KIDNEY WEEK 2020 REIMAGINED

OCTOBER

Abstract Supplement

KIDNEY WEEK 2020 REIMAGINED OCTOBER

Abstract Supplement

Abstract Publication
More than 3,000 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date* for orals, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 31, 2020: Page(s).

Abstract Disclaimer and Copyright
This abstract issue of JASN® contains proprietary information belonging to the American Society of Nephrology. It is published as a service for the personal, noncommercial, and informational use only of the kidney community. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such materials within Kidney Week and other ASN publications or online postings does not constitute endorsement by ASN.

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The ASN website lists all abstract experts.

ASN General Information
Kidney Week Program and Presentations
The Kidney Week program, which can be found on the ASN website, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week to complete a disclosure form. Responses are listed on the ASN website.

TH-OR01

Global Phase 3 Clinical Trials of Vadadustat vs. Darbepoetin Alfa for Treatment of Anemia in Patients with Dialysis-Dependent CKD

Kai-Uwe Eckardt, INNO2VATE Author Group *Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: Vadadustat (VADA) is an investigational, oral, hypoxia-inducible factor prolyl hydroxylase inhibitor that has advanced to phase 3 development for treatment of anemia of CKD. In phase 2 trials, VADA raised and maintained Hb concentrations.

Methods: Two randomized, phase 3, global, open-label, sponsor-blind, parallel-group active-controlled noninferiority (NI) trials comparing VADA vs darbepoetin alfa (DA) were conducted in patients with anemia of DD-CKD ($INNO_2VATE$ trials). The trials included 1) Correction/Conversion trial of patients new to dialysis (incident trial, NCT02865850) and 2) Conversion trial of patients on maintenance dialysis (prevalent trial, NCT02892149). The primary safety endpoint was time to first major adverse cardiovascular event (MACE: all-cause mortality, nonfatal MI, nonfatal stroke) prespecified as a pooled analysis of both trials. Primary and key secondary efficacy endpoints, prespecified as separate analyses for each trial, were mean difference in change in Hb from baseline between VADA vs DA to wks 24-36 and wks 40-52, respectively.

Results: 3923 patients were randomized 1:1 to VADA or DA (incident, N=369; prevalent, N=3554). Median (Q1, Q3) duration of follow-up was 1.2 (0.8, 1.7) and 1.7 (1.2, 2.2) years in the incident and prevalent trials, respectively. VADA was noninferior to DA for time to first MACE (HR 0.96; 95% CI: 0.83, 1.11) and met a prespecified NI margin of 1.25. Among incident dialysis patients, the least squares (LS) mean difference in change in Hb between VADA vs DA from baseline to wks 24-36 was -0.31 g/dL (95% CI: -0.53, -0.10) and from wks 40-52 was -0.07 g/dL (95% CI: -0.34, 0.19). In the prevalent trial, the LS mean difference in change in Hb from baseline to wks 24-36 was -0.17 g/dL (95% CI: -0.23, -0.10), and wks 40-52 was -0.18 g/dL (95% CI: -0.25, -0.12). Primary and key secondary efficacy endpoints met the prespecified NI margin of -0.75 g/dL in both trials. Incidence of treatment-emergent adverse events (TEAEs) in VADA vs DA was 83.8% vs 85.5% in the incident trial and 88.3% vs. 89.3% in the prevalent trial, respectively.

Conclusions: VADA was noninferior to DA in time to first MACE and correction/maintenance of Hb in DD-CKD patients with anemia. The incidence of TEAEs was comparable between VADA and DA.

TH-OR02

Roxadustat for the Treatment of Anemia in CKD Patients Not on Dialysis (NDD): A Phase 3, Randomized, Open-Label, Active-Controlled Study

Jonathan Barratt,[1] Branislav Andric,[4] Avtandil Tataradze,[3] Michael Schoemig,[2] Michael Reusch,[5] Udaya Valluri,[5] Christopher R. Mariat.[6] *[1]University of Leicester, Leicester, United Kingdom; [2]Center of Dialysis and Nephrology, Heilbronn and Neckarsulm, Germany; [3]National Center of Urology, Tbilisi, Georgia; [4]Health Center Krusevac, Kruševac, Serbia; [5]Astellas Pharma Europe B.V., Leiden, Netherlands; [6]CHU St Etienne, Service Nephrologie Dialyse Transplantation, St Etienne, France*.

Background: Roxadustat is an orally administered hypoxia-inducible factor prolyl hydroxylase inhibitor to treat anemia in adult CKD patients (pts). Efficacy and safety of roxadustat versus darbepoetin alfa (DA) were assessed in NDD CKD pts in a randomized, open-label, active-controlled phase 3 study.

Methods: NDD CKD pts with anemia were randomized to roxadustat or DA for up to 2 years. Dose adjustments were permitted to correct and maintain hemoglobin (Hb) within 10–12 g/dL. The primary endpoint was Hb response, defined as Hb ≥11.0 g/dL and Hb increase from baseline (BL) of ≥1.0 g/dL in pts with BL Hb >8.0 g/dL, or an increase of ≥2.0 g/dL in pts with BL Hb ≤8.0 g/dL, during the first 24 weeks of treatment without rescue therapy. Noninferiority of roxadustat to DA was declared if the lower bound of the two-sided 95% confidence interval (CI) for the difference (roxadustat – DA) in proportion of responders was >-0.15. Key secondary endpoints included change in low-density lipoprotein (LDL) cholesterol, time to first IV iron use, change in mean arterial pressure (MAP), and occurrence of hypertension. Treatment-emergent adverse events (TEAEs) were assessed.

Results: Of 616 randomized pts (roxadustat, 323; DA, 293), 424 completed 2 years of treatment (roxadustat, 215; DA, 209). Mean BL Hb was 9.55 g/dL in both groups. In the per protocol set, the proportion of pts who achieved Hb response during the first 24 weeks was 89.5% (roxadustat; n=256/286) and 78.0% (DA; n=213/273), with a difference of 11.51% (95% CI: 5.66%, 17.36%), thereby establishing roxadustat's noninferiority to DA. Noninferiority of roxadustat to DA was demonstrated for MAP and time to occurrence of hypertension. Superiority of roxadustat to DA was demonstrated for decreasing LDL cholesterol ($p<0.001$) and increasing time to first IV iron use ($p=0.004$). The incidence of TEAEs was comparable between roxadustat (91.6%) and DA (92.5%). Common TEAEs in both groups were end-stage renal disease, hypertension, decreased eGFR, and peripheral edema.

Conclusions: Roxadustat was noninferior to DA for Hb response during the first 24 weeks of treatment in NDD CKD pts. Safety profiles were comparable between groups.

TH-OR03

Roxadustat Treatment of Anemia in Non-Dialysis-Dependent CKD Is Not Influenced by Iron Status

Robert Provenzano,[1] Steven Fishbane,[2] Daniel W. Coyne,[3] Carol A. Pollock,[4] Maksym Pola,[5] Willis Chou,[6] Khalil G. Saikali,[6] Kin-Hung P. Yu.[6] *[1]Wayne State University, Detroit, MI; [2]Northwell Health, Great Neck, NY; [3]Washington University in Saint Louis, Saint Louis, MO; [4]Royal North Shore Hospital, St Leonards, NSW, Australia; [5]AstraZeneca, Warsaw, Poland; [6]FibroGen Inc, San Francisco, CA.*

Background: Roxadustat, a hypoxia-inducible factor prolyl hydroxylase inhibitor for anemia in CKD, improves iron absorption and bioavailability. This analysis of Phase 3 studies explored the efficacy of roxadustat in pts with non-dialysis-dependent (NDD) CKD with iron repletion or depletion at baseline.

Methods: Data from 3 completed randomized Phase 3 studies in NDD-CKD pts were analyzed individually and in the pooled population by iron status. Pts were randomized to roxadustat or placebo for up to 4 years. Baseline (BL) hemoglobin (Hb) and change from BL (CFB) were summarized overall and in pts with iron repletion or iron depletion. Iron repletion was defined as ferritin ≥100 µg/L and transferrin saturation (TSAT) ≥20%; the remainder were defined as iron depleted. Oral iron was allowed on study and IV iron was allowed as rescue.

Results: Across studies, 2391 and 1886 pts with NDD-CKD were treated with roxadustat and placebo, respectively. Mean (SD) BL Hb was 9.10 (0.74) g/dL (roxadustat) and 9.10 (0.73) g/dL (placebo). At BL, 1433 (60%) pts were iron replete for roxadustat and 1127 (60%) pts were iron replete for placebo. Mean CFB in Hb with roxadustat was summarized by study and iron status (Table 1). Hb CFB was similar in iron-replete and -depleted patients receiving roxadustat. Roxadustat dose and iron use in subgroups will be explored.

Conclusions: Roxadustat corrected and maintained Hb in patients with NDD-CKD and anemia regardless of iron status at baseline.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

Change from baseline in Hb overall and by iron status with roxadustat treatment across NDD studies over Weeks 28 to 52 regardless of rescue therapy

Study	N in analysis	Mean (SD) baseline Hb for study (g/dL)	Adjusted LS mean Change from baseline in Hb
001 (OLYMPUS)	Overall = 1384	9.11 (0.73)	1.75 (0.03)†
	Iron-replete = 782		1.71 (0.04)†
	Iron-depleted = 552		1.76 (0.05)†
060 (ANDES)	Overall = 616	9.10 (0.75)	2.02 (0.04)†
	Iron-replete = 366		1.98 (0.05)†
	Iron-depleted = 241		2.10 (0.07)†
608 (ALPS)	Overall = 391	9.08 (0.76)	1.99 (1.82, 2.16)§
	Iron-replete = 204		1.97 (1.74, 2.20)§
	Iron-depleted = 187		1.99 (1.69, 2.29)§
Pooled	Overall = 2391	9.10 (0.74)	1.94 (0.02)†
	Iron-replete = 1433		1.94 (0.03)†
	Iron-depleted = 956		1.94 (0.03)†

†Least squares mean change from baseline to average during Weeks 28–52 (± standard error) in the intention to treat population for overall results; least squares mean change from baseline to average during Weeks 28–36 (± standard error) in the FAS population for baseline iron subgroup results.
§Least squares mean change from baseline to average Hb during Weeks 28-52 (95% confidence interval) in the all randomized population.
Least squares mean was derived using the multiple imputation strategy by combining the results of the ANCOVA model with other covariates.
For 001, iron replete was defined as ferritin >100 µg/L and transferrin saturation >20%.
For 001, iron depleted was defined as ferritin <100 µg/L and <20%.
Hb, hemoglobin; LS, least squares; NDD, non-dialysis dependent; standard deviation, SD.

Roxadustat Is Not Associated with an Increased Risk of Neoplasm in Patients with CKD and Anemia

Daniel W. Coyne,[1] Steven Fishbane,[2] Pablo E. Pergola,[3] Robert Leong,[4] Ming Zhong,[4] Dustin J. Little,[5] Kin-Hung P. Yu.[4] *[1]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [2]Northwell Health, Great Neck, NY; [3]Renal Associates PA, San Antonio, TX; [4]FibroGen Inc, San Francisco, CA; [5]AstraZeneca, Gaithersburg, MD*.

Background: Roxadustat is a novel, orally bioavailable, small molecule that reversibly inhibits hypoxia-inducible factor (HIF) prolyl hydroxylase enzymes and activates HIF and transcription of HIF-responsive genes, including for erythropoietin. Preclinical studies of roxadustat in multiple animal species did not demonstrate a carcinogenic signal. We report neoplasm-related adverse events (AEs) and serious adverse events (SAEs) from the roxadustat global phase 3 program.

Methods: Data from six pivotal studies were pooled: 3 compared roxadustat to placebo in patients with non–dialysis-dependent (NDD) CKD, and 3 compared roxadustat to epoetin alfa in patients with dialysis-dependent (DD) CKD. Patients were excluded from the studies if they had a history of malignancy, except for those determined to be cured or in remission for ≥5 years, curatively resected basal/squamous cell cancers, cervical cancer in situ, or resected colon polyps. AEs/SAEs reported during the treatment period +28 days and +7 days after the last dose of study drug in the NDD- and DD-CKD populations, respectively, were compared. Events were coded using the Medical Dictionary for Regulatory Activities, System Organ Class "Neoplasms benign, malignant and unspecified (incl cysts and polyps)."

Results: In the NDD population, 4270 patients were randomized (roxadustat=2386, placebo=1884), corresponding to 3870.7 and 2323.2 patient-exposure years (PEY), respectively. Neoplasm-related AE rates were 2.5/100 PEY in both the roxadustat and placebo groups. Neoplasm-related SAE rates were 1.1/100 PEY and 1.3/100 PEY in the roxadustat and placebo groups. In the DD population, 3880 patients were randomized (roxadustat=1940, epoetin alfa=1940), corresponding to 3315.3 and 3743.6 PEY, respectively. Neoplasm-related AE rates were 2.7/100 PEY and 2.3/100 PEY in the roxadustat and epoetin alfa groups. Neoplasm-related SAE rates were 1.1/100 PEY and 1.2/100 PEY. In both the NDD- and DD-CKD populations, there were no between–treatment-group differences in the organ types of neoplasms.

Conclusions: There were no clinically meaningful between–treatment-group differences in neoplasm-related AE and SAE rates in the roxadustat phase 3 clinical trials.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

TH-OR05

Roxadustat Treatment Results in Consistent Improvements in Hemoglobin (Hb) vs. Placebo: An Analysis of Three Multinational Randomized Clinical Trials in Patients with Non-Dialysis-Dependent CKD (NDD-CKD)

Roberto Pecoits-Filho,[1,2] Tak Mao D. Chan,[3] Elise Hardy,[4] Kin-Hung P. Yu,[5] Steven Fishbane.[6] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]School of Medicine, Pontifical Catholic University of Parana, Parana, Brazil; [3]Division of Nephrology, Department of Medicine, Queen Mary Hospital, The University of Hong Kong, Pok Fu Lam, Hong Kong; [4]Clinical Research, AstraZeneca, Gaithersburg, MD; [5]FibroGen Inc., San Francisco, CA; [6]Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

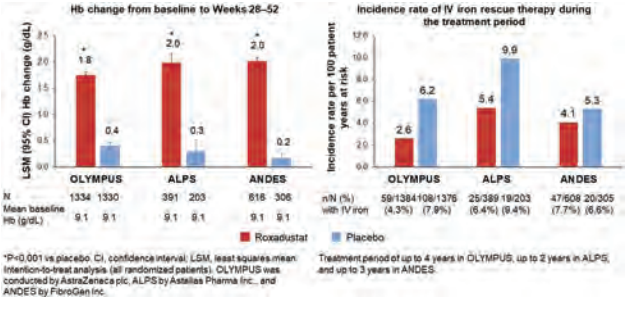
Background: Roxadustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor that increases endogenous erythropoietin and enhances iron utilization. To evaluate the consistency of Hb increases across studies and global geographic regions, we analyzed data from three pivotal Phase 3 trials of roxadustat in patients with anemia and NDD-CKD.

Methods: While based on the same trial design, the studies were performed by different investigators and companies in differing global regions. Patients with baseline Hb <10 g/dL and eGFR <60 ml/min/1.73 m^2 not on dialysis were randomized to roxadustat or placebo (pbo) in the OLYMPUS (North and South America, Asia-Pacific and Europe; N=2781, 1:1 ratio to pbo), ALPS (South America, Europe and South Africa; N=597, 2:1 ratio to pbo), and ANDES (North and South America, Asia-Pacific and Australasia; N=922; 2:1 ratio to pbo) double-blind randomized controlled trials (RCTs). Oral iron was administered unrestricted; intravenous (IV) iron was limited to rescue therapy in those with low iron stores and poor treatment response. The primary endpoint was the mean change in Hb from baseline to the average over Weeks 28–52.

Results: Significant (P<0.001) and consistent improvements in Hb were observed with roxadustat vs pbo across all studies (Figure) and were maintained over time. IV iron rescue therapy use was lower with roxadustat vs pbo (Figure). Overall safety of roxadustat was comparable with pbo and consistent with the CKD patient population.

Conclusions: Roxadustat consistently improved anemia in patients with NDD-CKD across the global roxadustat clinical program, in studies performed by different investigators and companies and in varying global locations.

Funding: Commercial Support - AstraZeneca



TH-OR06

Hemoglobin (Hb) Correction with Roxadustat Is Associated with Improved Iron Homeostasis in Patients with Dialysis-Dependent CKD (DD-CKD)

Pablo E. Pergola,[1] Chaim Charytan,[2] Dustin J. Little,[3] Stefan Tham,[4] Lynda Szczech,[5] Steven Fishbane.[6] *[1]Renal Associates PA, San Antonio, TX; [2]New York Hospital Queens, Division of Nephrology, Flushing, NY; [3]Clinical Research, AstraZeneca, Gaithersburg, MD; [4]Clinical Research, AstraZeneca, Gothenburg, Sweden; [5]FibroGen Inc., San Francisco, CA; [6]Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Background: Anemia in CKD is multifactorial, with contributions from reduced erythropoietin production and hepcidin-induced functional iron deficiency. Roxadustat, a hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by enhancing erythropoietin synthesis and increasing iron availability via reducing hepcidin and increasing iron transport. We assessed the effect of roxadustat on iron parameters in patients with DD-CKD.

Methods: Patients were randomized to open label roxadustat or epoetin alfa in 3 pivotal DD-CKD trials. Intravenous (IV) iron was administered per usual care with epoetin alfa and was limited to rescue therapy with roxadustat. Mean changes from baseline in Hb, hepcidin, and iron parameters were evaluated. Pooled results are reported.

Results: Overall, 3890 patients were evaluated (roxadustat N=1943; epoetin alfa N=1947; mean baseline Hb 9.7 g/dL for both groups), including 1515 incident dialysis patients (roxadustat N=756; epoetin alfa N=759; overall mean baseline Hb values ~8.8 g/dL). Mean Hb increased more from baseline averaged over Weeks 28–52 with roxadustat vs epoetin alfa (1.21 vs 0.95 g/dL; P<0.0001). Roxadustat-treated patients used less IV iron, with mean monthly IV iron use over Weeks 28–52 of 80.3 mg for roxadustat and 108.2 mg for epoetin alfa (P<0.0001). Roxadustat reduced hepcidin and increased transferrin and serum iron; transferrin saturation did not change vs epoetin alfa (Figure). Reduction in ferritin occurred predominantly in patients with the highest baseline values when assessed by quartile (>800 μg/L).

Conclusions: Roxadustat facilitated iron transport and utilization by increasing both iron-carrying capacity (transferrin) and serum iron, in contrast to the effects on these parameters seen with epoetin alfa. Overall, these changes contributed to decreased need for IV iron use while achieving greater Hb increase from baseline with roxadustat vs epoetin alfa.

TH-OR07

Renoprotective Effects of Ferric Citrate in a Mouse Model of CKD

Mark R. Hanudel, Shirley Wong, Kristine Chua, Grace Jung, Bo Qiao, Victoria R. Gabayan, Tomas Ganz. *University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

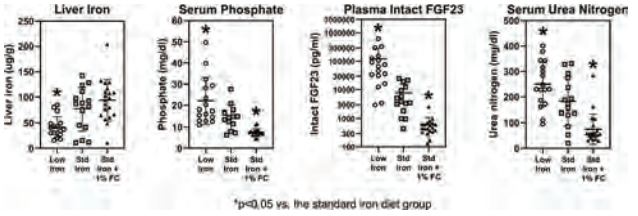
Background: Ferric citrate (FC) is an effective phosphate binder and iron replacement product. In the setting of chronic kidney disease (CKD), both decreasing enteral phosphate absorption and improving iron status could lower pathologically elevated FGF23 levels and indirectly improve kidney function. In a murine model of CKD, we assessed how FC (and iron status in general) affects FGF23 levels and kidney function.

Methods: Five-week-old *Col4α3* knockout mice were placed on five-week diets containing low iron (4 ppm), standard iron (48 ppm), or standard iron supplemented with FC (48 ppm + 1% FC) (n = 15-20 mice per group). Mice were euthanized at ten weeks of age.

Results: Compared to the standard iron diet group, the mice on low iron diets developed iron deficiency anemia (lower liver iron, lower hemoglobin, lower mean corpuscular volume, and higher red cell distribution width); markedly worsened kidney function (higher serum urea nitrogen, creatinine, and phosphate); and markedly higher FGF23 levels (increased bone and marrow *Fgf23* mRNA expression, and approximately ten-fold higher plasma intact FGF23 concentrations) (**Figure**). Conversely, compared to the standard iron diet group, the mice treated with FC had similar hemoglobin (with increases in liver and serum iron not reaching statistical significance), but decreased serum phosphate; decreased marrow *Fgf23* mRNA expression; approximately ten-fold lower plasma intact FGF23 concentrations; decreased systemic inflammation; and markedly improved kidney function (decreased serum urea nitrogen, serum creatinine, urine albumin-to-creatinine ratio, and expression of renal fibrosis markers, along with increased kidney *Klotho* mRNA expression) (**Figure**).

Conclusions: In the setting of CKD, iron deficiency anemia is associated with markedly increased intact FGF23 levels and worsened kidney function. In this CKD model, compared to either iron-deficient or standard iron conditions, FC decreased serum phosphate, markedly decreased intact FGF23, and dramatically improved kidney function. These data support further human studies of how FC affects CKD progression.

Funding: Commercial Support - Akebia Therapeutics, Inc.



*p<0.05 vs. the standard iron diet group

TH-OR08

Regional Variation of Erythropoietin-Stimulating Agent Hyporesponsiveness in the Global Daprodustat Dialysis Study (ASCEND-D)

Ajay K. Singh,[1] Allison Blackorby,[8] Borut Cizman,[7] Alexander R. Cobitz,[7] Sergio A. Godoy,[6] Vivekanand Jha,[2] Kirsten L. Johansen,[3] Gearoid M. McMahon,[1] Amy M. Meadowcroft,[8] Gregorio T. Obrador,[4] Muh Geot Wong,[5] Iain C. Macdougall.[9] *[1]Brigham and Women's Hospital, Boston, MA; [2]George Institute for Global Health, Sydney, NSW, Australia; [3]Hennepin Healthcare, Minneapolis, MN; [4]Universidad Panamericana, Mexico, Mexico; [5]Royal North Shore Hospital, St Leonards, NSW, Australia; [6]George Clinical, Pilar, Argentina; [7]GlaxoSmithKline, Collegeville, PA; [8]GlaxoSmithKline, Research Triangle Park, NC; [9]King's College Hospital, London, United Kingdom.*

Background: Hyporesponsiveness to erythropoiesis-stimulating agents (ESA) is present in 10%–15% of the prevalent dialysis population. We explored baseline characteristics and predictors of ESA hyporesponsiveness in a global randomized cardiovascular outcomes study comparing an investigational hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI), daprodustat, with conventional ESA treatment.

Methods: ASCEND-D (NCT02879305) recruited 2964 prevalent dialysis patients receiving ESA treatment (standardized to weekly intravenous [IV] epoetin) who were iron replete at baseline. Primary ESA hyporesponsiveness definition: ESA Resistance Index (ERI, ESA Units/kg/week/hemoglobin g/L) ≥2 or IV ESA equivalent dose ≥450 Units/kg/week. Predictors of ESA hyporesponsiveness were determined using a multivariable regression model. Alternate hyporesponder definitions were explored.

Results: Using the primary definition, 354 (12%) patients were ESA hyporesponsive. Selected baseline characteristics in the overall population and by ESA responsiveness, along with the results from the multivariable analysis, are shown below. Additional predictors of ESA hyporesponsiveness include a history of heart failure (0.013), dialysis vintage (0.033), smoking status (0.046), aspirin use (0.039), and ACEi/ARB use (0.081).

Conclusions: This is the first global HIF-PHI study to report pre-specified definitions and predictors of ESA hyporesponsiveness. While most of the strong predictors identified in our study have been previously reported, geographic region stands out as an unexpected finding that requires further investigation.

Funding: Commercial Support - GlaxoSmithKline

Adverse Event Rates Are Higher Post-Transfusion vs. Overall Follow-up and Independent of Background Anemia Treatment in Patients with CKD

Robert Provenzano,[1] Carol A. Pollock,[2] Roberto Pecoits-Filho,[3,4] Anjay Rastogi,[5] Rachel Lai,[6] Ming Zhong,[6] Lynda Szczech.[6] *[1]Wayne State University, Detroit, MI; [2]The University of Sydney, Sydney, NSW, Australia; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Pontificia Universidade Catolica do Parana Departamento de Medicina, Curitiba, Brazil; [5]University of California Los Angeles, Los Angeles, CA; [6]FibroGen Inc, San Francisco, CA.*

Background: The use of transfusion can treat anemia in the short term but may increase the risk of adverse events. Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Roxadustat has been shown to decrease the need for transfusions in patients with chronic kidney disease (CKD).

Methods: Data were pooled from three pivotal, phase 3 studies of roxadustat vs. placebo in patients with non-dialysis-dependent (NDD) CKD and three pivotal phase 3 studies of roxadustat vs. epoetin alfa in patients with dialysis-dependent (DD) CKD. We evaluated rates of intravascular volume-related adverse events (AEs; reported from a predefined list [heart failure, pulmonary edema, respiratory failure] as a direct cause of excess intravascular volume or as a potential symptom) and treatment-emergent adverse events (TEAEs) during the 14-day post-transfusion period and the overall follow-up period (last dose + 28 days) in patients who had ≥1 transfusion.

Results: Intravascular volume-related AE and TEAE rates were at least 9-fold higher during the 14-day post-transfusion period vs. the overall follow-up period across all subgroups (Table). Trends in overall TEAE rates were similar across treatment groups.

Conclusions: Intravascular volume-related AEs occurred at higher rates post-transfusion across all populations. The reduction in transfusions for patients taking roxadustat could lower patient risk and healthcare resource use in managing CKD-related anemia.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

Table: Rates* of intravascular volume-related AEs and TEAEs

Intravascular volume-related AEs	NDD (n=4270) Rate (n/PEY)	ID (n=1526) Rate (n/PEY)	DD (n=3880) Rate (n/PEY)
During 14-day post-transfusion period	130.0 (62/47.7)	158.1 (11/7.0)	146.2 (45/30.8)
During total follow-up period	13.2 (134/1012.5)	12.8 (22/172.4)	13.8 (131/951.8)
Rate ratio	9.82	12.39	10.62
TEAEs			
During 14-day post-transfusion period	859.6 (410/47.7)	862.1 (60/7.0)	919.6 (283/30.8)
During total follow-up period	66.4 (672/1012.5)	57.4 (99/172.4)	47.2 (449/951.8)
Rate ratio	12.95	15.02	19.49

*Defined as the number of patients per 100 PEY
AEs, adverse events; DD, dialysis dependent; ID, incident dialysis; NDD, non-dialysis dependent; PEY, patient-exposure years; TEAEs, treatment-emergent adverse events

A Real-World Longitudinal Analysis of Anemia Treatment Prescriptions in Non-Dialysis-Dependent CKD Patients, a CKDopps Study

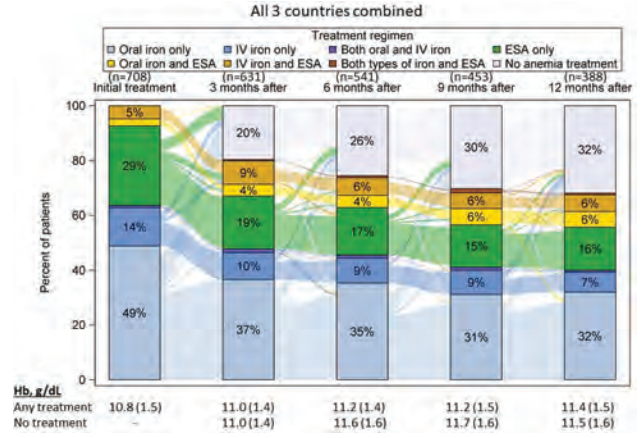
Marcelo Lopes,[1] Charlotte Tu,[1] Jarcy Zee,[1] Murilo H. Guedes,[2] Ronald L. Pisoni,[1] Bruce M. Robinson,[1] Katarina Hedman,[3] Glen James,[3] James A. Sloand,[3] Ziad Massy,[4] Antonio A. Lopes,[5] Helmut Reichel,[6] Sandra Wachter,[7] Michelle M. Wong,[8] Roberto Pecoits-Filho.[1] DOPPS *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [3]AstraZeneca Pharmaceuticals LP, Wilmington, DE; [4]Universite Paris-Saclay, Villejuif, France; [5]Universidade Federal da Bahia, Salvador, Brazil; [6]Nephrological Center, Villingen Schwenningen, Germany; [7]Vifor Pharma Ltd, Glattbrugg, Switzerland; [8]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada.*

Background: Previously lacking in the literature, this analysis aims to comprehensively describe longitudinal patterns of anemia management, including prescriptions of ESA and iron replacement, for non-dialysis dependent chronic kidney disease (NDD-CKD) stage 3 to 5 patients under nephrologist care.

Methods: We analyzed data from a prospective cohort of 2455 NDD-CKD patients from Brazil, Germany and the US, who were not using anemia medications (oral iron, intravenous [IV] iron, or erythropoiesis stimulating agent [ESA]) at enrollment in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDOPPS). We reported the cumulative incidence function (CIF) [HK1] of anemia treatment initiation, stratified by patient characteristics. For patients that started therapy, we report the frequency of medication type at the moment of initiation, as well as switches and discontinuation over 12 months.

Results: The CIF of any anemia treatment initiation at 12 months was 54% for patients with Hb <10 g/dL. For oral iron therapy, the CIF at 12 months was 26% (19%, 32%) for TSAT<20%, and 22% (17%, 28%) for ferritin <100. For IV iron use, CIF at 12 months was 6% (3%, 11%) for patients with TSAT<20% and 4% (2%, 7%) for patients with ferritin <100ng/mL. For ESA use, the CIF at 12 months was 38% (29%, 47%) for patients with Hb <10 g/dL, and 11% (8%, 14%) for Hb 10 to <12 g/dL. Medication types at initiation and longitudinal treatment patterns (switches and discontinuation) are shown in the figure.

Conclusions: In a period of 12 months, anemia medication is initiated in a limited number of NDD-CKD patients with clinical signs that would indicate to do so. This longitudinal analysis using data from the real-world setting, call attention to a sub-optimally management of anemia in the NDD CKD setting.



Anemia medication starts and switches within a year of follow-up.

TH-OR11

Heparin Aggravates Cardiac Injury in Animal Models with High FGF-23

Dominik Kentrup, Christopher Yanucil, Gunars Osis, Isaac D. Campos, Brian A. Czaya, Kylie Heitman, Christian Faul. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: It has been assumed that fibroblast growth factor (FGF) 23 as an endocrine FGF family member has low affinity for heparin, and instead requires klotho, a transmembrane protein, as a co-receptor on specific target cells. However, we and others have shown that elevated FGF23 levels can specifically activate FGFR4 in cardiac myocytes lacking klotho and thereby induce cardiac hypertrophy in animal models of chronic kidney disease (CKD). We have recently found that heparin does act as a FGF23 co-receptor by mediating FGF23 binding mainly to FGFR4 and thereby increases the pathologic actions of FGF23 on cultured cardiac myocytes. Here, we determine the *in vivo* relevance of these findings by studying the cardiac effects of heparin injections in three different mouse models with elevated serum FGF23 levels.

Methods: First, 12-week old, male BALB/cJ mice received serial i.v. injections of isotonic saline, heparin, FGF23, or FGF23 and heparin combined twice daily for 5 consecutive days. Second, 4-week old Alport mice (Col4a3^{tm1Dec}), received serial i.v. injections of saline or heparin 3 times per week for 6 weeks. Third, 5-week old BALB/cJ mice on either 0.2% adenine diet or control chow were injected with either saline or heparin 3 times per week for 10 weeks. At the end of the experiment, echocardiographic analysis was performed, and tissue and serum were isolated for further analysis.

Results: Administration of heparin worsened cardiac outcomes in all three animal models. Compared with saline and FGF23 injections, BALB/cJ mice receiving FGF23 and heparin in combination developed a significant increase in heart weight / tibia length ratio, as well as in left ventricular (LV) mass and epicardial area. Alport mice receiving heparin injections showed increased heart weight / body weight ratios, LV mass and cardiac myocyte area, compared to wildtype littermates and Alport mice receiving saline. In addition, BALB/cJ mice on the adenine diet showed increased heart weight / body weight ratios and cardiac myocyte area when heparin was administered.

Conclusions: Our animal studies suggest that frequent heparin injections in individuals with elevated serum FGF23 levels, as the case in end-stage renal disease patients receiving hemodialysis, might contribute to adverse cardiac outcomes and high mortality.

Hypoxia-Inducible Factor 1 Alpha Regulates FGF-23 Production and Bone Metabolism in CKD

Guillaume Courbon, Marta Martinez-Calle, Jadeah J. Spindler, Bridget Hunt-Tobey, Emily P. Lynch, Xueyan Wang, Aline Martin, Valentin David. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Renal osteodystrophy (ROD) is a complex bone disorder associated with chronic kidney disease (CKD) which affects over one in ten Americans. CKD also leads to increased bone production of the phosphate regulating hormone, fibroblast growth factor 23 (FGF23). ROD and FGF23 are associated with adverse clinical outcomes, including cardiovascular events and death. Hypoxia-inducible factor 1 alpha (HIF1α) regulates FGF23 expression in osteoblasts and osteocytes, and we hypothesized that osseous HIF1α plays an important role in ROD and FGF23 excess in CKD.

Methods: We generated mice harboring a conditional deletion of *Hif1α* in osteocytes (Hif1α$^{Dmp1\text{-}cKO}$) and crossed them to Col4a3^{KO} mice, a mouse model of progressive CKD. We studied bone and mineral metabolism alterations of wild-type (WT), Hif1α$^{Dmp1\text{-}cKO}$, Col4a3^{KO} and compound Col4a3^{KO} Hif1α$^{Dmp1\text{-}cKO}$ (CPD) mice. In parallel, we also treated 6 week-old WT and Col4a3^{KO} mice with a HIF inhibitor (BAY 87-2243) for 4 weeks. Finally, we compared the differentiation and mineralization potential of newly generated MC3T3-E1 osteoblast cell lines overexpressing *Hif1α* (Hif1α^{Tg}) or *Hif1α* shRNA (Hif1α^{KO}) to MC3T3-E1 transfected with an empty vector (Ctr).

Results: Deletion of Hif1α delayed progression of CKD, as CPD mice showed reduced levels of BUN compared to age-matched Col4a3^{KO} mice (-25%). CPD mice also showed lower FGF23 levels (-80% vs. Col4a3^{KO}) and we obtained similar results in Col4a3^{KO} mice administered with a HIF inhibitor (-80% FGF23, -30% BUN, vs. Ctr-Col4a3^{KO}). CPD mice also showed improved trabecular and cortical bone parameters (+50% trabecular bone volume, -20% cortical porosity vs. Col4a3^{KO}). Finally, deletion of *Hif1α* increased alkaline phosphatase (ALP) positive colonies and mineral deposits in Hif1α^{KO} cultures compared to Ctr cells, and led to a 30% reduction in *Fgf23* expression. In contrast, Hif1α^{Tg} cells showed reduced osteogenic potential, with fewer ALP colonies and mineral deposits, and a 2-fold increase in *Fgf23* expression.

Conclusions: Our data suggest that osseous HIF1α stimulates FGF23 production in CKD and is a negative regulator of osteoblast differentiation and function. Thus, inhibition of HIF1α in bone might represent a novel therapeutic strategy to improve bone and mineral outcomes in CKD.

Deletion of the Sodium/Hydrogen Exchanger Isoform 6 in Mice Is Associated with an Age-Dependent Loss of Bone Volume

Daniela Hanke,[1,2] Giuseppe Albano,[1,2] Manuel A. Anderegg,[1,2] Daniel G. Fuster.[1,2] *[1]Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [2]Department for BioMedical Research, University of Bern, Bern, Switzerland.*

Background: The sodium/hydrogen exchanger isoform 6 (NHE6) localizes to recycling endosomes, where it mediates endosomal alkalinization through K+/H+ exchange. NHE6 function in the endosome is essential for clathrin-mediated endocytosis, receptor recycling and endosomal signaling. Mutations in the SLC9A6 gene encoding the NHE6 isoform cause severe X-linked mental retardation, epilepsy, autism and corticobasal degeneration in humans. Patients with SLC9A6 mutations exhibit skeletal malformations, and a previous study suggested a role of NHE6 in osteoblast-mediated mineralization. The goal of this study was to explore the role of NHE6 in bone homeostasis

Methods: NHE6 expression, osteoclast differentiation and cell-mediated resorption were assessed in osteoclast precursor cells isolated from wild-type and NHE6 knock-out mice. In a next series of experiments, we used primary osteoblasts, extracted from calvaria of new-born mice, to study NHE6 expression, proliferation, and cell-mediated mineralization in vitro. To determine the impact of the in vitro findings on structural bone parameters, we performed high-resolution microcomputed tomography (μCT) studies on lumbar vertebrae of wild-type and NHE6 knock-out mice

Results: NHE6 transcript and protein are expressed in both primary osteoclasts and mineralizing osteoblasts. In vitro studies with osteoclasts and osteoblasts derived from NHE6 knock-out mice demonstrated normal osteoclast differentiation and osteoblast proliferation. However, NHE6-deficient osteoclasts exhibited a resorptive deficit, and the mineralization capacity was increased in osteoblasts lacking NHE6. Microcomputed tomography studies revealed a reduced bone volume at a single lumbar vertebral site (L4) but otherwise unaltered structural bone parameters in NHE6 knock-out mice compared to wild-type mice at 3 months of age. At 6 months of age, however, NHE6 knock-out mice displayed a significantly reduced bone volume and trabecular number as well as an increased trabecular space at all lumbar vertebrae studied (L3-L5) compared to wild-type mice

Conclusions: Thus, loss of NHE6 results in an age-dependent loss of bone volume in mice. The results of our in vitro studies argue against a direct bone cell-autonomous cause of the bone phenotype observed in NHE6 knock-out mice and suggest extraosseus factors as likely mediators

Circadian PTH Secretion Is Entrained by Feeding, While the Internal Circadian Parathyroid Clock Is Independent but Affected by CKD

Søren Egstrand,[1,2] Anders Nordholm,[1,2] Maria L. Mace,[2] Marya Morevati,[2] Klaus Olgaard,[2] Ewa Lewin.[1,2] *[1]Dept. of Nephrology, Herlev Hospital, Copenhagen, Denmark; [2]Dept. of Nephrology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.*

Background: We have previously shown that an internal molecular circadian clock operates in the parathyroids. Whether this circadian clock regulates the 24h rhythm of PTH secretion and whether it is impacted by feeding or CKD is unknown.

Methods: Rats were kept in 12h:12h light:dark cycle and fed *ad libitum*. Blood samples and parathyroid glands were harvested at 4h interval (N=38). Then feeding was restricted to the inactive light phase at ZT2-ZT12 (ZT: *zeitgebertime*, time since lights on) for 4 weeks and blood and glands obtained again (N=39). CKD was induced by 5/6 nephrectomy and high phosphate (P) diet for 8 weeks and parathyroid glands were harvested every 4th-hour (N=44). Plasma PTH, P, total calcium, FGF23, and urea were measured. Parathyroid expression of core circadian clock genes was examined by qPCR.

Results: Circadian rhythmicity was found for PTH ($p<0.0002$), P ($p<0.0001$), FGF23 ($p<0.02$), and urea ($p<0.0001$). Restricted feeding to the habitual inactive period inverted the acrophase timing of PTH (ZT9.6 → ZT23.6), P (ZT8.7 → ZT21), FGF23 (ZT7.4 → ZT22.9) and urea (ZT21.2 → ZT8.4). Restricted feeding did not significantly affect the period, acrophase timing, MESOR or amplitude of circadian clock genes: *Bmal1, Per1-3, Cry1-2* and *Rev-erbα*. The rhythmicity of parathyroid circadian clock genes was severely deregulated in CKD with significant upregulated MESOR of *Per1* ($p<0.0002$), *Per2* ($p<0.03$), and *Rev-erbα* ($p<0.004$) and downregulation of *Npas2* ($p<0.05$). The

significant rhythmicity of *Per1* ($p<0.02$) was abolished. In CKD the best fitting period of rhythmicity was reduced to 20h as opposed to the normal 24h for *Per1, Per2, Per3* and *Cry2*. Significant shifts in acrophase were found for *Npas2, Per3* and *Cry1,* while amplitude of *Rev-erbα* increased.

Conclusions: Feeding restricted to the inactive period inverted the acrophase of plasma PTH, P and FGF23 and revealed a clear dissociation between the phase of PTH secretion rhythm and the phase of the circadian clock in the parathyroid glands. In CKD the circadian rhythm of core clock genes were significantly interfered, affecting MESOR, phase, period, amplitude as well as rhythmicity.

TH-OR15

A Single-Cell Transcriptome Atlas of Adult Parathyroids in Secondary Parathyroidism

Shensen Li, Wenwen Li, Qingqing Liu, Haiyan Shen, Bingquan Deng, Changchun Cao. *Sir Run Run Hospital, Nanjing Medical University, Nanjing, China*.

Background: Secondary hyperparathyroidism (SHPT) is one of the common complications in patients with chronic kidney disease. The development of SHPT is accompanied by the change of cell composition, while the exact cell type changes and mechanism are yet to be defined. Therefore, single cell sequencing was conducted to analysis the cell composition of parathyroid gland.

Methods: In current study, parathyroids from 3 SHPT patients were digested to obtain single cell suspension. A total of 21519 cells were obtained and the mRNA expression profiles were analyzed by single cell sequencing and bioinformatics. Furthermore, the development separation track of cell subpopulations was constructed by pseudotime analysis (Figure 1A).

Results: There may be 21 cell subpopulations in parathyroid, among which 6 subpopulations (clusters 0, 1, 2, 5, 11, 17) are high function subpopulations of parathyroid, which were indicated by high expression of gcm2 (glial cells missing homolog 2), PTH (parathyroid hormone), CaSR (calcium sensing receptor) and KL (Klotho) genes (Figure 1B-D). The results of pseudotime analysis in the 6 high function subpopulations show that cluster 0 is at the beginning of the main group separation track, cluster 1, 2, 5 are in the middle, while cluster11 and 17 are at the end (Figure 1E). Multiple genes may play major role in the differentiation of cluster 0, including tspan1, park7, atp6v0b, rpl11, rps8 and etc (Figure 1F).

Conclusions: There are 6 subpopulations out of total 21 cell subpopulations of parathyroid cells with higher parathyroid hormone secretion and regulation function in SHPT patients. Among which, cluster 0 may be the initiation differentiation cell of high functional cells, because it may be a subpopulation with high proliferation and differentiation potential.

Calcium Isotopes: A Novel Biomarker of Bone Mineralization in CKD

Rukshana Shroff,[1] Mary Fewtrell,[1] Ana Kolevica,[2] Alexander D. Lalayiannis,[1] Claus peter Schmitt,[4] Dagmar-Christiane Fischer,[3] Anton Eisenhauer.[2] *[1]University College London Great Ormond Street Institute of Child Health, London, United Kingdom; [2]Geomar Helmholtz Centre for Ocean Research, Kiel, Germany; [3]Rostock University Medical Center, Rostock, Germany; [4]Center for Pediatrics and Adolescent Medicine, Heidelberg, Heidelberg, Germany*.

Background: Serum Ca, bone biomarkers and radiological imaging do not allow accurate evaluation of bone mineral balance (BMB), a key determinant of bone mineral density (BMD) and fracture risk. Naturally occuring stable (non-radioactive) Ca isotopes, ^{42}Ca and ^{44}Ca, are absorbed from our diet and sequestered into different body compartments following kinetic principles of isotope fractionation. Isotopically light ^{42}Ca is preferentially incorporated into bone, and heavier ^{44}Ca excreted in urine and feces. Their ratio ($\delta^{44/42}Ca$) in serum and urine gives a direct measure of BMB; $\delta^{44/42}Ca$ is higher during bone formation than bone resorption.

Methods: Ca isotopes were measured by plasma-ionization mass-spectrometry in blood, urine, feces and dialysate. The relationship between bone Ca gain and loss was calculated using a compartment model, and expressed as $\delta^{44/42}Ca$ 128 children in CKD4-5 and on dialysis (CKD4-5D) and 117 healthy participants (age <30) underwent Ca isotope measurement, bone biomarkers, DXA and tibial peripheral quantitative CT (pQCT), an accurate measure of cortical BMD.

Results: In healthy children the $\delta^{44/42}Ca_{Blood}$ and $\delta^{44/42}Ca_{Urine}$ were higher than in adults ($p<0.0001$), reflecting avid Ca uptake during bone formation. Since urinary Ca excretion is impaired in CKD, $\delta^{44/42}Ca_{Blood}$ was higher and $\delta^{44/42}Ca_{Urine}$ lower in CKD4-5D compared to controls ($p<0.0001$ for both). In CKD2-5D $\delta^{44/42}Ca_{Blood}$ positively correlated with cholecalciferol ($p=0.01$) and alfacalcidol ($p=0.002$) doses, implying increased bone Ca uptake when Ca bioavailability is increased. $\delta^{44/42}Ca_{Blood}$ positively correlated with biomarkers of bone formation (ALK, $p=0.05$) and inversely with resorption markers (PTH, $p=0.013$; TRAP5b, $p<0.001$ and CTX, $p=0.006$). $\delta^{44/42}Ca_{Blood}$ correlated positively with tibial cortical BMD-Z-score ($p=0.006$, $R^2=0.39$), and DXA hip BMD-Z-score ($p=0.02$). Significant and independent predictors of tibial cortical BMD-Z-score were $\delta^{44/42}Ca_{Blood}$ ($\beta=0.68$, $p=0.006$) and PTH (β-0.39, $p=0.04$), together predicting 67% of the variability in BMD.

Conclusions: Ca isotope ratios provide a novel, non-invasive method of assessing bone mineralization. Defining an accurate biomarker of BMB forms the basis of future studies investigating Ca dynamics in disease states and the impact of treatments that affect bone homeostasis.

Funding: Government Support - Non-U.S.

Secondary Hyperparathyroidism Is Associated with Weight Loss and Longer-Term Mortality Among Patients Undergoing Hemodialysis: Results from the Dialysis Outcomes and Practice Patterns Study

Hirotaka Komaba,[1,2] Junhui Zhao,[3] Suguru Yamamoto,[4] Takanobu Nomura,[9] Douglas S. Fuller,[3] Keith McCullough,[3] Pieter Evenepoel,[5,6] Anders Christensson,[10] Xinju Zhao,[7] Mona Al Rukhaimi,[11] Fadwa M. Al-Ali,[8] Eric W. Young,[3] Bruce M. Robinson,[3] Masafumi Fukagawa.[1] *[1]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [2]The Institute of Medical Sciences, Tokai University, Isehara, Japan; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [5]Department of Nephrology and Renal Transplantation, University Hospitals Leuven, Leuven, Belgium; [6]Laboratory of Nephrology, Department of Microbiology and Immunology, KU Leuven, Leuven, Belgium; [7]Department of Nephrology, Peking University People's Hospital, Beijing, China; [8]Fahad Bin Jassim Kidney Center, Department of Nephrology, Hamad General Hospital, Hamad Medical Corporation, Doha, Qatar; [9]Medical Affairs Department, Kyowa Kirin Co., Ltd., Tokyo, Japan; [10]Department of Nephrology, Skåne University Hospital, Lund University, Malmö, Sweden; [11]Department of Medicine, Dubai Medical College, Dubai, United Arab Emirates.*

Background: Wasting is a common complication of kidney failure that leads to weight loss and poor outcomes. Recent experimental data identified parathyroid hormone (PTH) as a driver of adipose tissue browning and wasting, but little is known about the relations among secondary hyperparathyroidism (SHPT), weight loss, and risk of mortality in patients undergoing hemodialysis.

Methods: We included 42,319 participants receiving hemodialysis for at least one year in the DOPPS phases 2-6 (2002-2018). Linear mixed models were used to estimate the association between baseline PTH and percent weight change over 12 months, adjusting for country, demographics, comorbidities, and labs. Accelerated failure time models were used to assess 12-month weight loss as a mediator between baseline high PTH and mortality after 12 months.

Results: At baseline, mean (SD) body weight was 74 (22) kg and the median PTH level was 251 pg/mL (interquartile range [IQR], 131-444 pg/mL). Baseline PTH was inversely associated with 12-month weight change: 12-month weight loss >5% was observed in 21%, 18%, 18%, 17%, 16%, and 14% of patients for PTH ≥600 pg/mL, 450-600, 300-450, 150-300, 50-150, and <50 pg/mL, respectively. In adjusted analysis, 12-month weight change compared to PTH 150-299 pg/mL was -0.60%, -0.12%, -0.10%, +0.15%, and +0.35% for PTH ≥600, 450-600, 300-450, 50-150, and <50 pg/mL, respectively ($P<0.01$). Interacting baseline PTH*appetite, high PTH was associated with weight loss only in persons with preserved appetite ($P<0.01$). During follow-up after the 12-month weight measure (median, 1.0 [IQR, 0.6-1.7] years; 6125 deaths), patients with baseline PTH ≥600 pg/mL had 11% (95% CI, 9-13%) shorter lifespan, and 18% (95% CI,14-23%) of this effect was mediated through weight loss ≥2.5%.

Conclusions: Our findings indicate that SHPT may be a novel mechanism of wasting in dialysis patients, corroborating experimental data, and that this pathway may be a mediator between elevated PTH levels and mortality. Future research should determine whether PTH-lowering therapy can limit or prevent weight loss and improve longer-term dialysis outcomes.

SNF472 Consistently Slows Progression of Coronary Artery Calcification Across Subgroups of Patients on Hemodialysis

Glenn M. Chertow,[12] Paolo Raggi,[1] Antonio Bellasi,[2] David A. Bushinsky,[3] Jordi Bover,[4] Mariano Rodriguez,[5] Markus Ketteler,[6] Smeeta Sinha,[7] Rekha Garg,[8] Claire S. Padgett,[9] Joan Perelló,[10,11] Alex Gold.[9,12] *[1]Mazankowski Alberta Heart Institute and University of Alberta, Edmonton, AB, Canada; [2]Research, Innovation and Brand Reputation Unit, ASST Papa Giovanni XXIII, Bergamo, Italy; [3]Department of Medicine, University of Rochester Medical Center, Rochester, NY; [4]Department of Nephrology, Fundació Puigvert and Universitat Autònoma, IIB Sant Pau, REDinREN, Barcelona, Spain; [5]Nephrology Unit, Hospital Universitario Reina Sofia, IMIBIC, REDinREN, Cordoba, Spain; [6]Department of General Internal Medicine and Nephrology, Robert-Bosch-Krankenhaus, Stuttgart, Germany; [7]Department of Renal Medicine, Salford Royal NHS Foundation Trust, Salford, United Kingdom; [8]Research and Development, Sanifit (now with PharmaDRS Consulting), San Diego, CA; [9]Research and Development, Sanifit, San Diego, CA; [10]Research and Development, Sanifit, Palma, Spain; [11]University of the Balearic Islands, Palma, Spain; [12]Department of Medicine, Stanford University, Palo Alto, CA.*

Background: In the CaLIPSO study, SNF472 significantly attenuated progression of coronary artery calcium (CAC) volume score compared with placebo. This pre-specified analysis examined CAC progression in key subgroups.

Methods: Patients were randomized to SNF472 300 mg (n=92), SNF472 600 mg (n=91) or placebo (n=91) infused 3x/week during hemodialysis (HD) for 52 weeks on top of standard care therapy determined by each investigator. We examined change in log CAC volume score from baseline to week 52 in the combined SNF472 dose groups vs placebo for subgroups of age, sex, diabetes, dialysis vintage, arteriosclerotic cardiovascular disease (ASCVD), use of non-Ca phosphate binders, Ca-based phosphate binders, calcimimetics, activated vitamin D, warfarin, or statins in the modified ITT population (mITT, defined as subjects who received at least one dose of study drug and had an evaluable post-baseline CT scan).

Results: Baseline characteristics were similar across treatment groups: mean age was 64 y, 39% were female; 62% had diabetes, and 41% had prior ASCVD. Median HD vintage was 42 mo; 33% received HD for ≥5 years. Concomitant medications at baseline were: 62% non-Ca phosphate binders, 28% Ca-based phosphate binders, 31% calcimimetics, 51% activated vit D, 8% warfarin, and 64% statins. In the overall mITT, CAC volume progression was 11% in the combined SNF472 groups vs 20% in placebo (p=0.016). Treatment differences for CAC volume progression were similar across subgroups (Figure). All interaction p-values were non-significant and comparisons favored SNF472 vs placebo in each subgroup.

Conclusions: SNF472 treatment for 52 weeks attenuated CAC progression compared with placebo in all subgroups.

TH-OR19

Pharmacodynamic (PD) Profiling of Reloxaliase in Patients with Severe Hyperoxaluria

Felix Knauf,[2,1] Danica Grujic,[1] Mira T. Keddis,[3] Alicia Weeks,[1] Annamaria T. Kausz.[1] *[1]Allena Pharmaceuticals, Newton, MA; [2]University Hospital Charite, Berlin, Germany; [3]Mayo Clinic Hospital, Phoenix, AZ.*

Background: Hyperoxaluria is a major risk factor for kidney stones and can lead to chronic kidney disease (CKD). With decreasing kidney function, plasma oxalate (POx) rises and oxalate may deposit in the kidneys and other tissues (systemic oxalosis) leading to ESRD. Reloxaliase (REL), a non-absorbed, oxalate specific oral enzyme therapy designed to degrade oxalate along the GI tract, may potentially reduce the systemic and renal oxalate burden in patients with enteric and primary hyperoxaluria (EH and PH). This study tested the PD of REL, and addressed questions regarding potential formate accumulation (by-product of oxalate degradation) and systemic absorption of oxalate decarboxilase (OxDc, the active component of REL).

Methods: This 12-week, open label study enrolled subjects with EH, CKD and hyperoxalemia (UOx ≥40mg/d, eGFR <45mL/min and POx>5µmol/L, n=10) and PH (UOx ≥40 mg/d, n=5) who received 7,500u of REL 5x/day with meals/snacks. Parameters assessed at baseline, and weeks 4, 8 and 12 included POx and UOx (only if eGFR >15mL/min), plasma formic acid (pre- and post-prandial/post-dose; Q² Solutions) and OxDc (specific ELISA, Absorption Systems).

Results: Reported adverse events (AEs) were mostly GI related; there were no related serious AEs. In EH, both POx and UOx decreased substantially; in PH, UOx did not change, and POx stayed normal at baseline and during treatment (Table). There was no formate accumulation, as all samples were below or within normal range (1-9mg/L). Similarly, there was no detectable absorption of REL, as all samples were below the limit of detection of the assay for OxDc (<0.0001% of the administered dose of 37,500 u/day).

Conclusions: Reloxaliase was well tolerated; the absence of formate accumulation further supports its safety. The lack of REL absorption, in addition to supporting low potential for systemic toxicity, confirms its site of action within the GI tract. This best aligns with the pathophysiology of EH as evidenced by the substantial reduction in both POx and UOx in EH subjects with CKD/ESRD.

Efficacy and Safety of Upacicalcet in Hemodialysis Patients with Secondary Hyperparathyroidism: A Phase 3 Study

Tadao Akizawa,[1] Daisuke Honda,[2] Masaki Taniguchi,[3] Fumihiko Koiwa.[4] *[1]Showa University School of Medicine, Tokyo, Japan; [2]Sanwa Kagaku Kenkyusho Co., Ltd., Nagoya, Japan; [3]Sanwa Kagaku Kenkyusho Co., Ltd., Nagoya, Japan; [4]Showa University Fujigaoka Hospital, Yokohama, Japan.*

Background: Secondary hyperparathyroidism (SHPT) is a major complication of hemodialysis (HD) patients. Calcimimetics suppress the hyperfunction of parathyroid and reduce serum calcium and phosphorus levels, and are currently used for the treatment of SHPT. Upacicalcet (UPA) is a novel intravenous small molecule calcimimetic in late-stage development in Japan to treat SHPT of HD patients. We report the efficacy and safety of UPA in HD patients.

Methods: This study was a phase 3, multicenter, randomized, double-blind, placebo-controlled, parallel-group study. UPA or placebo (PBO) was administered t.i.w. at the end of HD at an initial dose of 50 mcg or 25 mcg. The doses were subsequently adjusted to maintain serum intact PTH (iPTH) levels between 60-240pg/ml (recommended level of Japanese guideline) every 3 weeks between 25 and 300 mcg during 24 weeks of treatment. The primary endpoint was the percentage of patients who achieved a mean iPTH level of 60–240 pg/ml in weeks 22 to 24.

Results: A total of 154 SHPT patients were enrolled, and randomly allocated to UPA group (n: 103) or PBO group (n: 51). The primary endpoint, percentage of patients achieving the target iPTH range was greater for UPA (67.0%) than for PBO (8.0%) (P<0.001). UPA significantly reduced iPTH and cCa levels compared with PBO (Fig.). Concerning phosphorus, no statistically significant difference between the groups was observed while it tended to decrease in the UPA group. In the safety assessment, treatment emergent adverse events (AE) occurred in 88 patients (85.4%) and 36 patients (72.0%) in the UPA and the PBO groups. The incidences of upper-gastrointestinal-related AE were 20.4% in the UPA and 18.0% in the PBO groups (P=0.8298). As an AE, hypocalcemia did not occur in either group.

Conclusions: This study demonstrates that UPA significantly decreases iPTH without increasing the incidence of upper-gastrointestinal symptoms as compared to PBO. It is suggested that UPA will be a promising calcimimetic agent capable of safe and appropriate management of SHPT.

Primary Cilia and the Glycocalyx Are Flow Sensors for Nitric Oxide Production by Thick Ascending Limbs

Jeffrey L. Garvin, Nancy J. Hong. *Case Western Reserve University, Cleveland, OH.*

Background: The primary cilium is an organelle found on essentially all epithelial cells. Similarly, the glycocalyx is a matrix-like layer of proteoglycans, glycosaminoglycans (GAGs) and plasma proteins covering the surface of all cells. In vascular endothelial cells, primary cilia and GAGs such as heparan sulfate and chondroitin sulfate mediate responses to the mechanical forces exerted by blood flow. In thick ascending limbs, increases in luminal flow enhance nitric oxide (NO) production, an important regulator of kidney function including sodium reabsorption; however, the role of primary cilia and the glycocalyx in NO production by thick ascending limbs is unknown. We hypothesized that primary cilia and the glycocalyx act as flow sensors and thus mediate flow-induced NO production by thick ascending limbs.

Methods: We measured flow-induced NO in isolated rat thick ascending limbs using DAF-FM. Intracelllular NO was first measured during the control period without and with luminal flow. NO was measured again during the experimental period after treating tubules for 15 min to deciliate cells or to degrade major glycocalyx GAGs. Dibucaine (0.1 mM) was used to remove cilia from cells. Heparinase III (0.2 or 0.4 U/ml) and chondroitinase ABC (0.2 U/ml) were used to degrade heparin sulfate and chondroitin sulfate, respectively.

Results: In untreated control tubules, flow-induced NO did not differ between the two periods, 4.33 ± 1.03 vs 4.68 ± 0.84 arbitrary units (AU)/min. Dibucaine decreased flow-induced NO from 4.25 ± 0.62 to 1.19 ± 0.65 AU/min ($p < 0.002$). Heparinase (0.2 U/ml) attenuated flow-induced NO from 4.02 ± 0.84 to 1.80 ± 0.74 AU/min ($p < 0.04$); a higher concentration (0.4 U/ml) caused a greater decrease from 4.24 ± 0.86 to 1.56 ± 0.41 AU/min ($p < 0.006$). Heat inactivation of heparinase (0.2 U/ml) abolished its effect (3.01 ± 0.34 to 2.83 ± 0.22 AU/min). Chondroitinase (0.2 U/ml) decreased flow-induced NO from 4.17 ± 0.96 to 2.45 ± 0.49 AU/min ($p < 0.038$).

Conclusions: We conclude that both primary cilia and the glycocalyx act as flow sensors in thick ascending limbs and transduce mechanical stimuli into chemical signals that ultimately result in NO production by this segment.

Cell-Autonomous Expression of Membrane Transport Proteins in Mammalian Distal Nephron

Martin N. Thomson, Kerim Mutig, Sebastian Bachmann. *Department of Functional Anatomy, Charité - Universitätsmedizin Berlin, Berlin, Germany.*

Background: Reabsorption of NaCl in kidney thick ascending limb (TAL) via NKCC2 involves the action of luminal (ROMK) and basolateral (Kir4.1/Kir5.1 multimers) potassium channels, a basolateral calcium sensing receptor (CaSR), and the claudin (Cldn) family of proteins. Morphological heterogeneity of TAL cells has been reported, as well as mosaic expression of ROMK and Kir4.1. We hypothesized that this variability between TAL cells extends to other aspects of their function.

Methods: We studied TAL EM morphology, zonal and cell-autonomous heterogeneity of the transport proteins at steady state in mice, rats and humans, and under stimulation by vasopressin (AVP; V2R agonist dDAVP for 72 h) using AVP-deficient Brattleboro rats. NKCC2, phosphorylated (p) NKCC2, ROMK, Kir4.1, CaSR, Cld-10 and Cld-16 signals were analyzed by immunofluorescence, in situ hybridization (ISH), EM and Western blot (WB).

Results: Between cortex and medullary kidney zones, TAL morphological cell heterogeneity was observed, but not at a cell-to-cell level within each zone. NKCC2 was continuously expressed in all TAL cells, while pNKCC2 signals were heterogeneous, increasing from inner stripe of outer medulla to cortex and varying between cells of each zone. ROMK and Kir4.1 protein expression showed conspicuous heterogeneity in a mutually exclusive pattern, with stronger pNKCC2 expression in the ROMK-negative, Kir4.1-positive cell type. CaSR and Cldn-16 signals were moderate to absent in ROMK-positive cells, but intensified in ROMK-negative cells, while Cld-10 was strongly expressed only in ROMK-positive cells. ISH revealed no cell heterogeneity of ROMK mRNA. In Brattleboro rats, 72h dDAVP increased the number of ROMK- and Kir4.1-positive cells and the overlap of both signals in mTAL, and stimulated NKCC2 phosphorylation. Cldn-10 expression was induced in the outer stripe of outer medulla. Morphological alterations in the TAL included proliferation of microvilli. WB showed 2.2-fold increase of ROMK and 1.3-fold increase of Kir4.1 abundance, but down-regulation of CaSR to 60%.

Conclusions: These results demonstrate mosaic expression of ROMK, Kir4.1, CaSR, Cld-10, and Cld-16 in TAL, which correlate with cell-heterogeneous levels of NKCC2 activation.

Optical Clearing and 3D Imaging Reveal a Sexual Dimorphism in the Structure and Remodeling Response of the Distal Convoluted Tubule

Seyedmohammadebrahim Tahaei,[1] Richard A. Coleman,[1] Turgay Saritas,[3] David H. Ellison,[2] Paul A. Welling.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Oregon Health & Science University Oregon Clinical & Translational Research Institute, Portland, OR; [3]University Hospital RWTH, Aakhen, Germany.*

Background: The abundance of the distal convoluted tubule (DCT) thiazide-sensitive sodium chloride cotransporter (NCC) is greater in females than males. Because structural remodeling of the DCT is dependent on NCC activity, it has been generally assumed that there is a corresponding sexual dimorphism in DCT morphology. Until now, this has never been directly examined. Here, combining new optical clearing techniques with staining for markers of DCT segments, volumetric imaging we quantitatively assess DCT morphology in male and female mice and study DCT remodeling response to furosemide.

Methods: Male and Female (3-month-old) mice were treated with vehicle or Furosemide administered in the food (100 mg/kg per day) for seven days. Total NCC and phospho-active NCC abundance (pNCC) was evaluated by Western Blot in one kidney, the other kidney was perfused and fixed for imaging. Kidneys were cleared using the Clear, Unobstructed Brain/Body Imaging Cocktails and Computational Analysis (CUBIC) pipeline, co-stained with antibodies that label the early DCT (DCT1, parvalbumin) and the entire DCT (DCT1 & 2; NCC), imaged using a high-speed spinning disc confocal microscope, and processed with 3D rendering and analysis software (IMARIS).

Results: We confirmed previous studies that females have greater NCC abundance in the basal state. Surprisingly, the length of the DCT was longer in males (~620 μm) than female mice (~560 μm). Furosemide treatment significantly increased the abundance of NCC and pNCC in both sexes, and this was paralleled by an expansion of the DCT length and volume. The remodeling response to furosemide was more profound in females (~20% increase in DCT length and 50% in DCT1 volume) than males (~8% and 30%, respectively). The DCT elongation effect of furosemide treatment in females stemmed largely from an increase in DCT1 length. Furosemide expanded the DCT2 significantly in males but not females.

Conclusions: Our study reveals a surprising sexual dimorphism of the DCT. The greater NCC density in a shorter structure may provide a means for females to protect sodium balance in face of greater basal distal sodium delivery, yet have larger reserve and remodeling capacity to adapt to unique physiological stresses.

Positive Allosteric Modulation of the Calcium-Sensing Receptor (CaSR) by Glucose or Fructose Induces Activation of the Sodium-Chloride Cotransporter (NCC)

Jessica P. Bahena-López,[1,4] Lorena L. Rojas,[1] Silvana Bazua-Valenti,[1] Norma H. Vázquez,[1] Maria Chavez-Canales,[2] Maria Castañeda-Bueno,[1] Magdalena Madero,[3] Gerardo Gamba.[1,4] *[1]Molecular Physiology Unit, INCMNSZ and IIB, UNAM, Mexico City, D.F., Mexico; [2]Traslational Medicine Unit, INCICH and IIB, UNAM, Mexico City, D.F., Mexico; [3]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, D.F., Mexico; [4]PECEM, Faculty of Medicine, UNAM, Mexico City, D.F., Mexico.*

Background: NCC is activated via the CaSR-WNK4-SPAK pathway. Glucose and other sugars act as positive allosteric modulators of the CaSR. This might be relevant in the distal convoluted tubule (DCT), since most glucose is reabsorbed proximally and fructose delivery to the DCT depends largely on dietary intake. Here we studied if positive allosteric modulation of the CaSR by glucose/fructose induces NCC activation via CaSR-WNK4-SPAK.

Methods: We used 1) HEK-293 cells cotransfected with SPAK, WNK4 and/or CaSR and exposed to 0.5 mM extracellular Ca^{2+} with 0, 5.5 or 25mM of glucose/fructose. 2) C57BL/6 wild-type mice treated with vehicle, 20% fructose or dapagliflozin (3 mg/kg ip), +/- calcilytic NPS2143 (30 mg/kg oral gavage). Renal proteins for western blot were extracted 3 h latter. 3) Urinary exosomes from male healthy volunteers to assess NCC activity after exposure to placebo, cinacalcet 30mg at time 0 (n=4) or 5% fructose with water intake (n=3).

Results: Stimulation of HEK293 cells with glucose or fructose increased SPAK phosphorylation, but only if both WNK4 and CaSR were present ($p<0.01$). In mice, we observed increased pNCC in kidneys, together with increased activation of WNK4-SPAK ($p<0.01$), after exposure to 20% fructose. Dapagliflozin also induced activation of SPAK and NCC. These effects of fructose and dapagliflozin were abrogated by co-administration of NPS2143 ($p<0.01$). Preliminary data on human subjects show that when compared to baseline (urinary exoxome pNCC/NCC ratio = 1.0), cinacalcet induced a 77% increase in pNCC/NCC ratio (1.77, $p=0.018$) and fructose induced a a near two-fold increase in pNCC/NCC ratio (2.69, $p=0.006$).

Conclusions: *In vitro* glucose or fructose increases SPAK phosphorylation in a CaSR-WNK4-dependent manner. *In vivo* glucose (dapagliflozin) or fructose increases NCC activity via WNK4-SPAK and data suggest a calcimimetic-like behavior for glucose or fructose in the DCT; this effect appears to be reproduced in humans and represents the

first evidence of NCC activation via CaSR with cinacalcet in humans. Our results suggest that the presence of glucose or fructose in DCT could increase the activity of NCC via CaSR-WNK4-SPAK pathway.

TH-OR25

Cross-Talk Between Epithelial Sodium Channel and Basolateral $K_{ir}4.1$/$K_{ir}5.1$ Channels in the Cortical Collecting Duct

Oleg Palygin,[1] Elena Isaeva,[1] Vladislav Levchenko,[1] Jerod S. Denton,[3] Alexander Staruschenko.[1,2] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]Clement J. Zablocki VA Medical Center, Milwaukee, WI; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: The growing body of evidence suggest that inwardly rectifying K^+ (K_{ir}) channels located on the basolateral membrane of epithelial cells in the distal nephron play a crucial role in K^+ handling and blood pressure control, making these channels attractive targets for the treatment of hypertension. The purpose of the present study was to determine how the inhibition of basolateral $K_{ir}4.1$ homomeric or $K_{ir}4.1$/$K_{ir}5.1$ heteromeric K^+ channels affects ENaC-mediated Na^+ transport in the cortical collecting duct (CCD) principal cells.

Methods: Electrophysiological approaches were used to test the effect of fluoxetine, amitriptyline, and recently developed $K_{ir}4.1$ inhibitor, VU0134992, on the activity of $K_{ir}4.1$, $K_{ir}4.1$/$K_{ir}5.1$, and ENaC. Channel activity was recorded in CHO cells transfected with respective channel subunits, cultured polarized epithelial $mCCD_{c11}$ cells, and native freshly isolated rat and human CCD tubules. To test the effect of pharmacological $K_{ir}4.1$/$K_{ir}5.1$ inhibition on electrolyte homeostasis *in vivo*, Dahl salt-sensitive rats were injected with amitriptyline (15 mg/kg/day).

Results: We found that inhibition of $K_{ir}4.1$/$K_{ir}5.1$, but not $K_{ir}4.1$ channel, substantially suppresses both amiloride-sensitive I_{SC} in $mCCD_{c11}$ cells and single-channel ENaC activity in principal cells of rat and human CCD tubules. Furthermore, we demonstrate that i.p. injection of $K_{ir}4.1$/$K_{ir}5.1$ antagonist for three days leads to a significant drop in plasma K^+ level, triggering sodium excretion, and diuresis.

Conclusions: These data uncover a putative mechanism underlying a renal control of blood electrolytes mediated by $K_{ir}4.1$/$K_{ir}5.1$ and introduce a new molecular target for the treatment of salt-sensitive hypertension.

TH-OR26

ClC-K2 Chloride Channel Determines Acid-Base Transport and Chloride Reabsorption in Intercalated Cells of the Collecting Duct

Naghmeh Hassanzadeh Khayyat, Victor N. Tomilin, Oleg L. Zaika, Oleh Pochynyuk. *University of Texas John P and Katherine G McGovern Medical School, Houston, TX.*

Background: Intercalated cells (ICs) of the collecting duct (CD) play a critical role in regulation of systemic acid-base homeostasis. In addition, ICs are capable of performing trans-cellular Cl^- reabsorption particularly during volume depletion. While the major apical membrane transport systems are well characterized, little is known about mechanisms and contribution of the basolateral membrane in both processes. Kidney specific ClC-K2 is expressed in the basolateral membrane of the distal nephron segments, including the CD.

Methods: We generated ClC-K2 deficient mice using cre-loxP strategy to investigate the role of the channel in acid-base and Cl^- transport. We combined BCECF-sensitive intracellular pH (pH_i) measurements with fluorescent AQP2-based identification of principal cells (PCs) and ICs to assess ClC-K2-dependent pH_i changes in different cell types.

Results: ClC-K2 inhibition with NPPB (100 μM) had no effect in PCs of WT mice, whereas it induced rapid intracellular acidification in B-type and alkalization in A-type of ICs. NPPB failed to significantly affect pH_i in CDs from ClC-K2 deficient mice. Extracellular Cl^- removal to drive basolateral Cl^- exit via ClC-K2 had no effect on pH_i in PCs, but caused alkalization in B-type and acidification in A-type of ICs. Importantly, Cl^- removal did not induce pH_i changes in both A- and B-type of ICs from ClC-K2 deficient mice. This suggests that ClC-K2 mediates trans-cellular Cl^- reabsorption and determines apical acid-base transport by controlling intracellular Cl^- concentration. Moreover, application of Angiotensin II (Ang II, 500 nM) increased ClC-K2 single channel activity and augmented respective ClC-K2-dependent pHi changes in B- but not A-type of ICs to favor apical Cl^-/HCO_3^- exchange. In addition, induction of metabolic acidosis with NH_4Cl supplementation in water, increases H^+ secretion from ICs of WT but not ClC-K2 deficient mice. Furthermore, ClC-K2 activity (measured as NPPB-dependent pH_i changes) was increased in A-type but decreased in B-type of ICs, overall favoring urinary acidification in WT mice.

Conclusions: Altogether, our results show that ClC-K2 is central for acid-base transport in the CD. ClC-K2 activity can be independently regulated in A- and B-type of ICs during different physiological conditions to allow fine tuning of renal acid-base handling.

TH-OR27

Evolutionary Conserved TLDc Domain Defines a New Class of V-ATPase Interacting Proteins

Amity F. Eaton, Dennis Brown, Maria Merkulova. Program in Membrane Biology *Massachusetts General Hospital, Boston, MA.*

Background: Kidney-specific V-ATPase regulates acid-base homeostasis, and its disfunction causes distal renal tubular acidosis (dRTA). We recently found that nuclear receptor coactivator 7 (Ncoa7) interacts with kidney V-ATPase, and its deletion in mice resulted in dRTA. Ncoa7 belongs to a group of proteins playing a role in the oxidative stress response, that contain the evolutionarily conserved TLDc domain. We found that another of these proteins, Oxr1, also interacts with the V-ATPase. Here we asked if other proteins from this family, i.e. Tbc1d24, Tldc1 and Tldc2 interact with V-ATPase in kidney and if their TLDc domains mediate this interaction.

Methods: Interaction between endogenous Tbc1d24, Tldc1 and Tldc2 and V-ATPase was assessed by co-immunoprecipitation (co-IP) and western blotting of mouse kidney lysates. Interaction with the V-ATPase was also studied by GST pull-downs from kidney lysates using purified GST-tagged wild-type TLDc domains of Ncoa7, Oxr1, Tbc1d24, Tldc1 and Tldc2, or mutant TLDc domains of Ncoa7 (G802A, G815A, S817A, G845A, G896A, L926A, E938A) followed by western blotting for B1.

Results: In Co-IP studies of mouse kidney lysates we found that endogenous Tbc1d24 interacted with the B1 subunit isoform of V-ATPase, but not with the more ubiquitous B2 subunit isoform. However, we did not detect any interaction between V-ATPase and endogenous Tldc1 or Tldc2 in Co-IPs, possibly due to low sensitivity of the anti-Tldc1 and anti-Tldc2 antibodies. Additionally, we found that the purified TLDc domains of Ncoa7, Oxr1 and Tldc2, but not Tbc1d24 or Tldc1, interacted with V-ATPase in GST pull-downs. Finally, the G815A, G845A and G896A mutants in evolutionarily conserved regions of the Ncoa7 TLDc domain did not interact with V-ATPase, L926A and E938A mutations resulted in a decreased interaction, while S817A or the non-conserved G802A mutation (used as a positive control), did not decrease interaction at all.

Conclusions: In the kidney, Tbc1d24 and possibly Tldc2, as well as Ncoa7 and Oxr1, interacted with V-ATPase and may play a role in the V-ATPase-dependent regulation of renal acid-base homeostasis. We conclude, that the TLDc motif is a protein-protein interaction domain that defines a new class of V-ATPase interacting regulatory proteins. The evolutionary conserved amino acids within the TLDc domain of Ncoa7 are critical for its interaction with the V-ATPase.

Lysine Acetylation of Aquaporin 3 Affects Water Permeability of the Collecting Duct

Kelly A. Hyndman, Parker R. Davis, Luciano D. Mendoza. *The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

Background: We recently reported that there are > 400 proteins in the inner medullary collecting duct (IMCD) that are post-translationally lysine acetylated (ac), including the basolateral water channel, aquaporin-3 (AQP3). The purpose of this study was to determine if lysine acetylated AQP3 (acAQP3) affects water permeability.

Methods: We developed an antibody to detect acAQP3 and found acAQP3 localized to the basolateral membrane of the cortical and outer medullary CD in mice and human kidney biopsies. In mice, following 24 h of water deprivation, acAQP3 was also found in the IMCD. Next, we developed AQP3 K point mutation plasmids; an acetylated mimetic K282Q ($AQP3^{Q/Q}$), and a deacetylated mimetic K282R ($AQP3^{R/R}$). These were stably expressed in vasopressin-responsive mouse cortical CD cells and loaded with a volume sensitive dye. Finally, using CRISPR/CAS we engineered whole body point mutation mice. The $AQP3^{Q/Q}$, $AQP3^{R/R}$ and littermate controls $AQP3^{WT/WT}$ were placed on standard chow and: 1) ad lib water, 2) 5% sucrose water for hydration, or 3) 24 h water deprivation and urine flow measured.

Results: Following osmotic stimulus, we found $AQP3^{Q/Q}$ cells had the highest water permeability followed by the $AQP3^{WT/WT}$ cells and the $AQP3^{R/R}$ cells. From our mutant mice, as adults, control and $AQP3^{Q/Q}$ mice had similar urine flow on all protocols. However, the $AQP3^{R/R}$ mice produced double the urine on protocols 1 and 2. Thus, maintenance of deacetylated AQP3 enhances fluid excretion under normal and hydrated conditions. To further determine whether the increased urine flow was due to impaired water permeability, we immunolocalized AQP2 and AQP3 under ad lib conditions. $AQP3^{Q/Q}$ mice had enhanced expression of AQP3 in the basolateral membrane, and reduced AQP2 expression in the apical membrane. In contrast, the $AQP3^{R/R}$ mice had diffuse AQP3 localization in the CD, with no obvious change in AQP2.

Conclusions: Together, these preliminary data suggest that acAQP3 promotes localization to the basolateral membrane of the CD and supports the hypothesis that acAQP3 could serve as an important regulator of CD function in fluid homeostasis.

TH-OR29

Role of TRPC3 in the Control of Osmosensitivity and Renal Water Handling in the Mouse Collecting Duct

Victor N. Tomilin,[1] Mykola Mamenko,[2] Naghmeh Hassanzadeh Khayyat,[1] Oleg L. Zaika,[1] Oleh Pochynyuk.[1] *[1]University of Texas John P and Katherine G McGovern Medical School, Houston, TX; [2]Augusta University Medical College of Georgia, Augusta, GA.*

Background: Kidney is central in the control of systemic water balance of the organism. AVP facilitates aquaporin 2 (AQP2) translocation to the apical plasma membrane to augment water permeability of the collecting duct (CD). Inability of CD to respond to AVP signal causes NDI leading to polyuria, dehydration and thirst. Stimulation of CD water reabsorption by AVP can only occur in the presence of positive osmotic difference between the cytosol and luminal fluid. Extracellular hypotonicity increases $[Ca^{2+}]_i$ and causes cell swelling due to AQP2-driven water influx. The role of the osmosensitive $[Ca^{2+}]_i$ signaling in renal water transport and urinary concentration remains unknown.

Methods: The employed techniques include simultaneous measurement of $[Ca^{2+}]_i$ dynamics with Fura 2 and the rate of cell swelling as a readout of the AQP2-dependent water reabsorption in freshly isolated split-opened CD of wild type and TRPC3 -/- mice; immunofluorescent detection of AVP-induced AQP2 trafficking to the apical membrane and metabolic cage balance studies.

Results: TRPC3 is a Ca^{2+} permeable mechano-activated channel abundantly expressed in the CD. We found that TRPC3 deletion or pharmacological inhibition precluded $[Ca^{2+}]_i$ elevations induced hypotonicity and severely slowed the rate of cell swelling indicative of diminished water transport in the CD. TRPC3 -/- and WT mice had comparable serum and urine osmolarity in control conditions, but exhibited a significantly greater bodyweight loss, and urinary volume excretion after 24 h of water deprivation (WD) despite higher AVP levels when compared to WT. Furthermore, osmosensitive $[Ca^{2+}]_i$ elevations were greatly increased in CDs from WT but not TRPC3 -/- animals after 24 h WD. Greatly accelerated rate of cell swelling was observed in WT, while it was only modestly increased in TRPC3 -/- mice under the same condition. Using immunofluorescent microscopy, we found that AQP2 translocated to the apical plasma membrane in WT, while maintaining mostly cytosolic localization in TRPC3 -/- after 24 h WD.

Conclusions: Our studies show a significant role of TRPC3 in osmosensitivity and regulation of AVP-dependent AQP2 trafficking in the CD. TRPC3 deletion compromises systemic water balance producing an NDI-like phenotype.

TH-OR30

Distinct Cellular Osmoregulatory Response in the Skin of Patients with Disturbed Glycosaminoglycan Biosynthesis

Jetta J. Oppelaar, Eliane Wenstedt, Nienke M. Rorije, Rik H. Olde Engberink, Bert-jan Van den born, Jan Aten, Liffert Vogt. *Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: Several studies have shown that during high Na^+ diet (HSD) sodium content of the skin increases. Nuclear factor of activated T cells 5 (NFAT5) is a hypertonicity driven transcription factor responsive to environmental osmotic changes. Sulfated glycosaminoglycans (GAGs) have been suggested to neutralize Na^+-induced hypertonic effects by facilitating a dynamic non-osmotic Na^+ storage compartment. Patients with diabetes mellitus type 1 (DM1) and hereditary multiple exostoses (HME) display decreased GAG sulfation. We questioned whether these patients show distinct cellular osmoregulatory responses to a HSD.

Methods: We performed an experimental randomized cross-over study in 8 DM1, 7 HME, and 12 healthy males with similar age, BMI and eGFR. All subjects followed both an 8-day low Na^+ diet (<50mmol/d) and a HSD (>200mmol/d) in randomized order, separated by a 7-to-10-day washout period. After each diet, blood samples and skin biopsies were obtained. With immunohistochemistry, skin NFAT5 expression and GAG sulfation patterns were semi-quantitatively analyzed by researchers blinded for diet status.

Results: HSD increased dermal NFAT5 expression in controls, whereas in DM1 and HME no changes were observed (Fig1A). In controls, HSD also increased averagely sulfated heparan sulfate in the dermis (Fig1B). During HSD, dermal NFAT5 expression and plasma osmolality were negatively correlated in controls (Fig1C).

Conclusions: In response to HSD, controls showed a hypertonicity-driven response in skin tissue. No hypertonicity-driven changes could be observed in the skin of patients with disturbed GAGs. In controls during HSD, dermal NFAT5 was associated with lower plasma osmolality, suggesting interstitial hypertonicity. Our study implicates that intact GAGs might be important for the skin interstitium to increase hypertonicity and respond to HSD with remodeling the sodium buffering compartment. This underlines the importance of intact GAGs in non-osmotic sodium buffering in humans.

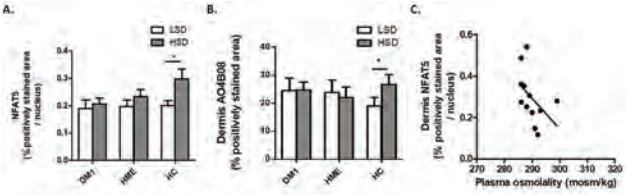

Fig 1 A. High salt diet (HSD) increased expression of NFAT5 in dermal skin (median % positively stained area (IQR) 0.19 (0.09) vs. 0.28 (0.13), p=0.02) of healthy controls. **B.** HSD increased dermis averagely sulfated heparan sulfate (AO4B08) (median % positively stained area (IQR) 15.3 (14.5) vs. 29.9 (20.9), p=0.019) in healthy controls. **C.** Significant negative correlation between dermis NFAT5 expression and plasma osmolality in healthy controls (r=-0.62, p=0.032).

TH-OR31

Risk Factors for AKI During Autologous Stem Cell Transplantation in AL Amyloidosis

Ralph Nader,[1] Stephanie S. Pavlovich,[1] Avital Angel-Korman,[1] Alexander Pogrebinsky,[2] Gheorghe Doros,[2] Hanni Menn-Josephy,[1] Lauren D. Stern,[1] Shayna Sarosiek,[1] Dina Brauneis,[3] Vaishali Sanchorawala,[1] Andrea Havasi.[1] *[1]Boston University School of Medicine, Boston, MA; [2]Boston University School of Public Health, Boston, MA; [3]Boston Medical Center, Boston, MA.*

Background: Acute kidney injury (AKI) is a common complication after high dose melphalan and autologous stem cell transplantation (HDM/SCT) in AL amyloidosis patients. However, its incidence, outcome and risk factors are not well known.

Methods: This observational study included 173 AL amyloidosis patients who underwent HDM/SCT in the Amyloidosis Center at Boston University School of Medicine. Demographic, laboratory and clinical data were prospectively collected and analyzed retrospectively. AKI was defined as an increase in serum creatinine to ≥ 1.5 times the baseline value and occurring within the first 30 days after HDM/SCT.

Results: The median age was 57 years (range 32-77). Fifty-nine percent of patients were male. Renal and cardiac involvement were present in 65.3% and 19.7% of patients, respectively. Median eGFR was 83 mL/min/1.73m^2 (range 9-213) and median proteinuria was 2,503 mg/24h (range 0-19,996). The median time from diagnosis to SCT was 4 months (range 1-100). AKI occurred in 28.3% of patients. The causes of AKI were: ATN (27.9%), pre-renal injury (26.4%), melphalan-induced AKI (12.0%), cardiorenal physiology (5.8%), AIN (2.9%), contrast-induced AKI (1.5%), obstructive nephropathy (1.5%), and no clear etiology (22.0%). AKI was associated with increased overall mortality with a hazard ratio of 4.78 (95% CI, 1.9-11.9, p<0.001). The 10-year overall survival was 87.5% for patients who did not have AKI versus 56.2% who had AKI. Baseline characteristics significantly associated with AKI development were: amyloid renal involvement, renal function, proteinuria, hypoalbuminemia, IVSD, atrial fibrillation, use of midodrine or diuretics. Sepsis in the post-transplant period, IV vancomycin use, and *C. difficile* infection were significantly associated with AKI. In terms of hematologic factors, anemia severity, and the need for red blood cell transfusion were significantly associated with AKI. Prolonged thrombocytopenia was associated with AKI; however, delayed WBC engraftment was not associated with AKI.

Conclusions: AKI occurs frequently after HDM/SCT in AL amyloidosis patients and is associated with several risk factors and an increased overall mortality. Prophylactic measures addressing some of these risk factors may reduce this risk.

Associations Between the Immunoglobulin Germline Gene Usage and the Tropism of Organ Involvement and Renal Amyloid Deposition Patterns in Immunoglobulin Light-Chain Amyloidosis by Mass Spectrometry

Dan Y. Li,[1] Dan Liu,[2] Su-xia Wang,[1] Ming Hui Zhao.[1] *[1]Peking University First Hospital, Beijing, China; [2]Peking University Health Science Center School of Foundational Education, Beijing, China.*

Background: The goal of this study was to characterize the associations between the immunoglobulin light chain variable region (IGVL) germline gene usage and organ tropism, renal amyloid deposition patterns in Chinese patients with AL amyloidosis.

Methods: 105 patients were selected randomly from an overall database of 310 patients with AL amyloidosis diagnosed by renal biopsies during 2000 to 2018. The clinical manifestation and organ involvement were assessed. The renal amyloid deposits on different compartments were evaluated and classified into three patterns: (1) glomerular dominant amyloid deposition pattern (G-AL, n=27); (2) vascular dominant deposition pattern (V-AL, n=32); (3) diffuse amyloid deposition pattern (D-AL, n=46). IGVL germline gene usage was identified based on proteomic analysis of renal amyloidotic tissue by mass spectrometry using a reference database supplemented with sequences of IGVL of AL amyloidosis. The associations of IGVL genes with organ involvement, renal amyloid deposition patterns and survival were assessed.

Results: IGVL genes were successfully identified in 84.8% patients (89/105). LV 6-57 (31.2%) was the most common λ IGVL gene identified among patients with AL amyloidosis, and KV 1-33 (50.0%) was predominant in κ IGVL patients. When compared with patients with renal involvement, the frequency of LV 1-44 (12.1% vs 4.3%, P=0.639)

and LV 1-47 (9.1% vs 4.3%, P=0.636) were high among patients with combined renal and cardiac involvement. Among the specific compartment of kidney with amyloid deposits, LV 6-57 was more likely to have G-AL (42.9% vs 26.9% vs 26.7%, P=0.399), and LV 1-51 was associated with V-AL (19.2% vs 3.3% vs 0, P=0.019). Patients with LV 2 family had a tendency at increased risk of developing into ESRD compared with other IGVL families (P=0.027).

Conclusions: IGVL germline gene usage was associated with organ tropism, renal amyloid deposition patterns and renal survival in Chinese patients with AL amyloidosis. Whereas, the results were preliminary and exploratory, and should be proved in a large cohort of AL amyloidosis patients.

Treatment of AL Amyloidosis with Daratumumab Monotherapy

Roberta Fenoglio, Savino Sciascia, Dario Roccatello. *Nephrology and Dialysis Unit & CMID (Center of Research of Immunopathology and Rare Diseases), Coordinating Center of the Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital of Turin, and Department of Clinical and Biological Sciences, University of Turin, Turin, Italy, Turin, Italy.*

Background: Immunoglobulin light chain amyloidosis (AL) is characterized by poor outcome. Daratumumab (D) is a first in class anti CD38 human antibody (IgG1κ) which proved to be effective in combination with bortezomib in MM refractory to conventional bortezomib-based regimens. Its effectiveness and safety in the treatment of AL amyloidosis is under study. This study reports the experience with D monotherapy in a series of severe patients (pts) with AL amyloidosis and multiorgan and biopsy-proven renal involvement.

Methods: Five pts, mean age 64 years were treated with D following antibody testing and extended RBC antigen phenotyping. Treatment protocol was as follows: 16 mg/kg D i.v. administered weekly for 8 weeks, then every 2 weeks (8 doses), and then monthly for 1 year.

Results: In pt #1, in dialysis, who was refractory to conventional therapies D administration resulted in normalization of the FLC ratio with disappearance of serum M-component and Bence-Jones (BJ) proteinuria. In pt #2 who had a relapsing disease, D treatment resulted in a rapid decrease of proteinuria and N-terminal propeptide (NT-pro-BNP) levels with disappearance of serum M-component and BJ proteinuria and normalization of the FLC ratio. Pt #3 was treated front-line. He had an impressive decrease of proteinuria and NT-proBNP levels with normalization of FLC ratio and disappearance of serum M-component. In pt #4, who was intolerant to conventional regimens, D therapy resulted in decrease in proteinuria, disappearance of serum M-component and improvement in the FLC ratio, which were paralleled by a reduction of NT-proBNP levels. Pt #5 had a relapsing disease. D achieved a decrease of proteinuria, a decrease of serum M-component with increase of FLC ratio. This was the only patient who experienced an infusion reaction during the first dose. The 4 pt with still preserved renal function also showed renal response with sCr improvement or stabilization and a decrease in proteinuria levels These data were paralleled by the reduction of NT-proBNP values in the 3 pts with cardiac involvement.

Conclusions: Daratumumab monotherapy resulted in the disappearance of M-proteins in every pt with FLC ratio normalization in 4 out of 5 subjects and impressive decrease of proteinuria and pro-BNP values proving to be an effective therapeutic option for pretreated/naïve patients with severe AL with renal involvement.

Immune Checkpoint Inhibitor Use in Kidney Transplant Recipients: A Multicenter Study

Naoka Murakami,[1] Leonardo V. Riella,[1] Rimda Wanchoo,[2] Vinay Nair,[2] Kenar D. Jhaveri.[2] Immune Checkpoint Inhibitor in Solid Organ Transplant Consortium *[1]Brigham and Women's Hospital, Boston, MA; [2]Northwell Health, Great Neck, NY.*

Background: Immune checkpoint inhibitors (ICIs) significantly improved the survival in many cancers, but the data on survival benefit in KTx recipients are lacking. ICIs are reported to be associated with higher acute rejection rate in KTx recipients, but the risk factors of ICI-associated rejection are not fully understood.

Methods: We conducted a multicenter observational study to investigate the clinical characteristics of ICI-associated rejection and the survival outcomes of KTx recipients treated with ICI. 66 KTx patients with a functioning allograft at the time of ICI initiation were collected from 18 institutions. In addition, historical control groups of KTx recipients with advanced stage melanoma (AJCC stage III-IV, n=17) and cutaneous squamous cell carcinoma (cSCC, AJCC stage III (unresectable)-IV), n=23), who could be considered as potential ICI candidates, were collected to compare the overall survival (OS).

Results: In ICI cohort, median age was 64, male dominant (83%) and transplant to ICI initiation was median 11 years. cSCC was the most frequent malignancy (n=22), followed by melanoma (n=21). 28 patients (42.4%) experienced rejection, of which 18 (64.2%) lost allograft and returned to dialysis. Median time from ICI initiation to rejection was 26 days. In biopsy-proven rejection (n=13), both mixed acute cell and antibody-mediated rejection (n=7, 53%) and acute cell-medicated rejection (n=6, 47%) were seen. By Chi square test, mTOR inhibitor use (*p=0.012) and the use of higher number of immunosuppression drugs (*p=0.049) were associated with lower risk of rejection. For both melanoma and cSCC cohort, ICI groups experienced higher rejection rate (57% and 40%, for melanoma and cSCC, respectively), compared to non-ICI control groups (12% and 4.3%), suggesting the higher rejection rate in ICI groups was not solely explained by reduction in immunosuppression. OS didn't show statistical difference in melanoma cohort (log rank test p=0.22), but OS was significantly longer in cSCC cohort (log rank test *p=0.015), when compared ICI vs non-ICI control groups.

Conclusions: Our multi-center study provides a novel data on the survival benefit and the risk factors of rejection in KTx recipients with ICI use compared to non-ICI control groups.

Daily Caffeine Consumption and Risk of AKI Related to Platinum-Salt Chemotherapy: A Prospective Cohort Study

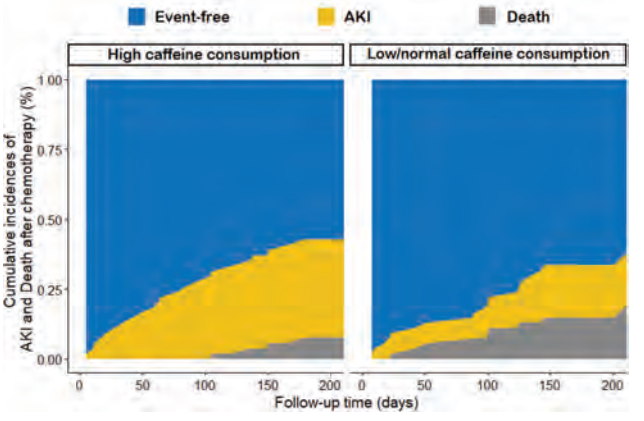
Aghiles Hamroun,[1] Decaestecker Antoine,[1] David Blum,[2] Christelle Cauffiez,[2] François Glowacki.[1] *[1]Centre Hospitalier Regional Universitaire de Lille, Lille, France; [2]Universite de Lille, Lille, France.*

Background: Although their efficacy has been well-established in Oncology, the use of platinum salts remains limited due to the occurrence of acute kidney injury (AKI). Caffeine has been suggested as a potential pathophysiological actor of platinum salt-induced AKI, through its hemodynamic effects. This work aims to study the association between caffeine consumption and the risk of platinum salt-induced AKI.

Methods: We conducted a single-center prospective cohort study that has included 108 consecutive thoracic cancer patients receiving a first-line platinum-salt chemotherapy between January 2017 and December 2018. Before the first course of chemotherapy, they were all invited to fill in a previously validated auto-questionnaire, designed for a detailed evaluation of their daily caffeine consumption (mg/day). The association of daily caffeine consumption with the risk of platinum-salt induced AKI was estimated by cause-specific Cox proportional hazard model adjusted for several known confounders (baseline renal function and serum albumin level, nature and dose of platinum-salt, tobacco exposure, and Performans status).

Results: Overall, 34 patients (31.5%) (mean age 61.7 years, 65% men, 80% tobacco users) experienced a platinum salt-induced AKI (67% grade 1) and 47 (43.5%) died during follow-up (6.2 months [3.4; 8.4]). The group of high-caffeine consumption (≥ 386mg/day) had a twice higher risk of AKI (HR=2.12 [1.01; 4.45]) in the fully adjusted model. The cumulative incidence of AKI (considering the competing risk of death) was also significantly increased in the high-caffeine consumption group (p=0.03, see figure 1).

Conclusions: In a population of thoracic cancer patients, the group of high-caffeine consumption was exposed to a significantly higher risk of platinum salt-induced AKI.



TH-OR36

Kidney and Cancer Outcomes with Standard vs. Kidney Protective Chemotherapy Regimens for First-Line Treatment of Metastatic Urothelial Carcinoma

Gabrielle Côté,[1] Husam A. Alqaisi,[1] Srikala S. Sridhar,[3] Abhijat Kitchlu.[2] *[1]University of Toronto, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada; [3]Princess Margaret Hospital Cancer Centre, Toronto, ON, Canada.*

Background: Cisplatin-based combination chemotherapy regimen is the optimal initial treatment for metastatic urothelial carcinoma, but kidney function eligibility and nephrotoxicity are treatment-limiting for many patients. For patients unfit to receive cisplatin, other options include alternative administration schedules (e.g. split dose cisplatin), carboplatin-based regimens and non-platinum regimens. The aims of this study were to compare cancer outcomes and incidence of acute kidney injury (AKI) during treatment among 3 regimens of chemotherapy.

Methods: We conducted a single-center retrospective study of patients receiving first-line chemotherapy for metastatic urothelial carcinoma (2005-2019). We compared standard gemcitabine-cisplatin (gem-cis) to: 1) gemcitabine-cisplatin split dose regimen (split) with cisplatin divided over day 1 and 8; and 2) combination of gemcitabine-carboplatin or single-agent gemcitabine (gem/gem-carbo). We used Fine and Gray hazard models accounting for baseline covariates and competing risk of death.

Results: We identified 183 patients (98 gem-cis, 32 split and 53 gem/gem-carbo). Median age was 67 years-old (IQR: 61-73) and 76% were male. Median baseline eGFR was 78 mL/min/1.73m^2 (IQR: 66-91) in gem-cis, 64 (48-77) in split, and 45 (33-57) in gem/gem-carbo. Patients receiving split and gem/gem-carbo were older, had worse performance status, and hypertension was more frequent. Split and gem/gem-carbo regimens were associated with higher mortality and progressive disease relative to gem-cis when adjusted for age, baseline eGFR, ECOG, hypertension and diabetes with hazard ratio (HR) of 1.56 (95%CI: 1.04-2.34; p=0.03) and 2.02 (95%CI: 1.36-3.01; p<0.01) respectively. Median time to progressive disease was 242 (IQR: 137-444), 182 (122-279) and 131 (68-257) days in gem-cis, split and gem/gem-carbo groups. There was no significant association between regimen type and AKI with HR of 1.32 (95%CI: 0.62-2.81; p=0.47) and 0.98 (95%CI:0.46-2.09; p=0.96) for split and gem/gem-carbo groups versus gem-cis.

Conclusions: Kidney protective chemotherapy regimens were associated with increased disease progression and mortality, without a significant difference in AKI. Alternative kidney protective strategies are needed for patients with CKD and urothelial cancer.

TH-OR37

Risk Factors for Nephrotoxicity with High-Dose Methotrexate (HDMTX) in Haematological Malignancies

Darragh O'Donoghue, Huong L. Truong, Heidi D. Finnes, Jennifer McDonald, Nelson Leung. *Mayo Clinic Minnesota, Rochester, MN.*

Background: HDMTX is a key component for treatment of haematological malignancy. Nephrotoxicity remains a significant risk factor for HDMTX and therefore, hyper-hydration and urinary alkalinisation are employed to optimise excretion but despite these measures, nephrotoxicity remains 2-12%. Determination of risk factors is key in order to further stratify and ameliorate the risk of acute kidney injury.

Methods: A retrospective review of the electronic medical record was conducted to identify patients with leukaemia or lymphoma who received HDMTX from 1/1/2002 to 12/31/18. We characterised the incidence of AKI, using the acute kidney injury network criteria, and the time to AKI. We assessed key baseline demographics, underlying malignancy, delivered MTX dose, and previous nephrotoxicity. Significant factors on univariate analysis were further assessed on Multivariate analysis. Analysis was performed on Minitab.

Results: We identified 3091 cycles of HDMTX with lymphoma accounting for 90.7% of cases. The incidence of AKI was 19.1% in the lymphoma cohort and 13.6% in the leukaemia cohort (p=0.023). The median time to AKI grade shortened with higher severity of AKI (p<0.001). In those with AKI N3, creatinine increased to this level in a median time of 1 day. All patients requiring dialysis (n=7) developed an AKI at day 1 post HDMTX. Univariate analysis revealed age (p=0.022), Gender (p<0.001), higher BSA (p<0.001), type of malignancy (p=0.023), nephrotoxicity on previous dose (p<0.001), cycle number (p<0.001), GFR by Cockcroft-Gault (p=0.016) and 48-hour MTX level (p<0.001). There was no association between AKI and MTX dose (p=0.225), or GFR by MDRD (p=0.497). Multivariate analysis revealed increased age (p<0.001), male Gender (p<0.001), Lymphoma (p=0.002), previous AKI (p<0.001), cycle number (p=0.032), and 48-hour MTX level (p<0.001) to be significant risk factors for nephrotoxicity.

Conclusions: Nephrotoxicity remains a significant complication with HDMTX despite current prevention measures. High grade AKI occurs early post HDMTX and therefore, risk stratification is vital. Our study identified key risk factors as older, male, AKI on previous dose, diagnosis of lymphoma, elevated 48-hour MTX level and earlier cycle.

TH-OR38

Characterizing the Risk of Development of Proteinuria with Bevacizumab Therapy

Tomas I. Guerrero Nunez, Abigail B. Shoben, Jason Prosek. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Bevacizumab is a well-known cause of proteinuria. There are multiple hypotheses regarding mechanism that involve the VEGF receptor, nitric oxide metabolism and increased arteriolar glomerular pressure. The most accepted explanation is that Bevacizumab induces thrombomicroangiopathy. However, there is no current model or description of potential risk factors to identify at-risk patients who may need closer monitoring, although a dose dependent relationship has been described previously. There also exists no proven therapy for mitigating or reversing the proteinuria. Current guidelines advise that therapy be either discontinued or completely stopped depending on the level or proteinuria that develops. Some authors have proposed RAAS inhibition, but no data is available to support that theory.

Methods: 1224 patients on Bevacizumab were sampled, with 714 having at least one P/Cr value needed for analysis. The time frame in which data was collected was 600 days. Data sampled included, age, baseline P/Cr, status of type 2 diabetes, chronic kidney disease stage 3, hypertension, use of Angiotensin Converting Enzyme inhibition, and sequential P/Cr values. Cox proportional hazard models were used to assess differences in the instantaneous risk of the event by categories, no violations of proportional hazard models were observed. The primary endpoint was defined as a P/Cr of 1.0 g/g, indicative of progression of proteinuria.

Results: A baseline P/Cr above 0.25 (HR 5.83, p=<0.001), Type 2 Diabetes (HR 1.68, p=0.074), and CKD III (HR 3.25. p=0.007) were associated with an increased risk of developing proteinuria, while age, hypertension (HR 1.11, p = 0.86), a baseline P/Cr < 0.25 (HR 1.04, CI 0.53,2.04, p<0.001) were not. ACE inhibitors had the following association: (Lisinopril; {10 mg, 20 mg, > 20mg}, HR {1.47, 1.76, 1.67}, p=0.67). Treatment duration was also shown to increase risk of the primary endpoint. The cumulative incidence was 23% after 600 days of treatment.

Conclusions: A presence of a baseline P/Cr greater than 0.25 g/g, type 2 diabetes, and CKD III, all showed a significant increase in risk of progressing to proteinuria of greater than 1.0 g/g. Age and hypertension were not associated with increased risk. Due to lack of randomization and incomplete data, further analysis is needed.

TH-OR39

CKD Prevalence, Patterns of Treatment, and Outcomes in Patients with Cancer: A Population-Based Cohort Study

Abhijat Kitchlu,[1] Bin Luo,[2] Nivethika Jeyakumar,[2] Amit X. Garg,[3] Eitan Amir,[1] Joseph Kim,[1] Ron Wald.[4] *[1]University Health Network, Toronto, ON, Canada; [2]Institute for Clinical Evaluative Sciences, London, ON, Canada; [3]London Health Sciences Centre, London, ON, Canada; [4]St. Michael's Hospital, Toronto, ON, Canada.*

Background: Chronic kidney disease (CKD) may impede optimal cancer treatment and result in worse outcomes. There are limited data to assess receipt of systemic therapy, radiation therapy, and palliative care in patients with cancer and CKD.

Methods: We conducted a population-based cohort study of all patients (≥18 years old) with a new cancer diagnosis in Ontario, Canada (2007-2015). We categorized patients according to CKD status at cancer diagnosis [estimated glomerular filtration rate (eGFR) ≥60 (referent group), 45-59, 30-44, 15-29, <15 mL/min/1.73m^2, dialysis and transplant recipients]. We used multivariable Fine and Gray proportional hazards models to assess overall survival, receipt of systemic therapy, radiation and palliative care (6-months prior to death) in the 5 most common solid cancers (bladder, breast, colon, prostate, lung) and kidney cancer.

Results: We identified 128,489 patients with a new cancer diagnosis, of whom 16% had pre-existing CKD (eGFR <60 mL/min/1.73m^2). Patients with the 6 cancers of interest accounted for 73% (93,751). Kidney function at cancer diagnosis was associated with (progressively) worse overall survival in CKD stages 3a-5, dialysis, and transplant recipients (Figure a). Increasing CKD stage was associated with significantly reduced receipt of all treatment modalities [systemic therapy, radiation and palliative care (Figure b-d)]. Patients receiving dialysis had 2-fold increased mortality in bladder, breast and colon cancers, and 3-fold mortality in kidney cancers.

Conclusions: In patients with cancer, CKD is associated with reduced exposure to systemic, radiation and palliative treatments and worse overall survival. Strategies to improve cancer care in the CKD population are needed.

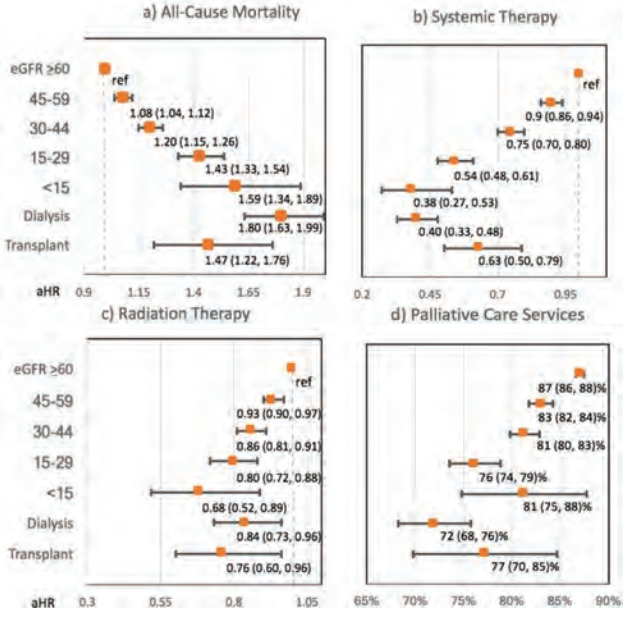


Figure - Adjusted HR by CKD Status

Assessment of Estimated Glomerular Filtration Rate in a Cohort of 1200 Cancer Patients Using Serum Creatinine and Cystatin C

Veronica T. Costa e Silva,[1] Luiz A. Gil,[1] Renato A. Caires,[1] Elerson Costalonga,[1] George B. Coura-Filho,[3] Gilberto Castro,[1] Lesley A. Inker,[2] Paul Mathew,[2] Andrew S. Levey,[2] Emmanuel A. Burdmann.[3] *[1]São Paulo State Cancer Institute - University of São Paulo School of Medicine, São Paulo, Brazil; [2]Tufts Medical Center, Boston, MA; [3]University of São Paulo School of Medicine, São Paulo, Brazil.*

Background: eGFR using creatinine (eGFRcr) with the CKD-EPI equation is recommended as the first test for GFR evaluation in clinical practice, but CG equation is commonly used for the prescription of chemotherapy, despite increasing evidence of its inaccuracy compared to measured GFR (mGFR). eGFR using cystatin C (eGFRcys)

is less influenced by muscle mass or nutritional status, and eGFR using both markers (eGFRcr-cys) is more accurate than either eGFRcr or eGFRcys, but neither has been widely assessed in cancer patients. Our aim is to compare the performance of eGFR equations (Table) in cancer patients compared to mGFR.

Methods: This analysis is a cross-sectional evaluation of a prospective cohort of cancer patients in treatment at the ICESP. mGFR was determined by plasma clearance of ^{51}Cr-EDTA indexed for body surface area.

Results: A group of 1,200 patients recruited between April 2015 and September 2017. Patients were 60 (51 – 68) y, 50.8% male. The most common cancer sites were breast (22.6%), prostate (19.8%) and gastrointestinal (13.4%). All eGFRcr equations overestimated mGFR with varying bias. CG had the lowest precision and was least accurate. eGFRcys underestimated mGFR and eGFRcr-cys had minimal bias and was the most accurate of all equations (Table).

Conclusions: All eGFRcr equations overestimated mGFR in our study. CG was the least accurate and should not be preferred over CKD-EPI. eGFRcr-cys is more accurate and can be used as a confirmatory test.

eGFR filtration marker	eGFR equation (year)	Bias (median) (ml/min/1.73 m2)	Precision (IQR) (ml/min/1.73 m2)	Accuracy (1-P30) (%)	Accuracy (RMSE)
eGFRcr	CG (1976)	-8.12 (-9.34 to -6.74)	24.1 (22.4 – 25.7)	24.9 (22.3 – 27.2)	0.23 (0.22 – 0.25)
eGFRcr	MDRD (2006)	-4.83 (-5.98 to -3.63)	20 (18.5 – 21.4)	18.1 (15.9 – 20.3)	0.21 (0.22 – 0.22)
eGFRcr	CKD-EPI (2009)	-8.0 (-8.82 to -7.06)	18.3 (17 – 19.5)	19 (16.8 - 21.2)	0.20 (0.19-0.21)
eGFRcr	Janowitz-Williams (2017)	-5.68 (-6.66 to – 4.93)	20.2 (18.8 – 21.8)	19.6 (17.3 – 21.7)	0.21 (0.20 – 0.22)
eGFRcys	CKD-EPI (2012)	4.57 (3.71 to 5.5)	17.5 (16.3 – 19.3)	12.3 (10.4 - 14)	0.21 (0.20 – 0.22)
eGFRcr-cys	CKD-EPI (2012)	-1.97 (-2.57 to -1.11)	15.9 (14.7 – 16.8)	7.83 (6.25 – 9.26)	0.16 (0.15 – 0.17)

SCr and SCys were measured through certified reference materials. CG (Cockcroft Gault); MDRD (Modification of Diet in Renal Disease), CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration), IQR, interquartile range; RMSE, squared root of mean squared error, P30: percentage of estimates that are 30% over or below mGFR. Non-overlapping confidence intervals indicates statistical significance

TH-OR41

Hematopoietic-Specific Melanocortin 1 Receptor Signaling Protects Against Crescentic Glomerulonephritis and Mediates the Beneficial Effect of Melanocortin Therapy

Xuejing Guan,[1,2] Rong Zhou,[2] Lance D. Dworkin,[1] Rujun Gong.[1] *[1]Department of Medicine, Division of Nephrology, University of Toledo College of Medicine, Toledo, OH; [2]Department of Nephrology, Yangpu Hospital, Tongji University School of Medicine, Shanghai, China.*

Background: Emerging evidence suggests that melanocortin 1 receptor (MC1R) signaling may contribute to the beneficial action of melanocortins in glomerular diseases. However, whether hematopoietic MC1R signaling is implicated is unknown.

Methods: MC1R mutant (e/e) or wild-type (WT) mice were injured with rabbit nephrotoxic serum (NTS) and treated with melanocortins, including the Repository Corticotropin Injection (RCI, Acthar® Gel, Mallinckrodt ARD, LLC), NDP-MSH, and the MC1R selective agonist MS05. Some mice received adoptive transfer of syngeneic bone marrow-derived cells (BMDC) beforehand. Kidney function and injuries were evaluated.

Results: Upon NTS injury, e/e mice developed more severe crescentic glomerulonephritis than WT mice, featured by heavier proteinuria, higher serum creatinine levels and exacerbated renal lesions, including crescent formation, renal inflammatory infiltration and fibrosis as well as podocyte damage, marked by loss of expression of podocyte homeostatic markers in glomeruli. Melanocortin therapy substantially improved renal injury in WT mice and this protective effect was blunted in e/e mice. In contrast, adoptive transfer of BMDC derived from WT mice to e/e mice markedly ameliorated NTS nephritis and reinstated the therapeutic efficacy of melanocortins in e/e mice. Mechanistically, the beneficial action of WT BMDC in e/e mice was associated with diminished glomerular deposition of autologous anti-rabbit IgG and reduced fixation of C5b-9 along glomerular capillary loops, entailing a regulatory effect of BMDC-specific MC1R signaling on humoral immune response to NTS antigens. In addition, melanocortin therapy prominently tilted macrophage polarization towards the anti- inflammatory M2 phenotypes in NTS-injured kidneys in WT mice. MC1R signaling is likely involved in this modulation of macrophage behavior, because MC1R was evidently expressed in bone marrow-derived macrophage (BMM) prepared from WT mice but absent from e/e BMM. Furthermore, MS05 diminished M1 phenotypes and promoted M2 polarization in M1-primed WT BMM but not e/e BMM, thus denoting a pro-M2 skewing effect of MC1R signaling.

Conclusions: Hematopoietic MC1R signaling attenuates NTS nephritis *via*, at least in part, regulation of humoral immune response and a pro-M2 skewing effect on macrophage polarization.

Spatial Transcriptomics (ST): Integrating Molecular Profiles with Histomorphology in Kidney Tissue Sections

Arti M. Raghubar,[1] Duy T. Pham,[1] Xiao Tan,[1] Laura F. Grice,[1] Pui Yeng Lam,[1] Joanna Crawford,[1] Stacey Andersen,[1] Sohye Yoon,[1] Samuel E. Holland,[1] Leo Francis,[3] Alexander N. Combes,[2] Andrew J. Kassianos,[3] Helen G. Healy,[3] Quan Nguyen,[4] Andrew J. Mallett.[3] *[1]The University of Queensland, Saint Lucia, QLD, Australia; [2]Monash University Monash Biomedicine Discovery Institute, Clayton, VIC, Australia; [3]Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [4]The University of Queensland Institute for Molecular Bioscience, Saint Lucia, QLD, Australia.*

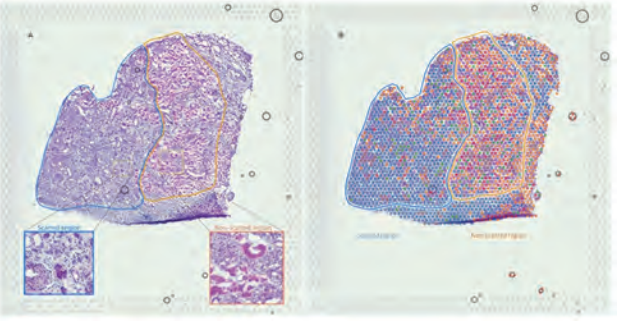
Background: Advances in sequencing methods have increased available molecular information on dissociated cells and tissues. Spatially linking this molecular information with histomorphology is needed to understand a complex organ like the kidney, in both health and disease.

Methods: Here we used the commercially available 10x Genomics ST platform to investigate the spatially resolved transcriptome expressions in fetal (n=2), adult male (n=3) and female (n=3) mouse frozen kidney and a healthy human cortical frozen kidney tissue sections. We utilised Space Ranger (10x Genomics), Seurat and stLearn analysis pipelines to explore the spatial transcriptome expression within the kidney tissue sections. Furthermore, we confirmed the robustness of our ST data against matched publicly available mouse and human kidney scRNA-seq data.

Results: We identified a unique transcriptome plasticity in fetal and adult mouse kidneys, and healthy human cortical kidney tissue. Further dimensional reduction identified transcriptome clusters which correlated with distinct developing kidney structures in fetal mouse kidney tissue, functional cortical and medulla regions in adult mouse kidney tissue, and scarred and non-scarred regions in human cortical kidney tissue.

Conclusions: ST is a non-dissociative sequencing and imaging method which allows molecular profiles to be integrated with histomorphology of frozen kidney tissue sections. This provides a novel opportunity to inform physiological and non-physiological conditions at the cell-cell, nephron and tissue levels.

Funding: Government Support - Non-U.S.



ST provides transcriptome expression within intact kideny tissue sections. **(A)** H&E stained human cortical kidney tissue with scarred and non-scarred regions. **(B)** The same human cortical kidney tissue with the transcript capture spots coloured by clustering using t-SNE projection demonstrates distinct transcriptome expression in scarred and non-scarred regions.

Automated Atubular Glomeruli Detection Using 3D Glomerular Quantification Algorithms

Haichun Yang,[1] Ruining Deng,[2] Yuankai Huo,[2] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: Atubular glomeruli are associated with decreased glomerular filtration rate and kidney disease progression. To identify atubular glomerulus requires serial section analysis, tracking individual glomeruli, and then determining whether each glomerulus has or does not have connection to the proximal tubule. This process is labor intensive and very time-consuming, limiting its use. We aimed to test feasibility of automatically detecting atubular glomeruli by using Multi-Object Association for Pathology in 3D (Map3D).

Methods: The Map3D was created including a glomerular detection algorithm, dual-path multi-object tracking algorithm, and pixel-wise large-scale glomerular association algorithm across routine serial sectioning with whole slide imaging (WSI). Atubular glomerular counting was done on 6 normal mouse kidneys, and 3 mice with diphtheria toxin (DT)-mediated proximal tubule-specific injury in mice with tubular cell expression of the DT receptor, and 4 mice with patchy tubulointerstitial fibrosis induced by folic acid (FA). Data from this automated approach was compared with standard manual assessment detailed above and correlated with functional and structural parameters.

Results: The Map3D substantially reduced the time needed for average atubular glomerular counting per sample (30 min Map3D vs. 30 hours human). Atubular glomerular size were smaller than normal glomeruli. The number of complete (i.e. from pole to pole) glomeruli assessed increased by 25.6% using GQuant-3D (86±8.8 per mouse) vs human counting (72±2.7 per mouse). GQuant-3D recognized 14.3±5.5 atubular glomeruli per mouse sample, slightly less (83%) than the 16.7±3.0 atubular glomeruli per mouse sample

recognized by manual human assessment. The percentage of atubular glomeruli by GQuant-3D was increased in DT mice (9.7±2.15%) and FA mice (36.5±7.44%) compared with normal mice (6.0±0.91%). The percentage of atubular glomeruli, counted by either GQuant-3D or human, correlated with interstitial fibrosis (R^2=0.49 or 0.61 respectively), but not with tubular injury marker, KIM-1 and N-GAL.

Conclusions: The Map-3D algorithms reduced time required for atubular glomeruli assessment, provided data correlating well with human manual-based assessment, and correlated well with relevant morphology data. This methodology can be extended to 3D glomerular phenotype analysis.

A Deep-Learning Approach to Kidney Donor Biopsy Frozen Sections

Richard Davis,[1,2] Xiang Li,[3] Nao Souma,[1] Zehan Wang,[3] Yuemei Xu,[4,3] G. Sotolongo,[1,2] Jonathan Bell,[1] Matthew J. Ellis,[1,2] David N. Howell,[1,2] Xiling Shen,[3] Kyle Lafata,[3] Laura Barisoni.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]Duke University Health System, Durham, NC; [3]Duke University, Durham, NC; [4]Nanjing University Medical School Affiliated Nanjing Drum Tower Hospital, Nanjing, China.*

Background: Pre-implant assessment of donor kidney biopsies to determine allograft viability is often performed by non-renal pathologists, and carries limited accuracy and reproducibility. The purpose of this work is to develop a deep learning (DL) method for the classification of relevant histologic primitives from donor biopsies as an aid tool to pathologists. Non-sclerotic and sclerotic glomeruli were selected to test this approach.

Methods: A total of 268 frozen sections stained with hematoxylin and eosin (H&E) from cadaveric donor kidney biopsies (128 performed at Duke and 140 at outside institutions) were scanned into whole slide images (WSI) at 40x (Leica Biosystems AT2). Duke WSIs were divided at the patient level into training and validation cohorts (0.8:0.2) and non-Duke WSIs were used as testing dataset. QuPath was employed to manually annotate non-sclerotic (22767) and sclerotic glomeruli (1366). A 9-layer convolutional neural network (CNN), based on the common U-NET architecture, was developed in Python, using randomly selected 256x256 patches from WSI, and image augmentation to boost generalization performance. CNN hyper-parameters were tuned via cross-validation. The CNN's performance was quantified based on the Dice Similarity Coefficient (DSC) between the predicted and ground-truth annotations.

Results: For non-sclerotic glomeruli, the average DSC for train, validation and testing was 0.93, 0.91, 0.90 respectively. The F1, Recall, and Precision for testing was 0.93, 0.96, 0.90 respectively. For sclerotic glomeruli, the average DSC for train, validation and testing was 0.89, 0.87, 0.83 respectively. The F1, Recall, and Precision for testing was 0.87, 0.93, 0.81 respectively. The CNN had higher performance in the regions of high glomerular density and occasionally, outperformed the pathologists in glomerular detection. Lower model performance was observed in the presence of image artifacts and in regions of low glomerular density.

Conclusions: DL applied to image analysis may help standardize and improve accuracy and reproducibility of quantification of histologic primitives in kidney frozen sections, enabling the establishment of synergistic machine-human protocols that can be deployed in clinical practice. The development of DL-segmentation of other relevant histologic primitives is in process.

Evaluation of a Direct-to-Digital Histology Method for Rapid Evaluation of Kidney Biopsies

Sudhir Perincheri, Randy L. Luciano, Gilbert W. Moeckel, Richard Torres. *Yale University School of Medicine, New Haven, CT.*

Background: Digitization of clinical renal biopsy histology is motivated by the importance of early intervention in acute kidney conditions, assessment by remotely-based experienced nephropathologists, and application of emerging computerized quantitative evaluation tools. Despite the interest, image quality and workflow impact are concerns for digital renal pathology. A newly developed tool for rapid, slide-free microscopic image preparation called Clearing Histology with MultiPhoton Microscopy (CHiMP) has demonstrated high efficiency and high quality morphology for diagnostic review in renal disease in a research environment. We sought to commence clinical validation of CHiMP for renal biopsies, including assessing effects on downstream traditional special stains and ability to detect a broad range of clinically relevant pathologic lesions in renal biopsies.

Methods: Kidney core biopsies were procured from 50 consented individuals undergoing renal biopsy for any reason and CHiMP processing was integrated into the routine clinical workflow, using previously-described methods. Images were obtained through entire core biopsies with a prototype fast, high resolution, multiphoton microscope system (Applikate Technologies, Washington, DC) and visualized with web-based software. Samples were subsequently processed using standard methods for clinical interpretation under transmitted-light microscopy, including special stains. A subset of 20 core biopsies underwent detailed morphologic feature detection analysis and quantitative lesion comparison.

Results: Diagnostic quality remotely-reviewable renal images of 10-16 digital slices were available within < 3 hours of receipt. H&E detected morphologic findings were equally detectable in digital images compared to physical, paraffin-embedded sections including cases showing tubular injury, proliferative glomerulonephritis, glomerular deposition disease, and interstitial nephritis. No significant negative effects on downstream processing were identified.

Conclusions: CHiMP can be used in rapid morphologic evaluation of kidney biopsies integrated into clinical work enabling rapid rendering of preliminary diagnoses while simultaneously making digital images available for remote expert evaluation and digital analysis. Continuing validation will test ability to augment detection of rare lesions and quantitative precision.

Kidney Biopsy Transcript Patterns Offer a Novel Approach to Distinguishing Etiologies of Acute Interstitial Nephritis

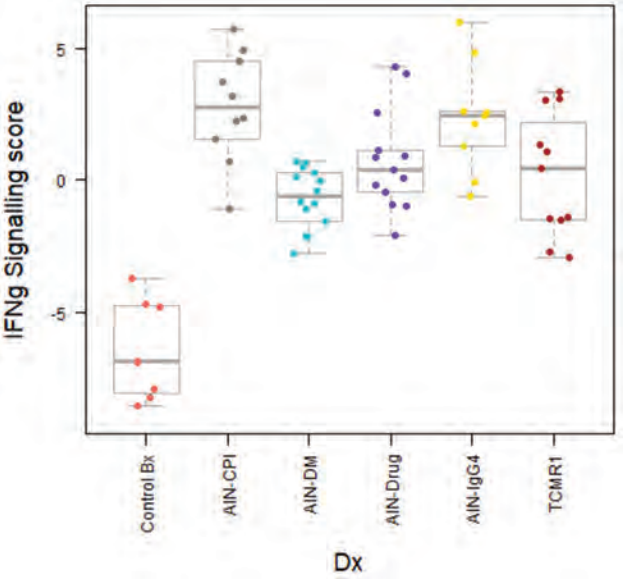
Ivy Rosales,[1] Kristen Tomaszewski,[1] Ellen Acheampong,[1] Astrid Weins,[2] Rex N. Smith,[1] Meghan E. Sise,[1] Robert B. Colvin.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: One of the challenges in renal pathology is distinguishing causes of acute interstitial nephritis (AIN). Based on encouraging results from renal allografts, we sought mRNA transcript profiles of checkpoint inhibitor associated AIN (CPI), drug induced AIN (Drug), AIN in diabetes (DM), IgG4-related renal disease (IgG4) and T cell rejection type I (TCMR1).

Methods: Three 20 um sections were obtained from 65 FFPE blocks: 9 controls, 46 AIN types (10 CPI, 13 DM, 14 Drug, 9 IgG4) and 10 TCMR1. RNA was extracted and hybridized with NanoString HOT Panel of 770 probes and analyzed on an nCounter Max instrument. The gene list is available at nanostring.com. Pathway analysis, differential expression and cell type scores were analyzed from normalized mRNA counts using nSolver.

Results: Similarities were found across AIN however each had one or more distinct patterns of transcripts. **CPI AIN** was distinguished from the other causes of AIN by higher IFNγ signaling pathway scores (Fig 1). CPI AIN had more exhausted CD8 cells ($p<0.05$) and NK cells ($p<0.001$) than drug induced AIN. **DM AIN** differed from histologically indistinguishable **Drug AIN** by several genes (e.g. higher *TGFβ2*, p=0.007). **IgG4 AIN** showed the highest levels of B cell receptor signaling, MAPK and mTOR pathways, and highest Th17 and Treg differentiation scores. **TCMR1** had lower scores for TGFβ and TNF pathways and lower Treg scores compared with the other causes of AIN. TCMR1 had the most favorable scores for AKI and pathways related to outcome (eGFR later, GoCAR progression).

Conclusions: Our initial findings suggest that once extended to customized algorithms and validated, this approach may prove fruitful in distinguishing the underlying diagnosis and pathogenesis of diverse causes of AIN.



TH-OR47

Identification of Novel Biomarkers of Kidney Disease Histopathology and Prognosis: Results from the Boston Kidney Biopsy Cohort

Insa M. Schmidt,[1,2] Suraj Sarvode mothi,[2] Ragnar Palsson,[2] Anand Srivastava,[3] Zoé A. Kibbelaar,[1,2] Min Zhuo,[4] Afolarin A. Amodu,[1] Isaac E. Stillman,[4] Helmut G. Rennke,[2] Sushrut S. Waikar.[1,2] *[1]Boston University Medical Center, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Biomarkers for non-invasive assessments of histopathology and prognosis are needed in patients with kidney disease.

Methods: Using a novel proteomics assay, we measured a multi-marker panel of 225 circulating plasma proteins in a prospective cohort study of 557 individuals with biopsy-confirmed kidney diseases and adjudicated semi-quantitative assessments

of histopathologic lesions. We tested the associations of each biomarker with clinicopathologic diagnoses, histopathologic lesions, and the risks of kidney disease progression (≥40% decline in estimated glomerular filtration rate (eGFR) or end-stage kidney disease) and death.

Results: After multivariable adjustment and correction for multiple testing, 39 proteins were independently associated with clinicopathologic diagnoses and 53 with different histopathologic lesions. Kidney-injury molecule-1 (KIM-1) associated with diabetic nephropathy and glomerular and tubulointerstitial diseases. The top performing markers for acute tubular injury and interstitial fibrosis and tubular atrophy were KIM-1 and tumor necrosis factor receptor superfamily member-9 (TNFRSF-9), respectively. Thirty proteins were significantly associated with kidney disease progression and 35 with death (Figure 1 A, B). The top performing markers for kidney disease progression were placental growth factor (PGF; HR 5.4, 95% CI 3.4 to 8.7) and BMP and Activin Membrane Bound Inhibitor (BAMBI; HR 3.0, 95% CI 2.1 to 4.2); the top performing markers for death were TRAIL-receptor-2 (TRAIL-R2; HR 2.9, 95% CI 2.0 to 4.0) and CUB Domain Containing Protein-1 (CDCP1; HR 2.4, 95% CI 1.8, 3.3). Five proteins were significantly associated with decreased risks of death (Figure 1 B).

Conclusions: We identified several biomarkers of kidney disease histology, pathology, and prognosis – many of which have not been reported previously and may represent important avenues for future research.

Funding: NIDDK Support, Private Foundation Support

Complement Activation Assay in an Ex Vivo Microfluidic Cell-Culture System

Martin Reinhardt, Yulia Kiyan, Hermann G. Haller. *Medizinische Hochschule Hannover Zentrum Innere Medizin, Hannover, Germany.*

Background: Discrimination between different diseases in patients suffering from thrombotic microangiopathies is often challenging. Measuring C5b9 deposit on endothelial cells using confocal microscopy have been shown to be convenient in diagnostic and therapy monitoring of Atypical hemolytic uremic syndrome (aHUS) but methods are complex and costly.

Methods: We developed a cell-based C5b9-ELISA to measure C5b9-deposits on activated endothelial cells. Patients with suspected aHUS and other thrombotic microangiopathies were identified in early disease stage. Serum was drawn and tested versus healthy controls. After confirmation of the diagnosis aHUS therapy efficiency was monitored using the assay.

Results: In patients with the clinical diagnosis of aHUS we were able to show up to six-fold higher C5b9-deposits in contrast to normalized human serum (NHS) (p-value < 0,0001). In comparison to healthy controls, patients suffering from either Shiga-Toxin-HUS or Thrombotic Thrombocytopenic Purpura (TTP) we could demonstrate a two- to three-fold higher deposit (p-value=0.0103 and below). After onset of eculizumab treatment, the amount of C5b9-deposits becomes lower than in healthy controls, proving the efficiency of the therapy. One-Way-ANOVA shows significant differences between aHUS-groups and controls, but not between aHUS patients using Tukeys-multiple comparisons test.

Conclusions: We described a novel, fast and reproducible ELISA to identify aHUS-patients by measuring C5b9-deposits and monitor disease activity. This can give a rise to diagnostic speed and therapy decisions. Further investigation and validation are needed to show interactions with other complement diseases like systemic lupus erythematosus.

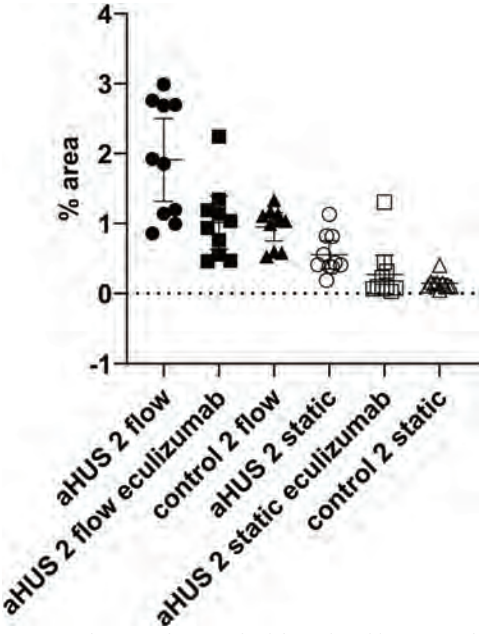

Figure 1: Percentage of area per image stained for C5b9 with 95% CI after treatment with patient serum.

Barriers and Opportunities to Improve Variability in CKD Laboratory Methodology and Reporting: Results from the College of American Pathologists (CAP) 2019 Survey

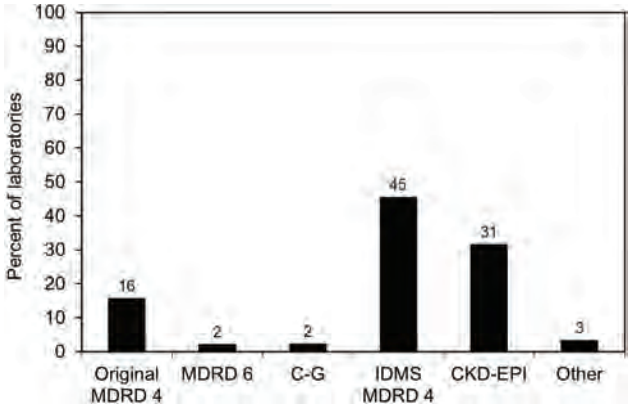
Joseph A. Vassalotti,[1,2] Greg Miller.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]National Kidney Foundation, New York, NY; [3]Virginia Commonwealth University, Richmond, VA.*

Background: Variability in laboratory practices for estimated GFR (eGFR) and urine albumin-creatinine ratio (uACR) is a barrier to optimal CKD testing and interpretation by clinicians. The CAP serial surveys assess CKD laboratory methodology and reporting.

Methods: The CAP 2019 General Chemistry Survey conducted in December, included 9 questions regarding CKD tests.

Results: Respondents included 7,105 laboratories (83.8% U.S. and 16.2% international) with a response rate of 87.5%. Laboratory reporting of eGFR based on serum creatinine has increased overall from 3% to 92% in CAP surveys between 2003 and 2019. The Figure shows 76% of laboratories were using an isotope dilution mass spectrometry (IDMS) traceable version of the MDRD 4-variable equation (45%) or the CKD-EPI equation (31%), but an incorrect equation was used for IDMS creatinine by 23% of the respondents, resulting in systematic over estimation of kidney function. Barriers for the pediatric population less than 18 years include only 10% of laboratories report the correct bedside Schwartz equation and 20% of laboratories applied an incorrect adult eGFR equation for children. The microalbumin term that KDIGO and KDOQI recommend be eliminated continues to be used by 64.5% of U.S. and 42.2% of international labs, see Table. Lastly, 12.6% of U.S., and 9.4% of international laboratories report only the urine albumin concentration without uACR, which is uniformly not recommended.

Conclusions: Laboratory variability is a call to action for nephrologists to collaborate with clinical laboratorians to improve appropriate CKD testing.



eGFR Equation Reporting

Test order name	U.S. labs	International labs
uACR	911	379
Microalbumin	3537	466
Total responding	5462	1104
Test reporting	**U.S. labs**	**International labs**
Any uACR	3673	744
Urine albumin only	563	81
Total responding	4463	860

Immunotactoid Glomerulopathy: A Rare Entity with Monoclonal and Polyclonal Variants

Samih H. Nasr,[1] Satoru Kudose,[2] Samar M. Said,[1] Dominick Santoriello,[2] Sanjeev Sethi,[1] Mary E. Fidler,[1] Nelson Leung,[1] Vivette D. D'Agati,[2] Glen S. Markowitz.[2] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Columbia University Medical Center, New York, NY.*

Background: Immunotactoid glomerulopathy (ITG) is a rare disease currently classified as an MGRS lesion for which our understanding is limited.

Methods: 73 patients with ITG were identified by retrospective review of all native renal biopsies received at two large renal pathology laboratories from 1993-2019.

Results: ITG biopsy incidence was 0.04%. Median age at diagnosis was 61 years, 86% were Caucasian, and there was no gender predilection. Patients presented with proteinuria (median 6.6 g/day, 58% with full nephrotic syndrome), hematuria (86%), and renal insufficiency (median creatinine 1.6 mg/dl). Hematologic disorders were present in 66%, including lymphoma in 41% (mainly CLL) and plasma cell dyscrasia in 26% (most commonly MGRS). 14% had underlying autoimmune disease and 33% had hypocomplementemia. Light microscopy revealed endocapillary proliferative (35%), membranoproliferative (29%) and membranous (29%) patterns. Immunohistochemical staining for DNAJB9 was negative on all cases tested. Electron microscopy showed microtubular deposits with diameter of 14-60 nm, hollow cores, frequent parallel alignment, and a predominant distribution outside of the lamina densa of the GBM. Immunofluorescence revealed IgG-dominant staining which was light chain restricted and IgG subclass restricted in 67% of cases (most commonly IgG-κ), indicating monoclonal composition. This finding was used to distinguish monoclonal ITG from polyclonal ITG. As compared to polyclonal ITG, monoclonal ITG had a higher incidence of lymphoma (53% vs. 11%), multiple myeloma (8% vs. 0), and MGRS (22% vs. 0). On follow up (median 47 months), 31% had complete remission, 11% partial remission, 35% persistent renal dysfunction, and 24% progressed to ESRD. The median survival (not reaching ESRD or death) was 123 months. Monoclonal ITG was more commonly treated with clone-directed therapy, which was associated with more frequent remission and less frequent ESRD compared to polyclonal ITG. ITG recurred within 10 months in 3 of 5 patients who received kidney transplants.

Conclusions: ITG is an extremely rare disease. Based on our observations, we propose that ITG should be subclassified as two overlapping but distinct entities – monoclonal ITG and polyclonal ITG. Prognosis is good if the underlying hematologic condition is treated.

FR-OR01

Terlipressin Improves Renal Replacement Therapy–Free Survival in Hepatorenal Syndrome Type 1

Juan Carlos Q. Velez,[1] Alex Befeler,[4] Ira Kurtz,[8] Juan F. Gallegos-Orozco,[5] Hugo E. Vargas,[3] John M. Vierling,[7] S. Chris Pappas,[6] Khurram Jamil.[2] *[1]Ochsner Health System, New Orleans, LA; [2]Mallinckrodt Pharmaceuticals Specialty Brands Principal Office, Bedminster, NJ; [3]Mayo Clinic, Phoenix, AZ; [4]Saint Louis University, Saint Louis, MO; [5]University of Utah Health, Salt Lake City, UT; [6]Orphan Therapeutics, Lebanon, NJ; [7]Baylor College of Medicine, Houston, TX; [8]UCLA Medical Center, Los Angeles, CA.*

Background: Hepatorenal syndrome type 1 (HRS-1) is an ominous form of acute kidney injury in patients with cirrhosis. Recently, the results of the randomized placebo (PBO)-controlled trial (RCT) CONFIRM demonstrated that terlipressin (TERLI) is effective in reversing HRS-1 and in reducing the cumulative need for renal replacement therapy (RRT). However, whether TERLI reduces the need for RRT among survivors has not been determined.

Methods: CONFIRM (NCT02770716) was a North American RCT (n=300) that compared HRS-1 reversal rates between patients treated with albumin plus TERLI (n=199) or albumin plus PBO (n=101) (2:1). We conducted a post hoc intention-to-treat analysis to assess the incidence of RRT among CONFIRM survivors. We also conducted a pooled analysis of the 3 TERLI RCTs in HRS-1 (OT-0401 [NCT00089570], REVERSE [NCT01143246], and CONFIRM) to examine 90-day RRT-free survival rates.

Results: In CONFIRM, the cumulative incidences of need for RRT for TERLI at day 14, 30, and 90 were 23%, 26%, and 29% compared with 35%, 36%, and 39% for patients assigned to PBO (P=0.03, 0.07, and 0.1, respectively). Among survivors, significantly fewer TERLI-treated patients remained dependent on RRT at day 14, 30, and 90 (22%, 26%, and 30%, respectively) compared with PBO (39%, 43%, and 46%; P<0.01, P=0.03, and P=0.05, respectively). The 90-day RRT-free survival rate was 35% in the TERLI group vs 30% in the PBO group (P=0.08), with a numerically longer median number of days in the TERLI group (20 vs 11). Pooled analysis of the 3 RCTs revealed a greater 90-day RRT-free survival rate for TERLI-treated (n=352) compared with PBO-treated (n=256) patients (37% vs 29%, P=0.03; OR [95% CI], 1.47 [1.04, 2.07]).

Conclusions: Treatment with TERLI added to albumin decreased the rate of RRT and improved RRT-free survival in patients with HRS-1. This is the first pharmacological intervention proven to reduce the need for RRT in patients with HRS-1. Because of the significant impact of RRT on quality of life, this observation expands the clinical benefit of TERLI and enhances the reported efficacy of TERLI in inducing HRS-1 reversal.

FR-OR02

A Parsimonious Model for Diagnosis of Biopsy-Proven Acute Interstitial Nephritis Using Electronic Health Record Data

Dennis G. Moledina,[1,2] Yu Yamamoto,[1] Chirag R. Parikh,[3] Francis P. Wilson.[1,2] *[1]Yale University School of Medicine, New Haven, CT; [2]Clinical and Translational Research Accelerator, New Haven, CT; [3]Johns Hopkins Medicine, Baltimore, MD.*

Background: Due to its atypical clinical features and difficulty in establishing diagnosis without a biopsy, acute interstitial nephritis (AIN) diagnosis is delayed or missed. We developed a predictive model for AIN using clinical data from all patients who underwent a kidney biopsy available through the electronic health record.

Methods: We obtained data on all patients who underwent a native kidney biopsy at two centers between 2013-18 and obtained corresponding information of demographics, comorbidities, and all laboratory tests collected up to one year before biopsy. We used least absolute shrinkage and selection operator (LASSO) method to select features associated with AIN and performed area under received operating characteristics curve (AUC) analysis in temporally-split training (70%) and test (30%) sets. We also applied this model to a separate cohort of kidney biopsies with AIN diagnosis adjudicated by 3 pathologists and compared it to the clinician's prebiopsy impression of AIN obtained through chart review.

Results: Among 551 patients who underwent native kidney biopsies, 60 (11%) had AIN on clinical pathology diagnosis. We evaluated 163 potential features for their association with AIN. The five features with the highest AUC were last creatinine at the time of biopsy (AUC, 0.73), BUN to creatinine ratio (0.70), urine specific gravity before biopsy (0.67), serum bicarbonate (0.62), and urine protein (0.62). The top 4 variables picked using LASSO had an AUC of 0.76 in the test set (table). Applying this model to a separate cohort of participants with adjudicated AIN, we noted an AUC of 0.80 (0.73, 0.87), which was higher than the clinician's pre-biopsy impression of AIN (0.61 (0.52, 0.70), P<0.001).

Conclusions: We noted four variables associated with AIN and the model containing these showed a modest AUC but was an improvement on clinician's pre-biopsy impression of AIN.

Funding: NIDDK Support

Features associated with AIN

Risk factor for AIN	OR (95% CI)
Higher creatinine before biopsy (per 1 mg/dl increase)	1.2 (1.0, 1.3)
Lower BUN: Cr ratio (per unit increase)	1.1 (1.0, 1.2)
Lower proteinuria (0 and 1+ vs. 2+ or higher)	2.5 (1.4, 4.4)
Lower specific gravity (per 0.001 increase)	1.1 (1.0, 1.1)
AUC test	0.76 (0.70, 0.82)

AUC, area under receiver operating characteristic curve; OR, odds ratio; CI, confidence interval

AUC training set=0.79

FR-OR03

Development and Validation of a Convolutional Neural Network Model for Intensive Care Unit AKI Prediction

Jacob Calvert,[1] Angier O. Allen,[1] Sidney H. Le,[1] Paul M. Palevsky,[2] Gregory L. Braden,[3] Sharad Patel,[4] Emily Pellegrini,[1] Abigail Green-Saxena,[1] Jana Hoffman,[1] Ritankar Das.[1] *[1]Dascena, Oakland, CA; [2]VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]Baystate Medical Center, Springfield, MA; [4]Cooper University Health Care, Camden, NJ.*

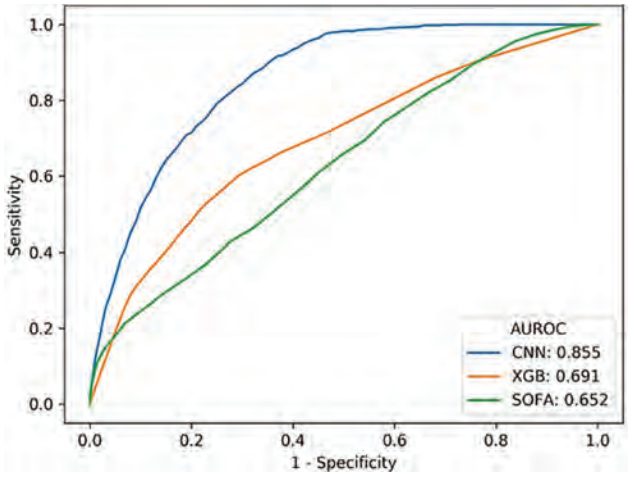
Background: Acute kidney injury (AKI) is common among hospitalized patients and has a significant impact on morbidity and mortality. While early prediction of AKI has the potential to reduce adverse patient outcomes, it remains a difficult condition to predict and diagnose. The purpose of this study was to evaluate the ability of a machine learning algorithm to predict for AKI KDIGO Stage 2 or 3 up to 72 hours in advance of onset using convolutional recurrent neural nets (CNN) and patient Electronic Health Record (EHR) data.

Methods: A CNN prediction system was developed to continuously and automatically monitor for incipient AKI. 7122 patient encounters were retrospectively analyzed from the Medical Information Mart for Intensive Care III (MIMIC-III) database. The CNN machine learning-based AKI prediction model was compared to an established XGBoost AKI prediction model and the Sequential Organ Failure Assessment (SOFA) scoring system. AKI onset was used for the outcome. The model was trained on routinely-collected patient EHR data.

Results: On a hold-out test set, the algorithm attained an Area Under the Receiver Operating Characteristic (AUROC) of 0.85 and PPV of 0.25, relative to a cohort AKI prevalence of 5.21%, for long-horizon AKI prediction at a 72-hour window prior to onset. The ROC curve comparison of 72-hour prediction on the 10% hold-out test set is shown in **Figure 1**. The CNN model, which was provided text data through Doc2Vec input, outperformed the XGBoost model and the SOFA score.

Conclusions: A CNN machine learning-based AKI prediction model outperforms XGBoost and the SOFA scoring system, demonstrating superior performance in predicting acute kidney injury 72 hours prior to onset, without reliance on changes in serum creatinine.

Funding: Other NIH Support - This work was supported by the National Institute on Alcohol Abuse and Alcoholism (NIAAA) [grant ID: 1R43AA02767401]



ROC curve comparison of prediction performance using a CNN classifier, an XGB classifier, and the SOFA score, 72 hours prior to AKI onset on the MIMIC III ICU hold out data set.

Outcomes from the Use of the Selective Cytopheretic Device (SCD) in Critically Ill Children Receiving CRRT: A Report of the Multicenter Pediatric SCD (pSCD) Study

Stuart Goldstein,[1] Kelli A. Krallman,[1] Cassie L. Kirby,[1] David J. Askenazi,[2] Rajit K. Basu,[3] David T. Selewski,[4] H. David Humes.[5] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]Children's Healthcare of Atlanta Inc, Atlanta, GA; [4]Medical University of South Carolina, Charleston, SC; [5]University of Michigan, Ann Arbor, MI.*

Background: Critically ill children who develop acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) are at increased risk of death. The SCD promotes an immunomodulatory effect in a hypocalcemic environment (ionized Ca (ionCa) < 0.4 mmol/L) in animal models of inflammation. In a randomized trial, adult ICU patients on CRRT treated with the SCD, who maintained CRRT ionCa < 0.4 mmol/L, had improved survival/dialysis independence. We conducted an FDA grant sponsored safety evaluation (adverse and serious adverse events) of the SCD in 16 critically ill children.

Methods: 4 center US study of the SCD in children (>15 kg, ≤22 years) with AKI and multiorgan failure receiving CRRT. The SCD was integrated post CRRT membrane, changed daily, and circuit ionCa maintained <0.4 mmol/L. Pts received SCD treatment for up to 7 days or CRRT discontinuation.

Results: 16 pts (8F/8M) completed the study from 12/2016 thru 2/2020. Mean pt age was 12 yr (range 4-21 yr), weight was 53 kg (range 19-111 kg) and PRISM 2 score was 7 (range 2-19). Two pts received ECMO. The most common ICU diagnosis was shock. Circuit ionCa were maintained at <0.4 mmol/L for 90.2% of assessments. Median SCD duration was 6 days (range 1 to 7). 15/16 pts survived SCD therapy, 12/16 patients survived to ICU discharge. All 12 ICU survivors were dialysis independent at 60 days. No SCD related adverse events were noted.

Conclusions: Our data suggest the SCD is safe in critically ill children who require CRRT. While we cannot make efficacy claims, the 75% survival rate and 100% renal recovery rate in surviving children suggest a favorable benefit to risk ratio.

FR-OR05

Nicotinamide Riboside with Pterostilbene Increases NAD^+ in Patients with AKI: A Randomized, Double-Blind, Placebo-Controlled, Stepwise Safety Study of NRPT in Patients with AKI

Petra Simic,[1] Xavier F. Parada,[1] Samir M. Parikh,[2] Ryan Dellinger,[3] Leonard P. Guarente,[4,3] Eugene P. Rhee.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Elysium Inc, New York, NY; [4]Massachusetts Institute of Technology, Cambridge, MA.*

Background: Preclinical studies have identified both NAD^+ and sirtuin augmentation as potential strategies for the prevention and treatment of AKI. Nicotinamide riboside (NR) is a NAD^+ precursor vitamin and pterostilbene (PT) is potent sirtuin activator found in blueberries. Here, we tested the effect of combined NR and PT (NRPT) on whole blood NAD^+ levels and safety parameters in patients with AKI.

Methods: We conducted a randomized, double-blind, placebo-controlled study of escalating doses of NRPT in 24 hospitalized patients with AKI. The study was comprised of four Steps during which NRPT (5 subjects) or placebo (1 subject) was given twice a day for two days. NRPT dosing was increased in each Step: Step 1 250/50mg, Step 2 500/100mg, Step 3 750/150mg and Step 4 1000/200mg. Blood NAD^+ levels were measured by liquid chromatography-mass spectrometry and safety was assessed by history, physical exam, and clinical laboratory testing.

Results: AKI resulted in a 50% reduction in whole blood NAD^+ levels at 48 hr compared to 0 hr in patients receiving placebo (p=0.05). There was a trend for increase in NAD^+ levels in all NRPT Steps individually at 48 hr compared to 0 hr, but only the change in Step 2 reached statistical significance (47%, p=0.04), and there was considerable interindividual variability in the NAD^+ response to treatment. Considering all Steps together, NRPT treatment increased NAD^+ levels by 37% at 48hr compared to 0hr (p=0.002). All safety laboratory tests were unchanged by NRPT treatment, including creatinine, estimated glomerular filtration rate (eGFR), electrolytes, liver function tests, and blood counts. Three of 20 patients receiving NRPT reported minor gastrointestinal side effects.

Conclusions: NRPT increases whole blood NAD^+ levels in hospitalized patients with AKI. In addition, NRPT up to a dose of 1000mg/200mg twice a day for two days is safe and well tolerated in these patients. Further studies to assess the potential therapeutic benefit of NRPT in AKI are warranted.

Role of Angiopoietins in CKD Progression After Hospitalization

Sherry Mansour,[1] Steven G. Coca,[2] Yaqi Jia,[3] Vernon M. Chinchilli,[4] Wassim Obeid,[3] Francis P. Wilson,[1] Samir M. Parikh,[5] Edward D. Siew,[8] Talat Alp Ikizler,[8] Jonathan Himmelfarb,[6] Paul L. Kimmel,[7] Chirag R. Parikh.[3] ASSESS-AKI Consortium *[1]Yale University School of Medicine, New Haven, CT; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Johns Hopkins University, Baltimore, MD; [4]Pennsylvania State University, University Park, PA; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]University of Washington, Seattle, WA; [7]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [8]Vanderbilt University Medical Center, Nashville, TN.*

Background: The factors determining chronic kidney disease (CKD) progression after an episode of acute kidney injury (AKI) are poorly understood. Angiopoietins play a role in vessel remodeling after AKI, where Angiopoietin-1 (Angpt-1) maintains vessel stability and Angiopoietin-2 (Angpt-2) destabilizes quiescent vessels. We investigated whether the balance of Angpt-1 and -2 was prognostic of CKD and mortality after hospitalization in patients with and without AKI.

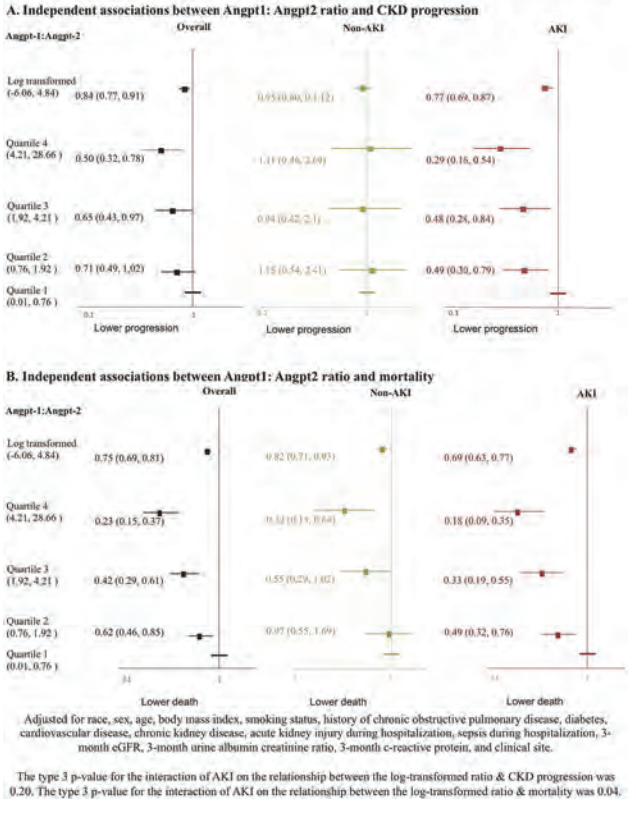
Methods: Using plasma samples from ASSESS-AKI, we measured Angiopoietins 3 months after hospitalization. We assessed the ratio of Angpt-1:Angpt-2 with CKD progression (composite of incident and progression of CKD, and end stage kidney disease), and all-cause mortality.

Results: Angiopoietins were measured in 1503 hospitalized patients, among whom 746 (49.6%) had AKI. Median (IQR) age was 65.8 (56.6, 73.9) years, 555 (37%) were female, and 196 (13%) were black. Median times to CKD progression, and all-cause mortality were 4.4 (2.5, 5.7), and 4.9 (3.6, 6.0) years, respectively. CKD progression developed in 293 (19%) and mortality in 314 (21%) participants. The highest quartile of Angpt-1:Angpt-2 ratio was independently associated with 50% reduced risk of CKD progression and 77% reduced risk of mortality as compared to the lowest quartile. Stratified analyses by AKI status revealed stronger associations between Angpt-1:Angpt-2 ratio and both outcomes in the AKI group (**Figure**).

Conclusions: A higher Angpt-1:Angpt-2 ratio was strongly associated with lower risk of CKD progression and mortality after hospitalization, particularly in patients with AKI. Angiopoietins may help risk stratify patients with AKI after discharge for those in need of close follow-up and CKD management.

Funding: Private Foundation Support

Figure. Associations between Angpt-1:Angpt-2 ratio and CKD progression and all-cause mortality



Adjusted for race, sex, age, body mass index, smoking status, history of chronic obstructive pulmonary disease, diabetes, cardiovascular disease, chronic kidney disease, acute kidney injury during hospitalization, sepsis during hospitalization, 3-month eGFR, 3-month urine albumin creatinine ratio, 3-month c-reactive protein, and clinical site.

The type 3 p-value for the interaction of AKI on the relationship between the log-transformed ratio & CKD progression was 0.20. The type 3 p-value for the interaction of AKI on the relationship between the log-transformed ratio & mortality was 0.04.

FR-OR07

Determinants of Major Adverse Kidney Events (MAKE) in Extra Corporeal Membrane Oxygenation (ECMO) Survivors

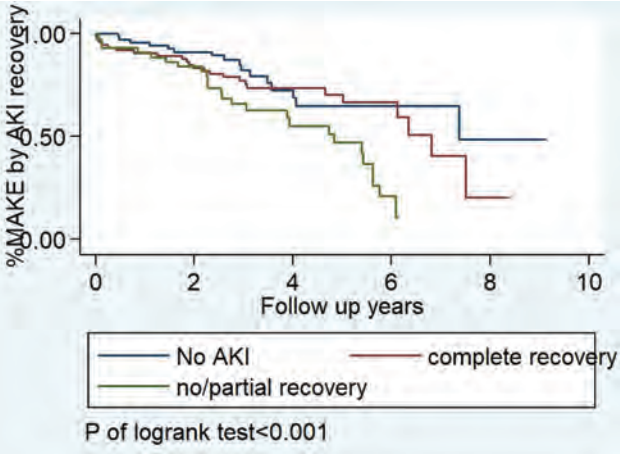
Aniesh Bobba,[1] Christy Costanian,[2] Sola A. Bahous,[2] Fadi Tohme.[1,2] *[1]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [2]Lebanese American University School of Medicine, Byblos, Lebanon.*

Background: The majority of ECMO patients develop acute kidney injury (AKI) and 40-60% require renal replacement therapy (RRT). Little is known about the effects of AKI on long-term renal outcomes after ECMO. The aim of this study was to examine the determinants of MAKE in ECMO survivors.

Methods: Patients who were admitted to a single-center between 2008 and 2017, were on ECMO for more than 24 hours & survived to hospital discharge were included. MAKE was defined as either doubling of serum creatinine (Scr), incident ESRD or death. USRDS and NDI databases were used to obtain information about ESRD and death. AKI was defined as KDIGO stages 2-3. Complete AKI recovery was defined as a return to 50% of baseline Scr and partial recovery as an improvement in the AKI stage without a return to 50% of baseline Scr. Survival analysis plots & Cox regression models were fitted to examine the associations of AKI status, AKI recovery and other factors with MAKE

Results: Among 188 ECMO patients who survived until hospital discharge, 63% had AKI, and 41% required RRT. The mean follow-up time was 3.4 years. Patients with AKI were more likely to be on ECMO for a cardiac rather than respiratory indication and had a longer length of stay compared to patients with no AKI. Kaplan-Meier survival curves showed that patients with no/partial recovery from AKI had a higher rate of MAKE compared to those with no AKI (Figure 1). Results of the unadjusted analysis showed that ECMO type and timing of initiation of RRT were associated with MAKE. Multivariate analysis showed that AKI [aHR=1.79 (95%CI=1.00-3.21)], no/partial recovery from AKI [aHR= 2.94 (95%CI=1.46-5.92)] and initiation of RRT after ECMO [aHR 5.4 (95%CI=1.14-25.6)] were significant determinants of MAKE after adjustment for potential confounders.

Conclusions: AKI, AKI recovery status, and timing of initiation of RRT are determinants of major adverse kidney events in patients who received ECMO.



FR-OR08

AKI Among African Americans with Sickle Cell Trait and Disease

Kabir O. Olaniran,[1,2] Andrew S. Allegretti,[1] Sophia Zhao,[1] Sagar U. Nigwekar,[1] Sahir Kalim.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]University of Texas Southwestern Medical Center at Dallas, Dallas, TX.*

Background: Sickle cell trait (SCT) and disease (SCD) are independent risk factors for estimated glomerular filtration rate (eGFR) decline among African Americans (AA). However, our understanding of the risk for acute kidney injury (AKI) and the role of AKI in eGFR decline in patients with SCT/D remains limited. We aimed to describe the relative risk for AKI in SCT/D and the effect of AKI on eGFR decline in SCT/D.

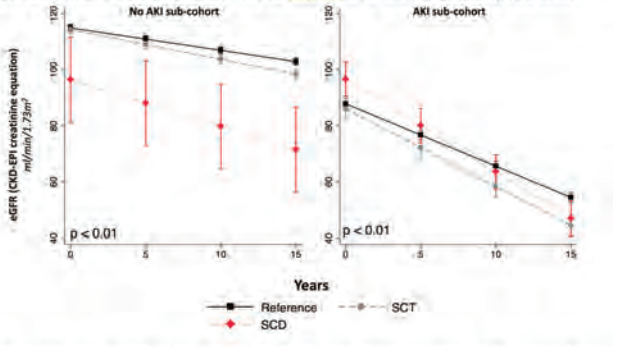
Methods: We performed a multi-center observational study of adult AA patients with a baseline eGFR ≥15 ml/min, and ≥1 year follow-up between 2005-2018. The presence of SCT/D (exposure) and normal hemoglobin phenotype (reference) was determined by hemoglobin electrophoresis. Outcomes of interest (incident All AKI [Kidney Disease: Improving Global Outcomes criteria], incident Severe AKI [doubling of baseline creatinine] and incident Sustained AKI [AKI persisting for ≥72 hours]) were adjudicated by chart review and evaluated by Cox regression. Only first AKI events were used. The effect of All AKI on eGFR decline (mixed linear models) was also investigated. Models were adjusted for predictors of AKI.

Results: We identified 8968 reference, 1279 SCT, and 254 SCD patients with a median follow-up of 7.6 years and mean serum creatinine of 0.8 mg/dl. SCT was associated with Sustained AKI (adjusted hazard ratio [aHR] 1.42; 95% CI, 1.08-1.88) compared to the reference. SCD was associated with All AKI (aHR 3.13; 95% CI, 2.33-4.21), Severe AKI (aHR 3.04; 95% CI, 1.90-4.87) and Sustained AKI (aHR 2.10; 95% CI, 1.24-3.53) compared to the reference. Effect of AKI on eGFR is shown in Figure 1.

Conclusions: The risk for AKI is increased in both SCT (Sustained) and SCD (all forms) and may contribute to faster eGFR decline in SCT/D. Further studies are needed to understand the mechanisms of AKI in SCT/D. Such studies will inform best practices that will help attenuate the burden of kidney disease in SCT/D.

Funding: Private Foundation Support

Figure 1. Difference in eGFR decline between the reference, SCT and SCD patients by AKI status.



Both models were adjusted for baseline age, sex, hypertension, diabetes mellitus, cardiovascular disease, hemoglobin electrophoresis indications and baseline eGFR. Among non-AKI patients, SCT was associated with a 0.26 (95% CI, 0.20-0.31) ml/min faster decline in eGFR compared to the reference. Also, among non-AKI patients, SCD was associated with a 0.86 (95% CI, 0.78-0.94) ml/min faster decline in eGFR compared to the reference. Among AKI patients, SCT was associated with a 0.54 (0.42–0.67) ml/min faster decline in eGFR compared to the reference. Also, among AKI patients, SCD was associated with a 1.09 (95% CI, 0.94-1.23) ml/min faster decline in eGFR compared to the reference.

FR-OR09

Assessment of Kidney Proximal Tubular Secretion in Critical Illness

Pavan K. Bhatraju,[1] Edward D. Siew,[2] Jonathan Himmelfarb,[1] Andrew N. Hoofnagle,[1] Mark M. Wurfel,[1] Bryan R. Kestenbaum.[1] *[1]University of Washington, Seattle, WA; [2]Division of Nephrology and Hypertension Vanderbilt University, Nashville, TN.*

Background: Serum creatinine concentrations (SCr) are used to determine the presence and severity of acute kidney injury. SCr is primarily eliminated by glomerular filtration; however, most mechanisms of kidney injury in critical illness involve kidney proximal tubules, where tubular secretion occurs. Proximal tubular secretory clearance is not currently measured in the ICU. To estimate the kidney clearance of secretory solutes in critically ill adults.

Methods: We collected matched blood and spot urine samples from 170 ICU patients and from a comparison group of 70 adults with normal kidney function. We measured seven endogenously produced secretory solutes using liquid chromatography-tandem mass spectrometry. We computed a composite secretion score incorporating all seven solutes, and evaluated associations with 28-day major adverse kidney events ($MAKE_{28}$), defined as doubling of SCr, dialysis dependence, or death.

Results: The urine/plasma ratio of six of seven secretory solutes were lower in critically ill patients compared with normal individuals after adjustment for SCr. The composite secretion score was moderately correlated with SCr and cystatin C (r = -0.51 and r = -0.53, respectively). Each standard deviation higher composite secretion score was associated with a 52% lower risk of $MAKE_{28}$ (95% CI 25% - 70% lower) independent of ICU severity of illness and SCr. Higher urine to plasma ratios of individual secretory solutes isovalerylglycine and tiglylglycine were associated with $MAKE_{28}$ after accounting for multiple testing (p<0.001).

Conclusions: Among critically ill adults, tubular secretory clearance is associated with adverse outcomes, independent of SCr and SOFA score, and measurement could improve assessment of kidney function.

Funding: NIDDK Support

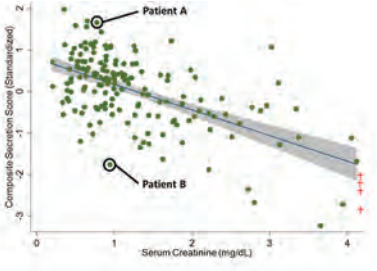


Figure 1. Visualization of correlations between ranges of composite secretion score and SCr measured at study enrollment in a critically ill population. The scatter plot allows for visual examination of the range, variability, and interindividual differences between the composite secretion score and SCr. To ease comparison of different tubular solutes, we standardized or rescaled solute measurements to have a mean of 0 and a standard deviation of 1. We then computed the composite secretion score as the average of the seven standardized U/P ratios. Red crosses at the right represent participants with extremely high SCr who are displayed at an arbitrary maximal-range value for graphic examination purposes; these participants are included in all statistical analyses using the true data value. Regression line is fit with 95% confidence intervals. To demonstrate the interindividual variability in tubular secretion, we highlight two patients (A and B) with similar SCr (approximately 1 mg/dL) but extremes of tubular secretion. Patient A is in the highest tertile of tubular secretion, while patient B is in the lowest tertile of tubular secretion.

FR-OR10

Endotrophin, Released During Collagen Type VI Formation, Predicts Long-Term Mortality After AKI

Nadja Sparding,[1,2] Daniel Guldager Kring Rasmussen,[1] Federica Genovese,[1] Morten A. Karsdal,[1] Rebecca A. Packington,[3] Nicholas M. Selby.[3] Fibrosis, Renal and Cardiovascular Research *[1]Nordic Bioscience, Herlev, Denmark; [2]Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark; [3]Centre for Kidney Research and Innovation, University of Nottingham, Nottingham, United Kingdom.*

Background: Acute kidney injury (AKI) is defined as a rapid decrease in kidney function which may be associated to structural damage. Early markers predicting AKI are emerging, but tools to monitor patients subsequent to AKI are still lacking. The novel biomarker PRO-C6 reflects formation of collagen type VI (COL6) and levels of endotrophin, a bioactive molecule derived from COL6. Here we evaluated the potential of PRO-C6 as a biomarker of mortality in AKI patients.

Methods: We measured PRO-C6 in plasma samples collected 1 year after the episode of AKI, using a novel ELISA in 801 patients from the AKI Risk in Derby (ARID) study, who were then followed prospectively until year three. 393 of the patients had been hospitalized for an episode of AKI, and 408 patients who did not sustain AKI were included as controls (non-AKI). The groups were matched for age, baseline renal function and diabetes.

Results: PRO-C6 levels were significantly higher in the AKI compared to the non-AKI group (median (m): 10.85 vs 9.23 ng/mL, P<0.0001). By year 3, a total of 70 patients died; 43 in the AKI group and 27 in the control group. In the AKI group, patients who died had significantly higher PRO-C6 levels than the patients who did not die (m: 12.66 vs 10.68 ng/mL, P=0.004), whereas there was no difference between patients who died and did not die in the non-AKI group (m: 9.97 vs 9.21 ng/mL, P=0.23). In a multivariate Cox regression analysis with backwards elimination including age, gender, baseline CKD and diabetes status, albuminuria, serum creatinine, eGFR and PRO-C6, only age (P=0.04) and albuminuria (P=0.007) remained in the final model for the non-AKI group. In the AKI group, PRO-C6 had a stronger association with mortality than eGFR, as only age (P=0.005), albuminuria (P=0.04) and PRO-C6 (P=0.004) remained in the final model. When stratified into tertiles, patients with higher levels of PRO-C6 at year 1 were significantly more likely to die (P=0.009).

Conclusions: In this study, we compared levels of PRO-C6 in patients with and without AKI, and show that PRO-C6 levels measured in plasma can predict mortality in patients with AKI. Our findings may indicate that PRO-C6 identifies patients with active fibrogenesis after AKI, suggesting that long-term renal injury after AKI is important for patient outcome.

FR-OR11

Association of Use of Kidney Disease Education Benefit with ESKD-Related Outcomes

Kirsten L. Johansen, James B. Wetmore, David T. Gilbertson, Eric D. Weinhandl, Jiannong Liu. *Chronic Disease Research Group, Minneapolis, MN.*

Background: ESKD onset in the US is marked by poor outcomes, including little use of home dialysis, widespread catheter dependence among patients on hemodialysis, and high mortality. Consequently, in 2010, the Centers for Medicare and Medicaid Services (CMS) initiated a new kidney disease education (KDE) benefit to ensure that beneficiaries with stage 4 CKD are informed about the effects and treatment of kidney disease, diet and nutrition, transplantation, dialysis modalities, and vascular access. Following the US president's Executive Order on Advancing American Kidney Health in 2019, CMS plans to expand KDE. However, the current use and efficacy of KDE have not been examined.

Methods: We used USRDS data to identify eligible patients and to ascertain KDE and ESKD outcomes. We examined use of KDE in the 2 years prior to ESKD onset in 2013-2017 among 106,465 individuals aged ≥67 years who had CKD stage 4. We examined patient characteristics associated with receipt of KDE. We matched each KDE recipient with 4 controls using propensity scores and estimated the association between receipt of KDE and ESKD outcomes in this matched cohort using logistic regression.

Results: 3171 patients (3%) received KDE, 56% of whom received a single session. 49.5% of KDE sessions were delivered by nephrologists and 42% by physician extenders. Younger patients, men, and non-Hispanics were more likely to receive KDE. There was substantial regional variation in KDE utilization, and rural residents were less likely to receive KDE. In the matched cohort, receipt of KDE was associated with higher odds of transplant waitlisting before dialysis initiation, pre-emptive transplantation, home dialysis, or in-center HD initiation with an AVF or AVG (vs. catheter; Table).

Conclusions: A very small percentage of eligible patients reaching dialysis receive Medicare-reimbursed KDE within the previous 2 years. KDE was associated with favorable outcomes, at least among those who advanced to ESKD.

Funding: NIDDK Support

Outcome	KDE	No KDE	OR (95% CI)
Transplant waitlisting prior to ESKD	4.0	2.9	1.41 (1.15 - 1.74)
Pre-emptive transplant	1.9	1.4	1.34 (1.00 - 1.80)
Home dialysis	18.1	11.5	1.70 (1.53 - 1.89)
Hemodialysis with AVF or AVG	41.6	26.3	2.00 (1.84 - 2.19)
Optimal ESKD start*	52.2	34.7	2.06 (1.90-2.23)

*Pre-emptive transplant or home dialysis or in-center HD with AVF or AVG

FR-OR12

Correlation Between Patient Activation and Quality of Life Among Patients with CKD

Mujahed M. Dauleh, Aria Ghahramani, Ali M. Zebi, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Quality of Life (QOL) is an important outcome in patients with chronic kidney disease (CKD). We have previously demonstrated that online peer mentoring (PM) improves patient activation and QOL. In this study, we evaluate the correlation between patient activation and QOL among patients with CKD who received online PM.

Methods: We randomized 155 patients with stage 4 or stage 5 CKD to one of 3 groups: online PM, face-to-face (FTF) PM, or usual care. Participants in all 3 groups received a book that contained detailed information about kidney disease. Participants assigned to intervention groups received 6 months of PM, either FTF or through a secure online platform. At baseline and at 18 months, the participants completed the Patient Activation Measure® (PAM) and the Kidney Disease QOL-36 (KDQOL-36) instrument. We used linear mixed effect models to estimate the slope of change of PAM and subsets of KDQOL over time. We then calculated the correlation between PAM and individual subscales of KDQOL by Pearson's Correlation Coefficient. We used SAS, version 9.4 (SAS Institute Inc., Cary, NC) for data analysis.

Results: Baseline KDQOL-36 and PAM scores, as well as demographic characteristics were similar among the 3 groups. Among the online PM group, there was a statistically significant improvement in: 1. The mean PAM score between baseline and 18 months (Slope estimate [SE]: 5.65; 95% confidence interval [CI]: 2.75, 8.52; P= 0.0001). 2. The following components of the KDQOL-36 score: Effects of Kidney Disease (EKD) (SE: 4.13; CI: 0.87, 7.4; P= 0.01); Burden of Kidney Disease (BKD) (SE: 5.44; CI: 1.24, 9.64; P= 0.01); Symptoms and Problems of Kidney Disease (SPKD) (SE: 6.00; CI: 3.09, 8.91; p= 0.006); SF-12 Physical Composite Score (PCS) (SE: 2.50; CI: 0.95, 4.06; P= 0.002); SF-12 Mental Composite Score (MCS) (SE: 3.46; CI: 1.78, 5.13; P<0.0001). Among the online PM group, the improvement in PAM was correlated with improvements in 4 components of the KDQOL-36: EKD (Pearson Coefficient [PC]: 0.36; p=0.04); BKD (PC: 0.44; p=0.01); SPKD (PC: 0.47; p=0.005), PCS (PC: 0.35; p=0.04). There was no correlation between PAM and MCS.

Conclusions: Among CKD patients who receive online PM, there is a correlation between the improvements in PAM and KDQOL, suggesting that improved QOL may be a result of improved activation. Funding: PCORI

FR-OR13

Breath Ammonia Is a Useful Biomarker Predicting Kidney Function in CKD Patients

Ya-chung Tian. *Linkou Chang Gung Kidney Research Center and Department of Nephrology, Gueishan, Taoyuan, TW, Taoyuan, Taiwan.*

Background: Chronic kidney disease (CKD) is a public health problem and its prevalence has increased worldwide; patients are commonly unaware of the condition. Early identification and immediate intervention are crucial to delay CKD progression. Finding a tool to predict kidney function without visiting hospitals is an attractive method for CKD monitoring in COVID-19 pandemic. The present study aimed to investigate whether exhaled breath ammonia measurement could be used for rapid CKD screening.

Methods: CKD patients (n=121), including CKD stage 1-5 patients, were enrolled and breath ammonia was detected. Correlation between breath ammonia and blood urea nitrogen (BUN) levels, serum creatinine levels, estimated glomerular filtration rate (eGFR) were determined. The predictive value of breath ammonia for the presence of CKD was assessed.

Results: Correlation analysis demonstrated a good correlation between breath ammonia and blood urea nitrogen levels (R=0.756, p<0.0001), serum creatinine levels (R=0.735, p<0.0001), eGFR (R=-0.535, p<0.0001) and inversed eGFR (R=0.685, p<0.0001). Breath ammonia concentration was significantly elevated with increased CKD stage compared with the previous stage (CKD stage 1/2/3/4/5: 636±94; 1020±120; 1943±326; 4421±1042; 12781±1807 ppb, p<0.05). The receiver operating characteristic curve analysis showed an area under curve (AUC) of 0.835 (p<0.0001) for distinguishing CKD stage 1 from other CKD stages at 974 ppb (sensitivity, 69%; specificity, 95%, positive predictive value [PPV] 0.99; negative predictive value [NPV], 0.36). The AUC was 0.831 (p<0.0001) for distinguishing between patients with/without eGFR ≥60 mL/min/1.73 m^2 (cut-off 1187 ppb: sensitivity, 71%; specificity, 78%; PPV, 0.84; NPV, 0.61). At 886 ppb, the sensitivity increased to 80% but the specificity decreased to 69%. For a non-life threating or non-serious CKD, breath ammonia at a cut-off concentration of 886 ppb is a good screening tool for detection of patients with potential CKD and suitable for kidney function monitoring.

Conclusions: Because CKD is non-life threating and breath ammonia detection was conducted in real time, inexpensive, easy to administer, and had an acceptable diagnostic accuracy, breath ammonia can be used as a good surrogate for kidney function and a reliable tool for CKD screening.

Estimated Glomerular Filtration Rate Equations: Do We Need to Use the Ethnicity Correction Factor in People of African Ancestry Outside of the United States?

Rouvick Gama,[1] Amanda Clery,[2] Kieran R. Palmer,[1] Henry A. Kibble,[1] Hugh Cairns,[1] Claire C. Sharpe,[1,2] Adrien M. Peters,[2] Neil Heraghty,[2] Kate Bramham.[1,2] *[1]King's Kidney Care, King's College Hospital, London, United Kingdom; [2]King's College London, London, United Kingdom.*

Background: Recent African studies suggest ethnicity factors in estimated glomerular filtration rate (eGFR) equations is not required.

Methods: To assess accuracy of eGFR equations, with and without ethnicity factors compared with gold standard ^{51}Cr-ethylenediaminetetraacetic acid (^{51}Cr-EDTA) clearance assays. Patients with albumin <30g/dl, hepatology referrals, <18 years old, non-white or black, mixed ethnicities were excluded. Accuracy of CKD-EPI and MDRD equations compared to ^{51}Cr-EDTA GFR were assessed with and without correction factor.

Results: 2,776 ^{51}Cr-EDTA studies were identified (Mean age-54yrs; 43% female; 12% Black ethnicity). In Black patients, CKD-EPI and MDRD eGFR equations significantly overestimated GFR compared to White (p<0.001) but without ethnicity correction factor estimates were considerably improved (p<0.001)(Table 1). Accuracy was superior for GFR≥60ml/min/1.73m^2 compared to <60ml/min/1.73m^2 using CKD-EPI equation for both White and Black patients (p<0.001).

Conclusions: Overestimation of measured GFR with eGFR equations using ethnicity correction factors identified in this study may lead to reduced rates of CKD diagnosis and under-recognition of CKD severity in people of Black ethnicity in the UK. These findings require prospective validation in other countries.

Table 1: Estimated Glomerular Filtration equations bias, precision and accuracy compared with ^{51}Cr-EDTA clearance for people of Black and White ethnicities according to ^{51}Cr-EDTA GFR categories

			GFR Mean (SD)	Bias	Precision	Limits of agreement	30% Accuracy (%)
Black	Corrected ^{51}Cr-EDTA GFR <60 (N=56)	Corrected ^{51}EDTA	41.0 (13.8)				
		CKD-EPI adjusted	59.4 (27.3)	18.4	19.8	-21.2 to 58	39.3
		CKD-EPI unadjusted	51.2 (23.6)	10.2	16.7	-23.2 to 43.6	55.4

Mechanism of Higher Incidence of ESKD Among Blacks and Hispanics vs. Whites in the United States

Guofen Yan,[1] Keith C. Norris,[2] Robert Nee,[3] Julia J. Scialla,[1] Wei Yu,[1] Tom Greene,[4] Alfred K. Cheung.[4,5] *[1]University of Virginia, Charlottesville, VA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Walter Reed National Military Medical Center, Bethesda, MD; [4]University of Utah, Salt Lake City, UT; [5]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: In the U.S., Blacks and Hispanics have higher incidence of ESKD than Whites. Whether this is driven by lower mortality prior to ESKD or inherently faster progression to ESKD has not been clearly determined because most studies used prevalent cohorts that created survival bias. We examined this issue using a newly constructed national cohort of patients with new-onset CKD.

Methods: We identified 834,270 individuals with new-onset CKD in the US Veterans Health Administration (VHA) between 2002 and 2015, followed through 2016. CKD onset was defined as the first occurrence when there were two eGFR values (CKD-EPI equation) <60 mL/min/1.73 m^2 that were >90 days apart, not in ESKD. We excluded patients in VHA for <2 years prior to the first eGFR<60. Thus, the time of study entry should be close to the CKD onset for each individual. We examined jointly the cause-specific (CS) hazards ratios for two competing events, occurrence of ESKD and pre-ESKD death.

Results: Upon study entry, 704,557 Whites, 98,082 Blacks, and 31,631 Hispanics had similar mean eGFRs (49-50 ml/min/1.73m^2). Ten years after CKD onset, fractions of patients entering ESKD were 1.3-2.5 times greater for Blacks and Hispanics vs. Whites across six age groups (Table). CS hazards for ESKD was 2.1-2.9 times greater for Blacks and 1.2-2.7 times greater for Hispanics vs. Whites. CS hazards for pre-ESKD death were similar for Blacks and only modestly lower for Hispanics vs. Whites across ages.

Conclusions: More Blacks and Hispanics to ESKD were driven by their greater hazards for ESKD due to more rapid decline in kidney function, not through lower mortality prior to ESKD. Delineation and elimination of the causes of faster kidney function declines are therefore the appropriate strategies to improve clinical outcomes in Blacks and Hispanics with CKD, instead of attributing the higher incidence to pre-ESKD survival bias.

Incidence of CKD and Environmental Inequities: An Integration of Ecological and Spatial Approaches in US Veterans

Yun Han,[1] Jennifer L. Bragg-Gresham,[1] Diane Steffick,[1] Xiaosong Zhang,[1] April Wyncott,[1] Tiffany C. Veinot,[2] V. G. Vinod Vydiswaran,[2] Brenda W. Gillespie,[2] William Weitzel,[3] Karandeep Singh,[1] Susan T. Crowley,[4] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Veterans Health Administration, Ann Arbor, MI; [4]Veterans Health Administration, West Haven, CT.*

Background: Disparities in chronic kidney disease (CKD) can be linked to social and environmental determinants of health, which vary geographically across the US. We assessed geographic variation and the impact of environmental factors on incident CKD in US veterans.

Methods: We used a linked dataset from Veterans Health Administration (2014-18), the American Community Survey(2018); National Environmental Public Health Tracking Network(2018); EPA(2019) and Reference USA(2017). Incident cases of CKD were individuals with eGFR < 60 mL/min/1.73m^2 and without prior indication of CKD for at least 3 years. The county-level incidence rate of CKD was number of cases/1000 person-years during 2016-18. County-level environmental factors included Townsend deprivation index; neighborhood indices; average daily PM2.5; walkability index; number of recreational facilities and fast-food restaurants. A geographically-weighted regression model(GWR) was applied to investigate the relationship between environmental factors and incidence rate of CKD.

Results: Average of incident rate of CKD was 34.8/1000 person-years (SD=12.3, n=2,718). Incident rate was higher in the rust-belt area and Appalachian region (Fig 1.a). Townsend deprivation index associated with higher incident rate in the Midwest, Northern California and Texas (Fig 1.b). PM2.5 was associated with higher incident rate in the East North Central and East West Central regions (Fig 1.c).

Conclusions: Different environmental factors were associated with incident CKD in US counties. This highlights the potential importance of allocating resources for varied approaches to preventing and slowing the progression of CKD based on residence.

Chlorthalidone and Bumetanide in Advanced CKD: HEBE Trial

Fabio Solis-Jimenez, L. M. Perez-Navarro, Rafael Valdez-Ortiz. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: Current treatment for hypertension and volume overload in chronic kidney disease consists of loop diuretics, nevertheless, chronic use leads to adaptive changes at the distal nephron, which in turn decreases their efficacy. The use of thiazide diuretics could be another treatment option in these patients, notwithstanding, there's not enough evidence to justify their use in this population.

Methods: To evaluate the efficacy and safety of treatment with bumetanide plus chlorthalidone in patients with advanced chronic kidney disease a double-blind randomized controlled trial was conducted.

Results: Thirty-two patients with hypertension, chronic kidney disease stage IV/V, and chronic loop diuretic use where divided in two groups. The dual treatment group received bumetanide (2 mg BID) plus chlorthalidone (50 mg BID), while the control group was given bumetanide (2 mg BID) plus placebo, both for twenty-eight days. There was a decrease of systemic blood pressure in the dual treatment group when compared with the control group; systolic blood pressure -26.1±15.3 vs. -10±23.3 mmHg (p=0.028), diastolic blood pressure -13.5±10.7 vs. -3.4±11.9 mmHg (p=0.018), and mean arterial pressure -18.1±8.7 vs. -5.4±14.3 mmHg (p=0.006). There was also a decrease of volume overload in the dual treatment group when compared to the control group; total body water -4.36±3.29 vs. +0.075±1.78 liters (p<0.001), extracellular water -2.55±1.1 vs. +0.150±1.2 liters (p<0.001), and extracellular water to total body water ratio -2.92±4.76 vs. -0.24±1.42 (p=0.039).

Conclusions: In advanced chronic kidney disease plus hypertension patients whose treatment with loop diuretics is insufficient, combined use of bumetanide plus chlorthalidone can be useful for systemic blood pressure and volume overload control.

Benefits of Icosapent Ethyl Across a Range of Baseline Renal Function in Patients with Established Cardiovascular Disease or Diabetes: Results of REDUCE-IT RENAL

Arjun Majithia,[1] Deepak L. Bhatt,[1] Allon N. Friedman,[2] Michael Miller,[3] Philippe Gabriel Steg,[4] Eliot A. Brinton,[7] Terry A. Jacobson,[11] Steven B. Ketchum,[9] Rebecca A. Juliano,[9] Lixia Jiao,[9] Ralph T. Doyle,[9] Craig B. Granowitz,[9] Matthew J. Budoff,[5] Preston Mason,[1] Jean-Claude Tardif,[10] William E. Boden,[8] Christie Ballantyne.[6] REDUCE-IT Investigators *[1]Brigham and Women's Hospital, Boston, MA; [2]Indiana University School of Medicine, Indianapolis, IN; [3]University of Maryland School of Medicine, Baltimore, MD; [4]Hopital Bichat - Claude-Bernard, Paris, France; [5]University of California Los Angeles, Los Angeles, CA; [6]Baylor College of Medicine, Houston, TX; [7]Utah Lipid Center, Salt Lake City, UT; [8]VA Boston Healthcare System, West Roxbury, MA; [9]Amarin Pharma Inc, Bridgewater, NJ; [10]Institut De Cardiologie de Montreal, Montreal, QC, Canada; [11]Emory University School of Medicine, Atlanta, GA.*

Background: Chronic kidney disease is associated with adverse outcomes among patients with established cardiovascular disease (CVD) or diabetes. Medications for treatment of CVD among patients with low estimated glomerular filtration rate (eGFR) may be ineffective.

Methods: The Reduction of Cardiovascular Events with Icosapent Ethyl-Intervention Trial (REDUCE-IT) randomized patients with CVD or diabetes and one additional risk factor to treatment with icosapent ethyl or placebo. Patients from REDUCE-IT were categorized by prespecified eGFR categories for analysis of the effect of icosapent ethyl (IPE) on the primary endpoint (composite of cardiovascular (CV) death, nonfatal myocardial infarction (MI), nonfatal stroke, coronary revascularization, or unstable angina) and key secondary endpoint (a composite of CV death, nonfatal MI, or nonfatal stroke). In post hoc analysis, patients were categorized by additional eGFR cutoffs consistent with current medical guidelines.

Results: Among the 8179 REDUCE-IT patients, median baseline eGFR was 75 mL/min/1.73m^2 (range: 17 to 123 mL/min/1.73m^2). There were no meaningful changes in median eGFR for IPE versus placebo across study visits. IPE benefit was consistent across baseline eGFR for the primary (Figure) and key secondary endpoints. The numerical reduction in CV death was greatest in the eGFR <60 mL/min/1.73m^2 group (IPE: 7.6%; placebo: 10.6%; HR 0.70, 95%CI 0.51, 0.95, p=0.02). The rate of microalbuminuria in adverse event reporting was lower among IPE-treated patients (0.1% versus 0.3%, p=0.01).

Conclusions: In REDUCE-IT, icosapent ethyl reduced fatal and nonfatal ischemic events across the broad range of baseline eGFR categories.

Dapagliflozin Reduces the Risk of Hyperkalaemia in Patients with Heart Failure and Reduced Ejection Fraction: A Secondary Analysis from DAPA-HF

Søren L. Kristensen,[8] Kieran F. Docherty,[1] Pardeep Jhund,[1] Olof Bengtsson,[2] Silvio E. Inzucchi,[4] Mikhail Kosiborod,[5] Anna Maria Langkilde,[2] Felipe Martinez,[6] Piotr Ponikowski,[3] Marc S. Sabatine,[7] Mikaela Sjostrand,[2] Scott D. Solomon,[7] John McMurray.[1] *[1]BHF Cardiovascular Research Centre, University of Glasgow, Glasgow, United Kingdom; [2]AstraZeneca, Gothenburg, Sweden; [3]Wroclaw Medical University, Wroclaw, Poland; [4]Yale University, New Haven, CT; [5]St Lukes Mid America Heart Institute, Kansas City, KS; [6]National University of Cordoba, Cordoba, Argentina; [7]Brigham and Women's Hospital, Boston, MA; [8]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark.*

Background: Hyperkalaemia often limits the use of mineralocorticoid receptor antagonists (MRAs) in patients with heart failure and reduced ejection fraction (HFrEF), denying these patients a life-saving therapy.

Methods: The risk of developing mild hyperkalaemia (potassium > 5.5 mmol/L) and moderate/severe hyperkalaemia (>6.0 mmol/L) was examined in the Dapagliflozin And Prevention of Adverse-outcomes in Heart Failure trial (DAPA-HF) according to background MRA use, and randomized treatment assignment, by use of Cox regression analyses.

Results: Overall, 3370 (70.1%) patients in DAPA-HF were treated with an MRA. Mild hyperkalaemia and moderate/severe hyperkalaemia occurred in 182 (11.1%) and 23 (1.4%) patients treated with dapagliflozin as compared to 204 (12.6%) and 40 (2.4%) of patients given placebo (Table and Figure). This yielded a hazard ratio (HR) of 0.86 (0.70-1.05) for mild hyperkalaemia and 0.50 (0.29, 0.85) for moderate/severe hyperkalaemia, comparing dapagliflozin to placebo.

Conclusions: Patients with HFrEF and taking an MRA who were randomized to dapagliflozin had half the incidence of moderate/severe hyperkalaemia, compared with those randomized to placebo.

Funding: Commercial Support - AstraZeneca

Table: Incident hyperkalaemia in DAPA-HF

	Dapagliflozin		Placebo			
	No. events/patients	Rate per 100py	No. events/patients	Rate per 100py	HR (95% CI)	P-value
Mild hyperkalaemia (>5.5 mmol/L)*						
No MRA at baseline	63/661	7.1	58/684	6.5	1.20 (0.84-1.72)	0.32

Metformin Improves Vascular Function in CKD Patients with Metabolic Syndrome

Everly Ramos,[1] Melis Sahinoz,[1] Carlos O. Pena,[3] Elvis A. Akwo,[2,1] Christianne Roumie,[1,2] Zhihong Yu,[1] Edward D. Siew,[1,2] Talat Alp Ikizler,[1,2] Adriana Hung.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Tennessee Valley Healthcare System, Nashville, TN; [3]Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of.*

Background: Cardiovascular (CV) risk is increased in CKD. Insulin resistance (IR), highly prevalent in CKD patients, contributes to endothelial dysfunction and arterial stiffness, leading to poor CV outcomes. It remains unknown if insulin sensitization with metformin improves CV risk, in patients with CKD Stage 3-4 and metabolic syndrome (MS).

Methods: In a double-blinded randomized trial (NCT02252081), 50 patients with CKD Stage 3, and MS and/or pre-diabetes, received either metformin or placebo for 16 weeks. Dosing was initiated at 500 mg and up-titrated over 7-14 days based on GI tolerance up to 1500 mg/day in CKD3a and 1000 mg/day in CKD 3b. Co-therapies for optimal CV risk reduction were continued. The co-primary outcomes included change in brachial artery flow-mediated dilation (FMD), aortic pulse-wave velocity (aPWV), and carotid intima-media thickness (CIMT) in common (CCA) and internal (ICA) carotid arteries, at 16 weeks. Lactic acid was obtained throughout the study for safety.

Results: Participants were 65 ± 10 years old and 80% were men. Mean [SD]: BMI 31.4 ± 5.1 kg/m^2; SBP 130.5 ± 16 mmHg; DBP 74 ± 9 mmHg; HDL 46.4 ± 15 mg/dl; fasting glucose (FG) 92.3 ± 10.3 mg/dl; HbA1c 5.7 ± 0.24%; HOMA-IR 2.4±1.5, and eGFR was 50 ± 7 ml/min/1.73 m^2. There were 8 patients (16%) in CKD Stage 3b, 3 in the metformin and 5 in the placebo group. Compared with placebo, metformin improved FMD_{BA} (baseline: 6.24% ± 4.5% [mean±SD], 16 weeks: 12.06% ± 8.4% [mean±SD] with metformin and baseline: 6.12% ± 3.34% [mean±SD], 16 weeks: 7.6% ± 4.6% [mean±SD] with placebo, *P*=0.03 [**Fig 1**]), without changing aPWV (*P*=0.84) or CIMT: R CAA (*P*=0.10) L CCA (*P*=0.96) R ICA (*P*=0.74) L ICA(*P*=0.44).

Conclusions: Treatment with metformin improved FMD_{BA} but not aPWV or CIMT in patients with CKD and IR. Studies of larger sample size and longer duration are required to further evaluate the effects on cardiovascular outcomes.

Associations Between Enrollment in ESRD Special Needs Plans and Outcomes

Bryan N. Becker,[1] Jiacong Luo,[2] Kathryn S. Gray,[2] Carey Colson,[2] Dena E. Cohen,[2] Stephen D. McMurray,[3] Bryan W. Gregory,[1] Nathan Lohmeyer,[1] Steven M. Brunelli.[2] *[1]DaVita Integrated Kidney Care, Denver, CO; [2]Davita Clinical Research, Minneapolis, MN; [3]DaVita Inc, Denver, CO.*

Background: Chronic condition special needs plans (C-SNPs) are Medicare Advantage plans that offer care coordination and specialized services for patients with conditions such as end-stage renal disease (ESRD) via specific benefits packages and provider networks. Although ESRD C-SNPs have been offered for over 10 years, an understanding of their impact on patient outcomes is lacking.

Methods: This observational study considered dialysis patients receiving care at a large dialysis organization who enrolled in a C-SNP from January 2013 to September 2017; study data were derived from deidentified medical records. As of C-SNP enrollment date (or matched date for controls), enrollees and controls were matched on the basis of index month, sex, race, etiology, and dialysis modality, as well as a propensity score. Eligible controls were patients who (separately): 1) dialyzed in the same facility as the C-SNP patient but had not enrolled in the C-SNP; 2) dialyzed in counties with no C-SNP but that were otherwise socio-demographically similar to C-SNP counties. Outcomes were evaluated from enrollment date through the first of study end (31 Dec 2018) or censoring for death, insurance change, or loss to follow-up. Within each matched cohort, outcomes were compared using generalized linear or Fine and Gray subdistribution hazard models.

Results: Hospitalization rates were 10% to 24% lower among C-SNP enrollees compared to controls, with an incidence rate ratio of 0.90 (95% confidence interval [CI] 0.84, 0.97) for patients in the same facility and 0.76 (95% CI 0.70, 0.83) for patients in similar counties. The mortality rate for C-SNP enrollees was approximately 23% lower than that of controls, with a hazard ratio of 0.77 (0.68, 0.88) for patients in the same facility and 0.77 (0.68, 0.88) for patients in similar counties. No meaningful differences were observed between groups with respect to serum calcium, phosphate, potassium, parathyroid hormone levels, or Kidney Disease Quality of Life scores.

Conclusions: C-SNP enrollment is associated with markedly lower rates of hospitalization and mortality, compared to non-enrollment.

FR-OR22

Organizational Characteristics Associated with High Performance in Medicare's ESRD Seamless Care Organizations

Kelsey M. Drewry,[1] Amal Trivedi,[2] Adam S. Wilk.[1] *[1]Emory University, Atlanta, GA; [2]Brown University, Providence, RI.*

Background: In 2016, the 1% of beneficiaries with end-stage renal disease (ESRD) constituted >7% of Medicare spending ($35 billion). To improve the value of care for the ESRD population, CMS implemented an alternative payment model (APM) for ESRD care, the ESRD Seamless Care Organization (ESCO), which shares savings with provider groups that reduce spending for ESRD patients below a defined benchmark. This study evaluated the relationship between key organizational, provider, community characteristics, and ESCO performance.

Methods: We constructed a novel ESCO-level dataset capturing key information for Wave 2 (2017) ESCOs using data from CMS reports, the National Provider Identification registry, and the Area Health Resource File. After describing all 37 ESCOs, we performed bivariate comparisons of high- and low-performing (above vs below median) ESCOs based on gross savings/losses, composite quality score, and standardized mortality ratio (SMR). We then estimated generalized logistic regression models of ESCO performance as a function of organizational, provider, and community characteristics.

Results: ESCO composition and performance were highly varied (ranges: savings/losses -3.9-10.2%; quality 76.4-100%; SMR 0.75-1.14). Bivariate analysis showed that ESCOs with above (vs below) median savings had more aligned physicians (58 vs 29, p=0.06), fewer dialysis facilities (8.7 vs 17, p=0.07), a smaller non-Hispanic Black population (14% vs 22%, p=0.06), and higher median household income ($56k vs $49k, p<0.01). Facilities reporting a quality score of 100% (vs <100%) had fewer practices (22 vs 43, p=0.05) and smaller non-Hispanic Black (16% vs 21%, p=0.06) and Medicaid eligible (6.5% vs 8.9%, p=0.14) populations. Low (vs above-median) SMR was associated with higher median household income ($58k vs $46k, p<0.01). Regression model results were consistent with these findings, though small sample size prevented statistically significant estimates.

Conclusions: Our findings offer the first evidence of the impact of organizational composition and social disparities on ESCO performance. We show that the diversity in ESCOs' composition and settings partially explained the high variation in performance. This study provides crucial evidence that will inform the design and implementation of APMs in nephrology and the decisions of provider groups considering participation.

Progress in Preventing Bloodstream Infections in Hemodialysis: Data from the National Healthcare Safety Network, 2014-2018

Shannon Novosad, Lucy V. Fike, Minn Soe, Shunte Moon, Preeti Ravindhran, Erikka J. Woolfolk, Lauren Moccia, Duc B. Nguyen, Priti R. Patel. *Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Patients on hemodialysis are at high risk of bloodstream infections (BSIs) and associated morbidity and mortality. National prevention efforts have resulted in widespread practice changes, including central venous catheter (CVC) care. We analyzed Dialysis Event surveillance data submitted to the National Healthcare Safety Network (NHSN) to describe BSI rates among hemodialysis outpatients from 2014 to 2018.

Methods: Outpatient hemodialysis facilities report BSIs (positive blood cultures collected in the outpatient setting or within 1 day after hospital admission) and the number of hemodialysis patients treated during the first 2 working days of each month to NHSN. For each BSI, the suspected source and vascular access type [e.g., CVC, arteriovenous fistula (AVF) or arteriovenous graft (AVG)] are indicated. Pooled mean rates (per 100 patient-months) were calculated. Annual BSI rate trends were evaluated using a negative binomial regression model including access type, year, and an access-year interaction variable.

Results: More than 6,000 outpatient hemodialysis facilities reported 134,961 BSIs from 2014 to 2018. Of these BSIs, 102,505 (76%) were categorized as access-related. Pooled mean BSI rates decreased 27% from 0.64 to 0.47 per 100 patient-months. Significant decreases in rates occurred across vascular access strata (Table); the reduction was most pronounced among patients with CVCs. BSI rates in patients with CVCs decreased 32% from 2.16 per 100 patient-months to 1.46 (annual average decrease 9.5%).

Conclusions: Substantial reductions in BSI rates among hemodialysis patients occurred during this 5-year period. Improvements in infection prevention practices, including CVC care, have likely contributed. Efforts to increase uptake of known prevention practices and identify new strategies for prevention might contribute to continued decreases in infections.

Funding: Other U.S. Government Support

BSI rates per 100 patient-months and annual trends, by access type, NHSN 2014-2018

Event	Access type	2014	2015	2016	2017	2018	Annual incidence rate ratio (95% CI)	Average annual % change (95% CI)

Efficacy and Safety of Difelikefalin for Moderate-to-Severe CKD–Associated Pruritus: A Global Phase 3 Study in Hemodialysis Patients (KALM-2)

Thomas D. Wooldridge,[1] Kieran Mccafferty,[2] Michael Schoemig,[3] Botond Szabolcs Csiky,[6] Rafal Zwiech,[4] Warren Wen,[5] Catherine Munera,[5] Frederique Menzaghi.[5] *[1]Nephrology and Hypertension Associates, Ltd., Tupelo, MS; [2]The Royal London Hospital - Barts Health NHS Trust, London, United Kingdom; [3]Dialysezentrum Heilbronn, Heilbronn, Germany; [4]Norbert Barlicki Memorial Teaching Hospital No. 1 of the Medical University of Lodz, Lodz, Poland; [5]Cara Therapeutics, Stamford, CT; [6]FMC Szatellita Dialysis Center Pecs, Pecs, Hungary.*

Background: Chronic kidney disease (CKD)-associated pruritus (CKD-aP) is a common and distressing condition in CKD patients (pts) and has a serious negative impact on quality of life (QoL). Difelikefalin (DFK), a novel, peripherally restricted and selective kappa opioid receptor agonist, demonstrated efficacy in a US phase 3 study (KALM-1) in hemodialysis (HD) pts with CKD-aP. Here we report primary results from the global phase 3 study of DFK in HD pts with CKD-aP (KALM-2; NCT03636269).

Methods: HD pts with moderate-to-severe CKD-aP in the US, Europe, and Asia were randomized to receive intravenous DFK 0.5 mcg/kg (N=237) or placebo (PBO; N=236) after dialysis sessions. The primary endpoint was the proportion of pts who achieved ≥3-point improvement from baseline (BL) in the weekly mean of the daily Worst Itching Intensity Numerical Rating Scale (WI-NRS) score at wk 12. Secondary endpoints were the proportion of pts who achieved ≥4-point improvement in WI-NRS score and mean change in itch-related QoL scores (5-D Itch and Skindex-10) from BL to wk 12.

Results: BL mean weekly WI-NRS scores were 7.3 and 7.1 in the DFK and PBO groups. The primary endpoint was met, with 54% of pts who received DFK achieving

a ≥3-point improvement in WI-NRS score vs 42% in the PBO group (*P*=.020). The proportion of pts who achieved a ≥4-point improvement in WI-NRS score was also significantly greater with DFK vs PBO (41% vs 28%, *P*=.010). Itch reduction was evident at wk 1 and was sustained through wk 12. Improvement in itch-related QoL assessed by 5-D Itch and Skindex-10 was observed. Treatment-emergent AEs ≥5% with DFK vs PBO were diarrhea (8.1% vs 5.5%), fall (6.8% vs 5.1%), dizziness (5.5% vs 5.1%), vomiting (6.4% vs 5.9%), and nausea (6.4% vs 4.2%). The incidence of serious AEs was similar across the groups.

Conclusions: In this second phase 3 study, IV DFK demonstrated rapid and sustained itch reduction in HD pts with CKD-aP in multiple regions of the world. DFK was generally well tolerated; safety was consistent with findings in prior studies. With no approved therapies for CKD-aP in the US or Europe, DFK is a potential therapeutic that may address this unmet need.

Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD and Anemia on Hemodialysis

Robert Provenzano,[1] Jayant Kumar,[2] Pablo E. Pergola,[3] Bui Pham van,[4] Gopal Saha,[5] Cameron S. Liu,[5] Dustin J. Little,[6] Kin-Hung P. Yu.[5] *[1]Wayne State University, Detroit, MI; [2]Renal Medicine Associates, Albuquerque, NM; [3]Renal Associates PA, San Antonio, TX; [4]Truong Dai hoc Y khoa Pham Ngoc Thach, Ho Chi Minh, Viet Nam; [5]FibroGen Inc, San Francisco, CA; [6]AstraZeneca, Gaithersburg, MD.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Dialysis modality in patients with ESRD may impact clinical outcomes and survival. Thus, evaluation of safety and efficacy of roxadustat in patients on hemodialysis (HD) is of clinical importance.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, epoetin alfa-controlled studies of roxadustat for the treatment of anemia in patients with dialysis-dependent (DD) CKD were assessed in the subgroup of patients on HD. Endpoints evaluated were: mean change from baseline (CFB) in hemoglobin (Hb) averaged over Weeks 28–52 regardless of rescue therapy and Hb CFB averaged over Weeks 28–36 censored for rescue therapy. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the DD-CKD study population, 90% (3515/3887) of patients were on HD (roxadustat=1761, epoetin alfa=1754). Baseline characteristics were generally similar between treatment groups. Mean (SD) Hb levels (mg/dL) at baseline were 9.64 (1.31) in the roxadustat group and 9.67 (1.31) in the epoetin alfa group. Patients achieved a larger mean (SD) CFB to Weeks 28–52 in Hb with roxadustat vs. epoetin alfa (1.20 [1.49] vs. 0.98 [1.51]), corresponding to a least-squares mean (LSM) difference of 0.25 (95% CI: 0.19, 0.31) (p<0.0001). Patients achieved a larger mean (SD) CFB to Weeks 28–36 in Hb with roxadustat vs. epoetin alfa (1.27 [1.63] vs. 1.02 [1.60]), corresponding to a LSM difference of 0.25 (95% CI: 0.16, 0.33) (p<0.0001). TEAE rates were comparable between treatment groups.

Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing and maintaining Hb levels in patients with DD-CKD on HD. The safety and tolerability profiles were similar to the overall population and consistent with that observed in this patient subgroup.

Stroke and Bleeding Risk Among US Veterans with Preexisting Atrial Fibrillation Transitioning to ESRD

Cachet Wenziger,[3,1] John Sy,[3,1] Maria V. Marroquin,[3,1] Kamyar Kalantar-Zadeh,[1] Csaba P. Kovesdy,[4,2] Elani Streja.[3,1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]VA Long Beach Healthcare System, Long Beach, CA; [4]Memphis VA Medical Center, Memphis, TN.*

Background: Anticoagulation has been the mainstay of stroke prevention among patients with atrial fibrillation (AF). However, end stage renal disease (ESRD) patients on hemodialysis are at higher risk of bleeding and stroke outcomes, even without anticoagulation. It is unclear if patients should be continued on anticoagulation at the time of transition to ESRD.

Methods: We retrospectively examined a cohort consisting of 29,054 pre-dialysis US veterans that had a diagnosis of AF prior to transition to ESRD without a history of stroke. Patients were first stratified by CHA_2DS_2-VASC and modified HAS-BLED scores, ascertained at the time of transition. Prescriptions for warfarin were determined 180 days prior to and 90 days post transition. Incidence Rate Ratios (IRR) for stroke and bleeding events prior to ESRD transition stratified by warfarin vs no warfarin across risk scores were estimated with Poisson regression.

Results: The median age was 77±9 years, 4% were female, 85% were white, and 13% were African American. The median (IQR) CHA_2DS_2-VASC and HAS-BLED scores were 7 (5,8) and 2 (2,3), respectively. Stroke rates by CHA_2DS_2-VASC scores ranged from 0.67 (scores 0/1/2) to 4.27 (score 9) per 100 pt-years while bleeding rates by HAS-BLED scores ranged from 6.83 (score 0/1) to 46.3 (score 7) per 100 pt-years (Figure). Those with a CHA_2DS_2-VASC score of 0/1/2, had a stroke IRR of 0.28 (95% CI: 0.09-0.90, p=0.03) favoring no warfarin. Among patients with other CHA_2DS_2-VASC scores, there was no difference in stroke risk between warfarin and non-warfarin users. No difference was also seen in bleeding risk among warfarin vs non-warfarin users by HAS-BLED score.

Conclusions: In low stroke risk individuals (CHA_2DS_2-VASC score of 0, 1, or 2), warfarin use was associated with a higher risk of stroke. There was no significant difference in stroke and bleeding outcomes among other ESRD patients with AF transitioned to dialysis regardless of CHA_2DS_2-VASC and HAS-BLED scores.

Forecasting the Distribution of Dialytic Modalities in the Era of Advancing American Kidney Health

Kristine Kubisiak,[1] Eric D. Weinhandl,[1,2] Lorien S. Dalrymple,[1] Michael A. Kraus,[1] Dinesh K. Chatoth,[1] Robert J. Kossmann,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Chronic Disease Research Group, Minneapolis, MN.*

Background: The Executive Order on Advancing American Kidney Health aims to increase home dialysis utilization in patients with end stage kidney disease (ESKD). We constructed a simulation projecting dialytic modality distributions between 2019 and 2030 as a function of changing modality transition rates.

Methods: We specified the US ESKD population in Dec. 2018 and used Markov chain Monte Carlo methods to randomly assign patients to a dialytic modality, transplant, or death each month until Dec. 2030, according to parameters that regulate the inflow and outflow of each state. Incident ESKD patients entered the cohort each month and were subject to the same transition parameters. We assessed how changing transition parameters affects projected dialytic modality distributions.

Results: By prevailing conditions, the simulation projects home dialysis will comprise 12% of the dialysis population in 2025. Increasing home hemodialysis (HD) and peritoneal dialysis (PD) utilization among incident ESKD patients from rates of 0.3% to 7.5% and from 11.5% to 37.5%, respectively, by 2025 results in home dialysis utilization of 25% in 2025 and 29% in 2030. Concurrently increasing the rate of conversion from in-center HD to home dialysis from 3.0 to 15.0 events per 100 patient-years by 2025 results in home dialysis utilization of 37% in 2025 and 44% in 2030, as displayed. Decreasing home dialysis attrition rates has a smaller effect on home dialysis utilization.

Conclusions: Substantial growth of home dialysis utilization in the next decade will require a two-pronged approach to inflow: higher utilization of home dialysis in incident patients, emphasizing PD, and increased conversion of patients from in-center HD to home dialysis.

Hospitalization and Day of the Week: Comparing Peritoneal Dialysis, Home Hemodialysis, and In-Center Hemodialysis

Karthik K. Tennankore,[1] Annie-Claire Nadeau-Fredette,[3] Kara Matheson,[6] Christopher T. Chan,[2] Emilie Trinh,[5] Jeffrey Perl.[4] *[1]Dalhousie University, Halifax, NS, Canada; [2]Toronto General Hospital, Toronto, ON, Canada; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]St. Michael's Hospital, Toronto, ON, Canada; [5]McGill University, Montreal, QC, Canada; [6]Nova Scotia Health Authority, Halifax, NS, Canada.*

Background: Studies have shown that there are daily variations in mortality for patients receiving in-center hemodialysis (HD) but not home HD, peritoneal dialysis or more frequent in-center HD. Less is known about daily variations in hospitalization according to dialysis modality.

Methods: We analyzed all chronic dialysis patients in Canada (excluding Manitoba and Quebec) from 1 Jan 2005 to 31 Dec 2014 using the Canadian Organ Replacement Register (CORR). Dialysis modalities were defined (using CORR) as peritoneal dialysis, conventional HD or frequent HD (nocturnal or short daily) and HD modalities were furthered categorized as home versus in-center. All switches between modalities after dialysis initiation were included provided the duration of the switch was >30 days.

The absolute number of hospitalizations for each day of the week was reported for each treatment type and differences in the distribution of hospitalizations were compared using the Chi-Square test.

Results: The cohort consisted of 36,334 individuals. Median age was 67 and 61% were of male sex. A total of 81% of patients were receiving hemodialysis at dialysis initiation and the cause of end-stage kidney disease was secondary to diabetes in 37%. Overall, there were 119,466 hospitalizations over the observation period. The cumulative number of hospitalizations was highest for conventional in-center HD (92,707) and lowest for conventional home HD (701). Day of the week admissions for each treatment type are noted in Table 1 (P<0.001). Hospitalizations were least frequent on saturday and sunday for all groups. The proportion of admissions was highest on monday or tuesday for conventional HD (regardless of location) and frequent in-center HD. In contrast, frequent home HD had a higher proportion of admissions on wednesday.

Conclusions: There are daily variations in hospitalization comparing dialysis modalities. Future planned analyses will evalute whether there are adjusted differences in day of the week hospitalization across modalities accounting for differences in patient characteristics.

Treatment Group	Total	Sunday	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday
Conventional In-Center HD*	92707	8971 (10)	15496 (17)	16138 (18)	14643 (16)	14108 (15)	13508 (16)	9843 (11)
Frequent In-Center HD	1426	137 (10)	262 (18)	228 (16)	211 (15)	219 (15)	201 (14)	168 (12)
Conventional Home HD	701	60 (9)	137 (20)	129 (18)	115 (16)	93 (13)	95 (14)	72 (10)
Frequent Home HD	1439	149 (10)	213 (15)	231 (16)	273 (19)	230 (16)	191 (13)	152 (11)
Peritoneal Dialysis	23193	2562 (11)	3684 (16)	3800 (16)	3727 (16)	3533 (15)	3473 (15)	2414 (10)

Improving Supportive Care of Seriously Ill Dialysis Patients with Goals-of-Care Conversations

Alvin H. Moss,[1] Annette Aldous,[2] Glenda Harbert,[3] Amanda C. Nicklas,[3] Louis Diamond,[3] Nancy Armistead,[3] Dale Lupu.[3] *[1]West Virginia University Health Sciences Center, Morgantown, WV; [2]George Washington University School of Public Health and Health Services, The George Washington University Milken Institute of Public Health, Washington, DC; [3]The George Washington University School of Nursing, Ashburn, VA.*

Background: Dialysis patients are frequently known to receive unwanted high intensity end-of-life care. Families rate the quality of this care lower than families of patients with other chronic diseases. The purpose of this study was to test the feasibility of a supportive care intervention--the Pathways Project, an evidence-based change package of best practices--to identify seriously ill patients (SI), engage them in goals of care discussions, and track outcomes for patient goal concordance.

Methods: Pathways researchers recruited 10 dialysis centers with 1,546 patients. Dialysis staff screened patients with the surprise question (SQ)-"Would I be surprised if this patient died in the next 6-12 months?"- to identify those who were SI and recorded patient outcomes including the number screened, SI, goals of care conversations, hospitalizations, referred to hospice, death, and place of death. An odds ratio was calculated for the odds of SI dying versus those who were not SI, and one-sided Cochran-Armitage trend tests were used to assess for increasing goals of care conversations and deaths at home. The study was interrupted at 9 months due to COVID-19.

Results: On average, 98.8% of patients were screened monthly, and 18.4% were identified as SI. Of 114 patients who died, the SI constituted 66% of deaths though only 18.4% of patients. The mortality for the SI was 27% versus 3% for those who were not, and the odds ratio for SI dying was 11.22 (95% CI 7.42 to 16.98, P < .0001). Dialysis interdisciplinary teams implemented site-specific approaches to adding goals of care conversations into usual workflow; the number conducting conversations with SI within 30 days of hospital discharge increased from 30% to 80% (P=.02). The proportion of the patients who died at home in the last 2 months was higher than baseline (32.6% vs 18.8%), but a trend was not yet evident (P=.12).

Conclusions: The Pathways intervention is feasible to implement supportive care best practices into existing workflow of dialysis centers. It takes time for teams to get comfortable with new processes and communication approaches; after 9 months more centers were conducting goals of care conversations and more patients were dying at home. Future research is needed to determine if the Pathways intervention results in outcomes more aligned with patient preferences.

Implementation of a Decision Aid for Recognition and Correction of Volume Alterations (Recova®) in Hemodialysis

Jenny Stenberg,[1] Magnus Lindberg,[3,2] Hans Furuland.[1] *[1]Uppsala University Department of Medical Sciences, Uppsala universitet Institutionen for medicinska vetenskaper, Uppsala, Sweden; [2]Uppsala University Department of Public Health and Caring Sciences, Uppsala Universitet Institutionen for folkhalso- och vardvetenskap, Uppsala, Sweden; [3]Hogskolan i Gavle, Gavle, Sweden.*

Background: Chronic fluid overload is an independent predictor of mortality in hemodialysis. Clinical assessment of fluid status is subjective and unprecise, and 30% of the patients remain fluid overloaded at dry weight. This study evaluates the effects of implementing a recently developed decision aid, Recova®, which combines a systematized fluid status procedure with bioimpedance spectroscopy, for individualized dry weight determination in hemodialysis.

Methods: The study was a prospective implementation intervention carried out at two hemodialysis units. The impact of the intervention was measured as the proportion of participants at an adequate dry weight at the end of the study, assessed as change in symptoms, hydration status, and N-terminal pro-brain natriuretic peptide (NT-proBNP). Hemodialysis nurses were instructed to use Recova® every two weeks, assessing the study participants' fluid status and adjusting their dry weights as appropriate. The process of the intervention was measured as frequencies of fluid status assessments, bioimpedance measurements, and dry weight adjustments.

Results: Forty-nine patients were enrolled. In participants with fluid overload (n = 10), both bioimpedance-measured overhydration and fluid overload symptom score decreased. In fluid-depleted participants (n = 20), dry weight adjustment frequency and dry weight increased. The post-dialytic negative overhydration was reduced, but NT-proBNP increased. In the remaining 19 participants, with low volume status scores, no significant changes were observed.

Conclusions: Recova® defines how and when dry weight should be evaluated in hemodialysis patients. Its purpose is to provide the multidisciplinary team with a common language, and thereby facilitate early recognition and appropriate response to fluid alterations. Implementation of Recova® in hemodialysis care increased the monthly frequencies of bioimpedance measurements and dry weight adjustments, and contributed to symptom reduction.

FR-OR31

Development of Alport-Syndrome-on-a-Chip to Study the Glomerular Filtration Barrier Pathophysiology

Laura Perin,[1] Valentina Villani,[1] Astgik Petrosyan,[1] Charmi Dedhia,[1] Geremy Clair,[2] Roger E. De Filippo,[1] Stefano Da Sacco.[1] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]Pacific Northwest National Laboratory, Richland, WA.*

Background: Alport Syndrome (AS) is a genetic disorder in which podocytes fail to correctly assemble the COL4α3α4α5 trimer, a major constituent of the GBM. Disruption of the COL4 network leads to podocyte depletion and progressive kidney failure. While important advances in our understanding of AS progression have been made possible by animal models, we still lack an efficient and faithful in vitro model that can mimic the human AS disease. We have recently developed a glomerulus-on-a-chip system (GOAC) that replicates the features of the glomerular filtration barrier and generated AS chips by combining this novel tool with COL4-defective podocytes.

Methods: Podocytes derived from amniotic fluid of patients affected by AS (AS-POD) were seeded with human glomerular endothelial cells (hGEC) on Organoplates in a barrier-free system to generate AS-GOAC. The system was assessed by confocal microscopy, WB, proteomics and RNA-seq. Permselectivity was assessed by measuring albumin leakage. Transcriptomics studies were performed on podocytes by RNA-seq and qPCR and results confirmed in vivo in a mouse model of AS. Primary human podocytes were used as control.

Results: We confirmed AS phenotype in AS-POD by RNA-seq and WB. GOAC generated with AS-POD show absence of COL4A3-4-5 confirmed by WB. AS-GOAC

present impaired permselectivity to albumin, due to a dysfunctional assembly of the GBM, typical of AS. Our data confirmed high upregulation of miR-193a, a microRNA known to target key players in AS and CKD like WT1, osteopontin, vinculin as well as VEGF and TGFβ pathways. Results were confirmed in vivo in glomeruli of AS mice, further validating the AS-GOAC as an efficient tool for AS studies. Proteomics analysis of the filtrate revealed a distinctive signature in AS-GOAC, including presence of apoliprotein A, vWF and ceruloplasmin.

Conclusions: We have successfully developed an Alport-on-a-chip system that closely mimics the GFB structure and provides a powerful tool for studying the effect of a defective GBM at the cellular level. We have also identified some specific AS proteins, indicative of disease manifestation. This system has the potential to improve our knowledge on AS patho-physiology, able novel therapeutic targets and become a transformative tool, thus ultimately benefiting patients affected by renal failure.

FR-OR32

Development of a Personalized Medicine Platform for Nonsense Readthrough Therapy in Alport Syndrome

Kohei Omachi,[1] Hirofumi Kai,[2] Jeffrey H. Miner.[1] *[1]Washington University in Saint Louis, Saint Louis, MO; [2]Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan, Kumamoto, Japan.*

Background: Alport syndrome (AS) is characterized by glomerular basement membrane (GBM) abnormalities leading to progressive glomerulosclerosis. Mutations in the COL4A3, COL4A4 or COL4A5 genes encoding type IV collagen α3α4α5 cause AS. Nonsense mutations resulting in premature termination codons (PTCs) account for about 6% of AS cases. Type IV collagen chains have a C-terminal NC1 domain, which is essential for assembly of heterotrimers inside cells and for network formation in the GBM. Truncated α3, α4, α5 chains without an intact NC1 domain due to PTCs cannot assemble in the GBM. Therefore, achieving full-length protein expression is a potential therapy for AS due to nonsense mutations. Small compound-based nonsense readthrough therapy has been well studied in other genetic diseases, but whether nonsense readthrough therapy is applicable to Alport syndrome is unexplored.

Methods: To investigate the feasibility of PTC readthrough in AS, we made a C-terminal NanoLuc-fusion COL4A5 reporter cDNA to monitor full-length translation. The full-length COL4A5-NLuc produces luminescence, but truncated forms do not. To screen for COL4A5 nonsense mutants susceptible to PTC readthrough therapy, we introduced 49 nonsense mutations found in X-linked AS patients into the COL4A5-NLuc gene. We transfected these individually into HEK293 cells and measured luminescence in the presence of Geneticin (G418), which is known to have high readthrough activity.

Results: The COL4A5-NLuc gene produced luminescence when wild type, but not when carrying COL4A5 nonsense mutations. Among 49 nonsense mutants, we found that 11 were susceptible to PTC readthrough. The efficacy of readthrough was higher for UGA nonsense codons than for UAG and UAA. Gentamicin also induced readthrough of these same 11 PTCs.

Conclusions: We found 11 nonsense mutations in COL4A5 susceptible to PTC readthrough drugs. This luciferase-based COL4A5 translation reporter system will contribute to the development of PTC readthrough therapy in a personalized medicine approach to treating AS.

A ROBO2 Fusion Protein (PF-06730512) Traps SLIT Ligands and Therapeutically Ameliorates Podocyte Injury

Stephen Berasi,[1] Janet E. Buhlmann,[1] Michael Shamashkin,[1] Matthew V. Russo,[1] Hongying Yang,[1] Kelly M. Knowlton,[1] Nathan Higginson-Scott,[1] Hank Lin,[1] Catharine Andresen,[1] Rhys Jones,[1] Xueping Fan,[2] Sudhir Kumar,[2] Richa Sharma,[2] Aneesha Pydi,[2] David J. Salant,[2] Weining Lu.[2] *[1]Pfizer Inc, Cambridge, MA; [2]Boston University Medical School, Boston, MA.*

Background: ROBO2/SLIT2 signaling negatively regulates nephrin-induced actin polymerization and destabilizes podocyte focal adhesions and attachment to the glomerular basement membrane (GBM) by inhibiting non-muscle myosin IIA. Mice lacking ROBO2 in podocytes are protected from podocyte injury. Based on these findings we hypothesized that blocking this pathway might have therapeutic potential in podocytopathies. Here we provide evidence to support that hypothesis from a case with a genetic defect in ROBO2 and a rodent model of podocyte injury.

Methods: We investigated a patient with a chromosomal translocation that disrupted the ROBO2 gene, produced transcripts encoding dominant negative proteins, and caused high-grade vesicoureteral reflux (VUR). We designed a novel therapeutic ROBO2 fusion protein (ROBO2-Fc, PF-06730512) that inhibits the ROBO2/SLIT2 pathway. In vivo efficacy of ROBO2-Fc was tested in the rat Passive Heymann Nephritis (PHN) model. We also studied the molecular and cellular functions of SLIT2 in kidney glomeruli.

Results: In contrast to most adults with long-standing VUR that develop focal and segmental glomerulosclerosis (FSGS) and proteinuria, the patient with a disrupted ROBO2 gene had stable renal function without proteinuria. In vitro, ROBO2-Fc bound to SLIT ligands with high affinity and dose-dependently inhibited SLIT binding to cell surface ROBO2, and it inhibited ROBO2-dependent cell migration ex vivo. ROBO2-Fc has a terminal half-life of about 5 days in rat and 8 days in monkey. Treatment with ROBO2-Fc reduced proteinuria, shortened podocyte foot process width, and increased slit-diaphragm density in the rat PHN model. Mechanistically, we found that SLIT2 is localized to the GBM and binds to COL4A3/laminin to inhibit podocyte adhesion.

Conclusions: We have generated a novel therapeutic ROBO2 fusion protein that functions as a SLIT ligand trap to treat podocyte injury in a pre-clinical animal model. Inhibiting the ROBO2/SLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-Fc (PF-06730512) in patients with FSGS is currently ongoing (NCT03448692).

FR-OR34

Semaphorin 3B-Associated Membranous Nephropathy

Sanjeev Sethi,[1] Hanna Debiec,[2] Benjamin J. Madden,[1] Marina Vivarelli,[4] Cristine Charlesworth,[1] Aishwarya Ravindran,[1] Louann Gross,[1] David Buob,[2,3] Cheryl L. Tran,[1] Francesco Emma,[4] Francesca Diomedi-Camassei,[4] Fernando C. Fervenza,[1] Pierre M. Ronco.[2,3] *[1]Mayo Clinic, Rochester, MN; [2]Sorbonne Universite, Paris, France; [3]Tenon Hospital, Paris, France; [4]Ospedale Pediatrico Bambino Gesu, Roma, Italy.*

Background: Membranous nephropathy (MN) results from subepithelial antigen-antibody complex deposition along the glomerular basement membrane (GBM). Although PLA2R, THSD7A, and NELL-1 account for a majority (approximately 80%) of the target antigens, the target antigen in the remaining MN is not known.

Methods: We performed laser microdissection and mass spectrometry (MS) of glomeruli in kidney biopsies of 70 cases of PLA2R-negative MN. We detected high spectral counts of a unique protein Semaphorin 3B (Sema3B) in 3 cases. Immunohistochemistry (IHC) for Sema3B was then performed to confirm MS results. Next, we analyzed 3 validation cohorts (2 French and 1 Italian) of 118 PLA2R-negative MN cases by immunofluorescence microscopy (IF). Confocal microscopy studies were done to confirm colocalization of IgG and Sema3B along the GBM. Next, serum antibodies were detected by Western blotting (WB).

Results: MS identified a unique protein, Sema3B in 3 cases of PLA2R-negative MN. MS failed to detect Sema3B in the remaining 67 PLA2R-negative MN, in 23 PLA2R-associated MN, and 88 controls that included IgA nephropathy, diabetes, FSGS and minimal change disease. Semaphorin 3B in all 3 positive cases localized as granular deposits along the GBM by IHC (Figure 1). Next, an additional 8 cases of Sema3B-associated MN were identified in 3 validation cohorts by IF. Confocal microscopy showed that both IgG and Sema3B co-localized to the GBM. In 4 of 11 cases, kidney biopsy also showed tubular basement membrane (TBM) IgG deposits, the TBM deposits were negative for Sema3B. WB analysis in 5 available sera showed reactivity to reduced Sema3B in 4 of 4 patients with active disease and no reactivity in 1 patient in clinical remission; there was also no reactivity in control sera. Eight (73%) of the 11 cases of Semaphorin 3B-associated MN were pediatric cases. In 5 of the 8 children, the disease started below the age of 2 years.

Conclusions: Semaphorin 3B-associated MN is a distinct type of MN, and is predominantly present in pediatric patients.

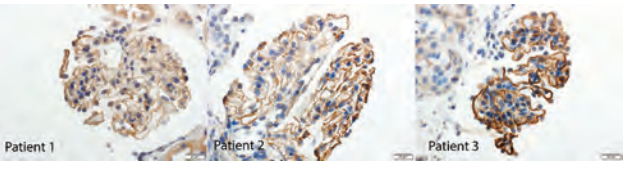

Figure 1 shows bright granular capillary wall staining for Sema3B in 3 cases of Sema3B-associated MN.

High Temperature Recombinant Protein A1 (HTRA1): A Novel Antigen in Membranous Nephropathy

Laith Al-Rabadi,[1] Tiffany Caza,[2] Claire Avillach,[3] Aylin R. Rodan,[1] B. Williams,[1] Josephine Abraham,[1] Monica P. Revelo Penafiel,[1] Nicole K. Andeen,[5] I. Kawalit,[6] Frederic Clayton,[1] Timothy Cummins,[4] Michael Merchant,[4] Jon B. Klein,[4] Christopher P. Larsen,[2] Laurence H. Beck.[3] *[1]University of Utah Health Hospitals and Clinics, Salt Lake City, UT; [2]Arkana Laboratories, Little Rock, AR; [3]Boston University, Boston, MA; [4]University of Louisville, Louisville, KY; [5]Oregon Health and Science University School of Medicine, Portland, OR; [6]Jordan University of Science and Technology, Irbid, Jordan.*

Background: Previous discoveries in MN included identification of PLA2R, THSD7A and NELL-1 as target antigens in 80-85% of primary MN cases. However, target antigens in the remaining 15-20% of cases remain unidentified.

Methods: We present a multi-pronged approach using traditional and modern technologies to converge on a novel target antigen. Instead of a case-vs-control design, we capitalized on the temporal variation in autoantibody titer for our biomarker discovery. Western blotting (WB) of human glomerular extract (HGE) proteins followed by differential immunoprecipitation and mass spectrometric analysis was complemented by laser-capture microdissection / mass spectrometry as well as autoimmune profiling on a protein expressed sequence tag microarray. Commercial antibodies to the candidate antigen were used for immunostaining MN biopsies, and reactivity of patient sera with a recombinant HTRA1 (rHTRA1) by WB and ELISA was assessed.

Results: Using these combined approaches, we identified HTRA1 as a novel antigen in a subset of patients with primary MN. Serum from those patients reacted by WB with a 51 KDa protein in non-reduced HGE as well as rHTRA1, which correlated with clinical disease activity.(Fig A and B) Consistent with PLA2R and THSD7A, anti-HTRA1 antibodies were predominantly IgG4. HTRA1 specifically was detected in a capillary loop fine granular pattern. (Fig C) and colocalized with IgG4. Whole-proteome peptide microarrays detected significantly higher titer (6.9 SD) of anti-HTRA1 antibody in the active stage as opposed to the remission stage which was informative of its candidacy as a podocyte targeted protein. We have 3 confirmed cases of HTRA1-associated MN and are currently screening several large biopsy cohorts of MN that are negative for PLA2R, THSD7A, and NELL-1 to better assess the prevalence of this novel form of MN.

Conclusions: This report demonstrates the convergence of conventional with more modern techniques to identify HTRA1 as a target podocyte antigen in MN.

Protocadherin 7-Associated Membranous Nephropathy

Sanjeev Sethi,[1] Benjamin J. Madden,[1] Louann Gross,[1] Vivian C. Negron,[1] Cristine Charlesworth,[1] Hanna Debiec,[2] Pierre M. Ronco,[2,3] Fernando C. Fervenza.[1] *[1]Mayo Clinic, Rochester, MN; [2]Sorbonne Universite, Paris, France; [3]Tenon Hospital, Paris, France.*

Background: Membranous nephropathy (MN) results from subepithelial antigen-antibody complex deposition along the glomerular basement membrane (GBM). Although PLA2R, THSD7A, and NELL-1 account for a majority (approximately 80%) of the target antigens, the target antigen in the remaining MN is not known.

Methods: We performed laser microdissection and mass spectrometry (MS) of glomeruli in kidney biopsies of 85 cases of PLA2R-negative MN. We detected high spectral counts of a unique protein Protocadherin 7 (PCDH7) in 8 cases. Immunohistochemistry (IHC) for PCDH7 was then performed to confirm MS results.

Results: MS identified a unique protein, PCDH7 in 8 cases (9.4%) of PLA2R-negative MN. MS failed to detect PCDH7 in remaining 77 PLA2R-negative MN, 23 PLA2R-positive MN, and 88 controls that included IgA nephropathy, diabetes, FSGS and minimal change disease. Among the 77 PLA2R-negative MN, MS detected NELL1 (14 cases), EXT1/EXT2 (6 cases), PLA2R (4 cases labeled PLA2R-negative on IF), Sema3B (3 cases), THSD7A (2 cases), and DNAJB9 (4 cases of fibrillary GN, misdiagnosed as MN as EM was not done). PCDH7 localized as granular deposits along the GBM by IHC (Figure 1). Kidney biopsy showed a grade II MN in 6 cases, grade I in 1 and grade III in 1 case. Immunofluorescence microscopy showed GBM staining for IgG and C3 in all cases. IgG subtyping done in 2 cases showed IgG4 in both. The mean age was 64 years (+/- 11) and 7 of the 8 patients were males. The average serum creatinine and proteinuria was 1.28 mg/dL (+/- 0.3) and 4.9 gm/L (+/- 3.0), respectively. Interestingly, 3 of 8 cases had associated malignancies. Further studies including evaluation for circulating antibodies are ongoing.

Conclusions: Protocadherin 7-associated MN may represent distinct type of MN.

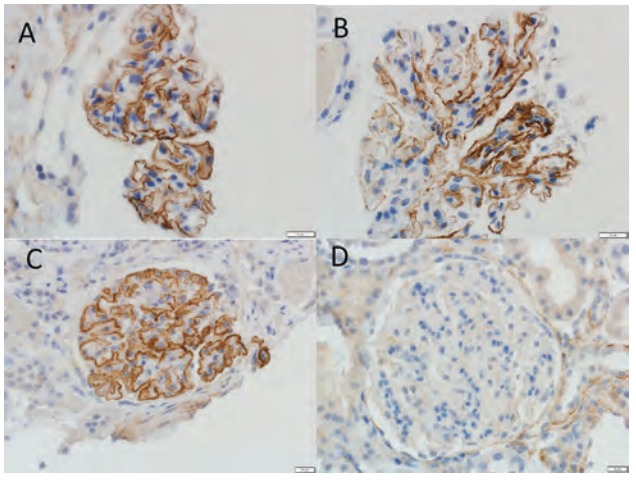

Figure 1 shows bright granular capillary wall staining for PCDH7 in 3 cases (A, B, C) of PCDH7-associated MN, and negative staining in a case (D) of PLA2R-negative MN.

Nefecon® (Budesonide) Selectively Reduces Circulating Levels of BAFF (BLyS) and Soluble BCMA and TACI in IgA Nephropathy

Karen Molyneux, Jonathan Barratt, David H. Wimbury. *Mayer IgA Nephropathy Laboratory, University of Leicester, UK, Leicester, United Kingdom.*

Background: Evidence supports a pivotal role for gut-associated lymphoid tissue (GALT) as a major source of poorly *O*-galactosylated immunoglobulin A (IgA) 1 in patients with IgA nephropathy (IgAN). IgA synthesis in GALT is regulated by B-cell activating factor (BAFF) [B-lymphocyte stimulator (BLyS)] and A PRoliferation-inducing ligand (APRIL). BAFF and APRIL bind to specific cell-surface receptors: transmembrane activator and calcium modulator and cyclophilin-ligand interactor (TACI), B-cell maturation antigen (BCMA), and the BAFF receptor. Elevated levels of BAFF and APRIL have been linked to worse clinical outcomes in IgAN. The therapeutic potential of targeting GALT was demonstrated in the NEFIGAN trial (NCT01738035), which assessed the efficacy of a novel targeted-release formulation of budesonide (Nefecon®), designed to deliver budesonide to the GALT-rich distal ileum in patients with IgAN. The trial comprised 6-month run-in, 9-month treatment, and 3-month follow-up phases: 48 patients received Nefecon® 16 mg/day, 51 patients received Nefecon® 8 mg/day, and 50 patients received placebo. As a result, Nefecon® 16 mg/day, added to optimised renin–angiotensin system blockade, reduced proteinuria and stabilized estimated glomerular filtration rate in patients with IgAN. This study investigated whether Nefecon® treatment altered serum levels of BAFF and APRIL and their receptors.

Methods: Serum levels of BAFF, APRIL, BCMA, and TACI were measured using Luminex technology. Changes in the levels of each biomarker with treatment were compared using a one-way analysis of variance. Significance was set as $p<0.05$.

Results: A significant, dose-dependent reduction in serum BAFF levels was seen with Nefecon®, which reversed on cessation of Nefecon®. There were similar significant reductions in the levels of soluble BCMA and TACI with treatment, but no effect was seen on circulating levels of APRIL. These changes were mirrored by parallel changes in soluble CD27 levels and were consistent with our previous reports on dose-dependent reductions in circulating IgA–IgG immune complexes, secretory IgA, and galactose-deficient IgA levels with Nefecon®.

Conclusions: Delivering budesonide to the GALT-rich distal ileum modulates key regulators of GALT B-cell maturation and IgA class switch recombination in patients with IgAN.

KZR-616, A Selective Inhibitor of the Immunoproteasome: Preclinical and Clinical Mechanism of Action Studies in Lupus Nephritis

Tony Muchamuel, Rong A. Fan, Janet L. Anderl, Henry Johnson, Dustin L. Mcminn, Brian Tuch, Christopher Kirk. *Kezar Life Sciences Inc, South San Francisco, CA.*

Background: Selective inhibition of the immunoproteasome blocks progression of nephritis in a mouse model of systemic lupus erythematosus (SLE). Here we describe the effects of KZR-616 in this model and in patients from MISSION (KZR-616-002; NCT03393013), an open-label study of KZR-616 in patients with SLE with and without nephritis.

Methods: 24-week old NZB/W mice were treated weekly with subcutaneous administration of 5 mg/kg KZR-616 for 11 weeks. SLE patients with active disease and stable background medication (N=34) were dosed subcutaneously with KZR-616 at 30, 45 or 60 mg weekly for 13 weeks with a 12-week follow-up. Clinical samples were evaluated for proteasome subunit binding, and immune cell profile was evaluated by flow cytometry. Gene expression analysis was performed by RNAseq in mouse tissue (whole blood, spleen, and kidneys) and patient (whole blood) samples.

Results: KZR-616 treatment resulted in complete resolution of proteinuria, prevention of glomeruli damage, and absence of renal IgG deposition. Depletion of splenic activated T- and B-cells and short and long-lived plasma cells in treated animals was noted and correlated with decreased gene expression associated with inflammation, T helper (Th) 1 and Th17 pathways, interferon signaling, antibody secreting cells, and differentiation of plasma cells (PC). KZR-616 reduced kidney tissue transcripts associated with inflammation, cell and myeloid glomerulus trafficking and renal genes implicated in LN pathogenesis. In SLE patients, KZR-616 treatment was determined to be safe and tolerated at all dose levels and reductions in disease activity parameters were noted. KZR-616 treatment was associated with a reduction in class-switched memory B cells and PC in peripheral blood. Decreased expression of gene modules for PC, T-cell activation, inflammation, neutrophil, and type I IFN responses were seen in response to treatment.

Conclusions: KZR-616 resolves nephritis in a mouse model of SLE/LN by regulating immune effector cell gene expression and glomerular injury. In SLE patients, KZR-616 demonstrated broad anti-inflammatory activity across T, B, and innate immune effector cells. These results support further clinical evaluation of KZR-616 in patients with LN.

NCAM1 Is an Autoantigen in Membranous Lupus Nephritis

Tiffany Caza,[1] Samar Hassen,[1] Michael B. Kuperman,[1] Ricky Edmondson,[2] Christian Herzog,[2] Aaron J. Storey,[2] John M. Arthur,[2] Zeljko Dvanajscak,[1] Shree G. Sharma,[1] Daniel J. Kenan,[1] Laith Al-Rabadi,[3] Christopher P. Larsen.[1]
[1]Arkana Laboratories, Little Rock, AR; [2]University of Arkansas for Medical Sciences, Little Rock, AR; [3]University of Utah Health Hospitals and Clinics, Salt Lake City, UT.

Background: Membranous lupus nephritis is a frequent cause of proteinuria in patients with systemic lupus erythematosus. In patients with membranous lupus nephritis, the target autoantigens are largely unknown. Determination of a target autoantigen can have diagnostic significance, inform prognosis, and enable non-invasive monitoring of disease activity. We utilized mass spectrometry to identify target autoantigens in membranous lupus nephritis and report neural cell adhesion molecule-1 (NCAM1) as a novel target podocyte antigen.

Methods: We utilized mass spectrometry for antigen discovery of laser capture microdissected (LCMD) glomeruli and protein G immunoprecipitation studies to interrogate immune complexes. Confocal microscopy was used to examine co-localization with IgG within glomerular immune deposits. Case series of biopsies from PLA2R-negative membranous nephropathy patients (n=101) and patients with membranous lupus nephritis (n=212) were used to determine the overall frequency of these antigens. Western blotting reacting patient sera against recombinant NCAM1 protein was used to detect circulating anti-NCAM1 antibodies.

Results: NCAM1 was uniquely identified in a subset of patients with membranous lupus nephritis in LCMD glomeruli and protein G immunoprecipitations by mass spectrometry. NCAM1 co-localized with IgG within glomerular immune deposits. The prevalence of NCAM1 positivity by immunofluorescence was 6.1% of cases of membranous lupus nephritis and 2.0% of idiopathic membranous nephropathy cases. Additionally, serum from NCAM1 patients showed reactivity to NCAM1 recombinant protein, demonstrating the presence of circulating antibodies.

Conclusions: We propose that NCAM1, a cytoskeleton-linked transmembrane protein, is a target autoantigen in a subset of patients with membranous lupus nephritis and within rare cases of idiopathic membranous nephropathy. The presence of anti-NCAM1 antibodies in sera could allow for non-invasive monitoring.

Alpha1-Antitrypsin Diminishes Neutrophil Activation by PR3-ANCA and Endothelial Injury by Neutrophil Serine Proteases

Ralph Kettritz,[2,1] Uwe Jerke,[1] Claudia Eulenberg-Gustavus,[1] Dieter E. Jenne.[3]
[1]Experimental and Clinical Research Center, Charité, Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; [2]Charite Universitatsmedizin Berlin, Berlin, Germany; [3]German Center for Lung Research, Helmholtz Zentrum München, Munich, Germany.

Background: Neutrophil serine proteases (NSPs) contribute to ANCA-associated vasculitis (AAV). PR3 is a unique NSP family member because it is both a proteolytic enzyme and an ANCA antigen. Alpha1-antitrypsin (AAT) is the major natural NSP inhibitor. We hypothesized that AAT protects from ANCA-induced neutrophil activation and neutrophil-mediated glomerular endothelial cell injury.

Methods: We produced recombinant wild-type (wt) AAT and a mutant (mu) form that does not inhibit proteolytic NSP activity. We used flow cytometry to study membrane PR3 (mPR3) and MPO (mMPO), ferricytochrome C assay for superoxide release, FRET assays for proteolytic NSP activity, human neutrophils and glomerular microvascular endothelial cells (gMVEC), confocal and electron microscopy, and assessed ECs by phalloidin staining and gene expression.

Results: Wt-AAT reduced mPR3 on TNF-primed neutrophils dose-dependently from 0.1 to 10 μM (n=3). Five μM wt-AAT, but not mut-AAT, reduced neutrophil mPR3 in suspension, on fibronectin, and on an EC monolayer to approximately 25% (n=3). Parallel comparisons in neutrophil-EC co-cultures using antibodies to different PR3 epitopes showed that 5 μM AAT reduced mPR3 but not mMPO. Importantly, reduced mPR3 by AAT resulted in significantly less superoxide release by TNFa-primed neutrophils when activated with PR3-, but not with MPO-ANCA IgG from AAV patients (n=4). Next, we studied the NSP transfer from activated neutrophils to gMVEC and found that gMVEC acquired NSPs, exemplified by PR3, from both cell-free supernatants (cf-SN) and under neutrophil-EC co-culture conditions. Importantly, wt-, but not muAAT abrogated the PR3 transfer from cf-SN. In contrast, AAT did not inhibit the PR3 transfer under neutrophil-EC co-culture conditions. Finally, we observed by RT-PCR that cf-SN from activated neutrophils increased two NF-κB dependent genes in gMVEC, namely IkBa and IL-8. This effect was reduced by wt-, but not by mu-AAT suggesting an NSP-dependent activation mechanism.

Conclusions: AAT has protective effects by reducing neutrophil activation in response to PR3-ANCA, and NSP-mediated glomerular microvascular endothelial cell injury. Disturbances of the AAT-NSP balance possibly contribute to neutrophil-mediated vascular injury in AAV, particularly, but not exclusively, in patients with PR3-ANCA.

Harnessing Expressed Single-Nucleotide Variation and Single-Cell RNA Sequencing to Define Immune Cell Chimerism in the Rejecting Kidney Transplant

Andrew F. Malone, Haojia Wu, Joseph Gaut, Benjamin D. Humphreys.
Washington University in Saint Louis, Saint Louis, MO.

Background: In solid organ transplantation, donor derived immune cells are assumed to decline with time after surgery. Whether donor leukocytes persist within kidney transplants or play any role in rejection is unknown, however, in part because of limited techniques for distinguishing recipient and donor cells.

Methods: We performed paired whole exome sequencing of donor and recipient DNA and single cell RNA sequencing (scRNA-seq) of 5 human kidney transplant biopsy cores. Exome sequences were used to define single nucleotide variants (SNV) across all samples.

Results: By analyzing expressed SNVs in the scRNA-seq dataset we could define recipient vs. donor cell origin for all 81,139 cells. The leukocyte donor to recipient ratio varied with rejection status for macrophages and with time post-transplant for lymphocytes. Recipient macrophages were characterized by inflammatory activation and donor macrophages by antigen presentation and complement signaling. Recipient origin T cells expressed cytotoxic and pro-inflammatory genes consistent with an effector cell phenotype whereas donor origin T cells are likely quiescent expressing oxidative phosphorylation genes relative to recipient T cells. Finally, both donor and recipient T cell clones were present within the rejecting kidney, suggesting lymphoid aggregation. Our results indicate that donor origin macrophages and T cells have distinct transcriptional profiles compared to their recipient counterparts and donor macrophages can persist for years post transplantation.

Conclusions: This study demonstrates the power of this approach to accurately define leukocyte chimerism in a complex tissue such as the kidney transplant coupled with the ability to examine transcriptional profiles at single cell resolution.

Proteomics Reveals Extracellular Matrix Injury in the Glomeruli and Tubulointerstitium of Kidney Allografts with Early Antibody-Mediated Rejection

Sergi Clotet Freixas,[1] Caitriona M. McEvoy,[1] Ihor Batruch,[2] Chiara Pastrello,[3] Max Kotlyar,[3] Madhurangi Arambewela,[1] Julie Anh Dung Van,[4] Yun Niu,[3] Sofia Farkona,[1] Alexander Boshart,[1,4] Andrea Bozovic,[5] Vathany Kulasingam,[5] Olusegun Famure,[1] Joseph Kim,[1] Tereza Martinu,[1,8] Stephen C. Juvet,[1,8] Andrzej Chruscinski,[1,7] Rohan John,[1,5] Ana Konvalinka.[1,6]
[1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada; [2]Department of Laboratory Medicine and Pathobiology, Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [3]Krembil Research Institute, University Health Network, Toronto, ON, Canada; [4]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [5]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada; [6]Department of Medicine, Division of Nephrology, University Health Network, Toronto, ON, Canada; [7]Soham and Shaila Ajmera Family Transplant Centre, University Health Network, Toronto, ON, Canada; [8]Division of Respirology and Toronto Lung Transplant Program, University Health Network, Toronto, ON, Canada.

Background: Antibody-mediated rejection (AMR) accounts for >50% of kidney allograft losses. AMR is caused by donor-specific antibodies (DSA) against HLA antigens in the glomeruli and the tubulointerstitium, which together with interferon-γ and tumor necrosis factor-α (TNFα), trigger graft injury. The reasons behind cell-specific injury in AMR remain unclear. Identifying compartment-specific proteome alterations may help uncover mechanisms of early antibody-mediated injury.

Methods: We studied 30 for-cause kidney biopsies with early AMR, acute cellular rejection (ACR) or acute tubular necrosis (ATN). We laser-captured microdissected glomeruli and tubulointerstitium and subjected them to unbiased proteome analysis.

Results: We found 107 glomerular and 112 tubulointerstitial proteins significantly differentially expressed in AMR vs ACR ($p<0.05$). Similarly, 112 (glomeruli) and 124 (tubulointerstitium) proteins were altered in AMR vs ATN. Basement membrane and extracellular matrix (ECM) proteins were decreased in both compartments in AMR, compared to ACR and ATN. We verified decreased glomerular and tubulointerstitial LAMC1 expression, and decreased glomerular NPHS1 and PTPRO expression in AMR. Cathepsin-V (CTSV) was predicted to cleave ECM-proteins in the AMR glomeruli. We identified galectin-1, an immunomodulatory protein increased in AMR glomeruli and linked to the ECM. An external dataset (GSE36059) also demonstrated increased galectin-1 expression in AMR. Anti-HLA class-I antibodies induced inflammation and significantly increased CTSV expression, and galectin-1 expression and secretion, in human glomerular endothelial cells. We also studied GSTO1, an ECM-modifying enzyme, increased in the AMR tubulointerstitium. GSTO1 expression was significantly increased in TNFα-treated proximal tubular epithelial cells.

Conclusions: Basement membranes are often remodeled in chronic AMR, and we demonstrated that this remodeling begins early in glomeruli and tubulointerstitium. ECM-remodeling in AMR may represent a new therapeutic target.

FR-OR43

Interim Update of the MDR-101-MLK Phase 3 Trial: MERCURY Study

Dixon Kaufman,[1] Mark D. Stegall,[2] Ethan P. Marin,[3] Ahmed O. Gaber,[4] Titte Srinivas,[9] Erik Stites,[5] Stephan Busque,[6] Martin L. Mai,[7] Matthew Cooper,[8] Suzanne Crowley,[10] James B. Piper,[11] Asheh P. Shah,[12] Sanjeev Akkina,[13] Kenneth Chavin.[9] Mercury Study Group *[1]University of Wisconsin System, Madison, WI; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Yale University Department of Internal Medicine, New Haven, CT; [4]Houston Methodist, Houston, TX; [5]University of Colorado, Denver, CO; [6]Stanford University School of Medicine, Stanford, CA; [7]Mayo Clinic's Campus in Florida, Jacksonville, FL; [8]MedStar Georgetown University Hospital, Washington, DC; [9]University Hospitals, Cleveland, OH; [10]Medeor Therapeutic, South San Francisco, CA; [11]Inova Health Systems, Falls Church, VA; [12]Jefferson Health, Wayne, PA; [13]Loyola University Health System, Maywood, IL.*

Background: The goals of tolerance in patients with kidney transplants (Ktxp) are to eliminate the lifelong need for immunosuppressive (IS) drugs and to prevent graft loss due to rejection or drug toxicity. MDR-101 is a novel cellular immunotherapy, to produce persistent mixed chimerism without graft versus host disease (GvHD) to allow elimination of all IS therapy without rejection, and, thus, to produce operational tolerance. The randomized study evaluated the need for chronic IS therapy in recipients of HLA-matched living donor (LD) kidney transplants as compared to standard of care (SOC) (NCT03363945).

Methods: Eligible adult pairs (donor/recipient) of a first kidney allograft from an HLA-identical LD were enrolled and randomized 2:1 to either the Investigational Arm (IA; n=20) or Control Arm (CA; n=10). Donors in the IA received G-CSF mobilization for 5 days before undergoing apheresis (1 or 2 cycles). IA recipients receive ATG conditioning, low-dose total lymphoid irradiation (TLI) over 10 days and IS followed by an infusion of MDR-101 on d11. After 180 days of persistent mixed chimerism, IA subjects initiated a 6-month taper of CNI and could withdraw all IS on D365. CA subjects were treated as institutional SOC.

Results: As of June 1 2020, 26 subject pairs (donor/recipient) have been enrolled, comprising 18 pairs randomized to the IA and 8 pairs randomized to the CA. MDR-101 infusion was completed in 12 subjects in the IA. To date, 9 subjects in the IA have reached Day 180 with 6 months of positive mixed chimerism. Five subjects have reached D365 and were able to withdraw from all IS. Two subjects lost chimerism – 1 at D545 (off IS) and 1 at D240 continue to wean IS. There have been no events of GvHD, biopsy-proven acute rejection, dnDSA. There have been no graft losses or deaths in either group.

Conclusions: Administration of MDR-101 in HLA-identical LD Ktxp recipients conditioned with ATG and TLI have produced promising results to date. These results show that MDR-101 induces mixed chimerism without GvHD and permits withdrawal of IS without rejection or dnDSA. Further analysis continues.

Single-Cell Profiling of Peripheral Blood Mononuclear Cell Identifies Immune Populations Associated with High Risk of Early Acute Rejection

Weijia Zhang, Samira S. Farouk, Zeguo Sun, Zhengzi Yi, Jia Fu, Chengguo Wei, Miguel Fribourg, John C. He, Paolo Cravedi, Barbara T. Murphy. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Our previous transcriptomic analysis of pre-transplant peripheral blood of 235 kidney transplant recipients in a multi-center GoCAR cohort revealed a 23-gene set predictive of early acute rejection (EAR) post kidney transplant, but the associated immune profile is unknown.

Methods: We first developed a reliable targeted RNA expression (TREx) sequencing assay based on the EAR prediction gene set and applied the assay to assess the EAR risk of 21 dialysis patients who were recruited at Mount Sinai Hospital. We next performed extensive singe-cell immune profiling of PBMCs of these patients using 33 surface markers with CyTOF technology. Lastly, using 10X genomics technology, we performed single cell RNA sequencing (scRNAseq) of the PBMCs to identify immune cell (sub) populations and their transcriptomic signatures from two patients with high and low risk of EAR, respectively.

Results: Using the established TREx assay to stratify patients, we identified had 6 high, 9 intermediate and 6 low risk patients. CyTOF immune profiling of PBMCs of these patients indicated that NK cell population was negatively associated with the risk score ($p=0.008$) while CD4 T cells were positively associated ($p=0.056$). scRNAseq analysis of the transcriptomic profiles of a total number of 11,966 cells confirmed these findings. In addition, scRNA sequencing profiling identified NK and T cell subsets and their transcriptomic signatures associated with the EAR risk, especially decreased NK $CD56^{Dim}$ and increased CD4 CTL populations in EAR high risk patients, which was further validated using PBMC composition deconvoluted from bulk RNAseq profiles of GoCAR cohort (n=235).

Conclusions: The Baseline Acute Rejection assay is associated with clear cellular and molecular Phenotype which may help us further understand the underlying mechanisms that lead to the development of acute rejection.

FR-OR45

Single-Cell RNA-Sequencing Analysis of Kidney Transplant Biopsies Demonstrates a Proinflammatory Role for Renal Tubular Cells in Rejection

Andrew F. Malone, Aidan Leckie-Harre, Haojia Wu, Benjamin D. Humphreys. *Washington University in Saint Louis, Saint Louis, MO.*

Background: Antibody mediated rejection (AMR) remains one of the major causes of allograft failure and our understanding of this disease process is poor. CXCL12 is thought to contribute to allograft rejection through T cell recruitment and a CXCL12 promotor variant is associated with worse graft outcomes. We performed single cell RNAseq on biopsies from transplant patients to examine ligand expression in kidney cells.

Methods: The 10X Genomics platform was used to make libraries which were sequenced to a depth of ~50k reads/cell. Gene-cell matrices were obtained from CellRanger and the downstream analysis (clustering, integration analysis, expression analyses) were done using R and Seurat. This study had IRB approval.

Results: 81139 cells in total (avg = 1124 genes/cell) from 5 kidney transplant biopsy samples (2 non-rejecting, 3 ABMR) were included in the final integrated analysis using UMAP. All major kidney cell types were identified as well as macrophages, B cells and T cells. Renal epithelial cells from rejection samples differentially expressed ligands with cognate receptors found on immune cells. All renal tubular cell types increase HLA gene expression allowing allowing for ligation of macrophage and T cell cognate receptors LILRB and CD3, respectively. Interestingly, only loop of Henle cells increased expression of *CXCL12* whereas stromal cells decreased *CXCL12* expression in rejection samples.

Conclusions: Comprehensive single cell RNAseq of human kidney transplant biopsies suggests a role for loop of Henle cells in rejection though expression of *CXCL12*. We also demonstrate that stromal cells, known to express *CXCL12*, downregulate *CXCL12* expression in rejection. These data suggest a pro-inflammatory role for tubular cells in rejection.

Modified Immune Cell Infusion in Kidney Transplantation

Christian Morath,[1] Matthias Schaier,[1] Eman H. Ibrahim,[1] Lei Wang,[1] Christian Kleist,[1] Gerhard Opelz,[1] Caner Süsal,[1] Mostafa G. Aly,[1] Claudius Speer,[1] Florian Kälble,[1] Christian Nusshag,[1] Luiza Pego silva,[1] Claudia Sommerer,[1] Angela Hückelhoven-Krauss,[1] Arianeb Mehrabi,[1] Carsten Mueller-Tidow,[1] Jochen Reiser,[2] Martin G. Zeier,[1] Michael Schmitt,[1] Peter Terness,[1] Anita Schmitt,[1] Volker Daniel.[1] *[1]Ruprecht Karls Universitat Heidelberg, Heidelberg, Germany; [2]Rush University Medical Center, Chicago, IL.*

Background: We have shown that donor blood cells, modified *in vitro* by an alkylating agent (MIC, modified immune cells), induced specific immunosuppression against the allogeneic donor when administered prior to transplantation. An additional finding was an up to 68-fold increase in the frequency of immunosuppressive $CD19^+CD24^{hi}CD38^{hi}$ transitional B lymphocytes compared to transplanted controls without MIC infusions. The question arises whether donor-specific immunosuppression and increased regulatory B lymphocytes (Breg) are permanently detectable in MIC-treated patients.

Methods: Four patients from a phase-I trial who had received $1.5x10^8$ MIC per kg b.w. on day -7 before living donor kidney transplantation and who were on low immunosuppression were compared to 12 transplanted control patients without MIC infusions.

Results: MIC-treated patients showed an excellent clinical course with no donor-specific HLA antibodies or rejection. On day 1080 after transplantation, median serum creatinine was 1.59 mg/dL. Patients had absent *in vitro* lymphocyte reactivity against stimulatory donor blood cells while reactivity against third party cells was preserved as an indication of continued donor-specific unresponsiveness. $CD19^+CD24^{hi}CD38^{hi}$ and $IL10^+CD19^+CD24^{hi}CD38^{hi}$ Breg were with 2.2/µL and 1.0/µL, respectively, strikingly higher than the 0.0/µL (P<0.001) and 0.0/µL (P<0.001) in transplanted controls and in the range of the numbers of healthy individuals (N=34, P=0.73 and P=0.60). In addition, significantly higher Breg numbers were found for $CD1d^+$ (P=0.0071), $CD19^+CD38^+CD147^+CD1d^+$ (P=0.0071), $CD19^+CD25^+$ (P=0.0077), $CD19^+CD25^+CD73^+CD71^+$ (P=0.013), $CD19^+CD25^+CD73^-CD71^+$ (P=0.0011), $CD19^+CD24^{hi}CD27^+$ memory (P=0.029), and $IL10^+CD19^+CD24^{hi}CD27^+$ memory Breg (P=0.042). No such differences were observed for $CD4^+CD25^+CD127^-FoxP3^+$ Treg (P=0.68) or different Treg subsets when comparing the four MIC-treated patients to transplanted controls without MIC infusions.

Conclusions: Donor-specific immunosuppression after MIC infusion is long-lasting and is associated with a striking increase in Breg at various stages of B cell development, including memory Breg.

Normothermic Ex Vivo Kidney Perfusion in a Porcine Auto-Transplantation Model Preserves the Expression of Key Mitochondrial Proteins: An Unbiased Proteomics Analysis

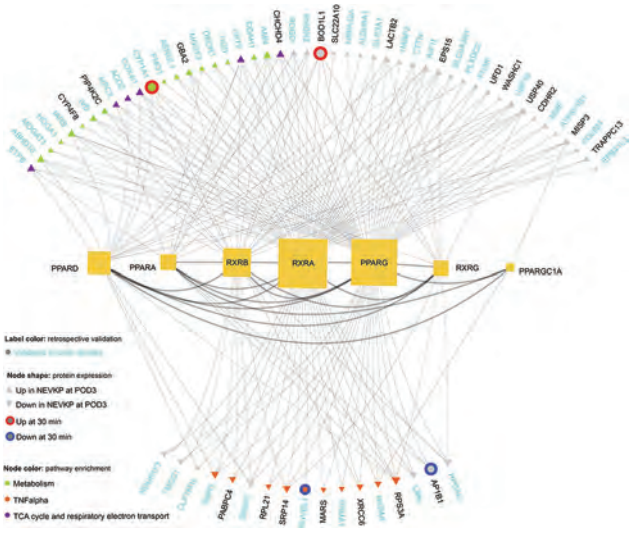
Caitriona M. McEvoy,[1,2] Sergi Clotet Freixas,[1] Tomas Tokar,[3] Chiara Pastrello,[3] Shelby Reid,[4] Ihor Batruch,[5] Adrien A. RaoPeters,[6] Peter Urbanellis,[1,4] Sofia Farkona,[1] Julie Anh Dung Van,[4] Brad Urquhart,[6] Rohan John,[7] Lisa Robinson,[8,9] Markus Selzner,[2,1] Ana Konvalinka.[1,2] *[1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada; [2]Soham and Shaila Ajmera Family Transplant Centre, Toronto General Hospital, University Health Network, Toronto, ON, Canada; [3]Krembil Research Institute, Toronto Western Hospital, University Health Network, Toronto, ON, Canada; [4]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [5]Department of Laboratory Medicine and Pathobiology, Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada; [6]Department of Physiology and Pharmacology, Schulich School of Medicine & Dentistry, Western University, London, ON, Canada; [7]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada; [8]Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada; [9]Program in Cell Biology, The Hospital for Sick Children Research Institute, Toronto, ON, Canada.*

Background: Normothermic *ex-vivo* kidney perfusion(NEVKP) results in significantly improved graft function in porcine auto-transplant models of DCD injury compared to static cold storage (SCS); however, the molecular mechanisms underlying these beneficial effects remain unclear.

Methods: We performed an unbiased proteomics analysis of 28 kidney biopsies obtained at 3 timepoints from pig kidneys subjected to 30-minutes of warm ischemia, followed by 8 hours of NEVKP or SCS, and auto-transplantation.

Results: Of 6593 proteins quantified, 70 were differentially expressed between NEVKP and SCS groups (2-way ANOVA, q<0.05). Proteins increased in NEVKP mediated key metabolic processes including fatty acid ß-oxidation, the TCA cycle and oxidative phosphorylation. Comparison of our findings with external datasets of ischemia-reperfusion, and other models of kidney injury confirmed that 47 of our proteins represent a common signature of kidney injury reversed or attenuated by NEVKP. We validated key metabolic proteins (ETFB, CPT2) by immunoblotting. Integrated transcription factor databases identified PPARGC1A, PPARA/G/D and RXRA/B as the upstream regulators of our dataset, and we confirmed their increased expression in NEVKP with RT-PCR.

Conclusions: The proteome-level changes observed in NEVKP mediate critical metabolic pathways that may explain improved graft function with NEVKP compared to SCS. These effects may be coordinated by PPAR-family transcription factors, and may represent novel therapeutic targets in ischemia-reperfusion injury.



FR-OR48

Cyclosporine-Induced Endothelial Injury and Complement Activation Is Caused by Impaired Complement Factor H Binding to the Glycocalyx

Chia Wei Teoh, Carolina Ortiz, Magdalena Riedl Khursigara, Valentina Bruno, Lisa Robinson, Christoph Licht. *The Hospital for Sick CHildren, Toronto, ON, Canada.*

Background: Calcineurin inhibitors are associated with nephrotoxicity, endothelial cell (EC) dysfunction and thrombotic microangiopathy. Evolving evidence suggests a central role for complement dysregulation in the pathogenesis of CNI-induced thrombotic microangiopathy. However, the exact mechanism of calcineurin-induced complement-mediated injury remains unknown.

Methods: In an in-vitro model utilising Blood Outgrowth EC (BOEC) from healthy donors, we evaluated the effects of cyclosporine (CsA) on EC injury, complement activation (C3c, C9) and regulation (CD46, CD55, CD59 and complement factor H [CFH]) on EC surfaces, and on the EC glycocalyx, utilising flow cytometry, Western blot, and immunofluorescence imaging. Functional activity of CFH was assessed via CFH co-factor assay. Co-immunoprecipitation of Angiopoietin-2 (Angpt-2), Angiopoietin-1 (Angpt-1) and Tie2 was assessed by Western blot.

Results: CsA resulted in a dose and time dependent enhancement of EC complement deposition and EC death. CsA (10 µg/ml for 24 h) led to upregulation of CD46, CD55 and CD59 on EC surface. CsA led to Angpt-2 mediated breakdown of the EC glycocalyx, which was mitigated by Angpt-1. This EC glycocalyx breakdown led to decrease in CFH surface binding and surface cofactor activity.

Conclusions: Our findings confirm a role for complement in CsA-induced EC injury, and suggest Angpt-2 mediated glycocalyx abolishment, induced by CsA, as a mechanism leading to complement alternative pathway dysregulation via decreased CFH surface binding. Insights into this mechanism may provide a potential therapeutic target that might lead to improved patient outcomes which is subject to further studies. It might also apply to other thrombotic microangiopathies, in which a role for complement has so far not been recognized.

FR-OR49

Epigenome-Wide Microarray Analysis of Pre- and Post-Transplant Methylation Profiles in Kidney Transplant Recipients

Katie Kerr,[1] Laura J. Smyth,[1] Jill Kilner,[1] Alexander P. Maxwell,[2,1] Helen Mcaneney,[1] A.J. Mcknight.[1] *[1]Queen's University Belfast, Belfast, United Kingdom; [2]Belfast City Hospital Nephrology Service, Belfast, United Kingdom.*

Background: Kidney transplantation is the optimal treatment for suitable individuals with end-stage kidney disease (ESKD). Serious post-transplant complications include infections, cardiovascular events, malignancy, and new onset of diabetes after transplant (NODAT). Our regional nephrology centre has the highest living kidney donor transplant rate per million population in Europe, and promotes research to improve patient outcomes. We compared pre and post-transplant methylation profiles in samples derived from matched participants.

Methods: Epigenome-wide analysis was conducted using the Illumina Infinium MethylationEPIC array to interrogate 862,987 sites across the genome and identify any differentially methylated regions (DMR) in samples derived from peripheral blood mononuclear cells of age and sex matched pre (n=25) and post (n=25) kidney transplant recipients. DNA was extracted in a uniform manner and stored carefully undergoing minimal freeze thaw cycles. Samples were run on the same instrument and regression calibration was performed in R to estimate leukocyte cell proportions.

Results: Association analysis using Partek® GenomicsSuite® identified 53 DMR (FDR adjusted p≤0.1 x 10^{-8}, fold change +/-2). Within the top ranked CpG probes we identified DMR within genes dysregulated in melanoma (*e.g. EXOC2, VEPH1*), genes encoding extracellular matrix proteins that could influence structural glomerular changes (e.g. *SPAM1*) and genes with prior chronic kidney disease associations (e.g. *FNTA*). A DMR was also identified within the long intergenic non-protein coding RNA *LINC01544*, suggesting possible regulatory function. Additionally, Partek® Pathway™ identified enrichment of DMR in the mitogen-activated protein kinase (MAPK) signalling pathway, primarily implicated in malignancy but also ESKD and cardiovascular disease. Gene ontology analysis identified enrichment of terms associated with localization and binding within cells.

Conclusions: This analysis provides a novel epigenomic perspective on molecular changes caused by kidney transplantation, and highlights markers that may be of relevance to post-transplant complications. We provide evidence supporting further methylation and transcriptomic analyses in larger cohorts to help identify epigenetic risk factors associated with post-transplant complications.

FR-OR50

Impact of Caspase-1 Deletion on Apoptosis and AKI in a Murine Transplant Model

Swati Jain,[1] Robert J. Plenter,[1] Trevor Nydam,[1] Alkesh Jani.[1,2] *[1]University of Colorado, Denver, CO; [2]Rocky Mountain Regional VA Medical Center, Aurora, CO.*

Background: Prolonged cold ischemia (CI) is a known risk factor for acute kidney injury (AKI) after kidney transplantation. However, the mechanism by which CI leads to AKI is unknown. Caspase-1 knockout mice (Casp1KO) are protected from AKI after warm ischemia/reperfusion injury. We hypothesized that Casp1KO mice would be protected from AKI following transplant.

Methods: Renal tubular cells (RTECs) were subjected to cold storage and rewarming (CS/REW). C57Bl/6J wild type or Casp1KO kidneys were subjected to CI for 30 min and then transplanted into wild type recipients (CI+Txp). The recipients underwent bilateral native nephrectomy at the time of transplant. Serum creatinine (sCr) was measured 24hrs after native nephrectomy to assess transplant function.

Results: In vitro: We observed significantly increased expression of NLRP1 inflammasome protein and Caspase-1 in cells subjected to CS/REW. Using Imagestream flow cytometer we observed spatial overlap between two different fluorescent labels of Caspase-1 and NLRP1 in RTECs exposed to CS/REW compared to control cells. **In vivo studies:** Wild-type kidneys subjected to CI+Txp demonstrated significantly increased Caspase-1 and NLRP1 protein expression. Caspase-1 deletion results in significantly decreased RTEC apoptosis in transplanted Casp1KO vs WT kidneys. Renal function, brush border injury, cast formation, tubular simplification were similar in both groups and not significantly different [Table 1].

Conclusions: CS/REW and CI+Txp increase NLRP1 and Caspase-1 expression and co-localization. Deletion of Caspase-1 improves tubular cell apoptosis following CI+Txp. However, Caspase-1 deletion did not prevent AKI and necrosis in kidneys subjected to CI+Txp, suggesting that other triggers of inflammation and programmed necrosis may need to be inhibited in addition to deletion of Caspase-1 to fully prevent AKI after kidney transplant.

Studying Proteinuria in COVID-19 to Define Markers of Severity and New Treatments

Yask Gupta, Juntao Ke, Jeremiah Martino, Qingxue Liu, Byum hee Kil, Tze Yin Lim, Gina Ying Jin, Dina Ahram, Nicholas J. Steers, Simone Sanna-Cherchi. *Columbia University Irving Medical Center, New York, NY.*

Background: The recent SARS-CoV-2 pandemic has led to ~375,000 fatalities worldwide as of June 1st. Nearly, 43% of COVID-19 patients have been reported to have proteinuria, which can result from direct podocyte infection, podocytopathy related to cytokine storm, or both. This association between respiratory viruses, proteinuria, and primary kidney disease has also been observed in the context of respiratory syncytial virus (RSV), where patients can develop nephrotic syndrome. Therefore, studying primary and virus-dependent models of proteinuria and podocyte injury is critical to shed light into COVID-19 pathobiology, severity of disease and potential treatments.

Methods: We accessed transcriptomic data (RNA-seq) for lung cell lines (A549) infected with three different viruses and identified differentially expressed genes (DEGs) for SARS-CoV-2, RSV and IAV. In parallel, we also investigated DEGs for FSGS and MCD using LIMMA R package. We investigated the statistical correlation between the log-fold change of DEGs (Nephroptic syndrome and SARS-COV-2) using R. Pathway analysis was performed using WebGestalt. Possible drugs correcting the skewed gene expression in FSGS and SARS-COV-2 were identified using the Connectivity map (cMAP).

Results: 120 gene signatures were specific to SARS-CoV-2. By using gene expression data from glomeruli of FSGS/MCD we identified 902 DEGs for FSGS and 5 for MCD. Out of these, 6 were overlapping and upregulated in COVID-19 and FSGS/MCD (*B2M, EIF2AK2, IFI16, IFI27, TCIM* and *UBE2L6*). Strikingly, *IFI27* has been recently reported as a marker of disease severity in COVID-19. We found significant positive correlation between the log2 fold change of 94 FSGS/MCD genes intersecting with the 120 COVID-19. The results were specific to glomeruli and to high proteinuric diseases, supporting a common cellular response in lung and podocytes. We then searched the cmap data and identified 59 drugs significantly inversely associated with SARS-COV-2 and 72 for FSGS. Out of these, 7 drugs were in common, representing novel potential drugs for COVID-19 and podocytopathies.

Conclusions: Overall, our results suggest transciptional congruency between NS and SARS-COV-2 which can possibly be used to design novel therapies treat these diseases.

SA-OR02

Machine Learning for Predication of Severe AKI in Hospitalized Patients with COVID-19

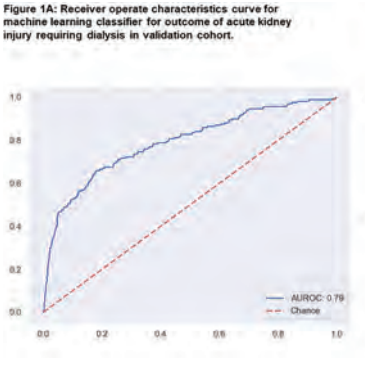
Kumardeep Chaudhary, Lili Chan, Aparna Saha, Kinsuk Chauhan, Akhil Vaid, Barbara T. Murphy, John C. He, Steven G. Coca, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Preliminary reports indicate that acute kidney injury (AKI) is common in coronavirus disease (COVID-19) patients and is associated with worse outcomes. Identification of patients at high risk for developing severe AKI in hospitalized COVID-19 patients in the United States is not well-described.

Methods: This is a retrospective observational study of patients aged ≥18 years with laboratory confirmed COVID-19 admitted to the Mount Sinai Health System between February 27 and April 15, 2020. We trained and tested a machine learning algorithm, extreme gradient boosting (XGBoost), a boosted decision-tree based machine learning (ML) model, with 5-fold cross validation to predict AKI requiring dialysis. Patients from the Mount Sinai (MSH) were randomly split into a training and validation set for the model. To increase model generalizability and help minimize bias, the model's performance was assessed on a test set composed entirely of patients from the other hospitals in the Mount Sinai Health System (MSHS). Input features for the model included demographics, laboratory values, and vital signs that occurred in the first 48 hours of admission.

Results: Of 3,235 hospitalized patients with COVID-19, AKI occurred in 1406 (46%) patients and 280 (20%) with AKI required dialysis. In the training set (n=1,317 patients), the classifier achieved good performance with an area under the receiver operating characteristic curve (AUROC) of 0.79 and area under the precision recall curve (AUPRC) of 0.38 for predicting AKI requiring dialysis. Performance was similar in the testing set (n=1,918) with 0.79 AUROC and 0.36 AUPRC. The features that had a larger impact on the model included serum creatinine, age, potassium, and heart rate.

Conclusions: A machine-learned model using admission features had good performance for dialysis prediction and could be used for resource allocation.



SA-OR03

SARS-CoV-2 Detection in Urine Sediment Suggests Infection of Kidneys and Correlates with Risk of AKI and Poor COVID-19 Prognosis

Paulo S. Caceres, Gina Savickas, Junior Uduman, Kausik Umanath, Yuvraj Sharma, Jerry Yee, Shannon Murray, Sarah Sarkar, Jamie Fitzgerald, Dipak Maskey, Adrian Ormsby, Pablo A. Ortiz. *Henry Ford Hospital, Detroit, MI.*

Background: Since the emergence of the novel severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), most of the focus has been on the respiratory failure caused by the resulting disease, COVID-19. However, the effects of COVID-19 in the kidney are increasingly recognized. Acute kidney injury (AKI) has been identified with varying prevalence around the world with higher rates (37-46%) reported in the USA. It is debatable whether AKI is an indirect consequence of systemic inflammation or a consequence of viral renal cell infection and tropism. We hypothesize that SARS-CoV-2 directly infects kidney tissue and increases the risk of developing AKI, worsening prognosis of COVID-19 patients.

Methods: We studied 88 COVID-19 patients admitted to the Henry Ford Hospital, Detroit after April 15, 2020. Demographics were: mean age 60, 71% African American, 55% male. We quantified viral copies by RT-PCR (S and N genes) in urine sediments from 52 PCR-confirmed COVID-19 patients. We performed immunofluorescence for Membrane and Spike viral proteins in two COVID-19 biopsies.

Results: The prevalence of AKI was 72%, with 32% of patients admitted to the ICU. The overall mortality rate was 14%, with no deaths in non-AKI patients. Viral proteins M and S were detected in the glomerulus, parietal cells and tubules of COVID-19 patients. In some tubules, positive SARS-CoV-2 overlapped with ACE2, the receptor for viral entry. Virus was detected in 61% of urine sediments, with 6-fold greater viral load in AKI-patient urines (copies/ng RNA: AKI, 7422±1338 vs No-AKI: 1523 ± 404; $p<0.05$, n=52). The highest viral loads were detected three weeks post-AKI at 11,374±2248 copies/ng RNA ($p<0.01$). Among COVID-19 AKI-patients who died, the urine viral load exceeded 8000 copies/ng RNA. Above this threshold, the mortality rate was 55%.

Conclusions: Our data support that direct viral renal cell infection occurs in COVID-19 AKI patients with urinary viral genome detection. Greater urinary viral loads portend increased mortality. Urinary viral detection can facilitate management and treatment of COVID-19 and improve outcomes. Future research should focus on studying whether urine contains infective virus or sheds non-infective genomic fragments.

SARS-CoV-2 Receptor Networks in Diabetic Kidney Disease, BK Virus Nephropathy, and COVID-19 Associated AKI

Rajasree Menon,[1] Edgar A. Otto,[1] Rachel S. Sealfon,[2] Viji Nair,[1] Aaron Wong,[2] Chandra L. Theesfeld,[4] Xi Chen,[2] Yuan Wang,[4] Jennifer A. Schaub,[1] Celine C. Berthier,[1] Sean Eddy,[1] Chrysta C. Lienczewski,[1] Brad A. Godfrey,[1] Ryann Sohaney,[1] Helen C. Looker,[3] Laura H. Mariani,[1] Abhijit S. Naik,[1] Robert G. Nelson,[3] Olga Troyanskaya,[4] Matthias Kretzler.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Flatiron Institute, New York, NY; [3]National Institutes of Health, Bethesda, MD; [4]Princeton University, Princeton, NJ.*

Background: COVID-19 shows increased disease burden in patients with diabetic kidney disease (DKD). SARS-CoV-2 uses angiotensin-converting enzyme 2 (ACE2) for host cell entry, so ACE2 levels may influence SARS-CoV-2 susceptibility. We investigated how pre-existing conditions and drug treatments alter receptor expression in kidney cells (Figure 1).

Methods: Single cell RNA profiling of 7 healthy living donor kidneys, 44 DKD, 3 BK virus nephropathy (BKVN) and a urine COVID19 patient with acute kidney injury (COV-AKI) revealed ACE2 expression primarily in proximal tubular epithelial cells (PTEC).

Results: ACE2 mRNA expression levels were higher in proximal tubule epithelial cells (PTEC) in DKD versus LD, but unaltered by exposures to renin angiotensin aldosterone system inhibitors. Bayesian integrative analysis of public -omics datasets identified molecular network modules induced in ACE2 positive versus negative PTEC in DKD and BKVN (hb.flatironinstitute.org/covid-kidney), that were linked to viral entry, immune activation, endomembrane reorganization, and RNA processing. Similar programs were seen in COV-AKI ACE2-positive PTEC, and overlapped with programs in SARS-CoV-2 infected cells.

Conclusions: A consistent ACE2-coregulated expression program in PTEC may interact with SARS-CoV-2 infection processes. These networks can seed further research into developing therapeutic strategies and assessing risk in patients with COVID-19.

SA-OR05

Genomic Datasets from Traditional Murine Models of AKI and AKI-Lung Cross-Talk Reveal Molecular Pathways Relevant to COVID-19 Infection

Dmitry N. Grigoryev,[1] Hamid Rabb.[2] *[1]University of Chicago Division of Biological Sciences, Chicago, IL; [2]Johns Hopkins Medicine, Baltimore, MD.*

Background: COVID-19 infection leads to ARDS and AKI, and there are established mechanistic links between acute kidney injury (AKI) and lung injury. SARS-CoV-2 uses for cell entry angiotensin-converting enzyme 2 (ACE2) and transmembrane protease, serine 2 (TMPRSS2), which are expressed in kidney and lung. Using publicly available genomics data of ischemic and sepsis induced AKI in mice, we searched for established and novel molecular players of AKI and AKI-lung cross-talk relevant to COVID-19.

Methods: The microarray datasets GSE6730 (AJP Renal 2007, JASN 2008) and GSE60088 (Shock 2016) were downloaded from Gene Expression Omnibus (GEO). GSE6730: lungs from mice with moderate and severe ischemic AKI were studied at 6h and 36h. GSE60088: kidneys were studied from mice after 6h of pneumonia+mechanical ventilation (PMV). Isolated RNA was hybridized to MG_430 microarray. To identify differentially expressed genes, GEO-built in GEO2R tool was used.

Results: AKI led to downregulated kidney ACE2 gene at both 6h (fold change (FC)=-2.41) and 36h (FC=-3.23) after severe (60min clamp) but not moderate ischemia (30 min clamp; 6 h: FC=-1.3, 36h: FC=-1.16). In lung from AKI mice, ACE2 was significantly downregulated (FC=-2.89, $P=5.56*10^{-5}$). Ischemic AKI and PMV led to a decrease in lung TMPRSS2 FC=-1.83, $P=1.19*10^{-2}$ and FC=-1.68, $P=6.58*10^{-6}$, respectively. The filtering for known genes with P-value<0.01 and FC>4 identified 53 kidney genes upregulated by PMV; and 254 lung genes upregulated by AKI, of which 9 genes were common to both organs. 3 of 9 genes were previously linked to kidney-lung cross-talk: Lcn2 (FC_{Lung}=18.6, FC_{Kidney}=6.32), Socs3 (FC_L=10.5, FC_K=10.4), Inhbb (FC_L=6.20, FC_K=6.17). This finding validates our approach and makes other 6 genes appealing candidates, especially Maff (FC_L=7.21, FC_K=5.98). This gene participates in the cellular stress response and also binds the oxytocin receptor promoter, which may be involved in gender differences in disease severity.

Conclusions: We identified changes in COVID-19 related genes ACE2 and TMPRSS2 in traditional mouse models of AKI and lung cross talk. We also found new candidate genes activated in kidney during pneumonia+mechanical ventilation and in lung during AKI, which warrants further investigation of their involvement in the combined kidney-lung injury during COVID-19.

SA-OR06

AKI in Patients Hospitalized with COVID-19

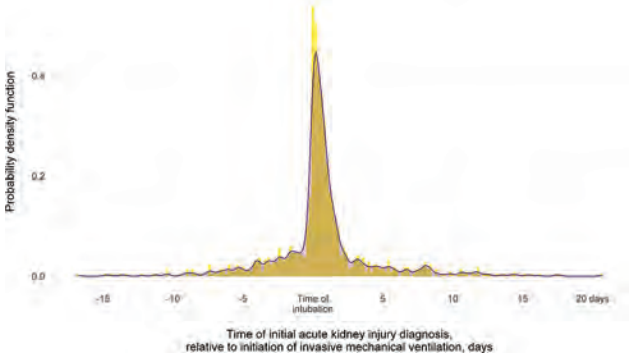
Jia Hwei Ng, Jamie S. Hirsch, Steven Fishbane, Kenar D. Jhaveri. on behalf of the Northwell Renal COVID19 Consortium *Northwell Health, Great Neck, NY.*

Background: The rate of AKI associated with patients hospitalized with Covid-19, and associated outcomes are not well understood.

Methods: We reviewed the health records for all patients hospitalized with Covid-19 between March 1, and April 5, 2020, at 13 hospitals in metropolitan New York. Patients younger than 18 years of age, with ESKD or with a kidney transplant were excluded. AKI was defined according to KDIGO criteria. The primary outcome was the development of AKI. Secondary outcomes included need for RRT and hospital disposition, i.e., discharge or death. The RRT modalities offered to patients with AKI in our health system were intermittent HD or CRRT. All patients were followed up through April 12th, 2020. We additionally analyzed urine results including urine electrolytes and urinalysis with automated microscopy that were obtained within 24 hours before or 48 hours after the initial development of AKI.

Results: Of 5,449 patients admitted with Covid-19, AKI developed in 1,993 (36.6%). The peak stages of AKI were stage 1 in 46.5%, stage 2 in 22.4% and stage 3 in 31.1%. Of these, 14.3% required renal replacement therapy (RRT). AKI was primarily seen in Covid-19 patients with respiratory failure, with 89.7% of patients on mechanical ventilation developing AKI compared to 21.7% of non-ventilated patients. 276/285 (96.8%) of patients requiring RRT were on ventilators. Of patients who required ventilation and developed AKI, 52.2% had the onset of AKI within 24 hours of intubation(Figure and Table). Risk factors for AKI included older age, diabetes mellitus, cardiovascular disease, black race, hypertension and need for ventilation and vasopressor medications. Among patients with AKI, 1136 died (57%), 519 (26%) were discharged and 338 (17%) were still hospitalized.

Conclusions: AKI occurs frequently among patients with Covid-19 disease. It occurs early and in temporal association with respiratory failure and is associated with a poor prognosis.



The probability of acute kidney injury diagnosis relative to time of mechanical ventilation.

SA-OR07

A Multicenter Observational Study of Clinical Features and Outcomes of AKI in Critically Ill Patients with COVID-19

Shruti Gupta, David E. Leaf. STOP-COVID Investigators *Brigham and Women's Hospital Department of Medicine, Boston, MA.*

Background: Acute kidney injury (AKI) is emerging as an important sequela of COVID-19 infection. Existing data on the incidence and clinical features of AKI in patients with COVID-19 are mainly limited to single-center studies. Given the high incidence of severe AKI among patients with COVID-19 and its strong association with mortality in other settings, we conducted a multicenter nationally representative cohort study to examine the incidence, clinical features, risk factors, and outcomes of AKI in critically ill patients with COVID-19.

Methods: We used data from a multicenter observational study that collected granular, patient-level data from >3,000 critically ill adults with laboratory-confirmed COVID-19 admitted to participating ICUs from 67 centers across the United States. Using multivariable logistic regression, we examined risk factors for the primary composite outcome, AKI requiring renal replacement therapy or death (RRT/death) in the 14 days following ICU admission.

Results: Among 3099 patients, 1205 (38.9%) developed the primary outcome of RRT/death (n=637 required RRT, n=792 died within 14 days, and n=224 both required RRT and died within 14 days). Independent risk factors for RRT/death included chronic kidney disease (odds ratio [OR], 5.02; 95% CI, 3.55-7.10 for eGFR<30 vs. ≥60; OR 1.90; 95% CI, 1.55-2.33 for eGFR 30-59 vs. ≥60), as well as older age, male sex, higher body mass index, and greater severity of hypoxemia on ICU admission (**Figure**). Patients admitted to hospitals with higher degrees of strain also had a greater risk of RRT/death (OR 1.49; 95% CI, 1.06-2.06 for highest versus lowest quintile of hospital strain).

Conclusions: This multicenter study identifies several key insights into the risk factors for RRT/death in critically ill patients with COVID-19.

Screening for SARS-CoV-2 (COVID) Infection in Chronic Dialysis Patients: A Nonprofit Provider's Experience

Harold J. Manley,[1] Karen M. Majchrzak,[1] Ronald Sanders,[1] Serena Cumber,[1] Gideon N. Aweh,[1] Vladimir Ladik,[1] Carol Stewart,[1] Doug Johnson,[1] Antonia Harford,[1] Eduardo K. Lacson.[1,2] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts Medical Center, Boston, MA.*

Background: The CDC recommends screening of all patients for COVID exposure history and or signs and symptoms prior to treatment. In order to limit the spread of COVID within our facilities, Dialysis Clinic Inc. screens all patients prior their in-center hemodialysis treatment or peritoneal dialysis visit consistent with recommendations.

Methods: We describe the outpatient screening results of our dialysis patients having a positive screen as patients under investigation (PUI) to activate local protocols for isolation and testing. We determined the frequencies of positive screening parameters and rate of identifying COVID patients.

Results: From 2/17 to 5/1, 2020, facilities screened 15,602 patients over 402,002 in-person visits, identifying 959 PUI's (6%). Among PUIs, 61 of 351 (17%) COVID+ patients were correctly triaged prior to COVID+ diagnosis. In the subset of 788 PUIs screened prior to 4/11/20 where we were able to catalogue reasons for positive screening, 149 (19%) had exposure only and 639 exhibited symptoms (81%), of which 15 had exposure; 34 resided in group home (GH) and 7 had both exposure and GH residence. It was determined 41 (6.4%) were COVID+. Frequency of symptoms elicited by PUI are shown below.

Conclusions: 959 PUIs were identified and isolated by our screening process, resulting in the successful preemptive triage of 61 COVID+ (6%) patients before testing positive, potentially limiting infection spread in the facility. Cough and fever were the most common reasons for positive screen, and fever was most commonly associated with COVID+ diagnosis. However, the majority (83%) of COVID+ patients were primarily asymptomatic and hence not captured by screening.

COVID-related Symptom	COVID+ (n=41)	Non-COVID (n=598)	Overall (n=639)
Cough	11 (27%)	320 (54%)	331 (52%)
Fever (≥100 F)	30 (73%)	153 (26%)	183 (29%)
Shortness of Breath	8 (20%)	132 (22%)	140 (22%)
Sore Throat	1 (2%)	138 (23%)	139 (22%)
O2 Saturation ≤90%	6 (15%)	60 (10%)	66 (10%)
Other Symptom	2 (5%)	43 (7%)	45 (7%)
Chills	3 (7%)	24 (4%)	27 (4%)

Urgent Peritoneal Dialysis Catheter Placement at a New York City Hospital During the COVID-19 Pandemic

Dhwanil Patel, Nina J. Caplin, Manish Tandon. *NYU Langone Health, New York, NY.*

Background: During the COVID-19 pandemic, there has been an unparalleled burden on nephrology services to provide kidney replacement therapy to patients admitted to the hospital with COVID-19, who develop severe AKI. Given the unprecedented surge in COVID-19 admissions, ability to provide inpatient hemodialysis and continuous kidney replacement therapy (CKRT) was quickly saturated. We present data from our acute peritoneal dialysis (PD) program that was quickly assembled to provide kidney replacement therapy due to shortage of hemodialysis and CKRT resources.

Methods: Patients admitted to an academic NYC hospital during COVID-19 pandemic with AKI requiring kidney replacement therapy were evaluated for candidacy for bedside PD catheter placement via cut-down method with the majority having COVID respiratory failure. A dedicated surgery team was assembled to place PD catheters within 12-24 hours of request by the nephrology team. Catheters were placed in patients with BMI up to 51. Patients requiring proning were not excluded. Exclusion criteria were prior lower abdominal surgery, known varices, or imminent death.

Results: Thirty-eight PD catheters were placed during the 4 week time period from April 8 to May 8, 2020. Majority of the catheters were placed bedside in an ICU setting (36/38 - 95%), with 2 being placed laparoscopically in the OR. There were no episodes of peritonitis. Three catheters required revision due to poor flows. Six catheters required floseal for bleeding along the catheter tract, which resolved without additional intervention. There were no major bleeding complications during PD catheter placement despite many patients being on systemic anticoagulation. Dwell volumes of up to 2.2L did not appear to have negative effects on the ability to ventilate patients. One patient required transition to hemodialysis due to catheter malfunction.

Conclusions: Acute peritoneal dialysis successfully allowed kidney replacement therapy for patients with severe AKI during the peak phase of the COVID-19 pandemic at our hospital in NYC. There were no major complications with acute PD catheter placements.

SA-OR10

Recovery from AKI and Acute Respiratory Distress Syndrome (ARDS) with the Use of Low-Dose Steroids During COVID-19 Infection in an African American Population: A Retrospective Analysis

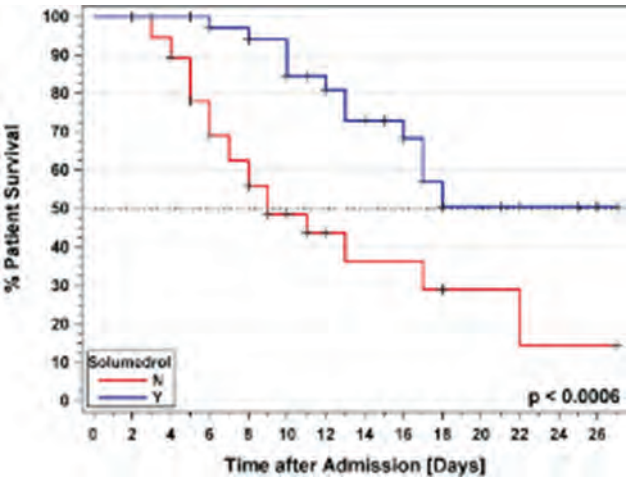
Subodh J. Saggi,[1] Sridesh Nath,[1] Roshni Culas,[2] Seema Chittalae,[1] Aaliya Burza,[1] Patrick Geraghty,[1] Jie Ouyang,[1] Angelika C. Gruessner,[1] Moro O. Salifu.[1] *[1]SUNY Downstate Health Sciences University, Brooklyn, NY; [2]Saint Barnabas Hospital, Bronx, NY.*

Background: Corona Virus Disease-19 (CoVID-19) infection associated with AKI and ARDS results in a mortality of 80%. In AA population COVID 19 presentations and outcomes are worse. NIH and Interim WHO guidelines suggest against steroids use unless in the context of clinical trials. We conducted a retrospective analysis on the impact of 2 different doses of IV steroids in AA adult population.

Methods: 75 patients between March 1 and April 30, 2020 were enrolled. Primary outcomes (21-day mortality) and secondary outcomes (improvement in lung function and renal function) were analyzed. Comparisons between the steroid doses (methylprednisolone 1 mg/kg/day or 2 mg/kg/day) and no-steroid groups were performed with the Wilcoxon, Kruskal-Wallis, and Chi-Square tests. Factors affecting the recovery of AKI or ARDS were analyzed. AKI recovery was defined as 50% increase of GFR, and cessation of RRT; lung function recovery was defined as improved oxygenation by P/F ratio > 200 and extubation.

Results: 38 out 75 patients received steroids. Survival in the steroids group reached 73% at 21 days compared to 36% in the non-steroids group ($p<0.0006$). Steroids improved the likelihood of renal function improvement by 300% ($p=0.06$). Lung functionwas 73% in the steroids group versus 45% in the other ($p=0.01$). Use of anticoagulants (16% vs 51%, $p= 0.001$) seemed to be interacting with steroids on outcomes. Low dose steroids had the most beneficial impact.

Conclusions: In patients with COVID-19 infection and ARDS with AKI, low dose IV methylprednisolone was associated with a significantly lower incidence of mortality and higher likelihood of renal and lung function recovery. Further investigation with a randomized control trial consisting of low dose steroids seems warranted.



Mortality in stroids and non-steroids groups

p53/MicroRNA-214/ULK1 Axis Impairs Renal Tubular Autophagy in Diabetic Kidney Disease

Zhengwei Ma,[1,2] Lin Li,[3] Man J. Livingston,[1,2] Changlin Mei,[3] Zheng Dong.[1,2] *[1]Department of Cellular Biology and Anatomy, Medical College of Georgia at Augusta University, Augusta, Augusta, GA; [2]Charlie Norwood VA Medical Center, Augusta, GA; [3]Department of Nephrology, Changzheng Hospital, Second Military Medical University, Shanghai, China.*

Background: The pathogenesis of diabetic kidney disease (DKD) is unclear. Dysregulation of autophagy in DKD has been reported, but the underlying mechanism and its pathogenic role in DKD remain elusive.

Methods: Autophagy changes in DKD were investigated in high glucose treated renal tubular cells in vitro and in Akita mice and streptozotocin (STZ)-induced diabetic mice in vivo. Autophagy-related gene 7 (Atg7), microRNA-214 (miR-214), or p53 were ablated specifically from kidney proximal tubules to elucidate the pathogenic role and underlying mechanism of autophagy dysregulation in DKD. The expression of autophagy-related proteins, miR-214, and p53 were analyzed in human diabetic kidney tissues along with renal pathologies to determine their correlations.

Results: Autophagy was inhibited in DKD models and in human diabetic kidneys. Ablation of Atg7 from kidney proximal tubules led to autophagy deficiency and worsened renal hypertrophy, tubular damage, inflammation, fibrosis, and albuminuria in diabetic mice, indicating a protective role of autophagy in DKD. Autophagy impairment in DKD was associated with the downregulation of ULK1, a key serine/threonine protein kinase for the initiation of autophagy. ULK1 downregulation in DKD involved miR-214, which was induced in diabetic kidney cells and tissues to repress ULK1 expression. Ablation of miR-214 from kidney proximal tubules prevented ULK1 decrease and autophagy impairment in diabetic kidneys, resulting in less renal hypertrophy and albuminuria. Furthermore, blockade of p53 attenuated miR-214 induction in DKD, leading to higher levels of ULK1 and autophagy, accompanied by the amelioration of DKD. Compared to non-diabetic samples, renal biopsies from human diabetic patients showed the induction of p53 and miR-214, associated by the downregulation of ULK1 and autophagy. There was a significant positive correlation between p53/miR-214 and renal fibrosis, whereas a negative correlation between ULK1/LC3 and renal fibrosis in diabetic patients.

Conclusions: Autophagy dysfunction occurs in renal tubules in DKD, and contributes to renal hypertrophy and related pathologies. Mechanistically, p53 is activated in DKD to induce miR-214, which represses ULK1 resulting in autophagy dysfunction. The results identify the p53/miR-214/ULK1 axis of autophagy impairment for the development and progression of DKD.

Podocytes-Derived Extracellular Vesicles Mediate Renal Proximal Tubule Cells Dedifferentiation via MicroRNA 221 in Diabetic Nephropathy

Hong Su,[1] Jiao Qiao,[1] Qun Yu,[1] Bing Liu,[1,2] Junhui Zhen,[3] Zhimei Lv,[1,2] Rong Wang.[1,2] *[1]Department of Nephrology, Shandong Provincial Hospital, Cheeloo College of Medicine, Shandong University, Jinan, China; [2]Department of Nephrology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China; [3]Department of Pathology, School of Medicine, Shandong University, Jinan, China.*

Background: Podocyte injury is a key event in the initiation of diabetic nephropathy (DN), and the proximal tubule has been regarded as a target of injury. Evidence suggests that cross-talk between podocytes and tubular epithelium is a key component in the pathogenesis of DN, but the mechanisms are not fully understood.

Methods: The podocytes and proximal tubular epithelial cells (PTECs) were co-cultured in high glucose conditions to detect the intercellular communication. Podocytes-derived extracellular vesicles (EVs) was isolated and identified by specific morphology and surface markers. Immunofluorescence, PCR, western blot, electron microscope, and transwell were conducted to assess the dedifferentiation of PTECs. The expression level of miRNA in EVs was detected and Cy3-labeled mimics was used to demonstrate its direct transfer into target cells. A dual-luciferase reporting system was utilized to confirm the binding of miRNA to its target gene. The roles of miRNA and target gene were assessed using specific miRNA inhibitors, mimics and shRNA. In addition, Streptozotocin-induced mice models were construct, and miRNA antagomir were used to explore its role in proximal tubule injury.

Results: Podocytes induced dedifferentiation of PTECs in high-glucose conditions and EVs mediated the interaction. The podocytes-derived EVs were extracted and identified as exosome, and the EVs treatment induced PTECs injury. miR-221 was remarkably increased in EVs and could be directly transferred into target cells, moreover, this miRNA was shown to play a key role in PTECs dedifferentiation. The dual-luciferase reporter assay confirmed that miR-221 direct target DKK2, and miR-221 positively regulated β-catenin activation. Importantly, inhibition of β-catenin markedly diminished the EVs and miRNA induced PTECs dedifferentiation. Furthermore, inhibition of miR-221 in diabetic mice reversed the PTECs injury and relative β-catenin activation.

Conclusions: Podocyte-derived EVs in diabetes acted as key mediators of proximal tubule cell injury and the exosomal-miR-221 mediated the cells damage through Wnt/β-catenin signaling. These findings provide unique insights in the mechanisms of proximal tubule cell injury in diabetic nephropathy, and miR-221 can be used as a new target for the treatment of renal fibrosis in DN.

Whole-Genome Sequencing Identifies a Dominant Negative ADIPOQ Mutation in a Type 2 Diabetic Family Enriched for ESRD

Marcus G. Pezzolesi,[1] Christopher A. Simeone,[1] Joseph L. Wilkerson,[1] Jose M. Lazaro guevara,[1] Edgar J. Hernandez,[1] Bushra Gorsi,[1] Scott G. Frodsham,[1] Kristina V. O'Neil,[2] Scott Summers,[1] Andrzej S. Krolewski,[2] William L. Holland.[1] *[1]University of Utah Health Care, Department of Internal Medicine, Salt Lake City, UT, US, Salt Lake City, UT; [2]Joslin Diabetes Center, Harvard Medical School, Boston, MA, US, Boston, MA.*

Background: Diabetic nephropathy (DN) is a complex, heterogeneous complication of diabetes. Despite evidence of its strong genetic predisposition, identification of the genetic factors that contribute to DN and the risk of end-stage renal disease (ESRD) has been challenging.

Methods: We performed whole genome sequencing (WGS) in a multi-generational family enriched for both type 2 diabetes and ESRD followed by unified linkage analysis and rare variant association testing using pVAAST.

Results: Using WGS to evaluate this family, we identified a rare loss-of-function mutation in adiponectin (*ADIPOQ*^{Gly93GlufsTer73}; seen only once among 56,810 non-Finnish Europeans included in the gnomAD database) observed among 6 ESRD cases in this family. This 10-nucleotide deletion results in a premature termination codon and a complete loss of adiponectin's globular domain. We found that carriers of this mutation have low circulating adiponectin (15% of normal levels) and dramatically high ceramide levels (double the level of C16 ceramides as compared with *ADIPOQ*^{wt} diabetic patients). In cell culture, we observed that *ADIPOQ*^{Gly93GlufsTer73} is degraded by the proteasome. Likely due to its incorporation to trimeric adiponectin, over-expression of the mutant protein decreases stability of wildtype adiponectin and exerts a dominant-negative effect that results in reduced adiponectin levels.

Conclusions: Here we report the first human family with a dominant-negative mutation in adiponectin. Importantly, while adiponectin is known to play important roles in insulin sensitivity, it also has a protective role in mitigating renal injury in patients with diabetes. Moreover, adiponectin knockout mice are prone to DN and podocyte apoptosis. Together, these data provide strong evidence supporting the role of adiponectin in kidney disease in patients with diabetes.

SA-OR14

Enhancing Kidney DDAH-1 Expression by Adenovirus Delivery Reduces Asymmetric Dimethylarginine and Ameliorates Diabetic Nephropathy

Michael Wetzel,[1] Ting Gao,[2] Kristen Stanley,[1] Timothy K. Cooper,[4] Sidney M. Morris,[3] Alaa S. Awad.[1,2] *[1]University of Texas Health Science Center at San Antonio Department of Medicine, San Antonio, TX; [2]Pennsylvania State University College of Medicine Department of Medicine, Hershey, PA; [3]University of Pittsburgh Department of Microbiology and Molecular Genetics, Pittsburgh, PA; [4]National Institute of Allergy and Infectious Diseases, Division of Clinical Research, Frederick, MD.*

Background: Endothelial dysfunction, characterized by reduced bioavailability of nitric oxide and increased oxidative stress, is a hallmark characteristic in diabetes and diabetic nephropathy (DN). High levels of asymmetric dimethylarginine (ADMA) are observed in several diseases including DN and are a strong prognostic marker for cardiovascular events in patients with diabetes and end-stage renal disease. ADMA, an endogenous endothelial nitric oxide synthase (NOS3) inhibitor, is selectively metabolized by dimethylarginine dimethylaminohydrolase (DDAH). Low DDAH levels have been associated with cardiac and renal dysfunction, but its effects on DN are unknown. We hypothesized that enhanced renal DDAH-1 expression would improve DN by reducing ADMA and restoring NOS3 levels.

Methods: DBA/2J mice injected with multiple low doses of vehicle or streptozotocin were subsequently injected intrarenally with adenovirus expressing DDAH-1 (Ad-h-DDAH-1) or vector control [Ad-green fluorescent protein (GFP)], and mice were followed for 6 wk.

Results: Diabetes was associated with increased kidney ADMA ($p<0.05$) and reduced kidney DDAH activity ($p<0.05$) and DDAH-1 expression ($p<0.05$) compared to normal mice but had no effect on kidney DDAH-2 expression. Ad-GFP-treated diabetic mice showed significant increases in albuminuria ($p<0.005$), histological changes ($p<0.005$), glomerular macrophage recruitment ($p<0.001$), inflammatory cytokine ($p<0.01$) and fibrotic markers ($p<0.01$), kidney ADMA levels ($p<0.05$), and urinary thiobarbituric acid reactive substances excretion ($p<0.001$) as an indicator of oxidative stress, along with a significant reduction in kidney DDAH activity ($p<0.05$) and kidney NOS3 mRNA ($p<0.05$) compared with normal mice. In contrast, Ad-h-DDAH-1 treatment of diabetic mice reversed these effects.

Conclusions: These data indicate, for the first time, that DDAH-1 mediates renal tissue protection in DN via the ADMA-NOS3-interaction. Enhanced renal DDAH-1 activity could be a novel therapeutic tool for treating patients with diabetes.

Cell Type Specificity of Hypoxia Signaling in Early Diabetic Kidney Disease (DKD)

Jennifer A. Schaub,[1] Rajasree Menon,[1] Viji Nair,[1] Edgar A. Otto,[1] Joel M. Weinberg,[1] Helen C. Looker,[2] Robert G. Nelson,[2] Matthias Kretzler.[1] *[1]University of Michigan Health System, Ann Arbor, MI; [2]National Institutes of Health, Bethesda, MD.*

Background: Chronic hypoxia is considered a driver of kidney disease progression. Given the spatial heterogeneity of hypoxia, we evaluated the cell type specificity of Hypoxia Related Genes (HRG) in DKD along the nephron and the association of HRG with structural parameters.

Methods: Cell-specific expression and normalized gene signatures (Z scores) were calculated for 237 HRG in single cell RNA profiles of 44 kidney biopsies from American Indians with Type 2 Diabetes (T2D) and 7 healthy living donor kidneys (LD), and replicated in 49 independent micro-dissected biopsies of T2D with DKD (DN).

Results: Mean measured glomerular filtration rate was 159 ml/min (SD 54) in T2D and 147 ml/min (SD 45) in DN, and mean urine albumin/creatinine ratio was 304 mg/g (SD 1542) for T2D and 35 mg/g (SD 90) for DN. Average HgA1c was 9.2 for T2D and 9.3 for DN. HRG expression showed highly cell-type specific elements in both LD and T2D (**Figure 1**). HRG signature in stressed proximal epithelial cells (sPEC), unique to T2D, was dominated by apoptosis and glycolysis signals, while endothelial cells (EC) signatures expressed more genes involved in fibrosis in T2D compared to LD. In DN, Z score of the EC signature was associated with increased mesangial volume (R 0.33, p-value 0.02) and Z score of sPEC signature was associated with interstitial fibrosis (R 0.35, p-value 0.02), which are strong predictors of long-term outcomes in this cohort.

Conclusions: HRG expression varies by cell type in LD and DKD, suggesting transcriptional regulation changes of HRG in diabetes and DKD. Association of HRG signatures with morphometrics that are associated with progressive GFR loss implicate chronic hypoxia processes in early DKD.

Loss of Functional SCO2 Attenuates Diabetic Kidney Disease in db/db Mice

Nehaben A. Gujarati, Alexandra R. Leonardo, Jessica M. Vasquez, Sandeep K. Mallipattu. *Division of Nephrology, Department of Medicine, Stony Brook University, Stony Brook, NY.*

Background: Synthesis of Cytochrome C Oxidase 2 (SCO2), a Cu^{2+} metallochaperone located in the inner mitochondrial membrane, is essential for the assembly of Complex IV (COX IV) of the electron transport chain, maintenance of the proton gradient, and redox signaling. Altered COX activity and reduced mitochondrial function have been reported in diabetic kidney disease (DKD), but the mechanism mediating this process remains to be explored.

Methods: *db/db* mice were bred with *Sco2* mutant mice (E129K, most common human missense mutation in the Cu^{2+} binding domain) to generate $Sco2^{KO/KI}$*;db/db* and $Sco2^{KI/KI}$*;db/db* mice. $Sco2^{KO/KI}$, $Sco2^{KI/KI}$, *db/db*, and wildtype mice served as controls. All mice were euthanized at 24 weeks of age and assessed for functional and histological changes in the kidney.

Results: Data mining in *Nephroseq* showed that *SCO2* expression was increased in micro-dissected glomeruli in human DKD kidney biopsies (Ju et al. 2013), which we confirmed by immunostaining in human kidney biopsies with DKD as compared to healthy donor nephrectomies. Since $SCO2^{-/-}$ mice are embryonically lethal, we ascertained the role of mutant and heterozygous knockout SCO2 in DKD ($SCO2^{KI/KI}$, $SCO2^{KO/KI}$). As compared to *db/db* mice, $SCO2^{KO/KI}$*;db/db* and $SCO2^{KI/KI}$*;db/db* mice had a significant reduction in albuminuria, serum creatinine, glomerular hypertrophy, glomerular oxidative stress (8-oxoG staining) with an increase in podocyte number (WT1+ cells per glomerular cross-sectional area), synaptopodin expression, and overall survival. $SCO2^{KO/KI}$*;db/db* and $SCO2^{KI/KI}$*;db/db* mice also exhibited less glomerular endothelial injury with a decrease in glomerular capillary loop dilatation and a trend towards decrease in *Icam* and *Vcam1* and an increase in *Angpt1*, *Vegfa*, *Kdr* and *Klf2* expression as compared to *db/db* mice.

Conclusions: Loss of *SCO2* and mutant *SCO2* reduced glomerular endothelial injury, oxidative stress, and early diabetic injury in the kidney with improved mice survival in a murine model of DKD.

SA-OR17

Reversal of Diabetic Nephropathy After 10 Years of Pancreas Transplantation Occurs Despite Parallel Podocyte Loss

Behzad Najafian,[1] Michael Mauer,[2] Paola Fioretto.[3] *[1]University of Washinton, Seattle, WA; [2]University of Minnesota, Minneapolis, MN; [3]University of Padova, Padova, Italy.*

Background: Diabetic nephropathy (DN) is associated with podocyte (PC) injury and loss. PC injury is believed to play important role in DN progression. DN reversal following 10 years (10Y) of euglycemia after pancreas transplantation (PTx) is documented (N Engl J Med 1998; 339:69-75). We hypothesized that if PC loss is crucial for DN development, DN reversal would be associated with PC regeneration and improvement in PC structure

Methods: Paired kidney biopsies prior to PTx (BL) and 10Y after PTx were compared for classical DN lesions, PC number and foot process width (FPW) using electron microscopy morphometry in 10 type 1 diabetic (T1D) patients with age 33 (30-54) years [median (range)], diabetes duration 23 (16-33) years and albumin excretion rate (AER) 134 (0-951)µg/min at BL. The results were compared with biopsies from 10 age matched living donor biopsies [controls (C)].

Results: Glomerular basement membrane (GBM) width, fractional volume of mesangium/glomerulus [Vv(Mes/glom)] and fractional volume of mesangial matrix/glomerulus [Vv(MM/glom)] and FPW were all increased at BL compared to C (data not shown). There were significant reductions in GBM width (30%; p=0.0002), Vv(Mes/glom) (21%; p=0.001), Vv(MM/glom) (30%; p=0.002), and glomerular volume (27%; p=0.02) at 10Y compared to BL. However, while PC number density did not change from BL to 10Y, there was a significant decrease in PC number/glomerulus (31%; p=0.049). FPW in T1D patients at BL (p=0.0008) or 10Y (p=0.002) was greater than C with no significant change from BL to 10Y. No relationship was found between change in GBM width, Vv(Mes/glom) or Vv(MM/glom) and PC number density, PC number per glomerulus or FPW. Creatinine clearance was reduced by 25% from BL to 5y post PTx in these calcineurin treated patients, and remained stable between 5 and 10Y. AER did not change significantly.

Conclusions: Substantial reversal of GBM and mesangial extracellular matrix (ECM) accumulation in T1D occurs following long term PTx despite decrease in PC number, persistence of foot process widening and no change in PC density. This study does not support PC loss to be an important mediator of glomerular extracellular dynamics in DN in T1D. Moreover, despite long-term normoglycemia, PC do not regenerate and PC injury does not regress in T1D patients.

Urinary Proteomics Identifies Proteins Associated with Rapid eGFR Decline in Type 1 Diabetes

Christine P. Limonte,[1] Loki Natarajan,[2] Erkka A. Valo,[3] Manjula Darshi,[4] Viktor Drel,[4] Andrew N. Hoofnagle,[1] Daniel Montemayor,[4] Niina Sandholm,[3] Tomas Vaisar,[1] Jing Zhang,[2] Peter Rossing,[5] Per-Henrik Groop,[3] Janet Snell-Bergeon,[6] Trevor J. Orchard,[7] Ian H. de Boer,[1] Kumar Sharma.[4] *[1]University of Washington, Seattle, WA; [2]University of California San Diego, La Jolla, CA; [3]Folkhälsan Research Center, Helsinki, Finland; [4]UT Health Science Center San Antonio, San Antonio, TX; [5]Steno Diabetes Center Copenhagen, Copenhagen, Denmark; [6]University of Colorado Denver Barbara Davis Center for Childhood Diabetes, Denver, CO; [7]University of Pittsburgh, Pittsburgh, PA.*

Background: Varying rates of eGFR decline have been observed in patients with type 1 diabetes (T1D), the pathophysiologic mechanisms of which remain poorly understood.

Methods: We performed a case-control study nested within four T1D cohorts (EDC, CACTI, STENO, FinnDiane) to identify urinary proteins associated with rapid eGFR loss. Cases and controls were defined by annual eGFR decline ≥3ml/min/1.73m^2 and <1ml/min/1.73m^2, respectively. We developed a targeted liquid chromatography-tandem mass spectrometry assay to measure 38 peptides of 20 proteins implicated in diabetic kidney disease. Peptide associations with rapid eGFR loss in discovery and validation sets were compared using logistic regression. Associations of significant peptides with diabetic kidney disease were investigated in the Nephroseq transcriptomic database.

Results: 1271 participants (508 cases, 763 controls) with baseline median eGFR 95ml/min/1.73m^2 and ACR ≥30mg/gCr in 36% were included. Over 8 years median follow-up, mean eGFR slope was -5.65 and 0.57ml/min/1.73m^2 per year for cases and controls, respectively. Out of 38 urine peptides, 2 cathepsin D (CatD) peptides were associated with rapid eGFR loss adjusting for demographic and clinical variables with a false discovery rate of <5% in the discovery set (fully-adjusted OR per SD 1.52, 95%CI 1.22-1.88; 1.41, 95%CI 1.14-1.74). In the validation set, CatD peptides were associated with rapid eGFR decline adjusting for demographic but not clinical variables (1.26, 95%CI 0.99-1.60; 1.15, 95%CI 0.91-1.46). When stratified by baseline urine albumin creatinine ratio (UACR), CatD peptides were associated with rapid eGFR loss among those with UACR 30-300mg/g in both discovery (2.36, 95%CI 1.39-4.03; 2.28, 95%CI 1.32-3.92) and validation (1.93, 95%CI 1.10-1.39; 1.84, 95%CI 1.08-3.13) sets. Across several Nephroseq cohorts, CatD transcription was increased in tubulointerstitial but not glomerular specimens in diabetic kidney disease compared to healthy living donors.

Conclusions: Among patients with T1D and largely normal kidney function, differences in renal lysosomal function as suggested by increased urine CatD may represent a mechanism of rapid eGFR loss early in the course of T1D.

Reduction in the Rate of eGFR Decline with Semaglutide vs. Placebo: A Post Hoc Pooled Analysis of SUSTAIN 6 and PIONEER 6

Katherine R. Tuttle,[1] David Cherney,[2] Samy Hadjadj,[3] Thomas Idorn,[4] Ofri Mosenzon,[5] Vlado Perkovic,[6] Soren Rasmussen,[4] Benjamin Wolthers,[4] Stephen C. Bain.[7] *[1]Institute of Translational Health Sciences, Kidney Research Institute, and Nephrology Division, University of Washington, Seattle, WA; [2]Division of Nephrology, University Health Network, University of Toronto, Toronto, ON, Canada; [3]L'institut du thorax, INSERM, CNRS, University of Nantes, CHU Nantes, Nantes, France; [4]Novo Nordisk A/S, Søborg, Denmark; [5]Diabetes Unit, Department of Endocrinology and Metabolism, Hadassah Medical Center, Hebrew University of Jerusalem, Jerusalem, Israel; [6]University of New South Wales, Sydney, NSW, Australia; [7]Diabetes Research Unit, Swansea University Medical School, Swansea, United Kingdom.*

Background: The SUSTAIN 6 cardiovascular outcomes trial (CVOT) indicated that once-weekly (OW) subcutaneous (s.c.) semaglutide may have beneficial effects on kidney function in subjects with type 2 diabetes (T2D) at high CV risk. SUSTAIN 6 and the PIONEER 6 CVOT (once-daily [OD] oral semaglutide) had similar designs and populations, and both evaluated the effects of semaglutide vs placebo (PBO) on macro- and microvascular outcomes. This *post hoc* analysis of pooled data from the two trials evaluated the effects of semaglutide vs PBO on kidney function decline.

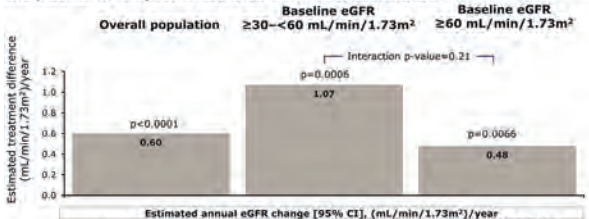
Methods: Data for 6,480 subjects with T2D from SUSTAIN 6 (OW s.c. semaglutide 0.5 and 1.0 mg or PBO, N=3,297; median follow-up 2.1 years) and PIONEER 6 (OD oral semaglutide 14 mg or PBO, N=3,183; median follow-up 1.3 years) were pooled into two groups: semaglutide and PBO. Annual change in estimated glomerular filtration rate (eGFR) was compared (semaglutide vs PBO) in the overall population and subgroups by baseline (BL) eGFR (≥30–<60 or ≥60 mL/min/1.73 m^2). Changes in eGFR from BL during trial were analyzed using a linear random regression model with individual intercept and time slope. The estimated treatment difference (ETD) at 1 year between annual rates of eGFR slope from BL was calculated; an interaction p-value <0.05 indicated difference between subgroups.

Results: In the overall population, the annual rate of eGFR change was 0.60 mL/min/1.73 m^2 (p<0.0001) lower with semaglutide vs PBO. In the eGFR ≥30–<60 mL/min/1.73 m^2 and ≥60 subgroups, the ETDs for semaglutide vs PBO were, respectively, 1.07 and 0.48 mL/min/1.73 m^2/year, with a non-significant interaction p-value (Figure).

Conclusions: Semaglutide was associated with a significantly smaller decline in kidney function than PBO in subjects with T2D at high CV risk across tested BL eGFR categories; the data suggest the main benefit might be observed in those with kidney disease.

Funding: Commercial Support - Novo Nordisk

Figure: Estimated treatment difference in annual eGFR change between semaglutide and placebo in the pooled SUSTAIN 6 and PIONEER 6 trials



Estimated annual eGFR change [95% CI], (mL/min/1.73m²)/year					
Overall population		≥30–<60 mL/min/1.73m² at baseline		≥60 mL/min/1.73m² at baseline	
Semaglutide	Placebo	Semaglutide	Placebo	Semaglutide	Placebo
N=3,232	N=3,231	n=779	n=777	n=2,375	n=2,374
−0.95 [−1.16;−0.74]	−1.55 [−1.77;−1.34]	−0.29 [−0.73;0.14]	−1.36 [−1.80;−0.92]	−1.15 [−1.40;−0.91]	−1.63 [−1.87;−1.38]

eGFR was calculated using the CKD-EPI equation. Change in eGFR from baseline were analyzed using a linear random effects regression model with individual intercept and time slope, and for subgroups interaction between time slope and subgroups. p-values above bars sre from tests for difference between treatments. Estimated treatment difference calculated for pooled semaglutide – placebo.
CI, confidence interval; CKD-EPI, Chronic Kidney Disease-Epidemiology Collaboration; eGFR, estimated glomerular filtration rate.

Patiromer to Enable Spironolactone in Patients with Resistant Hypertension and CKD (AMBER): Results in the Prespecified Subgroup with Diabetes

Rajiv Agarwal,[1] Patrick Rossignol,[2] Susan Arthur,[3] Ansgar Conrad,[3] William B. White,[4] Bryan Williams.[5] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Lorraine and FCRIN INI-CRCT, Nancy, France; [3]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [4]University of Connecticut School of Medicine, Farmington, CT; [5]University College London (UCL), London, United Kingdom.*

Background: Spironolactone (SPIRO) reduces BP in patients (pts) with resistant hypertension (RHTN); however, its use in pts with advanced chronic kidney disease (CKD) is often limited by hyperkalemia (HK). In AMBER, patiromer (PAT) enabled more persistent use of SPIRO in pts with RHTN and CKD. As SPIRO is recommended in RHTN and diabetes mellitus (DM) increases HK risk, we report results in prespecified subgroups with Type 1 or 2 DM (DM$^+$) and without (DM$^-$).

Methods: Randomized, double-blind, placebo (PBO)-controlled trial in adults with RHTN and eGFR 25 to ≤45 mL/min/1.73 m^2. Pts were assigned (1:1) to PBO or PAT, and SPIRO 25 mg QD, with dose titrations permitted after 1 wk for PAT/PBO and 3 wks for SPIRO. The primary endpoint, between-group difference at Wk 12 in % of pts on SPIRO, was assessed prospectively in prespecified DM subgroups.

Results: 295 pts were randomized, 145 (49%) DM$^+$ and 150 (51%) DM$^-$. Baseline mean (SD) serum K$^+$ (mEq/L) was 4.76 (0.34) in DM$^+$ and 4.67 (0.39) in DM$^-$. Significantly more pts treated with PAT than with PBO remained on SPIRO at Wk 12 in both subgroups (**Figure**). LS Mean (SE) cumulative SPIRO dose was higher with PAT than PBO, by 438.7 (177.7) mg in DM$^+$ and 317.8 (175.0) mg in DM$^-$. Adverse events occurred in 61% (PBO) and 60% (PAT) of DM$^+$ pts and in 46% (PBO) and 51% (PAT) of DM$^-$ pts. Four pts had serum magnesium (Mg^{2+}) <1.4 mg/dL between baseline and Wk 12 (none <1.2 mg/dL), including 3 DM$^+$ (1 PBO, 2 PAT) and 1 DM$^-$ (PAT) pts. None of these pts had cardiac arrhythmias temporally associated with low Mg^{2+} levels, neuromuscular abnormalities, or serum K$^+$ below the LLN (3.5 mEq/L).

Conclusions: PAT enabled more pts with advanced CKD and RHTN to continue treatment with SPIRO, regardless of DM status.

Figure. Proportion of Patients Who Remained on SPIRO at Wk 12.

Single-Cell Transcriptomic Analysis to Define Cellular Heterogeneity in Human ADPKD

Yoshiharu Muto,[1] Eryn E. Dixon,[3] Chidambaram Ramachandran,[2] Andrew J. King,[2] Stephen L. Seliger,[3] Owen M. Woodward,[3] Paul A. Welling,[4] Terry J. Watnick,[3] Benjamin D. Humphreys.[1] *[1]Washington University School of Medicine, St. Louis, MO; [2]Chinook Therapeutics, Inc., Vancouver, BC, Canada; [3]University of Maryland School of Medicine, Baltimore, MD; [4]Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Deciphering the molecular pathogenesis of human autosomal dominant polycystic kidney disease (ADPKD) requires a detailed understanding of the distinct cell types and cell states driving cyst growth. Unlike single cell RNA-seq, single nucleus RNA-seq can be performed on cryopreserved samples, and we hypothesized that it might reveal unique cell states from biobanked human ADPKD samples.

Methods: We performed snRNA-seq on 8 ADPKD kidney samples (4 males and 4 females, mean = 50 +/- 8.5 years old, all had ESRD). Cystic kidneys weighed 1631 +/- 728 g. Nuclear preparations were processed using 10x Genomics Chromium 3' kit and sequenced by NovaSeq. Reads were counted with CellRanger 3.1.0 and analyzed with Seurat v3. Gene expression was validated by fluorescence in situ hybridization.

Results: Samples were stored at -80°C prior to processing (median, 20 mo; range 7-40 mo). All samples yielded good libraries (Avg. genes/nucleus = 1560 +/- 526). 63,289 nuclei originating from all 8 ADPKD kidneys passed quality control filters. Large clusters of cystic epithelial cells could be distinctly identified as originating from PT, TAL and CD. Compared to non-cystic epithelia, TAL-derived cystic epithelia showed strong induction of ERBB4 and gene ontology terms including fibroblasts/ECM and secretion of TGFb. CDH6^{high} /LRP2^{high} cystic epithelia expressed the PT injury markers HAVCR1 and VCAM1, suggesting stress-induced dedifferentiation. Cyst-specific marker gene expression was validated by RNAscope on human ADPKD sections. Analysis also revealed four separate fibroblast subtypes, most expressing markers of activation and inflammation, as well as endothelial clusters, podocytes and four separate macrophage sub-clusters.

Conclusions: To our knowledge this is the first single cell transcriptomic atlas of human ADPKD. We demonstrate the utility of this approach by revealing (1) excellent gene expression from all samples including those stored > 3 yrs, (2) segment specific cystic epithelial expression profiles, (3) activated interstitial fibroblast subsets and (4) pro-inflammatory macrophage cell types and states.

Single-Cell RNA Sequencing Provides Insights into the Mechanism Through Which Adaptive Immune Cells Promote Injury-Induced Cyst Formation

Kurt Zimmerman,[1] Bradley K. Yoder,[2] Michal Mrug,[2] Katharina Hopp.[3] *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.*

Background: Inducible disruption of cilia related genes in adult mice results in slow progressing cystic disease, which can be greatly accelerated by renal injury. However, cells that promote accelerated cystogenesis following renal injury are poorly understood.

Methods: To identify cells that may be responsible for driving rapid, injury induced cystic disease, we performed single cell RNA sequencing on cells isolated from sham operated CAGGCre^{ERT2+} *Ift88*$^{f/f}$ (hereafter referred to as cilia mutant mice), ischemia-reperfusion (IR) injured cre negative control, and IR injured cilia mutant mice 56 days post injury, a time point in which injured cilia mutant mice had mild cystic disease.

Results: Comparison of single cell RNA sequencing data from sham- and injured-cilia mutant mice indicate that renal injury in the setting of cilia loss results in alterations in T cell clusters with limited differences in other cell populations. In contrast, single cell RNA sequencing data comparing injured cre negative control and injured cilia mutant mice reveals that loss of primary cilia in the setting of IR injury resulted in major changes in clusters of tubular epithelia and macrophages with minimal effects on T cells. These data suggest that accelerated cystogenesis in cilia mutant mice requires both injury induced changes in T cells as well as cilia-dependent alterations in the injured epithelium and macrophages. Using NicheNet to identify ligand-receptor-gene regulatory networks, we show that T cells from injured cilia mutant mice produce ligands that cause alterations in the gene expression signature of the cilia mutant epithelium and macrophages suggesting that these cells are master regulators of injury induced cystic disease. In agreement with this hypothesis, our data indicate that loss of adaptive immune cells (including T cells) significantly reduced injury induced cystic disease. In contrast, loss of adaptive immune cells did not affect cyst progression in the absence of injury in multiple cystic models, even when animals were aged out several months.

Conclusions: Collectively, our data indicate that IR injury creates a unique population of ligand-producing T cells that crosstalk with macrophages and epithelium of cilia mutant mice to drive rapid, injury induced cystogenesis.

Activation of AMP-Activated Protein Kinase In Vivo Leads to a Polycystic Kidney Disease

Laura Wilson,[1] David Carling.[2] *[1]University College London Institute of Child Health, London, United Kingdom; [2]MRC London Institute of Medical Sciences, London, United Kingdom.*

Background: Polycystic kidney disease (PKD) is a genetic disorder in which numerous fluid-filled cysts form in the kidney. Despite having identified the causative genes that are mutated in PKD, our understanding of the molecular signalling pathways involved in cystogenesis is limited, hindering PKD drug discovery. In this project, we generated a mouse model of AMP-activated protein kinase (AMPK) activation and observed a polycystic kidney phenotype, reminiscent of PKD. AMPK is known for its role in regulating energy homeostasis and is activated in response to cellular stress. It is currently unknown whether AMPK could play a role in PKD pathogenesis.

Methods: AMPK activation mouse models were generated by expressing the AMPKγ1 isoform with a D316A mutation under the control of β-actin (global) and Ksp (kidney-specific) promoters using the Cre-LoxP system. A constitutively active form of AMPK is produced when AMPKγ1-D316A is incorporated into the enzyme complex. Renal function was assessed using metabolic cages, serum and urine samples were collected for analysis. Kidneys were collected and snap-frozen for biochemical studies or wax-embedded for histological studies.

Results: Global activation of AMPKγ1 resulted in a striking polycystic kidney phenotype. Tubule dilations were evident from 11 days of age, which progressed to heavily cystic kidneys by 3 weeks of age. Adult mice showed signs of polyuria associated with a concentrating defect, polydipsia, kidney damage and compromised renal function. Cysts were observed in the collecting ducts of these mice, consistent with the distal nephron being most heavily afflicted in PKD. Mechanistically, the cystic kidneys had increased cAMP levels and ERK activation (a pathway known to be dysregulated in PKD), increased hexokinase I expression and altered lysosomal protein expression. Kidney-specific activation of AMPKγ1 also produced polycystic kidneys in mice, demonstrating that AMPK activation within the kidney was causative.

Conclusions: These results show that activation of AMPK causes polycystic kidneys to form in mice, raising the possibility that AMPK activation could be a contributing factor in PKD pathogenesis. Dysregulation of the cAMP-ERK pathway in this model suggests a possible mechanism for how AMPK activation could be implicated in renal cystogenesis. Future studies should investigate whether AMPK has a pathogenic role in other PKD models.

CU062, the Product of the *C21orf62* Gene, Is a Polycystin-1 Ligand

Christopher J. Ward,[1] Steven J. Kleene,[2] James P. Calvet,[1] Wendy A. Lea.[1] *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of Cincinnati, Cincinnati, OH.*

Background: The *PKD1* gene, encoding the protein polycystin-1 (PC1), is responsible for 85% of cases of mutation positive autosomal dominant polycystic kidney disease (ADPKD) and is the most common genetic cause of renal failure (1:800). PC1 has been shown to be present on easily accessible urinary exosome-like vesicles (ELVs) and to be decreased in individuals with *PKD1* mutations. Label-free mass spectrometry comparison of ELVs from normal and *PKD1* urine showed that several other proteins were decreased to a degree similar to PC1, including a small signal peptide bearing protein of unknown function, CU062, the product of the *C21orf62* gene.

Methods: To determine whether this novel protein is involved in cystogenesis, we applied a genetic approach and deleted the entire *C21orf62* open reading frame in c57Black6/J mice. We also investigated the ability of CU062 to interact with the entire 4302 aa ORF of PC1 and mapped the interacting domains. Furthermore, we probed its ability to gate the PC1/PC2 channel using primary cilium patch clamp.

Results: A TALEN induced deletion of the entire *C21orf62* ORF generated mice that were grossly phenotypically normal, and both sexes were fertile. Close inspection of the kidney showed that about 25% of the homozygous null animals had mild tubular dilation in the loop of Henle and collecting duct. The *C21orf62*^{del} allele exacerbated the *Pkd1*^{R3277C} phenotype as assessed by kidney weight/body weight ratio, ANOVA interaction p=0.0017. *In vitro* binding studies indicated that CU062 interacts with PKD domains 2-17 and most tightly with domains 15-17 in an SDS stable manner. We subsequently showed that extracellular application of pure CU062 activated polycystin-2 (PC2) dependent currents in primary cilia of mIMCD-3 cells. CU062 was shown to be expressed most prominently in the *vasa recta* (VR) and the endothelium of large blood vessels but not in kidney tubules.

Conclusions: These data suggest that CU062 might be a circulating ligand for PC1 and may be filtered through the glomerulus to interact with PC1 on exosomes. CU062 accounts for a subset of PC1 functions as its genetic deletion leads to a milder phenotype than that observed in *Pkd1* homozygous null mice.

Intercalated Cells and the Transcription Factor FOXI1 Drive the Kidney Cystogenesis in Tuberous Sclerosis Complex

Sharon L. Barone,[1,2] Kamyar A. Zahedi,[1,2] Marybeth Brooks,[1] Elizabeth P. Henske,[3] John J. Bissler,[5,6] Jane J. Yu,[4] Manoocher Soleimani.[1,2] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Raymond G Murphy Department of Veterans Affairs Medical Center, Albuquerque, NM; [3]Brigham and Women's Hospital, Boston, MA; [4]University of Cincinnati College of Medicine, Cincinnati, OH; [5]LeBonheur Center for Children in Crisis, Memphis, TN; [6]St Jude Children's Research Hosptial, Memphis, TN.*

Background: Tuberous sclerosis complex (TSC) is caused by mutations in either the TSC1 or TSC2 gene and affects multiple organs, including the kidney. Patients can present with benign tumors (angiomyolipomata) and cysts, which can lead to kidney failure. Factors that promote cyst formation and tumor growth in TSC are poorly understood.

Methods: Mice with principal cell specific inactivation of Tsc1 were generated. In addition, mice with double deletion of Foxi1 and Tsc1 (Foxi1/Tsc1 double KO) or carbonic anhydrase 2 (CAII) and Tsc1 (CAII/Tsc1 double KO) were generated based on RNA-seq and expression studies.

Results: Tsc1 KO mice showed numerous kidney cortical cysts, which were overwhelmingly comprised of A-intercalated (A-IC) cells that showed strong expression of apical V H^+-ATPase. RNA-seq studies demonstrated a 3-fold enhanced expression of Foxi1, which is critical to the development of IC cells and regulation of V H^+-ATPase and CAII. The expression of Foxi1 in Pkd1 mice remained unchanged vs. WT mice. Deleting Foxi1 completely abrogated the cyst burden in Foxi1/Tsc1 dKO mice (Kidney MRI in image 1) and caused a profound reduction in V H^+-ATPase expression in the A-IC cells. Mice with double deletion of Tsc1 and CAII, a regulator of V H^+-ATPase, showed significant reductions in cyst burden and increased longevity vs. Tsc1 KO mice.

Conclusions: We propose that A-IC cells, V H^+-ATPase and CAII are critical to cystogenesis, and their inhibition or inactivation is associated with a significant protection against cyst generation and/or enlargement in TSC. Carbonic anhydrase inhibitors may be viable treatments for the prevention of kidney cyst expansion in TSC. Supplementing carbonic anhydrase inhibitors with HCO_3^- (to minimize the untoward side effects of metabolic acidosis) may be warranted.

Genome-wide Analyses Provide Insights into the Architecture of Kidney Function and CKD in African Americans in the Million Veteran Program (MVP)

Bryce Rowan,[1,2] Cassianne Robinson-Cohen,[1] Elvis A. Akwo,[2] Hua-Chang Chen,[2] Ran Tao,[2] Cecilia P. Chung,[2] Csaba P. Kovesdy,[4] Katalin Susztak,[5] Christopher J. O'Donnell,[3] Edward D. Siew,[1,2] Adriana Hung.[1,2] *[1]Nashville VAMC, Nashville, TN; [2]VUMC, Nashville, TN; [3]Boston VA, Nahsville, MA; [4]Memphis VA, Memphis, TN; [5]Penn Medicine, Philadelphia, PA.*

Background: End-stage kidney disease (ESKD) incidence rates for African Americans are more than 3 times higher than for European-Americans. This disparity has been only partly explained by known determinants of ESKD and the presence of high-risk APOL1 variants. The identification of "second hit" triggers may explain kidney outcome disparities observed in African Americans.

Methods: We performed a GWAS of eGFR among 84,544 African Americans from the MVP at or closest to enrollment. Exclusion criteria were: dialysis, kidney transplant, and BMI<18. We evaluated the association of common (minor allele frequency > 1%) SNPs with linear eGFR (by CKD-EPI equation), adjusted for age, sex, BMI, and the top ten principal components of ancestry. Analyses were performed by strata of diabetes and estimates were aggregated with fixed-effects meta-analysis.

Results: We identified 2,275 SNPs in 22 independent loci associated with eGFR ($p<5x10^{-8}$). The SNP with the strongest signals replicated previously detected associations at *SPATA5L1*/*GATM* (rs2486272, $p = 1.7 \times 10^{-60}$). Of these, 19 represented previously reported loci from GWAS of kidney function or CKD. Known CKD genes from case-control studies such as *APOL1* (rs73885319 p=9.09x10-28) were included in the known loci. Three were novel loci for the association with kidney function in African Americans. Of the novel variants, we discovered SNPs in *ABCA1* (rs10991574 $p = 2.97x10^{-8}$) associated with accelerated atherosclerosis and lipid metabolism through PPAR alpha, *PIK3AP1*(rs556476 $p = 3.1 x10^{-09}$) associated with leukocyte count and *BLNK*(rs9664029 p=2.49 10-8) associated with colorectal adenoma. Some of the strongest signals previously reported for kidney phenotypes included: *DAB2* (rs2542713 $p=1.5 \times 10^{-8}$), *OCT2* (rs2279463, $p=1.98\ 10^{-14}$), *UNCX* (rs62435145 $p=1.97\ 10^{-12}$) and *PRKAG2* (rs10253736 $p=3.0x10^{-8}$). 70 SNPs were exonic variants overall. SNPs within *UMOD/PDILT*, the top hits for kidney function GWAS and CKD progression among European-Americans, did not reach genome-wide ($p=9.19x10^{-8}$) significance.

Conclusions: In this large GWAS of eGFR among African Americans to date, we replicate over 19 previously identified loci, identify 3 novel loci associate with kidney function.

3D Genome Architecture of Human Renal Cortex and Medulla

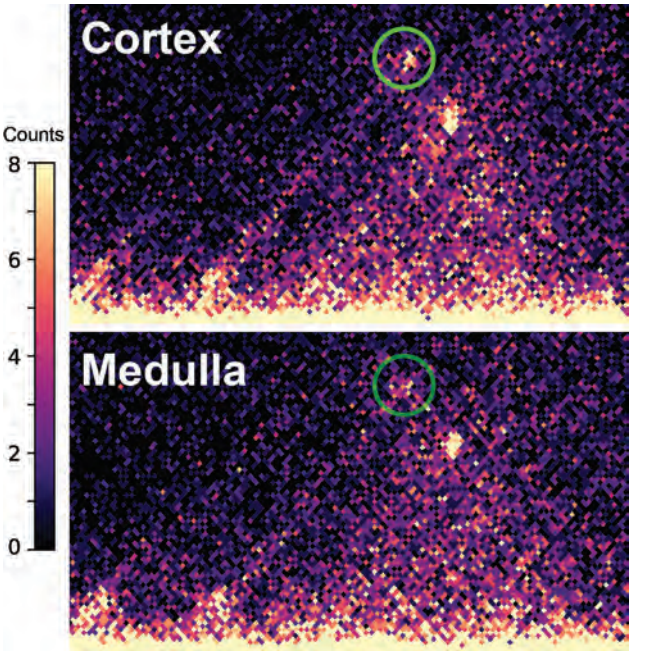
Selvaraj Muthusamy, Shreeram Akilesh. *University of Washington, Seattle, WA.*

Background: Genomic DNA is organized in a non-random manner within the mammalian nucleus. How this three-dimensional genome architecture influences cell-type specific phenotypes is poorly understood. Genome-wide methods such as Hi-C can systematically map out 3D genome architecture. However until now, technical and cost limitations have prevented these powerful approaches from being applied to intact human kidney tissues.

Methods: We performed global genome conformation (Hi-C) analysis on macrodissected human renal cortex and medulla from the same individual. Since existing algorithms to identify intra and inter-chromosomal interactions in Hi-C sequencing data are plagued by low concordance, we developed a novel machine learning algorithm used in the domain of computer vision to identify significant contacts in our Hi-C data.

Results: Each kidney Hi-C sample was deeply sequenced to >400 million mapped contacts enabling visualization of topologically associated domains (TADs) and contacts at 10kb resolution. Comparing even these highly similar samples, our novel algorithm identified significantly different genome conformation at multiple intra-chromosomal contacts in renal cortex (n=1789) and medulla (n=1841) (figure). Further validation by DNA-FISH and comparison to orthogonal functional genomic data sets (ATAC-seq, RNA-seq) are ongoing.

Conclusions: These high-resolution chromatin conformation maps of intact human kidney will provide an valuable resource for the study of kidney genome regulation. Our novel loop-calling algorithm enabled identification of fine genome architectural differences between renal cortex and medulla. Our data can also be used to link genetic risk loci to target genes in genome-wide association studies.



Hi-C contact matrices for cortex and medulla for chr2:117,860,000-118,850,000; Green circle = differential loop.

Clonal Hematopoiesis of Indeterminate Potential and Somatic Mutation Role in CKD: The First Study

Enrico Cocchi,[1,2] Ali G. Gharavi.[1] Gharavi lab *[1]Division of Nephrology and Center for Precision Medicine and Genomics, Department of Medicine, Columbia University, New York, NY; [2]Universita degli Studi di Torino, Torino, Italy.*

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is an age-related somatic mutagenesis associated with inflammation and increased risk of death due to cardiovascular disease. Chronic kidney disease (CKD) is strongly associated with cardiovascular disease, suggesting shared pathophysiologic mechanisms. Inflammation is a well-established component of CKD but CHIP has never been investigated in CKD.

Methods: We analyzed whole-exome sequencing data to determine CHIP prevalence and variant allele frequency (VAF) in a cohort of 2,187 CKD patients and 1,686 age-matched controls. Somatic variants were called using Mutect2 and filtered using strict standard criteria. The presence of CHIP mutations was evaluated for associations with demographic and clinical variables, including age, sex, CKD etiology, treatment with immunosuppressive therapies, end-stage renal disease (ESRD), and history of renal transplant.

Results: In a multivariate logistic regression model focused on the most frequently mutated CHIP genes (DNMT3A, TET2, ASXL1, JAK2), we observed an age-independent association between CHIP and CKD, where both prevalence (p=0.04, OR: 1.62) and VAF (3.48% vs. 1.89%, p=0.004) were higher in CKD cases than in controls. Among CKD cases, CHIP was independently associated with history of renal transplant >10 years (p<0.01, OR: 5.8) and treatment with immunosuppressive therapies (p<0.01, OR: 2.6). Differences were primarily driven by TP53, DNMT3A, ASXL1, ATM, and JAK2. In univariate analysis, we also found a higher prevalence of CHIP in patients with lupus nephritis and other autoimmune glomerulonephritis than in patients with other diagnoses (p=0.04), but this association did not persist in multivariate analyses.

Conclusions: Our analysis of a large case-control cohort suggests an independent association between CHIP and CKD. This association was most evident in patients with ongoing inflammation due to renal transplantation or immune-mediated conditions. These data will require replication in larger human cohorts and validation in animal models.

Loss of Diacylglycerol Kinase ε Causes Thrombotic Microangiopathy by Impairing Endothelial Vascular Endothelial Growth Factor A Signaling

Dingxiao Liu,[3,2] Qiong Ding,[3] Madison Purvis,[1] Biswajit Padhy,[3] Chou-Long Huang,[3] Massimo Attanasio.[3] *[1]University of Iowa, Iowa City, IA; [2]the Second Xiangya Hospital, Central South University, Changsha, China; [3]University of Iowa Carver Collage of Medicine, Iowa City, IA.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a thrombotic microangiopathy (TMA) accompanied by hemolytic anemia, thrombocytopenia, and acute renal failure due to glomerular damage. Mutations in complement genes have been identified in about 50% of aHUS cases. We reported that mutations in the gene *DGKE*, encoding the lipid kinase diacylglycerol kinase epsilon (DGKε) that is unrelated to the

complement system, also cause aHUS. In the glomeruli, *DGKE* is expressed in endothelial cells and podocytes. The molecular mechanisms by which loss of DGKε causes TMA are not known. Phosphatidyl-inositol diphosphate [PtdIns(4,5)P_2] levels are reduced in *Dgke* knockout cells. Since the disruption of vascular endothelial factor A (VEGFA) signaling in humans and mice results in glomerular lesions that resemble those in humans with loss-of-function mutations in *DGKE*, we hypothesized that loss of *DGKE* may impair VEGF signaling in endothelial cells due to shortage of PtdIns(4,5)P_2.

Methods: To test this hypothesis, we performed in vitro studies on *DGKE* knockdown human umbilical vein endothelial cells (HUVECs) and generated endothelial-specific ^{Tie2Cre}*Dgke*$^{f/f}$ conditional knockout mice.

Results: We found that signaling downstream of VEGFA receptor 2 (VEGFR2) is compromised in *DGKE* knockdown HUVECs due to decreased activation of Akt, a phenotype that is rescued by supplementation the culture medium with PtdIns(4,5)P_2. Endothelial-specific ^{Tie2Cre}*Dgke*$^{f/f}$ conditional knockout mice spontaneously developed thrombocytopenia, schistocytosis, and renal insufficiency, indicating that the endothelium is the cellular compartment responsible of the DGKE disease. Remarkably, these mice also developed albuminuria at later times, indicating that the impairment of the glomerular barrier, which is characteristic of the DGKE disease, is a later and secondary event.

Conclusions: Our data indicate that loss of *DGKE* compromises signaling downstream of VEGFR2 in endothelial cells by decreasing cellular levels of PtdIns(4,5)P_2, inducing aHUS and, secondarily, disruption of the glomerular barrier. These results also implicate that pharmacological manipulation of the VEGFA signaling may be used to modify the clinical course of other forms of aHUS.

SA-OR30

Re-Envisioning the APOL1 Cation Channel Structure

Russell P. Thomson,[1] Charles M. Schaub,[2,3] Penny Lee,[1] Nada Terra,[1] Jayne Raper.[1,2] *[1]Hunter College, New York, NY; [2]City University of New York, The Graduate Center, New York, NY; [3]Vanderbilt University, Nashville, TN.*

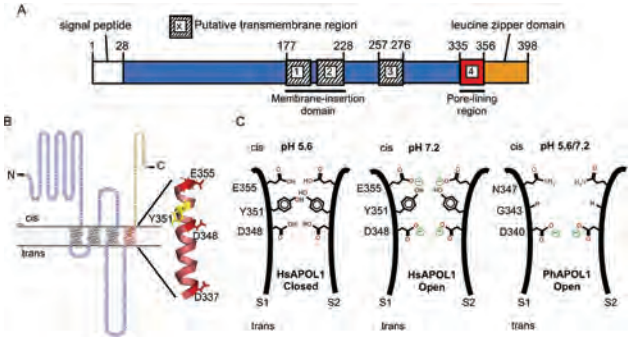
Background: Apolipoprotein L-I (APOL1) is a channel forming protein that protects humans and other primates from African trypanosome infection. African Americans have inherited common APOL1 variants with increased trypanolytic potential; however, these variants are responsible for an increased risk of kidney disease compared with other variants. Human APOL1 forms non-selective cation channels in a strictly pH dependent manner: channel formation requires acidic pH, whereas channel opening requires pH neutralization. Current APOL1 structural models rely on tenuous comparisons with unrelated channel forming proteins. Here we introduce a new model of APOL1 channel structure and topology based on functional characterization of divergent APOL1 orthologs and interspecies chimeras in a planar lipid bilayer system.

Methods: We tested interspecies APOL1 chimeras and point mutations in planar lipid bilayers to identify molecular determinants of pH dependence and ion selectivity.

Results: Strikingly, we demonstrate that cation conductance depends on the C-terminal domain, rather than the N-terminal region as previously suggested, with both pH gating and selectivity functions largely governed by a single residue - aspartate-348. Dual substitution of Asp-348 and nearby glutamate-355 eliminated pH gating, with tyrosine-351 having a steric influence. Acidic residues within a putative hairpin region (residues 177-228) affected the pH-dependence of channel formation.

Conclusions: Based on these data we present a radically updated domain structure of APOL1, including a putative 4-pass transmembrane topology and a pore-lining helix near the C-terminus (see Image abstract). We propose a mechanism of channel gating based on dual proton-sensing residues (Asp-348 and Glu-355) within the pore-lining helix, with Asp-348 also determining selectivity for cations over anions.

Funding: Other U.S. Government Support



(A) Domain structure. (B) Topology model and pore-lining helix. (C) Model of the pore. Two APOL1 subunits (S1 and S2) are brought into apposition via the C-terminal leucine zipper domain.

Small Molecule Inhibitor of TMEM16A Chloride Channel Blocks Vascular Smooth Muscle Contraction and Lowers Blood Pressure in Spontaneously Hypertensive Rats

Onur Cil,[1] Xiaolan Chen,[1] Henry Askew Page,[4] Maria C. Jordan,[3] Pyone Myat Thwe,[2] Samuel N. Baldwin,[4] Marc O. Anderson,[2] Iain A. Greenwood,[4] Kenneth P. Roos,[3] Alan S. Verkman.[1] *[1]University of California San Francisco, San Francisco, CA; [2]San Francisco State University, San Francisco, CA; [3]University of California Los Angeles, Los Angeles, CA; [4]St George's University of London, London, United Kingdom.*

Background: Hypertension is a major cause of cardiovascular morbidity and mortality, despite the availability of antihypertensive drugs with different targets and mechanisms of action. There is an unmet need for antihypertensive drugs with novel mechanisms of action for better BP control. TMEM16A (transmembrane member 16A or anoctamin-1) is a Ca^{2+}-activated Cl^- channel expressed in vascular smooth muscle. TMEM16A activation produces membrane depolarization that results in secondary activation of voltage-dependent ion channels that modulate vasoconstriction. TMEM16A is a potential target for hypertension treatment.

Methods: We recently identified by high-throughput screening and subsequent medicinal chemistry, small molecule TMEM16A inhibitor TM_{inh}-23 that inhibits TMEM16A current fully, with IC_{50} ~ 30 nM. Here we tested TM_{inh}-23 pharmacokinetics in rodents and its effects on vascular smooth muscle contraction (via wire myograph) and BP in spontaneously hypertensive rats (SHR) and wild type rodents.

Results: TM_{inh}-23 pretreatment blocked maximum in vitro vascular smooth muscle contractions induced by a thromboxane mimetic (U46619) in rat mesenteric arteries by 90%. Intraperitoneal (ip) administration of TM_{inh}-23 to rodents at 10 mg/kg produced sustained serum concentrations of >10 μM for >4 hours. BP measurements by tail-cuff and telemetry showed a maximum ~45 mmHg reduction in SBP in spontaneously hypertensive rats (SHR) after a single dose TM_{inh}-23 (10 mg/kg, ip) compared to vehicle administration, with BP gradually returning to baseline values within 6-8 hours after TM_{inh}-23 treatment. Minimal effect on BP (less than 10 mmHg decrease in SBP) was seen in wild-type rats and mice with TM_{inh}-23 treatment (10 mg/kg, ip). Chronic 5-day treatment of SHR with TM_{inh}-23 (10 mg/kg, ip, twice daily) caused sustained decreases (~25 mmHg) in daily average SBP, DBP and MAP during the treatment period. TM_{inh}-23 action was reversible, with BP returning to baseline (~170/115 mmHg) by 3 days after discontinuation of treatment.

Conclusions: These studies provide validation for TMEM16A as a target for hypertension therapy, and demonstrate the proof-of-concept for efficacy of TM_{inh}-23 as an antihypertensive with a novel mechanism of action.

Funding: NIDDK Support, Private Foundation Support

Intravital Imaging of Afferent Arteriole Calcium Dynamics and the Role of Connexin 45

Anne Riquier-brison, Georgina Gyarmati, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: The glomerular afferent (AA) and efferent (EA) arterioles are the most critical resistance vessels in the autoregulation of renal blood flow and glomerular filtration rate. Calcium dynamics of vascular smooth muscle cells (VSMC), in part mediated by gap junction communication via connexin 45 (Cx45), are important regulators of AA contractility and myogenic tone. We aimed to study the role of Cx45 in renal hemodynamics in vivo.

Methods: Intravital imaging with multiphoton microscopy (MPM) of renal functional parameters was performed in mice expressing a genetically encoded calcium indicator (GCaMP3 or GCaMP5) in cells of renin lineage with or without connexin 45 knockout (KO). Suramin treatment was used to test the effects of purinergic receptor blockade.

Results: Compared to the uniform upstream AA segment, high baseline and $\Delta(Ca^{2+})_i$ were observed in a few AA VSMCs at the glomerular entrance, which appeared to function as sphincter cells. The diameter of the AA (9.24±0.27μm WT, vs. 11.39±0.37μm KO) and EA (7.18±0.36μm WT, vs. 8.58±0.30μm KO) were larger in KO animals, although no difference was found in SBP, snGFR and glomerular diameter. Blood flow in AA was also increased (1.42±0.15μm/ms WT, vs. 2.0±0.12μm/ms KO). AA myogenic tone was visualized 3-4 weeks after unilateral ureteral obstruction (UUO). In WT animals, regular AA contractions were observed uniformly in all AAs with an average frequency of 0.12±0.01 Hz, with large magnitude $\Delta(Ca^{2+})_i$ in VSMCs during every contraction ($\Delta(Ca^{2+})_i$ = 5564±855 AU). In contrast, KO animals showed highly heterogeneous and irregular AA vascular activity. In those AAs that did exhibit some myogenic tone-like contractions, a higher frequency was observed (0.28±0.02 Hz), however the magnitude of $\Delta(Ca^{2+})_i$ in AA VSMCs was much lower than in the WT ($\Delta(Ca^{2+})_i$ = 395±249 AU). In both WT and KO animals, treatment with suramin rapidly blocked AA VSMC calcium increases and the myogenic contractions, and the AA became dilated.

Conclusions: AA sphincter cells have robust effects on AA $(Ca^{2+})_i$ dynamics and contractility in vivo, and Cx45 and purinergic signaling are essential components of AA calcium signaling and vascular contractility. Cx45 and purinergic signaling in the AA regulate the myogenic response and renal blood flow, and may be culprit and potential target in vascular pathologies.

Inorganic Nitrite Supplementation Improves Endothelial Function with Aging: Translational Evidence for Suppression of Mitochondria-Derived Oxidative Stress

Matthew J. Rossman,[1] Rachel A. Gioscia-Ryan,[1] Jessica R. Santos-Parker,[1] Brian P. Ziemba,[1] Kara L. Lubieniecki,[1] Natalie E. Poliektov,[1] Lawrence C. Johnson,[1] Erzsebet E. Nagy,[1] Kayla A. Woodward,[1] Amy L. Sindler,[1] Michel Chonchol,[2] Douglas R. Seals.[1] *[1]University of Colorado Boulder College of Arts and Sciences, Boulder, CO; [2]University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.*

Background: We previously observed improvements in vascular endothelial function with inorganic nitrite supplementation in old mice, which we translated to older humans in a pilot study of sodium nitrite supplementation.

Methods: Here, we sought to confirm the efficacy of sodium nitrite in humans and determine mechanisms of action using: 1) a randomized, placebo-controlled, parallel-group clinical trial with sodium nitrite (80 mg/day, 12 weeks) in older adults (n=49, 68±1 yr) and 2) reverse translation experiments in young (6 mo) and old (27 mo) male C57BL6 mice.

Results: In humans, sodium nitrite increased plasma nitrite ($p<0.05$) and was well-tolerated over 12 weeks. Endothelial function (brachial artery flow-mediated dilation) was increased by 28% vs. baseline after nitrite supplementation ($p<0.05$), but unchanged with placebo. Serum from nitrite-treated subjects reduced whole-cell (CellROX) and mitochondria (mito)-specific (MitoSOX) reactive oxygen species (ROS) in human umbilical vein endothelial cell culture ($p<0.05$), whereas serum from placebo-treated subjects had no effect. Old mice (OC, n=9) had ~30% lower *ex vivo* carotid artery endothelium-dependent dilation (EDD) vs. young mice (YC, n=9) due to reduced nitric oxide (NO) bioavailability ($p<0.05$). Nitrite supplementation (drinking water, 50 mg/L, 8 weeks) restored EDD and NO bioavailability in old mice (ON, n=10). MitoROS suppression of EDD was present in OC (increased EDD with a mito-targeted antioxidant, $p<0.05$), but not in Y or ON. A mito stressor (rotenone) further impaired EDD in OC ($p<0.05$), whereas Y and ON were protected.

Conclusions: Nitrite supplementation improves age-related endothelial dysfunction and is associated with increased NO, reduced mito ROS and improved mitochondrial stress resistance.

Paracrine FGF-23 Signaling in the Heart Causes Cardiac Hypertrophy

Isaac D. Campos, Beatrice Richter, Christopher Yanucil, Brian A. Czaya, Kylie Heitman, Dominik Kentrup, David G. Westbrook, Christian Faul. *The University of Alabama at Birmingham Department of Medicine, Birmingham, AL.*

Background: Elevated serum levels of the phosphaturic hormone, fibroblast growth factor (FGF) 23, contribute to cardiac hypertrophy in chronic kidney disease (CKD). FGF23 directly targets cardiac myocytes via FGF receptor (FGFR) 4 to induce hypertrophic growth and FGFR4 blockade not only protects rodent models of CKD from cardiac hypertrophy but also from fibrosis. Our cell culture studies indicate that cardiac fibroblasts do not directly respond to FGF23. It is known that a miscommunication between cardiac myocytes and fibroblasts contributes to pathologic cardiac remodeling. It has been shown that in rodent models and patients with CKD, as well as in mice on high phosphate diet without kidney injury, the heart starts to produce FGF23. Here, we studied if by targeting cardiac myocytes FGF23 promotes paracrine signaling that drives fibrosis. We aimed to determine the cardiac cell type(s) that act as FGF23 source and study if FGF23 serves as a novel paracrine signal mediator between cardiac cell types.

Methods: We treated cultured cardiac myocytes with FGF23 and determined expression levels of established paracrine signal mediators (IL6, LIF, TGFβ, FGF2), or with high phosphate and analyzed FGF23 expression, all by qPCR. We isolated cardiac fibroblasts from wildtype mice on a high phosphate (2%) diet or control chow (0.7%) for 12 weeks. We analyzed paracrine signal mediators by qPCR, as well as FGF23 by qPCR and ELISA. After plating cardiac fibroblasts for 24 and 48 hours, we transferred cell supernatants to myocytes and analyzed hypertrophy.

Results: FGF23 did not increase the expression of paracrine signal mediators in cardiac myocytes or fibroblasts. Phosphate elevations induced FGF23 expression in cardiac fibroblasts, but not in myocytes. Cardiac fibroblast-derived supernatants showed pro-hypertrophic activity when transferred to myocytes, which could be inhibited by co-administration of blocking antibodies for FGF23 or FGFR4.

Conclusions: FGF23 does not affect cardiac fibroblasts by regulating paracrine signal mediators in myocytes. However, FGF23 acts as a novel fibroblast-derived paracrine signaling mediator that induces hypertrophic growth of cardiac myocytes in an FGFR4-dependent manner in scenarios of hyperphosphatemia, such as CKD.

A Renal Potassium-Switch Prioritizes Dietary Potassium Over Sodium, Driving Salt-Sensitive Hypertension

Paul R. Grimm,[1] Robert Little,[3] Robert A. Fenton,[3] Eric J. Delpire,[2] Paul A. Welling.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Vanderbilt University, Nashville, TN; [3]Aarhus University, Aarhus, Denmark.*

Background: Reducing dietary salt (NaCl) is well appreciated to lower blood pressure (BP), but a growing body of evidence indicates that increasing dietary potassium (K) intake is equally important. A 'renal K switch' that turns on the thiazide-sensitive NaCl cotransporter (NCC) in response to low dietary K intake and off in response to high K intake has been implicated. Here we test this idea in genetically engineered mice (CA-SPAK) in which the K switch is 'locked on.'

Methods: Kinase-activating mutations were introduced in SPAK. Expression of the constitutively active (CA) SPAK mutant was limited to the early DCT and results in NCC hyperactivation. BP responses to small changes in plasma [K+] (P[K]) in CA-SPAK were compared to control mice. Dietary K content was varied over 4 days to titrate P[K] over a narrow range (3.7mM (LK), 4.4mM (MK), and 5.1mM (HK)). Blood pressure was monitored by telemetry at each P[K] level in mice consuming control or high salt diet (HNa). At the end of each treatment, the BP response to hydrochlorothiazide (HCTZ) was measured to assess the contribution of NCC to BP.

Results: BP decreased by ~10 mmHg when P[K] increased from 3.7 to 5.1 mM in control mice, coincident with the inactivation of NCC. When the switch was on (LK and MK groups), HNa significantly elevated BP but had no effect when the switch was inactivated by HK. HCTZ significantly reduced BP in the LK/HNa and MK/HNa groups but had no effect on BP in the HK/HNa group, supporting the idea that low K-dependent activation of NCC exacerbates the effects of Na. Studies in CA-SPAK mice reveal a causal relationship between switch activation and BP responses to Na and K. In contrast to control mice, increasing P[K] in CA-SPAK mice had no effect on BP under control salt conditions and failed to blunt the significant hypertensive effects of HNa. HCTZ significantly decreased BP in all CA-SPAK groups to near control levels, consistent with NCC-driven salt reabsorption. Thus, locking on the K switch prevents the anti-hypertensive effects of HK. No sex differences were found.

Conclusions: In summary, low K consumption, common in modern diets, presses the switch pathway to turn on to conserve K at the expense of increasing Na retention, even in the face of high dietary Na, and this elevates BP. Thus, switch activation can drive salt-sensitive hypertension.

Risk of Cardiovascular Events Is Higher in Patients with Glomerular Disease Compared with the General Population

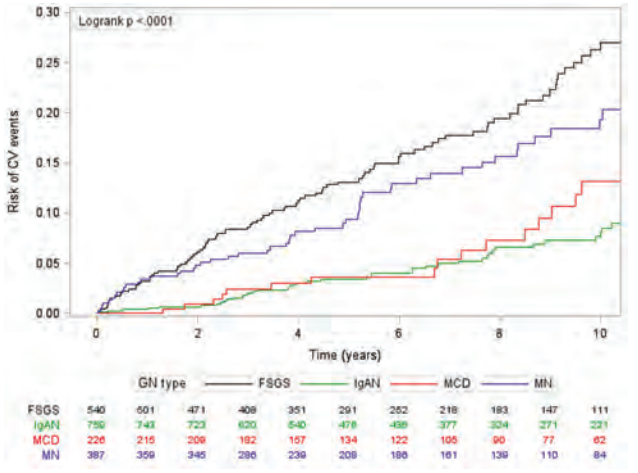
Heather M. Gunning,[1,2] Mark Canney,[2,1] Heather N. Reich,[3] Yuyan Zheng,[1] Anahat Sahota,[4] Seo Am Hur,[4] Arenn S. Jauhal,[3] Sean Barbour,[2,1] Caren L. Rose.[5] *[1]BC Provincial Renal Agency, Vancouver, BC, Canada; [2]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [3]Division of Nephrology, University of Toronto, Toronto, ON, Canada; [4]School of Medicine, University of British Columbia, Canada, Vancouver, BC, Canada; [5]British Columbia Centre for Disease Control, Vancouver, BC, Canada.*

Background: Cardiovascular (CV) disease is a recognized cause of morbidity and mortality in chronic kidney disease; however, understanding of CV risk in patients with glomerular disease (GN) is limited. We sought to define CV risk in GN patients and compare incidence rates to the general population.

Methods: A centralized kidney pathology registry (2000-2012) was used to capture all incident cases of focal segmental glomerulosclerosis (FSGS, n=540), IgA nephropathy (IgAN, n=759), membranous nephropathy (MN, n=387), and minimal change disease (MCD, n=226) in British Columbia, Canada. The primary outcome was a composite of major CV events, ascertained from a hospital discharge registry and evaluated using the Kaplan-Meier method. Hazard ratios (HR, 95% CI) were determined using Cox proportional hazards regression. Event rates were age and sex standardized to the general adult population to generate standardized incidence ratios (SIR, 95% CI).

Results: Over a median follow-up of 6.8years there were 338 CV events; 10-year risk (95% CI) was 16.0% (13.8-18.3) and differed by GN type (Figure): IgAN=7.7% (5.4-10.4), MCD=13.2% (7.6-20.4), MN=19.4% (14.3-25.0), and FSGS=27.0% (21.9-32.4). Compared to IgAN, MN (HR=2.6, 1.7-3.9) and FSGS (HR=3.7, 2.6-5.3) had higher risk, but MCD (HR=1.3, 0.8-2.4) did not. Results were similar when comparing CV events before versus after ESKD. CV risk in GN patients was 2.5-fold higher than the general population (SIR 2.5, 2.1-2.8), and was higher in each GN subtype (IgAN=1.4, 1.0-1.8; MCD=1.8, 1.0-2.8; MN=3.0, 2.2-4.0; FSGS=4.0, 3.2-4.9).

Conclusions: Patients with GN are at high risk of CV disease, both before and after ESKD onset. The CV risk for all GN subtypes was higher than the general population, including MCD and IgAN. This suggests CV preventive strategies should be considered in all patients with GN.



Kaplan-Meier Curve by GN Type

Prediction of Atrial Fibrillation Using Clinical and Cardiac Biomarker Data: The CRIC Study

Leila R. Zelnick,[1] Michael Shlipak,[2] Elsayed Z. Soliman,[3] Amanda H. Anderson,[4] Robert Christenson,[5] James P. Lash,[6] Rajat Deo,[7] Panduranga S. Rao,[8] Farsad Afshinnia,[8] Jing Chen,[4] Jiang He,[4] Stephen L. Seliger,[5] Raymond R. Townsend,[7] Debbie L. Cohen,[7] Alan S. Go,[9] Nisha Bansal.[1] *[1]University of Washington Department of Medicine, Seattle, WA; [2]University of California San Francisco, San Francisco, CA; [3]Wake Forest University, Winston-Salem, NC; [4]Tulane University, New Orleans, LA; [5]University of Maryland School of Medicine, Baltimore, MD; [6]University of Illinois at Chicago, Chicago, IL; [7]University of Pennsylvania, Philadelphia, PA; [8]University of Michigan, Ann Arbor, MI; [9]Kaiser Permanente Northern California, Oakland, CA.*

Background: Clinically available biomarkers of myocardial injury (high sensitivity troponin T, hsTnT) and hemodynamic stress (N-terminal brain natriuretic peptide, NT-proBNP) are strongly associated with atrial fibrillation (AF) in chronic kidney disease (CKD), and have been included in AF prediction models in community-based populations. We investigated the incremental prognostic value of NT-proBNP and hsTnT for AF prediction compared to standard clinical variables in CKD patients enrolled in the Chronic Renal Insufficiency Cohort (CRIC) using machine learning methods.

Methods: Among 2690 CRIC participants without prior AF with complete cardiac biomarker, demographics, medical history/lifestyle, medications, physical characteristics, and laboratory data, we evaluated the utility of Cox regression, LASSO, ridge regression, elastic net, and boosting methods, as well as a previously validated clinical prediction model (CHARGE-AF, using both original and re-estimated coefficients) to predict incident AF. Discriminatory ability of each model was assessed using 10-fold cross-validation; calibration was evaluated graphically.

Results: Mean (SD) age of participants was 57 (11) years, 55% men, 38% black, and mean (SD) eGFR 45 (15) mL/min/1.73m^2; 251 incident AF events occurred during 7.3 (SD 2.8) years of follow-up. CHARGE-AF prediction equations using original and re-estimated coefficients each had a cross-validated C-index of 0.69 (Figure 1a). A LASSO model using only clinical data had a C-index of 0.69, while adding NT-proBNP, hsTnT, or both biomarkers improved the C-index to 0.75, 0.73, and 0.76, respectively (p for difference compared to clinical only model <0.0001 for all). Calibration of top biomarker models was generally adequate (Figure 1b).

Conclusions: Cardiac biomarkers NT-proBNP and hsTnT can improve AF prediction in CKD, particularly when paired with machine learning algorithms.

Renal Hyperfiltration and the Effect of Intensive vs. Standard Blood Pressure Lowering on Cardiovascular Outcomes

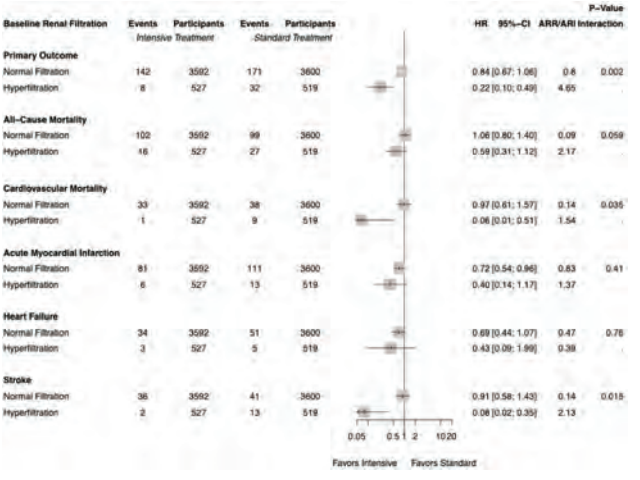
Ayodele Odutayo, Samir M. Iskander, Fatimah Roble, Peter Juni, Fahad Razak, Amol Verma. *University of Toronto, Toronto, ON, Canada.*

Background: Using the Action to Control Cardiovascular Risk in Diabetes (ACCORD) trial and Systolic Blood Pressure Intervention Trial (SPRINT), we examined whether the effect of intensive versus standard blood pressure (BP) lowering on cardiovascular outcomes varies by the presence of renal hyperfiltration (RHF).

Methods: We pooled data on adults in ACCORD and SPRINT without chronic kidney disease (eGFR>60 and urine albumin-to-creatinine ratio <30 mg/g). RHF was defined as an eGFR above the 95th percentile for healthy adults in the National Health and Nutrition Examination Survey. Outcomes of interest were major adverse cardiovascular events (MACE, as defined in the ACCORD primary outcome): a composite of cardiovascular (CV) mortality, acute myocardial infarction (AMI) and stroke. Secondary outcomes were all-cause mortality, CV mortality and CV events. We used fixed effect cox regression.

Results: There were 1046 (13%) adults with RHF and 7192 adults with normal filtration. RHF modified the effect of intensive versus standard BP lowering on MACE (p-interaction=0.002) but not all-cause mortality (p-interaction=0.059). For adults with RHF, intensive BP lowering reduced incidence of MACE compared with standard BP lowering (HR: 0.22, 95%-CI: 0.10-0.49). The risk reduction was smaller in adults with normal filtration (HR: 0.84, 95%-CI: 0.67-1.06). Intensive BP lowering was also associated with a larger reduction in the incidence of CV mortality and stroke among adults with RHF (Figure, p-interaction≤0.035) but not AMI or heart failure (p-interaction≥0.41). Separate analyses of ACCORD and SPRINT were similar.

Conclusions: RHF modified the effect of intensive versus standard BP lowering on cardiovascular outcomes.



Intensive Versus Standard Blood Pressure Lowering and Cardiovascular Outcomes in Adults With and Without Renal Hyperfiltration (Pooled Analysis)

SA-OR39

Pooled Analyses of the Phase 3 Roxadustat Studies: Congestive Heart Failure Hospitalization Rates in Dialysis and Non-Dialysis Patients with Anemia Treated with Roxadustat vs. Comparators

Robert Provenzano,[1] Lynda Szczech,[2] Ming Zhong,[2] Bryant Lai,[2] Robert Leong,[2] Dustin J. Little,[3] Kin-Hung P. Yu.[2] *[1]Wayne State University, Detroit, MI; [2]FibroGen Inc, San Francisco, CA; [3]AstraZeneca, Gaithersburg, MD.*

Background: Roxadustat is an orally bioavailable hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Phase 3 roxadustat studies were performed to treat anemia of chronic kidney disease (CKD). Congestive heart failure (CHF), a common comorbidity in CKD, was also analyzed. CHF is associated with a poorer prognosis in CKD patients, with a prevalence that increases with CKD severity; approximately 20% in mild CKD (>65 years) to 40% in patients on hemodialysis.

Methods: Safety data were pooled from pivotal phase 3 studies comparing roxadustat to placebo in Stage 3-5 non-dialysis-dependent (NDD) CKD patients, and to epoetin alfa in the overall dialysis-dependent (DD) patients, and subgroup of incident-dialysis (ID-DD) patients. Patients with baseline (BL) moderate to severe CHF were not enrolled. CHF hospitalization events were a component of the MACE-plus endpoints that were adjudicated by a blinded independent committee, and analyzed by a Cox proportional hazards regression model; these analyses were not powered for individual component endpoints.

Results: In the pooled NDD studies, 4270 patients were analyzed (2386 roxadustat; 1884 placebo). BL CHF history was comparable between roxadustat (13.0%) and placebo (13.6%) arms. Using ITT long-term follow-up, the HR (95% CI) of hospitalization for CHF among the NDD pooled population was 0.89 (0.72, 1.12) for roxadustat vs placebo. In the pooled DD studies, 3880 patients were analyzed (1940 roxadustat; 1940 epoetin alfa). BL CHF history was comparable between roxadustat (25.7%) and epoetin alfa

(25.3%) arms, and in the incident dialysis (ID-DD) subgroup (≤4 months of dialysis at BL, n=1526) of 26.4 vs 27.0%, respectively. Using on-treatment analysis comparing roxadustat with epoetin alfa in the DD studies, the HR (95% CI) of hospitalized CHF was 0.73 (0.58, 0.94; p=0.013). In the ID-DD subgroup, the HR (95%CI) was 0.77 (0.42, 1.40).

Conclusions: Roxadustat showed a 27% reduction in risk for CHF hospitalization compared to epoetin alfa in the DD population, and a trend based on the point estimates toward reduction of risk compared to placebo in NDD, and to epoetin alfa in ID-DD patients.

Effect of Apabetalone on Major Adverse Cardiovascular Events in Patients with CKD, Diabetes, and Recent Acute Coronary Syndrome: Results from the BETonMACE Trial

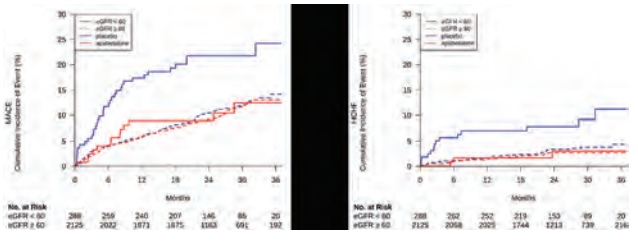
Kamyar Kalantar-Zadeh,[1] Gregory G. Schwartz,[2] Kevin A. Buhr,[8] Henry N. Ginsberg,[7] Jan O. Johansson,[3] Ewelina Kulikowski,[4] Stephen J. Nicholls,[9] Peter P. Toth,[5] Norman C. Wong,[4] Michael Sweeney,[3] Kausik K. Ray.[6] BETonMACE Investigators *[1]University of California Irvine, Irvine, CA; [2]University of Colorado Denver School of Medicine, Aurora, CO; [3]Resverlogix Corp., San Francisco, CA; [4]Resverlogix Corp., Calgary, AB, Canada; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]Imperial Centre for Cardiovascular Disease Prevention, Imperial College London, London, United Kingdom; [7]Columbia University, New York, NY; [8]Statistical Data Analysis Center, University of Wisconsin-Madison, Madison, WI; [9]Monash Cardiovascular Research Centre, Monash University, Melbourne, VIC, Australia.*

Background: Chronic kidney disease (CKD) in type 2 diabetes mellitus (T2DM) patients (pts) is associated with increased cardiovascular disease (CVD) and heart failure risk. We hypothesized that a maladaptive epigenetic response engaging the bromodomain and extraterminal (BET) protein transcription system contributes to excess CVD risk. Hence, the efficacy of BET inhibition (BETi) treatment with apabetalone (APB) was assessed according to presence of CKD in the phase 3 BETonMACE trial.

Methods: BETonMACE compared APB with placebo in 2425 pts with T2DM and recent acute coronary syndrome. The primary outcome was CV death, non-fatal myocardial infarct or stroke (MACE). Hospitalization for congestive heart failure (HCHF) was a secondary endpoint. Both outcomes were evaluated according to the presence of CKD (estimated GFR <60 mL/min/1.73 m2 at baseline).

Results: CKD pts were older (71 vs. 61 years), more likely female (42% vs. 23%) or non-white (18% vs. 12%), had longer duration of diabetes (mean 11.3 vs. 8.2 years) and higher serum alkaline phosphatase (91 vs. 81 U/L), and were less likely to receive metformin (69% vs. 84%) or SGLT2 inhibitors (6% vs. 13%) (P<0.05 for all). Under placebo, risk of endpoints was higher in CKD vs. non-CKD pts [MACE: 35/164 (21.3%) vs.114/1041 (11.0%), HR=2.40, 95% CI [1.67, 3.44]; HCHF: 14/164 (8.5%) vs. 34/1041 (3.3%), HR=3.19, 95% CI [1.66,6.12]; P<0.001 for both). Under APB treatment, pts with CKD had significant reductions in MACE (HR=0.50, 95% CI [0.26, 0.96], P=0.034) and HCHF (HR=0.26, 95% CI [0.07,0.94], P=0.028) vs. placebo, see Kaplan-Meier figures.

Conclusions: CKD patients with T2DM and recent acute coronary syndrome have a high risk of MACE that was substantially reduced with APB BETi in the phase 3 BETonMACE trial.



SA-OR41

Racial-Ethnic and Socioeconomic Disparities in Healthcare Utilization Among Children with Glomerular Disease in the CureGN Project

Jill Krissberg,[1] Margaret Helmuth,[2] Michelle M. O'Shaughnessy.[3] for CureGN *[1]Stanford University School of Medicine, Stanford, CA; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Cork University Hospital Group, Cork, Ireland.*

Background: Inpatient charges for nephrotic syndrome differ across racial-ethnic groups. This study compares rates of ACU (acute care utilization i.e., hospitalization or ED visit) across racial-ethnic groups in children with glomerular disease (GD) and explores demographic, socioeconomic (SE), and disease-related factors that might explain any observed differences.

Methods: CureGN is a multinational prospective cohort study of prevalent patients with GD. We compared patient and disease characteristics at enrollment and rates of ACU during follow-up across racial-ethnic groups. We used multivariable recurrent event proportional rate models to determine rate ratios of ACU, serially adjusting for potential confounders.

Results: In 785 children with GD (median age 11.3 yrs, 58% male, 66% White, 88% residing in US, 51% privately insured, median urine protein/creatinine 0.4g/g, 34% with edema, 39% receiving steroids, 48% receiving other immunosuppression), with a median follow-up of 2.4 yrs, the ACU rate was significantly higher in Black, lower in Asian, and similar in Hispanic, vs. White children (0.85, 0.22, 0.55, and 0.56 events per patient yr, respectively, p<0.001). After multivariable adjustment, poorer SE status and more severe disease explained the excess events observed in Black Children, while an independent association between Asian race-ethnicity and lower rate of ACU was maintained (adjusted RR 0.42, 95% CI 0.25 - 0.72), Table.

Conclusions: The higher rate of ACU observed in Black children with GD enrolled in CureGN was largely explained by poorer SES and more severe disease. Strategies to prevent socioeconomic consequences of GD, or more effectively treat GD, among Black children with GD might begin to target ACU disparities.

Table: Unadjusted and serially adjusted associations between race-ethnicity and rate of hospitalization or ER visit in children with glomerular disease enrolled in CureGN

	Model 1		Model 2		Model 3		Model 4		Model 5

Prevalence of Left Ventricular Hypertrophy in Pediatric Patients on Maintenance Dialysis and After Kidney Transplantation: A NAPRTCS Study

Kyle Merrill,[1] Shirley Galbiati,[2] Mark Mitsnefes.[1,3] on behalf of NAPRTCS Investigators *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]EMMES, Rockville, MD; [3]University of Cincinnati, Cincinnati, OH.*

Background: Left ventricular hypertrophy (LVH) is recognized as the most common cardiovascular complication in children on maintenance dialysis. There have been small single-center, or cross-sectional multi-center studies but there has been no large multi-center studies looking at prevalence of LVH during long-term maintenance dialysis. Using the NAPRTCS database, we determined the prevalence of LVH at time of initiation of maintenance dialysis and changes during long-term dialysis and post kidney transplantation. We also assessed the risk factors associated with LVH in children initiating maintenance dialysis.

Methods: Echocardiographic data were obtained from the NAPRTCS database which initiated collection of echo data in 2013 with the last data obtained in March 2020. LVH was defined as left ventricular mass index (LVMI, height-indexed) >95th percentile for age and sex. Patients with cardiovascular diagnoses, those younger than 1 year old at the time of echocardiography, LVMI values >200 g/m$^{2.7}$, and LVMI values based on outlying heights were excluded from analysis. Multivariable logistic regression to assess risk factors for LVH at baseline (within first 3 months after initiation of dialysis) was performed.

Results: The study cohort included 606 patients between 1 and 18 years of age (median 10y (IQR 3.8-15.1), 53% females, 48% whites, 27% African-American, and 25% others/unknown) who had LVH data during time on dialysis. Of 182 patients who had echocardiography within first 3 months after initiation of dialysis (baseline), 67% had LVH. In logistic regression, hypertension (OR 2.9, 95% CI 1.4-6.3), anemia

(OR 2.8, 95% CI 1.3-6.2), and higher serum phosphorus level (OR 2.4, 95% CI 1.1-5.1) were significantly associated with the presence of LVH at baseline, while adjusting for age, race, and sex. Prevalence of LVH remained about 40-50% during long-term dialysis, with no improvement in LVH seen in patients within 6 months (47%) as well as 12 months post-transplant (43.5%), Table 1.

Conclusions: LVH remains very prevalent, difficult to control in chronically dialyzed children, and persistent after kidney transplantation.

Table 1: Percent with LVH by dialysis and transplant visit

	Baseline (0-3mo.)	6 months	12 months	18 months	24 months	Any Time Post-Dialysis	Post Transplant (<6 months)	Post Transplant (12 ± 3 months)
N	182	183	169	106	83	606	49	46
% with LVH (95% CI)	67 (59.9,73.4)	51.9 (44.7,59)	41.4 (34.3,49)	35.8 (27.4,45.3)	45.8 (35.5,56.4	56.4 (52.5,60.3)	46.9 (33.7,60.6)	43.5 (30.2, 57.8)

Biomarker Panels for Discriminating Risk of CKD Progression in Children

Jason H. Greenberg,[1] Yunwen Xu,[2] Alison G. Abraham,[2] Jeffrey R. Schelling,[3] Harold I. Feldman,[4] Michael Shlipak,[5] Venkata Sabbisetti,[6] Bradley A. Warady,[7] Steven G. Coca,[8] Paul L. Kimmel,[9] Joseph V. Bonventre,[6] Michelle Denburg,[4] Chirag R. Parikh,[2] Susan L. Furth.[4] CKD Biomarker Consortium *[1]Yale University, New Haven, CT; [2]Johns Hopkins University, Baltimore, MD; [3]Case Western Reserve University, Cleveland, OH; [4]University of Pennsylvania, Philadelphia, PA; [5]University of California San Francisco, San Francisco, CA; [6]Brigham and Women's Hospital, Boston, MA; [7]Children's Mercy Hospitals and Clinics, Kansas City, MO; [8]Mount Sinai Health System, New York, NY; [9]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: We used multivariate survival trees to identify plasma and clinical biomarkers to predict CKD progression in children.

Methods: The CKiD study prospectively enrolled children aged 6 months to 16 years old with an eGFR of 30-90 and eGFR was assessed annually. The primary outcome of CKD progression was a composite of 50% decline in eGFR or incident ESKD. We used multivariate survival trees to determine combinations of baseline clinical predictors and plasma biomarkers as well as identify optimal thresholds for predicting the time to the composite event.

Results: Of the 651 children included, median age was 11 years [IQR,8-15], 405(62%) were male, 195(30%) had a glomerular cause of CKD, and baseline eGFR was 53 [IQR,40-67]. 223(34%) out of 651 children reached the primary outcome over a median follow-up time of 5.7 years. The Figure shows the best-sized multivariate survival tree and 4 prognosis groups selected after bootstrapping the sample. Plasma KIM1, TNFR1, TNFR2, and baseline eGFR were used to define branching patterns, while MCP1, YKL40, suPAR and the known risk factors of sex, age, glomerular diagnosis, BMI, hypertension, and proteinuria were not included as they did not reach a level of predictive importance. In the final model, KIM1 was the variable with the highest importance, with a level of 1335 mg/L(98th percentile) determining the first branching split and identifying the highest risk group of 14 children with predominantly glomerular types of kidney disease and nephrotic range proteinuria. When the tree-based prognosis classification was added to the clinical risk factors, the C-statistic increased from 0.81[95%CI:0.78-0.84] to 0.85[95%CI:0.83-0.88].

Conclusions: Using multivariate survival trees we identified a biomarker panel of plasma KIM1, TNFR1, TNFR2 and baseline eGFR which improved discrimination for CKD progression.

Puberty Is Associated with Decline in Estimated Glomerular Filtration Rate in Children with CKD

Hannah Kim,[1] Derek Ng,[1] Matthew Matheson,[1] Meredith A. Atkinson,[1] Yasmin Akhtar,[1] Bradley A. Warady,[2] Susan L. Furth,[3] Rebecca Ruebner.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Children's Mercy Hospitals and Clinics, Kansas City, MO; [3]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Puberty is a high-risk period for decline in kidney function among children with CKD. We aimed to describe changes in eGFR before and after pubertal onset using different objective markers of puberty among children with CKD.

Methods: We conducted a prospective cohort study using data from the Chronic Kidney Disease in Children (CKiD) study. Children who had onset of CKD after pubertal onset were excluded. GFR was estimated annually using the bedside and complete CKiD equations. Pubertal onset was defined by three separate definitions: transition to Tanner Stage 2, peak growth velocity, and menarche. A mixed effects model with random intercept and random slope was used to compare the slope of eGFR before and after pubertal onset. The model was adjusted for age, race, glomerular diagnosis, baseline proteinuria, and BMI.

Results: 339 girls and 552 boys were included; Median age of pubertal onset for girls was 11.0 years (IQR 9.8, 12.1), 14.1 years (IQR 12.4, 17.0), and 14.4 years (IQR 13.1, 15.7) as defined by Tanner stage 2, peak growth velocity, and menarche, respectively. Median age of pubertal onset for boys was 12.4 years (11.3, 13.3) and 14.6 years (IQR 13.4, 16.6) as defined by Tanner stage 2 and peak growth velocity, respectively. Annual percent change in eGFR declined faster among girls and boys after pubertal onset when defined by all measures, after adjustment. For example, annual percent decrease in eGFR was seen to increase from 2.6% prior to 9.0% after Tanner stage 2 in boys using the complete CKiD equation (p<0.001).

Conclusions: Estimated GFR declined faster after the onset of puberty among girls and boys with CKD. Clinicians should be aware that puberty may be an important time of kidney function decline among children with CKD.

Funding: NIDDK Support

CLVS1 H310Y Is a Novel Cause of Familial Childhood Steroid-Sensitive Nephrotic Syndrome

Brandon M. Lane,[1,2] Megan Chryst-Stangl,[2] Guanghong Wu,[2] Mohamed A. Shalaby,[3] Sherif M. El desoky,[3] Jameela A. Kari,[3] Rasheed A. Gbadegesin.[1,2] *[1]Department of Pediatrics, Duke University School of Medicine, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC; [3]King Abdulaziz University Hospital, Jeddah, Saudi Arabia.*

Background: Nephrotic syndrome (NS) is the most common glomerular disease seen in children. It is estimated that up to 30% of steroid resistant NS (SRNS) may be due to mutations in one of sixty genes reported in cohort of patients with familial or idiopathic SRNS. However, the genetic causes of the more common steroid sensitive NS (SSNS) and the molecular basis for variability in glucocorticoid response have remained elusive. Our overarching hypothesis is that single gene causes of SSNS can be identified in cohorts of sibling pairs with SSNS and identification of such genes can provide insight into the molecular basis of glucocorticoid response.

Methods: To identify single gene causes of SSNS in a cohort of patients with familial SSNS and examine the molecular basis of glucocorticoid response, we carried out whole genome sequencing in forty families with hereditary SSNS. After identifying a potential disease-causing variant, we examined the effects of loss of gene function in cultured human podocytes through the creation of lentiviral shRNA knockdown and CRISPR-Cas9 knockout cell lines as well as morpholino-based gene knockdown in zebrafish.

Results: We identified a rare homozygous variant, *CLVS1 H310Y*, that segregates with disease in a consanguineous family with two affected siblings and a cousin. *CLVS1* encodes clavesin1, a component of clatherin mediated endocytosis. This variant was not present in a homozygous state in >200,000 chromosomes and is predicted to be pathogenic by *in silico* analyses. Morpholino knockdown of the orthologous *CLVS1* gene in zebrafish resulted in edema phenotypes indicative of loss of glomerular filtration barrier (GFB) integrity. This edema phenotype could be rescued with wildtype human *CLVS1* mRNA but not the *H310Y* variant. Knockdown of *CLVS1* in cultured human podocytes as well as overexpression of the *H310Y* variant in HEK 293 cells decreased endocytosis of fluorescently labeled dextran and increased susceptibility to apoptosis. These aberrant podocyte phenotypes could be rescued in the presence of glucocorticoid, mimicking the steroid responsive phenotype in patients bearing the *CLVS1 H310Y* variant.

Conclusions: We identified a mutation in *CLVS1* as a new cause of hereditary SSNS. Our data demonstrates the requirement of functional *CLVS1* in the maintenance of podocyte viability and GFB integrity.

Cross-Talk Between Neutrophils and Macrophages Dictates the Outcome of Acute Pyelonephritis

Juan de Dios Ruiz-Rosado, Hanna H. Cortado, John D. Spencer, Brian Becknell, Santiago Partida-Sanchez. *Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Pediatric urinary tract infections (UTI) account for 1.5 million clinician visits annually in the United States. Uropathogenic *Escherichia coli* (UPEC) causes over 80% of UTIs. Up to 50% of infants with a UTI develop a kidney infection (acute pyelonephritis, APN). Despite prompt diagnosis and treatment with appropriate antibiotics, a population of children with APN develops renal scarring, which can lead to kidney injury and renal dysfunction. The cellular immune mechanisms underlying renal scarring after an APN episode remain incompletely understood. In this study, we determined the contribution of neutrophils and monocytes to the development of kidney pathology following experimental APN.

Methods: C3H/HeOuJ female mice were treated with monoclonal antibodies to deplete neutrophils (anti-Ly6G), monocytes (anti-CD115), or both neutrophils and monocytes (anti-Gr1). After cell depletion, the animals were transurethrally infected with UPEC strain CFT073. Bacterial ascent was assessed via biophotonic imaging and quantification of bacterial burden in the kidney. The cell dynamics of monocytes and neutrophils were determined by flow cytometry and immunofluorescence microscopy. Renal inflammation and fibrosis were assessed by H&E and Sirius-Red, respectively. Transcriptomic analyses of infected kidneys were performed using TaqMan Arrays.

Results: Our data indicate that neutrophils, not monocytes, are required to prevent widespread UPEC dissemination during APN. In contrast, monocyte-derived macrophages promote bacterial dissemination and induce an early inflammatory response upon UPEC infection. Exacerbated, macrophage-dependent inflammation during APN leads to increased renal abscess formation, tubular injury, renal fibrosis, and azotemia.

Conclusions: While highlighting the essential antimicrobial role for neutrophils, our findings point to a novel detrimental function for macrophages during APN, and the potential utility of macrophage targeted therapies to reduce long-term sequelae following APN.

Proliferation Control of Interstitial Cells in the Neonatal Kidney

Leif Oxburgh. *The Rogosin Institute, New York, NY.*

Background: Expansion of interstitial cells in the adult kidney is a hallmark of chronic disease, whereas their proliferation during fetal development is necessary for organ formation. An intriguing difference between adult and neonatal kidneys is that the neonatal kidney has the capacity to control interstitial cell proliferation when the target number has been reached. In this study, we define the consequences of inactivating the TGFb/Smad response on proliferation control of the renal interstitium in the neonatal mouse.

Methods: Smad4 was inactivated using the Foxd1cre mouse strain, which is specifically expressed in interstitial progenitor cells in the developing kidney. Loss of Smad4 in interstitial cells was confirmed by single cell genotyping and immunostaining. Interstitial cell lines with tamoxifen-inducible loss of Smad4 were generated from primary interstitial cells for molecular interaction studies.

Results: We find that loss of *Smad4* leads to over-proliferation of interstitial cells regionally in the kidney medulla. Analysis of signaling pathway markers in tissue showed that activation of Smad3 is deficient, whereas activation of Smad1/5 is largely unaffected, indicating an effect specifically on TGFb signaling. Genetic and molecular interaction studies showed that Smad3/4 participates in the Wnt/b-catenin signaling pathway in interstitial cells, which is responsible for promoting their proliferation. Specifically, *Smad4* is required for the expression of the Wnt feedback inhibitor *Apcdd1*.

Conclusions: Based on these findings, we propose a model for interstitial cell proliferation control in which the Wnt/b-catenin proliferative signal is attenuated by TGFb/Smad signaling to ensure that proliferation ceases when the target number of interstitial cells has been reached in the neonatal medulla.

Single-Cell Resolution Regulatory Landscape of the Kidney Highlights Cellular Differentiation Programs and Renal Disease Targets

Zhen Miao, Michael S. Balzer, Ziyuan Ma, Hongbo Liu, Junnan Wu, Katalin Susztak. Susztak Lab *University of Pennsylvania, Philadelphia, PA.*

Background: The kidney cells undergo complex differentiation during development, among which the nephron progenitors differentiate to more than 10 different epithelial cells. However, the driver pathways, cell type specific transcription factors and regulatory circuits are not fully understood.

Methods: Here we conducted single-nucleus ATAC sequencing (snATAC-seq) and single cell RNA-sequencing (scRNA-seq) of kidneys from developing and adult mice. After quality control, we obtained 66,254 scRNA-seq and 28,316 snATAC-seq profiles.

Results: Through clustering analysis, we identified all major cell types in the kidney. By integrating snATAC-seq and scRNA-seq data, we revealed cell type- and developmental stage-specific cis-regulatory elements and inferred promoter-enhancer regulatory units. We defined key cell identity TFs and their gene targets through co-expression patterns. To study cell-type specification of renal epithelial cells, we conducted trajectory analysis and resolved the developmental pseudotime along cell differentiation from nephron progenitors. We show that early differentiation of podocytes from the nephron progenitor pool is associated with sustained *Foxl1* expression. Differentiation of renal tubule cells followed a more complex pattern, where *Hfn4a* expression is associated with a more proximal fate, while *Tfap2b* is coupled to the distal tubule differentiation. After cell specification, terminal differentiation was strongly linked to metabolic nuclear receptors such as *Essra* and *Ppara* for proximal tubules and *Esrrb* and *Ppargc1a* in loop of Henle. We also implemented snATAC-seq data to leverage our understanding of human kidney disease development. By overlapping the chromatin landscape with kidney disease GWAS signals, we inferred key cell types for GWAS loci in the proximity of *Shroom3* and *Dab2* genes. Interestingly, we observed that some kidney disease-associated loci, such as those in the vicinity of *Uncx*, are only accessible in the developing kidney cells, indicating a developmental stage regulatory role of genetic variants.

Conclusions: Here we present a comprehensive open chromatin and gene expression landscape for developing mouse kidney and illustrate the use of single-cell multi-omics data to study gene regulatory dynamics and its relationship to complex human disease genetics.

Expansion of Human Induced Pluripotent Stem Cell-Derived Ureteric Bud Organoids with Repeated Branching Potential

Makoto Ryosaka, Shin-ichi Mae, Kenji Osafune. *Center for iPS Cell Research and Application (CiRA), Kyoto University, Kyoto, Japan.*

Background: The mammalian adult kidney, metanephros, develops by the reciprocal interaction between two embryonic progenitor tissues, metanephric mesenchyme and ureteric bud (UB). UB has epithelial polarity and tubular lumens, consists of two domains, the tip and trunk, and repeats branching morphogenesis. The tip cells produce both new tip and trunk cells that further differentiate into collecting ducts (CDs). Recently, we reported a stepwise protocol to induce human induced pluripotent stem cells (hiPSCs) and embryonic stem cells (hESCs) into UB-like structures through anterior intermediate mesoderm. However, the generation of hiPSC/ESC-derived UB-like tissues that show tubular lumens or sufficient branching has not been achieved.

Methods: We established a novel method to induce hiPSCs to differentiate into induced UB (iUB) organoids. We evaluated our iUB organoids using immunostaining and single cell RNA sequencing analysis.

Results: Our iUB organoids showed RET^+ tip and $CK19^+$ trunk domains, epithelial polarity, tubular lumens and developmental potential to repeat branching morphogenesis. The isolated tip regions from the iUB organoids showed repeated branching to reconstitute the iUB organoids. We also succeeded in establishing *in vitro* monitoring and expansion methods for tip cells that can efficiently reconstitute iUB organoids and differentiate into CD progenitors. In addition, we confirmed that our iUB organoids recapitulate *in vivo* development accompanied by spatiotemporal regulation of the gene network by high-resolution transcriptome analysis using single cell RNA sequencing, which showed the reciprocal expression of UB tip and trunk markers.

Conclusions: Our induction method for iUB organoids will help elucidate the developmental mechanisms of UB branching and develop a selective differentiation method for CD cells, contributing to the creation of disease models for congenital renal abnormalities.

Rhesus Macaque Serves as a Model for Human Lateral Branching Nephrogenesis

Meredith P. Schuh, Lyan Alkhudairy, Andrew Potter, Steven Potter, Kashish Chetal, Nathan Salomonis, Raphael Kopan. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Premature infants are at risk for chronic kidney disease later in life due to low nephron endowment. Lateral branching nephrogenesis (LBN), not occurring in the mouse, is a poorly understood but critical period of human nephrogenesis. Here, we analyze third trimester LBN in the rhesus macaque at the molecular and morphological level.

Methods: The morphology of third trimester rhesus kidneys was assessed by immunostaining after tissue clearing. 3D renderings were created using Bitplane Imaris. Single-cell RNA sequencing (scRNA-seq) and single-nucleus RNA sequencing (snRNA-seq) were performed on 4 kidneys from 4 rhesus using cold protease digestion and 10xGenomics platform. Unsupervised analyses using ICGS2 were used to identify distinct cell populations and GO-Elite was used to compare rhesus with human and mouse datasets.

Results: The gestational period of the rhesus lasts 165 days. We determined that cessation of rhesus nephrogenesis occurs between 136- and 138-days gestational age (GA). LBN was observed along the ureteric stalks at 126-138 days GA. We noted rosette-like patterns of ureteric tips and nephron progenitor cells (NPC) in both rhesus and human third trimester archival samples. scRNA-seq was performed on 4 cortically enriched rhesus samples 129-131 days GA revealing 37 transcriptionally distinct cell clusters. C25 was predicted to contain the naïve NPCs and included CITED1, MEOX1, and EYA1. snRNA-seq yielded 5,972 nuclei, corresponding to 29 ICGS2 clusters. We found a single cluster (c26), with a near identical GO-Elite enrichment profile to that the naïve NPC scRNA-seq cluster (c25). snRNA-seq c26 contained many unique markers not found in the matching scRNA-seq c25 (e.g., BMPER, DPP6, KIRREL3). GO-ELITE showed that late-gestation rhesus NPC markers more closely aligned to late-gestation murine NPCs, whereas the 2nd trimester human NPCs more closely aligned to mid-gestation murine NPCs. Novel surface markers predicted in the rhesus include CACNA1E, KIRREL3, and KCNB2.

Conclusions: The rhesus is the first animal model to demonstrate LBN, suggesting that LBN is conserved in old world primates. We identified novel genes upregulated during LBN and surface markers that could be used during cell-sorting. snRNA-seq of naïve NPC nascent transcripts may provide mechanistic insights that would otherwise be missed.

Keap1 Gene Edited T Cells Using CRISPR/Cas9 Improve Outcomes from Experimental AKI

Johanna T. Kurzhagen, Sanjeev Noel, Somayeh Gharaie fathabad, Mohanraj Sadasivam, Sul A Lee, Jing Gong, Lois J. Arend, Abdel Hamad, Hamid Rabb. *Johns Hopkins Medical Institutions Campus, Johns Hopkins Medicine, Baltimore, MD.*

Background: T cells have been demonstrated to modulate responses in ischemic AKI, and *Keap1/Nrf2* pathway regulates T cell functions. We hypothesized that using the gene editing technique CRISPR/Cas9 could set the stage for T cell therapy for human AKI. We therefore edited *Keap1* gene in murine CD4 T cells using CRISPR technology and tested its effects in an ischemic AKI model.

Methods: Primary CD4 T cells isolated from spleen of WT mice were used for *ex vivo* CRISPR/Cas9 mediated *Keap1* editing. Control CD4 T cells were electroporated without sgRNA and Cas9. *Keap1* editing was confirmed by sequencing, qRT PCR of *Nrf2* target genes and immunophenotyping using flow cytometry. *Keap1* edited CD4 T cells were studied under hypoxic or normoxic conditions *in vitro*. For *in vivo* studies, *Keap1* edited or control CD4 T cells were adoptively transferred into T cell deficient nu/nu mice (n=6-8/group). Mice were subjected to bilateral IR surgery, serum creatinine, histology, kidney immune cell trafficking and cytokine production were measured.

Results: *Keap1* editing resulted in significant increase in *Nrf2* targets *Nqo1* (8.5-fold), *Hmox1* (4.4-fold) and *Gclc* (2-fold) mRNA. *Keap1* edited CD4 T cells displayed higher expression of *Hif1a* mRNA than control cells in hypoxic conditions (1.5-fold, p=0.02). *Ifng* mRNA expression was significantly decreased in *Keap1* edited cells compared to control cells under normoxic (0.4-fold, p=0.04) or hypoxic (0.6-fold, p=0.01) conditions. nu/nu mice that received *Keap1* edited CD4 T cells showed significantly reduced SCr (0.55±0.05mg/dl vs 1.14±0.19mg/dl, p=0.05) at 24h compared to mice that received control cells. They also had significantly reduced percentage of necrotic tubules (40±16% vs 63±15%, p=0.055). Kidney *Keap1* edited CD4 T cells had significant reduction in TNFα protein expression (43±9% vs 54±7%, p=0.03) compared to control cells post IRI. Kidney CD4 IFN-γ (p=0.16), CD25 (p=0.16) and CD69 (p=0.46) expression was similar in *Keap1* edited and control cells.

Conclusions: CRISPR/Cas9 mediated *Keap1* editing increases murine CD4 T cell *Nrf2* regulated antioxidant gene expression and modifies responses to *in vitro* hypoxia. Adoptive transfer of *ex-vivo Keap1* edited CD4 T cells ameliorates ischemic AKI in mice. These results are important to set the stage for T cell-based therapy for AKI in humans.

Cyclin G1/CDK5-Mediated Dedifferentiation of Proximal Tubular Cells Drives AKI-to-CKD Transition

Kensei Taguchi, Bertha C. Elias, Craig R. Brooks. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Acute kidney injury (AKI) is associated with increased morbidity and mortality in hospitalized patients and predisposes patients to chronic kidney disease (CKD). While kidney cells, particularly proximal tubule cells (PTCs), can undergo dedifferentiation, proliferation, and re-differentiation to facilitate kidney repair after injury, maladaptive repair resulting in prolonged dedifferentiation of PTCs drives fibrosis. We have found that cyclin G1 (CG1), an atypical cyclin, not only promotes G2/M cell cycle arrest, but also regulates dedifferentiation of PTCs. The aim of the current study is to determine if CG1 regulates dedifferentiation through its cyclin dependent kinase, CDK5.

Methods: 1; Aristolochic acid nephropathy (AAN) was induced by administration of three doses of AA in 8 to 12-week-old male wild-type (WT) and CG1 globally knockout mice (CG1KO). 2; Unilateral ureteral obstruction (UUO) was performed and kidneys were harvested on day 9. 3; To determine the interacting partners of CG1, immunoprecipitation (IP) was performed in CG1-overexpressing LLC-PK1 cells treated with AA. 4; To examine the pathological role of CDK5, LLC-PK1 cells or primary PTCs with or without siRNA or pharmacological inhibitors of CDK5 were treated with AA.

Results: CG1 was rapidly upregulated in PTCs in response to kidney injury and remained high in chronic phase following AAN and UUO. Kidney fibrosis and markers of dedifferentiation, such as SOX9, Vimentin, and Snail, were reduced in CG1KO animals following AAN and UUO injuries, compared to WT. IP demonstrated that CG1 binds to p53, mouse double minute 2 homolog (MDM2), and CDK5. Of these, the interaction of CG1 activates CDK5 and translocates the complex into nuclei. Phosphorylation of CDK5 in response to injury was reduced by genetic ablation of CG1. Genetic or pharmacological inhibition of CDK5 preserved E-cadherin in AA-induced cellular injury with reduction of profibrotic markers; however, it showed no additional effect in CG1KO PTCs.

Conclusions: CG1 partnering with CDK5 drives a maladaptive dedifferentiation of PTCs after kidney injury, resulting in increased secretion of profibrotic cytokines and progression of fibrosis. As CG1 is highly expressed in injured PTCs, it represents a potential therapeutic target for prevention of kidney fibrosis.

Incorporation of Urine-Derived Stem Cells into Kidney Organoids Derived from Human Induced Pluripotent Stem Cells

Julie Bejoy, Richard C. Welch, Lauren E. Woodard. Woodard Lab *Vanderbilt University Medical Center, Nashville, TN.*

Background: Donor-derived somatic cells or stem cells can be differentiated into renal cell types for disease modeling, drug screening, or therapeutic studies. Modeling of kidney disease with kidney organoids derived from human induced pluripotent stem cells (hiPSCs) has been termed a "kidney in a dish." The recent advances in stem cell-based therapies have shown great promise for the treatment of kidney injuries. To evaluate the therapeutic properties, we studied the incorporation of urine-derived stem cells (USCs) into a kidney organoid model of acute kidney injury. UCSs are viable cells from urine which can be expanded *in vitro* for more than ten passages. There is evidence suggesting that USCs are most likely cultured glomerular parietal epithelial cells.

Methods: For this project, we cultured kidney organoids from fibroblast-derived hiPSCs by the established protocol from Takasato and Little, following optimization. Co-culturing of USCs labeled with a membrane dye and Day 25 kidney organoids revealed that USCs incorporated into the organoids efficiently within two days of the co-culture. For injury models, we established nephrotoxicity in the proximal tubule by adding the nephrotoxic drug Cisplatin (5 μm) at Day 21 of kidney organoid culture.

Results: The kidney organoids derived form IPSCs expressed the kidney cell type markers ECAD (distal tubule), GATA3 (collecting duct), LTL (proximal tubule) and NEPHRIN (Glomeruli) at Day 21. The organoids were then treated with 5 x 10^4 USCs at Day 22 for 48 hours and evaluated for the expression of kidney injury molecule-1 (KIM-1). Immunostaining revealed that KIM-1 expression was significantly reduced in the organoids treated with USCs compared to the organoids without USCs, suggesting a positive therapeutic impact of USCs. We are currently performing RNAseq on three sets of whole kidney organoids (Control, +Cisplatin, +Cisplatin+USC) to provide detailed interrogation of cellular apoptosis and related signaling pathways in these three different sets of organoids.

Conclusions: The ability of USCs to reduce KIM-1 expression in human kidney organoids suggests that further investigation into the therapeutic potential of USC for treatment of acute kidney injury is warranted.

Supramolecular Nanofibers Containing Arginine-Glycine-Aspartic Acid (RGD) Boost Therapeutic Efficacy of Extracellular Vesicles in Kidney Repair

Chuyue Zhang,[1,2] Jie Wu,[1] Lingling Wu,[1] Xiangmei Chen.[1,2] *[1]Chinese PLA General Hospital, Beijing, China; [2]Nankai University, Tianjin, China.*

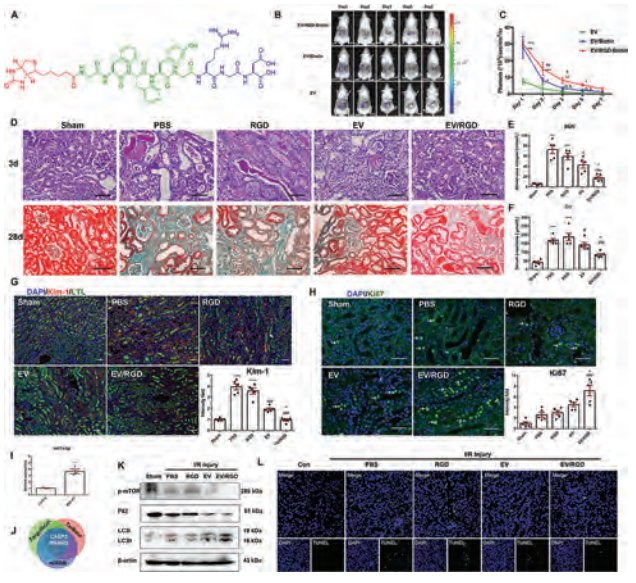
Background: Extracellular vesicles (EVs) derived from mesenchymal stem cells (MSC-EVs) have been recognized as a promising cell-free therapy for acute kidney injury (AKI), which avoids safety concerns associated with direct cell engraftment. However,

low stability and retention of MSC-EVs have limited their therapeutic efficacy. RGD peptide binds strongly to integrins, which have been identified on the surface of MSC-EV membranes, yet RGD has not been applied to EV scaffolds to enhance and prolong bioavailability.

Methods: Here, we developed RGD hydrogels, which we hypothesized could augment MSC-EV efficacy against AKI.

Results: *In vivo* tracking of the EVs revealed that RGD hydrogels increased retention and stability of EVs. Upon intrarenal injection, EV-RGD hydrogels provided superior rescuing effects at functional, histopathological and molecular levels. Further analysis revealed that the presence of microRNA let-7a-5p in MSC-EVs served as a novel mechanism contributing to the reduced cell apoptosis and elevated cell autophagy in AKI.

Conclusions: RGD hydrogels boosted the therapeutic efficacy of let-7a-5p-containing-EVs in AKI repair. This study developed an RGD-scaffold to increase the EV integrin-mediated loading and in-turn improved therapeutic efficacy, therefore this strategy shed light on MSC-EVs application as cell-free treatment for potentiated efficiency.



RGD Hydrogels Boost Therapeutic Efficacy of Extracellular Vesicles in Kidney Repair. (A) The structure of the hydrogels. (B-C) RGD hydrogels enhanced the stability and retention of EVs. (D-H) RGD hydrogels improved the therapeutic efficacy of EVs at functional, histopathological and molecular levels. (I-L) Underlying mechanisms of let-7a-5p-containing-EVs protected against AKI.

Pannexin 1 Channel Regulates Mitochondrial Function and Cell Survival During AKI

Nabin Poudel,[1] Colleen Schinderle,[1] Nataliya Skrypnyk,[1] Christopher B. Medina,[2] Diane L. Rosin,[1] Kodi S. Ravichandran,[2] Mark D. Okusa.[1] Center for Immunity, Inflammation and Regenerative Medicine (CIIR), University of Virginia *[1]Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Microbiology, Immunology, and Cancer Biology, University of Virginia, Charlottesville, VA.*

Background: Pannexin 1 (Panx1) is a membrane associated non-selective channel that, when activated, serves as a conduit for release of small metabolites that have pro- or anti-inflammatory function. We have previously shown that pharmacological inhibition or genetic deletion of *Panx1* in mice prior to injury is protective against renal ischemia-reperfusion injury (IRI). How Panx1 contributes to acute kidney injury (AKI) pathology is unknown. We hypothesized that Panx1 induces cell death by mediating both intracellular and extracellular events.

Methods: We subjected a novel human Panx1 overexpressing mouse (*hPANX1*-Tg) to IRI or cisplatin-mediated AKI and assessed plasma creatinine and renal expression of neutrophil gelatin associated lipocalin (*Ngal*). For *in vitro* studies, *PANX1* overexpressing TKPTS cells (OX) were challenged with cisplatin. Cell death was assessed by flow cytometry using Annexin-V/7AAD. Mitochondrial function was assessed by measuring oxygen consumption rate, mitochondrial membrane potential and ROS production. mRNA expression was measured using real-time PCR.

Results: *hPANX1-Tg* mice had significant rise in plasma creatinine and expression of *Ngal* in the kidneys in both models of AKI compared to their littermate controls. Cisplatin-induced cell death was greater in OX cells compared to control cells. Moreover, cisplatin induced greater death in OX cells than control cells when cultured together. Among genes involved in the cell death pathway, OX cells had reduced expression of *Bcl2* and a greater increase in *Ho-1* after cisplatin exposure. Assessment of mitochondria showed that OX cells had reduced mitochondrial DNA, *Pgc1a* expression, and mitochondrial respiration at baseline, a greater reduction in mitochondrial function and a higher increase in mitochondrial ROS production after cisplatin exposure compared to controls.

Conclusions: Our data demonstrate that PANX1 overexpression results in overt renal injury during AKI that is in part mediated by reduced mitochondrial function and in part by metabolites released via Panx1 channels, which facilitates cell death. These results complement our prior studies demonstrating that Panx1 deficiency protects kidneys from IRI and provide strong rationale for the development of selective strategies to inhibit Panx1 in the prevention or treatment of AKI.

Targeting Angiopoietin-Tie2 Signaling in Kidney Ischemia-Reperfusion Injury

Yanyang Li,[1] Tuncer Onay,[1] Pan Liu,[1] Michael Ryczko,[2] Mohammed Javeed Ansari,[1] Jing Jin,[1] Susan E. Quaggin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Mannin Research Inc, Toronto, ON, Canada.*

Background: The endothelial angiopoietin (ANG)–Tie2 signaling pathway is required for vascular development and homeostasis. Dysregulation of ang-Tie2 pathway has been implicated in diseases including venous malformation, glaucoma, diabetic nephropathy, and septic acute kidney injury (AKI). The endothelial-specific phosphatase VE-PTP/PTPRB is a negative regulator of Tie2 phosphorylation. Here we investigate the therapeutic roles of Angiopoietin/Tie2 signaling in kidney ischemia-reperfusion injury (IRI).

Methods: A bitransgenic doxycycline-inducible system (Veptp$^{flox/flox}$, Rosa26-rtTA$^{+/+}$, tetO-Cre$^{Tg/+}$) was used to knockout VE-PTP at postnatal day 0 (VE-PTPiKO). Adult male VE-PTPiKO and littermate control mice underwent bilateral IRI or sham surgery. Serum creatinine was measured on day1, day3 and day7 after surgery by HPLC method. Data were analyzed using two-way ANOVA. Tissues were harvested on day 7 for histology, immunohistochemistry and RNA/protein analysis. Bulk RNAseq was performed with RNA extracted from whole kidney 5 hours after IRI. Normalization and differential expression were determined using DESeq2. For pharmacological studies, adult male C57BL/6J mice were used. A new soluble ANGPT1 mimetic (C4BP-ANG1) or vehicle were administered by intraperitoneal injection.

Results: Western blot analysis showed VE-PTP protein levels were increased in kidneys post-IRI and following hypoxia-inducible factor stabilization. Genetic deletion of VE-PTP rescued declined Tie2 phosphorylation in kidney after IRI. While serum Creatinine was elevated 1day post-IRI in control mice, this increase was minimal in VE-PTP iKO mice (p=0.0055). Global gene expression analysis indicated minimal kidney transcriptome change at base line whereas in the setting of IRI, VEPTPiKO mice showed a less activated renal endothelium and downregulation of acute stress response gene signature. A corresponding decrease in pro-fibrotic genes was observed in VE-PTPiKO mice on day7. In the pharmacological study, systemic administration of C4BP-ANG1 activated Tie2 and its downstream AKT/eNOS/NO pathways in mouse kidney in physiological condition. Ongoing studies are analyzing its protective effect in ischemic AKI.

Conclusions: Our data provide evidence for augmenting Tie2 activation-induced vascular protection as a promising therapeutic strategy for renal protection following IR-AKI.

Exosome-Based Delivery of Super-Repressor IκBα Ameliorates Kidney Ischemia-Reperfusion Injury

Sul A Lee,[1,2] Seonghun Kim,[3] Jimin Park,[2] Boyoung Nam,[2] Jung Tak Park,[2] Seung Hyeok Han,[2] Shin-Wook Kang,[2] Tae-Hyun Yoo.[2] *[1]Metrowest Medical Center, Framingham, MA; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [3]Yonsei University Dental Hospital, Seoul, Republic of Korea.*

Background: Ischemia-reperfusion (IR) injury (IRI) is a major cause of acute kidney injury (AKI). Recent studies on the pathophysiology of IR-induced AKI showed that immunologic responses significantly affect renal IRI and repair. Nuclear factor (NF)-κB signaling, which controls cytokine production and cell survival, is significantly involved in IR-induced AKI; its inhibition can ameliorate ischemic AKI. We assessed whether the systemic delivery of the NF-κB inhibitor using exosomes could alleviate the course of ischemic AKI.

Methods: Using EXPLOR, a novel, optogenetically engineered exosome technology, we successfully delivered the exosomal super-repressor inhibitor of NF-κB (Exo-srIκB) into B6 wildtype mice before/after kidney IR surgery, and compared outcomes with those of the control exosome (Exo-Naïve)-injected group. To better understand the protective mechanism of Exo-srIκB in renal IRI, the expression of pro-inflammatory cytokines/chemokines and adhesion molecules and the level of apoptosis were measured using quantitative real-time PCR (qRT-PCR), enzyme-linked immunosorbent assay, western blot, and immunohistochemical/immunofluorescent (IF) staining. Immune cell populations of post-ischemic kidneys and spleens were analyzed using flow cytometry and IF staining.

Results: Exo-srIκB treatment resulted in lower levels of serum blood urea nitrogen (BUN), creatinine, and neutrophil gelatinase-associated lipocalin (NGAL) in post-ischemic mice than in the Exo-Naïve treatment group (24-h/48-h BUN, creatinine, and NGAL, $P < 0.001$). Systemic delivery of Exo-srIκB decreased NF-κB activity in post-ischemic kidneys, leading to reduced apoptosis levels. Post-ischemic kidneys showed decreased gene expression of pro-inflammatory cytokines and adhesion molecules with

Exo-srIκB treatment as compared with the control. Exo-srIκB treatment also significantly affected post-ischemic renal immune cell populations, lowering neutrophil, monocyte/macrophage, and T cell frequencies than those in the control.

Conclusions: Thus, the modulation of NF-κB signaling through exosomal delivery can be used as a novel therapeutic method for IR-induced AKI.

Enhancer and Super-Enhancer Dynamics in Repair After Ischemic AKI

Julia Wilflingseder,[1,2] Michaela Willi,[2] Hye kyung Lee,[2] Hannes Olauson,[3] Jakub Jankowski,[4,2] Takaharu Ichimura,[1] Reinhold Erben,[4] M. Todd Valerius,[1] Lothar Hennighausen,[2] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital, Renal Division, Harvard Medical School, Boston, MA; [2]Laboratory of Genetics and Physiology, National Institute of Diabetes, Digestive and Kidney Diseases, US National Institutes of Health, Bethesda, MD; [3]Division of Renal Medicine, Department of Clinical Sciences, Intervention and Technology, Stockholm, Sweden; [4]University of Veterinary Medicine, Department of Physiology, Pathophysiology and Endocrinology, Vienna, Austria.*

Background: The endogenous repair process of the mammalian kidney allows rapid recovery after acute kidney injury (AKI) through robust proliferation of tubular epithelial cells. There is currently limited understanding of which transcriptional regulators activate these repair programs. Here we investigate the existence of enhancer and transcription factor dynamics in the regenerating mouse kidney.

Methods: RNA-seq and ChIP-seq (H3K27ac, H3K4m3, BRD4, BRD2, BRD3, Pol II, HNF4A, GR, STAT3 and STAT5) were performed on samples from repairing kidney cortex 2 days after ischemia/reperfusion injury (IRI) to identify activated genes, transcription factors, enhancer and super-enhancers associated with kidney repair. Furthermore we investigated the role of enhancer dynamics in kidney repair through pharmacological BET inhibition using the small molecule JQ1 in AKI models in vivo.

Results: Response to injury leads to genome-wide alteration in enhancer repertoire *in*-vivo. We identified 16,781 enhancer and 380 super-enhancer sites (H3K27ac and BRD4 positive) with dynamic binding in SHAM and IRI samples; 6,512 enhancer, 164 super-enhancer lost and 9,774 enhancer, 214 super-enhancer gained after IRI. The lost and gained enhancer sites can be annotated to 62% and 63% of down- and up-regulated transcripts after AKI, respectively. ChIP-seq profiles of predicted transcription factors show specific binding at corresponding enhancer sites with dynamic binding of HNF4A, GR and STAT3. HNF4A and GR show a reduced binding at enhancer and super-enhancer sites after injury, whereas STAT3 binding can be observed at injury gained enhancer and super-enhancer sites. BET (BRD4) inhibition before IRI leads to suppression of 40% of injury-induced transcripts associated with cell cycle regulation, genome-wide Pol II pausing and significantly increased mortality after AKI.

Conclusions: This is the first demonstration of enhancer and super-enhancer and transcription factor binding dynamics in the repairing kidney. In addition, our data call attention to potential caveats for use of BET inhibitors that are currently being tested in clinical trials. Understanding of enhancer dynamics after kidney injury in vivo has the potential to lead to indentification of new targets for therapeutic intervention.

Developmental Reprograming of Kidney Resident Macrophages During Human AKI and Its Implications to CKD

Abolfazl Zarjou,[1] Elias Mrug,[1] Kurt Zimmerman,[4] Jiandong Chen,[3] David K. Crossman,[1] Frida Rosenblum,[1] Phillip H. Chumley,[1] Juling Zhou,[1] Anupam Agarwal,[1,2] James F. George,[1] Bradley K. Yoder,[1] Xiangqin Cui,[3] Michal Mrug.[1,2] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Department of Veteran Affairs Medical Center, Birmingham, AL; [3]Emory University, Atlanta, GA; [4]The University of Oklahoma, Norman, OK.*

Background: Kidney tissue-resident macrophages (KRM) promote naturally progressing or AKI-induced cystic renal disease in mice. AKI also reprograms KRM into an early development state in mice. The relevance of KRM to human AKI and chronic kidney disease (CKD) remains mostly elusive.

Methods: We characterized KRM expression in renal biopsies and urine sediment from patients with AKI and non-AKI controls using a 255 gene Nanostring Inflammation panel. We mapped differentially expressed genes to single-cell RNA sequencing (scRNAseq) data from the Mouse Cell Atlas. We identified candidate injury-induced KRM markers and supported their validity in several available gene expression AKI- and CKD-relevant datasets (using limma package empirical Bayes smoothing in R).

Results: Both acute interstitial nephritis (AIN) and acute tubular necrosis (ATN) trigger transcriptional changes in similar genes (more prominently in AIN despite higher serum creatinine in ATN). Mapping of these AKI-regulated genes to normal adult kidney single scRNAseq data revealed the best fit for cell clusters defined by transcriptional signatures of KRMs. Such a fit was even stronger when the AKI-regulated genes were mapped to fetal kidney scRNAseq data. A similar fit was obtained by analyses of bulk RNAseq data of urine sediment from patients with AKI. Based on the strength of these associations, we prioritized *C1qa*, *C1qb*, *C3ar1*, *Tlr1*, *Itgb2*, *Ccr7* and *Ifit1* as transcriptional signatures of injury-induced KRMs. We validated the relevance of these candidate markers to the following: renal aging, protective effects of caloric restriction, and drug-induced forms of AKI in mice, pre-cystic kidney milieu in the model of polycystic kidney disease in a rat, and CKD including focal segmental glomerulosclerosis in human patients.

Conclusions: Together, we point to a KRM-like transcriptional response as a hallmark feature of AKI and CKD across species. The better fit of this response to fetal scRNAseq data supports the AKI-induced developmental reprogramming in human kidneys. A similar pattern of these responses in kidney tissues and urine cells points to urine-derived KRM assessment as an alternative to renal biopsies.

Endothelial-Derived miR-17~92 Promotes Angiogenesis to Protect Against Renal Ischemia-Reperfusion Injury

Takuto Chiba, Jacqueline Ho, Sunder Sims-Lucas. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: Acute kidney injury (AKI), resulting from renal ischemia reperfusion injury (IRI) among others, is an independent predictor of morbidity and mortality, and is identified in as many as 50% of ICU patients. Damage to the renal microvasculature is a hallmark of renal IRI. miR-17~92 encodes 6 polycistronic microRNAs that show potent pro-angiogenic capacity by targeting anti-angiogenic factors. The function of miR-17~92 in renal microvasculature after renal IRI remains unknown.

Methods: Antibodies bound to magnetic beads were utilized to selectively enrich for renal endothelial cells from mice. Endothelial-specific miR-17~92 knockout (miR-17~92endo-/-) mice were generated and a renal IRI model was performed. Mice were monitored for the development of AKI using serum chemistries and tissue analysis, and for renal blood flow using a magnetic resonance imaging (MRI). Mice were treated with miRNA mimics during renal IRI to test its therapeutic efficacies.

Results: we demonstrate that miRs-17, -18a, -20a, and -19b are up-regulated in renal endothelial cells after renal IRI in mice. miR-17~92endo-/- exacerbates ischemic AKI in male and female mice. Specifically, miR-17~92endo-/- promotes renal tubular injury, reduces renal blood flow, promotes microvascular rarefaction, increases renal oxidative stress and promotes macrophage infiltration to injured kidneys. The potent anti-angiogenic factor, thrombospondin 1 (TSP1), is highly expressed in renal endothelium in miR-17~92endo-/- after renal IRI and is a target of miR-18a and miR-19a/b. Beyond defining a critical role for miR-17~92 in the angiogenic response after ischemic AKI, we show that co-treatment with a combination of miR-18a and miR-19b mimics is sufficient to mitigate ischemic AKI.

Conclusions: These data suggest that endothelial-derived miR-17~92 stimulates a reparative response in damaged renal vasculature during ischemic AKI by regulating angiogenic pathways.

Inhibition of Cadherin 11 Improves Outcomes in Murine Models of CKD

Tessa Huffstater,[1] Michael A. Raddatz,[1] Leslie S. Gewin,[2] W. David Merryman.[1] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Chronic kidney disease (CKD) represents a massive unmet clinical need, as there are virtually no pharmaceutical options for treatment of renal injury. A recent study identified cadherin-11 (CDH11) as a potential biomarker for CKD, as it is present in kidney biopsies and urine samples of CKD patients and its expression is increased in CKD mouse models. We have investigated the role of CDH11 as both a mediator and therapeutic target of CKD.

Methods: In the current study, we used three mouse models of CKD to evaluate the role of CDH11: aristolochic acid nephropathy, unilateral ureteral obstruction, and uninephrectomy/angiotensin II administration. In each of these models, we inhibited CDH11 genetically using transgenic mice and pharmacologically with the administration of a functional blocking antibody to CDH11.

Results: Although CDH11 has been found on immune cells and fibroblasts in other fibrotic diseases, we found that in the kidney CDH11 is exclusively expressed in injured proximal tubules (PTs). PTs play a significant role in CKD, as they are both a target and mediator of chronic injury. In our models of CKD, we found that both genetic and pharmacologic CDH11 inhibition improves renal function (BUN and ACR), diminishes cytokine production (TGF-β1 and IL-6 expression), and reduces tubular injury (expression of KIM-1 and histological analysis). Using primary PT cells, we found that genetic ablation of CDH11 improves cell survival *in vitro*. Although the specific mechanism by which CDH11 mitigates PT injury is still under investigation, preliminary data shows that inhibition of CDH11 increases Wnt/β-catenin activity in the kidneys of injured mice. Wnt/β-catenin signaling promotes cell survival, which in this context could result in reduced tubular atrophy, cytokine production, and fibrosis. Such pro-survival signaling could be driving the reduction in renal injury we see when CDH11 is inhibited, as PT death strongly correlates with outcomes in CKD.

Conclusions: These results clearly identify CDH11 inhibition as a novel means of improving outcomes in murine CKD models. The mechanism by which CDH11 inhibition mitigates renal injury is likely through CDH11 interactions with the Wnt/β-catenin signaling pathway to enhance PT survival. These results could prove an important step towards developing new therapeutic strategies for the treatment of CKD.

SU-OR12

METTL10: A Kidney Disease Risk Gene by Altering Protein Methylation

Hailong Hu, Katalin Susztak. *Renal Electrolyte and Hypertension Division, Department of Medicine and Genetics, University of Pennsylvania, Philadelphia, PA.*

Background: Genome-wide association studies (GWAS) have identified more than 300 loci where genetic variants are associated with kidney function, however, the causal variants, genes, cell types and the disease mechanism remain mostly unknown.

Methods: We have generated expression of quantitative trait (eQTL) data from microdissected human kidney tubules and glomeruli. We used Bayesian colocalization of eQTL and GWAS to identify likely causal genes for kidney function. We used single cell RNA and ATACseq data to identify causal cell types. Finally, we generated mice with genetic deletion to study kidney disease mechanism.

Results: Kidney disease associated genetic variants showed a strong association with METTL10 expression. Methyltransferase-like protein 10 (METTL10), is a non-histone lysine methyltransferase. Patients with CKD variants showed lower level of METTL10 in their kidneys. METTL10 was relatively broadly expressed in kidney tubule cell by single cell expression analysis. Its expression was markedly reduced in mice and patients with kidney disease. We found that Mettl10 controls methylation and the activity of the eukaryotic translation elongation factor 1 alpha (eEF1A). eEF1A is the alpha subunit of the eukaryotic elongation complex, controlling RNA translation. Methylation of eEF1A was markedly reduced in kidneys of Mettl10 KO mice. The reduction in eEF1A activity lead to lower protein translation and tubule cell proliferation. Mettl10 KO mice was more susceptible to kidney injury, it showed increased structural damage and collagen expression in the folic acid induced kidney injury model.

Conclusions: Taken together, GWAS and eQTL studies identified Mettl10 a kidney disease risk gene. METTL10 controls the methylation of eEF1A, downstream RNA translation, cell proliferation altering kidney disease risk, defining a novel mechanism for kidney disease development.

Renal Proximal Tubule Cell Differentiation and Metabolism Are Coupled by Nuclear Receptors

Poonam Dhillon,[1] Jihwan Park,[1] Carmen Hurtado del Pozo,[2] Lingzhi Li,[1] Shizheng Huang,[1] Rojesh Shrestha,[1] Nuria Montserrat,[2] Katalin Susztak.[1] Susztak Lab *[1]University of Pennsylvania, Philadelphia, PA; [2]Barcelona Institute of Science and Technology, Barcelona, Spain.*

Background: Kidney proximal tubule (PT) cells have high mitochondrial density to perform their highly energy demanding function to secrete and reabsorb metabolites and electrolytes. Chronic kidney disease is characterized by tubule epithelial atrophy and dedifferentiation, resulting in a decline in kidney function. In this study, we aimed to define upstream regulators that control PT differentiation.

Methods: We performed scRNA and snATACseq analysis on kidneys of developing and adult mice, kidney organoids, and kidneys from control and folic acid-induced kidney injury model. Bioinformatic methods included dimension reduction, differential expression, cell fraction and cell trajectory analysis. Functional studies included mice and cultured tubule cells with genetic deletion of ESRRA.

Results: Single cell differential expression analysis identified PT cells as the key vulnerable cell type in kidney fibrosis. Cell trajectory analysis showed a sequential differentiation path from precursor to differentiated PT cell state in development and in healthy adult and diseased kidneys. But this differentiation path showed more complexity in fibrosis, such as enhanced cell proliferation and a blockade of terminal differentiation. Pathway analysis indicated fatty acid oxidation (FAO) and oxidative phosphorylation (OXPHOS) were key variable genes along the PT cell differentiation path in the adult, and developing mouse PT cells and organoids. Single cell epigenetics data identified the critical role of nuclear receptors; HNF4A, HNF1B, PPARA, and ESRRA driving the PT cell differentiation program. These transcription factors did not only directly control FAO and OXPHOS but also the expression of PT differentiation genes. Genetic and pharmacological deletion of these transcription factors lead to marked changes in differentiation state of cultured PT cells. Analysis of healthy and disease human kidneys samples and mice with ESRRA deletion showed a defect in FAO, OXPHOS and PT differentiation and was more susceptible for injury, defining a novel role for ESRRA in PT cells and CKD.

Conclusions: The coupling of cell state and metabolism is established by nuclear receptors such as PPARA and ESRRA that not only control cellular metabolism but also the expression of PT cell-specific genes in mice and patient samples.

Funding: NIDDK Support

SU-OR14

COX17-Mediated Abnormal Mitochondrial Copper Metabolism Promotes Renal Fibrosis

Saiya Zhu, Chen Yu. *Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China.*

Background: Copper is a trace element essential for almost all living organisms. Previously, we found that elevated intracellular copper contributes a unique role to kidney fibrosis. Furthermore, copper ions in cells were mainly accumulated in mitochondria, which damage the structure and function of mitochondria. However, the mechanisms of the accumulation of copper ions in the mitochondria and how a disturbed copper balance induces mitochondrial dysfunction remain to be identified. Copper chaperone COX17, a protein required for cytochrome c oxidase (COX) assembly, was previously hypothesized to shuttle copper between the cytosol and mitochondria based on its dual localization. We found that in the fibrosis model COX17 was highly expressed and COX activity decreased. Therefore, we speculated that COX17 might be involved in mitochondrial copper overload and renal fibrosis.

Methods: Expression level and pattern of COX17 were examined in ischemia-reperfusion injury (IRI) AKI mice. The regulatory mechanisms of COX17 was investigated in renal tubule epithelium cell line (NRK-52E) and rat fibroblast(NRK-49F) by treating with copper or copper chelator tetrathiomolybdate (copper-chelating agent). ICP-MS, mitoSOX, electron microscopy, realtime-PCR and western blot analysis were applied in the current study.

Results: Firstly, the expressions of COX 17, Col1 in the kidney of IRI group were extremely upregulated compared with the sham group. Unexpected, we found dysfunction of mitochondria in IRI kidneys evidenced by it's appearing swollen and ruptured. Secondly, stimulated by TGF-β1, COX activity was declined, and mitochondrial copper content, mitochondrial reactive oxygen species and the expression of cox17, Col1 were significantly upregulated. More importantly, mitochondrial copper content and col1, fibronectin expression were reduced and mitochondrial function was improved after transfecting with COX17 shRNA. Meanwhile, treatment with copper chelator tetrathiomolybdate also alleviated renal fibrosis both in vivo and in vitro.

Conclusions: COX17 was significantly increased in renal fibrosis and transported excessive intracellular copper ions into the mitochondria. Copper overload inhibits the activity of COX and impairs mitochondria, subsequently leading to renal fibrosis.

SU-OR15

Protective Effect of Prostacyclin in Renal Fibrosis

Jing Li, Chuan-Ming Hao. *Division of Nephrology, Huashan Hospital Fudan University, Shanghai, China.*

Background: Inadequate repairing process to injury has been reported to play an important role in renal fibrosis. Mounting evidence suggests that prostaglandins are important in serving as a "buffer" in response to physiological changes or pathophysiologic insults to tissues including the kidney. Importantly, under certain conditions such as aging and hypertension, prostacyclin (PGI_2), an active production of COX/PGI_2 Synthase (PGIS), is reduced. The present study provides data showing that low levels of PGI_2 are associated with enhanced renal fibrosis.

Methods: Unilateral ureteral obstruction (UUO) was used as a renal fibrosis model. At days 10 after UUO, the mice were sacrificed. Ischemia-reperfusion (I/R) model was induced by clamping the left renal pedicle for 35 minutes on D0. After 4 weeks, the right kidney was removed. The mice were treated with beraprost sodium (300μg/kg bodyweight per day by twice daily gavage) or vehicle from D32 to D55, and were sacrificed on D56.

Results: The PGIS heterozygous (PGIS+/-) mice had normal body weight, blood pressure and blood urea nitrogen (BUN) level. Losing one allele of PGIS significantly attenuated the increase of PGIS expression after UUO and aggravated UUO -induced renal fibrosis, showing increased levels of fibronectin, collagen I and α-SMA compared with wild-type littermates. Masson trichrome staining shows more extracellular matrix accumulation in the kidney of $PGIS^{+/-}$ mice after UUO. Endothelial PGIS gene deletion also significantly attenuated the increase of PGIS expression after UUO and aggravated UUO-induced renal fibrosis. I/R model was performed on wild-type mice. Treatment with beraprost sodium (BPS), a analog of PGI2, inhibited the expression of fibronectin, collagen I and α-SMA in the kidney and ameliorated extracellular matrix deposition in the histology study. Furthermore, the level of phosphorylated PKA substrates in the ureteral obstructed kidney of deficient mice was significantly reduced, suggesting the role of IP receptor. IP agonist treatment reduced the expression of fibronectin, collagen I and α-SMA in rat renal fibroblasts (NRK-49F), which were induced by TGF-β.

Conclusions: PGIS/PGI_2 plays an important role in protecting the kidney from fibrosis. Lack of PGIS enhances renal fibrosis, and supplementation with PGI_2 analog ameliorates renal fibrosis. PGIS/PGI_2 is a potential target for CKD.

SU-OR16

Proteomic Risk Assessment of CKD Progression in the Chronic Renal Insufficiency Cohort

Ruth F. Dubin,[1] Rajat Deo,[2] Zihe Zheng,[2] Haochang Shou,[2] Yue Ren,[2] Hongzhe Li,[2] Mark Segal,[1] Harold I. Feldman,[2] Peter Ganz.[1] *[1]University of California San Francisco, San Francisco, CA; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Quantification of thousands of plasma proteins simultaneously is now feasible in large cohorts using the SomaScan aptamer assay. In this study, we applied large-scale proteomics to patients with chronic kidney disease (CKD) to discover new biomarkers and risk models of CKD progression.

Methods: We measured 4638 unique plasma proteins among 3249 participants in the Chronic Renal Insufficiency Cohort(CRIC), with follow-up to 13 years. Mean age was 59 years, mean estimated glomerular filtration rate (eGFR) 42 ml/min/1.73m^2, and 50% were diabetic. The study outcome was 10-year risk of 50% decline in eGFR, end-stage renal disease or renal transplant (n=1171 events). Associations of individual proteins with the composite outcome were analyzed in Cox survival models adjusted for demographics, comorbidities, eGFR and proteinuria. Protein-only risk models were constructed using elastic net regression and compared to the 4-variable Kidney Failure Risk Equation

(KFRE). KFRE variables (age, gender, eGFR and proteinuria) were refit to CRIC. For risk modeling, the cohort was split into 80% derivation/20% validation.

Results: Among the 4638 assayed proteins, after adjustment for eGFR, 1535 proteins were associated with CKD progression at FDR <0.05; 529 were significant at Bonferroni $p<1x10^{-5}$. After full adjustment, 459 proteins met FDR significance and 77 proteins met Bonferroni significance. A 58 protein risk model for 10-year CKD progression derived by elastic net achieved a c-statistic of 0.860 (95% CI: 0.834, 0.885) in the validation set, equal to the refit KFRE c-statistic of 0.857 (95% CI 0.831, 0.884). The c-statistic for the proteomic model was not enhanced by addition of clinical risk factors. Additionally, we were able to identify protein biomarkers that are unique to progression of diabetic vs. non-diabetic CKD.

Conclusions: Through large-scale proteomics, we discovered numerous novel biomarkers that predict the risk of CKD progression. The proteomic risk model has excellent discrimination, equal to the refit clinical model. Ongoing analyses of the biological functions of the newly discovered biomarkers may identify new therapeutic targets to slow CKD progression.

Molecular Mechanisms Underlying Sex-Specific Association of Circulating Transforming Growth Factor B1 with the Risk of Accelerated Kidney Function Decline

Jon V. Norvik,[1,2] Inger Therese T. Enoksen,[2] Christopher L. O'Connor,[3] Marit D. Solbu,[1,2] Viji Nair,[3] Matthias Kretzler,[3] Wenjun Ju,[3] Bjorn O. Eriksen,[2,1] Markus Bitzer,[3] Toralf Melsom.[1,2] *[1]Universitetssykehuset Nord-Norge, Tromso, Norway; [2]UiT Norges arktiske universitet Det helsevitenskapelige fakultet, Tromso, Norway; [3]University of Michigan, Ann Arbor, MI.*

Background: Study of sex differences in kidney function decline and risk of chronic kidney disease (CKD) is a stated research goal. We recently found serum transforming growth factor β1 (TGF-β1), a key mediator in kidney fibrosis development, to be associated with risk of accelerated age-related loss of glomerular filtration rate (GFR) in women, but not men, in the general population. We therefore investigated the effect of sex on intrarenal TGF-β1 pathway and structural damage in kidney biopsies from a cohort of patients with early kidney impairment.

Methods: Kidney tissue samples from 22 female and 33 male patients undergoing nephrectomy included in the PRECISE study (age 31 to 83 years) were used for transcriptomic analysis of micro-dissected glomeruli (Affymetrix Human Gene 2.1 ST Array). Interaction of the expression of genes in the TGF-β1 signaling pathway with sex was evaluated between expression level and global glomerulosclerosis (GGS), a structural parameter of kidney disease. Genes exhibiting significant interaction with sex were used to generate a sex-dependent TGF-β1 pathway activity score.

Results: Out of the 136 genes downstream of TGF-β1, expression of 20 genes exhibited significant interaction with sex for GGS. BMP6, ID1, MYC, and TNF were among the genes that showed the most significant interaction. An increased activity score for sex-specific TGF-β1 downstream effectors was associated with higher degree of GGS in women (p<0.001), but with less GGS in men (p=0.01, p for interaction with sex <0.001, Figure 1).

Conclusions: Higher levels of the sex-specific TGF-β1 pathway activity was associated with higher GGS in women, but with less GGS in men. These results, along with our findings of an association between higher serum TGF-β1 and accelerated GFR decline in women only, point to a sex-specific TGF-β1 driven mechanism of kidney fibrosis that may shed light on sex differences in age-related GFR loss and CKD.

Defining the Correlation Between Kidney Function and Histopathological Changes

Ghazal Z. Quinn,[1] Amin Abedini,[1] Matthew Palmer,[1] Andrea Havasi,[2] Katalin Susztak.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Boston Medical Center, Boston, MA.*

Background: Estimated glomerular filtration rate (eGFR) is an imperfect measure of kidney function and does not correlate well with prognosis. Histopathologic analysis of renal biopsy is considered the gold standard to establish disease etiology and prognosis. Kidney biopsy, however, is rarely performed in patients with diabetes due its associated risks. Here we examined whether we could predict the degree of histological damage and kidney function decline based on clinical and demographic information.

Methods: Descriptor based histopathological analysis was performed in 759 human kidney tissue samples obtained from unaffected portion of tumor nephrectomies. Samples were limited to healthy, hypertensive and diabetic kidney disease. Changes in the glomeruli, tubules, interstitium and the vasculature were scored in an unbiased manner. Regression analyses were performed to assess the association between histopathology based on eGFR quantiles. Decline in renal function over time (eGFR slope in ml/min/1.73m² per year) was assessed in subjects with at least 3 months of follow up. Validation analysis was performed on 467 clinically indicated kidney biopsies.

Results: Mean subject age was 61, eGFR was 66 ml/min/1.73m², 70% had hypertension and 37% had diabetes. The association between eGFR and interstitial fibrosis was relatively weak (r^2=0.3, p <0.001). There was no association between fibrosis and eGFR greater than 45 ml/min/1.73m2. Samples with eGFR below 45 ml/min/1.73m² showed a reasonably strong association between eGFR and fibrosis (r^2=0.51, p <0.001) indicating a non-linear relationship. Hypertension and black race were independently associated with more severe histopathologic changes (p<0.05). Similar non-linear trends and significant associations were observed in our validation cohort. There was an association between severity of histopathologic findings and kidney function decline which did not reach significance in the primary cohort but was significant in the validation cohort.

Conclusions: The eGFR is a poor predictor of fibrosis at values > 45 ml/min/1.73m² but predicts renal structural changes well at lower eGFR. Hypertension and black race were independently associated with renal fibrosis, which may warrant more aggressive therapy in these cohorts. Predictions of kidney function decline are enhanced when eGFR and histopathology are used in combination.

SU-OR19

Low Birth Weight for Gestational Age and Risk of Different Groups of Kidney Disease During the First 50 Years of Life

Anna Gjerde,[1] Rannveig Skrunes,[2] Hans-Peter Marti,[2] Bjorn Egil Vikse.[1] *[1]Haugesund sjukehus, Haugesund, Norway; [2]Universitetet i Bergen, Bergen, Norway.*

Background: Previous studies have shown that Low Birth Weight (LBW) is associated with increased risk of end-stage renal disease. Few population based studies have investigated risk of Small for Gestational Age (SGA) on kidney disease. Our study investigates SGA and risk of chronic kidney disease (CKD), other kidney diagnoses as well as different stages of kidney failure.

Methods: The Norwegian Patient Registry (NPR) has registered ICD diagnostic codes for all admissions and outpatient visits to Norwegian hospitals since 2008. The Norwegian Medical Birth Registry (MBR) has registered birth weight, gestational age and several other data on maternal and offspring health for all birth in Norway since 1967. Data from these registries were linked and risk of CKD and other groups of kidney disease were analyzed with logistic regression statistics. Based on birth weight, gestational age and gender, a z-score of birth weight for gestational age has been calculated. SGA defined as birth weight less than the 10th percentile for gestational age and gender with cut-off -1.30 for male and -1.28 for female. LBW (less than the 10th percentile) and preterm birth (less than 37 weeks) were analyzed as risk markers. Adjusted analyses were performed for the main analyses by including birth year, gender, maternal disease, maternal marital status and malformations in the newborn

Results: Of the 2,663,010 included sunjects, 4495 had been diagnosed with CKD and 12,818 with acute kidney disease, glomerulonephritis, hereditary kidney disease or kidney disease due to kidney or urinary tract malformations. SGA was associated with odds ratio (OR) for CKD of 1.79 (1.65-1.94), LBW with an OR of 1.72(1.59-1.86) and preterm birth with an OR of 1.48 (1.32-1.67). There were no significant gender differences. Analyses of CKD stage 3, 4 and 5 showed similar results. An adjusted odds ratio (aOR) for other groups of kidney disease showed that SGA was associated with aOR of 1.60 (1.49-1.73) for acute kidney disease, 1.18 (1.070-1.30) for glomerulonephritis, 1.31 (1.12-1.52) for hereditary kidney disease and 1.13 (1.03-1.23) for kidney disease due to kidney or urinary tract malformations

Conclusions: SGA is a strong risk maker for diagnosis of all stages of CKD during the first 50 years. The risks seem to increase also for other groups of kidney disease.

SU-OR20

Large-Scale Kidney Volumetry from MRI: Initial Results and Relations to Sex, Age, and Body Size in UK Biobank

Joel Kullberg,[1,2] Taro Langner,[1] Salvador Daniel Rivas-Carrillo,[3] Iris Friedli,[2] Tove Fall,[4] Robin Strand,[1,5] Håkan Ahlström,[1,2] Lars Johansson.[2] *[1]Uppsala University, Department of Surgical Sciences, Radiology, Uppsala, Sweden; [2]Antaros Medical, Mölndal, Sweden; [3]Uppsala University, Department of Medical Biochemistry and Microbiology, Uppsala, Sweden; [4]Uppsala University, Department of Medical Sciences, Molecular Epidemiology, Uppsala, Sweden; [5]Uppsala University, Department of Information Technology, Uppsala, Sweden.*

Background: Kidney volume has been associated with age, kidney function, diabetes, and other cardiovascular risk factors. Body size, body surface area (BSA) and lean tissue mass are important confounders. UK Biobank (UKB) is a large-scale study aiming to examine 100,000 subjects aged 44 to 82 years using MRI. Resulting images allow measurements of kidney volume. Currently 40,264 scans have been released.

Methods: A deep learning-based method for direct kidney parenchymal volume (KPV) segmentations was developed and validated (Accuracy: Dice 0.956, R^2=0.95) and applied to UKB MRI. Absolute and relative change with age and associations to body weight, BSA and fat free mass from bioimpedance analysis (BIA-FFM) and lean tissue volume from MRI (MRI-LT) were studied using linear regression. Rate changes were compared below and above group mean ages. MRI-LT values (n=8,524) were inferred for 30,308 additional subjects by MRI-based deep learning regression with validated R^2=0.96(arXiv:2002.06862).

Results: Resulting KPVs from 37,468 subjects (47,6% males) and age changes are shown in Fig1a and Table 1. Correlations between total KPV and BSA and MRI-LT over age are shown in Fig1b. The associated overall correlations were (males / females): Body weight: 0.568/0.460, BSA: 0.574/0.496, BIA-FFM: 0.597/0.536, MRI-LT: 0.636/0.600.

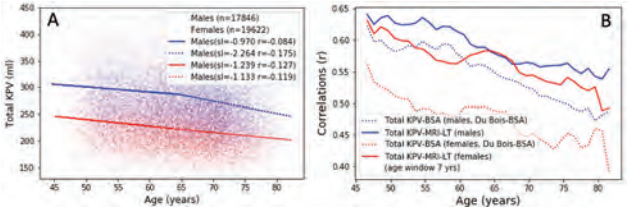
Conclusions: Both sexes show continuous volume decline in the studied age interval. Males show an increasing rate of decline with age. MRI-LT showed strongest correlations to KPV.

Funding: Other NIH Support - The Swedish Heart-Lung Foundation, Swedish Research Council (2016-01040, 2019-04756), Research conducted using the UK Biobank resource (application 14237)., Government Support - Non-U.S.

Table 1

	Kidney Volume (ml)		Absolute age change (ml / year)		Relative age change (% / year)	
	Males	Females	Males	Females	Males	Females
Total	281.9±51.4	224.0±39.7	-0.970, -2.264	-1.239, -1.133	-0.397, -0.926	-0.635, -0.580
Left	142.5±29.0	113.5±22.4	-0.478, -1.185	-0.682, -0.607	-0.392, -0.973	-0.699, -0.622
Right	139.2±27.8	110.4±21.6	-0.494, -1.081	-0.555, -0.525	-0.413, -0.903	-0.584, -0.551

Age changes are given as two regression slopes, from below and above the sex-specific mean age.



A) Scatter plot of total KPV and age for males and females including regression lines for subjects below and above respective mean age. An increasing rate of decline is found in males ($p<10^{-15}$) but not in females. B) Correlation between total KPV and BSA and MRI-LT for males and females over age.

Variation in Peritoneal Dialysis-Related Peritonitis Outcomes and Treatment Practices: Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study

Muthana Al sahlawi,[1,2] Keith McCullough,[3] Ronald L. Pisoni,[3] Douglas S. Fuller,[3] Junhui Zhao,[3] Neil Boudville,[4] Yasuhiko Ito,[5] Talerngsak Kanjanabuch,[6] Sharon Nessim,[7] Beth M. Piraino,[8] Isaac Teitelbaum,[9] David W. Johnson,[10,11] Graham Woodrow,[12] Jeffrey Perl.[1] *[1]Division of Nephrology, St. Michael's Hospital and the Keenan Research Center in the Li Ka Shing Knowledge Institute, St. Michael's Hospital, University of Toronto, Toronto, Ontario, Canada, Toronto, ON, Canada; [2]Department of Internal Medicine, College of Medicine, King Faisal University, Al-Hasa, Saudi Arabia, Al-Hasa, Saudi Arabia; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Medical School, University of Western Australia, Perth, Australia, Perth, WA, Australia; [5]Aichi Medical University, Nagakute, Japan, Nagakute, Japan; [6]Center of Excellence in Kidney Metabolic Disorders and Division of Nephrology, Department of Internal Medicine, Chulalongkorn University, Bangkok, Thailand, Bangkok, Thailand; [7]Division of Nephrology, Jewish General Hospital, McGill University, Montreal, Canada, Montreal, QC, Canada; [8]University of Pittsburgh, Pittsburgh, PA, United States, Pittsburgh, PA; [9]University of Colorado, Aurora, CO, United States, Aurora, CO; [10]Department of Nephrology, Princess Alexandra Hospital, Brisbane, Australia, Brisbane, QLD, Australia; [11]Australasian Kidney Trials Network, University of Queensland, Brisbane, Australia, Brisbane, QLD, Australia; [12]Renal Unit, St James's University Hospital, Leeds, United Kingdom, Leeds, United Kingdom.*

Background: Peritoneal dialysis (PD)-associated peritonitis is a leading cause of technique failure and transition to hemodialysis. In the Optimizing Peritonitis Prevention in The United States (OPPUS) study, we explored the impact of various patient, facility and treatment factors on the likelihood of cure following a peritonitis episode.

Methods: Using Peritoneal Dialysis Outcomes and Practice Patterns Study phase 1 (2014-2017) data from Australia and New Zealand, Canada, Japan, Thailand, the UK, and the US, cure was defined as the absence of a peritonitis relapse or recurrence, PD catheter removal, transition to hemodialysis or death during the 50 days following a peritonitis episode. Multivariable logistic regression was used to test associations between cure and patient, facility, and treatment characteristics.

Results: We identified 1677 peritonitis episodes in 1190 patients across 126 facilities. Overall, 63% of episodes resulted in a cure. Cure was associated with APD (OR v. CAPD=1.35, 95% CI 1.02-1.80), higher serum albumin (OR=1.04 per 0.1 g/dL, 95% CI=1.01, 1.06), facility icodextrin use (OR=1.06 per 10% greater icodextrin use, 95% CI = 1.01-1.12), and aminoglycoside use for Gram-negative peritonitis (OR v. ceftazidime=3.10, 95% CI=1.02, 9.36). Prior peritonitis (OR v. no prior peritonitis episodes during follow-up=0.84, 95% CI=0.74, 0.97) and concomitant exit-site infection (OR= 0.42, 95% CI=0.28, 0.63) were associated with lower cure odds. Higher odds of peritonitis relapse were seen among patients with greater residual urine volume (OR= 1.14 per 200 ml, 95% CI=1.07, 1.22).

Conclusions: Different characteristics and management practices can impact the likelihood of cure following a peritonitis episode. Our findings can inform future guidelines in addressing the effect of different modifiable patient, facility, and treatment factors on reducing morbidity associated with PD peritonitis.

Rate of Decline in Residual Kidney Function Before and After Peritoneal Dialysis Initiation: A Post Hoc Analysis of the IDEAL Study

Isabelle Ethier,[1,2] Yeoung Jee Cho,[2,3] Carmel Hawley,[2,3] Elaine Pascoe,[3] Andrea K. Viecelli,[2,3] Scott B. Campbell,[2,3] Carolyn L. Van Eps,[2,3] Nicole Isbel,[2,3] Bruce A. Cooper,[6] David Harris,[4,5] Carol A. Pollock,[6,5] Muh Geot Wong,[6,7] David W. Johnson.[2,3] *[1]Centre Hospitalier de L'Universite de Montreal, Montreal, QC, Canada; [2]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [3]The University of Queensland Faculty of Medicine, Herston, QLD, Australia; [4]Westmead Institute for Medical Research, Westmead, NSW, Australia; [5]The University of Sydney School of Medicine, Sydney, NSW, Australia; [6]Royal North Shore Hospital, St Leonards, NSW, Australia; [7]George Institute for Global Health, Camperdown, NSW, Australia.*

Background: Residual kidney function (RKF) is associated with improved survival and quality of life in dialysis patients. Previous studies have suggested that commencement of peritoneal dialysis (PD) may slow RKF decline compared to the pre-dialysis period. We sought to evaluate the association between PD initiation and RKF decline in the Initiating Dialysis Early And Late (IDEAL) trial.

Methods: In this *post hoc* analysis of the IDEAL randomized controlled trial, PD participants were included if results from 24-hour urine collections had been recorded within 30 days of dialysis initiation (-30 to +30 days from start), and at least one value pre- and one value post-dialysis commencement were available. The primary outcome was slope of RKF decline, calculated as mean of urinary creatinine and urea clearances. Secondary outcomes included slope of urine volume decline and time from PD initiation to anuria.

Results: The study included 151 participants (79 early-start group, 72 late-start group). The slope of RKF decline was slower after PD commencement (-2.69±0.18 mL/min/1.73m^2/yr) compared to before PD commencement (-4.09±0.33 mL/min/1.73m^2/yr; change in slope +1.19 mL/min/1.73m^2/yr, 95% CI 0.48-1.90, p<0.001). In contrast, urine volume decline was faster after PD commencement (-0.74±0.05 L/yr) compared to beforehand (-0.57±0.06 L/yr; change in slope -0.18 L/yr, 95%CI -0.34—-0.01, p=0.04). No differences were observed between the early- and late-start groups with respect to RKF decline, urine volume decline or time to anuria.

Conclusions: Commencement of PD was associated with a slower decline of RKF compared to the pre-dialysis period.

Funding: Government Support - Non-U.S.

Steady Concentration Peritoneal Dialysis Increases Ultrafiltration and Sodium Removal Compared with Continuous Ambulatory Peritoneal Dialysis (CAPD)

Olof Heimburger,[5] Giedre Martus,[3] Martin E. Wilkie,[2] Jorgen B. Hegbrant,[4] Ola Carlsson,[1] Charlotte De Leon,[1] Ann Cathrine Johansson.[3] *[1]Triomed AB, Lund, Sweden; [2]Sheffield Teaching Hospital, NHS Foundation Trust, Sheffield, United Kingdom; [3]Department of Nephrology, Skåne University Hospital, Malmö, Sweden; [4]Department of Nephrology, Lund University, Lund, Sweden; [5]CLINTECH, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.*

Background: Fluid and sodium removal (NaR) may be a challenge during glucose-based PD, leading to increased use of high glucose solutions to maintain sufficient fluid removal. This may lead to increased sodium sieving, resulting in reduced NaR. Carry Life® UF uses steady concentration PD (SCPD), where the intraperitoneal (IP) glucose concentration is maintained by infusion of glucose to provide a continuous ultrafiltration (UF) throughout the dwell. The present study investigated the effect of Carry Life® UF *vs.* CAPD regarding UF, NaR and glucose absorption.

Methods: Eight stable PD patients were included in the study. Subjects were treated with 5-hour Carry Life® UF treatments using three different glucose doses (11, 14, 20 g/h). An initial fill with 1.5 l, 1.36% glucose PD solution was used. A small volume of dialysate was drained hourly to avoid overfill. A 4-hour peritoneal equilibration test (PET) (2.0 l, 2.27% glucose) served as control. Data expressed as mean±SD, statistical analysis using ANOVA.

Results: UF volumes were significantly increased during Carry Life® UF treatments (646±256, 739±312, 863±380 ml for 11, 14 and 20 g/h) *vs.* PET (162±242 ml, p<0.01). NaR increased significantly during Carry Life® UF treatments (86±27, 92±33 110±37 mmol/dwell for 11, 14 and 20 g glucose/h) compared to PET (22±33 mmol/dwell, p<0.001).

Conclusions: SCPD performed with Carry Life® UF maintained a stable IP glucose concentration during the treatment (figure a) which generated significantly higher UF volumes compared to PET. During the Carry Life UF treatments glucose was used more efficiently, particularly for the two lowest doses, in comparison to PET (figure b). In summary, SCPD using Carry Life® UF increases the efficiency of PD compared to standard, glucose-based CAPD with respect to UF and NaR.

Funding: Commercial Support - Triomed AB

Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD and Anemia on Peritoneal Dialysis

Tak Mao D. Chan,[1] Lynda Szczech,[5] Jayant Kumar,[2] Anjay Rastogi,[3] Carol A. Pollock,[4] Gopal Saha,[5] Tyson T. Lee,[5] Maksym Pola,[6] Kin-Hung P. Yu.[5] *[1]University of Hong Kong, Queen Mary Hospital, Hong Kong SAR, China; [2]Renal Medicine Associates, Albuquerque, NM; [3]University of California Los Angeles, Los Angeles, CA; [4]The University of Sydney, Sydney, NSW, Australia; [5]FibroGen Inc, San Francisco, CA; [6]AstraZeneca, Warsaw, Poland.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Dialysis modality in patients with ESRD is associated with different incidence rates of anemia and clinical outcomes. Therefore, evaluating the safety and efficacy of roxadustat in patients with dialysis-dependent (DD) CKD on peritoneal dialysis (PD) is of clinical importance.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, epoetin alfa-controlled studies of roxadustat for the treatment of anemia in patients with DD-CKD were assessed in the subgroup of patients on PD. Endpoints evaluated were: mean change from baseline (CFB) in hemoglobin (Hb) averaged over Weeks 28–52 regardless of rescue therapy, Hb CFB averaged over Weeks 28–36 censored for rescue therapy, and risk for blood/RBC transfusion during the treatment period. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the DD-CKD study population, 10% (372/3887) of patients were on PD (roxadustat=180, epoetin alfa=192). Baseline characteristics were generally similar between treatment groups. Mean (SD) Hb levels (g/dL) at baseline were 9.58 (1.22) in the roxadustat group and 9.56 (1.23) in the epoetin alfa group. Patients achieved a larger mean (SD) CFB to Weeks 28–52 in Hb (g/dL) with roxadustat vs. epoetin alfa (1.41 [1.45] vs. 1.08 [1.53]), corresponding to a least-squares mean (LSM) treatment difference of 0.37 (95% CI: 0.11, 0.63) (p=0.0048). Patients achieved a larger mean (SD) CFB to Weeks 28–36 in Hb (g/dL) with roxadustat vs. epoetin alfa (1.53 [1.54] vs. 1.01 [1.63]), corresponding to a LSM treatment difference of 0.46 (95% CI: 0.17, 0.74) (p=0.0018). Risk for blood/RBC transfusion was significantly reduced with roxadustat vs. epoetin alfa (HR, 0.50 [95% CI: 0.26, 0.98]; p=0.0422). TEAE rates were comparable between treatment groups.

Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing/maintaining Hb levels and reducing the risk for blood/RBC transfusion in patients with DD-CKD on PD. Safety and tolerability profiles were similar to the overall population and consistent with that observed in this patient subgroup.

Development and Content Validity of a Patient-Reported Experience Measure for Home Dialysis

Matthew B. Rivara, Todd C. Edwards, Donald Patrick, Lisa D. Anderson, Jonathan Himmelfarb, Rajnish Mehrotra. *University of Washington, Seattle, WA.*

Background: The population of patients with kidney failure in the United States utilizing home dialysis modalities is growing rapidly. Unlike for in-center hemodialysis, there is no patient-reported experience measure for assessment of patient experience of care for peritoneal dialysis or home hemodialysis. We sought to develop and establish content validity of a patient-reported experience measure for patients undergoing home dialysis using a mixed-methods multiple stakeholder approach.

Methods: We conducted a systematic literature review, followed by concept elicitation focus groups and interviews among 65 participants, including 21 home dialysis patients, 33 home dialysis nurses, 3 patient care partners, and 8 nephrologists. We generated a list of candidate items for possible measure inclusion, and conducted a national aspects of care prioritization exercise among 91 home dialysis patients and 39 providers using a web-based platform. We drafted the Home Dialysis Care Experience (Home-DCE) instrument and conducted 3 rounds of cognitive debriefing interviews to evaluate item comprehensibility, order, and structure. We iteratively refined the measure based on interview findings.

Results: The literature review and concept elicitation phases supported 15 domains of home dialysis care experience in 6 general areas: communication and education of patients; concern and helpfulness of the care team; proficiency of the care team; patient-centered care; care coordination; and amenities and environment. Focus groups results showed that domains of highest importance for measure inclusion were home dialysis staff education and patient-centered communication, care coordination, and personalization of care (Figure). Aspects of care prioritization exercise results confirmed focus group findings. Cognitive debriefing indicated that the final measure was easily understood and supported content validity.

Conclusions: The Home-DCE instrument is a 26-item patient-reported experience measure for use in peritoneal dialysis and home hemodialysis. Qualitative focus group and prioritization survey data support measure content validity. To our knowledge, the Home-DCE instrument represents the first rigorously developed and content valid English language survey instrument for assessment of patient-reported experience of care in home dialysis.

FIGURE. Home dialysis care domains and aspects of care from concept elicitation focus groups

Grouped area	Home Dialysis Care Domain	Number of mentions	Key aspects of care
Communication and Education	Dialysis center staff education of patients and patient-centered communication	107	• Clarity and quality of communication between staff, patient, caregiver • Accuracy, completeness, flexibility of education content • Effectiveness in addressing patient's questions
	Nephrologist education of patients and patient-centered communication	15	• Frequency of communication between nephrologist, patient, caregiver • Availability of nephrologist and communication with dialysis staff
Concern and helpfulness of the care team	Concern and helpfulness of the dialysis center staff	36	• Perception by patient that staff are caring, informed, respectful • Perception by patient that staff are proactive and helpful when asked
	Concern and helpfulness of the nephrologist	7	• Perception by patient that nephrologist is caring, informed • Nephrologist shows respect and takes patient seriously
	Support services	38	• Availability of social work, dietitian, transportation services • Availability of backup and respite care
	Caregiver training and support	7	• Degree to which care partners receive training and support from staff
Proficiency of the care team	Dialysis center staff proficiency	36	• Perception by patient that dialysis staff can manage problems, deliver timely care, and show/perform technical aspects of dialysis
Patient-centered care	Personalization of care	39	• Patient perception that staff take patients' values and preferences into account in treatment decisions and integration of treatment into life
	Patient involvement in care	12	• Inclusion of patients in decisions regarding dialysis modality • Patient comfort in asking questions about care
	Access and convenience of care	31	• Accessibility of home dialysis center • Ease of contacting dialysis center staff • Accessibility of different dialysis modalities
	Confidence and safety to perform dialysis at home	33	• Confidence in performing all steps of dialysis procedure • Knowledge of response to complications, emergencies, disasters
	Handling of grievances	3	• Response by dialysis staff to complaints, and comfort of patients in raising complaints
Care coordination	Care coordination	39	• Perception of patient regarding cooperation among providers
Amenities and environment	Facility amenities and environment	15	• Cleanliness, convenience, quality of dialysis facility space
	Dialysis supplies, equipment, and home environment	30	• Convenience and accessibility of dialysis supply and delivery process • Helpfulness of staff in dealing with supply issues

SU-OR26

Cardiovascular Thromboembolic Outcomes by Dialysis Modality Following Primary Total Knee Arthroplasty

Chavely Valdes Sanchez,[1] Matthew R. Lozier,[1] Mauricio Tellez,[1] Alexandra M. Sanchez,[1] Gabriel A. Valle.[2] *[1]University of Miami at Holy Cross Hospital, Fort Lauderdale, FL; [2]The Kidney and Hypertension Group of South Florida, Fort Lauderdale, FL.*

Background: There is a paucity in the literature evaluating the impact of dialysis modalities on cardiovascular thromboembolic outcomes following primary total knee arthroplasty (TKA). Therefore, the purpose of this study was to investigate whether patients treated with hemodialysis (HD) or peritoneal dialysis (PD) have higher rates of: 1) medical complications, 2) readmission, and 3) cost of care.

Methods: Patients undergoing primary TKA while receiving HD served as the study group (n = 82,518) and matched 1:1 to a control group of PD patients (n = 82,518) by distribution, age, sex, and Elixhauser-Comorbidity Index (ECI). Outcomes analyzed included rates of 90-day medical complications, readmission rates, and cost of care. Logistic regression analysis was used to calculate odds-ratios (OR) for medical complications and readmission rates. Welch's t-test was used to test for significance on cost of care and ECI between cohorts. P-value less than 0.05 was considered statistically significant.

Results: Patients undergoing HD prior to primary TKA were found to have a significantly lower incidence and odds of cerebrovascular accidents (PD vs. HD: 0.19 vs. 0.13%; OR: 1.44, p=0.003) and venous thromboemboli (0.15 vs. 0.10%; OR: 1.52, $p<0.001$), specifically deep vein thromboses (0.13 vs 0.10%; OR 1.75, p<0.001). HD patients did however incur significantly higher 90-day cost of care ($104,341.89 vs. $209,611.67; p<0.001). No statistically significant differences were noted in myocardial infarction, pulmonary embolism, or 90-day readmission rates between the two groups.

Conclusions: While incurring a lower 90-day cost of care, patients treated with PD prior to primary TKA may have a greater odds of developing a cerebrovascular accident or deep vein thrombosis when compared to HD.

Table 1

Cardiovascular Thromboembolic Adverse Outcomes	Incidence (PD vs. HD)	Odds Ratio	95% Confidence Interval	P-Value
Myocardial Infarction	0.14 vs. 0.13%	1.11	0.85 - 1.45	0.42
Cerebrovascular Accident	0.19 vs. 0.13%	1.44	1.13 - 1.85	0.003
Venous Thromboembolism	0.15 vs. 0.10%	1.52	1.15 - 2.00	0.0003
Deep Vein Thrombosis	0.13 vs. 0.10%	1.75	1.28 - 2.40	<0.001
Pulmonary Embolism	0.02 vs. 0.03%	0.86	0.46 - 1.59	0.64
Readmission Rates & Cost of Care at 90 Days	Incidence (PD vs. HD)	Odds Ratio	95% Confidence Interval	P-Value
Readmission Rates	51.94 vs. 51.62%	1.01	0.99 - 1.03	0.18
Cost of Care	$104,341.89 vs. $209,611.67			<0.0001

Outcome comparisons by dialysis modality following TKA.

Prognostic Roles of Peritoneal Dialysis Effluent Mitochondrial DNA Level

Win H. Than,[1,2] Cheuk-Chun Szeto.[1,2] *[1]Carol & Richard Yu Peritoneal Dialysis Research Centre, Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, New Territories, Hong Kong; [2]Li Ka Shing Institute of Health Sciences (LiHS), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong.*

Background: Circulating mitochondrial DNA (mtDNA) level is associated with the systemic inflammatory state and prognosis of peritoneal dialysis (PD) patients. We explore the relation between mtDNA level in PD effluent and peritoneal transport characteristics and outcomes of PD patients.

Methods: We measured PD effluent mtDNA levels by quantitative polymerase chain reaction and the result is expressed as copy per 1000 copies of the housekeeping gene. Both PD effluent sediment and cell-free supernatant mtDNA levels were measured. Peritoneal transport was determined by the peritoneal equilibration test and represented as mass transfer area coefficient (MTAC) of creatinine. All patients were followed for technique and overall survival.

Results: 168 PD patients were followed for 41.3 (IQR: 19.3-52.0) months. Their mean age was 60.4±11.8 years; 99 (58.9%) were men. Median PD effluent (PDE) supernatant mtDNA was 255.4 unit (IQR: 157.5-451.3); median PDE sediment mtDNA was 201.6 unit (147.8-267.3). PDE supernatant mtDNA level had a modest but significant correlation with MTAC creatinine (r = -0.364, p<0.001) and the number of previous peritonitis episode (r = -0.235, p=0.002). After adjusting for age, gender, Charlson's Comorbidity Score, total weekly Kt/V, and residual renal function, PDE sediment mtDNA was a significant predictor of technique survival (adjusted hazards ratio [AHR] 1.002, 95%CI 1.000-1.003, p=0.011). In contrast, PDE sediment mtDNA level did not predict patient survival (p = 0.7). In contrast, the PDE supernatant mtDNA level did not correlate with technique or patient survival.

Conclusions: PDE supernatant mtDNA level had a significant correlation with peritoneal transport. PDE sediment mtDNA level was a significant predictor of technique survival for PD patients. The mechanism of the differential implications between PDE sediment and supernatant mtDNA levels deserves further investigations.

SU-OR28

Hemodynamics and Geometry of Rat Arteriovenous Fistulas: Effect of Sildenafil Treatment

Hannah M. Northrup,[1] Yan-Ting E. Shiu,[1,2] Isabelle D. Falzon,[1] Maheshika S. Somarathna,[3] Timmy C. Lee.[3,4] *[1]University of Utah, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT; [3]University of Alabama at Birmingham, Birmingham, AL; [4]Veterans Affairs Medical Center, Birmingham, AL.*

Background: Arteriovenous fistula (AVF) maturation is dependent on hemodynamics and remodeling of the vessel wall to increase the AVF flow rate and lumen area for dialysis. Sildenafil is a phosphodiesterase 5 inhibitor that promotes vasodilation and is used clinically to treat erectile dysfunction and pulmonary hypertension. Here we investigate the effect of sildenafil on lumen geometry and hemodynamics in rat AVFs.

Methods: Femoral AVFs were created in 12-16 week-old male Sprague-Dawley rats. Sildenafil was administered at 90 mg/kg in drinking water starting 14 days prior to AVF creation surgery (n=4). 21 days post creation, animals were subject to non-contrast MRI scans, and the MR images were used for reconstruction of the AVF lumen and computational fluid dynamic simulations of the AVF blood flow. Hemodynamic parameters (flow rate, wall shear stress (WSS), vorticity, and oscillatory shear index (OSI)) and geometrical analysis (cross sectional lumen area, anastomosis angle (AA), tortuosity, and nonplanarity angle (NA)) were calculated.

Results: Sildenafil significantly increased the lumen area and flow rate of both the venous and arterial limbs of the AVFs when compared to no-treatment controls (p<0.0001) (Fig. 1). WSS, vorticity and OSI of treated rats were also significantly higher than controls (p<0.0001)(Fig. 1). AA, tortuosity, and NA were not significantly different between the two groups. AA was approximately 40° in both groups.

Conclusions: The AA of our AVF rat model is similar to the AA in human radiocephalic AVFs in the literature. Sildenafil leads to significantly higher flow rate and larger lumen in both vein and artery than controls. Vorticity, WSS, and OSI are significantly higher in treated rats compared to control, which may be due to the increased flow rate. Sildenafil may have therapeutic potential to enhance AVF maturation by affecting the hemodynamics.

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

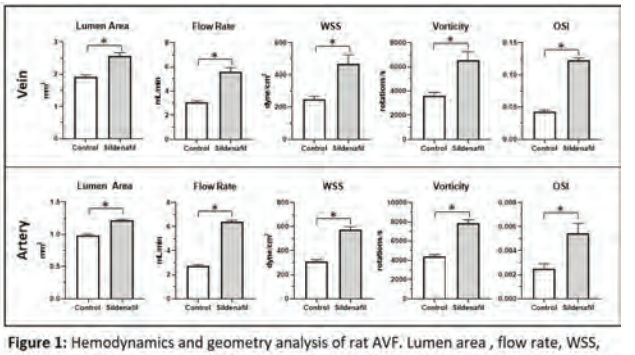

Figure 1: Hemodynamics and geometry analysis of rat AVF. Lumen area , flow rate, WSS, vorticity, and OSI were averaged from start of anastomosis to 10 mm in the vein or artery and throughout a cardiac cycle. Error bars show SEM. *: p<0.0001. Control: n=4, Sildenafil Treatment: n=4.

SU-OR29

Single-Center Real-World Experience with Endovascular Arteriovenous Fistulas

Kareem Genena,[1] Harold M. Szerlip,[1] Neghae Mawla.[2] *[1]Baylor University Medical Center at Dallas, Dallas, TX; [2]Dallas Nephrology Associates Vacular Center - Plano, Plano, TX.*

Background: Endovascular arteriovenous fistulas (EndoAVFs) are created percutaneously via an anastomosis between the radial artery and the perforator vein (Ellipsys), or between the ulnar artery and vein or radial artery and vein (Wavelinq). Flow is directed via the perforator vein to the superficial veins.

Methods: We report partial outcomes for 69 technically successful endoAVF creations for patients on hemodialysis between 5/2019 and 4/2020 using 2 catheter-based devices.

Results: 12/69 endoAVFs failed (17%), all before reaching physiologic usability (ok to use) except for 1 which failed due to failure to cannulate at the dialysis center. The most common reason for failure was thrombosis of the perforator vein. In 49 endoAVFs that reached physiologic usability at time of data review, mean duration from creation to physiologic usability was 92 days and mean number of procedures between endoAVF creation and physiologic usability was 1. At time of data review, 9 endoAVFs were pending physiologic usability. 14/49 (29%) of endoAVFs that reached physiologic usability did so with 0 secondary procedures. Mean postoperative brachial artery flow in this subset was 718 ml/min (range 400-1100 ml/min). Mean flow at 4-6 weeks was 843 ml/min. 35/49 (71%) needed at least 1 procedure. Mean postoperative flow in this subset was 545 ml/min. Mean flow at 4-6 weeks was 721 ml/min. In 44 endoAVFs that had been cannulated at time of data review, mean duration from physiologic usability to cannulation was 9 days. In 33 patients whose dialysis catheters had been removed at time of data review, mean duration from first cannulation to dialysis catheter removal was 57 days.

Conclusions: Successfully created endoAVFs have shorter maturation time than surgical AVFs and require less maturation procedures. Immediate postoperative brachial artery flow is an important predictor of endoAVF behavior/outcome. All endoAVFs that reached physiologic usability with 0 secondary procedures had a postoperative flow above 400 ml/min, and mean postoperative flow was higher than those that needed at least 1 procedure. Time from first cannulation to dialysis catheter removal represents a pragmatic measure for endoAVFs. Cannulation injuries sometimes obligate a period of endoAVF rest. Removal of the dialysis catheter not only indicates functional usability of the endoAVF but also proficiency of the dialysis units in cannulating them.

SU-OR30

Association Between Antimicrobial Barrier Cap Use and Outcomes Among Hemodialysis Patients Using a Central Venous Catheter

Scott Sibbel,[1] Abigail Hunt,[1] David B. Van Wyck,[2] Lysa Jordan,[1] Francesca Tentori,[1] Allen R. Nissenson,[2] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Bloodstream infections (BSIs) are a common complication of central venous catheter (CVC) use and contribute to hospitalization, mortality, and high costs of care in patients on hemodialysis (HD). In a prior randomized clinical trial, patients using CVCs with antimicrobial barrier caps (AmBC; ClearGuard® HD, Pursuit Vascular Inc, Maple Grove, MN, USA) had significantly lower catheter-related BSI rates compared to patients using CVCs with the historical standard of care. Based on these findings, AmBCs were introduced in May 2019 as standard of care for CVC patients across a large dialysis organization (LDO). This study assessed changes in clinical outcomes in a real-world HD population following implementation of AmBC use.

Methods: Study data were derived from LDO electronic medical records over two 3-month periods: Pre (Jul-Oct 2018) and Post (Jul-Oct 2019) AmBC adoption. Included patients were adults receiving in-center HD treatment 3x/week using a CVC. Crude outcome rates were calculated for individual calendar months and for the pre- and post-periods overall; formal comparisons were made using generalized linear models.

Results: A total of 37,642 patients in the pre-period and 40,498 patients in the post-period met eligibility criteria. Overall BSI rate fell from 0.54/100 CVC days in the pre-period to 0.36/100 CVC days after AmBC implementation. Hospitalization rates were lower during the post-period versus the pre-period overall and within each calendar month; the contribution of underlying temporal changes (eg, background year-over-year change) could not be quantified.

Conclusions: Adoption of AmBCs for use in HD patients using a CVC for vascular access was associated with an early 34% reduction in infections assessed on the basis of positive blood cultures and 0.22 fewer hospital admissions per patient-year.

Two-Year Results from a Randomized, Controlled Study of Obinutuzumab for Proliferative Lupus Nephritis

Brad H. Rovin,[1] Gustavo Aroca Martinez,[2] Analia Alvarez,[3] Hilda E. Fragoso loyo,[4] Adolfina E. Zuta,[5] Richard Furie,[6] Paul G. Brunetta,[7] Thomas Schindler,[8] Imran Hassan,[9] Matthew Cascino,[7] Jay P. Garg,[7] Ana Malvar.[10] *[1]Ohio State University, Columbus, OH; [2]Simon Bolivar University y Clinica de la Costa, Barranquilla, Colombia; [3]CEMIC, Buenos Aires, Argentina; [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [5]Instituto de Ginecología y Reproducción, Lima, Peru; [6]Northwell Health, Great Neck, NY; [7]Genentech, Inc, South San Francisco, CA; [8]F. Hoffmann-La Roche AG, Basel, Switzerland; [9]Hoffmann-La Roche Ltd, Mississauga, ON, Canada; [10]Organizacion Maedica de Investigacion, Buenos Aires, Argentina.*

Background: NOBILITY demonstrated improved renal responses and complete B-cell depletion with the humanized type II anti-CD20 monoclonal antibody obinutuzumab (OBI) compared with placebo (PBO) through 18 months in patients with proliferative lupus nephritis (LN) when added to standard of care therapies. Two-year results from NOBILITY are reported here.

Methods: Patients with class III/IV LN received mycophenolate and steroids and were randomized to OBI or PBO. The primary endpoint was complete renal response (CRR) at week 52. Patients were followed through week 104. Secondary endpoints included overall renal response (ORR) and modified CRR (mCRR).

Results: CRR was greater with OBI than PBO at week 52 (35% vs. 23%, $P = 0.115$), week 76 (40% vs. 18%, $P = 0.007$), and week 104 (41% vs 23%, $P = 0.026$; Table). At week 104, OBI patients had greater improvement in eGFR (+6.5 vs. -3.2 mL/min/1.73 m^2, $P = 0.018$), UPCR, anti-dsDNA, C3, and C4. Serious adverse events (OBI 25% vs. PBO 30%), serious infections (8% vs. 18%) and deaths (1 vs. 4) were not increased with OBI.

Conclusions: NOBILITY demonstrated a sustained benefit of OBI through week 104, approximately 18 months after the final OBI infusion. There were no unexpected safety findings. OBI use in LN will be further evaluated in the Phase 3 REGENCY trial.

Table. Week 104 Results

Week 104 Endpoint	OBI (n=63)	PBO (n=62)	Difference (80% CI)	P Value
CRR	41%	23%	19% (8, 29)	0.026
ORR	54%	29%	25% (14, 36)	0.005
mCRR	56%	33%	22% (11, 33)	0.015
C3 >90 mg/dL	76%	47%	29% (19, 40)	0.008
C4 >10 mg/dL	95%	74%	21% (13, 29)	0.001
Mean change in eGFR from baseline (mL/min/1.73 m^2)	+6.5	-3.2	9.7 (1.7, 18)	0.018
Mean change in UPCR from baseline	-2.3	-1.4	-0.96 (-1.4, -0.57)	0.002

CRR=UPCR <0.5, serum creatinine (SCr) ≤upper limit of normal (ULN) and ≤115% of baseline, <10 red blood cells per high power field (RBCs/HPF), and no RBC casts.

ORR = CRR or partial renal response=UPCR <1 (<3 if baseline UPCR ≥3) and ≤50% of baseline, SCr ≤115% of baseline, and ≤50% increase in urinary RBCs (or <10 RBCs/HPF).

mCRR = UPCR <0.5, SCr ≤ ULN.

SU-OR32

Complement C5a Receptor Inhibitor Avacopan Improves Renal Function in ANCA Vasculitis

David R. Jayne,[1] Peter A. Merkel,[3] Huibin Yue,[2] Catherine L. Kelleher,[2] Thomas J. Schall,[2] Pirow Bekker.[2] *[1]Addenbrooke's Hospital, Cambridge, United Kingdom; [2]ChemoCentryx Inc, Mountain View, CA; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Renal impairment is common in anti-neutrophil cytoplasmic autoantibody-associated vasculitis. The resulting chronic kidney disease and exacerbation of the toxicity risks of high dose or prolonged glucocorticoid use, a mainstay of ANCA treatment, are major consequences. Avacopan was tested for efficacy and effects on renal function compared to standard prednisone therapy in a randomized double-blind Phase 3 trial in ANCA vasculitis.

Methods: Subjects randomized 1:1 received either prednisone (60 mg tapered to 0 over 20 weeks) or avacopan (30 mg twice daily for 52 weeks), combined with *either* cyclophosphamide (CYC) followed by azathioprine, *or* rituximab (RTX). Primary endpoints: Disease remission at week 26 and sustained remission at week 52. Changes in urinary albumin to creatinine ratio (UACR) and estimated glomerular filtration rate (eGFR) were also assessed.

Results: 330 subjects were treated: 166 to avacopan and 164 to prednisone treatment groups. Avacopan remission at week 26 was 72.3% vs. 70.1%, for prednisone (P<0.0001 for non-inferiority); avacopan was superior to prednisone for sustained remission (week 52, 65.7%, avacopan vs. 54.9%, prednisone, P=0.0066). 81% percent of subjects had renal disease. UACR decreased more rapidly with avacopan than prednisone: week 4 avacopan was 40% below baseline vs. no change for prednisone (P<0.0001). Baseline to week 52 eGFR (mL/min/1.73 m²) improvement: avacopan eGFR +7.3 vs. prednisone +4.1 (P=0.029). In subjects with baseline eGFR <30: mean eGFR improved 67% more with avacopan than prednisone to week 52: avacopan eGFR +13.7 vs. prednisone +8.2 (P=0.01).

Conclusions: Treatment with avacopan for ANCA vasculitis compared with standard glucocorticoid therapy (both combined with either CYC or RTX) is as effective for remission induction at 26 weeks, and superior to prednisone for sustained remission after 52 weeks. Avacopan led to faster falls in UACR and greater recovery in eGFR when compared to standard prednisone therapy. These findings have important implications for the long term health of AAV patients through better overall disease control, reduced prednisone exposure and reduced severity of chronic kidney disease.

SU-OR33

Prognostic Value of Persistent Proteinuria and Hematuria After Induction Therapy in ANCA-Associated Vasculitides

Nicolas Benichou,[1,2] Loïc Guillevin,[6,2] Pierre Charles,[5] Benjamin Terrier,[6,2] Luc Mouthon,[6,2] Thomas F. Hiemstra,[4,3] Rachel B. Jones,[4] David R. Jayne,[4] Alexandre Karras.[1,2] *[1]HEGP, Hopital Europeen Georges Pompidou, Paris, France; [2]Universite de Paris, Paris, France; [3]Cambridge Clinical Trials Unit, Cambridge, United Kingdom; [4]Addenbrooke's Hospital, Cambridge, United Kingdom; [5]Institut Mutualiste Montsouris, Paris, France; [6]Hopital Cochin, Paris, France.*

Background: In ANCA-associated vasculitides (AAV), hematuria and proteinuria are biomarkers reflecting renal involvement at diagnosis. Yet, the prognostic value of their persistence after immunosuppressive induction therapy, which may reflect renal damage or persistent disease, remains uncertain.

Methods: This is a *post hoc* study including participants of 5 European randomized clinical trials on AAV (MAINRITSAN, MAINRITSAN2, RITUXVAS, MYCYC, IMPROVE). We examined the association of PCR (urine protein-creatinine ratio) and hematuria on spot urine samples collected at the end of induction therapy with the occurrence of i) a combined endpoint of death and/or end stage renal disease (ESRD), and ii) relapse during follow-up.

Results: Among 571 patients (59% men, median age 60 years), 60% had PR3-ANCA, 35% had MPO-ANCA, 77% had renal involvement. After induction therapy, 157/526 (29.8%) had persistent hematuria, 165/481 (34.3%) had PCR ≥ 0.05 g/mmol. After a median follow up of 28 months (IQR : 18-42), and adjustment for sex, age, ANCA serotype, initial eGFR, persistent hematuria, a PCR ≥ 0.05 g/mmol after induction was associated with risk of death and/or ESRD (adjusted Hazard Ratio (HR) = 4.08, 95% confidence interval (CI95) 1.48-11.25, p = 0.006). Persistent hematuria was associated with renal relapse (adjusted subdistribution HR = 2.18, CI95 1.14-4.18, p = 0.019) but not with any relapse (adjusted sHR = 1.10, CI95 0.78-1.56, p = 0.59) nor with death and/or ESRD (adjusted HR = 1.88, CI95 = 0.83-4.29, p = 0.132).

Conclusions: In this large cohort of AAV patients, persistent proteinuria after induction therapy was an independent predictor of death and/or ESRD, whereas persistent hematuria after induction therapy was an independent predictor of renal relapse. These parameters must be taken into account to assess long-term renal prognosis of AAV patients.

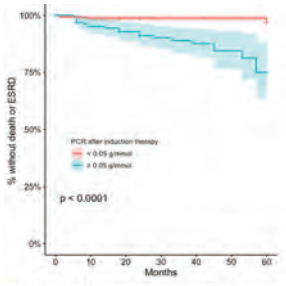

Figure 1. Freedom from composite outcome of death or ESRD

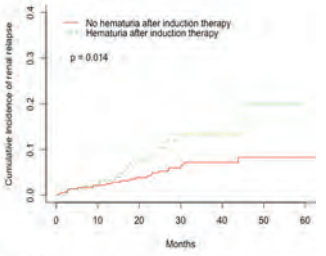

Figure 2. Cumulative incidence of renal relapse (with death, ESRD, non renal relapse as competive risks)

Belimumab (BEL) Improves Renal Outcomes in Active Lupus Nephritis (LN): A Phase 3 Randomized, Placebo (PBO)-Controlled Trial

Brad H. Rovin,[1] Frederic Houssiau,[2] Richard Furie,[3] Ana Malvar,[4] Yoe Kie Onno Teng,[5] Chi chiu Mok,[12] Gabriel Contreras,[6] Xueqing Yu,[7] Sebastian Dolff,[13] Beulah Ji,[8] David A. Roth,[9] Christi Kleoudis,[10] Susan Makowiak,[9] Anuradha Madan,[9] Jennifer Gilbride,[11] Yulia Green.[8] *[1]Division of Nephrology, The Ohio State University, Columbus, OH; [2]Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Université Catholique de Louvain and Service de Rhumatologie, Cliniques Universitaires Saint-Luc, Brussels, Belgium; [3]Division of Rheumatology, Northwell Health, Great Neck, NY; [4]Organizacion Medica de Investigacion, Buenos Aires, Argentina; [5]Expert Center for Lupus-, Vasculitis- and Complement-mediated Systemic diseases, Department of Internal Medicine – section Nephrology, Leiden University Medical Center, Leiden, Netherlands; [6]Division of Nephrology, Division of Hypertension, Department of Medicine, University of Miami Miller School of Medicine, Miami, FL; [7]Department of Nephrology, Guangdong Provincial People's Hospital, Guangzhou, China; [8]GlaxoSmithKline, Uxbridge, United Kingdom; [9]GlaxoSmithKline, Collegeville, PA; [10]Parexel, Durham, NC; [11]GlaxoSmithKline, Stevenage, United Kingdom; [12]Tuen Mun Hospital Department of Medicine and Geriatrics, Hong Kong, Hong Kong; [13]Department of Infectious Diseases, University Hospital Essen, University of Duisburg-Essen, Essen, Germany.*

Background: BEL is approved for patients (pts) with systemic lupus erythematosus (SLE). We evaluated intravenous (IV) BEL in active LN.

Methods: This 104-week trial (GSK Study BEL114054; NCT01639339) randomized adults with active LN (class III, IV, and/or V) 1:1 to monthly BEL 10 mg/kg IV or PBO, plus standard therapy (ST) with high-dose corticosteroids + either cyclophosphamide (CyC) or mycophenolate mofetil (MMF) for induction at the investigator's discretion. CyC was followed by azathioprine (AZA), and MMF by MMF maintenance. The primary endpoint was Primary Efficacy Renal Response (PERR = urine protein:creatinine ratio [uPCR] ≤0.7; estimated glomerular filtration rate [eGFR] no more than 20% below pre-flare value or ≥60 ml/min/1.73m^2; no rescue therapy) at Week 104. Other endpoints were Complete Renal Response (CRR = uPCR <0.5; eGFR no more than 10% below pre-flare value or ≥90 ml/min/1.73m^2; no rescue therapy) at Week 104; time to renal event (end-stage kidney disease, doubling of serum creatinine, increased proteinuria and/or impaired renal function, renal disease-related treatment failure) or death. Endpoints were analyzed by ST regimen.

Results: 224 pts were randomized to each arm. At Week 104, there were significantly more PERR and CRR responders on BEL vs PBO: (43.0% vs 32.3%, OR [95% CI] 1.6 [1.0, 2.3]; p=0.03) and (30.0% vs 19.7%, OR [95% CI] 1.7 [1.1, 2.7]; p=0.02), respectively. Risk of renal event or death was lower in BEL pts relative to PBO (HR [95% CI] 0.5 [0.3, 0.8]; p<0.01). Week 104 PERR response rates in pts on CyC/AZA were 33.9% with BEL and 27.1% with PBO, and 46.3% with BEL vs 34.1% with PBO in those on MMF. BEL reduced risk of renal event or death on background of CYC/AZA (HR [95% CI] 0.5 [0.2, 1.0]) and MMF (HR [95% CI] 0.5 [0.3, 0.8]) relative to PBO. Adverse events (AEs; ≥1) occurred in 95.5% of BEL and 94.2% of PBO pts, and 25.9% of BEL and 29.9% of PBO pts had ≥1 serious AE.

Conclusions: The addition of BEL to commonly used ST for the treatment of LN significantly improved renal responses with no unexpected safety signals.

24-Week Interim Analysis of a Randomized, Double-Blind, Placebo-Controlled Phase 2 Study of Atacicept in Patients with IgA Nephropathy and Persistent Proteinuria

Jonathan Barratt,[3] James A. Tumlin,[1] Yusuke Suzuki,[2] Amy Kao,[4] Aida Aydemir,[4] Yulia Zima,[4] Gerald B. Appel.[5] *[1]Emory University School of Medicine, Atlanta, GA; [2]Juntendo University, Tokyo, Japan; [3]University of Leicester, Leicester, United Kingdom; [4]EMD Serono Research Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica, MA; [5]Columbia University Medical Center, New York, NY.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis and currently has no approved therapy. Its central pathogenic feature is circulating immune complexes of poorly O-galactosylated polymeric IgA1 (Gd-IgA1) that often deposit in the kidneys (causing inflammation and scarring) and trigger formation of IgA/G autoantibodies. Atacicept, a human TACI-Ig fusion protein, inhibits B cell-stimulating factors BLyS and APRIL and is associated with reduced serum IgA/G, mature B cells and plasma cells. This Phase II study (NCT02808429) examines atacicept safety and efficacy in reducing Gd-IgA1 and renal activity in IgAN.

Methods: Patients with IgAN and proteinuria ≥1 g/day or 0.75 mg/mg on 24-hr urine protein-creatinine ratio (UPCR) despite maximal standard of care (ACE inhibitor and/or ARB) were enrolled. Patients were randomized to subcutaneous placebo, atacicept 25mg or 75mg weekly. Primary endpoint: change in proteinuria at Week 48; secondary endpoints: changes in eGFR, serum IgA, IgG, and IgM, and Gd-IgA1.

Results: This interim analysis showed that, at Week 24, IgAN patients (placebo=5; atacicept 25mg=6; 75mg=5) had a consistent, dose-dependent reduction in IgA, IgG and IgM, and in Gd-IgA1 (Fig 1A), and a higher median % reduction from baseline in UPCR with atacicept than with placebo (Fig 1B); eGFR remained stable. TEAEs were reported by 81% of patients (mild/moderate, none severe), with no serious related events, severe hypogammaglobulinemia, or fatal outcomes.

Conclusions: These results provide proof of concept for the potential treatment of patients with IgAN and persistent proteinuria with atacicept.

Funding: Commercial Support - EMD Serono Research & Development Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany)

Grading System Utilizing Total Score of Oxford Classification for Predicting Renal Prognosis in IgA Nephropathy

Yoei Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta, Takahito Moriyama. *Department of Nephrology, Tokyo Women's Medical University, 8-1 Kawada-Cho, Shinjuku-ku, Tokyo, Japan.*

Background: The Oxford classification of IgA nephropathy (IgAN) can evaluate each MEST-C score individually. However, no research has evaluated the prognosis of IgAN patients using the MEST-C score comprehensively. Therefore, we aimed to analyze the usefulness of a new grading system that utilized the total score of each MEST-C score in predicting renal prognosis.

Methods: A total of 871 IgAN patients were classified into three groups using the new Oxford classification system (O-grade) that utilized the total score of each MEST-C score (O-grade I: 0-1, II: 2-4, and III: 5-7 points) according to the renal survival rate (<10%, 10%-30%, >30%, respectively). The 20-year renal prognosis was analyzed, and the O-grade combined with the Japanese clinical classification (C-grade) was also evaluated.

Results: The clinical findings became significantly severer with increasing O-grades, and the renal survival rate by the Kaplan-Meier method was 78.5%, 74.9%, and 42.2% for O-grades I, II, and III, respectively (P<0.001). The hazard ratios (HRs) for O-grades II and III with reference to O-grade I were 1.7 (95% confidence interval [CI], 1.0-2.9; P=0.036) and 4.7 (95% CI, 2.6-8.4; P<0.001), respectively. In the multivariate analysis,

mean blood pressure and renal function, proteinuria, and O-grade (HR, 1.39; 95% CI, 1.02-1.90; P=0.036) were the independent factors predicting the renal prognosis. The renal prognosis in the nine groups classified by the O-grade combined with the C-grade showed HR of 33.7 (P<0.001) in the severest group with reference to the mildest group.

Conclusions: The O-grade classified by the total score of the Oxford classification was associated with renal prognosis, and renal prognosis could be accurately predicted by combining the O-grade with the C-grade. The O-grade allows easier evaluation of the total activity and chronicity of IgAN and prediction of the renal prognosis of this disease.

SU-OR37

Development of a Deep Learning Model to Predict ESKD in Patients with Immunoglobulin A Nephropathy (IgAN) at Kidney Biopsy Time

Francesco P. Schena,[1,2] Vito walter Anelli,[3] Joseph Trotta,[3] Tommaso Di noia,[3] Carlo Manno,[2] Giovanni Tripepi,[4] Graziella D'Arrigo,[4] Maria Luisa Russo,[5] Maria J. Stangou,[6] Aikaterini A. Papagianni,[6] Carmine Zoccali,[4] Vladimir Tesar,[7] Rosanna Coppo.[5] *[1]Schena Faoudation, Bari, Italy; [2]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [3]Polytecnic of Bari, Bari, Italy; [4]CNR -IFC, Reggio Calabria, Italy; [5]Fondazione Ricerca Molinette, Torino, Italy; [6]Aristotle University of Thessaloniki School of Medicine, Nephrology, Thessaloniki, Greece; [7]University of Prague, Prague, Czechia.*

Background: Many prediction models to support clinical decision making have been developed for decades but they are based on traditional statistic linear methods. Another approach is the application of artificial intelligence (AI) that is based on machine learning or deep learning algorithms. We developed an artificial neural network (ANN) tool to predict ESKD in IgAN patients at kidney biopsy time.

Methods: The classifier model to predict ESKD was composed of 4 hidden layers with 100 neurons in each layer. The regression model to predict the time-to-event endpoint consisted of 3 layers containing 125 neurons each.

Results: Our tool, based on these two models, was developed in a cohort of 948 IgAN patients of the VALIGA and Greek cohort. Then, the tool was validated in an independent cohort of 167 IgAN patients from 6 nephrology units. After Cox's regression analysis 7 variables (age, sex, blood pressure values, serum creatinine, daily proteinuria, MESTC classification for the kidney biopsy and therapy at baseline) were chosen to develop the ANN model. The AUC of the ANN model in the study cohort was 0.80. The performance was 0.82 (precision 0.83, accuracy 0.80) for ESKD prediction at 5 years of follow-up and 0.89 (precision 0.81; accuracy 0.83) for patients with 10 years of follow-up. Stable renal function and ESKD were correctly predicted in 91% of IgAN patients in the test cohort.

Conclusions: (i) Our ANN is a promising alternative to the mathematical models in solving non-linear and multidimensional problems. (ii) We have developed a new clinical decision support system that provides additional information to identify IgAN patients at high risk of ESKD. (iii) This tool may stratify patients in the context of a personalized therapy. (iv) This tool will be validated in a clinical prospective study.

Complete Remission of Proteinuria in Patients with Focal Segmental Glomerulosclerosis Treated with Sparsentan, a Dual Endothelin and Angiotensin Receptor Antagonist, in the DUET Trial

Jonathan Hogan,[1] Ulysses Diva,[2] Edward Murphy,[2] Noah Rosenberg,[2] Howard Trachtman,[3] Radko Komers.[2] *[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Retrophin, Inc., San Diego, CA; [3]NYU School of Medicine, NYU Langone Medical Center, New York, NY.*

Background: In FSGS, partial remission (FSGS partial remission endpoint [FPRE]: 40% proteinuria reduction and urine protein/creatinine ratio (UP/C) <1.5 g/g) and complete remission (CR) of proteinuria are strong predictors of kidney survival. In the DUET trial, sparsentan (SPAR) resulted in greater reductions in proteinuria and higher rate of FPRE vs irbesartan (IRB) over the 8-week double-blind (DB) period. This antiproteinuric effect of SPAR was sustained during the open-label extension (OLE) period of DUET. Here we analyze patients who achieved CR (UP/C <0.3 g/g) in DUET.

Methods: DUET randomized patients age 8-75 years with biopsy-proven FSGS, UP/C>1 g/g, and eGFR>30 mL/min to SPAR or IRB for 8 weeks, followed by OLE with all patients receiving SPAR. UP/C and other parameters were measured every 12 weeks during OLE. This post-hoc analysis included all patients on SPAR treatment regardless of original randomization.

Results: Median follow-up on SPAR was 42.5 months. Of 108 subjects dosed with SPAR, 44 (41%) reached CR at least once and 30 (28%) patients reached CR in ≥2 visits (68% of CR patients). CR was achieved by 28 patients within the 1st year on SPAR (Kaplan-Meier estimate: 29%). A history of, or nephrotic syndrome at baseline, was documented in 8 (18%) of CR patients. Of subjects with CR, 14%, 41%, and 45% were originally assigned to 200, 400, and 800 mg/day of SPAR dose cohorts, respectively. No patient achieved CR while on IRB during the DB period. Compared to the overall DUET population, CR patients had similar age, sex, and baseline eGFR, but lower baseline mean UP/C (1.67 g/g vs 2.65 g/g), and higher proportion of baseline immunosuppression (45% vs 35%), in particular with mycophenolate mofetil (18% vs 12%). Achieving CR was associated with better preservation of kidney function compared to not achieving CR. In 6 patients (14%), occurrence of CR followed the initiation of new steroid treatment.

Conclusions: In the DUET trial, a high proportion of patients achieved CR on at least one occasion. These observations support the long-term nephroprotective potential of SPAR in FSGS.

LNP023: A Novel Oral Complement Alternative Pathway Factor B Inhibitor Safely and Effectively Reduces Proteinuria in C3 Glomerulopathy

Edwin K. Wong,[5] Manuel Praga,[3] Carla M. Nester,[4] Erica Daina,[2] Giuseppe Remuzzi,[2] Prasanna Kumar Nidamarthy,[1] Peter R. End,[1] Julie M. Milojevic,[1] Andrea Biondani,[1] Angelo J. Trapani,[1] Nicholas Webb,[1] Dr Guido Junge.[1] *[1]Novartis AG, Basel, Switzerland; [2]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Bergamo, Italy; [3]Hospital 12 de Octubre, Madrid, Spain; [4]The University of Iowa Stead Family Children's Hospital, Iowa City, IA; [5]Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom.*

Background: LNP023 is a highly selective oral low molecular weight inhibitor of complement Factor B, a key alternative pathway (AP) protease. The aim of the preliminary interim analysis (IA) of this Phase 2 study (NCT03832114) was to determine whether LNP023 safely and effectively reduces proteinuria in patients with C3 glomerulopathy (C3G).

Methods: Adults with biopsy-proven native C3G received open-label LNP023 for 12w (10-100mg bid during w1-3 then 200mg bid w4-12). All had proteinuria >1g/24h, low plasma C3, stable ACEi/ARB and were vaccinated vs. encapsulated bacteria. Complement inhibition was measured by the *ex vivo* Wieslab assay and fragment Bb and soluble C5b-9 (sC5b-9) levels. Study primary end-point was the ratio of UPCR at 12w vs. baseline. On study completion, all patients received ongoing LNP023 in a long-term extension study (NCT03955445).

Results: 7 patients completed therapy at the time of this IA: mean (range) age 25 (18-39)y, median (range) eGFR 80 (29-130)ml/min/1.73m^2. There were no treatment discontinuations. UPCR levels fell by 53% (80% CI 40-64%) from a Geo-Mean (Geo-CV%) value of 399 (67.6)mg/mmol at baseline to 187 (104.3)mg/mmol at 12w, p=0.0035. eGFR improved or stabilised; median (IQR) change +4.0 ml/min/1.73m2 (-0.5 - +7.5ml/min/1.73m^2). There were no deaths or treatment-emergent SAEs. Blood and urine complement biomarkers confirmed abnormal pre-dosing AP activity in all. Plasma C3 levels recovered, with complete normalisation in 5/7 at 12w. LNP023 inhibited AP activity, with maximal effects obtained at 100mg to 200mg bid (median percent changes from BL at maximum inhibition were Wieslab: -66.3% (N=5), plasma Bb: -13.6% (N=5), plasma SC5b-9 (N=6): -75.9%, urine SC5b-9: -94.9% (N=4)). There was little impact of reduced eGFR on LNP023 systemic exposure. In 6 patients who have entered the long-term extension study to date there has been further reduction in proteinuria; Geo-CV% UPCR value at 6m was 129 (109.9)mg/mmol, a fall of 67.7% from baseline.

Conclusions: LNP023 200mg bid resulted in AP blockade and reduced proteinuria in patients with C3G treated for 12w with excellent safety and tolerability. Extended treatment resulted in further proteinuria reduction.

Characteristics and Outcomes of Pregnancy-Triggered Atypical Hemolytic-Uremic Syndrome (aHUS): Global aHUS Registry Analysis

Fadi Fakhouri,[1] Benjamin Miller,[2] Marie Scully,[3] Gianluigi Ardissino,[4] Imad Al-Dakkak,[2] Eric Rondeau.[5] *[1]University of Lausanne, Lausanne, Switzerland; [2]Alexion Pharmaceuticals Inc., Boston, MA; [3]University College London, London, United Kingdom; [4]Center for HUS Control, Prevention and Management, Milan, Italy; [5]Hôpital Tenon, Paris, France.*

Background: Pregnancy-triggered aHUS (P-aHUS) accounts for 10–20% of aHUS diagnoses. Complement-mediated thrombotic microangiopathy (CM-TMA) may be associated with high maternal and fetal morbidity and mortality such as ESRD. The clinical characteristics of P-aHUS and survival probability in patients treated with the complement C5 inhibitor eculizumab are described, using the largest collection of P-aHUS data available in a single study.

Methods: Patients with a clinical diagnosis of aHUS were included in the global aHUS registry (NCT01522183). Patients with P-aHUS were selected as those with first TMA manifestations during pregnancy or within 60 days postpartum. Patients with other triggers of aHUS were excluded. Survival, based on time to ESRD, was calculated by the Kaplan-Meier method.

Results: In the registry, 51/1029 female patients were selected with P-aHUS and 27 received eculizumab. Mean ± SD age at pregnancy onset was 30.7 ± 5.9 years. P-aHUS occurred during pregnancy in 28 (54.9%) patients, with the remainder occurring postpartum. A diagnosis of pre-eclampsia or HELLP (hemolysis elevated liver enzymes low platelet count) syndrome was reported in 28 (54.9%) and 17 (33.3%) patients, respectively. A complement pathogenic variant was identified in 23 (45.1%) patients, of whom 3 (8.3%) also tested positive for anti-complement factor H antibodies. Mean ± SD eculizumab treatment duration was 1.8 ± 1.8 years. Survival probability was higher in eculizumab-treated patients compared with patients not receiving eculizumab (Figure).

Conclusions: Survival probability was higher in patients who received eculizumab compared with patients who did not receive eculizumab. Successful treatment with eculizumab, in addition to almost half of the patients having a complement pathogenic variant, confirms the appropriate classification of P-aHUS as a CM-TMA.

SU-OR41

Differences in Kidney Failure Risk by Race/Ethnicity at the Time of GFR-Based Transplant Eligibility

Chi D. Chu,[1,2] Neil R. Powe,[1,3] Delphine S. Tuot.[1,3] *[1]University of California San Francisco, San Francisco, CA; [2]OptumLabs Visiting Scholar, Cambridge, MA; [3]Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.*

Background: Glomerular filtration rate (GFR) less than 20 ml/min/m^2 is a criterion for kidney transplant listing, but variation in underlying end-stage kidney disease (ESKD) risk distributions by race/ethnicity has the potential to produce systematic racial disparities due to under recognition of the higher progression risk when a singular eGFR threshold is used as a decision point.

Methods: We compared predicted kidney failure risk by race/ethnicity for patients at the time their eGFR fell below 20 ml/min/m^2 using the OptumLabs® Data Warehouse (OLDW), a longitudinal, real-world data asset with de-identified administrative claims and electronic health record (EHR) data. We identified patients 18-70 years old from 1/1/2014-6/30/2019 who had at least one eGFR >20 ml/min/m^2, and at least two later eGFR values ≤20 ml/min/m^2 that were ≥90 days separated, who also had a urine albumin/creatinine ratio (UACR) measured within 90 days of the first eGFR ≤20 ml/min/m^2. We calculated 2-year risk of ESKD for each patient using the 4-variable Kidney Failure Risk Equation and compared the distributions by race/ethnicity.

Results: Of 2926 patients, 2024 were non-Hispanic white (NHW), 649 non-Hispanic black (NHB), and 253 Hispanic. At the time of incident eGFR ≤20 ml/min/m^2, NHWs were older than NHB or Hispanic patients (mean age 59.2 versus 56.2 or 54.3 years, respectively) and had lower median UACR (0.67 versus 1.36 or 1.72 g/g, respectively). Compared to ESKD risk among NHWs (median predicted risk 38.7%), the risk distribution was skewed toward higher risk for NHB and Hispanic patients, who had median predicted risks of 49.4% and 55.8% respectively (Figure).

Conclusions: At the time of incident eGFR ≤20 ml/min/m^2, NHB and Hispanic populations had greater risk of ESKD. A racial/ethnic disparity in time from GFR-based transplant eligibility to ESKD may exist even with elimination of disparities in timing of transplant referral and waitlisting. Consideration of kidney failure risk might be given greater attention in access to transplantation.

Exploration of Racial Disparities in the Kidney Transplant Process Among Dialysis Patients

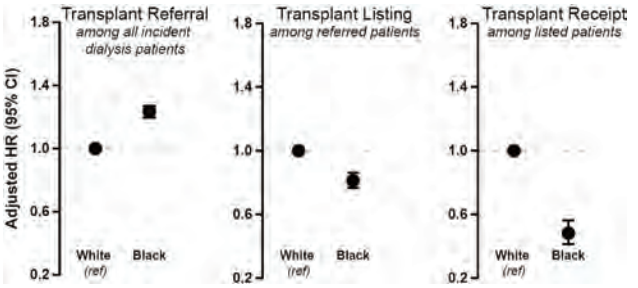
Steven M. Brunelli, Abigail Hunt, Carey Colson, Francesca Tentori. *Davita Clinical Research, Minneapolis, MN.*

Background: Kidney transplant is generally considered the best long-term treatment for dialysis patients. Before receiving a transplant, a patient must be referred to a transplant center, undergo extensive clinical evaluation, and then be placed on a wait list. Previous studies have observed that black patients are less likely to receive kidney transplants than white patients. However, it is unclear at which points in the transplant process inequity is imparted. In this analysis, we used a single source of data to compare the entire transplant process among black and white patients at a large dialysis organization (LDO).

Methods: Eligible patients were those who, between Jul 2015-Jun 2018, were 18-80 years old; were incident to dialysis and began care at the LDO within 30 days of first ever dialysis; and had not undergone a transplant evaluation or listing prior to dialysis start. Exposure was ascribed based on race as documented in LDO medical records (black or white). Patients were followed forward in time from study entry until 31 Mar 2019 or censoring or loss to follow-up. Transplant referrals, listings, and receipts were compared across exposure categories using time-to-event models adjusted for demographics, comorbidities, biochemistries, and socioeconomic factors

Results: We identified 60,229 eligible incident patients (23,499 black; 36,730 white). Compared to whites, black patients were 23% more likely to be referred for transplant (hazard ratio [HR] and 95% confidence interval [CI] = 1.23 [1.20, 1.27]). Among referred patients, black patients were 19% less likely to be placed on a wait list than whites (HR [95% CI] = 0.81 [0.77, 0.86]). Among wait-listed patients, black patients were 52% less likely to receive a transplant than whites (HR [95% CI] = 0.48 [0.41, 0.56]). Overall, black patients were only 46% as likely to receive transplants as white patients (HR [95% CI] = 0.46 [0.39, 0.53]).

Conclusions: These results support prior findings that racial disparities exist within the kidney transplant process and indicate that these disparities occur downstream of the referral.



SU-OR43

Do Social Determinants of Health Predict Patient-Reported Outcomes in Transplant-Eligible ESRD Patients?

Samuel L. Swift,[1] Shu Wang,[2] Chung-Chou H. Chang,[3] John R. Pleis,[7] Mary amanda Dew,[3] Ron Shapiro,[4] Mark L. Unruh,[1] Emilee J. Croswell,[3] Kellee Kendall,[5] John D. Peipert,[6] Larissa Myaskovsky.[1] *[1]University of New Mexico, Albuquerque, NM; [2]University of Florida, Gainesville, FL; [3]University of Pittsburgh, Pittsburgh, PA; [4]Mount Sinai Health System, New York, NY; [5]Highmark Inc, Pittsburgh, PA; [6]Northwestern University Feinberg School of Medicine, Chicago, IL; [7]Centers for Disease Control and Prevention, Hyattsville, MD.*

Background: Measuring and understanding patient reported outcomes [PRO, e.g., health related quality of life (HRQoL) and satisfaction with transplant clinic service] is a critical consideration for the care of kidney transplant (KT) eligible patients with end-stage renal disease (ESRD), because research has demonstrated that pre-transplant HRQoL predicts both the receipt of a KT as well as post-KT mortality. Although research demonstrated the importance of social determinates of health (e.g., cultural factors, psychosocial characteristics, transplant knowledge) on clinical outcomes, less is known about how they predict PRO in KT-eligible ESRD patients.

Methods: We examined whether social determinants of health (Time 1, assessed shortly after initiating KT evaluation) are risk or protective factors for PRO (Time 2, assessed after notification of KT evaluation outcome – accepted or not), controlling for evaluation outcome, in a prospective cohort study. Of the initial 1152 adults referred for KT evaluation (2010-2012), 955 completed a Time 2 interview, most within 1 year of completing KT evaluation [n≤6 months=70% (669), n>6 months to≤12 months=8% (76), n>12 months=22% (210)]. We used the Physical Composite Score (PCS), Mental Health Composite Score (MCS), and Kidney Summary Score (KSS), from the Kidney Disease Quality of Life Short Form (KDQoL-SF) to measure HRQoL, and the Client Satisfaction Questionnaire to measure satisfaction with KT clinic service.

Results: Participants completed KT evaluation in an average of 11.7 months (range= 0-43 months). In adjusted multivariable regression models, a stronger sense of mastery predicted higher PCS (β=4.5, p <0.001), MCS (β=5.4, p<0.001), and KSS (β=5.6, p=<0.001). Depression predicted lower MCS (β=-6.2, p=0.001), and lower KSS (β=-5.1, p=0.002). More medical mistrust predicted lower odds of higher patient satisfaction scores (OR= 0.6, 95% CI=0.4, 0.8, p=0.002).

Conclusions: Transplant teams should consider identifying and targeting patients with a low sense of mastery, greater depressive symptoms, or an increased sense of medical mistrust, with additional psychosocial support to improve PRO during the KT evaluation process.

Genetic vs. Self-Reported African Ancestry and Kidney Allograft Outcome: Analysis of Two Large Multiethnic Urban Transplant Cohorts

Francesca Zanoni,[1] Y. Dana Neugut,[1] Sumit Mohan,[1] Ali G. Gharavi,[1] Brendan Keating,[2] Krzysztof Kiryluk.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]University of Pennsylvania, Philadelphia, PA.*

Background: African-American (AA) kidney transplant recipients have higher risk of allograft rejection and failure. However, it is unknown to what extent the inferior outcomes in self-reported AA's are due to genetic versus environmental effects. Herein, we compared the effects of self-reported race versus genetic African admixture on graft outcomes.

Methods: A discovery multiethnic cohort of 1,083 kidney transplant recipients from Columbia University and a replication cohort of 761 kidney transplant recipients from University of Pennsylvania were genotyped with high resolution SNP arrays. African admixture proportions, a genetically-derived quantitative measure of African ancestry, was estimated with ADMIXTURE software. Multivariable Cox models were used to investigate associations between African ancestry measures and time to rejection and time to death-censored graft failure, with adjustments for relevant covariates. Akaike information criterion (AIC) was used to compare the models.

Results: 206 and 346 self-identified AA were included in the discovery and replication cohorts, respectively. Over a median follow-up time of 78 months, 432 patients had rejection and 193 had graft failure in the discovery cohort. Self-reported AA ancestry and African admixture were associated with acute rejection (self-report: HR 1.47, 95% CI: 1.18-1.83, AIC: 5540.1; admixture: HR 1.64, 95% CI: 1.22-2.19, AIC: 5541) and graft failure (self-report: HR 1.42, 95% CI: 1.02-1.97, AIC: 2281.9; admixture: HR 1.48, 95% CI: 0.96-2.29, AIC: 2282.9). In the replication cohort, during a median follow-up time of 49 months, 113 patients had rejection and 121 had failure. Self-reported AA ancestry and African admixture measures confirmed to be associated with both acute rejection (self-report: HR 3.06, 95% CI: 1.96-4.78, AIC: 1289.5; admixture: HR 3.69, 95% CI: 2.21-6.16, AIC: 1288.9) and failure (self-report: HR 2.16, 95% CI: 1.43-3.27, AIC: 1113.8; admixture: HR 2.46, 95% CI: 1.54-3.94, AIC: 1113.1). In this cohort, the models including African admixture proportion had a better fit when compared to self-report.

Conclusions: In conclusion, self-reported AA race and a genetically-derived continuous measure of African ancestry predict the risk of allograft rejection and failure in multiethnic and genetically diverse cohorts.

Deceased Donor Families and Authorization for Research: Differences Among Ethnic Groups

Mariella O. Goggins,[1,2] Giselle Guerra.[1,2] Miami Transplant Institute *[1]University of Miami School of Medicine, Miami, FL; [2]Miami Transplant Institute, Miami, FL.*

Background: Research in transplantation requires next of kin(NOK) to authorize for participation in research. Aim was to determine the rate of research authorization by the NOK within different ethnic groups: African American(AA), White (W) or Hispanic(H).

Methods: Single center study of all deceased donor kidney transplants referred to our institution during 3/1/2019-10/31/2019 from multiple organ procurement organizations(OPO) across the United States. We looked at the authorization for donation form in DonorNet. We searched for the NOK research authorization agreement at the time of organ donation. Donors were grouped by self-identified ethnic groups as W, AA or H

Results: We had a total of 297 donors, yielding 401 kidney offers. 71% were imported from 46 different OPOs and 29% from our local OPO. Mean donor age (±SE) was 45.7±0.9. Donor ethnicity distribution was W 180 (60.6%); AA 66 (22.2%) and H 50 (16.8%). Overall 226 (76.1%) donors' NOK authorized for research and 71 (23.9%) declined research. Donor age <35yr had a lower rate of authorization 62.9% vs 81.3% and 80.6% for 35-49yr and>50yr respectively p=0.006. Table 1 shows ethnic distribution on rate of NOK authorization for research, which was significantly lower within AA donors 38/66 (57.6%). Logistic regression showed donor age<35yr and AA donor as more likely to decline research authorization, yielding multivariable p=0.0001 for AA donor and p=0.002 for younger donor age. Multivariable percentages who declined research authorization had highest rate among AA donors<35yr at 55%(11/20) compared to 37.0%(17/46) in AA donors>35yr; 31.0%(18/58) in W/H donors <35yr; and 14.5%(25/173) in W/H donors>35yr. Out of 401 donated kidneys, 93(23%) were not authorized to participate in research, of which 38/93(40.9%) were AA; 15/93(16.1%) were H and 40/93(43.1%) were W donors

Conclusions: In deceased donors from local and imported OPOs, the rate of declined authorization for research participation from NOK was higher among donors from AA ethnicity compared to donors from W or H backgrounds, especially when donor age is <35. Community education is crucial in the field.

Table 1: Rate of NOK Authorization for Research

Agree to Research	W (n=181)	AA (n=66)	H (n=50)
yes n(%)	152 (83.9%)	38 (57.6%)	36 (72%)
no n(%)	29 (16.1%)*	28 (42.4%)*	14 (28%)*

Minimum Diagnostic Criteria for Thrombotic Microangiopathy in Renal Allograft: The Banff TMA Working Group Phase I Results

Marjan Afrouzian. Banff TMA Working Group *University of Texas Medical Branch at Galveston, Galveston, TX.*

Background: Thrombotic Microangiopathy (TMA) TMA is a serious complication of renal transplantation, usually with poor outcome. The Banff TMA Working Group (TMA-WG) was formed to study renal transplant TMA (t-TMA) aiming to: 1- Survey current practices used in the diagnosis of t-TMA; 2- Define minimum diagnostic criteria (MDC); and 3- Develop recommendations for accurate diagnosis integrating morphological, clinical, laboratory and molecular findings, where available. The project started with Phase I (pathology phase) and is continuing in Phase II (Nephrology phase).

Methods: Using the Delphi methodology during phase I, 23 nephropthologists who had >3 years of experience with t-TMA were asked to list their MDC for t-TMA in the following categories: 1- Light, 2- immunofluorescence, and 3- electron microscopy, 4- clinical history, 5- laboratory findings, 6- genetic testing and 7- raised differential diagnoses. Nine rounds (R) of surveys were designed. At the end of each R, MDC were narrowed down following Delphi rules. R6 and R7 were designated as the validation Rs in which the narrowed criteria were validated on 37 renal biopsies (25 TMA and 12 non-TMA cases) using Aperio Imagescope and whole slide digital images scanned @ X400. For each biopsy, pertinent pathology/history/laboratory/genetic information were provided. Descriptive statistical analysis was performed using SPSS program.

Results: Starting with 338 criteria in R1 and following analysis of total 82,677 data entries, MDC were narrowed down to 35, by the end of R9. The graph illustrates the evolution of the criteria over 9 R. A complete list of 35 MDC will be presented at the meeting.

Conclusions: Applying the Delphi methodology to a cohort of t-TMA biopsies in Phase I of the project, nephropathologists from 4 continents generated histopathologic, clinical and laboratory MDC for renal t-TMA. Phase II (Nephrology consensus) and Phase III (consensus of the consensus groups- Combined Phases I & II) will follow Phase I to generate final MDC for t-TMA.

Does Screening for Coronary Artery Disease Predict Cardiac Outcomes Following Renal Transplantation?

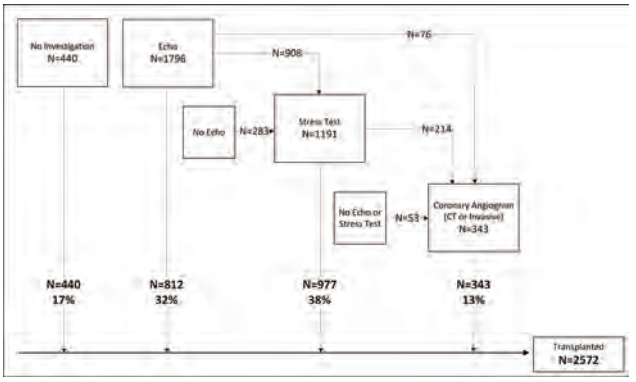
Ailish Nimmo, Dominic M. Taylor, Rommel Ravanan. *Southmead Hospital, Bristol, United Kingdom.*

Background: Screening for asymptomatic coronary artery disease (CAD) prior to transplantation aims to reduce perioperative cardiac events. There is conflicting evidence as to whether this is achieved.

Methods: Individuals recruited to the Access to Transplant and Transplant Outcome Measures (ATTOM) study in England who received a renal transplant between 2011-2017 were studied. Patient demographics and details of screening investigations from ATTOM were linked to outcome data from the Hospital Episode Statistics dataset. Major Adverse Cardiac Events (MACE) comprised unstable angina, myocardial infarction, coronary bypass graft, coronary angioplasty or cardiac death. The effect of screening on MACE was analysed in propensity score-matched groups, using Cox survival analyses, up to 5 years post-transplant.

Results: 2572 individuals received a renal transplant; 51% underwent CAD screening (Figure 1). Age, ethnicity, ischaemic heart disease and diabetes were independently associated with screening. The incidence of MACE at 90 days, 1 and 5 years was 0.9%, 2.1% and 9.4%. After propensity score matching, 1854 individuals were examined. There was no association between screening and MACE at 90 days (HR 0.68, 95% CI 0.28-1.64), 1 year (HR 1.24, 95% CI 0.60–2.54) or 5 years (HR 1.31, 95% CI 0.95–1.79) (Figure 2).

Conclusions: Screening for CAD did not influence the rate of ischaemic cardiac events up to 5 years post-transplant. Units should review protocols with lengthy cardiac workup processes.



Workup patterns. Stress tests: exercise tolerance test, stress echo or myocardial perfusion scan.

Albuminuria in Kidney Transplantation Patients Predicts Cardiovascular Morbidity After Two Years

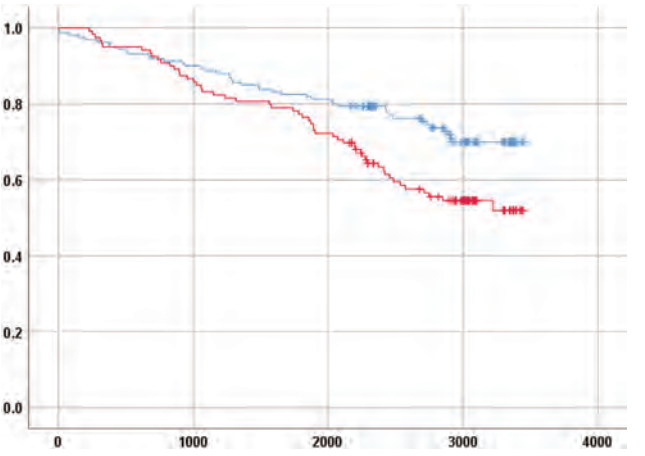
Dana Bielopolski,[1,2] Ruth Rahamimov,[2] Boris Zingerman,[2] Avry Chagnac,[2] Limor Azulay gitter,[2] Benaya Rozen-zvi.[2] *[1]The Rockefeller University, New York, NY; [2]Rabin Medical Center, Petah Tikva, Israel.*

Background: Moderately Increased Albuminuria (MIA) is a well characterized marker of kidney malfunction, both in diabetic and non-diabetic populations, and is used as a prognostic marker for cardiovascular morbidity and mortality. A few studies implied that it has the same value in kidney transplanted patients, but the information relies on spot or dipstick urine protein evaluations, rather than the gold standard of timed urine collection.

Methods: We revisited a cohort of 286 kidney transplanted patients, several years after completing a meticulously timed urine collection and assessed the prevalence of major cardiovascular adverse events (MACE) in relation to albuminuria.

Results: During a median follow up of 8.3 years (IQR 6.4-9.1) 144 outcome events occurred in 101 patients. By Kaplan-Meier analysis MIA was associated with increased rate of CV outcome or death (p=0.03), and this was still significant after stratification according to propensity score quartiles (p=0.048). Time dependent Cox proportional hazard analysis showed independent association between MIA and CV outcomes two years following MIA detection (HR 1.83, 95% CI 1.07-2.96).

Conclusions: Two years after documenting MIA in kidney transplanted patients, their CVD risk was increased, most likely, as a result of endothelial dysfunction. This should prompt the caregiver for strict primary prevention and risk factors modification.



Kaplan-Meier analysis showing rate of CV outcome or death in relation to MIA. X axis shows days since urine collection, Y axis shows cumulative survival. Blue curve – patients without MIA, red curve – patients with MIA.

SU-OR49

Renal Graft Outcomes in Simultaneous Kidney-Heart Transplant Recipients: Analysis of the UNOS Database from 1987-2018

Krishna A. Agarwal, Het Patel, Francesca Cardarelli, Nikhil Agrawal. BIDMC *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Simultaneous kidney and heart transplants (SKHT) are employed for patients with both end-stage heart failure and severely impaired kidney function. Renal outcomes in such recipients have been described, albeit in single-center cohorts. We analyzed the United Network for Organ Sharing (UNOS) dataset comprising of 1702 simultaneous kidney-heart transplant recipients since 1987.

Methods: This is a retrospective analysis of SKHT recipients in the UNOS dataset who received transplants between October 1987 and December 2018. We compared the incidence and risk factors of renal allograft loss in SKHT recipients versus deceased donor kidney (DDKT) alone recipients. The Student t-test or Kruskal Wallis tests were used to compare continuous variables, and the Chi2 test for categorical variables between groups. Cox regression hazard model was used to study the factors associated with graft failure.

Results: SKHT recipients were mostly white, males, 5-years older than DDKT recipients. The SKHT donors were younger than DDKT donors, predominantly white males who died from a CVA. Five year patient survival was similar in both the groups (80%) but 1-year mortality was 3 times higher in the SKHT group (12.5%) than DDKT (4.6%). Nearly 20% recipients in both groups died with a functioning graft. Renal graft survival in SKHT group was lower in the first year but equalized with DDKT group over 5 years. Cox regression analysis revealed male gender [HR 2.14], pre-emptive renal transplantation [HR 6.57] and HLA mismatch >4 [5.60] as significant risk factors for renal graft failure in SKHT recipients as compared to DDKT recipients at 4 years. Predominant cause of graft failure in SKHT recipients was primary failure (36%) and in DDKT recipients was acute rejection (26%).

Conclusions: This is the largest analysis of the UNOS database till date to describe risk factors associated with renal graft loss in SKHT recipients. We also showed that 38% of grafts that fail in SKHT recipients, failed in the first year following transplant and primary failure was the predominant cause. Our analysis provides much needed data to policy makers for future combined organ allocation policies.

Recurrence of IgA Nephropathy After Kidney Transplantation: TANGO Multicenter Study

Audrey Uffing,[1,2] Paolo Cravedi,[3] Leonardo V. Riella.[1] TANGO-project *[1]Brigham and Women's Hospital, Boston, MA; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

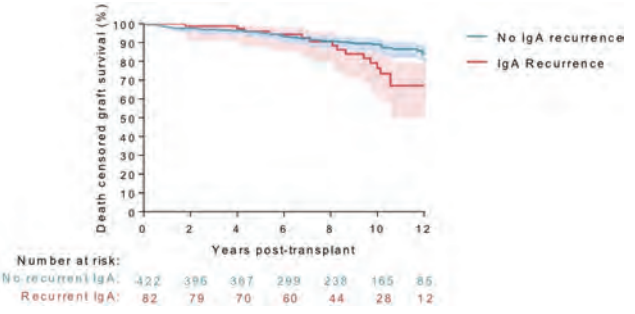
Background: In patients who received a kidney transplantation for end-stage renal disease (ESRD) due to IgA nephropathy, IgA deposits can recur in the transplanted kidney. The incidence, impact and predictors of these recurrent deposits is unclear.

Methods: As part of The Post-Transplant Glomerular Disease (TANGO) project, we performed a multicenter, international, retrospective study to determine the incidence, predictors and treatment response of recurrent IgA deposits after kidney transplantation. Patients with biopsy-proven IgA nephropathy, transplanted in the period 2005-2015 were selected in 16 TANGO centers in Europe, United States and Brazil.

Results: In a total of 504 patients, recurrent IgA deposits were identified by kidney biopsy in 82 patients (16%; 95%CI: 13-19), with a median time to recurrence of 3.4 years (IQR 1.4-5.7 years). Kaplan-Meier analysis showed similar graft survival between patients with and without recurrence in the first years after kidney transplant, though after 8 years, graft failure rates were higher in patients with recurrence (10 year death-censored graft survival 76% and 89%, respectively). Multivariable Cox-regression revealed a higher risk for IgA recurrence

in patients with a pre-emptive kidney transplant (HR 2.56, 95%CI: 1.59-4.17), patients with DSA at time of transplant (HR 2.74, 95%CI: 1.22-6.14) and patients with shorter time from diagnosis to ESRD (HR 0.84 per month, 95%CI: 0.74-0.96). The presence of systemic autoimmune diseases associated with IgA nephropathy did not affect recurrence rates, nor did early steroid withdrawal. In multivariate analysis of post-transplant complications, *de novo* DSA was associated with recurrence of IgA deposits (HR 1.91, 95%CI: 1.04-3.51).

Conclusions: In our international cohort, IgA deposits recurred in 16% of patients and was associated with worse graft outcomes after 8 years of transplant compared to patients without recurrence. A pre-emptive transplant, shorter time from native diagnosis to ESRD, DSA at time of transplant and *de novo* DSA after kidney transplantation were associated with recurrence of IgA deposits



PO2614

Renin Does Not Associate with Mortality or AKI in Acute Respiratory Distress Syndrome

Ian Mccoy,[1] Michael Matthay,[2] Jason Abbott,[2] Chi-yuan Hsu,[2] Kathleen D. Liu.[2] *[1]Stanford University School of Medicine, Palo Alto, CA; [2]University of California San Francisco, San Francisco, CA.*

Background: Renin may be a marker of severity of illness and mortality in critically ill patients. Angiotensin II infusions in patients with lower renin levels may increase the rate of renal recovery from dialysis-requiring AKI. Given that most ACE is found in the lungs and an ACE defect would lead to higher renin levels, we tested associations between renin and clinical outcomes in patients with acute respiratory distress syndrome (ARDS).

Methods: We studied 63 patients with plasma renin measurements enrolled in a phase 1/2 trial of bone marrow-derived human MSCs for moderate-severe ARDS. We estimated associations between renin levels (as a continuous variable) and ARDS severity (assessed by PaO_2/FiO_2), mean arterial pressure (MAP), and serum creatinine at randomization. We then examined if renin was associated with subsequent AKI (defined as ≥ 2x ↑ SCr or new dialysis) or in-hospital mortality.

Results: The median renin was 72 pg/mL (25^{th}-75^{th} percentile 33-181 pg/mL). At randomization, there was no cross-sectional correlation between renin level and PaO_2/FiO_2 (R^2 = 0.03, 95% CI 0.00-0.14, p = 0.21), between renin level and MAP (R^2 = 0.01, 95% CI 0.00-0.12, p = 0.35), or between renin level and serum creatinine (R^2 = 0.003, 95% CI 0.00-0.08, p = 0.68). In longitudinal unadjusted analysis, renin did not significantly associate with AKI (OR 1.006 per 10 pg/mL increase, 95% CI 0.992-1.021, p = 0.41) or 28-day mortality (OR 1.000 per 10 pg/mL, 95% CI 0.987-1.014, p = 0.97). Results were similar in adjusted analyses. Serum creatinine at randomization was associated with AKI (OR 3.27 per mg/dL, 95% CI 1.47-7.30, p = 0.004).

Conclusions: We did not find that renin level is a risk factor for mortality or AKI in moderate-severe ARDS.

Renal Denervation Alleviates Renal Ischemic-Reperfusion Injury-Induced Acute and Chronic Kidney Injury Partly by Modulating MiRNAs in Rats

Xiangyu Zou. *Shanghai Childrens Medical Center Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: Renal denervation (RDN) has been used as a potential medium for kidney injury repair and miRNAs involved in the pathophysiology of renal injury. However, the change of miRNAs after RDN and its proper protective mechanisms has yet to be determined.

Methods: Renal ischemic reperfusion injury (IRI) rat model was established and RDN was applied. Animals were sacrificed at 24 hours and 2 weeks after operation. Tyrosine hydroxylase (TH), renal functions, tubular cell apoptosis and histology staining were examined at 24 hours, and renal fibrosis and capillary vessels were measured at 2 weeks. What is more, the expression of miRNAs in injured kidney was determined by micro-array and the target genes were analyzed. Lastly, human renal biopsy samples with chronic kidney disease were picked for the TH and fibrosis analysis.

Results: TH was eliminated and renal functions were improved in the denervation group at 24 hours. RDN reduce tubular cell apoptosis and mitigate the histological lesion. Meanwhile, the increase of capillary vessel density and reduce of renal fibrosis was observed after 2 weeks. Moreover, numbers of miRNAs were up-regulated after RDN treatment both at 24 hours and 2 weeks, and the miRNA targeted pro-angiogenesis, anti-fibrosis and inflammatory pathways were modulated. Lastly, less fibrosis regions were found in TH high expression regions of human renal biopsy samples.

Conclusions: RDN was a reliable method in alleviating IRI induced acute and chronic kidney injury, and the modulation of miRNA related pro-angiogenesis, anti-fibrosis or inflammatory pathways involved in this process.

PO2616

Obesity Has Opposing Effects on Acute vs. Chronic Kidney Disease

Thomas V. Rousselle, James D. Eason, Daniel Maluf, Valeria R. Mas, Amandeep Bajwa. *UTHSC, Memphis, TN.*

Background: With an accumulation of lipid droplets, mitochondria become incapable of upregulating the glucose-dependent response to ischemia and the cell becomes dependent upon glycolysis to satisfy metabolic need. This dysregulation has contributed to the exacerbation of ischemic injury in various tissues in diet-induced obese (DIO) mice. However, very little is known in how DIO can contribute to ischemic kidney disease. We hypothesized that obesity may dampen the response to acute kidney injury (AKI) and further exacerbate the development of dysfunction in chronic kidney disease.

Methods: Fat content and lean muscle mass of 20-wk old B6 lean and DIO mice were analyzed via EchoMRI (calculate fat %) and data used to randomize mice between either acute (AKI, 26 mins of bilateral ischemia with 24 hrs of reperfusion) or chronic (CKD, 26 mins of unilateral ischemia with 14 days of reperfusion) models of kidney injury. Kidney injury was assessed by plasma creatinine (PlCr; mg/dL), blood urea nitrogen (BUN; mg/dL), and histological analysis (H&E or MT).

Results: Fat % significantly differed between lean and DIO mice (4.18±0.4 vs 17.49±1.2; p<0.001) along with blood glucose levels (384±27.8 vs 522±16.1; p<0.01). In AKI, DIO mice had worsened kidney function when compared to lean mice as shown by the significant increase in PlCr (1.43±0.23 vs 2.32±0.14; <0.05). However, the degree of injury was not reflected in BUN or acute tubular necrosis (ATN). Interestingly, there was no significant changes in either PlCr or BUN between DIO and lean mice at 14 days.

Conclusions: When compared to lean controls, mice fed HFD and then subjected to IRI expressed significant exacerbation of injury by a heightened expression of clinical chemistry markers. Though this dysregulation has been associated in other tissues with an accumulation of dysfunctional mitochondria secondary to the increased accrual of lipid-droplets, this does not seem to be the case in the kidney as no lipid-deposits were observed in the histological analysis. In addition, no significance existed between DIO and lean mice having undergone unilateral ischemia. With the increasing prevalence of obesity and obesity-related co-morbidities, more studies are warranted to explicitly unravel the effects of DIO in relation to acute and CKD.

PO2617

Protective Effects of Apelin on Contrast-Induced Nephropathy

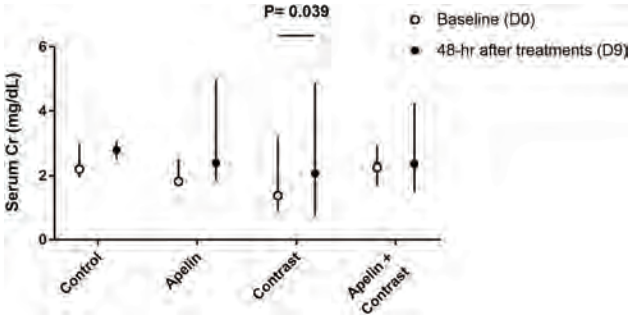
Jae seok Kim, Miryung Kim, Hanwul Shin, Jun Young Lee, Jae Won Yang, Minseob Eom, Seung-Ok Choi. *Wonju Severance Christian Hospital, Wonju, Gangwon-do, Republic of Korea.*

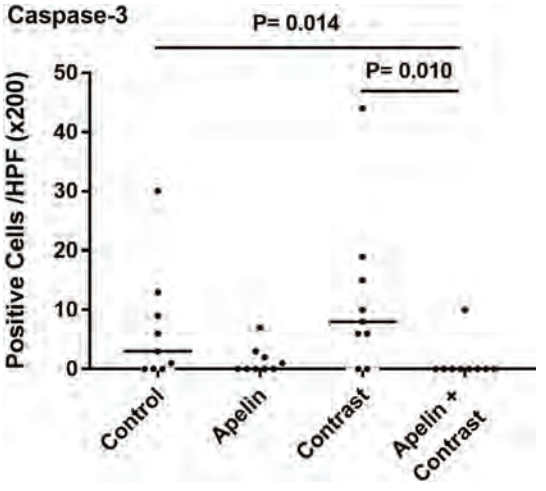
Background: Contrast induced nephropathy (CIN) has no proven preventive measures yet except for saline administration. Apelin is a endogenous ligand to apelin receptor in body, which has physiologic roles such as increasing cardiac output and peripheral vasodilation. This study aims to examine the protective effect of apelin on CIN.

Methods: A total of 22 rats were divided into 4 groups: Control, Apelin, Contrast, and Apelin/Contrast. In order to effectively induce CIN, 50 mg/kg of gentamycin IV was injected daily to all rats from Day-1 to Day-6. On Day-7, the rats were pre-treated as follows; Control and Contrast groups: Saline SQ, Apelin and Apelin/Contrast groups: apelin-13, 300 μg/kg SQ. After 1-hour of pre-treatment, main treatments were followed; Control and Apelin groups: Saline IV, Contrast and Apelin/Contrast groups: Iohexol-350 mg Id/mL, 1.8 g Id/kg IV. We performed serum and 24-hour urine tests on Day-0 and Day-9 which was 48 hours after contrast administration. We collected the kidney with sacrifice on Day-9.

Results: The results showed a significant increase in serum creatinine (Cr) in only Contrast group (p=0.039). In Contrast (p=0.015) and Apelin/Contrast (p=0.007) groups, urinary Cr excretion significantly increased indicating renal tubular injury. The immunohistochemistry for caspase-3 indicated that Contrast group had significant tubular cell damages, while other groups including Apelin/Constrast were less damaged (p=0.014).

Conclusions: We could identify the protective effects of apelin against CIN in the study.





PO2618

Male, but Not Female, Spontaneously Hypertensive Rats (SHR) Have Sustained Renal Injury Following a Single Ischemic Insult Progressing to CKD

Riyaz Mohamed, Jennifer C. Sullivan. *Augusta University, Augusta, GA.*

Background: Renal ischemia-reperfusion (IR) injury is a major cause of acute kidney injury (AKI), which is an independent risk factor for the development of CKD and all-cause mortality. The goal of the current study was to test the hypothesis that hypertensive males will have greater IR injury than hypertensive females resulting in the development of CKD.

Methods: 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral ischemia followed by reperfusion (n=5-6). Systolic blood pressure (BP) measured weekly by tail-cuff.

Results: Plasma creatinine (Pcr) and urine protein creatinine ratio (UPCR) remained elevated at 1-week post IR in male SHR compared to sham (PIR*sex=0.005); Pcr and UPCR returned to baseline in SHR females. Histological examination of SHR kidneys 7 days post-IR showed greater increases in vascular congestion ($P_{sex*IR=}$0.002) and tubular damage (P_{sex*IR}=0.001) in males. However, glomerular filtration rate (GFR) and systolic BP were not altered in both male and female SHR at 1-week post IR. To determine if this was sustained dysfunction or simply delayed recovery, additional 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral ischemia followed by 20 weeks of reperfusion (n=4-5). Male SHR showed progressive increases in UPCR (PIR<0.05) and systolic BP up to 20 weeks post-IR compared to respective shams (PIR=0.001). Whereas in female SHR, UPCR remained at baseline up to 16-week post IR compared to respective sham. However, at 20 weeks of post IR, both male and female SHR exhibit an increase in UPCR compared to respective sham control; although the increase in UPCR was greater in males (P_{sex}=0.01; PIR*sex=0.09). Male SHR also exhibited greater decreases in glomerular filtration rate (GFR: P_{sex}=0.025; P_{sex}=0.12) and increases in systolic BP (P_{sex}=0.0001; P_{IR*sex}=0.27) compared to females.

Conclusions: Our data demonstrated that impaired renal recovery following IR in SHR males results in exaggerated progression towards CKD.

High Serum Strontium May Predict AKI After Cardiac Surgery with Cardiopulmonary Bypass

Natsumi Tomita,[1] Yuji Hotta,[1] Karin Matsuta,[1] Hidekazu Ito,[5] Yuko Yamamoto,[4] Kazuki Ohashi,[2] Masahiro Kondo,[2] Tomoaki Hayakawa,[2] Tomoya Kataoka,[1,3] Kazuya Sobue,[5] Kazunori Kimura.[1,3] *[1]Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [2]Department of Pharmacy, Nagoya City University Hospital, Nagoya, Japan; [3]Department of Clinical Pharmaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [4]Aichi-ken Eisei Kenkyujo, Nagoya, Japan; [5]Department of Anesthesiology and Intensive Care Medicine, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.*

Background: The prevalence of acute kidney injury after cardiac surgery under cardiopulmonary bypass (AKI-CPB) is high and it worsens patient prognosis, which renders it a major concern during intensive care. Therefore, a predictable marker of AKI-CPB is required. Because some trace metals have been found to affect renal injury, we investigated their association with AKI-CPB.

Methods: Study 1. We enrolled 30 patients from the Nagoya City University Hospital. Serum concentrations of 19 trace metals were measured before surgery and immediately after CPB withdrawal. We defined AKI according to the KDIGO criteria. Factors associated with AKI-CPB were identified by univariate and multivariate analyses. **Study 2.** We treated male Wistar-ST rats with 1 mg/kg/day of strontium (Sr) or vehicle orally for 3 days, followed by the application of 30 min of ischemia and reperfusion to cause renal injury. Serum creatinine (SCr) and blood urea nitrogen (BUN) levels were evaluated 24 h later. We also incubated human kidney (HK)-2 cells with Sr (0.25 μM, high-Sr or 0.19 μM, normal-Sr) or PBS for 24 h *in vitro*. These Sr concentrations were determined according to the average serum Sr concentrations in patients with and without AKI. The cells were incubated under normoxia (20% O_2) or hypoxia (1% O_2) conditions; then, cell viability and mRNA expression were assessed.

Results: Study 1. The incidence of AKI-CPB was 30% (n = 9). Serum Cr levels before surgery were high in the AKI group. Intraoperative factors did not differ between patients with and without AKI. Univariate analysis revealed significantly higher levels of Sr and arsenic before surgery, and higher Sr, arsenic, and zinc levels after CPB in the AKI group ($p < 0.05$). Multivariate analysis showed that only Sr levels after CPB withdrawal correlated independently with AKI. **Study 2.** The SCr and BUN levels were higher in Sr treated rats than vehicle treated rats. Incubating HK-2 cells with Sr did not affect their viability under normoxia and hypoxia conditions. However, NF-κB mRNA levels increased only under hypoxia conditions following exposure to high Sr levels.

Conclusions: High Sr levels before CPB may be a useful predictor of AKI-CPB. This study suggested that high Sr levels enhance ischemia-induced inflammation following CPB.

PO2620

BAM15 and Mitochondrial DNA Form a Drug-Companion Biomarker Pair Working Through Reactive Oxygen Species in Septic AKI

Naoko Tsuji, Takayuki Tsuji, Tetsushi Yamashita, Xuzhen Hu, Peter S. Yuen, Robert A. Star. *National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Sepsis is multifactorial, so drug-biomarker co-development is likely necessary for developing effective therapeutics. Administration of BAM15, a mitochondrial uncoupler, improved sepsis AKI mortality, kidney function, and mitochondrial function in kidney tubules (ASN, 2019). We now evaluate if BAM15 and mtDNA form a drug companion biomarker pair and are linked mechanistically.

Methods: Mice with sepsis AKI [cecum ligation/puncture (CLP) in CD-1 mice] were treated with BAM15 (5mg/kg IV) at 0h (early) or 6h (delayed) after surgery. Serial plasma and urinary mtDNA was measured by qPCR. This was mimicked *in vitro* by incubating mouse primary cultured proximal tubular cells (PTCs) with serum from CLP mice. Mitochondrial superoxide generation was measured by live cell imaging with MitoSox-Red. Mitophagy detected in Mt-Keima mice [transgenic for pH-sensitive ratiometric fluorescent protein] by measuring mitochondrial pH.

Results: Plasma and urinary mtDNA were increased in CLP mice starting at 3 hr after CLP. Delayed treatment with BAM15 (6 hr) decreased mtDNA at 12 hrs (Fig 1).

CLP serum stimulated superoxide production and release of mtDNA into cultured PCT media; both were proportionately inhibited by BAM15 (Fig 2A-C). Released mtDNA correlated with superoxide production. BAM15 recovered mitochondrial biogenesis through activation of PGC1α pathway and, inhibited CLP reduction of mitophagy.

Conclusions: Sepsis increased kidney mtROS and released mtDNA from PT cells. BAM15 attenuated generation of mtROS and inhibited mtDNA release into urine and also circulating mtDNA even delayed BAM15 treatment. In sepsis AKI, BAM15 changed the trajectory of mitochondrial fate. Our results suggest that BAM15 and mtDNA are mechanistically linked via ROS, and form a drug-companion biomarker pair.

Funding: NIDDK Support

Grb2 Promotes Cardiorenal Syndrome Type 3: Roles of Cardiomyocyte Contractile Cytoskeleton, Mitochondria Damage, and Inflammation Response

Jin Wang, Xiangmei Chen. *Chinese PLA General Hospital, Beijing, China.*

Background: Cardiorenal syndrome type-3 (CRS-3) is a damage to heart following acute kidney injury. Although many experiments have found that inflammation, oxidative stress, and cardiomyocyte death are involved in cardiomyocyte pathophysiological alterations during CRS-3, it lacks a non-bias analysis to figure out the primary mediator of cardiac dysfunction. Herein, the aim of our study is to figure out the primary upstream regulator of these intracellular molecular biological events.

Methods: In this study, proteomic analysis was operated in CRS-3 and growth factor receptor-bound protein 2 (Grb2) was identified as a regulator involving AKI-related myocardial damage.

Results: Increased Grb2 was associated with cardiac diastolic dysfunction, mild cardiomyocyte death and prominent myocardial inflammation; these pathological changes could be reversed through administration of Grb2-blocking peptide after AKI. Molecular investigation illustrated that augmented Grb2 promoted cardiomyocytes contractile cytoskeleton degradation through inhibiting the expression of Myosin. In addition, increased Grb2 triggered mitochondrial fission, inactivated mitochondrial autophagy, induced mitochondrial potential reduction, and triggered caspase-9/3 activation. Pro-inflammatory signaling pathways, including NF-κB, MAPK/JNK, and MAPK/p38, were activated by Grb2 in cardiomyocytes following AKI.

Conclusions: Our results identify CRS-3 is caused by Grb2 upregulation which contributes to cardiac dysfunction, cardiomyocyte apoptosis and myocardial inflammation. This finding provides a potential target for the clinical treatment of patients with CRS-3.

PO0001

AKI Identification: Use of Electronic AKI Alerts vs. Electronic Health Records in Hospital Episode Statistics

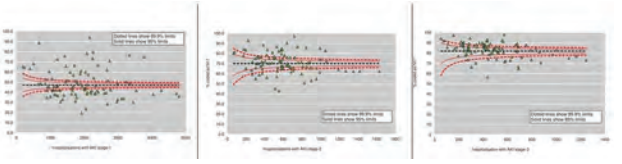
Manuela Savino,[1] Anna Casula,[1] Esther H. Wong,[1] Nitin V. Kolhe,[2] James Medcalf,[1,4] Dorothea Nitsch.[1,3] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Royal Derby Hospital, Derby, United Kingdom; [3]London School of Hygiene & Tropical Medicine, London, United Kingdom; [4]Leicester General Hospital, Leicester, United Kingdom.*

Background: Acute Kidney Injury (AKI) refers to an abrupt decline in the glomerular filtration rate (GFR) potentially associated with significant morbidity and mortality. Since April 2015, an automated real-time electronic (e)-alert system for AKI has been introduced and progressively implemented in England, with alert data being sent to the UK Renal Registry (UKRR) for collection into a master patient index (MPI). Historically, the only way to routinely measure AKI incidence in hospital was to analyse the Hopital Episode Statistics (HES). This project aims to determine whether episodes of AKI identified in the UKRR MPI correspond to coded diagnoses on the discharge record held in HES.

Methods: The UKRR MPI of all AKI e-alerts (stages 1, 2 and 3) in patients aged ≥18 years, between 01/01/2017 and 31/12/2017 were linked to HES data to identify a hospitalised AKI population. Descriptive analyses were conducted to describe the demographics and to investigate whether those with an AKI e-alert also had an International Classification of Diseases (ICD)-10 code for AKI (N17) in HES.

Results: From 01/01/2017 to 31/12/2017, 301,504 hospitalised adults received an AKI e-alert. AKI severity was positively associated with the percentage of AKI alerts coded in HES. There was a significant variation in HES coding between hospitals, most pronounced for AKI stage 1 (mean 48.2% SD 14) versus AKI stage 3 (mean 83.3 % SD 7.3) (figures 1). Younger adults with AKI e-alerts were less often coded in HES for all three AKI stages (33% people aged 18-29 years versus 64% people aged ≥ 85 years).

Conclusions: In 2017, earlier stages of AKI e-alerts were poorly coded in HES. There was also high degree of inter-hospital variability, particularly for AKI stage 1, reflecting potentially poor clinical recognition and documentation in medical records and subsequent clinical coding. AKI e-alerts were poorly captured in HES for younger adults in comparison to those of older age. Use of HES to identify cases of AKI is likely to underestimate the incidence of AKI, especially for AKI stage 1, though a high proportion of the most severe cases will be captured.



PO0002

Assessment of a Modified Renal Angina Index for the Prediction of AKI in Hospitalized Adult Patients

Ana A. Mariscal-Campos,[1] Rolando Claure-Del Granado.[1,2] *[1]Clinica Los Olivos, Cochabamba, Bolivia, Plurinational State of; [2]IIBISMED; Universidad Mayor de San Simon Facultad de Medicina, Cochabamba, Bolivia, Plurinational State of.*

Background: Risk-stratification tools of incident AKI in hospitalized patients are needed. The renal angina index (RAI) was developed and validated in the pediatric population. The purpose of this study was to evaluate the performance of a modified RAI (mRAI) for the prediction of AKI in hospitalized patients.

Methods: We analyzed data from 55 hospitalized patients admitted to our center. Inclusion criteria consisted of age ≥18, hospital stay ≥3 days, at least 2 serum creatinine (SCr) measures in the first 2 days of hospital stay and one measure at 3-7 days of stay. Exclusion criteria consisted of ESKD, kidney transplant or baseline eGFR <15. At admission, mRAI was calculated using the following formula: **risk level criteria** 1) ICU admission, 2) mechanical ventilation or vasoactive drug support, and 3) diabetes ***X* injury level criteria** of SCr increments of <0.1 mg/dL, ≥0.1 mg/dl, ≥0.3 mg/dL and ≥0.4 mg/dL. AKI was defined as an increase of serum creatinine level ≥ 0.3 mg/dL or ≥ 1.5 times within 48 hours or ≥1.5 times in contrast to baseline creatinine level. We assessed the performance of the mRAI to predict the subsequent development of AKI using KDIGO sCr criteria.

Results: Mean (SD) age was 67.9 (13.3), 47.3% were women and 100% Hispanic. The incidence of AKI at 3-7 days of hospital or ICU stay was 52.7%. Most patients developed AKI stage 1 (61.3%) and 38.7% developed severe AKI (KDIGO-SCr stage ≥2) at 3-7 days. Performance metrics are reported in **Table**. The RAI exhibited a good, AUC of 0.87 (95% confidential interval [CI]: 0.77–0.96; p <0.0001) in ROC analysis, with a cutoff of 8.

Conclusions: The mRAI have robust predictive capacity to identify hospitalized adults patients at high risk of developing AKI. Incorporation of AKI biomarkers into the RAI may potentially improve prediction. The preliminary data of our ongoing study warrants future studies to validate these findings.

Funding: Private Foundation Support

Table: Performance of the mRAI for the prediction of AKI in hospitalized patients

Statistic	Value	95% CI
Sensitivity	89.6%	72.6% to 97.8%
Specificity	76.9%	56.3% to 91.0%
Positive Likelihood Ratio	3.89	1.91 to 7.92
Negative Likelihood Ratio	0.13	0.05 to 0.40
PPV	81.2%	68.0% to 89.8%
NPV	86.9%	69.1% to 95.2%

PO0003

Early Prediction of Hospital-Acquired AKI from Electronic Health Records Using Machine Learning

Gurmukteshwar Singh,[1] Yirui Hu,[1] David Riviello,[1] Jason Brown,[1] Sara Saunders,[1] Andres Garcia-Arce,[1] Kevin Ho,[2] H. Lester Kirchner.[1]
[1]Geisinger Medical Center, Danville, PA; [2]Sanofi Genzyme, Cambridge, MA.

Background: Hospital-acquired acute kidney injury (HA-AKI) leads to increased morbidity and mortality. Early prediction of HA-AKI using Electronic Health Records may enable clinicians to modify treatment to minimize risk and AKI severity

Methods: Inpatient admissions from 7/13/2012 – 7/11/2018 who had serum creatinine measured were included. Patients with end-stage renal disease, length of stay <48 hours and AKI at admission were excluded. A validated algorithm was used to determine baseline renal function. AKI was defined according to KDIGO guidelines. Machine learning algorithms were implemented to predict development of HA-AKI beyond the initial 24-hours of admission. 50 input variables to machine learning algorithms (random forest, XGBoost, logistic regression) included demographics, initial laboratory values taken within the first 24-hours of admission, active medications at time of admission, and prevalent comorbidities. Multiple imputation by chained equations (MICE) was used for missing variables. Univariate Feature Selection was utilized where variables were ranked by evaluating contribution to classification outcome. Randomized search strategy was performed to obtain the optimal hyperparameter set for each algorithm. Models were evaluated using a mean area under the receiver operating characteristic curve (AUC) over 5-fold cross-validation

Results: Among 209,300 inpatient admissions, 26,410 (12.6%) developed HA-AKI. For AKI prediction, the AUC of the full model was 0.88 for both random forest and XGBoost, and 0.86 for logistic regression. To balance the tradeoff between model simplicity and performance, 23 variables from univariate feature selection evaluated using random forest were selected in predicting HA-AKI (AUC = 0.87). The probability cut-off point of AKI prediction outcome was determined using Youden's Index based on the balance between false positives and false negatives. A probability cutoff of > 0.23 provided sensitivity and specificity of 78% and 81%, respectively

Conclusions: Our machine learning algorithm applied at 24 hours of admission identifies patients at risk for HA-AKI with excellent accuracy. Significant variables included in this algorithm should be monitored in real-time to allow early identification and preventive interventions in patients at risk for HA-AKI

A Meta-Analysis of Clinical Predictors for Renal Recovery and Mortality in AKI Requiring Continuous Renal Replacement Therapy

Panupong Hansrivijit,[1] Max Puthenpura,[5] Nasrollah Ghahramani,[3] Charat Thongprayoon,[2] Wisit Cheungpasitporn.[4] *[1]UPMC Pinnacle, Harrisburg, PA; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Penn State College of Medicine, Hershey, PA; [4]University of Mississippi Medical Center, Jackson, MS; [5]Drexel University College of Medicine, Philadelphia, PA.*

Background: Acute kidney injury (AKI) is a common complication in critically ill patients and can result in a broad spectrum of severity. It is well-established that severe AKI requiring continuous renal replacement therapy (CRRT) carries a significant risk for increased mortality compared to non-dialysis AKI. However, there are no concensus guidelines describing the discontinuation criteria from CRRT. Thus, we performed this meta-analysis to determine the clinical predictors for CRRT discontinuation and overall mortality in patients with AKI.

Methods: Ovid MEDLINE, EMBASE, and Cochrane Library were searched without language restrictions up to January 2020. Our inclusion criteria included patients ≥ 18 years of age, non-end-stage kidney disease patients who required CRRT for AKI. Renal recovery was defined by CRRT discontinuation. Intermittent hemodialysis was excluded. Only articles utilizing multivariate analysis were included. We divided our analyses into two cohorts based on the primary outcomes: renal recovery cohort and overall mortality cohort.

Results: For renal recovery cohort (n = 4,497 from 14 studies), the mean effluent dose of CRRT was 24.93 ± 5.87 ml/kg/h with a median duration of CRRT of 3.75 days (IQR 2.45). Increasing urine output at time of CRRT discontinuation (per 100 ml/day), elevated initial SOFA score (per 1 score) and serum creatinine level at CRRT initiation (per 1.0 mg/dl) were predictive of renal recovery with odds ratio of 1.021 (95% CI, 1.012-1.031), 0.890 (95% CI, 0.805-0.984) and 0.995 (95% CI, 0.991-0.999), respectively. For overall mortality cohort (n = 16,948 from 11 studies), The mean effluent dose of CRRT was 26.22 ± 6.47 ml/kg/h with a median CRRT duration of 4.5 days (IQR 3.40). Age (per 1 year) and presence of sepsis were significantly associated with overall mortality with odds ratio of 1.023 (95% CI, 1.006-1.040) and 2.031 (95% CI, 1.267-3.257), respectively. All analyses remained significant through sensitivity analyses. No potential publication bias was identified.

Conclusions: Urine output at CRRT discontinuation, initial SOFA score, and serum creatinine level are predictive of renal recovery and successful CRRT discontinuation. Increasing age and the presence of sepsis are independent risk factors for elevated overall mortality.

PO0005

Regional Variation in Recovery of Kidney Function in Patients Requiring Maintenance Hemodialysis with Acute Tubular Necrosis

Yuenting D. Kwong,[1] Kirsten L. Johansen,[2] Charles E. McCulloch,[1] Kathleen D. Liu,[1] Barbara A. Grimes,[1] Elaine Ku.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Hennepin Healthcare, Minneapolis, MN.*

Background: Geographic variations in the likelihood of recovery of kidney function in ESKD attributed to acute tubular necrosis (ATN) has not been well established.

Methods: Using data from United States Renal Data System, we performed a retrospective cohort study of incident maintenance hemodialysis (HD) patients between 1/1/1996-12/31/2015 with ESKD attributed to ATN followed up to 1 year. Recovery of kidney function was defined as discontinuation of HD for at least 90 days and alive without the need for kidney transplantation during this period. We used Fine-Gray models to determine unadjusted and adjusted hazard of recovery while accounting for the competing risk of death.

Results: In 48,771 patients included for analysis, 30% recovered kidney function within 1 year. Most patients received HD within a 10-mile radius of their home. Recovery rates at 1 year were lowest in the northeast and highest in the south; lower in metropolitan compared to micropolitan/rural areas. Recovery of kidney function was less likely to occur with distance between patient and dialysis facilities in adjusted analysis.

Conclusions: Patients living in rural/micropolitan locations and receiving dialysis close to home had higher recovery rates. Studies examining regional differences in practice patterns are warranted.

Development and Validation of a Model to Predict In-Hospital AKI Among Hospitalized US Veterans

Karandeep Singh,[1] Xiaosong Zhang,[1] Maggie Yin,[1] Vahakn Shahinian,[1] William Weitzel,[1,2] Rajiv Saran,[1] Susan T. Crowley,[3] Michael Heung.[1]
[1]University of Michigan, Ann Arbor, MI; [2]VA Ann Arbor Healthcare System, Ann Arbor, MI; [3]VA Connecticut Health System, West Haven, CT.

Background: Acute kidney injury (AKI) occurs commonly in hospitalized patients, affects millions of Americans annually, and is recognized as one of the most significant contributors to chronic kidney disease (CKD). As the primary treatment for most AKI is limited to supportive care, improving the health consequences of AKI (most notably CKD) relies on identifying high-risk patients in a timely manner and targeting them for preventive interventions.

Methods: Using data from a random sample of 100,000 hospitalized veterans, we developed and internally validated a gradient-boosted decision tree (GBDT) model for the prediction of in-hospital acute kidney injury. We excluded patients without an available creatinine during their hospitalization (n = 21,165), and randomly divided the remaining patients into a training cohort (n = 39,418), tuning cohort (n = 13,139), and a test cohort (n = 26,278). We divided each patient's hospitalization into 6-hour steps and removed all steps where a patient actively had known AKI. We then used the prior 48 hours of clinical data to predict the onset of AKI during the next 48 hours. After fitting the GBDT model on all steps from the training cohort, we iteratively checked model performance on the tuning cohort to determine optimal parameters for early stopping to prevent overfitting. We then evaluated the model's performance on the test cohort using the maximum predicted score for each patient prior to the onset of AKI.

Results: Our cohort had a mean age of 72, was 96% male, 34% with baseline diabetes mellitus, and 24% with baseline CKD. 11% of patients experienced in-hospital AKI by creatinine-based KDIGO criteria (3.8% in any 6-hour window), and 1.6% of patients experienced AKI stage 2+. The area under the curve (AUC) was 0.76 (95% bootstrap CI 0.75-0.77) for predicting any AKI in the next 48 hours and 0.70 (95% CI: 0.67-0.73) for predicting AKI stage 2+ in the next 48 hours. Patients who met or exceeded a risk threshold of 14.5% had a 33% chance of developing AKI during their hospitalization with a 42% sensitivity.

Conclusions: In a retrospective validation in a large national cohort of veterans, a predictive model for acute kidney injury identifies nearly half of patients who will experience AKI prior to its onset.

PO0007

Adequacy of Kidney Follow-Up Among AKI Survivors After Hospital Discharge

Erin F. Barreto, Diana J. Schreier, Heather P. May, Kristin C. Mara, Kianoush Kashani, Alanna Chamberlain, Chung-Il Wi, Andrew D. Rule. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Acute kidney injury (AKI) affects 20% of hospitalized patients and results in long-term adverse outcomes. To limit its complications, post-discharge follow-up is advised. The objective of the study was to evaluate the frequency of appropriate follow-up after discharge among AKI survivors.

Methods: This was a population-based cohort study of adult Olmsted County residents hospitalized at their local hospital (Mayo Clinic in Rochester, MN) with an episode of stage II or III AKI between 2006 and 2014. Those dismissed from the hospital on dialysis or who died within 30-days after discharge were excluded. The cumulative incidence of adequate kidney follow-up defined by a serum creatinine (SCr) level and/or an in-person healthcare visit within 30-days, 90-days, or 1-year after discharge was described.

Results: There were 563 survivors of AKI studied [Stage II: N=360 (64%); Stage III: N=203 (36%)]. The 30-day cumulative incidence of follow-up with SCr was 78% (95% confidence interval (CI) : 74%, 81%), by provider visit was 80% (95% CI: 77%, 83%), by *both* SCr assessment and provider visit was 70% (95% CI: 65%, 73%). Within 90-days and 1-year, the cumulative incidences of *both* SCr assessment and provider visit rose to 81% and 91%, respectively. Within 30-days after discharge, only 13% (95% CI: 10%, 16%) of these stage II or III AKI survivors saw a nephrologist. The statistically significant predictors of receiving *both* a SCr assessment and provider visit within 30-days included higher body mass index, worse baseline and discharge kidney function, higher comorbidity burden, greater maximum AKI severity, and longer duration of AKI during the hospitalization. Age, sex, race/ethnicity, education status, and socioeconomic status did not predict kidney follow-up.

Conclusions: These data demonstrated that 30% of patients with moderate to severe AKI received insufficient kidney follow-up in the 30-day post-discharge interval. Medical risk factors rather than social/demographic characteristics were the primary determinants of kidney follow-up.

PO0008

Predicting Intra-ICU Mortality Using Machine Learning Algorithms in Patients Who Require Acute Renal Replacement Therapy in a Critical Care Unit

Hsin-Hsiung Chang,[1,2] Huiwen Chen,[2,3] Manisha Jhamb.[2] *[1]National Cheng kung College of Computer Science and Information Engineering, Tainan, Taiwan; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: The Acute Physiology, Age, Chronic Health Evaluation (APACHE) and Simplified Acute Physiology Score(SAPS) are not a fair mortality prediction tools for patients receiving acute renal replacement therapy (RRT) in the ICU. Our objective was to develop a series of machine learning models to predict intra-ICU mortality for patients requiring acute dialysis therapy using data obtained one day prior to RRT initiation.

Methods: We extracted data on patients who commenced acute RRT captured in eICU and MIMIC databases. We trained machine learning models by using the eICU and MIMIC dataset. The validity of those models was then evaluated by using MIMIC and eICU.

Results: The eICU cohort included 2,360 patients and MIMIC included 1,274 patients who met our eligibility criteria. The discrimination power of the model was evaluatedby calculating the area under the receiver operating characteristic curve (AUC). The intra-ICU mortality AUC of the Sequential Organ Failure Assessment (SOFA) score using data collected one day before RRT initiation was 0.803 (95% CI 0.777-0.829) in eICU and 0.683 (95% CI 0.636-0.729) in MIMIC. The intra-ICU mortality AUC of machine learning models using logistic regression (LR), XGBoost, random forest (RF) and multilayer perceptron (MLP) trained in eICU cohort were 0.858 (95% CI 0.850-0.867), 0.858 (95% CI 0.850-0.866), 0.859 (95% CI 0.848-0.870), 0.864 (95% CI 0.851-0.876) and validated in MIMIC were 0.799 (95% CI:0.775-0.824), 0.809 (95% CI:0.786-0.833), 0.814 (95% CI 0.791-0.837), 0.800 (95% CI 0.776-0.825), respectively. When training the models using MIMIC dataset, the intra-ICU mortality AUCof LR, XGBoost, RF and MLP were 0.818 95% CI (0.786-0.852], 0.821 (95% CI 0.787-0.856) 0.822 (95% CI 0.791-0.854), 0.827 (95% CI 0.795-0.858), respectively. Validating these models using eICU dataset, the AUC of LR, XGBoost, RF and MLP were 0.846 95% CI:0.828-0.864, 0.847 (95% CI 0.829-0.865), 0.853 (95% CI 0.835-0.870), 0.846 (95% CI 0.828-0.865), respectively.

Conclusions: In this study, we designed machine learning models to make intra-ICU mortality prediction for patients who required RRT. Our models correlated better than SOFA score in predicting the mortality of patients requiring RRT in ICU. All of the models almost had excellent performance in both databases.

PO0009

Risk Factors for Mortality and Hospital Readmission Following AKI

Benjamin R. Griffin,[1,2] Jason Wachsmuth,[1,2] Eli Perencevich,[1,2] Heather Reisinger,[1,2] Mary V. Sarrazin,[1,2] Diana I. Jalal.[1,2] *[1]Center for Comprehensive Access & Delivery Research & Evaluation (CADRE), Iowa City VA Health Care System, Iowa City, IA; [2]The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Acute kidney injury (AKI) occurs in over 20% of hospitalized patients and is associated with long-term morbidity and mortality. The purpose of this study is to identify risk factors for readmission for renal cause and mortality following a hospitalization with AKI in US Veterans.

Methods: AKI was defined as a creatinine increase of ≥0.3 mg/dL at or after admission to a VA hospital between 2013 and 2018. The primary outcomes were death and readmission for a renal indication. Proportional hazards frailty model was applied. Variables evaluated included demographics, comorbidities, and laboratory data. The final model was chosen based on clinical relevance and parsimony.

Results: From a cohort of 624,822 Veterans with AKI, 218,839 (35%) met inclusion criteria. Reasons for exclusion were <1 year of prior patient data (35%), missing serum creatinine values (14%), palliative status or metastatic cancer (13%), or death during the hospitalization (4%). AKI was present on admission in 71% of patients and developed after admission in 29%. Overall, 48,202 (22%) died within one year. Between 2013 and 2018, 101,170 (46%) died and 21,116 (9%) experienced a renal readmission. The patient characteristics associated with increased hazard of death included age (HR=1.53 per 10 years, CI 1.52-1.54, p<.001), male sex (HR=1.27, CI 1.22-1.32, p<.001), heart failure (HR=1.55, CI 1.53-1.57, p<.001), prior myocardial infarction (HR=1.14, CI 1.11-1.17, p<.001), peripheral vascular disease (HR=1.15, CI 1.13-1.17, p<.001), anemia (HR=1.32, CI 1.30-1.33, p<.001), chronic kidney disease (HR=1.15, CI 1.13-1.17, p<.001), creatinine at time of admission (HR 1.012, CI 1.009-1.015, p<.001) and increase from pre-admission values (HR 1.045, CI 1.041-1.048, p<.001). The same patient characteristics were significant predictors of readmission for a renal indication.

Conclusions: We report factors in AKI survivors that predict long-term mortality and hospital readmission due to renal indication among US Veterans. Cardiovascular diseases were prominent predictors, and AKI follow-up should focus on those with heart disease. Future studies should evaluate the potential benefit in this population from post-hospitalization specialty AKI follow-up.

PO0010

CRRT Is Associated with Improved Kidney Recovery from Dialysis-Requiring AKI in a Multicenter Retrospective Analysis

John M. Arthur,[1,2] Javier A. Neyra,[5] Yevgeniya Gokun,[1] Jihad S. Obeid,[3] Milos N. Budisavljevic,[3] David Redden,[4] Michael J. Connor,[6] Jin Chen,[5] Lucas J. Liu,[5] Mahanazuddin Syed,[1] Ahmad Baghal,[1] Jean Craig,[3] Brian Harmon,[4] Vinay Narasimha Krishna.[4] The Southern Acute Kidney Injury Network (SAKInet) *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System John L McClellan Memorial Veterans Hospital, Little Rock, AR; [3]Medical University of South Carolina, Charleston, SC; [4]The University of Alabama at Birmingham, Birmingham, AL; [5]University of Kentucky, Lexington, KY; [6]Emory University, Atlanta, GA.*

Background: AKI requiring dialysis (AKI-D) is common with a high rate of adverse outcomes. Little is known about modifiable factors that promote kidney recovery.

Methods: Five CTSA universities (UAMS, UAB, UKY, MUSC and Emory) formed a consortium to identify modifiable risk factors for kidney recovery in AKI-D patients. We selected all patients that received dialysis while in the hospital, then excluded patients from the cohort with a diagnosis related to ESKD, kidney transplantation or CKD stage V at the time of the first RRT. Modality of dialysis, comorbidities and outcomes were analyzed.

Results: The total number of patients in the four available cohorts was 4537 (range 647-1477). Outcomes were determined at the time of discharge from the hospital. The primary outcomes in the study were death (n=2190, 48.3%), alive and dialysis-dependent at discharge (n=1160, 25.6%) or alive and dialysis-free at discharge (n=1187, 26.2%). We defined dialysis dependence as receiving dialysis within the last four days of hospitalization. We compared patients that were initiated on CRRT to patients that were initiated on intermittent hemodialysis (iHD) while adjusting for confounders: sepsis, age, race, gender, qSOFA, mechanical ventilation, serum bicarbonate and serum potassium at the time of dialysis initiation. We analyzed hospital cohorts separately. There was a higher risk of death in patients initiated on CRRT vs. iHD. The odds ratios and 95% CIs for death were: UAMS 2.8, 1.9-4.2; UAB 3.2, 2.1-4.9; MUSC 3.7, 2.6-5.3 and UKY 3.1, 2.3-4.2. Among survivors, patients started on CRRT generally had a lower risk of being dialysis-dependent at discharge. The odds ratios and 95% CIs for renal recovery were: UAMS 0.1, 0.04-0.2; UAB 0.3, 0.1-0.5; MUSC 0.3, 0.2-0.5 and UKY 0.8, 0.5-1.2.

Conclusions: The odds of kidney recovery were significantly better for patients started on CRRT in three of the four cohorts examined in this study and trended toward favoring CRRT in the fourth. This has important implications for care of patients with AKI in the ICU. We believe the increased mortality in the CRRT group reflects the sicker nature of patients in that group and is not inherent to CRRT as an initial dialysis modality.

Region-wide Implementation of Best Practice in AKI

Anirudh Rao, Kottarathil A. Abraham. On behalf of the Cheshire & Merseyside Acute Kidney Injury Network (CHAMKIN) *Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom.*

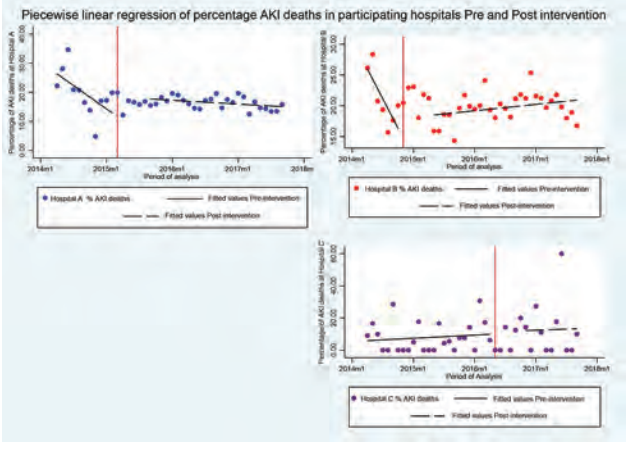
Background: The Cheshire & Merseyside Acute Kidney Injury Network, United Kingdom, rolled out best practice guidelines of13 interventions for Acute Kidney Injury (AKI) in October 2014. The aim was to assess the impact of the guidelines.

Methods: Setting & Population: Hospitals in Cheshire & Merseyside. **Predictor:** Time period before & after introduction, allowing six-month bedding in period. **Outcome: Percentage AKI:** Number of AKI per month, divided by total number of admissions/ month expressed as %. **Percentage AKI deaths:** Number of AKI related deaths per month divided by total deaths/month expressed as %. **Data analysis:** Descriptive & Piecewise Linear Regression.

Results: The region saw a notable increase in the number of admissions/month (31,173 vs 38,443) and AKI episodes (4,871 vs 44,493) in the 8 hospitals in pre and post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-implementation data (1). The outcomes in the 2 periods are detailed in the Table. The introduction of E-alert saw an increase in AKI detection across the hospitals. The figure shows longitudinal piecewise regression curves. The most significant reduction was noted in hospital A.

Conclusions: The rollout of interventions caused an increased and sustained recognition of AKI, across the hospitals. The % AKI deaths stayed the same except in Hospital A. We theorise that the onsite nephrology team in Hospital A aided implementation of the guidelines and training of wider healthcare staff which made the impact. This study highlights the hurdles faced in implementing AKI improvement strategies across various healthcare settings.

		Pre-intervention	Post-intervention	P-Value
HOSPITAL A	% AKI Median (IQR)	1.1 (1.0-1.9)	4.9 (4.7-5.2)	0.0001
	% AKI deaths Mean (95% CI)	19.6 (16.9-22.4)	16.4 (14.5-18.2)	0.05
HOSPITAL B	% AKI Median (IQR)	5.2 (1.3-5.7)	4.9 (4.6-5.2)	0.85
	% AKI deaths Mean (95% CI)	21.1 (18.9-23.3)	19.7 (18.6-20.8)	0.24
HOSPITAL C	% AKI Median (IQR)	4.2 (2.5-5.3)	3.3 (2.9-4.7)	0.40
	% AKI deaths Mean (95% CI)	7.9 (2.8-12.9)	12.8 (5.1-20.4)	0.30



PO0012

Impact of Impella on Renal Outcomes in High-Risk Percutaneous Coronary Intervention and Cardiogenic Shock: Meta-Analysis

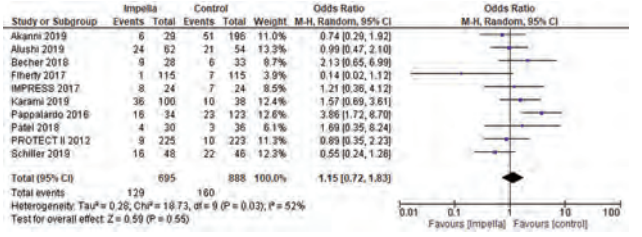
Takayuki Yamada,[1,2] Sera Satoi,[1] Satoshi Miyashita.[1] *[1]Mount Sinai Beth Israel Hospital, New York, NY; [2]Yokohama Shiritsu Daigaku Fuzoku Byoin, Yokohama, Japan.*

Background: Several studies have examined the impact of Impella on renal outcomes in high-risk PCI and cardiogenic shock (CS). These studies were limited in study sample size and exhibited mixed results. We conducted a meta-analysis of these studies to evaluate the association between the use of Impella and adverse renal outcomes.

Methods: We searched multiple databases up to March 2020 for studies, which evaluated the effect of Impella use on adverse renal outcomes in cardiogenic shock and high-risk PCI. Studies that reported adverse renal outcomes were included. Odds ratios (ORs) with corresponding 95% confidence interval (CI) were synthesized.

Results: A total of ten studies were included in the meta-analysis. The included studies evaluated a total of 1,583 patients with CS or undergoing high-risk percutaneous coronary intervention (PCI), including 695 patients assisted with Impella. The incidence rate of adverse renal outcomes ranged from 0.87% to 47.1% in the Impella group and from 4.48% to 69.6% in the control group. The HRs or ORs ranged from 0.14 to 3.86. Use of Impella was not associated with significant increase in the risk of adverse renal outcomes as compared with controls (OR: 1.15, 95% CI: 0.72-1.83, I^2 = 52%). Subgroup analysis revealed that the risk of adverse renal outcomes was comparable with comparators in patients with refractory CS, myocardial infarction complicated by CS, and patients undergoing high-risk PCI.

Conclusions: Our meta-analysis showed that the use of Impella may not have impact on renal outcomes in CS and high-risk PCI. Further randomized controlled trials are needed to better assess the effects of Impella on renal outcomes.



PO0013

Incidence and Impact of AKI on Patients with Implantable Left Ventricular Assist Devices: A Meta-Analysis

Charat Thongprayoon,[1] Wisit Cheungpasitporn,[2] Panupong Hansrivijit,[3] Tibor Fulop,[4] Swetha Rani Kanduri,[2] Michael A. Mao,[5] Kianoush Kashani.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]University of Mississippi Medical Center, Jackson, MS; [3]UPMC Pinnacle, Harrisburg, PA; [4]Medical University of South Carolina, Charleston, SC; [5]Mayo Clinic's Campus in Florida, Jacksonville, FL.*

Background: This systematic review and meta-analysis was performed to evaluate the acute kidney injury (AKI) incidence and its associated risk of mortality in patients with implantable left ventricular assist devices (LVAD).

Methods: A systematic literature search in MEDLINE, EMBASE, and Cochrane Databases was conducted through January 2020 to identify studies that provided data on the AKI incidence, and AKI-associated mortality risk in adult patients with implantable LVADs. Pooled effect estimates were examined using random-effects, generic inverse variance method of DerSimonian-Laird.

Results: 56 cohort studies with 63,663 LVAD patients were enrolled in this meta-analysis of AKI incidence. The pooled incidence of reported AKI was 24.9% (95%CI: 20.1%-30.4%), but rose to 36.9% (95%CI: 31.1%-43.1%) when applying the standard definition of AKI per RIFLE, AKIN, and KDIGO criteria. The pooled incidence of severe AKI requiring renal replacement therapy (RRT) was 12.6% (95%CI: 10.5%-15.0%). AKI incidence did not differ significantly between types of LVAD (p = 0.35) or indication for LVAD use (p = 0.62). While meta-regression analysis did not demonstrate a significant association between study year and overall AKI incidence (P=0.55), the study year was negatively correlated with incidence of severe AKI requiring RRT (slope = -0.068, p <0.001). The pooled odds ratios (ORs) of mortality at 30 days and 1 year in AKI patients were 3.66 (95% CI, 2.00-6.70) and 2.22 (95% CI, 1.62-3.04), respectively. The pooled ORs of mortality at 30 day and 1 year in severe AKI patients requiring RRT were 7.52 (95% CI, 4.58-12.33) and 5.41 (95% CI, 3.63-8.06), respectively.

Conclusions: 37% of LVAD patients developed AKI based on standard definitions and 13% developed severe AKI requiring RRT. There has been potential improvement in the incidence of severe AKI requiring RRT for LVAD patients. AKI in LVAD patients was associated with increased 30-day and 1-year mortality.

PO0014

AKI in the Emergency Department: A Prospective Case-Control Study

Telma H. Ragnarsdóttir,[1,2] Margret Kristjansdottir,[1] Gisli Gislason,[2] Vicente Sanchez-Brunete,[1] Margret O. Tomasdottir,[3,2] Olafur H. Samuelsson,[1] Runolfur Palsson,[1,2] Olafur S. Indridason.[1] *[1]Landspitali University Hospital, Reykjavik, Iceland; [2]University of Iceland, Faculty of Medicine, Reykjavik, Iceland; [3]Primary Health Care of the Capital Area, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) is an abrubt decline in kidney function that occurs in hours or days. AKI has been throughly studied in the hospital setting, however data on community-aquired AKI are scarce. The aim of this study was to investigate the incidence, causes and prognosis of patients presenting with AKI to the emergency department (ED).

Methods: This was a prospective case-control study in which serum creatinine (SCr) measurements of all patients presenting to the ED of Landspitali–The National University Hospital in Reykjavík were examined for the presence of AKI. The study started on January 1, 2020, and we present data until March 3, 2020. All patients who met the criteria for AKI were invited to participate. Randomly selected control cases (1:2) were paired according to age, sex and time of ED admission. Participants signed informed consent and were questioned about their medical history, habits and use of medications, including over-the-counter (OTC) medications and supplements, in the week prior to admission. Medical records were also reviewed with regard to prior diseases and medical prescriptions.

Results: From January 1 to March 3, 124 cases of AKI were identified among patients presenting to the ED, 114 (92%) of whom participated in the study. The mean (±SD) age of the 114 AKI cases and the 228 controls was 68.7±15.2 years and 68,8±15.0 years, respectively; 43% of cases and controls were female. AKI cases were significantly more likely than controls to have been taking non-steroidal anti-inflammatory drugs (NSAIDs) (36,0% vs 20,6%, p<0,01) in the week preceding the ED visit. In both cases and controls, the usage of OTC NSAIDs was more common than prescription NSAIDs (72.2% and 66.0%). No significant difference was observed between AKI cases and controls in use of ACE-inhibitors/angiotensin receptor blockers (45.6% vs 39.9%, p=0.314). The use of proton pump inhibitors was less common among AKI cases than controls (27.2% vs 41.7%, p<0.01) and same was true for statins (22.8% vs 33.3%, p=0.045).

Conclusions: These preliminary results suggest a significant contribution of OTC NSAID use to AKI among patients presenting to the ED. A detailed information on adverse events should be provided when these medications are sold over the counter.

PO0015

Prehospital Systolic Blood Pressure and Lactate Are Early Predictors of AKI After Trauma: A Prospective Validation Study

Toru Nasu,[1] Kentaro Ueda,[1] Shuji Kawashima,[1] Yuko Okishio,[1] Kosei Kunitatsu,[1] Yasuhiro Iwasaki,[2] Seiya Kato.[1] *[1]Wakayama Medical University, Wakayama, Japan; [2]Wakayama Rosai Hospital, Wakayama, Japan.*

Background: We have already reported that prehospital systolic blood pressure and lactate can be predictive factors for acute kidney injury (AKI) after trauma. This study is a prospective validation study to determine whether these risk factors are helpful.

Methods: We evaluated all trauma patients who were admitted from January 2019 to December 2019. Patients who were <16 years of age, patients with burns, and patients with chronic kidney disease were excluded from the present study. AKI was defined according to the risk, injury, failure, loss of the kidney function, and end-stage kidney disease (RIFLE) classification from serum creatinine alone.

Results: Four hundred -three patients were included in the analysis. The prevalence of AKI in the overall population was 14.7% including 11.7% of patients with stage R, 2.0% of patients with stage I and 1.0% with stage F. The incidence of stage I and F AKI in the high-risk group (5 of 38 patients, with the positive predictive value of 13.2%) was significantly higher (P<0.001) than that in the low-risk group (7 of 358 patients, with the negative predictive value of 98.1%).

Conclusions: The prehospital systolic blood pressure and early hospital arterial lactate showed good performance in the early prediction of AKI after trauma. These parameters are associated with the early onset of AKI after trauma and may be an early predictor of the effects of treatment to prevent AKI.

PO0016

Association of Race and Risk of Future Scleroderma Renal Crisis at Systemic Sclerosis Diagnosis

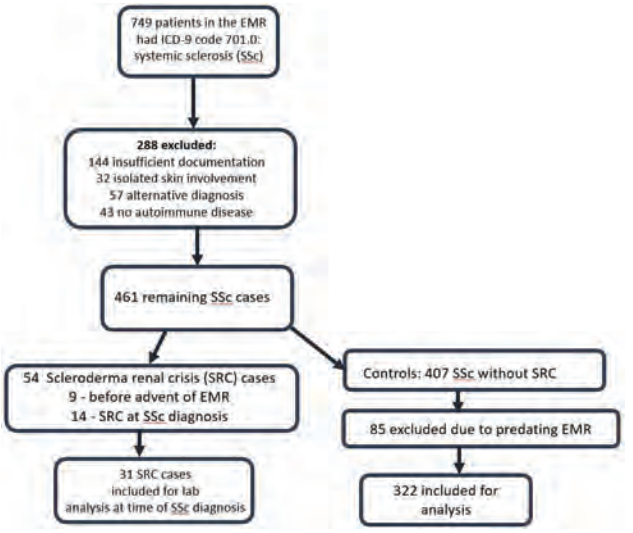
Crystal Forman,[1] Stephen W. Olson,[2] Sarah M. Gordon,[2] James B. Hughes,[2] Rodger S. Stitt,[2] Wayne Bailey,[2] Jess D. Edison,[2] Robert Nee.[2] *[1]San Antonio Uniformed Services Health Education Consortium, Fort Sam Houston, TX; [2]Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Scleroderma renal crisis (SRC) is a rare and severe manifestation of systemic sclerosis (SSc). Although it is well documented that Blacks with SSc have worse morbidity and mortality than non-Blacks, racial predilection for SRC is underreported. We examine the association of race and future development of SRC in an SSc cohort.

Methods: Using the electronic medical record of the U.S. Military Health System which consisted of 9.6 million beneficiaries worldwide, we conducted a comprehensive chart review of each patient with SSc from 2005 to 2016 (see flowchart). The final study cohort was comprised of 31 SRC cases and 322 SSc without SRC controls. We conducted logistic regression of SRC as the outcome variable and race (Black vs. non-Black) as the primary predictor variable, adjusted for age, estimated glomerular filtration rate (eGFR), hypertension and proteinuria at SSc diagnosis.

Results: Out of 353 patients, 294 had identifiable race (79 Black, 215 non-Black). Thirteen out of 79 Blacks (16.5%) vs. 16/215 (7.4%) non-Blacks developed SRC (p=0.02). Black SRC patients were younger (47 ± 12 vs. 57 ± 13 years, p=0.04) and had a higher eGFR at baseline (93 ± 30 vs. 61 ± 17 ml/min/1.73m2, p=0.003) than their non-Black counterparts. Other baseline clinical and laboratory characteristics were comparable between the 2 racial groups with SRC. On adjusted analysis, Blacks had a significantly higher risk of developing SRC than non-Blacks (odds ratio 6.4, 95% CI 1.3-31.2, p=0.02).

Conclusions: Black race was independently associated with a higher risk of future SRC. Future studies are needed to elucidate the mechanisms that underlie this important association.



Flowchart of study participants. EMR: electronic medical record; ICD-9: International Classification of Diseases, 9th Revision; SRC: scleroderma renal crisis; SSc: systemic sclerosis.

PO0017

Racial Differences in AKI Following Percutaneous Coronary Intervention

Joseph Lunyera,[1] Robert M. Clare,[2] Karen Chiswell,[2] Julia J. Scialla,[3] Patrick H. Pun,[2,1] Kevin L. Thomas,[2,1] Monique Starks,[2,1] Clarissa J. Diamantidis.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Duke Clinical Research Institute, Durham, NC; [3]University of Virginia School of Medicine, Charlottesville, VA.*

Background: Percutaneous coronary intervention (PCI) is a risk factor for AKI, but few studies have quantified racial differences in AKI incidence following PCI.

Methods: We examined the association of self-reported race – black, white, and other – and baseline eGFR with AKI incidence among patients captured in the Duke Databank for Cardiovascular Disease (DDCD) who underwent PCI at Duke between January 1, 2003 and December 31, 2013. AKI was defined as ≥ 1.5-fold increase in serum creatinine from outpatient reference value before PCI to the peak value within 7 days post-PCI or a 0.3 mg/dl increase from the reference value within 48 hours. We used logistic regression adjusted for demographics, comorbidities, predisposing medications (NSAIDS, RAAS inhibitors, diuretics), PCI indication (presenting with vs without acute coronary syndrome), peri-procedural prophylaxis with IV fluids and n-acetylcysteine, urgency of PCI and BP at time of PCI.

Results: Of 9422 patients (median age 63y [IQR 54 to 72]; 33% female; 75% white, 20% black, 5% other race), 9% developed AKI: 14% of blacks, 8% of whites, 10% in other race groups. After adjustment, black race was associated with greater likelihood of AKI: odds ratio (OR) 1.80 in black (vs white) patients (95% confidence interval (CI) 1.49 to 2.18. Compared to white, other race was not associated with AKI: OR 1.31, 95% CI 0.91 to 1.87. Low baseline eGFR was associated with graded, higher likelihood of AKI: p for trend <0.001. There was no interaction between race and baseline eGFR.

Conclusions: Black patients had nearly twice the likelihood for AKI following PCI than whites despite adjustment for baseline kidney function, prophylaxis and procedural characteristics. Future investigations should identify other factors that predispose black individuals to disparate AKI risk following PCI.

PO0018

The Spectrum of Biopsy-Proven Kidney Diseases in 2027 Patients with AKI

Zulihumaer Abuduwupuer, Shao-shan Liang, Feng Xu, Dandan Liang, Xue Yang, Ying Zhu, Zhihong Liu, Cai-hong Zeng. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: Acute kidney injury (AKI) is a group of highly heterogeneous, complicated clinical syndrome. The kidney biopsy plays an irreplaceable role in the evaluation of patients with unexplained AKI and may offer fresh insights into disease heterogeneity. Hence, in this study we aim to analyze the pathological disease spectrum, etiology, and renal recovery of biopsy-proven AKI patients.

Methods: We retrospectively analyzed the clinical and pathological data of AKI patients who went to a kidney biopsy during the hospitalization at our center from January 2013 to December 2018. We classified included patients into pure AKI and ACKD two groups.

Results: The study included 2027 AKI patients who had undertaken renal biopsy, which accounting for 6.8% of the total renal biopsy cases and 31.7% of the total hospitalized AKI cases during the same period. The majority of AKI patients were male (65.1%), with an average age of 42±16.5 years, pure AKI and ACKD account for 21.6% and 78.4%.%. Pure AKI mainly presented as AKI-3 (74.8%), while ACKD mostly presented as AKI-1 (53.5%). The proportion of patients undergoing renal replacement therapy in pure AKI group was significantly higher than ACKD group (29.3% vs 11.9%, P <0.001).) In pure AKI group, acute interstitial nephritis (AIN) was most common (56.1%), followed by acute tubular necrosis (ATN) (34.6%). The main cause of AIN was due to drugs (84.9%) and the main causes of ATN were infections (41.7%) (epidemic hemorrhagic fever) and drugs (38.4%). In ACKD group, primary and secondary glomerular disease accounted for 70.6%.and 26.9%, and the most frequent pathological disease were IgAN, followed by MCD, FSGS, MN, LN, AAV. Among the followed-up patients the proportions of complete, partial and non-renal recovery were 73.2%, 13.3% and 13.5%, respectively.

Conclusions: Among biopsy-proven AKI patients, pure AKI was relatively rare while ACKD accounts for the majority. Pure AKI tend to be more serious than ACKD and more patients required dialysis. ACKD patients had a wide spectrum of pathological diseases, and the prognosis of renal recovery was worse than pure AKI.

PO0019

Higher Ambient Level of Nitrogen Dioxide Is Associated with an Increased Risk of AKI

Xin Xu, Yanqin Li, Licong Su, Fan Fan Hou. Xin Xu *Nanfang Hospital, Southern Medical University, Guangzhou, China*.

Background: Previous studies have suggested that long-term exposure to air pollution increased the risk of chronic kidney disease and its progression. However, the effect of air pollution on the risk of acute kidney injury (AKI) has not been studied.

Methods: We selected from the Epidemiology of AKI in Chinese Hospitalized patients (EACH2 study) AKI cases of which the onset date could be unambiguously determined. We obtained city-specific daily averages of the ambient level of $PM_{2.5}$, PM_{10}, CO, NO_2, SO_2 and O_3, from the Ministry of Environmental Protection of China. We used the time-stratified case crossover approach to examine the association between the ambient level of air pollutants and the risk of AKI in the selected cases.

Results: A total of 11,293 AKI cases that met the inclusion and exclusion criteria were selected, of which, 3175 (28.1%) were severe AKI (stage 2 or 3). In univariable analysis, the ambient levels of NO_2 and SO_2, were significantly associated with the risk of AKI. In the multivariable analysis that incorporated all six pollutants in the same model, NO_2 was the sole pollutant whose level remained to be associated with the risk of AKI ($p<0.001$). The relationship between level of NO_2 and the risk of AKI appeared to be linear, with an estimated odds ratio of 1.072 (95% CI: 1.033, 1.113) for each increment of one standard deviation in the exposure. The association was consistent across the subgroups stratified by age, gender, baseline eGFR, AKI severity, need for intensive care, and season.

Conclusions: Higher ambient level of NO_2 was associated with an increased risk of AKI in hospitalized adults in China.

PO0020

AKI After Procedures of Orthotopic Liver Transplant: Risk Factors, Renal Outcomes and Survival

Francisco javier Antiga lopez, Olynka Vega, Ricardo Correa-Rotter. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico*.

Background: The incidence of acute renal injury (AKI) after orthotopic liver transplantation (OLT) ranges between 40 and 70%. The etiology of this syndrome is multifactorial.

Methods: Medical records of patients undergoing OLT in the period from January 2012 to August 2019 were reviewed. A total of 355 patients were included. 171 patients presented AKI. Baseline characteristics, variables during surgery and variables during their stay in intensive were analyzed. Renal outcomes and survival were also analyzed.

Results: In the group without AKI age mean was 45.8 years and 37% were men, in the group with AKI the age mean was 51.2 years and 54% were men (P = 0.001). Mean baseline creatinine was 0.77 while vs 0.88 mg/dl P = 0.003. Furosemide prior to transplantation was found: 51.6% vs 71.9% P = 0.001. A difference was also found between the incidence of AKI and the number of AKI events in the 3 months prior to transplantation (17.3% vs. 37.4% P = 0.001) and (0.21 vs. 0.53) During surgery. Difference was found in maximum lactate, maximum dose of norepinephrine and vasopressin use during surgery: (5.1 vs. 5.8 P = 0.014), (0.59 vs 0.34 P = 0.001), (36% vs 51% P = 0.003) Differences were also found in drained ascites and anehepatic period: (1508 vs 973 SD vs 1871 P = 0.021) and (52.9 vs 57.4 P = 0.014). In the stay in the ICU, there was a difference in the income of liquids first and second 8 hours after transplant (1319 vs 1984 P = 0.001) and (1208 vs 1606 P = 0.009), norepinephrine dose in the first 24 hours (0.14 vs 0.27 P = 0.001), use of vancomycin and anidulafungin (27.1% vs. 42.1% P = 0.02) and (3.8% vs. 13.4% P = 0.001), transfusion of blood derivatives 33.15% vs 59% (P = 0.001). There was difference in creatinine and GFR at the end of hospitalization (0.67 vs 0.97 P = 0.001) and (104 vs 82.6 P = 0.001). Survival at 7 days after the transplant 100% vs 96.5% P = 0.01. Survival 30 days 99.5% vs 93.6% P = 0.002.

Conclusions: The incidence of AKI in the first 7 days was 48%, which is consistent with that reported in the world literature. The development of AKI seems to be multifactorial influencing baseline characteristics of patients before transplantation and renal insults during surgery and intensive care stay. AKI was associated with higher mortality at 7 and 30 days, in addition to lower GFR at patient discharge and higher risk of CKD.

PO0021

Anemia Following AKI After Non-Cardiac Surgery and Long-Term Outcomes: The NARA-AKI Cohort Study

Masatoshi Nishimoto,[1] Miho Murashima,[2] Maiko Kokubu,[1] Masaru Matsui,[3] Masahiro Eriguchi,[1] Ken-ichi Samejima,[1] Yasuhiro Akai,[1] Kazuhiko Tsuruya.[1] *[1]Nara Kenritsu Ika Daigaku, Kashihara, Japan; [2]Nagoya Shiritsu Daigaku Daigakuin Igaku Kenkyuka Igakubu, Nagoya, Japan; [3]Nara-ken Sogo Iryo Center, Nara, Japan*.

Background: The aim of this study was to investigate whether acute kidney injury (AKI) is an independent predictor of anemia and whether anemia following AKI is a mediator of mortality after AKI.

Methods: This is a retrospective cohort study. Adults who underwent non-cardiac surgery from 2007 to 2011 were included. Those with obstetric or urological surgery, missing data for analyses, or preoperative dialysis were excluded. Subjects were followed until the end of 2015 or loss to follow-up. The exposure of interest was postoperative AKI defined by KDIGO criteria. The outcome variables were hematocrit values measured at 3, 6, and 12 months postoperatively and mortality. Associations between AKI and hematocrit or association between AKI and mortality were examined by multivariable linear regression or cox regression analyses, respectively. Data were adjusted for potential confounders.

Results: Among 6692 subjects, 445 (6.6%) developed AKI. Among those with postoperative data, AKI was independently associated with lower hematocrit values at 3, 6, and 12 months postoperatively, with coefficients [95% confidence interval] of −0.79 [−1.47 to −0.11], n=1750, −1.35 [−2.11 to −0.60], n=1558, and −0.91 [−1.59 to −0.22], n=2463, respectively. Higher stages of AKI and longer duration of AKI were associated with more severe anemia. AKI was associated with higher mortality after 3 months postoperatively with hazard ratio [95% confidence interval] of 1.54 [1.12 to 2.12]. Further adjustment with hematocrit values at 3 months attenuated the association (1.45 [1.05 to 2.00]). Mediation effect was significant (p=0.02) by mediation analysis.

Conclusions: AKI was an independent predictor of anemia following AKI. This might be due to permanent interstitial damage and impaired erythropoietin production. Higher mortality associated with AKI was at least partially mediated by anemia following AKI. Whether correction of anemia following AKI improves outcome of AKI requires further research.

Funding: Private Foundation Support

PO0022

The Association of Intraoperative Gross Hematuria on Postoperative AKI After Cytoreductive Surgery Combined with Hyperthermic Intraperitoneal Chemotherapy: A Retrospective Study

Yumi Mitani,[1] Yohei Arai,[1] Tomohiro Mitani,[2] Yoshimasa Gohda,[1] Isao Kondo,[1] Emi Sakamoto,[1] Daisuke Katagiri,[1] Fumihiko Hinoshita.[1] *[1]Kokuritsu Kenkyu Kaihatsu Hojin Kokuritsu Kokusai Iryo Kenkyu Center, Shinjuku-ku, Japan; [2]Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Bunkyo-ku, Japan*.

Background: Cytoreductive surgery combined with hyperthermic intraperitoneal chemotherapy (CRS+HIPEC) has been established in the management of peritoneal carcinomatosis (PC). Although it's still necessary to take adequate measures against major postoperative complications including acute kidney injury (AKI), there is no consensus on how to assess and stratify risk for patients with postoperative AKI following CRS+HIPEC. The aim of this retrospective cohort study is to investigate the association of intraoperative gross hematuria as a surrogate marker of ureter injury with post-operative AKI incidence.

Methods: We conducted a retrospective cohort study consisting of patients without impaired pre-operative kidney function who underwent CRS+HIPEC at a single referral center, Center Hospital of the National Center for Global Health and Medicine, and evaluated the relationship between intra-operative gross hematuria and the incidence of post-operative AKI defined by the Kidney Disease Improving Global Outcomes practice guidelines. We estimated the adjusted odds ratio of hematuria for AKI by multivariate logistic regression with linear terms of intra-operative hematuria, PC index score(PCI), sum of the subscores for abdominoperitoneal region 4-8(4:left flank, 5: left lower, 6: pelvis, 7: right lower, 8:right flank) of PCI ,Body Mass Index, estimated blood loss, age, pre-operative estimated glomerular filtration rate and platina-based infusion (cisplatin) without any interaction terms.

Results: We enrolled 185 patients (males, 37%) and 25 patients developed intra-operative gross hematuria. Post-operative AKI occurred in 10 (40%) of 25patients with hematuria and 28 (17.5%) of 160 patients without hematuria. The crude odds ratio for exposed to hematuria was 3.14 (95% confidence interval: 1.30-7.60, p=0.020) for post-operative AKI. Adjusted odds ratio estimated by the multivariate logistic regression was 4.57 (95% confidence interval : 1.55-13.45, p=0.006).

Conclusions: We first disclosed that the intra-operative gross hematuria is significantly associated with post-operative AKI incidence after CRS+HIPEC.

PO0023

Decreased Urinary Uromodulin Is Potentially Associated with AKI: A Systemic Review and Meta-Analysis

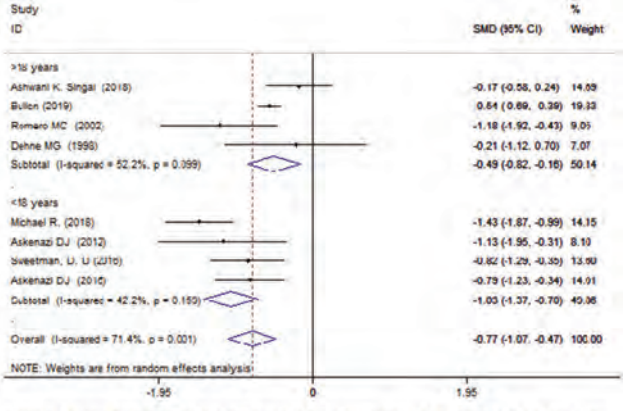
You Ruilian, Hua Zheng, Limeng Chen. *Peking Union Medical College Hospital, Beijing, China.*

Background: Conventional diagnostic criteria based on the serum creatinine isn't sensitive enough to detect Acute Kidney Injury (AKI) timely. Urinary uromodulin (uUMOD) is one of the novel biomarkers being studied for the value of predicting AKI. However, currently available publications showed inconsistent outcomes. This meta-analysis aimed to evaluate the potential association between uUMOD and AKI.

Methods: We searched research articles in Pubmed-Medline, Web of Science, Cochrane library, Embase, China National Knowledge Infrastructure, and Weipu Database(up to 2020.3). Random-effects models were used to estimate the standardized mean difference (SMD) between AKI and Non-AKI. The sensitivity analysis was conducted using the leave-one-out method. Random-effects meta-regression was performed to evaluate the impact of potential confounders on age and surgery.

Results: The meta-analysis was comprising 2678 subjects of 8 studies, which showed that the uUMOD in the patients with AKI was significantly lower than the Non-AKI patients (SMD:-0.77, P=0.001, 95% confidence interval -1.07,-0.47). Subgroup analysis indicated a significant difference in different ages and surgery group(Figure1-2). Sensitivity analysis displayed the synthetic outcome always in the 95% CI of the pool SMD suggesting a robust result.

Conclusions: The study suggests a potential negative association between uUMOD and AKI. Further studies are needed to investigate the promising diagnostic values and mechanisms in protecting AKI.



Ficure 1.Subgrcup analysis for age difference of urine uromodulin in the patients of AKI and Non-AKI. CI: Confident Interval, SMD: Standardized Mean Difference; AKI: Acute Kidney Injury

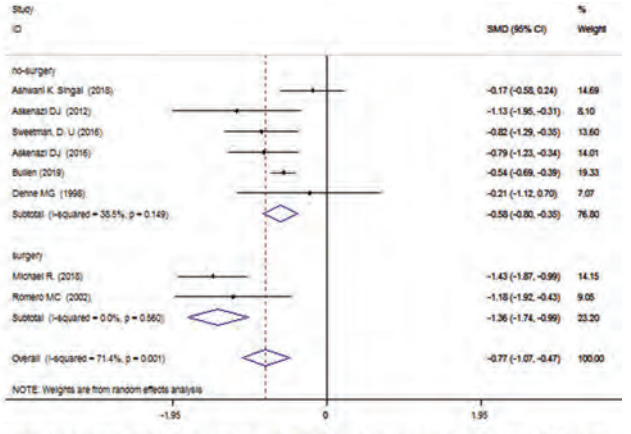


Figure 2. Subgroup analysis for surgery condition of urine uromodulin in the patients of AKI and Non-AKI. CI:Confident Interval,SMD: Standardised Mean Difference,AKI:Acute Kidney Injury.

PO0024

Independent Predictors of Checkpoint Inhibitor-Associated AKI

Mónica Bolufer, Clara García-Carro, Roxana Bury, Eva Muñoz, Enriqueta Felip, Alejandra Gabaldon, Maria Josep Carreras, Daniel Serón, Maria Jose Soler. *Vall d Hebron, Barcelona, Spain.*

Background: Checkpoint inhibitors(CPI)–associated acute renal injury(AKI) is an adverse effect of these therapies and its incidence is 13-29%. Clinical characteristics and risk factors of CPI-associated AKI were investigated

Methods: Clinical and demographic data of patients receiving CPI March2018-May2019 were evaluated. Patients were divided into two groups depending on the development of AKI.

Results: 821 patients received CPIs. Mean age 62.03±12.06 and 486(59.2%) men. Malignancies: lung 249(30.3%), urogenital tract 168(20.5%), melanoma 89(10.8%) and others 315(38.4%). 446(54.3%) anti-PD1, 230(28%) anti-PDL1, 13(1.6%) anti-CTLA4, 36(4.4%) other drug and 96(11.7%) both anti-CTLA4 and anti-PD1 or anti. PDL1. Baseline creatinine(bCr) 0.85±0.30 mg/dL and 188(22.9%) Cr>1mg/dL before starting CPI.125 (15.2%) developed AKI, 85(68%) men and mean age 65.1±10.7. Baseline Cr 0.97±0.45 mg/dL and 44(35.2%) presented bCr>1mg/dL.Cr at AKI diagnosis 2.27±1.34mg/dL and two required haemodialysis. 5 AKI secondary to obstructive uropathy. Time from CPI initiation to AKI 5.6±5.8months. Of those 125 patients, 23(18.4%) referred to Nephrology and 9(7.2%) underwent kidney biopsy. 1 endocapillar non-CPI related glomerulonephritis and 8(6.4%) acute tubule-interstitial nephritis(ATIN). 23(18.4%) were treated with corticosteroids. Cr at 6months after AKI 1.04±0.34 mg/dl and 40 showed complete recovery of kidney function at 6 months. AKI stage 2 or 3 were lower bCr(0.86±0.25 vs 1.06±0.54 mg/dL, p=0.01), increased latency from CPI initiation to AKI(6.9±6vs 4.5±5.5 months, p=0.03) and worse recovery of kidney function at 6 months than AKI patients stage 1(Cr 1.18±0.40 mg/dL, p=0.04 and complete recovery of kidney function 70.5%vs 93.3%,p=0.03). AKI patients were older (65.1±10.7 vs 62.03±12.06years, p=0.01), male (68%vs57.9%), p=0.03) and higher bCr(0.97±0.45 vs 0.85±0.30 mg/dL,p<0.01), bCr>1mg/dL (35.2%vs20.7%,p=0.04). Older age (OR 1.020, CI 95%1.002-1.038) and bCr(OR 3.293, CI 95% 1.678-6.461) were identified as independent predictors of AKI development in CPI

Conclusions: CPI-associated AKI is 15.2%,44% developed severe AKI.18.4% were referred to a nephrologist and kidney biopsy performed in 7.2%. 18.4% received corticosteroids. Older age and higher bCr were identified as independent predictors for AKI development in patients with cancer CPI-treated

PO0025

Relationship of Loop Diuretic with Hospital-Acquired AKI: A Multi-center, Propensity Score-Matching Analysis

Yanqin Li, Licong Su, Xin Xu. *Nanfang Hospital of Southern Medical University, Nephrology Guangzhou, China; National Clinical Research Center for Kidney Disease; State Key Laboratory of Organ Failure Research, Guangzhou, China.*

Background: Loop diuretics have been widely used to prevent and treat acute kidney injury (AKI). However, there is no clear consensus on the role of loop diuretics in AKI.

Methods: The Epidemiology of AKI in Chinese Hospitalized patients is a multicenter retrospective cohort included 3,044,024 hospitalized patients from 25 tertiary hospitals across China during 2013-2015. Patient data were obtained from the electronic hospitalization information system. We selected 57589 adult patients who had at least two serum creatinine tests within any 7-day window during their first 30 days of hospitalization and excluded those with end-stage renal disease, community-acquired AKI and without prescription data. AKI was defined using the SCr data by the Kidney Disease Improving Global Outcomes criteria. Exposure to Loop diuretics as any filled prescription within 14 days prior to the detection date of AKI in patients with HA-AKI and within 14 days prior to the last SCr testing date in those without AKI. Propensity scores (PS) were calculated using a logistic regression model with age, gender, hospital, division, baseline SCr, SCr testing times, comorbidities, operation procedures, need for intensive care and exposure to other nephrotoxic drugs. Moreover, the inverse probability of the treatment weighting (IPTW) method and standardized mortality ratio weighting method was also used.

Results: Of 57589 adult analysed, 20599 (35.8%) used diuretics, 17077 (29.7%) used loop diuretics, and 6277 (10.9%) had HA-AKI events during hospitalization. 8,274 pairs matched after nearest-neighbor matching without replacement and within caliper width (0.2*SD of the logit of PS). By IPTW, use of loop diuretics was associated with a significantly increased risk of HA-AKI compared with non-users (OR, 1.39; 95% CI, 1.28-1.52). The associations were consistent across multiple regression models.

Conclusions: Loop diuretics were widely used and associated with an increased risk of HA-AKI in hospitalized adult in China.

Funding: Government Support - Non-U.S.

Table 1. Use of Loop diuretics and the Risk of HA-AKI in the 1:1 propensity score-matched cohorts.

Variable	AKI Events, N	Total patients, N	Crude rate (95% CI)	Crude OR (95% CI)	Adjusted OR (95% CI)

AKI and Bleeding Risks Associated with Vitamin K Antagonists and Antiplatelet Agents in Patients with CKD

Solene M. Laville,[1] Marie Metzger,[1] Aghiles Hamroun,[8,1] Oriane Lambert,[1] Christian Jacquelinet,[2] Maurice Laville,[3] Luc Frimat,[4,5] Denis Fouque,[3] Christian Combe,[6,7] Roberto Pecoits-Filho,[12] Benedicte Stengel,[1] Ziad Massy,[9,1] Sophie Liabeuf.[10,11] *[1]CESP - INSERM U1018, Clinical Epidemiology Team, Paris-Saclay University, UVSQ, Villejuif, France; [2]Agence de la biomedecine, La Plaine Saint-Denis, France; [3]Nephrology Dept, Centre Hospitalier Lyon Sud, Universite de Lyon, Carmen, Pierre-Bénite, France; [4]Nephrology Department, CHRU de Nancy, Vandoeuvre-les-Nancy, France; [5]Lorraine University, APEMAC, Vandoeuvre-les-Nancy, France; [6]Service de Nephrologie Transplantation Dialyse Apherese, Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France; [7]INSERM, U1026, Univ Bordeaux Segalen, Bordeaux, France; [8]Regional and University Hospital Center of Lille, Nephrology Department, Lille, France; [9]Department of Nephrology, Ambroise Pare University Hospital, APHP, Boulogne-Billancourt, France; [10]Department of Clinical Pharmacology, Amiens University Hospital, Amiens, France; [11]MP3CV Laboratory, EA7517, University of Picardie Jules Verne, Amiens, France; [12]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Anticoagulation in patients with chronic kidney disease (CKD) is challenging because of altered pharmacodynamics/pharmacokinetics. Patients prescribed vitamin K antagonists (VKA) are at high risk of bleeding, and possibly also acute kidney injury (AKI). We assessed bleeding and AKI risks associated with VKA and/or antiplatelet agents (AP) prescription in patients with moderate or advanced CKD.

Methods: CKD-REIN is a prospective cohort of 3022 nephrology outpatients with CKD stages 2-5 at inclusion. Drug prescriptions and their duration were collected prospectively. We used cause-specific Cox proportional hazard models to estimate hazard ratios (HR) of bleeding (identified through hospitalizations) and AKI (as defined according to KDIGO 2012) associated with VKA only, AP only, or VKA + AP prescriptions treated as a time dependent variable and adjusted for baseline comorbidities, laboratory data, and medications.

Results: At baseline, 65% of the patients were men, median age was 69 (interquartile range (IQR), 60-76), median eGFR was 32 mL/min/1.73m^2 (IQR, 23-41), 328 (10%) patients were prescribed VKA only, 1196 (40%) AP only, and 100 (3%) both VKA and AP. Over a median follow-up of 3.0 years (IQR, 2.6-3.1), 71 (2%) patients were newly prescribed VKA and 187 (6%) AP; 152 patients experienced a bleeding event requiring hospital visit/stay (crude incidence rate (IR): 1.9% person-years [95%CI,1.6-2.2]) and 414 patients experienced AKI (crude IR: 5.4 % person-years [95%CI, 4.9-5.9]. The adjusted HRs for bleeding associated with prescriptions of AP only, VKA only and AP+VKA were 0.77 [95%CI, 0.48-1.22], 2.29 [95%CI, 1.41-3.73] and 3.77 [95%CI, 2.08-6.83], respectively. Prescription of VKA was associated with increased AKI risk, adjusted HR, 1.79 [95%CI,1.39; 2.32], but not that of AP, 1.19 [95%CI, 0.94; 1.49].

Conclusions: This study confirms the high risk of AKI associated with VKA prescription in CKD patients. It also highlights the potential aggravating effect of combining VKA and AP on the risk of bleeding in this population.

PO0027

Use of Ibuprofen and the Risk of Hospital-Acquired AKI in Children

Licong Su, Yanqin Li, Xin Xu. *Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Ibuprofen is widely used in children worldwide, especially in children with cancer, fever or trauma. However, large and high-quality studies on the association between ibuprofen and acute kidney injury (AKI) in children have been lacking.

Methods: The Epidemiology of AKI in Chinese Hospitalized patients (EACH2 study) is a multicenter, retrospective study of 3,044,023 patients admitted from 2013 to 2015 at 25 academic medical centers in China. Patient-level data were obtained from the electronic hospitalization information system. We included 50,420 hospitalized children aged between 1 month to 18 years who had at least one SCr test during the first 3 days and any interval between two continuous SCr testing <14 days during the first 30 days of hospitalization, excluding those with end-stage renal disease, community-acquired AKI, insufficient SCr testing and without prescription. AKI was defined as an increase in SCr by 26.5 μmol/L within 48 hours or a 50% increase in SCr from the baseline. We estimated the effect of exposure to ibuprofen on the risk of HA-AKI using a COX proportional hazard model with adjustment for age, sex, standardized baseline creatinine, comorbidities, clinical procedures, other nephrotoxic drugs use and stratification by hospital and division. We also compared the effect sizes of ibuprofen among subgroups stratified by age, gender, chronic kidney disease, need for intensive care and exposure to other nephrotoxic drugs.

Results: Among 50,420 children who met the inclusion and exclusion criteria, 5,526 (11.0%) were ibuprofen users, and 3,476 (6.9%) had HA-AKI during hospitalization. Ibuprofen use was associated with significantly increased risk of HA-AKI (hazard ratios, 1.23; 95% CI, 1.14-1.34) after adjusting for confounders. The greater nephrotoxicity of ibuprofen was observed in children who had chronic kidney disease, required intensive care, or were of elder age.

Conclusions: Ibuprofen was widely used and associated with an increased risk of HA-AKI in hospitalized children in China.

Use of ibuprofen and the risk of HA-AKI in patients by Cox proportional hazard

	Total, N	No. of AKI	Crude HR (95% CI)	P value	Adjusteda HR (95% CI)	P value

Nonsteroidal Anti-Inflammatory Drugs and Risk of Acute Adverse Renal Outcomes in Diabetes

Cynthia C. Lim,[1] Hanis B. Abdul Kadir,[1] Jason Choo Chon Jun,[1] Teck W. Ang,[2] Yong Mong Bee,[1] Ngiap chuan Tan.[2] *[1]Singapore General Hospital, Singapore, SG, Singapore, Singapore; [2]SingHealth Polyclinics, Singapore, Singapore.*

Background: Individuals with diabetes mellitus (DM) may be susceptible to non-steroidal anti-inflammatory drug (NSAID) –induced acute kidney injury (AKI). However, data on their risk of NSAID-related adverse renal events is sparse. We aimed to evaluate the risk and factors for acute kidney injury and/or hyperkalemia after NSAID prescription to individuals with DM.

Methods: Retrospective cohort study of individuals ≥21 years with DM who received prescriptions between 1st July 2015 and 30th December 2017 from the largest tertiary hospital and a major public primary care institution in Singapore. Laboratory, hospitalization and medication data from 6 months before until 30 days after first prescription were retrieved from electronic medical records. Individuals prescribed systemic NSAID >14 days were identified as the "NSAID" group. We excluded those with systemic NSAID in the preceding 6 months, missing laboratory values, or had baseline estimated glomerular filtration rate (eGFR) <15 ml/min/1.73 m^2. The outcome was the incidence of AKI (serum creatinine increased >50%) and/ or hyperkalemia (serum potassium >5.5 mmol/L) within 30 days after prescription.

Results: We studied 3896 individuals (mean age 64.5 ± 13.3 years) with incident prescriptions: 138 in the NSAID group and 3758 in the non-NSAID group. 30-day AKI and/or hyperkalemia occurred in 525 individuals (13.5%). After adjusting for age, gender, ethnicity, baseline CVD, eGFR, serum potassium, NSAID, RAAS blocker and diuretic, baseline CVD (adjusted OR 1.41, 95% CI 1.03-1.93, p=0.03), RAAS blocker (adjusted OR 1.42, 95% CI 1.15-1.75, p=0.001), diuretic (adjusted OR 1.91, 95% CI 1.53-2.38, p<0.001) and higher baseline serum potassium (adjusted OR 1.36, 95% CI 1.19-1.57, p<0.001) were independent predictors for the outcome. NSAID prescription for >14 days was associated with a higher 30-day risk of AKI and/or hyperkalemia (adjusted OR 1.62, 95% CI 0.99 – 2.65, p=0.05). However, the risk of AKI and/or hyperkalemia was markedly increased if NSAID was prescribed concurrently with RAAS blocker (adjusted OR 4.17, 95% CI 1.74–9.98, p=0.001) or diuretic (adjusted OR 3.31, 95% CI 1.09-10.08, p=0.04).

Conclusions: NSAID prescription in individuals with DM may be associated with higher 30-day risk of AKI and/or hyperkalemia, especially with concurrent RAAS blocker or diuretic.

PO0029

A Retrospective Cohort Study of Chemotherapy-Related AKI

Xin Kang, Li Yang. *Renal Division, Peking University First Hospital, Peking University, Beijing, China.*

Background: Chemotherapy-related acute kidney injury (CR-AKI) is increasing with the growing number of cancer patients and the development of chemotherapeutic agents, whereas systemic information about CR-AKI is still limited.

Methods: This is a multicenter retrospective cohort study of cancer patients with CR-AKI screened from a cohort of hospital-acquired adult AKI patients based on a nationwide AKI survey in China. The enrolled CR-AKI patients were divided into three groups according to peak AKI stages (1 to 3) during hospitalization. The primary outcome was all-cause death in hospital, and the secondary outcome was AKI recovery.

Results: Of 3,468 adult inpatients with hospital-acquired AKI identified basing on the China nationwide AKI survey, 258 patients with CR-AKI were enrolled in our study, of which 20.1% (52/258) were ≥ 70 years old. A total of 413 person-time chemotherapeutic agents were related to AKI, of which platinum compounds (24.5%, 101/413) were the most common ones, followed by fluoropyrimidines (13.1%, 54/413), and anthracyclines (9.2%, 38/413). Among the 258 CR-AKI patients, 61 (23.0%) reached AKI stage 3, and 12 (4.7%) received RRT. The in-hospital mortality was 14.7% (38/258). Of the 207 surviving patients with a reliable serum creatinine value at discharge, 48.3% (100/207) failed to renal recovery. AKI stage 3 remained the independent risk factor for in-hospital death (OR 2.930, 95%CI 1.156~7.427) after adjustment for gender, age, comorbidities, and medications. It is surprising to note that, although patients of AKI stage 1 had lower levels of SCr both at peak and at discharge compared to patients with AKI stage 2 or 3, there was a higher proportion of patients of AKI stage 1 not achieving renal function significantly improved at discharge (failure to recover) compared to those of AKI stage 2 or 3 (57.1% vs. 41.4% vs. 36.4%, P = 0.032). More importantly, a lot more AKI episodes were not recognized or diagnosed by physicians in charge in patients of AKI stage 1 compared to the other two groups (82.8% vs. 60.0% vs. 36.1%, P < 0.001).

Conclusions: CR-AKI accounted for a considerable proportion of hospital-acquired AKI. Severe CR-AKI increases in-hospital mortality. Mild CR-AKI that overlooked by physicians yet sustained kidney injury was common in these patients. Recognizing CR-AKI at an early stage and making personalized treatment should be emphasized when offering chemotherapy to patients.

PO0030

Characterizing AKI from Vancomycin-Associated Nephrotoxicity in Adult Non-ICU Patients at an Inner City Hospital: Incidence and Predictors

Gerald Fletcher,[1,3] Levard G. Roberts,[1,2] Sai S. Achi,[1] Sheldon Ferguson,[1] Maryam M. Handoo,[1] Richard S. Sheppard,[1] Aye M. Aung,[1] Sudhanshu Jain,[1] Suhaib A. Andrabi.[1] *[1]Harlem Hospital Center, New York, NY; [2]Emory University, Atlanta, GA; [3]The University of Arizona Health Sciences, Tucson, AZ.*

Background: Vancomycin is a widely used antibiotic in the in-patient setting. Concerns of vancomycin-associated nephrotoxicity(VAN) were raised due to impurities associated with the first released parenteral formulations in the 1950s. Nephrotoxicity is reported to have markedly declined with a wide variability in the incidence. There is a dearth of information on the current incidence of VAN as a cause of acute kidney injury(AKI) in adult non-ICU populations. The purpose of this study was to estimate the incidence of VAN AKI and identify risk factors of VAN for this population.

Methods: A cohort of patients admitted between January 2015 and December 2017 with the diagnosis of sepsis and who received at least 3 days of parenteral vancomycin were identified through a retrospective chart review. Exclusions were ESRD or CKD history. Our primary outcome was the occurrence of VAN AKI, defined as an increase in serum creatinine by 0.3 mg/dl or 50% above baseline after vancomycin exposure. The incidence of VAN AKI was determined and we estimated risk factors associated with VAN in a logistic regression model.

Results: 587 adult patients received at least 72hours of parenteral vancomycin for the treatment of sepsis during the period. Demographics were: male 350(59.6%), female 237(40.4%) and mean age of 62.3 years. Distribution by ethnicity: non-Hispanic Blacks 71.2%, Hispanics 12.6%, non-Hispanic white 3.4% and 12.4% were other ethnicities. The incidence of VAN AKI was 15.24%. These patients had a longer hospital stay (26.8 versus 21.5 days for no VAN AKI), higher mean vancomycin trough levels, longer duration of exposure to vancomycin and a higher Charlston Comorbidity Index (3.5 versus 2.6). Independent predictors for VAN were: mean vancomycin trough level, hypertension, COPD, congestive heart failure, liver disease, severe obesity and dementia (all p values <0.05). Previous ICU admission and hypotension status did not predict VAN AKI.

Conclusions: We report an incidence of VAN AKI of 15.24% in non-ICU adult patients with no history of ESRD or CKD. Risk factors associated with the development of VAN include mean vancomycin trough level, hypertension, congestive heart failure, COPD, liver disease, severe obesity and dementia.

PO0031

Baseline Urinary Protein Biomarkers as Predictors of eGFR Decline in Cancer Patients Receiving Cisplatin

Melanie S. Joy,[1] Blessy George,[3] Yichun Hu,[2] Susan L. Hogan,[2] Xia Wen,[3] Lauren Aleksunes.[3] *[1]University of Colorado, Skaggs School of Pharmacy, Cancer Center, and Division of Renal Diseases and Hypertension, Denver, CO; [2]University of North Carolina, Kidney Center, Chapel Hill, NC; [3]Rutgers University, Ernest Mario School of Pharmacy, Piscataway, NJ.*

Background: Previous data from our group reported significant changes in urinary biomarkers of sub-clinical kidney injury over 10 days after receiving i.v. cisplatin. The current study evaluated the performance of single and a combination of two urinary biomarkers at the time of cisplatin initiation in predicting a reduction in eGFR.

Methods: Patients (n=57) with solid tumors receiving i.v. cisplatin (≥25 mg/m^2) were enrolled in a study to characterize concentrations of 9 urinary proteins (Table). For the outcome of eGFR decline, the eGFR (MDRD equation) after the first dose and prior to the second dose was used. Statistical models used the baseline urinary biomarker concentrations as predictors. Logistic regression was used to assess Maximum Likelihood Estimates for models containing single and a combination of two urinary biomarkers for prediction of the reductions in eGFR outcome, and reported as odds ratios (OR) with 95% confidence intervals (CI). ROC curves for each model were based on the eGFR reduction outcome. Models were adjusted for age, gender, race and BMI.

Results: A single model for KIM-1 was significant (p=0.0421; OR 0.08; 95% CI 0.01, 0.91) for capturing eGFR decline according to ROC analysis (Table). The six combined models with ROC >0.70 are included in the Table. KIM-1 was a significant contributor in two models when combined with B2M or albumin, but ROC analyses demonstrated similar AUC as the single significant KIM-1 model. Although cystatin C was not significant in a single model (ROC AUC of 0.75), when combined with B2M the ROC AUC (0.77) was the best of all combined models.

Conclusions: Urinary biomarkers have emerged as tools to identify overt and sub-clinical kidney injury. However, single and double combinations of urinary proteins are insufficient to reliably predict reductions in eGFR as an ideal model outcome. Future studies must determine an improved outcome benchmark for evaluating urinary protein biomarkers.

Funding: NIDDK Support

Urinary Sediment Score Is a Useful Predictor of AKI in Hospitalized Patients

Pablo J. Heredia-Murillo,[2] Rolando Claure-Del Granado.[1,2] *[1]Universidad Mayor de San Simon Facultad de Medicina, Cochabamba, Bolivia, Plurinational State of; [2]Clinica Los Olivos, Cochabamba, Bolivia, Plurinational State of.*

Background: Risk-stratification tools of incident AKI in hospitalized patients are needed. Early documentation of impaired kidney function through a simple examination like the urinary sediment may provide risk reduction in such patients. The present study aims to explore an association between urinary sediment score described by Perazella et. al. and hospital-acquired AKI.

Methods: This study included 86 patients who underwent urinalysis, including scoring the urinary sediment during the first 24 hour of admission. Inclusion criteria consisted of age ≥ 18, hospital stay ≥ 3 days, at least 2 serum creatinine (SCr) measures in the first 2 days of hospital stay and one measure at 3-7 days of stay. Exclusion criteria consisted of ESKD, kidney transplant or baseline eGFR <15 ml/m/1.73m^2. AKI was defined as an increase of serum creatinine level ≥ 0.3 mg/dL or ≥ 1.5 times in contrast to baseline creatinine level within 48 hours. We evaluated if the microscopic examination of the urine sediment (score ≥2) could be use as a non-invasive detector of renal damage.

Results: Mean (SD) age was 65.1 (17.2), 38.4% were women and 100% Hispanic. The incidence of AKI at 3-7 days of hospital or ICU stay was 34.9%. From the 30 patients that developed AKI, 20 were on stage 1 (66.6%), 8 were on stage 2 (26,6%) and 2 were stage 3 (26.6%). Performance metrics of the urinary score used are reported in **Table**. A urinary sediment score ≥ 2 exhibited a fair, but not good, AUC of 0.681 (95% confidential interval [CI]: 0.554–0.808) in ROC analysis.

Conclusions: Cellular casts and granular casts are occasionally observed in hospitalized adult patients with risk factors for AKI. The urinary sediment score proposed by Perazella el al. could be a potentially useful marker for early documentation of hospital-acquired AKI.

Kidney Biopsy Findings in AKI in the Cohort of Patients of Mexico Tertiary Hospital

Belen Martinez-Vazquez, Bernardo Moguel, Virgilia Soto, Octavio R. Garcia-Flores. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Background: The study of the epidemiology of biopsy-confirmed renal disease provides useful information about the prevalence of renal disease and its clinical manifestations. Performing a kidney biopsy is necessary to accurately diagnose diseases such as glomerulonephritis and tubulointerstitial nephritis, among other such conditions Kidney biopsy in acute kidney injury (AKI) of unknown origin provides irreplaceable information for diagnosis, treatment, and prognosis. In this report, we analyze the frequency and clinicopathologic correlations of renal native biopsied AKI in Mexican cohort during the period 2014 through 2019.

Methods: We analyzed the frequency and clinicopathologic correlations of AKI confirmed by native renal biopsy in Mexico tertiary hospital and the distribution of the different clinicopathologic findings. From 2014-2019 period, totally 515 patients first received renal biopsy. AKI was diagnosed based on the Kidney Disease: Improving Global Outcomes criteria.

Results: Of the 515 patients investigated, 200 (38.8%) showed AKI. Of these, 102 (51%), 47 (23.5%), and 51 (25.5%) presented with AKI classified as stages 1, 2, and 3, respectively. The primary indication for performing biopsy was rapidly progressive glomerulonephritis (RPGN) in 70 (35%) and nephrotic syndrome in 47 (23.5%). Dialysis previous kidney biopsy was necessary in 48 patients (24%). Focal segmental glomerulosclerosis was the most prevalent primary disease in 37 (18.5%) and lupus nephritis wast the most prevalent secondary disease in 53 (26.5%). In the early patients the most prevalent disease was pauci-immune rapidly progressive GN Multivariate analysis of risk factors associated with AKI showed hemoglobin levels (OR 0.800, 95% confidence interval [CI] 0.671–0.941, p=0.01), dialysis previous kidney biopsy (OR 3.970, 95% CI 2.949–4.392, p=0.008), and baseline serum creatinine levels (OR 2.402, 95% CI 1.371–4.758, p=0.001) were significantly associated with AKI.

Conclusions: We observed a high prevalence of AKI in patients who underwent kidney biopsy to investigate their renal disease, particularly glomerulonephritis. The prevalence of vasculitis and crescentic GN is high, especially in elderly patients.

PO0034

Risk of Incident Bleeding After AKI: A Retrospective Cohort Study

Farah Zarka,[1] Alexandre Tayler-Gomez,[1] Thierry Ducruet,[2] Anatolie Duca,[1] Martin Albert,[1] Amelie Bernier-Jean,[1] Josee Bouchard.[1] *[1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [2]CHU Ste-Justine, Montreal, QC, Canada.*

Background: End-stage kidney disease (ESKD) causes bleeding diathesis; however, whether these findings are extrapolable to acute kidney injury (AKI) remains uncertain. We assessed whether AKI is associated with an increased risk of de novo bleeding.

Methods: We conducted a one-year single-center retrospective cohort study, excluding readmissions, admissions less than 24 hours, ESKD or kidney transplant patients. The primary outcome was the development of incident bleeding analyzed by multivariate time-dependent Cox models and independently adjudicated by two investigators.

Results: In 1,001 patients, bleeding occurred in 48% of AKI and 57% of non-AKI patients (p=0.007). To identify predictors of incident bleeding, we excluded patients who bled before ICU (n=488). In bleeding-free patients (n=513), we observed a trend toward higher risks of bleeding in AKI (22% vs. 16%,p=0.06), and a higher risk of bleeding in AKI-requiring dialysis (38% vs. 17%, p=0.01). Cirrhosis, AKI-requiring dialysis, anticoagulation, and coronary artery disease were associated with bleeding (HR 3.67, 95%CI:1.33-10.25; HR 2.82, 95%CI:1.26–6.32; HR 2.34, 95%CI:1.45–3.80; and HR 1.84, 95%CI:1.06–3.20, respectively), while SOFA score and sepsis had a protective association (HR 0.92 95%CI:0.84-0.99 and HR 0.55, 95%CI:0.34–0.91, respectively). Incident bleeding was not associated with mortality.

Conclusions: AKI-requiring dialysis was associated with incident bleeding, independent of anticoagulant administration. Studies are needed to better understand how AKI affects coagulation and clinical outcomes.

PO0035

Relationship Between Serum Uric Acid Levels and Reduction in Kidney Function Associated with Blockade of the Renin-Angiotensin System

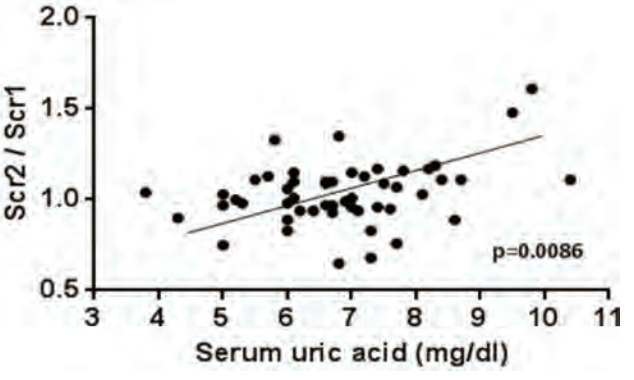
Marcos G. Nava,[1] María Guadalupe C. Núñez,[1] Pedro Gudiño Bravo,[1] Alfredo Fonseca Chávez,[1] Bernardo Rodriguez-Iturbe,[1,2] Magdalena Madero.[1] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Nephrology Department, Mexico, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Departamento de Nefrologia y Metabolismo Mineral, Tlalpan, Mexico.*

Background: Renin-angiotensin system blockade(RASb) induced by treatment with angiotensin type 2 receptor antagonists and angiotensin converting enzyme inhibitors is frequently associated with a reduction in glomerular filtration rate(GFR). Experimental hyperuricemia is associated with dysregulation of renal hemodynamics and reduced GFR. We studied if serum uric acid(sUA) levels are related to the depression of renal function associated to RASb

Methods: 107 patients(23-77 years, 53 females) when they were first prescribed RASb for primary hypertension(PHT)(n=25), diabetic nephropathy(DN)(n=12), PHT&DN(n=8), congestive heart failure(n=26) and proteinuric nephropathes(n=36). Changes in serum creatinine(Scr), mean sUA levels and systolic(SBP) and diastolic(DBP) blood pressures(mmHg) were obtained from records before and 3,1±0,2 months after RASb

Results: Baseline eGFR(ml/min/1,73m2) was 43,6±2,81 and 64±4,89 in male and female patients, respectively .55% male and 51% female patients increased Scr with RASb but only 8 male and 2 female patients increased baseline Scr more than 0,3mg/dl. RASb reduced significantly SBP (pre130,7±1,67 vs. post124,1±1,57,p=0,004) but not DBP. Reduction in eGFR was found in 87% of the patients in whom SBP was reduced by RASb. Reduction of SBP was unrelated to the increase in Scr. sUA(mg/dl) was 6,9±018(males) and 6,1±0,23(females) (p=0,09). In female there was no relation between UA levels and change in Scr. In male there was a direct relationship between changes in Scr (ScrPre/ScrPost) and the mean serum UA levels(r:0,36, p=0,008) that was unrelated to SBP changes. Relationship was stronger in male patients with sUA ≥7,0(r=0.051)

Conclusions: Since 14% of the male patients treated with RASb increased Scr more than 0,3 mg/dl and deterioration of kidney function was directly related to sUA levels, the potential benefit of reducing sUA in male patients treated with RASb should be investigated further



PO0036

Seizure-Induced Hyperuricemia and Associated Urate Nephropathy: A Prospective Cohort Study

Jean Maxime Cote,[1,2] Guillaume Bollee.[1] *[1]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]University College Dublin, Dublin, Ireland.*

Background: Urate nephropathy is an uncommon cause of acute kidney injury (AKI). Although most factors are associated with tumor lysis syndrome and rhabdomyolysis, occurrence following severe seizure has also been described. There are effective ways to prevent and treat urate-associated AKI, when adequately identified. However, uric acid measurement following convulsion episodes is rarely performed and therefore, the incidence of hyperuricemia in this context is unknown. Our objective was to quantify these metabolic disturbances following severe generalised tonic-clonic seizures (GTCS).

Methods: We prospectively recruited patients admitted in our hospital for severe GTCS (≥5 min or a series of seizures with an incomplete return to baseline) and described the kinetics of serum uric acid, creatinine, creatine kinase and lactate during a 72h follow-up. Urine urate-to-creatinine ratio was used to monitor urate tubular toxicity.

Results: From August 2018 to September 2019, 13 patients with a median GTCS duration of 5.0 minutes (IQR 2.0-12.5) were included. The median serum uric acid was initially 346.0 μmol/L (IQR 155.0-377.5) and decreased to 178.0 μmol/L (IQR 140.0-297.5), while serum creatinine passed from 73.0 μmol/L (IQR 151.0-80.0) to 57.0 μmol/L (IQR 44.0-70.0) over follow-up (Figure). AKI occurred in 4 patients (KDIGO Stage ≥1).

Conclusions: Serum uric acid levels increase acutely following a severe GTCS than return to baseline within 3 days. During that period, there is an increased risk of AKI that might be associated with urate nephropathy. To quickly identify and manage patients at risk of acute hyperuricemia and related complications, measurement of uric acid following a GTCS might be beneficial.

Funding: Clinical Revenue Support

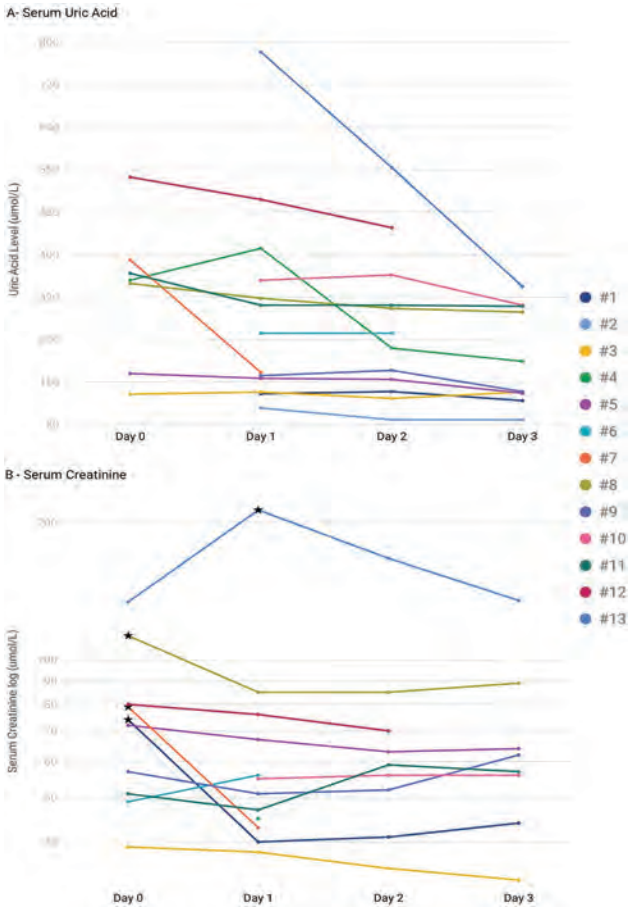


Figure. Post-seizure laboratory values for each participant. Star dots are the maximal value of creatinine where AKI was diagnosed.

PO0037

Late Presentations of Secondary Oxalate Nephropathy

Muna Hale, Pranay Kathuria. *The University of Oklahoma - Tulsa, Tulsa, OK.*

Introduction: Secondary Oxalate nephropathy is an important differential diagnosis for acute kidney injury (AKI) in chronic malabsorptive disease. Mean presentation is typically within 1-2 years. The following three cases are example of late, abrupt presentations of secondary oxalate nephropathy.

Case Description: Our first case includes a 69-year-old female, with gastric bypass surgery 14 years prior, who presented to emergency room (ER) with AKI. Six months prior her creatinine (Cr) was 1.6 mg/dL, but abruptly increased to 5.99 mg/dL. Serologic work up was negative. Renal biopsy was obtained that revealed deposition of oxalate crystals within renal tubules (Figure 1). Our second case showed a 59-year-old male with history of recurrent pancreatitis due to bulimia that presented to the ER for nausea and vomiting. In the ER, patient had a serum Cr of 5.79 mg/dL. Two months prior, Cr was 1.1 mg/dL. Renal biopsy showed widespread oxalate crystals in the interstitium. The last case was a 48-year-old male with chronic pancreatitis who presented with AKI with suspect acute tubular necrosis. He had been diagnosed with chronic pancreatitis for at least 6 years with Cr 0.9 mg/dL. Patient's Cr remained at 4.00 mg/dL one month later. Renal biopsy revealed interstitial fibrosis and calcium oxalate crystals.

Discussion: Secondary oxalate nephropathy is a side effect of malabsorptive gastrointestinal (GI) disorders. According to prior case series, the mean presentation of oxalate nephropathy is 1-2 years. These cases illustrate that secondary oxalate nephropathy can present at a later course with rapid onset. Patients also likely progress to ESRD after diagnosis. A systemic review of 108 cases, with 13 months follow up, showed 55% of patients required hemodialysis. Currently, there is no treatment and lifestyle changes include a low fat, oxalate diet. Secondary oxalate nephropathy should be considered in the differential of all patients with malabsorptive states presenting with AKI.

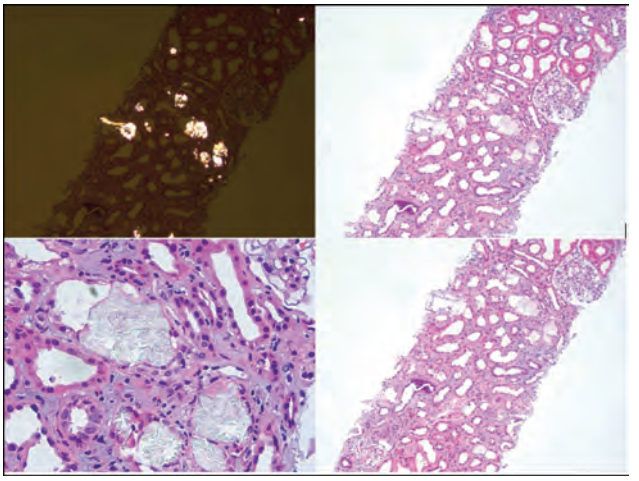

Figure 1

PO0038

Presentation and Outcome of Oxalate Nephropathy Without Known Genetic or Gastrointestinal Cause

Erin E. Bolen,[1] Mina Abdelmalek,[1] John C. Lieske,[2] Mira T. Keddis.[1] *[1]Mayo Clinic Arizona, Scottsdale, AZ; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Oxalate nephropathy (ON) is a frequent and often unexpected finding on kidney biopsy. This study aimed to characterize causes and outcomes in biopsy-proven ON not due to known enteric cause or primary hyperoxaluria (PH) in a multisite health system.

Methods: Cases were identified based upon diagnosis of ON on kidney biopsy between 2009 to 2020 without known enteric or primary cause.

Results: Thirty-four cases were identified with a median follow-up of 11.9 months. None had known fat malabsorption. Genetic testing for PH was negative in 11, and there was no clinical suspicion of PH in the rest. Likely causes of ON included documented high dietary oxalate (7, 21%), oral and/or IV vitamin C supplementation (7, 21%), ethylene glycol (3, 9%), and orlistat (1, 3%). No cause could be identified in 16 (47%). Table 1 shows variables across three etiologies: unknown cause, diet-related, and vitamin C. All cases except one had diffuse intratubular calcium oxalate deposition on biopsy. End stage kidney disease (ESKD) was present in 53%. AKI stage III at biopsy was predictive of ESKD at last follow-up ($p<0.05$). Treatments included low oxalate diet (29, 85%), calcium supplementation (18, 53%), pyridoxine (12, 35%), and prednisone taper (12, 35%). Diet-related ON appeared to have lower rates of AKI stage III at diagnosis (5, 67%), ESKD (3, 43%), and mortality (2, 29%) compared to vitamin C-related ON and ON of unknown etiology.

Conclusions: This is the largest study of ON not due to PH or enteric cause. The most common causes were high-oxalate diet and high-dose vitamin C. In 47% of cases no cause was identified. ESKD was common, and AKI severity at presentation predicted ESKD at last follow up. Cases attributed strictly to dietary excess may have better short and long term outcomes.

The Clinical Impact of Extended-Spectrum Beta-Lactamase-Producing Bacteria in Patients with Community-Acquired Acute Pyelonephritis in a Korean Hospital, 2010-2018

Se-Hee Yoon, Won Min Hwang, Sung-Ro Yun. *Konyang University College of Medicine, Daejeon, Daejeon, Republic of Korea.*

Background: Acute pyelonephritis (APN) is known to be the most complicated, severe urinary tract infection. It is not uncommon to experience the initial empirical antibiotic treatment failure of APN due to the increasing prevalence of ESBL producing bacteria. In this study, we investigated the microbial etiologies of acute pyelonephritis and resistance to antibiotics in APN.

Methods: We retrospectively reviewed microbial etiologies and resistance among patients who were admitted to Konyang University Hospital with APN from 2010 to 2018. Two blood cultures at different sites, and urine culture were performed at the time of admission. Statistical analysis was performed using R (version 4.0.0).

Results: The total number of patients with APN was 882, and *Escherichia coli* (57.3%) was the most common pathogen followed by *Klebsiella spp.* (2.8%), *Enterococcus spp.*(2%), *Proteus spp.* (0.9%), *Enterobacter spp.* (0.6%) and *Pseudomonas aeruginosa* (0.5%). The rate of ESBL producing bacteria has steadily increased over 9 years from 6.3% to 37.8%. Multivariate analysis showed that male sex (OR 2.395; 95% CI 1.201-4.776), APN occurence after 2015 (OR 1.170; 95% CI 1.057-1.296) and previous antibiotics exposure (OR 2.102; 95% CI 1.014-4.356) were risk factors for acquiring ESBL producing bacteria in urine or blood cultures. ESBL producing bacteria of blood or urine cultures in patients with APN was a significant prognostic factor for recurrence of APN within 1 year and mortality (HR 8.439; 95% CI 2.399-29.694).

Conclusions: Although quinolone and 3rd cephalosporin are recommended for empirical treatment of APN, there is a high risk of treatment failure due to the significant increase of ESBL producing bacteria in the community. Antibiotic therapy with APN should ideally be based on local patient characteristics and their antibiotic susceptibility profiles.

PO0040

Incidence of AKI After IV Vitamin C Treatment for Septic Shock: A Cohort Analysis of Real-World Application

Thomas R. McCune,[1,3] Jaingtao Luo,[1,2] Brynn E. Sheehan,[1,2] Stephen T. Petr,[1] Muhammad K. Sherani,[1] Sunita Dodani.[1,2] *[1]Eastern Virginia Medical School, Norfolk, VA; [2]EVMS-Sentara Healthcare Analytics and Delivery Science Institute (HADSI), Norfolk, VA; [3]Nephrology Assocites of Tidewater, Norfolk, VA.*

Background: Septic shock patients exhibit a high prevalence of vitamin C deficiency, and intravenous vitamin C (IVvC) may provide a survival advantage. Preliminary findings from early studies were promising, however, recent studies fail to show a benefit of vitamin C on mortality. Case reports observed that IVvC may be related to acute kidney injury(AKI) through oxalate-nephropathy. While IVvC in sepsis merit further research, clinicians at one institution began the use of IVvC as additional treatment for septic shock. This study is a retrospective analysis of real-world experience to evaluate the effects of IVvC on AKI in patients with septic shock

Methods: Patient-level clinical data of one 525-bed Hospital from 1 February 2016-31 December 2018 was evaluated in the current study. Institutional IRB approval was obtained and data were de-identified. Data included patients between the ages of 18 and 89 who were hospitalized for 48 hours with 2 serum creatinines 48 hours apart or 6 hours of UOP in ICU. Patients with GFR <35ml/min (MDRD formula), creatinine > 4.0mg/dL, or diagnosis of ESRD or kidney transplant (ICD-10 codes) were excluded. Clinical data collected included; admission demographics and past history; UOP; pre-identified medications, laboratory results and order sets; specific consultations; and discharge diagnoses.

Results: A total of 22980 patient visits were evaluated. Of the 2067 patients who were admitted through the ED with a discharge diagnosis of septic shock, 433 (20.9%) received one dose of IVvC 1500mg and were categorized as the IVvC group; 1634 (79.1%) did not receive IVvC. A chi-square analysis can be seen in Table 1.

Conclusions: This retrospective study EMR observed that IVvC in the treatment of septic shock is associated with an increase in the incidence of AKI.

Funding: Clinical Revenue Support

Table 1. Chi-square Analysis Examining the Relationship between IVvC and the Development of AKI among Inpatients with Septic Shock.

	IVvC	IVvC	
AKI	NO	YES	Row Total
NO	876(53.6%)	134(30.9%)	9951010
YES	758(46.4%)	299(69.0%)	1057
Column Totals	1634	433	p≤.0001

Note. A logistic regression revealed that the odds of AKI were 2.57 times higher for IVvC patients compared to non-IVvC patients (95% CI 2.05,3.23)

PO0041

Murine Typhus-Related Thrombotic Microangiopathy, Bilateral Renal Cortical Necrosis, and Acute Disseminated Encephalomyelitis

Mahendra L. Agraharkar,[2,1] Lucas S. Blanton,[1] Radheshyam Bhatt,[1,2] Marjan Afrouzian.[1] *[1]University of Texas Medical Branch at Galveston, Galveston, TX; [2]Baylor College of Medicine, Houston, TX.*

Introduction: Thrombotic Microangiopathy (TMA), Bilateral Renal Cortical Necrosis (BRCN) and Acute Disseminated Encephalomyelitis (ADEM) are rare complications of infections. Murine Typhus (MT), a mild rickettsial infection rarely involves kidneys. We present a young male with rash, anuric renal failure, schistocytes, elevated LDH and high IgG and IgM levels for MT. A CT scan and renal biopsy revealed TMA and BRCN. A week after treatment he developed seizures from ADEM. MT should be considered in unexplained TMA, BRCN or ADEM in endemic area.

Case Description: A 22-yr-old male admitted with truncal rash, vomiting and anuria for 5 days. His admission platelet count was141k/ul with 1+ schistocytes. His Sodium was 128, Potassium 5.8, Chloride 82, and HCO3 13 all in mEq/L. His BUN was 200, creatinine 20 and LDH 4232 U/L. Complement levels, ANA and anti DNA, blood cultures, viral serologies for most viruses including SARC-COV-19 IgG were negative. ADAMTS-13 activity was 61%. MT antibodies titers were >1:1024 for both IgG and IgM. A CT scan and renal biopsy revealed severe BRCN. The glomeruli and arterioles contained microthrombi. IF revealed bright staining fibrinogen in the lumen, endothelium and walls of arterioles and arteries. EM revealed endothelial cell injury and necrosis, and fragmented red cells under the endothelium. He was effectively treated with doxycycline but later he developed encephalopathy and seizures.

Discussion: MT is a mild infection caused by *Rickettsia typhi* transmitted by rat and cat fleas and is endemic to Texas, California and Hawaii in the US. MT is mostly self limiting and mild. In severe cases MTpresents with renal, neurologic, hepatic, cardiac and pulmonary symptoms. Renal dysfunction is due to interstitial nephritis or ATN from renal hypoperfusion. RCN is a rare cause of AKI encountered in 1-2 percent of all cases of AKI. ADEM or post infectitious encephalomyelitis is a rare neurologic complication triggered by vaccinations and infections. Recently authors published a case of MT with collapsing glomerulopathy likely a result of TMA. In our patient the only identifiable infection was MT, which usually is a mild infection. We report a case of MT causing BRCN, TMA and ADEM. We suggest that MT should be cosidered in multiorgan involment the endemic area when no other cause is identified.

PO0042

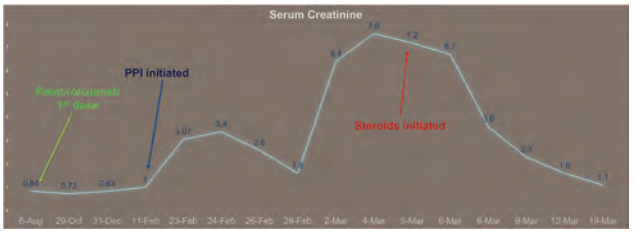
Pembrolizumab and Proton Pump Inhibitor-Induced Nephrotoxicity: A Case Report

Nicholas L. Karo. LewisGale Medical Center *LewisGale Medical Center, Salem, VA.*

Introduction: Immune checkpoint-blocking antibodies have shown promise in the treatment of a wide-range of malignancies. These medication function by blocking down-regulators of innate immunity, thus augmenting anti-tumor immunity. This upregulation of the immune system can result in immune related adverse events and can affect any organ system. One immune-related adverse event is acute interstitial nephritis. Proton pump inhibitors, themselves, have been implicated in causing acute interstitial nephritis. There is little research regarding synergism of checkpoint inhibitors and proton pump inhibitors and resultant kidney injury. This case report reviews one patient's clinical course in which they experienced acute interstitial nephritis while receiving both pembrolizumab and omeprazole.

Case Description: A 64 year old female with non-small cell lung cancer stage IV with brain metastasis was initiated on pembrolizumab therapy seven months prior to presentation. Three weeks prior to presentation she started omeprazole 20mg daily. At time of presentation the creatinine was found to be 3.07 mg/dL, up from 0.8 mg/dL eleven days prior, improved with cessation of the PPI, however shortly there after the PPI was restarted and creatinine again rose and peaked at 7.6 mg/dL. Renal biopsy was performed and confirmed interstitial nephritis. The patient was started on prednisone 1mg/kg/day with rapid improvement in renal function back to baseline.

Discussion: There has been some research linking both pembrolizumab and pembrolizumab in combination with other chemotherapeutic agents to kidney injury. However, in these trials many patients who suffered kidney injury were also receiving proton pump inhibitors, a class of medications known to provoke acute interstitial nephritis. If synergism can be proven, this combination would be avoided, thus preventing this immune related adverse event. Furthermore, reinitiation of check point inhibitors alone after cessation of the PPI and normalization of kidney function in cases such as these, could be trialed.



PO0043

Zolpidem Mega Dose Resulting in Hemodialysis

Sixto R. Medina, Eddie M. Rodriguez. *Universidad Central Del Caribe, Bayamon, Puerto Rico.*

Introduction: Depression and hypoventilation syndromes are factors that may be overlooked when prescribing Zolpidem. Although hypnotics are not directly associated with rhabdomyolysis, they can lead to severe intoxication and prolonged immobilization. This can lead to compartment/ crush syndromes and depressed respiratory drive and may cause seizures. As consequence of the above renal failure ensued and hemodialysis was required.

Case Description: This case portrays a 36-year-old law student who tried to end his life with the ingestion of 90 Zolpidem pills. As consequence of his metabolic derangement he had seizures, rhabdomyolysis and renal failure that required hemodialysis. Due to promt intervention, hemodynamic stability and full recovery were achieved.

Discussion: 36-year-old man with hypertension, insomnia and epilepsy was brought to the emergency room by ambulance. Chief complaint was of disorientation and seizures after the ingestion of 90 Zolpidem pills. He was initially combative, disoriented and with incoherent speech. Once consulted, he presented a Glasgow Coma Scale of 3 for which he was intubated. He was diaphoretic with scattered petechiae and associated subconjunctival hemorrhage. On lab work he had central bicarbonate at 4.6 mEq/ L. Arterial pH was at 6.5 and PaCO2 at 24, which represented severe metabolic acidosis for which initial bicarbonate drip and hyperventilation were provided to correct acidosis. He was admitted to Intensive Care Unit where he was extubated on his second day of admission. He developed progressive renal dysfunction evidenced by rapidly increasing BUN and serum creatinine as well as rapidly increasing CPK from 500 to 44,101 U/ liter for which fluid expansion and observation became the new therapy goals. Even with aggressive hydration, he developed oliguria. BUN and creatinine reached 129.7 and 13.7 mg/dl respectively for which on day 7 of admission, he received 3 session of hemodialysis within 4 days. His recovery was enough to be discharged for follow up as an outpatient. Remarkably after such insult, full renal function was regained. Mental illness is an epidemic, which is often overlooked and as consequence not adequately treated. As physicians, we have the responsibility to individualize therapy. Insomnia may be the symptom of a wide array of etiologies. In this case prescribing a limited amount of medication and/ or treating the underlying depression would have prevented a near fatality.

PO0044

Severe Exertional Rhabdomyolysis with AKI Associated with Sickle Cell Trait

Zi R. Zhang, Edward Qian, Roger A. Rodby. *Rush University Medical Center, Chicago, IL.*

Introduction: Exertional rhabdomyolysis (ER) is a pathological breakdown of muscle cells which can result in acute kidney injury (AKI) from multiple mechanisms including tubular toxicity from heme pigment, cast formation, and volume depletion. ER has a host of etiologies including drugs, ingestions, infections, electrolyte abnormalities, trauma, venom, and metabolic disorders. Sickle Cell Trait (SCT), a generally asymptomatic condition, has been rarely associated with ER. We present a case of severe ER with AKI in a previously healthy patient who was determined to have SCT as the only risk factor.

Case Description: A 39 y/o previously healthy black police recruit on no medications presented with myalgias and dyspnea following a routine training regimen. He was found to have diffuse tenderness and weakness of arms and legs. Initial labs showed serum creatinine (sCr) 2.0 mg/dL, Na 148 mmol/L, CO2 <5 mmol/L, Creatine Kinase (CK) 1,516 U/L. A peripheral blood smear showed few sickle cells. His urine was dark tea-colored and on urinalysis had large blood and minimal RBCs. Illicit drug panel, autoimmune studies, myophosphorylase deficiency, and myositis panel including anti-SSA, anti-PM/Scl, and anti-U1RNP were normal or negative. A hemoglobin electrophoresis demonstrated 35% Hgb S and 62% Hgb A consistent with SCT. He was oliguric and was started on renal replacement therapy (RRT) with CVVH initially and then iHD. His CK and sCr peaked at 565,000 U/L and 13.9 mg/dL respectively (figure 1). He required 18 days of RRT. His sCr after discharge improved to 1.4 mg/dL.

Discussion: SCT is normally a relatively benign condition as there is enough normal Hgb to prevent significant sickling. However, increased O2 demand with exertion may promote clinically significant sickling and lead to vaso-occlusion and hypoxic muscle injury. ER in SCT is rare and unpredictable and therefore specific recommendations for re-introduction of exercise are not available. However, guidelines for Exercise Collapse Associated with Sickle Cell Trait (ECAST) can be used to guide long term patient management.

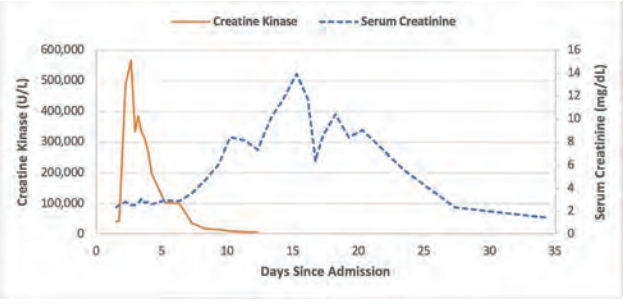


Fig. 1. sCr and CK since admission.

PO0045

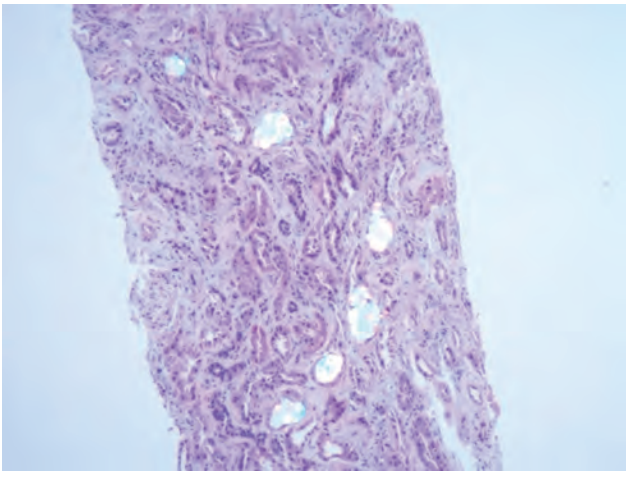
A Case of Oxalate Nephropathy in the Setting of Clostridium difficile Infection

Yasolatha Chalicheemala,[3,2] Niraj Desai,[1,2] Krishna P. Balabhadrapatruni.[1,2] *[1]Louis Stokes VA Medical Center, Cleveland, OH; [2]Case Western Reserve University School of Medicine, Cleveland, OH; [3]University Hospitals Cleveland Medical Center Department of Orthopaedics, Cleveland, OH.*

Introduction: While hyperoxaluria is a known complication of inflammatory bowel diseases, it is rarely associated with infectious forms of colitis. We report a case of oxalate nephropathy in the setting of Clostridium difficile colitis in a patient with high dietary oxalate ingestion.

Case Description: A 73 year-old black male with stage 3 CKD, diabetes mellitus, hypertension, and hyperlipidemia presented with a 2-week history of intractable diarrhea after finishing a course of oral antibiotics prescribed for acute diverticulitis. Laboratory data showed serum creatinine 15.4 mg/dL, blood urea nitrogen (BUN) 107 m/dL, potassium 8.7 meq/L, total CO2 8 mmol/L. Urinalysis was unremarkable. Imaging showed no renal obstruction. Stool sample tested positive for C difficile. Emergent dialysis was initiated for hyperkalemia. Despite adequate supportive measures, the patient remained oliguric and dialysis dependent. A kidney biopsy, on day 5, showed extensive tubular deposition of calcium oxalate crystals, and moderate to severe tubulointerstitial fibrosis. Further inquiry elicited dietary intake of 1-2 cups of peanuts daily. 24-hr urine collection showed no hyperoxaluria (urine oxalate 24 mg/24h; ref range: 7-44). The patient remains dialysis dependent.

Discussion: Acute oxalate nephropathy in the setting of Clostridium difficile colitis is rarely reported. The hypothesized etiopathogenesis likely relates to altered gut microbiome, specifically decreased Oxalobacter formigenes, leading to impaired oxalate degradation, increased oxalate absorption, and subsequent hyperoxaluria (potentially transient) leading to calcium oxalate deposition in the kidneys and AKI. Treatment is mainly supportive. For acute kidney injury in the setting of acute or chronic diarrhea illness, oxalate nephropathy should be considered. Recovery rates are low, with over 50% of patients remaining dialysis dependent.



Calcium oxalate crystals in tubules (PAS stain, polarized light)

PO0046

Postrenal AKI due to a Rarely Seen Neoplastic Phenomenon in an Adolescent

Ana L. Prashad cortez,[1] Rasheda Amin,[2] Carly R. Varela.[2] *[1]Inova, Falls Church, VA; [2]Pediatric Specialists of Virginia, Fairfax, VA.*

Introduction: AKI is an important cause of morbidity & mortality in adult and pediatric patients. Based on a lit review by Cleto-Yamane, et. al., the pediatric incidence & mortality of AKI in the USA in 2013 was 0.39% and 15.3%, respectively. In general, a patient's presentation may provide clues to the etiology of AKI (i.e. prerenal, intrarenal and postrenal). AKI due to postrenal/obstructive causes is less common in children as compared to adults and is usually associated with congenital abnormalities e.g. posterior urethral valves, or acquired due to stones or tumors. We report the case of a 14 yo previously healthy female with a unique clinical presentation due to lower urinary tract obstruction secondary to a tumor.

Case Description: The patient presented with 3 weeks of back pain, R leg swelling, headaches, urinary frequency, n/v and hematuria. In the ED, her BUN and creatinine were 107 mg/dL and 21.1 mg/dL, respectively. A RUS showed enlarged non-echogenic kidneys with mild bilateral hydronephrosis & a heterogeneous pelvic mass. Further labs revealed anemia, low PTH, normal complement levels, ASO & ANA titers. A LE Doppler study was negative for venous thrombosis. A non-contrast MRI showed a pelvic mass & possible metastasis. Peds Oncology was consulted, and biopsies of bone marrow & pelvic tumor revealed a small round blue cell tumor with immunohistochemical stains diagnostic for rhabdomyosarcoma. She developed oliguria, hyperkalemia & hyperuricemia (24mg/dL). Rasburicase was given & CRRT was initiated. She received emergent chemotherapy with cyclophosphamide, doxorubicin & vincristine. Bilateral percutaneous nephrostomy tubes were placed with improvement in UOP & renal function allowing CRRT to be stopped. Labs showed a downward trend of BUN & creatinine to 14 mg/dL and 0.8 mg/dL, respectively.

Discussion: Our patient's clinical presentation was atypical in that her initial US findings of mild hydronephrosis were not consistent with the severity of her renal injury. Her AKI was likely a combination of obstructive uropathy from the large pelvic tumor compressing her lower urinary tract & uric acid nephropathy. Decompression of the urinary system, management of hyperuricemia & initiation of tumor directed chemotherapy resulted in marked improvement of kidney function. Our case highlights the importance of considering an obstructive etiology in older children presenting with AKI.

PO0047

Profiling AKI Trajectories: Early Results from the Million AKI Project

Benjamin C. Bowe,[1,2] Yan Xie,[1,2] Andrew K. Gibson,[1] Miao Cai,[1,2] Hong Xian,[2] Geetha S. Maddukuri,[1] Ziyad Al-Aly.[1] *[1]VA St. Louis Health Care System, St. Louis, MO; [2]Saint Louis University, Saint Louis, MO.*

Background: Clinical guidelines for risk stratification of acute kidney injury (AKI) patients are based on peak increases in serum creatinine (SC). These definitions do not consider other characteristics of change in SC that may provide information on risk of adverse outcomes. Identification of patient groups that display distinct patterns in trajectory of SC and outcome profiles may lead to more nuanced risk-based definitions of AKI.

Methods: Data from the United States Veterans Health Administration were obtained. A latent class growth model identified patient groups based on similar patterns of trajectory in serum creatinine during a hospitalization with an AKI. Regression models examined associations of trajectory groups with risk factors and in-hospital mortality.

Results: We constructed a cohort of 480,575 veterans with an AKI during an inpatient stay (a subset of the Million AKI Project cohort). Of these, 343,471 (71.5%), 63,665 (13.3%), and 73,439 (15.3%) met KDIGO AKI stages 1, 2, and 3 criteria. 9.4% died during their hospitalization. We identified 9 latent trajectories summarized by 4 phenotypes: a mild increase in SC from low baseline (66%), and varying degrees of increase in SC with no (9%), moderate (17%), and near-full recovery (8%). Higher systolic blood pressure (OR=1.02; 95% CI=1.01-1.02 per 1 mmHg), sepsis (2.24; 2.10-2.39), non-use of ACE/ARB (1.54;1.47-1.61), diuretic use (1.16; 1.12-1.20), albuminuria (1.36; 1.31-1.41), and prior history of AKI (1.27, 1.22-1.32) were associated with trajectories with larger increases in SC, while major surgeries (2.48; 2.37-2.60) were associated with trajectories that recovered. Compared to the mild increase group, those with partial or no recovery had a higher odd of in-hospital mortality (1.64; 1.57-1.71) that increased in magnitude with higher baseline SC and a greater increase in SC (2.73; 2.66-2.80). Groups that experienced near-full recovery showed no evidence of a difference in mortality profile (0.97; 0.90-1.05) despite differences in other aspects of the trajectory.

Conclusions: Leveraging the depth and breadth of a high-quality longitudinal electronic health record system, we characterized nearly half a million cases of AKI; our results suggest that profiling of AKI trajectories informs risk stratification and may guide deployment of post AKI care.

Trends in Nephrology Follow-Up After an Episode of AKI in US Veterans

Ryann Sohaney,[1] Houssam Mhanna,[1] Maggie Yin,[1] Diane Steffick,[1] Vahakn Shahinian,[1] Nilka Rios Burrows,[2] Meda E. Pavkov,[2] Raymond K. Hsu,[3] Neil R. Powe,[3,4] Kara Zivin,[5,6] Rajiv Saran,[1] Michael Heung.[1] *[1]University of Michigan Division of Nephrology, Ann Arbor, MI; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]University of California San Francisco, San Francisco, CA; [4]Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA; [5]University of Michigan, Ann Arbor, MI; [6]US Department of Veterans Affairs, Ann Arbor, MI.*

Background: KDIGO guidelines recommend evaluating patients following AKI for new onset or worsening CKD. Yet, historically nephrologist referral post-AKI has been low. We sought to determine recent trends in outpatient nephrologist follow-up after a hospitalization with AKI.

Methods: We assembled a national cohort of US veterans surviving 30-days post hospitalization with KDIGO creatinine-defined AKI from 2008 to 2017, excluding those with ESRD or kidney transplant, those requiring dialysis within 30 days of hospital discharge, or discharged to hospice. The primary outcome was the proportion of AKI survivors completing an outpatient visit with a nephrologist within 6 months of their AKI hospitalization. To assess trends, we assessed the association of year (as a continuous variable) with follow-up in a Cox proportional hazards model adjusting for age, race, sex, AKI stage, hypertension, diabetes, CKD, Charlson Comorbidity Index, ICU utilization, acute myocardial infarction, acute heart failure, and hospital admitting service.

Results: Of the 480,200 survivors of AKI, 12.2% had a visit with a nephrologist within 6 months. The proportion of patients with nephrology follow-up ranged from 10.0% in stage 1 AKI to 43.8% in patients with AKI requiring inpatient dialysis. The proportion of patients receiving post-AKI care increased across the study period, from 11.8% in 2008 to 15.4% in 2017 (figure). Upon adjusting for demographics, comorbid conditions, and hospitalization characteristics, year remained a significant predictor of increasing nephrology follow-up after AKI (per year HR 1.024, 95% CI 1.021-1.027, p<0.01).

Conclusions: From 2008 to 2017, there was a modest increase in post-AKI follow-up that persisted after accounting for changing demographic, comorbid conditions and hospitalization characteristics. However, most patients with severe AKI did not have an outpatient visit with a nephrologist at 6 months, highlighting opportunities to improve processes of post-AKI care.

PO0049

Preoperative Urine Alpha 1 Microglobulin Levels Are Associated with AKI and Mortality After Cardiac Surgery

Jonathan G. Amatruda,[1,2] Amit X. Garg,[3,4] Heather Thiessen Philbrook,[5] Eric McArthur,[4] Steven G. Coca,[6] Chirag R. Parikh,[5] Michael Shlipak.[1,2] TRIBE-AKI Consortium. *[1]University of California San Francisco, San Francisco, CA; [2]Kidney Health Research Collaborative, UCSF, San Francisco, CA; [3]Western University Schulich School of Medicine and Dentistry, London, ON, Canada; [4]ICES, London, ON, Canada; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Higher urine alpha-1 microglobulin (a1m) levels are a marker of proximal tubule dysfunction and may improve CKD assessment and risk stratification. We hypothesized that a1m levels would be associated with adverse outcomes after cardiac surgery.

Methods: In 1464 adults undergoing cardiac surgery (CABG and/or valve) and prospectively enrolled in the multicenter TRIBE-AKI study, we measured urine a1m pre- and post-operatively. Outcomes were post-operative AKI during index hospitalization (AKIN stage ≥1) and all-cause mortality (median follow-up (IQR) 6.7 (4.0, 7.9) years). Urine a1m was analyzed as a continuous ($\log_2$) predictor in multivariable analyses adjusting for demographics, surgery characteristics, comorbidities, baseline eGFR, urine albumin, and urine creatinine.

Results: There were 230 AKI events and 459 deaths. Higher pre-operative a1m was independently associated with AKI (aOR=1.36, 95% CI 1.14-1.62) and all-cause mortality (aHR=1.19, 95% CI 1.06-1.33) (see table). We observed a significant interaction (p=0.01), whereby a1m had a stronger association with mortality in the subset without CHF (aHR=1.29, 95% CI 1.12-1.47) than among those with CHF (aHR=1.06, 95% CI 0.85-1.32). However, post-operative changes in a1m were not associated with AKI or mortality risk.

Conclusions: Even after adjusting for baseline kidney function and comorbidities, pre-operative a1m was associated with post-operative AKI and all-cause mortality.

Funding: Other NIH Support - NHLBI; study also supported by supported by NIH grant RO1HL085757 (CRP) to fund the TRIBE-AKI Consortium.

Elevated Serum Tenascin C Predicts All-Cause Mortality in Critically Ill Patients with Multiple Organ Dysfunction

Qionghong Xie, Xu Yunyu, Chuan-Ming Hao. *Huashan Hospital Fudan University, Shanghai, China.*

Background: Tenascin-C (TNC) is a matricellular protein that is rarely expressed in most of adult tissues, but re-induced following injury. This study aimed to evaluate serum TNC in predicting all-cause mortality in critical ill patients with multiple organ dysfunction.

Methods: Adult critical ill patients who met the criteria of at least two organs dysfunction and acute organ injury with an increase of SOFA ≥ 2 points within 7 days were prospectively enrolled in one derivation cohort (Medical ward) and one external validation cohort (Emergency ward). Serum TNC was measured within the first 24 hours after enrollment and the association between serum TNC and 28-day all-cause mortality was analyzed.

Results: A total of 115 patients with median age 56 (38, 66) years and male of 65.2% in derivation cohort and 110 patients with median (quartile) age of 64 (53, 73) and male of 67% in validation cohort were enrolled. Serum TNC was 210.2 (96.8, 469.6) ng/ml in derivation cohort and 229.4 (141.6, 472.5) ng/ml in validation cohort, both significantly higher than that in healthy controls (median 80.9 ng/ml, n=46, p<0.01 for both). The TNC levels were positively associated with the critical illness scores such as SOFA, APACHE II and SPAS II, as well as 28-day mortality (p<0.01 for all). Compared to the patients with TNC<300ng/ml, patients with TNC≥300ng/ml had a remarkably higher 28-day mortality (38.6% vs. 14.1%, p=0.003 in derivation cohort; 57.8% vs. 13.8%, p<0.001 in validation cohort). In multivariate analysis, serum TNC was independently associated with the mortality after adjustment for age, gender and SOFA in both cohorts. The areas under the Receiver Operating Curve of TNC for 28-day mortality was 0.797 in derivation cohort and 0.803 in validation cohort, not inferior to SOFA (0.844 and 0.808), APACHE II (0.86 and 0.762) and SPAS II (0.872 and 0.779).

Conclusions: Serum TNC was significantly increased in critical ill patients with multiple organ dysfunction and was positively associated with the severity of illness and all-cause mortality. It was a useful prognostic tool for predicting all-cause mortality in critical ill patients.

PO0051

Predominance of Mitochondrial Protein Composition in Urinary Sediment Enriched with Muddy Brown Granular Casts During Acute Tubular Necrosis

Vipin Varghese,[1] Megan Golbus,[2] Frank C. Abbruscato,[3] Michael G. Janech,[2] Juan Carlos Q. Velez.[1,3] Ochsner Nephrology *[1]Ochsner Clinical School - University of Queensland, New Orleans, LA; [2]Department of Biology, College of Charleston, Charleston, SC; [3]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Detection of copious number of "muddy" brown granular casts (MBGCs) during microscopic examination of the urinary sediment (MicrExUrSed) is pathognomonic of acute tubular necrosis (ATN). Because hospital laboratories do not properly report MBGCs, nephrologists are required to independently perform MicrExUrSed, a time-consuming and logistically challenging endeavor that requires expertise. Thus, a diagnostic test to identify MBGCs without the performance of MicrExUrSed could prove useful for busy clinicians. We hypothesized that MBGCs-enriched urinary sediment (MBGC-sedi) contains unique proteins that could serve as surrogate and biomarker of ATN.

Methods: MicrExUrSed was performed in specimens from patients with acute kidney injury (AKI) seen for nephrology consultation with a suspected etiology of ATN. Urine specimens from 3 patients containing numerous (>10 casts per low power field) MBGCs were collected and subjected to low-speed centrifugation (100 g) and stored at -80°C. Thawed pellets and urine were proteolytically digested and analyzed by nano-LC tandem mass spectrometry (Orbitrap Fusion Lumos). Proteins were identified by MASCOT and classified by gene ontology.

Results: We identified 1678 proteins (1% false discovery rate) from supernatant and MBGC-sedi combined. Among them, 711 proteins were unique to MBGC-sedi and 27 were unique to the supernatant. Normalized spectral abundance of 242 MBGC-sedi proteins was greater compared to the supernatant (p<0.05) and had proportionally more mitochondrial proteins (17 ± 1% vs. 6 ± 1%, respectively, p=0.0004). Based on spectral counts, the most abundant and unique mitochondrial proteins in all 3 samples included: ATP synthase alpha and beta-subunit, isocitrate dehydrogenase, 60kDa heat shock protein, and aconitate hydratase. Six out of 7 cytochrome proteins identified were unique to MBGC-sedi.

Conclusions: MBGC-sedi contains unique proteins compared to the supernatant. These proteins can serve as a foundation for the search of an ATN biomarker and surrogate for MBGCs detection by MicrExUrSed in patients with AKI. The predominance of mitochondrial proteins in MBGCs-sedi may explain the characteristic brown pigmentation of MBGCs.

PO0052

Treatment of Hepatorenal Syndrome Type 1 with Terlipressin Reduces Need for Renal Replacement Therapy After Liver Transplantation

Juan Carlos Q. Velez,[1] Seth Sclair,[5] Antonio J. Sanchez,[2] Stephen Caldwell,[7] Samuel Sigal,[3] Paul J. Thuluvath,[9] Rohit Satoskar,[6] S. Chris Pappas,[8] Khurram Jamil.[4] *[1]Ochsner Health System, New Orleans, LA; [2]University of Iowa Hospitals & Clinics, Iowa City, IA; [3]Montefiore Medical Center, Bronx, NY; [4]Mallinckrodt Pharmaceuticals Specialty Brands Principal Office, Bedminster, NJ; [5]University Hospitals Cleveland Medical Center Department of Orthopaedics, Cleveland, OH; [6]MedStar Georgetown University Hospital, Washington, DC; [7]University of Virginia, Charlottesville, VA; [8]Orphan Therapeutics, Lebanon, NJ; [9]Mercy Medical Center & University of Maryland School of Medicine, Baltimore, MD.*

Background: Hepatorenal syndrome type 1 (HRS-1) is a severe but reversible acute kidney injury in patients with cirrhosis. The need for renal replacement therapy (RRT) posttransplant is associated with prolonged intensive care unit stays and decreased survival. Recently, a randomized placebo (PBO)-controlled trial (CONFIRM, NCT02770716) demonstrated the efficacy of terlipressin (TERLI) for inducing reversal of HRS-1 and reducing the cumulative need for RRT. This study assessed whether TERLI reduces the rate of RRT following liver transplantation (LT).

Methods: CONFIRM was a North American trial (N=300) that compared HRS-1 reversal rates between patients treated 2:1 with albumin plus TERLI (n=199) or albumin plus PBO (n=101). In a post hoc analysis, we assessed the rate of RRT post-LT by intention-to-treat analysis through 90 days of follow-up. We also conducted a pooled analysis of the 3 TERLI RCTs in HRS-1 (OT-0401 [NCT00089570], REVERSE [NCT01143246], and CONFIRM) to examine 90-day overall and RRT-free survival rates in patients who received LT.

Results: In CONFIRM, 23.1% (46/199) of patients in the TERLI group and 28.7% (29/101) of patients in the PBO group underwent LT. Following LT, the rate of post-LT RRT in patients who received TERLI was significantly lower than that in those who received PBO (19.6% [9/46] vs 44.8% [13/29], respectively; *P*=0.036). The overall 90-day survival rate for those transplanted in the TERLI group was 100% (46/46) compared with 93.1% (27/29) in the PBO group (*P*=not significant). Further, in the pooled analysis of the 3 phase 3 studies, the 90-day survival rates were 98.9% (93/94) and 91.0% (71/78), respectively (*P*=0.014). In the pooled analysis of REVERSE and CONFIRM, for transplant-listed patients, 50.0% (46/92) of patients in the TERLI group were alive without RRT at Day 90 compared with 32.2% (19/59) in the PBO group (*P*=0.032).

Conclusions: Treatment with TERLI added to albumin for patients with HRS-1 significantly decreases the need for RRT following LT.

PO0053

Urinary Waxy Casts Are Associated with Persistence of AKI Requiring Dialysis

Maria Soledad Rivera,[1] Vipin Varghese,[1] Akanksh Ramanand,[1] Ali A. Alalwan,[2] Juan Carlos Q. Velez.[1,2] Ochsner Nephrology *[1]Ochsner Clinical School - University of Queensland, New Orleans, LA; [2]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Waxy casts (WxCs) can be identified during microscopic examination of the urinary sediment (MicrExUrSed) and they have been classically linked to chronic kidney disease (CKD). We previously shown that WxCs predict severity of acute kidney injury (AKI). Thus, we hypothesized that WxCs may inform about duration and persistence of AKI and AKI requiring renal replacement therapy (AKI-RRT).

Methods: We conducted a prospective observational study in patients seen in inpatient nephrology consultation with AKI stage ≥ 2 (AKIN) over 2.5 years. On the day of consult, MicrExUrSed was performed to determine the percentage of low power fields with WxCs. The outcome measures were persistence of need for RRT at the time of hospital discharge (AKI-RRT-Persist) and ≥ 50% rise in serum creatinine (sCr) from baseline at the time of hospital discharge (AKI-Persist).

Results: Urine specimens from 286 patients [median age 60 (20 – 88), 37% women] were assessed. The etiology of AKI (de novo AKI 67%, AKI on CKD 33%) was ischemic ATI (47%), toxic ATI (9%), ischemic/toxic ATI (11%) or other (33%). WxCs were found in 85 patients (30%), 61 (72%) of which had de novo AKI. Median sCr for those with WxCs was 3.5 (0.9 – 22.0)mg/dL and 3.1 (0.9 – 12.5) mg/dL for those without WxCs (p=0.12). AKI-RRT at any point during the course of AKI was seen in 45% (38/85) of those with WxCs compared to 32% (54/201) of those without WxCs (p=0.043). There was a greater risk for AKI-RRT-Persist for those withWxCs [15.3% vs 7.5%, odds ratio (OR): 2.2, CI 1.1 – 4.9, p=0.046)]. Presence and abundance of WxCs were also associated with a greater risk for AKI-Persist [62% (94/152), 75% (45/60), 81% (29/36) and 93% (13/14), for those with no WxC, any WxC, >10% WxCs and >50% WxCs, respectively; chi-square for trend, p=0.014].

Conclusions: In patients with AKI, the presence and abundance of WxCs are associated with a greater risk for persistent need for RRT and persistent increase in sCr at the time of hospital discharge. These findings suggest that WxCs inform about the severity of AKI and the timeline of significant AKI recovery.

PO0054

Retrospective Analysis of the Efficiency of Caplacizumab in the Treatment of Acquired Thrombotic Thrombocytopenic Purpura: Results from the REACT-2020 Study Group

Lucas Kuehne,[1] Jessica K. Kaufeld,[2] Jan Menne,[2] Paul T. Brinkkoetter,[1] Linus A. Volker.[1] REACT-2020 study group *[1]University Hospital Cologne, Koeln, Germany; [2]Hannover Medical School, Medizinische Hochschule Hannover, Hannover, Germany.*

Background: Acquired thrombotic thrombocytopenic purpura (aTTP) is a rare but life-threatening disorder, caused by the formation of inhibitory and occasionally non-inhibitory autoantibodies against ADAMTS13. Despite plasma exchange and immunosuppression, long-term mortality and morbidity associated with acute episodes remain high. Here, caplacizumab – a nanobody approved in Germany in 2018 – has recently expanded the therapeutic options.

Methods: Retrospective analysis of the use of caplacizumab in more than 60 patients from more than 30 different medical centers in Germany during acute disease management.

Results: Caplacizumab led to a rapid normalization of the platelet count (median 3, mean 3.78 days). In 34/60 instances, caplacizumab was stopped prior to day 30 with favorable outcome whenever ADAMTS13 activities were >10%. In contrast, 11/34 patients with ADAMTS13 activities <10% at the time of stopping caplacizumab treatment develop a non-favorable outcome comprising disease exacerbation or relapse. In some cases, prolongation of the treatment interval to every other day was feasible and resulted in a sustained reduction of the vWF activity.

Conclusions: Caplacizumab is efficacious in the treatment of aTTP independent of timing and adjunct treatment modalities. Based on this real-world experience and published literature we propose to administer caplacizumab to all patients with an acute episode of aTTP immediately. ADAMTS13 activity measurements are central for a rapid diagnosis in the acute setting but also to tailor disease management. In addition, vWF activity may serve as biomarker for drug monitoring.

PO0055

Erythropoiesis-Stimulating Agents in AKI Requiring Dialysis

Ian Mccoy,[1] Kathleen D. Liu,[2] Chi-yuan Hsu.[2] *[1]Stanford University School of Medicine, Palo Alto, CA; [2]University of California San Francisco, San Francisco, CA.*

Background: Erythropoiesis-stimulating agents (ESAs) are used in patients with CKD to treat anemia. AKI may also be a state of erythropoietin deficiency, although data on this is conflicting. Few studies have examined ESA use in AKI, including the most severe AKI cases requiring dialysis (AKI-D). It is unknown whether and to what extent clinicians prescribe ESAs in AKI-D.

Methods: Among the more than 40,000 patients admitted to Beth Israel Deaconess Medical Center ICUs between 2001 and 2012 in the MIMIC-III database, we selected 591 AKI-D patients and 276 ESKD patients based on ICD-9 diagnostic codes. In a cross-sectional analysis, we determined the frequency of ESA usage and estimated associations between ESA usage and age, sex, surgical (vs medical) ICU admission, ICU length of stay, admission hemoglobin, admission serum creatinine, history of CKD, and ESKD (versus AKI-D) status using multivariable logistic regression. We also examined the relationship between ESA use and the number of blood transfusions during the ICU stay.

Results: ESA usage (any time during ICU stay) was 13% in AKI-D (vs 21% in ESKD). Among AKI-D patients (**Table 1**), CKD (adjusted OR 3.59, 95% CI 2.06-6.25, p<0.0001), length of stay (1.06 [1.04-1.08] per day, p<0.0001), sepsis (2.06 [1.08-3.92], p=0.03), and female sex (0.56 [0.31-1.00], p=0.05) were significantly associated with ESA use. Patients treated with ESAs received six more blood transfusions on average than patients who were not treated with ESAs (6.1 more transfusions, 95% CI 2.6-9.7, p=0.0006), but this difference disappeared when adjusted for the variables significantly associated with ESA usage (0.07 more transfusions, 95% CI -3.4 to +3.2, p=0.97).

Conclusions: ESAs usage in patients with AKI-D was not rare. Baseline renal function was the biggest predictor of ESA usage. Use of this costly therapy of unclear risk-benefit ratio in the AKI-D population should be studied further.

Funding: NIDDK Support

Patients with AKI-D

Characteristics	ESA (n = 74)	No ESA (n = 517)
Age, yrs	62 (16)	62 (15)
Female	27%	38%
Baseline chronic kidney disease	45%	23%
Admission serum creatinine, mg/dL	3.1 (2.1)	2.8 (2.4)
Admission hemoglobin, g/dL	10.8 (2.1)	11.3 (2.3)
Surgical ICU	45%	39%
Sepsis during ICU day 1	77%	70%
ICU LOS, days	28 (25)	13 (12)
Blood transfusions during ICU stay	15 (21)	9 (13)

PO0056

Survey of US Critical Care Practitioners on Perspectives Toward Net Ultrafiltration Prescription and Practice

Huiwen Chen,[1,2] Raghavan Murugan.[2] *[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Previous studies suggest international practice variation in net ultrafiltration (UF_{NET}) among critically ill patients with acute kidney injury treated with kidney replacement therapy. We examined U.S. critical care practitioner attitudes toward UF_{NET} prescription and practice.

Methods: Secondary analysis of a multinational, cross-sectional, internet-assisted, open survey administered to intensivists, nephrologists, advanced practice providers, ICU and dialysis nurses in the U.S.

Results: Of 1,569 international survey respondents, 465 (29.6%) practitioners were from the U.S. Practitioners were mostly nurses and nurse practitioners (58%) and intensivists (38.2%). Median duration of practice was 8.7 (IQR, 4.2-19.4) years and 63.4% practiced in a university- based hospital. Practitioners reported using continuous kidney replacement therapy (CKRT) as the first modality for UF_{NET} in 60% (IQR 20-90%) of their patients with median UF_{NET} rate of 51 mL/h (IQR 25-100 mL/h) for hemodynamically unstable and a maximal rate of 285 mL/h (IQR,200 - 341 mL/h) for hemodynamically stable patients. 58.3% (range 28.7%-79.2%) of practitioners assessed net fluid balance hourly. Hemodynamic instability was reported in 25% (IQR, 10-100%) of the patients, and practitioners decreased the rate of fluid removal (71.2%); started or increased dose of a vasopressor (56.8%); completely stopped fluid removal (44.5%); and administered a fluid bolus (28.7%). Most clinicians (79.8%) reported patient intolerance as a major barrier. Other barriers include frequent interruptions (50.1%), under prescription (17.8%), unavailability of trained staff (17%), inability to titrate fluid removal (10.1%), unavailability of dialysis machines (8.6%) and cost (2.4%) (Figure 1). More than 70% of clinicians agreed with early protocolized fluid removal and expressed desire to enroll their patients in a future clinical trial.

Conclusions: This study provides new knowledge on UF_{NET} in practices in the U.S. We also identified barriers and specific targets for quality improvement initiatives. Our data reflect the need for evidence-based practice guidelines for UF_{NET}.

PO0057

A Pilot Trial to Evaluate the Clinical Usefulness of Contrast-Enhanced Ultrasound in Predicting Renal Outcomes in Patients with AKI

Suyeon Hong,[1] Da won Kim,[2] Dongryul Kim,[2] Seok Joon Shin,[2] Hye Eun Yoon.[2] *[1]Uijeongbu St. Mary's Hospital, Uijeongbu, Republic of Korea; [2]Incheon St. Mary's Hospital, Incheon, Republic of Korea.*

Background: Contrast-enhanced ultrasound (CEUS) enables the assessment of real-time renal microcirculation. This study investigated CEUS-driven parameters as hemodynamic predictors for renal outcomes in patients with acute kidney injury (AKI).

Methods: Forty-eight patients who were diagnosed with AKI were prospectively enrolled and underwent CEUS at the occurrence of AKI. Parameters measured were the wash-in slope (WIS), time to peak intensity, peak intensity (PI), area under the time–intensity curve (AUC), mean transit time (MTT), time for full width at half maximum, and rise time (RT). The predictive performance of the CEUS-driven parameters for Kidney Disease Improving Global Outcomes (KDIGO) AKI stage, initiation of renal replacement therapy (RRT), AKI recovery, and chronic kidney disease (CKD) progression was

assessed. Receiver operating characteristic (ROC) analysis was performed to evaluate the diagnostic performance of CEUS.

Results: Cortical RT (Odds ratio [OR] = 1.21) predicted the KDIGO stage 3 AKI. Cortical MTT (OR = 1.07) and RT (OR = 1.20) predicted the initiation of RRT. Cortical WIS (OR = 76.23) and medullary PI (OR = 1.25) predicted AKI recovery. Medullary PI (OR = 0.78) and AUC (OR = 1.00) predicted CKD progression. The areas under the ROC curves showed reasonable performance for predicting the initiation of RRT and AKI recovery. The sensitivity and specificity of the quantitative CEUS parameters were 60–83% and 62–77%, respectively, with an area under the curve of 0.69–0.75.

Conclusions: CEUS may be a supplemental tool in diagnosing the severity of AKI and predicting renal prognosis in patients with AKI.

A Clinical Score to Predict Recovery in ESKD due to AKI

Silvi Shah,[1] Anthony C. Leonard,[1] Kathleen Harrison,[1] Karthikeyan Meganathan,[1] Annette Christianson,[1] Samantha M. Kramer,[1] Charuhas V. Thakar.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA Medical Center, Cincinnati, OH.*

Background: Acute kidney injury (AKI) is a major contributor to end-stage kidney disease (ESKD). About one-third of patients with ESKD due to AKI recover kidney function. However, there is lack of clinical models to predict kidney recovery in ESKD due to AKI.

Methods: Using data from the United States Renal Data System (2005-2014), we developed a clinical score to predict kidney recovery by 90-days post-dialysis initiation in patients with ESKD due to AKI (N=22,922). We used multivariable logistic regressions to model the effects of patient demographics, comorbidities, and laboratory measures on kidney recovery. The resulting logistic parameter estimates were transformed into integer point totals by doubling and rounding the estimates. The predictive accuracy of the score models was compared to the underlying logistic models by comparing areas under the receiver operating characteristic curves (AUROC) and internal validation was performed.

Results: In ESKD due to AKI, kidney recovery within 90-days occurred in 24% of patients. Median recovery time for patients who recovered was 2 months; 72% recovered within 90-days. In the logistic models of recovery at 90-days, older age, lower body mass index, hemoglobin < 12 gm/dl, Black and Native American race, Hispanic ethnicity, congestive heart failure, amputation, poor functional status, and pre-dialysis nephrology care were associated with a lower likelihood of recovery. Eight patient characteristics were included in the final clinical score- age, body mass index, race, congestive heart failure, amputation, functional status, and prior nephrology care. Recovery scores ranged from zero to 11, with corresponding recovery rates ranging from 6% to 86%. Three risk categories (score range of 0-5, 6-7, and 8-11) exhibited 90-day recovery rates of 11%, 23%, and 45%. The internal validation assessment showed no overfitting of the models. The AUROC of the score was 0.70, similar to the original AUROC of 0.71.

Conclusions: A simple clinical risk score derived from information available at incident dialysis can accurately predict kidney recovery at 90 days in ESKD due to AKI. This predictive tool can be utilized by dialysis providers and policymakers to individualize care, and to improve the quality and processes of care.

AKI in Hospitalized Patients with Influenza Is Associated with Worse Outcomes: A Study of National Inpatient Sample from 2012 to 2014 in the United States

Nasha Elavia, Si Li, Ibitola Yusuf, Bojana Milekic. *The Wright Center for Graduate Medical Education, Scranton, PA.*

Background: Influenza causes significant morbidity and mortality every year. Physiologically, kidneys receive only 25% of the cardiac output in an average weight adult and therefore often develop acute kidney injury (AKI). Our study determines outcomes of AKI in adults hospitalized with influenza between 2012 and 2014 in the US.

Methods: We analyzed adult patients with a principal diagnosis of influenza from the 2012 to 2014 National Inpatient Sample. ICD-9-CM was used to identify the diagnosis variables. Patients were divided into two cohorts; with and without AKI. Patient characteristics between both groups were compared. Chi-squared analysis for categorical variables and multivariate regression analysis was done using STATA 16.0 to determine the relationship of outcomes. P <0.05 was used as the level of statistical significance.

Results: 120,730 hospitalizations with influenza were sampled. 16,270 (13.5%) of these had AKI (image 1). After adjusting for potential confounders, patients with AKI had higher odds of mortality (adjusted odds ratio (aOR): 3.83; 95% confidence interval (CI) 3.00-4.89, p<0.001), developing severe sepsis (aOR 8.65; 95% CI 6.46-11.57), septic shock (aOR 9.53; 95% CI 6.42-14.16), rhabdomyolysis (aOR 3.03; 95% CI 2.39- 3.84), requiring intubation (aOR 5.57; 95% CI 4.61-6.74, p<0.001), a longer length of stay (1.8 day; 95% CI 1.52-2.08, p<0.001) and higher costs ($5054.4; 95% CI $3918.8-$6190.1, p<0.001).

Conclusions: Influenza complicated with AKI in hospitalized patients is associated with a worse outcome in terms of morbidity and mortality along with increased healthcare costs and a longer length of stay.

Impact of Chloride-Rich Crystalloids on Sepsis-Associated Community-Acquired AKI Recovery in Critically Ill Patients

Shahrzad Tehranian,[1] Khaled Shawwa,[1] Erin F. Barreto,[2] Casey M. Clements,[3] Kianoush Kashani.[1,4] *[1]Department of Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Department of Pharmacy, Robert D. and Patricia E. Kern Center for the Science of Health Care Delivery, Mayo Clinic, Rochester, MN; [3]Department of Emergency Medicine, Mayo Clinic, Rochester, MN; [4]Department of Medicine, Division of Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN.*

Background: The use of chloride-rich crystalloids for resuscitation is associated with developing acute kidney injury (AKI). We aimed to explore the impact of resuscitation with chloride-rich crystalloids compared to balanced crystalloids on the recovery of kidney function in patients presenting with established sepsis-associated community-acquired AKI (SACA-AKI).

Methods: This was a single-center, historical cohort study of patients admitted to the intensive care unit (ICU) who presented to the emergency department (ED) with SACA-AKI at Mayo Clinic, Rochester, MN, from January 2011 to April 2018. We divided the cohort into two groups based on the primary type of crystalloids received in the ED and the first 48-hours of ICU. The first group received primarily normal saline with <20% balanced solutions, and the second group received at least ≥20% balanced crystalloids during the initial volume resuscitation.

Results: We included 736 patients who were resuscitated with crystalloids after SACA-AKI diagnosis (mean age 64±16, n = 463 (63%) males). There were 286 (39%) patients in the second group, found to have higher positive fluid balance during the first 48-hours of admission compared to the first group [median 5.7 (IQR: 3.6; 8) vs. 3.8 (IQR: 2.1; 6.1) L, $P < .001$]. By multivariate logistic regression, the patients in the second group had a higher rate of kidney function recovery after adjustments for known recovery risk factors (OR 1.4; 95% CI: 1.04-2, $P = .027$).

Conclusions: The use of balanced crystalloids during the initial resuscitation is associated with higher odds of kidney function recovery in patients with SACA-AKI.

The Effect of Care Bundles for AKI: A Systematic Review and Meta-Analysis

Yixin Chen, Fangfang Zhou, Qun Luo. *HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo, China.*

Background: Acute kidney injury (AKI) is common and associated with increased morbidity and mortality. Implementation a set of evidence-based AKI care bundles may have some benefits to patient outcomes by reducing variable standards of care. We aimed to systematically review the literature to quantify the effect of AKI care bundles on patient outcomes.

Methods: We searched Pubmed (Medline), EMBASE and Cochrane databases for studies that compare the effect of AKI care bundles with usual standard care in patients with or at risk of AKI from database inception to December 31, 2019. The quality of included studies was assessed using the Newcastle-Ottawa Scale. Heterogeneity was

assessed using Cochrane Q test and I^2 test statistics. Data were analyzed by RevMan 5.3 and Comprehensive meta-analysis (CMA 3.0). The primary outcome was in-hospital or longest follow-up mortality. Secondary outcomes included AKI incidence and AKI severity.

Results: A total of 11 studies (23,491 patients) were included in the meta-analysis. The implementation of AKI care bundles significantly reduced mortality in all patients (odds ratio, 0.87; 95% CI, 0.79–0.94; P =0.001; I^2 = 0%; Fig 1). And in patients at high risk for AKI(identified by novel biomarker, risk prediction score or electronic alert), care bundles significantly reduced AKI incidence(odds ratio, 0.62; 95% CI, 0.44–0.86; P=0.005; I^2 = 70%; Fig 2) and rates of AKI severity (odds ratio, 0.52; 95% CI, 0.35–0.76; P<0.001; I^2= 41%; Fig 3). In addition, there was no evidence of publication bias among the included studies.

Conclusions: The introduction of AKI care bundles can effectively improve outcome in patients with or at risk of AKI, especially when combined with novel biomarker, risk prediction score or electronic alert to manage AKI at early stage. However, the evidence so far is limited and not strong enough to make definite conclusions.

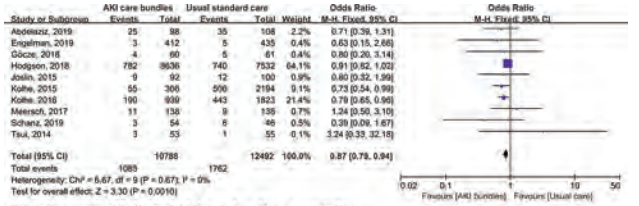

Fig. 1 Forest plot of effect of AKI care bundles on mortality.

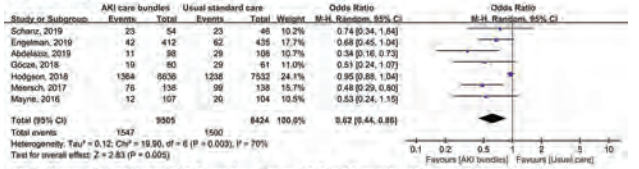

Fig. 2 Forest plot of effect of AKI care bundles on AKI incidence in patients at risk of AKI.

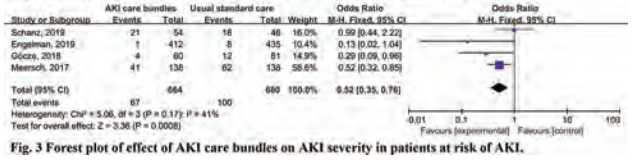

Fig. 3 Forest plot of effect of AKI care bundles on AKI severity in patients at risk of AKI.

Block Randomized Implementation of a Decision-Making Algorithm for Renal Replacement Therapy Initiation in AKI Compared with Standard Care on AKI-Related Outcomes

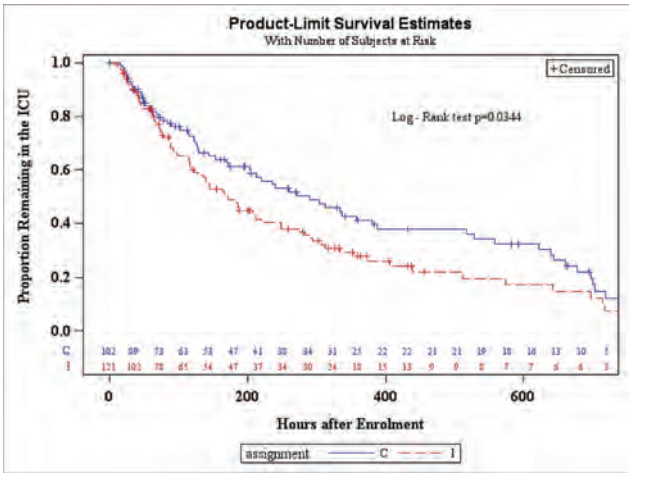
Yvelynne P. Kelly,[1] Salman Ahmed,[1] David E. Leaf,[1] Ernest I. Mandel,[1] Emily S. Robinson,[1] Gearoid M. McMahon,[1] Peter G. Czarnecki,[1] David M. Charytan,[1] Sushrut S. Waikar,[2] Mallika L. Mendu.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Boston Medical Center, Boston, MA.*

Background: Acute kidney injury (AKI) requiring renal replacement therapy (RRT) is associated with high mortality and utilization. Clinical decision-making related to AKI-RRT initiation in the intensive care setting is not standardized.

Methods: We conducted a 12 month single center block randomized controlled trial in the intensive care units (ICUs) of a large academic tertiary medical center; alternating use of an AKI Standardized Clinical Assessment and Management Plan (SCAMP), a decision-making algorithm to guide front-line clinicians, with use of a "sham" control form in 4-6 week randomization blocks. The SCAMP provided recommendations about optimal indications for initiating RRT on the basis of various clinical parameters, whereas the sham control form did not provide any recommendations for management of AKI-RRT.

Results: 122 patients were managed with AKI-SCAMP while 102 patients were managed using the sham control form. There was no significant difference in the primary outcome of odds of inpatient, 30-day or 60-day mortality associated with use of the AKI-SCAMP. With respect to secondary outcomes, use of the AKI-SCAMP resulted in a significantly reduced ICU length of stay (relative risk 0.68; 95% CI 0.66-0.69, p < 0.0001) and hospital length of stay (relative risk 0.75; 95% CI 0.72-0.79, p < 0.0001), as well as a reduced 30-day hospital readmission rate (odds ratio 0.38; 95% CI 0.15-0.99, p = 0.05).

Conclusions: Use of an AKI-SCAMP clinical decision support tool for assessment and management of AKI-RRT led to reduced ICU and hospital length of stay and 30-day hospital readmission rates. We advocate for increased study and use of this clinical decision support tool.



Kaplan-Meier curves for ICU length of stay according to treatment group; censoring for ICU mortality

PO0063

The Effect in Renal Function and Vascular Decongestion in Type 1 Cardiorenal Syndrome Treated with Two Strategies of Diuretics: A Randomized Clinical Trial

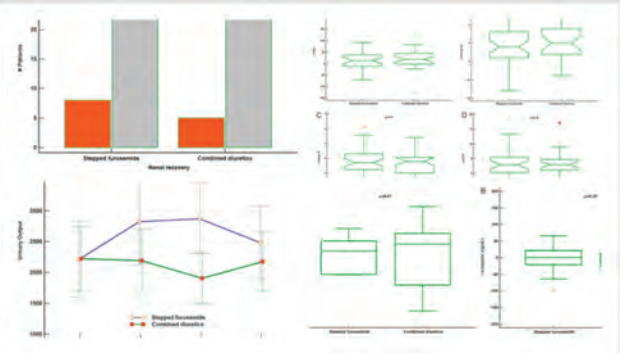
Jonathan Chavez,[1,2] Miguel A. Ibarra-Estrada,[1,2] Sergio J. Sánchez Villaseca,[1,2] Juan Gómez Fregoso,[1,2] Natashia L. Gongora,[1,2] Andres Aranda,[1,2] Joana G. Navarro gallardo,[1,2] Oscar D. Sauceda Diaz,[1,2] Guillermo Garcia-Garcia.[1,2] *[1]Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Mexico; [2]Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, CUCS, Guadalajara, Mexico.*

Background: The main treatment strategy in type 1 cardiorenal syndrome (CRS1) is vascular decongestion, it is probable that sequential blockage of the renal tubule with combined diuretics (CD) will obtain similar benefits when compared with stepped furosemide (SF).

Methods: We conducted a double-blind randomized clinical trial in CRS1 consecutive patients, we randomized in a 1:1 fashion to SF group or CD. The SF group received a continuous infusion of furosemide 100mg during the first day, with daily incremental doses to 200mg, 300mg and 400mg during the second, third and fourth day, respectively. The CD group consist in the combination of diuretics trying to block different tubular segments, including 4 consecutive days of oral chlortalidone 50mg, spironolactone 50mg and infusion of furosemide 100mg. The objectives were asses renal function recovery, and variables associated with vascular decongestion.

Results: During July 2017 to February 2020, 80 patients were randomized, 40 to the SF and 40 to the CD group, both groups were similar at baseline and had several very high-risk features. Mean age was 59 ± 14.5 years, male gender was 37 (46.2%), the median follow up was 182 days, Primary endpoint occurred in 20% in the SF group and in 15.2% in the DC group (p= 0.49), all secondary and exploratory endpoints were similar between groups with non-significant differences. Adverse events occurred frequently (85%) with no differences between groups (p = 0.53).

Conclusions: In patients with SCR-1 and high risk of resistance to diuretics, the strategy of CD compared to SF, offers the same frequency of renal recovery, diuresis, vascular decongestion and adverse events, so it can be considered as an alternative, especially in cases where it is not considered advisable to increase furosemide.



PO0064

Renin Levels Are Higher in Patients with AKI and Associate with Mortality and Major Adverse Kidney Events

Victor M. Ortiz-Soriano,[1] Fabiola Gianella,[2] Alexander H. Flannery,[1] Xilong Li,[2] Chirag R. Parikh,[4] Sherry Mansour,[3] Orson W. Moe,[2] Stuart Goldstein,[5] Javier A. Neyra.[1] *[1]University of Kentucky, Lexington, KY; [2]University of Texas Southwestern Medical School, Dallas, TX; [3]Yale University School of Medicine, New Haven, CT; [4]Johns Hopkins University, Baltimore, MD; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Renin is a marker of tissue perfusion and may be useful in predicting mortality in critically ill patients. Renin might also reflect structural kidney damage in heterogeneous AKI settings. We examine if renin levels are different in patients with vs. without AKI and if renin levels associate with adverse outcomes in critically ill patients.

Methods: Multicenter observational study utilizing blood samples of critically ill patients (KLAKI) and patients undergoing cardiac surgery (TRIBE-AKI). Renin was measured by ELISA in serum from 296 critically ill patients at 24-48 h of AKI diagnosis (KDIGO ≥2) or ICU admission (controls), and perioperatively in plasma from 105 patients undergoing cardiac surgery (35 with AKI [≥0.3 mg/dL increase or ≥50% increase in serum creatinine from baseline preoperative level to postoperative level] and 70 controls without AKI). The association of renin levels with hospital mortality and major adverse kidney events at hospital discharge (MAKE: composite of death, need of renal replacement therapy or inability to recover more than 75% of baseline eGFR) was evaluated in the critically ill group.

Results: Renin levels were higher in critically ill patients with AKI vs. ICU controls without AKI (median [IQR], 67.9 [21.7-343.7] vs 22.2 [6.4-73.0] pg/mL, p<0.001). Similarly, patients undergoing cardiac surgery who developed postoperative AKI had pre and postoperative renin levels differentially higher than those without AKI, sustained from POD1 to POD3 (157.9 [80.0-390.8] vs. 68.9 [20.6-149.9] pg/mL at POD1 in AKI vs. no AKI, p=0.003). In adjusted models, higher renin levels independently associated with increased risk of hospital mortality (OR: 1.27, 95%CI: 1.02-1.58 for every 1-unit increase in renin and OR: 3.44, 95%CI: 1.08-11.02 when the highest tertile was compared to the lowest tertile). Further, every 1-unit increase in renin increased the risk of MAKE by 16% (95%CI: 1-33%).

Conclusions: Renin levels are differentially higher in patients with heterogeneous AKI when compared to controls without AKI. Renin levels associate with hospital mortality and MAKE in critically ill patients and therefore its utility in risk-stratification should be further explored in this vulnerable population.

PO0065

Angiotensin 1-7 as a Novel Biomarker of AKI in Pediatric Kidney Transplant Recipients

Lauren Ehrhardt-Humbert, Ashton Chen, Andrew M. South. *Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: While graft survival rates of pediatric kidney transplant recipients have improved dramatically, acute kidney injury (AKI) accounts for up to 21% of graft failure in pediatric patients and prompt diagnosis of AKI is difficult. AKI activates the renin-angiotensin system (RAS), leading to increased angiotensin (Ang) II-induced inflammation and fibrosis. The ACE2/Ang-(1-7) pathway mitigates these effects but may be downregulated in AKI. The objective was to investigate Ang II and Ang-(1-7) as biomarkers to predict AKI in pediatric kidney transplant recipients. We hypothesized that changes in Ang II and Ang-(1-7) over time would predict biopsy-proven AKI in the first 6 months post-transplant.

Methods: This was a prospective cohort study of children recruited from a kidney transplant evaluation clinic. Blood and urine were collected pre-transplant and post-transplant at several time points. Ang II and Ang-(1-7) were measured with radioimmunoassays. Participants underwent for-cause or surveillance biopsies and histologic findings were recorded. We applied directed acyclic graph-informed Cox proportional hazards regression analysis with robust standard errors adjusted for age to estimate the association of time-varying Ang II and Ang-(1-7) with AKI.

Results: Of the 27 participants, mean age was 11.7 ±6.1 years, 63% were male, and 44% were Caucasian. The most common cause of kidney failure was congenital anomalies of the kidney and urinary tract (30%) and 74% received a deceased-donor transplant. Ten patients (37%) had AKI, most commonly due to tacrolimus toxicity (19%). In the urine, a 1-unit increase per day in Ang II (HR 0.97, 95% CI 0.93-1.0), Ang-(1-7) (0.99, 0.98-0.999), and Ang II:Ang-(1-7) (0.56, 0.28-1.11) over time predicted AKI, while blood levels did not.

Conclusions: Among pediatric kidney transplant recipients, changes in urinary Ang II and Ang-(1-7) over time predicted biopsy-proven AKI in the first 6 months post-transplant. Conversely, our findings suggest that for every 1-unit per day decrease in urine Ang-(1-7)[AMSM1], AKI risk increases by 1%. Our findings support the notion that both pathways of the renin-angiotensin system are involved in transplant AKI. Larger studies are needed to confirm the utility of measuring Ang II and Ang-(1-7) as biomarkers to detect transplant AKI and inform its pathophysiology.

PO0066

Biomarker and Safety Results from a Phase 1b Study of RBT-9 in Healthy Volunteers and Subjects with CKD Stage 3/4

Richard A. Zager,[1,2] Bhupinder Singh,[3,4] Alvaro F. Guillem,[3] Stuart Goldstein.[5] *[1]Fred Hutchinson Cancer Research Center, Seattle, WA; [2]University of Washington Department of Medicine, Seattle, WA; [3]Renibus Therapeutics, Southlake, TX; [4]University of California Irvine, Irvine, CA; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Acute kidney injury (AKI) remains a major unmet medical need without any FDA approved preventive or therapeutic options. Safe administration of pharmacologic agents that can prevent AKI in the hospital setting have great potential given the high rate of AKI-related morbidity and mortality. Organ preconditioning to elicit a state of induced cytoresistance prior to insult, such as cardiac surgery, is a mechanism by which the drug RBT-1 has been shown to be protective in various animal models of AKI including glycerol-induced rhabdomyolysis, maleate-induced hypoxic/ischemic renal injury, and ischemia reperfusion injury. RBT-1 is composed of proprietary formulations of stannous protoporphyrin (RBT-9) and iron sucrose (RBT-3). We conducted three phase 1 clinical trials to study the effect of RBT-1, RBT-3, and RBT-9 on biomarkers of cytoprotection observed in experimental animals and on clinical safety. Herein, we report results from the Phase 1b study of RBT-9 in both healthy volunteers and subjects with CKD Stage 3/4.

Methods: Forty-two subjects were enrolled and received a single dose of RBT-9 at 9 mg (N=6), 27 mg (N=18), and 90 mg (N=18). None of the subjects in the 9 mg group had CKD; 12 subjects (67%) in each of the 27 and 90 mg groups had CKD. Mean age was 59.5 years.

Results: RBT 9 dose-dependently induced cytoprotective biomarker responses (heme oxygenase-1 [HO-1], ferritin, NAD[P]H dehydrogenase [quinone] 1 [NQO1], and interleukin-10 [IL-10]) in both healthy volunteers and CKD subjects. Treatment-emergent adverse events (TEAEs) were reported in 20 subjects (47%), the majority of which were photosensitivity events and largely confined to the 90 mg treatment group. TEAEs were generally mild in severity. Only 3 TEAEs were moderate; no TEAEs were severe. No serious adverse events were reported. All TEAEs resolved during follow-up. There was no evidence of renal injury, as assessed by albuminuria and various biomarkers of renal tubular injury (KIM-1, NGAL, cystatin C, NAG).

Conclusions: We conclude that RBT-9 was safe and well tolerated in healthy volunteers and subjects with CKD. Adverse events were generally mild and related to photosensitivity reactions. Dose-dependent cytoprotective protein responses were observed that have previously corresponded with AKI protection in experimental animals.

PO0067

Analysis of AKI in Patients with Systemic Lupus Erythematosus

Si Li, Yichen Wang, Nasha Elavia, Bojana Milekic. *The Wright Center for Graduate Medical Education, Scranton, PA.*

Background: Renal involvement is commonly seen in systemic lupus erythematosus (SLE). The goal of our study is to analyze the impact and burden of acute kidney injury (AKI) on patients with SLE.

Methods: We analyzed the Healthcare Cost and Utilization Project Nationwide Inpatient Sample from the years 2012 to 2014. We included patients aged 18 years or older with either a primary or secondary diagnosis of SLE. Descriptive analyses were performed with a focus on patient characteristics and comorbidities. We used weighted multivariable survey regression methods to assess outcomes. Statistical analysis was performed using STATA 16.0. We considered a P value of <0.05 as statistically significant.

Results: We identified a total of 101,615 hospitalizations with SLE, of which 9,475 (9.3%) had AKI. Patients with a diagnosis of AKI were younger (mean age 39.3 vs. 45.4), more likely to be male (16.5% vs. 8.9%), black (45.6% vs. 33.3%), discharged from a teaching institution (72.2% vs. 65.4%). Patients with AKI had a higher prevalence of chronic kidney disease (53.2% vs. 10.1%), hypertension (74.5% vs. 47.5%). After adjustment with the patient and hospital level of confounder, the presence of AKI was independently associated with increased overall in-hospital mortality in patients with SLE (adjusted odds ratio [aOR] 12.1, 95% confidence interval [CI] 6.5- 22.4, p < 0.001). Length of stay (LOS) was 5.0 days longer (95% CI 4.5- 5.6, p < 0.001) in patients with AKI, and total hospital costs were $12485.6 more than in patients without AKI (95% CI 10656.1- 14315.2, p < 0.001).

Conclusions: Patients with AKI were more likely to die in the hospital, had a longer length of stay, higher inpatient care costs. Thus, the presence of AKI poses a significant burden on patients with SLE. Close monitoring and early treatment are warranted in this population.

AKI After Lung Transplantation: A Retrospective Analysis from a Single Transplantation Center

Johanna Wijk,[1,2] Sven-Erik Ricksten,[1,2] Göran Dellgren,[3] Per Ederoth,[4] Edgars Grins,[4] Lukas Lannemyr.[1,2] *[1]Department of Anesthesia and Intensive Care, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Cardiothoracic Anesthesia and Intensive Care, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Cardiothoracic Surgery, Sahlgrenska University Hospital, Gothenburg, Sweden; [4]Department of Thorcacic Anesthesia and Intensive Care, Skåne University Hospital, Lund, Sweden.*

Background: Acute kidney injury (AKI) is a common and serious complication after lung transplantation (Ltx). No data from the Swedish Ltx program have been published, and thus we performed a retrospective analysis of AKI after Ltx at our unit.

Methods: After ethical board approval, all patients ≥18 years who underwent Ltx in Gothenburg, Sweden, between 2012–2016 were assessed. Exclusion criteria were: death within 48 hours, multiple organ transplantations or pre-operative dialysis. AKI was defined according to the KDIGO creatinine criteria and the AKI group was compared to the patients without AKI using Mann-Whitney U-tests or Chi²-tests as appropriate. A multivariate logistic regression model for pre- and intraoperative predictors of AKI was built.

Results: In total, 211 patients were transplanted 2012–2016, and 197 patients were analyzed. Of these, 37% developed AKI within 1 week after Ltx (grade 1; 58%, grade 2; 12%, grade 3; 29%). AKI was associated with increased mortality at 30 days (5.5% vs. 0.8%, p=0.044) and at 1 year (26.0 % vs. 8.9%, p=0.001). In the regression model, higher body mass index, diabetes mellitus, measured GFR < 60 ml/min, tricuspid regurgitation and the use of extra-corporeal circulation during Ltx were independent predictors of postoperative AKI ($p<0.001$, $R^2=0.273$).

Conclusions: AKI affected more than 1/3 of the patients after Ltx, and was associated with increased time on mechanical ventilation, longer stay in the intensive care unit and increased mortality. The multivariate regression model had a modest predictive value, suggesting that postoperative factors may be important contributors to the development of AKI efter Ltx.

Efficacy Evaluation of Neutrophil Gelatinase-Associated Lipocalin and Cystatin C in Urine as Biomarkers in Early Diagnosis of AKI in Preterm

Dong Li. *Dalian Municipal women and children's medical center, Dalian, China.*

Background: To investigate the value of neutrophil gelatinase-associated lipocalin(NGAL) and cystatin C in urine in the early diagnosis of acute kidney injury in preterm and the efficacy of these two biomarkers in urine.

Methods: A prospective study was conducted on 98 preterm admitted to the NICU, including 55 males and 43 females. According to the diagnostic criteria for neonatal AKI published by the Acute Kidney Injury Network and the Kidney Disease Improving Global Outcomes (KDIGO), the serum creatinine is 1.5 times of the basic level or the urine volume is less than 1.5 mL/ (kg*h) ×24 h, 10 cases of AKI and 88 cases of non-AKI were confirmed on the first day of inclusion, 3 cases of AKI and 95 cases of non- AKI were confirmed on the seventh day of inclusion. Urine samples were collected on the day1, day7 of inclusion and the day of urine volume significant decrease (urine volume < 1.5ml/k*h), urine NGAL (uNGAL) and urine cyst-C values were measured by ELISA, meanwhile serum creatinine were measured. The study was approved by the ethical community board and written consent was obtained from the kids' parents.

Results: Among 98 cases, 10 cases were separated in AKI group and 88 in non-AKI group on the admission day, uNGAL and urine cyst-C in the AKI group were significantly higher than those in the non-AKI group ($P < 0.05$). On day 7, 3 cases were diagnosed AKI and 95 cases in non-AKI group. uNGAL and urine cyst-C in the AKI group were significantly higher comparing with those in the non-AKI group ($P < 0.05$). Receiver operating characteristic curves (ROC) for the diagnosis of AKI on day 1 and day 7 were drawn, the area under the curve(AUC) of urine cyst-C on day1 and day7 was 0.922 vs. 0.849, the sensitivity was 0.900 on day1(when set the critical value for AKI as 25.19ng/ml), and the sensitivity on day7 was 1(When the critical value was set 23.16ng/ml), and the specificity of urine cyst-C on day1 vs. day7 was 0.795 and 0.737 separately. The area under the curve(AUC) of uNGAL for AKI diagnosis was 0.860(day1) and 0.867(day7). When the critical value for AKI diagnosis was 100.12 g/L, the sensitivity for uNGAL was 1, and the specificity was 0.695. The positive value for uNGAL on day1 and day7 were 90% and 100% separately.

Conclusions: NGAL and cyst-C in urine can be used as biological indicators for the diagnosis of AKI in premature infants.

PO0070

AKI in Sickle Cell Disease

Si Li, Nasha Elavia, Yichen Wang, Bojana Milekic. *The Wright Center for Graduate Medical Education, Scranton, PA.*

Background: Sickle cell disease may cause acute injury to the kidney, especially during sickle cell crisis. Which mainly related to underlying stress-induced renal vasculopathy and alterations in glomerular hemodynamics. There is a paucity of national-level evidence showing the effect of acute kidney injury (AKI) on patients hospitalized with sickle cell disease. We aim to quantify the relationship between AKI and mortality and resource utilization in patients with sickle cell disease.

Methods: We analyzed adult patients admitted from 2012 to 2014 with a primary or secondary diagnosis of sickle cell disease using the Nationwide Inpatient Sample (NIS). The NIS is the largest publicly available inpatient database in the United States (U.S.). It contains data from approximately 8 million hospital stays each year, representing a 20% stratified sample of all U.S. non-federal hospitals, and is sponsored by the Agency for Healthcare Research and Quality and the Healthcare Cost and Utilization Project (HCUP). The International Classification of Diseases, Ninth Revision, Clinical Modification Coding System (ICD-9-CM) was used to identify comorbidities. Survey multivariate regression analysis was performed using STATA 16.0.

Results: We included 240,550 admissions with sickle cell disease, majority of them were black patients (93%). 10,825 (4.5%) of sickle cell disease patients had AKI. Patients with AKI were older (mean age 41.3±12.5 vs. 31.1±10.4, p<0.001), more likely to be male (53.1% vs. 44.4%, p<0.001). Sickle cell disease patients had higher prevalence of hypertension (49.9% vs. 16.8%, p<0.001), coronary artery disease (6.3% vs. 2.1%, p<0.001), congestive heart failure (22.5% vs. 4.4%, p<0.001), diabetes mellitus (9.8% vs. 3.5%, p<0.001). After adjusting for patient and hospital-level confounders, patients with AKI had higher odds of mortality (adjusted odds ratio [aOR] 11.3, 95% confidence interval [CI] 7.04- 18.34, p<0.001), a longer length of stay (2.6 days, 95% CI: 2.21- 2.93 days, p<0.001), higher costs ($6707.2; 95% CI: $5816.2-$7598.3, p<0.001).

Conclusions: The demographic characteristics were significantly different between patients with or without AKI. Sickle cell nephropathy imposes a burden on both individual and health care systems. Randomized controlled trials are needed to investigate the role of vaso-occlusive events on AKI development.

PO0071

Combining Renal Arrest and Damage Biomarkers to Predict the Progression of AKI in Patients with Sepsis

Xiaobing Yang, Xiaolei Tao. *Southern Medical University Nanfang Hospital, Guangzhou, China.*

Background: Septic AKI accounts for approximately half of all AKI in ICU, and up to 40% of mild or moderate septic AKI would progress to more severe AKI which is associated with significantly increased risk for in-hospital death and later CKD/ESRD.

Early identifying high risk patients for AKI progression might help physicians to enhance individualized monitoring and personalized management in patients with septic AKI.

Methods: This is a prospective, multicenter cohort study which enrolled adult septic patients who initially developed stage 1 or stage 2 AKI in the ICU from January 2014 to March 2018. Sepsis was diagnosed based on the 2016 Sepsis-3 criteria, and AKI was diagnosed and staged according to 2012 KDIGO-AKI guidelines. Renal arrest biomarkers (urinary TIMP2*IGFBP7 [u TIMP2*IGFBP7])and renal damage biomarkers (urinary KIM-1[uKIM-1] and urinary IL-18 [uIL-18]) were measured at time of AKI clinical diagnosis, and the utility of biomarkers for predicting septic AKI progression alone or in combination were evaluated. The primary outcome was AKI progression defined as worsening of AKI stage. The second outcome was receiving dialysis or death during ICU stay.

Results: A total of 149 septic patients with stage 1 or 2 AKI were included, 63 patient developed progressive AKI, 49 patients received dialysis or died during ICU stay. uTIMP2*IGFBP7, uKIM-1 and uIL-18 independently predicted the progression of septic AKI in which uTIMP2*IGFBP7 showed the greatest AUC (0.745; 95%CI, 0.667-0.823) as compared to uKIM-1 (AUC 0.719; 95%CI 0.638-0.800) and uIL-18 (AUC 0.619; 95%CI 0.525-0.731). Combination of uTIMP2*IGFBP7 with uKIM-1/uIL-18 further improved the performance of predicting septic AKI progression with AUCs of 0.752 (uTIMP2*IGFBP7 with uKIM-1) and 0.747 (uTIMP2*IGFBP7 with uIL-18), respectively. uTIMP2*IGFBP7, alone or combined with uKIM-1/uIL-18, improved the risk reclassification over the clinical risk factor model alone both for the primary and secondary outcomes, as evidenced by significant category-free net reclassification index.

Conclusions: Combination of renal arrest and damage biomarkers enhanced the prediction of AKI progression in patient with sepsis and improved risk reclassification over the clinical risk factor model alone.

Bicarbonate May Not Be the Best Treatment for Rhabdomyolysis: A Retrospective Cohort Study

Hye Won Kim,[1] Yunseo Lee,[2] Sejoong Kim.[1] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: It is controversial whether the use of bicarbonate solution, which has been traditionally attempted to treat rhabdomyolysis, has the beneficial effect of reducing acute kidney injury (AKI) and mortality, compared with the use of non-bicarbonate solution. The purpose of this study is to analyze whether bicarbonate therapy versus non-bicarbonate therapy may be effective in preventing AKI and death in patients with rhabdomyolysis.

Methods: We collected 4077 hospitalized patients with creatinine kinase (CK) > 1000 U/L and divided them into 2 groups: patients who received fluid with bicarbonate and who received fluid without bicarbonate. Patients were subgrouped into low (<2ml/kg/hr), middle (2-4ml/kg/hr) and high (≥4 ml/kg/hr) amounts of fluid to receive in first 72 hours of admission. Cox regression analysis models were used to identify risks for dialysis and mortality. Safety profiles were assessed by volume overload and electrolyte imbalances.

Results: In a total of patients with a mean age of 57.9 years (male 66.7%), bicarbonate-containing solution was used in 61.1% of the participants. The proportion of the subjects were 34.6%, 36.5%, and 28.9% for the low, middle, and high fluid group, respectively. The bicarbonate group showed higher incidence rate of AKI (OR 4.5), higher 1-year mortality (OR 3.1) and longer hospital stay (26.6 ± 54.4 vs. 22.0 ± 22.7 days) than the non-bicarbonate group. Patients given high amount of fluid therapy showed higher incidence rate of AKI (OR 3.1), higher rate of dialysis dependency (OR 2.7) and higher 1-year mortality (OR 1.4), compared with low fluid group, regardless of the use of bicarbonate. The use of bicarbonate (adjusted HR [aHR] 1.55), volume overload (aHR 1.28) were associated with higher mortality while the use of furosemide (aHR 0.8) showed the preventive effect. Baseline CK or peak CK were not related to the risk of dialysis or death. Volume overload was significantly higher in the bicarbonate group compared with the non-bicarbonate group.

Conclusions: We showed bicarbonate therapy or high-volume fluid management in patients with rhabdomyolysis were not beneficial in preventing AKI and death, compared with the non-bicarbonate therapy or low-volume fluid management. It suggests that limited use of bicarbonate and adjustment of fluid volume may improve the short-term and long-term outcome of rhabdomyolysis.

Plasma Metabolites Do Not Change Significantly After 48 Hours in Patients on CRRT

Benjamin R. Griffin,[1] Matthew Ray,[2] Kristy Rolloff,[2] John T. Brinton,[2] Javier A. Neyra,[3] J Pedro Teixeira,[4] Kirby Mayer,[3] Katja M. Gist,[2] Muhammad Aftab,[2] Diana I. Jalal,[1,5] Julie Haines,[2] Sarah Faubel.[2,6] *[1]University of Iowa, Iowa City, IA; [2]University of Colorado, Denver, CO; [3]University of Kentucky, Lexington, KY; [4]University of New Mexico, Albuquerque, NM; [5]Iowa City VA Medical Center, Iowa City, IA; [6]VA Eastern Colorado Health Care System, Aurora, CO.*

Background: Continuous renal replacement therapy (CRRT) is used in critically ill patients with hemodynamic instability. One of the primary aims of CRRT is to remove solutes that accumulate due to impaired kidney function. Surprisingly, few studies have assessed plasma solute levels during CRRT, and the duration of CRRT necessary to achieve adequate solute removal is unknown.

Methods: To assess the effect of CRRT on plasma solutes, metabolites were determined via untargeted ultra-high pressure liquid chromatography coupled to mass spectrometry (UHPLC-MS) in 13 critically ill patients requiring CRRT. Metabolites were assessed on plasma collected prior to CRRT initiation, and on plasma and effluent collected on days 1, 2, and 3 thereafter.

Results: A total of 101 annotated metabolites were evaluated. Plasma levels of 22 metabolites (21.8%) were significantly reduced by Day 1 of CRRT, and included creatinine, phosphate, lactate, and the amino acids alanine, proline, and cysteine. Only 2 metabolites (2.0%) were significantly reduced between Day 1 and Day 2, and *none* were reduced between Day 2 and Day 3. Figure 1 demonstrates that marginal changes in solute levels decrease as CRRT progresses. All metabolites were detected in the effluent, and the sieving coefficients for metabolites that were reduced versus not reduced after CRRT were not statistically different.

Conclusions: No further reduction in plasma metabolites occurred after 48 hours of CRRT. Since the median CRRT treatment time is 4-7 days nationwide, with some patients treated substantially longer, these data bring into question the utility of prolonged, uninterrupted CRRT therapy, and have major potential implications for the duration of CRRT in the ICU population.

Sustained Low-Efficiency Dialysis with Regional Citrate Anticoagulation and a Standard Hemodialysis Machine in Critically Ill Patients with AKI

Francesca Di Mario,[1] Filippo M. Fani,[2] Paolo Greco,[1] Caterina Maccari,[1] Elisabetta Parenti,[1] Tommaso Di Motta,[1] Maria Teresa Farina,[1] Giuseppe Regolisti,[1] Enrico Fiaccadori.[1] *[1]UO Nefrologia, Azienda Ospedaliera-Universitaria Parma, Parma, Italy., Parma, Italy; [2]UO Nefrologia e Dialisi, Ospedale San Giovanni di Dio, USL Toscana centro, Firenze, Italy.*

Background: Sustained-Low Efficiency Dialysis (SLED) is an increasingly used Kidney Replacement Therapy (KRT) modality in critically patients with Acute Kidney Injury (AKI); in this setting regional citrate anticoagulation (RCA) is a rational approach to avoid extracorporeal circuit clotting. The present study was aimed at evaluating the safety and efficacy of a simplified RCA protocol for SLED with a conventional hemodialysis machine.

Methods: SLED was performed for 8-12 hours (daily or every other day) with a Surdial X Nipro® hemodialysis machine and a cellulose triacetate filter (Sureflux-19L, 1.9 m2, KUF 19 ml/mmHg/h). Blood flow was set at 200 ml/min and dialysis fluid flow at 100 ml/min. Citrate was infused in pre-dilution as ACD-A solution (citrate 2.2%, 112.9 mmol/L) at 200-400 ml/h rates (estimated pre-filter citrate concentration 2-4 mmol/L). Treatment was monitored by serial evaluations of ionized calcium (Ca^{++}) and ACT at the beginning, at the 2nd hour and at the end of SLED session. Blood in the extracorporeal circuit was recalcified by the dialysis fluid itself (Ca^{++} 1.5 mmol/L) through Ca^{++} backfiltration; i.v. calcium supplementation was started only if patient Ca^{++} at the 2nd hour was ≤0.9 mmol/L.

Results: 41 SLED sessions were performed in 12 critically ill patients with AKI (mean age 69 ± 18 SD, mean APACHE II 22). Average pre- and post-SLED urea values were respectively 94 and 32 mg/dL. Most sessions (38/41, 93%) were completed for elapsed prescribed time. No statistically significant differences were observed between systemic ACT values measured during SLED as compared to baseline values. Ca supplementation

(10% Ca gluconate at fixed rate 5 ml/hour) was needed in 10/41 treatments, with rapid normalization of serum Ca^{++}. No new cardiac arrhythmia episode or hemorrhagic events were observed.

Conclusions: Our preliminary data suggests that a simplified RCA protocol for SLED using a conventional dialysis machine is easy and safe, also ensuring a good match between prescribed and actual dialysis dose administered.

PO0075

Prediction of AKI in Inpatient General Medical Ward Units

Cassandra Chiao, Rachel Urbas, Fauzia Osman, Tripti Singh. *University of Wisconsin System, Madison, WI.*

Background: Acute kidney injury (AKI) is common in hospitalized patients (A). A few scoring systems have been proposed to predict the risk of developing AKI in certain populations such as cardiac catheterization patients (B, C, D, E, F). However, there is no scoring system for predicting AKI in patients on the general medical wards. Our aim is to predict the development of AKI in acute general medical patients.

Methods: Retrospective single center study of all adult patient admitted to a tertiary care university hospital between July 2016-July 2018. AKI was defined by the KDIGO definition of AKI and all stages of AKI were included. We used chi-squared tests, ANOVA, and Kruskal Wallis to determine statistically significant factors. We calculated odds of AKI using logistic regression models. All analyses were conducted using STATA SE 15.

Results: A total of 10,981 were included in the study, 1573 (14.3%) with AKI and 9408 (85.7%) without AKI. Baseline demographics were significantly different between the two groups including age, race, length of hospital stay (p<0.001). In the univariate analysis, history of cancer and diabetes, proteinuria, admission BUN, hemoglobin (HGB), and hypotension during admission were predictive of AKI. After adjustment for significant univariate factors, age (OR 0.97 [0.96–0.99], P<0.001), admission BUN (OR 1.02 [1.01–1.04], P<0.001), and HGB (OR 0.79 [0.73–0.85], P<0.001) were significant in the multivariate analysis (Table 1).

Conclusions: We found that the age, admission BUN, and HGB were predictive of AKI in inpatient general medical units. These criteria can be used in acute general medicine patients to create a scoring system to determine the likelihood of developing AKI and therefore prevent AKI and its downstream complications in these patients.

Table 1: Risk Predictors of AKI	Univariate Odds Ratio	95% CI	P	Multivariate Odds Ratio	95% CI	P
Age	1.01	1.01 – 1.01	<0.001*	0.97	0.96 – 0.99	<0.001*
Male	0.95	0.85 – 1.05	0.32			
Black	1.48	1.19 – 1.83	<0.001*	1.34	0.74 – 2.42	0.34
Length of hospital stay	1.04	1.03 – 1.05	<0.001*	0.98	0.94 – 1.0	0.20
BMI	1.0	0.99 – 1.01	0.67			
History of Cancer	1.24	1.1 – 1.4	<0.001*	1.31	0.89 – 1.94	0.17
History of Diabetes	2.07	1.82 – 2.36	<0.001*	1.18	0.78 – 1.79	0.42
Proteinuria	1.96	1.76 – 2.19	<0.001*	0.79	0.55 – 1.13	0.21
BUN	1.03	1.02 – 1.03	<0.001*	1.02	1.01 – 1.04	<0.001*
Hemoglobin	0.71	0.69 – 0.73	<0.001*	0.79	0.73 – 0.85	<0.001*
Mean Arterial Pressure	0.99	0.99 – 0.99	<0.001*	0.99	0.98 – 1.0	0.16

Is Procalcitonin a Reliable Marker of Bacterial Infection in Patients with AKI?

Mariam Charkviani, Sumit Sohal, Natia Murvelashvili, Maria Yanez Bello, Daniela Trelles, Alisha Sharma. *Amita Saint Francis Hospital, Evanston, IL.*

Background: Procalcitonin (PCT) is a biomarker that helps to distinguish bacterial infections from other causes of infection or inflammation and can be used as a helpful adjunct to clinical judgment for resolving diagnostic uncertainty. Limited data is available about the diagnostic value of PCT in patients with acute kidney injury (AKI). We aimed to assess the diagnostic usefulness of serum PCT level as a marker of bacterial infection in patients with AKI and assess the correlation of serum creatinine clearance to serum PCT level.

Methods: This retrospective case-control observational study involved patients admitted to the hospital during the study period and had PCT checked. Patients were categorized into proven, possible, and no bacterial infection groups. We compared PCT level in AKI group with proven bacterial infection vs no bacterial infection and PCT level during proven and no bacterial infection groups with AKI vs non-AKI. Patients with end-stage kidney disease and other causes of elevated PCT (pancreatitis, cancer, severe burns) were excluded.

Results: 379 patients were analyzed, 24 patients were excluded from the study. 66 patients classified into the AKI group and 226 into the non-AKI group. 107 patients were in a proven bacterial infection group and 98 Patients in no bacterial infection group. The mean value of PCT was significantly higher with confirmed bacterial infection compared to no bacterial infection in all patients despite their renal function (4.9±8.75 vs 1.66±4.88, p<0.001). PCT level was higher in the AKI group than in the non-AKI group (10.99±12.24 vs 2.39±2.93, p>0.001) in patients with a proven bacterial infection. Patients with no infection had much higher PCT level in the AKI group as compared to the non-AKI group (5.76±14.67 vs 0.7±1.39, p=0.003). PCT level was also significantly higher during confirmed bacterial infection vs no bacterial infection in patients with AKI (9.2±11.05 vs 0.72±1.27, p=0.04). There was a weak positive correlation between creatinine clearance and PCT level (correlation coefficient 0.125, p=0.15).

Conclusions: Higher cutoff level of PCT is needed in patients with AKI to use it as a marker of infection. The specificity of PCT may decrease in patients in AKI if current reference cutoff values are used to guide clinical decisions.

PO0077

Predicting Outcomes After AKI: Are You Better Than a Machine?

Tanima Arora, Aditya Biswas, Yu Yamamoto, Michael Simonov, Melissa Martin, Francis P. Wilson. *Clinical and Translational Research Accelerator, Yale School of Medicine, New Haven, CT.*

Background: While multiple studies have used statistical models to predict outcomes after AKI, no studies have compared these models to physician intuition at the time of AKI consult. We studied the accuracy of physicians in predicting outcomes after AKI and compared it to the strength of predictive statistical models.

Methods: Our pilot study focuses on the prediction of 3 outcomes after AKI : Recovery, progression to dialysis and mortality. Postgraduate years 4 and 5 level Nephrology providers were asked, at the time of initial renal consult, to forecast outcomes at 3 timepoints : 24hr, 48hr and 7 days. We compared physician prognosis to a gradient boosted trees model trained using retrospective EHR data. Our primary measure of performance was area under the receiver operating characteristic curve (AUROC) at each time point.

Results: Data was captured from 56 patients with stage 2 AKI. Nephrology providers (n=7) were good to excellent at predicting dialysis at all three timepoints and death at 48 hours and 7 days. In contrast, their ability to predict recovery of AKI was relatively poor. The statistical model performed significantly better at predicting death at all timepoints, however was poorer at predicting dialysis (Figure 1.0).

Conclusions: Both physician clinical acumen and our statistical model showed good performance in predicting need for dialysis and death after AKI, however performed poorly when predicting recovery. This highlights the need to conduct further in-depth analysis into this area and implement strategies to enhance prediction of recovery after AKI.

Funding: Other NIH Support - NIH R01DK113191

Outcome after AKI	Recovery		Dialysis		Mortality	
	Physician	Model	Physician	Model	Physician	Model
24 hours	0.51	0.65	0.94	0.79	0.59	0.92
48 hours	0.49	0.47	0.82	0.70	0.78	0.90
7 days	0.64	0.57	0.75	0.65	0.79	0.93

PO0078

Short-Term Prognosis of Patients with Cardiorenal Syndrome Type 1-Induced AKI Requiring Continuous Renal Replacement Therapy

Yusuke Watanabe, Kei Sugiyama, Daichi Fukaya, Hiroaki Amano, Tsutomu Inoue, Hirokazu Okada. *Saitama Medical University, Iruma-gun, Japan.*

Background: Cardio-renal syndrome (CRS) type 1 is a condition wherein an acute heart failure (AHF) leads to the development of acute kidney injury (AKI). Continuous renal replacement therapy (CRRT) is used to remove excess solutes and fluids in CRS type 1 patients who have diuretic resistance. However, little is known about the outcomes of CRS type 1 patients who undergo CRRT.

Methods: We reviewed the clinical data of 74 consecutive CRS type 1 patients treated with CRRT from 2012 to 2015. Patients who underwent cardiovascular surgery and those who had chronic kidney disease stage 5 prior to admission were excluded. The primary outcome examined was in-hospital mortality.

Results: The mean age of patients was 70.6 ± 13.6 years old. The causes of AHF were ischemic heart disease (54.1%), valvular disease (13.5%), and other diseases. At the time of the CRRT initiation, the mean serum creatinine was 2.8 ± 1.0 mg/dL. The in-hospital mortality rate was 77.0%. Compared with non-survivors, the survivors had fewer number of previous hospitalizations for heart failure (50.9% vs. 23.5 %, $p = 0.046$), higher systolic blood pressure (97.7 ± 22.2 mmHg vs. 112.3 ± 21.1 mmHg, $p = 0.02$), better ejection fraction (31.4 ± 17.9% vs. 42.0 ± 15.7%, $p = 0.03$), smaller inferior vena cava (IVC) diameter (18.0 ± 5.8 mm vs. 14.8 ± 4.4 mm, $p = 0.04$), lesser respiratory variations in the IVC diameter (59.6% vs. 13.3 %, $p = 0.002$), lesser vasopressor requirement (96.5% vs. 31.9%, $p = 0.001$), and lesser respirator support (56.1% vs. 23.5%, $p = 0.02$) at CRRT initiation. The survivors required a shorter CRRT duration over the non-survivors (6.1 ± 6.9 days vs. 11.7 ± 12.4 days, $p = 0.03$). Through the multiple logistic regression analysis, certain factors were associated with a poor short-term prognosis. These factors were history of previous hospitalizations for heart failure, vasopressor requirement upon the start of CRRT, and the need for respirator support at CRRT initiation.

Conclusions: In our single-center experience, the use of CRRT for treating AKI caused by CRS type 1 was associated with a high in-hospital mortality rate. Patients with a history of previous hospitalization for heart failure, those who required vasopressors, and patients needing respirator support at CRRT initiation had an especially poorer prognosis.

PO0079

Roux-en-Y Gastric Bypass Is the Most Common Current Cause of Biopsy-Proven Oxalate Nephropathy

Swetha Reddy,[1] John C. Lieske,[2] Mira T. Keddis.[1] [1]*Mayo Clinic Arizona, Scottsdale, AZ;* [2]*Mayo Clinic Minnesota, Rochester, MN.*

Background: The objective of this study was to analyze patient characteristics and outcomes of biopsy-proven oxalate nephropathy likely due to an enteric cause at a single large tertiary health system.

Methods: Cases of oxalate nephropathy were identified based on documented kidney biopsy findings between 2009-2019 in patients with an associated enteric process likely to cause fat malabsorption.

Results: A total of 30 cases were identified (mean age of 65.2±8.56 years; 18(60.0%) female) with a median follow-up of 5 months; Risk factors included: hypertension in 21(70%), diabetes in 14 (46.7%), chronic kidney disease (CKD) stage 3A or greater in 16(53.3%) and prior kidney stones in 6(20%). The most common enteric causes were Roux en Y gastric bypass (RYGB) in 17(56.7%), pancreatic insufficiency in 6(20%), inflammatory bowel disease in 4(13.3%), and recurrent *C. difficile* infection in 3(10%). At the time of diagnosis, acute kidney injury (AKI) stage II and stage III were present in 9 (30%) and 15 (50%) respectively, while 11(36.7%) required dialysis. Urinalysis revealed proteinuria in 16(55.2%), oxalate crystals in 10(33.3%), and hematuria in 9(31%). Median plasma oxalate at the time of biopsy was 18.3 [reference <2.0]) µmol/L in 26 patients and median 24 hour urine oxalate excretion was 53 (reference [9.7-40.5]) mg/24 hrs in 17 patients. RYGB patients had a higher plasma oxalate compared to patients with other enteric causes (median 24.6 vs 16.5 µmol/L, p=0.03). Renal biopsy and clinical outcomes are shown in table1 [table1]. Patients with acute tubular injury had greater number of tubules with calcium oxalate crystals by biopsy (median 19 vs 4), as did patients with CKD5 at last follow-up (20 vs 6). Features at the time of biopsy predictive of CKD5 at follow-up included AKI severity (p=0.002), dialysis at diagnosis (p=0.0008), and the presence of moderate to severe tubulointerstitial atrophy (p=0.001).

Conclusions: In this series RYGB was the most common enteric cause of biopsy-proven oxalate nephropathy. Severity of AKI at presentation and degree of tubulointerstitial fibrosis were both associated with worse renal outcome. The amount of renal crystal deposits at diagnosis associated with the short and long term renal injury.

Renal Histology (A) & Outcome (B)

(A) Acute tubular injury	26 (86.6%)
Interstitial inflammation	21 (70%)
Number of tubules with calcium oxalate crystals	Median 19 (range 2, 40)
Moderate to severe tubular atrophy	23 (76.7%)
(B) Renal recovery	1 (3.33%)
CKD Stage 3	5 (16.7%)
CKD Stage 4	8 (26 %)
CKD Stage 5	5 (16.7%)
Dialysis	10 (33.3%)
Kidney transplant	1(3.33%)

PO0080

Impact of AKI on In-Hospital Outcomes in Chinese Patients with Community-Acquired Pneumonia

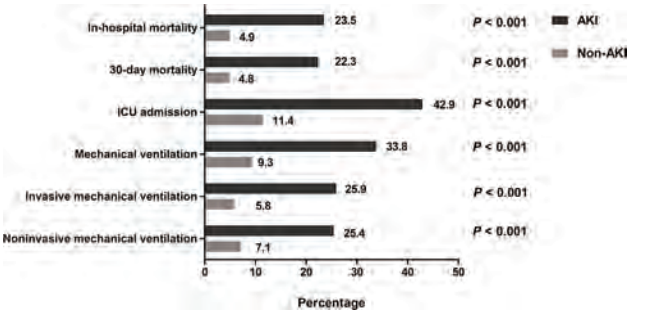
Dawei Chen, Xin Wan. *Nanjing First Hospital, Nangjing, China.*

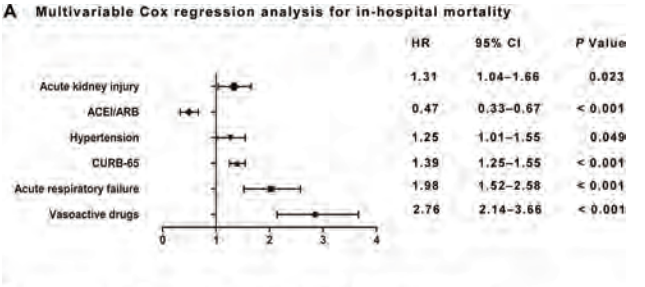
Background: Acute kidney injury (AKI) is common in community acquired pneumonia (CAP). However, the impact of AKI on in-hospital outcomes of patients with CAP in the population of Chinese remains largely unknown.

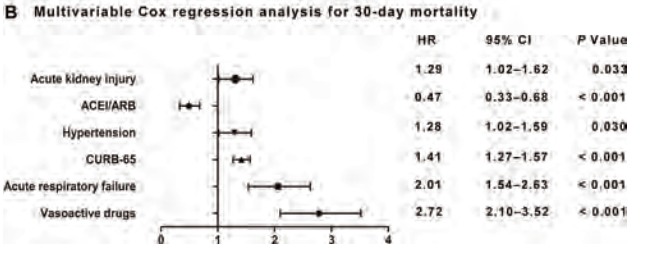
Methods: Multiple Cox regression models were employed to identify the association between AKI and in-hospital mortality and 30-day mortality.

Results: 4213 patients were included, and 950 (22.5%) patients were AKI. The independent risk factors for AKI were age, male, hypertension, cardiac dysfunction, diabetes, chronic kidney disease, acute respiratory failure, diuretic, vasoactive drugs, and CURB-65. After multivariable Cox regression, independent risk factors of in-hospital mortality and 30-day mortality were similar: AKI, ACEI/ARB, hypertension, CURB-65, acute respiratory failure, and using vasoactive drugs. Patients developed AKI had increased 1.31-fold (HR 1.31, 95 % CI, 1.04–1.66, P = 0.023) and 1.29-fold (HR 1.29, 95 % CI, 1.02–1.62, P = 0.033) risk for in-patient mortality and 30-day mortality, respectively. In addition, patients with AKI were more vulnerable to require intensive care unit (ICU) admission (42.9% vs. 11.4%; P < 0.001), mechanical ventilation (33.8% vs. 9.3%; P < 0.001), invasive mechanical ventilation (25.9% vs. 5.8%; P < 0.001), non-invasive mechanical ventilation (25.4% vs. 7.1%; P < 0.001), and had a longer length of hospital stay (14 days vs. 10 days; P < 0.001) than those without AKI.

Conclusions: AKI was common in Chinese patients with CAP. Patients with CAP who developed AKI had worse in-hospital outcomes.







PO0081

Risk of Nephrotoxicity in Patients Receiving Concomitant Vancomycin and Intravenous Contrast Media

Amy Hsu, Helen S. Lee, Benjamin Lee, Kamyar Kalantar-Zadeh, Ramy M. Hanna, Mark A. Baje. *University of California Irvine, Irvine, CA.*

Background: Contrast-induced nephropathy (CIN) has been described as a significant cause of acute kidney injury (AKI). Although the nephrotoxic potential of vancomycin has widely been published, the contributory effect of these two agents towards AKI has not been fully elucidated. We sought to better define this interaction.

Methods: The primary objective of this retrospective cohort study was to compare the incidence of AKI among adult patients receiving vancomycin (VAN) and vancomycin plus IV contrast (VC) within 96 hours of administration. Secondary outcomes included time to AKI development, hospital length of stay (LOS), and 30-day, all-cause mortality. A logistic regression was performed to identify potential risk factors for AKI among vancomycin-treated patients.

Results: A total of 114 patients receiving ≥ 4 consecutive days of vancomycin were included, 50 receiving VAN and 64 receiving VC. An additional 50 patients who received IV contrast alone were independently assessed for CIN, of which only 3 (6%) developed AKI. In the unadjusted analysis, no statistically significant difference in the rate of AKI (10% vs 20.3%; p=0.13), days until AKI (6 days vs 5 days; p=0.37), highest vancomycin trough (16.7 vs 17.8; p=0.62), and hospital LOS (7.5 days vs 8 days; p=0.62) were found between VAN and VC patients. The addition of IV contrast to vancomycin was not an independent risk factor for AKI after adjusting for relevant confounders (aOR 1.65; 95% CI, 0.48-5.65; p=0.42).

Conclusions: The addition of IV contrast was not associated with an increased risk of AKI in vancomycin-treated patients. The incidence of CIN was rare.

Mortality Prediction of Serum Neutrophil Gelatinase-Associated Lipocalin in Patients Requiring Continuous Renal Replacement Therapy

Byung ha Chung,[1] Yohan Park,[1] Hyung Duk Kim,[1] Eun jeong Ko,[1] Tae Hyun Ban,[2] Cheol Whee Park,[1] Chul Woo Yang.[1] *[1]Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; [2]Eunpyeong Saint Mary's Hospital, Eunpyeong-gu, Seoul, Republic of Korea.*

Background: We investigated whether serum neutrophil gelatinase-associated lipocalin (NGAL) can predict mortality in patients with acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT).

Methods: This study enrolled 169 patients who underwent serum NGAL testing at CRRT initiation from June 2017 to January 2019. The predictive power of serum NGAL level for 28-day mortality was compared to the Acute Physiology and Chronic Health Evaluation-II (APACHE-II) score and Sequential Organ Failure Assessment (SOFA) score via area under the receiver operating characteristic curve (AuROC) value.

Results: There were 55 survivors and 114 non-survivors at 28 days post-CRRT initiation. Median serum NGAL level was significantly higher in the non-survivor group than in the survivor group (743.0 vs. 504.0 ng/mL, P=0.003). The AuROC value of serum NGAL level was 0.640, which was lower than APACHE-II score and SOFA score values (0.767 and 0.715, respectively). However, in the low APACHE-II score group (<27.5), AuROC value of serum NGAL was significantly increased (0.698), and it was an independent risk factor for 28 day-mortality (hazard ratio 2.405, 95% confidence interval (1.209-4.783), P=0.012).

Conclusions: In patients with AKI requiring CRRT, serum NGAL levels may be useful for predicting short-term mortality in those with low APACHE-II scores.

The Impact of AKI on Patients with Out-of-Hospital Cardiac Arrest Managed with Venoarterial Extracorporeal Membrane Oxygenation at the University of Minnesota

Prasanth Ravipati, Paul E. Drawz, Jason Bartos, Sean Murray. *University of Minnesota, Minneapolis, MN.*

Background: Since 2015, the Minnesota Resuscitation Consortium (MRC) in conjunction with the University of Minnesota medical center have been treating patients who suffer out of hospital refractory ventricular fibrillation/ventricular tachycardia (VF/VT) with a protocolized treatment strategy utilizing mechanical cardiopulmonary support including venoarterial extra corporeal membrane oxygenation (VA ECMO). In this unique and new group of patients, the incidence and clinical impact of acute kidney injury (AKI) and AKI requiring renal replacement therapy (RRT) is not known. Additionally, we observed electrolyte abnormalities in these patients that have not been previously described.

Methods: We conducted a retrospective chart review of patient data obtained via an electronic database created as part of the MRC's program in conjunction with the health system's electronic health record. Descriptive statistics were utilized to describe baseline characteristics. We restricted analyses to participants without end stage kidney disease on admission and those who survived at least 24 hours to allow for development of AKI. Kaplan-Meier plots were utilized to show death free survival by AKI category. All analyses were conducted using the R Statistical Computing Environment.

Results: We obtained data for 116 patients in the time period since 2015. Among the 116 patients, 55 patients had AKI defined as doubling of creatinine within 7 days but did not require RRT. Of the remaining 61 patients, 28 developed AKI requiring RRT. Patients who developed AKI or AKI requiring RRT had a mortality of 70% at 30 days. The remaining 33 patients who did not develop AKI had a mortality of 52% at 30 days. Regarding electrolyte derangements, cooling was associated with hypokalemia and hypophosphatemia with 64% percent of patients with potassium less than 3 mmol/L and 57% of patients with phosphorus less than 2 mg/dL.

Conclusions: AKI is associated with a high rate of mortality in this unique patient population, and additionally there is marked hypokalemia and hypophosphatemia in the setting of therapeutic cooling. Given the high mortality, this study raises questions regarding optimal treatment strategy for patients who develop AKI, including timing and delivery of RRT and the ideal approach to volume and electrolyte management.

PO0084

Prevalence, Length of Stay, and Hospitalization of AKI in Patients with and Without Sjogren Syndrome

Mohamedanwar M. Ghandour, Yahya M. Osman Malik. *Wayne State University School of Medicine, Detroit, MI.*

Background: Acute Kidney Injury (AKI) has emerged as a significant cause of morbidity and mortality in patients with autoimmune diseases. However, this has not been examined in patients with Sjogren's syndrome (SJS). To achieve this, we examined the prevalence, mortality, outcomes, Length of Stay (LOS), and hospital charges in patients with AKI with SJS compared to patients without SJS from a National Inpatient Sample database in the period 2010-2013.

Methods: Data retrieved from the National Inpatient Sample (NIS) for adult patients admitted with a principal diagnosis of acute kidney injury between 2010 and 2013, using the respective ICD-9 codes. The study population divided into two groups, with and without Sjogren's disease. Multivariate and linear regression analysis conducted to adjust for covariates.

Results: The study population represented 97,055 weighted patient discharges with acute kidney injury. Analysis revealed acute kidney injury patients with Sjogren's compared to patients without Sjogren's had statistically significant lower hyperkalemia rates (adjusted Odds ratio (OR)0.65, CI 0.46 to 0.92; p =0.017). There was no statistically significant difference in mortality, length of stay, hospital charges, and other outcomes. Moreover, The charges of hospitalization and length of stay were found to be statistically insignificant by the adjusted linear regression model. In addition, nearly three quarters of patients had Medicare, followed by privately insured patients with the least number being on Medicaid. More than half of the population have received their treatment in a tertiary center hospital. Charlson's index reported more than two-thirds of study subjects to have two or more co-morbidities.

Conclusions: At present, our study is unique as it has examined the prevalence, mortality, and outcomes of Sjogren's in patients with acute kidney injury. Patients with Sjogren's had significantly lower hyperkalemia during the hospitalization. Further research is needed to identify the underlying protective mechanisms associated with Sjogren's that resulted in lower hyperkalemia.

Clinical Characteristics and In-Hospital Outcomes for 1519 Consecutive Patients with AKI

Christina I. Montgomerie,[1] Jonas Spaak,[3] Marie Evans,[2] Stefan H. Jacobson.[1] *[1]Karolinska Institutet, Danderyd University Hospital, Department of Clinical Sciences, Division of Nephrology, Stockholm, Sweden; [2]Karolinska University Hospital Huddinge Department of Renal Medicine, Stockholm, Sweden; [3]Karolinska Institutet, Danderyd University Hospital, Department of Clinical Sciences, division of Cardioloy, Stockholm, Sweden.*

Background: Acute kidney injury (AKI) occurs in about 15% of hospitalized patients. Patients who recover from AKI have a higher long-term risk of end-stage kidney disease and death. The aim of this large single center study was to report differences in laboratory findings and short-term hospital outcomes in relation to cause of AKI in consecutive patients in a nephrology department.

Methods: All patients diagnosed with AKI between 2009 and 2018 and admitted to the nephrology department at Danderyd University Hospital, Stockholm, Sweden, were included. Relevant laboratory and physiological measures were registered. Patients on dialysis treatment were excluded. Patients were followed until discharge or death, whichever came first.

Results: In 1519 AKI patients, the majority (n=687) was of prerenal, followed by combined (defined as chronic kidney disease combined with any type of AKI) (n=536), renal (n=166), and postrenal (n=130) etiology. Patients with renal AKI were younger, had longer duration of stay, and had higher bicarbonate levels on admission. 63.2% of patients had a sCr decrease of at least 30% from admission during their stay. Most of these had prerenal followed by postrenal etiology. There was no statistically significant difference in mortality between the four etiologies of AKI.

Conclusions: This study provides data from a large, contemporary AKI patient cohort under nephrology care. We confirm that patient characteristics as well as short-term outcomes differ substantially in patients of variable AKI etiology. Greatest in-hospital reduction of sCr was seen in patients with prerenal and postrenal AKI, whereas patients with renal and combined AKI had poorer renal recovery. These findings have important implications for prognostic evaluation upon admission and further resource planning.

Traditional and Non-Traditional Risk Factors and Their Influence on In-Hospital Mortality in Community- vs. Hospital-Acquired AKI

Maria Isabel Acosta-Ochoa, Armando Coca, Jimmy R. Sanchez Gil, Alicia Mendiluce. *Hospital Clinico Universitario de Valladolid, Valladolid, Spain.*

Background: Many studies compare hard outcomes in Community Acquired (CA-AKI) vs. Hospital Acquired AKI (HA-AKI), but few works contrast how various risk factors (RF) impact in-hospital mortality risk in both groups.

Methods: Retrospective study of in-patients with AKI. AKI was classified by KDIGO-2012 Stages. CA-AKI occurred in the first 48h, and HA-AKI >48h after admission. We compared clinical and epidemiological features, and the traditional RF (age, Charlson's Index (ChI), ICU entrance, and AKI severity). We analyzed hyponatremia Max (Na <134 associated with peak SCr) (HNa Max), anemia Max (Hb <10 with peak SCr), and AKI etiology as non-traditional RF. All RF relationship with mortality was calculated with a multivariate Cox regression.

Results: We included 1269 cases, 69% in the CA-AKI group. The HA-AKI group showed a higher ChI, had longer hospital stay, were less frequently admitted to medical wards, and less HD dependent at discharge. Mortality was significantly higher among HA-AKI vs. CA-AKI (31% vs.18% p<0.001). See Table 1. Traditional RF correlated with higher risk of death in both groups. Hypertension, heart failure and anemia Max were associated with mortality in CA-AKI but not in HA-AKI. On the other side, HA-AKI had a higher risk of death associated with HNa, which was not significant among CA-AKI patients. See Figure 2.

Conclusions: We found that HA-AKI is more deadly than CA-AKI (consistent with previous studies), but shows lesser HD dependence at discharge. The traditional RF: older age, higher ChI, ICU admission, and AKI stage 3 influenced in-hospital mortality in both groups. Non-traditional RF showed an heterogeneous influence on outcomes according to AKI type, probably due to diverse baseline characteristics, evolution time, and AKI etiologies between cohorts. We conclude that these novel associations (e.g. anemia and HNa) should be explored and modifiable factors should be tackled in order to prevent AKI mortality.

One-Year AKI Stage 3 Outcome in Elderly Patients at a Secondary Care Hospital in the United Kingdom

Jeetendra R. Rathod, Matthew James, Syed A. Shafqat, Jonathan Kwan. *Darent Valley Hospital, Dartford, United Kingdom.*

Background: Elderly patients are prone to Acute Kidney Injury (AKI) 3 due to multiple co-morbidities and frailty. The short term and long term outcome and mortality in this group of patients is unclear.

Methods: We prospectively collected data on patients aged over 70 years with AKI 3 from the daily e-alert sent by the hospital biochemistry lab. 117 patients attended or admitted to secondary care hospital in West Kent, UK over 6.5 months between 13 December 2018 and 26 May 2019 were analysed and followed up for next 12 months. AKI 3 was defined as per KDIGO Criteria. Data was collected for age, co-morbidities, serum creatinine at admission, peak, discharge and 12 months, cause of AKI 3 and mortality. Exclusion criteria: AKI stage 1, stage 2 and patients on regular dialysis.

Results: 57% patients had community acquired and 43% developed AKI 3 while as in-patient. The mean age was 80.1 ± 6.2 years with co-morbidities of Chronic Kidney Disease (>3) 64.7%, Cardiovascular disease (CVD) 50%, Diabetes Mellitus 42.2% and Malignancy 8.7%. The stable baseline, peak and discharge s. creatinine (mean ± std dev) were 127.7 ± 85.6, 420.9 ± 222.7 and 248.5 ± 184.5 umol/L respectively. 59.5% patients were reviewed by nephrologists and 20.7% were transferred under renal care. 30.4% had oliguria at presentation. The reasons for AKI 3 were classified as pre-renal (59.48%), urinary obstruction (11.2%) and renal that included sepsis (13.79%), cardio-renal syndrome (3.45%), drug induced nephrotoxicity (2.6%), other renal including ATN (9.70%). Renal function recovery was complete in 44.8%, Partial in 22.4% whereas 32.8% did not have any recover. 6 (5.17%) patients needed acute haemodialysis, of these 2 died and 4 (66.6%) were discharged off dialysis and were alive at 12 months. 47.4% patients were alive at discharge with s.creatinine of 173.2 ± 143.2 umol/L while only 32% of the overall patients were alive at 12 months with s. creatinine (eGFR) (mean ± std dev.) 161.5 ± 127 umol/L (48 ± 28 ml/min) with mean follow up of 331 ± 112 days. All patients that did not recover from AKI died.

Conclusions: We conclude that short and long term outcome in patients with AKI 3 aged more than 70 years has high mortality at discharge (52%) and 12 months (68%). AKI 3 is common in patients with co-morbidity of CKD, CVD and Diabetes mellitus. Outome of acute haemodialysis is effective in select group of patients.

PO0088

Urinalysis and Urine Electrolytes Among Patients with COVID-19 Infection and AKI

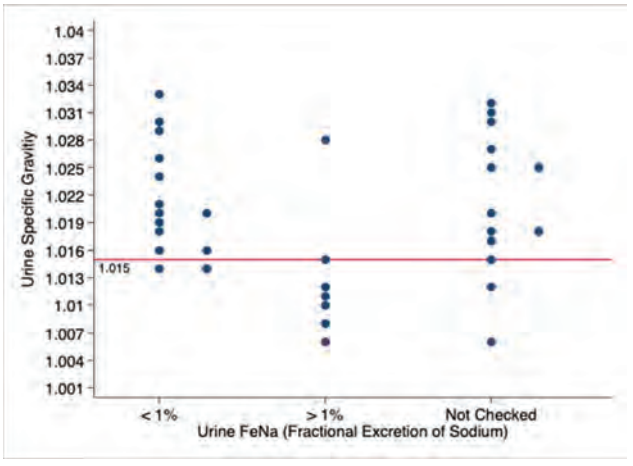
Vishnu S. Potluri, Sadichhya Lohani, Forrest F. Lindsay-McGinn, Claire A. Centeno, Jennifer Morganroth, Christy Moore, Felipe Teran, Nathaniel C. Reisinger. *University of Pennsylvania, Philadelphia, PA.*

Background: Determining intravascular volume status for patients who have COVID-19 infection and AKI is critical for guiding decisions about fluid management and treating AKI. In this study, we present data on urinalysis and urine electrolytes among patients with COVID-19 infection who developed AKI at our hospital.

Methods: This is a cohort of patients with COVID-19 who were diagnosed with AKI at our center in Spring of 2020 and had a urinalysis performed within 48 hours of diagnosis of AKI. When applicable we used Mann-Whitney test to compare groups.

Results: 34 patients had AKI, 21 (61%) were female, and 21 (61%) were Black race. All patients had a urinalysis, 23 (68%) had a urine sodium (UNa), and a 21 (61%) had a urine FeNa (fractional excretion of sodium). The median urine specific gravity (SG) was 1.019 (IQR 1.04 – 1.026). The median UNa was 39 (IQR 24 - 55). The median FeNa was 0.69% (IQR 0.18% - 1.07%). **Figure 1** shows the distribution of urine SG by FeNa. The median serum creatinine at the time of diagnosis was 2.42 (IQR 1.52 - 3.92). A diagnosis of ATI (acute tubular injury) was made by the treating physician in 17 (50%) patients. The median creatinine at the time of diagnosis for patients who were diagnosed with ATI was 3.35 (IQR 2.29 – 5.16), and for those without ATI was 1.61 (IQR 1.48 - 2.63), p-value 0.0641. The median FeNa for patients who were diagnosed with ATI was 0.85% (IQR 0.56%-1.97%), and for those without ATI was 0.33% (IQR .12%-1.27%), p-value 0.105.

Conclusions: In our cohort, the majority of patients with AKI had urine studies consistent with volume depletion, suggesting that volume depletion is common. Implementation of urine studies in COVID-19 patients as part of regular care might help guide treating physicians deciding about fluid management.



PO0089

Recovery of Renal Function Among Left Ventricular Assist Device Patients with Severe AKI Requiring Renal Replacement Therapy: A Meta-Analysis

Swetha Rani Kanduri,[1] Wisit Cheungpasitporn,[1] Karthik Kovvuru,[1] Pradeep Vaitla,[1] Charat Thongprayoon,[2] Kianoush Kashani.[2] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Mayo Clinic Rochester, Rochester, MN.*

Background: Acute kidney injury (AKI) is a common and severe complication after left ventricular assist devices (LVAD) implantation with an incidence of 37%; 13% of which requiring renal replacement therapy (RRT). Severe AKI requiring RRT in LVAD patients is associated with high short-term and long-term mortality, compared with those without RRT. While recovery of renal function is associated with better outcomes, the rates of recovery of renal function among LVAD patients with severe AKI requiring RRT are unclear.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Databases were systemically searched from database inceptions through January 2020 to identify studies evaluating the rates of recovery from severe AKI requiring RRT after LVAD placement, which is defined by regained kidney function resulting in the discontinuation of RRT. Random-effects and generic inverse variance method of DerSimonian-Laird were used to combine the effect estimates obtained from individual studies.

Results: A total of 268 patients from 14 cohort studies with severe AKI requiring RRT after LVAD were enrolled. Follow-up time ranges from hospital discharge up to 12 months. 78.5% of renal recovery occurred at the time of hospital discharge or within 30 days. Majority (85%) of patients used continuous-flow LVAD. Overall, the pooled estimated rates of AKI recovery among patients with severe AKI requiring RRT was 50.5% (95%CI: 34.0%-67.0%), respectively. While the data on pulsatile-flow LVAD were limited, subgroup analysis of continuous-flow LVAD demonstrated the pooled estimated rates of AKI recovery among patients with severe AKI requiring RRT of 52.1% (95%CI: 36.8%-67.0%). Meta-regression analysis did not demonstrate a significant association between study year and AKI recovery rate (p = 0.08). There was no publication bias as assessed by the funnel plot and Egger's regression asymmetry test in all analyses.

Conclusions: Recovery from severe AKI requiring RRT after LVAD occurs approximately 50.5%, and it has not significantly changed over the years despite advances in medicine.

PO0090

Early Nephrologist Interventions to Avoid Kidney Replacement Therapy in AKI

Christian P. Flores,[1] Pablo Maggiani,[2] Jonathan Chavez,[1] Jorge J. Font,[1] Joana G. Navarro gallardo,[1] Noe Martinez murillo,[1] Jose A. Torres,[1] Juan Gómez Fregoso.[1] *[1]Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; [2]Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

Background: Is well know that early nephrologist involvement in patients with AKI improve outcomes. Determine which intervention has a greater impact on avoiding the need for KRT will be an important advance.

Methods: Our objective was to Identify which nephrologist intervention decrease the need of KRT. We analyze age, gender, comorbid conditions, cause of AKI, pharmacology therapy, cause of KRT, **early interventions: fluid, antibiotic and nutritional adjustment, nephrotoxic withdrawal and removal of hyperchloremic solutions** and death. Kaplan Meier survival analysis. Multivariable logistic regression model was performed. P< 0.05 which is significant.

Results: From 2017 to 2020 288 patients with AKI where analyzed prospectively with a 10 days follow-up, 45 (15%) patients die, overall survival of 84.4% (IC 95% 0.80 – 0.88) (Figure1). Only fluid adjustment decreases the risk of KRT (OR 0.74, 95% CI 0.68-0.81, p < 0.001) while having AKI KDIGO 3 increases the risk (OR 1.12, 95% CI 1.05-1.20, p<0.001) being the fluid overload the main cause of KRT (OR 1.67, 95% CI 1.53-1.82, p<0.001). Between all interventions, just fluid adjustment avoid progression to AKI KDIGO 3 (OR 0.76, 95% CI 0.65-0.89, p < 0.001). (Table1)

Conclusions: In AKI, fluid adjustment was the most important nephrologist intervention to avoid KRT.

Variable	OR	95% CI		p
KDIGO 3	1.12	1.05	1.20	<0.001
KDIGO 1	1.03	0.95	1.12	0.35

Usefulness of the Neutrophil-to-Lymphocyte and Platelet-to-Lymphocyte Ratios in Community-Acquired AKI

Jose M. Pena Porta, Almudena Castellano, Ana Coscojuela Otto, José F. Gascó, Alejandro Tomás, Pablo J. Inigo Gil, Rafael Alvarez lipe. *Nephrology Service. Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain.*

Background: The neutrophil-to-lymphocyte (NLR) and platelet-to-lymphocyte (PLR) ratios have been identified as markers of inflammation and endothelial dysfunction. To date, its usefulness as prognostic markers in community-acquired acute kidney injury (CA-AKI) has not been evaluated.

Methods: We established a cohort of patients with CA-AKI admitted to our Nephrology service from January 2010 to February 2015. NLR and PLR ratios were obtained with the first analysis performed.

Results: We studied 308 patients with CA-AKI, 58 % were men, mean age 73.22. Etiology of CA-AKI: prerenal 69.5%; renal 23.1%; obstructive 7,5%. AKI KDIGO stages: I, 14.6%; II, 11%; III 74.4%. CKD was detected in 68.8%.17,15% of cases required hemodialysis and 12,3 % died. Mean NLR was 9.14 ± 8,47. Mean PLR was 236,99 ± 228,41. NLR according to etiology was: prerenal 8,55±6,8*;* renal 9,37±9,8; obstructive 13,99±14,82 (significant differences between obstructive and prerenal). PLR according to etiology: prerenal 228,31±216,34*;* renal 236,15±233,77*;* obstructive 320,37±304,89 (non-significant differences). Within the group prerenal, 79 cases were complicated by acute tubular necrosis (ATN). These cases presented a higher NLR (10,7±10,28 vs NLR 7,8±5,6; p=0,026). There were no significant differences between the PLR of both grups. The NLR showed a significant correlation with the peak creatinine (r= 0,186; p = 0,001) and with serum albumin (r= -0,237; p < 0,001). The PLR also showed the same correlations (r= 0,134, p = 0,018 and r = 0,165, p= 0,07).The NLR, but not the PLR, was associated with the length of hospital stay (multiple linear regression analysis). Through a multivariate binary logistic regression analysis, the variables that were independently associated with mortality during admission were the Liaño individual severity index and the NLR (OR 1,060; IC 95 % 1.014 – 1,108). The best cut-off point of the NLR to predict mortality was 6,68 (AUC 0,584; sensitivity 0.60; specificity 0.58; Youden index 0.178)

Conclusions: In our CA-AKI patients cohort, the NLR was associated with the morbidity and the mortality. More studies are need to confirm this finding, but the easiness of obtaining it and its economic cost make it cost-effective, giving the NLR a leading role in assessing the risk of CA-AKI.

PO0092

Clinical Characteristics and Histologic Descriptions of Acute Tubular Injury: A Systematic Review

Yumeng Wen,[1] Chen Yang,[2] Steven Menez,[1] Avi Z. Rosenberg,[1] Chirag R. Parikh.[1] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: The term acute tubular injury (ATI) represents histopathologic renal tubular injury and often manifests clinically as acute kidney injury (AKI). Studies systematically summarizing the clinical presentation and histologic changes in human ATI are limited.

Methods: We comprehensively searched human studies of ATI from 1936 to July 2019. We extracted study characteristics, clinical characterstics and histologic descriptions of ATI by bright field, immunofluorescence or electron microscopy (EM) and by immunohistochemistry. We also compared histology of tubular cell injury as a function of tissue procurement timing and etiologies.

Results: We included 292 studies comprising of 1987 patients. The majority of studies (76%) were single center case reports. The mean age of patients included was 47 years old. 39.3% of patients had hypertension and 24.9% of them had diabetes mellitus. Baseline, peak and latest creatinine were 1.29 mg/dL, 7.04 mg/dL and 1.86 mg/dL respectively. 48.9% of studies were native kidney biopsy cases, of which 86.7% were performed after serum creatnine peaked. There were significant amount of missing data in these clinical characteristics reported across studies. We identified 16 histologic descriptions used to report tubular injury (shown in Figure 1), including tubular cell sloughing (39.4%), tubular epithelial flattening/simplification (37.7%), tubular dilatation (37.3%), tubular cell necrosis (31.9%), regenerative changes (28.1%) and tubular cell vacuolization (26.4%). There was no difference in tubular injury histology either before or after creatinine peaked or between etiologies. EM and immunohistochemistry were used in minority of studies.

Conclusions: Tubular injury manifests with diverse histological changes. Efforts to establish protocols to harmonize biopsy practices, handle kidney biopsy and report results across clinical practice are needed to improve our understanding of this complex disease.

Figure 1. Overall reporting of histology descriptors of tubular injury.

PO0093

AKI and CKD Distribution in the Novel Clinical Phenotypes for Sepsis

Luca Molinari,[1,2] Gaspar Del Rio-Pertuz,[1] Sadudee Peerapornratana,[1,4] Hernando Gomez Danies,[1,3] John A. Kellum.[1,3] *[1]Center for Critical Care Nephrology, Department of Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Department of Translational Medicine, Università degli Studi del Piemonte Orientale, Novara, Italy; [3]Clinical Research Investigation and Systems Modeling in Acute illness (CRISMA) Center, Department of Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]Excellence Center for Critical Care Nephrology, Division of Nephrology, and Department of Laboratory Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.*

Background: Sepsis is the most common cause of Acute Kidney Injury (AKI) in critically ill patients. Four clinical phenotypes (alpha, beta, gamma, delta) of sepsis have been recently described. Our objective was to investigate which of these sepsis phenotypes were associated with severe AKI, chronic kidney disease (CKD), AKI with CKD, and acute kidney disease (AKD).

Methods: We examined the 4 phenotypes using patient data from a previously published multicenter sepsis trial. After excluding patients with end-stage kidney disease and missing data, we analyzed 1243 patients with septic shock. We described the presence of severe AKI within the first 24 hours defined as KDIGO stage 2 or 3 or stage 1 with [TIMP-2]●[IGFBP7] at 6 hours >2.0. AKD was defined for patients with severe AKI as the presence of any AKI on day 7 or, if death occurred before 7 days, death without AKI recovery. The Chi-square test was used to compare distributions between groups, if $p<0.05$ then a pairwise comparison between groups was made using the Chi-square test adjusted with Bonferroni correction.

Results: We found a total of 633 patients with severe AKI (53.6%) within 24h. The rate of severe AKI at 24h was different across phenotypes being highest in the delta and beta phenotypes (80.8% and 73.6% respectively), and lowest in the alpha phenotype (30.1%, overall $p<0.0001$). CKD was most common in the beta phenotype (52.0%, overall $p<0.0001$) while in the others was lower (31.4% in alpha, 28.6% in gamma, and 35.0% in delta). The highest prevalence of AKI with CKD was again in the beta phenotype (52.8%), compared to alpha (25.0%), gamma (26.6%), or delta (34.8%, $p<0.0001$). AKD occurred more often in the delta (57.4%) and beta (50.0%) phenotypes compared to alpha (32.7%) and gamma (40.1%, $p=0.0002$).

Conclusions: Severe AKI was significantly more common among patients with beta and delta phenotypes. However, the beta phenotype had a higher level of underlying CKD that predisposed to new AKI. Alpha and gamma phenotypes not only had lower rates of AKI, but these cases were less likely to progress to AKD.

	Total	Alpha	Beta	Gamma	Delta	P-value
Severe AKI	633/1180 (53.6%)	116/386$_a$ (30.1%)	195/265$_b$ (73.6%)	158/326$_c$ (48.5%)	164/203$_b$ (80.8%)	<0.0001
CKD	445/1243 (35.8%)	131/417$_a$ (31.4%)	144/277$_b$ (52.0%)	98/343$_a$ (28.6%)	72/206$_a$ (35.0%)	<0.0001
AKI* with CKD	231/633 (36.5%)	29/116$_a$ (25.0%)	103/195$_b$ (52.8%)	42/158$_a$ (26.6%)	57/164$_a$ (34.8%)	<0.0001
AKD*	290/626 (46.3%)	37/113$_a$ (32.7%)	97/194$_{b,c}$ (50.0%)	63/157$_{a,b}$ (40.1%)	93/162$_c$ (57.4%)	0.0002

Values in the same row not sharing the same subscript letter are significantly different for the pairwise comparisons within a row. *Includes only patients with severe AKI.

PO0094

Comparison of Clinical Characteristics of AKI in Patients with Glyphosate and Glufosinate Herbicide Poisoning

In O Sun, A young Cho. *Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.*

Background: This study aimed to investigate the clinical characteristics of acute kidney injury in patients with glyphosate and glufosinate herbicide poisoning.

Methods: From 2008 to 2019, 230 patients admitted to our hospital after glyphosate or glufosinate herbicide poisoning. We compared the clinical characteristics of acute kidney injury in patients with glyphosate (n=173) and glufosinate (n=57) herbicide poisoning.

Results: The patinets included 155 men and 75 women with a mean age of 59 years (range, 22-101 years). There were no differences in the clinical characteristics between glyphosate and glufosinate poisoning except for serum bicarbonate and intensive care unit admission. The serum bicarbonate level was lower in glufosinate intoxication than in glyphosate intoxication (19.8 ± 4.5 vs. 21.5 ± 3.9, p<0.01). In comparison with patients of glyphosate poisoning, patients with glufosinate poisoning experienced intubation (59.6% vs. 19.7%, P<0.01) and intensive care unit admission (68.4% vs. 38.2%, p<0.01) more frequently. The overall incidence of acute kidney injury was 38.3% in this study, and there was no difference between two groups (35.8% vs. 45.6%, p=0.123).

Conclusions: Patients with glufosinate intoxication showed more severe type of clinical manifestation and intensive care unit admission rates than glyphosate intoxication.

PO0095

Clinical Significance of Hypoalbuminemia for AKI in Patients with Scrub Typhus

In O Sun, A young Cho. *Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.*

Background: The aim of this study is to investigate the clinical significance of hypoalguminemia for acute kidney injury in patients with scrub typhus.

Methods: From 2009 to 2018, 611 patients were diagnosed with scrub typhus. We divided the patients into two groups (normoalbuminemia vs. hypoalbuminemia) based on the serum albumin level of 3.0 g/dL, and compared the incidence, clinical characteristics, and severity of acute kidney injury based on RIFLE classification between two groups.

Results: Of the total 611 patients, 78 (12.8%) were categorized as hypoalbuminemia group. Compared with patients in normoalbuminemia group, patients in hypoalbuminemia group were older (73 ± 9 vs. 62 ± 14, p<0.01) and had higher total leukocyte counts (10.2×10^3/mL vs. 6.7×10^3/mL, p<0.01). Hypoalbuminemia group showed significantly longer hospital stay (9.6 ± 6.1 vs. 6.1 ± 3.0, p<0.01) and higher incidence of complications in respiratory system (50% vs. 14%, p<0.01), cardiovascular system (28% vs. 11%, p<0.01), neurologic system. Furthermore, acute kidney injury (58% vs. 18%, p<0.01) was also developed in hypoalbuminemia group. The overall incidence of acute kidney injury was 23.1%; of which, 14.9%, 7.0% and 1.2% were classified as Risk, Injury and Failure, respectively. The serum albumin level correlated with acute kidney injury severity (3.4 ± 0.5 vs. 3.0 ± 0.5 vs. 2.6 ± 0.3, p<0.05). In a multivariate logistic regression analysis for predicting acute kidney injury, age, presence of co-morbidities such as chronic kidney disease, diabetes, or hypertension, total bilirubin, leukocytosis and hypoalbuminemia were significant predictors of acute kidney injury.

Conclusions: Hypoalbuminemia was closely associated with scrub typhus associated with acute kidney injury.

PO0096

Risk Factors for Patient Subgroups with Distinct Health Utility Profiles Following AKI

Yuenting D. Kwong,[1] Kathleen D. Liu,[1] John A. Kellum,[2] Christine Miaskowski.[1] *[1]University of California San Francisco, San Francisco, CA; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Health-related quality of life (HRQOL) after dialysis initiation for acute kidney injury (AKI) is low. We sought to determine patient subgroups with distinct health utility profiles at 60 days after diagnosis of AKI and evaluated the potential risk factors for these profiles.

Methods: The Biologic Markers of Renal Recovery for the Kidney (BioMaRK) study is an observational cohort of patients nested within the Veterans Affairs/National Institutes of Health Acute Renal Failure Trial Network study. Clinical characteristics and biomarkers of inflammation were collected from 817 patients with AKI around the time of dialysis initiation. Of these patients, 402 were alive at 60 days and 328 completed the Health Utility Index, which measures 8 health attributes and calculates an overall HRQOL score. Using latent class analysis (LCA) of these 8 attributes, we identified patient subgroups with distinct health utility profiles and risk factors associated with subgroup membership.

Results: Two subgroups were identified with 47% of patients being included in the low healthy utility subgroup (i.e. Low HU subgroup). This subgroup was characterized as having higher median ambulation, emotion, cognition, and pain scores. The remaining (i.e., 53%) were labeled as belonging in the subgroup with higher health utility (i.e. High HU subgroup). No significant differences were found between the two subgroups in terms of age, gender, or race. However, patients in the Low HU subgroup were more likely to have diabetes, lower albumin levels, and higher SOFA score. In addition, patients in the Low HU subgroup had more dialysis days, hospital days, and ICU days. No between groups differences were found in the assignment of high versus normal dialysis intensity. Day 1 biomarkers of GM-CSF, IL1, IL6, IL8, TNF-alpha, IL10, TNFR1, TNFR2, MIF, IL18 and DR5 were not statistically different between the two subgroups. However, patients in the Low HU subgroup had higher IL8, TNFR1, TNFR2, and DR5 levels at day 8.

Conclusions: Using a person-centered analytic technique (i.e., LCA), we found two subgroups of patients with distinct health utility profiles among 60 day survivors following acute kidney injury. Demographic, clinical, and biomarker characteristics associated with each subgroup may be used to identify patients at high risk of poor HRQOL.

PO0097

Safety and Efficacy of a New Simplified Regional Citrate Anticoagulation Protocol for Continuous Venovenous Hemodiafiltration and Sustained Low-Efficiency Dialysis Focused on Acid-Base Balance Optimization and Prevention of Kidney Replacement Therapy-Induced Hypophosphatemia

Francesca Di Mario,[1] Paolo Greco,[1] Caterina Maccari,[1] Elisabetta Parenti,[1] Giovanni maria Rossi,[1] Valentina Pistolesi,[2] Santo Morabito,[2] Enrico Fiaccadori.[1] Nephrology Unit, Parma University Hospital, Parma, Italy *[1]UO Nefrologia, Azienda Ospedaliera-Universitaria Parma, Parma, Italy; [2]Umberto I Policlinico di Roma, Roma, Italy.*

Background: Regional citrate anticoagulation (RCA) is the first-line anticoagulation strategy for Kidney Replacement Therapy (KRT) in Acute Kidney Injury (AKI). Hypophosphatemia is a common electrolyte disorder in the ICU, especially in course of prolonged and highly efficient KRTs. This pilot study is aimed at evaluating a simplified RCA protocol for Continuous Venovenous Hemodiafiltration (CVVHDF) and Sustained Low Efficiency Dialysis (SLED), based on the combination of a low-concentration citrate solution with a phosphate-containing solution.

Methods: KRT was performed in ICU patients with AKI by the Prismax system (Baxter) and polyacrylonitrile AN69 filters (ST 150, 1.5 m2, Baxter), combining a 18 mmol/l pre-dilution trisodium citrate solution (Regiocit 18/0, Baxter) with a phosphate-containing solution used as both dialysate and post-dilution replacement (Ca^{2+} 0, HPO_4^{2-} 1, Mg^{2+} 0.75, HCO_3^- 22 mmol/l; Biphozyl, Baxter). Calcium chloride (CaCl 10%) was infused in a central venous line to maintain the systemic Ca^{2+} within a normal range. In each patient three consecutive daily 8-h SLED sessions or 72-h CVVHDF were evaluated. Phosphorus (P) losses were replaced, when needed, with sodium glycerophosphate pentahydrate (Glycophos™ 20 mmol/20 ml, Fresenius Kabi Norge AS, Halden, Norvegia).

Results: 20 patients with AKI on SLED and 10 on CVVHDF were studied (mean APACHE II score 23.8). No premature interruptions for irreversible filter clotting occurred; prescribed dialysis dose was delivered in 95% of cases. No statistically significant differences were observed between systemic ACT measured at KRT start and at different times during KRT. No major hemorrhagic events nor clinically relevant episodes of hypo- or hypercalcemia were observed. Acid-base status and serum phosphorus levels were effectively maintained.

Conclusions: Our simplified RCA protocol is safe and efficacious both for SLED and CVVHDF, allowing to optimizing acid-base balance and to preventing KRT-related hypophosphatemia.

PO0098

Relationship Between the Presence of Infectious Disease and Clinical Outcomes of Patients with Cardiorenal Syndrome Type 1

Jonathan Chavez,[1,2] Guillermo Garcia-Garcia,[1,2] Jorge I. Michel gonzález.[1,2] *[1]Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; [2]Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud. CUCS, Guadalajara, Mexico.*

Background: Cardiorenal Syndrome type 1 (CRS-1) can be triggered by an infection. The pathophysiological basis is vascular congestion, which is why it has been treated with different strategies of diuretics, but in the presence of infection, the inflammatory, neurohormonal and hemodynamic effects can compromise the efficacy of the diuretic therapy and potentially worsen clinical evolution. Here we compare the clinical evolution during the hospitalization of CRS-1 patients with and without infection.

Methods: This is a retrospective cohort study conducted in the Hospital Civil of Guadalajara "Fray Antonio Alcalde", from January 2015 to September 2018. Conducted in CRS-1 patients, we showed the clinical evolution and diuretic strategies analyzed according to the presence or absence of infection.

Results: We identified 63 patients classified as having CRS-1, 28 (44.4%) were classified as having an infectious disease. The mean age was 62 years (±14.6) and 58 (±12.4) in the group with infection and no infection, respectively. There were no statistically significant differences between the clinical outcomes of both groups. The median length of hospital stay was 8 days in the group with infection and 7 days in the group without infection (p=0.065). Three patients (10.7%) of the group with infection received renal replacement therapy and 1 patient (2.9%) in the group without infection (p=0.315). In the group with infection, 2 patients died (7.1%), whereas in the uninfected group there were no deaths (p=0.194). sCr values tend to diminish in a similar manner in both groups. We found that all patients received furosemide at least during the first five days of hospitalization and the strategy of the diuretic chosen was similar between groups.

Conclusions: We showed that the clinical evolution of patients with CRS-1 is similar in the presence or absence of infection. We anticipate that this study may be a reason to expand knowledge in patients with CRS-1 and the presence of infection.

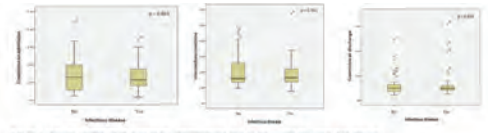

Figure 1- serum creatinine at admission, intermediate and at discharge between two groups.

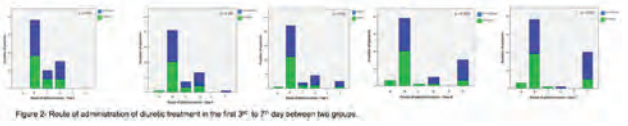

Figure 2- Route of administration of diuretic treatment in the first 3rd to 7th day between two groups.

PO0099

Design of START: A Phase 2 Study Evaluating the Safety and Efficacy of RBT-1 on Preconditioning Response Biomarkers in Subjects Undergoing Cardiac Surgery

Bhupinder Singh,[1,2] Philip T. Lavin,[8] Andreas Orfanos,[3] Stacey Ruiz,[2] Donald J. Keyser,[2] Alvaro F. Guillem,[2] Richard A. Zager,[4,5] Navdeep Tangri,[6] Jean-Claude Tardif.[7] *[1]University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA; [2]Renibus Therapeutics, Southlake, TX; [3]Montreal Health Innovations Coordinating Center, Montreal, QC, Canada; [4]Fred Hutchinson Cancer Research Center, Seattle, WA; [5]University of Washington Department of Medicine, Seattle, WA; [6]University of Manitoba, University of Manitoba, Winnipeg, MB, CA, Winnipeg, MB, Canada; [7]Institut De Cardiologie de Montreal, Montreal, QC, Canada; [8]Boston Biostatistics Research Foundation, Framingham, MA.*

Background: Cardiac surgery is associated with an increased risk of acute kidney injury (AKI). RBT-1 induces non-ischemic tissue preconditioning that has shown organ protective effects in several animal models of AKI. Markers of cytoprotection observed with RBT-1 treatment in animals were also found to be upregulated in a Phase 1 study of RBT-1 in healthy volunteers and subjects with Stages 3 and 4 chronic kidney disease (CKD). Based on these data, we have designed a Phase 2, placebo-controlled, double-blind, randomized, multicenter study that will assess the effect of RBT-1 on preconditioning response biomarkers in subjects scheduled to undergo cardiac surgery

Methods: Study Design: This study will enroll 126 subjects scheduled to undergo coronary artery bypass graft (CABG) and/or cardiac valve surgery. Eligible subjects will be randomized to receive a single dose of RBT-1 or placebo via intravenous infusion between 24 and 48 hours prior to scheduled cardiac surgery. Subjects will be followed through Day 90. **Inclusion/Exclusion Criteria:** Subjects eligible for enrollment include adults who are scheduled to undergo non-emergent, on-pump coronary artery and/or cardiac valve surgery. Major exclusion criteria include CKD with eGFR ≤20 ml/min/1.73m^2 or need for dialysis.

Results: Objectives: The primary objective of this study is to evaluate the efficacy of RBT-1 on preconditioning response biomarkers from baseline through Day 3 post-cardiac surgery. Based on preclinical data, plasma heme oxygenase-1 [HO-1], ferritin, and interleukin-10 [IL-10]) have been identified as the relevant biomarkers for this study. Secondary objectives include change in tubular injury biomarkers and incidence of AKI based on KDIGO classification. Exploratory objectives include the occurrence of major adverse kidney events (MAKE) through Days 30 and 90.

Conclusions: The multinational START study will assess the cytoprotective preconditioning response to RBT-1 in subjects undergoing cardiac surgery.

Acute Peritoneal Dialysis During the COVID-19 Pandemic in New York City

Nina J. Caplin,[1,2] Manish Tandon,[1,2] Olga Zhdanova,[1] Richard Amerling,[3] Nathan Thompson.[1] *[1]NYU Langone Health, New York, NY; [2]Bellevue Hospital Center, New York, NY; [3]Saint George's University, Saint George, Grenada.*

Introduction: The dramatic spread of COVID-19 in March 2020 threatened to overwhelm ICU capacity. At the peak we had more than 120 patients in the ICU. About 40% of the ICU patients required RRT due to AKI. Our ability to provide RRT with CVVH and IHD was severely limited by critical shortages of equipment and personnel. We rapidly established an acute PD program at Bellevue hospital for AKI patients. The acute PD program turned out to be instrumental in the BH response to COVID AKI.

Case Description: Patients All patients who needed RRT in the ICU were eligible to receive PD catheters except for those with prior abdominal surgery. 36/38 patients who received catheters were Covid (+). Proning was not always planned; we did not use this as a contraindication. We were able to successfully perform adequate PD on patients who were proned with minimal complications. **Surgical Support** Catheters were placed using a limited cut down to the peritoneal membrane through the rectus muscle at bedside; most of the patients were intubated and sedated. **Training and Initial Experience** A nurse affiliated with Bellevue's outpatient dialysis unit helped make videos and trained the lead nephrologist on how to perform PD and how to use a Cycler. 25 people were on the PD team and we were able to provide exchanges 24 hours per day. Exchanges were initially performed manually every 1-2 hours. Eventually we acquired 18 cyclers which greatly eased the workload. **Outcomes** As of May 8, 2020 63 patients were evaluated, 38 PD catheters were placed with 35 used for exchanges. 2 patients had catheters placed but recovered renal function prior to starting PD. 1/38 was nonfunctioning and changed to IHD. 15/35 survived >30 days; 8 recovered renal function; 20 expired <30 days.

Discussion: Because of the shortage of our typically used dialysis modalities we were compelled to start an acute PD program. No patient on PD required additional dialytic support with IHD or CVVH. PD was well tolerated by ventilated patients with hemodynamic instability. Acute PD more than adequately filled the gap in treatment options during this unprecedented crisis

PO0101

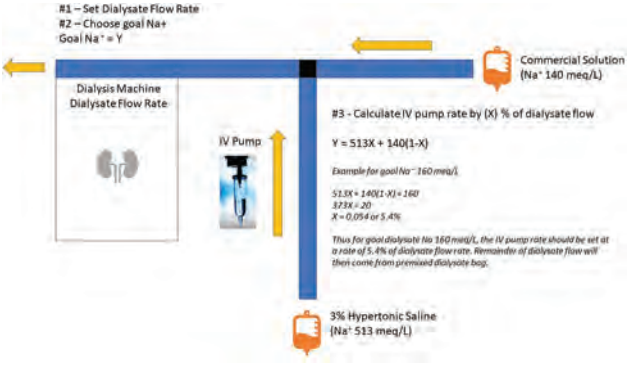
Novel Prescription of Continuous Venovenous Hemodialysis Dialysate Na^+ in a Patient with Cerebral Edema and Severe Hypernatremia

Brian Y. Young, Nasim Wiegley, John Howard. *University of California at Davis, Division of Nephrology, Department of Internal Medicine, Sacramento, CA.*

Introduction: AKI necessitating dialysis is difficult in patients with traumatic brain injury. Slow clearance and increased dialysate Na^+ are recommended. Yet, barriers in adjusting dialysate Na^+ may occur with premixed commercial dialysate. We present a unique method of prescribing CVVHD to prevent Na^+ overcorrection in a patient with cerebral edema and severe hypernatremia.

Case Description: An 18 year old male presented with polytrauma after a motor vehicle accident. His injuries included multiple intracranial bleeds. On day 13, nephrology was consulted for AKI, BUN > 150 mg/dl, and refractory hyperkalemia. Head CT scan showed known bleeds and diffuse cerebral edema. At consult, IV 3% saline had already resulted in plasma Na^+ ranging 161-166 meq/L for > 3 days. Our hospital performs CVVHD via NxStage with commercial dialysate bags with Na^+ fixed at 140 meq/L. To avoid Na^+ overcorrection, we combined commercial bags and 3% saline in-circuit. Initially, clearance goals were set by dialysate flow rate. Then, separate IV pump for 3% saline was Y connected to the pre-pump dialysate line, and IV pump rate was calculated to adjust final dialysate Na^+ (Figure). Final dialysate flow equated to IV pump flow plus residual drawn from commercial bags. Our initial goal dialysate Na^+ was 160 meq/L. Dialysis solution labs steadily showed adjusted dialysate Na^+ of about 158$^+$ meq/L at initiation. Changes to other dialysate factors (i.e. K^+, $HCO3^-$) were negligible. CVVHD was started with titration of the dialysis-attached 3% saline IV pump to control of dialysate Na^+. All other 3% saline was discontinued. Though the patient ultimately died from overall injuries, change in plasma Na^+ was slow and controlled (10 meq in 7 days).

Discussion: We present a new method for adjusting dialysate Na^+ using in-circuit mixing of commercial dialysate and 3% saline. Our method used readily available solutions, was easy to titrate, depended solely on dialysis, and did not require manipulation of commercial bags. We suggest consideration of our method in CVVHD, brain trauma, and hypernatremia.



PO0102

Use of Azathioprine in Treating Severe Corticosteroid-Resistant Acute Interstitial Nephritis

Sameed K. Lodhi,[1] Sravan Jasti,[1] Hareem Ghazanfar.[2] *[1]Carle Foundation, Urbana, IL; [2]King Edward Medical University, Lahore, Pakistan.*

Introduction: Acute interstitial nephritis (AIN) is a pattern of renal injury characterized by inflammatory infiltrate in renal interstitium leading to decline in renal function. It is commonly caused by drugs such as penicillin, diuretics and proton pump inhibitors. Other causes include autoimmune diseases or systemic infections. Treatment involves removing the offending agent and steroids in severe cases. We describe a case of drug induced severe AIN refractory to steroids that is treated with azathioprine, an immunosuppressant drug that inhibits purine synthesis.

Case Description: A 20 year old Caucasian female with past medical history of gastroesophageal reflux disease (GERD) presented to the emergency with severe nausea, vomiting and oliguria. She had been taking omeprazole for 2 weeks prior to presentation. Initial labs indicated eosinophilia, raised creatinine levels of 3.5 mg/dl and Blood Urea Nitrogen of 27 mg/dl. Renal biopsy was done which showed severe acute interstitial nephritis with raised eosinophils. The diagnosis of Acute Kidney Injury secondary to drug induced AIN was made and patient was given pulse dose steroids for 3 days. She was discharged on 60 mg of prednisolone daily. A month later, the patient's creatinine improved to 1.75 from a peak of 6.27 mg/dl. The steroid dose was tapered to 40 mg. However, the creatinine raised to 2.7 mg/dl again due to which prednisolone dose was

increased to 60 mg/dl. Kidney function did not improve even after 2 months and re-biopsy revealed ongoing interstitial nephritis. Consequently, the patient was given a trial of azathioprine 200 mg daily with reduced prednisolone dose (40 mg/dl). Creatinine levels decreased moderately after 2 weeks to 1.70 mg/dl due to which the prednisolone dose was further tapered to 20 mg/dl.

Discussion: In past, azathioprine has shown promise in treatment of lupus nephritis and IgA nephropathy. To our knowledge, this is the first reported case of successful treatment of steroid resistant severe drug induced AIN with azathioprine. As it has lesser side effects and better compliance than steroids, it is suggested that azathioprine may be considered in future as an adjuvant or alternative first line of treatment for AIN. Larger, randomized clinical trials need to be conducted in order to establish optimal dosing and long term effectiveness of azathioprine in treating AIN.

PO0103

The Successful Treatment of Bile Cast Nephropathy with Plasma Exchange

Swetha Reddy, Theresa Kinard, Margaret Ryan, Leslie F. Thomas. *Mayo Clinic Arizona, Scottsdale, AZ.*

Introduction: Bile cast nephropathy is a condition of renal dysfunction in the setting of hyperbilirubinemia. There are very few cases of this condition reported in literature, and there is a lack of established treatment guidelines. We report the successful management of three patients with bile cast nephropathy using therapeutic plasma exchange (TPE).

Case Description: CASE 1: A 59 year old man with stage 3 colon carcinoma on Capecitabine developed chemotherapy-induced liver toxicity resulting in severe cholestasis and biopsy-proven bile cast nephropathy. He underwent TPE. CASE 2: A 69 year old man with history of colon cancer status post remote hemicolectomy was admitted with pruritus and acute kidney injury (AKI). CT abdomen without contrast showed a 6 cm liver mass with bile duct dilatation, a biopsy proven metastasis from his previous colon cancer. A kidney biopsy confirmed bile cast nephropathy. The patient was started on hemodialysis (HD), and a biliary stent was placed. He was treated with TPE. He opted for hospice due to cancer CASE 3: A 38 year old man was admitted with severe acute alcoholic hepatitis and AKI. A kidney biopsy confirmed bile cast nephropathy. He underwent TPE and a total of four sessions of HD. The clinical course in our patients with biopsy proven bile cast nephropathy prior to and after TPE therapy is noted in Table 1.

Discussion: Our patients had acute liver and kidney failure with no underlying chronic liver disease. 1-1.2 plasma volume exchange was performed with each procedure with a combination of plasma and 5% albumin. A good response to TPE in decreased total bilirubin level and improvement in renal function was noted. There were no serious apheresis adverse events, and all procedures were tolerated well by the patients. Medical management of bile cast nephropathy such as steroids and cholestyramine have shown limited or no benefit. Renal replacement therapy has also been shown to be of limited benefit and should be mainly instituted for the treatment of AKI. In bile cast nephropathy, TPE may help in the clearance of bile acid crystals and reduction of proinflammatory molecules which contribute to acute liver and kidney injury. In this small case series, institution of TPE appeared to improve the clinical course of patients with bile cast nephropathy.

Case Number	AKI Stage on admission	Number of TPE sessions	Creatinine (mg/dl) At Baseline	Creatinine (mg/dl) Admission	Creatinine (mg/dl) At last TPE	Creatinine (mg/dl) 3 weeks post TPE	Direct Bilirubin (mg/dl) Admission	Direct Bilirubin (mg/dl) After last TPE	Complications from TPE
Case 1	3	12	0.9	3.5	1.3	0.8	16.3	7.7	None
Case 2	3	7	1.1	7.1	2.8	Hospice	31.8	3.6	Mild Hypocalcemia
Case 3	3	7	0.8	3.76	1.8	1.3	46.4	7.1	None

PO0104

An Unusual Case of IgA Nephropathy Associated with Parvovirus B19

Laila S. Lakhani, Hashim Abbas, Mohamed G. Atta. *Johns Hopkins University, Baltimore, MD.*

Introduction: Parvovirus is known to cause upper respiratory infections in children and the immunosuppressed. It's association with kidney disease has been sporadically reported in literature, mostly causing lupus like glomerulonephritis with endocapillary proliferation. We describe a unique case of IgA Nephropathy (IgAN) in an African American patient associated with Parvovirus B19.

Case Description: A 23 year old African American female with a history of Hemoglobin C disease presented with one week of generalized malaise, abdominal pain and nausea, found to have non-oliguric AKI with Creatinine 2.5 mg/dL (baseline Cr: 0.6 mg/dL). Within one week, her Creatinine peaked at 7.4 mg/dL. Urinalysis showed 3+ protein, 5 white cells and 9 red cells. Urine microscopy was bland. Spot urine protein to creatinine ratio was 3.84g. Serologies were notable for normal Complements, negative ANA, ANCA, Hepatitis B, Hepatitis C and HIV along with unremarkable serum and urine electrophoresis. Renal ultrasound ruled out hydronephrosis. Labs were also notable for worsening hemolytic anemia. A renal biopsy was pursued, that showed diffuse proliferative glomerulonephritis with dominant IgA deposits. Mesangial and endocapillary proliferation was noted without any crescents. The oxford classification was: M1, E1, S0, T0, C0. Given this atypical IgA phenotype, infectious work was pursued, that came back positive for Parvovirus IgM and detectable Parvovirus DNA. She was started on Pulse dose steroids; immunosuppressives were held off given the absence of crescents. Her proteinuria partially responded to steroids along with an improvement in AKI (Cr: 1.1 mg/dL), after which steroids were tapered.

Discussion: This case provides an example of AKI associated with Parvovirus infection. Since IgAN is predominantly seen in Caucasians, it is not surprising that only 3% African Americans were included in the cohort on which the Oxford Classification was coined. The improvement in acute kidney injury with a short course of steroids is suggestive of Parvovirus related process more than the typical endocapillary proliferation related to IgAN. The extension of Oxford Classification in the African American population can thus be challenging and potentially misleading as seen in this case. A repeat renal biopsy may be warranted to assess the underlying diagnosis of IgA Nephropathy and should be treated based on findings.

PO0105

Angioimmunoblast T-Cell Lymphoma Masquerading as Type II Cryoglobulinemia and AKI: A Case Report

Li Xiangyang, Haiyan He. *University of Hong Kong-Shenzhen Hospital, Shenzhen, China.*

Introduction: Angioimmunoblastic T cell lymphoma (AITL), which belongs to the non-Hodgkin's lymphoma (NHL), is an infrequent hematological malignancy yet with variable and often atypical presentations. The presence of dysproteinemia, autoantibodies and systemic involvement in AITL have often led to a delay in diagnosis and/or misdiagnosis in practice.

Case Description: A 67-year old previously healthy housewife presented with 2-month history of intermittent joint pain affecting the right wrist and right hand, and a 3-day history bilateral lower limb edema. Her serum creatinine rose from 67 to 197 μmol/L and leg swelling appeared after a moderate fever prior to admission. The physical examinations at presentation were insignificant except for bilateral lower-leg pitting edema. Laboratory investigations after admission were notable for ascending serum creatinine levels, moderate anemia, marked hypocomplementemia with multiple autoantibodies of ANA, anti-cardiolipin-IgM and direct antiglobulin. The serum and urinary Immunofixation and serum cryoglobulinemia tests were all negative, while the serum κ to λ light chain ratio was depressed to 0.231. A renal biopsy conducted on day 9 revealed a diffuse proliferative glomerulonephritis with intracapillary pseudo-thrombi formation with orderly arranged microtubular structures of 20-35 nm in diameter in the subendothelial and mesangial area on electron microscopy. The patient developed on day 13 symmetrical finger-tip numbness and tingling with weaknesses in her hands and legs. A diagnosis of cryoglobulinemia complicated with cryoglobulinemic glomerulonephritis and polyneuropathy was made. She responded well with methylprednisolone (1500mg in divided pulse, maintained on 40 mg daily afterwards), intermittent hemodialysis, 5 alternate-day plasma exchange and 600mg rituximab (375mg/m^2). 3 months later, however, generalized pruritic rash, weight loss, and significant groin lymphadenopathy emerged and progressed. An inguinal excisional lymph node biopsy performed at month 8 revealed AITL as the underlying disease.

Discussion: AITL and associated dysimmunity can give rise to multiorgan involvement, while the presence of autoantibodies, monoclonal gammopathy and cryoglobulinemia might conceal it as the underlying disorder. In various auto-immune diseases, it is advisable the clinicians take into consideration the multi-faceted lymphoma.

PO0106

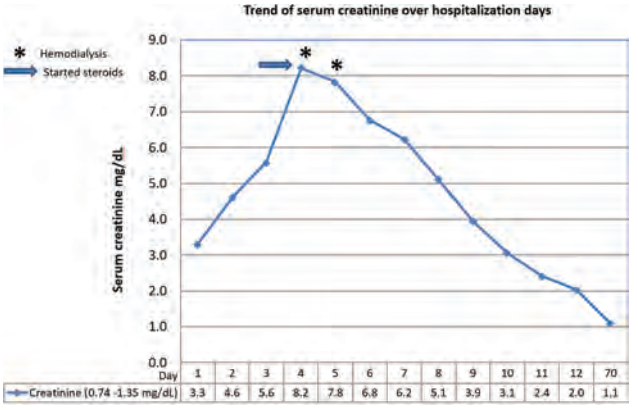
Weil Disease Causing Kidney Failure Responsive to Steroids

Lagu A. Androga. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Introduction: Weil's disease is a life-threatening form of leptospirosis with a potential mortality >22%. Multi-organ dysfunction, acute interstitial nephritis (AIN) and/or acute tubular necrosis (ATN) can occur. We present a patient with Weil's disease who developed acute kidney injury requiring hemodialysis. Treatment with steroids resulted in return to baseline renal function.

Case Description: A 61 year old Caucasian male presented with fevers, lower extremity myalgias, non-bloody emesis, and abdominal pain that began 11 days after swimming in Jamaica. On admission, he was febrile, tachycardic but normotensive with jaundice and leg edema. Admission labs revealed BUN 37, serum creatinine (SCr) 3.3mg/dL (baseline SCr 1), Hemoglobin 14.6g/dL, platelets 25,000, CRP 171.5mg/dL, ESR 41mm/h, serum albumin 3g/dL, AST 153, ALT 75, and direct bilirubin 7.8mg/dL. Urinalysis showed proteinuria 545mg/dL, sterile pyuria of 4-10 WBC, and positive hemoglobin. Creatinine kinase was 5143. Given his history and presentation, leptospira IgM testing was performed and found to be positive. He received supportive therapy and a 10 day course of IV ceftriaxone. His kidney function deteriorated with SCr peak of 8.22mg/L on day 4 (Figure 1). Given anuria and fluid overload, hemodialysis was started. A kidney biopsy was contemplated to assess for AIN, podocytopathy, pigment nephropathy, ATN or a combination, but contraindicated due to thrombocytopenia. Empiric treatment with steroids was started on day 4 (Figure 1) with 250mg IV Solumedrol for 3 days, followed by 40mg daily of oral prednisone tapered by 10mg every 2 weeks over 8 weeks. Urine output improved gradually on day 6 and day 7 to 1.5 and 5.7 L/day, respectively. SCr also started to decrease. At 2 months post hospital discharge, SCr was 1mg/dL on 4mg of prednisone.

Discussion: Renal failure in Weil's disease can be severe, requiring dialysis. Treatment with steroids for presumed AIN can be beneficial when initiated early.



PO0107

Renal Artery Thrombosis in a Patient Homozygous for Plasminogen Activator Inhibitor-1 4G Allele

Frank S. Santana Martinez, Siddharth Mehta, Shyam K. Poudel, Parth R. Shah. *American College of Physicians, Philadelphia, PA.*

Introduction: Renal artery thrombosis is a serious, uncommon, and often undiagnosed condition. Physicians need to consider this diagnosis in unexplained flank pain, especially in the presence of risk factors. Plasminogen activator inhibitor-1 (PAI-1) is the major inhibitor of tissue-type plasminogen activator. Fibrinolysis is impaired due to increased plasma PAI-1 levels which play an important role in the pathogenesis of thrombotic disorders. Homozygous for the 4G allele had increased plasma PAI-1 concentrations.

Case Description: A 53 years old male smoker with hypertension, presented to the emergency room complaining of abdominal pain and pink urine for 3 days. His BP was 186/120 mmHg and pulse 100/min. Physical exam was consistent with right flank tenderness. Urinalysis showed high gravity, high amount of protein, glucose, and blood. Creatinine was 1.6 and the baseline was unknown. CTA showed right renal artery occlusion. The patient was transferred to CCU and started on clevidipine and heparin drip. Arteriogram and directed thrombolysis were performed. Despite these interventions, his creatinine trend peaked at 2.85, whereas hemoglobin started dropping substantially. High rate IV fluids, a workup for malignancy, and hypercoagulable were started with subsequent stent placement for reperfusion. After 3 days of directed thrombolysis, he was transferred to wards. Urine output decreased and a Foley catheter was placed. the patient was started on clonidine, amlodipine, and labetalol. After 10 days of hospitalization, all workup was unremarkable. PAI-1 4G/5G study was homozygous for 4G allele. The patient's medical condition improved. He was discharged and advised to follow up as an outpatient.

Discussion: Studies have proven the link between PAI-1 4G and thrombotic events, however, most of the evidence shows a link between PAI-1 4G and venous thrombosis. In this patient, the fact of him being homozygous for PAI-1 4G allele led to arterial thrombosis. Therefore, it might be prudent to include a PAI-1 workup in prothrombotic studies. In renal artery thrombosis, a cause must be established. Although there are other common causes of arterial thrombosis, PAI-1 4G should be considered as a potential cause in patients with few or no risk factors. This case report glimpses the relationship between an uncommon genetic mutation and a rare diagnosis.

PO0108

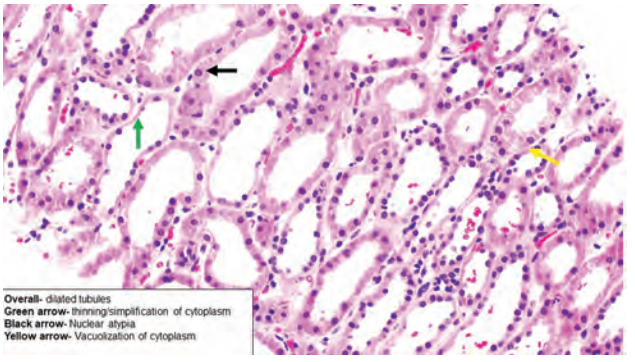
Ganja Kidney: Acute Tubular Injury Associated with Synthetic Marijuana, A Rising Incidence

Ivette Cardenas Esprit,[3,4] Fernando Lopez Osma,[1,2] Don H. Esprit.[1,2] *[1]Northern Florida Kidney Care by NPS, Gainesville, FL; [2]North Florida Regional Medical Center, Gainesville, FL; [3]Universidad del Sagrado Corazon, San Juan, Puerto Rico; [4]Hospital Provincial Universitario Camilo Cienfuegos, Sancti Spiritus, Cuba.*

Introduction: Synthetic cannabinoids (SC), "Ganja", have been used as recreational drugs with increasing popularity among young adults but have significant toxicity. We present a case of acute kidney failure in a relatively healthy young male individual after using marijuana pills.

Case Description: 31-year-old hispanic male with no known past medical history presented to the emergency room with nausea and vomiting for 2 days. He stated that he has recently started taking "Ganja" pills to help with relaxation after losing work due to the Covid -19 pandemic. Vital signs were within normal limits and physical findings were unremarkable. Laboratory data were significant for serum creatinine of 10.14 mg/dl, blood urea nitrogen of 91 mg/dl, estimated glomerular filtration rate of 8 ml/min, and serum potassium of 7 meq/l. Urine toxicology was positive for cannabinoids. Complements and serologies were all negative. Renal ultrasound was unremarkable. A renal biopsy showed acute tubular injury with tubular dilatation, cytoplasmic simplification and vacuolization (image). Intermittent hemodialysis was initiated but later discontinued after renal recovery. On discharge, serum creatinine was 1.2 mg/dl.

Discussion: Cannabinoids are found in natural marijuana and contain many active compounds, but delta-9 tetrahydrocannabinol (THC) and cannabidiol (CBD) are of most interest. THC is the primary ingredient in marijuana that makes people "high". Synthetic cannabinoids are analogs of natural occurring cannabinoids that are chemically synthetized. This synthetic compound is added to the natural marijuana or other herbs to appear as a natural product. The clinical effects can be like natural marijuana which include tachycardia, conjunctival injection, slurred speech, and increase appetite due to the partial or full agonistic effect at the cannabinoid receptors. Compared to cannabis, synthetic cannabinoids have a greater risk for serious neuropsychiatric toxicity and severe acute kidney injury. We need more clinical research to identify the specific nephrotoxic agents.



PO0109

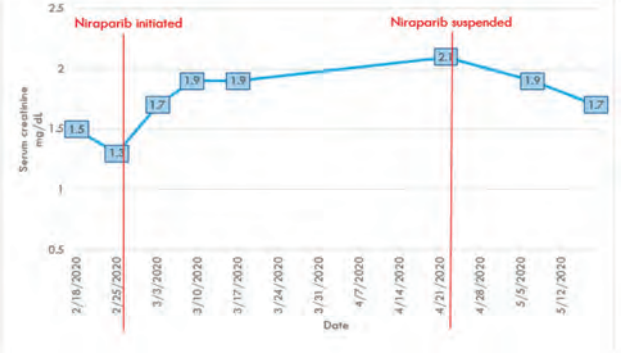
A Case of AKI Secondary to Niraparib, a Poly ADP Ribose Polymerase Inhibitor

Krishna S. Ravipati, Prathima Gopinath, Pramodh Chanumolu, Siddhartha Kattamanchi. *Marshfield Clinic, Marshfield, WI.*

Introduction: Niraparib is a poly (ADP-ribose) polymerase (PARP) inhibitor indicated for the maintenance therapy of recurrent ovarian and other gynecological cancers in patients who have complete or partial response to platinum-based chemotherapy. We present a unique case of Niraparib resulting in AKI.

Case Description: 73/F with past H/o HTN, hyperlipidemia, persistent ovarian cancer after Cisplatin treatment, currently on Niraparib therapy was evaluated for worsening creatinine. Her baseline creatinine was 0.9-1.0 mg/dL and eGFR was 54.4 - 61.4 mL/min. She initially developed AKI (creatinine 1.8 mg/dL) with cisplatin which subsequently improved to 1.3 mg/dL with eGFR of 40.2 mL/min, upon completion of cycle. Following the initiation of Niraparib, creatinine gradually trended up to 2.1 mg/dL and calculated eGFR was 23.1 mL/min. No obvious etiology for AKI was identified. Urinalysis revealed muddy brown casts w/ protein of 100 mg/dl without any evidence of UTI. Cystatin C was measured (1.72 mg/L) and Cystatin C based eGFR was 33 mL/min which indicates true AKI as opposed to elevated creatinine without renal injury. Niraparib was suspended following which creatinine started to improve (1.7 mg/dL) along with an improvement in eGFR (29.5 mL/min).

Discussion: Niraparib is a PARP inhibitor which functions by causing DNA damage resulting in apoptotic cell death. PARP inhibition in animal models has shown to be reno-protective from ischemia and it has been shown to elevate serum creatinine in drug trials without causing AKI. In our case though, patient developed AKI 2/2 ATN from niraparib. Mechanism for this is unclear as this is one of the earliest reported cases. One possible mechanism could be Apoptotic cell death of renal tubular cells.



Creatinine trend in our patient

PO0110

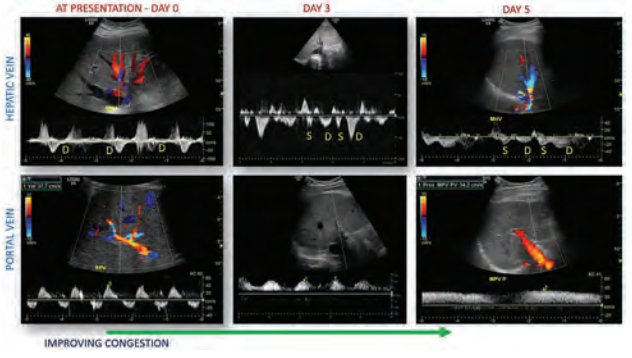
The Emerging Role of Bedside Doppler Ultrasound for Precise Assessment of Venous Congestion in Cardiorenal Syndrome

Abhilash Koratala,[1] Saqib Mahmud,[1] Olanrewaju A. Olaoye,[2] Amir Kazory.[2] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]University of Florida, Gainesville, FL.*

Introduction: Congestion is an integral component of cardiorenal syndrome and the primary reason for hospitalization in patients with heart failure (HF), making it a key target in the management of these patients. Routinely used parameters to monitor response to decongestive therapy such as physical examination, B-type natriuretic peptide, changes in weight and net fluid balance, even inferior vena cava ultrasound (IVC US) are all error prone. Doppler ultrasonography (DUS) of the portal, hepatic and when possible, intrarenal veins is an attractive alternative that can be used at bedside to accurately assess the degree of congestion and guide management strategies.

Case Description: A 55-year-old man with a history of HF with reduced ejection fraction of ~25%, hypertension and chronic kidney disease stage 3 presented with acute kidney injury of uncertain etiology. Serum creatinine (Scr) was 3.5 mg/dL for a baseline of 1.6 mg/dL. He had no symptoms except for his usual dyspnea on exertion. Physical examination was significant for crackles at lung bases and mild pitting pedal edema. Bedside US revealed increased extravascular lung water and a dilated but collapsible IVC. DUS revealed stigmata of severe congestion with a pulsatile portal vein and systolic flow reversal, and a hepatic vein with only diastolic (D) component below the baseline. Therefore, the diagnosis of congestive renal failure due to acute cardiorenal syndrome was made and high dose intravenous diuretics were initiated. The follow up DUS on days 3 and 5 showed remarkable improvement (reversal of waveforms to normal pattern) indicating progressive decongestion [Figure]. His diuretic therapy was titrated based on these findings and Scr improved to 2 mg/dL at discharge.

Discussion: Bedside DUS assessment of hepatic and portal veins aids in management of patients with HF by non-invasively monitoring the efficacy of decongestive therapy, and serves as a valuable adjunct to conventional clinical evaluation.



PO0111

Furosemide: An Unusual Cause of Acute Interstitial Nephritis Requiring Hemodialysis: First Case Report

Hassan Alhalabi. *Dallas Nephrology Associates, Irving, TX.*

Introduction: Furosemide, a loop diuretic, is widely used for volume control and is a known cause of acute interstitial nephritis. However, AIN due to furosemide is not typically associated with abrupt and severe acute kidney injury (AKI). Here we report a patient who developed severe AKI requiring hemodialysis shortly after receiving furosemide.

Case Description: A 65 year old male with a history of hypertension was started on oral furosemide 20 mg daily for edema in his legs. One week later he presented to the emergency room complaining of oliguria and worsening edema. Laboratory findings were significant for a serum creatinine of 37.8 mg/dL and potassium 7.8 mmol/L. Patient required emergent hemodialysis for volume control, clearance and hyperkalemia, and continued to require HD every other day. Serologic work-up included a normal C3, C4, ANA, ANCA, anti-GBM, and SPEP/UPEP. Urinalysis showed small blood, no protein, 12-15 RBC's, 10 WBC's. Renal ultrasound was normal. A kidney biopsy was performed which demonstrated interstitial edema with patchy inflammatory cell infiltrates with eosinophils. The tubules were dilated and showed significant degenerative changes in tubular epithelial cells. The patient was started on treatment for acute interstitial nephritis with oral prednisone 60 mg daily with a subsequent slow taper. Kidneys did not recover and he was placed on hemodialysis three times a week with close monitoring of kidney functions.

Discussion: Furosemide, a loop diuretic, is widely used for volume control. To our knowledge, this is the first report of AIN associated with loop diuretics that resulted in severe AKI requiring hemodialysis. Unfortunately, our patient did not respond to high dose steroids and he continued to require hemodialysis three times a week. Our report highlights the importance of close monitoring of any potential toxicities that may be associated with such medications.

PO0112

Hypothyroidism-Induced AKI: A Case Series

Spoorthi Ramineni, Varun kumar Bandi. *Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Gannavaram, India.*

Introduction: Thyroid hormones affect the development and various functions of the kidney. Such effects are partly mediated by direct renal action and partly by cardiovascular and systemic effects

Case Description: We present a series of 3 patients who presented with unexplained acute kidney injury (AKI). All patients were male, and one was hypertensive on amlodipine. Investigations showed blood urea levels ranging from 20 to 88 mg/dl, serum creatinine between 1.3 to 3.65 mg/dL with estimated glomerular filtration rate (eGFR) of 17.88 to 63.18 ml/min/1.73m2. Urine routine and ultrasound abdomen did not reveal any abnormalities. The patients had features suggestive of hypothyroidism and thyroid evaluation was done. Thyroid stimulating hormone (TSH) was elevated in all patients and T3 and T4 were decreased. The TSH levels ranged between 88.4 to 100 mIU/l. Creatine phosphokinase (CPK) level was modestly elevated in only one case, with absent urine myoglobin in all cases. A possibility of hypothyroidism induced AKI was considered and renal biopsy was deferred. After starting levothyroxine, complete renal recovery was seen in 2 patients and partial recovery in one within 8 weeks (Table 1).

Discussion: AKI has been reported in patients with severe hypothyroidism, and most cases were suspected to be due to rhabdomyolysis and had rapid normalization. Few cases of slower and incomplete recovery have been noted in cases with prolonged periods of severe hypothyroidism. In our series, normal urinalysis, absence of myoglobin, and normal or modest elevation of CPK makes rhabdomyolysis unlikely. The AKI could be due to hypothyroidism induced changes in renal hemodynamics. Our study relies on eGFR for renal function, and extent to which this reflects true changes in GFR is unclear. Hypothyroidism is a reversible cause of AKI and should be evaluated in cases with unexplained AKI. These patients can attain normal renal function with prompt initiation of levothyroxine therapy.

Characteristics of patients

Case No	Age (years)	Urea-0 weeks (mg/dl)	Urea-8 weeks (mg/dl)	Creatinine-0 weeks (mg/dl)	Creatinine-8 weeks (mg/dl)	eGFR (ml/min/1.73m2)-0 weeks	eGFR (ml/min/1.73m2)-8 weeks	TSH (mIU/l)-0 weeks	TSH (mIU/l)-8 weeks
1	53	88	40	3.65	1.5	17.88	49	100	0.92

3	37	45	30	1.7	1.0	50.40	95.72	88.4	16.10

PO0113

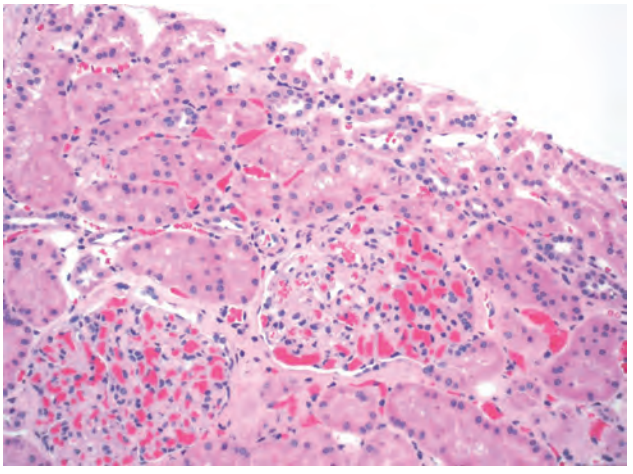
Glomerular Congestion Secondary to Renal Vein Stenosis After Kidney Transplant

Muna Alnimri. *University of California Davis Department of Internal Medicine, Sacramento, CA.*

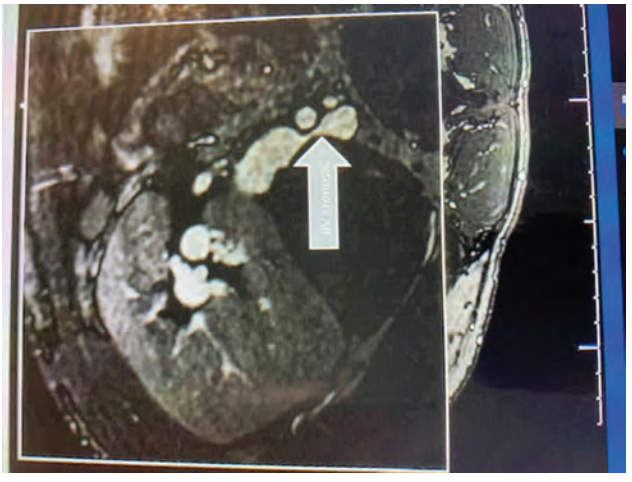
Introduction: Renal vein stenosis (RVS) post kidney transplant is uncommon complication, especially when it causes severe glomerular congestion, and AKI We present a case of RVS 3 months post kidney transplant with kidney biopsy showing severe glomerular congestion

Case Description: 33 y old male CKD secondary to HTN underwent LKT, smooth post op course discharged with a creatinine of 1.1mg/dl presented for 3 months protocol biopsy with creatinine of 1.5mg/dl, kidney biopsy showed severe glomerular congestion No rejection figure1, Doppler US showed suspicion for renal vein stenosis. Renal venogram demonstrated narrowing of the transplant renal vein at the anastomosis with the right common iliac vein figure 2 Successful 10 mm angioplasty balloon was inflated along the narrowed segment follow up creatinine back to 1.1mg/dl

Discussion: Transplant RVS is a rare vascular complication after renal transplantation that may cause graft dysfunction. Correction of RVS with either angioplasty or stent placement is safe and effective approach. Our patient presneted with AKI and severe glomerular congestion that warranted doppler US, the finding of RVS and glomerular congestion from back pressure warranted urgent venogram and angioplasty with excellent results. Conclusion : in evaluating AKI post kidney transplant ureteral obstruction, rejection, CNI toxicity and renal artery stenosis should be ruled out if all negative RVS should be evaluated



Glomerular congestion on kidney biopsy



Renal vein stenosis with post stenosis dilation

PO0114

Brain Got Spongy at Angry Kidneys

Ubaldo R. Madera Sanchez,[1,2] Christian Rodriguez Cintron.[3] *[1]Hospital Universitario Ramon Ruiz Arnau, Bayamon, PR; [2]Universidad Central Del Caribe, Bayamon, Puerto Rico; [3]Doctors Center Carolina, Carolina, PR.*

Introduction: Brain edema is a rare complication of acute kidney injury in patients who have not received renal replacement therapy. Immunologic and pro-inflammatory cascades mediate brain edema that is not dependent on the uremia, and instead, it is due to crosstalk between the kidneys and brain in the so-called reno-cerebral reflex. We are presenting an 88-year-old female with a history of hypertension and hypothyroidism with acute colitis that developed acute kidney injury and cerebral edema. We want to raise awareness of the need for early diagnosis and treatment to prevent severe clinical outcomes.

Case Description: 88-year-old woman with a past medical history of hypertension, hypothyroidism came to the ER complaining of green-colored non-bloody diarrhea with associated epigastric pain for 2 days. Examination remarkable for left lower quadrant tenderness, tachycardia, alerted, awake, oriented to person only, cooperative and following commands. Labs were remarkable for leukocytosis with neutrophilia, fecal leukocyte positive, and metabolic alkalosis. Abdominal CT showed acute colitis localized to descending colon and sigmoid. The patient was admitted with acute colitis. On day 2 of admission creatinine went up to 2.35 from 1.07. On urine, sediment was evident with renal tubular epithelial cells and oxalate crystal. Renal sonogram with no renal abnormality. On day 3 the creatinine continued increasing doubled to 4.4. The patient's mental status started declining, and metabolic acidosis was present. Renal replacement therapy was advised, but the patient's family member refused it and signed off DNR. The creatinine keeps trending up to 9.37. Brain CT without contrast was done and showed diffuse cerebral edema with no acute hemorrhage or ischemic changes. On day 11, the patient passed away.

Discussion: The brain edema seen in this patient was a byproduct of oxidative stress, activation of the immunologic pathway, and activation of the Reno-cerebral reflex occurring in acute kidney injury that is entirely independent of the mechanism seen in uremia. Not every functional or structural brain alteration in acute kidney injury is caused by uremic encephalopathy. Many pathways are activated in acute kidney injury that contributes to the effects of the kidneys in distant organs being the brain one of them. This case will serve to raise awareness to study the crosstalk between organs to prevent complications and improve outcomes.

PO0115

Renal Cortical Necrosis: An Atypical Case from Presentation to Recovery

Liann Abu Salman,[1] Rachel Hilburg,[2] Abdallah Sassine Geara.[2] *[1]Lankenau Medical Center, Wynnewood, PA; [2]University of Pennsylvania, Philadelphia, PA.*

Introduction: Renal cortical necrosis (RCN) is a rare cause of acute kidney injury (AKI) accounting for 1-2% of cases. It is most often associated with obstetric emergencies in developing countries. The most common non-obstetric etiology is hemolytic uremic syndrome, but it has also been described in renal allograft rejection, sepsis, and in rare cases pancreatitis where ten cases have been reported. We describe a case of severe renal cortical necrosis in a previously healthy young man with acute pancreatitis.

Case Description: A 29-year-old man with no significant medical history presented with severe epigastric pain and anuria for three days. He was diagnosed with alcohol-induced pancreatitis with a lipase level of 35,534U/L and AKI with a creatinine of 5.8mg/dL (baseline 1.2mg/dL). The anuria did not improve with fluid resuscitation, the AKI progressed and he was initiated on hemodialysis. Evaluation of AKI with hepatitis B and C serologies, HIV, complement levels and ANA was unremarkable. Kidney ultrasound showed increased echogenicity without hydronephrosis. An abdominal CT scan with IV contrast done for worsening fever and leukocytosis showed diffuse areas of non-enhancement involving bilateral renal cortices consistent with acute renal cortical necrosis. To note, throughout his presentation and admission, the patient was not hypotensive. He remained dialysis dependent for three months with oliguria that eventually improved and dialysis was discontinued with a stable eGFR of 20ml/min/1.73m^2. He has remained off dialysis for the past five months and is undergoing transplant evaluation.

Discussion: RCN is thought to be an irreversible cause of AKI secondary to decreased perfusion, vasospasm and endothelial injury resulting in ischemia. It is frequently associated with hypotension but in our case the patient was normotensive. The mechanism leading to RCN associated with pancreatitis remains poorly understood. Acute pancreatitis, on the other hand, has been associated with other vasoocclusive ischemic complications (e.g. Purtscher's retinopathy). RCN is a devastating complication that often leads to dialysis dependence. Despite our patient showing signs of recovery, his prognosis remains poor. Further study is needed to understand its pathophysiology and potentially mitigate its consequences.

PO0116

Severe Vancomycin Nephrotoxicity

Jefferson L. Triozzi, Layth Al Attar, Maryam K. Saeed, Jingyin Yan, Bryan M. Tucker. *Baylor College of Medicine, Houston, TX.*

Introduction: We report a case of acute kidney injury with biopsy-proven changes related to a vancomycin level of 136.6 mg/L. From our review of the literature, this is the highest vancomycin level ever recorded.

Case Description: A 60-year-old female with type two diabetes mellitus, hypertension, Sjogren's disease not requiring immunosuppression, baseline normal kidney function, and left ankle osteomyelitis on home intravenous vancomycin presented with vertigo. Workup revealed oliguric acute kidney injury with sub-nephrotic range proteinuria (blood urea nitrogen 56 mg/dL, creatinine 6.70 mg/dL, urine protein to creatinine ratio 0.98) and an elevated random vancomycin level (136.6 mg/L). A comprehensive evaluation including physical examination, serologic testing, and renal imaging was unremarkable. Due to high vancomycin levels and minimal improvement in renal function despite resuscitation with intravenous crystalloids, hemodialysis was initiated via a tunneled dialysis catheter. A renal biopsy was then obtained, which demonstrated acute tubuloepithelial injury, morphologically consistent with acute tubular necrosis. There was also mild arterial sclerosis, minimal interstitial fibrosis and tubular atrophy, and no immune-mediated glomerulonephritis.

Discussion: Vancomycin is renally-eliminated by glomerular filtration and, to a lesser degree, excretion in the proximal tubule. Various mechanisms of renal injury are reported, including acute tubular necrosis and interstitial nephritis. Accrual of vancomycin-uromodulin complexes lead to inflammation. In this case, a comprehensive workup and kidney biopsy was important to rule out other causes of renal failure and support the diagnosis of vancomycin-induced nephrotoxicity. Renal recovery often occurs with discontinuation of vancomycin therapy. Severe cases, however, are frequently exacerbated by oliguria and require high-flux hemodialysis for effective drug removal by approximately thirty percent. Prolonged exposure to high levels of vancomycin increases the risk of permanent renal failure. This patient developed vancomycin nephrotoxicity despite drug monitoring, dosing based on creatinine clearance, and using the minimum inhibitory concentration required. Further research to establish precise mechanisms of vancomycin-induced nephrotoxicity is needed.

PO0117

DRESS Syndrome and Acute Interstitial Nephritis Relapse: A Case for Caution

Janina Paula T. Sy-Go, James R. Gregoire. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: The syndrome of drug reaction with eosinophilia and systemic symptoms (DRESS) is a rare but potentially life-threatening drug-induced type IV hypersensitivity reaction that usually occurs 2-6 weeks after drug initiation. Typical findings include skin eruption, fever, hematologic abnormalities, and visceral organ involvement. Prolonged corticosteroid treatment is often required as relapse after initial improvement is not uncommon.

Case Description: A 62-year old woman with a history significant for right total hip arthroplasty complicated by a prosthetic joint infection requiring hardware explantation and antibiotic spacer placement initially presented to the ED with fever, rash, and pruritus. She was treated with cefepime and vancomycin for positive intra-operative bacterial cultures. Urinalysis showed pyuria (51-100/hpf) and eosinophils (1-5%). Skin biopsy showed a drug reaction. She was diagnosed with DRESS syndrome and acute interstitial nephritis (AIN) secondary to the antibiotics, which were then changed to aztreonam and daptomycin. She was treated with systemic and topical steroids and was discharged on oral prednisone 40 mg daily with plan to taper by 10 mg every week over 1 month. Serum creatinine peaked at 3.36 mg/dL and improved to 0.62 mg/dL on discharge. Patient was seen again the ED 5 days after discharge with fever and worsening rash and pruritus. Physical examination was notable for mild facial swelling and scattered pink macules coalescing into patches on both upper and lower extremities and on the groin. Laboratory studies revealed leukocytosis with peripheral eosinophilia [7.35x10(9)/L] (on discharge: 0.87), elevated serum creatinine of 4.8 mg/dL, and elevated LFTs, ESR, and CRP. She was diagnosed with DRESS syndrome and AIN relapse secondary to rapid steroid taper. She was started on a higher dose of oral prednisone (80 mg daily) and had clinical improvement. She was then discharged with plan to taper by 10 mg every 2 weeks over 4 months.

Discussion: Long-term supra-physiologic doses of steroids are necessary to treat DRESS syndrome even after patients appear to have improved. Relapses do occur and frequently follow treatment discontinuation or rapid steroid taper, leading to increased morbidity and mortality. In such cases, a more prolonged steroid treatment is needed, which can cause well-known adverse events and complications. Close monitoring is thus required.

PO0118

Rivaroxaban-Induced Anticoagulant-Related Nephropathy

Bharat Neelam Raju, Birmaji Ali, Vahid Namdarizandi, Cesar E. Abdul-Massih, Amit K. Rajput. *TriHealth, Cincinnati, OH.*

Introduction: Anticoagulant-related nephropathy (ARN) is a rare and newly recognized cause of acute renal failure (ARF). A lack of serologic studies and hesitancy to perform high risk biopsies due to concerns for thrombosis or hemorrhage, make ARN a challenging diagnosis. The pathophysiology is believed to be from diffuse glomerular hemorrhage which manifests as numerous RBC casts. These RBC casts obstruct and damage tubular epithelial cells resulting in renal failure. We will examine a case of ARN.

Case Description: An 83-year-old Caucasian female presented with complaints of lower extremity weakness and was found to have ARF on laboratory investigation (Cr 5.18mg/dL from 1.1mg/dL one month prior). The patient was recently started on rivaroxaban after being diagnosed with a stroke caused by atrial fibrillation. The patient was admitted for evaluation and management of oliguric ARF, requiring the initiation of HD. Initial evaluation was significant for uncontrolled hypertension, 1+ pitting bilateral lower extremity edema, hypoalbuminemia (Alb 1.8 mg/dL), UA with 3+ blood but no casts on microscopy, and non-nephrotic range proteinuria (UPCR 2.9g), raising concern for rapidly progressive glomerulonephritis. Serologic work up was only remarkable for a mildly positive rheumatoid factor. A renal biopsy was performed after holding rivaroxaban for 5 days. Preliminary results showed IgA nephropathy with oxford classification score of M1E0S1T1C0, prompting initiation of steroid therapy. With no crescentic glomerular lesions to explain the degree of renal failure upon further investigation, the prominent RBC casts provided the diagnosis of ARN with underlying non-proliferative IgA nephropathy. Steroids were tapered and the patient is slowly recovering renal function.

Discussion: The use of novel oral anticoagulants (NOAC), has become prevalent in the medical community as a treatment strategy for various diseases. While previous cases have been mostly described in patients on warfarin, this case illustrates the importance of recognizing the new phenomenon of ARN as a risk factor for patients on NOACs. Due to limited data and no prospective studies, expert opinion has recommended switching one oral anticoagulant to another or reducing the dose of the offending agent. Further research is needed to understand this disease process to help design prevention and treatment strategies.

PO0119

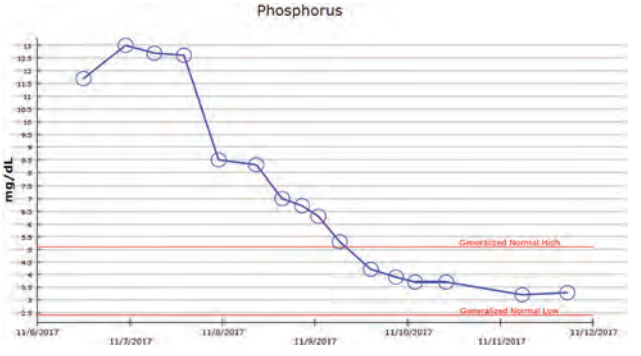
Continuous Venovenous Hemofiltration for Hypouricemic Tumor Lysis Syndrome and Extreme Hyperphosphatemia Complicated by AKI

Muhammad O. Saleem,[1] Ambreen Chughtai.[2] *[1]Augusta University Medical College of Georgia, Augusta, GA; [2]FMH College of Medicine and Dentistry, Lahore, Pakistan.*

Introduction: Tumor lysis syndrome (TLS) is an oncological emergency and can cause Acute Kidney Injury (AKI) mostly by acute urate nephropathy. We present a case of hypouricemic TLS and severe hyperphosphatemia leading to AKI, effectively managed by Continuous Veno-Venous Hemofiltration (CVVH).

Case Description: 44-year male with newly diagnosed Burkitt's lymphoma and currently receiving first cycle of da-EPOCH chemotherapy, was found to have clinical TLS per Cairo-Bishop definition. Laboratory studies were significant for hyperkalemia (K 6.4 mEq/L), hyperphosphatemia (Phosphate 13.0 mg/dL), hypocalcemia (Ca 6.9 mg/dL) and high LDH in addition to oliguric AKI with elevated serum creatinine (2.5 mg/dL, baseline 0.8 mg/dL). Surprisingly Uric acid level was low (1.8mg/dL) as patient had been on prophylactic Allopurinol. Patient did not have any signs of hypovolemia or post renal obstruction. Urine microscopy was bland. Urgent Hemodialysis (HD) session was provided for malignant hyperkalemia. AKI was assumed to be hyperphosphatemia-induced rather than urate nephropathy in TLS. Renal biopsy was considered but deferred due to high risk of bleeding. Hyperkalemia resolved with one session of HD, but hyperphosphatemia rebounded with worsening of creatinine. So CVVH was initiated and carried out for 72 hours. It lowered serum phosphate level to normal range with resolution of AKI.

Discussion: With the broad use of hypouricemic agents, calcium phosphate deposition, rather than hyperuricemia is becoming the leading cause of AKI in TLS. Choosing an appropriate dialysis modality is crucial to prevent further phosphate nephrotoxicity. Intermittent HD followed by CVVH may be an effective approach. CVVH should be considered as a preferred modality to achieve a sustained lowering of phosphate level and prevent rebound hyperphosphatemia. Our case is an excellent example when HD followed by CVVH helped in early renal recovery by effectively lowering serum phosphate levels.



PO0120

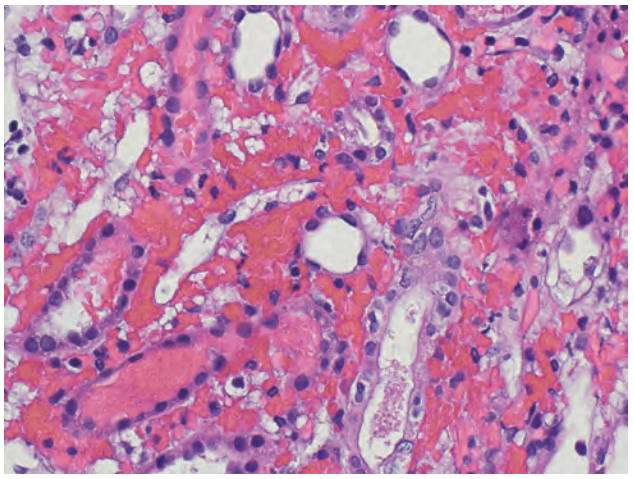
Gross Hematuria, Intense Interstitial Hemorrhages, Red Blood Cell Casts: An Atypical Triad of Amoxicillin-Clavulanate-Induced Acute Tubulointerstitial Nephritis

Ramzi A. Rahiman, Farooq Ahmad, Mohammed Akhtar, Muhammad Asim. *Hamad Medical Corporation, Doha, Qatar.*

Introduction: Drug induced tubulointerstitial nephritis (TIN) usually presents with acute kidney injury, pyuria, white cell casts and micro-hematuria. We report this case to highlight a unique pattern of presentation.

Case Description: A 33-years-old man presented with gross hematuria and acute kidney injury three weeks after a throat infection treated with Amoxicillin-Clavulanate. He denied any previous episodes of hematuria, family history of renal disease or use of any other medication. Physical examination was normal other than mild cervical and axillary lymphadenopathy. Laboratory tests revealed serum Creatinine of 5.3mg/dl, hematuria, sterile pyuria and minimal proteinuria. Immunology screen and renal ultrasound were normal. Peripheral blood smear demonstrated eosinophilia and 7% blast cells. Flow cytometry and bone marrow studies confirmed Acute T-cell Lymphoblastic Leukemia. Kidney biopsy showed acute interstitial nephritis but normal glomeruli. The most striking features were multifocal intense interstitial hemorrhages, abundant red blood cells (RBC) in several tubules [Figure] and RBC casts in some. Direct immunofluorescence, SV40 staining and immunohistochemical studies for leukemic infiltration were negative. Treatment with systemic steroids was initiated. Serum creatinine started to decrease within 3 days. Steroids were continued as a part of induction chemotherapy instituted subsequently for leukemia. Renal function normalized and hematuria subsided within 2 months.

Discussion: Drug induced TIN can present with atypical features masquerading as glomerulonephritis, vasculitis or infectious interstitial nephritis. It is plausible that severe inflammation led to a major breach in the integrity of interstitial vascular walls resulting in interstitial hemorrhages that extended into the tubules through ruptured basement membrane producing gross hematuria and RBC casts.



PO0121

Use of Continuous Venovenous Hemodialysis and Plasmapheresis to Treat Simultaneous Iron and Acetaminophen Overdose

Tripti Singh, Rebecca Nye. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Introduction: Iron may fatally exacerbate toxicity in polypharmacy overdoses, including acetaminophen overdose. We present a case of intentional acetaminophen and iron overdose and treatment with continuous veno-venous hemofiltration (CVVH) and plasmapheresis.

Case Description: 31-year-old male with history of schizophrenia and previous suicide attempts presented to an outside hospital with abdominal pain and emesis 1.5 hours after ingestion of 100 tablets each of 325 mg acetaminophen and 325 mg ferrous sulfate. Vitals on admission were BP 121/83 mmHg, pulse 93 bpm, RR 18/min, O2 saturation 98% on RA. Labs showed bicarbonate 23 mEq/L, anion gap (AG) of 14, BUN 16 mg/dL, creatinine 1 mg/dL, total bilirubin 0.7 mg/dL, AST 24 units/L, ALT 16 units/L, iron 356 ug/dL, and acetaminophen 269.8 ug/mL. Patient was started on IV acetylcysteine. Repeat labs 12 hours later revealed iron level 4326 ug/dL, total bilirubin 4.8 mg/dL, AST 476 units/L, and ALT 855 units/L. IV deferoxamine was initiated. Patient became lethargic and hypotensive and required intubation. He was transferred to our hospital for further management. Labs upon arrival showed AG of 16, bicarbonate of 12 mEq/L, creatinine 1.98 mg/dL, ALT 13129 units/L, AST 7351 units/L, total bilirubin 3.6 mg/dL, ammonia 882 umol/L, acetaminophen 179 ug/mL, iron >900 ug/dL. On physical exam, patient was unresponsive, euvolemic, and NG tube drain was bloody. CVVH was started via left femoral dialysis catheter with blood flow rate of 250 ml/min and replacement fluid rate of 3500 ml/hour. 6 hours after CVVH, labs revealed an iron level of 362 ug/dL and an acetaminophen level of 100 ug/mL. Due to continued deterioration including hemodynamic instability and persistent acidosis, plasmapheresis was initiated. Labs 2 hours later showed iron level of 20 ug/dL and acetaminophen level of 91 ug/mL. The patient's clinical status continued to decline despite removal of iron and acetaminophen and he died after 24 hours due to fulminant liver failure.

Discussion: In this case of simultaneous massive iron and acetaminophen overdose, CVVH was effective in removal of iron (60%) and acetaminophen (44%) over 6 hours. Plasmapheresis may be considered as an additional modality to remove excess free iron from the blood.

PO0122

Severe AKI Associated to Acquired Autoimmune Hemolytic Anemia and Hemophagocytic Syndrome: A Case Report

Afonso Santos, Anna Lima, Ana Gaspar, Ana C. Brás, Patricia S. Carrilho, Karina Soto. *Nephrology Department, Hospital Professor Doutor Fernando Fonseca, EPE, Lisboa, Portugal.*

Introduction: Autoimmune hemolytic anemia (AIHA) is a rare entity with an annual incidence of 1-3/100.000. Secondary AIHA is associated to lymphoproliferative disorders (LD), autoimmune diseases, drugs, and less frequently to infections, being an unusual cause of AKI. Hemophagocytic lymphohistiocytosis (HLH) is an uncommon syndrome of excessive immune activation that can be triggered by infection that disrupts immune homeostasis. Herein, we present a very rare case of a patient with AKI requiring RRT associated to severe AIHA and HLH.

Case Description: A 46-year-old caucasian man was admitted with fever, anuria and severe anemia. Three days prior to admission he had vomiting, diarrhoea and oliguria. Physical examination revealed normal BP, fever and pale skin. Blood tests showed SCr 8.8mg/dL (baseline 0.9mg/dL), metabolic acidosis and urine dipstick Hb3+.He had AIHA with Hb 6.7g/dL, LDH 1194U/L; haptoglobin<30mg/dL; total bilirubin 1.35mg/dL; and positive Coombs test. Blood smear revealed atypical lymphocytes and rare blasts; platelet count was normal. HLH was diagnosed based on clinical (fever, splenomegaly) and laboratorial criteria, with high ferritin (46833ng/mL); triglycerides 308mg/dL, high levels of IL2 receptor (13547pg/mL). Sedimentation rate was 85mm/h and CRP 19mg/dL.LD were ruled out through bone marrow biopsy, lymphocyte immunophenotyping test and full-body CT scan. Viral serology revealed EBV infection. Early treatment was initiated with corticosteroids associated to IV immunoglobulin (IVIG). Kidney recovery started after 10d and haematological recovery started after 3d of IVIG with remission after 15d. The patient remains in complete kidney and hematological remission at 6mo FU.

Discussion: Secondary HLH occurs in response to an inciting stimulus and has been associated to malignancy and infection, particularly with EBV. AIHA is a condition characterized by autoantibodies directed against erythrocytes and can be secondary to EBV infection. Intravascular hemolysis can lead to AKI due to erythrocyte destruction and release of free Hb causing tubular injury by heme proteins' toxicity. This case illustrates the severe presentation of a rare complex entity of AIHA associated to HLH, both caused by EBV infection, and complicated with severe AKI. Early diagnosis was challenging and determined the good outcome.

PO0123

IgG4-Related Disease with Renal Involvement in a Patient with HIV Infection

Karen Flores, Samir V. Parikh, Ganesh B. Shidham. *The Ohio State University, Columbus, OH.*

Introduction: Immunoglobulin G4-related disease (IgG4-RD) is a fibroinflammatory disease that can affect multiple organs. It is characterized by lymphadenopathy and diffuse enlargement of one or multiple organs. Pathologic features include tissue infiltration by IgG4-positive plasma cells, storiform fibrosis, and increased tissue eosinophils. Tubulointerstitial nephritis is the most common renal manifestation. We describe a case of IgG4-RD in a patient with co-existing HIV infection.

Case Description: A 65-year old male with CKD 3, hypertension, hepatitis B, and HIV was hospitalized due to malaise and acute kidney injury with serum creatinine of 4.2 mg/dL and 1.5 g/d proteinuria. HIV was controlled with undetectable viral load on treatment. Infectious work up was negative. CT scan revealed diffuse retroperitoneal lymphadenopathy. PET scan showed diffuse lymphadenopathy and increased uptake in bilateral kidneys and parotid glands. Right inguinal lymph node biopsy showed atypical interfollicular T-cell infiltrate and dense polytypic plasmacytic infiltrate with a kappa/lambda ratio of 3:1 by ISH. TCR gene rearrangement and IGH studies were negative for a monoclonal population. Testing for HHV8 and EBV was negative. SPEP showed a small IgG lambda clone (0.3 g/dL). UPEP showed a small amount of lambda free light chains. Bone marrow biopsy showed no evidence of T cell lymphoma but revealed hypocellular marrow. Total IgG (5048 mg/dL) and IgG4 (572 mg/dL) were elevated and both C3 and C4 were low. Kidney biopsy revealed dense interstitial infiltration of plasma cells strongly positive for IgG4 (>50/hpf) and no electron dense deposits. The patient was diagnosed with IgG4-RD with renal involvement. He was treated with high dose prednisone and mycophenolate mofetil. Renal function improved from 4.6 mg/dL to a 1.9mg/dL after 3 months of treatment. IgG4 levels improved 70mg/dL and C3/C4 normalized suggesting disease control had been achieved.

Discussion: We describe a case of IgG4-RD with renal involvement in a patient with HIV infection. There are only a few reports in the literature. Differential diagnosis of kidney disease during HIV infection is broad. IgG4-RD is a severe systemic disorder that can be mistaken for infection or malignancy. IgG4-RD should be considered in the differential for acute kidney injury in the setting of HIV.

PO0124

Renal Replacement Therapy in Pheochromocytoma

Jennifer Griffiths, Hay Me Me, Aromma Kapoor. *Westchester Medical Center, Valhalla, NY.*

Introduction: Pheochromocytoma is a rare tumor derived from chromaffin cells of the sympathetic nervous system. The triad of headache, palpitations and diaphoresis is often present, but catecholamine excess can present in various contexts. Tumors secreting epinephrine can present with episodic hypotension; rapid cycling fluctuations of hypotension and hypertension also occur. Most acute kidney injury (AKI) in the setting of pheochromocytoma crisis is due to ischemic acute tubular necrosis (ATN). For cases requiring renal replacement therapy, there are no studies supporting one form over another. We describe a patient with Pheochromocytoma who developed AKI requiring renal replacement therapy (RRT).

Case Description: 29 year old woman with history of migraines presented to outside hospital with headache and chest pain, and found to be in hypertensive emergency with mild elevation of troponins. Patient was transferred to our hospital for evaluation of possible myocardial infarction. Cardiac catheterization showed clear coronaries. Patient became hypotensive during the procedure and Intra-Aortic Balloon Pump was placed. Imaging showed high density mass in the left adrenal gland. Patient was started on Phenoxybenzamine. Biochemical tests confirmed Pheochromocytoma. Labs showed creatinine of 5.38. Patient became anuric and RRT was initiated with intermittent hemodialysis(iHD). On the third dialysis session, patient had wide blood pressure fluctuations and became hypotensive with decreased responsiveness. Imaging was negative for acute bleed but concerning for cerebral edema. RRT was switched to continuous renal replacement therapy(CRRT) which was better tolerated.

Discussion: Our patient experienced an acute hypertensive crisis followed by cardiovascular collapse likely precipitated by intravenous glucocorticoids given for presumed myocarditis. Glucocorticoids increase catecholamines ; the excess causes cardiotoxicity which in turn leads to ischemic ATN. Patient was able to tolerate iHD initially. However, as the Phenoxybenzamine was up titrated, the fluctuations included hypotensive episodes and was worsened on dialysis. Given the unpredictable fluctuations in blood pressure and the possibility of associated hypertensive encephalopathy and/or

cerebral edema in the setting of Pheochromocytoma, it may be prudent to choose CRRT when RRT is warranted, though there are no guidelines regarding which modality is superior in these patients.

PO0125

Blast from the Past: A Rare Case of AKI from Sulfadiazine-Induced Nephrolithiasis

Shamir Hasan, Varun Madireddy, Hitesh H. Shah. *Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Introduction: Sulfadiazine has been used for the treatment of neurotoxoplasmosis in patients with HIV infection. Nephrolithiasis is a known complication of high dose sulfadiazine therapy. However, this complication is rarely seen in HIV patients due to improved antiretroviral therapy. We present a rare case of sulfadiazine-induced nephrolithiasis in a patient with AIDS.

Case Description: 55-year-old female with DM and HTN was hospitalized for worsening mental status and CT scan finding of frontal lobe mass. During hospital stay, pt. also found to have HIV infection and a very low CD4 count. Antiretroviral therapy and high-dose intravenous sulfadiazine 1,500 mg every 6 hours was initiated for presumed neurotoxoplasmosis. On admission, serum creatinine (Scr) was 0.68. Seventeen days after initiation of sulfadiazine therapy, Scr increased to 2.42. Urinalysis revealed microscopic hematuria. Kidney sonogram showed left hydronephrosis and echogenic foci in both kidneys concerning for kidney stones. Sulfadiazine was discontinued and patient was started on sodium bicarbonate infusion to alkalinize her urine but Scr continued to worsen, peaking at 4.73 within few days. Serial kidney sonograms revealed alternating fullness of the collecting systems of both kidneys. Urology team was consulted and patient underwent cystoscopy with bilateral ureteral stent placement. Scr subsequently returned to normal limits within one week of ureteral stent placement.

Discussion: Our patient developed severe but reversible post-obstructive AKI secondary to high-dose sulfadiazine-induced nephrolithiasis. In the modern era of antiretroviral therapy**,** sulfadiazine-induced nephrolithiasis is a very rare occurrence in clinical practice. Hence, clinicians and nephrology care providers should be aware of this rare cause of AKI in patients with HIV infection.

PO0126

Rhabdomyolysis as Initial Presentation of COVID-19

Hugo Andrade paz, Mala Sachdeva, Nupur N. Uppal. *Northwell Health, Great Neck, NY.*

Introduction: Rhabdomyolysis has infectious etiology including Mycoplasma pneumoniae infection, *Legionella*, and Influenza. To date, there has been one case report from Wuhan China of a patient who developed rhabdomyolysis from COVID-19 during their hospitalization. We report a case where acute kidney injury and rhabdomyolysis was the initial presentation.

Case Description: A 57 year old African American male with history of HTN for more than 10 years, presented with complaints of decreased urine output for 3 days associated with dark urine that progressed to anuria, fever for 11 days, decreased appetite and oral intake and generalized muscle weakness. Labs on admission were notable for acute kidney injury (creatinine 1.77mg/dL) which progressed rapidly to a peak creatinine of 11.10mg/dL within 72 hours, and other electrolyte abnormalities including mild hyperkalemia and acidosis. His CPK was >92,000U/L on admission and COVID-19 PCR was positive. Other labs included: peak AST 1692 U/L and ALT 291U/L, ferritin 1436 ng/mL, 4.86mg/dL, DDimer 2330 DDU, urinalysis specific gravity 1.030 with large blood, 10RBCs, 20WBCs, urine spot protein/creatinine 2.1 and random urine sodium 65. Serologic workup was negative for glomerular etiology. He was presumed to have acute tubular necrosis from rhabdomyolysis. He was started on hemodialysis on day 3 of admission for anuria and worsening of renal function. He was maintained on hemodialysis with minimal ultrafiltration three times a week, intravenous fluid resuscitation along with intermittent doses of bumex. He received total of five hemodialysis treatments until he became non-oliguric and started showing signs of recovery. He was taken off dialysis approximately three weeks after his initial presentation. His creatinine decreased and is 1.4 mg/dL one month after being taken off of hemodialysis.

Discussion: COVID-19 has its usual presentation of fevers, shortness of breath, dry cough and myalgias. This case highlights the importance that rhabdomyolysis can be one of the only presenting features of COVID-19. Checking CPK levels should be an integral part of not only an acute kidney injury workup in the COVID-19 patient but also for any COVID-19 newly diagnosed case as this diagnosis requires prompt and specific treatment.

PO0127

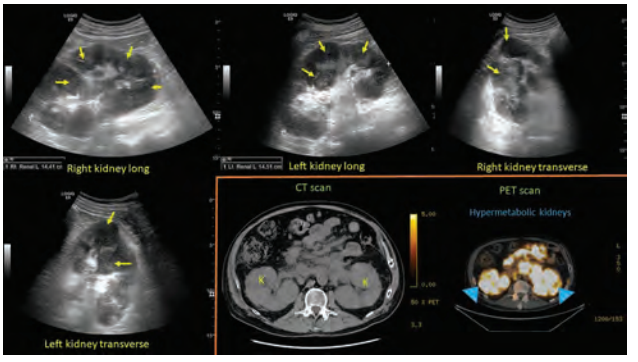
Lymphomatous Infiltration of the Kidney: A Sonographic Diagnosis

Bhavna Bhasin, Abhilash Koratala. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: The purpose of this case study is to illustrate the sonographic findings seen in kidney infiltration by lymphoma.

Case Description: A 56-year-old man with a history of hypertension, diabetes mellitus type 2 and follicular lymphoma with transformation to diffuse large B-cell lymphoma presented with worsening fatigue, headache and diplopia. MRI of the brain demonstrated central nervous system involvement by the lymphoma. He was also found to have worsening renal function with a serum creatinine of 4.5 mg/dL (baseline: 1.6-2 mg/dL). A renal sonogram (RUS) was performed, which demonstrated bilateral enlarged kidneys (~14.5 cm each) with irregular outlines and multiple parenchymal hypoechoic to heterogeneous lesions. No internal vascularity was noted on color Doppler. These findings are consistent with lymphomatous infiltration of the kidneys, confirmed later by PET (positron emission tomography) scan [Figure]. The renal function continued to worsen despite supportive care, and he required initiation of hemodialysis. Acute kidney injury was initially attributed to poor oral intake and mild hypercalcemia, but lymphomatous infiltration likely contributed to his renal impairment as well. Renal biopsy was not undertaken due to progression of the lymphoma and limited life expectancy.

Discussion: Kidney is the most common extra-reticular site of leukemic and lymphomatous infiltration, and tumor-cell infiltrates in the kidney are seen in up to 30% of patients with lymphoma. Rarely, renal involvement may be the first manifestation of lymphoma. The kidneys may appear normal on RUS because of the small size of the nodular infiltrates or with the typical findings described above. Unilateral and perirenal infiltration with lymphoma has also been described. Hydronephrosis may be noted on RUS if there is compression of the renal hilum or ureters by the lymphomatous tissue. Nephrologists performing point of care ultrasonography should be aware of these findings. These patients will require a prompt referral to the Hematology & Oncology team when renal ultrasonography leads to a new diagnosis of lymphoma.



PO0128

Minimal Change Nephrotic Syndrome Superimposed on Anti-Glomerular Basement Membrane Antibody Glomerulonephritis: A Case Report

Yuko Shibata, Kazuhito Fukuoka, Shinya Kaname. Kyorin university school of medicine *Kyorin Daigaku, Mitaka, Japan.*

Introduction: Background : The renal prognosis of anti-GBM glomerulonephritis (anti-GBM GN) is extremely poor as renal dysfunction often progresses acutely before the initiation of treatment. It is also known that once the disease activities are controlled by aggressive treatment, its recurrence is rare. Here we experienced a case of anti-GBM GN that improved from severe renal dysfunction but later relapsed. A possible cause was thought to be a rare complication of minimal change nephrotic syndrome (MCNS).

Case Description: A 30-year-old man was admitted to our hospital because of general malaise, fever, oliguria and renal dysfunction. The patient's laboratory data showed serum creatinine as high as 6.6 mg/dl and severe inflammation (C-reactive protein 20.6mg/dl). Anti-glomerular basement membrane antibody (anti-GBM Ab) was detected in his serum, leading to a diagnosis of anti-GBM GN. Treatment was initiated with high-dose glucocorticoid (GC) and plasma exchange therapy (PE), and the patient's renal function and oliguria improved rapidly and he was discharged 40 days after admission. Renal biopsy findings showed cellular crescents associated with linear IgG depositions along the glomerular tufts compatible with anti-GBM GN, but only about one-third of the glomeruli was involved, suggesting that it still remained an early stage of the disease. However, two months after discharge, he had a relapse and was readmitted due to severe proteinuria associated with positive anti-GBM Ab. On the second admission, he was treated with high-dose GC and PE combined by intravenous cyclophosphamide, and completed remission was achieved a few weeks later. Electron microscopy of the renal biopsy that returned later showed significant foot process effacement on podocytes in the apparently normal glomeruli without electron dense deposits.

Discussion: Considering clinical course and renal pathology findings, it is suggested that the present case was a rare complication of an early stage of anti-GBM GN and MCNS. Although the cause of concurrent development of anti-GBM GN and MCNS associated with anti-GBM antibody titers is unclear, it might have been precipitated by influenza infection or some unknown factor.

PO0129

Thrombotic Microangiopathy with Acute Interstitial Nephritis Secondary to Trimethoprim-Sulfamethoxazole

Armando T. Cardenas, Tiffany Prachachalerm, Grace Mcnutt, Julio P. Zavala Georffino. *University of the Incarnate Word, San Antonio, TX.*

Introduction: Thrombotic Microangiopathy (TMA) and Acute Interstitial Nephritis (AIN) are well recognized entities that individually cause significant morbidity and mortality. The relationships with several medications have been described, but the two conditions coexisting are rare.

Case Description: 28-year-old man with no significant past medical history presented with bilateral lower extremity edema, excoriations, discharge, and weakness for one week. He initially presented to an outpatient clinic and was discharged on trimethoprim-sulfamethoxazole (TMP/SMX). His symptoms progressed leading to admission. Physical

examination revealed an obese man with bilateral lower extremity edema, eczematous rashes, and excoriations on both feet. Initial laboratory results were significant for a creatinine of 5.2 mg/dL and oliguria. Urinalysis revealed proteinuria, hematuria, and pyuria. He then developed thrombocytopenia and anemia. Haptoglobin and lactate dehydrogenase were elevated, and schistocytes were identified on peripheral smear consistent with microangiopathic hemolytic anemia. He also had eosinophilia. Work-up for autoimmune, infectious, and connective tissue diseases was ordered and results were unrevealing. ADAMTS13 activity was decreased at 42%. The patient started hemodialysis and a kidney biopsy was performed with findings of acute tubular necrosis, thrombotic microangiopathy, and acute interstitial nephritis. TMP/SMX was discontinued and he was started on steroids. His renal function improved, and he was discharged home without need for further dialysis.

Discussion: TMA is characterized by endothelial damage causing microangiopathic hemolytic anemia, thrombocytopenia, and end-organ damage. TMA can be attributed to genetic, external, autoimmune causes, or may emerge secondary to medical diseases. AIN is a common cause of kidney injury and is associated with multiple drugs. This case demonstrates the unique coexistence of TMA and AIN in a patient receiving TMP/SMX, which has been related to decreased creatinine clearance, bone marrow suppression, hyperkalemia, and hypersensitivity reactions. This case supports the cessation of the offending drug and the use of steroid treatment as an option for TMA and AIN. In conclusion, TMA and AIN may occur simultaneously as an adverse drug reaction.

PO0130

Rhabdomyolysis in SARS-CoV-2 Infection

Zhabiz Solhjou,[2] Ignacio A. Portales Castillo,[2] Bassem Mikhael,[2] Nicholas Chedid,[1] Ebrahim Barkoudah,[1] Alice M. Sheridan.[2] *[1]Brigham and Women's Hospital, Department of Medicine, Boston, MA; [2]Brigham and Women's Hospital, Renal Division, Boston, MA.*

Introduction: Acute kidney injury (AKI) is a common complication of SARS-CoV-2 infection. Multiple mechanisms have been proposed including acute tubular necrosis (ATN) due to shock, cytokine release syndrome, hypoxia or vascular injury and thrombosis. Direct viral injury to tubular epithelial cells and podocytes has also been described. Rhabdomyolysis has been reported in infection with SARS-CoV, Respiratory Syncytial Virus and Influenza A. Although mild CK elevation was reported in cohorts of patients with COVID-19 and there is a single case report of late onset rhabdomyolysis, overt rhabdomyolysis on presentation has not been described. To our knowledge this is the first patient who presented with signs and symptoms of severe rhabdomyolysis and AKI that was likely secondary to SARS-CoV-2 infection.

Case Description: A 51 year-old male with hypertension and diabetes, presented with 2 days of diffuse myalgia and mild dry cough without shortness of breath. He denied trauma, new medications, changes in diet, strenuous exercise or illicit drug use. Physical exam notable for fever and mild tachypnea, but no hypoxia. Lungs were clear and all muscles groups were soft and non-tender. Polymerase chain reaction was positive for SARS-CoV-2. Serum creatinine was 2.4 mg/dL (baseline 1.3 mg/dL), Urinalysis showed 3+ blood, 2+protein and 1-2 RBC per high power field. Initial serum creatinine kinase was 340,000 U/L and peaked at 464,000 U/L on day 4. Serum and urine myoglobin levels were elevated at 15,175 mg/L and >5000 mcg/L respectively on day 5. He received isotonic intravascular (IV) fluids but developed oliguria on day 2, requiring diuresis to maintain urine output. BUN and creatinine increased to 130 and 19 mg/dL respectively by day 8 and hemodialysis was initiated. Renal clearance and urine output then slowly improved, and dialysis was discontinued by day 15.

Discussion: Myalgia and fatigue are common symptoms of COVID-19 infection. In addition, dipstick hematuria is reported in up to 10% of patients. Thus diagnosis of rhabdomyolysis and myoglobinuria requires a high index of suspicion. Early consideration and timely diagnosis of rhabdomyolysis and the treatment of myoglobinuria with intravenous fluids is critically important to prevent ATN. However, administration of IV fluids may be challenging in COVID-19 patients at risk of hypoxia and acute respiratory distress syndrome.

PO0131

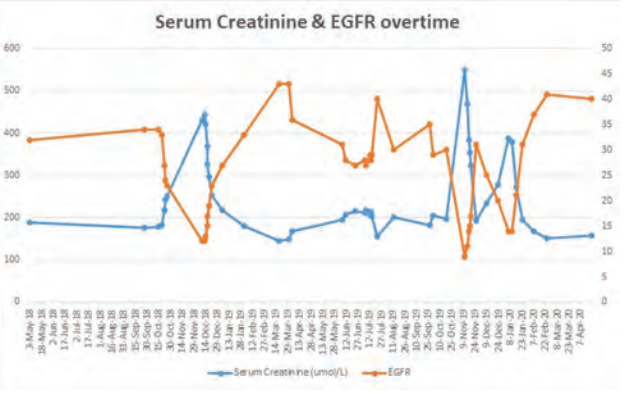
Using a Peritoneal Dialysis Catheter as a Tool for AKI Prevention in a Patient with Refractory Cardiac Ascites: A Case Report

Raja M. Rashid, Amar M. Mahdi. *University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Introduction: Recurrent large volume paracentesis (LVP) is currently the followed management option for refractory cardiac ascites. We are presenting a case where placement of tunneled peritoneal catheter (PD) for such a patient resulted in prevention of repeated AKI, reduced hospitalization, dramatic improvement in quality of life and stabilization of renal function.

Case Description: 59 year old male patient of CKD ¾ secondary to Cardio-Renal syndrome was admitted in Apr 2019 with worsening heart failure, massive ascites and AKI on CKD (Serum Creatinine (cr) worsening from 150 to 210 umol/L). His last echo showed severely impaired biventricular dysfunction with LVEF of 24%. Ascites was sterile and transudative. Kidneys were of normal size and urine PCR was only 20. Owing to poor diuretic response, he underwent LVP (30 Litres) with resolution of AKI. He presented similarly in Nov 2019 (Cr worsened from 197 to 550umol/l) and underwent LVP. 6 weeks later, he presented again with AKI (Cr rose from 190 to 380 umol/l). PD catheter was medically inserted in Jan 2020. 8 litre of ascites was drained and patient was trained to aseptically drain the ascites regularly. He drained the fluid himself 2 to 3 L twice a week. His Cr improved and stabilized around 157 umol/l. His serum albumin (29to 40 g/l), Hb (77 to 135 g/l), quality of life, blood pressure and diuretic response has improved significantly with body weight maintained at 83 kg. He has not been admitted once in past 5 months.

Discussion: Our patient was having repetitive AKI (known cause of CKD progression) due to worsening congestion and possibly raised intra-abdominal pressure (IAP). Increased systemic venous pressure can cause a decline in GFR by increasing renal interstitial pressure. Venous congestion also causes an inflammatory response within the renal parenchyma. Clinical parameters improved once the gentle PD catheter drainage was instituted at home. No further AKI episode was observed and eGFR was stabilized.



PO0132

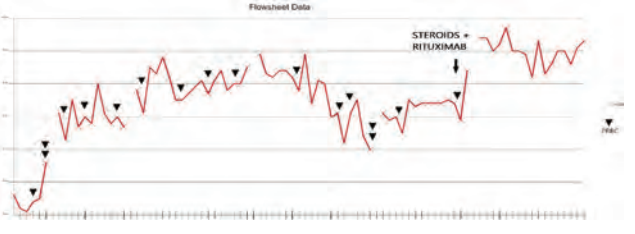
A Rare Case of a 27-Year-Old Man with IgG4-Related Disease

Sai Shalini Pillarisetty, Sumedha Sonde, Winston Lee. *New York City Health and Hospitals Coney Island, Brooklyn, NY.*

Introduction: IgG4-related disease(IgG4-RD) is a rare multisystem autoimmune disease that was first reported in 2010. We present an unusual case of IgG4-RD in a young man demonstrating the heterogeneity of IgG4-RD with multisystem involvement and irreversible organ damage.

Case Description: A 27 year old obese male who presented with 3 month history of vomiting, diarrhea, epigastric pain, left lower extremity edema and severe fatigue. On admission patient appeared toxic, tachycardic and hypertensive with left leg elephantiasis nostras verrucosa. Lab work was significant for: Hgb 4 mg/dl, BUN/Cr 247/33.04, lipase 1100 U/L (13-60),TPO antibodies 43.6 IU/mL (<=34.9), TSH 8.71uIU/mL (0.35-5.50). CT scan confirmed acute pancreatitis with diffuse lymphadenopathy. Hemodialysis was initiated and the patient received multiple blood transfusions (17 units of PRBC) while on Aranesp with no significant improvement in hemoglobin. Blood antibody screening showed IgG4 warm antibodies and elevated serum IgG4 229 mg/dl (2.4- 24), IgG 2305 mg/dl (610-1660) and IgE 4303KU/L (<100). Renal biopsy showed chronic tubulointerstitial nephritis with global and focal segmental glomerulosclerosis and arterial sclerosis. Immunofluorescence stained for IgG, IgA, IgM, C3, C1q, kappa and lamda. Electron microscopy showed plasma cells staining IgG4 and 80% interstitial fibrosis.

Discussion: IgG4-RD is a fibroinflammatory condition characterized by lymphoplasmacytic infiltrates rich in IgG4 and plasma cells with storiform fibrosis and elevated serum IgG4. Our patient presented with interstitial nephritis, pancreatitis, lymphadenopathy, thyroiditis, lower extremity lymphedema and anemia with elevated serum IgG4 levels and histopathology findings of IgG4-RD. The diagnosis was made based on the Japanese comprehensive diagnostic criteria for IgG4-RD. He responded to rituximab and steroids with decreased transfusion requirements. Severe anemia has not been reported with IgG4-RD. In our case the transfusion requirement decreased after initiation of therapy which suggests the anemia may have been secondary to anti-EPO IgG4 or poor response to EPO in the setting of an underlying inflammatory process.



PO0133

Zosyn Induced Neutrophil-Rich Allergic Interstitial Nephritis: A Rare Case

Aulio E. Bustos, Sanjeev Gupta, Savneek S. Chugh, Viviam I. Becerra rivera, Amol Mittal, Xiaotong Wang. *Westchester Medical Center Health Network, Valhalla, NY.*

Introduction: Acute interstitial nephritis (AIN) is a clinico-pathological syndrome associated with infections or drugs. AIN is responsible for 1-3% acute kidney injury (AKI) cases. Drug induced-AIN (DI-AIN) rarely presents with the classic triad of rash,

fever and eosinophilia, and is usually a diagnosis of exclusion. On renal biopsy (Bx), DI-AIN usually presents with interstitial inflammation rich with eosinophils and plasma cells and, in rare occasions, with neutrophils. Here, we report a Zosyn induce neutrophil-rich AIN case

Case Description: A 40-year-old female with medical history breast cancer came with fever, pain and induration over her left breast. On admission she got Zosyn for suspect breast abscess. Next day, AKI noted, creatinine (Cr) increased from 0.6 to 3.3mg/dL. She remained hemodynamically stable. Laboratories showed no anemia, leukocytosis or peripheral eosinophilia. BUN/Cr of 38/4.7. Urinalysis negative for protein, blood, crystals, casts, white blood cells, red blood cells, nitrites, urine sodium and chloride <20mmol/L, positive urine eosinophils. Negative autoimmune and hepatitis B/C work up. Blood and urine cultures were negative. Renal bladder ultrasound (US) showed normal kidney size with no sign of infection. Breast US findings were concerning for neoplasm. Zosyn was held and prednisone (1mg/kg) was given for suspicious of DI-AIN. Renal Bx was done showing interstitial inflammation rich with neutrophils and neutrophilic cast without glomerular injury. Immunofluorescence with negative IgG, IgA, IgM, C3, C1q, fibrinogen, albumin, kappa and lambda light chains. Electron microscopy was unremarkable. Cr at 3rd day peaked at 4.7mg/dL, then trended down. Upon discharge BUN/Cr39/2.36. One week after at renal clinic visit her kidney function came back to her baseline. We continued steroids for 3 weeks due to suspicion of AIN as repeated renal imaging and urine culture remained negative

Discussion: This is a rare case where Zosyn was promptly stopped and prednisone was initiated early in the course of AIN despite neutrophilic infiltration on renal Bx. DI-AIN can present with predominant neutrophilic infiltration; however, this makes the diagnosis more challenging. High suspicion, prompt antibiotic discontinuation and early institution of steroid can prevent further kidney injury or potential chronic kidney disease

PO0134

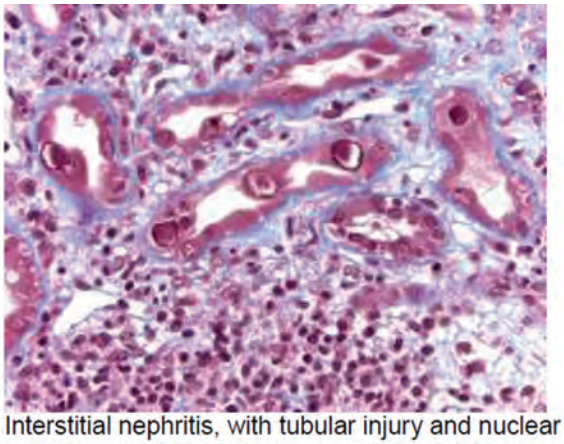
A Case of BK Polyomavirus-Associated Nephropathy of Native Kidneys in a 19-Year-Old Woman with a History of Orthotopic Cardiac Allotransplantation

Ao Wang. LLU nephrology *Loma Linda University Adventist Health Sciences Center, Loma Linda, CA.*

Introduction: BK polyoma virus associated nephropathy (BKPyVAN) is common among kidney transplant recipients. Approximately one to ten percent of kidney transplant recipients will develop BKPyVAN. BKPyVAN can lead to failure of the transplanted kidney allograft.

Case Description: A 20-year-old woman who had orthotopic cardiac allotransplantation in November of 2016 presented to the hospital in January of 2020 with upper respiratory tract infection like symptoms. Her baseline serum creatinine was 1.4 mg/dL three months prior to presentation. Her maintenance immunosuppression included tacrolimus and siroliumus. On admission her serum creatinine was 4.4 mg/dL. Nephrology was consulted and they recommended investigating for BK nephropathy. BK virus DNA quantification was positive for 352,364 BK virus copies/mL. On hospital day nine. The left native kidney biopsy revealed active BK-virus nephritis, patchy interstitial fibrosis and tubular atrophy.

Discussion: BK polyoma virus associated nephropathy of native kidneys is relatively rare. Upon our research we have only found a few case reports.



Interstitial nephritis, with tubular injury and nuclear inclusions typical of BK-virus nephritis (trichrome stain)

PO0135

A Case of Secondary IgA Nephropathy and Response to Steroids

Zain A. Javed,[1] Arooj F. Shah.[2] *[1]MacNeal Hospital, Berwyn, IL; [2]Shifa College of Medicine, Islamabad, Pakistan.*

Introduction: Secondary IgA nephropathy a lesser known variant of primary IgA, has been reported to occur after a bacterial illness. These have led to rapid progression towards kidney failure. Victims of the disease are likely to become dialysis dependent shortly after acquiring the disease process.

Case Description: Patient is an 87 year old male with past medical history of DMT2, CKD IIIb, Prostrate Ca, Bladder Ca and a recent admission for sepsis due to MSSA bacteremia, was admitted to an elevated Cr to 3. His symptoms comprised only of fatigue and confusion with no decrease in urine output. Admission labs showed BUN of 78 and Cr of 4.13 and >300 protein on UA. Urine studies showed FEUrea of 59.3% and 24 hour Urine protein of 5g. Renal U/S and CT abdomen and pelvis did not reveal any obstructive process. Patient was placed on IV fluids while a GN workup was in progress followed by a biopsy and was discharged to be followed up on outpatient. Biopsy demonstrated IgA nephropathy with diffuse proliferative glomerulonephritis with acute tubular injury without crescenteric involvement. There was also evidence of mild chronic tubulointerstial injury and global glomerulosclerosis. His Cr had up trended to 7.4 and BUN 146 without any signs of azothemia. Decision was made to start 500mg methylprednisone once daily for 3 days followed by 0.5mg/kg of oral steroids on discharge and 1 month follow up. 1 month later, Cr was found to have down trended to 5 with no electrolytes disturbances with improvement activities of daily living with adequate urine output. Decision was made to continue oral steroids in an attempt to delay dialysis.

Discussion: Post infectious IgA nephropathy is rare but continues to be responsible for progression towards ESRD. The infections responsible include E Coli Sepsis and Osteomyelitis. Variable approaches have been made which revolve around the inflammatory infiltrates. Immuno-suppressive therapies like cyclophosphamide and rituximab have been typically used for crescenteric glumerolonephritis but have shown limited response. Their use in secondary IGA nephropathy has been limited to transplant recipents. Our case demonstrated one of the rare instances in which there was presence of active inflammatory infiltrate in absence of any crescent formation which guided our decision to initiate steroids. In this process, dialysis was delayed as the patient continued to have adequate renal function.

PO0136

Case of Paraneoplastic Pauci-Immune Glomerulonephritis

Golriz Jafari, Masood Mahmood, Anita Kamarzarian. *UCLA Medical Center Olive View, Sylmar, CA.*

Introduction: This case highlights the importance of complete systemic evaluation for patients presenting with rapidly progressive glomerulonephritis (RPGN).

Case Description: 58 year old male with history of DM type 2 and hypothyroidism presents with acute kidney injury (AKI). Notable findings include a rash which was biopsied and due to leukocytoclastic vascullitis. Baseline Cr 0.59 mg/dl and continued to increase rapidly leading to patient becoming hemodialysis dependent. Urine showed an active sediment; serology including ANCA and anti-GBM were all negative. Patient was empirically started on steroids for possible Immunoglobulin A glomerulonephritis and also due to diagnosis of adrenal insufficiency. Renal biopsy subsequently showed pauci-immune crescentic glomerulonephritis with 89% og glomeruli with crescents, 74% of which are active and negative immunefluorescence. Patient was started on cytoxan. However further work up revealed a inguinal mass which was biopsied and found to be Hodgkin's lymphoma. Patient was started on chemotherapy however did not make any renal recovery and remains dialysis dependent.

Discussion: This case illustrates the importance of thorough evaluation in patients presenting with rapidly progressive glomeronephritis. Although ofent times it is due to a primary renal or renal/pulmonary disorder, paraneoplastic conditions should not be overlooked and need further investigation.

PO0137

Renal Abnormalities in Patients with e-Cigarette, or Vaping, Product Use-Associated Lung Injury (EVALI)

Josephine Abraham, Miekan A. Stonhill, Martin C. Gregory, Sean J. Callahan. *University of Utah Hospital, Salt Lake City, UT.*

Background: The use of electronic cigarettes is linked to the development of lung injury. There are no reports to date of renal injury secondary to vaping. Animal studies suggest that vaping could be associated with renal injury (1,2).

Methods: A retrospective chart review of the first twenty cases of patients with EVALI was performed. We present the urinary abnormalities noted in patients with EVALI.

Results: Twenty patients admitted for EVALI underwent urinalysis as part of their laboratory workup. None of these patients had known pre-existing renal disease. All patients except for one had normal creatinine on admission. Proteinuria was seen in thirteen patients (65%) and microscopic hematuria (>4 RBC/hpf) was seen in five patients (20%). All patients with microscopic hematuria also had proteinuria.

Conclusions: EVALI can be associated with hematuria and proteinuria. In animal studies, E cigarette vapor is hypothesized to diminish airway barrier function, release inflammatory protein into the circulation creating systemic inflammation leading to distant organ injury and dysfunction (2). There are several limitations to this study. This is a retrospective chart review and long term outcome is unknown as data is lacking. Nevertheless the high prevalence of urinary abnormalities on admission in patient with EVALI calls for further investigation. While the pathogenesis of vaping-associated renal injury is unclear, urine analysis should be considered in all patients presenting with EVALI. Ref 1. Impact of e cigarette refill liquid exposure on rat kidney Golli NE et al. Regul Toxicol Pharmacol 2016 Jun;77:109-16 2. Chronic inhalation of e-cigarette vapor containing nicotine disrupts airway barrier function and induces inflammation and multiorgan fibrosis in mice Crotty Alexander et al Am J Physiol Regul Integr Comp Physiol. 2018 Jun 1;314(6):R834-R847

Urinary abnormalities in 20 patients with EVALI

PROTEINURIA	13	65%
1+proteinuria(30mg/dL)	8	40%
2+proteinuria(100mg/dL)	4	20%
3+proteinuria(>300mg/dL)	1	5%
HEMATURIA	5	25%
Hematuria and 1+proteinuria	4	20%
Hematuria and 3+proteinuria	1	5%

PO0138

Kidney Biomarkers and Major Adverse Kidney Events in Critically Ill Patients

Alexander H. Flannery,[1] Victor M. Ortiz-Soriano,[2] Fabiola Gianella,[3] Victor E. Prado,[3] Robert D. Toto,[3] Orson W. Moe,[3] Javier A. Neyra.[2] *[1]University of Kentucky College of Pharmacy, Lexington, KY; [2]University of Kentucky College of Medicine, Lexington, KY; [3]University of Texas Southwestern Medical Center at Dallas, Dallas, TX.*

Background: Several biomarkers of acute kidney injury (AKI) have been examined for their ability to predict AKI earlier than serum creatinine. Few studies have focused on using kidney biomarkers to better predict major adverse kidney events (MAKE), an increasingly used composite outcome in critical care nephrology research.

Methods: Single-center prospective study collecting blood and urine samples from critically ill patients with AKI KDIGO stage 2 or above, and matched controls from a single, tertiary care intensive care unit. Samples were collected at 24-48 hours after AKI diagnosis (cases) or ICU admission (controls), 5-7 days later, and 4-6 weeks following discharge for AKI patients. The primary outcome of interest was MAKE at hospital discharge.

Results: Serum/urinary neutrophil gelatinase-associated lipocalin, serum/urinary cystatin C, and urinary kidney injury molecule-1 early in the AKI or ICU course were all significantly higher in patients with MAKE compared to those not experiencing MAKE. Serum cystatin C, and to a lesser extent serum NGAL, significantly improved upon a clinical prediction model of MAKE as assessed by the area under the receiver operating characteristic curve. Patients without MAKE experienced a greater decline in serum NGAL from initial measurement to second measurement than those patients experiencing MAKE.

Conclusions: Early values of kidney biomarkers in critically ill patients are associated with MAKE. This relationship appears to be greatest with serum NGAL and cystatin C, which display additive utility to a clinical prediction model. Trending serum NGAL may also have utility in predicting MAKE.

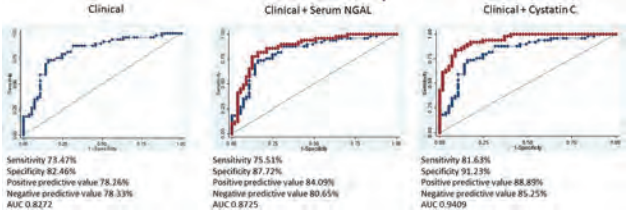

Figure 2. Receiver operating characteristic curves for MAKE-Discharge

PO0139

Urine Biomarkers and Risk of Long-Term Kidney Outcomes After Cardiac Surgery: the TRIBE-AKI Study

Steven Menez,[1] Dennis G. Moledina,[2] Amit X. Garg,[3,4] Heather Thiessen Philbrook,[1] Eric McArthur,[4] Yaqi Jia,[1] Wassim Obeid,[1] Sherry Mansour,[2] Michael Shlipak,[5] Steven G. Coca,[6] Chirag R. Parikh.[1] TRIBE-AKI Consortium *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Yale University School of Medicine, New Haven, CT; [3]Western University Schulich School of Medicine and Dentistry, London, ON, Canada; [4]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [5]University of California San Francisco, San Francisco, CA; [6]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The urine biomarkers epidermal growth factor (EGF) and monocyte chemoattractant protein-1 (MCP-1) show promise as biomarkers of chronic kidney disease (CKD) progression in settings such as diabetes mellitus, but their role in the transition from AKI to CKD remains unclear. EGF is produced specifically by renal tubular epithelium of the thick ascending limb and MCP-1 is extensively studied as a marker of kidney inflammation. We evaluated the associations of urine EGF and MCP-1 with CKD incidence or progression after cardiac surgery.

Methods: In this sub-study of the prospective TRIBE-AKI cohort, we evaluated 865 adult patients who underwent cardiac surgery from 2007–2010 at two sites in Canada and the US. We tested the association of first post-operative urine EGF and MCP-1, and the ratio EGF/MCP-1, with the composite outcome of CKD incidence or progression. We assessed for interaction by peri-operative AKI status.

Results: Over a median (IQR) follow-up of 5.8 (4.2-7.1) years, 266 (30.8%) patients developed the composite outcome at an event rate (95% CI) of 55.4 (49.2-62.5) per 1,000 person-years. Elevated levels of first post-operative urinary EGF and MCP-1 were each independently associated with the composite outcome, in opposing directions (**Table 1**), and the ratio (EGF/MCP-1) was strongly associated with decreased risk of CKD incidence or progression in both continuous and categorical analysis (aHR 0.50 [0.33-0.74] for T3 compared to T1). There was no interaction by AKI status.

Conclusions: Urine EGF and MCP-1 measured post-cardiac surgery were independently associated with CKD incidence and progression. The ratio of urine EGF/MCP-1 may be useful for risk prediction of future CKD outcomes after peri-operative injury in cardiac surgery.

Funding: NIDDK Support

Table 1: Risk of CKD Incidence or Progression by Urine Biomarker Level

Biomarker	Level/Tertile	Unadjusted HR (95% CI)	Adjusted HR for Urine Creatinine (95% CI)	Fully Adjusted* HR (95% CI)

Higher Plasma KIM-1 Is Associated with Increased Mortality and Decreased Renal Recovery in Patients with AKI Requiring Renal Replacement Therapy

Yvelynne P. Kelly,[1] Finnian R. McCausland,[1] Mallika L. Mendu,[1] Venkata Sabbisetti,[1] David E. Leaf,[1] Sushrut S. Waikar.[2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Boston Medical Center, Boston, MA.*

Background: Plasma kidney injury molecule-1 (KIM-1), a protein synthesized by renal proximal tubular cells, increases during periods of ischemia and thereby acts as a sensitive marker for AKI severity. We hypothesized that higher plasma KIM-1 levels assessed prior to commencing renal replacement therapy (RRT) would associate with higher mortality and RRT dependence in critically ill patients with severe AKI.

Methods: We measured plasma KIM-1 levels in 806 Day 0 samples from participants in Acute renal failure Trial Network (ATN) trial, a randomized controlled trial of intensive versus less-intensive RRT. For our primary analysis we used a logistic regression model to assess the risk of 28-day mortality and an inverse probability weighted logistic regression model to assess the odds of 28-day renal recovery, per doubling in log-transformed Day 0 KIM-1. Both models were adjusted for components of the ATN trial mortality risk score (age, chronic hypoxemia, CVS disease, malignancy, immunosuppressive therapy, ischemic AKI, post open surgery and vital signs at RRT initiation).

Results: Higher levels of plasma KIM-1 were associated with an increased risk of death within 28 days (adjusted odds ratio 1.15; 95% CI 1.03-1.29; $p = 0.02$) per doubling in log-transformed plasma KIM-1. Higher levels of Day 0 plasma KIM-1 were also associated with an increased risk of persistent RRT dependence at 28 days (adjusted odds ratio 0.76; 95% CI 0.66-0.87; $p < 0.0001$) per doubling in log-transformed plasma KIM-1.

Conclusions: Higher plasma KIM-1 levels measured prior to initiation of RRT are independently associated with higher 28-day mortality and lower probability of 28-day renal recovery in critically ill patients with severe AKI.

Estimated vs. Measured Glomerular Filtration Rate in Acute Decompensated Heart Failure

Jutta S. Swolinsky,[1] Enkhtuvshin Tuvshinbat,[1] Fabian Knebel,[2] Niklas P. Nerger,[1] Caroline Lemke,[1] Daniel Meier,[3] Edis Gasanin,[4] Veselin Mitrovic,[4] Kai-Uwe Eckardt,[1] Bruce A. Molitoris,[5] Kai M. Schmidt-Ott.[1] *[1]Charité Universitätsmedizin Berlin, Department of Nephrology and Medical Intensive Care, Berlin, Germany; [2]Charité Universitätsmedizin Berlin, Department of Cardiology and Angiology, Campus Mitte, Berlin, Germany; [3]FAST Biomedical, Indianapolis, IN; [4]Kerckhoff-Klinik Department of Cardiology, Bad Nauheim, Germany; [5]Indiana University School of Medicine, Indianapolis, IN.*

Background: Kidney function is closely monitored in patients with acute decompensated heart failure (ADHF). Recent studies indicate that rise in endogenous filtration markers (serum creatinine (SCr) or cystatin c (Cys)), is neither associated with tubular injury nor with adverse outcomes when accompanied by efficient decongestion. The imperfections of SCr or Cys to estimate GFR in non-steady state could contribute to misjudgment of renal function in ADHF. In this study we measured GFR (mGFR) in patients treated for ADHF and correlated them with estimated GFR dynamics.

Methods: In a prospective cohort study in 50 hospitalized subjects treated for ADHF, GFR was measured using a two-component intravenous visible fluorescent injectate (VFI) at two timepoints 48h apart. Serum concentrations of a high molecular weight dextran component of VFI were measured 15 and 60 min after injection to quantify plasma volume (PV) using indicator-dilution principle. Concentrations of a low molecular weight component were measured to determine mGFR based on PV-normalized plasma pharmacokinetics. Pearson's r, Bland-Altman plots, precision, accuracy and bias were calculated for 4 established equations (CKD EPI_{Scr}, CKD EPI_{Cys}, CKD $EPI_{Scr\ Cys}$, sMDRD) and kinetic GFR (kGFR, Chen et al., JASN 2013). 38 subjects had complete serial mGFR data.

Results: eGFR calculated by any estimating equation correlated significantly with measured GFR (CKD EPI_{Scr}, r=0.81; CKD EPI_{Cys}, r=0.81.; CKD $EPI_{Scr\ Cys}$, r=0.84.; sMDRD, r=0.81; kGFR r=0.81, p<0.0001). CKD $EPI_{Scr\ Cys}$ had the best overall performance with an accuracy (P30) of 75%. However, changes in mGFR during 48h of ADHF treatment were not adequately reflected in corresponding changes of eGFR. KDIGO SCr-based AKI criteria frequently failed to detect relevant decreases of mGFR (Sensitivity 55%).

Conclusions: In patients hospitalized for ADHF undergoing decongestion, GFR estimates based on SCr and CC display substantial deficits in estimating GFR. In particular, changes of SCr- and CC- based GFR displayed a remarkable disconnect from mGFR dynamics. KDIGO SCr criteria displayed a poor sensitivity in detecting relevant decreases of mGFR, indicating a need for improved diagnostic approaches to identify true worsening renal function in ADHF.

Multiple Beneficial Effects of Renal Exosomes on Ischemic Injury

Katherine J. Kelly,[1,2] Jesus H. Dominguez.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Richard L Roudebush VA Medical Center, Indianapolis, IN.*

Background: Ischemic injury to the kidney and other organs is deadly and expensive. We have demonstrated the effectiveness of adult cell-based therapies in multiple models of renal failure. Given the large benefits of relatively few cells, we hypothesized that exosomes from transplanted cells were the therapeutic effector. We and others have shown beneft with exosomes in renal injury models. To define the mechanisms of benefit from renal exosomes, the effects of exosomes from platelets and dermal epithelia were compared to those of renal exosomes.

Methods: The hypothesis that renal exosomes improve multiple pathways of injury postischemia and contain anti-oxidant and anti-inflammatory cargo was tested in a renal ischemia model. Exosomes from post-ischemic kidneys, platelets or skin were isolated by serial centrifugation. Renal function was estimated from serum creatinine. Oxidative stress and inflammation were assessed by immunostaining for 4-hydroxynoneal and neutrophils, respectively. Anti-inflammatory cytokine levels were measured by enzyme-linked immunoassay.

Results: We found significant improvements in renal function (figure) and structure with renal exosomes, given 24 hours postischemia, when renal failure was present. Exosomes from skin epithelia or platelets were not effective. Renal, but not skin or platelet, exosomes decreased evidence of oxidative stress in post-ischemic kidneys by 67%, with preservation of catalase and superoxide dismutase. Significantly less renal neutrophil infiltration was found in the renal exosome group as compared to postischemia groups that received vehicle or skin or platelet exosomes. Anti-inflammatory IL-10 levels were significantly higher in post-ischemic kidneys in the renal exosome group.

Conclusions: Exosomes derived from kidney cells effect multiple pathways of injury to improve postischemic kidney function.

Although Human Mesenchymal Stem Cells Effectively Treat AKI in Rats, They Elicit an Immune Response, Abolishing Their Subsequent Protective Activity

Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Christof Westenfelder.[1,2] *[1]SymbioCellTech, LLC, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: Preclinical and clinical studies have shown renoprotective effects of allogeneic Mesenchymal Stem Cell Therapy (MSC) in preventing AKI, obtained without eliciting an antibody response, confirming MSCs' immune privileged/immune-modulating properties. Many groups have attempted to enhance MSCs' potency by introducing beneficial genes via xenogeneic expression vectors. Whether such alterations conserve MSCs' immune privileged characteristics is unknown. We here tested whether (1) the expression of human antigens by MSCs from Fischer344 (F344) rats transgenic for human Alkaline Phosphatase (hPAP-rMSC), human MSCs (hMSC) or human Adipose-derived Stem Cells (hASC) alters the cells' renoprotective function in female F344 rats with IRI-induced AKI; (2) whether the administration of these cells elicits an antibody response; (3) whether such a response affects the reno-protective efficacy of the cells in subsequent treatments.

Methods: IRI AKI (42 min. bilateral pedicle clamp) was induced (n=6/group). Post reflow, groups were infused via the suprarenal aorta (s.a.) with hPAP-rMSC, hASCs or hMSC, 0.5-2x10e6 cells), or vehicle. Ten days post-AKI, serum samples were obtained and analyzed by FACS to assess for antigenic responses (IgG antibodies) to (1) MSC-specific genes, or (2) to hPAP. Two more groups of F344 rats (n=6 each) were inoculated i.p. with hASC (5x10e5). Immune response to hASCs was assessed 14 days post inoculation, and IRI AKI was induced as above, followed upon reflow by an identical s.a. infusion of hASCs or vehicle.

Results: Versus controls, all 3 cell types significantly protected renal function and hastened recovery from AKI (SCr levels, tissue injury scores); but within 14 days, each treatment elicited a significant IgG antibody response (57-99%) against the infused cell type. Rats inoculated i.p. with hASCs and confirmed to have positive immunity to hASCs were no longer renoprotected by hASCs when treated with them for IRI AKI.

Conclusions: While xenogeneic use of MSCs/ASCs is renoprotective, the demonstrated induction of an immune response makes such applications unsafe/ineffective in pre-clinical studies. Caution is advised in interpreting results of studies using cell lines containing xenogeneic expression vectors for genes meant to enhance MSCs' clinical efficacy. (Not U of Utah work)

Point-of-Care Prevention and Treatment of AKI with Adipose-Derived Stem Cells: Efficacy and Cost Advance over Culture-Expanded Bone Marrow-Derived Mesenchymal Stem Cells

Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Christof Westenfelder.[1,2] *[1]SymbioCellTech, LLC, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: Our pre-clinical studies (AJP 2005) and a Phase I Clinical Trial (Nat Rev Neph 2010) show that administration of bone marrow-derived, culture expanded, allogeneic Marrow Stromal Cells (MSC) is effective in the prevention and hastened recovery from experimental AKI; and safe and renoprotective in on-pump cardiac surgery patients at high risk for post-op AKI. Significantly, MSC treated unlike historical control on-pump cardiac surgery patients did not develop Chronic Kidney Disease (CKD) long term (>7 years). Expansion and banking of MSCs is expensive and time consuming. To address these limitations, we compared treatment with syngeneic, culture-expanded MSCs or vehicle to treatment with either syngeneic, minimally manipulated abdominal Adipose Derived Stem Cells (ASCs) or autologous Stromal Vascular Fraction (SVF, immediately isolated from fat, containing ASCs, endothelial precursor and other cells) for efficacy in preventing AKI. ASCs share therapeutically critical activities with MSCs and are found in sufficiently high numbers/gram fat to present an alternative to culture-expanded MSCs.

Methods: ASCs and SVFs were isolated by minimal processing from abdominal fat harvested from male Fisher344 (F344) rats. IRI AKI was induced (bilateral renal pedicle clamping x 40 min) in 5 groups of male F344 rats (~200 g b.wt.; n=7 each). Upon reflow, groups were infused (suprarenal aorta) with either (1) $1x10^6$ ASCs, (2) $1x10^6$ autologous SVF cells, (3) $1x10^6$ syngeneic, cultured MSCs, (4 and 5) vehicle in animals with or without fat harvest.

Results: Outcomes were compared to those of sham treated animals (n=7). Renal function assessed by serum Cr (SCr) in ASC or SVF treated animals was significantly better protected, and recovery more rapidly achieved compared to vehicle and MSC treated rats.

Conclusions: Our data suggest therefore that autologous ASCs and the SVF, obtained by minimal manipulation from a patient's lipoaspirate, have the potential to treat that same patient with an efficient, inexpensive and safe point-of-care protocol to prevent or treat AKI and prevent subsequent progression to CKD. PO0145

Administration of Exosomes from Mesenchymal Stem Cells Provides Effective Survival Benefits and Functional Rescue from Severe, Progressive Ischemia-Reperfusion Injury-Induced AKI in Rats

Anna Gooch,[1] Mikhail Skliar,[2] Ping Zhang,[1] Zhuma Hu,[1] Christof Westenfelder.[1,2] *[1]SymbioCellTech, LLC, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: While administration of Mesenchymal Stem Cells (MSCs) has been demonstrated clinically to prevent Acute Kidney Injury (AKI) such as that caused by cardiac bypass surgery, administration 48 hrs post-insult was found to be ineffective or potentially damaging, likely because the introduction of large cells (~50μm) into the compromised microvasculature may impair renal function. MSCs' renoprotection is mediated by their paracrine release of anti-inflammatory and trophic cytokines and their exosomes. Exosomes signal, post uptake by target cells, through the lateral transfer of mRNAs, miRNAs, DNA, proteins, and lipids. Since MSC-derived exosomes can prevent AKI we tested whether their small size and ability to move through the compromised renal microvasculature might allow them to provide effective rescue therapy for late stage AKI.

Methods: Exosomes from Sprague Dawley (SD) rat MSCs were isolated post 24 hr culture, purified using the ExoQuick-TC kit, and characterized for size (nanosight), protein and gene expression of relevant markers. I/R AKI (52 min bilateral renal pedicle clamp) was induced in female SD rats. If the SCr value on Day 2 was greater than that on Day 1, demonstrating progressive AKI, then rats were administered via left carotid artery either 1 ml of Vehicle (PBS; n=8), Exosomes (200 μg protein-equivalent; ~4x10e10 exosomes; n=6), or MSCs (2x10e6; n=6) on Day 3.

Results: 1x10e6 MSCs secrete ~ 4.9x10e10 exosomes and other microvesicles (mode 136.7 nm) and >95% express CD44 and CD29, and carry mRNAs of renoprotective genes expressed in MSCs. While both MSC and exosome administration improved survival over PBS, renal function only showed significant and sustained improvement in exosome-treated rats.

Conclusions: MSC-derived exosome therapy 3 days post progressive AKI, when renal blood flow is significantly impaired and when most clinical AKI is diagnosed, is superior to MSC therapy, likely due to their ability to deliver their renoproetective cargo into the compromised renal microcirculation. These data have, we posit, significant translational promise for the development of an effective rescue therapy for advanced AKI. (No University of Utah resources were used for this work.)

PO0146

Microparticles Released in Response to AKI May Influence Glucose and Salt Metabolism

Begoña Campos,[1] Kathleen Harrison,[1] Samantha M. Kramer,[1] Bassam G. Abu Jawdeh,[1,2] Charuhas V. Thakar.[1,2] *[1]University of Cincinnati College of Medicine, Cincinnati, OH; [2]Cincinnati VA Medical Center, Cincinnati, OH.*

Background: Renal epithelial injury due to ischemia or toxic/inflammatory insults is the primary cause of acute kidney injury (AKI). Due to their high metabolic activity renal tubular epithelial cells (RPTEC) are especially vulnerable to damage leading to a clinical syndrome of disruption in salt, water and glucose homeostasis. We have previously shown that microparticles (MP) derived from renal epithelial cells are released in the setting of kidney injury and can be detected in vitro as well as in human plasma, and can carry the biological activity.

Methods: In this study, we evaluated the release of MP carrying SGLT2, and SLC12A3 (NCC) in response to kidney injury. Immortalized RPTEC lines were treated with Oxidative stress (H_2O_2) or inflammatory stress (TNFα) agents by the validated methodology to study in vitro models of AKI. Human samples were derived from a prospectively collected repository (31 cases of AKI in critically ill patients compared to 22 living kidney donor healthy controls). Samples were prepared to measure MP (standard methods), and flow cytometric analysis was evaluated using antibodies against SGLT2, and SLC12A3 (NCC). FlowJo software was used for analysis. Mann-Whitney test was used for comparisons.

Results: RPTEC models of injury (H_2O_2) resulted in a significant increase in the release of MP positive for SGLT2 MP 5.49×10^{10}/ml vs 0.41×10^{10}/ml for control cells (p=0.05) and NCC (SLC12A3) 4.2×10^5 vs 0.63×10^5 for control cells (p=0.05). Similar changes were observed when cells were treated with TNFα (p=0.05) for SGLT2 and NCC. We also confirmed the presence of MP containing SGLT2 and NCC in AKI (104.60 $X10^5$ /ml and 1.77×10^5 /ml, respectively). However, when compared to controls, the difference was statistically similar.

Conclusions: This is one of the first reports to confirm that key transporters from renal epithelium can be released and detected as MP in both in vitro and clinical settings of AKI. These findings may provide novel insights into the mechanisms of glucose, salt and water dysregulation during kidney injury and repair.

PO0147

Sex as a Biological Variable in Cardiac Outcomes after AKI in Mice

Danielle Soranno, Lara A. Kirkbride-Romeo, Chris Altmann, Peter R. Baker, Sarah Faubel. *University of Colorado, Denver, CO.*

Background: Acute kidney injury (AKI) is common in patients, and predisposes patients to cardiovascular disease. Estrogen is known to protect against ischemic AKI, however it is unknown whether it also protects against the cardiac sequelae of AKI. We report a 1 year study evaluating the cardiac and metabolic effects of bilateral renal ischemia-reperfusion injury in male and female C57BL/6 mice.

Methods: Males received 25 minutes of ischemia, while females received 34 minutes. Serial glomerular filtration rate (GFR), echocardiograms and blood pressure assessments were performed with sacrifice at 1 year. Plasma and cardiac metabolomics were measured. Mead's resource calculation was utilized to calculate sample size of n = 5-11. Comparison between two groups was performed using unpaired t tests assuming Gaussian distribution with Welch's correction, $P < 0.05$ for statistical significance.

Results: Serial measurements of GFR showed that the AKI model was matched between males and females throughout the 1 year study. Males with AKI developed diastolic dysfunction (quantified on echocardiogram data by E'/A' <1), hypertension, reduced cardiac adenosine triphosphate (ATP) levels; females with AKI developed hypertension but not diastolic dysfunction and had normal cardiac ATP levels.

Conclusions: This is the first study to show chronic diastolic dysfunction after AKI and variations in cardiorenal outcomes with regards to sex. Diminished cardiac ATP is a known cause of diastolic dysfunction.

Funding: NIDDK Support

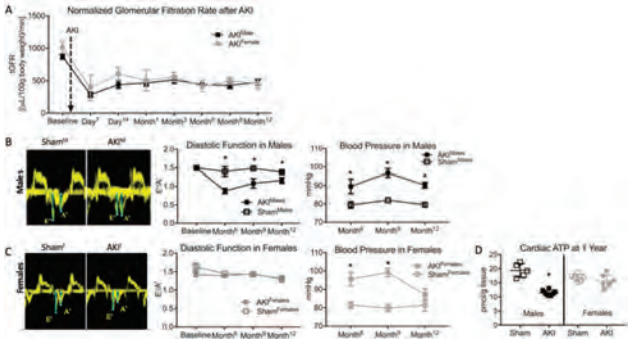

Figure 1. (A) 25 minutes of ischemia in males (AKIMales) and 34 minutes of ischemia in females (AKIFemales) results in a matched model of kidney injury with no statistically significant difference in normalized glomerular filtration rate measured over the 1 year study. (B) Males developed impaired diastolic function (E' < A') and hypertension after AKI. (C) Females maintained normal diastolic function after AKI, but did develop hypertension that resolved by 1 year. (D) 1 year after AKI, males had reduced levels of cardiac ATP whereas females did not.

PO0148

Glomerular Filtration Fails to Increase During Pregnancy After Recovery from Ischemia-Reperfusion Injury

Ellen E. Gillis, Michael W. Brands, Jennifer C. Sullivan. *Augusta University, Augusta, GA.*

Background: Renal demands are increased during normal pregnancy due to the large increase in plasma volume and cardiac output, with a corresponding increase glomerular filtration rate and decreased blood pressure (BP). Recent studies in our laboratory have reported that pregnancy after recovery from ischemia reperfusion (IR) injury results in poor maternal and fetal outcomes, including decreased fetal weight, increased fetal demise, and mild uremia in the dams. In the current study, we hypothesized that glomerular filtration fails to increase during pregnancy in these dams after recovery from IR.

Methods: Female Sprague Dawley rats (10 weeks of age, n=3) were implanted with telemeters into the femoral artery for continuous BP measurements. Following 10 days of recovery, rats were randomized to receive either 45 minutes of warm, bilateral renal ischemia or sham surgery. Rats were then given 1 month to recover. Full recovery from IR was confirmed by return of plasma creatinine and urinary protein excretion to baseline prior to mating. Vaginal smears were performed daily once mating began, to identify gestational day 1. Glomerular filtration rate was calculated using creatinine clearance (using 24 hour urine collection from gestational days 19-20 and plasma creatinine on gestational day 20).

Results: BP decreased to a similar extent (7±1.2mmHg in control vs 8±1.2mmHg in IR dams) by gestational day 20, however the decrease in BP was delayed in the IR dams, resulting in an overall higher pressure load as determined by area under the curve analysis (2080±33 vs 2184±16, $p<0.05$, t-test). Glomerular filtration rate was significantly higher in control dams compared to IR dams (3.1±0.7mL/min vs 1.6±0.1mL/min, $p<0.05$).

Conclusions: These data suggest that after recovery from IR, the kidneys are unable to appropriately increase glomerular filtration rate during pregnancy. Ongoing studies in the laboratory are focused on alterations in plasma volume expansion during pregnancy after IR. We propose that plasma volume expansion, characteristic of normal pregnancy, is absent in this model, leading to decreased placental perfusion and poor fetal growth.

Polymorphisms in HAVCR1 Alter KIM-1-Mediated Phagocytosis

Ji yun Lee,[3] Bradly Shrum,[3] Lakshman Gunaratnam.[1,2] *[1]Western University Department of Medicine, London, ON, Canada; [2]London Health Sciences Centre University Hospital, London, ON, Canada; [3]Schulich School of Medicine and Dentistry Department of Microbiology and Immunology, Western University, London, ON, Canada.*

Background: During renal ischemia reperfusion injury (IRI), necrotic cells, and apoptotic tubular epithelial cells (TECs) undergoing secondary necrosis, release their immunogenic contents into the extracellular milieu, exacerbating inflammation. Kidney Injury Molecule -1 (KIM-1) is a cell-surface glycoprotein upregulated on TECs during acute kidney injury (AKI). We previously uncovered that KIM-1 protects against renal IRI by enabling TECs to bind and engulf dying neighbouring cells, limiting inflammation and tissue damage. The gene encoding KIM-1 *(HAVCR1)* is highly polymorphic, but the relevance of human KIM-1 polymorphisms in renal IRI has not been studied. We hypothesized that *HAVCR1* variant expressing TECs would have decreased phagocytic activity *in vitro*.

Methods: Using site-directed mutagenesis, we generated constructs for 3 high-frequency *HAVCR1* coding variants in addition to an expression plasmid-encoding wild-type KIM-1 (pcDNA3-KIM-1). We then expressed the pcDNA3 vector, or *HAVCR1* variants in HEK-293 cells using stable transfection.

Results: We report that all 3 variants had altered cell surface KIM-1 expression compared to the wild-type. Importantly, the phagocytic uptake of apoptotic cells was significantly reduced in HEK-293 cells expressing each of the KIM-1 variants compared to those expressing wild-type KIM-1, indicating that mutations in these coding regions contribute to a functional impairment of KIM-1 activity.

Conclusions: This is the first study suggesting that human polymorphic variants in *HAVCR1* may have consequences on the functional role of the KIM-1 protein in the kidney. This work strengthens the plausibility of a biological role for KIM-1 during AKI.

Sympathetic Signaling in Macrophages Mitigates Systemic Inflammatory Response and Renal Ischemia-Reperfusion Injury

Sho Hasegawa,[1] Tsuyoshi Inoue,[2] Masaomi Nangaku,[1] Reiko Inagi.[1] *[1]The University of Tokyo, Tokyo, Japan; [2]Nagasaki University, Nagasaki, Japan.*

Background: The sympathetic nervous system is known to control immune cell dynamics. However, the detailed role of sympathetic signaling in inflammatory diseases is still unclear. Here, we focused on sympathetic signaling in macrophages and aimed to determine whether its activation attenuates lipopolysaccharide (LPS)-induced sepsis and renal ischemia/reperfusion injury (rIRI).

Methods: <*In vitro*> Three types of macrophages (RAW 264.7 cells [murine macrophage cell line], murine peritoneal cells, and differentiated U937 cells [human monocyte cell line]) were used to determine the effects of sympathetic signaling, especially β_2 adrenergic receptor (ADRB2) signaling, on LPS-induced proinflammatory cytokine (TNF-α) production. <*In vivo*> We examined the effects of salbutamol (β_2 selective agonist) on LPS-induced sepsis and rIRI models. Macrophage-specific ADRB2 conditional knockout (ADRB2 cKO) mice were used to elucidate the contribution of ADRB2 signaling in macrophages.

Results: <*In vitro*> Norepinephrine, a main sympathetic neurotransmitter, reduced LPS-induced TNF-α production in the three types of macrophages. This anti-inflammatory effect was also induced by salbutamol and reversed by butoxamine (β_2 selective antagonist) in a dose-dependent manner, indicating the importance of ADRB2 in this process. Furthermore, T-cell immunoglobulin and mucin-3 (TIM-3) expression was upregulated in macrophages by ADRB2 signaling and partially mediated the anti-inflammatory phenotypic alteration. <*In vivo*> Salbutamol administration immediately before LPS treatment significantly reduced plasma TNF-α levels in mice, which was mitigated in macrophage-specific ADRB2 cKO mice. Salbutamol administration 24 h before rIRI also attenuated acute kidney injury, which was relieved in macrophage-specific ADRB2 cKO mice. The protection against rIRI was abolished in the mice in which splenectomy was performed 10 days before salbutamol administration, which suggests the contribution of splenic macrophages to the protective effects. In fact, adoptive transfer of salbutamol-treated splenic macrophages conferred protection to the recipient mice subjected to rIRI.

Conclusions: Sympathetic signaling via ADRB2 in macrophages attenuates systemic inflammatory response and rIRI. Phenotypic alterations in splenic macrophages might play critical roles in the protection against rIRI.

Myeloid Lactate Dehydrogenase A (LDHA) Regulates Macrophage Polarization and Promotes Fibrosis in AKI

Gunars Osis, Amie Traylor, Hannah Eckenrode, Laurence M. Black, Steven L. Cochrun, Anupam Agarwal. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Renal ischemia/reperfusion injury (IRI), a major cause of AKI, is characterized by an initial decrease of blood flow, followed by its subsequent restoration. IRI facilitates infiltration of proinflammatory macrophages as well as proliferation of intrarenal resident macrophages that, upon activation, undergo glycolytic switch, and can further exacerbate injury by inducing excessive inflammation. LDHA, a key enzyme involved in the glycolytic switch, catalyzes the conversion of pyruvate to lactate, regenerating NAD+ from NADH. Here we investigate the role of LDHA in myeloid cells and its effect on AKI.

Methods: To test the hypothesis that myeloid LDHA expression regulates macrophage polarization, RNA-Seq studies were performed in bone marrow derived macrophages (BMDM) from wild-type and LysM-Cre LDHA knockout (LDHA KO) mice grown in M-CSF for 7 days and then polarized with IFN-γ for 24 h. To test the effect of myeloid deletion on AKI, in vivo studies were performed using wild-type and LDHA KO mice using a bilateral IRI model (20 min ischemia at 37°C).

Results: RNA-seq analysis of BMDMs lacking LDHA showed significant decrease in HIF-1α and GLUT1, which are essential for the glycolytic switch. NOS2 was increased indicating diminished oxidative phosphorylation. Pro-inflammatory genes, Ccl5, IL-18, and IL-1β were downregulated. Over-representation pathway analysis (ORA) and notable altered genes are shown below (Table). While serum creatinine and GFR were similar between wild-type and LDHA KO mice, renal cortical fibrosis was significantly diminished ($p<0.014$) in myeloid LDHA KO mice, 7 days post IRI.

Conclusions: LDHA deficient BMDMs exhibited significant decrease in essential glycolytic switch machinery in addition to the decrease in the efficiency of oxidative phosphorylation. As a result, LDHA deficient BMDMs showed a diminished pro-inflammatory and fibrotic profile ensuing lesser renal fibrosis despite similar functional injury in both genotypes. These results suggest that LDHA is a potential target to manipulate immunometabolism in the pathogenesis of AKI.

Funding: NIDDK Support, Veterans Affairs Support, Private Foundation Support

ORA Pathways and notable genes in BMDM of LDHA KO vs WT

Pathways affected by LDHA deletion	Up-regulated genes		Down-regulated genes	
Regulation of leukocyte activation	IL-7r	Tnfrsf1b	IL-1β	IL-18
Adaptive immune response	IL-12β	Tnfsf4	IL-27	Tnfsf18
Myeloid cell differentiation	Itgb3	Cdkn1c	Hif-1α	Irf8
Cytokine-cytokine receptor interaction	Csf3	Ccl22	Ccl5	Ccl6

PD-1 Regulates Metabolic Fitness of Tregs in Protection from Kidney Ischemia-Reperfusion Injury

Murat Dogan, Rajkumar Venkatadri, Vikram Sabapathy, Sandhya Xavier, Didier Portilla, Rahul Sharma. *University of Virginia, Charlottesville, VA.*

Background: Regulatory T cells (Tregs) protect the kidney in models of ischemia reperfusion injury (IRI) induced acute kidney injury (AKI). Previous studies suggested programmed cell death protein 1 (PD-1) expression by Tregs is required for their protective function in AKI. However downstream mechanisms of PD-1 signaling in Tregs in AKI is not clear. We aimed to investigate the role of PD-1 in Tregs with respect to mitochondrial function in AKI.

Methods: We induced AKI in male C57Bl/6 mice with 26 min bilateral renal IRI. $CD4^+$ $CD25^+$ Tregs were isolated from PD-$1^{+/+}$ and PD-$1^{-/-}$ Foxp3-GFP mice and then injected (100,000 cells/200ul) via tail vein into recipient mice 24h prior to ischemia reperfusion surgery. Kidney function was determined by measuring creatinine and tissue KIM-1 and NGAL mRNA expression levels. Histological damage was assessed by light microscopic analysis of H&E stained kidney sections. In different set of experiments, to understand the metabolic fitness of Tregs, we treated isolated T-cells from PD-$1^{+/+}$ and PD-$1^{-/-}$ mice and incubated them overnight with anti-CD3-Ab to mimic antigenic stimulation or with high concentration of IL-2, which is critical for Treg survival and function. Mitochondrial membrane potential of Tregs was measured with TMRE to monitor the mitochondrial fitness. FACS-sorted Tregs from PD-$1^{+/+}$ and PD-$1^{-/-}$ mice were also analyzed for the expression of genes involved in mitochondrial dynamics and biogenesis.

Results: In the mouse kidney IRI, PD-$1^{-/-}$ Tregs offered no protection from AKI. Compared to PD-$1^{+/+}$, PD-$1^{-/-}$ Tregs had reduced mitochondrial mass and mitochondrial membrane potential. In FACS-sorted Tregs, expression of markers of mitochondrial function, antioxidant pathways as well as those for mitochondrial dynamics were remarkably attenuated in the Tregs from PD-$1^{-/-}$ mice as compared to PD-$1^{+/+}$ mice.

Conclusions: Ability of Tregs to protect kidney from IRI-induced AKI is dependent on PD-1 expression by Tregs. Mitotracker green and TMRE experiments suggest that in the absence of PD-1, Tregs have reduced mitochondrial number and/or function. Tregs require mitochondrial fitness for their development and optimal function. Additionally, these genes may regulate cytoskeleton rearrangement and microtubule movement related to cell motility, granule release and cell division.

ST2/IL33 Signaling Axis in Tregs Critical for Restoring Kidney Tissues Homeostasis on Injury

Vikram Sabapathy,[1] Nardos T. Cheru,[2] Airi Price,[1] Rajkumar Venkatadri,[1] Murat Dogan,[1] Saleh Mohammad,[1] Brian K. Stevens,[1] Rahul Sharma.[1] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]National Institutes of Health, Bethesda, MD.*

Background: Renal diseases are a major cause of morbidity and mortality worldwide. Thus, leading to a great financial burden on health care systems. Inflammation elicited by a variety of cytokines and chemokines is a major player in the initiation and progression of the disease. Interleukin 33 (IL-33) acts as an 'alarmin' that regulates the immune response during injury. IL-33 acts in an autocrine/paracrine manner through membrane receptor (ST2) aka IL33R or IL-1 receptor-like 1 (IL1RL1), triggering an innate and adaptive immune response. There is no evidence determining the importance of the ST2/IL33 axis in Tregs during kidney injury. In this study, we attempt to delineate the role of the ST2/IL33 pathway in Tregs cells using murine renal injury models and kidney organoids.

Methods: Murine ischemia-reperfusion injury (IRI) model was used to investigate the importance of cell-specific ST2/IL-33 signaling using IL1RL1^{tm1a} and Foxp3 cre mice to delete ST2 expression in Tregs. RNA sequencing analysis, flow cytometry, histology, immunohistochemistry, quantitative gene expression, and biochemical analysis were applied to dissect the role of ST2/IL33 signaling. Kidney organoid based 3D cell culture platform was used to setup co-culture experiments with ST2-/- and ST2+/+ Tregs for *invitro* evaluation.

Results: The RNA sequencing analysis of ST2-High Tregs indicated higher expression of regenerative factors such as amphiregulin (AREG) and Growth/differentiation factor (GDF15). The *in vivo* renal injury experimental data indicated that elimination of ST2/IL33 signaling from Tregs resulted in exacerbation of renal injury leading to worsening of renal function as determined by plasma creatinine, blood urea nitrogen, kidney injury markers (kim1 and Ngal) and fibrosis markers (Col1a1, Col3a1, SMA, and vimentin). Co-culture of kidney organoids with ST2+/+ expressing Tregs protected organoids from cellular apoptosis under *invitro* ischemia-reoxygenation conditions compared to ST2-/- Tregs.

Conclusions: Impairment of ST2/IL33 signaling in Tregs leads to worsening of renal function following ischemic injury. This indicating that activation of ST2/IL33 signaling in Tregs mediate in the regulation of inflammation, apoptosis, and repair in renal tissue during inflammation and injury.

PO0154

Toll-Like Receptor 4 Blockade Ameliorates Kidney Ischemia-Reperfusion Injury

Su Woong Jung, Seo Jung-Woo, Yang gyun Kim, Ju young Moon, Sangho Lee. *Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

Background: Renal ischemia-reperfusion injury (IRI) is a key mechanism in various clinical conditions including sepsis and transplantation, and animal studies have demonstrated that toll-like receptor 4 (TLR4) is a key mediator of IRI. Since few study have tried the pharmacolgic inhibition of TLR4 in renal IRI, we investigated the effect of TLR4 blockade on this condition with the goal of persuing better therapeutic options.

Methods: We subjected C57BL/6 mice to 23 minutes of renal pedicle clamping following an intraperitoneal injection of TLR inhibitory peptide (TIP1), a TLR4 inhibitor, or vehicle. Sham mice underwent only a flank incision. Then, the kidneys were harvested after 24 hours of reperfusion for histology, western blot, RT-PCR, and flow cytometry. We also performed primary mouse renal tubular cell culture to assess the effects of TLR4 inhibition on tubular epithelial cells under hypoxia and subsequent reoxygenation.

Results: TIP1 pretreatment lowered the magnitude of an increase in serum creatinine levels and attenuated tubular injury. In addition, TIP1 administration decreased mRNA expressions of inflammatory cytokines, and apoptotic cells, and lowered oxidative stress in postischemic kidneys. The kidneys pretreated with TIP1 also showed less infiltration of macrophages and T helper 17 cells. In primary mouse tubular cells subjected to hypoxia and reoxygenation, the addition of TIP1 into culture media ameliorated the magnitude of an increase in mRNA levels of KIM1 and inflammatory cytokines.

Conclusions: Our data demonstrated that inhibition of TLR4 with TIP1 reduced tubular injury and an inflammatory and immune response in a mouse model of IRI.

Six1 Activation Is Involved in Cell Proliferation and Migration and Anti-Inflammation of Acute Ischemia-Reperfusion Injury in Mice

Yong Jin,[1] Xin Wan,[2] Changchun Cao.[1] *[1]Department of Nephrology, Sir Run Run Hospital, Nanjing Medical University, Nanjing, China; [2]Department of Nephrology, Nanjing First Hospital, Nanjing Medical University, Nanjing, China.*

Background: Nephrogenic proteins are re-expressed during the regeneration process after ischemia reperfusion (IR) injury, while the role of these proteins in the repair of kidney injury is still unknown. We found that Six1, a developmentally regulated homeoprotein is reactivated in tubular epithelial cells (TECs) after IR injury.

Methods: We established Six1 overexpresstion cell lines to confirm its effect on kidney repair in vitro. Cell proliferation and cell migration was detected by flow cytometry and cell migration assays respectively. Luciferase reporter assay was used to measure the anti-inflammation capacity of Six1 overexpressing cells, and chromatin immunoprecipitation (ChIP)-qPCR was used to analyze Six1 protein occupancy of the indicated genes. In vivo,

we injected adeno-associated viral vector serotype 9 (AAV9)-Six1 into uninjured renal pelvis before IR injury, then assessed morphologic and functional parameters and gene expression in IR injury kidney.

Results: We demonstrated that Six1 promoted cell proliferation by upregulating cyclin and glycolytic genes, and that cell migration through increasing the expression of matrix metalloproteinases (MMPs) in the cell model. Notably, the overexpression of Six1 could suppress inflammation through NF-κB-mediated pathway. Six1 target the promoters of amino-terminal enhancer of split (AES) and translocated in liposarcoma (TLS), which are cofactors of NF-κB subunit RelA, and then inhibit the transactivation function of RelA in a negative feedback circuit. Six1 overexpression resulted in inhibiting inflammation and promoting cell proliferation to reduce kidney damage of mice from IR injury in vivo.

Conclusions: Our studies suggested that Six1 promoted kidney recovery and regeneration through cell proliferation/migration and anti-inflammation which might be a potential therapeutic target that can be used to improve kidney repair after IR injury.

PO0156

IRF8-Dependent Regulation of Kidney Dendritic Cells in Ischemic AKI

Li Na,[1,2] Stefanie Steiger,[2] Zhihua Zheng,[1] Hans J. Anders,[2] Julia Lichtnekert.[2] *[1]Division of Nephrology, The Seventh Affiliated Hospital, Sun Yat-sen University, Shenzhen, China; [2]Division of Nephrology, Department of Medicine IV, Hospital of the LMU Munich, Munich, Germany.*

Background: Ischemic acute tubular necrosis is a common cause of acute kidney injury (AKI), which involves a greater functional diversity of mononuclear phagocytes (MPCs) such as dendritic cells (DCs). The deletion of DCs induce more kidney injury and impair the recovery of AKI. The hematopoietic transcription factor IRF8 mediates the phenotype of DC. However, the role of IRF8 dependent mechanism during AKI is not well known. Hence, we hypothesized that the dynamically altered expression of IRF8 in DCs could contribute to AKI.

Methods: AKI was induced by transient renal pedicle clamping in C57BL6/J. Kidneys, lymph nodes and spleens were collected on D1, D3 and D7. MPCs were identified by Flow cytometry. Expression of IRF8 and MHC II were quantified by IHC. The knockdown of IRF8 was performed by transfecting siRNA in bone marrow-derived DCs (BMDCs). BMDCs were stimulated with necrotic supernatant from tubular epithelial cells or histones and analyzed by phagocytosis assay, T cell differentiation assay, RT-PCR or flow cytometry.

Results: *In vivo*, we identified four distinct phenotypically MPCs with diverse expression patterns of CD11b/CD11c during post-ischemic AKI. During the late injury and repair phase (D3 and D7), $CD11b^{low}CD11c^{hi}$ R4 subsets significantly increased (Figure), which were identified as $CD103^{+}$ $CD11b^{-}$ DCs with significantly upregulated expression of IRF8. This pattern was consistent in spleen and lymph nodes. In kidney, more $IRF8^{+}$ cells distributed among the tubulointerstitium and the expression of IRF8 increased significantly during D3 and D7. Further, $IRF8^{+}$ cells showed co-staining with MHCII. *In vitro*, IRF8 knockdown in BMDCs induced a significant downregulated $CD8a^{+}$ $CD11b^{-}$ cells and expression of IL-22 upon necrotic supernatant or histone stimulation. Furthermore, IRF8 knockdown significantly reduced DCs maturation, phagocytosis capacity and naïve T cells polarization.

Conclusions: DC-like MPCs appear in the recovery phase of AKI in a IRF8-dependent mechanism. Selective deletion of IRF8 profoundly alters the phenotype of DCs in response to injury. It implies that selective targeting of $IRF8^{hi}$ DCs may provide an effective strategy to induce immune-modulation of the progression of AKI.

PO0157

VNN1 Mediates Renal Maladaptive Repair After AKI by Inducing Premature Senescence of Renal Tubular Cells

Kehong Chen. *Daping hospital, Chongqing, China.*

Background: Renal maladaptive repair can promote lead to the transition of acute kidney injury (AKI) to chronic kidney disease. Sustained renal interstitial damage caused by accelerated senescence of renal tubular cells leads to renal fibrosis after AKI. Vanin-1 (VNN1) is an extracellular enzyme with panthenylmethylaminease activity that indirectly reduces the synthesis of glutathione, causing oxidative stress. This study aimed at investigating the role of VNN1 in senescence of renal tubular cells after renal ischemia reperfusion (I/R) injury.

Methods: Thirty male wild BALB/c mice were randomly divided into control group, sham group and I/R group. In the I/R group, bilateral renal pedicles were clamped for 35 min and reperfusion was performed. The expression of VNN1 were detected. Furthermore, the degree of renal damage and the senescence of renal tubular cells were compared in wild type mice and VNN1 knockout mice after I/R injury.

Results: Scr, BUN and renal injury score increased significantly at the early stage (3d) of renal injury after I/R. Renal fibrosis was observed in the advanced stage (28-42d). The expression of VNN1 in renal tubular cells of I/R group increased after I/R injury. The SCr, BUN levels in VNN1 KO mice were significantly lower than those in wild type mice at 7-28 d after renal reperfusion. The renal interstitial fibrosis level was significantly higher in VNN1 KO mice than that of wild type mice at 42d after reperfusion. The results suggest that VNN1 KO promotes renal repair of AKI. It is found that 50% of the VNN1 up-regulated genes after IR renal injury were stress-related genes through mRNA microarray analysis. The ratio of P16 positive tubule cells in VNN1 KO mice was significantly higher than that in wild-type mice at 7d after renal reperfusion. The expression levels of phosphorylated RB1 in VNN1 KO renal tubular cells were significantly higher than those in the wild type renal tubular cells after hypoxia/reoxygenation, suggesting that VNN1 could promote the senescence of renal tubule cells through P16- RB1 pathway during AKI repair

Conclusions: VNN1 mediates renal maladaptive repair after AKI by inducing premature senescence of renal tubular cells through P16-RB1 pathway.

CDK4-Related Tubular Epithelial Cell Proliferation Was Regulated by Pax2 in Renal Ischemia-Reperfusion Injury

Keisuke Sako,[1] Yuta Yamamura,[1] Yasunori Iwata,[1] Norihiko Sakai,[1] Miho Shimizu,[1] Kengo Furuichi,[2] Takashi Wada.[1] *[1]Kanazawa University, Kanazawa, Japan; [2]Kanazawa Medical University School of Medicine, Uchinada, Japan.*

Background: Pax2 is a transcription factor necessary for kidney development. It has been reported that Pax2 is reactivated in tubular epithelial cells at the recovery phase of kidney injury. However, the roles of Pax2 in the regeneration of kidney injury is unknown. Here in we hypothesized that Pax2 reactivation is involved in the regeneration of impaired tubular cells.

Methods: To determine the function of Pax2 reactivation in mouse proximal tubules, we generated kidney proximal tubule-specific Pax2 conditional knockout (KO) mice. The conditional KO mice were established by KAP (kidney androgen regulated protein) Cre mice and Pax2 flox mice. Six to eight-week old male mice were used for ischemia-reperfusion (I/R) injury (left kidney, 60 minutes). The intensity of cell proliferation and fibrosis of injured kidney was evaluated. A Pax2 inhibitor (EG1) was used to evaluate the roles of Pax2 in the hypoxia condition of cultured tubular epithelial cells (O_2 5%, 24 hour).

Results: The number of Pax2-positive cells and Pax2 mRNA increased after I/R injury. However, the reactivation of Pax2 was significantly suppressed in conditional KO mice ($p<0.05$). In analysis of interstitial fibrosis, the area of Sirius red staining and the content of hydroxyproline (chemical marker of collagen) were higher those observed in conditional KO mice 14 days after I/R injury ($p<0.05$). Moreover, the expression of CTGF was significantly increased in conditional KO mice ($p<0.05$). Furthermore, the number of Ki-67 and BrdU positive cells was significantly decreased in the conditional KO mice 14 days after I/R injury ($p<0.001$). In the cell cycle, the number of CDK4-positive cells (G1 phase marker) and the expression of CDK4 were significantly decreased in conditional KO mice ($p<0.001$). *In vitro* study revealed that CDK4 mRNA and protein expression were decreased by administration of Pax2 inhibitor, however Cyclin D mRNA and protein expression were not decreased by the inhibitor.

Conclusions: Pax2 reactivation may be involved in CDK4 related tubular epithelial cell proliferation. Inadequate Pax2 reactivation (or suppression of Pax2 expression) may be related in exacerbation of kidney fibrosis.

PO0159

Protein Deacetylase SIRT2 Regulates Exosome Release of GPRC5B for Epithelial Tubule Growth

Sang-Ho Kwon. *Augusta University, Augusta, GA.*

Background: Exosomes, small membrane vesicles, are formed intracellularly within multivesicular bodies (MVBs) and are released extracellularly upon fusion with the plasma membrane. Previously we have shown that exosomal release of GPRC5B, an orphan G protein-coupled receptor (GPCR) promotes epithelial tubule growth, and the L-type lectin LMAN2 limits trans-Golgi Network-to-endosomes traffic of GPRC5B.

Methods: Using mass spectrometry, CRISPR/Cas9 genetic manipulation, and imaging, we studied how LMAN2 regulates exosomal release of GPRC5B.

Results: Here, we report the protein deacetylase sirtuin 2 (SIRT2) as a novel interactor of LMAN2. Loss of SIRT2 expression resulted in exosomal release of LMAN2, a Golgi resident protein, together with increased exosomal release of GPRC5B. Furthermore, loss of SIRT2 increased total number of extracellular vesicles (EVs) including exosomes, indicating increased MVB-to-EV flux. While knockout of SIRT1 increased EV release with enlarged late endolysosome, knockout of SIRT2 did not exhibit endolysosome enlargement for increased EV release.

Conclusions: Taken together, our study suggests that SIRT2 regulates cargo loading to MVBs and MVB-to-EV flux through a mechanism distinct from that of SIRT1.

PO0160

The Proximal Tubule Is a Source of De Novo NAD$^+$ Synthesis, the Metabolites of Which Are a Valuable Predictor of AKI

Yujia Wang, Chuan-Ming Hao. *Huashan Hospital Fudan University, Shanghai, China*.

Background: Reduced NAD+ is reported to increase the susceptibility of AKI. De novo synthesis pathway from tryptophan is an important source of NAD+ in the liver and probably kidney. In the present study, we characterized the expression of the enzymes of de novo NAD+ synthesis pathway in the human kidney. We then examined the association of the urine metabolites in this pathway and AKI development in patients who received high-dose methotrexate(HDMTX) chemotherapy or liver transplantation(LT) and analyzed their predictive value for AKI.

Methods: The expression of the enzymes of de novo NAD+ synthesis pathway was examined by immunohistochemistry. To examine the predictive value of urine tryptophan metabolites in AKI, 71 patients who received a total of 191 HDMTX treatments were prospectively enrolled as a discovery cohort and 49 patients receiving LT were enrolled as a validation cohort. Urine samples were collected within 72 hours before chemotherapy/surgery. AKI was defined by KDIGO criteria. Urine tryptophan metabolites were measured by LC-MS and adjusted by creatinine. The performance of these metabolites to predict AKI after HDMTX/LT was analyzed.

Results: Enzymes of de novo NAD+ synthesis pathway including KMO, KYNU, HAAO, QPRT, and ACMSD were detected in renal tubules that were positive for LTL, but not labeled by AQP2, NCCT, nor THP, consistent with proximal tubule expression. A total of 191 HDMTX treatments were included in the discovery cohort and AKI developed after 35 HDMTX treatments (18.3%). In those who developed AKI, the urine level of 3-hydroxyanthranilic acid (3-OH AA) was significantly higher while the level of quinolinic acid (QA) was significantly lower compared with those who did not develop AKI (3-OH AA: 4.42[2.74-9.52] vs 3.57[1.86-5.73], p=0.023; QA: 13.43[9.69-22.34] vs 20.64[14.80-32.05], p=0.004). The area under the receiver operating characteristic curve (AUC) of urine QA/3-OH AA for AKI prediction was 0.748. The discrimination ability of the urine QA/3-OH AA on AKI susceptibility was validated in LT cohort, with the AUC as 0.729.

Conclusions: The proximal tubules are an important source of de novo NAD synthesis. Reduced urine QA / 3-OH AA ratio is associated with development of AKI. The present study suggests that urine QA / 3-OH AA ratio is a potential biomarker to predict AKI and NAD+ synthesis pathway is a potential therapeutic target.

PO0161

Sphingolipid Transporter 2 (Spns2) Expression, Localization, and Role in AKI

Nataliya Skrypnyk,[1] Shuqiu Zheng,[1] Sylvia Cechova,[1] Nabin Poudel,[1] Kevin Lynch,[2] Mark D. Okusa.[1] *[1]Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacology, University of Virginia, Charlottesville, VA.*

Background: The sphingosine 1-phosphate (S1P) transporter Spns2 exports S1P from the cell and regulates the gradient of high circulating S1P levels to low tissue levels. Activation of S1P receptors can protect kidneys from acute injury, but little is known of the role of Spns2 in kidney. In these studies, we investigated the expression, localization, and role of Spns2 in the kidney after ischemia-reperfusion injury (IRI).

Methods: ***In vivo***. Expression of Spns2 mRNA and protein in the kidneys and urine of C57BL/6 mice was analyzed 24 hours after sham surgery or IRI. Spns2 protein was assessed by western blot (WB) of membrane-enriched fractions of kidney. Renal function was evaluated by measurement of plasma creatinine. Spns2 localization and its co-localization with tubular markers in kidney (lens culinaris agglutinin, marker of brush border of S1-S3 segment of proximal tubules (PT) and wheat germ agglutinin a marker of brush border of S3 segment and cytosol of distal nephron) was by immunofluorescence (IF). To study the role of Spns2 after kidney injury, we pretreated mice 24h before IRI with Spns2 inhibitor (10 and 30 mg/kg, ip). ***In vitro.*** We generated clone with the highest Spns2 expression by the method of limited dilutions in TKPTS; Spns2 expression was validated by WB, quantitative real time PCR and IF.

Results: We demonstrated that the kidney has the highest mRNA expression of Spns2 when compared to other organs (liver, lung, spleen, heart, thymus). We determined that Spns2 is localized to the brush border of S1-S2 segment of PT and its expression is reduced 24h after IRI, while levels of Spns2 protein increased in urine. Pretreatment of mice with Spns2 inhibitor produced dose dependent protection against AKI, as judged by plasma creatinine and Kim1 mRNA expression at 24h after IRI and also induced dose dependent lymphopenia in mice. Spns2-overexpressing cells had increased TGFβ1 mRNA expression.

Conclusions: Spns2 is expressed in high abundance in kidney and is localized to the brush border of S1-S2 segments of the PT. Following IRI, PT Spns2 expression is reduced and appears in the urine. SPNS2 can serve as a potential target to prevent AKI, however further studies are needed to determine whether the protective effect of Spns2 inhibitor was due to lymphopenia or to a direct effect of Spns2 expressed in PT.

PO0162

Dietary Omega-3 Fatty Acids Alter the Lipid Mediator Profile and the Fatty Acid Composition of Membrane Phospholipids but Is Not Enough to Improve Renal Insufficiency

Ryotaro Shioda,[1,2] Airi Jo,[2] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Biochemistry, Juntendo University Graduate School of Medicine, Tokyo, Japan*.

Background: The efficacy of omega-3 fatty acids on ischemia-induced AKI has been reported, but the underlying mechanisms remain poorly understood. There have been no reports that demonstrated how dietary omega-3 fatty acids influenced the components of membrane phospholipids in the kidney. In this study, we focused on the effect of dietary omega-3 fatty acids on the membrane phospholipids components in the kidney, and examined the disease course of ischemia-induced AKI in the presence of the lipid mediator alterable by dietary omega-3 fatty acids.

Methods: Male 4-week-old wild-type Sprague-Dawley rats were fed for 2 months on AIN-93M, which contains 4% soy oil, or modified AIN-93M, which contains 4% perilla oil instead of soy oil. AKI was induced by unilateral ischemic reperfusion with right nephrectomy. Left renal ischemia was induced by using non-traumatic vascular clamps for 30 min. At 24h after reperfusion, left kidneys and serum were collected. The fatty acid composition of membrane phospholipids and lipid mediators were quantified by HPLC-tandem mass spectrometry (HPLC/MS/MS).

Results: In the kidney of omega-3 diet fed rats, the levels of arachidonic acid-derived proinflammatory lipid mediators, except for 5-HETE, were not reduced compared with omega-6 fed rats. Eicosapentaenoic acid (EPA) and EPA-derived lipid mediators were significantly increased in the kidney of omega-3 diet fed rats. Furthermore, membrane phospholipids which contained EPA and docosahexaenoic acid (DHA) were significantly increased in the kidney of omega-3 diet fed rats. However, there was no significant difference in serum creatinine, blood urea nitrogen or histological damage between omega-3 diet fed rats and omega-6 diet fed rats.

Conclusions: Dietary omega-3 fatty acids altered the lipid mediatorsthe and the fatty acid composition of membrane phospholipids, but was not enough to improve renal insufficiency or histological damage.

PO0163

A Vago-Sympathetic Reflex Mediates Kidney Protection from Ischemia-Reperfusion Injury

Shinji Tanaka,[1] Chikara Abe,[2,3] Shuqiu Zheng,[1] Yusuke Yamaoka,[1,3] Jonathan E. Lipsey,[1] Nataliya Skrypnyk,[1] Junlan Yao,[1] Tsuyoshi Inoue,[4] Daniel S. Stornetta,[2] Stephen Abbott,[2] Diane L. Rosin,[2] Ruth Stornetta,[2] Patrice G. Guyenet,[2] Mark D. Okusa.[1] *[1]Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacology, University of Virginia, Charlottesville, VA; [3]Department of Physiology, Gifu University Graduate School of Medicine, Gifu, Japan; [4]Division of CKD Pathophysiology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan*.

Background: We recently showed that electrical stimulation of the cervical vagus nerve (VNS) protected mouse kidneys from ischemia-reperfusion injury (IRI) by activating the cholinergic anti-inflammatory pathway (PMID: 27088805). Whether the protection is caused by the activation of vagal efferent or afferent fibers needs clarification.

Methods: We generated choline acetyltransferase-channelrhodopsin-2 (*Chat-ChR2*) mice and vesicular glutamate transporter 2 (*Vglut2*)-*ChR2* mice, which express ChR2 in vagal efferent and afferent neurons, respectively. Selective optogenetic stimulation of vagal sensory afferent fibers (*Vglut2-ChR2* mice) or efferent fibers (*Chat-ChR2* mice) was performed 24 h before bilateral renal IRI, and mice were euthanized 24 h after IRI.

Results: Optogenetic VNS protected kidneys from IRI in both *Chat-ChR2* and *Vglut2-ChR2* mice as shown by decreased plasma creatinine, reduced renal Kim-1 expression and improved kidney histology. Next, we sought to identify the circuitry responsible for the renal protection elicited by vagal sensory afferent stimulation (afferent VNS). The protective effect of afferent VNS persisted after blocking the rise in corticosterone with mifepristone or after subdiaphragmatic vagotomy, but was abolished by the sympathetic/parasympathetic ganglionic blocker hexamethonium. Moreover, ablation of the splenic nerve (predominantly sympathetic nerve) and splenectomy abolished the protective effect of afferent VNS. Finally, adoptive transfer of splenocytes from mice subjected to afferent VNS, as opposed to sham stimulation, protected recipient mice from kidney IRI, suggesting that splenocytes activated through the splenic nerve mediate the kidney protection.

Conclusions: Stimulation of either vagal efferent or afferent neurons protected the kidneys from IRI. The beneficial effect of afferent VNS requires the spleen and is mediated via a vago-sympathetic reflex.

Kidney Functional Improvements by a Novel Potent and Selective Vasopressin V1a Antagonist After Ischemia/Reperfusion Injury (I/RI) in Rats

Karoline Droebner, Hana Cernecka, Chantal Fuerstner, Marie-Pierre L. Collin, Mira Pavkovic, Peter Hein, Frank Eitner, Peter Kolkhof. *Bayer AG, Wuppertal, Germany*.

Background: Alteration in renal perfusion is a key pathologic mechanism implicated in the development of ischemic acute kidney injury (AKI). We have reported that activation of V1a receptor decreases renal blood flow (RBF) and oxygenation in settings of increased vasopressin (AVP) levels. Here we studied the role of BAY 2327949, a recently identified potent and selective V1a antagonist, in a rat renal I/RI model.

Methods: In a first setting, rats were infused with BAY 2327949 (100 µg/min/kg i.v.) or vehicle and baseline measurements were determined for 20 min. Unilateral ischemia was induced by clamping of left kidneys for 15 min, followed by 20 min of reperfusion. RBF and intrarenal oxygenation (pO_2) were continuously measured via Laser Doppler Flowmetry. In a second setting, kidney function (creatinine, cystatin C, urea) was studied 24h after 45 minutes of ischemia in uninephrectomised male rats treated with BAY 2327949 (0.5, 1 and 3 mg/kg BID, i.v.).

Results: Unilateral clamping resulted in an immediate drop of RBF and pO_2 that partially recovered during reperfusion (figure). Treatment with BAY 2327949 significantly ameliorated the severity of ischemic hypoxia and resulted in an improved and almost complete restoration of RBF and pO_2 during reperfusion (figure). In the second setting, preventive treatment with BAY 2327949 resulted in dose-dependent, significant improvements of kidney function parameters 24h post I/RI as compared to placebo treated rats.

Conclusions: BAY 2327949 is a novel potent and selective vasopressin V1a receptor antagonist blocking the detrimental effects of elevated vasopressin levels on renal perfusion and oxygenation. For these reasons, BAY 2327949 could become a viable treatment option in conditions of increased AVP levels, such as AKI and CKD.

Augmenter of Liver Regeneration Protects Kidney from Ischemia-Reperfusion Injury via Regulation of TLR4/MAPKs Signaling Pathway

Ying Li,[2,1] Weijian Xiong.[2] [1]*The Second Affliated Hospital, Chongqing Medical University, Chongqing, China;* [2]*ChongqingTraditional Chinese Medicine Hospital, Chongqing, China*.

Background: Toll-like receptor 4 (TLR4) expressed within the ischemic kidney is a crucial mediator of innate activation and inflammation. The augmenter of liver regeneration (ALR) is an immunoregulator which is highly expressed in kidney upon induction of renal I/R injury. It has been shown that exogenous ALR can protect kidney against I/R injury. However, whether ALR's protective effect results from its immune regulatory function has yet to be determined. In this study, we show that treating renal I/R induced-rats with recombinant human ALR (rhALR) protects them from kidney I/R.

Methods: Rats were randomized into 4 groups as follows: sham-operated group; I/R group; I/R+rhALR1 group; I/R+rhALR2 group. TLR4, neutrophils and macrophages were detected by immunochemistry. ERK, JNK, and p38 proteins were tested by WB. mRNA of HMGB-1, Biglycan, HAS1, HAS2 and HAS3 was detected by real-time PCR. The cytokines and chemokines were measured by ELISA.

Results: This result is corroborated by less tubular damage on rhALR treated rats than those on untreated rats. rhALR treated rats have significantly less apoptosis in tubular epithelial cells, less tubulointerstitial infiltration by neutrophils (24 h) and macrophages (72 h), as well as lower levels of inflammatory cytokines compared to the untreated control rats. Furthermore, rhALR downregulate mRNA expression of endogenous liagands for TLR4 and restrain activation of TLR4 and downstream signaling molecules (ERK, JNK and p38) on rats with renal I/R injury.

Conclusions: rhALR protects kidney from I/R injury by relieving the inflammatory responses via regulation of TLR4 signaling pathway. These results suggest that ALR might be used in the development of novel immune therapy for the renal IRI

DPP-4 Inhibitor Attenuated Renal Vasoconstriction Following Ischemia-Reperfusion Injury in Cirrhotic Rats

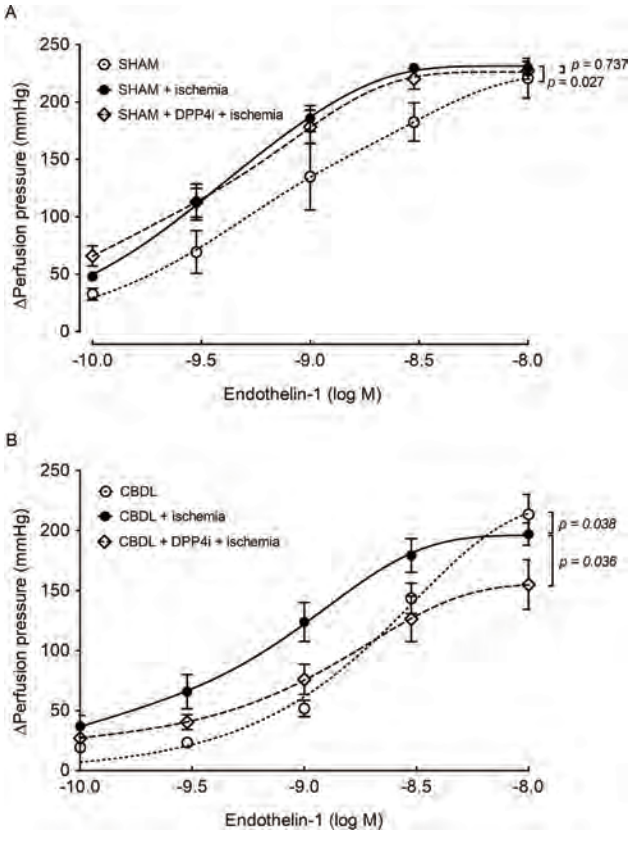
Chiao-Lin Chuang,[1,2] Hui-Chun Huang.[1,2] [1]*Department of Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan;* [2]*Department of Medicine, National Yang-Ming University School of Medicine, Taipei, Taiwan*.

Background: Cirrhotic patients may develop esophageal varices to cope with portal hypertension. Variceal bleeding is usually associated with hypotension and ischemia-reperfusion injury (IRI) which may activate endogenous vasoconstrictors, leading to severe renal vasoconstriction and renal failure (so called hepatorenal syndrome). Previous studies reported that dipeptidyl peptidase-4 inhibitor (DPP4i) could attenuate the endothelin-1 (ET-1) induced vasocontraction and increase vasodilation. The aim of this study is to delineate the effect of DPP4i in renal vascular reactivity of cirrhotic rats following IRI.

Methods: Male S-D rats were used for experiments. Biliary cirrhosis was created by common bile duct ligation (CBDL). Control group received sham surgery (SHAM). After surgery, Linagliptin (3 mg/kg/d) or distilled water (DW) was administered for 28 days. On the 29th day, bilateral renal pedicles were clamped with microvascular clamps for 45 minutes in IRI group. The clamps were then removed followed with 60 minutes of reperfusion. Kidneys were perfused in situ via right renal artery for continuous monitoring of renal perfusion pressure.

Results: There was no difference in mean arterial pressure, heart rate, portal pressure, and blood sugar between DW and DPP4i treated rats. IRI enhanced renal vascular response to ET-1 in both SHAM (p=0.027) and CBDL (p=0.025) rats, implying renal vasoconstriction. Compared with corresponding DW-treated rats, DPP4i treatment abrogated renal hyperreactivity following IRI in CBDL rats (p=0.036), but not in SHAM rats (p=0.737).

Conclusions: We concluded that DPP4i may attenuate the development of renal vasoconstriction following IRI in cirrhotic rats. The potentially mechanisms remained to be elucidated.



Concentration-response curves to ET-1 in perfused kidneys of SHAM (A) and BDL (B) rats.

PO0167

PTEN Protects Against Ischemia Reperfusion-Induced AKI via Regulating TNF-α Mediated Apoptosis

Huizhen Wang, Aiqing Li. *Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China*.

Background: Recently, PTEN, a vital tumor suppressor, has been raised its role in kidney homeostasis. We previous demonstrated that podocyte-specific knock-in of PTEN alleviated albuminuria and glomerulosclerosis in diabetic kidney disease. However, whether PTEN involves in acute kidney injury (AKI) remains unclear.

Methods: The levels of PTEN in renal tissue and serum were detected in ischemia-reperfusion (IR)-induced AKI mice with different ischemia time. Expression of PTEN was also detected in IR-induced cultured HK-2 injury with different ischemia and reperfusion time using ATP/glucose depletion that concentration of antimycin A mimicked the severity of ischemia. Immunoprecipitation and mass spectrometry were combined to analyze differential PTEN-interacting proteins among control, IRI+LV-NC and IRI+LV-PTEN groups. PTEN intervention including knock-down (si-PTEN) and knock-in (lentivirus-PTEN) was performed in HK-2 to reveal the role and mechanism of PTEN in IRI-AKI.

Results: PTEN was significantly reduced in renal tissue and serum in AKI mice at bilateral renal artery occlusion for 28 min and 35 min, and reperfusion for 1 day compared with sham group (P<0.05). Concentration of serum PTEN was negatively correlated with level of serum creatinine (r=-0.87, 95% CI: -0.94 to -0.71). PTEN was also downregulated in IR-induced HK-2 injury in an antimycin A concentration dependent manner (P<0.05). There were 23 upregulated (ACO2, BRCA1, USP30), and 20 downregulated (BIN1, pericentrin, SLC12A5) PTEN-interacting proteins in IRI+LV-PTEN group compared with IRI+LV-NC group. Gene Ontology enrichment analysis showed that overrepresentation of differential PTEN-interacting proteins functionally related to cytoskeleton, and ATPase activity. Pathway analysis showed a great role of differential PTEN-interacting proteins in apoptosis, and necroptosis. Knockdown of PTEN increased the expression of NGAL, CTGF and TNF-α in IR-induced HK-2 injury (P<0.05), while overexpression of PTEN alleviated IR-induced injury (P<0.05).

Conclusions: PTEN was decreased in renal tissue and serum associated with severity of renal injury in IRI-AKI mice, suggesting that PTEN is promising to be a serum biomarker for early prediction and evaluation of AKI. PTEN protected HK-2 from IR-induced injury possibly via regulating cytoskeleton and TNF-α mediated apoptosis signal.

PO0168

Endothelial Prolyl-Hydroxylase Domain Proteins Regulate Capillary Rarefaction Following Ischemic AKI and Reprogram Endothelial Metabolism

Ratnakar Tiwari, Pinelopi P. Kapitsinou. *Northwestern University Feinberg School of Medicine, Chicago, IL*.

Background: Endothelial cell (EC) metabolism has emerged as a new regulator of EC behaviour, but its role in capillary rarefaction, a common feature of progressive renal disease, remains unknown. Because EC sense oxygen and metabolic alterations through Prolyl hydroxylases 1 to 3 (PHD1-3), here we wished to define the impact of PHD inactivation on post-ischemic kidney injury outcomes, while in vitro studies focused on metabolic consequences.

Methods: Following the induction of renal ischemia-reperfusion injury (IRI), concurrent deletion of PHD1,2,3 was achieved by the Cdh5(PAC)CreER inducible system. Analysis was performed at day 14 post-IRI. Furthermore, we examined the impact of DMOG, a PHD inhibitor on angiogenic capabilities and global metabolic profiles of endothelial cells.

Results: Post-ischemic kidneys of PHD1,2,3^{ECKO} showed more fibrosis, as indicated by 68% increase in collagen area (P=0.005) and significant upregulation of profibrotic genes *Loxl2*, *Tgf-β and Acta2* (n=6-8, P<0.5) compared to controls. Quantitative analysis of endomucin staining showed 50% decrease in peritubular capillary density, associated with reduced endothelial proliferation as indicated by Ki-67 immunostaining (n=4, p=0.005). Notably, biochemical inactivation of PHDs by DMOG reduced EC proliferation in MTT assay (P= 0.0001) while cell cycle analysis showed decrease of cells in S (~39%, n=3, p=0.0007) and G2/M phase (~24%, n=3, p=0.04). Furthermore, DMOG reduced EC migration (50%, n=3, p=0.005) and tube formation. LC-MS analysis showed a profound effect of DMOG in glycolytic, TCA cycle, lipid and, nucleotide metabolites. Specifically, EC treated with DMOG showed an increase in lactate (1.46-fold, p<0.05) and significant reductions in citrate (2.2 fold, p<0.001), alpha-ketoglutarate (2.5 fold, p<0.001), fumarate (1.4-fold, p<0.05) and malate (1.3 fold, p<0.01). Supplementation with citrate partially rescued the proliferation defect induced by DMOG, suggesting that PHDs may affect angiogenic responses through alterations in mitochondrial metabolism.

Conclusions: Post-ischemic endothelial inactivation of PHDs promotes peritubular capillary rarefaction and fibrosis following AKI, a response which could involve alterations in mitochondrial metabolism.

Treprostinil Inhibits Mitochondria-Mediated Apoptosis During Renal Ischemia-Reperfusion Injury in Rats

Meiwen Ding,[1] Evelyn Tolbert,[2] Mark Birkenbach,[2,3] Reginald Y. Gohh,[2,3] Fatemeh Akhlaghi,[1] Nisanne S. Ghonem.[1] [1]*University of Rhode Island, Kingston, RI;* [2]*Lifespan Health System, Providence, RI;* [3]*Brown University, Providence, RI*.

Background: Renal ischemia-reperfusion (I/R) injury is a major factor that contributes to acute kidney injury, which is associated with high morbidity and mortality. Renal I/R injury compromises mitochondrial structure and function, further exacerbating renal tubular injury. Currently, there is no treatment for I/R injury available. We recently demonstrated the efficacy of treprostinil (Remodulin®), an FDA-approved prostacyclin analog, in reducing acute kidney injury during bilateral rat renal I/R injury. This study investigates the role of treprostinil in reducing mitochondria-mediated apoptosis during rat renal I/R injury.

Methods: Male Sprague Dawley rats were randomly assigned to groups: control, sham, I/R-placebo or I/R-treprostinil and subjected to 45 minutes of bilateral renal ischemia followed by 1-72 hours reperfusion. Placebo or treprostinil (100 ng/kg/min) was administered subcutaneously via an osmic minipump. Blood and kidney tissue were collected for analysis.

Results: Treprostinil significantly reduced peak elevated SCr vs. placebo (0.6 ± 0.05 vs. 2.1 ± 0.2 mg/dl, p<0.001) at 24-hour post-reperfusion. Treprostinil also prevented I/R-mediated renal apoptosis at 6-hour post-reperfusion vs. placebo (1.0 ± 0.01 vs. 1.4 ± 0.01, p<0.001) relative to control, determined by TUNEL assay. Mitochondrial DNA (mtDNA) copy number was reduced by 23% in I/R-placebo group (p=0.067) from control, starting by 1-hour post-reperfusion. In contrast, treprostinil preserved mtDNA content to control levels (p<0.01). In addition, placebo increased cytochrome c release into cytosol by 2.4-fold vs.control (p<0.05) at 1-hour post-reperfusion, which treprostinil prevented. Non-targeted semi-quantitative proteomics data using SWATH-MS show decreased renal ATP levels in placebo, which were restored by treprostinil to that of control at 6-hour post-reperfusion (p<0.05).

Conclusions: Our results demonstrate that treprostinil reduces mitochondrial-mediated renal apoptosis, evidenced by reduced cytochrome C release, restored mtDNA copy number and ATP protein concentration to that of control kidney levels, thereby accelerating mitochondrial recovery and protecting renal tubules from I/R-induced apoptosis. These results suggest that treprostinil is a viable therapy to reduce renal I/R injury.

DNA Repair Factor KAT5 Acts Against Ischemia-Reperfusion Injury Through Promoted DNA Repair and KCC3-Dependent TGF Regulation in Proximal Tubular Cells

Akihito Hishikawa, Kaori Hayashi, Toshiaki Monkawa, Hiroshi Itoh. *Keio University School of Medicine, Tokyo, Japan.*

Background: It is known that an episode of ischemia-reperfusion (IR) results in tolerance to subsequent IR, which is so-called "pre-conditioning (PC) effect". However, the molecular mechanisms of the pre-conditioning effect have not been adequately elucidated. We have recently discovered that DNA double strand break (DSB) repair factor KAT5 is essential for maintenance of podocyte integrity (Cell Rep. 2019). Here we investigated the role of KAT5 in PC effect.

Methods: Wild-type (WT) mice and proximal tubular epithelial cell (PTEC)-specific KAT5 knockout (KO) mice underwent IR injury by clamping bilateral renal arteries for 30 minutes followed by reperfusion. Ischemic pre-conditioning was performed 1 week prior to IR injury. In vitro studies using cultured human PTECs (HK2 cells) were conducted with ATP depletion by Antymicin A (AMA), an in vitro model of acute tubular cell damage.

Results: Serum UN, Cr, urine NGAL, DNA DSB marker γH2AX and KAT5 expression of the PTECs were increased and chloride transoporter KCC3 expression was decreased at 24 hours after IR. IR with PC showed an attenuated increase in serum UN, Cr, urine NGAL and DNA DSBs with accelerated KAT5 and KCC3 expression. Mass spectrometry imaging of the kidney cortex following the first IR demonstrated elevated glomerular adenosine, which is used as a marker of accelerated tubule-glomerular feedback (TGF), whereas it was decreased after the second IR with PC in WT mice, suggesting attenuated TGF in the second IR. Therefore, increased chloride uptake through KCC3 in PTECs may contribute to the suppression of TGF, which maintained GFR. In KAT5 KO mice, PC effect was attenuated with increased DNA damage and decreased KCC3 expression. In vitro ATP depletion studies showed elevated KAT5 and KCC3 expression following second treatment with AMA. Chromatin accessibility assay showed promoted chromatin accessibility of the KCC3 promoter region after the second treatment with AMA. ChIP analysis revealed that KAT5-binding KCC3 promoter region was significantly increased after the second injury compared with the first injury, indicating that elevated KCC3 expression was caused by increased binding of KAT5 to the KCC3 promoter region.

Conclusions: PTEC KAT5 may act against IR injury through promoted DNA repair and regulation of TGF via KCC3 expression.

Kidney Proximal Tubular NFκB Essential Modulator Exacerbates Ischemic AKI

Sang Jun Han, Mihwa Kim, Vivette D. D'Agati, H. Thomas Lee. *College of Physicians and Surgeons of Columbia University, New York, NY.*

Background: Ischemic acute kidney injury (AKI) is a major clinical problem. We previously showed that renal tubular peptidylarginine deiminase 4 exacerbates ischemic AKI by promoting pro-inflammatory NFκB activation pathway via selective citrullination of NFκB Essential MOdulator (NEMO). Since NEMO plays important and diverse physiological roles in almost all cell types, here, we tested whether renal proximal tubular (PT) NEMO plays a critical role in ischemic AKI utilizing mice lacking PT NEMO and by targeted PT NEMO inhibition with mesoscale nanoparticle encapsulated NEMO binding peptide (NBP MNP) delivery.

Methods: We subjected PT NEMO deficient mice, wild type (WT) mice and C57BL/6 mice to 30 min renal ischemia and 24 hours reperfusion (RIR). C57BL/6 mice received NBP MNP before RIR injury to test whether selective PT NEMO inhibition attenuates ischemic AKI. Separate cohorts of PT NEMO deficient mice or WT mice were injected with recombinant PAD4 (rPAD4) before 20 min renal ischemia to test whether PAD4-mediated exacerbation of ischemic AKI is PT NEMO dependent. In addition, isolated PT from PT NEMO deficient mice and WT mice were treated with rPAD4 or human PT cells were treated rPAD4 after pretreatment of NBP MNP to determine whether PAD4 activates renal proximal tubular pro-inflammatory signaling via NEMO activation.

Results: PT NEMO deficient mice and C57BL/6 mice treated with NBP MNP were protected against ischemic AKI with decreased plasma creatinine (1±0.2, 1.7±0.2 mg/dL), NGAL mRNA (153.6±31.8, 433.2±54.7 fold increase over sham, N=5-7), renal tubular necrosis, inflammation and apoptosis compared to WT or control MNP treated mice (Cr=2.1±0.03, 2.7±0.2 mg/dL, NGAL=752.8±176.3, 840.8±74.7 fold increase over sham, N=5-7). Exogenous rPAD4 exacerbated RIR injury in WT mice but not in PT NEMO deficient mice. Furthermore, rPAD4 upregulated pro-inflammatory cytokine and NFκB activation in freshly isolated PT cells from WT mice but not from PT NEMO deficient mice. Treatment of NBP MNP also protected rPAD4-mediated pro-inflammatory cytokine induction in cultured human PT cells.

Conclusions: Taken together, our studies suggest that renal PT NEMO plays a critical role in ischemic AKI by promoting renal tubular inflammation, apoptosis as well as necrosis. Our studies provide novel insight to the pathophysiology of PT NEMO in ischemic AKI, suggesting a potential therapy for ischemic AKI.

PO0172

Blocking the Histone Lysine 79 Methyltransferase DOT1L Ameliorates AKI

Yingjie A. Guan, Shougang Zhuang. *Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI.*

Background: The Disruptor of telomeric silencing 1-like (DOT1L) gene encodes a histone methyltransferase that methylates lysine-79 of histone H3 (H3K79). DOT1L-dependent H3K79 methylation plays an important role in various physiological and pathological processes, including transcriptional regulation, embryonic development and renal fibrosis. However, its role in acute kidney injury (AKI) tissue injury remains unknown.

Methods: AKI was induced in Male C57/B6 mice by bilateral ischemia-reperfusion (IR) injury or intraperitoneally injection with folic acid (FA). EPZ5676, a highly selective inhibitor of DOT1L (20 mg/kg) or an equal volume of vehicle was administered immediately after IRI or FA injection and then daily for two days. Renal function and histology were assessed by serum creatinine and HE staining. Immunohistochemistry and Western blotting were performed to identify tubule injury (NGAL), apoptosis (TUNEL and cleaved Caspase 3), proliferation (PCNA and Cyclin D) and Wnt signaling activation (active β-catenin and β-catenin).

Results: Mice developed AKI at 48 h after IR injury or FA administration as shown by the upregulation of serum creatinine and NGAL expression levels. Pharmacologic inhibition of DOT1L with EPZ5676 resulted in less severe tubular injury as evidenced by reduced renal dysfunction, diminished NGAL expression. Furthermore, the administration of EPZ5676 significantly reduced the number of TUNEL-positive and cleaved caspases-3 positive tubular cells in kidney tissues. Conversely, renal tubular cell proliferation was enhanced as indicated by increased expression of PCNA and cyclin D. Moreover, DOT1L inhibition by EPZ5676 up-regulated the expression of active β-catenin form and β -catenin.

Conclusions: Our data reveals that blocking DOT1L with EPZ5676 may protect against AKI in mice through inhibition of apoptosis and enhancement of kidney repair by a mechanism involved in the modulation of the canonical Wnt signaling pathway.

Triptolide Treats Renal Tubular Injury Induced by Renal Ischemia-Reperfusion Through Specific Delivery of Kidney-Targeting Nanoplatform

Zeng Tao, Aiqing Li. *Southern Medical University Nanfang Hospital, Guangzhou, China.*

Background: Triptolide (TP) has been proved to be effective in the treatment of a variety of kidney diseases. Unfortunately, its clinical application is limited because of its high toxicity and low specificity. Here, we report a novel and safe kidney-targeting nanoplatform for specific delivery of TP.

Methods: Nano-polymer MNPs-TP was synthesized by encapsulating TP in a mesoscale nanoparticles (MNPs) with kidney targeting ability. MNPs-TP was injected into mice via tail vein to evaluate its toxicity to organs and immune system, and compared with free TP. The targeting and mechanisms of MNPs-TP treatment were explored by organ imaging, Transwell and other experimental methods. Finally, the model of renal ischemia-reperfusion injury (IRI) in mice was established, and the protective effects and mechanisms of TP and MNPs-TP on renal tubules in different concentrations were compared.

Results: Toxicity test showed serious pathological changes in liver, testes and the proportion of CD4+/cd8+ in blood of mice in TP group, while MNPs-TP showed no obvious toxic effect on these organs and immune system. The organ imaging and pharmacokinetic experiments indicated that free TP showed a fast metabolism and no specificity in the distribution of free TP in various organs, while the MNPs-TP showed longer metabolic cycle and clear kidney targeting. Immunofluorescence assay of kidney sections showed that MNP-TP was mainly concentrated in the cytoplasm of renal tubular cells. After administration of TP at the dose of 0.1mg/kg body weight to the IRI mice, the renal function represented by BUN and SCr of IRI mice was alleviated. Down-regulation of p-ERK and NGAL suggested that TP could help protect the renal tubules by down-regulating MEK-ERK pathway and alleviated apoptosis of renal tubules. Free TP at the dose of 0.01mg/kg lacked these protective effects, and surprisingly, MNPs-TP kept the protection, which demonstrated that the effective therapeutic dose of MNPs-TP was significantly lower relative to free TP.

Conclusions: MNPs-TP showed superior therapeutic effect on renal ischemia-reperfusion injury in comparison with TP. Furthermore, MNPs-TP conjugate presented much lower hepatotoxicity and no adverse effect on the immune and genital system. The kidney-targeting MNPs may provide a promising drug delivery platform of hydrophobic drugs for treatment of renal diseases.

PO0174

Fractional Excretion of NGAL Is Useful to Distinguish Prerenal Azotemia (PRA) from Acute Tubular Injury (ATI) in Mice

Nataliya Skrypnyk, Chris Altmann, Sarah Faubel. *University of Colorado, Denver, CO.*

Background: NGAL (*Lcn2*) is one of the most widely studied biomarkers of acute kidney injury (AKI). Our previous studies demonstrated that the primary source of plasma and urine NGAL after AKI is the liver and it is IL-6 dependent. Since the primary source

of urine NGAL is from the plasma, our next step was to examine the renal handling of plasma NGAL.

Methods: Mice: C57Bl/6J. Interventions: bilateral kidney ischemia reperfusion (IR) - 27 minutes; maleic acid (MA) (400mg/kg pH7.4 in saline, IP); furosemide (4mg, IP); uninjured vehicle animals served as a control. Recombinant human (rh) NGAL (5µg, IV) was injected to determine the fate of circulating NGAL. Measurements: transcutaneous glomerular filtration rate (tGFR), rhNGAL and mouse (m) NGAL in the plasma and urine, megalin in the urine. To link proximal tubular (PT) function with plasma and urine NGAL levels, we calculated the fractional excretion of rhNGAL (FE-rhNGAL): FE-rhNGAL = ([urine {rhNGAL} x plasma creatinine]/ [plasma {rhNGAL} x urine creatinine]) x 100.

Results: Uninjured vehicle: mice had 100% tGFR and low levels of plasma and urine (rh)NGAL. IR (ATI model) and MA (PT injury model): 1% and 29% tGFR respectively, increased plasma and urine rhNGAL in both models. Furosemide (PRA model): tGFR – 30%, plasma rhNGAL was slightly elevated, urine rhNGAL was similar to control. FE-rhNGAL was less than 1% in normal and PRA mice, and it was greater than 20% in IR and MA treated mice. mNGAL plasma and urine levels, and FE-mNGAL were similar to rhNGAL levels and FE-rhNGAL respectively. Urine concentration of megalin correlated with FE-rhNGAL in every intervention (see Figure). Megalin is expressed on the brush border of PT and is responsible for the resorption of most filtered proteins, including NGAL.

Conclusions: Our data suggest that normal PT function is required for the clearance of plasma NGAL. Consideration of plasma NGAL with FE-NGAL is important to interpret urine NGAL levels and PT function and effectively distinguishes PRA from ATI.

PO0175

A Case Report of Vaping-Related Renal Thrombotic Microangiopathy

Pye Oo, Laura J. Maursetter, Ali I. Gardezi, Tripti Singh, Gauri Bhutani. *University of Wisconsin-Madison, Madison, WI.*

Introduction: Acute kidney injury (AKI) and hematuria have been reported in patients with E-cigarette use (vaping)-associated lung injury (EVALI) but exact renal pathology is not well understood. We report a case of biopsy proven renal thrombotic microangiopathy (TMA) in a patient with EVALI.

Case Description: A 40-year-old woman with history of vaping tetrahydrocannabinol (THC) and depression presented to emergency room with 2 days of fatigue, body aches, non-productive cough, and dyspnea on exertion. On admission, BP was 157/85 mmHg, hemoglobin 6.9, platelet count 239, serum creatinine (SCr) 1.76 with 10-30/hpf non-dysmorphic RBC and 2+ proteinuria on urinalysis. Patient failed initial treatment with diuretics and on day 3, was intubated for respiratory distress. By this time, SCr had increased to 4.68 and LDH was quite elevated (1456) but platelet count was normal (194), haptoglobin high (551) and peripheral schistocytes only occasional. Her EVALI improved with standard cares in the next week but renal function further worsened, and hemodialysis was started on day 13. Renal biopsy revealed acute TMA with diffuse endothelial swelling, focal segmental glomerular and arteriolar thrombi and acute tubular injury. Patient was not taking any medications known to cause TMA. Serologic and infection work up were negative including pneumococcus, HIV, antinuclear, anti-Scl70 and antiphospholipid antibodies. The ADAMTS-13 activity was 48% and serum homocysteine was low (3.8). Imaging studies showed no evidence of malignancy. Functional complement work-up did not reveal increased alternative complement pathway activity or autoantibodies. On day 20, patient was started on plasma exchange (PLEX) for 5 sessions followed by a slow renal recovery - last hemodialysis on day 22 and now, more than 1 month after last PLEX and after approximately 2 months of vaping cessation, most recent SCr is 2.57

Discussion: There is no clear association of kidney disease with marijuana use in large population studies but there are case reports of AKI with synthetic cannabinoid use including one report of biopsy proven TMA. Drug-induced TMA is usually a diagnosis of exclusion and temporal correlation. Given the lack of other evident cause of TMA, our case suggests a potential association between THC and/or vaping and renal TMA.

PO0176

A Rare Case of Obstructive Nephropathy with Intratubular Tamm-Horsfall Polyps Secondary to Acquired Hemophilia

Kyle Meissner, Amal Musa, Vikas D. Reddy, Liye Suo, William F. Glass, Jade M. Teakell. *University of Texas Health Science Center at Houston, Houston, TX.*

Introduction: Acquired hemophilia has been rarely implicated in obstructive nephropathy. We present a case of gross hematuria, bilateral hydronephrosis, and biopsy-confirmed tubulointerstitial nephritis with intratubular Tamm-Horsfall Protein (THP) polyps. These atypical pathological aggregations of urinary glycoproteins were previously described to be located in renal veins or lymphatics. Our case represents a rare etiology of obstructive nephropathy, with unique pathological findings, secondary to an acquired hemophilia.

Case Description: A 64-year-old man with hypertension and tobacco use presented with bilateral flank pain and gross hematuria. Urinalysis showed hematuria, pyuria, and proteinuria. He had oliguric acute kidney injury (AKI) with creatinine (Cr) of 3.2 mg/dL. Renal ultrasound showed bilateral hydronephrosis. Renal function deteriorated over 3 days to Cr of 7.4 mg/dL with proteinuria of 10 g/day. Serologic markers revealed mildly elevated PR3-ANCA. Pulse steroid therapy was begun and kidney biopsy was performed. Pathology report described acute tubulointerstitial nephritis with THP polyps and interstitial non-caseating granulomas. Immunohistochemistry assay showed THP polyps within markedly dilated renal tubules, consistent with obstructive nephropathy. No glomerulitis or vasculitis was seen. After biopsy, the patient developed retroperitoneal hemorrhage requiring embolization. Further studies indicated the presence of a factor VIII inhibitor. He improved with transition from steroids to mycophenolate mofetil. A few months later, his renal function returned to normal with a bland urinalysis, proteinuria less than 100mg/day and resolution of hydronephrosis.

Discussion: We encountered a rare presentation of acquired hemophilia with macroscopic hematuria and AKI. We suspect that bladder clots and associated intraluminal clots resulted in elevated tubular pressures causing obstructive nephropathy and the formation of intratubular THP polyps. Administration of immunosuppressive therapy decreased tubulointerstitial inflammation as well as factor VIII inhibitor production, reinforcing our hypothesis. Anti-factor VIII antibodies are a rare complication of solid tumors and urologic malignancy work-up is ongoing.

PO0177

Reflex Anuria: A Forgotten Urologic Etiology of AKI

Hassan Mahmoud, Jasvinder S. Bhatia. *Boston Medical Center, Boston, MA.*

Introduction: Reflex anuria (RA) is a rare entity that can lead to severe acute kidney injury (AKI). It was defined by Hull and colleagues in 1980 as "cessation of urine output from both kidneys in response to irritation or trauma to one kidney or its ureter or severe painful stimuli to other pelvic organs". RA represents a gray area between nephrology and urology that should be considered in the differential diagnosis of AKI. We present a case of AKI and anuria where the prompt recognition and management of RA resulted in full recovery of kidney function and avoidance of renal replacement therapy and unnecessary testing.

Case Description: A 40-year-old male with Crohn's disease status post prior right and left hemicolectomy was admitted with worsening abdominal pain and hematochezia consistent with Crohn's flare. He underwent open abdominoperineal resection. Pre-operatively, urology performed cystoscopy and prophylactic bilateral ureteral stent placement. Stents were removed without complication at the end of the case. On post-op day 1, he developed oliguria that progressed to complete anuria. This was associated with rapid rise in serum creatinine up to 5.5 from baseline of 0.6 (Figure 1). The differential diagnosis was broad, including acute tubular necrosis, vascular thrombosis and obstruction, but because of the temporal relationship with recent procedures, RA was suspected as the etiology of AKI. Patient underwent urgent bilateral ureteral stent placement which was followed by brisk urine output (~11 L/24 hours) and normalization of serum creatinine.

Discussion: RA is a rare diagnosis that requires high index of clinical suspicion. It is a functional rather than parenchymal disease that can cause dramatic cessation of urine output and AKI. Neurovascular reflex leading to arteriolar vasoconstriction and ureteric spasm is a proposed mechanism. This case illustrates that acute anuria and AKI after surgical procedures should prompt nephrology consultants to consider this uncommon diagnosis.

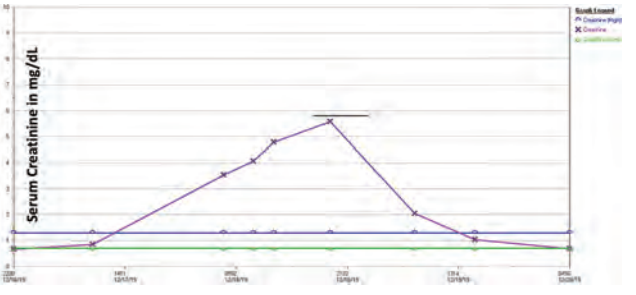

Figure 1. Acute rise in serum creatinine on post-op day 1 followed by rapid resolution of AKI after bilateral ureteral stent placement.

PO0178

AKI in a Patient with COVID-19, G6PD Deficiency, Acetaminophen Overdose, and Methemoglobinemia: What a Broad Differential!

M. Catalina Morales-Alvarez, Benjamin Benhuri, Michelle Shah, Boram Kim. *Mount Sinai Beth Israel Hospital, New York, NY.*

Introduction: Acute kidney injury (AKI) is a common complication in hospitalized and critically-ill patients. Prompt evaluation and subsequent management is warranted to avoid long term kidney dysfunction. However, a clear diagnostic pathway is not always possible. We present a case and the diagnostic analysis of intrinsic AKI in an unusual confluence of comorbidities.

Case Description: 39 year-old man with no past medical history referred from another institution with COVID-19 pneumonia, for which he completed 4 days of hydroxychloroquine. On admission, patient was found to have SCr of 2.0 mg/dL, which increased to 10.8 mg/dL during a 3-day period. Urinalysis showed dysmorphic RBCs but no casts. Total albumin/cr ratio in urine was 3.2 mg/g and FeNa >1%. Renal ultrasound showed no obstruction or masses. Other laboratory results showed methemoglobinemia (14 mg/dL), acute liver failure, schistocytes in the peripheral smear and a G6PD assay with marked deficiency. Other serologies were negative. Patient reported prior ingestion of 1 gr acetaminophen (APAP) every 4 hrs for several days; treated with 48 hrs of N-acetylcysteine infusion. The AKI was complicated by hyperkalemia, severe anion gap metabolic acidosis and volume overload requiring long term renal replacement therapy after failure of resuscitation with crystalloid, albumin, and vasopressors.

Discussion: Our patient presented with significant abnormalities in multiple organ systems, including AKI. An analysis of comorbid conditions and typical AKI diagnostics allowed an expansive differential diagnosis (fig 1). One remaining interrogate was the value of a kidney biopsy. Although the etiology of his AKI would remain uncertain and presumably multifactorial, the lack of a clear therapeutic option and both hemodynamic instability and high risk of complications impeded a kidney biopsy. This case exemplifies the challenging but common scenarios and dilemmas that nephrologists face every day. AKI is a well-described entity, yet its diagnosis is complex and dynamic.

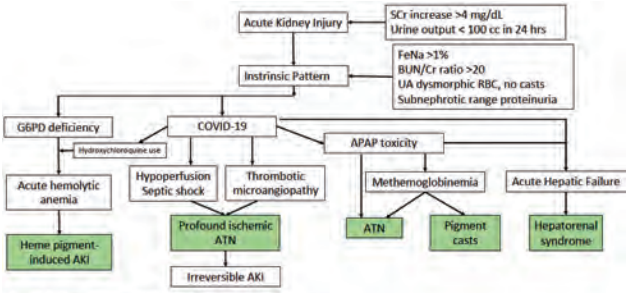

Figure 1. Diagnostic approach and differential diagnosis

PO0179

Catch 22: The Vicious Cycle of Malignant Hypertension and Worsening Renal Thrombotic Microangiopathy

Sneha Lakshman,[1] Larissa Kruger gomes,[2] Jeffrey H. William.[2] *[1]North Shore Medical Center, Salem, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Renal Thrombotic microangiopathy (TMA) may arise from multiple distinct etiologies. Malignant hypertension is one of these conditions that can precipitate and worsen Renal TMA. The detection of C5B-9 on endothelial cells may help determine the timing and selection of treatment to break the vicious cycle of malignant hypertension and worsening renal TMA.

Case Description: 34-year-old woman with a history of gestational hypertension, presented to the ED with complaints of a viral URI and was found to be in hypertensive emergency with an SBP in the 260's. She was a non-smoker and did not use drugs or alcohol. She denied having any other symptoms or any recent medication use. Her labs were notable for hemolytic anemia and acute kidney injury with a creatinine of 4.0 mg/dL. A peripheral smear confirmed schistocytes, along with a normal serum ADAMTS 13 activity at 89. Extensive work-up for atypical hemolytic uremic syndrome was negative and complement levels were normal. Renal ultrasound showed diffusely increased renal cortical echogenicity. Renal biopsy confirmed the diagnosis of acute on chronic thrombotic microangiopathy with severe endothelial swelling and onion-skin lesions of the arterioles and small arteries. Her creatinine peaked at 5.49 mg/dL, but urine output was stable, and she never required dialysis. She was treated with aggressive antihypertensives with consideration of eculizumab therapy.

Discussion: Eculizumab was approved to inhibit complement-mediated TMA in atypical HUS in 2011. The literature describes complement-amplifying conditions including malignant hypertension, complications of pregnancy, and autoimmune diseases being associated with the onset of TMA as they activate the alternative complement pathway in up to 69% of cases with atypical HUS. Standard therapies for malignant hypertension do not address underlying complement dysregulation and TMA may persist despite blood pressure management. The 'domino effect' created by this inflammatory cascade is difficult to reverse and may benefit from eculizumab therapy, whether they have a genetic predisposition or not. The detection of C5B-9 formation on the endothelial cells may reflect complement defects among patients with TMA and severe hypertension, which can be a valuable tool in sub-stratifying whether these patients may benefit from terminal complement inhibitor therapy.

PO0180

Acute Interstitial Nephritis and Diffuse Pulmonary Infiltrates in Recreational Drug User

Jessica Cruz Whitley,[2] Samuel Mon-Wei Yu,[2] Pui Susan W. Cheung.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Introduction: Synthetic cannabinoids are designer drugs smoked as an alternative to marijuana with lower cost and greater potency. Here we describe a patient who presented with acute kidney injury and diffuse pulmonary infiltrates with recent inhaled synthetic cannabinoids use.

Case Description: A 26-year-old man with history of alcohol and recreational drug abuse including marijuana, tobacco and vaping, presented with acute kidney injury and diffuse pulmonary infiltrates. He recalled attending a party a week ago where he smoked someone else's marijuana. On presentation, he was hypertensive to 170/115 mmHg with benign physical examination. Laboratory values were significant for serum creatinine of 17 mg/dL and BUN of 162 mg/dL. Urine sediment showed no cellular casts, but some monomorphic red blood cells, rare dysmorphic red blood cells and white blood cells. He had a spot protein/creatinine ratio of 230 mg/g, Chest X-ray showed bilateral pulmonary infiltrates. Renal ultrasound showed normal kidneys. Laboratory studies were all negative including CK, ANCA, anti-GBM, ANA, dsDNA, SPEP and legionella urinary antigen. His urine toxicology screen was positive for opiates and cannabinoids. Renal biopsy revealed widespread edema of the interstitium and a mild to focally moderate inflammatory infiltrate involving approximately 80% of the cortical area. Tubular dilation, cytoplasmic vacuolization, and rare mitoses were seen in the tubules. He required 2 sessions of hemodialysis, but he had a rapid resolution of his kidney failure with steroid initiation. A repeat chest CT showed resolution of bibasilar opacities, although with persistent upper lobe ground glass opacities consistent with smoking and vaping-related injury.

Discussion: Synthetic cannabinoids use should be considered in young healthy patients who present with unexplained AKI, as there are more case reports suggesting its direct nephrotoxicity. The etiology of tubulointerstitial injury from synthetic cannabinoids remains elusive, but a dysregulation of the endocannabinoid system in kidneys via endogenous cannabinoid receptors, CB1 and CB2, may be part of the mechanisms of injury. The cannabinoid receptors are now recognized to play potential roles in diabetic nephropathy and chronic kidney disease progression, and our case highlights the need of future research on their possible role in immunue activation.

PO0181

Renal Limited Lupus-Like Nephritis in an Elderly Male

Abdulhadi T. Gelaidan,[1,2] Saud O. Abaalkhail,[3,2] Sheryl C. Caberto.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]University of Jeddah, Jeddah, Saudi Arabia; [3]Saint Vincent Hospital, Worcester, MA.*

Introduction: Lupus nephritis is a major cause of morbidity in Systemic Lupus Erythematosus (SLE). 60% of SLE patients develop renal impairment, which is more common in age < 55 years old. SLE has a female predominance with a female-to-male ratio of 8:1. We report a case of an elderly male, who has negative serology and absence of extra-renal manifestations of SLE, diagnosed with renal limited lupus-like nephritis (RLLLN).

Case Description: A 76-year-old Caucasian male with no previous history of renal or autoimmune diseases was admitted because of acute kidney injury (AKI). Patient had no history of joint pain and swelling, rash, or oral ulcers. He was not taking NSAID or Hydralazine. Laboratory test showed creatinine 2.7 mg/dL, serum albumin 2.1 g/dL, urine protein creatinine ratio 725mg/g, and urinalysis with dysmorphic RBC of >5 RBC/HPF. Serology showed negative anti-dsDNA, ANA titer <1:40 and undetectable complements C3 and C4. Hepatitis B and C, Human immunodeficiency virus, and rapid plasma reagin were also negative. Patient's renal function continued to worsen that he eventually required hemodialysis. A renal biopsy was performed. Light microscopy revealed diffuse endocapillary hypercellularity and no crescent lesion. There was a full house with global granular mesangial and basement membrane staining for IgG, IgA, IgM, C1q, C3, free kappa and lambda light chains under immunofluorescence microscopy. Electron microscopy revealed mesangial and subendothelial dense deposit and segmental duplication. All these findings are consistent with RLLLN.

Discussion: This is a case of an elderly male patient who developed AKI with kidney biopsy that showed lupus nephritis; however, ANA and anti-dsDNA antibody were negative and there were no clinical manifestations of SLE. The patient was treated with Methylprednisolone, which was followed by Prednisone and Mycophenolate Mofetil (MMF). On 1-month follow-up, there was improvement in C3 and C4, and 24-hour CrCl estimated the GFR of 35 ml/min; hence, hemodialysis was discontinued. On 6-month follow-up, serum creatinine 1 mg/dL, BUN 14 mg/dL, and GFR >60 ml/min. Our patient's kidney function recovered; however, there is no definite prediction of RLLLN prognosis due to limited data. 47% had a poor outcome with a permanent decrease of renal function and 62 % of patients with poor outcome had glomerular crescents involving 43–75% of the glomeruli.

PO0182

Postpartum Thrombotic Microangiopathy of Unknown Etiology: Is It Too Late to Save the Kidneys?

John K. Guirguis, S. J. Sher, Simit Doshi. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Thrombotic microangiopathy (TMA) is a rare (0.004%) but life threatening complication in pregnancy. Differentials include uncontrolled hypertension, Hemolysis elevated liver enzymes low platelet count (HELLP) syndrome, atypical Hemolytic Uremic Syndrome (HUS), Thrombotic Thrombocytopenic Purpura (TTP) among others. Lack of randomized trials and absence of gold standard laboratory tests can make diagnosis and treatment challenging. We present a patient with post-partum TMA confirmed on renal biopsy with no conclusive etiology identified.

Case Description: A 36 years old African American patient, G7P5 with history of Hypertension (HTN) and preeclampsia was noted to have blood pressure elevated to 180/103 mmHg during an antenatal care visit at 36 weeks of gestation. Serum Creatinine (sCr) was 0.5mg/dl with urine protein/Cr ratio (UPCR) of 0.75 g/g. She had an induced labor with persistent HTN postpartum. She left against medical advice and was readmitted 10 days later with acute kidney injury (AKI) with sCr of 6 mg/dl and UPCR was 4g/g, urinalysis showed positive protein but no RBCs. BP was elevated to 143/97 mmHg/ Laboratory data showed AST 33 U/L, ALT 24 U/L, Hb 9.5 g/dL, platelet counts 211 $X10^9$/L, C3 of 74 mg/dL, C4<2 mg/dL, negative ANA, ADAMTS 13 >94, Cryo results was inconclusive although RF was elevated at 160 IU/mL. Blood smear showed no schistocytes. She was started on pulse steroids for clinical suspicion of eclampsia related TMA. While awaiting biopsy therapeutic plasma exchange (TPE) was initiated, it was stopped after 3 sessions. Kidney biopsy on day 12 of delivery showed TMA, with negative immune-florescence (IF), minimal interstitial fibrosis/tubular atrophy, focal 2/15 glomerular crescents and minimal arterial intimal thickening. Patient became progressively oliguric, requiring hemodialysis. At the time of writing this report, there has been no recovery at 4 weeks as patient remains oliguric on thrice weekly dialysis.

Discussion: Peri-partum care is crucial in early detection and prompt management of TMA in patients with pre-eclampsia/Eclampsia. Benefit of TPE in post-partum period is not well established. A kidneybiopsy was obtained but the diagnosis remained elusive with negative IF in setting of reduced complement levels. Further studies should evaluate treatment strategies in the late-presenting patient to avoid irreversible kidney injury.

PO0183

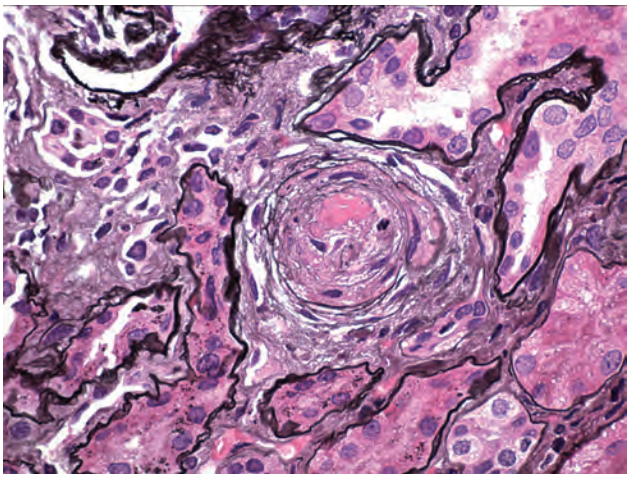
Thrombotic Microangiopathy as a Complication of Malignant Hypertension

Hany Eskarous. *Easton Hospital, Easton, PA.*

Introduction: Thrombotic microangiopathies (TMA) are defined as disorders characterized by the presence of microangiopathic hemolytic anemia (MAHA), thrombocytopenia, and microthrombi. Of all the known causes of TMAs, malignant hypertension is one of the most underreported ones.

Case Description: A 23-year-old African American male patient presented to the emergency department with a 2-week history of nausea, vomiting, diarrhea, and abdominal pain. His past medical history is significant for hypertension treated with lisinopril, but the patient is noncompliant with his medication. He had a blood pressure of 245/176 mmHg. Laboratory tests revealed hemoglobin of 10.7g/dl, platelet count of 88,000/microliter, white blood count of 14,300/microliter, blood urea nitrogen of 29 mg/dl, creatinine of 4.7 mg/dl (unknown prior creatinine levels), lactate dehydrogenase of 900 units/l, low haptoglobin, serum potassium of 2.1mg/dl and normal coagulation profile. With control of blood pressure, the platelet counts improved. ADAMTS13 test and stool Shiga toxin were negative. Peripheral blood smear showed schistocytes. Workup for secondary hypertension were all negative. A diagnostic CT guided left kidney biopsy revealed active and chronic TMA.

Discussion: In our patient presenting with renal TMA and severe hypertension, TTP was thought to be less likely as the patient did not have the classical presentation of fever and neurological symptoms. In addition, thrombocytopenia and LDH levels normalized with aggressive control of blood pressure. Hence, plasma exchange was deferred. Since the patient presented with diarrhea, HUS was high on the differential, but a negative Shiga toxin PCR ruled out the possibility. Renal biopsy revealed acute and chronic TMA in renal blood vessels with focal severe arteriolosclerosis, fibrin, and onion skinning of arteries supporting the diagnosis of malignant nephrosclerosis as the cause of TMA.



Arteriolar narrowing with fibrin

PO0184

Drug-Induced Thrombotic Microangiopathy from Trimethoprim-Sulfamethoxazole

Krishna A. Agarwal, Larissa Kruger gomes, Esilida Sula Karreci, Ruth Schulman, Yael K. Heher, Bradley M. Denker. BIDMC *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Thrombotic microangiopathy (TMA) is a common condition manifesting with microangiopathic hemolytic anemia, thrombocytopenia and end-organ damage including, acute kidney injury. TMA can be associated with many clinical syndromes and is most often due to malignant hypertension, malignancy or complement dysregulation but can also be triggered by medications. Here we describe a rare case of TMA caused by trimethoprim-sulfamethoxazole (TMP-SMX).

Case Description: A 62-year-old man with recent diagnosis of Sweet's syndrome was started on high dose prednisone and TMP-SMX for prophylaxis. He presented 4 days later with confusion, profuse diarrhea and "brown-colored" urine. He was normotensive on exam, without cardiac murmurs, clear lungs, soft non-tender abdomen and no skin rashes. Initial labs showed microangiopathic hemolytic anemia, thrombocytopenia and acute kidney injury with hyperkalemia. Blood smear showed schistocytes. He received emergent hemodialysis followed by plasma exchange for suspected TTP/HUS. Extensive workup during his hospital admission revealed a normal ADAMTS13 activity, negative blood and urine cultures, negative 0157:H7 stool antigen, negative urinary streptococcal antigen, negative autoimmune screen, negative hepatitis and HIV serologies, normal vitamin B12 level, normal bone marrow and pan-imaging without malignancy. A renal biopsy confirmed TMA. He remained anuric and dialysis dependent on discharge.

Discussion: Patients with TMA have symptoms arising from anemia, thrombocytopenia, renal failure, or from underlying diseases like systemic infections, malignancies or drug toxicities. Once TMA is confirmed, elucidating the cause of TMA is important because there are specific treatments available for primary TMA syndromes like TTP and complement-mediated TMA. High suspicion of TTP requires urgent plasma exchange until ADAMTS-13 levels return, and if complement-mediated TMA is likely, the terminal-complement inhibitor eculizumab can be used. Drug-induced TMAs require prompt discontinuation of the drug and supportive management. Trimethoprim-sulfamethoxazole is a rare cause of thrombotic microangiopathy, and the exact mechanism is not understood. Our case highlights the importance of considering TMP-SMX as a potential cause in patients presenting with TMA.

PO0185

Hemoglobin Cast Nephropathy in Rifampin-Induced Hemolytic Anemia

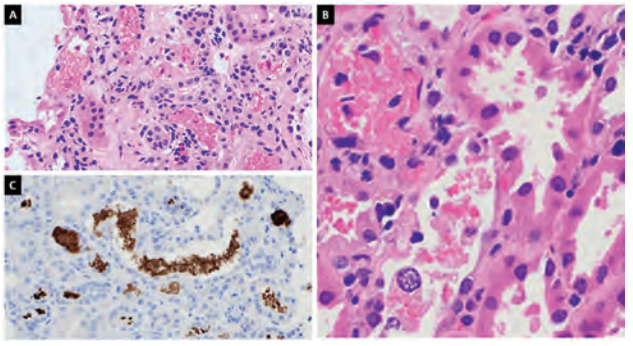
Saqib Mahmud, Carl S. Dernell, Naveet Bal, Abhilash Koratala, Alexander J. Gallan, Daniel A. Sturgill. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Hemoglobin released after intravascular hemolysis causes acute kidney injury (AKI) by various mechanisms including hemoglobin cast nephropathy. This can resemble other causes of AKI such as acute tubular necrosis, acute interstitial nephritis (AIN) and thrombotic microangiopathy (TMA). Few studies have demonstrated immunohistochemically-proven hemoglobin casts on kidney biopsy associated with intravascular hemolysis. Below is a case of Rifampin-induced hemolysis associated hemoglobin cast nephropathy.

Case Description: A 64-year-old female with recurrent pulmonary Mycobacterium Avium Complex (MAC) infection treated with Rifampin, Ethambutol and Azithromycin presented with nausea and vomiting two weeks after starting therapy. Physical exam was remarkable for small purpuric lesions on the back. Labs showed a serum creatinine of 6.6 mg/dL, BUN 66 mg/dL, hemoglobin 11.1 g/dL and platelets 9,000/uL. Haptoglobin was normal. LDH was elevated at 507 units/L. A direct antibody test was negative. Urinalysis showed large blood and microscopy showed 2-5 RBCs per hpf and dark granular casts.

Renal ultrasound was unremarkable. Plasma exchange was initiated for possible TMA but discontinued when ADAMTS13 level returned normal. On day four, serum creatinine was 8.1 mg/dL. She received methylprednisolone 120 mg daily for three days due to concern for possible Rifampin induced AIN. A kidney biopsy was planned and hemodialysis was performed to optimize platelet function. Kidney biopsy demonstrated intratubular pigmented casts that were strongly positive for hemoglobin A immunohistochemical stain confirming the diagnosis of hemoglobin cast nephropathy [Figure 1]. She received supportive care with kidney function gradually improving. Creatinine was 2.87 mg/dL on discharge and 1.18 mg/dL four weeks later.

Discussion: Hemoglobin cast nephropathy is a rare diagnosis and requires high index of suspicion in patients with hemolysis and AKI. Diagnosis is multifaceted requiring a clinical history, exam, lab workup and most importantly, a kidney biopsy.



PO0186

Recurrent Stage 3 AKI Resolves with Establishing the Diagnosis of TAFRO Syndrome and Treatment with Anti-IL-6 Antibody

Ibrahim Tawhari, Yashpal S. Kanwar, Vikram Aggarwal. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: TAFRO syndrome, a unique variant of idiopathic multicentric Castleman's disease (iMCD), is a syndrome with a constellation of **T**hrombocytopenia, **A**nasarca, **F**ever, **R**eticulin myelofibrosis/renal insufficiency, and **O**rganomegaly. Its pathogenesis is driven by excessive cytokine storm, most notably from IL-6, causing multiorgan failure. 30% of patients with TAFRO-iMCD patients require dialysis. Glomerular thrombotic microangiopathy (TMA) and membranoproliferative glomerulonephritis are the most characteristic lesions. We present a challenging case of recurrent dialysis requiring AKI in whom recognition of TAFRO syndrome and glomerular TMA-like lesion led to successful treatment with anti-IL-6 therapy and subsequent definitive diagnosis of iMCD.

Case Description: A 35-year-old Hispanic female presented in May 2019 with fever, hypotension, anemia, thrombocytopenia, anasarca, hepatosplenomegaly, generalized lymphadenopathy, and anuric AKI. She was admitted to the intensive care unit, required vasopressors, mechanical ventilation, and initiation of continuous renal replacement therapy (CRRT). A comprehensive workup for infectious and autoimmune etiologies was unrevealing. This puzzling presentation was presumed to be driven by an unidentified viral illness. She received an empiric course of IVIG and steroids with mild improvement in anemia, thrombocytopenia, and complete renal recovery. A month later, she was admitted with a similar presentation and proteinuria. She once again required CRRT. Lab work revealed elevated IL-6. Lymph node and bone marrow biopsy were non-contributary. A renal biopsy revealed glomerular capillary endotheliosis. This time it became clear that she had a TAFRO phenotype and decided to treat her with tocilizumab (anti-IL-6 antibody) every two weeks. She had complete recovery of AKI, anemia, and thrombocytopenia within four weeks. She has been on anti-IL6 antibody for one year, and the disease is in remission. An excisional lymph node biopsy in May 2020 confirmed the diagnosis of Castleman's disease.

Discussion: TAFRO syndrome-iMCD related renal involvement has been reported from Japan and France. For the first time, we describe these findings from a North American center. This case highlights that knowledge of TAFRO syndrome as a cause of AKI, its diagnostic approach, and renal histology is valuable for Nephrologists.

PO0187

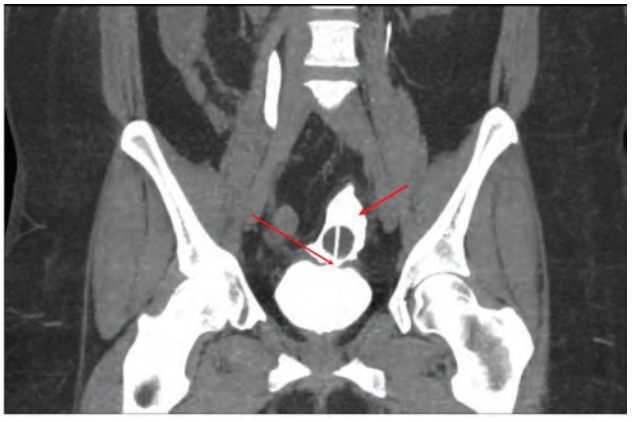
Apparent AKI in a Patient with Ascites Following Laparoscopic Hysterectomy

Carmen E. Cervantes,[1] Steven Menez,[1] Mohamad A. Hanouneh.[1,2] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Nephrology Center of Maryland, Baltimore, MD.*

Introduction: Bladder injury occurs following blunt or penetrating trauma. Gynecological and colorectal surgeries are the most common surgeries associated with bladder injury. Bladder injury can be classified as intra versus extra-peritoneal. Clinical manifestations include gross or microscopic hematuria, ascites, and/or difficulty voiding. Peritonitis and sepsis are common complications.

Case Description: A 39-year-old woman who underwent laparoscopic hysterectomy presented to ED 4 days following surgery with abdominal pain. Her vitals revealed hypotension and tachycardia. Initial laboratory values were as follows: WBCs 18.0x 10^9/L, Na 134 mmol/L, K 4.9 mmol/L, Cl 101 mmol/L, HCO3 17 mmol/L, BUN 45 mg/dL, serum Cr 7.4 mg/dL, lactate 2.4 mmol/L. UA was remarkable for hematuria with 25 isomorphic RBCs/HPF. Abdominal US revealed moderate ascites. An indwelling bladder catheter was placed, and she underwent diagnostic paracentesis, with WBC noted at 1288/µl (35% neutrophils) and ascites-to-serum Cr ratio of 2.14. CT abdomen with IV contrast confirmed a full-thickness tear of the superior wall of the urinary bladder, with the bulb of the indwelling catheter extending beyond the bladder and an associated urinoma surrounding the catheter (Figure 1). She was diagnosed with bladder perforation and underwent open bladder repair emergently. Her serum Cr improved to 0.5 mg/dL in 24 hours.

Discussion: Uroperitoneum can result in the reabsorption of urine into the systemic circulation, while sodium and chloride ions move in the opposite direction. This results in hyponatremia, metabolic acidosis, azotemia and rise in serum Cr. Uroperitoneum should be expected when ascites to serum Cr ratio is >1.0. It is essential to recognize that the rise in serum BUN and Cr is due to pseudo-azotemia from the reabsorption of urine and not from true kidney dysfunction. Bladder injury is diagnosed by CT cystography, which was deferred in our patient giving the clear evidence of bladder injury in the CT abdomen. Complex extraperitoneal and all intraperitoneal bladder injuries require surgical repair.



PO0188

Urine Proteomics Among Children Developing AKI After Hematopoietic Stem Cell Transplant (HCT): A Pilot Study

Daniella Levy Erez,[1,2] Hossein Fazelinia,[3] Hua Ding,[3] Lynn Spruce,[3] Benjamin L. Laskin,[1,2] Kathleen E. Sullivan.[4,2] *[1]Division of Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]Proteomics Core, Children's Hospital of Philadelphia, Philadelphia, PA; [4]Division of Allergy and Immunology, Children's Hospital of Philadelphia, Philadelphia, PA.*

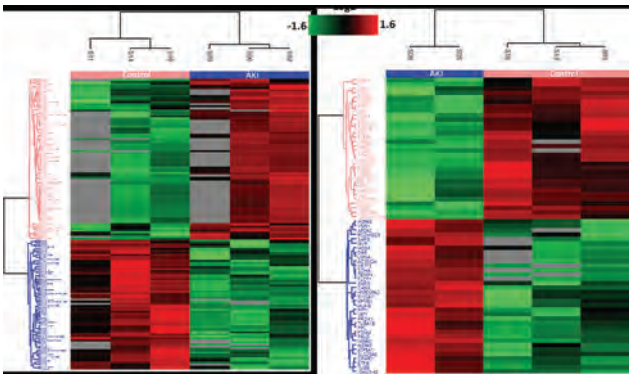
Background: AKI is common after HCT and contributes to high morbidity and mortality. Understanding the mechanisms of injury is essential to develop targeted therapies. Our objective was to examine urinary proteins among children after HCT to provide insights into the pathophysiology of AKI in a population whose immune system is newly developing.

Methods: Children (>2 years old) undergoing their first allogeneic HCT and enrolled in a prospective, observational cohort had urine collected at baseline and monthly for the 4 months post HCT. Six patients were selected for pilot proteomic analysis (age 7-19 years, median 10 years, 66% male, 3 with AKI, 3 without AKI). Stored urine samples were tested pre-HCT and at 1 and 4 months post-HCT. Samples were tested with liquid chromatography/tandem mass spectrometry with data-independent acquisition. Proteins were assigned and intensities compared between AKI and controls using t-tests at $p<0.05$. AKI was defined as a 1.5-fold increase in the monthly serum creatinine value compared to baseline.

Results: At 1 month post-HCT, 143 proteins were found distinct among the urine of children with AKI(n=3) compared to those without AKI (n=3). Pathway enrichment analysis linked these proteins to cell cycle and ubiquitous pathways. The 4 month time point resulted in identification of 67 proteins which were differentially expressed between AKI and control groups. These proteins were mostly involved in immune regulation. In both groups, unsupervised hierarchical clustering perfectly segregated the subjects based on AKI or control status (Figure).

Conclusions: The urinary proteomic fingerprint is distinct after AKI and are mostly cell cycle proteins in early AKI (first month) and immune mediated at 4 months, when most patients are fully engrafted. Additional studies are needed to define and understand the specific pathways.

Funding: Private Foundation Support



Urine proteomics comparing AKI and controls at 1 and 4 months.

PO0189

Triptan-Induced Vascular CKD, the Importance of a Differential Diagnosis

Kevin Mitchell,[1,2] Ankur Shah.[1,2] *[1]Brown University, Providence, RI; [2]Providence Veterans Affair Hospital, Providence, RI.*

Introduction: Triptans are selective (5-HT) receptor agonists resulting in vasoconstriction reversing the vasodilatory mechanisms of migraine headaches. Animal studies have shown 5-HT2 receptors in the renal arteries and intense vasoconstrictive effect of 5-HT on the renal arteries. We describe a case of progressive CKD with biopsy proven vascular injury due to sumatriptan use.

Case Description: A 52-year-old male with history of CKD stage 3, migraine headaches, and hyperlipidemia presented to nephrology clinic for evaluation of CKD. Review of records revealed a rise in sCr from 1.2 to 2.8 mg/dl over the preceeding 4 years. Urinalysis was negative for hematuria, proteinuria, and pyuria. CT revealed symmetric kidneys without dilation. A kidney biopsy was performed and showed patchy cortical atrophy and interstitial fibrosis with moderate vascular sclerosis and focal remodeling of the glomerular basement membranes consistent with prior vascular injury as well as acute tubular injury. A hematologic evaluation did not reveal an etiology and further history revealed use of sumatriptan 8-10 times per month. After discontinuation of sumatriptan, sCr improved from 2.8 to 2.2 mg/dl

Discussion: This case highlight the broad differential diagnosis of acute and chronic kidney injury. The biopsy findings of primarily vascular injury were initially felt to be cryptogenic, but further review revealed the etiology to most likely be triptan induced. After discontinuation of sumatriptan the creatinine improved in spite of increased NSAID use. Currently botulinum injections are being used as migraine prophylaxis. This case highlights the importance of a review of all medications and for potential nephrotoxicity.

PO0190

Roid Renal Failure

Margaret Mallari, Priyesh T. Thakkar. *AtlantiCare Regional Medical Center, Atlantic City, NJ.*

Introduction: Athletes and bodybuilders often utilize anabolic steroids and high-protein supplements to gain muscle mass, however the use of such performance enhancers comes with a significant risk of renal failure.

Case Description: A 34-year-old male weightlifter presented with worsening exertional dyspnea, hemoptysis, and bilateral leg swelling over 2-3 months. He admitted to weekly testosterone injections, testosterone-increasing supplements, and a high-protein diet for the past 5 years. To address his lower leg swelling, the patient started Expel, an over-the-counter potassium-sparing diuretic, 2 months ago. Labs were significant for bicarb 19 mmol/L (21-30), BUN 166 mg/dL (8-25), Cr 13.4 mg/dL (.3-1.2), and CPK 2630 U/L (26-308). Chest X-ray showed right lower lobe pneumonia. Urinalysis showed proteinuria. Renal ultrasound revealed cortical echogenicity with no hydronephrosis. The patient was admitted for acute renal failure, rhabdomyolysis, and pneumonia. He was started on Ceftriaxone and Azithromycin and placed on IV fluids. During the hospitalization, the patient's renal function deteriorated. Renal biopsy showed global and segmental glomerulosclerosis, tubular atrophy, severe interstitial fibrosis, arteriosclerosis, and arteriolar hyalinosis. The patient was counseled at length about long term renal replacement therapy and the gravity of his diagnosis. He underwent placement of a tunneled dialysis catheter and was discharged with close outpatient follow up. Unfortunately despite multiple hospitalizations, the patient repeatedly missed dialysis treatments and continued to use anabolic steroids and high-protein supplements.

Discussion: The utilization of anabolic steroids and high-protein supplements is widespread among athletes and bodybuilders seeking to enhance performance and achieve greater muscle mass. However, steroids and high-protein supplements are not benign and their use comes at the risk of renal failure requiring possible long term renal replacement therapy. High-protein supplements increase glomerular filtration rates (GFR) and are associated with the development of focal segmental glomerulosclerosis (FSGS). Anabolic steroids are directly toxic to renal glomeruli. Anabolic steroids bind to podocyte androgen receptors resulting in the apoptotic destruction of podocytes. The patient's clinical course highlights the significant risk of renal failure in young athletes abusing anabolic steroids and high-protein supplements.

PO0191

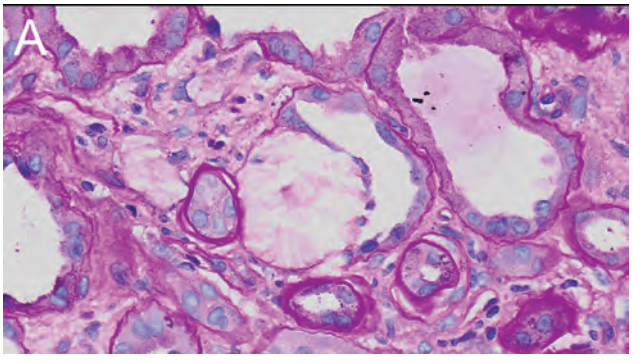
Crystal Clear: A Case of Oxalate Nephropathy

Deanna N. Jones, James L. Pirkle. *Wake Forest University, Winston-Salem, NC.*

Introduction: Oxalate nephropathy is an uncommon and potentially devastating cause of acute kidney injury that can lead to end-stage kidney disease. Oxalate nephropathy can be hereditary (as in hereditary hyperoxaluria), related to toxins (such as ethylene glycol), medications, like high-dose vitamin C, or enteric malabsorption (such as gastric bypass surgery or malabsorptive disorders). Oxalate nephropathy occurs when calcium oxalate crystals form and deposit in the renal tubules and interstitium, leading to acute tubular necrosis.

Case Description: A 71 year old female with a medical history of pancreatic adenocarcinoma s/p Whipple procedure seven months earlier and chronic kidney disease stage 3 (baseline creatinine 1.0 mg/dL) presented to the hospital with elevated serum creatinine found incidentally on outpatient labs. Initial evaluation was concerning for volume depletion, as she improved with intravenous fluids. Over the next several months, she had repeated hospital admissions with worsening non-oliguric renal failure that seemed to respond to intravenous fluids in the hospital but worsened at outpatient visits. Urinalysis repeatedly showed no microscopic hematuria and low-level proteinuria, and urine microscopy showed coarse granular casts, consistent with acute tubular necrosis. Kidney biopsy was consistent with acute tubular injury and extensive tubular calcium oxalate deposition concerning for oxalate nephropathy.

Discussion: Oxalate nephropathy is a rare complication of pancreatic surgery and ascorbic acid use. Vitamin C is metabolized to oxalate and then excreted in the urine. In malabsorptive disorders, a higher concentration of fatty acids are present in the gastrointestinal tract, which bind calcium, leaving less to bind oxalate, and thus more oxalate is absorbed. High urinary oxalate can cause crystallization in tubules, leading to acute renal failure. Treatment is supportive, with removal of offending agents, oral calcium supplementation, and adequate oral hydration. Despite this, our patient progressed to end-stage renal disease requiring dialysis.



PO0192

A Novel Flow Cytometry Approach Identifies Kidney Mononuclear Phagocyte Subsets Involved in Mouse Kidney Injury Models

Johannes Nordlohne, Ilona Hulsmann, Svenja Schwafertz, Frank Eitner, Michael S. Becker. *Bayer AG, Wuppertal, Germany.*

Background: Mononuclear phagocytes (MNPs) are heterogenous in phenotype and function, which reflects their double-edged role as drivers of inflammation and repair after kidney injury. Dissection of this complex network of cells into functional subunits has been challenging and more granular approaches could help to identify relevant subsets in preclinical kidney injury models. Here we used a novel flow cytometric approach to phenotypically and functionally dissect renal MNPs and perform a thorough comparison of MNP dynamics between two different kidney injury models.

Methods: The dynamic regulation of MNP subsets was monitored over 10d in two frequently used murine kidney injury models: ischemia reperfusion injury (IRI) and unilateral ureter obstruction (UUO). Using flow cytometric markers F4/80, CD11b and CD11c, kidney MNPs were phenotypically divided into five distinct subsets, which were further subdivided into functional subsets of proinflammatory M1-like (CD86+MHCII+CD206-) and regulatory M2-like (CD206+) cells.

Results: Three of the five renal MNP subsets were heavily contributing to both M1- and M2-like cell pools in both IRI and UUO, highlighting their functional multimodality regarding for example *in vitro* phagocytosis. The F4/80^{high} MNP subset contributed most M2-like cells as from day 3 with a comparable MNP profile in both models. However, M1-like cells from two CD11b^{high} subsets spiked 24h after IRI, while this spike was shifted to day 3 in the UUO model, which had a temporary early influx of M1-like F4/80^{high} cells after 3h in turn. After 10d, total MNP numbers were decreasing in the UUO model, while M2-like F4/80^{high} cells persisted in IRI kidneys.

Conclusions: Our novel flow cytometric approach unravels functional multimodality among MNP subsets and identifies distinct subsets responsible for an earlier M1-response and a more persistent M2-response in IRI compared to UUO. These results might support preclinical model selection and disease understanding in kidney injury.

Microparticles Containing M2 Monocyte and Other Inflammatory Markers Are Released in AKI

Begoña Campos,[1] Kathleen Harrison,[1] Samantha M. Kramer,[1] Bassam G. Abu Jawdeh,[1,2] Charuhas V. Thakar.[1,2] *[1]University of Cincinnati College of Medicine, Cincinnati, OH; [2]Cincinnati VA Medical Center, Cincinnati, OH.*

Background: Renal epithelial cell injury in AKI and induces a pleiotropic inflammatory cell response. Monocyte phenotypes (M1 = $CD14^+/CD16^-$; M2 = $CD14^+/CD16^+$), and subsequently derived tissue-resident macrophages play a critical role in inflammation and repair in acute kidney injury (AKI). It is accepted that M1 phenotype serves a pro-inflammatory/phagocytic role, whereas M2 phenotype influences tissue repair and remodelling. We have previously shown that microparticles (MP) derived from renal epithelial cells are released in the setting of kidney injury and can be detected in vitro as well as in human plasma, and can carry the biological activity.

Methods: In this study, we evaluated presence of MP expressing markers of inflammation in AKI (defined by standardized criteria). Human samples were derived from a prospectively collected repository (31 cases of AKI in critically ill patients compared to 22 living kidney donor healthy controls). Samples were prepared to measure MP (standard methods), and flow cytometric analysis was evaluated using antibodies against inflammatory proteins. FlowJo software was used for analysis. Mann-Whitney test was used for comparisons.

Results: The average age was 54 years; mean admission creatinine was 1.8 mg/dl, and the time between admission and sample collection was 3-4 days. MP containing M2 Monocyte markers were significantly higher in AKI patients compared to controls (347.03 vs 271.36 /ml respectively; p=0.02). MP containing M1 markers were similar compared to control (177.85 vs 285.40 /ml, p=0.19), AKI cases also showed significantly higher levels of MP containing other inflammatory markers: Leukocytes (CD45, p=0.015), eosinophils (CD66b, p=0.0001), and also in platelets (CD42b, p=0.05).

Conclusions: MP containing monocyte/macrophage markers of M2 phenotype are released in the early phase of AKI, which can influence tissue modelling and repair. Moreover, a pattern of MP representing markers of M2 and other inflammatory cells may have prognostic significance to predict the severity of tissue injury or the prospect of recovery.

PO0194

Novel Immune Defense Cells of the Kidney Epithelia

Katherine Xu, Run Banlengchit, Abraham D. Levitman, Tian Shen, Jonathan M. Barasch, Krzysztof Kiryluk, Peter A. Sims. *Columbia University Irving Medical Center, New York, NY.*

Background: Urinary tract infections (UTIs) are one of the most common bacterial infections worldwide, affecting infant boys, older men, and most prominently, women of all ages. It is predominately caused by uropathogenic *E. coli* and can lead to urosepsis and kidney failure if untreated. We have found a major role for kidney epithelia, specifically the intercalated cells (IC), that are activated in defense against bacteria. Given the heterogeneity of kidney cell types, we hypothesized that there could be other cells that respond to a UTI.

Methods: We performed 10x Genomics single cell RNA-seq (scRNAseq) of whole kidneys from mice with UTI at 12 hrs and from mice without infection. We also performed scRNAseq of IC from lipopolysaccharide (LPS)-induced mice at 0, 8, and 24 hrs using a novel mRNA profiling method, pooled library amplification for transcriptome expression (PLATE)-seq. We used $ROSA26^{nT\text{-}nG}$;Atp6v1b1Cre mice that activated GFP in IC and subsequently sorted GFP+ cells for PLATE-seq.

Results: scRNAseq across 16 samples from 10 mice (5 UTI-Control pairs) yielded 64,760 cells and resulted in populations of all major kidney cell types, as well as rare populations, i.e., pelvic transitional epithelial cells and double positive (DP) collecting duct cells, which have markers of both intercalated and principal cells. By gene set enrichment analysis, we found that DP cells activated gene sets involved in cell killing and innate immune responses at 12 hrs of UTI. DP cells were also found to be highly transcriptionally active in response to infection in a cross analysis with our dataset from 4-thiouracil-labeled nascent RNAs purified from Atp6v1b1+ cells. scRNAseq on Atp6v1b1+ population after LPS induction (525 cells) further revealed time-dependent activation of immune responses. We found that these IC/DP cells increased *Umod* expression in both UTI (1.6 fold change; padj=1E-2) and LPS (1.7 fold change; padj=1E-6) analyses. *Umod*, known to have immune properties, is commonly expressed in the loop of Henle and distal tubule, but may have a novel bacterial defense role in the IC/DP cells.

Conclusions: We found a novel immune defense role of the double positive collecting duct cells in response to UTI. These transcriptionally active cells induce genes involved in cytotoxic and innate immunity and can provide new insights into the epithelial defense of the kidney.

Role of Glomerular Filtration Rate (GFR)-Modifying Drugs in Prevention of Anticoagulant-Related Nephropathy (ARN)

Sergey V. Brodsky, Ajay kumar Medipally, Min Xiao, Anjali A. Satoskar, Tibor Nadasdy, Lee A. Hebert. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Acute kidney injury (AKI) with red blood cell (RBC) tubular casts secondary to different anticoagulants has been recognized as ARN. ARN is seen in patients with underlying kidney diseases. 5/6 nephrectomy (5/6NE) animal model reproduces morphologic features of ARN. One of the possible pathogenetic mechanisms of ARN proposed to be increased GFR. Aim of the current study was to investigate the role of GFR-modifying drugs in prevention of ARN.

Methods: 5/6NE rats 3 weeks after the surgery were treated with direct thrombin inhibitor dabigatran (150mg/kg/day) and with GFR-reducing Enalapril (1.5mg/kg/dl) or GFR-increasing Albuterol (4mg/kg/day) for 7 days. Daily monitoring of serum creatinine (SCr), blood pressure and hematuria was performed. Morphology of the kidney was evaluated at day 7 after animals were euthanized.

Results: Dabigartan resulted in gradual increase in SCr (Fig 1), hematuria, acute tubular necrosis (ATN) and RBC tubular casts in all treatment groups. Neither of GFR-modifying drugs significantly changed there parameters. ATN was 0.75±0.27, 0.67±0.25 and 0.79±0.27 in Dabigatran, Dabigatran + Enalapril and Dabigartan + Albuterol treatment groups, respectively. Systolic blood pressure was reduced with Enalaprilbut did not change significanlty with Albuterol. Diastolyc blood presuure was not changed significantly with either treatment.

Conclusions: Our data indicate that GFR-modifying drugs do not prevent or aggravate ARN at least secondary to direct thrombin inhibitor.

Tubular β-Catenin Ameliorates AKI by Regulating Apoptosis and Necroptosis

Hongyu Li,[1] Joseph C K Leung,[1] Loretta Y.Y. Chan,[2] Bin Li,[1] Wai Han Yiu,[1] Kar Neng Lai,[1] Sydney C. Tang.[1,2] *[1]The University of Hong Kong, Hong Kong, China; [2]Queen Mary Hospital, Hong Kong, China.*

Background: Renal tubular β-catenin signaling plays a protective role in acute kidney injury (AKI) but the underlying mechanisms remain debatable. Apoptosis and necroptosis of tubular cells are responsible for the renal dysfunction in AKI. This study aims to investigate the role of β-catenin activation in tubular cell death upon AKI and its underlying mechanism.

Methods: Transgenic 'Tubcat' mice conditionally expressing stabilized β-catenin in renal tubules following tamoxifen administration were used to establish septic (LPS-induced) and non-septic (ischemia-reperfusion injury or IRI-induced) AKI models. Tubcat mice and their littermate controls were divided into the LPS and IRI groups. LPS mice received intraperitoneal injection of LPS (20 mg/kg). IRI mice received bilateral ischemia for 28 minutes, followed by 24 hours of reperfusion. All the mice were sacrificed at 24 hours. Kidney function and renal histological changes were assessed. Renal apoptosis and necroptosis were evaluated by real-time quantitative PCR, western blot and TUNEL assay. Signaling cascade was examined by western blot.

Results: Compared to the controls, Tubcat mice under septic and non-septic AKI had significantly improved renal function (lower serum creatinine levels) and reduction of (i) tubular injury score; (ii) apoptosis (Bax/Bcl2 ratio and number of renal TUNEL-positive apoptotic cells); (iii) necroptosis (expression of RIP1, p-RIP3 and p-MLKL); and (iv) renal expression of phosphorylated p53. Renal expression of phosphorylated Akt was increased significantly.

Conclusions: Activation of β-catenin signaling in tubular cells reduces apoptosis and necroptosis in septic and non-septic AKI. Tubular β-catenin might play a protective role in AKI by regulating cell death via modulating the p53/Akt signaling pathway. **Fundings:** General Research Fund (HKU 17119818), RGC Collaborative Research Fund (Ref: C7018-16G) and Hong Kong Society of Nephrology Research Grant (2019)

Pulsed Ultrasound Improves Dysregulated Oxygen Metabolism and Reduces Tissue Injury in Sepsis-Associated AKI

Shuqiu Zheng, Naidi Sun, Diane L. Rosin, Nabin Poudel, Junlan Yao, Shinji Tanaka, Jieru Cai, Song Hu, Mark D. Okusa. *University of Virginia Health System, Charlottesville, VA.*

Background: Sepsis associated-acute kidney injury (SA-AKI) results in part from oxidative stress and cytokine-induced inflammation. We showed that pulsed US (pUS) reduces inflammatory conditions and kidney injury in sepsis (PMID: 25644106). Using multi-parametric photoacoustic microscopy (PAM) we demonstrated that the imbalance between oxygen supply and oxygen demand is one of the earliest (10 min) findings in the pathogenesis of S-AKI. We tested the hypothesis that US attenuates kidney injury and improves early tissue oxygen metabolism and cellular bioenergetics.

Methods: We used PAM imaging to assay the change of renal blood oxygen saturation (sO_2), peritubular capillary (PC) blood flow (BF) and the metabolic rate of oxygen (MRO_2) in saline- and LPS-treated mice and mice pretreated with US 24 hr before LPS (as described PMID: 25644106). Mice received a single injection of LPS (5 mg/kg, i.p.), and oxygen consumption and blood flow were measured 10-80 min later by PAM imaging with an image penetration depth of up to 200 μm, and MRO_2 was calculated. Additional animals were treated with LPS and euthanized at increasing time intervals for measurement of blood creatinine and injury and inflammatory biochemical markers.

Results: PAM imaging revealed heterogeneous cortical regions of LPS- induced markedly enhanced oxygen consumption and MRO_2. Pretreatment with US reversed the early renal sO_2 decline observed 30-80 min after LPS and reversed the cortical regions of increased MRO_2. pUS prevented the overall reduction of PCBF. LPS-induced AKI, confirmed by increased plasma creatinine, mRNA expression of kidney injury marker Kim1 and Ngal 12-24 hr after LPS, and acute tubular necrosis (by H&E staining), was attenuated by US pretreatment. pUS reduced Kim1 expression in the brush border membrane of proximal tubules in cortex and medulla. pUS attenuated the increase in *IL-6* and *IFN-γ*, but not TNF-α, mRNA expression.

Conclusions: Our results demonstrate that pUS reverses kidney MRO_2, improves oxygen metabolism and reduces proinflammatory cytokines in SA-AKI. These results provide insight into the mechanisms of kidney tissue protection by US in AKI.

Targeting Gadd34 Upstream Open Reading Frame to Treat Sepsis-Induced Kidney Injury

Ashley N. Kidwell, Bernhard Maier, Pierre C. Dagher, Takashi Hato. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Sepsis-induced acute kidney injury remains a major clinical problem with no effective therapy to date. We have previously shown that bacterial sepsis causes global translation shutdown via phosphorylation of the eukaryotic translation initiation factor 2α (eIF2α). Under physiological conditions, this eIF2α phosphorylation is counter-regulated by two eIF2α holophosphatases. Of the two holophosphatases, Growth Arrest DNA-inducible Gene 34 (Gadd34) is the only stress-inducible regulatory subunit. Using ribo-seq, we found that Gadd34 is translationally repressed during late phase sepsis even though eIF2α is heavily phosphorylated. We postulate that this blunted Gadd34 induction could explain the sustained phosphorylation of eIF2α and translation shutdown that contributes to delayed renal recovery in sepsis.

Methods: The 5'-untranslated region (UTR) of Gadd34 has an upstream open reading frame (uORF) that is conserved across mammalian species. Our ribo-seq analysis of the kidney from septic mice revealed high ribosomal occupancy of the uORF, but not the main protein coding sequence (CDS), consistent with a model in which the uORF serves as a translational inhibitor of the downstream CDS. To investigate the inhibitory role of the Gadd34 uORF, we designed plasmid constructs consisting of a full length Gadd34 5'UTR where a single nucleotide mutation was introduced to abolish the uORF start codon. We also designed antisense oligonucleotides (ASO) that are complementary to a specific portion of the uORF to modulate ribosomal scanning on the native Gadd34 mRNA.

Results: The uORF point mutation led to a two-fold increase in the readout luciferase signal compared with the wild-type control, confirming the inhibitory property of the Gadd34 uORF. We also found that masking of uORF by ASO resulted in sequence-specific increases in translation of the downstream CDS, possibly due to enhanced leaky ribosomal scanning. Finally, we tested the applicability of antisense approach in vivo using a mouse model of endotoxin-induced kidney injury. Despite late intervention (8 hrs post endotoxin challenge), the administration of uORF-targeted ASOs rescued translation and reduced kidney injury.

Conclusions: These findings indicate that translational suppression of Gadd34 in late phase sepsis is a maladaptive response that could be therapeutically modulated by targeting its uORF.

PO0199

STC1 Prevents Lipopolysaccharide-Induced AKI via TGF-β

Li Tan, Wei Qin, Yi Tang. *Sichuan University West China Hospital, Chengdu, China.*

Background: Lipopolysaccharide (LPS)-induced Epithelial injury plays a critical role in the pathogenesis of acute kidney injury (AKI). Stanniocalcin-1 (STC1), a pleiotropic glycoprotein, has been reported to protect ischemic renal injury by reducing redox oxygen species, modulating inflammatory release, and inhibiting cell apoptosis. However, regulators of STC1 expression as well as its physiologic function in kidneys were unknown. We sought to elucidate the relationship between TGF β and STC1 in LPS-induced kidney injury in vitro and in vivo and to define the functional role of STC1 expression in renal tubular epithelium.

Methods: C57BL/6 J mice, STC1-/- (C57BL/6 J background) mice were randomly divided into blank control group, experimental control group. A mouse model of AKI was established. Primary mouse renal tubular epithelial cells isolated from wide type mice and STC 1-/- mice were cultured. We detected changes in serum creatinine (Scr) and blood urea nitrogen (BUN) before and after model establishment, observed and scored renal tubular injury, and measure the expression of signal pathway proteins and downstream inflammatory factors.

Results: LPS caused elevation of SCr, BUN level, morphological injury and tubular apoptosis, enhanced NLRP3 and Col 1 expression, and increased expression of TGF β and STC 1 ($P<0.05$).

Conclusions: Our study reveals a novel TGF β-STC1 pathway that has homeostatic as well as LPS-induced cytoprotective functions in renal tubular epithelium. STC 1 has protective effects on LPS-induced acute renal tubular injury in mice, possibly by targeting TGF β, enhencing TLR4 expression, regulating the TGF β/STC1 signaling pathway, and inhibiting the expression of downstream inflammatory factors.

Lipopolysaccharide Induces NEAT 1 Expression in AKI via TLR4/NF-κB Signaling

Rui Xue,[1] Wai Han Yiu,[1] Sarah W.Y. Lok,[1] Loretta Y.Y. Chan,[1] Joseph C K Leung,[1] Kar Neng Lai,[1] Hui Y. Lan,[2] Sydney C. Tang.[1] *[1]University of Hong Kong, Hong Kong, Hong Kong; [2]The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

Background: Toll-like receptor 4 (TLR4)/ Nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) have been implicated in the pathogenesis of acute kidney injury(AKI). Nuclear Paraspeckle Assembly Transcript 1 (NEAT1) is a long non-coding RNA that plays key roles in a variety of biological processes and is involved in many other diseases. Beyond its fundamental role of maintaining function of the nucleus, it remains unknown whether interaction between TLR4/NF-κB signaling and NEAT1 is involved in the process of the development of AKI.

Methods: Septic AKI model was established with injection of LPS into mice. Mouse tubular cells were stimulated with LPS for the study of tubular inflammation. The role and upstream regulatory mechanisms of NEAT1 in the inflammatory processes were studied by using signaling inhibitors.

Results: In LPS-induced AKI, NEAT1 expression was upregulated in tubular cells, accompanied by elevated TLR4/NF-κB signaling In vitro, mouse tubular cells treated with LPS also showed increase in NEAT1, prior to the production of proinflammatory

cytokines including IL-6 and CCL-2, whereas treatment with an inhibitor of TLR4 or NF-κB signaling suppressed LPS-induced NEAT1 expression.

Conclusions: NEAT1 expression was induced in LPS-induced AKI model via TLR4/NF-κB signaling, suggesting its potential role in the inflammatory process. Our findings open the door to exploit NEAT1 expression as a potential novel therapeutic approach for AKI and other inflammation-related renal diseases. **Funding:** Research Grants Council of Hong Kong (Collaborative Research Fund, grant no. C7018-16G), and Hong Kong Society of Nephrology/HK Kidney Foundation Research Grant 2019.

Effect of Renal Tubular Epithelial Cell Forkhead Box O1 on Endotoxin-Induced AKI

Xinling Liang, Mengxi Zhang, Wei Dong. *Guangdong Academy of Medical Sciences, Guangzhou, China.*

Background: Mitochondrial damage in renal tubular epithelial cells (RTECs) is a hallmark of endotoxin-induced acute kidney injury (AKI). Forkhead box O1 (FOXO1) is responsible for regulating mitochondrial function and is involved in several kidney diseases. Herein, we investigated the effect of FOXO1 on endotoxin-induced AKI and related mechanism.

Methods: In vivo, the mouse model of endotoxin-induced AKI was induced by intra-abdominal injection of LPS (10 mg/kg). The expression of FOXO1 and PGC1-α in mouse kidney were determined. Then we established a mouse model of renal overexpression of FOXO1 by in situ injection of FOXO1 adeno-related virus in renal cortex before intra-abdominal injection of LPS. In vitro, Human proximal tubular epithelial (HK-2) cells were stimulated with LPS (40μg/ml), then infected with FOXO1 overexpression adenoviruses. The cell viability was measured by MTT assay. The morphological changes of mitochondria were observed using mitotracker staining. Mito-SOX was used to detect the changes of mitochondrial superoxide content and the expression of FOXO1.

Results: *In vivo*, FOXO-1 downregulation in mice RTECs and mitochondrial damage was found in endotoxin-induced AKI. Overexpression of FOXO1 could improve renal function and reduce mitochondrial damage. PGC1-α was reduced in endotoxin-induced AKI and reversed by FOXO-1 overexpression. *In vitro*, exposure to LPS led to HK-2 cell viability decline, mitochondrial fragmentation, and mitochondrial superoxide accumulation, as well as downregulation of the FOXO1, PGC1-α and mitochondrial complex I/V. Moreover, over-expression of FOXO1 in HK-2 cells could increase HK-2 cell viability and PGC1-α expression, and alleviated altered mitochondrial injury and superoxide accumulation induced by LPS. Meanwhile, inhibition of FOXO1 in HK-2 cells by siRNA decreased PGC1-α expression and HK-2 cell viability. Chromatin immunoprecipitation assays and PCR analysis confirmed FOXO1 binding to the PGC1-α promoter in HK-2 cells.

Conclusions: In conclusion, downregulation of RTECs FOXO1 mediated endotoxin-induced AKI and mitochondrial damage. Over-expression of FOXO1 could improve renal injury and mitochondria dysfunction, at least partly via PGC1-α signaling. FOXO1 might be a potential target for the prevention and treatment of endotoxin-induced AKI.

Humanin Improves Mitochondrial Function and Alleviates Renal Tubular Injury in Lipopolysaccharide-Induced AKI

Zhenmeng Xiao, Zhilian Li, Wei Dong, Yuanhan Chen, Xinling Liang. *Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.*

Background: Mitochondria dysfunction is increasingly recognized to be a key role in the pathogenesis of sepsis-induced AKI. Whether Humanin (HN), a well-known mitochondrial-encoded cytoprotective peptide, has similar effect in septic AKI remains unknown. We hypothesize that HN improves mitochondrial function in sepsis-induced AKI.

Methods: LPS (10mg/kg) was given to C57BL/6 mice intraperitoneally to induce murine septic AKI, and HNG (a potent analog of humanin, 1mg / kg) was injected 15 minutes later. Mice were euthanized at 24 h after LPS injection. Blood samples and kidney tissues were collected. Blood urea nitrogen was measured to evaluate renal function. Electron microscopy was used to observe mitochondrial morphology and structure. Renal inflammation (IL-1β, IL-6 and HMGB1) was evaluated by real-time PCR. The expression of PGC1-α and TFAM, which can promote mitochondrial biogenesis, was measured by real-time PCR, western bolt and immunohistochemistry.

Results: HNG significantly reduced blood urea nitrogen levels (62.10 ±3.554 mg/dl vs. 30.30±2.558 mg/dl, n=3, $p<0.05$). Electron microscopy showed mitochondrial damage of renal tubular epithelial cells in the LPS group, such as mitochondrial swelling and deformation and the crista disorder or disappearance. Treatment with HNG restored mitochondrial morphology and structure. Compared with LPS group, HNG reduced the renal expression of IL-1β, IL-6 and HMGB1 and significantly increased the expression of PGC1-α and TFAM in the kidney.

Conclusions: Our data showed that humanin ameliorated renal dysfunction and attenuated renal tubular injury by alleviating mitochondrial dysfunction in LPS-induced AKI, which may be associated with upregulation of PGC1-α and its downstream transcriptional factor TFAM.

Renal Angiotensin (Ang) Receptor Changes Following Cecal Ligation and Puncture (CLP)-Induced AKI

Jake R. Lehman,[1,2] Daniel E. Leisman,[1,4] Tiago Fernandes,[1] Matthew D. Taylor,[1,3] Mariana R. Brewer,[1,3] Mabel N. Abraham,[1] Clifford S. Deutschman.[1,3] *[1]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [3]Cohen Children's Medical Center, Queens, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Angiotensin-II (Ang2) modulates renal function and thus may contribute to sepsis-induced acute kidney injury (SIAKI). We have shown that CLP reduced renal Ang2 type-1 receptors (AT1R), but effects on non-classical Ang receptors are unknown. We hypothesized that CLP altered renal abundance of Ang2 type-2 receptors (AT2R) and Ang(1-7), Mas receptors (Ang(1-7)R, MasR), initiators of signaling axes that oppose AT1R.

Methods: C57BL6 mice were randomized to euthanasia at 6, 24, or 48hrs post-CLP (n=5/group). Unoperated mice (T0) served as controls. Mice were resuscitated (50mL/kg NS SQ) immediately and 25 hrs post-operatively. Prior to sacrifice we removed the kidneys under deep isoflurane anesthesia to minimize tissue ischemia. We obtained blood by cardiac puncture. Kidney Injury Molecule-1 (KIM-1) was measured in whole tissue homogenate (ELISA). AT1R, AT2R, and MasR were measured within specific regions of the kidney using immunofluorescence, (IF). We also used IF to compare kidney sections collected from sepsis patients within an hour of death (n=7) to sections from healthy controls (n=10).

Results: KIM-1 and BUN increased 6h post-CLP. Creatinine increased 48h post-CLP. We have previously shown that CLP reduced AT1R in arterioles, macula densa, and glomeruli. However, CLP did not alter MasR abundance in any region ($p>0.05$). The ratio of total renal MasR to AT1R more than doubled by 6hrs post-CLP ($p<0.001$ vs. T0). Renal AT2R intensity was increased in renal mesangium by 24h and in glomeruli by 48h ($p<0.01$ for both). We previously showed decreased AT1R IF in human sepsis kidney sections. In contrast, human sepsis kidneys did not show any decrease in MasR ($p>0.05$), again suggesting an increase in the MasR to AT1R ratio.

Conclusions: 1. Data on CLP-induced changes in KIM-1 in tissue and BUN in blood suggest that these are earlier markers of CLP-induced renal injury than serum creatinine. 2. CLP and septic AKI may be associated with a shift from classical to non-classical angiotensin signaling in the kidney. Studies of non-classical angiotensin system modulation in septic AKI may enhance understanding of pathobiology and reveal therapeutic targets in septic AKI.

PO0204

The Fibrogenic Response to Renal Injury Is Epigenetically Regulated Through the Activation of Bivalent Genes

Elizabeth D. Nguyen,[1,2] Daryl M. Okamura,[1,2] Scott R. Houghtaling,[2] Sarah J. Collins,[2] Andrew E. Timms,[2] David R. Beier,[2] Mark W. Majesky.[2] *[1]Seattle Children's Hospital Department of Pediatric Nephrology, Seattle, WA; [2]Seattle Children's Research Institute, Seattle, WA.*

Background: Bivalent genes are regions of epigenetically modified nucleosomes that carry both H3K4me3 and H3K27me3 simultaneously and exist in a poised transcriptional state, ready for activation or repression depending on stimuli. While important in directing gene expression during development, the role of bivalency has not been fully characterized in renal injury. In this work, we demonstrate that activated bivalent genes are associated with upregulation of genes that drive the response to unilateral ureteric obstruction (UUO) in the mouse.

Methods: CUT&RUN ChIP-Seq analysis using antibodies to H3K4me3 and H3K27me3 was carried out on normal kidneys and kidneys of mice 5 days after UUO. Enriched peaks were identified using SEACR, and HOMER was used to perform peak annotation. To determine fold change gene expression, RNA was collected and analyzed from samples 5 days after they were subjected to sham or UUO surgery.

Results: Through peak annotation of CUT&RUN results, 1546 bivalently marked genes were identified in the normal kidney. With the onset of UUO, 62% of these bivalent genes (951/1546, *activated bivalent genes*) are activated by the loss of the repressive H3K27me3 mark and the persistence of the activating H3K4me3 mark, indicating these genes are available for transcription. Upon correlation of *activated bivalent genes* with RNA Seq data after UUO only 13% were significantly upregulated (fold change >1.5, FDR <0.05). Functional analysis of these *activated bivalent genes* identified enriched pathways associated with kidney injury including apoptotic signaling, regulation of fibroblast proliferation and inflammation. Significantly increased expression of genes involved in these pathways were noted after UUO, including *Nfkb2* (7 fold), *Rhob* (6 fold), *Cdkn1* (5 fold) and *Tgfbr2* (2.5 fold). The activated bivalent gene with the most significant increase in gene expression (20 fold in UUO compared to sham) was *Atf3*, a transcription factor which plays a protective role in kidney injury by attenuating the inflammatory response.

Conclusions: We provide evidence to suggest that the response to renal injury via inflammatory, apoptotic and fibrogenic pathways is orchestrated through the epigenetic regulation of bivalent genes that are poised for response in the normal kidney.

PO0205

The Effect of Overexpression of Intestinal Alkaline Phosphatase (IAP) on Intestinal Permeability and Renal Failure in Lipopolysaccharide (LPS) Treated IAP Transgenic (IAPTg) Mice

Siddhartha S. Ghosh, Austin J. Mullaly, Shobha Ghosh, Todd W. Gehr. *Virginia Commonwealth University, Richmond, VA.*

Background: LPS associated sepsis is known to cause intestinal dysfunction in septic AKI. IAP is known to dephosphorylate LPS and render it inactive. We generated IAPTg mice who overexpress human IAP. We hypothesized that if IAPTg mice were subjected to septic AKI their kidney function and intestinal barrier permeability will be better preserved than non-transgenic mice.

Methods: IAPTg mice were developed in C57Bl6 background using human chimeric IAP under the control of villin promoter making them intestine and kidney specific overexpressing IAP. LPS (10 mg/Kg) was given to IAPTg (IAPTg+LPS) and C57Bl6 (C5+LPS) to induce septic AKI. The control IAPTg (IAPTg-LPS) and C57Bl6 (C5-LPS) received saline. FITC-Dextran (FD) was gavaged 2 hours before sacrifice to measure intestinal permeability. Blood, intestine (duodenum, jejunum, ileum), and colon were harvested for biochemical and immunoblot analysis.

Results: Serum urea and creatinine of IAPTg mice were 0.6 mg/dl and 65 mg/dl respectively which were 2 and 1.5 fold lower than C5+LPS mice ($p<0.05$). Serum FD levels of IAPTg+LPS (1.2± 0.1 ng/μl) were 2.5 fold lower than C5+LPS ($p<0.05$) suggesting improved intestinal integrity. Expression of tight junction protein (ZO-1), pro-apoptotic proteins (Caspase3, Bax), antiapoptotic protein Bcl2 in the colon, and intestine was measured by immunoblot. ZO-1 expression in the intestine and colon of C5+LPS was significantly lower than IAPTg+LPS ($p<0.05$) and the controls ($p<0.01$). Expression of intestinal and colon caspase 3 in the IAPTg was 4 fold lower than C5+LPS ($p<0.01$). Intestinal and colon Bax of IAPTG+LPS were lower and Bcl2 higher than C5+LPS ($p<0.05$). Apoptotic markers of IAPTg+LPS were not significantly different from the control suggesting low apoptosis in IAPTg. Plasma TNFα and IL-6 levels of IAPTg+LPS were 70±20 and 95+26 pg/ml respectively which were about 1.5 fold lower than C5+LPS ($p<0.05$) suggesting decreased inflammation in transgenic mice.

Conclusions: Improved ZO-1 expression probably due to reduced apoptosis decreases intestinal permeability in transgenic mice subjected to endotoxemia. This can prevent leakage of bacterial contents from the gut and result in improved renal function and decreased inflammation, as evidenced by decreased plasma cytokines, in IAPTg group.

Changes in NAD and Lipid Metabolism Drive Acidosis-Induced AKI

Milica Bugarski,[1] Susan Ghazi,[1] Marcello Polesel,[1] Joana R. Martins,[1,2] Andrew Hall.[1,3] *[1]Institute of Anatomy, University of Zurich, Zurich, Switzerland; [2]Center for Microscopy and Image Analysis, Zurich, Switzerland; [3]Department of Nephrology, University Hospital Zurich, Zurich, Switzerland.*

Background: The kidney has an important role in maintaining normal blood pH. Mitochondria in the proximal tubule (PT) produce ammonia and bicarbonate from glutamine, and during metabolic acidosis (MA) this pathway (ammoniagenesis) is acutely upregulated. MA is frequently associated with acute kidney injury (AKI); however, to what extent the former causes the latter was unclear.

Methods: Multiphoton imaging of mitochondrial function in mouse kidney cortical slices and *in vivo*; oxygen consumption rate (OCR) in isolated PTs; histological analysis and electron microscopy (EM) in fixed tissue. MA was induced using an established protocol (gavage with 0.8 g/kg NH_4Cl).

Results: Acutely lowering extracellular pH to 6.5 decreased mitochondrial NADH fluorescence signal specifically in PTs, without changing total NADH content, baseline OCR or mitochondrial membrane potential. However, maximal OCR was decreased and response to rotenone was exaggerated, suggesting a switch to complex I and increased oxidation of NADH to NAD^+, which is required for ammoniagenesis. PTs in acidotic animals displayed intense Oil Red O staining and large multi-lamellar bodies (MLBs), consistent with a major decrease in lipid metabolism. Supplementing or reducing NAD (with lactate) and increasing pH back to 7.4 inhibited/reversed the appearance of MLBs, implying that changes in NAD and lipid metabolism are linked. Histological analysis of acidotic animals showed thinning of PTs and shedding of debris, indicative of AKI. Intravital imaging revealed that mitochondria remained energized, but endocytosis of fluorescently labeled dextrans was markedly decreased, confirming a severe functional defect in solute transport. Partially reversing MA with intravenous injection of bicarbonate (0.42 g/kg) or supplementing NAD with nicotinamide (0.4 g/kg, prior to MA induction) both substantially improved dextran uptake.

Conclusions: MA induces major changes in PT NAD and lipid metabolism that result in a functional AKI state, which can be reversed or prevented. These findings might also help to explain why MA accelerates decline in function in chronic kidney disease.

PO0207

Loss of HDAC8 Leads to γH2AX-Induced Cellular Repair and Decreased Epithelial-Mesenchymal Transition in Renal Tubule Epithelial Cells

Amanda Crunk, Hwa I. Han, Michael D. McDaniels, Neil A. Hukriede. *University of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) remains a significant worldwide problem. Our previous work has shown that *hdac8*$^{-/-}$ larval zebrafish model of AKI improved survival and increased repair and proliferation after AKI. However, these mechanisms have not been elucidated. AKI is known to induce double stranded DNA breaks (DSB), activating factors including the phosphorylation of the histone variant H2AX producing γH2AX. Damaged cells undergo a complex multifactorial fate determination leading to either DNA repair and cell survival or apoptosis.

Methods: hdac8$^{sa14948/-}$ and hdac8 $^{sa14948/+}$ mutant zebrafish were injected with gentamicin to induce AKI. Immunofluorescent microscopy, fluorescently activated cell sorting (FACS) of renal tubule epithelial cells (RTEC) were isolated for RNA-seq.

Results: We evaluated DNA DSB in RTEC through immunohistochemistry of γH2AX in WT and *hdac8*$^{-/-}$ zebrafish with and without AKI. There were a greater number γH2AX foci in RTEC of the *hdac8*$^{-/-}$ larvae with AKI than in either the uninjured *hdac8*$^{-/-}$ or WT AKI larvae. *hdac8*$^{-/-}$ zebrafish with AKI exhibited less apoptosis compared to WT zebrafish with AKI, and as expected there were undetected levels of TUNNEL positive cells in WT and *hdac8*$^{-/-}$ uninjured tubules. We observed more Pax2a positive cells in *hdac8*$^{-/-}$ larvae with AKI than WT larvae with AKI. Immunohistochemical analysis of Na^+/K^+-ATPase, a marker for epithelial polarization, in *hdac8*$^{-/-}$ zebrafish tubules maintain partial to full polarization during AKI, whereas WT larvae with AKI had complete mis-polarization of RTEC. RNA-Seq data analysis confirmed the epithelial polarization data demonstrating increased expression of mesenchymal genes and decreased epithelial gene expression in WT tubules with AKI compared to *hdac8*$^{-/-}$ in AKI injured zebrafish.

Conclusions: This study suggests a mechanism of repair and recovery after AKI in *hdac8*$^{-/-}$ zebrafish is mediated through increased γH2AX at sites of DNA damage. *hdac8*$^{-/-}$ mutant zebrafish preferentially uses mechanism of DDR for repair and proliferation, as opposed to apoptosis. In the absence of apoptosis *hdac8*$^{-/-}$ tubules can prevent depolarization of epithelial membranes and maintain their epithelial gene signatures, whereas the WT zebrafish lose their polarization and begin EMT. These data support our hypothesis that the loss of HDAC8 allows cells to repair after injury from AKI

PO0208

Protein Phosphatase 2A Cα Reprograms Cellular Energy Metabolism to Promote Tubular Cell Death and Kidney Injury

Mengru Gu, Chunsun Dai. *Nanjing Medical University, Nanjing, China.*

Background: Protein phosphatase 2A (PP2A), one of the primary serine-threonine phosphatases in mammalian cells, regulates various biological processes. The role and mechanisms for PP2A in kidney injury remains to be determined.

Methods: Generating the mice with PP2Aca ablation with Cre-Loxp system. Mice were injected with cisplatin to induce AKI. UUO was performed on the mice to induce kidney fibrosis.

Results: In this study, we found that the expression of protein phosphatase 2A Cα (PP2Acα) in tubular cells was upregulated in both patients and animal models with acute and chronic kidney injury. Ablation of PP2Aca in tubular cells alleviated cisplatin-induced acute kidney injury and unilateral ureteral obstruction-induced kidney fibrosis in mice. In cultured tubular cells, ablation of PP2Acα promotes oxidative phosphorylation of fatty acids by increasing p-ACC levels and thus protects against cisplatin-induced cell death and TGFβ1-induced fibronectin production.

Conclusions: This study reveals the essential role for PP2Acα in regulating tubular cell energy metabolism and survival, which may shed light on treating patients with kidney injury.

PO0209

In Vitro Inhibition of Renal OCT2 and MATE1 Secretion by Antiemetic Drugs

Blessy George,[1] Xia Wen,[1] Edgar A. Jaimes,[2] Melanie S. Joy,[3] Lauren Aleksunes.[1] *[1]Rutgers The State University of New Jersey, Piscataway, NJ; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.*

Background: The organic cation transporter 2 (OCT2) and multidrug and toxin extrusion protein 1 (MATE1) regulate the renal secretion of drugs including metformin, cisplatin, and entecavir. Studies suggest that ondansetron, an antiemetic drug and 5-HT_3 antagonist, can inhibit OCT2- and MATE1-mediated transport. The purpose of this study was to test five structurally similar 5-HT_3 antagonist drugs for their ability to inhibit the OCT2 and MATE1 transporters.

Methods: Transport of the fluorescent prototypical cation ASP^+ (25 μM) was assessed in the presence and absence of 5-HT_3 antagonists (0.5-20 μM) using two *in vitro* models: 1) HEK293 kidney cells overexpressing human OCT2 or MATE1 and 2) double-transfected hOCT2-MATE1 MDCK cells. Cimetidine (50 μM) was included as a positive control.

Results: The relative order of potency for inhibition of ASP^+ uptake by OCT2 was palonosetron > ondansetron > granisetron > tropisetron > dolasetron and by MATE1 was ondansetron > palonosetron = tropisetron > granisetron > dolasetron. In hOCT2-MATE1

MDCK cells, ondansetron (0.5-20 μM) inhibited the transcellular transport of ASP^+ up to 64%. Palonosetron, tropisetron, and dolasetron (10 and 20 μM) reduced the transcellular transport of ASP^+ up to 80-90%. Granisetron did not alter the transcellular transport of ASP^+ at concentrations up to 20 μM.

Conclusions: 5-HT_3 antagonist drugs may inhibit the renal secretion of cationic drugs resulting in potential drug-drug interactions. These data could have important implications for drug-induced kidney injury since 5-HT_3 antagonists are routinely prescribed with the highly emetogenic and nephrotoxic chemotherapeutic drug cisplatin. Funding: Other NIH Support - Funded by GM123330, ES005022, ES007148, CA072720, and CA046934.

Inhibition of OCT2-MATE1 Secretion of ASP^+ by Ondansetron in MDCK Cells

PO0210

Klotho Deficiency Intensifies Hypoxia-Induced Expression of INF-α/β Through Upregulation of Rig-I

Asako Urabe,[1] Shigehiro Doi,[1] Toshiki Doi,[1,2] Ayumu Nakashima,[1,3] Takao Masaki.[1] *[1]Department of Nephrology, Hiroshima University Hospital, Hiroshima, Japan; [2]Harada Hospital, Hiroshima, Japan; [3]Department of Stem Cell Biology and Medicine, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan.*

Background: Hypoxia is a common pathway to progression of end-stage kidney disease. Although numerous studies have provided evidence that inflammation plays a major role in this process, the mechanism by which hypoxia induces inflammation remains unknown. Retinoic acid-inducible gene-I (RIG-I) encodes an RNA helicase that recognizes viruses including SARS-CoV2, which is responsible for production of interferon (IFN)-α/β to prevent the spread of a viral infection. Recently, RIG-I activation was found under hypoxic conditions, and klotho deficiency intensified the activation of RIG-I in mouse brains. However, the roles of these functions in renal inflammation remain elusive.

Methods: *In vitro*, expression of RIG-I and INF-α/β was examined in normal rat kidney (NRK)-52E cells incubated under hypoxic conditions (1% O_2) for 30, 60, 90, and 120 min. Next, siRNA targeting RIG-I or scramble siRNA was transfected into NRK52E cells to examine expression of RIG-I and INF-α/β under hypoxic conditions. *In vivo*, we induced renal hypoxia by clamping the renal artery for 10 min in wildtype mice (hypoxic WT mice) and Klotho knockout mice (hypoxic $Kl^{-/-}$ mice). Lastly, we investigated the expression levels of RIG-I and INF-α/β in 33 human kidney biopsy samples diagnosed with IgA nephropathy.

Results: *In vitro*, incubation under hypoxic conditions increased expression of Rig-I and IFN-α/β in NRK52E cells. Their upregulation was inhibited in NRK52E cells transfected with siRNA targeting Rig-I. *In vivo*, the expression levels of Rig-I and IFN-α/β were upregulated in kidneys of hypoxic WT mice and further upregulation was observed in hypoxic $Kl^{-/-}$ mice. In patients with IgA nephropathy, immunohistochemical staining of renal biopsy samples revealed that expression of Rig-I was correlated with that of IFN-α/β (r=0.57, *P*<0.001, and r=0.81, *P*<0.001, respectively).

Conclusions: These findings suggest that hypoxia induces expression of INF-α/β through upregulation of Rig-I, and that klotho deficiency intensifies this hypoxia-induced expression.

PO0211

suPAR Determines Outcomes in Septic AKI

Christian Nusshag,[1,2] David C. Wei,[1] Roman Szudarek,[2] Florian Kälble,[2] Claudius Speer,[2] Florian Uhle,[2] Jesper Eugen-Olsen,[5] Thomas Krarup,[4] Markus A. Weigand,[2] Martin G. Zeier,[2] Christian Morath,[2] Thorsten Brenner,[3] Jochen Reiser.[1] *[1]Rush University Medical Center, Chicago, IL; [2]Heidelberg University Hospital, Heidelberg, Germany; [3]University Hospital Essen, Essen, Germany; [4]ViroGates A/S, Birkerod, Denmark; [5]Copenhagen university hospital Hvidovr, Hvidovre, Denmark.*

Background: Sepsis is the main contributor to the development of acute kidney injury (AKI) in critically ill patients. Plasma soluble urokinase plasminogen activator receptor (suPAR) is a circulating risk factor for AKI and a prognostic marker for the need of renal replacement therapy (RRT). We analyzed the pathophysiological role and kinetic properties of suPAR in septic AKI in critically ill patients and in a murine model of septic AKI.

Methods: 200 critically ill patients were enrolled prospectively after meeting Sepsis-3 criteria. Serum suPAR levels were measured at 0, 12, 24, 48, 72, 96, 120 and 168-hour after enrollment and the need for RRT within 7 days was assessed as the primary outcome measure. Polybacterial sepsis was induced by cecal slurry injection in three mouse strains, respectively wild type (WT, N=9), uPAR-knockout (KO, N=13), and suPAR transgenic overexpression (OE, N=11).

Results: No or mild AKI occurred in 62 patients (31.0%), moderate or severe AKI without the need for RRT in 102 patients (51.0%), criteria for RRT were met in 36 patients (18.0%) and 7 patients (3.5%) died within the 7-day period. Compared to all other maximum AKI stages and AKI disease courses within 7 days, patients requiring RRT showed significantly higher suPAR levels at all time-points. Patients with suPAR levels ≥ 12.7 ng/mL (highest quartile) had an adjusted odds ratio of 5.22 (95% confidence interval [CI], 2.16-12.65) for the need for RRT; and 4.44 (95% CI, 1.98-9.97) for RRT or death within 7 days compared to patients with levels < 12.7 ng/mL. Compared to KO mice, WT and OE mice showed a significantly greater impairment of renal function and structure 24 hours after induction of sepsis. Kaplan-Meier analysis revealed a survival benefit of KO mice over OE mice within 24h (84.6% vs. 45.5%, p=0.041).

Conclusions: SuPAR distinguishes between divergent AKI stages/courses and the need for RRT at any time within 7 days after sepsis diagnosis. Our experimental data suggest that suPAR is a pathophysiological driver of septic AKI and may serve as a target for future interventional strategies.

PO0212

Cardiorenal Effects of the American College of Radiology (ACR) Group II Agent Gadobutrol (Dotarem): Renal Proximal Tubular Mitochondrial Toxicity and Acute Tubular Damage

Brent Wagner,[1,2] G. P. Escobar,[2] Tamara A. Howard,[2] Joshua Deaguero.[2] Kidney Institute of New Mexico *[1]New Mexico VA Health Care System, Albuquerque, NM; [2]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Patients are concerned about gadolinium (Gd) deposition from magnetic resonance contrast agents. Gd is the known cause of iatrogenic 'nephrogenic' systemic fibrosis and long-term gadolinium retention in every organ. Without prospective evidence, the ACR partitions brands of Gd-based contrast agents (GBCAs) into three groups: I, associated with the greatest number of systemic fibrosis cases; II, associated with few, if any, unconfounded cases of iatrogenic systemic fibrosis; and III, data are limited.

Methods: Male and female mice were randomized to GBCA treatment with an increasingly popular, ACR group II macrocyclic agent (Dotarem, 2.5 mmol/kg intraperitoneally, 20 doses over 4 weeks). Echocardiographic parameters were compared at the endpoint, tissues examined with transmission electron microscopy.

Results: Gd *reduced* cardiac systolic volume (29 ± 6 vs 34 ± 4 μL, mean ± SD, M-mode), *increased* fractional shortening (30 ± 4 vs 25 ± 2%, M-mode), and *increased* ejection fraction (57 ± 5 vs 50 ± 4%, M-mode). Renal tissue was characterized by tubular damage, pathologic lipid vacuolization, and diffuse mitochondrial toxicity (**Figure**).

Conclusions: GBCA treatment leads to diffuse and long-term intracellular retention in every vital (and non-vital) organ. These studies demonstrate that the American College of Radiology group II agents are far from clinically inert. Consistent with the first element of the Nuremberg Code, voluntary consent for GBCA administration should be obtained from every patient.

Funding: NIDDK Support, Veterans Affairs Support, Commercial Support - DCI

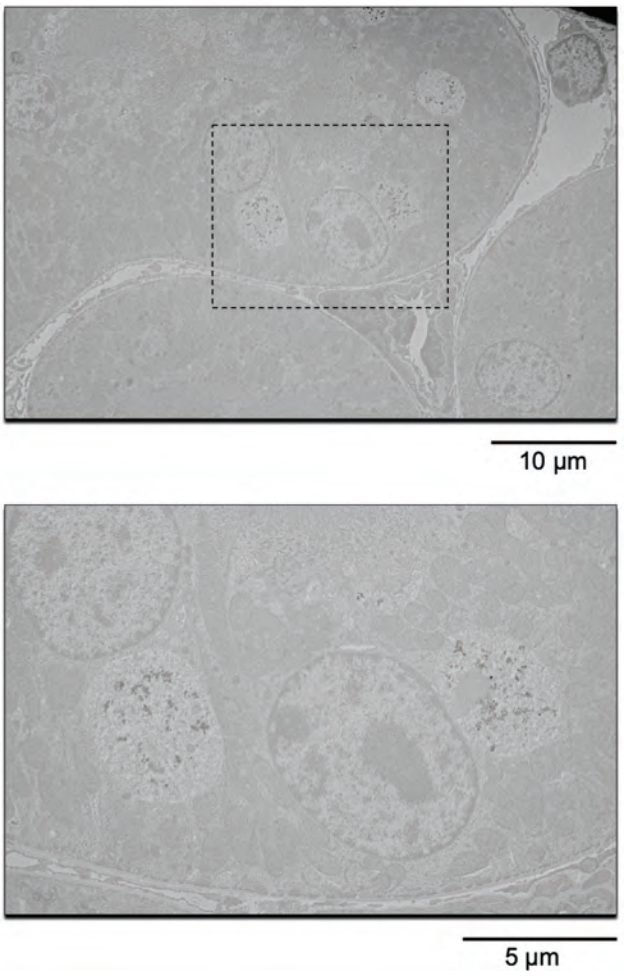

Figure. Systemic Gd treatment induced lipid-laden vacuoles with electron-dense material and pathologic mitochondrial changes. Transmission electron microscopy, renal proximal tubule.

Identification of Predictive Biomarkers Associated with Antibiotic Associated Nephrotoxicity from Polymyxin and Tobramycin Antibiotics Using a Kidney Microphysiological Device

Kirk P. Van Ness. *University of Washington, Seattle, WA.*

Background: With the emergence of multi-drug resistant gram-negative infections, polymyxin and aminoglycoside antibiotics are ever more important for effective bacterial treatment. However, the use of these antibiotics is limited due to concerns of acute kidney injury (AKI). We have employed a kidney microphysiological device system (MPS) with cultured human primary proximal tubule epithelial cells (PTECs) to identify potential sensitive renal biomarkers arising from exposure to aminoglycosides and polymyxins.

Methods: We exposed human PTECs to various concentrations of Polymyxin B (PMB), Polymyxin E (colistin) and tobramycin for 72 hours and collected daily effluents for biomarker discovery. In addition, we evaluated PTEC mRNA transcripts (RNAseq) from control and antibiotic treated MPS devices after 72 hours of antibiotic exposure. Biomarkers associated with epithelial cell injury [kidney injury molecule 1 (KIM-1) and neutrophil gelatinase-associated lipocalin (NGAL)], inflammation/apoptosis [soluble Fas Receptor (sFAS), Fas Ligand and tumor necrosis factor receptor 1 (TNFR-1)] were measured in the MPS effluents using ELISA.

Results: In MPS devices, we observed with PMB and colistin, elevations of KIM-1 at 24 and 48 hours, sFAS at 24 hours and NGAL at 48 hours. In contrast, tobramycin exposures up to 100 mg/mL (5 times clinical Cmax) showed no evidence of toxicity either through lack of elevation of nephrotoxicity biomarkers in effluents or by changes in differentially expressed genes compared to controls. In discovery RNAseq analyses, 7641 genes were differentially regulated between colistin and control MPS. Specific pathways included upregulation of metallothionein and cholesterol biosynthesis genes with colistin exposure. With tobramycin exposure, no genes were differentially regulated compared to controls.

Conclusions: We found that different biomarkers have variable kinetics after PTEC injury. sFas and KIM-1 concentrations rose the earliest after antibiotic exposure. In RNAseq analyses, we found that pathways of metallothionein and cholesterol biosynthesis were dysregulated after colistin exposure. Finally, we found minimal PTEC injury with tobramycin, suggesting that this antibiotic may be less toxic than previously believed. Future work seeks to test these candidate biomarkers in human urine samples.

PO0214

GTS-21 Attenuates the Inflammation of AKI Independent of α7 Nicotinic Acetylcholine Receptor

Yasuna Nakamura,[1] Tsuyoshi Inoue,[2] Rie Uni,[1] Daichi Fukaya,[1] Sho Hasegawa,[1] Masaomi Nangaku,[1] Reiko Inagi.[1] *[1]The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan; [2]Nagasaki University School of Medicine Graduate School of Biomedical Sciences, Nagasaki, Japan.*

Background: Vagus nerve stimulation protects from kidney injury by activating the cholinergic inflammatory pathway (CAP). It is considered that α7 nicotinic acetylcholine receptor (α7nAChR) in splenic macrophages are important for CAP activation. To elucidate the mechanism of receptor signaling, we promoted further experiments using macrophage-specific α7nAChR knockout mice.

Methods: We generated macrophage-specific α7nAChR-deficient mice by crossbreeding LysM-Cre and α7nAChR flox mice. *In vivo*, GTS-21 (an α7nAChR specific agonist) was intraperitoneally injected to either wild type C57BL/6J mice (WT) or macrophage-specific α7nAChR-deficient mice prior to administration of lipopolysaccaride (LPS). 4 hours after LPS administration, the mice were euthanized and, plasma TNF-α level, plasma creatinine, BUN were evaluated. *In vitro*, murine macrophage cell line RAW264.7 and primary peritoneal macrophages from either WT or α7nAChR-deficient mice were used. These cells were stimulated with LPS after nicotine (pan nicotinic acetylcholine receptor agonist) or GTS-21 was administrated, then TNF-α level was evaluated 4 hours later.

Results: GTS-21 protected the kidney and suppressed the increase of plasma TNF-α induced by LPS in WT mice. Surprisingly GTS-21 decreased plasma TNF-α level induced by LPS in not only WT mice but also macrophage-specific α7nAChR-deficient mice. In vitro experiments, GTS-21 or nicotine treatment suppressed TNF-α induction by LPS in RAW264.7 cells or peritoneal macrophages from WT mice. Furthermore, nicotine also suppressed the induction of TNF-α by LPS even in peritoneal macrophages from α7nAChR-deficient mice.

Conclusions: These results suggest that nicotine or GTS-21 might suppress the inflammation independent of α7nAChR in macrophages *in vivo* and *in vitro.*

PO0215

Platelets vs. Neutrophils as Therapeutic Targets in Cholesterol Embolism-Related Arterial Occlusion, Kidney Infarction, and AKI

Chongxu Shi, Hans J. Anders. *Medizinische Klinik und Poliklinik IV, AG Klinische Biochemie, Klinikum der Universität München, Munchen, Germany.*

Background: Cholesterol crystal embolism (CCE), a life-threatening complication, is a consequence of the rupture of atheromatous plaques in patients with advanced atherosclerosis. CCE often missed as a cause of AKI. We hypothesized that platelet contributes to CCE-related artery occlusion leading to AKI and kidney infarction.

Methods: C57/BL6 mice were injected with various doses of cholesterol crystals (CC) to induce CCE in kidney. Primary endpoint: GFR. Secondary endpoints: infarct size, vascular occlusions. 3D MRI and µCT. In vitro studies CC with neutrophils, platelets, endothelial cells.

Results: At 24h, MRI and µCT showed perifocal edema around ischemic lesion and vascular rarefication in CCE kidney. CC-induced clots causing a dose-dependent GFR loss and infarct size. Immunostainings revealed crystal clots contained fibrin, platelets, ecDNA, neutrophils. To study the role of platelets in this process, we treated mice with platelet antagonist clopidogrel. At 24h, clopidogrel completely protected mice from intravascular obstructions, GFR loss, and kidney infarction. In contrast, neutrophil depletion significantly decreased kidney infarction but not arterial obstructions or GFR loss. Maybe because mononuclear cells had partially replaced neutrophils within clots and ecDNA was still present. DNase I treatment also significantly reduced the percentage of ecDNA positive clots, occluded arterial, GFR loss, infarct size. In vitro studies show, CC induced ATP secretion and enhanced fibrinogen release from platelet granules which promotes fibrin clot formation. DNase I can strongly inhibit ATP secretion, fibrin formation, also normalized collagen-driven platelet aggregation.

Conclusions: In summary, not CC itself but the CC-induced fibrin clots obstructed peripheral arteries causing tissue infarction and organ failure. Platelets and ecDNA are central for crystal clots formation. Hence, crystal clots represent the primary target for therapeutic interventions. Among the possible molecular targets in thrombosis, especially enhancing fibrinolysis or inhibiting platelet purinergic signaling could reduce arterial occlusions, infarction, and organ failure. DNase I could have a synergistic effect on CC induced clot formation in mice and might be a prophylactic/therapeutic approach in human patients with a risk for procedure-related CC embolism.

PO0216

Characterizing De Novo Lymphangiogenesis During AKI Using 3D Imaging and Tissue Cytometry

Laurence M. Black,[1] Seth Winfree,[3] Malgorzata Kamocka,[3] Suraj Deepak Khochare,[3] Amie Traylor,[1] Stephanie Esman,[1] Shehnaz Khan,[3] Abolfazl Zarjou,[1] Anupam Agarwal,[1,2] Tarek M. El-Achkar.[3] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Birmingham VA Medical Center, Birmingham, AL; [3]Indiana University School of Medicine, Indianapolis, IN.*

Background: The renal lymphatic system is essential for fluid and electrolyte homeostasis, lipid and cholesterol transport, and immune surveillance with lymphatic vessels (LV) primarily intertwined with the blood vasculature. LV development, or lymphangiogenesis (LA) is regulated by its master transcription factor, prospero-related homeobox-1 (Prox-1), which determines lymphatic cell fate. LA is accentuated during inflammation or injury states such as acute kidney injury (AKI), though mechanisms of LA in AKI remain unclear. Understanding the LA process is essential because it will elucidate potential therapeutic targets in AKI.

Methods: Using 10-week old male Prox1-tdTomato lymphatic reporter mice (ProxTom), we investigated the effect of AKI on the abundance and distribution of Prox-1$^+$ cells at the mesoscale level using large scale three-dimensional (3D) imaging and tissue cytometry. ProxTom mice and their controls were subjected to ischemia-reperfusion (IR) or no surgery and kidneys were fixed on day 3. Large scale 3D imaging with confocal microscopy was done on 50mm thick sections spanning the entire cross section of the kidney, followed by tissue cytometry using the volumetric tissue exploration and analysis (VTEA) software tool.

Results: The average number of cells surveyed per specimen was 347,360 ± 36,647. Using VTEA, a gating strategy was devised to account for autofluorescence in the red channel, which was increased after IR due to cell debris and injury. IR samples displayed a significant increase in Prox-1$^+$ cells compared to baseline controls: 717.2 ± 161.8 vs. 174.4 ± 62.1 Prox-1+ cells/mm^3, respectively ($p<0.05$). In baseline controls, Prox-1$^+$ cells were well-organized and predominately localized around large vessels in the hilum. However, after injury, the distribution of Prox-1$^+$ cells shifted to the hilar parenchyma and inner medulla in a consistent pattern. Few cells could also be detected in the outer medulla and cortex.

Conclusions: We demonstrate a scale of analytics that is amenable to characterizing de novo renal LA during AKI, which informs the origin and distribution of renal LVs and the dynamics of LA. Such findings will enhance our understanding of the functional role of LVs during injury and help identify novel therapeutics for intervention in AKI.

PO0217

Peritubular Transcytosis Enables Mesoscale Nanoparticle Treatment of AKI

Ryan Williams,[1] Janki Shah,[2] Edgar A. Jaimes,[2] Daniel A. Heller.[2] *[1]City College of New York, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: In prior studies we demonstrated that mesoscale nanoparticles (MNP) localize to the kidneys up to 26-fold more than to any other organ and that they specifically target the renal tubular epithelium. In this study we investigated the mechanism of MNP localization to the renal tubules and evaluated this platform's potential for therapeutic delivery in a model of cisplatin-induced acute kidney injury (AKI).

Methods: We synthesized ~400 nm diameter MNPs from the biocompatible polymers poly(lactic-*co*-glycolic acid) and polyethylene glycol (PLGA-PEG). MNPs were encapsulated with a fluorescent far-red dye or the reactive oxygen species scavenger edaravone. Male C57BL/6 mice, were sacrificed 30 minutes after injection for immune-electron microscopy studies. We also performed intravital microscopy to visualize the transit of MNPs in *Cx3cr*$^{gfp/+}$ C57BL/6 mice with GFP-expressing renal macrophages. We also evaluated their therapeutic potential in a cisplatin-induced AKI (25 mg/kg IP) model. 24 hours following cisplatin, mice received edaravone-loaded MNPs or appropriate controls. Serum creatinine and histology were analyzed 72 hours following cisplatin.

Results: We found that MNPs localize to the proximal tubular eoithelium via transcytosis from the peritubular capillaries. We observed MNPs flowing in these capillaries and in transit across the tubular interstitium. We also found that transcytosis of MNPS was not facilitated by macrophage uptake. Finally, we found that therapeutic MNPs use this mechanism to localize to the proximal tubules of mice with cisplatin-induced AKI (Figure).

Conclusions: These studies characterized transcytosis from the peritubular capillaries as the mechanism of particle localization to the kidneys and portend the development of additional therapeutic targeting tools for renal diseases.

PO0218

Role of the Exocyst, Cilia, and Mitochondria in AKI

Daria Ilatovskaya, Xiaofeng Zuo, Peifeng Deng, Wayne R. Fitzgibbon, Joshua H. Lipschutz. *Medical University of South Carolina, Charleston, SC.*

Background: AKI has high morbidity and mortality. Management consists of supportive care. Among the critical pathways in AKI are alterations of tubular mitochondrial metabolism, and, as recently suggested, disruption of primary ciliary homeostasis. Mitochondria are also involved in ciliopathies. Here we tested if cilia acting via mitochondria are involved in AKI.

Methods: We previously showed that the exocyst trafficking complex is necessary for ciliogenesis. Overexpression of Exoc5, a central exocyst component, protected renal tubule cells against H_2O_2-induced injury, whereas Exoc5 knockdown worsened it. In AKI, proximal tubules are most susceptible to injury. To determine the effect of Exoc5 loss, we crossed Exoc5$^{fl/fl}$ mice with mice expressing CreERT2 driven by the proximal tubule sodium-dependent inorganic phosphate transporter (SLC34a-CreERT2). Proximal tubule-specific Exoc5 knockout (KO) mice and littermate controls were subjected to bilateral ischemia reperfusion (I/R) injury by clamping the renal arteries. In order to gain mechanistic insight, we evaluated mitochondrial function in Exoc5 overexpressing (OE), Exoc5 knockdown (KD), Exoc5 ciliary targeting sequence point mutant (cts-mut), and control Madin-Darby canine kidney tubule (MDCK) cells.

Results: Proximal tubule-specific Exoc5 KO mice had worse renal injury, and higher serum creatinine following I/R injury compared to control mice ($p=0.005$). Seahorse assays revealed diminished spare respiratory capacity in Exoc5 KD and Exoc5 cts-mut cells, which was increased in Exoc5 OE cells, compared to control MDCK cells. Tetramethylrhodamine methyl ester was employed to measure mitochondrial membrane potential and we found mitochondrial uncoupling in Exoc5 KD and Exoc5 cts-mut as compared with control cells. Transmission electron microscopic imaging revealed healthy circular-shaped mitochondria with dense matrix in control and Exoc5 OE cells. Exoc5 KD cells exhibited mitochondrial damage and swelling consistent with the observed reduced respiration. Interestingly, Exoc5 cts-mut cells demonstrated formation of elongated mitochondria with pronounced cristae and large intracristae spaces, which could indicate less intensive bioenergetics, and would explain the reduced respiration.

Conclusions: For the first time we show that the exocyst and cilia are centrally involved in AKI and the effect may be mediated through mitochondria.

PO0219

Ascending Vasa Recta Responsible for Medullary Vascular Congestion

Sarah C. Ray, Paul O'Connor. *Augusta University Medical College of Georgia, Augusta, GA.*

Background: Vascular congestion of the renal medulla is common in acute kidney injury and has been shown to prolong ischemia and promote injury. We have reported that pretreatment with low dose lipopolysaccharide (LPS) attenuates ischemia reperfusion (IR) induced congestion. The temporal localization of congestion during IR and how LPS prevents congestion remains unknown. We hypothesized that 'vascular congestion

originates in the medullary vasa recta (VR) prior to the peritubular (PT) capillary plexus, and that pretreatment with low dose LPS aids in early VR reperfusion'.

Methods: To test this hypothesis, male WKY rats (10wks) were pretreated (i.p) with 1000μg/kg LPS or saline daily for 3 days and a 45-minute warm, bilateral ischemia was performed. Rats were randomized to 0, 1, 2, 6, 10, or 24 hour(s) of reperfusion (n=4-6/group). Congestion of the medullary VR and PT capillaries was assessed in histological sections (scale: 0-5, 0=0%, 5=100% congestion).

Results: At time 0 (no reperfusion), congestion of the medullary VR averaged 80% in both saline and LPS treated rats. Following reperfusion for 1, 2, 6, and 10 hours, VR congestion was >60% in saline treated rats. In contrast, VR congestion in LPS rats rapidly declined within 1 hour (<20%) and remained lower than saline scores through 24 hours ($p_{TREATMENT}$<0.0001). In both groups, PT congestion was less than 20% at time 0 (no reperfusion) but rapidly increased in saline treated rats to >60% by 6 hours of reperfusion. Conversely, in LPS treated rats, PT congestion remained low (average 13.4%, $p_{INTERACTION}$=0.0144) across the 24-hour reperfusion period. Immunofluorescent staining of neural-glial antigen 2 (NG2) and urea transporter (UTB) localized initial congestion to the ascending VR (AVR).

Conclusions: Our data provides the first evidence that congestion originates in the medullary AVR during the ischemic period and that blockage of AVR drives congestion in the PT capillary plexus during reperfusion by preventing drainage of the renal medullary circulation. Rapid reperfusion of the AVR (LPS group) prevented congestion of the PT capillaries. These data provide new insight into the pathophysiology of vascular congestion following ischemia and identify the AVR as the renal defect responsible for PT congestion. Understanding the mechanisms by which LPS aids in AVR reperfusion may be critical in order to find therapeutic targets for vascular congestion.

VEGF-R2 Signaling in Renal Stroma Exacerbates Post-AKI CKD Progression

Takuto Chiba, Sunder Sims-Lucas. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: Acute Kidney Injury (AKI) is widespread, identified in 30% of post-operative and 50% of ICU patients, and associated with increased rates of chronic kidney disease (CKD) and end stage renal failure. Peritubular capillary beds are significantly damaged, and it causes vascular rarefaction during many types of AKI. Vascular rarefaction is closely associated with post-AKI CKD progression. Vascular endothelial growth factor (VEGF) is a well defined angiogenic protein via its major receptor, VEGF receptor 2 (VEGF-R2). However, prior work from others demonstrated a role of VEGF as a negative regulator of pericyte function and vessel maturation. The functional implications of the VEGF-R2 signaling in renal stroma remains poorly understood.

Methods: We generated genetic mouse models for renal stromal cells (RSCs)-specific loss-of-function of VEGF-R2 with constitutively expressed Foxd1-Cre (*cVEGF-R2$^{RSC-/-}$*) and tamoxifen inducible Foxd1-Cre (*iVEGF-R2$^{RSC-/-}$*). AKI/CKD models induced either by a renal ischemia/reperfusion injury (IRI) model or by low/dose repeated treatment of cisplatin were performed. Mice are monitored for the development of AKI and post-AKI CKD using serum chemistries and tissue analysis.

Results: *cVEGF-R2$^{RSC-/-}$* protects against ischemic AKI in male and female mice. Specifically, *cVEGF-R2$^{RSC-/-}$* reduces renal tubular injury and microvascular rarefaction. *cVEGF-R2$^{RSC-/-}$* also mitigates CKD progression post ischemic-AKI. *cVEGF-R2$^{RSC-/-}$* reduces expression of kidney injury markers, *Havcr1* and *Lcn2*, in a cisplatin-AKI/CKD model. Interestingly, *iVEGF-R2$^{RSC-/-}$* demonstrates higher degree of protection against ischemic AKI as compared to *cVEGF-R2$^{RSC-/-}$* studies. We showed previously that *cVEGF-R2$^{RSC-/-}$* shows mild defects in kidney development. Our new data suggests that *iVEGF-R2$^{RSC-/-}$* bypasses deleterious effect by the mutation during kidney development.

Conclusions: These data suggest that VEGF-R2 signaling in renal stromal cells exacerbates ischemic AKI and its post-AKI CKD progression as well as cisplatin AKI.

Pericyte and Macrophage C5aR1 Mediate Renal Fibrosis

Ranjit K. Sahu,[1] Sandhya Xavier,[1] Daniel Chauss,[2] Ronald P. Taylor,[1] Majid Kazemian,[3] Behdad Afzali,[2] Didier Portilla.[1] *[1]University of Virginia, Charlottesville, VA; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [3]Purdue University System, West Lafayette, IN.*

Background: We reported that kidney complement plays an important role in the pathogenesis of renal scarring. Here we used a floxed green fluorescent protein (GFP)-C5aR1 reporter mouse and the model of Folic acid (FA)-mediated fibrosis to examine mechanisms by which C5aR1 contributes to fibrosis.

Methods: We used flow cytometry, confocal microscopy and image stream analysis of kidney tissue cell suspensions from vehicle and FA-treated GFP-*C5ar1$^{fl/fl}$* reporter mice to characterize cell types where *C5ar1* mRNA and protein levels were expressed. To address the functional role of C5aR1 during fibrosis we generated pericyte-specific and myeloid-specific C5aR1 KO mice by crossing GFP-*C5ar1$^{fl/fl}$* mice with mice expressing Cre-recombinase under the control of the *Foxd1* or *LyzM* promoter, respectively. We established primary cell cultures of PDGFRß+ kidney pericytes isolated from GFP-*C5ar1$^{fl/fl}$* mice and FoxD1-C5aR1 KO mice and performed qPCR and luminex analysis.

Results: Immunofluorescence confocal microscopy demonstrated increased GFP$^+$ (C5aR1+) cells in tubulo-interstitium of FA-treated mice, which co-stained with F4/80 antibody. ImageStream analysis confirmed surface expression of C5aR1 in GFP$^+$PDGFRB+ cells and CD45+F4/80+ cells. Flow cytometry showed increased GFP in CD45+F4/80+ cells. Mice with pericytes-specific deletion of C5aR1 had reduced fibrosis, measured by picrosirious red staining, and reduced α-SMA, fibronectin and collagen1A1, compared to wild-type mice. Pericytes isolated from Foxd1-C5aR1 KO mice treated with FA showed reduced expression and secretion of IL6, TNF, macrophage inflammatory proteins, and MMP-9, when compared to pericytes isolated from GFP-C5aR1$^{fl/fl}$ mice. Myeloid-specific deletion of C5aR1 resulted in significant reduction of C5aR1 in kidney homogenates, confirming macrophages as the major population expressing C5aR1 following FA injury. These mice also showed reduced kidney fibrosis by picrosirious red staining, and qPCR analysis of fibronectin and collagen.

Conclusions: Our findings demonstrate that pericytes and macrophages play important roles in the pathogenesis of renal scarring and implicate C5aR1 as a key mediator. Conditional deletion of C5aR1 in these two interstitial cell types reduces inflammation and extracellular matrix protein formation in pericytes as well as macrophage migration and profibrotic phenotype of kidney macrophages.

Selective Expansion of Kidney Double-Negative T Cells Is Driven by Renal Tubular Epithelial Cells Through Direct Cell-Contact and by Soluble Mediators

Mohanraj Sadasivam, Sanjeev Noel, Somayeh Gharaie fathabad, Johanna T. Kurzhagen, Abdel Hamad, Hamid Rabb. *Johns Hopkins University, Baltimore, MD.*

Background: Kidney TCRα/β$^+$CD4$^-$CD8$^-$CD1d$^-$ double negative (DN) lymphocytes are a recently recognized unconventional T cell population with important roles in AKI and possibly other diseases like lupus. DN T cells expand after experimental AKI and exogenous delivery improves outcome. However, mechanisms underlying their regulation and expansion in the kidney are poorly understood. Here, we demonstrate a direct role for renal tubular epithelial cells (RTEC) in regulating homeostasis of kidney DN T cells.

Methods: Age-matched B6 WT, MHC I KO, MHC II KO and DKO (MHC I and II KO) mice were studied. T cell functional assays and an *in-vitro* co-culture system were used to investigate the functional relationship between RTEC and DN T cells. RTECs were isolated, purified and cultured in collagen-coated plates. Lymphocytes from both kidney and periphery were isolated, co-cultured with RTEC and analyzed by FACS.

Results: DN T cells were anergic when cultured alone, even after stimulation with anti-CD3/CD28, but spontaneously proliferated when co-cultured with RTEC (DN; 1.2 ± 0.6% **vs** RTEC+DN; 13.8 ± 3.5%, p≤0.0001). Expansion was due to increased proliferation and decreased apoptosis of DN T cells. RTEC mediated expansion of DN T cells occurred by multiple mechanism including direct cell-contact and secretion of IL-7. Although activation of T cells required direct TCR crosslinking, activation of DN T cells was TCR-MHC independent as indicated by the ability of RTEC from mice lacking MHC class-I, class-II or DKO mice to induce proliferation of DN T cells (DN; 2.1 ± 0.8% **vs** RTEC (WT)+DN; 17.1 ± 1.5%, **vs** RTEC (MHC I KO)+DN; 21.2 ± 0.5%, **vs** RTEC (MHC II KO)+DN; 17.9 ± 1.8%, **vs** RTEC (DKO)+DN; 32.8 ± 0.3%, p≤0.0001). Reciprocally, DN T cells increased survival of RTEC as demonstrated using *in-vitro* assays. Our ongoing experiments are focusing on identifying surface molecules involved in mediating interactions between DN T cells and RTEC.

Conclusions: These results demonstrate a previously unknown functional relationship between RTEC and DN T cells that may explain the selective accumulation of DN T cells in the kidney and roles in normal and diseased kidney. The results have important implications for developing strategies to ameliorate AKI by promoting the survival of kidney DN T cells.

TGF-β-Induced CD8+CD103+ Regulatory T Cells but Not Nature Regulatory T Cells Alleviates Acute Renal Injury Induced by Ischemia-Reperfusion

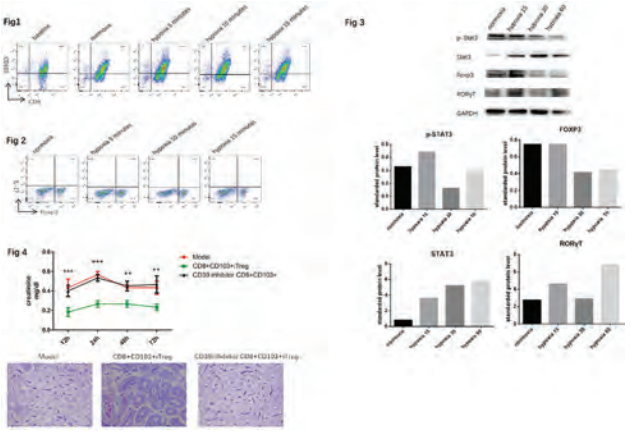
Zhenjian Xu, Tongtong Xu, Anping Xu. *Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Acute kidney injury (AKI) is one of the most common complications in clinical practice, inflammatory response induced by hypoxic-reoxygenation is the key mechanism of ischemia-reperfusion acute kidney injury. Regulatory T cells are crucial players in the maintenance of immune homeostasis. Our previous researches show that natural regulatory T cells (nTreg) tend to transfer into Th17 under conditions of inflammation and hypoxia. On the contrary, TGF-b induced CD8+CD103+Treg (CD8+CD103+iTreg), a new subpopulation of iTreg we have identified, maintains stable phenotype and immunomodulatory function. The instability of nTreg under conditions of inflammation and hypoxia suggesting that nTreg are not suitable for treatment of AKI. Accordingly, we studied the role of CD8+CD103+iTreg in alleviating AKI.

Methods: In vitro study, we test the phenotype and immunomodulatory function of CD8+CD103+iTreg or nTreg under 1% O2 concentration. In vivo study, CD8+CD103+iTreg(2×10^6/mouse)or nTreg(2×10^6/mouse)were injected intravenously daily to the AKI mice from the day of surgery (for 3 days).

Results: The expression of CD103 is stable in CD8+iTreg in vitro under 1% O2 concentration(Fig 1). nTreg transfer into Th17 under hypoxic condition. However, CD8+CD103+iTreg seldom transfer into Th17, remain Foxp3 under hypoxic condition (Fig 2,3). In addition, the suppressive function of CD8+CD103+iTreg over T cells proliferation under hypoxia remain steadily. In vivo study, we found that CD8+CD103+iTreg ameliorate the development of AKI by decreasing the level of serum creatine, alleviating acute tubular necrosis (ATN) and reducing the mortality of AKI mice. (Fig 4).

Conclusions: CD8+CD103+iTreg maintains stable phenotype and immunomodulatory function under condition of hypoxia, decrease the severity of AKI induced by ischemia-reperfusion. CD8+CD103+iTreg provide a promising approach for the treatment of AKI.



PO0224

A Novel Renoprotective Strategy: Upregulation of PD-L1 Expression Mitigates Cisplatin-Induced AKI

Jun Zhang, Shenwen V. Gu, Ssu-Wei Hsu, Ching-Hsien Chen. *University of California, Davis, Davis, CA.*

Background: Cisplatin is an effective chemotherapeutic agent against various types of cancers; however, the use of cisplatin is associated with a major side-effect of nephrotoxicity, resulting in acute kidney injury (AKI). Growing evidence suggests that programmed death-1(PD-1)/programmed death ligand (PD-L1) immune checkpoint signaling plays a critical role in mediating inflammatory responses and immune homeostasis. While PD-L1 has emerged as a promising target for immunotherapy, little is known concerning how PD-L1 is regulated. In this study, we aimed to determine the expression and contribution of PD-L1 in cisplatin-induced AKI.

Methods: PD-L1 expression in kidney cells and tissues were determined by immunohistochemistry (IHC), real-time polymerase chain reaction and western blot assays. PD-L1-containing lentiviruses were subcapsularly injected into the kidneys of mice. 7 days after the injection, mice were intraperitoneally treated with cisplatin for 3 days and subjected to kidney function tests. High-dimensional single-cell mass spectrometry was used to reveal immune profiling and discover the underlying immunological mechanisms of PD-L1 in an AKI mouse model.

Results: IHC staining of PD-L1 shows a significantly lower intensity of staining and less stained proximal tubule epithelial cells in cisplatin-exposed mice tissues than that in the PBS controls. Next, we demonstrate that cisplatin exposure decreased mRNA expression and protein levels of PD-L1 in primary renal proximal tubular epithelial cells and this inhibition appeared to be dose-dependent. Interestingly, we also find a decrease in PD-L1 expression with a concomitant increase in pro-inflammatory cytokines in response to cisplatin. Mass spectrometry analyses reveal cisplatin-induced multiple pro-inflammatory leukocytes infiltration in kidneys. Through genetically engineered kidney tissues in mice, ectopic expression PD-L1 in kidneys was able to suppress leukocytes infiltration and pro-inflammatory cytokines. In addition, both serum creatinine and blood urea nitrogen levels were significantly reduced in cisplatin-treated mice with PD-L1 overexpression.

Conclusions: Our data suggest a renoprotective effect of PD-L1 upregulation on cisplatin-induced AKI and also provide an alternative therapeutic strategy against nephrotoxicity.

Regulation of Renal Calbindin Expression During Cisplatin-Induced Kidney Injury

Blessy George,[1] John T. Szilagyi,[1] Melanie S. Joy,[2] Lauren Aleksunes.[1] *[1]Rutgers The State University of New Jersey, Piscataway, NJ; [2]University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.*

Background: Since the discovery of calbindin release into urine during renal injury, there has been growing interest in the utility of this calcium-binding protein as a biomarker of nephrotoxicity. However, little is known about the intrarenal regulation of calbindin during acute kidney injury. We sought to characterize the time-dependent expression and excretion of the distal tubule protein calbindin in comparison to the proximal tubule protein Kim-1 in a mouse model of cisplatin nephrotoxicity.

Methods: Male C57BL/6 mice were administered saline vehicle or 20 mg/kg of cisplatin i.p. Urine was collected in metabolic cages for 24 h periods on days 0 – 4. Blood and kidneys were collected between days 2 and 4. Kim-1 and calbindin proteins were measured in urine, kidneys, and blood. *Kim-1* and calbindin (*Calb1)* mRNAs were quantified in kidneys by qPCR.

Results: SCr and BUN levels increased in cisplatin-treated mice by day 3, confirming development of acute kidney injury. Urinary concentrations of calbindin and Kim-1 were elevated by 11.6-fold and 2.5-fold, respectively by day 2. Time-dependent decreases in intrarenal calbindin protein to levels 60% of control were observed on days 3 and 4. A 200-fold up-regulation of *Calb1* and *Kim-1* mRNAs was seen on day 3. These data suggest that early loss of calbindin protein into the urine along with declines in renal calbindin protein initiates a compensatory induction of mRNA expression at later time points (days 3 and 4).

Conclusions: Understanding the regulation of calbindin during cisplatin nephrotoxicity further enhances its utility as a urinary biomarker of kidney damage. The results of the current study support the combined use of a proximal (Kim-1) and distal tubule (calbindin) marker to phenotype acute kidney injury secondary to cisplatin administration.

Neutral Ceramidase and Autophagy Play Diverse Roles in Cisplatin-Induced AKI and Fibrosis

Sophia M. Sears, Tess Dupre, Mark A. Doll, Parag P. Shah, Levi J. Beverly, Leah J. Siskind. *University of Louisville School of Medicine, Louisville, KY.*

Background: Cisplatin (CDDP) is a commonly used chemotherapeutic agent with a dose-limiting nephrotoxicity. 30% of patients given CDDP develop acute kidney injury (AKI), increasing risk of chronic kidney disease (CKD) development and mortality. Currently, there are no agents to treat or prevent CDDP-induced kidney injury. We believe this is due in part to a lack of clinically relevant animal models. In the past, only a single high-dose model has been used to study CDDP-induced AKI. Our lab and others have developed a repeated low dose model to also study CKD development following CDDP treatment. Acute and chronic injuries can both be affected by sphingolipids, a family of bioactive lipids. Metabolism of sphingolipids is carried out in part by neutral ceramidase (nCDase), which hydrolyzes ceramide into sphingosine that can then be phosphorylated to form sphingosine-1-phosphate. The regulation of these sphingolipids affects cellular processes implicated in the pathology of CDDP-induced kidney injury, including cell proliferation, autophagy, and apoptosis. Additionally, our lab has previously observed that nDCase knockout protected mouse embryonic fibroblasts from ER-stress induced apoptosis *in vitro* by upregulating autophagic flux. We hypothesized that loss of nCDase would confer protection from CDDP-induced kidney injury.

Methods: We assessed renal outcomes in nCDase knockout (KO) and wild type (WT) C57BL/6 mice in both the acute and chronic models of cisplatin treatment.

Results: We demonstrated that nCDase KO provides protection from AKI in the high-dose model of CDDP-induced kidney injury. This protection was reversed when the autophagy-inhibitor chloroquine was co-administered. In the repeated low dose CDDP model, however, we found nCDase KO does not protect against development of renal fibrosis. We also observed that nCDase KO reduces induction of ER stress in the single high-dose model but not in the repeated low dose model.

Conclusions: This study suggests that there are different underlying mechanisms that induce divergent pathologies in the two models of CDDP dosing.

PO0227

Cisplatin-Induced MARCKS Phosphorylation Activates NF-kB Signaling and Contributes to AKI

Shenwen V. Gu, Jun Liu, Kuang-Yu Jen, Ching-Hsien Chen. *University of California, Davis, Davis, CA.*

Background: Cisplatin is widely used for cancer treatment but is known to induce nephrotoxicity with severe damage to the proximal tubules, leading to acute kidney injury (AKI). Although a major substrate of protein kinase C, MARCKS, was shown to be induced phosphorylation at Ser 159/163 (phospho-MARCKS) in response to cisplatin, the molecular mechanism underlying increased phospho-MARCKS and its functional consequence in AKI remain to be established. Herein, we investigated how phospho-MARCKS is regulated in proximal tubular cells, and its role in the context of cisplatin exposure.

Methods: The clinical relevance of phospho-MARCKS was first confirmed using immunohistochemistry. Next, we examined the effect of cisplatin exposure on phospho-MARCKS levels in kidney tubular epithelium. The MARCKS-interactome was identified by mass spectrometry. We also used genetic and pharmacological approaches to verify the functionality and molecular mechanism of cisplatin-induced phospho-MARCKS.

Results: In a screen of 75 renal biopsies from patients, we find that strong phospho-MARCKS expression was observed in kidney specimens from patients with acute renal tubular necrosis and was positively correlated. Western blot analyses demonstrate that an elevated abundance of phospho-MARCKS in cisplatin-exposed tubular epithelial cells and this increase appeared to be concentration–dependent. Mechanistically, we show that MARCKS protein directly bound to nuclear factor-kappa-B-activating protein (NKAP). Following cisplatin-induced phosphorylation at ser159 and ser163, the interaction of MARCKS with NKAP was inhibited, contributing to p65 phosphorylation and NF-κB activation. Surprisingly, an elevation of phospho-MARCKS by cisplatin occurred in parallel with upregulation of inflammatory cytokines and markers of nephrotoxicity. Conversely, targeting of MARCKS phosphorylation with the MPS peptide, a novel MARCKS inhibitor, downregulated NF-κB signaling as well as suppressed levels of serum creatinine and blood urea nitrogen in cisplatin-treated mice.

Conclusions: Our results suggest that MARCKS phosphorylation is a novel NF-kB activator in cisplatin-induced proximal tubule damage and also present a proof of concept for the use of MPS peptide as a renal protection agent for AKI.

PO0228

Mechanistic Insight for Enhanced Cisplatin (CIS) Nephrotoxicity in Na-H Exchanger Regulatory Factor 1 (NHERF1) Deficiency

Adrienne M. Bushau-Sprinkle,[1] Michelle T. Barati,[1] Walter H. Watson,[1] Yuxuan Zheng,[1] Kenneth Gagnon,[1] Kathleen Kitterman,[1] Leah J. Siskind,[1] Michael E. Brier,[1] Eleanor D. Lederer.[2,3] *[1]University of Louisville School of Medicine, Louisville, KY; [2]University of Texas Southwestern Medical School, Dallas, TX; [3]VA North Texas Health Care System, Dallas, TX.*

Background: Proximal tubule transport and metabolism of CIS play critical roles in the development of CIS-induced acute kidney injury (AKI). Mice lacking NHERF1 have exacerbated CIS nephrotoxicity. We hypothesize that NHERF1 loss leads to altered oxidative state and/or altered CIS metabolism resulting in increased CIS toxicity.

Methods: We treated 2-4 mo old male wild-type (WT) C57BL/6 and NHERF1 knock out (KO) mice with vehicle or CIS (20 mg/kg IP) for 4, 24, or 72h. Glutathione (GSH), glutathione disulfide (GSSG), cysteine (Cys), cystine (CySS), cysteine-glutathione disulfide (CySSG) were measured in plasma and kidney cortex by HPLC. Kidney cortex was assayed for γ-glutamyl transferase (GGT) activity, platinum (Pt) levels by ICP-MS, cysteine s-conjugate beta lyase (CCBL1) and GGT by Western blot and immunohistochemistry (IHC); and RT-qPCR for glutathione s-conjugate-translocating ATPase (ABCC1) and γ-glutamylcysteine synthetase (GCLC).

Results: KO mice showed decreased plasma CySS and increased kidney GSSG at baseline. GGT activity was similar 4h after CIS treatment, but significantly greater at 24h in CIS treated WT compared to KO. ABCC1 and GCLC mRNA levels were upregulated 72h post CIS treatment in KO compared to WT. GGT and CCBL1 protein levels were similar by Western blot regardless of genotype or treatment 24h post CIS, but IHC showed greater brush border membrane GGT loss in KO kidneys. CCBL1 localization showed a checkered staining pattern in KO proximal tubules compared to WT linear pattern at baseline. Pt levels were similar 24h post CIS treatment, but decreased significantly more 72h post treatment in KO compared to WT.

Conclusions: We conclude loss of NHERF1 results in increased levels of GSSG, upregulation of genes involved in GSH synthesis in oxidizing conditions, and lower GGT activity that sensitize the kidney to increases in oxidative stress induced by CIS nephrotoxicity. While NHERF1 loss does not affect initial Pt uptake, the aberrant CCBL1 localization in KO proximal tubules suggests a role for enhanced production of toxic CIS metabolite.

Decreased IFT88 Causes Cilia Shortening and Mitochondrial Dysfunction in Cisplatin-Induced Tubular Injury

Rie Fujii,[2] Tsuyoshi Inoue,[1] Sho Hasegawa,[2] Kentaro Yoshioka,[2] Masaomi Nangaku,[2] Reiko Inagi.[2] *[1]Nagasaki University School of Medicine Graduate School of Biomedical Sciences, Nagasaki, Japan; [2]The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan.*

Background: Renal primary ciilia are associated with the pathogenesis of various diseases, including acute kidney injury (AKI). The length of the primary cilia dynamically change during the progression of diseases: tubular primary cilia shortened in cisplatin-induced AKI mouse model. However, its relevance in kidney disease and the underlying mechanism are largely unknown. Tubular damage in AKI closely links to mitochondrial dysfunction. Thus, we investigated the interaction between primary cilia and mitochondria in cisplatin-induced tubular injury.

Methods: C57BL6 mice with cisplatin-induced AKI were euthanized at 72 h after disease induction to collect blood and kidney samples. In *in vitro* experiments, we used RPTEC/TERT1 cells, which are human proximal tubular epithelial cells that maintain the cilia length at high cell densities, and knocked down Ift88 (Ift88-KD), a cilia maintenance protein, by siRNA. Cisplatin-treated or Ift88-KD cells were assessed for the cellular phenotypic changes or mitochondrial metabolic function using the Flux Analyzer.

Results: We found that the expression of protein IFT88 was decreased in damaged tubules of cisplatin-induced AKI mice. These data were consistent with that Ift88 expression decreased in the cilia of cisplatin-treated RPTEC/TERT1 at mRNA and protein levels in association with shortening of the primary cilia, suggesting the pathogenic link between tubular damage and Ift88-mediated cilia alteration. Interestingly, Ift88-KD cells significantly exhibited shorter cilia as compared to control siRNA-transfected cells and showed downregulation of mitochondrial oxidative phosphorylation capacity and decreased ATP production, indicating the contribution of Ift88 to mitochondrial homeostasis. Of note, such mitochondrial alteration linked to tubular inflammation. Our findings suggest that tubular mitochondrial dysfunction in cisplatin-induced AKI is mediated by a decreased Ift88 with shortening cilia, at least in part.

Conclusions: Tubular mitochondrial damage followed by tubular injury in AKI may occur by the alteration of Ift88 expression, and subsequent cilia shortening in the tubular epithelial cells.

PO0230

Apobec 1 Limits Cisplatin-Induced AKI by Regulating the Disposal of Pro-Ferroptotic Lipids

Xiaojia Guo,[1] Heino Velazquez,[1,2] Tian-Min Chen,[1] Valerie Blanc,[3] Nicholas Davidson,[3] Robert L. Safirstein,[1,2] Gary V. Desir.[1,2] *[1]Yale University School of Medicine, New Haven, CT; [2]VAMC, West Haven, CT; [3]Washington University in Saint Louis, Saint Louis, MO.*

Background: Cisplatin (CP) causes proximal tubules to undergo regulated necrosis. We previously reported that the RNA editing-specific cytosine deaminase Apobec1, which regulates mitochondrial metabolism, cell fate and proliferation pathways, plays a crucial role in recovery from this injury. Among the known RNA editing targets for APOBEC1 is the lipid transport protein *Apob* and as the resultant smaller APOB48 is the preferred secretory route of potentially cytotoxic triglycerides (TG), we now ask if absence of *Apobec1* during CP-induced AKI, whose toxicity is accompanied by the accumulation of TGs and oxidant stress, worsens AKI.

Methods: *Apobec1* knockout (ko) mice were given CP 15 mg/kg i.p. and renal function, histology, mRNA, protein and lipid content were analyzed and compared to wild type (WT) mice of similar genetic background. We overexpressed rat Apobec-1 in PT cells and assessed cell viability histologically and by WST-1 assay after CP exposure.

Results: *Apobec-1* deletion resulted in more severe AKI, plasma creatinine 2.07 mg/dL ± 0.59 (n=13) vs 0.23 mg/dL ± 0.09 (n=8) 3d, $p < 0.01$ in WT. Remarkably all *Apobec1* ko mice died after 6 days, while WT animals all survived. *Apobec1* KO kidneys showed greater necrosis and neutrophil counts. mRNA and protein levels of RIPK3, MLKL, TLR2, TLR4, and ASCL4 were markedly increased in *Apobec-1* ko compared to WT kidneys ($p<0.01$). Overexpression of Apobec-1 in mouse PT reduced CP-induced cell death 2.35-fold versus cells transduced with vector alone ($n = 4$, $p < 0.05$). Overexpression of Apobec-1 increased the activities of kinases associated with survival (ERK, STAT3, and AKT) and inhibited those inducing cell death (IRF4, and JNK). Plasma tTG increased 2-fold higher in CP-treated Apobec1 ko mice compared to WT animals (104.3 ± 12.6 vs. 57.4 ± 9.1, n=4, $p<0.05$), while renal TG trended upward (437.1 ± 130.0 vs. 223.8 ± 121.5, n=4, $p=0.27$).

Conclusions: We have identified Apobec1 as a crucial gene regulating the necrotic response to CP-induced nephrotoxicity. Apobec1 limits lipid accumulation in the kidney following CP-induced AKI and limiting lipotoxicity. Increasing Apobec-1 activity could be an effective strategy to reduce or prevent CP-induced AKI.

Lipidomics Approach to Characterize Lipid Alterations in Human Kidney 2 Cells Treated with Iohexol

Fangfang Zhou, Yixin Chen, Luo L. Xin, Yi Lu, Qun Luo. *HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo, China.*

Background: In our previous study, we found plasma high density lipoprotein cholesterol and apolipoprotein A-I levels were significant lower in the contrast induced nephropathy (CIN) group, compared to the non-CIN group. The aims of our study was to uncover lipid alterations that may contribute to the development of CIN.

Methods: We investigated lipids of HK-2 cells treated with iohexol (100mg I/ml, 6hrs and 12hrs), compared with HK-2 cells treated without iohexol (as control) using nontargeted lipidomics based on ultrahigh-performance liquid chromatography-Orbitrap Q-Exactive plus mass spectrometry.

Results: Based on the principles of t-test P-value < 0.05, variable importance at projection (VIP) value >1 and fold change >1.5 or <0.67, differential expression of 134 lipids were identified in both HK-2 cells treated with iohexol for 6hrs and 12hrs, compared with the control HK-2 cells. The top three class to which these lipids belonged were phosphatidylcholine (PC, 42 species), triglyceride(TG, 39 species) and phosphatidylethanolamine (PE, 18 species).

Conclusions: Our results indicate that PC, TG and PE may contribute to the development of CIN, providing the basis for further evaluation of the role of lipids in the mechanism of CIN.

PO0232

Proximal Tubular S3 Cells Expressing Angiotensinogen Localize to the Outer Stripe of the Outer Medulla

Danielle Janosevic,[1] Ricardo Melo ferreira,[1] Michael T. Eadon,[1] Farooq Syed,[1] Takashi Hato,[1] Pierre C. Dagher.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Roudebush Indianapolis Veterans Affairs Medical Center, Indianapolis, IN.*

Background: The S3 segments of proximal tubules (PT) are observed in the cortex as well as the outer stripe of the outer medulla (OS-OM). Using single cell RNA sequencing (scRNAseq), we and others have identified a unique S3 population, referred to as S3-Type 2 (S3T2, Figure a). These S3T2 cells express *Rnf24* and *Slc22a7* as defining genes, in addition to other classical S3 markers. In this work, we combined spatial transcriptomics (SpT) and scRNAseq to further localize this novel S3T2 cell population in the murine kidney.

Methods: We performed SpT on OCT frozen murine kidney sections stained with hematoxylin & eosin. Images were collected with Keyence BZ-810 microscope. RNA was isolated from tissue, sequenced, and clustering performed with Seurat R package. This yielded seven clusters that could be overlaid over the tissue section. To increase resolution, we combined scRNAseq data with SpT. Gene expression was visualized with the Loupe Browser. Expression of specific genes was also confirmed with single molecule FISH (smFISH).

Results: The combination of scRNAseq with SpT increased the spatial resolution and resulted in 15 unique cell clusters that could be easily overlaid over the tissue section. While regular S3 cells localized to the cortex, S3T2 cells localized specifically to the OS-OM (Fig. b). In addition to *Rnf24* and *Slc22a7*, S3T2 cells showed strong expression of angiotensinogen (*Agt*, Fig. c). smFISH of *Agt* and *Aqp1* confirmed these results (Fig. d).

Conclusions: The combination of scRNAseq and SpT allows for a greater resolution in the spatial layout of renal cell populations. This approach localized S3T2 cells specifically to the OS-OM. These cells also exhibited strong expression of *Agt*, possibly indicating an important role in the renin-angiotensin system. These transcriptomic differences between classical S3 and S3T2 are likely dictated by the unique microenvironments of the cortex and the OS-OM.

Figure a-d: **a** scRNAseq UMAP highlights S3 and S3T2 **b** SpT highlighting S3 and S3T2. **c-d** Feature plot of *Agt* and smFISH of *Agt* (green) localizes to S3T2.

PO0233

Salubrinal Attenuates Proximal Tubular Cell Injury Induced by Cisplatin

Guie Dong, Zheng Dong. *Medical College of Georgia at Augusta University, Augusta, GA.*

Background: Cisplatin is a widely used chemotherapy drug, but it has notorious side effects in kidneys. Effective kidney protective agents are not available for clinical use. Salubrinal is a specific inhibitor of eIF2alpha phosphatase, it promotes eIF2alpha phosphorylation which blocks the formation of the pre-initiation complex and halts global protein translation and protein synthesis. In this study, we examined the effect of salubrinal on cisplatin-induced injury in kidney proximal tubular cells.

Methods: Rat proximal tubular cells (RPTC) were treated with cisplatin or cisplatin with salubrinal for 4, 8, and 24hrs. Cell lysates were collected for immunoblot analysis to examine phospho-eIF2alpha and its related proteins. In addition, other signaling proteins implicated in cisplatin injury were examined, including p53, JNK, p38, and pkcdelta, and ERK. Apoptosis was determined at 24hrs of treatment by phase contrast and fluorescence microscopy following nuclear staining with Hoechst. Caspase activities were measured enzymatically by using DEVD. AFC, a fluorogenic peptide substrate. To examine cell survival, the cells were changed to fresh medium for 48 hrs after 24 hrs of cisplatin treatments with or without Salubrinal.

Results: Salubrinal suppressed apoptosis and caspase activation in RPTC during cisplatin treatment. It also promoted long-term cell survival after cisplatin treatment. In immunoblot analysis, during cisplatin treatment salubrinal increased eIF2alpha phosphorylation. It also increased PERK phosphorylation and the expression of GRP78 and CHOP, indicative of ER stress or unfolded protein response. Signaling pathways including MAP kinases, PKCdelta, and p53 are involved in cisplatin-induced kidney injury. In this regard, Salubrinal decreased JNK and p38 phosphorylation, but increased ERK phosphorylation during cisplatin treatment. Salubrinal diminished phosphorylation of PKCdelta at late time point of cisplatin treatment. However, Salubrinal did not affect p53 expression or its phosphorylation.

Conclusions: Salubrinal has protective effects against cisplatin-induced kidney cell injury. Mechanistically, the protective effects are associated with the increase of UPR and suppression of MAPK signaling but not with p53 activation. The results also suggest that inhibition of global protein synthesis may be a new therapeutic strategy for the side-effects of cisplatin chemotherapy.

PO0234

Quantitative Prediction of Cisplatin-Induced AKI Using RENAsym, a Mechanistic Quantitative Systems Toxicology Model, and Renal Proximal Tubule Epithelial Cell In Vitro Assays

Yeshitila Gebremichael, Nader Hamzavi, Jeffrey L. Woodhead, Shailendra Tallapaka, Scott Q. Siler, Brett A. Howell. *DILIsym Services Inc., a Simulations Plus Company, Durham, NC.*

Background: Nephrotoxic drugs like cisplatin cause acute kidney injury (AKI) through complex cellular mechanisms that include mitochondrial dysfunction, oxidative stress, and immune mediated injury pathways. However, quantitative prediction of the underlying toxicity mechanisms remains a challenge. Quantitative system toxicology (QST) modeling offers a promise for quantitative description of toxicity mechanisms leading to drug-induced AKI. We developed a QST model of cisplatin induced AKI using *in vitro* assays to characterize key cellular injury mechanisms.

Methods: RENAsym was used to quantify cisplatin induced AKI. The model represents aspects of renal proximal tubule epithelial cells (RPTEC) including cell life cycle and death pathways, bioenergetics, immune signaling pathways and biomarker responses. *In vitro* data related to cisplatin mitochondrial toxicity and oxidative stress generation were measured using RPTEC assays incubated with cisplatin (Cyprotex Inc.). To quantify cisplatin-induced mitochondrial dysfunction, oxygen consumption rate (OCR) was measured using the Seahorse XF analyzer. Cisplatin-induced oxidative stress was measured using high content imaging (HCI).

Results: The Seahorse study shows substantial OCR decline at 24 hours, suggesting cisplatin-induced electron transport chain (ETC) inhibition. Similarly, HCI reveals significant oxidative stress elevation after 9 days. Toxicity parameters for cisplatin-induced mitochondrial dysfunction and oxidative stress mechanisms were determined using the *in vitro* data. Simulations predict dose-dependent cisplatin toxicity as quantified by elevations in αGST, a biomarker that marks RPTEC death. A simulated single high dose of 533 mg/m^2 i.v. cisplatin results in 14-fold change in αGST, while a simulated clinical dose of 100 mg/m^2 shows 7-fold increase. The 100 mg/m^2 result is in qualitative agreement with 3.4-fold change observed in a clinical study where patients administered 100 mg/m^2 i.v. cisplatin exhibited 20% incidence of AKI (Ummer. 2012, IJBBB).

Conclusions: RENAsym simulations predicted dose-dependent cisplatin-induced AKI that is in qualitative agreement with clinical data. RENAsym shows promise in providing a unique tool for drug-induced AKI prediction.

Diuretic Resistance: When to Consider Hydralazine?

Mohammed Alshehri, Ramez S. Jabaji, Christopher S. Wilcox. *MedStar Georgetown University Hospital, Washington, DC.*

Introduction: We present a case of acute cardiorenal syndrome complicating heart failure with preserved ejection fraction (HFpEF) leading to severe diuretic resistant fluid retention that was alleviated by coincident hydralazine therapy.

Case Description: A 52-Year-old woman with a history of obesity, hypertension, congestive heart failure with HFpEF (EF60-65%), and alcoholic liver disease presented with a 3-day history of mental status change. Her serum creatinine was 3.6mg/dL, compared to 0.8mg/dL a month prior. She was volume overloaded with distended jugular veins, pulmonary crackles, and +2 edema to her lower abdomen; she had a 30Kg weight gain over 5 months. Her urine sodium and chloride were <10mmol/L. Urine analysis had a SG of 1.017 without proteinuria. Diuretic therapy was initiated with IV furosemide 80 mg twice daily and was escalated progressively to IV furosemide 20 mg/h with IV

chlorothiazide 500 mg twice daily. However, these large doses of intravenous diuretics failed to increase daily urine output above 1000 ml. After 20 hours of stable diuretics, vasodilator therapy was initiated with low dose hydralazine 10 mg thrice daily. Within one day, her urine output more than doubled and, over the next 3 days of the stable therapy, it peaked at 4 liters. Her fraction Na excretion (FE_{Na}) was initially 0.1%; it increased to a maximum of 1.9% with the high IV continuous diuretic therapy but increased further to 3.8%-6.2% over 9 days after hydralazine was added to the diuretic regimen. After addition of hydralazine, her congestion dissipated, she lost 23 Kg and the diuretic regimen was reduced eventually to furosemide 80 mg BID and spironolactone 200 mg daily prior to her discharge with a serum creatinine of 1.3 mg/dl. At follow up after 3 months, her symptoms remained well controlled, her weight was reduced by a further 10 kg and her serum creatinine was 0.9 mg/dl.

Discussion: Hydralazine has been recommended to treat diuretic resistance in HF by increasing cardiac output, renal blood flow and renal diuretic delivery. However, our case suggests that hydralazine greatly improves renal tubular diuretic responsiveness as her FE_{Na} increased 3 fold. This is not likely due to better renal diuretic delivery since the patient received constant IV infusions of two diuretics at doses well above their ceiling. Further clinical trials and mechanistic studies of hydralazine-diuretic interaction are warranted.

PO0236

Carfilzomib-Induced Thrombotic Microangiopathy Effectively Treated with Eculizumab

Jorge M. Chancay rodriguez, Fadi Salem, Mohamed Rizwan Haroon Al Rasheed, Priya Deshpande. *Mount Sinai Health System, New York, NY.*

Introduction: Proteosome inhibitor (PI), Carfilzomib, have been associated with drug-induced microangiopathy (DITMA) in rare cases[1-7]. We present a patient with acute kidney injury (AKI) from Carfilzomib-induced DITMA who was successfully managed with Eculizumab, which is a monoclonal antibody that inhibits the alternate pathway of the complement cascade.

Case Description: A 56-year-old woman with refractory IgG Lambda Multiple Myeloma (MM) was admitted with fatigue and decreased oral intake one week after restarting Carfilzomib. She had been on Carfilzomib in the past and tolerated it well. On admission, she had non- oliguric AKI with a serum creatinine (sCr) of 12mg/dL (one week prior to starting Carfilzomib, her SCr = 0.8mg/dL). Peripheral smear revealed anemia with schistocytes and thrombocytopenia. Carfilzomib was immediately discontinued. Serologic work up, including ADAMTS13, was within normal limits. Her free kappa/ lamba ratio 0.41. She was dialyzed twice for clearance and underwent a renal biopsy. The renal biopsy showed diffuse thrombotic microangiopathy (TMA) with minimal tubular injury and interstitial fibrosis. Eculizumab 900mg weekly was started, and sCr declined to 1.6mg/dL over 3 weeks. She did not require further hemodialysis treatments. Currently, her sCr is 1.1mg/dL, and she is on Eculizumab 1200mg every two weeks.

Discussion: Our case is the fourth report using Eculizumab in Carfilzomib induced DITMA. The timing of our patient's Carfilzomib exposure supports that DITMA caused her AKI (as opposed to MM- induced TMA). The first line of treatment requires immediate cessation of the drug. Interestingly, Bhutani et al, demonstrated the activation of the alternate complement pathway in a patient with Carfilzomib- induced TMA, indicated by elevated levels of fragment Bb and membrane attack complex (MAC)[6]. Portuguese et al, proposed that Carfilzomib may lower the gene expression of Complement factor H resulting in decreased inhibition of the alternate complement pathway[7]. Given the effects of Carfilzomib on the alternate pathway, Eculizumab is a reasonable therapeutic option because it targets complement C5 and inhibits the assembly of the MAC.[4,5,6,7]. Since PIs are the mainstay of MM treatment, the nephrologist should be aware of the rare but serious consequences of PI- associated DITMA and should consider Eculizumab as a management strategy[1,2,3].

PO0237

Tubulointerstitial Lupus Nephritis with Coexisting Renal Limited IgG4 Disease

Bushra Z. Saleem, Lilian Saro-Nunez, Ayesha Ahmed, Hammad Siddiqui. *Rutgers The State University of New Jersey, New Brunswick, NJ.*

Introduction: The classic pattern of Lupus Nephritis (LN) is an autoimmune complex mediated glomerulonephritis. Rare cases have been described with predominant tubuluinterstitial nephritis (TIN) with tubulointerstitial immune deposits in the absence of significant glomerular lesions. We describe a patient with such pattern of disease along with co- existing renal limited IgG4 related disease (IgG4 RD).

Case Description: 27-year- old man with no past medical history presented with fever, malaise and cough for 3 days. It was associated with occasional epistaxis and weight loss for 3 months. He denied any rash, joint pains, oral ulcers or photosensitivity. On admission he was noted to have creatinine of 7.2 mg/ dl with eGFR of 9ml/ min/1.73m2. His UA showed 3 + blood, protein to creatinine ratio of 1.61 microgram/ mg and microalbumin to creatinine ratio of 334 microgram/ mg. His pertinent positive blood work includes ANA titer of 1:1280, complements levels C3 < 26.3 and C4 < 7.9. He underwent a renal biopsy that showed immune complex mediated chronic active interstitial nephritis and increased IgG4 positive plasma cells, minimal glomerular alterations with rare mesangial deposits. Full house pattern was observed in tubules on immunoflorence. Lymph node FNA performed did not demonstrate increased IgG4 levels, however his serum IgG4 levels returned high at 205 mg/dl. He was diagnosed with Tubuluinterstitial Lupus Nephritis with renal limited IgG4 disease. He was started on high pulse dose steroid followed by taper and mycophenolate mofetil (MMF). He demonstrated good response with improvement in proteinuria, complement levels and ANA titers. His serum creatinine improved to 2.6 mg/ dl at 6 months.

Discussion: A very few cases of lupus TIN without glomerular involvement are described in the literature and management options remain unclear. The most frequent renal manifestations of IgG4-RD are TIN, membranous glomerulonephropathy and obstructive nephropathy due to retroperitoneal fibrosis. The presence of an overlap of LN with IgG4 RD has been reported in very limited number that our patient had. Our patient responded well to the treatment with MMF and Steroids. However, there is need to describe and study more such cases to delineate management protocols. We continue to follow him in clinic and monitor him for involvement of other organ system.

PO0238

Hepatorenal Syndrome Type 1 as a Consequence of Transarterial Chemoembolization

M. Catalina Morales-Alvarez, Larab L. Giniyani, Alexander Davidovich. *Mount Sinai Beth Israel Hospital, New York, NY.*

Introduction: Hepatorenal syndrome (HRS) is characterized by marked kidney dysfunction in the setting of advanced liver disease. HRS can manifest in two different patterns, type 1, representing an acute onset of kidney injury and type 2, corresponding to the chronic manifestation of kidney injury secondary to liver dysfunction. Here we present a case of HRS type 1 following transarterial chemoembolization (TACE) in a patient with advanced cirrhosis and hepatocellular carcinoma (HCC).

Case Description: A 69-year-old male presented to the hospital with worsening weakness, lethargy and decreased urinary output. His family stated the symptoms began shortly after his last session of TACE the week prior. There were no fevers, sick contacts or recent travel. He had underlying CKD stage IIIa (baseline SCr 1.7 mg/dL) and alcoholic cirrhosis with HCC treated with partial resection and multiple sessions of TACE. On admission, the SCr was 9 mg/dL associated with symptomatic hyperkalemia, anion gap metabolic acidemia, severe hyponatremia, junctional bradycardia and hypotension. Additionally, urinary sodium was < 20 mmol/L with a bland sediment. Once admitted to the ICU, he required vasopressors and emergent hemodialysis. He was given HRS treatment with albumin 1gm/Kg/day plus vasopressin for 2 days. His urine output and kidney function improved back to baseline in the following days with no further requirement of hemodialysis.

Discussion: HRS represents an entity of kidney dysfunction secondary to severe renal vasoconstriction in response to splanchnic vasodilation. HRS occurs in states of advance liver disease. Our patient had alcoholic cirrhosis and HCC. TACE had been implemented as a palliative treatment to the unresected lesions. Iodinated contrast and chemotherapeutic agents are used in low dose with this therapeutic option, however, several cases of acute kidney injury have been reported likely due to contrast induce nephropathy. The need for renal replacement therapy has been not extensively reported but overall long-term outcomes were satisfactory. HRS as a consequence of TACE has never been described but given the laboratory findings and significant improvement following treatment we suspected this case was HRS type 1

PO0239

Thyroid-Cardiorenal Syndrome

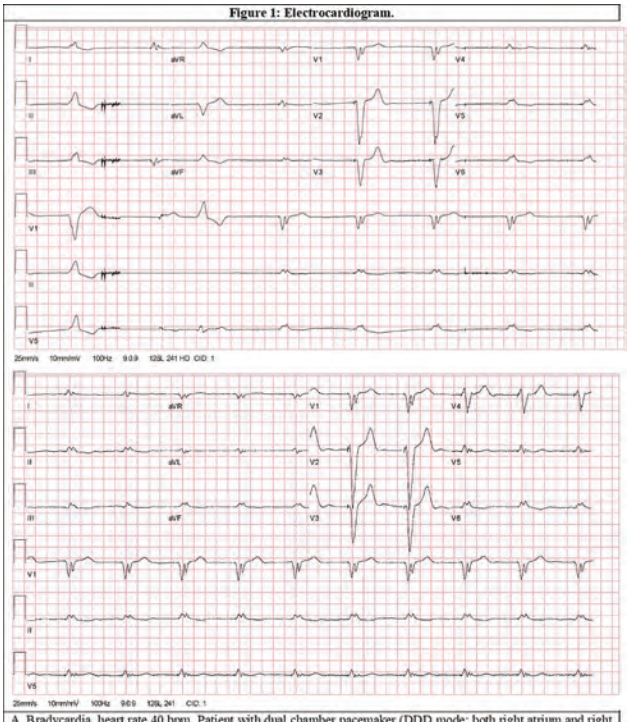
Juan D. Salcedo Betancourt,[2] Karla G. Carias martinez,[2] Vasuki N. Venkat,[1] Daniel J. Soberon,[1] Marco A. LadinoAvellaneda.[1] *[1]Miami VA Healthcare System, Miami, FL; [2]University of Miami School of Medicine, Miami, FL.*

Introduction: In severe hypothyroidism, acute kidney injury (AKI) may occur from hypothyroidism-induced myopathy. We report the first case of AKI in the setting of severe bradycardia without rhabdomyolysis.

Case Description: An 85-year-old man with heart failure and a dual-chamber implantable cardio defibrillator was admitted with bilateral lower extremity edema. Vital signs included asymptomatic bradycardia 40 bpm (Figure 1), blood pressure 107/74 mmHg, without fever or respiratory distress. Laboratories showed serum creatinine (SCr) of 2.3 mg/gL (baseline 1.5 mg/dL), serum sodium 127 mg/dL, serum creatine kinase (CPK) levels of 170 U/L (38-174 U/L), thyroid secreting hormone levels (TSH) of 97.77 uIU/L (0.45 – 4.70 uIU/mL) and free thyroxine levels (Free T4) of 1.4 ng/dL (0.71 – 1.85 ng/mL). Renal ultrasound was unremarkable. The pacemaker was programmed to VVI mode 60 bpm (ventricular pacing and sensing) with prompt improvement in the heart rate and renal function. He was discharged on oral levothyroxine.

Discussion: Hypothyroidism increases systemic vascular resistance and decreases blood volume, cardiac contractility, and heart rate, with an overall decrease in cardiac output. AKI may occur from hypothyroidism-induced rhabdomyolysis; however, SCr is rarely elevated or may increase over several weeks. Our case contrasts given the acute rise in SCr and prompt recovery after the bradycardia resolved. We believe that the AKI was predominantly due to hypothyroidism-induced bradycardia, with a subsequent reduced cardiac output and effective renal flow. AKI workup should include hypothyroidism screening, particularly in the context of persistent bradycardia, even with normal blood pressure and CPK levels. We propose the term Thyroid-Cardio-Renal syndrome for this unusual association.

Figure 1: Electrocardiogram.



A. Bradycardia, heart rate 40 bpm. Patient with dual chamber pacemaker (DDD mode: both right atrium and right ventricle sensing and pacing), found to have atrial undersensing with ventricular paced rhythm.
B. After this episode of bradycardia, the pacemaker was programmed to VVI mode 60 bpm (ventricular pacing and sensing).

PO0240

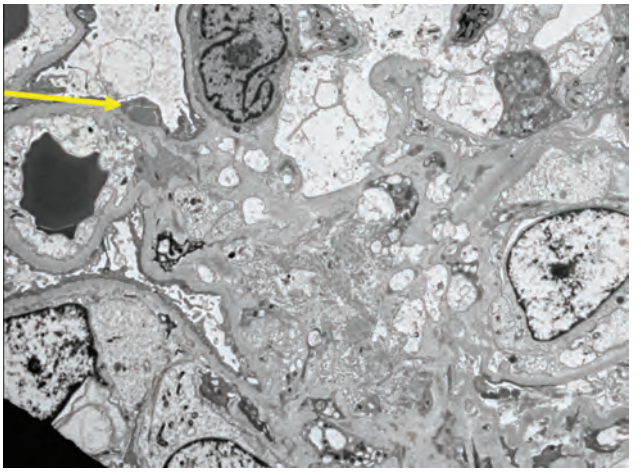
Cat Scratch Kidney

Roy Rajan, Jason R. Pettus, Charles W. Hopley. *Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.*

Introduction: A case of anuric RPGN secondary to post infectious glomerulonephritis in setting of bartonella infection

Case Description: An 84-year-old female presented with creatinine of 7.85mg/dl (baseline 0.81mg/dl) during a workup for painless hematuria. She developed progressive hypoxia and blood-tinged sputum concerning for pulmonary/renal syndrome and was treated with immunosuppression and plasma exchange. Serologic tests including ANA/ENA, anti-GBM, C-ANCA, P-ANCA, and MPO Ab were negative. However, PR3 Ab was elevated at 29.3 Units. Complement C3 and C4 levels were normal. Blood/urine cultures, assays for hepatitis B/C, HIV and Respiratory panel were negative. Renal biopsy showed an MPGN-pattern proliferative glomerulonephritis with necrotizing crescents. IF displayed global 3+ granular staining for both IgG and C3 as well as trace granular C1q. EM confirmed mixed mesangial (dominant), subendothelial, and a few distinct subepithelial hump-like deposits by EM, suggestive of an infection related glomerulonephritis. With a biopsy suggesting an infectious process and BAL without evidence of alveolar hemorrhage, immunosuppression and PLEX were discontinued. Broader infectious workup was negative for ASO titers, Borrelia antibody, Quantiferon/AFB cultures, and BAL for fungal organisms. However, Bartonella IgG was positive at 1:1024 (normal <1:128). Bartonella PCR was negative. Both TTE and TEE were negative for valvular lesions. Additional patient history elucidated recent acquisition of a pet cat and multiple scratches. Treatment focus shifted from immunosuppression to antibiosis.

Discussion: Our case highlights an underappreciated entity associated with GN, particularly in the absence of overt clinical endocarditis. There has been a crossover association reported with ANCAs, particularly anti-PR3, which can demonstrate either a pauci-immune or immune complex pattern as with our patient. The case demonstrates how renal biopsy and social history remain vital diagnostic tools in patients presenting with non-specific systemic illness.



PO0241

Two Cases of Oxalate Nephropathy: An Uncommon Disease, Often Missed

Claire F. Schretlen, Michelle Neuman, Vishy Chaudhary. *West Virginia University Health Sciences Center, Morgantown, WV.*

Introduction: Oxalate nephropathy is a state of excess oxalate availability leading to damaging calcium oxalate crystal deposition in the renal tubules and interstitium. It is an uncommon but severe cause of renal damage and leads to dialysis dependence in the majority of patients; thus, diagnostic index of suspicion must be high.

Case Description: Patient A was a 58 year old male with 2 prior renal stones but no history of gastric bypass, IBD, or other malabsorptive state who presented with vomiting, metallic taste, and behavior changes. Serum creatinine (SCr) on admission was 10.2 mg/dL (baseline 1.1 mg/dL). Basic workup including ANCA, ANA, dsDNA, C3, C4, and Hepatitis B and C was unremarkable. A renal biopsy showed severe interstitial fibrosis and tubular atrophy with abundant calcium oxalate crystals, and dialysis was initiated. Dietary history revealed daily consumption of 1,000 mg Vitamin C, salads, and nuts. Genetic testing for primary hyperoxalosis was negative. After 1.5 months he was no longer dialysis-dependent but only attained partial renal recovery (SCr 2.67 mg/dL, eGFR 25). Patient B was a 68 year old male with no history of renal or GI disease who presented with emesis, weakness, and urinary retention. Admission SCr was 7.7 mg/dL (baseline 1.4 mg/dL). Renal function improved slightly after Foley placement for newly diagnosed BPH, but SCr remained elevated with negative initial AKI workup. Renal biopsy showed oxalate nephropathy. Further history revealed only occasional consumption of nuts with daily servings of tea and polyethylene glycol. Patient B's genetic testing was also negative. He remains on hemodialysis and has been referred for transplant.

Discussion: Oxalate nephropathy can result from primary (genetic) or secondary mechanisms. The most common secondary causes include increased intestinal oxalate availability ("enteric" hyperoxaluria) and increased dietary consumption. A basic medical history can reveal risk factors for enteric hyperoxaluria, while a thorough review of diet and supplements is often deferred, delaying the diagnosis. In some cases a single cause is not identified, and instead a combination of dietary and pharmacologic factors are to blame. We present 1 case of oxalate nephropathy most likely caused by high-dose Vitamin C, and another case with a less clear etiology aside from vague dietary and medication factors.

PO0242

AKI due to Renal Limited Thrombotic Microangiopathy (TMA) in a Patient with Metastatic Prostate Cancer

Supriya Gerardine,[1] Matthew Abramson,[2] Surya V. Seshan,[3] Sheron Latcha.[2] *[1]New York Presbyterian - Weil Cornell, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Weill Cornell Medicine, New York, NY.*

Introduction: In this report we describe a case of AKI caused by TMA without evidence of microangiopathic hemolytic anemia (MAHA) and thrombocytopenia as a paraneoplastic syndrome due to metastatic prostate cancer versus radiation injury.

Case Description: 65 year old man with metastatic prostate cancer treated with hormonal therapy, Cabazitaxel (last dose 5 months ago) and radiation to the prostate, T-12-L5 and pelvic region was admitted for gastrointestinal bleed and AKI. He was hypertensive to 182/82 mmHg and labs with white blood cell count 13.8 K/mcL, hemoglobin 6.7g/dl, platelets 228 K/mcl and Creatinine 2.3mg/dl (baseline 0.6 mg/dl). Urine sodium was 54 meq/L, creatinine 57 mg/dl and proteinuria of 4.9g/day. Peripheral smear had 2-3 schistocytes per high power field. Lactate dehydrogenase was 449 U/L, haptoglobin 155 mg/dL and ADAMTS13 level 47%. Renal ultrasound showed mild right hydronephrosis. He was given blood, intravenous fluids and right percutaneous nephrostomy was place but creatinine rose to 5mg/dl so renal biopsy was done. The specimen had 120 glomeruli and 12 were sclerosed There was focal organizing arterial and arteriolar thrombi. C5b-9 positive staining was seen within the affected glomeruli and

most arteriolar walls and tubular basement membranes. There was no immune complex electron dense deposits. This was indicative of severe, acute, subacute and chronic TMA involving all small arterial vessels with acute tubular necrosis. The patient required hemodialysis without renal recovery.

Discussion: TMA is reported in metastatic adenocarcinomas. Cancer treatment can also lead to TMA's. Cabazitaxel was unlikely etiology for the TMA as it had been a few months since the last dose. There are no cases reported of radiation causing renal limited TMA which we thought could also be a potential cause. Hypertension and severe anemia with schistocytes were the only clues to a TMA process. The elevated haptoglobin and normal platelet count was unusual. The TMA is thought to be likely secondary to paraneoplastic syndrome or possibly from the radiation treatments.

PO0243

Myeloid-Specific PKM2 Deletion Reduces Kidney Damage in Oxalate-Induced AKI

Orestes Foresto-Neto,[2,1] Magaiver A. Silva,[2] Ingrid K. Watanabe,[2,1] Tâmisa S. Honda,[2] Marcos A. Cenedeze,[1] Meire I. Hiyane,[2] Alvaro Pacheco-Silva,[1] Niels O. Camara.[2,1] [1]*Universidade Federal de Sao Paulo, Sao Paulo, Brazil;* [2]*Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil.*

Background: Reprogramming of immune cell metabolism have been associated with the development of kidney injury. The M2 isoform of pyruvate kinase (PKM2) catalyzes a critical stage of glycolysis, which was shown to be a crucial metabolic pathway for pro-inflammatory macrophages. We investigated whether deletion of PKM2 in myeloid cells exerts renoprotection in calcium oxalate (CaOx) crystal-induced acute kidney disease (AKI).

Methods: AKI was induced in myeloid-specific PKM2-knockout ($PKM2^{fl/fl}$;LysM-Cre^{+}) mice and their Cre-negative littermates ($PKM2^{fl/fl}$) by a single *i.p.* injection of sodium oxalate (NaOx, 100mg/kg) and 3% NaOx in drinking water for 24hr before sacrifice. Healthy controls received vehicle only. Serum creatinine and urea were evaluated as markers of renal function. CaOx crystal deposition (Pizzolato staining), IL-6, NGAL and KIM-1 mRNA expression (quantitative PCR), macrophage number/phenotype (FACS), and lactate levels were assessed in kidney tissue.

Results: In $PKM2^{fl/fl}$, intrarenal CaOx deposition increased the serum levels of creatinine and urea, as well as the expression of IL-6, NGAL and KIM-1 in kidney tissue compared to healthy controls ($p<0.01$). Despite a similar deposition of crystals, loss of renal function and markers of renal inflammation/injury were reduced in $PKM2^{fl/fl}$;LysM-Cre^{+} ($p<0.05$). FACS analysis indicated that the number of F4/80+CD11b+ cells in kidneys were similarly elevated by CaOx in both $PKM2^{fl/fl}$ and $PKM2^{fl/fl}$;LysM-Cre^{+}, while macrophages with the pro-inflammatory phenotype Ly6C+CD206- were significantly reduced in $PKM2^{fl/fl}$;LysM-Cre^{+} mice ($p<0.01$). In addition, PKM2 deletion also reduced renal levels of lactate ($p<0.05$).

Conclusions: The pro-inflammatory status of macrophages relays on glycolysis in CaOx nephropathy. Therefore, deletion of PKM2 in myeloid cells can reduce CaOx-induced renal inflammation and injury. FAPESP (2019/02893-9 and 2017/05264-7), CNPq and CAPES.

PO0244

High-Content Imaging of Kidney Cell Function to Elucidate Mechanisms of Antiviral Drug Toxicity

Adam Pearson,[1] Dominik Haenni,[1] Andrew Hall.[1,2] [1]*Universitat Zurich, Zurich, Switzerland;* [2]*University Hospital Zurich, UniversitatsSpital Zurich, Zurich, Switzerland.*

Background: Globally, millions of people live with HIV and hepatitis B virus (HBV). Toxicity from antiviral drugs is a major cause of kidney disease in these individuals. Tenofovir disoproxil fumarate (TDF) is a first line therapy for HIV and HBV. TDF induces functional proximal tubule (PT) defects for reasons that are unknown, partly due to a lack of appropriate experimental models. Clinically, TDF toxicity is characterized by two major phenotypes: isolated defects in PT solute transport; and severe tubular damage (Fanconi syndrome/acute kidney injury) associated with grossly enlarged mitochondria. The aim of our study was to establish realistic *in vitro* models of TDF toxicity, to investigate the underlying mechanisms.

Methods: Experiments were performed on monolayers of differentiated human-derived PT cells (RPTEC/TERT1). A high-content image analysis pipeline was established, using automated microscopy and machine learning, to quantify transport function, using dome formation as a readout. Metabolism was evaluated by antibody staining for mitochondrial morphology and autophagy.

Results: We screened numerous treatment regimens and generated phenotypes matching those observed in patients, including transport inhibition and mitochondrial hypertrophy. Further experiments using these models revealed that TDF caused a dose dependent decrease in ATP despite increased glycolysis and mtDNA content. Basal and ATP-linked respiration were decreased but maximal respiration was achieved, suggesting inhibition of complex V (ATP synthase). Metabolomic analysis confirmed that TDF was converted to the active antiviral metabolite Tenofovir diphosphate (TFVpp), a structural analogue of ATP. Using an *in vitro* assay of complex V activity, we observed a dose dependent inhibition with TFVpp. Metabolomics revealed no major defects in the TCA cycle or beta-oxidation, but clear evidence of oxidative stress.

Conclusions: In summary, we have developed a high-content image analysis pipeline of human-derived PT cells to generate realistic *in vitro* models of functional TDF toxicity. Metabolic characterization of these revealed a clear phenotype consistent with ATP synthase inhibition, which most likely explains toxicity observed in patients, since PT solute transport is heavily dependent on aerobic respiration. ATP depletion might trigger compensatory mitochondrial biogenesis, leading to hypertrophy.

Immunological Changes Following Cholinergic Anti-Inflammatory Pathway Stimulation

William Nash, Shinji Tanaka, Mark D. Okusa. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: The cholinergic anti-inflammatory pathway (CAP) protect mice from ischemia reperfusion injury (IRI). The interactions and mechanisms that regulate this effect are of great interest as targets for clinical intervention. Vagus nerve stimulation (VNS) induces neurotransmitter cascades that culminate in release of norepinephrine (NE) in the spleen. NE stimulates CD4+ T cells to produce acetylcholine via the choline acetyltransferase enzyme. Acetylcholine then stimulates anti-inflammation via splenic immune cells that express the α7 nicotinic acetylcholine receptor (α7nAChR). Adoptive transfer of splenic cells from VNS-treated mice protects kidneys from IRI. However, the downstream effects on splenic structure and function that lead to protection are still not fully understood. The goal of this study is to profile immune cells following CAP stimulation and identify key downstream mechanisms.

Methods: VNS was performed on mice in vivo and nicotine stimulation on immune cells ex vivo. Vagus nerve stimulation was triggered optogenetically using blue light to target the vagus nerve of mice expressing channelrhodopsin-2 under control of the vesicular glutamate transporter 2 promoter. Cells were collected from the spleen between 24- and 48-hours post-stimulation. A concentration of 50 μM nicotine in culture media was used to stimulate α7nAChR-expressing immune cells collected from the peritoneum of mice. Analysis of immune cell populations was performed with flow cytometry and single cell RNA sequencing.

Results: Overall optogenetic VNS led to a reduced number of CD45+ cells from the spleen. Within the CD45+ population, B1 cells and macrophages exhibited increased representations of ~30% and 60%, respectively. Monocyte and neutrophil representation remained relatively stable, but eosinophils displayed a marked reduction of ~60%. Single cell RNA sequencing showed increased novel gene expression in subpopulations of macrophages, including cell-cell adhesion genes (*Spa17*) and guanine nucleotide exchange factors (*Arhgef5*) that could regulate function.

Conclusions: Cholinergic stimulation triggers reorganization of immune cell populations and alterations in gene expression that are likely important for regulating the inflammatory environment. Additional characterization and functional studies are currently underway to fully identify the importance of observed changes.

PO0246

Reduced Levels of Cyclic-GMP and Inhibition of cGMP-Dependent Protein Kinase Activate $p21^{Cip1}$/$p27^{Kip1}$ and Lead to Renal Fibrosis and Dysfunction

Subhankar Das, Kandasamy Neelamegam, Kailash N. Pandey. *Tulane University Health Sciences Center School of Medicine, New Orleans, LA.*

Background: Targeted-deletion of *Npr1* (coding for guanylyl cyclase/natriuretic peptide receptor-A, GC-A/NPRA) exhibits hypertrophic and proliferative effects in target organs of *Npr*1 gene-knockout mice; however, the molecular mechanisms of these pathologies are poorly understood. Fibrosis and hypertrophy are regulated by $p21^{Cip1}$ and $p27^{Kip1}$, cell-cycle regulatory proteins that inhibit cyclin and cyclin-dependent kinase (cyclin-CDK) complex.

Methods: We examined the activation of CDK blocker ($p21^{Cip1}$/$p27^{Kip1}$) in *Npr1* gene-knockout (0-copy; $Npr1^{-/-}$) mice and the GC inhibitor, A71915-treated and cGMP-dependent protein kinase (cGK) inhibitor, Rp-8-Br-cGMPS (Rp)-treated wild-type 2-copy ($Npr1^{+/+}$) and gene-duplicated 4-copy ($Npr1^{++/++}$) mice using Western blot and quantitative real-time PCR. Systolic blood pressure (BP) was determined by non-invasive tail-cuff method.

Results: Renal cGMP levels and cGK activity were significantly decreased in 0-copy mice ($p<0.0001$), A71915-treated ($p<0.001$) and Rp-treated ($p<0.05$) 2-copy and 4-copy mice as compared with control animals. The results showed a high BP level in 0-copy mice (138.6 ± 3.1 mmHg; $p<0.001$) and significantly lower BP in 4-copy mice (86.0 ± 2.8 mmHg; $p<0.01$) compared to 2-copy mice (102.2 ± 1.7 mmHg). Treatment with A71915 and Rp showed significant increase in BP in 2-copy mice but only a small increase in 4-copy mice compared with untreated control animals. Increased phosphorylation of p-Erk1/2 (3-fold), p-p38MAPK (4-fold), $p21^{Cip1}$ (6-fold), and $p27^{Kip1}$ (5-fold) occurred in 0-copy, A71915-treated 2-copy, and A71915-treated 4-copy mice; however, Rp treatment caused minimal changes compared to controls. Proinflammatory and profibrotic cytokines, including TNF-α (6-fold), IL-6 (3-fold), and TGF-β1 (4-fold) were increased in plasma and kidney of 0-copy and A791915-treated 2-copy mice, but less in A71915-treated 4-copy mice. Renal pathology, including fibrosis, mesangial matrix expansion, and tubular hypertrophy were significantly higher in 0-copy and A71915-treated 2-copy mice but minimally in 4-copy mice compared with controls.

Conclusions: The present results suggest that *Npr1* has a pivotal role in inhibiting the renal fibrosis and pathology and exerts renal protective effects through the cGMP/cGK axis by repressing the CDK inhibitors, $p21^{Cip1}$ and $p27^{Kip1}$.

Inhibition of Acetyl-CoA Carboxylase in Acutely Injured Tubular Cells Exacerbates DNA Damage and Mitochondria Fission in Diabetic Nephropathy

Xiangchun Liu,[1,2] Jiahua Li,[1] Shun-Yang Cheng,[1] Guixia Li,[1,3] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]The Second Hospital, Cheeloo College of Medicine, Shandong University, Jinan, China; [3]Shenzhen Third People's Hospital, Shenzhen, China.*

Background: Both diabetes and acute tubular injury (ATI) alter lipid metabolism of proximal tubules. Inhibiting lipogenesis causes G2/M cell cycle arrest, which can cause maladaptive tubular repair. Acetyl-CoA carboxylase (ACC) stimulates lipogenesis and inhibits fatty acid oxidation (FAO). Phosphorylation (p-ACC) inhibits ACC, which inhibits lipogenesis and promotes FAO. We hypothesized that p-ACC exacerbates DNA damage and mitochondria dysfunction in diabetic nephropathy (DN) after ATI.

Methods: Human DN samples were co-stained for p-ACC, KIM-1, and a-SMA. ATI was introduced by a single diphtheria toxin (DT) injection in Akita mice in which the DT receptor (DTR) was introduced genetically into the kidney tubule (Akita$^{SIX2\text{-}DTR}$). Mice were fed a high-fat diet (HFD). The expression ratio of p-ACC/ACC was determined at 3 days after DT and markers for tubular injury and DNA damage (g-H2AX) were evaluated at 3 days and 4 months. Cisplatin-injured HK2 cells were treated with an ACC inhibitor, PF-05175157 (ACCi) or a carnitine palmitoyltransferase 1 inhibitor, etomoxir (CPT1i) and examined for DNA damage and mitochondria fission.

Results: P-ACC expression was increased and correlated with expression of tubular injury marker KIM-1 and myofibroblast marker a-SMA in human DN specimens. At day 3 after DT, ATI increased the p-ACC/ACC ratio in the Akita $^{SIX2\text{-}DTR}$ mice on HFD and resulted in enhanced expression of g-H2AX in KIM-1 positive tubules and kidney fibrosis at 4 months. When cisplatin-injured HK2 cells were treated with ACCi, which allowed b-oxidation of acyl-CoA, there was an increase in mitochondrial fission factor (MFF) without a further increase of g-H2AX. Etomoxir, which blocked acylcarnitine entry into mitochondria, reduced MFF and g-H2AX expression.

Conclusions: Increased levels of p-ACC were associated with increased tubular injury and fibrosis in human DN. P-ACC in injured renal epithelial cells permitted b-oxidation of acyl-CoA in damaged mitochondria and enhanced mitochondrial fission resulting in DNA damage plausibly from reactive oxygen species. Prevention of mitochondrial overload of acyl-CoA is a potential therapeutic target to mitigate mitochondria damage and DNA damage after ATI in DN.

PO0248

The Effect of ANG-3777 on In Vitro Cell Proliferation

Latha Paka, Itzhak D. Goldberg. *Angion Biomedica Corp, Uniondale, NY.*

Background: Hepatocyte growth factor (HGF) regulates tissue growth and development by inducing cell motility, proliferation and morphogenesis in multiple cell types including endothelial and epithelial cells. However, it has no effect on proliferation in fibroblasts. ANG-3777 is a novel molecule that exerts similar cytoprotective and regenerative effects as HGF. This study compared the effect of ANG-3777 with that of HGF in stimulating cell proliferation.

Methods: *In vitro* cell proliferation assays were conducted in triplicate using human umbilical vein endothelial cells (HUVEC), rat neuronal Schwann cells, and mouse fibroblasts. HUVEC and fibroblasts were exposed to 5 μM ANG-3777 or 25 ng/mL HGF for up to 24 hours. Schwann cells were exposed to increasing doses of ANG-3777 (up to 10 μM) or HGF (up to 100 ng/mL) for 16 to 24 hours to evaluate the effective concentration at 50% proliferative activity (EC_{50}). Radiolabeled [3H]-thymidine incorporation was used as a measure of cell proliferation. An unpaired T-test was used to compare ANG-3777 or HGF versus vehicle (dimethyl sulfoxide) treatment.

Results: A statistically significant increase in cell proliferation (~3-fold) was observed in HUVECs exposed to ANG-3777 and HGF compared with vehicle ($p<0.01$; Figure 1). Similarly, Schwann cell proliferation increased in a concentration-dependent manner following exposure to ANG-3777 (EC_{50} 0.012 μM) and HGF (EC_{50} 6.5 ng/mL). In mouse fibroblasts (negative control), neither ANG-3777 nor HGF exposure stimulated cell proliferation compared with vehicle.

Conclusions: *In vitro* cell-based proliferation assays confirmed that the activity of ANG-3777 is comparable to that of HGF in inducing cell proliferation in HUVECs and rat Schwann cells with neither agent stimulating proliferation in mouse fibroblasts.

Figure 1. Effect of ANG-3777 vs HGF on Human Umbilical Vein Endothelial Cell Proliferation

PO0249

The Effect of ANG-3777 on the Growth of c-MET-Expressing Human Tumor Cells in Immunocompromised Mice

Itzhak D. Goldberg. *Angion Biomedica Corp, Uniondale, NY.*

Background: In the injured organs, hepatocyte growth factor (HGF) stimulates c-MET, leading to the activation of intracellular pathways involved in tissue repair. ANG-3777 is an HGF mimetic. In a Phase 2 study, renal transplantation patients with signs of delayed graft function treated with ANG-3777 showed renal function improvement relative to placebo up to 1 year post-transplantation. However, uncontrolled activation of c-MET can stimulate tumor growth. The objective of these studies was to assess the potential of ANG-3777 to stimulate tumor growth in human cell lines.

Methods: c-MET-expressing human tumor xenografts (U87-MG glioma cells, HT29 colon cancer cells, and SUIT-2 pancreatic ductal carcinoma cells) were implanted into 20 BALB/c nude mice per xenograft model. The animals were administered an intraperitoneal injection of 2 mg/kg ANG-3777 or vehicle (dimethyl sulfoxide) daily for up to 28 days. Overall survival (glioma transplant model) and tumor growth and weight (colon and pancreatic tumor xenograft models) were assessed.

Results: Overall survival did not differ in animals treated with ANG-3777 vs vehicle. No significant increase in tumor growth or weight was observed with ANG-3777 treatment. ANG-3777 significantly reduced the mean volume of pancreatic tumors (1747 vs 923.3 mm^3, $p<0.01$;), but not the weight of the tumor (Fig. 1 A&B).

Conclusions: Administration of ANG-3777 in human tumor cells expressing c-MET was not associated with increased tumor volume or weight in pancreatic and colon tumor models and did not increase mortality in the glioma model in BALB/c nude mice.

A Combination of Contrast Media and Radiation Increases DNA Damage and Delays DNA Damage Repair in Mouse Kidneys

Shu Fujino, Shigehiro Doi, Toshiki Doi, Ayumu Nakashima, Takao Masaki. *Department of Nephrology, Hiroshima University Hospital, Hiroshima, Japan.*

Background: Contrast-induced nephropathy (CIN), resulting from contrast media (CM) administration, is a major complication of angiographic procedures. CIN may also be induced by exposure to radiation. However, the molecular mechanism of CIN has only been investigated using a CM-injected rodent model. Here, we examined the dual effect of CM and irradiation (IR) on DNA damage and repair in *in vitro* and *in vivo*.

Methods: Human renal tubular epithelium (HK)-2 cells were stimulated by medium containing 100 mg iodine/ml of iohexol (Ihx-HK2), 1 Gy of X-ray irradiation (IR-HK2), or both (Ihx+IR-HK2). Mannitol-treated cells were used as an experimental control (Man-HK2 or Man+IR-HK2). For the *in vivo* study, ischemic reperfusion injury (IRI)

was induced in mice after right kidney removal, then IRI mice were treated with 200 μL iohexol (IRI/CIN) and/or 10 Gy X-ray irradiation (IRI+IR or IRI/CIN+IR). We performed immunohistochemistry, immunofluorescence staining, and western blotting for DNA damage markers (γH2AX, pATM, 53BP1, and RAD51), an oxidative stress marker (8-OHdG), a macrophage marker (F4/80), and klotho.

Results: Immunofluorescence staining revealed increased expression of γH2AX, 53BP1, and RAD51 in Ihx+IR-HK2 compared with Ihx- or IR-HK2. These proteins remained highly expressed at 24 h in Ihx+IR-HK2, but not in Ihx- or IR-HK2. Cells positive for γH2AX, pATM, 53BP1, and RAD51 were significantly increased in IRI/CIN+IR mice, and 8-OHdG and F4/80 expression was also remarkably increased, whereas that of klotho was decreased in IRI/CIN+IR mouse kidneys.

Conclusions: Both CM administration and exposure to radiation induce DNA damage and delay DNA damage repair, which are accompanied by increased levels of oxidative stress and inflammation and downregulation of klotho expression.

PO0251

Whole-Transcriptome Sequencing of Proximal Tubule Cells Exposed to Free Light Chains

Rohit Upadhyay,[1] Vecihi Batuman.[1,2] [1]*Tulane University School of Medicine, New Orleans, LA;* [2]*SLVHCS, Southeast Louisiana Veterans Health Care System, New Orleans, LA.*

Background: Despite medical advancements, molecular markers for early detection of kidney injury (KI) are limited. Serum creatinine, the only functional marker for KI, has poor predictive accuracy, particularly in the early stages of acute KI due to free light chains in multiple myeloma (MM) patients. Identification of new markers would be highly useful in a select group of MM patients who do not present initially with a detectable rise in creatinine level.

Methods: Human kidney proximal tubule cells (PTCs; RPTEC cell line) were exposed to κ or λ FLCs. Control/ treated cells were harvested, and total RNA (mRNA+miRNA) was isolated following standard procedures for whole transcriptome analysis. After checking RNA quality by Bioanalyzer (Agilent Bioanalyzer 2100), RNA sequencing for whole transcriptome was performed by using Illumina NextSeq 500 to generate >60M paired-end 75bp reads per sample. After initial data quality checking by FastQC and RSeQC, bioinformatics analysis was performed using TopHat, Samtools, and Picard. Further classification, annotation, and visualization were facilitated by Partek and R statistical packages. RNA sequencing data were validated through qPCR.

Results: Whole transcriptome RNA-Seq data suggested role of several genes involved in innate immunity (VNN1, MX1, OAS2, TLRs, IFI6, IFI27, IFIT1, ISG15, BST2), ERK signaling (KCTD12, IFI6, MAP3K, ERK1/2, JNK,p38), and inflammation (CXCL6, TNFA, IL6, CXCL8, IL8, IRAK1, IRAK4, TRAF6, NFKB, IKBA, IKK) as well as miRNAs (hsa-146a-5p, hsa-miR-574-3p, hsa-miR-331-3p, hsa-miR-125a-5p) in FLC induced tubular injury in MM patients. We also found a KI mechanism involving cross-talk among innate immunity, ERK signaling, and the inflammatory pathway by different FLCs types.

Conclusions: Our results show differentially expressed genes and a mechanism of injury involving cross-talk between innate immunity and inflammatory pathways in PTCs exposed to FLCs.

Single-Cell Profiling of AKI in Mice Highlights Differential Immune Cellular Response Programs in Regeneration and Fibrosis

Michael S. Balzer,[1,2] Yawen Yang,[1,2] Ziyuan Ma,[1,2] Rojesh Shrestha,[1,2] Matthew Palmer,[3] Katalin Susztak.[1,2] Susztak Lab [1]*University of Pennsylvania, Perelman School of Medicine, Department of Medicine, Renal, Electrolyte and Hypertension Division, Philadelphia, PA;* [2]*University of Pennsylvania, Perelman School of Medicine, Institute for Diabetes, Obesity, and Metabolism, Philadelphia, PA;* [3]*University of Pennsylvania, Perelman School of Medicine, Department of Pathology and Laboratory Medicine, Philadelphia, PA.*

Background: After acute injury the kidney has the ability to regenerate and repair to a certain extent. On the other hand, maladaptive injury response leads to kidney fibrosis and chronic kidney disease. We are only beginning to understand the complex interactions of epithelial, stromal and immune cells involved in these adaptive processes.

Methods: Here we profiled gene expression changes at single cell resolution over time in acutely injured kidneys of mice subjected to mild and severe bilateral ischemic reperfusion injury (IRI). Kidney function, structure, bulk and single cell gene expression analysis was performed on day 1, 3 and 14. We used gene regulatory network and trajectory analyses to define key drivers of successful and failed regeneration.

Results: Bilateral ischemia resulted in similar kidney function decline as analyzed by serum BUN, however long ischemia led to severe kidney fibrosis, while mild ischemia prompted minimal structural changes. In total, we obtained scRNAseq data for >160,000 cells. IRI lead to very significant cell proportion changes including a decrease in renal tubule cells and increase in immune cell fractions. Proximal tubules showed distinctly different differentiation signatures for successful repair vs. maladaptive response in animals subjected to moderate vs. severe IRI. We also identified several discrete immune cell clusters, such as progenitors, naïve B and T cells, T memory and Tgd cells, natural killer and dendritic cells, Ly6Chi and lo monocytes, macrophages and granulocytes and we define their differentially expressed gene network along pseudotime trajectories towards either successful or maladaptive repair.

Conclusions: Single cell RNA-seq analysis of kidney cells revealed differential gene expression changes during regenerative vs. maladaptive response after acute injury. We define patterns of maladaptive proximal tubule repair and characterize important signatures in immune cell composition and activation in regenerating vs. fibrosing kidneys.

Spatial Transcriptomic Signatures in Murine AKI Models

Ricardo Melo ferreira, Tarek M. El-Achkar, Kimberly S. Collins, Yinghua Cheng, Seth Winfree, Pierre C. Dagher, Michael T. Eadon. *Indiana University School of Medicine, Indianapolis, IN.*

Background: The localization of whole transcriptome differential expression in different forms of acute kidney injury (AKI) is incompletely understood. We investigated the distribution of expression across the entire kidney, mapping expression patterns to renal histology in the ischemia-reperfusion injury (IRI) and cecal ligation and puncture (CLP) murine models of AKI.

Methods: Sham, IRI, and CLP kidneys were excised and sections were affixed to Visium 10x genomics slides. Sections underwent H+E staining, followed by permeabilization, RNA isolation, and sequencing. The IRI and CLP samples were clustered using Seurat and differential expression was assessed in clusters co-defined by histology and marker gene expression in both models. We then assessed pathway enrichment of differentially expressed genes (DEGs) using ClusterProfiler and ReactomePA.

Results: We examined the distribution of total expression (sum of all gene counts) across the entire kidney between IRI and CLP. In CLP, uniform upregulation was seen in the medullary S3 cluster. In contrast, total expression differences were patchy in the IRI model with regions of increased and reduced expression seen in both the cortex and medulla. Using spatial transcriptomics clustering, we compared the affected clusters, including the cortical collecting duct, S3 outer stripe proximal tubule, and thick ascending loop of Henle. The IRI model was enriched in wound healing and apoptosis related pathways, while the CLP model was enriched in oxidative phosphorylation and energy metabolism. Strong neutrophil signatures were identified in IRI and macrophage signatures in CLP.

Conclusions: Using spatial transcriptomics, we uncovered regional differences in total RNA expression between the IRI and CLP models. The identified regions housed specific cell types with differences in enriched pathways. The enriched apoptotic pathways in IRI may be consistent with a lower relative expression compared to sepsis. The neutrophil and macrophage spatial distribution indicate how those models respond to injury. The localization of transcriptomic alterations in AKI is not uniform across both models.

Long-Term Use of Ferric Citrate in the Treatment of Iron Deficiency Anemia in Patients with Non-Dialysis-Dependent CKD: The COMPASS Trial

Pablo E. Pergola,[1] Diogo S. Belo,[2] Paul W. Crawford,[5] Moustafa A. Moustafa,[3] Wenli Luo,[4] Alex Goldfarb.[4] [1]*Renal Associates PA, San Antonio, TX;* [2]*California Institute of Renal Research, Chula Vista, CA;* [3]*South Carolina Nephrology & Hypertension Center, Inc, Orangeburg, SC;* [4]*Akebia Therapeutics, Inc., Cambridge, MA;* [5]*Research by Design, Chicago, IL.*

Background: Ferric citrate (FC) is an FDA-approved oral iron replacement for adults with iron deficiency anemia (IDA) and non–dialysis-dependent (NDD) CKD and as a phosphate binder in adults with dialysis-dependent CKD. For IDA, the recommended FC starting dose is 1 tablet (1 g, contains 210 mg ferric iron) 3 times daily (TID) titrated to maintain hemoglobin (Hb) goal. We studied the long-term efficacy and safety of various FC regimens for IDA treatment in adults with NDD-CKD (stages 3-5).

Methods: 48-wk, phase 4, randomized, open-label, multicenter study (NCT03236246). Patients received (1:1) FC 1 g tablet TID (3 g/day) or 2 tablets BID (4 g/day). At Wk 12, if Hb was <10 g/dL or changed <0.5 g/dL from baseline (BL), dose was increased to 2 tablets TID (from 1 TID) or 3 tablets BID (from 2 BID). Primary endpoint was change in Hb from BL to Wk 24. Secondary endpoints included change in transferrin saturation (TSAT), ferritin, and phosphate to Wk 48.

Results: This analysis included 183 of 206 randomized patients. Groups were well matched, with mean age 69.5±10.3 y and 54% with CKD due to diabetes. Mean BL eGFR was 33.6±10.9 mL/min/1.73 m^2, and Hb was 10.45±0.74 g/dL. Efficacy measures at 48 wks are presented in the Table. Adverse events (AEs) occurring in ≥5% included diarrhea (13.2%), discolored stool (12.7%), and constipation (12.2%). Incidence of serious AEs was 13.9% in BID and 17.3% in TID groups. Five deaths were reported, none deemed FC related by investigators.

Conclusions: Both FC regimens studied increased and maintained Hb through 48 wks in patients with NDD-CKD with IDA. Patients with lower baseline Hb and iron parameters had a higher increase in Hb with FC treatment. Serum phosphate remained within normal range over study duration. Mean changes in Hb, TSAT, ferritin, and phosphate were similar in the BID and TID and the 3 and 4 g/day dosing groups. These results support the potential for FC dosing flexibility in the long-term treatment of IDA.

Triferic (Ferric Pyrophosphate Citrate, FPC) Maintains Hemoglobin and Reduces IV Iron: Results from a Single-Site 2-Year Observational Analysis

Marc L. Hoffman,[1] Richard Delvalle,[2] Raymond D. Pratt.[1] *[1]Rockwell Medical Inc, Wixom, MI; [2]Center for Renal Replacement, LLC, Lincolnwood, IL.*

Background: Triferic (ferric pyrophosphate citrate, FPC) is approved as an iron (Fe) replacement product to maintain hemoglobin (Hgb) in adult patients (pts) receiving chronic hemodialysis (HD). Trial data have demonstrated that FPC maintains Fe stores and Hgb while reducing IV Fe usage with a well-tolerated safety profile. We now report one clinic's experience using FPC for all HD patients (pts) during a 2 yr period.

Methods: FPC was added to centrally delivered liquid bicarbonate to provide 110 µg Fe/L dialysate. All patients received FPC at each HD. Anonymized retrospective data from the electronic health record were collected between Sep 2016--Dec 2018. A recommended FPC Fe protocol was provided, but the clinic was allowed to adjust anemia management at their discretion. Supplemental Fe gluconate (IV Fe) was administered according to a protocol based on serum ferritin and TSAT values. All pts receiving IV Fe received single doses of 125 mg elemental Fe up to a max of 500 mg Fe/month when criteria for supplementation was met. During the first 4 months of FPC, the center converted pts from epoetin alfa (EPO) to darbepoetin alfa (INN), therefore INN equivalents were calculated using the published conversion guide (EPO dose/300). IV iron and ESA dose were standardized and changes from pre-FPC were reported for Hgb, IV Fe and ESA usage. KDQoL data were available for the years 2016--2018.

Results: Within 3 months of initiation of FPC, Hgb increased by 0.3 g/dL and was maintained during the observation period. Total IV Fe dose was significantly reduced by 78.4%. Darbepoetin equivalent doses were reduced from pre-FPC by 31.5% by the end of the observation period. Compared to the first year of assessments (2016), post FPC assessments of QoL showed improvements in the Burden of Kidney Disease (KD), Symptoms and Problems of KD and Effects of KD on daily life scales. No adverse events related to FPC were reported.

Conclusions: This observational study demonstrates that FPC is a well tolerated replacement for IV Fe when administered to all patients in a HD unit. The findings of this real-world observational study align with those of clinical trials in terms of reduction of IV Fe use and maintenance of Hgb. ESA was gradually reduced and the KDQoL showed a trend to improvement in the burden and symptoms of kidney disease.

Roxadustat Lowers Risk of Red Blood Cell Transfusion in Patients with Anemia of CKD

Steven Fishbane,[1] Robert Provenzano,[2] Anjay Rastogi,[3] Daniel W. Coyne,[4] Roberto Pecoits-Filho,[5] Chaim Charytan,[6] Maksym Pola,[7] Lona Poole,[8] Gopal Saha,[8] Willis Chou,[8] Tyson T. Lee,[8] Kin-Hung P. Yu.[8] *[1]Northwell Health, Great Neck, NY; [2]Wayne State University, Detroit, MI; [3]University of California Los Angeles, Los Angeles, CA; [4]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [5]Arbor Research Collaborative for Health, Ann Arbor, MI; [6]Nephrology Associates, PC, New Rochelle, NY; [7]AstraZeneca, Warsaw, Poland; [8]FibroGen Inc, San Francisco, CA.*

Background: RBC transfusions may cause reactions, lead to allo-sensitization, or rarely transmit infections, so treatments reducing transfusions are desirable. This analysis assessed whether roxadustat, an oral hypoxia–inducible factor prolyl hydroxylase inhibitor, reduced the need for RBC transfusions in patients with non-dialysis-dependent (NDD) and dialysis-dependent (DD) chronic kidney disease (CKD) and anemia.

Methods: Data from six completed randomized Phase 3 studies (up to 4y duration) in patients with Stage 3–5 CKD, comparing roxadustat with placebo in NDD-CKD, and with epoetin alfa in DD-CKD were assessed. Risk of first RBC transfusion was evaluated in individual studies and within pooled NDD and DD populations.

Results: In total, 4277 patients with NDD-CKD were evaluated (2391 roxadustat; 1886 placebo). Mean ± SD baseline Hb was 9.10 ± 0.74 g/dL (roxadustat) and 9.10 ± 0.73 g/dL (placebo). The DD-CKD studies comprised 3857 patients (1929 roxadustat; 1928 epoetin alfa). Mean ± SD baseline Hb was 9.63 ± 1.30 g/dL (roxadustat) and 9.67 ± 1.30 (epoetin alfa). Roxadustat reduced the risk of RBC transfusion by 74% versus placebo in NDD patients and by 18% versus epoetin alfa in DD patients (**Table 1**).

Conclusions: Roxadustat markedly and significantly reduced the risk of RBC transfusion during anemia treatment compared with placebo in NDD CKD and, versus epoetin alfa in DD CKD in the pooled patient populations.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

Hemoglobin (Hb) Correction with Roxadustat Is Associated with Improved Iron Homeostasis in Patients with Non-Dialysis-Dependent CKD (NDD-CKD)

Steven Fishbane,[1] Chaim Charytan,[2] Dustin J. Little,[3] Stefan Tham,[4] Robert Leong,[5] Pablo E. Pergola.[6] *[1]Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]New York Hospital Queens, Division of Nephrology, Flushing, NY; [3]Clinical Research, AstraZeneca, Gaithersburg, MD; [4]Clinical Research, AstraZeneca, Gothenburg, Sweden; [5]FibroGen Inc., San Francisco, CA; [6]Renal Associates PA, San Antonio, TX.*

Background: Anemia in CKD is multifactorial, with contributions from reduced erythropoietin production and hepcidin-induced functional iron deficiency. Roxadustat, a hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by enhancing erythropoietin synthesis and increasing iron availability via reducing hepcidin and increasing iron transport. We assessed the effect of roxadustat on iron parameters in patients with NDD-CKD.

Methods: Patients were randomized to double-blind roxadustat or placebo in 3 pivotal NDD-CKD trials. Oral iron was administered without restriction per discretion of the treating physician, and intravenous (IV) iron use was limited to rescue therapy. Mean changes from baseline (BL) in Hb, hepcidin, and iron parameters were evaluated. Pooled results are reported.

Results: Overall, 4277 patients were evaluated (roxadustat N=2391; placebo N=1886). Mean eGFR was 20 ml/min/1.73 m^2 in both groups. Roxadustat was superior to placebo in increasing mean Hb from BL (9.1 g/dL for both groups) averaged over Weeks 28–52: 1.9 vs 0.2 g/dL (P<0.0001). IV iron use was required in 2.1% of roxadustat vs 4.8% of placebo patients during the first 52 weeks after randomization. Roxadustat reduced hepcidin and increased both transferrin and serum iron (Figure). Reductions in ferritin and transferrin saturation occurred predominantly in patients with the highest BL values of these parameters when assessed by quartile (>328 µg/L and >35%, respectively).

Conclusions: Roxadustat increased both serum iron and iron-carrying capacity (transferrin) while simultaneously inducing erythropoiesis and correcting anemia in patients with NDD-CKD, without the need for regular IV iron supplementation.

Health-Related Quality of Life in Roxadustat-Treated Patients with Anemia and Non-Dialysis-Dependent CKD

Daniel W. Coyne,[1] Roberto Manllo-Karim,[2] Pablo E. Pergola,[3] Carol A. Pollock,[4] Roberto Pecoits-Filho,[5,6] Tyson T. Lee,[7] Elise Hardy,[8] Kin-Hung P. Yu.[7] *[1]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [2]South Texas Kidney Specialists, P.A., McAllen, TX; [3]Renal Associates PA, San Antonio, TX; [4]The University of Sydney, Sydney, NSW, Australia; [5]Arbor Research Collaborative for Health, Ann Arbor, MI; [6]Pontificia Universidade Catolica do Parana Departamento de Medicina, Curitiba, Brazil; [7]FibroGen Inc, San Francisco, CA; [8]AstraZeneca, Gaithersburg, MD.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Anemia in CKD impacts health-related quality of life (HRQL) by reducing physical capacity and energy levels. Studies have demonstrated a direct relationship between HRQL scores and hemoglobin (Hb) levels in non–dialysis-dependent (NDD) and dialysis-dependent patients with CKD. We assessed the impact of roxadustat on HRQL in patients with NDD-CKD.

Methods: Pooled data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with NDD-CKD were assessed. Patients with data up to the time of dialysis treatment and who had pretreatment and ≥1 post-treatment HRQL measurement were included. Mean changes from baseline to Week 12 in HRQL scores were compared between the treatment groups.

Results: Least-squares mean treatment differences favored the roxadustat group at Week 12 (all *p*-values <0.05) in the majority of measures analyzed (Table). Between-group differences were larger in subgroups with lower (ie, worse) baseline scores.

Conclusions: Roxadustat demonstrated improvement in most HRQL measures vs. placebo in patients with NDD-CKD.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

PO0259

Subgroup Analyses of Efficacy of Roxadustat for Treatment of Anemia in Patients with Incident Dialysis-Dependent CKD

Robert Provenzano,[1] Jayant Kumar,[2] Steven Fishbane,[3] Anjay Rastogi,[4] Lona Poole,[5] Cameron S. Liu,[5] Dustin J. Little,[6] Kin-Hung P. Yu.[5] *[1]Wayne State University, Detroit, MI; [2]Renal Medicine Associates, Albuquerque, NM; [3]Northwell Health, Great Neck, NY; [4]University of California Los Angeles, Los Angeles, CA; [5]FibroGen Inc, San Francisco, CA; [6]AstraZeneca, Gaithersburg, MD.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism.

Methods: Pooled data from 3 pivotal phase 3 studies of roxadustat v. epoetin alfa forincident–dialysis-dependent dialysis patients (ID-DD; on dialysis for ≤4 m)were assessed. Prespecified, subgroups were analyzed for mean change from baseline (CFB) in hemoglobin (Hb) (weeks 28–52 regardless of rescue therapy) and mean monthly IV iron use (Weeks 28–52). Death, MI, and stroke (MACE), as well as heart failure or unstable angina requiring hospitalization (MACE+) were adjudicated.

Results: Roxadustat- (n=760) v. epoetin alfa-treated patients (n=770) achieved non-inferiority (NI:lower limit of 95% CI >0), and a significantly larger mean (SD) CFB in Hb (g/dL) (2.12 [1.45] v. 1.91 [1.42]), with a least-squares mean (LSM) difference of 0.22 (95% CI: 0.05, 0.40) (*p*=0.013). All subgroupswere consistent with the overall population, achieving NI for Hb CFB (Table). Subgroup analyses of mean monthly IV iron use during Weeks 28–52 were significant in favor of roxadustat v. epoetin alfa in the overall population and by age group (18–64), gender (male), race (white), region (US, Europe), baseline iron status (ferritin ≥100 ng/mL & TSAT ≥20%), baseline Hb (<8.0 and ≥8.0 g/dL), and dialysis modality (hemodialysis). HR of MACE and MACE+ were lower in the roxadustat v. epoetin alfa group: 0.70 (95% CI: 0.51, 0.96) (*p*=0.03) and 0.66 (95% CI: 0.50, 0.89) (*p*=0.005).

Conclusions: The efficacy of roxadustat vs. epoetin alfa for improving Hb level and reducing IV iron use was consistent across prespecified subgroups in the ID-DD population. Roxadustat reduced MACE and MACE+ vs. epoetin alfa.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

PO0260

Subgroup Analyses of Efficacy of Roxadustat for Treatment of Anemia in Patients with Non-Dialysis-Dependent CKD

Daniel W. Coyne,[1] Mohamed A. El-Shahawy,[2] Roberto Pecoits-Filho,[3,4] Hakan M. Gurcan,[5] Cameron S. Liu,[5] Elise Hardy,[6] John Houghton,[6] Kin-Hung P. Yu.[5] *[1]Washington University School of Medicine, St. Louis, MO; [2]Keck School of Medicine, University of Southern California, Los Angeles, CA; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]School of Medicine, Pontifical Catholic University of Parana, Parana, Brazil; [5]FibroGen Inc, San Francisco, CA; [6]AstraZeneca, Gaithersburg, MD.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism.

Methods: Data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with non–dialysis-dependent (NDD) CKD were assessed. Data from prespecified, clinically relevant patient subgroups were analyzed for: mean change from baseline (CFB) in hemoglobin (Hb) averaged over weeks 28–52 regardless of rescue therapy (primary US efficacy endpoint) and patients (%) that received rescue therapy in the first 52 weeks.

Results: Roxadustat- (n=2391) vs. placebo-treated patients (n=1886) achieved a significantly larger mean (SD) CFB in Hb level (1.85 [0.94] vs. 0.13 [1.01]), corresponding to a least-squares mean (LSM) difference of 1.72 (95% CI: 1.65, 1.79) (*p*<0.0001). The results of all subgroup analyses were consistent with those for both the primary US efficacy endpoint and the percentage of patients requiring rescue therapy in the overall NDD population (Table). Significantly fewer patients required rescue therapy during roxadustat treatment vs. placebo (8.9% vs. 31.1%), corresponding to a hazard ratio of 0.19 (95% CI: 0.16, 0.23) (*p*<0.0001). The effect was consistent in all subgroups and especially pronounced in patients with baseline Hb <8.0 g/dL (18.1% vs. 59.3%) and those with baseline eGFR <10.0 mL/min/1.73m² (14.8% vs. 48.3%).

Conclusions: The efficacy of roxadustat vs. placebo for a larger mean CFB in Hb and fewer patients that received rescue therapy was consistent across a wide range of prespecified subgroups in the NDD-CKD population.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

Risk of Transfusion in Patients with Non-Dialysis-Dependent CKD Increases with Hemoglobin Levels <10 g/dL vs. ≥10 g/dL: Pooled Results from Roxadustat Phase 3 Studies

Daniel W. Coyne,[1] Roberto Pecoits-Filho,[2,3] Anjay Rastogi,[4] Lynda Szczech,[5] Tyson T. Lee,[5] Maksym Pola,[6] Kin-Hung P. Yu.[5] *[1]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Pontificia Universidade Catolica do Parana Departamento de Medicina, Curitiba, Brazil; [4]University of California Los Angeles, Los Angeles, CA; [5]FibroGen Inc, San Francisco, CA; [6]AstraZeneca, Warsaw, Poland.*

Background: Roxadustat is a novel, orally bioavailable, heterocyclic small molecule that reversibly inhibits hypoxia-inducible factor (HIF) prolyl hydroxylase enzymes and activates HIF and transcription of HIF-responsive genes, including erythropoietin. In patients with ESRD, the risk for blood/RBC transfusion is higher in patients with hemoglobin (Hb) levels <10 g/dL vs. those with Hb ≥10 g/dL. We evaluated the efficacy of roxadustat vs. placebo on blood/RBC transfusion by Hb level in US-based patients with non–dialysis-dependent (NDD) CKD.

Methods: Data from three pivotal phase 3, randomized, placebo-controlled studies of roxadustat for the treatment of anemia in NDD patients were assessed. Patients were randomized to receive roxadustat or placebo with periodic dose evaluation/titration. Transfusion was allowed at any time if it was deemed a medical necessity by the Investigator. The incidence rate of transfusion was calculated based on Hb level categorized as: <8.0, 8 to <10, and ≥10 g/dL. Data were evaluated for the on-treatment period + 28 days after the last dose of study drug.

Results: In the overall pooled population of patients with NDD-CKD, roxadustat reduced the risk of transfusion by 74% (HR, 0.26 [95% CI: 0.21, 0.32]; p<0.0001) vs. placebo. When patient-exposure data were stratified by achieved Hb levels, the risk for transfusion increased as Hb levels decreased (Table). The incidence rate of transfusion increased approximately 4-fold in patients with Hb between 8.0 and <10.0 g/dL vs. those with Hb ≥10 g/dL regardless of treatment arm.

Conclusions: In US-based patients with NDD-CKD and anemia treated with roxadustat, the risk of transfusion was approximately 4 times higher in patients with Hb between 8.0 g/dL and <10 g/dL vs. those with Hb ≥10 g/dL.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

PO0262

Roxadustat Favorably Modifies Iron Indices in Patients with Non-Dialysis-Dependent CKD-Related Anemia

Daniel W. Coyne,[1] Simon D. Roger,[2] Willis Chou,[3] Anatole Besarab,[4] Robert Leong,[3] Tyson T. Lee,[3] Lynda Szczech,[3] Dustin J. Little,[4] Kin-Hung P. Yu.[3] *[1]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [2]Renal Research, Gosford, NSW, Australia; [3]FibroGen Inc, San Francisco, CA; [4]Stanford University School of Medicine Center for Neuroscience in Women's Health, Palo Alto, CA.*

Background: Roxadustat is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis by increasing endogenous erythropoietin and improving iron metabolism.

Methods: We analyzed data from a Phase 3, randomized, double-blind study (ANDES) comparing roxadustat to placebo for the treatment of anemia in NDD-CKD patients. 922 patients were randomized (2:1) to receive roxadustat (n=616) or placebo (n=306) thrice weekly with monthly dose titrations. Patients were encouraged to receive oral iron daily unless not tolerated. Change in Hb was compared to changes in key iron and red blood cell (RBC) parameters.

Results: All baseline (BL) parameters were comparable between the study arms. Roxadustat was superior to placebo in increasing mean Hb from BL over weeks (wks) 28-52: +2.00 vs. +0.16 g/dL (p<0.0001), respectively. As expected, Hb, iron and RBC parameters were unchanged over time in the placebo arm. In the roxadustat arm, significant erythropoiesis was noted with mean Hb increases of 1.52 and 1.89 g/dL at wks 4 and 24; mean decrease in hepcidin was –54.6 µg/L at wk 4 and DTIBC was +63.1 µg/dL at wk 8. An initial decline in mean ferritin and TSAT was noted primarily in the higher BL quartiles, with little change in the 2 lower BL quartiles. Serum iron increased by 13.6 µg/dL at wk 20 from baseline. All initial changes in iron parameters plateaued by wks 16-20, and remained unchanged thereafter. Reticulocyte Hb content at wk 20 were at baseline level, and it was maintained at Weeks 28- Week 52. Mean MCV was slightly increased by 1-4 fL at wk 4 before plateauing and stabilizing, while mean MCHC was unchanged.

Conclusions: Roxadustat lowered serum hepcidin, accompanied with initial decline in ferritin and TSAT in patients with high BL levels but little change in ferritin and TSAT in patients with low-normal BL levels despite active erythropoiesis. Maintenance of reticulocyte Hb content level during treatment reassures sufficient iron availability during erythropoiesis with roxadustat. These findings in iron parameters suggest that iron is efficiently absorbed and mobilized for erythropoiesis during anemia correction and Hb maintenance with roxadustat in NDD-CKD patients.

Roxadustat Increases Hemoglobin in Anemic Non-Dialysis-Dependent (NDD) CKD Patients Independent of Inflammation

Carol A. Pollock,[1] Simon D. Roger,[2] Roberto Manllo-Karim,[3] Maksym Pola,[4] Stefan Tham,[5] Kin-Hung P. Yu,[6] Mohamed A. El-Shahawy.[7] *[1]The University of Sydney, Sydney, NSW, Australia; [2]Renal Unit, Gosford Hospital, Gosford, NSW, Australia; [3]Gamma Medical Research, McAllen, TX; [4]Clinical Research, AstraZeneca, Warsaw, Poland; [5]Clinical Research, AstraZeneca, Gothenburg, Sweden; [6]FibroGen Inc., San Francisco, CA; [7]Keck-USC School of Medicine, Los Angeles, CA.*

Background: Inflammation is a common cause of decreased responsiveness to erythropoiesis-stimulating agents. Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by inducing endogenous erythropoietin production and increasing iron utilization via reducing hepcidin. Roxadustat efficacy has been shown in those with inflammation, as defined by baseline (BL) elevation of high sensitivity C-reactive protein (hsCRP). This pooled analysis explored the efficacy of roxadustat in correcting Hb in NDD-CKD patients across the spectrum of BL hsCRP values.

Methods: Data from three randomized Phase 3 pivotal trials in anemic patients with Stage 3–5 NDD-CKD were pooled and the efficacy of roxadustat in increasing hemoglobin (Hb) from BL was assessed. hsCRP concentration was used as a marker of inflammation; patients with hsCRP >5 mg/L were considered to have inflammation at BL. Mean Hb change from BL (CFB) to Weeks 28–52 was summarized by baseline hsCRP quintile. Roxadustat dose requirements at Week 24 were based on mean weekly dose in mg per kg of mean BL weight.

Results: Overall, 1691 roxadustat-treated NDD-CKD patients were assessed and had a mean BL hsCRP of 7.4 mg/L. Mean BL Hb measures were similar across the hsCRP quintiles (range 9.0–9.2 g/dL). In patients with BL inflammation (n=523), mean Hb CFB to Weeks 28–52 was 1.95 g/dL with roxadustat. Mean Hb CFB to Weeks 28–52 was also

similar across all hsCRP quintiles in roxadustat-treated patients (**Figure**). Mean weekly roxadustat doses at Week 24 for baseline hsCRP quintiles 1 through to 5 were comparable at 3.2, 2.9, 2.5, 3.0, and 3.0 mg/kg, respectively.

Conclusions: Roxadustat increased Hb in anemic NDD-CKD patients independent of inflammation.

Roxadustat Treatment Corrects Anemia to Hemoglobin (Hb) Values ≥10 g/dL in the Majority of Patients with Non-Dialysis-Dependent Chronic Kidney Disease (NDD-CKD)

Anjay Rastogi,[1] Roberto Pecoits-Filho,[2] Steven Fishbane,[3] Dustin J. Little,[4] Elise Hardy,[4] Kin-Hung P. Yu,[5] Robert Provenzano.[6] *[1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [4]Clinical Research, AstraZeneca, Gaithersburg, MD; [5]FibroGen Inc., San Francisco, CA; [6]Department of Nephrology, Hypertension & Transplantation St. John Hospital & Medical Center, Detroit, MI.*

Background: The KDIGO clinical practice guidelines recommend the treatment of anemia in NDD-CKD patients with Hb <10 g/dL to reduce associated symptoms and prevent the need for red blood cell transfusions. Roxadustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor studied for the treatment of anemia in patients with CKD through increasing erythropoietin synthesis and enhancing iron utilization. We studied the percentage of patients with NDD-CKD treated with roxadustat achieving Hb ≥10 g/dL.

Methods: Patients with Hb <10 g/dL and eGFR <60 mL/min/1.73 m^2 were randomized to roxadustat or placebo in 3 pivotal double-blind NDD-CKD trials (OLYMPUS, ANDES and ALPS). The cumulative percentage of patients with Hb ≥10 g/dL for at least 2 consecutive visits was analyzed monthly over 12 months of roxadustat treatment, using the number of patients remaining on roxadustat treatment at each time point as the denominator. Hb values were censored for 6 weeks following rescue therapy.

Results: In total, 2391 patients received roxadustat. Mean Hb at baseline was 9.1 g/dL and mean eGFR was 19.7 mL/min/1.73 m^2. Among patients still on roxadustat treatment, the cumulative percentage of patients with Hb ≥10 g/dL for at least two consecutive visits was 38.3%, 75.5%, and 87.0% at months 1, 2, and 3, respectively, and 96.4% at month 6 (Figure). Among patients still receiving roxadustat treatment at 12 months, the cumulative percentage with confirmed Hb ≥10 g/dL was 99.0%.

Conclusions: Roxadustat effectively raised Hb levels in NDD-CKD patients, with over 95% of patients achieving Hb ≥10 g/dL after 5 months of treatment.

Roxadustat Increases Hemoglobin in Anemic Dialysis-Dependent (DD) CKD Patients Independent of Inflammation

Mohamed A. El-Shahawy,[1] Simon D. Roger,[2] Roberto Manllo-Karim,[3] Maksym Pola,[4] Stefan Tham,[5] Lynda Szczech,[6] Carol A. Pollock.[7] *[1]Keck-USC School of Medicine, Los Angeles, CA; [2]Renal Research, Gosford, NSW, Australia; [3]Gamma Medical Research, McAllen, TX; [4]Clinical Research, AstraZeneca, Warsaw, Poland; [5]Clinical Research, AstraZeneca, Gothenburg, Sweden; [6]FibroGen Inc., San Francisco, CA; [7]The University of Sydney, Sydney, NSW, Australia.*

Background: Inflammation is a common cause of decreased responsiveness to erythropoiesis-stimulating agents. Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by inducing endogenous erythropoietin production and increasing iron utilization via reducing hepcidin. Roxadustat efficacy has been shown in those with inflammation, as defined by baseline (BL) elevation of high sensitivity C-reactive protein (hsCRP). This pooled analysis explored the efficacy of roxadustat in correcting Hb in DD-CKD patients across the spectrum of baseline hsCRP values.

Methods: Data from three randomized Phase 3 pivotal trials in anemic patients with DD-CKD were pooled and the efficacy of roxadustat in increasing hemoglobin (Hb) from BL was assessed. hsCRP concentration was used as a marker of inflammation; patients with hsCRP >5 mg/L were considered to have inflammation at BL. Mean Hb change from BL (CFB) to Weeks 28–52 was summarized by BL hsCRP quintile. Roxadustat dose requirements at Week 24 were based on mean weekly dose in mg per kg of mean BL weight.

Results: Overall, 1538 roxadustat-treated DD-CKD patients were assessed and had a mean BL hsCRP of 10.5 mg/L. Mean BL Hb measures were similar across the hsCRP quintiles (range 9.5–9.7 g/dL). In patients with BL inflammation (n=723), mean Hb CFB to Weeks 28–52 was 1.29 g/dL with roxadustat. Mean Hb CFB to Weeks 28–52 was similar across all hsCRP quintiles in roxadustat-treated patients (**Figure**). Mean weekly roxadustat doses at Week 24 for BL hsCRP quintiles 1 through to 5 were comparable at 3.9, 3.4, 3.5, 3.3, and 3.6 mg/kg, respectively.

Conclusions: Roxadustat increased Hb in anemic DD-CKD patients independent of inflammation.

PO0266

Effects of Roxadustat Treatment on Serum Parathyroid Hormone (PTH) in Hemodialysis Patients with Erythropoiesis-Stimulating Agent (ESA) Resistant Anemia

Jyunichiro Hashiguchi,[1] Satoshi Funakoshi,[1,2] Kenji Sawase,[1] Tayo Kawazu,[1] Kanako Hayashi,[1] Kosei Yamaguchi,[1] Mineaki Kitamura,[1] Takashi Harada,[1] Tomoya Nishino.[2] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki University Hospital, Nagasaki, Japan.*

Background: Roxaduastat, an oral HIF-prolyl hydroxylase inhibitor, is shown to stimulate erythropoiesis thereby improving iron metabolism. Of note, recent research suggests that iron utilization plays a key role in bone turnover in hemodialysis patients.

Methods: A total of 64 hemodialysis patients with ESA-resistant anemia despite high-dose epoetin α (3000 units 3 times weekly) therapy participated in the study after giving informed consent. Patients were switched from intravenous epoetin α to oral roxaduastat therapy (100 mg 3 times weekly), with no dose change in any of the iron supplements, calcimimetics or vitamin D formulations being used, and were assessed after 8 weeks of roxaduastat therapy for improvements in anemia, as well as for changes in parameters related to iron metabolism and bone turnover.

Results: The study included 39 men and 25 women (age, 70.8 ± 11.8 years; Hb concentration, 10.3 ± 1.2 g/dL). After 8 weeks, the Hb concentration tended to be increased ($P = 0.06$). As shown in Table, the serum iron, ferritin concentration and TSAT significantly decreased ($p < 0.05$), suggesting increased iron utilization. Again, the serum calcium concentration was significantly decreased from 8.54 to 8.36 mg/dL, while the intact-PTH (i-PTH) concentration was significantly decreased from 98.61 to 75.80 pg/mL ($P < 0.001$).

Conclusions: Switching hemodialysis patients with ESA-resistant anemia from intravenous ESA to oral roxadustat therapy may result in a decrease in their serum PTH concentrations presumably through improved iron utilization, thus potentially improving their bone mineral metabolism.

Ophthalmological Effects of Roxadustat in the Treatment of Anemia in Dialysis-Dependent and Non-Dialysis-Dependent CKD Patients: Findings from Two Phase 3 Studies

Quan D. Nguyen,[1] Yasir J. Sepah,[1,2] Yusuke Yamaguchi,[3] Tetsuro Otsuka,[3] Yoshikatsu Majikawa,[3] Michael Reusch,[4] Tadao Akizawa.[5] *[1]Byers Eye Institute, Stanford School of Medicine, Stanford, CA; [2]Ocular Imaging Research and Reading Center, Sunnyvale, CA; [3]Astellas Pharma, Inc., Tokyo, Japan; [4]Astellas Pharma Europe B.V., Leiden, Netherlands; [5]Showa University School of Medicine, Tokyo, Japan.*

Background: Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor in late-stage development for the treatment of chronic kidney disease (CKD) anemia. Nonclinical data had suggested that hypoxia-inducible factor stabilization may promote angiogenesis, increasing the risk of retinal pathologies. We herein report the 24-week ophthalmological findings from two phase 3 studies of roxadustat in Japan.

Methods: Dialysis-dependent (DD) and non–dialysis-dependent (NDD) CKD patients (pts) with anemia were randomized to roxadustat (three times weekly) or darbepoetin alfa (DA; once weekly [DD]; once every two weeks [NDD]). Doses were titrated to maintain target hemoglobin. Ophthalmological assessments (funduscopic photograph, optical coherence tomography) were performed by centralized grading; visual acuity was assessed locally.

Results: A total of 302 DD pts (150, roxadustat; 152, DA) and 262 NDD pts (131, roxadustat; 131, DA) were randomized and received ≥1 dose of study drug. Results from the ophthalmological funduscopic photograph assessments are reported in Table 1. No meaningful changes occurred in visual acuity or retinal thickness in the treatment groups of either study.

Conclusions: In DD and NDD CKD pts with anemia, the risk of developing ophthalmic abnormalities was comparable between roxadustat and DA.

Funding: Commercial Support - Astellas Pharma, Inc.

Ophthalmological Assessments

	Dialysis-Dependent		Non-Dialysis-Dependent	
Parameter	Roxadustat	Darbepoetin	Roxadustat	Darbepoetin
Pts with previous or concurrent retinal vascular disorders at baseline	62/150 (41.3%)	57/152 (37.5%)	64/130 (49.2%)	63/131 (48.1%)
Pts with new or worsening retinal hemorrhages[a] during 24-week treatment period	46/142 (32.4%)	53/145 (36.6%)	38/121 (31.4%)	51/128 (39.8%)
Pts with new retinal hemorrhages in pts with no retinal hemorrhage at baseline	18/94 (19.1%)	24/96 (25.0%)	8/62 (12.9%)	18/72 (25.0%)
Pts with new or worsening retinal hemorrhages[a] in pts with ≥1 retinal hemorrhage at baseline	28/48 (58.3%)	29/49 (59.2%)	30/59 (50.8%)	33/56 (58.9%)

[a] Any evidence of retinal hemorrhage, from "No" at baseline to "Yes," and/or an increase from baseline in the total number of retinal hemorrhages.

PO0268

Risk of Transfusion in Patients with Dialysis-Dependent CKD Increases with Hemoglobin Levels <10 g/dL vs. ≥10 g/dL: Pooled Results from Roxadustat Phase 3 Studies

Robert Provenzano,[1] Roberto Pecoits-Filho,[2,3] Anjay Rastogi,[4] Robert Leong,[5] Khalil G. Saikali,[5] Maksym Pola,[6] Dustin J. Little,[5] Kin-Hung P. Yu.[5] *[1]Wayne State University, Detroit, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Pontificia Universidade Catolica do Parana Departamento de Medicina, Curitiba, Brazil; [4]University of California Los Angeles, Los Angeles, CA; [5]FibroGen Inc, San Francisco, CA; [6]AstraZeneca, Warsaw, Poland.*

Background: Roxadustat is a novel, orally bioavailable, heterocyclic small molecule that reversibly inhibits hypoxia-inducible factor (HIF) prolyl hydroxylase enzymes and activates HIF and transcription of HIF-responsive genes, including erythropoietin. In patients with ESRD, the risk for blood/RBC transfusion is higher in patients with hemoglobin (Hb) levels <10 g/dL vs. those with Hb ≥10 g/dL. We evaluated the efficacy of roxadustat vs. epoetin alfa on blood/RBC transfusion by Hb level in US-based patients with dialysis-dependent (DD) CKD.

Methods: Data from three pivotal phase 3, randomized, active-controlled studies of roxadustat for the treatment of anemia in DD patients were assessed. Patients were randomized to receive roxadustat or epoetin alfa with periodic dose evaluation/titration. Transfusion was allowed at any time if it was deemed a medical necessity by the Investigator. The incidence rate of transfusion was calculated based on Hb level categorized as: <8.0, 8 to <10, and ≥10 g/dL. Data were evaluated for the on-treatment period + 28 days after the last dose of study drug.

Results: In the overall pooled population of patients with DD-CKD, roxadustat vs. epoetin alfa reduced the risk for transfusion by 18% (HR, 0.82 [95% CI: 0.68, 1.00]; *p*=0.0461). When patient-exposure data were stratified by achieved Hb level, the risk for transfusion increased as Hb levels decreased (Table). The incidence rate of transfusion increased approximately 5-fold in patients with Hb <10 g/dL vs. those with Hb ≥10 g/dL.

Conclusions: In US-based patients with DD-CKD and anemia treated with roxadustat, the risk for transfusion was approximately 5 times higher in patients with Hb <10 g/dL vs. those with Hb ≥10 g/dL, regardless of treatment arm.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

Table: Incidence rate of transfusion (events/100 PEY) based on Hb level and treatment group

	Roxadustat (n=874)				Epoetin alfa (n=879)			
Hb (g/dL)	Events	PEY	Transfusion Rate*	% of PEY	Events	PEY	Transfusion Rate*	% of PEY
≥10.0	72	1166.9	6.2	79.0	134	1208.8	11.1	69.3
8.0 to <10.0	93	298.1	32.3	19.5	160	507.8	31.5	29.1
<8.0	51	22.4	227.7	1.5	57	28.2	202.1	1.6

PO0269

A Phase 3, Multicenter, Randomized, Open-Label, Active Comparator Conversion Study of Roxadustat in Non-Dialysis-Dependent (NDD) Patients with Anemia in CKD

Tadao Akizawa,[1] Manabu Iwasaki,[2] Tetsuro Otsuka,[3] Yusuke Yamaguchi,[3] Michael Reusch.[4] *[1]Showa University School of Medicine, Tokyo, Japan; [2]Yokohama City University, Yokohama, Japan; [3]Astellas Pharma, Inc., Tokyo, Japan; [4]Astellas Pharma Europe B.V., Leiden, Netherlands.*

Background: Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor for the treatment of anemia in CKD. Efficacy and long-term safety of roxadustat was assessed, following conversion from darbepoetin alfa (DA), recombinant human erythropoietin (rHuEPO), or epoetin beta pegol (EBP) to roxadustat, in NDD-CKD patients (pts) with anemia. Noninferiority of roxadustat efficacy against DA was evaluated.

Methods: This study enrolled adult Japanese NDD-CKD pts receiving DA, rHuEPO, or EBP for ≥8 weeks before prescreening. Patients who had used rHuEPO or DA were randomized to receive roxadustat or DA (comparative group [CG]). EBP-using pts were allocated to receive roxadustat (referential group [RG]). The primary endpoint was change in average hemoglobin (Hb) from baseline (BL) at Weeks 18-24. Roxadustat efficacy was confirmed if the 95% CI of average Hb at Weeks 18-24 was within 10-12 g/dL; noninferiority of roxadustat to DA was confirmed if the lower limit of the 95% CI of the difference between roxadustat and DA (CGs) was above -0.75 g/dL. Treatment-emergent adverse events (TEAEs) were assessed.

Results: A total of 262 pts were randomized to CGs and received ≥1 dose of roxadustat (n=131) or DA (n=131); 70 pts were allocated to RG and received ≥1 dose. The mean (95% CI) of average Hb at Weeks 18-24 in roxadustat (CG) was 11.14 (11.01, 11.27) g/dL, confirming the efficacy of roxadustat. The difference between roxadustat and DA (CGs) in the change in average Hb from BL at Weeks 18-24 was -0.07 g/dL (95% CI: -0.23, 0.10), confirming noninferiority of roxadustat to DA. The incidence of TEAEs observed during the 24-week treatment period was 78.6% in roxadustat (CG), 70.2% in DA (CG), and 77.1% in roxadustat (RG). Common TEAEs included nasopharyngitis, CKD, hyperkalemia, and hypertension; rates of these were comparable between groups.

Conclusions: This study confirmed the efficacy of roxadustat after conversion from DA, rHuEPO, or EBP, as well as its noninferiority to DA, in NDD-CKD pts with anemia. The safety profile of roxadustat was consistent with previous reports. A final analysis of this study (including 52-week data) will be presented at the congress.

Funding: Commercial Support - Astellas Pharma, Inc.

PO0270

HIF Prolyl Hydroxylase Inhibitor Improves Exercise Endurance and Hardly Affects Instantaneous Force in Mice

Koji Takemura, Hiroshi Nishi, Takaaki Higashihara, Masaomi Nangaku. *Tokyo Daigaku, Bunkyo-ku, Japan.*

Background: Erythropoietin (EPO) and hypoxia-inducible factor (HIF) stabilizers (PH inhibitors) are efficient therapeutic modalities against anemia in CKD. Compared to EPO and EPO receptor system, extra-renal action of PH inhibitors has still not been fully investigated. Previous reports caution us about the actual misuse of PH inhibitors in doped athletes, but nonhematopoietic effects of PH inhibitors on skeletal muscles remain controversial. Metabolic shift from oxidative phosphorylation toward glycolysis in myotubes *in vitro* was previously reported. Direct pharmacological effects of PH inhibitors on skeletal muscles and exercise performance were assessed *in vivo*.

Methods: Roxadustat, one of PH inhibitors, was administered via oral gavage to 8-week-old C57BL6 mice. Plasma EPO levels and HIF-targeted gene expression were

analyzed after a single administration. Exercise ability was also assessed by treadmill exhaustion test, forelimb grip test, and electric-pulse-induced isometric plantar flexion torque measurement after a single dose or chronic 5-week treatment, in addition to which muscle weight and muscle fiber-type were also measured.

Results: Even a single administration of roxadustat increased plasma EPO levels and gene expression downstream of HIF in skeletal muscles. Mice treated with the agent for 5 weeks showed higher blood hemoglobin levels and improved exercise endurance in treadmill exhaustion test, while the treatment provided comparable results in isometric plantar flexion torque measurement. Although PH inhibitor treatment induced fast-to-slow muscle fiber-type conversion which seem beneficial to exercise endurance, better running performance with increased hemoglobin level was blunted with forced hemodilution alone.

Conclusions: Treatment with a PH inhibitor, roxadustat, improves exercise endurance principally via pharmacological hematopoietic effect and hardly affects instantaneous force in mice although it also affects skeletal myocytes at molecular levels.

PO0271

Temporal Trends in Anemia Management and Major Clinical Outcomes in Incident Dialysis Patients in Canada

Mark Canney,[1] Peter C. Birks,[2] Selena Shao,[2] Patrick S. Parfrey,[3] Ognjenka Djurdjev,[2] Adeera Levin.[1] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada; [3]Memorial University of Newfoundland, St. John's, NL, Canada*.

Background: Several jurisdictions have adopted a more conservative approach to anemia in patients receiving dialysis amid safety concerns from target hemoglobin trials. Outside of the US, it is unknown if this has contributed to a change in outcomes. In this retrospective national cohort study, we sought to examine the association between the era of anemia management and major clinical outcomes in incident dialysis patients in Canada.

Methods: The Canadian Organ Replacement Register was used to identify 35,945 adult patients who initiated hemodialysis or peritoneal dialysis from Jan 1 2007 to Dec 31 2015. Time at risk started on day 90 of dialysis and continued for a minimum of 12 months to capture outcomes via data linkage with hospital discharge diagnoses. Patients were categorized into 3 time periods anchored to landmark target hemoglobin trials and publication of anemia guidelines: Era 1 (Jan 2007-Dec 2009); Era 2 (Jan 2010-Dec 2012); Era 3 (Jan 2013-Dec 2015). Cox proportional hazards regression models were used to investigate the association between era and the primary composite outcome (acute myocardial infarction (AMI), stroke or mortality).

Results: The mean hemoglobin at dialysis initiation decreased from 102.9g/L in 2007 to 95.5g/L in 2015, corresponding with a doubling in the prevalence of hemoglobin <80g/L (8% to 17%) and a reduction in ESA use (49% to 44%). A total of 11,810 events were observed during 66,844 person years of follow-up. After multivariable adjustment, Era 3 was associated with an 8% relative risk reduction in the primary outcome compared to Era 1 (hazard ratio (HR) 0.92, 95% confidence interval (CI) 0.88-0.96), driven by a reduction in all-cause mortality (HR 0.90, 95% CI 0.85-0.94) without a reduction in AMI or stroke. In a model without era, neither hemoglobin nor ESA use was an independent predictor of mortality.

Conclusions: There have been modest declines in average hemoglobin values and ESA use among incident dialysis patients in Canada. Unlike the US, there has been no temporal reduction in stroke. Patient survival has improved over time, likely for reasons other than anemia management. An increasing number of patients are starting dialysis with a hemoglobin <80g/L, which represents a substantial shift in practice and merits further investigation in terms of patient-centered outcomes.

PO0272

Reported Caregiver Burden in CKD with and Without Anemia: A US-Based Survey

Efstathios N. Michalopoulos,[1] Marjolaine Gauthier-Loiselle,[2] Myrlene Sanon,[1] Elizabeth Serra,[2] Rebecca Bungay,[2] Diana Clynes,[3] Martin Cloutier,[2] Erin Kahle,[3] Annie Guerin,[2] Youssef M. Farag,[4] Jay B. Wish.[5] *[1]Otsuka Pharmaceutical Development & Commercialization, Inc., Princeton, NJ; [2]Analysis Group, Inc., Montreal, QC, Canada; [3]American Association of Kidney Patients, Tampa, FL; [4]Akebia Therapeutics, Inc., Cambridge, MA; [5]Division of Nephrology, Indiana University, Indianapolis, IN*.

Background: Chronic kidney disease (CKD) has a far-reaching impact that extends beyond the affected patients. An online survey was conducted to explore caregiver burden in providing care for an adult with CKD, with or without anemia.

Methods: The survey was administered in January-February 2020 to adult participants recruited from the American Association of Kidney Patients (AAKP) and a third-party recruiter, Dynata. Eligible participants provided care to an adult with CKD within the last 4 weeks. The 15-20 minute survey included questions related to caregiver and patient demographics, clinical characteristics, preferences on anemia treatment, caregiver quality of life (Burden Scale for Family Caregivers [BSFC-S]), and work productivity (Work Productivity Activity Impairment: Caregiver). Outcomes were summarized descriptively for caregivers of patients with anemia (A+) and without anemia (A-).

Results: Among 258 caregivers who completed the survey, 42.6% cared for a patient with anemia (A+; non-dialysis dependent [NDD], 38.2%; dialysis dependent [DD], 61.8%) and 57.4% cared for a patient without anemia (A-; NDD, 45.9%; DD, 54.1%). Nearly 90% identified themselves as the primary caregiver; ≥60% were aged 35 to 64 years and >70% were female. Comorbidities reported most frequently by caregivers included anxiety (A+, 43.6%; A-, 32.4%), depression (A+, 36.4%; A-, 30.4%), headache (A+, 35.5%; A-, 31.8%), and sleep disturbance (A+, 30.9%; A-, 31.1%). Most caregivers reported a high burden (BSFC-S≥15: A+, 69.1%; A-, 58.8%) and work impairment (absenteeism: A+, 19.0%; A-, 14.8%; presenteeism: A+, 37.9%; A-, 33.2%). In the A+ group, >75% of caregivers described anemia as being moderate or severe, and >90% of patients had received anemia treatment in the past month (oral iron, 45.5%; intravenous iron, 33.6%; erythropoiesis-stimulating agents, 22.7%; red blood cell transfusion, 20.9%). If a patient was to initiate a new anemia treatment, 46.4% of caregivers would prefer an oral agent, of which 41.2% prefer a once daily formulation.

Conclusions: There is substantial burden experienced by caregivers of patients with CKD, especially when anemia is present. Further studies are needed to better understand its full extent and explore support strategies for caregivers.

PO0273

Understanding Treatment of Severe Anemia due to CKD: A Descriptive Study in Non-Dialysis Medicare Advantage Prescription Drug Plan Patients

Jill Davis,[2] Brandon Suehs,[1] Yihua Xu,[1] Sushma Patel,[2] Craig G. Schilling,[2] Suvapun Bunniran,[1] Robert M. Perkins,[2] Kelly Vuong.[1] AZ-HUM *[1]Humana Inc, Louisville, KY; [2]AstraZeneca Kabushiki Kaisha, Osaka, Japan*.

Background: Chronic kidney disease (CKD) is more common in people over 65 years (38%) than in people aged 45–64 (13%) or 18–44 (7%). Anemia, a common sequela in CKD patients, affects 8-53% and is more prevalent as CKD progresses. These patients are also at greater risk for hospitalizations and emergency department (ED) visits. The objective of this study was to examine patient characteristics, treatment rates, and time to treatment among Medicare Advantage Prescription Drug Plan (MAPD) patients with CKD Stage 3-5 and severe anemia (defined as lab of Hgb <10 g/dL) within a non-dialysis dependent (NDD) cohort.

Methods: This retrospective cohort study of CKD patients with anemia used Humana claims data (medical, pharmacy, lab) from 2016-2019. The index date was the first anemia diagnosis (Hgb <10 g/dL) date after CKD diagnosis. CKD stage and dialysis independent status were classified in the 12 months pre-index. Treatments [(intravenous (IV) iron, oral iron, erythropoiesis-stimulating agents (ESA), red blood cell transfusions (RBCT)] and all-cause healthcare resource use (HCRU) were examined 12 months post-index.

Results: A total of 31,026 NDD CKD patients with anemia were identified (mean age, 75 years; 60% female). Overall, 36% had an anemia treatment. As the CKD progressed, the percentages of treated patients increased (32%, 39%, and 50% in stage 3, 4, and 5, respectively), ESA use increased (7%, 17%, and 34%), as did IV iron use (11%, 15%, and 21%). RBCT rates (9%) and oral iron use (~13%) stayed consistent across all stages. The median number of days from anemia diagnosis to first anemia treatment was 48 days. As CKD advanced, HCRU increased; in NDD patients with anemia, inpatient admissions in stage 3, 4, and 5, respectively were 46%, 53%, 59% and emergency visits were 64%, 70%, 72% in the 12 months post-index period.

Conclusions: This descriptive examination of treatment by CKD stage for NDD patients with anemia found that anemia was oftentimes left untreated, especially in the stage 3-4 CKD patients. After NDD CKD patients were diagnosed with anemia, it was almost 1.5 months before treatment was initiated. In NDD CKD patients with anemia, as stage increased, HCRU increased, highlighting the importance of care coordination as CKD progresses.

PO0274

Cost and Healthcare Resource Use in Patients with Anemia in CKD Using Linked US Claims and Electronic Health Records

Eric T. Wittbrodt,[1] Glen James,[2] Supriya R. Kumar,[3] Juan Jose Garcia Sanchez,[2] Hungta (tony) Chen,[3] Kamyar Kalantar-Zadeh,[4] James A. Sloand.[3] *[1]AstraZeneca, Wilmington, DE; [2]AstraZeneca, Cambridge, United Kingdom; [3]AstraZeneca, Gaithersburg, MD; [4]University of California - Irvine, Irvine, CA.*

Background: Anemia is a routinely occurring complication in patients with chronic kidney disease (CKD), but current data regarding its economic impact are lacking. This study described direct costs and healthcare resource utilization in non-dialysis CKD patients with and without baseline anemia in real-world practice.

Methods: This retrospective analysis of the integrated Limited Claims and Electronic Health Record (IBM Health, Armonk, NY) spanned Jan 1, 2012 to Sept 30, 2018. Patients were aged ≥18 years with ≥2 eGFR measures <60 mL/min/1.73 m^2 ≥90 days apart. Anemia was defined as any hemoglobin (Hb) value <10 g/dL observed within 6 months of confirmatory eGFR (baseline period). Total and site-specific costs and selected healthcare resource utilization were analyzed and stratified by presence of baseline anemia, Hb range, CKD stage, sex, and insurance type.

Results: Of 22,720 patients, 23% (n=5283) had baseline anemia, 77% (17,437) did not; females accounted for 60% and 56% of the patients, mean ages (± SD) were 70 (14) and 70 (12) years, and median follow-up times were 2.9 and 3.8 years, respectively. Baseline anemia prevalence by CKD stage was 18% (stage 3a), 25% (3b), 41% (4), and 73% (5). Median per patient total costs were $49012 and $31667, total hospitalization costs were $33479 and $22695, and total ER costs were $2232 and $1891, respectively. Median annual number of transfusions doubled (2 vs 1) and annual transfusion cost was 50% greater in patients with vs without baseline anemia, respectively. Slightly increased

costs were associated with male sex and were markedly increased by advancing CKD stage (>3a), baseline Hb <10, and supplemental Medicare and non-capitated insurance coverage.

Conclusions: Anemia is associated with substantially added direct cost and healthcare resource utilization experienced by patients with non-dialysis CKD, in both early and advanced stages and with lower Hb. Effective management of anemia in CKD offers an opportunity to address this ongoing burden.

Modelling the Clinical and Economic Burden of Anaemia in Patients with CKD

Oliver T. Darlington,[1] David Booth,[1] Peter D. Gabb,[1] Myrlene Sanon,[2] Efstathios N. Michalopoulos,[2] Youssef M. Farag,[3] Xinyu Wang,[4] Philip McEwan.[1,5] *[1]Health Economics and Outcomes Research Ltd., Cardiff, United Kingdom; [2]Otsuka Pharmaceutical Development and Commercialization, Inc., Princeton, NJ; [3]Akebia Therapeutics, Inc., Cambridge, MA; [4]Otsuka Pharmaceutical Europe Ltd., Slough, United Kingdom; [5]Centre for Health Economics, Swansea University, Swansea, United Kingdom.*

Background: Chronic Kidney Disease (CKD) imposes a significant societal burden. Anemia is a common complication of CKD and is independently associated with poorer patient outcomes, including CKD progression, cardiovascular (CV) events and death. The objective of this study was to develop a natural history model to characterize the consequences of anemia in patients with CKD.

Methods: A lifetime Markov model was developed to estimate the economic impact of anemia. Two cohorts aged 58 years with CKD stage 3b were modelled with and without anemia (Hb 9-10 g/dL and Hb > 12 g/dL) to estimate differences in life expectancy (LE) and quality adjusted life years (QALYs), and event incidence. Hb level was linked to CKD progression, CV hospitalization and mortality using published data. Published direct costs and utility estimates associated with CKD and event incidence were incorporated, and costs were inflated to 2019 US dollars. Costs associated with anemia treatment such as erythropoiesis-stimulating agents or supplemental iron were not considered. Future costs and benefits were discounted at 3.0% per annum.

Results: Predicted LE was 10.21 years in patients with anemia compared to 12.36 years in patients without anemia, or a reduction of 2.15 years. Decreased patient LE and reduced quality of life with anemia resulted in 2.18 fewer QALYs. Time to end stage renal disease was 10.4 years with anemia and 12.5 years without anemia. Patients with anemia experienced 25 additional CV-related hospitalizations per 1,000 patients. Total lifetime costs were higher in the non-anemic cohort due to improved LE ($342,867 vs. $316,510), however, annual costs were lower with an undiscounted saving of $2,628 per year due to reduced CV event incidence and CKD management costs.

Conclusions: This analysis supports that those without anemia have increased LE and QALYs, and account for less costs to the healthcare system. Therefore, anemia management, aligned with clinical guidelines, has the potential for better outcomes for both the patient and the healthcare system.

PO0276

Prevalence of Severe Anemia and Transfusion Risk in Medicare and Non-Medicare Populations with CKD Stages 3 and 4

Jill Davis,[2] Robert M. Perkins,[2] Allison A. Petrilla,[1] Scott B. Robinson,[1] Dakota C. Powell,[1] Anne Murunga,[1] Shambhavi Kumar,[1] Kevin Dietz.[1] *[1]Avalere Health, Washington, DC; [2]AstraZeneca, Wilmington, DE.*

Background: While 30 million people in the United States have chronic kidney disease (CKD), the real-world clinical burden of anemia in non-dialysis dependent (NDD) CKD patients is poorly documented, which we seek to address.

Methods: A retrospective cohort analysis was conducted using the 100% sample of Medicare Fee-For-Service (FFS) beneficiaries (parts A/B/D) and a convenience sample of Commercial (Com), Medicare Advantage (MA), and Managed Medicaid (MM) lives from Inovalon's Medical Outcomes Research for Effectiveness and Economics (MORE^2) Registry® linked to eGFR and hemoglobin (Hgb) values from Prognos laboratory data. Patients with ≥2 consecutive eGFR tests with eGFR 15-59 mL/min/1.73m^2 (≥90 days apart) between 1/1/2016 to 12/31/2018 were retained for analysis; patients on maintenance dialysis were excluded. Severe anemia was defined as Hgb<10 g/dL, measured within 90 days of index eGFR. Red blood cell transfusion (RBCT) during a 12-month follow up was identified using procedure codes. A logistic regression model identified baseline factors associated with receiving RBCT.

Results: A total of 1,305,354 patients were identified from Medicare FFS and 154,163 from MORE^2. Prevalence of severe anemia in the Medicare FFS cohort was 3.1% and 3.3% in the MORE^2 cohort (Table 1). Severe anemia was highest among stage 4 CKD patients at 11.3% in the FFS cohort and 13.4% in MORE^2 cohort, with prevalence among MM patients at 17.1%. Hgb value, cancer, diabetes, liver disease, and hospitalizations were risk factors for RBCT. Within the MORE^2 cohort, the odds of receiving RBCT increased by 47% for each 1 g/dL decrease in hemoglobin.

Conclusions: The proportion of severe anemia increases with worsening CKD stage in NDD patients primarily enrolled in Medicare FFS. Many clinical factors influence the odds of severely anemic NDD CKD patients receiving RBCT.

PO0277

Association of Anemia with Activities of Daily Living in CKD: The National Health and Nutrition Examination Survey (NHANES), 1999-2016

Efstathios N. Michalopoulos,[1] Di Zhao,[2] Youssef M. Farag,[3] Myrlene Sanon,[1] Fredric O. Finkelstein.[4] *[1]Otsuka Pharmaceutical Development and Commercialization, Inc., Princeton, NJ; [2]Johns Hopkins University, Baltimore, MD; [3]Akebia Therapeutics, Inc., Cambridge, MA; [4]Yale University, New Haven, CT.*

Background: Anemia is a major contributor to clinical burden and may negatively impact patient outcomes in chronic kidney disease (CKD). We assessed the impact of anemia on activities of daily living (ADLs) among participants with CKD in the US population.

Methods: A cross-sectional study (n=33,300; aged ≥20 years) using NHANES data (1999-2016) was conducted. Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI formula. Participants were classified as no CKD, CKD stage 1-2, and CKD stage 3-5 using KDIGO criteria. Anemia was defined using WHO criteria. ADL impairment was defined as "some difficulty" or worse in ≥1 activity (19 items).

Results: Mean age of participants was 46.7 years; 51.0% were female. The percentage of participants with no CKD, CKD stage 1-2, and CKD stage 3-5 was 86.4%, 7.6%, and 6.0%, respectively. Anemia prevalence in each CKD category was 4.9%, 8.7%, and 18.6%, respectively. Multivariable-adjusted prevalence of impairment in ≥1 ADL, by CKD and anemia status, is presented along with covariates in the **Table**. Compared to participants with no anemia, the adjusted prevalence ratio for impairment in ≥1 ADL was 1.06 (95%CI: 0.98-1.14; p=0.13) in no CKD, 1.14 (0.99-1.28; p=0.06) in CKD stage 1-2, and 1.20 (1.05-1.35; p=0.01) in CKD stage 3-5.

Conclusions: In a large representative sample of US adults, anemia was significantly associated with an increased prevalence of impaired ADLs in subjects who are CKD stage 3-5. The clinical implications of this association should be investigated further.

Funding: Commercial Support - Otsuka Pharmaceutical Development & Commercialization, Inc. & Akebia Therapeutics, Inc.

Adjusted prevalence (95%CI) of impairment in ≥1 ADL, by CKD and anemia category

	No CKD	CKD stage 1-2	CKD stage 3-5
No anemia	30.9 (24.3, 37.5)	32.7 (26.4, 39.1)	33.5 (27.0, 40.0)
Anemia	32.7 (25.8, 39.6)	37.3 (29.9, 44.7)	40.2 (32.9, 47.4)
p-value	0.13	0.06	0.01

Table reports percentages.

Marginally-adjusted prevalence derived using logistic regression models (age, sex, race, education, marital status, income, health insurance, employment, smoking, alcohol use, congestive heart failure, coronary heart disease, angina pectoris, heart attack, stroke, arthritis, chronic obstructive pulmonary disease, body mass index, hypertension, diabetes, and hyperlipidemia).

P-values compare anemia vs. no anemia.

PO0278

Clinical Outcomes in Patients with Anemia in CKD Using Linked US Claims and Electronic Health Records

Eric T. Wittbrodt,[1] Glen James,[2] Supriya R. Kumar,[3] Juan Jose Garcia Sanchez,[2] Hungta (tony) Chen,[3] James A. Sloand,[3] Kamyar Kalantar-Zadeh.[4] *[1]AstraZeneca, Wilmington, DE; [2]AstraZeneca, Cambridge, United Kingdom; [3]AstraZeneca, Gaithersburg, MD; [4]University of California - Irvine, Irvine, CA.*

Background: Anemia is common in pts with CKD, yet contemporary outcome data to understand the long-term clinical burden are scarce. This analysis describes selected cardiovascular and renal outcomes in non-dialysis CKD pts with and without anemia at baseline (BL) in US real-world practice.

Methods: This retrospective observational study evaluated the integrated Limited Claims and Electronic Health Record data (IBM Health, Armonk, NY). Pts were aged ≥18 y with ≥2 eGFR measures <60 mL/min/1.73 m^2 ≥90 days apart. Anemia was defined as the presence of any observed Hb <10 g/dL within ± 6 months of confirmatory eGFR (anemia BL period). In addition, the BL period for disease history was defined as the start of pt data + 6 months, and for lab measures and medications was defined as date of the second confirmatory eGFR + 6 months. Pts with active bleeding, chronic dialysis, and iron deficiency anemia were excluded. BL pt characteristics and clinical outcomes during follow-up were analyzed for the period from Jan 1, 2012 to Sep 30, 2017. Descriptive data were summarized; no inferential statistics were performed.

Results: Of the total study cohort (N=22,720), 23% (n=5283) had BL Hb <10 g/dL. The following results are for pts with and without anemia at BL, respectively. Females accounted for 60% and 57% and mean ages (± SD) were 70 (14) and 71 (12) y. Proportions by BL CKD stage were: 3a, 50% and 68%; 3b, 27% and 24%; 4, 15% and 7%; 5, 9% and 1%. Median follow-up times were 2.9 and 3.8 y. Acute coronary syndrome (ACS) events during follow-up occurred in 2.2% of pts with BL anemia and 2.3% of pts without BL anemia, heart failure hospitalizations (hHF) occurred in 5.9% and 3.7%, and stroke hospitalizations and emergency visits (S) occurred in 2.8% and 3.0% of pts. Incidence rates rates/100 pt-y were 0.8 and 0.7 for ACS, 1.6 and 0.8 for hHF, respectively, and 0.7 in both groups for S. ESRD occurred in 4% and 1%, 40% eGFR decrease in 44% and 25%, and CKD stage progression in 67% and 59% of pts. Median change in eGFR slope was –0.6 and –0.3 mL/min/1.73 m^2.

Conclusions: This analysis highlights worsened outcomes associated with anemia in CKD, particularly hHF and eGFR decline, in pts of a large US cohort.

PO0279

Prevalence of Anemia and Associated Erythropoiesis-Stimulating Agent Use in 5.9 Million Non-Dialysis CKD Patients

Danielle K. Farrington,[1] Yingying Sang,[2,3] Morgan Grams,[1] Shoshana Ballew,[2] Stephan C. Dunning,[5] Nikita Stempniewicz,[4] Josef Coresh.[2] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]OptumLabs Visiting Fellow, Cambridge, MA; [4]American Medical Group Association, Alexandria, VA; [5]OptumLabs, Cambridge, MA.*

Background: Chronic kidney disease (CKD) leads to anemia through erythropoietin deficiency and resistance, and a heightened inflammatory state. Characterizing the burden and factors associated with severe anemia (hemoglobin < 10 g/dL) is of particular interest since treatment with erythropoiesis-stimulating agents (ESAs) or other therapies is often considered at this level.

Methods: We analyzed patients in the OptumLabs® Data Warehouse, which contains de-identified claims and electronic health record data, with a complete blood count and serum creatinine measured within 30 days of each other in 2016. Patients requiring dialysis were excluded. We examined the association between low hemoglobin (Hb) categories (<9 g/dL, 9-10 g/dL, 10-11 g/dL) and age, sex, diabetes, history of cardiovascular disease (CVD), and categories of eGFR using polychotomous logistic regression to estimate adjusted relative risk ratios (RRR).

Results: Among 5,875,383 patients in 52 centers, mean age was 56 years (SD 17), and 42% were male. The prevalence of Hb <10 g/dL in CKD stages G1-2, G3a, G3b, G4 and G5 was 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were strongly associated with increased risk of anemia, even after adjustment for female sex (RRR 2.6-3.9), diabetes (RRR 1.4-1.8), history of CVD (RRR 1.7-1.9), and age (RRR 2.2-2.4 for age 75+). The frequency of ESA use in patients with hemoglobin <10 g/dL was 0.24%, 0.41%. 0.96%, and 1.0% in CKD stage G3a, 3b, 4 and 5.

Conclusions: Severe anemia was common and strongly associated with low GFR, female sex, older age, diabetes and history of CVD in a wide range of health care systems. ESA use in non-dialysis CKD patients was very uncommon.

PO0280

Lower Transferrin Saturation (TSAT) Index Is Associated with an Anemia-Independent Risk of Increased Mortality in Non-Dialysis (ND) CKD Patients

Murilo H. Guedes,[1,2] Daniel G. Muenz,[2] Jarcy Zee,[2] Brian Bieber,[2] Sandra Wachter,[8] Benedicte Stengel,[3] Ziad Massy,[3,4] Helmut Reichel,[7] David M. Charytan,[6] Michelle M. Wong,[5] Ronald L. Pisoni,[2] Bruce M. Robinson,[2] Roberto Pecoits-Filho.[2,1] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [4]Division of Nephrology, Ambroise Paré University Hospital, APHP, Boulogne-Billancourt, France; [5]The University of British Columbia, Vancouver, BC, Canada; [6]NYU Langone Health, New York, NY; [7]Nephrological Center, Villingen-Schwenningen, Germany; [8]Vifor Pharma Ltd, Glattbrugg, Switzerland.*

Background: Iron Deficiency (ID), defined by a TSAT index <20 %, is present in approximately half of ND-CKD patients, varying little by CKD stage. Distinct from approaches in conditions such as heart failure, the importance of iron reserves and the basis for iron therapy in CKD has focused primarily on supporting effective erythropoiesis. A comprehensive approach and design to estimate the impact of ID, independently from hemoglobin (Hb) levels, on mortality risk has not been explored in ND-CKD until the present.

Methods: 5144 patients from Brazil (N=294), France (N=2227), the US (N=494), and Germany (N=2129) enrolled in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps) from 2013-2019 with available TSAT were included in the analysis. We categorized patients by first available TSAT at enrollment. Hb measurements at same time as TSAT were used. Cox models were used to estimate hazard ratios (HR) of TSAT on mortality, censored at start of dialysis or kidney transplantation. Models were progressively adjusted for confounders, including demographics, comorbidities, inflammation surrogates, treatment with erythropoietin stimulating-agents and Hb.

Results: Sample characteristics were: 59% male; 45% diabetes; and mean (SD) age 69 (13) years, eGFR 28 (11) mL/min, Hb 12 (2) g/dL, TSAT 24 (2) %, ferritin 196 (214) ng/dL. TSAT levels below 25% were progressively associated with higher mortality risk, while patients with TSAT greater than 45% tended to have higher risks for mortality (Figure).

Conclusions: ID, as measured by the TSAT index, is associated with higher risk of all-cause mortality in ND-CKD patients, even after extensive adjustments for clinical, demographic and biochemical confounders, including Hb levels. Interventional studies evaluating the impact of iron supplementation and alternative targets on clinical outcomes in ND-CKD patients are needed to better inform ID management strategies.

PO0281

Lower Transferrin Saturation (TSAT) Is Associated with Worse Health-Related Quality of Life (HRQOL) in Non-Dialysis CKD (NDD-CKD) Patients Independently from Hemoglobin (Hb) Levels

Murilo H. Guedes,[1,2] Daniel G. Muenz,[2] Jarcy Zee,[2] Marcelo Lopes,[2] Sandra Wachter,[7] Benedicte Stengel,[4] Ziad Massy,[4,6] Elodie Speyer,[4] Fredric O. Finkelstein,[5] Ricardo Sesso,[3] Ronald L. Pisoni,[2] Bruce M. Robinson,[2] Roberto Pecoits-Filho.[2,1] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Universidade de Sao Paulo, Sao Paulo, Brazil; [4]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [5]Yale University, New Haven, CT; [6]Division of Nephrology, Ambroise, APHP, Paris, France; [7]Vifor Pharma Ltd, Glattbrugg, Switzerland.*

Background: Iron Deficiency (ID) is a common condition in NDD-CKD patients that is associated with poorer outcomes. However, the effect of ID on HRQOL in this population is unknown. We analyzed real world data from a multinational cohort of ND-CKD stage 3 to 5 patients to test the association between TSAT and ferritin with HRQOL.

Methods: Patients from Brazil (N=205), France (N=2015), and the US (N=293) in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps, 2013 to 2019) with TSAT, ferritin, and HRQOL data were included. We grouped patients according to TSAT and ferritin levels closest to the HRQOL measurement. Our primary analyses evaluated the associations of TSAT and ferritin with mean differences in physical component summary (PCS) and mental component summary (MCS). Secondary analyses evaluated joint TSAT and ferritin categories, as well as additional pre-specified HRQOL measures. Linear mixed models were adjusted for potential confounders including Hb level.

Results: 2513 patients were included. In the primary analyses, TSAT ≤15% and both ferritin <50 ng/mL and ≥300 ng/mL were associated with worse PCS scores, while MCS was not directionally associated with iron parameters (Figure). Patients with the composite TSAT ≤15%/ferritin ≥300 ng/mL had lower functionality scores and worse PCS, compared to those with TSAT between 20-30% and ferritin 50-299 ng/mL. Adjustment for Hb only slightly attenuated the effects, and the results were similar for subgroups of patients with Hb <11.5 vs ≥ 11.5 g/dL.

Conclusions: Low TSAT levels, and both low and high ferritin levels, are associated with poorer physical HRQOL in ND-CKD patients, even after adjustment or stratification by Hb level. Intervention studies of iron therapy on HRQOL among ND-CKD individuals are needed to confirm these findings.

PO0282

Predicting the Optimal Approach to IV Iron: Understanding the Requirements to Attain and Maintain Target Haemoglobin in Non-Haemodialysis CKD

Christopher Brown,[1] Ashraf I. Mikhail,[1] Felicity P. Cameron,[1] Giles Greene.[2]
[1]Swansea Bay University Health Board, Port Talbot, United Kingdom; [2]Cardiff University, Cardiff, United Kingdom.

Background: The UK Renal Association recommends a High-dose Low-frequency (HDLF) approach to IV iron management for non-haemodialysis (non-HD) CKD. HDLF is defined as at least 500mg per infusion with a maximum of two infusions. Reducing the frequency of repeat infusion benefits healthcare resource & patient acceptance. This study retrospectively examined IV iron strategies used to attain & maintain effective treatment response. These data may predict a future dosing strategy that is more likely to meet iron requirements in a single, or at least a minimum number of infusions.

Methods: This retrospective analysis of 170 non-HD patients examined a 12 month Hb response to a single infusion of iron isomaltoside (HDLF1); max permissible 20mg/kg/infusion. The cumulative amount of iron to attain and maintain a target Hb >100g/L was determined.

Results: Of the 170 patients 111 (65%) attained a Hb target of 100g/L with a mean single infusion dose (HDLF1) of 985mg (equating to 11.9mg/kg); the mean time to Hb target was 91 days. Repeat doses were defined as either HDLF (>500mg) or LDHF (Low dose - High frequency). Where a 2nd dose was given the mean dose for the two approaches was 946mg for HDLF and 200mg for LDHF. The number with at least 1 additional infusion given by 3, 6 & 12 months were: for HDLF n=26, 56, & 113, & for LDHF n=24, 43 & 70.

Conclusions: These data suggest that the majority of patients with a Hb <100g/L who are treated with a 12mg/kg HDLF approach to IV iron will require repeated infusions within 12 months. The maximum permissible dose in a single infusion varies by product label. In this UK study the maximum single infusion dose of 20mg/kg meant that the mean cumulative iron requirements at 3 & 6 months could have been achieved in one infusion. At 12 months this threshold was exceeded. This gives an insight into how future approaches to iron dosing could be considered.

PO0283

A Novel, Fast-Acting Iron Sucrose Formulation for CKD Patients with Iron Deficiency Anemia

Charles M. Cook,[3] Bhupinder Singh,[2,1] Stacey Ruiz,[1] Alvaro F. Guillem.[1]
[1]Renibus Therapeutics, Southlake, TX; [2]University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA; [3]CMC SQUARED, Southlake, TX.

Background: Intravenous (IV) iron is commonly used to treat iron deficiency anemia in patients with chronic kidney disease (CKD). We report the results of the physicochemical and safety profile of RBT-3, a novel iron sucrose formulation, which was assessed in a Phase 1b study conducted in healthy volunteers and subjects with chronic kidney disease (CKD) Stage 3 or 4.

Methods: Analytical testing was conducted to examine the physicochemical profile of RBT-3. Safety of RBT-3 was assessed in a Phase 1b study in healthy volunteers and subjects with CKD. RBT-3 was administered IV as a single dose of 120, 240, or 360 mg. Plasma and urine ferritin were measured at baseline, then 2 h (plasma) or 24 h (urine) through 168 h post-treatment to assess clinical response.

Results: RBT-3 particle size is similar to commercially available iron sucrose. However, RBT-3 has a lower molecular weight and higher water content than similar IV iron formulations, suggesting faster uptake and greater solubility, respectively. RBT-3 also has a negative Zeta potential, demonstrating low cytotoxic potential. The quantity of labile iron in RBT-3 is 1.48%, suggesting very low availability of free inorganic iron hydroxide, with a low cytotoxic potential. Furthermore, Fe2+, which is associated with oxidative stress, is present in much lower quantities in RBT-3 (3.4%) compared to commercially available iron sucrose (15.8%). In this Phase 1b study of RBT-3, 18 subjects were enrolled; 6 subjects (3 healthy volunteers and 3 subjects with CKD) randomized to 3 cohorts received a single dose of RBT-3 at 120, 240, or 360 mg. Mean age was 60.3 years; 66.7% of the subjects were female. Dose-dependent increases in plasma ferritin were observed in all subjects within 2 h of treatment and reached statistical significance by 8-12 h. Urine levels were increased at 24 h. Both plasma and urine ferritin levels remained elevated through 168 h (7 days). No treatment-related adverse events (AEs) were observed, and no serious AEs (SAEs) were reported.

Conclusions: RBT-3 represents a novel iron sucrose formulation with desirable physicochemical characteristics that makes it a fast-acting mediator of iron hemodynamics. This is the first report of ferritin level increases within only 2 h by an iron formulation. RBT-3 is safe and well tolerated in healthy volunteers and subjects with CKD at a single dose up to 360 mg.

PO0284

Response to Oral Iron Therapy in Children with Anemia of CKD

Sharmi Biswas,[1] Kelly Meza,[1] Haneen Aljayyousi,[1] Dmitry V. Samsonov,[2,3] Sonia Solomon,[2,3] Eduardo M. Perelstein,[1,4] Juhi Kumar,[1,4] Oleh M. Akchurin.[1,4]
Pediatric Nephrology *[1]Weill Cornell Medicine, New York, NY; [2]Westchester Medical Center, Valhalla, NY; [3]Boston Children's Hospital, Boston, MA; [4]NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY.*

Background: Anemia is a common complication of chronic kidney disease (CKD). Current guidelines recommend oral iron therapy as the initial treatment of anemia in CKD. However, the efficacy of iron therapy in children with pre-dialysis CKD has not been evaluated. Factors determining the response to oral iron in pediatric CKD remain poorly understood.

Methods: An ongoing retrospective observational study. Data were abstracted from health records of children with pre-dialysis CKD at the time of iron therapy initiation and at the next clinic visit and compared using paired T-test. Children receiving erythropoiesis-stimulating agents were excluded. Response to iron therapy was defined as improvement in both hemoglobin and hematocrit after iron therapy. Changes of serum iron were used as a surrogate measure of adherence to iron therapy. Data are presented as median (interquartile range).

Results: We identified 44 children (48% boys) who met the inclusion criteria. Median age was 11 (5-15) years, glomerular filtration rate (GFR) 46 (31-60) mL/min/1.73m^2. Ferrous sulfate was used in 86.4% of children. The interval between visits was 61 (31-120) days. Iron therapy resulted in a significant increase in transferrin saturation (14 to 21%, p<0.001) and serum iron (45 to 65 µg/dL, p<0.001). While there was an overall improvement of hemoglobin (from 10.6 to 11.2 g/dL, p=0.02), 45% of children did not respond to iron therapy. Non-responders had a significantly smaller change in serum iron after iron therapy compared to responders (3 vs. 35 µg/dL, p=0.03), likely indicating low adherence to iron therapy by non-responders. Baseline age, GFR, hemoglobin, transferrin saturation, serum iron, and serum ferritin were not different between responders and nonresponders. Baseline body weight and height Z scores were significantly lower in non-responders than in responders (-0.67 vs. 0.12, p=0.04 and -1.66 vs. -0.25, p=0.02, respectively), possibly representing differences in nutritional status.

Conclusions: This is the first study that systematically assesses response to oral iron therapy in children with pre-dialysis CKD after 2012 Kidney Disease Improving Global Outcomes (KDIGO) guidelines. Response to iron therapy may be related to medication adherence and baseline nutritional characteristics of study participants.

PO0285

Improving Knowledge of Nephrologists Regarding an Emerging Class to Treat Anemia Associated with CKD

Amy Larkin, David R. Anderson, George Boutsalis. *Medscape LLC, New York, NY.*

Background: As emerging therapies hold promise to improve treatment of anemia in patients with CKD, clinicians need to understand mechanisms of action in order to understand the potential place in therapy when available. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologist related to emerging Hypoxia-Inducible Factor Prolyl Hyproxylase Inhibitors (HIF-PHIs).

Methods: The effect of 2 online, 30-minute, CME-certified activities were analyzed. Multiple-choice knowledge and self-efficacy confidence questions were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and chi-square test (5% significance level, P <.05) assessed educational effect. Cramer's V was used to calculate the effect size (0.06-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activity launched June 20, 2019 and data were collected through July 11, 2019.

Results: In total, 167 nephrologists were included in the study. Overall improvements were seen for both activities after participation: Activity 1: N=75, P<.001, V=.156; Activity 2: N=93, P<.001, V=.162 Individual question-level improvement was also demonstrated: 21% of nephrologists (N=75, *P*<.05; V=.169) improved at correctly identifying the mechanism of action of HIF-PHIs 20% of nephrologists (N=75, *P*<.05; V=.197) improved at recognizing clinical trial data for HIF-PHIs 33% of nephrologists (N=92, *P*<.05; V=.315) improved at recognizing clinical trial data for HIF-PHIs 21% of nephrologists (N=93, *P*<.05; V=.103) improved at recognizing CVOTs for HIF-PHIs 45% (N=75) and 47% (N=92) reported increased confidence in understanding HIF PHI clinical trial data Continued educational gaps: 55% (activity 2) and 59% (activity 1) of nephrologists did not recognize the mechanism of action of emerging HIF-PHIs 46% of nephrologists did not recognize clinical trial data for emerging HIF-PHIs 62% of nephrologists did not recognize CVOT data for emerging HIF-PHIs

Conclusions: This study demonstrates the success of online, video-based CME on improving knowledge of nephrologists related to emerging treatments for anemia associated with CKD. Continued knowledge gaps were identified for future educational targets.

Online CME Successful at Improving Nephrologist Understanding of Emerging Class to Treat Anemia Associated with CKD

Amy Larkin, David R. Anderson, George Boutsalis. *Medscape LLC, New York, NY.*

Background: As emerging therapies hold promise to improve treatment of anemia in patients with CKD, clinicians need to understand mechanisms of action in order to understand the potential place in therapy when available. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologist related to emerging Hypoxia-Inducible Factor Prolyl Hyproxylase Inhibitors (HIF-PHIs).

Methods: The effect of an online, CME-certified, roundtable video discussion was analyzed to determine efficacy of online education. Three multiple-choice knowledge/competence questions and 1 self-efficacy confidence question were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and McNemar's chi-squared test (5% significance level, P <.05) assessed educational effect. Cramer's V was used to calculate the effect size (0.06-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activity launched June 27, 2019 and data were collected through August 27, 2019.

Results: In total, 62 nephrologists answered all pre-/post-assessment questions and were included in the study. Overall improvements were seen after participation in both CME activities: 24% of nephrologists (*P*<.05; V=.216) improved at correctly identifying the mechanism of action of HIF-PHIs 11% of nephrologists (*P*=.72; V=.032) demonstrated improvement at selecting the recommended use of erythropoiesis stimulating agents (ESAs) in the treatment of anemia 21% of nephrologists (*P*<.05; V=.181) improved at recognizing clinical trial data of HIF-PHIs 47% reported increased confidence in understanding of HIF stabilizers in the treatment of anemia in patients with CKD Continued educational gaps: 52% of nephrologists did not recognize the mechanism of action of emerging HIF-PHIs 47% of nephrologists did not recognize the role of ESAs in the treatment of anemia 31% of nephrologists did not recognize clinical trial data for emerging HIF-PHIs

Conclusions: This study demonstrates the success of online, video-based roundtable discussion on improving knowledge of nephrologists related to emerging treatments for anemia associated with CKD. Continued knowledge gaps were identified for future educational targets.

Treatment Pathways of Non-Dialysis-Dependent CKD Patients with Anemia: A Report from the DISCOVER CKD Retrospective Cohort

Eric T. Wittbrodt,[2] Juan J. Carrero,[3] Glen James,[1] Steven Fishbane,[4] Supriya R. Kumar,[2] Roberto Pecoits-Filho,[5,6] Juan Jose Garcia Sanchez,[1] Carol A. Pollock,[7] James A. Sloand,[2] Katarina Hedman,[8] David C. Wheeler.[9]
[1]AstraZeneca UK Ltd, Cambridge, United Kingdom; [2]AstraZeneca, Gaithersburg, MD; [3]Karolinska Institutet, Stockholm, Sweden; [4]Northwell, Manhasset, NY; [5]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [6]Arbor Research Collaborative for Health, Ann Arbor, MI; [7]University of Sydney, Sydney, NSW, Australia; [8]AstraZeneca, Gothenburg, Sweden; [9]University College London, London, United Kingdom.

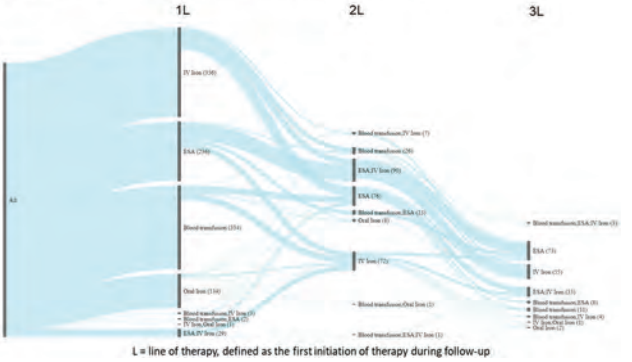
Background: Anemia is a frequent complication of chronic kidney disease (CKD), yet most patients experiencing this problem remain untreated until the initiation of renal replacement therapy. We describe treatment pathways of key medications prescribed to non-dialysis dependent (NDD) CKD patients with anemia in DISCOVER CKD.

Methods: Patients included in this analysis were extracted from the Limited Claims and EHR (LCED) data. The study cohort included patients aged >18 years with 2 estimate glomerular filtration rate (eGFR) measures <60 mL/min/1.73m2 >90 days apart between January 2008 and September 2018. The index date was the first Hb measure (<12 g/dL [females], <13 g/dL [males] per WHO criteria), or an anemia therapy (iron, ESA or blood transfusion) prescription after the 2nd eGFR measure. Exclusion criteria were: <1-year registration/medical history prior to index, active bleeding in the 30 days preceding and inclusive of index, an Hb value (only) within 30 days from transfusion or bleeding and no Hb measure within a year after CKD diagnosis. Oral iron was incompletely captured in LCED. Sankey Plots were used to visualize chronological treatment pathways (1st to 3rd line) post-index of key treatments commonly prescribed to CKD patients with anemia including: oral iron, IV Iron, ESA and blood transfusion.

Results: Preliminarily, 1446 (2.6% of anemia base cohort) patients were prescribed anemia therapies during follow-up, with IV iron (32.5%), transfusions (30.5%), ESA (21.6%), oral iron (12.2%) and ESA+IV Iron (2.7%) used as 1st-line therapies, Figure 1. Median times to 1st-line therapy initiation after index were: 108 days for oral iron, 194 days for ESA, 197 days for IV iron, and 244 days for blood transfusion.

Conclusions: In routine clinical care, anemia in NDD CKD is under treated and rescue therapies are used for anemia more often than preventive therapies.

Figure 1 – treatment pathways of key treatment in patients with NDD CKD anemia.



L = line of therapy, defined as the first initiation of therapy during follow-up

PO0288

Physician Attitudes Toward Diagnosis, Treatment Initiation, and Unmet Needs in the Management of Anemia due to CKD: Results from a Real-World Survey in Germany, Italy, and the United Kingdom

Madhusudan Kabra,[2] Tim Hammond,[2] Allison Fleetwood,[2] Lewis Harrison,[1] James Jackson,[1] Sarah Clayton.[1] *[1]Adelphi Real World, Bollington, United Kingdom; [2]Otsuka Pharmaceutical Europe Limited, Slough, United Kingdom.*

Background: Anemia, a complication of chronic kidney disease (CKD), is often defined as serum hemoglobin (Hb) levels of <12 g/dL in women and <13 g/dL in men. Traditionally, primary care physicians (PCPs) have less involvement managing and treating patients with anemia due to CKD while nephrologists play a greater role in treatment decisions. We describe current physician perceptions towards the diagnosis and treatment of anemia due to CKD and unmet needs in anemia management, in a real-world setting.

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme, a point-in-time study conducted between November 2019 and April 2020 with nephrologists and PCPs from Germany, Italy and the United Kingdom. Physicians completed an online survey providing information on their demographics, opinions on the diagnosis and treatment of anemia, and the current unmet needs they believe exist in the management and treatment of anemia. Results were descriptively analyzed.

Results: A total of 200 physicians (n=140 nephrologists; n=60 PCPs) were included in the analysis. Among those who responded, the majority (98% nephrologists; 80% PCPs) used Hb levels to diagnose anemia in CKD patients. Over two thirds of physicians mentioned using ferritin to diagnose anemia and over half reported using transferrin saturation (TSAT) levels. Approximately 4 in 5 nephrologists and PCPs (78%

nephrologists; 81% PCPs) reported Hb levels to be the most important factor that triggers initiation of anemia treatment in CKD patients. The top unmet needs in the management and treatment of CKD anemia reported by both nephrologists and PCPs were treatment for refractory/resistant patients (37% nephrologists; 40% PCPs) and the need for more oral treatments (31% nephrologists; 37% PCPs).

Conclusions: These data reinforce that Hb levels, ahead of ferritin and TSAT levels, have an important role in the diagnosis and initial prescription of therapy for anemia in CKD patients. It also highlights an unmet need for treatment of refractory/resistant patients and the desire among nephrologists and PCPs for more alternative modes of administration to treat anemia due to CKD.

PO0289

Patient Preferences Study for Treatments of Anemia in CKD Patients Not on Dialysis (NDD)

Ana filipa Alexandre,[1] Antonia Morga,[2] Caitlin Thomas,[3] Nicolas Krucien,[3] Tommi Tervonen,[3,4] Alina Jiletcovici,[5] Kevin P. Marsh.[3] *[1]Astellas Pharma Europe B.V., Leiden, Netherlands; [2]Astellas Pharma Europe Ltd, Addlestone, United Kingdom; [3]Evidera, London, United Kingdom; [4]University Medical Center Groningen, Groningen, Netherlands; [5]Astellas Pharma, Inc., Northbrook, IL.*

Background: Erythropoietin analogues (EAs) are a mainstay of treatment of anemia in adult patients with CKD but they are associated with increased risk of cardiovascular (CV) events. Furthermore, their mode of administration (intravenous or subcutaneous [SC]) may represent a barrier to some patients. As such, the aim of this study was to understand patients' valuation of attributes associated with CKD anemia treatments.

Methods: Adult (≥18 years) patients from UK, Spain, Germany, and France, who had self-reported NDD CKD anemia and were being treated with EAs, participated in this online discrete choice experiment (DCE). Patients were presented with choice tasks, each with two anemia treatment options described in terms of five attributes (mode of administration, need for iron supplementation, risk of gastrointestinal [GI] side effects, risk of major CV events, and impact on energy levels). A multinomial logit model with an error component was used to analyze participants' choices and estimate their treatment preferences. Estimated preferences were used to determine maximum level of CV and GI risk that patients were willing to tolerate to improve other treatment features.

Results: Between November 2019 and March 2020, 200 eligible patients (53% male) completed the DCE survey. The mean (SD) age was 53.78 (12.73) years; patients had been diagnosed with CKD 6.02 (7.49) years prior, and with CKD anemia 3.45 (3.44) years prior. Patients were found, on average, to value each of the five attributes associated with the treatments of CKD anemia. Patients were willing to tolerate a 5.12% (95% CI: 1.99; 8.25) increase in the risk of a major CV event and an 11.73% (95% CI: 4.96; 18.50) increase in the risk of GI side effects to switch from an at-home SC injection administered once every 2 weeks to an at-home oral pill administered three times a week. Patients would be willing to tolerate a 20.31% increase in the risk of GI side effects and an 8.86% increase in the risk of a major CV event to move from sometimes having a lot of energy to always having a lot of energy.

Conclusions: Patients would be willing to tolerate increased risks of CV and GI events to obtain an oral treatment for NDD CKD anemia and to always have a lot of energy.

PO0290

Success of CME/CE in Promoting Performance Improvements Related to Iron Deficiency Anemia Management in Women

Amy Larkin, Kelly L. Hanley. *Medscape LLC, New York, NY.*

Background: We studied the effect of online education designed to improve the clinical performance of clinicians in the OB/Gyn and primary care setting related to iron deficiency anemia (IDA) management in women.

Methods: The continuing medical education (CME) activity was a 45-minute online text- and video-based activity focusing of different aspects of anemia management in the women's health setting. The impact of the education on performance outcomes was measured with a follow-up Planned Change Assessment® (PCA) survey immediately post-education to assess planned changes in clinician practice. Survey participants were contacted 8 weeks later to assess self-reported actual changes in practice.

Results: In total, 1,239 clinicians completed the initial PCA questionnaire 275 OB/Gyn physicians, 142 OB/Gyn NPs and PAs, 446 PCPs, and 376 NP/PA in the primary care setting Of those, 1,171 (95%) indicated they planned to make changes 3,610 changes were planned, an average of 3.1 per completer Of immediate PCA completers, 92 completed the follow-up PCA 89 completers (97%) made 331 changes in practice, an average of 3.7 changes per completer Most common changes in practice: better screening for new mothers and those with abnormal uterine bleeding for anemia, consideration of IV iron in various cases, and improved counseling of patients related to causes and symptoms of IDA.

Conclusions: The outcomes gathered in this assessment provide compelling evidence that participation in an online CME activity can be successful at prompting changes in practice, and in this case prompted clinicians in the OB/Gyn and primary care setting to provide better care for women with or at risk for IDA.

Amelioration of CKD-Associated Anemia by Vadadustat in Mice Is Not Dependent on Erythroferrone

Mark R. Hanudel, Shirley Wong, Grace Jung, Bo Qiao, Victoria R. Gabayan, Tomas Ganz. *University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Vadadustat is an investigational hypoxia inducible factor prolyl hydroxylase inhibitor that increases endogenous erythropoietin (EPO) production, and has been shown to decrease hepcidin levels, improve iron status, and increase hemoglobin concentrations in anemic chronic kidney disease (CKD) patients. Increased EPO induces erythroblast secretion of erythroferrone (ERFE), which acts on the liver to suppress serum hepcidin production. To determine whether vadadustat mechanisms of action are dependent on ERFE, we treated wild type (WT) and ERFE knockout (EKO) mice, with and without adenine diet-induced CKD, with vadadustat.

Methods: 6-week-old male C57BL/6 WT and EKO mice were placed on 8-week diets that did or did not contain 0.2% adenine. For the last 3 weeks of the diets, the mice were treated with vadadustat (75 mg/kg/day via oral gavage) or vehicle solution. Mice were euthanized at 14 weeks of age (n=8 mice per group).

Results: Unlike the WT mice, EKO mice had undetectable spleen *Erfe* mRNA, minimal marrow *Erfe* mRNA, and no increase in ERFE mRNA or protein in response to vadadustat. However, in both WT and EKO CKD models, vadadustat normalized hemoglobin concentrations (**Fig 1a**), increased expression of duodenal iron transporters, tended to lower serum hepcidin, and decreased tissue iron concentrations (consistent with increased iron mobilization), suggesting ERFE-independent pro-erythropoietic effects. Vadadustat treatment was also associated with improved kidney function (**Fig 1b**) and decreased expression of renal fibrosis markers. Lastly, vadadustat affected FGF23 profiles: In non-CKD mice, vadadustat increased plasma total FGF23 out of proportion to intact FGF23, consistent with the known effects of HIF1α and EPO on FGF23 production and metabolism. However, in the CKD mice, vadadustat markedly decreased both total and intact FGF23 (**Fig 1c**), effects likely contributed to by improved kidney function.

Conclusions: Vadadustat ameliorates CKD-associated anemia independently of ERFE, and also improves kidney function and lowers FGF23 in this CKD model. How vadadustat affects CKD progression in humans may warrant future studies.

Oxidative Stress and Heme Metabolism in Red Blood Cells of Hemodialysis Patients

Gabriela F. Dias,[1,2] Gabriela B. Andrade,[2] Nadja Grobe,[1] Xia Tao,[1] Roberto Pecoits-Filho,[2,4] Peter Kotanko,[1,3] Andrea N. Moreno-Amaral.[2] *[1]Renal Research Institute, New York, NY; [2]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: We have previously described that indoxyl sulfate promotes red blood cells (RBC) ROS generation through organic anion transporter 2 as well as NADPH oxidase activity-dependent and GSH-independent mechanisms (Dias et al., 2018). However, there is little information regarding pathways of antioxidant balance to protect RBC from extensive oxidative stress that occurs during hemodialysis (HD). Intracellular free heme is degraded by Heme Oxygenase 1 (HO-1), which is regarded as the major cytoprotective enzyme (Maines, 1988; Gozzelino et al., 2010). In the current study, we assessed HO-1 activity and ROS production in RBC from healthy subjects and hemodialysis (HD) patients before and after HD.

Methods: Blood was drawn from 6 healthy individuals (CON-RBC) and 6 HD patients (HD-RBC) before (pre/HD-RBC) and after high flux HD (post/HD-RBC). Isolated RBC were stained with DCFH-DA (Abcam) for ROS measurements. To quantify HO-1, RBC were incubated with anti-HO-1 antibody (Abcam) and m-IgGκ BP-CFL 488 (Santa Cruz Biotechnology) as a secondary antibody. Samples were analyzed by flow cytometry.

Results: Our results show a 4-fold increase in ROS levels in pre/HD-RBC compared to CON-RBC. ROS levels were even further increased by 1.65-fold after HD treatment in post/HD-RBC (Figure 1). Both pre/HD-RBC and post/HD-RBC showed a similarly significant increase of 3.3-fold in HO-1 compared to CON-RBC. (Figure 1).

Conclusions: High levels of HO-1 may represent a defense against oxidative stress that occurs in ESKD and particularly during the HD session. Further research is needed to evaluate whether HO-1 overexpression could accelerate heme degradation and contribute to renal anemia.

Funding: Private Foundation Support, Government Support - Non-U.S.

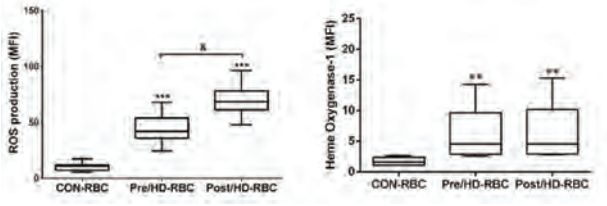

Figure 1. Reactive oxygen species (ROS) and Heme Oxygenase-1 levels in red blood cells (RBC) from healthy individuals (CON-RBC) and patients pre (Pre/HD-RBC) and post (Post/HD-RBC) hemodialysis. Data are shown as median and interquartile range of the Mean Fluorescence Intensity (MFI). ***p<0.001 and **p<0.01 represent the difference compared to CON-RBC. &p<0.001 represents the difference between pre- and post/HD-RBC.

PO0293

Daprodustat Interaction with Phosphate Binders Has Minimal Impact on Hemoglobin Values in Hemodialysis Population

Borut Cizman, Amy M. Meadowcroft, Nandita Biswas, Michael Sprys, Alexander R. Cobitz. *GlaxoSmithKline, Collegeville, PA.*

Background: Daprodustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor (PHI) in phase 3 development for the treatment of anemia of chronic kidney disease. Phosphate binders (PB) are widely prescribed for patients on hemodialysis (HD) to control hyperphosphatemia. PB may interfere with medication absorption; thus, coadministration with a PHI may potentially impact the latter's efficacy on hemoglobin (Hgb). The purpose of this analysis was to determine whether administration of daprodustat in subjects receiving PB has an impact on Hgb values in the HD population.

Methods: The 24-week GSK PHI113633 study (NCT01977482) included 216 subjects on maintenance HD previously treated with recombinant human erythropoietin (*Clin Kidney J 2019;12:139–148*). Target Hgb range was 10.0 g/dL to 11.5 g/dL. Baseline PB users were defined as a prespecified study subgroup. The difference in mean Hgb values at Week 24 between treatment groups was summarized overall and by subgroup. Comparisons were performed for the Week 24 Hgb (post hoc), as well as the final dose of daprodustat, for those receiving/not receiving PB.

Results: The majority of HD subjects received PB at baseline; 136/177 (77%) of daprodustat and 33/39 (85%) of control subjects were taking PB, with comparable phosphate control at baseline (mean [±SD] phosphate: daprodustat 1.76 mmol/L [0.56]; control 1.67 mmol/L [0.44]]). All subjects receiving PB at baseline, except two, continued them throughout the study. No meaningful difference in Hgb change from baseline (CFB) at Week 24 was noted between treatment groups. The final median dose for subjects on daprodustat was the same for those receiving and those not receiving PB (6 mg), with no meaningful difference in the Hgb at Week 24 (mean [±SD]: PB use=Yes 10.40 g/dL [0.95]; PB use=No 10.79 g/dL [0.95]).

Conclusions: These results suggest that PB use does not have a major impact on Hgb values during the 24-week study. Results of an ongoing, phase 3 dialysis study of daprodustat compared with conventional treatment are awaited to confirm these initial observations.

Funding: Commercial Support - GlaxoSmithKline

Group	Mean (±SD) baseline Hgb (g/dL) for daprodustat vs control	Mean (95% CI) difference in CFB Hgb (g/dL) at Week 24
Overall population	10.39 (0.66) vs. 10.55 (0.94)	-0.12 (-0.51, 0.27)
Baseline PB use = Yes	10.38 (0.62) vs. 10.48 (0.73)	-0.21 (-0.63, 0.21)
Baseline PB use = No	10.43 (0.77) vs. 10.94 (1.76)	0.25 (-0.72, 1.23)

PO0294

Prevalence and Severity of Anemia Between Non-Dialysis and Dialysis Outpatients Referred to Nephrology Consultation: Epidemiologic Data from 1568 Mexican Patients at a National Reference Hospital

L. M. Perez-Navarro,[1] Samantha Escorza Valdivia,[1] Alberto Sigfrido Benitez Renteria,[2] Rafael Valdez-Ortiz.[1] *[1]Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; [2]AstraZeneca, Ciudad de Mexico, Mexico.*

Background: Anemia is a frequent complication in chronic kidney disease (CKD), and is frequently associated with symptoms such as physical disability, decreased neurocognitive function, and poor quality of life. Our objective is to know the prevalence and severity of anemia between stages of CKD in patients who attended a nephrology clinic for the first time.

Methods: Transversal, descriptive, observational study. Records of adult patients who attended an outpatient nephrology clinic in the period from February 2019 to February 2020 were included. Anemia staging was performed according to the world health organization. Descriptive statistics were performed, with a 95% CI and a p-value ≤0.05.

Results: 1568 patient records were included. Mean age was 56.01 ± 16 years and 51% (804) were women. Distribution of patients by CKD stage: 9% stage 1, 11% stage 2, 12% stage 3a, 18% stage 3b, 23% stage 4, and 27% stage 5. 12% were undergoing renal replacement therapy. 53% of the population had anemia at the cut-off point of Hb<13 for men and <12 for women; stratification of anemia severity between stages of CKD is presented in figure 1. The main comorbidities and risk factors in the subjects with anemia were type 2 diabetes mellitus and hypertension (55%), proteinuria (38%), hypoalbuminemia (34%), hyperkalemia (37%) overweight or obesity (58%), hyperglycemia (45%) hypertriglyceridemia (35%) and hypercholesterolemia (31%).

Conclusions: In patients who attended for the first time an outpatient nephrology clinic, a high prevalence of anemia was found in CKD patients, being more frequent and more severe from stage 3b to stage 5. Identifying these findings will allow establishing public health policies and models of care for patients with CKD.

PO0295

Hemoglobin Requirements of Clinical Trials Involving Anemia in CKD and Implications on Future Work: A Systematic Literature Review

Youssef M. Farag,[1] Bryony Langford,[2] Najeeda Yasmeen,[2] Laura M. Sawyer,[2] Myrlene Sanon,[3] Xinyu Wang,[4] Linda Mccormick,[3] Efstathios N. Michalopoulos.[3] *[1]Akebia Therapeutics, Inc., Cambridge, MA; [2]Symmetron Ltd., London, United Kingdom; [3]Otsuka Pharmaceutical Development & Commercialization, Inc., Princeton, NJ; [4]Otsuka Pharmaceutical Europe Ltd., Slough, United Kingdom.*

Background: Anemia is a common complication in patients with chronic kidney disease (CKD), contributing to reduced quality of life and increased risk of morbidity and mortality. Erythropoiesis-stimulating agents (ESAs) are the established standard of care for anemia management in CKD patients. This review examines hemoglobin (Hb) requirements in randomized controlled trials (RCTs) of ESAs as treatment of anemia in CKD.

Methods: Embase, Medline, and Cochrane Library were searched from 1946 to November 2019 for RCTs evaluating the safety and efficacy of ESAs as treatment for adults with anemia and CKD. Descriptive analyses were performed to assess between-trial differences with respect to baseline Hb and Hb target ranges. Studies were classified by dialysis status (non-dialysis-dependent [NDD] vs dialysis-dependent [DD] vs renal transplant recipient [RTR]), and by treatment goal (correction vs conversion).

Results: Searches retrieved 3,482 records, from which 57 trials met the inclusion criteria. Thirty-seven studies reported a Hb target, including 15 correction studies (NDD, 11; DD, 3; RTR, 1), 19 conversion studies (NDD, 2; DD, 16; RTR, 1) and 3 that were mixed/unclear (DD, 2; NDD/DD, 1). The unweighted medians (range) of the mean baseline Hb in correction and conversion studies were 10.1 g/dL (7.0-11.7) and 11.2 g/dL (9.8-12.1), respectively. There were 20 different Hb target ranges used to assess efficacy; 10-12 g/dL was utilized most often (n=8). Three of 37 RCTs used a singular Hb target threshold, whilst the remaining studies used a Hb target range, which varied from narrow (0.5 g/dL) to wide (5.0 g/dL) between the lower and upper limits. Target Hb ranges used an upper limit of >12 g/dL in 21/37 RCTs (correction, 11/15; conversion, 10/19); however, only 3/21 RCTs were published after 2012 (the last update of KDIGO Clinical Practice Guideline).

Conclusions: This systematic review shows that changing Hb requirements over time are a source of difference in RCTs of ESAs for treatment of anemia in CKD. Such differences may introduce bias when using quantitative synthesis methods (e.g. network meta-analysis) to assess the comparative efficacy and safety of ESAs relative to new treatment options.

PO0296

Excessive Decrease of Hematocrit After Discontinuation of Dapagliflozin

Yoshiharu Wada,[1] Yoshiyuki Hamamoto,[2] Yoshihisa Nakatani,[3] Sachiko Honjo,[1] Yamato Keidai,[1] Yohei Seno,[1] Kanako Iwasaki,[1] Yorihiro Iwasaki,[1] Jun Fujikawa,[1] Hiroko Kakita,[1] Akihiro Hamasaki.[1] *[1]Tazuke Kofukai Medical Research Institute Kitano Hospital, Osaka, Japan; [2]Kansai Electric Power Hospital, Osaka, Japan; [3]Kindai University, Osakasayama, Japan.*

Background: Recently, sodium-glucose cotransporter 2 (SGLT-2) inhibitors were indicated to have hematopoietic effect, but it is still unclear how long the effect continues after discontinuation. In this study, we investigated changes in hematocrit, urinary gravity and HbA1c after discontinuation of SGLT-2 inhibitor in patients with type 2 diabetes.

Methods: A total of 8 patients (male: n=4, age: 54.4±11.9 [mean±SD] years, BMI: 27.1±3.4 kg/m², HbA1c: 9.2±1.2 %) with type 2 diabetes who were newly administered 5mg per day of dapagliflozin from March 2015 to September 2019 and discontinued the drug due to adverse events or side effects which did not require admission were retrospectively identified. Changes in HbA1c, hematocrit and urine specific gravity levels between before the administration and after the discontinuation of the drugs were evaluated.

Results: The drug was discontinued 8.4±6.6 months after administration due to non-benefit on glycemic control (n=4), polyuria (n=2), weight loss (n=1) and genital infection (n=1). HbA1c was not changed (-0.3±1.1 %; p=0.45) whereas urine specific gravity (0.014±0.009 g/mL; p<0.001) and hematocrit (1.63±1.99 %; p=0.04) were significantly increased at the time of discontinuation. Urine specific gravity (0.005±0.009 g/mL; p=0.12) and hematocrit (0.15±2.14 %; p=0.84) levels were returned to the levels of before drug administration 60 days after the discontinuation. After the 120 days of discontinuation, hematocrit was still continued to decrease below the level of baseline (-1.29±1.70 %; p=0.05) whereas urine specific gravity was not.

Conclusions: Our data demonstrate that the increased urine specific gravity and hematocrit return to original levels within 60 days after the discontinuation of dapagliflozin, and that hematocrit may continue to decrease below the original level even after.

PO0297

Human Mesenchymal Stem Cells Cultured in a Hollow Fiber Bioreactor Maintain Constant Levels of Exosomes in the Perfusion Medium: Relevance to the Simultaneous Production of Two Biotherapeutic Agents

Christof Westenfelder,[1,2] Anna Gooch,[1] Mikhail Skliar,[2] Sabiha Sultana Chowdhury,[1] Ping Zhang,[1] Zhuma Hu.[1] *[1]SymbioCellTech, LLC, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: We have shown that the administration of allogeneic Mesenchymal Stem Cells (MSC) to patients at high risk for Acute Kidney Injury (AKI) following on-pump cardiac surgery prevents AKI and progression to Chronic Kidney Disease (CKD). Treatment of rats with severe, progressive IRI AKI with MSC-derived exosomes affords significant survival benefits and rescues their renal function (see abstract this meeting). The current study examined the possibility to simultaneously collect MSC-derived exosomes while culturing human MSCs, both used for various therapies in renal and other diseases. This approach, if successful, would be cost saving, efficient and facilitate up-scaling of the production of both MSCs and their exosomes.

Methods: Human MSCs (20x10e6) were loaded into a hollow fiber Cell Expansion System (Quantum®, TERUMOBct; pre-conditioned for cell adhesion with Fibronectin) and expanded using αMEM with 5% human Platelet Lysate (hPL). The number of exosomes in aliquots of the perfusion medium were monitored (NanoSight instrument) throughout the course of cell expansion.

Results: MSCs reached ~ 90% confluence within 12 days, yielding 500x10e6 MSCs. The number of exosomes/nanoparticles derived from the 5% hPL per se was 4±1x10e11/mL. Post seeding of MSCs in the bioreactor, exosome numbers in the perfusate decreased and stabilized at 1-1.5x10e11/mL. The size of collected exosomes was between 60 and 100 nm.

Conclusions: The data from this pilot study demonstrate that hPL-derived exosomes or nanoparticles are taken up by the expanding MSCs, which lowers their total number in the perfusion medium. However, exsome numbers stabilized during the subsequent cell expansion, indicating that growing MSCs release high numbers of exosomes. This conclusion will be confirmed by speciating hPL- and MSC-derived exosomes, using specific markers for each type of nanoparticle. Together, these observations show promise for the efficient generation of MSCs and their exosomes to be used for various clinical applications.

Clinical Study Results Confirming a Novel Fluorescent Compound Is a Glomerular Filtration Rate (GFR) Tracer Agent in Humans

Richard B. Dorshow, Jeng-Jong Shieh, Ivan R. Riley, Thomas E. Rogers. *MediBeacon Inc., Saint Louis, MO.*

Background: A fluorescent GFR tracer agent for use in the clinic would enable a noninvasive transdermal continuous GFR detection method. This would make possible a point-of-care true GFR measurement for an individual, and possibly obviate the use of estimated GFR from ensemble equations. The plasma pharmacokinetics of the novel fluorescent compound MB-102, constructed to have the properties of a GFR tracer agent, is compared to that of iohexol, an established GFR tracer agent.

Methods: Intravenous administration of MB-102 followed immediately by iohexol (Omnipague 300) was given to 120 subjects enrolled with estimated GFR in the range from normal to stage 4 CKD. Fifteen blood draws post-administration over 12 hours were obtained. Plasma was analyzed for both agent concentrations at each time point. Analysis of MB-102 in plasma used methodology developed internally, and analysis of iohexol used the standard multi-step method employing an internal standard, drying, and reconstitution.

Results: Plasma pharmacokinetic parameters, which includes GFR, were determined from the concentration vs. time data for each agent separately using standard pharmacokinetic software. For every subject, each agent exhibited a two-compartment model, the initial compartment being the vascular to tissue equilibrium, and the terminal compartment being the renal excretion only. The terminal compartment yielded a single GFR value and was unperturbed over the approximate 10 hour time span for which the subjects were eating and taking their usual medications. The comparison of GFR from the MB-102 data to that of GFR from the iohexol data is shown in Figure 1.

Conclusions: The correlation of GFR from plasma MB-102 to that of plasma iohexol is excellent (r-squared = 0.99). Thus MB-102 is a fluorescent GFR tracer agent in humans. This result is the first step in the development of a noninvasive transdermal GFR measurement at the point-of-care.

Dialysate Exposure Does Not Compromise the Function of Bioengineered Proximal Tubules for Bioartificial Kidney

Rosalinde Masereeuw,[1] Silvia M. Mihaila,[1] Dimitrios Stamatialis,[2] Igor R. Middel,[1] Marianne C. Verhaar,[3] Karin G. Gerritsen.[3] *[1]Universiteit Utrecht, Utrecht, Netherlands; [2]Universiteit Twente, Enschede, Netherlands; [3]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.*

Background: Protein-bound uremic toxins (PBUTs) accumulate in plasma of end-stage kidney disease patients and are associated with a wide range of comorbidities. Their removal by conventional hemodialysis is severely limited, warranting the development of novel renal replacement therapies such as the bioartificial kidney (BAK). Recently, we developed bioengineered kidney tubules as functional BAK units capable of active PBUTs secretion via organic anion transporter-1 (OAT1). To accelerate their application, a comprehensive assessment under clinical-like conditions is essential. Here, we assessed the extent to which exposure to dialysate and uremic plasma would affect the viability and function of the kidney tubules.

Methods: Human conditionally immortalized proximal tubule epithelial cells equipped with OAT1 (ciPTEC-OAT1) exposed to medical-grade dialysate (10-240min) were evaluated for metabolic activity, membrane integrity (LDH release), inflammatory response (IL-6 and IL-8), oxidative stress (ROS) and OAT1 function (fluorescein uptake). Further, ciPTECs grown on biofunctionalized hollow fiber membranes were extraluminally exposed to dialysate fluid, intraluminally perfused with human uremic plasma (30min) and assessed for PBUTs clearance (indoxyl sulfate (IS), kynurenic acid (KA), L-kynurenine (L-Kyn), hippuric acid (HA) and indole-3-acetic acid (I3-AA)), determined by LC-MS/MS (n=7). Membrane integrity was evaluated by paracellular FITC-inulin leakage.

Results: Prolonged exposure (240min) of flat monolayers of ciPTEC-OAT1 to dialysate slightly reduced the metabolic activity to 80±4% (p<0.001) and OAT1 function to 81±5% (p<0.001) and an increased LDH release (from 10±2% in controls to 15±3%, p<0.05), without inducing the release of IL-6 or IL-8. After 30min, a 3.4±0.9 fold increase in ROS production was noticed. Still, exposure of ciPTEC-OAT1-containing hollow fiber membranes to dialysate enabled the concomitant clearance of five PBUTs (IS = 2980±1438; KA = 223±120; L-Kyn = 324±100; HA = 6547±1278 and I3-AA = 884±130 nmol/cm², n=6-7), without compromising the membrane integrity as observed by FITC-inulin leakage (20±4 % vs 25±5%).

Conclusions: The demonstrated functionality of bioengineered kidney tubules in PBUT clearance under clinical-like conditions advances the development of a BAK.

May the (Mechanical) Force Be with You: Modeling Shear Stress on the Glomerulus-On-a-Chip

Stefano Da Sacco,[1] Owen Richfield,[2] Valentina Villani,[1] Geremy Clair,[3] Roger E. De Filippo,[1] Laura Perin.[1] *[1]Children's Hospital of Los Angeles, Los Angeles, CA; [2]Tulane University, New Orleans, LA; [3]Pacific Northwest National Laboratory, Richland, WA.*

Background: In the glomerulus, mechanical forces generated on glomerular endothelial cells (GEC) by the passage of blood in capillaries and by the flow of ultrafiltrate between adjacent podocytes play a critical role in regulating glomerular filtration. In vivo modeling of shear stress is difficult and traditional in vitro 2D systems are unable to faithfully replicate shear and tensile stress. We have recently developed a barrier-free glomerulus-on-a-chip (GOAC) system that closely mimics architecture, physiology and function of the GFB. In this work we have further modeled shear stress on the chip and assessed how changes in mechanical forces affect the barrier formation and function.

Methods: Mathematical modeling of the shear stress on the GOAC was performed and shear stress was calculated for standard GOAC culture conditions. Using model simulations, angle of inclination and rocking frequency of the GOAC were changed to modify shear stress, and results were assessed after 5 days. Phenotypical analysis by IF were performed and function was measured by albumin-leakage assay. Podocytes and GEC were separated by FACS and transcriptomics and proteomics analysis performed.

Results: Under standard culture conditions, time-averaged shear stress generated by rocking the GOAC is equal to 0.1Pa. By changing angle of the rocking platform, shear stress could be modulated from 0 to ~4Pa exerted on the GEC with each rocking motion. Permselectivity was not significantly affected by different rocking angles (but was impaired under static conditions) after 5 days. Importantly, Gene and protein expression analysis on podocytes and GEC have identified important changes in cytoskeleton regulation, ECM-cell interaction, proliferation and transcription factors, suggesting that longer-term modification of the shear stress might significantly impact phenotypical and functional cell activity.

Conclusions: The glomerulus-on-a-chip is an ideal system to model architecture and function of the glomerular filtration barrier, including mechanical forces. Changes in shear stress affect cellular gene and protein expression in the GFB and can have long-term effects on phenotype and function. The glomerulus-on-a-chip system can provide an important in vitro tool to study the role of shear stress in physiological and pathological conditions.

Chronic AMPK Activation Reprograms Glucose Metabolism and Oxygen Respiration in Renal Tubule Epithelial Cells

Kuniko Hunter,[1] Rachel C. Evans,[2] Harold D. Love,[2] William H. Fissell.[2] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: *In vitro* human renal tubule epithelial cells (HREC) exhibit a glycolytic, dedifferentiated phenotype that limits their use in bioartificial kidney development. We have identified AMP-activated protein kinase (AMPK) and Transforming Growth Factor-β (TGFβ) as critical modulators of HREC differentiation. Here we show that inhibition of TGFβ signaling enhances increased respiration induced by activation of AMPK.

Methods: Primary HREC were seeded on polystyrene tissue culture plates (100,000 cells cm^{-2}). After one week, cells were supplemented with AMPK activator Metformin (200μM), TGFβ receptor I inhibitor SB431542 (10μM), or both. After five weeks, cell oxygen consumption (OCR) and extracellular acidification rates (ECAR) were assessed using a Seahorse XFe96 Analyzer and respiratory inhibitors oligomycin (2μM), CCCP (2μM), Rotenone (0.5μM), Antimycin A (0.5μM) and 2-deoxyglucose (50mM). Statistical differences were estimated by paired, two-tailed Student's t-test in MatLab.

Results: Metformin and Combination treatments increased cell glycolytic capacity as shown in **Fig 1A**. Metformin and Combination treatments significantly decreased ATP-coupled respiration, while increasing maximal oxidative phosphorylation capacity and non-mitochondrial respiration capacity as shown by elevated OCR following injections of Oligomycin, CCCP, and Rotenone/Antimycin A, respectively, as shown in **Fig 1B**.

Conclusions: Concomitant increases in both glycolytic and oxidative phosphorylation capacity suggest AMPK activation and TGFβ inhibition modulate cell mitochondrial and non-mitochondrial metabolic activity.

An In Vitro Model of the Glomerular Filtration Barrier Using Tissue-Derived Glomerular Basement Membrane

Dan Wang, Snehal Sant, Nicholas J. Ferrell. *Vanderbilt University Medical Center, Nashville, TN.*

Background: The glomerular filtration barrier consists of the glomerular basement membrane (GBM), podocytes and endothelial cells that regulate kidney permeability to macromolecules. Damage to podocytes increases albumin permeability, resulting in proteinuria. Interactions between podocytes and the GBM are important for regulating glomerular permeability and are not captured in standard in vitro cell culture systems. This work aims to investigate molecular permeability of the GBM and podocytes using a novel in vitro model that incorporates decellularized GBM.

Methods: GBM substrates were made by pressure compacting decellularized glomeruli from porcine kidneys against a Transwell membrane in a stirred cell. GBM was evaluated by immunofluorescence staining of decellularized glomeruli. Mouse podocytes were plated on the GBM at low and high concentrations. Transepithelial electrical resistance (TEER) was measured before molecular permeability measurements. Podocytes on GBM were imaged by staining with phalloidin and DAPI. Permeability of the GBM with and without podocytes were analyzed by measuring FITC-BSA and FITC-Ficoll diffusion through the filtration barrier.

Results: GBM characterization showed that cells are efficiently removed from the glomeruli, and the GBM retains laminin and collagen IV after decellularization. GBM alone provided a stringent barrier to diffusion of both albumin and Ficoll. Podocytes attached and spread on the GBM to further restricted albumin diffusion. TEER showed an increased resistance of GBM with podocyte compared to GBM alone. Podocytes resulted in slightly lower permeability at high seeding concentration than low concentration.

Conclusions: Interactions between the GBM and podocytes are important for regulating the permeability of the glomerulus. We developed a new in vitro model of the glomerular filtration barrier that incorporates tissue derived GBM to support podocyte culture. GBM alone restricted albumin and Ficoll diffusion and incorporation of podocytes further restricted albumin diffusion. Future work will focus on the co-culture of podocytes and endothelial cells on both sides of the GBM for evaluating the permeability of the filtration barrier and evaluate how podocyte and endothelial injury regulate permeability.

Extraction of *Escherichia coli* in Urine by New Static Electricity Technique In Vitro

Tokunori Yamamoto,[1] Shoichi Maruyama,[1] Satoshi Morita,[2] Yoshikazu Wakizaka.[2] *[1]Dept of nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]AFI Corporation, Kyoto, Japan.*

Background: The treatment results for sepsis are poor due to infectious diseases, and the mortality rate is over 25%. It is clinically significant that the detection identifies patient specimen primary causative organisms as promptly as possible to give appropriate antimicrobial treatment, and to save patients with serious infectious disease. However, it usually takes 2-3 days from the submission of the sample to the identification of the primary causative organism. We newly developed the device (PixeeMo™ approved by **AOAC® *Performance Tested*℠** Certificate No. **012002** in January 14, 2020.) with quick extraction of bacteria in drinking water by static electricity technique. In this report, we evaluated the ability of PixeeMo™ to extract *E. coli* from urine.

Methods: Samples were prepared by adding Ecoli to artificial urine. 27 mL of a dedicated buffer was added to 3 mL of the sample, and after centrifugation (8000 xg, 20 min), 27 mL of the supernatant was removed. This operation was performed 3 times. After the preparation, E. coli was extracted from each sample using PixeeMo™ less than 0.5 hour. The number of bacteria in the sample prepared on the standard agar medium was measured by colony count.

Results: The table shows results of the experiments. The components of artificial urine and E. coli were separable and the extraction results by PixeeMo were consistent with the culture method. It was also suggested that the detection limit concentration is 10cells / mL.(Table)

Conclusions: The new technique could detect clinical pathological conc. of *E. coli* in short time less than 2.0 hour. Extremely useful possibility is suggested as the new measurement technology of sepsis to reflect a diagnosis and evaluation of treatment, curative effect, very quickly.

Kidney Segmentation with Deep Learning in MRI of 40,000 UK Biobank Subjects

Taro Langner,[1] Andreas Östling,[1] Lukas Maldonis,[2] Albin K. Karlsson,[1] Daniel Olmo,[1] Dag Lindgren,[2] Andreas H. Wallin,[2] Lowe Lundin,[2] Robin Strand,[1] Håkan Ahlström,[1,2] Joel Kullberg.[1,2] *[1]Uppsala Universitet, Uppsala, Sweden; [2]Antaros Medical AB, Mölndal, Sweden.*

Background: Kidney volume and its association to several demographic and physiological parameters are subject of ongoing research. The UK Biobank (UKB) studies over half a million volunteers, examining blood samples, lifestyle, genetics, and body composition, including medical imaging for 100,000 participants, and 10,000 repeat scans. We have developed a system for automated kidney segmentation in 40,000 currently available MRI scans for image-based measurements of parenchymal kidney volume.

Methods: UKB neck-to-knee body MRI has been released for 40,264 participants (52% women), aged 44-82 (mean 64) years, with BMI 14-62 (mean 27). The kidneys are imaged in two 17s breath-hold stations with a Siemens 1.5T Aera device at (224 x 174 x 44) voxels of (2.23 x 2.23 x 4.5) mm. In this work, three operators marked cortex and medulla, excluding cysts, in 122 subjects (Fig a, b) for training and validation of a 2.5D U-Net with short skip connections. This neural network learned to segment axial slices.

Results: The network predictions matched the references in total kidney volume for a mean error below 4% (or 10 cm^3, Dice score 0.956), whereas human repeat segmentation yielded 3% (or 6 cm^3, Dice score 0.962). While imaging limitations such as motion may compound this error, similar performance is expected for future UKB releases. After 30 minutes of training, the network can process all scans within two days. Exclusion of anomalies, such as 40 cases of renal fusion, left 37,468 subjects with median voxel count volumes of 277 cm^3 for men and 220 cm^3 for women (Fig c).

Conclusions: The proposed system may ultimately provide measurements of left and right kidney volume for all imaged UKB subjects which can be analyzed and shared for further large-scale investigation of associations and longitudinal changes in kidney volume.

Funding: Other NIH Support - The Swedish Heart-Lung Foundation and Swedish Research Council (2016-01040, 2019-04756) supported this work, which used the UKB, application no. 14237., Government Support - Non-U.S.

A Simplified Fluid Dynamics Model of Ultrafiltration

Christopher R. Cardimino,[1] Michael J. Germain,[2] Yossi Chait.[1] *[1]University of Massachusetts Amherst, Amherst, MA; [2]Renal and Transplant Associates of New England, Springfield, MA.*

Background: We recently presented a novel approach for the design of personalized ultrafiltration rate (UFR) profiles during hemodialysis (HD) treatments. The success of this approach depends on an accurate parameter estimation of a simplified fluid volume dynamics during ultrafiltration.

Methods: We used a simplified model derived from a validated fluid volume model during HD comprising intravascular and interstitial pools, microvascular refilling/ filtration, and lymphatic flow. Input data used for parameter estimation are UFR profile and hematocrit (HCT) from CLIC obtained during actual HD treatments. Estimation was based on initial 30-min segment of the data and the model was validated based on the subsequent 30-min response. Model time constant and steady-state gain were obtained for a single patient at 5 treatments over a 3-week period.

Results: Estimation/validation results (Figure 1) demonstrate reasonable accuracy of the simplified fluid dynamics model. Underlying model parameters of a single patient exhibit significant variability between similar days of treatment and between treatment days (Figure 2). Both HCT response to same UFR profile (steady-state gain) and response time (time constant) vary by as much as 100%.

Conclusions: Successful estimation of fluid volume model parameters during HD is feasible which supports the concept of online design of personalized UFR profiles, A non-negligible variability of a patient's model parameters may complicate the design of personalized UFR profiles.

PO0306

Human Amniotic Membrane as a Novel Scaffold for Induced Pluripotent Stem Cell-Derived Kidney Organoids

Maria Figetakis, Kevin J. James, Richard Torres, William G. Chang. *Yale University, New Haven, CT.*

Background: Human inducible pluripotent stem cells (hiPSCs) can be differentiated into kidney organoids that could be used to tissue-engineer functional renal tissue. However, there are several challenges to therapeutic implementation. Among these is how to deliver organoids in a manner that would allow for both vascularization and filtrate outflow. Previous research has demonstrated in animal models, that kidney organoids can be perfused when implanted in the kidney subcapsular space. One limitation though is that there is no obvious filtrate outflow tract. Furthermore, in ESRD patients there would likely be significant fibrosis or even cystic disease that would prevent successful perfusion and filtrate outflow of kidney organoids implanted in a similar manner. Alternative heterotopic organoid implantation strategies should be considered. Examples include, but are not limited to, peritoneal implantation (with peritoneal dialysis catheter drainage) or tissue engineered tubular constructs for ureteral anastomoses. Here we describe a biomaterial, decellularized human amniotic membrane (dhAM), that could be used for differentiation of iPSC derived kidney organoids. Because kidney organoids will be exposed to mechanical forces in heterotopic implant locations, we examine the effects of uniaxial stretch on the structure of kidney organoid tubules.

Methods: We decellularized hAM with mild detergents, and differentiated kidney organoids in a manner previously described by the Little research group. We constructed a titanium stretch device that allowed for kidney organoid differentiation and uniaxial stretch of the dhAM acutely or over 10 days. We performed multiphoton microscopy to image the kidney organoids and then used 3D reconstructions to measure tubular volumes.

Results: We have observed that iPSC-derived kidney organoids can be differentiated on dhAM, and that uniaxial stretch of the dhAM elongates and increases tubular volumes within the kidney organoids, without tubular disruption or increased cell death.

Conclusions: dhAM is a promising scaffold for studying effects of mechanical forces on human kidney organoids *in vitro*. dhAMs could be used to facilitate the implantation of kidney organoids into the peritoneum or other heterotopic locations. The constructs have the flexibility to be used as a patch, modified into tubes after rolling, or form saclike structures.

Renal Cell-Derived Extracellular Vesicles Improve Functional Phenotype of Kidney Tubuloids

Rafael S. Lindoso,[4,2] Estela Mancheño Juncosa,[1] Fjodor Yousef Yengej,[3] Maarten B. Rookmaaker,[3] Marianne C. Verhaar,[3] Rosalinde Masereeuw.[4] *[1]Universiteit Utrecht, Utrecht, Netherlands; [2]Universidade Federal do Rio de Janeiro Instituto de Biofisica Carlos Chagas Filho, Rio de Janeiro, Brazil; [3]University Medical Center Utrecht, Utrecht, Netherlands; [4]Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands.*

Background: Kidney tubuloids (KT) are adult stem cell-derived organoid that hold great potential in therapeutic applications as cell source for bioartificial kidney (BAK). However, reproducing complete cell maturation and function remains a challenge. Extracellular vesicles (EVs) are cell-derived structures that regulate several cellular processes. In the kidney, EVs mediate intranephron communication through the transfer of bioactive molecules. This study aimed to investigate the use of renal EVs as modulator of KT phenotype by increasing the levels of organic anion transport 1 (OAT1), involved in renal waste handling, and explore their use for BAK engineering.

Methods: EVs from conditionally immortalized proximal tubule epithelial cells overexpressing OAT1 (ciPTEC-OAT1) were isolated with 100 K filters, quantified via nanoparticle tracking analysis and incubated with KT. The 24 h conditioned media (CM) of ciPTEC-OAT1, depleted or not of EVs, were used as controls. Gene expression was determined by QPCR and Western blotting. For renal tubule engineering, KT were seeded on hollow fibers and were exposed to EVs or CM. Monolayer integrity and cell polarity were analyzed by immunofluorescence and confocal microscopy.

Results: KT exposed to CM showed increased OAT1 levels (protein: 2.0±0.3-fold and mRNA: 2.8±0.5-fold). Moreover, EVs mimicked CM effects (2.6±0.4-fold), while CM EV depleted didn't induce OAT1. EVs were shown to contain OAT1 protein and mRNA as cargo. Visual observations of KT seeded on hollow fibers with CM containing EVs, presented slightly improvement in 3D tubular structure organization with the expression of tight junction protein (ZO-1) and cell polarity (apical cilia formation and Na^+/K^+-ATPase presence at the basolateral side) when compared with the control condition.

Conclusions: KT phenotype can be directed by renal EVs obtained from ciPTEC-OAT1. In addition, renal EVs can support KT to form tight monolayers on hollow fiber membranes. Further research is aimed at a full functional characterization of these bioengineered proximal tubules for application in BAK. Nitric Oxide (NO) Based Urinary Catheter Balloon Inflation Solution to Prevent Urinary Tract Infection

Alexander S. Yevzlin, Karthik Ramani, Faroug Suliman. *University of Michigan, Ann Arbor, MI.*

Background: UTI is the most common hospital acquired infection with indwelling catheters being a major risk factor and are difficult to treat due to the formation of bacterial biofilms which are resistant to systemic antibiotics. NO is an endogenously formed gas molecule known to play a key role in preventing infection by dispersing biofilm formed by a variety of bacterial strains. In this abstract, we describe the effectiveness of a novel urinary catheter balloon inflation fluid to effectively reduce catheter associated urinary tract infections (CAUTI) by providing up to 7 days of bactericidal effect via NO release.

Methods: Our innovative approach to prevent CAUTI involves employing a balloon inflation fluid using novel NO secreting materials based on using S-nitrosothiol type NO donors like S-nitrosoglutathione (GSNO) within the balloon of urinary catheters that slowly releases NO over a period of up to one week. The advantages of the use of NO in CAUTI prevention is its short half-life with a very low steady-state level immediately adjacent to the surface of the device required to achieve the desired anti-microbial effect with no risk of systemic effects when using NO secreting materials with fluxes that are near physiological levels.

Results: We performed in vitro studies using a Foley catheter placed in a long-necked flask with a shape resembling the urinary bladder and the urethra. (Fig 1) The Foley catheter retention balloon was filled with GSNO solution and the balloon was used to seal the neck of the flask. Then the flask was filled with synthetic urine inoculated with E. coli and incubated for seven days at 37 ^{0}C with horizontal shaking at 80 rpm. The results showed a 7-log reduction in planktonic bacterial growth (Fig 2) and a 3-log reduction in biofilm (Fig 3) of the GSNO Foley balloon solution compared to the control.

Conclusions: These data suggest that NO-based urinary catheter balloon fluid results in significant anti-microbial effects in our in vitro model of CAUTI.

Feature-Rich Covalent Stains for Interrogation of Kidney Tissue

Chenyi Mao, Min Yen Lee, Joshua C. Vaughan. *University of Washington, Seattle, WA.*

Background: Fluorescence microscopy is a workhorse tool in biomedical imaging but often poses significant challenge to practitioners in achieving bright or uniform labeling. In addition, while antibodies are effective specific labels, they often suffer poor penetration in thick tissues, loose binding in heavily fixed or processed specimens (e.g., FFPE tissue), high cost, and inconsistent reproducibility or commercial availability. Thus, it would be highly useful to develop a simple yet robust labeling alternative that could rapidly produce even staining for thick tissues and be compatible with a wide range of sample processing or clearing methods.

Methods: We use conventional fluorescent dyes to covalently label abundant chemical functional groups on kidney tissues. These include the use of amine-reactive

dyes for proteins and aldehyde-reactive dyes for carbohydrates. We term this approach Fluorescent Labeling of Abundant Reactive Entities (FLARE).

Results: We first showed FLARE's utilities in freshly fixed mouse kidney tissues (~100 μm) using super-resolution fluorescent microscopy. Within glomeruli, the carbohydrate stain specifically labeled the basement membranes of the capillary loops and the mesangial matrix, while the amine stain outlined cell boundaries and the intricate details of interdigitated podocyte epithelial cells that are a major component of the glomerular filtration barrier (**Fig. A**). In proximal convoluted tubule, the basement membrane was also labeled by the carbohydrate stain, and the amine stain revealed mitochondria and brush border microvilli (**Fig. B**). Then we stained optically cleared FFPE human kidney tissues (~50 μm) without performing antigen retrieval (**Fig C**), revealing more general features. Furthermore, FLARE does not perturb antigenicity, where immunolabeling of proteins can be easily integrated afterwards (data not shown).

Conclusions: We have shown that FLARE reveals abundant details in a wide range of kidney tissue processing methods using super-resolution and cleared-tissue microscopy, and is compatible with other staining modalities.

Funding: NIDDK Support, Other NIH Support - R01

Ex Vivo Perfusion and Initial Function of a Recellularized Human-Scale Bioengineered Kidney

Joseph S. Uzarski,[1] Emily C. Beck,[1] Emily Russell,[1] James Jaffe,[1] Ron Shapiro,[3] Sander Florman,[2] Dominique Davidow,[1] Thomas Gilbert,[1] Jeff Ross.[1] *[1]Miromatrix Medical, Inc., Eden Prairie, MN; [2]Mount Sinai Health System, New York, NY; [3]Recanati/Miller Transplantation Institute at Mount Sinai, New York, NY.*

Background: The need for more transplantable kidneys is greater than ever, with nearly 100,000 patients actively waiting for a kidney. To meet this growing demand, our team is developing a fully transplantable bioengineered kidney (BEK) by seeding cells into perfusion-decellularized porcine kidney scaffolds. Previously, orthotopic transplantation of HUVEC-only BEKs in pigs resulted in 83.3% (n=5/6 pigs) renal perfusion at 7 days post in vivo implantation. Building on these results, the focus of the current study was to recellularize the glomerulus of a clinically relevant whole kidney matrix and then assess the preliminary filtration function.

Methods: Adult porcine kidneys were decellularized via detergent perfusion through the vasculature. Primary glomerular cells were isolated from fresh porcine kidneys or rejected human kidneys. The porcine matrix was then seeded with either human umbilical vein endothelial cells (HUVECs), HUVECs and porcine glomerular cells as a model system, or HUVECS and human glomerular cells. The recellularized grafts were then cultured using a custom perfusion recellularization bioreactor until sufficient cellular coverage of the vasculature was obtained through nondestructive metabolic markers. Both HUVEC-only and co-culture BEKs were then implanted in an *ex vivo* blood loop for 30 minutes, where ureter effluent was collected and analyzed for filtration function.

Results: Sufficient histological vascular coverage with endothelial cells and thromboresistance with vascular patency was found for grafts with a minimum glucose consumption rate of 20 mg/hr. From the *ex vivo* blood loop test, the ureter effluent hematocrit concentration in the co-culture BEK was found to be undetectable. In comparison, the endothelial-only BEK and the pig's blood hematocrit levels were both 22%. Finally, the addition of glomerular cells in the BEK restored physiological flow rates of ureter effluent.

Conclusions: These results demonstrated human cellular engraftment and growth, long-term vascular patency, sustained hemoperfusion, removal of processed filtrate, and early signs of filtration and waste clearance in BEKs, which moves the field closer to an alternative for kidney transplantation.

Stiffening of Decellularized Tubular Basement Membrane Regulates Renal Tubular Epithelial Cell Function

Snehal Sant, Dan Wang, Nicholas J. Ferrell. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Damage to renal proximal tubular epithelial cells (RPTEC) plays an important role in chronic kidney disease. Epithelial cells are supported by a specialized extracellular matrix called the basement membrane (BM). The structure of the BM is altered in various kidney diseases such as diabetic nephropathy and may result in increased BM stiffness. We have developed a novel cell culture model that utilizes tissue derived tubular basement membrane (TBM) with tunable stiffness as a culture substrate for RPTEC. The aim of this study was to determine if TBM stiffening promotes activation of pro-fibrotic signaling pathways and/or regulates RPTEC differentiation.

Methods: TBM was isolated from decellularized porcine kidneys. TBM cell culture substrates were made by pressure compacting the TBM on Tranwell inserts. Conditionally immortalized mouse RPTEC were grown TBM substrates. To induce stiffening, TBM was treated with the chemical crosslinker genipin. Decellularized TBM was characterized by western blot and immunofluorescence staining. Viability and morphology of RPTEC were performed on TBM of varying stiffnesses. Real-time PCR was performed on RPTEC to evaluate the effect of stiffness on multiple genes related to kidney fibrosis and RPTEC differentiation.

Results: Western blot analysis of decellularized TBM showed the presence of laminin and collagen IV and absence of lamin B1 showing proper decellularization of TBM. Genipin treatments (0.05% and 0.5%) resulted in average stiffness of 2 kPa and 3.2 kPa respectively, compared to 0.5 kPa for untreated TBM. Neither decellularization nor genipin modification had a significant effect on cell viability. Pro-fibrotic downstream targets of YAP activation (CTGF, AREG, and ANKRD1) were upregulated on stiff TBM substrates. Additionally, stiffness regulated expression of cell-cell junction markers E-cadherin and N-cadherin.

Conclusions: A new cell culture model was developed using tissue derived TBM as a culture substrate for tubular epithelial cells. Stiffness of the TBM was tuned using genipin. Increased TBM stiffness upregulated pro-fibrotic targets of YAP activation and altered RTPEC cell differentiation. These data show that stiffness significantly affects renal tubular cell function and suggest that TBM stiffening in chronic kidney disease may play a role in disease progression.

HIF-PHI Improves Anemia and Controls Circulating FGF-23 in a CKD Model

Megan L. Noonan, Pu Ni, Rafiou Agoro, Elizabeth A. Swallow, Matthew R. Allen, Kenneth E. White. *Indiana University School of Medicine, Indianapolis, IN.*

Background: The phosphaturic hormone FGF23 is a critical factor in chronic kidney disease-mineral and bone disorder (CKD-MBD), with elevated levels in blood associated with increased odds for patient mortality (>6-fold). Anemia is a potent driver of FGF23 expression, and patients with CKD ultimately develop anemia as the kidneys lose the ability to produce erythropoietin (EPO), in concert with FGF23-mediated alterations in mineral metabolism. Our goal was to investigate a HIF-PHI (hypoxia-inducible factor prolyl hydroxylase inhibitor) for effects on anemia-dependent FGF23 levels and key outcomes in a mouse model of CKD.

Methods: Female C57BL6 mice were fed a casein control or adenine-containing diet to induce CKD, which resulted in markedly elevated iFGF23 and BUN, hyperphosphatemia, and anemia. After 12 weeks of CKD induction, mice were treated with the HIF-PHI BAY 85-3934 ('BAY'; Molidustat) at a human equivalent dose every other day for 3 weeks.

Results: Compared to saline controls, BAY elevated serum EPO and restored CBCs to normal levels in CKD mice. iFGF23 was significantly elevated in saline-treated CKD mice (120-fold, $p<0.01$). Importantly, circulating iFGF23 was significantly attenuated (>60%; $p<0.05$) in BAY-treated mice with CKD, coinciding with downregulated renal Egr-1 expression ($p<0.01$). Renal 1,25D anabolic Cyp27b1 and catabolic Cyp24a1 mRNAs were up and downregulated, respectively, in BAY-treated CKD mice. This extended treatment resulted in decreased BUN ($p<0.01$) and reduced expression of renal fibrosis markers ($p<0.01$). The bone marrow Erfe, Transferrin receptor, and EpoR mRNAs were all upregulated ($p<0.05$-$p<0.01$), and liver hepcidin expression was downregulated in both control and CKD groups treated with BAY ($p<0.05$-$p<0.01$). HIF activation in osteoblasts/osteocytes is associated with increased bone mass, therefore we investigated femur trabecular parameters and cortical porosity, however saw no effect with BAY over this time course. Serum alkaline phosphatase was significantly elevated in CKD-BAY mice compared to CKD controls ($p<0.01$), suggesting increased osteoblast activity.

Conclusions: Collectively, these results support that resolving anemia using a HIF-PHI may improve kidney function and lower FGF23 during CKD, potentially providing modifiable outcomes beyond improving iron utilization for this patient population.

Second Harmonic Generation and Fluorescence Imaging Reveal Collagen Fibrils and Cell Nuclei in Mature Randall Plaque

Victor Hugo Canela,[1] Sharon B. Bledsoe,[1] Seth Winfree,[1] Angela R. Sabo,[1] Elaine M. Worcester,[2] Tarek M. El-Achkar,[1] James C. Williams.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Chicago, Chicago, IL.*

Background: The formation of calcium oxalate (CaOx) stones on Randall's plaque (RP) is a common phenomenon (perhaps 25% of CaOx stones), yet this mechanism of stone formation is still poorly understood. The objective of the study was to devise novel techniques to study RP structure.

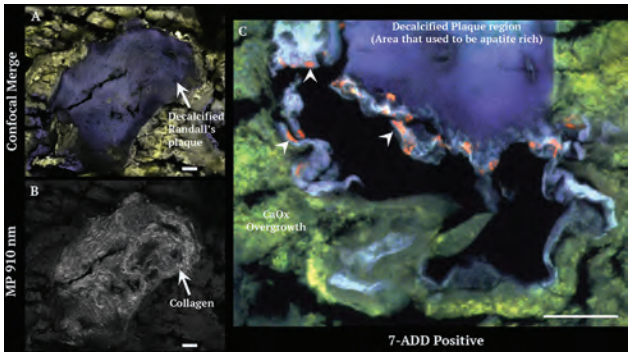
Methods: Micro CT was used to orient RP stones for decalcification and sectioning. Sections were examined for collagen using Second Harmonic Generation (SHG)

signals with multiphoton excitation. Other sections were stained with the DNA marker 7-aminoactinomycin D (7-AAD).

Results: SHG showed collagen fibrils in the plaque but not in the CaOx overgrowth region. Demineralized RP displayed autofluorescence in the far-blue region, as we have previously described in mineralized RP. Staining of plaque sections with the DNA marker, 7-AAD, confirmed the presence of cell nuclei within mature RP.

Conclusions: Our results show that collagen fibrils and cell nuclei are present in RP. The nature of cells and their role in plaque formation are yet to be determined. Our data suggest that these cells contain ordinary nuclear morphology and were well-preserved within the mature plaque. The presence of cell nuclei in the plaque raises critical questions about the role of apoptosis/necrosis and survival in this mineralized environment. Future studies exploring organization of collagen and the nature of cells in plaque will be invaluable in understanding plaque and stone pathogenesis.

Funding: NIDDK Support



Mature Randall's plaque (RP) contains collagen and cell nuclei. **A.** Representative image of a decalcified RP stone. The white arrow is pointing to the decalcified plaque area in the far-blue range spectrum. Its second harmonic generation counterpart image (**B**) shows collagen within the plaque area (white arrow). **C.** Fluorescent staining with the DNA marker 7-AAD clearly depicts cell nuclei in regions of RP (arrowheads).

PO0314

Cell Cycle Acceleration in Parathyroid Glands Is Caused by the Suppression of LncRNA Gas5 Expression in the Presence of a High-Phosphorus Diet in an Adenine-Induced CKD Rat Model

Taketo Uchiyama, Ichiro Ohkido, Yatsumu Saito, Akio Nakashima, Takashi Yokoo. *Jikei University School of Medicine, Minato-ku, Japan.*

Background: Chronic kidney disease (CKD), especially secondary hyperparathyroidisim (SHPT), is strongly associated with systemic calcification, including that in blood vessels. Therefore, it is important to elucidate its underlying pathological mechanism. SHPT is characterized by an unusually increased proliferation of parathyroid cells. We analyzed the expression of multiple cyclins, cyclin-dependent kinases (CDKs) and CDK inhibitors and demonstrated that the accelerated cell cycle in SHPT is caused by a reduction in *CDKN1B* expression (ASN 2019). To investigate the mechanism underlying SHPT development, we analyzed factors regulating *CDKN1B* expression in the parathyroid gland using two phosphorus-containing diets in a rat model of adenine-induced CKD.

Methods: CKD was induced by a diet containing 0.75% adenine. For 5 days, few rats in the CKD and control groups were fed a diet containing 0.9% phosphorus, and the remaining were fed a diet containing 1.3% phosphorus. We investigated the expression levels of approximately 20 miRNAs, such as miR-221, known to regulate *CDKN1B* expression, as well as the long noncoding RNA Gas5, using TaqMan probes for quantitative polymerase chain reactions.

Results: There were no significant differences in miRNA expression levels among the four groups (Figure 1). Gas5, known to be downregulated in prostate cancer cell, directly upregulates *CDKN1B* expression and further interacts with E2F1, which binds and activates CDKN1B. This strengthens the binding between E2F1 and CDKN1B stronger. It was observed that the expression of Gas5 was significantly decreased when the high-phosphorus diet was added to the CKD environment, and *E2F1* expression did not change significantly (Figure 2).

Conclusions: These results suggest that parathyroid cell proliferation might be due to the suppression of Gas5 expression in response to the addition of the high-phosphorus diet to the CKD environment, with a subsequent reduction in *CDKN1B* expression.

Treatment with β,γ-Methyleneadenosine 5′-Triphosphate Prevents Arterial Media Calcification in a Warfarin Rat Model

Britt Opdebeeck,[1] Isabel Orriss,[2] Jessal J. Patel,[2] Geoffrey Van den bergh,[1] Patrick D'Haese,[1] Anja Verhulst.[1] *[1]Universiteit Antwerpen Laboratorium voor Pathofysiologie, Wilrijk, Belgium; [2]The Royal Veterinary College Department of Comparative Biomedical Sciences, London, United Kingdom.*

Background: Arterial media calcification (AMC) is a severe complication in patients with chronic kidney disease, diabetes and osteoporosis. *In vitro* studies showed that the synthetic P2X receptor agonist β,γ-meATP is a potent inhibitor of vascular smooth muscle cell (VSMC) calcification. Here, we aimed to evaluate whether β,γ-meATP prevents the development of AMC in a rat model of warfarin-induced AMC.

Methods: To induce AMC, rats received a diet containing 0.30% warfarin + 0.15% vitK1 throughout the entire study and were subjected to daily i.p. treatments with vehicle (n=10) or 2 mg/kg/day β,γ-meATP (n=10) from start of the study until sacrifice at wk7. Four rats on a standard chow diet were included as a control group. Serum calcium (Ca) and phosphorus (P) levels were analyzed at sacrifice. To evaluate the bone-like switch of VSMCs, aortic mRNA expression of TNAP and SOX9 were analyzed by qPCR. AMC was evaluated by analysis of total Ca content in the arteries and quantification of the area % calcification on Von Kossa stained aortic sections. To determine arterial stiffness, ultrasound-based pulse wave velocity (PWV) was evaluated in the abdominal aorta.

Results: Serum P levels were unchanged in all groups while serum Ca was significantly lower in rats treated with β,γ-meATP vs vehicle group. Exposure to warfarin induced distinct calcification in the aorta and peripheral arteries in vehicle treated rats which led to an increase in PWV score. Interestingly, daily treatment with β,γ-meATP significantly reduced the Ca content in the aorta (mean ± SEM; vehicle 1.49 ± 1.51 mg Ca/g wet tissue vs β,γ-meATP 0.38 ± 0.20 mg Ca/g wet tissue; $p<0.05$) and peripheral vessels which was further reinforced by a significant ($p<0.01$) reduction in aortic Von Kossa positive area % vs vehicle group. However, β,γ-meATP did not significantly affect PWV scores. Treatment with β,γ-meATP also did not alter the mRNA expression of bone-like marker genes.

Conclusions: β,γ-meATP significantly decreased AMC in the aorta and peripheral vessels of warfarin exposed rats, however, without affecting the bone-like switch of VSMCs suggesting that β,γ-meATP mediates its inhibitory effects on AMC probably by interfering with the formation of Ca-P crystals via its breakdown product methylene bisphosphonate. Further research will be conducted to evidence this hypothesis.

Efficacy of Oxidative Stress Inhibitor Alone or Combined Therapy with a Calcimimetic in a Rat Model of CKD-MBD

Neal X. Chen,[1] Kalisha O'Neill,[1] Shruthi Srinivasan,[1] Corinne E. Metzger,[1] Alexander J. Stacy,[1] James M. Dominguez,[1] Annabel Biruete,[1] Matthew R. Allen,[1] Keith G. Avin,[1] Sharon M. Moe.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Roduebush Veterans Affairs Medical Center, Indianapolis, IN.*

Background: We previously demonstrated the role of NADPH oxidase (NOX 1 & 4) and hyperparathyroidism in the pathogenesis of arterial calcification, a component of CKD-MBD. We hypothesized that the combination of reduced NOX activity and lower PTH would have additive benefit on CKD-MBD. To test this hypothesis, we evaluated the efficacy of the NOX 1/4 inhibitor GKT137831(GKT) alone or combination with the PTH-lowering calcimimetic KP-2326 (KP) on CKD-MBD in a slowly progressive rat model of CKD, the Cy/+ rat.

Methods: We compared five groups of animals: 1: Normal (NL); 2: CKD; 3:CKD+GKT (60mg/kg s.q. daily); 4: CKD+ KP (0.6mg/kg i.p., 3x/wk) and 5: CKD+GKT+KP. Treatment began at 18 weeks of age (~60% NL kidney function) and ended at 28 weeks (~25% NL function). Serum biochemistries, aorta and heart calcification and bone architecture were assessed. One Way ANOVA was used for statistical analysis.

Results: As expected, there was a decline in kidney function in all CKD groups compared to NL. There was no difference in serum phosphorus or calcium levels between NL and any of the CKD groups. PTH and FGF23 serum levels were elevated by 5 and 2.3 fold, respectively, in CKD rats; only KP treatment reduced PTH levels ($p<0.003$). Interestingly, GKT alone or combined with KP increased FGF23 levels by 2-fold in

CKD rats (p<0.002). Serum 8-OHdG (marker of DNA oxidation) was higher in all CKD animals (p<0.01) and unaffected by treatment. There was increased aorta calcification (by 45%) and heart calcification (by 32%) in all of the CKD animal groups (p<0.01) and only GKT treatment reduced aorta calcification (p<0.03). Compared to NL, trabecular bone volume (BV/TV%) and trabecular number were lower and trabecular separation was higher in all CKD rats (p<0.001). GKT also increased trabecular separation in CKD rats (p<0.04).

Conclusions: In a progressive rat model of CKD-MBD, treatment with a NOX1/4 inhibitor (GKT) early in the course of CKD reduced aorta calcification but did not decrease oxidative stress and also increased FGF23 levels in CKD rats. KP treatment decreased serum PTH levels in CKD, but had no effect on aorta calcification or bone architecture. There were no additive beneficial or adverse effects with the combination of KP and GKT.

PO0317

Comparison of the Effects of Ferric Citrate and Intravenous Iron on Markers of Mineral and Bone Disorder and Oxidative Stress in a Rat Model of CKD-MBD

Annabel Biruete,[1] Neal X. Chen,[1] Corinne E. Metzger,[1] Alexander J. Stacy,[1] Shruthi Srinivasan,[1] Kalisha O'Neill,[1] James M. Dominguez,[1] Keith G. Avin,[1] Matthew R. Allen,[1,2] Sharon M. Moe.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Richard L Roudebush VA Medical Center, Indianapolis, IN.*

Background: Anemia and chronic kidney disease-mineral and bone disorder (CKD-MBD) are common in CKD. Ferric citrate is an oral therapy approved as an oral iron replacement product in non-dialysis dependent CKD and as a phosphate binder for dialysis-dependent CKD patients. However, studies comparing the effects of ferric citrate vs. IV iron on markers of CKD-MBD and oxidative stress in moderate CKD are limited.

Methods: We compared four groups of male rats (n=11-14 rats/group): 1) Rats with normal kidney function (NL), 2) CKD rats without iron treatment (CKD), 3) CKD rats treated with 2% ferric citrate in food (CKD + FC), and 4) CKD rats treated with 1mg/kg/every other week of iron sucrose (CKD + IV iron). Treatments started at 18 weeks of age (mild CKD) until euthanized at 28 weeks of age (moderate-to-advanced CKD). We determined biochemical markers of CKD-MBD, oxidative stress, bone morphology (by CT), and bone formation rate at 28 weeks. One-way ANOVA was performed with Tukey's post hoc comparisons.

Results: Untreated and iron-treated CKD rats had higher concentrations of BUN and creatinine than NL rats. Untreated CKD rats had elevated plasma phosphorus and intact FGF23 compared to NL. CKD+FC rats had lower plasma phosphorus and intact FGF23, while CKD+IV iron rats had lower intact FGF23 compared to CKD rats. However, the C-terminal FGF23 remained high in the untreated CKD and the CKD+IV iron rats compared to NL, but CKD+FC rats tended to be lower than the untreated CKD rats (p=0.07). PTH was elevated in the untreated and iron-treated CKD rats compared to NL. A marker of oxidative stress, 8OHdG, was increased in the untreated and iron-treated CKD rats compared to NL rats and was not different between iron treatments. At this stage of CKD, there was no cortical porosity in all the CKD rats compared to NL. CKD-induced alterations in trabecular and cortical bone properties and bone formation rate were not changed compared to untreated CKD rats in the iron-treated rats.

Conclusions: Ferric citrate led to more robust reductions in plasma phosphorus and FGF23 than IV iron, while neither source of iron had adverse effects on oxidative stress or bone parameters in a rat model with moderate CKD-MBD.

Upacicalcet, a Novel Non-Peptide Calcimimetic for the Treatment of Secondary Hyperparathyroidism, Has a Low Risk of Hypocalcemia

Go Nishimura,[1] Yu Yamaguchi,[1] Moritaka Goto,[1] Daisuke Honda,[2] Naoki Takahashi.[1] *[1]Sanwa Kagaku Kenkyusho, Co.,Ltd., Inabe, Japan; [2]Sanwa Kagaku Kenkyusho, Co., Ltd., Nagoya, Japan.*

Background: Calcimimetics are widely used for the treatment of secondary hyperparathyroidism (SHPT) in chronic renal failure patients. However, there are some problems with calcimimetics treatment. One of the biggest problems is hypocalcemia that leads to treatment interruption. Upacicalcet is expected to be a novel non-peptide calcimimetic that does not cause excessive hypocalcemia from the results of clinical studies. In the present study, we investigated the pharmacological characteristics of upacicalcet and effect on hypocalcemia in preclinical studies.

Methods: *In vitro* study was conducted using human CaSR-expressing (hCaSR$^+$) HEK-293T cells. In *in vivo* study, upacicalcet was intravenously administered in a single dose to Double-Nephrectomized (Double-Nx) rats, an animal model of SHPT, and serum intact parathyroid hormone (iPTH) and Ca concentrations were measured.

Results: Upacicalcet increased the intracellular Ca^{2+} concentration in hCaSR$^+$ HEK-293T cells dose-dependently. Additionally, upacicalcet shifted the EC_{50} value for extracellular Ca^{2+} to lower concentrations in a dose dependent manner. In Double-Nx rats, 0.3, 3, and 30 mg/kg of upacicalcet dose-dependently reduced the serum iPTH level at 24h and 48h after administration, and the reductions were significantly greater than that in Control (Pre; upacicalcet 0.3 mg/kg: 483±70 pg/mL vs. Control: 460±39 pg/mL, 24h; upacicalcet 0.3 mg/kg: 397±40 pg/mL vs. Control: 1306±86 pg/mL; *P<0.001*, 48h; upacicalcet 0.3 mg/kg: 795±91 pg/mL vs. Control: 1889±77 pg/mL; *P<0.001*). Upacicalcet also significantly decreased the serum Ca level dose-dependently at 24h and 48h after administration. However, interestingly, it bottomed out without getting too low even with 30 mg/kg of upacicalcet, 100-fold higher than the efficacious dose (0.3 mg/kg) (Table 1).

Conclusions: These findings suggest upacicalcet is a novel non-peptide positive allosteric modulator on human CaSR with a low risk of hypocalcemia for the patients with SHPT.

Table 1. The effect of upacicalcet on serum Ca level in Double-Nx rats

PO0319

Influence of Vitamin D and Uremia on Functional Expression of Drug Transporters in Human Proximal Tubule Cells

Stacey M. Tuey,[1] Thomas D. Nolin,[2] Melanie S. Joy.[1] *[1]University of Colorado, Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; [2]University of Pittsburgh, Department of Pharmacy & Therapeutics, Pittsburgh, PA.*

Background: Vitamin D (VitD) deficiency is common in patients with chronic kidney disease (CKD), with prevalence rates as high as 90%. CKD and VitD have independently been shown to modulate the function and expression of various drug transporters, potentiating drug-drug interactions and pharmacokinetic alterations. However, it remains unclear how the combination of CKD and VitD alters drug transporters. The purpose of this study was to evaluate the function and expression of drug transporters in human proximal tubule cells (hPTCs) following treatment with VitD analogues under *in vitro* conditions employing human healthy serum (HS) and uremic serum (US) to mimic the CKD environment.

Methods: hPTCs were exposed to 10% HS or 10% US for 24 h, followed by treatment with cholecalciferol (D_3) or the active form, calcitriol ($1,25D_3$) at 100 or 240 nM concentrations or 2% ethanol vehicle control (VEH) for 6 days. RT-qPCR and immunoblotting were used to assess effects on gene and protein expression, respectively of P-gp (efflux) and OATP4C1 (uptake) transporters. Apical to basolateral (A->B) and basolateral to apical (B->A) transport was assessed in hPTCs using transwell inserts and the transporter probe [^{3}H]Digoxin (DIG).

Results: Data are shown in the Table. Compared to VEH, $1,25D_3$ increased P-gp gene expression under HS and US (with exception of the 240 nM concentration). $1,25D_3$ also increased SLCO4C1 protein in HS, but no increase was demonstrated in US. B->A transport was enhanced in HS under treatment with $1,25D_3$.

Conclusions: These data suggest that uremia decreases OATP4C1 expression and prevents an induction of OATP4C1 expression and function by $1,25D_3$. Enhanced B->A transport in HS under treatment with $1,25D_3$ was consistent with the up-regulation of P-gp and SLCO4C1. These alterations may help to inform disposition of transporter substrates under VitD treatments.

Funding: Other NIH Support - NIGMS

SNF472 Inhibits Heart Valve Calcification in a Novel In Vitro Method Using Porcine Whole Leaflets

Carolina Salcedo,[1] Arsenii Zabirnyk,[3,4] Maria del mar Perez,[1] Marc Blasco Ferrer,[1] Kåre-Olav Stensløkken,[4,3] Miquel D. Ferrer,[1,2] Ingvar Jarle Vaage.[3,4] *[1]Sanifit Therapeutics, Palma, Spain; [2]University of the Balearic Islands, Palma, Spain; [3]University of Oslo, Oslo, Norway; [4]Oslo University Hospital, Oslo, Norway.*

Background: Chronic kidney disease and end-stage kidney disease (ESKD) patients are prone to develop calcific aortic or mitral valve disease. Currently, there exists no pharmacological treatment to prevent or stop the calcification process of aortic valves that causes aortic stenosis, and the models to study this process in vitro and in vivo are scarce. SNF472 is an inhibitor of calcium phosphate crystallization in development for the treatment of calciphylaxis and cardiovascular calcification in ESKD patients. The aims of this study were to develop a robust *in vitro* model of induced calcification in whole aortic valve leaflets suitable for testing potentially inhibitory drugs, and to test the effects of SNF472 in this model.

Methods: Aortic valve leaflets from commercial pig hearts were dissected free and randomized between experimental groups. Whole leaflets were cultured in individual wells. Two growth media were used for cultivation: standard growth medium and an antimyofibroblastic growth medium. The latter was employed to inhibit contraction of the leaflet into a ball-like structure. Calcification was induced in the growth media by supplementation with an osteogenic medium. Leaflets were cultivated for four weeks and medium was changed every third day. To block calcification, SNF472 was used at concentrations between 1 and 100 μM. Calcium amount in leaflets after four weeks was measured by inductively coupled plasma optical emission spectroscopy.

Results: Osteodifferentiation with calcium accumulation was in principle absent when standard medium was used. However, when the antimyofibroblastic medium was used, a strong calcium accumulation was induced (p=0.006 compared to controls), and this was blocked in a dose-dependent manner by the calcification inhibitor SNF472 (p=0.008), with an EC_{50} of 3.3 μM.

Conclusions: Cultured whole leaflets of porcine aortic valves are a new *in vitro* model to study calcification of heart valves. This model will be useful for studying the basic mechanisms of valve calcification and to test pharmacological approaches to inhibit calcification. The latter was shown by SNF472, which strongly inhibited calcification in this model of aortic valve disease.

Amelioration of Uremic Vascular Calcification After Experimental Aorta Transplantation

Maria L. Mace,[1] Søren Egstrand,[1] Anders Nordholm,[1] Marya Morevati,[1] Geert J. Behets,[2] Patrick D'Haese,[2] Klaus Olgaard,[1] Ewa Lewin.[3] *[1]Rigshospitalet, Kobenhavn, Denmark; [2]Universiteit Antwerpen, Antwerpen, Belgium; [3]Herlev Hospital, Herlev, Denmark.*

Background: CKD causes a shift in phenotype of the vascular smooth muscle cell (VSMC) to a bone-like secretory cell and promotes vascular calcification (VC). Our aim was to study whether VC is reversed by transplantation of a uremic calcified aorta into a healthy recipient.

Methods: A novel model of isogenic aorta transplantation in the rat was used (ATx). VC was induced in inbred Dark Aguti rats by 5/6 nephrectomy, high phosphate diet and alfacalcidol treatment. The abdominal aorta of the uremic rat was transplanted into a normal rat (uremic ATx, n=16). Control groups were: ATx between normal rats (normal ATx, n=9) and age-matched rats (control, n=6). Four weeks after ATx, the aorta was analyzed for genes related to the osteochondrogenic transition by RT-qPCR. Data are presented as mean±SD. mRNA levels are normalized to stabile housekeeping genes and expressed as the ratio to control.

Results: The uremic donor rat had severe CKD with disturbed mineral and bone metabolism as well as severe aorta calcification with altered expression of genes related to the osteochondrogenic phenotype. ATx mitigated some of these genetic changes as indicated by a significant downregulation of the expression levels of mineralization inhibitors and fibrosis matrix proteins. More specifically, mRNA levels of *MGP* (control 1±0.18 vs. uremic 3.74±0.18 vs. uremic ATx 1.67±0.61), *Spp1* (control 1±0.20 vs. uremic 13.69±4.47 vs. uremic ATx 2.62±0.84), *ANKH* (control 1±0.15 vs. uremic 10.43±6.90 vs. uremic ATx 4.49±1.72), *Postn* (control 1±0.34 vs. uremic 3.19±0.77 vs. uremic ATx 1.74±0.85), *Fn1* (control 1±0.25 vs. uremic 7.26±2.49 vs. 3.02±1.45), all p<0.01. No difference in expression of these genes between control and normal ATx was noticed. The VSMC markers *ACTA2 & Eln* were downregulated in uremic VC with no recovery through ATx. The upregulated Wnt inhibitor sclerostin showed a trend towards downregulation by ATx. Activin A & TGF-beta were highly upregulated in uremic VC with no reversibility. Plasma biochemistry did not differ between control, normal ATx and uremic ATx.

Conclusions: Our results for the first time show downregulation of genes related to mineralization and fibrosis, indicating amelioration of uremic vasculopathy after experimental aorta transplanation.

Impaired Arterial Vitamin D Signaling Is Pathogenic in Vascular Calcification

Kenneth Lim,[1] Guerman Molostvov,[2] Maria A. Lubczanska-Hadley,[4] Simon Fletcher,[3] Rosemary Bland,[4] Thomas F. Hiemstra,[5] Daniel Zehnder.[6] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Birmingham, Birmingham, United Kingdom; [3]University Hospital Coventry and Warwickshire, Coventry, United Kingdom; [4]University of Warwick, Coventry, United Kingdom; [5]University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom; [6]North Cumbria Integrated Care University Hospital NHS Trust, Carlisle, United Kingdom.*

Background: Conflicting data exists as to whether vitamin D receptor agonists (VDRa) are protective of arterial calcification. This is confounded by inherent physiological differences between human and animal experimental models and conflicting published data. Herein, the study aims to address these problems by leveraging frontiers in human arterial organ culture models.

Methods: Human arteries were collected from 24 patients (healthy controls, n=12; end-stage CKD, n=12). Cross-sectional and interventional studies were performed using arterial organ cultures treated with normal and calcifying (containing 5mmol/L $CaCl_2$ and 5mmol/L b-glycerophosphate) medium, *ex vivo*. To assess the role of VDRa therapy, arteries were treated with either calcitriol or paricalcitol.

Results: Human arteries express a functionally active vitamin D system, including VDR, 1α-hydroxylase and 24-hydroxylase (24-OHase) components and these were dysregulated in CKD arteries. Arteries from CKD patients exhibited reduced capacity to synthesize $1,25(OH)_2D$, increased basal expression and excessive induction of the vitamin D catabolic pathway in response to VDRa. VDRa therapy increased VDR expression in healthy (p<0.01) but not CKD arteries. VDRa treatment suppressed Runx2 and MMP-9 expression in CKD arteries, however only paricalcitol suppressed MMP-2. VDRa exposure did not modulate arterial calcification in all organ culture models. However, VDRa reduced senescence associated β-galactosidase (SAβG) staining in human aortic-smooth muscle cells under calcifying conditions, *in vitro.*

Conclusions: Maladaptation of arterial vitamin D signaling components occurs in CKD. VDRa exposure can exert vasculo-protective effects and seems critical for the regulation of arterial health in CKD.

Analysis of Human Jackstone Protrusions Show a Protein-Rich Core, Suggesting That Proteins Drive Their Rapid and Linear Growth

Victor Hugo Canela,[1] Sharon B. Bledsoe,[1] Cornelius Dzien,[2] Michael S. Borofsky,[3] James E. Lingeman,[1] Tarek M. El-Achkar,[1] James C. Williams.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Medical-Center Innsbruck, Innsbruck, Austria; [3]University of Minnesota, Minneapolis, MN.*

Background: Jackstones are urinary stones that have arm-like extensions from the body of the stone. This morphology of stone has been long recognized but poorly studied.

Methods: Micro CT was used to analyze 96 jackstones from 47 different patient specimens. Additional analyses included infrared spectroscopy (IR), fluorescence microscopy, and immunohistochemistry for Tamm-Horsfall protein (THP).

Results: Jackstone arms consisted of an X-ray lucent core (high in protein by IR) and a tightly layered calcium oxalate monohydrate (COM) shell that matched the COM on the stone body. The layering in the shell regions showed that the arms had grown at a faster rate away from the center of the stone than had the stone body. Microscopy studies showed brilliant autofluorescence in the core region but less in the COM shell. Immuno-staining showed that THP content was richer in the core region than in the COM shell. **Figure 1A** shows surface rendering of jackstone by micro CT. **B:** Slice through micro-CT image stack to show the x-ray lucent cores of two jack arms from **A**. **C & D** show negative controls (no primary antibody) for human cortical tissue and demineralized jackstone arm cross-section. **Panel E** shows a positive control for THP in human renal tissue (black arrowheads). **Panel F** shows THP aggregation in the core of the jackstone arm (white arrowheads).

Conclusions: We hypothesize that the protein-rich core of a jackstone arm preferentially binds more protein from the urine and resists deposition of COM, such that the arm tip grows rapidly, with the sides (shell) of the arm being covered with COM layers just like the body of the stone. This hypothesis points to enrichment of growth-accelerating proteins in the core of the jack arm, which bind preferentially to the protein-rich tip but which bind less avidly to the COM surface of the stone. Identificaiton of such proteins could provide clues as to how proteins modulate the deposition of mineral layers in kidney stone growth.

PO0324

Hyperphosphatemia Contributes to Inflammation, Iron Dysregulation, and Skeletal Muscle Wasting

Brian A. Czaya, Kylie Heitman, Isaac D. Campos, Christopher Yanucil, Dominik Kentrup, Christian Faul. *Univeristy of Alabama at Birmingham, Birmingham, AL.*

Background: Fibroblast growth factor (FGF) 23 is a phosphaturic hormone that promotes phosphate (Pi) excretion. In patients with chronic kidney disease (CKD), serum levels of Pi & FGF23 gradually rise as renal function declines & associates with various pathologies such as systemic inflammation, anemia, vascular calcification & muscle wasting. Our previous studies have showed FGF23 induces inflammatory cytokine expression by targeting hepatocytes via FGF receptor 4 (FGFR4). Other studies have shown Pi accelerates vascular calcification. However, whether Pi contributes to inflammation, anemia or skeletal muscle wasting remains unclear. Here we compare the

effects of Pi versus FGF23 to determine their contributions towards these CKD-associated pathologies, utilizing in vivo & in vitro models.

Methods: We subject mice with global FGFR4 deletion & wild-type littermates to an increasing dietary Pi load (0.7%, 2.0%, or 3.0%) or an adenine-rich diet (CKD model) to examine systemic inflammation, iron metabolism and skeletal muscle function. Furthermore, we study primary hepatocytes treated with FGF23 or Pi to examine activation of downstream signaling events & expression levels of specific target genes. We determine if co-treatment with inhibitors of Pi uptake & of downstream mediators block these observed effects.

Results: A 3% Pi diet as well as an adenine-rich diet promote inflammation, iron dysregulation & skeletal muscle wasting in mice. Outcomes are not alleviated in FGFR4 knockout mice. Furthermore, liver Pi accumulation occurs before hyperphosphatemia, as shown by 2% Pi diet. In cultured hepatocytes, inflammatory cytokine and hepcidin expression are induced by Pi in a dose-dependent manner. Moreover, Pi activates NFkB signaling. Blocking Pi uptake & NFkB attenuates the observed Pi-induced effects.

Conclusions: We postulate in CKD, gradual elevations in serum Pi as well as tissue Pi accumulation, which may occur before detectable changes in systemic Pi, promotes inflammation & anemia by targeting the liver to induce gene programs that regulate inflammatory responses & iron metabolism. In turn, these events promote muscle wasting. Our study indicates these Pi effects may be FGF23-independent. Pharmacological approaches targeting Pi uptake and excretion or Pi's direct hepatic actions may alleviate various CKD-associated pathologies.

PO0325

Extrarenal Expression of the Kidney-Related Longevity Gene, α-Klotho, in the Long-Living Naked Mole Rat (Heterocephalus glaber): A Comparative Biology Study

Marya Morevati,[1] Søren Egstrand,[1,2] Anders Nordholm,[1,2] Maria L. Mace,[1,2] Klaus Olgaard,[1] Ewa Lewin.[1,2] *[1]Rigshospitalet, Kobenhavn, Denmark; [2]Herlev Hospital, Herlev, Denmark.*

Background: The naked mole-rat (NMR) is expanding in popularity as a model for studying biomarkers of aging and mineral metabolism. NMR has a lifespan of 30 years, almost ten times longer than the mouse and rat (app. 3-4 years). α-*klotho* (*Kl*) is an aging-suppressor gene. Knockout of *Kl* is associated with decreased lifespan, and overexpression of this gene is linked to extended lifespan in mice. *Kl* is predominantly expressed in the kidney. We speculated that the expression level of this gene might play a role in the longevity of NMR. The present comparative study aimed to establish the expression level of *Kl* in long-living NMR vs. normal rats, *Rattus norvegicus* (RN).

Methods: Ten NMR, kindly provided by Randers Regnskov (Danish Zoo) (N=5) and Gorbunova and Seluanov laboratory (Aging Research Center, University of Rochester, USA) (N=5) were used and compared to corresponding tissues from RN (N=9). Methods used were: QPCR, standard PCR, and Sanger sequencing.

Results: In the kidney, similar levels of *Kl* mRNA were observed between those two species by qPCR (RN: 0.9± 0.1 vs. NMR: 1.2± 0.2; n.s.). The expression of *Kl* was further examined in the lung, skin, and liver of NMR, compared to RN. There was no expression of *Kl* in the lung and skin of NMR. In the liver of NMR, a high expression of *Kl* mRNA was observed (Cp: 25) by qPCR in contrast to RN, where no expression was detected. Sanger sequencing was performed to confirm that the gene expressed in the liver was *Kl*. In order to ensure that this was not a truncated form of *Kl*, which could be a target for mRNA decay, the predicted region for alternative splicing sites for *Kl* was sequenced in NMR. These results indicated that this was not the case, neither in the kidney nor in the liver.

Conclusions: This comparative study showed for the first time that α-klotho is significantly expressed in the liver of NMR, while the gene is absent in the liver of RN. The expression levels of α-klotho were similar in kidneys of NMR and RN. Further experimental work is required to clarify whether the hepatic expression of α-klotho might contribute to the longevity of the NMR.

PO0326

Increased Urinary Leukocyte Esterase Distinguishes Brushite Stone Formers from Patients with Other Stone Types

Kristin J. Bergsland, Fredric L. Coe, Elaine M. Worcester. *University of Chicago, Chicago, IL.*

Background: Compared with calcium oxalate (CaOx) stone formers (SF), patients with brushite (Br) stones have elevated neutrophil infiltration in their renal papillae which may be associated with the observed marked increase in papillary scarring and inflammation. We investigated whether a signal of neutrophil elevation in the kidney could be detected in the urine when not associated with infection.

Methods: We performed urine dipstick analyses for leukocyte esterase (LEU), an enzyme produced by neutrophils, and various markers of infection including nitrite (NIT), blood (BLO) and protein (PRO). 24-hr urine specimens were tested using the Siemens Multistix 10SG dipstick read on a Clinitek Status analyzer. We measured urine ammonia on a Beckman DxC600. We retrospectively analyzed 812 urines from 215 patients; stone type of patients was determined by stone analysis containing >50% apatite (Ap), Br, CaOx or uric acid (UA), respectively. BLO, PRO and LEU measurements were on a 5 point scale (negative=0, trace=0.5, small=1, moderate=2, large=3); NIT was yes or no.

Results: In a fully adjusted ANOVA model by stone type and sex with LEU as the dependent variable and BLO, PRO, NIT, ammonia excretion and patient age as covariates, brushite SF had significantly higher LEU than CaOx or UA (Table). By Chi-square, NIT was not different between the stone types (p = 0.25). Ammonia excretion was not different between stone types. In an ANOVA of the mean LEU by patient adjusted for the number of stone removal procedures, LEU in Br SF was higher than in CaOx SF (p<0.01).

Conclusions: Dipstick LEU is informative in SF aside from predicting infection. Dipstick LEU was significantly higher in Br SF than in CaOx SF but NIT, indicating infection, was not different between stone types. Adjusting for other indicators of infection, such as ammonia, BLO, and PRO as well as the number of stone removal procedures did not abolish this difference. Dipstick LEU may serve as a urine biomarker of the inflammatory activity and neutrophil infiltration that we have observed in the kidneys of Br SF and may reflect the papillary histopathology.

Funding: NIDDK Support

Table. Dipstick LEU by Sex and Stone Type

	Women				Men			
	Ap	Br	CaOx	UA	Ap	Br	CaOx	UA
LEU	0.59±0.07	0.95±0.06*$	0.40±0.06	0.23±0.10	0.35±0.06	0.57±0.06#+	0.17±0.07	0.12±0.05

Mean±SE. *p<0.0001 vs CaOx or UA; $p<0.001 vs Ap; #p<0.0001 vs UA; +p<0.001 vs CaOx

PO0327

Heterogeneity of Mechanisms for Idiopathic Hypercalciuria in Calcium Stone Formers

George A. Helding,[1,2] Elaine M. Worcester,[1] Kristin J. Bergsland,[1] Fredric L. Coe.[1] *[1]University of Chicago, Chicago, IL; [2]Medical College of Wisconsin, Milwaukee, WI.*

Background: In past research, we have found evidence that patterns of segmental nephron tubule calcium reabsorption differ between the sexes in calcium (Ca) stone formers (SF) demonstrating a different underlying mechanism of their hypercalciuria. Whether or not these mechanisms differ between calcium oxalate (CaOx) and calcium phosphate (CaP) SF is not known.

Methods: We studied 18 CaOx subjects (12 male), 17 CaP subjects (9 male), and 25 normal (N) subjects (13 male) in both the fasted and fed state. Subjects ate a diet consisting of three isocaloric meals with hourly blood and urine samples for 14 hours. We measured endogenous lithium clearance to assess proximal tubule (PT) sodium reabsorption. To account for within-subject correlation due to repeated measures, generalized estimating equations (GEE) were used to estimate and test mean laboratory values between groups. Linear mixed effects models were used to model urine Ca, distally delivered Ca, absolute reabsorption of distally delivered Ca, and the urine-plasma lithium ratio.

Results: In SF women, distal Ca reabsorption is decreased compared to N women, while in SF men, PT Ca reabsorption is significantly decreased with a more modest reduction in distal Ca reabsorption compared to normal men. Among female CaP SF we found an abnormally high response of urine Ca to PTH that appears to affect post PT Ca reabsorption. Among female CaP and CaOx SF and male CaOx SF we found a clear difference of urine Ca response to ultrafiltrate Ca concentration. This difference was absent in male CaP SF who had a unique increase in the dependence of distal Ca delivery on lithium reabsorption in the PT. CaOx male SF also had other PT abnormalities such as modeled urine Ca that was abnormally dependent on the urine-plasma lithium ratio. In addition, CaOx male SF had modeled lithium reabsorption that was abnormally responsive to both urine sodium, an ECF volume marker, and UF Ca concentration, presumably mediated through the cell surface Ca receptor (CaSR).

Conclusions: CaP and CaOx SF have differing abnormalities of Ca handling as compared to their same sex normals. In particular, phenotype specific abnormalities related to the CaSR exist in CaOx men and abnormalities related to the PTH receptor exist in CaP women.

Funding: NIDDK Support

PO0328

Magnesium's Roles in the Treatment of Hyperphosphatemia of CKD

Deanna J. Nelson. *BioLink Life Sciences, Inc., Cary, NC.*

Background: Hyperphosphatemia is causally related to atherosclerotic cardiovascular disease, the most important cause of death in all stages of renal failure and the single greatest threat to survival among ESRD patients undergoing dialysis. To meet the current K/DOQI guideline, patients use cationic binders to bind phosphate (Pi) in the gastrointestinal tract and prevent its uptake. FDA-approved phosphate binders include calcium salts, lanthanum salts, sevelamer, and ferric citrate. Combinations of calcium and magnesium salts have the potential both for phosphate binding with reduced calcium load and for reduction in oxidative stress, vascular calcification, and bone dysfunction.

Methods: Recent literature describing treatment of hyperphosphatemia with phosphate binders composed of calcium acetate/magnesium carbonate and calcium citrate/magnesium carbonate was analyzed. The results highlight aspects of magnesium's roles in the treatment of hyperphosphatemia of Stage 4-5 CKD and illustrate the potential benefits of these combination therapies in treatment of hyperphosphatemia.

Results: Recent clinical data strongly suggest that combinations of calcium and magnesium salts exhibit pleiotropic benefits for hyperphosphatemic Stage 4-5 CKD patients. In addition to reducing the calcium load, magnesium appears to act in the following ways. (1) Treatment lowered serum phosphorus into the K/DOQI target range in about 24 weeks. (2) Although treatment increased serum magnesium concentrations, [Mg^{2+}] was in the high normal range and comparable to the intracellular magnesium concentration. (3) Short-term treatment raised the T_{50} value. Since lower values are associated with accelerated conversion of soluble calciprotein particles composed of

amorphous calcium phosphate to secondary (insoluble) calciprotein particles containing needle-like calcium phosphate particles, higher magnesium appeared to beneficially slow the rate of conversion. (4) Analyses of bone turnover parameters suggested that higher magnesium may have supported more normal bone remodeling.

Conclusions: Clinical data from several sources suggest that combinations of calcium and magnesium have unique potential for providing pleiotropic benefits to Stage 4-5 CKD patients of all ages. Additional preclinical studies are underway to confirm that calcium magnesium citrates and propionates can be effectively and safely administered to hyperphosphatemic ESRD patients.

PO0329

Vitamin D Deficiency, Investigating the Connection Between Osteoporosis and CKD

Reanna A. Dona, John M. Greally. *Albert Einstein College of Medicine, Bronx, NY.*

Background: Chronic kidney disease (CKD) is estimated to afflict thirty-seven million people in the United States and leads to drastic alteration in bone and calcium metabolism. Metabolic bone disease is a common complication, resulting in skeletal consequences and CKD-associated osteoporosis. This occurs due to a combination of abnormalities in calcium, phosphorus, parathyroid hormone, vitamin D metabolism, and dysregulation in both bone formation, and bone resorption. One mechanism of the pathophysiology of age-associated osteoporosis is the shift in lineage commitment of mesenchymal stem cells (MSCs) towards adipogenesis at the expense of osteogenesis. Recent studies have implicated MSCs as mediators of osteoporosis due to the disrupted endocrine signaling pathways in aging individuals, similar to individuals with CKD.

Methods: We performed a re-analysis of a published single cell transcriptomics dataset investigating differentiation of MSCs to osteoblasts and adipocytes. We employed a standard pipeline from the R package "Seurat" to examine transcriptional heterogeneity of undifferentiated mesenchymal stem cells. Additionally, we tested the effects of 1,25D on MSC differentiation towards the osteogenic lineage.

Results: Here, we demonstrate heterogeneity of bone-marrow derived MSCs at the transcriptional level, implying potential underlying functional heterogeneity. Using single cell transcriptomics, we characterize the subpopulations of MSCs, multipotent stem cells and cells poised for differentiation. Once we confirmed this heterogeneity, we investigated stem cell priming with the vitamin D metabolite 1α,25-dihydroxyvitamin D3 (1,25D), testing the memory of a prior exposure to stem cells influences later lineage commitment choices. Vitamin D supplementation is a common therapeutic intervention for osteoporosis and is especially key for patients with CKD-associated osteoporosis as Vitamin D deficiency is prevalent in populations at-risk for developing osteoporosis and patients already diagnosed with CKD.

Conclusions: This project supports the commonly used treatment for development and prevention of osteoporosis and demonstrates functional heterogeneity of MSCs. Further steps in this project will explore the response to vitamin D priming at a higher resolution by employing single cell RNA-sequencing.

PO0330

Dissecting Ferric Citrate- and FGF-23-Associated Mineral Metabolism During the Anemia of CKD

Michael P. Liesen,[1,2] Megan L. Noonan,[1] Erica Clinkenbeard,[1] Pu Ni,[1] Rafiou Agoro,[1] Julia M. Hum,[2] Kenneth E. White.[1] White Laboratory *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Marian University, Indianapolis, IN.*

Background: Ferric citrate (FC) is a dual therapy used in patients with chronic kidney disease (CKD). This drug is given as a phosphate (Pi) binder for dialysis-dependent CKD, and for iron deficiency anemia in non-dialysis CKD due to delivery of elemental iron. Elevated Pi and anemia both lead to increased FGF23 during CKD, however, the roles of iron and FGF23 on CKD pathologies are unclear.

Methods: Iron and Pi utilization was tested in a mouse model of CKD receiving FC, with and without osteocyte deletion of FGF23 (flox-Fgf23/Dmp1-Cre). Male mice (n=4-7) with the genotype flox-Fgf23/Dmp1-Cre+ and -Cre- were placed on a customized 0.2% adenine (AD)-containing diet for 6 weeks to induce CKD in the presence or absence of 0.5% FC.

Results: After the diet regimen, iFGF23 increased significantly in all CKD mice ($p<0.05$-0.01). iFGF23 was lower in Cre+ mice fed FC ($p<0.01$), with Cre+ AD-only mice following a similar trend, demonstrating that the Dmp1-Cre was effective in reducing circulating FGF23. Cre+ mice fed AD-only had higher serum Pi than Cre- controls ($p<0.05$), and regardless of treatment, the Cre+ mice had higher BUN ($P<0.01$), showing that FGF23 was required to maintain serum Pi and lessen renal disease. Total serum iron was higher in all mice receiving FC, demonstrating effectiveness of the drug. Consistent with increased serum iron in the FC fed mice, liver Tfrc, BMP6, and hepcidin mRNAs were increased regardless of genotype ($p<0.05$-0.01); liver IL6 showed decreased mRNA expression in FC fed mice ($p<0.01$). Key enzymes that control 1,25D production in kidney were also examined. In Cre+/- mice fed FC the 1,25D anabolic enzyme Cyp27b1 was higher ($p<0.05$-0.01), and catabolic Cyp24a1 was lower ($p<0.01$), suggesting that FC may aid in restoring vitamin D metabolism in CKD.

Conclusions: In sum, delivery of FC during genetic reductions in FGF23 allowed the identification of FGF23-dependent and -independent actions in CKD. Loss of FGF23 was associated with higher serum Pi and worse renal function, demonstrating that FGF23 was protective of mineral metabolism, an effect independent of FC. In contrast, FC had FGF23-independent actions during CKD of increasing serum iron, correcting inflammation markers, and restoring the balance of Cyp24a1 and Cyp27b1 mRNAs, potentially providing beneficial effects on renal 1,25D metabolism.

PO0331

Reduced DMP1 Expression Precedes Bone Loss and FGF-23 Elevation in CKD

Emily P. Lynch,[1] Xueyan Wang,[1] Jian Feng,[3] Tom Nickolas,[2] Valentin David,[1] Aline Martin.[1] *[1]Northwestern University, Chicago, IL; [2]Columbia University Irving Medical Center, New York, NY; [3]Texas A and M University, Dallas, TX.*

Background: Chronic kidney disease (CKD) is associated with major disorders of bone and mineral metabolism, including renal osteodystrophy and increased secretion of the phosphaturic hormone FGF23 by bone, which is independently associated with cardiovascular mortality. Dentin matrix protein 1 (DMP1) is an extracellular matrix protein produced by osteocytes that stimulates osteoblast differentiation and inhibits FGF23 production. We previously showed that DMP1 supplementation prevents bone loss, FGF23 elevation and cardiovascular outcomes in mice with advanced CKD.

Methods: To determine if altered DMP1 expression contributes to the pathogenesis of renal osteodystrophy and FGF23 elevations during CKD progression, we measured bone DMP1 mRNA in wild-type (WT) and Col4a3^{KO} mice with progressive CKD every 4 weeks from 4 weeks of age until their death (24 weeks). In parallel, we assessed kidney function, serum FGF23 levels and bone microarchitecture. We also assessed osteocyte morphology in mice and in patients with early CKD.

Results: Col4a3^{KO} mice showed increased albumin to creatinine ratio (ACR) and blood urea nitrogen (BUN) levels starting respectively at 8 and 16 weeks, indicating onset of proteinuria and impaired kidney function. Consistent with BUN, FGF23 levels showed sustained increases starting at 16 weeks. This coincided with alterations in trabecular bone measured by 3D-microtomography of femurs from 16 to 24 week-old Col4a3^{KO} mice. However, analysis of cortical (Ct) bone showed reductions in bone mineral density, Ct thickness and Ct area as early as 12 weeks of age, and alterations in osteocyte morphology as early as 10 weeks in Col4a3^{KO} mice with early CKD and in patient with CKD stage 1-2. Bone DMP1 mRNA was reduced by 50% prior to the onset of proteinuria at 4 weeks of age and remained low at all time points throughout CKD progression; each $p<0.05$ vs. age-matched WT.

Conclusions: These data show that reduction in DMP1 expression occurs prior to major changes in kidney function and precedes altered osteocyte morphology, cortical bone loss, and FGF23 elevation in CKD. Although further studies are needed to identify the factors that suppress DMP1 expression in CKD, DMP1 administration might represent an effective therapeutic strategy to prevent alterations in bone and mineral metabolism in early CKD.

PO0332

A Role of FHL2 in the Pathogenesis of VOT and Calcification Induced by High Phosphate

Xiaowen Huang,[2] Weichun He.[1] *[1]Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: Hyperphosphatemia is germane to the development and progression of arterial medial calcification (AMC) in patients with chronic kidney disease. Vascular smooth muscle cells (VSMCs) to osteoblast-like cells transdifferentiation (VOT) induced by high phosphate is a crucial step in AMC. Either β-catenin or HIF-1α signal activated by high phosphate promotes VOT and calcification in VSMCs. As an adaptor protein, four-and-a-half LIM domains protein 2 (FHL2) has been demonstrated involving in β-catenin and HIF-1α signaling, respectively. However, the potential role and mechanism for FHL2 in high-phosphate-induced VOT and AMC remains to be clarified.

Methods: The regulation and function of FHL2 in high-phosphate-induced VOT and calcification were examined in cultured VSMCs. The expression of FHL2 in AMC induced by high phosphate was examined in cultured arterial rings. The regulation of FHL2 on β-catenin and HIF-1α signaling during VOT was also examined in VSMCs, respectively.

Results: The expression of FHL2 was induced in VSMCs and arterial rings cultured in a high phosphate environment. Knockdown of FHL2 suppressed high-phosphate-induced Runx2 and osteocalcin expression and calcium deposition, whereas overexpression of FHL2 was sufficient to induce the expression of Runx2 and osteocalcin in VSMCs. Downregulation of FHL2 partially inhibited the high-phosphate-induced upregulation of active β-catenin and β-catenin-mediated gene transcription, whereas ectopic expression of FHL2 was able to induce active β-catenin and β-catenin-mediated gene transcription. Similarly, downregulation of FHL2 partially inhibited the expression of HIF-1α induced by high phosphate, while ectopic expression of FHL2 enhanced HIF-1α-mediated gene transcription, although it didn't significantly increase the expression of HIF-1α. Moreover, high phosphate induced physical interactions between FHL2 and β-catenin, FHL2 and HIF-1α, respectively, especially in the nucleus. Meanwhile, high phosphate also induced a combination of β-catenin and HIF-1α, suggesting that the high-phosphate-induced upregulation of FHL2 facilitates the formation of a FHL2/β-catenin/HIF-1α ternary complex.

Conclusions: Our results suggest that FHL2, through activating β-catenin and HIF-1α signaling, plays a notable role in regulating high-phosphate-induced VOT and could be a potential therapeutic target for AMC in patients with chronic kidney disease.

CKD Decreases Cardiac PGC-1α Through Activin A Disrupting Mitochondrial Function

Matthew J. Williams,[1] Kishor B. Devalaraja-Narashimha,[2] Keith A. Hruska.[1] *[1]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [2]Regeneron Pharmaceuticals Inc, Tarrytown, NY.*

Background: The CKD-MBD syndrome is a cause of cardiac risk. Our hypothesis was that a new component of the syndrome, activin A, is responsible for systemic activation of activin receptor (ActRII) signaling in kidney disease, and is a mechanism of cardiac disease.

Methods: Two models of CKD were employed, Col4A5 Alport Syndrome mice and ablative CKD in Rosa26 cre ERT+/inhbafl/fl mice. Inhibition of Activin A in CKD was accomplished by either knockdown in Rosa26 cre ERT+/inhbafl/fl CKD mice or by monoclonal antibody in Alport mice. PGC-1α, mitochondrial gene expression and oxidative phosphorylation were measured by PCR and western analysis Cardiac mitochondrial respiration was measured by respirometry.

Results: In two kidney disease models, we show that activin A is the responsible ligand for cardiac and aortic ActRIIA activation in CKD. In untreated CKD mice, cardiac levels of pSmad2 and inhibin βa mRNA and preprotein (activin A monomer) were increased. Activin A inhibition, accomplished by either knockdown in Rosa26 cre ERT+/inhbafl/fl CKD mice or by monoclonal antibody in Alport mice, prevents CKD-induced cardiac ActRIIA activation and loss of PGC-1α, the master regulator of mitochondrial biogenesis and fatty acid oxidative phosphorylation. Mitochondrial gene expression and oxidative phosphorylation were decreased by CKD but prevented by activin A inhibition in CKD. Cardiac hypertrophy by echocardiography and heart weight was increased by CKD and prevented by activin A inhibition in the absence of vascular stiffness and without change in FGF23 levels.

Conclusions: We conclude that activation of cardiac activin/ActRIIA signaling by CKD induces mitochondrial dysfunction through decreased PGC-1α which contributes to compensated cardiac hypertrophy in the early stages of CKD associated cardiac disease.

Response of Bone to Acid: Effect of Deletion of the Proton Receptor OGR1 in the Osteoblast

Nancy S. Krieger, Luojing Chen, Jennifer Becker, Michaela Chan, David A. Bushinsky. *University of Rochester Medical Center Department of Medicine, Rochester, NY.*

Background: Metabolic acidosis induces bone resorption by inhibiting osteoblast (OB) bone formation and stimulating osteoclast (OC) bone resorption. Mice generate large amounts of endogenous acid and we have shown that OGR1 is the proton (H^+) receptor in bone and is stimulated by this endogenous acid. Mice with a global deletion of OGR1 have increased bone density which appears due to increased bone formation. There is communication between OB and OC and OGR1 is present in both. To determine if the response of OGR1 in the OB is independent of a response in OC, we generated a conditional knockout with an osteoblast-specific deletion of OGR1 (OB-cKO).

Methods: OB-cKO mice were generated from a col1a-cre mouse and an OGR1flox/flox mouse. We examined bones from 3 month old female mice using micro-computed tomography (μCT) and immunohistochemistry. Bone marrow mesenchymal stem cells (BMSC) from femurs of OB-cKO and wild type (WT) mice were differentiated to OB. Mineralization was detected with alizarin red and gene expression was analyzed by QPCR. All indicated changes are significant ($p<0.05$).

Results: Immunofluorescent staining of OGR1 in differentiated OB from BMSC confirmed the absence of OGR1 in OB-cKO cells compared to WT. μCT demonstrated an increase in tibia cortical bone area (0.76±0.01 vs 0.71±0.01 mm^2), but no change in femoral cortical bone in OB-cKO compared to WT. Femoral trabecular bone was decreased (8.64±1.03 vs 11.81±0.70 %BV/TV), but there was no change in tibia trabecular bone. Alizarin red staining of differentiated BMSC showed greater mineralization of OB from OB-cKO mice compared to WT (5.14±0.02 vs 4.39±0.03 relative intensity). Relative gene expression of *col1a* (1.53±0.15 vs 0.88±0.10), *osteocalcin* (1.79±0.05 vs 1.13±0.18) and *RANKL* (2.89±0.48 vs 1.11±0.21) was higher in differentiated BMSC from OB-cKO mice compared to WT cells.

Conclusions: Our results demonstrate that specific loss of OB OGR1 alters the response of bone to endogenous acid on bone content, in vitro mineralization and gene expression compared to WT, indicating that the response of OGR1 in the OB is independent of the response in OC. Characterization of the direct role of OGR1 in acid-induced bone resorption may assist in understanding bone loss associated with the metabolic acidosis in patients with chronic kidney disease.

Testing Patterns for CKD-MBD Abnormalities Before and After Treatment

James B. Wetmore,[1] Yuanyuan Ji,[2] Akhtar Ashfaq,[3] David T. Gilbertson,[2] Nicholas S. Roetker.[2] *[1]Hennepin Healthcare, Minneapolis, MN; [2]Chronic Disease Research Group, Minneapolis, MN; [3]OPKO Health Inc, Miami, FL.*

Background: We examined patterns of testing, treatment, and retesting after treatment initiation in CKD-MBD to determine if they were concordant with KDIGO guidelines.

Methods: We utilized 2010-19 data from IBM Explorys, an electronic health database. We created cohorts of incident CKD stage 3, 4, and 5 patients using a diagnosis code for CKD stage and a confirmatory eGFR lab value. Patterns of lab test ordering for PTH, phosphorus, 25D, calcium, and ALP and drug prescribing for activated vitamin D compounds, nutritional vitamin D, and phosphate binders were assessed during follow-up. We estimated the cumulative incidence of lab retesting following treatment (with death as a competing risk). We used multivariable Cox regression to examine whether pre-treatment test result values predicted retesting.

Results: We identified 215,553 stage 3, 43,576 stage 4, and 11,407 stage 5 CKD patients; mean follow-up was 2.3, 1.7, and 0.6 years, respectively. Only 46% of stage 4 and 41% of stage 5 patients underwent a PTH test; only 74% and 73%, respectively, a test for phosphorus; and only 38% and 25%, respectively, a test for 25D. By one year after treatment with activated vitamin D compounds, only 50% (stage 3), 53% (stage 4), and 60% (stage 5) of patients had received retesting for PTH [Figure]. By one year after treatment with 25D, retesting of 25D occurred in 46% (stage 3), 49% (stage 4), and 55% (stage 5) of patients by one year. Pretreatment levels of PTH and 25D were not associated in a graded fashion with retesting after treatment commenced.

Conclusions: Frequency of initial testing and retesting following treatment initiation are suboptimal. Unexpectedly, patients with the highest and lowest pre-treatment levels of PTH and 25D, respectively, did not have the highest rate of retesting, suggesting room for improvement.

Using a Quantitative Systems Pharmacology Model of CKD-MBD to Guide Therapy Minimizing Calcium Flux from Bone and into Vasculature

Adam E. Gaweda,[1] Michael E. Brier,[1,2] Eleanor D. Lederer.[3,4] *[1]University of Louisville, Louisville, KY; [2]Robley Rex VA Medical Center, Louisville, KY; [3]University of Texas Southwestern Department of Internal Medicine, Dallas, TX; [4]Dallas VA Medical Center, VA North Texas Health Care System, Dallas, TX.*

Background: CKD-MBD is characterized by bone loss and vascular calcification. Pharmacologic treatment of CKD-MBD involves dosing of three agents to minimize these complications through optimal balance of Calcium (Ca), Phosphorus (P), and PTH. Having developed a Quantitative Systems Pharmacology (QSP) model of CKD-MBD, we test the hypothesis that an AI method called Deep QLearning (DQL) in conjunction with our model can be used to determine the impact of precision therapy on the mineralization defect in patients with End Stage Renal Disease (ESRD).

Methods: Applying a quantitative systems pharmacology (QSP) model of CKD-MBD to mimic disease progression, we trained a Deep Neural Network (virtual physician) to minimize the Ca bone efflux and the Ca vascular tissue influx regardless of achieved serum Ca, P, and PTH predicted by the model. The virtual physician observed Ca, P, PTH and adjusted the doses of P binder, vitamin D, and a calcimimetic. We evaluated a trained virtual physician through simulation of CKD-MBD treatment over 18 months on a population of 100 virtual ESRD patients with varying baseline Ca, P, PTH levels, P intake, and Ca sensing receptor sensitivity.

Results: Simulations produced an average 30% decrease in bone Ca efflux and a 20% decrease in Ca influx to vascular tissue over baseline values. Average P decreased from 7.4 to 5.1 mg/dL, average Ca increased from 8.5 to 9.2 mg/dL, median PTH decreased from 1650 to 315 pg/mL.

Conclusions: Using a QSP model of CKD-MBD, we trained an AI agent to minimize the Ca fluxes from the bone and into the vascular tissue by prioritizing optimization of Ca fluxes over the achievement of specific Ca, P, and PTH levels. Our approach demonstrates beneficial synergy of Systems Biology and AI in modeling complex biologic processes.

Mineral Metabolism Changes in Renal Transplantation

Ana Carina Ferreira,[1,2] Marco Mendes,[1,2] Cecilia Silva,[1] Patrícia Cotovio,[1] Ines Aires,[1,2] David Navarro,[1] Fernando C. Pereira,[1,2] Rute M. Salvador,[2] Bruna F. Correia,[2] M. Guadalupe Cabral,[2] Fernando E. Nolasco,[1,2] Manuel A. Ferreira.[1,2] *[1]Hospital Curry Cabral, Lisboa, Portugal; [2]Nova Medical School, Lisbon, Portugal.*

Background: Successful renal transplant restores many physiologic abnormalities. The aim of this study was to analyse the evolution of CKD-MBD players [alpha-klotho, fibroblast grow factor (FGF) 23, sclerostin, parathyroid hormone (PTH), bone alkaline phosphatase (bAP), calcitonin, vitamin D (vitD), phosphorus (Pi), Calcium (Ca) and Magnesium (Mg)] pre and post transplantation.

Methods: Prospective cohort study of *de novo* renal transplanted patients (pts). A inclusion and after 12 months (time 0 and 1) pts performed laboratory evaluation. The difference between values (time1 - time 0) is the delta value. Associations between variables were performed using Wilcoxon matched-pairs test and Spearman correlation test. STATA software was used and $p < 0.05$ was considered statistically significant.

Results: We recruited 85 pts in 29 months and included 69 pts in the study. Mean age 50.2±12.4 years, 48 men, 53 caucasian (78.8%), median BMI 24.5 (22.7 – 27.8), median dialysis vintage 55 (42 – 84). We observe a significant reduction on Pi, Mg, PTH, calcitonin, sclerostin, bAP and FGF23. Both Ca and alpha-klotho levels increased, with no significant changes in vitD levels. With restoring renal health (time 1) and comparing with time 0, PTH maintain the negative correlation with sclerostin ($p=0.02$) and the positive correlation with FGF23 ($p=0.0002$); modify the correlation with Pi, becoming a negative correlation instead of positive ($p=0.001$) and gain new correlations with Ca ($p=0.001$) and vitD levels ($p=0.03$). Also, PTH correlated with the delta FGF23 (rho=-0.4, $p=0.003$) and sclerostin correlated with delta PTH ($p=0.01$). FGF23 didn't reveal statistical association with Pi or Ca levels after transplant, contrasting with positive associations in pre transplant ($p=0.002$, $p<0.0001$). On the contrary, sclerostin developed a new correlation with Pi ($p=0.0004$) and a negative correlation with Ca ($p=0.01$). We didn't find correlations between these molecules and alpha-klotho.

Conclusions: It seems that sclerostin influences PTH levels and that PTH is the stimulus for the increase or decrease of FGF23 serum levels. Levels of Ca and Pi seemed to be directly influenced by the level of PTH in post transplant, and those minerals seemed to be key factors for sclerostin secretion.

PO0338

Quantitative Systems Pharmacology Approach to the Treatment of CKD Metabolic Bone Disorder (CKD-MBD) Using Deep Learning

Adam E. Gaweda,[1] Michael E. Brier,[1,2] Eleanor D. Lederer.[3,4] *[1]University of Louisville, Louisville, KY; [2]Robley Rex VA Medical Center, Louisville, KY; [3]University of Texas Southwestern Department of Internal Medicine, Dallas, TX; [4]VA North Texas Health Care System, Dallas, TX.*

Background: CKD-MBD is a common comorbidity that leads to serious skeletal and cardiovascular complications. Using a Systems Biology model of CKD-MBD and Artificial Intelligence (AI) -guided precision dosing approach, we tested the hypothesis that this approach can effectively achieve recommendations for Ca, P, and PTH by balancing the administration of vitamin D and a calcimimetic when faced with varying adherance to phosphate binder dosing.

Methods: Using a Quantitative Systems Pharmacology (QSP) approach to model the disease trajectory, we trained a Deep Neural Network AI-agent to adjust doses of a P binder, vitamin D, and a calcimimetic to drive P, Ca, and PTH to recommended targets. We evaluated the agent through treatment simulation in a cohort of 100 virtual patients (defined by dietary P and sensitivity of the Ca receptor) under 3 experimental conditions: 100%, 50%, and 0% adherence to P binder prescription. Using model derived doses of vitamin D and calcimimetic, we analyzed the effect of P binder adherence on achieving the recommended Ca, P, and PTH target ranges. Drug doses were determined by simultaneously maximizing the percent in range of Ca, P, and PTH while minimizing the changes in bone Ca efflux and vascular Ca influx. Simulations were performed over 18 months.

Results: Results are shown in Table 1.

Conclusions: Using a QSP model of CKD-MBD, we trained an AI agent to guide precision dosing of P binder, vitamin D, and calcimimetic. We validated the agent under three simulated scenarios of P binder adherence. Simulation results show that control of intestinal P absorption is paramount in treatment of CKD-MBD. Failure to control P level severely limits ability to control vascular tissue calcification even when Ca and PTH are controlled pharmacologically.

PO0339

Differences in 25-Hydroxyvitamin D Clearance by eGFR and Race: A Pharmacokinetic Study

Simon Hsu, Leila R. Zelnick, Yvonne S. Lin, Cora M. Best, Bryan R. Kestenbaum, Lynn M. Rose, Andrew N. Hoofnagle, Ian H. de Boer. *University of Washington, Seattle, WA.*

Background: 25-hydroxyvitamin D (25(OH)D) clearance is an essential yet often overlooked determinant of circulating 25(OH)D concentration, the prevailing marker of vitamin D status. Observational studies associate markers of low 25(OH)D clearance with poor clinical outcomes and suggest differences in 25(OH)D clearance by kidney function and race, but these potential variations have not been tested using gold-standard methods.

Methods: We administered intravenous deuterated 25(OH)D_3 (d-25(OH)D_3) in a pharmacokinetic study of 87 adults with a wide range of kidney function, including normal estimated glomerular filtration rate (eGFR ≥ 60 ml/min/1.73m^2, n=43), non-dialysis chronic kidney disease (CKD; eGFR < 60 ml/min/1.73m^2, n=24), and kidney failure treated with hemodialysis (n=20). We measured d-25(OH)D_3 and deuterated 24,25-dihydroxyvitamin D_3 concentrations 5 minutes, 4 hours, and 1, 4, 7, 14, 21, 28, 42 and 56 days post-administration. We calculated 25(OH)D clearance using non-compartmental analysis of d-25(OH)D_3 concentrations over time. We re-measured 25(OH)D clearance in a subset of participants after 12-16 weeks of 2000 IU/day of oral vitamin D_3 (n=18).

Results: The mean age of the study cohort was 64 ± 11 years; 41% were female and 30% were black. Mean 25(OH)D clearances were 360 ± 108, 313 ± 86 and 263 ± 163 mL/day in participants with normal eGFR, CKD and kidney failure respectively (p = 0.02). After adjustment, lower eGFR was associated with reduced 25(OH)D clearance (-17 mL/day per 10 ml/min/1.73m^2 decrement, 95% CI: -21, -12). Black race was associated with higher 25(OH)D clearance in participants with normal eGFR (71 mL/day, 95% CI: 16, 125), but not in those with CKD or kidney failure (p-for-interaction = 0.052). 25(OH)D clearance did not differ after compared with before vitamin D_3 supplementation, although lower 25(OH)D clearance was correlated with a larger increase in serum total 25(OH)D concentration following supplementation (r = -0.41).

Conclusions: Through direct pharmacokinetic measurements, these findings confirm impaired 25(OH)D clearance as a feature of disordered mineral metabolism in CKD, and may help understand racial differences in vitamin D metabolism. Surrogate measures of 25(OH)D clearance may allow clinicians to more accurately anticipate individual response to vitamin D supplementation.

PO0340

The Vitamin D Metabolite Ratio and Change in Bone Density and Fracture Risk in Older Adults

Charles Ginsberg,[1] Ronit Katz,[2] Andrew N. Hoofnagle,[2] Jan M. Hughes-Austin,[1] Lindsay M. Miller,[1] Jessica O. Becker,[2] Stephen B. Kritchevsky,[5] Michael Shlipak,[3] Mark J. Sarnak,[4] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]University of Washington School of Medicine, Seattle, WA; [3]University of California San Francisco, San Francisco, CA; [4]Tufts Medical Center, Boston, MA; [5]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Recent studies have suggested that 25-hydroxyvitamin D [25(OH)D] may be a poor biomarker of bone health. Higher concentrations of its catabolic product 24,25-dihydroxyvitmin D [24,25$(OH)_2D_3$] and a higher ratio of 24,25$(OH)_2D_3$ to 25(OH)D_3 (the vitamin D metabolite ratio [VMR]) may provide additional information on vitamin D receptor activity and bone health.

Methods: We measured 24,25$(OH)_2D_3$, 25(OH)D_3, 25$(OH)_2D_3$ and serial bone densitometry scans over a 9-year period, in 761 community dwelling older adults, that participated in the Health Aging and Body Composition Study. Participants were followed for a median time of 11 years for any fractures. 24,25$(OH)_2D_3$ and 25(OH)D_3 were used to calculate the VMR. We used linear mixed models to assess the relationship between 24,25$(OH)_2D_3$, 25(OH)D_3,1,25$(OH)_2D_3$ and the VMR with annual change in hip, lumbar and thoracic spine bone mineral density (BMD). We used Cox models to assess the relationships between these parameters and fracture risk.

Results: Study participants had mean age 75+/- 3 years, 49% were female, 42% were black, and 23% had CKD. In fully adjusted models, a doubling of VMR and 24,25$(OH)_2D_3$ were associated with an 0.6% (95% CI 0.3, 0.9%) and an 0.3% (95% CI 0.1, 0.3%) increase in annual change in hip BMD, respectively (**Table 1**). We found similar relationships with thoracic and lumbar spine BMD. 25(OH)D_3 and 1,25$(OH)_2D_3$ concentrations were not associated with any of the BMD measurements. There were 194 fractures in follow-up. A higher VMR was associated with a lower risk of fracture [HR 0.71 (95% CI 0.51, 0.97) per doubling of VMR, **Table 1**]. Associations of 24,25$(OH)_2D_3$, 25(OH)D_3,1,25$(OH)_2D_3$ with fracture risk did not reach statistical significance.

Conclusions: In diverse cohort of community dwelling older adults, a higher VMR was associated with improvement in BMD and a lower risk of fracture. Trials are needed to evaluate the VMR as a therapeutic target in persons at risk for worsening BMD and fracture.

Funding: NIDDK Support, Private Foundation Support

Table 1: Adjusted Association of Vitamin D Metabolites and the VMR with Change in Hip BMD and Risk of Fracture*

	Annual Change in Hip BMD Per Doubling of Metabolite (95% CI)	P	HR of Fracture Per Doubling of Metabolite (95% CI)	P
24,25$(OH)_2D_3$	0.3% (0.1%, 0.4%)	0.003	0.84 (0.71, 1.00)	0.051
25(OH)D_3	0.2% (-0.1%, 0.5%)	0.190	0.85 (0.65, 1.11)	0.223
1,25$(OH)_2D_3$	0.1% (-0.2%, 0.4%)	0.598	0.77 (0.56, 1.05)	0.102

PO0341

The Vitamin D Metabolite Ratio Is Independent of Vitamin D Binding Protein Concentration

Charles Ginsberg,[1] Andrew N. Hoofnagle,[2] Ronit Katz,[2] Jessica O. Becker,[2] Stephen B. Kritchevsky,[5] Michael Shlipak,[3] Mark J. Sarnak,[4] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]University of Washington School of Medicine, Seattle, WA; [3]University of California San Francisco, San Francisco, CA; [4]Tufts Medical Center, Boston, MA; [5]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: 25-hydroxyvitamin D [25(OH)D] may be a poor marker of vitamin D status due to variability in vitamin D binding protein (VDBP) between individuals and groups. The vitamin D metabolite ratio [VMR, the ratio of 24,25(OH)2D3 to 25(OH)D3] is a marker of vitamin D status that has been hypothesized to be independent of variability in VDBP. This hypothesis has not been directly evaluated.

Methods: We measured 25(OH)D3, 24,25(OH)2D3, 1,25(OH)2D3, and VDBP in 377 community dwelling older adults that participated in the Health Aging and Body Composition Study. 24,25(OH)2D3 and 25(OH)D3 were used to calculate the VMR. We used linear regression to assess the relationship between VDBP with the VMR, 24,25(OH)2D3, 25(OH)D3, and 1,25(OH)2D3.

Results: Study participants had mean age 75+/- 3 years, 52% were female, 40% were black, and 24% had CKD. Lower VDBP concentrations were associated with male sex, lower serum albumin and Gc2/Gc2 VDBP phenotype in multivariable models. In fully adjusted models, each 1% higher VDBP was associated with a 0.92%, 0.76% and 0.57% higher 24,25(OH)2D3, 25(OH)D3, and the 1,25(OH)2D3 (**Table 1**). The VMR was independent of VDBP concentration, [0.16% (95% CI(-0.11, 0.44)) higher VMR per 1% higher VDBP, p=0.247].

Conclusions: In diverse cohort of community dwelling older adults, the VMR was independent of VDBP concentration whereas VDBP was strongly directly associated with the individual vitamin D metabolite concentrations. The VMR may serve as an important biomarker of vitamin D status and clinical outcomes that can be utilized in populations with a large spectrum of VDBP concentrations

Funding: NIDDK Support, Private Foundation Support

Meta-Analysis of the Impacts of Supplementation with Nutritional Vitamin D on Mineral and Bone Markers in Non-Dialysis CKD

Joel Gunnarsson,[1] Guiseppe Cianciolo,[4] Rosa Lauppe,[1] Philipp Csomor,[2] Edelgard Kaiser,[2] Marco Soro,[2] Jordi Bover.[3] *[1]Quantify Research AB, Stockholm, Sweden; [2]Vifor Pharma Ltd, Glattbrugg, Switzerland; [3]Fundacio Puigvert, Barcelona, Spain; [4]Universita di Bologna, Bologna, Italy.*

Background: Secondary hyperparathyroidism (SHPT) is a critical component of mineral and bone disorder in chronic kidney disease (CKD-MBD), characterized by excessive parathyroid hormone (PTH) secretion and low levels of vitamin D. Nutritional vitamin D (NVD) supplements are frequently used to treat SHPT, especially in early CKD. The objective of this meta-analysis (MA) was to evaluate the impact of NVD supplements on PTH, vitamin D (25D), calcium (Ca), phosphate (P) and fibroblast growth factor 23 (FGF23).

Methods: Study level results were pooled using a fixed effect model with inverted-variance weighting. The impact of the NVDs was measured in two ways: as change versus placebo or 'no treatment' and as change within the NVD study arm (before versus after NVD supplementation).

Results: Overall changes in PTH from NVD supplementation were small when measured within the NVD study arms (pooled reduction of 10.53 pg/ml, 95 % confidence interval (CI): -16.33 to -4.73) but larger when compared to placebo/no treatment (reduction of 49.74 pg/ml, 95 % CI: -70.17 to -29.3). NVDs tended to increase levels of 25D both within the NVD study arms (increase of 20.62 ng/ml, 95 % CI: 19.58 to 21.65) and when compared to placebo/no treatment (increase of 26.87 ng/ml, 95 % CI: 24.44 to 29.30). At the end of the study periods, average levels of 25D in the NVD study arms were >30 ng/ml in all but two RCTs and >50 ng/ml in only five of the included RCTs. Ca levels increased statistically significant from supplementation with NVDs versus placebo/no treatment (increase of 0.23 mg/dl, 95 % CI: 0.12 to 0.34 mg/dl). Only small and statistically non-significant impacts were observed on levels of P and FGF23.

Conclusions: Our results suggest that the magnitude of 25D increase caused by NVD may be insufficient to effectively and consistently lower PTH. While supplementation with NVDs can be used to correct vitamin D insufficiency, the potential of NVDs to actively reduce PTH in ND-CKD patients with SHPT is limited.

PO0343

Fibroblast Growth Factor 23 (FGF-23), Calcification Propensity, and Heart Failure with Preserved Ejection Fraction (HFpEF) in Patients with CKD: The CRIC (Chronic Renal Insufficiency Cohort) Study

Alexander S. Leidner,[1] Xuan Cai,[1] Leila R. Zelnick,[2] Nisha Bansal,[2] Andreas Pasch,[3] Mayank Kansal,[4] Jing Chen,[5] Amanda H. Anderson,[5] James H. Sondheimer,[6] James P. Lash,[4] Raymond R. Townsend,[7] Alan S. Go,[8] Harold I. Feldman,[7] Myles Wolf,[9] Tamara Isakova,[1] Rupal Mehta.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]University of Washington, Seattle, WA; [3]Calcison, Bern, Switzerland; [4]University of Illinois at Chicago, Chicago, IL; [5]Tulane University, New Orleans, LA; [6]Wayne State University, Detroit, MI; [7]University of Pennsylvania, Philadelphia, PA; [8]Kaiser Permanente, Oakland, CA; [9]Duke University School of Medicine, Durham, NC.*

Background: HFpEF represents half of all HF events and is common in patients with CKD. Given lack of treatments, identifying factors that impact HFpEF development is critical. FGF23 is an osteocyte-derived hormone involved in phosphorous homeostasis and is implicated in HF development. Calcification propensity (T50) is an in vitro assessment of the time for secondary calciprotein particle formation.

Methods: Using multivariable adjusted Cox proportional hazards models, we investigated the associations of FGF23 and T50 with incident HFpEF. FGF23 and T50 were measured at the baseline and Year 1 visits, respectively. Incident HFpEF was

defined as ejection fraction > 50% on echocardiogram at the time of event or by a CRIC Study echocardiogram within 1 year. After excluding individuals with baseline HF and individuals with HF events prior to analyte measurement, we included 3502 and 3029 individuals for our FGF23 and T50 analyses, respectively.

Results: In the FGF23 cohort, 333 incident HFpEF events occurred over a median follow-up of 10.8 years. In the T50 cohort, 259 incident HFpEF events occurred over a median follow-up of 10.2 years. Individuals in the highest FGF23 and lowest T50 quartiles had the highest rates of incident HFpEF (Figure). When adjusted for demographics, cardiovascular risk factors and kidney function, elevated FGF23, but not T50, was independently associated with incident HFpEF (Table).

Conclusions: FGF23, but not T50, was associated with incident HFpEF in patients with CKD. These data are consistent with studies demonstrating cardiac toxicity of FGF23 and may inform future trials of HFpEF development in CKD.

Funding: NIDDK Support, Other NIH Support - R01s and K awards

Figure 1. Rates of Incident HFpEF Events by FGF23 and T50 Quartiles

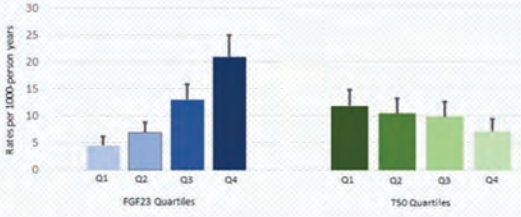

Table 1. FGF23 and T50 and HFpEF events

FGF23 and incident HFpEF events – 333 HFpEF events over 10.8 years follow-up				
Unadjusted	Model 1	Model 2	Model 3	Model 4
1.71 (1.56, 1.87)	1.73 (1.57, 1.91)	1.53 (1.36, 1.72)	1.43 (1.25, 1.62)	1.38 (1.21, 1.58)
T50 and incident HFpEF events – 259 events over 10.2 years follow-up				
Unadjusted	Model 1	Model 2	Model 3	Model 4
1.15 (1.02, 1.30)	1.04 (0.92, 1.19)	0.96 (0.84, 1.09)	0.90 (0.79, 1.02)	0.88 (0.77, 1.00)

Results are reported as hazard ratios per 1 SD increase in natural log FGF23 and per 1 SD decrease in natural log T50. Covariates for the FGF23 analyses are from Visit 3 and for T50 analyses are from Visit 5.

Model 1: adjusted for age, sex, race, and ethnicity

Model 2: Model 2 plus eGFR and UPCR

Model 3: Model 2 plus diabetes, smoking, systolic blood pressure, any cardiovascular disease, total cholesterol, statins, anti-hypertensive medications, phosphate, ln_PTH

Model 4: time-varying eGFR

Abbreviations: FGF23, fibroblast growth factor 23; HFpEF, heart failure preserved ejection fraction; SD, standard deviation; eGFR, estimated glomerular filtration rate; UPCR, urine protein-creatinine ratio; ln_PTH, natural log parathyroid hormone

PO0344

Genetic Determinants of Circulating Fibroblast Growth Factor 23 and Risk of Coronary Artery Disease

Mindy Pike, Elvis A. Akwo, Loren Lipworth, Adriana Hung, Talat Alp Ikizler, Cassianne Robinson-Cohen. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Observational studies suggest that elevated levels of circulating fibroblast growth factor-23 (FGF-23) contribute to the burden of cardiovascular disease, in the setting of chronic kidney disease and in the general population. These studies can suffer from confounding and reverse causation, limiting their ability to identify causal associations. Mendelian randomization (MR) has emerged as a powerful study design to provide evidence supporting or refuting causality by utilizing the genetic determinants of a risk factor. We used MR to evaluate whether genetically predicted higher FGF-23 levels are associated with the risk of coronary artery disease (CAD).

Methods: We performed two-sample MR of the relationship between FGF-23 and CAD with the use of summary statistics from the CARDIoGRAMplusC4D consortium's genome-wide association meta-analysis of 48 studies with a total of 60,801 CAD cases and 123,504 non-cases. We selected 5 single nucleotide polymorphisms (SNPs) robustly associated with FGF-23 at genome-wide significance among 16,624 individuals as instrumental variables.

Results: A genetic predisposition to higher FGF-23 levels was associated with CAD. In conventional MR analysis, the odds ratio of CAD was 1.44 (95% confidence interval 1.14 to 1.7, p=0.03) per 10-fold increase in genetically predicted FGF-23 levels. Results were consistent in sensitivity analyses using the weighted median and heterogeneity-penalized model averaging methods.

Conclusions: This study provides evidence that FGF-23 levels are causally associated with risk of CAD. Whether interventions to lower FGF-23 result in decreased risk of CAD remains to be determined but warrants investigation.

Renal Clearance of Intact and C-Terminal FGF-23 in Man

Joachim H. Ix,[1,2] Alfons J. Houben,[3] Abraham A. Kroon,[3] Peter W. de Leeuw,[3] Andrew N. Hoofnagle,[4] Charles Ginsberg,[1] Ronit Katz,[4] Alexander Bullen,[1] Shilpa Sharma.[5] *[1]University of California San Diego, La Jolla, CA; [2]VMRF/VA San Diego Healthcare System, San Diego, CA; [3]Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands; [4]University of Washington, Seattle, WA; [5]University of California Los Angeles, Los Angeles, CA.*

Background: The ratio of C-terminal (cFGF23) to Intact FGF23 (iFGF23) is higher in persons with higher eGFR. Mechanisms are unclear. Differential renal clearance is one possibility.

Methods: Patients were referred for clinically suspected renal artery stenosis (RAS), and maintained off BP meds for 21 days before angiography. This study includes those found without RAS (N=93). Blood was obtained from the aorta (Ao) and bilat. renal veins (RV), and renal blood flow (RBF) was measured using ^{131}Xenon washout. Single pass % reductions of each measure ([Ao – RV/Ao]*100) was calculated, left and right was averaged, and multiplied by RBF to provide renal clearance in ml/min/100g kidney tissue. To determine the relative renal clearance, we calculated the cFGF23/iFGF23 clearance ratio (C/I ratio) and evaluated its relationship with eGFR.

Results: Mean age was 52±11 years, 22% were women, all were white, eGFR was 77±26 ml/min/1.73m^2 and directly measured Cr clearance was 72 ± 42 ml/min/100g. Renal clearance of cFGF23 was similar to Cr, while iFGF23 was 37% higher (C/I ratio 0.73 ± 1.10). The clearance of cFGF23 and iFGF23 were directly correlated to eGFR (r=0.31 and 0.35). However, their relative clearance was similar across the range of eGFR (r=0.01). Results were similar in models adjusted for age, sex, and BMI

Conclusions: Renal cFGF23 clearances (which measures both iFGF23 and c-terminal fragments) is similar to Cr, whereas iFGF23 clearance is higher, suggesting that renal clearance of c-terminal fragment clearance is low. While renal cFGF and iFGF23 clearance were both reduced in persons with lower eGFR, the relative efficiency of clearance of cFGF23 vs. iFGF23 appeared similar across the range of eGFR.

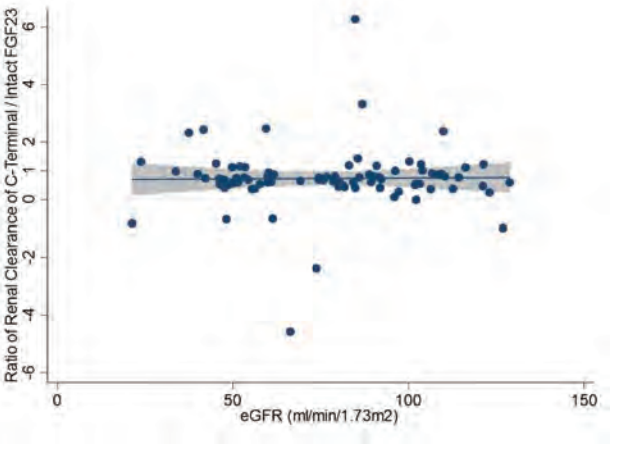
Single Pass Percent Reduction and Renal Clearance of C-terminal and Intact FGF23 in Man (N=93)

	Single Pass % Reduction	Renal Clearance (ml/min/100g)
Creatinine	15.7 ± 8.3	71.8 ± 41.4
C-terminal FGF23	15.5 ± 11.9	69.7 ± 57.8
Intact FGF23	21.6 ± 15.4	96.9 ± 75.2



PO0346

Association of Changes in Levels of eGFR and Fibroblast Growth Factor 23 from Midlife to Late Life with Risk of Mortality: The ARIC Study

Junichi Ishigami,[1] Yasuyuki Honda,[1] Amy B. Karger,[2] Elizabeth Selvin,[1] Josef Coresh,[1] Pamela L. Lutsey,[2] Kunihiro Matsushita.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]University of Minnesota, Minneapolis, MN.*

Background: Aging from midlife to late-life involves the dynamics of levels of eGFR and fibroblast growth factor 23 (FGF23). Whether changes in levels of eGFR and FGF23 from midlife to late-life are independently and jointly associated with subsequent risk of mortality is unknown.

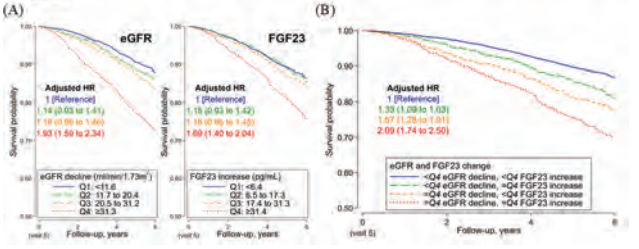
Methods: We included 5639 participants of the Atherosclerosis Risk in Communities Study who had eGFR and serum level of FGF23 measured during midlife (visit 3, 1993-1995, mean age 58 [SD, 5] years, 58% women, 23% black race) and late-life (visit 5, 2011-2013, mean age 76 years). We used Cox regression to examine the associations of past changes in levels of eGFR and FGF23 levels (in quartiles)-- separately and jointly-- with mortality from visit 5 (2011-2013) through December 31, 2017.

Results: The median eGFR 15-year decline (from visit 3 to 5) was 20.5 ml/min/1.73m^2 (from median eGFRs 87.8 to 65.7 ml/min/1.73m^2). The median FGF23 increase was 17.4 pg/mL (median FGF23s 37.5 to 54.8 pg/mL). During a median follow-up of 5.5 years after visit 5, 868 participants died. Adjusted HRs of mortality were 1.93

(95%CI, 1.59-2.34) for the highest quartile for eGFR decline, and 1.69 (1.40-2.04) for the highest quartile for FGF23 increase compared the lowest quartile (**Figure A**). When assessing in the cross-category of eGFR and FGF23 changes, the risk was highest for the highest quartiles of eGFR decline and FGF23 increase (HR, 2.09 [1.74-2.50]; **Figure B**).

Conclusions: In this community-based cohort, greater eGFR decline and FGF23 increase from midlife to late-life were independently associated with a higher risk of mortality, with the risk highest when eGFR decline was accompanied by FGF23 increase.

Figure: Changes in eGFR and FGF23 levels and subsequent risk of mortality. The HRs were adjusted for age, sex, race, Medicare Advantage enrollment status, diabetes, ever smoke, systolic blood pressure, hypertension medication, total cholesterol, high-density lipoprotein cholesterol, and history of heart failure, coronary heart disease, and stroke. Interaction between eGFR and FGF23 changes was not significant.



PO0347

Intact and C-Terminal Fibroblast Growth Factor 23 Assays: Do Kidney Function, Inflammation, and Iron Deficiency Influence Relationships with Clinical Outcomes?

Shilpa Sharma,[1] Ronit Katz,[5] Alexander Bullen,[2] Alfons J. Houben,[4] Michael Shlipak,[3] Joachim H. Ix.[2] *[1]University of California Los Angeles, Los Angeles, CA; [2]University of California San Diego, La Jolla, CA; [3]University of California San Francisco, San Francisco, CA; [4]Maastricht Universitair Medisch Centrum+ Interne Geneeskunde, Maastricht, Netherlands; [5]University of Washington, Seattle, WA.*

Background: Higher fibroblast growth factor-23 (FGF23) concentrations are associated with heart failure (HF) and mortality, but strengths of associations differ depending upon FGF23 assay type. We investigated whether iron deficiency, inflammation, and kidney function account for these differences.

Methods: In 844 Cardiovascular Health Study participants, using a case-cohort design, we examined associations of intact and C-terminal FGF23 with risk of mortality and HF, using modified Cox models to account for case-cohort design, adjusting sequentially by iron status, inflammation, kidney function or their combinations.

Results: C-terminal FGF23 more strongly correlated with ferritin (r= -0.26) and CRP (r= 0.21) than intact FGF23 (r=0.04 & r=0.07, respectively). The two FGF23 assays moderately correlated with one another (r=0.47). During follow up, there were 658 deaths, and 220 incident HF events. FGF23 measured by either assay was associated with mortality in unadjusted analysis (intact FGF23 HR per two-fold higher 1.45; 1.25-1.68; C-terminal FGF23 1.38; 1.26-1.50). Adjustment for kidney function completely attenuated associations of intact FGF23 with mortality (HR 1.00; 0.85, 1.17; **Figure 1**), but had less influence on the C-terminal FGF23-mortality association (HR 1.15; 1.04, 1.28). Results were similar for HF where the HR for intact FGF23 went from 1.57 (1.25, 1.97) to 0.99 (0.76, 1.28) with eGFR and albuminuria adjustment, whereas C-FGF23 went from 1.45 (1.25, 1.68) to 1.16 (0.97, 1.38). Adjustment for iron deficiency and inflammation did not meaningfully influence the differential associations of the two assays with either endpoint.

Conclusions: The associations of biologically active FGF23 with clinical endpoints may be weaker than previously thought.

Effects of Adjustment for Iron Parameters, Inflammation, and Kidney Function on the Associations of C-terminal and intact FGF23 with Mortality

PO0348

Factors Associated with Change in Fibroblast Growth Factor 23 Levels from Midlife to Late-Life: The ARIC Study

Junichi Ishigami,[1] Yasuyuki Honda,[1] Amy B. Karger,[2] Elizabeth Selvin,[1] Josef Coresh,[1] Pamela L. Lutsey,[2] Kunihiro Matsushita.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]University of Minnesota, Minneapolis, MN.*

Background: Factors associated with change in fibroblast growth factor 23 (FGF23) levels from midlife to late-life are not well-characterized in the general population.

Methods: Among 5,881 participants of the Atherosclerosis Risk in Communities Study who had serum level of FGF23 measured during midlife (visit 3, 1993-1995, mean age 58 years, 58% women, 23% black race) and late-life (visit 5, 2011-2013, mean age 76 years), we explored demographic and clinical factors associated with change in FGF23 levels. Change in FGF23 levels was regressed on pre-specified factors assessed at visit 3 of age (above vs. below median), sex, race, ever smoke, high BMI (≥ vs. <30 kg/m^2), hypertension, diabetes, history of CVD, and reduced eGFR (≥ vs. <60 ml/min/1.73m^2) using multivariable linear regression models.

Results: The mean FGF23 level increased by 21.0 (95%CI, 20.3-21.6) pg/mL from 39.7 at visit 3 to 60.6 pg/mL at visit 5. Reduced eGFR, diabetes, hypertension, female, older age, and white race were significantly associated with a greater increase in FGF23 levels (**Table**). Although history of CVD demonstrated a similar magnitude as race, the β coefficient was not significant. We also did not observe significant associations for BMI or smoking. The associations were strongest for reduced eGFR and diabetes with similar degrees of associations (ΔFGF23, 6.7 [95%CI, 2.7 to 10.6] pg/mL for reduced eGFR and 6.7 [4.4 to 9.0] pg/mL for diabetes) independent of each other.

Conclusions: In addition to reduced eGFR, we identified diabetes, hypertension, female, older age, and white race as predictors of an increase in FGF23 levels from midlife to late-life. Among these, the strong association of diabetes independent of kidney function deserves future investigations.

Table: Factors associated with changes in FGF23 levels from midlife to late-life. Multivariable linear regression simultaneously included all factors listed here.

Characteristics at visit 3 (1993-1995)		No.	Mean increase in FGF23 (pg/mL) from visit 3 to 5	Adjusted difference in FGF23 change (pg/mL)

FGF-23 Is Induced by Glucocorticoid Stimulation In Vivo and In Vitro: Translational Approach

Luis Toro, Rodrigo Alzamora, Victor Barrientos, Angela Delucchi, Luis Michea. *Universidad de Chile Facultad de Medicina, Santiago, Chile.*

Background: Previous data have suggested that glucocorticoid (GC) treatment may induce plasma fibroblast growth factor 23 (FGF23). Recently, we have reported that in prepubertal renal trasplantion children, chronic GC treatment was associated with increased plasma FGF23 levels, that was related to decreased bone growth in vivo and in vitro. Our objective was to evaluate whether GC treatment modulate FGF23 in adult patients.

Methods: Translational approach. This included an observational clinical study of patients who began GC treatment (prednisone 1 mg/kg/day), estimated glomerular filtration rate (eGFR) over 60 mL/min/1.7m2. Measurements of intact FGF23 were performed before initiation and 2 months later. Also we performed in vitro and in vivo analysis with cell cultures and experimental rat models which were treated with GC, measurements of plasma and bone FGF23 expression were performed.

Results: We recruited 10 patients who began GC treatment. We observed a significant increase in plasma intact FGF23 levels at 2 months (57% increase as compared to baseline values): baseline values: 18.9 +/- 4.2 pg/mL; 2 months: 29.7 +/- 5.2 pg/mL; p<0.001. No significant changes in renal function were detected. Also, rats treated with prednisone had a significant increase in plasma FGF23 and bone FGF23 expression after GC treatment. Finally, pharmacological blockage of glucocorticoid receptor alpha in vitro prevented the increase of FGF23 expression in bone tissue.

Conclusions: Sustained glucocorticoid treatment is associated to increased FGF23 expression and plasma levels. This effect should be evaluated in larger groups of patients to evaluate its potential relevance.

PO0350

PTH 1-84 and Bone Alkaline Phosphatase Are Independently Associated with Mortality, Whereas FGF-23 Predicts Dialysis Initiation in CKD Patients

Silvia M. Titan,[1,2] Isabela M. Bensenor,[1] Paulo Lotufo,[1] Rosa M. Moyses.[1] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Tufts Medical Center, Boston, MA.*

Background: Despite the fact that CKD-MBD is a risk factor for CKD morbidity and mortality, the results of studies regarding the role of individual biomarkers are variable. In addition, dimensionality reduction techniques have not been applied in CKD-MBD. The aim of our study was to evaluate a panel of CKD-MBD biomarkers, namely Ca, P, PTH 1-84, FGF-23, 25-vitamin D, 1.25-vitamin D, bone alkaline phosphatase (BAP) and sclerostin, individually and collectively in relation to death and KRT.

Methods: Events of death and KRT in 454 participants of the Progredir Cohort (Sao Paulo, Brazil) with predominantly CKD G3 and G4 were ascertained after a median follow-up of 6 years. Those with missing values were excluded (n=25) and 4 were lost to follow-up. The association of individual CKD-MBD parameters (DiaSorin® assays) and factors derived from factorial analysis was evaluated through Cox and Competitive Risk models (R package "cmprsk").

Results: Mean age was 68(12)y, mean eGFR was 38(15) mL/min/1.73m^2, 63% were male and 56% diabetic. In univariable analysis, sclerostin, BAP, PTH, and factor 1 were associated with death and 1.25vitD, sclerostin, BAP, FGF-23, PTH, Ca, P, and factor 1 were associated with KRT. After adjustments, BAP, PTH, and factor 1 remained associated with death, and FGF-23 remained associated with KRT (Table). The addition of BAP and PTH (with interaction) to a reference model significantly improved the model fit for death (p=0.01). The addition of FGF-23 with interaction with P significantly improved the model fit for KRT (p=0.0046).

Conclusions: PTH and BAP are positively associated with death and improved its prediction model. This finding suggests that BAP could be reflecting not only bone turnover but also vascular calcification. FGF-23 is associated with the risk of KRT, showing interaction with P. Factorial analysis was helpful in identifying factors significantly associated with events but did not improve prediction.

Parathyroid Hormone Serum Levels and Mortality Among Hemodialysis Patients in the Gulf Cooperation Council Countries: Results from the DOPPS (2012-2018)

Issa Al Salmi,[2] Mona Al Rukhaimi,[3] Ali AlSahow,[4] Faissal A. Shaheen,[5] Saeed Al-Ghamdi,[6] Jamal S. Al Wakeel,[6] Fadwa M. Al-Ali,[7] Ali Alaradi,[8] Fayez F. Alhejaili,[9] Yaqoob A. Almaimani,[2] Essam F. Abdelhamid,[10] Brian Bieber,[1] Bruce M. Robinson,[1] Ronald L. Pisoni.[1] On behalf of the GCC-DOPPS Study Group *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]The Royal Hospital, Ministry of Health, Muscat, Oman; [3]Dubai Medical College, Dubai, United Arab Emirates; [4]Jahra Hospital, Jahra, Kuwait; [5]DSFH, Jeddah, Saudi Arabia; [6]King Abdulaziz University, Jeddah, Saudi Arabia; [7]Hamad General Hospital, Doha, Qatar; [8]Salmaniya Medical Complex, Manama, Bahrain; [9]King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; [10]Amgen UAE, Dubai, United Arab Emirates.*

Background: The prospective Dialysis Outcomes and Practice Patterns Study (DOPPS) has collected data since 2012 in all six Gulf cooperation council (GCC) countries (Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, United Arab Emirates). Here, we report the relationship of PTH with mortality in the largest GCC hemodialysis (HD) patient cohort studied to date.

Methods: Data were from randomly-selected national samples of HD facilities in GCC DOPPS phases 5 and 6 (2012-2018). PTH descriptive findings and case-mix adjusted PTH/mortality Cox regression analyses were based on 1825 and 1422 randomly-selected HD patients, respectively.

Results: Mean patient age was 55 years (median dialysis vintage = 2.1 years). Median PTH ranged from 259 pg/mL (UAE) to 437 pg/mL (Kuwait), with 22% having PTH <150 pg/mL, 24% (PTH 150-300), 34% (PTH 301-700), and 20% (PTH >700) pg/mL. Patients with PTH >700 pg/mL were younger, on dialysis longer, less likely to be diabetic, have urine>200 mL/day, prescribed 3.5 mEq/L dialysate calcium, had higher mean serum creatinine and phosphorus levels, lower white blood cell counts, and more likely to be prescribed cinacalcet, phosphate binders, or IV vitamin D. A "U-shaped" PTH/mortality relationship was observed with >2-fold and 1.5 fold higher adjusted HR of death at PTH>700 pg/mL and <300 pg/mL, respectively, compared to PTH 301-450 pg/mL.

Conclusions: Secondary hyperparathyroidism is highly prevalent among GCC HD patients, with a strong U-shaped PTH/mortality relationship seen at PTH <300 and >450 pg/mL. Future studies are encouraged for further understanding this PTH/mortality pattern in relationship to unique aspects of the GCC HD population.

Effect of PTH Dosing Frequency and Amplitude on Bone Health: From Anabolism to Catabolism

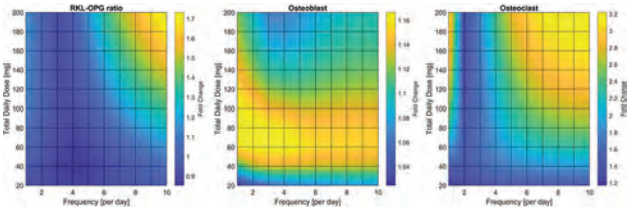
Alhaji Cherif,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: In patients with chronic kidney disease or primary hyperparathyroidism, chronically elevated parathyroid hormones (PTH) levels exert catabolic effects on the bone. In contrast, PTH cycling or daily application of teriparatide (TP) promotes bone formation. These responses have important clinical and therapeutic implications. Although the anabolic effects of PTH cycling are widely accepted, the underlying dynamics are not well understood.

Methods: We developed a physiology-based model quantitating the interrelations of osteoclasts, osteoblasts and osteocytes on bone remodeling (Cherif et. al., NDT 33(1), 2018, i165-6). Using the validated model, we explore the effect of altered PTH (TP) dosing (e.g., dosing frequency and amplitude) on bone catabolism and anabolism, respectively.

Results: The model accurately predicts differential responses of anabolic and catabolic effects of continuously and intermittently elevated PTH (TP) levels, respectively. We observe that intermittent dosing of PTH with a high frequency and amplitude induces bone catabolism similar to that seen with chronically elevated PTH. We see a more than 3-fold change from baseline in osteoclastic over osteoblastic activities, resulting in catabolism. Low PTH frequency with high dosing amplitude induces both osteoclastic and osteoblastic activities, but the net result is bone anabolism. Figure 1 shows a region where high osteoblastic activities exceed osteoclastic resorption. These findings suggest the existence of optimal PTH (TP) frequency-amplitude values that enhance anabolic gains, beyond which there can be a detrimental effect on bone.

Conclusions: Our results suggest that both frequency and amplitude of PTH (TP) cycling affect the balance of catabolic and anabolic effects. Understanding the underlying mechanism of differential responses induced by intermittent and continuous levels of PTH, respectively, may provide new therapeutic options for patients and minimize unintended consequences of intervention.



Illustrates regions with high osteoblastic and osteoclastic activities corresponding to anabolic gains and/or catabolic loss in bone health as a function of dosing frequency and amplitude.

PO0353

Chemical Characterization and Quantitation of Circulating Intact Parathyroid Hormone and Parathyroid Hormone Fragments by High-Resolution Mass Spectrometry in Chronic Renal Failure

Kittrawee Kritmetapak,[1] Louis A. Losbanos,[3] Jolaine M. Hines,[3] Katherine O'Grady,[3] Candice Z. Ulmer,[2] Hubert W. Vesper,[2] Felicity T. Enders,[3] Ravinder Singh,[3] Rajiv Kumar.[3] *[1]Khon Kaen University, Khon Kaen, Thailand; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]Mayo Clinic Minnesota, Rochester, MN.*

Background: The precise concentrations of full-length parathyroid hormone (PTH 1-84) and the identity and concentrations of PTH fragments in patients with various stages of chronic renal failure (CRF) are unknown.

Methods: We developed a liquid chromatography-high resolution mass spectrometry (LC-HRMS) method to characterize and quantitate PTH 1-84 and PTH fragments in the serum of 221 patients with progressive renal dysfunction. Following capture by matrix-bound amino-terminal or carboxyl-terminal region-specific antibodies and elution from matrix, full-length PTH and PTH fragments were identified and quantitated using LC-HRMS. PTH was simultaneously measured using an intact PTH (iPTH) immunoassay.

Results: Full-length PTH 1-84 and eight PTH fragments (PTH 28-84, 34-77, 34-84, 37-77, 37-84, 38-77, 38-84, and 45-84) were unequivocally identified and were shown to increase significantly when the eGFR declined to less than 17-23 mL/min/1.73 m^2. Serum concentrations of PTH 1-84 were similar when measured by LC-HRMS following capture by amino-terminal or carboxyl-terminal immunocapture methods. Serum PTH 1-84 concentrations measured by LC-HRMS were significantly lower compared with PTH measured by an iPTH immunoassay in patients with eGFRs of less than 30 mL/min/1.73 m^2. PTH 7-84 was below the lower limit of quantitation of the method (<50 pg/mL).

Conclusions: LC-HRMS accurately quantitates full-length PTH, carboxyl-terminal PTH fragments, and mid-region PTH fragments, in the serum of patients with progressive renal failure. Serum concentrations of PTH 1-84 and PTH fragments increase when eGFR decreases to less than 17-23 mL/min/1.73 m^2. PTH values measured by LC-HRMS are lower than those obtained from an iPTH immunoassay in severe CRF

Management of Secondary Hyperparathyroidism Among Patients Who Transition from Daily At-Home to Three-Times-Weekly Oral Cinacalcet Given In-Center

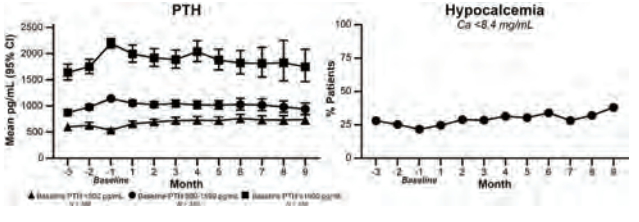
Steph Karpinski,[1] Scott Sibbel,[1] Adam G. Walker,[1] Gilbert Marlowe,[1] George R. Aronoff,[2] Deborah A. Benner,[2] Steven M. Brunelli,[1] Francesca Tentori.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Results of a small phase 1 clinical trial demonstrated the safety and potential utility of 3X weekly in-center administration of cinacalcet to control secondary hyperparathyroidism (SHPT) in hemodialysis (HD) patients. Moreover, a larger observational study demonstrated comparable control of SHPT among HD patients who initiated 3X weekly cinacalcet in-center to those who initiated cinacalcet at home. The present study assessed the effectiveness of 3X weekly in-center cinacalcet among HD patients who transitioned from cinacalcet administered daily at home in the management of SHPT.

Methods: Patients included in this analysis were ≥18 years of age, receiving standard in-center HD, Medicare beneficiaries, and had a physician order to transition from daily at-home cinacalcet to cinacalcet given 3X weekly in-center (July 2018 to December 2019). Patients were followed forward in time for up to 9 months after transition to in-center cinacalcet or until loss to follow-up or end of study. Generalized linear modeled means and 95% confidence intervals (CIs) were calculated for parathyroid hormone (PTH), calcium (Ca), and phosphorus (Phos). Hypocalcemia events were defined as Ca <8.4 mg/dL.

Results: We identified 874 qualifying HD patients who transitioned from at-home to in-center cinacalcet administration during the study period. Among patients with baseline PTH <800 pg/mL, PTH levels initially increased but stabilized after transition. Among patients with baseline PTH 800 to 1599 pg/mL and PTH >1600 pg/mL, PTH levels initially decreased but then stabilized following transition. Ca and Phos levels were generally stable for all patients following transition. Hypocalcemia was observed in approximately 25% to 38% of patients during follow-up. up.

Conclusions: These results suggest that SHPT can be stably maintained by transitioning patients from daily at-home cinacalcet to cinacalcet given in-center 3X per week. We postulate that increased prescription adherence is the likely factor mediating this effect.



PO0355

Real-World Experience with Etelcalcetide in an Academic Dialysis Program

Dennis Hu, Benjamin Lobo, Brendan T. Bowman. *University of Virginia Health System, Charlottesville, VA.*

Background: High parathyroid hormone (PTH) levels may increase fracture risk, vascular calcification, and cardiovascular disease in end-stage kidney disease (ESKD) patients. Treatments include phosphorus binders, Vitamin D analogues, and cinacalcet. However, many ESKD patients persist with high PTH levels. Etelcalcetide (ETC) is an injectable calcimimetic recently approved to treat hyperparathyroidism in ESKD. To date, few studies have described the safety and efficacy of ETC on calcium (Ca) and PTH levels in real world usage.

Methods: This retrospective chart review of 195 in-center HD patients describes those who received a stable dose of ETC for at least 12 consecutive weeks. ETC dose, Ca, albumin, and PTH levels were obtained monthly x 3 months prior to ETC start and up to 9 months post. 23 patients were included for 2 or more doses of ETC. Overall and severe hypocalcemia were defined as corrected Ca <8.3 and <7.5 mg/dL, respectively.

Results: See Table 1. PTH changed from +3.37% (2.5mg) to -32.57% (10mg) to -3.19% (15mg). As expected, ETC use yielded a statistically significant lower PTH when compared to pre-treatment average of 1 and 2 months pre-drug PTH values versus 3 months post drug average (p=0.0034 via t-test for related samples). Corrected Ca decreased in a dose dependent fashion from 0.22% (2.5mg) to 11.89% (15mg). Overall, hypocalcemia occurred in 36.6% of patients. Severe hypocalcemia ranged between 0% (2.5, 5, 12.5, 15mg) and ~ 1% (7.5, 10mg).

Conclusions: Prior studies have used aggressive PTH lowering targets (<300pg/mL or >30% reduction from baseline) yielding high rates of hypocalcemia (61-68%). Our study is the first to describe results of a typical real world dosing strategy. Our results suggest that PTH levels decrease in a dose dependent fashion and severe hypocalcemia is rare. At doses > 10mg diminishing PTH reductions occur which could be due to a preponderance of patients with refractory / tertiary hyperparathyroidism. Rates of overall and severe hypocalcemia were lower here. Limitations of this study include limited adjustment for confounding variables, retrospective nature and small population at higher doses.

ETC dose	2.5mg	5mg	7.5mg	10mg	12.5mg	15mg
Number of patients	45	106	40	17	6	4
Percent change in corrected Ca at 3 months	-0.22%	-5.5%	-9.47%	-7.37%	-8.21%	-11.89%
Rate of severe hypocalcemia (%)	0	0	0.9	0.9	0.45	0
Percent change in PTH at 3 months	+3.37%	-16.21%	-7.32%	-32.5%	-24.18%	-3.19%

PO0356

The Cost Effectiveness of Alternate-Day Cinacalcet Therapy for Secondary Hyperparathyroidism (SHPT) in Hemodialysis Patients

Mohammed A. Alhomrany,[1] Muhammed Saeed,[1] Dujanah H. Mousa,[1] Ali Alharbi,[1] Saeed Al-Ghamdi.[2] Diaverum AB *[1]Diaverum AB, Riyadh, Saudi Arabia; [2]King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia.*

Background: CKD defines as abnormalities of kidney structure or function, present for more than 3 months with implication for health. Secondary hyperparathyroidism (SHPT) is one of implication of CKD, which eventuate with decrease in GFR. The Initial treatment starts with incremental approach, constrain of Dietary Phosphorus, use of calcium and non-calcium phosphorus binders and additional Vit D Analogues. Next approach to Secondary hyperparathyroidism (SHPT) after poor response to initial therapy is to use Cinacalcet. Cinalcalcet act by activating calcium sensing receptor of parathyroid hormone gland directly and it bypass normal physiological process. It has half-life of 30-40 hours. Cinacalcet is excreted 80 % through kidney and 20 % through liver.

Methods: We did prospective control study by following Dialysis patients (N=88) who were receiving alternate day Cinacalcet either by physician's choice or due to noncompliance to home medications. We followed Intact PTH every 3 months, Serum Calcium and serum phosphorus every month after start of alternate day therapy until six months and compared it with 6 months data before start of alternate day Cinacalcet. Data was analyzed by using paired T-Test.

Results: A total of 88 patients were enrolled in the study, who were on hemodialysis for at least one year. The mean age of patients was 49.17± 15.89, and 56.8 percent of them were males. The mean duration of dialysis was 6.68 ± 5.27 years and 40.9 percent of patients had diabetic nephropathy as a cause of End stage renal disease. The patients were transferred from once daily dosing to 3 times post hemodialysis dose. The mean post hemodialysis dose of cinacalcet was 62.73 ± 27.71 mg. The baseline mean PTH value before shifting to alternate dose was 986.69 ± 503.370 and after was 798.24 ± 526.92 and the P value was 0.001. The mean serum calcium before was 8.28 ± 2.30 and after it was 8.72 ± 1.42 with a p value of 0.03. Serum phosphorous before and after was, 4.66 ± 1.53, 4.86 ± 1.19 with a P – value of 0.147.

Conclusions: Cinacalcet effectively controls secondary hyperparathyroidism even with modified regimen as used in our study. Cinacalcet showed significant reductions of PTH with intermittent (3/week) dosing and thus is more cost effective and has better directly observed compliance.

PO0357

A Real-World Observational Study of Calcimimetic Use in Hemodialysis (HD) Patients with Secondary Hyperparathyroidism (SHPT) in Europe

Bruno Fouqueray,[9] Karly S. Louie,[1] Matthias Kohnle,[10] Daniel Cejka,[2] Giorgina B. Piccoli,[3,4] Marianne Rix,[5] Corrado Camerini,[11] Johannes M. Boots,[6] Andreja Marn Pernat,[12] Laura Labriola,[7] Jose-Vicente Torregrosa,[13] Chidozie U. Nduka,[1] Kate Tsirtsonis,[1] Jürgen Floege.[8] *[1]Amgen Ltd Uxbridge, Uxbridge, United Kingdom; [2]Department of Medicine III, Division of Nephrology and Dialysis, Medical University Vienna, Vienna, Austria; [3]Nephrology, Centre Hospitalier Le Mans, Le Mans, France, Le Mans, France; [4]Department of Clinical and Biological Sciences, University of Torino, Orbassano, Italy; [5]Department of Nephrology, University Hospital Copenhagen, Copenhagen, Denmark; [6]Department of Internal Medicine and Nephrology, Maasstad Hospital, the Netherlands, Rotterdam, Netherlands; [7]Department of Nephrology, Cliniques Universitaires Saint-Luc, Universite Catholique de Louvain, Brussels, Brussels, Belgium; [8]Division of Nephrology, RWTH University of Aachen, Aachen, Germany; [9]Amgen GmbH, Rotkreuz, Rotkreuz, Switzerland; [10]Nephrologisches Zentrum Mettmann, Gartenstrasse 8, Mettmann, Mettmann, Germany; [11]Spedali Civili Brescia, Brescia, Brescia, Italy; [12]University Medical Center Ljubljana, Ljubljana, Ljubljana, Slovenia; [13]Nephrology and Renal Transplant Department, Hospital Clinic, University of Barcelona, Barcelona, Barcelona, Spain.*

Background: Calcimimetics, oral cinacalcet (CIN) and intravenous etelcalcetide (ETEL), are approved for treating SHPT in adult patients on maintenance HD. Data on real-world use of calcimimetics are needed to provide guidance in clinical practice.

Methods: In this observational study, Chronic HD patients treated with calcimimetics for SHPT, with ≥1 parathyroid hormone value (PTH) recorded within ≤90 days before calcimimetic initiation, were included. Data on demographics, clinical history, laboratory values and calcimimetic use were abstracted from medical charts.

Results: Interim data for 503 HD (96 CIN and 407 ETEL) patients from 57 sites across 12 countries are reported. At baseline, CIN patients had been calcimimetic naive while 45% (183/407) of ETEL patients had switched from CIN to ETEL (≤90 days from last CIN prescription). ETEL patients were younger than CIN (median: 63 vs. 69 yrs). Dialysis vintage was longer for ETEL patients (median: 5 vs. 2 yrs). Starting dose was 30 mg/day for 98% of CIN, and 5 mg and 2.5 mg thrice weekly for 58% and 41% of ETEL patients respectively. **Table 1** summarizes median PTH and mean total calcium (Ca) and phosphate (P) levels. Among 341 ETEL and 79 CIN patients who had normal Ca at baseline, the cumulative incidence of hypocalcemia (<2.1 mmol/L) at 3 and 6 months was greater for CIN (47% and 58%) than ETEL (35% and 52%). As recorded in medical charts, nausea and vomiting rates at 12 months were similar for CIN (3.7% and 1.8%) and ETEL (3.6% and 1.9%). ETEL persistence (89.6%) was greater than CIN (71.8%) at 12 months. During follow-up, 13.5% switched from CIN to ETEL and 2.5% from ETEL to CIN. The proportion of patients achieving >30% reduction in PTH from baseline was greater for CIN than ETEL at 6 months (64% vs. 54%) but similar at 12 months (73% vs. 74%).

Conclusions: This is the largest real-world study on calcimimetics following 2016 approval of ETEL in Europe. There were marked reductions in PTH, Ca, and P levels. Gastrointestinal events did not differ between ETEL and CIN groups.

PO0358

Indirect Comparison of Treatments for Secondary Hyperparathyroidism Through a Network Meta-Analysis

Joel Gunnarsson,[2] Rosa Lauppe,[2] Philipp Csomor,[1] Astride Grava,[1] Marco Soro.[1] *[1]Vifor Pharma Ltd, Glattbrugg, Switzerland; [2]Quantify Research AB, Stockholm, Sweden.*

Background: Secondary hyperparathyroidism (SHPT) is a complication of chronic kidney disease (CKD) affecting mineral and bone metabolism and characterized by excessive parathyroid hormone (PTH) production and parathyroid hyperplasia. Currently the only 2 treatments indicated for the treatment of SHPT in non-dialysis CKD (ND CKD) are paricalcitol (PCT) and more recently extended release calcifediol (ERC). The objective of this analysis was to compare the efficacy and safety of ERC and PCT by assessing their effect on biomarkers PTH, calcium and phosphate.

Methods: A systematic literature research (SLR) was performed in PubMed to identify randomized control trials (RCTs) to be included in a Network Meta-Analysis (NMA). In all articles, the comparator groups were consisting of placebo. A quality assessment was done with the GRADE method. The treatment effects of ERC and PCT were compared using random effects in a frequentist setting, and a sensitivity analysis with Bayesian approach was performed using random effects model. Comparisons were made between the overall treatment effects of the drugs.

Results: Nine RCTs comprising a total of 1426 patients were included in the analyses. Compared to placebo, treatment with both PCT and ERC lowered levels of PTH in a statistically significant manner. No statistically significant differences in PTH reduction were found between PCT and ERC. Treatment with PCT significantly increased calcium levels compared to placebo (effect size: 0.30 mg/dl, 95 % CI: 0.21 to 0.40 mg/dl), while the estimated effect of ERC on calcium (effect size: 0.10 mg/dl) was not significant (95 % CI: -0.03 to 0.23 mg/dl). The calculated difference of effects between treatment with PCT and ERC shows that PCT significantly raises levels of calcium by 0.2 mg/dl (95 % CI: -0.37 to -0.04 mg/dl). No differences in effects on phosphate were observed. Sensitivity analyses using a Bayesian approach confirmed the general pattern of similar PTH reductions and larger increases in calcium from PCT observed in the analyses.

Conclusions: This NMA showed that ERC is non inferior in lowering PTH levels vs PCT. ERC displayed avoidance of clinically relevant increases in serum phosphorus and calcium, offering a new, effective and well tolerated treatment option for the early management of SHPT in patients with ND CKD.

PO0359

Parathyroidectomy Improves Muscular Function but Not Muscle Mass in Hemodialysis Patients with Severe Hyperparathyroidism

Eduardo J. de Sa C. Filho,[1] Shirley F. Crispilho,[2] Carla M. Avesani,[3] Rosa M. Pereira,[1] Vanda Jorgetti,[1] Peter Stenvinkel,[3] Bengt Lindholm,[3] Rosilene M. Elias,[1,2] Rosa M. Moyses.[1] *[1]Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil; [2]Universidade Nove de Julho, Sao Paulo, Brazil; [3]Karolinska Institutet, Stockholm, Sweden.*

Background: Increased levels of parathyroid hormone (PTH) are associated with a negative impact on the bone-muscle axis including sarcopenia and osteoporosis, and it is possible that treating hyperparathyroidism (HPT) can ameliorate these disturbances. However, the effects of parathyroidectomy (PTX) on muscle mass, strength and performance have not been thoroughly investigated. This study aims to evaluate the impact of PTX on muscle (mass, strength, and performance), body fat and resting energy expenditure (REE) in patients on hemodialysis with severe HPT

Methods: We are prospectively evaluating muscle mass, strength and performance of 30 patients before and after 6 months of PTX by using Actigraph GT3X accelerometer, timed-up-and-Go(TuG), Sit-to-Stand-to-Sit(STS) and muscle strength tests [handgrip(HGS), supine(SP), leg press(LP)]. Body composition was assessed by dual-energy x-ray absorptiometry, and REE was examined by indirect calorimetry. Participants completed the SARC-F questionnaire.

Results: At 6 months after PTX, 20 patients who already completed the protocol, showed a significant drop in PTH [1510(1368-1885) vs. 91(38-260) pg/mL; p<0.01], a significant increase of number of steps/day [4759(3572–6185) vs. 6343(4123–8540) p 0.01] and improvements of strength tests: HGS(27±14 vs 31±14 kg p 0.01); SP(26±15 vs 31±16 kg p 0.01] and LP[24±23 vs.50±43 kg p 0.01]. In addition, there was an improvement of SARC-F scores [6(2-8)vs 3(1-7) p<0.01] and STS [8±4 vs.10±2 p=0.02] and a reduction of TuG [10 vs. 8 s p<0.01]. A significant increase in bone mineral content [1.8(1.6-2.2) vs 2.2(2-2.6) kg p=0.001], fat mass [21±8 vs 24.5±9kg p<0.01] and visceral adipose tissue [530(287-871) vs 975(383-1476)g p<0.01] was seen. No change was noted in skeletal muscle index and in REE [1643 vs.1573 kcal/d p=0.7). We noticed an increase in IGF-1 [199 vs 201 μg/L p=0.04] and HOMA index [1.6 vs 1.72 p=0.02], but no variation was found in serum albumin.

Conclusions: In hemodialysis patients with sHPT undergoing PTX, there were improvements of muscular function and bone mass, but not of muscle mass, at 6 months after PTX. Our findings suggest that PTH-associated sarcopenia is mediated not only by a decrease in muscle mass but also by muscle dysfunction.

PO0360

Indications and Justification for Parathyroidectomy in Secondary Hyperparathyroidism

Aswin Srinivasan,[4,3] Sangeeta Mutnuri,[6] Shabbir Safri,[5] Mahendra L. Agraharkar.[1,2] *[1]University of Texas Medical Branch at Galveston, Galveston, TX; [2]Baylor College of Medicine, Houston, TX; [3]HCA Gulf Coast Division, Houston, TX; [4]University of Houston System, Houston, TX; [5]Montefiore Medical Center, Bronx, NY; [6]Creighton University, Omaha, NE.*

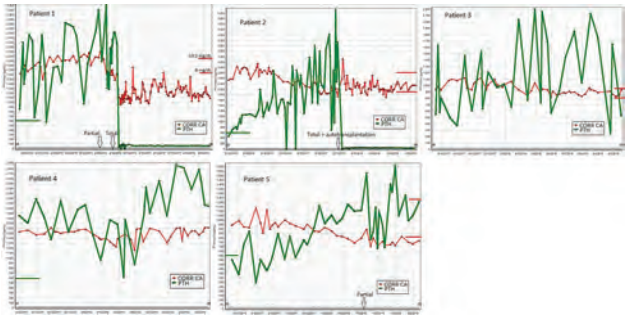
Introduction: Hyperparathyroidism (HPT) is a common complication of CKD, which is treated by diet, medications and surgery. Parathyroidectomy (PTectomy) is reserved for patients with refractory HPT. There are no guidelines for the timing or type of surgery. We describe five patients with HPT, who were treated with different modalities with unsatisfactory outcomes.

Case Description: We present 5 patients in a table format. Patient 1 had total PTectomy that resulted in serious hypocalcemia needing hospitalizations. After 3 years, she remains hypocalcemic requiring high doses of Vit D and calcium. Selecting a suitable phosphate binder in this patient was difficult due to hypocalcemia. Patient 2 underwent total PTectomy with autotransplantation which resulted in low calcium levels that resolved over time, but PTH levels remained very low. Patients 3 and 4 refused surgery and their PTH levels fluctuated significantly, falling to levels much below the acceptable level of 600 pg/ml. Patient 5 underwent partial PTectomy and 2 enlarged PT glands were removed. This resulted in lower calcium and higher PTH levels than prior to surgery.

Discussion: The medical management for HPT in all five patients failed. We opted for surgery when the PTH levels were in a range of 1300 to 4000 pg/ml. The surgeon decided the type of surgery. In patient 1, intraoperative PTH was measured that resulted in removal of only three glands. But within a very short time, the PTH bounced back to 2500 pg/ml which was much higher than presurgery level, and total parathyroidectomy was performed. We cannnot recommend specific surgical modality based on this experience. Therefore, we strongly feel that there is a need for larger controlled studies to elucidate specific guidelines for treating refractory HPT.

Patient Demographics

Patients	Age/Sex	PTectomy: P=Partial, T=Total, T+A=Total + Autotransplantation	Ca, PO4 and PTH
1	49-yr male	P then T	↓Ca, ↑PO4, ↓PTH
2	49-yr female	T+A	N Ca, N PO4, ↓PTH
3	59-yr male	No	Fluctuating
4	59-yr male	No	Fluctuating
5	56-yr male	P	↓Ca, ↑PTH, ↑PO4,



PO0361

Palatal Brown Tumor in a Dialysis Patient

Nawal Habib, Scott Mullaney, Alexander Bullen, Danuta Trzebinska, Tamara T. Rubenzik. *University of California San Diego, La Jolla, CA.*

Introduction: Secondary hyperparathyroidism (SHPT) is a common complication of end stage kidney disease (ESKD) causing loss of bone density through increased osteoclastic activity. Imbalanced bone resorption and peri-trabecular fibrosis causes formation of hemosiderin-laden giant cell granulomas – brown tumors. Here is a case of palatal brown tumor in an ESKD patient which led to complications of hungry bone syndrome after parathyroidectomy.

Case Description: A 57 yo F with ESKD on HD and SHPT presented with a growing palatal mass. She reported difficulty chewing and shortness of breath. A friable mass was located over the hard palate. Labs showed serum calcium (Ca) 9.5 mg/dL, PTH 4477 pg/mL, phosphate 5.1 mg/dL, and alkaline phosphatase (ALP) 1124 U/L. Parathyroid scan showed a focus of activity in the left thyroid bed. She underwent a mass resection and parathyroidectomy. Pathology revealed an atypical parathyroid adenoma without features of carcinoma. Her postoperative course was complicated by hungry bone syndrome with prolonged hypocalcemia, hypomagnesemia and hypophosphatemia which persisted despite aggressive Ca supplementation and high Ca dialysate. She was also started on teriparatide to stimulate osteoblast activity and bone formation. After a long hospital course, she was discharged on oral supplemental Ca and calcitriol with close follow-up.

Discussion: Despite the advent of effective management strategies for renal osteodystrophy, we must be mindful of brown tumors. Surgical excision with parathyroidectomy is the preferred treatment. Post-operatively, patients must be monitored for hungry bone syndrome. As bone formation increases, rising ALP levels can serve as a biomarker for increasing Ca requirements requiring escalating dosage of supplements. Teriparatide is a recombinant human PTH which can be used to augment bone density.

PO0362

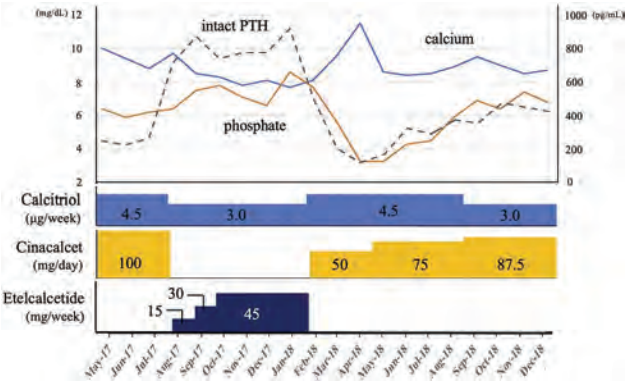
A Case of a Hemodialysis Patient with Secondary Hyperparathyroidism, Effectively Treated with Cinacalcet Hydrochloride but Not with Etelcalcetide

Hironori Nakamura,[1] Anayama Mariko,[1] Yasushi Makino,[1] Masaki Nagasawa,[1] Masanori Tokumoto.[2] *[1]Department of Nephrology, Shinonoi General Hospital, Nagano, Japan; [2]Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan.*

Introduction: Although both cinacalcet hydrochloride and etelcalcetide are calcimimetics that directly inhibit the parathyroid hormone (PTH) secretion by activating the calcium (Ca)-sensing receptor, their binding sites are different.

Case Description: We report a rare case of a hemodialysis (HD) patient with secondary hyperparathyroidism, in whom cinacalcet was effective to reduce serum intact PTH (i-PTH) level but not etelcalcetide. A HD patient underwent total parathyroidectomywith autotransplantation to his right forearm 19 years ago. His i-PTH level had been almost controlled with 100 mg of cinacalcet. At a month after switching to etelcalcetide, serum i-PTH level increased from 269 pg/mL to 716 pg/mL. Although the dose of etelcalcetide was gradually increased to 45 mg/week, the maximal dose of etelcalcetide, serum i-PTH level increased to 919 pg/mL. Therefore, etelcalcetide was switched to 50 mg/day of cinacalcet, and his i-PTH level decreased to 208 pg/mL.

Discussion: Thus, the present case has resistance to etelcalcetide treatment but not cinacalcet, suggesting that his parathyroid gland might have partial deletion or mutation in the extracellular domain of the Ca-sensing receptor. Therefore, we should consider the possibility of resistance to etelcalcetide treatment while treating secondary



PO0363

Hypercalcemia Resulting from Spindle Cell Tumor-Induced Calcitriol Production

Tejas Gopal,[1,2] Pranu Neelam,[1,2] Paul C. Nader.[1,3] *[1]University of Texas at Austin, Austin, TX; [2]Ascension Texas, Austin, TX; [3]Austin Kidney Associates, Austin, TX.*

Introduction: Less than 1% of cases of hypercalcemia of malignancy are caused by overproduction and release of 1,25-dihydroxy vitamin D (calcitriol) by tumor cells.[1] Calcitriol excess has been identified most often in sarcoidosis, hematologic malignancy, and infection.[2] We present a patient who developed severe hypercalcemia and acute kidney injury as a result of spindle cell neoplasm-mediated calcitriol excess, with normalization of serum calcium and creatinine in response to treatment with prednisone.

Case Description: A 65yo man with a history of a large retroperitoneal mass presented with malaise. He was not taking calcium or vitamin D supplements. Initial lab showed serum calcium 15.7 mg/dL, 1,25-dihydroxy Vit. D 126 pg/mL (elevated), and creatinine 4.5 mg/dL. His PTH 8 pg/mL, PTHrP 0.8 pmol/L, and 25-hydroxy Vit. D 26 ng/mL were suppressed or normal. SPEP, UPEP, serum immunofixation, and serum free light chains were unremarkable. Pathology of the mass revealed a spindle cell neoplasm embedded within fibrous stroma. Prednisone was prescribed to suppress tumor-associated calcitriol production. His serum calcitriol level fell to 33.2 pg/mL, with a serum calcium of 10.9 mg/dL, after taking prednisone 40 mg/day for 2 weeks. His calcitriol 39.2 pg/mL, calcium 8.7 mg/dL, and creatinine 0.81 mg/dL levels were normal while on prednisone 20 mg/day at 76 days after starting corticosteroids and before any anti-tumor therapy or surgical debulking.

Discussion: The conversion of 25-hydroxy Vit. D to calcitriol is catalyzed by 1-alpha hydroxylase, a phenomenon that can occur in extra-renal tissues, such as within macrophages in sarcoid tissue.[3-6] We hypothesize that elevated 1-alpha hydroxylase activity in spindle tumor cells or in activated macrophages within tumor stroma was responsible for excess calcitriol production and the resultant hypercalcemia. Corticosteroids inhibit the 1-alpha hydroxylase conversion of 25-hydroxy Vit. D to calcitriol and have been used successfully to reduce malignancy-induced calcitriol production.[6,7] This case provides evidence of severe hypercalcemia due to endogenous production of calcitriol associated with a large spindle cell neoplasm, with rapid normalization of both serum calcium and calcitriol levels in response to treatment with prednisone, without anti-tumor therapy or surgical debulking.

PO0364

Unexplained Persistent Hypercalcemia After Liver Transplantation

Luba Muaddi, Kalathil K. Sureshkumar, Bhavna Chopra. *Allegheny General Hospital - Western Pennsylvania Hospital Medical Education Consortium, Pittsburgh, PA.*

Introduction: Hypercalcemia has been reported as a sequela of chronic liver disease in association with hyperbilirubinemia. Previous reports of hypercalcemia post liver transplant were thought to be potential rare complication of altered bone metabolism under intense immunosuppression and from prolonged immobilization. However the pathogenesis of this rare phenomenon has not been clarified to this date. We present cases of unexplained severe persistent hypercalcemia in three liver transplant recipients.

Case Description: Hypercalcemia post liver transplant in 3 recipients described in Table 1 and calcium trends shown in Figure 1.

Discussion: Extensive work up for hypercalcemia was negative in our patients. Although immobilization could be contributory, other unrecognized possibilities are plausible. Immunosuppression with steroids and other agents, especially cyclosporine, has been hypothesized to cause calcium imbalance by inhibiting T cell activation and transcription of interleukin-2 which are involved in bone turnover. Depletion of T cells upregulates osteoclastogenesis through prostaglandin production; by interfering with receptor activator of nuclear factor kappa ligand (RANK-L) and osteoprotegerin on osteoblasts. However, only one patient was on cyclosporine. Other, yet unidentified, factors modifying calcium metabolism could be involved. We would like to draw attention to this fascinating phenomenon in order to gain more insight. Low dialysate calcium, pharmacotherapy (Calcitonin, Pamidronate and Denusomab) along with improved mobility had successfully lowered serum calcium in these patients. One patient had hypocalcemia after Denusomab administration, hence needed careful monitoring.

Descriptions of hypercalcemia cases post liver transplant.

Patient	Age / Gender	Medical History	Cause of liver failure	Associated AKI	Immunosuppression	Calcium levels (mg/dL)	Treatment of hypercalcemia	Hypercalcemia work up	Other Complications

PO0365

A Rare Case of Hyperthyroidism Presenting with Symptomatic Hypercalcemia

Sameed K. Lodhi,[1] Sravan Jasti,[1] Hareem Ghazanfar.[2] [1]*Carle Foundation, Urbana, IL;* [2]*King Edward Medical University, Lahore, Pakistan.*

Introduction: Primary hyperparathyroidism and hypercalcemia are by far the most common causes of hypercalcemia in clinical practice. Asymptomatic hypercalcemia with minimally raise calcium levels have been documented in 20% of cases of hyperthyroidism as well and is related to increased bone resorption by osteoclasts and subsequent release of calcium into circulation. We describe a rare case of hyperthyroidism with symptomatic hypercalcemia as the first clinical manifestation.

Case Description: A 60 year old male with a history significant for chronic kidney disease, stroke and hypertension was admitted to the hospital following a syncopal event. Physical examination and baseline investigations were normal other than elevated calcium levels of 12.1 mg/dl. PTH levels and PTHrP levels were normal ruling out hyperparathyroidism and paraneoplastic related hypercalcemia. Vitamin D levels were also found to be normal. Workup for multiple myeloma was negative. Thyroid panel was done which showed extremely low levels of TSH (<0.005 mIU/L) with elevated T3 and T4 levels (12.9 ng/dL and 5.52 ng/dL respectively). Thyroid scan was performed which showed significant thyroiditis. Thyrotropin receptor antibody test also came positive. The patient was diagnosed with Graves' disease based on the laboratory investigations and subsequently started on 5 mg methimazole TID. He also received one dose of zolendronic acid in the hospital. His calcium levels stabilized, falling from 12.4 to 9-10 mg/dL within 1 month. Patient received methimazole for a total of 7 months after which it was discontinued as his TSH levels (1.38 mIU/mL), T3 levels (2.19 ng/dL) and T4 (0.78ng/dL) normalized. Patient further underwent radioiodine ablation for the treatment of Graves' disease.

Discussion: In past, multiple cases have been reported of concurrent hyperparathyroidism or vitamin D deficiency in hyperthyroid patients. This case is unique as the patient presented with symptomatic hypercalcemia in the absence of other causes and in the absence of other more common symptoms of hyperthyroidism. To our knowledge, only 2 cases of hyperthyroidism have been reported previously with hypercalcemia as the first clinical manifestation. Clinicians should be aware of association of hypercalcemia with hyperthyroidism as it will facilitate early diagnosis and appropriate intervention.

PO0366

Low Phosphate and Low Calcium Levels Predict Higher Risk for Adverse Events of Maintenance Hemodialysis

Takahiro Kuragano, Takeshi Nakanishi. *Hyogo College of Medicine Kidney and dialysis, Nisinomiya, Japan.*

Background: It is well known higher serum levels of phosphate (P) and calcium (Ca) associated with higher risk of cardiovascular disease (CVD) and premature death of hemodialysis (HD) patients. However, in the current situation that guidelines penetrated widely, there are few reports which investigated the association CKD-MBD related factors and adverse events of HD patients.

Methods: The study design was the multiple centers, observational study for 3yeras. 989 HD patients were enrolled in this study. Hb, ferritin, creatinine, total protein, albumin, total cholesterol, Ca and P levels were measured every 3 months. Hhigh-sensitivity C-reactive protein (hCRP) and intact-parathyroid hormone (int-PTH) were also measured every six months. The correlation between CKD-MBD factors and adverse events were evaluated by the time depended cox hazard model.

Results: 82% (P), 83% (Ca), and 78% (int-PTH) of patients were maintained in a target range. After correlated with age, sex, past history of CVD, Hb, albumin, and hCRP, compared with the patients with target levels of P, patients with low P levels were significantly higher risk for CVD (P=0.042, HR:2.27), hospitalization (P=0.034, HR:2.44), and all caused mortality (P=0.03, HR:2.29). Compared with the patients who maintain target int-PTH levels, patients with lower (P=0.025, HR:1.46) and higher (P=0.04, HR:1.44) int-PTH were significantly higher risk for hospitalization. Furthermore, compared with the patients who maintain the target levels both of Ca and P, the patients with target Ca and low P levels (P=0.042, HR: 2.75) were significantly higher risk for CVD. And compared with the patients who maintain the target levels both of Ca and P, the patients with low Ca and low P levels (P<0.001, HR: 4.4) and target Ca and low P levels (P=0.22, HR: 2.0) were significantly higher risk for hospitalization.

Conclusions: Although after corelated by several clinical factors, we found that patients who maintain the low serum P levels beard significantly higher risk for CVD and all caused mortality than patients who maintained higher Ca and P levels. Without doubt, extremely higher serum P, Ca, and int-PTH levels should be treated according to guidelines. However, in the current situation that guidelines penetrated widely, CKD-MBD managements which considered the clinical conditions of low P, Ca, and int-PTH are needed.

PO0367

The True State of Hyperphosphatemia Management in Dialysis

Tucker B. Hurtado, Jennifer Robinson. Spherix Advanced Analytics Group *Spherix Global Insights, Exton, PA.*

Background: Hyperphosphatemia affects more than 80% of US dialysis patients and has been shown to have a direct link to increased morbidity and mortality. The objective of this study was to assess the current management of hyperphosphatemia in US dialysis patients and the ability to consistently control serum phosphorus over a six-month period.

Methods: Patient level data was collected via an online, HIPAA-compliant form in June 2019 as part of an independent chart audit. A total of 1,015 patient records (789 in-center HD, 200 PD, and 26 home HD) were submitted by 159 nephrologists. Patients had been on dialysis for at least six months (Mean: 26, Median: 15) and most were in LDO-affiliated units.

Results: Patients in the consistently high group had been on dialysis longer than those consistently in target or in the target-high variability group (36 months vs. 23 months) and were also younger on average (53 years vs. 61 years). Those in the consistently high and high-target group (CH/HT) had a 37% higher daily pill burden (from binders) than those consistently in target. Patients dialyzing in Fresenius units were the most likely to be consistently in target (27%). Compared to those consistently in target, those in the CH/HT group were significantly more likely to have diabetes, obesity, heart failure and coronary artery disease. They were also six times as likely to have poorly controlled hypertension. Ethnicity also was correlated with phosphate control with a disproportionate percent of non-white patients in the consistently high and high-target variability groups.

Conclusions: Not only is hyperphosphatemia rampant at any given time, but only a small minority of patients on phosphate binders (19%) are able to achieve consistent control; most patients fluctuate in and out of target. Increased phosphate binder dosing was not associated with better control and suggests that a new approach to the management of hyperphosphatemia is warranted.

PO0368

Hyperphosphatemia with Elevated Serum FGF-23 and PTH, Reduced Calcitriol, and Normal FGF7 Concentrations Characterizes Chronic Renal Failure in Humans

Kittrawee Kritmetapak,[1,2] Louis A. Losbanos,[1] Taylor Berent,[1] Susan L. Ashrafzadeh-Kian,[1] Alicia Algeciras-Schimnich,[1] Jolaine M. Hines,[1] Ravinder Singh,[1] Rajiv Kumar.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Khon Kaen University, Khon Kaen, Thailand.*

Background: Fibroblast growth factor 23 (FGF23), a phosphatonin produced by osteocytes, regulates phosphate (Pi) homeostasis and is increased in CKD. A recent study showed that low serum (s) concentrations of FGF7 may contribute to hyperphosphatemia in patients with hypophosphatasia, and are elevated in some patients with tumor-induced osteomalacia and hypophosphatemia. We hypothesized that FGF7 might play a role in compensating for elevated Pi concentrations in CKD.

Methods: We measured serum concentrations of intact FGF7 (iFGF7, R&D Systems), iFGF23 (Eagle Biosciences), intact parathyroid hormone (iPTH) by enzyme-linked immunosorbent assays and determined s Pi, and 1,25-dihydroxyvitamin D ($1,25(OH)_2D$, by mass spectrometry) among 75 non-kidney transplant patients with varying estimated glomerular filtration rate (eGFR). Relationships between these parameters and eGFR were explored.

Results: For eGFR of 60 or more (n=29), 45-59 (n=14), 30-44 (n=9), 15-29 (n=13), and under 15 mL/min/1.73 m^2 (n=10), the median (IQ25-75) iFGF23 concentrations were 41.9 (33.1-47.4), 56.4 (47.4-58.6), 62.9 (53.2-75.6), 117.5 (87.6-137.2), and 327.5 (195.1-456.3) pg/mL, respectively (P <0.01). At comparable eGFRs, median (IQ25-75) iFGF7 concentrations were 46.1 (40.8-56.1), 43.1 (39.2-49.2), 45.4 (38.5-53.8), 47.7 (38.5-54.6), and 46.1 (40.8-54.6) pg/mL, respectively (P = 0.81). Negative correlations between Pi (r = –0.46; P <0.01), iPTH and eGFR (r = –0.33; P <0.05), and a positive correlation between $1,25(OH)_2D$ and eGFR (r = 0.51; P <0.01) were demonstrated. Significant increases in iFGF23, iPTH, and Pi were observed at eGFRs of less than 33 (95% CI, 26.40-40.05), 29 (95% CI, 22.51-35.36) and 22 mL/min/1.73m^2 (95% CI, 19.25-25.51), respectively. Moreover, significant decreases in $1,25(OH)_2D$ were observed at eGFRs of less than 59 mL/min/1.73m^2 (95% CI, 36.57-81.43). iFGF7 concentrations did not significantly correlate with eGFR, Pi, iFGF23, iPTH, and $1,25(OH)_2D$.

Conclusions: Increases in serum concentrations of Pi, iFGF23, iPTH, but not iFGF7, and decreases in $1,25(OH)_2D$ are observed as renal function declines in CKD.

PO0369

Effects of a Reduced Phosphorous Diet on the Circulating Metabolome in Healthy Adults

Shejuti Paul, Orlando M. Gutierrez. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Excess phosphorus intake is linked to hypertension, heart failure, and disorders of bone and mineral metabolism. The reasons for these associations are unclear. Most prior work on the effects of diet phospohrus have focused on changes in specific endocrine factors in the blood. Less is known about the effects of nutritional phosphorus intake on the human metabolome, which represents the integrated biologic response to changes in diet.

Methods: In 37 healthy adults, we performed a global metabolomic analysis using untargeted mass spectrometry in plasma samples obtained after consuming a high phosphorus diet (1900/day) for 2 weeks (considered baseline for this study) and after consuming a reduced phosphorus diet (1200 mg/day) fo 6 weeks. Metabolomic profiling was conducted by Metabolon, Inc. using standard protocols. Matched pairs t-tests were used to identify analytes that significantly changed from baseline to six weeks, with each individual serving as his or her own control.

Results: The mean age of study participants was 34±12 years, 36% were black and 49% were men. A total of 222 metabolites significantly changed from baseline to six weeks on a reduced phosphorus diet using a false discovery rate < 0.05 to take into account multiple comparisons. Major analytes which differed in six-week vs. baseline samples included metabolites related to tryptophan metabolism, microbiome related biochemicals, urea cycle, bile acids, corticosteroids and androgenic steroids, and acyl carnitines. Changes in specific analytes of note within each of these pathways are depicted in the Figure.

Conclusions: In healthy adults, a reduced phosphorus diet altered metabolites related to the microbiome, urea cycle, steroid hormones, energy and lipid metabolism.

PO0370

Hospital Admission Rates Among Hemodialysis Patients with Persistent Hyperphosphatemia Who Were Prescribed Changes in Phosphate Binder Treatment: A Retrospective Analysis of Real-World Data

Sagar U. Nigwekar,[1] Vidhya Parameswaran,[2] Linda Ficociello,[2] Claudy Mullon,[2] Michael S. Anger,[2] Robert J. Kossmann.[3] *[1]Massachusetts General Hospital, Boston, MA; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: Phosphate binders (PB) may have different formulations, potency, and pill burden, however, there is limited data on hard outcomes to support decisions in PB therapy. The goal of this retrospective analysis is to determine the rate of all-cause hospital admissions of patients who, at baseline, remained hyperphosphatemic despite treatment with sevelamer carbonate (SC) and had prescriptions to either (1) switch to monotherapy sucroferric oxyhydroxide (SO) or (2) switched to Non-SO binders [Calcium Acetate, Lanthanum Carbonate, or Ferric Citrate] or added one of these PBs to SC therapy.

Methods: Deidentified clinical and prescription data were retrospectively extracted from the Fresenius Kidney Care data warehouse and pharmacy records. All prescription changes were the result of routine clinical care. We aimed to control for selection bias by using Inverse Probability of Treatment Weighting (IPTW). This method was chosen due to its ability to balance baseline characteristics between the two groups and maintain adequate sample size.

Results: We identified 1,076 patients with baseline hyperphosphatemia despite SC prescription who switched PB therapy, including 319 patients with SO therapy and 757 patients with Non-SO therapy. Patients switched to SO had 27 fewer hospital admissions per 100 patient-years compared to patients with Non-SO therapy (Table 1)

Conclusions: In a retrospective database analysis of hemodialysis patients previously treated with sevelamer carbonate and switched to SO or Non-SO phosphate binder therapy, patients switched to SO monotherapy had a lower rate of hospital admissions than patients switched to other, non-SO phosphate binders

Funding: Commercial Support - Fresenius Medical Care Renal Therapies Group

	Incidence Rate per 100-PY [95% CI]	Incidence Rate Ratio [95% CI]	Incidence Rate Difference per 100-PY [95% CI]	p
SO (319 pts)	152.7 [147.0, 168.0]	0.849 [0.792, 0.904]	-27.1 [-41.3, -13.4]	0.002
Non-SO (757 pts)	179.8 [170.2, 189.4]

PO0371

An Observational Analysis of Hospital Admissions and Total Member Costs Associated with the Use of Various Phosphate Binders Used in Dialysis Patients Included in ESRD Seamless Care Organizations

Kristain C. Lindemann,[1] Christiana Ajala,[1] Melissa M. Rosen,[2] Claudy Mullon,[2] Robert J. Kossmann,[3] Terry L. Ketchersid,[3] Linda Ficociello.[2] *[1]Fresenius Health Partners, Waltham, MA; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: A prior observational study using real world data and estimates of hospitalization costs based on national data, found patients continuing sucroferric oxyhydroxide (SO) therapy had fewer hospital admissions and expected lower healthcare costs when compared to patients switching to another phosphate binder (PB). End Stage Renal Disease (ESRD) Seamless Care Organizations (ESCOs) coordinate treatment for 10% of Medicare dialysis patients in the U.S. By providing quality care, ESCOs may control costs by avoiding unnecessary hospitalizations. The aim of this analysis was to assess hospitalizations and costs associated with various PBs prescribed to dialysis patients in ESCOs.

Methods: Patients included in the analysis had PBs prescribed during 2016-2018 in ESCOs along with parathyroid (PTH) levels <600 pg/ml. Aggregated utilization and cost data from 24 ESCOs were used over 3 years. Total hospital admissions and member months (MM) were used to calculate hospital admission rates and rate ratios. *The statements contained in this document are solely those of the authors and do not necessarily reflect the view or policies of CMS. The authors assume responsibility for the accuracy and completeness of the information contained in this document.*

Results: Hospital admission rates were found to be lower for SO (Table). Compared to MM treated with SO, an increased hospital admission rate of 11%, 20%, 32%, and 42% was observed for MM treated with SEV, CaAC, FC, and LC, respectively. In addition, the total per member per month (PMPM) healthcare costs were lower for SO ($5670) compared to FC ($5908), LAN ($6104), CaAC ($6303), and SEV ($6354), respectively.

Conclusions: Data from 24 ESCOs showed differences in hospital admission rates with the lowest rate in SO (7.97 per 100-member month (MM)) and the highest in CaAc (11.28 per 100- MM). In addition, total costs of care per MM where SO was prescribed were lower when compared to other PBs.

Funding: Commercial Support - Fresenius Medical Care Renal Therapies Group

Phosphate Binder	# hospital admissions	Member Months (MM)	Hospital Admission Rate per 100 MM	Hospital Admission Rate ratio	Rate Ratio 95% CI
sucroferric oxyhydroxide (SO)	896	11239	7.97	1	–
Sevelamer (SEV)	14109	134125	10.52	1.32	1.23, 1.41
Calcium Acetate (CaAC)	11429	101302	11.28	1.42	1.32, 1.52
Ferric Citrate (FC)	869	9111	9.54	1.20	1.09, 1.31
Lanthanum carbonate (LC)	402	4538	8.86	1.11	0.99, 1.25

PO0372

Determining the Value of Pharmaceutical Treatment of Hyperp hosphatemia with Phosphate Binders: A Systematic Review

Linda Ficociello,[1] Melissa M. Rosen,[1] Michael S. Anger,[1] Robert J. Kossmann,[2] Claudy Mullon.[1] *[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Phosphate binders (PBs) are the primary therapeutic treatment for hyperphosphatemia in ESRD patients receiving dialysis. Medicare spending on PBs has been estimated to be over $1.5 billion. There is increased focus on value-based prescribing as a method to control rising healthcare spending in the U.S. However, guidance to support such decisions is limited. The purpose of this study was to review economic evaluations of PBs to understand if specific binders are associated with greater value to patients and payers.

Methods: We conducted a systematic literature review with results restricted to economic evaluations published in English in peer reviewed journals between January 2015 and May 2020. Studies included in the review reported cost-effectiveness outcomes.

Results: After removing irrelevant articles and duplicates, 8 publications were found that met our inclusion criteria. Four (50%) studies compared either sevelamer carbonate (SEV) or lanthanum carbonate (LC) to calcium-based binders. SEV or LC was cost-effective compared to calcium-based binders. Two studies focused on ferric citrate (FC) with one comparing FC to the standard of care (either calcium acetate, SEV, or LC), and the other to SEV or calcium acetate. The results favored FC based on differences in the use of erythropoiesis-stimulating agents and hospitalization risk. However, these studies did not examine the potential for unsafe levels of iron absorption associated with FC use. The remaining two studies evaluated sucroferric oxyhydroxide (SO). One study found SO to be cost-effective relative to SEV based on clinical trial data. The other analysis looked at patients prescribed SO for two years compared to those who discontinued use after 90 days and switched to another binder. This model estimated that SO use had the potential to be cost-saving based on reduced risk of hospitalization. We were unable to find an economic evaluation that compared the two iron-based binders, SO to FC.

Conclusions: This review demonstrates the need for more economic evaluations of phosphate binders. Only one cost-effectiveness analysis was found that compared two non-calcium binders (SO vs SEV) head-to-head. In addition to cost analyses, payers may benefit from reviewing real-world data to examine the clinical benefits of specific phosphate binders.

PO0373

Effect of Lanthanum Carbonate on Blood Pressure in CKD: The COMBINE TRIAL

Mitra Jamshidian,[3] Brett Larive,[1] Jennifer J. Gassman,[1] Kalani L. Raphael,[4] Michel Chonchol,[2] Joachim H. Ix,[3] Charles Ginsberg.[3] *[1]Cleveland Clinic, Cleveland, OH; [2]University of Colorado Denver School of Medicine, Aurora, CO; [3]University of California San Diego School of Medicine, La Jolla, CA; [4]University of Utah Health, Salt Lake City, UT.*

Background: Higher serum phosphate concentrations are associated with vascular calcification, cardiovascular events, and all-cause mortality. Emerging data suggests that higher serum phosphate may also be associated with increased blood pressure (BP). The effect of phosphate-lowering medication on BP has not been studied in a chronic kidney disease (CKD) cohort.

Methods: We evaluated patients from the CKD Optimal Management with Binders and Nicotinamide (COMBINE) Trial, a randomized, double-blind, placebo-controlled trial of phosphate binders and/or nicotinamide in patients with eGFR 20-45 ml/min/1.73m2. Our primary end point for this analysis was 12-month change in systolic BP (SBP). Randomization to lanthanum vs non-lanthanum treatment arms was our primary predictor variable. The secondary predictor variable was 24-hour urine phosphate excretion (a marker of dietary phosphate intake).

Results: 205 participants underwent randomization. The mean (± SD) baseline age was 69±12 years, eGFR was 32±7 ml/min per 1.73 m2, and SBP was 129±17 mmHg. Over the 12-month trial, compared to the non-lanthanum arms (N=102), SBP in the lanthanum arms (N=103) rose by 5 mm Hg (P value 0.0497) after adjusting for baseline BP, age, sex, baseline eGFR, clinical center and number of antihypertensives over time. Within the lanthanum arms SBP rose by 5 mm Hg (95% CI 1, 9 mm Hg) and diastolic BP rose by 2 mm Hg (95% CI 0.4, 4mm Hg). BP did not change in the non-lanthanum carbonate arms. There was no association between 24-hour urine phosphate excretion and change in BP.

Conclusions: Among trial participants with moderate to severe CKD, randomization to lanthanum carbonate was associated with increased BP. Future studies should determine whether lanthanum carbonate influences absorption of anti-hypertensive medications.

Change in Systolic Blood Pressure in Lanthanum vs Non-Lanthanum Arms

PO0374

Efficacy of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis: Novel Mechanism of Action Allows for Both Monotherapy and Dual-Mechanism Approach

David P. Rosenbaum, Yang Yang. *Ardelyx Inc, Fremont, CA.*

Background: Tenapanor (TEN) is an investigational, first-in-class, non-binder, phosphate absorption inhibitor being developed to control serum phosphorus (sP) in patients with chronic kidney disease (CKD) on dialysis. It has a unique mechanism of action and acts locally in the gut to inhibit the sodium-hydrogen exchanger 3 (NHE3). This results in the tightening of epithelial cell junctions, reducing paracellular uptake of phosphate, the primary pathway of phosphate absorption, thereby reducing serum phosphorus concentrations.

Methods: Two Phase 3 studies were completed. An 8-week, double-blind (DB), randomized treatment period (RT) with a 4-week placebo (PBO)-controlled randomized withdrawal period (RW) examining the efficacy of TEN as monotherapy to treat hyperphosphatemia (HP) in patients with CKD on dialysis (NCT03427125) and a 4-week, randomized, DB, PBO-controlled study examining the efficacy of TEN administered with phosphate binders (BIND) using a dual mechanism approach to treat patients with uncontrolled HP (≥5.5. mg/dL) in patients with CKD on dialysis (NCT 03824587).

Results: In the monotherapy study, 219 patients were randomized to the RT, 164 patients (75%) completed the RT, and of these, 152 (93%) completed the RW. TEN achieved the primary endpoint with a LS mean difference of -0.8 (95% CI: -1.4, -0.2, p=0.01) in sP between TEN and PBO during the RW period. Approximately 50% of the patients treated with TEN achieved a mean sP reduction of 2.56 mg/dL from baseline to the end of the RT period. In the dual mechanism study, 236 patients were randomized to treatment. At week 4, the mean change in sP was significantly greater in the TEN+BIND arm (-0.84 mg/dL v. -0.19 mg/dL in the PBO+BIND arm, p=0.0004). Twice as many patients achieved sP<5.5 mg/dL with TEN+BIND than with PBO+BIND (up to 49.1% v. up to 23.5%, p<0.01). In both studies, the most common adverse event for patients treated with TEN was loose stools/diarrhea, leading to discontinuation in 7.8% and 3.4% of patients respectively.

Conclusions: Results from two DB PBO-controlled clinical trials have demonstrated the potential utility of tenapanor: 1. as effective monotherapy to treat HP in patients with CKD on dialysis, and 2. with phosphate binders for a dual mechanism approach in patients with CKD on dialysis who have difficult to treat HP.

PO0375

Efficacy and Safety of Add-on Tenapanor to Phosphate Binders for Refractory Hyperphosphatemia in Japanese Patients on Hemodialysis: A Phase 2, Double-Blind Study

Tadao Akizawa,[1] Yu Sato,[2] Masayuki Takanuma,[2] Hironori Kanda,[2] Masafumi Fukagawa.[3] *[1]Showa University School of Medicine, Tokyo, Japan; [2]Kyowa Kirin Co., Ltd., Tokyo, Japan; [3]Tokai University School of Medicine, Kanagawa, Japan.*

Background: Among hemodialysis (HD) patients, some patients have poorly controlled serum phosphorus levels, even while using phosphate binders (PB). Tenapanor is a novel agent, which reduces phosphate uptake by selectively inhibiting sodium/hydrogen exchanger isoform NHE3 on the apical surface of the enterocytes and then decreasing paracellular phosphate permeability. The mechanism of action is different from conventional PB used to treat hyperphosphatemia. The additional treatment of tenapanor is expected to reduce serum phosphorus levels in HD patients with poorly managed serum phosphorus levels by PB. Here, we evaluated the efficacy and safety of add-on tenapanor to PB for refractory hyperphosphatemia in patients on HD.

Methods: This was a multicenter, randomized, double-blind, placebo (PLA)-controlled, Ph2 study. The study consisted of a screening period, a 2 or 3-week observation period, and a 6-week treatment period. Patients whose serum phosphorus level was ≥6.1 and <10.0 mg/dL with PB were randomized to either tenapanor+PB or PLA+PB group in 1:1 ratio. Starting dose of tenapanor was 30 mg BID, which could be reduced in a step-wise manner (30, 20, 10 and 5 mg BID) at the investigator's discretion, based on GI tolerability. The primary endpoint was the change in serum phosphorus level from baseline value at the end of treatment.

Results: 47 subjects were randomized. Mean change in serum phosphorus level from baseline was −1.99 mg/dL in the tenapanor group and 0.08 mg/dL in the PLA group (95%CI −2.89, −1.26 mg/dL, p<0.001). The achievement ratio of target serum phosphorus level (≥3.5, ≤6.0 mg/dL) at the end of treatment was 87.0% in the tenapanor group and 37.5% in the PLA group. Diarrhea was the most frequent adverse event (tenapanor=65.2%; PLA=16.7%), all were of mild to moderate severity.

Conclusions: Tenapanor showed a significant decrease in serum phosphorus levels compared with PLA (p<0.001) under PB combination. This result suggests that coadministration of tenapanor with PB could satisfy the unmet needs to better control serum phosphorus in HD patients with refractory hyperphosphatemia.

PO0376

Tolerability of Tenapanor, an Investigational, First-in-Class, Non-Binder Therapy for the Control of Serum Phosphorus in Patients with CKD on Dialysis

David P. Rosenbaum,[1] Stuart M. Sprague.[2] *[1]Ardelyx Inc, Fremont, CA; [2]NorthShore University HealthSystem, Evanston, IL.*

Background: Phosphate binders are associated with gastrointestinal (GI) tolerability issues including constipation, diarrhea, nausea, and vomiting. Tenapanor (TEN), a first in class, targeted therapy that blocks the paracellular absorption of phosphate in the GI tract by local inhibition of the sodium-hydrogen exchanger (NHE3), and may have a different GI profile because of its unique mechanism which also reduces dietary sodium absorption, increasing the sodium and water content of stool.

Methods: Data from a 12-week monotherapy study (TEN201), a 52-week monotherapy study (PHREEDOM), and a 4-week combination study (AMPLIFY) were analyzed to evaluate the GI tolerability of TEN. Adverse events were coded to system organ class and preferred term using the Medical Dictionary for Regulatory Activities (MedDRA) (v 18, 20, 21). MedDRA classifies loose stool(s), loose bowel(s), and mushy stool(s) as diarrhea even without a reported increased frequency. Additionally, daily stool frequency and stool consistency using the Bristol Stool Form Scale (BSFS) were measured in TEN201.

Results: In each of the studies, the only adverse event that occurred in > 5% of TEN-treated patients was diarrhea as classified by MedDRA. Incidence of diarrhea during the treatment periods among patients on TEN 30 mg BID was 47.9%, 53.0%, and 42.7% for TEN201, PHREEDOM, and AMPLIFY, respectively, vs the placebo (PBO)-controlled randomized withdrawal period which was 2.9% vs. 2.4% in TEN201 and 4.0% vs. 1.6% in PHREEDOM, TEN vs. PBO, respectively. Across all studies, the diarrhea associated with TEN was most often mild-to-moderate and transient (with a median resolution within approximately 2 weeks); ~ 5% of patients experienced severe diarrhea. In TEN201, mean stool frequency increased by 2.8 bowel movements per week over baseline, and stool consistency increased by 0.8 points using the 7-point BSFS score, both remaining within the normal range.

Conclusions: These results demonstrate that TEN is associated with few GI side effects. Diarrhea, based on the MedDRA classification, occurred in approximately one-half of TEN-treated patients, most often reported as a modest and transient increase in stool frequency or loosening of stool.

PO0377

Changes in Serum Phosphorus Among Patients Who Switch from Sevelamer Carbonate to Sucroferric Oxyhydroxide or Other Phosphate Binders After Persistent Hyperphosphatemia

Vidhya Parameswaran,[1] Linda Ficociello,[1] Claudy Mullon,[1] Robert J. Kossmann,[2] Michael S. Anger,[1] Sagar U. Nigwekar.[3] *[1]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA; [3]Massachusetts General Hospital, Boston, MA.*

Background: Despite being prescribed phosphate binders (PB), many HD patients have persistent hyperphosphatemia. The current analysis examines serum phosphorus (sP) and pill burden changes among patients who have 3 months of sP > 5.5 mg/dl despite prescription of sevelamer carbonate (SC) and switched to (1) sucroferric oxyhydroxide (SO) monotherapy, or (2) Non-SO binders [Calcium Acetate, Lanthanum Carbonate, or Ferric Citrate] monotherapy or added one of these PBs to SC therapy.

Methods: All deidentified clinical and prescription data were extracted retrospectively from the Fresenius Kidney Care database. Follow-up was divided into quarters (Q1-Q4) to determine mean sP and PB pills/day. We applied Propensity Score Matching (PSM), Coarsened Exact Matching (CEM), and Inverse Probability of Treatment Weighting (IPTW) to address potential confounding/selection bias. PSM and CEM were used to match patients using overall PSM or agreement with each variable (CEM), and IPTW used weights on all patients.

Results: We identified 1,076 SC patients with baseline hyperphosphatemia who switched to SO (319 patients) and Non-SO (757 patients) PB therapy. Results from IPTW method that allowed retention of the entire sample size (n=1,076) are presented in Table 1. Application of CEM and PSM methods identified 197 and 257 matches for SO patients, respectively and noted results comparable to IPTW.

Conclusions: In a retrospective database analysis of HD patients with persistent hyperphosphatemia despite being prescribed SC, patients switched to SO had a mean sP decrease of 1.1 mg/dL compared to 0.79 mg/dL decrease among patients prescribed non-SO PBs. The PB pills/day decreased by 6.3 for SO-treated and 2.2 for Non-SO-treated patients.

The Effect of Phosphate Lowering Using Sucroferric Oxyhydroxide on Endogenous Calciprotein Particle Formation in Dialysis Patients: Post Hoc Analysis of a Randomized Controlled Trial

Ursula Thiem,[1] Timothy D. Hewitson,[5,6] Nigel D. Toussaint,[5,6] Maria C. Haller,[1,2] Andreas Pasch,[3,4] Daniel Cejka,[1] Edward R. Smith.[5,6] *[1]Department of Medicine III - Nephrology, Hypertension, Transplantation, Rheumatology, Geriatrics, Ordensklinikum Linz - Elisabethinen Hospital, Linz, Austria; [2]CeMSIIS - Center for Medical Statistics, Informatics, and Intelligent Systems, Medical University Vienna, Vienna, Austria; [3]Calciscon AG, Nidau, Switzerland; [4]Department of Physiology and Pathophysiology, Johannes Kepler University Linz, Linz, Austria; [5]Department of Nephrology, The Royal Melbourne Hospital, Parkville, VIC, Australia; [6]Department of Medicine (RMH), The University of Melbourne, Melbourne, VIC, Australia.*

Background: We have recently demonstrated in a randomized, controlled, cross-over study in 39 chronic hemodialysis patients with hyperphosphatemia that high-dose phosphate binder therapy with 2000 mg/d of sucroferric oxyhydroxide (SO) over two weeks significantly reduces calcification propensity as determined by the T_{50}-test compared with a two-week wash-out phase (Cejka, Kidney Week 2019, FR-PO149). Based on these results, we hypothesized that SO would influence endogenous calciprotein particle (CPP) formation and crystallization, i.e. conversion from primary to secondary CPP.

Methods: To test this hypothesis, we conducted post-hoc analyses of our RCT (74% men, mean age 63±27 years, median dialysis vintage 24, IQR 16-36 months). We compared native serum CPP levels (measured by a fluorescent probe-based flow cytometric assay) by Wilcoxson matched-pairs test and hydrodynamic radii (R_h) of secondary CPP formed after enrichment with exogenous calcium and phosphate (measured by three-dimensional cross-correlation dynamic light scattering) by paired t-test between the phosphate binder wash-out and high-dose treatment phase.

Results: Upon SO therapy serum phosphate levels decreased from 2.28±0.5 mmol/l to 1.63±0.43 mmol/l (p<0.0001), coincident with a reduction (median, IQR) in primary

(-62%, 44-78%, p<0.0001) and secondary CPP (-40%, 0.5-62%, p<0.0006, figure). Mean R_h of secondary CPP was significantly lower during SO therapy compared to wash-out (214±55 nm vs. 231±52 nm, p<0.01).

Conclusions: In dialysis patients, lowering serum phosphate with SO is associated with a reduction in the load of primary and secondary CPP and a smaller size of secondary CPP.

PO0379

Changes in Serum Phosphorus and Pill Burden in Peritoneal Dialysis (PD) Patients Treated with Sucroferric Oxyhydroxide (SO) as Part of Routine Clinical Care: A Contemporary Cohort

Kamyar Kalantar-Zadeh,[1] Linda Ficociello,[2] Meijiao Zhou,[2] Vidhya Parameswaran,[2] Claudy Mullon,[2] Robert J. Kossmann.[3] *[1]University of California Irvine, Orange, CA; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: Previous real-world analyses of SO in PD patients (pts) included pts first prescribed SO within the first 2 years of SO availability in the US (2014 Cohort: Kalantar 2018). A more contemporary cohort of pts prescribed SO may have different patient characteristics or treatment patterns than earlier SO pts. The current retrospective study assessed changes in serum phosphorus (sP) and phosphate binder (PB) pill burden in PD pts recently and previously prescribed SO.

Methods: Included were adult Fresenius Kidney Care PD pts first prescribed SO monotherapy during 5/2018- 5/2019 with PB monotherapy during a 3-month baseline (BL), and sP measured the month before SO initiation (-M1) and ≥4 months of the 6-month follow-up (2108 Cohort). Means were calculated monthly (-M1, M1-M6) for PB pills/day and monthly labs and quarterly for iPTH using mixed-effects linear regression.

Results: At BL, the 2018 Cohort (n=201) included slightly older pts (52.3 vs 50.6 yrs) with shorter dialysis vintage (22 vs 29 months) and different BL PB: sevelamer (42 vs 63%), calcium acetate (35 vs 21%), lanthanum (3 vs 5%), ferric citrate (12 vs 0%), or switched PB (8 vs 11%) compared to 2014 cohort. Lower pill burden (7 vs 10) and sP (6.52 vs 6.59) at BL were observed in 2018 cohort. In the 2018 cohort, pts achieving sP≤5.5 mg/dL increased from 21.9% at -1M to 40.5-47.3% during follow-up and the pattern was similar in 2014 cohort (25.8% at -1 M to 35.3-44.4% at follow-up). Mean SO pills/day was higher (4.7) in 2018-2019 cohort than the 2014 cohort (4.3).

Conclusions: PD pts prescribed SO as part of routine care in 2018 and 2014 experienced significant reductions in sP, and PB pill burden, and an increase in pts with sP≤5.5mg/dL.

Assessment of Serum Phosphorus Levels in Patients Following Administration of Ferric Pyrophosphate Citrate: A Retrospective Study

David M. Brooker,[1] David R. Brooker,[2] Ali M. Ayyash,[1] Yossi Chait,[5] Brian H. Nathanson,[6] Michael J. Germain.[3,4] *[1]Grace Hospital, Morganton, NC; [2]Brooker Kidney Care, Cranberry, PA; [3]Div of Nephrology, Baystate Medical Center, Springfield, MA; [4]Renal and Transplant Associates of New England, PC, Springfield, MA; [5]University of Massachusetts Amherst Department of Mechanical and Industrial Engineering, Amherst, MA; [6]OptiStatim, LLC, Longmeadow, MA.*

Background: Iron deficiency is common among hemodialysis patients contributing to chronic anemia. Ferric pyrophosphate citrate (FPC) is FDA-approved to replace iron and maintain hemoglobin in adult hemodialysis patients by delivering iron directly and rapidly to transferrin. FPC is a mixed-ligand iron complex in which iron is bound to pyrophosphate and citrate, along with containing phosphate, sodium, and sulfate. Phosphorus regulation in ESRD patients can be challenging thus administering products containing phosphates risks increasing serum phosphorus in addition to exacerbating underlying endocrine abnormalities. The objective of this study is to assess any changes in phosphorus levels in hemodialysis patients receiving FPC.

Methods: Retrospective data from patients at a single center hemodialysis clinic was reanalyzed looking at serum phosphorus level of hemodialysis patients receiving FPC over a one-year span of time. The data analyzed included serum phosphorus levels prior to initiating therapy compared to serum phosphorus levels after being administered FPC 1-month, 6-months, and 12-months on therapy.

Results: Forty-nine patients were included in the study. Median serum phosphorous values were at pre-therapy (median 4.8), 1-month of FPC (median 4.7, p=0.56), 6-months of FPC (median 4.8, p=0.49), and 12-months of FPC (median 5.1, p=0.36) as represented in Figure 1.

Conclusions: After analysis of serum phosphorus levels in hemodialysis patients receiving ferric pyrophosphate citrate, the findings show that there was no difference in average serum phosphorus levels before and after therapy. Clinicians who are prescribing this medication should be aware that there is no increase in serum phosphorus in patients while receiving this therapy considering how difficult it can be to regulate phosphorus along with managing the potential consequences of phosphorus abnormalities.

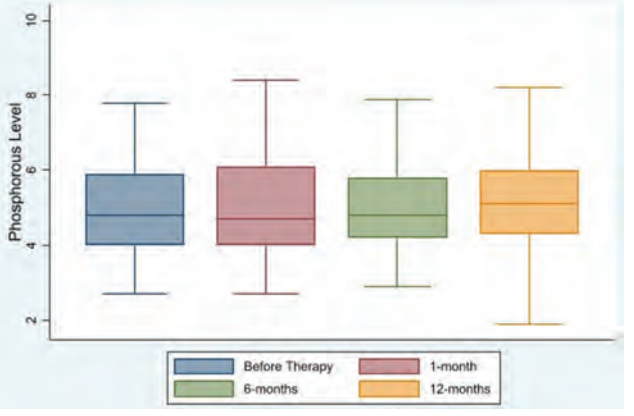

Figure 1

PO0381

Real-World Effectiveness of Sucroferric Oxyhydroxide (SO) in Lowering Serum Phosphorus (sP) Among a Contemporary Hemodialysis (HD) Cohort: A 6-Month Follow-Up

Daniel W. Coyne,[1] Meijiao Zhou,[2] Vidhya Parameswaran,[2] Linda Ficociello,[2] Claudy Mullon,[2] Michael S. Anger,[2] Stuart M. Sprague.[3] *[1]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [3]NorthShore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL, USA, Evanston, IL.*

Background: Clinical trial and real-world data demonstrated the effectiveness of SO in managing sP among dialysis pts. Previous real-world analyses included HD pts prescribed SO within the first 2 years following SO availability in the US (2014 Cohort, Coyne 2017). With greater physician experience with SO and increased availability, prescription patterns may have changed over time. The current retrospective study assessed changes in sP and phosphate binder (PB) pill burden in pts prescribed SO in 2018-2019 (2018 Cohort) and compare these results to the 2014 Cohort findings.

Methods: We included adult Fresenius Kidney Care HD pts first prescribed SO monotherapy between 5/2018- 5/2019, on other PB monotherapy during a 3-month baseline (BL), and had sP measured the month before SO start and in ≥5 months during SO. We compared BL to quarterly (Q1, Q2) means, calculated using mixed-effects linear regression, for PB pill burden and lab measurements.

Results: Compared to the 2014 Cohort, the 2018 cohort (n=2018) was larger (vs 424), older (56 vs 51 years) with shorter dialysis vintage (47 vs 56 months), more likely prescribed calcium acetate (42 vs 22%) and less likely prescribed sevelamer (41 vs 63%). The 2018 Cohort had better BL sP control (25.7 vs 15.6% pts with sP≤ 5.5 mg/dL), yet in both cohorts SO conversion was associated with significant reductions in sP (6.39 to 6.00 vs. 6.86 to 6.41) and PB pills/day (7.6 to 4.4 vs. 9.7 to 4.0). % pts with sP ≤ 5.5 mg/dL increased from 15.6 to 30.4% in 2014 Cohort and 25.7 to 41.3% in Cohort 2018.

Conclusions: Similar to the 2014 Cohort, a contemporary cohort of HD pts converted to SO experienced improvements in sP and achieving sP ≤ 5.5 mg/dL with fewer PB pills/day. Physicians are prescribing SO to a broader patient population with different distributions of baseline PB therapy.

PO0382

Dose-Response Efficacy and Tolerability of Tenapanor on Hyperphosphatemia in Japanese Hemodialysis Patients: Results of a Randomized Phase 2 Study

Daijo Inaguma,[1] Yu Sato,[2] Masayuki Takanuma,[2] Hironori Kanda,[2] Masafumi Fukagawa,[3] Tadao Akizawa.[4] *[1]Fujita Health University School of Medicine, Aichi, Japan; [2]Kyowa Kirin Co., Ltd., Tokyo, Japan; [3]Tokai University School of Medicine, Kanagawa, Japan; [4]Showa University School of Medicine, Tokyo, Japan.*

Background: Tenapanor is a novel, non-binder, targeted therapy that reduces paracellular phosphate absorption in the gut by selectively inhibiting the intestinal sodium/hydrogen exchanger isoform NHE3. In a US clinical trial by Ardelyx, Inc. tenapanor significantly reduced serum phosphorus level in hemodialysis (HD) patients with hyperphosphatemia as compared to the placebo (PLA). The purpose of this study was to confirm the efficacy, dose-response and tolerability of tenapanor on hyperphosphatemia in Japanese HD patients.

Methods: This was a multicenter, randomized, double-blind, PLA-controlled, parallel-group and dose-finding Ph2 study. The study consisted of a screening, a 2 or 3-week 1st washout (WO) period, a 6-week treatment period, and a 3-week 2nd WO period. Patients were enrolled when screening serum phosphorus level was 3.5–6.0 mg/dL and increased by ≥1.0 mg/dL to 6.1–9.9 mg/dL after 1st WO. Thereafter patients were randomized to one of 5 groups (PLA, tenapanor 5 mg, 10 mg, 30 mg or 30 mg down titration (DT) twice/day). 30 mg DT group could be down-titrated in a step-wise manner to 20, 10 and 5 mg on the basis of GI tolerability. The primary endpoint was the mean change in serum phosphorus level from baseline to end of treatment in each group.

Results: 207 subjects were enrolled (41 or 42 subjects were randomized to each group). The mean change in serum phosphorus at the end of treatment from baseline was 0.64 mg/dL in the PLA group, –0.93 mg/dL in the 5 mg group, –1.36 mg/dL in the 10 mg group, –1.92 mg/dL in the 30 mg group and –1.99 mg/dL in the 30 mg DT group (p<0.001 in all tenapanor groups vs PLA). The major adverse event was diarrhea, which occurred in a dose-dependent manner (PLA: 22.0%, tenapanor 5 mg: 57.1%, 10 mg: 65.9%, 30 mg: 76.2%, 30 mg DT: 70.7%). Most of the events were mild in severity, and, in each tenapanor group, only 1 to 3 subjects were discontinued from the study due to diarrhea.

Conclusions: Tenapanor was well tolerated in Japanese HD patients and significantly decreased serum phosphorus level in a dose-dependent manner compared with PLA (p<0.001).

PO0383

CKD and Vitamin D Status Alter Vitamin D Metabolism

Lauren E. Thompson,[1] Stacey M. Tuey,[1] Linda Prebehalla,[2] Raymond E. West,[2] Michel Chonchol,[3] Nirav A. Shah,[4] Thomas D. Nolin,[2,4] Melanie S. Joy.[1,3] *[1]University of Colorado Denver Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; [2]University of Pittsburgh Department of Pharmacy and Therapeutics, Pittsburgh, PA; [3]University of Colorado Denver Division of Renal Diseases and Hypertension, Aurora, CO; [4]University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA.*

Background: Up to 90% of people with chronic kidney disease (CKD) are vitamin D (VitD) deficient. VitD is subsequently prescribed and has documented health benefits, including nephro-, cardio-, and immune- protection. This paired study sought to evaluate and compare VitD metabolism in CKD patients and healthy controls (HC) under both VitD deficiency and repletion.

Methods: VitD deficient (25[OH]D_3 <30 ng/mL) CKD patients (n=30) and HC (n=11) were recruited (Phase 1). Participants were administered 5,000 I.U. oral D_3 daily for 12 weeks. At week 12 (Phase 2), participants received their final dose of D_3 after 25[OH]D_3 was confirmed to be replete (≥30 ng/mL). Blood was collected at serial time points for up to 336 h at each phase for determination of D_3, 25[OH]D_3, 1,25[OH]$_2D_3$, and 24,25[OH]$_2D_3$. Metabolism ratios (MR) were defined by the area under the plasma concentration-time curve (AUC) of pre-cursor to a subsequent metabolite. Analyses for differences were assessed by ANOVA with a Tukey-Kramer post-hoc test.

Results: Metabolism was differentially altered by VitD status and CKD. Significant differences in assessment of MR were determined in both an immediate precursor to the next metabolite in the sequence and by the parent compound (D_3) to the final metabolite in the metabolism sequence. The metabolism of D_3 to 25[OH]D_3 and of 25[OH]D_3 to 1,25[OH]$_2D_3$ were significantly decreased by CKD severity, with differences more pronounced after VitD repletion.

Conclusions: CKD severity decreased metabolism by the cytochrome 2R1 and 27B1 sequential pathways resulting in reductions in the D_3 to 25[OH]D_3 and 25[OH]D_3 to active VitD (1,25[OH]$_2D_3$), respectively. Daily dosing leading to repletion appears to decrease the overall conversion of cholecalciferol to its metabolites in HC and CKD patients, possibly due to saturation of metabolism pathways. Future research will evaluate the influence of daily vs. intermittent dosing on metabolism efficiency.

PO0384

Long-Term Safety and Efficacy of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis

Glenn M. Chertow,[2] Yang Yang,[1] David P. Rosenbaum.[1] *[1]Ardelyx, Inc., Fremont, CA; [2]Stanford Medicine, Stanford, CA.*

Background: Tenapanor (TEN) is an investigational, first-in-class, non-binder therapy that targets the primary pathway of phosphate absorption, providing a novel approach to treating hyperphosphatemia. TEN blocks the paracellular absorption of phosphate in the GI tract by local inhibition of the sodium-hydrogen exchanger (NHE3) and is dosed as one small pill (<12x7 mm) twice daily. Two previously conducted pivotal trials of TEN met their primary efficacy endpoint.

Methods: A 52-week study consisting of a 26-week, open-label, randomized treatment period (RT) with a 12-week placebo-controlled randomized withdrawal period (RW), followed by a 14-week open label safety extension period (SE). Patients on maintenance dialysis with serum phosphorus (sP) ≥ 6.0 mg/dL and <10.0 mg/dL and a 1.5 mg/dL increase in sP following washout were randomized 3:1 to receive one 30 mg TEN tablet BID or sevelamer carbonate (SEV; a safety control) dosed per package insert. At end of RT all patients in the TEN arm were re-randomized 1:1 to either TEN or placebo for the RW. Primary endpoint was the mean change in sP from the end of RT to the end of the RW and was compared between TEN and placebo for the efficacy analysis set, defined as patients demonstrating a ≥ 1.2 mg/dL decrease in sP at the end of RT.

Results: The study achieved its primary endpoint demonstrating a statistically significant difference in least squares (LS) mean sP change (-1.4 mg/dL, p<0.0001), between TEN and placebo. For the efficacy analysis set (n=131), the mean sP decreased from 7.7 mg/dL at baseline to 5.1 mg/dL at the end of the 26-week TEN treatment, with a mean reduction of 2.6 mg/dL. During the 26-week treatment period, 77% of TEN-treated patients in the intent-to-treat population (n=407) had a decrease in sP, with a mean reduction from baseline of 2.0 mg/dL. TEN was generally well tolerated; the only AE with incidence >5% during RT was loose stools/diarrhea (53.0%), the majority of which were mild-to-moderate and transient in nature. In the RT, 17.4% of tenapanor-treated patients compared to 23.4% of sevelamer-treated patients experienced a serious adverse event.

Conclusions: The trial results suggest that among patients on maintenance dialysis with hyperphosphatemia, TEN dosed one tablet twice daily is safe and efficacious as monotherapy.

PO0385

Diagnostic Accuracy of Static Bone Histomorphometry Parameters to Define Low Bone Turnover

Jan M. Hughes-Austin,[1] Renata C. Pereira,[2] Vanda Jorgetti,[3] Isidro B. Salusky,[2] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Tetracycline labeling for bone biopsy allows pathologists to measure the pace of new bone production, which is critical to defining bone pathology in CKD. In the setting of clinical fractures, bone tissue is available, but tetracycline labeling is not possible. Therefore, we sought to determine the diagnostic accuracy of static measures of bone turnover relative to that measured by tetracycline in CKD patients undergoing iliac crest biopsy and histomorphometry.

Methods: We evaluated 147 individuals ages 12.4 ±8.9 who had undergone iliac crest bone biopsy with tetracycline labeling for clinical indications of CKD-MBD. Using the tetracycline labels under florescence, we defined bone formation rate relative to bone surface (BFR/BS) < 8 (normal range 8-73) as our gold standard to define low bone turnover. A blinded investigator used light microscopy without fluorescence to measure static bone turnover parameters. We then compared the area under the ROC curve (AUC), sensitivity, and specificity of each bone turnover parameter with low turnover based on tetracycline using the Youden J Index, which is the point on the ROC curve farthest from line of equality that maximizes sensitivity and specificity.

Results: Among the 147 biopsies, 35 (24%) had low bone turnover based on tetracycline. Weevaluated 5 parameters available by static bone microscopy, among which Osteoblast Surface relative to Bone Surface (Ob.S/BS), Osteoclast Surface relative to Bone Surface (Oc.S/BS), and Osteoid Volume to Bone Volume (OV/BV) had the highest AUCs for low bone turnover based on tetracycline labeling. Using the best cut-offs from the AUC curves, a %Ob.S/BS of 82% had a sensitivity and specificity of 80% and 75% for low bone turnover.

Conclusions: Static measures of bone turnover have high sensitivity and specificity for identifying low bone turnover defined by tetracycline labeling at the iliac crest in CKD patients. Bone tissue without tetracycline labeling may be useful clinically to define bone turnover.

Funding: Other NIH Support - NIA (R01 AG065876)

Table. Criteria for defining low bone turnover using static histomorphometry measures

	AUC	Sensitivity	Specificity	Youden J	Cutpoint
Ob.S/BS	0.8245	0.80	0.75	0.55	2.30
Oc.S/BS	0.7753	0.91	0.60	0.49	1.70
OV/BV	0.7212	0.49	0.91	0.40	1.38
O.Th	0.6969	0.80	0.51	0.31	1.61
Ob.S/BS + Oc.S/BS	0.8252	0.75	0.78	0.52	NA
Ob.S/BS + Oc.S/BS + OV/BV	0.8487	0.71	0.86	0.57	NA

PO0386

Acid-Base Status More Than Dietary Acid Intake Determines Urine Citrate Excretion in CKD

Nimrit Goraya,[1,2] Nicolaos E. Madias,[3] Abdullah A. Mamun,[4] Jan Simoni,[5] Donald E. Wesson.[4,2] *[1]Baylor Scott and White Central Texas, Temple, TX; [2]Texas A&M University System, College Station, TX; [3]Tufts University School of Medicine, Boston, MA; [4]Baylor Scott and White Health and Wellness Center, Dallas, TX; [5]Surgery, Texas Tech University HSC, Lubbock, TX.*

Background: Lower urine excretion of the pH-sensitive metabolite citrate (UcitV) might be a clinically useful biomarker of steady-state acid (H^+) retention not evident by plasma acid-base parameters in patients with CKD. Ongoing dietary H^+ intake might also be an important determinant of UcitV and possibly confound its utility as a biomarker of underlying H^+ retention.

Methods: We examined the influence on 8-hour UcitV (UcitV), its plasma citrate concentration (Pcit) and kidney clearance (UcitV/Pcit) components, and 8-hour urine net acid excretion (8h NAE) of 1) ongoing dietary acid addition assessed by potential renal acid load (PRAL) and 2) steady-state acid-base status assessed by plasma total CO_2 ($PTCO_2$) and by H^+ retention [estimated by comparing observed to expected $PTCO_2$ increase in response to retained HCO_3 (administered minus $UHCO_3V$) 2 hours after oral $NaHCO_3$ bolus (0.5 mmol/kg bw), assuming 50% body wt HCO_3 apparent space of distribution] in 224 patients with CKD stages 1-3 due to macroalbuminuric, non-diabetic, hypertension-associated nephropathy.

Results: Because Pcit, UcitV, UcitV/Pcit, and $PTCO_2$ each directly associated with eGFR ($p<0.01$) and because H^+ retention inversely associated with eGFR ($p<0.01$), we adjusted reported associations for eGFR. PRAL associated directly with 8h NAE ($p<0.01$, $R^2=0.05$) and inversely with UcitV/Pcit ($p=0.03$, $R^2=0.13$) but not with $PTCO_2$ ($p=0.15$), H^+ retention ($p=0.85$), UcitV ($p=0.21$) or Pcit ($p=0.49$). $PTCO_2$ associated inversely with H^+ retention ($p<0.01$, $R^2=0.06$) but not with 8h NAE ($p=0.14$), UcitV ($p=0.59$), Pcit ($p=0.11$) or with UcitV/Pcit ($p=0.79$). By contrast, H^+ retention associated inversely with UcitV ($p<0.01$, $R^2=0.55$), Pcit ($p<0.01$, $R^2=0.52$) and with UcitV/Pcit ($p<0.01$, $R^2=0.20$) but not with 8h NAE ($p=0.12$).

Conclusions: Ongoing dietary acid intake assessed by PRAL associated inversely with UcitV/Pcit, although quantitatively less than did H^+ retention (R^2 0.13 vs. 0.20), but did not associate with the remaining measures of citrate homeostasis. By contrast, steady-state acid-base status assessed by H^+ retention associated inversely with each measure of citrate homeostasis. The data show that steady-state acid-base status is a more important determinant of UcitV than dietary acid intake and support continued exploration of UcitV as a biomarker of underlying H^+ retention in CKD.

PO0387

Calciphylaxis (Calcific Uremic Arteriolopathy) in a Predominantly African-American Urban US Patient Population

Sitarama Arvind Mudunuru, Jose E. Navarrete, Doris J. Armour, Jason Cobb. *Emory University, Atlanta, GA.*

Background: Calcific Uremic Arteriolopathy (CUA) which is commonly called calciphylaxis is a rare and serious condition characterized by painful skin ulcerations due to ischemia with necrosis of the skin. The disorder carries a mortality rate > 50% in the first year, and death is often due to recurrent infections. Risk factors for calciphylaxis includes end-stage renal disease (ESRD), a history of diabetes, obesity, female gender, Caucasian race, and the use of medications such as warfarin. We present clinical characteristics of CUA patients admitted to a large academic medical center which serves as a CUA referral center due to the presence of a wound center with hyperbaric oxygen therapy available.

Methods: Retrospective chart review of CUA patients from 2001-2019 in our single center academic hospital. Baseline data reported included age, calcium, phosphorus, PTH, albumin, hemoglobin, creatinine, BUN, the use of medications such as warfarin or steroids, and treatment options.

Results: There were 110 patients included. Patient identified racial (n=108) make-up included African-American (n=89), Caucasian (n=18), and Asian (n=1). Average age was 56±14 years and 80% of patients were female (n=88). Also, 59% (n=65) of patients were diabetic. Dialysis modalities included hemodialysis (n=82) and peritoneal dialysis (n=24). Also 4 patients with CKD not yet on dialysis at the time of diagnosis. Average calcium levels of 8.9±1.1 mg/dL and phosphorus of 5.1±1.9 mg/dL. The average PTH was 569.6±714.9 pg/mL, albumin 2.5±0.7 g/dL, and hemoglobin 9.8±1.7 g/dL. Approximately 50% of patients received hyperbaric oxygen therapy as inpatient, 25% received sodium thiosulfate therapy, and 20% received a surgical intervention during the admission. Approximately 33% of patients were currently or recently on warfarin therapy, and approximately 25% were currently or recently exposed to high dose steroids.

Conclusions: We reported the largest single center and predominantly African-American (81%) calciphylaxis case series. In comparison to other reported calciphylaxis series our average PTH was lower and a high percentage of our patients were using warfarin or steroids. The PTH levels were higher in the African American group compared to others. Also, with a lower than expected parathyroidectomy rate which is likely due to our lower than average PTH.

PO0388

Citric Acid-Containing Dialysate (CD) Attenuates Vascular Calcification in Hemodialysis Patients (HD)

Kenichi Akiyama, Norio Hanafusa, Yoei Miyabe, Kazunori Karasawa, Takahito Moriyama, Ken Tsuchiya, Kosaku Nitta. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: The main causes of death in patients with CKD, especially in HD, are heart failure, cardiovascular, and cerebrovascular disease, which are due to a high degree of systemic vascular calcification. Progression of aortic calcification, simply evaluated by chest radiography, was reported to be significantly associated with overall and cardiovascular mortality in HD. Recently, it was reported that the use of CD reduced blood calciprotein particles (CPPs) associated with arteriosclerosis and inflammation in HD. Therefore, we investigated the effect of using CD on blood CPPs and vascular calcification in HD in a retrospective observational study.

Methods: The subjects were 262 HD who were visiting the Joban Hospital in Japan. These patients were divided into two groups, those who continued to use acetate-containing dialysate (AD) or switched to CD from October 2017. A one-year retrospective observational study was conducted on the association with blood, laboratory test values, and AoACS (aortic arch calcification score) evaluated by chest X-ray. At baseline, patients with AoACS>50%, bisphosphonate, and warfarin use were excluded. Univariate, multivariate, subgroup analyses were used for statistical analysis. The main outcome was the presence or absence of AoACS exacerbation of 5% or more in one year.

Results: A total of 115 patients with AD and 102 patients with CD matched to the criteria were included. As a result, the use of CD (HR 0.53, [95% confidence interval (CI) 0.30-0.92], P = 0.026), ALP (HR 0.97, 95 %CI 0.94-0.99, P = 0.013), and AoACS (HR 1.36, 95% CI 1.15-1.63], P = 0.0004) were significantly associated with an exacerbation of AoACS. Subgroup analyses showed the characteristics of patients who benefit from using CD are those older than 75 years old, those with non-diabetes as the underlying disease, low nPCR(normalized protein catabolic rate), high blood CRP, and not severe calcification. In other words, patients with MIA syndrome can benefit from the use of CD.

Conclusions: Among patients with mild to moderate vascular calcification, HD with CD had a significantly reduced progression of AoACS compared with AD. The results indicate that the dialysis method using CD in HD may be a useful therapeutic method for suppressing vascular calcification.

PO0389

Vascular Calcifications in Renal Transplantation

Ana Carina Ferreira,[1,2] Marco Mendes,[1,2] Cecilia Silva,[1] Patrícia Cotovio,[1] Ines Aires,[1,2] David Navarro,[1] Fernando C. Pereira,[1,2] Rute M. Salvador,[2] Bruna F. Correia,[2] M. Guadalupe Cabral,[2] Fernando E. Nolasco,[1,2] Manuel A. Ferreira.[1,2] *[1]Hospital Curry Cabral, Lisboa, Portugal; [2]Nova Medical School, Lisbon, Portugal.*

Background: The aim of this study was to analyse the progression of vascular calcifications (VC) in a cohort of renal transplanted patients.

Methods: Prospective cohort study of de *novo* renal transplant patients. All patients were submitted to X-ray of the pelvis and hands (Adragão score); bone biopsy; laboratorial and echocardiographic evaluation at baseline and after 12 months (time 0 and 1). At the end of the study, bone densitometry and non-contrast cardiac CT (Agatston score) were performed. Associations between variables were performed using Wilcoxon rank sum test and Spearman correlation test. STATA software was used and $p < 0.05$ was considered statistically significant.

Results: We recruited 85 patients during 29 months and 69 were included in the study (6 patients refuse to perform the 2nd evaluation, 5 had primary non-function of the kidney graft, 1 had no sample on bone biopsy in time 0 and 4 patients died). Mean age 50.1±12.7 years, 59 men (69.4%), 66 caucasian (77.6%), median BMI 25.1±3.4. The median baseline and 12 months Adragão score had no differences. The median coronary artery calcium score (CACS) was 48.5 (0 – 535) and median percentile was 80 (0 – 92.5). Valvular calcifications were present in 15 and 16 patients at baseline and after 1 year ($p>0.05$). CACS were correlated with age ($p<0.001$), both Adragão score ($p<0.001$), presence of valvular calcification in time 1 ($p=0.004$), baseline calcium ($p=0.02$), baseline and 1-year sclerostin ($p=0.01$; $p=0.04$). CACS were higher in patients with highest values of FGF23 at baseline ($p=0.04$). Using a pairwise correlation, vitamin D levels ($r=0.4$, $p=0.0004$), iPTH ($r=0.6$, $p<0.001$) and total cholesterol levels ($r=-0.3$, $p=0.01$) were correlated with the score. Coronary calcium percentile was correlated with Adragão score in the two time points ($p=0.0001$; $p=0.002$), with presence of valvular calcifications in time 1 evaluation ($p=0.02$), baseline and 1-year calcium levels ($p=0.004$; $p=0.02$) and baseline sclerostin ($p=0.01$).

Conclusions: VC stabilize after renal transplantation. Adragão score can assess VC in renal transplanted patients. Calcium and sclerostin correlated with Agatston scores.

PO0390

Vascular Calcification and Progression of CKD

Salim Bou Slaiman, Harish R. Alappan, W. Charles O'Neill. *Emory University, Atlanta, GA.*

Background: Vascular calcification, particularly the medial form, is common in advanced chronic kidney disease (CKD) and leads to poor outcomes. However, the extent to which medial calcification affects the kidneys and could exacerbate CKD is unknown. To this end, progression of CKD was compared in women with and without breast arterial calcification (BAC), a marker of systemic medial arterial calcification, and the prevalence of renal arterial calcification was assessed radiologically and histologically in patients undergoing nephrectomy.

Methods: Women with CKD (eGFR <60 ml/min/m2) were identified from previous studies of breast arterial calcification, and those with a subsequent measurement of serum creatinine at least 1 year later were included. Consecutive patients with CKD and nephrectomies were identified from a computerized search of medical records. Computed tomography (CT) scans were reviewed for aortic and renal artery calcification, and histology (hematoxylin and eosin staining) was reviewed for calcification of main renal arteries and parenchymal arteries. Current or past warfarin use was an exclusion in all cohorts.

Results: Women with (n=51) and without (n=67) breast arterial calcification had similar yearly eGFR declines (1.55 vs. 1.60 ml/min/1.73 m^2) despite a greater age (75.4 ± 1.3 vs 70.4 ± 1.5) and lower baseline eGFR (33.8 ± 1.8 vs. 39.2 ± 1.6) in women with BAC. There was no correlation between the quantity of BAC and the decline in eGFR ($r = 0.10$). Of 246 patients with nephrectomies who were screened, 50 had an eGFR < 30. End-stage renal disease was present in 82% and 36% had diabetes. CT scans were available in 34 patients and showed aortic and renal artery calcification in 59% and 38%. Prevalences of histologic calcification of renal artery and intraparenchymal arteries were 16% and 15%. When present, calcification of parenchymal arteries was usually very mild, and was severe in only 3 cases and limited to large arteries. In patients with CT scans, only those with renal artery calcification had parenchymal artery calcification (4 of 11 vs. 0 of 17 without, $p=0.016$).

Conclusions: Vascular calcification does not contribute to the progression of CKD. This is explained by the surprisingly low prevalence and severity of calcification in intrarenal arteries. Patients without renal artery calcification on imaging are at low risk for parenchymal artery calcification.

PO0391

Clinical Outcomes in Patients with Calcifications on Kidney Biopsy

Anna R. Gaddy,[1] Ranjani N. Moorthi,[1] Michael T. Eadon,[1] Tae-Hwi Schwantes-An,[1,2] Carrie L. Phillips,[1] Sharon M. Moe.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Regenstrief Institute Inc, Indianapolis, IN.*

Background: Calcification is often noted on kidney biopsies, but the consequences of this finding is not known.

Methods: We searched a biobank for specimens with at least two years of linked clinical data and identified those which had calcification on report. Biopsy specimens were further classified to be described as calcium oxalate (CO), calcium phosphate/ dystrophic (DC), or both. Linked clinical data was examined in 3 month intervals before and after index date of kidney biopsy. Cox proportional hazard analysis was performed using a split time model to evaluate relationships between presence of calcification, type of calcification, and clinical outcome endpoints. Linked clinical data was examined in 3 month intervals before and after index date of kidney biopsy. Cox proportional hazard analysis was performed using a split time model to evaluate relationships between presence of calcification, type of calcification, and clinical endpoints.

Results: Patients with any calcification (n=429) vs. without (n= 3936) were ($p < 0.05$) older, more likely to be white, have diabetes, lower eGFR and higher AKI/ATN on kidney biopsy specimen (31 vs. 13%). Patients with COX (n = 126) vs. DC (n = 260) were older, less diabetes, lower eGFR, more likely to have malabsorption or gastric bypass, and used more vitamin D. By univariate analyses, patients with any calcification were more likely to have a decline in the slope of creatinine at 6 months, 1 year, and 2 years; these changes persisted even after adjustment for baseline eGFR, htn, proteinuria, negative biopsy findings, CAD (for 1 year beta 0.029, $p < 0.001$). When adjusted for age, diabetes, and baseline eGFR, patients with any calcification were less likely than those without calcification to advance to ESKD (HR 0.59; 95%CI 0.38-9.82; $p < 0.05$) but not to meet the outcome of death.

Conclusions: The presence of calcification on kidney biopsy specimen is associated with lower progression to ESKD and decrease in rate of decline of eGFR over time at 6 months, 1 year, and 2 years. This paradoxical finding may be due to increased AKI with recovery, rather than progressive chronic disease but requires further analyses.

PO0392

Urine Phosphate Excretion and Microvascular Function in a Population-Based Cohort

Charles Ginsberg,[1,3] Alfons J. Houben,[2] Rakesh Malhotra,[1] Tos Berendschot,[2] Jeroen Kooman,[2] Carroll A. Webers,[2] Coen Stehouwer,[2] Joachim H. Ix.[1,3] *[1]University of California San Diego, La Jolla, CA; [2]Universiteit Maastricht, Maastricht, Netherlands; [3]VA San Diego Healthcare System, San Diego, CA.*

Background: Higher serum phosphate is associated with cardiovascular events and all-cause mortality. While these associations have largely been attributed to an increased risk of large vessel calcification, our previous work demonstrated a higher morning serum phosphate is associated with microvascular dysfunction. However, the relationship between 24-hour urinary phosphate excretion ([(UPE) a surrogate for dietary phosphate] and microvascular function has not been explored.

Methods: We performed a cross-sectional analysis of 3,116 community-living participants that underwent a 24-hour urine collection and skin capillaroscopy, laser-Doppler flowmetry, and flicker-light induced retinal vessel responses as part of the Maastricht Study. The primary outcome was post-occlusive finger skin capillary recruitment. Secondary outcomes included capillary recruitment during venous congestion, heat-induced skin hyperemic response, and flicker-light induced retinal arteriolar and venular dilation.

Results: The mean age of the cohort was 60 years, 48% were women, 7% had an eGFR< 60ml/min/1.73 m^2, and the mean serum phosphate concentration was 3.2mg/dl. The mean UPE was 874 ± 315 mg/day. UPE was not associated with any of the microvascular outcomes (**Table 1**) and there were no significant interactions between UPE and sex, diabetes status or eGFR on any of the outcomes (P>0.43). We found an inverse relationship between UPE and serum phosphate ($r=-0.26$, $p<0.001$)

Conclusions: We found no relationship between UPE and microvascular function in community-living individuals predominantly with normal kidney function. Relationships between urine phosphate, serum phosphate and microvascular function require further exploration.

Funding: NIDDK Support, Private Foundation Support

Table 1: Association of 24 Hour Urine Phosphate Excretion and Serum Phosphate Concentration with Microvascular Measurements*

Measurement Technique	Per 100 mg/day Higher (Urine)	P	Per 1 mg/dl Higher † (Serum)	P
% Capillary Recruitment during Post-Occlusive Reactive Hyperemia	0.01 (-0.4, 0.8)	0.82	-5.0(-10.0, -0.1)	0.04
% Capillary Recruitment during Venous Congestion	0.2 (-0.6, 1.0)	0.65	-4.5 (-9.8, 0.7)	0.09
% Heat-Induced Skin Hyperemic Response	-9 (-24, 5)	0.20	- 25 (-113, 63)	0.57
% Retinal Arteriolar Dilation	0.00 (-0.04, 0.04)	0.88	-0.12 (0.3, 0.15)	0.39
% Retinal Venular Dilation	0.00 (-0.03, 0.04)	0.94	-0.23 (-0.44, -0.02)	0.03

*Relationships are adjusted for age, sex, body mass index, smoking status, blood pressure, use of antihypertensive medications, use of lipid modifying medications, glucose metabolism status, eGFR, and serum calcium.

PO0393

Complete Resolution of Calciphylaxis in a Renal Transplant Patient with Calcifediol

Mohankumar Doraiswamy,[1] Priyamvada Singh,[1] Shumei Meng,[2] Todd E. Pesavento.[1] *[1]Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Columbus, OH; [2]Division of Endocrinology, The Ohio State University Medical Center, Columbus, OH.*

Introduction: Calciphylaxis is a rare but lethal disorder (mortality 60-80%) characterized by occlusion of microvasculature in the subcutaneous adipose tissue and dermis, resulting in excruciating painful, ischemic skin lesions. It commonly occurs in dialysis patients but only few cases in transplants reported. Treatment options are meager, and a multidisciplinary approach (dermatology, nephrology, nutrition, pain, palliative medicine, plastic surgery, and wound care), with surgical debridement, antimicrobial therapy, optimization of calcium-phosphorus product, dialysis adequacy, sodium thiosulfate, and hyperbaric oxygen been suggested.

Case Description: A 62-year-old female with a LDKT (2008) complicated with CKD III, lupus nephritis, hypothyroidism, presented with painful, bilateral, medial calf ischemic ulcerations, which on punch biopsy revealed calciphylaxis. Her baseline iPTH, calcium, phosphorus, and 25-hydroxy-vitamin D, was 372 pg/mL, 9.4 mg/dL, 3.8 mg/dL, and 17.4 ng/mL, respectively. She was on calcitriol 0.75 mg/daily, ergocalciferol 50,000 units weekly and cinacalcet 30 mcg every other day. We started her on Calcifediol 30 mg, which increased to 60 mg daily. Her calcitriol and ergocalciferol doses were reduced slowly, while cinacalcet remained the same. This led to gradual increase in 25-hydroxyvitamin D and reduction in iPTH levels without effect on the calcium-phosphorus product. Over 1-year follow-up, her ulcers completely resolved as shown in the images with marked improvement in the pain.

Discussion: Treatment of hyperparathyroidism is limited as calcitriol and ergocalciferol worsen the calcium-phosphorus product while calcimimetics cause hypocalcemia, which hinders the attempt to lower calcitriol. Calcifediol is well tolerated and causes a progressive increase in serum 1,25-dihydroxy vitamin D and reductions in plasma iPTH without a significant effect of serum calcium and phosphorus levels. This led to remarkable clinical improvement with resolution of calciphylaxis in this case. Large clinical trials mandated to test these findings

PO0394

Rapidly Growing "Calcified Cauliflower" in the Lung of an Orthotopic Heart Transplant (OHT) Recipient on Hemodialysis (HD)

Rui Song, Ali Arif, Chandra Dass, Iris J. Lee, Dina Abdelwahab. *Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Introduction: Pulmonary calcinosis is commonly seen in ESRD patients but rarely in OHT recipients. We report a rare case of an OHT recipient who developed AKI requiring RRT. CT chest was noted for rapid progressive calcifications of lungs with both dystrophic and metastatic features.

Case Description: A 48-year old male with non-ischemic cardiomyopathy who underwent OHT. The post-transplant course was complicated by biventricular failure requiring VA/ECMO and IABP support, aortic anastomotic bleeding, multiple surgeries, recurrent bacterial and viral pneumonia dependent on mechanical ventilation, and ischemic acute tubular injury requiring CRRT then switched to HD. The imaging was noted for cardiac calcification, followed by rapidly progressive lung calcification. CT chest showed diffuse ground-glass opacity and "calcified cauliflower" signs with a mixture of dystrophic and metastatic lung calcifications. Work up for hyperparathyroidism, vitamin D toxicity, malignancy was negative. Contributing factors for pulmonary calcinosis included multiple surgeries, infections of the lungs, massive transfusion with subsequent IV calcium repletion, calcium concentration in replacement fluid of CRRT, use of calcium acetate. Subsequently, the patient was put on the lowest calcium bath and longer HD hours.

Discussion: Dystrophic pulmonary calcification occurs in the injured lung due to inflammation, infection, or hemorrhage. While metastatic calcification is more common in ESRD patients, primary and secondary hyperparathyroidism, or malignancy. Our case report emphasizes the importance of bone mineral disease as an underlying etiology for pulmonary calcinosis in dialysis-dependent OHT patients. The supportive approach includes avoidance of massive transfusions, IV calcium infusion, and calcium-based phosphorus binder, use of low calcium bath in HD.

CT chest: cauliflower calcification bilaterally

PO0395

Calciphylaxis and Ectopic Parathyroid Gland: Chicken or the Egg?

Jonathan Berry, Carissa Wilkins, Tauseef A. Sarguroh, Habeeb S. Amatul. *Franciscan Health Inc, Mishawaka, IN.*

Introduction: Calciphylaxis is a vascular calcification disorder that is clasically seen in patients(pts) with end stage renal disease on hemodilaysis. It is most common in caucasian females and risk factors include hypercalcemia, hyperphosphatemia, hyperparathyroidism, coumadin use and iron therapy. This is a case of a patient with severe calciphylaxis, ectopic primary hyperparathyroidism with chronic kidney disease(CKD) not yet on dialysis.

Case Description: 64 year old female with CKD-4, obesity, HTN, pulmonary embolism not on anticoagulation, undiagnosed mediastinal mass came with lower extremity pain and a non-healing ulcer over the left anterior shin. Initial labs showed BUN:68mg/dl, Creatinine:5.4mg/dl, Calcium:11.3mg/dl, PTH:3,059 pg/ml. She underwent punch biopsy of the skin lesion that was consistent with calciphylaxis and was subsequently initated on hemodialysis and sodium thiosulphate infuson. A nuclear uptake scan showed an anterior mediastinal mass that was consistent with ectopic parathyroid adenoma after surgical excision.

Discussion: This case highlights a rare cause of calciphylaxis in a pt. with undiagnosed ectopic primary hyperparathyroidism and CKD. Our pt. had hypercalcemia and a mediastinal mass which upon work-up was found to be a hypersecretory ectopic parathyroid adenoma that likely triggered her calciphylaxis in the setting of concomitant secondary hyperparathyroidism due to chronic kidney disease as evident by hypercellularity of the reamaining three parathyroid glands. Only 12 known cases of calciphylaxis are attributed to primary hyperparahtyroidism and none due to an ectopic adenoma. Our pt. underwent hemodialysis, parathyroidectomy of the adenomatous gland and sodium thiosulphate infusion after which her PTH and calcium levels significantly improved and her skin lesions healed with no recurrence.

PO0396

Penile Calciphylaxis: Challenges in Its Diagnosis and Management

Isabelle Dominique V. Tomacruz, Carl Arenos, Sachiko S. Estreller, Blythe N. Ke, Shahara Abalos-Babaran, Elizabeth Montemayor. *Philippine General Hospital, Manila, Philippines.*

Introduction: Penile calciphylaxis is an uncommon presentation of a rare systemic disorder.

Case Description: We discuss 2 cases of penile calciphylaxis in patients with end stage kidney disease on hemodialysis presenting with painful ulcerations and eschar formation on their penile shaft. Diabetes mellitus, hyperphosphatemia and vascular calcifications on radiographs were common in both patients. A multidisciplinary approach to management involved wound care with irrigation followed by application of petrolatum-impregnated wet-to-dry dressing, antibiotic therapy, intensification of hemodialysis and use of intravenous sodium thiosulfate. Both patients showed good wound healing on discharge.

Discussion: Skin biopsy may aid in confirmation, but should be weighed against the risks of provoking nonhealing wounds & secondary infection. A high index of suspiscion and multidisciplinary management are key components; but, prognosis is poor with survival rates reported to be less than a year upon diagnosis.

Case 1. Penile ulcer

Case 2. A&B. Penile and lower extremity lesions. **C.**Vascular calcifications on radiograph. **D.**Punch biopsy of the leg ulcer consistent with calciphylaxis(H&E stain,40x). **E.**Thready calcium deposits in the lobular panniculus together with calcification of a medium-sized vessel(H&E stain,10x)

PO0397

High Turnover Bone Disease After Successful Parathyroidectomy in a Dialysis Patient

Yahya R. Ahmad, Katherine M. Donaldson, Matthew Shea, Florence Lima, Madhumathi Rao. University of Kentucky Department of Nephrology *University of Kentucky, Lexington, KY.*

Introduction: We report a patient with end stage renal disease (ESRD) on hemodialysis (HD) with history of successful near-total parathyroidectomy (PTX) and normal to low parathyroid hormone (PTH) levels, found to have high-turnover/hyperparathyroid (HPT) bone disease on biopsy (bx).

Case Description: 54-year-old female with ESRD on HD for 10 years presented with declining bone density and osteoporosis (left radial T-score of -2.7). She had a near-total PTX in 2014 for secondary hyperparathyroidism and bx proven severe HPT bone disease, complicated by calciphylaxis treated with wound care and sodium thiosulfate. Patient also has history of focal segmental glomerular sclerosis of her native kidneys, gastric bypass, uterine cancer requiring radiation, and psoriatic arthritis and gout requiring steroids. Labs showed corrected calcium 9.4 mg/dL, serum phosphorus 7.9 mg/dL, 25-OH-vitamin D3 16.9 ng/mL, bone specific alkaline phosphatase 12.8 ug/L, intact PTH level 34 pg/mL (consistent with past values), PTH-(1-84)/-(7-84) ratio 1.1 (Scantibodies CA). She was started on weekly ergocalciferol. Bone bx showed persistent high-turnover/HPT bone disease with normal mineralization and low bone volume (2019, Figure 1). Relative to her prior bx, however, there was a demonstrable decrease in bone turnover and volume.

Discussion: Bone bx studies showing the evolution of bone disease after PTX in ESRD patients are limited. Development of adynamic bone disease is often presumed, but not established. In this patient, osteoporosis was related to high bone turnover, despite near-total PTX and successful reduction of serum PTH. These observations suggest that more research is needed into mechanisms other than PTH that contribute to bone turnover and loss in ESRD patients.

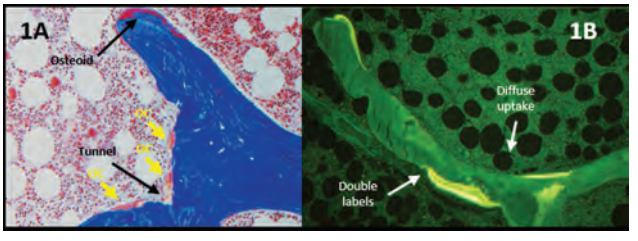

Figure 1: Anterior iliac crest bone biopsy: 1A – Trichrome stain 10x showing osteoclastic activity with tunneling in trabecular bone and increased osteoid volume and surface 1B – Fluorescent microscopy for tetracycline labeling 10x showing double labels and diffuse uptake in woven bone

PO0398

Successful Treatment of Severe Osteoporosis with Romosozumab in a Patient Undergoing Combined Peritoneal Dialysis and Hemodialysis: A Case Report

Hyeryong Lee, Kazuhito Fukuoka, Shinya Kaname. Kyorin University School of Medicine, Department of Rheumatology and Nephrology *Kyorin Daigaku, Mitaka, Japan.*

Introduction: Recently osteoporosis is becoming a bigger problem as aging of dialysis population progresses. However, the use of anti-osteoporotic drugs is limited because of concerns for increased rates of adverse events associated with decreased drug clearance and comorbidities such as CKD-MBD in dialysis patients. Here we present a case of severe osteoporosis that was successfully treated with romosozumab.

Case Description: A 57-year-old woman ESKD patient due to lupus nephritis had been on peritoneal dialysis (PD) combined with hemodialysis for the last 4 years. She has been suffering from systematic lupus erythematosus and complicated by severe osteoporosis probably due to long-term use of glucocorticoids and renal dysfunction. Although she was treated with vitamin D3 analogues, bisphosphonates, and denosumab, severe pains continued and had pelvic bone and vertebral fractures, followed by repeated pathological bone fractures of the ribs. Thus, we decided to use romosozumab. After administration of romosozumab, bone pains dramatically improved and fragile bone fractures became less frequent, without progression of bone destruction. Four months later levels of tartrate-resistant acid phosphatase-5b decreased, total type 1 procollagen N-terminal propeptide increased, and bone mineral density significantly improved. Serum calcium and inorganic phosphate levels slightly decreased, and intact PTH slightly increased, but no overall adverse effects were noted.

Discussion: Romosozumab is a humanized anti-sclerostin monoclonal antibody that has recently been introduced for the treatment of osteoporosis. While it demonstrates strong effects on osteogenesis and bone reabsorption, it also raises concerns about increased cardiovascular events. Our case suggests that romosozumab can be safely and effectively used for the treatment of osteoporosis, at least for a short period, in patients undergoing dialysis, although further study is clearly required to evaluate the efficacy of the agent.

PO0399

Bone Fractures and Antihypertensive Drugs in CKD Patients: The Fukuoka Kidney Disease Registry (FKR) Study

Tomoya Shukuri,[1] Kentaro Nakai,[1] Yoshiki Sato,[1] Nao Yamaoka,[1] Yukiko Ishimatsu,[1] Megumi Inoue,[1] Chiaki Kohara,[1] Koji Mitsuiki,[1] Shigeru Tanaka,[2] Toshiaki Nakano,[3,5] Kazuhiko Tsuruya,[4] Takanari Kitazono.[3] *[1]Japanese Red Cross Fukuoka hospital, Fukuoka, Japan; [2]Division of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [3]Department of Medicine and Clinical science, Graduate school of Medical Sciences, Kyushu University, Fukuoka, Japan; [4]Department of Nephrology, Nara Medical University, Nara, Japan; [5]Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Patients with chronic kidney disease (CKD) are known to be at high risk for bone fractures. Bone fractures are serious complication that causes inactivity, hospitalization, and premature death. Some reports showed the association between bone fractures and antihypertensive drugs in elderly persons, but there are few reports in CKD patients. The aim of this study is to elucidate the relationship between bone fractures and antihypertensive drugs in CKD patients.

Methods: The Fukuoka Kidney disease Registry (FKR) Study is a prospective, multicenter cohort study of approximately 5000 patients with CKD. This is a cross-sectional study that investigated the relationship between antihypertensive drugs and bone fractures. The odds ratio (OR) of bone fractures in each risk factors was calculated by performing a logistic regression model analysis with adjustment factors, such as age, sex, body mass index(BMI), smoking history, presence of diabetes mellitus, eGFR levels, serum levels of albumin, sodium, calcium, phosphate, parathyroid hormone(intact assay).

Results: A total of 4474 patients were included in this study (age 63.9 years, men 56.0%, BMI 23.4 kg/m^2, diabetes mellitus 27.5%, and smoking history 52.0%). The average eGFR was 44.0ml/min/1.73 m^2, with 60.0 ml/min/1.73 m^2 or more at 24.2%, 30.0-60.0 ml/min/1.73 m^2 at 39.5%, and less than 30.0 ml/min/1.73 m^2 at 36.3%. Bone fractures were found in 282 patients(6.3%). Loop diuretics were independently associated with bone fractures (OR: 1.75, 95% confidence interval [CI]: 1.24-2.49), and angiotensin II receptor blockers (ARB) had significantly fewer bone fractures (OR: 0.64, CI: 0.49-0.85). Angiotensin-converting enzyme inhibitors, calcium channel blockers, alpha blockers, beta blockers, and thiazide diuretics were not showed significant association with bone fractures.

Conclusions: It is suggested that loop diuretics may be associated with higher bone fractures risk and ARB may be associated with lower bone fractures risk in CKD patients. The results are being verified in this prospective cohort by future.

PO0400

Differences in Bone Biomarkers by Renal Osteodystrophy Pathology

Marciana Laster, Renata C. Pereira, Isidro B. Salusky. *University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: The gold standard for the diagnosis of Renal Osteodystrophy (ROD) remains the iliac crest bone biopsy. Given its limited availability, it is important to consider whether serum markers of bone metabolism will allow the ability to predict ROD type. Here we assess how major markers of bone metabolism differ by ROD category.

Methods: 93 pediatric patients with CKD underwent measurement of calcium, phosphate, alkaline phosphate (ALP), PTH, intact and c-terminal FGF23, sclerostin and TRAP5B at the time of bone biopsy. Patients were categorized by ROD diagnoses and biomarker comparisons were made according to turnover and mineralization status. Comparisons of bone markers within each category were made using the Wilcoxin Rank Sum test.

Results: Cohort characteristics are presented in Table 1. Of the ROD categories, 30.1% had normal bone, 30.1% adynamic bone disease, 11.8% mixed uremic osteodystropy, 14% osteitis fibrosa cystica, 4.3% osteomalacia and the remainder unknown disease. Those with high turnover disease had greater ALP ($p<0.0001$) and PTH ($p=0.001$) and lower calcium ($p=0.04$) than those with non-high turnover disease. Of those with low turnover bone disease, TRAP5B ($p=0.01$) and ALP ($p=0.0003$) were significantly lower and calcium ($p=0.03$) higher as compared to those with non-low turnover disease. In those with a mineralization defect, ALP ($p=0.001$) was higher and sclerostin ($p=0.02$) lower than those without a defect (Figure 1).

Conclusions: Comparisons within ROD categories demonstrate differences in serum biochemical markers. With further study, these differences may help to predict the type of CKD-related bone lesion without the need for bone biopsy. Promising markers such as TRAP5B, which is unaffected by renal function, may be valuable in distinguishing low turnover disease but this requires further investigation.

Ethnic Differences in the Association of Kidney Function and Low Bone Density

Joshua Chang, Malini Chandra, Jeanne A. Darbinian, Nirmala D. Ramalingam, Joan C. Lo, Sijie Zheng. *Kaiser Permanente Oakland Medical Center, Oakland, CA.*

Background: Chronic kidney disease (CKD) is an important risk factor for bone disease and fracture. Here, we examined the relationship between reduced kidney function (RKF) and bone mineral density (BMD) in women. We also examined PTH and calcium levels among a subset of patients with advanced CKD and low BMD (osteoporosis range).

Methods: We examined femoral neck BMD in 118,484 women age 60-79 with an ambulatory creatinine/eGFR within 1 year of the BMD scan and compared the proportion with low BMD (T-score ≤ -2.5) by kidney function. Presence of hyperparathyroidism (PTH > 65 and > 130 pg/mL) and hypercalcemia (Ca ≥ 10.5 mg/dL) was examined in a subset of 257 patients with low BMD and advanced CKD G3B (eGFR < 45) and G4/G5 (eGFR < 30) who had PTH, calcium, and confirmatory eGFR measured within 2 years of BMD scan.

Results: Among 118,484 women, 83% had eGFR ≥ 60, 12% had eGFR 59-45, 4% had eGFR 44-30, and 1% had eGFR < 30. Overall, 12% of women age 60-69 and 21% of women age 70-79 had low BMD, but this varied by race/ethnicity. Asians had the highest burden of low BMD. Within each race/ethnicity group, the burden of low BMD varied by RKF/eGFR (Figure). In the subset with low BMD, advanced CKD, and measured PTH and calcium, 9.7% of G3B (n = 145) and 5.4% of G4/G5 (n = 112) patients were hypercalcemic. Of these hypercalcemic patients, 57% with G3B had PTH > 65 pg/mL (28.6% had PTH > 130 pg/mL), and all with CKD G4/G5 (n = 6) had PTH > 65 pg/mL (n = 4 > 130 pg/mL). Of the remainder with normal/low calcium, 57% with G3B and 84% with G4/G5 had PTH > 65 pg/mL (19% of G3B and 53% of G4/G5 had PTH > 130 pg/mL).

Conclusions: The burden of low BMD and the association of RKF with low BMD varied by race/ethnicity. The majority of patients with advanced CKD and low BMD also had evidence of hyperparathyroidism when laboratory data were assessed. Our findings support guidelines for PTH and BMD screening in advanced CKD patients to optimize bone health.

Serum Biomarkers, but Not Dual-Energy X-ray Absorptiometry, Predict Cortical Bone Mineral Density in Children and Young Adults with CKD

Alexander D. Lalayiannis,[1,2] Nicola J. Crabtree,[3] Charles Ferro,[9] Varvara Askiti,[4] Andromachi Mitsioni,[4] Lorenzo Biassoni,[1] Amrit Kaur,[10] Manish Sinha,[5] David C. Wheeler,[6] Neill D. Duncan,[7] Joyce Popoola,[11] David Milford,[3] Jin Long,[8] Mary B. Leonard,[8] Mary Fewtrell,[1,2] Rukshana Shroff.[1,2] *[1]Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; [2]University College London Institute of Child Health, London, United Kingdom; [3]Birmingham Women's and Children's NHS Foundation Trust, Birmingham, GB, Birmingham, United Kingdom; [4]Children's Hospital "P. & A. Kyriakou", Athens, Greece; [5]Evelina London Children's Hospital, London, United Kingdom; [6]University College London, London, United Kingdom; [7]Imperial College Healthcare NHS Trust, London, London, United Kingdom; [8]Stanford University, Stanford, CA, US, Stanford, CA; [9]University Hospitals Birmingham NHS Foundation Trust, Birmingham, Birmingham, GB, Birmingham, United Kingdom; [10]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [11]St Georges Healthcare Trust, London, United Kingdom.*

Background: Currently available serum biomarkers and Dual-energy X-ray Absorptiometry(DXA) are thought to be poor predictors of bone mineral density(BMD). We set out to determine the clinical utility of DXA and routine clinical biomarkers in the young CKD population, by comparing them with tibial cortical BMD measured by peripheral Quantitative Computed Tomography(pQCT).

Methods: A multi-centre cross-sectional study with 77 patients on dialysis and 26 in CKD4-5 (n=103 total, ages 5-30 years). Participants underwent hip and lumbar spine (LS) DXA, tibial pQCT [for cortical (cortBMD) and trabecular BMD (trabBMD)] and measurement of routine serum biomarkers. All bone measures were expressed as Z-scores adjusted for age, sex, race and height. Tibial cortical BMD Z-scores was used as the gold standard to evaluate the predictive value of other measures.

Results: Bone pain was present in 58%, hindering activities of daily living. 10% had suffered at least one previous low-trauma fracture. DXA LS Z-scores were higher in the CKD compared to the dialysis population, with a corresponding higher trabBMD Z-score on pQCT (p=0.006 & p=0.02). pQCT cortBMD and cortical mineral content Z-scores were significantly lower in dialysis compared to CKD patients (p=0.01 & p=0.05 respectively). Hip and LS DXA Z-scores did not correlate with any biomarkers or cortBMD. CortBMD Z-scores were negatively associated with PTH (r=-0.44, p<0.001) and alkaline phosphatase (ALP)(r=-0.22, p=0.03) and positively with calcium (r=0.33, p=0.001). None of the patients with PTH levels less than three times the upper limit of normal had a cortBMD below -2 SD (OR 95%CI 7.331 to infinity). Multivariable linear regression analysis showed the independent predictors of cortBMD Z-scores were PTH (β -0.43, p<0.001), ALP (β -0.36, p<0.001) and serum calcium (β 0.21, p=0.005), which together predicted 57% of variability in cortBMD. DXA imaging did not improve this model.

Conclusions: Routinely used biomarkers are moderate predictors of tibial cortical BMD. DXA is not a clinically useful tool and should not be performed routinely in children and young adults with CKD4-5 and on dialysis.

PO0403

Advanced Glycation End Products Are Related with Cortical Bone Quality and Increased Risk for Fractures in CKD Patients

Noemi A. Roza,[2] Kelcia Rosana da Silva Quadros,[2] André B. Esteves,[2] Renata A. Franca,[2] Wagner Dominguez,[1] Luzia N. Furukawa,[1] Rodrigo B. de Oliveira.[2] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Estadual de Campinas, Campinas, Brazil.*

Background: The risk of bone fractures is higher in chronic kidney disease (CKD) patients than general population. We aim to investigate the relationships between advanced glycation end-products (AGEs) and cortical bone in a cohort of CKD patients.

Methods: 86 CKD patients (stages 3-4, N=26; hemodialysis, N=32; peritoneal dialysis, N=28) were included. AGEs levels were measured in serum (pentosidine and glycated hemoglobin), in skin (by AGE-Reader device) and in cortical bone by immunohistochemistry; receptor activator of nuclear factor kappa-B (RANK) and its

ligand (RANKL) and SOST mRNA expression were evaluated by real-time PCR. Bone histomorphometry was performed to measure cortical porosity, thickness and volume. Fracture risk was predicted using FRAX tool.

Results: Age was 51±13 years; 48 (56%) were male, 41 (48%) Caucasian and 16 (19%) diabetics; dialysis vintage was 21 (10-44) months. AGEs levels in skin were 3.0±0.7 AU (reference: <2.0 AU), serum pentosidine 71 (44–121) pmol/mL and glycated hemoglobin 5.4 (5-6)%; cortical bone volume, thickness and porosity were 22.3±9.8 μm², 619±213 μm and 1.55 (0.9-2.7)%, respectively. AGEs levels in skin were correlated with age (R=0.538; P=0.0001), risk for major osteoporotic fracture (R=0.562; P=0.0001) and hip fractures (R=0.49; P=0.0001). The mean area of AGEs deposits in the cortical bone was 5.4 (3-12.1)%; cortical thickness were negatively correlated with serum pentosidine levels (R=-0.27; P=0.02) and age (R=-0.235; P=0.04); cortical porosity were positively correlated with glycated hemoglobin (R=0.278; p=0.02), SOST mRNA expression (R=0.321; p=0.03), RANKL mRNA expression (R=0.414; p=0.004). Finally, RANK mRNA expression was correlated with serum pentosidine levels (R=0.304; p=0.045).

Conclusions: AGEs were detected in cortical bone and skin of CKD patients and correlates with their risk for osteoporotic fractures. Serum pentosidine levels were associated with low thickness of cortical bone. Cortical porosity was associated with serum glycated hemoglobin levels, SOST and RANKL mRNA expression. RANK was positively influenced by serum pentosidine levels. Together these data point to a direct relationship between AGEs and fractures in patients with CKD.

PO0404

Low Bone Turnover and Increasing Calcification with Lower Trabecular Bone Score in Early CKD Patients

Amr E. Mohamed, Mohamed Ahmed, Michael Winkler, Habib Srour, Daniel Davenport, Marie-Claude M. Faugere, Hartmut H. Malluche. University of Kentucky *University of Kentucky, Lexington, KY*.

Background: Little information is available on turnover abnormalities early during the development of loss of kidney function. Vascular calcifications may develop in association with bone turnover abnormalities. This study was designed to evaluate bone changes and cardiovascular calcification in early CKD patients without clinically known bone or cardiovascular disease.

Methods: This is a cross-sectional analysis of 32 adult volunteers with CKD stage 2-4. All patients underwent 1) dual energy x-ray absorptiometry including trabecular bone score (TBS). 2) Non-contrast CT for cardiovascular calcium scoring, and 3) anterior iliac crest bone biopsy after double tetracycline-labelling and mineralized bone histology with histomorphometry.

Results: The mean age of the patients was 61±11 years. Patients tended to be obese (75%), white (72%), and female (59%). The mean eGFR was 44±16 ml/min/1.73 m². On bone histology low turnover was found at the higher eGFR levels in 78% and normal or high turnover at lower eGFR levels. Mineralization was normal in all. Bone volume was normal in 75% and slightly low in the others. Correlation between bone parameters and eGFR are shown in Table 1. Coronary artery calcium (CAC) score was above 400 in 31%, between 100 and 400 in 24%%, and less than 100 in 45% of patients. TBS correlated negatively with CAC-scores (rho -0.43, p=0.023), and with aortic calcium scores (rho -0.62, p <0.001) (Figure 1)

Conclusions: Low bone turnover, normal total bone volume and absence of mineralization defect are seen in early stages of CKD. There are increased vascular calcifications with low TBS pointing to a relationship between bone quality and vascular calcifications.

Table 1

		Linear regression adjusted for age		
Dependent Variable	**rho with eGFR**	**B**	**95% CI**	**p-value**

PO0405

Bone-Derived Hormones, Mineral Metabolism, Cardiovascular Disease, and Patient Survival in ESRD

Ana Carina Ferreira,[1,2] Marco Mendes,[1,2] Cecilia Silva,[1] Patrícia Cotovio,[1] Ines Aires,[1,2] David Navarro,[1] Fernando C. Pereira,[1,2] Rute M. Salvador,[2] Bruna F. Correia,[2] M. Guadalupe Cabral,[2] Fernando E. Nolasco,[1,2] Manuel A. Ferreira.[1,2] *[1]Hospital Curry Cabral, Lisboa, Portugal; [2]Nova Medical School, Lisboa, Portugal.*

Background: The aim of this study was to analyse the associations between chronic kidney disease-mineral and bone disorder (CKD-MBD) players [alpha-klotho, fibroblast grow factor (FGF) 23, sclerostin, parathyroid hormone (PTH), bone alkaline phosphatase (bAP), vitamin D (vitD), phosphorus (Pi), Calcium (Ca) and Magnesium (Mg)], and echocardiographic findings [left ventricular mass index (LVMI) measured by Devereux formula, valvular calcifications], vascular calcifications and patients (pts) outcomes.

Methods: We performed a prospective cohort study of a sample of ESRD pts listed for renal transplant. All pts were submitted to renal transplant and were followed for 12 months. Patient and graft survival were recorded. At inclusion, demographic and clinical data were collected, laboratory evaluation, bone biopsy and X-ray of the pelvis and hands (Adragão score) were performed. Associations between variables were performed using Wilcoxon rank sum test and Spearman correlation test. STATA software was used and $p < 0.05$ was considered statistically significant.

Results: We included 85 pts. Mean age 50.1±12.7 years, 59 men (69.4%), 66 caucasian (77.6%). The median LVMI was 108.5 (92 – 129) g/m², with 32 patients presenting LVH and 19 valvular calcifications. Median Adragão score was 1 (0 – 2). At the end of 12 months, 4 pts died and 5 had graft failure (non-primary function). Alpha-klotho correlated with bAP (p=0.0006) and marginally with PTH and absence of valvular calcifications (p=0.05). FGF23 correlated with Pi (p<0.001), Ca (p=0.004), PTH (p=0.003), Mg (p=0.002), and inversely with bAP (p=0.003), and presented a marginal association with Adragão score (p=0.06). We didn't find correlations between FGF23 and alpha-klotho or dialysis vintage or echocardiographic characteristics. Sclerostin correlated negatively with bAP (p=0.007) and PTH (p=0.04). The 3rd sclerostin tertile was associated with high scores of vascular calcifications (p=0.02). Lower levels of sclerostin were associated with pt survival at the end of 12 months (p=0.02).

Conclusions: Sclerostin, a bone formation inhibitor, seems to act as a risk factor for vascular calcifications and worse outcomes.

PO0406

Bone Mineral Density Is Not Associated with Coronary Artery Calcification in Children and Young Adults with CKD

Alexander D. Lalayiannis,[1,2] Nicola J. Crabtree,[3] Charles Ferro,[10] Varvara Askiti,[4] Andromachi Mitsioni,[4] Lorenzo Biassoni,[1] Amrit Kaur,[9] Manish Sinha,[5] David C. Wheeler,[6] Neill D. Duncan,[7] Joyce Popoola,[11] Simon Mcguirk,[3] Kristian H. Mortensen,[1] David Milford,[3] Jin Long,[8] Mary B. Leonard,[8] Mary Fewtrell,[1,2] Rukshana Shroff.[1,2] *[1]Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; [2]University College London Institute of Child Health, London, United Kingdom; [3]Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom; [4]Children's Hospital "P. & A. Kyriakou", Athens, Greece; [5]Evelina London Children's Healthcare, London, United Kingdom; [6]University College London, London, GB, London, United Kingdom; [7]Imperial College Healthcare NHS Trust, London, United Kingdom; [8]Stanford University, Stanford, CA; [9]Manchester University NHS Foundation Trust, Manchester, Manchester, United Kingdom; [10]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [11]St Georges Healthcare Trust, London, United Kingdom.*

Background: Coronary artery calcification(CAC) has been linked with bone demineralization in older adults with CKD, but there are no studies examining this relationship in children and young adults. We studied bone mineral density(BMD) by tibial peripheral quantitative CT(pQCT) and measures of vascular health to examine the association between bone demineralization and vascular calcification in a young CKD population.

Methods: Patients with CKD4-5 & on dialysis aged 5-30 years underwent tibial pQCT [for cortical(cortBMD) and trabecular BMD(trabBMD)], cardiac CT for CAC, ultrasound for carotid intima-media thickness(cIMT), carotid-femoral pulse wave velocity(cfPWV) and measurement of routine serum biomarkers. All measures were expressed as Z-scores and adjusted for age, and height. CAC was expressed as Agatston score(AS).

Results: One hundred participants [median 13.82 years(IQR 10.7 to 16.5), 20% above 18 years, 44% female, 77% on dialysis] were included. The median cIMT-SDS was 2.17(IQR 1.14 to 2.86). On multivariable regression analysis TrabBMD-SDS was the only independent predictor of cIMT-SDS(R^2 0.17, β 0.29, p=0.02). The median cfPWV-SDS was 1.45(IQR -0.16 to 2.57) and correlated with systolic (r=0.32, p=0.001) and diastolic (r=0.36, p<0.0001) BP. There were no independent predictors of cfPWV-SDS. 10% of all participants had CAC(AS range 0.8 to 413). CAC correlated with vitamin D doses(r=0.34, p=0.04) but there were no independent predictors. Patients above 18 years had a higher prevalence of CAC(25% vs 6.5% in children, p=0.006) and higher PTH levels(58.5 vs 12.8 pmol/L, p<0.0001), although children had a greater Ca intake from P-binders(median 18.75 vs 0 mmol/day, p=0.03) and superior cortBMD Z-scores (-0.23 vs -2.43, p<0.0001).

Conclusions: Despite a high prevalence of bone and cardiovascular disease(CVD), there was no correlation between bone mineral density and CAC or surrogate measures of CVD in this cohort of children and young adults with CKD4-5D. The skeleton accrues calcium until the third decade of life, perhaps allowing a buffering effect that protects against vascular calcification. Confirmation through longitudinal studies is required.

PO0407

A Randomized, Double-Blind, Placebo-Controlled Trial Assessing Efficacy of Standard and Low-Dose Hydrochlorothiazide Treatment for Prevention of Recurrent Calcareous Nephrolithiasis (NOSTONE Trial)

Nasser Dhayat,[1] Olivier Bonny,[3] Beat Roth,[3] Grazia M. Cereghetti,[1,2] Daniel G. Fuster.[1] on behalf of the NOSTONE Investigators *[1]Inselspital Universitatsspital Bern, Bern, Switzerland; [2]University of Bern, CTU Bern, Bern, Switzerland; [3]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.*

Background: Nephrolithiasis is a global healthcare problem with a current lifetime risk of up to 18.8 % in men and 9.4 % in women. Without specific treatment, 5- and 20-year recurrence rates are 40 % and 75 %, respectively. Given the high cost of medical treatments and surgical interventions as well as the morbidity related to symptomatic stone disease, medical prophylaxis for stone recurrence is an attractive approach. Efficacy of thiazides for kidney stone prevention was tested in 11 trials in the past. However, all these trials had major methodological deficiencies. Nowadays, thiazides are widely used in the treatment of recurrent nephrolithiasis and arterial hypertension, but at significantly lower doses. In the case of recurrent nephrolithiasis, however, this practice is not supported by randomized evidence. Thus, evidence for benefits and harms of thiazides in the prevention of kidney stones remains unclear.

Methods: NOSTONE is a multicenter, randomized, placebo-controlled, double-blind, parallel-group trial with the purpose to assess the dose-response relationship for three different dosages of hydrochlorothiazide (placebo, 12.5mg, 25.0mg, 50.0mg) in kidney stone prevention. The primary outcome is incidence of stone recurrence (a composite of symptomatic or radiologic recurrence) at 3 years, a low-dose CT will be performed at the beginning and the end of the trial. Patients from 12 hospitals throughout Switzerland were included in the trial.

Results: NOSTONE received all necessary approvals by the end of February 2017. Recruitment started in Bern on the 9th of March 2017, all study sites are operative since June 30th 2017. As of October 31st 2019, the target number of 416 patients randomized in the trial was reached and therefore recruitment stopped (www.nostone.ch). In March 2020 the first patient randomized in the trial completed the treatment phase. All patients are expected to reach end of treatment by the end of August 2021.

Conclusions: The NOSTONE study will provide critical information to physicians for the treatment of kidney stones. The impact of the results of this study will affect many patients currently treated with hydrochlorothiazide for the prevention of recurrent nephrolithiasis.

PO0408

Roux-en-Y Gastric Bypass and Kidney Stones

Megan Prochaska, Arlene B. Chapman, Fredric L. Coe, Elaine M. Worcester. *University of Chicago, Chicago, IL.*

Background: Roux-en-Y gastric bypass (RYGB) is a bariatric surgical procedure that is highly effective in the management of morbid obesity but also associated with higher risk of kidney stone formation after surgery. It is not known why RYGB is associated with higher kidney stone risk but it may be due to changes in urine composition, such as high urine calcium oxalate supersaturation (CaOx SS) and calcium phosphate supersaturation (CaP SS). It is not known who is at risk for high urine CaOx SS after surgery. We examined 24-hour urine composition in 18 men and women before and after RYGB to look for predictors of urine high CaOx SS and CaP SS.

Methods: Patients were recruited from a bariatric surgery clinic prior to scheduled laparoscopic long-limb RYGB. Three consecutive 24-hour urine collections performed in a Clinical Research Center both before and 1 year after surgery. We performed Welch's 2-sample and paired t-tests to compare mean urinary values for pre- to post-RYGB collections and to compare men to women in the post-RYGB collections. We used linear regression to evaluate predictors of urine CaOx SS and CaP SS.

Results: Seven men and eleven women completed pre- and post-RYGB urine collections. Post-RYGB, women had a significantly higher urine CaOx SS (13.1 vs. 4.6, p=0.002), CaP SS (0.59 vs. 1.04, p=0.05), and lower urine volumes (1.7 vs. 2.7L, p<0.001) compared with men. There were no differences by sex in CaOx SS or urine volume pre-RYGB. Both men and women had high oxalate in the pre- and post-RYGB collections. Urine volume was most strongly associated with urine CaOx SS with a difference in urine CaOx SS of -6.4 (-8.7 to -4.0) for every 1 liter of urine volume excretion. Citrate was also associated with change in -0.01 (-0.01 to -0.002) per mg of citrate. Calcium and oxalate were not significantly associated. For CaP SS, higher urine calcium and pH (1.3, 0.8 to 1.7) were associated with higher CaP SS (Calcium 0.01mg, 0.008 to 0.12mg; pH 1.3, 0.8 to 1.7). Higher urine volume (-0.4 -0.6 to -0.1) was associated with lower CaP SS and citrate was not significant.

Conclusions: There are important differences in urinary parameters by sex that may contribute to differences in kidney stone risk after RYGB. Women may be at higher risk for kidney stone formation after RYGB compared with men.

PO0409

Nephrocalcinosis at Baseline Did Not Increase the Risk of Nephrocalcinosis Progression After Long-Term Burosumab Treatment in Adults and Children with X-Linked Hypophosphatemia (XLH)

Farzana Perwad,[2] Angel Chen,[1] Lin Zhang,[1] Mary Scott Roberts,[1] Anthony A. Portale.[2] *[1]Ultragenyx Pharmaceutical Inc., Novato, CA; [2]University of California, San Francisco, San Francisco, CA.*

Background: In patients with XLH, excess FGF23 induces hypophosphatemia, leading to musculoskeletal impairments. In two Phase 3 trials (NCT02526160, NCT02915705), burosumab significantly improved serum phosphorus concentrations in adults and children with XLH. We examined subject characteristics and long-term safety of burosumab by the absence or presence of nephrocalcinosis (NC) at baseline (BL) from these trials.

Methods: Adults were randomized (1:1) to burosumab 1.0 mg/kg every 4 weeks or placebo for 24 weeks; after 24 weeks, adults received burosumab through 96 weeks. Children were randomized (1:1) to burosumab 0.8 mg/kg every 2 weeks or oral phosphate and active vitamin D (Pi/D) for 64 weeks. NC was determined at BL and during study by ultrasound and graded by central readers from 0 (normal) to 4 (stone formation).

Results: In adults, NC was found in 73/134 patients (54%) at BL. Age, sex, and duration of treatment with Pi/D as adults did not differ by baseline NC group. Compared with adults without NC at BL, those with NC had longer duration of treatment with Pi during childhood (mean [SD] 13.2 [3.2] vs 11.3 [4.9] years) but not with D. After 96 weeks in adults, median 24-hr urine calcium increased by 35% overall but remained within the normal range. NC scores increased by +1 in 5/73 adults with NC at BL and 5/61 adults without NC at BL. In children, NC was found in 14/61 (23%) at BL. Compared with children without NC at BL, children with NC were older (7.6 [2.8] vs 5.7 [3.4] years), more likely to be male (71% vs 36%), treated longer with Pi/D pre-enrollment (4.8 [3.3] vs 3.6 [3.0] years), and had higher 24-hr urine calcium (4.4 [5.4] vs 2.3 [1.9] mg/kg/day [normal <4.0 mg/kg/day]). After 64 weeks in children, median urine calcium decreased by 50% overall. At week 64, NC scores did not increase in any child and decreased by 1 in 8 children. Serum creatinine and estimated GFR did not change in adults or children.

Conclusions: In adults with XLH, NC at BL was associated with longer duration of Pi during childhood. In children with XLH, NC was associated with longer duration of Pi and D pre-enrollment and with BL hypercalciuria. With long-term burosumab, the presence of NC at BL did not increase the risk of NC progression.

PO0410

Proton-Pump Inhibitors Are Associated with Decreased Urinary Citrate Excretion

Parth M. Patel,[1] Alexander Kandabarow,[1] Eseosa Aiwerioghene,[1] Enrique Blanco-Martinez,[1] Spencer Hart,[1] David J. Leehey,[1,2] Ahmer Farooq,[1] Kristin Baldea,[1] Thomas Turk.[1] *[1]Loyola University Health System, Maywood, IL; [2]Edward Hines Junior VA Hospital, Hines, IL.*

Background: Proton-pump inhibitors (PPIs) may increase the risk of kidney stone formation, but the mechanism(s) has not been elucidated. PPI-associated hypomagnesemia is due to impaired intestinal magnesium absorption thought to result from changes in intestinal pH that decrease binding of magnesium to its transporters. Citrate is a tricarboxylic acid with pKa values of 2.9, 4.8, and 5.6. Since citrate is transported primarily in the divalent form ($citrate^{2-}$) by the intestinal sodium dicarboxylate transporter (NaDC1), changes in intestinal pH by PPIs might decrease the amount of the divalent form, thus reducing intestinal absorption of citrate, thereby decreasing alkaline load and urinary citrate excretion.

Methods: We performed a retrospective review of nephrolithiasis patients treated at our institution and compared patients who were taking PPIs or not at the time of their 24-hour urine collections. Hierarchical multivariate linear regression was used to evaluate the independent relationship between PPI use and urinary composition.

Results: We identified 301 consecutive patients, 88 (29%) of whom were taking PPIs at the time of their 24-hour urine collections. Patients taking PPIs were older and more likely to have medical comorbidities associated with metabolic syndrome such as hypertension, diabetes, and dyslipidemia (p<0.01). Controlling for these factors, patients taking PPIs were found to have lower 24-hour urine citrate excretion (β=-0.12, ΔF=4.24, p=0.04). 24-hour urine magnesium excretion was numerically but not significantly lower in patients taking PPIs. There were no other differences in urinary composition between the groups.

Conclusions: Our findings suggest that patients who take PPIs regularly may be at risk for decreased urinary citrate excretion, which is a known risk factor for kidney stone formation. It is possible that the decrease in urinary citrate with PPIs may have clinical significance, particularly in patients with idiopathic hypocalciuria or other conditions associated with hypocitraturia such as genetic polymorphisms of the renal sodium-citrate transporter, chronic metabolic acidosis, use of carbonic anhydrase inhibitors, high animal protein diet intake, and incomplete distal RTA.

PO0411

Dietary Intake and Risk of Incident and Recurrent Kidney Stones

Api Chewcharat,[1] Eric N. Taylor,[2] Charat Thongprayoon,[1] Lisa E. Vaughan,[1] Ramila A. Mehta,[1] Felicity T. Enders,[1] John C. Lieske,[1] Andrew D. Rule.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]VA Maine Healthcare System, Augusta, ME.*

Background: Dietary factors associated with recurrent kidney stones (KS) may differ from those associated with incident KS.

Methods: We recruited adult incident symptomatic KS formers and controls from local residents surrounding the Mayo Clinics in Minnesota and Florida between 2009 and 2018. Participants were administered a Viocare Food Frequency Questionnaire, a KS survey, and completed a 24h urine chemistry evaluation at a baseline study visit. Medical records of stone formers were reviewed for symptomatic recurrence with a visually confirmed stone through May 2019. Analyses compared baseline dietary factors between incident symptomatic stone formers and controls and assessed whether these same dietary factors predicted symptomatic recurrence.

Results: There were 416 incident symptomatic KS formers (74 had a recurrence during follow-up) and 384 controls. Higher dietary potassium, calcium and phytate were associated with lower odds of an incident symptomatic KS adjusting for age, race, BMI, underlying diseases, family history of KS, education status, fluid and energy intake. During median follow-up time of 4.1 years, higher dietary calcium and lower oxalate intake predicted a lower risk of symptomatic KS recurrence (Hazard ratio for highest tertile vs lowest tertile = 0.53, 95%CI [0.28, 0.99] and 2.09, 95%CI [1.18, 3.69], respectively) adjusting for BMI, fluid and energy intake, and Recurrence of Kidney Stone score. **(Table)**

Conclusions: Certain dietary factors may differ in their association with incident and recurrent KS. In particular, dietary oxalate intake may be more important for preventing recurrence than for preventing a first KS episode.

Funding: NIDDK Support

Multivariate Cox regression model was adjusted for BMI, ROKS score, fluid intake and energy intake (using residual method)

PO0412

Cross-Sectional Study of Metabolomic Profiles and the Association with Kidney Stone Disease in the Nurses' Health Studies I and II

Punyapat Maprapho,[1,2] Yukun Li,[4] Raji Balasubramanian,[4] Eric N. Taylor,[3] Gary C. Curhan.[1] *[1]Brigham and Women's Hospital Channing Division of Network Medicine, Boston, MA; [2]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [3]VA Maine Healthcare System, Augusta, ME; [4]University of Massachusetts Amherst, Amherst, MA.*

Background: Kidney stone disease is a painful and expensive health condition with a high recurrence rate and substantial morbidity; however, the mechanisms underlying the disease remain incompletely understood. Metabolomics is one novel approach that might provide important insights into the etiology of stone disease.

Methods: In a subset of participants from the Nurses' Health Study I and II cohorts (NHSI and NHSII), subjects were divided into stone and non-stone former groups. Data from existing mass-spectrometry based plasma metabolomic profiling that had been performed in multiple case-control studies of other diseases were used. Multivariable logistic regression models were employed to identify metabolites which were associated with kidney stone history after adjusting for multiple comparisons using false detection rate correction.

Results: We included 230 prevalent kidney stone cases among 5380 NHSI participants and 114 cases among 2283 NHSII participants. 277 metabolites were measured and passed the 10% missing threshold. In NHSI, one metabolite was significantly inversely associated with kidney stones (p=0.01) and passed the false-detection rate correction for multiple testing. The identified metabolite was cinnamoylglycine (HMDB0011621), which is a metabolite in the carboxylic acids and derivatives class. There were no significant metabolites in NHSII. When the cohorts were combined, HMDB0011621 was significantly inversely associated with stone history (p<0.01). The odds ratio per standard deviation increase in the metabolite for the combined cohorts was 0.87 (0.81, 0.95).

Conclusions: We identified one plasma metabolite associated with a history of kidney stones. The metabolite has been recently identified as one of the potential biomarkers of proximal tubule function, colonization of antibiotic resistant gut microbiome, and diabetes, which are also known to correlate with kidney stone disease. Larger studies are needed to identify other potential metabolites that may be involved in kidney stone formation.

PO0413

Type 3 Renal Tubular Acidosis in Association with a Pelvic Kidney

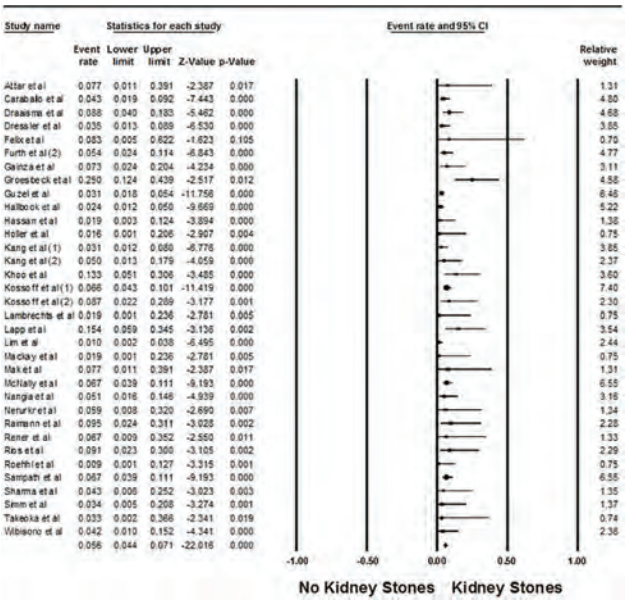
Prince Singh, Stephen B. Erickson, Janina Paula T. Sy-Go, James R. Gregoire. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Introduction: The association of renal tubular acidosis (RTA) from carbonic anhydrase isoenzyme II (CA II) deficiency, cerebral calcifications and osteopetrosis is known as *marble brain disease*

Case Description: 21-year-old woman with a medical history of multiple fractures since childhood, recurrent episodes of nephrolithiasis and, renal tubular acidosis (RTA), presented to establish care at our clinic. Genetic testing had revealed she had CA II gene mutation. Her brother had the same condition but her sisters were healthy. Her medication included potassium citrate and vitamin D3. Laboratory assessment revealed the following: serum Na+ 143 mmol/L, K+ 3.9 mmol/L, Cl- 109 mmol/L, HCO3 21 mmol/L, creatinine 0.73 mg/dl, Ca2+ 9 mg/dl, PO43- 4.4 mg/dl, vitamin D 7.6 mg/dl. Urine pH was 6. CT urogram revealed a normal right kidney and an ectopic left kidney with numerous small stones. (Figure 1). Spine X rays showed osteopetrosis of vertebral endplates and MRI brain showed calcifications in basal ganglia. Pyelolithotomy of the pelvic stone was performed and stone analysis revealed 90% calcium phosphate and 10% calcium oxalate. 24-hour urine showed a low urine citrate with low urine volume. Thus the findings were consistent for RTA with low serum bicarbonate, low urine citrate and calcium phosphate predominant stones.

Discussion: CA II deficiency syndrome is a rare autosomal recessive disorder that results in Type 3 RTA (combined proximal and distal RTA). Pelvic kidneys, which result from a failure of mesonephros to ascend normally during early gestation, are prone to urolithiasis due to poor urinary drainage. In our patient RTA, along with altered urine flow due to pelvic kidney predisposed to nephrolithiasis.

Ectopic (pelvic) left kidney with multiple stones with a normal looking right kidney



PO0414

Incidence and Characteristics of Kidney Stones in Patients on a Ketogenic Diet: A Meta-Analysis

Prakrati C. Acharya,[2] Juan A. Medaura,[1] Chirag Acharya,[3] Charat Thongprayoon,[4] Wisit Cheungpasitporn.[1] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Texas Tech University Health Sciences Center El Paso, El Paso, TX; [3]LCCF, Hobbs, NM; [4]Mayo Clinic Minnesota, Rochester, MN.*

Background: Very-low-carbohydrate diets or ketogenic diets have frequently been used for weight loss in adults and as a therapy for epilepsy in children. The incidence and characteristics of kidney stones in patients on ketogenic diets are not well studied.

Methods: A systematic literature search was performed using MEDLINE, EMBASE, and Cochrane Database of Systematic Reviews from the databases' inception through April 2020. Observational studies or clinical trials that provide data on the incidence and/or types of kidney stones in patients on ketogenic diets were included. We applied a random-effects model to estimate the incidence of kidney stones.

Results: A total of 36 studies with 2,795 patients on ketogenic diets were enrolled. The estimated pooled incidence of kidney stones was 5.6% (95%CI, 4.4%-7.1%) in patients on ketogenic diets at mean follow-up time 3.7+/- 2.9 years. Subgroup analyses demonstrated the estimated pooled incidence of kidney stones of 5.6% (95%CI, 4.3%-7.2%) in children and 5.6% (95%CI, 2.3%-12.6%) in adults, respectively. Within reported studies, 48.7% (95%CI, 33.2%-64.6%) of kidney stones were uric stones, 36.5 % (95%CI, 10.6%-73.6%) were calcium based (CaOx/CaP) stones, and 27.8% (95%CI, 12.1%-51.9%) were mixed uric acid and calcium based stones, respectively.

Conclusions: The estimated incidence of kidney stones in patients on ketogenic diets is 5.6%. Its incidence is comparable among adults and children. Uric acid stones are the most prevalent kidney stones in patients on ketogenic diets followed by calcium based stones. These findings may impact the prevention and clinical management of kidney stones in patients on ketogenic diets.

PO0415

Association of Urine Findings with Metabolic Syndrome (met-s) Traits in Patients with Nephrolithiasis

Virginia L. Hood,[1,2] Carley Mulligan,[1] Desiree de Waal,[2] Peter W. Callas,[3] Kevan M. Sternberg.[1,2] *[1]University of Vermont College of Medicine, Burlington, VT; [2]University of Vermont Medical Center, Burlington, VT; [3]University of Vermont, Burlington, VT.*

Background: Met-s is a health concern related to lifestyle habits including acidogenic and high protein diets. The odds of nephrolithiasis increases with an increasing number of met-s traits. Prior studies have shown relationships among the number of met-s traits and decreasing urine pH and other acid excretion markers. We evaluated associations of urine factors including acid excretion and stone composition with the number of met-s traits in a large cohort of stone-forming patients.

Methods: A retrospective review was performed of 24-hour urine studies (Litholink, Chicago, Il) from patients seen in Urology and Nephrology divisions, UVMMC July 2009 to December 2018. Patients <18 years and those with improper collections based on creatinine/kg were excluded. Patient variables, laboratory values, associated diagnoses, and medications were identified within 6 months of urine collection and 1 year of kidney stone composition. Four groups based on the number (0, 1, 2, 3-4) of met-s traits (hypertension, obesity, dyslipidemia, diabetes) were evaluated. Trends across groups were tested using linear contrasts in analysis of variance.

Results: 1250 unique patients, 49% F, 703 with stone composition met criteria for inclusion. Met-s groups n were 0=509, 1=381, 2=203, 3+4=157. There was no difference or trends among the groups for urine volume, calcium or citrate. There was a significant trend p<0.001 for increasing number of met-s traits with decreasing urine pH and SS calcium phosphate (CaP) and increasing age, weight, protein intake, urine uric acid (UA), SS UA, oxalate, sodium, potassium, phosphorus, urea nitrogen, chloride, estimated net acid excretion and p<0.05 for sulfate (S), ammonium, magnesium. When adjusted for age and protein intake the trend remained significant only for urine pH and a reversed trend for S. There was a significant trend for more UA and fewer predominately CaP stones in those with more met-s traits.

Conclusions: High protein intake accounted for most of the difference in urinary markers of stone risk except low urine pH. The latter facilitates more UA and less CaP contribution to stone composition. Future studies could determine if changing diet can reduce risk for stones in met-s

PO0416

Primary Hyperoxaluria (PH) Types 1 and 2 with Kidney and/or Liver Transplant Achieve Best Health-Related Quality of Life (HRQoL)

Frank Modersitzki,[1] Dawn S. Milliner,[2] John C. Lieske,[2] David S. Goldfarb.[3] *[1]New York University Grossman School of Medicine, New York, NY; [2]Mayo Clinic Rochester, Rochester, MN; [3]VA New York Harbor Healthcare System Manhattan Campus, New York, NY.*

Background: Our previous study showed that PH without a transplant (tx) had worse HRQoL compared to the US Standard Population and worsened with increased stone frequency. We now show the first longitudinal HRQoL profiles for PH patients with transplants.

Methods: PH participants were enrolled from the Rare Kidney Stone Consortium registry. HRQoL was measured with a generic non-disease specific instrument (SF-36v2). Results were calculated as norm-based scores (NBS) based on US Standard Population

(Mean domain score = 50). We created three groups based on the time of last stone event (<= 30 days, 31 – 365 days, >366 days). The study compared HRQoL for participants with a kidney and/or liver transplant over 5 different time points.

Results: This sub-sample included 100 surveys of 32 PH participants (16 males and 16 females) with a tx. The mean age was 47 years for both males and females. This sub-sample includes 24 participants with liver/kidney tx (75%) and 8 with kidney tx only (25%). Participants with only a kidney tx reported significantly more stone events within a year (26% vs 13%, X^2 =0.028). Two way ANOVA did not find a change in HRQoL profiles over time for PH participants with kidney or kidney/liver tx (figure). Most mean domain scores are 50 or above, except for the domain of General Health which was less. Participants with only a kidney tx scored significantly lower in role physical, bodily pain, general health, social function, and physical component score (data not shown) than participants with kidney/liver tx. There was no difference between male and female participants over time.

Conclusions: PH participants with kidney/liver tx achieve better HRQoL, measured with a non-disease specific generic instrument, than those with kidney alone; both are better when compared to the US Standard Population. The majority of PH participants with a tx are stone-free, with a direct beneficial impact on their HRQoL.

Assessment of Blood Oxalate Concentrations in Patients with CKD

Anja C. Pfau,[1] Monika Wytopil,[2] Kinsuk Chauhan,[3] Martin Reichel,[1] Steven G. Coca,[3] Peter S. Aronson,[4] Kai-Uwe Eckardt,[1,2] Felix Knauf.[1,4] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Universitatsklinikum Erlangen, Erlangen, Germany; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Yale University Department of Internal Medicine, New Haven, CT.*

Background: Alterations in oxalate homeostasis are associated with kidney stone disease and progression of chronic kidney disease (CKD). However, accurate measurement of plasma oxalate (P_{Ox}) concentration is challenging as prompt processing and acidification of samples has been deemed necessary. In the present study we examined the effects of variations in sample handling on P_{Ox} results. Subsequently, a standardized analytical protocol was established, and P_{Ox} concentrations were measured in a large cohort of patients with CKD.

Methods: We tested the effects on P_{Ox} results of storage time at room temperature (RT), storage on dry ice and maintenance of samples at -80°C. P_{Ox} was measured in 1826 patients enrolled in the German Chronic Kidney Disease (GCKD) study, an ongoing multicenter, prospective, observational cohort study.

Results: P_{Ox} concentrations increased rapidly when samples were maintained at RT. This was most relevant for P_{Ox} < 10 µM as concentrations more than doubled within a few hours. Immediate freezing on dry ice and storage at -80°C provided stable results and allowed postponement of acidification for > 1 year. In the GCKD study, mean (SD) eGFR at the time of P_{Ox} measurement was 44.0 (17.9) ml/min/1.73 m². More than half of the patients had a P_{Ox} concentration below 2.0 µM. P_{Ox} correlated positively with urinary albumin to creatinine ratio and inversely with eGFR (P <0.001). In the lowest eGFR quartile, median eGFR was 25.1 ml/min/1.73 m² (IQR 20.3 - 28.1) with a median P_{Ox} of 2.7 µM (IQR 1.9 – 4.2).

Conclusions: We conclude that immediate freezing and maintenance of plasma samples at -80°C facilitates the sample collection process and allows accurate P_{Ox} assessment in large patient cohorts. Our study presents a critical and useful modification of the complex preanalytical procedure. Moreover, we demonstrate that P_{Ox} concentrations in patients with CKD are substantially lower than previously reported. The present study may serve as a reference for sample handling to assess P_{Ox} in clinical trials and to determine its role in CKD progression.

Safety and Efficacy of Reloxaliase in Enteric Hyperoxaluria (EH): An Aggregate Review of Completed Studies

Christina M. Wyatt,[2,1] Alicia Weeks,[1] Danica Grujic,[1] Annamaria T. Kausz.[1] *[1]Allena Pharmaceuticals, Newton, MA; [2]Duke University, Durham, NC.*

Background: EH occurs when excess oxalate is absorbed from the gastrointestinal (GI) tract due to underlying fat malabsorption, increasing renal oxalate load and as a result, risk of both kidney stones and chronic kidney disease. Reloxaliase is a first-in-class oral enzyme that specifically targets and degrades oxalate within the GI tract to treat EH. An aggregate safety and efficacy assessment of reloxaliase in subjects with EH across completed clinical trials was performed.

Methods: There were a total of four Phase 2 and 3 trials that enrolled EH subjects; 2 were single-arm and 2 were randomized, placebo (PBO) controlled. Subjects took reloxaliase orally (7,500 units/dose) 3 to 5 times/day, for 4 days to 12 weeks. The efficacy endpoint in all trials was change in 24-hour urine oxalate (UOx) excretion (mg/d). For this aggregate analysis, percent change from baseline was calculated using the average of all values obtained during treatment.

Results: There were a total of 168 randomized subjects with EH (94 reloxaliase and 74 PBO), most with bariatric surgery as the cause of malabsorption. Baseline estimated glomerular filtration rate (eGFR) ranged from normal to as low as 33 mL/min/1.73m². In subjects with baseline UOx ≥ 50 mg/d, reloxaliase treatment consistently reduced 24-hr UOx by a mean of 23 to 35% across the studies, despite differences in dosing frequency and duration of treatment. Efficacy appeared to be unrelated to baseline eGFR. Adverse events (AEs) were reported in 67% of reloxaliase subjects compared to 51.4% on PBO, with GI AEs most common in both groups. There were no treatment-related serious AEs or deaths, and none of the reloxaliase treated subjects withdrew from the study due to a related AE.

Conclusions: Reloxaliase reduces 24-hr UOx excretion and is well tolerated in EH patients independent of eGFR, dosing frequency, or duration of treatment. Further studies are ongoing to assess the long-term benefits of reloxaliase and its potential to decrease kidney stone events and preserve kidney function.

Trends in Treatment of Secondary Hyperparathyroidism and Association with Post-Transplant Outcomes

Aarti Mathur, Whitney Sutton, JiYoon B. Ahn, Dorry L. Segev, Mara McAdams-DeMarco. *Johns Hopkins University, Baltimore, MD.*

Background: Secondary hyperparathyroidism(SHPTH) affects nearly all patients with kidney failure on maintenance dialysis and has been independently associated with increased mortality and cardiovascular disorders. Treatment includes vitamin D analogs, calcimimetics, or parathyroidectomy. However, treatment choice for SHPTH on outcomes after kidney transplantation(KT) is not well understood. The primary objectives of our study were to understand treatment trends in SHPTH and their association with post-transplant outcomes.

Methods: Using SRTR and Medicare claims data, we identified 12,372 adults(age≥18) who received KT in 2007-2016 and had a diagnosis of SHPTH during dialysis. We examined the association between treatment method for SHPTH and development of tertiary hyperparathyroidism, delayed graft function, graft failure, and death using adjusted Cox proportional hazards models.

Results: Of 12,372 patients with a diagnosis of SHPTH, 4,554(36.8%) received cinacalcet, 205(1.7%) underwent parathyroidectomy, and 7,613(61.5%) had no treatment prior to KT. Cinacalcet use increased throughout the duration of the study period with 18.4% of patients receiving it 2007 versus 46.2% in 2017(p<0.001). Utilization of parathyroidectomy increased from 0.8% in 2007 to 3.1% in 2016(p=0.005). Compared to patients treated with cinacalcet, those treated with parathyroidectomy had a lower risk of developing tertiary hyperparathyroidism(aHR=0.49,95%CI:0.29-0.82) at 3 years post-KT and those who received no treatment had lower odds of delayed graft function(aOR=0.87,95%CI:0.78-0.96). There was no association between treatment of SHPTH and post-transplant death-censored graft failure, all-cause graft failure or death.

Conclusions: The use of calcimimetics and parathyroidectomy to treat SHPTH has been steadily increasing since 2007. Importantly, patients who underwent parathyroidectomy for SHPTH had lower risk of developing tertiary hyperparathyroidism post-transplant. Therefore, patients treated with cinacalcet pre-transplant may need closer surveillance post-transplant for development of tertiary hyperparathyroidism.

PO0420

A Combined MicroRNA and Target Protein-Based Panel for Predicting the Probability and Severity of Uremic Vascular Calcification

Chia-Ter Chao.[1,2] *[1]National Taiwan University Hospital Beihu Branch, Taipei, Taiwan; [2]Graduate Institute of Toxicology, National Taiwan University, Taipei, Taiwan.*

Background: Vascular calcification (VC) increases the future risk of cardiovascular events in uremic patients, but effective therapies are still unavailable. Accurate identification of those at risk of developing VC using pathogenesis-based biomarkers is of particular interest and may facilitate individualized risk stratification. We aimed to uncover miRNA-target protein-based biomarker panels for evaluating uremic VC probability and severity.

Methods: We created a 3-tiered *in vitro* VC model and an *in vivo* uremic rat model receiving high phosphate diet to mimic uremic VC. RNAs from the *in vitro* and *in vivo* models underwent miRNA and mRNA microarray, with results screened for differentially expressed miRNAs and their target genes as biomarkers. Findings were validated in all models and human cells, followed by functional assays of identified miRNAs, and tests of sera from end-stage renal disease (ESRD) and non-dialysis dependent chronic kidney disease (CKD) patients without and with VC.

Results: Totally 122 down-regulated and 119 up-regulated miRNAs during calcification progression were identified initially; further list-narrowing based on miRNA-mRNA pairing, anti-correlation, and functional enrichment left 16 and 14 differentially expressed miRNAs and mRNAs. Levels of 4 miRNAs (miR-10b-5p, miR-195, miR-125b-2-3p, and miR-378a-3p) were shown to decrease throughout all models tested, while 1 mRNA (SULF1, a potential target of miR-378a-3p) exhibited the opposite trend concurrently. Among 77 ESRD (88.3% with VC) (Figure A) and 59 CKD patients (61% with VC) (Figure B), serum miR-125b2-3p and miR-378a-3p decreased with greater VC severity, while serum SULF1 levels increased. Adding serum miR-125b-2-3p, miR-378a-3p, and SULF1 into regression models for VC substantially improved performance compared to using clinical variables alone.

Conclusions: Using a translational approach, we discovered a novel panel of biomarkers for gauging the probability/severity of uremic VC based on miRNAs and their target proteins, which improved the diagnostic accuracy.

Clinical Characteristics and eGFR and Urine Albumin-to-Creatinine Ratio Distribution According to the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD International Retrospective Cohort

Juan Jose Garcia Sanchez,[1] Juan J. Carrero,[2] Supriya R. Kumar,[3] Roberto Pecoits-Filho,[4,5] Glen James,[1] Hiddo J. L Heerspink,[6] Stephen Nolan,[1] Lam S. Carolyn,[7,8] Hungta (tony) Chen,[3] Eiichiro Kanda,[9] Alyshah Abdul Sultan,[1] Naoki Kashihara,[9] Mikhail Kosiborod,[10] Carol A. Pollock,[11] David C. Wheeler.[12] *[1]AstraZeneca, Cambridge, United Kingdom; [2]Karolinska Institutet, Stockholm, Sweden; [3]AstraZeneca, Gaithersburg, MD; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; [6]Rijksuniversiteit Groningen, Groningen, Netherlands; [7]National Heart Centre Singapore, Singapore, Singapore; [8]Duke-NUS Medical School, Singapore, Singapore; [9]Kawasaki Ika Daigaku, Kurashiki, Japan; [10]Saint Luke's Mid America Heart Institute, Kansas City, MO; [11]Royal North Shore Hospital, St Leonards, NSW, Australia; [12]University College London, London, United Kingdom.*

Background: Contemporary studies describing the prevalence and characteristics of patients with CKD categorised according KDIGO 2012 are scarce. We describe patient characteristics and the prevalence of CKD according to the 2012 KDIGO categories in patients with CKD.

Methods: The DISCOVER-CKD retrospective cohort of patients was extracted using real-world data from the integrated Limited Claims and Electronic Health Record (LCED) data and TriNetX. Patients were aged ≥18 years, with ≥1 UACR measure and required first diagnostic coding of CKD (Stages3A to ESRD) or two estimated glomerular filtration rate (eGFR) measurements of <75 mL/min/1.73 m² recorded at least 90 days apart (max 730) between January 2008 and March 2020. Index date was date of diagnostic coding or 2nd eGFR. UACR closest to index was used to categorise patients. Descriptive analyses were used to summarise prevalence and patient characteristics.

Results: Preliminarily, among 22229 included patients, 63.6% (n=10979, TriNetX) and 76.6% (n=3813, LCED) had normal to mildly increased albuminuria, 26.6% (n=4581, TriNetX) and 17.9% (n=889, LCED) had moderately increased albuminuria and 9.8% (n=1694, TriNetX) and 5.5% (n=273, LCED) had severely increased albuminuria (Figure 1). Hypertension and type 2 diabetes were the most common comorbidities (prevalence >60%) and their prevalence increased with albuminuria.

Conclusions: This study, utilising real-world data, fills an important knowledge gap regarding the characteristics of patients with CKD in different eGFR and UACR strata according to the KDIGO 2012 definitions.

The DAPA-CKD-Like Population in a Contemporary US Healthcare System: Cohort Characteristics and Clinical Outcomes

Tope Olufade,[1] Lois Lamerato,[3] Juan Jose Garcia Sanchez,[2] Like Jiang,[1] Joanna C. Huang,[1] Stephen Nolan.[2] *[1]AstraZeneca, Wilmington, NC; [2]AstraZeneca UK Ltd, Cambridge, United Kingdom; [3]Henry Ford Health System, Detroit, MI.*

Background: The DAPA-CKD Trial is the first SGLT-2i renal outcome trial to test the efficacy and safety of an SGLT-2i, dapagliflozin, in patients with diagnosed CKD with and without T2D. To appropriately evaluate future results and aid clinical interpretation of the DAPA-CKD trial, the present study assessed the renal and CV outcomes of a "DAPA-CKD-like population" (eGFR 25-75ml/min/1.73m² and UACR 200-5000mg/g) in a contemporary US healthcare system.

Methods: Administrative data from the Henry Ford Health System was used to identify patients with CKD stages 2 through 4 between 2006 and 2016 based on eGFR lab reading (n=38,376). Exclusions included no confirmatory eGFR > 90 days from index date, death within 30 days, history of renal transplant, and evidence of renal replacement therapy, or progression to CKD stage 5 during the baseline period (6 months pre or post index date). Within that cohort, 17,742 had eGFR (25-75ml/min/1.73m²) and 9,177 had a UACR (0-5000 mg/g) within 12 months of index date. Additional exclusions were type 1 diabetes, lupus nephritis and polycystic kidney disease. Patients were followed through December 31st, 2018.

Results: Of the 6,557 patients that met the eligibility criteria and were included in the study cohort, the mean age was 62.9 years and 46.2% were male. The population was stratified by UACR (0-<30, 30–199, 200–5,000mg/g). Across all outcomes assessed, incidences were highest in the DAPA-CKD-like cohort (UACR 200-5000mg/g) (HF 36.1%; MI 11.3%, Stroke 8.9%; ESKD 18.6%; Mortality 18.5%; see Table 1). The greatest increase was observed for renal outcomes particularly ESKD, increasing from 0.9% (UACR 0-<30mg/g) to 3.4% (UACR 30-199mg/g) to 18.6% (UACR 200-5000mg/g).

Conclusions: In a contemporary US healthcare system, there remains significant adverse renal, CV and mortality outcomes among patients fitting the DAPA-CKD study inclusion criteria. These results highlight the unmet need existing for additional therapies to delay disease progression and improve outcomes and survival in this high risk population.

Funding: Commercial Support - AstraZeneca

NSAID Use Is Not Associated with Kidney Injury or Dysfunction in Ambulatory Older Adults

Jonathan G. Amatruda,[1,2] Harini Sarathy,[1] Carmen A. Peralta,[1,8] Michelle M. Estrella,[1,2] Ronit Katz,[3] Joachim H. Ix,[5] Linda F. Fried,[4] Chirag R. Parikh,[6] Anne B. Newman,[9] Mark J. Sarnak,[7] Michael Shlipak.[1,2] *[1]University of California San Francisco, San Francisco, CA; [2]Kidney Health Research Collaborative, UCSF, San Francisco, CA; [3]University of Washington, Seattle, WA; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]University of California San Diego, La Jolla, CA; [6]Johns Hopkins University, Baltimore, MD; [7]Tufts Medical Center, Boston, MA; [8]Cricket Health, San Francisco, CA; [9]University of Pittsburgh, Pittsburgh, PA.*

Background: NSAIDs cause AKI and may worsen CKD, especially in vulnerable populations such as older adults. We hypothesized that NSAID use would be associated with markers of both tubular and glomerular damage in older adults.

Methods: In the multicenter Health ABC cohort of ambulatory older adults, prescription and OTC NSAID use was self-reported. Estimated GFR by cystatin C, and urine albumin (ACR), KIM-1, and IL-18 were measured in 2,999 participants; urine a1m, NGAL, PIIINP, and UMOD were measured in a random subset of 500 participants. We evaluated cross-sectional associations between NSAID use and these biomarkers with separate linear regression models. The association between time-updated NSAID use and eGFR decline over 10 years was estimated with linear mixed models.

Results: Participants had a mean age of 74 years, 51% were female, and 41% African-American. No eGFR differences were detected between NSAID users (n=655) and non-users (n=2344) at baseline (72 mL/min/1.73m^2 in both groups). Compared to non-users, NSAID users had 33% (95% CI: 11%-49%) lower adjusted odds of having ACR >30 mg/g and 11% (95% CI: 4%-18%) lower mean urine IL-18 concentration at baseline. No significant differences in baseline concentrations of the remaining urine biomarkers were detected. NSAID users and non-users did not differ significantly in the rate of eGFR decline (-2.2% vs. -2.3% per year).

Conclusions: Among ambulatory older adults, NSAID use was not associated with kidney dysfunction or injury based upon eight measures of kidney health, and NSAIDs were associated with significantly lower urine albumin and IL-18 concentrations. These findings illustrate the potential for NSAID use without kidney harm, even in a presumably high-risk population.

Table: Association of NSAID use with annual change in eGFR

All (n = 2999)	Mean eGFR change, % per year (95% CI)	Adjusted β (95% CI)
NSAID users (n = 655)	-2.21 (-2.49, -1.92)	-0.06 (-0.39, 0.28)
NSAID non-users (n = 2344)	-2.31 (-2.47, -2.16)	0 (reference)
eGFR ≥60 (n = 2249)		
NSAID users (n = 496)	-2.36 (-2.62, -2.11)	-0.001 (-0.31, 0.31)
NSAID non-users (n = 1753)	-2.42 (-2.56, -2.29)	0 (reference)
eGFR <60 (n = 750)		
NSAID users (n = 159)	-1.74 (-2.52, -0.96)	-0.29 (-1.19, 0.61)
NSAID non-users (n = 591)	-2.00 (-2.41, -1.59)	0 (reference)

PO0424

The Prevalence of CKD Among First-Degree Relatives of Saudi Hemodialysis Patients and Associated Factors

Dujanah H. Mousa, Ali Alharbi, Mohammed A. Alhomrany, Imed Helal, Fayez F. Alhejaili. Diaverum Saudi Arabia *Diaverum Renal Services Group, Riyadh, Saudi Arabia.*

Background: In Saudi Arabia, there are currently over 20,000 patients on dialysis and 9810 patients followed up for functioning renal transplantation. The combined prevalence of renal replacement therapy (stage 5 CKD) in Saudi Arabia is estimated to 1294.3 PMP. There are no local data or registry about stages 1 to 4 CKD in the Kingdom. Objective: To assess the prevalence of CKD among first degree relatives of Saudi hemodialysis patients and evaluate the associated characteristics

Methods: 1st degree relatives of all hemodialysis patents in Diaverum clinics in Saudi Arabia were screened for CKD. Demographic data were collected as well as history of hypertension or diabetes mellitus. Serum creatinine, urinalysis and a single Blood pressure reading were measured. eGFR was calculated using EPI formula. For the index cases, the cause of CKD, age and gender were recorded. The prevalence rates of CKD stages among relatives were calculated and the association between different variables and CKD stages assessed

Results: Out of 4500 dialysis patients, 20258 1st degree relatives were approached of whom 5177 responded. The cause of CKD among the index cases was DM in 52.5% followed by hypertension (20.6%). The eGFR was < 90 mls /min in 39.6% and < 60 mls/ min in 5.8% of the screened cases. Proteinuria was present in 8%, making the combined prevalence of CKD of 13.8%. In the screened group, the prevalences of glycosuria, hematuria and proteinuria were 9.5%, 17.9% and 26.5% respectively and systolic hypertension (>130 mmHg) was observed in 28.1% and diastolic hypertension in 8.6%. Screened relatives in stages 0-1 were significantly younger than those in stages 2-5 (31.3 ±12.8 versus 40.9± 15 years (p=0.0001). The relationship of the screened persons to the index patients among those in stages 2-5 were offspring (35.8%), sibling (41.6%) and parent (50.0%) (p=0.0005). The prevalences of the primary renal diseases in the index cases did not differ between screened relatives in CKD stages 0-1 and those in stage 2-5.

Conclusions: The overall combined prevalence of CKD was 13.8% and is highest in the Southern region of Saudi Arabia. The presence of CKD in the screened relatives was not associated with identifiable cause of CKD in the index cases or use of analgesics. Many relatives were discovered to have undiagnosed hypertension and undiagnosed diabetes.

Sex Differences in CKD Prevalence in Asia: A Systematic Review and Meta-Analysis

Carinna Hockham,[1] Lexia Bao,[1] Anushree Tiku,[1] Sunil Badve,[1,2] Martin P. Gallagher,[1,3] Meg J. Jardine,[1,3] Vivekanand Jha,[1] Mark Woodward,[1,4] Min Jun.[1] *[1]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [2]St. George Hospital, Sydney, NSW, Australia; [3]Concord Repatriation General Hospital, Sydney, NSW, Australia; [4]The George Institute for Global Health, University of Oxford, Oxford, United Kingdom.*

Background: Individual studies reporting sex-specific chronic kidney disease (CKD) prevalence in Asia have shown inconsistent sex differences in CKD prevalence. We sought to synthesise available sex-disaggregated data to better define and compare CKD prevalence in women and men in Asia.

Methods: We systematically searched the literature for observational studies of ≥500 adults reporting sex-disaggregated CKD prevalence data in Asia. We calculated the women-to-men prevalence ratio (PR) for each study and pooled these using random-effects meta-analysis. Subgroup analyses were performed to explore potential sources of heterogeneity in the PR.

Results: Sex-disaggregated CKD prevalence data were available for 12 of the 26 Asian countries (109 studies; 1,452,308 women and 1,391,995 men). Most studies (83%) came from China, Taiwan, Japan and South Korea. Sex-specific CKD prevalence estimates varied substantially between studies (median [IQR] reported prevalence was 19% [9-35%] in women and 17% [8-28%] in men). Overall, CKD prevalence was higher in women compared to men (pooled PR 1.14; 95%CI 1.07-1.21), with evidence of significant heterogeneity (I^2=99%). In subgroup analyses, prevalence was higher in women among studies with a younger mean age, a higher proportion of diabetes and that defined CKD using eGFR only (Table 1). The pooled PR varied considerably by country.

Conclusions: Existing sex-disaggregated data suggest a higher overall prevalence of CKD in women compared to men in Asia. However, adequate assessment of sex differences in CKD prevalence is limited by the absence of sex-disaggregated data for a large part of the region. Standardised reporting of sex-disaggregated CKD prevalence data in Asia is needed.

PO0426

Increased Circulating suPAR Levels in African Patients with HIV

David C. Wei,[1] Beata Samelko,[1] Martin G. Zeier,[2] Rulan S. Parekh,[3] Jochen Reiser.[1] *[1]Rush University Medical Center, Chicago, IL; [2]University Hospital Heidelberg, Heidelberg, Germany; [3]University of Toronto, Toronto, ON, Canada.*

Background: Decline in kidney function associated with APOL1 risk alleles is dependent on circulating suPAR levels in African American (AA) patients. Yet, little is known among HIV infected persons in sub-Saharan Africa, and epidemiological data from

this region regarding APOL1 risk status is scarce. We aimed to determine APOL1 risk variants, plasma suPAR levels and estimated kidney function in HIV patients in Zambia.

Methods: We performed a cross-sectional study with 480 adult HIV infected persons on anti-retroviral treatment (ART) (women, 64.8%) in Lusaka, Zambia. APOL1 genotyping was done to determine the prevalence of the risk alleles; plasma suPAR levels were assayed and estimated GFR (eGFR) was calculated by CKD-EPI creatinine-based formula.

Results: Plasma suPAR levels were increased and were negatively correlated to eGFR, whether less than 60 or not (r=-0.15, p=0.001). Women while younger (42 vs 46 years old for men, p=0.0003), had higher suPAR than men (3.68 ng/ml vs 3.07 ng/ml, p<0.0001). Ten out of 480 patients (2.1%) had CKD, and their suPAR levels were higher than patients without CKD (5.6 ng/ml vs 3.44 ng/ml, p<0.0001). Fifty patients (10.4%) had 2 APOL1 risk alleles (35 for women vs 15 for men); among those, 3 (6%) developed CKD (p=0.07). No difference in suPAR levels or eGFR was observed between patients who carried 2 APOL1 risk alleles and those with 1 or 0 risk allele.

Conclusions: HIV infected persons in Zambia on ART have increased suPAR levels. The prevalence of two APOL1 risk alleles is similar as with AA HIV patients. A longitudinal study with a bigger cohort should reveal the relationship between suPAR, APOL1 risk alleles and kidney function.

Kidney Tubular Injury and Dysfunction Relate to Frailty and Cognitive Function in Persons with CKD in SPRINT

Lindsay M. Miller,[1] Manjula Kurella Tamura,[2] Nicholas M. Pajewski,[3] Daniel E. Weiner,[4] Dena E. Rifkin,[1] Michael Shlipak,[5,6] Joachim H. Ix.[1]
[1]University of California San Diego Division of Nephrology-Hypertension, San Diego, CA; [2]Stanford University School of Medicine, Stanford, CA; [3]Wake Forest University School of Medicine, Winston-Salem, NC; [4]Tufts Medical Center, Boston, MA; [5]Kidney Health Research Collaborative, San Francisco, CA; [6]VAHCS/UCSF, San Francisco, CA.

Background: The association of markers of kidney disease (eGFR and albuminuria) with frailty and cognition is well established. However, these markers do not specifically evaluate kidney tubule injury or dysfunction.

Methods: We measured 8 biomarkers of kidney tubule dysfunction and injury among 2,282 SPRINT participants with eGFR < 60 and evaluated their associations with frailty and cognitive function. Frailty was defined with a previously validated frailty index (FI), categorized as fit (FI < 0.10), less fit (0.10 < FI < 0.21), and frail (FI > 0.21). Global cognitive function was measured using the Montreal Cognitive Assessment (MoCA). Models were adjusted for, demographic, behavioral, and clinical variables including urine creatinine, eGFR and albuminuria.

Results: Higher urine concentrations of MCP-1 & α1M were independently associated with frailty (Figure). These associations were independent of demographics, other CKD risk factors, eGFR and albuminuria, and were comparatively stronger than associations of albuminuria with frailty (Figure). Higher urine β2M was associated with lower cognitive function (β: -0.09; 95% CI -0.17, -0.01), whereas albuminuria was not (β: -0.03; 95% CI -0.13, 0.08).

Conclusions: Urine markers of tubulointerstitial fibrosis (captured by MCP-1) and diminished proximal tubule reabsorptive capacity (captured by α1M and β2M) were associated with frailty and worse cognition independent of eGFR and albuminuria in hypertensive trial participants with CKD.

Funding: NIDDK Support, Other NIH Support - NIA, NINDS, NHLBI, Veterans Affairs Support

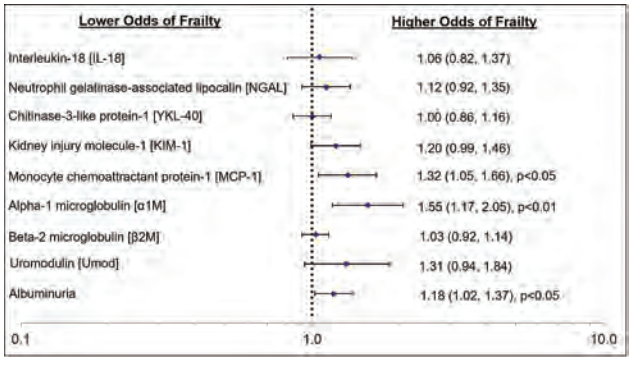

Figure. Multinomial regression showing the baseline association between biomarkers of kidney tubule dysfunction and injury with frailty compared with fit older adults (less fit group omitted). Models were adjusted for age, sex, race, BMI, alcohol use, years of education, SBP and DBP, smoking status, urine creatinine, eGFR, and albuminuria.

PO0428

Association of Kidney Tubule Injury and Dysfunction with Cognitive Function in the Health, Aging and Body Composition Study

Lindsay M. Miller,[1] O. Alison Potok,[1] Dena E. Rifkin,[1] Mark J. Sarnak,[2] David A. Drew,[2] Linda F. Fried,[3] Michael Shlipak,[4,5] Joachim H. Ix.[1]
[1]University of California San Diego Division of Nephrology-Hypertension, San Diego, CA; [2]Tufts Medical Center, Boston, MA; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA; [4]Kidney Health Research Collaborative, San Francisco, CA; [5]VAHCS/UCSF, San Francisco, CA.

Background: The association of lower levels of eGFR and higher levels of albuminuria with poor cognition is well established. However, these markers do not specifically evaluate kidney tubule injury or dysfunction.

Methods: We measured 5 urinary biomarkers of kidney tubule injury and dysfunction (alpha-1 microglobulin [α1m], kidney injury molecule-1 [KIM-1], interleukin-18 [IL-18], uromodulin [Umod], and neutrophil gelatinase-associated lipocalin [NGAL]) among a random sample of 502 participants, and serum bicarbonate [sHCO3] among 2,288 community-living elders aged 70-79. We evaluated the cross-sectional associations with cognitive function using the Modified Mini-Mental State Exam (3MSE) and the Digit Symbol Substitution Test (DSST), where higher scores represent better cognitive function.

Results: None of the urine kidney tubule markers were associated with 3MSE, whereas higher urine NGAL was associated with lower scores of 3MSE but not DSST (table). These associations were independent of demographics, eGFR, and albuminuria.

Conclusions: Among urine markers of tubule injury and dysfunction, only higher NGAL was associated with lower cognitive function testing by DSST. Similarly sHCO3 was associated with worse cognitive function by 3MSE independent of eGFR, albuminuria, or other risk factors

Funding: NIDDK Support, Other NIH Support - This research was supported by National Institute on Aging (NIA) contracts #N01-AG-6-2101; N01-AG-6-2103; N01-AG-6-2106; NIA grant R01-AG028050; NINR grant R01-NR012459., Veterans Affairs Support

All models were adjusted for age, sex, race, years of education, clinic site, BMI, smoking status, Center for Epidemiologic Studies Depression Scale score, SBP, any antihypertensive medication, diabetes, stroke, cystatin C and creatinine-based eGFR, albuminuria, and urine creatinine. sHCO3 was additionally adjusted for spirometry (horizontal dry rolling seal spirometer).

PO0429

Risk of Pneumonia Hospitalization Associated with Serum Triglycerides Across CKD Stages in US Veterans

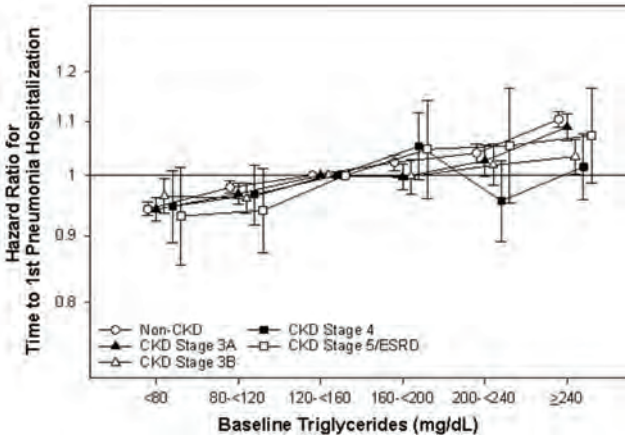
Melissa Soohoo,[3] Jui-Ting Hsiung,[3,1] Csaba P. Kovesdy,[2,4] Kamyar Kalantar-Zadeh,[1,3] Elani Streja.[3,1]
[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Memphis VA Medical Center, Memphis, TN; [3]VA Long Beach Healthcare System, Long Beach, CA; [4]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Background: Small studies have suggested that chronic kidney disease (CKD) is an independent risk factor for pneumonia hospitalization. Although lipid modulating therapies are known for atherosclerotic cardiovascular disease risk reduction, they have been shown to also lower risk of pneumonia. Cholesterols were recently identified as having important roles in lung physiology and maintenance, yet the relationship of another lipid, serum triglycerides (TG) with pneumonia across CKD stages is relatively unknown.

Methods: Our cohort comprised 2,963,176 US veterans who received care from 2004-2006 (baseline) and were followed until 2014. Primary diagnosis ICD-9 codes identified inpatient pneumonia events. Using Cox proportional hazards models, we evaluated the association between baseline TG and time to first pneumonia hospitalization, stratified by CKD stage at the time of the TG measurement. Models were adjusted for demographics, comorbidities, use of lipid modulating therapies, and other biomarkers including serum lipids.

Results: Our patient cohort was on average 63±14 years old, had a median [IQR] TG of 127[87, 189] mg/dL and 23% had CKD at baseline. After full adjustment, TG <160 mg/dL were generally associated with a lower time to first pneumonia event (ref: TG 120-<160 mg/dL) for all CKD stages (Figure). Conversely, high TG ≥240 mg/dL were associated with higher risk of a pneumonia hospitalization in non-CKD and CKD stage 3A-3B patients. Notably, elevated TG >200 mg/dL were not associated with a higher risk of pneumonia among CKD stage 4, 5 and end-stage renal disease patients.

Conclusions: We observed that elevated TG were associated with higher risk of pneumonia hospitalization in non-CKD and CKD stage 3A-3B patients, but this relationship was not observed in late-stage CKD patients. While use of statins and cholesterol levels have been studied in the context of pneumonia and lung function, future studies are warranted to also investigate the role of triglycerides in pneumonia risk especially among early stage CKD patients.



PO0430

The Reference Interval and Risk Factors of NT-ProBNP in CKD Patients Without Heart Failure

Junzhe Chen, Ying Tang, Zhenjian Xu, Qiuyan Huang, Anping Xu. *Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China, Guangzhou, China*.

Background: N-terminal pro-B-type natriuretic peptide (NT-proBNP), a diagnostic marker of heart failure (HF), as well as the specific and sensitive biomarker of HF is been demonstrated to be affected by renal function. NT-proBNP is significantly associated with the severity of GFR loss. However, the reference interval (RI) of NT-proBNP in non-dialysis chronic kidney disease (CKD) patients without HF remains unclear. The aim of our study was to establish the threshold value of NT-proBNP which could help to early recognition, prevention and treatment for HF.

Methods: All patients diagnosed with CKD aged more than 18 years old in our hospital from Jan 01, 2014 to Dec 31, 2019 were recruited into this study. Individuals who diagnosed with HF were excluded. The RI for NT-proBNP was defined by nonparametric method and risk factors were analyzed by linear regression analysis.

Results: A total of 1260 CKD patients without HF were included in this study. Of them, 588(46.67%) were female. NT-proBNP were increased with the advanced stage of kidney function in CKD patients without HF. The median level of NT-proBNP in CKD stage 5 ND (non-dialysis) patients without HF were the highest, as 610.25 pg/ml. The RIs for NT-proBNP in CKD patients without HF with respect to kidney function stage (ranges of stage 1, stage 2, stage 3, stage 4, stage 5 ND) were 8.15-536.32, 12.38-811.90, 16.62-1411.05, 33.14-2945.05, 88.58-5533.73pg/ml. We also demonstrated that NT-proBNP was significantly correlated with the serum levels of Hb (β=-0.174, P<0.001), Ca (β=-0.214, P<0.001), P (β=0.111, P<0.001), hs-CRP (β=0.140, P<0.001), and eGFR(β=-0.243, P<0.001).

Conclusions: Our study proved that NT-proBNP was increased with the advanced stage of GFR in CKD patients without HF. The RI of NT-proBNP varied among the different stages of CKD without HF and multiple factors contributed to NT-proBNP, which could help clinicians to prevent and take actions against the occurrence of HF.

Funding: Government Support - Non-U.S.

Soluble Urokinase Plasminogen Activation Receptor and Major Adverse Cardiac Event Morbidity in CKD Patients in the German Chronic Kidney Disease (GCKD) Cohort

Claudia Sommerer,[1] Sandra Müller-Krebs,[1] Jennifer Nadal,[2] Matthias Schmid,[2] Kai-Uwe Eckardt,[3] Jochen Reiser,[4] Martin G. Zeier.[1] *[1]Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany; [2]Department of Medical Biometry, Informatics, and Epidemiology (IMBIE), University Hospital of Bonn, Bonn, Germany; [3]Department of Nephrology, Charité, University Medicine Berlin, Berlin, Germany; [4]Department of Medicine, Rush University Medical Center, Chicago, IL*.

Background: Soluble urokinase plasminogen activation receptor (suPAR) is supposed as risk factor for both chronic kidney disease (CKD) and biomarker for major adverse cardiac events (MACE) disease. A long-term longitudinal analysis in a large cohort of patients suffering from both diseases simultaneously, CKD and cardiovascular (CV) disease including MACE criteria, to analyze suPAR as a predictive biomarker has not been performed, yet.

Methods: SuPAR was studied in the GCKD Study Group with a follow-up time of 4 years. Association of suPAR with CKD (estimated glomerular filtration rate, eGFR) and overall risk of all-cause death, CV death, and MACE (three-point MACE, MACE3; four-point MACE, MACE4) was estimated by Cox proportional hazards regression according to quintiles of suPAR.

Results: Altogether, 4994 participants were enrolled (60.1 ± 12.0 years; eGFR of 49.4 ±18.3 mL/min/1.73m^2). Median suPAR concentration was 1771 pg/mL (25th-75th percentile, 1447-2254 pg/mL). Hazard ratio for CV mortality was 1.58 (95%CI 0.62-4.00) in the second, 2.15 (95%CI 0.87-5.26) in the third, 3.48 (95%CI 1.53-7.93) in the fourth, and 5.30 (95%CI 2.34-12.0) in the fifth quintile. If additionally adjusted for eGFR, UACR, NT-proBNP, hsCRP results were confirmed.

Conclusions: In the GCKD study cohort suPAR predicts all-cause death, cardiovascular death, and MACE independent of NT-proBNP, renal function and of markers of systemic inflammation.

PO0432

Incidence and Racial Disparities in Cardiovascular Disease and CKD Progression in Young Adults with CKD

Alexander J. Kula,[1,2] Nisha Bansal,[2] David K. Prince.[2] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington, Seattle, WA*.

Background: Cardiovascular disease (CVD) is a major source of morbidity and mortality in adult CKD patients; yet is not well elucidated in young adults with CKD. Furthermore, racial and ethnic disparities in CVD and CKD progression has been found in research of pediatric and older-adult CKD populations, but has not been investigated specifically in young adults.

Methods: We studied 317 participants aged 21-40yrs of age with mild to moderate CKD enrolled in the Chronic Renal Insufficiency Cohort (CRIC) Study, of whom, 174 were black or Hispanic. We calculated incidence rates for CV events (heart failure [HF], MI, stroke, and death) and CKD progression (50% decline in eGFR or ESRD) for all young adult participants and as stratified by race and ethnicity. Cox proportional hazards regression models were constructed to test the association between race/ethnicity and CV events and CKD progression, adjusting for age, sex, eGFR, UACr, baseline SBP, and APOL1 status.

Results: HF, mortality and CKD progression had the highest incidence rates amongst young adults with CKD (**Figure 1**). Rates of these events were higher among Black and Hispanic participants: HF (17.5 vs. 5.1/1000 person-years), all-cause mortality (15.2 vs. 7.1/1000 person-years), and CKD progression (125 vs. 59/1000 person-years). Lastly, in adjusted models, black or Hispanic status was significantly associated with higher risk of CV events (HR: 1.25, 95%CI: 1.12-1.41) and CKD progression (HR: 1.38, 95%CI: 1.21-1.57).

Conclusions: Young adults with CKD in the CRIC study experience high incidence rates of cardiovascular disease. The burden of disease is even higher for black and Hispanic participants with CKD. Further research is required to better understand the factors underlying racial disparities in young adults with CKD.

Trends in the Transition to ESRD Among Native Hawaiians and Pacific Islanders Across the United States

Connie Rhee,[1] Amy S. You,[1] Keith C. Norris,[2] Merle R. Kataoka-Yahiro,[3] James Davis,[4] Glen Hayashida,[5] Victoria Page,[5] Shiuh-Feng Cheng,[4] Roland C. Ng,[4] Linda L. Wong,[4] Kamyar Kalantar-Zadeh.[1] *[1]University of California Irvine, Irvine, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]University of Hawaii Manoa, Honolulu, HI; [4]John A. Burns School of Medicine, Honolulu, HI; [5]National Kidney Foundation Hawaii, Honolulu, HI.*

Background: Census data indicate there are >1.5 million Native Hawaiians and other Pacific Islanders (NHOPIs) in the US. While growing data show NHOPIs have a high prevalence of kidney disease risk factors (diabetes, obesity, hypertension, limited healthcare access), there are major knowledge gaps regarding the burden of end-stage renal disease (ESRD) in this population. We examined trends in the transition to ESRD in NHOPIs.

Methods: Using United States Renal Data System (USRDS) and Census Bureau data, we compared annual incident ESRD rates among NHOPI, African Americans (AA), and other racial subgroups over 2010-16. Rates were calculated as the observed incident ESRD count divided by the race-specific Census population size of that year. Multiple race designations were considered by utilizing Census categorizations that incorporated primary race in combination with one or more other races (alone or combination). We estimated crude rates and rates standardized to the age-sex distribution of 2011 race-specific Census population data.

Results: Over 2010-16, NHOPIs and AAs demonstrated the highest crude incident ESRD rates over time (**Fig 1A**). A similar pattern was observed for standardized incident ESRD rates (**Fig 1B**): 918, 638, 308, 226, and 162 incident ESRD patients per million (population)/year in 2016 for NHOPI, AA, Caucasian, Asian, and American Indian/Alaska Native subgroups, respectively. While standardized incident ESRD rates among AAs gradually declined, there was a steady rise in NHOPIs' incident ESRD rates over time.

Conclusions: NHOPIs demonstrated the highest incident ESRD rates over time. Further studies are needed to determine sociodemographic, biologic/genetic, cultural, and health care related ESRD risk factors among NHOPIs to inform targeted interventions in this population.

PO0434

Association Between eGFR-Cystatin C/eGFR-Creatinine Ratio and Fat Weight

Agne Laucyte-Cibulskiene,[1,2] Anders Christensson.[1,2] *[1]Lunds Universitet Institutionen for kliniska vetenskaper i Lund, Lund, Sweden; [2]Skanes universitetssjukhus Malmo, Malmo, Sweden.*

Background: The ratio of eGFR-cystatinC/eGFR-creatinine less than 0.7 is a condition that demonstrates different filtration for small and large molecules and is associated with accumulation of atherosclerosis-promoting proteins, higher cardiovascular event and mortality risk. Though, we hypothesize that this ratio could also be an indirect reflection of certain body composition. For example creatinine/cystatin C ratio has been used as a marker for sarcopenia, whereas cystatin C is highly expressed in human adipose tissue and might be increased in obesity. So the aim was to explore whether eGFR-cystatinC/eGFR-creatinine ratio is valid independently on body composition measures.

Methods: Data were extracted from the population based Malmö Diet and Cancer (MDC) study (n= 28 449) cardiovascular cohort (MDC_CC) that enrolled a random sample of study subjects invited to participate in carotid artery disease epidemiological analysis (n = 6103) during the year 1991-1994. Our study sample consisted of 5061 subjects who had body composition measurements and cystatin C available. Estimated glomerular filtration rate (eGFR) according to Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) 2012 creatinine-cystatin C equation was calculated. Bioimpedance analysis of body composition was estimated by following procedures provided by manufacturer (BIA-103 RJL Systems, Detroit, MI, single frequency (50kHz))

Results: In our study sample 11% (n=564) of subjects, mainly women (n=562), were classified as with eGFR-cystatinC/eGFR-creatinine ratio lower that 0.7. Therefore, we applied logistic regression analysis explicit in women and compared 2430 women without SPS with the rest of 562. We found that the ratio adjusted for age was associated with obesity (OR 3.49, p<0.001) and in multivariate analysis only with fat weight (OR 1.19, p<0.001). Lower lean weight showed also significant relationship with lower eGFR-cystatinC/eGFR-creatinine ratio, but not after adjustment to other cofounders.

Conclusions: The ratio of eGFR-cystatinC/eGFR-creatinine lower than 0.7 is dependent on fat weight in females from population based study.

PO0435

Discovery of Obesity and Adiposity-Related CKD Subgroups and Preliminary Metabolomics Findings: The CRIC Study

Zihe Zheng,[1] Hongzhe Li,[1] Eugene P. Rhee,[3] Wei Yang,[1] Sushrut S. Waikar,[4] Ryan Urbanowicz,[1] Amanda H. Anderson,[2] Dawei Xie,[1] Harold I. Feldman.[1] Chronic Renal Insufficiency Cohort Study *[1]University of Pennsylvania, Philadelphia, PA; [2]Tulane University, New Orleans, LA; [3]Massachusetts General Hospital, Boston, MA; [4]Boston Medical Center, Boston, MA.*

Background: Obesity/adiposity perturbs the plasma metabolome, as does chronic kidney disease (CKD). Understanding the complex relationships across CKD patient subphenotypes, obesity, and the metabolome may shed light on finding novel risk factors and the mechanisms for CKD progression.

Methods: Among 1,529 participants in the Chronic Renal Insufficiency Cohort (CRIC) Study for whom metabolomics data (Broad Institute) were generated, we first applied consensus clustering with K-means on 20 baseline clinical adiposity-obesity-related attributes to identify patient subgroups. We individually examined the association of 634 known metabolites with the identified subgroups using separate multivariable linear models. Finally, Cox model was used to examine the prospective association of the adiposity-obesity subgroups (the biggest subgroup as reference) with CKD progression, ESRD, a composite cardiovascular disease outcome, and death.

Results: We identified four distinct adiposity-obesity-related CKD subgroups: Subgroup 1 (N=429) - favorable obesity/diabetes profiles and elevated lipid levels; Subgroup 2 (N=349) - favorable diabetes profiles, but slightly obese; Subgroup 3 (N=357) - less favorable diabetes profile, lower lipid levels and severe obesity; and Subgroup 4 (N=394) - less favorable diabetes profiles, but less obese. Among the 634 known metabolites, after adjusting for demographics, health history, eGFR and UACR, 260 were significantly associated with CKD subgroups at Bonferroni-adjusted $p<7.9\times10^{-5}$. Survival analyses showed that compared to Subgroup 1 (ref), Subgroup 4 had the highest risk for CKD progression (HR 1.78, 95% CI 1.40, 2.26) and ESRD (HR 1.92, 95% CI 1.45, 2.52), and Subgroup 3 had the highest risk for the composite CVD outcome (HR 1.87, 95% CI 1.40, 2.50) and death (HR 1.51, 95% CI 1.09, 2.10).

Conclusions: With consensus clustering and metabolomics analysis, we discovered four distinct adiposity-obesity-related subgroups of CKD patients that were associated with numerous metabolites and different risks of clinical endpoints. Novel biomarkers that co-segregate with patient subgroups of high risk could reveal new insights into the obesity related biology of CKD progression and subsequent CVD events, and potentially suggest tailored therapeutic targets among CKD patients.

PO0436

Defining the Excess Risk of Adverse Kidney Outcomes in CKD Patients with Type 2 Diabetes in the DISCOVER-CKD Cohort

Alyshah Abdul Sultan,[1] Stephen Nolan,[1] Juan J. Carrero,[2] Zhuoxin Jiang,[3] Supriya R. Kumar,[3] Roberto Pecoits-Filho,[4,5] Glen James,[1] Juan Jose Garcia Sanchez,[1] Lam S. Carolyn,[6,7] Hungta (tony) Chen,[3] Eiichiro Kanda,[8] Naoki Kashihara,[8] Mikhail Kosiborod,[9] Carol A. Pollock,[10] David C. Wheeler,[11] Hiddo J. L Heerspink.[12] *[1]AstraZeneca, Cambridge, United Kingdom; [2]Karolinska Institute, Karolinska Institutet, Stockholm, Sweden; [3]AstraZeneca, Gaithersburg, MD; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; [6]National Heart Centre Singapore, Singapore, Singapore; [7]Duke-NUS Medical School, Singapore, Singapore; [8]Kawasaki Ika Daigaku, Kurashiki, Japan; [9]Saint Luke's Mid America Heart Institute, Kansas City, MO; [10]Royal North Shore Hospital, St Leonards, NSW, Australia; [11]University College London, London, United Kingdom; [12]Rijksuniversiteit Groningen, Groningen, Netherlands.*

Background: Chronic Kidney Disease (CKD) patients with type 2 diabetes (T2D) are considered at a high risk of cardiovascular events. However, the excess risk of major kidney events in T2D patients compared to patients without T2D is unknown.

Methods: DISCOVER-CKD is an international observational study of patients with CKD that encompasses large retrospective electronic medical records (EMR) and claims data between 2008 and 2020. Preliminarily, data from US-based Limited Claims and Electronic Health Record (LCED) data (IBM Health, Armonk, NY) and TriNetx (hospital-based EMR) were analysed. CKD patients (eGFR <75 mL/min/1.73m^2) aged ≥18 years with ≥1 record of urine albumin to creatinine ratio (UACR) were identified. T2D status was ascertained any time before the index date (2nd eGFR measurement). The risk of kidney outcomes (sustained ≥50% eGFR decline or end-stage kidney disease) was compared between patients with and without T2D at 5 years' follow-up.

Results: Compared to non-T2D patients, T2D patients had a slightly higher incidence rate of adverse renal outcomes (LCED: 2.7% versus 2.3% per year; TriNetX: 1.8% versus 1.2% per year). After adjusting for all confounding factors (Figure 1) we observed no increased risk of adverse renal outcomes in patients with T2D compared to non-T2D patients in LCED (hazard ratio (HR): 1.08: 95%CI 0.81-1.43) and a 34% increased risk in TriNetX database (HR:1.34; 95%CI 1.11-1.62).

Conclusions: There is an excess risk of adverse renal outcomes in CKD patient with T2D compared to those without T2D. This is explained to a large extent by conventional risk markers in LCED but not completely in TriNetX. Both groups (T2D and non-T2D) should be managed proactively to reduce the risk of poor clinical outcomes.

Funding: Commercial Support - AstraZeneca

Table 1: Cox regression analysis for adverse renal outcome (sustained ≥50% reduction in eGFR, or ESKD [composite chronic dialysis, renal transplant or sustained eGFR<15mL/min/1.73^2]) in patients with T2D versus without T2D

	Hazard Ratio (95% CI)			
	Model 1 (Age, gender, race†, index year)	Model 2 (Model 1 + systolic BP, diastolic BP, BMI, LDL, CV history)	Model 3 (Model 2 + baseline eGFR)	Model 4 (Model 3 + UACR)
LCED CKD with T2D = 4,156 CKD without T2D (unexposed) = 1,189	1.48 (1.12-1.95)	1.07 (0.80-1.42)	1.11 (0.83-1.47)	1.08 (0.81-1.43)
TriNetX CKD with T2D = 13,405 CKD without T2D (unexposed) = 4,615	1.40 (1.17-1.69)	1.33 (1.10-1.61)	1.43 (1.18-1.74)	1.34 (1.11-1.62)

†Only available in TriNetX

Note: patients with CKD were identified based on two eGFR measures of <75 mL/min/1.73 m^2 recorded at least 90 days apart (max 730)

PO0437

Increased Risk of Progression to ESRD or Death in CKD Patients with Symptoms of Depression: A Systematic Review and Meta-Analysis of Cohort Studies

Jiahao Zeng,[1] Xindong Qin,[2,1] Xusheng Liu.[2,1] *[1]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; [2]Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China, Guangzhou, China.*

Background: Comorbid symptoms of depression are common psychiatric disorder in patients with chronic kidney disease (CKD). It remains unclear whether it is an independent risk factor for progression of patients with CKD not requiring dialysis. We conducted a systematic review to assess the association of depressive symptoms with poor clinical outcomes in patients with CKD not requiring dialysis.

Methods: PubMed, Embase and CINAHL were searched (up to February 15th, 2020) for cohort studies assessing the association of depression with progression to end-stage renal disease (ESRD), defined as requiring maintenance dialysis, or all-cause mortality in patients with CKD not requiring maintenance dialysis. Two independent researchers extracted data, assessed risk of bias and evidence certainty.

Results: Seven cohort studies of 6145 patients were included. Methodological quality of studies was generally low risk of bias. Compared with non-depression or low depressive symptoms, high depressive symptoms increased the risk of progression to ESRD (HR, 2.09 95%CI 1.43 to 3.07, I^2=37%), all-cause mortality (HR, 1.51 95%CI 1.13 to 2.01, I^2=57%) and hospitalization (HR, 1.52 95%CI 1.20 to 1.93, I^2=32%).

Conclusions: Depressive symptoms in CKD are independent risk factors of poor clinical outcomes, including ESRD, all-cause death, and hospitalization. There is necessary to design high quality studies to assess the effects of treating depressive symptoms in patients with CKD.

PO0438

Association of the Creatinine-to-Cystatin C Ratio with Overall Survival with and Without CKD

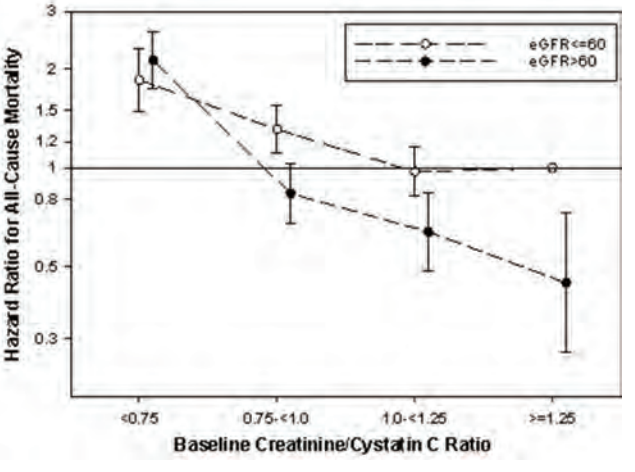
Elani Streja,[3,1] Cachet Wenziger,[3,1] John Sy,[3,1] Ekamol Tantisattamo,[1] Ramy M. Hanna,[1] Csaba P. Kovesdy,[4,2] Susan T. Crowley,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]VA Long Beach Healthcare System, Long Beach, CA; [4]Memphis VA Medical Center, Memphis, TN.*

Background: Creatinine and Cystatin C are measured as glomerular filtration markers. Creatinine is highly correlated with skeletal muscle mass, whereas Cystatin C is not. We hypothesized that persons, in whom serum Cystatin C is lower than creatinine level, i.e., creatine to Cystatin C ratio (CrCCR) >1.00 (regardless of measurement units) have incrementally greater survival chance, likely due to a larger muscle mass.

Methods: We examined a cohort of 7,849 Veterans with baseline measured Cystatin C and creatinine data between 2004-2015. Veterans were divided into 0.25 increments of CrCCR, i.e., <0.75, 0.75-<1.0,1.0-<1.25,≥1.25. They were further stratified into groups based on normal vs. low eGFR (>60 vs. ≤60 mL/min/1.73 m^2, and the associations of CrCCR with survival across two eGFR strata were examined.

Results: The mean age (±SD) in the Veterans' cohort was 69±12 years. There were 4% female, 77% white, and 15% African American. The median (IQR range) for cystatin C was 1.28 (0.99,1.71) mg/L, for creatinine 1.24 (0.92,1.68) mg/dl, and for the CrCCR was 0.99 (0.81,1.17). Compared to the reference (CrCCR≥1.25 and eGFR≤60 mL/min/1.73 m^2) the multivariable adjusted model showed that those with a lower CrCCR <0.75 (suggesting lowest muscle mass) had the highest mortality risk for both eGFR strata, with the normal eGFR group having higher death risk than the low eGFR group (HR(95%CI): 1.86(1.49,2.31) and 2.13(1.75,2.59), respectively). In the highest CrCCR group (≥1.25) indicating more muscle mass, the normal eGFR group had the best overall survival than those with low eGFR (HR(95%CI):0.45(0.27,0.73)).

Conclusions: A lower CrCCR indicating higher cystatin C relative to creatinine levels are strongly associated with worse overall survival in Veterans regardless of kidney function level. Future studies should examine the clinical utility of this potential surrogate of muscle mass and overall health over creatinine or Cystatin C alone in evaluating risk stratification in patients with and without kidney disease.



PO0439

CKD by Previous Diabetes or Hypertension: A Longitudinal Outcomes Study in Primary Care

David Vizcaya,[1] Betlem Salvador-González,[2,4] Oriol Cunillera,[3] Neus Gil.[2,4] *[1]Bayer Pharmaceuticals, Sant Joan Despí, Spain; [2]Fundació Institut Universitari per a la recerca a l'Atenció Primària de Salut Jordi Gol i Gurina (IDIAPJGol), Cornella, Spain; [3]Unitat de Suport a la Recerca Costa de Ponent, Fundació Institut Universitari per a la recerca a l'Atenció Primària de Salut Jordi Gol i Gurina (IDIAPJGol), Cornella, Spain; [4]Direcció Atenció Primària Costa de Ponent- Institut Català de la Salut, Cornella, Spain.*

Background: To compare mortality and progression to end-stage-renal-disease (ESRD) in patients with new chronic kidney disease (CKD) by previous occurrence of type 2 diabetes (DM) and/or arterial hypertension (HT) in Catalonia

Methods: We designed a longitudinal retrospective study of adults with new CKD between 2007 and 2017 identified using electronic medical records from primary care

in Catalonia, Spain. New CKD was considered the index event and defined as a first occurrence of an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m2, a urine albumin-creatinine ratio ≥ 30 mg/g or albuminuria ≥ 20mcg for 90+ days, or a diagnostic code for CKD. Variables were extracted from the SIDIAP research database and the Spanish hospital basic minimum dataset. Patients were classified according to previous occurrence of DM, HT, both or none. The resulting mutually exclusive cohorts, DM-CKD, HT-CKD, DM/HT-CKD and unspec-CKD, were followed until ESRD and death within the study period. We defined ESRD as an eGFR<15 mL/min during 90+ days or renal replacement therapy. Fine and Grey regression models were used to assess differences in incidence of ESRD among the four CKD groups, considering mortality as a competing risk, and Cox regression for mortality. Both models were adjusted for multiple confounders

Results: In total, 467,802 persons were included (median age 75 years; 46.8% men]. At baseline, 51% had HT-CKD, 4% had DM-CKD, 33% had HT/DM-CKD and 12% had unspec-CKD. The DM-CKD group were the youngest in average, more likely to be men, had the highest proportion of persons with an eGFR below 60 mL/min/1.73m2 and the highest proportion of altered albuminuria. Compared to unspecific-CKD, DM- and HT-CKD had lower risk of ESRD -adjusted subdistribution hazard ratio (SHR) and 95% confidence interval (CI): 0.68 (0.54-0.84) and 0.71 (0.65-0.79), respectively, but HT/DM-CKD had a higher risk: SHR(CI) 1.11 (1.06-1.15). In turn, the risk for death was higher in DM-CKD, HR (CI): 1.19 (1.11-1.27) and lowest in the HT-CKD group, 0.84 (0.79-0.88), as compared to unspec-CKD. For the group HT/DM-CKD the HR(CI) was 0.92 (0.87-0.97)

Conclusions: According to these results, there are no differences in ESRD risk among CKD patients by prior DM or HT, but there is a synergistic effect. Mortality is different in CKD patients with HT vs with DM.

PO0440

Elderly Patients Are Likely to Have Faster CKD Progression if Plasma Brain Natriuretic Peptide (BNP) Is Elevated

Shiho Morimoto, Hiroshi Tanaka. *Mihara Red Cross Hospital, Mihara, Japan.*

Background: Elderly CKD patients have been mostly believed that they have slower decline in eGFR than younger individuals. However, this is not the case, especially when the patient has well-known factor(s) that accelerate(s) CKD progression, such as cardiac dysfunction. Plasma concentration of brain natriuretic peptide (BNP) is often elevated in patients with cardiac dysfunction and is known to be associated with higher mortality. This study was conducted to find out whether plasma BNP level can be used to predict future decline in eGFR.

Methods: A hospital-wide study with all the laboratory data for a period of 4 years and 2 months was performed. Non-dialysis CKD patients (median eGFR <60 mL/min/1.73m2) with an age 65 or more in whom the eGFR slope was obtained over 731 days or more with BNP measured at least three times were retrieved. An eGFR slope per each patient was calculated and its relationship with plasma BNP level and other factors was assessed. Statistical analysis was done with R 3.6.0 on Ubuntu.

Results: A total of 339 patients (M:F = 154:185, age 65-102 (median 84) years) were included whose initial BNP was 130.0+-184.2 (0-1,641.5, median 75.6) pg/mL. A "random forest" analysis, one of the multivariate analyses, was performed using an R package {randomForest}, in order to elucidate risk factors associated with faster decline in GFR; factors with the highest importance, i.e., with the highest change in Gini indices, were found to include initial eGFR, initial BNP and variability of BNP. With linear regression analysis, the eGFR slope was significantly associated with initial eGFR and initial BNP (P<0.0001). Patients with higher-than-average initial BNP (>130.0 pg/mL and higher-than-average initial eGFR (>49.1 mL/min/1.73m2) had significantly faster decline in eGFR than the rest of the population (-3.83+-4.62 vs -1.72+-3.57, P=0.0001). A combination of initial eGFR and initial BNP correctly differentiated the fastest quartile from the rest in 72.9% of the population.

Conclusions: Elevated plasma BNP might predict faster decline in eGFR in the elderly CKD patients.

PO0441

Proton-Pump Inhibitors (PPIs) vs. H2 Blockers (H2B) Users and Overall Risk of CKD Progression

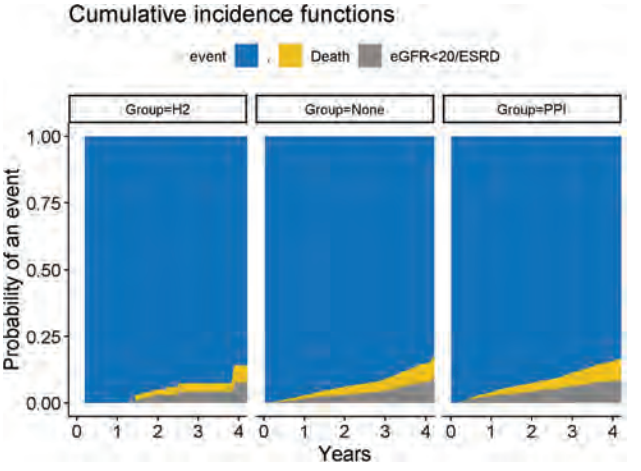
Liza Cholin,[1] Tarek Ashour,[1] Ali Mehdi,[1] Jonathan J. Taliercio,[1] Remy Daou,[2] Susana Arrigain,[1] Jesse D. Schold,[1] Nazih L. Nakhoul,[3] Georges Nakhoul.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Universite Saint-Joseph, Beirut, Lebanon; [3]Tulane University School of Medicine, New Orleans, LA.*

Background: PPI use is associated with adverse kidney events. The relationship between PPI use and the development of acute interstitial nephritis (AIN) is well established. However, the relationship between PPI use and CKD progression is less clear. Notably, there is a lack of data concerning renal outcomes in established CKD patients. The aim of our study is to determine the risk of CKD progression amongst CKD patients on PPI, H2B, or no anti-acid therapy.

Methods: Using our CKD registry, we evaluated the relationship between the use of PPI and H2B and outcomes among patients with CKD stage 3 and 4 with at least 2 PCP visits in the year prior. We evaluated the relationship between medication group and overall mortality using a Cox proportional hazards model while adjusting for demographics and comorbidities, and the relationship between medication group and progression to eGFR<20 or ESKD with death as a competing risk using regression models as described by Fine and Gray.

Results: Among 3,930 patients, 1,374 were in PPI group, 119 were in H2 blocker group, and 2,437 were on no medication. Average age was 72.8±11.1, and 42.5% male. Among PPI 28% had Coronary Artery Disease compared to 22% among H2B and 19% among no medication (P<0.001). Congestive Heart Failure was 13%, 8% and 7% for each group respectively (P < 0.01). Overall mortality was not different amongst the three groups (PPI vs. none HR 0.94, 95% CI: 0.80, 1.10, and PPI vs. H2B HR 0.80, 95% CI: 0.52, 1.24). The cumulative incidence of ESKD/eGFR<20 with death as a competing risk was also not different across groups in univariate (Fig. 1) or adjusted models (PPI vs. none SHR 0.99, 95% CI: 0,74, 1.34, PPI vs. H2B SHR 1.82, 95% CI: 0.91, 3.63).

Conclusions: Use of PPI in a CKD population was not associated with increased mortality or CKD progression to ESKD when compared to the use of H2 blockers and to no acid suppressing therapy.



PO0442

Renin-Angiotensin-Aldosterone System (RAAS) Blockade Does Not Affect Kidney Progression in Patients with CKD Without Diabetes and Without Proteinuria

Shirley S. Chang,[2,1] Kabir Jalal,[1] Andre F. Charest.[2] *[1]University at Buffalo - The State University of New York, Buffalo, NY; [2]Erie County Medical Center, Buffalo, NY.*

Background: Non-proteinuric CKD contributes to about 80% of end stage kidney disease and is poorly studied in terms of risk factors & pathogenesis. RAAS blockers such as angiotensin-converting enzyme inhibitors (ACEI) and angiotensin receptor blockers (ARB) have been shown to be renoprotective in CKD progression in patients with diabetes and proteinuria. There is a paucity of data on effect of ACEI/ARB in non-diabetic non-proteinuric CKD patients.

Methods: This is a retrospective observational study of insurance claim database from 1/1/07 to 12/31/17 examining the effect of ACEI or ARB use on CKD progression. Inclusion criteria: adults at least 18 years of age, with CKD stage 3 or higher [based on at least 2 serum creatinine (SCr) values 90 days apart] with at least 2 urinalyses with dipstick urine protein with negative or trace, follow-up (FU) period of at least 3 yrs. Patients with diabetes or proteinuria were excluded. Primary outcomes were doubling of SCr, or reaching CKD stage 5. Mortality data was not available. Duration of ACEI/ARB exposure is defined as number of prescribed days. The eGFR was calculated based on CKD-EPI equation. Analysis are performed with 2 models: time varying Cox regression, and mixed model (which included time-period fixed effect and random effects). A greedy 1:1 propensity score matching scheme was applied.

Results: Of 20,000 CKD patients, there were 2,853 with CKD stage 3 or higher without proteinuria, with 301 on ACEI/ARB during mean FU 6 yrs. Percentage of patients with HTN or CHF, mean age, gender, and eGFR did not differ between ACEI/ARB *vs.* non-ACEI/ARB groups. The eGFR decrease per year was not statistically different between those on ACEI/ARB *vs.* non-ACEI/ARB group (matched cox model, p = 0.2285; mixed model, p = 0.4346 respectively). Age and ACEI/ARB duration of exposure have no effect. ACEI/ARB patients had lower rate of developing diabetes during the study (OR 0.57, p = 0.0044), and higher rate of proteinuria at the end of study (OR 1.59, p = 0.0048), though these associations were not observed in the matched sample.

Conclusions: This study suggests ACEI/ARB does not affect CKD progression in non-diabetic & non-proteinuric patients, irrespective of age. Further studies are needed to confirm those findings.

PO0443

Biomarkers of Immune Activation and ESKD: Results from AASK

Teresa K. Chen,[1] Michelle M. Estrella,[2] Lawrence J. Appel,[1] Josef Coresh,[1] Shengyuan Luo,[1] Jochen Reiser,[3] Wassim Obeid,[1] Chirag R. Parikh,[1] Morgan Grams.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]University of California San Francisco, San Francisco, CA; [3]Rush University, Chicago, IL.*

Background: Immune activation is fundamental to the pathogenesis of many kidney diseases, and innate immune molecules such as soluble urokinase-type plasminogen activator receptor (suPAR) have been linked to incidence and progression of CKD.

Whether other biomarkers of immune activation are associated with ESKD in African Americans with non-diabetic kidney disease is unclear.

Methods: Utilizing baseline serum samples from AASK, we measured 4 biomarkers of immune activation (soluble tumor necrosis factor receptors 1 and 2 [sTNFR1, sTNFR2], tumor necrosis factor alpha [TNF-α], interferon gamma [IFN-γ]) and examined their associations with ESKD and all-cause mortality. Covariates included age, sex, systolic BP, BMI, smoking, baseline GFR and urine PCR. We also considered interactive effects of each biomarker with *APOL1* risk status.

Results: Among 500 participants with available samples, mean GFR was 44.7 ml/min/1.73 m^2 and median urine PCR was 0.09 g/g at baseline. Over a median follow-up 9.6 yrs, there were 161 (32%) ESKD and 113 (23%) death events. In fully adjusted models, each two-fold higher baseline level of sTNFR1, sTNFR2, and TNF-α was associated with 3.66, 2.29, and 1.35-fold greater risks of ESKD, respectively (**Table**). In comparison, the association between suPAR and ESKD was 1.39 (95% CI: 1.04, 1.86). These three biomarkers were also significantly associated with death (up to 2.2-fold higher risks per 2-fold higher baseline level; p≤0.01). IFN-γ was not associated with either outcome. None of the biomarkers modified *APOL1*-associated risks for ESKD (p-interaction>0.05). The C-statistic for the fully adjusted clinical model in predicting ESKD was excellent at 0.849 (95% CI: 0.820, 0.878). Adding sTNFR1, the biomarker with the strongest association, to the clinical model led to a small but statistically significant improvement in the C-statistic at 0.860 (95% CI: 0.833, 0.887; difference of 0.011; 95% CI: 0.001, 0.021).

Conclusions: Among African Americans with CKD attributed to hypertension, baseline levels of sTNFR1, sTNFR2, and TNF-α but not IFN-γ were associated with ESKD and mortality.

Funding: NIDDK Support

Table: Associations of biomarkers of immune activation with end-stage kidney disease in AASK.

Novel Fibrosis Biomarker Development and Validation in Human Kidney Disease

Insa M. Schmidt,[1,2] Mia Colona,[1,2] Bryan R. Kestenbaum,[6] Leonidas G. Alexopoulos,[7] Ragnar Palsson,[2] Anand Srivastava,[3] Jing Liu,[1] Isaac E. Stillman,[5] Helmut G. Rennke,[2] Vishal S. Vaidya,[2] Haojia Wu,[4] Benjamin D. Humphreys,[4] Sushrut S. Waikar.[1,2] *[1]Boston Univeristy Medical Center, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Washington University in Saint Louis, Saint Louis, MO; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]University of Washington School of Medicine, Seattle, WA; [7]ProtATonce LTD, Athens, Greece.*

Background: Biomarkers for non-invasive assessment of kidney fibrosis are not available. This study illustrates the characterization of five novel candidate biomarkers of kidney fibrosis—Cadherin-11 (CDH11), Sparc-related modular calcium binding-2 (SMOC2), Pigment epithelium-derived factor (PEDF), Matrix-gla protein (MGP), and Thrombospondin-2 (THBS-2)—which were selected from transcriptomic findings in animal models of fibrosis.

Methods: We developed Luminex-based assays and measured proteins in plasma and urine samples of two independent prospective cohort studies, the Boston Kidney Biopsy Cohort (BKBC, n=801), a cohort of individuals with biopsy-confirmed semi-quantitative assessment of kidney fibrosis, and the Seattle Kidney Study (SKS, n=252). Ordinal logistic regression and Cox proportional hazard models tested associations of biomarkers with interstitial fibrosis and tubular atrophy (IFTA) in the BKBC and progression to end-stage kidney disease (ESKD) in both cohorts, respectively. snRNA datasets of human kidneys assessed cell-specific gene expression profiles.

Results: In the BKBC, higher levels of urinary PEDF and plasma and urinary SMOC2 and CDH11 were independently associated with more severe IFTA (Figure 1). In both cohort studies, higher levels of plasma and urinary SMOC2 and urinary CDH11 associated with progression to ESKD (HR-range 1.27 to 1.89) after adjustment for age, sex, race, proteinuria, and eGFR. Higher levels of urinary PEDF were associated with ESKD in the SKS (HR=1.29, 95% CI 1.14 to 1.45), with consistent signals in the BKBC, although the latter narrowly missed statistical significance. snRNA-sequencing data demonstrated expression of all biomarkers in human fibroblasts.

Conclusions: Novel plasma and urine biomarkers of kidney fibrosis, developed from animal models, are associated with higher levels of human kidney fibrosis and subsequent progression to ESKD.

PO0445

Urinary Fibrosis Markers and Risk for ESKD: The Chronic Renal Insufficiency Cohort (CRIC) Study

Amanda H. Anderson,[1] Robin L. Baudier,[1] Wei Yang,[2] Katalin Susztak,[2] Mirela A. Dobre,[3] Hua He,[1] Mahboob Rahman,[3] Sylvia E. Rosas,[4] Anand Srivastava,[5] Sushrut S. Waikar,[6] Harold I. Feldman.[2] The CRIC Study *[1]Tulane University, New Orleans, LA; [2]University of Pennsylvania, Philadelphia, PA; [3]Case Western Reserve University, Cleveland, OH; [4]Joslin Diabetes and Endocrinology Research Center, Boston, MA; [5]Northwestern University, Evanston, IL; [6]Boston University, Boston, MA.*

Background: Connective tissue growth factor (CCN2) and amino-terminal peptide of procollagen type III (PIIINP) are both correlated with kidney fibrosis. However, it is unclear if these markers are independently associated with the risk for ESKD.

Methods: We measured CCN2 and PIIINP in baseline urine and standardized to urine creatinine (Cr) in a multi-center cohort study of men and women with chronic kidney disease (CKD), the CRIC Study (N=3727). ESKD was defined as initiation of kidney replacement therapy (N=1118 events). Cox proportional hazards models were adjusted hierarchically as indicated (Table).

Results: The mean age of the study population was 58 years; mean eGFR: 45 mL/min/1.73m2; and 48% had diabetes. After multivariable adjustment and median follow-up of 10 years, the highest quartiles of CCN2/Cr and PIIINP/Cr were associated with a 1.8-fold and 1.7-fold higher risk for ESKD compared to the lowest quartiles, respectively (Table). The association was no longer statistically significant after adjustment for proteinuria.

Conclusions: Urinary CCN2 and PIIINP are strongly associated with risk for ESKD, an association that may be mediated through proteinuria. Future studies should investigate if these markers add to the identification of those at highest risk for progression to ESKD.

Funding: NIDDK Support

Urinary Retinol-Binding Protein Is Associated with the Risk of Kidney Replacement Therapy in CKD

Maria Alice M. Domingos, Paulo Lotufo, Isabela M. Bensenor, Silvia M. Titan. *University of Sao Paulo, Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Urinary Retinol-Binding Protein (uRBP), a biomarker of proximal tubular injury, is used in clinical practice as a risk factor for CKD in tubular diseases, such as Dent's disease and cystinosis, and in renal transplantation. However, its role as a biomarker of CKD progression outside these conditions is less clear. The aim of our study was to evaluate the association of uRBP with the risk of mortality and kidney replacement therapy (KRT) in CKD of multiple etiologies.

Methods: The Progredir Cohort is composed of 454 older adults with CKD (predominantly G3 and G4) recruited from the outpatient services of a tertiary hospital in Sao Paulo, Brazil. Baseline uRBP was measured using an immunoenzymatic assay with monoclonal antibody and expressed as mg/g urinary creatinine, and those with missing values were excluded (n=22). Events of death (n=184) and KRT (n=60) were ascertained

(median follow-up of 6 years, with 5 participants lost to follow-up). Uni and multivariable Cox and Competitive Risk models (R package "cmprsk") were computed.

Results: Mean age was 67(12)y, mean eGFR was 38(15) mL/min/1.73m^2, 64% were male and 58% were diabetic. Median (P25, P75) for uRBP were: 0.29 (0.08, 1.47) in all; 0.24 (0.06, 0.84) vs. 0.46 (0.10, 2.87) in those who remained alive vs. those who died (p=0.001); and 0.26 (0.08, 0.90) vs. 2.98 (0.21, 17.5) in those without and with KRT, respectively (p<0.0001). In Cox models, RBP was not related to mortality. However, competitive models showed that uRBP was related to the risk of KRT, even after adjustments (Table). This association was also present when only normoalbuminuric participants (CKD A1) were included.

Conclusions: URBP is significantly associated with the risk of KRT in the setting of CKD, and may be particularly useful as a biomarker in CKD patients with normoalbuminuria (CKD A1).

Funding: Government Support - Non-U.S.

Competing risk models for the risk of KRT.

	SHR (95%CI)	p-value
uRBP (mg/g creatinine) - unadjusted	1.03 (1.01 to 1.04)	<0.0001
uRBP (mg/g creatinine) - adj. 1	1.01 (1.00 to 1.02)	0.015
uRBP (mg/g creatinine) - adj. 2	1.01 (1.00 to 1.02)	0.03

Adj.1= age, sex, eGFR; adj.2 = same as 1 + SBP, DM, MI, ACR, smoking. Models for KRT were computed considering the competing risk of death. SHR, subdistribution hazard ratio.

PO0447

Tubular Secretion of Creatinine and Risk of Kidney Failure: The Modification of Diet in Renal Disease Trial

Pranav S. Garimella,[1] Hocine Tighiouart,[2] Andrew S. Levey,[2] Mark J. Sarnak,[2] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]Tufts Medical Center, Boston, MA.*

Background: Whether tubular secretion is associated with clinical outcomes beyond glomerular filtrate rate (GFR) or proteinuria is unknown. By using measured GFR and creatinine clearance, we evaluate the association of tubular secretion of creatinine with long-term kidney and mortality outcomes.

Methods: The Modification of Diet in Renal Disease (MDRD) Study was a randomized controlled trial conducted to examine the effects of strict blood pressure control and dietary protein restriction on progression of stages 3 to 4 CKD. This prospective analysis included 838 participants with baseline measures of iothalamate glomerular filtration rate (mGFR) and 24-hour urine creatinine clearance (CrCl). Tubular secretion of creatinine (TS_{cr}) was calculated as the difference between CrCl and mGFR. The primary outcome was incident end-stage kidney disease (ESKD) and secondary outcomes were cardiovascular disease (CVD) related and all-cause mortality.

Results: At baseline, mean mGFR was 33 ml/min/1.73 m^2 and the mean CrCl was 42 ml/min/1.73 m^2. Over 21 years of follow up there were 626 ESKD, 202 CVD-related mortality, and 444 all-cause mortality events. Each 10 ml higher TS_{cr} was associated with a lower risk of ESKD (HR 0.74, 95% CI 0.66-0.84)) after adjustments for mGFR, proteinuria, and other potential confounding factors [Image]. Higher TS_{cr} was associated with lower risk of CVD related mortality (HR 0.78, 95% CI 0.65, 0.95) and all-cause mortality (HR 0.86, 95% CI 0.75, 0.97) in unadjusted models but these associations were no longer statistically significant after adjusting for confounders (HR 0.82, 95% CI 0.66, 1.02 and HR 0.92, 95% CI 0.79, 1.06 respectively).

Conclusions: Higher TS_{cr} is associated with lower risk of ESKD, independent of mGFR, proteinuria, and other kidney disease factors. Tubular secretion provides prognostic information above and beyond GFR and proteinuria.

Funding: NIDDK Support

Clinical Significance and Related Factors of GFR Slope in a Large Multicenter Observational Study in Japan

Yuji Kamijo,[1,2] Koji Hashimoto,[1,2] Yosuke Yamada,[1,2] Makoto Harada,[1,2] Masatsugu Aida,[2,3] Shitotomo Yamauchi.[2,3] NKEA study group *[1]Shinshu University School of Medicine, Matsumoto, Japan; [2]Nagano Kidney Evaluation Association, Matsumoto, Japan; [3]Ethic Co., Ltd., Chiyoda-ku, Japan.*

Background: Recently, GFR slope has attracted attention as an important surrogate marker for the prognosis of CKD, with a reduction in slope of GFR decline by 0.75 mL/min/1.73 m^2 per year reportedly having clinical significance. This investigation addresses the clinical significance of GFR slope and its related factors on Japanese CKD patients.

Methods: CKD patients in 15 general hospitals between January and March 2014 were surveyed using medical records. The selection criteria were age ≥20 years, eGFR <60 mL/min/1.73 m^2, and receiving medical treatment for CKD. Baseline patient characteristics, eGFR changes, and hard endpoints (death or ESKD requiring RRT) were analysed. We calculated GFR slope using GFR data of 2 years by 2 calculation methods, the linear mixed model and least squares linear regression, and examined the relationship of GFR slope with the hazard ratio (HR) of the endpoints. The factors related to GFR slope were also assessed by multiple regression analysis.

Results: Among a total of 11233 patients, we analyzed the data of 7490 CKD G3 and G4 patients (60% male, mean age: 71 years, CKD G3a: 55%, G3b: 30%, G4: 15%, mean eGFR: 44 mL/min/1.73 m^2, urine protein positive: 51%, diabetes mellitus: 49%, use of RAS-I: 57%). The mean observation period was 1040 days. Hard endpoints after the GFR slope measurement period occurred in 301 subjects. The GFR slope of the cohort was -0.948 mL/min/1.73 m^2 per year (95% confidence interval [CI] -1.016, -0.880) in the linear mixed model and -0.982 mL/min/1.73 m^2 per year (95% CI -1.075, -0.889) according to least squares linear regression. Both calculated GFR slopes were significantly related to the HR of the composite hard endpoints. HR decreased by 0.85 (linear mixed model) and 0.9 (least squares linear regression) times in case of a reduction in slope of GFR decline by 0.75 mL/min/1.73 m^2 per year. Multiple regression analysis revealed strongly significant associations for GFR slope with urine protein and CKD stage and undetectable relationships for GFR slope with diabetes and age.

Conclusions: This study demonstrated the clinical significance of GFR slope as a surrogate marker for renal prognosis in Japanese CKD patients. In order to reduce slope of eGFR decline, active intervention for proteinuria before the progression to an advanced CKD stage appears to be effective.

PO0449

The Kidney Failure Risk Equation: Testing Previous eGFR Slopes, Clinical Variables, and Novel Populations

Morgan Grams, Nigel J. Brunskill, Angela Yee Moon Wang, Navdeep Tangri. CKD Prognosis Consortium *CKD Prognosis Consortium, Baltimore, MD.*

Background: The 4-variable kidney failure risk equation (KFRE) is a well-validated tool that accurately predicts the 2- and 5-year risk of kidney failure in patients with eGFR <60 ml/min/1.73 m^2 using baseline eGFR, ACR, age, and sex. The aim of this study was two-fold: to assess whether KFRE can be improved using previous eGFR slope or other variables; and to evaluate whether the KFRE can be used in patients with eGFR ≥60 ml/min/1.73 m^2.

Methods: We used 36 cohorts in development and 17 cohorts in validation to accomplish these aims; all cohorts participate in the CKD-Prognosis Consortium and had data on the four variables, previous 2-year eGFR slope, and at least 25 ESKD events.

Results: There were 205,004 participants with eGFR <60 ml/min/1.73 m^2 (12,794 ESKD events) and 441,915 participants with eGFR ≥60 ml/min/1.73 m^2 (1,220 ESKD events). In the eGFR <60 group, previous 2-year eGFR loss >3 ml/min/1.73 m^2/year was associated with ESKD (meta-analyzed HR 1.36, 95% CI: 1.19-1.56) with a small improvement over the 4-variable model (baseline c-statistic in validation cohorts, 0.87-0.95; meta-analyzed difference in c-statistic in validation cohorts when adding slope, 0.001, 95% CI: 0.000-0.002). Using previous 5-year slope resulted in slightly better c-statistic compared to the model using 2-year slope (meta-analyzed difference in c-statistic in validation cohorts, 0.003, 95% CI: 0.001-0.005). Other approaches, such as using 1-year average eGFR or 1-year average ACR as inputs in the 4-variable KFRE, or incorporating black race, heart failure, or atrial fibrillation, did not result in meaningful improvements. The KFRE had poor discrimination and calibration in the eGFR ≥60 ml/min/1.73 m^2 population. In a model that instead predicted 40% decline in eGFR and included age, sex, ACR, diabetes, hypertension, heart failure, and coronary heart disease, previous eGFR loss > 3 ml/min/1.73 m^2/year over 2- and 5-years were associated with greater risk (HR, 1.43, 95%CI: 1.19-1.70; 1.84, 95%CI: 1.40-2.42).

Conclusions: In summary, the KFRE was improved only slightly by the inclusion of previous eGFR slope. For populations with eGFR >60, a more relevant and predictable outcome may be percent eGFR decline.

Comparison of Predicted Risk of Renal Replacement Therapy vs. eGFR for Arteriovenous Fistula Placement in CKD: A Retrospective Analysis

Ken J. Park,[1] Micah L. Thorp,[1] Erin Keast,[2] Jose G. Benuzillo,[3] David Mosen,[2] Eric S. Johnson.[1] *[1]Kaiser Permanente Northwest, Portland, OR; [2]Kaiser Permanente Center for Health Research Northwest Region, Portland, OR; [3]Edwards Lifesciences Corp, Irvine, CA.*

Background: The complexity in predicting which and when patients with chronic kidney disease (CKD) will progress to renal replacement therapy (RRT) contributes to 80% of patients starting hemodialysis without a functioning permanent access. Studies suggest AVF referral at eGFR of 15-20 ml/min increases the likelihood of starting dialysis with an AVF. We were interested in whether a prediction model developed at Kaiser Permanente Northwest better predicted progression to RRT at 1 year compared to eGFR.

Methods: We retrospectively followed 613 patients with stage 4 CKD between ages of 18 to 89 from May 2013 to May 2018 followed by nephrology who had a nephrology visit with an eGFR and a calculatable 2-yr risk for RRT around 12 months before end of follow up (defined as death, initiation of RRT, or 2 years from initial enrollment date). We calculated sensitivity, specificity, and area under the curve (AUC) based on a range of 2-yr risk for RRT (20%, 40%, 60%, and 80%) and compared them to eGFR threshold of 15 ml/min and 20 ml/min at the 12 month visit prior to end of follow up. We compared 2-yr risk for RRT vs. eGFR using a decision curve analysis.

Results: At end of follow up, 12% had died and 14% had progressed to RRT (69% hemodialysis, 22% peritoneal dialysis, 9% transplant). Compared to eGFR threshold of 20 ml/min, specificity and specificity was greater at 2-yr RRT risk of 40% (73% and 49% for eGFR threshold of 20 ml/min respectively compared to 85% and 54% respectively for 2-yr RRT risk threshold of 40%). Compared to eGFR threshold of 15 ml/min, specificity and specificity was greater at 2-yr RRT risk of 80% (97% and 11% for eGFR threshold of 15 ml/min respectively compared to 98% and 18% respectively for 2-yr RRT risk threshold of 80%). The AUC was greater between 2-yr RRT of 20% to 40% (0.73 to 0.70) compared to eGFR between 15 ml/min to 20 ml/min (0.54-0.61). Decision curve analysis showed better net benefit using 2-yr risk >40% compared to eGFR of 20 ml/min above a 1 year threshold of 25%.

Conclusions: In patients with CKD stage 4, 2-yr risk for RRT better predicted progression to RRT at 1 year compared to eGFR alone. Our study suggests that use of prediction model for RRT may be an important tool for determining optimal timing for AVF referral.

PO0451

Risk Factors of Renal Replacement Therapy in Hospitalized Patients with CKD Stage 4

Qiaoli Hua,[1,3] Xusheng Liu,[1] Chuan Zou.[2] *[1]Department of Nephrology, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; [2]Department of Dialysis, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; [3]The Second Clinical Medical College, Guangzhou University of Chinese Medicine Guangzhou, China.*

Background: Data on risk factors of renal replacement therapy (RRT) in hospitalized patients with CKD4 may help nephrologists to delay dialysis. The study was designed to describe the risk factors of RRT in CKD4 inpatients.

Methods: Medical records of CKD4 inpatients in Guangdong Provincial Hospital of Chinese Medicine during January, 2010 - January, 2020 were collected. Related indicators such as demography characteristics, laboratory and echocardiography test results, treatments, comorbidities and primary diseases were collected. Patients were followed up till they reached clinical outcomes (RRT) or the end of the study (January, 2020). Patients who were followed up for less than one year were excluded. Descriptive statistics and survival analysis were performed with Cox regression, with 95% CI, considered a value of $p < 0.05$ as statistically significative.

Results: 222 CKD4 inpatients [age, 60.00(47.75-72.25) years); female, 55.9%] were enrolled. In a median follow-up of 2.41 years, 199 inpatients (10.6%) started RRT. Among those patients, the median time progression to RRT was 2.10 (1.20-3.58) years. All patients were divided into two groups according to whether progressed to RRT within 2.41 years. For those received RRT within 2.41 years, they had heavier urine protein, urine occult blood and account for a higher proportion of inpatients with diabetes mellitus(63.6%), chronic heart failure (43.6%), diabetic kidney disease (55.5%). Their serum albumin and ejection fraction(EF) were lower(P<0.001). The multivariate Cox proportional hazards models showed that age[hazard ration (HR): 0.986; 95% confidence interval(CI): (0.976-0.995); P=0.004], diabetic kidney disease(DKD) [HR:1.727,95%CI: (1.274-2.391), P=0.001], urinary protein [HR:1.148, 95% CI: (1.094-1.205), P<0.001], serum albumin [HR:0.971,95%CI: (0.949-0.994), P=0.013], LVMI [HR:1.010,95%CI: (1.004-1.016), P=0.002], left ventricular dimension systolic(LVDs) [HR:0.948, 95%CI: (0.910-0.986), P=0.008] and EF [HR:0.970, 95%CI: (0.950-0.990), P=0.004] were independently associated with factors for progression to RRT in CKD4 inpatients.

Conclusions: DKD, urinary protein, LVMI were risk factors that were significantly associated with CKD4 progression to RRT in inpatients. Whereas, serum albumin, LVDs, and EF are protective. The urinary protein, serum albumin and echocardiographic parameters need to be taken seriously for patiens with CKD4.

PO0452

Development and Validation of a Predictive Model to Identify Patients with Undiagnosed CKD

Steven M. Brunelli, Adam G. Walker, Kathryn S. Gray. *Davita Clinical Research, Minneapolis, MN.*

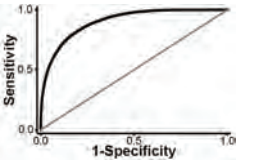
Background: Chronic kidney disease (CKD) is a common condition and often goes undiagnosed. Unmanaged CKD can progress rapidly, resulting in poor clinical outcomes and increased health care costs. Identification of individuals who may have undiagnosed CKD would allow for implementation of CKD management practices in order to slow progression, potentially improving outcomes and reducing health care costs. Here, we report the development and validation of a claims-based algorithm to identify CKD.

Methods: This model was developed using Medicare Part A and Part B claims from calendar year 2017. Data from 378,460 unique patients with no evidence of end-stage kidney disease or claims for dialysis through April 2017 were split into derivation (n = 189,203) and validation (n = 189,257) sets. The predicted outcome was the presence of a diagnosis code for CKD stages 3 to 5, which occurred in 4.4% of patients within the data. To simulate the use case, codes for kidney disease were not eligible as predictors in the model. Area under the curve (AUC) of the receiver operating curve and positive predictive value (PPV) were used to assess the performance of candidate models.

Results: The best model was a logistic regression algorithm based on 94 input terms derived from 13 clinical constructs. The model demonstrated an excellent ability to discriminate (AUC = 0.90), which was stable when tested in the validation set (AUC = 0.90). The PPV in the top 1% and top 2% of patients identified by the model was approximately 72% and 59%, respectively.

Conclusions: We developed an algorithm that uses medical claims to identify patients who are most likely to have unrecognized CKD. If the algorithm were applied to a population of 10,000 patients, it could identify the 100 patients at highest risk, among whom 72 would have CKD if tested.

	Derivation Set	Validation Set
Patients	189,203	189,257
CKD 3-4 Prevalence	4.3	4.4
AUC	0.90	0.90
PPV (1% Threshold)	71.80%	72.20%
PPV (2% Threshold)	58.9%	59.1%



PO0453

Predicting Progression to ESKD: Application of Novel Statistical Methodologies

Kristina Looper,[1] Priscila Preciado,[2] Yue Jiao,[1] Carly Hahn Contino,[1] Len A. Usvyat,[1] Yuedong Wang,[3] Peter Kotanko.[2,4] *[1]Fresenius Medical Care, Global Medical Office, Waltham, MA; [2]Renal Research Institute, New York, NY; [3]University of California Santa Barbara, Santa Barbara, CA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Estimating time to end-stage renal disease (ESRD) in chronic kidney disease patients (CKD) is important in preparing patients for a smooth transition to dialysis. In this analysis we explored patterns in trajectories of blood urea nitrogen (BUN), systolic blood pressure (SBP), and estimated glomerular filtration rate (eGFR) in patients with CKD and associated them to time to ESRD.

Methods: We used data from a registry of CKD patients from practices using Acumen electronic medical records, obtaining 8,572 patients with CKD 3 from 2003 to 2018 based on their first eGFR value. BUN, SBP, and eGFR were observed for 3 years after first eGFR measurement. Time to ESRD is calculated from the start of the follow-up period to when eGFR < 15 mL/min/1.73m2. Functional data for each patient was generated by fitting cubic splines to BUN, SBP, and eGFR, respectively. Trajectories of each variable were grouped into 3 clusters using principle component analysis (PCA) scores; time to ESRD was compared between them by Kaplan-Meier analysis. We fit Cox proportional hazards model with eGFR, SBP, BUN clusters and age, sex, and race as predictors of ESRD onset.

Results: BUN, SBP, and eGFR have stable, increasing, and decreasing trajectory clusters (Figure). In a Cox model with these clusters as well as age, gender, and race, trajectories of eGFR, BUN, and SBP were significant predictors of ESRD onset.

Conclusions: Since BUN, SBP, and eGFR trajectories were all significant predictors of progression to ESRD, it is important to consider all three to ascertain CKD progression.

PO0454

Indexing Proteinuria to Renal Function Improves Prediction for Renal Events in Individuals with CKD

Afshin Parsa,[1] Ivonne H. Schulman,[1] Kenneth J. Wilkins,[1] Susan R. Mendley,[1] Paul L. Kimmel,[1] Adan Z. Becerra.[2] *[1]Division of Kidney, Urologic, and Hematologic Diseases, National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Behtesda, MD; [2]Social & Scientific Systems, Siver Spring, MD.*

Background: Identifying the optimal measurement of proteinuria in clinical settings has been challenging. To determine the potential consequence of varied measures of proteinuria, we contrasted their clinical significance primarily in relation to renal events and secondarily to cardiovascular (CVD) and mortality events.

Methods: We compared the predictive ability of four measures of proteinuria and albuminuria, among 3592 CKD participants from the Chronic Renal Insufficiency Cohort (CRIC) Study, for incident renal events (halving of glomerular filtration rate [GFR] or end-stage renal disease), CVD events (myocardial infarction, congestive heart failure, stroke and peripheral arterial disease) and mortality over 3 years. The four measures included timed urinary albumin and protein excretion rates (AER, PER), albumin/protein: creatinine ratios (ACR, PCR), albumin/protein: adjusted creatinine (accounting for creatinine production) ratios (eAER, ePER), and lastly albuminuria/proteinuria indexed to GFR (ACR-G, PCR-G), as an estimation of glomerular permeability. We used Harrell's C-Statistics to measure model discrimination.

Results: Predictive performance for renal events was lowest for AER and PER. Results were generally similar for ACR vs eAER and PCR vs ePER. Notably, PCR-G showed significant improvement in predicting renal outcomes and performed better than albuminuria-based measures. C-statistics for renal events were 0.831, 0.840, 0.841, 0.846 and 0.862 for AER, eAER, ACR, PCR and PCR-G, respectively. Trends were similar for CVD and mortality events, except that ACR performed better than PCR for CVD events, but not as well as PCR-G or ACR-G. Results were overall consistent across diabetes, gender and race strata, and were validated in an additional 1443 participants from the third phase of CRIC.

Conclusions: Indexing proteinuria to GFR is a simple and economical measure, compared to albuminuria, that significantly enhances the prediction of CKD progression and associated outcomes.

PO0455

The Phosphate-to-Urinary Urea Nitrogen Ratio (P/UUN): A Tool to Evaluate Phosphate Intake and Excretion in CKD Patients

Victoria Pendon-Ruiz de Mier,[1,2] Cristian Rodelo-Haad,[1,2] Rafael Santamaria,[1,2] Rodrigo López baltanás,[1] Cristina Membrives González,[1] Juan R. Munoz-Castaneda,[1,2] Alejandro Martin-Malo,[1,2] Sagrario Soriano,[1,2] Mariano Rodriguez Portillo.[1,2] *[1]Instituto Maimonides de Investigacion Biomedica de Cordoba, Cordoba, Spain; [2]Hospital Universitario Reina Sofia, Cordoba, Spain.*

Background: Phosphate (P) restriction is crucial in CKD patients. Classically, P intake has failed to correlate with 24-h phosphaturia. Organic or inorganic P have different intestinal absorption rates, which might explain the lack of correlation between P intake and phosphaturia. Thus, we aimed to evaluate if the source of dietary P rather than the total P ingested determines phosphaturia, and to what extent inorganic P intake modifies phosphaturia

Methods: A 3-day dietary survey was performed in 71 stages G2-3 CKD patients to estimate the amount and source of P intake. 24-h urine samples were collected. Total phosphaturia, the FeP(%), and P/UUN, which reflect intestinal absorption of P relative to proteins absorbed and metabolized), were evaluated. P/UUN ratio tertiles were contrasted with the other variables analyzed (T1<58.9mg/g, T2=58.9-71.1mg/g, T3>71.1mg/g). Statistics were performed using Rv3.6.2

Results: The P intake was 1086.5±361.3 mg/day. P intake was 64.0%,22.1%, and 14.1% from animal, vegetables, and inorganic sources respectively. Total P intake did not correlate with urinary P (p=0.12), nor FeP. Patients ingesting more P ingested more inorganic P (Fig1). P intake correlated with P/UUN ratio(p=0.008). Patients in the upper P/UUN tertile showed the highest daily P intake (p=0.04) from inorganic sources (p=0.03), and the highest phosphaturia (p=0.04)

Conclusions: P/UUN reflects the total P intake and provides information about the amount of inorganic P, and could be used to guide the appropriate nutritional advice for CKD patients.

PO0456

Hypophosphatemia as a Surrogate Marker of Renal Outcome in Chronic Hepatitis B Patients Receiving Antiviral Therapy

Mee yeon Park, Junseok Jeon, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae joong Kim, Hyun Suk Lee, Hye Ryoun Jang. Division of Nephrology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea *Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea.*

Background: Antiviral therapy is crucial for the treatment of chronic hepatitis B (CHB). Although hypophosphatemia has been known to be an important adverse effect of antiviral agents, the clinical significance is yet to be revealed. In this study using a large cohort of CHB patients, the incidence and clinical significant of hypophosphatemia was investigated.

Methods: CHB patients who started antiviral therapy between 2005 and 2015, and had received at least one year of therapy, were included after excluding liver cirrhosis, diabetes mellitus, hypertension, concomitant administration of diuretics, and ESRD. Hypophosphatemia was defined as serum phosphorous level ≤ 2.5mg/dL. The primary outcome was changes in renal function. Secondary outcomes included the incidence of infection and changes in serum potassium, uric acid, and total carbon dioxide (tCO2)

Results: Of the 4,335 patients, hypophosphatemia developed in 75 patients (1.7%). When patients were categorized depending on the change of serum phosphate level, median phosphate level of 728 patients (16%) decreased by more than 0.5mg/dL from the baseline. During the 2-year follow-up period, patients with hypophosphatemia showed lower eGFR compared to the control group. Also, patients whose serum phosphate level decreased by more than 0.5mg/dL showed significantly lower eGFR compared to the control group at all time points. The incidence of infection and changes in serum potassium, uric acid, and tCO2 were similar between groups.

Conclusions: Hypophosphatemia was associated with renal function decline in CHB patients receiving antiviral therapy. Although the incidence of hypophosphatemia during antiviral therapy was relatively low, our results support the clinical significance of hypophosphatemia as a surrogate marker of adverse renal outcome in CHB patients.

PO0457

Dietary Phosphorus Restriction Improves Renal Function, Blood Pressure, FGF-23, and Klotho Levels in CKD Stages 1 and 2

Anita Saxena, Trisha Sachan, Amit Gupta, Anup Kumar, Sachin Sharma. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India*.

Background: To evaluate Impact of dietary education and intervention (phosphorus restriction) on creatinine, eGFR, FGF23, Klotho and blood pressure.

Methods: 105 subjects (CKD stages 1, 2 N 70; 35controls) evaluated for eGFR, creatinine, phosphorus, calcium, FGF-23, soluble α-Klotho iPTH FGF 23, blood pressure and 3 days dietary intake, using standard methodology on first visit, 6 and 12 months. CKD patients were grouped based on dietary phosphorus intake:Group 1 (n 42): phosphorous intake <1000mg/day and Group 2 (n=37; 17 in CKD 1; 20 CKD 2): high phosphorous intake (>1000mg/d). Patients in Group 2 were counselled for low phosphorus diet.

Results: Parameters of controls and CKD patients differed significantly. Dietary, serum and urinary phosphorus (0.001) had significant association. Systolic and diastolic BP, protein intake, dietary phosphorus, iPTH, FGF23 were significantly high (p 0.001) and Klotho significantly low(p 0.001) in Group 2 compared to Group 1. Impact of dietary intervention was seen at 6 and 12 months as reduction in protein intake from 0.64±0.95 to 0.58±0.11 (CKD 1) and 0.71±0.074 to 0.64±0.095 (p 0.012 CKD 2); decline in creatinine from 1.13±0.14 to 1.07±0.14 (CKD 1) and 1.06±8.56 (p 0.009 CKD 1); serum phosphorus from 3.57±0.19 to 3.23±0.58 (CKD 1) and 4.32±0.42 to 3.35±0.85 mg/dL (p 0.001 CKD 2), FGF-23 from 55.01±1.65, to 51.27±11.17 (CKD 1); 65.42±4.80 to 56.60±11.23 (p 0.010 CKD 2); **systolic BP** from **127.95±3.14 to 121.05±14.40**(CKD 1); **134.22±3.54 to 118.38±9.08** (p 0.001 CKD 2) and **diastolic BP** from **85.14±3.40 to 83.29±8.03**(CKD 1); **89.11±4.74 to 80.33±8.02** (p 0.003 CKD 2) and a significant increase in **eGFR** ml/min from **95.17±5.50 to 97.75±20.26** (CKD 1); **69.82±8.56 to 74.08±11.07** (p 0.019 CKD 2)was observed. sKlotho increased from 700.79±27.82 to 897.39±168.37 (p0.001 CKD 1); from 633.52±60.56 to 823.37±156.67 (p 0.001 CKD 2). Ca x P product declined from 36.10±4.84 to 29.48±7.63 (p0.001). **eGFR can predicted using dietary protein, creatinine systolic BP, haemoglobin, cholesterol (r^2 0.868).**

Conclusions: Dietary counselling had significant effect on all the parameters in early CKD stages. Dietary intervention can preventrise in FGF23, reduce blood pressure and prevent decline in renal function as demonstrated by significant increase in eGFR with phosphorus restriction in early stages of CKD.

PO0458

Baseline Serum Magnesium and Risk of CKD Progression in the Chronic Renal Insufficiency Cohort (CRIC) Study

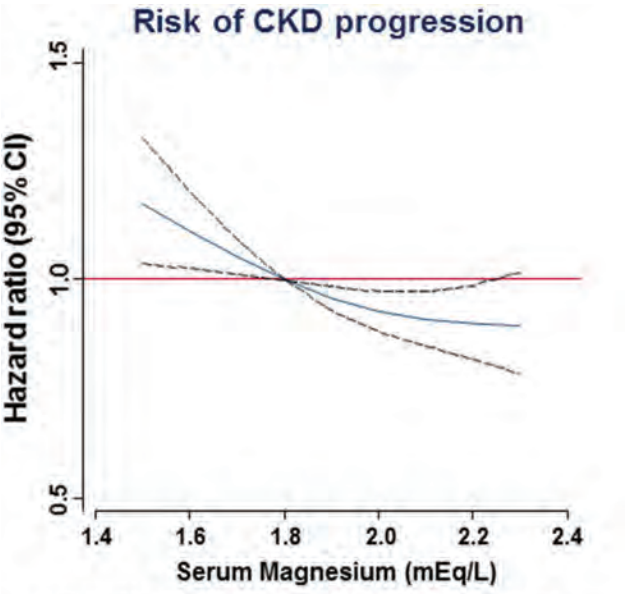
Simon Correa,[1,2] Sushrut S. Waikar,[3] Finnian R. McCausland.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Boston Medical Center, Boston, MA.*

Background: Serum magnesium (sMg) concentration is regulated by intestinal absorption and renal handling which are impaired in CKD. While Mg has been implicated in blood pressure regulation and sMg has been associated with the risk of hypertension, the association of sMg with long-term risk of CKD progression remains unclear.

Methods: Adjusted cox-proportional hazard regression models were fit to determine the association of baseline sMg with CKD progression in CRIC. CKD progression was defined as 1) development of end-stage renal disease (renal transplantation or dialysis initiation) or 2) a 50% decline in baseline eGFR (CKD-EPI). All models were stratified by clinical site and adjusted for demographics, BMI, DM, CV comorbidities, hematocrit, baseline eGFR CKD-EPI, serum albumin, 24-hour urine protein, serum and urine electrolytes, total-PTH, CV biomarkers associated with CKD progression, antihypertensive medications and diuretics. Adjusted splines were also fit.

Results: We analyzed data from 3,866 participants from CRIC who had sMg assessed at baseline. Median sMg was 2.0 mEq/L (25^{th}-75^{th} percentile 1.9 to 2.1 mEq/L). After multivariate adjustment, higher baseline sMg was associated with a 27% lower hazard of CKD progression (aHR 0.73, 95% CI 0.58-0.92; P<0.01, per 1 mEq/L). Compared to the lowest quartile (Q1), sMg concentration in the top quartile (Q4) was associated with a 23% lower hazard of CKD progression (aHR Q1:Q4 0.78, 95% CI 0.65-0.94; P<0.01). The adjusted relationship of sMg with CKD progression appeared to be linear (Fig 1).

Conclusions: In patients with CKD, higher sMg is associated with a lower risk of CKD progression independent of clinical and biochemical data. Whether correction of hypomagnesemia prevents CKD progression deserves future prospective studies.



Adjusted for age, sex, race, BMI, diabetes, hypertension, coronary artery disease, peripheral vascular disease, heart failure, hematocrit, baseline eGFR CKD-EPI, serum albumin, 24-hour urine protein, serum sodium, serum potassium, serum calcium, serum phosphate, urine sodium, urine potassium, total-PTH, hsTnT, BNP, CRP, FGF-23, ACE-I, ARB, aldosterone antagonist, diuretics. Stratified by clinical site. Plotted serum magnesium values between 5th and 95th percentile.

PO0459

The Effects of Intermittent Fasting on the Progression of CKD

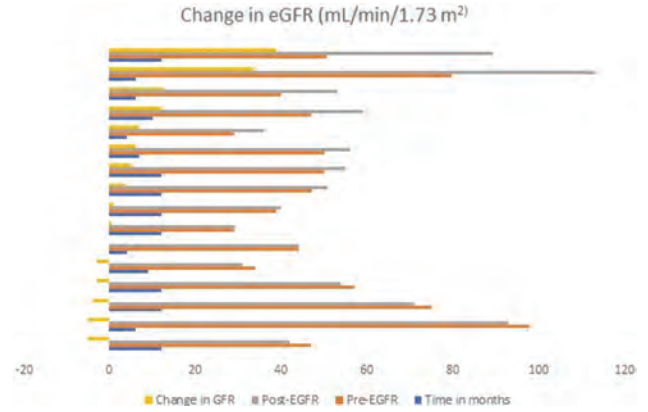
Deepthi Gunasekaran,[1,3] Buthayna A. Dinary.[1,2] *[1]Fairview Hospital, Cleveland, OH; [2]University Hospitals, Cleveland, OH; [3]Cleveland Clinic, Cleveland, OH.*

Background: Intermittent fasting (IF) refers to the practice of restricting food intake to a short period of the day alternating with a prolonged period of fasting. Preclinical studies and clinical trials have shown that IF has broad-spectrum benefits for many health conditions, such as obesity, diabetes mellitus, cardiovascular disease, cancers, and neurologic disorders. There are currently few studies suggesting a decrease in the progression of chronic kidney disease (CKD) with IF.

Methods: Retrospective chart review was done on patients from outpatient nephrology clinic with CKD stage I to IV who were self-reported to practice intermittent fasting. Patients with ESRD on dialysis, hospital admission during the study period, and reported poor compliance with fasting regimens were excluded. The primary outcome was the change in eGFR at the end of the period of intermittent fasting.

Results: Here we report current findings from 16 patients practicing IF regimen with continued ongoing enrolment. 75% of these patients were diabetic. Duration of the IF regimen ranged from 4 months to 12 months, 50% of patients had completed 12 months of IF regimen. 62.5% of patients were found to have an improvement in eGFR at the end of the period of IF. The change in eGFR was found to range from 0.4 ml/min/1.73 m^2 to 38.8 ml/min/1.73 m^2 (1.4-76.5%). The median increase in eGFR was 6.5 ml/min/1.73 m^2 (18.1%) during an average period of 8.8 months of IF (p-value = 0.04). There was no significant correlation between change in eGFR and change in weight or hemoglobin A1C during this period.

Conclusions: A significant increase in eGFR was seen in a small population of patients with CKD practicing intermittent fasting for four months or more. Previous studies report an average annual decline in GFR of 1.5-2 ml/min/1.73 m^2 in the general CKD population, with a more rapid decline in certain subsets. Intermittent fasting as a preventive measure for the progression of CKD needs to be studied further.



Change in eGFR after the period of IF

PO0460

The Association Between Dietary Fiber Intake and Clinical Outcomes in CKD: A Report from the Chronic Renal Insufficiency Cohort (CRIC)

Sumeet S. Brar, Sarah Delozier, Nishi Pradhan, Mahboob Rahman, Mirela A. Dobre. *Case Western Reserve University, Cleveland, OH.*

Background: Standard dietary interventions for individuals with chronic kidney disease (CKD) consist of reductions in salt, phosphorus, potassium, and protein intake, with no specific guidance regarding dietary fiber intake. In animal models of kidney disease, a diet high in amylose resistant starch has been found to trigger a reduction in inflammation and CKD progression. It is unclear whether low dietary fiber intake is associated with a higher risk of incident kidney disease progression, cardiovascular disease, and overall mortality in individuals with CKD.

Methods: A total of 3791 participants with chronic kidney disease and information on dietary fiber intake at the baseline visit in the Chronic Renal Insufficiency Cohort (CRIC) Study were included in the analyses. Cox proportional hazards models adjusted for sociodemographic, comorbidities, medications and laboratory data, including eGFR and proteinuria were used to analyze the association between dietary fiber intake and clinical outcomes.

Results: The mean age was 59±11 years, 46% were female, 47% had diabetes, and the average eGFR was 48±17 ml/min/1.73m^2. The average dietary fiber intake was 17.3±9.6 g. After a median follow up of 8.8±4.5 years, there was an inverse association between crude death rates and baseline dietary fiber intake: increasing from 3.1 per 100 person-years (PY) for the highest to 3.4 per 100 PY for the lowest fiber tertile. After multivariable adjustments, individuals in the middle and low fiber tertiles were at greater risk of death compared to those in the highest fiber tertile (HR[95%CI], 1.18 [1.01, 1.38], p =0.04 and 1.10 (0.94, 1.29), 0.24, respectively). We found no significant association between dietary fiber intake and kidney and cardiovascular disease outcomes. Results were similar in sensitivity analyses by subgroups defined by age, gender, ethnicity, diabetes, eGFR (< and >/= 45 ml/min/1.73m^2), and proteinuria.

Conclusions: Dietary fiber intake may be associated with the risk of death, but not with cardiovascular outcomes or kidney disease progression in individuals with CKD. Future intervention trials should investigate whether a diet enriched in fibers would influence mortality and other clinical outcomes.

Funding: Other NIH Support - NHLBI

PO0461

Changes in Dietary Protein Intake and Outcomes Among Patients with CKD

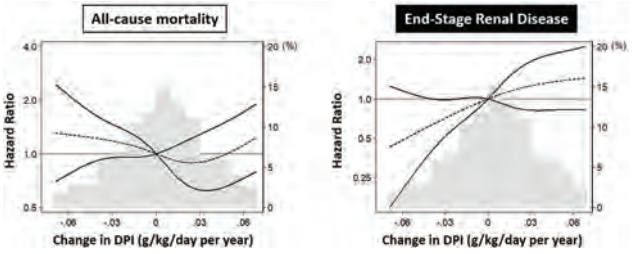
Yoshitsugu Obi,[1] Mahmoud M. Mohamed,[1] Waleed Hassan,[1] Hisham N. Abu Farsak,[1] Abhishek J. Patel,[1] Jawed Akhtar,[1] Mahmoud A. Mahmoud,[1] Keiichi Sumida,[1] Miklos Z. Molnar,[1] Barry M. Wall,[1,2] Csaba P. Kovesdy.[1,2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]Memphis VA Medical Center, Memphis, TN.*

Background: Protein energy wasting is common and associated with poor outcomes in CKD while low protein diet is recommended to delay the development of ESRD. However, the clinical relevance of the temporal change in dietary protein intake (DPI) in real-world data remains unclear in this population.

Methods: We performed repeated collections of morning spot urine in a prospective cohort of non-dialysis dependent veterans with CKD at a single institution. We assessed urine urea nitrogen-to-creatinine ratio to estimate 24-hour urine urea excretion and then estimated DPI using the Maroni formula. Among 345 patients who had data on DPI between 6-12 months from the initial measurement, we estimated the slope of DPI in mixed effects models and examined its association with subsequent ESRD and all-cause mortality in cause-specific hazard models with adjustment for demographics, Charlson Comorbidity Index, eGFR, urinary protein, smoking status, body mass index, and baseline DPI.

Results: Patients were 68±10 years old, 97% were male, 36% were African American, and their baseline eGFR was 34±12 ml/min/1.73m^2. Baseline DPI was median 0.55 (IQR, 0.45–0.67) g/kg/day and its slope was 0.01±0.04 g/kg/day per year. During a median follow-up of 4.2 years, 129 died (104/1000 PY) and 87 developed ESRD (83/1000 PY). Decrease in DPI was associated with lower risk of ESRD (HR 0.94 [95%CI, 0.89-0.99] per 0.01 g/kg/day per year; P=0.025), but not with mortality risk (P=0.84). Non-linear regression models confirmed these findings (**Figure**). Compared to patients who had no change in DPI, the hazard ratio (95%CI) of death and ESRD in those with a change of -0.03 g/kg/day per year were 1.12 (0.95-1.47) and 0.71 (0.52-0.98), respectively.

Conclusions: In patients with CKD, DPI showed a relatively small intraindividual temporal variation, but decrease in DPI was significantly associated with lower risk of ESRD, without an association with mortality.



PO0462

Effect of Zinc Deficiency on CKD Progression and Effect Modification by Hypoalbuminemia

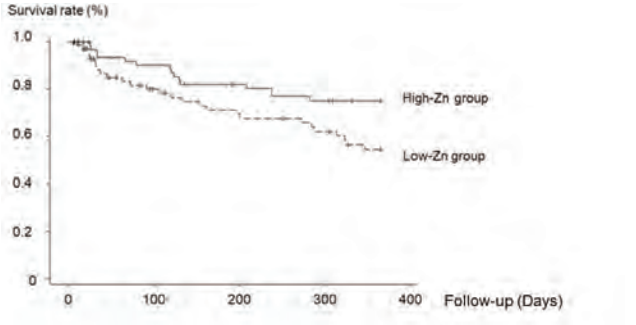
Atsuyuki Tokuyama,[1] Eiichiro Kanda,[2] Seiji Itano,[1] Megumi Kondo,[1] Yoshihisa Wada,[1] Hiroyuki Kadoya,[1] Kengo Kidokoro,[1] Hajime Nagasu,[1] Tamaki Sasaki,[1] Naoki Kashihara.[1] *[1]Department of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Japan; [2]Department of Medical Science, Kawasaki Medical School, Kurashiki, Japan.*

Background: Serum zinc (Zn) levels tend to be low in chronic kidney disease (CKD) patients. However, it has not been shown whether zinc deficiency itself leads to poor renal prognosis. The purpose of this study was to investigate the relationship between zinc deficiency and CKD progression.

Methods: This is a retrospective cohort study using the CKD patient database of electronic medical records (n=325). The study patients were classified into two groups: Zn levels<60μg/dl (low-Zn group, n=163) and Zn levels≥60μg/dl (high-Zn group, n=162). The primary outcome was defined as end-stage kidney disease (ESKD) or death, and the observation period was one year. The relationship between low Zn levels and the outcome was assessed using Cox proportional hazard model and by competitive risk analysis. Furthermore, the propensity score-matched analysis for low Zn level was also conducted.

Results: Among the subjects, 51.7% were male; mean age, 69.3years; mean Zn level, 59.9μg/dl; and median eGFR, 20.4ml/min/1.73 m^2. The incidence of the primary outcome was higher in the low-Zn group than in the high-Zn group (42.3% vs 19.1%, p<0.001). The risk of the primary outcome was higher in the low-Zn group [adjusted hazard ratio (HR) 1.88 (95% CI 1.08, 3.28; p=0.025)]. The analysis using competitive risk models showed that low Zn levels were associated with ESKD, but not with death. Moreover, in the propensity score-matched analysis, the low-Zn group showed a high risk of the primary outcome [HR 2.05 (95%CI, 1.09, 3.86; p=0.026)]. Furthermore, the relationship between the low Zn levels and the primary outcome was aggravated in the hypoalbuminemia patients (interaction p=0.011).

Conclusions: This study indicated that zinc deficiency is a risk factor for ESKD among CKD patients. Hypoalbuminemia affects the CKD progression due to zinc deficiency.



Kaplan-Meier curves for the primary outcome in the propensity score-matched population

PO0463

Association of Plasma Selenium with Renal Function in Hypertensives: Modification by Folate

Youbao Li, Xianhui Qin, Jing Nie, Min Liang, Fan Fan Hou. *Division of Nephrology, Nanfang Hospital, Southern Medical University; National Clinical Research Center for Kidney Disease; State Key Laboratory of Organ Failure Research; Guangdong Provincial Institute of Nephrology, Guangzhou, China.*

Background: We aimed to investigate the association between plasma selenium (Se) and renal function decline in adults with hypertension and to explore the possible modifiers.

Methods: This was a prospective study, including a total of 935 hypertensive adults from a folic-acid intervention trial (CSPPT) with baseline plasma Se measurements and renal outcome data available. The primary outcome was rapid decline in renal function, defined as an average decline in eGFR ≥5 mL/min/1.73m^2 per year.

Results: Over a median follow-up of 4.4 years, the primary outcome occurred in 72 participants. After multivariate-adjusted, there was an inverse association between plasma Se and rapid decline in renal function (per 10-unit increment; OR, 0.85; 95% CI: 0.72, 0.99). Consistently, compared to the lowest tertile of baseline plasma Se (<74.5 μg/L), the highest tertile (89.4~<150 μg/L) was significantly associated with a 60%(0.40; 0.21, 0.79) reduction in the odds of the outcome. A stronger inverse plasma Se-renal function decline association was observed in those received folic acid treatment (per 10-unit increment: OR, 0.70; 95% CI: 0.54, 0.90; *P*-interaction=0.036) or with a higher baseline folate concentration (≥9.0 ng/mL: 0.59; 0.43, 0.82; *P*-interaction=0.004).

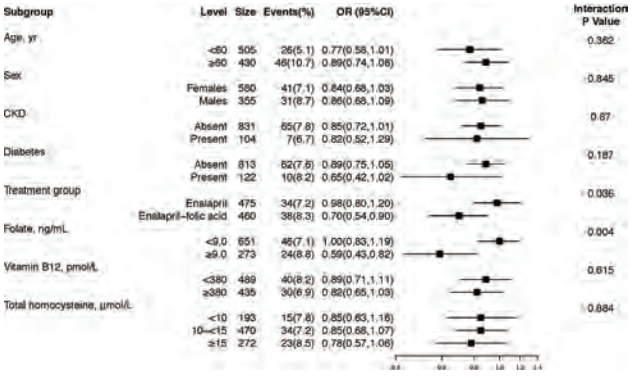
Conclusions: In China hypertensives with plasma Se <150 μg/L, there was an inverse relationship of plasma Se with the renal function decline, especially in those with folic-acid supplementation or a higher folate level.

Funding: Government Support - Non-U.S.

Association between plasma Se and the outcome

Plasma selenium, μg/L	Events (%)	Adjusted OR (95%CI)*	P
Per 10-unit increment	72(7.7)	0.85(0.72-0.99)	0.04
Tertile 1 (<74.5)	35(11.2)	Ref (1.0)	
Tertile 2 (74.5~<89.4)	22(7.1)	0.59(0.33-1.07)	0.081
Tertile 3 (89.4~<150)	15(4.8)	0.40(0.21-0.79)	0.008

*Adjusted for age, sex, eGFR, treatment group, BMI, MTHFR C677T polymorphisms, proteinuria, SBP, TC, glucose, smoking status at baseline, and averaged SBP during follow-up period.



Subgroup analyses on plasma Se (per 10-unit increment) and the outcome.

PO0464

Association Between CKD and New Onset of Dyslipidemia: Results from a Longitudinal Nationwide Survey

Takaaki Kosugi,[1] Masahiro Eriguchi,[1] Hisako Yoshida,[2] Hikari Tasaki,[1] Masatoshi Nishimoto,[1] Masato Kasahara,[3] Kunitoshi Iseki,[4] Koichi Asahi,[5] Kunihiro Yamagata,[6] Tsuneo Konta,[7] Shouichi Fujimoto,[8] Ichiei Narita,[9] Yugo Shibagaki,[10] Toshiki Moriyama,[11] Masahide Kondo,[6] Tsuyoshi Watanabe,[12] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Kashihara, Japan; [2]Osaka City University Graduate School of Medicine School of Medicine, Osaka, Japan; [3]Institute for Clinical and Translational Science Nara Medical University Hospital, Kashiara, Japan; [4]Nakamura Clinic, Urazoe, Japan; [5]Iwate Medical University, Morioka, Japan; [6]University of Tsukuba, Tsukuba, Japan; [7]Yamagata University Graduate School of Medical Science, Yamagata, Japan; [8]University of Miyazaki, Miyazaki, Japan; [9]Niigata University, Niigata, Japan; [10]St Marianna University Hospital, Kawasaki, Japan; [11]Osaka University Health Care Center, Suita, Japan; [12]Fukushima Medical University School of Medicine, Fukushima, Japan.*

Background: Dyslipidemia is a significant risk factor of CVD and seems to be associated with CKD onset and progression. On the contrary, CKD patients have dyslipidemia more frequently than non-CKD patients, but it is unclear whether CKD affects new onset of dyslipidemia.

Methods: This is a longitudinal study based on data obtained from the Japanese Specific Health Check and Guidance System. Among 664,926 individuals who participated in this program from 2008 to 2014, we excluded participants who met the following criteria: 1) health check only one time, 2) missing values for creatinine or proteinuria, 3) dyslipidemia at baseline, or 4) medication for dyslipidemia at any point. We evaluated new onset of dyslipidemia according to each factor; hypertriglyceridemia (High-TG), hyper-LDL cholesterolemia (High-LDL), or hypo-HDL cholesterolemia (Low-HDL), defined as triglycerides ≥150 mg/dL, LDL cholesterol ≥140 mg/dL, or HDL cholesterol <40 mg/dL, respectively, and compared between participants with and without CKD. These associations were analyzed using Kaplan-Meier methods and Cox regression analysis after adjustment for clinically relevant factors.

Results: During a median follow-up period of 3.1 years, the cumulative incidences of High-TG, High-LDL, and Low-HDL were 45,300, 51,940, and 13,313 participants, respectively, among 305,893 participants (non-CKD: 254,884; CKD: 51,009). In the univariable analyses, hazard ratios (HRs) [95% confidence intervals (CIs)] in CKD vs non-CKD participants were 1.31 [1.27-1.34], 1.02 [0.99-1.05], and 1.70 [1.63-1.77] for High-TG, High-LDL, and Low-HDL, respectively. After adjustment for clinically relevant confounders, adjusted HRs [95% CIs] in CKD participants were 1.10 [1.07-1.13], 0.99 [0.96-1.02], and 1.16 [1.11-1.22] for High-TG, High-LDL, and Low-HDL, respectively.

Conclusions: CKD was associated with new onset of High-TG and Low-HDL, but not High-LDL among general population in Japan.

PO0465

Relationship of Serum Triglycerides with Incident Albuminuria Among 114,817 US Veterans

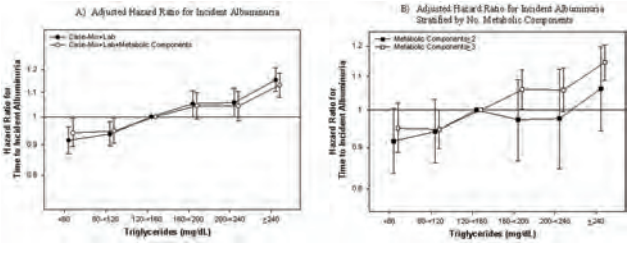
Melissa Soohoo,[2] Jui-Ting Hsiung,[2,3] Maria V. Marroquin,[2,3] Csaba P. Kovesdy,[4,1] Kamyar Kalantar-Zadeh,[3,2] Elani Streja.[2,3] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]VA Long Beach Healthcare System, Long Beach, CA; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]Memphis VA Medical Center, Memphis, TN.*

Background: The association of metabolic syndrome (MetS) components of impaired glucose, obesity, low high-density lipoprotein, hypertension, and serum triglycerides (TG), with renal endpoints such as incident chronic kidney disease (CKD) have been previously studied individually. Urine albumin to creatinine ratio (UACR) remains an integral part of CKD staging and incidence, yet it remains understudied. Thus, we sought to examine the relationship of TG with incident albuminuria among normal UACR patients with consideration for other MetS components.

Methods: Our cohort comprised 114,817 veterans with albuminuria stage A1 (<30 mg/g) and data on TG and MetS components. Incident albuminuria was defined as at least two UACR measurements of >30 mg/g at least 90 days apart. We used Cox proportional hazards models to evaluate the association of TG with incident albuminuria, adjusted for case-mix characteristics, laboratory values and individual MetS components, as well as stratified by ≤2 and ≥3 MetS components.

Results: The mean±SD age was 65±11, with a median[IQR] of TG, UACR and eGFR of 144[97, 214] mg/dL, 7[4, 13] mg/g, and 75[61, 89] mL/min/1.73m^2 respectively, and 70% had at least 3 MetS components. We observed a linear association between TG and incident albuminuria after adjustment for case-mix and laboratory variables (ref: TG 120-<160 mg/dL). The association did not differ after adjustment for MetS components (Figure A). Moreover, stratification by number of MetS components showed similar linear associations between TG and incident albuminuria, especially in patients with ≥3 MetS components. In patients with ≤ 2 MetS components, the linear relationship of TG and incident albuminuria was attenuated (Figure B).

Conclusions: Higher TG are associated with incident albuminuria independent of other components of MetS. Further study is needed to understand the drivers of this association, with a specific focus of how to best manage TG levles in addressing albuminuria development.



PO0466

Short-Term Associations of Triglycerides with Atherosclerotic and Non-Atherosclerotic Cardiovascular Disease Hospitalizations Across CKD Stages

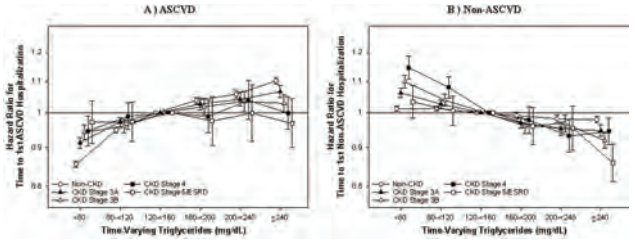
Melissa Soohoo,[3,1] Jui-Ting Hsiung,[3,1] Csaba P. Kovesdy,[4,2] Kamyar Kalantar-Zadeh,[1,3] Elani Streja.[3,1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]VA Long Beach Healthcare System, Long Beach, CA; [4]Memphis VA Medical Center, Memphis, TN.*

Background: In chronic kidney disease (CKD) patients, we showed that the risk of atherosclerotic cardiovascular disease (ASCVD) and non-ASCVD events with high baseline triglycerides (TG) incrementally attenuated across worse CKD stages, where high TG was associated with lower risk of non-ASCVD events in late-stage CKD. TG levels can change with CKD progression, but associations of time-varying TG with ASCVD or non-ASCVD hospitalizations is unknown.

Methods: We examined time-varying TG with time to first ASCVD or non-ASCVD hospitalization in 2,963,176 US veterans who received care in 2004-2006 (baseline) and were followed to 2014. Events were classified by primary ICD-9 codes. Using time-varying Cox models, we evaluated associations of time-varying TG with first ASCVD or non-ASCVD events stratified by baseline CKD stage, with adjustment for demographics, and time-varying comorbidities and laboratory values.

Results: The cohort was 63±14 years old with a median[IQR]TG 127[87,189] mg/dL, and 23% had CKD 3A or higher at baseline. TG <80 mg/dL was associated with a lower risk of time to first ASCVD event (ref: TG 120-<160 mg/dL) for all baseline CKD stages (Fig A). There was a linear association between time-varying TG and ASCVD events. High TG≥240 mg/dL had the highest risks for ASCVD, for baseline non-CKD, and CKD 3A-3B. Among late-stage CKD patients, the association of high TG and ASCVD was null. We observed an inverse association between time-varying TG with time to first non-ASCVD event (Fig B). Patients with low TG had faster times to first non-ASCVD event for non-CKD and CKD 3A-4, while high TG were associated with slower times in all stages. CKD stage 5/end-stage renal disease patients with TG ≥240 mg/dL had the lowest risk of non-ASCVD event.

Conclusions: Short-term risk of higher TG with ASCVD or non-ASCVD events incrementally decreased across CKD stages, where risk was lower to null in late stage patients. High TG were associated with lower risks of non-ASCVD across all CKD stages. Investigation is needed to evaluate the pathways involving TG and cardiac events as CKD severity progresses in order to best manage health.



PO0467

Metabolic Acidosis and Progression to Renal Replacement Therapy

Vandana S. Mathur,[1] Susan E. Funk,[2] Nancy L. Reaven,[2] Navdeep Tangri.[3] *[1]MathurConsulting, Woodside, CA; [2]Strategic Health Resources, La Canada, CA; [3]University of Manitoba, Winnipeg, MB, Canada.*

Background: Metabolic acidosis is common in advanced chronic kidney disease (CKD) and is associated with its progression (Kraut J, *Adv Chronic Kidney Dis*. 2017).

Methods: De-identified electronic health records (Optum® EHR), 2007 to 2017 were queried to identify patients with non-dialysis CKD Stages 3-5 with ≥2 serum bicarbonate tests 28–365 days apart, ≥3 eGFR values <60 mL/min/1.73 m² and ≥2 years of post-index data or who died during that period. Cohorts with metabolic acidosis and normal serum bicarbonate were established based on the index serum bicarbonate (< 22 mEq/L or 22 - 29 mEq/L). Progression to RRT was defined as initiation of dialysis or kidney transplantation, identified in EHR data by diagnosis or procedure codes, or eGFR ≤ 9 mL/min/1.73 m². We evaluated the impact of baseline serum bicarbonate on RRT initiation, adjusted for age, sex, race, diabetes, hypertension, heart failure, Charlson Comorbidity Score (index of comorbidity burden), and baseline eGFR and log albumin-to-creatinine ratio (ACR) using logistic regression models (2-year outcome period) and Cox proportional hazards models (up to 10 years).

Results: 51,558 patients qualified for analysis; 17,350 with metabolic acidosis, 34,208 with normal serum bicarbonate at baseline. Unadjusted rates of progression to RRT within 2 years were higher among patients with metabolic acidosis vs. normal serum bicarbonate overall (19.6% vs. 5.5%, respectively, p< 0.001) and at all baseline CKD stages (p< 0.001) except stage 5 (p=0.4). Each 1 mEq/L increase in serum bicarbonate between 12 and 29 mEq/L was associated with a 2.5% decrease in the 2-year risk of initiating RRT, (OR: 0.975, 95% CI: 0.965, 0.985), and a 4.5% decrease in risk up to 10 years (HR: 0.955, 95% CI: 0.948, 0.963).

Conclusions: The presence of metabolic acidosis was associated with an increased risk of CKD progression to dialysis or kidney transplantation. This finding was independent of age, sex, race, pre-existing comorbidities, and baseline eGFR and ACR.

Funding: Commercial Support - Tricida, Inc.

PO0468

Relationship Between Metabolic Acidosis and CKD Progression Is Evident Across US Racial and Ethnic Groups

Navdeep Tangri,[1] Vandana S. Mathur,[2] Nancy L. Reaven,[3] Susan E. Funk,[3] Donald E. Wesson.[4] *[1]University of Manitoba, Winnipeg, MB, Canada; [2]MathurConsulting, Woodside, CA; [3]Strategic Health Resources, La Canada, CA; [4]Baylor Scott & White Health and Wellness Center, Dallas, TX.*

Background: Metabolic acidosis is a known risk factor for CKD progression, but little is known about the impact of race and ethnicity on this relationship. We used a large electronic medical record (EMR) database of >100 million patients from all 50 states and insurance types to evaluate the relationship between metabolic acidosis and adverse renal outcomes and death by race and ethnicity.

Methods: De-identified electronic medical records (Optum® EHR), 2007–2019 were queried to identify patients with non-dialysis CKD Stages 3-5, ≥2 years of post-index data or death within 2 years, and grouped by baseline metabolic acidosis (12 to < 22 mEq/L) vs normal serum bicarbonate (22 to < 30 mEq/L). Patients (N = 136,067) were classified as Asian (N=1,328), Black (N=15,248), Hispanic (N=4,137), White (N=111,953) or Other (N=3,401). The primary endpoint was the composite outcome of death, kidney dialysis or transplant, or 40% decline in eGFR from baseline (DD40). Cox proportional hazards models examined the impact of serum bicarbonate on DD40 within each racial/ethnic group, adjusted for age, sex, eGFR, log albumin-to-creatinine ratio, diabetes, hypertension, heart failure, Charlson Comorbidity Score.

Results: Overall, 47,032 patients (34.6%) experienced DD40 events within 2 years: Asian, 35%; Black, 44%; Hispanic, 48%; White, 32%; Other, 48%. Serum bicarbonate independently predicted DD40 in all racial/ethnic groups. Adjusted Hazard Ratios for DD40 per 1 mEq/L increase in serum bicarbonate (median 4.2 yrs, max 11.5 yrs follow-up) were as follows: Asian, 0.942 (CI: 0.917- 0.968); Black, 0.976 (CI: 0.969-0.983); Hispanic, 0.970 (CI: 0.956-0.984); White, 0.960 (CI: 0.957-0.963); *P*< 0.0001 for all groups.

Conclusions: In a large community-dwelling US population, serum bicarbonate was independently associated with adverse kidney outcomes and death in Asians, Blacks, Hispanics and Whites with CKD. Since race and ethnicity are associated with other sociodemographic factors that affect health, further exploration of the potential reasons for the observed range of hazard ratios across these groups is warranted.

PO0469

Metabolic Acidosis Is Associated with CKD Progression: A Longitudinal Analysis of >100,000 US Community-Based Patients

Vandana S. Mathur,[1] Nancy L. Reaven,[2] Susan E. Funk,[2] Navdeep Tangri.[3] *[1]MathurConsulting, Woodside, CA; [2]Strategic Health Resources, La Canada, CA; [3]University of Manitoba, Winnipeg, MB, Canada.*

Background: To delay the progression of CKD, it is imperative to identify modifiable risk factors and then to evaluate efficacy of interventions. Here we assess the role of metabolic acidosis as an independent risk factor for CKD progression in patients (pts) with non-dialysis-dependent CKD Stages 3-5.

Methods: De-identified electronic medical records (Optum® EMR), 2007–2019 were queried to identify pts with non-dialysis CKD Stages 3-5, (2 consecutive eGFR values >10 and <60 mL/min/1.73m² 90-365 days apart) followed by 2 consecutive serum bicarbonate values 28–365 days apart, both 12 to <22 mEq/L (metabolic acidosis) or 22 to <30 mEq/L (normal serum bicarbonate) and ≥2 yrs of post-index data or death within 2 yrs. Pts (N = 136,067) were followed for up to 11.5 yrs for evidence of CKD progression, measured as a ≥40% decline in eGFR from baseline and as progression of ≥ 1 CKD stage from baseline using laboratory data. We describe outcomes at 2 yrs and used Cox proportional hazards models over the entire follow-up period to examine potential confounders: age, sex, race/ethnicity, eGFR, log albumin-creatinine ratio, diabetes, hypertension, heart failure, and weighted Charlson Comorbidity Index.

Results: 75,127 pts (55%) progressed 1 or more CKD stages within 2 yrs. The incidence of CKD progression within 2 years was significantly higher in pts with metabolic acidosis compared to pts with normal serum bicarbonate, irrespective of the endpoint (≥40% decline in eGFR: 38.3% vs. 20.4%, *P*< 0.0001; progression of ≥ 1 CKD stage: 66.7% vs. 54.5%, *P*< 0.0001). During the up to 11.5-yrs of follow-up (median 4.2 yrs), serum bicarbonate was independently associated with CKD progression; hazard ratios per 1 mEq/L increase in serum bicarbonate were 0.969, CI: 0.965-0.973 for a ≥40% decline in eGFR and 0.975, CI: 0.972-0.977 for progression ≥1 CKD stage.

Conclusions: In pts with non-dialysis CKD, serum bicarbonate levels below 22 mEq/L were independently associated with increased risk of CKD progression. Large randomized trials targeting treatment of metabolic acidosis to slow CKD progression are needed. There was a 2.5–3.0% risk reduction for a ≥40% decrease in eGFR or progression by ≥1 CKD stage for every 1 mEq/L increase in serum bicarbonate.

PO0470

Lower Urine Citrate Excretion Associated with Advanced CKD Stage Is Mediated by Reduced Plasma Citrate and Decreased Kidney Citrate Clearance

Nimrit Goraya,[1] Nicolaos E. Madias,[3] Abdullah A. Mamun,[2] Jan Simoni,[4] Donald E. Wesson.[2] *[1]Texas A&M University College Station, College Station, TX; [2]Baylor Scott and White Health and Wellness Center, Dallas, TX; [3]Tufts University School of Medicine, Boston, MA; [4]Surgery, Texas Tech University HSC, Lubbock, TX.*

Background: Lower urine citrate excretion (UcitV) might be a biomarker of covert acid (H^+) retention in patients with CKD but without metabolic acidosis and so mechanisms that mediate UcitV differences among patients with CKD would help assessment of its biomarker utility. Because longitudinal eGFR decreases in patients with CKD associated with decreasing UcitV (Goraya, et al. AJP 317:F502, 2019), we examined cross-sectional differences in UcitV across CKD stages and mechanisms that mediate such differences.

Methods: We measured 8-hour UcitV (8h UcitV), plasma citrate concentration (Pcit), and kidney citrate clearance citrate (UcitV/Pcit) in 52 patients with CKD 1 (eGFR=99.5±7.7 ml/min/1.73 m^2), 120 with CKD 2 (eGFR=73.4±6.1 ml/min/1.73 m^2), and 52 with CKD 3 (eGFR=40.1±7.6 ml/min/1.73 m^2) with macroalbuminuric, non-diabetic, hypertension-associated nephropathy. We assessed ongoing dietary H+ intake as potential renal acid load (PRAL) and steady-state acid-base status with plasma total CO_2 ($PTCO_2$) and H^+ retention, the latter estimated by comparing observed to expected $PTCO_2$ increase in response to retained HCO_3 (administered minus $UHCO_3V$) 2 hours after oral $NaHCO_3$ bolus (0.5 mmol/kg bw), assuming 50% body weight HCO_3 apparent space of distribution.

Results: Although PRAL was not different among CKD 1, CKD 2, and CKD 3 groups (62.4±11.9, 62.9±14.7, and 65.2±7.9 mmol/day, respectively, p=0.47), $PTCO_2$ was progressively lower (26.4±0.7, 25.9±0.6, and 21.6±1.9 mM, respectively, p<0.01) and H^+ retention progressively higher (3.9±12.9, 18.2±14.0, and 25.1 ±13.4 mmol, respectively, p<0.01) with advancing CKD stage. 8h UcitV was progressively lower with advancing CKD stage (1.14±0.03, 1.00±0.25, and 0.86±0.10 mmol/1.73m^2, respectively, p<0.01) as was Pcit (0.16 ± 0.01, 0.15 ± 0.02, and 0.14 ± 0.01 mM, respectively, p<0.01) and UcitV/Pcit (0.015 ± 0.001, 0.014 ± 0.003, and 0.013 ± 0.001 ml/min/1.73 m^2, respectively, p<0.01).

Conclusions: Cross-sectional advanced CKD stage was associated with greater H^+ retention and lower UcitV, the latter mediated by lower Pcit and lower UcitV/Pcit. The data support that reduced UcitV associated with decreased eGFR reflects underlying H^+ retention with reduced body citrate stores and increased citrate conservation through reduced kidney citrate clearance.

PO0471

Urinary Calcium Excretion and Risk of CKD Progression: The CRIC Study

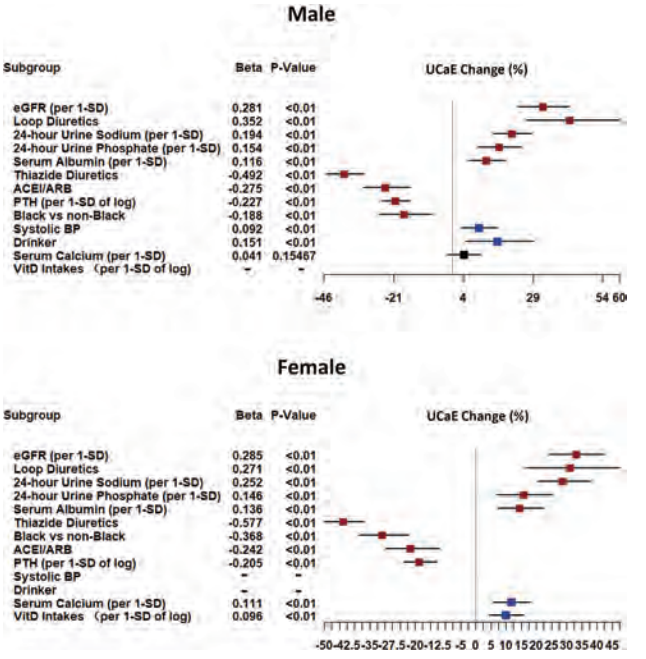
Jing Liu,[1,2] Maria Clarissa Tio,[3] Titilayo O. Ilori,[1] Ashish Verma,[3] Insa M. Schmidt,[1,3] Sushrut S. Waikar.[1,3] *[1]Renal Section, Department of Medicine, Boston University Medical Center, Boston, MA; [2]Division of Nephrology, Kidney Research Institution, West China Hospital of Sichuan University, Chengdu, China; [3]Renal Division, Brigham & Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Hypercalciuria is implicated in nephrolithiasis and nephrocalcinosis, conditions associated with chronic kidney disease (CKD). We aimed to study the determinants of urinary calcium excretion (UCaE) and its association with adverse clinical outcomes in CKD.

Methods: 24-hour UCaE was measured in 3,768 Chronic Renal Insufficiency Cohort (CRIC) participants. We used multivariable linear regression models to determine independent predictors of UCaE in CKD. Weighted Cox regression analyses tested the associations of UCaE with incident end stage kidney disease (ESKD), CKD progression (50% eGFR decline or incident ESKD), atherosclerotic cardiovascular disease (ASCVD) events, and death.

Results: Estimated glomerular filtration rate (eGFR) correlated most strongly with UCaE (r=0.417, P<0.001). In both males and females, determinants of UCaE included eGFR, African American race, iPTH, 24-hour urine sodium and phosphate, serum albumin and the use of diuretics and angiotensin receptor blockers (Figure 1). Certain predictors of UCaE differed between sexes: systolic blood pressure and alcohol drinker were associated with UCaE in males, while serum calcium and vitamin D intakes were significantly associated with UCaE in females. Higher UCaE was significantly associated with lower risk of ESKD, CKD progression, death and ASCVD events in unadjusted models. These associations were attenuated after adjusting for baseline characteristics, and for most outcomes the associations became insignificant after adjusting for eGFR.

Conclusions: Predictors of UCaE in CKD differed between males and females. eGFR is extremely strongly associated with UCaE and greatly confounds the associations between UCaE and all the outcomes.



β is from the linear model setting ln (UCaE) as dependent variable. UCaE Change= Exp(β)-1.

PO0472

Neighborhood Socioeconomic Status and Patterns of Kidney Care: Data from Electronic Health Records

Lama Ghazi,[1,2] Paul E. Drawz.[1] *[1]University of Minnesota, Minneapolis, MN; [2]Yale University School of Medicine, New Haven, CT.*

Background: Electronic health records (EHR) can be leveraged to assess quality of care measures in patients with CKD. Neighborhood socioeconomic status (SES) could be a potential barrier to receiving appropriate evidence-based therapy and follow up. Our goal was to examine whether neighborhood SES is independently associated with quality of care received by CKD patients.

Methods: EHR data for patients seen at a healthcare system in the 7-county Minneapolis/St Paul area and linked census tract data were used. Census tract SES measures used were: median value of owner occupied housing units (wealth), percentage of residents >25 years with ≥ Bachelor's degree (education), and median household income (income). A patient was considered to be living in low and high SES tracts if they belong to the first and fourth quartile of each SES measures, respectively. CKD quality of care indicators used were: prescription for ACEi/ARB in patients with moderate to severe CKD or mild CKD+UACR >300 mg/day; UACR measurement; and CKD identified on the problem list or coded for at an encounter among patients with CKD (eGFR<60 ml/min/1.73 m^2). We used a multilevel Poisson regression with robust error variance with a random intercept at the census tract level to estimate the association between each quality of CKD care measure and neighborhood SES.

Results: Of the 16,776 patients who should be on ACEi/ARB, 65% were prescribed these medications. In patients with CKD (n=25,097), UACR was measured in 27% of patients and only 55% of patients with CKD had CKD identified in their EHRs. Belonging to low neighborhood SES compared to high neighborhood SES was not associated with ACEi/ARB prescription compliance after adjusting for demographics and clinical characteristics (prevalence ratio (PR): wealth-0.96[0.91,1.03], education-1.01[0.97,1.05], income-0.97[0.94,1.02]). Neighborhood SES was not associated with UACR measurement after adjustment (PR: wealth-1.01[0.91,1.12], education-1.07[0.98,1.17], income-0.96[0.87,1.06]). Similarly, neighborhood SES was not associated with CKD identification in the EHR after adjustment (PR: wealth-1.02[0.98,1.06], education-1.03[0.98,1.07], income-1.01[0.97,1.06]).

Conclusions: Neighborhood SES is not associated with quality of CKD care received. However, adherence to CKD guidelines is low, indicating an opportunity to improve care for all patients, regardless of SES.

PO0473

Neighborhood Socioeconomic Status, Health Insurance, and CKD Prevalence: Findings from a Large Healthcare System

Lama Ghazi,[1,2] Paul E. Drawz.[1] *[1]University of Minnesota, Minneapolis, MN; [2]Yale University School of Medicine, New Haven, CT.*

Background: The association of neighborhood characteristics and insurance status with chronic kidney disease (CKD) remain unclear. Therefore, we investigated the association of neighborhood socioeconomic (SES) and insurance type with CKD prevalence.

Methods: We utilized electronic health record (EHR) data of patients seen at a healthcare system in the 7-county metropolitan area in Minnesota and linked census tract data. Census tract measures [median value of owner occupied housing units (wealth), percentage of residents >25 years with ≥ Bachelor's degree (education), and median household income (income)] and individual level insurance status (<65 years: Medicaid vs. other insurance; ≥65 years: Medicare vs. supplemental insurance plan) were obtained from the American Community Survey (2008-2012) and the EHR, respectively. A patient was considered to be living in low and high SES tracts if they belong to the first and fourth quartile of each SES measures. CKD prevalence was defined as having an estimated glomerular filtration rate (eGFR) <60/mL/min/1.73m^2 or proteinuria. We used a multilevel Poisson regression with robust error variance with a random intercept at the census tract level to estimate the association between tract SES [low (first quartile) vs. high (fourth quartile)], insurance, and CKD.

Results: We included 185,269 patients. Tract SES (wealth and education) and insurance are independently associated with CKD prevalence. After adjusting for demographic and clinical characteristics, patients (<65 and ≥ 65 years) living in low vs. high SES tracts had higher CKD prevalence (Prevalence Ratio PR, 95%CI of low vs. high tract SES for education among patients <65 years: 1.11 [1.05, 1.18] and 1.08 [1.04, 1.12] for ≥65 years). Patients (<65 years) on Medicaid vs. other insurance had higher CKD prevalence (PR, 95%CI: 1.51 [1.43, 1.60]). For patients ≥65 years, insurance type was not associated with prevalence of CKD in the fully adjusted model.

Conclusions: In conclusion, we found that patients from low SES tracts and Medicaid recipients (among patients <65 years) have greater rates of CKD compared to patients from high SES tracts and patients with other insurance. These may be two of several socioeconomic and individual factors influencing the complexity of identification, management, and treatment of CKD.

PO0474

Social Determinants of CKD in the Military Health System

Jenna M. Norton, Lindsay Grunwald, Cara H. Olsen, Eric S. Marks, Tracey L. Koehlmoos. *Uniformed Services University of the Health Sciences, Bethesda, MD.*

Background: A growing body of evidence suggests that negative social determinants of health—or social risks—contribute to socioeconomic and racial disparities in chronic kidney disease (CKD). One mechanism through which social risks appear to produce disease is by impeding access to healthcare. The Military Health System (MHS) provides an opportunity to assess CKD disparities in the context of universal healthcare.

Methods: We identified all MHS beneficiaries aged 18 to 64 who received care through the MHS from October 1, 2015 to September 30, 2018. CKD was identified by ICD-10 code and/or a validated laboratory value-based electronic phenotype for CKD. Directed acyclic graphs were developed to understand potential confounding or mediating roles of covariates. Multivariable logistic regression models were used to compare the prevalence of CKD by race, rank, zip code level median household income, and marital status, controlling separately for suspected confounders (age, sex, active duty status, service branch, and depression) and mediators (hypertension, diabetes, HIV and BMI). For family beneficiaries, the sponsor's rank and zip code were used.

Results: Of the 3,330,893 MHS beneficiaries in this analysis, 105,504 (3.2%) were identified as having CKD. In confounder-adjusted models, CKD prevalence was statistically elevated in beneficiaries of black vs white race, lower vs higher rank (as a proxy for socioeconomic status), lower vs higher income, and married vs single status (p <.0001). As expected, associations were partially or fully mitigated when further adjusting for suspected mediators, indicating the mediators may indeed be on the causal pathway between social risks and CKD.

Conclusions: Racial and socioeconomic disparities persist in CKD under the conditions of universal healthcare coverage provided by the MHS. While racial disparities may result in part from underlying genetic differences, the presence of disparities by rank and area income suggest social factors remain pertinent despite access to universal healthcare coverage.

PO0475

Low Documentation of Social Determinants of Health Among US Veterans and Medicare Patients with CKD

Yun Han,[1] Maggie Yin,[1] Diane Steffick,[1] April Wyncott,[1] Jennifer L. Bragg-Gresham,[1] Kara Zivin,[2,3] Nilka Rios Burrows,[4] Carla I. Mercado,[4] Delphine S. Tuot,[5] Neil R. Powe,[5,6] Rajiv Saran.[1] *[1]University of Michigan Division of Nephrology, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]US Department of Veterans Affairs, Ann Arbor, MI; [4]Centers for Disease Control and Prevention, Atlanta, GA; [5]University of California San Francisco, San Francisco, CA; [6]Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.*

Background: The implementation of ICD-10 codes in 2015 included new codes (Z-codes) to identify social determinants of health (SDOH). We sought to identify differences in SDOH-related Z-code (SDOH-ZC) utilization in Veterans Health Administration (VHA) and Medicare patients identifying differences in SDOH-ZC utilization in those with and without chronic kidney disease (CKD).

Methods: We used 5% sample of Medicare claims data (2015-2018) and 100% VA health data (2015-2019). A list of SDOH-ZCs were grouped into 17 categories (education and literacy, employment status, occupational risk factors, housing, economic circumstances, lifestyle factors, etc.). Proportion of claims assigned a SDOH-ZC were measured quarterly across different healthcare encounters and described by patient characteristics including age, sex, race, and hypertension, diabetes, and CKD. Use of SDOH-ZC were compared between those with and without CKD.

Results: SDOH-ZCs appeared more frequently in the VA health system than in Medicare data (Fig 1.a-b). Tobacco use was the most common SDOH-ZC in both the Medicare and VA data. More SDOH-ZCs were evident in the VA employment, environment, housing and economic, and family circumstances. Compared to those without CKD, use of SDOH-ZC was higher in individuals with CKD in outpatient settings but lower among those with inpatient visits, observation stays, and emergency department visits (Fig 1.c-d).

Conclusions: We observed lower recording of SDOH overall and among those with CKD in health care settings. Additional efforts might consider increasing SDOH documentation to help assess need for social services, which could potentially reduce disparities in health outcomes by socioeconomic status.

Funding: Other U.S. Government Support

PO0476

Association of Health-Related Social Needs with Kidney Protective Measures in an Urban Population

Tessa K. Novick,[1] Dingfen Han,[2] Elizabeth A. Jacobs,[1] Michele K. Evans,[3] Alan B. Zonderman,[3] Deidra C. Crews.[2] *[1]University of Texas at Austin Dell Medical School, Austin, TX; [2]Johns Hopkins University, Baltimore, MD; [3]National Institute on Aging, Bethesda, MD.*

Background: Health-related social needs are individual-level social determinants of health, such as food insecurity and housing insecurity. Maintaining blood pressure ≤130/80 mmHg, hemoglobin a1c ~7%, sodium intake <2 g/day, regular physical activity, BMI 20-25 kg/m^2, and smoking cessation reduce risk of CKD and CKD progression. We evaluated whether having unmet needs was associated with achieving kidney protective measures.

Methods: We performed a cross-sectional analysis of data from the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study (Baltimore, MD) during study visit 4. We used multivariable regression to quantify associations between having and least one unmet social need (food insecurity or housing insecurity), and the number of protective measures met (BP ≤130/80 mmHg, a1c 6.5-7.5%, daily sodium intake <2g, BMI 20-25 kg/m^2, physical activity, non-smoker), and each measure independently.

Results: Among 1805 HANDLS participants, 899 (49.8%) reported at least one unmet health-related social need. Compared to those without unmet needs, those with unmet needs were younger (mean age 55.0 versus 57.8 years), more likely to be black (63.7% versus 58.5%), report income <125% of federal poverty level (46.8% versus 31.9%), and had higher eGFR (mean 90.0 versus 85.8 ml/min/1.73m^2). The likelihood of achieving a higher number of protective measures was significantly lower for those with unmet needs compared to those without unmet needs (**Table**). Having unmet needs was significantly associated with lower likelihood of being a non-smoker and engaging in physical activity.

Conclusions: Individuals with unmet social needs may be less likely to achieve measures to prevent incident CKD and CKD progression.

Association Between Unmet Health-related Social Needs and Kidney Protective Measures

	Total # measures	BP ≤130/80 mmHg	HgbA1c 6.5-7.5%	Sodium <2g/day	BMI 20-25 kg/m2	Physical activity	Non-smoker

PO0477

Association Between Air Pollution and Renal Outcomes: A Systematic Review and Meta-Analysis

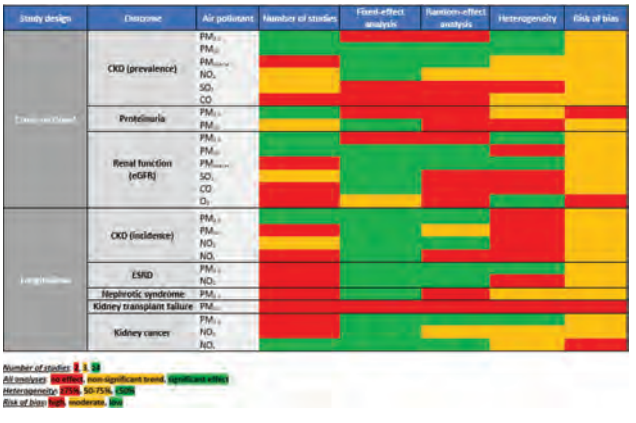
Aghiles Hamroun,[1,2] Aurore Camier,[3] Jean Joel Bigna,[4] François Glowacki.[1]
[1]Centre Hospitalier Regional Universitaire de Lille, Lille, France; [2]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [3]INSERM, UMR1153 Center for Research in Epidemiology and StatisticS (CRESS), Research Team on Early Life Origins of Health (EAROH), Paris, France; [4]Centre Pasteur, Yaounde, Cameroon.

Background: Although several risk factors of chronic kidney disease (CKD) have been well-established, mainly diabetes and hypertension, many remain less studied, such as chronic exposure to air pollution. Our purpose is to exhaustively summarize the current evidence on the association between air pollution and various renal outcomes.

Methods: We searched EMBASE, Pubmed, Web of Science, Cochrane library, and CINAHL database, for relevant records using a combination of keywords related to the type of exposure (O_3, CO, NO_x, NO_2, SO_2, $PM_{2.5}$, PM_{coarse}, and PM_{10}) and outcome (CKD, end-stage renal disease -ESRD-, proteinuria/albuminuria, renal function, kidney transplant failure, nephrotic syndrome, and kidney cancer). Using random-effects meta-analyses, we pooled summary statistics (hazard ratios, odds ratios, or beta-coefficients with their respective 95% confidence intervals) associated with a standardized increased level of each pollutant and presented the results by air pollutant and outcome. Heterogeneity has been assessed using the $\chi 2$ test on Cochran's Q statistic and quantified I2 calculation.

Results: Within 1214 eligible studies, 42 articles fulfilling the selection criteria were included in this work (11 cross-sectional, 15 prospective, and 16 retrospective cohort studies). The most significant associations are for $PM_{2.5}$ exposure and higher risks of CKD, ESRD, and kidney cancer incidence (HR=1.24 [1.15; 1.34]; 1.27 [1.18; 1.36]; 1.26 [1.02; 1.57] respectively, per 10µg/m^3 increased level); NO_2 exposure and higher risks of CKD and ESRD incidence; PM_{10} /PM_{coarse} exposure and higher CKD prevalence, as well as lower renal function (see details in Figure 1). These results should however be interpreted with caution, due to significant between-studies heterogeneity and risks of methodological bias.

Conclusions: Chronic exposure to particulate matter and nitrite dioxide seems to be associated with poorer renal outcomes. Further studies are warranted to confirm these results.



PO0478

Living Kidney Donors from a Hotspot for CKD of Unknown Origin

Armando Armenta álvarez, Lillana Pacchiano, Francisco Rodríguez, Magdalena Madero. Nephrology Deparment, National Institute of Cardiology, Ignacio Chávez, México. *National Institute of Cardiology, Instituto Nacional de Cardiologia, México, Mexico City, Mexico.*

Background: Tierra Blanca region has been identified as a Chronic Kidney Disease of unknown origin (CKDu) hotspot. At the National Heart Institute 52 young patients with CKDu from Tierra Blanca have been transplanted from living kidney donors from the same area The objective of the study was to determine the prevalence of decreased kidney function in living kidney donors from Tierra Blanca

Methods: Medical records from 1995 to 2019 were reviewed in order to obtain anthropometric measurements, occupation, past medical history and family history Laboratory data included serum creatinine (SCr), albumin-creatinine ratio (ACR), 24 hour urinary protein-creatinine ratio (PCR), at baseline and at 1,3,5, and 10 years. Time zero kidney biopsies were obtained in a subset of the cohort. eGFR ACR and PCR were used as indicators of kidney function

Results: 32 patients were included the mean age was 36 ± 10 y and mean eGFR at donation was 95.1±15.5 mL/min. 35% worked in agriculture 50% in household 6% in construction 6% in a storage company 3% unemployed. The mean change in eGFR at 1, 3, 5, and 10 years was - 18.2 ± 12.4, -7.5 ± 19.8, -6.9 ± 19, -8.1 ± 11.9ml/min. There was a significant difference between agriculture and domestic workers in eGFR decrease at 5 and 10 years. 50% underwent time zero biopsy and 69 % had some evidence of histological damage 62% showed glomerular abnormalities 40% had glomerular sclerosis, tubulointerstitial infiltrates 31% interstitial fibrosis 50% and either medial hypertrophy or intimal fibrosis 69 % These findings were not associated to occupation In multivariate analysis using a lineal model of repetitive measurements, working in agriculture was the most important risk factor associated to eGFR decrease (p= .023)

Conclusions: Baseline histological changes were observed in the majority of the kidney donors, Agricultural work was the most important risk factors for eGFR decline

Table 1. Demographic characteristics, and difference in eGFR between groups

PO0479

Prevalence and Severity of Hyperkalemia in Patients Referred to Nephrology Consultation: Epidemiologic Data from 1106 Mexican Patients at a National Reference Hospital

Mayra Aviles,[1] L. M. Perez-Navarro,[1] Samantha Escorza Valdivia,[1] Alberto Sigfrido Benitez Renteria,[2] Rafael Valdez-Ortiz.[1] *[1]Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; [2]AstraZeneca, Ciudad de México, Mexico.*

Background: Hyperkalemia (HK, serum K > 5 mEq / L) is an electrolyte disorder that occurs frequently in patients with chronic kidney disease (CKD), heart failure. In CKD, the ability to excrete K+ is reduced, impairing quality of life and increasing morbidity and mortality

Methods: Cross-sectional retrolective, observational study. Records of adult patients who attended an outpatient Nephrology consultation in the period from February 2019 to February 2020 were included, with laboratory reports from the last 15 days prior to the date of the medical consultation. Descriptive statistics were performed, with a 95% CI and a p-value ≤0.05

Results: 1106 patient records were included. 51% (563) were women. The mean age was 55.8 ± 15.6 years. 47% of the population had Diabetes mellitus and / or hypertension as their main comorbidity and 61% were overweight or obese. HK was identified in 29% of the study population. Figure 1 shows the frequency of HK by stage of CKD. 13% of the patients who entered the study were on renal replacement therapy, of which 54% had HK. 54% of the subjects with HK were diabetic, 56% hypertensive, 25% consumed ACE inhibitors and 13% consumed NSAIDs on a regular basis and 48% had proteinuria.

Conclusions: The presence of HK is a risk factor that increases the risk for cardiovascular complications and accelerates the progression to more advanced stages of CKD. It is important to intentionally search for this alteration in all stages of CKD and implement measures that help correct and mitigate its impact on patients with CKD

PO0480

Serum Potassium and Survival Among Advanced CKD Patients Transitioning to Dialysis

Yoko Narasaki,[1] Kamyar Kalantar-Zadeh,[1] Antoney J. Ferrey,[1] Ekamol Tantisattamo,[1] Amy S. You,[1] Elani Streja,[1] Kaushik Ivaturi,[1] Cachet Wenziger,[1] Jui-Ting Hsiung,[1] Danh V. Nguyen,[1] Csaba P. Kovesdy,[2] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Most laboratories designate a wide reference range for "normal" serum potassium levels (3.5-<5.5 mEq/L), yet the precise concentrations associated with favorable outcomes in chronic kidney disease (CKD) remain uncertain. While dietary potassium is commonly restricted in CKD patients to mitigate hyperkalemia, there may be ill effects of this strategy by restricting healthy potassium-rich foods (fruits, vegetables). We hypothesized that high-normal serum potassium levels are associated with better long-term survival in advanced non-dialysis dependent (NDD) CKD patients transitioning to dialysis.

Methods: Among 43,798 US Veterans with NDD-CKD transitioning to end-stage renal disease (ESRD) over 10/2007-3/2015, we examined the association of serum potassium levels averaged over the one-year pre-dialysis transition period (pre-ESRD prelude period) with post-ESRD mortality (**Fig 1A**) using national Veterans Affairs (VA) data linked to United States Renal Disease System data. Associations of serum potassium levels (categorized as <3.5, 3.5-<4.0, 4.0-<4.5, 4.5-<5.0, and 5.0-<5.5mEq/L) with all-cause mortality were estimated using adjusted Cox models.

Results: In adjusted Cox analyses, high-normal serum potassium levels ranging from 5.0-<5.5mEq/L were associated with greater survival (ref: 4.5-<5.0mEq/L): HR (95%CI): 0.95 (0.91-0.98) (**Fig 1B**). In contrast, serum potassium concentrations at or below low-normal serum potassium ranges were associated with higher death risk (ref: 4.5-<5.0mEq/L): HRs (95%CIs) 1.07 (1.04, 1.10), 1.05 (1.01, 1.09), and 1.16 (1.06, 1.27) for serum potassium levels 4.0-<4.5, 3.5-<4.0, and <3.5mEq/L, respectively.

Conclusions: In NDD-CKD patients transitioning to dialysis, serum potassium levels in the high-normal range were associated with greater long-term survival, whereas serum potassium levels at or below low-normal ranges were associated with higher long-term death risk. Further studies are needed to determine whether dietary factors may be a potential mechanistic link underlying these relationships.

Hyperkalemia, CKD, and RAAS Inhibition: A Triad with a Fine Balance to Prevent Mortality

Luis F. Goncalves, Mario R. Raimundo. *Hospital Beatriz Angelo, Loures, Portugal.*

Background: Hyperkalemia (HK) is a common and dangerous complication of CKD. HK is also a complication of beneficial therapeutic agents acting on the RAAS. Our goal was to investigate incidence, prevalence and clinical outcomes of at least one episode of HK in a CKD population outpatient setting. Additionally, we investigated the association of HK with changes in RAAS inhibition and mortality risk.

Methods: Retrospective analysis of all adult patients referred to a nephrology clinic over a 6 years period. We included CKD stage 3 patients with at least 24 months of follow up and 3 or more serum potassium determinations. The prevalence of HK at first consultation and incidence during follow up were accessed. Patients were spited in two groups prior to analysis: A) Patients without any HK episode and B) Patients with at least one HK episode.

Results: Out of the 3008 patients referred, 575 (19.1%) met the inclusion criteria (mean age: 70.4 years; 63.7% male and 94.0% white color). Mean follow-up was 4.1±1.8 years. The prevalence of HK at first consultation was 8.7% and follow up incidence 21.7%. From this cohort, 164 (28.5%) had at least on episode of HK (Group B) and 101 (17.6%) died. During the follow up, RAAS inhibition drugs was removed or not started in 200 (34.8%) and diuretic was initiated in 165 (28.7%). At least one HK episode was associated with Diabetes (65.9 vs 42.3%, p<0.001), Heart failure (36.6 vs 28.0%, p=0.007), Macroalbuminuria (34.1 vs 21.2%, p=0.001), CKD progression (33.5 vs 16.3. p<0.001) higher frequency of diuretic initiation (38.4 vs 24.8%, p<0.001) and higher mortality (27.6 vs 13.7%, p<0.001). The independent predictors of mortality were: At least one HK episode (OR 1.82, 95% CI 1.08-3.04); Heart Failure (OR 1.97, 95% CI 1.16-3.35); Older age (OR per 1 year increase 1.04, 95% CI 1.02-1.07); CKD progression (OR 4.18, 95% CI 2.43-7.19); Patients who maintained RAAS inhibition during follow up (OR 0.50, 95% CI 0.26-0.96); Patients who started RAAS inhibition during follow up (OR 0.38, 95% CI 0.16-0.88).

Conclusions: Our study confirms that RAAS inhibition had and protector and independent impact in mortality when prescribed in CKD early stages. Patients with at least one episode of HK have a higher risk of mortality. All efforts should be made to maintain these therapeutic agents, looking for other ways to control hyperkalemia rather than stop it.

PO0482

High Serum Alkaline Phosphatase Predicts CKD Progression: Effect Modification by GFR

Francesca Mallamaci,[2,1] Graziella D'Arrigo,[1] Francesco Marino,[2] Graziella Caridi,[2] Giovanna Parlongo,[2] Daniela Leonardis,[1] Patrizia Pizzini,[1] Sebastiano Cutrupi,[1] Anna Pisano,[1] Giovanni Tripepi,[1] Carmine Zoccali.[1] *[1]CNR-IFC, Reggio Calabria, Italy; [2]Nephrology, Dialysis and Transplantation Unit, Reggio Calabria, Italy.*

Background: In the post-hoc analyses of SUSTAIN/ASSURE trials, Apabetalone, an epigenetic modulator which lowers alkaline phosphatase (AlkPhos), stabilized the GFR in patients with CV disease and GFR <60/ml/min/1.73m2. Analyzing the relationship between AlkPhos and renal outcomes in patients with CKD is useful to explore the biological hypothesis that AlkPhos is implicated in CKD progression.

Methods: We investigated the relationship between AlkPhos and the risk of a combined end-point (30% GFR loss or dialysis/renal transplantation) in 609 stage 3-5 CKD patients (mean GFR: 34.8±12.1ml/min/1.73 m2).

Results: Median AlkPhos was 91 IU/L and in the majority of patients had values below 147 IU/L (the upper limit of the normal range). Over a median follow up of 3 yrs, 200 patients had the combined end-point. In an unadjusted analysis, 1 ln increase in AlkPhos entailed a 49% risk excess for the renal end-point (HR:1.49, 95% CI 1.11-2.01, P=0.008). Adjusting for age, gender, smoking, diabetes, cholesterol, BMI, systolic BP, CV comorbidities, hemoglobin, albumin, phosphate, and hs-CRP, did not modify this association (HR:1.48, 95% CI 1.08-2.02, P=0.016). In a fully adjusted analysis testing the GFR as an effect modifier of the AlkPhos - combined renal end point link showed a GFR-AlkPhos interaction (Figure). Indeed, the risk for the combined end-point was gradually more pronounced at progressively more severe degrees of renal dysfunction (see Figure).

Conclusions: In stage 3-5 CKD patients, AlkPhos within the normal range is associated with the progression to ESRD and the GFR is an effect modifier of this relationship. These findings are compatible with the hypothesis that within the normal range of this biomarker, the risk for CKD progression by AlkPhos is amplified by CKD severity. These data are in keeping with post-hoc analyses of SUSTAIN/ASSURE trials and support the hypothesis that interventions lowering AlkPhos may mitigate CKD progression.

PO0483

The Association Between Fibroblast Growth Factor 23 (FGF-23) and Pulse Pressure (PP) in CKD Stage G5 Patients

Cristian Rodelo-Haad,[1,2] Isabel López-López,[2] Rafael Santamaria,[1,2] Juan R. Munoz-Castaneda,[1,2] Sagrario Soriano,[1,2] Mariano Rodriguez Portillo,[1,2] Alejandro Martin-Malo.[1,2] *[1]Instituto Maimonides de Investigacion Biomedica de Cordoba, Cordoba, Spain; [2]Hospital Universitario Reina Sofia, Cordoba, Spain.*

Background: FGF23 is associated with increased cardiovascular events and mortality in CKD patients. Non-classical biological effects of FGF23, such as left ventricular hypertrophy and vascular remodeling, may potentially explain this association. Experimental models suggest that FGF23 stimulates renal tubular sodium reabsorption and volume overload. It is plausible that FGF23 also increases blood pressure. The linking of FGF23 increment with blood pressure control may help identify novel risk factors of mortality in CKD patients. Therefore, we aimed to evaluate the relationship between FGF23, blood pressure control, and indirect signs of arterial stiffness in subjects with CKD G5

Methods: Clinical and analytical variables were analyzed in 159 CKD G5 patients immediately before starting kidney replacement therapy. The association between these variables and the levels of intact FGF23 (iFGF23) was evaluated with linear regression models. PP was used as an indirect surrogate of arterial stiffness. Statistics were performed using R v3.6.2

Results: The mean SBP was 158.8±21.3 mmHg, whereas the mean DBP was 87.2±12.3 mmHg, and the mean PP was 76.6±20 mmHg. The median iFGF23 was 468.3 (268.8—904.9) pg/ml. iFGF23 was positively correlated with serum phosphate (p<0.001), plasma sodium (p=0.02), C-reactive protein (p<0.01), SBP (p<0.001), DBP (<0.01) and PP (p=0.02). Linear multivariable analysis (Table1) showed that iFGF23 was independently associated with the increase in SBP, DBP, and PP, suggesting that for each 10 pg/ml increase in iFGF23, the SBP increased 3.7 mmHg, the PAD increased 3.0 mmHg, and PP increased 2.1 mmHg. By every ten years of increment in age, PP increased 2.4 mmHg (p<0.01).

Conclusions: The increase in FGF23 is associated with higher SBP, DBP, and PP. These data suggest that iFGF23 may increase the risk of cardiovascular events in patients with CKD G5 through increasing blood pressure and arterial stiffness.

	SBP (mmHg)		DBP (mmHg)		PP (mmHg)	
	Beta	p*	Beta	p*	Beta	p*
iFGF23 (pg/ml)	0.37	<0.0001	0.30	0.003	0.21	0.04
Age (yr)	—	—	0.28	0.003	0.24	<0.01

PO0484

Pulse Mass Index and Pulse Mass Pressure Product in CKD Patients

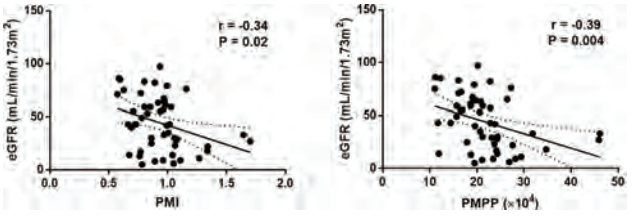
Rina Oba, Go Kanzaki, Kotaro Haruhara, Takaya Sasaki, Yusuke Okabayashi, Kentaro Koike, Nobuo Tsuboi, Takashi Yokoo. *The Jikei University School of Medicine, Division of Nephrology and Hypertension, Department of Internal Medicine., 3-25-8 Nishi-Shimbashi, Minato-ku, Japan.*

Background: Recent studies have conflicting findings on the association between obesity and the risk of chronic kidney disease (CKD). The body mass index (BMI) by itself is an imperfect marker of metabolically unhealthy obesity. The pulse mass index (PMI) and the pulse mass pressure product (PMPP) show strong correlations with the risk of cardiovascular disease and may reflect an individual's metabolic energy state. However, it is still unclear whether PMI and PMPP can be useful parameters for the risk of CKD.

Methods: We retrospectively identified 51 subjects who underwent ambulatory blood pressure monitoring and kidney biopsy simultaneously at the Jikei University Hospital, Tokyo, from 2017 to 2019. All subjects were diagnosed as primary or secondary glomerular diseases by kidney biopsy. The PMI and the PMPP were calculated from the following formula: PMI = BMI × resting heart rate (RHR) /1730. PMPP = BMI × RHR × systolic blood pressure. We evaluated the clinicopathological findings associated with PMI and PMPP.

Results: Of 51 subjects, the age was 50.3 ± 16.1 years (mean ± standard deviation), and 60.8% were male. The eGFR was 44.4 ± 25.3 mL/min/1.73m^2. The median glomerulosclerosis index (GS) was 18.3 (interquartile range, 4.7-44.4) %, and the tubular injury level was 17.5 (5.0-36.3) %. The PMI was 0.94 ± 0.23, the PMPP was 21.6 ± 7.3 ×10^4, and the BMI was 22.9 ± 4.47 kg/m^2. Both PMI and PMPP were positively associated with GS, HbA1c, and triglyceride, whereas negatively associated with eGFR (P = 0.02 and 0.004; respectively), CKD stages (P = 0.04 and 0.02; respectively) and HDL. Of note, each parameter such as BMI, RHR, and blood pressure was not correlated with either eGFR or CKD stages.

Conclusions: We observed correlations between both PMI and PMPP and kidney function. This study indicates that PMI and PMPP may be possible makers of the relative risk of unhealthy obesity with CKD.



PO0485

Thyroid Status and Mortality Among CKD Patients Transitioning to Dialysis

Jia Li,[1] Amy S. You,[1] Gregory Brent,[2] Elani Streja,[1] Dorsa F. Maryska,[3] Monica Thornhill-Joynes,[3] Yoko Narasaki,[1] Jui-Ting Hsiung,[1] Cachet Wenziger,[1] Christina Park,[1] John J. Sim,[4] Danh V. Nguyen,[1] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]Kidney Specialists Medical Corporation, Los Angeles, CA; [4]Kaiser Permanente Southern California, Pasadena, CA; [5]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Hypothyroidism has been associated with higher death risk in non-dialysis dependent chronic kidney disease (NDD-CKD) and end-stage renal disease (ESRD) patients, presumably due to cardiovascular pathways. We examined whether pre-ESRD thyroid status is a predictor of survival in NDD-CKD patients transitioning to dialysis.

Methods: Among US Veterans with NDD-CKD transitioning to dialysis from 10/2007-3/2015, we examined the association of serum thyrotropin (TSH) levels averaged over a three-year pre-ESRD transition period ("pre-ESRD prelude period") with post-ESRD mortality. Patients were followed for the outcome for up to three-years, and HRs for all-cause mortality were estimated using expanded case-mix+laboratory adjusted Cox models. In sensitivity analyses, we examined varying pre-ESRD prelude and post-ESRD mortality intervals.

Results: Among 43,161 patients in the primary cohort (three-year pre-ESRD prelude cohort), increasingly higher TSH levels >3.0mIU/L were associated with incrementally higher mortality (ref: TSH 0.5-<3.0mIU/L): adjusted HRs (95%CI) 1.04 (0.95-1.13), 1.04 (1.00-1.07), and 1.16 (1.11-1.22) for TSH levels of <0.5, 3.0-5.0, and >5.0mIU/L, respectively. A similar pattern of findings was observed for patients whose TSH levels were examined over one-year and two-year pre-ESRD prelude periods, with follow-up for the outcome of interest for up to one and two years, respectively.

Conclusions: There was a dose-dependent relationship between higher pre-ESRD TSH levels exceeding 3.0mIU/L and higher post-ESRD mortality in NDD-CKD patients transitioning to dialysis. Further studies are needed to determine the underlying determinants of thyroid dysfunction in CKD, and whether reduction of TSH levels with thyroid hormone supplementation ameliorates mortality in this population.

PO0486

Baseline Characteristics of Non-Dialysis CKD Patients with and Without Anemia: A Report from the Retrospective Cohort from DISCOVER CKD

Eric T. Wittbrodt,[1] Juan J. Carrero,[2] Glen James,[3] Steven Fishbane,[4] Supriya R. Kumar,[1] Roberto Pecoits-Filho,[5,6] Juan Jose Garcia Sanchez,[3] Carol A. Pollock,[7] James A. Sloand,[1] Katarina Hedman,[8] David C. Wheeler.[9]
[1]AstraZeneca, Gaithersburg, MD; [2]Karolinska Institutet, Stockholm, Sweden; [3]AstraZeneca UK Ltd, Cambridge, United Kingdom; [4]Northwell Health, Manhasset, NY; [5]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [6]Arbor Research Collaborative for Health, Ann Arbor, MI; [7]University of Sydney, Sydney, NSW, Australia; [8]AstraZeneca, Gothenburg, Sweden; [9]University College London, London, United Kingdom.

Background: Anemia is a frequent complication of chronic kidney disease (CKD), associated with adverse clinical outcomes and reduced quality of life. This analysis describes baseline characteristics of non-dialysis dependent (NDD) CKD patients with and without anemia in DISCOVER CKD.

Methods: The DISCOVER CKD retrospective cohort of patients in this analysis were extracted from the TriNetX health research network, Japan Medical Data Vision (JMDV) and integrated Limited Claims and EHR (LCED) databases. Patients were aged >18 years with 2 estimated glomerular filtration rate (eGFR) measures <60 mL/min/1.73m2 >90 days apart between January 2008 and March 2020. The index date was the first Hb measure (regardless of value) or an anemia therapy (iron, ESA or blood transfusion) prescription after the 2nd eGFR measure. Exclusion criteria included: <1-year registration/medical history prior to index, active bleeding, a Hb value (only) within 30 days from transfusion or bleeding and no Hb measure within a year after CKD diagnosis. Anemia was defined as <12 g/dL [females], <13 g/dL [males] per WHO criteria. Baseline characteristics were summarized and stratified by presence of anemia.

Results: Preliminarily**,** of 709183 CKD patients meeting our I/E criteria, 67% were not anemic at baseline. In patients with anemia (33%): 191451 (81%) had a baseline Hb of 10-12(female)/10-13(male)g/dL, 36889 (16%) 8-10g/dL and 6906 (3%) <8g/dL. Compared to patients without anemia: patients with anemia were older, more likely to be female, to have more advanced CKD, and more likely to have comorbidities.

Conclusions: In routine clinical care, the presence and severity of anemia increases as CKD advances and is associated with a higher comorbidity burden.

Table 1 - Prevalence and baseline characteristics of CKD patients with and without anemia.

Non-anemic patients includes all patients fulfilling the I/E criteria. For anemia severity, this included patients with eligible Hb values only.

PO0487

Incidence of and Risk Factors for Incident eGFR <60 in the REasons for Geographic and Racial Differences in Stroke Study

Katharine L. Cheung,[1] Mary Cushman,[1] Deidra C. Crews,[2] Suzanne E. Judd,[3] David G. Warnock,[3] Orlando M. Gutierrez.[3] *[1]The University of Vermont Larner College of Medicine, Burlington, VT; [2]John Hopkins University School of Medicine, Baltimore, MD; [3]The University of Alabama at Birmingham School of Public Health, Birmingham, AL.*

Background: Few contemporary US cohorts examined the incidence of and risk factors for developing a low estimated glomerular filtration rate (eGFR) or whether these factors vary by race, sex or region of US residence.

Methods: We studied 11,814 black or white participants with an eGFR> 60 ml/min/1.73m^2 at baseline and who had 10-year follow-up eGFR. Low eGFR was defined as incident eGFR<60 ml/min/1.73m^2 at the second visit and ≧40% decline from baseline. Incidence rates were calculated overall and by age, sex and race groups. We used Poisson regression to calculate the risk of incident low eGFR, adjusting for demographics, socioeconomic status and clinical factors, and across race, sex and region strata.

Results: At baseline, mean age was 62 (±8.1) years, 54% were female, 36% black and 56% resided in the US stroke belt. The overall incidence of low eGFR was 9% and ranged from 4% in those aged 45-54 to 18% in those 75 years and older. Age, systolic blood pressure, diabetes, heart disease, BMI, smoking, lower income, higher education, and residence in the US stroke belt were independent risk factors for incident low eGFR. Blacks had higher risk, accounting for sociodemographic risk factors, but this was fully attenuated after adjusting for clinical factors. Low eGFR risk factors did not differ substantially by race, sex or region.

Conclusions: The higher incidence of low eGFR in black compared to white participants was accounted for by modifiable clinical risk factors. Residence in the US stroke belt was independently associated with incident low eGFR in REGARDS participants.

Funding: Other NIH Support - National Institute of Neurological Disorders and Stroke, National Institute on Aging

High Prevalence of CKD Among Individuals Living with HIV in the United States

Jennifer L. Bragg-Gresham,[1] Ann Andrews,[2] Hal Morgenstern,[3] Brenda W. Gillespie,[3] Neil R. Powe,[4] Tanushree Banerjee,[4] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]National Kidney Foundation of Michigan, Ann Arbor, MI; [3]University of Michigan, Ann Arbor, MI; [4]University of California San Francisco, San Francisco, CA.*

Background: Chronic kidney disease (CKD) is an important comorbidity among people living longer with human immunodeficiency virus (HIV). We report the prevalence, trends and characteristics of individuals with HIV in the US, with the aim of better understanding this understudied, but important risk factor for CKD.

Methods: Data from 22,626 adults aged 20-59 who had consented for HIV testing in the National Health and Nutrition Examination Survey (NHANES; 1999-2014), were analyzed. Those with HIV + vs. - serology were compared with respect to demographics, comorbidities, and social determinants of health in the full sample and those with CKD, as defined by either eGFR<60 ml/min/1.73m^2 or urine albumin to creatinine ratio of >30 mg/g. Logistic regression was used to assess the odds of CKD by HIV status. Comparisons were assessed using survey weights for all analyses.

Results: Prevalence of HIV+ remained stable, from 0.4% to 0.6% during this time period. Individuals HIV+ were older than those HIV- in both the full sample and among those with CKD. A higher proportion of HIV+ than HIV- individuals were black, current smokers, had < high school education, with income <$45k, and reported either Medicare or other government insurance (Table). Among individuals with CKD, those HIV+ had almost twice the prevalence of diabetes (30% vs. 19%, p=NS) and over 4 times higher awareness of their CKD (28% vs. 6%, p=0.002) compared to HIV-. HIV+ vs. HIV- individuals had more than twice the prevalence of CKD (15.3% vs. 7.1%, p=0.002). CKD was associated with HIV + status [unadjusted odds ratio (OR) = 2.37; 95% CI: 1.36-4.17]. Adjusting for other covariates, attenuated the association only slightly (adjusted OR=2.17; 95% CI: 1.21-3.89).

Conclusions: CKD was associated with HIV+ status among younger adults living with the disease in the US. However, larger, longitudinal studies among individuals living with HIV and CKD are needed to increase awareness of this complication among survivors of the disease.

Measure	All Tested (mean or %, 95% CI)			With CKD (Mean or %, 95% CI)

Oxygen Kinetics and Microvascular Function in CKD

Natalie J. Bohmke,[1] Meghan G. Ramick,[3,2] David G. Edwards,[2] Danielle L. Kirkman.[1,2] *[1]Virginia Commonwealth University, Richmond, VA; [2]University of Delaware, Newark, DE; [3]West Chester University of Pennsylvania, West Chester, PA.*

Background: Patients with chronic kidney disease (CKD) have reduced cardiorespiratory fitness levels that are associated with reduced quality of life and mortality. Impaired oxygen uptake kinetics create a larger oxygen deficit that promotes fatigue. CKD related microvascular dysfunction may contribute to impaired oxygen uptake kinetics by hampering oxygen delivery to the working muscle. The purpose of this study is to investigate the relationship between oxygen kinetics and a measure of microvascular function in CKD.

Methods: 13 patients with stage 3-5 CKD (Mean±SD, Age 60±14 years; eGFR 48.5±10.3 ml/min/1.73m^2) were included in the analysis. Peak oxygen consumption (VO_{2peak}) was measured via breath by breath expired respiratory gas analysis during a symptom limited graded cycle ergometry test. Oxygen kinetics were quantified as mean response time (MRT), the exponential time constant to reach 63% of steady state VO_2. MRT was analyzed from three minutes of steady state submaximal cycling (<60% VO_{2peak}). Microvascular function was assessed as cutaneous vasodilation during local heating coupled with intradermal microdialysis, measured by laser Doppler flowmetry.

Results: VO_{2peak} was 20.36±6.87ml/kg/min. A moderate inverse correlation was shown between oxygen uptake kinetics and microvascular function (Figure 1; r=-0.56, p=0.02).

Conclusions: Microvascular dysfunction may contribute to a larger oxygen deficit in CKD patients. Following further studies, microvascular function could serve as a potential treatment target to improve exercise tolerance in these patients.

Funding: Other NIH Support - Grant number: 17GRNT33670462

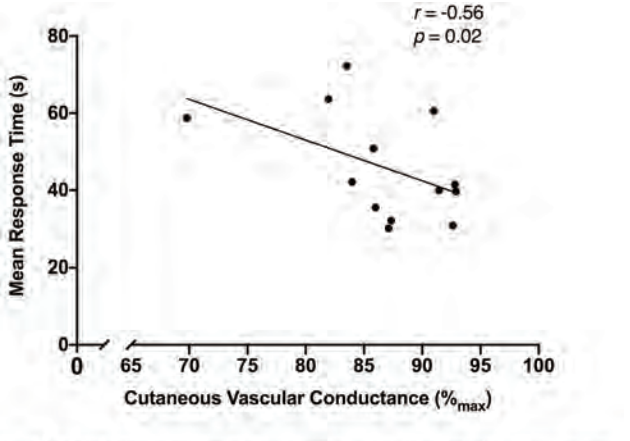

Figure 1. Reduced microvascular function (cutaneous vascular conductance) is associated with slower oxygen uptake kinetics (mean responsne time) in non-dialysis CKD patients. Cutaneous blood flow response to standardized local heating is expressed as percentage of maximal dilatory capacity obtained with local infusion of sodium nitropruisside via intradermal microdialysis.

PO0490

Trends, Prevalence, and Predictors of Illicit Drug Use in CKD Patients

Nattawat Klomjit, Api Chewcharat, Andrea G. Kattah. *Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN.*

Background: Illicit drugs use is an important problem in general populations and chronic kidney disease (CKD) patients. Since 2012, marijuana has been legalized in several parts of United States, however, the trend and prevalence of illicit drug use in CKD patients in the current era remains unknown.

Methods: We conducted a cross-sectional analysis using the data from the National Health and Nutrition Examination Survey between 2007 and 2018. We calculated the trend of self-reported illicit drug use (marijuana, cocaine, heroin, methamphetamine, and intravenous drug use) and defined current use if the last use was within 1 year of the survey. We then assessed whether the use of illicit drugs is associated with CKD (defined by estimated glomerular filtration rate ≤ 60 ml/min/1.73 m^2 and/or urine albumin-creatinine ratio (UACR) ≥ 30 mg/g), microalbuminuria (UACR≥ 30 mg/g) and macroalbuminuria (≥ 300 mg/g). Lastly, we assessed any predictors for drug use in CKD patients.

Results: Between 2007 to 2018, there were 22,214 adult patients between 18-59 years old. Of these, 2,148 had CKD as defined above. CKD patients were significantly older, more likely to be female, obese, cigarette smoker, alcohol drinker, and to have diabetes, and hypertension. We found that prevalence of marijuana (21.9% vs 21.9%, p=0.23), cocaine (4.9 vs 3.6, p=0.95) and methamphetamine (1.5% vs 1.3%, p=0.52) did not differ between CKD and non-CKD. However, heroin use (0.2% vs 0.5%, p=0.02) were significantly lower in CKD compared to non-CKD. Interestingly, there is significant trend towards increasing marijuana use in CKD patients overtime as prevalence increase from 17.3% in 2007-2010 to 21.7% in (2011-2014), and up to 26.5% in 2015-2018 (p trend 0.02). Recent Illicit drug use was not associated with CKD, microalbuminuria or macroalbuminuria. Age, black race, current smoker and alcohol drinking were significant predictors of drug use within 1 year in CKD patients.

Conclusions: In a national sample, marijuana was the most common illicit drug use among CKD patients and the trend of marijuana use in CKD patients is increasing, likely due to marijuana legalization. Age, black race, current smoker and alcohol drinking increase the odds of illicit drug use in CKD patients.

PO0491

Evaluating the Longitudinal Association of Marijuana Use and Adverse Kidney Outcomes

Flor Alvarado,[1] Alan B. Zonderman,[3] Michele K. Evans,[2] Deidra C. Crews.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]National Institutes of Health/National Institute on Aging, Baltimore, MD; [3]Intramural Research Program, NIA, NIH, Baltimore, MD.*

Background: Marijuana use has increased for recreational and medicinal purposes, however, its long-term effects on the kidneys remain uncertain. We examined the longitudinal association of marijuana use and adverse kidney outcomes among adults living in Baltimore, MD.

Methods: We used data from the prospective Healthy Aging in Neighborhoods of Diversity across the Life Span study. Baseline exposure, defined as self-reported never, former, or current marijuana use, and covariates were obtained between 2004 and 2009. The primary outcome was incident reduced kidney function, defined as an eGFR<60 ml/min/1.73m^2. Rapid kidney function decline (defined as ≥3% eGFR decline per year) among those with a baseline eGFR>=15 and incident albuminuria (albumin-to-creatinine ratio (ACR) >= 30 mg/g) at follow-up was also assessed. Participant characteristics were evaluated using ANOVA or χ^2 tests. Multivariable-adjusted logistic regression was used to evaluate associations of marijuana use with kidney outcomes. Covariates included baseline eGFR, age, sex, race, education, poverty status; current cigarette, opiate, cocaine use; hypertension, diabetes, and body mass index (BMI).

Results: Among 1,529 participants, 54.5%, 31.8% and 13.7% reported never, former, or current marijuana use, respectively. Participants with current marijuana use were more likely to be younger, male, African American, have lower BMI and concurrently use cigarettes, opiates and/or cocaine; but were less likely to have hypertension or diabetes. Mean follow-up time was 8.6 years. 337 deaths occurred in this cohort, but there was no significant difference in deaths between marijuana exposure groups (Pearson χ^2, p= 0.524). After adjustment, marijuana use was not significantly associated with incident reduced kidney function (OR 1.08 [95% CI, 0.49-2.36] among those with current use, and OR 0.90 [95% 0.49-1.61] for former use). Marijuana use was not significantly associated with rapid kidney function decline (OR 0.73 [95% CI, 0.42-1.27] for current use) or incident albuminuria (OR 0.63 [95% CI, 0.11-3.48] for current use).

Conclusions: In this Baltimore-based cohort, there was no independent association of marijuana use and longitudinal adverse kidney outcomes.

Life's Simple 7 and CKD Progression: Results from the Mexico Chronic Renal Insufficiency Cohort (MCRIC) Study

Magdalena Madero,[2] Ana P. Hernandez Martinez,[2] Ana K. Fernandez Yepez,[2] Jinsong Chen,[1] Claire T. Larkin,[1] Natalie Meza,[1] Eunice Carmona,[1] Christopher G. Viamontes,[1] Carlos L. Morales Cruz,[2] Zuleyma T. Vasquez Vasquez,[2] Tania J. Ramos Estrada,[2] Areli d. Avalos Galicia,[2] Bernardo Moguel,[2] Carlos Linares Koloffon,[1] Ana C. Ricardo,[1] James P. Lash.[1] *[1]University of Illinois at Chicago, Chicago, IL; [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Background: The American Heart Association developed the Life's Simple 7 metric to promote cardiovascular health. We evaluated the association of this metric with chronic kidney disease (CKD) progression among individuals with CKD living in Mexico.

Methods: MCRIC is an ongoing, prospective observational cohort study of adults with CKD recruited in Mexico City, with entry estimated glomerular filtration rate (eGFR) 20-70 ml/min/1.73 m^2. Using data from 371 participants, we conducted Cox proportional hazards regression analysis to evaluate the association between Life's Simple 7 (score range 0-14) and CKD progression (30% decline in eGFR from baseline).

Ideal cardiovascular health was defined as nonsmoker; body mass index <25 kg/m^2; ≥150 minutes/week of physical activity; healthy dietary pattern (high in fruits and vegetables, fish, and fiber-rich whole grains; low in sodium and sugar-sweetened beverages); total cholesterol <200 mg/dL; blood pressure <120/80 mm Hg; and fasting blood glucose <100 mg/dL).

Results: At study entry, mean age was 57 years, 71% were male, and 57% had diabetes. The mean baseline eGFR was 47 ml/min/1.73m^2, and the median urine protein excretion 633 mg/24 hours. Nine percent met all seven criteria for ideal cardiovascular health. During a median follow-up of 2.9 years, there were 78 CKD progression events. In sex- and age-adjusted analysis, each point higher Life's Simple 7 score was associated with 13% lower risk of CKD progression (HR, 95% CI, 0.87, 0.78-0.96). This association attenuated after adjusting for baseline eGFR and proteinuria (0.94, 0.83-1.05).

Conclusions: In this cohort of adults with CKD in Mexico, the prevalence of ideal cardiovascular health as measured by Life's Simple 7 was low. The protective effect of Life's Simple 7 on CKD progression was explained by baseline kidney function.

Facilitators and Barriers to Self-Management of CKD

Sarah J. Schrauben,[1] Eleanor Rivera,[1] Sandra Amaral,[2,1] Laura M. Dember,[1] Harold I. Feldman,[1] Frances K. Barg.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Self-management is integral for the treatment of chronic kidney disease (CKD). Despite low adherence to self-management behaviors, few studies provide insight into barriers and facilitators of self-management from the perspective of patients.

Methods: Semi-structured interviews were conducted with 30 participants who were purposively recruited for representation by CKD stage (3 or 4), age (<65, ≥65 yrs), race (white, non-white), and sex. Interviews focused on patient experiences with CKD and efforts to follow treatment recommendations. They were recorded, transcribed, and entered into NVivo 12.0 for coding and analysis. Transcripts were coded inductively and analyzed thematically.

Results: We identified three key phases of CKD self-management behavior engagement: prioritization, participation, and maintenance. Facilitators and barriers were organized according to these phases. Participants needed to **prioritize** the behavior to consider engagement, which was favorably influenced by optimism, stress management, and effective patient-provider communication. Prioritization was impeded by fatalism and competing priorities. One of the most widely reported impediments to behavior **performance** was comorbid conditions that caused treatment burden and adverse symptoms. Notable facilitators of behavior performance included the presence of motivating factors, self-efficacy, social support, low cost, and convenience. For **maintenance**, participants' ability to integrate and sustain behaviors in their lives was influenced by the aforementioned behavior performance factors, but also by behavior-specific factors, such as pets and physical therapy (for physical activity) and pharmacy assistance (for medication adherence). Key elements of effective maintenance included the use of memory aids, goal-setting, self-monitoring, and proactive preparation.

Conclusions: Individuals who adhered to CKD self-management behaviors viewed them as a priority, and developed strategies that fit their life to allow for behavior performance and maintenance. To increase self-management behavior prioritization, performance, and maintenance, we need to assess patients' attitudes and beliefs, improve patient-provider communication, help patients overcome barriers such as high costs and conflicting treatment regimens, and leverage facilitators such as memory aids and goal-setting.

PO0494

Relationship Between Renal Function and Quality of Life in Patients with CKD at the Pre-Dialysis Stage

Hironori Nakamura,[1] Minoru Murakami,[3] Anayama Mariko,[1] Shigekazu Kurihara,[1] Yasushi Makino,[1] Masaki Nagasawa,[1] Naoki Kashihara,[2] Kunihiro Yamagata,[2] Takashi Wada,[2] Ichiei Narita,[2] Hirokazu Okada.[2] *[1]Department of nephrology, Shinonoi General Hospital, Nagano, Japan; [2]REACH-J Steering committee, Tukuba, Japan; [3]Department of Nephrology, Saku Central Hospital, Saku, Japan.*

Background: There have been several studies evaluating the effect of kidney function on health-related quality of life (HRQOL). However, the association between kidney function and the burden of kidney disease, symptoms, and the effects of kidney disease among patients with advanced-stage kidney disease remains unclear.

Methods: The nationwide prospective Reach-J cohort study was successfully conducted. Of these patients, 2,248 with advanced chronic kidney disease (CKD) stage G3b (n = 632), G4 (n = 1010), and G5 (n = 606) were included in our study. A questionnaire regarding the kidney-disease-specific domains of quality of life (QOL) including burden, symptoms, and the effects of kidney disease at the baseline was cross-sectionally evaluated. Moreover, factors influencing the QOL were studied.

Results: Patients' characteristics were as follows: age, 69.1±12.6 years; male, 64.6%; estimated glomerular filtration rate, 23.2 ± 10.4 mL/min/1.73m^2; and serum creatinine level was 2.64 ± 1.49 mg/dL. The rates of comorbidities were as follows: diabetes, 33.6%; hypertension, 87.3%; ischemic heart disease, 8.2%; and chronic obstructive pulmonary disease (COPD), 2.3%. Crude scores in CKDG4 and CKDG5 as comparison to CKDG3b were as follows: burdens, -8.7 and -17.5; symptoms; -2.1 and -4.5; effects of kidney disease, -4.4 and -8.1, respectively. After adjusting for age, sex, body mass index (BMI), diabetes, hypertension, ischemic heart disease, COPD, and CKD stage; multivariate analysis to identify independent factors that caused reduced QOL scores revealed that age (β = 0.053, p = 0.024), BMI (β = 0.091, p < 0.001), diabetes (β = –0.058, p = 0.014), and CKD stage (β = –0.25, p < 0.001) were significant factors for burden; that age (β =–0.153, p < 0.001), diabetes (β =–0.093, p < 0.001), and CKD stage (β =–0.11, p < 0.001) were significant factors for symptoms; and that age (β = –0.128, p < 0.001), BMI (β = 0.067, p = 0.005), diabetes (β = –0.066, p = 0.006) and CKD stage (β = –0.196, p < 0.001) were significant factors for the effects of kidney disease.

Conclusions: This study suggests that the progression of CKD stage could be associated with a reduction in some aspects of HRQOL in advanced-stage CKD patients.

PO0495

Patterns of Hospital Admissions Among Patients with CKD

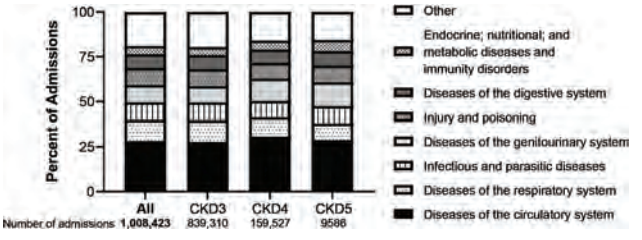
Kathryn S. Gray, Dena E. Cohen, Steven M. Brunelli. *Davita Clinical Research, Minneapolis, MN.*

Background: Although chronic kidney disease (CKD) is relatively common in the United States, an understanding of the frequency, causes, and costs of hospital admissions among patients with CKD at the national level is lacking.

Methods: Study data were derived from the Centers for Medicare & Medicaid Services 100% claims sample (2017-2018). Included patients were adults enrolled in Medicare Parts A and B who had a claim including a diagnosis code for CKD stage 3, 4, or 5 during 2017; exposure was ascribed as the most severe observed stage. Patients with evidence of commercial insurance, diagnosis of end-stage kidney disease, dialysis treatment, or death, prior to 31 Dec 2017 were excluded. Hospital admissions and paid costs were considered from 01 Jan 2018 through the first of 31 Dec 2018 or censoring for loss of Medicare Part A, dialysis initiation, or death. Hospitalization causes were ascribed on the basis of ICD-10 codes, grouped using Clinical Classification Software Level 1 categories.

Results: A total of 1,352,401 patients with CKD3, 208,963 patients with CKD4, and 16,159 patients with CKD5 met eligibility criteria. Annual hospitalization rates were 0.66, 0.87, and 0.77 admissions/patient-year among patients with each CKD stage, respectively. Across all 3 stages, admissions for "Diseases of the Circulatory System" accounted for approximately 25% of hospitalizations, with "hypertension with complications and secondary hypertension" contributing approximately half of the hospitalizations in this category. Considerable regional variation was observed with respect to annual hospitalization costs among this population, with the Southwest, Northeast, and Mid-Atlantic regions tending to have higher costs than other parts of the country.

Conclusions: Patients with CKD are frequently hospitalized, with associated costs that display marked regional variation. Clinically and regionally targeted programs may result in improved patient outcomes and lower health care costs.



PO0496

Critical Care Resource Use in CKD in the Safety-Net Setting

Jefferson L. Triozzi, Jingbo Niu, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: Chronic kidney disease (CKD) is associated with adverse outcomes among patients with critical illness. There is limited data on the extent of critical care resource use among patients with CKD in safety-net settings.

Methods: We conducted a retrospective cohort study of patients in a safety-net healthcare system with non-dialysis-dependent CKD and critical illness, defined as admission or transfer to the intermediate or intensive care unit. Poisson regression was used to identify risk factors for critical illness based on sociodemographic factors, comorbidities, and baseline stage of CKD. Critical care resource use was extracted from the medical record, including dialysis initiation, ventilatory support, blood products, and vasoactive medications. Results were stratified by baseline stage of CKD.

Results: Out of 1,298 patients with CKD who were hospitalized during a three-year period (stage 3a- 43%, stage 3b- 35%, stage 4- 22%), 495 patients required intermediate or intensive care. In the multi-adjusted model [IRR (95% CI)], critical illness was associated with stage of CKD [stage 3a- 1 (referent), stage 3b- 1.24 (1.10,1.40), stage 4- 1.99 (1.72, 2.30)]. Hispanic and non-Hispanic black race, congestive heart failure, and moderate/severe anemia were also associated with risk of receiving critical care (Table 1).

Conclusions: We report a high burden of hospitalizations requiring critical care resources in a safety-net setting. Notably, a third of patients with CKD stage 4 and critical illness required hemodialysis initiation. Further research is needed to prevent critical illness and the need for critical care resources in patients with CKD.

	CKD Stage 3a	CKD Stage 3b	CKD Stage 4
Number of patients hospitalized, n			
Any hospitalization	554	456	288
Hospitalization with critical illness	193	173	129
Risk of hospitalization with critical illness, IRR (95% CI)[1]			
Female Sex	0.67 (0.57, 0.78)[t]	0.81 (0.67, 0.99)[t]	1.01 (0.75, 1.35)
Hispanic Race	1.64 (1.25, 2.16)[t]	2.38 (1.63, 3.48)[t]	1.50 (0.89, 2.52)
Non-Hispanic black race	1.18 (0.89, 1.55)	1.71 (1.17, 2.49)[t]	1.78 (1.07, 2.98)[t]
Congestive Heart Failure	3.75 (3.13, 4.49)[t]	1.51 (1.20, 1.91)[t]	1.45 (1.03, 2.04)[t]

PO0497

Usual Source of Care and Clinical Outcomes in Adults with CKD: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study

Stephanie M. Toth-Manikowski,[1] Jesse Y. Hsu,[2] Michael J. Fischer,[1] Jordana B. Cohen,[2] Claudia M. Lora,[1] Thida C. Tan,[3] Jiang He,[4] Raquel C. Greer,[5] Matthew R. Weir,[6] Sarah J. Schrauben,[2] Milda R. Saunders,[7] Ana C. Ricardo,[1] James P. Lash.[1] *[1]University of Illinois at Chicago, Chicago, IL; [2]University of Pennsylvania, Philadelphia, PA; [3]Kaiser Permanente Northern California, Oakland, CA; [4]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [5]Johns Hopkins Medicine, Baltimore, MD; [6]University of Maryland School of Medicine, Baltimore, MD; [7]University of Chicago, Chicago, IL.*

Background: In general populations, having a usual source of care (USOC) increases use of preventive care and is associated with higher survival. However, there are limited data in adults with chronic kidney disease (CKD).

Methods: In the CRIC Study, we categorized participants' self-reported USOC as follows: 1) clinic/doctor's office, 2) emergency room (ER)/urgent care, and 3) other. Using multivariable regression analyses, we evaluated the association between USOC and incident end stage renal disease (ESRD), cardiovascular events (myocardial infarction, heart failure, stroke and peripheral arterial disease), hospitalizations, and all-cause death.

Results: Among 3,140 participants, mean age was 65 years, 45% were non-Hispanic white, 43% non-Hispanic black, 9% Hispanic, and mean estimated glomerular filtration rate (eGFR) was 50 mL/min/1.73m^2. 90% identified clinic/doctor's office as USOC, 9% ER/urgent care, and 1% other. Over a median follow-up time of 3.6 years, there were 288 deaths, 181 incident ESRD events, 444 cardiovascular events, and 7,957 hospitalizations. In multivariable analyses, compared to clinic/doctor's office as USOC, ER/urgent care was associated with higher risk for death and hospitalizations (**Table**). No significant association was seen with incident ESRD or cardiovascular events.

Conclusions: ER/urgent care as USOC was associated with higher risk for adverse outcomes in this large and diverse adult cohort with CKD. Further studies are needed to identify barriers to accessing appropriate preventive care to reduce negative health outcomes in this population.

Funding: NIDDK Support

Association between usual source of care (ER/urgent care vs. clinic/doctor's office) and outcomes

Outcome	HR (95% CI)
Incident ESRD	0.86 (0.49-1.52)
Cardiovascular Events	1.28 (0.94-1.75)
All-Cause Death	1.53 (1.05-2.23)*
	RR (95% CI)
Hospitalizations	1.41 (1.32-1.51)*

PO0498

Healthcare Resource Utilisation and Costs of CKD According to the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD Retrospective Cohort

Juan Jose Garcia Sanchez,[1] Juan J. Carrero,[2] Supriya R. Kumar,[3] Hiddo J. L Heerspink,[4] Glen James,[1] Stephen Nolan,[1] Lam S. Carolyn,[5,6] Hungta (tony) Chen,[3] Alyshah Abdul Sultan,[1] Carol A. Pollock,[7] Roberto Pecoits-Filho.[8,9] *[1]AstraZeneca, Cambridge, United Kingdom; [2]Karolinska Institutet, Stockholm, Sweden; [3]AstraZeneca, Gaithersburg, MD; [4]Rijksuniversiteit Groningen, Groningen, Netherlands; [5]National Heart Centre Singapore, Singapore, Singapore; [6]Duke-NUS Medical School, Singapore, Singapore; [7]Royal North Shore Hospital, St Leonards, NSW, Australia; [8]Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; [9]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: The DAPA-CKD trial finished early due to overwhelming efficacy. Real-world data reporting healthcare resource utilization (HCRU) and cost associated with CKD categorized according to the 2012 KDIGO recommendations are scarce. We assessed HCRU and costs in a "DAPA-CKD-like population" (eGFR 25-75ml/min/1.73m^2 and UACR 200-5000mg/g) compared to patients categorized according to KDIGO 2012 recommendations.

Methods: DISCOVER CKD is an observational study in patients with CKD, data was extracted using the integrated Limited Claims and Electronic Health Record data. Patients were aged ≥18 years, with ≥1 UACR measure and two eGFR measures of 0-75ml/min/1.73m^2 recorded at least 90 days apart between January 2008 and September 2018. Index date was 2nd eGFR. We calculated total and annualized number of encounters and estimated annualized per-patient and total costs. Incidence rates per 100 person-years (PY) were estimated for outpatient and hospitalization events.

Results: Preliminarily, 6270 patients met the KDIGO 2012 definition (mean[SD] age 64.0(10.9) years, 51.0% female) and 383 patients met the DAPA-CKD-like criteria (mean[SD] age 64.0(11.9) years, 38.9% female). The rate of hospitalizations almost doubled for the DAPA-CKD-like population vs the KDIGO 2012 defined population (Rate 100-PY[95CI] 59.0[53.7-64.8] vs 26.4[25.5-27.3]) and length of stay was also higher (Mean[SD] 6.5[9.4] vs 5.4[6.6] days). The DAPA-CKD-like population incurred substantially higher annualized per patient hospitalization costs (mean[SD] USD39782[78572] vs USD25717[60019]); Figure 1.

Conclusions: This analysis demonstrated that the DAPA-CKD-like population is associated with a higher HCRU and cost burden. These results highlight the need for innovative therapies to improve patient outcomes in this population.

PO0499

Healthcare Resource Utilization and Costs in a DAPA-CKD-Like Population Using a Contemporary US Healthcare Cohort

Tope Olufade,[1] Lois Lamerato,[3] Juan Jose Garcia Sanchez,[2] Like Jiang,[1] Joanna C. Huang,[1] Stephen Nolan.[2] *[1]AstraZeneca, Wilmington, NC; [2]AstraZeneca UK Ltd, Cambridge, United Kingdom; [3]Henry Ford Health System, Detroit, MI.*

Background: The DAPA-CKD Trial is the first SGLT-2i renal outcome trial to test the efficacy and safety of an SGLT-2i, dapagliflozin, in patients with diagnosed CKD with and without T2D. The objective of this study is to assess the healthcare resource utilization and cost in a "DAPA-CKD-like population" (eGFR 25-75ml/min/1.73m^2 and UACR 200-5000mg/g) using a contemporary US healthcare system.

Methods: Data from the Henry Ford Health System (HFHS) were used to identify patients with CKD stages 2 through 4 between 2006 and 2016 (based on eGFR labs) and patients were followed through 2018. Patients with no confirmatory eGFR > 90 days from index date, death within 30 days, history of renal transplant, and evidence of renal replacement therapy, or progression to CKD stage 5 during the baseline period (6 months pre or post index date) were excluded. Cumulative primary and secondary utilization was evaluated for all patients during the follow-up time. Annual utilization rates are the total observed utilization divided by follow-up time. Billing records with HFHS were used to estimate costs.

Results: 6,557 patients (mean age 62.9 years, 46.2% male) met the eligibility criteria and are included in the study cohort. The population was stratified by UACR (0-<30, 30–199, 200–5,000mg/g). The DAPA-CKD-like population (200-5000mg/g) was associated with significantly higher annualized per-patient healthcare costs, $39,222/yr (UACR

200-5000mg/g) vs. $19,547/yr (UACR <30mg/g). Persons in the highest UACR category were almost three times more likely to have a hospital admission compared to the lowest (rates 0.55/year vs. 0.20/year, respectively; see Table 1).

Conclusions: This analysis of a contemporary US healthcare system demonstrated that there exists a high disease burden in the DAPA-CKD-like population as seen by the substantial increase in healthcare resource utilization and costs compared to other cohorts of patients with a lower UACR. These results highlight the need for innovative therapies to improve patient outcomes in this high risk population.

PO0500

Understanding Patterns of Medical Spend Informs Design of Upstream Intervention in CKD

Titte Srinivas. *University Hospitals, Cleveland, OH.*

Background: Despite ease of diagnosis based on laboratory testing, CKD is often unrecognized and comorbid decompensation results in delayed diagnosis in acute care settings. The purpose of our inquiry was to inform the design of systems of care that would prevent escalation of total cost of care (TCOC) of CKD through minimization of acute care spend.

Methods: Unrecognized CKD was defined as CKD that was evident by laboratory data in the EHR but not captured by an ICD10 code or DRG for chronic kidney disease. Recognized CKD or ESRD had both ICD10 and DRG data and laboratory evidence of CKD. We then compared inpatient and total medical spends as well as the density of preventive measures such as wellness visits among these groups. The data respository was built on the MS Power BI platform and machine learning and high throughput analyses were conducted using Alteryx utilities.

Results: A total of 217,125 patients were included that had eGFR and spend data in 2019. Annual wellness visits occurred on average among 38 percent (n=142,373) of those with no CKD diagnosed or evident by lab values vs. 19.1 percent of those with unrecognized Stage 3b to 4 CKD (n=31,435) vs. 18 percent among those with recognized Stage 3-5 CKD or ESRD (n= 52,242; P < 0.001). No statistical difference was observed between wellness rates and stage 1 and stage 2 unrecognized CKD cohorts. Of annual spend in 2019, those with recognized CKD/ESRD, incurred 61.9 percent of spend in the inpatient setting vs. 25 percent among those with unrecognized CKD. The number of chronic condition increased from an average of 3.5 among those with Stage 3-5 unrecognized CKD to 10 among those with recognized CKD/ESRD. Average 12 mo spend was $ 6500 among those with unrecognized CKD stage 3b-5 and $ 22,978 among those with recognized CKD/ESRD (p<.0001). A diagnosis of CHF was recorded in 13.1 %, 20.5 %, and 24.3 % of those with undiagnosed CKD stage 3a-5 vs. 46.9 percent of those with diagnosed CKD/ESRD (Chi square for trend <0.001).

Conclusions: CKD is often unrecognized clinically despite eGFR support of its existence in the medical record Decompensation of unrecognized heart disease likely contributes to increased inpatient utilization and costs with clinical recognition of CKD Wellness measures are unfortunately deficient in this population and systems of care triggered by eGFR values could inform care upstream of CKD decompensation to capture value.

PO0502

Treatment Pathways of CKD Patients Defined by the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD Retrospective Cohort

Juan Jose Garcia Sanchez,[1] Juan J. Carrero,[2] Supriya R. Kumar,[3] Roberto Pecoits-Filho,[4,5] Glen James,[1] Hiddo J. L Heerspink,[6] Stephen Nolan,[1] Lam S. Carolyn,[7,8] Hungta (tony) Chen,[3] Eiichiro Kanda,[9] Alyshah Abdul Sultan,[1] Naoki Kashihara,[9] Mikhail Kosiborod,[10] David C. Wheeler,[11] Carol A. Pollock.[12] *[1]AstraZeneca, Cambridge, United Kingdom; [2]Karolinska Institutet, Stockholm, Sweden; [3]AstraZeneca, Gaithersburg, MD; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; [6]Rijksuniversiteit Groningen, Groningen, Netherlands; [7]National Heart Centre Singapore, Singapore, Singapore; [8]Duke-NUS Medical School, Singapore, Singapore; [9]Kawasaki Ika Daigaku, Kurashiki, Japan; [10]Saint Luke's Mid America Heart Institute, Kansas City, MO; [11]University College London, London, United Kingdom; [12]Royal North Shore Hospital, St Leonards, NSW, Australia.*

Background: Treatment strategies to delay the progression of CKD focus on use of RAASi, anti-hypertensive and, for patients with type 2 diabetes, anti-diabetic therapy. Data describing treatment pathways in patients defined according to the 2012 KDIGO classification are scarce.

Methods: The DISCOVER CKD retrospective cohort of patients was extracted using the integrated Limited Claims and EHR data. Patients were aged ≥18 years, with ≥1 UACR measure and two measures of eGFR 0-75 mL/min/1.73 m^2 recorded at least 90 days apart between 2008-2018. Sankey Plots were used to visualize chronological treatment pathways (1st-3rd line) post-index, of key treatments commonly prescribed to these CKD patients including: RAASi, anti-diabetic therapy, beta-blockers and anticoagulants. We also describe median time to 1st line therapy initiation.

Results: Preliminarily, 4283 patients were prescribed key treatments during follow-up with anti-hyperglycaemic therapy and RAASi therapy being the most common 1st-line therapy, Figure 1. Median time to 1st-line therapy initiation was: 34 days for anti-diabetic therapy, 45 days for beta-blockers, 49 days for RAASi therapy and 50 days for anticoagulants. Anti-diabetic therapy and RAASi therapy accounted for the highest proportion of time in which treated patients remained on therapy during follow-up (68% and 61%, respectively).

Conclusions: We observed a high proportion of time on therapy for key pharmacological treatments during the follow-up period. However, it is well established that a substantial residual risk and unmet need exists with current standard of care.

Treatment Pathways of Patients with CKD: A Report from the DISCOVER CKD Retrospective Cohort

Glen James,[1] Juan J. Carrero,[2] Supriya R. Kumar,[3] Steven Fishbane,[4] Carol P. Moreno Quinn,[1] Hiddo J. L Heerspink,[5] Eric T. Wittbrodt,[3] Eiichiro Kanda,[6] Katarina Hedman,[7] Naoki Kashihara,[6] Hungta (tony) Chen,[3] Mikhail Kosiborod,[8] Lam S. Carolyn,[14,15] Carol A. Pollock,[9] Peter Stenvinkel,[10] Roberto Pecoits-Filho,[11,12] David C. Wheeler.[13] *[1]AstraZeneca UK Ltd, Cambridge, United Kingdom; [2]Karolinska Institutet, Stockholm, Sweden; [3]AstraZeneca, Gaithersburg, MD; [4]Northwell, Manhasset, NY; [5]University of Groningen, Groningen, Netherlands; [6]Kawasaki Medical School, Kurashiki, Japan; [7]AstraZeneca, Gothenburg, Sweden; [8]Saint Luke's Hospital of Kansas City Health Sciences Library, Kansas City, MO; [9]University of Sydney, Sydney, NSW, Australia; [10]Karolinska Universitetssjukhuset, Stockholm, Sweden; [11]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [12]Arbor Research Collaborative for Health, Ann Arbor, MI; [13]University College London, London, United Kingdom; [14]National Heart Centre Singapore, Singapore, Singapore; [15]Duke-NUS Medical School, Singapore, Singapore.*

Background: Chronic kidney disease (CKD) is a global health problem associated with clinical complications. Gaps exist in real-world data to understand treatment pathways of CKD patients. We describe treatment pathways of key medications prescribed to CKD patients in DISCOVER CKD.

Methods: The DISCOVER CKD retrospective cohort of patients were extracted using Japan Medical Data Vision (JMDV) and integrated Limited Claims and EHR (LCED) data. The study included patients aged ≥18 years with a diagnostic CKD code (stage 3A through end stage renal disease or renal replacement therapy) or 2 estimate glomerular filtration rate (eGFR) measures <75 mL/min/1.73m^2 at least 90 days apart between January 2008 and October 2018. The index date was the date of first diagnostic code or 2nd eGFR. Sankey Plots were used to visualize chronological treatment pathways (1st to 3rd line) post-index of key treatments (including combinations) commonly prescribed to at least 500 CKD patients including: RAASi, statins, diuretics and anti-hypertensives. We also describe median time to first line therapy initiation.

Results: Preliminarily, in the study cohort (N=159849) anti-hypertensives were the most common first-line therapy prescribed. Median time to first-line therapy initiation for LCED and JMDV was: 48 days and 168 days for anti-hypertensives, 39 days and 89 days for diuretics, 51 days and 259 days for RAASi and 56 days and 133 days for statins, respectively. In both databases patients remained on anti-hypertensives the most (33.7%) during follow-up.

Conclusions: Patients with CKD have high therapy burden, with varying time to initiation of therapies.

PO0504

Increased Urinary Albumin Creatinine Testing in CKD Stage 3 and Effect on Quality Metrics

Ken J. Park, Micah L. Thorp, Robert Unitan. *Kaiser Permanente Northwest, Portland, OR.*

Background: One of the goals of Advancing American Kidney Health Initiative is "reducing the number of Americans developing End Stage Renal disease by 25% by 2030." An important part in achieving this goal is increased use of interventions backed by high quality evidence including use of ACE inhibitors or ARBs, control of hypertension, and diabetes (DM) control. Albuminuria has been clearly linked to CKD progression, but evidence is lacking as to whether more frequent monitoring slows CKD progression. We were interested in whether more frequent monitoring of albuminuria via automated testing improved CKD quality metrics.

Methods: This was a cross sectional study using a CKD registry in Kaiser Permanente Northwest. The CKD registry was population-based which did not require patient consent. We compared urinary albumin creatine (ACR) testing, filled ACE inhibitor and ARB prescriptions, DM control (hgba1c < 8%), and hypertension control (blood pressure <140/90) at one time point before and after implementing a quality improvement project targeting patients with stage 3 CKD based on eGFR criteria or ICD-10 codes. A web-based tool examined the registry and ordered an ACR in those patients that did not have an ACR checked within the past year. Primary care providers received an received an alert in the electronic health record (EHR) for those patients not on an ACE inhibitor or ARB who had a renal indication. Renal indications for an ACE inhibitor or ARB were hypertension and an ACR > 30 mg/g with DM or an ACR > 300 mg/g without DM.

Results: There were 10,335 patients in the CKD registry on 12/5/2017 and 10,515 on 12/5/2019. Average age was 73, 81% had hypertension, 38% had DM, and 44% were male. Automated ACR testing in patients with stage 3 CKD was implemented on 5/23/2018. One and half years after implementation of ACR testing, ACR testing increased from 26% to 61% (p < 0.001). ACE inhibitor or ARB use among patients with renal indication did not increase significantly (79% vs. 81%, p = 0.08). Control of DM increased (78% vs. 81%, p < 0.001) while control of hypertension worsened (76% vs. 74%, p = 0.001).

Conclusions: In patients with stage 3 CKD, increased albuminuria testing via automated testing linked with EHR alerts did not results in an overall improvement in CKD quality metrics. However, our study was limited by the cross-sectional design as well as the short follow up.

PO0505

Albuminuria Testing and Prevalence and Incidence of Elevated Albuminuria

Jung-Im Shin, Alex R. Chang, Yingying Sang, Ron T. Gansevoort. CKD Prognosis Consortium *CKD Prognosis Consortium, Baltimore, MD.*

Background: Guidelines recommend an annual evaluation of urine albumin creatinine ratio (ACR) in patients with diabetes (DM) or hypertension (HTN) for early identification and close monitoring of kidney damage. The aim of this study was to inform ACR testing strategies by 1) evaluating the frequency of ACR testing, 2) determining the prevalence and incidence of ACR≥30 mg/g, and 3) developing and validating a risk prediction model for incident ACR≥30 mg/g.

Methods: We analyzed 28 cohorts from the CKD Prognosis Consortium including 1,909,350 persons with DM or HTN from 5 countries. Analysis was performed separately for persons with DM and those with HTN but without DM. We selected a two-year baseline period for administrative cohorts and used the baseline visit for research cohorts to assess frequency of testing and prevalence of a single ACR≥30 mg/g. Confirmed incident ACR≥30 mg/g (elevated twice) was assessed 5 years after baseline in those with baseline ACR<30 mg/g. Development of prediction models for incident ACR≥30 mg/g used logistic regression and age, sex, baseline systolic blood pressure, HTN and DM medication use, coronary heart disease, heart failure, BMI, A1c, and eGFR as covariates. Models were validated in 5 DM cohorts and 4 HTN only cohorts.

Results: The median frequency of ACR testing across administrative cohorts was 48.9% (IQI, 32.5-58.3%) and 4.3% (IQI, 3.2-7.1%) in DM and HTN only. Among those tested at baseline, the median prevalence of ACR≥30 mg/g was 32.7% (IQI, 28.4-37.0%) and 21.9% (IQI, 18.6-29.6%) in DM and HTN only. Among 107,754 persons with DM and 15,676 persons with HTN only who had baseline ACR<30 mg/g, the median incidence of ACR≥30 mg/g at 5 years was 23.3% (IQI, 18.6-28.5%) and 21.7% (IQI, 15.7-26.3%) in DM and HTN only. Risk prediction models for 5 year incidence of ACR≥30 mg/g had only modest accuracy in DM (median C statistic: development cohorts 0.629, IQI: 0.600-0.655; validation cohorts 0.635, IQI: 0.619-0.641) and in HTN only (median C statistic: development cohorts 0.649, IQI: 0.621-0.695; validation cohorts 0.663, IQI: 0.638-0.671).

Conclusions: ACR testing in DM or HTN is low in clinical practice. The risk prediction models for incident ACR≥30 mg/g performed only modestly, suggesting focused efforts based on risk stratification may not be a viable strategy. Universal albuminuria testing for individuals with DM or HTN is likely necessary.

Urine Albumin and Serum Creatinine Dual Testing in US Veterans: Trends and Associations with Subspecialty Care

Nicole M. Bhave,[1] Yun Han,[1] Diane Steffick,[1] Jennifer L. Bragg-Gresham,[1] Kara Zivin,[1,2] Nilka Rios Burrows,[3] Meda E. Pavkov,[3] Delphine S. Tuot,[4] Neil R. Powe,[4,5] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]US Department of Veterans Affairs, Ann Arbor, MI; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of California San Francisco, San Francisco, CA; [5]Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.*

Background: Urine albumin and serum creatinine (SCr) help define chronic kidney disease (CKD). Despite the fact that urine albumin and SCr are multiplicatively associated with cardiovascular and all-cause mortality, dual testing remains limited. We sought to characterize trends in dual testing in all veterans and those seen by nephrologists.

Methods: We used Veterans Health Administration (VA) data (2009-18). VA patients with any inpatient or outpatient visit in a given calendar year were included. Time trend of dual testing and patient characteristics including age, sex, race, hypertension, diabetes, CKD, and cardiovascular diseases (CVD) were noted.

Results: The study population included 58,508,942 patients (90.3% male). Overall, 12.5% of VA patients had both Scr and urine albumin testing in 2009 as compared with 18.6% in 2018 (Fig.A, p_{trend}<0.001). Among patients seen by nephrologists, 30.1% had both SCr and urine albumin testing in 2009, increasing to 43.3% in 2018 (Fig.B, p_{trend}<0.001). Compared to VA patients with SCr testing only, those with both SCr and urine albumin testing were older, more likely to be male, and more likely to have diabetes, hypertension, and CKD, but less likely to have CVD (p<0.001).

Conclusions: Dual SCr and urine albumin testing among VA nephrology patients is more common than among all VA patients and has increased over time, However, in a given year, less than half of nephrology patients undergo dual testing. Efforts to encourage screening for albuminuria among patients at high risk for CKD and CVD might be considered.

PO0507

Dipstick Urinalysis Can Identify Patients with Early CKD Who Lack a Quantified Proteinuria Measurement

Meredith McAdams, Duwayne L. Willett, Yu-Lun Liu, Vaishnavi Kannan, L Parker Gregg, Susan Hedayati. *University of Texas Southwestern Medical Center at Dallas, Dallas, TX*.

Background: Urine protein-to-creatinine ratio (UPCR)>0.15 g/g or albumin-to-creatinine ratio (UACR)>30 mg/g is the gold standard for identifying patients with stages 1-2 CKD with eGFR>60 mL/min/1.73m^2, but are not routinely obtained. Dipstick urinalysis semi-quantitative protein (DSP) is widely available and commonly measured.

Methods: To develop a pragmatic EHR tool to identify patients with stages 1-2 CKD, we investigated diagnostic utility of various DSP cutoffs (negative/trace, 30, 100, 300, or ≥500 mg/dL) against gold-standard proteinuria (UPCR>0.15 g/g or UACR>30 mg/g) using logistic regression. We also investigated whether addition of SG improved the diagnostic utility of DSP by comparing areas under the receiver-operating characteristic curves (AUC) for DSP with and without addition of SG. DSP was obtained from the EHR in 3,897 individuals with UPCR or UACR measured on the same date. A development model was created in a random sample of 2,728 (70%) using a bootstrap method and validated in the remaining 1,169 individuals.

Results: Mean age was 57.6±16.9 years, 51.7% were female, 25.6% Black, and 42.8% had an eGFR≤60 mL/min/1.73m^2. Gold-standard proteinuria was present in 1,775 (45.5%). DSP cutoff=30 had specificity 81.1 (95% CI 79.0, 83.1), +LR=2.43 (95% CI 2.15, 2.75), -LR=0.67 (95% CI 0.63, 0.71). The combination of DSP and SG, taken continuously, performed better than DSP alone (**Figure A**). When including SG, a DSP cutoff of 30 had the best diagnostic accuracy vs. other cutoffs (**Figure B**). In the validation cohort, addition of SG to DSP also yielded a higher AUC than DSP alone, P=0.03. For DSP ≥30 as a screening test, an SG of at least ≥1.025 is needed. A more dilute urine, with a SG of 1.020, would be allowed if DSP ≥100. A DSP cutoff of 30 had an AUC of 0.652 (0.621, 0.684), P<0.001, vs. a cutoff of 300 or 500. Using DSP≥30 identified an additional 141 individuals with CKD than use of eGFR<60 alone.

Conclusions: Combining DSP and SG from a dipstick urinalysis can identify patients with early CKD who do not have a measured UPCR or UACR.

PO0508

Prevalence of Coded and Uncoded CKD in the Military Health System

Jenna M. Norton, Lindsay Grunwald, Cara H. Olsen, Eric S. Marks, Tracey L. Koehlmoos. *Uniformed Services University of the Health Sciences, Bethesda, MD*.

Background: Despite the substantial human and financial costs associated with chronic kidney disease (CKD) and its high prevalence in the general population, little is known about rates of CKD in the nearly 9.5 million beneficiaries of the Military Health System (MHS). Diagnostic codes lack adequate sensitivity and validity for identifying CKD using health system data. Using laboratory-data may enable a more accurate assessment of the burden of CKD in the MHS.

Methods: We identified all MHS beneficiaries aged 18 to 64 who received care through the MHS from October 1, 2015 to September 30, 2018. CKD was identified by ICD-10 code and/or a validated laboratory value-based electronic phenotype for CKD. CKD was considered coded if an ICD-10 code was present and uncoded if no ICD-10 code was present. Characteristics of the coded and uncoded CKD populations were compared using two-tailed t tests (continuous variables) and Pearson's Chi Square test for independence (categorical variables).

Results: The total study population included 3,330,893 MHS beneficiaries. Of those, 105,504 (3.2%) were identified as having CKD. Of those with CKD, only 37% had an ICD-10 code for CKD. Compared to individuals with coded CKD, those with uncoded CKD were younger (average age 45 vs 52), more likely to be female, and more likely to be active duty, but less likely to be of Black race, to have diabetes or to have hypertension (p <.0001). Among those with test results recorded in the MHS, those with coded CKD had greater numbers of urine albumin, urine albumin-to-creatinine ratio, urine protein-to-creatinine ratio, serum creatine, and eGFR results (p <.0001).

Conclusions: Many MHS beneficiaries with laboratory values indicative of CKD were not coded for CKD, suggesting they may not be receiving appropriate management for this progressive and burdensome disease. Individuals with commonly recognized risk factors for CKD (e.g., older age, male sex, black race, diagnosed diabetes, diagnosed hypertension) were more likely to be coded for CKD, suggesting clinicians may be missing CKD in traditionally lower risk groups—despite available laboratory data to asses disease status.

PO0509

Factors Associated with Screening and Recognition of CKD in the VA Healthcare System

Shweta Bansal,[1,2] Michael J. Mader.[2] [1]*The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Mediciine, San Antonio, TX;* [2]*South Texas Veterans Health Care System, San Antonio, TX*.

Background: The successful implementation of interventions to improve kidney disease outcomes requires early identification of CKD which involves screening at-risk population as well as recognizing CKD. We have reported suboptimal detection of proteinuria and documentation of CKD previously and now aim to identify factors associated with these rates.

Methods: We interrogated VISN-17 database for at-risk Veterans with hypertension (HTN) and diabetes seen regularly in primary clinics during 2012-19. The final cohort (N=270,170) charts were analysed for serum creatinine/eGFR, urine protein/albumin, ICD codes for CKD, and nephrology referral. CKD was defined as eGFR <60ml/min at least twice 90 days apart and/or urine albumin creatinine ratio (uACR) of >30 mg/g. Factors were examined which could be associated with screening and recognition.

Results: As shown in table, 94.3% patients had one or other screening procedures done. Urine protein/albumin was present in 56.4% charts, the least in patients with HTN only (40%). CKD by lab evidence was present in 42%; however, only 40% of these had documented ICD-codes for CKD or nephrology referral. There was no clinically significant difference between screened vs. unscreened or recognized vs. unrecognized groups in age, sex, and BMI. Hispanic race associated with decrease screening procedures but no difference in CKD recognition. Patients were more likely to have screening procedures as well documented CKD, if they had heart disease, stroke, cancer; higher frequency of specialty care visits, hospitalizations or ER visits; or elective procedures as vascular and cardiac catheterizations. There was no difference in BP control in screened vs. unscreened group but more patients with documented CKD had BP>140/90mmHg.

Conclusions: Protienuria was detected and CKD was recognized in half of the at-risk Veterans. Co-morbidities and health care visits other than primary care associated with increased screening and recognition suggest utility of initiatives at primary care level to educate the need for CKD detection and awareness.

Spatial Distribution of Newly Detected CKD Among US Veterans, 2009-2018

Jennifer L. Bragg-Gresham,[1] Brenda W. Gillespie,[2] Yun Han,[1] Xiaosong Zhang,[1] Diane Steffick,[1] William Weitzel,[4] Susan T. Crowley,[3] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Veterans Health Administration, West Haven, CT; [4]Veterans Health Administration, Ann Arbor, MI.*

Background: While the rate of new end stage renal disease (ESRD) cases has slowed in recent years, less is known about trends in the incidence of pre-ESRD CKD. Using national data from the Veterans Health Administration (VHA) we examined the rates and spatial distribution of newly detected cases of CKD using laboratory measures.

Methods: Using data from 8.5+ million US Veterans over a decade (2009-18), in the VHA system during the previous 3 years with no indication of kidney disease, rates of newly detected kidney disease were calculated by year. Three measures of kidney disease were assessed by laboratory reports; 1) eGFR < 60 ml/min/1.73m^2, 2) albuminuria, and 3) either low eGFR or albuminuria. Spatial maps contain 3-year incidence rates (2016-18) by county, based on patient residence.

Results: Rates of newly detected low eGFR were steady from 2011 forward (~30/1,000 PY), after a drop from 55 to 31 cases between 2009 and 2011, a time when standardization of creatinine calibration to IDMS became mandatory and may explain the change in rates. Rates of newly detected albuminuria showed little variability (~10/1,000 PY). Areas of high incidence of low eGFR were present in northern Michigan, northern Indiana, central Illinois, and western North Carolina. Newly detected albuminuria was highest in coastal North Carolina, northern Idaho, northeastern Indiana, and on the border of Washington and Oregon.

Conclusions: Rates of newly detected disease reflect a combination of the true incidence rate as it presents to a health system, but is also influenced by the rate of testing for the disease in question. Despite this limitation, these findings are important for both individual and population health management, early detection, management and prevention.

Defining Criteria for CKD Stage 3 Patients Nephrology Referral: An Analysis Focused on CKD Progression and Mortality Risk

Luis F. Goncalves, Adriana Fernandes, Mario R. Raimundo. *Hospital Beatriz Angelo, Loures, Portugal.*

Background: The high prevalence of CKD and its increasing awareness by primary care clinicians. While the referral of CKD stage 4 and 5 to a nephrology clinic is undisputable, the need for stage 3 patients referral is still subject to debate. Our objective was to investigate baseline characteristics of CKD stage 3 patients associated with subsequent CKD progression, in order to help determine which patients should be referred at this stage.

Methods: Retrospective analysis of all patients referred to a nephrology clinic over 6 years. We included CKD stage 3 patients with at least 36 months of follow-up or 24 of follow up with more than 3 serum creatinine determinations. CKD progression was defined by one of the following: 1) an eGFR decline superior to 5mL/min/year; 2) creatinine duplication; 3) The need for chronic RRT. Baseline covariates included demographics, comorbid conditions and laboratory values. Univariate and multivariate analysis were employed to determine independent predictors of CKD progression and mortality.

Results: Out of the 3008 patients 594 (19.8%) met the inclusion criteria (median age: 71.9 years; 63.8% male). Median follow-up was 4.9 years (IQR 2.2). 133 (22.4%) met the criteria for CKD progression and 110 (18.6%) died. CKD progression was associated with higher proteinuria (405.7 vs 65.5mg/gr, p<0.001), Diabetes (60.9 vs 45.3%, p=0.002), CHF (40.6 vs 28.7%, p=0.009), Anemia (68.0 vs 44.7%, p<0.001), higher diuretic use (48.9 vs 34.1%, p=0.002) and mortality (40.9 vs 12.2%, p<0.001) Albuminuria over 300 mg/gr [Odds ratio (OR) 3.57, 95% CI 2.20 - 5.80] and Anemia (OR 1.97, 95% CI 1.20 – 3.22) were associated with CKD progression. The independent predictors of mortality were: CKD progression (OR 4.49, 95% CI 2.69-7.50), Older age (OR per 1 year increase 1.03, 95% CI 1.01-1.05), presence of CHF (OR 1.75, 95% CI 1.03-2.98), presence of Hyperkalemia at first consultation (OR 2.12, 95% CI 1.00 – 4.52) and Anemia (OR 1.93, 95% CI 1.03 - 3.62).

Conclusions: Patients with macroalbuminuria and anemia at first consultation are at increased risk for rapid CKD stage 3 progression. In this group, patients with CHF, anemia and hyperkalemia (even at first consultation) have a higher risk of mortality. This study may be useful and help us in guiding which CKD stage 3 patients should be referred to a nephrology clinic.

PO0512

Laboratory-Based Potential Indications vs. Risk-Based Triage for Nephrology Referrals in the Veterans Affairs Health System

Vishal Duggal,[1,2] Maria E. Montez-Rath,[3] I-Chun Thomas,[4] Mary K. Goldstein,[1] Manjula Kurella Tamura.[3,4] *[1]VA Palo Alto Health Care System, Palo Alto, CA; [2]Stanford University Stanford Health Policy, Stanford, CA; [3]Stanford University School of Medicine, Stanford, CA; [4]VA Palo Alto Geriatric Research Education and Clinical Center, Palo Alto, CA.*

Background: Clinical decision support tools may facilitate identification of chronic kidney disease (CKD) and timely nephrology referral. Little is known about the potential effects they might have on the volume of nephrology referrals. We sought to estimate how the implementation of a CKD decision support tool could affect potential nephrology referral volume based on U.S. Veterans Affairs Health System (VA)/Department of Defense (DoD) guidelines, and the risk profile of referred patients.

Methods: In a retrospective cohort study of 434,735 patients with CKD, we determined the number of patients who met laboratory-based potential indications for nephrology referral based on VA/DoD guidelines. We used the Kidney Failure Risk Equation to estimate end-stage kidney disease (ESKD) risk and to determine how incorporating ESKD risk thresholds would modify referral volume.

Results: Among 70,972 patients meeting potential indications for referral who had not visited a nephrologist in 2013, 12,008 (16.9%) were referred in 2014. The two-year risk of ESKD was low in both groups, 2.9% [0.9-8.6%] in the referred group, compared to 1.3% [0.3-3.9%] in the unreferred group ($P < 0.001$). The number of patients meeting potential indications for referral was approximately equivalent to the number of patients with a two-year risk of ESKD exceeding 1%, or N=81,132. Among potential indications for referral, rapid eGFR decline accounted for 37.6% of eligible unreferred patients and was associated with the lowest two-year ESKD risk.

Conclusions: Laboratory-based potential indications for referral identify a large number of patients at low risk of ESKD. Further study is needed to determine the value of nephrology care for these populations.

Variation in Kidney Failure Risk Across Health Organizations Among Adults with CKD in Nephrology Ambulatory Care

Chi D. Chu,[1,2] Neil R. Powe,[1,4] Michael Shlipak,[1,3] Rebecca Scherzer,[1,3] Sri Lekha Tummalapalli,[1] Michelle M. Estrella,[1,3] Delphine S. Tuot.[1,4] *[1]University of California San Francisco, San Francisco, CA; [2]OptumLabs Visiting Scholar, Cambridge, MA; [3]San Francisco VA Medical Center, San Francisco, CA; [4]Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.*

Background: Since most adults with chronic kidney disease (CKD) have low risk for end-stage kidney disease (ESKD) progression, subspecialty nephrology care should focus on patients at highest risk of progression. To optimize utilization of nephrology care, a threshold of 3% risk of ESKD at 5 years based on the Kidney Failure Risk Equation (KFRE) has been proposed for nephrology referral. To understand how application of this threshold in practice could impact CKD care delivery and subspecialty referral, we examined variation in 5-year ESKD risk distributions of patients in nephrology ambulatory care across U.S. healthcare organizations.

Methods: In 22 healthcare organizations, we identified patients age ≥18 years, with eGFR <60 ml/min/m² and concurrently measured urine albumin/creatinine ratio, who had an ambulatory encounter with a nephrologist from 1/1/2017-12/31/2018 using the OptumLabs® Data Warehouse, a longitudinal, real-world data asset with de-identified administrative claims and electronic health record data. We compared the distribution of patient-derived KFRE 5-year risk across healthcare organizations with ≥500 patients in nephrology care.

Results: Among 45,145 patients with CKD in nephrology care, the overall median 5-year ESKD risk was 2.4%. However, between organizations, the median 5-year ESKD risk varied widely, ranging from 0.8% to 6.7% (**Figure**). 54.5% of patients were below the 3% recommended referral threshold risk of ESKD.

Conclusions: There is substantial heterogeneity of ESKD risk across healthcare organizations in the population receiving ambulatory nephrology care. A greater understanding of the patient population and delivery system characteristics is needed to explain this heterogeneity, and associated health outcomes could inform recommended risk thresholds for referral and ongoing nephrology care.

PO0514

Prevalence of Comorbid Conditions at CKD Onset Among US Veterans

Meda E. Pavkov,[1] Devasmita Choudhury,[2,3] Wei Yu,[3] Nilka Rios Burrows,[1] Robert Nee,[4] Alfred K. Cheung,[5,6] Keith C. Norris,[7] Guofen Yan.[3] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]Salem VA Medical Center, Salem, VA; [3]University of Virginia, Charlottesville, VA; [4]Walter Reed National Military Medical Center, Bethesda, MD; [5]University of Utah Health, Salt Lake City, UT; [6]VA Salt Lake City Health Care System, Salt Lake City, UT; [7]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Comorbid conditions such as hypertension (HTN) and diabetes increase risk of adverse outcomes among patients with CKD. It is less clear whether such conditions develop prior to CKD onset or subsequently emerge as the disease progresses. Using a newly constructed national incident CKD cohort, we examined the prevalence of major comorbidities at the time of CKD onset by demographic groups.

Methods: The cohort included 1,074,238 subjects with new-onset CKD between 2002 and 2017 in the US Veterans Health Administration (VHA). CKD onset was defined as the first time when estimated GFR (eGFR; CKD-EPI equation) decreased to a value <60 mL/min/1.73 m² for >3 months. We excluded subjects in VHA for <2 years prior to first eGFR <60, or with CKD stage 4 or 5, or end-stage kidney disease (ESKD) when first identified. Thus, the first time identified was close to the onset of CKD stage 3. Comorbidities at CKD onset were ascertained from ICD-9/ICD-10 codes during any time before onset and through 6 months after onset.

Results: All subgroups (age, gender, race and ethnicity) had similar mean eGFRs at onset (51 ml/min/1.73m²). The percentage with age at onset ≤65 years was greater in males (74%) than females (43%), greater in Black (48%) than in American Indian or Alaska Native (39%), Asian or Pacific Islander (33%), and Hispanic (30%), which in turn were greater than Whites (23%). At CKD onset, HTN was highly prevalent, varying from 83% in females to 96% in Blacks; diabetes ranged from 36% in females to 61% in Hispanics; more than two-thirds had cardiovascular disease (CVD); and 19-28% had cancer across subgroups (Table).

Conclusions: This finding suggests that many veterans at the time of CKD onset had already developed some major comorbidities, which could make them particularly susceptible to death before ESKD.

Funding: NIDDK Support, Other U.S. Government Support

Percentages of patients with the individual comorbidity at CKD onset

Comorbidity	Age		Gender		Race and ethnicity				
	18-65 years	>65 years	Female	Male	American Indian or Alaska Native	Asian or Pacific Islander	Black	Hispanic	White

PO0515

Classification of Cause of CKD Using ICD-9 and ICD-10 Codes

Jennifer Chen,[1] Matthew F. Blum,[1] Aditya L. Surapaneni,[2] Yingying Sang,[2] Alex R. Chang,[3] Josef Coresh,[1,2] Morgan Grams.[1,2] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins School of Public Health, Baltimore, MD; [3]Geisinger Health, Danville, PA.*

Background: Current KDIGO guidelines classify CKD using three parameters: glomerular filtration rate (GFR), albuminuria, and cause of disease. While prognosis based on estimated GFR and albuminuria have been studied, less is known about the prevalence of disease etiology in CKD patients. We sought to classify various causes of CKD using billing codes for better assessment of the prevalence and risk implications of disease etiology in CKD staging.

Methods: We categorized cause of CKD with 18 potential etiologies and assigned relevant Internal Classification of Diseases (ICD) 9th and 10th revision Clinical Modification codes pertaining to each etiology. We applied the algorithm to two study populations, Johns Hopkins Medicine and Geisinger Health, to assess the prevalence of different etiologies of CKD in large health systems. To validate our CKD classification system, we determined CKD cause among 101 outpatients treated within Johns Hopkins Medicine through internal chart reviews and compared our findings to the classification algorithm generated CKD etiology.

Results: 43.3% and 26.4% of patients with eGFR <60 ml/min/1.73 m^2 in 2016 in the Geisinger and Johns Hopkins study population, respectively, had a billing code used in our classification algorithm. The most prevalent etiologies of CKD in patients with available billing codes at Geisinger were hypertensive nephrosclerosis (27%), diabetic nephropathy (13.6%), obstructive nephropathy (5.2%), and nephritic syndrome (4.9%). In contrast, the most common causes of CKD in the Johns Hopkins cohort were miscellaneous (12%), obstructive nephropathy (6.3%), and non-PKD hereditary disease (3.2%). Chart review revealed 56% concordance between cause of CKD determined by chart review and that by billing code, with higher agreement for polycystic kidney disease, kidney transplant, autoimmune disease, diabetic nephropathy, neoplasm, hypertensive nephrosclerosis, and solitary kidney.

Conclusions: We developed an algorithm for classifying CKD cause by ICD-9 and ICD-10 codes using electronic medical record data; however, validation suggests varying degrees of accuracy across different CKD etiologies.

PO0516

Epidemiology of Patients with High-Risk CKD: A Demographic Evaluation of Patients Who Had Indications for SGLT2 Inhibitors and GLP-1

Huiwen Chen,[1,2] Melanie R. Weltman,[1] Manqi Cai,[1] Jonathan Yabes,[1] Thomas D. Nolin,[1] Manisha Jhamb,[1,2] Khaled Abdel-Kader.[3] *[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: The emerging evidence of the favorable effects of sodium-glucose co-transporter-2 inhibitors (SGLT2is) and glucagan-like peptide 1 receptor agonists (GLP-1) on renal function has brought hope and excitement to the nephrology communities in the US. However, many patients with high risk CKD and indications for SGLT2is and GLP-1 were not on the medication. We would like to identify the features of these patients and their primary care providers to offer targeted recommendations regarding concerns for initiating SGLT2is and GLP-1.

Methods: This is a preliminary analysis of data obtained from the Kidney Coordinated Health Management Partnership (K-CHAMP) study (NCT03832595), an ongoing, NIH funded pragmatic randomized control trial testing an electronic health record-based population health management approach to improve CKD care. The studied population included patients between ages 18 and 85 with either chronic kidney disease stage IV and above or features of high-risk progression based on CKD risk progression score calculated by the kidney failure risk equation. Patients were screened based on their risk score calculated by Epic EMR and arranged based on their upcoming PCP's appointments. Patients who were taking SGLT2is or GLP-1 were compared with patients who had the indications for either medication but were not on the medications.

Results: Baseline demographics such as median age, gender, race, and BMI were compared. Comorbidities, the presence of endocrinology referral, laboratory values and whether or not patients have been on angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) were also compared. Clinicians' characteristics were compared as well. Patients who had the indications for SGLT2is but were not on them were more likely to be older in age, had low GFR (around low 30 ml/min) and low hemoglobin A1C. Patients who had the indications for GLP-1 but not on them were likely to have high A1C and likely to have already been on insulin.

Conclusions: Identification of features of high risk patients who had clinical indications for SGLT2i and GLP-1 but were not on the medication would be helpful in finding better ways to provide nephrology recommendations regarding SGLT2is and GLP-1.

PO0517

Disparities in CKD Progression by Medicare Advantage Enrollees

Clarissa J. Diamantidis,[1] Lindsay Zepel,[1,3] Virginia Wang,[1,2] Valerie A. Smith,[1,2] Sarah H. Scholle,[4] Loida A. Tamayo,[5] Matthew L. Maciejewski.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]HSRD, Durham VA HCS, Durham, NC; [3]OptumLabs Visiting Fellow, Minnetonka, MN; [4]National Committee for Quality Assurance, Washington, DC; [5]Centers for Medicare and Medicaid Services, Baltimore, MD.*

Background: The prevalence of chronic kidney disease (CKD) in Medicare beneficiaries has quadrupled in the past two decades, but little is known about risk factors affecting the progression of CKD. This abstract aims to understand the progression of CKD up to five years after study entry in a large cohort of Medicare Advantage (MA) enrollees and whether it differs by provider recognition of CKD, race and ethnicity, or geographic location.

Methods: In a cohort of 1,002,388 MA enrollees with CKD stages 1-4 based on 2013-2018 labs, progression was estimated using a mixed-effects model that adjusted for demographics, urbanicity, comorbidity, urine albumin-to-creatinine ratio, clinical recognition via diagnosed CKD, and time fixed effects. Race and ethnicity, geographic location, or clinical recognition of CKD were interacted with time in three separate regression models.

Results: Mean (median) follow-up was 3.1 (3.0) years. At study entry, Black and Hispanic MA enrollees had greater kidney function at study entry than other beneficiaries, but their kidney function declined faster compared to non-Hispanic Whites. At study entry, MA enrollees with clinically recognized CKD had estimated glomerular filtration rate levels that were 18.6 units (95% confidence interval (CI): 18.5-18.7) lower than levels of unrecognized patients, but kidney function declined more slowly in enrollees with clinical recognition of CKD. There were no differences in CKD progression by metropolitan or non-metropolitan areas.

Conclusions: These results suggest that patients with clinically recognized CKD and racial and ethnic minorities merit closer surveillance and management to reduce their risk of faster progression.

Funding: Other U.S. Government Support

PO0518

Impact of the Race Multiplier in the Estimated Glomerular Filtration Rate Equation on Care Delivery Among African-American CKD Patients

Salman Ahmed, Mallika L. Mendu. *Brigham and Women's Hospital, Boston, MA.*

Background: African-American patients with chronic kidney disease (CKD) have poorer outcomes, including in dialysis access placement and transplantation. Estimated glomerular filtration rate (eGFR) equations, which assign higher eGFR values to African-American patients, may be an inadvertent mechanism for inequitable outcomes. Electronic health record-based registries enable population-based examination of care across racial groups.

Methods: Cross-sectional study at two large academic medical centers and affiliated community primary care and specialty practices.

Results: Of 2225 African-American patients, 743 (33.4%) would hypothetically be reclassified to a more severe CKD stage if the race multiplier were removed from the CKD-EPI equation. Similarly, 167 of 687 (24.3%) would be reclassified from stage 3B to stage 4. Finally, 64 of 2069 patients (3.1%) would be reassigned from eGFR > 20 ml/min/1.73m^2 to eGFR ≤ 20 ml/min/1.73m^2, meeting the criterion for accumulating kidney transplant priority. Zero of 64 African-American patients with an eGFR ≤20 ml/min/1.73m^2 after the race multiplier was removed were referred, evaluated or waitlisted for kidney transplant, compared to 19.2% of African-American patients with eGFR≤20 ml/min/1.73m^2 with default CKD-EPI equation.

Conclusions: Our study reveals a meaningful impact of race-adjusted eGFR on the care provided to the African-American CKD patient population.

Funding: Private Foundation Support

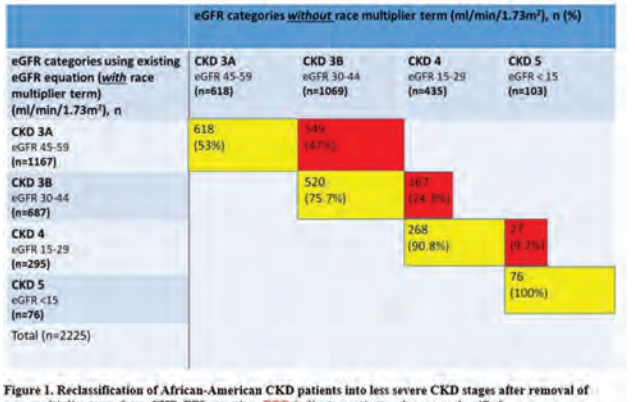

Figure 1. Reclassification of African-American CKD patients into less severe CKD stages after removal of race multiplier term from CKD-EPI equation. RED indicates patients who are reclassified.

Abbreviations: CKD, chronic kidney disease, eGFR, estimated glomerular filtration rate

PO0519

Prevalence of Diabetes, Hypertension, Anemia, and Hyperkalemia as Frequent Comorbidities in Patients with CKD Regardless of their KDIGO Staging

L. M. Perez-Navarro,[1] Samantha Escorza Valdivia,[1] Alberto Sigfrido Benitez Renteria,[2] Rafael Valdez-Ortiz.[1] *[1]Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; [2]AstraZeneca, Ciudad de México, Mexico.*

Background: Chronic kidney disease (CKD) is a worldwide public health problem. Currently in Mexico, the prevalence of CKD is only an estimate, based primarily on records of advanced stages of the disease. It is necessary to identify comorbidities and thus establish strategies to delay its progression and reduce morbimortality associated with CKD.**Objective:** To know the prevalence of comorbidities associated with CKD at different stages in an outpatient population who attended a 3rd level hospital.

Methods: This is a cross-sectional retrolective study. Records of adult patients who attended an outpatient nephrology consultation in the period from February 2019 to February 2020 were included, with laboratory reports from 15 days prior to the inclusion date. Descriptive statistics were performed, with a 95% CI and a value of p≤0.05.

Results: 1772 patient records were included. 51% (907) were women, the mean age was 42 ± 24.2 years. 12% were on renal replacement therapy, 11% hemodialysis and 1% peritoneal dialysis. 87% (1546) lacked family history of CKD; 11% (192) were smokers. Regarding body mass index, 2% (32) presented low weight, 37% (562) normal weight, 53% (804) overweight and 8% (122) obesity. *Figure 1* shows the distribution by CKD stage and main comorbidities. The prevalence of proteinuria was 39% (693). 53% (826) had anemia. The prevalence of hyperkalemia (HK; $K^+ \geq 5$) was 29% (325). The prevalence of serum albumin <3.5 was 26%; 44% of the population had glucose> 100 mg/dl; 53% with triglyceride >150 mg/dl and 29% with total cholesterol ≥200 mg/dL.

Conclusions: A high prevalence of CKD comorbid risk factors such as diabetes, hypertension, anemia and HK were identified regardless of CKD staging, increasing in proportion in later stages.

Cystatin C Use in Clinical Practice

Jennifer Torres,[3] Jennifer L. Ennis,[2] Rita L. McGill.[1] *[1]University of Chicago, Chicago, IL; [2]Laboratory Corporation of America, Burlington, NC; [3]DaVita Inc, Denver, CO.*

Background: Cystatin C is a filtration biomarker that can be used as an alternative for serum creatinine. The 2012 KDIGO guidelines advocate for the use of cystatin C to confirm the diagnosis of chronic kidney disease (CKD), but 9 years later it is not clear how this test is being used in clinical practice.

Methods: We examined 87,803 cystatin C levels obtained among 55,360 patients between 11/2011-6/2018 in the database of Laboratory Corporation of America Holdings (LabCorp®). The CKD-EPI cystatin equation was used to calculate the estimated GFR for each level. Descriptive analyses of patient age, sex, and ordering provider were constructed, and relationships between serum cystatin C and creatinine levels were examined with correlation analysis and linear regression.

Results: The mean age was 58±17;50.2% were women. Frequency of orders increased over time, from 6,323 tests in 2012, to 17,822 tests in 2017. Providers ordering cystatin C included: Internal/Family Medicine MDs (83%), radiologists (4%), mid-levels (4%), and 9% unknown. Cystatin C was ordered on patients with a wide range of estimated GFR values (Figure). Linear regression showed that 75% of the variation in cystatin C could be modeled if age, sex, BUN, and creatinine were known. Dispersion between actual and predicted cystatin was minimal at cystatin C levels ≤ 3.0 mg/L, representing estimated GFR values ≥ 15 mL/min/1.73m2.

Conclusions: Providers are ordering cystatin C with increasing frequency over time, for a variety of indications besides confirmation of borderline CKD. Cystatin can be modeled fairly reliably, using BUN, creatinine, sex, and age, for cystatin levels≤ 3.0 mg/L.

Appropriate Interval Between Two eGFR Measurements for the Evaluation of the Association of eGFR Slope with Incidence of Renal Events

Maiko Kokubu,[1] Masaru Matsui,[1] Takayuki Uemura,[1] Kazuhiko Tsuruya.[2] *[1]Nara-ken Sogo Iryo Center, Nara, Japan; [2]Nara Kenritsu Ika Daigaku, Kashihara, Japan.*

Background: In recent years, growing evidence has shown the prognostic utility of eGFR slope for the risk of ESRD. Previous observational studies have assessed the association between renal events and eGFR slopes estimated by two measurements of eGFR but had great differences in the interval between two eGFR measurements. In this study, we thus aimed to determine the appropriate interval between two eGFR measurements to evaluate the association of eGFR slope with incidence of renal events.

Methods: This is a retrospective cohort study in 203 CKD patients who visited Nara Prefecture General Medical Center, Japan between 1 January 2013 and 31 December 2016 and in whom two or more than two measurements of eGFR levels were confirmed in medical records. eGFR slopes were estimated by using two measurements of eGFR at baseline and 0.5, 1, 1.5, 2, or 3 years. We excluded patients with acute kidney injury, urologic malignancies, nephrotic syndrome with steroid treatment or collagen diseases. Outcome was renal events defined as a composite of ESRD and eGFR decline of > 30%. C statistics were used to evaluate the association between eGFR slope and incidence of renal events.

Results: The median age of study participants was 67 (56-77) years and 71 (37%) were male. The median levels of baseline eGFR were 34 (21-48) mL/min/1.73m^2 and diabetes was present in 80 (39%) participants. During the median follow-up period of 38 months, renal events occurred in 52 participants. Medial levels of eGFR slopes$_{0.5,\ 1,\ 1.5,\ 2\ \text{and}\ 3yr}$ were -7.8, -3.6, -2.9, -0.9, -1.5 mL/min/1.73m^2, respectively. C-statistics of eGFR slopes$_{0.5,\ 1,\ 1.5,\ 2\ \text{and}\ 3yr}$ for renal events were 0.622, 0.691, 0.797, 0.858, 0.806, respectively, and that of eGFR slope$_{1.5yr}$ was significantly higher than that of eGFR slope$_{0.5yr}$ and eGFR slope$_{1yr}$ ($p<0.001$ and $p=0.001$, respectively). In stratified analysis, eGFR slope$_{1.5yr}$ had higher prognostic ability of renal events in patients with versus without diabetes, advanced CKD and proteinuria. C-statistics of renal events when considering baseline eGFR alone was 0.853 but combination use of baseline eGFR and eGFR slope$_{1.5y}$ significantly increased c-statistics, to 0.913 ($p=0.01$).

Conclusions: eGFR slope for high prognostic ability of renal events may be needed to be calculated by at least 1.5-year interval between two eGFR measurements.

Rates of Clinical Events in Patients with CKD: A UK Population-Based Cohort Study

Alyshah Abdul Sultan,[1] Ping Sun,[1] Katarina Hedman,[2] Xia Wang,[3] Mark T. Houser,[3] Dustin J. Little,[3] Glen James.[1] *[1]AstraZeneca, Cambridge, United Kingdom; [2]AstraZeneca, Gothenburg, Sweden; [3]AstraZeneca, Gaithersburg, MD.*

Background: Epidemiology of clinical event rates in patients with chronic kidney disease (CKD) is limited and can impede the ability of dialysis organizations, government agencies, other institutions, and payers to counsel patients and assess quality of care.

Methods: The Clinical Practice Research Datalink (CPRD) is a large, longitudinal UK-based primary care database that covers 6% (~4 million people) of the population. CPRD is linked to Hospital Episode Statistics (HES), which contains information on all hospital admissions in England. We identified CKD patients with eGFR <60 ml/min/1.73m^2 in CPRD between 2004 and 2017. Adverse clinical events were identified using ICD-10 and READ codes. Non-dialysis dependent (NDD) patients were staged by eGFR. Dialysis dependent (DD) patients were identified using Classification of Interventions and Procedures (OPCS) and READ codes. Clinical events were identified by ICD10 and READ codes. Incidence rates per 100 person-years (PY) were calculated for selected adverse event stratified by dialysis status and CKD stage.

Results: We identified 310362 NDD and 5248 DD patients with a mean (standard deviation [SD]) age of 75.5 (10.2) years and a median (interquartile range [IQR]) follow-up of 87.5 (46.5-130.9) months. Among NDD patients 96%, 3%, and 1% of patient-years came from CKD 3, 4, and 5, respectively. Most event rates were consistently higher in DD CKD patients, compared to NDD CKD patients; and higher among CKD 4/5 compared to CKD 3 patients (Table 1).

Conclusions: Our results help establish baseline rates of specific clinical events and provide additional evidence of increased morbidity for DD vs. NDD patients, and for NDD patients with more severe vs. less severe kidney disease.

Funding: Commercial Support - AstraZeneca

Table 1: Incidence rates of adverse clinical events per 100 PY

Adverse events	NDD CKD 3 Rate	NDD CKD 4/5 Rate	DD Rate
Acidosis	0.5	1.2	2.3
Allergic anaphylaxis	0.1	0.1	0.1
Gastrointestinal hemorrhage	2.5	3.2	5.8
Hyperkalemia	0.7	2.2	4.9
Sepsis	1.3	2.2	7.4
Pancreatitis	0.1	0.2	0.4
Pneumonia	7.8	12.2	15.2
Pyelonephritis	0.1	0.2	0.7
Rhabdomyolysis	0.1	0.1	0.3
Seizure	0.4	0.5	1.0
UTI	7.1	12.6	9.8

End Point Abstraction and Incident Events in a Cohort of >5000 CKD Patients After 6.5 Years of Follow-up in the German CKD (GCKD) Study

Ulla T. Schultheiss,[1] Fruzsina K. Kotsis,[1] Monika Wytopil,[2] Inga Steinbrenner,[3] Helena Stockmann.[4] *[1]Universitatsklinikum Freiburg Institute of Genetic Epidemiology and Renal Division, Freiburg, Germany; [2]University Hospital Erlangen Department of Nephrology, Erlangen, Germany; [3]Universitätsklinikum Freiburg Institute of Genetic Epidemiology, Freiburg, Germany; [4]Charite University Medicine Berlin Department of Nephrology, Berlin, Germany*.

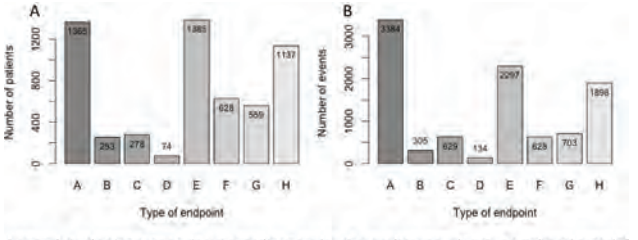
Background: Etiopathologies and progression of chronic kidney disease (CKD) differ among affected individuals with a differential risk to develop comorbid conditions like cardiovascular disease, adverse renal events like end-stage kidney disease (ESKD) or acute kidney injury (AKI), and early mortality. Evidence about CKD trajectories and a broad spectrum of adverse events in large cohorts of CKD patients under regular nephrological care is scarce, motivating the generation of such evidence from the ongoing GCKD study with 5217 enrolled patients.

Methods: In GCKD, endpoints are continuously abstracted from hospital discharge letters and death certificates based on a standardized endpoint catalogue (Fig. 1 legend). To reduce inter-observer variability, endpoints were abstracted by a trained physicians endpoint committee. Data from the first 6.5 years of follow-up was evaluated (data freeze 04/2020).

Results: Among all 5217 patients 2867 had at least one endpoint and 9978 endpoints occurred. At the end of the first 6.5 years, 628 patients were deceased. Cardiovascular endpoints occurred most frequently (Fig. 1) driven by arrhythmias (N_{events}=713) and decompensated heart failure (N_{events}=707), followed by renal events, which were driven mostly by 1176 non-dialysis dependent AKIs and 207 temporary dialysis events. 522 ESKD events occurred (457 dialysis, 65 kidney transplants). Hospitalizations due to infections were also frequent. Death occurred mainly due to cardiovascular disease (N=175) and due to infections (N=147). 26 patients died due to forgoing of dialysis.

Conclusions: Over an observation period of 6.5 years, 9979 incident endpoints occurred in a cohort of 5217 CKD patients. The highest number of endpoints occurred for cardiovascular and renal events. The high risk of recurrent events for patients in these categories underscores the need to focus on high-risk patient subgroups.

Funding: Government Support - Non-U.S.



Legend: Endpoint categories: A: cardiovascular, B: cerebrovascular, C: peripheral arterial disease, D: microangiopathy in diabetes, E: renal, F: mortality, G: malignomas, H: hospitalization due to infection

Estimating the Future Burden of CKD Through Microsimulation Methods

Lise Retat,[1] Michael Xu,[1] Laura Webber,[1] Claudia S. Cabrera,[2] Elisabeth SOrstadius,[2] Stephen Nolan,[3] Juan Jose Garcia Sanchez.[3] *[1]HealthLumen, London, United Kingdom; [2]AstraZeneca AB, Sodertalje, Sweden; [3]AstraZeneca PLC, Cambridge, United Kingdom.*

Background: Chronic kidney disease (CKD) is a debilitating and costly condition, impacting over 10% of people globally. Early diagnosis and proactive management could potentially mitigate the rates of progression to end stage renal disease. Understanding the future trajectory of CKD prevalence, progression, outcomes and the related economic burden are important considerations for public health and policy planning. This study estimates the epidemiological and cost burden of CKD with an emphasis on high-risk populations with macroalbuminuria, type 2 diabetes (T2D) and/or heart failure (HF), from 2020 to 2025.

Methods: A patient-level microsimulation was developed to estimate the epidemiological and economic burden of CKD in the UK. KDIGO 2012 recommendations were used to categorise patients according to eGFR and albuminuria using the Health Survey of England extrapolated to the UK population. The future prevalence and healthcare costs for the CKD population, as well as for subpopulations – macroalbuminura, T2D, HF – were estimated. Finally, "current practice" management scenario was compared to an early detection and proactive scenario.

Results: By 2025, CKD prevalence in the UK is expected to grow by 11% from ~9.1M to 10.2M corresponding to a £4B (18%) increase in annual cost from £18B, of which, £0.58B is incurred due to macroalbuminuria where prevalence is projected to reach 860,000 by 2025. Within the macroalbuminuria population, costs were comparable between patients with (390,000; £0.31B) and without (465,000; £0.27B) T2D. However, costs for patients with macroalbuminuria were 3-times higher than for CKD patients with HF (£0.11B, 140,000). Early identification and proactive management of patients with CKD and macroalbuminuria resulted in a cumulative £0.65B direct healthcare cost saving by 2025.

Conclusions: This model predicts that CKD poses a serious public health threat. The overall epidemiological burden for patients with macroalbuminuria was comparable between patients with and without T2D. Early detection along with proactive treatment may reduce CKD progression and more directly improve patients' quality of life while also reducing the long-term economic burden of CKD.

Identifying and Clustering CKD Progression Trajectories Using Machine Learning

Alyshah Abdul Sultan,[1] Kirsty Rhodes,[1] Michail Doulis,[2] Irena Brookes-Smith,[1] Jolyon S. Faria,[1] Jose D. Salazar,[1] Glen James,[1] Iain MacPhee,[1] Robert J. Unwin,[1] David Wright,[1] Mishal Patel,[1] Paul D. Metcalfe,[1] Lutz Jermutus.[1] *[1]AstraZeneca, Cambridge, United Kingdom; [2]AstraZeneca, Gothenburg, Sweden.*

Background: There is evidence suggesting that estimated glomerular filtration rate (eGFR) slope can be used as a surrogate clinical endpoint in renal clinical trials. However, there are limited data on the characteristics of fast and slow progressors based on eGFR slope from large population-based studies.

Methods: We identified CKD patients (based on two consecutive eGFRs of <75ml/min/1.73m^2 recorded more than 90 days apart) aged ≥18 years from the UK Clinical Practice Research Datalink (CPRD) between 2004 and 2019. Estimated GFR measurements over a 3-year observation period post-index date (date of 2nd eGFR measurement) were extracted. Patients were clustered based on their eGFR trajectories using statistical (linear mixed effect models (LMM)) and machine learning techniques (unsupervised machine learning and Bayesian approaches). Association between trajectory clusters and all-cause mortality was assessed using Cox regression analysis.

Results: Preliminarily, 407,108 patients with 1.8 million eGFR measurement (median 4 (IQR: 2-6) eGFR measurements per patient) were identified. Using LMM, we found 5% of patients declined rapidly with an average rate of eGFR change per year -4.78 (95%CI: -9.40 to -3.28) whereas the majority (95%) remain stable or progressed slowly. A distinct fast progressing cluster was also detected using unsupervised machine learning and Bayesian methods which showed broadly linear patterns. Overall, there was an agreement between all three clustering approaches. These findings were replicated in the validation dataset showing consistent findings. Compared to stable/slow progressors, fast progressors were 3 times more likely (Hazard Ratio (HR)=2.82: 95%CI 2.75-2.90) to die following the 3-year observation period.
