 2 diabetes and substantial albuminuria, with the greatest absolute renal benefit in those with uACR of 3000-5000mg/g.

Lower Cardiorenal Risk with SGLT2 Inhibitor vs. DPP4 Inhibitor in Type 2 Diabetes Patients Without Established Cardiovascular and Renal Diseases

Kåre I. Birkeland,[1] Johan Bodegard,[2] Amitava Banerjee,[8] Dae Jung Kim,[6] Jan W. Eriksson,[3] Marcus Thuresson,[7] Suguru Okami,[5] Kyoung Hwa Ha,[6] Nils Kossack,[10] Jil Billy Mamza,[5] Ruiqi Zhang,[5] Toshitaka Yajima,[5] Issei Komuro,[9] Takashi Kadowaki.[4] *[1]Oslo Universitetssykehus, Oslo, Norway; [2]AstraZeneca PLC, Luton, United Kingdom; [3]Uppsala Universitet, Uppsala, Sweden; [4]Toranomon Byoin, Minato-ku, Japan; [5]AstraZeneca PLC, Luton, United Kingdom; [6]Ajou University School of Medicine and Graduate School of Medicine, Suwon, Gyeonggi-do, Republic of Korea; [7]Statisticon, Uppsala, Sweden; [8]University College London, London, United Kingdom; [9]The University of Tokyo Graduate School of Medicine Faculty of Medicine, Tokyo, Japan; [10]Wissenschaftliches Institut fur Gesundheitsökonomie und Gesundheitssystemforschung, Berlin, Germany.*

Background: Cardiorenal disease, defined by chronic kidney disease (CKD) or heart failure (HF), is a frequent disease manifestation associated with serious risks in T2D patients. We compared new use of sodium-glucose cotransporter-2 inhibitor (SGLT2i) vs. dipeptidyl peptidase 4 inhibitor (DPP4i) and the risk of cardiorenal disease in T2D patients without history of established cardiovascular and renal disease, defined as CVRD-free.

Methods: In this observational cohort study, patients were identified in health care databases in England, Germany, Japan, Norway, Sweden, and South Korea between the years 2012 and 2018. New users of SGLT2i were propensity score matched 1:1 with users of DPP4i. Unadjusted Cox regressions were used to estimate hazard ratios (HRs) for outcomes; cardiorenal disease, HF, CKD, stroke, myocardial infarction (MI) cardiovascular (CV) - and all-cause death (ACD).

Results: Baseline characteristics were well balanced between the treatment groups (n=105,130 in each group) with mean follow up of 1.5 years and 315,015 patient-years. The distribution of follow-up time for SGLT2i and DPP4i types was, dominated by dapagliflozin (91.7%) and sitagliptin/linagliptin (55.0%). SGLT2i was associated with lower risk of cardiorenal disease, HF, CKD, CV- and all-cause death, HR (95% CI) 0.56 (0.42-0.74), 0.71 (0.59-0.86), 0.44 (0.28-0.69), 0.67 (0.59-0.77) and 0.61 (0.44-0.85) respectively. No differences for stroke (0.87 [0.69-1.09]) and MI (0.94 [0.80-1.11]).

Conclusions: In this large multinational observational study of CVRD-free T2D patients, the unique preventive effects of SGLT2is on cardiorenal disease reported from clinical trials are confirmed in a real-world setting.

In Patients with Biopsy-Proven Diabetic Nephropathy, 38% Have a Second Significant Diagnosis

Patrick D. Walker,[1] Vivek Charu,[2] Dao-Fu Dai.[3] *[1]Arkana Laboratories, Little Rock, AR; [2]Stanford University School of Medicine, Stanford, CA; [3]The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA.*

Background: AIM: determine the renal biopsy (Bx) incidence of a second kidney disease (2nd DX) in patients (Pts) with diabetic nephropathy (DN) Bx'ed for various clinical indications.

Methods: Of 45,422 non-transplant cases received from 2001-2014 (2222 nephrologists, 39 states), 7,746 Pts with DN were found. 1,749 cases were excluded for insufficient data. 1,398 cases with FSGS were excluded (separate study). 4,599 cases were analyzed (age range: 8 - >89 years; males 53.5%). Bx indication: acute kidney injury (AKI), acute nephritic syndrome (ANS), rapidly progressive renal failure (RPRF), hematuria (Heme), suspect a non-DN renal disease (Non-DN), sudden increase in

proteinuria (Prot) or chronic kidney disease (CKD). We recorded a specific rule out (r/o) diagnosis if one was given. BX DN Grade: I EM changes; II Mesangial increase; III Nodular Sclerosis; IV >50% Global Sclerosis.

Results: A 2nd DX was found in 1750 (38%) cases. Overall, there were 40 2nd DXs: ATI 41%, acute interstitial nephritis 14%, infection-related glomerulopathy (GN) 7%, etc. There were multiple unexpected 2nd DXs: fibrillary GN, amyloid, dense deposit disease, among others. The highest odds ratio (OR) of a 2nd DX was in Pts with AKI at 3.25 whereas CKD had an OR of 0.03 (Table). Age correlated with a 2nd DX ($p<0.001$) with the Bx incidence ranging from 29% in Pts <30 to 56% for those ≥ 80. In 1,589 cases, a specific DX was to be ruled out. A 2nd Dx was found in 48% of Bx's with a r/o Dx versus 33% when no r/o Dx was given (OR=1.83, CI (1.62, 2.08), $p<0.001$). Lesser grades of DN significantly correlated with a 2nd DX; I - 75%, II - 64%, III - 38%, IV - 20% ($p<0.001$).

Conclusions: In Bx proven DN, a significant 2nd DX was found in 38%, with AKI and ANS most likely to yield a 2nd DX. Age and a r/o DX can further differentiate patient groups most likely to have a 2nd DX. Given the worldwide toll of diabetes, the finding of a potentially treatable 2nd DX in diabetics already at high-risk of end stage kidney disease should provide significant savings in morbidity, mortality and health care expense.

Table: Clinical indication: Odds Ratio of a 2nd DX

Clinical	OR of a 2nd Dx	95% CI	p-value
AKI	3.25	(2.91, 3.63)	<0.001
ANS	2.32	(1.59, 3.37)	<0.001
RPRF	1.43	(0.93, 2.20)	0.099
Heme	0.71	(0.54, 0.93)	0.012
Non-DN	0.64	(0.45, 0.90)	0.01
Prot	0.36	(0.32, 0.40)	<0.001
CKD	0.03	(0.01, 0.08)	<0.001

PO0956

A Clinical and Pathological Study on Association of 4-Hydroxynonenal with Diabetic Kidney Disease

Zhimei Peng, Fanna Liu. *First Affliated Hospital of Jinan University, Guang Zhou City, China*.

Background: To explore the potential correlation between plasma 4-HNE level ,tubulointerstitial 4-HNE deposition and DKD renal tubular atrophy during disease progression.

Methods: 59 patients with clinical diagnosis of DKD and 11 normal control were collected in the First Affiliated Hospital of Jinan University from Dec 2018 to Dec 2019. The 59 patients were divided into CKD Phase 1-3, 4-5 according to the estimate glomerular filtration rate(eGFR). Oxidative stress indicators 4-HNE, superoxide dismutase (SOD) were measured in DKD patients.34 cases of diabetic nephropathy(DN) diagnosed by biopsy in the hospital were divided into 3 groups(CKD 1-2,3,4-5). Biopsy cases were subjected to 4-HNE immunohistochemical staining. Univariate and multivariate logistic regression analysis was performed to identify independent risk factors of DKD incidence, and establishment of DKD eGFR multiple linear regression model was made.

Results: Compared with the normal group, oxidative stress index 4-HNE gradually increased in CKD phase 1-3, 4-5 groups, but SOD gradually decreased ($P<0.05$). Logistic regression analysis found that plasma 4-HNE is an independent risk factor for DKD. ($P=0.008$; OR=1.003,95%CI 1.001~1.006) Pearson correlation analysis showed that plasma 4-HNE levels were positively correlated with systolic blood pressure, mean arterial pressure, urea nitrogen, cystatin C and creatinine, and negatively correlated with hemoglobin and eGFR. The eGFR multiple linear regression model showed that eGFR is independently negatively correlated with tubulointerstitial 4-HNE expression (ß=-0.50,$P<0.001$), urea, history of hypertension, renal tubular atrophy, and independently positively correlated with hemoglobin($R^2=0.84$,$P<0.001$). Variance analysis revealed that there was a statistically significant difference between tubulointerstitial 4-HNE staining scores with the degree of renal tubular atrophy and interstitial infiltrates. ($P< 0.05$)

Conclusions: In the progression of DKD, tubular atrophy, anemia, hypertension were associated with oxidative stress, based on serum and staining of 4-HNE. Staining of 4-HNE can be used as a predictor of renal dysfunction, which may be related to tubular atrophy and interstitial infiltrates. 4-HNE is an independent risk factor for progression of DKD.

Association of Renal Pathological Lesions and Renal Prognosis in Patients with Diabetic Nephropathy and Effect Modification by Proteinuria

Fumihiro Fukata,[1] Masahiro Eriguchi,[1] Hikari Tasaki,[1] Riri Furuyama,[1] Masatoshi Nishimoto,[1] Takaaki Kosugi,[1] Kaori Tanabe,[1] Katsuhiko Morimoto,[2] Masaru Matsui,[3] Ken-ichi Samejima,[1] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Kashihara, Japan; [2]Nara Prefecture Seiwa Medical Center, Ikoma-gun, Japan; [3]Nara Prefecture General Medical Center, Nara, Japan.*

Background: There are few detailed studies on renal pathological findings in diabetic nephropathy (DN) with low urinary protein (UP). We examined whether the association of renal histology with renal prognosis was modified by UP levels in DN diagnosed by renal biopsy.

Methods: The total of 396 participants diagnosed with DN by renal biopsy were divided into 2 groups by the level of UP; ≥0.5 g/day (high-UP group, n = 197) or <0.5 g/day (low-UP group, n = 199). The association of glomerular lesion (GL) and interstitial/tubular lesion (IFTA) with incidence of end-stage kidney disease (ESKD) was examined using Cox proportional hazard model with the adjustment for confounding factors in each proteinuria group.

Results: Compared to high-UP group, low-UP group had a higher eGFR (median [interquartile range (IQR)]: 66 [48, 89] mL/min/1.73m^2 vs 49 [31, 70], $p<0.001$), lower systolic blood pressure (128 [112, 140] mmHg vs 140 [126, 154], $p<0.001$), lower prevalence of severe GL (6.1% vs 56.8%, $p<0.001$) and IFTA (12.2% vs 61.3%, $p<0.001$). During a median [IQR] observation period of 8.3 [3.9, 17.6] years, 14 and 78 patients reached ESKD in low-UP and high-UP groups, respectively. Cox hazard model adjusted for confounding factors showed that both GL and IFTA were significantly associated with renal prognosis in the high-UP group, whereas only IFTA showed significant association in the low-UP group. The association of IFTA with renal prognosis was consistent (p for interaction = 0.45), but that of GL was significantly different between the two groups (p for interaction <0.01).

Conclusions: IFTA is consistently associated with renal prognosis regardless of UP levels, but GL is associated with renal prognosis only in patients with overt UP.

PO0958

Comprehensive Ultrastructural Analysis Strongly Predicts Kidney Function Decline in the Multicenter TRIDENT Cohort

Matthew Palmer,[1] Amin Abedini,[1] Casey Jackson,[1] Shira Blady,[1] Shatakshee Chatterjee,[1] Katie Sullivan,[1] Raymond R. Townsend,[1] Amy K. Mottl,[2] Salem Almaani,[5] Anand Srivastava,[4] Rupali S. Avasare,[6] Michael J. Ross,[3] Jens Brodbeck,[7] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Albert Einstein College of Medicine/ Montefiore Medical Center, Bronx, NY; [4]Northwestern University Feinberg School of Medicine, Chicago, IL; [5]The Ohio State University Wexner Medical Center, Columbus, OH; [6]Oregon Health & Science University, Portland, OR; [7]Inflammation & Respiratory Therapeutics, Gilead Sciences Inc., Foster City, CA.*

Background: While diabetic kidney disease (DKD) is responsible for more than half of all chronic and end stage kidney disease (ESKD), the association of light (LM) and electron microscopical (EM) structural changes with clinical parameters and prognosis in late stage DKD is not completely determined.

Methods: TRIDENT (Transformative Research in Diabetic Nephropathy) is a multi-center observational cohort aimed to identify changes associated with kidney function decline in an unbiased manner. Sixty-two patients diagnosed with biopsy-confirmed DKD were enrolled. Digital scans of biopsy slides and EM were scored for twelve LM and eight EM parameters. Demographic and clinical features of the patients were recorded at enrollment and patients were followed-up every six months.

Results: The median estimated glomerular filtration rate (eGFR) was 28.91(20.87) ml/min/1.73m^2 and the urine protein to creatinine ratio (UPCR) at enrollment was 4.64(7.25) mg/mg. During a mean follow-up time of 10.6 months, the median change in eGFR was -25.8(58) % and median fold change in UPCR was 1.29(2.15) and 17 patients progressed to ESKD. Multiple linear regression analysis revealed that interstitial fibrosis independently associated with eGFR at enrollment. Glomerular lesions including global glomerulosclerosis and mesangiolysis were associated with eGFR decline. Foot process effacement significantly associated with UPCR at enrollment and mesangial hyalinosis predicted UPCR fold change. Unbiased clustering analysis identified three disease subgroups of which cluster 2(N=11) showed more pronounced damage by LM and EM parameters and had the fastest eGFR decline, while cluster 1(N=25) had the slowest eGFR decline and the least severe structural lesions. Cox regression analysis showed that the subjects in cluster 2 had the highest risk to reach ESKD (HR=14.8, 95%CI; 1.76-123.73, P=0.01).

Conclusions: This study confirms association of structural and clinical parameters even in late stage DKD. Furthermore, it highlights specific ultrastructural features that can strongly predict kidney function decline.

PO0959

The Association Between Kidney Biopsy Findings in Diabetic Patients and Renal Replacement Therapy Initiation

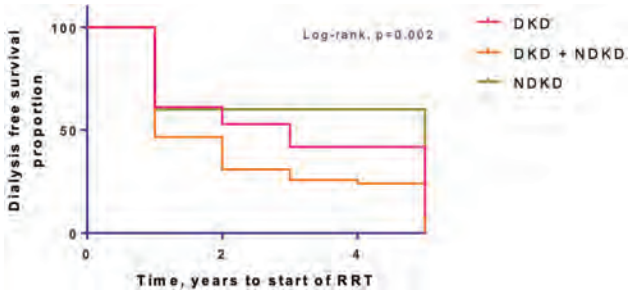
Enzo C. Vasquez jiménez,[1] Ana Lucia L. Diez de Sollano Basila,[1] Ivan A. Osuna Padilla,[2] Virgilia Soto,[1] Magdalena Madero.[1] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico.*

Background: Diabetic Kidney Disease (DKD) is the leading cause of Chronic Kidney Disease (CKD) worldwide. Nevertheless, about a third of type 2 diabetic patients with kidney involvement have Non-Diabetic Kidney Disease (NDKD). The distinction between DKD and NDKD can only be done accurately with kidney biopsy. There is lack of evidence in regards to the association between NDKD and CKD progression. The objective of the study was to evaluate the association of DKD, NDKD or both with Renal Replacement Therapy (RRT) initiation.

Methods: This is a retrospective study of patients with T2DM who underwent a kidney biopsy between 2006 and 2019 at the Department of Nephrology at the National Institute of Cardiology in Mexico City. The included patients were followed for five years or until start of RRT. According to presence of diabetic nephropathy and non-diabetic glomerular disease, three groups were identified: group 1: patients with DKD, group 2: patients with NDKD and group 3: patients with combined DKD and NDKD.

Results: A total of 141 DM patients were included, the mean age was age 52.4 ± 12.2 years and 48.2%. The main indication for kidney biopsy was nephrotic proteinuria in 46 patients (32.6%), rapidly impaired kidney function in 23 patients (16.3%), nephrotic syndrome in 24 patients (17%) and suspicion of others glomerulopathies in 4 patients (2.8%). Based on kidney biopsy findings, 53 (39.1%) had DKD, 13 (9.2%) had NDKD and 75 (53.5%) had both DKD and NDKD. One hundred and four (74%) patients required RRT in the follow-up, 36 in DKD group, 10 in the NDKD group and 58 in the group with both DKD and NDKD. Patients with highest degree of fibrosis (grade 2 and 3 vs 1) (n =93) had a higher risk of starting RRT (RR 9.53, CI 95% 1.77- 51.3, p=0.009). Kidney survival was poorer in the DKD and NDKD group (p = 0.002) (**Figure 1**).

Conclusions: Kidney biopsies is this population could be of use in order to risk stratify this population. Subjects with the combination of DKD and NDKD have the worst renal prognosis.



PO0960

The Aging Kidney: Renal Parenchymal Volumes from MRI, a Comparison Between Type 2 Diabetes and Non-Type 2 Diabetes in 37,450 UK Biobank Participants

Lars Johansson,[1] Taro Langner,[3] Paul Hockings,[1] Lisa Jarl,[1] Lukas Maldonis,[1] Tove Fall,[2] Håkan Ahlström,[3,1] Joel Kullberg.[3,1] *[1]Antaros Medical, Mölndal, Sweden; [2]Uppsala universitetet Institutionen for medicinsk biokemi och mikrobiologi, Uppsala, Sweden; [3]Uppsala University, Department of Surgical Sciences, Radiology, Uppsala, Sweden.*

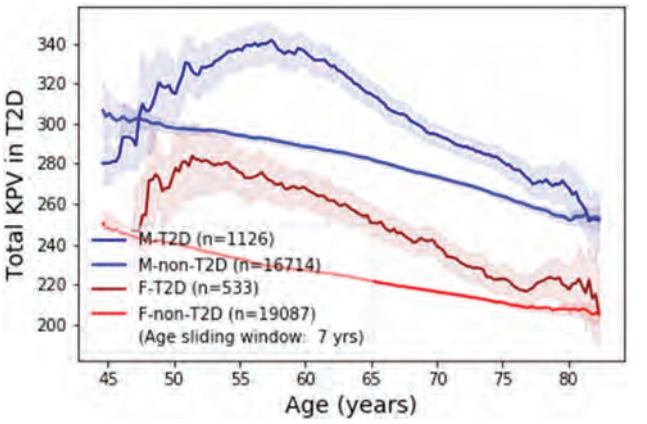
Background: It is well known that Type 2 Diabetes (T2D) early on is associated with increased kidney volumes but also can cause Diabetic Nephropathy. UK Biobank (UKB) is a large-scale cross-sectional study aiming to examine 100,000 subjects aged 44 to 82 years using Magnetic Resonance Imaging (MRI). Resulting images allow measurements of Kidney Parenchyma Volume (KPV). The purpose of this study was therefore to quantify KPV and investigate the association with age in T2D and non-T2D subjects.

Methods: An automated deep learning-based method for direct KPV segmentations and measurements was developed and validated and applied to UKB MRI in 37,450 subjects. KPV was analyzed as a function of diagnosed T2D (defined as diagnosis of diabetes after 40 y/o), sex and age. Furthermore, correction for lean tissue volumes assessed by MRI was performed in all subjects.

Results: KPVs from 37,450 subjects (47.6% males) as a function of T2D, sex and age are shown in Fig1. In non-T2D a steady decline in KPV is seen in both males and females. KPV is significantly larger in T2D subjects (1126 males, 530 females), over 50 years of age compared to non-T2D. This is followed by a faster KPV decline in T2D compared to non-T2D subjects. Adjusting for lean tissue volumes from MRI did not change the difference in decline rates between T2D and non-T2D subjects.

Conclusions: T2D subjects have a larger KPV than non-T2D in middle aged subjects but show a faster KPV decline, independent of lean tissue volume differences. The faster decline in T2D can potentially be explained by increased hyperfiltration and oxidative stress in T2D.

Funding: Private Foundation Support, Government Support - Non-U.S.



Total KPV as a function of T2D, sex and age. Mean values and 95% confidence intervals are shown from a sliding window of 7 years.

Assessment of Histopathological Prognosticators in Diabetic Nephropathy: Single-Center Experience

Ahmad M. Khalaf, Awais Nauman, Mohamad M. Alkadi, Adel A. Abdelaziz, Ahmed F. Hamdi, Muhammad Asim, Omar Fituri, Hassan A. Al-Malki, Mohammed Akhtar, Essa Abuhelaiqa. *Hamad Medical Corporation, Doha, Qatar.*

Background: Diabetic nephropathy (DN) is the leading cause of end stage kidney disease worldwide. Identification of clinical, laboratory and histopathological predictors of kidney failure in DN may improve outcomes.

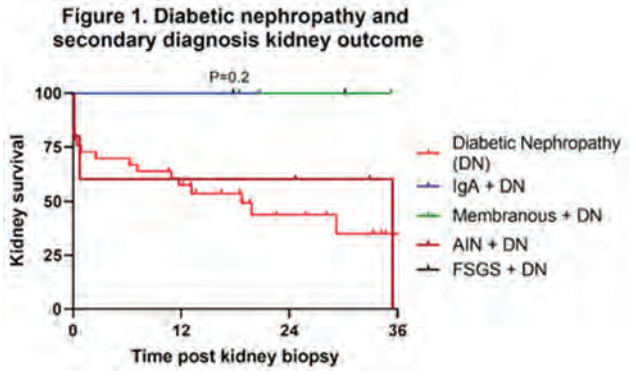
Methods: We identified 45 kidney biopsies between 2017 to 2018 that were diagnosed with DN. Clinical, laboratory and histopathological variables were analyzed to prognosticate 1-year kidney failure.

Results: Sixteen of 45 patients with DN had kidney failure within 12 months of kidney biopsy while 29 patients did not. All patients who developed kidney failure had diabetic retinopathy as shown in table 1. Laboratory findings such a serum creatinine (597umol/L vs. 205umol/L, P<0.0001) and presence of hematuria (88% vs. 45%, P=0.01) prognosticated kidney outcome, while neither proteinuria or Hemoglobin A1C did. IFTA score (2.4 vs. 1.8, P=0.02) and global glomerular sclerosis (52% vs. 32%, P=0.002) were the only histological findings that prognosticate kidney failure. Patients who have a second kidney diagnosis in addition to DN such as IgA, FSGS and MN had favorable outcomes compared to DN and AIN or DN only [figure 1].

Conclusions: We identified serum creatinine, hematuria, IFTA and glomerular sclerosis as prognosticators of kidney failure at 1-year following DN diagnosis. Identification of patients at risk of kidney failure help individualize therapy and hence improve kidney outcomes.

Table 1. Predictors of kidney failure in diabetic nephropathy

Variable	Kidney failure (n=16)	No kidney failure (n=29)	P value
Clinical Findings			
Age at biopsy	50±14	50±11	0.9
Female gender	3 (13%)	3 (10%)	0.7
Duration of diabetes mellitus (years)	13±7	13±9	0.9
Diabetic Retinopathy at biopsy	13/13 (100%)	13/18 (72%)	0.06
Indication of biopsy			
Proteinuria	7 (44%)	17 (59%)	0.4
Worsening CKD/AKI	5 (31%)	8 (28%)	0.9
Laboratory Finding			
Hemoglobin A1C at biopsy	7.4±1.6	7.6±2.2	0.7
Creatinine at biopsy	597±382	205±107	<0.0001
Urine protein/creatinine ratio at biopsy (mmol/g)	948±509	670±393	0.07
Hematuria at biopsy	14 (88%)	13 (45%)	0.01
Biopsy finding			
Interstitial fibrosis and tubular atrophy score (IFTA, 0-3)	2.4±0.8	1.8±1.0	0.02
Glomeruli with global sclerosis (%)	52±20	32±22	0.002
Nodular hyalinosis	11 (69%)	17 (59%)	0.5
Arteriosclerosis	16 (100%)	26 (90%)	0.5
Immunofluorescent deposition	13 (81%)	18 (62%)	0.3
Second diagnosis in addition to diabetic nephropathy	3 (19%)	11 (38%)	0.3
Focal Segmental glomerular sclerosis	0	3 (10%)	0.5
IgA nephropathy	0	1 (3%)	1
Acute interstitial nephritis (AIN)	2 (13%)	3 (10%)	0.3



PO0962

Phosphorylated Akt (pAkt) and Myostatin: The Yin and Yang of the Control of Muscle Protein Metabolism in Patients with Diabetic Kidney Disease

Daniela Picciotto,[1] Samantha Milanesi,[1] Michela Saio,[1] Giuliano Brunori,[2] Chiara Venturelli,[2] Giacomo Garibotto,[1] Daniela Verzola.[1] *[1]Department of Internal Medicine, Nephrology Division, Policlinico San Martino, Genova, Italy; [2]Ospedale Santa Chiara, Trento, Italy.*

Background: Muscle wasting is common in patients with diabetic kidney disease (DKD). Both uremia and diabetes cause inflammation and insulin resistance in skeletal muscle, thus promoting wasting. However, the muscle response in DKD is not known yet. Our aim was to evaluate the intracellular signals controlling protein synthesis and degradation in muscle of patients with DKD. We studied intracellular pAkt (a downward effector of the insulin signal), myostatin (MSTN), p38MAPK, MURF and Atrogin in skeletal muscle of patients with diabetic CKD (DCKD) (n=17, age 69 years±7, eGFR 9 ± 3 ml/min/1.73m^2) as compared to non diabetic CKD (NDCKD) (n=32, age 67 years±11, eGFR 7.5 ± 2 ml/min/1.73m^2) and controls (C) (n=24, age 67 years±11, eGFR 77 ± 13 ml/min/1.73m^2).

Methods: Rectus abdominis muscle biopsies were obtained during the insertion of peritoneal dialysis catheters and during elective surgery for abdominal wall hernias (C). Protein expression (pAkt, MSTN, p38MAPK) was evaluated by immunohistochemistry and western blot, mRNA expression (MSTN, Murf, Atrogin) by rt-PCR.

Results: The expression of pAkt was significantly more downregulated in DCKD as compared to NDCKD and C (P <0.05). MSTN expression was significantly lower in C as compared to DCKD and NDCKD (P<0.05). MSTN mRNA was similary upregulated in DCKD and in NDCKD with respectively a 21- and a 18- fold increase compared to controls. Atrogin and Murf mRNA were both upregulated in DCKD and in NDCKD; in DCKD Murf mRNA presented a 18- and atrogin mRNA a 16- fold increase compared to controls while in NDCKD we found respectively a 12- and a 9- fold increase.

Conclusions: With respect to non DKD, intracellular insulin signaling is particularly blunted in muscle of patients with DKD, while myostatin is similarly overexpressed. In diabetes, the abnormal pAkt levels in conjuction with myostatin overexpression are likely to orchestrate the wasting syndrome.

PO0963

Incident CKD in Diabetes, Hypertension, and Prediabetes

Cami R. Jones,[1] Kenn B. Daratha,[1] Susanne B. Nicholas,[2] Radica Z. Alicic,[1] Obidiugwu Duru,[2] Keith C. Norris,[2] Nilka Rios Burrows,[3] Katherine R. Tuttle,[1] Meda E. Pavkov.[3] *[1]Providence Health and Services, WA, Spokane, WA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Hypertension (HTN), diabetes mellitus (DM), and prediabetes (PDM) are major risk factors for chronic kidney disease (CKD), yet community-level longitudinal studies of CKD incidence are lacking. The study aim was to determine CKD incidence rates in these at-risk groups by practice- and guideline-based definitions.

Methods: The Center for Kidney Disease Research, Education, and Hope (CURE-CKD) registry is curated from electronic health records with clinical and administrative data from two large non-profit healthcare systems. CKD incidence (95% CI) in adults was calculated over 4, two-year time periods during 2010-2017 adjusted for age, sex, and race/ethnicity. CKD was identified by 2 definitions: 1. Practice-based, CURE-CKD: At least 2 laboratory measures for CKD ≥90 days apart (estimated glomerular filtration rate - eGFR <60 mL/min/1.73m^2, urine albumin/creatinine ratio - UACR ≥30 mg/g, or urine protein/creatinine ratio - UPCR ≥150 mg/g) or CKD administrative code; 2. Guideline-based, Kidney Disease Improving Global Outcomes (KDIGO): At least 2 eGFRs <60 mL/min/1.73m^2 or 2 UACRs/UPCRs >30 mg/g/≥150 mg/g ≥90 days apart.

Results: Overall adjusted CKD incidence rates declined over 2010-2017 by both definitions with lower rates by KDIGO (Table). By CURE-CKD, CKD incidence increased in the HTN group.

Conclusions: The practice-based CURE-CKD definition produced higher estimates of CKD incidence than the stricter guideline-based KDIGO definition. CKD incidence declined in all groups, except for HTN by the CURE-CKD definition, and was highest in patients with DM/HTN. Targeting these at-risk conditions for control may mitigate new onset CKD in these groups.

Funding: Other U.S. Government Support

Table: Adjusted CKD incidence rates per 1000 person-years (95% CI)

	2010-2011	2012-2013	2014-2015	2016-2017
Overall				
CURE-CKD (N=2,172,467)	65.9 (65.3-66.5)	62.0 (61.6-62.4)	52.3 (52.0-52.6)	52.6 (52.3-52.9)
KDIGO (N=2,181,246)	58.6 (58.0-59.2)	39.8 (39.5-40.1)	30.8 (30.6-31.0)	28.1 (27.9-28.3)
DM/HTN				
CURE-CKD (N=435,847)	124.0 (121.1-126.8)	130.4 (129.0-131.8)	104.5 (103.6-105.4)	97.0 (96.1-97.9)
KDIGO (N=444,947)	94.6 (92.2-97.0)	80.3 (79.2-81.4)	61.5 (60.8-62.2)	51.8 (51.2-52.4)
DM/no HTN

New Diagnostic Model for the Differentiation of Diabetic Nephropathy from Non-Diabetic Nephropathy in Chinese Patients

Xiaomin Liu, Weiguang Zhang, Zheyi Dong, Qian Wang, Yizhi Chen, Yong Wang, Liangmei Chen, Guangyan Cai, Xiangmei Chen. *Department of Nephrology Chinese PLA General Hospital, Chinese PLA Institute of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing, Beijing, China.*

Background: The differential diagnostic criteria of non-diabetic nephropathy (NDRD) and diabetic nephropathy (DN) usually depend on the 2007 KDOQI guideline, which is not accurate enough. Renal pathological biopsy is the gold standard for diagnosis, which is an invasive method and may cause several complications. This study aimed to construct a new noninvasive evaluation method for the differentiation of DN and NDRD.

Methods: We retrospectively screened 1030 patients (January 2005-March 2017). Variables were ranked in terms of importance, and random forest (RF) and support vector machine(SVM) were then used to construct the models. The final model was validated using an external group (338 patients, April 2017-April 2019), and compared with previous models.

Results: A total of 929 patients were assigned for model development. Ten variables were selected for model development. The area under the receiver operating characteristic curve (AUCROC) for the RF and SVM methods were 0.953 and 0.947. A total of 329 patients were analyzed for external validation. The AUCROC for the external validation of the RF and SVM method were 0.920 and 0.911.

Conclusions: We successfully constructed predictive model for DN and NDRD by machine learning methods, which were better than traditional ways.

Funding: Government Support - Non-U.S.

Performance for SVM and other models in external validation

	Models	Sensitivity	Specificity	PPV	NPV	AUCROC
Isolated DN vs. Isolated NDRD	SVM	0.8671	0.8889	0.9257	0.8073	0.9108
	RF	0.9048	0.8636	0.8986	0.8716	0.9203
	Model-2008	0.8926	0.7059	0.7297	0.8807	0.8855

A Simulation Model for CKD Progression Among Patients with Type 2 Diabetes in the United States

Wen Ye,[2] Shihchen Kuo,[3] Ryan Farej,[1] Rakesh Singh,[1] Xuemei Ding,[2] Nathaniel Putnam,[2] Sheldon Kong,[1] Jay Elliott,[1] Jason Lott,[1] William H. Herman.[3] *[1]Bayer U.S. LLC, Whippany, NJ; [2]Department of Biostatistics, University of Michigan, Ann Arbor, MI; [3]Department of Internal Medicine, University of Michigan, Ann Arbor, MI.*

Background: Patients with type 2 diabetes (T2D) and chronic kidney disease (CKD) are at a higher risk of end-stage renal disease (ESRD), cardiovascular diseases and mortality. Modeling CKD progression in patients with T2D can help guide disease management for reducing clinical and economic burdens of CKD.

Methods: We developed a discrete-state and discrete-time microsimulation model for predicting changes of underlying risk factors over time and the progression of kidney disease, coronary heart disease, and cerebrovascular disease among patients with T2D and CKD. Transition probabilities were modeled as patient-level characteristics and risk factors, current disease state, and treatment status, with model parameters derived from individual-level data and summary data in published literature. Changes in risk factors for ESRD (urine albumin to creatinine ratio [UACR], estimated glomerular filtration rate [eGFR]), and risk equations for ESRD, myocardial infarction (MI), congestive heart failure (CHF), stroke, and death without ESRD were developed using longitudinal data of a T2D subpopulation in the Chronic Renal Insufficiency Cohort (CRIC). This model underwent calibration and validation against the CRIC patients with T2D and CKD over a 7-year follow-up period.

Results: At baseline, 1,441 CRIC participants with T2D and CKD (mean age: 61.6 years) were available for model development and validation. Concordance between observed and predicted outcomes for the five risk equations ranged from 0.71 to 0.90. The simulated event rates of ESRD, CHF, MI and stroke using estimated changes in key risk factors, and the related 95% confidence intervals covered the observed event rates in CRIC.

Conclusions: The model provided reliable estimates of disease progression among T2D patients with CKD. Modeling disease progression in this population will allow assessment of the impact of early detection and interventions, which may alter the economic and quality of life burden of CKD.

Joint Model of eGFR Slope: Data from LEADER in Patients with Type 2 Diabetes and High Risk of Cardiovascular Events

Johannes F. Mann,[1,2] Heidrun Bosch-Traberg,[3] Soren Rasmussen,[3] Benjamin Wolthers,[3] Hiddo J. L Heerspink.[4,5] *[1]KfH Kidney Centre, Munich, Germany; [2]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [3]Novo Nordisk A/S, Søborg, Denmark; [4]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [5]The George Institute for Global Health, University of New South Wales Sydney, Sydney, NSW, Australia.*

Background: The LEADER cardiovascular (CV) outcome trial (NCT01179048) suggested liraglutide provides renal benefits vs placebo in patients with type 2 diabetes and high CV risk. Aiming to improve the modeling of eGFR slope (surrogate marker of renal outcomes), this *post hoc* analysis compared a joint model with the usual random slope model.

Methods: Two models were applied: 1) random slope model for eGFR using an effect modifier for treatment (liraglutide vs placebo) in change from baseline; 2) joint model using two processes (the same random slope model *and* a hazard model for time to a composite endpoint [all-cause death or ESRD]). These processes were correlated using predicted patient-level effects of eGFR across time, adjusting eGFR slopes for dropouts due to the composite. Those with renal impairment (eGFR <60 mL/min/1.73 m^2 and UACR ≥30 mg/g) at baseline were also analyzed.

Results: Comparing the joint vs random slope models, average eGFR slopes were decreased for liraglutide (-1.77 vs -1.70 mL/min/1.73 m^2/year) and placebo (-2.03 vs -1.96 mL/min/1.73 m^2/year) for all participants (Table). For those with renal impairment, the eGFR slopes estimated using the two models were markedly different for both liraglutide (-2.49 vs -2.08 mL/min/1.73 m^2/year) and placebo (-3.50 vs -3.04 mL/min/1.73 m^2/year). A 1 mL/min/1.73 m^2 lower eGFR value at baseline increased risk of the composite by 3% and change from baseline of -1 mL/min/1.73 m^2 increased it by 6% for all participants. Respective values for those with renal impairment were 6% and 13%.

Conclusions: Liraglutide reduced eGFR slope vs placebo in both models. Joint modeling, which utilized dropout due to death or ESRD, altered the estimation of eGFR slope in LEADER, with a more marked decrease in the high risk group vs the random slope model. It did not change the liraglutide vs placebo treatment effect. Joint modeling may be useful in analyzing future trial data.

Funding: Commercial Support - Novo Nordisk A/S

PO0967

Large Database Longitudinal Assessment of Electrolyte Abnormalities in Diabetic Patients Receiving SGLT2 Inhibitors

Harish Shanthanu Seethapathy, Sophia Zhao, Andrew S. Allegretti, Sahir Kalim, Sagar U. Nigwekar. *Massachusetts General Hospital, Boston, MA.*

Background: In diabetic patients, the osmotic diuresis and natriuresis induced by sodium glucose co-transporter 2 (SGLT2) inhibitors produces changes in the serum level of electrolytes such as potassium, magnesium and calcium. Incidence of electrolyte abnormalities induced by these agents in a 'real-world' setting has not been studied.

Methods: We included all patients with diabetes who were prescribed canagliflozin, empagliflozin or dapagliflozin at our healthcare system between 2012-2019. Demographics, baseline medication use, comorbidities, and laboratory values were obtained by querying a centralized research repository. Serum electrolyte levels at SGLT2 inhibitor initiation were compared to electrolyte levels in the 6 months after initiation and the most extreme post-baseline levels were used to determine incidence of electrolyte abnormalities.

Results: In total, 1630 patients were included. Average age was 61 (SD 11) years, 63% identified as male, 71% as white. Hypertension was present in 85%, congestive heart failure in 20%; 18% had an estimated glomerular filtration rate (eGFR) <60 mL/min/m^2 and 12% had uncontrolled diabetes (A1C>10g/dL). ACE inhibitor/ARB use was present in 80% and 5% of patients (n=81) had elevated potassium (>5mEq/L) at baseline. In the first 6 months after drug initiation in patients without elevated potassium at baseline (n=1549), 12% experienced new hyperkalemia (>5 mEq/L) with 4% of patients experiencing a potassium level >5.5 mEq/L. Potassium >6 mEq/L was seen in 1%. Ten percent of patients with eGFR≥60 mL/min/m^2 experienced hyperkalemia when compared to 21% of patients with eGFR<60 mL/min/m^2 (p<0.01). Hyponatremia (<135 mEq/L) was seen in 12% of patients, with values <130 mEq/L seen in 2%. Hypomagnesemia (<1.5 mg/dL) was present in 3% and hypocalcemia (albumin-corrected calcium<7 mg/dL) was seen in 0.1%.

Conclusions: Patients with eGFR≤60 mL/min/m^2 are particularly at high risk of developing hyperkalemia post-SGLT2 initiation. Effective monitoring and treatment strategies are needed to mitigate risks associated with hyperkalemia.

Funding: Commercial Support - Relypsa Fellowship grant

Incidence of electrolyte abnormalities (%)

Hyperkalemia (>5 mEq/L)	12%
Hyponatremia (<135 mEq/L)	12%
Hypomagnesemia (<1.5 mg/dL)	3%
Hypocalcemia (<7 mg/dL)	0.1%

PO0968

Hyperkalaemia Risk and Mortality in Patients with Diabetes

Philip McEwan,[1] Michael A. Hurst,[1] Louise Hoskin,[1] Eskinder Tafesse,[2] Karolina Badora,[1] Daniel Sugrue,[1] Glen James.[3] *[1]Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; [2]Global Health Economics, Astrazeneca, Gaithersburg, MD; [3]Global Medical Affairs, AstraZeneca, Cambridge, United Kingdom.*

Background: Diabetes mellitus (DM) is associated with micro- and macrovascular complications, including chronic kidney disease (CKD) and cardiovascular events. Renin-angiotensin-aldosterone system inhibitors (RAASi) are recommended for the management of these conditions; however, their usage may increase the risk of hyperkalaemia (HK), a potentially fatal electrolyte imbalance.

Methods: Patients with type 1 or 2 DM aged ≥18 years were identified from linked primary and secondary care data from the UK Clinical Practice Research Datalink and Hospital Episode Statistics, respectively. DM and relevant complications/comorbidities (CKD; history of major adverse cardiovascular events [MACE] comprising arrhythmia, heart failure, myocardial infarction and stroke) were identified through READ codes recorded during the study period (2008–June 2018) or the five-year look-back period (2003–2007). Index date was the latter of 1st January 2008 or initial DM diagnosis. Event rates (adjusted for age and sex) of HK (serum potassium [SK^+] ≥5.0 mmol/L; ≥5.5 and ≥6.0 mmol/L were also explored) and all-cause mortality (ACM) were estimated over the follow-up period (from index date to the first of: death, loss to follow-up, end of study). Accumulation of complications/comorbidities over time resulted in re-classification.

Results: 288,871 DM patients were included with a mean follow-up of 5.87 (standard deviation [SD] 3.23) years. Available follow-up (1,000 patient-years [PYs]) was 1,038 for DM; 149 for DM + CKD; 129 for DM + MACE and 89 for DM + CKD + MACE. ACM incidence increased in line with increasing comorbidity burden, to 146.73 per 1,000 PYs in the DM + CKD + MACE cohort. At the SK^+ threshold of ≥5.0 mmol/L, the incidence of HK was highest in patients with CKD (779.27/635.26 per 1,000 PYs with/without MACE, respectively) and lower in patients without CKD (384.13/246.83 per 1,000 PYs with/without MACE, respectively). The same between-cohort pattern was observed at thresholds of ≥5.5 and ≥6.0 mmol/L. CKD and/or MACE was associated with higher levels of RAASi prescription (61.91% vs 74.86%–76.28%).

Conclusions: DM patients with CKD and/or MACE are at increased risk of HK and ACM. Routine monitoring of SK^+ and prompt management of HK episodes could improve clinical outcomes in DM patients, particularly those with CKD and/or a history of MACE.

PO0969

Cumulative Average and Variability of Blood Glucose, Blood Pressure, and Lipids Are Associated with Incidence of Albuminuria, but Not Reduced Kidney Function, Among Patients with Type 2 Diabetes

Jinwei Wang,[1] Luxia Zhang,[1,2] Ming Hui Zhao.[1,3] *[1]Peking University First Hospital, Beijing, China; [2]National Institute of Health Data Science at Peking University, Beijing, China; [3]Peking-Tsinghua Center for Life Sciences, Beijing, China*.

Background: We evaluated the effect of cumulative average and variability of fasting blood glucose, blood pressure and lipids on the incidence of albuminuria and reduced estimated glomerular filtration rate (eGFR) among a population with diabetes.

Methods: The study was based on the Kailuan cohort in Tangshan of China. The study baseline was the 2014-2015 circle of health examination. Totally, 1569 patients with type 2 diabetes identified in the 2008-2009 circle, with participation of at least 3 circles of health examination (3-5 times) between 2008 and 2015, and with negative finding in dipstick test and a normal eGFR at baseline were included. The occurrence of albuminuria (urine albumin to creatinine ratio≥30mg/g) and eGFR<60ml/min/1.73m^2 (with an absolute decline of >10%) was ascertained during 2016-2017. eGFR was determined with the CKD-EPI creatinine equation in the 2014-2015 circle and corresponding cystatin-C equation in the 2016-2017 circle. Cumulative average and intraindividual standard deviation (SD) of fasting blood glucose (FBG), systolic blood pressure (SBP), triglycerides and low-density lipoprotein cholesterol (LDL-C) were calculated. Multivariable logistic regression was used to estimate the association of the average and SD values of each variable with the events.

Results: The mean age of the population was 61.8±8.6 years, with a male dominance (77.6%). In the 2016-2017 circle, there were 499 events of albuminuria and 184 of reduced eGFR occurred. Cumulative average, but not SD of FBG, was significantly associated with incident albuminuria, with odds ratios (ORs) and 95% confidence interval of 1.20 (1.11-1.29) per 1 mmol/L increase. Both average and SD of SBP were associated with incident albuminuria with ORs of 1.17 (1.07-1.28) per 10 mmHg increase of average SBP and 1.16 (1.06-1.28) per 5 mmHg increase of SD of SBP. Triglycerides was associated with incident albuminuria with OR of 2.15(1.47-3.13) per one log-transformed value increase. However, no associations between the cumulative average and SDs of FBG, SBP, triglycerides and LDL-C and occurrence of reduced eGFR were found.

Conclusions: Cumulative exposure of FBG, SBP and triglycerides, as well as variability of SBP, could increase the risk of albuminuria among patients with type 2 diabetes.

The Application of Estimated Glomerular Filtration Rate Equations in Diabetic Kidney Disease Patients

Ming Li, Canming Li, Zengchun Ye, Hui Peng. *Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*.

Background: To evaluate the application of formulas based on serum creatinine and cystadin-C levels in Chinese patients with type2 DM.

Methods: 224 type-2 DM patients were included in this study. Take the 99mTc-DTPA-GFR (sGFR) which standardization by Body Surface Area(BSA) as the golden standard. Estimated GFR (eGFR) was calculated respectively with abbreviated MDRD equation, modify and abbreviated MDRD equation, Cockcroft-Gault equation, CKD-EPI equation, RuJin equation, EPI-Cys2 equation. eGFR were compared with 99mTc-DTPA-GFR (sGFR).

Results: (1)Bland-Altman analysis results demonstrated that consistency of EPI-Cys2 equation and RuJin with sGFR were better than other equation, but all the equation were above the limite professional point. The slopes of EPI-Cys2 equation were closer to the identical line. (2)Bias of EPI-Cys2 equation was smaller than other equations. EPI-Cys2 equation underestimated actual GFR and other equations overestimated GFR. 30% and 50% accuracy rate of Ruijin equation and EPI-Cys2 equation were higher than other equations. (3)As to diagnosis CKD in DM patients, EPI-Cys2 equation was more sensitive and acurrate, and the cut-point of EPI-Cys2 equation and Ruijin equation was closer to 60ml/min.

Conclusions: All six equations show bias in estimating actual GFR. Compared with the equations induced by plasma creatine, EPI-Cys2 equation was more accurate and efficient, and followed by Ruijin equation. All equations should be amended when applying to Chinese DM patients.

PO0971

Advanced CKD Augments the Risk of Hypoglycemia with Insulin Use

Daulton Grube,[1] Guo Wei,[2] Robert E. Boucher,[2] Srinivasan Beddhu.[2] *[1]University of Washington School of Medicine, Seattle, WA; [2]The University of Utah School of Medicine, Salt Lake City, UT.*

Background: Both insulin use and CKD are known risk factors for hypoglycemia in type 2 diabetes (T2D) but it is unclear whether advanced CKD augments the risk of hypoglycemia with insulin use.

Methods: We analyzed a national veteran cohort (N =944,891) with T2D defined by ICD-9 codes and outpatient serum creat measurements from 1/2008 to 12/2010. Index date was defined as the date of first outpatient serum creat measurement. Duration of T2D was calculated by the first occurrence of ICD-9 codes for T2D, HbA1C > 6.5% or use of anti-diabetic meds from 10/1999 to the index date. Baseline comorbidities were similarly defined by ICD-9 codes. Insulin use at index date was determined by prescription data. Hypoglycemic episodes requiring medical attention were defined by ICD-9 codes and tracked from index date until 2/2016. A multivariate logistic regresssion model of baseliine variables including demographics, duration of T2DM, HbA1C, retinopathy, BMI, other anti-diabetic meds and comorbidities was used to develop propensity scores of baseline insulin use (22% were on insulin at baseline). A propensity score matched cohort (N = 324,064) was used to relate baseline insulin use and CKD stages with subequent hypoglycemic episodes in Cox regression models.

Results: Baseline mean age was 65±11 yrs, 19% black and mean eGFR 71±24. There were 16,048 of hypoglycemic episodes over 1,529, 224 years of follow up. There was a graded increase in incidence rate of hypoglycemic events by CKD stages and insulin use (Fig). In a Cox regression model adjusted for propensity scores as well as above covariates, compared to eGFR >90 with no insulin use (Fig), the risk of serious hypoglycemic episodes was highest in the stage 4/5 CKD group on insulin (HR 4.79, 95% CI 4.31 to 5.32). Interaction p = 0.018 for insulin use and CKD stages for the risk of hypoglycemia.

Conclusions: Advanced CKD augments the risk of hypoglycemia with insulin use. Whether novel anti-diabetic agents are safer than insulin for the risk of hypoglycemia in advanced CKD needs to be studied.

PO0972

The Effect of Microalbuminuria on Long-Term Outcomes in Elderly Patients with Diabetes

Subin Hwang,[1] Kyungho Lee,[2] Do Hee Kim,[2] Hye Ryoun Jang,[2] Wooseong Huh,[2] Yoon-Goo Kim,[2] Dae joong Kim,[2] Jung eun Lee.[2] *[1]Inje University Seoul Paik Hospital, Jung-gu, Seoul, Republic of Korea; [2]Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea*.

Background: In current aging society, the number of elderly diabetes is rapidly growing worldwide. Despite strong evidence on the prognostic power of microalbuminuria in patients with diabetes, it remains uncertain that moderately increased urinary albumin excretion can identify elderly diabetes at high risk of ESRD (end stage renal disease) or mortality. This longitudinal study evaluated incidence of ESRD and mortality according to albuminuria amounts focusing on elderly diabetes.

Methods: We retrospectively identified 3,065 elderly (aged ≥65 years) diabetes. The primary outcomes were incidence of ESRD (considering competing risk with death) and all-cause death. The association between albuminuria (normoalbuminuria, urine albumin to creatinine ratio [uACR] <30mg/g, microalbuminuria, uACR 30-300mg/g, and macroalbuminuria, uACR >300mg/g) and outcomes focusing on elderly (≥65 years) and very elderly (≥75 years) with diabetes were evaluated.

Results: The age was 71.1 (5.0) years and the duration of diabetes was 13.4 (8.7) years. Median follow-up duration was 89 (19.6) months. Overall, microalbuminuria and macroalbuminuria were observed in 25.5% and 9.4% of subjects, respectively. For normoalbuminuria, microalbuminuria, and macroalbuminuria, probability of ESRD and cumulative all-cause death at 8 years was 1.0%, 6.3%, and 29.7% (P<.0001), and 13.1%, 27.4%, and 31.7% (P<.0001), respectively. Using proportional-hazards regression models, albuminuria amounts were independently associated with increased risk of ESRD (fully adjusted hazard ratios [HR] including kidney function: 3.92 [1.29-6.70] for microalbuminuria, 11.16 [6.47-19.24] for macroalbuminuria). The HR of all-cause death were 1.46 (1.21-1.76) for microabuminuria and 1.42 (1.08-1.86) for macroalbuminuria. The associations between albuminuria amounts and the risk of ESRD and all-cause death were consistent in very elderly (≥75 years).

Conclusions: We demonstrated that microalbuminuria is a risk factor of incident ESRD and death even in elderly diabetes, as well as in very elderly. Further studies are needed to determine whether albuminuria can be a therapeutic target in this population.

PO0973

Risk of Cardiovascular Disease, CKD, and Cardiovascular Mortality According to 2017 ACC/AHA Blood Pressure Categories in Diabetes

Miryung Kim, Jun Young Lee, Jae Won Yang, Seung-Ok Choi, Jae seok Kim, Minseob Eom, Hanwul Shin. *Yonsei University Wonju College of Medicine, Wonju, Republic of Korea*.

Background: The association between blood pressure (BP) and cardiovascular disease (CVD) and chronic kidney disease (CKD) in diabetes patients remains unclear.

Methods: By using an analysis based on the National Health Insurance Database of Korea, 8, 922, 940 persons were screened between 2009 to 2014. We determined the BP status of 490,352 persons: Level 1 ((systolic <120 mmHg and diastolic <80 mmHg, n = 109,427), level 2 (systolic 120-129 mmHg and diastolic <80 mmHg, n = 98,360), level 3 (systolic 130-139 mmHg or diastolic 80-89 mmHg, n= 188,728), and level 4 (systolic ≥140 mmHg or diastolic ≥90 mmHg, n= 93,837).

Results: Overall, 490,352 diabetes patients were analysed over a mean follow-up of 5 years and 6,508 CVD events occurred. Compared to people with BP levels 1, the adjusted hazard ratios (HRs) for CVD in people with BP levels 2, 3, and 4 were 1.07 (95% confidence interval [CI], 0.98-1.16), 1.12 (95% CI, 1.04-1.20) and 1.17 (95% CI, 1.08-1.26), respectively. There were also increased risks of CKD [1.18 (95% CI, 1.12-1.24) and 1.22 (95% CI, 1.15-1.29)] and CVD mortality [1.31 (95% CI, 1.09-1.56) and 1.91 (95% CI, 1.58-2.32)] among subjects with BP levels 3 and 4 compared with those with BP level 1.

Conclusions: These findings provide evidence supporting the 2017 ACC/AHA guidelines for BP targets in diabetes patients.

Background: The CAPTURE study estimated the contemporary (2019) prevalence of cardiovascular disease (CVD) in people with type 2 diabetes across 13 countries. This post hoc analysis describes the occurrence of CVD and medication use by chronic kidney disease (CKD) risk groups.

Methods: CAPTURE was a multinational, cross-sectional, non-interventional study conducted between December 2018 and September 2019. Data on CVD diagnoses, estimated glomerular filtration rate (eGFR), urine albumin level and glucose-lowering agents (GLA)/CVD medication use was collected during routine visits. Participants were categorized by CKD risk by eGFR and urine albumin thresholds according to the KDIGO classification.

Results: Of 9823 participants, 7923 (81%) had eGFR data, 6482 (66%) had urine albumin creatinine ratio (UACR) data, and 5829 (59%) had both measures available. The distribution by eGFR (>89, 60–89, 30–59, <30 ml/min/1.73m²) was 35%, 44%, 18% and 3%, respectively, and by UACR (<30, 30–300, >300 mg/g) 67%, 25% and 8%, respectively. By KDIGO risk group (low, moderate, high, very high), CVD prevalence was 29%, 44%, 53% and 59%, respectively. Use of GLA decreased with increasing CKD except for insulin which increased. Use of renin angiotensin aldosterone system inhibitors was 49–72% across risk groups (Table).

Conclusions: This post hoc CAPTURE analysis demonstrated a positive association between CVD prevalence and CKD risk. CVD medications with proven CVD benefits, including GLA, were underused.

Funding: Commercial Support - Novo Nordisk

Table. Cardiovascular disease and selected medication use according to KDIGO risk categories in CAPTURE population (N=5829)

KDIGO Classification: risk for CKD progression	Low risk	Moderately increased risk	High risk	Very high risk
N (%)	3370 (58)	1391 (23.9)	565 (9.7)	503 (8.6)
CVD	979 (29.1)	607 (43.6)	299 (52.9)	299 (59.4)
AsCVD	852 (25.3)	508 (36.5)	257 (45.5)	246 (48.9)
RAAS inhibitors	1658 (49.2)	883 (63.5)	405 (71.7)	344 (68.4)
SGLT2i	664 (19.7)	276 (19.8)	80 (14.2)	38 (7.6)
GLP-1 RA	443 (13.1)	185 (13.3)	56 (9.9)	47 (9.3)
Biguanides	2850 (84.6)	1147 (82.5)	381 (67.4)	200 (39.8)
Insulins, any	1088 (32.3)	584 (42.0)	311 (55.0)	326 (64.8)

Albuminuria (mg/g): eGFR (ml/min/1.73m²) per KDIGO risk categories: Low risk: (<30:>89) and (<30:60–89). Moderately increased risk: (<30:45–59); (30–299:>89); (30–299:60-89). High risk: (<30:30–44); (30-299:45–59); (≥300:>89) and (≥300:60–89). Very high risk: (<30:≤29); (30–299:30-44); (30–299:≤29); (≥300:45–59); (≥300:30–44) and (≥300:≤29). The total proportion of people within each risk category is calculated from the overall population (N=5829) from CAPTURE (N=9823) who had both eGFR and albuminuria information available. Proportion of people with CVD and AsCVD and specified medication use are based on number of patients in the respective risk category. AsCVD, atherosclerotic cardiovascular disease; CVD, cardiovascular disease; GLP-1 RA, glucagon-like peptide receptor agonists; KDIGO, The Kidney Disease: Improving Global Outcomes; RAAS, renin angiotensin aldosterone system; SGLT2i, sodium-glucose co-transporter 2 inhibitors.

PO0975

Cardiovascular Autonomic Dysfunction Is Associated with Decline in Kidney Function in Type 2 Diabetes and Healthy Controls

Jens christian Laursen,[1,3] Ida Rasmussen,[1] Emilie Hein Zobel,[1] Christian S. Hansen,[1] Marie Frimodt-Moller,[1] Bernt Johan Von Scholten,[2] Tine Hansen,[1] Peter Rossing.[1,3] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Novo Nordisk AS, Bagsvaerd, Denmark; [3]Kobenhavns Universitet, Kobenhavn, Denmark.*

Background: Cardiovascular autonomic dysfunction is a prevalent and severe complication in type 2 diabetes. We assessed the impact of cardiac autonomic dysfunction on change in kidney function and albuminuria in a cohort of persons with type 2 diabetes and healthy controls.

Methods: In 2013 we recruited 60 persons with type 2 diabetes and 30 controls. Estimated glomerular filtration rate (eGFR) and urinary albumin excretion rate (UAER) were measured at baseline and follow up. Cardiovascular reflex tests were performed, and continuous parameters of cardiovascular autonomic function was assessed from heart rate variability in a 5-minute resting ECG.

Results: For the follow up, 32 persons with type 2 diabetes and 21 controls were willing to participate and included in the analyses. Median [IQR] follow-up time was 6.2 [6.0 to 6.3] years. At baseline, mean ± SD age was 60 ± 10 years, median known diabetes duration was 12 [5 to 21] years and mean Hba1c in the type 2 diabetes group was 54 ± 11 mmol/mol. At baseline, mean eGFR was similar between groups (type 2 diabetes: 79 ± 21 ml/min/1.73m^2 and controls: 86 ± 12 ml/min/1.73m^2 p=0.183) and median UAER was higher (p<0.001) in the type 2 diabetes group (33.5 [6.5 to 107.5] mg/24-h) than controls (5.5 [5.0 to 6.5] mg/24-h). During follow up, eGFR decreased in both groups (type 2 diabetes: -1.0 (95%CI: -1.4 to -0.5) ml/min/1.73m^2/year p<0.001 and controls: -0.7 (95%CI: -1.1 to -0.3) ml/min/1.73m^2/year p=0.001) and the change was similar between groups (p=0.179). Albuminuria did not change. After adjustment for age, sex, smoking, Hba1c, body mass index, heart rate, 24-hour systolic blood pressure, plasma cholesterol, baseline UAER and baseline eGFR, a lower response in heart rate variability during Valsalva (p=0.016) and a lower SDNN (p=0.029) were significantly associated with a steeper yearly decline in eGFR. Cardiovascular autonomic function was not associated with change in albuminuria.

Conclusions: Cardiovascular autonomic dysfunction assessed by heart rate variability was associated with steeper decline in kidney function during 6 years of follow up. Cardiovascular autonomic dysfunction may be a marker of higher risk of decline in eGFR. Whether there is a causal link remains to be established.

PO0976

Changes in Cardiac Microvascular Function in Persons with Type 2 Diabetes in Relation to Kidney Function

Ida Rasmussen,[1] Philip Hasbak,[2] Bernt Johan Von Scholten,[1] Jens christian Laursen,[1] Emilie Hein Zobel,[1] Lene Holmvang,[2] Rasmus S. Ripa,[2] Peter Rossing,[1] Andreas Kjaer,[2] Tine Hansen.[1] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Rigshospitalet, Kobenhavn, Denmark.*

Background: The myocardial flow reserve (MFR) reflects the function of both large epicardial arteries and the microcirculation. Coronary artery calcium score (CACS) is a measure of coronary atherosclerosis. Cardiac ^{82}Rb PET/CT provides a measurement of both MFR and CACS. Knowledge on changes in MFR and CACS over time and the impact of kidney function on these changes is lacking

Methods: In 2013 we recruited 60 persons with type 2 diabetes (T2D) and 30 non-diabetic controls (C); all free of overt cardiovascular disease. All underwent a cardiac ^{82}Rb PET/CT scan. In 2019, survivors (n=82) were invited for a repeated cardiac ^{82}Rb PET/CT after a similar protocol. 29 with T2D and 19 C participated.

Results: Median [interquartile range] duration between visits was 6.2 [6.0–6.3] years. The Table summarizes kidney function, MFR and CACS at the 2 visits. MFR was lower in persons with T2D compared to C but change in MFR was similar between groups (p=0.62) and did not differ between visits within the groups (C:p=0.51, T2D:p=0.08). CACS was higher in persons with T2D compared to C at both visits. CACS increased between visits within both groups (C:p=0.015, T2D:p<0.001), and the change was higher in T2D (p=0.002). In the total cohort, lower eGFR at baseline was associated with higher decline in MFR (p=0.027), but not after adjustment (p=0.70). Increase in CACS was higher in men (p=0.03), but not after adjustment (p=0.07). Changes in MFR and CACS were not associated with other risk factors at baseline.

Conclusions: MFR was lower in T2D compared to C but did not change significantly in either of the groups when evaluated over 6 years. Kidney function had no independent impact on changes in MFR or CACS

	Type 2 diabetes (n=29)	Controls (n=19)	P (unadjusted)	P (adjusted)
UAER visit 1 (mg/24-h)	27.3 [6.5, 145]	5.5 [5.0, 6.5]	<0.001	
eGFR visit 1 (ml/min/1.73m2)	81.1 (21.5)	87.6 (11.1)	0.23	
MFR visit 1	2.6 (0.7)	3.3 (0.7)	0.001	0.83
MFR visit 2	2.4 (0.6)	3.2 (0.9)	<0.001	0.46
MFR difference	-0.27 [-0.48, 0.06]	-0.20 [-0.65, 0.50]	0.62	0.32
CACS visit 1	180 [22, 275]	0 [0, 54]	<0.001	0.03
CACS visit 2	560 [136, 981]	18 [0, 116]	<0.001	0.04
CACS difference	301 [72, 830]	9 [0, 62]	0.002	0.12

Adjustment included; age, sex, BMI, eGFR, urinary albumin excretion rate, 24-h systolic BP, heart rate, total cholesterol and smoking

PO0977

Risk of Hospitalization for Heart Failure (HHF) by eGFR and Urinary Albumin-to-Creatinine Ratio (UACR): Pooled Analyses from the CANVAS Program and CREDENCE

Vlado Perkovic,[1] George L. Bakris,[2] Jaime Blais,[3] David Cherney,[4] Cv Damaraju,[3] Jagadish Gogate,[3] Hiddo J. L Heerspink,[1,5] Mikhail Kosiborod,[1,6] Kenneth W. Mahaffey.[7] *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]Department of Medicine, University of Chicago Medicine, Chicago, IL; [3]Janssen Scientific Affairs, LLC, Titusville, NJ; [4]University of Toronto, Toronto, ON, Canada; [5]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [6]Saint Luke's Mid America Heart Institute and University of Missouri – Kansas City, Kansas City, MO; [7]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA.*

Background: People with type 2 diabetes (T2D) are at particularly elevated risk of cardiovascular (CV) events including heart failure (HF) if they have chronic kidney disease (CKD). Albuminuria and eGFR are each associated with increased risk, leading to recommendations for annual assessment of these parameters. We analyzed the combined effects of eGFR and UACR on risk of HHF, and the effect of canagliflozin (CANA) on reducing risk, in patients with T2D using pooled data from the CANVAS Program and CREDENCE.

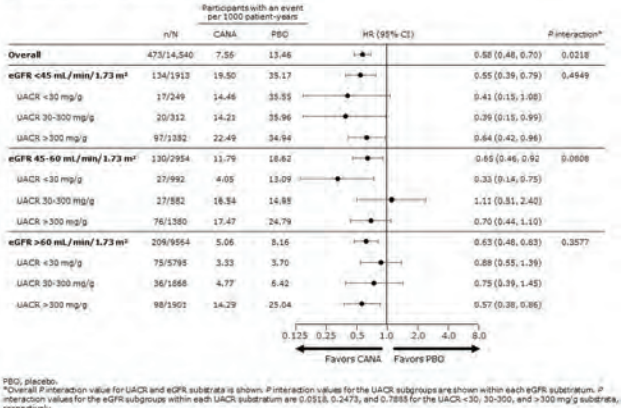
Methods: The CANVAS Program enrolled 10,142 patients with T2D and CV disease or high CV risk. CREDENCE enrolled 4401 patients with T2D and CKD. Risk of HHF was examined in subgroups by baseline eGFR (<45, 45-60, and >60mL/min/1.73m^2) and UACR (<30, 30-300, and >300mg/g). Hazard ratios (HR) and 95% CI were estimated using a Cox proportional hazards model.

Results: In placebo-treated participants (**Figure**), the risk of HHF was generally lowest in people with UACR <30 and eGFR >60, and highest in those with eGFR <45 and UACR >300. HHF rates increased 6.5-fold between those with UACR <30 and >300 and eGFR >60 at baseline and almost 10-fold as eGFR declined from >60 to <45 in patients with UACR <30 at baseline. CANA reduced the risk of HHF overall with some evidence of treatment heterogeneity by UACR and eGFR (*P* interaction=0.0218).

Conclusions: People with T2D and reduced eGFR, increased albuminuria, and especially both, were at increased risk of HHF. The risk of HHF was reduced overall by CANA.

Funding: Commercial Support - Janssen Scientific Affairs, LLC

Figure. HHF by eGFR and UACR.



PBO, placebo.
*Overall P interaction value for UACR and eGFR substrata is shown. P interaction values for the UACR subgroups are shown within each eGFR substratum. P interaction values for the eGFR subgroups within each UACR substratum are 0.0518, 0.2473, and 0.7855 for the UACR <30, 30-300, and >300 mg/g substrata, respectively.

PO0978

The Predictive Value of Diabetic Retinopathy on Subsequently Diabetic Nephropathy in Patients with Type 2 Diabetes: A Systematic Review and Meta-Analysis of Prospective Studies

Tianjun Guan, Yu Li, Anqun Chen. *Division of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China.*

Background: Studies have already demonstrated diabetic retinopathy (DR) was associated with an increased risk of diabetic nephropathy (DN) in patients with type 2 diabetes (T2D), whereas the predictive value of DR on subsequent DN for T2D were not illustrated. Therefore, we conducted a meta-analysis of prospective cohort studies to assess the predictive value DR on further DN risk in patients with T2D.

Methods: The PubMed, EmBase, and the Cochrane library were systematically searched for eligible prospective cohort studies through March 2020. The predictive value of NR were assessed using sensitivity, specificity, positive and negative likelihood ratio (PLR and NLR), diagnostic odds ratio (DOR), and area under the receiver operating characteristic curve (AUC).

Results: Ten prospective cohort studies recruited a total of 635 patients with T2D were selected for this study. After pooling all studies, we noted the pooled sensitivity, and specificity of DR for predicted DN were 0.64 (95%CI: 0.54-0.73), and 0.77 (95%CI: 0.60-0.88), respectively. The pooled PLR and NLR of DR for predicted DN were 2.72 (95%CI: 1.42-5.19), and 0.47 (95%CI: 0.33-0.67), respectively. The summary DOR for the relationship between DR and subsequent DN for T2D patients was 5.53 (95%CI: 2.00-15.30), and the AUC of DR for predicted DN was 0.73 (95%CI: 0.69-0.77). The predictive value of DR for subsequent DN could affect by mean age, percentage male, and study quality.

Conclusions: This study found significant associations between DR and subsequent DN risk for patients with T2D, while the predictive value of DR was mild. Further prospective study should be assessed for the predictive value of DR on other conditions in T2D patients with specific characteristics.

Cellular Proteomic Phenotypes Underlying Plasma Signature of 10-Year Risk of Kidney Failure

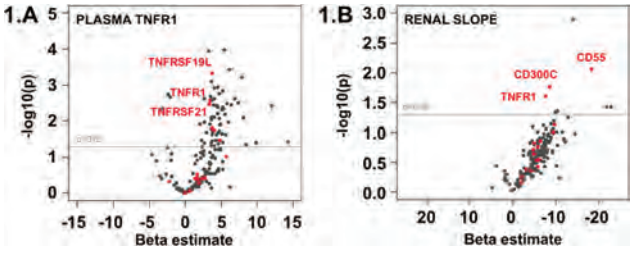
Salina Moon,[1] Heather L. Donsky,[1,2] Sylvia E. Rosas,[1,2] Simon T. Dillon,[3,2] Monika A. Niewczas.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: A robust circulating proteomic signature of 10-year risk of kidney failure (KRIS) in a large prospective three-diabetes cohort study was recently identified (Niewczas et al, Nat Med 2019), but the source of the KRIS proteins remains unknown. Therefore, we aimed to evaluate potential contributions of the peripheral blood mononuclear cells (PBMC) and its subset, CD14, to the KRIS in a proteome-wide fashion.

Methods: Our study group consisted of a sample of Joslin Kidney Study participants with Type 2 Diabetes (n=16) with an average eGFR of 59±23 mL/min/1.73m^2 and median albuminuria of 57 (8, 312) at baseline. Within a median of 12 years, our study group experienced a median annual renal function decline of -1.4 (-2.6, -0.5) mL/min/1.73m^2/yr. We obtained PBMC and CD14 lysates using cell density and immunomagnetic separation techniques. Cell lysate samples were subjected to aptamer proteomics (1305 proteins).

Results: In the targeted evaluation, six out of 17 KRIS proteins in PBMC lysates associated significantly with the top KRIS protein in plasma (TNFR1 $_{PBMC}$:β: 3.4, p=0.003) (Fig.1A). TNFRSF members and IL17F accounted for most of these associations. TNFR1 $_{PBMC}$ was also associated with the renal slope (TNFR1 $_{PBMC}$:β: -7.6, p=0.025) (Fig.1B). In the untargeted evaluation, 68 proteins were associated with the renal slope (MAPKAPK3, ILT-2, and IL17R, among others). CD14 cellular KRIS patterns did not robustly associate with the phenotypes of our interest.

Conclusions: Our pilot study suggests potential contributions of the PBMC to the plasma KRIS that requires validation in a larger population. We also demonstrate the potential for biomarker and novel drug target discoveries using an approach that relies on the proteomics in white blood cell subpopulations.



PO0980

Investigations on Urinary mRNA Biomarkers That Reflect Pathologic Features of Patients with Diabetic Kidney Diseases

Yu ho Lee,[1] Seo Jung-Woo,[2] Miji Kim,[2] Hye yun Jeong,[1] So-young Lee,[1] Yang gyun Kim,[2] Sangho Lee,[2] Jin sug Kim,[2] Hyeon Seok Hwang,[2] Kyung hwan Jeong,[2] Ju young Moon.[2] *[1]CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [2]Kyung Hee University, Seoul, Republic of Korea.*

Background: Diabetic kidney disease (DKD) is a leading cause of end-stage renal disease worldwide. Despite that histological severity of DKD is a well-established predictor of adverse renal outcomes, investigations on the identification of non-invasive biomarkers that can reflect intrarenal status are scarce. The purpose of this study was to discover urinary mRNA biomarkers of DKD and to examine their associations with the degree of various pathologic features.

Methods: We collected and analyzed urinary samples obtained from 68 patients with biopsy-proven DKD and 32 healthy controls. Using two public GEO dataset (GPL22945 and GPL24120), we compared renal transcriptomic profiles of DKD and healthy living kidney donors and selected candidate genes for DKD (|fold change| > 2 and p < 0.001, compared to controls). The levels of selected candidate genes were measured by quantitative real-time polymerase chain reaction using urine cell pellet.

Results: Mean estimated glomerular filtration rate and urinary protein-to-creatinine ratio of enrolled patients were 45.5 mL/min/1.73 m^2 and 7.4 g/g creatinine, respectively. A total of 30 candidate genes were selected based on the analysis of GEO dataset, among which 22 genes were significantly elevated in urines of patients with DKD compared to controls. In particular, urinary *col1a1* levels were significantly higher in patients with advanced glomerular pathologic scores, while urinary *cx3cr1* and *sox4* levels were significantly lower in these patients. The expression of urinary *cx3cr1* levels was also lower in patients with more severe IFTA. On the other hand, urinary *pdk4* levels showed positive correlation with its scores. Urinary *c3* and *nnmt* levels were positively correlated with the severity of interstitial inflammation and arterial hyalinosis, respectively. Finally, we found significant correlation between the amount of urinary protein-to-creatinine ratio and urinary levels of *nnmt*, *thbs2*, *plk2*, and *cola1a1*.

Conclusions: Urinary mRNAs could reflect the degree of intrarenal pathologic status in patients with diabetic kidney disease.

Funding: Government Support - Non-U.S.

PO0981

Association Between the Urinary Proteome and Diabetic Retinopathy in the DIRECT-Protect 1 and 2 Trials

Viktor Rotbain Curovic,[1] Pedro Magalhães,[2] Tine Hansen,[1] Harald Mischak,[2] Peter Rossing.[1,3] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Mosaiques Diagnostics, Hannover, Germany; [3]Kobenhavns Universitet, Copenhagen, Denmark.*

Background: Diabetic retinopathy (DR) is a complication of paramount importance in type 1 and type 2 diabetes. Given the association of DR and diabetic kidney disease (DKD), we investigated the association between the urinary proteome and the presence and deterioration of DR in individuals with type 1 and type 2 diabetes.

Methods: Baseline proteomic analysis was performed in both the DIRECT-Protect 1 and 2 studies in a random selection of 800 and 821 subjects respectively. The DIRECT-Protect studies were designed to assess the effect of candesartan in relation to development of DR endpoints. DIRECT-Protect 1 was considered the discovery cohort and DIRECT-Protect 2 the validation cohort. Endpoints were defined as a two-step (RET2) or three-step (RET3) change in DR score according to the Early Treatment Diabetic Retinopathy Study (ETDRS) protocol. Urinary peptide levels were correlated to baseline DR score in the discovery cohort. Thereafter, identified peptide fragments were investigated for association to baseline DR score in the validation cohort and for development of endpoints in both cohorts, adjusted for sex, age, diabetes duration, smoking, total cholesterol, HbA_{1c}, systolic blood pressure, urinary albumin excretion rate, serum creatinine, and randomization group at baseline.

Results: Follow-up ranged from 4.0-4.7 years. Eleven out of 427 peptide fragments were inversely associated to baseline DR in the discovery cohort after adjustment. In multivariate Cox regression analyses lower alpha-1 type I collagen (COL1A1) (seq. ApGD~, GKNG~, and LDGA~) was significantly ($p<0.05$) associated to the development of RET2 and lower COL1A1 (seq. LDGA~) and COL3A1 (seq. EDGK~) to RET3. However, when attempting to validate these results, only a KER12 fragment was inversely associated to baseline DR in the validation cohort, as well as to development of RET3. Furthermore, lower levels of one COL1A1 fragment (seq. AEGS~) was associated to development of RET2 in the validation cohort.

Conclusions: Several urinary peptide fragments were associated to the presence and worsening of DR in type 1 diabetes. However, this could not be validated in type 2 diabetes, and the identified peptide fragments were not conclusively associated to deterioration of DR across both cohorts.

PO0982

Urinary Cubilin Shedding Predicts Progressive Diabetic Nephropathy in Type 1 Diabetes Mellitus

Eileen A. Ciccia,[2] Tina Costacou,[3] Elif Erkan.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Saint Louis Children's Hospital, Saint Louis, MO; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Diabetes mellitus (DM) is the leading cause of end-stage renal disease worldwide. Microalbuminuria(MA) is considered a gold standard to diagnose diabetic nephropathy (DN) however its detection of early kidney damage is questionable. Therefore, there is an emergent need for novel biomarkers to capture early molecular alterations preceding MA. Cubilin is a 460 kd size protein lacking a transmembrane domain and is coexpressed with megalin facilitating albumin endocytosis in proximal tubule epithelial cells. We hypothesize that cubilin trafficking is compromised and is amenable to urinary shedding in DM. We propose that urinary cubilin shedding predicts DN.

Methods: This study assessed urinary IL-8, cubilin, monocyte chemoattractant factor (MCP-1), NGAL and vitamin D binding protein (VDBP) levels by ELISA (normalized for creatinine) across three groups of individuals with type 1 diabetes (T1D): Group 1(n=9) preserved normal kidney function, group 2 (n=10) developed proteinuria (albumin excretion >200microgram/min) and group 3 (n=9) developed progressive DN >40% decline in glomerular filtration rate (GFR) and proteinuria during follow-up of ~10 years. Urine samples for these assessments were obtained from the baseline examination of the Pittsburgh Epidemiology of Diabetes Complications (EDC) cohort. All patients had normal urine albumin excretion and kidney function. Duration of diabetes was comparable between groups (13.5 years±1.1). Mann-Whitney U and Kruskal Wallis tests were used to compare groups.

Results: Urinary IL-8 levels were (pg/gr) 229 ± 71, 270 ±146 and 549 ± 41.5 (NS) respectively. Urinary cubilin excretion(pg/gr) was 23±71, 38±9.2 and 47±8.8 ($p<0.05$). A urinary cubilin excretion >30 pg/mg predicted progressive DN with a 67% sensitivity and 89% specificity and an area under the ROC curve of 0.81($p<0.05$). Urinary MCP-1, NGAL and VDBG levels did not significantly differ across the groups.

Conclusions: We demonstrated that urinary cubilin shedding is a reliable biomarker for predicting progressive DN in T1D preceding microalbuminuria. Although not statistically significant urine IL-8 levels were elevated in patients with significant proteinuria and decline in GFR. The role of urinary cubilin shedding as a biomarker for the diagnosis and treatment of diabetic nephropathy at an early stage should be examined in a larger patient population.

PO0983

Comparison of Natriuretic Peptides as Risk Markers for Mortality and Cardiovascular and Renal Complications in Persons with Type 1 Diabetes

Nete Tofte,[1] Simone Theilade,[1] Signe Abitz Winther,[1] Jens P. Goetze,[2,3] Tine Hansen,[1] Peter Rossing.[1,3] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Rigshospitalet, Kobenhavn, Denmark; [3]Kobenhavns Universitet, Kobenhavn, Denmark.*

Background: Assessment of natriuretic peptides, N-terminal pro-brain natriuretic peptide (NT-proBNP) and Midregional Proatrial Natriuretic Peptide (MR-proANP), represents a useful addition for evaluating risk of cardiovascular and renal complications. Only very few studies have compared these two risk markers. We compared the value of NT-proBNP and MR-proANP as risk markers for mortality and development of cardiovascular and renal complications in persons with type 1 diabetes (T1D).

Methods: Plasma NT-proBNP and MR-proANP were measured (using commercially available kits) in 664 persons with T1D and various degrees of albuminuria. Endpoints were traced through National Registers and laboratory records and comprised mortality (n=57), composite cardiovascular events (CVE, n=94), heart failure (HF, n=27), end-stage kidney disease (ESKD, n=21) and decline in estimated glomerular filtration rate (eGFR) ≥30% (n=93). Median follow-up ranged from 5.1-6.2 years. From Cox regression models Hazard ratios (HRs) were assessed per doubling of NT-proBNP or MR-proANP with 95% confidence interval in models adjusted for cardiovascular risk factors: sex, age, systolic blood pressure, LDL-cholesterol, smoking, HbA_{1c}, BMI, eGFR and urinary albumin excretion rate and additionally with mutual inclusion of MR-proANP and NT-proBNP.

Results: Of the 664 persons (55% male), mean±SD age was 55±13 years, eGFR 81±26 ml/min/1.73m^2, median (IQR) MR-proANP was 74 (49-116) pmol/L and NT-proBNP 70 (29-162) pg/L. Higher NT-proBNP level was associated with higher risk of mortality (HR 1.5 (1.2-1.8)), CVE (HR 1.3 (1.1-1.5)) and HF (HR 1.7 (1.3-2.1)) independent of cardiovascular risk factors ($p<0.001$) and MR-proANP ($p<0.004$). Higher MR-proANP level was associated with higher risk of mortality (HR 1.7 (1.1-2.7)), CVE (HR 1.6 (1.1-2.2)), HF (HR 2.8 (1.5-5.2)) and ESKD (HR 3.1 (1.2-7.8)) independent of cardiovascular risk factors ($p<0.03$), however, after addition of NT-proBNP significance for all endpoints was lost. None of the markers were significantly associated with decline in eGFR ≥30%.

Conclusions: Higher NT-proBNP concentration was independently associated with mortality and cardiovascular events. Our results suggest that NT-proBNP may be useful singly or in combination with MR-proANP for risk-stratification in persons with T1D.

The Importance of Addressing Multiple Risk Markers in Type 2 Diabetes: Results from the LEADER Trial

Emilie Hein Zobel,[1] Tine Hansen,[1] Frederik Persson,[1] Soren Rasmussen,[2] Bernt Johan Von Scholten,[1,2] Benjamin Wolthers,[2] Peter Rossing.[1,3] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Novo Nordisk A/S, Søborg, Denmark; [3]Kobenhavns Universitet, Kobenhavn, Denmark.*

Background: The benefit of multifactorial intervention in type 2 diabetes (T2D) was demonstrated in the small Steno-2 study in microalbuminuric T2D. Larger studies in more diverse cohorts are limited. We investigated the importance of multiple risk-marker improvement for micro- and macrovascular outcomes in the LEADER trial.

Methods: LEADER (n=9340, ClinicalTrials.gov number NCT01179048) randomized patients with T2D to liraglutide or placebo (1:1) in addition to standard of care. We categorized patients according to number of risk markers with a clinically relevant change at year 1 of treatment and investigated subsequent risk of an expanded cardiovascular outcome (MACE-6) or nephropathy. We defined clinically relevant change as: body weight loss ≥5%, HbA_{1c} reduction ≥1%, systolic blood pressure reduction ≥5 mmHg, LDL reduction ≥0.5 mmol/L, eGFR reduction ≥0 ml/min/1.73m^2 and urinary albumin-to-creatinine ratio reduction ≥30% of baseline value. Numbers of risk markers with change were classified as: none (group G0), 1 (G1), 2 (G2), 3 (G3) and ≥4 (G4). Cox regression analyzed risk of the outcomes adjusted for continuous baseline levels of the risk markers and treatment group.

Results: Compared to patients with no risk-marker change, risk of cardiovascular disease was lower for patients with 2 (HR [95% CI] 0.81 [0.66–0.98] or 3 (0.80 [0.65–0.99]) risk-marker changes, and risk of nephropathy was lower for those with 3 (0.50 [0.35–0.72]) or ≥4 (0.48 [0.31–0.73]) risk-marker changes (Table). Test for trend with number of improved risk markers as a continuous variable: p=0.004 and $p<0.001$, respectively.

Conclusions: Improvement in multiple risk markers within 1 year translates into reduced risk of micro- and macrovascular outcomes in T2D, underscoring the benefit of pleiotropic antidiabetic treatments.

Funding: Commercial Support - Novo Nordisk A/S

Table: Outcomes according to total number of risk markers improved at year 1 from randomization

Number of improved risk markers	Outcome	N (%)	IR	HR	[95% CI]	p value
G0 (n=802)	Cardiovascular outcome	149 (18.6)	4.9	Reference group		
	Nephropathy	55 (6.9)	1.8			
G1 (n=2408)	Cardiovascular outcome	448 (18.6)	4.8	0.96	[0.79–1.16]	0.65
	Nephropathy	192 (8.0)	2.1	1.06	[0.77–1.46]	0.73
G2 (n=2656)	Cardiovascular outcome	458 (17.2)	4.5	0.81	[0.66–0.98]	0.03
	Nephropathy	179 (6.7)	1.7	0.73	[0.53–1.02]	0.07
G3 (n=1844)	Cardiovascular outcome	315 (17.1)	4.4	0.80	[0.65–0.99]	0.04
	Nephropathy	93 (5.0)	1.3	0.50	[0.35–0.72]	0.0002
G4+ (n=928)	Cardiovascular outcome	157 (16.9)	4.4	0.80	[0.63–1.02]	0.07
	Nephropathy	48 (5.2)	1.3	0.48	[0.31–0.73]	0.0006

Expanded cardiovascular outcome (from year 1) defined as MACE-6: death from cardiovascular causes, nonfatal myocardial infarction, nonfatal stroke, coronary revascularization, or hospitalization for unstable angina pectoris or heart failure. Nephropathy defined as new-onset macroalbuminuria, doubling of serum creatinine and eGFR ≤45 ml/min/1.73m^2, continuous renal replacement therapy, or renal death. IR: events per 100 patient years of observation. G0: subjects with zero clinical responses at year 1 (reference group), G1–G3: subjects with 1–3 clinical responses, G4+: subjects with ≥4 clinical responses at year 1. HR: compares subgroups G1–G4 to G0. Cox regression model adjusted for treatment (liraglutide vs placebo), baseline body weight, HbA_{1c}, systolic blood pressure, LDL cholesterol, eGFR and urinary albumin-to-creatinine ratio. CI, confidence interval; eGFR, estimated glomerular filtration rate; HbA_{1c}, glycated hemoglobin; HR, hazard ratio; IR, incidence rate; LDL, low-density lipoprotein; MACE, major adverse cardiovascular events.

PO0985

Associations of Circulating Angiopoietins with Renal Function Decline and Progression to ESKD in CKD Stage 3 Patients with Diabetes

Zaipul I Md Dom,[1,2] Eiichiro Satake,[1,2] Kristina V. O'Neil,[1] Hiroki Kobayashi,[1,2] Katsuhito Ihara,[1,2] Jan Skupien,[3] Andrzej S. Krolewski.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Jagiellonian University Medical College, Krakow, Poland.*

Background: The literature on plasma angiopoietins (Ang) levels in patients with diabetes and CKD Stage 3 is sparse. The data pertaining the association of Ang with progression of renal decline and development of ESKD is similarly limited. This study aimed to investigate relationships between circulating angiopoietins with risk of progressive renal decline and ESKD in diabetic patients with already existing moderate renal impairment.

Methods: We prospectively studied 214 T1D patients and 144 T2D patients over a follow-up period of 7-15 years to determine eGFR slope and ascertain time of onset of ESKD. Serial measurements of serum creatinine were used to estimate the rate of eGFR decline. Fast decliners were defined as eGFR loss ≥ 3.0 ml/min/year. We quantified Ang1, Ang2 and Tie-2 present on the SOMAscan proteomic platform in baseline plasma samples in diabetics as well as in 79 non-diabetics. We examined the association of plasma levels of each Ang and the rate of fast renal decline using logistic regression models.

Results: There were 143 and 75 fast decliners in T1D and T2D (Median eGFR slope -6.2 ml/min/year in both cohorts), respectively. In regression models adjusted for baseline eGFR, HbA1c, ACR and type of diabetes, Ang1 (OR (95% CI): 0.77 (0.61, 0.96)) or Ang1/Ang2 ratio (OR: 0.74 (0.59, 0.94)) was significantly associated with protection against fast renal decline. Neither Ang2 (OR: 1.21 (0.96, 1.51)) nor Tie-2 (OR: 1.12 (0.89, 1.39)) was associated with the rate of fast renal decline. Patients with Ang1 levels above median and Ang2 below median had very low cumulative incidence of ESKD of 30%. The lowest baseline Ang1 levels were observed in non-diabetic controls (Median (25^{th}, 75^{th} percentiles): 757 (641, 1189)) and the highest values were observed in slow decliners (Median: 1565 (1093, 2522)), while fast-decliner levels (Median: 1248 (934, 1916)) fell between the two other sub-groups.

Conclusions: Elevated Ang1 levels or the ratio of Ang1/Ang2 had a protective effect against fast renal decline and progression to ESKD. As such, Ang1 and Ang2 may be useful targets for preventing or delaying the onset of renal function decline and ESKD in diabetes.

Microscopic Hematuria Is a Risk Factor for ESKD in Patients with Biopsy-Proven Diabetic Nephropathy

Riri Furuyama,[1] Masahiro Eriguchi,[1] Hikari Tasaki,[1] Fumihiro Fukata,[1] Masatoshi Nishimoto,[1] Takaaki Kosugi,[1] Kaori Tanabe,[1] Katsuhiko Morimoto,[2] Sadanori Okada,[1] Masaru Matsui,[3] Ken-ichi Samejima,[1] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Kashihara, Japan; [2]Nara Prefecture Western Medical Center, Ikoma, Japan; [3]Nara Prefecture General Medical Center, Nara, Japan.*

Background: Microscopic hematuria is rarely observed in patients with diabetic nephropathy (DN). Some studies have reported that hematuria is a risk factor for end-stage kidney disease (ESKD) in glomerulonephritis, but association of hematuria with renal prognosis in DN is unknown.

Methods: The present study is a retrospective cohort study of patients with DN confirmed by renal biopsy between June 1981 and December 2014. The participants were followed until October 2018 or death. Exposure of interest is the presence of hematuria (U-RBC >5) and main outcome was the occurrence of ESKD. The association of hematuria with ESKD was evaluated using Cox hazard model with adjustment for clinically relevant factors [age, sex, eGFR, proteinuria, body mass index, systolic blood pressure (SBP) and pathological evaluations].

Results: Patients who had microscopic hematuria at the time of renal biopsy were defined as the hematuria group (N = 91), and the remainder as the non-hematuria group (N = 306). Hematuria group had more proportion of male, higher SBP, more proteinuria, and lower eGFR compared with non-hematuria group. Pathological findings revealed that glomerular, tubulointerstitial, and vascular lesions in the hematuria group were significantly more severe than those in non-hematuria group. During a median follow-up period of 80 months, 44 and 52 patients developed ESKD in the hematuria group and non-hematuria groups, respectively. Survival analyses showed that incidence of ESKD was significantly higher in the hematuria group (P <0.0001). The significance remained robust even after adjustment for confounding factors (adjusted HR 1.64, 95% CI; 1.03-2.60). In the subgroup analyses, the associations of hematuria with ESKD among male and overt proteinuria (≥0.5 g/day) were stronger than those among female and micro proteinuria (<0.5 g/day), respectively (P values for interaction <0.1 and <0.03, respectively).

Conclusions: The presence of microscopic hematuria is an independent risk factor for ESKD in diabetic nephropathy.

PO0987

A Profile of Multiple Circulating TNF Receptors Associated with Early Progressive Renal Decline in Type 1 Diabetes: Similar to Profiles in Autoimmune Disorders

Katsuhito Ihara,[1,2] Jan Skupien,[3] Bozena Krolewski,[1,2] Zaipul I Md Dom,[1,2] Kristina V. O'Neil,[1] Eiichiro Satake,[1,2] Hiroki Kobayashi,[1,2] Narges M. Rashidi,[4] Monika A. Niewczas,[1,2] Andrzej S. Krolewski.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Jagellonian university medical college, Krakow, Poland; [4]Olink Proteomics, Watertown, MA.*

Background: This study comprehensively evaluated the association between known circulating tumor necrosis factor (TNF) superfamily ligands and receptors and the development of early progressive renal decline (PRD) leading to end-stage kidney disease (ESKD) in Type 1 diabetes (T1D).

Methods: The Macro-Albuminuria Study comprised of 198 individuals, and the Micro-Albuminuria Study consisted of 148 individuals. All individuals had normal renal function and were followed for 7-15 years to determine estimate glomerular filtration rate (eGFR) slopes and to ascertain onset of ESKD. Plasma concentrations of 25 TNF superfamily proteins were measured using proximity extension assay applied in the OLINK proteomics platform.

Results: In the both studies risk of early PRD, determined as eGFR loss greater than or equal to 3 ml/min/1.73m^2/year, was associated with elevated circulating levels of 13 TNF receptors out of 19 examined. In the Macro-Albuminuria Study, we obtained similar findings for risk of progression to ESKD. These receptors comprised: TNF-R1A, -R1B, -R3, -R4, -R6, -R6B, -R7, -R10A, -R10B, -R11A, -R14, -R21, and -R27. Serial measurements showed that circulating levels of these TNF receptors had increased before the onset of PRD. In contrast, none of the 6 measured TNF ligands showed association with risk of early PRD.

Conclusions: The disease process that underlies PRD which leads to ESKD in T1D is enriched with up-regulated levels of multiple TNF receptors, a profile also seen in autoimmune disorders. The mechanisms of this enrichment may be causally related to the development of PRD in T1D and must be investigated further. Some of these receptors may be used as new predictors of risk of ESKD.

Associations Between TNFR-1, TNFR-2, and KIM-1 with Kidney and Cardiovascular Outcomes: Results from the CANVAS Trial

Taha Sen,[1] Jingwei Li,[2] Brendon L. Neuen,[2] Chirag R. Parikh,[3] Steven G. Coca,[4] Bruce Neal,[2] Vlado Perkovic,[2] Dick de Zeeuw,[1] Kenneth W. Mahaffey,[5] Michael K. Hansen,[6] Hiddo J. L Heerspink.[1,2] *[1]Department of Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands; [2]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [3]Johns Hopkins School of Medicine, Baltimore, MD; [4]Division of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [5]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [6]Janssen Research & Development, LLC, Spring House, PA.*

Background: Tumor Necrosis Factor Receptor (TNFR)-1, TNFR-2 and Kidney Injury Molecule-1 (KIM-1) are blood-based biomarkers that are known to predict kidney outcomes in patients with diabetic kidney disease. We sought to examine the association of baseline TNFR-1, TNFR-2 and KIM-1 with cardiovascular (CV) and kidney outcomes in patients with type 2 diabetes mellitus (T2DM) in the CANagliflozin cardioVascular Assessment Study (CANVAS) study, and secondly, whether these markers modified the effect of the SGLT2 inhibitor canagliflozin (CANA) on these outcomes.

Methods: The CANVAS trial randomized participants with T2DM at high CV risk to CANA or placebo. Plasma TNFR-1, TNFR-2 and KIM-1 were measured with immunoassays (proprietary multiplex assay performed by RenalytixAI, NY, USA). Associations between the 3 biomarkers and the CV (nonfatal myocardial infarction, stroke, or CV death) and kidney outcome (40% eGFR decline, end-stage kidney disease, or renal death) were assessed using multivariable adjusted Cox regression.

Results: We included 3548 (82% of original cohort of 4330) CANVAS participants with available baseline plasma samples (mean age 62.8 y, 33.0% female, mean eGFR 76.9 mL/min/1.73 m^2, median uACR 11.6 mg/g, median TNFR-1, TNFR-2 and KIM-1: 2578 pg/mL, 9684 pg/mL, and 110 pg/mL). During a mean follow-up of 5.6 y, 554 CV and 137 kidney outcomes occurred. After adjustment for demographics and clinical characteristics, each doubling of baseline TNFR-1, TNFR-2, KIM-1 was significantly associated with higher risk of kidney outcomes: TNFR-1, HR 3.74 (95% CI 2.28, 6.15); TNFR-2, HR 2.68 (95% CI 2.01, 3.57); KIM-1, HR 1.50 (95% CI 1.23, 1.82). The biomarkers were not associated with the CV outcome. The protective effect of CANA on the CV and kidney outcome (HR 0.56, 95% CI 0.40, 0.78) was consistent regardless of baseline TNFR-1, TNFR-2, or KIM- 1 (all P-interaction>0.10).

Conclusions: Higher levels of TNFR-1, TNFR-2 and KIM-1 were independently associated with a higher risk of kidney but not CV outcomes in patients with T2DM at high CV risk. The baseline markers did not modify the effect of CANA on these outcomes.

PO0989

The Clinical Importance of Phenyl Sulfate as a Predictive Marker of Albuminuria in Diabetic Kidney Disease

Koichi Kikuchi,[1] Daisuke Saigusa,[1] Koki Mise,[2] Eikan Mishima,[1] Takafumi Toyohara,[1] Shun Watanabe,[1] Takehiro Suzuki,[1] Jun Wada,[2] Yoshihisa Tomioka,[1] Takaaki Abe.[1] *[1]Tohoku University, Sendai, Sendai, Japan; [2]Okayama University, Okayama, Japan.*

Background: Diabetic kidney disease (DKD) is one of the major causes of end-stage renal diseases (ESRD), and it is important to prevent from onset or progression of DKD. However, it is difficult to identify type 2 diabetes patients who are at risk of developing progressive DKD based only on measurements of glomerular filtration rate and albuminuria. Therefore, specific biomarkers are needed for a breakthrough in the good management of DKD.

Methods: Among 777 patinets in a multi-center clinical study in diabetic nephropathy cohort (U-CARE), 362 patients with full data were selected. The plasma PS, PCS, IS and TMAO level were measured by LCMS/MS. The correlation between these level and various factors were calculated using the Spearman Rank-Order Correlation. Multiple regression analysis and a logistic regression analysis were used to identify the factors associated with PS, IS, PCS, TMAO, suPAR, urine acid or the development of 2-year ACR deterioration, respectively.

Results: As we previously reported (Kikuchi et al. Nat. Commun. 2019, ASN 2019), serum PS level significantly related with the basal albuminuria level in U-CARE study. In addition, logistic regression analysis showed among known ACR predictive factors, PS was the only factor which significantly related 2-year progression of albuminuria especially in patients with microalbuminuria. We next examined the relationship between albuminuria or renal function with IS, PCS, TMAO which were well-known as gut derived uremic solutes as well as PS. In addition, we examined the relationship between albuminuria or renal function and suPAR, uric acid. As a result, IS, PCS, suPAR were inversely correlated with eGFR. PS, IS, suPAR and uric acid were correlated with albuminuria. Among them, PS and uric acid were the factor which significantly correlated with the 2-year albumin-creatinine ratio (ACR) deterioration. Furthermore, we clarified that serum PS concentration level was high even in same patients who are preserved renal function (eGFR>60 ml/min/1.73cm^2), and high PS concentration patients were significantly increased 2-year ACR deterioration rate.

Conclusions: PS is a predictive marker of albuminuria in the patients with microalbuminuria in DKD.

PO0990

Virtual Patient Simulation in Diabetic Kidney Disease: Successful Strategy for Improving Recognition and Management

Amy Larkin. *Medscape LLC, New York, NY.*

Background: We sought to determine if virtual patient simulation (VPS)-based continuing medical education (CME) intervention could improve performance of nephrologists related to recognition and management of diabetes kidney disease (DKD).

Methods: The intervention comprised a patient presenting at two different time points in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments in a manner matching the scope and depth of actual practice. Tailored clinical guidance (CG), based on current evidence and expert recommendation, was provided following each decision, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user's baseline (pre-CG) decisions using a McNemar's test to determine *P* values. The activity posted August 30, 2019; initial data was collected through November 7, 2019.

Results: 139 nephrologists completed the activity (all decisions within at least 1 case) and were included. Significant improvements were observed after CG: 1st Patient: Diagnose CKD stage 3b: 28% absolute improvement (19% pre-CG vs 47% post-CG; P<.01) Diagnose T2D: 33% absolute improvement (5% pre-CG vs 38% post-CG; P<.01) Initiate SGLT2 inhibitor: 53% improvement (17% pre-CG vs 70% post-CG; P<.01) Order patient education: 15% improvement (52% pre-CG vs 67% post-CG; P<.01) 2nd Patient: Diagnose CKD stage 3a: 33% absolute improvement (24% pre-CG vs 57% post-CG; P<.01) Diagnose T2D: 41% absolute improvement (10% pre-CG vs 51% post-CG; P<.01) Initiate SGLT2 inhibitor: 36% improvement (48% pre-CG vs 84% post-CG; P<.01) Initiate ACE inhibitor: 18% improvement (82% pre-CG vs 100% post-CG; P<.01) Order patient education: 14% improvement (59% pre-CG vs 73% post-CG; P<.01)

Conclusions: VPS that immerses and engages specialists in an authentic and practical learning experience can improve evidence-based clinical decisions related to patient identification and management of hyperkalemia.

Effect of Multidisciplinary Care Models on Glomerular Filtration Rate for Patients with Diabetic Kidney Disease: Systematic Review and Meta-Analysis

Andrea Dib, Andric C. Perez-Ortiz, Daniela Contreras Estrada, Laura Cantillo, Lorea Anasagasti, Bani Antonio Aguirre, Diego S. Gutiérrez, Gregorio T. Obrador. *Universidad Panamericana, Ciudad de Mexico, Mexico.*

Background: Since 2015, the Kidney Disease Improving Global Outcomes guidelines advocate for comprehensive conservative care for diabetic nephropathy (DN) patients. Multidisciplinary care (MCD) models are such strategies that offer integrated care to delay renal disease progression, reduce micro- and macrovascular complications of diabetes, increase the quality of life, and reduce associated costs. Prior reviews have assessed the effect of MCDs in all-cause mortality, hospitalization rate, and need for temporal or permanent renal replacement therapy. However, to date, there are no reviews on their impact on glomerular filtration rate (GFR).

Methods: We conducted a systematic search of observational and randomized trials on DN GFR assessments. We searched Ovid and PubMed databases. Following the STROBE and CONSORT recommendations, we assessed the quality of evidence and any selection/information bias from our resulted pool of evidence. Our primary outcome was GFR quantifications between MCD vs. non-MCD DN treated patients. We performed a meta-analysis of these measurements using random and fixed effects models and examined inter-study heterogeneity with meta-regression models.

Results: There were 93 records from our systematic search. We screened titles and abstracts and retrieved eight records (9,892 participants) for qualitative and quantitative assessments. By subgroup analyses, MCD had a statistically significant effect on GFR among younger patients (<65 years, x0.53-fold increase in GFR vs. non-MCD) with long-term follow-up (>2 years, x0.57-fold increase in GFR vs. non-MCD) (Table).

Conclusions: Based on eight records with significant sample size, MCDs might have a positive effect on GFR if implemented earlier (preferably before age 65). However, this benefit might not be seen immediately, rather in the long-term. We suggest implementing these approaches as standard of care for DN.

Subgroup	Pooled SMD (95% CI)	Sample size	I-squared
Age ≥65 vs <65 years	0.53 (0.40, 0.65)	1,011	62%, p = 0.07
Follow-up time < 2 vs ≥ 2 years	0.57 (0.43, 0.70)	917	43%, p = 0.19

PO0992

Outcomes of Diabetic vs. Non-Diabetic Patients in the GCC Dialysis Outcomes and Practice Patterns Study

Brian Bieber,[1] Saeed Al-Ghamdi,[2] Mona Al Rukhaimi,[3] Ali AlSahow,[4] Issa Al Salmi,[5] Fadwa M. Al-Ali,[6] Ali Alaradi,[7] Bruce M. Robinson,[1] Ronald L. Pisoni.[1] On behalf of the GCC-DOPPS Study Group *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]King Abdulaziz University, Jeddah, Saudi Arabia; [3]Dubai Medical College, Dubai, United Arab Emirates; [4]Jahra Hospital, Jahra, Kuwait; [5]The Royal Hospital, Ministry of Health, Muscat, Oman; [6]Hamad General Hospital, Doha, Qatar; [7]Salmaniya Medical Complex, Manama, Bahrain.*

Background: Diabetes is a common comorbidity among hemodialysis (HD) patients in the Gulf Cooperation Council (GCC) countries, higher than any other region participating in the Dialysis Outcomes and Practice Patterns Study (DOPPS). Objectives of this analysis were to describe the prevalence of glycated-hemoglobulin (HbA1c) measurement, distribution of HbA1c, and association of HbA1c with mortality among participants in the GCC DOPPS.

Methods: 2,274 HD patients were analyzed from 6 GCC (Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, United Arab Emirates) participating in DOPPS phase 5 (2012-2015) and 6 (2015-2018). Diabetic status was based on cause of ESKD or medical chart diagnosis. Cox regression was used to assess the associations of diabetes (among all GCC patients) and baseline HbA1c (among diabetic patients) with mortality adjusted for demographics, comorbidities, creatinine, and Kt/V.

Results: Overall 60% of GCC DOPPS participants were diabetic (country prevalence ranged from 45% in Saudi Arabia to 74% in Kuwait). Compared to non-diabetic patients, patients with diabetes were older (60 vs. 47) on dialysis fewer years (1.5 vs. 3.0), and had higher BMI (27.6 vs. 24.9). Diabetes was associated with elevated mortality; adjusted HR(95% CI)=1.69(1.21-2.34). Measurement of HbA1c within the four months prior to enrollment was variable – ranging from 0% in Bahrain and 33% in Saudi Arabia to 60-78% in the other GCC countries. Among diabetic patients with HbA1c measured, median [IQR] HbA1c was 6.8 [5.8-7.1]. A moderate U-shaped relationship with HbA1c and mortality was observed after adjustment.

Conclusions: Although diabetes is highly prevalent in the GCC HD population, measurement of HbA1c remains variable among this population. The relationship of HbA1c with mortality appears similar to that see in other DOPPS regions. Further investigation related to frequency of measurement and control of HbA1c via treatment is warranted.

PO0993

Self-Management and Progression of Patients with Diabetic Kidney Disease (DKD): A Retrospective Cohort Study

Yifan Wu,[1] Ping Wang,[2] Li Luo,[3] Min Zhang,[3] Bingqing Xia,[3] Lizhe Fu,[4] Fang Tang,[4] Xianlong Zhang,[3] Xusheng Liu,[1] Fuhua Lu.[1] *[1]Renal Division, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine (Guangdong Provincial Hospital of Chinese Medicine), Guangzhou, China; [2]Department of Internal Medicine, Yunfu hospital of Chinese medicine, Yunfu, China; [3]The Second Clinical College, Guangzhou University of Chinese Medicine, Guangzhou, China; [4]Chronic Disease Management Outpatient, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.*

Background: Few specifics were proved effective to delay DKD progression while accumulating evidence supported potential merits of self-management on it. This study aimed to evaluate the association between self-management and progression of non-dialysis CKD3-5 DKD patients.

Methods: Data including demographics, procedure notes, laboratory findings, and medication of the included cohort were analyzed. The cohort was divided into self-management group and control group based on previous self-management exposure. The between-group comparison of renal function at 2 years and survival analysis were conducted.

Results: Total 92 patients were included(47 in self-management group and 45 in control group). Declined serum creatinine level and preserved eGFR were detected in self-management group after 2 years both with no significant difference(P =0.695,0.922), while significantly higher serum creatinine level(P=0.010) and decreased eGFR with no evident significance(P =0.059) after 2 years were found in control group. We defined eGFR<5ml/min/1.73 m2, initiation of renal replacement therapy and death as composite endpoints, and performed time-to-event survival analysis. Ten endpoint events in self-management group(mean survival time 221.31±12.97 weeks) and 17 in control group(mean survival time 168.63±15.03 weeks) were recorded, with significant difference between group comparison(χ2=6.319,P =0.012). Further Cox proportional hazards regression with three adjusted models showed that self-management engagement was an independent factor associated with reduced risk of incident endpoints.

Conclusions: The findings documented predisposing preserved renal function of patients with self-management at 2 years and self-management engagement as an independent factor for decreased risk of endpoints, indicating its potential benefits on delaying DKD progression.

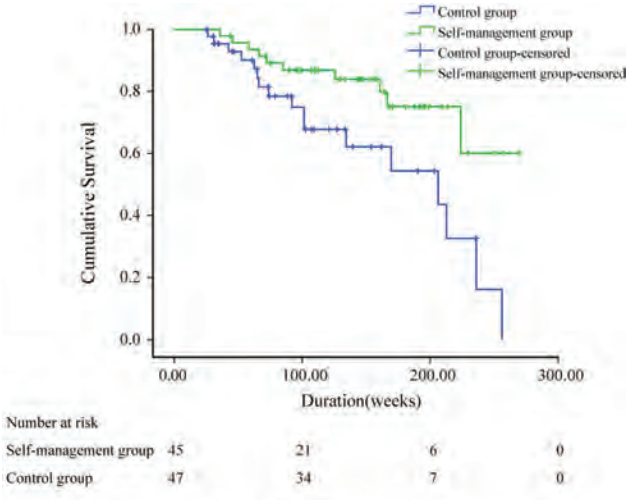

Fig 1. Survival function of self-management group and control group.

PO0994

Attitude Toward Care and Dietary Patterns Differ in CKD and Transplant Patients with and Without Diabetes

Iqra Nadeem, Takisha Morancy, Ahmad Saleh, Kingsley Cruickshank, Mariana Markell. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: Diabetes mellitus requires dietary changes and increased interaction with the health care team over that required by kidney disease alone. We compared dietary adherence and attitudes in pts with kidney disease with and without diabetes in inner-city Brooklyn.

Methods: A face-to-face survey was conducted in a random convenience sample of pts from CKD (23) and transplant (33) clinics. Diet was studied by 24-hour recall using ASA24 software. Healthy Eating Index was calculated using the HEI-15 score. The Beliefs in Medicine Questionnaire (BMQ) was used to elicit attitudes toward the healthcare environment. Comparisons were by t-test.

Results: 15 (45%) transplant (TXP) and 13 (57%) CKD pts had diabetes (DIAB). DIAB were older than pts without diabetes (NODIAB) (62.1±1.98 vs 50.4±2.4 yrs, p<0.0001) but age did not correlate with any finding. Mean creat was 1.83±0.15 mg/dl and did not differ between CKD and TXP, or DIAB and NODIAB. Mean HbA1c was 8.0± 0.28, time with diabetes was 97.7±20.3 months and did not differ between clinics. DIAB were more likely to agree that their health depends on medications in the future (1.36±0.12 vs 2.00±0.26, p=0.024), less likely to believe that if doctors had more time, they would prescribe fewer medications (3.61±0.25 vs 2.79±0.28, p=0.034) and less likely to believe that medicines are poisons (4.5±0.14 vs 3.93±0.23, p=0.039). DIAB pts ate fewer carbohydrates (137.4±11.6 vs 211.8±13.4, p<0.0001), less sugar (44.7±5.6 vs 89.4±9.5, p<0.0001), less fiber (10.9±1.1 vs 16.1±1.4, p<0.005), less vitamin C (54.2±9.9 vs 110.2±23.3, p=0.031), less fruit (0.3±0.1 vs 1.96±0.6, p=0.015) and less refined grains (3.01±0.43 vs 4.61±0.59, p=0.035). There was no difference for HEI score, total caloric or protein intake.

Conclusions: In our population: 1. Approximately 50% of our pts had diabetes. 2. Pts with diabetes had a more positive opinion of the healthcare environment.and ate fewer carbohydrates, sugars and refined grains but less fresh fruit, fiber and vitamin C. 3. Education of our pts with kidney disease and diabetes should reinforce their attitudes towards the healthcare environment while encouraging an eating plan that includes fruits and vegetables, as pts appear to be focusing on restricting sugar and carbohydrates and plant based eating has been shown to be beneficial for pts with kidney disease.

PO0995

Racial and Ethnic Similarities of Adherence to Diabetic Hemoglobin A_{1c} Testing and Control Measures Between Providers and Patients in Federally Qualified Health Centers in Eastern North Carolina

Aparesh Balla,[1] Rebecca Wurtz.[2] [1]*Rural Health Group Inc, Roanoke Rapids, NC;* [2]*University of Minnesota Twin Cities, University of Minnesota, Minneapolis, MN.*

Background: Type 2 Diabetes is a chronic metabolic disorder that occurs when there is a dysregulation of insulin production and cellular insulin response, leading to hyperglycemia. The test for glycated hemoglobin, HbA1C, is the basic blood test used for diagnosis. There is limited exploration of the relationship between adherence to HbA1c testing, diabetes control, and congruent provider/patient race and ethnicity. This study examines the correlations among HbA1c testing, provider race/ethnicity, and patient race/ethnicity.

Methods: Twelve consecutive monthly diabetes reports and dashboards compiled by the Rural Health Group, starting on October 1, 2018, were retrieved and analyzed in the investigation of the racial and ethnic similarities of HbA1c adherence to diabetic testing and control measures between providers and patients in the Federal Qualified Health Center in eastern North Carolina. Comparative statistical analyses permitted the juxtaposition of the comparison groups of patients and providers: White, Black, Hispanic, or other.

Results: As per adherence with the order of testing, there were no statistically significant differences found for White, Black, or Hispanic patients when they were seen by different providers. However, as per adherence to diabetes control measures, Black patients seen by Black providers were much more likely to have an HbA1c < 7% (52% when seen by a Black provider vs. only 45% when seen by a White provider, p-value = 0.0001, 95% confidence interval). Similarly, White patients had an HbA1c < 7% 50% of the time when seen by White providers, but only 43% of the time when seen by Black providers (p-value < 0.05). Therefore, patients who are the same race as their providers are statistically more likely to have an HbA1c, which reflects adherence to diabetes control measures.

Conclusions: Patients who are the same race/ethnicity as their providers did not play a significant role on HbA1c testing than patients who are the same race/ethnicity as their provider. However, patients who are the same race/ethnicity as their provider were more likely to have a HbA1c < 7%, which was statistically significant and reflected adherence to diabetes control measures. This finding was particularly true of White patients to White providers and with Black patients to Black providers.

PO0996

Low Serum Transferrin Saturation Is Associated with Incident Diabetes in Veterans with CKD

Monique E. Cho,[1,2] Jared Hansen,[1,2] Alfred K. Cheung,[1,2] Tom Greene.[2] [1]*George E. Wahlen Department of Veterans Affairs Medical Center, Salt Lake City, UT;* [2]*University of Utah Health, Salt Lake City, UT.*

Background: Chronic kidney disease (CKD) is associated with increased risk for new-onset diabetes. Decreased circulating iron, as expressed by low transferrin saturation (Tsat), is associated with diabetes in the general population, but it has not been investigated if Tsat or ferritin is independently associated with incident diabetes in CKD.

Methods: We developed a historical cohort using the Veterans Affairs Informatics and Computing Infrastructure. We identified non-diabetic Veterans with CKD (MDRD eGFR <60 mL/min/1.73m^2) with at least one set of iron indices between 2006-2015. Veterans with diabetes, end-stage renal disease, genetic or chronic disorders affecting iron metabolism, or those who received intravenous iron or erythropoietin stimulating agents within 3 months of the iron indices were excluded. A generalized additive Cox model was applied to the cohort to explore the joint dose-response relationship of the hazard for incident diabetes following the iron assay. A contour surface plot relating the covariate-adjusted hazard for incident diabetes to both Tsat and ferritin was developed using cubic regression splines.

Results: Of the 1,159,371 Veterans with CKD, 54,990 met the inclusion criteria. The mean±SD for age and eGFR were 73.8 ± 11.8 years and 43.8 ± 10.4 mL/min/1.73 m^2, respectively. The median (IQR) Tsat and ferritin values were 23.0 (16.9, 29.7) % and 112.1 (56.0, 210.0) ng/mL. Over the mean follow-up period of 4 years, the risk of diabetes was inversely associated with Tsat, while it was positively correlated with serum ferritin. The surface contour map suggests that lower Tsat range (<20%) has a stronger relationship with diabetic risk than serum ferritin.

Conclusions: In Veterans with pre-dialysis CKD, decreased Tsat is closely associated with incident diabetes risk, while increased ferritin exacerbates the risk.

Association of Glomerular Hyperfiltration with Glycemic Control and Serum Uric Acid Among NHANES Participants with Diagnosed Diabetes Mellitus

Mitra Mosslemi,[1] Elani Streja,[1] Ekamol Tantisattamo,[1] Connie Rhee,[1] Keith C. Norris,[3] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Los Angeles, Los Angeles, CA.*

Background: Glomerular Hyperfiltration (GH) is the earliest sign of diabetic kidney disease (DKD) even prior to the development of albuminuria. Some studies have reported that improvement in glycemic control reduces GH. Since elevated serum uric acid (SUA) level may herald worse diabetes outcomes including a higher likelihood of DKD, we sought to examine the association of GH status with glycemic control and SUA among diabetics.

Methods: We examined the National Health and Nutritional Examination Survey (NHANES) data from 1999 through 2016, comprising adults (age ≥ 20 years, n= 47,133, projected to N=214.9 million US population). We defined diagnosed diabetes cases as those who reported being diagnosed by a doctor or using glucose-lowering medications (n= 5,783, N=19.3M) and defined GH as eGFR ≥120 ml/min/1.73m2 (CKD-EPI) vs. normal-filtration as 60 ≤ eGFR <120 (GH: n=110, non-GH: n=3115). Cases with eGFR<60 were excluded (n= 2,558). We assessed the association of GH with average glycemic control (HbA1c) and SUA levels adjusted for demographic characteristics, diabetes duration, and diabetes treatment, using univariate and multivariable regression models.

Results: The prevalence of GH in persons under 10 years of diabetes was 2.7% but significantly less after 10 years (1.1%, p= 0.003). GH was more likely in younger age, female sex, Hispanic ethnicity, higher A1c, higher SUA, and those with no diabetes treatment. In the multivariable model, female sex was the strongest predictor followed by Hispanic ethnicity, higher SUA, and younger age [Table].

Conclusions: GH is more common in the first 10 years of diabetes and associated with higher SUA. It is more common among females, Hispanic race, and younger diabetes patients. Further studies should examine the potential role of sex, ethnicity, age, and SUA in the mechanism of GH among persons with diabetes.

Regression model for variables associated with Glomerular Hyperfiltration (GH) among patients with diagnosed diabetes

Variables	Odds Ratio (95% CI)	P-Value
Age (per SD)	0.91 (0.89, 0.92)	<0.0001
Gender (Female vs. Male)	16.34 (5.10, 52.34)	<0.0001
Ethnicity (Hispanic vs. White)	3.10 (1.39, 6.90)	0.006
HbA1c (per SD)	1.01 (1.00, 1.02)	0.06
SUA (Hypouricemia vs. Reference)	2.28 (1.13, 4.62)	0.02

PO0998

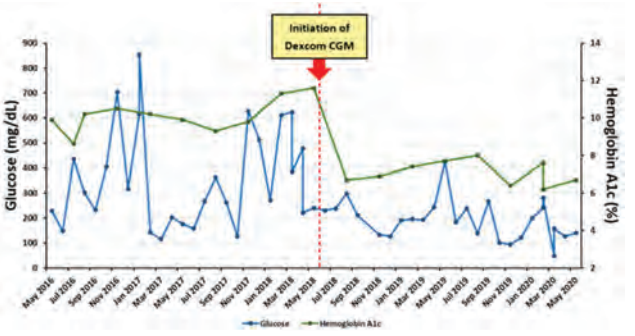
Continuous Glucose Monitoring in a Diabetic Hemodialysis Patient

Elisa Park,[1] Kamyar Kalantar-Zadeh,[1] Amy S. You,[1] David A. Price,[2] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]DexCom Inc, San Diego, CA.*

Introduction: Diabetes is the leading cause of end stage renal disease (ESRD) in the US. Patients with diabetic kidney disease (DKD) are susceptible to hypo- and hyperglycemia via multiple pathways. Continuous glucose monitoring (CGM) provides automated, less invasive glucose measurements (updated every 5 minutes) and more comprehensive glucose data vs. conventional self-monitored blood glucose (SMBG), and glycemic benefits for CGM use have been established. However, CGM use has been limited in diabetic hemodialysis (HD) patients as devices are not currently approved for use in this population.

Case Description: We describe a 48-year old male with ESRD due to DKD receiving HD. At the age of 26, the patient was diagnosed with diabetes after presenting with recurrent skin infections and unexplained weight loss. He was initially treated with glyburide which was changed to metformin, and was later transitioned to an insulin pump. Over time he developed DKD which progressed to ESRD by the time he was 41 years old. His diabetes was also complicated by neuropathy and retinopathy with right-eye blindness. For two decades, the patient utilized SMBG with capillary fingerstick measurements to monitor his glycemic status. During this time he had wide fluctuations in his glucose levels with asymptomatic hypo- and hyperglycemia, and his HbA1c levels were typically 10-12%. Due to poor glucose control, his endocrinologist advised him to use CGM (Dexcom G5, later transitioned to Dexcom G6, San Diego, CA). Since transitioning to CGM, the patient reports 1) greater adherence to glycemic monitoring, 2) improved hypoglycemia detection, 3) minimal lifestyle interruption, and 4) improved quality of life. In addition, he has less glycemic variability, increased time-in-target glucose range, and improved HbA1c levels to 6-8%.

Discussion: This case demonstrates CGM is a practical method for glucose assessment with the potential to improve glycemic control in diabetic ESRD patients. Further studies are needed to determine the comparative effectiveness of CGM vs. SMBG in diabetic HD patients.



PO0999

ESKD due to an Atypical Cause of Diabetes Mellitus

Christin M. Giordano McAuliffe, James M. Luther. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Diabetes mellitus (DM) is the most common cause of chronic kidney disease (CKD) in the United States. This case describes CKD caused by an atypical, potentially reversible cause of type 2 DM.

Case Description: A 70 year-old male presented to our Hypertension Clinic with new onset lower extremity edema, CKD, and hypertension. He had had type 2 DM for 20 years complicated by retinopathy and gastroparesis. Although body mass index was 29.8, he required more than 100 units of long-acting insulin daily. His blood pressure measured 200/115 and had been refractory to multiple medications. Initial laboratory evaluation demonstrated creatinine 2.7 mg/dL, glucose 245 mg/dL, urine protein-to-creatinine (uPCR) of 8.5, hemoglobin A1c of 7.5%, and negative serum and urine protein electrophoresis. Echocardiogram revealed severe left ventricular hypertrophy. CT of his abdomen demonstrated a 4 x 4 cm pancreatic cystic mass which had been biopsied 15 years previously and showed no malignant cells. Due to persistent gastrointestinal complaints, imaging was repeated 2 years later and demonstrated an increase in the pancreatic mass size to 5.8 x 5.1 cm without any evidence of metastasis. Further laboratory evaluation demonstrated C-peptide 2.4 ng/ml (normal) and glucagon 1760 ng/L (normal <208 ng/L). Elevated pancreatic polypeptide and chromogranin A levels confirmed the diagnosis: glucagonoma. He declined surgery and was intolerant of octreotide. Although uPCR decreased to a nadir of 1.5 with improved blood pressure control, his kidney function progressively declined and he required hemodialysis (HD). HD only minimally improved his nausea and vomiting. His physical condition declined over the course of a year, until he entered hospice and expired. At time of death, his pancreatic lesion measured 6 cm.

Discussion: Glucagonomas are rare tumors with an incidence of approximately 0.1 cases per 100,000, most commonly presenting in the 5th decade of life. Secondary causes of DM should be considered in patients without obesity, normal C-peptide levels despite advanced disease, and/or a pancreatic mass. Additionally, glucagon excess or mechanical obstruction by a pancreatic mass may cause gastrointestinal complaints attributed to uremia or diabetic gastropathy. Timely diagnosis and resection could prevent this disease cascade of diabetes, nephropathy, and end-stage kidney disease.

Effects of Canagliflozin on Cardiovascular, Renal, and Safety Outcomes by Baseline Loop Diuretic Use: Data from the CREDENCE Trial

Adeera Levin,[1] Brendon L. Neuen,[2] Kenneth W. Mahaffey,[3] Christopher P. Cannon,[4] Meg J. Jardine,[2] Hiddo J. L Heerspink,[5] Bruce Neal,[2,6] Clare G. Arnott,[1] Zien Zhou,[2,7] David M. Charytan,[8,9] Rajiv Agarwal,[10] George L. Bakris,[11] Dick de Zeeuw,[5] Tom Greene,[12] David C. Wheeler,[13] Norm Rosenthal,[14] Hong Zhang,[15] Bernard Zinman,[16] Vlado Perkovic,[1,17] Carol A. Pollock.[18] *[1]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [2]The George Institute for Global Health, Sydney, NSW, Australia; [3]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [4]Cardiovasular Division, Brigham & Women's Hospital and Baim Institute for Clinical Research, Boston, MA; [5]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [6]The Charles Perkins Centre, University of Sydney and Imperial College London, London, United Kingdom; [7]Department of Radiology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [8]Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, New York, NY; [9]Baim Institute for Clinical Research, Boston, MA; [10]Indiana University School of Medicine and VA Medical Center, Indianapolis, IN; [11]Department of Medicine, University of Chicago Medicine, Chicago, IL; [12]Division of Biostatistics, Department of Population Health Sciences, University of Utah, Salt Lake City, UT; [13]Department of Renal Medicine, UCL Medical School, London, United Kingdom; [14]Janssen Research & Development, LLC, Raritan, NJ; [15]Renal Division of Peking University First Hospital, Beijing, China; [16]Lunenfeld-Tanenbaum Research Institute, Mt Sinai Hospital, University of Toronto, Toronto, ON, Canada; [17]The Royal North Shore Hospital, Sydney, NSW, Australia; [18]Kolling Institute of Medical Research, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia.*

Background: Canagliflozin (CANA) reduces the risk of cardiovascular (CV) events and kidney failure in people with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD). Inherent in its mechanism of action is enhanced natriuresis and osmotic diuresis. It is unclear if the efficacy or safety of CANA is modified by concomitant diuretic use.

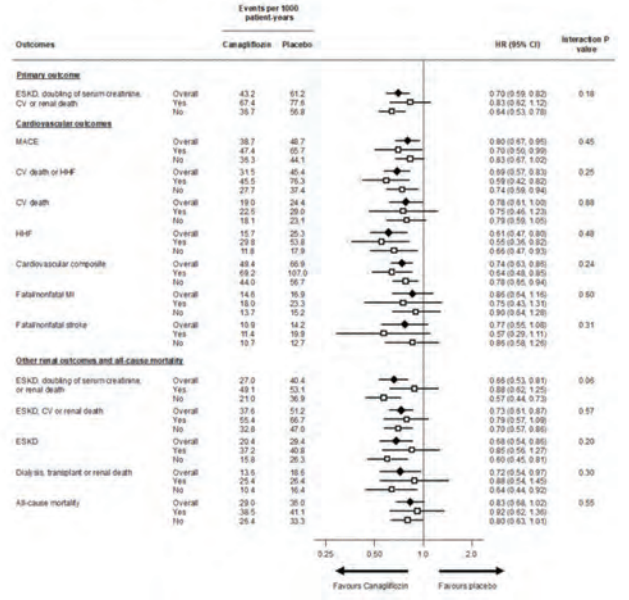
Methods: CREDENCE randomized participants with T2DM and CKD to CANA or matching placebo. The primary outcome was a composite of end-stage kidney disease, doubling of serum creatinine, CV or renal death. We estimated effects on key efficacy and safety outcomes by baseline use of loop diuretics.

Results: Of 4401 CREDENCE participants, 955 (21.7%) received loop diuretics at baseline. These participants were older (mean age 63.5 vs 62.7 y; P=0.01), with a longer diabetes duration (17.0 vs 15.5 y), lower eGFR (49.7 vs 58.0 mL/min/1.73m^2), and were more like to have a history of heart failure (27.6 vs 11.3%; all P<0.0001). Unadjusted event rates were higher in those using loop diuretics (Figure). Effects of CANA on the primary outcome and other CV and renal outcomes were consistent irrespective of loop diuretic use. The risk of renal-related adverse events, acute kidney injury, and volume depletion was not elevated by loop diuretic use (data not shown; all $P_{interaction}$>0.05).

Conclusions: CANA reduces the risk of CV and renal outcomes in people with T2DM and CKD irrespective of baseline use of loop diuretics, without additional adverse effects.

Funding: Commercial Support - Janssen Scientific Affairs, LLC

Figure. Effect of canagliflozin on cardiovascular and renal outcomes by baseline use of loop diuretics



Cardiovascular composite includes cardiovascular death, nonfatal MI, nonfatal stroke and hospitalization for unstable angina. MACE: major adverse cardiovascular events; CV: cardiovascular; HHF: hospitalization for heart failure; ESKD: end-stage kidney disease; MI: myocardial infarction; HR: hazard ratio; CI: confidence interval.

Acute Declines in eGFR During Treatment with Canagliflozin (CANA) and Its Implications for Clinical Practice: Insights from CREDENCE

Hiddo J. L Heerspink,[1,2] Megumi Oshima,[1,3] Meg J. Jardine,[1,4] Rajiv Agarwal,[5] George L. Bakris,[6] Christopher P. Cannon,[7] David M. Charytan,[8,9] Dick de Zeeuw,[2] Robert Edwards,[10] Tom Greene,[11] Adeera Levin,[12] Kenneth W. Mahaffey,[13] Bruce Neal,[1] Carol A. Pollock,[14] Norm Rosenthal,[10] David C. Wheeler,[15] Hong Zhang,[16] Bernard Zinman,[17] Vlado Perkovic.[1] *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [3]Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan; [4]Concord Repatriation General Hospital, Sydney, NSW, Australia; [5]Indiana University School of Medicine and Veterans Affairs Medical Center, Indianapolis, IN; [6]Department of Medicine, University of Chicago Medicine, Chicago, IL; [7]Cardiovascular Division, Baim Institute for Clinical Research, Boston, MA; [8]Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, New York, NY; [9]Baim Institute for Clinical Research, Boston, MA; [10]Janssen Research & Development, LLC, Raritan, NJ; [11]Division of Biostatistics, Department of Population Health Sciences, University of Utah, Salt Lake City, UT; [12]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [13]Stanford Center for Clinical Research, Stanford University School of Medicine, Stanford, CA; [14]Kolling Institute of Medical Research, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia; [15]Department of Renal Medicine, UCL Medical School, London, United Kingdom; [16]Renal Division of Peking University First Hospital, Beijing, China; [17]Lunenfeld-Tanenbaum Research Institute, Mt Sinai Hospital, University of Toronto, Toronto, ON, Canada.*

Background: CANA slows progression of chronic kidney disease (CKD) in people with type 2 diabetes. CANA also induces a reversible acute decline in estimated glomerular filtration rate (eGFR), which is believed to be a hemodynamic effect. Predictors of the initial decline and its association with long-term eGFR trajectories and safety outcomes are unknown.

Methods: This post hoc study of CREDENCE included 4289 patients with type 2 diabetes and CKD who had eGFR measured at both baseline and week 3. Participants were categorized by percentage decline in eGFR at week 3: greater than 10% decline; between 0 and 10% decline; and no decline. Baseline characteristics associated with acute eGFR drop >10% were evaluated using logistic regression. Long-term eGFR decline and safety outcomes were estimated in each eGFR decline category by linear mixed effects models and Cox regression after adjustment for laboratory measures and medication use.

Results: More participants in the CANA (956 [45%]) versus placebo (PBO) group (450 [21%]) had an acute eGFR decline >10% (p<0.001). A >30% decline occurred infrequently (89 [4%] with CANA and 39 [2%] with PBO; p<0.001). In the CANA but not in the PBO group, older age (OR CANA 1.17, 95% CI 1.05–1.31; per 10 years) and

history of heart failure (OR CANA 0.77, 0.59–0.99) were associated with a higher and lower likelihood of an acute eGFR decline >10%, respectively (both p interaction<0.05). Following the initial eGFR change, long-term eGFR trajectories were similar across eGFR decline categories (all p>0.05). Safety profiles were also similar except when the drop unusually exceeded 30%, in which case adverse events and renal related adverse events occurred more frequently. Results were consistent in subgroup analysis by baseline eGFR (30-<45, 45-<60, and 60-<90 mL/min/1.73m^2).

Conclusions: Although acute eGFR declines >10% occurred in nearly half of all patients following initiation of CANA, the benefit of CANA compared with PBO was observed regardless of the acute eGFR decline and safety profiles were similar.

PO1002

The SGLT2 Inhibitor Canagliflozin Reduces the Plasma Markers TNFR-1, TNFR-2, and KIM-1 in the CANVAS Trial

Taha Sen,[1] Jingwei Li,[2] Brendon L. Neuen,[2] Bruce Neal,[2] Chirag R. Parikh,[5] Steven G. Coca,[6] Vlado Perkovic,[2] Dick de Zeeuw,[1] Kenneth W. Mahaffey,[3] Michael K. Hansen,[4] Hiddo J. L Heerspink.[1,2] *[1]Department of Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands; [2]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [3]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [4]Janssen Research & Development, LLC, Spring House, PA; [5]Johns Hopkins School of Medicine, Baltimore, MD; [6]Division of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Tumor Necrosis Factor Receptor (TNFR)-1, TNFR-2 and Kidney Injury Molecule-1 (KIM-1) are biomarkers known to predict kidney outcomes in patients with type 2 diabetes (T2D). We assessed the effect of the SGLT2 inhibitor canagliflozin (CANA) on TNFR-1, TNFR-2 and KIM-1 in CANVAS study participants to determine whether early changes were associated with subsequent kidney outcomes.

Methods: The CANVAS trial randomized participants with T2D at high cardiovascular risk to CANA or placebo (PBO). TNFR-1, TNFR-2 and KIM-1 were measured with immunoassays (proprietary multiplex assay performed by RenalytixAI, NY, USA) at baseline, and years 1, 3, and 6. Mixed effects models for repeated measures assessed the effect of CANA vs PBO on TNFR-1, TNFR-2 and KIM-1. The association between early change (baseline to year 1) for each of the 3 markers and the kidney outcome (40% eGFR decline, end-stage kidney disease, or renal death) was assessed using multivariable adjusted Cox regression.

Results: Among 2872/4330 (67%) CANVAS participants with available plasma samples at baseline and follow-up, median baseline TNFR-1, TNFR-2 and KIM-1 were 2559, 9612, and 108 pg/mL. Difference between CANA and PBO in TNFR-1, TNFR-2, and KIM-1 during follow-up were 2.8% (95%CI −3.4, −1.3; P<0.001), −1.9% (95%CI −3.5, −0.2; P=0.028) and −26.7% (−30.7, −22.7; P<0.001). Increases in TNFR-1 and TNFR-2, but not KIM-1, at year 1 were independently associated with a higher risk of the kidney outcome (Table).

Conclusions: CANA reduces TNFR-1, TNFR-2 and KIM-1 in patients with T2D at high cardiovascular risk. Early increases in TNFR-1 and TNFR-2 were independently associated with higher risk of kidney disease progression and have the potential to be pharmacodynamic markers of non-response to CANA.

Table

		TNFR-1	TNFR-2	KIM-1
Change at year 1	Quartile 1	0.81 (0.42, 1.55)	0.98 (0.50, 1.92)	0.99 (0.56, 1.76)

PO1003

Canagliflozin Treatment Reduces Formation and Increases Degradation of Collagen Type III in the Canagliflozin Cardiovascular Assessment Study (CANVAS)

Daniel Guldager Kring Rasmussen,[1] Timothy Jatkoe,[2] Nadja Sparding,[1,3] Alexandra L. Møller,[1,3] Morten A. Karsdal,[1] Norm Rosenthal,[2] David E. Gutstein,[4] Bruce Neal,[5,6] Vlado Perkovic,[5,7] Kenneth W. Mahaffey,[8] Federica Genovese,[1] Michael K. Hansen.[4] *[1]Nordic Bioscience, Herlev, Denmark; [2]Janssen Research & Development, LLC., Raritan, NJ; [3]Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark; [4]Janssen Research & Development, LLC., Spring House, PA; [5]The George Institute for Global Health, Sydney, NSW, Australia; [6]The Charles Perkins Centre, University of Sydney, Sydney, NSW, Australia and Imperial College London, London, United Kingdom; [7]The Royal North Shore Hospital, Sydney, NSW, Australia; [8]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA.*

Background: The CANVAS trial investigated the effects of canagliflozin in T2D patients at high risk of cardiovascular (CV) disease. Collagen type III (COL III) is one of the main components of the interstitial extracellular matrix that is significantly upregulated in fibrosis. In the current study, we investigated the impact of canagliflozin treatment on biomarkers of COL III formation (PRO-C3) and degradation (C3M) in the CANVAS trial.

Methods: COL III formation was assessed with the PRO-C3 enzyme-linked immunosorbent assay (ELISA), detecting the cleaved pro-peptide released upon deposition in the extracellular matrix. COL III degradation was assessed with the C3M ELISA, detecting a neo-epitope fragment released after MMP-9 mediated degradation. The change in biomarker measurements at year 3 from baseline were compared between placebo and canagliflozin in plasma (n=2156) and urine (n=2137) samples using a linear model to assess whether biomarker levels were significantly affected by treatment. Urine biomarker levels were corrected for urine creatinine.

Results: Treatment with canagliflozin compared to placebo resulted in significantly lower plasma PRO-C3 levels -0.52 ng/mL (p=0.0054; 95% CI: -0.88, -0.15), with mean levels rising in the placebo group (0.48 ng/mL) but remaining stable in the intervention group (-0.04 ng/mL). Urinary PRO-C3 levels were increased 293.19 ng/mmol (p<0.001; 95% CI: 158.87, 427.51), with mean levels increasing 24.23 ng/mmol in the placebo group and 317.42 ng/mmol in the intervention group. Urinary C3M levels were increased 833.01 ng/mmol (p<0.001; 95% CI: 481.27, 1184.74), with mean levels decreasing -337.71 ng/mmol in placebo and increasing 495.30 ng/mmol on treatment. There was no correlation between the change in plasma and urine PRO-C3 (r=0.07).

Conclusions: The reduction in PRO-C3 levels in plasma and the increase in urine C3M levels following treatment with canagliflozin suggest an anti-fibrotic effect of canagliflozin. Further research is necessary to understand the mechanism for canagliflozin's effects on fibrosis.

Canagliflozin and Risk of Genital Infections and Urinary Tract Infections in People with Diabetes Mellitus and Kidney Disease in the CREDENCE Trial

Amy Kang,[1] Brendon L. Neuen,[1] Hiddo J. L Heerspink,[2] Gian Luca Di Tanna,[1] Bruce Neal,[1] Hong Zhang,[3] Carinna Hockham,[1] Rajiv Agarwal,[4] George L. Bakris,[5] David M. Charytan,[6] Dick de Zeeuw,[2] Tom Greene,[7] Adeera Levin,[8] Carol A. Pollock,[11] David C. Wheeler,[12] Bernard Zinman,[10] Kenneth W. Mahaffey,[9] Vlado Perkovic,[1] Meg J. Jardine.[1] *[1]The George Institute for Global Health UNSW Sydney, Sydney, NSW, Australia; [2]Rijksuniversiteit Groningen, Groningen, Netherlands; [3]Peking University First Hospital, Beijing, China; [4]Indiana University School of Medicine, Indianapolis, IN; [5]University of Chicago, Chicago, IL; [6]NYU Langone Health, New York, NY; [7]University of Utah Health, Salt Lake City, UT; [8]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [9]Stanford University, Stanford, CA; [10]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada; [11]University of Sydney - Camperdown and Darlington Campus Burkitt-Ford Library, Sydney, NSW, Australia; [12]University College London, London, United Kingdom.*

Background: Genital mycotic infections (GMI) and urinary tract infections (UTI) are common in patients with diabetes. We assessed the effects of canagliflozin on the risk of these infections in the CREDENCE trial population.

Methods: The CREDENCE trial randomised people with type 2 diabetes and albuminuric stage 2 and 3 chronic kidney disease to canagliflozin 100mg daily or placebo. We analysed the risk of GMI and UTI with canagliflozin compared to placebo overall and in subgroups. The primary analysis was conducted in the on-treatment population. When canagliflozin increased risk, we determined patient risk factors for GMIs using multivariable Cox regression models.

Results: Overall 31/2905 (1.1%) men and 32/1492 (2.1%) women experienced 91 GMIs and 166/2905 (5.7%) men and 300/1492 (20.1%) women experienced 669 UTIs. 58/669 (8.7%) UTIs but no GMIs were reported as serious. Most participants continued treatment following their first infection with similar recurrence rates in the canagliflozin and placebo groups. Canagliflozin increased the risk of GMI (HR 3.83 [95% CI 2.08-7.06] p<0.0001). The hazard ratio (HR) for canagliflozin compared to placebo was consistent across most subgroups, though canagliflozin led to a greater increase in risk in those with a BMI>30 kg/m^2 compared to those with a BMI<30 kg/m^2 (HR 5.91 vs 1.36, p interaction=0.03) and in men compared to women (HR 9.30 vs HR 2.10, p interaction=0.04). In those who were randomised to canagliflozin, independent risk factors for GMI were higher BMI (HR 1.53 [95% CI 1.29-1.83] per 5 units p<0.0001) and longer diabetes duration (HR 1.18 [95% CI 1.01-1.40] per 5 years p=0.04). Canagliflozin did not affect the risk of UTI (HR 1.08 [95% CI 0.90-1.29] p=0.42) overall or in any subgroup.

Conclusions: Canagliflozin increased risk of GMI but not UTI. The proportional increase in GMI with canagliflozin was greater in men and people with higher BMI.

Funding: Commercial Support - Janssen sponsored the CREDENCE trial but did not sponsor this post-hoc analysis

PO1005

Canagliflozin and Risk of Skin and Soft Tissue Infections in People with Diabetes Mellitus and Kidney Disease in the CREDENCE Trial

Amy Kang,[1] Brendan Smyth,[1] Brendon L. Neuen,[1] Hiddo J. L Heerspink,[2] Gian Luca Di Tanna,[1] Bruce Neal,[1] Hong Zhang,[3] Carinna Hockham,[1] Rajiv Agarwal,[4] George L. Bakris,[5] David M. Charytan,[6] Dick de Zeeuw,[2] Tom Greene,[7] Adeera Levin,[8] Carol A. Pollock,[9] David C. Wheeler,[12] Bernard Zinman,[11] Kenneth W. Mahaffey,[10] Vlado Perkovic,[1] Meg J. Jardine.[1]
[1]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [2]Rijksuniversiteit Groningen, Groningen, Netherlands; [3]Peking University First Hospital, Beijing, China; [4]Indiana University School of Medicine, Indianapolis, IN; [5]University of Chicago, Chicago, IL; [6]NYU Langone Health, New York, NY; [7]University of Utah Health, Salt Lake City, UT; [8]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [9]University of Sydney - Camperdown and Darlington Campus Burkitt-Ford Library, Sydney, NSW, Australia; [10]Stanford University, Stanford, CA; [11]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada; [12]University College London, London, United Kingdom.

Background: The skin's hypertonic microenvironment has a protective antimicrobial function that may be disrupted by sodium glucose cotransporter 2 inhibitors (SGLT2i). We aimed to describe skin and soft tissue infections (SSTI) in the CREDENCE trial and determine whether canagliflozin affects the risk of SSTIs.

Methods: We performed a post-hoc analysis of the CREDENCE trial that randomised people with type 2 diabetes and albuminuric stage 2 and 3 chronic kidney disease to either canagliflozin 100mg daily or placebo. Adverse events were assessed by two blinded authors following predetermined criteria for SSTI with discrepancies resolved by consensus. We analysed the risks of SSTIs in the on-treatment population as the more conservative approach, with sensitivity analyses conducted in the intention-to-treat population, for serious events only and for participant subgroups. Univariable time-to first-event regression models were assessed.

Results: Overall 373/4397 (8.5%) participants experienced 478 events comprising 252 bacterial skin infections (including 2 episodes of necrotising fasciitis), 94 fungal skin infections, 109 other skin infections and 23 soft tissue infections. Of these, 136/478 (28%) were serious. Canagliflozin did not increase the risk of SSTI (HR 0.85 [95% Confidence Interval (CI) 0.69-1.04] p=0.11), with similar results in the intention-to-treat population (HR 0.88 [95% CI 0.73-1.07] p=0.20), in analyses confined to serious SSTI (HR 0.83 [95% CI 0.58-1.21] p=0.33) and participant subgroups (all p interaction≥0.10). Both cases of necrotising fasciitis were in patients assigned to canagliflozin and the participants recovered after drug was withdrawn.

Conclusions: Canagliflozin did not increase the risk of skin and soft tissue infections overall or in any subgroup, in CREDENCE trial participants with type 2 diabetes mellitus and albuminuric chronic kidney disease.

Funding: Commercial Support - Janssen sponsored the CREDENCE trial but did not sponsor this post-hoc analysis

PO1006

Early Change in Albuminuria with Canagliflozin (CANA) Predicts Kidney and Cardiovascular (CV) Outcomes

Megumi Oshima,[1,2] Brendon L. Neuen,[1] Jingwei Li,[1] Vlado Perkovic,[1] David M. Charytan,[3] Dick de Zeeuw,[4] Robert Edwards,[5] Tom Greene,[6] Adeera Levin,[7] Kenneth W. Mahaffey,[8] Luca De Nicola,[9] Carol A. Pollock,[10] Norm Rosenthal,[5] David C. Wheeler,[1,11] Meg J. Jardine,[1,12] Hiddo J. L Heerspink.[1,13]
[1]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [2]Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan; [3]Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, New York, NY; [4]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [5]Janssen Research & Development, LLC, Raritan, NJ; [6]Division of Biostatistics, Department of Population Health Sciences, University of Utah, Salt Lake City, UT; [7]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [8]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [9]Department of Advanced Medical and Surgical Sciences, Nephrology and Dialysis Unit, University Vanvitelli, Naples, Italy; [10]Kolling Institute of Medical Research, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia; [11]Department of Renal Medicine, UCL Medical School, London, United Kingdom; [12]Concord Repatriation General Hospital, Sydney, NSW, Australia; [13]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Background: The association between early changes in albuminuria and kidney and CV events is primarily based on trials of renin-angiotensin system blockade. It is unclear whether this association is similar with sodium-glucose cotransporter 2 inhibitors.

Methods: In this post-hoc analysis of the CREDENCE trial in patients with type 2 diabetes and chronic kidney disease, we assessed the effect of CANA versus placebo on albuminuria at week 26, and the association of early changes in urinary albumin:creatinine ratio (UACR) for the first 26 weeks with kidney and CV outcomes using multivariable Cox regression. Kidney and CV outcomes were defined as (1) end-stage kidney disease, doubling of serum creatinine or death due to kidney disease, (2) major adverse cardiovascular events (MACE) and (3) hospitalization for heart failure (HHF) or CV death.

Results: This analysis included 3836 participants (87.2%) with complete data for early changes in UACR. CANA lowered UACR by 31% (95%CI 27–36%) at week 26 and increased the likelihood of achieving a 30% UACR reduction (OR 2.69, 95%CI 2.35–3.07). We observed log-linear associations of early changes in UACR during 26 weeks with kidney and CV outcomes (all p trend <0.001; Table). Each 30% UACR reduction was independently associated with a lower hazard for clinical outcomes, overall and in each treatment arm (all p <0.001).

Conclusions: In people with type 2 diabetes and CKD, canagliflozin results in early and sustained reductions in albuminuria, which was independently associated with long-term kidney and cardiovascular outcomes.

Table: Adjusted HRs (95% CIs) of early changes in UACR at week 26 for kidney and CV outcomes

		Kidney outcome	MACE	HHF or CV death	HHF
UACR change at week 26	<-30%	0.55 (0.24–0.52)	0.81 (0.56–1.16)	0.72 (0.49–1.07)	0.65 (0.38–1.13)
	-30% to <0%	0.70 (0.48–1.02)	0.92 (0.63–1.36)	0.79 (0.52–1.21)	0.89 (0.51–1.58)
	0% to <30%	1.00 (reference)	1.00 (reference)	1.00 (reference)	1.00 (reference)
	≥30%	1.76 (1.26–2.47)	1.33 (0.94–1.90)	1.55 (1.08–2.24)	1.78 (1.08–2.84)
Each 30% reduction in UACR		0.71 (0.67–0.76)	0.92 (0.88–0.96)	0.86 (0.81–0.90)	0.82 (0.76–0.88)

PO1007

Effects of Canagliflozin on Major Adverse Cardiovascular Events in Patients with Different Baseline Levels of Type 2 Diabetes Disease Severity: Results from the CANVAS Program

Tamara K. Young,[1] Jingwei Li,[1] Amy Kang,[1] Hiddo J. L Heerspink,[1,2] Carinna Hockham,[1] Clare G. Arnott,[1] Brendon L. Neuen,[1] Sophia Zoungas,[4] Kenneth W. Mahaffey,[1] Vlado Perkovic,[1] Dick de Zeeuw,[2] Greg Fulcher,[3] Bruce Neal,[1] Meg J. Jardine.[1]
[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]Rijksuniversiteit Groningen, Groningen, Netherlands; [3]University of Sydney - Camperdown and Darlington Campus Burkitt-Ford Library, University of Sydney - AU, Sydney, NSW, Australia; [4]Monash University, Clayton, VIC, Australia.

Background: Patients with type 2 diabetes mellitus (T2DM) included in trials of sodium-glucose cotransporter 2 inhibitors are heterogeneous in terms of disease severity. We assessed the effects of canagliflozin compared to placebo on cardiovascular and renal outcomes in the CANVAS program according to severity of T2DM as indicated by intensity of treatment, duration of diabetes and glycaemic control.

Methods: We compared effects on major adverse cardiovascular events ([MACE], defined as cardiovascular death, non-fatal myocardial infarction or non-fatal stroke) according to three indicators of T2DM severity at study baseline: number of glucose lowering treatments or insulin therapy (0-1, 2, 3+, insulin), duration of diabetes (<10, 10-16, >16 years) and HbA1c (<7.0, 7.0-7.5, 7.5-8.0, 8.0-8.5, 8.5-9, >9.0%). We also assessed effects on other pre-specified cardiovascular outcomes, and an adjudicated composite of end-stage kidney disease, renal death or sustained 40% decline in estimated glomerular filtration rate. We assessed for constancy of hazard ratios across subgroups by fitting an interaction term that tested for linear trend.

Results: Of 10,142 participants in the CANVAS Program, 1011 experienced a MACE during a mean follow-up of 3.6 years. The effect of canagliflozin on MACE in the overall population (HR 0.86, 95 % CI 0.75-0.97) was consistent irrespective of the number of glucose lowering treatments (p=0.509), duration of diabetes (p=0.174) and baseline HbA1c (p =0.314). Effects were also consistent across different levels of T2DM disease severity for all other outcomes studied.

Conclusions: The proportional risk reductions achieved with canagliflozin were comparable regardless of diabetes duration, number of therapies or HbA1C at baseline.

Funding: Commercial Support - Janssen

Kidney Effects of Empagliflozin in People with Type 1 Diabetes

David Cherney,[1] Petter Bjornstad,[2] Bruce A. Perkins,[3] Julio Rosenstock,[4] Dietmar Neubacher,[5] Jyothis T. George,[5] Jan Marquard,[6] Nima Soleymanlou.[7]
[1]University Health Network, University of Toronto, Toronto, ON, Canada; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada; [4]Dallas Diabetes Research Center at Medical City, Dallas, TX; [5]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [6]Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT; [7]Boehringer Ingelheim Canada Ltd/ Ltée, Burlington, ON, Canada.

Background: Empagliflozin lowers the risk of cardiovascular and kidney events in type 2 diabetes (T2D). In the empagliflozin in type 1 diabetes (T1D) clinical program (EASE), glycemic control, weight and blood pressure improved with empagliflozin as adjunct to insulin treatment, though diabetic ketoacidosis risk was higher with use of the 10 and 25mg doses vs the 2.5mg dose. The kidney effects of empagliflozin in T1D remain incompletely understood.

Methods: Here we report changes in kidney parameters in phase 3 placebo-controlled trials EASE-2 (empagliflozin 10/25mg; 52-week; n=730) and EASE-3 (empagliflozin 2.5/10/25mg; 26-week; n=975).

Results: Mean±SD baseline estimated glomerular filtration rate (eGFR in mL/min/1.73 m²) in EASE-2/EASE-3 was 97.3±18.2 and 98.5±18.2 and median (interquartile range) baseline urinary albumin-to-creatinine ratio (UACR in mg/g of creatinine) was 6.2 (2.7,14.1) in both studies. After 26 weeks of treatment in EASE-3, mean placebo-corrected eGFR changes with empagliflozin 2.5mg (n=230), 10mg (n=228) and 25mg (n=234) were -0.14 (p=0.87), -2.57 (p=0.004) and −3.56 (p<0.0001), respectively. Mean placebo-corrected eGFR changes with empagliflozin 10mg and 25mg were −2.09 (p=0.02; n=226) and −2.60 (p=0.002; n=228) after 52 weeks in EASE-2, respectively. Changes in eGFR 3 weeks after end of therapy (FU) returned to above baseline levels. In participants with UACR <30mg/g, no significant changes in urinary albumin-to-creatinine ratio (UACR) were observed. In a pooled analysis (EASE-2 + EASE-3), in participants with baseline UACR ≥30 mg/g, UACR decreased by 16% (p=0.27) and 30% (p=0.02) with empagliflozin 10mg (n=71) and 25mg (n=77) vs placebo (n=65), respectively, at 26 weeks. In EASE-3, in people with baseline UACR ≥30 mg/g, treatment with empagliflozin 2.5mg (n=36) for 26 weeks did not significantly attenuate UACR vs placebo (n=34). Hematocrit and serum albumin increased in EASE-2 and EASE-3 with empagliflozin treatment while serum uric acid decreased; changes in these parameters returned to near baseline values at the FU visit after 26 and 52 weeks of treatment.

Conclusions: In conclusion, empagliflozin doses >2.5 mg/day as adjunct therapy to insulin in T1D resulted in short-term changes in kidney markers comparable to changes observed with SGLT2 inhibitor use in T2D.

Funding: Commercial Support - Boehringer Ingelheim & Eli Lilly and Company Diabetes Alliance

PO1009

Empagliflozin Is Associated with Increased Plasma Lipid Metabolites in Type 1 Diabetes

Hongyan Liu,[2,1] Leif E. Lovblom,[3,1] Yuliya Lytvyn,[2,1] Hongping Ye,[4] Daniel Montemayor,[4] Daniel Scarr,[3,1] Bruce A. Perkins,[3,5] Kumar Sharma,[4] David Cherney.[2,1]
[1]University of Toronto, Toronto, ON, Canada; [2]Division of Nephrology, Department of Medicine, University Health Network, Toronto, ON, Canada; [3]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [4]Center for Renal Precise Medicine, Division of Nephrology, Department of Medicine, University of Texas Health San Antonio, San Antonio, TX; [5]Division of Endocrinology and Metabolism, Department of Medicine, University of Toronto, Toronto, ON, Canada.

Background: Sodium glucose cotransporter-2 (SGLT2) inhibition reduces the risk of cardiorenal complications in people with diabetes, possibly by altering energy substrate pathways. It has been hypothesized that SGLT2 inhibitors improve mitochondrial efficiency and may induce a shift towards increased lipid utilization as an energy substrate. In this exploratory, *post-hoc* analysis, we investigated the effects of SGLT2 inhibition on plasma lipid and tricarboxylic acid (TCA) cycle metabolites in patients with type 1 diabetes (T1D).

Methods: In the ATIRMA trial (NCT01392560), patients with T1D were assessed under clamped euglycemia and hyperglycemia at baseline and after 8 weeks of empagliflozin treatment. Plasma samples from the ATIRMA trial were analyzed for lipid and TCA cycle metabolites using the ZipChip method.

Results: Of the 15 lipid metabolites, 5 increased during clamped euglycemia in response to empagliflozin (Figure) while 1 increased after treatment during clamped hyperglycemia. Of the 3 TCA cycle metabolites, 2 increased during clamped euglycemia in response to empagliflozin. None of the metabolites decreased significantly after empagliflozin treatment.

Conclusions: In patients with T1D, SGLT2 inhibition increased plasma TCA cycle metabolite levels, suggesting an impact on mitochondrial function. Lipid metabolite levels were also increased after SGLT2 inhibition, suggesting a possible increase in beta oxidation. Further work is needed to determine if these changes contribute to cardiorenal protection with SGLT2 inhibitors.

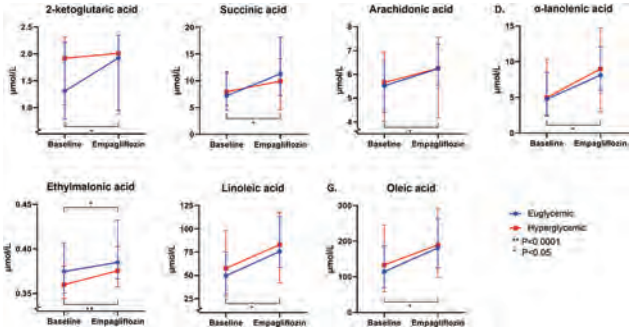

Figure Plasma concentrations of (A.) 2-ketoglutaric acid, (B.) succinic acid, (C.) arachidonic acid, (D.) α-lanolenic acid, (E.) ethylmalonic acid, (F.) linoleic acid, and (G.) oleic acid during clamped euglycemia and hyperglycemia at baseline and post 8 weeks treatment with empagliflozin. Data shown are medians ± Q_1/Q3. Succinic acid levels significantly increased after treatment during clamped euglycemia.

PO1010

Effect of Dapagliflozin on Risk for Fast Decline in eGFR: Analysis from DECLARE-TIMI 58 Trial

Ofri Mosenzon,[1] Stephen Wiviott,[6] Hiddo J. L Heerspink,[10] Jamie P. Dwyer,[8] Avivit Cahn,[1] Erica L. Goodrich,[6] Aliza Rozenberg,[1] Ilan Yanuv,[1] John P. Wilding,[5] Lawrence A. Leiter,[2] Deepak L. Bhatt,[6] Darren K. Mcguire,[7] Ronald C. Ma,[3] Tsvetalina Tankova,[9] Martin Fredriksson,[4] Ingrid A. Gause-Nilsson,[4] Anna Maria Langkilde,[4] Marc S. Sabatine,[6] Itamar Raz.[1]
[1]Hadassah Medical Center, Jerusalem, Israel; [2]St. Michael's Hospital and University of Toronto, Toronto, ON, Canada; [3]Dept of Medicine and Therapeutics The Chinese University of Hong Kong, Hong Kong, Hong Kong; [4]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [5]Department of Cardiovascular and Metabolic Medicine, University of Liverpool, UK, Liverpool, United Kingdom; [6]Brigham & Women's Hospital, Boston, MA; [7]University of Texas Southwestern Medical Center, Dalas, TX; [8]Vanderbilt University Medical Center, Nashville, TN, USA, Nashville, TN; [9]Department of Endocrinology, Medical University, Sofia, Bulgaria, Sofia, Bulgaria; [10]University Medical Center Groningen, Groningen, Netherlands.

Background: SGLT2 inhibitors may lead to short term decrease in eGFR with later stabilization and long-term reduction in risk for end stage kidney disease. Fast decline (FD) in eGFR can be defined as reduction of ≥3 ml/min/1.73m²/year and is associated with poor long-term renal prognosis. In this post hoc analysis we studied the effect of dapagliflozin (dapa) on risk for FD in the DECLARE-TIMI 58 trial.

Methods: In DECLARE-TIMI 58, 17,160 patients with T2D and established or increased risk for CVD, with mean baseline eGFR of 85.2 ml/min/1.73m², were randomized to dapa vs. placebo and followed for median of 4.2 years. The risk for FD was compared between treatment arms.

Results: In the time frame of 0.5 years (after stabilization) to 4 years, the proportion of patients with FD was reduced with dapa vs. placebo (26.8% vs. 37.1%, respectively, p<0.0001) and in all subgroups assessed (Figure). The mean (SD) reduction in eGFR per year was 6.3 (3.7) vs. 0.0 (2.5) ml/min/1.73m²/year in FD (N=4,788) vs. non-FD (N=10,224) patients. In patients that had FD, mean (SD) reduction in eGFR was -5.9 (3.2) vs. -6.6 (4.1) ml/min/1.73m²/year in dapa vs. placebo arm, while in patients that did not have fast decline it was 0.2 (2.5) vs. -0.2(2.5) ml/min/1.73m²/year, respectively. The proportion of patients with FD during entire study period (i.e. 0-4 years) was also reduced with dapa vs. placebo (33.6% vs. 37.0%, respectively, p<0.0001).

Conclusions: Dapa reduced the risk for FD in eGFR in a broad population of patients with T2D and relatively preserved renal function, irrespective of patients' baseline characteristics.

Comparative Effectiveness of SGLT2 Inhibitors, GLP1 Receptor Agonists, DPP4 Inhibitors, and Sulfonylureas on Risk of Kidney Outcomes: Emulation of a Target Trial Using Healthcare Databases

Yan Xie,[1] Benjamin C. Bowe,[1] Andrew K. Gibson,[1] Janet B. McGill,[2] Yan Yan,[1] Geetha S. Maddukuri,[3] Ziyad Al-Aly.[1] *[1]Clinical Epidemiology Center, VA Saint Louis healthcare system, St. Louis, MO; [2]Department of Medicine, Washington University School of Medicine, St. Louis, MO; [3]Nephrology Section, Medicine Service, VA Saint Louis Health Care System, St. Louis, MO.*

Background: The comparative effectiveness of SGLT2i, GLP1, DPP4, and sulfonylureas on risk of kidney outcomes among people with type 2 diabetes mellitus is not known.

Methods: We built a cohort of 216,558 US Veterans initiated on SGLT2i, GLP1, DPP4, or sulfonylureas and followed them for up to 3 years. The outcome was defined as the risk of the major adverse kidney events (MAKE) of estimated glomerular filtration rate (eGFR) decline >50%, end stage kidney disease, or all-cause mortality. Risks were estimated using survival models adjusted for pre-defined covariates as well as covariates identified by a high-dimensional variable selection algorithm through application of generalized propensity scores.

Results: During follow up, there were 14612 (6.75%) MAKEs. Adjusted KM curve for risk of MAKE across treatment arms are presented. Compared to those treated with sulfonylurea, treatment with SGLT2i, GLP1, and DPP4 was associated with lower risk of MAKE (HR=0.68 (0.63-0.74), HR=0.72 (0.67-0.77), and HR=0.90 (0.86-0.95), respectively). Both SGLT2i and GLP1 had lower risk of MAKE than DPP4 (HR=0.76 (0.70-0.82), and HR=0.79 (0.74-0.85), respectively). The associations were consistent regardless of metformin use at baseline. Analyses by eGFR category suggested that compared to the sulfonylureas arm, those in the SGLT2i and GLP1 arms exhibited lower risk of MAKE in all eGFR categories. Compared to DPP4, both SGLT2i and GLP1 exhibited reduced risk of MAKE in eGFR >90 to ≥60, <60 to ≥45, and <45 ml/min/1.73 m².

Conclusions: Among patients with diabetes mellitus type 2, treatment with SGLT2i or GLP1 compared to DPP4 or sulfonylureas was associated with lower risk of adverse kidney outcomes.

PO1012

Renal Outcomes and All-Cause Death Associated with SGLT-2 Inhibitor vs. Other Glucose-Lowering Drugs (CVD-REAL 3 Korea)

Eun Sil Koh,[1] Kyungdo Han,[3] Hyewon Lee,[2] You-Seon Nam,[2] Eric T. Wittbrodt,[4] Peter Fenici,[5] Mikhail Kosiborod,[6] Hiddo J. L Heerspink,[7] Soon-Jib Yoo,[8] Hyuk-Sang Kwon.[1] *[1]The Catholic University of Korea Yeouido Saint Mary's Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea; [2]AstraZeneca Korea Co Ltd, Seoul, Republic of Korea; [3]Soongsil University Department of Statistics and Actuarial Science, Dongjak-gu, Seoul, Republic of Korea; [4]AstraZeneca, Gaithersburg, MD; [5]AstraZeneca, Cambridge, United Kingdom; [6]Saint Luke's Mid America Heart Institute, Kansas City, MO; [7]University Medical Center Groningen, Groningen, Netherlands; [8]The Catholic University of Korea Bucheon Saint Mary's Hospital, Bucheon, Gyeonggi-do, Republic of Korea.*

Background: Real-world evidence from routine clinical practice elucidating the effects of sodium-glucose cotransporter-2 inhibitors (SGLT-2i) on renal outcomes and mortality in patients with type 2 diabetes (T2D) is limited.

Methods: Using data from the Korean National Health Insurance Service database from January 2014 to December 2017, a total of 701,674 patients were identified with T2D. We divided these patients into new-users of SGLT-2i and new-users of other glucose-lowering drugs (oGLD). Using propensity scores, patients in the two groups were matched 1:1. We examined for the risk of end-stage renal disease (ESRD) and all-cause death.

Results: There were 45,016 patients in each group, and baseline characteristics were well-balanced between groups: mean age 58.1 ± 10.6 years; mean estimated glomerular filtration rate (eGFR) 89.2 ± 27.4 ml/min/1.73m²; 8% of patients had proteinuria. We identified 167 incident ESRD and 1,070 all-cause deaths during follow-up. Use of SGLT-2i *versus* oGLD was associated with a lower risk of ESRD (HR: 0.47; 95% confidence interval [CI]: 0.34 to 0.65) and all-cause death (HR: 0.82; 95% CI: 0.73 to 0.93). In a subgroup analysis by eGFR, initiation of SGLT2i vs oGLD was associated with lower risk of progression to ESRD among patients with eGFR 60-90 and <60 ml/min/1.73m² and lower risk of all-cause death associated with SGLT-2i *versus* oGLD was observed across the entire range of renal function.

Conclusions: In this large nationwide study of Korean patients with T2D, initiation of SGLT-2i *vs* oGLD was associated with lower risk of ESRD and all-cause death.

PO1013

Cardiovascular Outcomes with SGLT-2 Inhibitors vs. GLP-1 Receptor Agonists in Patients with Type 2 Diabetes and CKD: A Systematic Review and Network Meta-Analysis

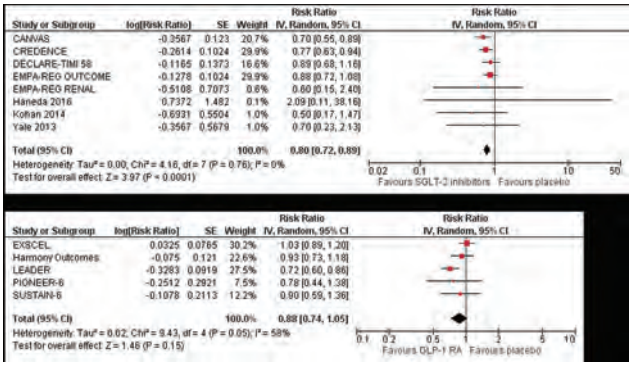
Takayuki Yamada,[1,3] Abhinav Bhalla,[1] Mako Wakabayashi,[2] Hirotaka Miyashita,[1] Hiroki Ueyama,[1] Tomohiro Fujisaki,[1] Takahisa Mikami,[1] Kouichi Tamura.[3] *[1]Mount Sinai Beth Israel Hospital, New York, NY; [2]Nihon Ika Daigaku Fuzoku Byoin, Bunkyo-ku, Japan; [3]Yokohama Shiritsu Daigaku Fuzoku Byoin, Yokohama, Japan.*

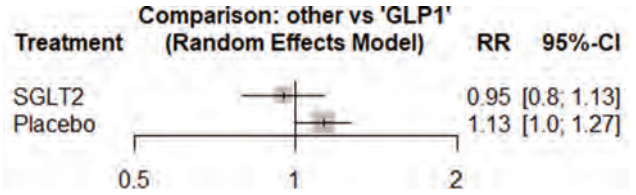
Background: Type 2 diabetes mellitus (DM) and chronic kidney disease (CKD) increase the risk of cardiovascular disease. Sodium-glucose cotransporter-2 (SGLT-2) inhibitors and glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are known to reduce cardiovascular disease. However, no study compared the effect of SGLT-2 inhibitors on cardiovascular diseases with that of GLP-1 RAs in CKD patients.

Methods: We performed a systematic literature search up to March 2020. We selected randomized control trials. First, we performed meta-analysis to compare SGLT-2 inhibitors vs placebo and GLP-1 RA vs placebo. Next, we performed a network meta-analysis to compare SGLT-2 inhibitors with GLP-1 RA indirectly. Risk ratios (RRs) with corresponding 95% confidence interval (CI) were synthesized.

Results: Total thirteen studies were selected. SGLT-2 inhibitors led to a risk reduction in MACE (RR [95% CI]; 0.80 [0.72-0.89], p <0.0001). On the other hand, GLP-1 RAs did not show significant difference with high heterogeneity (0.88 [0.74-1.04], p =0.15, I^2=58%) (Figure 1). The network meta-analysis did not show significant difference between SGLT-2 inhibitors and GLP-1 RA (0.90 [0.77-1.08]) (Figure 2).

Conclusions: In patients with type 2 DM and CKD, SGLT-2 inhibitors were associated with decreased risk of MACE, but GLP-1 RA did not. Network meta-analysis did not reveal significant difference between SGLT-2 inhibitors and GLP-1 RA.





PO1014

Comparative Effectiveness of SGLT2 Inhibitors vs. Other Antihyperglycemics on Risk of Kidney Outcomes: A Cohort Study

Yan Xie,[1] Benjamin C. Bowe,[1] Andrew K. Gibson,[1] Janet B. McGill,[2] Yan Yan,[1] Geetha S. Maddukuri,[3] Ziyad Al-Aly.[1] *[1]Clinical Epidemiology Center, VA Saint Louis healthcare system, St. Louis, MO; [2]Department of Medicine, Washington University School of Medicine, St. Louis, MO; [3]Nephrology Section, Medicine Service, VA Saint Louis Health Care System, St. Louis, MO.*

Background: In randomized controlled trials, sodium-glucose co-transporter-2 inhibitor (SGLT2i) reduced the risk of adverse kidney outcomes. We aimed to examine the comparative effectiveness of SGLT2i and other antihyperglycemics on the risk of major adverse kidney events (MAKE) of estimated glomerular filtration rate (eGFR) decline >50%, end-stage kidney disease, or all-cause mortality.

Methods: We built a cohort of 379,191 new users of SGLT2i or other antihyperglycemics. Risk of MAKE during follow up served as the primary outcome. Pre-defined covariates and covariates identified by a high-dimensional variable selection algorithm were used to build a propensity score. Linear mixed models were used to estimate the longitudinal change of eGFR and body mass index (BMI) and survival analyses were used to estimate the risk difference of MAKE.

Results: Compared to other antihyperglycemics, SGLT2i use was associated with 0.98 (0.48, 1.53) ml/min/1.73m^2 less annual reduction in eGFR, 0.24 (0.17, 0.32) kg/m^2 more annual decrease in BMI, and reduced risk of MAKE (HR=0.68 (0.64-0.73)). SGLT2i use was associated with reduced risk of MAKE in eGFR≥90, ≥60 to <90, ≥45 to <60, and ≥30 to <45 ml/min/1.73m^2 and in participants with and without albuminuria. The association was evident in per-protocol analyses which required continuation of the antihyperglycemic medication during follow up (HR=0.64 (0.60-0.70)), and in analyses requiring concurrent use of metformin in at least the first 90 days of follow up (HR=0.63 (0.57-0.69)).

Conclusions: Among people with diabetes mellitus type 2, SGLT2i use was associated with eGFR preservation, greater decline in BMI, and reduced risk of MAKE compared to other antihyperglycemics.

PO1015

Correlation of Anti-Albuminuric Effect by SGLT2 Inhibitor with Tubulointerstitial Impairment

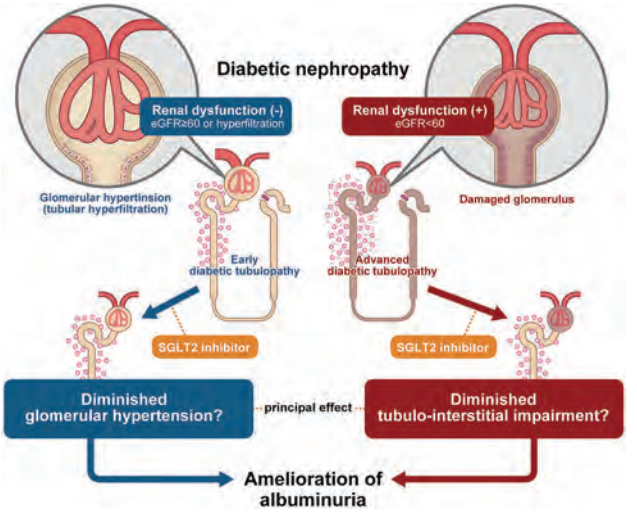
Saeko Sato, Kaori Takayanagi, Taisuke Shimizu, Takatsugu Iwashita, Hiroaki Hara, Tomonari Ogawa, Hajime Hasegawa. *Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Background: This study aimed to examine the anti-albuminuric effect of SGLT2 inhibitor (SGLT2i) in patients with or without renal dysfunction, and to investigate factors associated with the effect of SGLT2i.

Methods: Patients with diabetic nephropathy were enrolled and received 50 mg of Iplagliflozin. Their blood and urine were sampled at 0 M, 1 M and 12 M. Patients with renal dysfunction (DF; eGFR<60) and with normo-renal function (NF; eGFR≥60) were separately analyzed.

Results: In all patients (n=22), urine albumin-to-Cr ratio (ACR) was reduced at 1M and maintained until 12M (median: 236.2 at 0M, 115.0 mg/gCr at 1M), however, eGFR was not changed. In DF, ACR was also decreased (median: 311.8 at 0M vs 107.0 mg/gCr at 1M, n=10). In NF, ACR was similarly decreased at 1M. Next, the patients in DF and NF were divided by %ACR reduction (high responder: HR, low responder: LR). In NF, only %change of eGFR at 12M was significantly different (-6.5±8.6% in HR vs +5.0±7.6% in LR). In DF, MCP-1 at 1M (-33.0±7.3% in HR vs +45.9±33.1% in LR) and %change of NAG at 12M showed significant difference (-33.6±13.5% in HR vs +6.8±28.3% in LR), however, there was no difference in eGFR. Univariate analysis showed significant correlation between %ACR reduction and %MCP-1 at 1M (R=0.734, p=0.016) or %NAG at 12M (R=0.714, p=0.047) in DF whereas no significant correlation was observed in NF. Multivariate analysis confirmed the results.

Conclusions: In patients with normo-renal function, restoring glomerular hyperfiltration might be important for anti-albuminuric effect of SGLT2i. However, in patients with renal dysfunction, the effect of SGLT2i seemed to be associated with reduced tubulointerstitial damages.



Anti-albuminuric effect of SGLT2 inhibitor in patients with or without renal dysfunction

PO1016

SGLT2i Prescribing for Type 2 Diabetes and Comorbid Conditions Among 24 US Healthcare Organizations

Nikita Stempniewicz,[1] Cori Rattelman,[1] John W. Kennedy,[1] Elizabeth Ciemins,[1] John K. Cuddeback,[1] Yingying Sang,[2,3] Josef Coresh,[2,3] Morgan Grams,[2,3] Jung-Im Shin.[2,3] *[1]AMGA (American Medical Group Association), Alexandria, VA; [2]Johns Hopkins University, Baltimore, MD; [3]Welch Center for Prevention, Epidemiology, & Clinical Research, Baltimore, MD.*

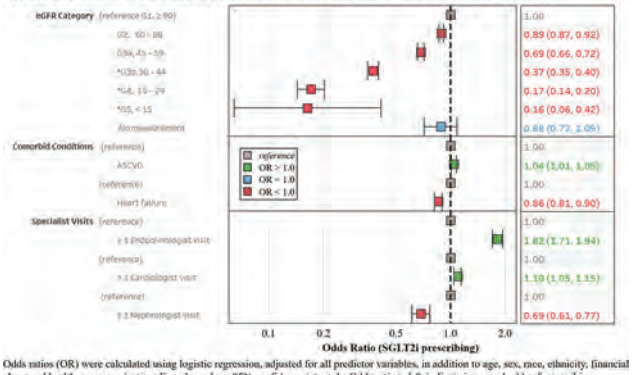
Background: Sodium glucose cotransporter-2 inhibitors (SGLT2i) are among several glucose-lowering therapies available. Clinical guidelines for type 2 diabetes recommend use of SGLT2i for people with ASCVD, heart failure (HF), or CKD when eGFR is adequate, to control glycemia, reduce cardiovascular risk, and slow progression of kidney disease.

Methods: Using an EHR-derived dataset from 24 AMGA member health care organizations (HCOs), we identified 248,469 patients with type 2 diabetes aged 18–85 who had ≥1 ambulatory encounter with a primary care provider and ≥1 prescription for a glucose-lowering medication other than metformin and insulin in the past year (9/2018–8/2019). Patients with end stage kidney disease or hospice care were excluded. We explored the proportion of patients with an SGLT2i prescribed in the past year, and used logistic regression to describe differences by eGFR category, comorbid conditions, and specialist visits, adjusted for all predictor variables, age, sex, race, ethnicity, financial class, and HCO.

Results: Across HCOs, median proportion of patients with an SGLT2i prescribed was 22% (range, 12–39%). Prescribing decreased with eGFR category from G1 to G4 (Figure 1). SGLT2i prescribing was lower for patients with HF and those who saw a nephrologist, marginally higher for patients with ASCVD and those who saw a cardiologist, and substantially higher for patients who saw an endocrinologist.

Conclusions: There was significant variation in SGLT2i prescribing across HCOs. While guidelines emphasize use of SGLT2is among patients with ASCVD, HF, or CKD, our findings suggest these recommendations have not been widely adopted in clinical practice. Endocrinologists may play an important role in prescribing new glucose-lowering medications, while nephrologists may be hesitant to prescribe medications for type 2 diabetes.

Figure 1: Association of eGFR category, comorbid conditions, and specialist visits with SGLT2i prescribing



Odds ratios (OR) were calculated using logistic regression, adjusted for all predictor variables, in addition to age, sex, race, ethnicity, financial class, and health care organization. Error bars show 95% confidence intervals. Odds ratio > 1.0 indicate increased odds of prescribing. eGFR was calculated from serum creatinine measurements using the CKD-EPI equation, reported in mL/min/1.73m². Reference groups for specialist visits are patients with no visits with the respective specialist.
* Indications for SGLT2i initiation and continued use vary by individual medication within the class for eGFR G3b, and are contraindicated for eGFR G4+.

PO1017

Dulaglutide and Kidney Function-Related Outcomes in Type 2 Diabetes: Post Hoc Analysis from the REWIND Trial

Jonathan E. Shaw,[1] Fady T. Botros,[2] Raleigh Malik,[2] Charles M. Atisso,[2] Hertzel C. Gerstein.[3,4] *[1]Baker Heart and Diabetes Institute, Melbourne, VIC, Australia; [2]Eli Lilly and Company, Indianapolis, IN; [3]Population Health Research Institute, Hamilton, ON, Canada; [4]Hamilton Health Sciences and McMaster University, Hamilton, ON, Canada.*

Background: Over the median follow-up of 5.4 years in the REWIND trial, which included participants with type 2 diabetes (T2D) and multiple cardiovascular (CV) risk factors, dulaglutide (DU) use was associated with a reduction in composite renal outcomes, defined as the first occurrence of new macroalbuminuria, sustained decline in estimated glomerular filtration rate (eGFR) of ≥30% (using the modification of diet in renal disease [MDRD] equation), or chronic renal replacement therapy. This posthoc analysis evaluated the potential effects of dulaglutide on renal outcomes using an alternative endpoint definition that is commonly used in renal outcomes studies; defined as the composite endpoint of sustained eGFR decline ≥40% (using the chronic kidney disease-epidemiology collaboration [CKD-EPI] equation), end-stage renal disease (ESRD), or all-cause death.

Methods: REWIND participants were randomized (1:1) to DU 1.5 mg once weekly or placebo. Cox proportional hazards model for time-to-first event analysis was used to determine the risk of renal outcomes. Subgroup analyses were conducted by baseline eGFR and albuminuria status.

Results: At baseline, treatment groups had similar eGFR values (mean±SD: DU=77.6 ± 19.4 mL/min/1.73 m²; placebo=77.1 ± 19.6 mL/min/1.73 m²). The incidence rate of the composite endpoint was significantly lower for the DU group compared with placebo. This effect was consistent regardless of baseline eGFR or albuminuria status (Table).

Conclusions: Treatment with DU 1.5 mg was associated with a 17% risk reduction in the composite renal outcome, suggesting potential delay in progression of diabetic kidney disease in patients with T2D at CV risk.

Funding: Commercial Support - Eli Lilly and Company

Table: Kidney function-related outcomes with dulaglutide 1.5 mg treatment

Endpoint	Dulaglutide N=4949 n (%) or n/N (%)	Placebo N=4952 n (%) or n/N (%)	Hazard Ratio (95% CI)	P value
Composite endpoint				
Sustained eGFR[a] decline ≥40%, ESRD[b], all-cause death	676 (13.7%)	800 (16.2%)	0.83 (0.75, 0.92)	<0.001
Composite endpoint components				
Sustained eGFR[a] decline ≥40%	156 (3.2%)	214 (4.3%)	0.72 (0.58, 0.88)	0.002
ESRD[b]	31 (0.6%)	43 (0.9%)	0.78 (0.49, 1.25)	0.308
Renal replacement therapy	16 (0.3%)	21 (0.4%)	0.85 (0.44, 1.65)	0.626
Sustained eGFR<15[c] mL/min/1.73m²	21 (0.4%)	32 (0.6%)	0.69 (0.39, 1.21)	0.191
All-cause death	536 (10.8%)	592 (12.0%)	0.90 (0.80, 1.01)	0.072
Subgroup analysis for the composite endpoint				
eGFR ≥60 mL/min/1.73 m²	438/3904 (11.2%)	534/3870 (13.8%)	0.80 (0.70, 0.90)	Interaction P=0.205
eGFR <60 mL/min/1.73 m²	225/944 (23.8%)	257/988 (26.0%)	0.92 (0.77, 1.10)	
UACR <30 mg/g	276/2917 (9.5%)	321/2863 (11.2%)	0.84 (0.72, 0.99)	Interaction P=0.893
UACR ≥30 mg/g	364/1707 (21.3%)	428/1760 (24.3%)	0.86 (0.74, 0.98)	

[a]eGFR was calculated using CKD-EPI equation; Sustained eGFR decline ≥40% is based on two consecutive eGFR values. [b]ESRD is defined as renal replacement therapy (chronic dialysis or renal transplant) or sustained eGFR<15. [c]Sustained eGFR<15 defined as two consecutive eGFR values <15 mL/min/1.73 m²; eGFR units: mL/min/1.73 m². ESRD=end stage renal disease; N=total number of patients, n=number of patients with events; UACR=urinary albumin/creatinine ratio.

PO1018

Efficacy and Safety of Cotadutide, a Dual GLP-1 and Glucagon Receptor Agonist, for Patients with Type 2 Diabetes Mellitus and CKD

Victoria E. Parker,[1] Thuong Hoang,[1] Heike Schlichthaar,[2] Yi-Ting Chang,[3] Marcella Petrone,[1] Lars Hansen,[3] Philip D. Ambery,[4] Hiddo J. L Heerspink,[5] Rory Mccrimmon,[6] Lutz Jermutus.[1] *[1]AstraZeneca, Cambridge, United Kingdom; [2]Study Center, SMO.MD GmbH, Magdeburg, Germany; [3]AstraZeneca, Gaithersburg, MD; [4]AstraZeneca, Gothenburg, Sweden; [5]University Medical Center, Groningen, Netherlands; [6]School of Medicine, University of Dundee, Ninewells Hospital, Dundee, United Kingdom.*

Background: Cotadutide is in development for nonalcoholic steatohepatitis and type-2 diabetes mellitus (T2DM). GLP-1 analogues have been shown to delay the development of macroalbuminuria in patients (pts) with T2DM. The glycemic and renal effects of cotadutide were assessed in a phase 2a, randomized, controlled trial.

Methods: The trial enrolled 41 pts with T2DM (HbA1c: ≥6.5—≤10.5%) and chronic kidney disease (CKD) stage G3 (estimated glomerular filtration rate [eGFR]: ≥30–<60 mL/min/1.73m²), on insulin and/or oral therapy, with a BMI of 25—45 kg/m². Pts were randomized to once-daily subcutaneous cotadutide (n=21), titrated up to 300 μg, or placebo (PBO; n=20) for 32 days. Endpoints included glucose response via mixed meal tolerance test (MMTT), HbA1c, body weight (BW), eGFR, urinary albumin creatinine ratio (UACR), and C-peptide levels. The trial was powered based on a 2-sided alpha of 0.1.

Results: Cotadutide significantly reduced MMTT glucose AUC vs baseline (-26.7%, 90% CI: -34.6 to -18.8) and vs PBO (3.7%, 90% CI: -3.8 to 11.2; $P<0.001$), with a 35.2% reduction in insulin dose ($P=0.012$). Cotadutide significantly reduced BW (-3.7%) and HbA1c (-0.7%; both $P<0.001$). After 32 days of cotadutide treatment, no significant changes were observed in eGFR or blood pressure. Fasting C-peptide levels in the cotadutide group increased significantly vs PBO (LS mean change: 0.88 μg/L, 90% CI: 0.57 to 1.19, $P<0.001$). In pts with baseline micro- or macroalbuminuria (n=18), UACR was reduced by 50.6% vs PBO ($P=0.0504$). Serious adverse events (AEs) were balanced between treatment arms; treatment-related AEs were more frequent with cotadutide (71%) vs PBO (35%). The most common AEs were nausea (cotadutide, 33%; PBO, 20%) and vomiting (cotadutide, 24%; PBO, 5%). Pulse rate was significantly increased (11 beats per minute; $P<0.001$) by day 32.

Conclusions: In pts with T2DM and CKD, cotadutide improved overall glycemic control and glucose responses to an MMTT with acceptable tolerability. Improvements in albuminuria suggest that cotadutide may be beneficial in this population to slow long-term progression of CKD. Further exploration of this effect is warranted.

PO1019

Dulaglutide Treatment in Patients with Type 2 Diabetes and Moderate-to-Severe CKD Improves Kidney Fibrosis Biomarker Levels

Katherine R. Tuttle,[1,2] Jonathan M. Wilson,[3] Yanzhu Lin,[3] Hui-Rong Qian,[3] Federica Genovese,[4] Morten A. Karsdal,[4] Kevin L. Duffin,[3] Fady T. Botros.[3] *[1]Providence Healthcare, Spokane, WA; [2]Institute of Translational Health Sciences, University of Washington, Seattle, WA; [3]Eli Lilly and Company, Indianapolis, IN; [4]Nordic Bioscience, Herlev, Denmark.*

Background: The AWARD-7 clinical trial demonstrated that once-weekly dulaglutide slowed the decline in estimated glomerular filtration rate (eGFR) and decreased urine albumin/creatinine ratio compared to insulin glargine in patients with type 2 diabetes and moderate-to-severe chronic kidney disease (CKD). Lower levels of urinary C3M (a marker for type III collagen degradation) and increased level of serum PRO-C6 (a marker for type VI collagen formation) are reported to correlate with CKD progression and lower eGFR.

Methods: This exploratory analysis evaluated changes in urinary C3M and serum PRO-C6 with dulaglutide 1.5 mg treatment as compared to insulin glargine in AWARD-7 in overall study population and the macroalbuminuria subgroup.

Results: At baseline, the macroalbuminuria subgroup had numerically higher serum PRO-C6 levels and lower urinary C3M levels than the total population for both treatment groups. At baseline, both biomarker levels were comparable between treatment groups. At week 26 and 52 of treatment in the overall population, urinary C3M levels were significantly elevated and serum PRO-C6 levels were significantly reduced in the dulaglutide 1.5 mg group compared with insulin glargine group. These effects were consistent in participants with baseline macroalbuminuria (Table).

Conclusions: Dulaglutide was associated with decreased levels of biomarkers for type VI collagen formation and increased type III collagen degradation, suggesting a potential effect to reduce kidney fibrosis. These anti-fibrotic effects could be a potential mechanism for the beneficial effects observed with dulaglutide treatment on CKD in type 2 diabetes.

Funding: Commercial Support - Eli Lilly and Company

Table: Changes in kidney fibrosis biomarker levels on treatment with dulaglutide 1.5 mg and insulin glargine in total population and in macroalbuminuria subgroup.

Parameters		Overall study population				Participants with baseline macroalbuminuria (Baseline UACR >300 mg/g)			
		Dulaglutide 1.5 mg		Insulin Glargine		Dulaglutide 1.5 mg		Insulin Glargine	
		N	LSM ± SE (ng/mL)	N	LSM ± SE (ng/mL)	N	LSM ± SE (ng/mL)	N	LSM ± SE (ng/mL)
Serum PRO-C6	Baseline	157	15.2 ± 0.4	172	16.0 ± 0.4	65	19.4 ± 0.9	77	20.5 ± 0.9
	Week 26 % CFB	149	-4.6 ± 1.9[#]	163	5.7 ± 2.0	60	-2.0 ± 3.5[#]	74	15.2 ± 3.9
	Week 52 % CFB	150	-0.2 ± 2.2[#]	150	8.0 ± 2.3	62	3.3 ± 3.8[#]	64	19.8 ± 4.3
Urinary C3M	Baseline	108	22.9 ± 1.7	109	21.3 ± 1.6	47	18.8 ± 1.9	55	16.6 ± 1.6
	Week 26 % CFB	89	10.9 ± 8.2[#]	98	-10.0 ± 8.5	37	18.5 ± 13.3[#]	49	-8.9 ± 9.0
	Week 52 % CFB	100	20.7 ± 8.8[#]	90	-16.9 ± 8.4	44	7.1 ± 12.1[#]	44	-20.4 ± 8.8

Results were analyzed in the safety population using a model of mixed effects for repeated measures of log transformed values with the following covariates: baseline biomarker value, eGFR, HbA1c, blood pressure, categorical groups indicating geographical region/macroalbuminuria, CKD stage, treatment, time, and treatment by time. *p<0.05 vs. insulin glargine; #p<0.01 vs. insulin glargine. CFB=change from baseline; UACR=urine albumin-to-creatinine ratio.

PO1020

Once-Weekly Exenatide Effects on eGFR Slope and Urine Albumin-to-Creatinine Ratio (UACR) as a Function of Baseline UACR: An EXSCEL Post Hoc Analysis

Lindsay Clegg,[1] Annemarie B. Aart, van der,[2] Robert C. Penland,[3] David W. Boulton,[1] David Sjostrom,[4] Robert J. Mentz,[6] Holman Rury,[5] Hiddo J. L Heerspink.[2] *[1]Clinical Pharmacology & Quantitative Pharmacology, R&D, AstraZeneca, Gaithersburg, MD; [2]Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands; [3]Clinical Pharmacology & Quantitative Pharmacology, R&D, AstraZeneca, Boston, MA; [4]Late-stage Development CVRM, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [5]Diabetes Trials Unit, University of Oxford, Oxford, United Kingdom; [6]Duke University and Duke Clinical Research Institute, Duke University School of Medicine, Durham, NC.*

Background: GLP-1 RA effects on major kidney outcomes in unselected T2D patients at high cardiovascular (CV) risk are modest or neutral. However, GLP-1 RA may provide renal benefits in those at high risk of worsening kidney disease. We examined once-weekly exenatide (EQW) effects on eGFR slope and UACR change, as a function of baseline UACR, in a subset of EXSCEL participants.

Methods: Of 14752 EXSCEL participants, eGFR slope was assessed in those with baseline UACR and ≥1 post-baseline eGFR (n=3503 [23.7%]) via mixed model repeated measures (MMRM) analysis (median follow-up 3.3 years). UACR percent change from baseline to first post-baseline measurement (median time 8.9 months) was assessed in those with baseline and ≥1 follow-up UACR (n=2828 [19.2%]) via ANCOVA of log-transformed UACR, with baseline UACR as a covariate.

Results: Participants with baseline UACR measurements were generally similar to the overall EXSCEL population, and balanced across treatment arms. EQW improved eGFR slope, compared with placebo, in patients with baseline UACR>100mg/g (+0.79 mL/min/1.73m2/year [95% CI 0.24–1.34]) and UACR>200mg/g (+1.32 mL/min/1.73m2/year 95% CI [0.57–2.06], but not at lower UACR thresholds (Figure A). No difference in EQW effect on eGFR was observed as a function of baseline eGFR, CV disease history, RAAS inhibitor use, or SBP. EQW, compared with placebo, reduced UACR by 28.2% in patients with baseline UACR>30 mg/g. This effect was consistent in subgroups with higher baseline UACR (baseline UACR>100 mg 22.5%; baseline UACR>200 mg 34.5%) (Figure B).

Conclusions: This post-hoc EXSCEL analysis suggests that EQW reduces UACR, with improvement in eGFR slope specifically in participants with elevated baseline UACR.

Hemoglobin A_{1c} Reduction with the GLP-1 Receptor Agonist Semaglutide Is independent of Baseline eGFR: Post Hoc Analysis of SUSTAIN and PIONEER Programs

David Cherney,[1] Samy Hadjadj,[7] Thomas Idorn,[2] Ofri Mosenzon,[3] Sascha Pilemann-Lyberg,[2] Vlado Perkovic,[4] Katherine R. Tuttle,[5,6] Soren Rasmussen,[2] Stephen C. Bain.[8,9] *[1]Toronto General Hospital, Toronto, ON, Canada; [2]Novo Nordisk A/S, Søborg, Denmark; [3]Hadassah Medical Center, Hebrew University of Jerusalem, Jerusalem, Israel; [4]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [5]Providence Medical Research Center, Providence Health Care, Spokane, WA; [6]Institute of Translational Health Sciences, University of Washington, Seattle, WA; [7]L'institut du thorax, INSERM CNRS, Univ Nantes, CHU Nantes, Nantes, France; [8]Swansea University Medical School, Swansea Univeristy, Swansea, United Kingdom; [9]Diabetes Research Unit Cymru, Swansea University, Swansea, United Kingdom.*

Background: Hyperglycemia is an established risk factor for the development and progression of chronic kidney disease. The glucagon-like peptide-1 receptor agonist semaglutide is approved for the treatment of type 2 diabetes (T2D) across a wide range of estimated glomerular filtration rates (eGFRs). We investigated whether baseline eGFR affected glycated hemoglobin (HbA_{1c}) reduction with semaglutide.

Methods: This *post hoc,* trial-level analysis considered all SUSTAIN (1–10) and PIONEER (1–10) trials where renal impairment was not an exclusion criteria and where the number of subjects receiving semaglutide with eGFR <60 mL/min/1.73m² was >10. It included data for once-weekly subcutaneous semaglutide (SUSTAIN 4–6, pooled 0.5 and 1.0 mg; SUSTAIN 10, 1.0 mg only) and once-daily oral semaglutide (PIONEER 5 and 6, 14 mg); comparator data were not analyzed. Subjects receiving semaglutide were grouped by baseline eGFR; the eGFR subgroups evaluated were selected according to number of subjects meeting eGFR cut-offs (≥60 and <60 mL/min/1.73 m² in SUSTAIN 4, 5, and 10; <45, 45 to <60 and ≥60 mL/min/1.73 m² in SUSTAIN 6 and PIONEER 5 and 6). Within each trial, absolute estimated change in HbA_{1c} from baseline to end of treatment (EOT) was compared between eGFR subgroups using a linear mixed model.

Results: Mean HbA_{1c} at baseline ranged from 7.9% to 8.7% across the subgroups. Semaglutide significantly reduced HbA_{1c} at a comparable magnitude across eGFR subgroups in all trials (mean reduction of 1.0–1.7% from baseline to EOT; p>0.148 for difference between eGFR subgroups within each trial; Figure).

Conclusions: Semaglutide (subcutaneous and oral) is an effective glucose-lowering agent in subjects with T2D, independently of baseline eGFR, including in those with chronic kidney disease.

Funding: Commercial Support - Novo Nordisk

Mean change in HbA_{1c} from baseline to end-of-treatment by eGFR subgroup for semaglutide in SUSTAIN 4–6 and 10 and PIONEER 5 and 6

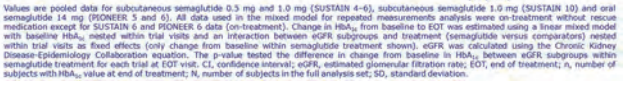
≥60		94.6 (14.5)	8.2 (1.0)	233/276	−1.7	[−1.8;−1.6]		
PIONEER 5	26							
<45		37.8 (4.8)	8.0 (0.8)	54/65	−1.2	[−1.5;−1.0]		0.71
45 to <60		51.3 (3.9)	8.0 (0.7)	60/83	−1.1	[−1.3;−0.9]		
≥60		65.5 (5.8)	7.9 (0.7)	12/15	−1.1	[−1.5;−0.6]		
PIONEER 6	≤83							
<45		37.4 (5.8)	8.0 (1.5)	121/167	−1.1	[−1.3;−0.9]		0.28
45 to <60		52.3 (4.4)	8.1 (1.6)	217/267	−1.0	[−1.2;−0.9]		
≥60		84.5 (13.6)	8.2 (1.6)	952/1,150	−1.1	[−1.1;−1.0]		



Values are pooled data for subcutaneous semaglutide 0.5 mg and 1.0 mg (SUSTAIN 4–6), subcutaneous semaglutide 1.0 mg (SUSTAIN 10) and oral semaglutide 14 mg (PIONEER 5 and 6). All data used in the mixed model for repeated measurements analysis were on-treatment without rescue medication except for SUSTAIN 6 and PIONEER 6 data (on-treatment). Change in HbA_{1c} from baseline to EOT was estimated using a linear mixed model with baseline HbA_{1c} nested within trial visits and an interaction between eGFR subgroups and treatment (semaglutide versus comparators) nested within trial visits as fixed effects (only change from baseline within semaglutide treatment shown). eGFR was calculated using the Chronic Kidney Disease-Epidemiology Collaboration equation. The p-value tested the difference in change from baseline in HbA_{1c} between eGFR subgroups within semaglutide treatment for each trial at EOT visit. CI, confidence interval; eGFR, estimated glomerular filtration rate; EOT, end of treatment; n, number of subjects with HbA_{1c} value at end of treatment; N, number of subjects in the full analysis set; SD, standard deviation.

PO1022

Effects of Semaglutide on CKD Outcomes: A Post Hoc Pooled Analysis from the SUSTAIN 6 and PIONEER 6 Trials

Katherine R. Tuttle,[1] David Cherney,[2] Samy Hadjadj,[3] Thomas Idorn,[4] Ofri Mosenzon,[5] Vlado Perkovic,[6] Soren Rasmussen,[4] Benjamin Wolthers,[4] Stephen C. Bain.[7] *[1]Institute of Translational Health Sciences, Kidney Research Institute, and Nephrology Division, University of Washington, Seattle, WA; [2]Division of Nephrology, University Health Network, University of Toronto, Toronto, ON, Canada; [3]L'institut du thorax, INSERM, CNRS, University of Nantes, CHU Nantes, Nantes, France; [4]Novo Nordisk A/S, Søborg, Denmark; [5]Diabetes Unit, Department of Endocrinology and Metabolism, Hadassah Medical Center, Hebrew University of Jerusalem, Jerusalem, Israel; [6]University of New South Wales, Sydney, NSW, Australia; [7]Diabetes Research Unit, Swansea University Medical School, Swansea, United Kingdom.*

Background: The SUSTAIN 6 cardiovascular outcomes trial (CVOT) indicated a benefit on kidney disease with subcutaneous (s.c.) once-weekly (OW) semaglutide vs placebo (PBO) in subjects with type 2 diabetes (T2D) at high CV risk. The PIONEER

6 CVOT reported CV safety with oral once-daily (OD) semaglutide in a similar cohort. This *post hoc* analysis evaluated the potential benefit of semaglutide vs PBO on chronic kidney disease (CKD) outcomes.

Methods: Data from 6,480 subjects (SUSTAIN 6: N=3,297; median follow-up, 2.1 years; mean baseline [BL] estimated glomerular filtration rate [eGFR], 76 mL/min/1.73 m^2; PIONEER 6: N=3,183; median follow-up, 1.3 years; mean BL eGFR, 74 mL/min/1.73 m^2) were pooled for semaglutide (0.5 and 1.0 mg s.c. OW, 14 mg oral OD) or PBO. Time to onset of persistent eGFR reduction (≥30, ≥40, ≥50, ≥57% [corresponding to doubling of serum creatinine]) was evaluated overall and by BL eGFR subgroup (≥30–<60, ≥60 mL/min/1.73 m^2). Analyses used a Cox proportional-hazards model with treatment group and eGFR subgroup and interaction between both as fixed factors stratified by trial.

Results: In the overall population, hazard ratios (HRs) for onset of persistent eGFR reductions with semaglutide vs PBO were not statistically significantly different from 1, but estimated HRs were <1.0, favoring semaglutide. Estimated HRs for semaglutide vs PBO in the eGFR ≥30–<60 mL/min/1.73 m^2 subgroup were generally lower than in the overall population; semaglutide significantly reduced the risk of developing a persistent 30% eGFR reduction vs PBO (p=0.03; Figure). No significant interactions between treatment and eGFR subgroup were observed.

Conclusions: This analysis of semaglutide CVOTs supports the possibility of a smaller magnitude of eGFR decline with semaglutide vs PBO and suggests a potential kidney disease benefit of semaglutide vs PBO in people with T2D and established CKD.

PO1023

Impacts of Glucagon-Like Peptide 1 Analogues and Sodium Glucose Cotransporter 2 Inhibitor on Type 2 Diabetes Patients with Renal Impairment

Takeyuki Hiramatsu. *Konan Kosei Hospital, Konan, Japan.*

Background: Diabetes mellitus (DM) is a progressive multifactorial disease associated with cardiovascular complications. To prevent the progression of cardiovascular complications in DM patients, we examined impact on cardiac function between glucagon like peptide-1(GLP-1) analogue and sodium-glucose cotransporter-2 (SGLT-2) inhibitors to treat type 2 diabetes patients with renal impairment.

Methods: A total of 156 type 2 DM patients with renal impairment were recruited for this study. All patients were divided into two groups according to the anti-diabetic agents at baseline : Group G; 0.9mg/day liraglutide, n=72, Group S; n=84; 5mg/day dapagliflozin, n=52, empagliflozin n=32. Blood glucose levels, glycosylated hemoglobin (HbA_1c), serum creatinine, and albuminuria were obtained 12 months before and every 3 months for 36 months. Echocardiography, cardio-ankle vascular index(CAVI) were obtained every 12 months for 36 months.

Results: HbA1c and systolic blood pressure were significantly decreased after ADAs. The eGFRs were gradually decreased in both groups. Albuminuria was decreased significantly after initiation of ADAs. Left ventricular mass index (LVMI) and left atrial volume index (LAVi) were significantly decreased in both groups. Cardiac systolic function indicated by ejection fraction and diastolic function indicated by E/e'or left atrial dimension were remained or improved only in group G. Moreover, arterial stiffness indicated by cardio-ankle vascular index (CAVI) was improved in group G (Table1).

Conclusions: These findings suggest that liraglutide and SGLT-2 inhibitor for type 2 DM patients with renal impairment have similar effects on renal function including eGFR and albuminuria and left ventricular and atrial volume. However, liraglutide could provide more benefit for arterial stiffness than SGLT-2 inhibitors.

Table 1 : Clinical Data

		at baseline	after 12 months	after 24 months	after 36 months

PO1024

AKI Associated with Semaglutide

David J. Leehey,[1] Maria M. Picken,[1] Mohamed A. Rahman.[2] *[1]Loyola University Health System, Maywood, IL; [2]Nephrology Associates Northern Illinois, Elk Grove Village, IL.*

Introduction: Recently there have been post-marketing reports of AKI and worsening CKD in patients taking glucagon-like peptide-1 (GLP-1) receptor agonists. Clinical details of these patients have not been published. Herein we report two patients who suffered rapid worsening of renal function after being prescribed semaglutide (Ozempic).

Case Description: Patient 1. An 83-year-old woman with diabetes, hypertension, and CKD was seen in Apr 2020 for increasing leg edema. In Nov 2019 she had been prescribed weekly semaglutide injections. At that time serum creatinine was 1.59 mg/dL (eGFR 30 mL/min/1.73m^2) and serum albumin 3.3 g/dL. Rate of decline of eGFR for the previous 6 years had been 1.5 mL/min/1.73m^2/yr. Attempts to increase the dose of semaglutide from 0.25 mg to 0.5 mg resulted in nausea and vomiting the day following the injection, so the drug had been stopped at the end of March 2020. She had no intercurrent illnesses, hospitalizations, or change in other medications. Examination revealed BP 162/82 and 3+ peripheral edema. Serum creatinine was 3.50 mg/dL (eGFR 11), serum albumin 2.9 g/d, and urine protein/creatinine ratio (UPCR) 4.9 g/g. Urinalysis revealed 3+ protein. Renal biopsy showed diffuse and nodular glomerulosclerosis with acute interstitial lymphocytic and eosinophilic infiltration and acute tubular injury. There has been no recovery of renal function in the 2 months since semaglutide was discontinued. **Patient 2.** A 65-year-old male with diabetes, hypertension, and CKD was initially seen in 2012 for CKD management. BP was well controlled and eGFR stable in the 30-35 range with UPCR of 400-500 mg/g for the next 7 years. In Nov 2019 he was started on weekly semaglutide 0.25 mg increased after 2 weeks to 0.5 mg, after which eGFR decreased to 22 in Mar 2020 accompanied by an increase in UPCR to 1333. The patient denied GI symptoms but did complain of decreased appetite and fatigue. Semaglutide was stopped with resolution of symptoms. His most recent eGFR is 24.

Discussion: AKI has been observed in both clinical trials with GLP-1 receptor agonists and post-marketing clinical experience. Most of these events have occurred in patients who experience adverse GI symptoms. To our knowledge, Patient 1 is the first reported case with biopsy findings. Patients developing new symptoms after starting semaglutide should have laboratory tests performed and the drug discontinued if there is worsening renal function.

PO1025

Association of Atrasentan Plasma Exposure with Variability in Responses in Proxies of Kidney Protection and Fluid Retention: A Post Hoc Analysis of the SONAR Trial

Jeroen Koomen,[1] Jasper Stevens,[1] Hans-Henrik Parving,[3,2] Dick de Zeeuw,[1] Hiddo J. L Heerspink.[1] on behalf of the SONAR steering committee *[1]Department of clinical pharmacy and pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]University of Copenhagen, Faculty of Health Science, Aarhus University, Kobenhavn, Denmark; [3]Rigshospitalet, Kobenhavn, Denmark.*

Background: Atrasentan reduced urinary albumin:creatinine ratio (UACR) and the risk of kidney failure in patients with type 2 diabetes and chronic kidney disease in the SONAR trial. However, in this high risk population, atrasentan was also associated with fluid retention in some patients. We evaluated whether plasma exposure to atrasentan could explain between-patient variability in UACR response, a surrogate for kidney protection, and in B-type natriuretic peptide (BNP), as a biomarker of fluid expansion.

Methods: All patients received 0.75 mg atrasentan for six weeks in the active run-in (enrichment) period. Individual area under the concentration time curve (AUC) was estimated using a population pharmacokinetic model. Subsequently, the association between atrasentan AUC as well as baseline clinical characteristics with UACR and BNP response was estimated with linear regression in univariable and multivariable analyses.

Results: The median atrasentan AUC was 43.8 ng.h/mL which varied considerably among patients [2.5^{th}-97.5^{th} percentiles: 12.6 to 197.5 ng.h/ml]. Median UACR change at the end of enrichment was -36% and BNP change was 8.7%, which also varied among patients [UACR; 2.5^{th}-97.5^{th} percentiles: -76.2 to 44.5%; BNP;-71.5 to 300.0%]. Atrasentan AUC, along with certain clinical characteristics at baseline such as age, eGFR, and hemoglobin, was independently associated with greater UACR reduction (β -7.0% per ng.h/ml AUC; p<0.01) and greater BNP increase (β 4.5% per ng.h/ml AUC; p<0.01).

Conclusions: Atrasentan plasma exposure varied among individual patients and in addition to other patient characteristics, explained the between-patient variability in UACR and BNP response.

Effect of Oral Supplementation with Curcumin in Diabetic Subjects with Proteinuric Kidney Disease: A Randomized Controlled Trial

Ana P. Hernandez Martinez,[1] Yao Cheng,[1] Alfonso Gindl-Bracho,[2] Alejandro Cabrera-Jara,[3] Ana K. Fernandez Yepez,[1] María F. Martínez Hernández,[1] L. Gabriela Sanchez-Lozada,[1] Edilia Tapia,[1] Francisco eugenio R. Castellanos,[1] Armando Vazquez-Rangel,[1] Magdalena Madero.[1] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico; [3]Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.*

Background: Proteinuria remains one of the most important risk factors associated with kidney disease progression. Curcumin is a powerful antioxidant, and different studies have demonstrated the increased expression of cytoprotective proteins through the Keap1/NrF pathway. We conducted a randomized controlled trial in proteinuric diabetic patients to assess the effect of curcumin on proteinuria

Methods: The trial was conducted between May, 2016 and September, 2019. We included diabetic patients over 18 years of age, with an estimated GFR by CKD EPI > 15 ml/min/1.73 m2 and proteinuria > 1 gram/g despite optimal dose or contraindication to RAAS blockade. We excluded patients without DM, renal replacement therapy, kidney transplantation, or pregnancy. The study group received 3.22g of turmeric powder equivalent to 1.67g of curcumin, divided into three doses every 8 hours for 24 weeks. Primary outcome was proteinuria at the end of follow up. Secondary outcomes included eGFR and blood pressure control. Our power calculation estimated a total of 100 patients. Results were analyzed on an intention to treat basis

Results: 100 diabetic patients were included. The mean age was 58.1 ± 10.3 years, 67% were female, 98% were hypertensive and the mean eGFR and 24h proteinuria were 35.9 ± 16.5 ml/min/1.73 m2 and 4.0±2.9 g/g, respectively. After 24 weeks of follow up, no significant differences were observed between groups for proteinuria, eGFR or blood pressure control (Table 1)

Conclusions: In this randomized double blinded controlled trial in diabetic subjects with nephrotic range proteinuria and moderate CKD, curcumin administration was not effective in proteinuria reduction or eGFR preservation. ClinicalTrials.gov Identifier: NCT03019848

Funding: Government Support - Non-U.S.

Effect of Praliciguat, a Once-Daily, Oral Soluble Guanylate Cyclase Stimulator, on Albuminuria in Patients with Diabetic Kidney Disease: A Randomized, Double-Blind, Phase 2 Trial

John P. Hanrahan,[1] Ian H. de Boer,[2] George L. Bakris,[3] Phebe Wilson,[1] James D. Wakefield,[1] Jelena P. Seferovic,[1] Jennifer Chickering,[1] Michael Cressman,[4] Mark Currie,[1] George T. Milne,[1] Albert T. Profy.[1] *[1]Cyclerion Therapeutics, Cambridge, MA; [2]The University of Washington, Seattle, WA; [3]The University of Chicago Medical Center Comprehensive Hypertension Center, Chicago, IL; [4]Covance Inc, Princeton, NJ.*

Background: Impaired nitric oxide (NO) signaling has been implicated in the progression of diabetic kidney disease (DKD). Praliciguat (PRL) is a soluble guanylate cyclase stimulator that amplifies NO signaling in vitro and reduces proteinuria and fasting plasma glucose in the ZSF1 rat model of DKD.

Methods: We evaluated the safety and efficacy of PRL in adults (25-75 y) with type 2 diabetes, eGFR 30-75 mL/min/1.73 m^2, urine albumin creatinine ratio (UACR) 200-5000 mg/g, hemoglobin A1c (HbA1c) <12%, systolic blood pressure (BP) 110-160 mmHg, on stable glucose-lowering and renin angiotensin system-inhibition therapy. Participants were randomized 1:1:1 to placebo (PBO), PRL 20 mg, or PRL 40 mg daily for 12 weeks. Two first morning void specimens for UACR were collected at baseline and weeks 1, 4, 8, 12. Adverse events, 24 h BP and serum chemistry were also assessed. The primary efficacy endpoint was change from baseline (CFB) in UACR to weeks 8 and 12 analyzed by mixed-effects repeated measures model to compare pooled PRL vs PBO.

Results: A total of 156 participants enrolled and 140 completed treatment. Of the 156, 66% were men, 71% were White, 24% Black, and 54% Latino. Model estimates of mean UACR CFB [90% CI] [intent-to-treat (ITT)] were -28% [-36, -18] for pooled PRL and -15% [-27, 0] for PBO; PBO-adjusted UACR CFB was -15% [-31, 4] (p=0.17). Quality checks identified a site with data inconsistent with that from the overall study population. In a post-hoc sensitivity analysis excluding this site, PBO-adjusted UACR CFB for PRL was -20% [-33,-5], nominal p=0.03. PBO-adjusted CFB for other variables at week 12 (ITT) were: 24 h systolic BP -4.2 mmHg [-7.5, -0.8], 24 h heart rate 3.4 bpm [1.6, 5.2], HbA1c -0.27% [-0.50,-0.03], and cholesterol -10.1 mg/dL [-19.2, -1.0]. Mediation analyses indicated that ~75% of the UACR decline was independent of SBP decrease. Both praliciguat doses were well tolerated.

Conclusions: PRL did not significantly reduce UACR in the primary ITT analysis, but favorable trends in UACR, BP, and metabolic variables warrant further clinical study of PRL in DKD.

PO1028

Preexisting CKD Increases Risk of Metformin Monotherapy Failure in US Veterans with Type 2 Diabetes

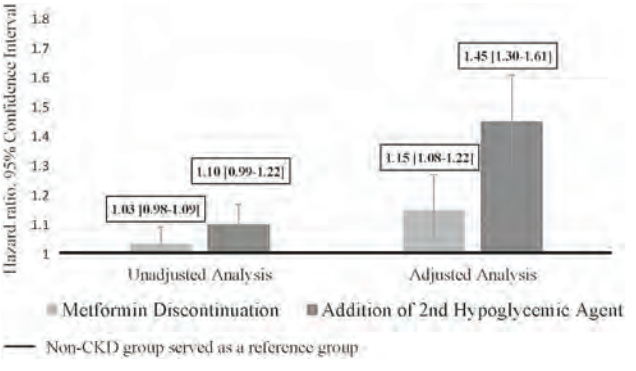
Elvira O. Gosmanova,[1,2] Darren E. Gemoets,[1] Laurence S. Kaminsky,[1] Csaba P. Kovesdy,[3,4] Aidar R. Gosmanov.[1,2] *[1]Albany Stratton VA Medical Center, Albany, NY; [2]Albany Medical College, Albany, NY; [3]Memphis VA Medical Center, Memphis, TN; [4]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Metformin (MET) is increasingly used for treatment of type 2 diabetes (T2D) in patients with chronic kidney disease stage 3 (CKD3); however, it is unknown if rates of MET monotherapy failure differs in patients with and without CKD3.

Methods: This was a retrospective study including 21,142 US Veterans with T2D and estimated glomerular filtration rate (eGFR) ≥30 ml/min/1.73m^2 who initiated MET monotherapy between 01/2010 and 03/2017. CKD3 was established as eGFR 30-59 ml/min/1.73m^2. MET monotherapy failure defined as the 1st 90-day gap in MET refill (MET discontinuation) or the addition of 2nd hypoglycemic agent (HA) during 3-yr follow up was compared between patients without and with CKD3 using univariate and multivariate Cox regression analyses adjusted for case-mix.

Results: The mean ± SD age for the total cohort was 59.9 ±1 0.2 yrs, 94.3% were males, 79.7 and 17.3% were Whites and Blacks, respectively. Preexisting CKD3 was present in 1,363 (6.5%) patients. Baseline patients' characteristics were similar between two groups except CKD patients were older (68.7 vs. 59.3 yrs in non-CKD) and had lower eGFR (54.1 vs. 87.4ml/min1.73m^2 in non-CKD). In Kaplan-Meyer analysis there were no difference in rates of MET discontinuation or addition of 2nd HA in patients without and with CKD3 (p=0.2 and p=0.09, respectively). However, in the adjusted analyses, patients with CKD3 had a significantly higher risk of MET discontinuation or addition of 2nd line HA (HR, 95% CI 1.15, 1.08-1.22 and 1.45; 1.30-1.61, respectively), as compared with no CKD (Figure 1).

Conclusions: In newly treated patients with T2D the presence of preexisting CKD stage 3 was associated with increased risk of MET monotherapy failure. MET discontinuation may be expected in CKD3 patients with the prorgession of CKD; however, our findings of the increased risk of addition 2nd HA warrant further studies to understand whether hypoglycemic efficacy of MET monotherapy is reduced in CKD stage 3.



PO1029

Utilization of Glucose-Lowering Medications Among US Medicare Beneficiaries with CKD Between 2007 and 2016

Julie Zhao,[1,2] Eric D. Weinhandl,[1,2] Angeline M. Carlson,[1] Wendy L. St. Peter.[1,2] *[1]University of Minnesota, Minneapolis, MN; [2]Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN.*

Background: Selecting effective and safe glucose-lowering medications for chronic kidney disease (CKD) patients is challenging. Twelve classes of glucose-lowering medications are on the US market today. Information regarding utilization of glucose-lowering medications in patients with CKD is limited.

Methods: We evaluated an adult CKD population from Medicare 5% random sample 2007-2016, provided by the United States Renal Data System. Yearly cohorts of patients with CKD and type 2 diabetes were created. Descriptive statistics were used to report proportions of patients using glucose-lowering medications. To test overall trends in glucose-lowering medication classes, linear probability models with adjustment for age, sex, race/ethnicity, CKD stage, and low-income subsidy (LIS) status were used.

Results: Use of metformin, newer glucose-lowering medication classes (DPP-4 inhibitors, GLP-1 receptor agonists, and SGLT2 inhibitors), and newer insulin analogs (aspart, lispro, glulisine, detemir, glargine, degludec) showed statistically significant upward trends during the study timeframe. Sitagliptin was the most commonly prescribed DPP-4 inhibitor; use increased from 5.6% in 2007 to 15.0% in 2016. Use of linagliptin (approved in 2011) increased from 0.1% in 2011 to 6.0% in 2016. Compared with other GLP-1 receptor agonists, use of liraglutide (approved in 2010) increased more (0.3% in 2010 to 3.6% in 2016), and use was higher in 2016. Use of SGLT2 inhibitors (canagliflozin, empagliflozin, or dapagliflozin) remained very low in 2016, but use was increasing. Use of newer analog insulin therapy increased, especially insulin detemir (2.4% in 2007 to 11.7% in 2016). Insulin was the most highly used single medication class in 2016. The most highly used dual combination therapies in 2016 were metformin and sulfonylureas and metformin and insulin. Combination therapy was less common as CKD stage increased.

Conclusions: Use of metformin and newer glucose-lowering medication classes is increasing in CKD patients with type 2 diabetes. We anticipate that percentages of CKD patients using these newer agents will increase.

PO1030

Role of Roxadustat in Improving Erythropoiesis-Stimulating Agent (ESA)-Resistant Anemia in Patients on Maintenance Hemodialysis

Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[1] Kenji Sawase,[1] Tayo Kawazu,[1] Mineaki Kitamura,[1] Kanako Hayashi,[1] Kosei Yamaguchi,[1] Tomoya Nishino,[2] Takashi Harada.[1] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki University Hospital, Nagasaki, Japan.*

Background: Roxadustat, an oral hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor, is shown to stimulate erythropoiesis thus improving iron metabolism. Again, while hyperglycemic states are known to be associated with a decreased tissue hypoxia response, to date, roxadustat has not been revaluated for its role in improving anemia in patients with or without diabetes in clinical settings.

Methods: A total of 64 hemodialysis patients being treated with epoetin α (9000 units weekly) participated in the study after giving informed consent. They were switched from intravenous epoetin α to oral roxadustat (100 mg 3 times weekly) therapy and were assessed 8 weeks later for improvements in anemia, as well as for changes in parameters for iron metabolism and C-reactive protein (CRP).

Results: The study included 39 patients without diabetes (mean age, 71.1 ± 12.1 years; mean dialysis vintage, 7.5 ± 7.4 years; mean GA, 16.2 ± 2.9%) and 27 patients with diabetes (mean age, 70.3 ± 10.3 years; mean dialysis vintage, 5.9 ± 5.5 years; mean GA, 24.9 ± 5.5%). As shown in Table, after 8 weeks the Hb concentration was significantly increased from 10.3 ± 0.8 g/dL at baseline to 10.7 ± 1.3 g/dL in patients without diabetes (P = 0.03) but was not increased in patients with diabetes (from 10.4 ± 0.6 at baseline to 10.5 ± 1.1 g/dL). Again, the serum iron, ferritin concentrations and the transferrin saturation ratio were decreased, irrespective of whether or not they had diabetes, with no change shown in serum CRP level.

Conclusions: Switching hemodialysis patients with ESA-resistant anemia from ESA to roxadustat led to improvements in anemia only in those without diabetes, while study results suggested the involvement of mechanisms, other than impaired iron utilization or inflammation, in the impairment of hematopoiesis in those with diabetes.

Funding: Private Foundation Support

Effects of Roxadustat on HD Patients without or with Diabetes

		without DM			with DM

Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD, Anemia, and Diabetes Mellitus

Tak Mao D. Chan,[1] Carol A. Pollock,[2] Mohamed A. El-Shahawy,[5] Pablo E. Pergola,[3] Lynda Szczech,[4] Khalil G. Saikali,[4] Kin-Hung P. Yu.[4] *[1]University of Hong Kong, Queen Mary Hospital, Hong Kong SAR, China; [2]The University of Sydney, Sydney, NSW, Australia; [3]Renal Associates PA, San Antonio, TX; [4]FibroGen Inc, San Francisco, CA; [5]University of Southern California Keck School of Medicine, Los Angeles, CA.*

Background: Roxadustat is an oral hypoxia inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Diabetes mellitus (DM) is a growing health problem often associated with CKD. The risk of cardiovascular (CV) events and CV mortality is significantly increased in patients with CKD and DM. Thus, evaluation of safety and efficacy of roxadustat in the subgroup of patients with CKD and DM is of clinical importance.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, epoetin alfa-controlled studies of roxadustat for the treatment of anemia in patients with dialysis-dependent (DD) CKD were assessed in patients with a history of DM at baseline. Efficacy endpoints were: mean change from baseline (CFB) in hemoglobin (Hb) averaged over Weeks 28–52 regardless of rescue therapy, time to first blood/RBC transfusion during the treatment period, and mean monthly IV iron use during weeks 28–52. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs)

Results: In the DD-CKD study population, 47% (1830/3890) of patients had DM (roxadustat 915; epoetin alfa 915). Baseline characteristics were generally similar between treatment groups. Mean (SD) Hb levels (g/dL) at baseline were 9.87 (1.15) in the roxadustat group and 9.88 (1.18) in the epoetin alfa group. Patients achieved a significantly larger least-squares mean (LSM) [SEM] CFB in Hb levels (g/dL) with roxadustat vs. epoetin alfa (0.94 [0.032] vs. 0.62 [0.031]), corresponding to a LSM difference of 0.32 (95% CI: 0.23, 0.40) (p<0.0001). Risk for blood/RBC transfusion was significantly reduced in the roxadustat vs. epoetin alfa group (HR, 0.72 [95% CI: 0.56, 0.93]; p=0.0121). Mean (SD) monthly IV iron (mg) use was lower in roxadustat- vs. epoetin alfa-treated patients: 58.0 (222.0) vs. 67.4 (146.5) (p<0.0001). TEAE rates were comparable between treatment groups and to those in the overall DD-CKD study population

Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing Hb levels, reducing the risk for blood/RBC transfusion, and lowering mean monthly IV iron use in patients with DD-CKD and DM. Safety and tolerability profiles were similar to the overall population and consistent with that observed in this patient subgroup.

PO1032

Efficacy and Safety of Roxadustat in Patients with Non-Dialysis-Dependent CKD, Anemia, and Diabetes Mellitus

Simon D. Roger,[1] Carol A. Pollock,[2] Mohamed A. El-Shahawy,[5] Pablo E. Pergola,[3] Willis Chou,[4] Khalil G. Saikali,[4] Kin-Hung P. Yu.[4] *[1]Renal Research, Gosford, NSW, Australia; [2]The University of Sydney, Sydney, NSW, Australia; [3]Renal Associates PA, San Antonio, TX; [4]FibroGen Inc, San Francisco, CA; [5]University of Southern California Keck School of Medicine, Los Angeles, CA.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Diabetes mellitus (DM) is a growing health problem often associated with CKD. In patients with DM, 37.0% have CKD (Stages 1–4), of which 52.5% have moderate-to-severe CKD (State 3 or 4). The risk of cardiovascular events and mortality is significantly increased in patients with CKD and DM. Thus, evaluation of the safety and efficacy of roxadustat in patients with CKD and DM is of clinical importance.

Methods: Pooled data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with non–dialysis-dependent (NDD) CKD were assessed in the subgroup of patients with a history of DM at baseline. Primary and key secondary endpoints were mean change from baseline (CFB) in hemoglobin (Hb) averaged over Weeks 28–52 regardless of rescue therapy and time to first blood/RBC transfusion in the first 52 weeks, respectively. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the NDD-CKD study population, 57% (2433/4277) of patients had DM (roxadustat=1337, placebo=1096). Baseline characteristics were generally similar between the treatment groups. Mean (SD) Hb levels (g/dL) at baseline were 9.12 (0.71) in the roxadustat group and 9.10 (0.71) in the placebo group. Patients achieved a larger mean (SD) CFB in Hb levels (g/dL) with roxadustat vs. placebo (1.81 [0.93] vs. 0.14 [0.98]), corresponding to a least-squares mean difference of 1.71 (95% CI: 1.61, 1.81) (p<0.0001). The risk for blood/RBC transfusion was significantly reduced in the roxadustat vs. placebo group (HR, 0.28 [95% CI: 0.21, 0.36]; p<0.0001). TEAE rates were comparable between treatment groups and with those reported in the overall NDD population.

Conclusions: Roxadustat was efficacious vs. placebo for increasing Hb levels and reducing the risk for blood/RBC transfusion in patients with NDD-CKD and DM. The safety and tolerability profile was similar to the overall NDD-CKD population.

PO1033

Effects of Veverimer on Serum Bicarbonate and Physical Function in Patients with Diabetes and CKD: Subgroup Analysis from a Randomized Trial

Donald E. Wesson,[1] Vandana S. Mathur,[2] Navdeep Tangri,[3] Yuri Stasiv,[4] Dawn Parsell,[4] Elizabeth Li,[5] Gerrit Klaerner,[4] David A. Bushinsky.[6] *[1]Baylor Scott & White Health and Wellness Center, Dallas, TX; [2]MathurConsulting, Woodside, CA; [3]University of Manitoba, Winnipeg, MB, Canada; [4]Tricida, Inc., South San Francisco, CA; [5]PharmaStat LLC, Fremont, CA; [6]University of Rochester Medical Center, Rochester, NY.*

Background: Metabolic acidosis (MA) is a complication of CKD and has deleterious effects on kidney function, bone (demineralization), and muscle (protein catabolism). Patients (pts) with diabetes and CKD are prone to functional limitations that adversely affect their quality of life. Veverimer, an investigational non-absorbed polymer that binds gastrointestinal hydrochloric acid, is being developed to treat MA in CKD.

Methods: TRCA-301E is a multicenter, Phase 3, randomized, blinded, placebo-controlled trial in 196 pts with CKD (eGFR 20-40 ml/min/1.73 m^2) and MA (serum bicarbonate 12-20 mEq/L) who were treated for up to 1 yr with veverimer or placebo, with dose titration targeted to achieve a normal serum bicarbonate.

Results: Compared with placebo, veverimer significantly increased serum bicarbonate and significantly improved physical function as reported on the Kidney Disease and Quality of Life-Physical Function Domain (KDQOL-PFD) and the 5-times repeated chair stand test (RCS) with a safety profile that was similar to placebo (Wesson, *The Lancet* 2019). In the subgroup with diabetes (n=70, veverimer; n=57, placebo), mean age was 63years, mean baseline eGFR was 28.5 mL/min/1.73 m^2, and mean serum bicarbonate was 17.3 mEq/L; 10% were on background oral alkali. In the veverimer group, at Week 52, mean serum bicarbonate increased by 4.39 mEq/L (P<0.05 vs. placebo) and significantly more pts had a ≥4mEq/L increase or normalization of serum bicarbonate (64% v 38%, P< 0.01). Pt-reported limitations of physical function (KDQOL-PFD) (e.g. walking several blocks, climbing a flight of stairs) significantly improved in the veverimer group (+12.5 v +0.3, P<0.001) as did objective physical performance on the RCS at Week 52 (P<0.0001). There was no significant effect of the presence or absence of diabetes on the effect of veverimer on improvement in either measure of physical function (rank-based ANCOVA, P≥0.6).

Conclusions: Few interventions for CKD have improved QOL or physical functioning. Our study demonstrates that veverimer is an effective treatment for diabetic pts with MA in CKD. Treatment with veverimer significantly improved how these pts felt and functioned.

PO1034

Monocyte-to-Lymphocyte Ratio, an Independent Risk Factor of Survival and Cardiovascular Disease in Hemodialysis Patients: Results from the International MONDO Consortium

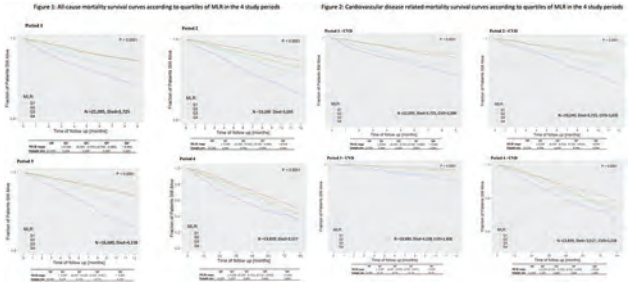
Rupert B. Bright,[1] Xiaoling Ye,[3] Kevin Woollard,[2] Charles D. Pusey,[2] Peter Kotanko,[3] Neill D. Duncan.[1] *[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]Renal Research Institute, New York, NY.*

Background: Patients with ESRD have a high prevalence of chronic inflammation and higher risk of death. Monocytes have a crucial inflammatory role, but there has been limited study to date. This analysis studed the independent relationship between MLR, all-cause and cardiovascular (CV) mortality in a large and ethnically diverse haemodialysis population

Methods: Four cohorts were described by phases of haemodialysis exposure. Kaplan-Meier (KM) curves were applied to explore the association between MLR quartiles with all-cause and CV mortality in the 4 cohorts. Cox proportional hazards models with spline terms (adjusted for age, gender, race, body mass index, diabetic (DM) and congestive heart failure (CHF)) were applied to explore the association between MLR levels and all-cause mortality in the cohorts

Results: 21,095 patients were included in acute phase cohort; 19,240 in the early-stable phase cohort, 16,680 in the mid-stable cohort, and 13,839 in the late-stable phase cohort. Notably, patients with higher baseline MLR by quartile tended to be older, male and with a higher percentage of DM and CHF as comorbidities. Lower lymphocyte count and higher neutrophil count, NLR, CRP were associated with higher MLR quartile, consistent with the observed association with other markers of inflammation and malnutrition: lower albumin, phosphate and higher ferritin. Adjusted all-cause and CV mortality was observed to be higher in patients with higher MLR quartile both in the KM and spline analyses (Fig1/2)

Conclusions: There is a positive relationship between higher levels of MLR and adjusted all-cause and CV mortality across all phase cohorts, including long-term follow-up in this large and ethnically diverse haemodialysis population. Higher prevelence of DM and CHF are seen in patients with higher levels of MLR. This work supports findings made previously in more restricted cohorts and warrants further mechanistic investigation



PO1035

Warfarin Increases the Risk of Vascular Calcification in Haemodialysis Patients: A Multicenter Case-Control Study

Rezzan Eren Sadioglu,[1] Evren Ustuner,[1] Ihsan Ergun,[2] T. Ecder,[3] Gokhan Nergizoglu,[1] Kenan Keven.[1] *[1]Ankara Universitesi Tip Fakultesi, Ankara, Turkey; [2]Ufuk Universitesi Doktor Ridvan Ege Egitim Arastirma Hastanesi, Ankara, Turkey; [3]T C Demiroglu Bilim Universitesi, Istanbul, Turkey.*

Background: Vascular calcifications (VC) are highly prevalent in maintenance haemodialysis patients and it is a recognized risk factor for increased mortality. Previous experimental studies showed the relation between warfarin which has been prescribed frequently in dialysis patients and VC. The aim of this study is to investigate the association between VC and warfarin use in haemodialysis patients.

Methods: This was a cross-sectional, observational, multicenter study. VC were assessed using Adragao (AS; pelvis and hands) and Kauppila (KS; lateral lumbar spine) scores in 76 haemodialysis patients from six centers. There were 32 patients (4.5%) being treated with warfarin for at least 1 year out of a total 711 haemodialysis patients and we included 44 control patients with matching parameters of age, sex and dialysis vintage to the study. Clinical characteristics, concomitant treatments, laboratory results were recorded and possible risk factors related to VC were analyzed.

Results: Of the patients, 47% were females, mean age was 65.8 ± 9 years, 23% were diabetics, their mean dialysis vintage was 68.39 ± 38.5 months and mean Kt/V 1.66 ± 0.27. No significant differences in clinical characteristics and basic laboratory results were found between control and warfarin group. In warfarin group, median Kauppila score was higher than control [11 vs 6.5, (25%-75% percentile, 5 vs 15), P=0.032] and percentages of Kauppila score >6 patients were higher, as well (76,6% vs 50%; P=0.029). Median Adragao score was not significantly different between two groups [7 vs 6, (%25,%75 percentile 6 vs 8), P=0.177]. Logistic regression analysis revealed that warfarin treatment was independently associated with Kauppilla scores of >6 (OR 3.28, 95% CI 1.17-9.22, P=0.024).

Conclusions: The results of this study showed that warfarin is a strong risk factor for vascular calcifications, especially in aorta of haemodialysis patients.

Table 1. Basic characteristics of the patients and summary of the results

Parameter	Warfarin (+) n=32	Warfarin (-) n=44	P value
Age (mean±SD)	67.6±9	64.54±8.3	0.143
Female/Male	14; 43%/18; 56%	22; 50%/ 22; 50%	0.646
Dialysis vintage (months, mean±SD)	74.9±44.2	63.6±33.4	0.209
Kt/V	1.62±0.2	1.7±0.2	0.205
Diabetes mellitus +/-(n,%)	6, 18%	12, %27	0,427
Warfarin usage time (months, mean±SD)	65.9±9.7	NA	NA
Kauppilla score (median,min-max)	11 (1-24)	6,5 (1,20)	**0,032**
Kauppilla score >6 (n, %)	23, 76.6%	22, 50%	**0,029**
Adragao score (median, min-max)	7 (2-8)	6 (0-8)	0,177
Adragao score ? 3 (n, %)	30, 93.7%	41, 93.1%	0,638
Serum calcium (mean±SD)	8.82±0.5	8.78±0.5	0.778
Serum phosphorus (mean±SD)	4.62±0.87	4.84±0.89	0.279
Serum parathyroid hormone (mean±SD)	376.23±192.8	457.36±251.2	0.116
Serum albumin (mean±SD)	3.81±0.38	3.91±0.52	0.361
Serum hemoglobin (mean±SD)	11.43±1.1	11.6±1.57	0.595
Serum C-reactive protein (mean±SD)	14.3±12.2	13.8±15.4	0.881

PO1036

Paradoxical Effect of Aldosterone on Cardiovascular Outcome in Maintenance Hemodialysis Patients

Kyu Sang Yun,[1] Sun Ryoung Choi,[2] Hayne C. Park,[1] Do Hyoung Kim,[1] Ajin Cho,[1] Juhee Kim,[1] Jung Woo Noh,[1] Youngki Lee.[1] *[1]Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [2]Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea.*

Background: Patients with end-stage kidney disease have an increased risk of cardiovascular (CV) events and left ventricular diastolic dysfunction (LVDD) is known to contribute to high occurrence of CV mortality. Although high serum aldosterone level is involved in the development of CV complications in general population, this association is unclear in patients undergoing hemodialysis (HD). We aimed to determine the impact of serum aldosterone on LVDD and CV mortality among HD patients.

Methods: We performed a prospective cohort study of maintenance HD patients without CV disease. Patients were divided into two groups according to the median level of serum aldosterone. All patients underwent echocardiography to evaluate diastolic dysfunction. Proportions of LVDD and CV mortality were compared between high and low aldosterone groups.

Results: We enrolled a total of 60 adult patients (mean age 57.9±12.1 years, male 30.0%). Low aldosterone group had an increased left ventricular diastolic dimension compared with high aldosterone group (52.2±8.4 vs. 50.3±5.2 mm, p=0.033). The E/e' ratio and the proportion of LVDD were significantly higher in the low aldosterone group than the high aldosterone group. Multivariate logistic regression revealed that low log-aldosterone (odds ratio (OR) 0.403; 95% confidence interval (CI) 0.188-0.862) and large left atrial dimension (OR 1.308; 95% CI 1.114-1.536) were independent risk factors for LVDD. During the mean follow-up period of 5.2 years, the cumulative incidence rates of CV mortality were significantly higher in low aldosterone group (log-rank test, p=0.027). In addition, cox regression analysis demonstrated that low serum aldosterone was an independent predictor of CV mortality in HD patients (hazard ratio 0.505; 95% CI 0.294-0.869, p=0.014).

Conclusions: Low serum aldosterone was not only associated with LVDD but also an independent predictor of CV mortality among HD patients.

PO1037

Variations in the Thrombin Generation Profile and Clotting Factor Levels in the Patients Undergoing Maintenance Hemodialysis

Fakiha Siddiqui, Emily Bontekoe, Debra Hoppensteadt, Walter Jeske, Vinod K. Bansal, Jawed Fareed. *Loyola University Medical Center, Maywood, IL.*

Background: Chronic kidney disease (CKD) patients are at high risk of cardiovascular disorders and thrombosis. CKD-V patients undergoing maintenance hemodialysis exhibit varying degrees of hemostatic dysregulation. Endogenous thrombin potential (ETP) is important to the pathogenesis of vaso-occlusive complications. This study investigated ETP and its relevance to circulating coagulation factor levels in CKD-V patients.

Methods: Citrated blood samples from 95 patients with CKD-V were collected prior to maintenance hemodialysis. Normal human plasma (NHP) was used for referencing purposes. Plasma levels of coagulation factor VII, IX, X and XIII were measured by ELISA. ETP was measured using a kinetic fluorogenic method. Such parameters as peak thrombin, lag time (LT) and area under the curve (AUC) were compiled. Correlation analysis between peak thrombin and coagulation factors was carried out by using GraphPad Prism software.

Results: CKD-V patients did not show any significant difference in factor VII levels (110.6 % vs 112.5 %) and factor X (81.5 % vs 88.2 %). Factor IX levels were elevated (124.3 %) in the CKD-V group in comparison to NHP (100.5 %) similarly factor XIII levels were significantly higher in CKD-V (104.8 %) in comparison to NHP (82.3 %). In the ETP studies, CKD-V patients showed a wide variation in ETP parameters. Peak thrombin levels (107.1 nM vs 168.3 nM) and AUC (589.8 nM*min vs 815.7 nM*min) were lower while lag time was higher (2.89 min vs 2.17 min) in the CKD-V group in comparison to NHP. Coagulation factor VII, IX and X correlated with peak thrombin levels (r = >0.3) whereas factor XIII did not show any significant correlation.

Conclusions: These studies demonstrate that CKD-V patients exhibit a decreased generation of endogenous thrombin with simultaneous consumption of coagulation factors suggesting an ongoing activation of coagulation system. Almost 10% of the CKD-V patients exhibit increased levels of peak thrombin values which correlated with relatively higher levels of clotting factors suggesting a decreased activation of ETP. These studies suggest that a majority of CKD-V patients are in a sustained state of ongoing thrombin generation which may contribute to the observed thrombotic complications in these patients.

PO1038

Physical Activity and Mortality in Adults Undergoing Hemodialysis: A DIET-HD Cohort Study

Amelie Bernier-Jean,[1,2] Germaine Wong,[1,2] Valeria M. Saglimbene,[1,3] Marinella Ruospo,[3] Suetonia Palmer,[4] Patrizia Natale,[3,5] Vanessa Garcia-Larsen,[6] David W. Johnson,[7,8] Marcello Tonelli,[9] Jonathan C. Craig,[10] Giovanni F. Strippoli.[1,5] *[1]School of Public Health, Faculty of Medicine and Health, The University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [3]Diaverum Medical-Scientific Office, Diaverum, Lund, Sweden; [4]Department of Medicine, University of Otago, Christchurch, New Zealand; [5]Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy; [6]Program in Human Nutrition, Department of International Health, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [7]Department of Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [8]Australasian Kidney Trials Network, University of Queensland, Brisbane, QLD, Australia; [9]University of Calgary, Calgary, AB, Canada; [10]College of Medicine and Public Health, Flinders University, Adelaide, SA, Australia.*

Background: People receiving maintenance hemodialysis (MHD) are at higher risk of cardiovascular disease (CVD) and death. Regular exercise training reduces CVD mortality in people with coronary heart disease, but the potential survival benefits for adults undergoing MHD are unproven. We assessed the association between self-reported physical activity (PA) and mortality in a very large cohort of people receiving MHD.

Methods: DIET-HD is a prospective, multinational study of adults undergoing MHD in Europe and South America. We classified participants as sedentary, exercises up to once a week ('occasional PA'), or exercises twice a week or more ('frequent PA'), using a self-reported question. We balanced the baseline characteristics, including socio-demographic factors, comorbidities, blood chemistry and dietary intake, across the PA groups using propensity scores. We conducted weighted Cox proportional hazards models with double robust estimators to assess the association between PA and mortality.

Results: Of the 8043 participants initially included in the DIET-HD study, 6147 (76%) had information on PA. 1226 (20%) exercised frequently, 1981 (32%) occasionally and 2940 (48%) were sedentary. During a median follow-up of 3.82 years (19 677 person-years), 2337 (38%) deaths occurred, of which 1050 (45%) were from CVD causes. After propensity score-weighing and adjustment for potential confounders, PA was associated with a lower risk of all-cause mortality, CVD mortality and non-CVD mortality (Table). We observed a dose-dependent effect of PA for CVD death.

Conclusions: Regular PA is associated with a lower risk of CVD mortality in adults receiving MHD. Until randomised control trials assess whether PA improves survival in MHD, it should be considered as part of the clinical management of MHD patients.

Impact of Age on the Association of Pre-ESRD Uric Acid with Post-Transition Mortality Among US Veterans

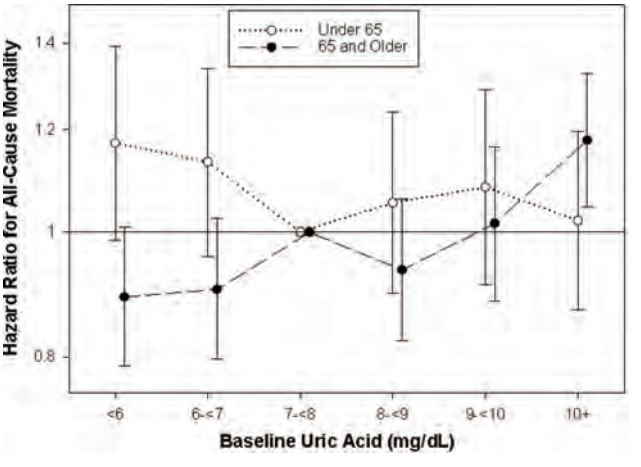
Nicholas Cuvelier,[1] Cachet Wenziger,[3,1] Jui-Ting Hsiung,[3,1] Ramy M. Hanna,[1] Ekamol Tantisattamo,[1] Connie Rhee,[1] Csaba P. Kovesdy,[4,2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[3,1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]VA Long Beach Healthcare System, Long Beach, CA; [4]Memphis VA Medical Center, Memphis, TN.*

Background: Elevated uric acid is a marker for gout and higher mortality in kidney disease patients. In a prior analysis we demonstrated that higher pre-dialysis uric acid was associated with higher post-transition outcomes. As higher uric acid is more commonly found in older patients, we examined the differences in the association between pre-dialysis uric acid and mortality post-transition to dialysis across age groups.

Methods: From US veterans who transitioned to dialysis between 10/2007-03/2015, we identified 9,110 patients with a uric acid measured 3 months before transitioning to ESRD. We examined the association of pre-ESRD uric acid category with all-cause mortality post-transition using Cox proportional hazards models adjusted for case-mix covariates, and additional adjustments for laboratory values and eGFR, separately in patients less than 65 or >= 65 years.

Results: The mean age of the cohort was 66±11 years old, 2% female, and 36% African American. The 3-month prelude uric acid average was 8.13 ± 2.29 mg/dL. 4,521 patients died during follow-up (median follow up time of 25 months). Compared to the reference group (7-<8mg/dL) in the fully adjusted model, lower uric acid led to a lower risk and the highest category of uric acid had an 18% higher risk of mortality in those 65 years or older. There was no significant association between uric acid and mortality among patient younger than 65. Wald Test for interaction showed a significant difference in association (p value: 0.0029). [Figure]

Conclusions: Elevated uric acid pre-transition is associated with a higher risk of mortality post-transition among older Veteran patients. In older patients, prelude uric acid can be informative of post-transition outcomes. Further study of this relationship is warranted to determine if uric acid should be more closely monitored in patients transitioning to dialysis and to further understand why age modifies the clinical impact of uric acid.



PO1040

Hemodiafiltration Reduces All-Cause Mortality in Korean Hemodialysis Patients: A Propensity-Matched Cohort Study

Miji Kim, Won-Hee Cho, Yang gyun Kim, Sangho Lee, Ju young Moon. *Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

Background: On-line hemodiafiltration(OL-HDF) is currently the most advanced hemodialysis modality. Several studies have found that high convection volume OL-HDF reduces the mortality in dialysis patients compared with that of conventional hemodialysis(HD). Most randomized controlled trials to demonstrate the effect of

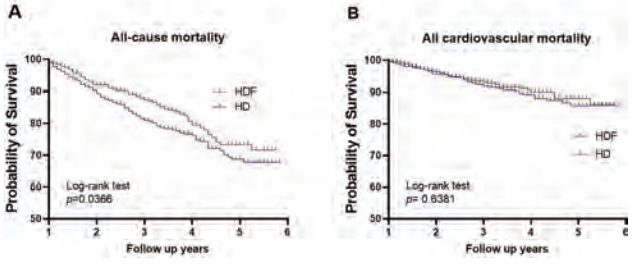
OL-HDF on survival benefit have failed. To date, the survival rate of OL-HDF has not been investigated in a large number of Koreans.

Methods: Using data from the Korean Society of Nephrology, The total 85,643patients undergoing hemodialysis between 2014 and 2019 were divided into two groups receiving only conventional HD and only OL-HDF with thrice sessions per week, dialysis vintage ≥3months, and ≥18years of age. Demographic characteristics, hemodialysis patterns, and overall survival were analyzed between the groups.

Results: The study included 8,955patients(750 OL-HDF, 8,205 conventional HD) with a median follow-up of 2.58(interquartile range 0.50–4.66)years. The mean age was younger, more male genders, and the dialysis vintage was slightly longer in patients with OL-HDF group compared with these of conventional HD group. We performed propensity score matching in 1:1 with the covariate of age, gender, cause of ESRD, and dialysis vintage. Compared with conventional HD, OL-HDF was associated with improved all cause-mortality(hazard ratio 0.659, 95% confidence interval 0.465 to 0.934). In cardiovascular mortality, no statistical difference was observed between the groups.

Conclusions: Our results indicate that OL-HDF was associated with reduced mortality without harmful effects on nutritional status across patient subgroups of age, sex and cause of ESRD, dialysis vintage.

Comparison of cumulative probabilities of survival between HD and HDF groups



Predictors of all-cause mortality in univariate & multivariate cox analyses

covariate	Unadjusted			Adjusted*

Energy Homeostasis Gene Polymorphisms and Survival of Hemodialysis Patients

Monika K. Swiderska, Adrianna Mostowska, Pawel P. Jagodzinski, Alicja E. Grzegorzewska. *Uniwersytet Medyczny imienia Karola Marcinkowskiego w Poznaniu, Poznan, Poland.*

Background: Patients who undergo hemodialysis (HD) therapy have an increased risk of death compared to the general population. Single nucleotide variants (SNVs) of energy homeostasis influence the susceptibility to diabetes mellitus (DM), dyslipidemia, and coronary artery disease (CAD). We investigated whether selected SNVs related to energy homeostasis are associated with mortality risk in HD patients.

Methods: The study included 471 HD patients who were tested for 11 SNVs in *FOXO3*, *IGFBP3*, *FABP1*, *PCSK9*, *ANGPLT6*, and *ANGPLT8* genes using HRM analysis and TaqMan assays. FOXO3, IGFBP3, L-FABP, PCSK9, ANGPLT6, and ANGPLT8 plasma concentrations were measured by ELISA in 71 HD patients. The Kaplan-Meier method and Cox proportional hazard models were used for survival analyses.

Results: Patients with *ANGPLT8* rs737337 CC genotype had over 3-fold increased risk of death compared with the carriers of the major allele (log-rank test p=0.002; HR 3.4; 95%CI 1.5–7.7;p=0.003). rs737337 CC genotype was in particular a risk factor for cardiac (2e-4; 5.5; 2–15.1; 8E-4) and cardiovascular deaths (0.004; 4; 1.5–10.7; 0.007). The associations mentioned above remained significant after adjustment for gender, DM, CAD, age at RRT onset, BMI and CRP (p=0.03, 0.004 and 0.02 for overall survival, cardiac and cardiovascular deaths, respectively). *ANGPLT8* rs737337 was also associated with an increased risk of diabetic nephropathy (OR 1.8;95%CI 1.1–2.9; p=0.02). Plasma ANGPLT8 levels were increased in patients diagnosed with CAD (p=0.028). Bearers of *IGFBP3* rs3110697 variant A allele had increased risk of cardiovascular mortality (HR 1.3; 95%CI 1–1.6; p=0.02, adjusted p=NS). *IGFBP3* rs3110697 positively correlated with the diagnosis of CAD (p=0.006), myocardial infarct (p=0.01) and dyslipidemia (p=0.02) as well as with CRP concentrations (p=0.005). Carriers of *FOXO3* rs4946936 CT genotype had increased risk of cardiac death (HR 1.6; 95% CI 1.1–2.4; p=0.03, adjusted p=NS), whereas FOXO3 rs2802292 TT genotype was associated with decreased risk of vascular mortality (HR 0.4; 95%CI 0.2–0.8; p=0.005). The association remained significant after adjustment (p=0.002). The analyzed proteins did not correlate with the survival probability of HD patients.

Conclusions: *ANGPLT8* rs737337, *IGFBP3* rs3110697, *FOXO3* rs2802292, and rs4946936 are prognostic factors of survival among HD patients.

PO1042

Short-Term Association of Pre-Dialysis Calculated Serum Osmolality and Its Per-Quarter Change with Mortality in Maintenance Hemodialysis Patients

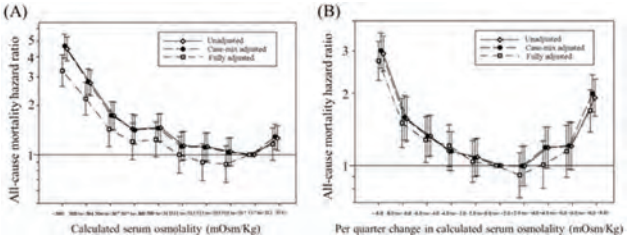
Tsuyoshi Miyagi,[1] Cachet Wenziger,[1] Jui-Ting Hsiung,[1] Yoko Narasaki,[1] Yoshikazu Miyasato,[1] Hiroshi Kimura,[1] Kunitoshi Iseki,[2] Ekamol Tantisattamo,[1] Connie Rhee,[1] Elani Streja,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Ryukyu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Nakagami-gun, Japan.*

Background: Homeostatic regulation of serum osmolality (SOsm) is critical for normal cellular function. Since kidney plays an important role in maintaining homeostasis, patients with kidney dysfunction might be unable to maintain homeostasis. However, it is unknown if SOsm can predict risk of mortality in maintenance hemodialysis (HD) patients.

Methods: We identified 16,402 patients who transitioned to maintenance HD in a large U.S. dialysis organization over 5 years (2007-2011) and had available calculated pre-dialysis SOsm (Sodium and Potassium and blood urea nitrogen (BUN) and Glucose) at baseline. We used the equation with the best fit between measured and calculated SOsm as follows: 2x([Na, in mmol/L]+[K, in mmol/L])+[Glucose, in mg/dL]/18+[BUN in mg/dL]/2.8. We divided the patients into ten groups based on their calculated SOsm (SOsm updated at quarterly intervals as a proxy of short-term exposure): <300, 300–<304, 304–<307, 307–<309, 309–<311, 311–<313, 313–<315, 315–<317, 317–<321 (reference group) and ≥321 mOsm/Kg, and calculated SOsm's per quarter change from the date of first dialysis: <-8.0, -8.0–<-6.0, -6.0–<-4.0, -4.0–<-2.0, -2.0–<0, 0–<+2.0 (reference group), +2.0–<+4.0, +4.0–<+6.0, +6.0–<+8.0and ≥+8.0 mOsm/Kg. All-cause mortality risk was estimated using multivariable Cox models.

Results: The patients were 56% male, 48% non-white, and the mean age was 63 ± 13 (mean ± SD) years. Those with low calculated SOsm tended to be older. In time-varying analysis, the association between all-cause mortality showed that patients with the lowest calculated SOsm had the highest hazard ratio after fully adjusted (Figure A). We observed a U-shaped association between all-cause mortality and per quarter change in calculated SOsm such that SOsm change levels ±8.0 mOsm/Kg were associated with higher mortality risk (Figure B).

Conclusions: This result suggests that short-term and a wide range of changes in serum osmolality may increase the risk of all-cause mortality in hemodialysis patients.



PO1043

Survival Differences Among ESRD Patients in the Mainland United States, Hawaii, and Pacific Islands

Connie Rhee,[1] Amy S. You,[1] Keith C. Norris,[2] Merle R. Kataoka-Yahiro,[3] James Davis,[4] Glen Hayashida,[5] Victoria Page,[5] Shiuh-Feng Cheng,[4] Roland C. Ng,[4] Linda L. Wong,[4] Kamyar Kalantar-Zadeh.[1] *[1]University of California Irvine, Irvine, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]University of Hawaii Manoa, Honolulu, HI; [4]John A. Burns School of Medicine, Honolulu, HI; [5]National Kidney Foundation Hawaii, Honolulu, HI.*

Background: Asians and Native Hawaiians and other Pacific Islanders (NHOPIs) are collectively the fastest growing racial minorities in the US. While certain Asian subgroups and NHOPIs have a high prevalence of kidney disease risk factors, there are sparse data

examining ESRD outcomes in these populations. As Hawaii is among the states with the highest representation of Asians and NHOPIs, we compared ESRD survival among Asians, NHOPIs, and other racial groups residing in the Mainland US vs. Hawaii and the Pacific Islands.

Methods: Using United States Renal Data System (USRDS) data, we examined the impact of geographic residence in the Mainland US vs. Hawaii and the Pacific Islands on associations of race and mortality among incident ESRD patients who transitioned to dialysis over 2010-16. HRs for all-cause mortality were estimated using Cox models adjusted for sociodemographics, comorbidities, dialysis characteristics, pre-ESRD nephrology care, BMI, laboratory tests, and medications.

Results: Compared with White incident ESRD patients residing in the Mainland US, Asians and NHOPIs in the Mainland US had lower mortality risk: HRs (HRs) (95%CIs) 0.67 (0.66-0.67) and 0.72 (0.70-0.73), respectively. When examining Asians and NHOPIs residing in Hawaii and the Pacific Islands, survival benefit was attenuated in Asians and was diminished to the null in NHOPIs (ref: White incident ESRD patients in Mainland US): HRs (95%CIs) 0.77 (0.74-0.79) and 1.00 (0.96-1.03), respectively.

Conclusions: In the Mainland US, Asians and NHOPIs had lower mortality risk compared with Whites. However, in Hawaii and the Pacific Islands, this survival benefit was diminished in Asians and was mitigated in NHOPIs. Further studies are needed to determine the factors contributing to the differential ESRD mortality risk across racial groups residing in the Mainland US vs. Hawaii and the Pacific Islands.

Association of All-Cause Mortality with Pre-Hemodialysis Pulse Pressure in Chronic Hemodialysis Patients

Hanjie Zhang,[1] Alhaji Cherif,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Pulse pressure (PP) reports cardiac and vascular conditions, where high PP values are associated with atrial fibrillation, aortic insufficiency, arterial stiffness, low PP values may be associated with aortic valve stenosis, cardiac insufficiency. However, the association of pre-hemodialysis (pre-HD) PP with mortality among hemodialysis patients is not well understood. In this study, we aim to explore the extent to which PP is associated with mortality.

Methods: We analyzed pre-HD PP (calculated as pre-HD SBP minus pre-HD DBP) between 1/2001 and 12/2012 in hemodialysis patients treated in U.S. Fresenius Medical Care facilities. A 3-months baseline period was defined as months 4 to 6 after hemodialysis initiation, all-cause mortality was noted during follow-up. Only patients who survived baseline were included. Censoring events were renal transplantation, modality change, or study end. We built Cox proportional hazards models with spline terms, allowing us to model nonlinear effects of pre-HD PP as a continuous variable and its relationship with all-cause mortality.

Results: We included 152,625 patients. Mean age was 60.8 years, 59% were white and 56% were male. During a median follow-up of 26.0 months 40.4% patients died. We found that for patients with pre-HD PP between 49.2 mmHg and 74.7 mmHg, were associated with better survival. In contrast, a PP below 49.2 mmHg and above 74.7 mmHg were associated with higher mortality. Similar nonlinear effects are seen in SBP for a given pre-HD PP value (see Fig. 1). Figure 1: Association between pre-HD pulse pressure and all-cause mortality. HRs (solid line) and 95% CIs (dashed lines) of pre-HD pulse pressure. The tick marks on the x-axis represents individual patients.

Conclusions: The association of pre-HD PP with mortality is nonlinear, a better understanding will provide further insights into disentangling the associated mediators affecting its dynamics. Our findings may aid risk stratification.

PO1045

Risk Factors and Mortality in Dialysis Patients with Abdominal Aortic Aneurysm

Di Xia, Daniel F. Linder, Jennifer L. Waller, Wendy B. Bollag, Azeem A. Mohammed, Sandeep A. Padala, N. Stanley Nahman, Mufaddal Kheda, Stephanie L. Baer, Varsha S. Taskar, Neal Weintraub, Budder Siddiqui. *Augusta University, Augusta, GA.*

Background: In the general population, abdominal aortic aneurysm (AAA) is associated with increased mortality. Once diagnosed, AAA can be followed noninvasively or corrected surgically. Vascular disease is common in dialysis patients, but there is limited information on the incidence and outcomes for AAA in this population. To address this question, we queried the United States Renal Data System (USRDS) for risk factors associated with diagnosis of AAA, survival of patients diagnosed with AAA, and overall risk factors for mortality.

Methods: Incident dialysis patients from 2005–2014 from the USRDS were queried. ICD-9 and ICD-10 codes were used to define a diagnosis of AAA and identify clinical co-morbidities. Cox proportional hazards (CPH) modeling was used to determine the adjusted hazard ratio (aHR) and 95% confidence intervals (CI) for death.

Results: From a total cohort of 868,799, we identified 22,121 subjects with a diagnosis of AAA. When compared to patients without the diagnosis, AAA patients were older and had higher percentages of white race, male gender, tobacco use, Charleson comorbidity index (CCI), and hypertension as end stage renal disease (ESRD) etiology, but lower percentages of diabetes as ESRD etiology. A bivariate CPH model of survival showed that AAA patients had significantly increased mortality compared to patients without a AAA diagnosis (HR=1.29, p-value<0.0001). However, in the final CPH model, patients with a AAA diagnosis had a decreased risk of mortality (aHR=0.85, 95% CI 0.844–0.860), after controlling for age, CCI, and other demographic and comorbid variables.

Conclusions: ESRD patients with a diagnosis of AAA are more likely to be older, white, male, smokers with hypertension as the cause of ESRD. Patients with AAA are less likely to have diabetes as an etiology of ESRD. AAA is associated with a decreased risk of death, which suggests that AAA in the ESRD population by itself may not increase mortality, but the comorbid factors that come with it do.

PO1046

Composite Comorbidity Scoring System to Predict Mortality in a Saudi Dialysis Population

Ezzedine Abderrahim, Ayman S. Moussa, Afef Dridi, Ibrahim A. Jubran, Saad S. Alobaili, Salwa I. AlAhmadi, Wisam H. Al-Badr. *DaVita Saudi Arabia, Riyadh, Saudi Arabia.*

Background: Most uremic patients starting hemodialysis (HD) have multiple comorbidities, resulting in a high risk of mortality. Our aim was to establish and evaluate a personal scoring system in which we included associated comorbidities, age and, other HD related factors known to predict mortality.

Methods: All patients referred to DaVita-KSA, from October 2014 to December 2019, to continue hemodialysis therapy, were included in this analysis. Cox proportional hazards model was used to identify factors influencing all-cause mortality. A personal scoring system was established based on the score assigned to each factor, according to its weight as predictor of death, judged on the value of the relative risk generated in the preliminary analysis. An index of co-morbidity was calculated for each patient that corresponded to the sum of scores assigned to each factor. Patients were divided into 4 groups according to percentile rank of their comorbidity index (Group1: low risk, Group 2: moderate, Group 3: high, Group 4: very high) and compared in terms of global and annual mortality rates and survival using Log rank analysis

Results: 3983 patients (2177 males, 55%) were included with a mean age of 52.5± 16.8 years. Diabetic and hypertensive nephropathies accounted for 78.1 % of all causes of ESRD. After a cumulative follow-up period of 7635 years, 15.3% of patients were transferred to other facilities, 8.7% were transplanted and 14.5% were deceased.

Conclusions: This new scoring system appears to be easily established at our clinics and may constitute a good predictor for all-cause mortality in our HD population.

The mortality parameters in the study groups

Mortality and Cost Track Yearly Changes in ESRD Quality Incentive Program Performance

Eric W. Young,[1,2] Zhechen Ding,[1] Alissa Kapke,[1] Yan Jin,[1] Delia Houseal,[3] Jeffrey Pearson,[1] Marc Turenne.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Centers for Medicare and Medicaid Services, Baltimore, MD.*

Background: Patients treated in dialysis facilities that receive payment reductions under the ESRD QIP experience higher mortality and cost (Medicare payments) during the same performance year. We asked whether these outcome measures track with yearly changes in the QIP payment reduction.

Methods: Mortality and cost per patient year were analyzed using claims files for dialysis patients enrolled in the traditional Medicare fee-for-service program for performance years 2010-2016.

Results: The table displays index-year mortality and cost (columns) according to the facility QIP payment reduction (PR) for the prior year (rows) and the direction of the change in QIP PR in the index-year (worse, unchanged, better). In almost all cases, mortality and cost were higher for patients in facilities that did worse in QIP and lower for patients in facilities that did better. For example, patients treated in dialysis facilities that received a 1.5% QIP PR in the prior year experienced 18.7% mortality if the index-year PR was unchanged, 16.9% mortality if the index-year PR was lower (≤1%) and 24.5% mortality if the index-year PR was higher (2%).

Conclusions: Patient mortality and average Medicare payments track with changes in facility QIP PRs. The finding suggests that facility efforts to improve QIP performance may translate into improved mortality and lower costs to Medicare. Moreover, it is unlikely that the observed association between outcome measures and QIP is attributable to unmeasured patient case-mix, which tends to be relatively stable from year to year. The findings suggest that the ESRD QIP captures meaningful aspects of quality and value.

Funding: Other U.S. Government Support

Prior Year QIP Payment Reduction (PR)	Mortality, by Change in QIP PR			Medicare Payment, by Change in QIP PR		
	Worse	Unchanged	Better	Worse	Unchanged	Better
0.0%	16.8%	15.6%	n.a.	$79,971	$76,227	n.a.
0.5%	17.1%	16.6%	16.1%	$81,864	$81,334	$78,384
1.0%	21.2%	16.3%	16.4%	$91,018	$75,786	$79,187
1.5%	24.5%	18.7%	16.9%	$91,816	$85,555	$81,323
2.0%	n.a.	24.6%	19.7%	n.a.	$98,216	$83,937

PO1048

Comparison of ESRD Quality Incentive Program (QIP) Performance and Dialysis Facility Compare (DFC) Star Rating

Alissa Kapke,[1] Zhechen Ding,[1] Claudia Dahlerus,[2] J. M. Messana,[2] Delia Houseal,[3] Jesse Roach,[3] Marc Turenne.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Nephrology Division, Michigan Medicine, Ann Arbor, MI; [3]Centers for Medicare and Medicaid Services, Baltimore, MD.*

Background: The DFC quality of patient care star rating system reached its 5-year mark in 2020 and the ESRD QIP surpassed its 10-year mark. Both programs have undergone considerable changes in a continuing effort to help patients make informed decisions when selecting a provider while also incentivizing high quality care. We assessed whether ESRD QIP scores and payment reductions aligned with facilities' star ratings in calendar year (CY) 2018.

Methods: Payment year (PY) 2020 QIP scores and payment reductions (PR) and CY 2018 star ratings (1-5 stars) were obtained from DFC public data files. Comparisons between the two programs were assessed with cross-tabulations of PR categories and star ratings and with t-tests comparing mean QIP Total Performance Scores (TPS) among adjacent PR and star rating levels.

Results: Facilities with higher PY 2020 QIP scores tended to receive higher star ratings. Among facilities with no PR (N=3,929), 79.4% received 4 or 5-stars and 91.7% of facilities with a 2% PR received 1 or 2-stars. The average facility TPS decreased by approximately 10 points with each decrease in star rating, with significant differences between all categories (Table 1).

Conclusions: The ESRD QIP and the star rating program have distinct goals which have led to differences in their design and methodology, such as the use of the small facility adjuster in the ESRD QIP and non-overlapping measures between the two programs. Nevertheless, there is strong overall correspondence between the two programs in their assessments of facility quality of care. These results are reassuring, in that QIP scores and star ratings are providing a consistent message about dialysis facility quality of care in most cases.

Funding: Other U.S. Government Support

Table 1. Mean TPS by PY 2020 QIP Payment Reduction and CY 2018 5-star Rating (N=6,703)

QIP PR	Facility %	Mean TPS (SD)	Star Rating	Facility %	Mean TPS (SD)
0.0%	58.6%	70.8* (8.7)	5	27.6%	74.3* (9.8)

PO1049

Comparison of 5-Year Survival Rate Between Hemodialysis and Peritoneal Dialysis Patients: A Prospective Cohort Study with Propensity Score Matching

Mami Miyazaki,[1] Shigehiro Doi,[1] Ayumu Nakashima,[1] Toshiki Doi,[2] Takao Masaki.[1] *[1]Hiroshima Daigaku Byoin, Hiroshima, Japan; [2]Harada Hospital, Hiroshima, Japan.*

Background: Chronic Kidney Disease patients who require dialysis have increased worldwide. However, whether hemodialysis (HD) or peritoneal dialysis (PD) independently affects prognosis is still controversial.

Methods: A multicenter prospective observational study was conducted from 1 January 2012 to 31 March 2018. Total of 646 HD patients and 72 PD patients were enrolled from Hiroshima Chronic kidney disease outcomes cohort study (Hi-COCS) in Japan. We excluded patients whose follow-up period was less than 3 months. One to one propensity score matching was performed to compare the survival rates between HD and PD patients and to find the factors that would affect prognosis.

Results: Of 621 HD patients and 71 PD patients, the mean average age was 74.2±12.5, 49.7% patients had DM, and 19.2% patients had CVD. The median follow-up period was 41 months. Total of 130 patients were selected with 1:1 propensity score matching (65 HD patients and 65 PD patients). In the PS matched cohort, there was no difference between the two groups in the 5-year survival rates of the overall events. (HD 71.2% vs PD 71.2%, respectively, $P = 0.97$) PD group had better survival rate of CVD events and it was significantly different between the two groups ($P = 0.043$). Multivariate Cox proportional hazard model showed that adjusted hazard ratio (HR) of overall events and CVD events were 1.06 (95% confidence interval (CI); 0.53-2.10, $P = 0.96$) and 4.90 (95% CI 1.37-23.8, $P = 0.014$), respectively. Age, non-HDL cholesterol and CRP were associated with prognosis in overall events. Only non-HDL cholesterol was associated with prognosis in CVD events.

Conclusions: In this study, we found out that 5-year survival rate was not significantly different between the HD and PD patients in overall events. However, PD group had better survival rate of CVD events than that of HD patients. It suggests that PD may potentially have treatment advantage for patients who have high risk factors of CVD events.

PO1050

Effects of Dialysate Magnesium Concentrations on Mortality: Results from the MONDO Initiative

Gero D. von Gersdorff,[3] Katherine G. Rascher,[3] Adrian M. Guinsburg,[2] Jochen G. Raimann,[1] Xiaoling Ye,[1] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care AG und Co KGaA, Buenos Aires, Argentina; [3]University Hospital, Cologne, Cologne, Germany.*

Background: Dialysate magnesium (DMg) is known to be positively associated with serum Mg levels in hemodialysis (HD) patients (pts). We aimed to study the associations between different DMg levels and mortality in HD pts.

Methods: We conducted a retrospective cohort study to examined the associations of different DMg levels (1.0, 1.5, or 2.0 mEq/L) and all-cause mortality. In-center HD pts treated in KfH and MONDO with constant DMg levels during their first year of observation were studied. The primary outcome variable was a 1-year mortality risk. In a second step, we used 1:1 propensity score matching (based on age, gender, catheter, and vintage) to create 4 matching groups: 1)DMg 1.0 versus 1.5 mEq/L (KfH and MONDO), 2)DMg 1.5 versus 2.0 mEq/L (only KfH), 3)1.0 versus 2.0 mEq/L (only KfH). The associations between different DMg levels and mortality after matching were evaluated by Cox proportional hazards models, Kaplan Meier survival curves, and the Log Rank test, respectively.

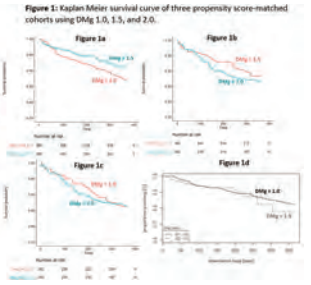
Results: We studied 32,117 pts from KfH [69 years, 64% males, 42% diabetics, 48% catheter; DMg 1.0: 31,460 (98%), DMg 1.5: 395 (1%) and DMg 2.0: 262 (1%)]; 15,211 pts from MONDO [57 years, 58% males, 41% diabetics, 24% catheter; DMg 0.75: 2,481

(16%), DMg 1.0: 12,508 (82%) and DMg 1.5: 222 (1%)]. Propensity score-matching created 4 well-balanced cohorts with DMg of 1.0 v.s. 1.5(KfH and MONDO), DMg 1.5 v.s. 2.0 and 1.0 v.s. 2.0 (KfH), respectively. Survival analysis show that DMg 1.5 is not statistically associated with survival benefits compared to 1.0 in both data sets (Table 1, Figure 1 a, d). In addition, compared to both DMg 1.0 and 1.5, we do not observe a survival benefit of DMg 2.0 in KfH's data (Table 1, Figure 1b, c).

Conclusions: Increased DMg was not associated with a survival benefit in either the KfH or MONDO datasets. One of the limitations is the lack of detailed dialysate information. Further studies directly addressing the association between serum Mg and DMg are needed to further delineate the complex relationship between DMg and patient outcomes.

Table1: Hazard Ratio of comparing different DMg groups in KfH [after matching]

	HR	95% CI	P-value
DMg 1.5 vs. 1.0	0.68	(0.44, 1.0)	0.08
DMg 2.0 vs. 1.0	1.00	(0.63, 1.60)	0.93
DMg 2.0 vs. 1.5	1.20	(0.74, 2.00)	0.44



PO1051

Risk of Hypokalemia in Hyperkalemic Hemodialysis Patients

Steven Fishbane,[1] Martin L. Ford,[2] Masafumi Fukagawa,[3] Kieran Mccafferty,[4] Anjay Rastogi,[5] Bruce S. Spinowitz,[6] Konstantin Staroselskiy,[7] Konstantin Vishnevskiy,[8] Vera Lisovskaja,[9] Ayman Al-shurbaji,[9] Nicolas J. Guzman,[10] Sunil Bhandari.[11] *[1]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]King's College Hospital Trust, London, United Kingdom; [3]Tokai University School of Medicine, Isehara, Japan; [4]Barts Health NHS Trust, London, United Kingdom; [5]David Geffen School of Medicine, Los Angeles, CA; [6]NewYork-Presbyterian Queens, Queens, NY; [7]B. Braun Avitum Russland Clinics, St Petersburg, Russian Federation; [8]First Pavlov State Medical University of St Petersburg, St Petersburg, Russian Federation; [9]AstraZeneca BioPharmaceuticals Research and Development, Gothenburg, Sweden; [10]AstraZeneca BioPharmaceuticals Research and Development, Gaithersburg, MD; [11]Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom.*

Background: Combined pre- and post-dialysis hypokalemia is associated with increased mortality risk. The Phase 3b DIALIZE study (NCT03303521) showed that sodium zirconium cyclosilicate (SZC) reduces pre-dialysis serum potassium (sK^+) and is well tolerated in hemodialysis patients (pts) with hyperkalemia. In this *post-hoc* safety analysis of DIALIZE, we report hypokalemia events in the SZC and placebo (PBO) arms.

Methods: In DIALIZE, 196 pts were randomized blindly 1:1 to receive PBO (n=99) or SZC (n=97) 5 g starting dose once daily on non-dialysis days (4 days/week [wk]) for 8 wks, comprising a 4-wk SZC or PBO dose-titration phase (max 15 g) to achieve target pre-dialysis sK^+ 4.0–5.0 mmol/L, and a 4-wk stable-dose evaluation phase. In this *post-hoc* analysis, the proportions of pts with hypokalemia (sK^+ <3.5 mmol/L) pre-dialysis, post-dialysis, and combined pre- and post-dialysis at the same visit were tabulated by visit. Pts' current pre-dialysis sK^+ stratified by post-dialysis sK^+ (≥3.5 vs <3.5 mmol/L) at the previous visit was also assessed.

Results: The frequency of pre-dialysis hypokalemia was comparable between SZC and PBO, with 5 pts in each arm accounting for 7 and 5 events, respectively. The proportion of pts with post-dialysis hypokalemia at each visit was greater with SZC than PBO. For all but 2 SZC pts with post-dialysis hypokalemia, pre-dialysis sK^+ returned to ≥3.5 mmol/L at the next visit (**Figure**). In each arm, 1 pt had combined pre- and post-dialysis hypokalemia.

Conclusions: Despite the efficacy of SZC in lowering pre-dialysis sK^+, SZC was not associated with a clinically significant increase in the frequency of pre-dialysis hypokalemia. Treatment with SZC vs PBO did not increase the frequency of combined pre- and post-dialysis hypokalemia which is associated with increased mortality risk.

Electrolyte Changes in Contemporary Hemodialysis: An Analysis of the Monitoring in Dialysis (MiD) Study

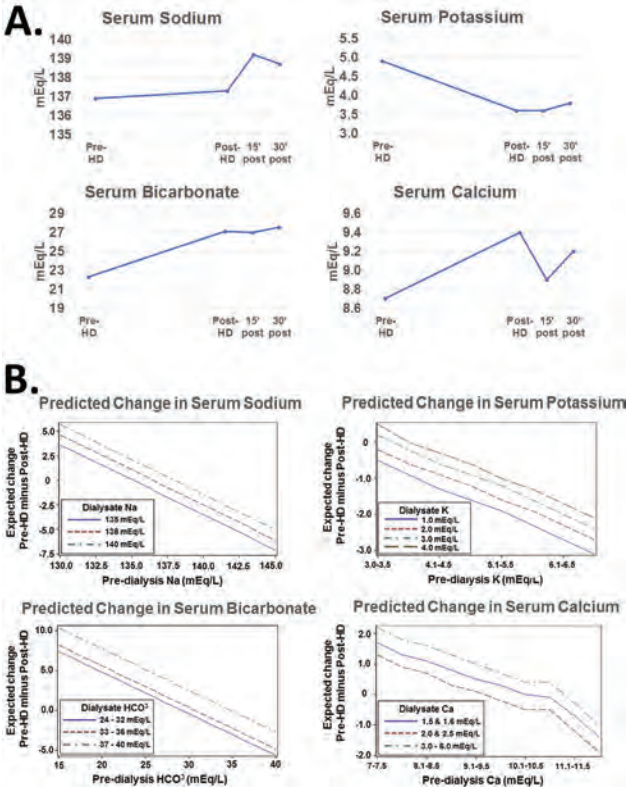
Simon Correa,[1,2] Katherine M. Scovner,[1,2] James A. Tumlin,[5] Prabir Roy-Chaudhury,[4] Finnian R. McCausland,[1,2] David M. Charytan.[3] Monitoring in Dialysis Study Group *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]New York University School of Medicine and NYU Langone Medical Center, New York, NY; [4]UNC Kidney Center, Chapel Hill, NC and WG (Bill) Hefner VA Medical Center, Salisbury, NC; [5]NephroNet Clinical Research Consortium, Atlanta, GA.*

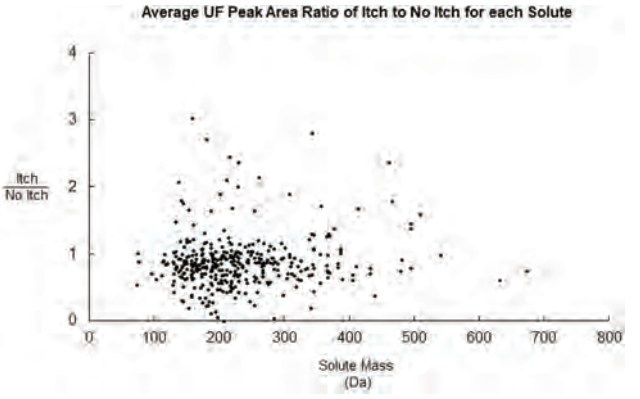
Background: There is a paucity of data examining electrolyte concentrations during and immediately after hemodialysis (HD) sessions. We describe these changes and provide predictive nomograms based on HD prescriptions and pre-HD electrolytes.

Methods: We leveraged patient (n=66) and HD session-level pre- and post-HD laboratory data (n=1,713) from the Monitoring in Dialysis study and fit mixed effects regression models to analyze differences between pre-, 15-minutes post-, and 30-minutes post-HD levels (compared with immediately post-HD) of electrolytes, blood urea nitrogen, creatinine, and albumin as well as the association of post-HD values with dialysate prescriptions.

Results: Serum bicarbonate, calcium, and albumin increased (mean increase 4.9mEq/L±0.3, 0.7mEq/L±0.1, and 0.4g/dL±0.03, respectively), and potassium, magnesium, and phosphorus decreased immediately post-HD (mean -1.2mEq/L±0.1, -0.3mEq/L±0.03, and -3.0mg/dL±0.2, respectively). Hypokalemia and hypophosphatemia were present in 34% and 67% of immediately post-HD samples, respectively. Changes were observed in electrolyte concentrations at 15- and 30-minutes post-HD compared to immediately post-HD (Fig. A: observed changes; Fig. B: predictive nomograms of post-HD electrolytes).

Conclusions: Contemporary HD results in marked changes in electrolyte concentrations during and after the treatment. We report a high frequency of post-HD hypokalemia and hypophosphatemia and present predictive nomograms relating post-HD changes to dialysate prescriptions. Whether the abnormalities observed in potassium and phosphorus post-HD predispose to adverse symptoms and arrhythmia is unclear and requires further research.





PO1053

Metabolomic Analysis Fails to Identify Uremic Solutes Associated with Pruritus in Hemodialysis Patients

Christian G. Bolanos,[1,2] Nhat M. Pham,[3,1] Margaret R. Stedman,[1] Timothy W. Meyer,[1,2] Tammy L. Sirich.[1,2] *[1]Stanford University, Stanford, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA; [3]Santa Clara Valley Medical Center, San Jose, CA.*

Background: Uremic pruritus is a debilitating symptom in hemodialysis (HD) patients. That uremic solutes contribute to pruritus is suggested by the improvement after transplantation. We aimed to identify solutes associated with pruritus using metabolomic analysis comparing plasma of HD patients with severe pruritus and mild/no pruritus.

Methods: Plasma and ultrafiltrate (UF) samples from 12 HD patients with severe pruritus (Itch) and 24 HD patients with mild/no pruritus (No Itch) were analyzed. Pruritus was assessed using a 100-mm visual analogue scale with severe defined as >70 mm and mild/no defined as <10 mm. Plasma and UF were analyzed using a metabolomics platform (Metabolon Inc.). Solutes were first identified as uremic based on the finding of higher average peak areas in all 36 HD patients than in 16 controls with normal kidney function. Solutes were deemed uremic if their HD/control ratio was >4 in plasma and/or UF with a false discovery rate of <0.05. Peak areas of each solute in the Itch and No Itch HD patients were then compared to identify uremic solutes associated with pruritus.

Results: HD vintage, spKt/V_{urea}, and lab values were similar in both groups (Table). Metabolomic analysis identified 593 uremic solutes. No difference in the levels of these uremic solutes was found between the Itch and No Itch patients using a false discovery rate < 0.05 (Figure).

Conclusions: Metabolomic analysis did not reveal any uremic solutes associated with pruritus in HD patients. The role of uremic solutes in pruritus remains to be established.

PO1054

Combined Value of Geriatric Nutritional Risk Index, Body Composition, and Bone Mineral Density for Predicting Mortality of Hemodialysis Patients

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Toshiki Doi,[2,1] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Shigehiro Doi,[2] Takao Masaki.[2] Hiroshima University *[1]Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Hiroshima University Hospital, Hiroshima, Japan.*

Background: Prognostic utility of the geriatric nutritional risk index (GNRI) and the association between body mass index and bone mineral density (BMD) in hemodialysis (HD) patients are uncertain. We assessed the combined predictive value of GNRI, body composition, and BMD in HD patients.

Methods: Pre-dialysis laboratory data, same-day post-dialysis body composition parameters by the Body Composition Monitor (Fresenius), and radius, lumbar spine, and femoral bone mineral density (BMD) using dual energy X-ray absorptiometry were assessed in HD patients at baseline. The data were compared according to GNRI tertiles (T). Logistic regression analysis was used to assess GNRI T1. Kaplan-Meier survival and Cox proportional hazard analyses were conducted. Comparison of multiple receiver operating characteristic curves was performed to assess whether mortality prediction accuracy improved after adding GNRI, body composition, and BMD to established risk factors.

Results: Among 264 patients (male: 65%, diabetes: 42%), mean age was 65±12 years and the median dialysis vintage was 79 (39–144) months. GNR T1, T2, T3 were 88 (85–91), 94 (93–95), 98 (97–101), respectively. GNRI T1 patients showed older age, lower male frequency, and lower serum albumin, body cell mass index (BCMI), lean tissue index, fat tissue index (FTI), lumbar spine, femoral neck, and right distal mid-third radius BMD, but higher overhydration/extracellular fluid than patients with GNRI T2 or T3 (P<0.05). FTI (OR: 0.88), femoral neck BMD (OR: 0.05), age (OR: 1.03), C-reactive protein (OR: 1.37) and hemoglobin (OR: 0.70) were significant predictors of GNRI T1 (P<0.05). Patients with GNRI T1 showed significantly lower 2-year survival and GNRI T was significant predictor for 2-year all-cause mortality [Hazard ratio (T1-2): 2.07 (0.56-9.83), (T1-3): 8.59e+9 (2.45-3.39e+37), P<0.05]. Area-under-the curve for all-cause mortality using established risk factors (age, sex, diabetes, serum phosphate) was 0.66, improving to 0.79 by adding GNRI alone or to 0.81 by adding GNRI, FTI, and femoral neck BMD (P<0.05).

Conclusions: Associations of GNRI, body composition, and BMD were confirmed in HD patients. Combining GNRI, body composition, and BMD to established risk factors improved mortality prediction in HD patients.

PO1055

Predicting Intradialytic Hypotension with Continuous Hemodynamic Monitoring Throughout Hemodialysis

David F. Keane,[1,2] Jochen G. Raimann,[2] Hanjie Zhang,[2] Stephan Thijssen,[2] Joanna Willetts,[3] Peter Kotanko.[2] *[1]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [2]Renal Research Institute, New York, NY; [3]Fresenius Medical Care Global Medical Affairs, Waltham, MA.*

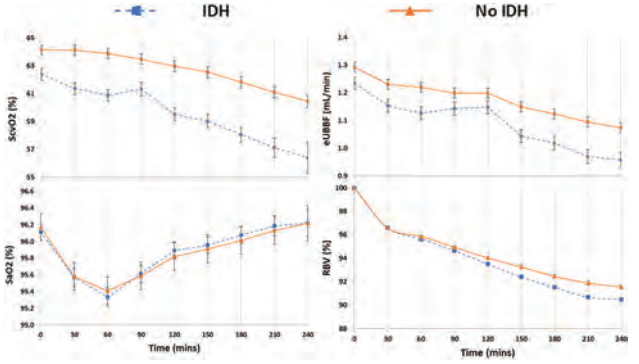
Background: Intradialytic hypotension (IDH) remains one of the most common complications associated with hemodialysis (HD). The CritLine Monitor (CLM) measures relative blood volume (RBV) and blood oxygen saturation (O_2Sat), but uncertainties remain in application of these parameters for predicting IDH. We looked at differences in CLM parameters based on whether an IDH episode was imminent or not as a function of time into a HD session to investigate whether their prognostic ability is dependent on the time into HD.

Methods: We studied routinely collected data from 17 US dialysis clinics. IDH was defined by systolic blood pressure (SBP) below 90 mmHg. The CLM directly measures RBV and O_2Sat, interpreted as arterial O_2Sat (SaO_2) for all sessions with a fistula or graft and as central venous oxygen saturation ($ScvO_2$) for those with a central venous catheter. For sessions with $ScvO_2$, we also calculated estimated upper body blood flow (eUBBF). We extracted each parameter every 30 minutes through each treatment. We compared

variables dependent on whether IDH occurred in the subsequent 30 minutes. Separate linear mixed effects regression models were used at each timepoint, with each CLM parameter as the dependent variable, IDH status as a dummy-coded predictor and subject as a random effect to account for repeated measures on individuals.

Results: We studied 2,791 patients and 197,526 sessions, 160,094 (81%) with SaO_2 and 37,432 (19%) with $ScvO_2$ data. IDH occurred in 13% of sessions. RBV was not different in the first 90 minutes for patients approaching IDH compared to those who were not, but was lower thereafter. Differences between the groups were observed throughout HD for $ScvO_2$ and eUBBF, but not SaO_2.

Conclusions: The ability for RBV to predict IDH depends on the time of onset. $ScvO_2$ and eUBBF better predict IDH than SaO_2, reflecting the dependence of $ScvO_2$ on cardiac output while SaO_2 more reflects pulmonary function.



Time course of CLM parameters based on whether IDH will occur in the following 30 mins or not

PO1056

Time of Hemodialysis and Risk of Intradialytic Hypotension and Intradialytic Hypertension

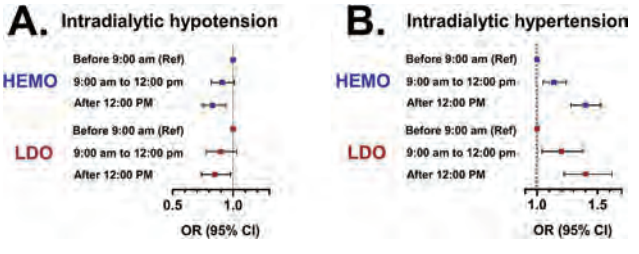
Murad Alostaz,[1,2] Simon Correa,[2,3] Sushrut S. Waikar,[4] Finnian R. McCausland.[2,3] *[1]University of California Los Angeles, Los Angeles, CA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Boston Medical Center, Boston, MA.*

Background: Blood pressure (BP) fluctuates throughout the day following a circadian pattern. BP control is of utmost importance in patients with ESRD undergoing hemodialysis (HD), and both intradialytic hypotension (IDH) and intradialytic hypertension (HTN) are associated with adverse CV events and death. Whether the risk of IDH and intradialytic HTN varies according to the time of the day of the HD session is unknown.

Methods: Random effects logistic regression models examined the association of HD start time (before 9:00 am [timecat1], 9:00 am to 12:00 pm [timecat2], and after 12:00 PM [timecat3]) with IDH and intradialytic HTN among adults undergoing thrice-weekly maintenance HD (N= 1,938 patients/n=64,503 sessions from the Hemodialysis [HEMO] Study, and N=3,408 patients/n=33,590 from a contemporary large dialysis organization [LDO]). IDH was defined as nadir intra-HD SBP <90mmHg if pre-HD SBP <160mmHg or <100mmHg if pre-HD SBP ≥160mmHg, and intradialytic HTN was defined as any increase in post-HD SBP compared to pre-HD SBP. Models were adjusted for demographics, CV comorbidities, HD dose, HD flux, pre-HD BUN, pre-HD SBP, UFR, HD vintage and HD session length.

Results: Mean age was 58 years and 56% were female in HEMO; mean age was 63 years and 42% were female in LDO. Compared to timecat1, timecat2 and timecat3 were associated with with a 9% (aOR 0.91, 95% CI 0.82-1.01) and a 17% (aOR 0.83, 95% CI 0.75-0.94) lower risk of IDH in HEMO, respectively (Fig 1A). Conversely, compared to timecat1, a monotonic increase in the risk of intradialytic HTN was observed for timecat2 (aOR 1.14, 95% CI 1.05-1.24) and timecat3 (aOR 1.40, 95% CI 1.28-1.53) in HEMO (Fig1B). These findings were consistent in LDO (Fig 1).

Conclusions: In two diverse and large cohorts of HD, we observed a monotonic decrease in the risk of IDH and a monotonic increase in the risk of intradialytic HTN as HD start time progressed throughout the day. Whether HD treatment allocation to certain times of the day in hypotensive-prone or hypertensive-prone patients improves outcomes deserves further investigation.



PO1057

Association Between Pulse Pressure and Extracellular to Intracellular Water Ration in Hemodialysis Patients

Robert Ekart,[1,2] Gasper Keber,[2] Masa Knehtl,[1] Eva Jakopin,[1] Benjamin Dvoršak,[1] Radovan Hojs.[1,2] *[1]University Medical Center Maribor, Maribor, Slovenia; [2]Medical Faculty University of Maribor, Maribor, Slovenia.*

Background: Optimal fluid management is a challenge in patients with end-stage kidney disease (ESRD) on maintenance hemodialysis (HD). Multifrequency bioimpedance spectroscopy (MBIS) is a non-invasive method to estimate body composition, including estimates of extracellular water (ECW) and intracellular water (ICW) and the ratio between both spaces (ECW/ICW). Pulse pressure is a significant risk factor of cardiovascular disease and death in general and dialysis population. Our study aimed to analyse the correlation between systolic, diastolic and pulse pressure with body composition status in ESRD patients before HD.

Methods: We performed a retrospective single-centre cohort study in 93 HD patients. The body composition was measured using the portable whole-body MBIS device, Body Composition Monitor-BCM(®) (Fresenius Medical Care, Bad Homburg, Germany). Blood pressure was measured with OMRON monitors.

Results: The mean age of patients was 64 ± 13 years, mean dialysis vintage 63 (1-352) months, 61% were men, all patients had arteriovenous fistula as vascular access. Sixty-nine (74.2%) patients were fluid overload (FO) with > 1.1 L overhydration. Other data are presented in table 1. We found a statistically significant correlation between the pulse pressure and ECW/ICW ratio (r=0.258; P=0.033) in FO patients. In contrast, there was no significant correlation between systolic, diastolic blood pressure and ECW/ICW ratio in FO patients.

Conclusions: Only pulse pressure and not systolic or diastolic blood pressure values measured before HD are associated with ECW/ICW ratio in FO patients.

Descriptive data of the patients included in the study (N=93)

Variable	All patients (N=93) Mean ± SD	Fluid overload patients (N=69) Mean ± SD	NOT fluid overload patients (N=24) Mean ± SD	P value
Age (years)	64.3 ± 13	64.3 ± 13	64.1 ± 12	0.943
Dialysis vintage (months)	63.2 ± 64	65.8 ± 68	55.8 ± 49	0.509
Systolic blood pressure (mmHg)	151 ± 21	151 ± 22	149 ± 19	0.708
Diastolic blood pressure (mmHg)	78 ± 13	79 ± 13	75 ± 12	0.168
Pulse pressure (mmHg)	73 ± 21	72 ± 22	75 ± 21	0.654
MBIS: Extracellular water (ECW) (L)	18.1 ± 4.2	19.03 ± 4.2	15.4 ± 3.1	<0.0001
MBIS: Intracellular water (ICW) (L)	18.8 ± 4.4	19 ± 4.5	18.3 ± 4.4	0.527
MBIS: ECW/ICW	0.97 ± 0.14	1.01 ± 0.13	0.84 ± 0.1	<0.0001
MBIS: Overhydration (L)	2.14 ± 1.9	2.83 ± 1.6	0.16 ± 1	<0.0001

PO1058

Plasma Refill Rate: A Potential Hemodynamic Marker of Intradialytic Hypotension During Hemodialysis

Hao Wang,[1] Dan Negoianu,[1] Sabrina Rogg,[2,4] Hanjie Zhang,[2] Jesse Y. Hsu,[1] Peter Kotanko,[2,3] Jochen G. Raimann,[2] Laura M. Dember.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Fresenius Kabi AG, Bad Homburg, Germany.*

Background: Intradialytic hypotension (IDH) is difficult to predict. Continuous hematocrit monitoring (CHM) measures relative blood volume to provide non-invasive dynamic monitoring during hemodialysis (HD). We used CHM data with time-updated ultrafiltration rate (UFR) to estimate plasma refill rate (PRR), a potential mediator of hemodynamic status, and studied its relationship to IDH.

Methods: We used CHM performed at 17 Renal Research Institute HD units from 2017 to 2019 to calculate intradialytic PRR standardized to weight and height. We defined IDH as 1) systolic blood pressure (SBP) <90 mmHg and 2) a drop in SBP ≥20 mmHg or in mean arterial pressure ≥10 mmHg associated with symptoms. IDH-prone was defined as having >20% of treatments with IDH. Uni- and multivariable mixed-effects logistic regression were used to evaluate factors associated with low initial PRR (lower quartile) within the first 10 minutes of HD. Bi- and multinomial logistic regression were used to evaluate the relationship between initial PRR and IDH. Data are presented as mean±SD or aOR; 95% CI.

Results: We studied 2,637 patients (61±15 yrs, 57% male, 51% white) with 184,044 total treatments, interdialytic weight gain (IDWG) 2.1±1.4 kg, and UFR 9.5±4.6 ml/kg/h. IDH occurred in 13.7% and 15.8% of treatments by definitions 1 and 2, respectively. PRR (ml/kg/h) over all sessions was 5.0±8.8, 8.4±6.0, 7.9±7.2, and 7.4±11.4 at 10m, 1h, 2h, and 3h, respectively, with substantial variability at both patient and treatment levels. Older age, low BMI, female sex, black race, low albumin, and multimorbidity were associated with low initial PRR. Patients with low initial PRR were more likely to be IDH-prone by definition 1 (aOR 1.95; 1.01-3.72) and definition 2 (aOR 1.50; 0.87-2.56). Patients with low initial PRR were more likely than patients with high initial PRR to be IDH-prone by definition 1 (aOR 2.12; 1.50-2.74).

Conclusions: The dynamics of PRR vary during an HD session and has promise as a marker of hemodynamic instability. We found that several patient and treatment factors classically associated with IDH were also associated with low initial PRR, independent of

IDWG, SBP, and UFR, and that low PRR was associated with IDH. Further investigation into the predictive utility of PRR throughout HD may offer novel insights to extend the use of CHM.

PO1059

Hypoaldosteronism in Chronic Hemodialysis Patients Causes Intradialytic Hypotension and Is Improved with Fludrocortisone

Spencer Hodgins,[1] Bikash Chapagain,[1] Jyovani W. Joubert,[2] Brian H. Nathanson,[3] Daniel L. Landry,[1] Gregory L. Braden.[1] *[1]Baystate Health, Springfield, MA; [2]Kidney Care and Transplant Services of New England, Springfield, MA; [3]Optistatim LLC, Longmeadow, MA.*

Background: Intradialytic hypotension (IDH) affects up to 30% of chronic hemodialysis (CHD) pts and hypoaldosteronism (HA) is common in these pts. Aldosterone (aldo) exerts potent non-genomic hypertensive effects via its arterial aldo receptor & enhanced sympathetic nervous system activity.

Methods: We identified 11 consecutive CHD pts with severe IDH & normal cosyntropin stimulation tests that had HA. Mean PRA was 3.3 +/-7.7 ng/mL/hr & serum aldo was 2.9 +/- 1.6 ng/dL. All pts had failed low temperature dialysate, UF and Na modeling and maximum doses of midodrine. We studied pre & post HD SBP & DBP, number of episodes of systolic BP <100 & mean UF volume (Kg) for the 13 dialysis treatments pre fludrocortisone (FC), 1 month post FC & 6 months post FC. FC dose was 0.1 mg BID. The mean pt age was 69 +/- 11 years & dialysis duration was 5.1 +/- 2.3 years.

Results: The mean +/- SD pre & post HD SBP & DBP & the mean number of hypotensive episodes were significantly improved at 1 & 6 months post-FC (Table 1). No changes occurred in UF volume. 4 pts have remained on FC for 2 years or more without side effects and with sustained good results.

Conclusions: Refractory IDH is associated with HA in CHD pts. FC therapy decreases IDH episodes as well as improves pre & post SBP & DBP & can be used safely in CHD pts.

Table 1. Results for pre & post HD SBP & DBP, Hypotensive episodes & UF volume.

	Pre-FC	1 Month Post-FC	Month 6 Post-FC	P-value (with Box-Correction)
Pre-SBP mmHg	117.9 (20.5)	131.8 (16.3)	131.0 (19.6)	**<0.001**
Pre-DBP mmHg	64.9 (12.6)	71.7 (16.0)	70.0 (16.0)	**0.002**
Post SBP mmHg	106.0 (14.5)	122.6 (17.9)	114.9 (17.2)	**<0.001**
Post-DBP mmHg	58.0 (11.1)	65.2 (16.0)	60.4 (11.0)	**<0.001**
Number of Episodes SBP <100	2.9 (2.3)	1.0 (1.4)	1.4 (1.6)	**<0.001**

Feasibility and Benefits of Hemodialyzer Filtration of Contaminated Water in Poor Rural Communities in Ghana

Friedrich K. Port,[1,4] Jochen G. Raimann,[1,3] Joseph M. Boaheng,[1] Philip K. Narh,[1] Seth Johnson,[1,2] Linda L. Donald,[1] Hongbin Zhang,[3] Nathan W. Levin.[1,5] *[1]Easy Water for Everyone, New York, NY; [2]Renal Research Institute, New York, NY; [3]City University of New York, New York, NY; [4]University of Michigan, Ann Arbor, MI; [5]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Contaminated water supplies for drinking water are a source of health problems in poor communities. Hemodialyzers with a pore size of 0.003 micrometers have been known to be effective in preventing transfer of bacteria and most viruses. Our NGO, "Easy Water for Everyone," investigated prospectively the incidence of diarrhea, before and after implementation of water treatment utilizing reused hemodialyzers in poor villages lacking electricity and sanitation in Ghana.

Methods: Data were collected monthly regarding the incidence of diarrhea and death in households of 8 villages that have no electricity during February to November 2018. In 4 "study" villages the main source of drinking water (river), was processed after the first 5 (pre) months through a set of 8 hemodialyzers that produced purified water at ~250 L per hour. River water was pumped weekly into an elevated holding tank to be drawn by gravity through the dialyzers whenever the faucet was opened. Manual back flushes (4x/day) by trained villagers maintained high output of clean water. The same data collection in 4 "control" villages where the polluted water was not (yet) treated during the same 10 month period. We also assessed the function of the devices over ≥11 months of use in 9 villages.

Results: [1] Monthly rates of diarrhea in the study villages decreased from 18 to 5 per 100 villagers from the pre to the post period for a rate reduction by 72 % (rate ratio = 0.27). In the control group the average monthly rate during the same calendar months decreased by 23% (p >0.05) from the first to the second 5 months. After >11 months of daily filtration in 9 villages (population ~2000) none of the filters had to be replaced, suggesting that daily back-flush management prevented hemodialyzer clogging.

Conclusions: We demonstrated feasibility and success of sustaining a simple and efficient treatment of infected water for entire villages in absence of available electricity. The continuous function over >11 months indicates low cost of the device over time. The reduction in diarrhea from before to after initiation of the hemodialyzer filtration device is large. The simplicity of hemodialyzer filtration by gravitational feed, low cost and relative ease suggest wider application to other needy villages.

PO1061

Combining a Heparin-Grafted Dialyzer with a Citrate-Enriched Dialysate Offers Acceptable Dialysis Adequacy Avoiding Systemic Anticoagulation: Results of the Randomized Noninferiority Evocit Study

Karlien Francois,[1,2] Dieter De Clerck,[1,2] Annelies Tonnelier,[1,2] Marie-Laure Cambier,[1,2] Wilfried Cools,[1] Karl M. Wissing.[1,2] *[1]Vrije Universiteit Brussel, Brussels, Belgium; [2]Universitair Ziekenhuis Brussel Division of Nephrology and Hypertension, Brussels, Belgium.*

Background: The combined use of a heparin-grafted membrane with a citrate-enriched dialysate is a hemodialysis (HD) strategy with low circuit clotting rates while avoiding systemic anticoagulation. Its adequacy in comparison to HD using systemic anticoagulation is unknown.

Methods: Prevalent HD patients were recruited for a randomized crossover non-inferiority trial powered at >90% to detect a prespecified non-inferiority threshold of 10% $spKt/V_{urea}$ (NCT03887468). HD using a heparin-grafted dialyzer in combination with a 1.0 mmol/L citrate-enriched dialysate ("evocit") was compared to HD using a heparin-grafted dialyzer, systemic unfractionated heparin and bicarbonate-based dialysate ("evohep"). Each treatment arm lasted 4 weeks: 3x4hours HD/week with fixed blood and dialysate flow rates and midweek biological analyses.

Results: 26 patients received 617 HD sessions: 307 evocit and 310 evohep sessions. Mean $spKt/V_{urea}$ was 1.46±0.23 for evocit and 1.50±0.24 for evohep sessions (p=0.06). Mean of the paired difference in $spKt/V_{urea}$ was 0.04 with a 95%CI of -0.002 to 0.08, the upper bound of the estimate lying within the prespecified non-inferiority threshold (i.e. <0.15). Urea reduction rate (RR) was 71.5±5.5% vs 72.1±5.7% and bèta2microglobulin RR 37.4±8% vs 37.8±8% for evocit and evohep sessions. Processed blood volume was 75.4±3L vs 75.8±1.5L and online Kt was 47.3±5L vs 48.3±4L for all evocit and evohep sessions. Circuit thrombosis leading to premature treatment end occurred in 13/307 (4.2%) of evocit sessions (n=6), but in none of the evohep sessions (p=0.0002), with a median 36(20-46)min treatment time shortening without impact on effective treatment times overall (236±12 vs 238±4min for evocit vs evohep). Retransfusion failure occurred in 3/307 (0.98%) of evocit sessions and none of the evohep sessions (p=0.25).

Conclusions: HD avoiding systemic anticoagulation using a heparin-grafted dialyzer with a citrate-enriched dialysate offers recommended $spKt/V_{urea}$ dose and is not inferior to HD using systemic anticoagulation in terms of $spKt/V_{urea}$. Circuit clotting complications occurred at low rates during evocit sessions and did not have clinically significant repercussions on dialysis efficacy.

PO1062

Cinacalcet Use and the Risk of Gastrointestinal (GI) Bleeding Among Hemodialysis Subjects with Secondary Hyperparathyroidism (SHPT) in the Dialysis Outcome and Practice Patterns Study (DOPPS)

Gill Karminder, Tzu-Chieh Lin, Rohini Hernandez. *Amgen, Inc., Thousand Oaks, CA.*

Background: Cinacalcet is an oral calcimimetic for the treatment of SHPT in US adult hemodialysis (HD) patients. We conducted an observational study to evaluate the potential association between cinacalcet and fatal and non-fatal GI bleeding using data from DOPPS, an observational longitudinal data system of a random sample of patients from dialysis facilities in more than 20 countries.

Methods: The eligibility criteria for study cohort inclusion was individuals ≥18 years of age with ESRD receiving in-center hemodialysis at a DOPPS facility for a minimum of four months during calendar years 2009-2015, in the following countries: Australia, New Zealand, Canada, France, Germany, Italy, Spain, Sweden, Japan, the UK, and the US. Nested within the cohort, we conducted a matched case-control study (1:4 matching ratio) to estimate the association between cinacalcet use and GI bleeding events. We used risk-set sampling and matched on the following: (1) duration of follow-up (a same number of days), (2) time on dialysis (≤1 year, >1 year), (3) age (+/- 1 year), and (4) sex. Multivariable conditional logistic regression models were used to generate adjusted odds ratios (ORs) and 95% confidence intervals (CIs), accounting for baseline comorbidities.

Results: A total of 9,349 HD patients with SHPT met the eligibility criteria for the cohort study, 4,399 subjects from the United States and 4,950 subjects from countries outside the United States. We estimated the incidence rate of hospitalization or death due to GI bleeding (per 1,000 person-years [PYs]) in the US as 10.2 (95% CI: 7.9, 13.3); and 26.4 (95% CI: 23.5, 29.7) in countries outside the US. There was no association between cinacalcet exposure and GI bleeding (fatal or nonfatal events) in HD subjects with SHPT in US (adjusted OR: 0.68 [95% CI: 0.47, 1.00]) and ex-US (adjusted OR: 0.75 [95% CI: 0.50, 1.12]) populations.

Conclusions: Cinacalcet use was not associated with an increased risk of GI bleeding events among US and ex-US adult hemodialysis subjects with SHPT. The study results are broadly generalizable to adult subjects with ESRD receiving center-based hemodialysis in the US and selected countries outside the US.

Medium Cut-Off Dialyzer Improves Erythropoiesis-Stimulating Agent Resistance in a Hepcidin-Independent Manner in Maintenance Hemodialysis Patients

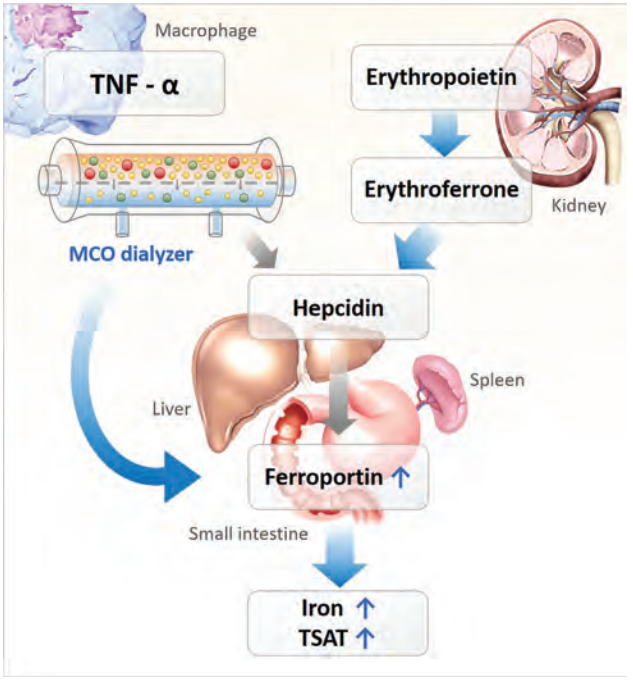
Jeong-Hoon Lim, Yong-Jin Kim, Hee-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jang-Hee Cho. *Kyungpook National University Hospital, Daegu, Republic of Korea.*

Background: The response to erythropoiesis stimulating agents (ESAs) is affected by inflammation linked to middle molecules in hemodialysis (HD) patients. We evaluated the effect of a medium cut-off (MCO) dialyzer on ESA resistance in maintenance HD patients.

Methods: Forty-nine patients who underwent high-flux HD were randomly allocated to the MCO or high-flux group. The primary outcome was the changes of erythropoietin resistance index (ERI; U/kg/wk/g/dL) between baseline and 12 weeks. The biomarkers associated with iron metabolism and inflammation at 12 weeks were compared between groups.

Results: The MCO group showed significant decrease in the ESA dose, weight-adjusted ESA dose, and ERI compared to the high-flux group at 12 weeks (all $p < 0.05$). In the MCO group, the ESA dose, weight-adjusted ESA dose, and ERI did not change until 8 weeks compared to those at baseline, but decreased significantly at 12 weeks (all $p < 0.01$). Serum iron and transferrin saturation were higher in the MCO group at 12 weeks (both $p < 0.05$). The MCO group showed a greater reduction in TNF-α and lower serum TNF-α level at 12 weeks compared to the high-flux group ($p = 0.025$ and $p = 0.027$), whereas no differences were found in the reduction ratio of hepcidin and serum levels of erythropoietin, erythroferrone, soluble transferrin receptor and hepcidin between groups.

Conclusions: HD with MCO dialyzer improves ESA resistance compared to high-flux HD in maintenance HD patients. The MCO dialyzer provides superior removal of the inflammatory cytokine such as TNF-α and thus improves iron metabolism in a hepcidin-independent manner.



The iron metabolism regulatory pathway Blue arrows indicate dominant effects.

PO1064

Recent Trends in Acute Care Admissions Among Medicare Beneficiaries Undergoing Dialysis

Eric D. Weinhandl,[1,2] Kristine Kubisiak,[1] Lorien S. Dalrymple.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Chronic Disease Research Group, Minneapolis, MN.*

Background: While the rate of hospital admissions has been a bedrock measure of morbidity among dialysis patients, patients today may receive acute care during a hospital admission, observation status, or an emergency department (ED) visit. There are no public reports summarizing the composite rate of these encounters among dialysis patients. We used claims data to estimate rates of acute care admissions in dialysis patients with Medicare fee-for-service coverage.

Methods: Using Medicare Limited Data Sets, we identified all patients with Medicare Part B claims documenting outpatient dialysis from January 2014 to December 2017. For each calendar week (Monday to Sunday), we identified patients with at least one outpatient dialysis session, who were alive at the end of the week, and who were not hospitalized at the last midnight of the week. We calculated the proportion of patients who were admitted to the hospital, observation status (with discharge to home), or an ED (with discharge to home) during the subsequent calendar week. From the time series of weekly admission risks, we fit an autoregressive integrated moving average model, both overall and within strata defined by concurrent enrollment in Medicaid.

Results: From 2014 to 2017, mean weekly incidence of acute care admission increased from 5.8% in 2014 to 6.0% in 2017 ($P < 0.01$ from test of secular trend), as displayed. The incidence of hospital admission was unchanged ($P = 0.35$), whereas the incidence of both observation status admissions and ED visits increased ($P < 0.01$). In 2017, 49% of acute care admission volume was attributed to observation status admissions and ED visits. In patients with Medicare coverage alone and patients with concurrent enrollment in Medicaid, mean weekly incidence of acute care admission increased to 5.2% and 6.9%, respectively, in 2017.

Conclusions: From 2014 to 2017, the incidence of acute care admission increased in dialysis patients with Medicare fee-for-service coverage, mostly because of increasing incidence of observation status admissions and ED visits.

PO1065

Poor Vitamin K Status Associates with Worse Clinical Outcome Independent of Coronary Artery Calcium and Aortic Valve Calcium in ESRD

Lu Dai,[1] Longkai Li,[1,2] Abdul Rashid T. Qureshi,[1] Jonaz Ripsweden,[3,4] Torkel B. Brismar,[3,4] Olof Heimburger,[1] Peter F. Barany,[1] Bengt Lindholm,[1] Leon J. Schurgers,[5] Peter Stenvinkel.[1] *[1]Division of Renal Medicine and Baxter Novum, Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [2]Department of Nephrology, First Affiliated Hospital of Dalian Medical University, Dalian, China; [3]Division of Medical Imaging and Technology, Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [4]Department of Radiology, Karolinska University Hospital, Huddinge, Stockholm, Sweden; [5]Department of Biochemistry, Cardiovascular Research School Maastricht, Maastricht University, Maastricht, Netherlands.*

Background: Patients with end-stage renal disease (ESRD) are at high risk of vitamin K deficiency and vascular calcification. The association between vitamin K status and vascular calcification is non-affirmative in clinical observations. We investigated the association of vitamin K status with all-cause mortality in ESRD and the modification effect of vascular calcification in this scenario.

Methods: We studied 493 stable ESRD patients (median age 55 years, 66% males) comprising non-dialysis patients (n=321), prevalent peritoneal dialysis (n=122) and hemodialysis patients (n=50). Plasma dephosphorylated-uncarboxylated matrix-Gla protein (dp-ucMGP), a circulating marker of vitamin K deficiency, and other relevant clinical and biochemical data were determined at baseline. A cohort of 553 controls (median 51 age years, 45% males) was referred to estimate vitamin K status in healthy subjects. Vascular calcification was estimated with coronary artery calcium (CAC, n=237) and aortic valve calcium (AVC, n=223) among ESRD patients undergoing cardiac computed tomography scan.

Results: Plasma dp-ucMGP (median 1445 pmol/L) levels were substantially elevated in ESRD patients compared to healthy subjects (median 376 pmol/L). During median 42 months' follow-up, 92 patients died (19%) and 128 patients (26%) underwent renal transplantation. 1-SD increase of dp-ucMGP associated with increased all-cause mortality (1.19 (1.01-1.40), sub-hazard ratio (95% confidence interval)), with adjustment for age, sex, presence of cardiovascular disease, diabetes, body mass index, inflammation, handgrip strength and dialysis. In subgroup analysis further adjusted for presence of CAC or AVC, dp-ucMGP remained as an independent risk factor of mortality (1.27 (1.03-1.56) and 1.36 (1.05-1.66), respectively). In multivariate linear regression model, increased dp-ucMGP levels were not associated with quantified calcification suggested by CAC ($p=0.11$, $R^2=0.30$) and AVC ($p=0.84$, $R^2= 0.12$).

Conclusions: Vitamin K deficiency is evident in ESRD and strongly associated with an increased risk of mortality which is not modified by the presence of vascular calcification. Plasma dp-ucMGP was not an independent risk factor of calcification quantified by CAC and AVC.

PO1066

Calcium Carbonate-Pre-Added Cheese to Improve Compliance, Nutrition, and Metabolic Balance of Patients on Renal Replacement Treatment

Gianluigi Ardissino,[1] Valentina Capone,[1] Elisabetta Margiotta,[2] Isabella Cropanese,[1] Francesca Raffiotta,[2] Giovanni Montini,[1] Piergiorgio Messa.[2] *[1]Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; [2]Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy.*

Background: Patients with chronic kidney disease have several dietary limitations that make their diet unappealing with detrimental consequences as adherence to prescriptions, malnutrition and overall poor quality of life. Cheese, an important component of the Western diet, has high phosphorus (P) content thus its consumption is generally restricted in patients on renal replacement therapy (RRT).

Methods: A special cheese was prepared by adding a fixed concentration of CaCO3 (5 gr/L) to cow milk prior to production procedures. The cheese was then provided to a cohort of patients on chronic RTT with the working hypothesis that while eating the modified cheese patients would have benefited from the phosphorus-binding effect of CaCO3. After a run-in period of 1 month, all patients were randomly assigned to receive standard cheese (SC) followed by modified cheese (FriP) or the opposite sequence in a double blind and cross-over fashion for 1 month for each product. The increase in inter-dialysis (48 hrs) P (DP) was regularly and repeatedly (n: 5) measured during each of the 2 periods. A washout period of 1 week was introduced between treatment periods.

Results: Twenty-one patients were enrolled and 16 successfully completed the 2 treatment periods. Drop outs were due to transplantation, COVID-19 infection or to documented non-adherence to the protocol. Observed mean (sd) DP were as follows: Run-in: 2.8 (0.7) mg/dL, SC: 2.8 (0.85) mg/dL, FriP 2.4 (0.61) mg/dL with the latter being significantly lower compared with both other periods. Pre-dialysis P was also lower with FriP compared with SC: 5.00 (1.00) vs 4.66 (0.91) while Pre-dialysis Ca was not diffent: 9.24 (0.73) vs 9.24 (0.63) with SC and FriP, respectively. All patients appreciated both products equally and the mean amount consumed per week was not different: SC: 307 gr vs FriP: 283 gr (p: 0.56). All patients reported a significant gratification by reintroducing cheese consumption in their diet.

Conclusions: In conclusion, FriP cheese may reduce dietary limitations of patients on RRT mith significant benefits on: malnutrition, adherence to P binders prescription and ultimately to quality of life.

PO1067

Efficacy of Double-Dose Influenza Vaccine with a Booster Compared with Standard Dose in Hemodialysis Patients: Randomized Controlled Trial

Ekapol Ritveeradej,[1] Kobporn Boonnak,[2] Suree Yoowannakul.[1] *[1]Bhumibol Adulyadej Hospital, Bangkok, Thailand; [2]Mahidol University Faculty of Tropical Medicine, Bangkok, Thailand.*

Background: Patients on hemodialysis may be at higher risk of illness and death from infected of influenza virus. The efficacy of dose of influenza vaccine across dialysis patients is uncharacterized. We assessed the efficacy of double-dose and booster influenza vaccine versus standard-dose in hemodialysis patients.

Methods: A prospective, open-label, randomized study with 100 hemodialysis patients were enrolled. Double-dose and booster group(n=50) received two doses of IM inactivated seasonal quadrivalent influenza vaccine and one dose at the next 2 weeks while standard-dose group(n=50) received one dose of vaccine. Demographics and co-morbidity were collected at baseline. HAI titers were assessed prior to vaccination and at 14, 28 days post-vaccination.

Results: Hemodialysis patients had age of 61 years approximately and had similar baseline laboratory and co-morbidity. Double-dose with booster group had higher rate of seroprotection(100% vs 86%, p=0.006) and seroconversion(84% vs 60%, p=0.008) measured by using HAI against H3N2 were different significantly. Moreover, Double-dose with booster group had higher rate of sustained antibody level at 4 weeks after first vaccination measured by using HAI against H1N1(88% vs 52%, p=0.006) and H3N2(84% vs 72%, p=0.003) were significant differences. However, no differences in HAI against B strains were seen. At 4 weeks after first vaccination, HAI against H1N1, H3N2, B/Colorado and B/Yamagata are similar in both groups.

Conclusions: The double-dose with booster influenza vaccine can provide higher seroprotection and seroconversion rates of HAI against in H3N2 but no different in other strains compared to standard-dose. This study is needed to explore the effect of double-dose with booster vaccine against all causes mortality or influenza related outcomes for adults undergoing hemodialysis compared to the standard-dose.

PO1068

Temporal Trends in Clinical Phenotype, Bacterial Genotype, and Clinical Outcomes in Hemodialysis-Dependent Patients with *Staphylococcus aureus* Bacteremia

Matthew R. Sinclair,[1,2] Maria Souli,[1] Felicia Ruffin,[1] Lawrence Park,[3] Michael M. Dagher,[1] Christina M. Wyatt,[1,2] Vance Fowler.[1,2] *[1]Duke University Hospital, Durham, NC; [2]Duke Clinical Research Institute, Durham, NC; [3]Duke Global Health Institute, Durham, NC.*

Background: *Staphylococcus (S.) aureus* bacteremia (SAB) is a common and potentially lethal infection among hemodialysis-dependent (HD) patients. The determinants of clinical outcomes in HD patients with SAB are not completely understood. We evaluated temporal trends in SAB-attributable mortality, metastatic infections, and bacterial genotype in HD patients over a 20-year period.

Methods: Hospitalized, non-neutropenic HD and non-HD adults with monomicrobial SAB were prospectively enrolled from Jan 1, 1995 to Dec. 31, 2015. Clinical characteristics, bacterial isolates, and outcome data were collected. Isolates were previously genotyped using *spa* typing. Differences between HD and non-HD patients were estimated using medians/quartiles or counts/percentages with statistical significance evaluated with Mann-Whitney-U or Fisher's Exact test. Proportions of participants experiencing each outcome were calculated overall and by calendar year. Secular trends in proportions were estimated with linear regression and associations between bacterial genotypes, clinical characteristics, and clinical outcomes were estimated using univariate and multivariate logistic regression.

Results: Among 2,347 unique participants, 495 (21.1%) were HD. Compared to the non-HD patients, HD patients were younger (median 57 years (y) vs 60 y, p=0.002) and more likely to be Black (74.6% vs 26% p<0.001), female (48.1% vs 42.1% p=0.019), and to have diabetes (56.2% vs 33.8% p<0.001). HD patients experienced significant increases in the annual prevalence of age- and diabetes-adjusted SAB-attributable mortality (0.49% per year p=0.05), metastatic infections (0.79% per year p=0.028), and infection with the highly virulent Methicillin resistant strain USA300 (0.97% per year, p<0.001). The increase in USA300 infections did not appear to explain the observed increases in metastatic infections (Odds Ratio [OR] 1.33, Confidence Interval [CI] 0.55-3.21) or SAB-attributable mortality (OR 0.57, CI 0.14-2.32).

Conclusions: Clinical characteristics differed significantly between HD and non-HD patients with SAB. Increases in mortality and metastatic infections over time were not explained by the rise in more virulent strains of *S. aureus*, but may be partially explained by changes in patients' characteristics.

PO1069

Hemodialysis-Associated Increased Intraocular Pressure: A Vision-Threatening Complication

Chad Y. Lewis,[1] Nikhil Batra,[2] Eric A. Steffen,[2] Martha L. Graber.[2] *[1]Dartmouth College Geisel School of Medicine, Hanover, NH; [2]Dartmouth-Hitchcock Medical Center, Lebanon, NH.*

Introduction: Elevation of intraocular pressure (IOP) is a potential complication of hemodialysis (HD). When patients with risk factors for angle closure undergo HD, aqueous humor volume may increase, thus elevating IOP.

Case Description: A 71M with ESRD secondary to type II diabetes and proliferative diabetic retinopathy reported one month of headache, left-sided eye pain and photophobia, and periorbital redness occurring with dialysis. Ophthalmology diagnosed neovascular glaucoma following an elevated IOP of 36 mmHg in the left eye (normal < 22). Pre-dialysis IOP returned to normal with medical therapy. Dialysis modifications reduced the rate and magnitude of change in plasma osmolality (Table 1). However, elevated IOP and symptoms persisted and he underwent surgery on 5/6/2020 with full resolution of symptoms.

Discussion: Sitprija et al. (1964) first observed increased IOP during HD in 83 of 89 cases. Subsequent studies report that IOP may increase, decrease, or remain unchanged

during HD. One proposed mechanism for increased IOP is as plasma urea is reduced, the aqueous humor lags, becoming hypertonic relative to plasma. The choroid may also thicken, obstructing outflow. We increased dialysate sodium and reduced HD time and dialysate flow. Other strategies include infusing mannitol or hyperosmolar glucose, ultrafiltration to increase plasma oncotic pressure, and more frequent or peritoneal dialysis. Nephrologists should have heightened awareness for angle-closure glaucoma and conditions predisposing to obstruction of aqueous outflow, including proliferative diabetic retinopathy. Headache, ocular pain, or visual changes during dialysis warrant urgent ophthalmic evaluation.

Table 1

Date	Pre-HD IOP (R/L; mmHg)	IOP 3 hrs. into HD (R/L; mmHg)	Net Δ in IOP (R/L; mmHg)	% Δ in IOP (R/L)
4/25/20	9/12	12/25	+3/+13	+33%/+108%
4/29/20	12/25	16/33	+4/+8	+33%/+32%
5/25/20	13/12	15/16	+2/+4	+15%/+33%

PO1070

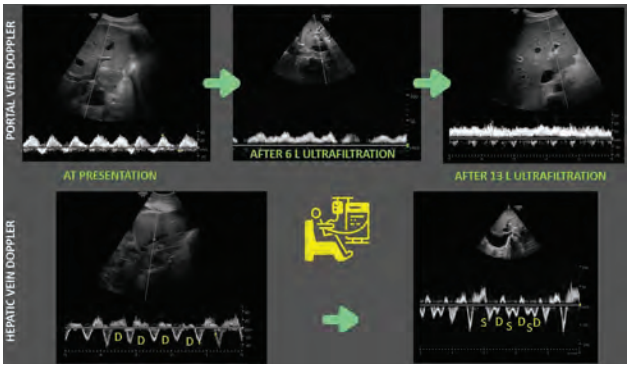
Point-of-Care Ultrasonography to Assess Venous Congestion and Guide Ultrafiltration: Another String to Our Bow?

Saqib Mahmud, Abhilash Koratala. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Point of care ultrasound (POCUS) is rapidly evolving as a valuable adjunct to bedside clinical examination in internal medicine and subspecialties. However, there is no single accurate sonographic application to determine fluid volume status. While sonographic assessment of inferior vena cava (IVC) is popular among novice POCUS users, its isolated use to determine and monitor volume status is subject to numerous limitations. Similarly, lung ultrasound gives an idea of left sided filling pressures but does cannot quantify venous congestion, which can have deleterious consequences in various organ systems including kidney. Novel scoring systems like venous excess ultrasound grading (VExUS) allow objective assessment of volume status using portal and hepatic venous Doppler waveforms in addition to IVC measurements. Herein, we demonstrate the natural history of these waveforms in a patient with advanced chronic kidney disease (CKD) during the course of ultrafiltration.

Case Description: A 39-year-old man with a history of CKD stage 5 presented with generalized weakness, shortness of breath on exertion, worsening leg edema and weight gain despite being compliant with prescribed diuretic therapy. He was admitted and initiated on hemodialysis for refractory volume overload. POCUS showed mild pericardial and pleural effusion as well as an enlarged IVC of ~3cm with <50% collapse. In addition, Doppler ultrasound showed 100% pulsatility of portal vein (normal <30%) with systolic flow reversal and hepatic vein with S wave reversal and only D wave below the baseline. These findings constitute VExUS grade 3, suggestive of severe congestion. While IVC continued to indicate high right atrial pressures, the Doppler waveforms showed parallel improvement with ultrafiltration reaching VExUS grade 1 (mild congestion) at discharge [Figure]. No episodes of intradialytic hypotension occured.

Discussion: POCUS-derived venous waveforms aid in monitoring the effectiveness of decongestive therapy and guide the amount of ultrafiltration.



PO1071

Can the Assessment of Ultrasound Lung Water in Hemodialysis Patients Be Simplified?

Claudia Torino,[2] Rocco Tripepi,[2] Maurizio Postorino,[1] Giovanni Tripepi,[2] Charalampos Loutradis,[3] Pantelis Sarafidis,[3] Francesca Mallamaci,[1,2] Carmine Zoccali.[2] *[1]Nephrology Unit, GOM Reggio Calabria, Reggio Calabria, Italy; [2]IFC-CNR, Reggio Calabria, Italy; [3]Aristoteleio Panepistemio Thessalonikes, Thessaloniki, Greece.*

Background: Lung Ultrasound (US) reliably estimates lung water and it is increasingly applied in clinical practice in dialysis patients. Lung water is measured by applying a semi-quantitative US score summing up the US-B lines detected in 28 lung intercostal spaces (LIS). A simplified assessment restricted to 8 LIS only has been proposed. However, the agreement among the scores has not been studied and their prognostic value has never been compared.

Methods: We included in the analysis 303 HD patients in which the pre-dialysis US-BL score was measured at baseline with both the semi-quantitative and the simplified method. The time needed for performing the 28-LIS and the 8-LIS score by six independent assessors with various experience on lung US assessment was accurately measured. Patients were divided into 4 categories, according to pre-established cut-offs specific for the two methods (28-LIS score: <5;6-15;16-30;>30 US-BL; 8-LIS score: <10;11-20;21-50;>50 US-BL). The prediction power of these scores was assessed by the explained variance (R^2).

Results: The 28-LIS score and the 8-LIS score were highly inter-related (ρ=0.93,P<0.001). During a mean follow-up of 3 years, 112 patients died and 129 experienced a CV event. At univariate and multivariate analysis, both scores were associated to the study outcomes. The R^2 of the 28-LIS score for death was 4.1% and that for CV events 4.6%. The corresponding R^2 of the 8-LIS score were 5.4% (death) and 4.7% (CV events), values close to those of the 28-LIS score. Accordingly, when the two scores were separately added to a clinical model including easily available clinical variables the R^2 of the model including the 28-LIS score (death:31.1%; CV events:23.9%) were again very similar to those of the 8-LIS score (30.7% and 23.1%, respectively). The median time needed to perform the examination was 3:05 min (IQR 2:22–5:00 min) for the 28 LIS score and 1:35 min (IQR 1:16–2:00 min) for the 8 LIS score.

Conclusions: The simplified 8-LIS score is tightly related to the classical 28 LIS score and the two scores hold an almost identical predictive power. Even though the 28-LIS score demands less than 5 minutes, the 8-LIS score can be done in only about 90 sec. and it is therefore better suited for application in everyday clinical practice in hemodialysis units.

PO1072

Longitudinal Assessment of Random Variability in ICH-CAHPS Scores

Dena E. Cohen, Steven M. Brunelli, Francesca Tentori. *Davita Clinical Research, Minneapolis, MN.*

Background: The Centers for Medicare & Medicaid Services mandates use of the In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems (ICH-CAHPS) survey to assess dialysis patients' experience of care. Survey responses, collected twice annually and reported at the facility level, are intended to evaluate facility performance over time and to compare across facilities at a given time. In order to be useful for these purposes, the random variability in ICH-CAHPS scores must be relatively low.

Methods: ICH-CAHPS scores were analyzed among 2735 facilities managed by a large dialysis organization that had at least one ICH-CAHPS score available between 2014 and 2018. The association between Center Global Rating score (1 of the 6 ICH-CAHPS domains) and survey period was assessed using a mixed model with random slopes and intercepts for each facility. Mean squared residuals were calculated for each facility and categorized on the basis of the number of survey responses received at the facility. Facilities with available scores in all 9 survey periods analyzed (N = 1074) were assigned to quintiles based on their position within the distribution of scores in each survey period, and movement across quintiles was assessed longitudinally.

Results: The mean Center Global Rating score in the fall of 2018 was 64.9, with an average increase of 0.2 points per period over the subsequent 8 survey periods. However, random variation in scores was considerable and dependent on the number of survey

responses received. The root mean square error, a measure of random variation, ranged from 6.9 points for facilities with >27 responses to 9.2 points for facilities with 11 to 12 responses. Among facilities with survey responses available in all 9 periods, movement between quintiles was frequent, with 39.7% of facilities occupying 4 of the 5 possible quintiles at least once, and 11.5% occupying all 5 quintiles.

Conclusions: Within facilities, there is substantial random variation in ICH-CAHPS scores over time. This diminishes the utility of ICH-CAHPS for its intended purposes. Improvements to ICH-CAHPS, or development of alternative measures of patient experience, are needed to enable accurate assessment of facility performance and to inform patient care.

PO1073

Implication of Trends in Timing of Dialysis Initiation on Population Incidence of ESRD

Chi-yuan Hsu,[1,2] Rishi V. Parikh,[2] Leonid Pravoverov,[2] Sijie Zheng,[2] David V. Glidden,[1] Thida C. Tan,[2] Alan S. Go.[2,1] *[1]University of California San Francisco, San Francisco, CA; [2]Kaiser Permanente, Oakland, CA.*

Background: In the past two decades, eGFR at start of chronic dialysis worldwide have changed notably. How changes over time in the likelihood of dialysis initiation at any given eGFR level impacts the population burden of ESRD has not been not well-defined.

Methods: We analyzed data from 2001-2015 in successive 3-year intervals among adult members of a large, integrated health care delivery system in Northern California who had ≥1 outpatient serum creatinine in the prior year. One-year risk of initiating chronic dialysis was delineated stratified by starting eGFR levels per 3-year cohort. To assess multivariable-adjusted temporal trends, we evaluated the significance of a 3-year cohort term in a logistic regression model adjusting for age, gender, race, and diabetes mellitus status. We then estimated a potential reduction in dialysis initiation in 2013-2015 using the relative difference between the standardized 1-year risks (95% CI) in 2001-2003 and 2013-2015.

Results: Among those with eGFR 16-17 mL/min/1.73m^2 (N=2753), 14-15 mL/min/1.73m^2 (N=2074), and 10-13 mL/min/1.73m^2 (N=2655), the 1-year risk of initiating dialysis increased for every 3-year period by 11% (adjusted odds ratio [aOR] 1.11 [95% CI:1.03 to 1.21]), 11% (aOR 1.11 [1.03 to 1.20]) and 7% (aOR 1.07 [1.01 to 1.14]) respectively, adjusting for age, gender, race, and diabetes mellitus (Figure). We estimate that incidence of ESRD could have potentially been 16% (95% CI:13% to 18%) lower if there were no changes in system-level practice patterns or patient-related or other factors from 2001-2003 to 2013-2015.

Conclusions: Our data suggest that approximately two thirds of the target 25% relative reduction in new ESRD cases by 2030 called for in the White House AAKH initiative could potentially be achieved by changes in the timing of initiation of chronic dialysis.

Investigation and Analysis of Post-Dialysis Fatigue in Maintenance Hemodialysis Patients

Jin-mei Yin,[1] Jun Yin.[2] *[1]the Fifth Affiliated Hospital of Sun Yat sen University, Zhuhai, China; [2]the Third Affiliated Hospital of Sun Yat sen University, Guangzhou, China.*

Background: post-dialysis fatigue is one of the concerns in recent years. The time of fatigue recovery can be used to predict the hospitalization rate and mortality rate. At the same time, there are few reports on the relationship between maintenance hemodialysis (MHD) and protein energy consumption (PEW). The purpose of this study is to investigate the status of fatigue in MHD patients, analyze the factors affecting fatigue and its correlation with PEW, and provide possible effective interventions.

Methods: 346 MHD patients in our blood purification center were selected. MHD patients were assessed with self-made general data questionnaire, international standard fatigue assessment scale (FAI) and subjective comprehensive nutrition assessment (SGA), and their blood routine and biochemical results were collected for statistical analysis

Results: More than half of patients claimed to experience post-dialysis fatigue. Time to recover from hemodialysis(TIRD) was different: the interquartile range time was 2.00(0.00, 3.00) hours. In the study, 30.1% patients reported no fatigue after hemodialysis. Recovery time in 30.5%% patients was more than 30 minutes to 2 hours, 26.1% was 3 to 4 hours, 12.3% was 5 to 12 hours, 1.0% patients took longer time to recover from a dialysis session. According to the recovery time, these patients were divided into three groups. Among the three groups, SGA score, the ultrafiltration, the serum sodium and bicarbonate level after dialysis showed significant difference. It was showed by the unconditional logistic regression analysis that high SGA(OR=1.312,95%CI 1.163-1.481), scoreultrafiltration (OR=2.15,95%CI 1.24-3.41) and serum sodium (OR=0.83,95%CI 0.71-0.98) were associated of TIRD.

Conclusions: The incidence of post-dialysis fatigue in MHD patients is high. Medical staff should pay attention to the nutritional status of MHD patients, control their weight growth, and maintain the stability of electrolyte and bicarbonate levels such as serum sodium.

PO1075

Recurrent Episodes of Angioedema During Hemodialysis

Abhay Mishra,[2,1] Cheryl C. Brown-Deacon,[1] Praveena Koneru,[1] Mili J. Shah,[1,2] Madhumita J. Mohanty.[1,2] *[1]John D.Dingell VAMC, Detroit, MI; [2]Wayne State University, Detroit, MI.*

Introduction: Angioedema during hemodialysis (HD) is uncommon but can be potentially life-threatening. We report a patient with recurrent episodes of angioedema during HD who posed a diagnostic and therapeutic challenge.

Case Description: A 73 year old male with end stage renal disease was initiated on HD in 2012. He did well on HD till February 2018 when he developed angioedema along with itchiness two minutes after initiation of HD and required intubation for airway support. No medications, food ingestions, contact with any external agents or insect bite were identified which may have triggered the angioedema. His C4 was not low, C1 esterase inhibitor and C1Q binding assay were normal, radioallergosorbent test was negative to aeroallergens, food allergens and latex. As no specific cause for angioedema was identified, a dialyzer reaction was considered. He was being dialyzed via Optiflux F180NR dialyzer (electron beam sterilized polysulfone membrane) since initiation of HD in 2012. He was subsequently dialyzed with other dialyzers including Optiflux F180 NR (sterilized with ethylene oxide), Exeltra 190 (gamma radiation sterilized tricellulose acetate membrane) and Rexeed 15S (gamma radiation sterilized polysulfone membrane). He developed angioedema with each of these dialyzers within a few months of using them and in spite of premedication with intravenous methylprednisolone, diphenhydramine and ranitidine and also rinsing the dialysis circuit with three liters of normal saline prior to HD initiation. These episodes of angioedema occurred within the first 30 minutes of HD initiation and required intubation on two occasions. At this point, a possible reaction to the dialysis blood tubing, which was ethylene oxide sterilized, was considered and the patient was switched to Streamline Express dialyzer (polyethersulfone membrane with pre-attached blood tubing, both sterilized with gamma radiation). The patient has had no further episodes of angioedema since this change was made five months back and has been off steroids for the last two months.

Discussion: In patients with unclear etiology of angioedema during HD, exposure to all components of the HD circuit, including the dialysis blood tubing, should be considered as a potential cause of angioedema and should be systematically ruled out.

PO1076

The Impact of Serum Albumin Levels on Excess Hospital Spending

Linda Ficociello,[1] Melissa M. Rosen,[1] Claudy Mullon,[1] Robert J. Kossmann,[2] Michael S. Anger.[1] *[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: National Kidney Foundation K/DOQI guidelines recommend that hemodialysis patients have serum albumin (sA) levels greater than or equal to 4 g/dL. Serum albumin lower than 4 g/dL has long been associated with an increased risk of morbidity and mortality in dialysis patients. Compared to both low and high flux dialyzers, a mean albumin loss of 3g per dialysis session has been observed with medium cut-off (MCO) dialyzers (Kim et al., BMC 2020; Kirsch et al. NDT, 2017) which may decrease sA levels and increase the risk of hypoalbuminemia (serum albumin ≤3.5 g/dL). The aim of this analysis was to estimate the impact of sA levels on hospitalization and associated cost.

Methods: Prior research conducted by Rocco et al. (J. Am. Soc. Nephrol., 1996) identified sA level as a risk factor for hospitalization in ESKD patients receiving dialysis and estimated hospital utilization associated with sA levels. Data from this analysis was used to show that relative to patients with sA ≥4 g/dL, on average each year, patients with sA of 3.5-3.99 g/dL, sA of 3.0-3.49 g/dL, and sA≤ 3.0 g/dL have 3.98, 7.65, and 7.8 more hospital days, respectively. Using an average cost per hospitalization for a dialysis patient of $15,907.18 and the average length of stay (11.3 days) from USRDS, and data from Rocco et al. (1996), we estimated the additional hospital spending associated with reduced serum albumin levels.

Results: Based on previous research demonstrating an association between sA levels < 4 g/dL and increased risk of hospitalization, we estimated the hospitalization costs

associated with having reduced serum albumin. Relative to hemodialysis patients with ≥4 g/dL, we calculated that having a lower average sA level may result in excess healthcare spending of $5,602 for sA of 3.5-3.99 g/dL, $10,769 for sA of 3.0-3.49, and $10,980 for sA less than or equal to 3.0 g/dL.

Conclusions: Lower serum albumin levels are associated with increased hospital admissions, which is estimated to lead to excess hospital spending on average of $5,602-$10,980 per patient per year. Preventing albumin loss in dialysis patients may help to reduce the risk of hospitalization.

A Pilot Randomized Control Trial of an Energy Management Program for Adults on Chronic Hemodialysis with Fatigue: The Fatigue-HD Study

Janine F. Farragher,[1] Pietro Ravani,[1] Braden J. Manns,[1] Meghan J. Elliott,[1] Chandra M. Thomas,[1] Maoliosa Donald,[1] Brenda Hemmelgarn.[2] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Alberta Faculty of Medicine and Dentistry, Edmonton, AB, Canada.*

Background: How to reduce fatigue and its impact on life participation is a top-ten unanswered research question among patients treated with chronic hemodialysis. We aimed to determine the feasibility of conducting a randomized controlled trial, to investigate an energy management education program for the chronic hemodialysis population.

Methods: We conducted a parallel-arm, 1:1, blinded pilot RCT at six hemodialysis units in Calgary, Canada. Patients who had moderate or severe fatigue on the Fatigue Severity Scale, and met other study eligibility criteria, were invited to participate. Consenting participants were randomized to general self-management education or the Personal Energy Planning (PEP) program, a tailored 7-9 week energy management program that guides participants in practicing efficient energy expenditure during valued life activities. We assessed study eligibility, recruitment and attrition rates. We then computed standardized intervention effects (Cohen's D statistic) on self-reported fatigue and life participation measures, compared to control, at immediate post-intervention and 12 weeks post-intervention.

Results: Of 253 people on hemodialysis screened, 153 were eligible to be approached (clinically stable and English-speaking). 42 (26%) were interested and consented to participate, and 30 met all study eligibility criteria were enrolled (mean age 62.4, 60% male). 22 (73%) enrolled participants completed all study procedures. Medium intervention effects were observed compared to control on the global life participation scale, global life participation satisfaction scale, and COPM-Performance Scale at immediate post-intervention follow-up. At 12-week post-intervention, large and very large intervention effects were observed on the COPM Performance and Satisfaction Scales, respectively, compared to control. Minimal to no intervention effects were seen on other life participation or fatigue measures.

Conclusions: We have shown it is feasible to enroll and follow patients on hemodialysis with fatigue in a randomized controlled trial of an energy management intervention. Since the intervention led to improved life participation on some scales, we have justified the need for, and feasibility of, a larger trial.

Coffee and Headache in Hemodialysis Patients: The CoffeeHD Trial

Mabel Aoun,[1,2] Najla Hilal,[3] Chadia H. Beaini,[4] Ghassan Sleilaty,[1] Joseph Hajal,[1] Celine El boueri,[2] Dania Chelala.[1] *[1]Saint-Joseph University, Beirut, Lebanon; [2]Saint-George Hospital, Ajaltoun, Lebanon; [3]Universite Saint-Esprit de Kaslik, Jounieh, Lebanon; [4]Bellevue Medical Center, Mansourieh, Lebanon.*

Background: Headache occurs in 40 to 75 % of HD patients. Caffeine circulates unbound in the blood and passes the dialysis membrane. Some suggested that headache can result from caffeine withdrawal. This study aims to compare the incidence of headache and hypotension between patients taking or not coffee during dialysis.

Methods: This is a randomized double-blind multicenter trial. Patients of 3 HD units were included. 156 patients were randomized to two groups, group A was given coffee and group B decaffeinated coffee mid-session for 12 sessions. UF rate was fixed to <13 ml/kg/h. Primary outcome was incidence of headache and secondary outcome incidence of hypotension. This clinical trial received the approval of the ethics committee and was registered on ClinicalTrials.Gov (NCT04057313).

Results: 139 patients completed the trial (6.4% vs 15.4 % of withdrawal in A and B respectively). Baseline characteristics are summarized in Table 1. Incidence of headache was not significantly different between A and B (34% vs 37% respectively, p=0.522), nor the incidence of hypotension (27% vs 26% respectively, p= 0.539). In subgroup analysis, headache was lower in A (p=0.06) in two categories of patients: those with higher potassium dialysate (K=2) and the non-hypertensive patients.

Conclusions: Headache occurred in 34 to 37% of dialysis sessions. There was no difference in headache or hypotensive episodes between patients in the coffee versus decaffeinated group.

Physical Activity Levels in Hemodialysis Patients Measure Using a Commercially Available Activity Tracker

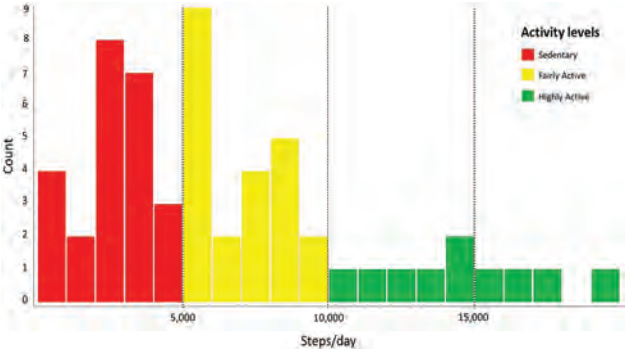
Priscila Preciado, Maggie Han, Ohnmar Thwin, Leticia Tapia, Xia Tao, Mohamad I. Hakim, Amrish U. Patel, Lemuel Rivera Fuentes, Nadja Grobe, Jochen G. Raimann, Stephan Thijssen, Peter Kotanko. *Renal Research Institute, New York, NY.*

Background: Sedentary life is a major risk factor for all-cause mortality in the general population, more in those with cardiovascular (CV) diseases. Hemodialysis (HD) patients have an increased CV mortality and it has been shown that they are less active than their healthy piers. The use of physical activity (PA) tracking devices could provide an objective measurement of PA in HD patients' everyday lives. We aimed to objectively quantify activity in a large HD population

Methods: This prospective, still ongoing study enrolled HD patients from 4 clinics in NYC beginning in May 2018 and followed them up to 1 year. Patients ≥18 years, HD ≥3 months, able to walk, owning a smartphone, mobile tablet or PC were enrolled. They were provided with a wrist-based tracking device (Fitbit® Charge 2). We present baseline characteristics and PA levels of the first 7 days of wear. Based on their average daily step counts, participants were separated into 3 categories:sedentary, fairly active, or active if they walked less than 5,000, 5,000 to 10,000, or >10,000 steps, respectively

Results: Fifty-six patients were included in this analysis (54±12 years, 71% male, 60% black, 28.6% had diabetes and 23.2% CHF, dialysis vintage 5.8±5.8 years and body mass index of 28.0±7.0 kg/m^2). Participants walked an average of 6,470±4,617 steps per day, median of 5,513 [IQR 3,043-8,268] steps/day. Of the 56 participants, 45%(n=25) were sedentary, 39%(n=22) were fairly active, and 16% (n=9) were active **(fig.1)**

Conclusions: In our study, only a small number of patients exceeded the WHO recommendation of 10,000 steps/day. Overall, 83% of patients walked <10,000 steps/day. Further analysis is needed after completion of the study to assess the impact of a physical activity tracker device on physical activity levels. We hypothesized that the daily use of a tracker will positively impact activity levels and overall self-perceived health



Histogram average daily steps

PO1080

Feasibility and Acceptability of Symptom Monitoring with Feedback Trial (SWIFT) for Adults on Hemodialysis: A Pilot ANZDATA Registry-Based Cluster Randomized Trial

Rachael L. Morton,[1] Kathryn Dansie,[2] Paul N. Bennett,[3] Emily Duncanson,[2] Andrea K. Viecelli,[4] Shilpa Jesudason,[5] Karan K. Shah,[1] Chris Brown,[1] Suetonia Palmer,[6] Fergus J. Caskey,[7] Stephen P. McDonald.[2,5] SWIFT *[1]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [2]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; [3]Satellite Healthcare, San Jose, CA; [4]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [5]Royal Adelaide Hospital, Adelaide, SA, Australia; [6]University of Otago Christchurch, Christchurch, New Zealand; [7]University of Bristol, Bristol, United Kingdom.*

Background: We designed a registry-based randomized trial to test whether the collection and feedback of symptoms improves health-related quality of life (HR-QoL). The pilot study's aim was to determine technical feasibility and patient-clinician acceptability of electronic tablet-based data capture and feedback integrated within the ANZDATA registry.

Methods: Hemodialysis units were cluster randomized to 3-monthly symptom monitoring using the Integrated Palliative Outcome Scale-Renal (IPOS-Renal) with feedback to clinicians plus 6-monthly HR-QoL using EQ-5D-5L questionnaire (intervention group); vs HR-QoL alone (control group). Feasibility and acceptability outcomes included, 1) individualized survey generation using QR codes linked to ANZDATA records; 2) patient completion rate and time; 3) delivery of individualized symptom reports.

Results: Technical feasibility was demonstrated by successful development of a Qualtrics survey platform presented on tablet computers, use of QR reader codes to verify correct patients from ANZDATA, with a link to the relevant survey for the patient's allocation and study timepoint. 226 patients (intervention =109; control =117), from 4 Australian units with median dialysis vintage of 1.6 years, mean age 62 years, 31% females, completed at least one symptom or HR-QoL measure, (72% of eligible patients, range 44-90%). Mean completion time was 6.5 minutes for IPOS-Renal (66% nurse assisted), 3.5 minutes for EQ-5D-5L. Consolidated symptom feedback reports and evidence-based symptom management guidelines for Nephrologists and dialysis nurse managers were delivered electronically within 2 weeks of measurement.

Conclusions: Electronic symptom monitoring in adults on hemodialysis with feedback to clinicians is feasible. These data support the commencement of the definitive trial in 3,072 patients.

Physiological Pre-Dialytic Changes Could Mediate the Effects of Extreme Heat Events on Hospital Admission Risk in Hemodialysis Patients

Richard V. Remigio,[1] Rodman E. Turpin,[1] Jochen G. Raimann,[2] Peter Kotanko,[2] Franklin W. Maddux,[3] Len A. Usvyat,[4] Xin He,[1] Amir Sapkota.[1] *[1]University of Maryland School of Public Health, College Park, MD; [2]Renal Research Institute, New York, NY; [3]Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany; [4]Fresenius Medical Care North America, Waltham, MA.*

Background: Thermoregulatory response to extreme heat events (EHE) includes reduced blood pressure and perspiration. EHE exposure increases the risk of hospitalizations among hemodialysis (HD) patients, though the underlying mechanism for this relationship is unclear. We employed traditional mediation analysis to decompose the total effect between EHE and hospital admissions using pre-HD systolic blood pressure (SBP) and interdialytic weight gain (IDWG) as mediators.

Methods: We assigned EHE exposure metric – calculated using calendar day and location-specific temperature thresholds – to HD patients treated at Fresenius Kidney Care clinics from 2003 to 2012. We used time-to-event methods using varying lag periods followed by VanderWeele's difference method with bootstrapping to test mediators.

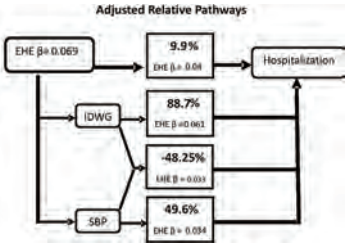
Results: EHE increased the hazard of hospital admission up to 17% after covariate adjustments (n=7,962). In one of the lag periods (two-day EHE exposure before hospital admissions), hazard ratio (HR) estimates from Cox models (Figure) exhibited statistical significance for all pathways. SBP and IDWG as a conjoined mediator suggest protective mediation (-48.3%), whereas IDWG, independent of SBP, accounts for a considerable proportion of the association (88.7%). Half of the association is mediated through SBP, independent of IDWG. Preliminarily, IDWG may have a consistent mechanistic role in hospital admissions after exposure. Also, lagged EHE does yield heterogeneity in mediating effects.

Conclusions: This work is a step forward to understanding potential physiological linkages between EHEs and health complications that may result in hospitalization. Such findings could be critical in discerning potential interventions to minimize the impact of extreme heat among HD patients.

Funding: Other U.S. Government Support

Risk Estimates

Estimate	EHE HR	Indirect Effect
EHE and only confounders	1.07 (0.98, 1.16)	
EHE, confounders, and PRE_SBP, and IDWG	1.01 (0.92, 1.11)	1.06 (1.04, 1.12)
EHE, confounders, and PRE_SBP	1.04 (0.95, 1.13)	1.0010 (1.0005, 1.0020)
EHE, confounders, and IDWG	1.01 (0.92, 1.11)	1.03 (1.01, 1.06)



L: HR and 95% CI for EHE-Hospital association (EHE HR) and for mediation effects of the association (Indirect Effects); **R**: Mediating EHE-Hospital association pathways and its relative proportions

PO1082

Frequency, Risks, and Outcomes of Sepsis Hospitalizations in the ESKD Population in the United States

Paul T. Merchant,[1] Silvi Shah,[1] Annette Christianson,[1] Anthony C. Leonard,[1] Karthikeyan Meganathan,[1] Kathleen Harrison,[1] Samantha M. Kramer,[1] Charuhas V. Thakar.[1,2] *[1]Division of Nephrology, University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA Medical Center, Cincinnati, OH.*

Background: Although a biologically plausible link between End Stage Kidney Disease (ESKD) and sepsis exists, little is known about frequency, risk factors, and outcomes of sepsis-related hospitalizations in ESKD patients.

Methods: Of a retrospective cohort of 1,123,731 incident ESKD patients on dialysis (2005 to 2014) from the United States Renal Data System (USRDS), we studied the 508,372 with linked Medicare claims at initiation of dialysis and complete demographic data. Hospitalization data were obtained from Medicare claims with a sepsis hospitalization being identified by previously validated ICD-9 codes. Using Cox proportional hazard models, we examined the risk factors associated with a sepsis hospitalization and effect of a sepsis hospitalization on mortality.

Results: The study cohort was 55% male, 62% white, and had an average age of 70 years. A sepsis hospitalization occurred in 20.8% of the cohort. The overall rate of sepsis hospitalizations was 15.4 per hundred patient years (PHPY), and the trend increased over time from 13.8 PHPY in 2005 to a peak of 16.7 PHPY in 2011. Factors associated with higher likelihood of a sepsis hospitalization included female sex (Hazard Ratio [HR] 1.05, 95% CI 1.03-1.06), age >80 (vs. age <40; HR 1.30, 95% CI 1.24-1.36), dialysis access via catheter (vs. fistula/graft; HR 1.61, 95% CI 1.58-1.63), congestive heart failure (HR 1.28, 95% CI 1.26-1.30), and diabetes mellitus (HR 1.14, 95% CI 1.12-1.16). Compared to white race, minority races had lower likelihood of developing a sepsis hospitalization (Black HR 0.89, 95% CI 0.87-0.90; Hispanic HR 0.82, 95% CI 0.80-0.84; Asian HR 0.79, 95% CI 0.76-0.82; Native American HR 0.80, 95% CI 0.75-0.86). Compared to no hospitalizations, ESKD patients had a twofold increase in mortality following a first non-sepsis hospitalization (HR 2.14; 95% CI 2.12 to 2.16), increasing to ninefold over baseline following a sepsis hospitalization (HR 9.00; 95% CI 8.87-9.13).

Conclusions: Sepsis hospitalizations are frequent and are associated with significant mortality in ESKD patients in the U.S. Further studies need to focus on modifiable risk factors of sepsis and explore optimal therapies for sepsis in ESKD subjects.

PO1083

Optimising Recruitment in Prepare for Kidney Care: A Clinical Trial Comparing Preparation for Dialysis vs. Responsive Management

Alba X. Realpe,[1] Leila Rooshenas,[1] Jenny Donovan,[1] Emer R. Gates,[2] Helen L. Winton,[1] Fergus J. Caskey.[1,2] On behalf of Prepare for Kidney Care team *[1]University of Bristol Faculty of Health Sciences, Bristol, United Kingdom; [2]North Bristol NHS Trust, Westbury on Trym, United Kingdom.*

Background: Randomised Controlled Trials (RCTs) are core to evidence-based practice, but often close prematurely or are not attempted for fear of recruitment issues. Prepare for Kidney Care ('Prepare') randomises adults aged 80+/65+ with comorbidities to prepare for Renal Dialysis or Responsive Management -a form of conservative care. An RCT of this nature has never been attempted, with concerns about recruitment feasibility. The Prepare RCT integrated the Quintet Recruitment Intervention (QRI) – a complex

intervention designed to rapidly diagnose and address recruitment issues in real-time. We report the root-causes of recruitment issues and how these were overcome using this novel methodology.

Methods: The QRI entailed monthly scrutiny of pre-randomisation screening data, interviews with nephrologists/nurses (n=27) and audio-recorded consultations between clinicians/patients (n=33). Data were triangulated, informing strategies to address recruitment issues.

Results: Recruitment was hampered by logistical issues that varied, requiring bespoke solutions by centre. More challenging to address were the underlying complex issues entwined with routine clinical practice, manifesting as reluctance to approach all eligible patients, and issues with conveying equipoise. Clinicians often only approached patients whom they felt could not decide between dialysis or conservative care, assuming other patients' treatment intentions were fixed. Audio-recorded consultations indicated patients were not necessarily committed to treatments, and preferences were often complicated by misconceptions. Recordings also revealed recruiters' tendencies to unknowingly undermine dialysis, and hesitancy in exploring preferences. The trial team iteratively produced guides/training to support equipoise communication and used presentations/ clinical vignettes to challenge assumptions that patients have fixed treatment plans. As of May 2020, 246 patients have been randomised (48% of target of 512).

Conclusions: Factors hindering recruitment to this challenging RCT were complex, but amenable to change once well-understood. Novel methodologies, like the QRI, can unlock the potential to deliver seemingly impossible- but vitally important- RCTs to improve renal practice.

PO1084

Time Course of Tissue Sodium Flux in Maintenance Hemodialysis (MHD) Patients

Hsin-Yu Fang,[1] Luis M. Perez,[1] Ryan J. Larsen,[1] Deepa H. Shankar,[1] Talat Alp Ikizler,[2] Kenneth R. Wilund.[1] [1]*University of Illinois at Urbana-Champaign, Urbana, IL;* [2]*Vanderbilt University Medical Center, Nashville, TN.*

Background: Recent ^{23}Na-MRI studies show that sodium can accumulate in tissues. MHD patients have higher tissue sodium concentration ([Na^+]) than healthy counterparts, while tissue [Na^+] can be partially reduced during hemodialysis (HD). This study aimed to evaluate the magnitude of tissue [Na^+] removed during HD and the time-course for its recalibration.

Methods: Seven HD patients (57% male; 60±12 yr; BMI: 36±10 kg/m^2; spKt/V: 1.4±.32; dialysate [Na^+]: 136±1.90 mEq/L; UFR: 7.2±1.4 mL/kg/hr; thrice-weekly HD) had sequential ^{23}Na-MRI scans (3T system) over 3 consecutive days, including 2 HD days and the non-HD day in between, at 4 time points: pre-first HD (T1), post-first HD (T2), 24 hours post-first HD (T3), and pre-second HD (T4). [Na^+] of the medial (MG) and lateral (LG) gastrocnemius, soleus (Sol), tibialis anterior (TA), and the whole lower leg (WL) were quantified from MRI images. Plasma [Na^+] was also assessed at T1, T2, and T4 by colorimetric enzymatic assays (Piccolo). Repeated measures ANOVA and the nonparametric Friedman test were used to test the differences in tissue and plasma [Na^+] over time.

Results: Tissue [Na^+] was reduced at the end of HD (T2) compared to baseline (T1) in the WL (P=.006), MG (P=.043), LG (P=.006), Sol (P=.029), and TA (P=.006), (Figure 1A-E). For the WL and all 4 examined muscles, tissue [Na^+] at both T3 and T4 did not differ from baseline (all P>.05), indicating that tissue [Na^+] returned to the baseline within 24 hours after last HD. In contrast, plasma [Na^+] did not change over time (P=.067; Figure1F).

Conclusions: We found that tissue [Na^+] was reduced by HD but returned to baseline levels within 24 hours that remained stable until next pre-HD. More studies are needed to determine the mechanisms for these shifts, and whether lifestyle or pharmaceutical interventions can inhibit tissue [Na^+] accumulation or enhance its removal.

PO1085

Association Between Dialysate Sodium Concentration and Interdialytic Weight Gain in Patients Undergoing Twice Weekly Haemodialysis

Soraiya Manji, Jasmit Shah, Ahmed Twahir, Ahmed P. Sokwala. *Aga Khan University - Kenya, Nairobi, Kenya.*

Background: Chronic kidney disease is highly prevalent in the world with more than two million people worldwide requiring renal replacement therapy. Interdialytic weight gain is the change in body weight between two sessions of haemodialysis. Higher interdialytic weight gain has been associated with increased mortality and adverse cardiovascular outcomes. It has long been questioned whether using a lower dialysate sodium concentration during dialysis would reduce the interdialytic weight gain and prevent these adverse outcomes.

Methods: This was a single blind cross-over study of adult patients undergoing twice weekly haemodialysis conducted over two six week periods. Patients were divided into two groups – the first underwent dialysis with dialysate sodium concentration of 137meq/l, the other underwent dialysis with a sodium concentration of 140meq/l. These groups switched over after a six-week period without a washout period. Interdialytic weight gain, pre and post dialysis blood pressures were measured at each dialysis session.

Results: 41 patients were included in the primary analysis after meeting inclusion criteria. Mean age was 61.37 years, and 73% were males. Mean duration for dialysis was 2.53 years. 13% were anuric, 56% were oliguric, and 31% were non-oliguric. 59% of patients had diabetes mellitus and 80% had hypertension. The interdialytic weight gain was not significantly different among the two groups (2.14 for the low DNa (137meq/l) group and 2.35 for the high DNa (140meq/l) group, p = 0.97). Mean blood pressures were as follows. Pre-dialysis: DNa 137meq/l: systolic 152.14 ± 19.99, diastolic 78.99 ± 12.20, DNa 140meq/l: systolic 156.95 ± 26.45, diastolic 79.75 ± 11.25 (p = 0,379, 0.629 respectively). Post-dialysis: DNa 137meq/l: systolic 147.29 ± 22.22, diastolic 77.85 ± 12.82 DNa 140meq/l: systolic 151.48 ± 25.65, diastolic 79.66 ± 15.78 (p = 0,569, 0.621 respectively).

Conclusions: There was no significant difference in the interdialytic weight gain as well as pre dialysis and post dialysis systolic and diastolic blood pressures between the low dialysate sodium concentration and high dialysate sodium concentration. Therefore using a lower dialysate sodium concentration does not appear useful in altering the interdialytic weight gain although further studies with a larger sample size are warranted.

PO1086

Low Sodium Dialysate for Hemodialysis Is Associated with Lower Blood Pressure and Interdialytic Weight Gain, but Not a Lower Pre-Dialysis Serum Sodium

Huyen Nguyen, Andrew I. Chin. *University of California Davis, Sacramento, CA.*

Background: The use of high dialysate sodium (NaD) concentrations for hemodialysis (HD) is associated with greater interdialytic fluid gain (IDWG). The association with higher blood pressure has not been found routinely. Conversely, use of a lower NaD may improve on these parameters, but may lead to a lower pre-dialysis serum sodium concentration, which may have adverse consequences in this population. We aimed to examine IDWG, blood pressure, calculated serum osmolality and serum Na in HD patients on a high NaD (145) who transitioned to a low NaD (137-138)

Methods: In this retrospective, single-center study of 3-times weekly HD patients without residual kidney function, we queried long-term HD patients who were prescribed NaD of 145 and were then switched to a NaD of 137 or 138, based on change in standard clinic dialysate sodium. Parameters investigated included: pre-HD serum Na and albumin, calculated pre-HD serum osmolality, pre and post-HD weights, and pre and post-HD blood pressures. Paired T-test was used for comparison of each parameter betwee dialysate time periods.

Results: We identified 136 patients who were started on HD with NaD of 145 for at least 1 year, subsequently changed to a NaD of 137-138 for at least 1 additional year. See Figure comparison of parameters.

Conclusions: In patients on 3-times a week HD, long-term use of a high NaD of 145, compared to a low NaD of 137-138, was associated with a higher IDWG, similar to what is found in other studies. A lower NaD was associated with lower pre and post-HD systolic and diastolic blood pressures, but we found no difference in pre-HD serum Na or calculated serum osmolality. The degree of drop in blood pressure during HD on the low NaD caused hypotensive events in some patients. There are some clinical parameter benefits to a lower NaD and serum Na does not appear to suffer.

Funding: Clinical Revenue Support

	Low NaD	High NaD	p-value
Serum Sodium	138.3 ± 2.6	138.2 ± 3.0	0.69
Serum Albumin	3.8 ± 0.4	3.8 ± 0.4	0.95
Post HD wt (kg)	71.5 ± 25.2	72.2 ± 25.1	0.45
Inter-HD wt gain (kg)	2.7 ± 1.1	3.33 ± 1.8	<0.001
Calculated serum Osm	300 ± 8	302 ± 8	0.06
PreHD SBP	151 ± 21	157 ± 18	<0.001
PreHD DBP	80 ± 13	85 ± 12	<0.001
PostHD SBP	138 ± 16	144 ± 16	<0.001
PostHD SBP	74 ± 11	78 ± 9	<0.001
PreHD MAP	104 ± 14	109 ± 13	<0.001
PostHD MAP	95 ± 11	100 ± 10	<0.001

PO1087

Medicare Reliance After Implementation of Medicare Payment Reform and the Affordable Care Act Marketplace

Virginia Wang,[1,2] Abby Hoffman,[1,3] Bradley G. Hammill,[1] Caroline E. Sloan,[1,2] Matthew L. Maciejewski.[2,1] *[1]Duke Univ, Durham, NC; [2]Durham VAHCS, Durham, NC; [3]UNC-Chapel Hill, Chapel Hill, NC.*

Background: Medicare finances health care for most US patients with ESKD, regardless of age. The 2011 Medicare bundled payment for dialysis reduced Medicare reimbursement for hemodialysis, increasing the difference between Medicare and private insurance that commonly reimburses dialysis providers at higher rates. Passage of the 2014 Affordable Care Act also increased patient access to new private insurance options. These policies may have influenced providers to adjust their payer mix, as dialysis facilities have reported increasing rates of patients not enrolled in Medicare since 2011. This study describes trends in Medicare enrollment among new ESKD patients in 2006-2016.

Methods: From the US Renal Data System, we identified a cohort of incident ESKD patients between 2006 and 2016. We identified each patient's insurance status (Medicare, pending Medicare, non-Medicare) at dialysis initiation and observed changes over time. We report trends for the overall incident population, for patients aged 18-64, and by race.

Results: The proportion of new ESKD patients enrolled in Medicare remained stable between 2006 (65%) and 2016 (67%). There was an increase in non-Medicare coverage (13.2% in 2006, 19% in 2016) and a reduction in pending Medicare applications (21% in 2006, 14% in 2016). These trends were more pronounced among patients aged 18-64 (i.e., not already in Medicare due to age) and among aged 18-64 non-Whites (Figure). Multivariable regression results are pending.

Conclusions: There was a modest shift in payer mix among new patients with ESKD after bundled payment reform in 2011 and private insurance expansion in 2014, with fewer patients applying for or enrolled in Medicare over time. To address concerns among policymakers about facilities encouraging private insurance coverage, future work should examine the implications of these trends on outcomes for patients.

PO1088

The Correlated Case of Dialysis Facility and Hospital Star Ratings

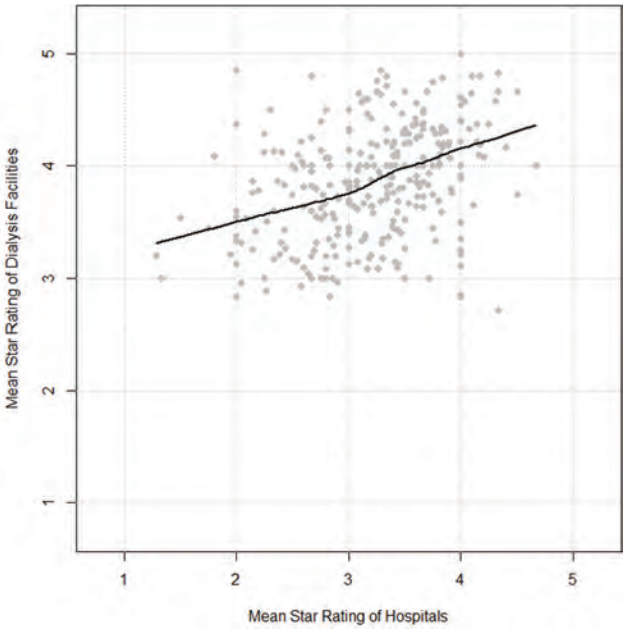
Eric D. Weinhandl,[1,2] David T. Gilbertson,[1] James B. Wetmore,[1,3] Kirsten L. Johansen.[1,3] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN; [3]Hennepin County Medical Center, Minneapolis, MN.*

Background: The Centers for Medicaid and Medicaid Services (CMS) periodically releases star ratings for several types of health care facilities, including acute care hospitals and outpatient dialysis facilities. Because respective rating systems utilize disparate quality measures, star ratings of dialysis facilities and nearby hospitals may be weakly correlated. However, hospital quality could influence dialysis patient outcomes. Furthermore, confounding by unmeasured economic, environmental, and social factors could induce correlation. We used public use files to assess whether star ratings of dialysis facilities and hospitals within the same region are correlated.

Methods: We ascertained dialysis facility star ratings from Dialysis Facility Compare and hospital star ratings from Hospital Compare (source: data.medicare.gov). Star ratings were based on quality measures that were accumulated in 2015-2018. We categorized each health care facility into 306 Hospital Referral Regions (HRRs), according to ZIP code. In each HRR, we estimated the mean star rating of all dialysis facilities and the mean star rating of all hospitals. Using loess regression, we estimated the correlation between these HRR-specific means.

Results: The analysis included 6667 dialysis facilities and 3565 hospitals, or approximately 22 dialysis facilities and 12 hospitals per HRR. The mean star rating in dialysis facilities was 3.7 (standard deviation, 1.0) and 3.2 (1.1) in hospitals. As displayed, HRR-specific mean star ratings of dialysis facilities and hospitals were positively and nearly linearly correlated. The correlation coefficient of these HRR-specific means was 0.4.

Conclusions: CMS star ratings of dialysis facilities and hospitals within the same region are positively correlated. Future studies should identify the sources of this correlation.



PO1089

The Budgetary Impact of Point-of-Care Hemoglobin Testing for Hemodialysis Patients

Linda Ficociello,[1] Melissa M. Rosen,[1] Claudy Mullon,[1] Robert J. Kossmann,[2] Mark Costanzo.[1] *[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Point of care (POC) testing in dialysis clinics can improve the quality of care provided to end-stage renal disease (ESRD) patients. The objective of this study was to estimate the budgetary impact of transitioning from weekly lab-based analysis of hemoglobin from each dialysis session to POC testing.

Methods: A budget impact model with a 1-year time horizon was developed. Our model included costs of POC testing in real-time in dialysis clinics compared to requiring the shipment of 3 blood samples per month to a lab for analysis. A non-invasive monitoring technology, the Crit-Line monitor® (CLM) measures hematocrit. Hemoglobin levels can be calculated from the measured hematocrit value. CLM is already used for fluid management in dialysis clinics and can also be used for POC testing. The model took the perspective of a healthcare organization responsible for providing dialysis treatments. The 2020 Medicare reimbursement value for a hematocrit test was used as a proxy value for lab testing costs. Our model also included costs associated with shipping, blood collection tubes, and erythropoiesis-stimulating agent (ESA) which is indicated for the treatment of anemia. Labor costs were excluded as they were considered fixed costs and would not change if POC testing was implemented.

Results: By replacing three blood draws per month, the use of a Crit-Line monitor® to assess hemoglobin levels could save $16.82 USD per patient per month.

Conclusions: The use of Crit-Line monitor® technology for point of care assessment of hemoglobin levels can result in decreased resource use and costs savings of $16.82 USD per patient per month compared to lab-based testing. Point of care testing may also have environmental benefits by reducing emissions associated with shipping samples and decreasing packaging needed to ship samples to a lab for analysis.

Physician Action on Medication Therapy Management (MTM) Recommendations Within 14 Days Associated with Lower 30-Day Readmission in Dialysis Patients

Harold J. Manley,[1] Gideon N. Aweh,[1] Eduardo K. Lacson.[1,2] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts Medical Center, Boston, MA.*

Background: We previously reported lower 30-day readmission rates associated with MTM (vs. no intervention) in maintenance dialysis patients.* After aggressive implementation of MTM, we now compare 30-day readmission risk in a more recent

cohort of Full -MTM that requires physician sign-off (including implementation orders) with Partial-MTM (med-rec with or without pharmacist review only) and determined the impact of providing Full-MTM early ≤ 14 days of discharge vs. delayed.

Methods: We reviewed electronic medical records of End-Stage Renal Disease Seamless Care Organization (ESCO) enrolled patients discharged home from acute-care hospitals between Nov 2018-Oct 2019 who returned to participating dialysis units. Patients readmitted ≤3 days, died, or entered hospice ≤30 days were excluded. Time-varying propensity score (from age, dialysis vintage, modality, cause and catheter use, prior hospitalization history, albumin, sex, marital status, and race) matched Cox models were constructed comparing hazard ratios for 30-day readmission between Full- and Partial-MTM exposure groups.

Results: MTM was provided in 1,752 discharges (456 Partial-MTM; 1296 Full-MTM). Of those, 455 Full- and 455 Partial-MTM cases were matched 1:1. Full-MTM had 25% lower risk for 30-day readmission even when compared to discharges that received partial-MTM services (HR 0.75; 95% CI 0.58-0.98). Full-MTM process was completed ≤14 days in 81% cases (n=1054). Of those, 444 early Full-MTM were matched to 444 Partial MTM cases and demonstrated a significantly lower risk for 30-day readmissions (HR 0.74, 95% CI 0.57-0.95), primarily driving the overall results.

Conclusions: Full MTM process is associated with lower 30-day readmission risk compared to Partial-MTM. The results are primarily driven by MTM process completion ≤14 days of discharge. These findings support that timely physician adjudication of pharmacists' recommendations and subsequent actions (i.e. medication changes as needed) influence the effectiveness of MTM programs to impact readmission rates. The statements contained in this document are solely those of the authors and do not necessarily reflect the views or policies of CMS. The authors assume responsibility for the accuracy and completeness of the information contained in this document. * = https://doi.org/10.1053/j.ajkd.2019.12.002

PO1091

Use of Predictive Analytics to Inform Integrated Care Programs to Reduce Hospitalizations Among Hemodialysis Patients

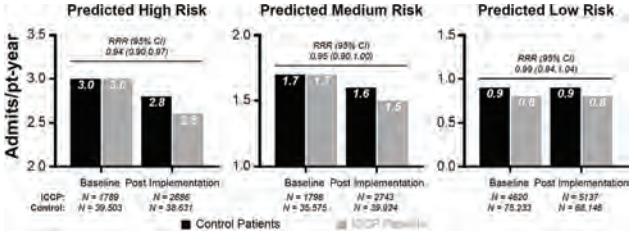
Katherine L. Mckeon,[1] Adam G. Walker,[1] Jiacong Luo,[1] Scott Sibbel,[1] Meredith L. Zywno,[2] Bryan N. Becker,[2,3] Tiffany L. Bray,[2,3] Juliana Stebbins,[3] Nick Lefeber,[3] David A. Roer,[2,3] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO; [3]DaVita Integrated Kidney Care, Denver, CO*.

Background: Integrated care for dialysis patients could benefit from identification of those who are at high risk for poor outcomes in order to efficiently deploy clinical resources. We recently developed a hospitalization risk stratification model to triage hemodialysis (HD) patients for clinician contact and assessment within an integrated care clinical program (ICCP). In this analysis, we compared hospitalization rates before and after model implementation for patients enrolled in an ICCP and control patients who were not.

Methods: All patients received our standard level of care consistent with industry best practices and regulations. ICCP patients predicted to be medium and high risk received additional services proportional to predicted risk level. Relative differences in annualized hospitalization rates for HD patients enrolled in an ICCP were compared to controls who were not by calculating relative rate ratios (RRR) and 95% confidence intervals (CI) in the baseline (Feb 2017-April 2018) and postmodel implementation (Jan-Aug 2019) eras. Comparisons were stratified by predicted risk level.

Results: The baseline hospitalization rate was 3.0 admissions/patient-year (pt-yr) for all high-risk patients. Post implementation, hospitalization rates decreased to a greater extent among ICCP patients (-0.4 admissions/pt-yr) versus controls (-0.2 admissions/pt-yr): RRR (95% CI) = 0.94 (0.90, 0.97). The baseline hospitalization rate was 1.7 admissions/pt-yr for all medium-risk patients. Post implementation, hospitalization rates decreased to a greater extent among ICCP patients (-0.2 admissions/pt-yr) versus controls (-0.1 admissions/pt-yr): RRR (95% CI) = 0.95 (0.90, 1.00). No differences were observed among low-risk ICCP patients and low-risk control patients.

Conclusions: These results support the potential utility of predictive analytics to support programs aimed at improving clinical outcomes among HD patients.



PO1092

Healthcare Staff Acceptance of Ultrafiltration Rate Recommendations Made by a Novel Feedback Controller

Mirell Tapia,[1] Lemuel Rivera Fuentes,[1] Sabrina Rogg,[2] Stephan Thijssen,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [3]Icahn School of Medicine at Mount Sinai, New York, NY*.

Background: Preciado et al. have identified relative blood volume (RBV) targets during hemodialysis (HD) that are associated with improved patient survival [1]. Attainment of RBV targets requires frequent adjustments to the ultrafiltration rate (UFR) by the dialysis nurse, which is logistically not feasible. We developed a novel proportional-integral controller that takes RBV data from the CLiC® device as an input and provides UFR recommendations to guide the RBV curve into the desired targets. We investigated the degree to which the nurses accepted the UFR recommendations made by this controller.

Methods: We conducted a prospective, interventional study in chronic HD patients at 3 Dialysis Clinics in Manhattan. RBV was measured with the CLiC® device. CLiC® and Fresenius 2008T HD machine data were fed into a research laptop running the UFR Feedback Controller software. UFR recommendations (generated every 10 minutes) were evaluated by dialysis nurses who then either implemented or rejected them as they deemed clinically appropriate.

Results: 56 HD treatments from 14 subjects had analyzable data. Out of 1,038 UFR recommendations, 926 (89.2%) were accepted, while 112 (10.8%) were overridden. For 25 HD treatments which had at least one recommendation overridden, we analyzed the direction and magnitude of disagreement between the Controller-suggested UFR and the implemented UFR (Fig. 1). From the overridden controller recommendations, 20 implemented UFRs were greater than the respective Controller-suggested UFRs, another 70 implemented UFRs were less than 100 mL/h lower than the Controller-suggested UFRs. Together, these two categories made up 83% of all "disagreements" between the nurse and the Controller. Of the total of UFR recommendations overrides, 59.6% were due to staff preference in the absence of clinical symptoms.

Conclusions: There was a high proportion (≈90%) of Controller-UFR recommendations that were accepted by the nurses. Of the few cases where nurses overrode the recommendation, the majority (≈60%) were due to "staff preference", this is likely owed to the fact that the nurses exclusively attended one patient at a time for the entire HD session.

PO1093

Intradialytic Online Multicomponent Total Removed Solute Monitoring in Spent Dialysate by a Novel Miniaturized Optical Sensor

Liisi Leis,[1] Annika Adoberg,[1] Joosep Paats,[2] Jürgen Arund,[2] Kristjan Pilt,[2] Merike Luman,[1,2] Ivo Fridolin.[2] *[1]North Estonia Medical Centre, Tallinn, Estonia; [2]Tallinn University of Technology, Tallinn, Estonia*.

Background: Urea is the most commonly exploited marker of dialysis adequacy, but also other uremic retention solutes accumulate in ESKD patients. Commonly, the uremic solutes are divided into three physicochemical types with the representative markers urea, uric acid (UA); indoxyl sulfate (IS); and β2-microglobulin (B2M). Instead of total dialysate collection for quantification of the amount of uremic solutes removed during dialysis, an optical on-line monitoring has been proposed. The aim of this study was to evaluate intradialytic on-line multicomponent total removed solute (TRS) monitoring in the spent dialysate by a novel miniaturized optical sensor during hemodialysis (HD) and hemodiafiltration (HDF) with different settings.

Methods: Ten ESKD patients (6 M, 4 F; 60.2±16.8 y.o.) on chronic HDF were enrolled into the study. For each patient 5 midweek dialysis sessions (240min; HD: N=1, Qb=200mL/min, Qd=300mL/min, 1,5m^2 ; HDF: N=4, Qb≥300mL/min, Qd≥500mL/min, V_{subst}≥15L, 1,8m^2 and 2,2m^2) were included. Spent dialysate from the drain was monitored on-line by a miniaturized sensor prototype (Optofluid Technologies OÜ, Estonia). For the reference, samples from the spent dialysate drain tube of the HD machine were taken 7, 60, 120, 180 and 240 min after the start of the dialysis session. Concentrations of urea and B2M in the dialysate were determined in the clinical laboratory. Concentrations of IS and UA were determined utilizing the HPLC. TRS values were calculated using the tank weight and the lab or optical tank solute concentrations. t-test was used to determine significant differences between the methods (P≤0.05).

Results: The laboratory and optical TRS values were 489±112mmol and 512±87mmol for urea (R^2=0.215), 4232±712μmol and 4331±756μmol for UA (R^2=0.829), 230±47mg and 231±40mg for B2M (R^2=0.551), 606±339μmol and 616±321μmol for IS (R^2=0.951), being not statistically different for any uremic solutes. The reason for higher correlation for UA and IS is direct measurements of UA and IS by the optical sensor whereas urea and B2M are estimated indirectly.

Conclusions: Novel miniaturized optical sensor successfully carried out intradialytic on-line multicomponent TRS monitoring for the uremic solutes urea, UA, B2M and IS in the spent dialysate.

PO1094

Patient Safety in a Large Multinational Renal Services Provider Network

Belen Marron, Israel P. Silva, Carlos Lucas, Marietta Török, Charlotta Wollheim, Filiz Akdeniz, Suzanne H. Pearce, Fernando Macario. *Diaverum Renal Services. Corporate Medical Office, Hyllie, Mälmo, Sweden*.

Background: Patient safety is considered of paramount importance under any qualified provision of care, but results from routine tracking of incidents have scarcely been reported, even when that may negatively impact survival. **Objectives** To analyze all types of incidents in a multinational renal service provider network during 2019.

Methods: For the last 10 years, our institution has tracked all incidents under a structured process program, as well as, educated our staff in the importance of proactively reporting and analyzing incidents in a quarterly basis at the clinic, by country and globally. Incidents are categorized in 4 different types: A-Patient related; B-Staff and visitors; C-Products and D-Equipment. Different incident codes are assigned to each type (up to 54). Communication to Health Authorities applies in accordance with local country regulations. "Serious incidents" are immediately notified to the Corporate Office and to each Country Medical lead.

Results: A total of 92.923 incidents (2.7 incidents/patient/year) have been reported during 2019 (higher than in 2018: 2.2). This means an increase of 20% in the total number of reported incidents. Total incidents/1000 treatments was 17.2 (12.2 patient-related incidents). Reporting follows a heterogeneous pattern among countries, being lowest in Argentina and highest in the UK. Top 5 reported incidents were as follows: Codes A15 (voluntarily shortened treatment) and A14 (Patient did not show up), both related to patient adherence to treatment, accounted for 36% of total incidents, vascular access (VA) complications (A4) for 10.2%, change of dialyzer and/or blood lines due to clotting (A2) for 8.5% and recurrent minor monitor malfunction (D1) for 7.6% of incidents. Codes related with unexpected death or cardiorespiratory arrest are not present among the total global top 10 incidents.

Conclusions: Detailed tracking of incidents and comparison between countries have potential to increase quality of care and patients outcomes. Room for improvement recently made the Corporate Medical Office to launch new strategies on VA management, anticoagulation and patient compliance, among others. This large series may help other institutions to better monitor and standardize patient safety on dialysis.

PO1095

Incidence of Intradialytic Hypotension Throughout a Hemodialysis Session: Does the Time of Onset Matter?

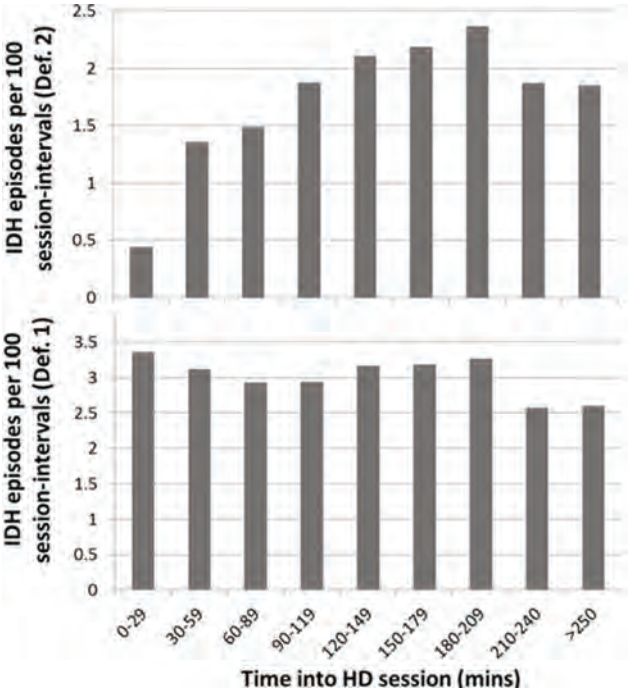
David F. Keane,[1,2] Jochen G. Raimann,[2] Hanjie Zhang,[2] Stephan Thijssen,[2] Joanna Willetts,[3] Peter Kotanko.[2] [1]*Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom;* [2]*Renal Research Institute, New York, NY;* [3]*Fresenius Medical Care Global Medical Affairs, United States, MA.*

Background: Intradialytic hypotension (IDH) is a common complication of hemodialysis (HD). Probability of IDH would be expected to increase during HD as removed ultrafiltration (UF) volumes increase. We aimed to describe the incidence of IDH throughout HD and associations of the time of IDH with clinical parameters and with survival.

Methods: We studied routinely collected data from 21 US dialysis clinics. IDH was defined as: 1) systolic blood pressure (SBP) < 90 mmHg; and 2) SBP< 90 mmHg and a reduction in SBP > 30 mmHg. Only the first IDH incident per session was included. Time of IDH was defined in 30-minute intervals. Patients who experienced IDH were classed as early- or late-onset based on whether most sessions with IDH had incidents in the first 2 hours or not. Association of early-onset IDH with clinical parameters and mortality were explored with logistic regression and Cox proportional hazard models.

Results: We studied 4,348 patients and 785,682 sessions. For definitions 1 and 2, IDH occurred in 13% and 7% of treatments with a range of 2.6-3.3 and 0.9-2.7 episodes per 100 session-intervals at risk, respectively. IDH occurred in the first 2 hours in 45% and 33% of IDH sessions, respectively. IDH incidence was not associated with time into HD using definition 1; a positive association was observed using definition 2. Adjusted hazard ratios for death comparing early-onset IDH with late-onset were 1.5 and 1.7 for definitions 1 and 2. Early-onset IDH was associated with female sex, higher age and UF rates and lower BMI and SBP.

Conclusions: Early-onset IDH is not uncommon. More consideration of the nature and time of IDH onset, in the context of how it is defined, could help to minimize IDH.



IDH episodes per 100 session-intervals at risk with time into HD session

PO1096

Endothelin 1 and Parameters of Systolic Blood Pressure in Hemodialysis Patients

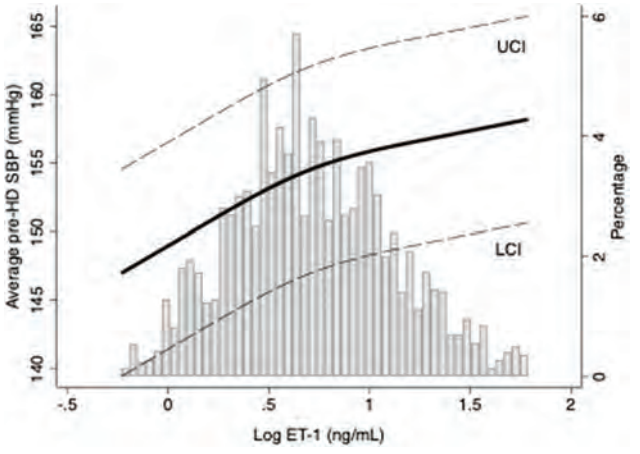
Anika T. Singh,[1,2] Suraj Sarvode mothi,[2] Ping Li,[4] Sushrut S. Waikar,[3,5] Finnian R. McCausland.[2,1] Mc Causland Lab [1]*Harvard Medical School, Boston, MA;* [2]*Brigham and Women's Hospital, Boston, MA;* [3]*Boston Medical Center, Boston, MA;* [4]*Chinese PLA General Hospital, Beijing, China;* [5]*Boston University, Boston, MA.*

Background: Blood pressure (BP) fluctuates widely during intermittent hemodialysis (HD), with greater variability associated with adverse cardiovascular outcomes. As endothelin-1 (ET-1) is a potent vasoconstrictor, we hypothesized that higher concentrations of ET-1 is associated with higher pre-HD systolic BP (SBP).

Methods: ET-1 concentrations were measured at baseline from the DaVita Biorepository (N=784), a longitudinal prospective cohort study with quarterly collection of clinical data and biospecimens. Unadjusted and adjusted linear mixed effects regression models were fit to determine associations of log-transformed ET-1 with SBP at dialysis (pre-HD, nadir intra-HD, post-HD, drop (pre- minus nadir-HD) and delta (pre- minus post-HD). Multivariable models were adjusted for age, sex, race, access, diabetes, heart failure, cardiovascular disease, peripheral vascular disease and pre-HD SBP.

Results: Mean age was 58 years, 59% were males, 40% black. Mean pre-HD SBP was 152 (± 28) mmHg and mean ET-1 concentration was 2.3 (±1.1) ng/mL. Subjects in higher quartiles of baseline ET-1 tended to be younger, diabetic, have higher SBP and lower serum albumin. In fully adjusted models, each unit increase in SD of log-transformed ET-1 was associated with a 3.0 (95% CI 1.8 to 4.2) mmHg higher pre-SBP; 1.2 (95%CI 0.5 to 1.9) mmHg higher nadir-SBP; 1.6 (95% CI 0.6 to 2.5) mmHg higher post-SBP; 1.2 (95%CI 0.2 to 1.5) mmHg lower SBP drop and 1.6 mmHg (95% CI 0.6 to 1.08) lower delta SBP. In categorical analyses a monotonic increase in pre-SBP was noted in higher quartiles of ET-1 (Q4: 7.8 mmHg increase (95% CI 4.5 to 11.2; P<0.001) compared with Q1. Similar patterns were noted for the other variables of interest.

Conclusions: Higher ET-1 is independently associated with higher SBP in maintenance HD patients. These results suggest a role for studying ET-1 antagonism in HD patients with resistant hypertension.



PO1097

Kidney Transplant Access Among Children and Young Adults on Dialysis in the United States

Yusuke Okuda,[1] Ekamol Tantisattamo,[1] Elani Streja,[1] Marciana Laster,[2] Connie Rhee,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of California Los Angeles, Los Angeles, CA.*

Background: Only 20% of children and young adults with advanced CKD receive preemptive kidney transplant (KT). This study aimed to investigate secular trends in KT access among incident US dialysis patients who were ≤21 years old.

Methods: In a cohort of incident dialysis patients ≤21 years of age who initiated dialysis between 1995-2014 from the USRDS database, we examined secular trends in the likelihood of receiving KT, using a Cox proportional hazards regression.

Results: Among 24,860 patients, the median (IQR) age at dialysis initiation was 17 (11–20) years of age, among whom 56% were <18 years old. A total of 16,912 (68%) patients underwent a KT during a median (IQR) follow-up of 2.0 (0.9–4.3) years (total follow-up: 82,244 patient-years). The 1-, 2-, and 3-year probabilities of receiving a KT were 23%, 43%, and 55%, respectively. The likelihood of receiving KT slightly improved but decreased after 2005 among patients <18 years old; a decreasing trend was remarkable among patients ≥18 years old [Figure A]. While increasing among patients <18 years old, the likelihood of receiving a deceased donor transplant declined among those ≥18 years old. For a living donor transplant, there were decreasing trends in both age groups [Figure B].

Conclusions: While the likelihood of receiving pediatric KT declined over two decades, there was an increase in deceased donor transplantation among those <18 years old. Since biological factors determine unmet need for KT in pediatric or young adult populations having short waiting time, an old kidney allocation system (KAS), which achieved the goal by transplanting patients with the longest waiting time, may not improve transplant access and outcomes. A new KAS commenced in December 2014, and living donor transplant may provide different trends or improve pediatric KT access, although further long-term studies are needed.

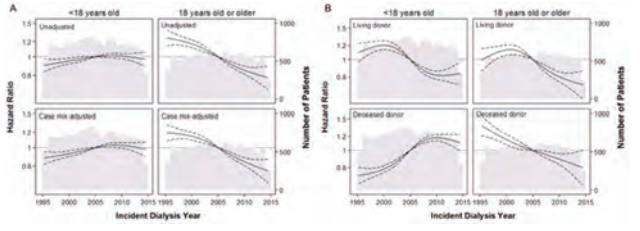


Figure: Time-to-event outcomes for receiving a kidney transplant among pediatrics(<18 years old) and young adults (≥18 years old) between 1995 and 2014.A. Unadjusted and case-mixed adjusted models

B: Stratified into living and deceased donor renal transplantations

Nephrologists' Practices, Perspectives, and Experiences Providing Care and Treatment Education to Patients with Varying Amounts of Pre-ESRD Care: A Mixed-Methods Study

Megan Urbanski,[1] Crystal A. Gadegbeku,[3] Laura A. Siminoff,[1] Amy D. Waterman,[2] Levent Dumenci,[4] Heather M. Gardiner.[1] *[1]Department of Social and Behavioral Sciences, College of Public Health, Temple University, Philadelphia, PA; [2]Transplant Research and Education Center, UCLA, Los Angeles, CA; [3]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [4]Department of Epidemiology and Biostatistics, College of Public Health, Temple University, Philadelphia, PA.*

Background: A third of patients newly diagnosed with end-stage renal disease (ESRD) in the U.S. had minimal or no pre-ESRD nephrology care and "crashed" onto dialysis. Little is known about treating nephrologists' practices and perspectives on renal replacement therapy (RRT) information delivery and decision-making for this subset of patients at the time of their ESRD diagnosis and RRT initiation.

Methods: A convergent mixed methods study design was used, and semi-structured interviews were conducted with nephrologists in Philadelphia and the surrounding region. Participants were queried on general practices and perspectives on RRT information delivery and decision-making practices for patients with varying amounts of pre-ESRD nephrology care and also queried on their experiences providing care to patients recently diagnosed with ESRD. Applied thematic analysis was used to analyze the qualitative responses and all quantitative data were fully described.

Results: A total of 15 nephrologists participated. Participants had been practicing nephrology for a median of 7 years and a third of participants were trainees at the time of the interview (i.e., nephrology fellows). The qualitative analyses revealed 12 themes, including: patients' clinical presentation guides RRT initiation, RRT initiation often occurs urgently irrespective of pre-ESRD care, utilize direct communication style during diagnosis, reliance on other providers for patient education, challenges to providing patient education, desire improved access to educational resources, and desire engaging patient in shared decision-making for RRT selection and initiation. Notably, participants identified patient- and institutional-level barriers inhibiting their ability to provide quality care and education to patients presenting with ESRD diagnosis for RRT initiation.

Conclusions: Nephrologists face significant challenges in providing quality care to patients with varying amounts of pre-ESRD nephrology care. Increasing availability of nephrology-trained interdisciplinary staff in outpatient chronic kidney disease clinics and hospital settings to assist providers with the logistics associated with RRT education and initiation has the potential to improve care for patients newly diagnosed with ESRD.

Excessive Unfractionated Heparin Dosing During Hemodialysis Explained by Access and Discordance Between Activated Clotting Time and Activated Partial Thromboplastin Time

Marijke De Troyer,[1,2] Karl M. Wissing,[1,2] Dieter De Clerck,[1,2] Annelies Tonnelier,[1,2] Marie-Laure Cambier,[1,2] Karlien Francois.[1,2] *[1]Vrije Universiteit Brussel, Brussels, Belgium; [2]Universitair Ziekenhuis Brussel Division of Nephrology and Hypertension, Brussels, Belgium.*

Background: Recommendations and practice patterns for heparin dosing during hemodialysis show substantial heterogeneity and are scantly supported by evidence. This study was designed to investigate factors conditioning the dose of unfractionated heparin (UFH) prescribed during maintenance hemodialysis.

Methods: We performed a cross-sectional study assessing UFH dosing, coagulation tests - activated partial thromboplastin time (aPTT) and activated clotting time (ACT) before dialysis start, 1h after start and at treatment end (4h) - and post dialysis measurement of residual blood compartment volume of the dialyzer ("total cell volume") during a single hemodialysis session.

Results: 94 patients, 57% male, with a median dialysis vintage of 34(6-84) months were dialyzed using a total UFH dose of 9271±4066 (range 3000-23050) IU/session (127±58 IU/kg/session). Use of a central venous catheter (n=48, 51%) was associated with higher UFH loading dose (51±22 vs 37±17 IU/kg in patients with arterio-venous (AV) access; $p<0.001$) and higher total UFH dose (158±55 vs 89±32 IU/kg; $p<0.001$). Dialysis sessions using catheters with recent history of thrombotic dysfunction tended to use higher total doses of UFH (174±61 vs 147±49 IU UFH/kg) ($p=0.09$). Compared to baseline values, aPTT increase was significantly higher than ACT increase both 1h (4.7-fold, 95%CI 4.2-5.3 vs 2.0-fold, 95%CI 1.7-2.3) and 4h after dialysis start (3.6-fold, 95%CI 3-4.2 vs 1.6-fold, 95%CI 1.3-1.9) ($p<0.0005$). One and 4h after dialysis start, 75% and 51% of patients presented a >2.5-fold increase in aPTT. Among patients with aPTT increase >2.5-fold at 4h, 84% had an ACT increase of ≤2.5-fold and 52% of ≤1.8-fold ($p<0.001$). No clinically significant clotting of the extracorporeal circuit was noted during the studied sessions. Dialyzer's total cell volume was reduced with a median of 9% (6-21%) without significant effect of UFH dose, aPTT or ACT measurements and catheter use. UFH dose, aPTT, ACT and catheter use were not associated with $spKt/V_{urea}$ either.

Conclusions: Routine clinical practice of UFH dose adaptations based on ACT measurements results in frequent over-anticoagulation according to aPTT results. Higher doses of UFH are used in patients with hemodialysis catheters without evidence that this reduces dialyzer clotting or improves urea clearance.

Predictors of Extracorporeal Circuit Clotting in Patients Requiring Continuous Renal Replacement Therapy

William F. Towers,[1] Michael J. Samarin,[1] Danielle L. Padgett,[1] Margaret C. Hastings,[2,1] Joanna Q. Hudson.[2,1] *[1]Methodist University Hospital, Memphis, TN; [2]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Extracorporeal circuit (ECC) clotting frequently occurs during continuous renal replacement therapy (CRRT) resulting in treatment interruption, blood loss and increased resource use. The purpose of this study was to evaluate risk factors for ECC clotting in patients receiving CRRT.

Methods: A retrospective chart review was conducted to identify adult patients who received CRRT at Methodist Le Bonheur Healthcare for a minimum of 24 hours during January 2015 to October 2019. The primary outcome was the occurrence of ECC clotting which was defined as documentation of a thrombotic event in the ECC. Demographic and laboratory data, anticoagulant medications, and CRRT parameters were evaluated for a maximum of 7 days to determine potential risk factors for clotting. Multivariable logistic regression was used to identify predictors of clotting.

Results: A total of 200 patients were included: [108 (54%) male; mean age 56±13 years; mean sequential organ failure assessment score 12±4; 52 (26%) with past medical history of liver disease; 143 (72%) with acute kidney injury; mean duration of CRRT 3.6±2.0 days; 97% receiving continuous venovenous hemodiafiltration]. Overall, 131 (66%) patients experienced an ECC clot with a mean time to first ECC clot of 1.3±1.3 days. Patients receiving an unfractionated heparin (UFH) infusion (n=25) had a lower probability of an ECC clot occurring compared to those receiving no anticoagulation (n=86) (40% and 70%, respectively; p=0.01) and those receiving prophylactic UFH (n=70) (40% and 64%, respectively; p=0.04). Factors associated with an increased odds of clotting in patients not receiving an anticoagulant were non-African American race [odds ratio (OR) 4.0; 95% confidence interval (CI) 1.1-14.6], lower blood flow rates (OR 1.01; 95% CI 1.0-1.03), internal jugular catheters (OR 3.32;95% CI 1.1-9.9), and no history of hypertension (OR 4.79; 95% CI 1.4-16).

Conclusions: This study suggests a high rate of ECC clotting, particularly in patients not receiving anticoagulation. Eligible patients on CRRT should receive an UFH infusion in preference to no anticoagulation or prophylactic UFH.

PO1101

Gram-Negative Bacteraemias in Haemodialysis Patients: Pathogen and Source Identification

Anna Naito, Fatima Malik, Christopher M. Cregg, Lisa Bradwell, David Makanjuola. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: Gram-negative bacteraemia (GNB) in haemodialysis (HD) patients is associated with significant morbidity and mortality. Efforts to reduce rates of bacteraemias caused by Methicillin Resistant Staphylococcus Aureus have been hugely successful. Epidemiological studies now show the re-emergence of gram-negative pathogens, particularly *Escherichia Coli* (*E.Coli*) in causing bloodstream infections. We aimed to determine the source and pathogens responsible for GNB's in our HD cohort.

Methods: Data on all confirmed bacteraemias in HD patients between 2007 and 2018 were collected from clinical and electronic records from the hospital's renal and microbiology databases.

Results: 283 episodes of GNB occurred in 1361 patients over the 12-year period. 58.7% were male. The median age was 71 years (range 26-95). 31.8% had arteriovenous fistulae or grafts, the remainder had dialysis lines, of which 21.2% had dual access. The organisms isolated are shown in table 1. *E.Coli* and *Klebsiella Pneumoniae* were the dominant pathogens, accounting for 40.6% and 15.9% of bacteraemias isolated respectively. The most common sources of infection were HD access related in 31.4% (n=89), urinary tract 18.4% (n=52), hepato-biliary 7.8% (n=22), chest 7.8% (n=22), gastro-intestinal 6.0% (n=17), skin/soft tissue in 4.9% (n=14), other in 4.6% (n=13), no information on 4 patients (1.5%) and unknown source in 50 (17.7%).

Conclusions: *E.Coli* bacteraemias remain a major cause of GNB in our HD population. Dialysis lines are a significant risk factor for bacteraemia, lending further weight to the importance of establishing early definitive vascular access. Resistance trends of gram-negative organisms are of particular and increasing concern. We have noticed changing sensitivity patterns of isolates and it is not clear whether local empiric antibiotic policy is contributing to selection pressures and antimicrobial resistance.

Table 1: Gram negative isolates from blood cultures

Organism	%
Escherichia coli	40.6
Klebsiella Pneumoniae	15.9
Pseudomonas Aeruginosa	7.8
Enterobacter spp	7.8
Proteus mirabilis	6.0
Serratia marcescens	4.9
Other	17

PO1102

Five-Year Outcome of a Retrospective Cohort Study of Patients with Two Hemodialysis Sessions per Week

Aurora E. Hernandez, L. M. Perez-Navarro, Gloria G. García Villalobos, Elba O. Medina, Rafael Valdez-Ortiz. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: The indication of two hemodialysis (HD) sessions per week is a common strategy in patients with chronic kidney disease without social security. Some studies reveal that the indication of fewer HD sessions per week has been shown to be associated with adequate clinical results. **Objective:** To describe the clinical and biochemical status of patients in HD program twice a week in the last five years

Methods: Retrospective cohort study of patients with two HD sessions per week. Their clinical, nutritional status was evaluated by vectors of impedanciometry and quality of life KDQOL-SF 36. The statistical package SPSS V 22.0 was used for data analysis.

Results: Forty-one patients with a mean age of 37.9 ± 12.6 years, 56% women, were analyzed. The mean time with renal replacement therapy was 5.1 years; Average session time was 180 minutes; average ultrafiltration of 2726.8 ± 755.98 ml / session and an average Kt / V single pool of 1.54 ± 0.38. In 59% of patients the cause of CKD was undetermined. 46% of the patients had an arteriovenous fistula. Laboratory tests with Urea Pre-dialysis 164.5 ± 38.9 mg / dL; hemoglobin 10.32 ± 1.9 g / dL; albumin 3.99 ± 0.4 g / dL; phosphorus 5.3 mg / dL; calcium 8.05 ± 0.9 mg / dL; parathyroid hormone 886 ± 747 pg / dL. Body composition BMI 23.6 kg / m2; R (Ω) 622.3; Xc (Ω) 48.4; and phase angle 4.3 °. 44% of the patients had mild malnutrition according to the Score Malnutrion Inflamation classification. The generic dimensions of the KDQOL-SF 36 revealed scores greater than 60 for CKD symptoms and effects, with an SF-12 Physical Health Composite 46.3 and SF-12 Mental Health Composite 56.3.

Conclusions: The costs of hemodialysis (HD) treatment are usually a huge financial burden for health systems and patients. HD sessions twice a week are common practice in many countries in patients without social security. Our results show that this therapy should not be categorized as a suboptimal therapy but as an option for patients with certain clinical characteristics.

PO1103

Feasibility of and Adherence to Using a Wrist-Based Activity Tracker in Hemodialysis Patients

Maggie Han,[1] Priscila Preciado,[1] Ohnmar Thwin,[1] Xia Tao,[1] Mirell Tapia,[1] Lemuel Rivera Fuentes,[1] Mohamad I. Hakim,[1] Amrish U. Patel,[1] Nadja Grobe,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Wearables allow insights into patient's status outside the clinical setting. We aim to quantify how long patients will use a wearable device before requiring an intervention to improve adherence.

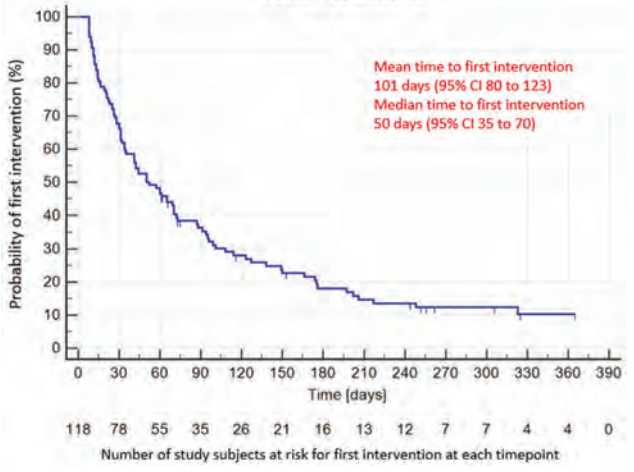
Methods: Hemodialysis (HD) patients were enrolled from 4 clinics in New York City from May 2018 and followed for up to 1 year. Patients ≥18 years, on HD ≥3 months, able to walk, owning a smartphone, mobile tablet or PC were enrolled, provided with a Fitbit Charge 2, and instructed on how to use the device and sync data. If a patient failed to sync data for 7 consecutive days, a SMS or email reminder was sent. Time to first intervention (TFI) was evaluated using Kaplan Meier time-to-event analysis. Predictors of TFI, including gender, age, living situation, and education level, was assessed via univariate Cox Regression. Patients were censored at the end of the observation period.

Results: 125 patients were enrolled into our study and 7 failed screening. At enrollment, patients were 54±12 years old with a dialysis vintage of 5.6±5.8 years; 37% lived alone, 56% were single, 59% unemployed, 64% were African American, and 42% had an education level of some college or higher. 82% of the patients required a text message reminder. Mean and median TFI were 101 days (95% CI 80 to 123) and 50 days (95% CI 35 to 70 days), respectively. The probability of no intervention is shown in Figure 1. None of the a priori defined parameters were significant predictors of TFI.

Conclusions: Majority of patients studied required at least some intervention to maintain the use of a wrist-based wearable device. While most patients require an intervention before 2 months, the patients who maintain use independently after that point are unlikely to require intervention.

Funding: Commercial Support - Fresenius Medical Care

Figure 1. Kaplan Meier curve of time to first intervention



PO1104

Routinely Measured Cardiac Troponin I and NT-ProBNP as Predictors of Mortality in Japanese Hemodialysis Patients: The Dialysis Outcomes and Practice Patterns Study

Masahiro Eriguchi,[1] Kazuhiko Tsuruya,[1] Marcelo Lopes,[2] Brian Bieber,[2] Keith McCullough,[2] Roberto Pecoits-Filho,[2] Bruce M. Robinson,[2] Ronald L. Pisoni,[2] Eiichiro Kanda,[3] Kunitoshi Iseki,[4] Hideki Hirakata.[5] *[1]Nara Medical University, Kashihara, Japan; [2]Arbor Health Care Co, Extendicare Health Services Inc, Milwaukee, WI; [3]Kawasaki Medical School, Kurashiki, Japan; [4]Nakamura Clinic, Urazoe, Japan; [5]Fukuoka renal clinic, Fukuoka, Japan.*

Background: Due to the interplay of chronic kidney disease and the heart, it is common for myocardial damage and strain to be present in hemodialysis (HD) patients. The cardiac troponin I (cTnI) and NT-proBNP are widely used as cardiac biomarkers to evaluate the patients at high risk for cardiovascular disease (CVD). However international The Dialysis Outcomes and Practice Patterns Study (DOPPS) data indicate that these cardiac biomarkers are measured in fewer than 2% of HD patients in real-world practice.

Methods: Pre-dialysis levels of cTnI and NT-proBNP at study enrollment were measured in 1176 prevalent Japanese HD patients (DOPPS phase 5). Cox regression was used to test the association of the cardiac biomarkers with all-cause mortality, adjusting for potential confounders. Subgroup analyses were performed to assess potential effect modification of clinical characteristics: age, systolic blood pressure, HD vintage, diabetes mellitus, CVD, and heart failure.

Results: Median [IQR] cTnI (99th percentile; 0.04 ng/mL) and NT-proBNP levels were 0.018 [0.005, 0.04] ng/mL and 3432 [1580, 8017] pg/mL, respectively. There were 175 deaths during a median [IQR] follow-up of 2.8 [2.3, 2.9] years. Higher levels of both cardiac biomarkers were incrementally associated with mortality after adjustment for potential confounders. Even after adjustment for the alternative cardiac biomarker, the HRs of death for cTnI >0.04 and NT-proBNP >8000 pg/mL versus those references (cTnI <0.01 and NT-proBNP <2000) were 2.67 (95% CI 1.47-4.87) and 2.05 (95% CI 1.10-3.84), respectively and still remained significant. Subgroup analyses showed the associations of both cardiac biomarkers with mortality were consistent between stratified groups. (the p values for interaction were >0.10 for all stratified models).

Conclusions: Routinely measured NT-proBNP and cTnI are strongly associated with mortality among prevalent Japanese HD patients. These associations were still significant even after adjustment for the alternative biomarker, suggesting that cTnI and NT-proBNP may reflect different pathologic aspects for cardiac abnormalities.

PO1105

Paraoxonase 1 Gene Polymorphisms Concerning Dyslipidemia, Related Comorbidities, and Mortality of Hemodialysis (HD) Patients

Alicja E. Grzegorzewska, Paulina Adamska, Kamila Ostromecka, Adrianna Mostowska, Wojciech J. Warchol, Pawel P. Jagodzinski. *Poznan University of Medical Sciences, Poznan, Poland.*

Background: Paraoxonase 1 (PON1), a protein product of *PON1*, may prevent atherosclerosis influencing lipid metabolism and exerting antioxidant and anti-inflammatory activities. We focused on *PON1* polymorphisms concerning dyslipidemia, coronary heart disease (CHD), myocardial infarction (MI), ischemic cerebral stroke (ICS), and mortality of HD patients.

Methods: HD subjects (n = 1407, men 782, CHD 542, MI 299, ICS 250) were genotyped for *PON1* polymorphisms by high-resolution melting curve analysis (rs662) or predesigned TaqMan SNV Genotyping Assay (rs854560 and rs705379). Dyslipidemia was diagnosed by K/DOQI guidelines (2003). The TG/HDL-cholesterol ratio of ≥3.8 indicated atherogenic dyslipidemia. Standard diagnostic rules were applied for CHD, MI, and ICS recognition. Survival probability was evaluated by the Kaplan-Meyer method and Cox regression analyses.

Results: The rs662 allele A (OR 1.70, 95% CI 1.07-2.70, P=0.023) and rs854560 TT vs. AA homozygosity (OR 1.59, 95% CI 1.09-2.32, P=0.017) contributed to the prevalence of atherogenic dyslipidemia. *PON1* rs705379 was not associated with frequency of the TG/HDL-cholesterol ratios ≥3.8, but patients showing the TT genotype presented higher values of this ratio (3.92, 0.65–39.4) than possessors of the CC+CT genotypes (3.46, 0.44–49.7, P=0.039) or the CC genotype (3.42, 0.66–34.5, P=0.026). The T allele of *PON1* rs854560 was associated with the higher prevalence of ICS (OR 1.38, 95% CI 1.02-1.85, P=0.034 together with age and diabetic nephropathy) and borderline with MI (OR 1.31, 95% CI 1.0-1.71, P=0.051 together with age, diabetic nephropathy, and male gender). The *PON1* rs705379 TT genotype contributed to mortality from all cardiovascular diseases (HR 1.28, 95% CI 1.04-1.57, n=485, P=0.022), all cardiac diseases (HR 1.33, 95%CI 1.04-1.69, n=354, P=0.023), and CHD and its complications (HR 1.57, 95% CI 1.08-2.27, n=117, P=0.019).

Conclusions: All three tested *PON1* polymorphisms correlate with atherogenic dyslipidemia in HD patients. Associations of *PON1* with dyslipidemia, ICS, and cardiovascular mortality provide arguments for the consideration of PON1 as a therapeutic target in the prevention of atherosclerosis and its complications in uremic subjects.

PO1106

Plasma and Erythrocytes Lipidomic Analysis of Adverse Cardio-Cerebrovascular Outcome in Maintenance Hemodialysis Patients

Yujun Qian, Ke Zheng, Xuemei Li. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Cardio-cerebrovascular diseases are prevalent and devastating in maintenance hemodialysis patients. Lipid metabolism is vital for cardiovascular diseases in non-dialysis population. The disorder of lipid metabolism in dialysis patients is prominent, but the relation of lipids to cardiovascular diseases in dialysis patients is still controversial. Traditional lipids makers failed to identity hemodialysis patients with high risk of cardio-cerebrovascular event. Using high-coverage targeted lipidomic analysis, this study aimed to evaluate the potential of lipids to assess risk of future cardio-cerebrovascular events in hemodialysis patient.

Methods: From July 2013 to August 2019, we followed up the dialysis patients in our dialysis center for stroke and myocardial infarction events, and these patients' plasma and hemocytes were stored at the baseline. Lipidomic analyses were performed on an Exion LC-system coupled with a QTRAP 6500 PLUS system (Sciex). Principal component analysis and orthogonal project to late structures discriminant analysis, and t-test were used to analyze the differences between patients in with /without adverse cardio-cerebralvascular outcome groups.

Results: A total of 45 plasma samples and 117 hemocytes samples were collected. 9 plasma samples and 28 hemocytes samples were from patients with cardio-cerebrovascular events. 539 kinds of lipid metabolites were detected in plasma, 237 kinds of lipid were detected in erythrocytes. Compared with the patients without cardio-cerebrovascular events, the patients with events presented higher level of plasma PS 34:2 and TAG 44:1 (16:1), lower level of plasma TAG 52:6 (16:2), TAG 58:9 (22:5), LPS 18:0, and lower level of erythrocytes Cer d18:1/20:0, Cer d18:1/18:0 and cerd18:1/21:0 (Fold change >1.5 or <1/1.5, P value <0.05).

Conclusions: These findings revealed novel plasma and erythrocytes lipid predictors for cardio-cerebrovascular diseases in hemodialysis patients.

PO1107

β-Blocker Dialyzability and Adverse Cardiovascular Outcomes in Hemodialysis Patients: A Meta-Analysis

Abhinav Tella, William V. Vang, Eustacia C. Ikeri, Olivia Taylor, Alicia Zhang, Srihari I. Raju, Areef Ishani. *Minneapolis VA Health Care System, Minneapolis, MN.*

Background: β-blockers (BB) are one of the most common medications among hemodialysis (HD) patients. There are several BB with different pharmacokinetic properties. Particularly relevant for HD patients is BB dialyzability. In non-dialysis patients, abrupt withdrawal of BB has been associated with adverse cardiovascular events (CVE). HD patients receiving dialyzable BB may also be at increased risk for CVE. This systematic review aims to determine in HD patients if highly dialyzable BB (HDBB) (metoprolol, atenolol, and acebutolol) compared to poorly dialyzable BB (PDBB) (carvedilol, labetalol, bisoprolol, and propranolol) alters CVE and mortality.

Methods: We searched MEDLINE from 1990 through February 2020 for studies of all forms. All cause mortality (ACM) and CVE were our primary outcomes. Random effects models were used to calculate pooled risk ratios (RR).

Results: An initial search identified 1,066 articles. Exclusion criteria eliminated articles that did not include HD participants or did not compare at least two BB. Ultimately, three cohort studies comparing HDBB and PDBB were identified. All studies were retrospective cohort studies of large HD datasets of patients in the U.S. and Canada. The combined population size of the analyzed studies was 38,580 patients: 24,596 on HDBB and 13,984 on PDBB. There was significant heterogeneity between studies, with two suggesting harm associated with HDBB and one suggesting a reduction in mortality. The risk ratio derived from pooled data across these studies was 1.03 (95% CL: 0.88-1.22) for ACM and 0.94 (95% CL: 0.80-1.11) for CVE. Significant heterogeneity was seen with I^2 values of 86% and 84% for ACM and CVE respectively.

Conclusions: After a comprehensive search, only three cohort studies were identified comparing BB of different dialyzabilities. No randomized control trials were identified. The three cohort studies had varying results with two favoring HDBB and one favoring PDBB. Pooled results suggested a greater incidence of CVE in patients on PDBB compared to those on HDBB, while ACM is lower for PDBB than for HDBB. Given the heterogeneity of results it is unclear what type of BB should be used in HD patients. A randomized controlled trial comparing BB of different dialyzabilities is warranted.

PO1108

Pre-Dialysis Transition Predictors of Vascular Access Type in 73,928 Veterans Who Started Hemodialysis Therapy Between 2007-2015

Jui-Ting Hsiung,[2,1] Kamyar Kalantar-Zadeh,[1] Elani Streja.[2,1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]VA Long Beach Healthcare System, Long Beach, CA.*

Background: Studies showed dialysis patients with central venous catheter (CVC) had worse outcomes compared to arterio-venous fistula/graft (AVF/AVG) patients. It is hypothesized that a CVC may be a surrogate for sicker patients. From the US Veteran transition of care (TC-CKD) cohort, we sought to characterize factors associated with initiating dialysis with CVC vs. AVF/AVG access type within a year prior to dialysis transition.

Methods: Among US veterans who transitioned to end-stage renal disease (ESRD) from 2007 to 2015, we examined predictors of access type using adjusted logistic regression. An adjusted reverse cox model was used to examine predictors at time of dialysis initiation to identify time to access placement surgery prior to transition.

Results: Logistic regression showed patients with higher Charlson comorbidity index, multiple preexisting comorbidities, and higher hospital and primary care visit before access surgery, had a higher odds of receiving CVC verses AVF or AVG. Among a subset of 28,759 patients, those who were older, female, black, had dementia, and had higher serum phosphorus, white blood cells, and eGFR are more likely to have CVC. Patients who were married, had higher serum albumin, calcium, sodium, hemoglobin, had slower 1 year eGFR decline, and higher nephrology visits, were less likely to have CVC. Fully adjusted reverse cox regression showed patients with higher serum alkaline phosphatase and blood urea nitrogen were more likely to have AVF/AVG placed closer to time of transition. Among 44,558 patients who had at least 1 VA primary care visit in the year prior to dialysis, patients with ≥2 nephrology visits were more likely to have a AVF/AVG placement surgery in the year prior to transition [figure].

Conclusions: We found that starting dialysis with CVC is a surrogate of adverse outcomes and faster CKD progression, while frequent nephrology visits in a year prior to transition is associated to higher likelihood of AVF/AVG placement.

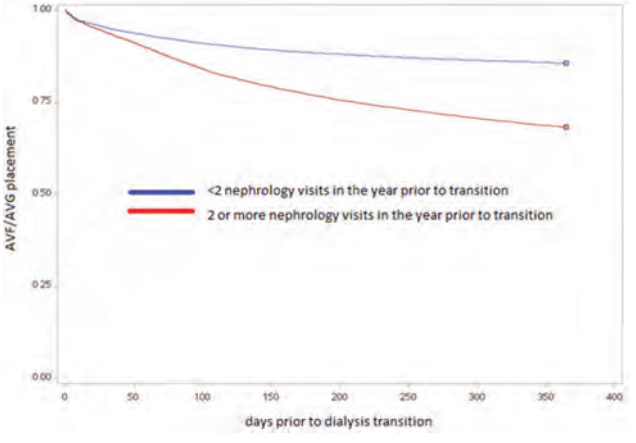

Figure: Time for dialysis transition back to AVF/AVG placement surgery prior to transition.

PO1109

Effect of Treatment According to Intervention Modality with Central Vein Stenosis in Hemodialysis Patients

Seon Deok Hwang,[1] Joon Ho Song,[1] Kipyo Kim,[1] Woo Yeong Park,[2] Seoung woo Lee.[1] *[1]Inha University, Incheon, Incheon, Republic of Korea; [2]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.*

Background: A general cause of hemodialysis vascular access failure, a primary cause of morbidity patients undergoing hemodialysis, is central venous occlusion or stenosis. There are several interventions to resolve problem; however whether method is best for dialysis patients. The purpose of this study is to compare which method is best choice to hemodialysis patients.

Methods: We searched Outcomes included the rate of primary patency, assisted primary patency, secondary patency, re-intervention subjects, re-intervention rate regarding balloon angioplasty, nondrug metal stent, drug-eluting balloon, or drug-eluting stent in PubMed, Embase, CENTRAL, Ovid and other relevant websites. We selected and assessed the trials that met the inclusion criteria and conducted a network meta-analysis using the R software.

Results: A total of eighteen studies were included in the network meta-analysis among treatment of intervention group. Overall, 967 patients were reviewed and analyzed for primary and secondary patency rates at 6, 12 months and 24 months post-treatment. Compared with nondrug metal stent, drug-eluting stent group showed a significantly lower secondary patency rates (odds ratio 0.67 [95% credible interval, 0.46–0.92]) at 12 month. However, primary patency and assisted primary patency rates showed no differences among the intervention during observational period. In rank probability, Percutaneous transluminal angioplasty was second in secondary patency rates. However, there is not statistically significant difference in rankgram.

Conclusions: We anticipate that the data of this study will assist physicians in making informed decisions when selecting intervention, such as drug-eluting stent, as a treatment option for central vein stenosis in hemodialysis patients

PO1110

Comparison of Mortality Risk Across Deciles of Cystatin C and Creatinine Among US Veterans

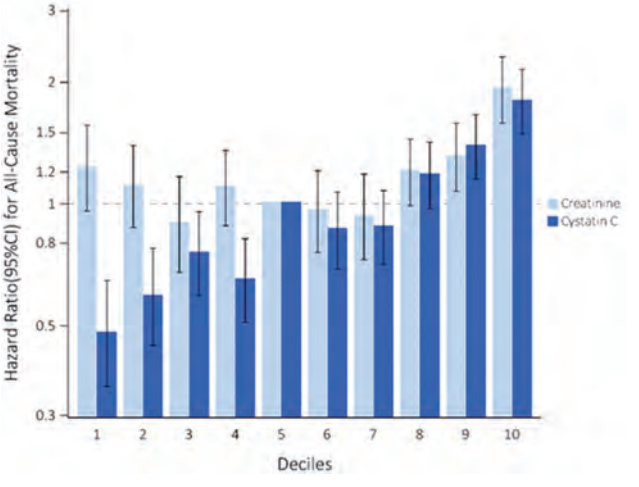
Cachet Wenziger,[4,1] Elani Streja,[4,1] John Sy,[4,1] Ekamol Tantisattamo,[1] Ramy M. Hanna,[1] Michael Shlipak,[3] Csaba P. Kovesdy,[5,2] Susan T. Crowley,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California San Francisco, San Francisco, CA; [4]VA Long Beach Healthcare System, Long Beach, CA; [5]Memphis VA Medical Center, Memphis, TN.*

Background: While both creatinine and Cystatin C (CysC) are markers of renal function, a low serum creatinine level can be related to less muscle mass and hence associated with worse outcomes. Prior studies among elderly persons found that higher serum CysC and creatinine levels were predictors of mortality. However, this relationship has not been examined in contemporary cohorts of US veterans. We sought to examine the relationship of creatinine and CysC with mortality risk in US veterans.

Methods: We examined a historical cohort consisting of 7,849 Veterans with baseline CysC and creatinine data between 10/01/2004-09/30/2015. Veterans were divided into deciles of serum creatinine and CysC levels separately. We examined the association of deciles with all-cause mortality using Cox proportional hazards regression adjusted for demographics, comorbidities, and other lab variables using decile 5 as the reference.

Results: The mean age in the cohort was 69±12, 4% were female, 77% were white, 15% were African American. The median (IQR (interquartile range)) for CysC was 1.28 (0.99,1.71) mg/L, for creatinine 1.24 (0.92,1.68) mg/dl. There were 1872/7849(24%) deaths during follow-up(follow-up time median(IQR): 794(461,1244) days). Patients with the highest decile of either CysC or creatinine had the highest mortality risk compared to the reference. Conversely, risk of mortality was incrementally lower for each decile below the reference for CysC while lower creatinine deciles were associated with a null to higher risk of death [figure].

Conclusions: Among US veterans, there is a linear relationship between CysC and mortality risk while the relationship between creatinine and mortality risk is U-shaped. These clinical results indicate that CysC may be a better marker of risk for adverse outcomes than creatinine, as previously shown in epidemiological studies.



Cox proportional hazards model showing the relationship between deciles of creatinine and cystatin C with all-cause mortality (Reference:5th decile). Model adjustments include demographics and comorbidities and lab variables.

PO1111

Comparative Mortality of ESKD from Nephrolithiasis or Urolithiasis in the United States

Jingyin Yan, Wolfgang C. Winkelmayer, Jingbo Niu. *Baylor College of Medicine Margaret M and Albert B Alkek Department of Medicine, Houston, TX.*

Background: Patient with nephro-/urolithiasis (NL/UL), when compared with patients without kidney stone disease, experience higher rates of adverse health outcomes, including increased mortality, cardiovascular morbidity, and progressive kidney disease. Little is known about the epidemiology and outcomes of patients who reach end-stage kidney disease (ESKD) secondary to NL/UL.

Methods: From the USRDS, we identified all patients with incident ESKD who initiated dialysis, 1995-2016. From the Medical Evidence Report (CMS-2728), we ascertained the kidney disease causing ESKD as reported by the patient's nephrologist. Categories included: NL/UL; diabetes; hypertension; glomerulonephritis, polycystic kidney disease (PKD); other urologic; and other/missing/unknown. We also noted patients' age, sex, race, Hispanic ethnicity, Medicaid coverage. Up to 11 comorbid conditions and health behaviors were also abstracted from form CMS-2728. Patients were followed from first dialysis to all-cause mortality, censoring at kidney transplant and end of database (12/2017). Cox proportional hazards regression models, stratified by year, estimated hazard ratios (HR) and corresponding 95% confidence intervals (CI).

Results: We studied 1,979,430 new ESKD patients, of whom 4190 (0.21%) patients had NL/UL as the reported cause of ESKD. Patients with NL/UL had similar age and sex distributions, but more were White (82 vs 66%) and fewer Black (11 vs 28%) or Hispanic (9 vs 13%) than among other causes of ESKD. All-cause mortality during median follow-up of 2.6 years was 173 per 1000 person-years among NL/UL patients. HR and 95% CIs comparing different causes of ESKD with NL/UL, at varying levels of model adjustment, are shown in **Table**.

Conclusions: Compared to patients whose ESKD was attributed to NL/UL, mortality was significantly higher among patients with DM, HTN, and other/unknown/missing cause of ESKD, but lower among patients with GN or PKD as cause of ESKD.

Mortality of Causes of ESKD vs. Nephro-/Urolithiasis [HR (95% CI)]

Nephro-/Urolithiasis (referent)	Adjusted for Year of ESKD	+Demographics and Medicaid	+Comorbidities and Labs
Diabetes	1.28 (1.23, 1.33)	1.46 (1.40, 1.51)	1.32 (1.27, 1.37)
Hypertension	1.23 (1.18, 1.27)	1.24 (1.19, 1.28)	1.16 (1.11, 1.20)
Glomerulonephritis	0.72 (0.70, 0.75)	0.94 (0.90, 0.97)	0.91 (0.88, 0.95)
Polycystic Kidney Disease	0.56 (0.54, 0.58)	0.68 (0.66, 0.71)	0.70 (0.67, 0.73)
Other Urologic Cause	1.12 (1.07, 1.16)	1.06 (1.02, 1.10)	1.02 (0.98, 1.07)
Other, Unknown, or Missing Cause	1.31 (1.26, 1.36)	1.38 (1.33, 1.43)	1.28 (1.23, 1.33)

PO1112

Sleep Patterns and Mortality Risk in a Prospective Hemodialysis Cohort

Amy S. You,[1] Sara S. Kalantar,[1] Antoney J. Ferrey,[1] Miklos Z. Molnar,[2] Ronald A. Fischman,[3] Michael A. Fischman,[3] Avedik Semerjian,[3] Yalitzi Guerrero,[1] Tracy Nakata,[1] Csaba P. Kovesdy,[2] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]Southland Renal Associates, Long Beach, CA.*

Background: While sleep disorders are common in hemodialysis (HD) patients, the association of sleep patterns and mortality remains uncertain. We sought to examine the association of sleep patterns with survival in a prospective HD cohort.

Methods: Among 452 HD patients from the prospective *Malnutrition, Diet, and Racial Disparities in Chronic Kidney Disease* study, we examined the association between sleep patterns and mortality. Patients underwent protocolized self-reported sleep questionnaires over 3/2014-6/2019. We examined associations of baseline sleep patterns with all-cause mortality using Cox regression adjusted for expanded case-mix covariates.

Results: In the overall cohort, the median (IQR) sleep duration was 6.0 (4.5, 8.0) hours vs. 7.0 (5.0, 8.0) hours on dialysis vs. non-dialysis days, respectively. In analyses examining the association of sleep duration with survival on dialysis days, patients with shorter sleep duration (defined as ≤median) had higher mortality (ref: longer sleep duration >median): adjusted HR (aHR) (95%CI) 1.59 (1.09, 2.31) (**Fig 1A**). Similar findings were observed for patients with shorter sleep duration (defined as ≤median sleep duration) on non-dialysis days (ref: longer sleep duration >median): aHR (95%CI) 1.51 (1.04, 2.19). When surveying patients with regards to having difficulty sleeping at night, those who reported a high frequency (often to almost always) had higher death risk (ref: never/rarely to sometimes): aHR (95%CI) 1.74 (1.17, 2.58). Upon surveying patients with respect to use of sleeping pills, those who reported moderate (sometimes) to frequent use (often/almost always) had higher mortality (ref: never/rare use): aHRs 2.07 (1.08, 3.97) and 2.00 (1.22, 3.28), respectively (**Fig 1B**).

Conclusions: In HD patients, shorter sleep duration, frequent sleeping difficulty, and moderate to frequent use of sleeping pills were associated with higher mortality risk. Future studies are needed to determine if interventions that improve sleeping patterns increase survival in this population.

Self-Reported Sleep Patterns in a Prospective Hemodialysis Cohort

Sara S. Kalantar, Amy S. You, Alejandra Novoa, Rene Amel Peralta, Tracy Nakata, Kamyar Kalantar-Zadeh, Connie Rhee. *University of California Irvine, Irvine, CA.*

Background: Growing evidence suggests that altered sleep patterns are prevalent in the general population, and are associated with worse health outcomes (obesity, hypertension, cardiovascular disease). However, there has been sparse examination of habitual sleep patterns in chronic kidney disease (CKD) patients, including those receiving dialysis. We thus examined self-reported sleep patterns in a well-defined prospective hemodialysis (HD) cohort.

Methods: Among 452 HD patients from the prospective *Malnutrition, Diet, and Racial Disparities in Kidney Disease* cohort recruited across 16 dialysis clinics, we administered protocolized sleep surveys during routine dialysis treatments over 10/2011-3/2015. Using self-reported questionnaires, patients were queried with respect to their habitual sleep patterns, including survey items related to 1) sleep duration, 2) sleep quality and disturbances, and 3) mental/emotional and physical symptoms potentially linked with sleep alterations.

Results: The mean±SD age of the study population was 55±14 years, among whom 54% were male, 28% were Black, 51% were Hispanic, and 55% had diabetes. In the overall cohort, the median (IQR) sleep duration was 6.0 (4.0, 8.0) and 7.0 (5.0, 8.0) hours on dialysis vs. non-dialysis days, respectively. Over two-thirds to three-quarters of the cohort reported sleeping during dialysis (76%), having difficulties sleeping at night (65%), and having insufficient sleep (72%); sleeping pill use was reported in 21% of patients. Half of the cohort reported stress/anxiety during dialysis, and 87% vs. 64% described feeling tired/exhausted on dialysis vs. non-dialysis days, respectively.

Conclusions: Our findings uncovered a high prevalence of altered sleep patterns in a well-defined prospective HD cohort. Further studies are needed to identify the modifiable and non-modifiable determinants of sleep alterations, as well as their downstream sequelae in dialysis patients.

PO1114

Self-Reported Sleep Apnea-Related Symptoms in a Prospective Hemodialysis Cohort

Sara S. Kalantar, Amy S. You, Alejandra Novoa, Rene Amel Peralta, Tracy Nakata, Connie Rhee. *University of California Irvine, Irvine, CA.*

Background: Obstructive sleep apnea (OSA) is the most prevalent sleep-related breathing disorder in the general population. While growing data suggests that OSA is more common in hemodialysis (HD) patients, there remains under-diagnosis of this disorder in end-stage renal disease (ESRD) due to symptom overlap with uremia. We thus sought to examine clinical features associated with OSA in a well-defined prospective cohort of HD patients.

Methods: Among 452 HD patients from the prospective *Malnutrition, Diet, and Racial Disparities in Kidney Disease* cohort recruited across 16 outpatient dialysis clinics, we administered protocolized questionnaires querying clinical features of OSA over 10/2011-3/2015. Using self-reported surveys, information was collected regarding OSA-related symptoms including presence and frequency of snoring and apneic events.

Results: The mean±SD age of the study population was 55±14 years, among whom 54% were male, 28% were Black, 51% were Hispanic, and 55% had diabetes. In the overall cohort, 68% of patients reported snoring, among whom 62% reported having frequent (i.e., sometimes, frequent, or always) symptoms. Approximately 17% of patients reported apnea symptoms, among whom 24% reported having frequent events. While over two-thirds of the cohort reported an OSA-related symptom (e.g., snoring, apnea), only 18% were diagnosed with a sleep disorder and 3% had received treatment.

Conclusions: Our findings suggest that clinical features of OSA are common in HD patients, although only a fraction are diagnosed with this disorder and/or undergo treatment for symptoms. Further studies are needed to identify effective OSA screening tools specific to the ESRD population, as well as the impact of OSA interventions in this population.

PO1115

High-Frequency Oscillations of Intradialytic Arterial Oxygen Saturation in Hemodialysis Patients

Xia Tao,[1] Ohnmar Thwin,[1] Priscila Preciado,[1] Matthew S. Cato,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: High-frequency oscillation of arterial oxygen saturation (SaO_2) presenting as repetitive "sawtooth" patterns was observed in sleep apnea patients, but it has never been reported during treatment in hemodialysis (HD) patients. In this study, we explored the prevalence of intradialytic "sawtooth" patterns and their clinical correlates in HD patients.

Methods: We prospectively studied chronic HD patients who didn't use breathing devices, cardiac pacemaker, nasal oxygen, alpha blockers, short-acting nitrates, or have history of sickle cell anemia and non-sinus cardiac arrhythmia. During two visits per subject, we used the Crit-Line® Monitor to record SaO_2 at a frequency of 1 Hz, and video recording to capture periods of wakefulness for the entire treatment. SaO_2 data were analyzed for occurrence of "sawtooth" patterns (100% increase in standard deviation lasting ≥10s) and oxygen desaturation episodes (ODE, 3% drop from baseline lasting for ≥10s).

Results: 16 subjects studied were 54±11 years old, 63% males, 69% African Americans. SaO_2 was 94.3±2.1%. "Sawtooth" patterns covered 19.1% of the recorded treatment time, whereas ODE made up only 0.3%. 9 out of 11 subjects who displayed "sawtooth" patterns, showed them in both visits. "Sawtooth" patterns were more likely to occur during the time when subjects were not awake than during wakefulness (25.3% vs. 17.0% of time in each status). Although ODE were rarely seen, 70% were observed during times when "sawtooth" patterns were also present. Figure 1 shows typical SaO_2 "sawtooth" patterns recorded.

Conclusions: Sleep-related breathing disorders are both highly prevalent and underdiagnosed in HD patients and may be underlying the high-frequency oscillations of intradialytic arterial SaO_2 observed in this study. These observations might be useful in identifying sleep-related respiratory abnormalities in HD patients that may warrant diagnostic workup. Further studies are needed to identify sleep-related SaO_2 oscillations and their relationship to clinical outcomes.

Funding: Commercial Support - Renal Research Institute, LLC

Blue shading indicates time periods during which the subject appeared to be sleeping.

PO1116

CKD and Concomitant Sleep-Disordered Breathing Is Associated with Increased Overall Mortality: A Meta-Analysis

Max Puthenpura,[1] Panupong Hansrivijit,[2] Nasrollah Ghahramani,[3] Charat Thongprayoon,[4] Wisit Cheungpasitporn.[5] *[1]Drexel University College of Medicine, Philadelphia, PA; [2]UPMC Pinnacle, Harrisburg, PA; [3]Penn State College of Medicine, Hershey, PA; [4]Mayo Clinic Minnesota, Rochester, MN; [5]University of Mississippi Medical Center, Jackson, MS.*

Background: Sleep-disordered breathing (SDB) is common in advanced chronic kidney disease (CKD) patients. However, the association between CKD with concomitant SDB and overall mortality remains inconclusive. As it has been established that SDB and CKD individually contribute to overall mortality and that a large proportion of CKD patients have concommittant SDB, there comes a question if their morbid effects are compounded together.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Library were searched for eligible publications, including non-transplant CKD patients older than 18 years-old with co-existing SDB. CKD is defined in this study by estimated glomerular filtration rate of <60 mL/min/1.73m^2.

Results: Seven observational studies (n = 186,686) were included in the meta-analyses. 94.2% of patients had end-stage kidney disease (ESKD) requiring hemodialysis (HD), 5.0% had ESKD requiring peritoneal dialysis (PD), and 0.8% had non-dialysis CKD. The mean patient age was 76.8 ± 2.2 years. Most patients were male (53.4%) and caucasian (76.8%). Up to 39.3% of patients had diabetes. The mean body mass index was 26.0 ± 0.6 kg/m^2. Upon analysis, patients with advanced CKD and SDB demonstrated a pooled estimated odds ratios for overall mortality and cardiovascular events were 2.092 (95% CI, 1.594-2.744) and 1.020 (95% CI, 0.929-1.119), respectively compared to patients with CKD alone. No potential publication bias was detected. There were no significant differences in odds ratios for overall mortality, based on subgroup analyses.

Conclusions: Co-existence between advanced CKD and SDB is associated with significantly increased overall mortality, but not cardiovascular (CV) events when compared with CKD alone. The analysis of CV events requires additional studies to corroborate these findings. Moreover, these results suggest clinical interventions should be aimed to prevent the progression of SDB and CKD to mitigate the mortality associated in patients with both diseases.

PO1117

A Randomized, Double-Blind, Phase 2a Study to Evaluate the Tolerability, Feasibility, and Efficacy of AKST1210 in Patients on Hemodialysis with ESRD and Cognitive Impairment

Jonas Hannestad, Anthony Kalife, Eva Czirr. *Alkahest Inc, San Carlos, CA.*

Background: Studies show that elevated levels of beta-2-microglobulin (b2M) negatively impact cognition. In patients on hemodialysis (HD) for end stage renal disease (ESRD), b2M levels are up to 60-fold higher than in those with normal kidney function; these patients also have a higher prevalence of cognitive impairment. AKST1210 is a device that removes b2M from plasma. To test if removal of b2M could improve cognition, we administered pooled human HD plasma with and without b2M to mice. Mice that received HD plasma with b2M showed a reduction in neurogenesis, neuronal activity, and synaptic markers, while few detrimental effects were seen in mice that received AKST1210 treated HD plasma, suggesting b2M removal is beneficial. Based on robust preclinical data, a clinical study was initiated to assess safety, tolerability, and feasibility of using AKST1210 during HD in subjects with ESRD and cognitive impairment (ESRD-CI).

Methods: In this study, subjects 40 years or older with ESRD-CI are randomly assigned to receive AKST1210 or control during HD sessions for 3 months. Approximately 26 subjects will be recruited and undergo a screening visit, run-in period, treatment visits, and end of study visit. Safety and tolerability will be assessed at every visit. Cognitive assessments will be administered periodically and b2M and proteomics samples collected at specific timepoints.

Results: Primary endpoints are the safety and tolerability of using AKST1210 in subjects with ESRD-CI undergoing HD. Safety is measured by the incidence of treatment-emergent adverse events and serious adverse events. Tolerability is measured by subject retention and compliance with visit completion. Secondary endpoints assess the change from baseline in cognitive assessments and the feasibility of conducting expanded

AKST1210 studies. Exploratory endpoints include plasma analysis to identify biomarkers associated with cognitive function and magnitude of b2M removal.

Conclusions: Preclinical evidence provides the foundation to test if b2M removal may improve cognition in people with ESRD. In this study, safety, tolerability, and feasibility of administering AKST1210 in subjects with ESRD-CI will be assessed. Continued clinical development will be informed by safety and efficacy data emerging from this trial.

PO1118

Selection of the Best Equation for Serum Osmolality Calculation in Hemodialysis Patients

Tsuyoshi Miyagi,[1] Cachet Wenziger,[1] Yoko Narasaki,[1] Yoshikazu Miyasato,[1] Hiroshi Kimura,[1] Kunitoshi Iseki,[2] Ekamol Tantisattamo,[1] Connie Rhee,[1] Elani Streja,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Ryukyu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Nakagami-gun, Japan.*

Background: Although the serum osmolality (SOsm) is determined by circulating solutes including sodium, potassium, glucose and urea, calculated serum osmolality formula without potassium (2[Na, in mmol/L] + [Glucose, in mg/dL] / 18 + [BUN in mg/dL] / 2.8) is commonly used. Several different equations have been previously described to estimate SOsm. Although in hemodialysis patients it is important to monitor homeostasis by means of estimating SOsm, few studies have examined the accuracy of those equations.

Methods: We identified 20 patients who transitioned to hemodialysis therapy and had repeated SOsm data along with, pre-dialysis sodium, potassium, glucose, and blood urea nitrogen (BUN) on the same day. We compared estimated SOsm by the 13 equations used in the previous literature and measured SOsm.

Results: The patients were 52% male, 33% non-white, and the mean age was 60 ± 17 (mean± SD) years. There were 65 measured SOsm and the mean (± SD) was 310.8 ± 12.0 mOsm/Kg. The following equation provided the best fit between measured and calculated SOsm: 2([Na, in mmol/L] + [K, in mmol/L]) + [Glucose, in mg/dL] / 18 + [BUN in mg/dL] / 2.8 (mean difference, -0.7 mOsm/Kg; 95% confidence interval, -2.12–0.71; P=0.32).

Conclusions: Our result suggests that the equation for estimating serum osmolality in hemodialysis patients should include serum potassium in addition to other components usually used to estimate serum osmolality in non-hemodialysis patient.

Number	Equation	Mean difference	Standard deviation	95% CI	P
1	2Na + (Glu / 18) + (BUN / 2.8)	7.95	5.31	6.54 to 9.36	<0.0001
2	2(Na + K) + (Glu / 18) + (BUN / 2.8)	-0.7	5.34	-2.12 to 0.71	0.32
3	1.75Na + (Glu / 18) + (BUN / 2.8) + 10.1	32.12	4.79	30.85 to 33.39	<0.0001
4	1.86Na + (Glu / 18) + (BUN / 2.8)	27.14	4.99	25.82 to 28.47	<0.0001
5	1.86Na + (Glu / 18) + (BUN / 2.8) + 5	22.14	4.99	20.82 to 23.47	<0.0001
6	1.86Na + (Glu / 18) + (BUN / 2.8) + 9	18.14	4.99	16.82 to 19.47	<0.0001
7	1.86(Na + K) + (Glu / 18) + (BUN / 2.8) + 9	10.1	5.02	8.77 to 11.43	<0.0001
8	2Na + 1.15(Glu / 18) + (BUN / 2.8)	6.79	5.36	5.37 to 8.22	<0.0001
9	1.86(Na + K) + 1.15(Glu / 18) + (BUN / 2.8) + 14	3.91	5.03	2.61 to 5.28	<0.0001
10	1.89Na + 1.38K + 1.08(Glu / 18) + 1.03(BUN / 2.8) + 7.45	8.38	5	7.05 to 9.71	<0.0001
11	1.86(Na + K) + (Glu / 18) + (BUN / 2.8) + 10	9.1	5.02	7.77 to 10.43	<0.0001
12	1.897Na + (Glu / 18) + (BUN / 2.8) + 13.5	8.57	5.07	7.22 to 9.91	<0.0001
13	1.90(Na + K) + (Glu / 18) + (BUN / 2.8) + 5	8.44	5.1	7.09 to 9.79	<0.0001

Na, sodium in mmol/L; K, potassium in mmol/L; Glu, glucose in mg/dL; BUN, blood urea nitrogen in mg/dL; CI, confidence interval

(The list of equations was adapted from J.L. Martin-Calderón et al. Clinical Biochemistry (2015) 48, 529–533)

PO1119

Effect of Dialysate Potassium on Interleukin 6 During Hemodialysis in Patients with ESRD

Monika Aggarwal (Gupta),[1] George M. Feldman,[1] Naveen Samuel,[1] Dipankar Bandyopadhyay,[2] Reuben P. Retnam,[2] Shobha Ghosh.[1,2] *[1]Hunter Holmes McGuire VA Medical Center, Richmond, VA; [2]Virginia Commonwealth University, Richmond, VA.*

Background: Chronic inflammation is associated with poor outcomes in end stage renal disease (ESRD). Pro-inflammatory markers including interleukin-6 (IL-6) increase during hemodialysis. Efflux of intracellular potassium in cell cultures result in activation of inflammasome and release of inflammatory markers. We studied the effect of potassium efflux during hemodialysis on serum IL-6.

Methods: 15 patients with ESRD on chronic maintenance hemodialysis at Hunter Holmes McGuire VAMC were enrolled. Each subject participated in both interventions separated by at least two weeks. Intervention A involved 2K dialysate for the 1st hour followed by 4K for the second hour. Intervention B involved 4K for the 1st hour followed by 2K for the second hour. After first two hours, dialysate potassium was switched to the prescribed concentration for the remaining time Blood was drawn at 0,30,60,90,120,180, and 240 minutes after start of dialysis. Serum IL-6 was measured using ELISA. Data were analyzed using Mixed linear model with $p<0.05$ considered significant.

Results: IL-6 was detectable at baseline and increased during dialysis. However, mean levels of IL-6 were parallel between the 2 interventions (Figure 1.), implying no change in the rate of IL-6 production over time between the 2 interventions (Table 1.)

Conclusions: IL-6 increases during hemodialysis but rate of increase is not affected by dialysate potassium.

Racial Differences in Physician Trust Among ESRD Patients in Upstate New York

Spencer Dahl, Basil S. Kazi, Fahad Saeed. *University of Rochester Medical Center, Rochester, NY.*

Background: Black patients have worse health outcomes in comparison to White patients, including 2.8 times higher incidence of End Stage Renal Disease, and a significantly higher age stratified risk of death on dialysis. Historically, low levels of physician trust in the healthcare system have been postulated as one of the mediators of healthcare disparities. Previous literature has suggested that black patients are less likely to trust their physicians, however there is a paucity of such data in the dialysis population.

Methods: We surveyed 223/380 (response rate 58%) of hospitalized patients receiving maintenance dialysis in Upstate New York, including 91 white and 82 black patients. We assessed physician trust using the Primary Care Assessment Survey (PCAS). This scale has been previously validated in adult and older adult populations.

Results: We found no difference in the level of trust between black and white patients (3.01 vs 2.95 respectively), assessed on the PCAS scale.

Conclusions: We found no difference in physician trust between black and white patients in our sample. Addressing healthcare disparities is a priority issue for maintenance dialysis patients. Future research to investigate issues related to access to the health care system, health literacy, and socioeconomic status may shed further light into health disparities.

PO1121

Mobile Health (mHealth) Readiness Among Dialysis Patients

Wael F. Hussein,[1,2] Paul N. Bennett,[1] Sloane Pace,[1] Shijie Chen,[1] Veronica Legg,[1] Sumi J. Sun,[1] Graham E. Abra,[1,2] Brigitte Schiller.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Stanford University School of Medicine, Palo Alto, CA.*

Background: Mobile health (mHealth) is the healthcare use of mobile devices such as mobile phones. mHealth has demonstrated improvement in patient-reported outcome measures, resource efficiencies and cost savings. The aim of this study was to examine the status and correlates of mHealth readiness among individuals on dialysis.

Methods: Cross-sectional 30-item questionnaire, adapted from Bonner's mHealth instrument guided by Khatun's mHealth readiness model, was distributed to people on dialysis from 13 in-center hemodialysis (HD) facilities and 14 home dialysis centers. Proficiency was determined by reported use of applications of increasing level of complexity. We used regression analysis to investigate the relationship between demographic and social factors with proficiency.

Results: 949 patients (632 HD and 317 home dialysis) completed the survey (56% response rate), 38% were female. 73% of respondents reported using the internet: 90% of

them requiring no assistance. 81% of respondents owned smartphones or other internet-capable devices. 70% had intermediate or advanced mHealth proficiency. Main reasons for using mHealth were appointments (56%), communication with healthcare personnel (56%), laboratory results (55%) and obtaining kidney care information (50%). The main reported concerns with mHealth were privacy & security (18%), and cost (6%). mHealth proficiency was lower in older patients: compared to the 45-65 years (yrs) group, respondents in age groups < 45 yrs, 61-70 yrs, and > 70 yrs had adjusted odds ratio (aOR) of 5.04 (95% Confidence Interval: 2.23-11.38), 0.39 (0.24-0.62), and 0.22 (0.14-0.35) respectively. Compared to those with college education, the aOR associated with below high school and high school only were 0.09 (0.05-0.16) and 0.26 (0.18-0.39) respectively. Hispanic ethnicity (aOR 0.49 [0.31-0.75]) compared with non-Hispanic was associated with lower mHealth proficiency, while employment was associated with higher proficiency (aOR 2.26 [1.18-4.32]). Although home dialysis was associated with higher proficiency in the univariate model, we did not observe this in the fully adjusted model.

Conclusions: The majority of dialysis patients surveyed were ready to use, and proficient in, mHealth. These results are encouraging for the nephrology community to increase endorcement of mHealth technologies in patient care.

PO1122

Clinician Perspectives on Access to Kidney Replacement Therapy in Rural Communities

Nicole J. Scholes-Robertson,[1,2] Talia M. Gutman,[2,1] Allison Tong.[2,1] Centre for Kidney Research *[1]The University of Sydney School of Medicine, Sydney, NSW, Australia; [2]Centre for Kidney Research, Westmead, NSW, Australia*.

Background: Patients with chronic kidney disease (CKD) requiring kidney replacement therapy in rural communities are at higher risk of mortality compared with patients in urban areas, and encounter many barriers in accessing care. We aimed to describe clinicians' perspectives of patient access to dialysis and kidney transplantation in rural communities.

Methods: We conducted 28 semi- structured interviews with clinicians (nephrologists, nurses, transplant co-ordinators and social workers) from Australia. Transcripts were thematically analyzed.

Results: We identified five major themes: the tyranny of distance (overwhelming burden of travel, minimizing relocation distress, scarcity of transportation options, concerns for patient safety), supporting navigating of health systems (reliance on local champions, negotiating variability of literacy, providing flexible pathways, frustrating presence of gatekeepers), disrupted care and lacking services (without continuity of care, scarcity of specialist services, fluctuating capacity for dialysis), pervasive financial distress (crippling out of pocket expenditure, widespread socio-economic disadvantage), and awareness of rurality (lacking availability of safe and sustainable resources for dialysis, sensitivity to local needs, dependence on social support, limited options available). Selected quotations are provided in Table 1.

Conclusions: Clinicians felt hampered and frustrated for patients living in rural communities who had limited access to quality care because of geography, financial burden, and complexity and rigidity of the health system. Increased use of telehealth, increased specialist outreach clinics in rural locations and improving flexibility of pathways were suggested to improve access.

Funding: Government Support - Non-U.S.

Table 1. Selected illustrative quotations

Overwhelming burden of travel	Even when I went to the bush (rural), I still had people traveling an hour, two hours to get to me. I know they're going to have to travel for another six hours to get there (transplant hospital).
Minimizing relocation distress	The problem with that is that still from PD catheter insertion to going home still works out to be about at least three months (with patients living away from home). Hopefully for those people that have got the tyranny of distance, more equality with them having actual designated accommodation, designated assistance (will make relocation easier).
Reliance on local champions	We're doing everything by telemedicine (Urban Doctor) and without Nurse on the ground up there (rural location) it would be impossible.
Fluctuating capacity for dialysis	They can't actually have it in their home town. They actually have to travel to somewhere else, look at a home therapy or something else. It's not the way dialysis is set up. It's like a hospital when it goes on bed block, when the dialysis unit in the local town is overwhelmed. I think about a chap [patient] that I was wanting to start on dialysis who was blind and, in a wheelchair, and our nearest chair was going to be over an hour away.
Crippling out of pocket expenditure	I've got one complicated patient who's had a lot of surgical complications post-transplant. And he told me the other day and it actually made me gasp that him and his wife, both on the Pension $20,000 in the red over the last two and a half years. I need a root canal and I don't have X number of thousands of dollars; therefore, I can't have my transplant because I cannot get my dental clearance.
Dependence on social support	If someone doesn't have the support net that is actually a very serious barrier to transplant. It's difficult for these patients who live alone, and don't have a lot of support, so they're the ones who really find it difficult."

PO1123

Estimation and Prediction of Prevalence of Patients Receiving Dialysis in China Based on Claims Data

Chao Yang,[1] Jinwei Wang,[1] Luxia Zhang,[1,2] Ming Hui Zhao.[1] China Kidney Disease Network (CK-NET) Work Group *[1]Peking University First Hospital, Beijing, China; [2]National Institute of Health Data Science at Peking University, Beijing, China*.

Background: The national prevalence of end-stage kidney disease in China has not been well studied. We aimed to estimate the prevalence of patients receiving dialysis and predict the trend using claims data in order to provide evidence for developing prevention strategies.

Methods: Medical claims data from Jan 1, 2013 to Dec 31, 2017 were extracted from a large claims database, which used a two-stage sampling design to obtain a national sample of insured population. Patients receiving maintenance dialysis, including hemodialysis (HD) and peritoneal dialysis (PD), were identified according to medical billings and ICD-10 codes. The age-adjusted prevalence and number of dialysis patients were calculated stratified by year and gender. The Verhulst model was used to predict the short-term prevalence from 2018 to 2025.

Results: From 2013 to 2017, the age-adjusted prevalence of dialysis patients increased from 252.46 per million population (PMP) to 419.23 PMP. In 2017, the age-adjusted prevalence of HD and PD was 384.32 PMP and 34.91 PMP, respectively, and the total number of dialysis patients in China was estimated to be 581,055. The overall trend in the predicted prevalence of dialysis patients was increasing. The predicted prevalence was 533.61 PMP in 2020 and 623.49 PMP in 2025, and the corresponding number of patients was 743,304 and 865,704, respectively.

Conclusions: We have firstly made an attempt to assess the prevalence of dialysis patients in China and establish a national surveillance system based on claims data. It is urgent to formulate prevention and control strategies to reduce the escalating burden of kidney diseases.

Funding: Government Support - Non-U.S.

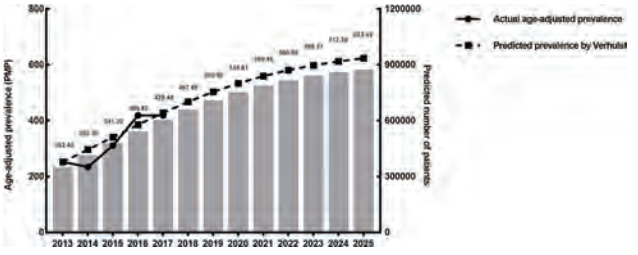

Figure 1. Prediction curve of prevalence and number of dialysis patients in China from 2013 to 2025 Note: The numbers and columns in the figure show predicted prevalence and predicted number of patients using grey Verhulst model, respectively.

Abbreviation: PMP, per million population.

PO1124

Low Socioeconomic Status Increases Risk of Mortality and Hospitalization in Korean Maintenance Hemodialysis Patients

Jung Woo Noh,[1] Hayne C. Park,[1] Young Eun Kwon,[2] Do Hyoung Kim,[1] Ajin Cho,[1] Juhee Kim,[1] Kyu Sang Yun,[1] Youngki Lee.[1] *[1]Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [2]Myongji Hospital, Goyang, Gyeonggi-do, Republic of Korea*.

Background: The number of hemodialysis (HD) patients and medical expenses are growing rapidly in Korea owing to aging society and accompanying diseases such as diabetes. Whether low socioeconomic status (SES) affects poorer HD outcome is controversial. Therefore, this study was performed to evaluate the effect of SES upon mortality and hospitalization in Korean maintenance HD patients.

Methods: We used HD quality assessment data from the year of 2013 and 2015 for collecting demographic and clinical data. The mortality data was collected until Dec 2017. We used insurance status as a proxy indicator of SES in which the subjects were classified into low SES (Medical Aid recipients) and high SES (National Health Insurance beneficiary). We analyzed mortality and hospitalization risk based on SES using Cox proportional hazard model.

Results: A total of 21,786 HD patients from 2013 survey and 35,454 HD patients from 2015 survey were included in the analysis. The ratio between high and low SES group was 76.7% versus 23.3%. The low SES group was younger and showed higher proportion of male, and lower proportion of diabetes, hypertension, and cerebrovascular accidents compared to the high SES group. The crude mortality rate was 93/1,000 person-year in 2013 and 106/1,000 person-year in 2015. After adjusting for age, gender, comorbidity and laboratory parameters, the low SES group showed significantly higher mortality risk compared to the high SES group (hazard ratio 1.151 [95% confidence interval (CI) 1.082-1.225], $P < 0.0001$ in 2013 survey and hazard ratio 1.073 [95% CI 1.009-1.14], $P = 0.0254$ in 2015 survey). The low SES group was also an independent risk factor for hospitalization after adjusting for age, gender, comorbidity and parameters (hazard ratio 1.129 [95% CI 1.09-1.17], $P < 0.0001$ in 2013 survey and hazard ratio 1.142 [95% CI 1.108-1.178], $P < 0.0001$ in 2015 survey).

Conclusions: Low SES independently increases risk of patient mortality and hospitalization in Korean maintenance HD patients

PO1125

Iron Overload in ESRD Treated with Deferoxamine for Chelation

Sylvester Barnes.[1,2] *[1]Loyola University Health System, Maywood, IL; [2]Edward Hines Junior VA Hospital, Hines, IL*.

Introduction: The patient is a 23-year-old female with a history of sickle cell disease, uncontrolled hypertension, and ESRD on HD 3x week for the past 4 years, requiring extensive blood transfusions from hemolysis. Due to the patient's uncontrolled hypertension epoetin alfa was withheld for a few months. The patient presented to Loyola with severe symptomatic anemia, and concerns for iron overload.

Case Description: The patient presented to the hospital with severe anemia and decreased level of consciousness. Labs revealed a Hgb of 5.8g/dl, SBP of 175mmHg, and platelets of 40,000/ml. Hematology was consulted for further evaluation of anemia and thrombocytopenia. Her reticulocyte index was calculated at only 0.10, LDH 206, haptoglobin < 15, with peripheral smear showing no schistocytes or sickles. Iron was 137mcg/dl, transferrin 100, ferritin 4284ng/ml, and iron saturation 98%. Bone marrow biopsy was obtained showing normal cellular marrow for her age and iron laden macrophages. Hgb electrophoresis showed HgS 3.3% indicating that most of the patient's blood was transfused blood volume. Epoetin alfa was restarted and chelation therapy was recommended by hematology for iron overload. The patient was started on deferoxamine 50 mg/kg three times per week following hemodialysis. Most recent labs obtained show a ferritin level decreased to 2378ng/ml after receiving several doses of deferoxamine for over a month.

Discussion: This represents a unique case of iron overload from sickle cell disease along with ESRD leading to transfusion dependence. The treatment of iron overload was from the chelating agent deferoxamine. Initial repeat ferritin levels indicate favorable treatment response without adverse events to date. There are only a few case reports of chelation therapy being used in ESRD. Most of these cases per literature review have been limited to cases of porphyria cutanea tarda. While no repeat iron levels have been obtained due to patient discharge, initial ferritin levels indicate possible treatment response. No adverse side effects have been noted with the patient receiving chelation therapy during her hospital admission.

PO1126

Role of Hemodialysis in Severe Ethanol Poisoning

Devin Driscoll,[1] Griffin Bleecker,[2] Aileen W. Zhen,[1] Jean M. Francis,[1] Aala Jaberi.[1] *[1]Boston Medical Center, Boston, MA; [2]Boston University Medical Campus, Boston, MA.*

Introduction: The treatment for acute ethanol intoxication remains largely supportive. About 1% of patients presenting with ethanol intoxication require the utilization of critical care resources. We present a case of a 19-year-old with altered mental status and a serum ethanol level above assay who required hemodialysis for rapid ethanol elimination and made a full recovery.

Case Description: A 19-year-old male with no past medical history presented with unresponsive after a night of heavy ethanol use. His serum ethanol level was above assay at >550mg/dL. Methanol and ethylene glycol levels were undetectable. He had normal kidney and liver blood tests, without metabolic acidosis. His osmolar gap was attributed purely to ethanol. Given a Glasgow Coma Scale of 3, he was intubated for airway protection. He then developed atrioventricular dissociation and required atropine, and hypotension requiring vasopressor support. A repeat serum ethanol level at 9 hours remained above assay at >550mg/dL and he remained unresponsive at 14 hours. Decision was made to initiate patient on hemodialysis. Two hours into his hemodialysis session, he became conscious and was successfully extubated at a serum ethanol level of 260mg/dL. His neurologic status returned to baseline and he was discharged from the hospital within 24 hours.

Discussion: The patient's ethanol metabolism elimination rate without hemodialysis was calculated to be at 15mg/dL/hour. Using this elimination rate, his initial serum ethanol level was predicted to be about 634mg/dL. Without hemodialysis, it would take roughly 41 hours for complete elimination. While on dialysis, the patient's rate of elimination increased by a factor of four from 15mg/dL/hr to 56mg/dL/hr. Complications of prolonged intubation and cardiac and neurologic toxicity from severe ethanol poisoning in this young patient include life-threatening arrhythmias, and possible permanent neurologic damage which was avoided using hemodialysis to expedite ethanol elimination. This case demonstrates the role and benefit of hemodialysis for a critically ill patient who is experiencing organ toxicity and exposes a need for updated recommendations in this specific set of patients.

PO1127

A Polyethersulfone Membrane with a Direct Thrombin Inhibitor to Decrease Local Thrombus Formation

Shuangshuang Fu, Yumei Liang. *Nephrology Department of Hunan Provincial People's Hospital (The First-affiliated Hospital of Hunan Normal University), Changsha, China.*

Background: Extracorporeal circulation, such as hemodialysis, is required systemic anticoagulation to avoid thrombus formation. However, conventional anticoagulation methods may induce hemorrhage complications, especially those patients who have bleeding diseases. As dialyzer membrane is the main site of thrombosis. Anticoagulant modification of the dialysis membrane may decrease local clotting of the dialyzer membrane, and doesn't increase the bleeding risk of dialysis patients.

Methods: We chose argatroban(AG), a direct thrombin inhibitor, to modify a polyethersulfone(PES) membrane. Fourier transform infrared spectroscopy(FTIR) was used to confirm that AG was grafted to the PES successfully. Scanning electron microscopy(SEM) was used to observe the characteristic morphology of the membranes. Activated partial thromboplastin time, prothrombin time, and thrombin time were detected to evaluate the antithrombotic property of the modified membrane.

Results: FTIR indicated that argatroban modified PES membranes(PES-AG) were successfully prepared. Compared with the PES membrane, the clotting time value of the PES-AG membrane was significantly prolonged, and the difference was statistically significant, which initially indicated that the PES-AG membrane had a better anticoagulant effect. SEM showed that the PES-AG membrane could decrease local thrombus formation.

Conclusions: Preparation of the argatroban modified PES membrane is feasible, and the anticoagulant performance is superior to the unmodified PES membrane.

Funding: Government Support - Non-U.S.

PO1128

Filter Operation Mode Affects the In Vivo Performance of a Synthetic Plasma Fractionation Membrane

Detlef H. Krieter,[1] Niclas L. Kiefer,[1] Marieke Rueth,[2] Horst-Dieter Lemke,[2] Christoph Wanner.[1] *[1]University Hospital Würzburg, Div. of Nephrology, Würzburg, Germany; [2]eXcorLab GmbH, Obernburg, Germany.*

Background: The mode a dialyzer or fractionator is operated may affect the fouling processes of the filter membrane and, hence, may determine its patency and performance. Purpose of the present study was to assess such effects *in vivo*. To avoid the often varying treatment conditions in humans, a large animal model was used.

Methods: In a prospective, randomized, controlled, crossover trial, four sheep were subjected to double filtration plasmapheresis with a polyethersulfone plasma fractionation membrane intended for lipid apheresis (FractioPES® 200; 3M, Germany). Five different operation modes were tested in each animal: Low (30 mL/min), medium (36 mL/min) and high (42 mL/min) plasma flow rates as well as high flow rate at increased plasma temperature (38.5 °C; thermofiltration) and reversed plasma filtration flow direction (outside-in), respectively. The totally treated plasma volume was 1500 mL. Reduction ratios (RR) and sieving coefficients (S_K) at 300, 600, 900 and 1200 ml of treated plasma were determined for LDL cholesterol (2.500-3.000 kDa), HDL cholesterol (175-360 kDa), fibrinogen (305-385 kDa), immunoglobulin IgG (150 kDA) and albumin (67 kDa).

Results: Compared to the other modes (medium flow rate, 0.05±0.02 to, high flow rate, 0.08±0.01), S_K for LDL were significantly higher (P<0.001) in outside-in filtration at 300 mL (0.21±0.03). S_K for LDL were also significantly higher (P<0.001) in both outside-in (0.19±0.07) and at high flow (0.17±0.02) conditions at 600 mL. For IgG at 900 mL, S_K for low flow (0.57±0.32) was lower (P=0.049) compared to the high flow rate (1.05±0.07). For fibrinogen, S_K at 600 mL (0.23±0.03) was higher (P=0.001) in outside-in filtration compared to the other modes. At 900 mL, the S_K for fibrinogen determined in outside-in (0.37±0.12) was superior to the low and high plasma flow modes (0.08±0.08 and 0.13±0.01, resp.). Several significant differences in S_K were identified at different plasma volumes within the same operation mode. No significant differences in RR were determined between operation modes.

Conclusions: Compared to the other operation modes, outside-in filtration and, less pronounced, also high plasma flow rates increase the permeability of a synthetic fractionation membrane for larger proteins. The differences in S_K did not translate into different reduction ratios.

PO1130

Online High-Volume Hemodiafiltration Reduces Pre-Dialysis Levels of Indoxyl Sulfate Compared with High-Flux Hemodialysis: Results from the HDFit Multicentric Randomized Controlled Trial

Jordana D. de Lima,[1] Murilo H. Guedes,[2] Silvia D. Rodrigues,[1] Ana clara S. Almeida,[2] Ana Beatriz L. Barra,[3] Maria Eugenia F. Canziani,[4] Americo L. Cuvello neto,[5] Carlos E. Poli de Figueiredo,[6] Roberto Pecoits-Filho,[2] Lia S. Nakao.[1] *[1]Universidade Federal do Parana, Curitiba, Brazil; [2]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [3]Fresenius Medical Care, Rio de Janeiro, Brazil; [4]Universidade Federal de São Paulo, Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [5]Hospital Alemão Oswaldo Cruz, São Paulo, Brazil; [6]Pontificia Universidade Catolica do Rio Grande do Sul, Porto Alegre, Brazil.*

Background: Although HDF improves the clearance and pre-dialysis concentration of middle size molecules, little is known about its effect on concentration of protein-bound uremic toxins (PBUT) particularly in comparison to HD. Here, we investigated whether HDF impacts pre-dialysis plasma levels of the PBUTs indoxyl sulfate (IxS), *p*-cresyl sulfate (pCS) and indole 3-acetic acid (IAA) compared to HD.

Methods: This is *post-hoc* analysis of the multicentric randomized controlled trial studying the impact of HDF *versus* hf-HD on measured physical activity (HDFit - clinicalTrials.gov: NCT02787161), which included clinically stable HD patients with a vintage >3 to <24 months. Total plasma levels of IxS, pCS and IAA were determined by high performance liquid chromatography with fluorescence detection at baseline, 3 and 6 months. Mean difference in pre-dialysis PBUTs between HDF and hf-HD during the 6 months was estimated by linear mixed effect models.

Results: One hundred ninety-three patients (mean age 53 years old, 70% males and 60% white) were analyzed. There were no differences between HD and HDF groups regarding clinical and biochemical characteristics at the baseline. In the HDF group, 99% of patients achieved a convective volume higher than 22 L. The mean differences (95% CI) in concentrations over time for PBUTs among HDF and HD groups are shown in the Figure.

Conclusions: In this *post-hoc* analysis of the HDFit trial, high-volume HDF consistently reduced pre-dialysis concentration of IxS compared to hf-HD. These results demonstrate the sustained effect of mixed-diffuse convective methods in the removal of PBUTs compared to predominantly diffuse techniques.

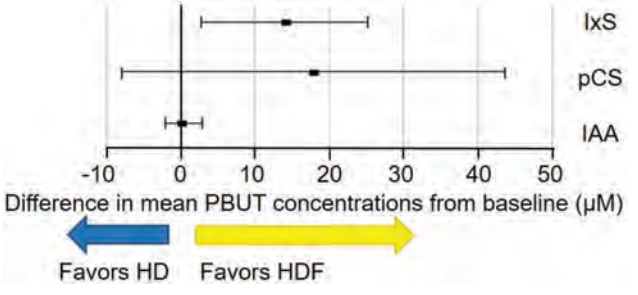

Figure - Mean differences between groups in the change from baseline along with 95% confidence intervals (CI). Results shown IxS favored by HDF compared to HD.

Use of Cytokine Adsorbing Membranes in Patients with Acute Renal Failure in Intensive Care Units

Eva Jakopin, Martin Hren, Tina Stropnik Galuf, Masa Knehtl, Tadej Zorman, Nina Vodošek Hojs, Robert Ekart, Radovan Hojs, Sebastjan Bevc. *Univerzitetni Klinicni Center Maribor, Maribor, Slovenia.*

Background: Use of cytokine adsorbents has been proposed as a novel therapeutic approach in sepsis management. Our aim was to evaluate laboratory markers, clinical parameters and SOFA (Sequential Organ Failure Assessment) score in patients who were treated with cytokine adsorbing membrane (CytoSorb®, CytoSorbents Corp. New Jersey, USA) and continuous veno-venous haemodialysis.

Methods: We included adult patients with septic shock and acute renal failure. We retrospectively collected laboratory results (leukocytes, thrombocytes, C-reactive protein, procalcitonin, lactate, urea, creatinine, bilirubin, PaO_2), clinical parameters (mean arterial pressure (MAP), FiO2, residual diuresis), SOFA score and vasopressor use at the beginning and at the end of the procedure.

Results: We included 69 patients, 51 men, aged 56.6 ± 15 years. 51 patients had 1 procedure, 14 patients had 2 procedures, 3 patients had 3 procedures and 1 patient had 4 procedures. Median time from admission to initiation of procedure was 47 hours, median treatment time was 23.6 hours. We discovered significant improvement in procalcitonin (35.36 ± 37.33 ng/mL vs. 24.25 ± 31.18 ng/mL; p<0.001), creatinine (345.06 ± 174.65 μmol/L vs. 233.11 ± 108.82 μmol/L; p<0.0001), SOFA score (14.20 ± 2.64 vs. 12.69 ± 3.52; p<0.001) and FiO_2 (48.17 ± 21.17 % vs. 44.63 ± 21.45 %; p=0.020). Patients with more than 1 procedure showed statistically significant reduction in lactate level (5.40 ± 4.74 mmol/L vs. 2.46 ± 1.74 mmol/L; p=0.010) and vasopressin dose (1.26 ± 1.61 vs. 0.88 ± 3.2 IU/h; p=0.022).

Conclusions: We observed potential beneficial effect of adsorptive membrane use in septic patients. According to our results two or more procedures were associated with improved laboratory markers and lower vasopressor requirement.

PO1132

Clinical Safety of a New Hemodialyzer with the Surface Modifying Molecule Endexo™

Jill M. Meyer,[1] Dylan Steer,[2] Lisa A. Weber,[3] Mayuri Thakuria,[4] Chiang-Hong Ho,[4] Claudy Mullon,[4] Robert J. Kossmann.[4] *[1]California Institute of Renal Research, Chula Vista, CA; [2]California Institute of Renal Research, San Diego, CA; [3]Research Management Inc./ Kansas Nephrology Research, Wichita, KS; [4]Fresenius Medical Care, North America, Waltham, MA.*

Background: The new Optiflux Enexa™ dialyzer (OED) contains a fluorinated polyurethane surface modifying macromolecule (Endexo™) blended in the membrane during manufacturing. Performance and safety of the dialyzer were assessed in a multi-center, open-label study (NCT# 03536663). This sub-analysis reports additional safety results for OED.

Methods: Subjects enrolled in the study underwent 12 HD treatments on the Optiflux® F160NR followed by 38 HD treatments (visits 13-50) with the OED. Safety was assessed by evaluating: 1) hematology tests and serum chemistry measured pre and post HD at the first use of OED and then measured pre HD for subsequent visits at approximately 2 weeks intervals; 2) Complement activation and serum albumin measured pre and post HD at the first use of OED; and 3) Adverse events recorded during the study.

Results: 23 subjects were enrolled in the study of which 18 subjects (safety population [SPOP]) had at least one HD treatment with the OED for a total of 664 OED treatments. SPOP median age was 63.5 years, female (77.78%) and white (66.67%). Table 1 reports SPOP (n=18) mean (SD) for chemistry and hematology. An increase in mean serum albumin level from 3.94 to 4.23 g/dL was observed. No overt complement activation was noticed. Thirty-two AEs (4.8%) and 3 SAEs were reported, none were device related. No deaths or AEs leading to study discontinuation occurred.

Conclusions: The novel Optiflux Enexa™ dialyzer was well tolerated in a clinical study including 664 HD treatments in ESRD patients.

Funding: Commercial Support - Fresenius Medical Care North America

Changes in Sensitivity Patterns of Gram-Negative Isolates in Bacteraemic Haemodialysis Patients

Fatima Malik, Anna Naito, Jonathan W. Hurst, Moira Stanley, David Makanjuola. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: Gram-negative bacteraemias (GNBs) in haemodialysis (HD) patients are associated with significant morbidity and mortality. While there is a paucity of global data around the quantitative impact of drug resistant organisms, it is clear that they result in increased mortality, longer length of illness and higher costs of delivering appropriate treatment. We aimed to determine the sensitivity patterns of GNBs in our HD cohort.

Methods: Data were collected from clinical records, electronic records, and the microbiology database of all bacteraemias in HD patients between 2007 and 2018.

Results: 283 episodes of GNB occurred in 1361 patients over the 12-year period. *Escherichia Coli* and *Klebsiella Pneumoniae* were the dominant pathogens, accounting for 40.6% and 15.9% of bacteraemias isolated respectively. Sensitivity pattern analysis reveals that Meropenem was almost universally effective against gram negative isolates, with little change over the study period. Similarly, Gentamicin had sensitivity rates of >80% each year except 2010 (50%). Co-Amoxiclav had a variable sensitivity profile and the resistance appeared more prevalent over time – see Figure 1.

Conclusions: Judicious antimicrobial use is a World Health Organisation objective in the fight against antimicrobial resistance. Our local HD policy includes Vancomycin and Gentamicin as empiric therapy. The emergence of Vancomycin-resistant enterococci and more recently staphylococci will influence our future use of Vancomycin. In our population group, Gentamicin therapy remains effective. Carbapenem resistant organisms are a global health threat so whilst Meropenem is efficacious, it should be reserved for more resistant strains or treatment failures. Resistance is increasing at a rate far greater than production of novel antimicrobials so antimicrobial stewardship is paramount; particularly in HD populations with high rates of infection, morbidity and antibiotic exposure.

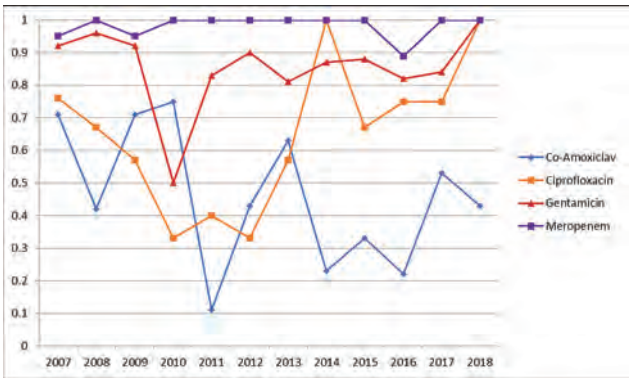

Figure 1: Sensitivity of gram negative isolates between 2007-2018

Association Between Nrf2 and CDKN2A Expression in Patients with ESRD: A Pilot Study

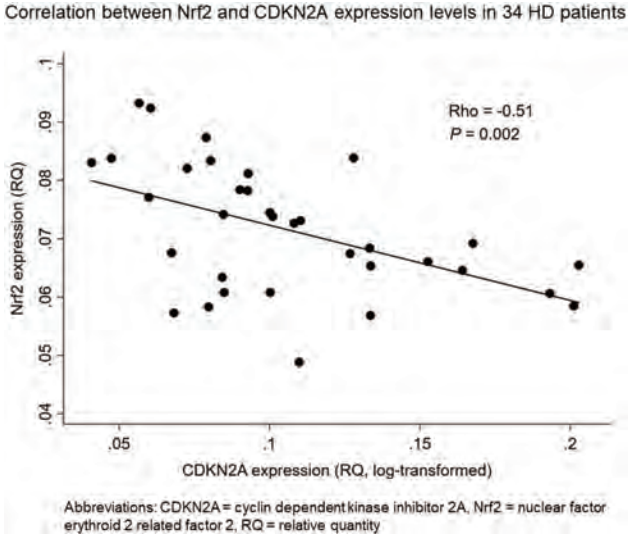
Keiichi Sumida, Zhongji Han, Ankur A. Dashputre, Praveen Kumar Potukuchi, Chi-Yang Chiu, Csaba P. Kovesdy. *The University of Tennessee Health Science Center, Memphis, TN.*

Background: Patients with ESRD display phenotypic features of premature biological aging, characterized by disproportionately high morbidity and mortality at a younger age. Nuclear factor erythroid 2-related factor 2 (Nrf2) activity, a master regulator of antioxidative responses, declines with age and is implicated in the pathogenesis of age-related disorders; however, little is known about the association between Nrf2 and premature biological aging in ESRD patients.

Methods: In a cross-sectional pilot cohort of 34 ESRD patients receiving maintenance hemodialysis, we measured the expression of Nrf2 and cyclin-dependent kinase inhibitor 2A (CDKN2A, or $p16^{INK4a}$, a biomarker of biological aging) genes in whole blood and examined the association of Nrf2 with CDKN2A expression and with chronological age, using Spearman's rank correlation and multivariable linear regression models with adjustment for chronological age, gender, race, and diabetes status.

Results: The mean (SD) age was 62.6 (9.8) years old; 52.9% of patients were male; 70.6% were African American; and 70.6% were diabetic. There was a significant negative correlation between Nrf2 and CDKN2A expression (rho=-0.51, *P*=0.002; **Figure**); while no significant correlation was found between Nrf2 expression and chronological age (rho=-0.02, *P*=0.91). After multivariable adjustment, Nrf2 expression remained significantly and negatively associated with CDKN2A expression (β coefficient=-0.0151, *P*=0.01).

Conclusions: Lower Nrf2 expression levels were significantly and negatively associated with higher CDKN2A expression levels in whole blood of patients with ESRD, independent of chronological age. Our findings suggest a potential contribution of Nrf2 dysfunction to the development of premature biological aging and its related morbidities in ESRD patients.



PO1135

Do Dialysis Facilities Improve Quality After Receiving a Penalty Under the ESRD Quality Incentive Program?

Jeffrey Marr,[1] Andrew Breck,[1] Shannon Griffin,[1] Tracy Yee,[1] Dominick Esposito,[1] Jeffrey Pearson,[2] Delia Houseal,[3] Adebola O. Adeleye.[3] *[1]Insight Policy Research Inc, Arlington, VA; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Centers for Medicare and Medicaid Services, Baltimore, MD.*

Background: We examined whether quality measures improve at dialysis facilities penalized under the Centers' for Medicare and Medicaid (CMS) End-Stage Renal Disease Quality Incentive Program (ESRD QIP) after receipt of a penalty.

Methods: Using data from CMS public use files from payment years (PY) 2014-2017, Medicare claims, and CROWNWeb, we used a difference-in-differences analysis to compare patient level measures of dialysis quality at facilities that did and did not receive penalties before and after the performance period. We also used a regression discontinuity design to compare patient quality measures two years after the performance period at facilities just above and just below ESRD QIP's performance score penalty threshold.

Results: Patients at penalized facilities had improved dialysis adequacy after the performance periods associated with PY2014-2017 and improved vascular access after the performance period associated with PY2014, compared to patients at nonpenalized facilities. Changes in vascular access after the PY2015 – PY2017 performance periods were not statistically significant. In the 5 years after the performance period associated with PY2014, the percent of patient-months with a fistula in use and the percent of patient-months meeting adult HD Kt/V standard (HD Kt/V ≥1.2) increased by 2.2 percentage points (95% CI 0.9 to 3.4) and 2.9 percentage points (95% CI 1.4 to 4.4), respectively, while the percent of patient-months with a catheter in use decreased by 2.6 percentage points (95% CI -3.7 to -1.5) at penalized facilities compared to nonpenalized facilities. Compared to those at nonpenalized facilities with relatively similar quality scores, patients at penalized facilities had lower catheter use two years after the PY2014 performance period and higher fistula use two years after the PY2016 performance period. However, these estimates are sensitive to specification changes. Other estimates were not statistically significant.

Conclusions: Receiving an ESRD QIP penalty is associated with subsequent improvements in some measures of dialysis quality, though results differ across payment years and analytic method.

PO1136

Predicting Dialysis Facilities at Risk of Low ICH-CAHPS Quality of Center Scores

Karen Lofty,[2] Yue Jiao,[1] Stephen Weber,[2] John W. Larkin,[1] Len A. Usvyat,[1] Angela McClure,[2] Jeffrey L. Hymes,[2] Franklin W. Maddux.[3] *[1]Fresenius Medical Care, Global Medical Office, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA; [3]Fresenius Medical Care AG & Co. KGaA, Global Medical Office, Bad Homburg, Germany.*

Background: Medicare administers biannual ICH-CAHPS surveys to capture patients' perceived experience of outpatient hemodialysis (HD) care. Recent operations efforts at a national dialysis provider aimed to develop prediction models to identify HD facilities at risk of low ICH-CAHPS rating in the subsequent survey period.

Methods: We used retrospective data from HD facilities at a national dialysis provider during 2018-2019. Two models were built to predict HD facilities that continued to have (Model 1) or decreased below (Model 2) a <60% top box ICH-CAHPS rating on the dialysis center staff, care, and operations subdomain in the spring 2019 survey period. Facility variables in 2018 included were: fall and spring ICH-CAHPS ratings; patient/employee net promoter (NPS) scores; employee retention rate; center quality Five Star rating; years of certification; facility size; composite clinical quality score; and % of HD non-adherence. Predictor variable importance was evaluated, and the performance of various modeling methods was assessed using several machine learning algorithms. We randomly selected derivation (70%) and validation (30%) datasets.

Results: We found the highest performance using GLM and GAM methods for both Models (**Figure 1**). The assessment of performance via the area under curve (AUC) showed use of GLM modeling correctly predicted true/false positives in 73% of facilities that continued to have (Model 1) and 70% of facilities that decreased below (Model 2) a <60% top box ICH-CAHPS rating.

Conclusions: The developed prediction models may be used as a tool in identifying HD facilities at risk of low patient ICH-CAHPS ratings. Prospective use in quality improvement efforts appears warranted.

Funding: Commercial Support - Fresenius Medical Care

Variability and Trends over Time and Across Centers in Hemodialysis Weekly Duration in Australia and New Zealand

Isabelle Ethier,[1,2] Yeoung Jee Cho,[2,3] Christopher E. Davies,[8,9] Carmel Hawley,[2,3] Scott B. Campbell,[2,3] Nicole Isbel,[2,3] Elaine Pascoe,[3] Kevan Polkinghorne,[6,7] Matthew A. Roberts,[10] Emily J. See,[4,5] David Semple,[11,12] Carolyn L. Van Eps,[2,3] Andrea K. Viecelli,[2,3] David W. Johnson.[2,3] *[1]Centre Hospitalier de L'Universite de Montreal, Montreal, QC, Canada; [2]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [3]The University of Queensland, Saint Lucia, QLD, Australia; [4]The University of Melbourne Faculty of Medicine Dentistry and Health Sciences, Melbourne, VIC, Australia; [5]Austin Health, Heidelberg, VIC, Australia; [6]Monash Medical Centre Clayton, Clayton, VIC, Australia; [7]Monash University Department of Medicine, Clayton, VIC, Australia; [8]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; [9]Adelaide Medical School, The University of Adelaide Adelaide Medical School Research, Adelaide, SA, Australia; [10]Monash University School of Public Health and Preventive Medicine, Melbourne, VIC, Australia; [11]Department of Renal Medicine, Auckland District Health Board, Auckland, New Zealand; [12]School of Medicine, University of Auckland, Auckland, New Zealand.*

Background: Hemodialysis treatment prescription varies widely around the world. This study explored patient- and center-level characteristics associated with weekly haemodialysis hours.

Methods: Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry data was analyzed. Characteristics associated with weekly duration were evaluated using mixed-effects linear regression models with patient- and center-level covariates as fixed effects, and dialysis center and state as random effects using the 2017 prevalent in-centre hemodialysis (ICHD) and home hemodialysis (HHD) cohorts. Evaluation of patterns of weekly duration over time analyzed the 2000 to 2017 incident ICHD and HHD cohorts.

Results: Overall, 12,494 ICHD and 1,493 HHD prevalent patients in 2017 were included. Median weekly treatment duration was 13.5 (interquartile range (IQR) 12-15) hours for ICHD and 16 (IQR 15-20) hours for HHD. Male sex, younger age, higher body mass index, arteriovenous fistula/graft use, Aboriginal and Torres Strait Islander ethnicity and longer dialysis vintage were associated with longer weekly duration for both ICHD and HHD. No center characteristics were associated with weekly duration. Variability in duration across centers was very limited in ICHD compared to HHD, with variation in HHD being associated with state. Duration did not vary significantly over time for ICHD, whereas longer weekly HHD treatments were reported between 2006 and 2012 compared to before and after this period.

Conclusions: This study in the Australian and New Zealand hemodialysis population showed that weekly treatment duration was primarily associated with patient characteristics. No center effect was demonstrated. Practice patterns seemed to differ across states/countries, with more variability in HHD than in ICHD.

PO1138

Clinical Outcomes Among Dual-Eligible Medicare and Medicaid Dialysis Patients in the United States

Robert Nee,[1] Jenna M. Norton,[3] Christina M. Yuan,[1] Lawrence Agodoa,[2] Kevin C. Abbott.[3] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]National Institutes of Health Office of the Director, Bethesda, MD; [3]National Institute of Diabetes and Digestive and Kidney Diseases Division of Kidney Urologic and Hematologic Diseases, Bethesda, MD.*

Background: Dual Medicare-Medicaid eligible beneficiaries generally live in poverty and account for approximately 28% of the US end-stage kidney disease (ESKD) population, but their clinical outcomes are largely unknown. We compared individual- and dialysis-facility level clinical quality measures and survival between dual-eligible and Medicare-only incident dialysis patients.

Methods: In this retrospective cohort study using the United States Renal Data System, we identified 52,863 patients who had Medicare as the primary payer, initiated on dialysis from January 1, 2016 through December 31, 2016, and followed until June 1, 2018. We incorporated data from the Consolidated Renal Operations in a Web-Enabled Network (CROWNWeb) and the Centers for Medicare & Medicaid Services (CMS) Dialysis Facility Compare files. We excluded those who were <18 years, transplanted or died within 90 days of dialysis initiation. We conducted multivariable Cox regression with death as the outcome, adjusted for demographic and clinical factors.

Results: The Medicare-primary cohort consisted of 19,819 (37.5%) dual eligible and 33,044 (62.5%) Medicare-only beneficiaries, with median follow-up of 1.8 years. Dual eligibles were more likely to be female, Black, Hispanic and younger than their Medicare-only counterparts (59 ± 15 vs. 66 ± 14 years, p<0.001). At 12 months after dialysis initiation, individual-level quality measures such as hemodialysis treatment time, KT/V, hemoglobin, albumin, calcium, and phosphorus were similar between the 2 groups. However, a slightly greater proportion of dual eligibles were dialyzed via catheter at 12 months compared with Medicare-only patients (47.2 vs. 43.0%, p<0.001). At a facility level, mortality rates, hospitalization rates, standardized infection ratios for bloodstream infection, and total performance scores were similar between the 2 groups. Adjusted analyses demonstrated higher risk of death in dual eligibles compared to Medicare-only patients (hazard ratio 1.29 (95% CI 1.23-1.34, p<0.001).

Conclusions: The Medicare-Medicaid dual eligibility status, as an indicator of poverty, was independently associated with higher mortality, despite similar individual- and facility-level performance measures. Further studies to delineate factors associated with death in this large segment of the ESKD population are needed.

PO1139

The Implementation of a Clinical Pharmacist in a Hemodialysis Center

Chantale Daifi. *Henry Ford Health System, Detroit, MI.*

Background: Hemodialysis (HD) patients have complicated disease states placing them at a higher risk for drug related problems (DRPs), medication discrepancies, and non-adherence. The objective of the study is to evaluate the impact of a clinical pharmacist in a HD center by assessing the efficacy of medication reconciliation (MR) in HD patients and evaluating the potential impact on the health system.

Methods: This is a retrospective study conducted in Greenfield Health Systems, a division of Henry Ford Health System that operates 14 dialysis centers throughout southeast Michigan. West Pavilion outpatient dialysis clinic, one of the centers in Detroit, Michigan consisting of an interprofessional team. Patients included in the study had at minimum four visits from the clinical pharmacist or pharmacy interns from August 2017 to October 2018. Study aim was to evaluate the impact of a clinical pharmacist in a HD center by assessing the efficacy of MR in HD patients and evaluating the potential impact on the health system. Descriptive statistics were used to collect DRPs and classified based on the modified Hepler-Strand approach.

Results: A total of 1403 DRPs with an average of 8.94 DRPs per patient were found with an average number of 7 visits per patient. Adherence was the most common DRP (31%). The most common drug class the pharmacist made interventions on was for medications used to treat blood pressure (37%) followed by vitamin D analogs/ calcimimetics (29%). A projected total of $447,355 was saved.

Conclusions: Pharmacists in HD clinics has a positive influence on HD patients through medication management and cost savings.

PO1140

Dietary Potassium Intake and All-Cause Mortality in Adults Undergoing Hemodialysis: The DIET-HD Cohort Study

Amelie Bernier-Jean,[1,2] Germaine Wong,[1,2] Valeria M. Saglimbene,[1,3] Marinella Ruospo,[3] Suetonia Palmer,[4] Vanessa Garcia-Larsen,[5] Patrizia Natale,[3,6] David W. Johnson,[7,8] Marcello Tonelli,[9] Jorgen B. Hegbrant,[3,10] Jonathan C. Craig,[11] Armando Teixeira-Pinto,[1,2] Giovanni F. Strippoli.[1,6]
[1]School of Public Health, Faculty of Medicine and Health, The University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [3]Diaverum Renal Services Group, Lund, Sweden; [4]Department of Medicine, University of Otago, Dunedin, New Zealand; [5]Program in Human Nutrition, Department of International Health, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [6]Department of Emergency and Organ Transplantation, University of Bari, Italy, Bari, Italy; [7]Department of Nephrology, Princess Alexandra Hospital, Brisbane, Australia, Brisbane, QLD, Australia; [8]Australasian Kidney Trials Network, University of Queensland, Brisbane, Australia, Brisbane, QLD, Australia; [9]University of Calgary, Calgary, Canada, Calgary, AB, Canada; [10]Department of Nephrology, Lund University, Lund, Sweden; [11]College of Medicine and Public Health, Flinders University, Adelaide, SA, Australia.

Background: Dietary modification to reduce the risk of hyperkalemia in people undergoing maintenance hemodialysis is standard practice and is commonly recommended in guidelines despite a lack of evidence. A low potassium diet may impair quality of life and nutritional status. We aimed to assess the association between dietary potassium intake and mortality and whether hyperkalemia mediates this association.

Methods: 9690 adults undergoing maintenance hemodialysis in Europe and South America were recruited in the DIET-HD study, of which 1647 were excluded for lack of data-linkage identifier or incomplete or implausible dietary assessment. We measured baseline potassium intake from the GA²LEN food frequency questionnaire and performed time-to-event and mediation analyses.

Results: The median dietary potassium intake at baseline was 3.5 g/day (IQR 2.5 to 5.0). During a median follow-up of 3.97 years (25,890 person-years), we observed 2921 (36%) deaths including 1316 (45%) from cardiovascular causes. After adjusting for baseline characteristics including presence of cardiac disease and food groups, dietary potassium intake was not associated with all-cause mortality (hazard ratio [HR] 1.00 95% confidence interval [CI] 0.95 to 1.05). A mediation analysis showed no association of potassium intake with mortality either through or independent of serum potassium (HR 0.999, 95% CI 0.996 to 1.002 and 1.000, 95% CI 0.999 to 1.002, respectively). Higher potassium intake was not associated with higher serum potassium (B=0.04 mEq/L 95% CI 0.00 to 0.09) or the prevalence of hyperkalemia (≥ 6.0mEq/L) at baseline (OR=1.08, 95% CI 0.93 to 1.24). Hyperkalemia was associated with cardiovascular death (HR=1.23 95% CI 1.03 to 1.48).

Conclusions: Higher dietary intake of potassium is not associated with hyperkalemia or death in patients treated with maintenance hemodialysis.

Funding: Government Support - Non-U.S.

PO1141

Serum-to-Dialysate Calcium Gradient and Its Association with Mortality in Incident Hemodialysis Patients

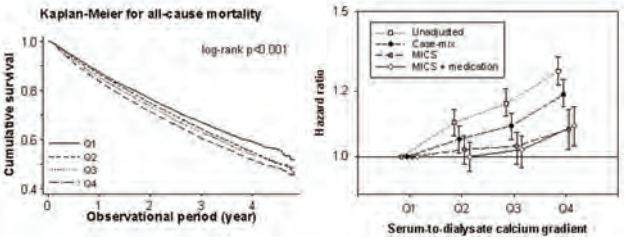
Hiroshi Kimura,[1] Cachet Wenziger,[1] Jui-Ting Hsiung,[1] Elani Streja,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2,3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [3]Memphis VA Medical Center, Memphis, TN.*

Background: A high serum-to-dialysate calcium gradient at start of hemodialysis leads to rapid lowering of serum calcium and was associated with higher risk of witnessed cardiac arrests. However, the association of serum-to-dialysate calcium gradient with mortality remains unclear. The objective of this study was to evaluate the serum-to-dialysate calcium gradient associated with a greater risk of adverse events in incident hemodialysis patients.

Methods: We retrospectively examined 96,339 in-center hemodialysis patients who initiated dialysis treatment between January 1, 2007, and December 31, 2011 in a large United States dialysis organization. Cox proportional hazards model was used to assess the multivariable association between serum-to-dialysate calcium gradient and patient survival.

Results: Higher serum-to-dialysate calcium gradient was associated with older age, higher proportion of hypertension, lower blood pressure in post dialysis, and worse nutritional indices. Adjusting for patients differences, there was a dose-response relationship between higher serum-to-dialysate calcium gradient and greater risk of all-cause mortality [adjusted hazard ratios: 1.00 (95% confidence interval [CI]: 0.96–1.04), 1.02 (95% CI: 0.97–1.06), and 1.09 (95% CI: 1.05–1.15) for subjects in the second, third, and fourth quartiles (reference: first quartile group)]. Similar trends were observed for cardiovascular and sudden cardiac mortalities.

Conclusions: Higher serum-to-dialysate calcium gradient is independently associated with greater risk of all-cause, cardiovascular, and sudden cardiac mortalities in hemodialysis patients.



PO1142

Pharmacokinetics, Pharmacodynamics (PK-PD), and Exposure-Efficacy Evaluation from CaLIPSO, a Phase 2B Study to Assess the Effect of SNF472 on Progression of Cardiovascular Calcification in Patients on Hemodialysis

Joan Perelló,[1,2] Joan J. Alberti,[3] Juan Vicente Torres Martin,[4] Maria del mar Perez,[1] Miquel D. Ferrer,[1,2] Firas Bassissi,[1] Carolina Salcedo.[1] *[1]Sanifit Therapeutics, Palma, Spain; [2]Universitat de les Illes Balears, Palma, Spain; [3]Admetra Consulting, Palma, Spain; [4]Syntax for Science SL, Palma, Spain.*

Background: Cardiovascular calcification (CVC) is a major contributor to increased morbidity and mortality in end stage kidney disease (ESKD) patients on dialysis. SNF472, a selective calcification inhibitor that interferes in the formation and growth of ectopic hydroxyapatite (HAP), has showed a significant reduction in CVC progression in CaLIPSO, a randomized, double-blind, placebo-controlled phase 2b trial. The drug is also currently in Phase 3 trial for the treatment of calciphylaxis. Our aim was to perform PK-PD and exposure-response analyses from the CaLIPSO trial.

Methods: PK and PD were assessed at weeks 1, 10, 22 and 52, following intravenous administration thrice weekly over 52 weeks. Efficacy was assessed as % change in coronary artery calcification score by volume (CACv) over 52 weeks. The relationship between PK (C_{max}) - PD (ex-vivo inhibition of HAP crystallization in plasma), PK-efficacy and PD-efficacy was evaluated using linear and E_{max} models.

Results: The analyses included data from 56 patients. C_{max} values and PD responses per group were similar over the 52 weeks of treatment, indicating no accumulation of SNF472. Mean plasma C_{max}, mean PD effect and % change in CACs over 52 weeks per group are shown in the table. An E_{max} model described well the relationship between PK-PD (E_0=8.8%, E_{max}=75.9%, EC_{50}=5.5 μM); and PK-efficacy (E_0=16.9%, E_{max}=-14.5%, EC_{50}=12.2 μM). The PD-efficacy relationship was better described by a linear model.

Conclusions: SNF472's PK showed no accumulation and PD remained constant over 52 weeks of treatment. E_{max} models showed a robust relationship between SNF472's C_{max} and both the ex-vivo inhibition of HAP crystallization and clinical efficacy measured by % change in CACv over 52 weeks. Higher SNF472 exposure and inhibition of HAP crystallization correlated with a reduction in CVC progression in ESKD patients on dialysis.

PO1143

Associations of Dialysis Facility Clinical Performance with Patient Outcomes in the Medicare ESRD Quality Incentive Program (QIP)

Yan Jin,[1] Dongyu Wang,[1] Alissa Kapke,[1] Delia Houseal,[2] Marc Turenne.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Centers for Medicare and Medicaid Services, Baltimore, MD.*

Background: In CY2017, CMS implemented the Meaningful Measures Initiative, which aimed to reduce data reporting burden and costs for health care providers and to focus improvement efforts on the most meaningful outcomes for patients. To assure the ESRD QIP is aligned with this initiative and is achieving CMS goals, we assessed whether facility clinical measure performance is associated with improved patient outcomes.

Methods: Patient outcomes at the facility level were evaluated using the CY17 standardized mortality ratio (SMR) and standardized hospitalization ratio (SHR) from Dialysis Facility Compare, and the ESRD QIP CY17 In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems (ICH-CAHPS) scores. Facility-level performance in CY17 on ESRD QIP measures for hypercalcemia, fistula, long-term catheter, comprehensive Kt/V, NHSN bloodstream infection (BSI) standardized infection ratio (SIR), and standardized transfusion ratio (STrR) was assessed using tertiles. Associations between facility measure performance and outcomes were tested using Poisson models for SMR and SHR and Analysis of Variance (ANOVA) models for ICH-CAHPS scores.

Results: For all ESRD QIP clinical measures, lower levels of performance were associated with higher relative risks (RR) for SMR and SHR (p<.05; Table). For all clinical measures except STrR and NHSN BSI SIR, lower levels of performance were also associated with lower ICH-CAHPS QIP scores (p<.05; Table).

Conclusions: The observed associations of facility performance on individual ESRD QIP clinical measures with mortality, hospitalization, and patient experience with care indicate that the program is incentivizing improvements in care that are related to important patient outcomes.

Funding: Other U.S. Government Support

Types of Incidents (Patient Safety) Managed at Two Different Medical Levels in a Large Multinational Renal Services Provider Network

Belen Marron, Israel P. Silva, Carlos Lucas, Marietta Török, Charlotta Wollheim, Suzanne H. Pearce, Filiz Akdeniz, Fernando Macario. *Diaverum Renal Services. Corporate Medical Office, Hyllie, Mälmo, Sweden.*

Background: Patient safety programs need a well-structured organization to facilitate proactive and fair reporting, prompt evaluation analysis and timely feedback followed by measure implementation and auditing. **Objectives** To analyze all types of incidents in our network during 2019 by two different levels (Corporate and Country) of medical management alert.

Methods: Our institution has tracked all incidents under a structured process program for the last 10 years, according to 4 incident types (Patient related, Staff-visitors, Products and Equipment) and 54 subcodes. Incidents are considered as serious when they may be life-threatening or result in death, impaired body function/structure and/or are deemed serious based on appropriate medical judgment. Communication to Health Authorities applies in accordance with local country regulations. "Serious incidents" are immediately notified to the Corporate Office and to each Country Medical lead, whilst different codes may generate alerts into Corporate or Country.

Results: 92.923 incidents (2.7 incident/patient/year) were reported during 2019. Total incidents/1000 treatments were 17.2 (12.2 were patients related incidents). Causes for alerts at Corporate level (n=81) were cardiorespiratory arrest (26%); unexpected death (19%); seroconversion (9%); wrong disposable/dialyzer (9%); hemolysis (7%); severe hypotension (5%) and different mix codes (25%). Reported incidents at country level (n=831) were more than half ascribed to equipment [water supply, power failure and flooding (53%)], medication errors (35%), venous needle dislodgment (20%) and staff-visitors Injuries (4%).

Conclusions: Tracking of incidents have potential to increase quality of care and patients outcomes. Despite continuous efforts to get better results, there is room for improvement on better staff compliance with our standard operating procedures especially regarding medications and venous needle dislodgment risk assessment.

PO1145

Roxadustat in Treating Anemia in Dialysis Patients (ROAD): Short-Term Impact on Serum Triglyceride

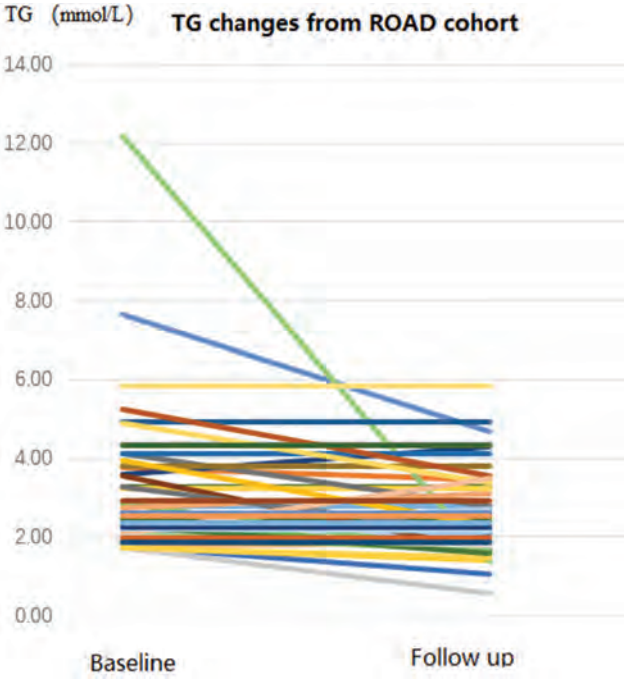
Daqing Hong,[1] Hen Xue,[2] Yanrong Cai,[3] Jingdong He,[4] Qiang He,[1] Guisen Li.[1] *[1]Department of Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, China; [2]Department of Nephrology, Ya'an People's Hospital, Chengdu, China; [3]Gao Xin Boli Hospital, Chengdu, China; [4]The Second Affiliated Hospital of Chengdu Medical College, Chengdu, China.*

Background: Roxadustat has been shown effective in lowering serum cholesterol in treating patients with anemia due to chronic kidney disease. However, its effect on serum triglyceride (TG), especially in dialysis patients that have high prevalence of hypertriglyceridemia remains unknow. This analysis is to provide clinical data of Roxadustat on serum TG in a real-world prospective observational cohort.

Methods: This is a multicenter, prospective, longitudinal observational cohort study assessing if Roxadustat improves prognosis in at least 250 dialysis patients with renal anemia. Primary outcomes will be major cardiovascular events. The current analysis was done in the enrolled 144 patients to compare the changes of serum TG from baseline to current follow up. The analysis was done in the whole cohort and subgroups according to baseline serum TG level.

Results: Till May 20, 2020. 144 dialysis participants (76 male, mean age 52+/-15 years) were enrolled from 11 sites of the study with a follow up of 8 (0~12) weeks. The primary disease of kidney failure was predominantly primary glomerulonephritis (67 cases, 46.5 %) and diabetes (28 cases, 19.4%). The serum TG at baseline and at the last follow up was 2.06+/-1.58 mmol/L (range from 0.14 to 12.04 mmol/L) and 1.90+/-1.09mmol/L respectively (p=0.162). In patients with TG greater than 1.7mmol/L, serum TG decreased significantly (n=53, 2.59+/-1.06 *vs.* 3.09+/-1.75 mmol/L, p=0.028) after Roxadustat treatment with -0.50mmol/L (95%CI: -0.05, 0.95mmol/L).

Conclusions: Hypertriglyceridemia is prevalent in ROAD cohort. Roxadustat could alter serum TG, especially lowering its level in dialysis anemia patients with hypertriglyceridemia which should be confirmed in future studies.



TG changes from ROAD cohort.

PO1146

Roxadustat in Treating Anemia in Dialysis Patients (ROAD): Short-Term Impact on Serum Iron Markers

Daqing Hong,[1] Guangyi Zheng,[4] Yang Zou,[1] Yanrong Cai,[2] Jingdong He,[3] Hen Xue,[4] Qiang He,[1] Guisen Li.[1] *[1]Department of Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, China; [2]Gao Xin Boli Hospital, Chengdu, China; [3]The Second Affiliated Hospital of Chengdu Medical College, Chengdu, China; [4]Department of Nephrology, Ya'an People's Hospital, Chengdu, China.*

Background: This analysis is to provide clinical data of Roxadustat on iron markers in a real-world prospective observational cohort.

Methods: This is a multicenter, prospective, longitudinal observational cohort study assessing if Roxadustat improves prognosis in at least 250 dialysis patients with renal anemia. Primary outcomes will be major cardiovascular events. The current analysis was done in the enrolled 144 patients to compare the changes of iron markers from baseline to present.

Results: Till May 20, 2020. 144 dialysis participants (76 male, mean age 52+/-15 years) were enrolled from 11 sites of the study with a follow up of 8 (0~12) weeks. Hemoglobin increased by 8.5g/L (95%CI:6.1 to 10.8 g/L, p<0.001) significantly from baseline to last follow up. The serum ferritin at baseline and at the last follow up was 639.13+/-530.18 pg/ml and 473.52+/-520.34 pg/ml respectively (p<0.001). TSAT remained stable from baseline to last follow up (36.8+/-20.5% *vs.* 36.7+/-22.7%, p=0.93). In patients with ferritin greater than 500 pg/ml or 800 pg/ml, changes of ferritin were 245 pg/ml (95%CI:117.62 to 373.46, p<0.001) and 362.01 pg/ml (95%CI: 99.34 to 580.30, p=0.008). In patients with low responsiveness to ESA, according to ESA dosage (greater than 300U/Kg/Week, 199.41pg/ml, 95%CI: 37.69 to 361.12, p=0.019) or by investigators' judgement (143.83pg/ml, 95%CI:55.99 to 231.67 pg/ml, p=0.002), the results were similar and significant. TSAT did not change significantly among the whole cohort and in the subgroup analysis.

Conclusions: Roxadustat could increase hemoglobin in dialysis patients in ROAD cohort. It could decrease serum ferritin in dialysis patients, regardless of the high ferritin or responsiveness of ESA treatment and maintains stable TSAT. These might indicate that Roxadustat partially increase hemoglobin by alter iron status even in patients have low responsiveness to ESA treatment.

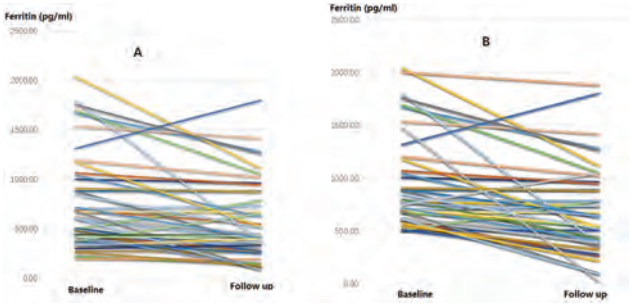


Figure 1 Ferritin changes from ROAD cohort.

A. patients with hyperresponsiveness to ESA

B. patients with baseline ferritin greater than 500 pg/ml.

PO1147

Relationship Between Fluid Overload (FO) and Hemoglobin Concentration (Hgb) in Hemodialysis (HD) Patients (Pts)

Lemuel Rivera Fuentes,[1] Mohamad I. Hakim,[1] Ulrich Moissl,[2] Ariella E. Mermelstein,[1] Jochen G. Raimann,[1] Laura Rosales,[1] Dewangi A. Kothari,[1] Fansan Zhu,[1] Stephan Thijssen,[1] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany*.

Background: FO is common in HD pts and the BCM (Fresenius Medical Care, Germany)allows the assessment of fluid volumes and FO. We studied the association between FO and Hgb concentration in a cross-sectional study in four urban US dialysis clinics and tested the effects of inflammation and erythropoiesis-stimulating agents (ESA).

Methods: We conducted BCM measurements in participating HD pts, and obtained Hgb, neutrophil-to-lymphocyte ratio (NLR) and ESA usage from the EMR. The association between FO (stratified into tertiles) and Hgb and NLR, resp., was tested using ANOVA and that between FO and ESA usage using Chi-Square Test. We further employed linear regression, stratified by ESA usage (yes/no), to test associations of FO with Hgb and NLR.

Results: We studied 170 pts (40% female, 52.9% black, 28.2% Hispanic, 61.3±14.4 years, FO 2.2±2.4 L, Hgb 10.9±1.3 g/dL, NLR 3.5±1.9). Greater FO associated with higher NLR (Figure 1a) and lower Hgb (Figure 1b) and also with ESA use (P<0. 001). Hgb negatively correlated with NLR (r=0.1, P=0.10) and FO (r=0.3, P<0. 01). The association between Hgb and FO remained after adjustment for NLR (Beta -0.17, P<0. 01). When the same association was tested separately for pts on ESA and those not on ESA, Hgb was inversely correlated with FO only in patients not on ESA (Beta -0.22, P<0.01), whereas its inverse relationship with NLR remained significant in both subgroups.

Conclusions: FO and inflammation inversely associates to Hgb and deserves consideration in anemia management. BIA can help the clinician assess whether FO may be contributing to low Hgb values. As such, it is a valuable diagnostic tool that should find its way into routine care for US HD pts.

PO1148

Automated Early Detection of Hyponatremia in Hemodialysis Patients Derived from Online Conductivity Measurement

Andreas Maierhofer,[1] Joachim Harlos,[2] Bernard J. Canaud.[1] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]MVZ Dialysezentrum Schweinfurt, Schweinfurt, Germany*.

Background: Hyponatremia in dialysis patients is a strong indicator of poor outcome that requires early detection to facilitate clinical workup and management. However, plasma sodium concentration as determined by lab methods (*Na-Lab*) is measured at the best monthly in clinical practice. Recently, online monitoring of predialytic plasma Na (*pPlNa*) as estimated from dialysate conductivity using an electrolyte model has become available at every hemodialysis session, thus providing an unprecedented close and almost continuous monitoring of this crucial indicator. This could be used as diagnostic tool to earlier alert the physician of underying clinical illnesses.

Methods: In a monocentric retrospective clinical study in 114 patients on maintenance hemodialysis (>90% online postdilution HDF) for whom online *pPlNa* was available for a period of at least 12 months at least once a week, kinetics of *pPlNa* were analyzed. For 11 patients with hyponatremic episodes as manifested in *pPlNa*, the agreement between time course of *pPlNa* and *Na-Lab* and the correlation to the manifestation of clinical findings was explored.

Results: Time course of *pPlNa* and *Na-Lab* showed very good agreement. In addition, in each case the onset of hyponatremia was linked to a subacute illness development (i.e., sepsis, congestive heart failure, …) underpinned by various degrees of fluid overload. Correction of the underlying pathology and fluid overload by dry weight adjustement permitted to improve clinical outcome.

Conclusions: The clinical examples show that due to the good agreement of the time course of *pPlNa* and *Na-Lab*, *pPlNa* can be used as adjuvant diagnostic tool for the early detection of onset and progression of morbid events. This online tool will support physicians in decision making for improving dialysis patient management and likely outcome. Further studies are deserved to confirm the clinical value of this tool.

Example for the agreement between the time course of *pPlNa* and *Na-Lab*, and to clinically manifested illness during a period of hyponatremia

PO1149

Prevalence of Fluid Overload in a US Dialysis Population

Ulrich Moissl,[2] Lemuel Rivera Fuentes,[1] Mohamad I. Hakim,[1] Laura Rosales,[1] Fansan Zhu,[1] Dewangi A. Kothari,[1] Jochen G. Raimann,[1] Stephan Thijssen,[1] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.*

Background: Hypervolemia remains one of the main reasons for increased cardiovascular (CV) morbidity and mortality in chronic hemodialysis (HD) patients. Quantification of fluid status using bioimpedance spectroscopy (BIS) has become routine in many countries outside the United States (US). Due to previous unavailability of FDA-cleared BIS devices, no cross-sectional appraisal of fluid status in HD patients has yet been done in the US. The aim of this study was to perform the first assessment of fluid status in a US dialysis population using a BIS device

Methods: Fluid overload (FO) was measured in 170 chronic HD patients from four clinics in New York City using the BCM Body Composition Monitor (Fresenius Medical Care) which provides the amount of excess extracellular water (ECW) in liters. Measurements were performed before dialysis; post-dialysis fluid status was estimated by subtracting the removed fluid from pre-dialysis FO

Results: Pre- and post-dialysis FO were found to be 2.2L ± 2.4 L and -0.2 ± 2.7 L (mean ± SD), respectively. Before the start of HD, 42.9% of patients were fluid overloaded (criterion: FO/ECW > 15% in males, and >13% in females), 53.5 % were normally hydrated, and 3.5% were fluid depleted (FO/ECW <-7%).

Conclusions: The prevalence of pre-HD fluid overload was significantly higher in this US population (42.9%) than in a previously published large European cohort (29.6%). This suggests the need for more adequate assessment of fluid status to support the clinicians in identifying and treating fluid overload in HD patients

PO1150

The Use of Loop Diuretics in Newly Initiated Hemodialysis Patients: The Clinician's Perspective

Tripta Kaur, Steven G. Coca, Girish N. Nadkarni, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY.*

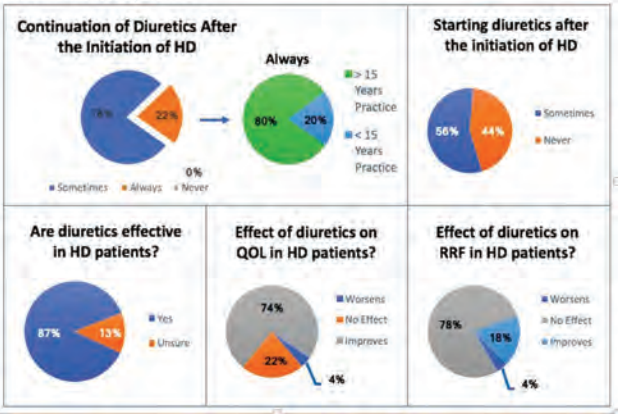
Background: ESRD patients newly initiated on HD have varying levels of residual renal function (RRF). The loss of RRF is associated with increased cardiovascular and all-cause mortality and decreased quality of life (QOL). There are no studies reported to date that have explored in detail the physicians' clinical opinion and approach to the use of diuretics after the initiation of HD.

Methods: A one-time anonymous electronic survey was created to explore the clinicians' opinion and practice pattern of diuretic use in new-start HD patients. 50 nephrologists associated with the Mount Sinai Health System were included.

Results: 23 (46%) completed the survey and 8 (35%) have practiced nephrology for > 15-years. 16 (70%) assess RRF monthly. The level of urine output per day (UOP/d) considered adequate for diuretic use was 200-250 mL by 7 (30%) and 400-500 mL by 12 (52%). While 20 (87%) and 18 (78%) of the physicians felt that diuretics are effective in HD patients and improve quality of life (QOL), respectively, only 5 (22%) always continue diuretics and 13 (57%) sometimes start diuretics after initiation of HD (Fig 1). Physicians with >15 years in practice were more likely to continue diuretics than physicians with less experience (50% vs. 7%, P=0.03). Volume status (70%) and the ineffectiveness of diuretics (64%) were considered more important factors in the decision to use diuretics. Only 5 (26%) routinely use furosemide > 240 mg/day, but only 10 (43%) were influenced by ototoxicity.

Conclusions: While a majority of physicians believe that diuretics are effective and improve patient QOL, few consistently continued diuretics and only half started diuretics "sometimes". The factors that were considered more important in decisions to continue or start diuretics were volume status and the opinion that diuretics can be ineffective in HD patients.

Figure 1. Diuretic use after the initiation of HD and the physician's opinion on the role of diuretics in HD patients.



PO1151

Assessment of Estimated Dry Weight in Dialysis Patients Undertaking Kidney Transplantation by Evaluating Post-Transplant Weight: The Kidney Knows Best

Spencer Hodgins,[1] Bikash Chapagain,[1] Twara K. Tarasaria,[1] Yossi Chait,[2] Michael J. Germain,[1] Barbara A. Greco.[1] *[1]Baystate Medical Center, Springfield, MA; [2]University of Massachusetts System, Boston, MA.*

Background: The consequences of volume overload include recurrent hospitalizations and increased mortality in dialysis patients. Dry weight (EDW) is estimated in dialysis patients to provide a target for ultrafiltration and to prevent the consequences of volume overload. New kidney transplant recipients with good allograft function provide a unique opportunity to evaluate the accuracy of EDW. With the assumption that a good functioning kidney allograft would return the patient to their optimal dry weight (ODW), we compared the differences between EDW and ODW in a cohort at our center.

Methods: We retrospectively reviewed 138 adult kidney transplant recipients at Baystate Medical Center between June 2015 and October 2019. Patients were excluded on the basis of not achieving a serum creatinine of ≤1.5 mg/dl at 2 weeks post-transplant. ODW was defined as the weight at 2 weeks in a patient with good allograft function. Patients with EDW in the range +3% and -1% of ODW were considered to be euvolemic pre-transplant. Patients with EDW below and above that range were considered hypovolemic and hypervolemic, respectively. 35 patients met criteria and were included in the analysis.

Results: The mean (SD) age was 54.3 (12.7) years with 52% male. 31.4% of patients had live donors. Based on pre-transplant EDW values, 23% were above (hypovolemia), 17% within, and 60% below (hypervolemia) the range of euvolemia (Figure 1).

Conclusions: We conclude that many dialysis patients (83%) may not be at their ODW. This illustrates the importance of finding novel tools to help achieve accurate dry weight patient undertaking dialysis in order to reduce hospitalizations and improve mortality.

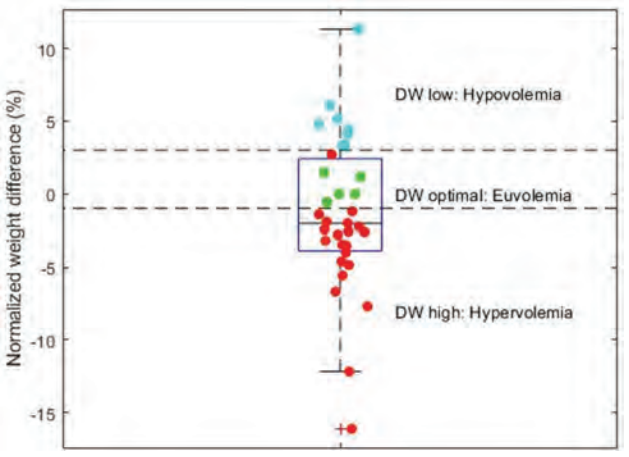


Figure 1. Box Plot Showing the normalized weight differeince in %.

PO1152

Novel Ultrafiltration Rate Feedback Controller for Attainment of Relative Blood Volume Targets During Hemodialysis

Lemuel Rivera Fuentes,[1] Mirell Tapia,[1] Sabrina Rogg,[2] Stephan Thijssen,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Preciado et al. have identified half-hourly relative blood volume (RBV) targets during a hemodialysis (HD) session that are associated with significantly improved patient survival. Attainment of these RBV targets would require incessant empiric adjustments to the ultrafiltration rate (UFR) by the dialysis nurse. We developed a novel proportional-integral controller that takes RBV data from the commercially available CLiC® device as an input and provides UFR suggestions to guide the RBV curve into the desired targets. The clinician specifies the desired UF goal with the maximum allowed upward/downward deviation from this goal, and the UFR Feedback Controller then optimizes the RBV trajectory within the limits of the prescription. The present study aimed to characterize the behavior of this feedback controller

Methods: We conducted a single-arm, prospective, interventional pilot study in subjects on chronic HD at 3 dialysis centers in NYC. RBV was measured with the CLiC® device. CLiC® and HD machine data were fed into a research laptop running the UFR Feedback Controller software. The UFR recommendations (generated every 10 min) were evaluated by dialysis nurses who then either implemented or disregarded them as they deemed clinically appropriate

Results: 15 subjects (58.9 ± 15.3 years, 53% black, weight gain 2.6 ± 0.8 L, HD time 222 ± 28 min) were studied (63 study visits, 4.2 ± 1.9 visits/subject). Of 300 analyzed RBV target timepoints, 63% had RBVs within the desired target range, 33% of the RBVs were above and 4% were below target. Stratified by timepoint, the on-target percentage increased from 37% at 30 min to 73% at 3h into HD. The rate of intradialytic morbid events did not appear to be increased. In subjects with at least 4 complete study visits (N=8), on average 71.8% of subjects were within the desired RBV target at 3h into HD

Conclusions: The UFR Feedback Controller behaved as expected, steering the patients' RBV curves toward the predefined target ranges while strictly observing the prescribed UF goal. Preciado et al. had reported a third of patients within the favorable RBV target range at 3h into conventional HD. In contrast, with the use of this novel UFR Feedback Controller, approx. 72% of subjects were within the desired RBV target range at 3h

PO1153

A Novel Algorithm to Identify Presumably Fluid Overloaded Hemodialysis Patients

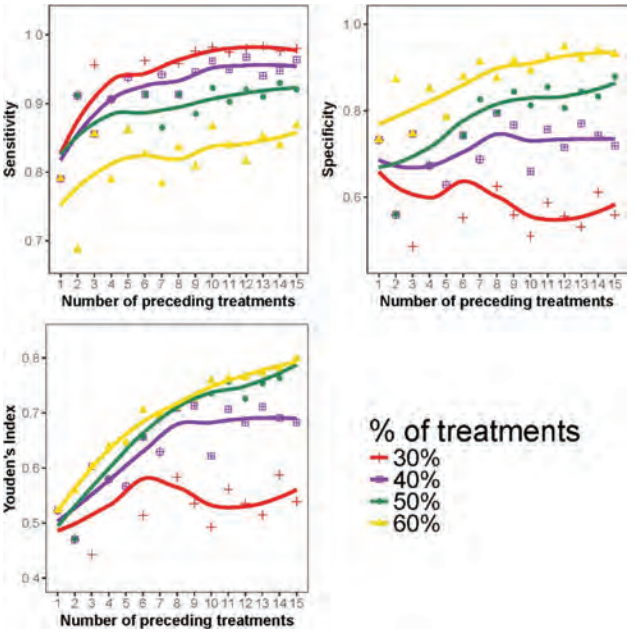
Priscila Preciado,[1] Hanjie Zhang,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Mount Sinai Health System, New York, NY.*

Background: Adequate volume control is a major challenge in hemodialysis (HD) patients. Relative blood volume (RBV) monitoring evidence suggests that flat RBV slopes indicate fluid overload. We aim to develop an algorithm to identify presumably fluid overloaded HD patients based on a small number of consecutive RBV recordings

Methods: We based our analysis on the 842 prevalent HD patients in our previously published study, RBV was assessed over a 6-month baseline period and all-cause mortality recorded;an RBV between 86 and 92% three hours into treatment was associated with significantly better survival. Our goal was to develop an algorithm that would require a much shorter observation period with clinically meaningful sensitivity and specificity to identify (presumably FO) patients with flat RBV profiles (RBV >92% at 3 hours). We categorized patients as either positive (mean RBV >92%) or negative. We computed sensitivities and specificities relative to the positive and negative cases for 1-15 HD sessions and various rates of treatments with flat RBV curves

Results: Sensitivities, specificities, and Youden's indices (=sensitivity+specificity–1) for 1-15 treatments and across the different rates of positive RBV curves are shown. We found a sensitivity of 92%, specificity of 80%, and Youden's index of 73% when >=50% of 10 preceding treatments were positive

Conclusions: Our algorithm requires only a small number of RBV readings to identify presumably fluid overloaded patients with a clinically acceptable sensitivity and specificity. It would be of interest to compare the performance of this algorithm with volume status as determined by bioimpedance;however, bioimpedance has not yet been approved for use in HD patients in the U.S.



Sensitivity, specificity & Youden's index as a function of HD treatments and rate of treatments with flat RBV curves.

PO1154

Peak Oxygen Capacity in Patients on Dialysis: The Role of Fluid Overload

Vanessa O. Gomes, Marília P. Viana, Lizbeth C. Benavides, Marcelo P. Menezes filho, Jose Mariano S. Pantoja, Luana R. Soares, Jukelson B. Silva, Valkercyo A. Feitosa, Rosa M. Moyses, Rosilene M. Elias. *Universidade de Sao Paulo Hospital das Clinicas, São Paulo, Brazil.*

Background: Exercise capacity is predictive of cardiovascular disease and mortality in patients with chronic kidney disease on dialysis. Fluid overload, a common feature in these patients, may play a role in this pathophysiology.

Methods: The Duke Activity Status Index (DASI) questionnaire was administered to 27 patients on peritoneal dialysis (PD) and 82 patients on hemodialysis (HD). Results were expressed as peak oxygen uptake (Vo2peak, ml/kg/min). Electrical bioimpedance was applied to assess body composition. Fluid overload was assessed as the ratio of extracellular water/total body water (ECW/TBW).

Results: The patients on HD and PD have no difference in age (44 ± 15 vs. 49 ± 18 years, p=0.224) and body mass index (25.0 ± 4.9 vs. 26.3 ± 4.9kg/m2, p=0.245), with similar gender distribution (p=0.870), prevalence of diabetes (p=0.404) and smoking habit (p=0.223). Vo2peak was lower among patients on PD than HD (21.4 ± 7.5 vs. 25.3 ± 7.6ml/kg/min, respectively, p=0.023). Vo2peak correlated with ECW/TBW (r=-0.436, p=0.0001) and age (r=-0.483, p=0.0001) in both groups and within each group. Vo2peak correlated with interdialytic weight gain in patients on HD (r=-0.236, p=0.031).

Conclusions: Patients on dialysis present reduced exercise capacity, which is even more pronounced for patients on PD. Volume overload seems to be involved in this reduction and might be a target for interventional therapies.

PO1155

Simplifying the 28-Zone Lung Ultrasound Protocol

Momodou L. Sonko, Ivan Kuznetsov, Thomas C. Arnold, Cameron Baston, Nathaniel C. Reisinger. *Penn Medicine, Philadelphia, PA.*

Background: Lung ultrasound (LUS) using a 28-zone quantitative B-line score (BLS) is a reliable marker of fluid overload (FO) among patients with end-stage kidney disease (ESKD) on hemodialysis (HD), outperforming physical exam and correlating well with cardiovascular outcomes. A trial comparing BLS-guided dry weight probing to usual care showed improved blood pressure and echocardiographic parameters. However, 28-zone BLS study is criticized as impractical for clinical practice. Using a machine learning algorithm we determined whether accurate assessment of FO can be determined using just 4, 6, and 8 scanning zones.

Methods: We analyzed an existing dataset of 28-zone BLS scores obtained from 100 HD patients presenting to acute care at our center for a total of 2800 scored LUS clips. Using linear correlation and discriminant analysis, we fit models that allowed us to approximate the 28-zone BLS based on 4, 6, or 8 zone protocols. We next applied linear discriminant analysis to study whether we could predict FO severity (low: BLS <15, moderate: BLS 15 to 30; high BLS>30) based on the limited zones. Finally, we tested whether we could achieve better diagnostic performance with subsets of scan-zones that had not previously been reported. Final outcome measures were reported as correlation coefficients and Cohen's kappa.

Results: We found that the BLS of the 4, 6, and 8-zone scan correlated strongly and linearly with the BLS of the full 28-zone scan with Pearson correlations of 0.95, 0.92, and 0.92, respectively. In determining FO severity based on the limited scanning zones, the model produced resultant Cohen's Kappa values of 0.74, 0.76, and 0.71 for the 4, 6, and 8-zone scans, respectively. We identified an undescribed 4-zone scan that produced a Kappa of 0.82. We found that equal linear weighting of all zones gave the best accuracy.

Conclusions: We found that 4, 6, and 8 zone BLS scores perform similarly to the 28-zone BLS. We identified a subset of 4 zones that gave better accuracy than existing 4, 6, or 8-zone scans. These findings support that a limited number of scanning zones can be used to reliably determine FO. Further work is needed on a larger dataset to validate these findings and to explore the physiological mechanism to support the novel 4-zone scan.

PO1156

Incidence and Outcomes of Gram-Negative Bacteraemias in Haemodialysis Patients: 12-Year Single-Centre Experience

Fatima Malik, Anna Naito, Lisa Bradwell, Christopher M. Cregg, David Makanjuola. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: Patients on haemodialysis (HD) are at increased risk of contracting infections. Gram-negative bacteraemia in HD patients is associated with early mortality. In our HD population, we looked at the incidence and clinical outcomes of gram-negative bacteraemias over 12 years.

Methods: Data were collected from clinical records and the hospital's microbiology database of all confirmed bacteraemias in HD patients between 2007 and 2018.

Results: 283 episodes of gram-negative bacteraemia occurred in 1361 patients over the study period. 166 (58.7%) were male. The median age was 71 years (range 26-95). The proportion of gram-negative bacteraemias fell significantly between 2007 and 2010 and has plateaued since then. 90 (31.8%) had arteriovenous fistulae (AVF) or grafts, the remainder had dialysis lines, of which 41 (21.2%) had dual access (AVF or graft + line), with the AVF/graft not yet in use. The bacteraemias were deemed to be access related in 89 events (31.4%). Of these, 73 (82.0%) were related to dialysis lines, 16 (18.0%) were related to AVF/graft. 190 (67.1%) were from other sources including urinary tract 18.4% (n=52), hepatobiliary 7.8% (n=22), chest 7.8% (n=22), gastro-intestinal 6.0% (n=17) and skin/soft tissue in 4.9% (n=14). There was no information on 4 patients (1.5%). Complications of the bacteraemias included: discitis (6, 2.1%); osteomyelitis (5, 1.8%); endocarditis (2, 0.7%); septic arthritis (2, 0.7%); and death (34, 12.0%).

Conclusions: The incidence of gram-negative bacteraemias in our cohort appears to have plateaued, with bacteraemias originating from other sources such as the urinary tract and intra-abdominal accounting for a greater proportion of gram-negative bacteraemias in our cohort - a trend reflected in other similar observational studies in HD populations. Dialysis lines remain a significant risk factor for bacteraemia, lending further weight to the importance of establishing early definitive vascular access. The increased incidence of pathogens from non-access related sources however, highlights that HD populations are exposed to both community and healthcare associated infections, and ongoing surveillance and strategies to reduce the burden of infections in this at-risk cohort remains imperative not just in dialysis centres, but also in the community

New Polymeric Dialysis Membrane with Endexo™ Surface Modifying Macromolecule

Chih-Hu Ho, Colleen M. Fisher, Claudy Mullon. *Fresenius Medical Care North America Ogden, Ogden, UT.*

Background: Surface-modifying macromolecules (SMM) may improve the hemocompatibility of hemodialyzers. We report the i*n vitro* characterization of a new Optiflux® Enexa™ dialyzer containing a membrane with a fluorinated polyurethane SMM (Endexo™).

Methods: Hollow fiber membranes were manufactured by mixing polysulfone (PS), polyvinylpyrrolidone (PVP), and the Endexo™ SMM. Contact angle and zeta potential were used to characterize the surface of the membrane compared to hollow fiber membranes from Optiflux® F160 dialyzers without Endexo™ SMM. *In vitro* hemocompatibility was assessed using freshly collected heparinized human blood. An *in vitro* simulation model was used to mimic the clinical frequency of blood contact with the dialyzer, and to evaluate platelet and complement activations as well as coagulation factors. Comprehensive biocompatibility evaluations and toxicological risk assessment were performed on Endexo™ SMM and the dialyzer, based on ISO 10993 guidelines.

Results: Surface characterization of the membrane revealed a slight increase in hydrophobicity in the inner lumen and up to 40% increase in the outer lumen, and a lower zeta potential on the blood side (-1.9 meV) compared to the control membrane (-12.9 meV). *In vitro* simulations with the Optiflux® Enexa™ dialyzer showed 58% and 67% lower platelet count reduction and platelet activation than observed with Optiflux® dialyzer. Extractable/leachable testing using 17.2% and 39.1% ethanol on the Optiflux® Enexa™ dialyzer resulted in margin of safety (MOS) values of > 1. Biological tests received passing/acceptable results.

Conclusions: Improved membrane surface characteristics and hemocompatibility performance were observed *in vitro* using a new dialyzer containing the Endexo™ fluorinated polyurethane surface modifying molecule. Based on the biocompatibility data, and toxicological assessment of exposure to chemicals from the device, the weight-of-evidence suggests that the concern for adverse effects following the intended use of the Dialyzer with Endexo™ is minimal.

PO1158

Procalcitonin Is a Biomarker for Inflammation in Outpatient Hemodialysis Patients

Sanjay P. Neupane,[1] Alana B. Barofsky,[2,5] John R. Lee,[3,4] Jeffrey I. Silberzweig.[2,3] *[1]NewYork Presbyterian, Weill Cornell Medical Center, New York, NY; [2]The Rogosin Institute, New York, NY; [3]Division of Nephrology and Hypertension, Weill Cornell Medicine, New York, NY; [4]Department of Transplantation Medicine, NewYork Presbyterian/ Weill Cornell Medical Center, New York, NY; [5]Hackensack Meridian School of Medicine, Nutley, NJ.*

Background: Procalcitonin is a widely used test to distinguish bacterial infections from viral infections, but its level is influenced by kidney function. The normal range of procalcitonin levels in end-stage renal disease (ESRD) patients on hemodialysis (HD) is not well established. In this study, we evaluated the relationship between Procalcitonin and inflammatory markers and outcomes in ESRD outpatients on HD.

Methods: We recruited 71 ESRD outpatients on HD from October 1st 2019 to December 15th 2019 and measured their procalcitonin levels prior to dialysis. We evaluated whether procalcitonin levels were associated with clinical characteristics, laboratory parameters, and future hospitalizations and infections.

Results: In this cohort, the median procalcitonin level was 0.38 ng/mL with an interquartile range of 0.23 ng/mL and 0.54 ng/mL. The distribution of procalcitonin values are found in Fig. 1A. African Americans had a significantly higher procalcitonin level than non-African Americans (P=0.02, Wilcoxon rank sum test). ESRD outpatients who had hypertension, diabetes mellitus, or HIV did not have significantly higher procalcitonin levels than those who did not (P> 0.05). Procalcitonin levels were positively correlated with CRP (r=0.57, P<0.001) (Fig. 1B) and negatively correlated with albumin (r=-0.28, P=0.02) (Fig. 1C). Procalcitonin levels were not correlated with Kt/V, white blood cell count, and ferritin levels (P>0.05). ESRD outpatients who developed infections or who were hospitalized did not have significantly higher initial procalcitonin levels than those who did not (P>0.05).

Conclusions: Procalcitonin levels are correlated with inflammatory markers such as CRP and albumin, suggesting its potential use to identify ESRD on HD at high risk for complications, especially in the era of COVID-19.

Funding: Private Foundation Support

Prolactin and Inflammatory Cytokines in Hemodialysis Patients: A Cross-Sectional Study

Marclebio M. Dourado, Fabricio Souto, Amaury Cantilino, Lucio Vilar, Frederico C. Cavalcanti. *Universidade Federal de Pernambuco, Recife, Brazil.*

Background: Cardiovascular disease (CV) is the main cause of mortality in patients with chronic kidney disease. Non-traditional CV risk factors such as hyperphosphatemia, inflammation and microalbuminuria are important in these patients. Among these, hyperprolactinemia emerges as a potential non-traditional risk factor because it

accumulates with loss of renal function and is associated with increased mortality. Initially described as a lactation hormone, today it is known that prolactin (PRL) has several actions, from pro-inflammatory effects to accelerated atherosclerosis. The aim of our study was to correlate serum levels of inflammatory cytokines in hemodialysis (HD) patients with normal and elevated PRL

Methods: Single-center cross-sectional study evaluating all patients regularly enrolled in HD program in September 2019. Patients over the age of 18, on HD for at least 6 months, using an arteriovenous fistula for dialysis access were included. Those with active viral or bacterial infections, active cancer, inadequate KtV, use of medication or disease known to elevate PRL(hypothyroidism, chronic liver disease, macroadenoma), pregnant women and using immunosuppressants were excluded. Clinical, biochemicals and inflammatory cytokines [interleukin (IL)-2,-4,-6,-10,-17A, TNF-α and gamma interferon] were evaluated and compared between HD patients with elevated and normal PRL

Results: Of the 360 regular HD patients, 249 were excluded: 110 temporary access, 87 active infection (viral or bacterial), 23 on drugs, 12 on immunosuppression, 5 cirrhosis, 4 inadequate KtV, 4 cancer, 3 less than 6 months on HD, 1 macroadenoma. Comparing data between patients with high(61) and normal(50) PRL, no statistical difference was seen in terms of age, sex, BMI, etiology, time on HD, cholesterol, albumin, calcium, phosphorus, PTH, glycated hemoglobin, hemoglobin, IL-2, IL-4, IL-17A, TNF-α,gIFN. There was a positive PRL correlation with serum levels of IL-6($p<0.0001$,$R=0.44$); between PRL and IL-10, the correlation was negative and also statistically significant($p<0.046$,$R=0.2$)

Conclusions: HD patients with elevated PRL have been shown to have higher levels of IL-6 and lower levels of IL-10

Funding: Commercial Support - Siemens Healthcare Diagnósticos Ltda, Private Foundation Support

Laboratory parameters of patients with high and normal Prolactin

Variables	Elevated Prolactin	Normal Prolactin	p-valor
Interleukin-6	8.18±7.09 (0.72-35.36)	3.23 ± 4.9 (0-28.46)	< 0.0001
Interleukin-10	1.4 ± 5.74 (0-43.66)	2.78 ± 18.04 (0-126.45)	0.046

Biphasic Dynamics of Inflammatory Biomarkers Following Dialysis Initiation: Results from the MONDO Initiative

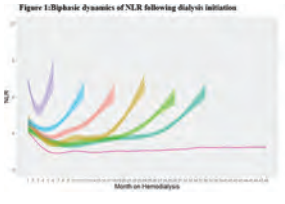
Xiaoling Ye,[1] Dalia E. Yousif,[1] Len A. Usvyat,[2] Stefano Stuard,[3] Adrian M. Guinsburg,[4] Jeroen Kooman,[5] Frank van der Sande,[5] Peter Kotanko.[1]
[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care AG und Co KGaA, Waltham, MA; [3]Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany; [4]Fresenius SE & Co KGaA, Buenos Aires, Argentina; [5]Maastricht University Medical Center, Maastricht, Netherlands.

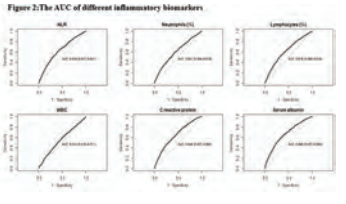
Background: Inflammation is highly prevalent among patients (pts) with end stage kidney disease and is associated with adverse outcomes. We aimed to investigate in a large diverse international cohort of incident hemodialysis (HD) pts firstly the dynamics of inflammatory indicators, namely white blood cells (WBC), neutrophil-to-lymphocyte ratio (NLR), serum albumin (lab) and C-reactive protein (CRP), following initiation of HD. Secondly their predictive power over all-cause of death.

Methods: We included all incident in-center adult HD pts treated 01/2000 to 12/2012 with ≥ 1 neutrophils, lymphocytes, WBC, and CRP values within the study periods. Following HD initiation, pts were stratified into 7 subgroups: 6 semi-annual groups according to the dialysis vintage at the time of the pts' death (0 to 6; 7 to 12; 13 to 18; 19 to 24; 25 to 30; 31 to 36 months) and a survivor group (pts who survived ≥37 months). Cubic smoothing spline functions were applied to study the trends of each marker. Receiver Operating Characteristic Curve (ROC) Analyses were performed to evaluate the predictive power of each of the markers with 1st year as the baseline and the following 1 year as the follow-up.

Results: In total, 18,276 incident pts who were treated in 25 countries were included. WBC, NLR (Figure 1), and CRP declined sharply after HD initiation and increased before death, while started & remained low in the survivors. In general, WBC, NLR, and CRP were highest at HD initiation and prior to death in non-survivors. Alb levels increased after HD initiation and remained high in the survivor cohort. In contrast, lab levels dropped significantly before death. Alb (AUC: 0.66), CRP (AUC: 0.64), and NLR (AUC: 0.62) all show stronger predictive power than WBC (AUC: 0.55) (Figure 2).

Conclusions: In non-survivors, NLR, WBC, and CRP showed a similar trend after HD initiation and before death. As CRP is not a routinely used marker in many regions of the world and NLR has near comparable predictive power, this marker could be used as an alternative indicator of inflammation in resource-limited areas.





PO1161

Accumulation in Hemodialysis Patients of Solutes Secreted by the Native Kidneys

Seolhyun Lee,[1,2] Christian G. Bolanos,[1,2] Robert Mair,[1,2] Natalie Plummer,[1,2] Timothy W. Meyer,[1,2] Tammy L. Sirich.[1,2] *[1]Stanford Medicine, Stanford, CA; [2]US Department of Veterans Affairs, Palo Alto, CA.*

Background: The native kidneys rapidly clear numerous solutes by tubular secretion, a function not replicated by hemodialysis (HD). We examined whether solutes which are normally cleared by secretion accumulate to high levels in the plasma when kidney function is replaced by HD.

Methods: Metabolomic analysis was performed on plasma ultrafiltrate (UF) and urine from 16 control subjects (NL) and on plasma UF from 36 HD patients using an established platform (Metabolon). The fractional excretion (FE) for each solute was calculated as its urine to UF ratio relative to that of creatinine. The extent of accumulation in HD patients was calculated as the ratio of the average UF peak area for each solute in HD relative to NL subjects (HD/NL). An FE > 2 was considered evidence of secretion and only solutes detected in samples from all 16 NL subjects and 36 HD patients were analyzed.

Results: 26 solutes had FE greater than 2 (mean 4.1±2.7, range 2.0 to 14.2). HD/NL ratios were significantly higher for solutes with greater FE values as shown in the Figure (R^2 0.45, $p < 0.001$). HD/NL ratios varied however among individual solutes with similar FE values.

Conclusions: Uremic solutes that are rapidly cleared by the kidneys tend to accumulate to high levels in HD patients. Non-renal clearance and differences in generation rate and distribution volumes may result in variable HD/NL ratios for solutes with similar secretory clearances in the native kidney.

The Accumulation of Various Uremic Retention Solutes Is Associated with Early Mortality After Starting Hemodialysis

Yohei Arai,[2,1] Shingo Shioji,[3] Hiroyuki Tanaka,[3] Haruka Noguchi,[2] Miria Chinen,[2] Suzuki Mikako,[2] Isao Kondo,[2] Emi Sakamoto,[2] Takahito Niikura,[2] Minami Suzuki,[2] Daisuke Katagiri,[2] Fumihiko Hinoshita.[2]
[1]Department of Nephrology, Graduate School of Medicine, Tokyo Medical and Dental University, Bunkyo-ku, Japan; [2]Department of Nephrology, National Center for Global Health and Medicine, Shinjuku-ku, Japan; [3]Department of Nephrology, Yokosuka Kyosai Hospital, Yokosuka, Japan.

Background: Uremic retention solutes (URS) generally accumulate in patients with end-stage renal disease (ESRD). Many of these URS have been shown to exert unfavorable biological activity resulting in poor prognosis. Although some kinds of URS before starting hemodialysis (HD) has been proven to be a risk factor for early mortality after starting HD, it remains unknown whether excess accumulation of various URS is associated with further worse prognosis after starting HD according to the degree.

Methods: We conducted a retrospective cohort study to investigate the association between the accumulation of various URS and early mortality after starting HD. The cohort consisted of adult patients who started HD for ESRD at the National Center for Global Health and Medicine from 2010 to 2019. To evaluate the accumulation of various URS, the uremic score was specifically defined as a total number of measurable variables related with uremia in clinical practice; blood urea nitrogen (BUN) >100 mg/dl, change in anion gap corrected for albumin (ΔAG) >5 mmol/l and β2-microglobulin (β2MG) >20 mg/l before starting HD. The primary outcome was death within a year of the start of HD. The hazard ratio for one score increase in the uremic score was calculated using Cox proportional hazard models with adjustments for baseline characteristics. Moreover, we investigated underlying characteristics related with these variables using logistic regression.

Results: We enrolled 206 patients (males, 76%). During a mean follow-up of 344 days, the primary outcome was observed in 16 patients. The uremic score was significantly associated with the primary outcome (hazard ratio: 1.97, 95% confidence interval 1.19-3.27; adjusted hazard ratio: 4.82, 95% confidence interval 1.97-11.7). Patients with high

BUN had a lower frequency of cardiovascular disease. High ΔAG and β2MG were associated with hypoalbuminemia respectively. Moreover, patients with high ΔAG were relatively young and had a lower frequency of diabetes.

Conclusions: The accumulation of various URS is associated with early mortality after starting HD.

PO1163

Routinely Measured Cardiac Troponin I and NT-ProBNP as Predictors of Mortality in Japanese Hemodialysis Patients: The Dialysis Outcomes and Practice Patterns Study

Marcelo Lopes,[1] Masahiro Eriguchi,[2] Kazuhiko Tsuruya,[2] Brian Bieber,[1] Roberto Pecoits-Filho,[1] Ronald L. Pisoni,[1] Keith McCullough,[1] Bruce M. Robinson,[1] Eiichiro Kanda,[3] Kunitoshi Iseki,[4] Hideki Hirakata.[5] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Nara Daigaku, Nara, Japan; [3]Kawasaki Ika Daigaku, Kurashiki, Japan; [4]Nakamura Naika Iin, Kumamoto, Japan; [5]Fukuoka Renal Clinic, Fukuoka, Japan.*

Background: Due to the interplay of chronic kidney disease and the heart, it is common for myocardial damage and strain to be present in hemodialysis (HD) patients. The cardiac troponin I (cTnI) and NT-proBNP are widely used as cardiac biomarkers to evaluate the patients at high risk for cardiovascular disease (CVD). However international The Dialysis Outcomes and Practice Patterns Study (DOPPS) data indicate that these cardiac biomarkers are measured in fewer than 2% of HD patients in real-world practice.

Methods: Pre-dialysis levels of cTnI and NT-proBNP at study enrollment were measured in 1176 prevalent Japanese HD patients (DOPPS phase 5). Cox regression was used to test the association of the cardiac biomarkers with all-cause mortality, adjusting for potential confounders. Subgroup analyses were performed to assess potential effect modification of clinical characteristics: age, systolic blood pressure, HD vintage, diabetes mellitus, CVD, and heart failure.

Results: Median [IQR] cTnI (99th percentile; 0.04 ng/mL) and NT-proBNP levels were 0.018 [0.005, 0.04] ng/mL and 3432 [1580, 8017] pg/mL, respectively. There were 175 deaths during a median [IQR] follow-up of 2.8 [2.3, 2.9] years. Higher levels of both cardiac biomarkers were incrementally associated with mortality after adjustment for potential confounders. Even after adjustment for the alternative cardiac biomarker, the HRs of death for cTnI >0.04 and NT-proBNP >8000 pg/mL versus those references (cTnI <0.01 and NT-proBNP <2000) were 2.67 (95% CI 1.47-4.87) and 2.05 (95% CI 1.10-3.84), respectively and still remained significant. Subgroup analyses showed the associations of both cardiac biomarkers with mortality were consistent between stratified groups. (the p values for interaction were >0.10 for all stratified models).

Conclusions: Routinely measured NT-proBNP and cTnI are strongly associated with mortality among prevalent Japanese HD patients. These associations were still significant even after adjustment for the alternative biomarker, suggesting that cTnI and NT-proBNP may reflect different pathologic aspects for cardiac abnormalities.

PO1164

Efficacy of Double Filtration Plasmapheresis Therapy on Patients with Lipoprotein Glomerulopathy

Wenjing Fan, Yongchun Ge, Jianhua Dong. *Nanjing General Hospital of Nanjing Military Command Research Institute of Nephrology, Nanjing, China.*

Background: To Retrospectively observe the clinical efficacy of double fltration plasmapheresis(DFPP) in patients with lipoprotein glomerulopathy(LPG).

Methods: 17 Patients with biopsy-proven LPG in our center who received DFPP treatment from 2010 to 2016 were involved, clinical parameters before and after DFPP treatment were recorded and analyzed.

Results: 15 of the patients underwent 3-10 courses of DFPP, and 2 patients were unable to tolerate DFPP due to allergic reactions. All patients received fenofibrate or statins and other relevant symptomatic treatments. After short-term DFPP treatments, serum creatinine(Scr, 1.76±0.87mg/dl vs 1.55±0.83mg/dl,P<0.01), plasma apolipoprotein E(7.94±1.87mg/dl vs 3.58±1.32mg/dl,P<0.01)and proteinuria (4.68±2.50g/24h vs 2.70±2.20g/24h,P<0.01),were relieved significantly. 1 patient (6.7%) achieved complete remission of proteinuria, and 5 patients (33.3%) achieved partial remission of proteinuria. Four patients underwent repeated renal biopsy after DFPP treatment, and 2 of them who received 10 courses of DFPP were observed disappearment of intraglomerular lipoprotein thrombi, and negative ApoE staining. While 2 patients who underwent only 3 and 4 courses of DFPP respectively showed no significant pathological improvement. After a median follow-up of 7 month(IQR 31.5-1), all patients had elevated ApoE level, 4 patients showed an elevation trend of Scr. 3 of the 4 patients who had got partially or completely remission of proteinuria after DFPP tend to be stable after 12 months' follow-up.

Conclusions: Short-term efficacy of DFPP in patients with LPG was definite. However, Scr and ApoE levels rebounded in some patients during long-term follow-up

PO1165

Disease Course of Hyperkalemia in Patients on Hemodialysis

Bruce S. Spinowitz,[1] Steven Fishbane,[2] Masafumi Fukagawa,[3] Martin L. Ford,[4] Nicolas J. Guzman,[5] Anjay Rastogi.[6] *[1]New York Presbyterian Queens, Queens, NY; [2]Zucker School of Medicine at Hofstra/Northwell, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [3]Tokai University School of Medicine, Isehara, Japan; [4]King's College Hospital NHS Trust, London, United Kingdom; [5]AstraZeneca BioPharmaceuticals Research and Development, Gaithersburg, MD; [6]David Geffen School of Medicine, Los Angeles, CA.*

Background: Hyperkalemia (HK) preceding hemodialysis (HD) is associated with increased risk of mortality and hospitalization. Longitudinal data on serum potassium (sK^+) in this population is sparse. This *post-hoc* analysis of data from the placebo (PBO) arm of DIALIZE (NCT03303521) explored the course of HK in HD pts.

Methods: In DIALIZE, 196 pts were randomized 1:1 to PBO (n=99) or sodium zirconium cyclosilicate (SZC) (n=97) 5 g starting dose once daily on non-dialysis days for 8 weeks (8w), comprising a 4-week SZC dose-titration phase (max 15 g) to achieve target pre-dialysis sK^+ 4.0–5.0 mmol/L, and a 4-week stable-dose evaluation phase. All pts received HD TIW and dietary counselling. *Post-hoc* analysis of PBO pts by baseline (BL) pre-dialysis sK^+ included mean pre- and post-dialysis sK^+ by visit, and proportions of pts who had mean pre-dialysis sK^+ of 4.0–5.0 and 4.0–5.5 mmol/L by visit (including pts receiving rescue therapy).

Results: Mean pre-dialysis sK^+ after the long interdialytic interval was 5.9 mmol/L at BL (Day 1) and 5.7 mmol/L at end of treatment (EOT; Day 57) (**Figure**). Across all BL pt strata, mean pre-dialysis sK^+ remained ≥5.0 mmol/L for all study visits (**Figure**). For pts with BL pre-dialysis sK^+ <5.5, 5.5–<6.0, 6.0–<6.5, and ≥6.5 mmol/L, mean pre-dialysis sK^+ at EOT was 5.4, 5.9, 5.6, and 5.9 mmol/L, respectively (**Figure**). Over 8w, only 7.0–23.1% and 31.1–60.6% of PBO pts had a pre-dialysis sK^+ of 4.0–5.0 and 4.0–5.5 mmol/L, respectively, at any study visit. Mean post-dialysis sK^+ was 3.9 mmol/L at BL and at EOT.

Conclusions: In pts receiving PBO and counselling following a HK event, mean sK^+ remains high over 8w. Most pts remain hyperkalemic over this period and are therefore at continued risk of adverse outcomes.

Funding: Commercial Support - AstraZeneca

A USRDS Database Study on the Use of Pegloticase in Patients Undergoing Dialysis

Anthony J. Bleyer,[1] Yi Zhang,[2] Onkar S. Kshirsagar,[2] Brad A. Marder,[3] Brian LaMoreaux.[3] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Medical Technology and Practice Patterns Institute, Bethesda, MD; [3]Horizon Therapeutics plc, Lake Forest, IL.*

Background: Gout is a common co-morbidity of chronic kidney disease, but prevalence in dialysis patients is not precisely known. Oral urate-lowering therapy use is limited in patients with advanced renal disease, particularly end-stage. Pegloticase (PEGylated uricase) rapidly lowers serum uric acid, but phase 3 trials did not include dialysis patients. However, a phase 1 trial in non-gout patients showed that pegloticase efficacy and pharmacokinetics are not affected by dialysis. Beyond this, pegloticase use in dialysis-dependent patients is not reported in the literature. This United States Renal Data System (USRDS) study sought to better quantify and understand real-world use of pegloticase in patients undergoing dialysis.

Methods: Patients with advanced renal disease, who are dialysis-dependent, or who have undergone renal transplant are in the USRDS. USRDS patients who were administered pegloticase and undergoing dialysis were identified in 2012-2017 Standard Analytical Files. Parameters examined included demographics, comorbidities, dialysis type, number of pegloticase infusions, and time between pegloticase infusions.

Results: 58 dialysis centers reported on 136 patients. Pegloticase was most prescribed by rheumatologists (68%) and internal medicine physicians (7%). The majority of patients were white (61%) and male (73%) and patient age averaged 56.9 ± 16.8 years; all adult age groups were represented (18-44 years: 27%, 45-64 years: 35%, ≥65 years: 39%). Hypertension (74%) and diabetes (46%) were the most reported comorbidities. 9 patients (7%) were donor kidney recipients. More patients were undergoing hemodialysis (108 patients [79%]) than peritoneal dialysis (23 [17%]). Patients received 13.4 ± 19.1

pegloticase infusions (median: 7, 46 [34%] patients ≥12) and median time between doses was 14 days (mean: 21 days). This treatment schedule reflected that of pegloticase labeling (biweekly infusions).

Conclusions: The literature contains few reports of pegloticase use in dialysis patients. Our real-world data suggest that pegloticase is well-tolerated in dialysis patients, as indicated by a median of 7 infusions per patient and the expected treatment schedule. Further research is needed to verify these findings.

Feasibility Study of Wrist-Based Wearable Activity Trackers in Hemodialysis Patients

Ohnmar Thwin, Maggie Han, Priscila Preciado, Xia Tao, Mirell Tapia, Lemuel Rivera Fuentes, Mohamad I. Hakim, Amrish U. Patel, Nadja Grobe, Stephan Thijssen, Peter Kotanko. *Renal Research Institute, New York, NY.*

Background: Wearable activity trackers allow physicians to access patient's physical activity (PA) outside the dialysis clinic. Hemodialysis (HD) population have an increased cardiovascular mortality and they are less active than their healthy counterparts. We aim to assess the feasibility of use of a wearable trackers in a HD population.

Methods: HD patients from 4 NYC clinics were enrolled in the study starting from June 2018, followed up to 1 year. Patients ≥18 years on maintenance HD, able to walk, owning a smartphone, tablet or PC were included. Each patient received a wrist-based monitoring device (Fitbit Charge 2) to wear for a year. They were trained how to use and sync data. A stepwise intervention was created. After 3 in-person visits are completed, patients were deemed non-adherent and withdrawn. Events such as device failure or broken band were not counted as an in-person visit. We used Kaplan-Meier analysis to study time to withdrawal for non-adherence and predictors of time to withdrawal were assessed by univariate Cox Regression. The end of the observation period was May 8, 2020.

Results: 118 patients were studied. Patients were 54±12 years old with a HD vintage of 5.2±5.1 years, 37% lived alone, 59% unemployed, 57% were African American, and 42% had an education level of some college or higher. Seventeen patients were withdrawn due to non-adherence. Mean and median time to withdrawal were 280 days (95%CI 260-301) and 359 days (95%CI 324-365). The probability of retention is shown in Fig.1. There was no association found between age, gender, race, living status, and education and time to withdraw due to non-adherence.

Conclusions: Only a small number of patients were withdrawn due to non-adherence, and the average time to withdraw was 9 months. We believe that the use of a wrist-based wearable device for remote patient monitoring, at least up to one year, is feasible in the HD population.

Evaluation of Biomarkers in Chronic Hemodialysis (HD) Patients Dialyzed with Optiflux High-Flux Dialyzers

Meijiao Zhou,[1] Linda Ficociello,[1] Mark Costanzo,[1] Claudy Mullon,[1] Robert J. Kossmann.[2] *[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Optiflux® (OPTI) dialyzers are single-use, high-flux dialyzers available in the following sizes: F160NR (1.5 m^2), F180NR (1.7 m^2), F200NR (1.9 m^2), and F250NR (2.5 m^2). They are designed to enhance small and middle molecule clearance without increasing albumin loss. Epidemiologic data has shown low serum albumin (sALB) to be a marker of increased mortality risk in dialysis patients (pts). Thus, loss of albumin should be avoided especially in pts with low sALB. This retrospective study aimed to assess changes in biomarkers in pts dialyzed with Optiflux dialyzers for 6 months, including a subset of pts with low sALB levels at baseline.

Methods: 976 in-center HD pts treated exclusively with Optiflux dialyzers for 6 months without liver disease, cancer, HIV, or history of drug abuse were analyzed in this study. Pre-HD labs at the first month of data collection (M1) and Month 6 (M6) were compared using paired t-test. A sub-analysis of pts with hypoalbuminemia (sALB ≤3.5mg/dL) at M1 was conducted. All analyses were performed separately for each dialyzer. Pts dialyzed with F200NR and F250NR were combined into 1 group.

Results: Mean biomarker levels during M1 and M6 are presented for the dialyzer groups (table). Most notably, significant increases of mean sALB and hemoglobin were observed in all groups. In the sub-analysis of pts with hypoalbuminemia at M1 (n=156), 87% of pts had increases in sALB by M6 (48/59=81.4% in F160NR, 82/92=89.1% in F180NR, and 5/5=100% in F200NR and F250NR) and 53.8% (84/156) achieved sALB >3.5 g/dL at M6.

Conclusions: During a 6-month follow-up, HD patients dialyzed with Optiflux dialyzers showed increases in serum albumin and hemoglobin while maintaining dialysis adequacy.

Funding: Commercial Support - Fresenius Medical Care Renal Therapies Group

Postoperative Outcomes After Bariatric Surgery in Chronic Dialysis Patients: A Meta-Analysis and Systematic Review

Dharmenaan Palamuthusingam,[1] Carmel Hawley,[2] Elaine Pascoe,[3] David W. Johnson,[2] Magid Fahim.[2] *[1]Logan Hospital, Loganholme, QLD, Australia; [2]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [3]The University of Queensland Faculty of Medicine, Herston, QLD, Australia.*

Background: Renal transplantation improves longevity and quality of life for patients on chronic dialysis. However, obesity is a growing surgical contraindication in this group such that bariatric surgery is increasingly being considered as a bridge to transplantation. The risks and benefits of bariatric surgery in the dialysis population have not been synthesized.

Methods: Authors performed a systematic review of observational studies indexed in Embase, MEDLINE and CENTRAL till April 2020 that reported postoperative outcomes in chronic dialysis and non-dialysis patients undergoing bariatric surgery. Summary level data on patient demographics and comorbidity were extracted. The primary outcome was death (30-day or in-hospital mortality); secondary outcomes were myocardial infarction, surgical site infection, pneumonia, unplanned return to theatre, sepsis, and rates of kidney transplantation. Random effects meta-analysis was performed to derive summary risk estimates.

Results: Four cohort studies involving 4,096 chronic dialysis and 732,204 non-dialysis patients undergoing bariatric surgery were included. Sleeve gastrectomy (34%), and roux-en-Y gastric bypass (24%) were the most common procedures performed followed by gastric band or biliopancreatic diversion. There were increased odds of postoperative mortality(0.4-0.5% vs 0.1%; OR 4.7, 95%CI 2.2-9.9,$I^2$0%), myocardial infarction(0.0-0.5% vs 0.1%, OR 3.4, 95%CI 2.0-5.9,$I^2$0%) and pneumonia(0.3-0.9% vs 0.2-0.4%, OR 2.3, 95%CI 1.1-4.5,$I^2$50%) in dialysis patients compared to non-dialysis patients. Patients on dialysis also had increased odds of return to theatre compared to non-dialysis patients (3.2-3.4% vs 1.4-2.0%, OR 2.2, 95%CI 1.7-3.0). There were no differences in the odds of surgical site infections, bleeding, or thromboembolic complications. Rates of renal transplant wait-listing among dialysis patients undergoing bariatric surgery were not reported in any of the studies.

Conclusions: Chronic dialysis patients have substantially increased odds of postoperative mortality and myocardial infarction. However, the absolute rates of complications are low and may not be prohibitive if they facilitate successful renal transplantation. Systematic reporting of both the benefits and risks of bariatric surgery in dialysis patients are needed.

Peridialytic Serum Cytokine Levels and Their Relationship with Postdialysis Fatigue and Recovery in Patients on Chronic Hemodialysis

Astrid Brys,[1,2] Enrico Di stasio,[1] Bert Lenaert,[2] Anna Picca,[1] Riccardo Calvani,[1] Emanuele Marzetti,[1] Giovanni Gambaro,[3] Maurizio Bossola.[1] *[1]Universita Cattolica del Sacro Cuore Facolta di Medicina e Chirurgia, Roma, Italy; [2]Universiteit Maastricht Faculty of Health Medicine and Life Sciences, Maastricht, Netherlands; [3]Azienda Ospedaliera Universitaria Integrata Verona Unita Operativa Nefrologia and Dialisi, Verona, Italy.*

Background: The etiology of postdialysis fatigue (PDF), an intermittent but debilitating fatigue occurring in 40-80% of chronic hemodialysis (HD) patients after HD treatment, is still unclear. In other illnesses, such as inflammatory diseases, mounting

evidence points toward the involvement of the immune system in the development of fatigue symptoms. Altered serum levels of inflammatory cytokines have also been shown in chronic HD patients and positive associations between interleukin-6 (IL-6) and fatigue symptoms in general in this patient population have been recently reported. Therefore, we investigated whether fatigue specifically occurring after HD (PDF) or the time needed to recover from HD treatment (TIRD) were related to pre- and postdialysis serum levels of pro- and anti-inflammatory cytokines (i.e. IL-1β, IL-6, TNF-α and IL-10) or their intradialytic changes (if any).

Methods: Serum levels of IL-1β, IL-6, TNF-α and IL-10 were measured immediately before and after HD in 45 chronic HD patients using commercially available kits on an ELLA™ automated immunoassay system. The presence and severity of PDF as well as TIRD duration were assessed by self-report measures.

Results: Thirty-three patients (74%) reported PDF, with a median PDF severity index of 3.30 [IQR: 3.00-4.30] on a scale from 1 to 5. Median TIRD was 120 min [IQR: 60-480]. PDF severity correlated strongly with TIRD, r_s=0.85, p<0.001. Only predialysis IL-10 serum levels significantly and positively correlated with PDF severity (r_s=0.43, p=0.003). Postdialysis cytokine levels and their intradialytic changes were not significantly related to PDF or TIRD.

Conclusions: The present study does not support the hypothesis that the immune system may be involved in the development of PDF or TIRD. The positive, but counterintuitive relation between predialysis anti-inflammatory IL-10 levels and PDF severity warrants further research. However, the present findings do not necessarily undermine the previously found positive relationship between IL-6 levels and chronically fatigue experience in HD patients, as fatigue as response to treatment may have other determinants than a more chronically fatigue.

PO1171

Tryptophan Removal in ESRD Patients Treated with High-Flux and Medium Cut-Off Dialyzers During Hemodialysis and Hemodiafiltration

Gabriela F. Dias,[1,2] Nadja Grobe,[1] Peiying Peng,[1] Xiaoling Wang,[1] Joshua E. Chao,[1] Jose S. Lopez Gil,[3] Armando Armenta álvarez,[3] Magdalena Madero,[3] Jochen G. Raimann,[1] Stephan Thijssen,[1] Xia Tao,[1] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [3]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Background: Tryptophan (Trp) loss in kidney failure patients is likely to be associated with poor nutritional status and depletion due to dialysis. However, Trp removal with medium cutoff (MCO) membranes has not been investigated. Here, we compared Trp reduction ratios (RR) between an MCO dialyzer and a high-flux polysulfone (HFPS) dialyzer

Methods: Clinically stable, anuric hemodialysis patients on thrice-weekly HD were enrolled. Over the course of 4 weeks, each subject traversed through the following combinations (with 2 study treatments per week, 4 hours per HD session): post-dilution hemodiafiltration (HDF) with FX120 (Fresenius Medical Care), HD with FX120, HDF with Theranova 400 (Baxter), HD with Theranova 400 (Fig. 1). All subjects exercised using stationary bicycles during HD. Blood samples were collected before dialysis (B0) and at 230 min (B230) upstream of the dialyzer. Trp in plasma was analyzed by liquid chromatography–mass spectrometry. RR was calculated using signal intensities for Trp according to RR=(B0-B230)/B0, with correction for hemoconcentration using hemoglobin levels (Schneditz, ASAIO 2012)

Results: Twelve subjects completed the study (50% female, 43.8±18.5 years old). With HD, RR was comparable between the MCO dialyzer and the larger HFPS dialyzer (median RR 0.29 for MCO, 0.33 for HFPS; surface areas 1.7 m^2 vs. 2.5 m^2, respectively). In HDF, our data suggest somewhat greater Trp loss with the MCO dialyzer despite its smaller surface area compared to the HFPS dialyzer

Conclusions: Use of an MCO dialyzer may result in similar or greater Trp loss as use of an HFPS dialyzer with a much larger surface area. When considering the use of MCO dialyzers, clinicians should consider the potential impact on removal of salutary substances (incl. protein-bound substances), an area that deserves further research

Effect of Hemodiafiltration with Medium Cut-Off Dialyzer on Uremic Toxins Removal

Jose S. Lopez Gil,[1] Armando Armenta álvarez,[1] Ivan A. Osuna Padilla,[3] Nadja Grobe,[2] Xia Tao,[2] Joshua E. Chao,[2] Jochen G. Raimann,[2] Stephan Thijssen,[2] Gabriela F. Dias,[2] Peiying Peng,[2] Xiaoling Wang,[2] Hector Alejandro P. Garza,[1] Peter Kotanko,[2] Magdalena Madero.[1] *[1]National Institute of Cardiology, Ignacio Chávez, Mexico, Mexico City, Mexico; [2]Renal Research Institute, New York, NY; [3]Centro de Investigacion en Enfermedades Infecciosas CIENI, Mexico City, Mexico.*

Background: To our knowledge no study has ever evaluated the use of middle cut-off membranes (MCO) with online hemodiafiltration (OL-HDF). This study aims to show if the combination of OL-HDF with MCO can achieve a higher reduction ratio of some uremic toxins in comparison to regular OL-HDF

Methods: Patients from our hemodialysis unit were treated twice with four different modalities, namely combinations of post-dilutional OL-HDF or hemodialysis (HD) with a high-flux dialyzer (CordiaxFX120, area 2.5 m^2) or the MCO (Theranova 400; area 1.7 m^2), respectively. We analyzed the reduction ratios (RR) of erythropoietin, beta2-microglobulin (B2M), phosphate, and urea.

Results: Twelve anuric patients were studied (6 females; mean age 43.818.5 years; HD vintage 35.2 ± 27.8 months.) Mean blood flow (Qb) was 367 23 ml / min, dialysate flow (Qd) was 493 57 ml / min, ultrafiltration volume was 2382 5683 ml. B2M RR of HDF+HiFlux was higher than HD+MCO (**p=0.003),** and HDF+MCO vs. HD+MCO **(p=0.029**). There was no difference in EPO, phosphate, and urea RR between any of the four groups.

Conclusions: Adding a medium cut-off (MCO) dialyzer to HDF does not add benefit. The B2M RR with HiFlux exceeds the one of a MCO dialyzer. HDF provides benefit over HD regarding the B2M RR regardless of the dialyzer used.

PO1173

pH-Dependent Protein Binding Properties of Uremic Toxins In Vitro

Suguru Yamamoto,[1] Kenji Sasahara,[2] Mio Domon,[1] Keiichi Yamaguchi,[2] Toru Ito,[1] Shin Goto,[1] Yuji Goto,[2] Ichiei Narita.[1] *[1]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Institute for Protein Research, Osaka University, Osaka, Japan.*

Background: Patients with chronic kidney disease undergoing dialysis treatment have worse clinical outcomes. One cause is the interactions between various uremic toxins and organ/tissues. Protein-bound uremic toxins (PBUTs), such as indoxyl sulfate (IS) and p-cresyl sulfate (PCS), are difficult to remove by conventional dialysis treatment owing to their high protein binding property. A possible treatment strategy is to weaken the protein binding of PBUTs. Acidic and alkaline pH change the conformation of proteins, which may be associated with the binding of uremic toxins. We examined the influence of pH on the protein binding properties of PBUTs *in vitro*.

Methods: Albumin conformation at pH 2 to 13 was analyzed using circular dichroism. Albumin reacted with IS at pH 4 to 11. The protein binding behavior was examined using isothermal titration calorimetry and free IS concentration was measured by mass spectrometry. Bovine serum with IS, PCS, indole acetic acid (IAA), or phenyl sulfate (PhS), as well as serum from hemodialysis patients, were adjusted to a pH of 4 to 11, and the concentration of the free form of PBUTs was measured.

Results: Albumin partially unfolded at pH <4 or >12. Calorimetric analyses revealed weakened interaction between IS and albumin at pH <5 or >10. The concentration of free IS in the presence of albumin was significantly increased at pH 4 (89.49±1.38 μg/dL) and pH 11 (22.45±1.38 μg/dL) compared to pH 7 (17.20±0.87 μg/dL) (both $p<0.01$). Addition of bovine serum to IS, PCS, IAA, or PhS at the physiological concentration of uremic patients and adjustment of pH from 4 to 11 resulted in increased concentrations of the free form of the solutes at acidic and alkaline pH, compared with the concentrations at neutral pH. Adjustment of serum from 19 hemodialysis patients from pH 4 to 11 resulted in increased concentrations of the free forms of IS, PCS, PhS, and IAA at acidic and alkaline pH. (e.g., IS: pH 4, 152.5±77.6 μg/dL; pH 11, 153.8±135.5 μg/dL vs pH 8, 38.8±33.4 μg/dL; $p<0.01$, respectively)

Conclusions: Acidic and alkaline pH changed albumin conformation and weakened protein binding property of PBUTs *in vitro*. The findings could inform strategies to increase the removal of PBUTs with convection/diffusion in hemodialysis treatment.

PO1174

Associations Between Prelude eGFR Category and Trajectories of Uric Acid and eGFR Prior to Dialysis Transition Among US Veterans

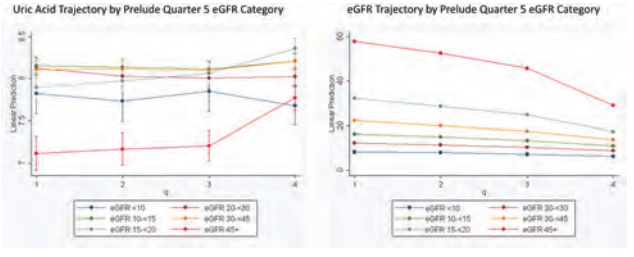
Nicholas Cuvelier,[1] Cachet Wenziger,[2,1] Jui-Ting Hsiung,[2,1] Ramy M. Hanna,[1] Ekamol Tantisattamo,[1] Connie Rhee,[1] Csaba P. Kovesdy,[3,1] Kamyar Kalantar-Zadeh,[1] Elani Streja.[2,1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]VA Long Beach Healthcare System, Long Beach, CA; [3]Memphis VA Medical Center, Memphis, TN.*

Background: Prior studies have demonstrated that elevated uric acid is associated with declining kidney function. However, how uric acid and estimated glomerular filtration rate (eGFR) levels change with progression towards end stage renal disease have not yet been fully characterized. We sought to examine trajectories of eGFR and uric acid 1 year prior to ESRD transition across strata of eGFR 5 quarters prior to transition.

Methods: From a cohort of US veterans who transitioned to dialysis between 10/2007-03/2015, we identified 15,725 patients with a pre-dialysis eGFR measurement 5 quarters prelude (15 months) before transitioning to ESRD and at least 1 uric acid measurement prior to ESRD. Trajectories were modeled across eGFR strata using mixed effects model with random slope and random intercept.

Results: The mean age of the cohort was 67±11 years old and included 2% females and 35% African American. In addition, the mean prelude quarter 5 uric acid level was 8±2 mg/dL and the median eGFR was 21 ml/min/1.73m^2. While the trajectories of uric acid were relatively stable for most strata, eGFR steadily declined across all strata. However, in the final 3 months prior to ESRD transition (PQ2 to PQ1), those in the highest PQ5 eGFR category (>=45 ml/min/1.73m^2) showed a sharp decrease in eGFR and corresponding sharp increase in uric acid, while there were less notable trends for other strata. [Figure]

Conclusions: Patients with the most rapid renal function decline also had a sharp increase in uric acid 3 months prior to transition to ESRD. The mechanism behind this relationship is currently unknown, and should be investigated in future studies. Future studies should also examine the clinical implications of elevated uric acid in patients transitioning to dialysis earlier due to a rapid renal function decline.



PO1175

Insulin Resistance and Hemodialysis

Varun kumar Bandi, Spoorthi Ramineni. *Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Gannavaram, India.*

Background: Insulin resistance is an important risk factor in Chronic Kidney disease (CKD) patients. We analysed insulin resistance indices in hemodialysis (HD).

Methods: Subjects with CKDV not on dialysis (CKD), and on HD (HD) were included. Age, gender, Body mass index (BMI), Wasit:Hip ratio (WHR) were noted. Fasting blood glucose, fasting insulin (Ins), C-peptide (Cp), bicarbonate (HCO3), calcium (Ca), phosphorus (Pi), Vitamin D (Vit D), parathyroid hormone (PTH), Albumin (Alb), Ferritin, C-reactive protein (CRP) were measured. HOMA-insulin resistance using Ins (IR-Ins) and Cp (IR-Cp), Insulin sensitivity and Beta cell function using Ins (IS-Ins, BF-Ins) and Cp (IS-Cp, BF-Cp) and C-peptide resistance index (CRI) were calculated.

Results: 20 patients with CKD, 22 on HD were analysed. In HD, IR-Cp had significant positive correlation with eGFR, and CRI with HCO3, Vit D, Ca, Pi, IR-Cp and negatively with PTH,CRP,eGFR. In CKD, IR-Cp had significant positive correlation with PTH,eGFR and negatively with HCO3,Ca. CRI had significant positive correlation with HCO3, Vit D, Ca, Pi, negatively with PTH, IR-Cp. Between groups, IR-Ins, IR-CP, IS-Ins, IS-Cp and BF-Ins had significant difference (Table 1)

Conclusions: IR-Ins, BF-Ins, IS-Cp, CRI were higher in HD, while IR-Cp,IS-Ins were higher in CKD. Cp based indices could be better markers of IR.

Comparison between groups

PO1176

Effect of Citrasate Dialysate on Intact Parathyroid Hormone (iPTH) in Prevalent Hemodialysis (HD) Patients: A Matched Retrospective Cohort Study

Meijiao Zhou,[1] Linda Ficociello,[1] Claudy Mullon,[1] Michael S. Anger,[1] Robert J. Kossmann.[2] *[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Citrate-acidified dialysate (CAD) has anti-coagulation properties compared to acetate-acidified dialysate (AAD), due to its binding of calcium. PTH regulates the calcium concentration through its actions on bone and kidney. The objective of this study is to assess any long-term changes in iPTH levels when patients (pts) are switched from AAD to CAD.

Methods: A retrospective cohort study of 3 clinics converting from AAD to CAD during 2009 to 2011 matched to 12 geographically proximate AAD clinics, on the same month as CAD conversion. Clinics were selected before year of 2013, so that the follow-up did not include time when the management of mineral bone disease changed at large dialysis organizations (LDOs). In-center HD pts included in the analysis received HD treatment for at least 6 months before (baseline, BL) and 6 months after (follow up, FU) CAD conversion. BL and 6-month FU average values of clinical measures were compared within and between CAD and AAD clinics. Measures included pre-dialysis iPTH and serum calcium (sCa), prescribed (Rx) dialysate calcium (dCa), Rx calcium-based phosphate binders (Ca-based PB), Cinacalcet and IV Vitamin D (VitD).

Results: Changes in iPTH and sCa were not significantly different from BL to FU between CAD and AAD clinics (Table). Mean iPTH decreased by 17 pg/mL (4.1%, p=0.49) in CAD clinics and increased by 13 pg/mL (3.8%, p=0.13) in AAD clinics. However, Rx dCa increased in CAD clinics, but not in AAD clinics. Increases of Ca-based PB and Cinacalcet prescriptions were greater in AAD clinics. No significant differences were observed in changes of VitD over time between CAD and AAD clinics.

Conclusions: Similar trends in iPTH and sCa were observed in clinics switched from AAD to CAD and geographically-matched clinics with continuous use of AAD.

High-Volume Hemodiafiltration Reduces Pre-Dialysis Beta-2 Microglobulin Concentration Compared with High-Flux Hemodialysis: A Post Hoc Analysis of the HDFit Trial

Murilo H. Guedes,[1] John W. Larkin,[2] Ana clara S. Almeida,[1] Ana C. Santos,[1] Ana Beatriz L. Barra,[4] Carlos E. Poli de Figueiredo,[7] Maria Eugenia F. Canziani,[9] Andrea N. Moreno-Amaral,[1] Jochen G. Raimann,[3] Peter Kotanko,[3] Bernard J. Canaud,[5,6] Roberto Pecoits-Filho.[1,8] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Fresenius Medical Care North America, Waltham, MA; [3]Renal Research Institute, New York, NY; [4]Fresenius Medical Care Brazil, Rio de Janeiro, Brazil; [5]Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany; [6]Montpellier Universite d'Excellence, Montpellier, France; [7]Pontificia Universidade Catolica do Rio Grande do Sul, Porto Alegre, Brazil; [8]Arbor Research Collaborative for Health, Ann Arbor, MI; [9]Clínica de Diálise Ingá, Rio de Janeiro, Brazil.*

Background: High-volume hemodiafiltration (HDF) is a diffusive-convective modality that provides higher clearance of middle-size uremic toxins, such as beta-2 microglobulin (β2M), compared to predominantly diffusive high-flux hemodialysis (HD). Previous studies have shown HDF may reduce circulating pre-dialysis concentrations of β2M compared to low-flux HD. We studied to which extent HDF reduces pre-dialysis β2M concentrations compared to high-flux HD.

Methods: HDFit randomized patients with a permanent vascular access time on HD between 3 and 24 months to either high flux HD or high volume HDF (convective volume (CV) target of 22L/session) / treatment). Patients were followed for 6 months. Measurements of circulating pre-dialysis β2M levels were made at baseline, 3 and 6 months during mid-week session. Linear mixed effects models were used to estimate the mean difference (95% confidence interval (CI)) in β2M levels between HDF and HD.

Results: A total of 195 patients (mean age 53±15 years, albumin 4±0.4 g/dL) were randomized (HDF n=97, HD n=98). Patient characteristics were balanced across intervention groups. Median treatment time was 235 min in both groups. Monthly mean CV ranged from 27.1 to 27.5L/treatment; the target CV was achieved in 96 out of 97 patients. Compared to HDF, in the HD arm monthly mean pre-dialysis β2M levels were 1.57 mg/L (95% CI 0.02 to 3.12) higher. In other words, HDF reduced mean circulating β2M levels over time compared to HD. (Figure).

Conclusions: In this *post-hoc* analysis of the HDFit trial, we describe for the first time that high-volume HDF sustainably reduces pre-dialysis β2M concentration compared to high-flux HD. High convective volume was easily achieved with online HDF. Our findings suggest that HDF can be readily implemented and that this treatment modality yields a sustained higher control of middle-size uremic toxins.

PO1178

Hand Grip and Leg Muscle Strength in Hemodialysis Patients and Its Determinants

Ran-hui Cha. *National Medical Center, Seoul, Seoul, Republic of Korea.*

Background: Chronic kidney disease is associated with chronic inflammation and progressive loss of peripheral muscle strength and the ability to exercise, and these changes are more pronounced in patients on hemodialysis (HD). We evaluated the hand grip and leg muscle strength in patients receiving HD and tried to find factors associated with muscle strength.

Methods: We screened hand grip (opposite to fistula side) and leg muscle strength (both sides) at single center (n=112) by using digital hand and leg dynamometer (T.K.K.5401 and 5710e/5715, Takei scientific instruments Co. Ltd., Niigata, Japan).

Results: Mean age was 62.6 years, and 73.2% of patients were men. Diabetes was the cause of kidney failure in 50% of patients and median HD vintage was 34 months. 77.7% of patients answered 'yes' to regular home exercise and 33% of patients regularly participated in the hospital based latex-band exercise. Hand grip strength (HGS) and leg muscle strength (LMS) showed good correlation (r = 0.715, p < 0.001). HGS (25.1 vs. 17.0 kg) and LMS (30.1 vs. 20.4 kg) were better in men (p < 0.001 and p < 0.001, respectively). Older patients (≥ 60 years) showed decreased LMS than others in men and women (p = 0.01 and p = 0.04, respectively), but HGS was not different by age. Patients doing regular home or hospital based exercise showed higher HGS (24.2 vs. 18.6 kg, p = 0.01) but LMS did not show statistical significance (29.3 vs. 23.6 kg, p = 0.19). Serum albumin and creatinine showed positive correlation with HGS and LMS, and hs-CRP was negatively correlated only with HGS. Multiple linear regression analysis proved male sex, younger age, and any type of exercise were factors associated with better HGS and LMS.

Conclusions: Sex, age, and exercise were the most important determinants of muscle strength in HD patients. We need to encourage patients to do regular home or group exercise and introduce new feasible form of exercise for HD patients.

Table 3. Multiple linear regression analysis of the factors related with hand grip and leg muscle strength

	Hand grip strength		Leg muscle strength

Effect of Intradialytic Exercise on the Removal of Tissue Sodium During Hemodialysis

Hsin-Yu Fang, Luis M. Perez, Ryan J. Larsen, Alexis King, Brett Burrows, Kenneth R. Wilund. *University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: Emerging evidence using ^{23}Na-MRI shows that sodium can be stored in the skin and muscle. Hemodialysis (HD) patients appear to have higher tissue sodium concentration ([Na^+]) compared to healthy controls, though tissue [Na^+] appears to be partially reduced during HD. In this study, we thus aimed to determine whether intradialytic cycling (IDC) potentiates the removal of tissue [Na^+] during HD.

Methods: Seven HD patients (sex: 57% male; age: 60±12 y; BMI: 36±10 kg/m^2; spKt/V: 1.4±.32; dialysate [Na^+]: 136±1.90 mEq/L; UFR: 7.7±3.4 mL/kg/hr; thrice-weekly HD) underwent ^{23}Na-MRI scans (3T system) before and after HD, on both a control (CON) and exercise (EX) day. Patients performed 30 minutes of IDC during the first hour of HD on the EX day and received standard care on the CON day. [Na^+] of the medial (MG) and lateral (LG) gastrocnemius, soleus (Sol), tibialis anterior (TA), and the whole lower leg (WL) were quantified from MRI images by trend analysis. Plasma [Na^+] was also assessed by a colorimetric enzymatic assay (Piccolo). Repeated measures ANOVA was used to examine changes in muscle and plasma [Na^+] between the EX and CON treatments from pre to post HD.

Results: There was a significant treatment by time interaction for [Na^+] in WL (P=.036) and Sol (P=.016), with the EX treatment attenuating the drop in [Na^+] during HD compared to the CON condition in both WL and Sol (Figure1A-B). [Na^+] of MG (P=.002), LG (P<.001),TA (P<.001), and plasma (P=.042) were reduced during HD, but these changes did not differ by treatment (treatment x time interaction P = N.S. for all; Figure1C-F).

Conclusions: Contrary to our hypothesis, it appears that IDC may attenuate, instead of potentiate, the magnitude of tissue [Na^+] removed during HD. However, this was not a consistent finding across all muscle beds analyzed. More studies are needed to examine if this result is a manifestation of the timing of MRI, the limited sample size, or other factors.

PO1180

Exercise Training to Improve Patient-Important Outcomes in Adults Undergoing Maintenance Dialysis: A Systematic Review and Meta-Analysis of Randomised Controlled Trials

Amelie Bernier-Jean,[1,6] Nadim A. Beruni,[3] Nicola P. Bondonno,[4,5] Gabrielle J. Williams,[6] Armando Teixeira-Pinto,[1,6] Jonathan C. Craig,[2] Germaine Wong.[1,6] *[1]School of Public Health, Faculty of Medicine and Health, The University of Sydney, Sydney, NSW, Australia; [2]College of Medicine and Public Health, Flinders University, Adelaide, NSW, Australia; [3]Western Sydney Local Health District, Westmead, NSW, Australia; [4]School of Biomedical Sciences, The University of Western Australia, Royal Perth Hospital, Perth, WA, Australia; [5]School of Medical and Health Sciences, Edith Cowan University, Perth, WA, Australia; [6]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia.*

Background: Multiple trials have assessed the potential for exercise training to improve outcomes in adults undergoing dialysis. However, uncertainties exist in its relevance and sustainable benefits for patient-important outcomes.

Methods: We conducted a systematic search of the Cochrane Kidney and Transplant Specialised Register for randomised controlled trials of structured exercise programs of eight weeks or more in adults undergoing maintenance dialysis (hemodialysis or peritoneal dialysis) compared to no exercise or sham exercise. Two authors independently assessed the trials for eligibility, extracted the data and assessed the risk of bias. We conducted random-effects meta-analyses.

Results: We identified 93 studies involving 4634 participants and 71 studies involving 3973 participants contributed to the meta-analyses. The interventions lasted from 8 weeks to 2 years and most often took place thrice weekly during hemodialysis treatments. Overall, the quality of the included studies was low. In adults undergoing dialysis, compared with no or sham exercise, exercise training may improve fatigue, the physical component of health-related quality of life (HR-QoL)(MD 4.5, 95% CI 2.2 to 6.8 points/100: low certainty evidence), depressive symptoms (SMD 0.73, 95% CI 0.39 to 1.07: moderate certainty evidence), pain (MD 6.1 95% CI 0.5 to 11.7 points on a 100-points scale: low certainty evidence), functional capacity measured in terms of the 6 Minutes-Walk Test (MD 49.9 meters, 95% CI 37.2 to 62.6; moderate certainty evidence) and the Sit-To-Stand test (MD 2.4 cycles, 95% CI 1.8 to 3.1; moderate certainty evidence). The impact on depression was greatest for those who had maintained exercise beyond 4 months (SMD 1.26, 95% CI 0.72 to 1.80). We could not draw conclusions for all-cause mortality, cardiovascular events, the mental component of HR-QoL, blood pressure and the safety of exercise training for adults undergoing maintenance dialysis due to the very low quality of the evidence.

Conclusions: In adults undergoing maintenance dialysis, exercise training is likely to improve depressive symptoms and functional capacity and may improve fatigue, the physical component of quality of life and pain.

PO1181

Comparative Risk of Fall-Related Fractures Among Hemodialysis Patients Newly Initiating Zolpidem vs. Trazodone Therapy

Magdalene M. Assimon, Jennifer E. Flythe. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Zolpidem, a non-benzodiazepine hypnotic, and trazodone, a sedating antidepressant, are the most common medications used to treat insomnia in the United States. Both drugs have side effects (e.g. drowsiness, dizziness, cognitive and motor impairment) that can increase the risk of falls and resultant fracture events. Despite widespread zolpidem and trazodone use, little is known about the comparative safety of these medications in hemodialysis patients, a vulnerable population with an exceedingly high fracture rate.

Methods: We conducted a retrospective cohort study using an active comparator new-user design to investigate the association between zolpidem vs. trazodone initiation and the 30-day risk of hospitalized fall-related fractures among Medicare-enrolled hemodialysis patients in the United States Renal Data System Registry (2013 – 2016). We used an intention-to-treat analytic approach and propensity score weighted survival models, adjusted for numerous demographic and clinical covariates, to estimate hazard ratios (HRs) and their 95% confidence intervals (CIs). Death was treated as a competing event.

Results: A total of 31,055 hemodialysis patients were included in the study, 18,941 zolpidem initiators (61%) and 12,114 trazodone initiators (39%). Newly initiating zolpidem vs. trazodone therapy was associated with a higher risk of hospitalized fall-related fractures, HR [95% CI] = 1.71 [1.11, 2.63]. The association was more pronounced among individuals prescribed higher zolpidem doses (1.92 [1.14, 3.21]) and in subgroups with fall-related risk factors, such as older and frailer patients (1.89 [1.14, 3.09] and 2.49 [1.31, 4.73], respectively) and individuals using other medications with central nervous system activity (2.04 [1.14, 3.67]). Sensitivity analyses using longer follow-up durations, evaluating a broader outcome (hospitalized fracture), and employing an on-treatment analytic approach yielded similar results (data not shown).

Conclusions: Hemodialysis patients newly initiating zolpidem had a higher risk of hospitalized fall-related fracture compared to patients initiating trazodone, suggesting that trazodone may be a safer pharmacologic treatment option for the management of insomnia in this vulnerable population.

PO1182

Relationship of Peripheral Nerve Function with Mobility in ESKD

Simit Doshi, Alissa A. Cranor, Keith G. Avin, Sharon M. Moe, Ranjani N. Moorthi. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Mobility limitation is widely prevalent in patients undergoing dialysis and is associated with frailty, disability, hospitalizations and mortality. Motor and sensory nerve impairments are reported in ESKD but their relationship with mobility is poorly studied. We tested the hypothesis that objective measures of nerve function in the lower extremity are associated with mobility limitation.

Methods: Twenty-five subjects with ESKD underwent nerve testing after their routine dialysis session. Nerve testing was done using the Natus Viking Quest NSC system and vibration detection threshold (VDT) was measures with a Medoc VSA-3000 analyzer. Predictors were nerve action potentials (amplitude) and nerve conduction velocity (NCV) in motor (peroneal) and sensory (sural) nerves as well as VDT quantitatively measured at the pulp of the big toe. Gait speed (mobility outcome) was measured over 4 meters and the better of 2 attempts used. Leg extensor strength, a covariate was measured by a dynamometer. Patient symptoms were assessed using the Neuropathic Pain Questionnaire.

Results: Subjects were 23-74 y, 14 male, 23 black, 14 diabetic, median dialysis vintage 4.5 yrs. Median gait speed was 0.70 m/s (IQR 0.61-0.86). Neuropathic pain was noted in ~57% patients, but did not correlate with objective measures of nerve function or gait speed. Median vibration detection threshold was 51μ (IQR 26-104) and showed significant negative correlation with gait speed ($p < 0.01$). Higher sensory (sural) nerve onset and peak latency and lower sensory conduction velocity were correlated with lower gait speed (all $p < 0.01$). Higher peroneal motor nerve amplitude was positively correlated with gait speed ($p < 0.05$). Higher VDT remained significantly associated with gait speed in multivariable regression model adjusted for demographics, diabetes, dialysis vintage and muscle strength (model R^2=0.74).

Conclusions: In patients with ESKD, objective measures of nerve function are associated with mobility dysfunction regardless of diabetes, muscle strength and dialysis vintage. In contrast, subjective assessment of neuropathy is not associated with mobility dysfunction. These results demonstrate that the neuropathy of ESKD is a contributing factor to the widespread impairment in mobility observed in patients undergoing dialysis and that objective testing is required for diagnosis.

Native Hawaiian/Pacific Islander Data in the USRDS

David T. Gilbertson,[1,2] James B. Wetmore,[1,3] Yi Peng,[1,2] Jiannong Liu,[1,2] Kirsten L. Johansen.[1,3] *[1]Chronic Disease Research Group, Minneapolis, MN, US, Minneapolis, MN; [2]Hennepin Healthcare Research Institute, Minneapolis, MN; [3]Hennepin County Medical Center, Minneapolis, MN.*

Background: The United States Renal Data System (USRDS) has reported very high ESRD incidence and prevalence rates among patients designated as Native Hawaiian or Other Pacific Islander (NH/PI) race. Xiang et al. (2019 NKF Spring Clinical Meeting) reported a "denominator problem," caused by a large percentage of NH/PI individuals reporting multiple races in the US census. By counting only single-race individuals, resulting dominators are too small, leading to rates that appear to be too large. We sought to assess whether reporting of race is accurate for these individuals by examining reported country of origin on the CMS 2728 Medical Evidence (ME) form.

Methods: Using data from the ME form for patients initiating dialysis in 2016, we examined the accuracy of the country/area of origin field, which is required to be filled out only when NH/PI race is chosen. We assumed all those reporting the US as the country of origin were correct.

Results: The figure displays country/area of origin or ancestry for the 1578 patients who reported NH/PI race, for the top 25 countries, which accounts for 90.8% of all NH/PI patients. Only 58.7% of them came from countries that are actually part of the census definition of NH/PI. The largest misclassified countries were Philippines (19.2%) and Mexico (2.5%).

Conclusions: The apparently high rates of ESRD among NH/PI individuals have gained increasing attention. Our finding of inaccurate understanding of the US census definition of NH/PI leading to numerators of rates that are too large, combined with the already important problem of the US census single vs. multiple race denominator, makes it difficult and perhaps even impossible to calculate accurate incidence and prevalence rates for this race group. Improvements in capturing accurate race information at the time of ESRD initiation are needed.

Workforce Capacity for ESKD Care: An Analysis from the Global Kidney Health Atlas Study

Parnian Riaz,[1] Mohamed A. Osman,[1] Meaghan Lunney,[3] Feng Ye,[1] Syed Saad,[1] Adeera Levin,[4] David W. Johnson,[2] Aminu K. Bello.[1] Global Kidney Health Atlas Investigators *[1]University of Alberta Faculty of Medicine and Dentistry, Edmonton, AB, Canada; [2]The University of Queensland Faculty of Medicine, Herston, QLD, Australia; [3]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [4]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada.*

Background: Despite the rising burden of chronic kidney disease, recent surveys reveal a global shortage of nephrologists and other kidney healthcare professionals. The objective of the second iteration of the International Society of Nephrology's (ISN) Global Kidney Health Atlas was to assess inter- and intra-national variability in the capacity for end-stage kidney disease (ESKD) care.

Methods: Data were collected in two steps: desk research and a cross-sectional survey. Desk research used data from online sources, such as the Central Intelligence Agency World Factbook and the World Health Organization Global Observatory. The survey was administered online to key stakeholders worldwide, and all country-level data were analyzed by ISN region and World Bank income classification.

Results: The results of desk research showed that the general healthcare workforce density varied by income level: high income countries had more healthcare workers per 10,000 population (30.30 physicians; 79.21 nursing personnel; 7.20 pharmacists; 3.47 surgeons) than low income countries (0.85 physicians; 5.02 nursing personnel; 0.10 pharmacists; 0.03 surgeons). A total of 182 countries responded to the survey, with 160 (88%) countries responding to questions pertaining to the ESKD workforce. Nephrologists were primarily responsible for providing care to ESKD patients in 92% of countries. Global nephrologist density was 9.95 per million population (pmp) and nephrology trainee density was 1.42 pmp. High income countries reported the highest densities of nephrologists and nephrology trainees (23.15 pmp and 3.83 pmp, respectively), whereas low income countries reported the lowest densities (0.24 pmp and 0.11 pmp, respectively). Compared to higher income countries, more low income countries reported shortages of all types of ESKD healthcare providers, including nephrologists, transplant surgeons, peritoneal and hemodialysis access surgeons, and peritoneal and hemodialysis access interventional radiologists.

Conclusions: In this global survey, a significant trend was demonstrated in workforce capacity and distribution for ESKD care across countries. There was limited capacity in low income compared to high income countries. National and international policies are required to build a workforce that can effectively address the growing burden of ESKD.

PO1185

Patient Activation in Prevalent Hemodialysis Patients in the United States

Wael F. Hussein,[1,2] Paul N. Bennett,[1,3] Sumi J. Sun,[1] Marc Reiterman,[1] Emily Watson,[1] Ian M. Farwell, DSW,[1] Brigitte Schiller.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Deakin University Faculty of Health, Burwood, VIC, Australia.*

Background: Patient activation (PA) is the product of knowledge, skills and confidence that enable a person to manage their health and care. PA is associated with healthy behaviors, disease management and hospitalization rates. This study aimed to investigate the status and correlates of PA among prevalent HD patients in the US.

Methods: We surveyed patients from 10 HD centers using the Patient Activation Measure 13-item instrument (PAM-13), which reports a score out of 100 and is categorized into four levels (higher scores or levels denoting higher activation). We described the distribution of PA status, and investigated associations with demographics, vintage, education level and HD center.

Results: 925 respondents completed the survey out of 1374 patients (response rate 67%). Mean age 62 ± 14 years, 40% female, and median vintage 41 months (IQR 19-77). Mean PAM score was 56 ± 13, and 14%, 50%, 25%, and 10% were in levels 1 to 4 respectively. Mean PAM scores were higher in younger patients (<55yrs: 59 ± 14, 55 to <65yrs: 55 ± 14, 65 to < 75: 55 ±12, >75 yrs:54 ± 12; p<0.001). Higher PAM scores were observed with higher education (College: 60 ± 14, High School: 57 ± 14, <High School: 51 ± 10; p<0.001) and in blacks (58 ± 15) compared to non-blacks (55 ± 13; p=0.008). Mean PAM scores varied significantly across centers ranging between 52 and 61 (p=0.004). In regression analysis, there were lower odds of having high activation (levels 3 or 4 vs levels 1 or 2) in association with age (for every 10 years: aOR 0.79 [95% CI: 0.71 – 0.87]) and male sex (0.72 [0.53 – 0.96]). Compared to having less than high school diploma, high school diploma and college were associated with high activation (2.36 [1.60 – 3.47], and 3.52 [2.25 – 5.54] respectively). HD center differences remained significant after adjustment. However, vintage, race, and ethnicity did not have a significant association with activation in the adjusted model.

Conclusions: Patient activation is low in a high proportion of HD patients. Older age, less education and male gender were associated with lower activation. This study is the first to report activation status among individuals on HD in the US, identifying an opportunity to direct resources to high-risk groups and develop programs to improve activation.

PO1186

Analysis of Psychological Detachment of Primary Caregivers of Maintenance Hemodialysis Patients

Jun Yin,[1] Jin-mei Yin.[2] *[1]Third Affiliated Hospital of Sun Yat sen University, Guangzhou, China; [2]the Fifth Affiliated Hospital of Sun Yat sen University, Zhuhai, China.*

Background: Long term care for maintenance hemodialysis patients will bring physical, mental and economic burden to the caregivers. If the caregivers cannot detach during non working hours, it will affect their physical and mental health. The goal was to Analysis the psychological detachment level of primary caregivers of maintenance hemodialysis patients and its influencing factors.

Methods: By convenient sampling method,240 caregivers of maintenance hemodialysis patients in our hospital from June to September 2019 were selected and investigated by using Psychological Detachment Scale, Zarit Burden Inventory Scale, and Warwick-Edinburgh Mental Well-being Scale.

Results: The total score of psychological detachment of caregivers in maintenance hemodialysis patients was 12.02 ± 3.31, which was negatively correlated with the burden of caregivers (P < 0.01), and positively correlated with the total score of Warwick Edinburgh positive mental health(P<0.01) and psychological detachment level was high at 53.2% and low at 46.8%.The main influencing factors of caregiver's psychological detachment were time of care, type of character, burden of care, positive mental health, duration of dialysis and types of complications(P<0.01).

Conclusions: Medical staff should pay attention to the psychological status of caregivers and take positive measures to improve the level of psychological detachment and promote their physical and mental health.

PO1187

Factors Contributing to Primary Care Provider (PCP) Use in ESKD Patients After Starting Hemodialysis (HD)

Raquel C. Greer,[1,2] JiYoon B. Ahn,[2] Laura Plantinga,[1,3] John Sperati,[1,2] Khaled Abdel-Kader,[1,4] Mara McAdams-DeMarco,[2] Kelly H. Beers,[1,5] Sandeep S. Soman,[1,6] Michael J. Choi,[1,7] Bernard G. Jaar.[1,2] National Kidney Foundation Education Committee *[1]National Kidney Foundation, New York, NY; [2]Johns Hopkins University, Baltimore, MD; [3]Emory University, Atlanta, GA; [4]Vanderbilt University Medical Center, Nashville, TN; [5]Albany Medical College, Albany, NY; [6]Henry Ford Hospital, Detroit, MI; [7]MedStar Georgetown University Hospital, Washington, DC.*

Background: While the importance of primary care is well-recognized, PCP use among HD patients has not been well-characterized and factors contributing to PCP use are unknown.

Methods: We characterized change in PCP use (≥1 PCP visit) 1 year before and 1 year after dialysis start among adults ≥67 years old with Medicare coverage initiating in-center HD between 2008-2014 (data from the United States Renal Data System). We used multivariable logistic models adjusting for demographics, clinical characteristics, and pre-ESKD nephrology care to identify factors associated with continuity of PCP care (defined as PCP use pre- and post-HD start) and new initiation of PCP care post-HD start.

Results: Among 111,424 older HD patients, 34% did not use PCP care post-HD start. Among patients with PCP use pre-ESKD, 15% did not continue to use PCP care post-HD start. Among patients without PCP use pre-ESKD, 70% did not initiate PCP care post-HD start. Black race, Medicaid insurance, impaired functional status, and residence in less urban or higher poverty neighborhoods were associated with lower odds of continuity of PCP care or initiating PCP care after HD start. (Table)

Conclusions: Among older incident HD patients, continuity of PCP care and initiation of PCP care were lower among patients who were black, of lower socioeconomic status,

from more rural areas, or had functional impairments. Research to understand the barriers to PCP use may inform interventions to improve delivery of primary care for these vulnerable populations.

Funding: Private Foundation Support

Factors Associated with Continuity of PCP Care and Initiation of PCP Care after Starting HD

Patient Characteristics	Continuity of PCP care after starting HD (n=74253) OR* (95% CI)	Initiation of PCP care after starting HD (n=37171) OR* (95% CI)
Medicaid enrollment	0.75 (0.71-0.79)	0.73 (0.68-0.77)
Non-Hispanic Black (vs. Non-Hispanic White)	0.83 (0.78-0.88)	0.71 (0.66-0.75)
Functional impairment	0.65 (0.61-0.68)	0.90 (0.85-0.96)
% neighborhood-level poverty (tertiles)		
Medium (vs. low)	0.89 (0.84-0.94)	0.88 (0.83-0.93)
High (vs. low)	0.85 (0.81-0.90)	0.82 (0.77-0.87)
% neighborhood urban (tertiles)		
Medium (vs. low)	1.28 (1.21-1.34)	1.38 (1.30-1.46)
High (vs. low)	1.20 (1.13-1.27)	1.41 (1.32-1.50)

*Adjusted for variables in Table and age, sex, employment, co-morbid conditions (hypertension, diabetes, CVD, CHF, COPD, and cancer), US region, and pre-ESKD nephrology care

PO1188

Status and Trajectory of Patient Activation Among Incident Dialysis Patients in the United States

Wael F. Hussein,[1,2] Anna R. Carrasco,[1] Paul N. Bennett,[1,3] Emily Watson,[1] Sumi J. Sun,[1] Brigitte Schiller.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Deakin University Faculty of Health, Burwood, VIC, Australia.*

Background: Patient activation (PA), a measure of knowledge, skills and confidence in managing one's health, is associated with healthy behaviors, better disease management and improved health outcomes. We investigated the status and correlates of PA among end-stage kidney disease (ESKD) patients at dialysis initiation, and changes in PA after the first 3 months of dialysis.

Methods: Adult ESKD patients commencing dialysis at 25 in-center hemodialysis (ICHD) and 12 home dialysis facilities completed the Patient Activation Measure 13-item instrument (PAM-13) at dialysis initiation (t0) and month 4 (t1). Logistic regression was used to examine factors associated with high PA levels at t0 (PAM levels 3 and 4). Paired t-test was used to examine changes in PAM scores from t0 to t1.

Results: 227 patients completed the survey at t0 between Jun – Nov 2019; 166 (73%) on ICHD and 61 (27%) on home dialysis, mean age 60 ± 15 years. At t0, mean PAM scores were 65.1 ± 16.8; and 44% of patients had low activation. Mean PAM scores were 63.7 ± 17.3 and 69.4 ± 14.5 in ICHD and home patients respectively. In the adjusted model, higher education level and longer pre-ESRD nephrology care were associated with high PA at t0, while increased age was associated with lower odds of high activation – Figure 1. There was no significant change in PA scores among 182 participants who completed the survey at t1 (mean 64.8 ± 17.8, mean change: -0.3 ± 17.3, p = 0.80).

Conclusions: Low activation is common among incident dialysis patients and is more common among those on ICHD. Patient activation does not seem to improve over the first 3 months of dialysis with current practice.

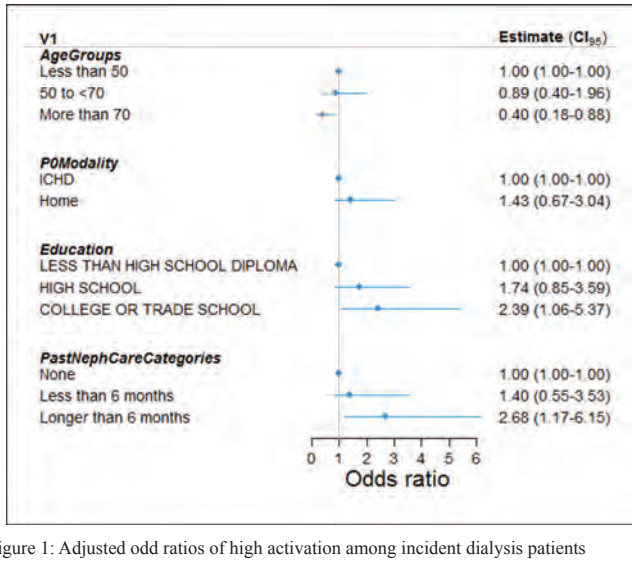

Figure 1: Adjusted odd ratios of high activation among incident dialysis patients

PO1189

Fully Immersive Virtual Reality-Based Mindfulness Intervention in Hemodialysis Patients: A Pilot Study Assessing Safety and Utility

Brett Burrows,[1] Matthew H. Browning,[2] Killivalavan Solai,[1] Drew Fast,[1] Natalia O. Litbarg,[3] Judith T. Moskowitz,[4] Kenneth R. Wilund,[1] Rosalba Hernandez.[1] *[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]Clemson University, Clemson, SC; [3]University of Illinois at Chicago College of Medicine, Chicago, IL; [4]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Virtual reality (VR) is an evolving technology that is becoming a more common treatment for pain management and psychological phobias. While non-immersive VR (i.e., Nintendo Wii) has been used in trials involving hemodialysis (HD) patients, no studies to date have used fully immersive VR as a tool for intervention delivery. Because HD treatment and fully immersive VR have similar potential adverse side effects (e.g., fatigue, nausea), the current pilot trial tests the initial safety and utility of fully immersive VR during maintenance HD treatment sessions.

Methods: HD patients (n=20) were enrolled in a single-arm pre-post pilot study. Participants were exposed to our fully immersive VR program, Joviality™, which delivered mindfulness training and guided meditation using the Oculus Rift head-mounted display. Participants experienced our 25-minute program on two separate occasions during HD treatment sessions. Participants recorded their level of HD treatment and/or motion-related symptoms prior to VR exposure and then again immediately following each VR exposure using the Simulator Sickness Questionnaire (SSQ). Validated utility measures included participant's ability to be fully immersed in the virtual environment, interact with virtual objects, and find our VR program user-friendly.

Results: Mean age was 55.3 (±13.1) years; 80% male; 60% African American; and mean dialysis vintage was 3.56 (±3.75) years. The SSQ displayed significant decreases in total composite symptom score following VR Exposure 1 (22.6 vs. 11.2; p=0.03). Decreases were evident after Exposure 2, though these were non-significant (11.97 vs 7.29; p= 0.18). Participants reported high levels of spatial presence in the VR world with an average of 5.03/7.0 and they rated our VR program as easy to operate, with average System Usability Scores of 82.8/100.

Conclusions: HD patients routinely suffer from fatigue, nausea, and dizziness during HD, and we hypothesized that fully immersive VR may exacerbate these symptoms. By contrast, we saw a significant reduction in severity of symptoms on at least one of the two exposure days. Fully immersive VR may be a safe mode of intervention delivery during HD.

PO1190

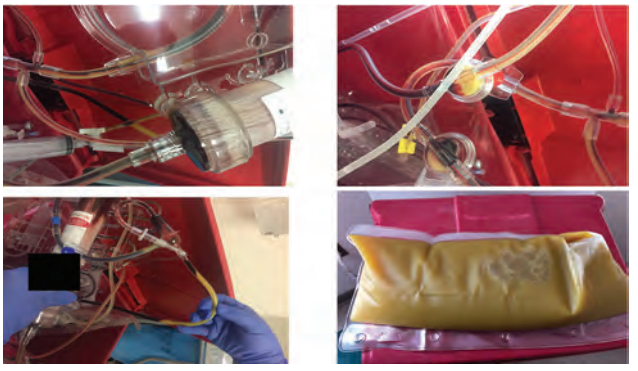
Skim the Fat: PLEX for Hypertriglyceridemia-Induced CRRT Clotting

Ruth Schulman, Larissa Kruger gomes, Krishna A. Agarwal, Esilida Sula Karreci, Jason A. Freed, Melanie P. Hoenig. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: CRRT filter clotting remains a significant barrier to providing adequate dialysis in critically ill patients. Clotting leads to reduced clearance and volume removal, blood loss in the circuit, and increased nursing workload. Elevated triglycerides have been reported to result in filter clotting. Here, we present a case of CRRT circuit clotting in a patient with familial hypertriglyceridemia-induced pancreatitis.

Case Description: A 46-year-old man with obesity, hyperlipidemia, recurrent pancreatitis secondary to hypertriglyceridemia, and DMII presents with 2 days of abdominal pain. CT abdomen showed pancreatic necrosis and stranding prompting admission for pancreatitis. Hospital course was complicated by hypoxic respiratory failure requiring intubation, shock, and oliguric AKI requiring initiation of CVVHDF. Shortly after initiation of CVVHDF, the filter and tubing clotted with a milky yellow substance. This recurred after circuit exchange and use of regional anticoagulation with Citrate Dextrose 3%. Triglyceride level returned at 3,668 mg/dL (reference range: <150 mg/dL). Given the severe hypertriglyceridemia and inability to effectively provide RRT, he underwent one session of therapeutic plasma exchange (PLEX) with subsequent fall in triglyceride levels to 433 mg/dL. Further CRRT was then effectively provided with typical filter and circuit life.

Discussion: This case highlights the impact of elevated triglyceride levels on CRRT filter life. Prior case reports have described clotting and shortened filter life in the setting of lipid infusion and propofol-induced hypertriglyceridemia despite regional Citrate anticoagulation. Triglyceride levels fell and clotting resolved with cessation of the infusions in both situations. In the setting of a non-iatrogenic etiology of elevated triglycerides, we suggest consideration of anticipatory plasma exchange to avoid CRRT filter clotting and to be able to provide more effective dialysis.



Milky Substance Noted Throughout CRRT Circuit and PLEX Effluent

PO1191

Mariachi Madness: A Unique Presentation of Acyclovir Toxicity

Ryan W. Polston, Maurice I. Khayat. *Madigan Army Medical Center, Tacoma, WA.*

Introduction: Acyclovir and valacyclovir (pro-drug) are often prescribed for treatment of infections caused by herpes viruses. Neurological toxicity consisting of hallucinations, seizures, and coma are rare reported side effects occurring predominantly in renal failure as a result of the renal clearance of the drug.

Case Description: A 71-year-old woman with end stage renal disease from amyloidosis on maintenance hemodialysis presented with recent onset of confusion, slurred speech, weakness, and intractable auditory hallucinations described as "mariachi music." She had been recently treated for herpes keratitis four days prior to presentation. On exam she was noted to be inattentive with disorganized thought-processes, diffuse hyporeflexia, generalized myoclonus, and up-beating nystagmus with superior gaze. A medication reconciliation revealed that she had been prescribed valacyclovir at a dose of 1,000 mg three times daily. She had additionally continued previously-prescribed prophylactic acyclovir at a dose of 200 mg twice daily. Urgent hemodialysis was performed for presumed acyclovir toxicity. An acyclovir level drawn 2 hours after initiation was elevated at 2.6 mcg/mL (typical therapeutic level 0.14 – 1.2 mcg/mL). After a four-hour session of hemodialysis her mental status improved, and her movement symptoms resolved. The following morning a repeat acyclovir level was 1.1 mcg/mL. An additional session of hemodialysis was performed due to persistent altered mentation with subsequent resolution to baseline. She was transitioned to topical ganciclovir for her keratitis and discharged home.

Discussion: This case describes the rare yet potentially underrecognized syndrome of acyclovir neurotoxicity, manifesting as delirium with prominent auditory hallucinations and myoclonus. Such toxicity is more likely to present in patients with acute or chronic renal failure given the drug's pharmacokinetics. Both acyclovir and valacyclovir are dialyzable (30-60% drug removal in a four-hour session). Given these medications are commonly prescribed, as well as the severity of neurotoxicity and the rapid improvement with hemodialysis, it is critical to maintain a high index of suspicion and begin treatment promptly. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense (DoD), or the U.S. Government.

PO1192

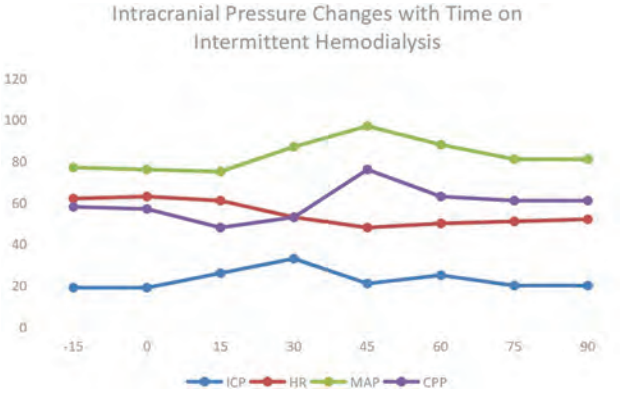
The New Face of Dialysis Disequilibrium Syndrome: A Case Report, Systematic Literature Review, and Suggested Management Guidelines

Chidambaram S. Valliappan, Emaad M. Abdel-Rahman. *University of Virginia Medical Center, Charlottesville, VA.*

Introduction: After implementation of standard protocols for new start dialysis, Dialysis Disequilibrium syndrome has become rare. Patients with preexisting neurologic damage, head trauma or stroke are more vulnerable to this complication. We present a case report of a patient who had a "near miss" safety event after starting intermittent hemodialysis in the setting of a traumatic brain injury (TBI). His deterioration on dialysis is not fully explained by the current leading theory on the pathogenesis of this syndrome (theory of "reverse urea effect") implying that either a multifactorial etiology is implicated or that impaired cerebral autoregulation may play a more significant role than previously believed.

Case Description: A 70 year old male was hospitalized after being involved in a motor vehicle accident. He suffered multiple injuries including cardiac arrest from which he was revived, TBI and acute kidney injury (AKI) requiring initiation of hemodialysis using the new start protocol. Trends of intracranial pressure (ICP), cerebral perfusion pressure (CPP) and heart rate (HR) before, during and after intermittent hemodialysis showed clear worsening of these parameters after beginning dialysis with subsequent improvement after discontinuing dialysis (Figure).

Discussion: This case points toward a change in the pattern of presentation of DDS, requiring new guidelines focusing on dialyzing vulnerable TBI patients. These guidelines include early initiation of dialysis, selection of CVVH as preferred modality given reduced dialysis dependency in AKI patients, adjusting dialysis settings to minimize urea clearance per unit time, utilizing ICP monitoring when available, using hypertonic saline to maintain serum sodium > 155 mmol/L and avoiding central lines on contralateral side to an internal jugular dialysis catheter to preserve cerebral venous return. The establishment of these guidelines may help reduce the risk of poor outcomes in this population.



PO1193

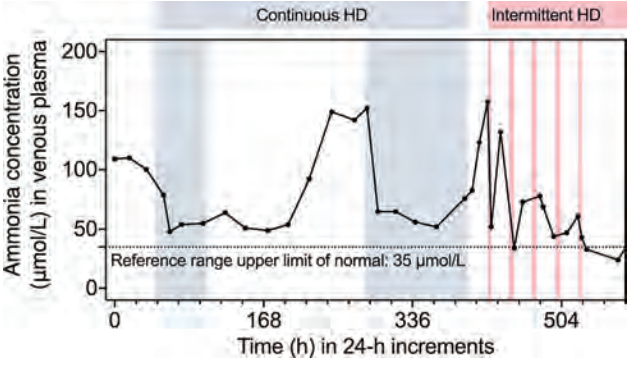
Rescue Hemodialysis for Paroxysmal Hyperammonemic Encephalopathy Sans Cirrhosis

Atiya Chachar, Brian Simba, Waqas Memon, Graham T. Gipson, Niraj R. Kothari. *Virginia Commonwealth University, Richmond, VA.*

Introduction: Ammonia is a product of protein catabolism that is converted to less toxic urea before excretion by the kidneys in urine. Hyperammonemia can be associated with coma, cerebral edema, and herniation. Ammonia levels do not correlate linearly with encephalopathy, especially in patients with chronic hyperammonemia.

Case Description: A 63-year-old female with a history of Roux-en-Y gastric bypass surgery > 20 years ago and malnutrition presented with three weeks of encephalopathy. Initial workup, including head CT and EEG, was negative. She was noted to have normal liver function and an elevated ammonia level of 110 µmol/L which was not responsive to conventional therapies. Continuous veno-venous hemodialysis (CVVHD) was successfully employed to prevent neurologic catastrophe. After discontinuation of CVVHD, she experienced recurrence of hyperammonemic encephalopathy prompting the use of hemodialysis (HD) intermittently throughout the hospital stay. We believe this patient's paroxysmal hyperammonemic encephalopathy is a consequence of progressive metabolic disarray following gastric bypass surgery coupled with an exceptionally poor diet.

Discussion: There is historical precedent for extracorporeal blood purification in hyperammonemic states, typically related to pediatric inborn errors of nitrogen metabolism or fulminant liver failure with hyperammonemic encephalopathy. Recurrent hyperammonemic encephalopathy in the absence of liver failure has been described after bariatric surgery. Ammonia, a small, water-soluble molecule without significant protein binding, is cleared well with dialysis. Due to a large volume of distribution, ammonia levels frequently rebound after discontinuation of HD. Intermittent HD allows for the highest rate of reduction of ammonia, though CVVHD may be superior in severe encephalopathy. This patient's ongoing need for HD, either chronically or episodically during decompensations, remains to be determined.



PO1194

A Case of Polysulfone Membrane-Induced Thrombocytopenia

Ivan L. Claudio-Gonzalez, Sarah Nicholls, James T. Someren, Susan M. Wall. *Emory University Emory College of Arts and Sciences, Atlanta, GA.*

Introduction: The development of biocompatible hemodialysis membranes has been a major advance in the treatment of renal failure. Newer, synthetic membranes such as polysulfone are considered to be more biocompatible than the older cuprophane or cellulose membranes. However, polysulfone dialyzers can interact with and thereby

reduce platelet counts. A few isolated case reports have observed thrombocytopenia in patients following hemodialysis with polysulfone membranes.

Case Description: We report a case of an 82 year old man with a history of hypertension, an abdominal aortic aneurysm Stage 5 chronic kidney disease and AV malformations admitted to with recurrent GI bleeding and acute kidney injury. Admission laboratory values were significant for Hgb 4.9, Plt 209, HCT 16.0, BUN 166, Cr 19.23, K 5.7, Bicarbonate 7 and Phosphorous 7.5. The bleeding site was found to be the transverse colon, which was ligated with resolution of the bleeding. Intermittent hemodialysis was initiated thrice weekly using an F180NR polysulfone hemodialysis membrane. On admission, the patient's platelet count was 233,000. However, each morning after a hemodialysis treatment, his platelet count was ~40% lower than that of the previous day, but then increased until the next dialysis session. Over the course of the admission, his platelet count therefore progressively fell, reaching a nadir of 37,000 on hospital day 38. The patient was anticoagulated with citrate and did not receive heparin. His heparin-induced thrombocytopenia panel (HIT) was negative. On hospital day 38, the dialysis membrane was changed to *Cellentia-H* cellulose triacetate single-use, hollow-fiber, high-flux hemodialyzer. Over the following week he underwent 3 additional dialysis treatments, over which time his platelet count rose to 120,000 and the post-dialysis drop in platelet count was no longer observed.

Discussion: Dialyzer membrane-associated thrombocytopenia was suspected by the platelet count decline observed the morning after a dialysis treatment, and by eliminating other possible causes. We observed significant improvement in platelet count when the membrane was changed to modified cellulose membrane (cellulose triacetate). In patients that develop thrombocytopenia following the initiation of dialysis with a polysulfone membrane, consideration should be given to a trial of an alternative membrane, such as cellulose triacetate.

PO1195

Drug Confusion: A Case of Valacyclovir-Induced Neurotoxicity

Nia Flemming, Latoya N. Gayle, Angelica Medina, Gene C. Otuonye, Louis C. Jan. *Englewood Hospital and Medical Center, Englewood, NJ.*

Introduction: Medication dose adjustment in ESRD is paramount to avoid serious adverse effects. Valacyclovir(VA) is >90% renally excreted after conversion to acyclovir, & if not adjusted can cause life threatening valacyclovir induced neurotoxicity(VAN). Prompt recognition and treatment(dialysis) to reduce mortality is crucial. We present a case of VAN in ESRD.

Case Description: 69-year-old male with ESRD on hemodialysis(HD),DM, HTN,CAD, prostate cancer presented with 1 day of confusion, weakness, flight of ideas, auditory/visual hallucinations & persecutory delusions. 3 days prior he was given VA 500mg bid after telemedicine encounter for a rash. On exam, BP 238/106, heart rate 71,T97.8F, he was oriented to person, time & place, had atomic aphasia, impaired short term memory & confabulation. There was no skin rash. Labs noted Hb 11g/dl,WBC 10.2,PLT 170,Na136,K5.6,BUN 70, creatinine 9.2 & calcium 10. Head CT showed no abnormalities. He underwent emergent HD for acute encephalopathy due to VA use & during HD, his confusion & confabulation improved. The morning after HD he returned to baseline mental status & was counseled on the importance of discussing new medications with his nephrologist so dosage adjustments can be made appropriately.

Discussion: VA is a prodrug of Acyclovir & is >90% renally excreted. Appropriate dose adjustment based on CrCl must be considered in CKD/ESRD to prevent serious adverse events such as VAN and reduce mortality. It may be difficult to differentiate VAN from Herpes encephalitis. Prompt recognition & urgent dialysis is needed in the former. The mechanism of VAN is poorly understood but postulated to be acyclovir inhibition of mitochondrial DNA polymerase & altering mitochondrial function. Half-life of acyclovir in ESRD is ~14 hours, which compounds the neurotoxicity if not emergently dialyzed. Our patient had typical symptoms of confusion/hallucinations with recent use of VA, but had no evidence of Zoster on exam, with rapid return to baseline after urgent dialysis. Recognition of the need for dosing adjustment in ESRD of medications such as VA is important to prevent & monitor for life-threatening adverse effects. Entertaining VAN as a differential in ESRD patients with acute encephalopathy & background use of VA is paramount in early recognition and treatment to prevent further morbidity and mortality.

PO1196

A Case of a Yellow Dialyzer in a Hemodialysis Patient

Rushang Parikh, Hugo Andrade paz, Nupur N. Uppal, Mala Sachdeva. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Yellowish discoloration of a dialyzer during hemodialysis (HD) can have various diagnostic and therapeutic implications, however its recognition must be made in a timely manner. Here we present a case of a patient whose dialyzer color was noted to be yellow after his HD session.

Case Description: A 65-year-old African American male with ESKD secondary to hypertension and diabetes mellitus, on intermittent hemodialysis for 9 years was noted to have a yellow dialyzer post hemodialysis. His only complaint during dialysis was severe itching for two days. On exam, he had no scleral or palatal icterus. Stat outpatient laboratory testing revealed a total bilirubin of 13.1 mg/dL with a direct bilirubin of > 10.0 mg/dL which led to his hospital admission. Further laboratory testing revealed an AST of 188 U/L, ALT of 188 U/L, alkaline phosphatase of 587 U/L, a normal amylase and lipase, and negative viral testing for hepatitis A, B, C, CMV, and EBV. Autoimmune workup revealed a normal ANA, anti-mitochondrial, and anti-smooth muscle antibody. An abdominal ultrasound showed mildly thickened gallbladder, without stones, sludge or ductal dilatation. Doppler showed no portal or hepatic vein thrombosis. A CT scan of his abdomen showed no discernable liver or gallbladder issues. He denied herbal medications or rifampin use. Although etiology was entirely unclear, there was suspicion for drug induced liver injury caused by hydralazine and high dose statin. Patient had a planned liver biopsy however he decompensated rapidly, and had a cardiac arrest which led to his demise.

Discussion: Although yellow dialyzers have been described they are still quite a rare entity. In this case, the presence of a yellow dialyzer was one of the only two presenting symptoms for this patient, the other being itching. Itching, which occurs in dialysis patients could have easily been disregarded if it were not for the dialyzer discoloration. We highly stress that close attention to dialyzer color is needed in patients who present with itching, in the absence of any other symptoms. Recognition of a yellow dialyzer in a timely manner can assist in discerning if the etiology is medication related or hyperbilirubinemia related where the yellow color is thought to be due to entrapment of unfiltered bilirubin-albumin complexes by the dialysis membrane. Hopefully this recognition can improve outcome.

PO1197

Life Finds a Way: Two Successful Pregnancies in a Woman Without Kidneys

Anna K. Curtis,[1] Christian C. Lamb,[2] Sarah Atallah,[1] Amit J. Patel.[1] *[1]University of Missouri Kansas City, Kansas City, MO; [2]US Army Brooke Army Medical Center Medical Library, Fort Sam Houston, TX.*

Introduction: Bilateral nephrectomy is a controversial and rarely used approach to control refractory hypertension in patients with anuric end-stage renal disease (ESRD) who require dialysis. This extreme measure results in complete dependence on dialysis to maintain metabolic homeostasis. This procedure has become rare due to advances in anti-hypertensive pharmacotherapy. Given the rarity of this approach, there is a paucity of literature regarding how the absence of kidneys after bilateral nephrectomy impacts childbearing. We present the first known case of successful pregnancy in a woman on intermittent hemodialysis (iHD) without kidneys due to bilateral nephrectomy.

Case Description: The patient was a 31-year-old female who had ESRD secondary to hypertension and atypical hemolytic uremic syndrome (aHUS). She was diagnosed with aHUS condition during her first pregnancy and was initiated on biweekly infusions of eculizumab after delivery. Seven months after delivery, she underwent bilateral nephrectomy to control her hypertension. Two years following nephrectomy, she presented to the Emergency Department (ED) with dyspnea. Her urine β-HCG was positive and ultrasonography confirmed an intrauterine pregnancy. Throughout this pregnancy, she required iHD six days weekly. She delivered at 27 weeks gestation and after a short stay in the neonatal intensive care unit (NICU) her baby was discharged home in healthy condition. Two years later, the patient presented to the ED and was again found to be pregnant. She was managed with HD six days weekly. This child was born at 23 weeks gestation and was discharged home after several weeks in the NICU.

Discussion: Theoretically, bilateral nephrectomy can curtail regulatory mechanisms leading to hypertension. This approach has fallen out of favor given advancements in pharmacotherapy. There is almost no known scientific literature regarding how the absence of kidneys after bilateral nephrectomy impacts childbearing. On an extensive review of the literature regarding bilateral nephrectomy and pregnancy, only one case report was identified. This article details a Saudi Arabian woman receiving intermittent peritoneal dialysis who successfully carried a pregnancy to 29 weeks, with the birth of a healthy child. This report highlights the lack of literature regarding managing pregnant patients on iHD, especially those without kidneys.

PO1198

First Report of Simultaneous HBsAg and Anti-HBs Reactivity in a Hemodialysis Patient

Namita Biala,[1] Pooja Sanghi,[2] Jesse M. Goldman.[2] *[1]Lower Bucks Hospital, Bristol, PA; [2]Thomas Jefferson University Hospital, Philadelphia, PA.*

Introduction: Of great concern to dialysis units is the presence of bloodborne pathogens. The incidence of HBV infection is quite low in the United States, however outbreaks of hepatitis B in hemodialysis units have occurred. CDC guidelines recommend hemodialysis patients be screened for HBV surface antigen (HBsAg) surface antibody (anti-HBs) and core antibody (anti-HBc) on admission to the dialysis unit. We present an usual case of a patient with both HBsAg and anti-HBs positive who required hemodialysis (HD).

Case Description: A 78-year-old Chinese female with past medical history of CKD stage V, Type 2 DM, hypertension, chronic HBV with no prior treatment, presented to the ED with signs of fluid overload. In the ED she was hypertensive to 170/107. Labs showed a creatinine of 5.7 (baseline) and a serum sodium of 116. Liver enzymes were mildly elevated with no associated jaundice. Physical exam showed +2 peripheral edema and bilateral crackles, neither abdominal tenderness nor scleral icterus was present. No neurological deficits appreciated. Acute coronary syndrome was excluded. She was admitted and scheduled for hemodialysis. Admission labs showed anti-HBc positive, HBsAg positive, as well as anti-HBs positivity. Confirmatory HBV quantitative PCR testing resulted at 28 IU/ml.

Discussion: Classically, anti-HBs antibodies neutralize and clear HBsAg from peripheral blood. Therefore, the presence of anti-HBs is considered an indicator of immunity from ongoing HBV infection. The typical serological feature of chronic HBV infection is circulating HBsAg and lack of anti-HBs. However, the coexistence of HBsAg and anti-HBs has been reported to be as high as 8% of chronic HBV patients. The coexistence of HBsAg and anti-HBs has been explained by the phenomenon of "escape variation". Point mutations or deletions in the pre-S/ S gene of HBsAg may give rise to

mutant surface proteins. The detectable HBsAg is thus a mixture of wild type and variants, whereas the detectable anti-HBs are only against wild type viruses. These patients are still in the chronic HBV infection category as they typically do not progress to active disease, however acute infection is possible. Given our patient's low HBV DNA (< 10,000 IU/ ml) and mild transaminitis, she fits the chronic, inactive carrier state. Appropriate infection control precautions for HD were taken as established for chronic HBV infection patients.

PO1199

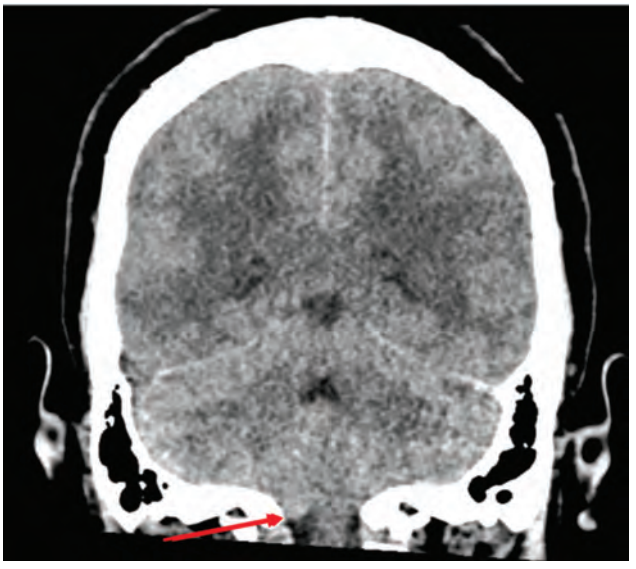
Dialysis Disequilibrium Syndrome and Cerebellar Herniation with Successful Reversal Using Mannitol

Christian C. Lamb,[2] Anna K. Curtis,[1] Amit J. Patel.[1] [1]*University of Missouri Kansas City, Kansas City, MO;* [2]*US Army Brooke Army Medical Center Medical Library, Fort Sam Houston, TX.*

Introduction: Dialysis disequilibrium syndrome (DDS) is a complication of hemodialysis. Symptoms can include headaches, seizures, and even death. An extensive literature review yielded thirteen documented reports of patients suffering from cerebral herniation secondary to DDS with poor outcomes.

Case Description: 47-year-old male with hypertension presented to the emergency department (ED) with complaints of abdominal pain. Initial laboratory studies were concerning for thrombocytopenia and acute renal failure. The patient was urgently admitted to the Intensive Care Unit (ICU) and hemodialysis was initiated. Approximately 20 minutes into the hemodialysis session, the patient became unresponsive. A right eye gaze deviation and right-sided fasciculations of the upper and lower extremities were observed. Hemodialysis was discontinued and a head CT was obtained. Imaging revealed pontine edema with mass effect and cerebellar tonsillar herniation (Figure 1). Intravenous mannitol was initiated. Within 30 minutes of initiation of the mannitol infusion, the patient regained consciousness. Follow-up neurological exam showed resolution of the right-sided fasciculations and gaze palsy. The follow-up head magnetic resonance imaging (MRI) showed resolution of the midline shift and tonsillar herniation.

Discussion: Historically, even with swift intervention, cerebral herniation due to DDS carries a grim prognosis. Current guidelines stress the importance of preventative measures and the use of IV mannitol if cerebral herniation is suspected. The case reported herein is the first documented account of reversal of the clinical and imaging findings of tonsillar herniation secondary to DDS using intravenous mannitol.



PO1200

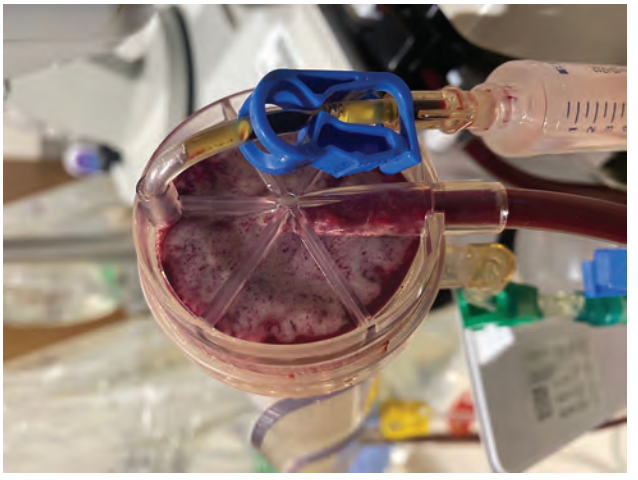
Gross and Microscopic Evidence of Platelet Clumping in the Extracorporeal Circuit Causing Thrombocytopenia in a Patient on Continuous Renal Replacement Therapy

Frank Liu,[1,2] Brian D. Robinson.[2] [1]*Rogosin Institute, New York, NY;* [2]*Weill Cornell Medicine, New York, NY.*

Introduction: Thrombocytopenia has been reported coincident with continuous renal replacement therapy (CRRT). We present a patient who developed thrombocytopenia on CRRT with gross and microscopic evidence of platelet clumping in the extracorporeal circuit.

Case Description: An 83 year old female with atrial fibrillation developed acute kidney injury requiring CRRT in the setting of ischemic bowel. Heparin was started due to suspicion of embolic phenomena. CRRT with citrate anticoagulation was begun using the NxStage System One (Purema H) without immediate issues. However, coincident with a progressive thrombocytopenia to a nadir of 75 $x10^3$/uL, the care team noticed a white substance at the venous header of the dialyzer (Figure 1). Heparin was stopped due to concern for heparin-induced thrombocytopenia. CRRT was stopped and the dialyzer was sent to Pathology for evaluation. The white substance was found to be composed of many platelets with entrapped white blood cells and red cells, consistent with platelet clot. CRRT was withheld for 2 days with improvement of platelet count from 75 to 140 $x10^3$/uL before the patient was restarted on CRRT due to clinical need; platelets subsequently decreased to 79 $x10^3$/uL with reappearance of the white substance in the dialyzer. HIT testing was negative. The patient expired several days later when her family requested comfort care.

Discussion: Thrombocytopenia is frequently seen in critically ill patients, and it is often difficult to pinpoint a specific cause. In our case, gross and microscopic evidence of platelet clumping were seen in the CRRT filter coincident with thrombocytopenia, which remitted when off and then recurred when restarted on CRRT. Care teams should examine the dialyzer carefully when there is unexplained thrombocytopenia, as platelet activation and trapping within the circuit may be responsible.



Venous header of dialyzer with representative white film

PO1201

Doctor, There Is a Blood Leak!

Deepthi C. Malepati, Sindhura Bobba, Monika Aggarwal (Gupta). *Hunter Holmes McGuire VA Medical Center, Richmond, VA.*

Introduction: Blood leak detector detects blood in the dialysate that is confirmed with a blood leak test strip. We report a case of false blood leak alarm due to hydroxocobalamin that was initially treated as a true positive blood leak due to the incorrect use of blood leak test strip, and required switching from hemodialysis (HD) to continuous veno-venous hemodialysis (CVVHD).

Case Description: 67 year old male with alcohol abuse presented with shortness of breath. Exam significant for tachycardia, confusion and respiratory distress. Laboratory data remarkable for serum potassium 3.1 meq/L, bicarbonate 6 meq/L, anion gap 45, serum osmolality 351 mosm/L, and osmolar gap 61. Serum creatinine was 2.5 mg/dl. Fomepizole and Hydroxocobalamin were given. HD with Fresenius 2008T was terminated after 2 minutes due to a blood leak alarm. Blood leak test strip (Serim Guardian) was read positive for blood. HD was reinitiated with a new setup, again triggering blood leak alarm. Effluent was pink (Figure 1.) and repeat blood leak test strip was negative at 60 seconds. Patient was successfully switched to CVVHD (Nxstage) without further blood leak alarms.

Discussion: False positive blood leak alarm was triggered due to change in the color of the effluent by hydroxocobalamin. Fresenius 2008T dialysis machine blood leak detector uses red and green light. Green light was absorbed due to the discoloration of the effluent, triggering blood leak alarm. Blood leak alarm was not triggered on NxStage, as it uses infrared wavelength, allowing continuation of dialysis. Initial blood leak test strip was read positive due to reading beyond recommended 60 seconds (subsequent test strip was negative). Correct use of blood leak test strip would have avoided second setup of HD and would have correctly identified false blood leak alarm due to hydroxocobalamin requiring switching to CVVHD.

Figure 1.

PO1202

Tailoring the Dialysis Prescription in Patients at Risk for Dialysis Disequilibrium Syndrome

Kareem Genena, Shahbaz Ahmed, Harold M. Szerlip, John C. Schwartz. *Baylor University Medical Center at Dallas, Dallas, TX.*

Introduction: The dialysis disequilibrium syndrome (DDS) is a potentially fatal, preventable syndrome in uremic patients treated with dialysis. Urea kinetics can be used to tailor the dialysis prescription to a goal urea reduction ratio (URR) of less than 40%.

Case Description: A 22-year-old female patient presented to the emergency department with severe renal failure and a failing transplant secondary to noncompliance with medications for 1 year. Serum creatinine was 32 mg/dl, blood urea nitrogen (BUN) 226 mg/dl, potassium 9.2 meq/l and serum total carbon dioxide content 6 meq/l. Intermittent hemodialysis was started using a dialyzer with a mass transfer coefficient (koA) of 1200 ml/min, a blood flow rate of 250 ml/min, a dialysate flow rate of 500 ml/min and zero ultrafiltration. She was given 12.5 g of mannitol to reduce the risk of DDS. Her weight was 60 kg. After 1.5 hours of dialysis, the patient developed generalized seizures secondary to brain edema. BUN 6 hours after dialysis was 137 mg/dl. She was declared brain dead 4 days later.

Discussion: The dialysis disequilibrium syndrome results from osmotic shifts between the blood and the brain compartments. Rapid changes in BUN are known to contribute, but other osmotic substances may contribute to the development of DDS as well. Patients at risk for DDS include those with very elevated BUN, concomitant hypernatremia, metabolic acidosis, and those with low total body water volumes. There is no absolute cut off value for URR that is guaranteed to prevent DDS. However, a URR of 40-45% over 2 hours and a total decrease in serum osmolality no more than 24 mosm/kg per 24 hours are recommended. A simplified relation between Kt/V and URR is provided by the equation: kt/V= -ln (1-URR). A URR of 40% is roughly equivalent to a kt/V of 0.5. Thus, targeting a kt/V of 0.5 is a reasonable goal for the initial treatment. k can be plotted on the nomogram in figure 1 (used with permission) for a given dialyzer koA and blood flow rate. Using a 400 koA dialyzer at a blood flow rate of 200 ml/min for 120 minutes in a patient with a V of 30 l, the estimated kt/V is 0.45 and the estimated URR is <40%. When low-efficiency dialyzers are not available, other measures to lower clearance such as reversing dialysis lines or CRRT need to be considered. Sodium modeling and mannitol may also mitigate rapid changes in osmolality.

PO1203

Association Between Serum Alkaline Phosphatase Levels and Stroke Risk in Patients Receiving Maintenance Hemodialysis: The Q-Cohort Study

Hiromasa Kitamura,[1] Shunsuke Yamada,[1] Hiroto Hiyamuta,[1] Ryusuke Yotsueda,[2] Masatomo Taniguchi,[3] Masanori Tokumoto,[4] Kazuhiko Tsuruya,[5] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Kyushu Daigaku, Fukuoka, Japan; [2]Munakata Medical Association Hospital, Munakata, Japan; [3]Fukuoka Renal Clinic, Fukuoka, Japan; [4]Fukuoka Shika Daigaku, Fukuoka, Japan; [5]Nara Kenritsu Ika Daigaku, Kashihara, Japan.*

Background: Elevated serum alkaline phosphatase (ALP) levels have been associated with increased risks of all-cause and cardiovascular mortality in patients receiving hemodialysis (HD). However, little is known about the impacts of serum ALP levels on the occurrence of stroke, including brain hemorrhage and brain infarction. This study aimed to explore the association between serum ALP levels and brain hemorrhage or brain infarction separately in HD patients.

Methods: A total of 3,497 maintenance HD patients registered in the Q-Cohort Study, a multicenter observational cohort study in Japan, were examined. The primary outcomes were the first-ever incidence of either brain hemorrhage or brain infarction during the follow-up period. The covariate of interest was serum ALP levels. Patients were divided into tertiles based on the serum ALP levels at baseline [ALP (U/L): T1, <69.3; T2, 69.3–98.4; T3, >98.4]. The risks for brain hemorrhage or brain infarction were estimated using a Cox proportional hazards model and a Fine-Gray proportional subdistribution hazards model with all-cause death as a competing risk. The restricted cubic spline model was used to plot the multivariable-adjusted association between serum ALP levels and hazard ratios (HRs) and 95% confidence intervals (CIs) for brain hemorrhage or brain infarction.

Results: During the follow-up period of four years, 89 patients developed brain hemorrhage and 195 patients developed brain infarction. The risk of brain hemorrhage in the highest tertile (T3) was significantly higher than that in the lowest tertile (T1): multivariable-adjusted HR [95% CI], 1.93 [1.15–3.35], subdistribution HR, 1.91 [1.10–3.30]. Furthermore, restricted cubic spline curves showed that higher serum ALP levels were significantly and incrementally associated with an increased risk for brain hemorrhage. In contrast, no significant association was identified between serum ALP levels and the risk of brain infarction.

Conclusions: Higher serum ALP levels were associated with an increased risk of brain hemorrhage in patients receiving maintenance HD. Our results suggest that ALP might play some roles in the pathogenesis of brain hemorrhage in HD patients.

PO1204

Effects of Improvements in Nutritional and Physical Conditions on Life Prognosis in Elderly Hemodialysis Patients in Japan

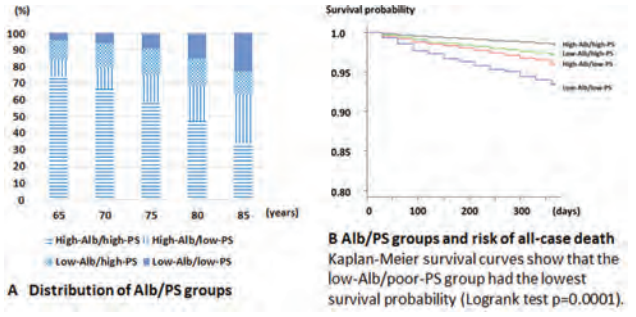
Eiichiro Kanda,[1] Akihiko Kato,[4] Yuki Tsuruta,[2] Kan Kikuchi,[3] Naoki Kashihara,[1] Masanori Abe,[5] Ikuto Masakane,[6] Kosaku Nitta,[7] Yoshihiko Kanno.[8] *[1]Kawasali Medical School, Kurashiki, Japan; [2]Tsuruta Itabashi Clinic, Itabashi, Japan; [3]Shimoochiai Clinic, Shinjuku, Japan; [4]Hamamatsu University School of Medicine, Hamamatsu, Japan; [5]Nihon University School of Medicine, Itabashi, Japan; [6]Yabuki Hospital, Yamagata, Japan; [7]Tokyo Women's Medical University, Shinjuku, Japan; [8]Tokyo Medical University, Shinjuku, Japan.*

Background: The increase in the number of elderly dialysis patients is an urgent worldwide issue. Among these patients, malnutrition and physical-function decline are often observed. Therefore, we conducted a nationwide cohort study using the elderly hemodialysis patient database (n=38227) of the Japanese Society for Dialysis Therapy to investigate the relationship of their nutritional and physical conditions with their risk of one-year death.

Methods: Malnutrition and poor performance status (PS) were defined as being indicated by low serum albumin levels, and high scores of the modified Eastern Cooperative Oncology Group PS, respectively. After a one-year follow-up of changes in these factors, the relationships between the changes in these factors and the risk of one-year death were evaluated using Cox proportional hazards models adjusted for baseline characteristics.

Results: Among the patients examined, 57.9% were males; age, 73.2±6.0 years; diabetes mellitus, 33.7%; serum albumin level, 3.7±0.3 g/dL. The prevalence of patients in the low-albumin/poor-PS group tended to increase with age: 65 to 69 years, 1.4%; 85 years or older, 22.7% (Figure A). The low-albumin/poor-PS group showed a higher risk of all-cause of death than the high-albumin/good-PS group: adjusted hazard ratio (aHR), 2.77 (95% CI, 2.24, 3.44) (Figure B). The 0.1 g/dL improvements in serum albumin levels and 1 point improvement in PS scores were independently associated with better life prognosis; aHR 0.93 (0.92, 0.95); aHR 0.76 (0.71, 0.81). These results were confirmed in subgroups categorized on the basis of age, and the presence of DM.

Conclusions: Malnutrition and PS decline are risk factors for death in elderly hemodialysis patients, and should be evaluated and treated simultaneously. It is expected that the treatments of patients with these factors will improve their life prognosis independent of their baseline characteristics.



A Distribution of Alb/PS groups

B Alb/PS groups and risk of all-case death
Kaplan-Meier survival curves show that the low-Alb/poor-PS group had the lowest survival probability (Logrank test p=0.0001).

PO1205

Ultrafiltration Accuracy of the Tablo® Hemodialysis System During 24-Hour Therapy

Michael A. Aragon, Amy Kerdok, Josh Schumacher. *Outset Medical, Inc., San Jose, CA.*

Background: Ultrafiltration (UF) accuracy is vital to ICU management of patients with kidney failure. Renal replacement options include intermittent hemodialysis, continuous renal replacement therapy and slow low efficiency dialysis. Regardless of therapy, clinicians need confidence that the dialysis device chosen will accurately remove volume to achieve the prescribed goal. The Tablo Hemodialysis System is an all-in-one system with on demand water purification and dialysate production indicated for use in clinic, hospital, and home settings. Prior reports have demonstrated UF accuracy over a wide range of conditions up to 12 hours. The objective was to report on the accuracy of Tablo's unique flow balancing technology over 24 hours of continuous therapy utilizing HD, isolated ultrafiltration, or a sequential therapy modes.

Methods: Bench testing was conducted to evaluate UF accuracy across clinically relevant parameters during a simulated 24-hour treatment with a single cartridge. Ten distinct treatment conditions were created. Effluent was weighed and compared to the prescribed goal at treatment completion. Treatment conditions included: mode (HD, UF-Only, and Sequential therapy (HD→UF only, UF only→HD), blood flow rates (Qb) from 150-400 ml/min, dialysate flow rates (Qd) from 50-300 ml/min, UF goals from 0 to 1.9 L/hr, and low to high venous and arterial pressure.

Results: Thirty simulated treatments were performed. Twenty-four treatments were performed with Qb from 150-250ml/min and 6 were performed with Qb 300 or greater. Twenty-seven treatments had fluid removal goals between 250ml/hr to 2000ml/hr and 3 treatments were performed with a UF goal of 0ml/hr. Ninety-three percent of treatments were within 20ml/hr of accuracy (< 480ml of total error). Sixty-seven percent of treatments were within 10ml/hr of the prescribed UF goal (< 240ml of total error). Blood flow and UF rate showed correlation to UF accuracy with minimum error between Qb 200-300ml/min and UF rate between 0-1000ml/hr. There was no impact to UF accuracy from treatment mode or dialysate flow rate.

Conclusions: Tablo's proprietary flow balancing technology maintains a high level of UF accuracy across a wide range of 24-hour treatment prescriptions. Optimal accuracy was noted at parameters typically prescribed in continuous renal replacement therapy.

PO1206

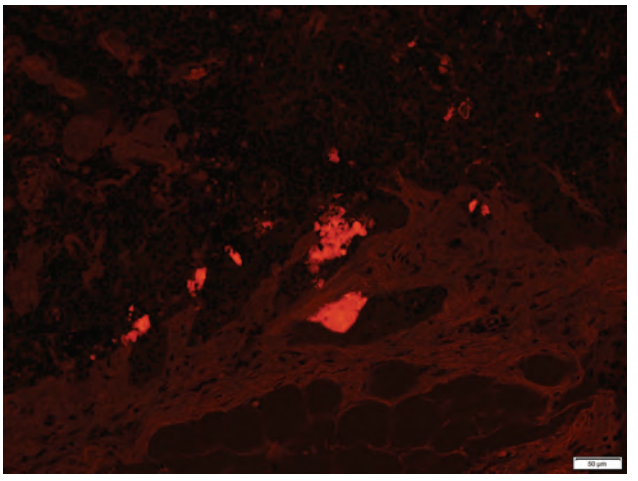
Unfavorable Vintage: Dialysis-Related Amyloidosis Discovered at Transplant

Shilpi Shah, Angelina Edwards. *University of Texas Health Science Center at Houston, Houston, TX.*

Introduction: Despite its life-sustaining potential, prolonged dialysis and inadequate clearance of middle molecules can have untoward consequences. Largely underdiagnosed, dialysis-related amyloidosis (DRA) is an effect of prolonged dialysis vintage. We present a case of DRA in a patient with nearly 25 years of dialysis-dependence, diagnosed histologically at time of transplant.

Case Description: A 60-year-old man with hypertension, on dialysis since 1996, presented for renal transplant evaluation. Hematology labs showed normal serum protein electrophoresis but elevated free kappa (κ) to lambda (λ) light chain ratio of 10.9. Bone marrow biopsy was normal but patient was found to have elevated serum β_2 microglobulin (β_2-m) at 23.6 μg/mL. He was listed and immediately received a diseased donor transplant. Intraoperatively, biopsy of a large iliac lymph node was submitted which showed Congo Red positive staining by light microscopy for amyloid but was negative for serum amyloid A (AA) and κ light chain and λ light chain (AL). Further testing identified the amyloid protein as β_2-m. Retrospective history revealed he had suffered years of joint pain, especially in his shoulders, and had bilateral carpal tunnel surgery. He was chronically dependent on hydrocodone but since transplant he no longer experienced pain. Nadir serum creatinine was 1.3 mg/dL and repeat β_2-m level decreased to 4.1 μg/mL.

Discussion: Present on all cell surfaces, β_2-m is freely filtered then reabsorbed and catabolized in proximal tubules. Prolonged reduction in glomerular filtration leads to accumulation and deposition of amyloid fibrils particularly in periarticular structures, leading to debilitating arthritis. Although no precise treatment for DRA exists, transplantation leads to renewed clearance and dramatic improvement in symptoms. This case reiterates the importance of remaining alert for such diseases in patients with prolonged dialysis vintage.



Congo Red Staining in Vessel Wall Demonstrates Amyloid Deposition

PO1207

Baclofen Pump Causing Electroencephalography Seizures

Niraj K. Yadav, Janame J. Kottey, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Baclofen is a centrally acting muscle relaxant that inhibits monosynaptic and polysynaptic reflexes at the spinal cord level resulting in relief of muscle spasticity. Baclofen is commonly used orally and intrathecally. We present the case of a patient on intrathecal baclofen through a pump presenting with respiratory failure and seizures.

Case Description: A 59 year old male with Atrial fibrillation, right MCA stroke and resultant left hemiparesis was under treatment with intrathecal baclofen through a pump. He underwent fluoroscopy guided pump refill and was found unresponsive later that night. EMS was called and he was intubated en route to the ED. He was hypotensive with recorded blood pressures 48/26-84/45 mm Hg. He had two seizures in ED and received IV lorazepam. Initial labs showed lactate 11.9 mmol/l, PCO2 80 mm hg, pH 6.9 and creatinine 2.0 mg/dl. Urine was positive for opiates and benzodiazepines. CT head did not show acute changes and was consistent with previously seen right cerebral encephalomalacia. He received intravenous fluids and creatinine improved to 0.9 mg/dl with resolving oliguria. Electroencephalography(EEG) was concerning for status epilepticus and he was transferred to our center for further management. Baclofen level was 0.13 mcg/ml. The acute encephalopathy, status epilepticus and respiratory failure were attributed to baclofen toxicity and nephrology was consulted for emergent dialysis. He underwent a 4 hour hemodialysis session using a Nipro 17H filter and maximum blood flow with dialysate flow at 600 ml/min. A post hemodialysis baclofen level was undetectable. Continuous EEG on the day after the hemodialysis session had improved.

Discussion: Role of hemodialysis in life threatening baclofen toxicity in a patient with AKI and improved renal function is not well described. Baclofen is small molecule with a molecular weight of 213g/mol that is primarily excreted unchanged by the kidneys with an apparent volume of distribution of 59 liters and is 30 percent protein bound. A single hemodialysis session may be adequate to clear baclofen in patients without advanced CKD. It is pertinent to recognize baclofen as possible cause of encephalopathy and seizures and consider hemodialysis in severe cases.

PO1208

Hep B or Not Hep B: The Mystery of Hepatitis B Serology in a Dialysis Patient

Wala Abusalah, Heather R. Lefkowitz. *Newark Beth Israel Medical Center, Newark, NJ.*

Introduction: Dialysis patients are susceptible to viral infections due to impaired cellular immunity. HepB remains a major problem in these patients. Hemodialysis, transfusions, frequent admissions and surgery, all increase risk of infections. While the introduction of vaccines and infection control measures have limited the spread of hepatitis infection within dialysis facilities, outbreaks occur and prevalence remains high. Serology testing is used to screen and identify infected patients. Interpretation of these serologies, as in our case, can be challenging.

Case Description: 83 y/o female with HTN, DM and ESRD on HD. Admitted from a NH with viral prodrome and tested +ve for COVID-19. Nephrology consult was requested for maintenance HD. She had HBsAg assay which came back positive. Full Hep B panel showed HBsAb +ve, HBcAB +ve (IgM), HepB DNA PCR –ve, HBeAg & Ab-ve. Surprisingly, old records showed HBsAg positivity 6 months prior to admission and the rest of the serology was identical to this admission. Within the last 6 months, she have had multiple HBsAg tests that all came back -ve. Up to this point, she wasnt receiving HD in dedicated HepB machines. Decision was to apply segregation and to contact the health department to trach down all patients that were dialyzed with the same machines.

Discussion: The prevalence of HepB in dialysis patients is 1%. Cirrhosis, which can result from HepB, is associated with a 35% increased mortality in dialysis patients. To prevent transmission, measures include barrier procedures, routine screening, disinfection and vaccination. Failure to use dedicated machines may increase incidence of HepB. Serology can identify infected patients. Screening consists of HBsAg, anti-HBs, and anti-HBc. Our patient's serology was unique. Her Anti-HBs was always positive. Due to anti-HBc positivity, we believe that she was infected in the past. Interestingly, the HBc-IgM was always +ve and DNA was always -ve. The occasionally positive HBsAg is bizarre. This can be seen in patients receiving vaccination but it doesn't apply to our patient. We don't have an explanation for positive HBsAg in the absence of DNA and there are no recommendations to guide clinicians in such cases. In our patient, we decided to consider her a chronic HepB patient for the purpose of dialysis segregation, however, she does not meet criteria for chronic HepB and will unlikely require treatment.

PO1209

Temporal Change in Formula-Derived Creatinine Index as a Surrogate for Lean Muscle Mass Correlates Well with Change in Post-Hemodialysis Weight but Not with the Volume of Urea Distribution

Xiao Ling, Andrew I. Chin. *University of California Davis, Sacramento, CA.*

Background: In hemodialysis (HD) patients, creatinine kinetic modeling to derive a Creatinine Index (CI) is a measure of lean muscle mass. Loss of lean muscle mass is associated with poor outcomes. This modeling process is complex and not routinely performed. A simplified formula for CI was developed in a previous study. We sought to determine if temporal change in the calculated CI using the simplified formula correlated with more commonly available data used in routine clinical care of HD patients.

Methods: We retrospectively queried long-term HD patients without residual function who had available serologic, urea kinetic, and clinical care data at least 18 months over a 24 month span. We used the simplified formula previously published for creatinine index: CI (mg/kg/day) = 16.21 + 1.12 x [1 if male, 0 if female] - 0.06 x age (yrs) – 0.08 x spKt/Vurea + 0.009 x Creat (pre-dialysis). Regression lines were created for each parameter over the 24 months. Slopes in the change of CI, post-HD wt, urea generation rate (G) and kinetic modeled distribution of urea (V) were compared by paired t-tests.

Results: We included 455 long-term HD patients without residual renal function (we measure this routinely) with at least 18 out of 24 months of complete data. Mean HD vintage was 40 months. We found the slope of CI to be poorly correlated to V or G, but did compare favorably to change over time slopes for V and post-HD weight.

Conclusions: In this retrospective analysis in HD patients, the temporal *change* of calculated Creatinine Index as an indicator of lean muscle mass compared best with *change* in post-HD weight. While the volume of urea distribution is related to body composition, the change V over time surprisingly did not mirror that of calculated CI. We also compared the slope of V to that of post-HD weight and found a strong association. The simplified equation for CI, applied to our population in Northern California, may correlate poorly with lean muscle mass.

Funding: Clinical Revenue Support

Comparisons of slope of regression lines for stated factors

	P-value of pair-wise t-test
Creatinine index (CI) to urea generation rate (G)	0.99
CI to urea distribution volume (V)	0.69
CI to post-HD weight	0.0005
V to post-HD weight	0.001

PO1210

Crit-Line Blood Volume Monitoring in a Community Hemodialysis Unit

Carl E. Dukes. *Carl E. Dukes, MD PA, San Antonio, TX.*

Background: A quality improvement (QI) project on fluid management using Crit-Line Blood Volume Monitors (CLM) was conducted by a nephrologist in one community hemodialysis unit in Texas. A goal of the QI project was to decrease the blood pressure medication burden to facilitate better ultrafiltration during treatment. This analysis examines the changes in blood pressure (BP) medication (Med) and associated changes in post-dialysis weight and systolic BP.

Methods: Chronic HD patients of the nephrologist leading the QI project, receiving care during baseline (month before QI project) and the first month of QI project follow-up were included in this analysis. Time was divided into 1-month Baseline, 3-month training period, and 7-month follow-up. The physician reviewed each Crit-Line session and directed the staff to challenge the patient's weight based on a positive refill curve. In order to facilitate further fluid removal, the vasodilating anti-hypertensive medications were discontinued. Thereafter, the other anti-hypertensive medications such as beta-blockers and RAASi agents were reduced or discontinued.

Results: Patients (n=43) were on average 63 years old, with a HD vintage of 5 years and had a fistula for vascular access (77%). 58% of patients identified as black/African American and 40% identified as Hispanic/Latino. Most patients (74%) had pre-HD systolic BP at baseline in the hypertensive range. 41 patients had BP Med information. During follow-up, 16.7% of patients discontinued BP med, 28.6% reduced BP med pills/day, 4.8% increased BP med pills/day, and the remaining had unchanged BP med. Changes in post and pre HD systolic BP and post-HD weight are presented in the table.

Conclusions: In a single-center QI project addressing fluid management through relative blood volume monitoring, 46% of patient were able to reduce (28.6%) or discontinue (16.7%) blood pressure medication. Patients able to discontinue the medications, had the largest decrease in post-HD weight.

Funding: Commercial Support - Fresenius Medical Care Renal Therapies Group

Change from baseline to last month of QIP	Unchanged BPM (n=19)	Reduced BPM (n=12)	Discontinued all BPM (n=7)	Increased BPM (n=2)
Post-HD Weight (kg)	-1.37 ± 4.57	-0.78 ± 6.77	-2.19 ± 4.44	0.18 ± 7.97
Pre-HD Systolic BP (mmHg)	0.18 + 14.5	1.8 ± 17.5	-2.7 ± 25.0	-19.4 ± 34.3
Post-HD Systolic BP (mmHg)	3.0 ± 14.2	-0.11 ± 18.2	-4.5 ± 25.4	-7.5 ± 18.2

PO1211

Effects of Combined Expanded Hemodialysis (HDx) and Hemoadsorption (HA) in Hemodialysis (HD) Patients: A Single Center's Experience

Katerina Damianaki, Dimitris Kourniotis, Zoe Alexakou, Margarita Mpora, Panagiota E. Giannou, Dimitrios I. Petras. *Nephrology Department, Hippokration General Hospital, Athens, Greece.*

Background: HDx appears to achieve a better removal performance of middle and large molecules due to the cut-off pores and the internal architecture of the membranes while recent studies have indicated the effective role of HA in reducing uremic symptoms in HD patients. The aim of our study was to assess the impact of the appliance of these two new modalities on several clinical parameters in chronic HD.

Methods: 15 HD patients (mean age=53.5 years, BMI= 26.5 kg/m^2, years on dialysis=5.5) were included. All subjects were already treated with HDx (Baxter Theranova) for 6 months. After this period, patients received combined HDx with HA (Jafron HA-130) weekly for 4 weeks and an additional combined treatment in week 12. The HA was applied in the middle-week day session for 2.5 hours. No change in their current medication was done during this period of time. Serum biomarkers were measured at baseline, at week 1, 12 and 16 (follow-up period) and included measurement of hemoglobin, platelet count, white blood cells, albumin, lipids, calcium, phosphorus, β2-microglobulin and Parathormone levels. Monthly kt/v was calculated appropriately.

Results: No statistically significantly differences were observed before and after the appliance of the combined treatment in respect of hemoglobin, white blood cells, platelets, phosphorus, Parathormone, HDL, triglycerides, albumin levels and the dialysis efficiency expressed by the monthly kt/v. However, a statistically significantly decrease of calcium levels were found between baseline levels and levels measured at the follow-up period (9.08±0.77mg/dl vs 8.37±0.66 mg/dl, p=0.005). Furthermore, LDL levels appeared to show a statistically significantly decrease until week 12 (110.33±28.99 mg/dl vs 103.00±27.19 mg/dl, p=0.048) and then a statistically significantly increase at the follow-up period (103.00±27.19 mg/dl vs 109.83±30.60 mg/dl, p=0.030). No adverse events were reported.

Conclusions: A combination of HDx and HA seems to show a potential effect in modifying lipid abnormalities in dialysis patients. These results can improve the outcome, especially in cardiovascular disease patients. However, the frequency of applying sorbent-based therapies for maintaining the desired results, needs to be evaluated and standardized in larger studies.

PO1212

Merits of Using mHealth Experience Sampling Methodology to Assess Fatigue in Chronic Hemodialysis Patients

Astrid Brys,[1,2] Maurizio Bossola,[2] Giovanni Gambaro,[3] Bert Lenaert.[1] *[1]Universiteit Maastricht, Maastricht, Netherlands; [2]Universita Cattolica del Sacro Cuore Facolta di Medicina e Chirurgia, Roma, Italy; [3]Azienda Ospedaliera Universitaria Integrata Verona Unita Operativa Nefrologia and Dialisi, Verona, Italy.*

Background: Understanding the development of fatigue and related behavioral, social and psychological factors in hemodialysis (HD) patients is crucial for the development of effective treatment. However, conventional fatigue measures provide limited insight in diurnal variations in fatigue and related factors in daily life and are prone to memory bias. The Experience Sampling Methodology (ESM) overcomes these limitations by repeatedly assessing 'real-time' symptoms in patients' natural environments. We aimed to gain in-depth understanding of HD patients' diurnal fatigue patterns and related variables using a mobile Health ESM application (*mHealth* app) and to investigate how retrospective fatigue reports correspond to real-time symptom experiences.

Methods: Forty HD patients used the *mHealth* app for seven days to assess real-time fatigue and potentially related variables, including daily activities, social company, location and mood. In addition, they retrospectively evaluated their experienced fatigue over the preceding week on an end-of-week questionnaire and the conventional Fatigue Severity Scale (FSS).

Results: Analyses of momentary observations (N=1778) revealed that fatigue as well as mood varied *between* and *within* individuals. Real-time fatigue significantly related to concurrent type of daily activity and mood. Interestingly, time-lagged analyses showed that HD treatment predicted more fatigue later in time (β=.22, p=.013), and that higher fatigue levels predicted lower mood later in time (β=.05, p=.019). Retrospective fatigue evaluation was significantly higher than the mean of real-time fatigue score, t(38)=3.54, p=.001. FSS-scores correlated moderately with mean real-time fatigue score, r=.63.

Conclusions: This study demonstrates that fatigue in chronic HD patients varies over time and increases after HD treatment, corroborating the occurrence of post-dialysis fatigue. Furthermore, our findings suggest that depressed mood may be secondary to fatigue in HD patients. Finally, retrospective fatigue evaluation overestimated real-time assessments, suggesting memory bias when using conventional fatigue measurement instruments. ESM provides novel insights and personalized information about fatigue symptoms in patients daily life, paving the way toward personalized interventions.

PO1213

Use of Triferic and Outcomes of Hemodialysis-Dependent Patients: Initial Analysis Using 2016-2017 USRDS

Yi Zhang,[1] Marc L. Hoffman,[2] Ajay Gupta.[2] *[1]MTPPI, Bethesda, MD; [2]Rockwell Medical Inc, Wixom, MI.*

Background: Use of iron oxide nanoparticles (IONP) to replace iron losses in CKD-HD patients has been associated with increased risk of infections. We have examined patient outcomes with ferric pyrophosphate citrate (FPC; Triferic®), a novel iron compound delivered via the hemodialysate, relative to the general U.S. hemodialysis patient population receiving IONPs in US Renal Data System (USRDS). A single outpatient free-standing hemodialysis center with ~57 adult CKD-HD patients between 2016 and 2017, converted to FPC in January 2017. Unadjusted all-cause and infection related hospitalizations and mortality were examined pre-FPC and post-FPC and compared with the general USRDS data during the same period.

Methods: USRS methods were utilized for calculation of the crude hospitalization and mortality rates. For each calendar study year, the period at risk begins at the later date of either January 1 or day 91 of ESRD, and censoring occurs at death, or December 31.

Results: Consistent with findings from USRDS, unadjusted all-cause hospital and mortality rates for the *general ESRD population* in 2016 were 2.12 hospital admissions, 16.0 hospital days, 0.35 infection-related admissions, 3.05 infectious hospitalization days per patient year, and 164 deaths per 1,000 patient years. Notably, patients in 2017 exhibited similar rates compared to 2016. In contrast, patients treated in the facility using Triferic experienced a reduction in both mortality and infection-related hospitalizations. Specifically, mortality rates reduced 58% from 101 per 1,000 patient-years in 2016 to 42 in 2017; infectious hospital admission reduced 73% from 0.49 admissions per patient-year in 2016 to 0.13 admissions in 2017. Furthermore, infection-related hospital days reduced 82% from 3.86 days per patient-year in 2016 to 0.71 in 2017.

Conclusions: This observational cohort study suggests that use of ferric pyrophosphate citrate as an iron replacement therapy is associated with reduction in all cause and infection-related hospitalizations and mortality. Further analysis is needed to confirm the findings from this initial analysis after controlling a variety of patient case-mix factors and dialysis center characteristics with a larger sample size.

PO1214

Association of Geriatric Nutritional Risk Index with Decline in Residual Kidney Function in Incident Hemodialysis Patients

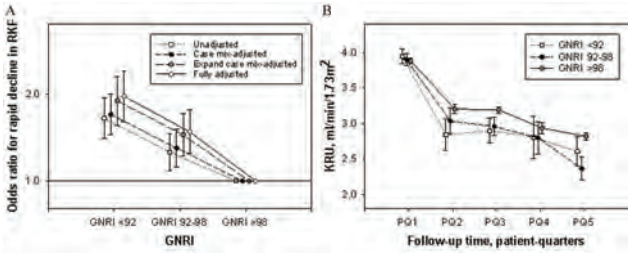
Hiroshi Kimura,[1] Cachet Wenziger,[1] Jui-Ting Hsiung,[1] Connie Rhee,[1] Elani Streja,[1] Csaba P. Kovesdy,[2,3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [3]Memphis VA Medical Center, Memphis, TN.*

Background: Malnutrition is highly prevalent and is a significant contributor to adverse outcomes among hemodialysis patients. Residual kidney function (RKF) provides effective and continuous clearance of both small and middle molecules, plays an important role in nutritional status. However, the impact of malnutrition on the decline of RKF has not been well studied. The objective of this study was to investigate the association of baseline Geriatric Nutritional Risk Index (GNRI) with a decline in RKF over 1 year after dialysis initiation among hemodialysis patients.

Methods: We included 6,649 hemodialysis patients who initiated dialysis treatment in a large United States dialysis organization between January 1, 2007, and December 31, 2011. Rapid decline in RKF was defined as the percent change in residual urea creatinine (KRU) greater than 50% per year. The associations of GNRI with decline in RKF were retrospectively examined across three strata of GNRI [low (GNRI <92), middle (GNRI 92-98), high (GNRI >98) GNRI group] using logistic regression models adjusted for clinical characteristics and laboratory valuables. Then, we used the linear mixed-effects model allowing for a random intercept and slope using unstructured covariance matrices to estimate the magnitude and decline of RKF over 1 year according to the GNRI groups

Results: The median GNRI and baseline KRU were 107.7 and 3.4 ml/min/1.73m^2, respectively. Lower GNRI was associated with a smaller proportion of diabetes, lower baseline KRU, BMI, nPCR, and serum albumin. Adjusting for patient's differences, there was an inverse relationship between lower GNRI and a higher odds of rapid decline in RKF [adjusted odds ratio: 1.97 (1.61–2.41) and 1.48 (1.25-1.76) for low and middle GNRI groups, (reference: high GNRI group]. KRU trajectories showed greater KRU decline over time in lower GNRI.

Conclusions: Lower GNRI was associated with a rapid decline in RKF, especially in the first 3 months after transitioning to hemodialysis.



PO1215

Prognostic Nutritional Index and Mortality Among Maintenance Hemodialysis Patients

Yoshikazu Miyasato,[1] Cachet Wenziger,[1] Jui-Ting Hsiung,[1] Elani Streja,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2,3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [3]Memphis VA Medical Center, Memphis, TN.*

Background: Malnutrition and inflammation are associated with the mortality of dialysis patients. Prognostic Nutritional Index (PNI), which is composed of serum albumin levels and total lymphocyte count, has been suggested as a simple and useful prognostic marker in postoperative cancer patients. We evaluated the usefulness of PNI for predicting mortality in hemodialysis patients.

Methods: This retrospective cohort study included the patients who started hemodialysis in a large U.S. dialysis organization from 2007 to 2011. We examined the association between the quartiles of PNI and mortality using Cox regression model. Besides, we compared the mortality predictability of PNI and its components (serum albumin levels and total lymphocyte count) using the receiver operating characteristic curve (AUROC), net reclassification improvement (NRI) and integrated discrimination improvement (IDI).

Results: The mean age (and standard deviation) of total 101,616 patients was 63±15 years, and 26,622 died during the median follow-up period of 1.4 years. Higher quartiles of PNI were associated with lower mortality; case-mix adjusted hazard ratios (95%CI) were 0.66 (0.64-0.68), 0.49 (0.48-0.51), 0.35 (0.34-0.37) among patients with PNI 39.5-<43.1, 43.1-<46.6, and 46.6-< (reference: PNI <39.5). PNI showed higher mortality predictability than serum albumin levels and total lymphocyte count; AUROC (95%CI); 0.746 (0.742-0.750), 0.743 (0.739-0.748), 0.711 (0.706-0.716), NRI (95%CI); 0.436 (0.418-0.454), 0.410 (0.392-0.429), 0.174 (0.156-0.192), IDI (95%CI);0.034 (0.032-0.035), 0.032 (0.030-0.033), 0.003 (0.003-0.004), respectively. The difference in the AUROC was statistically significant between PNI and its components. In subgroup analysis PNI well predicted mortality in younger than 75 year-old patients.

Conclusions: Higher PNI was associated with lower mortality in hemodialysis patients. Compared with serum albumin levels and total lymphocyte count, PNI seems to be a useful predicting marker of mortality.

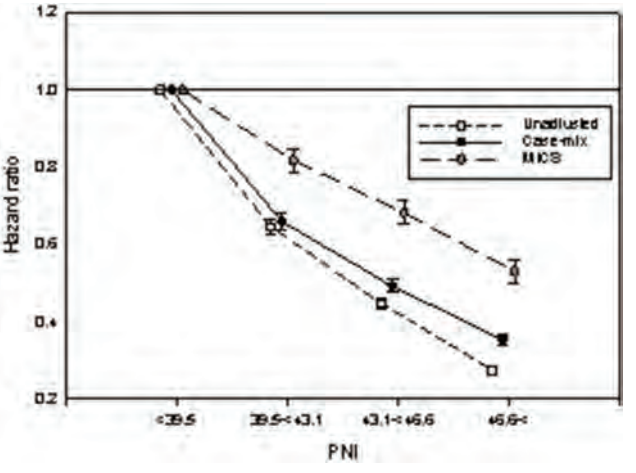


Figure: Mortality risk associated with PNI

PO1216

Hemodialysis-Assisted Management of Severe Hypoglycemia

Anirudh R. Gone, Michael J. Ross, Corinne Levitus. *Montefiore Medical Center Jack D Weiler Hospital, Bronx, NY.*

Introduction: Many medications are cleared by hemodialysis (HD)but the effectiveness of clearance depends on drug characteristics including molecular weight, protein binding, volume of distribution and water solubility. The effectiveness of HD in clearing endogenous insulin has not been well studied. We present a case of refractory hypoglycemia in a patient with ESRD, which was likely due to ciprofloxacin (cipro)-induced insulin release that was successfully managed with HD.

Case Description: A 77 year old man with ESRD receiving chronic HD and no previous history of diabetes, was admitted for management after he pulled out his tunneled HD catheter. The patient had HCV-induced cirrhosis and had been receiving outpatient cipro for spontaneous bacterial peritonitis prophylaxis. Initial electrolytes did not warrant urgent HD so was admitted to medical floor pending new HD catheter placement. During first several days after admission, the patient had persistently low blood glucose (BG) despite not receiving any hypoglycemic medications and receiving continuous infusion of dextrose solution and repeated boluses of 50% dextrose. Prior to receiving HD, serum insulin was elevated at 42 miU/ml and 148 miU/ml despite hypoglycemia and c-peptide was >40ng/ml consistent with excessive endogenous insulin secretion. The patient was suspected to have cipro-induced hyperinsulinemia. Emergently HD was performed to

increase clearance of cipro and insulin. After 1 HD session, insulin level decreased to 14.6 with improved BG levels. The patient was subsequently managed on octreotide with stable BG levels without further IV dextrose administration.

Discussion: Fluoroquinolones have been associated with hypoglycemia in diabetic and non-diabetic persons. Animal studies have suggested fluoroquinolones can block the ATP sensitive K+ channels in B-cells and increase the insulin secretion. Although our patient received his chronic dose of cipro (250mg daily), it is possible that lack dialysis for several days may have led to accumulation of cipro. The effect of HD on immune reactive insulin (IRI) was evaluated by Masanori et-al, in diabetic and non-diabetic patients. Analysis of pre and post-dialyzer samples revealed evidence of significant HD clearance of endogenous insulin. It is therefore likely that HD reduced insulin in our patient by reducing cipro-induced endogenous insulin secretion and via clearance of insulin.

PO1217

Low-Sodium Home-Delivered Meals Reduce Thirst and Xerostomia in Patients on Hemodialysis

Sadia anjum Ashrafi, Luis M. Perez, Kenneth R. Wilund. *University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: Hemodialysis (HD) patients are often advised to restrict dietary sodium and fluid. Thirst and xerostomia contribute to non-adherence with fluid restricted diets resulting in fluid retention and chronic volume overload. Dietary sodium restriction may reduce thirst and xerostomia, which may, in turn, reduce fluid intake and retention. The purpose of the study was to determine if 4-weeks of low-sodium home-delivered meals reduces HD patient's subjective thirst and xerostomia.

Methods: Twelve HD patients had 3 low sodium meals/day (Mom Meals, Inc) delivered to their homes for 4 weeks. On average they were on 17 medicines among which 7 (Mean) had prior evidence to induce xerostomia. Subjective thirst and xerostomia were measured at three time points: baseline (BL), after 4 weeks of low sodium meals (INT), and 4 weeks post-meals (POST[SAA1]). Thirst was measured using the dialysis thirst inventory scale (DTI) that had 7 domains describing thirst, and numerical rating scale for thirst (NRS-T) while xerostomia was measured with a numerical rating scale for dry mouth (NRS-X) and the xerostomia inventory scale (XI) that had 11 domains describing dry mouth symptoms.

Results: Participant's mean thirst during the day, thirst after HD, thirst's influence on social life, dry mouth feeling, total XI, NRS-T, NRS-X scores were significantly lower during INT compared to BL (Mean±SD scores from BL to INT: 3.1±1 to 2±1; 3.5±1 to 2.2±1; 2±2 to 1.3±0.9; 2.9±1 to 1.9±0.8 on the scale of 1-5; 28.5±12 to 19.3± 9 on the scale of 1-55; 6±3 to 2.8±2 and 5.5±3 to 3.1±2 on the scale of 0-10, respectfully; $p<0.05$). The score of thirst's influence on social life and NRS-T were significantly higher in POST compared to INT (Mean±SD scores from INT to POST: 1.3±0.9 to 1.7±1; 2.8±2 to 4.5±2.6; $p<0.05$). NRS-T is significantly lower in POST compared to BL (Mean±SD scores from BL to POST: 6±3 to 4.5±2.6; $p<0.05$)

Conclusions: Multiple domains of subjective thirst and xerostomia decreased after 4 weeks of home-delivered low sodium meal consumption but generally returned close to baseline 4 weeks after cessation of the meal delivery. The feasibility and efficacy of long-term meal provision for reducing thirst, xerostomia, and chronic volume overload need to be further evaluated in future studies.

PO1218

Survival Outcomes in Patients with Advanced CKD Who Opt for Dialysis Treatment or Conservative Care: A Systematic Review and Meta-Analysis

Carlijn G. Voorend,[1] Wouter Verberne,[2] Simon Mooijaart,[1] Marjolyn Van Buren,[1] Willem Jan W. Bos.[1,2] *[1]Universiteit Leiden, Leiden, Netherlands; [2]Sint Antonius Ziekenhuis, Nieuwegein, Netherlands.*

Background: Non-dialytic conservative care (CC) has been proposed as a viable treatment option for end-stage kidney disease, alternate to dialysis. This systematic review aims to compare survival outcomes on survival in dialysis and conservative care treatment pathways.

Methods: PubMed, Embase, Cochrane, CINAHL Plus and PsycINFO were searched from origin up to October 1st 2019 for studies comparing survival outcomes among patients choosing dialysis treatment or CC. Unadjusted survival for patients choosing dialysis versus CC was derived from Kaplan Meier curves. Meta-analysis was performed on outcomes of studies with limited clinical heterogeneity.

Results: From 6,126 citations, 21 observational cohort studies were included covering 20,212 adult patients. Studies varied in study design, target group, inclusion criteria (e.g. varying age groups), and starting point of survival analysis, and were receptive for selection bias and confounding. Patients opting for CC were in general older and had more comorbid conditions than patients who chose for dialysis treatment. Unadjusted median survival (reported in 16 studies) ranged from 8-67 months among patients who chose for dialysis and from 6-31 months in the CC group. Unadjusted one year survival (N=18 studies) ranged from 72% to 100% in patients choosing dialysis, and from 31% to 88% in patients choosing CC. Meta-analysis of studies (N=12) reporting survival adjusted for age, sex, and/or comorbid conditions, showed a pooled adjusted hazard ratio for death of 0.49 (95% CI 0.40-0.58) for patients choosing dialysis compared to CC. Survival benefit in patients choosing dialysis with severe comorbidities was highly reduced.

Conclusions: Observational studies, whilst heterogenous, suggest that patients who choose dialysis live twice as long as patients who opt for CC. Severe comorbidity is suggested to substantially reduce the survival benefit of dialysis compared to CC. Due to (high risk of) confounding, results should be interpreted cautiously and cannot be translated to individual patients. Future prospective data, using clear definitions and stratified for subpopulations, are critical to estimate relative survival benefit in clinical practice.

PO1219

End-of-Life Care Experiences and Beliefs Among African American Hemodialysis Patients

Daniel Ahn,[2] Milda R. Saunders.[1] *[1]UChicago Medicine, Chicago, IL; [2]University of Chicago Pritzker School of Medicine, Chicago, IL.*

Background: Prior work has shown that African Americans with end-stage renal disease (ESRD) are less likely than their White counterparts to have discussed end-of-life (EOL) care preferences with their providers, and more likely to prefer life-extending treatments. We sought to determine what demographic and institutional factors are associated with African American ESRD patients' experiences and beliefs on EOL care

Methods: Self-identifying African American adults receiving hemodialysis at three university-affiliated dialysis units completed surveys about their prior EOL care planning and preferences in various EOL situations. We used bivariable and multivariable logistic regression to analyze the association between EOL care views and several covariates including age, gender, education level, income, insurance, and previous experiences with EOL care discussions.

Results: From June to September 2019, 101 patients completed the study. The mean age was 58.7 years, 52% identified as female, and 42% have been on dialysis for >5 years. Almost 69% of patients reported they had never discussed EOL care with any healthcare provider; 95% (64/69) reported their providers never initiated EOL care conversations with them, though 37% desired them. There was no association between having past EOL care discussions and any clinical or demographic covariates. The proportion agreeing that at the EOL if was wrong to "withhold treatments," 2) "withdraw treatments," and 3) "to withhold nutrition and fluids" were 78%, 71%, and 63%, respectively. Previous experience with EOL care discussions with either family or healthcare providers was significantly associated with a decreased likelihood to prefer life-extending treatments at EOL ($p<0.05$).

Conclusions: A majority of African American patients with ESRD reported never having any EOL care discussions. Most of these patients are open to speaking about EOL care with their healthcare providers but are unwilling to initiate discussions. Furthermore, past experience with EOL care discussions with either family or medical team is associated with a decreased preference for aggressive life-extending care. Despite provider and patient discomfort with EOL care discussions, healthcare providers should address EOL care with African American patients with ESRD to identity how medical care at EOL can be more congruent with their values and needs.

PO1220

Impact of a Palliative Hemodialysis on Quality Standards and Hospice Utilization

Minna Park, Jeffrey I. Silberzweig. *Rogosin Institute, New York, NY.*

Background: Minimal data exists regarding effect of palliative dialysis on clinical outcomes and quality measure. Frail, elderly patients may find thrice weekly, 3-5 hour hemodialysis treatments burdensome. Numerous barriers exist to providing palliative dialysis, including quality standards set by the ESRD Quality Incentive Program (QIP). This study shows the impact of reduction in dialysis frequency and time on quality standards and hospice utilization in the seriously ill elderly.

Methods: A retrospective chart review was performed on four deceased patients who received palliative dialysis in one ambulatory dialysis center. Quality standards reviewed included: dialysis adequacy (Kt/V), metabolic control, nutrition, hemoglobin and ultrafiltration rate. Clinical outcomes were also reviewed.

Results: All four patients were elderly with reduced functionality, heavy symptom burden and difficulty tolerating regular hemodialysis sessions. Patients were decreased to three hour hemodialysis sessions twice weekly. Despite decreased treatment time and frequency, most quality measures did not differ from baseline. Duration of palliative dialysis ranged from 2-11 weeks. Most patients tolerated palliative dialysis, remained free of hospitalization, successfully transitioned to hospice and did not experience serious clinical issues. Lack of negative impact on quality measurements were attributed to patients poor oral intake, loss of body mass and minimal weight gains between dialysis sessions. Patients were observed to have a better quality of life and better utilization of time with family.

Conclusions: Palliative care, incorporating the patient and family, appears to be a good option for patients and families who are not ready to withdraw from dialysis. Palliative dialysis allows patients a slower transition to end-of-life care with more support and proper preparation in line with patients' wishes. In addition, with our recent experiences with covid 19 infections, this practice might be a possible option for someone with serious illness, hoping to avoid unwanted hospitalization and aggressive medical treatment. Goals of care conversation, timely plan of care for transition of care and close monitoring of patients are essential for palliative dialysis.

PO1221

Surprise Question: A Mortality Predictor in Hemodialysis Patients?

Patrícia Valerio,[1,2] Ana Farinha.[1,2] [1]*Centro Hospitalar de Setubal EPE, Setubal, Portugal;* [2]*Fresenius Medical Care Portugal, Setubal, Portugal.*

Background: Surprise question (SQ), used in Palliative Care (PC) and Oncology, has already been tested to assess prognosis in several chronic diseases. In Portugal, as worldwide, an elderly and fragile hemodialysis (HD) population has been emerging. Tools to screen patients who might benefit from end of life care would be useful. The present study aims to test SQ mortality prediction value in a Portuguese cohort of HD patients, answered by nephrologists and nurses. The study ran between November 2018 and November 2019.

Methods: We design an observational prospective study. All patients on regular HD for more than 3 months were included. Experienced nephrologists and dialysis nurses, but without PC training, answered SQ at the beginning of the follow-up. We collected demographic, clinical and analytical data. At the end of follow-up, we analyzed evolution during follow-up and survival status.

Results: We included 194 patients, median age of 69.9 y-o. Median age-adjusted Charlson Comorbidity Index (aCCI) was 6 (5-8). Table 1. After one year of follow-up 22 (11.3%) patients have died. Nephrologist and nurse SQ were both good predictors for mortality within one year, with an OR 7.44 (IC95% 2.92-20.74) and 8.47 (IC95% 3.00-30.34) respectively (both with a p-value <0.001). Institutionalization, aCCI, albuminemia and hospital admissions during follow-up also seems to be important predictors. Table 2. With multivariate analysis, SQ for nephrologists and nurses are no longer statistically significant: OR 1.25 (IC95% 0.31-5.11) and 3.09 (IC95% 0.81-11.86), respectively.

Conclusions: Our results showed that SQ answered by nephrologist and nurse are not good mortality predictors, reflecting this method subjectivity and the lack of PC training. Probably, SQ should be reserved to professionals with PC training, a profound gap in nephrologists training in Portugal.

Characteristic		Total patients (n=194)
	Age (years)	69.9 (58.4-77.8)
	Male Gender	122 (62.9%)
Race	Caucasian	177 (91.2%)
	Black	12 (6.2%)
	Other	5 (2.6%)
	Institutionalization	17 (8.8%)
Social support	Household	133 (68.6%)
	Single-handed	44 (22.7%)
	Elderly home	17 (8.8%)
Education	Compulsory education	156 (80.4%)
	Illiterate	21 (10.8%)
	High	17 (8.8%)
Kidney disease etiology	Indeterminate	37 (19.1%)
	Diabetes *Mellitus*	35 (18.0%)
	Tubulo-interstitial disease	29 (14.9%)
	Hypertension	26 (13.4%)
	Glomerular disease	21 (10.8%)
	Hereditary cystic disease	20 (10.3%)
	Others	26 (13.5%)
	aCCI	6 (5-8)
	Peripheric arterial disease	68 (35.1%)
	Diabetes Mellitus	67 (34.5%)
	Total RRT time (months)	117 (51.6-272.4)
	Candidate to kidney transplant	24 (12.4%)
	Albumin (g/dL)	4.1 (3.8-4.3)
	PTHi (ng/dL)	380.5 (200.1-668.1)
	Hemoglobin (g/dL)	11.1 ±1.3
	Ferritine (ug/L)	514.6 (368.1-648.5)
	Kt/V	1.7 ± 0.3
	Dry weight (Kg)	65.2 (57.6-75.0)
	HD adherence	183 (94.8%)
	Catheter (beginning of follow-up)	18 (9.3%)
	Need for VA interventions (during follow-up)	57 (29.4%)
	Hospital admissions (during follow-up)	38 (19.6%)

PO1222

Code Status Variability in a Regional Hemodialysis Program

Danielle Moorman, Samuel A. Silver, Hasitha Welihinda, Eduard A. Iliescu. *Queen's University, Kingston, ON, Canada.*

Background: Patients with end stage kidney disease (ESKD) treated with hemodialysis (HD) have poor life expectancy and may not benefit from aggressive measures at the end of life. Previous studies suggest variability in Do Not Resuscitate (DNR) orders in patients treatd with HD but they are limited by missing code statuses and inability to adjust for demographics. In our regional HD program, with complete code status ascertainment that is updated annually, our objective was to examine DNR variability while accounting for demographic factors.

Methods: We conducted a cross-sectional study of DNR prevalence in October 2019 in patients treated with in-centre HD in a regional program, which consists of a main centre and six smaller centers. Patients are transferred to smaller centres based on location. Each centre has an attending nephrologist who reviews code status yearly with every patient. Unadjusted DNR prevalance are compared using the Chi-square test and multiple logistic regression is used to control for covariates (age, sex, race, dialysis vintage, HD unit).

Results: We included 374 patients, 193 (52%) from the main centre and 181 (48%) from its satelite units. Mean age of patients is 67.2±14.3 years, 52% male, 87% Caucasian, and dialysis vintage 5.2±5.5 years. Code status was full code in 78% and DNR in 22% with significant variation across sites (range of 9% to 44%, p = 0.02) (Figure 1). Variation remained significant (p = 0.03) after controlling for covariates.

Conclusions: Variability in code status at different HD centres in our regional program persisted despite accounting for differences in patient age, sex, race, and HD vintage. This finding suggests factors related to the HD centre may affect code status decisions, such as local culture, question phrasing, and views of the treating nephrologist. Future studies are planned to determine if a standardized approach to discussing code status would normalize rates.

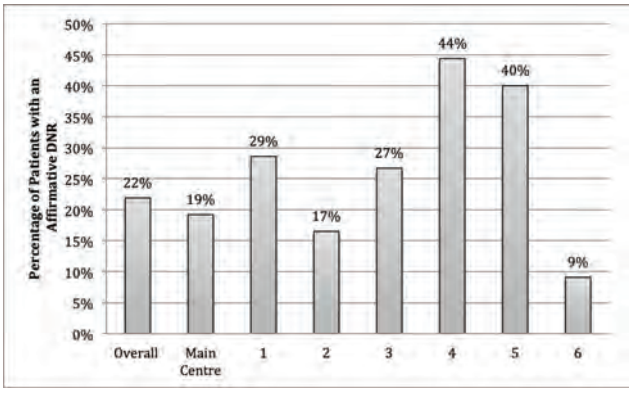

Figure 1: Unadjusted DNR prevalence in hemodialysis units across a regional dialysis program.

PO1223

Polypharmacy and Frailty Among Hemodialysis Patients

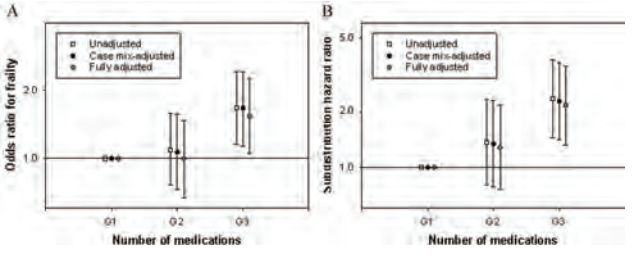
Hiroshi Kimura, John Sy, Connie Rhee, Elani Streja, Kamyar Kalantar-Zadeh. *Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA.*

Background: Most patients undergoing maintenance dialysis have multiple comorbidities, most of which require long term medication management and can inevitably lead to polypharmacy. Frailty is also highly prevalent among dialysis patients and has been associated with poor outcomes. With higher frailty and comorbidity rates among dialysis patients, it remains unclear if polypharmacy is still associated with the incidence of frailty among dialysis patients. The aim of this study was to examine the independent association between polypharmacy and frailty among hemodialysis patients.

Methods: We examined 337 patients enrolled in the ACTIVE/ADIPOSE dialysis cohort study. The number of prescribed medications and frailty were assessed at baseline, 12, and 24 months. We used logistic regression with generalized estimating equations to model the association of the number of medications and frailty over time; competing-risks regression to assess incidence of frailty.

Results: The mean number of medications was 10 ± 5, and 94 patients (28%) were frail at baseline. Patients taking greater than 11 medications showed higher odds for frailty as compared with patients taking less than 8 medications (OR 1.54, 95% CI 1.05-2.26). During two years of follow-up, 87 patients developed frailty among the non-frail patients at baseline. Compared with patients taking less than 8 medications, the incidence of frailty was approximately 2-fold in those taking greater than 11 medications (sub-distribution hazard ratio [SHR] 2.15, 95% CI 1.32-3.48).

Conclusions: Using a higher number of medications was associated with frailty and the incidence of frailty among hemodialysis patients. Minimizing polypharmacy may reduce the incidence and prevalence of frailty among dialysis patients.



PO1224

Optimal Patient Positioning for Chest Compressions in Dialysis Clinics: A Randomized Cross-Over Simulation Study

Patrick H. Pun,[1,2] Kevin T. McNamara.[3] *[1]Duke University School of Medicine, Durham, NC; [2]Duke Clinical Research Institute, Durham, NC; [3]Durham Veterans Administration Medical Center, Durham, NC.*

Background: Sudden cardiac arrest is the leading cause of death for hemodialysis patients, and often occurs during treatment in hemodialysis units. Resuscitation guidelines emphasize the need for rapid delivery of effective chest compressions to improve survival. How different methods of patient positioning (in the dialysis chair or on the floor) affects chest compression quality is unknown.

Methods: This was a prospective randomized cross-over study to assess the quality of chest compressions performed on a simulation manikin(Laerdal SimMan3G). Dialysis staff were recruited from a single center and asked to perform 2 minutes of compressions on the manikin positioned: 1) on a gurney with a code-cart backboard (baseline); 2) on the floor; 3) in a reclined dialysis chair; and 4) in a reclined dialysis chair with a backboard placed underneath. The sequence of manikin positions was randomized to reduce carryover effects and assessments were conducted ≥48 hours apart to reduce participant fatigue. Mean compression depth, %compressions at appropriate depth, %compressions fully released and %compressions at adequate rate were assessed for each position and for each participant. Paired sample T-tests were performed to assess the mean differences in compression measures between positions and baseline.

Results: 13 dialysis staff members including 7 RNs, 3 MITs and 3 providers participated in the study. Compared to baseline, mean compression depth (-6.5 mm) and % compressions fully released (-26%) were significantly worse for compressions performed in the dialysis chair, and quality reductions persisted even when a backboard was utilized in the dialysis chair (see Figure 1). No significant differences in compression quality measures were observed with manikin positioning on the floor compared to baseline.

Conclusions: Performing CPR in a reclining dialysis chair results in significant reductions in CPR quality. This should be considered in developing dialysis-specific CPR protocols, and further studies should investigate the relative merits of different patient positioning options for optimal CPR delivery.

The Plasma Factor Beta-2 Microglobulin Drives Cognitive Impairment in ESRD

Eva Czirr, David Le, Cindy F. Yang, Shreya Chand, Jyotasana Gulati, Scott C. Lohr, Sakura Minami. *Alkahest Inc, San Carlos, CA.*

Background: Our goal is to decode changes in the plasma proteome in age and disease to identify novel therapeutic targets. We and others have shown that administration of aged human plasma in young immunodeficient mice results in impaired neurogenesis and cognition. We are now extending these findings to plasma from end-stage renal disease (ESRD) subjects undergoing hemodialysis (HD). The prevalence of chronic kidney disease increases with age, and hemodialysis patients have a high incidence of cognitive impairment. The causes for this cognitive impairment are not fully understood and we hypothesize that plasma proteins, specifically beta-2 microglobulin (b2M) are a contributing factor. B2M has been identified as a detrimental pro-aging factor in mice, however aging increases b2M levels moderately by about 1.5 – 2-fold, while they are elevated up to 80-fold in ESRD-HD.

Methods: Plasma was collected from healthy controls and matched ESRD-HD subjects. HD plasma was depleted of b2M by AKST1210, a b2M removal device. Proteomic analysis was performed using affinity-based and mass spectrometry platforms. Plasma was administered IV into young immunodeficient NSG (NOD.Cg-Prkdc^{scid} Il2rg^{tm1Wjl}/SzJ) mice, followed by behavioral testing, and histological and molecular analysis. B2M was administered IP to wild-type (WT; C57BL/6) mice, followed by similar analyses.

Results: Injection of ESRD-HD plasma into young NSG mice resulted in cognitive impairment and molecular changes in the brain. Proteomic analysis of the plasma revealed many changes, with b2M as one of the most elevated proteins. We found that peripheral b2M injections lead to concentration dependent changes in cognition, neurogenesis, and synapse density. When we depleted plasma from ESRD-HD subjects using AKST1210 b2M levels were highly reduced and the proteomic profile was shifted towards healthy control plasma. Injection of depleted plasma into young NSG mice rescued some of the detrimental changes caused by undepleted plasma suggesting that removal of b2M has beneficial effects.

Conclusions: Taken together, our data shows that plasma-derived factors can impact cognition and suggests that accumulation of detrimental factors such as b2M contributes to the high incidence of cognitive deficits in ESRD-HD subjects.

PO1226

Association Among Iron, Coronary Artery Calcification, and Mortality in Hemodialysis Patients

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Toshiki Doi,[3,1] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Kohji Usui,[2] Shigehiro Doi,[3] Takao Masaki.[3] Ichiyokai, Hiroshima, Japan *[1]Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [3]Hiroshima University Hospital, Hiroshima, Japan.*

Background: Coronary artery calcification (CAC) is recognized as one of the main causes of cardiovascular disease and death in hemodialysis (HD) patients. It had been suggested that iron may be related to vascular calcification (Balla et al. Pharmaceuticals. 2019;12:96). This study aimed to investigate the association among iron, CAC, and mortality in HD patients.

Methods: This study included 173 HD patients. Clinical data and Agatston's coronary artery calcification score (CACS) were obtained at baseline. Two groups comprised patients with CACS ≥400 (n=109) and patients with CACS <400 (n=64). Logistic regression analyses for CACS ≥400 and Kaplan-Meier survival and Cox proportional hazard analyses were conducted.

Results: The median (interquartile range) age and dialysis vintage among all subjects were 67 (60–75) years and 73 (37–138) months, respectively. Serum iron (Fe) and transferrin saturation (TSAT) levels were significantly lower, but age, dialysis vintage, C-reactive protein (CRP), and albumin-adjusted serum calcium (Ca) levels were significantly higher in patients with CACS ≥400 than in patients with CACS <400 ($P<0.05$). No significant differences in the dosage of phosphate binders, active vitamin D, cinacalcet, and iron were observed. In the univariate logistic regression analysis, CACS ≥400 had a significant association with TSAT ≥20%, Fe ≥80 μg/dL, age, and dialysis vintage ($P<0.05$). In the subsequent multivariate analysis, including all variables that showed significance in the univariate analysis, excluding Fe ≥80 μg/dL, and well-known risk factors for coronary artery calcification in HD patients (diabetes mellitus, Ca, phosphate, and CRP), TSAT ≥20% remained independently and significantly associated with CACS ≥400 (odds ratio 0.44, $P<0.05$). HD patients with Fe ≥80 μg/dL showed significantly higher 5-year survival. However, patients with serum ferritin ≥36.6 ng/mL (median ferritin value in this study) showed significantly lower 5-year survival than patients with ferritin <36.6 ng/mL, and ferritin ≥36.6 ng/mL was a significant predictor of 5-year all-cause mortality in HD patients (hazard ratio: 2.71, $P<0.05$).

Conclusions: In HD patients, there is an association among iron, CAC, and mortality, and TSAT ≥20% was found to be an independent and significant factor in the prevention of CACS ≥400.

PO1227

Valvular Heart Disease in Prevalent Haemodialysis Patients

Mohamed Elewa,[1,2] Anuradha Jayanti.[1] *[1]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [2]Ain Shams University Hospital, Cairo, Egypt.*

Background: Valvular heart disease is observed in patients with Chronic Kidney Disease. Previous large studies found a prevalence rate of 14%-16% of valvular heart disease (VHD) in haemodialysis patients *(2018 USRDS; Hickson et al., 2016)*. KDIGO consensus group identified several evidence gaps where research is necessary in order to improve our understanding of diagnosis and management of VHD. The aim of our study is to assess the burden of VHD in a haemodialysis cohort in one center in the UK.

Methods: A single-center; retrospective, cross-sectional study of echocardiographic findings in prevalent haemodialysis patients. Patients were considered to have VHD if they had significant aortic or mitral valve disease (AVD, MVD) based on standard echocardiographic criteria. Medical records were reviewed for clinical information.

Results: This study included 425 haemodialysis recipients. Mean age was 61 years, (*SD: 14.96*). The cohort was predominantly male (*59.3%*). The mean BMI was 27.69 (*SD: 5.99*). 37.1% had a history of smoking. The median renal replacement therapy vintage was 3.19 years [*IQR: 1.99, 6.33*], with median haemodialysis vintage of 2.93 years [*IQR: 1.76, 5*]. 83% of patients had hypertension, 41% had diabetes, 29% had coronary artery disease (CAD) and 13% had a history of congestive cardiac failure (CCF). Atrial Fibrillation (AF) was present in 11.5%. 34% (n=143) had evidence of VHD. 18% had evidence of AVD (n=78); Aortic Regurgitation in 11%, and Aortic Stenosis in 7% of patients. 20% of patients (n=85) had MVD with Mitral Regurgitation in 18% of patients and Mitral Stenosis in 0.7% (n=3). 5% of patients had cardiothoracic intervention (n=21) for VHD. Compared to patients who had no evidence of VHD, those with VHD were significantly older ($p<0.001$), had lower relative BMI ($p=0.001$), and had co-existing AF, CAD and CCF ($p<0.05$). These patients had a significantly longer dialysis vintage ($p=0.001$). Patients, who had VHD, had a tendency to higher serum calcium, although this did not reach statistical significance ($p=0.057$). Similarly, diabetes was also higher in the non-VHD cohort (*44.3% vs 34.3%, $p=0.059$*).

Conclusions: 34% of patients had significant VHD, higher than the previously published figures. The lower prevalence of diabetes in the VHD cohort makes the metabolic milieu an additional important risk factor in VHD. Timely echocardiographic studies are essential to identify patients with significant VHD.

PO1228

The Effect of Intradialytic Potassium and Magnesium Fluctuations on Cardiovascular Functioning in ESRD Patients Undergoing In-Center Hemodialysis

Andy Chuu,[1] Gonzalo Matzumura Umemoto,[1] Michael I. Rauchman,[2,1] Frank J. O Brien.[1] *[1]Washington University in Saint Louis, Saint Louis, MO; [2]Saint Louis VA Medical Center John Cochran Division, Saint Louis, MO.*

Background: Patients with ESRD receiving in-center hemodialysis (HD) have an age-adjusted rate of mortality 4 times the general population. Increased mortality has been attributed to fatal arrhythmias. Mechanisms and risk factors for this are unknown. It has been postulated that changes in serum levels of Potassium(K)/Magnesium(Mg) with HD contribute to arrhythmia generation. Limited data is available to guide personalization of K prescription of HD to reduce this risk. No data exists describing the serum changes in Mg pre-, intra-, and post-HD. We examine the correlation between electrolyte fluctuations, arrhythmia generation, and heart rate variability (HRV) in ESRD patients undergoing in-center HD.

Methods: Single center, prospective, cross-sectional pilot study. 25 patients enrolled to achieve an 80% power. Demographic data, dialysis vintage, and HD prescription were recorded. Arrhythmia data was collected by placement of Holter monitor prior to 1st weekly HD session and recorded continuously for 5 days ending at completion of 3rd weekly HD session. Serum samples were obtained at time intervals 30, 60, 90, and 120 minutes during 1st weekly HD session for electrolytes. Pre and Post HD serum electrolyte analysis occurred during all 3 treatments. Associations were examined by count regression utilizing Poisson or negative binomial methods.

Results: 25 patients were included in data analysis. Mean age 63 and primarily African American (73%). 73% of individuals were dialyzed utilizing 2mmol/L. Ectopy data and serum potassium / magnesium data are summarized in Table 1.

Conclusions: There is a trend towards increased ectopy (particularly on HD day 1) and decreased HRV on HD days. There is a trend towards hypo-K post-HD after HD sessions 2 and 3. Serum Mg levels remained stable pre and post HD throughout all HD sessions. Data derived in this study will be utilized to guide a larger future study with the goal towards personalized HD treatments.

Results

	# Hypokalemia (n)	Mean Pre K (mmol/L)(std)	Mean Post K (mmol/L)(std)	Mean Pre Mg (mmol/L)(std)	Mean Post Mg (mmol/L)(std)

Human Factors Testing of the Quanta SC+ Haemodialysis System: Demonstrating Ease of Use with Minimal Upfront Training in Health Care Practitioners and Patients

Paul Komenda, John Milad, Kathryn Compton. *Quanta Dialysis Technologies, Alcester, United Kingdom.*

Background: Quanta Dialysis Technologies has developed a compact, powerful personal haemodialysis system intended for home and self-care use designed in collaboration with patients and healthcare practitioners. Human factors testing is necessary to demonstrate ease of use with minimal up-front training.

Methods: In compliance with FDA guidance and EU standards, the user interface of the system was evaluated through human factors testing to assess the safe and effective use of SC+. This included a series of user-based tasks whereby representative users independently setup SC+ into a simulated treatment, managed alarms to resolution and external SC+ cleaning/disinfection. All participants received an introduction to SC+ and completed a competency sign off at the end of training. 15 healthcare professionals (6 renal nurses, 8 dialysis technicians, 1 patient care technician) received up to 4 hours of structured training followed by a 1-day learning decay period. In addition, 10 lay users (8 dialysis patients, 2 caregivers) received between 5.5 and 7.5 hours training followed by a 2-day learning decay period.

Results: Between the two user groups, there were a total of 8,110 opportunities for use errors to occur. Despite minimal training and representative learning decay, only 4 significant use events were observed requiring some user manual enhancements. Other use errors captured were minor or could not be mitigated further due to clinical practices and shared inherent risks across all haemodialysis systems.

Conclusions: The results of the human factors testing demonstrated that healthcare practitioners, patients and caregivers successfully operated SC+ independently with a high level of use safety, despite minimal training and learning decay. The SC+ user interface is optimised for safe and effective use under FDA guidance and EU standards.

PO1230

Inpatient Dialysis Provider Type and Duration of Hospital Admissions of Dialysis Patients

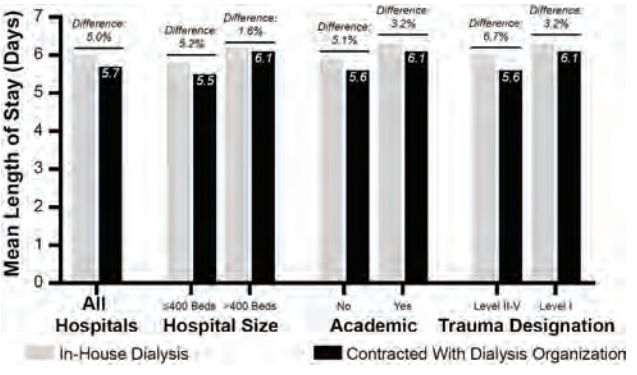
Joshua W. Morrison, Daniel Liu, David L. Mahoney, Jeffrey A. Giullian. *DaVita Inc, Denver, CO.*

Background: Inpatient dialysis treatments may be performed by hospital staff or by a contracted dialysis provider. In this study, we compared duration of hospitalizations of dialysis patients who were admitted to hospitals performing in-house dialysis to that of patients who were admitted to hospitals contracting with a dialysis provider.

Methods: Data for this analysis were derived from the electronic medical records of a large dialysis organization. We identified patients who were hospitalized between Jan 2017 and Sept 2019. Length of stay was compared for patients who were admitted to hospitals performing dialysis in-house versus patients who were admitted to hospitals that contracted with the dialysis organization.

Results: During the study period, we identified 155,458 hospitalizations among 64,662 patients at 572 hospitals in which dialysis was performed by in-house staff. There were 226,059 hospitalizations among 87,213 patients at 797 hospitals in which dialysis was performed by the dialysis organization. There were no meaningful differences in patient characteristics or reasons for admission among patients admitted to hospitals performing dialysis in-house compared to those of patients admitted to hospitals contracting with the dialysis organization. The mean length of stay for patients admitted to hospitals providing dialysis in-house was 6.0 days versus 5.7 days for patients admitted to hospitals contracting with the dialysis organization, a difference of 5.0%. We made similar observations for hospitals with ≤400 beds, hospitals that were not affiliated with an academic medical center, and hospitals designated trauma levels II to V. These differences were attenuated at hospitals with >400 beds, academic medical centers, and level I trauma hospitals.

Conclusions: These results suggest that use of a contracted dialysis organization may shorten the length of stay for patients who require dialysis during hospital admissions and this trend was more pronounced in smaller, non–university-affiliated hospitals.



PO1231

The Impact of CRRT Modality on Filter Life

Lewis Mann, Iiro Honkanen, Rebecca L. Hegeman, Chou-Long Huang, Prerna Kumar, Swe Zin Mar Winhtutoo, Christie P. Thomas, Melissa L. Swee, Benjamin R. Griffin. *University of Iowa, Iowa City, IA.*

Background: Increasing CRRT filter lifespan would save money, decrease iatrogenic blood loss, increase the time CRRT is actively running, and waste less nursing time. Filter clotting is a common reason for filter loss that can potentially be reduced. CRRT can be performed using convective clearance as in CVVH or diffusive clearance as in CVVHD. Whether convection or diffusion prolongs filter life over the other is unknown, but there are plausible arguments for both. CVVHD has no significant hemoconcentration within the circuit, whereas CVVH is subject to hemoconcentration as fluid is removed across the filter. However, pre-filter CVVH results in hemodilution prior to entering the filter that may mitigate the effects of the filter hemoconcentration. We hypothesize that filter life is longer in patients treated with CVVHD than CVVH.

Methods: In this unblinded prospective randomized trial, patients are assigned to either pre-filter CVVH or CVVHD. The standard treatment protocol at the University of Iowa is to use citrate anticoagulation with a blood flow rate of 200 mL/min and a dose of 25 mL/kg/hr. Using a power of 0.8 and an alpha of 5%, and historical filter loss attributable to clotting of 60%, a total of 1,010 filters are needed to show a hazard ratio of at least 1.3 for filter loss. The primary outcome is average filter life, and secondary outcomes are mortality, intensive care unit LOS, hospital LOS, and renal recovery.

Results: Beginning March 25, 2020, we have enrolled 30 patients using a total of 90 filters (Table 1). The average filter life in CVVH filters is 36.8 ± 26.8, compared to 37.0 ± 31.9 hours in CVVHD filters (p=NS).

Conclusions: Data from 2 months of a planned 12-month prospective study comparing filter life in CVVH vs CVVHD shows no significant difference in filter life.

Table 1: Patient characteristics

	CVVH (n=15)	CVVHD (n=15)	p value
Age	58.7 +/- 16.5	54.3 +/- 14.8	0.45
Male (%)	9 (60%)	9 (60%)	1.00
Caucasian (%)	9 (60%)	9 (60%)	0.30
Hispanic (%)	4 (27%)	4 (27%)	0.30
Black (%)	2 (13%)	1 (6.7%)	0.30
SOFA	11.5 +/- 2.12	9.1 +/- 2.67	0.011
COVID Positive (%)	3 (20%)	4 (27%)	0.66
Diabetes (%)	7 (47%)	9 (60%)	0.48
CAD / HF (%)	5 (33%)	3 (20%)	0.43

Acute Dialysis in a High-Dependency Unit: A New Service with a Long-Term Legacy

Nasreen Samad,[1,2] Franel Ave,[1] Nick Lever,[2] Ian R. Carrasco Barber.[2] *[1]Barts Health NHS Trust, London, United Kingdom; [2]Queens Hospital, London, United Kingdom.*

Background: Continuous Renal Replacement Therapy (CRRT) in the intensive care unit (ICU) was stretched to the limit during the COVID-19 pandemic. COVID-19 was commonly associated with dialysis requiring Acute Kidney Injury (AKI) in patients admitted to ICU, in addition to chronic dialysis patients with COVID-19 requiring ICU admission. During the peak of COVID-19 there was a critical national shortage of consumables and dialysis fluids In the United Kingdom (UK) required for CRRT in ICU. The ICU service at Queens hospital, Romford, UK was no exception with the need to develop a viable urgent alternative therapy. A modified prolonged intermittent haemodialysis treatment 4-8 hours every day in selected patients was set up in the high dependency unit. This method required the installation of additional equipment and staff training.

Methods: During the peak of the COVID-19 pandemic, 5 beds in HDU were created with mobile reverse osmosis (RO) units to provide acute dialysis. Within 10 days of service approval, the dedicated area in HDU was equipped with all necessary plumbing work, machines and consumables. In the interim nursing training was provided by the senior dialysis nurse from the satellite dialysis unit based in the hospital who also supervised all sessions of dialysis 6 days a week. Patients selected were relatively stable with or without the need for assisted ventilation and inotrope requirement with Noradrenaline up to 0.6mcg/kg/min. Dialysis treatmeant was provided 6 days week for 4-8 hours per session.

Results: 12 COVID-19 patients received haemodialysis in the newly established HDU dialysis unit between 30th April to 30th May 2020. 5 had AKI associated with COVID-19 and 7 COVID-19 patients were on chronic dialysis. Total 72 sessions were provided (range 1- 19 sessions per patient). Of the 12 patients 4 died, of whom 2 with AKI and 2 were on chronic dialysis. Of remaining 8, 5 patients were on chronic haemodialysis while 2 AKI patients continue to require haemodialysis and one became dialysis independent.

Conclusions: Prolonged intermittent renal replacement therapy in HDU was a viable alternative during the COVID-19 pandemic. The process was safe and manageable. The resources acquired during COVID-19 pandemic can be utilised in managing AKI and acutely ill chronic dialysis patients in a hospital where this service was not available before the pandemic.

PO1233

Predictors of 30-Day Hospital Readmission Among Minority ESRD Patients Receiving Maintenance Hemodialysis

Dhakrit "Jesse" Rungkitwattanakul, Chiemena Ohanele, Nkiruka Emezienna, Mary K. Maneno, Monika N. Daftary. *Howard University College of Pharmacy, Washington, DC.*

Background: End-stage renal disease (ESRD) is one of the most prominent disparities as racial/ethnic minorities are 1.5-4 times more likely than others to develop ESRD. Among patients with ESRD receiving hemodialysis, more than 1/3 of hospital discharges are followed by a readmission within 30 days. These subsequent readmissions are associated with increased healthcare costs and poor health outcomes. Therefore, knowing the incidence and risk factors for readmission are crucial steps needed for necessary prevention. This retrospective study aims to identify predictors within inpatient and outpatient care that contribute to 30-day hospital readmissions among minority ESRD patients receiving maintenance hemodialysis within an outpatient dialysis center located in the District of Columbia.

Methods: Data from electronic medical records were taken for patients who have had an unplanned hospital admission between January 1, 2017 and August 31, 2019. Descriptive statistical analysis was conducted for all study variables. Univariate and multivariable logistic regression analyses with 30-day readmission as the dependent outcome were conducted to identify and assess predictors of 30-day readmissions.

Results: A total of 96 patients were included in the study. Among these patients, 49 (51%) had 30-day hospital readmission. Overall, patients were predominantly African American (86.5%), age between the age of 60-69 (29.2%), and with a diagnosis of hypertension (89.6%). A diagnosis of secondary hyperparathyroidism, serum calcium < 8.5mg/dL at time of discharge, and serum PTH < 150pg/mL at time of discharge were significantly associated with higher readmission rates in multivariable analyses ($p < 0.05$). Gender, race, a weekend discharge, and serum phosphate at time of discharge were not associated with 30-day readmission.

Conclusions: Overall, the study findings provide some insight into risk factors associated with 30-day readmissions in minority patients receiving maintenance hemodialysis. These findings suggest that secondary hyperparathyroidism and chronic kidney disease mineral bone disorder (CKD-MBD) markers predict readmissions. Identifying inpatient and outpatient strategies to mitigate risks and prevent readmissions may improve outcomes among this high-risk ESRD population.

PO1234

Role of Lung Ultrasonography to Predict Intradialytic Hypotension in ICU Patients

Yuriy Khanin, Daniel Stalbow, Jamie S. Hirsch, Daniel W. Ross. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: Lung ultrasonography has emerged as a valuable tool in the assessment of volume status in hemodialysis (HD) patients. A-line profile noted on lung ultrasonography denotes low wedge pressure while B-line profile is associated with hypervolemia. We hypothesized that patients with A-line profile are more likely to experience intradialytic hypotension (IDH).

Methods: We identified all patients admitted to the Medical ICU at two tertiary care facilities in the Northwell Health system between Jan 1st, 2016 and Sep 23rd, 2019 in whom hemodialysis was performed and a lung ultrasound was documented the same day. We manually reviewed clinician documentation and included patients whose lung ultrasound findings demonstrated A-line profile or B-line profile. Patients with other lung ultrasound findings were excluded. IDH was defined as a decrease in systolic BP by ≥20 mmHg with a failure to meet UF goal or increase in pressor requirement during HD or associated symptoms of hypotension. In total 105 dialysis treatments were reviewed, 78 were included for analysis. Northwell IRB exempted the study for full IRB review.

Results: There were 55 treatments with A-line profile and 23 treatments with B-line profile on POCUS. The incidence of IDH in a HD treatment with A-line and B-line profile was 50.9% and 21.7% respectively. 13 HD treatments with A-line profile and 1 with B-line profile had an increase in pressor requirement.

Conclusions: Lung ultrasonography provides a quick and effective means of assessing volume status. Our data suggest that IDH occurs more frequently in patients with A-line profile compared to those with B-line profile. Further research should focus on describing the relationship between lung ultrasound and IDH.

Lung US Finding	Number of treatments	Intradialytic Hypotension (%)	Mean Pre-HD Blood Pressure	Mean Dialysate Temperature (C)	Na Modeling (%)
A-Line Profile	55	50.9	133/67	36.5	7.3
B-Line Profile	23	21.7	142/68	36.4	13

PO1235

Relationship Between Cardiac Output (CO) and Estimated Upper Body Blood Flow (eUBBF) During Hemodialysis (HD)

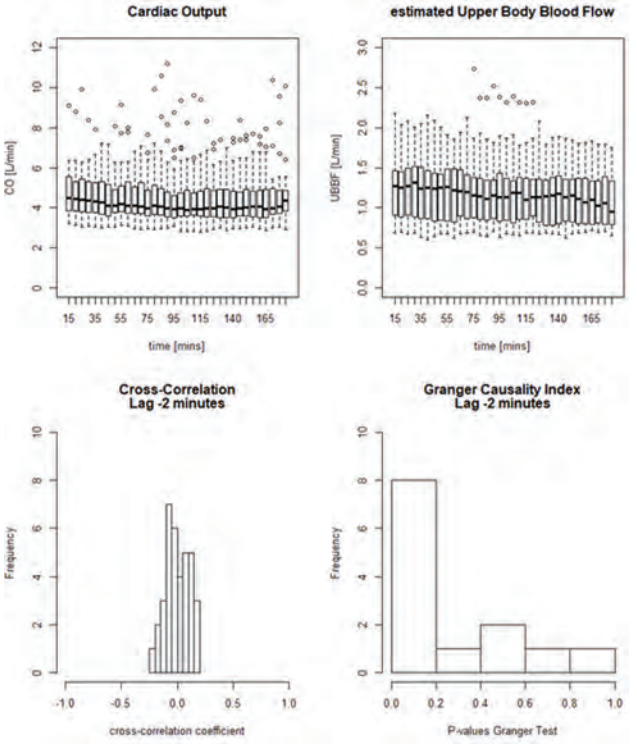
Jochen G. Raimann,[1] Gwendolyn Derk,[2] Maria Fox,[2] Elizabeth G. Poozhikunnel,[2] Stephan Thijssen,[1] Kenneth R. Wilund,[2] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]University of Illinois at Urbana Champaign, Champaign, IL.*

Background: Cardiopulmonary monitoring during HD could improve outcomes. Upper body oxygen consumption, arterial and central-venous oxygen saturation and hemoglobin concentration allows the calculation of eUBBF (Rosales 2019). We studied the association between eUBBF and CO during HD.

Methods: In patients with central-venous catheter we measured central-venous oxygen saturation and hemoglobin levels during HD using the Crit-Line Monitor (Fresenius Medical Care North America, Waltham, USA). We measured CO using the Task Force Monitor (CNSystems, Graz, Austria). We tested the time series for stationarity using the Dickey-Fuller test, employed differencing to make the time series stationary, analyzed the association between the time series using cross-correlations and Granger Causality test.

Results: We studied 13 patients (59±14 years, 5 (38%) male, 93±22 kg pre-dialysis weight 170±7 cm tall) during 34 hemodialyses. Averaged across all treatments, CO and UBBF were 4.7±1.0 and 1.3±0.4 L/min, respectively. CO showed a weak downward trend during hemodialysis. Cross-correlations showed no meaningful relationship between CO and eUBBF; Granger causality index was less than 20% in 8 treatments, albeit without clearly discernible patterns.

Conclusions: CO and eUBBF remained considerably stable during HD. Cross-correlations showed no significant relationships and Granger causality test suggests some form of a relationship which requires some further investigation. The clinical usefulness of eUBBF and future investigations will need to take additional parameters and dynamic relationships into account. **Figure 1:** Dynamic of CO and eUBBF flow during 34 HD; correlation coefficient from cross-correlations and Granger Causality index at a lag of -2 minutes.



PO1236

Point-of-Care Ultrasound Findings Among Dialysis Patients with COVID-19

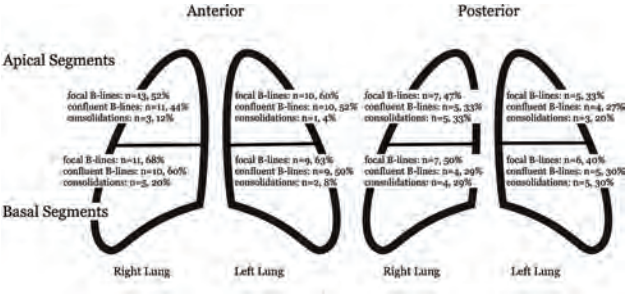
Sadichhya Lohani, Vishnu S. Potluri, Forrest F. Lindsay-McGinn, Jennifer Morganroth, Claire A. Centeno, Christy Moore, Felipe Teran, Nathaniel C. Reisinger. *University of Pennsylvania, Philadelphia, PA.*

Background: Dialysis patients are vulnerable in the COVID-19 pandemic due to advanced age, comorbidities, and obligate travel with frequent healthcare contacts. Point-of-care cardiac and lung ultrasound (US) has been used to enhance the physical exam in dialysis patients and is a potent tool for assessment COVID-19, comparing favorably to computed tomography. Here we report findings of focused cardiac and lung US among dialysis patients in an acute care setting.

Methods: This is a cohort of dialysis patients who presented to our institution in Spring of 2020 with COVID-19. All patients started dialysis prior to the index acute care visit. Focused 5-view cardiac assessment and 12-zone lung US were obtained according to published protocols.

Results: 25 patients were included. 88% were African American. 64% were female. Mean age was 61.96 and body mass index was 25.8 kg/m^2. 56% had history of heart failure, 28% lung disease. 15 (60%) were discharged with mean length of stay 10 days. 36% required invasive mechanical ventilation and 56% intensive care unit admission. 23 patients had cardiac US. 17 had an ejection fraction (EF) >55%, 3 had EF 30-55%, 1 had EF <30%. 23 had inferior vena cava (IVC) assessment, 18 had a normal or collapsed IVC, and 5 had a full, non-collapsing IVC. 3 had pericardial effusion. 4 had right-ventricular dysfunction. 25 completed anterior lung US zones and 12 also had posterior lung US. In at least 1 lung zone 16 (64%) had confluent B-lines, 16 (64%) consolidations, 16 (64%) isolated B-lines, and 17 (68%) pleural thickening. 8 had pleural effusions (3 bilateral). **Figure 1 details lung US findings across anatomical zones.**

Conclusions: We showed a high prevalence of thickened pleural lines, subpleural consolidations, and multifocal or confluent B-lines among dialysis patients with COVID-19. Most had a normal or collapsed IVC and intact cardiac function. Pleural and pericardial effusions were uncommon. More study is needed to determine whether US findings can help guide fluid management in dialysis patients.



PO1237

Accelerated Renal Replacement Therapy: Single-Institution Experience in Calculating Delivered Clearance During the COVID-19 Pandemic

Janis Cho, Shubha Ahya, Cybele Ghossein. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Continuous renal replacement therapy (CRRT) is commonly used in the intensive care unit (ICU) setting. A minimum delivered dose 20 ml/kg/hr is associated with improved survival. Previous studies have revealed significant discrepancy between prescribed and delivered CRRT dosing. Before the COVID 19 pandemic, CRRT was the main modality used at our medical center. But to accommodate the increase need for RRT and our limited resources, accelerated renal replacement therapy (ARRT), providing the same total CRRT clearance but in half the time, was used. To ensure that the delivered dose was appropriate given the reduction in time, we calculated delivered clearance.

Case Description: ARRT prescribed dose was based on patient's weight and time on therapy to achieve the equivalent 20cc/kg/hr over 24 hours. Delivered clearance (k) was calculated using the following formula K= Qd + Qr +Quf x FUN/BUN / weight/ 24 hours Qd =spent dialysate Qr= replacement fluid rate and Quf = net fluid removal rate. FUN = effluent urea nitrogen BUN= blood urea nitrogen. Hourly flowsheet with total time, Quf, Qd, and Qr were recorded during treatment by bedside nurse and reviewed to calculate the delivered clearance. 8 patients underwent 14 uninterrupted AVVHDF treatments. Total treatment time ranged from 8-10.5 hours. FUN/BUN ratio ranged from 0.5 to 1.05. The ratio between delivered clearance to prescribed clearance ranged from 0.83-1.08. Only 6 treatments (43%) achieved goal clearance.

Discussion: ARRT delivered clearance was only achieved 43% of time. While ARRT is a feasible modality when resources are limited, close monitoring of achieved clearance is needed to ensure that adequate dialysis is being delivered. Careful patient selection is important as delivered dose may be more difficult to achieve in obese patients. Although ARRT may be a practical alternative, continuous therapy would be ideal in the critical setting.

PO1238

Can COVID-19 Personal Hygiene and Social Distancing Reduce Bacteremia and Peritonitis Rates in Dialysis Patients

Nasreen Samad. *Barts Health NHS Trust, London, United Kingdom.*

Background: During COVID-19 pandemic affecting United Kingdom(UK) from March till May 2020 with social distancing guidelines in place (hand washing 5 times a day, 2 meter separation) and shielding in high risk individuals (including renal replacement therapy patients) and strict personal protective equipment (PPE) use in dialysis units we proposed the hypothesis that it may have positive impact on bacteremia in heamodialysis(HD) and peritonitis in peritoneal dialysis(PD) patients.

Methods: We compared Staphylococus Aureus (SA) bacteremia in HD patients and PD peritonitis rates over three months March, April and May 2020 and compared the results with similar duration during 2019. We also viewed SA colonization rate in a satellite unit during this period.

Results: Quarterly Staph. Aureus bacteremia results showed yearly rate on 31 May 2019, 31 August 2019, 30 November 2019, 28 February 2020 and 31 May 2020 as 0.014, 0.021, 0.039, 0.038 and 0.024 respectively. However yearly PD peritonitis rates were significantly down from 0.386 to 0.238 from January 2019 to April 2020. MRSA colonisation data from one satellite unit showed 2 out of 105 patients colonised in January 2019, of whom one decolonized by April 2020 while 16 patients in the same unit had MSSA colonization in January 2019 which was 15 out of 103 patients in February 2020 suggesting no significant difference in SA colonisation rate.

Conclusions: Improvement in peritonitis rates is indicative of personal behavioural change with regards to common sense hygienic principles being very important in PD. However, in HD patients it had no impact on bacteremia at similar time one year ago indicating that possibly colonisation with MSSA/MRSA are important and strategies to decolonisation of HD patients may help reduce episodes of bacteremia. There was some reduction in bacteremia rate from preceding quarter ending February 2020 to quarter ending May 2020 although not to May 2019 level. It will be difficult to say at this stage if this trend will be sustained in coming months.

PO1239

Effect of Lockdown to Stop Spread of COVID-19 on Physical Activity Levels of Hemodialysis Patients

Maggie Han,[1] Priscila Preciado,[1] Ohnmar Thwin,[1] Xia Tao,[1] Mirell Tapia,[1] Lemuel Rivera Fuentes,[1] Amrish U. Patel,[1] Mohamad I. Hakim,[1] Lela Tisdale,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: On March 20, 2020, to stop the spread of the COVID-19, the New York State Governor issued a strict stay at home order for all tasks that were deemed as "non-essential" starting March 22 at 8PM. We would like to determine what change, if any, in physical activity levels (PAL) took place because of the lockdown order in HD patients.

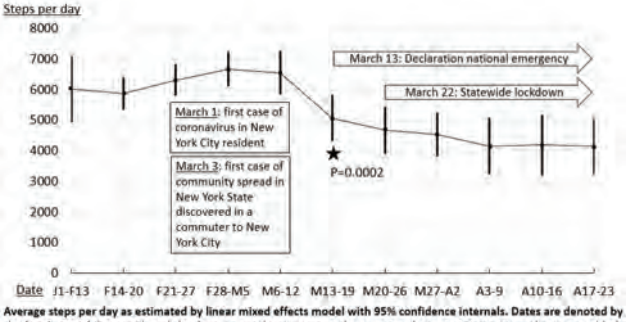
Methods: HD patients were enrolled from 4 clinics in New York City starting in May 2018 and followed for a period of up to 1 year. Patients ≥18 years, on HD ≥3 months, able to walk, and owning a smartphone were enrolled. PAL was defined by steps taken per day measured by with a wrist-based monitoring device (Fitbit Charge 2). Patients still in the study as of March 22, 2020 were included in the study cohort. Average steps per day was calculated for Jan 1-Feb 13, 2020 and the five weeks prior to and after the lockdown went into place. A linear mixed-effect model was used to estimate the average steps per day and 95% confidence intervals. Socioeconomic parameters such as age, race, employment status, and education level were taken at the beginning of the study.

Results: 42 patients were included in this analysis. At enrollment patients were 55±11 years old with a dialysis vintage of 4.5±4.4 years, and a BMI of 28.9±8.6 kg/m^2. 33% lived alone, 48% were single, 50% unemployed, 69% were African American, and 50% had an education level of some college or higher. Results on average steps per day are presented in Figure 1. Steps per day decreased significantly after the lockdown order with the most significant drop when the COVID-19 pandemic was declared a national emergency

Conclusions: There was a decrease in PAL due to the mandated lockdown. As sedentary behavior is a risk factor for negative outcomes in the HD population, we must implement interventions to promote PAL, such as intradialytic exercise.

Funding: Commercial Support - Fresenius Medical Care

Figure 1.



Average steps per day as estimated by linear mixed effects model with 95% confidence internals. Dates are denoted by the first letter of the month and the date. To put data in context, key events relating to COVID-19 pandemic are added.

PO1240

Affecting Factors on Circuit Lifespan in Continuous Renal Replacement Therapy

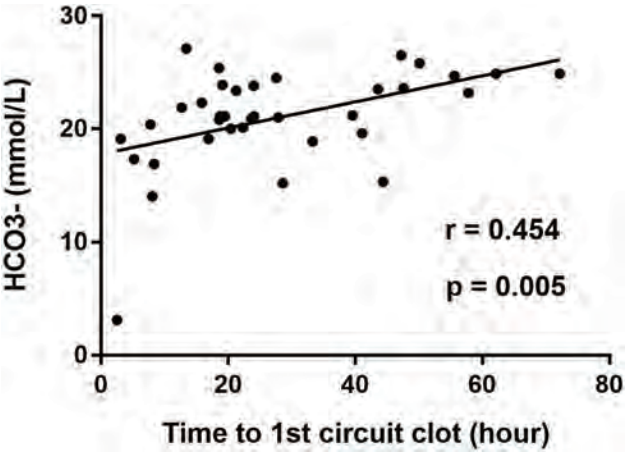
Hanwul Shin, Miryung Kim, Jun Young Lee, Jae Won Yang, Jae seok Kim, Seung-Ok Choi, Minseob Eom. *Wonju Severance Christian Hospital, Wonju, Gangwon-do, Republic of Korea.*

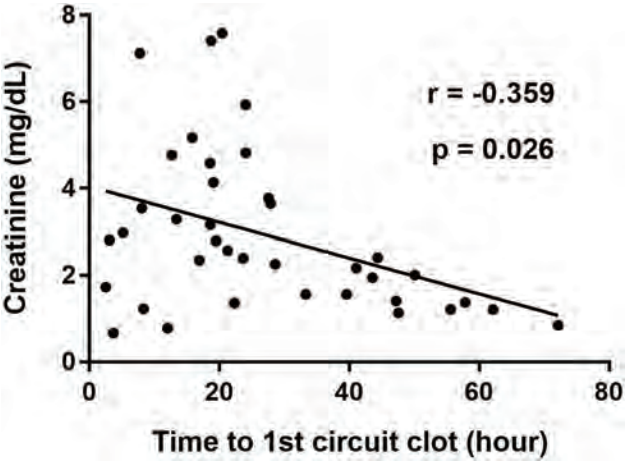
Background: CRRT is a useful dialysis modality in hemodynamically unstable patients. But despite use of anticoagulants, clotting of circuit frequently occurs, which reduces efficiency of dialysis and causes the consumption of RBC, platelets, and coagulation factors. Especially, the more severe patient is, the lower blood flow into circuit due to hypotension can lead to decrease circuit lifespan. This study aims to investigate the factors that affects CRRT circuit lifespan.

Methods: This is a retrospective observational study. From January 2018 to December 2019, 38 patients who underwent CRRT in the ICU were enrolled. Outcomes were defined as the time of first clotting in circuit from CRRT initiation and the number of clotting during total application period. We statistically analyzed association of circuit lifespan with patient's clinical characteristics.

Results: The results showed that first circuit clotting was significantly related to serum bicarbonate (r=0.454, p=0.005) and creatinine levels (r=-0.359, p=0.026). The total number of circuit clotting were related to RBC and platelet transfusion respectively (r=0.779, p<0.001 / r=0.652, p<0.001). Blood pressure, infection, blood flow of circuit showed no relationships with circuit lifespan. The use of heparin and nafamostat increased circuit lifespan compared to non-anticoagulant.

Conclusions: Circuit lifespan in CRRT is shorter in more serious metabolic acidosis and renal failure. Transfusion of RBC and platelet also reduces the circuit lifespan.





PO1241

Home Hemodialysis Patient Loss: A Quality Improvement Initiative to Review Technique Failure in Alberta Kidney Care - South

Bailey Paterson,[1] Victoria Riehl-Tonn,[2] Elena Qirjazi,[1] Jennifer M. MacRae.[1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]Mount Royal University, Calgary, AB, Canada.*

Background: The number of dialysis patients has increased 15% over 5 years in Alberta Kidney Care South (AKC-S) with most patients pursuing in-centre hemodialysis. Although home hemodialysis (HHD) offers advantages of improved quality of life for patients and cost savings for programs it has grown at a slower rate. To increase the number of HHD patients, programs need to promote more patients to start on HHD and reduce the number of patients leaving HHD. Understanding the reasons for exit from HHD may lead to strategies to reduce patient loss.

Methods: A retrospective cohort study of adult HHD patients who entered training for HHD between January 1 2013 to December 31 2018 in AKC-S, followed until exit/study end date. Reasons for technique failure (TF) identified, with KM estimates used to determine technique survival, and Cox proportional hazard model used to determine risk factors for TF.

Results: 147 patients entered the HHD program-48(33%) women; 44(30%) DM, 38(25.9%) CAD, 14(9.5%) CVD, mean age of 54(13) years. 12(8.1%) did not complete training. Overall time in program 28 +/- 20 months, average training time 6.7 +/- 3.3 weeks. Reasons for exit include transplant 24(48%), death 6(4.5%), TF 32(24%). TF reasons include medical 9(39.1%), psychiatric 2(8.7%), social 3(13.0%), safety 4(17.4%), patient request 4(17.45%), change to PD 1(4.3%). Technique survival at 1, 2, and 5 years 91%, 85%, and 63%. Risk factors for TF include DM 2.36(1.06, 5.28) p= 0.036, CVD 4.34(1.8, 10.5) p=0.001 and a longer training time 1.18(1.07, 1.30) p=0.001.

Conclusions: We found a high HHD turnover rate with technique survival rates decreasing with time. Risk factors for TF include patients with DM, CVD, longer training time. Improved identification of and education for potential HHD patients could reduce training failure rates. Interventions to provide better support for patients at risk of TF could help keep patients at home longer.

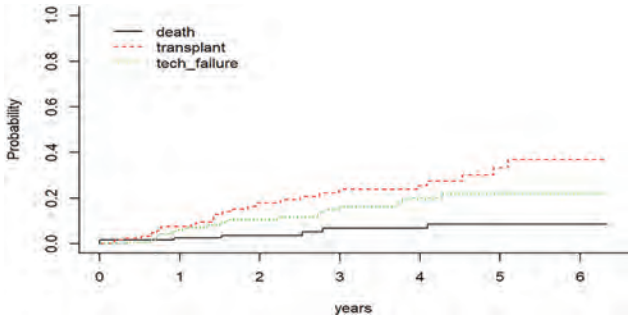


Figure 1. Cumulative Incidence of Competing Risks.

PO1242

Home Dialysis and Kidney Transplant Assessments in the ESRD Treatment Choices Payment Model

Kristine Kubisiak,[1] Eric D. Weinhandl,[1,2] Lorien S. Dalrymple,[1] Robert J. Kossmann.[1] *[1]Fresenius Medical Care, Waltham, Bouvet Island; [2]Chronic Disease Research Group, Minneapolis, MN.*

Background: The End Stage Renal Disease (ESRD) Treatment Choices (ETC) Model is a proposed mandatory payment model that assigns financial bonuses and penalties to dialysis facilities as a function of home dialysis prevalence and kidney transplant incidence among patients with Medicare fee-for-service coverage. We used claims data to estimate distributions of facility-level home dialysis prevalence and kidney transplant incidence.

Methods: Using Medicare Limited Data Sets, we identified all Part B claims for outpatient dialysis for the treatment of ESRD in 2017. In each dialysis facility with ≥132 adult patient-months, we estimated the percentage of patient-months with any home dialysis treatment. Using Part A claims in 2017, we also estimated the number of kidney transplants among dialysis patients in the facility.

Results: We identified 6263 dialysis facilities and 3,645,655 dialysis patient-months. Overall home dialysis prevalence was 10.8%. The distribution of facility-level home dialysis prevalence exhibited three features, as displayed: (1) over 54% of facilities with exactly 0% home dialysis prevalence; (2) among facilities with any home dialysis utilization, a unimodal distribution with peak prevalence near 12%; and (3) a small subset of facilities (4%) with home dialysis prevalence >90%. Regarding kidney transplant incidence, over half of facilities had ≤1 transplant. The 75th and 90th percentiles of transplant count were 2 and 4, respectively.

Conclusions: In patients with Medicare fee-for-service coverage, facility-level home dialysis prevalence exhibits a nonnormal distribution, while kidney transplant incidence typically manifests few (or no) events per year. Both patterns will complicate statistical analysis of performance in the ETC model. Alternative methodology should consider assessments in regional clusters of facilities.

PO1243

Identifying Barriers to Implementing an Assisted Home Hemodialysis Program in Canada

Drew Hager,[2] April Bertrand,[1] Nickie L. Cool,[1] Thomas W. Ferguson,[3] Claudio Rigatto,[2] Navdeep Tangri,[2] Clara Bohm,[2] Michelle S. DiNella,[4] Paul Komenda.[2] *[1]Winnipeg Regional Health Authority, Winnipeg, MB, Canada; [2]University of Manitoba College of Medicine, Winnipeg, MB, Canada; [3]University of Manitoba, Winnipeg, MB, Canada; [4]Seven Oaks General Hospital, Winnipeg, MB, Canada.*

Background: Policy changes such as the Advancing American Kidney Health Initiative and the impact of the COVID-19 pandemic will accelerate the trend for more home dialysis. Expanding the pool of patients eligible for HHD will require health care practitioner assisted models to be developed and deployed. We hypothesize that many barriers to delivering assisted HHD (aHHD) exist and implementation of a successful program would require meaningful input from frontline home dialysis nurses. Our primary objective of this study is to survey these key stakeholders to identify these barriers.

Methods: We conducted a semi-structured focus group of leaders within our large Canadian home dialysis program to anticipate key aspects of implementing aHHD, including gauging local demand, identifying eligible patients, and recognizing essential operational components. From this, we constructed questionnaires for frontline nursing staff within HHD, peritoneal dialysis (PD) and assisted PD (aPD) programs. We performed a qualitative analysis to identify common themes and implementation barriers.

Results: Twenty-six responses from three sites were received. 20/21 PD nurses reported existing aPD programs expanded the eligible pool of PD patients. 5/5 HHD nurses felt an aHHD program would keep more patients on the modality and prevent technique failure. Only 2/5 felt aHHD should be offered as a transition to HHD. While 18/21 PD nurses reported they could easily identify patients for aPD, only 2/5 HHD nurses agreed. Patients with sensory deficits, functional impairments, and limited support networks were felt to benefit most from aHHD. Lack of confidence and phobias were not agreed upon. Behavioral and safety issues, clinical instability, and inability to manage emergencies may be barriers to aHHD. Machine set-up, take-down, and establishing access were thought to be essential services. PD nurses felt clinical assessments should be routine. Few nurses felt complete assistance was necessary.

Conclusions: Our findings suggest there is a strong local demand for aHHD provided there is a clear criterion for enrollment and operational plans are well established. Frontline nurses have identified several important barriers to implementation which we will acknowledge and address when deploying our assisted home program over the upcoming year.

PO1244

Timed Repetitive Controlled Rotations of the CAR-170-C NXSTAGE Chronic Cartridge Hemodialysis Filter: An Original Newfangled Maneuver to Enable Heparin-Free Frequent Daily Home Hemodialysis

Macaulay A. Onuigbo, Adam Locke. *Larner College of Medicine, University of Vermont, Burlington, VT.*

Introduction: Heparin-free hemodialysis is usually obligatory in immediate post-operative states, bleeding diathesis and in critically ill patients. Conventionally, this is achieved through normal saline flushes, and regional citrate anticoagulation.

Case Description: An 87-yo white male with ESRD and atrial fibrillation on Warfarin, on maintenance daily Home Hemodialysis (HHD) with a NxStage machine, developed intra-abdominal abscess and sepsis following an urgent laparoscopic appendicectomy. He required emergent pericardiocentesis for cardiogenic shock from hemorrhagic pericardial effusion. Upon discharge, he was to continue heparin-free HHD. Despite the use of increasing volumes of normal saline flushes, his system clotted every day during HHD, therefore compromising his ability to carry out HHD. Our HD Senior Technician, had astutely observed that by a controlled timed manual and repeated to and fro rotation of the horizontally aligned CAR-170-C NXSTAGE Chronic cartridge, 60 degrees back and forth clockwise and counterclockwise, along the long axis of the filter, every 15 minutes, the filter stopped clotting. He has since then not needed saline flushes for smooth heparin-free HHD for several months.

Discussion: This is the first such report in the English literature. More studies are justified. We have hypothesized a mechanism and have named this the 'Adam Locke_ Onuigbo Maneuver'. If confirmed by subsequent research, we propose that a miniaturized motor set-up that would be programmed to mimic these timed controlled partial rotations of the horizontally aligned CAR-170-C NXSTAGE Chronic cartridge could translate to a commercial success with major clinical benefits to patients needing heparin-free hemodialysis in all settings.

PO1245

The Use of Etelcalcetide in a Special Cohort of Home Hemodialysis Patients with Severe Secondary Hyperparathyroidism

Ahmed A. Ewaida, Bassam O. Bernieh. *HHD Home Health Care, Al Ain, United Arab Emirates.*

Background: Secondary hyperparathyroidism (sHPT), a is common complication of chronic kidney disease. Its clinical consequences include extraskeletal vascular and valvular calcifications, changes in bone metabolism resulting in renal osteodystrophy, and an increased risk of cardiovascular morbidity and mortality. Etelcalcetide is an intravenous calcimimetic that increases sensitivity of the calcium-sensing receptor to calcium and decreases PTH, so it's indicated for the treatment of secondary hyperparathyroidism (SHPT) in dialysis patients. In this observational study we are reporting our experience in treating SHPT by Etelcalcetide, in a very special cohort of sick, highly co-morbid, bed, and home bound hemodialysis patients, at home with the assistance of a hemodialysis nurse, we called the program as Nurse Assisted Home Hemodialysis (NAHHD).

Methods: This is a retrospective observational sixth months study. Thirty home HD patients, managed by NAHHD program, were included in this study, average age 59.6 (26-87year, 60% female. Etiology of ESRD was DM in 63%, 53% of them have hypertension. Vascular access AVF & AVG 60%, CVC 37%. Average comorbidities 9.4 (6-16). Patients were either naïve (30%) or switched from cinacalcet to Etelcalcetide due to non-compliance 50%, PTH resistance 31%, and bad tolerance of Cinacalcet 19%.

Results: The medication was well tolerated, two patients had GI side effects (6.5%), only with high dose of Etelcalcitide. The results of treating secondary hyperparathyroidism by Etelcalcetide in a special cohort of the patients for 6 consecutive months are illustrated in the graph.

Conclusions: This study showed that Etelcalcetide is efficient and well tolerated in this special group of sick, highly comorbid, bed and home bound home hemodialysis patients. The drug was well tolerated with minimal GI side effects.

Funding: Government Support - Non-U.S.

Clinical Characteristics, Practice Pattern, and Outcome of Home Hemodialysis in India

Suresh Sankarasubbaiyan, Kaparaboina K. Kumar, Venkatraman Ganapathi Subraman, Mohammad S. Husain, Vikram A. Sonawane, Kamal D. Shah. *Nephroplus, Hyderabad, India.*

Background: Maintenance hemodialyis is growing steadily and is the dominant renal replacement modality and Home HD has been in recent times. But, the profile, treatment charactestics could be different from the western context but it remains unknown.

Methods: Prevalent patients on HD between Aug 2019 and Jan 2020 were reviewed for geographical location, age, gender, comorbidity, functional status, type of access, HD frequency, Hemoglobin, adequacy, S Albumin, S Calcium and S. phosphorus and survival. Descriptive statistics are presented to summarize data.

Results: n = 30. Mean age: 70.4 + 8.72, 15 males and 15 females. 26 were from large metropolitan cities. All patients underwent HHD with a help of HD technician deputed from a designated centre. 1388 sessions were done; total follow up:10610 patient days. 25 (83%) were diabetics, 21(70%) were Htn, 6(20%) had cardiovascular disease and 17(57%) were functionally dependant. 20(66.3%) patients had av fistula and 10(33.6%) had tunneled catheter. They reside at a distance of 13.85 + 8.76km from the HD centre. Range of HD frequency was from 1 to 3 per week. Mean Hb 9.80 + 1.34 g%. Kt/v: 1.50 + 016, S. Albumin: 3.52 + 0.44. Compliance for S. Ca testing was at 50% and S. Ca; 8.8 + 0.72, S Ph was 4.92 + 0.75 mg%. 3 patiens died during follow up after mean HD durtaion of 10.67 months

Conclusions: HHD patients in India are elderly with high prevalence of poor functional status, comorbidites, tunelled catheter and it is solely provider driven. Payer type was entirely out of pocket. HD outcomes are reasonable but long term survival remains unclear. Thus, HHD patient characteristics and practice pattern are distinctly different from developed countries

PO1247

A Pilot Evaluation of Thiol Metabolome in Peritoneal Dialysate as an Indicator of Peritoneal Fibrosis

Patricia Q. Branco,[1,2] Ana Rita M. Martins,[1,3] Rita A. Coelho,[5] Daniel G. Pinto,[4] Catarina Mateus,[1] Rita Calça,[1] Catarina O. Sequeira,[5] Judit Morello,[5] Sofia A. Pereira.[5] *[1]Santa Cruz Hospital/CHLO, Lisbon, Portugal; [2]Nova Medical School, Lisbon, Portugal; [3]Faculdade Medicina Lisboa, Lisbon, Portugal; [4]Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal; [5]Centro Estudos Doenças Crónicas, Lisboa, Portugal.*

Background: The peritoneal dialysate is a precious source to find out markers for a better management of intraperitoneal dialysis (IPD). Low molecular weight thiols have been implied in the epithelial to mesenchymal transition, a process known to occur in peritoneal fibrosis. This study aimed to evaluate thiol metabolome in peritoneal dialysate and its relationship with peritoneal fibrosis. Thiol metabolome definition: total, free and protein bound fractions of glutathione, cysteine, cysteinylglycine and glutamylcysteine.

Methods: Peritoneal fibrosis was evaluated in biopsy specimen, performed during the placement of Tenkhoff catheter. Histological analysis were performed according to standard methods. Thiol related metabolome in peritoneal dialysate was assessed by high performance liquid chromatography+fluorescence detection. The relation thiol metabolome/fibrosis were assessed by multivariate analysis including principal component analysis (PCA) and partial least squared discriminanting analysis (PLS-DA).

Results: 42 patients (26 males), fibrosis in 26%, 16 Diabetic Age, diabetes, body max index, residual diuresis, Kt/v,nPCR, D/P, GFR residual, peritoneal Ca125, did not influence the thiol metabolome, that differed among those with and without fibrosis (fig). PLS-DA (p=8.09x10-7) identified that among the several thiol fractions obtained, cysteine fractions mainly contributed to this difference.

Conclusions: There is a thiol metabolome profile that can be measured in intraperitoneal dialysate fluid, that is related to fibrosis and rich in oxidized cysteine. This pilot analyses shows the potential contribution of thiol metabolome profile for precision prescription in IPD and stratification of patients according to fibrosis risk. This preliminary data might also support the existence of cysteine-dependent mechanisms of intraperitoneal fibrosis.

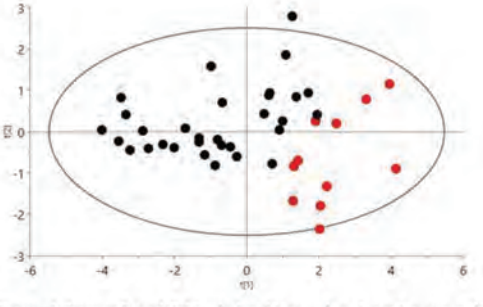

Figure 1 Score plot of PCA of the 42 samples. Samples are colored according to fibrosis at baseline (black: no, red: yes).

PO1248

Binding of TonEBP and ß-Catenin to the E-Cadherin Promoter Is a Key Process of Hypertonicity-Induced Phenotype Transition of Peritoneal Mesothelial Cells (MCs)

Hyun-Jung Kang, Dal-ah Kim, Duk-Hee Kang. *Ewha Womans University, Seoul, Republic of Korea.*

Background: Epithelial-to-mesenchymal transition (EMT) of MCs is considered as an early mechanism of peritoneal fibrosis. Tonicity-responsive enhancer binding protein (TonEBP) is a transcriptional factor that enables cellular adaptation to hypertonic osmotic

stress. Recent data demonstrated the role of TonEBP in EMT of cancer cells, however the exact mechanisms how TonEBP regulated cell phenotype were not known. The aim of this study is to investigate the role of TonEBP in hypertonicity-induced EMT of MCs and its mechanism.

Methods: The expressions of TonEBP and other osmotic stress-related genes including sodium-myoinositol cotransporter (SMIT), betaine/γ-aminobutyric acid transporter (BGT1) and aldose reductase (AR) were evaluated. EMT was evaluated by morphological changes of MCs and the expressions of E-cadherin and α-smooth muscle actin (α-SMA) after stimulation of high glucose (HG, 30-120 mM) and mannitol (30-120 mM). E-cadherin promoter activity was confirmed by luciferase assay. Binding of TonEBP- or β-catenin to E-cadherin promotor was identified by chromatin immunoprecipitation (ChIP) assay. The interaction between TonEBP and β-catenin was analyzed by immunoprecipitation.

Results: Both HG or mannitol enhanced the expression of TonEBP as well as SMIT, BGT1 and AR from the concentration of 30 mM. HG induced EMT of MCs with a decrease in E-cadherin promotor activity, however mannitol did not induce EMT. HG (>30 mM) induced nuclear translocation of TonEBP which was associated with an enhanced binding to β-catenin. Mannitol also promoted nuclear translocation of TonEBP only at the highest concentration we tested (120 mM), however it was not associated with nuclear binding of TonEBP to β-catenin. In addition, mannitol induced a transient increase in nuclear β-catenin only with the highest concentration (120 mM) whereas HG showed a persistent increase in nuclear β-catenin.

Conclusions: This is study demonstrated the role of TonEBP in peritoneal EMT for the first time. Not the increased expression of TonEBP per se but binding of TonEBP and β-catenin to the E-cadherin promoter is a key mechanism by which TonEBP induced EMT of MCs.

PO1249

CD4⁺ ICOS-Expressing T Cells Contribute to Peritoneal Fibrosis in Patients Receiving Peritoneal Dialysis

Yongjie Li, Jun Song, Hongchun Lin, Hui Peng. *the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Long-term peritoneal dialysis (LPD) can affect the morphology and function of the peritoneum, which causes peritoneal fibrosis one of the major causes of peritoneal dialysis (PD) failure. Reliable treatment strategies that successfully prevent progressive peritoneal fibrosis are still lacking. We performed single-cell RNA sequencing (scRNA-seq) on PD fluid from patients at different stages.

Methods: Firstly, PD fluid from patients with short-term peritoneal dialysis (SPD) (< 6 months) and LPD (>4 years) were collected for scRNA-seq analysis, and genomic expression differences of each sample were observed and analyzed. Secondly, peritoneum of PD patients and healthy inpatients were collected, and the expression of ICOS on $CD4^+$ T cells and ICOSL, COL1A1, COL1A2, FN, CDH, IL6 on peritoneal mesothelial cells (MSC) was detected by qPCR, ELISA, flow cytometry and immunofluorescence. Thirdly, $ICOS^+CD4^+$T cells and $ICOS^-CD4^+$ T cells in PD fluid were co-cultured with MSC cell lines, then stimulated with anti-ICOS monoclonal antibody. Lastly, we used gene pathway analysis and KEGG analysis to find out the possible mechanism pathway.

Results: A total of 13,167 T cells and 6,096 MSC from 8 PD fluid biopsies were included. Through scRNA-seq analysis, we found that under the stimulation of high glucose and other components in PD fluid, compared with SPD patients, the proportion of $ICOS^+CD4^+$ T cells within T cells and $ICOSL^+$ MSC within MSC from LPD patients was respectively increased by multiple of 0.58 and 0.29. Furthermore, the expression of COL1A1, COL1A2, FN, IL6 also increased in PD fluid and peritoneum from LPD patients. $CD4^+$ ICOS-expressing T cells interact with MSC by increasing the expression of profibrogenic proteins through ICOS/ICOSL pathway, then accelerate the progress of peritoneal fibrosis, anti-ICOS antibody can terminate these processes.

Conclusions: $CD4^+$ ICOS-expressing T cells contribute to peritoneal fibrosis, the anti-ICOS antibody can alleviate peritoneal fibrogenesis by interfering with the interaction between MSC and $ICOS^+CD4^+$ T cells, providing a new therapeutic target for progressive peritoneal fibrosis.

ICOS expression in T cells from SPD and LPD patients

PO1250

Geographic Variation of Home Dialysis Utilization in the United States

Eric D. Weinhandl,[1,2] David T. Gilbertson,[1] James B. Wetmore,[1,3] Kirsten L. Johansen.[1,3] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN; [3]Hennepin Healthcare, Minneapolis, MN.*

Background: Increasing home dialysis utilization is an aim of the Advancing American Kidney Health Initiative. We estimated geographic variation in home dialysis utilization in a contemporary population of end stage kidney disease (ESKD) patients. We also assessed the extent to which race and payers—possible systemic barriers to home dialysis—account for this variation.

Methods: Using USRDS Standard Analysis Files, we identified all prevalent ESKD patients on December 31, 2017 and ascertained the dialysis modality—in-facility hemodialysis, home hemodialysis (HHD), or peritoneal dialysis (PD)—of each patient on that date. We categorized patients into 306 Hospital Referral Regions (HRRs), according to ZIP code of the dialysis facility. We estimated the standardized home dialysis ratio (SHDR) in each HRR, with expected home dialysis utilization as a logistic regression of age, sex, primary cause of ESKD, and ESKD duration. Subsequently, we added race and payer to the regression.

Results: The cohort comprised 513,669 patients. Home dialysis utilization was 12.0% (1.8% HHD, 10.2% PD). Among HRRs, 5th and 95th percentiles of observed utilization were 5.3% and 23.2%, respectively, whereas 5th and 95th percentiles of SHDR were 0.43 and 1.82, as displayed. There were 87 HRRs (28%) with SHDR significantly <1.0 ($P < 0.05$) and 116 (38%) with SHDR significantly >1.0. Of the 10 HRRs with largest patient counts, seven—Los Angeles, Houston, Manhattan, Dallas, East Long Island, Philadelphia, and San Antonio—had SHDR significantly <1.0. The addition of race and payer improved the discrimination of logistic regression, with black race and concurrent Medicaid enrollment as negative predictors of home dialysis utilization. However, the distribution of SHDR did not greatly compress. There were 29 HRRs (9%) with SHDR that was revised from significant to non-significant and 22 (7%) with SHDR that was revised from non-significant to significant.

Conclusions: Large geographic variation in home dialysis utilization exists. Race and payer are associated with utilization, but adjustment for these factors does not alter variation in SHDR.

Funding: NIDDK Support

Standardized Home Dialysis Ratio

	Percentiles						
	1st	5th	25th	50th	75th	95th	99th
SHDR	0.26	0.43	0.80	1.06	1.33	1.82	2.40
SHDR (revised)	0.24	0.42	0.79	1.05	1.30	1.73	2.29

In the revised SHDR, expected home dialysis utilization also reflects race and payer.

PO1251

Cost Savings Associated with Extending Patient Time on Peritoneal Dialysis

Linda Ficociello,[1] Melissa M. Rosen,[1] Claudy Mullon,[1] Robert J. Kossmann,[2] Michael S. Anger.[1] *[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Only 7.1% of end-stage kidney disease (ESKD) patients receive peritoneal dialysis (PD) (USRDS, 2019). This number is expected to increase dramatically because of a 2019 U.S. presidential executive order which set the goal for 80% of patients to receive treatment at home or a transplant by 2025. To achieve this goal, providers and payers will not only need to encourage the use of PD but also will need to mitigate PD technique failure (TF). McGill et al. (AJKD, 2019) found that 6 out of 7 patients who start treatment with PD experience TF and will switch to hemodialysis (HD) within five years. Of patients who switch, Jaar et al. (BMC Nephrology, 2009) found that 20% did so by 6 months. Improving PD treatment time is important for patient quality of life and reducing healthcare costs. The goal of this study was to model Medicare cost savings associated with extending patient time on PD.

Methods: Using USRDS data, we calculated total Medicare spending per patient per day to be $226.71 for PD and $266.26 for HD, respectively. We estimated potential savings if treatment with PD could be extended each month up to 1 year using a base case of an incident ESKD patient who transitions to HD after receiving PD for 6 months. We assumed that during this year patients neither had a transplant nor died and that patients received HD once they stopped PD.

Results: Extending PD beyond 6 months for incident patients could result in potential savings to payers. Extending PD by 1 month, 2 months, 3 months, 4 months, 5 months, or 6 months could save $1,203.05, $2,406.10, $3,609.15, $4,812.20, $6,015.25, or $7,218.30, respectively per patient. We found that if a patient could avoid TF, $14,436.59 could be saved annually.

Conclusions: Extending the PD treatment time beyond 6 months has the potential to reduce treatment costs by $1,203.05-$7,218.30 for patients staying on PD 1 month to 6 months longer, respectively. Annually, avoiding TF could result in savings of $14,436.59. Multiple risk factors are associated with TF. Focusing on identifying and addressing modifiable conditions may help to keep more patients dialyzing at home.

PO1252

Higher Utilization of Peritoneal Dialysis Following the Executive Order on Advancing American Kidney Health

Eric D. Weinhandl,[1,2] David T. Gilbertson,[1] James B. Wetmore,[1,3] Kirsten L. Johansen.[1,3] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN; [3]Hennepin Healthcare, Minneapolis, MN.*

Background: On July 10, 2019, the president of the United States issued an Executive Order on Advancing American Kidney Health (AAKH). As part of the order, the Centers for Medicare and Medicaid Services (CMS) issued a proposed rule regarding the End Stage Renal Disease Treatment Choices (ETC) Model, which would employ payment mechanisms in Medicare Part B to incentivize home dialysis and kidney transplantation.

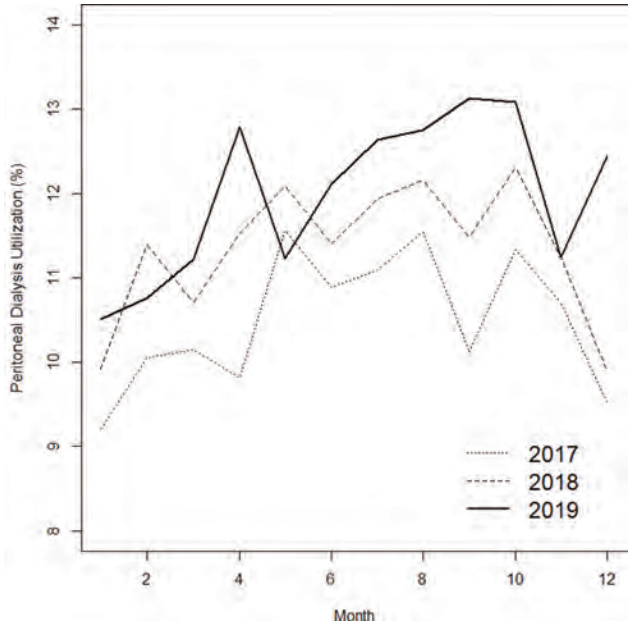
We assessed whether the period following the Executive Order was characterized by an increase in peritoneal dialysis (PD) utilization in incident end-stage kidney disease (ESKD) patients undergoing dialysis.

Methods: We analyzed submissions of form CMS-2728 ("ESRD Medical Evidence Report") among patients with dialysis initiation in 2017-2019, according to an April 2020 extract from the Renal Management Information System. For each calendar month in 2017-2019, we estimated the percentage of patients whose primary type of dialysis was PD. We used logistic regression to assess whether PD utilization during each quarter of 2019 exceeded corresponding norms in 2017-2018, with adjustment for age, race, and sex.

Results: The cohort comprised 375,815 incident ESKD patients undergoing dialysis. PD utilization increased each year, to an apex of 12.0% in 2019. In September and October 2019, PD utilization exceeded 13.0%, as displayed. Relative to corresponding quarters in 2017-2018, adjusted odds ratios of PD utilization in 2019 were 1.06 (95% confidence interval, 1.02-1.11) during January-March, 1.08 (1.04-1.13) during April-June, 1.16 (1.11-1.21) during July-September, and 1.16 (1.16-1.21) during October-December.

Conclusions: The Executive Order on AAKH and the proposed ETC Model together marked the advent of a period of significantly higher PD utilization among incident ESKD patients.

Funding: NIDDK Support



PO1253

Challenging Assumptions of Outcomes and Costs Comparing Peritoneal and Hemodialysis

Eugene Lin,[1] Khristina I. Lung,[2] Glenn M. Chertow,[3] Jay Bhattacharya,[3] Darius Lakdawalla.[2] *[1]University of Southern California Keck School of Medicine, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA; [3]Stanford University School of Medicine, Stanford, CA.*

Background: Policy makers have suggested that increasing peritoneal dialysis (PD) use would improve end-stage kidney disease (ESKD) outcomes and reduce Medicare spending.

Methods: Using Medicare claims, we exploited an idiosyncratic Medicare coverage rule to conduct an instrumental variable analysis comparing mortality, hospitalizations, and Medicare spending between PD and hemodialysis (HD) in uninsured adults with incident ESKD. Uninsured patients usually receive Medicare at dialysis month four; however, those starting with PD receive Medicare at dialysis start *and* retroactive pre-dialysis coverage for the entire calendar month of dialysis start. Because pre-dialysis coverage is essential for PD catheter placements, the rule encourages more PD use among patients starting at the end of the month by increasing pre-dialysis coverage. We used dialysis start day as an instrumental variable to mitigate selection bias when comparing outcomes and costs of the two modalities.

Results: Starting dialysis later in the calendar month was associated with an increased probability of using PD at day 1 (*absolute* increase of 1.0% for every 10 days later in the month, 95% CI: 0.8%, 1.3%) and at month 12 (*absolute* increase of 0.7% for every 10 days later in the month, 95% CI: 0.4%, 1.0%). We observed no significant *absolute* difference between PD and HD for all outcomes: 12-month mortality, –0.4% (–3.4%, 1.8%), hospitalizations during months 7-12, 0.01 (–0.16, 0.17) per patient, and Medicare spending during months 7-12, $2,803 (95% CI: –$6,355, $508) per patient. We assessed the potential role of selection bias in prior studies by repeating the same analyses using traditional regression methods. In contrast to the instrumental variable model, when using traditional regression methods, PD was associated with statistically significant decreases in mortality but significant increases in costs.

Conclusions: Using an instrumental variable analysis, PD did not result in improved outcomes or lower costs when compared to HD. We observed evidence of selection bias when using traditional study methods. Policy makers eager to promote home dialysis should temper expectations of improved outcomes and reduced spending.

Funding: NIDDK Support

PO1254

Disparities in Home Dialysis and Links to Kidney Transplantation: Inequities Among African American ESRD Patients in Detroit, Michigan

Mareena S. Zachariah,[2] Alexa Lupi,[1] Anurag Dawadi,[1] Ana Vazquez,[1] Todd Lucas.[1] Michigan State University *[1]Michigan State University, East Lansing, MI; [2]Wayne State University School of Medicine, Detroit, MI.*

Background: African Americans with ESRD continue to fare worse than their White counterparts for graft and patient survival after kidney transplantation. These disparities may partly reflect differential use of peritoneal dialysis (PD) and hemodialysis (HD) among African Americans who undertake maintenance renal replacement therapy – although PD and preemptive tranplants are linked to longer survival and better kidney transplantation outcomes, emerging studies suggest that African Americans less often receive PD than Whites. The current analysis sought to explore whether disparate use of PD would persist in the context of an inner-city hospital that serves a majority African American patient population, within a predominantly African American city.

Methods: We compiled electronic medical record data from 2012-2018 for African American (n = 1078) and White (n = 155) ESRD patients who initiated maintenance dialysis through either HD or PD. We also compiled data on successful kidney transplantation in these patients, as well as sociodemographic and health status data, including BMI, age, PRA peak, race, sex, diabetes, and hypertension.

Results: Fisher's exact tests showed that African American patients were 2.28 times more likely to receive HD than PD as compared to White patients (p = .004), and that patients receiving PD were 2.09 times more likely to be transplanted (p = .01). Although attenuated, a robust relationship between PD and kidney transplantation persisted in a logistic regression that controlled for sociodemographic and health status variables (OR = 1.60, p = .10).

Conclusions: Disparities in use of PD can be observed even in the context of an inner-city hospital serving a predominantly African American population. Aligned with the Advancing American Kidney Health initiative to achieve 80% home dialysis by 2025, future research must identify and intervene on patient and clinician factors that contribute to lower PD use among African Americans.

PO1255

Home-Based Dialysis Care Among Veterans Within the Veterans Affairs Health Care System, 1995-2014

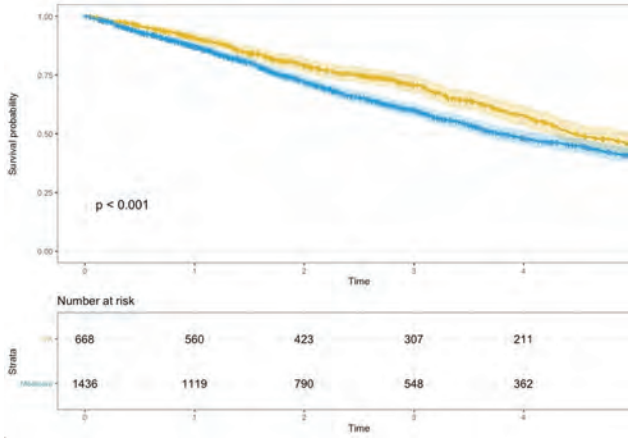
Scott Reule,[1] Areef Ishani,[1] Donal J. Sexton,[2] Robert N. Foley.[3] *[1]Minneapolis VA Health Care System, Minneapolis, MN; [2]University of Dublin Trinity College, Dublin, Ireland; [3]United States Renal Data System, Minneapolis, MN.*

Background: Contemporary US policy is focused on proportionally increasing home-based dialysis care, however overall rates are lower in the US compared to other similarly developed countries. Use of peritoneal dialysis (PD), the most common home-based dialysis modality, is even lower among US Veterans. How the characteristics and rates of PD utilization among US Veterans vary by health system affiliation, is unknown.

Methods: Using United States Renal Data Systems (USRDS) combined with Medicare data for the years 1995-2014, we matched US Veterans initiating dialysis (*n* =14,904) to Veterans and Medicare non-Veterans receiving care in the community. Matching was performed in a 1:1 ratio according to year of dialysis initiation (+/- 2 years), age (+/- 2 years), gender, race, and reported cause of kidney disease. A total of 668 veterans initiated PD within the VA, compared to 890 Veterans and 1,436 non-Veterans in the community.

Results: After adjustment for patient age, gender, race, ethnicity, and region of residence, odds (AOR) of PD initiation within the VA was highest among those with diabetes mellitus (AOR 1.36; CI 1.18-1.57), tobacco use (AOR 1.59; CI 1.25-2.02), and a history of cancer (AOR 1.49; CI 1.10-2.02) and lowest for those of Hispanic ethnicity (AOR 0.73; CI 0.56-0.95), history of heart failure (AOR 0.74; CI 0.62-0.88). In 1995-1996, patients receiving Medicare coverage within the community were most likely to utilize PD compared to Veterans within the community and within the VA (18.9% vs. 9.6% and 8.2%, respectively), an observation that remained consistent over time. PD utilization among African-American Veterans was lower overall, although more closely approached estimates in white Veterans in more recent years. Veteran survival vs. Medicare controls is shown in **Figure 1**.

Conclusions: While PD utilization among Veterans is lower within the VA, the observed mortality benefit for care receipt within the VA was reassuring.



PO1256

Trends in Automated Peritoneal Dialysis (APD) Prescriptions in Adult Chronic Dialysis Patients at a Large Dialysis Organization from 2015 to 2019

Linda Ficociello,[1] Vidhya Parameswaran,[1] Allison Comerford,[1] Claudy Mullon,[1] Michael S. Anger,[1] Robert J. Kossmann,[2] Harold E. Giles.[3,4]
[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA; [3]Nephrology Associates PC, Birmingham, AL; [4]Fresenius Medical Care Birmingham Home Clinic, Birmingham, AL.

Background: Benefits of patients dialyzing at home have been well-reported. Peritoneal dialysis (PD) has grown in recent years and is expected to grow further due to the recent executive order encouraging home dialysis. Trends in APD prescriptions have not been well-described in the literature. This current retrospective analysis aims to describe trends in APD prescriptions from 2015-2019

Methods: All demographic, lab, and prescription data were retrospectively extracted and de-identified from a LDO's (Fresenius Kidney Care) electronic data warehouse. Patients included in the analysis were adults with chronic kidney disease on dialysis, incident to APD from Jan 1, 2015 to Dec 31, 2019, completed APD training, had at least one APD treatment recorded, and no data quality issues with their records. Patients were stratified by the year they started PD (2015, 2016, 2017, 2018, 2019) and patients' first APD prescription information was summarized.

Results: 16,047 patients were eligible for inclusion. The number of APD new starts eligible increased from 2,005 patients in 2015 to 4,751 patients in 2019, as did mean patient age (56.0 years in 2015 to 58.3 years in 2019, p<0.05). Few patients were prescribed daytime exchanges (7.6% in 2015 to 4.8% in 2019, p<0.05) and of those with daytime exchanges, the majority (>93% in all years) had 1 exchange. Table describes other prescription parameters by year.

Conclusions: Comparing 2019 to 2015 initial PD prescription patterns, there have been reductions in cycler volume, total number of exchanges, and prescriptions for daytime exchanges. These findings may support future studies on the current use of lower volumes with newer catheters (e.g. urgent starts) and accommodations made for patient lifestyle and choice

Development of a Robust Peritoneal Dialysis Program

Gabriel A. Valle,[1,2] Barbara K. Valle.[1,2] *[1]Kidney and Hypertension Group of South Florida, Fort Lauderdale, FL; [2]VIP Kidney Health, Delray Beach, FL.*

Background: Despite ample evidence supporting the superior performance of Peritoneal Dialysis (PD) in a value-based heathcare system, this modality remains conspicuously underutilized in the USA. We implemented a multifaceted strategy to develop a high-performing PD facility in 28 months.

Methods: VIPKH, a private PD Center, was created through an affiliation with a five-doctor nephrology group in Florida and Medicare Certified 8/2017. Our physicians adopted an "upstream" approach to patient selection by promoting timely access to care for CKD 3b/4/5. KD education was mandatory. Social Media storytelling fostered a vibrant virtual CKD community. Patient vetting incorporated multidisciplinary evaluation of support systems and socio-economic and cultural determinants of health within their specific ecosystem. Expedited referral to an expert surgeon for laparoscopic catheter insertion was crucial. Home training and on-demand home visits were conducted routinely. 24/7 tele-access to clinicians and an open-door policy for non-routine care was instituted. Two satellite locations were available. FTE staff included an Administrator/ Population RN, two PDRN, Assistant Administrator and PTE RD and MSW.

Results: From 9/2017 through 12/2019 (28 months), 66 patients were admitted to VIPKH (Program Vintage 58 PD patient/years). Demographics: female 50%, 64.7 years (25-86), Caucasian 55%, African-american 23%, Hispanic 15%. Comorbidities: DM 47%, CHF 36%, DM/CHF 21%, Morbid Obesity 14%. As of 12/31/2019, 37 patients were on CCPD with good adequacy, 29 discharged: 1 Recovery, 7 Transplant, 3 Relocation, 4 Deceased, 1 Hospice, 13 Dropouts (5 peritonitis, 1 tunnel infection, 2 leaks, 1 inadequate dialysis, 3 disability, 1 burnout). Performance rates per 100 ESRD patient years (VIPKH vs Benchmarks): Peritonitis (10 vs 25), tunnel infection (2 vs 8), admissions (72.6 vs 170), hospitalization days (631 vs 1120), 30 day readmission (16.7% vs 37%), ED/Short-Stay (12.1 vs 350), transplant (12.9 vs 3.5), mortality (6.9 vs 22.5).

Conclusions: Our outcomes reflect the delivery of exceptional PD care. Our pragmatic approach to developing a successful PD program encompasses humble leadership which lays the foundation for building powerful relationships between all stakeholders through effective communication, education and collaboration, promotes shared decision-making and facilitates timely access to integrated, longitudinal, patient-centered care.

PO1258

Acute Peritoneal Dialysis in Obese Patients During the COVID-19 Pandemic

Leian Joseph,[1,2] Fnu Ranjeeta,[1,2] Nina J. Caplin,[1,2] Richard Amerling.[2] *[1]NYU Langone Health, New York, NY; [2]Bellevue Hospital Center, New York, NY.*

Background: Due to increased risk for infection, fluid leak, metabolic complications and poor uremic solute clearance, concerns have been raised in using peritoneal dialysis in obese patients. However, due to unprecedented need for renal replacement therapy (RRT) in New York City during the COVID-19 pandemic, acute peritoneal dialysis (APD) was initiated in patients regardless of body mass index (BMI).

Methods: 36 patients who received PD between April 8, 2020 and May 8,2020 were categorized into 3 groups based on BMI calculated using admission height and weight. Group 1 with BMI < 30, Group 2 with BMI 30-40 and Group 3 with BMI > 40 kg/m^2. Treatment goals included correction of hyperkalemia, hyperphosphatemia, acid-base abnormalities, reduction in blood urea nitrogen (BUN), creatinine and maintaining euvolemia. All patients were initially started on manual exchanges every 1-2 hours (Total volume 10-13L/24 hours) and eventually most were changed to automated PD (Total volume 18-20L/24 hours). We compared the frequency of treatment-related complications among the groups.

Results: Of the 36 patients, 13 had BMI < 30, 18 patients had BMI 30-40, and 5 had BMI > 40, one of whom had BMI > 50 kg/m^2. Patients showed improvement in serum creatinine, BUN, phosphorus, potassium, and bicarbonate. All had adequate ultrafiltration and improved volume status after optimization of PD prescription. No differences were observed between groups in achievement of treatment goals. No patients in any group required discontinuation of PD because of treatment-related complications or insufficient dialysis.

Conclusions: Acute PD was successfully performed in obese, and morbidly obese patients during the COVID-19 pandemic. Treatment goals were achieved based on relevant parameters and there were no increases of treatment related complications compared to non-obese patients. Acute PD should not be restricted based on elevated BMI.

PO1259

Comparing Mortality of Peritoneal and Hemodialysis Patients in an Era of Medicare Reform

Virginia Wang,[2,1] Cynthia Coffman,[2,1] Linda L. Sanders,[2] Abby Hoffman,[2,4] Caroline E. Sloan,[2,1] Shoou-Yih D. Lee,[3] Richard A. Hirth,[3] Matthew L. Maciejewski.[1,2] *[1]Durham VAHCS, Durham, NC; [2]Duke Univ, Durham, NC; [3]Univ Mich, Ann Arbor, MI; [4]UNC-CH, Chapel Hill, NC.*

Background: Medicare's 2011 prospective payment system (PPS) encouraged the expansion of peritoneal dialysis (PD), which is preferred by many patients and less costly than in-center hemodialysis (HD). Prior studies have shown PD to be associated with lower or equivalent mortality to HD. Expansion of PD services after the PPS may change

the relative mortality of PD and HD if PD is increasingly used by sicker patients. This study revisits the comparative risk of mortality between PD and HD modalities in cohorts of patients spanning Medicare PPS.

Methods: From the US Renal Data System, we compared 2-year all-cause mortality in a cohort of incident dialysis patients in 2006-2013. Patients were censored at renal transplant or the end of the 2-year follow-up. Baseline characteristics of HD and PD patients were assessed via standardized differences and Kaplan-Meier curves. To compare HD and PD 2-year survival, a Cox proportional hazards model was fit using inverse probability of treatment weights (IPTW, generated from patient demographic and clinical characteristics) by incident year, adjusting for patient and dialysis market characteristics.

Results: PD use in the first 90 days increased from 9.5% of incident patients in 2006 to 13.6% in 2013. Crude 2-year mortality was 16.7% for PD and 27.6% for HD. There were no differences in patient characteristics between pre- and post-policy cohorts. In IPTW survival analysis across all incident year cohorts, no differences in 2-year mortality were found for those who attempted PD in the first 90-days of dialysis compared to patients receiving HD (example: HR, 0.93; 95% CI, 0.84 to1.04 for 2006 incident cohort). Mortality differences between PD and HD did not change over time (p=0.23).

Conclusions: Growth in PD initiation over time occurred without changing the patient mix towards sicker patients. After accounting for confounding, we found no evidence of mortality differences between PD and HD before and after payment reform. These findings suggest that Medicare PPS improved the value of dialysis care such that PD service use increased without adversely affecting patient mortality. Still, PD uptake in the US still lags that of many countries. Future policy initiatives may be needed to continue to increase clinically appropriate PD uptake.

PO1260

Duration of Serum Phosphorus Control Associated with Overall Mortality in Patients Undergoing Peritoneal Dialysis

Jun Ai, Zhiwen Xiao. *Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Serum phosphorus (SP) level was closely associated with overall mortality and cardiovascular events, while the role of SP controlled duration was not fully recognized. Our study is to identify the relationships of SP controlled duration with clinical outcomes in patients undergoing peritoneal dialysis (PD).

Methods: This was a retrospective cohort study, including PD patients with regular follow-up in our center from Jan 1st, 2009 to Jun 30th, 2019. Clinical data were collected at baseline and at 3, 6, 9, 12, 18, 24, 30, 36, 48, 72, 96, and 120 months after dialysis. SP levels, changed degree of SP over baseline, and SP controlled duration were analyzed with overall mortality, PD withdrawal, and combined endpoint. Degree of SP change over baseline (%) = (SP level at following-up point - baseline SP level) × 100 / baseline SP level. Duration of SP control (months) = PD vintage when patients reached hyperphosphatemia - PD vintage when patients' SP decreased to less than 1.78 mmol/L after PD.

Results: 530 patients entered the analysis [the mean age was 45.4 ± 15.0-year-old, 57.2% were male, the median PD vintage were 32 (15-54) months]. 86.0% patients had hyperphosphatemia before dialysis, and the SP levels decreased soon after dialysis. Degree of SP change over baseline was the maximum at the 3rd month after dialysis (-31.0%), lower degree was associated with higher overall mortality [HR, 1.012(1.004-1.020); p=0.003]. The median SP controlled duration were 13 (5-28) months, the longer SP controlled duration, the lower overall mortality [HR, 0.968(0.956-0.981); p < 0.001], the lower incidence of PD withdrawal [HR, 0.964(0.954-0.973); p < 0.001] and combined endpoint [HR, 0.982(0.976-0.989); p < 0.001]. After categorized, patients whose SP never controlled had the maximum overall mortality (24.6%), the duration more than 12 months greatly improved the overall mortality [HR 0.197 (0.082-0.458); p < 0.001]. Phosphorus binders (PB) applying was significantly associated with overall mortality [HR 0.555(0.332-0.927); p=0.025] and PD withdrawal [HR, 0.523(0.391- 0.698); p < 0.001].

Conclusions: In PD patients, the level of SP and the degree of change after dialysis were tightly associated with overall mortality, PD withdrawal and combined endpoint. The longer SP controlled duration, the lower overall mortality. We should controll SP levels as early and as long as possible.

PO1261

Urgent-Start Peritoneal Dialysis and Outcomes

Steph Karpinski,[1,2] Scott Sibbel,[1,2] Dena E. Cohen,[1,2] Carey Colson,[1,2] David B. Van Wyck,[2] Arshia Ghaffari,[3] Martin J. Schreiber,[4] Francesca Tentori,[1,2] Steven M. Brunelli.[1,2] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Patient Safety Organization, Denver, CO; [3]University of Southern California, Los Angeles, CA; [4]DaVita Inc, Denver, CO.*

Background: Many patients start dialysis without adequate pre-dialysis planning, and generally initiate hemodialysis using a central venous catheter (HD-CVC). A minority utilize urgent start peritoneal dialysis (USPD), where a peritoneal dialysis catheter is placed and used for dialysis initiation without the usual 2-4 week waiting period. Few analyses have compared outcomes between patients utilizing these two dialysis initiation routes.

Methods: All data for this retrospective study were derived from deidentified electronic health records. Patients who initiated dialysis via HD-CVC during 2018 were matched 1:1 to patients who initiated dialysis using USPD during the same period on the basis of insurance type, etiology of end-stage kidney disease, race, and presence of diabetes. Hospitalization, mortality, and scores on the Kidney Disease Quality of Life (KDQOL) survey were evaluated from dialysis initiation through the first of death, transplant, loss to follow-up, or study end (30 June 2019). Outcomes were compared across exposure groups using models adjusted for age and sex.

Results: A total of 717 USPD patients were matched to HD-CVC patients. During follow-up (mean 1.2 ± 0.6 years in both groups), USPD patients were hospitalized at a rate of 1.21 admissions/patient-year (pt-yr), vs. 1.51 admissions/pt-yr for HD-CVC patients. This corresponded to a 24% lower rate of hospitalization among USPD patients (adjusted incidence rate ratio 0.76, 95% confidence interval [CI] 0.65 – 0.88). Mortality rates were likewise lower among USPD patients compared to HD-CVC patients (0.08 vs 0.11 deaths/pt-yr) although this trend did not achieve statistical significance (adjusted hazard ratio 0.84, 95% CI 0.62, 1.15). No differences were observed with respect to KDQOL scores.

Conclusions: Among patients with little to no predialysis planning, use of USPD is associated with a lower subsequent hospitalization rate and a trend towards lower mortality rate, compared to HD-CVC. In areas where facilities and clinical expertise exist, more widespread adoption of USPD may lead to better outcomes among patients with limited pre-dialysis planning.

PO1262

Efficacy of Statin Use in Patients Undergoing Peritoneal Dialysis

Hyung Woo Kim, Geun Woo Ryu, Shinchan Kang, Yooju Nam, Beom seok Kim. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: The efficacy of statin uses in patients with PD have not been proven in large studies. Because most of studies included only HD patients or a small number of PD patients, there is lack of evidence whether statin have positive effect on PD patients or not. The aim of this study was to reveal the efficacy of statin uses in PD patients.

Methods: A total 612 incident PD patients between January 2006 and August 2019 were included in this study. The primary outcome was all-cause mortality and the main exposure of interest was a cumulative dose of statin. For defining the cumulative dose for statin, the definition of defined daily dose by World Health Organization was used. Patients who used statin for at least 28 cumulative defined daily doses (cDDD) after initiation of PD were defined as statin user.

Results: During a median follow-up duration of 33.0 months (IQR, 15.0-63.0), the primary outcome occurred in 124 (20.2%) patients. The mean age at initiation of PD was 53.6±14.5 years and 329 (53.8%) patients were men. The number of statin users was 390 (63.7%) and the number of patients who use statin before starting PD was 311 (50.8%). Statin use (≥28 cDDD) was associated with a lower risk of all-cause mortality (HR, 0.32; 95% CI, 0.20-0.52) after adjustment and this association was also consistent regardless of the use of statin before PD initiation. Adjusted hazard ratios for the all-cause mortality were 0.87 (95% CI, 0.53-1.43), 0.39 (95% CI, 0.20-0.75), 0.41 (95% CI, 0.18-0.91), and 0.13 (95% CI, 0.06-0.26) for the 28-365, 366-730, and 731-1095, respectively, compared with cDDD<28. The risk reduction of statin may be dose dependent.

Conclusions: Statin use was associated with a reduced risk of all-cause mortality in incident PD patients with or without statin use before dialysis.

PO1263

Mortality and Hospitalization in a Large International Peritoneal Dialysis Institution During 2018

Belen Marron, Suzanne H. Pearce, Charlotta Wollheim, Marietta Török, Carlos Lucas, Filiz Akdeniz, Israel P. Silva, Fernando Macario. *Diaverum Renal Services. Corporate Medical Office, Hyllie, Mälmo, Sweden.*

Background: With the exception of some national registries, data referred to mortality or hospitalization within a single large international peritoneal dialysis (PD) institution are seldom reported. **Objectives:** To study all-cause mortality, transplantation rate, hospitalizations and peritonitis rates in our large PD program during 2018.

Methods: Observational, prospective registry in 8 countries. The following variables were tracked: crude mortality rate and causes, hospitalization variables (number of hospitalization days per patient; number of hospitalization episodes per patient; number of days per hospitalization episode; causes of hospitalization), peritonitis rate (episodes/year at risk and patient months at risk to a peritonitis episode) and transplantation rate.

Results: By the end of December 2018, 1207 pt. were treated (11 countries) but only 8 countries submitted data. Evaluated population as "*patients treated at risk during the year*": AR (319.5), RO (173.5), DE (137), HU (103), PL (97), UR (69.5), CL (27), KZ (7). Crude mortality rate was 13.1%, same if first 90 days on therapy were excluded. Lowest mortality was seen in HU (9.9%) and highest in DE (19.3%). Causes of death: cardiac 32%, all type infections 22% [Sepsis 78%, PD related 11% (as 0.7% of total mortality), pulmonary 3.7%, others 7.4%], vascular 10%, gastrointestinal 3.3%, unknown 10.7% (highest in DE, 23%), other known causes 21.5%. Hospitalization rates: 0.55 episodes/per patient-year and 7.6 days of hospitalization per patient-year. N. of days per hospitalization episode was 13.7. Causes of hospitalization: PD related 38%, cardiovascular 17%, non-PD infection sepsis 10.7% (higher in LA, 16.6%), vascular access 2.1%, unknown 4.5%, others 23.3%. Global peritonitis rate was 0.18 episodes/pt-year at risk (1 episode every 66 m.). However, large differences were seen among countries. Transplantation rate was 6.5% (much higher in UR). PD was withdrawal in 35% of pt. Country specific data have been evaluated but are not shown here.

Conclusions: The use of a common registry in our institution increases quality and allows homogeneous comparisons across countries that if promptly addressed may increase patients' outcomes. Our series may bring light into the PD community as one of the ever largest tracked in a single institution.

PO1264

Association Between Peritoneal Dialysis (PD) Patient-Reported Family Member Assistance and Peritoneal Dialysis Modality Persistence

Jasmine T. Washington,[1] Rachel B. Fissell,[1] Ebele M. Umeukeje,[1] Devika Nair,[1] Kerri L. Cavanaugh,[1] Beth Rust,[1] Amanda E. Dunn,[1] David G. Schlundt.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: Increasing the number of dialysis patients who start and maintain home therapies is an urgent national priority. PD patients perform their own dialysis procedures at home. Family members may assist with moving dialysate bags, catheter care, dialysis machine set-up and connections, and medication administration. Understanding and supporting caregivers is an important driver of successful home dialysis, necessary to inform program content and activities. This study describes associations between patient reported family member assistance with healthcare tasks, and modality persistence.

Methods: Prospective, single site, cohort study of adults receiving PD for kidney failure. A baseline survey assessing family assistance with healthcare tasks at home was administered during a routine outpatient visit. Longitudinal data were tested using Chi-squared (SPSS) for associations between patient reported family member assistance, and PD modality persistence at six months.

Results: This sample of N=100 patients was 57% male, 31% African American, and 4% Hispanic/other. Average age was 52 +/- 16 years. Most patients reported a family member provided help at home (65%). Among those reporting family member assistance, 20% reported help administering insulin, 65% reported help with the PD procedure, 54% managed medications, and 59% provided wound care. Also, 16% reported help with one or two tasks, 28% help with three tasks, 25% help with five tasks. Patients who self-identified as Black/Hispanic/other reported less family member assistance than whites (51% vs. 71%, p=0.04). In the 74% of the initial sample who completed 6 month follow-up, for patients reporting any family assistance compared to those reporting none, there was a trend toward higher PD modality persistence (86.4% vs. 70.4%, p=0.092).

Conclusions: Optimizing family assistance may be a strategy to promote PD modality persistence. More work is needed to better characterize the caregiver role and its impact on health outcomes specific to home dialysis.

PO1265

Patient Outcomes of a Two-Exchange Assisted Continuous Ambulatory Peritoneal Dialysis (CAPD) Programme for Frail Older Patients

Louise A. Ryan,[1] Titus Chelapurath,[1] Richard W. Corbett,[1] Edwina A. Brown.[1,2] *[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom.*

Background: Recognising the burden that hospital haemodialysis (HD) places on frail people in terms of time away from home, transport and haemodynamic shifts, we developed a 2-exchange assisted CAPD (aCAPD) programme to enable this group to receive a home-based therapy. Eligible patients include frail, mostly elderly patients who are symptomatic from advanced kidney disease and have residual kidney function. The focus of the programme is to optimise patients' symptoms while avoiding a high treatment burden.

Methods: In this observational study, all 2-exchange aCAPD patients attending for routine review are approached for assessment. Frailty is assessed with the Edmonton Frail Scale (EFS), cognitive function with the Montreal Cognitive Assessment (MOCA), treatment satisfaction with the Renal Treatment Satisfaction Questionnaire (RTSQ) and symptoms with the Palliative Outcome Scale-Symptom Renal (POS-S Renal). Data was collected via patient interviews and chart review.

Results: Of the 17 patients currently receiving 2-exchange aCAPD, results have been collected from 47% (N=8) to date. Mean age is 82 years (77-90) and 50% are male. Mean number of co-morbidities was 4.4. Mean time on 2-exchange aCAPD was 9 months (0-24). 63% had at least mild frailty with an EFS of >8/17 (3-11). 75% had memory impairment with a MOCA <26/30 (8-30). Median number of hospital admissions was 1 (0-3). 38% have travelled outside of the UK (with family support) since commencing aCAPD. 85% reported high satisfaction with treatment with a RTSQ of >55/66 (median 62). Patients reported a low symptom score with a median POS-S Renal of 14.5 (7-27). Pain, lack of energy and poor mobility were the most commonly reported symptoms.

Conclusions: Our results demonstrate a frail, elderly population with multiple co-morbidities. Although our population number is small and they are not matched to the assisted PD and HD populations published in the FEPOD study they do compare favourably in terms of the RTSQ score; median of 60 vs 55 for assisted PD and 60 vs 51 for HD. Our population was comparable to both groups in terms of the POS-S Renal symptom scores; 14.5 vs 14 for assisted PD and 14.5 vs 16 for HD. This indicates that 2-exchange aCAPD could potentially become the dialysis modality of choice for the frail, older person requiring dialysis.

PO1266

A Snapshot for Peritoneal Dialysis Clinic Visits: Addressing Hospitalization Rates with a Checklist

Samantha M. Saggese, Aditya V. Jain, Michael Bond, Janis Cho, Alexander S. Leidner, Tina S. Samuel, Harini Gurram, Vikram Aggarwal. *Northwestern Memorial Hospital, Chicago, IL.*

Background: Readmission rates are a component of quality metrics in home dialysis follow-up. Common causes of peritoneal dialysis (PD) related hospitalizations have been elucidated through National Readmission Database review. However, a systematic approach to identify individual risk factors leading to the index hospitalization and targeted interventions are not directly designed into clinic workflow. Often information regarding these specific risk factors are not exacted. We identified a need to standardize practice in our PD clinic by conceiving an action checklist for nephrologists and nurses to minimize index admissions.

Methods: Our quality improvement project sought to identify risk factors by analyzing the cause of admission from our cohort of 103 PD patients over 8 months. We divided reasons for admission into related and unrelated to PD. Based on these categories, we created a list of potential contributory risk-factors for admission. We also surveyed providers to determine key clinical components for a clinic checklist to encourage early recognition of the risk-factors.

Results: Of the 105 individual admission events identified from June 2018 to March 2019, 45% were identified as PD-related. Such admissions included peritonitis (34%), hypervolemia (19%), electrolyte derangement (13%), hypotension (13%), hypertension (10.6%) and catheter dysfunction (10.6%). 37 admissions (35%) were readmissions in the last 30 days, of which 60% were PD-related. From these results we designed a snapshot of trends of the prior 3 months' vital signs, electrolytes, weights, PET results, PD adequacy results, urine volume, peritonitis history and current medications for clinicians to review pre-visit.

Conclusions: We are currently implementing this checklist in our monthly PD clinic visits. Though the idea was conceived prior to the pandemic, we have increasingly seen the benefit of a clinical trends snapshot readily available as we transition to Telehealth visits to prevent patients' exposure to COVID-19. This method assists the clinician in triaging remotely. Ultimately, through utilization of this tool, we hope to unify our practice pattern in the clinic to reduce admission rates by prompting proactive, not reactive, interventions.

PO1267

Lung Comets and Hydration Status in Peritoneal Dialysis Patients

Robert Ekart,[1,2] Lucijan Lucic Srajer,[2] Katharina Marko,[2] Nina Vodošek Hojs,[1] Sebastjan Bevc,[1,2] Radovan Hojs.[1,2] *[1]University Medical Center Maribor, Maribor, Slovenia; [2]Medical Faculty University of Maribor, Maribor, Slovenia.*

Background: Multiple diagnostic options to determine hydration status in peritoneal dialysis (PD) patients are available. Multifrequency bioimpedance spectroscopy (MBIS) is a non-invasive method of estimating body composition, including total body water (TBW), extracellular water (ECW), intracellular water (ICW) and the ratio between both spaces (ECW/ICW). Lung ultrasonography (LUS) and lung B-lines (lung comets) can be used for the evaluation of extravascular lung water. Ultrasound evaluation of inferior vena cava (UIVC) provides a non-invasive assessment of a patient's hemodynamic and volume status. N-terminal pro-brain natriuretic peptide (NT-proBNP) is related to fluid status and fluid distribution. The aim of our study was to assess fluid status in PD patients comparing four different methods: MBIS,LUS,UIVC and NT-proBNP.

Methods: We performed a single-centre cohort study in 19 PD patients. The body composition was measured using the portable whole-body MBIS device, BCM(®) (Fresenius Medical Care, Germany), LUS with portable US device (VScan, GE Corporate),UIVC index with SonoSite US device. NT-proBNP was measured in a one-step sandwich chemiluminescent immunoassay (Siemens Healthcare Diagnostics, Newark, USA).

Results: The mean age of patients was 54±10 years, mean dialysis vintage 53 (10-194) months, 63% were men. Thirteen (68.4%) patients had fluid overload (FO)>1.1 L. Data of patients are presented in table 1. We found a statistically significant correlation between the number of lung comets and ECW/ICW ratio (r=0.496, P=0.031) and NT-proBNP (r=0.759, P<0.0001). In contrast, there was no significant correlation between the number of lung comets and UIVC (r=0.221, P<0.364).

Conclusions: According to our results, LUS with lung comets, MBIS with ECW/ICW ratio and NT-proBNP are useful and complementary methods for evaluation of fluid status in PD patients.

Descriptive data of the patients included in the study (N=19)

Variable	Mean ± SD
Lung comets (number;mean±SD)	1-87; 16±21
UIVC (mm/m2,mean±SD)	8.11±1.76
NT-proBNP (pmol/L)	1151±1077
MBIS: Total body water (L)	43.1±10.3
MBIS: Extracellular water (ECW) (L)	20.3±5
MBIS: Intracellular water (ICW) (L)	22.8±6.1
MBIS: ECW/ICW	0.9±0.14
MBIS: Overhydration (L)	2.45±3.05

Outcomes of Urgent-Start Peritoneal Dialysis in a Retrospective Cohort

Gonzalo Matzumura Umemoto, Frank J. O Brien. *Washington University in Saint Louis, Saint Louis, MO.*

Background: Peritoneal dialysis (PD) has shown to have early survival benefit and increased patient satisfaction when compared to in-center hemodialysis. Despite this, 87% of patients with End Stage Renal Disease (ESRD) start on hemodialysis, while only 10% of patients start RRT via peritoneal dialysis. The Advancing American Kidney Health Initiative was launched in July 2019, with the goal of having 80% of incident ESRD patients on a home modality or transplant by 2025. In this context, major changes will need to ensue so patients starting RRT can have increased access to home dialysis. Conventional start peritoneal dialysis requires the PD catheter to rest for several weeks

after insertion prior to use. This limits the use of PD for patients that need to start RRT urgently. An alternative is urgent start PD where dialysis can be started as soon as 1 day after catheter insertion. There is growing evidence that urgent start PD is a safe and effective alternative to urgent start hemodialysis.

Methods: A retrospective analysis of patients that underwent urgent start peritoneal dialysis from 2013 to 2019 at the Washington University Home Modalities Dialysis Clinic was conducted. Complications (including catheter leak, catheter malfunction, infections and bleeding episodes), hospital admissions in the first 30 days after catheter placement and time patients remained on PD after urgent start were examined.
