Conclusions: Low-sodium home-meal delivery appears to be an effective method to reduce dietary sodium intake, IDWG, BP, and VO in HD patients. It will be important determine if these changes can be sustained long-term with additional counseling and in larger sample sizes. The long-term benefits and cost-effectiveness of this approach also needs to be evaluated.

Funding: Commercial Support - Renal Research Institute

Changes in Volume-Related Parameters

Performance of GLIM for Nutritional Assessment of Hemodialysis Patients: Comparison with Subjective Global Assessment (SGA) and Malnutrition-Inflammation Score (MIS)

Carla M. Avesani,[1] Alice Sabatino,[4] Alessandro Guerra,[2] Juan J. Carrero,[3] Giovanni maria Rossi,[4] Peter Stenvinkel,[1] Enrico Fiaccadori,[4] Bengt Lindholm.[1] *[1]Karolinska institutet Department of Clinical Sciences Intervention and Technology, Huddinge, Sweden; [2]Università degli Studi di Genova, Genova, Italy; [3]Karolinska Institutet, Stockholm, Sweden; [4]Parma University Hospital, Parma, Italy.*

Background: There is a need for methods to identify and monitor malnutrition in maintenance hemodialysis (MHD) patients (pts). We assessed GLIM (Global Leadership Initiative on Malnutrition) and evaluated agreement and survival prediction of GLIM vs. SGA and MIS in MHD pts.

Methods: We investigated two cohorts, MHD_{Italy} (121 adult pts from Italy; 67±16y, 65% men, BMI 25±5 kg/m^2) and MHD_{Brazil} (169 elderly (age>60 y) pts from Brazil; 71±7y, 66% men, BMI 25±4 kg/m^2), followed for 40 (27; 46) and 17 (12; 31) months (median and 25th; 65th), respectively. GLIM comprises: 1. *Screening* and 2. *Confirming malnutrition by phenotypic and etiologic criteria*. For 1., presence of >1 criteria from protein energy wasting definition was used. Pts at risk were re-tested with GLIM's phenotypic criteria: non-volitional weight loss or low BMI (<20 kg/m^2 if <70y, or <22 kg/m^2 if <70y) and reduced muscle mass (MAMC<90%). As dialysis is a catabolic procedure, all pts were positive for the etiologic criteria. For SGA and MIS, a score ≤5 and ≧8 was considered for malnutrition, respectively.

Results: Malnutrition was present in 38.8% by GLIM, 25.6% by SGA and 29.7% by MIS in the MHD_{Italy} cohort, and in 47.9% by GLIM, 59.8% by SGA and 49.7% by MIS in the MHD_{Brazil} cohort. Cohen's kappa coefficient (κ) showed only "fair" agreement between GLIM and SGA and MIS respectively (Table). Cox regression analysis adjusted for gender and age showed that in the MHD_{Italy} cohort, only pts malnourished by MIS had higher risk for mortality (HR= 2.42; 95% CI 1.28 to 4.59; P=0.007) while in the MHD_{Brazil} cohort, pts malnourished by GLIM (HR= 2.09; 95% CI 1.13 to 3.86; P=0.02), SGA (HR= 1.96; 95% CI 1.01 to 3.79; P=0.04) and MIS (HR= 2.24; 95% CI 1.20 to 4.16; P=0.01) had higher risk for mortality.

Conclusions: In MHD pts, GLIM showed low agreement with SGA and MIS, raising question on its validity and usefulness in renal care. Only malnutrition by MIS predicted mortality risk in MHD_{Italy} cohort, but in the MHD_{Brazil} cohort, malnutrition by all three methods predicted higher mortality risk.

Agreement vs. GLIM	MHDItaly	MHDBrazil
GLIM x SGA, κ (P)	0.26 (0.003)	0.22 (0.003)
GLIM x MIS, κ (P)	0.33 (< 0.001)	0.25 (0.001)

PO2031

Dietary Fiber Intake, Cardiovascular Risk Factors, and Kidney Function: A Mediation Analysis

Gabrielle Jutras, Suzanne Dominique Genest, Amelie Bernier-Jean, Remi Goupil, Francois Madore. *Hôpital Sacré-Coeur De Montréal, Montréal, QC, Canada.*

Background: Higher fiber intake may be associated with higher eGFR but the mechanisms underlying this association are poorly understood. Considering that higher fiber intake is linked to improved cardiovascular (CV) risk factors, we hypothesize that the effect of fiber intake on eGFR could be mediated by these CV factors.

Methods: CARTaGENE is a population survey of healthy adults. We used multiple linear regression to study the association between fiber intake and eGFR while adjusting for confounding factors, including age, sex, diabetes, hypertension, dyslipidemia, body mass index [BMI], smoking, prior CV disease, physical activity and caloric intake. We assessed whether CV risk factors lie in the causal pathway between fiber intake and eGFR through mediation analyses.

Results: We included 9,854 of the CARTaGENE participants with a completed food questionnaire (mean age: 53 years, 56% males). The main comorbidities were hypertension (25%), diabetes (8%) and cardiovascular disease (7%). The median daily fiber intake was 17.2g (IQR 10.7-23.7) and the mean eGFR was 87.3 ±14.6 mL/min/1.73 m^2. After adjustment for the above factors, fiber intake was associated with higher eGFR and serum HDL levels, and lower BMI, glycated hemoglobin and triglyceride levels (Table). Other risk factors were found to be non-significant. The mediation analysis demonstrated that only 10% of the effect of fiber intake on eGFR was mediated through BMI and triglyceride levels.

Conclusions: Higher dietary fiber intake is associated with higher eGFR and better control of certain cardiovascular risk factors. While the association between fiber intake and kidney function may be marginally mediated by healthy weight and triglyceride levels, further studies are needed to understand the mechanisms underlying this association.

Association between dietary fiber intake and clinical variables.

	β coefficient† (95% CI)	p
eGFR	0.08 mL/min/1.73m2 (0.03, 0.13)	0.02
Body mass index	-0.06 kg/m2 (-0.08, -0.04)	0.001
HDL levels	0.002 mg/dL (0.001, 0.003)	0.02
Triglyceride levels	-0.01mmol/L (-0.01, -0.001)	0.001

Interplay Between Dietary Phosphorus and Protein Intake with Mortality in a Prospective Hemodialysis Cohort

Amanda R. Tortorici,[1] Yoko Narasaki,[1] Amy S. You,[1] Keith C. Norris,[2] Elani Streja,[1] Rene Amel Peralta,[1] Yalitzi Guerrero,[1] Andrea C. Daza Aguilar,[1] Ria Arora,[1] Robin H. Lo,[1] Tracy Nakata,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]University of California Los Angeles, Los Angeles, CA.*

Background: Current dietary recommendations for dialysis patients suggest that high phosphorus (P) diets may be associated with negative outcomes such as increased serum P and death. However, caution must be practiced to ensure dietary P intake is not compromised at the expense of dietary protein intake. We hypothesized that higher concentrations of dietary P intake is associated with higher mortality among a diverse cohort of hemodialysis (HD) patients.

Methods: Among 415 patients from the prospective multi-center Malnutrition, Diet, and Racial Disparities in Kidney Disease Study, we conducted standardized collection of dietary and dialysis treatment characteristics every six months starting in 2011. We examined the association of quartiles of dietary P scaled to 1000 kcal (mg/kcal), as measured by food frequency questionnaires, with all-cause mortality using Cox models adjusted for expanded case-mix+laboratory+nutrition covariates. To model the association between continuous daily dietary P intake scaled to protein (mg/g) and mortality, we conducted analyses in which dietary P/protein intake was examined as a restricted cubic spline.

Results: In baseline analyses, patients in the lowest quartile of dietary P scaled to 1000 kcal had increased mortality risk compared to those in the highest quartile: adjusted HR (95%CI) 1.80 (1.05, 3.09). In analyses examining the association between continuous dietary P/protein (mg/g) intake and mortality using a cubic spline, we observed that there was a monotonic decrease in death risk with higher dietary P/protein intake.

Conclusions: Contrary to current practice, we found that lower intakes of dietary P scaled to protein and caloric intake were each associated with higher mortality risk. National nutrient databases indicate that foods with lower vs. higher P/protein ratios tend to be from animal proteins vs. plant proteins and dairy. Further studies are needed to clarify the relationship between sources of dietary P intake and mortality in HD patients.

Protein Supplements and Proteinuria: A Case-Control Study in Military Candidates

Sofia H. Marques,[1,2] Alberto Freitas.[3] *[1]Hospital Militar Polo Porto, Porto, Portugal; [2]Hospital de Braga, Braga, Portugal; [3]Faculty of Medicine of the University of Porto, Porto, Portugal.*

Background: Man has long wanted to improve both image and physical performance using supplements some of which include proteins. Low protein diets are recommended by guidelines to attenuate the progression of chronic kidney disease. In healthy individuals, however, protein intake does not seem a risk factor. This study addressed whether protein supplements could cause proteinuria in a healthy population.

Methods: We performed a case-control study at the Military Hospital of Oporto including 1541 military academy candidates who had urinalysis in 2017. Among them, 102 (6.6%) had proteinuria (dipstick test ≥+/+++) and these were compared to a random sample of 106 non-proteinuric candidates. Telephone interviews collected data on comorbidities, exercise, smoke, alcohol habits, drugs, supplements, height and weight. Protein supplements were accessed as risk factors for proteinuria using the Pearson Qui-square test.

Results: Answers were obtained from 49 cases and 52 controls. Of these 101 candidates, 88 were males, had a median age of 19 and mean body mass index of 24.1±2.4kg/m2. Most (97%) exercised for a mean weekly time of 6±3.7h: 40% practiced only resistance training; the rest both resistance and strength. Half used supplements at some point in time and 32 were current users. All used protein powder, mainly whey protein. Additional supplements (mostly amino acids) were used by 13. The weekly powder dose ranged from 3 to 14 scoops (20-30g/scoop). No significant association was found between the use of protein supplements and proteinuria (p=0.51). Similarly, no difference was found in creatinine, urea or other laboratory parameters. Supplements were significantly used more by those who practiced strength, as compared with resistance-training subjects.

Conclusions: One third of Portuguese military candidates used protein supplements. Increased use was noted in strength training most likely due to peer pressure. Proteinuria was found in 6.6%, similar to screenings in other healthy populations. No relation was found between protein supplements and proteinuria which could mean that the kidneys of healthy individuals are capable of dealing with a higher metabolic strain after increasing protein loads. However we acknowledge that proteinuria as a marker of disease has limitations and that the cumulative exposure and longtime impact of protein supplements was not considered and may be relevant.

PO2034

Continuous Intradialytic Amino Acid Infusion from the Start of Dialysis Is Better to Avoid Catabolism Under the High-Volume Pre-Dilution Online Hemodiafiltration

Motoko Kato,[1] Shunichiro Urabe,[1] Yukie Kitajima,[2] Kenichi Kokubo,[3] Toru Hyodo.[4] *[1]Department of Clinical Engineering, Eijin Clinic, Hiratsuka, Japan; [2]Tokyo University of Technology School of Health Sciences, Setagaya, Japan; [3]Allied Health Science, Kitasato University, Sagamihara, Japan; [4]Dialysis Center, Eijin Clinic, Hiratsuka, Japan.*

Background: Amino acid infusion during dialysis is useful for improving nutritional status (Clin Nephrol 3:234,1975). Usually, amino acid is infused 60 to 90 minutes before the end of dialysis, but it is reported that continuous administration from the start of dialysis is better (Kidney Int 21: 500, 1982). Moreover, these effects are unclear in the high-volume pre-dilution on-line HDF (HVPO-HDF). The optimal administration method of amino acid infusion under the HVPO-HDF was analyzed.

Methods: The subjects were 10 patients receiving HVPO-HDF (7 males, 4 diabetics, mean age: 77.2±5.5 years). We compared the pre- and post-dialysis plasma amino acids levels and the total amino acids amount in the waste fluid when the amino acids infusion was performed from the start of dialysis (Group A) and from 1 hour before the end of dialysis (Group B). The treatment time is 4 hours. The mean blood flow rate was 200 mL/min. The dialysate flow rate was 600 mL/min. The replacement fluid flow rate was 400 mL/min and total replacement fluid volume was 90. Hemodiafilter MFX-21Meco (Nipro, Ltd) was used.

Results: In pre-dialysis plasma levels of total amino acid (TAA), Group A and Group B showed the same level (2472±267 nmol/mL and 2623±319 nmol/mL, respectively). In the essential amino acid (EAA) and non-essential amino acid (NEAA), similar results were obtained (827±145 nmol/mL and 847±99 nmol/mL of EAA, 1644±216 nmol/mL and 1120±193 nmol/mL of NEAA, respectively). Moreover, the losses of amino acids were also same (9008±113 mg and 8886±1204 mg of TAA, 4966±579 mg and 4544±453 mg of EAA, 4042±644 mg and 4342±862 mg of NEAA, respectively). However, in Group A, post-dialysis plasma levels of amino acids were significantly lower than in Group B (2066±370 nmol/mL and 3826±636 nmol/mL of TAA, 946±193 nmol/mL and 2249±439 nmol/mL of EAA, 1120±193 nmol/mL and 1577±260 nmol/mL of NEAA, respectively. $p < 0.01$).

Conclusions: The result of high post-dialysis plasma levels despite the same loss of amino acids suggests more catabolism from muscle to blood in Group B. The continuous intradialytic amino acid infusion from the start of dialysis is better to avoid catabolism under HVPO-HDF.

PO2035

Association of Low-Density Lipoprotein Cholesterol with Time to ESRD Across CKD Stages in 2 Million US Veterans

Jui-Ting Hsiung,[2,1] Maria V. Marroquin,[2,1] Melissa Soohoo,[2] Csaba P. Kovesdy,[3,4] Kamyar Kalantar-Zadeh,[1,2] Elani Streja.[2,1] *[1]Harold Simmons Center, UC Irvine, Orange, CA; [2]VA Long Beach Healthcare System, Long Beach, CA; [3]Memphis VA Medical Center, Memphis, TN; [4]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Background: Prior studies have noted that abnormal triglyceride (TG) and high-density lipoprotein cholesterol (HDL) are predictors for chronic kidney disease (CKD) outcomes. However, it remains unclear whether similar patterns are observed for low-density lipoprotein cholesterol (LDL). Therefore, we sought to investigate the relationship of LDL with time to end-stage renal disease (ESRD) risk across CKD stages.

Methods: The cohort comprised 1,961,854 US veterans with a serum LDL between 2004-2006 and were not on ESRD. Patients were followed until ESRD, death, loss to follow up or Dec 2014, whichever occured first. We used a Cox model to examine the association of LDL and time to ESRD stratified by baseline CKD stages. The model adjustment include demographics, comorbid conditions, smoking status, prescription of statins and non-statins, body mass index, albumin, HDL, and TG.

Results: Patients were an average age of 64±14 years, and included 5% females, 14% African- Americans, 19% diabetics, 32% statin-users, and 44% current smokers. The median [IQR] of serum LDL level and eGFR at baseline were 103[81,128] mg/dL and 75[60,91] mL/min/1.73m^2, respectively. Higher LDL (>100 mg/dL) was associated with incrementally higher ESRD risk across all CKD stages compared to the reference (LDL 70-<100 mg/dL). Notably, LDL≥ 160 mg/dL were associated with the highest risks of ESRD, and this association gradually diminished across progressive CKD stages. Low LDL (<70 mg/dL) was associated with null risk of ESRD across all CKD stages.

Conclusions: Higher serum LDL was associated with higher risk of ESRD across all CKD stage in the US veterans. However the strength of this relationship attenuated with worsening CKD. Future studies with considerations for competing death events, time varying covariates and the impact of lipid modifying therapies are warranted.

PO2036

Association of Low-Density Lipoprotein Cholesterol with Urine Albumin-to-Creatinine Ratio Slope Across Baseline Albuminuria Strata

Jui-Ting Hsiung,[1,2] Maria V. Marroquin,[1,2] Melissa Soohoo,[1] Csaba P. Kovesdy,[3,4] Kamyar Kalantar-Zadeh,[2,1] Elani Streja.[1,2] *[1]VA Long Beach Healthcare System, Long Beach, CA; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [3]Memphis VA Medical Center, Memphis, TN; [4]The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Background: Change in urine albumin to creatinine ratio (UACR) is considered as a marker of kidney disease progression. Prior studies showed abnormal lipid levels may predict the progression of renal function decline; however, associations of low-density lipoprotein cholesterol (LDL) with UACR change is unclear. Therefore, we sought to investigate the association of LDL and UACR slope across albuminuria stages.

Methods: We analyzed 175,392 US veterans who received care between 2004 and 2006, with available serum LDL and albuminuria (UACR) data. All UACR measurements until the end of follow-up (2014) were used to ascertain UACR slopes using mixed effects modeling. The relationships between LDL with faster UACR slope (≥10 mg/g/year) stratified by baseline albuminuria stage (A1-A3) were estimated using logistic models adjusted for baseline demographics, comorbidities, prescription of statins and non-statins, BMI, albumin, HDL, triglycerides, eGFR, and UACR.

Results: Cohort mean age was 65±11 and included 3% females, 14% African-Americans, and 87% diabetics. The median [IQR] of serum LDL level and eGFR were 97 [75,119] mg/dL and 73 [58,88] mL/min/1.73m^2, respectively. There was a U-shaped association between LDL and odds of faster UACR slope among A1 patients. A similar

yet attenuated relationship was observed among A2 patients. Odds of faster UACR slope was higher only in patients with LDL ≥160 mg/dL and with index UACR≤300 mg/g. For A3 patients, there was no association between LDL level and UACR slope.

Conclusions: Among patients with baseline UACR <300 mg/g, both low and very high LDL were associated with higher odds of having fast UACR change. Yet, among those with higher albuminuria, the relationship with LDL and UACR change was null. More studies are needed to delve into the mechanism between LDL and CKD progression in order to further manage patients kidney health.

PO2037

Lipidomic Markers for Cognitive Impairment in Maintenance Hemodialysis Patients

Ke Zheng, Yujun Qian, Xuemei Li. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Cognitive impairment (CI) was relatively common in maintenance hemodialysis patients. The pathophysiology of CI in this particular population was not well understood. Whether the classic lipid components that affect cognitive outcome in general population have similar effect in dialysis patients is not clear. In this study, we tried to get a better understanding of the pathogenesis CI in hemodialysis patients by lipidomic analysis and find potential lipids markers to predict cognitive decline.

Methods: From July 2013 to July 2019, we followed up the cognitive evaluation results of the hemodialysis patients in our dialysis center. The cognitive function was evaluation by the MMSE and MoCA at baseline and follow-up period. Plasma and hemocytes of enrolled patients were collected at baseline. Lipidomic analyses were performed on an Exion LC-system coupled with a QTRAP 6500 PLUS system (Sciex). Principal component analysis and orthogonal project to late structures discriminant analysis, and t-test were used to analyze the differences in patients in cognitive decline group and cognitive retained group.

Results: At the baseline, plasma from 21 patients and hemocytes from 65 patients were collected for lipidomic analyses. 539 lipids were detected in plasma and 237 lipids were detected in hemocytes. In individuals with plasma lipids files data, 10/21 suffered MMSE scores decrement and 16 /21 showed MoCA decrement. In patients with hemocytes lipids files date, 29/65 of them suffered MMSE scores decrement and 43/65 showed MoCA decrement. Compared with retained MMSE scores group, decreased MMSE scores group presented higher level of plasma PA 32:1, PA 38:5, CE-17:1, and lower level of plasma DAG 40:6(18:0/22:6), PE 36:4(18:1/18:3). There was no significant difference in erythrocytes lipids between the two groups. Compared with retained MoCA scores group, decreased MoCA scores group presented higher level of plasma LacCer d18:1/18:0, LPE 18:2, GM3 d18:1/20:1, PE 36:3(18:1/18:2), LPE 18:1, lower level of plasma PI 38:5(18:0/20:5), and higher level of erythrocytes GM3 d18:0/20:0 (Fold change >1.5 or <1/1.5, P value <0.05).

Conclusions: The pathogenesis of CI in dialysis patients may closely relate with vascular injury. Lipid analysis may contribute to a new approach to predict the risk of cognitive decline in hemodialysis patients.

PO2038

The Combination of Malnutrition Inflammation and Limitations in Functional Status Is Associated with a Very High Risk of Mortality in Hemodialysis Patients: Results from the DOPPS

Marcelo Lopes,[1] Eiichiro Kanda,[2] Brian Bieber,[1] Kazuhiko Tsuruya,[3] Hideki Hirakata,[4] Angelo Karaboyas,[1] Stefan H. Jacobson,[5] Indranil Dasgupta,[6] Bruce M. Robinson,[1] Roberto Pecoits-Filho.[1] DOPPS *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Kawasaki Ika Daigaku, Kurashiki, Japan; [3]Nara-ken, Nara, Japan; [4]Fukuoka Renal Clinic, Fukuoka, Japan; [5]Karolinska Institutet, Stockholm, Sweden; [6]University of Warwick Warwick Medical School, Coventry, United Kingdom.*

Background: The malnutrition-inflammation-complex (MIC) is a risk factor for mortality and lower quality of life in hemodialysis (HD) patients. The identification of MIC and its risk factors, which include the limited ability to perform functional status (FS), is key to improve the patient experience on HD. Our study investigates the association of MIC and FS combinations with mortality in HD patients

Methods: We analyzed data from a cohort of 5465 HD patients from Australia, France, Germany, Italy, Japan, New Zealand, Spain, Sweden, and United Kingdom, enrolled in the Dialysis Outcomes and Practice Patterns Study phases 4 (2009-2011) and 5 (2012-2015). MIC syndrome was defined as low serum albumin (<3.8 g/dL) and high serum C-reactive protein (>3mg/L in Japan; >10 mg/L elsewhere). Poor functional status was defined as the sum of scores from the self-reported limitations in the Katz Index of Independence in Activities of Daily Living (0 to 5) and the Lawton-Brody Instrumental Activities of Daily Living Scale (score ranges from 0 to 8) less than 11. We investigated the association between combinations of MIC (+/-) and FS (low/high) with death, using Cox proportional hazards models adjusted for possible confounders including patient demographics, comorbidity history, catheter use, serum creatinine, phosphorus levels, WBC count, hemoglobin level, and time on dialysis therapy.

Results: The prevalence of different combinations were: MIC-/High FS 57%, MIC-/Low FS 24%, MIC+/High FS 9%, and MIC+/Low FS 10%. Patients with MIC-/high FS were younger, better nourished, and had lower prevalence of comorbidities. Compared to the reference group, the hazard ratios [HR (95% CI)] for all-cause mortality were 1.56 (1.24-1.98) for MIC-/ low FS, 1.75 (1.32-2.32) for MIC+/ high FS, and 2.97 (2.31-3.82) for MIC+/ low FS groups. The adjusted HRs for infection-related mortality were 1.57 (0.91, 2.71) for MIC-/low FS, 1.67 (0.84, 3.31) for MIC+/High FS, and 5.45 (3.15, 9.45) for MIC+/low FS groups.

Conclusions: The combination of MIC and low FS is a strong predictor of mortality, and infectious mortality in particular, in HD patients. Identification of patients with MIC and FS.

PO2039

High-Amylose Resistant Starch (RS) Cookies Supplementation Does Not Decrease Trimethylamine N-Oxide (TMAO) Plasma Level in Hemodialysis (HD) Patients

Denise Mafra,[1] Julie ann Kemp,[1] Henrique F. Santos,[1] Hugo E. de Jesus,[1] Marta Esgalhado,[1] Bruna Paiva,[1] Bengt Lindholm,[2] Peter Bergman,[2] Peter Stenvinkel.[2] *[1]Federal University Fluminense, Rio de Janeiro, Brazil; [2]Karolinska Institutet, Stockholm, Sweden.*

Background: TMAO is generated from dietary nutrients by the gut bacteriome and it is associated with cardiovascular mortality in HD patients. Thus, to reduce its generation, nutritional strategies have been proposed. The aim of this study was to analyze the TMAO levels and potential changes in TMA-associated bacterial taxa in HD patients after RS supplementation.

Methods: This is a randomized, double-blind, placebo-controlled trial with HD patients that were allocated to RS or placebo group to receive alternately 9 cookies/d (dialysis days) and 1 sachet/d (non-dialysis days) containing 16g/d of RS (Hi-Maize 260, Ingredion®) or manioc flour as the placebo, during 4 weeks. Plasma TMAO, choline, and betaine levels were measured with LC-MS/MS. Fecal bacteriome composition was evaluated by high-throughput sequencing of 16S ribosomal RNA gene V1–V3 region, followed by a search for TMA-associated taxa.

Results: Thirty-one participants finished the study, 15 in RS group (53.3% ♀; 56.0±7.5 yrs; 50.0±36.5 months on HD and BMI 26.1±5.0 kg/m²) and 16 in the placebo group (31.2% ♀; 53.5±11.4 yrs; 44.3±26.4 months on HD and BMI 26.6±5.2 kg/m²). After four weeks of supplementation no significant changes in TMAO, choline and betaine plasma levels were observed (Table 1). Notably, after the RS supplementation, TMA-producing bacterial taxa such as *Ruminococcus* torques group [(0.026 (0.023 - 0.04) vs. 0.017 (0.017 - 0.02), p=0.06)] and *Streptococcus* had decreased the relative abundance, while *Prevotellaceae family and Enterococcus* increased their relative abundance in placebo group. However, the differences did not reach statistical significance. Additionally, the relative abundance of TMA-producing bacterial taxa was low in both groups.

Conclusions: RS supplementation did not influence TMAO plasma levels nor fecal taxa potentially linked to TMAO in HD patients, suggesting that RS did not modify the composition of gut bacteriome that convert its precursors into TMAO.

Funding: Government Support - Non-U.S.

Effects of RS supplementation or placebo on plasma TMAO, choline and betaine levels

	RS group (n=13)		p values	Placebo group (n=12)		p values
	Before	After		Before	After	
TMAO (ng/μl)	4.1 (3.0 - 8.2)	4.4 (2.6 - 6.3)	0.89	3.3 (2.5 - 5.2)	4.6 (3.1 - 5.6)	0.49
Choline (ng/μl)	12.3 (10.8 - 13.6)	12.5 (10.2 - 14.3)	0.97	10.8 (9.95 - 13.9)	11.2 (9.7 - 19.9)	0.21

Public Health Effects of Sterilized, Used Hemodialyzers for Water Purification in Rural Ghana

Joseph M. Boaheng,[1,2] Jochen G. Raimann,[1,6] Philip K. Narh,[3,1] Seth Johnson,[1,6] Linda L. Donald,[1] Harrison K. Matti,[1] Maria E. Ferris,[7] Mathieu Lamolle,[8] Hongbin Zhang,[5] Friedrich K. Port,[4] Nathan W. Levin.[1] *[1]Easywater for everyone, Accra, Ghana; [2]Department of Field Epidemiology and Applied Biostatistics, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; [3]Ghana Health Service, Ada, Ghana; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]Graduate School of Public Health and Health Policy, New York City, NY; [6]Renal Research Institute, New York, NY; [7]University of North Carolina System, Chapel Hill, NC; [8]Water for Everyone, Geneva, Switzerland*.

Background: Consumption of contaminated water is a risk factor for infectious diarrhea and according to estimates of the World Health Organization remains the most often reported cause of death in children and the elderly. Our organization "Easy Water for Everyone (EWfE)" uses a membrane filtration device with repurposed hemodialyzers and has achieved remarkable public health effects (Raimann for EWfE, SciRep 2020). Here we report the impact our project had on the incidence of diarrhea in two villages in rural Ghana.

Methods: This prospective study was conducted with approval from Ghana Health Services and involved the quantification of self-reported diarrhea 4 months before and after implementation of a membrane filtration device in a school and a primary healthcare center. Using a mixed-effects generalized linear model, the odds of developing diarrhea in presence of the membrane filtration device were estimated. We additionally tested the association of age on the estimate, and conducted a subset analyses in those younger than 15 years old. Analyses were conducted in R version 4.0 and odds ratios (OR) reported as OR (95%CI).

Results: We studied 927 villagers (55% female, 43% <15 yrs and 13% > 50yrs) and the incidence rate of diarrhea was 0.30 per subject month per village-month before and 0.26 after implementation of the device. We found a statistically significant association between the device and incidence of diarrhea [OR 0.79 (0.67 to 0.95)] with significantly higher odds of diarrhea in the younger [OR 1.32 (1.07 to 1.63)] and the elderly [OR 1.45 (1.06 to 1.99)].

Conclusions: Our study supports provision of clean drinking water as means to prevent diarrhea and its possible adverse sequelae such as acute kidney injury (AKI). Additionally, we conclude the youngest and the eldest in the population are at highest risk of diarrhea.

PO2041

Development and Validation of a Multifrequency Bioimpedance Spectroscopy Equation to Predict Appendicular Skeletal Muscle Mass in Hemodialysis Patients

Ting-yun Lin. *Taipei Tzu Chi Hospital, Taipei, Taiwan*.

Background: Sarcopenia is prevalent and associated with poor outcomes in patients with chronic kidney disease (CKD). Although bioimpedance analysis is accepted by major consensus statements as an alternative for muscle mass assessment, it can be affected by hydration status in CKD patients. The Body Composition Monitor (BCM), a multifrequency bioimpedance spectroscopy device, has been widely used to assess body composition and dry weight in hemodialysis patients because it can distinguish normally hydrated lean tissues from overly hydrated tissues. Therefore, our study aimed to develop and validate an equation for obtaining appendicular skeletal muscle mass (ASM) from BCM using dual-energy X-ray absorptiometry (DXA) as the reference among hemodialysis patients.

Methods: A total of 322 consecutive body composition measurements with BCM and DXA in 263 hemodialysis patients were randomly divided at a ratio of 2:1 into development and validation groups. Stepwise multiple regression modeling was applied to develop the ASM prediction equation. Tests for agreement included mean differences and Bland-Altman plots. We evaluated the model as a diagnostic tool for sarcopenia using cutoffs of ASM defined by the Asian Working Group for Sarcopenia (AWGS). We further explored the association between ASM predicted by the BCM equation and all-cause mortality in two independent cohorts: one with 326 stage 3–5 CKD patients and one with 629 hemodialysis patients.

Results: BCM yielded the following equation: ASM (kg) = –1.838 + 0.395 × total body water (L) + 0.105 × body weight (kg) + 1.231 × male sex – 0.026 × age (years) (R^2 = 0.914, standard error of estimate = 1.35 kg). In the validation group, Bland-Altman reliability analysis showed no significant bias of 0.098 kg and limits of agreement ± 2.440 kg. Using the AWGS criteria, the model was found to have a sensitivity of 94.1%, a specificity of 98.8%, a positive predictive value of 84.2%, and a negative predictive value of 99.6% for the diagnosis of sarcopenia. Low ASM predicted by the BCM equation was associated with significantly worse overall survival among CKD patients but not hemodialysis patients.

Conclusions: The new BCM equation provides a feasible and valid option for assessing ASM in hemodialysis patients. Its utility in clinical practice requires further research.

Indoxyl Sulfate Reduces the Inducibility of NLRP3 Inflammasome in Hemodialysis Patients

Li-chun Ho,[1,2] Chang Min-Yu,[3] Yi-che Lee,[3] Hsi-Hao Wang,[3] Ching-fang Wu,[3] Shih-Yuan Hung.[3] *[1]I-Shou University, School of Medicine, Kaohsiung City, Taiwan; [2]E-Da Hospital, Department of General Medicine, Yanchao, Taiwan; [3]E-Da Hospital, Division of Nephrology, Department of Internal Medicine, Yanchao, Taiwan*.

Background: The NLRP3 inflammasome is a cellular component of innate immunity responsible for the maturation of interleukin-1β (IL-1β). Studies have shown that the basal activity of the NLRP3 inflammasome is increased in the immune cells of hemodialysis (HD) patients, but the inducibility of the NLRP3 inflammasome upon canonical stimulation has not been studied.

Methods: Peripheral blood mononuclear cells (PBMCs) isolated from 13 HD patients and 18 volunteers without a history of chronic kidney disease (CKD) were treated with a combination of lipopolysaccharide (LPS) and nigericin to induce NLRP3 inflammasome activation. Likewise, THP-1 monocytic cell-derived macrophages, with or without indoxyl sulfate (IS) pretreatment, underwent the canonical NLRP3 inflammasome stimulus as well. The activity of the inflammasome was determined by immunoblot analysis.

Results: Despite the high plasma levels of IL-1β in HD patients, caspase-1 and IL-1β in the PBMCs of HD patients remained predominantly immature and were not secreted in response to the canonical stimulus. Further investigations showed that while IS treatment alone facilitated the secretion of IL-1β from THP-1-derived macrophages, IS pretreatment reduced the inducibility of NLRP3 inflammaosme in response to LPS and nigericin, characterized by the low mature rate of caspase-1. The PBMCs derived from the HD patients and the macrophages exposed to IS both had low expression levels of NLRP3 inflammasome components, suggesting insufficient supplies of inflammasome machinery.

Conclusions: The low stimulation response of the NLRP3 inflammasome attributed to indoxyl sulfate probably constitutes a breach of the immune defense system, which may explain the high infection risk in HD patients.

Prevalence and Risk Factors of High-Altitude Hyperuricemia in the Bai Ethnic Group

Chenni Gao, Xiaonong Chen. *Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital Department of Nephrology, Shanghai, China*.

Background: The Bai ethnic group is one of the 55 minorities in the People's Republic of China. Hyperuricemia is not rare among this ethnic partly due to the chronic exposure to high altitude. However, the prevalence of hyperuricemia in the Bai ethnic group remains unclear.

Methods: We collected retrospectively the demographic characteristics and laboratory measurements of 1393 Bai ethnic adults undergoing annual medical examination during Jan 2019 to Dec 2019 in the People's Hospital of Jianchuan County (average altitude 2300m), Yunnan Province. We investigated the prevalence of hyperuricemia as well as its clinical features and risk factors.

Results: Of the 1393 participants enrolled in the study, the prevalence of hyperuricemia was 24.8%, and the prevalence was significantly higher in male gender (33.2% in men vs. 11.0% in women, P<0.001). The prevalence of hyperuricemia increased from 19.2% among participants aged 30-40 years to 30.1% among participants aged 50 years and older. Also, the prevalence elevated from 17.2% among participants with normal body mass index (BMI) to 35.5% among those who were overweighed/obese. Interestingly, we found a positive correlation between hemoglobin level (Hb) and serum uric acid (β=2.19, P<0.01). Logistic regression analysis revealed main risk factors for hyperuricemia in the Bai ethnic group included age, sex, BMI, systolic blood pressure (SBP) and Hb.

Conclusions: Hyperuricemia is common in the Bai ethnic group. Besides traditional risk factors such as age, sex and BMI, polycythemia secondary to chronic exposure to high altitude may also contribute to the hyperuricemia.

Changes in the Gut Microbiota After a Controlled Feeding Study in Individuals with CKD and Healthy Controls

Annabel Biruete,[1] Gretchen Wiese,[2] Tzu-Wen L. Cross,[2] Riya Thakkar,[2] Stephen R. Lindemann,[2] Elizabeth Stremke,[2] Ranjani N. Moorthi,[1] Kelly Swanson,[3] Sharon M. Moe,[1] Kathleen M. Hill Gallant.[2,1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Purdue University, West Lafayette, IN; [3]University of Illinois System, Urbana, IL.*

Background: Diet has been shown to alter the gut microbiota composition and function. However, controlled diet studies assessing the gut microbiota in CKD patients are limited. We assessed the differences in the gut microbiota composition before and after a week of controlled meals in patients with moderate-to-advanced CKD and healthy adults.

Methods: In a secondary analysis, we studied patients with CKD (n=7, eGFR 29-55mL/min/1.73m^2) vs. controls (n=7) matched for sex, age, and race. Participants ate a diet controlled for macronutrients (protein 0.8g/kg/d), fiber (25g/d), P (1500mg/d), Ca (1400mg/d), K (3500mg/d), and Na (2400mg/d) for 1 week. Fecal samples were obtained before and after the dietary intervention. Fecal DNA was extracted and used to amplify the V4 region of the 16S rRNA gene. Sequencing was performed via Illumina MiSeq platform and analyzed using QIIME2 and LEfSe.

Results: Fecal microbial diversity did not differ between patients with CKD or matched controls and was not affected due to the dietary intervention. At baseline, control individuals had a higher relative abundance of *Blautia* and an unclassified genus within Coriobacteriaceae, while CKD patients had a higher relative abundance of *Lachnobacterium.* After receiving a week of controlled meals, CKD patients had a higher relative abundance of *Anaerofustis* and *Clostridium*, while controls had a higher relative abundance of *Parabacteroides* and *Sutterella.* Comparing data before and after dietary treatment within groups, CKD individuals had a lower relative abundance of *Lachnobacterium* and higher *Bacteroides* and *Holdemania*. Meanwhile, healthy controls had a lower relative abundance of unclassified Mogibacteriaceae, and a higher relative abundance of *Bacteroides, Phascolarctobacterium, Parabacteroides*, and *Sutterella.*

Conclusions: While there were no major changes in microbial diversity, healthy controls and CKD patients responded differently to a week of controlled meals.

PO2045

Mitochondrial Dysfunction and Uremic Toxins from Gut Microbiota in CKD Patients: Is There a Link?

Denise Mafra,[1] Bruna Paiva,[1] Drielly V. Reis,[1] Karla thais R. Teixeira,[1] Laís G. Moreira,[1] Estelina S. Capistrano,[1] Ludmila F. Cardozo,[1] Lia S. Nakao,[2] Jessyca S. Brito.[1] *[1]Federal University Fluminense, Rio de Janeiro, Brazil; [2]Universidade Federal do Parana, Curitiba, Brazil.*

Background: Dysbiosis in patients with chronic kidney disease (CKD) is associated with increased production of uremic toxins, such as indoxyl sulfate (IS), p-cresyl sulfate (p-CS) and indole-3-acetic acid (IAA), which are linked to oxidative stress and may be related to mitochondrial dysfunction with alterations in peroxisome proliferator activated gamma receptor coactivator 1 alpha (PGC-1α), respiratory nuclear factor 1 (NRF-1) and mitochondrial transcription factor (TFAM). The aim of this study was to verify possible associations between metabolites produced by gut microbiota and genes related to mitochondrial function (PGC-1α, NRF-1, TFAM) in CKD patients.

Methods: This was a cross-sectional, observational study, involving 46 patients with CKD: 20 patients on hemodialysis (HD) (12 men, 44.2 ± 8.9 years) and 26 non-dialysis patients (8 men, 57.6 ± 6.2 years, GFR 25.0 ± 13.0mL/min), selected by non-probabilistic sampling of convenience. Plasma levels of IS, p-CS and IAA were assessed by high-performance liquid chromatography (HPLC). The analysis of the gene expression of PGC1-α, NRF-1 and TFAM were performed by real time Polymerase Chain Reaction (RT-PCR) in peripheral blood mononuclear cells (PBMCs). For statistical analysis, software R, version 3.5.0 (R Core Team, Vienna, Austria) was used and the results were expressed as mean ± standard deviation, with a significance level of p <0.05.

Results: As expected, the levels of uremic toxins were higher in HD patients than in non-dialysis patients [IS: 31.1 ± 14.3 mg/L vs 2.9 ± 1.7 mg/L (p <0.001); p-CS: 53.4 ± 34.6 mg/L vs 14.6 ± 10.8 mg/L (p <0.001); IAA: 2560.1 ± 1379.6 ug/L vs 1050.4 ± 984.8 ug/L)]. There was no significant difference in the mitochondrial parameters TFAM and PGC1a between the groups of patients. In the HD group was observed a positive linear correlation between TFAM and NRF1 (r = 0.978, p <0.001); as well as between PGC1a and NRF1 (r = 0.8, p = 0.006). However, in both groups there was no correlation between mitochondrial genes and uremic toxins.

Conclusions: The uremic toxins levels were significantly higher in HD patients; however, we did not find any correlations with the parameters of mitochondrial function analyzed.

PO2046

Dysbiosis of Gut Microbiota in Adult Idiopathic Membranous Nephropathy with Nephrotic Syndrome

Jun Zhang. *Division of Nephrology, Department of medicine, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Gut bacterial microbiota is altered in patients with chronic kidney disease (CKD) and those on dialysis. However, it is not yet clear what bacterial composition changes occur in patients with idiopathic nephrotic syndrome. We present in this report the changes in gut bacterial microbiota in idiopathic nephrotic syndrome patients with membranous nephropathy.

Methods: A total of 158 individuals were recruited for this study. Of these, 80 were CKD3–5 stage patients without nephrotic syndrome, 48 patients had idiopathic nephrotic syndrome and pathological diagnosis of membranous nephropathy, and 30 were age- and sex-matched healthy controls. The gut microbiome composition was analyzed using a 16S ribosomal RNA gene-based sequencing protocol.

Results: The results indicate that the nephrotic syndrome (NS) patients had a significantly different alpha and beta diversity compared with the CKD3–5 group and healthy controls (p < 0.01). At the phylum level, the NS patients showed increased *Fusobacteria* and *Proteobacteria* but reduced *Firmicutes* when compared with the healthy controls. At the genus level, *Megamonas*, *Megasphaera*, *Akkermansia*, and the butyrate-producing bacteria *Lachnospira*, *Roseburia*, and *Fusobacterium* were more abundant in the controls (LDA score > 3) than the CKD3–5 and NS patients. Compared with the healthy controls, we found that *Parabacteroides* was increased in CKD3–5 and NS patients. In addition, *Oscillospira* and *Ruminococcus* were more abundant in CKD patients than in the other two groups (LDA score > 3). At the genus level, ten bacterial taxa were more prevalent in the healthy controls. *Providencia* and *Myroides* were more prevalent in NS patients.

Conclusions: Our findings highlight that, NS patients had a significantly different alpha and beta diversity and decreased gut microbiota-derived short-chain fatty acids, such as butyrate. However, large-scale prospective studies should be performed to identify the cause and effect factors of these changes in the microbiota in NS patients.

Funding: Government Support - Non-U.S.

PO2047

The Alter of Gut Microbiota in Dialysis Patients and Its Influence on the Prognosis for ESRD Patients

Jun Zhang, Dan Luo, Haixia Xiong, Hui-qun Li. *Department of Nephrology, the Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Previous studies have found that alteration in gut microbiota occurred in end-stage renal disease (ESRD) patients with or without dialysis, and are associated with complications such as inflammation and cardiovascular events. However, it has not been clarified whether gut microbiota are influenced by dialysis intervention in ESRD patients.

Methods: The fecal samples of 73 ESRD patients were collected, including 33 pre-dialysis ESRD patients, 19 peritoneal dialysis (PD) patients, and 21 hemodialysis (HD) patients; 19 healthy fecal samples were also collected as control in this study. The 16S rRNA sequencing and the bioinformatics was used to analyze the the composition and function of gut microbiota. The clinical outcomes of the patients were tracked from April 2017 to the end of May 2020.

Results: Compared with the pre-dialysis patients, Bacteroidetes decreased significantly in HD patients. At the genus level, a total of 14 genera showed differences between patients before and after dialysis. Pre-dialysis patients have a increased abundance of Parabacteroides, Prevetolla and Oscillospira, and the decreased abundance of Lachnospira, Klebsiella, Akkermansia and Roseburia. HD could repair the abnormal changes of these flora in pre-dialysis patients. We could not found any bacteria defference between PD and pre-dialysis patients in phylum and genus level. The PICRUSt analysis showed that PD and HD could change the signal transduction and metabolic pathways of ESRD patients. It was found that Bacteroides and SMB53 were associated with the occurrence of cardiovascular events. Blautia, Faecalibacterium, and Veillonella were associated with peritonitis in PD patients.

Conclusions: Our results suggested that compared with healthy control, the composition and function of gut microbiota of pre-dialysis patients were changed, HD could restored the relative abundance of beneficial bacteria and reduced some potential pathogenic bacteria. Some gut microbiota were associated with prognosis in all of ESRD patients and peritonitis in PD patients.

PO2048

Effect of Intradialytic Oral Nutritional Supplementation with and Without Exercise on the Skeletal Muscle Quantity and Quality of Adult Hemodialysis Patients

Geovana Martin-Alemañy,[1] L. M. Perez-Navarro,[1] Angeles Espinosa-Cuevas,[2] Gloria G. García Villalobos,[1] Elba O. Medina,[1] Miguel Angel Reyes Caldelas,[1] Rafael Valdez-Ortiz.[1] *[1]Hospital General de México, Dr. Eduardo Liceaga, Ciudad de México, Mexico; [2]National Institute of Medical Science and Nutrtion Salvador Zubira, Ciuad de México, Mexico.*

Background: The muscle mass (MM) is one of the major tissues affected by the chronic kidney disease. Patients undergoing chronic hemodialysis (HD) have loss of MM due to many factors. Intradialytic oral nutritional supplementation (ONS) and exercise (EX) have been shown to improve the amount and quality of MM and physical function (PF). We evaluate the effect of the ONS with and without exercise during the HD sessions for 6 months in the quality and quantity of MM in adult HD patients.

Methods: Patients were randomized in two different groups: 1) ONS and 2) EX + ONS. Patient's realized 30 minutes of aerobic EX using static bicycles and 30 minutes of resistance EX using Theraband Bands. Quantity and quality of MM were measured with anthropometrics and computed tomography (CT). PF was measured by short physical performance battery (SPPB), six-minute walk test (6 MWT) and handgrip strenght (HGS)). According to the data distribution Student t test or Mann-Whitney test were used to analyze the data.

Results: Twenty-three patients conclude the study. Both groups improves their weight (*ONS*: baseline, 53 ± 5.4kg; final, 54.3 ± 4.9kg; p = 0.020 and *ONS + EX*: baseline, 57.2 ± 9.2kg; final: 59 ± 9.2kg; p = 0.001) and the AMC (*ONS*: baseline, 227 ± 20mm; final; 241 ± 19mm; p = 0.040 and *ONS + EX*, baseline: 235 ± 27mm, final: 250 ± 31; p = 0.047). In the ONS group we observed decreases in the 6MWT; baseline: 417 ± 53.9m, final: 405 ± 52m; p= 0.016 and improvements in the SPPB; baseline:10.8 ± 1.3, final: 11.2 ± 1.4, p= 0.005) with no change in the intramuscular lipid infiltration (baseline: 53.5 ± 5.8UH, final: 53.5 ± 3.9UH; p= N.S.). The EX group had improvements in the 6MWT, HGS and in the SPPB (baseline: 383 ± 58m, final: 425 ± 46m; p= 0.000; baseline: 22.6 ± 8.8kg, final: 24.8 ± 8kg, p= 0.000 and baseline: 10.2 ± 1.1, final: 10.8 ± 1.4, p= 0.801, respectively) with decreases in the intramuscular lipid infiltration (baseline: 53.1 ± 4.5HU, final: 55 ± 3.8HU; p= 0.093).

Conclusions: Exercise training for 6 months improves the MM composition of HD patients measured by CT and this was reflected with the improvements in the PF tests and no changes were observed in MM composition in the ONS group.

PO2049

Muscle Mitochondrial Function and Physical Performance Are Associated with Branched-Chain Amino Acid Levels in Patients with CKD

Jorge Gamboa,[1] Berfu Korucu,[1] Dungeng Peng,[1] Baback Roshanravan,[2] Talat Alp Ikizler.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California Davis, Davis, CA.*

Background: Muscle mitochondrial function and physical performance are impaired in patients with chronic kidney disease (CKD). Previous studies suggest that decreased branched-chain amino acids (BCAA) levels are associated with muscle catabolism in patients with CKD. We hypothesized that BCAA is lower in patients with CKD and associated with mitochondrial function and physical performance, critical components of protein-energy wasting observed in patients with CKD.

Methods: In a cross-sectional study, we evaluated 63 participants [20 with CKD stage 3-5, 20 with CKD stage 5 on maintenance hemodialysis (MHD), and 20 controls with no history of CKD]. Mitochondrial function was evaluated using ^{31} phosphours magnetic resonance spectroscopy to evaluate the phosphocreatine (PCr) recovery after exercise. A longer PCR recovery results in a greater time constant tau (τ), which indicates worsening mitochondrial function. Physical performance was measure using the six-minute walk test. BCAA levels were measured in plasma samples using nuclear magnetic resonance. Linear regression analysis was used to evaluate association and adjusting by age, race, sex, and body mass index (BMI).

Results: Groups were similar in terms of gender, BMI, and history of diabetes and hypertension. Patients on MHD were younger than patients with CKD stage 3-4 (47.7±11.7 vs. 63.6±9.0) but had similar age compared to controls (46.9±9.5). BCAA levels were lower in patients with CKD and patients on MHD compared to controls (**Figure 1A**). Lower levels of BCAA, particularly leucine, were associated with worse mitochondrial function (higher time constant τ, **Figure 1B**) and lower physical performance (**Figure 1C**) in unadjusted and adjusted linear regression.

Conclusions: CKD is associated with lower levels of BCAA. Furthermore, low levels of BCAA are associated with impaired mitochondrial function and poor physical performance. Future studies should evaluate the effect of BCAA supplementation in mitochondrial function and physical performance in patients with CKD.

High Prevalence of Sleep Disordered Breathing and Its Association with Renal Function in Patients with CKD: A Cross-Sectional Study

Kanji Ota, Yosuke Nakayama, Tomofumi Moriyama, Yusuke Kaida, Kei Fukami. *Division of Nephrology, Department of Medicine, Kurume University, Kurume, Japan.*

Background: Sleep disordered breathing (SBD) is known as a novel risk factor for cardiovascular disease, and one of five adults suffer from SBD in general population. In non-dialysis chronic kidney disease (CKD) and hemodialysis (HD) patients, a high prevalence of SBD has been reported due to the excess accumulation of extracellular fluid. However, precise prevalence and associated factors of SBD in patients with peritoneal dialysis (PD) has not been known. This cross-sectional study aimed to investigate the prevalence and determinant factors associated with SBD in patients with CKD.

Methods: This was a single-center retrospective cohort study recruited 334 patients with CKD stages 1-3a, 3b-5, HD, and PD enrolled from 2018 to 2020. All patients were hospitalized and received our CKD educational program, and did not have sleep complaints. The diagnosis and assessment of the severity of SBD were evaluated using PULSOX-Me300 and SAS2100 systems. The 3% oxygen desaturation index and SpO_2 were measured during sleep. SBD was defined as 3% oxygen desaturation index (ODI)>15.0 and SpO_2<92% in this study.

Results: Proportion of the patients with CKD1-3a, CKD3b-5, HD, and PD were 28%, 53%, 11%, and 8%, respectively. 31% of the patients were diagnosed with SBD in all CKD patients. In a generalized linear model, 3% ODI>15.0 and SpO_2<92% were significantly correlated with apnea hypopnea index ($p<0.05$, $r=0.87$ and $p<0.05$, $r=-0.45$, respectively). Further, it became clear that the proportion of 3%ODI>15 and SpO_2<92% was significantly higher in PD patients (50%) than in other CKD patients. Furthermore, 3% ODI was significantly correlated with BMI and HDL cholesterol levels in PD patients ($p<0.05$, $r=0.67$ and $p<0.05$, $r=-0.54$, respectively).

Conclusions: We reported for the first time that the prevalence of SBD was very high and that the severity of SBD was significantly associated with BMI in patients with PD. These findings suggest that the extracellular fluid overload and excess glucose exposure due to PD fluid might accelerate SBD in patients with PD. Further clinical studies are needed to determine whether PD-associated SBD might influence the development of cardiovascular disease in CKD patients.

PO2051

Effects of Resistant Starch (RS) Type 2 Cookies on Gut Microbiota Profile in Hemodialysis (HD) Patients

Denise Mafra, Julie ann Kemp, Marta Esgalhado, Bruna Paiva, Hugo E. de Jesus, Henrique F. Santos. *Federal University Fluminense, Niterói, Brazil.*

Background: Dysbiosis is recognized as a new cardiovascular risk factor in HD patients. In this context, nutritional strategies as the use of high amylose RS have been proposed to modulate the gut microbiota in HD patients. The aim of the present study was to evaluated the effects of RS supplementation on gut microbiota modulation in HD patients.

Methods: This double-blind, placebo-controlled clinical trial evaluated HD patients randomized in two groups, RS or placebo. They received 9 cookies/day (16g of RS - Hi-Maize 260, Ingredion®), in the HD days and 1 sachet/day in non-HD days for 4 weeks. The placebo group received manioc flour. Fecal bacteriome composition and diversity were evaluated by high-throughput sequencing of 16S rRNA gene.

Results: Twenty patients concluded the study: 10 in the RS group (3 ♂, 53.2 ± 12.3 yrs, BMI, 24.6 ± 3.9 Kg/m²) and 10 in the placebo group (8 ♂, 55.1 ± 11.1 yrs, BMI, 25.6 ± 4.9 Kg/m²). Microbial diversity (Shannon index) and richness (ACE) were similar in both groups at baseline. RS supplementation increased mainly the relative abundance of the genus *Ruminococcus 2* and maintained genus *Blautia*, while the placebo group decreased both of these genera, as showed in the Fig 1. After RS supplementation the beta diversity (PCA) changed, increasing the short-chain fatty acid producers, which are related to benefits effects.

Conclusions: The RS supplementation was able to change the gut microbiota in HD patients. Linking these results with our previous studies, which RS was able to reduce the inflammatory and oxidative stress markers and uremic toxins plasma levels in HD patients, we suggest that RS can be a good nutritional strategy to modulate the gut microbiota in HD patients.

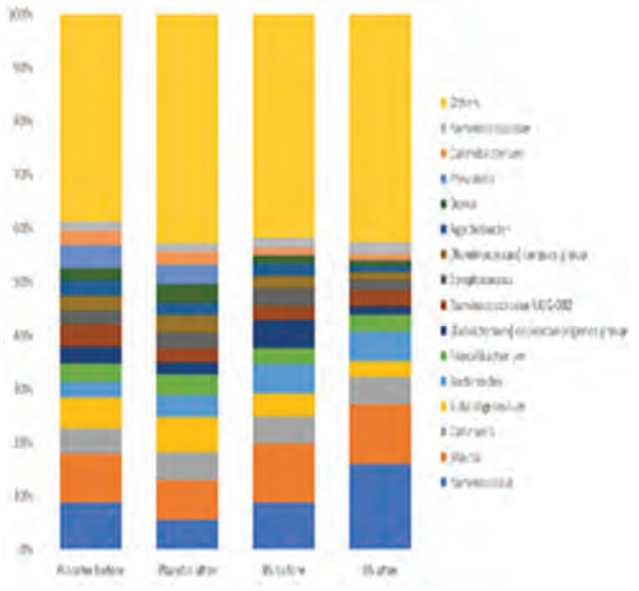

Fig.1: Relative abundance at genus level from RS and Placebo group.

PO2052

Gut Dysbiosis and Mortality in Hemodialysis Patients

Ting-yun Lin. *Taipei Tzu Chi Hospital, Taipei, Taiwan.*

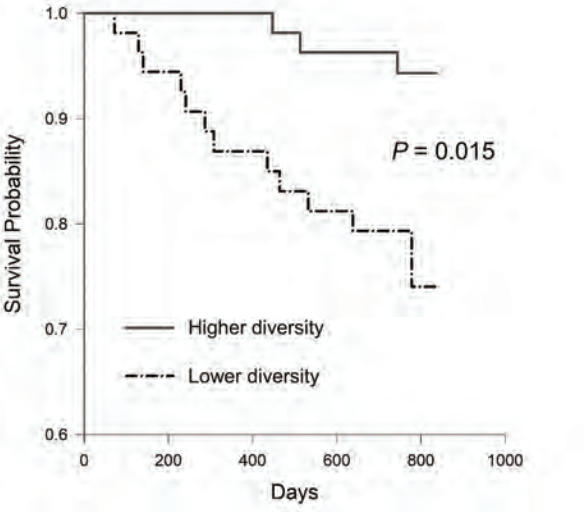
Background: Persistent inflammation plays a pathogenic role in CKD-associated protein-energy wasting, cardiovascular disease, and mortality. Gut dysbiosis, characterized by decreased microbial diversity, promotes inflammation. The gut microbiota is markedly altered in patients with ESKD. Therefore, we aimed to determine the relationship between gut dysbiosis and mortality in an ESKD cohort.

Methods: In an observational study, we examined the associations between microbial diversity and mortality in ESKD patients undergoing maintenance hemodialysis (*n*=109) using Cox proportional hazards models. The gut microbiota was assessed by 16S rRNA sequencing. Microbial diversity was calculated using the Simpson index. Participants were stratified into higher- (above the median) and lower-diversity (below the median) groups and were followed up for a median of 2.1 years. Next, in a matched case-control study, we compared the microbial composition between nonsurvivors and survivors.

Results: Kaplan-Meier analyses revealed a significant association between higher diversity and a lower risk of death (*P*=0.015). After adjustment for patient characteristics and comorbidities, the risk of death among patients with higher diversity was 74% lower than that among patients with lower diversity (hazard ratio, 0.26; 95% CI, 0.07 to 0.95). Nonsurvivors and survivors were matched 1:4 for age and sex. We observed significantly lower values of microbial diversity and higher levels of proinflammatory cytokines (IL-6 and TNF-α) among nonsurvivors (*n*=14) than survivors (*n*=56). Notably, the relative abundance of *Succinivibrio* and *Anaerostipes*, two short-chain fatty acid-producing bacteria, was reduced in nonsurvivors compared with survivors.

Conclusions: A unique gut microbial composition is associated with an increased risk of mortality in patients with ESKD and may be used to identify subjects with a poor prognosis. Our findings need to be validated in a larger independent cohort.

Funding: Private Foundation Support



Kaplan–Meier analysis curves. Hemodialysis patients were stratified by the median of the Simpson index to assess the unadjusted risks for all-cause mortality.

Insulin Resistance and Pancreatic Beta-Cell Function in Calcium Kidney Stone Formers

Olive W. Tang,[1] Kevin Mitchell,[2] Jie Tang.[2] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Alpert Medical School of Brown University, Providence, RI.*

Background: Diabetes mellitus is common among individuals with kidney stones; however, the risk factors associated with glucose dysregulation in this population is unclear.

Methods: We characterized the independent associations between vitamin D, urinary measures of dietary intake (sodium, magnesium), and urinary ammonia and citrate with homeostasis model assessment of β-cell (HOMA-B) and insulin resistance (HOMA-IR) in prevalent calcium kidney stone formers without diabetes mellitus recruited from Lifespan Kidney Stone Clinic (N = 96). We used linear regression with adjustment for demographics, body mass index, hypertension, hyperlipidemia, parathyroid hormone, and serum uric acid.

Results: The study population had a mean age of 53 years, 48% were male, and 83% were Caucasian. The mean 25-hydroxy-vitamin D (25D) was 30 ng/ml, 1,25-dihydroxy-vitmain D (1,25D) was 55 pg/ml, 24-hour urine sodium was 145 mmol, urine ammonia was 30 mEq, urine citrate was 590 mg, and urine magnesium was 102 mg. Mean HOMA-B was 172.1, and mean HOMA-IR was 5.4. Urine sodium was negatively associated with HOMA-B, but not HOMA-IR. Urine ammonia was positively associated with HOMA-IR, but not HOMA-B. Urine citrate was positively associated with both HOMA-B and HOMA-IR (**Table**).

Conclusions: In our cohort of calcium kidney stone formers, high salt intake and low urine citrate were associated with worse beta-cell function. High urine ammonia and citrate were associated with increased insulin resistance.

Funding: Clinical Revenue Support

Table. Association (β [95% confidence interval]) of risk factors with HOMA-IR and HOMA-B in prevalent calcium kidney stone formers from the Lifespan Kidney Stone Clinic, N = 96

Risk Factor	HOMA-B	HOMA-IR
25-hydroxy-vitamin D, per ng/mL	-1.1 (-3.1, 0.9)	-0.1 (-0.2, 0.1)
1,25-dihydroxy-vitmain D, per pg/mL	-0.5 (-2.3, 1.2)	-0.0 (-0,1, 0.1)
Urinary sodium, per mmol	-0.7 (-1.1, -0.3)**	-0.0 (-0.0, 0.0)
Urinary ammonia, per 10 mEq	-0.4 (-22.8, 22.1)	1.2 (0.1, 2.4)*
Urinary citrate, per 10 mg	0.9 (0.1, 1.7)*	0.1 (0.0, 0.1)**
Urinary magnesium, per mg	-0.2 (-0.8, 0.5)	0.0 (-0.0, 0.1)

Time to Hyperkalemia Recurrence in 1 Year Among 103,155 US Veterans

Jui-Ting Hsiung,[1] Rubeen K. Israni,[2] Cachet Wenziger,[1] Nipun Atreja,[2] Connie Ha,[2] Deborah A. Anzalone,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]AstraZeneca, Wilminton, DE.*

Background: Elevated serum potassium (sK) is commonly asymptomatic, but in a subset of patients, hyperkalemia (HK) is associated with worse outcomes and frequent recurrence. Whether the initial HK event was captured during a hospitalization may be associated with time to recurrence. Further characterizing time to recurrence in inpatient (INPT) and outpatient (OPT) settings may improve HK monitoring and treatment.

Methods: Among 3,958,837 US veterans that had a sK between 2004-2006, there were 589,019 that had an index HK event (sK >5.0 mEq/L) during this period where we could ascertain INPT/OPT status. We then identified patients who had a recurrent HK event 7-365 days after the index HK and had at least one normal sK ≤5.0 mEq/L in between events. We examined time to recurrence in 30-day intervals according to whether the index sK was INPT or OPT. Patients who's INPT/OPT status at HK recurrence could not be ascertained were excluded.

Results: HK recurrence over one year occurred in 103,155/589,019 (17.5%) patients, or 17,215/51,262 (34%) and 85,940/537,757 (16%) of patients with index INPT and OPT events, respectively. The 103,155 patients with HK recurrence had a mean patient age of 68±11 years, consisted of 98% males, 14% African Americans, 56% diabetics, and 60% with estimated glomerular filtration rate <60 mL/min/1.73m^2. In patients with HK recurrence, 50% (n=51,675) developed this event 6 months after the initial HK (table). Among patients who had an OPT index HK, 56% developed recurrence 6 months after index HK event. However, 51% of the patients who had an INPT index HK event developed recurrence within 60 days of the index HK.

Conclusions: A significant proportion of VA patients with HK developed another HK event within one year. Hospitalized patients with HK developed recurrence faster than patients in the OPT setting despite requiring 7 days between HK events and normalization of sK between events. This could be due to the fact that hospitalized patients are usually sicker or they were monitored more closely by the healthcare providers, therefore it is easier to catch HK recurrence in INPTs than OPTs.

Funding: Commercial Support - Astrazenenca

Days from index date to HK recurrence	Total Cohort, n (%)	Index HK: Inpatient, n (%)	Index HK: Outpatient, n (%)
0-30	10,651 (10)	6,072 (35)	4,579 (5)
31-60	8,803 (9)	2,701 (16)	6,102 (7)
61-90	7,859 (7)	1,615 (9)	6,244 (7)
91-180	24,167 (23)	3,184 (19)	20,983 (24)
181-365	51,675 (50)	3,643 (21)	48,032 (56)

PO2055

Primary Care and Annual Wellness Visits Before and After Dialysis Initiation

Virginia Wang,[1,2] Lindsay Zepel,[1] Clarissa J. Diamantidis,[1] Valerie A. Smith,[1,2] Sarah H. Scholle,[3] Matthew L. Maciejewski.[2,1] *[1]Duke Univ, Durham, NC; [2]Durham VAHCS, Durham, NC; [3]NCQA, Washington, DC.*

Background: Demands of dialysis regimens may pose challenges for patients to receive care for the management of non-renal conditions. Dialysis initiation may affect primary care provider (PCP) engagement and timely preventive care. Provided mostly by PCPs, AWVs provide a unique opportunity outside of routine evaluation and management visits to reassess health risks and functional limitations, update care plans, screen for depression, and better coordinate care. AWVs may be particularly useful for older adults undergoing dialysis who usually have other chronic, non-renal needs that commonly require ongoing monitoring and management. This study examined variation and patient factors associated with having PCP care and receipt of AWVs before and after initiating dialysis.

Methods: We used de-identified data from the OptumLabs® Data Warehouse to conduct a cohort study of Medicare Advantage (MA) enrollees initiating dialysis in 2014-2017. We used logistic regression to examine whether MA enrollees had an outpatient visit with a PCP in the year after dialysis initiation and whether they received an AWV, adjusting for demographic characteristics, dialysis modality, comorbidity, and pre-dialysis care by a PCP or nephrologist.

Results: One year after dialysis initiation, 93.3% of MA enrollees had an outpatient PCP visit. They were more likely to see a PCP if they had seen a nephrologist (OR=1.60, 95% CI: 1.01-2.52) or a PCP (OR=15.65, 95% CI: 9.26-26.46) prior to initiation. They were less likely to see a PCP if they had lower comorbidity burden (Charlson score 0-5 vs 6-9: odds ratio (OR)=0.59, 95% CI: 0.37-0.95). Of MA enrollees initiating dialysis, 24.4% had an AWV. Hispanic MA enrollees were less likely (OR=0.57, 95% CI: 0.39-0.84) to have an AWV compared to White MA enrollees. Peritoneal dialysis patients (OR=1.54, 95% CI: 1.07-2.23) or those with an AWV in the year before dialysis (OR=4.96, 95% CI: 3.88-6.34) were more likely to have an AWV.

Conclusions: While nearly all MA enrollees saw a PCP in the year after dialysis initiation, few had an AWV in this pivotal year. Since most MA enrollees who initiated dialysis continue to see primary care providers, there is opportunity to increase access to AWVs for these complex patients, through patient education and awareness of the value of AWVs and by encouraging providers to offer AWVs.

Workplace Outreach Program Facilitates Referral into Physician Care and Diagnosis of CKD

Olga A. Iakoubova, Carmen H. Tong, Charles M. Rowland, Andre Arellano, Lance A. Bare, Maren S. Fragala, James J. Devlin, Charles E. Birse. *Quest Diagnostics Nichols Institute, San Juan Capistrano, CA.*

Background: Chronic kidney disease (CKD) is often unrecognized and undertreated. Timely diagnosis can improve disease management and slow CKD progression. We asked whether a workplace outreach program facilitates CKD diagnosis and improves management of CKD.

Methods: An annual workplace health assessment that included eGFR testing was offered to employees. Those with confirmed CKD by repeat eGFR <60 mL/min/1.73 m^2 or by albumin to creatinine ratio test were eligible to participate in a CKD outreach program. A study coordinator made up to 3 phone calls in an effort to contact each eligible employee, to provide an explanation of CKD risk and to offer a physician consultation to discuss test results and referral into care. Those who accepted the phone call (participation group) were compared to those who were not reached by phone (control group). Using logistic regression models that adjusted for prevalent CKD, we analyzed claims data to estimate the effect of outreach participation on nephrologist visits, physician visits, and new CKD diagnoses 5 months after the outreach. Changes in eGFR levels were evaluated at the following annual health assessment.

Results: Of the 398 eligible employees, 156 participated in the outreach program; the remaining 242 served as the control group. CKD risk factor profiles at baseline were similar between participants and controls. Participants had 3-fold greater odds of visiting nephrologists, 60% greater odds of visiting physicians and 80% greater odds of being diagnosed with CKD, compared with the controls. Participants had 40% lower odds of an annual eGFR decline >5 ml/min/1.73 m^2 compared with controls (Table). One participant initiated kidney dialysis, compared with none in the control group.

Conclusions: A workforce CKD outreach program facilitates diagnosis of CKD and improves disease management including referral to a nephrologist.

Funding: Commercial Support - Quest Diagnostics supports annual health assessments and the CKD outreach program for employees and their spouses. It also provided funds for the analysis presented in the abstract

Effect of the CKD Outreach Program on Disease Management

Outcome	Adjusted Odds Ratio	95% CI	P value
Nephrologist visits	3.0	1.38 - 6.77	0.006
Physician visits	1.61	1.07 - 2.42	0.023
Newly diagnosed CKD	1.83	1.05 - 3.10	0.034
Annual eGFR decline >5 ml/min/1.73 m2	0.59	0.32-1.09	0.095

A Pilot Randomized Clinical Trial to Embed Technology-Enabled Group-Based Exercise Programming in the Clinic: The Exercise Is Medicine in Chronic Kidney Disease Trial

Susan Ziolkowski,[1] Shuchi Anand,[1] Ahad A. Bootwala,[2] Jianheng Li,[2] Nhat M. Pham,[1] Jason Cobb,[2] Felipe Lobelo.[2] *[1]Stanford University School of Medicine, PALO ALTO, CA; [2]Emory University School of Medicine, Atlanta, GA.*

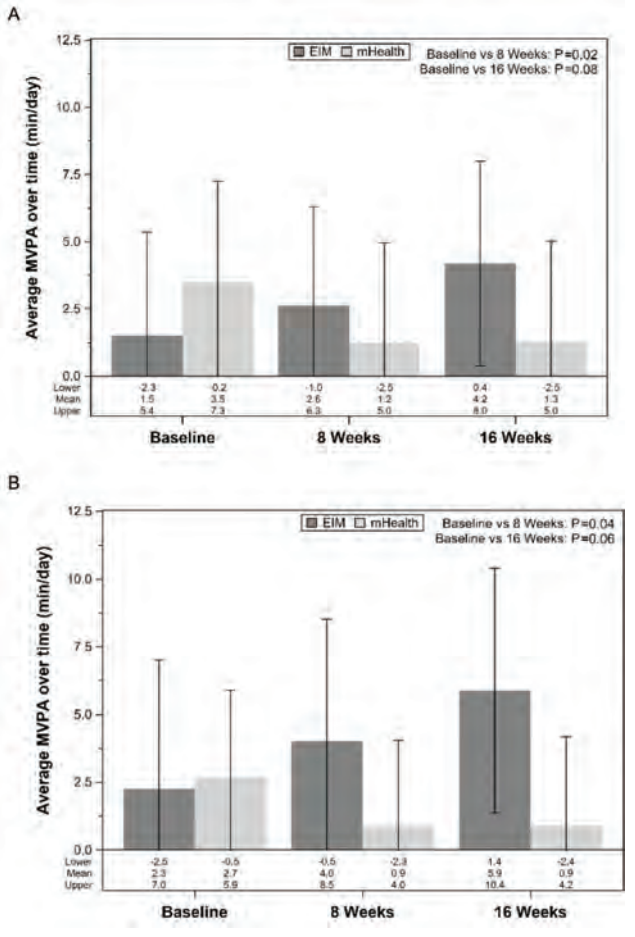
Background: Physical activity (PA) is associated with improvement of cardiovascular health, transplant outcomes, and survival in CKD. We evaluated the feasibility and effectiveness of integrating referral from nephrology clinics to a technology-enabled and/or group-based exercise program.

Methods: We conducted a pilot trial to test the ACSM Exercise is Medicine (EIM) framework in persons with eGFR <45 not on dialysis in San Jose, CA and Atlanta, GA. Participants were randomized to 1. mobile health (mHealth) group: wearable PA trackers + counseling, or 2. EIM group: mHealth + twice weekly small group exercise sessions. Physical and mental health assessments were done at baseline, 8, and 16 wks. Multilevel mixed models evaluated group differences.

Results: Of 56 participants, 86% belonged to a racial/ethnic minority. In intention-to-treat analyses, the EIM group increased moderate-vigorous PA compared to the mHealth group (time x intervention p=0.02) at 8 wks, no differences were observed between group daily step count. In as-treated analyses, daily step count, distance covered, light and moderate-vigorous PA improved in the EIM group and declined in the mHealth group at 8 wks (p ≤0.05) but group differences faded at 16 wks. No differences in physical function or mental health were found.

Conclusions: We successfully integrated recruitment, assessment, and group-based fitness interventions into clinical settings servicing minority patients with advanced CKD. Despite poor baseline measures, improvements in PA were observed in the EIM group, particularly in persons who participated in exercise sessions.

Funding: Private Foundation Support



Intention to treat (A) and as-treated (B) analyses: change moderate to vigorous physical activity (MVPA) in EIM vs mHealth

PO2058

Effect of Exercise on Quality of Life and Functional Capacity in Patients with CKD

Varun kumar Bandi,[1] Haneesha Kolli,[2] Sreelakshmi Nimmagadda,[2] Sandhya Komatla.[2] *[1]Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Gannavaram, India; [2]Kommareddy Venkata Sadasiva Rao Siddhartha College of Pharmaceutical Sciences, Vijayawada, India.*

Background: Chronic kidney disease patients have lower activity levels when compared to normal population, compounded by sedentary lifestyle and is associated with increased mortality, which might reduce with exercise

Methods: Patients with chronic kidney disease were evaluated for 12 weeks of supervised exercise program. The subjects were divided into 2 groups: Group I (CKD stage 3-5) and Group II (CKD on maintenance hemodialysis). Serum hemoglobin (Hb), calcium (Ca), phosphorous (Pi), and albumin (Alb) were done at baseline and at 12 weeks. Symptom burden was assessed using Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-F) and Leicester Uremic Symptom (LUS) Scale, Quality of life using SF-36 questionnaire, functional capacity using Duke Activity Status Index, Physical activity using Godin-Shephard Leisure time Exercise Questionnaire and Nutritional status using modified Subjective Global Assessment at baseline and at 12 weeks. Subjects in Group I were advised aerobic and resistance exercises at home, with once in 3 weeks hospital visit. Subjects in Group II underwent aerobic and resistance exercise in the pre-dialytic and intra-dialytic period during every dialysis visit

Results: Group I included 28 patients, while group II had 30 patients. At baseline, Hb and Albumin were significantly different between groups, while other parameters and scores were similar. At baseline, SF-36 and FACIT-F significantly correlated positively with Hb, Alb, Ca and Pi, while SGA correlated significantly with Alb, Ca & Pi. At end of study, in group I there was a non- significant increase in SF-36 (p=0.41), and DUKES (p=0.17), with a non-significant decrease in LUS (p=0.36), FACIT-F (p=0.83) and SGA (p=0.1136), while in group II there was a significant increase in SF-36 (p<0.001), with non-significant increase in Dukes (p=0.75), and a significant decrease in LUSS (p<0.001), SGA (p<0.05) and FACIT-F (p<0.001)

Conclusions: Exercise increased the quality of life and decreased symptom burden but there was an increase in fatigue perception in patients on dialysis. However, LUSS reduced with reduced FACIT-F which could mean decrease in symptom burden but persistence of fatigue. In patients not on dialysis there was no significant increase in quality of life or decrease in symptom burden.

PO2059

The Effect of Caloric Restriction and Aerobic Exercise on Serum FGF-23 in Patients with Moderate to Severe CKD

Elvis A. Akwo,[1] Thomas G. Stewart,[1] Cassianne Robinson-Cohen,[1] Adriana Hung,[1] Jonathan Himmelfarb,[2] Katherine R. Tuttle,[2] Talat Alp Ikizler.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Washington Department of Medicine, Seattle, WA.*

Background: Chronic kidney disease (CKD) is associated with elevated serum fibroblast growth factor 23 (FGF23) which correlates with increased cardiovascular risk. Prior data suggest serum FGF23 is also associated with increased adiposity. We tested the hypothesis that an intervention involving caloric restriction and aerobic exercise to reduce body weight would reduce serum FGF23 in patients with moderate to severe CKD.

Methods: We performed a secondary analysis of data from a 2X2 factorial randomized trial enrolling 103 participants randomized to receive combined caloric restriction and aerobic exercise, caloric restriction alone, aerobic exercise alone, or usual care. Enrollees were persons with a median estimated glomerular filtration rate (eGFR) of 40.5 ml/min/1.73m^2 (IQR: 30.3, 56.2). Measurements of Serum FGF23 (using C-terminal ELISA assay) and serum phosphate were obtained at baseline and month 4. Changes in serum FGF23 between baseline and month 4 across intervention arms were examined using analysis of covariance with robust standard errors.

Results: After adjustment for baseline differences, serum FGF23 levels fell by 20.6% [95%CI: 0.4, 36.7, p = 0.047] more in the combined intervention arm compared to usual care. Further adjustment for baseline serum phosphate attenuated the relative difference in serum FGF23 decline between the combined intervention arm and usual care [percent change = -18.6, 95% CI: -35.3, 2.9; p = 0.10]. Caloric restriction or exercise alone did not demonstrate significantly greater decline in serum FGF23 compared to usual care. The median values of change in serum phosphate between baseline and month 4 among participants in the combined intervention and diet-only arms were -0.15 and 0.05 mg/dl whereas the exercise and usual care arms experienced no change in serum phosphate. Neither intervention arm showed a significantly greater percent change in serum phosphate from baseline to month 4 compared to usual care.

Conclusions: A combined 4-month calorie restriction and aerobic exercise intervention led to significant reductions in serum FGF23. The magnitude of serum FGF23 reduction appeared to be influenced in part by baseline serum phosphate levels while the latter remained relatively unchanged at the end of the trial.

PO2060

Changes in Body Composition, Muscle Strength, and Fat Distribution Following Renal Transplantation

Susan Ziolkowski,[1] Simin Goral,[2] Jin Long,[4] Joshua F. Baker,[2] Justine Shults,[6] Babette Zemel,[3] Peter P. Reese,[2] Francis P. Wilson,[5] Mary B. Leonard.[1] *[1]Stanford University School of Medicine, Stanford, CA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]Lucile Salter Packard Children's Hospital at Stanford General Pediatrics, Palo Alto, CA; [5]Yale University School of Medicine, New Haven, CT; [6]University of Pennsylvania, Philadelphia, PA.*

Background: The impact of renal transplantation on body composition and muscle quality has not been established. Low muscle mass relative to fat mass (relative sarcopenia) has been associated with mortality and disability but has not been examined following transplantation.

Methods: DXA measures of fat mass index (FMI) and appendicular lean mass index (ALMI; representing muscle mass), CT measures of muscle density (low density represents increased intramuscular adipose tissue), and leg muscle strength were assessed in 60 transplant recipients (ages 20-60 years) at transplantation, and 6, 12, and 24 months after transplantation. ALMI relative to FMI (ALM_{FMI}) is an established index of relative sarcopenia. Measures were expressed as age, sex, and race-specific Z-scores and compared with 327 healthy controls.

Results: At transplantation, ALMI, $ALMI_{FMI}$, muscle strength and muscle density Z-scores were lower vs. controls (all p≤0.001). Transplant recipients received glucocorticoids throughout. The prevalence of obesity increased from 18 to 45%. Although ALMI increased following transplantation (p<0.001) and was comparable to controls from 6 months onward, gains were outpaced by increases in FMI, resulting in persistent $ALMI_{FMI}$ deficits (mean Z-score -0.31 at 24 months, p=0.02 vs controls). Fat gains were disproportionately visceral in distribution (p<0.05). Muscle strength improved but remained low compared with controls independent of ALMI (p<0.05). Exercise increased in the early months following transplantation (p<0.05) but remained lower than controls (p=0.02).

Conclusions: The two-year interval following renal transplantation was characterized by gains in muscle mass and strength that were outpaced by gains in fat mass resulting in persistent relative sarcopenia.

Change in Body Composition Z-scores from baseline after Transplantation

PO2061

Home-Based Aerobic Exercise and Resistance Training in Pre-Dialysis Patients with Advanced CKD: A Randomized Controlled Trial

Kiyotaka Uchiyama, Keika Adachi, Shu Wakino, Hiroshi Itoh. *Keio University School of Medicine, Shinjuku-ku, Japan.*

Background: Muscle wasting, a common and progressive condition in patients with uremia, is associated with increased risk for morbidity, lower health-related quality of life (HRQOL), and mortality. But, the potential effects of aerobic and resistance training in predialysis patients with advanced chronic kidney disease (CKD) have not been fully elucidated. This randomized controlled trial with a parallel-group design investigated the effects of a home-based exercise program on physical functioning and HRQOL in patients with stage 4 CKD.

Methods: A total of 46 patients (median age, 73 years; 33 males; estimated glomerular filtration rate, 23.2 ± 4.7 ml/min/1.73 m^2) were randomly assigned to exercise (n = 23) and control (n = 23) groups. The exercise group performed aerobic exercise thrice weekly and resistance training twice weekly at home for 24 weeks. The control group received no specific intervention. Primary outcomes were distance in incremental shuttle walking test (ISWT) and HRQOL assessed by the Kidney Disease Quality of Life-Short Form questionnaire. Secondary outcomes were kidney function assessed by combined urea and creatinine clearance, urinary biomarkers, and anthropometric/biochemical parameters associated with CKD.

Results: ISWT distance was significantly improved in the exercise group than in the control group (34.5 ± 50.5 vs. −21.9 ± 48.2 m; P < 0.001). The intervention increased several HRQOL subscales including symptoms/problems, quality of interaction, sleep, kidney disease component summary, and mental health. Although the change in combined urea and creatinine clearance was not significantly different between the groups (P = 0.69), natural log-transformed (ln) urinary excretion of liver-type fatty acid-binding protein, ln serum C-reactive protein, and acylcarnitine/free carnitine ratio were significantly decreased in the exercise group compared to the control group (P = 0.02, 0.005, and 0.03, respectively). No adverse events associated with the intervention were reported.

Conclusions: The 24-week home-based exercise program improved aerobic capacity and HRQOL with possible beneficial effects on kidney function and CKD-related parameters, in patients with stage 4 CKD. The present trial demonstrated the multifaceted efficacy of home-based training on predialysis patients with advanced-stage CKD.

PO2062

Association of Self-Reported and Objective Measures of Physical Activity with Leg Muscle Mitochondrial Oxidative Capacity in CKD

Se Ri Bae,[1] Tae Youn Kim,[1] Jorge Gamboa,[2] Chenoa R. Vargas,[1] Sophia Liu,[3] Kushang V. Patel,[3] Ian H. de Boer,[4] Bryan R. Kestenbaum,[4] Baback Roshanravan.[5] *[1]University of California Davis, Davis, CA; [2]Vanderbilt University Department of Medicine, Nashville, TN; [3]University of Washington, Seattle, WA; [4]University of Washington Department of Medicine, Seattle, WA; [5]University of California Davis Department of Internal Medicine, Sacramento, CA.*

Background: Chronic kidney disease (CKD) is associated with skeletal muscle dysfunction leading to lower muscle mitochondrial oxidative capacity and decreased physical performance. However, the influence of physical activity (PA) on muscle mitochondrial function remains unknown.

Methods: We included participants from the CKD Mitochondrial Energetics and Dysfunction (CKD-MEND) study. Muscle mitochondrial oxidative capacity (ATPmax) in the leg muscle was measured using in vivo ^{31}Phosphorus Magnetic Resonance Spectroscopy. We measured self-reported PA using the adjusted Human Activity Profile (HAP) score and objective PA using an Actigraph accelerometer. Linear regressions were used to test associations between CKD status and ATPmax adjusting for confounders.

Results: We included 36 participants with CKD (mean eGR=38) and 19 controls. Mean age was 61±13 years, 51% male, and 25% had diabetes. Diabetes and CKD were independently associated with lower ATPmax (-0.12 mM/s, p<.01 and -0.19 mM/s, p<.01, respectively). Accelerometry counts per minute (r=.58, p<.01) was more strongly correlated with ATPmax than HAP scores (r=.46, p<.01) with no interaction by CKD status (p=.9). Accelerometry counts explained 43% of the difference in ATPmax between CKD and controls and HAP scores 15% after adjustment.

Conclusions: Objective PA was more strongly associated with ATPmax and explained more of the differences in ATPmax between CKD and controls than self-reported PA. Further studies should demonstrate if exercise interventions can improve muscle ATPmax in CKD.

Funding: NIDDK Support, Private Foundation Support

PO2063

Serum and Skeletal Muscle Acylcarnitines And Physical Function in CKD Stage 5-5D

Ranjani N. Moorthi, Alissa A. Cranor, Kimberly Swinney, Ricardo Melo ferreira, Thomas Oconnell, Sharon M. Moe, Keith G. Avin. *Indiana University, Indianapolis, IN.*

Background: Sarcopenia is highly prevalent among those with advanced CKD. The metabolite signature of skeletal muscle in patients with CKD is poorly studied. We hypothesized that skeletal muscle metabolites would be different between serum and muscle in those with CKD 5-5D as compared to healthy adults.

Methods: *Subjects:* 34 subjects participated; 17 with CKD (10 CKD-5, 7 CKD 5D) undergoing renal transplant and 17 healthy donors. All had blood drawn and transversus abdominus muscle biopsy during surgery. *Physical Function tests done the week before were:* Sit to stand (STS), 6 minute walk test (6MW), 4m gait speed (fast and usual). *Metabolomics:* Targeted mass spectrometry (MS) was performed on serum and muscle using the Biocrates Absolute IDQ. Differences were tested between those with and without CKD.

Results: There were no differences in age, height, weight or BMI between CKD and healthy subjects. *Physical Function:* The CKD group had poorer performance for the STS(13 vs 19), 6MW(434 vs 589m), fastest gait speed(1.62 vs 2.00 m/s) and usual gait speed(1.18 vs 1.34m/s), all p<0.05. *Metabolomics:* The heatmap depicted two distinct signatures in both serum and skeletal muscle between CKD and donors. Serum demonstrated 59 significantly different metabolites, especially in fatty acid metabolism with increases in short and medium chain acylcarnitines C4-C12, and nine hydroxylated and dicarboxylated acylcarnitines in CKD (p<0.05). Lower 6MWT distance was independently associated with levels of C10-14 even after adjusting for CKD status and age in multivariate regression analyses. Skeletal muscle demonstrated significant differences in 42 metabolites, with consistently higher acylcarnitine levels in recipients, including short chain (i.e. C4.1, C5.1, C6.1), long chain and dicarboxyls.

Conclusions: Our data demonstrates patients undergoing renal transplant have increased acylcarnitine levels in serum and muscle that are independently associated with poor physical performance. These results suggest impaired b-oxidation of fatty acid metabolism that affects physical function. Understanding these pathways will allow targeted therapeutics to improve the disabling sarcopenia observed in patients with CKD.

Funding: NIDDK Support

PO2064

Metabolic Acidosis and Muscle Metabolic Health Are Important Determinants of Fatigue in Persons with CKD

Tae Youn Kim,[1] Se Ri Bae,[1] Jorge Gamboa,[2] Chenoa R. Vargas,[1] Sophia Liu,[2] Kushang V. Patel,[2] Ian H. de Boer,[2] Bryan R. Kestenbaum,[2] Baback Roshanravan.[1] *[1]University of California Davis, Davis, CA; [2]University of Washington, Seattle, WA.*

Background: Chronic kidney disease (CKD) is associated with a high prevalence of physical frailty, reduced physical function and fatigue, contributing to increased morbidity, mortality risk, and poor quality of life. Impaired muscle mitochondrial oxidative capacity (ATPmax) underlies poor physical endurance in persons with CKD. Metabolic acidosis may mediate effects of CKD on ATPmax. Little is known about the relevance of metabolic acidosis and ATPmax on patient-reported fatigue in CKD.

Methods: We performed a cross-sectional analysis of 58 participants (39 CKD and 19 non-CKD) from the CKD Muscle Mitochondrial ENergetics and Dysfunction (MEND). *Muscle metabolic health* of the tibialis anterior leg muscle was measured from the time course of phosphocreatine after exercise using ^{31}Phosphorus Magnetic Resonance Spectroscopy. *Fatigue* was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scale. *Metabolic acidosis* (MA) was determined from serum bicarbonate (< 22 mmol/L). Linear regression was used to test associations adjusting for age, sex, body mass index (BMI), and diabetes.

Results: The cohort included 48% female and 29% diabetes with a mean age of 61±12 years and a mean BMI of 28±5. The mean eGFR was 39±19ml/min per 1.73m^2 in CKD and 98±15 in non-CKD. The mean ATPmax was 0.672±0.185mM/sec and mean FACIT-F score was 40±11.5. CKD was associated with increased fatigue (mean difference: 7.6, 95% CI [1.8, 13.5], p<.05) compared to non-CKD after adjustment. Of those with CKD each 1 SD (standard deviation) greater ATPmax was associated with a 5.4-point (95% CI [1.03, 9.7], p=.017) reduction in fatigue after adjustment. Further adjustment for MA attenuated the estimated association by 38% (3.3 points, 95% CI [-1.1, 7.7], p=.134). Of those with CKD, participants with MA (n=18) had a 10. points greater fatigue (95% CI [1.8,18.1], p=.018) after adjustment compared to those without MA (n=21).

Conclusions: ATPmax is directly associated with fatigue. MA might play an important role in the association of muscle metabolic health with fatigue in CKD. Further research is needed to examine the impact of treating MA on improvement in muscle metabolic health, fatigue and quality of life in CKD.

Blood Pressure in Young Adults with CKD and Associations with Cardiovascular Events and CKD Progression

Alexander J. Kula,[1,2] Nisha Bansal,[2] David K. Prince,[2] Joseph T. Flynn.[1,2] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington, Seattle, WA.*

Background: Young adults (age 18-40yrs) with CKD are a poorly studied subset of CKD patients. Blood-pressure management for young adults with CKD relies on extrapolating findings from studies conducted in older adults or children. Our objective was to perform an observational study exclusively in young adults with CKD to test the association between BP and adverse outcomes.

Methods: Participants aged 21-40yrs of age enrolled in the Chronic Renal Insufficiency Cohort Study were included (n=317). Exposures included baseline systolic BP (SBP) category, <120, 120-120, ≥130, and per +10 higher baseline SBP. Outcomes included cardiovascular (CV) events, including heart failure, myocardial infarction, stroke, or all-cause death, and CKD progression, defined as 50% eGFR decline or ESRD. We used cox-proportional hazard models to test association between baseline SBP with outcomes. Adjusted models included age, race, eGFR, diabetes, with prevalent CV disease for CV event models and urine albumin to creatinine ratio for CKD progression.

Results: As seen in **Figure 1**, incidence rates for HF, death, CV events, and CKD progression were greater at higher SBP categories. In adjusted models, a baseline SBP >130 was significantly associated with CV events (HR: 3.32, 95% CI: 1.53-7.20) and CKD progression (HR: 1.63, 95%CI: 1.02-2.59) compared with SBP<120. Every +10 in SBP was significantly associated with CKD progression (HR: 1.13, 95%CI: 1.02-1.26) in adjusted models.

Conclusions: There is a graded association of higher SBP with greater risk of CV events and CKD progression in young adults with CKD. Among those with SBP>130, 5.8% per year had a CV event and risk was 3-fold higher compared with SBP<120; and 20.7% per year had CKD progression and risk was nearly 2-fold higher. These data suggest that higher SBP is an important risk factor for adverse outcomes in young adults with CKD.

Angiotensin Converting Enzyme Inhibitor and Angiotensin Receptor Blocker Use Among Hypertensive US Adults by Albuminuria Status, 2013-2018

Chi D. Chu,[1] Neil R. Powe,[1] Charles E. McCulloch,[1] Tanushree Banerjee,[1] Deidra C. Crews,[4] Rajiv Saran,[2] Jennifer L. Bragg-Gresham,[2] Hal Morgenstern,[2] Meda E. Pavkov,[3] Sharon Saydah,[3] Delphine S. Tuot.[1] CDC CKD Surveillance Team *[1]University of California San Francisco, San Francisco, CA; [2]University of Michigan, Ann Arbor, MI; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Since 2003, U.S. hypertension (HTN) guidelines have recommended angiotensin converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) therapy for urine albumin/creatinine ratio (UACR) ≥300 mg/g. Our objective was to assess the prevalence of ACEi/ARB use for UACR ≥300 mg/g among adults with HTN and to examine the association between UACR and ACEi/ARB use.

Methods: We studied adults with HTN in the National Health and Nutrition Examination Surveys 2013-2018. Respondents were classified as having HTN if they had systolic blood pressure ≥140 mmHg or diastolic blood pressure ≥90 mmHg, were currently using anti-hypertensive medications, or reported being told by a clinician they had HTN. ACEi/ARB use was assessed by review of medication containers by study staff. Modified Poisson regression was used to estimate crude and adjusted prevalence ratios (PR) for the association between ACEi/ARB use and UACR; adjustment was for age, sex, race/ethnicity, diabetes, systolic blood pressure (continuous), chronic kidney disease stage, and having a reported routine site for healthcare.

Results: Among 7,377 adults with HTN, 83.4% had UACR 0-29 mg/g, 13.5% had UACR 30-299 mg/g, and 3.2% had UACR ≥300 mg/g. ACEi/ARB use was 43%, 54%, and 48% in UACR categories 0-29, 30-299, and ≥300 mg/g, respectively. This represents approximately 1.5 million adults with UACR ≥300 mg/g who are not receiving ACEi/ARB therapy. Adjusted ACEi/ARB use was minimally associated with UACR ≥30 mg/g (PR = 1.09, 95% CI 1.03-1.17 for UACR 30-299 mg/g; PR = 0.96; 95% CI 0.83-1.10 for UACR ≥300 mg/g; reference = UACR <30 mg/g).

Conclusions: Nationally representative data indicate a large gap in guideline-concordant ACEi/ARB use among adults with HTN and UACR ≥300 mg/g. Improving uptake of ACEi/ARB therapy presents a substantial opportunity for prevention of cardiovascular disease and kidney disease progression for adults with HTN.

Increased Residual Cardiovascular Risk in US Veterans with Moderately Elevated Baseline Triglycerides, Well-Controlled LDL Cholesterol Levels on Statins, and Decreased Renal Function

Sarah Leatherman,[1] Ryan E. Ferguson,[1] Cynthia Hau,[1] Craig B. Granowitz,[2] Kelly M. Harrington,[1] Sephy Philip,[2] Peter P. Toth,[4] Deepak L. Bhatt,[3] William E. Boden.[1] *[1]VA Boston Healthcare System, Boston, MA; [2]Amarin Corp, Bridgewater, NJ; [3]Brigham and Women's Hospital, Boston, MA; [4]CGH Medical Center, Sterling, IL.*

Background: Recent studies have suggested a causal role for elevated triglycerides (TG) in incident cardiovascular (CV) events. Using a large cohort of U.S. veterans with statin-controlled LDL-C levels (40-100mg/dL), we explored whether increased residual CV risk existed in patients with elevated baseline TG levels versus those with normal TG levels in the subset who had reduced eGFR (<60 ml/min).

Methods: We identified veterans receiving a statin but not a TG-lowering agent from the VA Corporate Data Warehouse, a database of the VA electronic health record,

from 2010-2015. We compared CV event rates (nonfatal MI, stroke, unstable angina, or coronary revascularization) between the elevated TG (150-499 mg/dL) and normal TG (<150 mg/dL) groups. We calculated crude event rates, rate ratios, and 95% CI for both groups, and adjusted event rate ratios for age, sex, baseline blood pressure, glomerular filtration rate, and weight.

Results: We included 152,266 veterans (predominantly male and white) in the analysis cohort of whom 43,670 (29%) had elevated TG levels. These subjects were younger and had higher BMIs. Table 1 details the crude and adjusted CV event rates. The overall crude and adjusted CV event rate ratios were 1.28 (95% CI 1.23,1.33) and 1.12 (95% CI 1.07, 1.16), respectively.

Conclusions: In this large cohort of veterans, those with elevated TG levels and moderately decreased renal function showed a significant increase in CV events despite well-controlled LDL-C on statins compared to veterans whose baseline TG was in a normal range.

Deep Learning Analysis of Derived Cardiac Function Metrics for the Detection of CKD and Subsequent Outcome Prediction in Community-Dwelling Individuals

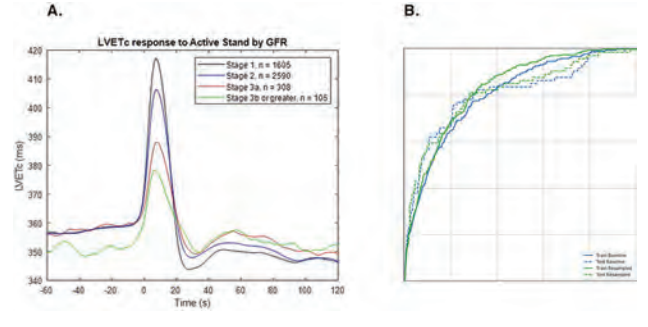
Niall Cosgrave,[1] John D. O'Connor,[1] George S. Mellotte,[4] Brenda Griffin,[2] Conall M. O'Seaghdha,[3] Scott Reule,[6,7] Robert N. Foley,[5] Silvin P. Knight,[1] Mark A. Little,[1,2] Donal J. Sexton.[1,2] *[1]University of Dublin Trinity College, Dublin, Ireland; [2]Trinity Health Kidney Center, St James's Hospital & Tallaght University Hospital, Dublin, Ireland; [3]Beaumont Hospital, Dublin, Ireland; [4]National Renal Office, Health Service Executive of Ireland, Dublin, Ireland; [5]United States Renal Data System Coordinating Centre, Minneapolis, MN; [6]Minneapolis VA Health Care System, Minneapolis, MN; [7]University of Minnesota System, Minneapolis, MN.*

Background: Whether subtle abnormalities in cardiac function exist in community dwelling individuals and can be used to agnostically discern those with reduced kidney function and incident adverse outcomes over follow up is unknown.

Methods: The Irish Longitudinal Study on Ageing (TILDA) is a prospective nationally representative cohort study based on random sampling of the community-dwelling general population aged ≥ 50 years in Ireland. Wave 1 was performed between June 2009-June 2011. Participants underwent a detailed health assessment including blood tests, and an active stand test using the Finometer, which measures continuous blood pressure and heart rate for 10 mins while supine at rest, then throughout the standing test and for 2 mins thereafter. Cardiac function metrics are derived : left ventricular ejection time (LVET), cardiac output, and total peripheral resistance. CKD-EPI equation was used for eGFR. We analysed repeated measures data at 10 second intervals over the entire observation period using sequential neural networks with the categorical outcomes of coincident CKD, and incident mortality. Follow up was approximately 10 yrs. Python v 3.77 and TensorFlow v2.0.0 were used for the analysis.

Results: N=4388 TILDA participants were included, N=2013 were male, mean age was 62 (8) yrs, 647 had CKD. 178 died over follow up. **Figure 1. A** demonstrates profiles in LVET by eGFR category and **B** an ROC curve output from the Neural Network model predicting conincident CKD AUC = 0.81(resampled model: which included an input layer, 2 hidden layers and an output layer based on cardiac metrics, age and sex). AUC for mortality was 0.75 (resampled model).

Conclusions: Deep Learning analysis of repeated measures of derived cardiac function metrics discerned community dwelling individuals with CKD and subsequent outcomes. This method has potential for population level risk dsicrimination.



PO2069

Risk of Mortality, ESKD, and Hospitalization Among Medicare Beneficiaries with Pulmonary Hypertension and CKD

Sankar D. Navaneethan,[1,3] Carl P. Walther,[1] L Parker Gregg,[2] Wolfgang C. Winkelmayer,[1] Vijay Nambi,[1,3] Jingbo Niu.[1] *[1]Baylor College of Medicine, Houston, TX; [2]University of Texas Southwestern Medical Center at Dallas, Dallas, TX; [3]Michael E DeBakey VA Medical Center, Houston, TX.*

Background: Pulmonary hypertension (PH) is highly prevalent among patients with non-dialysis dependent CKD (~20%). We studied the risks of mortality, ESKD, cardiovascular (CV) and non-CV hospitalizations among those diagnosed with both PH and CKD.

Methods: Patients with PH (based on 2 claims within 2 years) were identified from a Medicare 5% sample (1995-2016). For each PH patient we randomly selected 5 patients diagnosed with the same CKD stage as the PH patient but without a PH diagnosis. We used Cox proportional hazards models to assess the association between PH and mortality, adjusting for age, sex, race, and comorbidities. We considered death as a competing event in Fine-Gray models to assess the association between PH and ESKD.

Results: We studied 41,478 patients with PH and CKD and 207,390 CKD stage-matched patients without diagnosed PH. Over 59% of the study population were >80 years, 12% were African American, 47% had diagnosed diabetes and 46% had COPD. The presence of diagnosed PH (vs. no PH diagnosis) was associated with increased risk of mortality, ESKD, and CV and non-CV hospitalizations at 1-, 3-, and 5-year follow-up (Table 1). Diabetes modified these associations with higher risk of all outcomes noted among those without diabetes.

Conclusions: Among older Medicare beneficiaries diagnosed with CKD, the presence of PH increased risk of mortality, ESKD, and hospitalization. Mechanistic understanding of these associations, especially the increased risk of ESKD, requires additional study.

Funding: NIDDK Support

Table 1. Associations of PH with mortality, ESKD, and cardiovascular and non-CV hospitalization in those with PH and CKD

Outcome		Unadjusted HR (95% CI)	Multivariable adjusted HR (95% CI)
Mortality	1-year	3.24 (3.17, 3.31)	2.35(2.29, 2.41)
	3-year	2.71(2.67, 2.75)	1.98 (1.94, 2.01)
	5-year	2.54(2.50, 2.58)	1.87 (1.84, 1.90)
ESKD	1-year	2.73 (2.57, 2.90)	2.49 (2.33, 2.67)
	3-year	1.82 (1.74, 1.91)	1.70 (1.61, 1.79)
	5-year	1.59 (1.52, 1.66)	1.54 (1.47, 1.62)
		Unadjusted RR (95% CI)	Multivariable adjusted RR (95% CI)
Cardiovascular hospitalization	1-year	7.97 (7.82, 8.13)	5.92 (5.80, 6.05)
	3-year	6.72 (6.60, 6.83)	4.77(4.68, 4.85)
	5-year	6.39 (6.28, 6.49)	4.48 (4.40, 4.56)
Non-CV hospitalization	1-year	3.83 (3.77, 3.89)	2.98 (2.93, 3.03)
	3-year	3.36 (3.31, 3.40)	2.54 (2.51, 2.58)
	5-year	3.20 (3.15, 3.24)	2.41 (2.38, 2.45)

PO2070

A Marginal Structural Model to Estimate Causal Effect of Time-Dependent Anemia Status on Renal and Cardiovascular Outcomes Among Community-Dwelling Japanese Subjects at Beginning of Impaired Renal Function

Satoshi Onozawa,[1] Tomomi Kimura,[2] Masataka Morita,[1] Osamu Yamamoto,[1] Tadao Akizawa.[3] *[1]Astellas Pharma, Inc., Tokyo, Japan; [2]Astellas Pharma, Inc., Northbrook, IL; [3]Showa University School of Medicine, Tokyo, Japan.*

Background: We investigated whether anemia increases the risk of renal and cardiovascular (CV) outcomes considering the changes of anemic status over time, using a marginal structural model.

Methods: We retrospectively analyzed data from a Japanese database (JMDC) consists of annual health checkup data linked to medical and pharmacy claims for over 3 million of beneficiaries. Subjects with consequent eGFR values of ≥60 and then <60 mL/min/1.73 m^2 within 2 years and during the period between 2008 and 2019 were included. The first date where the eGFR value became <60 was defined as the index date. Patients without serum creatinine (SCr) record within 38 months from the index date were excluded. Anemia status (yes/no) was defined by the age-sex specific hemoglobin value according to the Japanese guidelines. Renal outcomes (composite of ≥30% eGFR decline over 3 years, eGFR <15 ml/min/1.73m^2, SCr doubling, initiation of chronic dialysis and kidney transplantation), CV outcomes (myocardial infarction, stroke, unstable angina and heart failure) and mortality was assessed. In order to incorporate dynamic change of anemia status and covariates during the follow-up, a time-dependent standardized inverse probability weight at time x was estimated based on propensity score to either be—or not be—anemia at time x. Weighted survival probability and weighted hazard ratio were estimated.

Results: 32,870 subjects were enrolled in the study cohort (median age 52, 73% male) and 4.2% of subjects had anemia at the baseline. Anemia treatment was rarely provided even in the anemia group (3.9%). During the average of 4.1-year of follow-up period, 210 renal outcomes and 1039 CV outcomes occurred. In 91% of the cases with the renal outcomes, eGFR decline occurred first. The weighted hazard ratios (95% confidence intervals) for renal outcomes, CV outcomes and mortality were 2.6 (1.7-3.8), 1.6 (1.2-2.2), and 2.8 (1.8-4.3), respectively.

Conclusions: Anemia was an independent risk for eGFR decline, CV events and mortality in these Japanese community-dwelling subjects at the very beginning of renal impairment, considering the time-dependent nature of anemia status.

PO2071

Estimation of Sodium Consumption by Novel Formulas Derived from 12-Hour Urine Collection

Pitchaporn Sonuch, Surasak Kantachuvesiri. *Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.*

Background: 24-hour urine sodium excretion is the gold standard for estimating sodium intake. Several equations have been used to estimate 24-hour urine sodium excretion from spot urine samples. However, a validated formula for predicting 24-hour urine sodium excretion from 12-hour urine collection has not been established. This study aims to establish novel equations for predicting 24-hour urine sodium excretion from 12-hour urine collection and to also validate spot urine equations for predicting 24-hour urine sodium excretion.

Methods: 209 adults were recruited from hospital personnel. Participants were asked to perform a 12-hour daytime, nighttime, and a random spot urine collection in 1 day. Pearson correlation was used to compare measured 24-hour sodium excretion to the estimated values from three different methods. A multivariate linear regression analysis was performed to create novel equations. Bland-Altman method was used to estimate bias and agreement between the equations.

Results: The mean 24-hour urine sodium excretion was 4,055±1,712 mg/day (male 4,307±1,694 and female 3,882±1,710 mg/day, P=0.078). The 24-hour urine sodium excretion in non-healthcare workers was higher than in healthcare workers (4,442±1,865 and 3,617±1,406 mg/day respectively, P<0.001). Estimated urine sodium excretion from 3 different equations using spot urine samples showed moderate correlation with actual 24-hour urine sodium excretion (r=0.54, P<0.001 for Kawasaki; r=0.57, P<0.001 for Tanaka; r=0.60, P<0.001 for INTERSALT). Novel equations for predicting 24-hour urine sodium excretion was then developed using variables derived from 12-hour daytime urine collection, 12-hour nighttime urine collection, and random spot urine samples which showed strong correlation with actual measured values; r=0.88, P<0.001, r=0.83, P<0.001, r=0.67, P<0.001 respectively. Bland-Altman plots indicated good agreement between predicted values and actual 24-hour urine sodium excretion using the new equations, with biases for 12-hour daytime urine collection of -0.28 mmol/day (95%CI: -5.09 to 4.53), for 12-hour nighttime urine collection of 0.85 mmol/day (95%CI: -4.86 to 6.56), and for random spot urine sample of 0.90 mmol/day (95%CI: -6.66 to 8.45).

Conclusions: Newly derived equations from 12-hour daytime urine collection and 12-hour nighttime urine collection can accurately predict 24-hour urine sodium excretion.

PO2072

Serum Magnesium, Blood Pressure, and Risk of Hypertension: Insights from the Chronic Renal Insufficiency Cohort (CRIC) Study

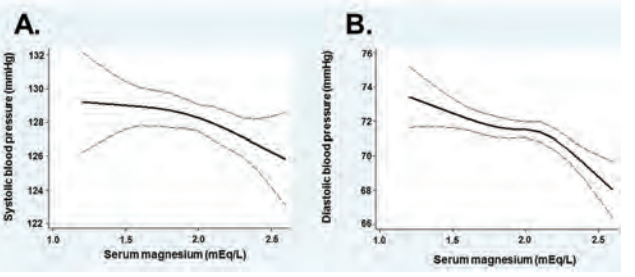
Simon Correa,[1,2] Xavier E. Guerra Torres,[3] Sushrut S. Waikar,[4] Finnian R. McCausland.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Hospital Universitario Principe de Asturias, Alcala de Henares, Spain; [4]Boston Medical Center, Boston, MA.*

Background: Magnesium (Mg) has been implicated in regulation of blood pressure (BP). Abnormalities in serum Mg (sMg) are common in CKD and ESRD due to decreased intestinal absorption, impaired renal handling and diuretics use. Studies assessing the association of sMg and BP are scarce, and the association of sMg with the risk of developing hypertension (HTN) is unknown.

Methods: We analyzed data from 3,866 participants from CRIC. Adjusted linear regression models assessed the association of sMg with SBP and DBP at baseline and adjusted smoothing splines were fit. Adjusted logistic regression models explored the association of baseline sMg with baseline HTN (CRIC-defined HTN: SBP ≥140 or DBP ≥90 or anti-HTN drug use; AHA-defined HTN: SBP ≥130 or DBP ≥80 or anti-HTN drug use) and sub optimally controlled blood pressure (SBP ≥120 or DBP ≥80). Adjusted cox-proportional hazard models stratified by clinical site explored the association of baseline sMg with incident HTN. All models were adjusted for demographics, CV comorbidities, eGFR, proteinuria, serum albumin, FGF-23, calcium, phosphate, total PTH, Na, K, urine Na, and urine K.

Results: Median sMg was 2.0 mEq/L (25th-75th percentile 1.9 to 2.1 mEq/L). Higher sMg at baseline was associated with lower SBP (-2.63 mmHg, 95% CI-5.01 to -0.25, per 1 mEq/L) and lower DBP (-2.75 mmHg, 95% CI -4.16 to -1.34, per 1 mEq/L) (Fig 1A, 1B). Higher sMg was associated with a lower risk of AHA-defined HTN at baseline (aOR 0.25, 95% CI 0.12-0.55, per 1 mEq/L), a lower risk of sub optimally controlled BP (aOR 0.22, 95% CI 0.10-0.53, per 1 mEq/L) but not with a higher risk of CRIC-defined HTN (aOR 0.77, 95% CI 0.50-1.20, per 1 mEq/L). In time-to-event analyses, higher baseline sMg was associated with a numerically lower risk of incident CRIC-defined HTN (aHR 0.68, 95% CI 0.40-1.13, per 1 mEq/L).

Conclusions: Higher sMg is associated with lower SBP, lower DBP and a nominally lower risk of incident HTN. Monitoring and optimal control of sMg should be considered in patients with CKD for improved BP control.



PO2073

Cardiac Structure and Function and Long-Term Risk of ESKD in African Americans: The Atherosclerosis Risk in Communities (ARIC) Study

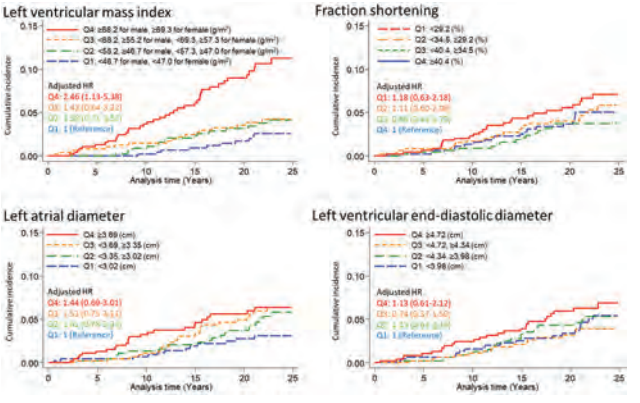
Manabu Hishida,[1,2] Junichi Ishigami,[1] Lena Mathews,[1] Morgan Grams,[1] Josef Coresh,[1] Scott D. Solomon,[3] Kunihiro Matsushita.[1] Welch Center *[1]Johns Hopkins University, Baltimore, MD; [2]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Cardiovascular disease and end-stage kidney disease (ESKD) disproportionally affect African Americans. Whether cardiac structure and function is associated with the risk of ESKD in this population is not well-characterized.

Methods: In 1,929 African American ARIC participants who underwent echocardiography between 1993-1995 (mean age 58.5 [SD 5.6] years, 36% male), we explored the association of left ventricular mass index (LVMI), fraction shortening (FS), left atrial diameter (LAD), and LV end-diastolic diameter (LVEDD) with the subsequent risk of ESKD using Kaplan-Meier method and multivariable Cox models.

Results: During a median follow-up of 22.3 years, 82 participants developed ESKD (incidence rate, 3.0 per 1,000 person-years). The cumulative incidence of ESKD was highest in the top quartile (bottom quartile for FS) of all echo parameters (Figure), although the risk separation was most evident for LVMI. The association of LVMI with ESKD remained significant even after accounting for potential confounders like blood pressure and clinical history of cardiovascular disease (HR, 2.46 [1.13-5.38] in the top vs. bottom quartile). FS, LAD, or LVEDD were not independently associated with ESKD.

Conclusions: Among African Americans, higher LVMI was robustly and independently associated with the risk of ESKD. Our findings support the importance of LVMI or its pathophysiology in CKD progression in African Americans.



PO2074

Myeloperoxidase and the Risk of Atrial Fibrillation in the Chronic Renal Insufficiency Cohort (CRIC) Study

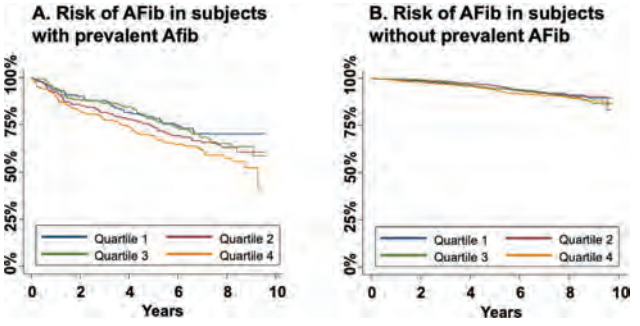
Katherine Curtis,[1,2] Simon Correa,[1,2] Sushrut S. Waikar,[3] Finnian R. McCausland.[1,2] Mc Causland Lab *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Boston Medical Center, Boston, MA.*

Background: Myeloperoxidase (MPO) catalyzes the formation of reactive oxygen intermediates and is associated with adverse CV outcomes and progression of chronic kidney disease (CKD). We wished to determine the association of MPO with hospitalization for atrial fibrillation (AFib) in patients with baseline CKD.

Methods: We evaluated 3,872 participants with MPO measured at baseline in the CRIC Study, a large prospective multicenter cohort of non-dialysis dependent CKD. The association of MPO with hospitalization due to AFib was evaluated through adjusted Cox proportional hazard models in all study participants, and separately in subjects with and without AFib at baseline. Models were adjusted for age, sex, race, DM, SBP, coronary artery disease, CHF, eGFR (CKD-EPI), proteinuria, ACEi- ARB, beta-blocker and diuretic use.

Results: Mean age was 57.5 years, 55.2% were male and 40.4% were black. In the overall population, MPO was associated with a 15% higher risk of AFib hospitalization (aHR 1.15, 95% CI 1.05-1.27, per 1 SD log transformed MPO). The association of MPO with future Afib hospitalization was predominantly noted in those with a prior history of AFib (n=650; P-interaction<0.01), such that there was a 16% higher risk in those with baseline AFib (aHR 1.16, 95% CI 1.01-1.34, per 1 SD log transformed MPO) (Fig 1A), while there was no significant association for those without baseline Afib (aHR 1.11, 95% CI 0.97-1.28, per 1 SD log transformed MPO) (Fig 1B).

Conclusions: In patients with CKD, higher MPO was associated with an increased risk of hospitalization due to AFib, which appeared to be restricted to those with a prior AFib diagnosis. Whether therapies targeting MPO activity and oxidative stress in this population reduce AFib hospitalizations remains to be tested.



PO2075

The Association Between Pre-Donation Hypertension and Early Post-Donation Systolic Blood Pressure Among Older Living Kidney Donors

Fawaz Al Ammary, Abimereki Muzaale, Daniel C. Brennan, Dorry L. Segev, Allan Massie. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: One mechanism underlying predonation hypertension in older (age≥50) living kidney donors is a reduced number of nephrons. The 50% nephron mass reduction associated with donor nephrectomy may exacerbate predonation, controlled hypertension. In light of evolving hypertension guidelines, we aimed to study systolic blood pressure (BP) trajectory in older donors with- vs. without hypertension.

Methods: We conducted a national registry study of 11,969 older living kidney donors from 2010-2018. We modeled the association between predonation hypertension and postdonation systolic BP using a mixed linear model with donor-level random intercept adjusting for age, sex, race, predonation systolic BP, BMI, and year of donation. We modeled odds of having 6-month postdonation systolic BP >130 mmHg and >140 mmHg using multivariable logistic regression.

Results: 1,161 of 11,969 older donors (9.7%) had hypertension. Median (IQR) predonation systolic BP was 130 mmHg (122-140) among donors with hypertension vs. 124 mmHg (115-132) among those without (p<0.001). After adjustment for baseline characteristics including predonation systokic BP, hypertension was associated with a $_{1.8}2.4_{3.0}$ mmHg increase in postdonation systolic BP (p<0.001). Hypertension was associated with 39% higher odds of having 6-month postdonation systolic BP >130 mmHg (aOR=$_{1.20}1.39_{1.61}$, p<0.001) and 50% higher odds of having 6-month postdonation systolic BP >140 mmHg (aOR=$_{1.25}1.50_{1.82}$, p<0.001).

Conclusions: Predonation hypertension was associated with higher risk of uncontrolled 6-month postdonation systolic BP among older donors, even after adjusting for predonation systolic BP. Our findings call for programs to monitor postdonation systolic BP in donors with hypertension to ensure adequate BP control following nephrectomy.

Postdonation Systolic BP Trajectories in Older Donors with vs. without Predonation Hypertension

PO2076

Temporal Trends of the Burden of CKD Among Hospitalized Aortic Stenosis Patients in the Province of Quebec, Canada

Nada Khelifi,[1] Denis Hamel,[2] Sonia Jean,[2,3] Claudia Blais,[2,4] Fabrice MacWay.[1] *[1]CHU de Québec Research Center, Faculty of Medicine, Université Laval, Québec, QC, Canada; [2]Institut national de santé publique du Québec, Québec, QC, Canada; [3]Faculty of Medicine, Université Laval, Québec, QC, Canada; [4]Faculty of Pharmacy, Université Laval, Québec, QC, Canada.*

Background: Aortic stenosis (AS) is associated with valvular calcifications which are highly prevalent in chronic kidney disease (CKD). The aim of this study was to describe the temporal trends of comorbid CKD status in patients hospitalized for AS and evaluate the impact of these two conditions on 1-year mortality in the province of Quebec, between 2000 and 2017.

Methods: Using the Quebec Integrated Chronic Disease Surveillance System, we identified patients ≥ 20 years with incident AS using ICD-9 and ICD-10 codes, in the hospital discharge database. We then combined hospital discharges and physician billing claims databases to identify patients with comorbid CKD status in the two years prior to the AS diagnosis. Three subgroups of CKD status were considered: 1) non-CKD, 2) pre-dialysis and 3) dialysis. To allow comparison over time, direct adjustment using age distribution of the 2016-2017 AS population was used for proportion, 1-year all-cause and cardiovascular mortality.

Results: We included 108,780 patients with incident AS (Women: 51.8%; mean age (±SD): 76.4 ±11.7; non-CKD: 74.2% (n=80,768); pre-dialysis: 24.6% (n=26,809); dialysis: 1.1% (n=1,203). During the study period, the age-adjusted proportion of AS patients with non-CKD comorbid status decreased by 14% (80.7% [95% CI 77.6-84.0] to 69.6% [95% CI 67.2-71.9]). Inversely, the age-adjusted proportion of AS patients with pre-dialysis and dialysis comorbid status increased by 58% (18.5% [95% CI 16.9-20.2] to 29.3% [95% CI 27.8-30.9]) and 46% (0.76% [95% CI 0.5-1.1] to 1.1% [95% CI 0.8-1.4]), respectively. Age-adjusted 1-year all-cause and cardiovascular mortality decreased over time but remained higher in patients with comorbid CKD. In 2015-2016, age-adjusted relative risk (RR) of 1-year all-cause mortality was significantly higher in pre-dialysis (RR=1.56 [95% CI 1.44, 1.69]) and dialysis (RR=2.04 [95% CI 1.62-2.61]) compared to non-CKD patients. Age-adjusted RR of 1-year cardiovascular mortality was also significantly higher in pre-dialysis (RR=1.83 [95% CI 1.66-2.03]) and dialysis (RR=2.28 [95% CI 1.68-3.09]) compared to non-CKD patients.

Conclusions: Proportion of patients with incident AS and comorbid CKD increased from 2000 to 2017. One-year all-cause and cardiovascular mortality improved over time but remained higher in AS patients with comorbid CKD.

PO2077

Troponin Level in Relation to Angiographic Coronary Artery Disease in CKD Patients

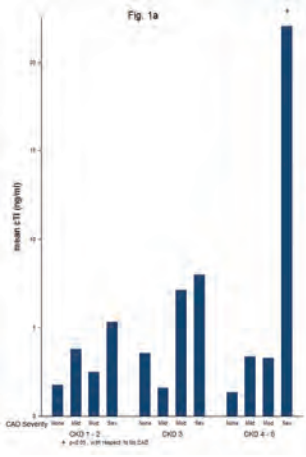
Sachin Batra,[4] Bhavin Chokshi,[3] Balaram krishna J. Hanumanthu,[2] Belinda Jim.[1] *[1]Jacobi Medical Center, Bronx, NY; [2]Mount Sinai Beth Israel Hospital, New York, NY; [3]Wayne State University School of Medicine, Detroit, MI; [4]James J Peters VA Medical Center, Bronx, NY.*

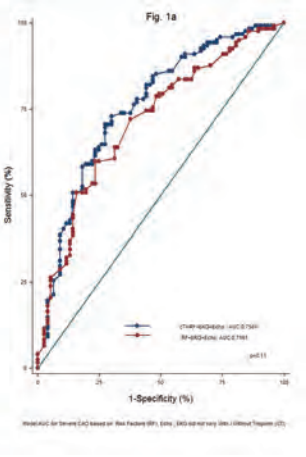
Background: An association between cardiac troponin I (cTI) in the diagnosis of angiographic coronary artery disease(CAD) is unclear in the CKD population. We evaluated the association between cTI to findings of angiographic significant CAD in CKD patients with traditional risk factors.

Methods: Data was collected from left cardiac catheterizations (LCHs) performed between 2006 -2017 at Jacobi Medical Center. CAD outcomes were defined as:none, mild(<50% stenosis), moderate(50-69% stenosis), severe (≥70% stenosis of any major epicardial artery). ROC characteristics of cTI as biomarker for severe CAD was performed in patients with CKD stages 3-5. C-Statistic/AUC were used to compare pretest probabilities for severe CAD based on CAD risk factors (age, race, HTN, HLD, DM, smoking), abnormalities on ECHO and ECG, cTI level, and CKD stage.

Results: 798 LHCs were included. Fig1a shows that cTI level is only significantly higher in severe CAD as compared to no CAD among CKD 1-2 patients. ROC showed cTI >0.3ng/mL displayed peak sensitivity (59%), specificity (62%). Multivariate analysis for predictors of severe CAD among 223 CKD patients was stratified by cTI >0.3 and cTI <0.3. Among cTI <0.3 subgroup, age >65(OR 4.6, 95% CI 1.55-13.9, p=0.006), segmental wall motion abnormalities(OR 6.46; 95% CI 1.49-27.9, p=0.012) and eGFR<30(OR 2.92; 95% CI 0.94-9.00; p=0.06) were associated with severe CAD. Among cTI>0.3 subgroup, none of the clinical factors were significantly associated with severe CAD. Fig1b shows that the addition of dichotomized cTI > or < 0.3 to CAD risk factors did not significantly change the AUC value.

Conclusions: cTI levels are not associated with different levels of CAD in patients with eGFR <=60. The addition of cTI>0.3 does not alter the predictive value of severe CAD when other cardiac risk factors are considered. It will be important to study if the change in cTI during a cardiac event would be more predictive in the CKD population.





PO2078

Pediatric vs. Adult Ambulatory Blood Pressure Monitoring (ABPM) Criteria for the Diagnosis of Hypertension (HTN) and Detection of Left Ventricular Hypertrophy (LVH) in Adolescents

Kumail Merchant,[1] Paras P. Shah,[2] Pamela Singer,[1] Laura J. Castellanos,[1] Christine B. Sethna.[1,2] *[1]Cohen Children's Medical Center, Queens, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: Normative values for clinic blood pressure (BP) measurements in adolescents were recently updated to align with adult HTN guidelines (CPG 2017). However, the most widely accepted pediatric normative values used to diagnose HTN by ABPM criteria have not been updated. The objective of this study was to compare pediatric ABPM criteria (pHTN) vs. adult ABPM criteria (aHTN) for the diagnosis of HTN and detection of LVH in adolescents.

Methods: ABPM and ECHO reports from adolescents age 13-21 years performed from 2015-2019 at a single center were analyzed. The concordance of HTN diagnosis based on pHTN (AHA 2014) was compared to aHTN from ACC/AHA 2017 (overall BP ≥125/75mmHg, wake BP ≥130/80mmHg, sleep BP ≥110/65mmHg) using Cohen's kappa statistic. Logistic regression adjusted for body mass index (BMI) z-score and receiver operating curves (ROC) were used to compare the ability of pHTN vs. aHTN to predict LVH (left ventricular mass index [LVMI] >95th%ile reference values and LVMI >51g/m$^{2.7}$).

Results: Of 306 adolescents (15.9±1.86 years, 73.5% male), 140 (45.8%) had HTN based on pHTN compared to 228 (74.5%) based on aHTN. There was poor agreement in the diagnosis of HTN between pHTN and aHTN (59.3%, N=137, kappa 0.41). 1.0% (N=3) had HTN by pHTN only while 29.7% (N=91) had HTN by aHTN only. Although a higher prevalence of LVH was captured by aHTN only, 9 (5.6%) adolescents who had LVH >95th%ile did not have HTN by either criteria. In logistic regression, adjusted for BMI z-score, there were no significant differences between pHTN and aHTN in the detection of LVH >95th%ile (OR 1.24, CI: 0.66-2.31, p=0.51) or >51g/m$^{2.7}$ (OR 1.06, CI: 0.47-2.40, p=0.89). ROCs for pHTN were not significant for detecting LVH >95th%ile (0.50, p=0.91) or >51g/m$^{2.7}$ (0.55, p=0.45). However, the ROC for aHTN was significant for detecting LVH >95th%ile (0.59, p=0.045) but not >51g/m$^{2.7}$ (0.63, p=0.07).

Conclusions: There is poor concordance between pHTN and aHTN for the diagnosis of HTN in adolescents. aHTN appears to better predict LVH than pHTN, although neither criteria diagnosed all patients who had LVH. A consideration to align the ABPM criteria for the diagnosis of HTN in adolescents with adult guidelines is warranted.

PO2079

Effect of Psychiatric Diagnosis and Selective Serotonin Reuptake Inhibitors (SSRIs)/Serotonin Norepinephrine Reuptake Inhibitors (SNRIs) Use on BP Using 24-Hour Ambulatory Blood Pressure Monitoring (ABPM)

Nabeel Aslam, Sobia H. Memon, Hani Wadei, Shehzad K. Niazi. *Mayo Clinic, Jacksonville, FL.*

Background: Hypertension (HTN) and psychiatric disorders frequently co-exist. Psychiatric conditions and their treatment by SSRIs/SNRIs affect serotonin & norepinephrine and may cause variation in blood pressure (BP). There is limited data to assess this variation by using ABPM.

Methods: Subjects who underwent psychiatric evaluation & ABPM within six month of each other between 1/2012 to 12/2017 were identified. Demographics, co-morbidities, medications, ABPM, lab data were retrospectively collected. Subjects were divided into group–subjects with no psychiatric diagnosis & no psychiatric medicine(Group 1), subjects with psychiatric diagnosis & on SSRIs/SNRIs(Group 2) and subjects with psychiatric diagnosis & on no medication(Group 3). BP systolic & diastolic levels(daytime, nighttime) were compared between groups controlling for age, sex, race, HTN, DM and smoking. Single and multivariable linear regression models were used to analyze group differences.

Results: Total of 475 subjects met inclusion criteria–Group 1=135, Group2=232, and Group3=108. First, Group 1 was compared with Group 2 for daytime systolic & diastolic, nighttime systolic & diastolic BP. In multivariable analysis adjusted for age, sex, race, HTN, DM, and smoking, subjects in Group 2 had higher nighttime systolic BP(122.7vs110.5 mm;β 8.36; 95%CI 4.21,12.51;P<0.0001) and nighttime diastolic BP(68.2vs63.4 mm;β 4.6;CI1.92,7.29;P=0.001). To determine whether higher nighttime systolic & diastolic BP in Group 2 were due to psychiatric diagnosis or effect of SSRIs/SNRIs, we compared ABPM between Group1 & Group3. In adjusted model, there was no statistically significant difference between Group 1 & 3 for daytime or nighttime systolic or diastolic BP suggesting higher nighttime BP in Group 2 was associated with SSRIs/SNRIs use.

Conclusions: In this single center retrospective study, use of SSRIs/SNRIs was associated with significantly higher nocturnal systolic & diastolic BP among subjects with psychiatric diagnosis using SSRIs/SNRIs. This may be due to ongoing sympathetic activation during sleep with serotonin & norepinephrine with SRRIs/SNRIs use. Further prospective studies using ABPM are needed to determine the risk of nocturnal hypertension with SSRIs/SNRIs use that could adversely impact cardiovascular outcomes.

PO2080

Obesity-Related Renal Damage in Adolescent Women: Body Surface Area Matters

Dana Bielopolski,[1] Neha Singh,[1] Caroline S. Jiang,[1] Robert B. Macarthur,[1] Kimberly S. Vasquez,[1] Dena S. Moftah,[2] Rhonda Kost,[1] Jonathan N. Tobin.[2,1] *[1]The Rockefeller University, New York, NY; [2]Clinical Directors Network Inc., New York, NY.*

Background: Obesity is a potentially modifiable risk factor for the development and progression of kidney disease, both in adults and children. We aim to assess the prevalence of early signs of kidney dysfunction among overweight and obese adolescents by examining routine labs including creatinine for hyperfiltration and albuminuria.

Methods: De-identified electronic health record (EHR) data were extracted for female adolescents aged 12-21 years, who received health care services from 1/1/2011 to 12/31/2015 in NYC from 12 academic health centers and community health centers that are part of PCORnet NYC Clinical Data Research Network (NYC-CDRN). Data were analyzed using SAS (v 3.2.5) on 60,549 unique subjects. Patient characteristics overall and by subgroups were examined using standard summary statistics. BMI groups were coded according to NHANES as underweight, normal weight, overweight or obese. Multiple linear regression analyses will control for covariates.

Results: Mean creatinine values were similar between normal weight, overweight and obese BMI groups, yet after calculating eGFR and adjusting for BSA, significant and alarming differences appeared. Obese adolescent women had significantly higher eGFR, estimated by CKD-EPI and the Schwartz formula according to age, compared to normal weight subjects. Only subjects in the obese group (BMI>30) exhibited hyperfiltration (eGFR>135 ml/min). Mean systolic and diastolic blood pressure across the four BMI groups increased linearly with a statistically significant trend (p<0.0001), even though means were within normal limits.

Conclusions: Obese adolescent women present with significant alteration in kidney function that without intervention will lead to ESRD, and adverse outcomes associated with the deleterious effects of adiposity. Awareness should be raised to consider body size when estimating GFR in adolescents.

Urinary Magnesium Predicts Risk of Cardiovascular Disease in Pre-Dialysis CKD Patients

Qiongjing Yuan,[1] Hui Xu,[1] Jinwei Wang,[2] on behalf of the C-STRIDE study group *[1]Xiangya Hospital Central South University, Changsha, China; [2]Peking University First Hospital, Beijing, China.*

Background: 24h Urinary magnesium concentration (24h UMg), an indicator of intestinal magnesium absorption, may provide a better insight in the connection of CKD progression.

Methods: We examined 3179 participants aged 18 to 74 years pre-dialysis patients in the Chinese Cohort Study of Chronic Kidney Disease (C-STRIDE) study. We performed a time-to-event analysis of the data using Kaplan-Meier Survival model, Cox proportional hazard and competing risks Fine and Gray sub-distribution hazard models.

Results: During the median follow-up of 4.19 (IQR 3.432-5.09) years, lower incidence rate of ESRD events was observed with increases in 24h UMg (Figure 1). Higher incidence rate of CVD events was seen with increase in 24 h UMg (Figure 2). After adjustment for demographic and traditional ESRD risk factors, 24h UMg was strongly associated with risk of CVD (HR of 1.509 [95% CI 1.031-2.208])(Table 1).

Conclusions: 24h UMg risk variants display a modest association with CVD in pre-dialysis CKD patients.

Funding: Government Support - Non-U.S.

Table 1 Association of 24h UMg with CVD events among pre-dialysis CKD patients

PO2082

Non-Dipping and Left Ventricular Hypertrophy Among Adolescents with White Coat Hypertension

Paras P. Shah,[1,2] Kumail Merchant,[2] Pamela Singer,[2] Laura J. Castellanos,[2] Christine B. Sethna.[2,1] *[1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]Cohen Children's Medical Center, Queens, NY.*

Background: Recent literature suggests that white-coat hypertension (WCH) may not be a benign phenomenon. In adults, WCH has been associated with increased cardiovascular disease (CVD) risk. Additionally, non-dipping has been independently linked to left ventricular hypertrophy (LVH) and CVD. However, the prevalence and prognostic impact of non-dipping in WCH in the pediatric population remains unclear. The objective was to determine the prevalence of non-dipping in adolescents with WCH and to examine the association of dipper status with left ventricular mass index (LVMI) and LVH.

Methods: Ambulatory blood pressure monitoring (ABPM) and echocardiogram (ECHO) reports from adolescents age 13-21 years performed from 2015-2019 at a single center were analyzed. WCH was defined as office blood pressure (BP) >95th%tile and mean ABPM <95th%tile (AHA 2014). Those with hypertension or pre-hypertension were excluded. Non-dipper status was defined as <10% drop in nocturnal BP. Non-dippers with an increase in nocturnal BP were classified as reverse dippers. T test and chi-square were used to compare LVMI and LVH (defined by LVMI >95th%ile reference values and LVMI >51g/m$^{2.7}$) by dipper status. Linear/logistic regression adjusted for age, sex and body mass index (BMI) z-score were used to determine the association of non-dipping with LVMI and LVH.

Results: Of 49 adolescents (15.7±1.7 years, 84% male), 17 (34.7%) were identified as non-dippers. Of the non-dippers, 4 (23.5%) exhibited reverse dipping. Of those with LVMI >95th%ile, 3 (33.3%) were non-dippers and 3 (23.1%) were dippers (p=0.68), and the only individual (11.1%) with LVMI >51g/m$^{2.7}$, was a non-dipper (p=0.24). There was no significant difference in LVMI between dippers and non-dippers (35.9±8.8 vs. 34.2±6.8 g/m^2, p=0.63). There were no significant associations between dipper status (reference dipper) and LVMI (β 0.67, CI: -7.92-9.26, p=0.87) or LVH by LVMI >95th%ile (OR 0.72, CI: 0.08-6.74, p=0.78) in adjusted regression models.

Conclusions: Although non-dipping is not associated with LVMI or LVH in adolescents with WCH, the fair prevalence (34.7%) of non-dipping among this population is of note. Given adult studies demonstrating the progression of non-dipping to poor CVD outcomes, these potentially high-risk patients should be monitored closely.

PO2083

Left Atrial Strain Measurements Are Associated with Cardiovascular Outcomes in Patients with ESRD

Ruth F. Dubin,[1] Amrita S. Ayer,[2] Catherine L. Donovan,[1] Lauren Nelson,[3] Sanjiv Shah.[3] *[1]University of California San Francisco, San Francisco, CA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Left atrial (LA) strain is a marker of diastolic dysfunction, heart failure and atrial fibrillation that has been validated in populations without chronic kidney disease. There are few studies of LA strain in patients with end-stage renal disease (ESRD), among whom cardiovascular (CV) mortality is high and there are no accepted methods of CV risk stratification. We sought to examine associations of LA reservoir strain with CV hospitalization and mortality in a cohort of patients with ESRD on dialysis, and to investigate prognostic utility of strain measurements for CV outcomes.

Methods: 190 ambulatory participants with ESRD on dialysis in the Cardiac, Endothelial Function and Arterial Stiffness in ESRD (CERES) study underwent 2D echocardiography at one study visit. The composite outcome, CV hospitalization or death, was adjudicated over a median of 2 years. Hospitalizations attributed to missing dialysis were not counted as events. LA and left ventricular (LV) structure and function were captured by a single technician, and de-identified images were read by a single reader using GE EchoPac software. Associations of LA reservoir strain with the composite outcome were analyzed with cox survival analyses, adjusting for age, gender, comorbidities, and systolic blood pressure.

Results: Mean age was 56 years, 1/3 were women, and the median time since dialysis initiation was 3.5 years. 45% were diabetic and 14% had a history of heart failure. Participants were relatively euvolemic, based on well-controlled blood pressure and weight. Mean (SD) LA volume index was 40ml/m^2(±12), mean LA reservoir strain was 24%(±6.9). There were 61 events: 40 hospitalizations and 21 deaths. In the adjusted model, HR (95%CI) per SD LA volume index was 1.4(1.04, 1.9); LA reservoir strain HR(95%CI) per SD was 0.67(0.47, 0.94). A risk model including age, LA reservoir strain and LV global longitudinal strain had a c-statistic(95%CI) of 0.72(0.63, 0.81) for the composite outcome.

Conclusions: Our results suggest that LA strain is independently associated with CV hospitalizations and death among patients with ESRD on dialysis. Strain measurements have the potential to contribute to CV risk stratification in this population. Larger studies are necessary to validate our findings.

PO2084

Under Diagnosis of Pediatric Hypertension

Anoosh Moin, Craig B. Langman. *Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL.*

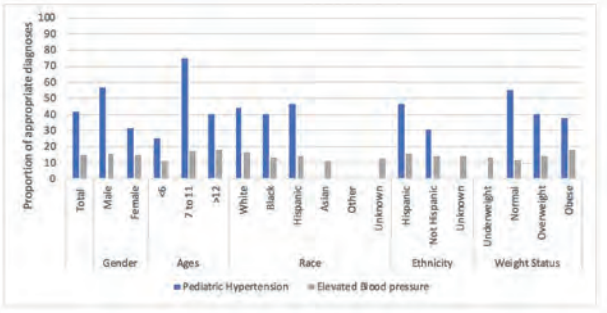
Background: Pediatric hypertension is associated with target organ damage in children and cardiovascular morbidity in adults. Therefore, prompt diagnosis and treatment are critical. Application of clinical practice guidelines is inconsistent.

Methods: Using electronic health record data (from 8 community centers), we evaluated the proportion of children (3-18 years) with elevated blood pressures (≥90th percentile) who were appropriately diagnosed as either hypertension or elevated blood pressure over 1 year (2016-17), and provided guideline directed follow-up; by age, sex, race/ethnicity and weight.

Results: The sample included 6233 children with elevated blood pressure, 15% were appropriately diagnosed. These children were more likely to be older, white, and obese. 55 children met criteria for hypertension with 23 being appropriately diagnosed, there was no difference by patient characteristics. Of children with blood pressure ≥95th percentile, 13% had follow-up within 1 month; they were more likely to be older, female, of Hispanic ethnicity or 'other' race. Of children with blood pressure ≥90th percentile, 41% had follow-up within 6 months, and were more likely to be older, of either white, Hispanic, Asian race or Hispanic ethnicity.

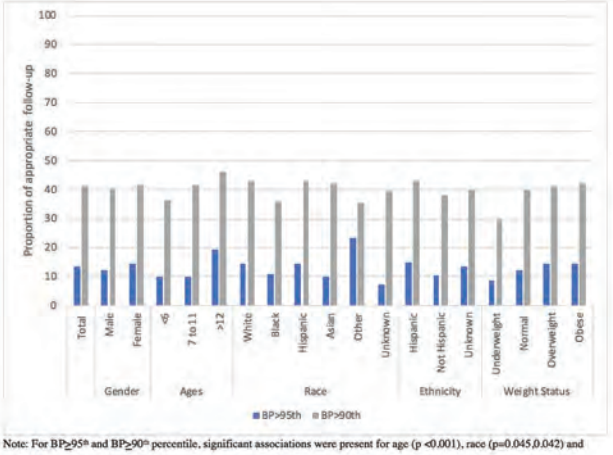
Conclusions: We found persistent underdiagnosis of pediatric hypertension and elevated blood pressure as well as disparities in the diagnosis of elevated blood pressure and guideline-directed follow-up among diverse children in a community setting. New strategies are needed to improve compliance with guidelines.

Funding: Other NIH Support - National Heart, Lung, and Blood Institute of the National Institutes of Health; National Institute on Drug Abuse



Note: For elevated blood pressure, significant associations present for age (p<0.001), race (p=0.03) and weight status (p<0.001).

Proportion of children who are appropriately diagnosed



Note: For BP≥95th and BP≥90th percentile, significant associations were present for age (p <0.001), race (p=0.045,0.042) and ethnicity (p=0.006,0.036).

Proportion of children with appropriate follow-up

PO2085

Associations of Blood Pressure Variability with Cardiovascular Events, Death, and ESKD in Patients with CKD

L Parker Gregg,[1,2] Susan Hedayati,[1] Hui Yang,[5,2] Peter N. Van Buren,[1,2] Sankar D. Navaneethan,[3,4] Salim S. Virani,[3,4] Wolfgang C. Winkelmayer,[3] Carlos A. Alvarez.[5,2] *[1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX; [3]Baylor College of Medicine, Houston, TX; [4]Michael E DeBakey VA Medical Center, Houston, TX; [5]Texas Tech University Health Sciences Center School of Pharmacy, Dallas, TX, US, Dallas, TX.*

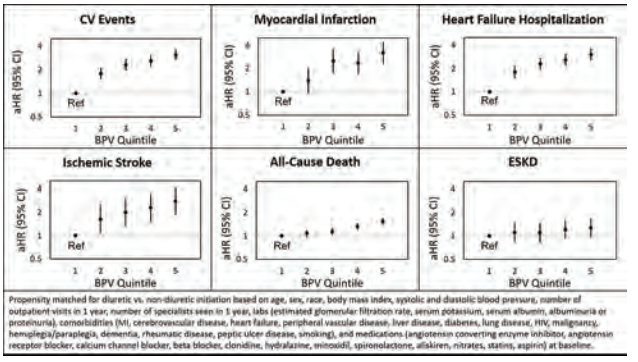
Background: Visit-to-visit blood pressure variability (BPV) is associated with cardiovascular (CV) events in individuals with chronic kidney disease (CKD) stages 3-5. We examined the associations of BPV with CV events, death, and end-stage kidney disease (ESKD) among veterans with CKD stages 1-5 and hypertension, and if treatment with a thiazide or loop diuretic modified these associations.

Methods: In a matched cohort study, patients seen between 2010-2016 with non-dialysis CKD and hypertension on single-agent therapy with a non-diuretic were propensity matched 1:1 for initiation of a loop or thiazide diuretic *vs.* other antihypertensive class as their second agent. BPV, defined as the coefficient of variation of outpatient systolic blood pressure over 6 months after prescription of the second antihypertensive, was divided into quintiles. Cox proportional hazards regression measured associations of BPV with time to CV events (first among myocardial infarction [MI], hospitalization for heart failure, or ischemic stroke), each component of the primary outcome, all-cause death, and ESKD.

Results: We included 31,394 new users of diuretics and 31,394 patients initiating other agents. Over a median (IQR) follow up time of 939 (404-1,606) days, there were 7,326 CV events, 16,567 deaths, and 2,029 ESKD events. Higher BPV was associated with composite CV events (**Figure**). Diuretic exposure attenuated these associations at the fourth and fifth quintiles of BPV (interaction *P*=.03 at the 4th and .04 at the 5th quintile). BPV was also associated with MI, heart failure, stroke, and death, but not with ESKD (**Figure**). Diuretic treatment did not modify these associations.

Conclusions: BPV was associated with CV events and all-cause death but not ESKD in patients with CKD and hypertension. Diuretic use attenuated the association of BPV with CV events at the highest quintiles of BPV. Future studies should test whether diuretics improve CV outcomes in those with high BPV.

Funding: Private Foundation Support



Propensity matched for diuretic vs. non-diuretic initiation based on age, sex, race, body mass index, systolic and diastolic blood pressure, number of outpatient visits in 1 year, number of specialists seen in 1 year, labs (estimated glomerular filtration rate, serum potassium, serum albumin, albuminuria or proteinuria), comorbidities (MI, cerebrovascular disease, heart failure, peripheral vascular disease, liver disease, diabetes, lung disease, HIV, malignancy, hemiplegia/paraplegia, dementia, rheumatic disease, peptic ulcer disease, smoking), and medications (angiotensin converting enzyme inhibitor, angiotensin receptor blocker, calcium channel blocker, beta blocker, clonidine, hydralazine, minoxidil, spironolactone, aliskiren, nitrates, statins, aspirin) at baseline.

PO2086

Importance of Continuous Blood Pressure Monitoring in CKD

Andreea G. Andronesi,[1,2] Cristina Cristache,[1] Bogdan Obrisca,[1,2] Bogdan M. Sorohan,[1,2] Roxana A. Jurubita,[1,2] Danut Andronesi,[1] Gabriela Lupusoru,[1,2] Mircea Lupusoru,[3] Gener Ismail.[1,2] *[1]Fundeni Clinical Institute, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Nephrology Department, Bucharest, Romania; [3]Carol Davila University of Medicine and Pharmacy, Physiology Department, Bucahrest, Romania.*

Background: A strong relationship exists between CKD and high blood pressure (BP), tight BP control is essential for delaying CKD progression and improving cardiovascular outcome. Automated blood pressure monitoring (ABPM) is associated with hypertension-related target-organ damage and cardiovascular outcomes compared with office-based BP in general population.

Methods: We performed a prospective study in CKD. Heart ultrasound and ABPM were performed at inclusion. Normative values for ABPM were defined according to AHA recommendation from 2019. Medical data were recorded for at least one year or until death. The aim was to analyze the correlation between ABPM and left ventricular (LV) changes and cardiovascular outcome.

Results: We included 339 pts (171F, mean age 60.1±14): 15.9% stage 1/2, 31.8% stage 3, 19.7% stage 4. 66 were in HD, 24 in PD. Prevalence of increased BP readings was higher in advanced CKD- 21.5% in stage 1/2, 56.7% in stage 5. Mean diastolic load was higher in LV hypertrophy (35.6±29 *vs* 19.7±19.6 mmHg, p<0.05). We found a negative correlation between mean arterial pressure (MAP) and GFR (r=-0.457, p<0.05). MAP was higher in PD compared to HD (109.1 ± 17.6 *vs* 98.9±9.3 mmHg, p=0.01). Serum albumin had a weak negative correlation (r=-0.245, p=0.01) and fibrinogen a weak positive correlation (r=0.266, p=0.02) with mean systolic BP, and mean LDL-cholesterol (as an indirect marker of malnutrition) was lower in non-dipper (95.4±35.4 vs. 130.5±27.2 mg/dl, p<0.05), suggesting a negative influence on BP control of malnutrition and inflammation. 225 (72.8%) were non-dipper, with 56 being extreme non-dipper. Anemia (OR 4.5, p=0.001) and C-reactive protein >10 mg/l (OR 3.7, p<0.001) induced a higher risk of non-dipper profile. We had 78 cardiovascular deaths (23.0%). Independent predictive factors for cardiovascular death were male gender, calcium x phosphate>55 mg^2/dl^2 and extreme non-dipper.

Conclusions: This study demonstrates an increased prevalence of high BP readings and non-dipper profile especially in advanced CKD. Malnutrition and inflammation were associated with non-dipper pattern and extreme non-dipper was an independent risk factor for cardiovascular death. ABPM monitoring may be useful in optimizing BP control and improving cardiovascular outcome in CKD.

PO2087

Ambulatory Blood Pressure Monitoring Patterns in Children and Adolescents with Lupus Nephritis

Alexandra Mazo, Minh Dien Duong, Joseph Mahgerefteh, Beatrice Goilav. *The Children's Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY.*

Background: Hypertension (HTN) is often underdiagnosed and undertreated. Masked HTN can reach 49% in chronic kidney disease (CKD) in children. The prevalence of HTN in systemic lupus erythematosus (SLE) varies from 30 to 77%. A small study demonstrated that children with SLE are prone to have blunted dipping. Nocturnal HTN and blunted dipping are independent predictors for all-cause cardio-vascular morbidity/mortality, independent of 24-hr systolic blood pressure (BP) levels.

Methods: Patients (<21 years) with lupus nephritis (LN) were enrolled. Clinical, laboratory, ambulatory blood pressure monitor (ABPM) and echo were reviewed. Max dose of steroids was 20 mg (1 patient). Variables included age, gender, ethnicity, CKD stage, BMI, MMF level, complement levels, dsDNA, proteinuria.

Results: Of the 10 patients (8 F, 2 M), 8 were Hispanic, 2 African American, 9 had CKD stage 1, 1 had CKD stage 2, and mean age was 16.2 y (11-20y). Class III LN was in 4 patients, class IV and V – in 3 patients each. BP during the previous 3 visits were normal in 8 patients and 6 patients were on BP medications. Based on ABPM data, 3 of 6 treated patients had uncontrolled HTN. Of the 4 patients without BP treatment 2 had pre-HTN. Blunted dipping was seen in 6 patients. Echo was done for 5 patients with ABPM

abnormalities. Left ventricular mass index (LVMI), relative wall thickness (RWT) and ejection fraction were normal. Left ventricle was dilated in 1 patient. Obesity, dsDNA, MMF level, proteinuria, use of steroids and antihypertensives did not differ significantly between the patients with and without BP abnormalities.

Conclusions: Masked HTN and blunted nocturnal dipping is common in adolescents with SLE and can be missed if ABPM is not applied in clinical practice. Additional studies are required to find risk factors and management strategy.

Patient	Obesity	LN class	Urine protein creatinine ratio, g/g	Prednisone, mg daily	Office BP	BP medications	ABPM	Blunted dipping	LVMI, g/m2.7	RWT

PO2088

Hypertension with Target Organ Damage and Discrepancy Between Ambulatory Blood Pressure Monitoring and Exercise Blood Pressure Results: A Pediatric Case Series

Uche E. Nwaogazie, Sonia M. Krishnan, Peter Varga. *University of Illinois Hospital and Health Sciences System, Chicago, IL.*

Introduction: The prevalence of hypertension is increasing worldwide in the Pediatric population. Ambulatory blood pressure monitoring (ABPM) is recommended by the American Academy of Pediatrics (AAP) for the screening and management of pediatric hypertension. ABPM has been shown to correlate with target organ damage and provides a more reliable assessment of blood pressure (BP) control compared to clinic BP. Exercise stress testing (EST) is not recommend by the AAP for the evaluation of hypertension although anecdotally, it is used frequently by pediatric cardiologists. Despite this, reports in adults show an association between exaggerated exercise systolic blood pressure (EESP) and cardiovascular mortality and morbidity, masked hypertension, and target organ damage. We report 2 pediatric patients with hypertension and evidence of target organ damage, but with a discrepancy between their ABPM and EST BP results.

Case Description: See table below.

Discussion: We describe 2 adolescent cases of hypertension diagnosed by clinic BP and target organ damage but not confirmed by ABPM. Both patients had EST done as part of their evaluation because they were first seen by cardiologists at the study center who frequently employ EST as part of evaluation for hypertension. The cut-off value of 180mmHg for EESP was employed in this report as a previous study had identified 181 mmHg as the most discriminatory systolic BP threshold for predicting hypertension at follow-up. The discrepant results between the ABPM and EST BP in our patients with target organ damage may indicate that multiple diagnostic tools may be required to confirm the diagnosis of hypertension. Both tests could be viewed as complimentary as ABPM is not recommended during exercise which is a part of everyday life. Furthermore, a normal ABPM may not exclude a diagnosis of hypertension in patients with elevated clinic BP and target organ damage. Further studies are needed to confirm these findings in a larger population, and to better understand how these 2 tests may perhaps be used adjunctively to diagnose hypertension.

Case Description

Cases	Age/Sex/Race	Clinical presentation	Weight/Height/BMI/Clinic BP	Cardiology Work-up	Renal Work-up	Treatment and Outcome
1	16y/Male/Hispanic	Elevated BP	86kg/173.7cm/ 28.5kg/m2/96th percentile)/131/81mmHg	EKG: NSR ECHO: Mild LV hypertrophy EST: Protocol: BRUCE (peds) Max BP: 191/61 mmHg Max workload: 13.4 METS Exaggerated BP response	Cr: 0.85mg/dl Urinalysis: Normal Pr/Cr: 0.08 cANCA: <1:20 ABPM: Normal Retroperitoneal USS with doppler: Normal	He received HCT for about 1 month and continued lifestyle modification. Resolution of PAMM lesions and Retinal vein occlusion. His BP at his last visit was 125/80mmHg.
2	14y/Male/African American	Fainting during exercise	70.9kg/169.3cm/ 24.7kg/m2/93rd percentile)/130/82mmHg	EKG: NSR ECHO: Mild LVH with increased LV mass-154g/m2. Protocol: BRUCE (Peds) Max BP: 209/051 mmHg Max workload: 11.6 METS Repeat EST BP:192/62mmHg.	Cr:0.87mg/dl Urinalysis: Normal Pr/Cr:0.05 Aldosterone:4.2ng/dl Renin:0.2ng/ml/hr Retroperitoneal USS with doppler: Normal	There was resolution of LVH and increased LV mass on repeat ECHO prior to starting antihypertensives. Low dose lisinopril was started due to EESP. His BP at last visit was 144/85mmHg.

Individualized Hypertension Management in CKD

Yossi Chait,[1] Brian H. Nathanson,[3] Barbara A. Greco,[2] Michael J. Germain.[2] *[1]University of Massachusetts Amherst, Amherst, MA; [2]Renal and Transplant Associates of New England, Springfield, MA; [3]OptiStatim, LLC, Longmeadow, MA.*

Background: The prevalence of hypertension (HTN) in chronic kidney disease (CKD) patients ranges from 60% to 90% with up to 50% having drug resistant hypertension.

Methods: We instituted a practice improvement project comparing hypertension Standard Care (Group B) to an Individualized Protocol (Group A) in non-dialysis CKD patients referred to our nephrology practice. The Individualized Protocol used noninvasive impedance cardiography (NICAS) and central arterial pressure waveform analysis (SphygmoCor) to define the hemodynamic state: vasoconstricted, hyperdynamic, or mixed. Recommendations for pharmacologic interventions were guided by the hemodynamic state, however, choice of specific drugs was left to the nephrologist. Group A nephrologists were trained to use the Individualized Protocol, and hypertensive patients were assigned to groups A or B during an initial 6-month period, then followed for 6 months (endpoint).

Results: There were 90 and 21 patients in groups A and B, respectively. At baseline, demographics were similar in both groups (Table 1). At endpoint, Group A had more patients at targeted blood pressure (BP) (55.6% vs 33.3% at 140/90 mmHg; 21.1% vs 19% at 130/80 mmHg), and larger reduction in both brachial and central BP parameters (Table 2). The mean (SD) of number of office visits were 3.1(1.0) and 2.9(1.1), in Groups A and B, respectively. In Group A, mean aorta compliance was increased 23.3% and 1.7% in the subgroups that met and did not meet target BP, respectively. Mean number of medications at baseline/endpoint were 1.7/2.6 and 1.9/2.0 in groups A and B, respectively. At endpoint, Group B had negligible change in distribution of drug classes, while Group A had significant increased use of calcium channel blockers (dihydropyridine) and beta-blockers.

Conclusions: Impedance cardiography is a simple, noninvasive method for evaluating underlying hemodynamic drivers of HTN. Hypertension management is more effective when guided by hemodynamic state.

Variable at Baseline	Group A (N = 90)	Group B (N = 21)
Age, mean (SD)	61.3 (15.9)	63.7 (10.7)
Female, N (%)	44 (48.9%)	13 (61.9%)
CKD 1-5, N	65 (72.2)	14 (66.7%)
SBP, mean (SD) mmHg	163.0 (16.4)	162.6 (16.4)
DBP, mean (SD) mmHg	89.9 (12.4)	88.4 (12.9)
MAP, mean (SD) mmHg	114.0 (10.5)	112.7 (10.4)
Central SBP, mean (SD) mmHg	142.2 (20.7)	142.7 (16.3)
Central DBP, mean (SD) mmHg	90.7 (15.6)	89.5 (14.0)

Table 1

Change from Baseline	Group A	Group B
SBP, mean (SD) mmHg	-22.0 (16.3)	-15.2 (21.2)
DBP, mean (SD) mmHg	-11.4 (10.0)	-6.9 (9.7)

PO2090

Associations of Diuretic Use with Cardiovascular Events and All-Cause Mortality in the Systolic BP Intervention Trial (SPRINT)

Shweta Bansal,[4] Jincheng Shen,[3] Guo Wei,[3] Robert E. Boucher,[3] Glenn M. Chertow,[1] Paul K. Whelton,[2] Alfred K. Cheung,[3] Srinivasan Beddhu.[3] SPRINT Consortium *[1]Stanford University School of Medicine, Stanford, CA; [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [3]The University of Utah School of Medicine, Salt Lake City, UT; [4]The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Mediciine, San Antonio, TX.*

Background: It has been suggested that the beneficial effects of intensive compared to standard treatment of systolic BP (SBP) on the primary outcome of cardiovascular events (CVE) and all-cause mortality (ACM) in the SPRINT were due to increased diuretics use in the intensive arm.

Methods: In a *post hoc* analysis of SPRINT, we used time-dependent Cox analyses to examine if adjusting for diuretic use during follow-up attenuated the effects of intensive treatment on CVE and ACM. We also examined the interactions of diuretic use with the SBP interventions to assess the presence of effect modification.

Results: Figure1 shows the percentage of intensive and standard treatment participants on diuretics over time. Intensive treatment resulted in lower CVE (HR 0.76,

95%CI 0.65-0.88) and ACM (HR 0.82, 95%CI 0.68-0.97) compared to standard treatment. In Cox regression analyses that controlled for time-dependent diuretic use, the HR for intensive treatment on CVE (HR 0.74, 95%CI 0.64-0.87) and ACM (HR 0.80, 95%CI 0.66-0.96) were similar to main effects, whereas diuretic use was not associated with CVE (HR 0.90, 95%CI 0.76-1.06) or ACM (HR 1.02, 95%CI 0.84-1.25). However, diuretic use was associated with a lower HR for CVE in intensive arm (HR 0.69, 95%CI 0.54-0.90) but not in standard arm (HR 1.07, 95%CI 0.86-1.33), interaction p=0.03. No such interaction was found on ACM.

Conclusions: The main effects of intensive treatment on CVE and ACM were independent of time varying diuretic use. While diuretic use by itself was not associated with a lower HR for CVE in the entire cohort, it associated with lower CVE in intensive but not standard arm. Causal role of diuretic use on CVE needs further study.

PO2092

The Influence of Baseline Diastolic Blood Pressure on the Effects of Intensive Blood Pressure Lowering on Incident Strokes in the SPS3 Trial

Robert E. Boucher,[1] Guo Wei,[1,2] Olesya Ilkun,[1] Srinivasan Beddhu.[1,3] *[1]Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; [2]Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; [3]Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT.*

Background: In persons with low baseline diastolic blood pressure (DBP) and previous stroke, ntensive systolic blood pressure (SBP) lowering might by decreasing cerebral perfusion increase the risk for recurrent stroke.

Methods: SPS3 was a 2x2 factorial RCT that examined the effects of intensive vs. standatd (<130 vs. 130-149 mmHg) SBP control and combination versus asprin alone antiplatelet therapy on stroke outcome in 3020 participants. We examined whether the effects of intensive SBP lowering on stroke were modified by baseline DBP using spline regression models.

Results: Mean age was 63±11 yrs, 63% male and 15% black. Mean baseline SBP was 143±19 mmHg and DBP was 78±11 mmHg. There were 267 strokes over10725 person-years of follow-up. In spline regression models, those with lower baseline SBP were at higher risk for stroke (Fig1, panel A) but stroke incidence was lower in intensive vs. standard SBP arm all three baseline DBP tertiles (Fig1, panel B). In a spline regression model, there was no evidence that intensive SBP lowering increased the risk of stroke in those with low baseline DBP (Fig 2). Repeating the analysis with a cardiovascular composite (MI, CHF, stroke, or cardiovascular death) showed similar results.

Conclusions: While observational analysis suggested higher risk of recurrent stroke with low baseline DBP, intensive SBP lowering did not increase recurrent stroke risk in those with low baseline DBP and previous stroke.

PO2093

The Influence of Baseline Diastolic Blood Pressure on the Effects of Blood Pressure Lowering on Death and ESKD Outcome

Olesya Ilkun,[1] Guo Wei,[1,2] Robert E. Boucher,[1] Srinivasan Beddhu.[1,3] *[1]Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; [2]Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; [3]Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Intensive systolic blood pressure (SBP) lowering decreased the risk of death in SPRINT. However, there are concerns in those with low baseline diastolic blood pressure (DBP) that intensive BP lowering might adversely affect kidney perfusion and increase the risk for death/ ESKD.

Methods: The African-American Study of Kidney Disease and Hypertension (AASK) trial examined the effects of two different BP goals (mean arterial pressure (MAP) < 92 vs ≥ 102-109) in African American men and women (N =1094) with kidney disease but no diabetes. We investigated whether the effectts of BP intervention on the risk of death/ESKD was modified by baseline DBP.

Results: Mean baseline age was 55 ± 11 yrs and DBP 95 ± 14 mmHg. There were 264 death/ESKD events over 4714 years of follow-up., Compared to usual BP control, low BP goal resulted in lower levels of follow-up SBP, MAP and DBP across baseline DBP tertiles (Fig 1). Despite the lower follow-up MAP and DBP values, there was no evidence that low BP goal increased the risk of death/ESKD in those with low baseline DBP (Fig 2). Interaction of baseline DBP and BP intervention for death/ESKD was not significant (p =0.22).

Conclusions: The effect of BP lowering on the risk of death/ESKD was not modified by low baseline DBP. Hence, low baseline DBP by itself should not be an impediment for intensive BP lowering in CKD.

Intensive BP Control Associates with Better Kidney Outcomes in Individuals with APOL1 High-Risk Genotypes

Alex Dinh,[1] Timothy P. Copeland,[1] Joachim H. Ix,[2] Barry I. Freedman,[3] Charles E. McCulloch,[1] Elaine Ku.[1] *[1]University of California San Francisco, San Francisco, CA; [2]University of California San Diego, La Jolla, CA; [3]Wake Forest University, Winston-Salem, NC.*

Background: Presence of two *APOL1* risk variants (high-risk genotypes) are associated with risk for chronic kidney disease. However, we previously reported that intensive blood pressure (BP) control may lower mortality risk in AASK trial participants with *APOL1* high-risk genotypes. Our current objective was to assess whether *APOL1* genotypes modified the effect of intensive BP control on kidney outcomes in the Action to Control Cardiovascular Risk in Diabetes-Blood Pressure (ACCORD BP) trial.

Methods: We performed a retrospective analysis of the ACCORD 2x2 factorial trial which randomized participants to intensive (systolic BP <120mmHg) vs. standard BP control (<140 mmHg) and intensive vs. standard glycemic control. Presence of 0-1 *APOL1* risk alleles were considered low-risk genotypes and 2 *APOL1* risk alleles as high-risk genotypes. Cox models were used to test for interaction between intensive BP control and *APOL1* risk categories for the outcome of serum creatinine doubling or eGFR decline >20 ml/min (as defined by ACCORD). We included glycemic control assignment, age, sex, GFR, and albuminuria as covariates in adjusted models.

Results: 3,108 participants (n=2,617 White, 430 Black with low-risk and 61 Black with high-risk genotypes) were included. An interaction was present between race/*APOL1* genotype and intensive BP control (p <0.05). Whites assigned to intensive (vs. standard) BP control had a 85% higher adjusted risk of the kidney outcome (95% CI 1.67-2.06). Blacks with *APOL1* low-risk genotypes had a 37% higher adjusted risk of the kidney outcome (95% CI 1.06-1.77), while the adjusted risk of kidney function decline was not higher with intensive (vs. standard) BP control (HR 1.00, 95% CI 0.48-2.07) in Blacks with high-risk genotype. [Figure]

Conclusions: Intensive BP control to SBP <120 mmHg associated with less kidney function decline in Blacks with *APOL1* high-risk genotypes compared to Whites or Blacks with low-risk *APOL1* genotypes.

Figure – Unadjusted Kaplan Meier Curve for Risk of Kidney Function Decline with Standard vs. Intensive BP Control by race and APOL1 genotype

PO2095

Early GFR Decline with Intensive BP Lowering and the Risk of Death and ESKD: Mediation Analysis of AASK Study

Srinivasan Beddhu,[1,2] Jincheng Shen,[3] Glenn M. Chertow,[4] Paul K. Whelton,[5] Guo Wei,[1,3] Robert E. Boucher,[1] Alfred K. Cheung,[1,2] Tom Greene.[3] *[1]Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; [2]Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT; [3]Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; [4]Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA; [5]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.*

Background: Intensive BP lowering decreased the risk of death in CKD in SPRINT but there are concerns that its acute, hemodynamic kidney effects might increase ESKD risk.

Methods: AASK Study (N =1094) was a RCT of low vs. usual mean arterial pressure (≤ 92 vs.102 to 107 mmHg) on kidney outcomes. Using the change in measured iothalamate GFR from baseline to the average of months 3 and 6 (early GFR change), we examined the acute effect of the intervention on subsequent death/ESKD in a mediation analysis. We partitioned the total effect of BP intervention on death/ESKD that was mediated through early GFR change (indirect effect) and independent of early GFR change (direct effect). We also used SIMEX method to access the impact of measurement error in early GFR change on the findings.

Results: We included 976 AASK participants with GFR measurements at baseline, 3 and 6 months. Mean baseline GFR was 55±11 ml/min/1.73m². There were 223 deaths, 293 ESKD events and 445 death/ESKD events during an average of 7.2± 3.3 years of follow-up. BP separation was maintained through the trial (Fig 1, panel A) with an early decline in GFR in the lower BP group but GFRs in the two arms that were similar at the end of the trial (Fig 1, panel B). After adjustment for covariates listed in the footnote to Fig 2, we observed a borderline significant beneficial total effect of the BP intervention on death/ESKD and a slightly stronger direct effect (Fig 2). The HR for the indirect effect was slightly > 1, consistent with the possibility of a small adverse effect of early GFR change.

Conclusions: Intensive BP lowering appears to have a largely beneficial direct effect and a small deleterious indirect effect on death/ESKD in CKD.

A Novel Marker of Resistant Hypertension in CKD

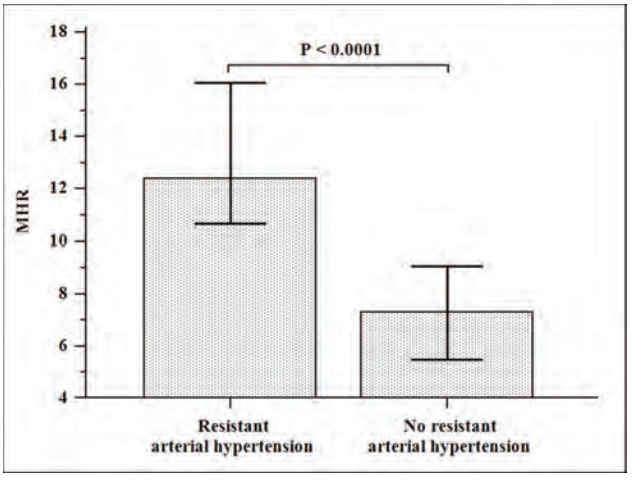
Guido Gembillo, Rossella Siligato, Valeria Cernaro, Domenico Santoro. *Policlinic G. Martino, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy.*

Background: Inflammation, oxidative stress (OS), atherosclerosis and resistant hypertension (RH) are common features of chronic kidney disease (CKD) leading to higher risk of death from cardiovascular disease. These effects seem to be modulated by impaired anti-oxidant, anti-inflammatory and reverse cholesterol transport actions of high-density lipoprotein cholesterol (HDL). Recently, monocyte count to HDL-cholesterol ratio (MHR) has emerged as a potential marker of inflammation and OS, demonstrating to be relevant in CKD. Our research was aimed to assess, for the first time, its reliability in RH.

Methods: We performed a retrospective study on 214 patients with CKD and arterial hypertension admitted between January and June 2019 to the Unit of Nephrology and Dialysis of Policlinic G. Martino in Messina, Italy. 72 patients were diagnosed with RH, defined as blood pressure >140/90 mmHg despite use of three different classes of antihypertensive medications (one of which must be a diuretic) at the maximum tolerated doses.

Results: MHR appeared inversely related to eGFR (ρ = -0.163; P = 0.0172). MHR was significantly higher among RH patients compared to non-RH ones (12.39 [IQR 10.67 - 16.05] versus 7.30 [5.49 - 9.06] (Figure 1); P < 0.0001). Moreover, MHR was significantly different according to the number of anti-hypertensive drugs per patient in the whole study cohort (F = 46.723; P < 0.001) as well as in the non-RH group (F = 14.191; P < 0.001). Lastly, MHR values differed according to gender, being higher among males (9.41 [6.75 - 12.07] versus 8.02 [5.94 - 10.57]; P = 0.0463).

Conclusions: MHR may be a reliable biomarker due to the connection between HDL and monocytes. HDL prevents and reverses monocyte recruitment and activation into the arterial wall and impairs endothelial adhesion molecule expression. Our study suggests that MHR can reflect inflammatory status and OS in CKD patients with RH, in order to implement appropriate treatment strategies.



PO2097

Renal Denervation (RDN) vs. Spironolactone in the Treatment of Resistant Hypertension (RH): A Meta-Analysis

Sherida N. Edding, Monica Therese Cating-Cabral, Brian Michael I. Cabral. *St. Luke's Medical Center - Global City, Taguig City, Philippines.*

Background: Resistant hypertension (RH) is defined as blood pressure that remains above guideline-directed goal despite the concurrent use of at least three antihypertensive agents of different classes, one of which is a diuretic. Treatment of RH is focused on the addition of fourth-line therapy. Several studies revealed impressive blood pressure reductions when spironolactone was added to the therapeutic regimen. In the recent years, there has been a growing perception that controlling blood pressure in resistant hypertension is beyond the reach of existing drug therapies, leading to the emergence of device-based therapies, such as renal denervation. Our aim is to do a systematic review of randomized controlled trials that compares the use of Spironolactone and Renal Denervation in patients with RH.

Methods: A comprehensive literature search from the PubMed, Embase, Cochrane Library, and Ovid was performed with the following search terms: Resistant Hypertension, Spironolactone, Renal Denervation. The search was limited to randomized-controlled trials that compared Spironolactone to Renal Denervation in patients with Resistant Hypertension. Three prospective clinical trials were selected and analyzed using Cochrane Revman v5.3. Primary outcome were mean changes in 24-hour Ambulatory Systolic Blood Pressure (SBP) and Diastolic Blood Pressure (DBP). Secondary outcomes include mean changes in Office SBP and DBP. Safety was assessed by changes in eGFR and potassium levels.

Results: Two trials comprising 130 patients were selected - 63 patients treated with RDN and 67 patients with Spironolactone. Pooled analysis of the 2 trials for 24H SBP and DBP showed an adjusted standardized mean difference of 0.55 mmHg (CI -0.72, 1.82; P = 0.39) and 0.32 mmHg (CI -0.72, 1.35; P = 0.55) with significant heterogeneity. No significant differences were also noted in terms of decline in eGFR (p = 0.07) and changes in serum potassium (p = 0.29) from baseline to 6 months.

Conclusions: Based on our results, RD appears to be safe and effective treatment for RH. However, additional larger studies should be done including a cost-benefit analysis to explore that possibility of RD as treatment alternative for those intolerant of spironolactone or as a possible 5th line of treatment for those already taking spironolactone.

PO2098

Primary Aldosteronism in CKD

Heather Wachtel,[1] Jae Ermer,[1] Angela C. Davio,[3] Yuta Tezuka,[3] Gregory L. Hundemer,[2] Adina Turcu,[3] Anand Vaidya,[4] Debbie L. Cohen.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Ottawa Hospital, Ottawa, ON, Canada; [3]University of Michigan, Ann Arbor, MI; [4]Brigham and Women's Hospital Department of Medicine, Boston, MA.*

Background: Primary aldosteronism (PA) is a common cause of secondary hypertension. Unilateral causes of PA are potentially cured with adrenalectomy. Treatment of PA in CKD is often avoided for concerns of safety and efficacy.

Methods: We conducted a retrospective cohort study of patients with PA and CKD (eGFR <60 ml/min/1.73m^2) at 3 institutions (2009-2019). eGFR was calculated using CKD-EPI. Statistical comparison utilized the student's t-test, Chi-square test, and Wilcoxon rank-sum test.

Results: Of 250 patients included, mean age was 56.6years (±10.5), and 64% were female. Median plasma aldosterone concentration was 29.0 ng/dl (IQR:20.3-47.4); median plasma renin activity was 0.2 ng/ml/hr (IQR:0.1-0.6) and aldosterone-renin ratio was 119 (ng/dl)/(ng/ml/hr) (IQR:63.5-240.0). Median eGFR on initial evaluation was 49.0 ml/min/1.73m2 (IQR:40.3-58.2). Adrenal vein sampling (AVS) was performed in all patients; unilateral PA was diagnosed in 67.6% (n=169). Adrenalectomy was performed in 163 subjects. Surgical pathology demonstrated adrenocortical adenomas in 66.9%, nodular hyperplasia in 4.9%, and nodular hyperplasia with a dominant nodule in 10.4%. The median tumor size was 1.2 cm (IQR:1.0-1.8). No differences were detected in baseline MAP, number of anti-hypertensive medications (AHM), serum creatinine, or potassium levels between adrenalectomy patients and those medically managed. Adrenalectomy patients had significantly lower AHM requirements at 1 month (2.0 vs. 4.5, p<0.001), 6 months (2.0 vs. 3.0, p=0.002) and 12 months after surgery (2.0 vs. 4.0, p<0.001) compared with medically managed patients. Adrenalectomy patients demonstrated stable eGFR from baseline to 12 months postoperatively, while medically managed patients had a statistically significant decrease in eGFR from baseline to 12 months (p=0.040). There was no difference between groups in cardiovascular outcomes.

Conclusions: Patients with CKD and unilateral PA experience significant and durable decrease in AHM requirement and demonstrate stabilization of eGFR after adrenalectomy when compared to medically managed patients. AVS was successful despite reduced GFR. This study demonstrates that patients with CKD and suspected PA should undergo evaluation to determine whether they have surgically curable disease, as there is a clear benefit in medication reduction and stabilization of eGFR at 12 months.

PO2099

Bilateral Nephrectomy in a Patient with Refractory Hypertension Prior to Development of ESKD

Anna M. Zemke,[2] Alexander Hlepas,[2] Martin Hertl,[4] Waleed Ali,[3] Roger A. Rodby,[1] George L. Bakris.[3] *[1]Department of Medicine, Division of Nephrology, Rush University Medical Center, Chicago, IL; [2]Department of Medicine, Rush University Medical Center, Chicago, IL; [3]Department of Medicine, Comprehensive Hypertension Center, University of Chicago Medicine, Chicago, IL; [4]Department Transplant Surgery, Rush University Medical Center, Chicago, IL.*

Introduction: Renal denervation (RDN) reduces increased sympathetic activation in refractory HTN (rHTN) while preserving kidney function, and trials in both the US and Europe demonstrate a 7-12 mmHg placebo subtracted reduction in systolic BP. Bilateral nephrectomy (BLN), originally performed in ESKD patients in the 1970s for rHTN is an effective treatment, but is reserved for ESKD pts. We present a case of life threatening rHTN in a pt with Stage 3b CKD that was unresponsive to open surgical renal denervation (OS RDN) but responded extremely well to BLN.

Case Description: A 43 y/o white woman with stage 3b CKD (eGFR 38 ml/min/1.73m^2) presented with a resting SBP between 180-240 mmHg on maximal doses of 8 different antihypertensive medications including spironolactone and minoxidil. She required frequent hospitalizations for symptomatic HTN with IV CCBs and beta blockers. Workup included an evaluation of all secondary causes including drug screening, urine metanephrines, renal MRI, and renin/aldo ratio. In an effort to avoid BLN, she initially underwent bilateral OS RDN by severing all neural tissue entering the kidney. Renal vein renin levels were 9.1, 7.8 ng/mL/hr pre OS RDN and 0.7, 1.4 ng/mL/hr post. Despite an initial drop in BP to 140/70 mmHg on only 2 medications, within 4 wks of OS RDN, her BP rose to 240/120 on 4 medications and she was symptomatic. At this point, BLN was performed as the only remaining option. Understanding of the need for RRT following BLN, the patient consented to proceed. Follow up BPs have been in the 130/80 mmHg range on carvedilol dose 12.5mg bid alone.

Discussion: Neither OS RDN nor pre-ESKD BLN for rHTN have been previously reported. Advancements in endovascular RDN are becoming more effective, but still only lower systolic BP by 7-12 mmHg placebo subtracted. Our case failed to respond to OS RDN, where we were guaranteed completed resection of the nerves and surrounding connective tissue, and suggests the effects of any form of RDN may be limited. BLN for rHTN for pts on RRT was started in the 1970s. Almost 50 yrs later, despite enormous improvements in medications, there is still a role for this procedure, and it emphasizes how little we still know about the etiology of rHTN. Requiring this in a patient pre-ESKD was extreme but we felt a life-saving requirement. She will be referred for transplantation.

PO2100

Rostral Ventrolateral Medullary Compression: A Rare but a Cardinal Cause of Refractory Hypertension (RfHTN)

Mrinalini Sarkar, Susanne B. Nicholas. *University of California Los Angeles, Los Angeles, CA.*

Introduction: RfHTN is defined as uncontrolled HTN with BP >140/90 mmHg despite ≥5 different classes of maximally tolerated antihypertensive agents, including a diuretic *and* a mineralocorticoid receptor antagonist. RfHTN may be underdiagnosed.

Case Description: A 43-year-old female with a history of mitral valve prolapse, iron deficiency anemia, mild asthma and migraines presented for management of uncontrolled severe HTN. Her HTN became increasingly resistant following use of pheniramine and fenfluramine for two years and a recent hysterectomy, with persistently elevated blood pressure (BP) up to 250/100 mmHg. Her medications included: hydralazine, lopressor, procardia, demadex, accupril, diovan, catapres and aldactone. On physical exam, her BP was 230/136 mmHg with regular pulse of 96 beats/min and no papilledema or bruits. Renal function and aldosterone levels were normal. Renal ultrasound/doppler, captopril scan, and angiograms showed no renal artery stenosis or coactation of the aorta, and 24-hour urine metanephrines were normal. Her echocardiogram showed concentric left ventricular hypertrophy with ejection fraction of 60%. Minoxidil was initiated and procardia and lopressor were maintained, with no effect on BP. A high-resolution brain MRI with spectroscopy showed a venous angioma in the right superior temporal lobe and CT angiogram showed irregularity of the basilar artery with outpouching at the left posterior communicating artery and right anterior choroidal artery. She was diagnosed with neurogenic arterial HTN from neurovascular compression (NVC) of the rostral ventrolateral (RVL) medulla. Left retro sigmoid craniotomy was performed for NVC decompression, but aborted eight hours later for fear of precipitating a massive stroke. The patient continues to have RfHTN despite maximal medical therapy and has now developed complications including a cervical ICA dissection, CKD stage 3, heart failure, and severe valvular disease.

Discussion: NVC is related to neurogenic HTN when occurring in the RVL medulla. This case highlights that brain MRI be performed in patients with intractable resistant HTN when all other secondary causes are ruled out.

PO2101

Adjunctive Mesenchymal Stem Infusion Boosts Recovery of GFR After Renal Revascularization for Atherosclerotic Renovascular Disease

Abdelrhman Abumoawad,[1,2] Ahmed Saad,[1,4] Christopher M. Ferguson,[1] Alfonso Eirin,[1] Sandra Herrmann,[1] LaTonya J. Hickson,[1] Emily Bendel,[3] Lilach O. Lerman,[1] Stephen C. Textor.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Department of Internal Medicine, University of Missouri Kansas city, Kansas city, MO, USA, Kansas City, MO; [3]Department of Radiology, Mayo Clinic, Rochester, MN; [4]Department of Family Medicine, Creighton University, Omaha, NE.*

Background: Atherosclerotic renovascular disease (ARVD) reduces renal blood flow RBF, GFR and accelerates poststenotic kidney (STK) tissue injury. Renal revascularization alone often fails to restore GFR in ARVD. Whether adjunctive infusion of autologous mesenchymal stem cells (MSC) can modify reparative processes during restoration of RBF is unknown.

Methods: We measured RBF (MDCT), GFR (iothalamate clearance), systolic blood pressure (SBP), in 16 human subjects with ARVD, before and 3 mo after MSC delivery and stent PTRA. MSC were administered at 3 dose levels (1, 2.5 and 5.0x10^5 MSC/kg, n=7,5,4 patients each) into STK, after stent PTRA. A cohort with ARVD n=17 matched for age, SBP and GFR studied under identical protocol treated with stent PTRA alone served as controls.

Results: SBP decreased in MSC + PTRA and PTRA alone groups 145±20 to 135±19, P=0.022, and 147±20 to 137±16 mmHg, p= 0.02. RBF increased in both MSC + PTRA and PTRA alone treated groups following the three-month hiatus 233±121, to 291±178 ml/min, p=0.015 and 315±260, to 376±304 ml/min, p=0.017. By contrast, GFR increased In the MSC + PTRA group 64±29 to73±34 ml/min p=0.017 whereas GFR did not change in the PTRA group 63.7±30.7 to 65.0±28.6, p =0.35. The increases in RBF and GFR were higher in the group treated with the highest MSC dose Fig1.

Conclusions: These data reinforce the dissociation between restoring RBF and recovery of GFR in ARVD. Adjunctive therapy with autologous MSC was associated with a dose-related increase in GFR after restoring blood flow, consistent with the ability of MSC to repair microvascular injury. Further clinical trials to characterize the durability and extent of these reparative pathways are warranted.

Percutaneous Angioplasty of Renal Artery Stenosis Most Beneficial in Patients with AKI Requiring Acute Hemodialysis

Nabil H. Abu amer,[1] Lesya Kukuy,[1] Uri Rimon,[1] Eliezer J. Holtzman,[1,2] Pazit Beckerman,[1,2] Dganit Dinour.[1,2] *[1]Sheba Medical Center at Tel Hashomer, Tel Hashomer, Israel; [2]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.*

Background: Treatment of atherosclerotic renal artery stenosis (RAS) is still contraversial and several studies have shown that percutaneous transluminal renal angioplasty with stenting (PTRAS) is not superior to medical treatment, and the procedure is commonly reserved for malignant hypertension, flash pulmonary edema or deterioration of kidney function. The benefit of endovascular intervention among acute kidney injury (AKI) patients requiring hemodialysis secondary to severe RAS has not been studied. We studied the effects of PTRAS in patients with atherosclerotic RAS, specifically those who presented with AKI indicated for hemodialysis.

Methods: 109 PTRAS were performed in 92 patients with RAS from 2003 to 2019 in a tertiary hospital. Eleven patients presented with AKI secondary to high grade RAS and underwent PTRAS after starting acute hemodialysis. Data collected included demographic parameters, medical background, indication for intervention, technical procedure parameters and complications and long term data including dialysis treatment and mortality. Patients were categorized as responders or non-responders based on improvement in kidney function and discontinuation of dialysis.

Results: A total of 109 procedures were performed in 92 patients with severe renal artery stenosis. Eleven patients (12%) underwent PTRAS for severe high grade stenosis causing renal hypoperfusion and hemodialysis-dependent AKI. After PTRAS, 8 of 11 patients (73%) improved kidney function and discontinued dialysis. The average time on dialysis was 17 days (range 3-35 days) to PTRAS and 22 days (range 3-42 days) to recovery of kidney function, which occurred 6.5 days (range 1-24 days) after PTRAS. Two of the 8 patients later required long term hemodialysis. Only two cases were reported with mild complications.

Conclusions: In patients with hemodialysis dependent AKI, PTRAS should be considered as a rescue treatment as kidney function may recover even after prolonged time on dialysis.

PO2103

Outcomes of Cardiac Surgery in CKD Stage 3 vs. Stage 4 and 5

Aimen Liaqat,[1] Elias Bassil,[1] Jonathan J. Taliercio,[1] Ali Mehdi,[1] Remy Daou,[2] Susana Arrigain,[1] Victoria Konig,[1] Jesse D. Schold,[1] Serge C. Harb,[1] Per Wierup,[1] Sevag Demirjian,[1] Georges Nakhoul.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Universite Saint-Joseph, Beirut, Lebanon.*

Background: Pre-operative kidney dysfunction is associated with worse outcomes following cardiac surgery. However, few studies have assessed the outcomes of advanced Stage 4 and 5 Chronic Kidney Disease (CKD) patients.

Methods: Using our Electronic CKD registry, we compared the outcomes of 988 patients with CKD stages 3 vs. 4 and 5 undergoing Coronary Artery Bypass Graft (CABG) and/or valvular cardiac surgery. We compared length of stay (LOS), ICU days, days on pressors, and days intubated as continuous values and as proportion above the 50th percentile using Kruskal-Wallis and Chi-square tests. We estimated Fine and Gray's competing risks cumulative incidence function of days to post-operative AKI requiring

dialysis (AKI-D) with mortality as a competing risk during hospitalization. We also compared the proportion developing AKI-D with Chi-square test.

Results: Among 988 total patients with cardiac surgery, 115 (12%) had CKD stage 4/5 and 873 (88%) had CKD stage 3. Average age was 71.2 ± 9.5 and 590 (59.7%) were male. Patients with CKD 4/5 had a higher proportion of diabetes (60% vs. 37%). Compared to CKD 3 patients, CKD 4/5 patients required longer intubation (33% more than 2 days compared to 20%, P=0.003), more pressors (47% more than 3 days vs. 32%, P=0.003), longer ICU LOS (median of 5 days vs. 4 days, P<0.001), longer post-operative LOS (median 12 days vs. 9, P<0.001). 24 patients (20.9%) with CKD 4/5 developed post-operative AKI-D vs. 42 (4.8%) in the CKD 3 group (p < 0.001). The cumulative incidence of End-Stage-Kidney Disease (ESKD) with death as a competing risk at 15 days was 5% (95% CI: 4, 8) in CKD 3 group vs. 24% (15, 33) in CKD 4/5 group (p < 0.001).(Table 1)

Conclusions: Advanced CKD stages 4/5 is associated with worse outcomes following cardiac surgery including prolonged ICU stay, intubation duration, days on pressors, development of AKI-D and ESKD.

Post-operative Outcomes in CKD Stage 3 Vs. Stage 4 and 5

Factor	N missing	Stage 3 (N=873)	Stage 4 or 5 (N=115)	p-value
N ICU days	11	4.0[3.0,7.0]	5.0[3.0,11.0]	<0.001b
Pressor days >3 (P50)	201	218(32.0)	49(46.7)	0.003c
Intubation days >2 (P50)	58	166(20.2)	36(32.7)	0.003c

PO2104

Cardiovascular Events and Mortality in Adults with Kidney Failure after Major Noncardiac Surgery

Tyrone Harrison,[1] Paul E. Ronksley,[1] James Wick,[1] Shannon M. Ruzycki,[1] Matthew T. James,[1] Deirdre Mccaughey,[1] Kelly B. Zarnke,[1] Brenda Hemmelgarn.[2,1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Alberta Faculty of Medicine and Dentistry, Edmonton, AB, Canada.*

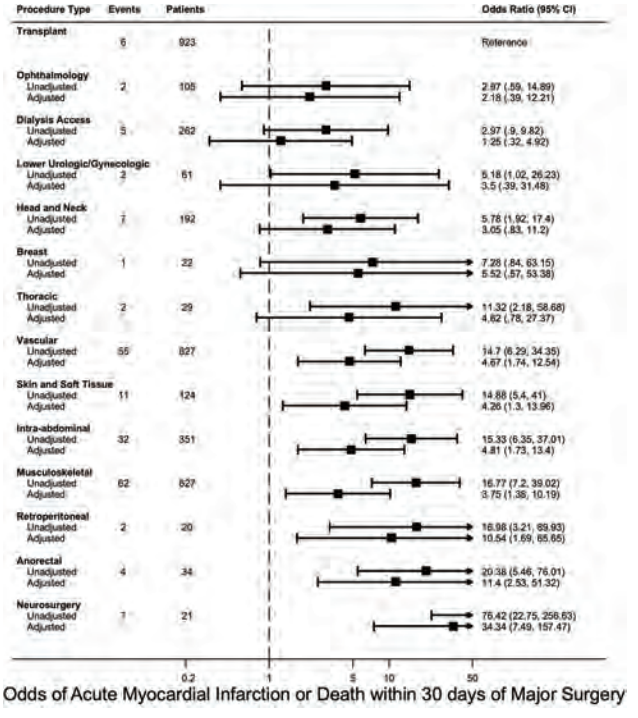
Background: People with kidney failure have a high incidence of major surgery. Despite this surgical exposure, there is a paucity of literature investigating postoperative CV events and death. We aimed to determine the risk of these outcomes based on surgery type.

Methods: This retrospective cohort study used administrative health data from Alberta, Canada from April 2005 to February 2017. Adults (≥18 years) with kidney failure (receipt of chronic dialysis or two outpatient eGFR measures <15 mL/min/1.73m^2) admitted to hospital for a surgical procedure were included. Surgery type, categorized using ICD-10 codes from hospitalization data, was examined for association with acute myocardial infarction (AMI) and death within 30 days of surgery using multivariable logistic regression. We adjusted for demographics, comorbidities, preoperative laboratory measures, procedure urgency, and kidney disease specific variables.

Results: 3398 people with kidney failure had a major surgery (1905 hemodialysis; 590 peritoneal dialysis; 903 non-dialysis). Most of the cohort was male (61.0%), the median age was 61.5 years (IQR 50.0, 72.7), and over half of the procedures were urgent (56.9%). 198 people (5.8%) had an AMI or died within 30 days of major surgery. Kidney transplantation had the lowest frequency of the outcome and were the reference group. After adjustment, vascular, skin and soft tissue, intraabdominal, musculoskeletal, retroperitoneal, anorectal, and neurosurgical procedures had statistically higher odds of AMI or death compared to kidney transplantation (Figure 1).

Conclusions: Major non-transplant surgery in people with kidney failure is associated with a high risk of AMI and death, which has implications for the direction of future perioperative research in this population.

Funding: Government Support - Non-U.S.



Odds of AMI and Death for people with kidney failure undergoing major non-cardiac surgery stratified by surgery type.

PO2105

Race Differences in Cardiovascular Events After Percutaneous Coronary Intervention-Induced AKI

Joseph Lunyera,[1] Robert M. Clare,[2] Karen Chiswell,[2] Julia J. Scialla,[3] Patrick H. Pun,[2,1] Kevin L. Thomas,[2,1] Monique Starks,[2,1] Clarissa J. Diamantidis.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Duke Clinical Research Institute, Durham, NC; [3]University of Virginia School of Medicine, Charlottesville, VA.*

Background: AKI portends a higher risk of subsequent cardiovascular disease (CVD). Although racial differences in AKI incidence have been found, it is unclear if the risk of CVD events following AKI also varies by race.

Methods: We quantified racial differences in the association of AKI with CVD events 1-year following percutaneous coronary intervention (PCI), using the Duke Databank for Cardiovascular Disease (DDCD). The DDCD captured all patients who underwent PCI at Duke between January 1, 2003 and December 31, 2013 with a combination of structured (forms) and electronic health record (EHR) data. Patients were followed prospectively for CVD events. AKI was defined as ≥ 1.5-fold increase in serum creatinine from outpatient reference value before PCI to the peak value within 7 days post-PCI or a 0.3 mg/dl increase from the reference value within 48 hours. The primary outcome was a CVD composite including all-cause death, myocardial infarction, stroke, and revascularization. Cox models from date of AKI to outcome were adjusted for demographics, baseline cardiac comorbidities, medication use (RAAS inhibitors and NSAIDS), indication and urgency of PCI, and BP at PCI and number of stents placed.

Results: Among 9432 patients (median age 63y; 33% women; 75% white, 20% black), 865 (9%) developed AKI. Among 8699 patients with follow-up, the cumulative incidence of CVD at 1-year was 21%. After adjustment, AKI vs no AKI was associated with 1.84 greater hazards for the composite CVD outcome [95% confidence interval (CI) 1.62 to 2.10]. Compared to whites, other race (HR 0.79, 95% CI 0.63 to 0.99) but not black race (HR 1.07, 95% CI 0.95 to 1.20) was associated with lower risk of subsequent CVD. There was no interaction between race and AKI (p-interaction 0.216). Results were similar with individual components of the outcome.

Conclusions: AKI vs. no AKI following PCI is associated with greater risk for CVD events, regardless of race. Efforts to offset long-term consequences of AKI should target all patients undergoing PCI.

PO2106

Frailty Is Associated with Higher Risk of Cardiovascular Events and Death in Adults with CKD: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study

Mary Hannan,[1] Ana C. Ricardo,[1] Julia Brown,[1] Eunice Carmona,[1] Zahraa Hajjiri,[1] Natalie Meza,[1] Jinsong Chen,[1] Milda R. Saunders,[2] James P. Lash.[1] [1]*University of Illinois at Chicago College of Medicine, Chicago, IL;* [2]*UChicago Medicine, Chicago, IL*.

Background: Frailty is common in individuals with chronic kidney disease (CKD). In the general population, frailty is associated with increased risk of cardiovascular events and mortality, but this association has not been fully examined in the CKD population. The objective of this study is to evaluate frailty status as a predictor of cardiovascular events and death in individuals with CKD.

Methods: Among 2,537 CRIC Study participants, frailty status was assessed using five criteria (slow gait speed, muscle weakness, low physical activity, exhaustion, and unintentional weight loss). Frailty was defined as meeting ≥3 criteria, pre-frailty as meeting 1-2 criteria, and non-frailty as meeting zero criteria. Cox proportional hazards models were used to evaluate associations with atherosclerotic events, incident heart failure, and death.

Results: Baseline age was 57.5 years, 45.5% were female, mean eGFR was 46.9mL/min/1.73m^2, and median urine protein was 0.13 mg/day. Frailty was present in 21% of the participants and 66% were pre-frail. During a median follow-up of 12.5 years, there were 349 atherosclerotic events, 398 incident heart failure events, and 398 deaths. In multivariable analyses, frail individuals had a higher risk of each outcome compared to non-frail individuals. Pre-frail individuals had a higher risk of atherosclerotic events compared to non-frail individuals (**Table**).

Conclusions: In adults with CKD, frailty is associated with increased risk for cardiovascular events and death. Future studies are needed to evaluate the impact of interventions to reduce frailty in individuals with CKD.

Funding: NIDDK Support, Other NIH Support - NHLBI, Private Foundation Support

CKD Predicts Stroke Severity, Disability, and Early Recurrence in a Population-Based Cohort Study

Dearbhla Kelly, Peter M. Rothwell. Oxford Vascular Study *Wolfson Centre for the Prevention of Stroke and Dementia, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom*.

Background: Chronic kidney disease (CKD) is associated with cerebrovascular disease and related mortality, and with under-utilisation of acute and preventive treatments, but any impact on initial event severity and recurrence risk is unclear. We aimed to determine whether CKD is associated with worse initial stroke severity and disability, and whether CKD is independently predictive of recurrent stroke and other vascular events.

Methods: In a population-based study of all TIA/stroke (Oxford Vascular Study), we studied initial stroke severity and disability using the National Institutes of Health Stroke Scale (NIHSS) and modified Rankin scale (mRS), respectively, in relation to CKD in all patients presenting with TIA and stroke from April 1, 2002 to March 31, 2017. Associations between CKD and event severity, and between CKD and risk of recurrent vascular events (stroke, myocardial infarction, and sudden cardiac death) were examined using ordinal and Cox regression models, respectively, adjusted for age, sex, and known vascular risk factors, and stratified by TOAST subtype.

Results: Among 3178 patients with TIA (n=1167), ischaemic stroke (n=1802), and intracerebral haemorrhage (n=209), 1267 (40%) had CKD. CKD was independently associated with greater risk of ischaemic stroke compared to TIA (adjusted OR=1.31, 95%CI=1.11-1.56; p=0.002) and with greater initial NIHSS (adjusted OR=1.28, 1.04-1.46; p=0.018), driven mostly by those with an estimated glomerular filtration rate (eGFR) < 30 ml/min/1.73m^2 (adjusted OR=2.59, 1.44-4.66; p=0.001 for ischaemic stroke; adjusted OR=4.06, 2.04-8.06; p<0.001 for initial NIHSS). Among patients with ischaemic stroke, CKD was also associated with higher one-month mRS scores (adjusted OR=1.40, 1.13-1.74; p=0.002), driven by those with an eGFR < 30 ml/min/1.73m^2 (Adjusted OR=6.51, 3.04-13.97, p<0.001). Risk of early (< 90 days) recurrent stroke was increased with CKD (adjusted HR=1.60, 1.15-2.21; p=0.005) as was the risk of longer-term (0-15 years) composite vascular outcomes (adjusted HR=1.14, 1.05-1.46; p=0.01).

Conclusions: The consistent independent impact of CKD on initial event severity, early disability and recurrence risk suggests that there may be processes intrinsic to CKD leading to uniformly worse outcomes. Further research should determine whether there are CKD-specific treatments that may improve stroke outcomes.

PO2108

Control of Blood Pressure in Elderly Patients with Heart Failure and Risk of Mortality

Antonios Douros,[3,1] Alice Schneider,[1] Natalie Ebert,[1] Martin K. Kuhlmann,[2] Nina Mielke,[1] Markus van der Giet,[1] Elke Schaeffner.[1] [1]*Charite Universitatsmedizin Berlin, Berlin, Germany;* [2]*Vivantes-Netzwerk fur Gesundheit GmbH, Berlin, Germany;* [3]*McGill University, Montreal, QC, Canada*.

Background: Blood pressure (BP) targets in elderly patients with heart failure (HF) are unclear and guidelines are based on expert consensus and extrapolation from populations without HF. Thus, our population-based prospective cohort study assessed if BP control <140/90 mmHg is associated with a decreased risk of mortality in elderly HF patients.

Methods: We included participants of the Berlin Initiative Study, all ≥70 yrs, with HF and treated with antihypertensive drugs at baseline (2009-2011). Demographics, lifestyle factors, medication, and comorbidities were obtained in face-to-face interviews and linked with administrative healthcare data. BP status was defined as normalized BP (systolic BP <140 and diastolic BP <90 mmHg) or non-normalized BP (systolic BP ≥140 or diastolic BP ≥90 mmHg) and updated every 2 yrs, so that each patient could contribute person-time to both exposure categories during follow-up. Time-dependent Cox proportional hazards models estimated adjusted hazard ratios (HRs) with 95% confidence intervals (CIs) of cardiovascular death and all-cause mortality associated with normalized BP compared with non-normalized BP in HF patients. Analyses were repeated in non-HF patients.

Results: There were 544 HF patients treated with antihypertensive drugs (mean age 82.8 yrs; 45.4% female). During a median f/up of 7.5 yrs and compared with non-normalized BP, normalized BP was associated with an increased risk of cardiovascular death (HR, 1.79; 95% CI, 1.23-2.61) and all-cause mortality (HR, 1.48; 95% CI, 1.15-1.90). No increased risks of cardiovascular death (HR, 1.23; 95% CI, 0.87-1.74) or all-cause mortality (HR, 1.19; CI 0.95-1.49) associated with normalized BP were observed among 1079 non-HF patients.

Conclusions: BP <140/90 mmHg was not associated with a decreased risk of mortality in elderly HF patients. The increased risk requires further confirmation.

Funding: Private Foundation Support

Risk of cardiovascular death and all-cause mortality associated with normalized BP in older adults with HF

Renal Outcomes of Sacubitril-Valsartan vs. ACE Inhibitors and Angiotensin Receptor Blockers in Heart Failure: A Systematic Review and Meta-Analysis

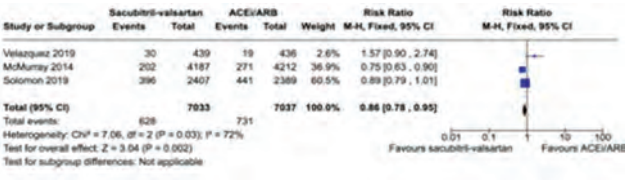
Eloisa Trina C. Generoso, Enrique L. Dimagiba, Jacqueline M. Crisostomo, Brian Michael I. Cabral. *St. Luke's Medical Center - Global City, Taguig, Philippines*.

Background: Chronic kidney disease is an important comorbidity in heart failure patients through elevation in blood pressure and activation of the RAAS. Angiotensin converting enzyme inhibitors and angiotensin receptor blockers have been linked to beneficial effects on clinical outcomes of HF patients with CKD; however, they have been found to increase the risks for renal impairment. Clinical trials on the angiotensin receptor neprilysin inhibitor, sacubitril-valsartan, have found that it causes kidney dysfunction less frequently. This study determined the effect of sacubitril-valsartan on renal outcomes among HF patients compared to ACEi and ARBs alone.

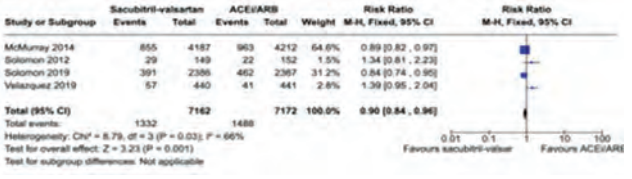
Methods: A comprehensive literature search was done through electronic databases and readings until November 2019. This analysis incorporated randomized controlled trials in which indicators of renal function of patients on sacubtril-valsartan were compared to those of patients on reference drugs--estimated glomerular filtration rate, rise in serum creatinine, and increase in serum potassium.

Results: Four RCTs were included with a total of 14,377 subjects for analysis. Two of the studies used an ACEi (enalapril), while the remaining 2 used an ARB (valsartan). Compared with ACEi and ARBs, there was a nonsignificant difference between decline in renal function (RR 0.75, 95% CI 0.55 to 1.02; participants = 14377; studies = 4; I2= 53%), but a significant difference between rise in serum potassium level (RR 0.90, 95% CI 0.84 to 0.96; participants = 14334; studies = 4; I2= 66%), and elevation of serum creatinine level (RR 0.86, 95% CI 0.78 to 0.95; participants = 14070; studies = 3; I2= 72%).

Conclusions: In HF patients, sacubitril-valsartan shows possible reduction of risks for renal impairment, and definite reduction of risks for both increasing serum creatinine and hyperkalemia, as compared to ACEi and ARBs.



Non-increase of serum creatinine



Non-increase in serum potassium

PO2110

The Accuracy of Current Ankle-Brachial Index and Toe-Brachial Index Diagnostic Criteria for Peripheral Artery Disease Among Patients with CKD

Jing Chen,[1,2] Hua He,[2] Charlton C. Starcke,[2] Yajun Guo,[2] Siyi Geng,[2] Chung-shiuan Chen,[2] Erin Mahone,[2] Jodie R. Laurent,[2] Christina L. Wiggin,[2] Prakriti Mehta,[2] Paige R. Pielet,[2] Vecihi Batuman,[1] L. Lee Hamm,[1] Jiang He.[2,1]
[1]Tulane University School of Medicine, New Orleans, LA; [2]Tulane School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Ankle-brachial index (ABI) less than or equal to 0.9 and toe-brachial index (TBI) less than or equal to 0.7 are used as diagnostic criteria for peripheral artery disease (PAD). The sensitivity and specificity of the ABI and TBI diagnostic criteria have not been evaluated in patients with chronic kidney disease (CKD).

Methods: We performed ABI, TBI, and doppler ultrasound among 100 patients with CKD using standard methods. Color doppler ultrasound, which has a high level of diagnostic performance with a sensitivity of 93% and a specificity of 95% for diagnosing PAD, was used as the reference standard. Doppler ultrasound diagnostic criteria were determined by multiple ultrasound features including reduction in luminal diameter, monophasic waveform, peak systolic velocity ratio (PSV ratio) >2.0, and presence of special broadcasting. Stenosis greater than or equal to 50% based on doppler ultrasound imaging was used to diagnose PAD. Sensitivity, specificity, positive predictive value, and negative predictive value were estimated. The areas under the curve (AUCs) for ABI and TBI were calculated.

Results: Participants with PAD were older, and more likely to be male and have a history of cardiovascular disease. The average estimated glomerular filtration rate and proteinuria were similar among participants with and without PAD. The sensitivity, specificity, positive predictive value, and negative predictive value were 15.6%, 88.3%, 20.8%, and 84.2% for ABI and 44.8%, 93.3%, 54.2%, and 90.5% for TBI, respectively. AUCs for ABI and TBI were 0.71 and 0.73, respectively.

Conclusions: These data indicate that current ABI and TBI diagnostic criteria have suboptimal accuracy in diagnosing PAD in CKD. New ABI and TBI diagnostic criteria with both optimal sensitivity and specificity need to be developed.

Efficacy and Safety of Roxadustat in Patients with Non-Dialysis-Dependent CKD, Anemia, and Heart Failure

Simon D. Roger,[1] Steven Fishbane,[2] Pablo E. Pergola,[3] Willis Chou,[4] Khalil G. Saikali,[4] Dustin J. Little,[5] Kin-Hung P. Yu.[4] *[1]Renal Research, Gosford, NSW, Australia; [2]Northwell Health, Great Neck, NY; [3]Renal Associates PA, San Antonio, TX; [4]FibroGen Inc, San Francisco, CA; [5]AstraZeneca, Gaithersburg, MD.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Patients with heart failure (HF) represent an important clinical subgroup of patients with CKD.

Methods: Pooled data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with non–dialysis-dependent (NDD) CKD were assessed in the subgroup of patients with a history of NYHA Class I or II HF recorded at baseline. Endpoints were mean change from baseline (CFB) in hemoglobin (Hb) level averaged over Weeks 28–52 regardless of rescue therapy and time to first blood/RBC transfusion in the first 52 weeks. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the NDD-CKD study population, 13% (569/4277) of patients had HF (roxadustat=312, placebo=257). Baseline characteristics were generally similar between the treatment groups. Mean (SD) Hb levels (g/dL) at baseline were 9.02 (0.86) in the roxadustat group and 9.04 (0.79) in the placebo group. Patients achieved a larger mean (SD) CFB in Hb levels (g/dL) with roxadustat vs. placebo (1.99 [0.99] vs. 0.29 [1.10]), corresponding to a statistically significant least-squares mean difference of 1.75 (95% CI: 1.54, 1.95) (p<0.0001). The risk for blood/RBC transfusion was significantly reduced in the roxadustat vs. placebo group (HR, 0.15 [95% CI: 0.08, 0.27]; p<0.0001). TEAE rates were comparable between treatment groups and similar to those reported in the overall NDD population.

Conclusions: Roxadustat was efficacious vs. placebo for increasing Hb levels and reducing the risk for blood/RBC transfusion in NDD-CKD patients with HF. The safety and tolerability profile was similar to the overall population and consistent with that observed in this patient subgroup.

PO2112

Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD, Anemia, and Heart Failure

Daniel W. Coyne,[1] Steven Fishbane,[2] Pablo E. Pergola,[3] Lynda Szczech,[4] Tyson T. Lee,[4] Dustin J. Little,[5] Kin-Hung P. Yu.[4] *[1]Washington University School of Medicine in Saint Louis, Washington University in Saint Louis School of Medicine, Saint Louis, MO; [2]Northwell Health, Great Neck, NY; [3]Renal Associates PA, San Antonio, TX; [4]FibroGen Inc, San Francisco, CA; [5]AstraZeneca, Gaithersburg, MD.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Patients with heart failure (HF) represent an important clinical subgroup of patients with CKD.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, epoetin alfa-controlled studies of roxadustat for the treatment of anemia in patients with dialysis-dependent (DD) CKD were assessed in the subgroup of patients with a history of NYHA Class I or II HF at baseline. Endpoints were: mean change from baseline (CFB) in hemoglobin (Hb) averaged over Weeks 28–52 regardless of rescue therapy, time to first blood/RBC transfusion during the treatment period, and mean monthly IV iron use during weeks 28–52. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the DD-CKD study population, 25% (991/3890) of patients had HF (roxadustat=499; epoetin alfa=492). Baseline characteristics were generally similar. Mean (SD) Hb levels (g/dL) at baseline were 9.59 (1.30) in the roxadustat group and 9.65 (1.29) in the epoetin alfa group. Patients achieved significantly larger least-squares mean (LSM) [SEM] CFB in Hb levels (g/dL) with roxadustat vs. epoetin alfa (1.24 [0.04] vs. 0.94 [0.04]), corresponding to a LSM difference of 0.29 (95% CI: 0.18, 0.40) (p<0.0001). The hazard ratio for first blood/RBC transfusion during the treatment period in the roxadustat and epoetin alfa groups was 0.76 ([95% CI: 0.54, 1.08]; p=0.1274). Mean (SD) monthly IV iron (mg) use was lower in roxadustat- vs. epoetin alfa-treated patients: 55.8 (288.8) vs. 68.6 (142.7) (p<0.0001). TEAE rates were comparable between treatment groups and similar to those in the overall DD-CKD study population.

Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing Hb levels and reducing mean monthly IV iron use in DD-CKD patients with HF. The safety and tolerability profile was similar to the overall population and consistent with that observed in this patient subgroup.

PO2113

Roxadustat Lowers Low-Density Lipoprotein Cholesterol in Patients with Anemia of CKD

Simon D. Roger,[1] Mohamed A. El-Shahawy,[5] Carol A. Pollock,[2] Rosa H. Jimenez,[3] Robert Leong,[3] Maksym Pola,[4] Kin-Hung P. Yu.[3] *[1]Renal Research, Gosford, NSW, Australia; [2]The University of Sydney, Sydney, NSW, Australia; [3]FibroGen Inc, San Francisco, CA; [4]AstraZeneca, Warsaw, Poland; [5]University of Southern California Keck School of Medicine, Los Angeles, CA.*

Background: Roxadustat is an oral hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor with positive safety and efficacy results in phase 3 studies in patients with anemia in CKD. The HIF pathway affects cholesterol metabolism; at high altitude, total and low-density lipoprotein cholesterol (LDL-C) decrease in healthy individuals. Roxadustat reduced LDL-C in phase 2 studies. We evaluated the effect of roxadustat on LDL-C in patients with anemia in non–dialysis-dependent (NDD) and dialysis-dependent (DD) CKD.

Methods: Data were pooled from three pivotal phase 3 studies in patients with NDD-CKD and three pivotal phase 3 studies in patients with DD-CKD, including the incident dialysis (ID; on dialysis <4 mo at randomization) population. Mean changes from baseline (CFB) in LDL-C (regardless of statin use) averaged over weeks 12–28 were analyzed using a mixed model of repeated measures and reported least-squares mean (LSM) treatment differences.

Results: In patients with NDD-CKD, there was a 17.2% reduction in LDL-C averaged over Weeks 12–28 in the roxadustat group (n=1994) and a 1.4% increase in the placebo group (n=1430). The LSM treatment difference was statistically significant (p<0.0001). In patients with DD-CKD, there was a 18.5% reduction in the roxadustat group (n=1650) and a 1.7% reduction in the epoetin alfa group (n=1741). The LSM treatment difference was statistically significant (p<0.0001). In patients with ID-DD-CKD, there was a 21.5% reduction in the roxadustat group (n=680) and a 4.6% reduction in the epoetin alfa group (n=691). The LSM treatment difference was statistically significant (p<0.0001).

Conclusions: Treatment with roxadustat vs. placebo or epoetin alfa lowered LDL-C in patients with NDD-CKD and DD-CKD, respectively.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

†Treatment comparison was made using an ANCOVA model with baseline Hb, baseline eGFR, baseline LDL-C as covariates, and study, treatment, study-by-treatment interaction, history of cardiovascular/cerebrovascular/ thromboembolic diseases (Yes vs. No) and region (US, Europe, Other) as fixed effects.
ANCOVA, analysis of covariance; CI, confidence interval; CFB, change from baseline; FAS, full analysis set; LDL-C, low-density lipoprotein cholesterol; LSM, least-squares mean; NDD, non-dialysis dependent; ID, incident dialysis; DD, dialysis dependent; SD, standard deviation; SEM, standard error of the mean.

PO2114

Roxadustat vs. Placebo or Epoetin Alfa Has No Clinically Meaningful Effect on Blood Pressure in Patients with Anemia of CKD

Tak Mao D. Chan,[1] Roberto Pecoits-Filho,[2,3] Anjay Rastogi,[4] Pablo E. Pergola,[5] Jacqueline G. Nolen,[6] Ming Zhong,[6] Lynda Szczech,[6] Kin-Hung P. Yu.[6] *[1]University of Hong Kong, Queen Mary Hospital, Pok Fu Lam, Hong Kong SAR, China; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Pontificia Universidade Catolica do Parana Departamento de Medicina, Curitiba, Brazil; [4]University of California Los Angeles, Los Angeles, CA; [5]Renal Associates PA, San Antonio, TX; [6]FibroGen Inc, San Francisco, CA.*

Background: Hypertension (HTN) is a leading cause of chronic kidney disease (CKD) and often worsens as CKD progresses. Erythropoiesis-stimulating agents have been associated with an increase in blood pressure (BP) and other cardiovascular risks. Roxadustat is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. We evaluated the effect of roxadustat on BP in dialysis-dependent (DD) and non–dialysis-dependent (NDD) patients with anemia of CKD.

Methods: Pooled data from three, phase 3, randomized, placebo-controlled trials in NDD patients (n=4270), and three pivotal phase 3 randomized, active-controlled trials in DD patients (n=3880), including incident-dialysis-dependent (ID-DD; on dialysis for ≤4 mo; n=1526) and stable dialysis-dependent (SDD; on dialysis for >4 mo; n=2354) patients, were assessed. All DD patients and NDD patients (data censored after dialysis initiation [NDD-NDD]) were included. Mean change from baseline (CFB) in mean arterial pressure (MAP) averaged over Weeks 20–28 (NDD-NDD, SDD) and over weeks 8–12 (ID-DD); time to first exacerbation of hypertension (SBP ≥170 mmHg or DBP ≥110 mmHg and an increase from baseline ≥20 mmHg [SBP] or ≥15 mmHg [DBP]); and adjudicated hypertensive emergency were analyzed.

Results: In NDD-NDD, the least squares mean (LSM) (SE) difference between roxadustat and placebo in MAP (mmHg) was 0.67 (0.30) [95% CI: 0.09, 1.25]. Values for ID-DD and SDD patients were −0.35 (0.66) [95% CI: −1.65, 0.95] and −0.06 (0.42) [95% CI: −0.88, 0.76]. Hazard ratios (95% CI) for HTN exacerbation in NDD-NDD, ID-DD, and SDD patients were 1.12 (0.95, 1.32), 1.02 (0.84, 1.25), and 1.06 (0.93, 1.21). Follow-up adjusted incidence rates [events/100 patient-exposure year] of adjudicated hypertensive emergency were 1.1 and 1.1 in roxadustat- and placebo-treated NDD-NDD, 2.2 and 2.5 in the overall roxadustat- and epoetin-alfa treated DD, and 1.7 and 1.7 in the subgroup of ID-DD.

Conclusions: Pooled analyses of phase 3 data across a continuum of patients with CKD and anemia showed that roxadustat did not have any clinically meaningful effect on BP, HTN exacerbation, or hypertensive emergency vs. placebo in NDD-NDD patients and epoetin alfa in DD patients.

Rivaroxaban Reduces Major Cardiovascular and Limb Events in Patients with CKD and Peripheral Artery Disease with Recent Lower Extremity Revascularization: Insights from VOYAGER PAD

Judith Hsia,[1,2] Mark R. Nehler,[2,1] Sonia Anand,[3] Manesh R. Patel,[4] William R. Hiatt,[2,1] Sebastian Debus,[10] Connie Hess,[2,1] Warren H. Capell,[5,1] Lihong Diao,[1] Scott D. Berkowitz,[6] Eva Muehlhofer,[8] Lloyd P. Haskell,[7] Rupert M. Bauersachs,[9] Marc P. Bonaca.[2,1] *[1]CPC Clinical Research, Aurora, CO; [2]University of Colorado Denver School of Medicine, Aurora, CO; [3]McMaster University, Hamilton, ON, Canada; [4]Duke University, Durham, NC; [5]University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; [6]Bayer Corp, Whippany, NJ; [7]Janssen Global Services LLC, Raritan, NJ; [8]Bayer AG, Leverkusen, Germany; [9]Klinikum Darmstadt, Darmstadt, Germany; [10]Universitatsklinikum Hamburg Eppendorf Universitares Herzzentrum Hamburg GmbH, Hamburg, Germany.*

Background: In the VOYAGER PAD trial, rivaroxaban reduced cardiovascular (CV) and limb ischemic events (HR 0.85 vs placebo, 95% CI 0.76-0.96; p=0.009) in peripheral arterial disease (PAD) patients following lower extremity revascularization (LER). This analysis examines the prespecified subgroup of VOYAGER PAD patients with CKD.

Methods: VOYAGER PAD (NCT02504216) randomized 6564 PAD patients following LER to rivaroxaban 2.5 mg twice daily or placebo on a background of aspirin 100 mg daily. The primary endpoint was a composite of acute limb ischemia, major amputation for vascular cause, myocardial infarction, ischemic stroke or CV death. Intention-to-treat analyses utilized Kaplan Meier estimates and Cox proportional-hazards models.

Results: Mean baseline eGFR was 75±23 ml/min/1.72m^2 with 79, 20, 1 and <1% of patients with CKD stage ≤2, 3, 4 and 5 respectively. During 28-month median follow up, rates of major CV and limb events were higher among patients with more severe CKD (placebo group event rate: 7.4/100 patient-years for eGFR ≥60, 10.0 for eGFR 30-<60 and 9.8 for eGFR 15-<30). Rivaroxaban reduced primary endpoint events with no heterogeneity by eGFR above or below 60 (mostly CKD stage 3)(Figure). Acute limb ischemia and major amputation were significantly reduced among patients with eGFR≥60 (HR 0.77, 95% CI 0.63, 0.94) and <60 (HR 0.55, 95% CI 0.36, 0.86). Major bleeding was infrequent with no heterogeneity by CKD category.

Conclusions: Rivaroxaban reduced CV and limb events in patients with CKD, PAD following LER, a particularly high-risk population.

PO2116

No Adverse Effects of Veverimer on Volume Status or Blood Pressure in Patients with CKD and Metabolic Acidosis

Donald E. Wesson,[1] Vandana S. Mathur,[2] Navdeep Tangri,[3] Yuri Stasiv,[4] Dawn Parsell,[4] Elizabeth Li,[5] Gerrit Klaerner,[4] David A. Bushinsky.[6] *[1]Baylor Scott & White Health and Wellness Center, Dallas, TX; [2]MathurConsulting, Woodside, CA; [3]University of Manitoba, Winnipeg, MB, Canada; [4]Tricida, Inc., South San Francisco, CA; [5]PharmaStat LLC, Fremont, CA; [6]University of Rochester Medical Center, Rochester, NY.*

Background: Current American Heart Association guidelines recommend sodium (Na) restriction of <1.5 g/day. Drugs can be a source of Na, potentially contributing to inadequate control of blood pressure (BP) and volume. For example, each $NaHCO_3$ tablet (650 mg) contains 170 mg of Na and multiple tablets per day are required to effectively treat metabolic acidosis. Veverimer is a non-absorbed polymer that treats metabolic acidosis by binding and removing HCl from the GI tract. It is not an exchange resin and does not introduce unwanted cations such as Na or K. We hypothesized that veverimer would not increase BP, weight or induce volume overload. In Phase 3 randomized, blinded placebo-controlled trials in acidotic patients (pts) with CKD (baseline mean eGFR 29 mL/min/1.73 m^2), veverimer significantly increased serum bicarbonate (LS mean +4.7 mEq/L at Week 52) with safety profile similar to placebo (Wesson et al. *Lancet*, 2019).

Methods: We analyzed parameters related to volume status in these Phase 3 trials.

Results: In these studies, 97% and 31% of pts, had HTN and CHF, respectively and 193 pts were treated with veverimer or placebo for up to 52 weeks. Treatment with veverimer (v placebo) had no effect on weight, BP, urine Na/creatinine ratio, volume-related adverse events, or increased use of diuretics or antihypertensives (**Table**).

Conclusions: Veverimer, a novel non-absorbed HCl binder, effectively treats metabolic acidosis in CKD without adversely affecting BP or volume status.

Optimal Medical Therapy Attainment by Dialysis Status in the ISCHEMIA-CKD Trial

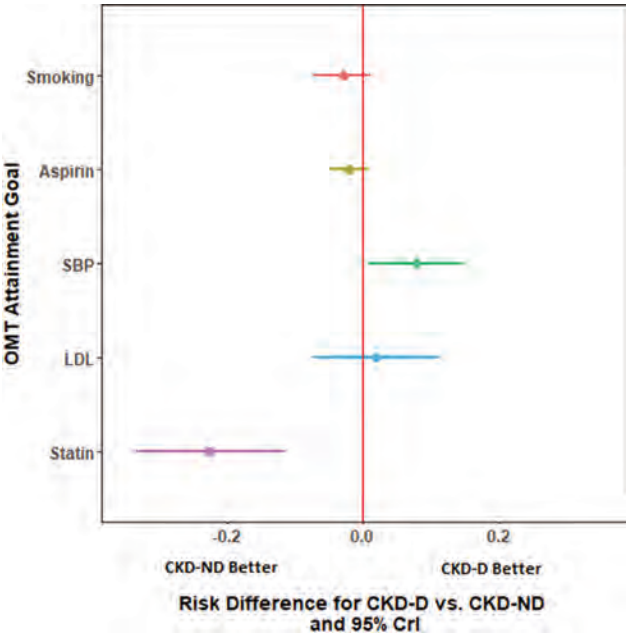
Roy O. Mathew,[13] David J. Maron,[8] Rebecca Anthopolos,[7] Jerome L. Fleg,[6] Sean O'Brien,[9] Frank W. Rockhold,[9] Carlo Briguori,[12] Marek Roik,[2] Tomasz Mazurek,[10] Marcin Demkow,[3] Robert Malecki,[3] Upendra Kaul,[11] Marius Miglinas,[1] Ron Wald,[4] David M. Charytan,[7] Mandeep S. Sidhu,[5] Judith Hochman,[7] Sripal Bangalore.[7] ISCHEMIA-CKD Research *[1]Vilniaus Universiteto ligonines Santariskiu klinikos, Vilnius, Lithuania; [2]Department of Internal Medicine, Infant Jesus Teaching Hospital, Medical University of Warsaw, Warsaw, Poland; [3]National Institute of Cardiology - II Cardiology Clinic, Mazovian, Poland; [4]St Michael's Hospital, Toronto, ON, Canada; [5]Albany Medical College, Albany, NY; [6]National Heart Lung and Blood Institute, Bethesda, MD; [7]New York University School of Medicine, New York, NY; [8]Stanford University Department of Medicine, Stanford, CA; [9]Duke Cinical Research Institute, Durham, NC; [10]Warszawski Uniwersytet Medyczny, Warszawa, Poland; [11]Batra Hospital and Medical Research Centre, New Delhi, India; [12]Mediterranea Cardiocentro, Naples, Italy; [13]William Jennings Bryan Dorn VA Medical Center Mental Health Department, Columbia, SC.*

Background: The efficacy of an aggressive multiple risk factor intervention approach – optimal medical therapy (OMT) – to reduce major adverse cardiovascular events in patients with CKD has not been tested. Objective: to examine OMT goal attainment in patients with CKD on dialysis (CKD-D) and non-dialysis CKD (CKD-ND) in the ISCHEMIA-CKD trial.

Methods: OMT was recommended to all participants in ISCHEMIA-CKD. Longitudinal trajectories of individual OMT components (smoking cessation, systolic blood pressure (SBP) <140 mmHg, low density lipoprotein (LDL) cholesterol <70 mg/dL, high-intensity statin use, and aspirin use) were modeled over study follow-up. Covariate-adjusted percentage point difference in each OMT goal achieved at 24 months between CKD-D and CKD-ND groups (% difference [95% credible interval (CrI)]) was estimated.

Results: There were 415 CKD-D and 362 CKD-ND patients at baseline. CKD-D were younger (61 v 67 yrs, p<0.001) and less often diabetic (53% v 62%, p=0.023). CKD-D patients were 7.9 % (0.7%, 14.8%) more likely than CKD-ND to attain the SBP goal at 24 months (Figure). CKD-D patients were 22.7% (-33.3%, -11.4%) less likely to receive high-intensity statins. There was a steady and similar increase in proportional achievement of OMT during follow up.

Conclusions: OMT improved over time in advanced CKD-ND and CKD-D. CKD-D achieved the SBP goal more than CKD-ND, yet CKD-D were less likely to be treated with high-intensity statin. Future studies should explore systemic and patient-related barriers to attainment of OMT in this high-risk cohort.



PO2118

Cardiovascular Determinants of Physical Function in Patients with ESKD on Hemodialysis

Sherna F. Adenwalla,[1] Gaurav S. Gulsin,[1] Roseanne Billany,[1,2] Daniel S. March,[1,2] Robin Young,[3] Alysha Careless,[1] Clare L. Tomlinson,[1] Gerry P. Mccann,[1,4] James Burton,[1,2] Matthew Graham-Brown.[1,2] *[1]University of Leicester and NIHR Leicester Cardiovascular Biomedical Research Centre, Leicester, United Kingdom; [2]John Walls Renal Unit, University Hospitals Leicester NHS Trust, Leicester, United Kingdom; [3]University of Glasgow Robertson Centre for Biostatistics, Glasgow, United Kingdom; [4]NIHR Leicester Biomedical Research Centre, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.*

Background: Patients with end-stage kidney disease (ESKD) are often sedentary and decreased functional capacity associates with mortality. The relationship between physical function and cardiovascular disease (CVD) has not been fully explored. Understanding the relationships between prognostically relevant measures of CVD and physical function and capacity may offer insight into whether exercise interventions could target specific elements of CVD.

Methods: 130 patients on haemodialysis underwent cardiovascular phenotyping with cardiac MRI (left ventricular (LV) structure and function, pulse wave velocity and native T1 mapping) and cardiac biomarker assessment. Participants completed the incremental shuttle walk test (ISWT) and sit-to-stand 60 (STS60) as field-tests of physical function and capacity. Separate linear regression analyses identified CV determinants of physical function measures. Multivariate models were adjusted for age, gender, BMI and diabetes.

Results: Mean age was 57±15 years, 73% were male and median dialysis vintage was 1.3 years (0.5, 3.4). In multivariate models, NT pro-BNP and global native T1 were independent determinants of ISWT and STS60 performance. LV ejection fraction was also an independent determinant of ISWT distance. However, age, gender and diabetes had the strongest relationship with physical function. Cardiovascular markers that were signficant in multivariate models are shown in Table 1.

Conclusions: Markers of CV health could be targeted in exercise interventions to improve outcomes in patients with ESKD. NT pro-BNP, global native T1 and LV ejection fraction were independent CV determinants of physical function. The influence of age and diabetes on performance had the strongest relationship. Improving strategies for prevention and management of diabetes may ameliorate deconditioning in these patients.

PO2119

The Relationship of Cardiovascular Morbidity with Death and End-Stage Kidney Failure in Patients with Diabetes and CKD Receiving Specialist Renal Care

Ken-Soon Tan,[1,2] Stephen P. McDonald.[3,4] CKD.QLD *[1]The University of Queensland Faculty of Medicine, Herston, QLD, Australia; [2]Griffith University School of Medicine, Gold Coast, QLD, Australia; [3]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; [4]The University of Adelaide Adelaide Medical School, Adelaide, SA, Australia.*

Background: Patients with diabetes (DM) and CKD have worse cardiovascular, renal and mortality outcomes than those with neither and either condition alone. However, relationships between these 3 outcomes remain unclear, especially in patients receiving specialist renal care. Aims: To determine the relationship of major adverse cardiovascular event (MACE), end stage kidney failure (ESKF) and death using competing risk analysis.

Methods: CKD.QLD is a large Australian registry of patients with CKD not on RRT receiving specialist renal care. Patients with DM enrolled between 1/1/2011 and 31/12/2016 inclusive were studied. Follow-up was censored by death, ESKF, 1st MACE post enrolment, movement of patient interstate/overseas, loss to follow-up or censor date of 31/12/2017, whichever occurred first. Competing risk analysis was performed with MACE, ESKF and death in turn as the primary outcome whilst the other 2 were competing risks. Covariates examined were age, gender, ethnicity, incident status, access to services, biopsy, smoking, diabetes treatment, Hba1c, MACE prior to enrolment, eGFR, proteinuria, Hb, RAAS blocker and lipid lowering therapy.

Results: 2355 patients underwent 6615 patient-years follow-up (pyfu), mean 2.8y. The first event was MACE in 571 patients (24.2%), ESKF in 299 patients (12.6%) and death in 268 patients (11.3%), giving respective event rates of 86, 45 and 41 per 1000 pyfu. 1137 patients (48.3%) experienced no event. Table 1 summarises the results of the best fit multivariable model with each primary outcomes. $p < 0.05$ was deemed significant.

Conclusions: Despite advances in cardiovascular risk management, MACE remains the dominant clinical outcome in diabetic CKD patients who are nearly twice as likely to experience a MACE first then they are to die or develop ESKF. One hypothesis is that advances in cardiovascular risk management may also concurrently decrease risk of CKD progression and delay death. The most consistent predictors of outcome were age and MACE prior to enrolment. Of note, neither ethnicity nor access to services predicted outcome.

Table 1: summary of competing risk analysis with the different primary outcomes.

Primary outcome	Competing risks	Positive predictors	Negative predictors
MACE	ESKF, Death	Age, proteinuria, HbA1c, Prior MACE	N/A
ESKF	MACE, Death	GFR, proteinuria, prior MACE	Age
Death	MACE, ESKF	Age, smoking, prior MACE	Hb

PO2120

The Combined Prognostic Significance of Red Blood Cell Distribution Width and Vascular Calcification in Patients with ESKD

Da won Kim, Dongryul Kim, Yeonhee Lee, Seok Joon Shin, Hye Eun Yoon. *Catholic University of Korea School of Medicine, Seoul, Seoul, Republic of Korea.*

Background: Red blood cell distribution width (RDW) is a simple parameter that reflects the degree of red blood cell volume variability. Recent evidence has shown that increased RDW is associated with adverse clinical outcomes in end-stage kidney disease (ESKD) patients. Vascular calcification (VC) is another major independent risk factor for mortality among ESKD patients. This study investigated the combined prognostic effect of RDW and VC in ESKD patients starting dialysis.

Methods: We conducted a retrospective observational cohort study of 582 ESKD patients treated at a single center from January 2006 to July 2017. VC was assessed by the aortic calcification index (ACI) using abdominal computed tomography. Patients were divided into four groups based on the median ACI (17.12) and serum RDW value (14.3) as low ACI-low RDW, low ACI-high RDW, high ACI-low RDW, or high ACI-high RDW. The association between RDW and VC on the composite of cardiovascular events (CVEs) and death was investigated.

Results: During a median follow-up of 3.1 years (range, 1.5–5.5 years), 165 (28.3%) CVEs and 126 deaths (21.4%) occurred. The Cox regression analyses showed that the patients with low ACI-high RDW (adjusted hazard ratio, 1.934; 95% confidence interval, 1.185-3.157; $P = 0.008$) and high ACI-low RDW (adjusted hazard ratio, 1.921; 95% confidence interval, 1.171-3.152; $P = 0.01$) had a greater risk of the composite endpoint than patients with low ACI-low RDW. Patients with high ACI-high RDW had the greatest risk (adjusted hazard ratio, 2.367; 95% confidence interval, 1.465-3.824; $P < 0.001$). The interaction between ACI and RDW on CVEs and mortality was statistically significant ($P = 0.043$).

Conclusions: In ESKD patients starting dialysis, the combined effect of VC and higher RDW was associated with a higher risk of CVEs and death. Also, high serum RDW amplified the risk associated with VC.

PO2121

Attention to the "Liddle" Details

Stefano Coppola fasick, Adrian P. Sequeira, James O. Onyirimba. *Louisiana State University Health Sciences Center Shreveport, Shreveport, LA.*

Introduction: Laboratory data provide clues to the etiology of resistant hypertension. We present one such case where in a presumptive diagnosis of Liddle's syndrome was made, and appropriate therapy initiated. Yet the hypertension failed to be controlled despite multiple antihypertensives.

Case Description: A 26-year-old African American male was evaluated 8 years ago for a history of resistant hypertension. He was compliant with five blood pressure medications yet his systolic blood pressures were greater than 180mmHg. He denied smoking or consuming licorice products. No family history of early deaths, hypertension, or strokes. He reported having early onset of puberty at around age 12, being taller than his peers and now being short as an adult. He was a thin individual with no abdominal striae. Investigations revealed hypokalemia with mild metabolic alkalosis along with low renin and aldosterone. His kidney ultrasound was normal as were his renal functions and free metanephrines. 24-hour urine cortisol was not elevated. A presumptive diagnosis of Liddle's syndrome was made and amiloride was added to his anti-hypertensive regimen, with little effect on BP control. Over the subsequent years, he was admitted repeatedly for hypertensive emergencies. This led to changes in his regimen along with a trial of Aldactone with no benefit. During one such episode, he complained of retrosternal pain. A CT was done to rule out a dissecting aneurysm, but it revealed a 5cm adrenal mass. Work up revealed high deoxycorticosterone, 11 deoxycortisol, dehydroepiandrostenedione sulphate and testosterone which was suggestive of 11-hydroxylase deficiency causing congenital adrenal hyperplasia (CAH) He was started on dexamethasone 2 mg daily and his blood pressure control began showing improvement.

Discussion: CAH due to 11-hydroxylase deficiency is commonly seen in Sephardic Jews. It presents with features suggestive of mineralocorticoid excess. The differential diagnoses are Liddle's syndrome, Chrousos syndrome, syndrome of apparent mineralocorticoid excess and Geller syndrome. This patient was wrongly diagnosed which led to repeated hospitalizations with inadequate therapy. Liddle's syndrome responds well to amiloride without the need for additional medications. The fact that he was on multiple medications in addition to amiloride should be a clue to the misdiagnosis.

PO2122

A Case of Disappearing Hypertension: Difficulties of Managing Hypertension in a Breast Cancer Survivor

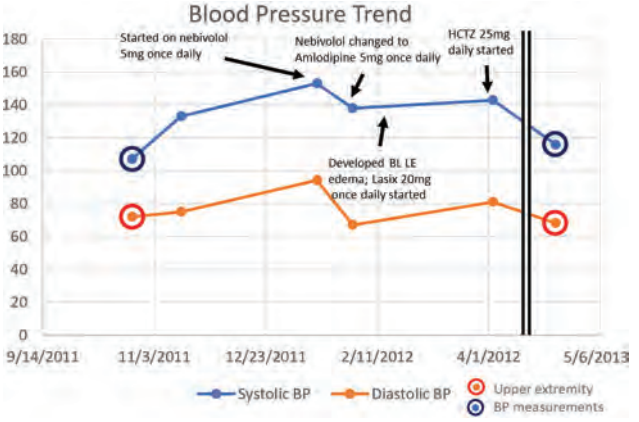
Xiao Ling, Shubha Ananthakrishnan. *University of California Davis Department of Internal Medicine, Sacramento, CA.*

Introduction: Treating hypertension in breast cancer survivors often hold unique difficulty. These patients may have undergone sentinel lymph node biopsy (SNB) or axillary lymph node dissection (ALND), and are often advised to avoid blood pressure measurement with affected by surgery. Here we present a case of young female after mastectomy, SNB and ALND, who was diagnosed with essential hypertension after mastectomy due to inaccurate measurements from avoiding the use of sphygmomanometer cuffs on her upper extremities.

Case Description: 32-year-old female with past medical history of breast cancer status post bilateral mastectomy and hypertension who presents for hypertension management. Hypertension was diagnosed after her breast cancer diagnosis. After diagnosis, she underwent bilateral mastectomy and sentinel node biopsy and subsequently underwent left axial lymph node dissection. Average clinic blood pressure prior to breast cancer diagnosis was 102/63 including days prior to surgery where BP was 107/72. On post-operative follow ups, the patient's BP was noted to be elevated (133/75 and then 154/94) and she was started on nebivolol 5 mg daily. Blood pressure continued to be high at clinic and home, nebivolol was changed to amlodipine 5mg daily. After starting amlodipine, patient developed lower extremity edema and headaches. Furosemide 20 mg PO daily was added which resolved the edema but headache persisted. Hydrochlorothiadize was further added when the patient continued to have blood pressures in the 140s/80-90s. On evaluation with nephrology, the was noted that her blood pressures had been measured

using her lower extremities since her mastectomy. Blood pressure measured with her right upper extremity was 116/68.

Discussion: Often patient after mastectomy with SNB or ALND avoids taking blood pressure on affected limb regardless of lymphedema in order to prevent lymphedema. Despite this, the evidence for this is sparse with most recent studies reporteding blood pressure measurement in ipsilateral affected arm as not being risk factor for lymphedema.



PO2123

A Curious Case of Hypertensive Emergency and AKI

Dennis Hu,[1] Ashkan Karimi,[2] Garland A. Campbell,[1,2] Negiin Pourafshar.[1,2] *[1]University of Virginia Health System, Charlottesville, VA; [2]Augusta Health, Fishersville, VA.*

Introduction: We report a case of a 75-year-old female with history of a prior right renal artery stent (coronary bare metal stent), stage IV chronic kidney disease (baseline serum creatinine (Scr) 2.1-2.3 mg/dL (eGFR 20-23 ml/min/1.73 m2)), diastolic heart failure, and hypertension who presented with hypertensive emergency (blood pressure (BP) 220/80 mmHg) and flash pulmonary edema.

Case Description: During her hospital stay, despite treatment with up to nine anti-hypertensive medications, her systolic BP remained 180-200 mmHg. Her Scr also increased to 3.92. Work-up showed normal kidney sizes and urine protein/creatinine ratio 1.26 g/g. Renal artery duplex revealed right renal artery peak systolic velocity 267 cm/sec, renal-to-aortic ratio 2.68, and resistive index 0.7-0.9, suggestive of right renal artery re-stenosis and some intrinsic damage. Due to progressive volume overload and worsening respiratory status, she required temporary hemodialysis. As her volume status improved, she underwent CO2 angiogram and was found to have 90% diffuse in-stent restenosis with marked deformity of the previous stent. She underwent re-stenting of the right renal artery with a proprietary FDA-approved Herculink Elite® renal stent with only 8 ml of contrast. Immediately post-intervention, her BP dramatically improved and after two months, her dialysis was stopped (new baseline SCr 1.5-1.9) and she only requires two BP medications.

Discussion: This case highlights several important points. First, renal ultrasound should be considered in the work-up of patients with hypertensive emergency and history of renal stent due to the risk of re-stenosis. Second, it highlights the importance of using an appropriate FDA approved stent in the renal position as placement of coronary stents in the renal position might have a higher incidence of structural failure and re-stenosis.

Deformed stent (arrow) with severe in-stent restenosis

PO2124

Effect of Dietary Salt Reduction on Blood Pressure in Kidney Transplant Patients: A Randomised Controlled Trial

Louise E. Ross,[1] Rebecca Suckling,[1] Mark E. Dockrell,[1] Thomas Bailey,[2] Pauline A. Swift.[1] *[1]Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom; [2]University of Warwick, Coventry, United Kingdom.*

Background: Cardiovascular morbidity and mortality are increased in kidney transplant patients. High blood pressure (BP) contributes significantly to this risk and is associated with shortened allograft survival. Dietary salt reduction is widely recommended as a strategy to lower BP in the general population and in chronic kidney disease. Due to a lack of evidence there is currently no consensus on dietary salt restriction in kidney transplant patients.

Methods: Sixty stable kidney transplant patients, ≥ 6-months post-transplantation, with BP ≥120/80 mmHg, and sodium intake ≥80 mmol/24hrs, were randomised in this parallel-designed study to receive either a regular-salt diet (target 150 mmol/24hr) or a low-salt diet (target 80 mmol/24hr) for 8-weeks. The primary outcome measure was systolic and diastolic BP. Secondary outcome measures included 24-hour ambulatory BP (ABP) and proteinuria. Dietary salt intake was assessed by 48-hour urinary sodium excretion.

Results: At baseline, patients (72% men) were 56±11 years with estimated glomerular filtration rate (eGFR) 53±18 mL/min/1.73m^2. Mean urinary sodium was 128±42 mmol/24hr, mean systolic BP was 132±12 mmHg, and mean diastolic BP was 77±10 mmHg. At the end of the intervention period sodium excretion was significantly lower in the low-salt group compared with the regular-salt group (90±37 vs. 132±51 mmol/24hr; adjusted mean difference, -36 [95% CI, -59 to -14] mmol/24hr; *P*=0.002). We found no difference in systolic BP (adjusted mean difference, -2 [95% CI, -12 to 9] mmHg; *P*=0.750), diastolic BP (adjusted mean difference, 0 [95% CI, -4 to 4] mmHg; *P*=0.887), 24-hour systolic ABP (adjusted mean difference, -3 [95% CI, -9 to 2] mmHg; *P*=0.213) or 24-hour diastolic ABP (adjusted mean difference, -2 [95% CI, -5 to 1] mmHg; *P*=0.267). There was no significant effect on proteinuria, eGFR, serum osmolality, uric acid, renin concentration, or aldosterone.

Conclusions: In this study baseline urinary sodium was lower than expected and baseline BP was well-controlled. Reducing dietary salt by 2g/day did not have a significant effect on office blood pressure readings.

PO2125

Left Atrial Reservoir Strain Is an Independent Predictor of End-Stage Renal Impairment in Patients with CKD

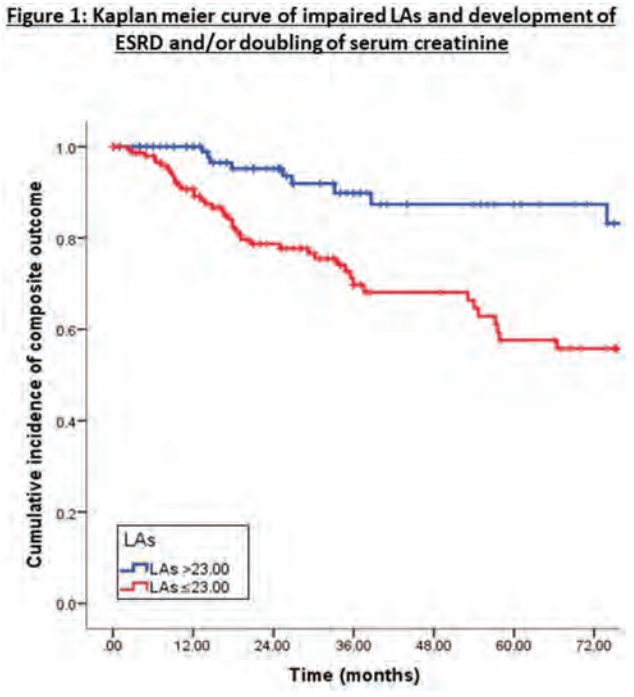
Gary Gan,[1,2] Krishna K. Kadappu,[3,2] Aditya Bhat,[1,2] Fernando Fernandez,[1] Kennith H. Gu,[1] Suzanne Eshoo,[1] Brian J. Nankivell,[4,5] Liza Thomas.[4,2] *[1]Blacktown & Mount Druitt Hospital, Blacktown, NSW, Australia; [2]University of New South Wales, Sydney, NSW, Australia; [3]Campbelltown Hospital, Campbelltown, NSW, Australia; [4]Westmead Hospital, Westmead, NSW, Australia; [5]The University of Sydney, Sydney, NSW, Australia.*

Background: Left atrial (LA) enlargement is common in patients with chronic kidney disease (CKD) and is a predictor of adverse cardiovascular events. Our study sought to evaluate the value of LA reservoir strain (LAs), a novel echocardiographic measure of LA function, as a prognostic marker of adverse renal outcomes.

Methods: Patients with stable Stage 3 and 4 CKD without prior cardiac history were prospectively recruited and underwent transthoracic and stress echocardiography. Patients with normal left ventricular (LV) function, without significant valvular disease and without ischaemia on stress testing were included and followed for up to 5 years for development of end stage renal disease (ESRD) and/or doubling of serum creatinine.

Results: 280 patients (65.8±12.2years, 63% male) were recruited and followed for a mean period of 3.9±2.7years. 56 patients developed the composite endpoint. On log rank tests, impaired LAs (Figure 1), older age, lower eGFR, anemia, diabetes mellitus, greater urinary albumin/creatinine, greater number of antihypertensive agents, higher indexed LV mass and larger LA volumes were significant predictors of the composite outcome ($p<0.01$ for all). On Multi-variable Cox proportional hazards regression analysis, impaired LAs in addition to eGFR, number of antihypertensive agents and urinary albumin/creatinine ($p<0.01$ for all) were independent predictors of ESRD and/or doubling of serum creatinine. Impaired LAs was associated with a 2.5-fold higher risk of the composite outcome.

Conclusions: LAs is an independent predictor for development of ESRD and/or doubling of serum creatine and thus has the potential to be a 'biomarker' for identification of high-risk patients, enabling early initiation of therapy.



PO2126

Weight Gain Is a Risk Factor for the Progression of Coronary Artery Calcification in CKD: From the KNOW-CKD Study

Ji Hye Kim, Young Youl Hyun. *Kangbuk Samsung Medical Center, Jongno-gu, Seoul, Republic of Korea.*

Background: In chronic kidney disease (CKD), patients with high body mass index or weight gain have better survival. However, their cardiovascular risk is uncertain. The aim of this study was to investigate the relationship between weight changes and the progression of coronary artery calcification (CAC) in CKD.

Methods: This study analyzed 839 participants (Mean age 52.51±12.03, Males 41.12%) from the KNOW-CKD cohort. Changes in weight between baseline and 4 year follow-up period were categorized in tertiles: first tertile (T1) (-31.3kg to -1.1kg), second tertile (T2) (-1kg to 0.9kg) and third tertile (T3) (1kg to 30kg). The coronary artery calcium score (CACS) was assessed using cardiac computed tomography at baseline and 4 years after enrolment. The CAC progression was defined as increase of CACS after 4 years.

Results: The study participants' baseline median CACS was 0.0 (median) [0 (25th quartile)- 34.5(75th quartile)] and 387 (46.13%) participants had baseline CACS above 0. After 4 years, numbers of patients in each tertile was 247 (29.4%) in T1, 258 (30.8%) in T2 and 334 (39.8%) in T3. Median difference in CACS between baseline and follow-up was 2 [0 -69.3] in T1, 0 [0-47.2] in T2 and 6.4 [0-64.77] in T3. (p=0.088) Multivariate adjusted odds ratios (OR) [95% confidence interval] (95% CI) for CAC progression in T1 and T3 group compared to T2 group were 1.21 [0.79-1.85] and 1.80 [1.20-2.70].

Conclusions: Third tertile group, which gained between 1 to 30kg after 4 years, was significantly and independently associated with CAC progression compared to weight stable second tertile group in Korean predialysis CKD patients. These results suggest that preventing excessive weight gain might help prevent cardiovascular complications in CKD.

	Crude OR	Model 1	Model 2	Model 3
Weight change				
1st tertile	1.24 (0.88-1.76)	1.28 (0.86-1.92)	1.21 (0.79-1.85)	1.21 (0.79-1.85)
2nd tertile	1 (Reference)	1 (Reference)	1 (Reference)	1 (Reference)
3rd tertile	1.37 (0.99-1.90)	1.77 (1.21-2.60)	1.82 (1.22-2.72)	1.80 (1.20-2.70)

Model 1 : Adjusted for age, sex

Model 2 : Adjusted for age, gender, BMI, SBP, diabetes, baseline statin medication, HDL, LDL, eGFR, CRP, urine protein to creatinine ratio, calcium, phosphorus, vitamin D, PTH

Model 3 : Adjusted for age, gender, BMI, SBP, diabetes, baseline statin medication, HDL, LDL, eGFR, CRP, urine protein to creatinine ratio, calcium, phosphorus, vitamin d, PTH, current smoker, alcohol drinking frequency and Metabolic syndrome equivalent

PO2127

The Circadian Clock Provides Beneficial Effects Against the Endothelial Dysfunction to Promote Atherogenesis by Regulating Heme Oxygenase 1 Expression

Hideyuki Negoro.[1,2] *[1]Harvard Medical School, Boston, MA; [2]The Graduate School of Project Design, Tokyo, Japan, Japan.*

Background: The circadian clock is a molecular mechanism that confers 24 hour variations in gene expression and function to regulate number of physiological functions in humans. Disruption of the clock is associated with pathological remodeling in the arterial structure and vascular stiffness. Chronic circadian clock disruption is also associated with dysfunction in endothelial signaling and responses. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence HO-1 which play an important part in the protection of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of HO-1 expression in the knocked down cells.

Results: Endothelial function was reduced in aorta from Bmal1-KO mice. In aorta from Bmal1 KO mice, there was a reduction in HO-1 expression in mice with a dysfunctional circadian rhythm. Moreover, Bmal1 KO mice display pre-mature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to changes in the regulation of key risk factors for cardiovascular disease. These include HO-1 which is significantly reduced in Bmal1 KO mice. We also confirmed that HO-1 levels follow a circadian pattern and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating HO-1 expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

PO2128

Modeling Endothelial Cell Dysfunction Using Human Induced Pluripotent Stem Cells Derived from Patients with ESRD

Suyeon Hong,[1] Sun Woo Lim,[3] Yoo-Jin Shin,[2,3] Eun jeong Ko,[2,3] Byung ha Chung,[2,3] Chul Woo Yang.[2,3] *[1]Uijeongbu St. Mary's Hospital, Uijeongbu, Republic of Korea; [2]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [3]Transplant research center, Seoul, Republic of Korea.*

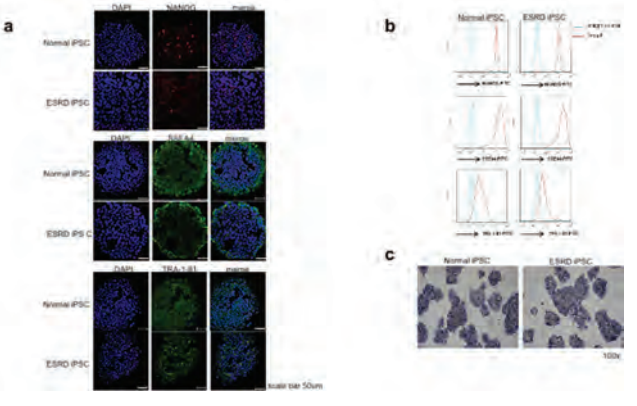
Background: Endothelial cell (EC) dysfunction is a frequent feature in end-stage renal disease (ESRD). The aim of this study was to generate human induced pluripotent stem cell-derived EC (hiPSC-ECs) from patients with ESRD as a model to investigate EC dysfunction.

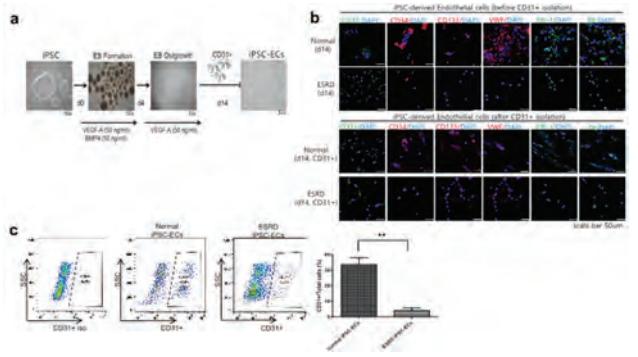
Methods: hiPSCs were obtained using peripheral blood mononuclear cells of patients with ESRD and healthy controls (HC). Next, we generated hiPSC-ECs and the expression of endothelial markers was assessed by immunofluorescence. The differentiation efficacy, EC dysfunction, and molecular signatures of EC-related genes based on microarray were compared between the ESRD and HC groups.

Results: In both groups, hiPSCs and hiPSC-ECs were successfully obtained based on iPSC or EC marker expression. However, the efficiency of EC generation from hiPSC was lower in ESRD than HCs. In addition, ESRD-hiPSC-ECs failed to form interconnecting branching point networks, unlike HC-hiPSC-ECs in the tube formation assays. In a microarray analysis, transcripts associated with oxidative stress and inflammation were upregulated and transcripts associated with vascular development and basement membrane extracellular matrix components were downregulated in ESRD-hiPSC-ECs compared with HC-hiPSC-ECs.

Conclusions: In conclusion, ESRD-hiPSC-ECs showed a greater EC dysfunction based on functional assays and molecular profiles and it can be a useful disease model to investigate EC dysfunction in ESRD.

Funding: Government Support - Non-U.S.





PO2129

Macrophage Neutrophil Gelatinase-Associated Lipocalin Has a Critical Role in Aldosterone-Induced Renal Fibrosis via the CCL5-IL4 Pathway

Benjamin Bonnard,[1] Marie Genty,[1] Jaime Ibarrola,[3] Amaya Fernández-Celis,[3] Natalia Lopez-Andres,[3] Frederic Jaisser.[1,2] *[1]INSERM U1138, PARIS, France; [2]INSERM Clinical Investigation Centre 1433, Nancy, France; [3]Universidad Publica de Navarra, Pamplona, Spain.*

Background: Neutrophil Gelatinase-Associated Lipocalin (NGAL) (or lipocalin 2) is a novel mineralocorticoid biotarget in the cardiovascular system. NGAL is also described as an acute renal lesion biomarker and NGAL serum concentration is associated with the severity of renal damages patients with a chronic kidney disease (CKD). Lipocalin2 (Lcn2) gene invalidation in a CKD mouse model protects from proteinuria and renal lesions. We hypothesized that NGAL produced from macrophages promotes expression of chemoattractant molecules involved in renal lesions induced by mineralocorticoid excess.

Methods: The role of Lcn2 was analyzed using full Lcn2 knock out mice (NGAL KO) challenged with uni-Nephrectomy, Aldosterone 200 mg/kg/day, Salt 1% (NAS model) during 6 weeks. Assessment of CCL5/IL4 in kidney fibrosis were studied using maraviroc administration (50 mg/kg/d in chow diet) or by injections of anti-IL4 antibody (600 mg/week).

Results: NAS induced a significant increase in the expression (relative values, mean±SEM, compared to 1 in the control samples, $p<0.05$) of extracellular matrix proteins such as collagen I (2.35±0.33), a-SMA (2.04±0.44) and fibronectin (3.38±0.42) in the kidney of WT mice associated with interstitial kidney fibrosis (6.49±0.70). This is fully prevented by Lcn2 deletion. Expression of macrophages markers *F4/80, CD80* and *CD86* was increased (5.11±0.46, 4.84±0.19 and 5.22±0.45 respectively) in WT NAS mice and partly prevented in Lcn2 KO mice. Macrophages isolated from Lcn2 KO or WT mice were co-treated with aldosterone (10^{-8}M) and NaCl (40mM). In WT macrophages, expression of *Lcn2* (2.81±0.30) and the *CCL5* chemokine (2.48±0.32) was increased. The increase of *CCL5* was blunted in Lcn2 KO macrophages. Similarly to Lcn2 inactivation, CCL5 receptor blockade improved renal fibrosis and reduced high levels of Th2 $CD4^+$ cell markers induced by NAS. Neutralization of IL4, a Th2 cytokine, in NAS mice injected with anti-IL4 antibody blunted kidney fibrosis and overexpression of profibrotic proteins such as collagen I, a-SMA and fibronectin.

Conclusions: NGAL produced by macrophages plays a critical role in renal interstitial fibrosis through the CCL5/IL4 pathway in mice exposed to mineralocorticoid excess.

PO2130

Water Intake and Blood Pressure in Children: Results from the SPA Project

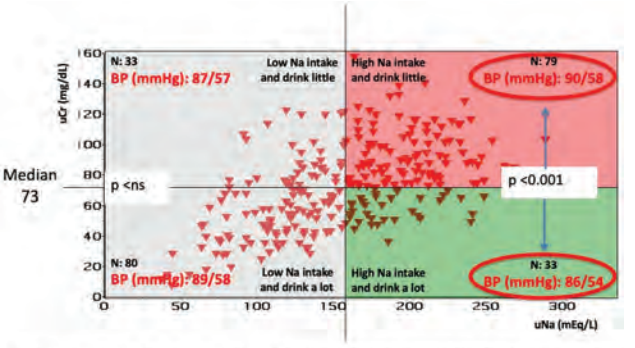
Gianluigi Ardissino,[1] Michela Perrone,[1] Silvia A. Ghiglia,[2] Patrizia Salice,[2] Francesca Tel,[3] Valentina Capone,[1] Maria Cristina Mancuso,[1] Sandra Piantanida,[4] Silvia Di michele.[5] SPA Project *[1]Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; [2]Cardiology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; [3]Pediatric Department, Vittore Buzzi Children's Hospital, University of Milano, Milano, Italy; [4]Polo Materno Infantile - Ospedale F. del Ponte, Varese, Italy; [5]UOC Pediatria Ospedale di Pescara, Pescara, Italy.*

Background: Sodium (Na) intake is involved in the development of hypertension (HPT); to reduce NaI is important in the treatment of HPT, but the increase in renal Na excretion might also be a potential preventive and/or therapeutic opportunity. The SPA Project studied blood pressure (BP) in relation to water (H2O) andNa intake with the working hypothesis that an increased water I can improve renal Na handling.

Methods: 339 healthy, non-overweight children (166 girls), 5.7 years old (IQR: 5.3-6.2) were characterized for: BP (using standardized multiple office BP measurement), Na and water intake (by means of urinary Na and creatinine from 4 samples taken in 4 different days). After categorizing subjects as low/high Na and low/high water intake (based on median value), BP was compared.

Results: Among children with higher Na intake, those introducing more water, showed a significantly ($p<0.001$) lower BP (both systolic and diastolic) compared to those who drink less (figure). This difference was not observed among children with lower Na intake.

Conclusions: Our findings support the hypothesis that an increased water intake, reduces BP perhaps by increasing Na renal excretion. We speculate that this simple, highly acceptable, inexpensive and harmless measure might have a role in preventing and minimizing the epidemics of HPT and related morbidities.



Arterial blood pressure (as measured with the mOBPM and urinary parameters (mean of 4 samples taken in diffent days) in healthy, non-overweight children according to water and Na intake

PO2131

Altered Tryptophan Catabolism via the Kynurenine Pathway Associates with CKD-Accelerated Atherosclerosis

Vetalise K. Cheofor, Nancy F. Roeser, Lixia Zeng, Jaeman Byun, Anna V. Mathew. *University of Michigan Medical School, Ann Arbor, MI.*

Background: Non-traditional risk factors like inflammation and oxidative stress play an essential role in the increased cardiovascular disease risk prevalent in chronic kidney disease (CKD). Tryptophan catabolism by the kynurenine pathway (KP) is linked to atherosclerosis and renal function in both clinical studies and experimental models. However, the role of KP in the pathogenesis of CKD accelerated atherosclerosis is unknown.

Methods: 9-week old 5/6 nephrectomized (CKD) and sham-operated (CON) $LDLr^{-/-}$ mice were placed on a high-fat/high-cholesterol diet (HFD) for 16 weeks. KP metabolites were measured using targeted mass spectrometry in the plasma, urine, and tissues. Expression and activity of Indoleamine 2,3 dioxygenase (IDO1- first step of the KP) were quantified by immunoblotting, immunohistochemistry, and kynurenine to tryptophan ratio (KTR) in aortic tissue in both groups.

Results: CKD mice demonstrate increased KP metabolites compared to sham-operated mice (CON) both at baseline and after exposure to HFD for 16 weeks. Exposure to HFD for 16 weeks increases most KP metabolites in both CON and CKD mice, except for levels of tryptophan and 3-hydroxy anthranilic acid that decrease with HFD exposure. 3-hydroxy kynurenine and kynurenic acid increase with HFD exposure in CKD mice, whereas these levels tended to decrease in controls. Hepatic tissue in the CKD mice fed HFD reveals no changes in KP metabolites except increased quinolinic acid, whereas the splenic tissue and renal tissue reveals low tryptophan levels and higher KTR, kynurenic acid, and anthranilic acid. These changes in the HFD fed CKD mice are likely due to a combination of increased synthesis in specific tissues and reduced clearance. IDO expression and activity were also increased in atherosclerotic lesions of CKD mice on HFD for 16 weeks compared to control mice with intact renal function.

Conclusions: In summary, KP metabolites are altered both in the circulation, tissues, and arterial wall of the CKD atherosclerosis model implicating KP in the pathogenesis of atherosclerosis in CKD.

Male Sex Hormones Drive an Increase in Renal Necrosis in Spontaneously Hypertensive Rats (SHR)

Mahmoud Abdelbary, Ellen E. Gillis, Michael W. Brands, Jennifer C. Sullivan. *Augusta University Medical Center, Augusta, GA.*

Background: We recently published that maturation in male SHR increases necrosis which contributes to the development of hypertension. Maturation in male SHR is associated with both increases in sex hormones and blood pressure (BP). Testosterone has been shown to induce renal tubular cell necrosis in vitro. This study tested the hypothesis that male sex hormones drive maturation-induced increases in renal necrosis in male SHR.

Methods: At 4 wks of age, male SHR were randomly assigned to one of three groups: sham, gonadectomy (ORX), or treatment with the BP lowering drugs hydrochlorothiazide (HCTZ; 55mg/kg/day) and reserpine (Res; 4.5 mg/kg/day) in drinking water to prevent age-related increases in BP (n=6-8). At 8 wks of age, telemeters were implanted in a subset of rats (n=3-4/group). Rats were allowed 1 wk of recovery, then BP was continuously recorded. All rats were euthanized at 13 wks of age. Renal necrosis was quantified using FACS analysis of $7AAD^+$ cells. Data are expressed as mean ± standard error. Kidneys were isolated from additional untreated 5 and 15 wk old male SHR (pre- and post-maturation) and processed for Western blot analysis of key proteins mediating necrosis, receptor-interacting protein kinase 3 (RIP-3) and high mobility group box 1 (HMGB-1).

Results: BP was significantly lower in ORX and HCTZ/Res-treated SHR compared to sham (mean arterial BP (mmHg): Sham = 139±2; HCTZ/Res = 117±3; ORX = 126±2; $p=0.002$). As expected, renal necrosis was greatest in sham control (renal necrosis

expressed as % total gated kidney cells: Sham = 6±0.3%). ORX significantly decreased renal necrosis vs. sham, while necrosis in HCTZ/Res treated rats was not significantly altered vs. sham despite having the lowest BP (ORX = 4±0.4%; HCTZ/Res = 5.3±0.3%; p=0.003). To begin to gain insight into the mechanisms mediating maturation-induced increases in necrosis, RIP3 and HMGB1 protein expression were measured in 5 and 15 wk old SHR. Expression of RIP-3 (1±0.1 vs. 0.7±0.1; P=0.008; n=5-6) and HMGB-1 (1±0.06 vs. 0.7±0.1; P=0.005; n=5-6) were greater in 15 wk old SHR.

Conclusions: In conclusion, these data suggest that male sex hormones contribute to maturation induced increase in renal necrosis in male SHR to a greater extent than maturation-induced increases in BP. Future studies will determine the relative contributions of RIP3 and HMGB1 to renal necrosis in adult male SHR.

SIRPα Interacts with the IGF-1 Receptor in CKD-Induced Cardiomyopathy

Jiao Wu,[1] William E. Mitch,[1] Sandhya S. Thomas.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]US Department of Veterans Affairs, Houston, TX.*

Background: A major consequence of chronic kidney disease (CKD) is associated with cardiomyopathy. Even at early stages of CKD with near normal GFR, and normal blood pressure, left ventricular hypertrophy (LVH) is present, which suggests an unidentified trigger unrelated to pressure overload. We now find that elevations of signal regulatory protein alpha (SIRPα), a substrate for tyrosine phosphatases, in cardiac muscle adversely influences insulin signaling via interactions with the insulin-like growth factor-1 receptor (IGF-1R) in CKD.

Methods: SIRPα floxed (control) vs. muscle-specific (mSIRPα) KO mice were subjected to subtotal nephrectomy. The binding affinity between IGF-1R immunoprecipitate lysates and purified recombinant SIRPα was determined based on the association rate (ka) and the dissociation rate (kdis) constants using bio-layer interferometry (BLI; Octet RED384 systems). Finally, SIRPα vs. GFP plasmids were transfected into muscle cells. n=4-6 mice/group, results are presented as mean ± SD.

Results: Control mice with CKD displayed reduced levels of tyrosine phosphorylation of IGF-1R in cardiac muscle. However, in mSIRPα KO mice with CKD there was no downregulation of IGF-1R phosphorylation despite the presence of CKD. Next, we examined the interactions of these proteins by immunoprecipitation analysis. SIRPα proteins were immunoprecipitated and immunoblotted with the IGF-1R confirming interactions. IGF-1R-SIRPα interactions were further validated using the BLI to assess protein quantities and characterization of kinetics. Specifically, IGF-1R was immunoprecipitated from cardiac muscle and the binding kinetics of Fc-tagged-recombinant SIRPα (rSIRPα) to the IGF-1R was identified via BLI. We concluded that rSIRPα was bound to immunoprecipitated IGF-1R with a kD of 147 uM, which futher validate their interactions. Lastly, SIRPα plasmids were transfected into myotubes, which led to an upregulation of SIRPα and impaired activation of insulin signaling mediators (IGF-1R and pAKT) plus worsening muscle fibrosis when compared to control transfected cells.

Conclusions: SIRPα interacts with the IGF-1R reducing receptor activities, confirming its role in regulating insulin/IGF-1 intracellular signaling in cardiac muscle while exacerbating cardiac muscle functions in CKD.

Increases in Renal CD81 and NCC Are Associated with Lipopolysaccharide-Induced Preeclampsia

Ping Wang,[1] Gangyi Zhu,[1] Yutao Jia,[1] Yanting Yu,[1] Xiaoyan Wang.[1,2] *[1]enQ Hospital of Nanjing Medical University, the Fourth Clinical Medical College, Nanjing, China; [2]George Washington University, DC, WA.*

Background: CD81, a member of the tetraspain superfamily, is an important component in the pathogenesis of pregnancy hypertension while the status of renal salt transport proteins plays an important role in blood pressure (BP) regulation.

Methods: In order to explore whether there is a connection between the two in the process of preeclampsia, we studied the interaction of CD81 and Na^+-Cl^- cotransporter (NCC) *in vivo* and *in vitro*.

Results: A rat model of pregnancy hypertension was built by injecting a small amount of lipopolysaccharide (LPS, 0.5μg/kg in 2ml saline) into the tail vein of pregnant rats on GD 5. On GD 18, BPs (SBP :99.9±1.4 vs 116.9±1.8,DBP :85.9±2.0 vs 94.4±1.8,mmHg, n=7/group) and urine protein (1185±35.0 vs 3550±158.0, μg/day, n=4/group) were higher in LPS -rats relative to vehicle-rats while renal protein abundance of CD81 (186.7±20, % of vehiclel, n=4/group, same as below) and NCC (278.0±53) was increased. The interaction of CD81 and NCC was found in the co-immunoparticipation complexes from rat kidney homogenates with the antibodies against CD81 or NCC. In order to further explore the relationship between renal CD81 and NCC, we treated mouse kidney distal tubule cells with LPS for 24h to construct an in vitro experimental model. The cell viability, detected by CCK-8, was not affected at all concentrations of LPS (0, 1, 10, 20, 30, μg/ml). The toxicity of LPS, detected by LDH release studies, was increased at concentrations of 20 (108.0 ± 3.4, n=6/group) and 30μg/ml (115.5±3.3) respectively but not altered at the lower concentrations. Relative to vehicle, LPS at concentration of 10ug / ml increased the protein abundance of CD81 (161.5 ± 23.22, n=6/group) and TNF-α (207.5 ± 27.67) but did not change the protein abundance of MCP-1. The protein abundance of NCC (193.5 ± 27.86) was increased remarkably while α1-NKA was also increased slightly (134.3 ± 4.51). The mRNA expression of CD81 mRNA was increased at LPS concentrations (μg/ml) of 1(154.9 ±11.13, % of vehicle, n=6/group), 10 (134,2±10.54),20 (148.0±8.61),30 (139.3±20.9) respectively.

Conclusions: Our findings in vivo and in vitro suggest that LPS can cause an increase in protein abundance and mRNA expression of CD81 and up-regulate NCC in renal distal convoluted tubules, which may contribute to an increase in blood pressure in pregnancy rats.

PO2135

Neurogenic Tachykinin Mechanisms in Experimental Nephritis of Rats

Kristina Rodionova,[1] Tilmann Ditting,[1,2] Gisa Tiegs,[3] Karl F. Hilgers,[1] Mario Schiffer,[1] Christian Ott,[1,2] Roland E. Schmieder,[1] Kerstin U. Amann,[1] Roland Veelken.[1,2] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Nuremberg, Germany; [2]Paracelsus Medizinische Privatuniversitat, Nurember, Germany; [3]Universitatsklinikum Hamburg Eppendorf Zentrum fur Experimentelle Medizin, Hamburg, Germany.*

Background: We demonstrated earlier that renal afferent pathways combine very likely "classical" neural signal transduction to the central nervous system and a substance P (SP) dependent mechanism to control sympathetic activity. SP content of afferent sensory neurons is known to mediate neurogenic inflammation upon release. We tested the hypothesis that alterations in SP dependent mechanisms of renal innervation contribute to experimental nephritis.

Methods: Nephritis was induced by OX-7 antibodies in rats, six days later instrumented for recording of blood pressure (BP), heart rate (HR), drug administration; intrarenal administration (IRA) of the TRPV1 agonist capsaicin to stimulate afferent renal nerve pathways containing SP and implantation of electrodes for renal sympathetic nerve recordings (RSNA). The presence of the SP receptor NK-1 on renal immune cells was assessed by FACS.

Results: IRA capsaicin decreased RSNA from 62.4±5.1 mV*sec to 21.6±1.5 mV*sec (*p<0.05) in controls, a response impaired in nephritis. Suppressed RSNA in nephritic rats and controls transiently but completely recovered after systemic administration of a neurokin 1 (NK1-R) blocker. NK-1 receptors occurred mainly on CD11+ dendritic cells (DCs). An enhanced frequency of CD11c+NK1R+ cell, NK-1 receptor+ macrophages and DCs were assessed in nephritis. Administration of the NK-1R antagonist aprepitant during nephritis reduced CD11c+NK1R+ cells, macrophage infiltration, renal expression of chemokines and markers of sclerosis.

Conclusions: Hence, SP promoted renal inflammation by weakening sympathoinhibitory mechanisms while at the same time substance SP released intrarenally from afferent nerve fibers aggravated immunological processes i.e. by the recruitment of DCs.

Renoprotective Effect of KLF2 on Glomerular Endothelial Dysfunction in Hypertensive Nephropathy

Eunjin Bae,[1] Mi-yeon Yu,[6] Ji Eun Kim,[3] Kyung Don Yoo,[4] Jong joo Moon,[2] Dong Jun Park,[1] Yon Su Kim,[2] Seung Hee Yang.[5] *[1]Gyeongsang National University Changwon Hospital, Changwon, Gyeongsangnam-do, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Korea University Guro Hospital, Seoul, Republic of Korea; [4]Ulsan University Hospital, Ulsan, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea; [6]Hanyang University Guri Hospital, Guri, Republic of Korea.*

Background: Kruppel-like factor 2 (KLF2) is a transcription factor, which regulates endothelial cell metabolism. KLF2 plays a role in maintaining normal vascular integrity by proinflammatory, anti-thrombotic, anti-angiogenic effects in endothelial cells. Endothelial dysfunction is associated with hypertension, and is a predictor of atherosclerosis development and cardiovascular events. Also, it is commonly observed in chronic kidney disease (CKD). The association between glomerular endothelial cell damage in diabetic nephropathy of KLF2 has been studied, but not in hypertensive nephropathy. Here, we present a role of KLF2 in hypertensive nephropathy.

Methods: Human primary glomerular endothelial cells were harvested and cultured under various duration, pressure condition by a rotational force device for mimic hypertensive nephropathy. We established the appropriate culture environment by confirming the pressure and survival rate applied to endothelial cells according to rotational force and evaluate the mRNA expression of α-smooth muscle actin (αSMA), KLF2 and KLF4. To induce hypertensive nephropathy in rat, 5/6 nephrectomy was done and kidney injury marker, blood pressure, KLF2 expression were evaluated. And we evaluated the KLF2 expression in hypertensive nephropathy patients' biopsied kidney tissue.

Results: The survival rate of human primary glomerular endothelial cells was maintained at a pressure of up to 4mmHg and decreased from above. After the application of 4mmHg pressure for 48hr in human primary glomerular endothelial cells, expression of KLF2 mRNA was decreased, while αSMA mRNA was increased and KLF4 mRNA was similar compared to control. 5/6 nephrectomy in rats resulted in increased blood pressure, decreased kidney function, as well as decreased KLF2 expression of glomerular endothelial cells. In addition, the expression of KLF2 in biopsied kidney tissue of hypertensive nephropathy patients was lower than that of normal kidney tissue.

Conclusions: We found that KLF2 expression of glomerular endothelial cells was reduced in both in vivo and in vitro models of hypertensive nephropathy. These findings suggest a new role for KLF2 in hypertensive nephropathy, which may be the basis for the development of new therapeutics.

Substance P: Differential Influences on Action Potential Production in Afferent Neurons of the Kidney?

Kristina Rodionova,[1] Tilmann Ditting,[1,2] Christian Ott,[1,2] Roland E. Schmieder,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Roland Veelken.[1,2] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat, Nuremberg, Germany*.

Background: Afferent nerve fibers of the kidney play a role in controlling sympathetic activity in hypertension and cardiovascular diseases. Proinflammatory substances influence the action potential production of these neurons. Therefore, we tested the hypothesis that proinflammatory substance P (SP) released from afferent nerves inhibits the action potential production in neurons with renal afferents.

Methods: Cultured dorsal root ganglion neurons (DRG Th11-L2) of rats with renal afferents were investigated in current clamp mode to assess action potential generation during both current injections and TRRPV1 stimulation with protons (pH 6) with and without exposure to SP (0.5 μmol) or CGRP (0.5 μmol). Neuronal classification as tonic (high AP generation upon stimulation) and phasic (AP ≤ 5 upon stimulation). Additional experiments were performed in voltage clamp mode to fully assess electrophysiological properties of the neurons.

Results: Renal neurons were stimulated with current injection (14,4+/-1,5 APs/600ms, mean+/- SEM) and protons (9,6+/-1,9 APs/10s of stimulation with pH6). The co-stimulation of renal neurons with current injections and SP ***decreased*** the number of action potentials in tonic neurons (15,2+/-1,1 APs/600ms vs. 10,1+/-1,6 APs/600ms, p<0.05, mean+/- SEM), however superfusion of renal neurons with both protons (pH 6) and SP ***increased*** it (9,6+/-1,9 APs/10s vs. 16,9+/-2,3 APs/10s, p<0.05, mean+/- SEM). Addition of SP itself did not stimulate cultivated neurons. Co-stimulation with CGRP was without significant effect under any circumstances.

Conclusions: Neuronal SP influences action potential production in renal neurons in a very complex way: Both inhibition and specific increases in action potentials via a TRPV1-dependent mechanism in acid-sensitive renal neurons could be demonstrated. Afferent nerve fibers are likely to respond very specific in different conditions while influencing sympathetic nerve activity and putatively renal physiology or pathology (proinflammatory actions of SP).

Tonic Inhibition of Sodium Reabsorption by Na^+/K^+-ATPase in the Renal Proximal Tubule

Shreya T. Mukherji,[1] Luca Brambilla,[1] Isabella Mayes,[1] Laura C. Kutz,[1] Jeff P. Mcdermott,[5] Steven T. Haller,[3] Michael F. Romero,[4] Jiang Liu,[2] Joseph I. Shapiro,[2] Gustavo Blanco,[5] Zi-jian Xie,[1] Sandrine V. Pierre.[1] *[1]Marshall Institute for Interdisciplinary Research, Huntington, WV; [2]Joan C Edwards School of Medicine at Marshall University, Huntington, WV; [3]University of Toledo College of Medicine and Life Sciences, Toledo, OH; [4]Mayo Clinic College of Medicine and Science, Rochester, MN; [5]University of Kansas Medical Center, Kansas City, KS*.

Background: In the renal proximal tubule (PT), Na^+/K^+-ATPase (NKA) is exclusively located in the basolateral domain. Through its classic ATP-dependent ion-pumping function, NKA generates the Na+ gradient that drives apical Na^+ reabsorption, mostly through Na^+/H^+ exchanger (NHE3). Accordingly, activation of NKA-mediated ion transport decreases natriuresis through activation of basolateral (NKA) and apical Na^+ reabsorption (NHE3). In contrast, activation of the more recently discovered NKA signaling triggers a cellular redistribution of PT NKA and NHE3 that decreases Na^+ reabsorption.

Methods: We used an *in vitro* and *in vivo* gene targeting approach to explicitly test the respective contributions of NKA signaling and ion-pumping in the control of PT Na^+ reabsorption.

Results: Knockdown of 90% of NKA in PT LLC-PK1 cells activated NHE3 (50% decrease in inhibitory phosphorylation), and increased basolateral Na^+/HCO_3^- cotransporter (NBCe1A) content. Rescue with wild-type but not Src signaling-null NKA restored NHE3 and NBCe1A to basal levels. In a hypomorphic PT $NKA^{-/-}$ mouse obtained by SGLT2-Cre/LoxP recombination, 70% decrease in PT NKA expression decreased inhibitory phosphorylation of NHE3 and increased membrane abundance of NHE3 and NBCe1A. Urine output and absolute Na^+ excretion were decreased by 65%, without histological or functional evidence of renal injury. Those changes were driven by increased PT Na^+ reabsorption, as indicated by a 65% decrease in lithium clearance and unchanged GFR. The hyper-reabsorptive phenotype of PT $NKA^{-/-}$ mice were rescued upon crossing with PT $NHE3^{-/-}$ mice, confirming the importance of NKA/NHE3 coupling.

Conclusions: Hence, NKA signaling exerts a tonic inhibition on Na^+ reabsorption by regulating key apical and basolateral Na^+ transporters. This action, which is lifted upon NKA genetic suppression in cells and *in vivo*, tonically counteracts NKA's ATP-driven function of basolateral Na^+ reabsorption. Strikingly, NKA/Src signaling is not only physiologically relevant, it is functionally dominant over NKA ion-pumping in the control of PT reabsorption. NKA signaling therefore provides a long sought-after mechanism for the natriuretic action of endogenous NKA ligands such as cardiotonic steroids.

NPFFR2 in the Kidney via Novel Transcriptional and Posttranslational Mechanisms Triggers Molecular Responses to Salt

Laureano D. Asico,[1] Selim Rozyyev,[2] Jessica Hunt,[1] Ron Jako D. Domingo,[3] Ines Armando,[1] Pedro A. Jose.[1] *[1]The George Washington University School of Medicine and Health Sciences, Washington, DC; [2]Children's National Health System, Washington, DC; [3]University of Maryland at College Park, College Park, MD*.

Background: Hypertension and salt sensitivity is dependent on NaCl intake. The kidney maintains sodium (Na) balance and blood pressure homeostasis. Neuropeptide FF (NPFF), is involved in nociception, hormonal modulation, and body temperature control. NPFF and its receptors, *NPFFR1* and *NPFFR2*, are found in the kidney and have prohypertensive properties.

Methods: Renal restricted bolus or chronic infusion of NPFF raised blood pressure and reduced Na excretion (n=4) in C57Bl/6 mice. Silencing *NPFFR*1 had no effect but, silencing *NPFFR2* raised UNaV (3 fold). *NPFFR2* with the D1 dopamine receptor interacts. Both coimmunoprecipitated (coIP) and colocalized in human renal proximal tubule cells (hRPTCs) and whole kidney. NPFF and the D1R/D5R agonist fenoldopam (FEN) antagonized cAMP production (2.54±0.1 pmol/mg/min for FEN vs. 1.23±0.2 for vehicle vs. 1.11± 0.2 for both, n=4) and Na transport (1.78±0.1 fold with FEN, 1±0.11 for vehicle, and 1.1±0.2 for both, n=4) in hRPTCs. Mice fed a 4% NaCl diet increased (>2.5 fold) the coIP between renal *NPFFR2* and *D1R*, enabling the *D1R* to limit *NPFFR2* effects. A normal (145 μM) to low (90 μM) NaCl raised both promoter activity (~2.5 fold, n=3), mRNA and protein expression (n=4; 0–8 hr). A normal to high (175 μM) Na concentration reduced promoter activity (–0.5 fold), mRNA and protein expression of *NPFFR2* (0–8 hr). The increased coIP between prohypertensive *NPFFR2* and antihypertensive *D1R*, resulted in an increased receptor antagonism to cAMP response and Na transport (*vs* FEN or NPFF treatment [1 mM/30 min], n=4).

Results: We found a "Sodium Response Element" (NaRE), homolog of "Dehydration Responsive Element" ("TACCGACAT") in *Arabidopsis thaliana* genome, at the *NPFFR2* promoter. We measured *NPFFR2* promoter activity to test NaRE response to Na. The *NPFFR2* promoter responded to low (4.1±0.05 fold increase,) and high (0.52±0.5 fold decrease) Na with wild type NaRE, but not in the absence of NaRE (mutant *NPFFR2*). Using a selective NaRE blocker, (antigene RNA) on mouse kidneys, showed no increased *NPFFR2* response to low Na intake (<0.04 G Na/day) but a decreased systolic blood pressure caused by the low Na diet (65±0.6 mm Hg vs. 83.3±1.3, n=4).

Conclusions: Our data identified NaRE and novel transcriptional and posttranslational mechanisms by which mammalian genes respond to sodium.

PO2140

Age-Dependent Regulation of the NCC and the Development of Salt-Sensitive Hypertension

Kiyoung Kim, Franco J. Puleo, Alissa Frame, Mohammed Z. Ferdaus, Richard D. Wainford. *Boston University School of Medicine, Boston, MA*.

Background: The prevalence of hypertension (HTN) increases with age, and age-dependent HTN is associated with increased sympathetic tone and blood pressure (BP). Dietary sodium intake is a major risk factor for HTN as excessive dietary sodium intake leads to increases in BP in individuals that demonstrate the salt sensitivity of BP to evoke salt sensitive HTN (SSH). We have previously demonstrated excessive release of norepinephrine upregulates the activity of the renal sodium chloride cotransporter (NCC) to promote sodium reabsorption and salt sensitive hypertension. However, the regulation of the NCC with age remain unclear. Thus, we tested the hypotheses that 1) upregulation of NCC contributes to age-dependent HTN, and 2) aged rats develop SSH.

Methods: Three different age groups (3, 8, 16 month old (MO)) of male Sprague-Dawley (SD) rats were fed a normal salt (NS; 0.6% NaCl) or HS (4% NaCl) diet for 21 days respectively. On day 21, basal MAP and NCC activity (peak natriuresis to IV hydrochlorothiazide (2mg/kg) infusion) were measured in vivo. The expression of total NCC, phosphorylated NCC, with-no-lysine [K] kinases (WNK) 1, WNK4, STE20/SPS1-related proline-alanine-rich protein kinase (SPAK), oxidative stress responsive kinase 1 (OxSR1), and phosphorylated SPAK/OxSR1 were assessed via immunoblotting (N=6/gp).

Results: Male SD rats develop age-dependent HTN with increased NCC activity and expression, and increased WNK1 expression. Aged male SD rats developed SSH, impaired dietary salt evoked suppression of NCC activity, phosphorylation, and the expression of kinases SPAK and OxSR1.

Conclusions: These data suggest that the NCC contributes to the development of age-dependent HTN. Moreover, dysregulation of the NCC may play a pivotal role in the development of age-dependent SSH.

A Novel Genetically Defined Mouse Model of Hypertensive Nephropathy

Anamaria Tatomir,[1] Hyun Jun Jung,[1] Parnaz Daneshpajouhnejad,[1] Avi Z. Rosenberg,[1] Eric J. Delpire,[2] Paul A. Welling,[1] Paul R. Grimm.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Vanderbilt University, Nashville, TN.*

Background: The molecular pathways that drive hypertensive nephropathy remain poorly understood. We overcome the roadblock with a new genetically-defined mouse model of HTN that exhibit a low-renin salt-sensitive form of the disease. The mice, created by introducing activating mutations in the Ste20p-related proline alanine-rich kinase (SPAK) in a distal convoluted tubule cell-specific manner, become hypertensive solely as a consequence of constitutive activation of the thiazide-sensitive sodium chloride cotransporter (NCC) and salt retention.

Methods: For these studies, the constitutively active (CA)-SPAK and control (C57BL/6J) mice were fed control or high salt diet (HSD), and renal function was evaluated over 40 weeks, together with telemetric measurements of blood pressure. RNA-Seq was performed to evaluate changes in the transcriptional profile in the renal cortex and corroborated biochemically.

Results: Kidney function in the CA-SPAK mice began to deteriorate at 20 weeks as evidenced by significant elevation of BUN, creatinine, and frank albuminuria, which gradually increased over the next 20 weeks. HSD consumption exacerbated hypertension in CA-SPAK mice and accelerated the decline in renal function. Trichrome-staining revealed no obvious histopathological changes, including nephroangiosclerosis. By contrast, a significant change in the transcription profile was observed between CA-SPAK mice and controls at an early stage when microalbuminuria begins to develop. Remarkably, the differentially expressed (DE) genes profile was enriched in 26% of the known genes associated with albuminuria in humans. Significant downregulation of key components of the glomerular filtration barrier slit diaphragm genes (nephrin, podocalyxin, synaptopodin) and the proximal tubule protein scavenger, Cubilin, were also observed in the CA-SPAK. Pathway analysis was especially enriched for genes associated with Major Histocompatibility Complex class II, T helper 17 lymphocytes and B lymphocytes markers in the CA-SPAK mice.

Conclusions: Progression of renal insufficiency in CA-SPAK mice indicates a causal role of hypertension in nephropathy and incriminates an inflammatory component as a key driver of early damage to the glomerular filtration barrier and tubular protein reabsorption.

PO2142

Different Renal and Cerebral Vascular Responses to Angiotensin II Infusions in Anesthetized Mice: Roles of Vasodilator Prostaglandins and Nitric Oxide

Christopher S. Wilcox, Glenn Solis, Margarida Mendonca, William J. Welch. *Georgetown University Medical Center, Washington, DC.*

Background: Since the cerebral PO_2 is much lower than the renal, the brain requires protection from vasoconstriction while the renal circulation must adapt to physiological demands often dictated by angiotensin II (Ang II). We tested the hypothesis that renal and cerebral blood flow (RBF and CBF) are differentially regulated by vasodilator prostaglandins (PGs) and nitric oxide (NO).

Methods: Mice (n = 6 – 8 per group) were anesthetized with a-chloralose/urethane and ventilated to a PCO_2 of 33-38 mmHg. Mean arterial pressure (MAP) was recorded via an aortic cannula, RBF via a transit time blood flow meter encircling a renal artery and CBF via a blood flow meter encircling the common carotid artery with the external carotid artery ligated. Renal and cerebral vascular resistances (RVR and CVR) were recorded on line during infusion of vehicle or Ang II (40 p mol min^{-1} Kg^{-1} iv) vs vehicle. L-NAME (30 mg^{-1} Kg^{-1} h^{-1}) and/or indomethacin (5 mg^{-1} Kg^{-1} h^{-1}) or vehicle were infused iv over 50 mins to test the roles of NO and PGs in basal and Ang II-stimulated vascular resistances.

Results: In the basal state, L-NAME increased RVR (+79 ± 9%; P < 0.01) and CVR (+78 ± 8%; P < 0.01) similarly whereas vehicle was ineffective. Indomethacin alone did not modify RVR or CVR but enhanced the effects of L-NAME to raise RVR (+132 ± 15%; P < 0.05) and CVR (+134 ± 30%; P < 0.05) similarly. Thereafter, Ang II infusion increased MAP (+10 ± 2%; P < 0.05) and RVR (+33 ± 6%; P < 0.05) but did not change CVR (+2 ± 2%; NS). Neither L-NAME nor indomethacin alone modified the MAP, RVR or CVR responses to Ang II but after indomethacin given to mice infused with L-NAME, Ang II infusion caused a greater rise in MAP (+30 ± 3%; P < 0.05), and RVR (+190 ± 5%; P < 0.05) but CVR remained quite unresponsive (-7 ± 5%; NS).

Conclusions: Low basal RVR and CVR depend on PG-dependent NO generation. Whereas CVR is entirely protected from vasoconstriction with Ang II, the increase in RVR with Ang II is moderated by PG-dependent NO generation. Thus, PGs and NO exert distinct action in the renal and cerebral vasculature.

PO2143

The Intrarenal RAS Upregulates SGLT2 Expression and SGLT2 Inhibitors Attenuate Angiotensin-II Induced Hypertensive Kidney Injury in Mice

Kana N. Miyata,[1] Chao-Sheng Lo,[1] Shuiling Zhao,[1] Junzheng Peng,[1] Matthias Kretzler,[2] Janos G. Filep,[3] Julie R. Ingelfinger,[4] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]Centre Hospitalier de l'Universite de Montreal Centre de Recherche, Montreal, QC, Canada; [2]University of Michigan, Ann Arbor, MI; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]Massachusetts General Hospital, Boston, MA.*

Background: Clinical trials have shown that SGLT2 inhibitors (SGLT2i) improve both cardiac and renal outcome in several diseases. However, the mechanisms underlying regulation of SGLT2 gene expression remain unclear. Here, we studied whether the intrarenal renin-angiotensin-system (RAS) modulates SGLT2 expression and SGLT2i efficacy.

Methods: We analyzed the association between RAS-related genes and SGLT2 gene expression in the tubulointerstitial compartment of the kidneys of adult non-diabetic patients in the Nephrotic Syndrome Study Network (NEPTUNE). We compared SGLT2 expression in transgenic mice overexpressing angiotensinogen (Agt) in their renal proximal tubular cells (RPTCs)(Agt-Tg) ± RAS blockers, and wild-type (WT) mice. We administered angiotensin II (AngII, 1000 ng/kg/min subcutaneously) in WT mice ± canagliflozin (Cana, 15mg/kg/day in drinking water- for 4 weeks). We also studied human immortalized RPTCs (HK2) as an *in vitro* model.

Results: In human kidney samples (N=183 patients), SGLT2 mRNA was significantly correlated with AGT (r=0.55, p<0.001), Renin (r=0.46, p<0.001), ACE (r=0.47, p<0.001), and AT1R (r=-0.28, p<0.001), but not with AT2R. SGLT2-immunopositive staining was higher in RPTCs of Agt-Tg mice than in WT mice and this was attenuated by losartan treatment. Ang II infusion in WT mice significantly increased blood pressure, which was not reversed by Cana co-treatment. Ang II caused glomerulosclerosis, tubulointerstitial fibrosis, and albuminuria, which were all attenuated by Cana. Fractional glucose excretion was significantly higher in Ang II+Cana than WT+Cana. *In vitro*, AngII dose-dependently stimulated SGLT2 mRNA in HK2 cells, and these were inhibited by losartan.

Conclusions: Our data demonstrate that the intrarenal RAS upregulates SGLT2 expression and show that SGLT2i ameliorate AngII-induced kidney injury independent of blood pressure.

PO2144

Loss of Soluble (Pro)renin Receptor Attenuates DOCA-Salt Hypertension

Nirupama Ramkumar, Deborah Stuart, Caitlin S. Peterson, William Wheatley, Donald E. Kohan. *University of Utah Health, Salt Lake City, UT.*

Background: Cleavage of the extra-cellular domain of the (pro)renin receptor (PRR) yields a soluble fragment (sPRR), which may be involved in mediating hypertension. We recently developed a mouse model with mutation in the cleavage site of the PRR using CRISPR/Cas9 such that sPRR is not generated and showed that absence of sPRR attenuated angiotensin-II induced hypertension and kidney damage. In this study, we examined if sPRR alters blood pressure (BP) in angiotensin-II independent hypertension using deoxycorticosterone acetate (DOCA)-salt treatment.

Methods: Mutant sPRR mice and littermate controls were treated with DOCA (50 mg/kg) and high Na^+ diet for 3 weeks. BP was monitored by radio-telemetry and metabolic balance studies performed on Day 17-18 of DOCA-salt treatment. Only male mice were studied as the PRR gene is on the X-chromosome.

Results: Compared to controls, male mutant sPRR mice had markedly lower plasma sPRR levels (control: 21.5 ± 2.5 vs mutant 0.2 ± 0.03 ng/ml) and baseline BP (systolic control: 122 ± 3 vs mutant 114 ± 3; diastolic control: 94 ± 5 vs mutant 82 ± 3 mm Hg). BP remained low in mutant sPRR mice relative to controls following 12 days of DOCA-salt treatment (systolic control: 141 ± 2 vs mutant 132 ± 5; diastolic control: 110 ± 4 vs mutant 95 ± 5 mm Hg). Mutant sPRR mice had lower body weight but similar food intake and urinary albumin excretion compared to controls (Table 1). Mutant mice had lower urine volume, water intake and urinary K^+ but not Na^+ excretion. No differences in renal histology were noted between control and mutant sPRR mice.

Conclusions: Loss of sPRR attenuates DOCA-salt mediated hypertension. The mechanisms by which sPRR might regulate BP and water/Na^+ homeostasis in DOCA-salt hypertension are currently being investigated.

Funding: Private Foundation Support

Table 1

	Control (N=6)	Mutant sPRR (N=7)
Food intake (g/day)	4.0 ± 0.3	3.6 ± 0.1
Water intake (ml/day) *	13.2 ± 1.4	8.8 ± 0.5
Urine volume (ml/day) *	10.4 ± 1.0	6.4 ± 0.5
Body weight (g)*	30.9 ± 1.5	25.0 ± 0.3
UNaV (μmol/day)	3279 ± 124	2865 ± 282
UKV (μmol/day) *	421 ± 29	335 ± 32
Urine albumin (μg/day)	77 ± 33	62 ± 36

PO2145

Effect of Dietary Magnesium Supplementation on Tubulointerstitial Damages in Angiotensin II-Induced Hypertensive Rats

Kaori Takayanagi,[1,2] Taisuke Shimizu,[2] Takatsugu Iwashita,[2] Hiroaki Hara,[2] Akira Kurosawa,[2] Masaaki Terao,[2] Hajime Hasegawa.[2] *[1]Ishikawa Kinenkai Kawagoe Ekimae Clinic, Kawagoe, Japan; [2]Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawaoe, Japan*.

Background: Recently, it has been epidemiologically suggested that Mg deficiency promotes progressive renal damage, and conversely, it has been reported that Mg load to Cyclosporine A-induced renal damage models attenuates renal impairment. This study aimed to investigate the ameliorating effect of high Mg diet on the renal impairment by use of hypertensive nephrosclerosis model.

Methods: Eight-week-old SD rats were subjected to continuous infusion of Angiotensine II by subcutaneously placed osmotic minipumps for 2 weeks (435 ng/kg/min) and then housed for 6 weeks. The food for animals was normal Mg diet (NMD): 4% NaCl+0.05% Mg or high Mg diet (HMD): 4% NaCl+0.5% Mg. PicroSirius Red staining was used to assess fibrosis, and immunostaining of claudin-16, which is known to be down-reguglated in the renal interstitial damage was also performed.

Results: No significant difference in mean blood pressure was seen between two groups (NMD: 97.8±7.6 mmHg vs HMD: 94.2±9.0 mmHg, n=4), and serum Mg was elevated in HMD group (NMD: 1.63±0.19 mg/dL vs HMD: 2.48±0.09 mg/dL, n=4). Analysis of PicroSirius Red staining positive area by semi-quantification showed that positive area in outer medullary resion was significantly reduced in HMD group (NMD: 1.61±0.15% vs HMD: 1.11±0.10%, n=4). Positive area of claudin-16 immunostaining in HMD was greater than NMD (NMD: 1.52±0.13% vs HMD: 1.70±0.15%, n=4).

Conclusions: Hypertensive nephrosclerosis is one of the major causes of end-stage renal failure, and its suppression is important. It was confirmed that the outermedullary fibrosis was inhibited by high Mg diet, while there was no change in the blood pressure, indicating that anti-fibrotic effect of high Mg diet seemed to be an independent mechanism from the blood pressure. We report the fact that claudin-16 expression is reduced and Mg excretion is increased in the interstitial fibrosis model (Shimizu, Magnesium Res 2018). These results suggest that high Mg diet has an inhibitory effect on fibrogenesis through suppressing the increased Mg-excretion.

PO2146

Pharmacological Sympathetic Denervation of the Kidney with Angiotensin II Receptor Blockade?

Kristina Rodionova,[1] Tilmann Ditting,[1,2] Karl F. Hilgers,[1] Christian Ott,[1,2] Roland E. Schmieder,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Roland Veelken.[1,2] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat, Nuremberg, Germany*.

Background: A putative interaction between angiotensin II (Ang II) and the renal sympathetic nervous system has been described. We tested the hypothesis that the angiotensin II receptor inhibitor candesartan mimicks a functional renal sympathetic denervation not distinguishable from surgical renal nerve ablation.

Methods: Measurement of arterial blood pressure (MAP), heart rate (HR), renal sympathetic nerve activity (RSNA), glomerular filtration (GFR), renal plasma flow (RPF), urine volume and urinary sodium. To assess neural control of volume homeostasis, 21 days after the induction of congestive heart failure (CHF) via myocardial infarction rats underwent volume expansion (0.9% NaCL; 10% body weight) to decrease RSNA. CHF rat and controls with or without renal denervation (DNX) or pretreated with the angiotensin II type 1 receptor antagonist candesartan (0.5 ug i.v.) were studied.

Results: CHF rats excreted only 68±5% of the volume load in 90 min. CHF rats pretreated with candesartan or after DNX excreted from 92% to 103% like controls. Decrease of RSNA induced by volume expansion were impaired in CHF rats but unaffected by candesartan pointing to an intrarenal drug effect. GFR and RPF were not significantly different in controls or CHF rendering mere hemodynamic effects on sodium and water excretion unlikely. 0.5 mg candesartan did not inhibit the pressor response to i.v. Ang II as compared to higher blood pressure lowerig doses.

Conclusions: The prominent function of increased RSNA – retaining salt and water - could no longer be observed after renal ANG II receptor blockade in CHF rats mimicking renal nerve ablation. Since inhibitors of the renin-angiotensin system are nowadays standard treatment of patients with CHF and hypertension, the role of *efferent sympathetic* denervation in these patients needs further meticulous scrutiny.

Extracellular Volume, Peripheral Resistance, and Cardiac Index May Be Altered in Early CKD

L Parker Gregg,[1,2] Peter N. Van Buren,[1,2] Subhash Banerjee,[1,2] Susan Hedayati.[1] *[1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX*.

Background: It is unknown if extracellular volume (ECV), cardiac index (CI), and peripheral resistance are altered in early stages of chronic kidney disease (CKD) before significant decline in glomerular filtration rate (GFR) or if these can be identified by routine laboratory measurements.

Methods: A total of 21 participants, including 13 with CKD stages 1-3 and 8 non-CKD controls, were prospectively recruited from outpatient clinics. CKD stage 3 was defined as an estimated GFR (eGFR) of 30-59 mL/min/1.73 m2, and stages 1-2 as a urine albumin-to-creatinine ratio >30 mg/g and eGFR ≥60. ECV was measured using bioimpedance spectroscopy and normalized to total body weight. CI and total peripheral resistance index (TPRI) were measured using non-invasive cardiac output monitoring. Measurements were compared using Fisher exact tests, Student's t tests, and Pearson correlations.

Results: Participants with CKD had a mean (SD) age of 65.4 (12.9) years vs. 59.8 (13.5) years for controls, *P*=0.36. Mean eGFR in the CKD group was 47.0 (17.9) mL/min/1.73 m2. In the CKD group there were 8 (61.5%) with diabetes, vs. 3 (37.5%) controls, *P*=0.39. Mean systolic blood pressure was 159.2 (22.3) in the CKD group vs. 143.1 (26.2) in the control group, *P*=0.17. Edema was present in 9 (69.2%) of the CKD group vs. 2 (25.0%) controls, *P*=0.08. Mean (SD) ECV/weight was marginally higher in the CKD group than in controls, 27.4% (3.7) vs. 24.7% (2.6), *P*=0.06. The CKD group had higher b-type natriuretic peptide (BNP), 182.8 (236.0) vs. 33.4 (35.4) pg/mL, *P*=0.04, lower CI, 2.4 (0.4) vs. 3.0 (0.5), *P*=0.04, and higher TPRI, 3800.2 (645.7) vs. 2980.8 (263.5) dyn.s.cm-5, *P*=0.001. Log-transformed BNP correlated with CI, r=-0.77, *P*=0.0002, and TPRI, r=0.50, *P*=0.04 (**Table**). ECV/weight did not correlate strongly with CI, r=-0.27, *P*=0.29, and TPRI, r=0.25, *P*=0.32.

Conclusions: In this hypothesis-generating study, patients with CKD had higher TPRI and lower CI than non-CKD controls. CI and TPRI correlated with BNP but not with ECV/weight. BNP, an easily measured and universally available test, may be used as a correlate for CI and TPRI in patients with early stage CKD. These findings need to be confirmed in larger cohorts.

Atrial Natriuretic Peptide Deficiency Alters Mitochondrial Bioenergetics in Dahl Salt-Sensitivity Rats

Mark Domondon, Regina F. Sultanova, Ryan Schibalski, Daria Ilatovskaya. *Medical University of South Carolina, Charleston, SC, US, Charleston, SC*.

Background: In the heart and fat tissue, Atrial Natriuretic Peptide (ANP) is known to affect mitochondrial bioenergetics. However, little is known about the effects of ANP on mitochondria in the kidney, especially in the context of salt-sensitivity (SS). We hypothesized that in SS hypertension ANP deficiency causes renal mitochondrial dysfunction and contributes to end-organ damage.

Methods: Hypertension was induced in male $SS^{NPPA-/-}$ (*Nppa* (encoding for ANP) knockout in Dahl SS background) and SS^{WT} (wild type Dahl SS) rats by a 21-day long high salt diet challenge (HS, 4% NaCl). Normal salt diet (NS, 0.4% NaCl) was given to age-matched control animals. A combination of *in vivo* techniques and studies on isolated renal mitochondria (seahorse respiration and spectrofluorimetry assays) were used to test the role of *Nppa* knockout in mitochondrial bioenergetics.

Results: $SS^{NPPA-/-}$ rats exhibit exacerbated salt-sensitivity of blood pressure and kidney injury when challenged with a HS diet. In order to test mitochondrial function in this model, we measured membrane potential and levels of superoxide and H_2O_2 in renal cortical mitochondria. TMRM, Amplex Red and MCLA were used to detect membrane potential, H_2O_2 and superoxide, respectively. We report a decrease in mitochondrial membrane potential in the $SS^{NPPA-/-}$ rats vs SS^{WT} (both on NS and HS diets), and an increase in mitochondrial H_2O_2 and superoxide levels in the same groups, indicative of leakage within the ETC. A Western analysis revealed that in SS^{WT} rats SOD2 levels are increased by a HS diet, while in $SS^{NPPA-/-}$ animals its expression is suppressed. In addition, we observed activation of the antioxidant capacity in the $SS^{NPPA-/-}$ rats vs SS^{WT} (on HS diet). $SS^{NPPA-/-}$ rats exhibited a difference in MCU (mitochondrial calcium uniporter) activity when compared to SS^{WT}, implying an effect on mitochondrial calcium uptake. Interestingly, seahorse analysis revealed elevation of the oxygen consumption rate (OCR) in the knockout rats on HS, while in HS fed SS^{WT} rats OCR was reduced (vs NS).

Conclusions: Lack of circulating ANP results in changes of mitochondrial bioenergetics in the renal tissue via effects on calcium uptake, and alters respiratory chain activity leading to changes in ROS production. Further studies will advance the understanding of the mitochondria-mediated mechanisms affecting renal damage susceptibility in SS hypertension.

Inhibition of Mineralocorticoid Receptor Ameliorates Salt-Sensitive Hypertension After Ischemic-Reperfusion Injury in Rats

Takumi Matsumoto,[1] Shigehiro Doi,[1] Ayumu Nakashima,[1,2] Takao Masaki.[1] *[1]Department of Nephrology, Hiroshima University Hospital, Hiroshima, Japan; [2]Department of Stem Cell Biology and Medicine, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan.*

Background: The transition from acute kidney injury (AKI) to chronic kidney diseases a major pathway for progression to end-stage kidney disease. Although hypertension is reported to be associated with the clinical progression of chronic kidney disease, the mechanism by which AKI induces hypertension remains elusive. Previous studies have demonstrated that salt-sensitive hypertension occurs in rats after ischemic reperfusion injury (IRI), a rodent model of AKI, and that distal nephrons play an important role in the development of salt-sensitive hypertension. Herein, we investigated the role of the mineral corticoid receptor (MR) in the progression of IRI-induced salt-sensitive hypertension in rats.

Methods: Seven days after right nephrectomy, IRI was induced by clamping of the left renal artery for 45 min in 8-week-old male Sprague-Dawley rats. Rats were sacrificed at 7 days after IRI, and expression of MR examined. IRI rats were also given drinking water with 1% sodium chloride (IRI/NaCl), or were implanted with an osmotic mini-pump to infuse aldosterone (IRI/Aldo). Esaxerenone (3 mg/kg/day; a non-steroidal MR antagonist [MRA]), or vehicle were administrated in IRI/NaCl and IRI/Aldo rats for 6 weeks. Blood pressure and urinary protein level were measured weekly during the study period. Protein expression in renal tissues was examined by immunoblotting and/or immunohistochemistry.

Results: MR expression was increased at 7 days after IRI. Further, blood pressure and urinary protein excretion increased in IRI/NaCl and IRI/Aldo rats over the 6-week observation period, whereas these effects were negated by MRA administration. Similarly, MRA ameliorated the expression of the β-epithelial sodium channel (ENaC), γ-ENaC, and fibrotic markers, but not α-ENaC or NaCl cotransporter channel in both IRI/NaCl and IRI/Aldo rats.

Conclusions: Upregulation of MR, β-ENaC, and γ-ENaC may play a pivotal role in the development of salt-sensitive hypertension in rats after IRI.

PO2150

The Effect of Epidermal Growth Factor Inhibition on Salt Sensitivity in Mice

Keyona King,[1,2] Robert S. Hoover.[1,2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Veterans Affairs Health Care System of Atlanta, GA, Atlanta, GA.*

Background: Every year in the United States, more than 3 million adults are determined to have high blood pressure. Studies have shown that the epidermal growth factor (EGF) decreases the open probability of the epithelial-Na+ channel (ENaC) along the apical surface of the kidney cortical collecting duct (CCD). Yet, it is unknown whether EGF influences renal Na+ transport via the Na+-Cl- cotransporter (NCC). Our laboratory has investigated whether EGF regulates NCC. We performed various in vitro experiments using mouse distal convoluted (mDCT-15) cells and found that EGF decreases NCC surface expression with an increase in endocytosis of surface NCC. Overall, our findings and those from other researchers, collectively suggest that EGF decreases the activity of two key mediators of salt-sensitive blood pressure, ENaC and NCC. This discovery served as our rationale for investigating whether EGF inhibition affects BP, and if this response is related to dietary sodium intake.

Methods: Using radio-telemetry, we collected the systolic blood pressure (SBP) measurements in five male mice ages 7 weeks old. These animals received a low salt (LS) diet (0.4% Na chow) for 6 days and high salt (HS) diet (4% Na chow) for 8 days. Over a period of two weeks, only the experimental (E) group (n=3) received gefitinib (an EGF receptor tyrosine kinase inhibitor) at a regimen of 100 mg/kg/d given orally while the control (C) group (n=2) received a placebo.

Results: The results for the change in awake-SBP while receiving diet (0.4% Na chow) for 6 days and high salt (HS) diet (4% Na chow), showed the *experimental (E) group* had a greater increase in SBP in response to a higher dietary Na+ intake (*E group*: 7.70 ± 0.17 vs. *control (C) group*: 0.311 ± 0.29 mmHg, p<0.001). The delta for the difference in BP change when increasing the dietary Na+ intake was greater for the *E group* of mice (delta = 7.40 mmHg, p<0.001).

Conclusions: Therefore, our data strongly suggests that inhibition of EGF increases the salt sensitivity of blood pressure. This may indicate that EGFR ligands act as tonic inhibitors of tubular sodium reabsorption. Future experiments will explore the in vivo effects of EGFR inhibition on NCC, ENaC and sodium excretion.

PO2151

The Effect of Epidermal Growth Factor Inhibition on Diurnal Variation of Blood Pressure in Mice

Keyona King,[1,2] Robert S. Hoover.[1,2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Veterans Affairs Medical Center of Atlanta, Atlanta, GA.*

Background: There are 78 million adults in the United States who have hypertension (HTN). HTN is a serious medical condition that serves as risk factor for cardiovascular disease (CVD) and chronic kidney disease (CKD). Blood pressure (BP) normally declines about 10% during sleep and this is called "dipping". Studies have demonstrated that an attenuated decline in nocturnal BP ("non-dipping") is associated with increased cardiovascular risks. Investigations by our group and others have demonstrated an effect of the epidermal growth factor (EGF) on sodium transport proteins and BP. However, an association between EGF and "dipping" has not been described.

Methods: Using radio-telemetry in five male mice ages 7 weeks old, we collected the systolic blood pressure (SBP) measurements over 24 hours daily for two weeks. These animals received a low salt (LS) diet (0.4% Na chow) for 6 days and high salt (HS) diet (4% Na chow) for 8 days. Only the experimental (E) group (n=3) received gefitinib (an EGF receptor inhibitor) at a regimen of 100 mg/kg/d given orally while the control (C) group (n=2) received a placebo. The change in SBP was evaluated during rest (9am-9pm) which are morning hours versus awake (9pm-9am) during evening hours since mice are nocturnal.

Results: The results showed the E group had less of a decrease in their SBP during sleep than the C group (E group: -9.7 ± 0.016 vs. C group: -14.4 ± 0.34 mmHg, p<0.001; delta = 4.7 mmHg, p<0.001). When increasing the dietary Na+ intake by giving the HS diet, once again the E group demonstrated an attenuation of their ability to lower their SBP during resting compared to the C group (E group: -7.3 ± 0.18 vs. C group: -13.5 ± 0.38 mmHg, p<0.001). Here the delta is 6.1 mmHg, p<0.001, which shows that the C group maintained a greater decrease in their resting SBP compared to the E group.

Conclusions: Overall, our results suggest that inhibition of EGF leads to decreased dipping in SBP regardless of the dietary Na intake and this effect is greater with a high dietary Na intake. Therefore, our data is the first to suggest that EGF may play a role in the nocturnal dipping of BP, which could have potential implications for managing HTN-related cardiovascular disease.

PO2152

The Klotho Deficiency and Not the FGF-23 Rise Is Associated with Heart Failure with Reduced Left Ventricular Ejection Fraction in Patients with Preserved Kidney Function

Sabra Aloui,[1] Feten Lamti,[1] Ahmed Letaief,[1] Mouna Hamouda,[1] Meriem Ben salem,[1] Manel Ben salah,[1] Insaf Handous,[1] Habib Skhiri,[1] Salima Ferchichi,[2] Samir Nouira.[3] *[1]Department of Nephrology Monastir University, Monastir, Tunisia; [2]Department of Biochemestry F HACHED, Sousse, Tunisia; [3]Department of Emergency Medecine, Monastir, Tunisia.*

Background: The FGF23-Klotho axis is increasingly implicated in the pathophysiology of heart failure, especially during advanced chronic kidney disease (CKD). Our objective is to study the association between this FGF23-Khloto axis and heart failure in patients without CKD. This topic is less studied in medical literature

Methods: This is a cross-sectional study of the FGF23 assessment, Klotho and the rest of the phosphocalcic assessment covering 70 patients with normal renal function. These patients had echocardiographic exploration which made it possible to distribute them in two groups: Group HF: LVEF(Left Ventricular Ejection Fraction)<55% (n = 18); Group NoHF: LVEF> 55% (n = 52). Heart failure(HF) was exclusively of ischemic origin.

Results: These were 36 women and 34 men, average age 58 + - 10 years with an estimated glomerular filtration rate (eGFR) at an average of 92 ml / min / 1.73m^2. No difference in eGFR between the two groups. Klotho was far lower with a statistically significant difference in Group HF. FGF23 was higher in Group HF but the difference was not statistically significant. PTH (parathyroid hormone)was statistically higher in Group HF and calcemia was statistically lower in Group HF. Phosphatemia and vitamin D were not associated with heart failure.

Conclusions: Although the sample studied is not large, Klotho but not FGF23 is strongly associated with systolic heart failure. This and other results will be further discussed.

PO2153

Aetiological Subtypes of Transient Ischemic Attack and Ischaemic Stroke in CKD: A Population-Based Study

Dearbhla Kelly, Peter M. Rothwell. Oxford Vascular Study *Wolfson Centre for the Prevention of Stroke and Dementia, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom.*

Background: Chronic kidney disease (CKD) is strongly associated with stroke risk but the mechanisms underlying this association are unclear, and might be informed by subtype-specific analyses. However, few studies have reported stroke subtypes in CKD according to established classification systems such as the Trial of ORG 10172 in Acute Stroke Treatment (TOAST) criteria. We therefore aimed to determine which transient ischaemic attack (TIA) and ischaemic stroke subtypes using the TOAST classification occur most frequently in patients with CKD.

Methods: In a population-based study of all TIA and stroke (Oxford Vascular Study; 2002-2017), all ischaemic events were classified by TOAST subtypes (cardioembolism, large artery disease, small vessel disease, undetermined, multiple, other aetiology, or incompletely investigated). Logistic regression was used to determine the relationship between CKD (defined as an estimated glomerular filtration rate [eGFR] < 60 ml/min/1.73m^2) and TIA/stroke subtypes adjusted for age, sex, and hypertension, and then stratified by age and eGFR category.

Results: Among 3178 patients with TIA (n=1167), ischaemic stroke (n=1802), and intracerebral haemorrhage (n=209), 1267 (40%) had CKD. Although there was a greater prevalence of cardioembolic events (31.8 vs 21.2%; p<0.001) in patients with CKD, this association was lost after adjustment for age, sex, and hypertension (Adjusted

OR=1.20, 95% CI=0.99-1.45; p=0.07). Similarly, although patients with CKD had a lower prevalence of small vessel disease (8.8 vs 13.6%; p<0.001), undetermined (26.1 vs 39.4%; p<0.001), and other aetiology (1.0 vs 3.6%; p<0.001) subtypes, these associations were also lost after adjustment (Adjusted OR=0.86, 0.65-1.13; p=0.27 and 0.73, 0.36-1.43; p=0.37 for small vessel disease and other defined aetiology, respectively) for all but undetermined aetiology (Adjusted OR=0.81, 0.67-0.98; p=0.03).

Conclusions: There were no independent positive associations between CKD and specific TOAST subtypes which suggests that renal-specific risk factors are unlikely to play an important role in the aetiology of particular subtypes. Future studies of stroke and CKD should report subtype-specific analyses to gain further insights into potential mechanisms.

PO2154

Identification of Novel Biomarkers and Pathways for Coronary Artery Calcification in Non-Diabetic Patients on Hemodialysis Using Metabolomic Profiling

Wei Chen,[1,6] Jessica Fitzpatrick,[2] Stephen M. Sozio,[3] Bernard G. Jaar,[3] Michelle M. Estrella,[4] Dario F. Riascos-Bernal,[7] Tong tong Wu,[6] Yunping Qiu,[7] Irwin J. Kurland,[7] Ruth F. Dubin,[5] Yabing Chen,[8] Rulan S. Parekh,[2] David A. Bushinsky,[6] Nicholas Sibinga.[7] PACE *[1]Montefiore Medical Center, Bronx, NY; [2]Hospital for Sick Children, Toronto, ON, Canada; [3]Johns Hopkins University, Baltimore, MD; [4]San Francisco VA Medical Center, San Francisco, CA; [5]University of California San Francisco, San Francisco, CA; [6]University of Rochester Medical Center, Rochester, NY; [7]Yeshiva University Albert Einstein College of Medicine, Bronx, NY; [8]University of Alabama at Birmingham, Birmingham, AL.*

Background: A better understanding of pathophysiology involving coronary artery calcification (CAC) in hemodialysis (HD) patients will help to develop new therapies. We sought to identify the differences in metabolomics profiles between HD patients with and without CAC.

Methods: This is a case-control study nested within a cohort of 568 incident HD patients from the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) study. Cases were non-diabetics with a CAC score >100 (n=51), and controls were non-diabetics with a CAC score of 0 (n=48). We measured 452 serum metabolites in each participant using liquid chromatography–mass spectrometry. Metabolites and pathway scores were compared using Mann–Whitney U tests, partial least squares-discriminant analyses, and pathway enrichment analyses. Multiple logistic regression was used to examine the associations of key metabolites and pathways with CAC.

Results: Cases had a median CAC score of 466 (IQR 246-981). Compared to controls, cases were older (64±13 vs. 42±12 years) and were less likely to be African American (51% vs. 94%). We identified three metabolites in bile acid synthesis (chenodeoxycholic, deoxycholic, and glycolithocholic acids) and one metabolic pathway (arginine/proline metabolism) that were associated with CAC. After adjusting for demographics, higher levels of chenodeoxycholic, deoxycholic, and glycolithocholic acids were associated with higher odds of having CAC. Comparing the third with the first tertile of each bile acid, the adjusted OR (95% CI) was 6.34 (1.12-36.06), 6.73 (1.20-37.82), and 8.53 (1.50-48.49), respectively. Using the first principal component (PC1) score, arginine/proline metabolism was associated with CAC after adjusting for demographics [OR: 1.83 (95% CI: 1.06-3.15) per 1 unit higher in PC1 score], and the association remained significant after additional adjustments for statin use.

Conclusions: Among HD patients without diabetes mellitus, chenodeoxycholic, deoxycholic, and glycolithocholic acids may be potential biomarkers for CAC, and arginine/proline metabolism may emerge as a new pathway in the pathogenesis of CAC and could be a potential treatment target.

PO2155

NaRE: A Novel "Salt Response Element" in the NPFFR2 Gene Promoter and Antagonist of the D_1 Dopamine Receptor

Selim Rozyyev,[1,2] Laureano D. Asico,[2] Jessica Hunt,[2] Pedro A. Jose,[2] Van Anthony M. Villar.[2] *[1]Children's National Hospital, Washington, DC; [2]The George Washington University School of Medicine and Health Sciences, Washington, DC.*

Background: The neuropeptide FF receptor R2 (NPFFR2) is one of two receptors for NPFF and is endowed with pro-hypertensive and anti-natriuretic activities. We looked for regulatory elements in the *NPFFR2* gene promoter and how it interacts with an anti-hypertensive and natriuretic protein, the dopamine type receptor (D_1R).

Methods: Human renal proximal tubule cells (hRPTCs) treated with low NaCl (90 mM) increased mRNA (2.3±0.4-fold) and protein (155±5% *vs*. 100±4%) levels of the salt-retaining NPFFR2, whereas treating the cells with high NaCl concentration (170 mM) decreased the mRNA (-0.70±0.05-fold) and protein (~50±4%, P<0.05) levels.

Results: Promoter analysis of the mouse and human *NPFFR2* genes for regulatory elements identified a single 8-bp region, aptly called "**NaRE**" for **Na**$^+$ **R**esponse **E**lement, at ~2.3 kb upstream of +1 position. This is 75% identical to the "Dehydration Responsive Element" ("TACCGACAT") in the *Rdc2a* gene of *Arabidopsis thaliana* which is a cis-acting element which responds to dehydration, low temperature, and salinity. In the presence of the wild-type NaRE, the *NPFFR2* promoter responded well to both low (4.1±0.05-fold increase) and high (0.52±0.5-fold decrease) NaCl concentrations, but not in the absence of NaRE in a mutant *NPFFR2* promoter construct. Antigene RNA to block NaRE expression in the kidneys of C57Bl/6 mice resulted in the inability of the mice to respond to a low sodium diet (<0.04 g sodium/day) and reduced further the decreased systolic blood pressure caused by the low sodium diet (65±0.6 mm Hg *vs*. 83.3±1.3, P<0.05). We then studied a mechanism by which NPFFR2 dynamically interacts with the D_1R. NPFFR2 and D_1R co-immunoprecipitated and colocalized in hRPTCs and mouse kidney. NPFF and the D_1R/D_5R agonist fenoldopam had antagonistic effects on cAMP production (2.54±0.1 pmol/mg/min for fenoldopam *vs*. 1.23±0.2 for vehicle *vs*. 1.11± 0.2 for fenoldopam and NPFF) and sodium transport (1.78±0.1-fold with fenoldopam) in hRPTCs. C57Bl/6 mice fed a 4% NaCl markedly increased (>2.5-fold) the co-immunoprecipitation between renal NPFFR2 and D_1R, thus increasing the ability of NPFFR2 to antagonize the D_1R effects.

Conclusions: Our data are the first to identify NaRE and demonstrate novel transcriptional and post-translational mechanisms by which mammalian genes respond to sodium.

PO2156

Discovery and Characterization of Small-Molecule Potentiators of $K_{ir}4.1/5.1$

Samantha J. Mcclenahan, Jerod S. Denton. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Heterotetrameric inward rectifier potassium (Kir) channels composed of Kir4.1 (*KCNJ10*) and Kir5.1 (*KCNJ16*) play key roles in regulation of sodium, potassium, and water balance by the distal convoluted tubule of the renal tubule. Loss-of- function mutations in *KCNJ10* lead to EAST syndrome, which is characterized by neurological dysfunction and renal salt wasting. Here we describe the discovery and characterization of small-molecule potentiators of Kir4.1/5.1 that could potentially be used to rescue the function of EAST syndrome mutant channels.

Methods: We established a monoclonal HEK-293 cell line that stably expresses human Kir4.1 and Kir5.1 from a bicistronic vector, and developed and validated a fluorescence-based thallium-flux assay of Kir4.1/5.1 channel function in 384-well format. This assay was used to screen small-molecules from the Vanderbilt Chemistry Institute Library and confirmed with whole-cell electrophysiology.

Results: To date, we have screened more than 60,000 compounds using this assay and identified 420 putative inhibitors and 354 putative potentiators of Kir4.1/5.1. Forty-five of these potentiators increase Kir4.1/5.1-mediated thallium flux by greater than 50% and are selective for Kir4.1/5.1 over homomeric Kir4.1 channels. Fourteen (14) potentiators are active at low single micromolar concentrations with EC_{50} values less than 5 μM, while six (6) compounds appear to be highly efficacious and increase Kir4.1/5.1-mediated thallium flux by more than 100%. Importantly, we have also verified with patch clamp electrophysiology the activity of one of the first-in-class activator of Kir4.1/5.1, termed VU206. In thallium flux assays, VU206 potentiates thallium flux dose-dependently with an EC_{50} of 1.9 μM and maximal efficacy of ~50% above baseline between 10-30 μM. In whole-cell patch clamp experiments, VU206 led to maximal activation of whole-cell currents at 10 μM, complementing the thallium assay. Analysis of current-voltage relationships showed robust activation at both negative and positive test potentials without a depolarizing shift in the reversal potential suggesting VU206 potentiates Kir4.1/5.1 activity without affecting ion selectivity.

Conclusions: Findings from this study provide a novel pharmacological tool for exploring renal Kir4.1/5.1 channel integrative physiology and therapeutic potential of Kir4.1/5.1 potentiators for the treatment of EAST syndrome.

PO2157

Improvement in Albuminuria and Hypertension in Renin Transgenic Mice by a Novel Filterable Form of Angiotensin-Converting-Enzyme 2 with Prolonged Half-Life

Jan Wysocki,[1] Arndt Schulze,[1,2] Gvantca Gulua,[1,2] Minghao Ye,[1] Daniel Batlle.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: ACE2 is a monocarboxypeptidase that converts angiotensin (Ang) II to Ang 1-7. Its large molecular size precludes it from being filtered by the kidneys. We have developed shorter forms of mouse(619 AA) and human ACE2(618 AA) that are filterable but, like the native ACE2, have a short(hours) half-life in vivo. We bio-engineered a fused protein using an albumin binding domain(ABD) and tested its long-lasting effects in mice transgenic for an unregulated secretion of Renin(Ren TgMK).

Methods: Short soluble mouse(m) and human(h) ACE2 variants were fused with Albumin-Binding Domain(ABD). In vivo pharmacokinetic was determined after i.v. and i.p. injection followed by repeated measurement of plasma ACE2 activity. Subsequently, m and h rACE2-ABD(2 mg/kg) were injected every 2-3 days i.p. to Ren TgMK mice. The endpoints included urinary albumin(ACR) and blood pressure.

Results: Administration of 619-ABD to ACE2KO mice resulted in detectability of urinary ACE2 activity which at the baseline was not detectable. Blocking proximal tubule (PT) reabsorption with L-lysine, further increased urinary ACE2 activity suggesting that the ABD-tagged ACE2 undergoes glomerular filtration and is taken up by PT. In WT mice, augmentation of plasma ACE2 activity could still be shown a week after administration. In Ren TgMK mice, both m and h ACE2-ABD markedly reduced SBP and ACR(Figure).

Conclusions: A shorter soluble ACE2 variant fused with ABD exhibits a prolonged half-life while maintaining full enzymatic activity. The protein is filterable and re-absorbable by the proximal tubule, thereby providing increased kidney ACE2 activity

as well as circulating plasma ACE2 activity. Its efficacy was documented by reduced BP and ACR in Ren TgMK, a hypertensive model due to RAS activation. Thus, this novel ACE2 variant with extended half-life offers potential for treatment of kidney disease and hypertension.

Fibroblast Growth Factor 23 Induces Ventricular Arrhythmias and Prolongs QTc Interval in Mice In Vivo Mediated Through FGF Receptor 4

Julian Vallejo,[1] Derek Wang,[1] Jonah M. Graves,[1] Christian Faul,[2] Michael J. Wacker.[1] *[1]Department of Biomedical Sciences, School of Medicine, University of Missouri-Kansas City, Kansas City, MO; [2]Division of Nephrology, Department of Medicine, The University of Alabama at Birmingham, Birmingham, AL.*

Background: Sudden cardiac death and arrhythmias are leading causes of mortality in those with compromised renal function, such as in chronic kidney disease (CKD). Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone released by osteocytes, which becomes markedly elevated in CKD. Previously, we found that FGF23 increases intracellular Ca^{2+} in cardiomyocytes and alters contractility in mouse ventricles *ex vivo* via stimulation of FGF receptor 4 (FGFR4). Since FGF23 could disrupt Ca^{2+} homeostasis, we hypothesized that FGF23 at pathological levels would alter depolarization/repolarization of the heart and induce arrhythmias *in vivo* via a mechanism involving FGFR4.

Methods: To asses our hypothesis, CD-1 male mice (3 months old) were anesthetized and electrocardiogram (ECG) needle electrodes were inserted into the limbs. The jugular vein was cannulated for infusion of vehicle or FGF23 (9ng/ml total blood volume) with and without pretreatment with an FGFR4-specific blocking antibody (anti-FGFR4; U3 Pharma). Lead II ECG and arrhythmias were monitored at baseline and then for 30 minutes post injection.

Results: FGF23 induced premature ventricular contractions (PVCs) in 5 out of 11 mice (P=0.038 vs vehicle) with an average maximal rate of PVCs in these 5 mice of 10.2 ± 5.2 PVC/minute (P<0.01 vs vehicle). Vehicle (n=9) and FGF23+anti-FGFR4 treated (n=8) mice did not exhibit PVCs. Treatment with Isoproterenol (0.1mg/kg) after FGF23 further augmented arrhythmias to a maximal rate of 28.0 ± 21.1 PVC/minute (P<0.05 vs vehicle) and 2 out of 8 mice displayed ventricular tachycardia. Upon examination of ECG intervals, FGF23 prolonged QTc within 30 minutes (P<0.05, n=8) compared to vehicle treatment (n=9), whereas no effect was found for PR interval or QRS duration. FGFR4 blockade abrogated the QTc prolonging effects of FGF23 (n=8).

Conclusions: We conclude that FGF23/FGFR4 signaling in the heart may contribute to ventricular arrhythmogenesis and repolarization disturbances commonly observed in patients with CKD and may be an important therapeutic target to reduce cardiac mortality in CKD.

PO2159

Use of Immune Checkpoint Inhibitors in ESKD

Rimda Wanchoo, Jia Hwei Ng, Jamie S. Hirsch, Rushang Parikh, Yuriy Khanin, Kenar D. Jhaveri. *Northwell Health, Great Neck, NY.*

Background: Use of immune checkpoint inhibitors(ICI) in ESKD patients is limited. We describe our single-center experience of ICI use in ESKD patients and summarize the current literature.

Methods: Using an analytics database, we identified all patients with a minimum of one ESKD diagnosis code who received ICI therapy at our health system. Charts were reviewed manually to confirm that patients were on HD or PD during the ICI therapy. Clinical details such as demographics, comorbidities, cancer type, immune-related adverse events (irAEs), cancer disease status, and patient survival were reviewed. Further literature search was performed for all published cases of ICI use in ESKD patients and was summarized as part of the methods.

Results: In total, 8 patients with ESKD were initiated on ICI. A variety of malignancies were identified. Four patients received pembrolizumab, two received nivolumab, one received both ipilumumab and nivolumab, and the last received PD-L1 inhibitor atezolizumab. All eight patients were receiving proton pump inhibitors. The mean duration on dialysis (dialysis vintage) prior to ICI therapy was 15.8 months (range: 3-60 months). Two patients had an immunotherapy-related adverse event. In both cases, the physicians discontinued the offending ICI agent and started the patients on systemic steroid therapy. Both patients subsequently suffered from cancer progression. The remaining patients tolerated the ICIs well, without significant complication or side effect. No dose adjustments were required. In regards to cancer status, the cancer did not progress in 3 patients but progressed in the remaining five. 4 patients died. Literature review revealed total of 26 patients mostly receiving HD (92%). Interestingly, 27% of these patients were on dialysis as a result of a rejected kidney transplant due to ICI therapy, and then continued to receive ICI. Over 80% of the patients had either partial or complete response to treatment. Aside from the kidney transplant rejection preceding dialysis, a minimal number of patients had a grade 2, 3, or 4 adverse immunotherapy related event (15%)

Conclusions: Based on our series and previously published literature review, the rate of adverse events appear similar to non-ESKD patients (15-25%). ESKD may not be a contraindication to the use of ICI therapy.

PO2160

AKI as a Risk Factor for Mortality in Oncological Patients Receiving Immunotherapy

Clara García-Carro,[1] Mónica Bolufer,[1] Roxana Bury,[1] Eva Muñoz,[2] Enriqueta Felip,[2] Alejandra Gabaldon,[3] Maria Josep Carreras,[4] Daniel Serón,[1] Maria Jose Soler.[1] *[1]Hospital Vall d'Hebron, Nephrology Department, Barcelona, Spain; [2]Hospital Vall d'Hebron, Oncology Department, Barcelona, Spain; [3]Hospital Vall d'Hebron, Pathology Department, Barcelona, Spain; [4]Hospital Vall d'Hebron, Pharmacy Department, Barcelona, Spain.*

Background: Checkpoint inhibitors (CPI) are used to treat cancer by promoting immune-mediated elimination of tumor. CPI–associated AKI (CPI-AKI) is an adverse effect and its incidence is 13-29%. The effect of CPI-AKI on patient survival is unknown. Our aim is to evaluate if CPI-AKI is a risk factor for mortality in patients with cancer under immunotherapy.

Methods: We evaluated data of all patients under CPI at our centre between March 2018-May 2019 and followed-up until April 2020. We divided them into 2 groups according the development of CPI-AKI. Kaplan-Meier and Cox survival analysis comparing patients who developed CPI-AKI with those who did not were performed.

Results: 821 patients received CPI during the study period. Mean age was 62.03 years and 59.2% men. Malignancies: lung 30.3%, urogenital 20.5%, melanoma 10.8%, others 38.4%. 54.34% patients received antiPD1, 28% antiPDL1, 1.6% antiCTLA4, 4.4% other drug, 11.7% two CPI. Mean baseline creatinine was 0.85±0.30 mg/dL. 125 patients (15.2%) developed CPI-AKI. 790 patients completed follow up and were included in the survival analysis, including all with CPI-AKI. Mean time of follow up 13.20months. 50.8% patients had died at the end of follow up, mean time after starting CPI 8.60 months. There were no differences in age/gender or basal creatinine between patients who died and those who survived. In patients who developed CPI-AKI, mortality was 70.40% vs 47.27% as compared with non-CPI-AKI (p<0.0001). Cox survival analysis including age/gender, malignance and type of CPI identified CPI-AKI as a risk factor for mortality (HR 1.597, 95%CI 1.258-2.028, p<0.001), as well as malignance (melanoma HR 1.897, 95% CI 1.290-2.793, lung HR 1.272, 95% CI 1.010-1.602 and urogenital HR 1.543, 95% CI 1.178-2.041, p=0.001) and CPI (PD1 HR 2.160, 95% CI 1.458-3.205, PDL1 HR 1.887, 95% CI 1.253-2.84 and 2 drugs HR 2.049, 95% CI 1.279-3.279,p=0.005).

Conclusions: In a study including more than 800 patients with advanced cancer receiving immunotherapy, CPI-AKI incidence was 15.2%. More than 50% of patients died during a mean follow up of 13 months. CPI-AKI development was a risk factor for mortality in our series. As far as we know, this is the first time that the association between AKI and mortality in patients receiving immunotherapy is described.

PO2161

A Single-Center Cohort Study of Nephrotoxicity due to Immune Checkpoint Inhibitors

Craig T. Irwin, Jennifer Panic, Fahad A. Lodhi, Joshua T. Lee, Sabri E. Elkhidir, Connie M. Folz, Soumya Pulipati, Adam M. Bissonnette, Zebi Fatima, Rebecca Blonsky, Chady A. Leon, Siddhartha Kattamanchi. *Marshfield Clinic Health System, Marshfield, WI.*

Background: Previous studies and case reports have demonstrated an increased risk of nephrotoxicity in patients receiving immune checkpoint inhibitors (CPIs) compared to clinical trials. The primary objective of this study was to contribute to the existing data regarding the frequency, causes of, and risk factors for CPI-induced AKI.

Methods: This was a retrospective cohort study of patients receiving at least one dose of a CPI at a health system in Central Wisconsin from 2013 to 2019. Baseline serum creatinine, defined as the average of all values obtained within 6 months of the CPI start date, was compared to all serum creatinine measurements during CPI therapy and through 60 days after the last CPI dose. Patients developing an AKI of at least three day duration were further assessed to determine the likely cause of AKI, with the incidence of potentially CPI-induced AKI being our primary outcome.

Results: A total of 936 patients received at least one dose of a CPI at MCHS during the study period. After applying exclusion criteria, a total of 910 patients were included in the analysis. A total of 8.4% of patients (76 of 910) were on dual CPI therapy (ipilimumab

and nivolumab). The incidence of AKI of any duration was 36.6% (333 of 910 patients), while sustained AKI (defined as 3 days or longer or not re-measured) occurred in 31.0% of patients (282 of 910). The incidence of presumed CPI-induced AKI was 3.2% (29/910). A total of 25.2% (71/282) of sustained AKI patients had at least one concurrent immune-related adverse effect (irAE), compared to 55.2% (16/29) of presumed CPI-induced AKI. CPI-induced AKI occurred on average 88.2 days (standard deviation 80.6) after starting the CPI, with several AKI events occurring within 60 days after stopping the CPI.

Conclusions: AKI secondary to CPI is a common side effect of CPI. In our population, it occurred at an incidence of 3.2% and sometimes occurred even after the last dose of CPI. The etiology of AKI in almost all cases of biopsy-proven CPI-induced AKI is acute interstitial nephritis. The risk appears to be increased if a patient has already developed an irAE.

PO2162

Checkpoint Inhibitor-Related Renal Vasculitis and Use of Rituximab

Omar Mamlouk,[1] Jamie Lin,[1] Maen Abdelrahim,[2] Amanda Tchakarov,[3] William F. Glass,[3] Umut Selamet,[4] Maryam Buni,[1] Ala Abudayyeh.[1] *[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]Houston Methodist, Houston, TX; [3]University of Texas John P and Katherine G McGovern Medical School, Houston, TX; [4]Brigham and Women's Hospital, Boston, MA.*

Background: The percentage of cancer patients eligible for checkpoint inhibitor (CPI) therapy has increased rapidly over the past few years and approaches 45%. As a result, more cases of CPI-related nephrotoxicity, including a rare subset with vasculitis, are being reported. To elucidate the clinical presentation of CPI-associated vasculitis with kidney involvement and its possible mechanisms, treatment options, and prognosis, we describe cases from a comprehensive cancer center and reviewed the literature for similar cases.

Methods: We retrospectively reviewed the charts of all cancer patients from 2014 to 2020 who were diagnosed with CPI-related nephrotoxicity and underwent a kidney biopsy

Results: We identified 5 cases of vasculitis with kidney involvement: 3 patients were diagnosed with renal vasculitis, 1 case with ANCA vasculitis, and 1 case with Immunoglobulin A (IgA) vasculitis. Of these cases, 4 patients were receiving nivolumab, and 1 patient was receiving tremelimumab. All patients had microscopic hematuria, four out of five had negative anti-neutrophil cytoplasmic antibodies (ANCA) serology, one patient had concurrent lung involvement and positive ANCA serology, and all had severe acute kidney injury with creatinine > 4.50 mg/dL upon diagnosis. All patients were treated by discontinuing CPI and initiating corticosteroids and rituximab. Three patients received plasmapheresis; 2 of these required renal replacement therapy (RRT) including the patient with lung involvement. All patients after rituximab had partial or complete renal response. Two patients died within 8 months of diagnosis due to malignancy progression. None of the patients had a relapse of vasculitis

Conclusions: We demonstrated that CPI can be associated with different types of vasculitis with kidney involvement that are predominantly ANCA negative and manifest as severe acute kidney injury. Despite the lack of strong evidence, treatment similar to treatment of primary ANCA vasculitis with corticosteroids and rituximab is well tolerated with favorable renal outcomes

PO2163

AKI and Immune-Related Adverse Events (irAEs) in Patients with Genitourinary Cancers Receiving Immune Checkpoint Inhibitors (ICIs)

Harish Shanthanu Seethapathy, Sarah E. Street, Meghan Lee, Ian A. Strohbehn, Nifasha Rusibamayila, Donald F. Chute, Kerry Reynolds, Meghan E. Sise. *Massachusetts General Hospital, Boston, MA.*

Background: ICI use is associated with AKI. Patients with advanced genitourinary (GU) malignancies, including renal cell and bladder carcinoma, are at increased risk of AKI due to the high prevalence of chronic kidney disease (CKD) and frequent need for combination ICI and nephrotoxic platinum-based chemotherapy. We evaluated the incidence of AKI and irAEs in these patients.

Methods: Retrospective cohort of patients with GU-cancers receiving ICIs within a large healthcare network from 2011-2018. Cancer type, ICI class, comorbidities, baseline medications, and irAEs were determined using electronic records. AKI in the first 12 months after ICI initiation was the primary outcome. Multivariable models were used to evaluate for predictors of AKI.

Results: 639 patients with GU-cancers were included. Average age was 66 years, 72% were male, 91% were white, 50% had CKD (eGFR<60 mL/min/1.73m^2) and 51% had undergone full nephrectomy. 61% received PD1, 32% PDL1 and 7% combination PD1/CTLA4. 32% received prior platinum-based regimens or gemcitabine, and 8% received concurrent bevacizumab. 164 patients (26%) experienced AKI in the first 12 months. In a multivariable model, baseline coronary artery disease was predictive of AKI (p=0.02); prior nephrectomy, baseline CKD, and nephrotoxic chemotherapy exposure were not (Table). 185 (29%) experienced immune-related adverse events, most commonly thyroiditis (16%), gastrointestinal (7%), rash (4%), pneumonitis (4%), and hepatitis (4%).

Conclusions: AKI and irAEs are common in patients with GU-cancers receiving ICIs. Baseline CKD, prior nephrectomy nor nephrotoxic chemo use predict AKI after ICI indicating these factors should not exclude individuals from receiving treatment.

Electrolyte Abnormalities in Patients Receiving Immune Checkpoint Inhibitors

Harish Shanthanu Seethapathy,[1] Nifasha Rusibamayila,[1] Donald F. Chute,[1] Meghan Lee,[1] Ian A. Strohbehn,[1] Alexander Faje,[1] Kerry Reynolds,[1] Kenar D. Jhaveri,[2] Meghan E. Sise.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Northwell Health, Great Neck, NY.*

Background: Hyponatremia due to endocrinopathies such as adrenal insufficiency and hypothyroidism has been reported in patients receiving immune checkpoint inhibitors. Other electrolyte abnormalities such as hypocalcemia and hypokalemia have also been associated with the use of these agents. We study the incidence and predictors of electrolyte abnormalities in cancer patients receiving immune checkpoint inhibitors.

Methods: Patients who received immune checkpoint inhibitors at Massachusetts General Hospital Cancer Center between 2011 and 2018 were included. Incidence of electrolyte abnormalities were determined in the first 12 months after drug initiation and graded for severity by using Common Terminology for Cancer Adverse Events criteria. The predictors of severe electrolyte abnormalities were determined using a multivariable logistic regression model.

Results: We analyzed 2458 patients started on checkpoint inhibitors in our cancer center. Average age was 64 (SD 13) years, 58% were male and 90% were White. In the first year of follow-up, 62% experienced hyponatremia, 27% had hypokalemia, 26% had hyperkalemia, 49% had hypophosphatemia and 9% had hypocalcemia. Grade 3 or 4 hyponatremia was seen in 136 patients (6%) and occurred 164 days (SD 100) after checkpoint inhibitor initiation; only 9 cases of grade 3 or 4 hyponatremia were due to endocrinopathies. CTLA4 inhibitors were associated with a higher risk of grade 3 or 4 hyponatremia and hypophosphatemia. Patients with gastrointestinal malignancies experienced the highest risk of grade 3 or 4 electrolyte abnormalities.

Conclusions: Electrolyte abnormalities are common in cancer patients receiving immune checkpoint inhibitors. Endocrinopathies leading to severe hyponatremia are rare (<0.5%).

Immune Checkpoint Inhibitor-Associated Glomerular Disease: A Systematic Review and Meta-Analysis

Abhijat Kitchlu,[1] Kenar D. Jhaveri,[6] Shikha Wadhwani,[2] Priya Deshpande,[3] Ziv Harel,[4] Teruko Kishibe,[4] Kammi J. Henriksen,[5] Rimda Wanchoo.[6] *[1]University Health Network, Toronto, ON, Canada; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]St. Michael's Hospital, Toronto, ON, Canada; [5]University of Chicago, Chicago, IL; [6]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: Immune checkpoint inhibitors (ICI) are increasingly used to treat several cancers. Kidney immune-related adverse events (IRAE) are now well-recognized, with purported incidence of 2-5%. The majority of initial data related to kidney IRAE has focused on acute interstitial nephritis (AIN). Recently various glomerular diseases have been reported; however, there is minimal data on the types and relative frequencies of glomerular diseases associated with ICI, their treatment, and outcomes.

Methods: We performed a systematic review and meta-analysis of all biopsy-proven published cases/series of glomerular pathology associated with ICI therapy. We searched the MEDLINE, EMBASE and Cochrane Central databases from inception to February 2020. We abstracted patient-level data, including demographics, cancer and ICI therapy details, and characteristics of kidney injury. We performed exploratory univariate logistic regressions for predictors of end stage kidney disease (ESKD) or death.

Results: After screening, 27 manuscripts with 45 cases of biopsy-confirmed ICI-associated glomerular disease were identified. Several types of lesions were observed, with the most frequent being pauci-immune glomerulonephritis and renal vasculitis (27%), minimal change disease (MCD) (20%), and C3 glomerulonephritis (11%). Concomitant AIN was reported among 41% of cases. The majority of patients had ICI discontinued (88%), and nearly all received corticosteroids (98%). Complete or partial remission of proteinuria was achieved in 45% and 38%, respectively. Most patients had full (31%) or partial (42%) recovery from AKI although 19% required dialysis and approximately one-third of patients died. In exploratory univariate logistic regression for predictors of endstage kidney disease (ESKD) or death, glomerular lesion, ICI class, peak creatinine and proteinuria were not significantly associated with this composite outcome.

Conclusions: Glomerular diseases associated with ICI are not uncommon. Pauci-immune glomerulonephritis, MCD and C3GN are the most frequently reported lesions. ICI-associated glomerular disease may be associated with poor kidney and mortality outcomes. Oncologists and nephrologists need to be aware of glomerular pathologies associated with ICI treatment.

PO2166

Statin Use, Renal Cell Carcinoma, and Combination Immunotherapy Increase Risk of Checkpoint Inhibitor-Induced Nephritis: A Single-Center Database Study

Jason Prosek, Dwight Owen, Marium Husain, Lai Wei, Gabrielle A. Lopez, Songzhu Zhao. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Immune checkpoint inhibitors (ICI) are associated with improved cancer outcomes, however immune related adverse events (irAE) develop and are poorly understood. Renal irAE (RirAE) are less common but may jeopardize effective cancer therapy, and no reliable risk factors for RirAE have been identified. Concomitant medications have been shown to play a role in response to ICI but the impact on toxicity is unknown. We report risk factors and clinical outcomes of patients who develop RirAE.

Methods: We queried a patient database with advanced cancer treated with ICI between 2010 and 2017 at Ohio State Univ for pts who developed AKI (defined as a doubling of creatinine after initiation of ICI). irAEs were reviewed by nephrologist and oncologist. Overall survival (OS) was calculated from date of initiation of ICI to death from any cause or date of last follow-up. Associations between irAE incidence and categorical outcomes were studied using chi-square or Fisher's exact test. The Wilcoxon test was used for continuous outcomes. Survival outcomes were studied using log-rank test or cox regression model.

Results: Of 1,091 pts treated with ICI, 160 (14.7%) developed AKI of any cause and 30 (2.74%) developed RirAE. PPI use (p=0.032), renal cell carcinoma (RCC) diagnosis (p=0.009) and line of therapy (p=0.033) were all associated with development of AKI, and RCC, BMI, and line of therapy remained significant in multivariate analysis[OD1]. Overall survival (OS) was 12.2 months in absence of AKI vs 10.7 months with AKI (p=0.0125). Statin use (p=0.007) and RCC diagnosis (p=0.012) were significantly associated with RirAE with a trend to higher rates in combination immunotherapy (p=0.064). These three variables were also significant in multivariate analysis. OS was not different in the RirAE group (10.8 months) vs no RirAE group (11.8 months).

Conclusions: Patients undergoing ICI therapy can develop AKI as well as RirAE. However, outcomes are worse for AKI. Survival for pts who develop RirAE does not appear to differ from patients without RirAE. AKI and RirAE share an independent risk factor in RCC. However, statin use and combination ICI therapy appear to be unique risk factors for RirAE. Further studies are needed to verify the finding regarding statin use, a drug with widespread use.

PO2167

A Potential Mechanism of Distal Renal Tubular Acidosis in Patients Treated with Immune Checkpoint Inhibitors

Sandra Herrmann,[1] Mariam P. Alexander,[1] Michael F. Romero,[1] Ladan Zand.[2] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: The main cause of acute kidney injury in patients on immune check point inhibitors(ICI) is acute interstitial nephritis(AIN). However, as their use continues to increase, we observe other renal manifestations being described. Distal renal tubular acidosis(dRTA) has been described, but the mechanism is not clear to date. We hypothesized that an alteration of H+-ATPase or anion exchanger(AE-1) in alpha intercalated cells(α-IC) in collecting duct is affected.

Methods: We present two patients with AIN and dRTA secondary to ICI: Patient#1 with metastatic adenocarcinoma of lung and patient#2 with metastatic melanoma, both treated with anti-PD1-antibodies(pembrolizumab/nivolumab). They had prominent electrolytes abnormalities consistent with dRTA(Figure 1A). Kidney biopsy was performed in each patient which showed diffuse AIN with negative routine immunofluorescence(IF) staining. Both patients had received PPI in addition to ICI therapy and had improvement in their kidney function following steroid therapy and with discontinuation of the drugs. In order to investigate the potential mechanism for developing dRTA, the kidney biopsy frozen sections from patients#1 and#2 were further stained by indirect IF for acid-base transporters in α-IC(α4 and B1)subunits of the vacuolar H+-ATPase(V-ATPase) and the AE1. In order to quantify the staining, data were normalized to a T_0 allograft biopsy as control.

Results: α-IC cell markers were decreased in both patients compared to the control as shown in Figure1B. Quantification of AE1, B1-V-ATPase and A4-V-ATPase were all reduced compared to control biopsy, however, staining for other markers of a-IC(c-kit) were not reduced. This suggests a more targeted reduction in V-ATPase subunits that may be immune-mediated.

Conclusions: The reduction in staining for V-ATPase subunit could be related to damage from AIN, however, an immune-mediated process that reduces the expression of V-ATPase in α-IC is likely. Comparing staining of V-ATPase in α-IC in patients with AIN secondary to ICI with and without dRTA in the future will be useful.

Clinical Features of AKI in Patients Receiving Tisagenlecleucel (CAR-T Therapy)

Meghan Lee,[1] Ian A. Strohbehn,[1] Harish Shanthanu Seethapathy,[1] Nifasha Rusibamayila,[1] Keagan S. Casey,[1] Shruti Gupta,[2] David E. Leaf,[2] Matthew Frigault,[1] Meghan E. Sise.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: CAR-T therapy uses genetically engineered T cells to target tumor antigens, but can lead to cytokine release syndrome (CRS), neurotoxicity, and in severe cases, AKI. Prior series demonstrated 20% incidence of AKI after axicabtagene ciloleucel (Yescarta), a CD28 costimulatory domain CAR-T. Tisagenlecleucel (Kymriah) is a 41BB CAR-T that targets CD19 on B cells but has delayed toxicities, slower expansion kinetics, longer persistence, and is associated with lower rates of severe CRS. We determined incidence and clinical features of AKI in patients receiving tisagenlecleucel.

Methods: We performed a retrospective review of adults with diffuse large B cell lymphoma treated with tisagenlecleucel at our institution between Jan 2019–Apr 2020. Baseline demographics, laboratory data, and clinical outcomes were obtained from electronic health records. The primary outcome, AKI, was defined as a ≥1.5-fold rise in creatinine from pre-CAR-T baseline and staged using KDIGO criteria.

Results: Overall, 37 patients received tisagenlecleucel: average age was 60 (SD 18), 65% male, 86% white. CRS occurred in 51% (no severe CRS); neurotoxicity occurred in 24%. Thirteen (35%) required steroids, 8 (22%) received tocilizumab, and 8 (22%) received anakinra to treat CRS/neurotoxicity. AKI occurred in 2 (5%) patients; both had stage 3 AKI. One had acute tubular necrosis due to septic shock starting post-infusion day 1. The other had AKI with new-onset nephrotic range proteinuria (5-6g/g) concurrent with a hemophagocytic lymphohistiocytosis-like syndrome beginning day +8. The patient was also receiving amphotericin and acyclovir. Both patients with AKI died (days 4 and 28, respectively). Among patients without AKI, the 30-day mortality was 8.6%. Clinically significant electrolyte disorders were also common **(Table).**

Conclusions: Compared to prior reports, we found lower rates of CRS and AKI in patients receiving Tisangenlecleucel. We report a case of new-onset nephrotic-range proteinuria and AKI following CAR-T.

Clinical outcomes among patients receiving tisagenlecleucel

Outcome (Total n=37)	Count (%)
Acute Kidney Injury	2 (5)
Cytokine release syndrome	19 (51)
Grade 1	15 (40)
Grade 2	4 (11)
Grade 3/4	0 (0)
Neurotoxicity	9 (24)
Grade 1/2	7 (19)
Grade 3/4	2 (5)
Electrolyte disorders	7 (19)
Hyponatremia < 130 mEq/L	5 (14)
Hypokalemia < 3.0 mEq/L	26 (70)
Hypophosphatemia < 2.0 mg/dL	
30-day Mortality	5 (14)

PO2169

Dabrafenib-Induced Acute Interstitial Nephritis (AIN) and AKI in Patients with Cancer

Meghan Lee, Harish Shanthanu Seethapathy, Orhan Efe, Ian A. Strohbehn, Nifasha Rusibamayila, Ivy Rosales, Robert B. Colvin, Donald F. Chute, Meghan E. Sise. *Massachusetts General Hospital, Boston, MA.*

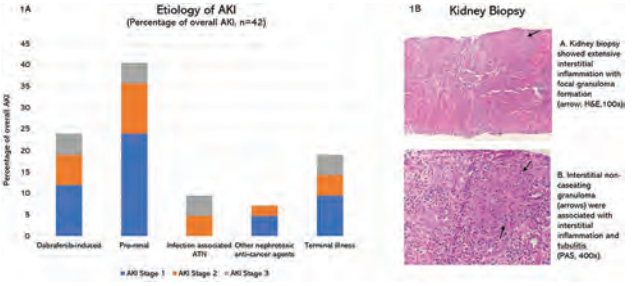
Background: BRAF inhibitors (vemurafenib, dabrafenib, encorafenib) commonly used to treat $BRAF^{V600}$ mutant cancers have been associated with AKI. Cases of acute and chronic tubular injury and AIN have been reported with dabrafenib. We aimed to define the incidence and clinical features of AKI in patients on dabrafenib.

Methods: We conducted a retrospective cohort of patients receiving dabrafenib from 2010-2018 in a large healthcare system. Baseline comorbidities and medication use was determined by chart review. The primary outcome was AKI (≥1.5-fold-increase in baseline creatinine) within 12 months. AKI etiology was reviewed by 2 nephrologists. Multivariable modeling was used to determine predictors of AKI.

Results: Overall, 199 patients were included; mean age was 59 (SD 16) years, 56% were male, and 94% were white. 96% received trametinib (a MEK inhibitor) concurrently. Mean baseline creatinine was 0.9 (SD 0.2) mg/dL, 20 (10%) had baseline CKD (eGFR<60 mL/min/1.73m^2), and 42 patients (21%) experienced AKI at a mean of 141 (SD 116) days after starting dabrafenib. In multivariable modeling, only baseline liver disease predicted AKI. Etiology and stage of AKI are shown in Fig 1A; clear alternative causes for AKI were found in 32 of 42 cases. Ten patients (5% of total cohort, 24% of AKI) experienced AKI attributed to dabrafenib-induced cytokine release syndrome (CRS); all experienced fever, chills, gastrointestinal distress (nausea/vomiting/diarrhea) +/- rash and transaminitis within 4-6 weeks of starting dabrafenib. The majority improved with intravenous hydration and discontinuation of the drug. One patient with persistent AKI underwent kidney biopsy demonstrating granulomatous AIN (Fig 1B); he was treated with intravenous solumedrol and a prednisone taper for two weeks with full resolution of AKI.

Conclusions: AKI is common in patients on Dabrafenib (21%). A febrile systemic response or CRS after dabrafenib may explain up to 24% of AKI; we report another case of AIN after dabrafenib.

Funding: NIDDK Support



PO2170

Temporal Trends of Palliative Care Use Among Hospitalized Patients with Metastatic Renal Cell Carcinoma

Si Li,[1] Yichen Wang,[1] Min Zhuo,[3] Qiyu O. Wang,[2] Nasha Elavia,[1] Nishant Sharma,[1] Bojana Milekic.[1] *[1]The Wright Center for Graduate Medical Education, Scranton, PA; [2]Cook County Health and Hospitals system, Chicago, IL; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Patients with metastatic renal cell carcinoma have a poor prognosis and they may suffer from hypercalcemia, venous thromboembolism, anorexia-cachexia syndrome. Little is known about the trends in the utilization of palliative care in this patient population.

Methods: We conducted a retrospective cohort study using data from 2004 to 2014, which were extracted from the National Inpatient Sample. ICD-9-CM was used to identify all diagnosis variables. We compared the baseline demographics. We assessed the annual trend over time in palliative care utilization rates. Statistical analysis was performed using STATA 16.0. We considered a two-tailed P value of <0.05 as statistically significant.

Results: We identified 181,199 hospitalizations with metastatic renal cell carcinoma from 2004 through 2014, of which 16,390 (9.0%) involved palliative care services. Inpatient palliative care utilization increased from 2.8% in 2004 to 16.3% in 2014 (p<0.001). Compared with patients discharged from non-teaching hospitals, we noticed a significantly higher rate of palliative care utilization in patients discharged from teaching hospitals [aOR 1.46; 95% CI 1.29 to 1.65]. There were higher odds of receiving palliative care in patients with private insurance (aOR 1.26; 95% CI 1.11 to 1.42). We also observed lower odds of receiving palliative care in Hispanic patients (aOR 0.83; 95% CI 0.70 to 0.98, p=0.03).

Conclusions: The rate of inpatient palliative care use in metastatic renal cell carcinoma patients sharply increased between 2004 and 2014. Our findings demonstrated improving adherence to the National comprehensive cancer network (NCCN) guidelines, which is highly encouraging. Patients from teaching hospitals and using private insurance and were more likely to receive palliative care.

AKI Secondary to Multiple Myeloma: Complications of Treatment with High Cut-Off Filters

Ana Berni, Ana Coscojuela Otto, Victoria Dourdil, Pablo J. Inigo Gil, Rafael Alvarez lipe. *Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain.*

Background: Acute kidney injury is a frequent complication of MM that can affect 18 to 56% of patients and more than 10% end up needing dialysis. One of the drawbacks associated with the technique is attributed to the albumin loss. The other complications are related with the dialysis technique itself, especially infections.

Methods: We have performed 28 treatments of hemodialysis with High cut off filters (HD-HCO). The HD-HCO protocol includes daily dialysis session of 6 hours during the first 6 days to subsequently switch to dialysis every other day until free light chains levels below 500 mg / L, or until the recovery of renal function allows the independence of dialysis. All these patients have a chemotherapy regimen based on Bortezomib (25 of the 28 treatments) and Dexamethasone (28 treatments). A retrospective analysis of the 28 treatments that are performed with HD-HCO after 8 years of experience (July 2011 to May 2019) to demostrate the presence of the same complications as the conventional HD.

Results: Loss of albumin is one of the main drawbacks of the technique. Our patients had no changes in albumin levels due to the fact that our protocol includes the infusion of 2 vials of 20% albumin of 50 ml. at the end of each HD-HCO session. Another concern is intradialytic complications. We have reviewed this topic and our results show that patients in HD-HCO do not present a greater number of complications than those who dialyze with HD-HD or other conventional dialysis. The total number of sessions was 298. 21 patients developed hypotension (7%). The number of sessions in which the patient presented fever was 6 (2%), coagulation of the circuit occurred in 23 sessions (7,7%). The catheter dysfunction (when it does not allow to reach 250 ml/min of blood flow) in 26 times (8.7%) and only 13 times the replacement of the catheter (4.26%) was necessary, consequently, in those who required a greater number of dialysis sessions. In only 1 case (patient who required 27 sessions) to place a permanent Tesio catheter was necessary. Figure 1

Conclusions: Our findings indicate that the HD-HCO has the same safety profile as the conventional HD. There is no serious infectious complications in our patients despite of the fact that all of them are immunosuppressed patients (AKI secondary to Multiple Myeloma in patients treated with chemotherapy).

PO2172

Acute Myeloid Leukemia Worsens Sepsis-Induced AKI

Takayuki Tsuji, Naoko Tsuji, Tetsushi Yamashita, Xuzhen Hu, Peter S. Yuen, Robert A. Star. Renal Diagnostics and Therapeutics Unit *National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Patients with hematological malignancies are at high risk for acute kidney injury (AKI), which is associated with high morbidity and mortality. Sepsis is the main cause of AKI in ICU patients with hematologic malignancies. However, the contributions that host or cancer cells make to systemic inflammation during sepsis-induced AKI is not known.

Methods: We created a mouse xenograft model of acute myelogenous leukemia (AML) associated sepsis AKI. Human leukemia HL-60 cells were injected into the tail vein of 6 week-old male NOD/SCID/IL-2Rγ^{null}(NSG) mice. After engraftment 2 weeks later, cecal ligation and puncture (CLP) was performed to induce sepsis (n=8-12 per group). Tumor engraftment in the bone marrow (BM) and blood tumor burden were measured by flow cytometry of human CD33 and human CD45 double positive cells. Multiple organ damage, and both mouse and human systemic cytokines were evaluated at 24 h after CLP or sham surgery.

Results: AML intensified sepsis-induced AKI. Both BUN and LDH were significantly higher in AML+CLP than CLP alone (AML+CLP vs vehicle+CLP, BUN 74.5±25.4 vs 42.7±25.3 mg/dl, LDH 3,969±1,720 vs 1,863±661 mg/dl, $p<0.05$). CLP dramatically increased the percentage of circulating leukemia cells (pre CLP vs post CLP, 2.2±1.3 % vs 20.6±13.3 %, $p<0.05$). Tumor burden in either BM or blood did not correlate with AKI severity. Systemic mouse IL-6 in AML+CLP at 24 hours after CLP was significantly higher than CLP alone (45.9±2.4 vs 15.1±2.4 ng/mL, $p<0.05$). Systemic human IL-6 in AML+CLP was higher, but not significantly, than vehicle+CLP. There was no correlation between human cytokines and severity of AKI, although human cytokines (IL-6 and TNFα) significantly correlated with tumor burden in both BM and blood at 24 hours after CLP.

Conclusions: We established a clinically relevant mouse xenograft model of human leukemia associated sepsis AKI. Leukemia intensified sepsis-induced AKI, and sepsis AKI increased the numbers of circulating AML cells. Systemic cytokines derived from the human leukemia cells correlated with tumor burden, but not with the severity of sepsis-induced AKI. Whereas malignant cells do not produce circulating cytokines that directly drive the systemic immune response to subsequent sepsis-induced AKI, cell-cell interactions in the BM niche may impact systemic inflammation indirectly, possibly through mouse IL-6.

PO2173

Acute Acquired Fanconi Syndrome (FS) in Multiple Myeloma (MM) After Autologous Hematopoietic Stem Cell Transplantation (HCT): A Case Series

Janina Paula T. Sy-Go, Nelson Leung. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Proximal tubular dysfunction can occur in patients with MM. The main clinical presentation is electrolyte abnormalities indicative of FS. The objective of the study was to describe and identify the rate and clinical predictors of developing acute acquired FS in adult patients with MM after autologous HCT.

Methods: We identified 2515 adult MM patients who underwent autologous HCT at Mayo Clinic from January 1, 2000 to December 31, 2018. 45 without research authorization were excluded. 13 patients were identified after searching for "Fanconi," "Fanconis," and "Fanconi's" in the EMR. 6 patients did not have FS. 4 patients were diagnosed with FS prior to HCT. The remaining 3 patients (0.12% of cohort) were clinically diagnosed to have FS based on features indicative of FS - hypokalemia, hypophosphatemia, hypouricemia, proximal renal tubular acidosis, and normoglycemia glycosuria - within 14 days after HCT. Of note, these patients did not have features of FS prior to HCT.

Results: The median age of the cohort was 65 years (range: 53-75). All were Caucasians. 2 were women and 1 was a man. Medical comorbidities included hypertension, dyslipidemia, CKD, hypothyroidism, and kidney stone. All had kappa-restricted light chain MM with a median M-spike of 1.2 g/dL (range: 0.4-2). All received dexamethasone while 2 received bortezomib and 1 each for cyclophosphamide and lenalidomide. They underwent HCT about 8.3 months after MM diagnosis and were clinically diagnosed with FS about 14.6 days after HCT. None underwent a kidney biopsy. All had hypokalemia, hypophosphatemia, and hypomagnesemia (<3.5, <2.5, and <1.7 respectively). 2/3 patients had AKI (≥1.5-fold increase in serum creatinine) and normoglycemia glycosuria. 1/3 had hypouricemia (low range of normal: 2.7-6.1) and proximal renal tubular acidosis (<22 and urine pH <5.3). Aminoaciduria was not checked. All received electrolyte replacement, whether PO or IV, and 2/3 received amiloride to help maintain normokalemia.

Conclusions: Although rare, severe electrolyte depletion after HCT in kappa MM patients could occur and should raise the suspicion for FS. Lenalidomide has been reported to induce FS. Concurrent GI symptoms could exacerbate these electrolyte losses, which concurrent AKI, conversely, could help correct. Timely electrolyte repletion and close monitoring are required.

PO2174

Hyponatremia Is Common After Indwelling Catheter Drainage of Malignant Ascites

Shruti Gupta,[1] Maria Clarissa Tio,[1] Emily D. Gutowski,[2] Michael S. Stecker,[1] Ashish Verma,[1] Shveta S. Motwani,[3] David B. Mount,[1] Gearoid M. McMahon,[1] Sushrut S. Waikar.[4] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Dana-Farber/Children's Hospital Cancer Center, Boston, MA; [4]Boston Medical Center, Boston, MA.*

Background: Indwelling peritoneal catheters (IPCs) are frequently used to drain tense, symptomatic, malignancy-related ascites. Large-volume drainage may lead to hyponatremia due to massive salt depletion. To date, no studies have examined the epidemiology of hyponatremia after IPC placement.

Methods: We retrospectively reviewed the charts of 461 patients who had IPCs placed between 2006 and 2016 at a tertiary care hospital. Among the 309 patients with labs available pre- and post-catheter, we studied the incidence of hyponatremia and its risk factors. We also examined the management of hyponatremia and its association with mortality.

Results: The overall incidence of hyponatremia post-IPC placement was 85%, of whom 8% had severe hyponatremia with a serum sodium (sNa) sNa<120 mEq/L. The mean decline in sNa pre- versus post-catheter was 5 mEq/L (+/- 5.1) and fell by ≥10 mEq/L among 52 patients (16.8%). Patients with hyponatremia prior to catheter placement had an 8-fold (95% CI, 2.9-21.7) higher adjusted odds of having persistent hyponatremia post-catheter (Table 1). Patients with hepato-pancreatic-biliary malignancies and lower BMI also had a higher adjusted odds of hypoonatremia. Hyponatremia was either unrecognized or untreated in 61% of patients. Patients who had sNa ≤120 mEq/L had shorter median survival compared with those with a post-IPC sNa>120 mEq/L (8 versus 17 days, log-rank p value = 0.03) (Figure 1).

Conclusions: Though IPC placement is often a palliative measure, hyponatremia is common, and severe hyponatremia may be associated with shorter survival. These patients may warrant closer monitoring post-catheter placement.

Funding: Other NIH Support - NIDCD F32DC017342

Table 1: Predictors of Hyponatremia Post-IPC

Variable	Univariable Analysis	Multivariable Analysis
	OR (95% CI)	OR (95% CI)
Age >60	0.58 (0.31,1.09)	0.60 (0.23, 1.57)
Hepato-Pancreato-Biliary Cancer	2.42 (1.05,5.60)	5.09 (1.05, 24.80)
BMI (continuous)	0.80 (0.83, 0.98)	0.90 (0.82, 0.99)
Sodium <1135 Pre-IPC	6.88 (3.39,13.95)	7.87 (2.86,21.70)

PO2175

Selinexor-Associated Hyponatremia: Single-Center Real-World Data

Omar Mamlouk,[1] Kenar D. Jhaveri,[2] Jaya Kala.[3] *[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [3]University of Texas John P and Katherine G McGovern Medical School, Houston, TX.*

Background: Introduction: Hyponatremia is a commonly reported side effect in recent clinical trials evaluating the efficacy and safety of selinexor in treatment of refractory multiple myeloma (MM). With incidence ranging 7-47%. the hyponatremia was reported to be generally asymptomatic, transient, and highly responsive to medication dose reduction and sodium. The etiology for hyponatremia is not yet completely understood and speculated to be multifactorial, hypovolemia, diarrhea, poor solute intake, or pseudohyponatremia from high M protein level.

Methods: We retrospectively reviewed the medical records of all relapsed MM patients at our cancer institute. The study was approved by the institutional review board. We reviewed data relevant to hyponatremia in patients' clinical presentation, medication history, comorbid conditions, physical examination, and laboratory review.

Results: Hyponatremia was seen in 13/17 patients within 5 weeks of therapy, 8 of whom required hospitalization. Three of these hospitalized patients had grade 3 hyponatremia (serum sodium 120 to ≤130 meq/l) with severe symptoms including fall and altered mental status. Both groups of patients received antiemetics, anti-depressants and diuretics that included thiazides. Cancer related pain was observed in both groups but the hyponatremic group was on higher dose selinexor and more likely to have more gastrointestinal side effects, sepsis, hypotension. Nephrology was consulted on only 4 out of 13 patients. These were the only patients with serological and urine studies done high urine osmolarity and high urine sodium concentration that along with euvolemia favored SIAD diagnosis in 3 out these 4 patients.

Conclusions: Our observations suggest that hyponatremia is multifactorial, as the patient's co-morbidities, medications, and selinexor side effects (hypovolemia, nausea and possible unidentified factor) may contribute to hyponatremia. It is possibly dose dependent, more likely to occur with patients who had gastro-intestinal side effects, sepsis and hypotension. We recommend discontinuation of medications associated with hyponatremia prior to starting/during selinexor therapy, obtaining basic hyponatremia investigations, and early referral to nephrology to prevent potential serious symptoms

PO2176

Antiemetic Drugs and the Risk of Cisplatin-Induced AKI

Roman A. Shingarev,[1] Andrea Knezevic,[1] Sheron Latcha,[1] Melanie S. Joy,[2] Lauren Aleksunes,[3] Edgar A. Jaimes.[1] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]University of Colorado, Denver, CO; [3]Rutgers, Rutgers The State University of New Jersey, New Brunswick, NJ.*

Background: Cisplatin (CIS) is an effective first line therapy for a variety of cancers. Acute kidney injury (AKI) is a common side effect of CIS seen in up to 30% of patients (Latcha et al CJASN, 2016). AKI results from the selective uptake and accumulation of CIS in proximal tubules. CIS is a highly emetogenic and fluid loss can also contribute to AKI. This retrospective study evaluated whether anti-emetics modfy the risk of AKI.

Methods: The medical records of adult cancer patients who received CIS between Jan 1, 2010 and Dec 31, 2016 (n=6,889) were reviewed. The association between use of anti-emetics and development of AKI (50% increase in serum creatinine (sCr)) was evaluated. Inclusion criteria were adults, baseline sCr, CIS dose and administration of anti-emetics. Fisher's exact test was used for univariable associations between categorical values and logistic regression analyzed multivariable associations with AKI at $p<0.05$.

Results: Out of ~8700 patients, 6889 met search criteria. A total of 3,881 (56.3%) patients received antiemetics. AKI developed after cisplatin in 1,666 (24.2 %) patients. Of those with AKI (n=1666), patients who received any antiemetic represented 52.6% (n=877), while patients with no documented antiemetic use represented 47.4% (n=789). Of patients without AKI (n=5223), patients who received any antiemetic represented 57.5% (n=3004), while patients who did not have documented antiemetic use represented 42.5% (n=2219). ($P<0.001$). Patients who received antiemetics also received a higher cumulative dose of CIS (360 vs 330 mg/m^2, $P < 0.001$). By univariate analysis older age, male gender, black race, and cumulative CIS dose were associated with higher risk for AKI ($P<0.001$). After adjusting for these variables, use of any antiemetic was protective for AKI (OR 0.84, 95% CI: 0.75, 0.94; P= 0.003).

Conclusions: Our study confirms the high rate of AKI in patients receiving CIS. While anti-emetic use appears to be associated with a lower rate of AKI, additional analyses will be needed to determine risk or benefit profiles of specific agents and/or class of agents given recent data demonstrating inhibition of kidney transporters with certain anti-emetics. Dissecting out other important covariates such as requirements for anti-emetics based on higher cumulative CIS will be necessary in prospective randomized controlled studies.

PO2177

Acute Kidney Disease After Microinvasive Radical Cystectomy for Bladder Cancer Is Associated with CKD

Shengnan Ge, Ying Tang, Junzhe Chen, Sha Fu, Qiuyan Huang, Wenjuan Yu, Anping Xu. *Sun Yat-Sen University Sun Yat-Sen Memorial Hospital, Guangzhou, China.*

Background: Acute kidney disease (AKD) proposed in 2012 by KDIGO is getting more and more attention for its vital role in acute kidney injury (AKI) to chronic kidney disease (CKD) transition. However, no study has explored the incidence, risk factors of AKD and its impact on new-onset CKD after microinvasive radical cystectomy(RC).

Methods: The medical records of 308 patients at our hospital between January 2014 and May 2019 were reviewed. We excluded 29 patients from the study due to missing SCr preoperatively or postoperatively. AKD was diagnosed as a ≥35% decrease in eGFR or >50% increase in SCr between 7-90 days after surgery. AKI alone was defined by the 2012 KDIGO classification but failed to meet AKD criteria after 7 days. No kidney disease (NKD) was defined if patients didn't meet either criteria. Logistic regression model was used to explore risk factors of AKD, while its significance for CKD was assessed using Kaplan-Meier analysis and Cox model.

Results: We evaluated 279 bladder cancer patients, including 168 for Robotic-assisted Laparoscopic RC and 111 for Laparoscopic RC. The incidence of AKD was 14.7% whereas AKI alone was 13.6%. Risk factors for AKD included chemotherapy (odds ratio [OR]=3.245,P=0.024), robotic RC(OR=2.437,P=0.029)and operation time (OR=1.005,P=0.012). Of 150 patients without CKD history, CKD developed in 62.5% of patients with AKD,33.3% with AKI alone and 30.6% with NKD during the 30 months follow up (p=0.013). K-M analysis showed AKD patients had the highest CKD incidence(Fig.1). Cox model also identified AKD (HR=2.224,p=0.012) but not AKI alone, was independent risk factor predicting CKD, along with age.

Conclusions: The incidence of AKD was higher than AKI alone after microinvasive RC and resulted in higher risk of new-onset CKD compared with No-AKD. This persistent or repetitive injury is significantly associated with CKD.Hence, interventions for AKD are needed to improve outcomes.

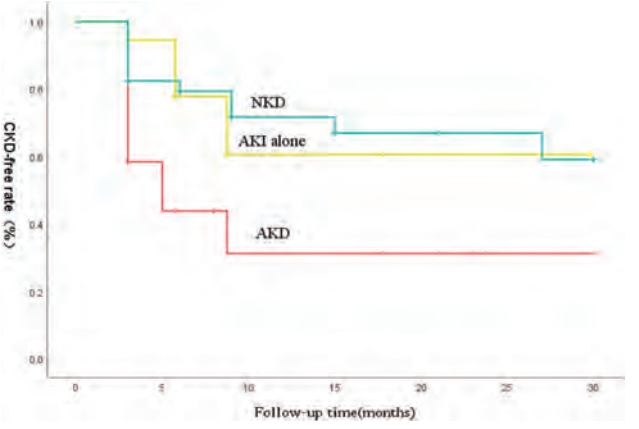

Figure 1. Kaplan–Meier analysis

Comparative Analysis of Characteristics and Survival Outcomes of Clear Cell and Sarcomatoid Subtypes of Renal Cell Carcinoma: Results from the SEER Database 2000-2017

Doaa Attia,[3,1] Tapas Ranjan Behera,[3,1] Sara A. Attia.[2] *[1]Taussig Cancer Institute, Cleveland, OH; [2]Northeastern University, Boston, MA; [3]Cleveland Clinic, Cleveland, OH.*

Background: Renal cell carcinoma (RCC) accounts for more than 90% of kidney cancers. Clear cell RCC (ccRCC) is the commonest type, while sarcomatoid RCC(sRCC) is rare and constitutes 5% of all RCCs. sRCC is known for aggressive clinical course and poor prognosis. In this study, we sought to compare the epidemiological features and survival trends of ccRCC with sRCC, using SEER dataset 2000-2017.

Methods: The Surveillance, Epidemiology and End Results (SEER) database was used to identify all adult patients (≥18 years) diagnosed with ccRCC and sRCC between 2000 and 2017. Variables included age, sex, ethnicity, laterality, staging, histological grade, and nephrectomy. Overall survival was estimated using the Kaplan-Meier method, and compared using the Log-Rank test. Multivariable covariate-adjust cox models were used for adjusted survival analyses.

Results: A retrospective cohort study of 20248 patients (19398 ccRCC, 850 sRCC) with overall survival rate of 38% (40% ccRCC and 16.2%ssRCC). Although the two subtypes share similar demographic characteristics, including mean age (66.8±13.7 for ccRCC vs 62.9±12 for sRCC), male-female ratio (1.71:1 vs 2.3:1), and having caucasian race more affected (79% vs 82%), sRCC had a significantly worse prognosis in univariate analysis with median overall survival of 7 months vs 30 months for ccRCC. Caucausian male patients were more affected in both types. But neither sex nor race significantly affected survival in sRCC (P 0.814, 0.794 respectively), however, black americans have worse outcomes in ccRCC (HR 1.123[1.083-1.163], $P < 0.001$). On multivariate

regression analysis, advanced stage, high histological grade, and older age 65+years (HR 1.002, 95%CI [1.001-1.00], P < 0.001) were associated with worse outcomes. Patients with cancer-related death had significantly shorter survival time in both RCCs (P<0.001). Nephrectomy was associated with better survival outcomes (HR 0.486 [0.459-0.514], P < 0.001).

Conclusions: sRCC had worse prognosis. Advanced stage, high histological grade, and older age are the most important predictors of survival in both subtypes of RCC. Although caucasian male patients were more affected in sRCC, gender and ethnicity have no impact on survival. Nephrectomy imparts better survival benefits in both subtypes.

PO2179

Acid-Base Biomarkers and Cancer Mortality

Ashish Verma,[1] Sonu Subudhi,[2] Ankit B. Patel,[1] Maria Clarissa Tio,[1] Sushrut S. Waikar.[3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Boston University Medical Campus, Boston, MA.*

Background: Acidosis in the tumor microenvironment is associated with cancer progression in animal models. We explored the association of serum bicarbonate and anion gap – measures of acid-base balance -- with cancer mortality in community-dwelling adults.

Methods: We conducted a prospective cohort study using the National Health and Nutrition Examination Survey (NHANES), a nationally representative cross-sectional survey of the US non-institutionalized population. Anion gap (mEq/L) was calculated as serum sodium (mmol/L) – (serum chloride (mmol/L) + serum bicarbonate (mmol/L). We used weighted Cox proportional hazards models to assess the associations between serum bicarbonate and anion gap with cancer-specific mortality, as recorded by the National Death Index. Multivariable models were adjusted for demographics data, BMI, smoking status, diabetes, systolic blood pressure, cardiovascular disease history, ACEi/ARB, diuretics, HIV drugs, metformin, serum albumin, total cholesterol, total protein, total calorie intake, hemoglobin, cancer diagnosis, eGFR and urine albumin to creatinine ratio.

Results: This study included total 39,137 participants [mean (SD) age, 46.83(19.25) years, 20,162(51.5%) females, 18,119 (46.3%) white]. During 4,433,277 person-years of follow up, 964 (2.46%) participants died secondary to cancer. A history of cancer at the time of enrollment was reported in 3186 (8.8%). Table 1 shows the associations between serum bicarbonate and anion gap in tertiles with cancer-related mortality. In analyses restricted to those with a history of cancer, results were 78% increased risk for cancer mortality in highest tertile compared to lowest tertile [HR 1.78; 95% CI (1.11,2.87)].

Conclusions: Increased anion gap may be a risk factor for cancer mortality. The reasons driving this association deserve further examination.

Risk of cancer mortality according to bicarbonate and anion gap as tertiles (method = weighted survey cox regression)

	Unadjusted hazard ratio	Adjusted hazard ratio
Bicarbonate T1 (10-22 mmol/l)	0.92 (0.75,1.12)	1.21 (0.94,1.57)
Bicarbonate T2 (22-26 mmol/l)	Reference	Reference
Bicarbonate T3 (26-43 mmol/l)	1.42 (1.18,1.7)	1.04 (0.82,1.32)
Anion gap T1 (< 10 mmol/l)	Reference	Refrence
Anion gap T2 (10-12 mmol/l)	1.12 (0.91,1.36)	1.21(0.94,1.57)
Anion gap T3 (> 12 mmol/l)	1.24 (0.99,1.56)	1.59 (1.21,2.07)

PO2180

In-Hospital and 1-Year Mortality Among Patients with AKI and Haematological Malignancies

Inês D. Coelho,[1] Teresa Chuva,[2] Hugo Ferreira,[2] Ana M. Paiva,[2] José M. Costa.[2] *[1]Hospital Amato Lusitano, Castelo Branco, Portugal; [2]Instituto Portugues de Oncologia do Porto Francisco Gentil EPE, Porto, Portugal.*

Background: Patients with haematological malignancies (HM) are at high risk for acute kidney injury (AKI), which is associated with high morbidity and mortality. The aim of this study was to identify the prognostic factors for in-hospital mortality and one-year mortality in this population.

Methods: We conducted a single centre, retrospective, observational cohort study of 101 in-hospital patients with AKI and HM between 1 January 2015 and 31 December 2019. We recorded essential demographic, clinical and laboratory data at baseline, 1 and 12 months. We classified AKI according to the KDIGO definition. Cox proportional hazard model was applied to investigate the one-year mortality, and logistic regression analysis was used to assess the in-hospital mortality.

Results: The study population included 64 males and 37 females, with a mean age of 58.7 ± 16.8 years. Multiple myeloma was present in 30.7% (n=31) of the patients, followed by non-Hodgkin lymphoma (LNH) in 27,7% (n=28). 51,5% (n=52) were admitted to intensive care unit (ICU). 60,4% (n=61) needed renal support therapy (RST). Basal GFR, one-month GFR and one-year GFR were, respectively, 65.7 ± 28.9 mL/min/1.73m^2, 57.1 ± 28.5 mL/min/1.73m^2 and 54.9 ± 28.1 mL/min/1.73m^2. Mean length of in-hospital stay was 18 days (IQR 1-88). In-hospital death was 52.5% and after one year only 26 patients were alive. In multivariate analysis, the independent predictors for in-hospital mortality were invasive mechanical ventilation (IMV) (OR 49.53; 95% CI:9.17 – 267.57; p<0.001) and sepsis (OR 5.09; 95% CI:1.18 – 21.89; p=0.029). The C-statistic was 0.93 (95% CI: 0.87 – 0.98), indicating that the equation had a great discriminatory power. The independent predictors for one-year mortality were LNH (HR 2.78; 95% CI:1.53 – 5.05; p=0.001), cancer progression (HR 2.91; 95% CI:1.56 – 5.41; p=0.001) and IMV (HR 5.79; 95% CI:3.30 – 10.15; p<0.001.). Elevated levels of albumin at the time of AKI conferred a better prognosis (HR 0.63; 95% CI:0.42 – 0.95; p=0.027).

Conclusions: Our model showed that HM patients with AKI are at high risk of sepsis and IMV, resulting in elevated in-hospital death. Elevated levels of albumin at the time of AKI correlated with a better one-year survival, while LNH, cancer progression and IMV were risk factors for death.

PO2181

Renal Recovery from AKI After Hematopoietic Stem Cell Transplant: A Systematic Review and Meta-Analysis

Karthik Kovvuru,[1] Swetha Rani Kanduri,[1] Wisit Cheungpasitporn,[1] Charat Thongprayoon,[2] Juan A. Medaura,[1] Kianoush Kashani.[2] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Patients with the recovery of renal function after an episode of acute kidney injury (AKI) have better outcomes compared to those without recovery. The current systematic review is conducted to assess the rates of kidney function recovery among patients with AKI or severe AKI requiring RRT within 100 days after hematopoietic stem cell transplant (HSCT).

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Databases were systemically searched from database inceptions through August 2019 to identify studies reporting the rates of recovery from AKI after HSCT. Random-effects and generic inverse variance method of DerSimonian-Laird were used to combine the effect estimates obtained from individual studies.

Results: A total of 458 patients from 8 cohort studies with AKI after HSCT were enrolled. Overall, the pooled estimated rates of AKI recovery among patients with AKI and severe AKI requiring RRT within 100 days were 58% (95%CI: 37%-78%) and 10% (95%CI: 2%-4%), respectively. Among patients with AKI recovery, the pooled estimated rates of complete and partial AKI recovery were 60% (95%CI: 39%-78%) and 29% (95%CI: 10%-61%), respectively. There was no clear correlation between study year and the rate of AKI recovery (p =0.26).

Conclusions: The rate of recovery from AKI after HSCT depends on the severity of AKI. While recovery is common, complete recovery is reported in about two-thirds of all AKI patients. The rate of recovery among those with AKI requiring RRT is substantially lower.

Table 2. Forest plots of the involved studies assessing renal recovery rates from AKI after HSCT

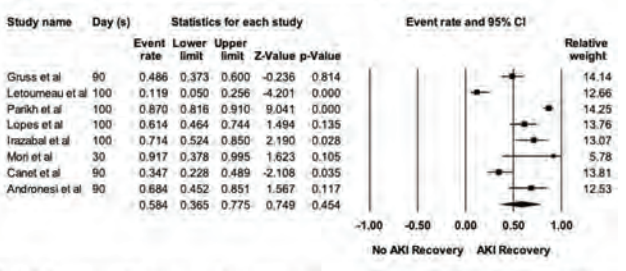

Table 3. Forest plots of the involved studies assessing renal recovery rates from severe AKI requiring RRT after HSCT

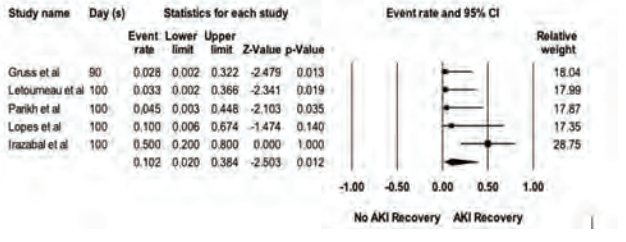

PO2182

Renal Outcomes After Autologous Stem Cell Transplant for AL Amyloidosis

Naresh Bumma, Michael Ozga, Isabelle Ayoub, Salem Almaani, Nidhi Sharma, Yvonne A. Efebera, Samir V. Parikh. *The Ohio State University, Columbus, OH.*

Background: Renal involvement in AL Amyloidosis is common and results in end-stage kidney disease (ESKD) in 30% of cases within 3 years of diagnosis. Newer therapeutic regimens directed at the plasma cell clone including high-dose melphalan with autologous stem cell transplantation (ASCT) are associated with improved survival but effect on renal outcome is not well established. We evaluated renal outcomes for patients who underwent ASCT and achieved a complete (CR) or very good partial (VGPR) hematologic response.

Methods: We performed a retrospective analysis of 50 AL Amyloidosis patients who underwent ASCT. Patients with renal involvement who achieved a hematologic response were included. Renal response was defined prior to transplant, according to consensus guidelines, as partial response (PR, > 30% decrease in proteinuria) or stable disease (SD, ≤ 30% proteinuria reduction). Primary endpoints were progression free survival (PFS) and overall survival (OS). PFS and OS were defined as the time from transplant to day of progression or death, respectively. Kaplan-Meier survival function estimated the PFS and OS. The log-rank test tested the equality of survivor functions between different groups of patients

Results: Following ASCT, 16 patients (32%) achieved hematological VPGR/CR after ASCT. All had renal involvement. Baseline and 1-year post-transplant proteinuria and serum creatinine (SCr) levels are shown in the Table. In the group of pts achieving VGPR/CR as hematological response PFS and OS were similar for patients having PR and SD as renal response (p=0.89 and p=0.44, respectively). No patients required hemodialysis. Median follow up for PFS was 4.1 years and for OS was 5.6 years (PR) and 11.9 years (SD).

Conclusions: Hematological response is important in AL amyloidosis and survival improves similarly with VGFR and CR. In patients with renal involvement, this study shows similar outcomes to patients who achieved a PR or SD as renal response prior to ASCT. However, our study has a small sample size and we would recommend a larger study.

RENAL RESPONSE METRICS PRE AND POST ASCT

		Partial Response (n=6)	Stable Disease (n=10)
AT DIAGNOSIS	Median 24hr Proteinuria g/d (range)	8.0 (1.9-11.3)	7.2 (2.0-15.0)
	Median SCr mg/dl (range)	3.0 (0.8-4.2)	1.3 (0.7- 4.8)
1 YR POST TRANSPLANT	Median 24hr Proteinuria mg/d (range)	2.5 (0.7-2.5)	2.2 (1.5-4.9)
	Median SCr mg/dl (range)	1.7 (0.5-3.1)	1.6 (0.6- 3.6)

Median serum Creatinine prior to ASCT in PR group was 1.2 mg/dl and 2.0 mg/dl in SD group.

PO2183

High-Dose Methotrexate (HDMTX) and Nephrotoxicity: Effect on Subsequent Dosing

Darragh O'Donoghue, Huong L. Truong, Heidi D. Finnes, Jennifer McDonald, Nelson Leung. *Mayo Clinic Minnesota, Rochester, MN.*

Background: HDMTX is an important part of various chemotherapeutic protocols due to its central nervous system penetrance. A key complication of HDMTX is nephrotoxicity as this leads to delayed MTX excretion and further morbidity. Nephrotoxicity in a previous cycle of HMDTX leads to an increased risk of future toxicity. Our aim was to establish how nephrotoxicity affected clinical decision making with regards to future dosing

Methods: A retrospective review of the electronic medical record was perfoemd to identify patients who developed nephrotoxicity post HDMTX from 1/1/02 to 12/31/18. We stratified the effect of nephrotoxicity by grade of AKI, according to the acute kidney injury network criteria, on resumption of MTX. In those who received a subsequent dose, we assessed whether a dose reduction have an impact on rate of Nephrotoxicity. Analysis was performed in Minitab.

Results: We identified 670 episodes of nephrotoxicity which equated to an overall incidence rate of 19% of total cycles. The majority were AKI grade 1 (79.7%). Higher grade AKI were significantly less likely to receive a future dose (p<0.001), with 71.3% of AKI N1, 59.2% of AKI N2, and 21.2% of AKI N3. Other factors associate with future dosing included elevated 48-hour MTX level (p<0.001), admission to ICU (p<0.001), and prolonged Hospital LOS (P=0.009). 449 patients received a future dose of Methotrexate with 152 (33.9%) receiving a reduced dose. The overall incidence of AKI with subsequent dosing was 33.85%. The incidence of AKI in subsequent dosing was 35.5% with no dose reduction compared to 30.3% with a dose reduction (p=0.29) (see table 1 for breakdown).

Conclusions: Nephrotoxicity had an important impact on subsequent dosing, especially with higher grade AKI. Previous AKI infers a higher rate of nephrotoxicity in future dosing with no significant reduction in incidence with reduction in MTX dose. Given the retrospective nature of the data and the many complexities to dosing calculation, this should be further explored with a prospective study.

Effect on dose reduction on subsequent AKI

	No AKI	AKI N1	AKI N2	AKI N3	Total
No dose reduction	196 (64.5%)	89 (29.3%)	18 (5.9%)	1 (0.3%)	304
Dose reduction	101 (69%)	37 (25.5%)	6 (4.1%)	1 (0.7%)	145

PO2184

Nephrology and Hematology Referral Trends in CKD Patients with Monoclonal Gammopathy and Factors Associated with Deferring Kidney Biopsy

Nattawat Klomjit,[1] Ladan Zand.[1,2] *[1]Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; [2]Division of Nephrology and Hypertension, Department of Medicine, University of Minnesota, Minneapolis, MN.*

Background: Many patients with CKD are managed by their primary care providers (PCP). The presence of monoclonal gammopathy (MG) in the setting of CKD raises the possibility of monoclonal gammopathy of renal significance (MGRS) which would require a nephrology or hematology referral. However, rate and factors that affect specialist referral in this population remains unknown. Moreover, factors for deferring a kidney biopsy are also unknown.

Methods: We retrospectively identified adult CKD patients with MG at our center from 2017-2018. Baseline characteristics and laboratories studies were compared between nephrology/hematology referral group (RG) vs. no referral group (NRG). We also assessed the rate of kidney biopsy and the reasons for not pursuing a biopsy in the referral group.

Results: We identified 596 CKD patients with MG. Of these, 416 (69.8%) were seen by nephrologis/hematologist & 180 (30.2%) were not referred to either. Of the 180, 32% were followed by their PCP (n=57), 30% by cardiologist (n=54), and 19% by neurologist (n=35). Demographics were similar between the two groups. Patients in the NRG were more likely to have coronary artery disease, dementia, active or metastatic cancer. In multivariate analysis, 24-hr urinary protein (OR: 1.36 (1.01, 2.09)), abnormal FLC (OR 2.46 (1.29, 4.93)), and serum creatinine (OR 2.38 (1.37, 4.59)) were strong independent predictors for referral. Of 416 patients in RG, 62 (15%) patients underwent a kidney biopsy and 26 had an MGRS lesion. There were no differences in the comorbidities between the patients that were biopsied vs. those that were not. The main reason for deferring biopsy was lack of awareness of CKD or MG (142, 40%) and low suspicion for MGRS (130, 37%). In 62 patients, biopsy was not pursued as it was unlikely to change management (majority had amyloidosis). Other reasons included watchful waiting and patients' frailty.

Conclusions: Up to 30% of CKD patients with MG are not referred to a specialist. Co-morbidities lower the rate of referral whereas impaired kidney function and higher M-spike & FLC increase referral. However, once patients are referred, the comorbidities had no impact on who underwent biopsy. Most common reason for not pursuing a biopsy was lack of awareness that patient had CKD or MG.

PO2185

Efficacy of Early Use of Double Filter-Based Extracorporeal Treatment Combined with Chemotherapy in Acute Myeloma Kidney

Fulvia Zappulo,[1] Gabriele Donati,[1] Elisa Maietti,[2] Anna Scrivo,[1] Giorgia Comai,[1] Olga Baraldi,[1] Lorenzo Gasperoni,[1] Lucia Pantani,[3] Elena Zamagni,[3] Gaetano La Manna.[1] *[1]Nephrology Dialysis and Renal Transplantation Unit, S.Orsola University Hospital, Bologna, Italy; [2]Biomedical and Neuromotor Sciences University of Bologna, Bologna, Italy; [3]Hematology and Oncology Unit, L. & A. Seràgnoli, S.Orsola University Hospital, Bologna, Italy., Bologna, Italy.*

Background: Before the introduction of modern chemotherapy, less than 25% of patients with AKI and Multiple Myeloma (MM) who required dialysis recovered sufficient renal function to no longer be dependent on dialysis, with a median overall survival of less than 1 year. Although impaired renal function has been a marker of poor prognosis there are may others factor involved in determining patient survival. We aimed to investigate the factors related to renal recovery and to an higher survival rate in MM patients.

Methods: A monocentric retrospective study was carried out enrolling 23 patients with biopsy-proven acute myeloma kidney and sFLC levels >1000 mg/l. Patients received Bortezomib-based chemotherapy and extracorporeal treatment for sFLC removal. For each session 2 dialyzers of the same kind were used and the dialytic dose was only related to the sFLC removal. The dialyzers had high absorptive properties: PMMA (polymethylmetacrylate; Filtryzer BK-F 2.1 m2 cut-off 20 kDa); PEPA (poly ester polymer alloy; FDX or FDY 210-GW 2.1 m2, cut-off undisclosed).

Results: The factors that have been found to be significantly and independently associated with higher survival rate were: baseline serum albumin, reduction of sFLC at day 12 and day 30, reduction of sFLC at day 30 above 50%, number of session and dialysis independence.

Conclusions: Our analysis highlights the importance of the early treatment for removal of sFLC in AKI for MM. In fact the variable associated with higher survival rate are the reduction of sFLC at day 12 and at day 30 and number of session. These results indicate that the early removal of sFLC can guarantee a better outcome. Baseline serum albumin is also associated with survival rate and it demonstrates that it still carries a prognostic value in the population with AKI. This finding suggests the importance of albumin-sparing extracorporeal treatments. In fact alternative techniques, as HD-HCO, have been proposed for sFLC removal but they present high costs and albumin leakage.

Table 1: Basal patients' characteristics and 1-year survival.

	HR	[95% CI]	P
Sex	0.38	0.08 – 1.88	0.236
Age	1.04	0.96 – 1.12	0.317

PO2186

Daratumumab for Management of Bortezomib-Resistant Monoclonal Gammopathy of Renal Significance

Salem Almaani, Samir V. Parikh, Naresh Bumma, Nidhi Sharma, Yvonne A. Efebera, Isabelle Ayoub. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: The management of monoclonal gammopathy of renal significance (MGRS) is challenging. In our center, MGRS patients are initially treated with a bortezomib-based regimen. Patients who do not respond have very limited therapeutic options. Daratumumab is an anti-CD38 monoclonal antibody that is being increasingly used in patients with multiple myeloma with a favorable adverse effect profile, and represents a potential therapeutic option for patients with MGRS.

Methods: Retrospective review of the use of daratumumab in management of patients with bortezomib-resistant MGRS.

Results: Five patients were treated with daratumamab after receiving a variety of immunomodulatory therapies (Table 1). All received bortezomib with no response. One patient had a dramatic improvement in proteinuria with a stable renal function. One patient had resolution of glomerular monoclonal protein deposits but had persistent proteinuria due to significant damage to the glomerular basement membrane. One patient suffered from an acute kidney injury due to acute tubular necrosis (noted on biopsy) and became dialysis dependent. Two patients were started on daratumumab recently and had limited follow up, however both demonstrated a reduction in proteinuria. Daratumumab was well-tolerated and no patients required hospitalization due to adverse effects.

Conclusions: Our experience in using daratumumab for management of bortezomib-resistant MGRS suggests good tolerability and short-term response rates.

PO2187

Diffuse Background Monoclonal Light Chain Staining in Kidney Biopsies, Without Electron Dense Deposits: Is It Relevant?

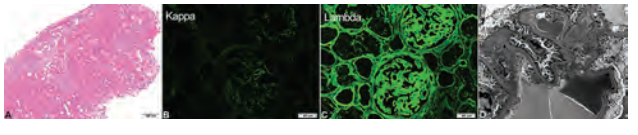
Anjali A. Satoskar,[1] Ahlim Al sanani,[2] Sergey V. Brodsky,[1] Jason Prosek,[1] Isabelle Ayoub,[1] Tibor Nadasdy.[1] *[1]The Ohio State University, Columbus, OH; [2]Marshall University, Huntington, WV.*

Background: Pathologic diagnosis of monoclonal gammopathy (MIg)-associated kidney disease requires specific morphologic and immunofluorescence (IF) findings with deposits on electron microscopy. We have encountered kidney biopsies showing only diffuse "background" monoclonal light chain staining the renal parenchyma, without characteristic lesions of MIg-associated kidney disease or organized/non-organized deposits on ultrastructural examination. Such staining is either overlooked if weak, or can be over-diagnosed as MIg-associated kidney disease if strong, causing dilemma over the need for immediate clone-directed therapy. We performed a clinico-pathologic study to better understand its significance.

Methods: Database search over 12-year period revealed such 32 cases. Clinical and laboratory data was retrieved along with a mean follow-up of 13 months.

Results: Out of the 32 patients, 15 (47%) had active myeloma by hematologic criteria (despite absence of myeloma casts on kidney biopsy) warranting immediate clone-directed therapy; but 11 (34%) did not have/develop myeloma-defining events till the end of follow-up period; 3 (9%) did not have detectable paraprotein; and 3 (9%) were lost to follow-up. The mean staining intensity of background monoclonal light chain was significantly higher in myeloma patients as compared to the non-myeloma patients (2.2 vs 1.5, p=0.03), but strong (2 or 3+) intensity of staining was seen in 36% (5/14) of the cases without active myeloma (Fig. 1).

Conclusions: It is important to recognize and document this isolated background monoclonal light chain staining in the biopsy report, but by itself, should not be classified as MIg-associated kidney disease. It does warrant a thorough hematologic work-up. It can help to unmask (previously unsuspected) underlying active myeloma which many patients. But it is important to note that there is a subset of patients that do not have active myeloma despite the strong background staining. Care must be taken to avoid inadvertant immediate clone-directed therapy in these patients, but periodic monitoring with hematologic and renal parameters to watch for possible malignant transformation is important.



PO2188

Immune Checkpoint Inhibitor-Induced p-ANCA Multiorgan Vasculitis

Marelle Montanez,[1,2] Jamie Lin,[2] Omar Mamlouk,[1,2] Ala Abudayyeh,[2] William F. Glass.[1] *[1]University of Texas Health Science Center at Houston, Houston, TX; [2]University of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Use of immune checkpoint inhibitors (ICIs) has led to improved mortality in melanoma, lung cancer, and lymphoma. ICIs augment immunologic reaction against tumor cells via blockade of cytotoxic T-lymphocyte antigen-4 (CTLA-4), programmed cell death-protein 1 (PD-1), or programmed death-ligand 1 (PD-L1). Renal complications from ICI use are uncommon but can involve development of glomerular diseases and interstitial nephritis. Below we present a case of p-ANCA vasculitis in a patient on ICI therapy.

Case Description: A 52-year-old female with adenocarcinoma of the right lung (T2N2) s/p right lower lobectomy, cisplatin/vinorelbine, radiation therapy, and durvalumab was hospitalized for evaluation of new onset oral blisters, fevers, hemoptysis, skin lesions, and acute kidney injury. Her creatinine rose to 3.2 mg/dL (baseline of 0.5 mg/dL). Urinalysis revealed >180 RBCs and 17 WBCs per high power field with a urine protein to creatinine ratio (UPCR) of 2.63 g/g. ANCA titers were positive for PR-3 antibody of 4.6 units. Patient underwent renal biopsy, which revealed evidence of renal vasculitis involving all glomeruli and crescents in 4 out of 20 glomeruli. There was concern for endocarditis with vegetation seen on echocardiogram; however, with negative blood cultures the etiology was attributed to autoimmunity (vasculitis) rather than infection. The patient was aggressively treated for ANCA vasculitis with pulse steroids, plasmapheresis, and rituximab (1g given 2 weeks apart). She had a dramatic improvement in her skin lesions, hemoptysis, cardiac and renal function. Two months following her last rituximab infusion, she has not had further hematuria, her UPCR remains < 0.5 g/day, and creatinine is stable at 1.2 mg/dL. PET/CT continues to demonstrate clinical remission of her underlying cancer.

Discussion: With the dramatic cancer responses seen in patients receiving immune checkpoint therapy, there has also increased understanding associated toxicities. Although reports of ANCA positive vasculitis from ICI has been reported; this case is unique due to the multiorgan involvement of her vasculitis including the heart valves. Aggressive treatment with steroids, plasmapheresis, and rituximab has proven effective without hindering her tumor response.

PO2189

IgA Nephropathy in the Setting of Dual Immune Checkpoint Inhibitor Use

Lorenz Leuprecht,[1] Steven Salvatore,[1] Victoria Gutgarts,[2,1] Ilya Glezerman.[2,1] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Acute kidney injury (AKI) is a recognized side effect of immune checkpoint inhibitors (ICPi), with acute tubulointerstitial nephritis (AIN) as the most common pathologic finding. Risk of AKI is higher with use of proton pump inhibitors (PPIs) and dual ICPi use. Glomerular disease with ICPi is infrequently found on kidney biopsy. We report a case of concomitant IgA nephropathy and AIN associated with dual ICPi blockade.

Case Description: 62-year-old male with metastatic sarcoma recently initiated on Ipilimumab and Nivolumab presented with dark colored urine for 2 days. He was recently hospitalized for neutropenic fevers with a negative infectious work up. On admission his blood pressure was 181/94 and he was afebrile. Physical exam was notable for new bilateral lower extremity edema, and no rash present. His creatinine was 2.2mg/dl (0.6-1.3), with a baseline creatinine of 0.8mg/dl. He started a PPI one month ago and denied NSAID use. Laboratory findings showed eosinophilia 7.7% (0.0-4.9) and urine eosinophils. His urinalysis had >50 RBCs and 5 WBCs per HPF and 24-hour urine protein was 5085mg. His serum complement levels were normal. Kidney biopsy showed moderate AIN and an exudative and mesangial glomerulonephritis with dominant IgA deposits. The patient was started on prednisone 60mg daily and PPI was stopped. No additional doses of immunotherapy were administered. His serum creatinine improved to 1.6mg/dl after 1 week, with plan for outpatient steroid taper. At 10mg prednisone daily, his creatinine increased to 4.5mg/dl prompting pulse steroids due to concern for ongoing interstitial inflammation versus worsening IgA nephropathy. One week later creatinine improved to 2.7mg/dl, though he developed several steroid related side effects. Due to inability to tolerate higher doses of steroids, mycophenolate was added to his treatment regimen while undergoing steroid taper.

Discussion: This case underscores the importance of considering acute glomerulonephritis as a cause for AKI in patients recently started on ICPi therapy. Risk of AKI in this patient was higher given use of PPI and dual ICPi therapy. This case is unique as the renal biopsy showed both AIN and IgA nephropathy. These findings had important implications for the treatment plan since the patient was unable to successfully stop prednisone and required a second immunosuppressive agent.

PO2190

Hypercalcemia Associated with Immune Checkpoint Inhibitors

Eshetu L. Obole, Isabelle Ayoub. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Immune checkpoint inhibitors revolutionized treatment of many cancers with marked improvement in prognosis. They target CTLA-4, PD-1/PD-L1 pathways. However immune related adverse events complicate their use. Here we present the first reported case of hypercalcemia as a result of immune checkpoint inhibitors

Case Description: A 68-year old man with metastatic renal cell carcinoma underwent right nephrectomy followed by immunotherapy with ipilimumab and nivolumab. Two weeks after his second cycle of immunotherapy, he presented with inflammatory arthritis and pruritis. Work up was significant for sCa 12.8 mg/dl and Scr 3.6 mg/dl. Hypercalcemia was suspected to be malignancy related from bone metastasis or humoral stimulation. He received fluids, calcitonin and Zoledronic acid. Further investigations showed a suppressed iPTH<6.3 pg/ml, normal PTrP, low TSH 0.04 uU/ml, free T4 1.91, normal 25-OH vitamin D, elevated 1,25dihydroxy vitamin D 142 pg/ml and normal ACE level. No monoclonal proteins were detected in serum. CRP and interleukin 6 were elevated to 80 mg/dl and 176 pg/ml respectively. PET scan showed diffuse hypermetabolic lymph nodes in mediastinum, neck, and abdomen. Transbronchial needle aspiration was negative for malignancy. Inflammatory arthritis, pruritis, hyperthyroidism, nonmalignant diffuse lymphadenopathy, and 1.25 dihydroxyvitamin D induced hypercalcemia are suggestive of immune related adverse effects rather than disease progression. Patient was started on prednisone 1mg/kg/d. Hypercalcemia, AKI, pruritis and inflammatory arthritis resolved. Repeat 1,25 dihydroxy vitamin D and CRP levels were back to normal

Discussion: Hypercalcemia related to checkpoint inhibitors was previously described in setting of increased PTrP. Our patient had hypercalcemia directly related to immunotherapy likely through increased alpha hydroxylation.

PO2191

Double Trouble with Pembrolizumab: Immune Checkpoint Inhibitor-Induced Type 1 Renal Tubular Acidosis and Secondary Adrenal Insufficiency

Dayyan M. Adoor, Hafsa Tariq, Arash Rashidi. *University Hospitals, Cleveland, OH.*

Introduction: Pembrolizumab is a novel immune checkpoint inhibitor (ICI) that targets programmed cell death protein (PD-1) signaling. Checkpoint inhibitor associated nephrotoxicity is an immune-mediated process that can manifest with a variety of clinical presentations. Here, we report a unique case of Pembrolizumab induced distal renal tubular acidosis (RTA) and secondary adrenal insufficiency (AI) which was successfully treated with steroids.

Case Description: A 72-year-old male with a history of stage IIIC malignant melanoma, who had recently completed 3 cycles of therapy with Pembrolizumab was admitted with generalized fatigue, weakness, and anorexia. Initial work up was notable for severe hyponatremia, and a non-anion gap metabolic acidosis (NAGMA); (Na: 120 mmol/L, Cl: 89 mmol/L, K: 3.8 mmol/L, HCO3: 20 mmol/L and creatinine 0.67mg/dL). Urine anion gap was positive at 8meq/L, urine osmolar gap was low at 57 mosm/kg and urine pH was 6.0. Subsequent laboratory work up was notable for AM cortisol of 1.0 ug/dL, serum ACTH 1.4 pg/mL and DHEA 12 ng/dl. Other pituitary hormones including LH, TSH and FSH were normal. An MRI of the sella was negative for hypophysitis. CT scan of the abdomen showed no adrenal hemorrhage or necrosis. Extensive serologic work-up including serum ANA, ANCA, anti-SSA/SSB, Hepatitis B, Hepatitis C, C3 and C4 levels were all unrevealing. A presumptive diagnosis of immune mediated central AI and distal RTA was made. A positive urine anion gap and low positive osmolar gap (<150mosm/kg) in the setting of NAGMA was highly suggestive of a distal RTA. Although this condition is associated with hypokalemia, simultaneous AI could have offset this finding. He was started on hydrocortisone 40 mg daily. This was accompanied by improvement in serum sodium and bicarbonate levels. Two days later, the patient's hyponatremia and metabolic acidosis had resolved. He was eventually discharged on a tapering dose of steroids.

Discussion: Recent studies have shown that acute interstitial nephritis is the most common type of Pembrolizumab associated nephrotoxicity. We report a novel case of Pembrolizumab toxicity, where distal RTA concurrently manifests with secondary AI. Rapid resolution of both these conditions upon initiation of steroids suggests that they are both immune mediated adverse effects associated with Pembrolizumab.

PO2192

Immune Checkpoint Inhibitor-Associated Reactivation of Primary Membranous Nephropathy Responsive to Rituximab

Jamie Lin,[1] Daniel Y. Wang,[2] Omar Mamlouk,[1] William F. Glass,[3] Ala Abudayyeh.[1] *[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]University of Texas Health Science Center at Houston, Houston, TX.*

Introduction: The same mechanisms that mediate immune checkpoint inhibitor (ICI) anti-tumor efficacy also increases the activity of the immune system and can lead to immune-related adverse events (irAEs). Those with preexisting autoimmune disease are particularly vulnerable. We report the first case of ICI associated reactivation of primary membranous nephropathy (MN) responsive to rituximab in a patient with mesothelioma and successful continued ICI treatment.

Case Description: A 60-year-old male with primary MN was diagnosed with stage IA malignant pleural mesothelioma (MPM) in September 2018. Shortly after receiving nivolumab his proteinuria began to increase and his nephrologist recommended conservative management. In November 2019, the patient came to nephrology clinic at MD Anderson Cancer Center for a second opinion. Notable labs included: albumin 1.9 g/dl, creatinine (Cr) 1.25 mg/dl (baseline Cr 0.82-0.91 mg/dl), and a 24-hour urine protein 13.4 g/day (<1.0 g/day prior to Nivolumab). Due to concern for reactivation of primary MN vs other causes, he underwent a renal biopsy which revealed chronic reactivated primary MN with strongly positive PLA2R stain. Consideration of immunosuppressive treatment options were discussed, and the patient was initiated on rituximab (1 g IV on Day 1 and 15), a monoclonal antibody binding specifically to CD20 on B cells. Labs one month later showed a Cr of 1.01 mg/dl, decrease in proteinuria by over 50% (4.6 g/day), and improved albumin to 2.9 g/dl. The patient restarted nivolumab in January 2020 and has stable to improved kidney function five months later. PET/CT imaging continues to demonstrate complete metabolic response and no new sites of increased FDG activity.

Discussion: Current guidelines for primary MN recommend therapy with cyclophosphamide and steroids, rituximab, or cyclosporine. All except for rituximab (in) directly suppress T cell function potentially impacting the anti-tumor effectiveness of ICI therapy. While the role(s) of B cells as pro- or anti-tumoral mediators in cancer and ICI is unknown, understanding B cell role(s) could be beneficial for those with autoimmune disease – allowing for split treatment should irAEs occur. Therapy for autoimmune reactivation should be directed by immunosuppressive mechanism in concert with goals of cancer treatment.

PO2193

Immune Checkpoint Inhibitor Therapy-Related Graft Intolerance Syndrome in a Failed Kidney Transplant Recipient on Hemodialysis

Christina Irene Mejia, Adam M. Frank, Pooja Singh, Anju Yadav. *Thomas Jefferson University, Philadelphia, PA.*

Introduction: Immune check-point inhibitors (ICPIs) are monoclonal antibodies against inhibitory receptors on T-cells resulting in anti-cancer activity. The use of ICPIs among kidney transplant (KT) recipients with cancer is controversial, as ICPIs counter immune tolerance and is associated with a higher risk of rejection in functioning allografts. In failed allografts, the effects of ICPIs are unknown. We present a unique case of a patient with a failed KT on maintenance hemodialysis (HD) who developed graft intolerance syndrome (GIS) after ICPI therapy for metastatic renal cell carcinoma (RCC).

Case Description: Our patient is a 66-year old male with a history of diabetes, RCC and left nephrectomy in 1996. He developed end-stage kidney disease and had a deceased donor KT in 2012. His graft failed 6 years post KT, due to biopsy-proven recurrent diabetic nephrosclerosis. He was started on HD in 2018 and immunosuppression was tapered off. In 2019, he was diagnosed with renal and urothelial cell cancer in the right native kidney and underwent nephrectomy. Ten months later, distant metastasis was detected, and he was started on Nivolumab and Ipilimumab. Twenty-eight days after his 1st cycle of immunotherapy, he had good oncological response, but developed gross hematuria, pain over his allograft, malaise, and anemia consistent with GIS. Urine culture and cystoscopy were normal. A computed tomography scan of the abdomen revealed an enlarged allograft with patchy enhancement and perinephric stranding consistent with GIS. After a multidisciplinary discussion, he underwent transplant nephrectomy. Histopathology revealed grade II chronic active T-cell mediated rejection (TCMR).

Discussion: Although acute graft rejection from ICPI therapy has been documented, this is the first known report of GIS developing with ICPI therapy in a failed allograft. GIS typically occurs within 6-12 months of graft failure. Meanwhile, in functioning allografts, rejection occurs around 24 days after ICPI initiation. The temporal relation of GIS to ICPI initiation in our patient suggests the potential role of the latter as a trigger for GIS. As ICPI use becomes more prevalent in cancer management, we need to be aware of the potential complications with its use among KT recipients even with failed allografts, which requires multidisciplinary management.

PO2194

Crescentic Glomerulonephritis and Phospholipase A2 Receptor-Positive Membranous Nephropathy in a Lung Cancer Patient on an Immune Checkpoint Inhibitor

Matthew Abramson,[1] Surya V. Seshan,[2] Insara Jaffer Sathick.[1,2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medicine, New York, NY.*

Introduction: Acute kidney injury (AKI) occurs in 3% of patients on immune checkpoint inhibitors (ICPI), usually due to interstitial nephritis, yet the array of ICPI-mediated AKI is not fully understood, with rare reports due to Crescentic Glomerulonephritis (cGN). To date there is no known case of PLA2R-positive Membranous Nephropathy (MN) associated with ICPI. Here we report the first case of ANCA-negative cGN with PLA2R MN, which developed after initiation of ICPI, with response to rituximab (RTX).

Case Description: Nephrology was consulted for AKI and hematuria in a 67-year-old male smoker with lung adenocarcinoma. He started on pembrolizumab and pemetrexed 8 months ago, last doses 3 weeks prior to consult. He developed throat irritation from local irradiation, and pantoprazole was initiated. No NSAIDs, herbal medications or iodinated contrast exposure. Prior to treatment, baseline Creatinine (Cr) was 0.8mg/dL and urinalysis (UA) was negative for albuminuria. Blood pressure was 112/66, and no edema was present. Cr was elevated at 3.7 mg/dL. UA showed 3+ protein, >50 RBC, 10-25 WBC, and no pathologic casts. Renal sonogram was normal. Urine protein:creatinine ratio (UPC) was 1.52g/g. Complements were normal. Serology workup (pANCA/cANCA/MPO/PR3, ANA, anti-PLA2R) was negative. Kidney biopsy showed diffuse cGN [Glomeruli: necrosis (2/38), cellular crescents (10/38), and fibrocellular

crescents (6/38)], diffuse PLA2R-positive glomerular deposits, focal tubular atrophy, and minimal interstitial fibrosis/inflammation. EM showed thickened basement membranes, focal subepithelial granular deposits and early spike formation, and 30% foot-process effacement. ICPI was discontinued and prednisone 60mg daily was started. Cr nadir'ed at 2.3mg/dL, but uptrended to 3.1mg/dL over 4 weeks; UPC increased to 2.59. He then received 4 doses of RTX over 8 weeks and was started on vinorelbine. UPC and Cr improved to 2.18 and 2.5mg/dL, respectively, and NSCLC disease stabilized.

Discussion: Interstitial nephritis is often implicated in AKI related to ICPIs, but rarely other pathologies are reported. Renal biopsy should be considered in patients with atypical features suggestive of GN. Given that our patient's biopsy showed cGN and PLA2R MN, we opted to treat with RTX, which has resulted in improvement in renal function and proteinuria.

PO2195

Diffuse Large B-Cell Lymphoma Presenting with Light Chain Cast Nephropathy: A Case Report

Sheng-Li Cho,[1] Hao-Yu Wu,[1] Tai-Chung Huang,[1] Tzong-Shinn Chu,[1] Taomin Huang.[1,2] *[1]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [2]Department of Epidemiology and Preventive Medicine, National Taiwan University College of Public Health, Taipei, Taiwan.*

Introduction: Light chain cast nephropathy is caused by filtration of excessive amounts of free light chains into the renal tubules, leading to acute kidney injury (AKI). The main associated malignancy is multiple myeloma (MM). No adult case of cast nephropathy associated with diffuse large B-cell lymphoma (DLBCL) was reported

Case Description: A 55-year-old previously healthy man presented with foamy urine for 3 months and exercise intolerance. Physical exam showed pale conjunctiva, multiple neck masses, and no edema. His serum creatine (SCr) was 7.6 and 15.2 mg/dL initially and on admission 4 weeks later, whereas baseline SCr had been normal one year ago. His hemoglobin level was 7.9 g/dL, and white blood cell count was 8750/μL without eosinophilia. No active urine sediments were found. A UPCR was 7250 mg/g, and a UACR 300 mg/g. Ultrasound showed decreased kidney sizes (R 9.0, L 9.7 cm). Immunoelectrophoresis detected monoclonal λ light chain in both his serum and urine, and a serum λ free light chain level was 8830 mg/L, with a κ-to-λ ratio of 0.0024. Following a diagnosis of DLBCL (Lugano stage IV) by neck mass biopsy, a renal biopsy disclosed diffuse aggregation of amorphous eosinophilic proteinaceous casts in the tubules, with a normal glomerular compartment and mild arteriosclerosis, findings consistent with IgG-λ light chain cast nephropathy. He was treated with 4 courses of R-CHOP, hemodialysis, and a short course of plasmapheresis. λ free light chain level decreased to 2830 mg/L after plasmapheresis. A complete response for DLBCL was achieved 6 months later but he remained on hemodialysis.

Discussion: This is, in the literature, the first adult DBLCL patient presenting with proteinuria and renal deterioration proven to be light chain cast nephropathy. Standard lymphoma treatments were given, and based on limited evidence, plasmapheresis was given to reduce the light chain load (Median serum free light chain level was 6590 mg/L in MM patients as reported by Bridoux in JAMA 2017). Decreasing plasma light chain concentration leading to improvement in AKI has been reported for MM. However, this case remained dialysis-dependent despite a decline in light chain levels. To conclude, we provide a unique case of DLBCL with cast nephropathy. Clinicians could take this entity into consideration and treatment may be tailored for better outcomes.

PO2196

A Case of Mixed Cryoglobulinemia Type II with Monoclonal Gammopathy in a Patient with Chronic Hepatitis B

Hui Zhuan Tan, Chandramouli Nagarajan, Alwin Hwai Liang Loh, Riece Koniman, Jason Choo Chon Jun. *Singapore General Hospital, Singapore, Singapore.*

Introduction: Non-Hepatitis C related mixed cryoglobulinemia Type II (MCT2) is rare. Causes include lymphoproliferative disorders, chronic infections like Hepatitis B and autoimmunity.

Case Description: A 68-year-old Chinese male presented with livedo reticularis and rapidly progressive glomerulonephritis requiring dialysis, on a background of chronic Hepatitis B (HBV) infection. Investigations showed a uPCR of 9.75g/g and serum creatinine (sCr) of 407 μmol/L (baseline sCr 82μmol/L). Rheumatoid factor was positive (>650U/ML). Both C3/C4 were low. HBV viral load was detected at 479, 452 copies/ml, while HCV, HIV and autoimmune screen were negative. A IgM kappa monoclonal band (3g/L) was detected on serum protein electrophoresis and immunofixation. Renal biopsy revealed MPGN with 28% crescents, capillary luminal hyaline thrombi, and IgM Kappa deposits. Findings were consistent with MCT2 despite negative serum cryoglobulins. Bone marrow aspiration and biopsy revealed a small clonal B-cell population confirmed on flow cytometry. Pulsed methylprednisolone followed by high-dose prednisolone, Rituximab and plasmapheresis were initiated for organ-threatening disease, together with entecavir. HBV viral suppression was observed after 1 month. Partial remission was achieved (sCr 140μmol/L; uPCR 2.39g/g) after 4 months. Development of sepsis and CMV reactivation prompted withdrawal of steroids, resulting in progressive deterioration of renal function (sCr 302μmol/L; uPCR 10.62 g/g). Commencement of Bortezomib and dexamethasone resulted in gradual improvement of renal function (sCr 107μmol/L; uPCR 4.71 g/g) after 3 cycles.

Discussion: MCT2 observed in our patient was possibly contributed by chronic HBV. However, suboptimal response despite HBV viral suppression prompted further treatment of the underlying lymphoproliferative disease causing monoclonal gammopathy of renal significance. Optimal treatment of MCT2 is not established, although immunosuppression consisting of corticosteroids with Rituximab or cyclophosphamide is required in severe renal involvement. We demonstrated a favourable outcome with Bortezomib-based clone directed therapy after achieving a non-sustained response with Rituximab/prednisolone. Long-term monitoring of the underlying low grade non-Hodgkin's lymphoma (NHL) is necessary.

PO2197

Myeloma Cast Nephropathy with Diffuse Amyloid Casts: Two Case Reports and Literature Review

Zihao Yong,[1,3] Yu Xiaojuan,[1] Su-xia Wang,[1,2] Ming Hui Zhao.[1,3] *[1]Renal Division, Department of Medicine, Peking University First Hospital; Institute of Nephrology, Peking University; Renal Pathology Center, Institute of Nephrology, Peking University; Key laboratory of Renal Disease, Ministry of Health of China; Key Laboratory of CKD Prevention and Treatment, Ministry of Education of China;, Beijing, China; [2]Laboratory of Electron Microscopy, Pathological Centre, Peking University First Hospital, Beijing, China; [3]Peking-Tsinghua Center for Life Sciences, Beijing, China.*

Introduction: Multiple myeloma (MM) is a plasma cell derived hematologic malignant disease. The malignant proliferating plasma cells can secrete massive monoclonal immunoglobulins which can cause various pathologic types of renal injury. Myeloma cast nephropathy (MCN) is the most common pathologic lesion with the worst renal prognosis. Rarely, the free light chains in the protein casts can form amyloid fibrils. Here, we report two rare cases of myeloma cast nephropathy with diffuse amyloid casts.

Case Description: Case 1: A 54-year-old Chinese man presented with a 4-year history of multiple myeloma, proteinuria and hematuria. He had Monoclonal IgAλ plus free λ spike in both serum and urine. He was treated with chemotherapy. His serum creatinine was normal until 11 months before admission, and he was on hemodialysis 1 month before admission. Renal biopsy showed diffuse amyloid casts in the tubular lumens, and he had no obvious amyloid deposits in other kidney compartments and no sign of extra-renal amyloidosis. The amyloid fibrils formed around mononuclear cells which were CD68 negative. The patient was maintained on chemotherapy and hemodialysis, and he died 8 months after renal biopsy. **Case 2:** A 58-year-old Chinese man presented with a one-and-a-half-year history of proteinuria and slowly rising serum creatinine. He had Monoclonal IgDλ spike in both serum and urine. Amyloid casts were observed in the tubular lumens and in the centre of some casts were mononuclear cells. There were no amyloid deposits in other kidney compartment and no sign of systemic amyloidosis. The patient also had fine granular deposits along the tubular basement membrane with λ linear staining along tubular basement membrane suggesting light chain deposition disease. The patient was treated with bortezomib-based followed by lenalidomide-based chemotherapy and achieved very good partial remission (VGPR). After twenty-seven months of follow-up, the patient still had no sign of systemic amyloidosis.

Discussion: These 2 cases of MCN with diffuse amyloid casts have different pathologic characteristics from the usual myeloma casts and tubular epithelial cells may play important roles in the pathogenesis.

PO2198

Masked Light Chain Proximal Tubulopathy (LCPT) and Focal Segmental Glomerulosclerosis (FSGS) in Multiple Myeloma (MM)

Matthew Abramson,[1] Surya V. Seshan,[2] Carlos D. Flombaum.[1,2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medicine, New York, NY.*

Introduction: Patients with MM often do not have a myeloma-defining disease, and delayed recognition/treatment of a monoclonal gammopathy of renal significance (MGRS) may confer worse renal outcome. Here we report 3 patients with "masked" LCPT (one also had FSGS) and a 4th patient with both FSGS and LCPT. None had crystalline deposits. All 4 patients had a history of untreated, smoldering MM and the initial kidney biopsy interpretation in 3 of the cases reported no evidence of MGRS. Treatment of the underlying MM resulted in improvement of renal parameters in all, suggesting MM as the etiology for the renal disease.

Case Description: 73 y/o, worsening renal function (WRF), albuminuria and monoclonal proteinuria (MP). Biopsy: FSGS. Initial immunofluorescence (IF) was negative. Re-examination after protease digestion 6 months later: LCPT. Therapy for MM resulted in decreasing free light chains (FLCs), improvement of renal function, and decreased albuminuria and MP. 72 y/o, WRF and albuminuria. Biopsy: FSGS and LCPT attributed to MM. Therapy for MM resulted in decrease in FLCs, stabilization of renal function and decreased albuminuria. 75 y/o, WRF and heavy MP. Biopsy: diabetic nephropathy with interstitial inflammation. IF was negative. Following autologous stem cell transplant for progression to symptomatic MM, there was a striking improvement in FLCs, renal function and MP. 73 y/o, WRF, heavy MP and Fanconi's syndrome. Biopsy: mild glomerulomegaly and focal sparse lymphocytic infiltrates. Initial IF was negative. Re-examination after protease digestion 6 months later: LCPT. Therapy for MM resulted in decreasing FLCs, improvement of renal function and a marked decrease in MP.

Discussion: FSGS has been rarely linked to MM. In view of the connection between treatment of the MM and improvement of the renal parameters, FSGS must be considered as an additional MM-related MGRS. The presence of monoclonal light chains (LCs) in the tubular epithelial cells (TECs) should raise the possibility of this diagnosis. Because monoclonal LCs deposits in TECs may not be detectable by standard IF techniques ("masked" LCPTs), paraffin IF after protease digestion should always be performed in

kidney biopsies of patients with monoclonal gammopathies. In addition, detailed EM examination of the tubules is essential to identify the lysosomal abnormalities typical of LCPT.

PO2199

CKD After 225Ac-PSMA617 Therapy in Patients with Advanced Metastatic Prostate Cancer: A Report of Two Cases

Karyne Pelletier, Gabrielle Côté, Abhijat Kitchlu. *University Health Network, University of Toronto, Toronto, ON, Canada.*

Introduction: A promising therapeutic efficacy has been demonstrated with targeted radionuclide therapy (TRNT) using 225Ac-PSMA617 in patients with advanced metastatic castration-resistant prostate cancer (mCRPC). However, these novel agents may be associated with significant toxicity. As seen in animal models, the multiple alpha particles generated in the decay chain of 225Ac may accumulate in the renal tubular cells, resulting in nephropathy. We report our experience with 225Ac-PSMA617 therapy in 2 patients with advanced mCRPC who developed kidney injury.

Case Description: Patient 1 is a 68-year-old man with widely metastatic mCRPC despite multiple lines of therapy and secondary chronic hydronephrosis with bilateral nephrostomy tubes. He received 3 rounds of 225Ac-PSMA617 in 2-month intervals. Baseline serum creatinine was 1.6 mg/dL (eGFR 44 mL/min/1.73m^2) and it increased up to 3.3 mg/dL (eGFR 18 mL/min/1.73m^2) after 225Ac-PSMA617 therapy. A kidney biopsy was obtained and revealed severe interstitial fibrosis with ongoing tubular injury and interstitial inflammation. A trial of corticosteroids therapy was attempted with no improvement in kidney function. 225Ac-PSMA617 therapy was discontinued because of related kidney failure. Patient 2 is a 67-year-old man with mCRPC with progression on multiple prior therapies. He first initiated Lu177-PSMA and one year later this was combined with 225Ac-PSMA617 in 2-month intervals. He received 5 rounds of 225Ac-PSMA617 in total, the last round being complicated with grade 3 cytopenias leading to cessation of treatment. Baseline serum creatinine at initiation of TRNT was 1.0 mg/dL (eGFR 82 mL/min/1.73m^2). He subsequently developed progressive CKD and serum creatinine was 1.7 mg/dL (eGFR 40 mL/min/1.73m^2) on last follow-up.

Discussion: We report 2 cases of progressive kidney disease in the setting of 225Ac-PSMA617 therapy for patients with advanced mCRPC. One underwent kidney biopsy showing tubulointerstitial injury, consistent with 225Ac-PSMA617-related tubular accumulation of toxic nuclides seen in animal models. This kidney injury was not responsive to corticosteroids therapy. Our case studies emphasized the need for careful assessment and monitoring of kidney function in patients receiving these novel agents.

PO2200

Successful Management of Chronic Ifosfamide Nephrotoxicity with Immunosuppression: A Case Series

Sankalp Malhotra,[1] Jason Prosek.[1,2] *[1]The Ohio State University, Department of Internal Medicine, Columbus, OH; [2]The Ohio State University, Division of Nephrology, Columbus, OH.*

Introduction: Ifosfamide is an alkylating chemotherapeutic agent that causes both acute and chronic kidney injury. Ifosfamide-induced chronic tubulointerstitial nephropathy can present months after exposure, thereby delaying diagnosis and treatment. Here, we describe three cases of chronic ifosfamide nephrotoxicity, wherein the time-course and outcomes suggest that earlier recognition and initiation of immunosuppression may benefit these patients.

Case Description: Three adult patients with distinct malignancies, status-post at least 3 cycles of ifosfamide chemotherapy, presented to our onco-nephrology clinic for worsening renal function. On average, the patients were referred to our clinic ~8 months after their last dose of ifosfamide. In this period, their serum creatinine (SCr) had risen to a peak ~2.5mg/dL from ~1mg/dL. The patients reported occasional frothy urine but were otherwise asymptomatic. Urine analysis and microscopy was significant for mild glucosuria/proteinuria, sterile pyuria, and granular casts, with urine protein/creatinine ratio of ~1.2. Autoimmune serologies, complement levels, protein electrophoresis, and renal ultrasound were unremarkable. Kidney biopsies, performed 10 months after the last ifosfamide cycle, demonstrated tubulointerstitial nephritis with moderately advanced interstitial fibrosis. Cytologic atypia of the tubular epithelium was consistent with karyomegalic interstitial nephritis (KIN), previously documented in cases of ifosfamide toxicity. In all cases, prednisone therapy led to improvement and plateau of SCr ~2.1. Curiously, multiple attempts to wean corticosteroids led to worsening SCr and active urinary sediment. In 2 patients, addition of mycophenolate mofetil enabled dose reduction but not cessation of corticosteroids. In all cases, SCr remained stable at ~2.1 after 1 year of follow-up.

Discussion: These cases illustrate the latent presentation and challenging management of chronic tubulointerstitial nephritis secondary to ifosfamide. On average, prednisone was started ~10 months after the last ifosfamide dose, when significant interstitial fibrosis had already developed. Delayed therapy and/or enduring inflammation may have also contributed to the failure to stop corticosteroids. Overall, early surveillance, prompt recognition, and long-term immunosuppression is likely important in these patients to stabilize and maintain renal function.

PO2201

Hyperphosphatemia in the Setting of Fibroblast Growth Factor Receptor Inhibitors

Shahrzad Zonoozi,[1] Bader Kfoury,[2] Abdallah Sassine Geara.[2] *[1]Pennsylvania Hospital, Philadelphia, PA; [2]Hospital of the University of Pennsylvania, Philadelphia, PA.*

Introduction: Fibroblast growth factor (FGF)-23 is a phosphaturic hormone which works by reducing apical membrane expression of sodium-phosphate co-transporters in the proximal renal tubule and thus decreasing phosphate re-absorption. Fibroblast growth factor receptors (FGFR) are ubiquitously expressed in different tissues and become altered in various types of cancer. TAS-120 is one of several pan-FGFR inhibitors currently in clinical trials for use in patients with cholangiocarcinoma. Hyperphosphatemia is seen in more than 70% of patients on this therapy.

Case Description: A 44-year-old female with metastatic intrahepatic cholangiocarcinoma with progressive disease despite conventional therapy was started on TAS-120. Fifteen days into treatment she developed pain in knees and hips and was noted to be hyperphosphatemic to 7 mg/dL. She was initiated on sevelemer but given persistent hyperphosphatemia to 6.4 mg/dL, acetazolamide, calcitonin and phytonadione were added. Despite this, phosphorus remained elevated at 5.8 mg/dL; addition of alendronate 35mg weekly alongside dose reduction of TAS-120 led to sustained improvement in serum phosphorus levels. A 49-year-old male with a history of cholangiocarcinoma was started on TAS-120. Four days into treatment he developed calf pain and was noted to be hyperphosphatemic to 7.3 mg/dL. The medication was briefly stopped and he was initiated on sevelamer with improvement in phosphorus to 2.7 mg/dL. Resumption of TAS-120 led to recurrent hyperphosphatemia for which acetazolamide was initiated. Three months after initiation of TAS-120 he had ongoing hyperphosphatemia; following dose reduction of TAS-120 and starting phytonadione, probenecid and calcitonin, serum phosphorus levels remained within normal limits.

Discussion: FGFR-induced hyperphosphatemia has a similar clinical presentation as hyperphosphatemic familial tumoral calcinosis (HFTC) with debilitating join pain and tissue calcification. The current management of hyperphosphatemia relies mainly on dietary modification and gastrointestinal phosphate binding that were insufficient for our patients. The hyperphosphatemia and calciphylaxis pain was successfully treated with phosphaturic medications (acetazolamide, calcitonin) and alendronate. Phytonadione (vitamin K) interferes with matrix Gla protein, a tissue inhibitor of calcification.

PO2202

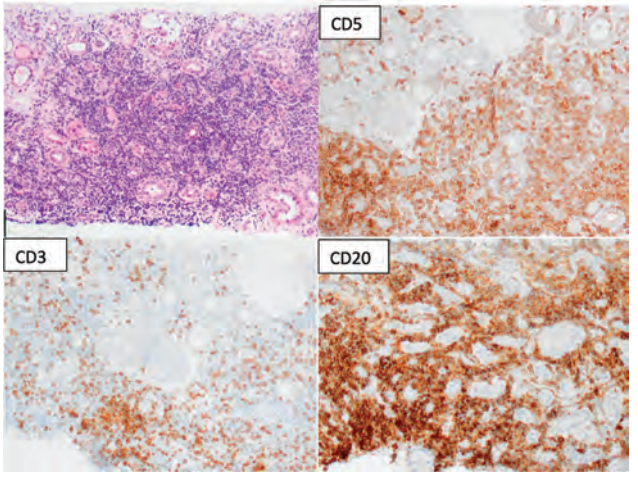
Direct Renal Infiltration in Chronic Lymphocytic Leukaemia: A Case Report

Michelle Clince, John N. Holian. *St Vincent's University Hospital, Dublin, Ireland.*

Introduction: CLL is a haematological malignancy characterised by lymphocytosis with uncontrolled accumulation of B lymphocytes. It is most commonly a disease of older adults with co-morbidities limiting treatment options. Renal involvement of CLL is common with autopsy findings showing up to 90% involvement however direct infiltration rarely causes clinically significant renal impairment.

Case Description: A 78 year old man was admitted to hospital with acute on chronic kidney injury, creatinine 759umol/l from 200umol/L. He had background of CLL and a supra-pubic catheter. His total white cell count was 33.9x10^9/L and lymphocyte count of 19x10^9/L. His SPC was draining with no recent obstruction or infection. An US showed no hydronephrosis or cortical scarring. A renal biopsy was performed and a tunnelled dialysis catheter inserted to commence haemodialysis. Biopsy showed a diffuse heavy infiltrate of lymphoid cells in the intersitium with no immune deposition and 70% fibrosis. Immunohistochemistry staining positive for CD20 and CD5. We started a tyrosine kinase inhibitor however after 3 months he remained dialysis dependent and died from COVID pneumonia.

Discussion: Renal injury is seen in approximately 16.2% of patients during disease course in CLL. This can be due to tumour lysis syndrome, immune deposits, cyroglobinaemia, obstruction to due lymphadenopathy and direct infiltration of B lymphocytes as seen in this case. Indications for commencing treatment for CLL usually involve evidence of marrow failure, massive lymphadenopathy and significant B symptoms. In this case treatment was initiated to manage the patients' renal involvement. It is important to pursue a renal biopsy in patients with CLL as it may reveal an indication to commence treatment.



H&E shows heavy infiltrate of small lymphoid cells. ICH positive for CD20 (B-cell marker) CD5 (expressed on normal T-lymphocytes but also expressed in CLL), mostly negative for CD3 (T-cell marker)

PO2203

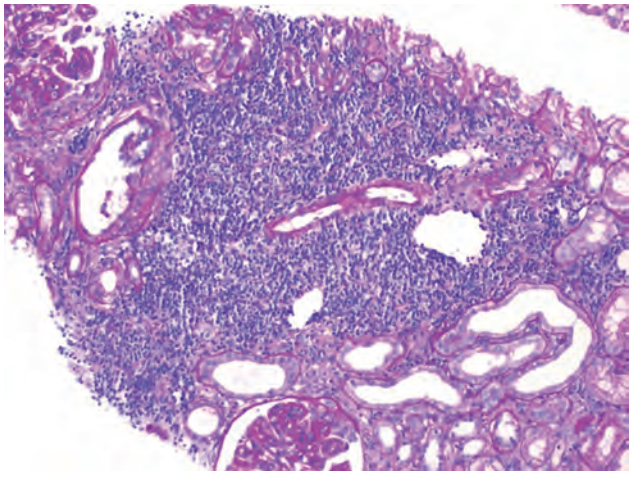
Attack of the Clones: Leukemia and Myeloma

Sara Wong, Shreya Patel, Elizabeth A. Alaimo, Shanaz Azad, Pankaj Jain, Tauseef A. Sarguroh. *Franciscan Health Inc, Mishawaka, IN.*

Introduction: Chronic lymphocytic leukemia(CLL) and multiple myeloma(MM) are both neoplastic diseases that are monoclonal tumors of differentiated B-cells that rarely occur simultaneously. There is disagreement and conflicting evidence as to whether these seemingly distinct disorders may arise from identical clones. In some cases MM maybe diagnosed up to 15 years after the established diagnosis of CLL. We describe a rare case of a patient with renal failure and nephrotic range proteinuria where both CLL and MM were diagnosed concomitantly from a single renal biopsy.

Case Description: 59 y/o Indian male with COPD, DM-type 2, HTN, recent pseudomonas aeruginosa pneumonia presented with bilateral temporal headaches and fevers. Work-up revealed creatitine: 1.7mg/dl, UPCR: 6.6 g/g, free kappa/lambda ratio of 0.25 and mildly depressed C3 and C4. Renal biopsy showed diffuse proliferative and crescentic g/omerulonephritis with IgG lambda light chain restriction, CD-20 positive lymphocytic interstitial infiltrate, ATN and diabetic glomerulopathy. EM also revelaed subepithelial hump-shaped depositis and abundant glomerular neutrophils suggesting a component of post-infectious GN. Both flow cytomtery and bone marrow biopsy revealed monotypic B-lymphocyte population with aberrant expression of CD5 and CD23 consistent with the diagnosis of CLL. The patient was treated with cyclophosphamide and dexamethasone and is currently stable on Ibrutinib with a creatinine of 1.3mg/dl.

Discussion: CLL is a common hematologic malignancy that has many systemic complications. Autopsies have shown that 90% of CLL pateints have renal infiltration; however there is seldom renal impairment. This is a rare case of renal CLL infiltration causing type-1 cryoglobulinemia with IgG lambda monocolonal gammopathy of renal significance. Early diagnosis with renal and bone marrow biopsy and subsequent treatment with immunosuppresive therapy is crucial.



CD20 positive lymphocytic renal interstitial infiltrate.

PO2204

Should We Give the Green Light to Green Top Tube? Reverse Pseudohyperkalemia in Leukemia Patient

Ming-Jen Chan. *Cnang Gung Memorial Hospital, Taoyuan, Taiwan.*

Introduction: Hewe we described a 69-year-old woman presented with hyperleukocytosis with reverse pseudohyperkalemia. This is also the first case of reverse pseudohyperkalemia in Philadelphia chromosome positive acute lymphoblastocytocytic leukemia.

Case Description: The 69-year-old woman was rushed to our emergency department due to progression of dyspnea for one week. Upon lab examination, hyperleukocytosis (> 500000/uL) with blasts that suggestive of acute leukemia. Notably, marked hyperkalemia (11.6 mEq/L) with normal renal function was noted but there is no typical electrocardiogram change. High LDH(3393 U/L) and low haptoglobin(<7.88 mg/dL) also noted. After clarification, the blood tube that had result of hyperkalemia is sodium heparin tube. We retested potassium by using serum separate tube with 5 minutes of 3000 revolutions per minute, revealing serum potassium level 3.8 mEq/L. Reverse pseudohyperkalemia was impressed. She recieved leukophresis and chemotherapy for leukostasis. The bone marrow biopsy later confirmed Philadelphia chromosome positive acute lymphoblastocytic leukemia. Reverse pseudohyperkalemia resolved after leukocyte return to normal level.

Discussion: Pseudohyperkalemia is suspected when the measured potassium is high but the patient does not manifest signs of hyperkalemia, such as abnormal electrocardiogram. Pseudohyperkalaemia is falsely elevation of serum potassium levels without elevation of plasma potassium levels, commonly occurred in patients with hematological disease. Heparin anticoagulated plasma samples provide more accurate measurement of the true potassium level in these patients and sodium heparin (green top) tube is widely used. However, in reverse pseudohyperkalemia, serum potassium is within normal range, and plasma potassium is falsely elevated, such as in our patients. The heparin in the plasma collection tube causes damage to the cell membrane during processing and centrifugation in the context of fragile cells of hematologic malignancy. Reverse pseudohyperkalemia had been reported in chronic lymphocytic leukemia patient. To our knowledge, this is the first case report of reverse pseudohyperkalemia in Philadelphia chromosome positive acute lymphoblastocytocytic leukemia patient. This case reminds us that potassium obtained using heparin tube is not panacea to get accurate level, and reverse pseudohyperkalemia is a must-known phenomenon for clinicians.

PO2205

A Rare Case of Composite Lymphoma with Kidney Infiltration of Nodal Marginal Zone B Cell Lymphoma and Three Different Types of Cast Nephropathy

Tianjun Guan, Yu Li, Anqun Chen. *Division of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China.*

Introduction: We present an interesting case of composite lymphoma (nodal marginal zone B-cell lymphoma and multiple myeloma) characterized by the rare kidney invasion of the nodal marginal zone B-cell lymphoma and three different types of cast nephropathy present simultaneously in patient with multiple myeloma.

Case Description: A 57-year-old Chinese male was admitted to hospital for proteinuria. He reported foam urine, abdominal distension, fatigue, and weight loss of 5 kg within one month. Laboratory tests demonstrated hemoglobin 108 g/L, blood urea nitrogen 27.1 mmol/L, serum creatinine 639.1 umol/L and urine acid 547 umol/L. The 24-hour urinary protein and microalbumin was 3193.3mg and 42.3mg, respectively. Immunofixation electrophoresis (IFE) showed IgD-Lambda+Lambda monoclonal protein. MRI identified diffuse osseous lesions. Bone marrow aspirate and biopsy demonstrated a hypercellular marrow with extensive plasma cell infiltration. Besides, multiple lymphadenopathies in both axillary and bilateral Inguinal lymph nodes were noticed. Lymph node biopsy suggested a nodal marginal zone B-cell lymphoma. To explore the involvement of kidney injury, we performed a kidney biopsy. Surprisingly, we found three types of nephropathy (myeloma casts, light chain crystal structure and light chain amyloidosis). At the same time, we also found focal lymphocyte infiltration, which are confirmed of nodal marginal zone B-cell lymphoma by immunohistochemistry with various molecule markers. To further explore the relationship between the two tumors, we performed the whole genome exon sequencing of the bone marrow and lymph nodes, surprisingly we found the similar mutation sites (V1982I of ARID1A gene) in both tissues, suggesting that the two tumors might originated from the same mutation. After BCT chemotherapy and PAD-T chemotherapy, urea nitrogen and blood creatinine decreased, the patients get rid of hemodialysis.

Discussion: nodal marginal zone B-cell lymphoma infiltrate kidney only is very rare. Also three kinds of nephropathy (myeloma casts, light chain crystal structure and light chain amyloidosis). present simultaneously is also very rare. And the sequencing of the genome exon suggested that nodal marginal zone B-cell lymphoma might developed in to multiple myeloma in bone marrow micro-environment.

PO2206

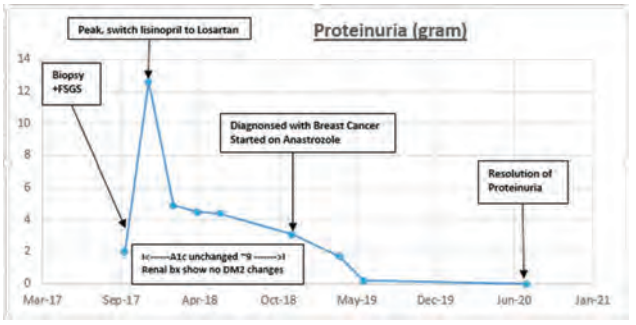
Breast Cancer-Associated Podocytopathy

Abdulrahman Muzib, Rimda Wanchoo, Kenar D. Jhaveri. *Northwell Health, Great Neck, NY.*

Introduction: Podocytopathies such as FSGS have not been classically associated with solid malignancy. Here we present a case of a female with a diagnosis of FSGS and its association bilateral lobular carcinoma in situ of the breast.

Case Description: A 52 year old Sri Lankan female with history of DM2 (with no prior proteinuria) was referred for sudden onset of proteinuria. The patient first reported profound foamy urine in October 2017 with workup significant for sub-nephrotic proteinuria of 2 gram with normal serum creatinine and albumin. A kidney sonogram unremarkable. Further workup was negative for infectious, autoimmune, vasculitis and para-protein etiologies. The patient was started on Lisinopril 10mg, however proteinuria worsened to 12.6 grams thereby switch to losartan (100mg daily) with slight improvement in proteinuria. A kidney biopsy was performed which showed focal global glomerulosclerosis secondary to adaptive changes with minimal fibrosis with no diabetic nephropathy related changes seen. Light microscopy showed globally sclerosis (9%) and IFTA (5-10%). Immunofluorescence microscopy showed no evidence of primary podocyte disease, immune complex-mediated disease or para-protein deposition disease. The patient was managed conservatively on anti-proteinuric agent. Almost a year after the diagnosis of FSGS, patient was diagnosed with bilateral lobular carcinoma in situ (breast) with atypical lobular hyperplasia. She underwent lobectomy and started on anastrozole. Following cancer surgery and initiation of hormonal therapy, she noticed resolution of her fatigue, urine foamy and proteinuria (repeat UP/Cr <23 mg (Figure 1)).

Discussion: Our case demonstrates a potential link of the diagnosis of lobular ductal cancer of the breast with a diagnosis of FSGS. Interestingly, the FSGS diagnosis preceded the diagnosis of the breast cancer. While the proteinuria came into partial remission with conservative management, a dramatic resolution of FSGS was noted post-surgery and hormonal therapy for the breast cancer.



PO2207

Snapshot of AKI Profile in Patients in Oncology Settings: A Single-Center Experience

Girish V. Kumthekar,[1,2] Praveen kumar Koppula,[1] Rajasekara C. Madarasu.[2] RENOWN Clinical Services, Hyderabad, Telangana, INDIA. [1]*Basavatarakam Indo-American Cancer Institute and Research Centre, Hyderabad, India;* [2]*RENOWN Clinical Services, Hyderabad, India.*

Introduction: Acute kidney injury (AKI) may result from the cancer itself, treatment of cancer or associated complications. In cancer patients with AKI complete recovery of renal function was seen in 82% and chronic dialysis was needed in 6% of patients. Overall severity of illness, age, and functional status have more of an impact on prognosis than underlying malignancy, and the presence of cancer may not be an absolute exclusion criterion for withholding RRT. Hospital mortality approaches 80% in cancer patients with AKI. Cancer associated AKI (CA-AKI) is very prevalent with reported incidence of 12% to 49%. We tried to look into incidence, etiology and outcome of AKI in a tertiary care cancer hospital.

Case Description: For two consecutive months all patients admitted in ICU at Basavatarakam Indo-American Cancer Hospital were observed for development of AKI with KGIDO criterion. We found 45 patients who developed AKI out of 83 total ICU admissions (54.21%). Chronic kidney disease was present in 17 patients (37.77%), diabetic kidney disease being the commonest (64.70%). The commonest etiology of AKI was sepsis (77.8%) and septic shock was present in majority of these patients (66.7%). Other causes of AKI were hypercalcemia (4.4%), chemotherapy associated (44.4%), obstructive nephropathy (8.9%). Metabolic acidosis was predominant finding (75.6%) with oliguria being least common (26%). Hematological malignancies were frequently associated with AKI (33.3%) followed by gastrointestinal tract tumors (24.44%). Urological malignancies were least associated with AKI (6.6%). Large number of patients required renal replacement therapy (RRT) (48.9%). SLED was commonest modality (n=15; 68.18%) of RRT followed by CRRT/CVVHDF (N=8; 34.78%). Regional citrate anticoagulation was commonest anticoagulation used (62.5%). 46% patients recovered their renal functions but creatinine did not reach baseline for 11% of patients. 29% patients with AKI died and a 14% of patients lost to follow up. CRRT was associated with better survival (n=4; 50%) followed by SLED (n=4; 26.66%).

Discussion: Incidence of AKI was higher among patients in oncological ICU with half of them required RRT. Commonest etiology of AKI was sepsis where shock state was observed in majority of patients. Although SLED was used more frequently, outcomes were better with CRRT/CVVHDF.

PO2208

A Patient with Hyper-Warburgism Successfully Treated with Peritoneal Dialysis

Suramath Isaranuwatchai, Thachanun Porntharukchareon, Chayapa Thookhamme. *Chulabhorn Hospital, Bangkok, Thailand.*

Introduction: The combination of hypoglycemia and lactic acidosis in cancer patients is usually known as hyper-warburgism.

Case Description: A 74-year-old Thai man presented to our hospital with symptomatic hypoglycemia. He was previously healthy, no history of diabetes. Further investigation revealed hyperbilirubinemia, hepatosplenomegaly and first-diagnosed HIV infection. Computerized tomography of abdomen showed large liver mass with multiple intraabdominal lymphadenopathy. Liver mass biopsy showed round cell neoplasm with immunohistochemistry staining compatible with Burkitt lymphoma: positive for CD20, Bcl-6, CD10, C-myc, Ki67 100%, and negative for Bcl-2. His lymphoma was initially treated with high-dose dexamethasone. During investigation and initial treatment, our patient developed acute kidney injury (AKI) with severe lactic acidosis. Hypoglycemia persist even he received intravenous glucose 18 g/hour. Serum ketone, insulin and c-peptide were normal. We suspected that he had hyper-warburgism due to Burkitt lymphoma, which was not respond to dexamethasone. Due to HIV seropositive status, we chose automated peritoneal dialysis (PD) for AKI and severe metabolic acidosis in this patient. PD dose in this patient was 19 liters per day. After PD initiation, the patient gradually recovered, with serum lactate dramatically decreased and intravenous glucose could be stopped. Clinical and laboratory parameters, including major clinical events, were shown in figure 1. After lactic acidosis resolved, we decided to treat this patient with chemotherapy. Unfortunately, this patient died later due to fungemia, neutropenia and septic shock.

Discussion: Hypercatabolic state such as hyper-warburgism was usually treated with continuous renal replacement therapy (CRRT). Here, we presented a case of hyper-warburgism successfully treated with PD. We hoped this report might offer alternative treatment in patients who unable to undergo CRRT.

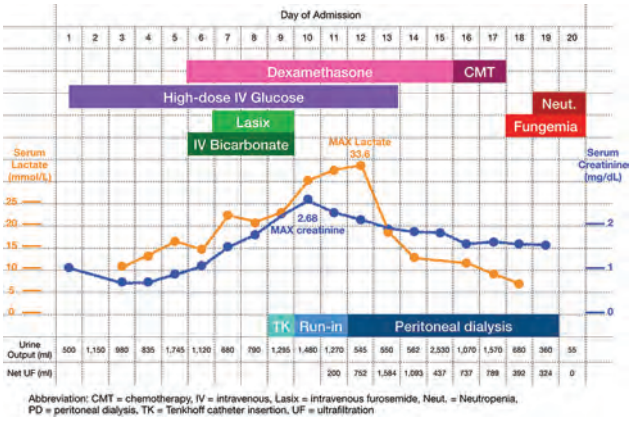


Figure 1: Clinical course of a patient with hyper-warburgism

PO2209

Narsoplimab, Another Tool in the Management of Thrombotic Microangiopathy in Stem Cell Transplant Recipients

Omar Mamlouk,[1] Ali A. Ahmed,[2] Howard H. Coke,[2] Sreedhar A. Mandayam.[1] [1]*Section of Nephrology, MD Anderson Cancer Center, Houston, TX;* [2]*Division of Renal Diseases and Hypertension, University of Texas Health Science Center at Houston- McGovern Medical School, Houston, TX.*

Introduction: Thrombotic microangiopathy (TMA) is a severe complication in recipients of hematopoietic stem cell transplants (HSCT). Its treatment remains controversial due to its complex and not fully understood mechanism. As more emerging evidence supports the role of complement dysregulation in the observed endothelial injury, anti-complement medications have emerged as a potential therapy. Narsoplimab is an anti-complement therapy that was granted FDA designations for HSCT-TMA as a breakthrough therapy. We hereby report the first case of Narsoplimab use in a HSCT adult recipient with TMA in the United states.

Case Description: A Caucasian women in her early 70s with medical history of relapsed B- cell acute lymphocytic leukemia post allogenic HSCT who was treated with Venetoclax and MiniCVD regimen with a hospital course significant for E. coli bacteremia, CMV pneumonia and acute kidney injury. Creatinine rose from 1.6 to 3.3 mg/dl, over 2-weeks, despite the discontinuation of tacrolimus and treating the sepsis. Urinalysis was significant for pyuria, hematuria, granular casts and +1 proteinuria. She had elevated C5b9 and LDH levels (363 ng/ml and 326 U/L respectively) with schistocytes noted in blood smear, suggestive of TMA. Renal biopsy was significant for ATN and acute TMA, for which we decided to treat her with anticomplement therapy with Narsoplimab. She received twice weekly doses for 4 weeks and had significant improvement in renal function (Cr improved to 0.8 mg/dl), however she developed worsening respiratory status secondary to possible diffuse alveolar hemorrhage and family withdrew care in week 4 of therapy.

Discussion: Narsoplimab is a human monoclonal antibody that inhibits mannan-binding lectin associated serine protease-2 (MASP-2) which is an essential enzyme in the complement system lectin pathway. It is designed to prevent endothelial injury without interfering with other complement pathway roles. Data from phase 2 study showed an improvement in patient survival and TMA blood markers (LDH, haptoglobin, and platelet count). It might improve renal function as well as its inhibition to lectin activation pathway can ameliorates proteinuria induced kidney injury. However she didnot have improvement in her platelet count, LDH and C5b9 levels. Further studies are ongoing (Phase 3 trials in IgA nephropathy and HSCT-TMA) to evaluate such renal benefits.

PO2210

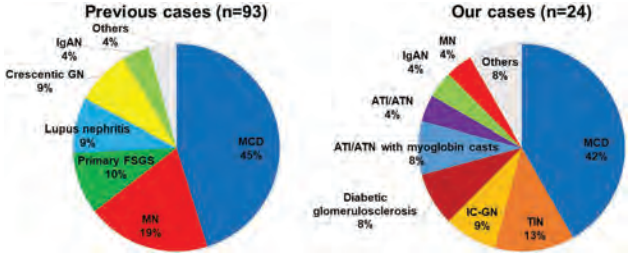
The Histopathologic Spectrum of Kidney Biopsies in Patients with Thymoma, Myasthenia Gravis, or Both: A Report of 24 Cases from a Single Institution

Akira Takahashi, Takamasa Miyauchi, Narihito Tatsumoto, Michifumi Yamashita. *Cedars-Sinai Medical Center, Los Angeles, CA.*

Introduction: Nephropathy in patients (Pts) with thymic diseases such as thymoma and myasthenia gravis (MG) is rare and has been the subject of case reports. Previously, 93 cases have been reported from multiple institutions, and of these, common diseases are minimal change disease (MCD; 45.2 %), membranous nephropathy (MN; 19.4 %), and primary focal segmental glomerulosclerosis (FSGS; 9.7 %). Here we characterize the spectrum of kidney biopsy findings in 24 cases from a single institution.

Case Description: Total 40,268 renal biopsy cases from 2005 through 2019 at Cedars-Sinai Medical Center were reviewed. 24 cases (0.0596 %) of Pts have history of thymoma and/or MG. Main pathological diagnoses are following: MCD (10 cases; 41.7%), Tubulointerstitial nephritis (TIN; 3 cases; 12.5 %), Immune complex-mediated glomerulonephritis (IC-GN; 2 cases; 8.3 %), Diabetic glomerulosclerosis (2 cases; 8.3 %), acute tubular injury/necrosis (ATI/ATN) with myoglobin casts (2 cases; 8.3 %), ATI/ATN (1 case; 4.2 %), IgA nephropathy (1 case; 4.2 %), MN (1 case; 4.2 %), secondary FSGS (1 case; 4.2 %), and Monoclonal Ig deposition disease (1 case; 4.2 %).

Discussion: Consistent with the previous reports, MCD is the most common renal lesion in Pts with thymic diseases. However, we experienced only one case of MN and no primary FSGS, the 2nd and 3rd common diseases in the reports. We, instead, observed kidney diseases that haven't been reported before: TIN, and ATI/ATN with myoglobin casts. Of 3 TIN cases, 1 showed granulomatous interstitial inflammation without infection; and 1 case showed acute tubulitis with immune complex deposits both in mesangium and along tubular basement membranes. In addition, 40 % of MCD cases showed an atypical feature: IC deposits in mesangial area. The possible mechanisms of thymic disease-associated nephropathy include T cell dysregulation, IC formation containing tumor antigen, and effects of tumor-releasing lymphokines. In conclusion, this is the largest and unique case series of nephropathy in Pts with thymic disease from a single institution.



PO2211

Erdheim-Chester Disease: A Rare Cause of Bilateral Renal Artery Stenosis and AKI

Monica S. Ng,[1,2] Saw Yu Mon,[1,5] Rachael O'Rourke,[4,5] Nigel Mott,[3] Touraj Taheri,[6,5] Kirk Morris,[7] Pedro H. Gois.[1,5] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Faculty of Medicine and Institute for Molecular Bioscience, University of Queensland, Brisbane, QLD, Australia; [3]Medical Imaging, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [4]Medical Imaging, Prince Charles Hospital, Brisbane, QLD, Australia; [5]Faculty of Medicine, University of Queensland, Brisbane, QLD, Australia; [6]Pathology Queensland, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [7]Department of Cancer Services, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia.*

Introduction: Erdheim-Chester disease (ECD) is a rare, non-Langerhans cell histiocytosis affecting multiple organ systems. We report a case of ECD with bone marrow, cardiac and vascular and renal involvement, presenting with hypertensive emergency and AKI, responsive to endovascular stenting and peg-interferon.

Case Description: A 72 y.o. female presented with hypertensive emergency and AKI. Her symptoms included fatigue, poor oral intake, 5kg weight loss and lower limb oedema. Her medical history included stage 3b chronic kidney disease secondary to hypertensive nephropathy, bilateral renal artery stenosis, coronary artery disease, rheumatoid arthritis, previous diverticulitis and osteoarthritis. Her examination was unremarkable. Her investigations showed anaemia; creatinine 2.45mg/dL (baseline 1.59mg/dL), BUN 47mg/dL; unremarkable electrolytes and liver function tests. A CT angiogram showed extensive, irregular mural thickening of the aorta present for 2 years, right atrial mass, high-grade stenosis of both renal arteries and left vertebral artery occlusion. Review of prior lower limb CT imaging showed bilateral, symmetrical sclerotic bone infiltrates in the diaphyses and metaphyses, corresponding to the regions of PET avidity, confirming the diagnosis of ECD. Echocardiogram and cardiac MRI confirmed a 21.7 x 18.3mm right atrial mass with small pericardial effusion. ECD was confirmed via right sacrum lesion biopsy showing sclerotic xantogranulomatous histiocytic(CD68+, CD163+, CD1a-) reaction. Despite taking 5 classes (7 agents) of anti-hypertensives at maximal doses, her blood pressure was suboptimally controlled. After bilateral endovascular renal artery stenting, anti-hypertensive requirement reduced to 2 agents and renal function improved to better than pre-AKI levels. She is receiving peg-interferon α2a and prednisolone for ECD.

Discussion: The disease affects renal arteries in 18-27% cases and should be considered as a cause of renal artery stenosis in older patients with multisystem anomalies. Renal artery stenting in this subset can improve hypertension and renal outcomes. The disease has characteristic radiological findings and the diagnosis is frequently reliant on imaging. Histological examination is often not sufficient to confirm the diagnosis. ECD diagnosis is essential for treatment of the underlying disease process.

PO2212

Renal Involvement as Initial Presentation of Mantle Cell Lymphoma: A Case Series

Ibrahim El Halabi,[1] Natacha Rigual Soler,[1] Elvira O. Gosmanova,[2] Swati Mehta,[1] Andrea R. Lightle,[1] Loay H. Salman,[1] Mauricio Monrroy.[1] *[1]Albany Medical Center, Albany, NY; [2]Albany Stratton VA Medical Center, Albany, NY.*

Introduction: Mantle cell lymphoma (MCL) rarely affects kidneys. We present 2 cases with different spectrum of kidney involvement in MCL.

Case Description: The 1st case was a 63-yr old male with incidental finding of Serum creatinine (SCr) of 10mg/dL. Chronic lymphocytic leukemia was diagnosed 2 weeks prior via peripheral blood cell analysis & flow cytometry (FC) done due to constitutional symptoms and headaches for which he was using daily ibuprofen for several months. On exam he had elevated blood pressure but no signs of volume overload. Initial supportive treatment did not improve kidney function and hemodialysis was initiated due to worsening azotemia and persistent nausea and vomiting suspicious for uremia. Renal biopsy showed diffuse acute on chronic interstitial nephritis with perivascular lymphoid aggregates of monoclonal CD 20+ B-cells positive for CD5 and Cyclin-D1 consistent with MCL. No significant immunostaining was found. Bone marrow biopsy confirmed renal biopsy findings and diagnosis of MCL. Until last follow up, the patient refused chemotherapy and remained dialysis dependent. The 2nd case was a 73-yr old male with incidental founding of SCr of 1.9mg/dL in association with glomerular hematuria and grade A3 proteinuria. He had no constitutional symptoms and had normal physical exam except for presence of diffuse lymph node (LN) enlargement. Renal biopsy was obtained and showed MPGN-pattern with 25% crescents on light microscopy, presence of all immunoglobulin classes with κ-light chain (KLC) predominance in glomeruli and lymphoid infiltration with KLC in the interstitium on immunostaining. MCL was confirmed with FC and excisional LN biopsy. Prednisone/Rituximab/Bendamustine therapy led to improvement in kidney function and proteinuria.

Discussion: MCL can cause differential kidney involvement from direct tumor infiltration to MCL-associated glomerulonephritis. Therefore, correct diagnosis with renal biopsy and prospective registries are needed to generate data about differences in outcomes in MCL with various kidney involvement.

PO2213

Cystatin C Measurement Improves Renal Function Estimation with Selpercatinib Use

Victoria Gutgarts,[1,2] Dazhi Liu,[1] Lauren A. Kaplanis,[1] Alexander Drilon.[1,2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medicine, New York, NY.*

Introduction: Selpercatinib (LOXO-292) is a selective RET inhibitor that is approved for the treatment of RET-dependent lung and thyroid cancers. In the LIBRETTO-001 trial of selpercatinib, a treatment-emergent increase in serum creatinine was noted in ~18% of patients. Creatinine is mainly excreted by glomerular filtration and is partly secreted via transporters such as MATE-1. Inhibitors of MATE-1, such as selpercatinib, can reduce creatinine clearance leading to an incorrect diagnosis of drug related kidney injury. Cystatin C is an alternative marker that is freely filtered, completely reabsorbed and not secreted like creatinine. It is therefore not affected by transporter inhibitors and may be a better marker of kidney injury in patients receiving Selpercatinib. We present a patient on Selpercatinib with significant difference in kidney function by creatinine and cystatin C.

Case Description: 58-year-old male with metastatic *RET* fusion-positive lung cancer who progressed on cabozantinib started selpercatinib. His pre-treatment creatinine was 0.8mg/dl and increased to 1.8mg/dl after 1 year of therapy. Urine sediment was bland with no significant proteinuria. Renal sonogram showed right sided hydronephrosis which prompted placement of ureteral stent. Creatinine did not improve with persistent hydronephrosis prompting conversion to a nephroureterostomy tube one year later. Creatinine remained elevated at 1.9mg/dl despite resolving hydronephrosis. Cystatin C levels were measured and showed significant discrepancy with serum creatinine as shown in Table below. This finding highlighted that although the patient did have chronic kidney disease, the extent was less than estimated by solely creatinine.

Discussion: This case highlights the benefit of checking both creatinine and cystatin C in patients on selpercatinib. Despite urological intervention, the persistence in elevated

creatinine is likely attributed to the drug inhibitory effect on creatinine secretion. Cystatin C may be a better measure of renal function in patients receiving MATE-1 inhibitors such as selpercatinib.

Discrepancy in Serum Creatinine and Cystatin C Trends

Clinic Encounters	Creatinine (mg/dL)	GFR (mL/min/1.73m2)	Cystatin C (mg/dL)	GFR by Cystatin C (mL/min/1.73m2)
1	1.9	38	1.2	62
2	2	36	1.4	49
3	1.9	38	1.2	61
4	1.4	55	1	77

PO2214

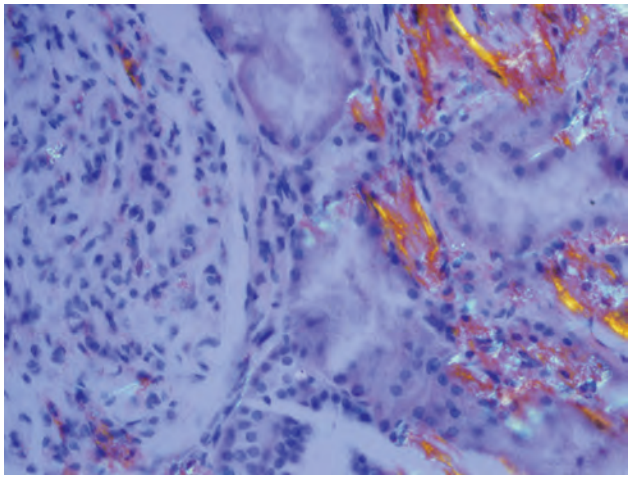
ALECT 2 and Hepatocellular Carcinoma: An Intriguing Association

Janame J. Kottey, Niraj K. Yadav, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Amyloidosis derived from leukocyte chemotactic factor 2 (ALECT2) is the third most common type of renal amyloidosis in the United States. The incidence of ALECT2 is highest among Hispanics and there is a predilection for involvement of the kidney and liver with sparing of the heart. We report a case of hepatocellular carcinoma (HCC) in a patient with ALECT2

Case Description: A 69-year-old Hispanic man with chronic kidney disease secondary to ALECT2 and monoclonal gammopathy of undetermined significance was admitted for constipation and distended abdomen. Creatinine on a dmission was 8mg/dL and he was initiated on dialysis. Imaging revealed cirrhosis, ascites and two liver masses involving the portal vein. Alpha fetoprotein was 7123ng/mL and he was diagnosed with multifocal HCC. Evaluation for hepatitis, autoimmune disease and other etiologies for chronic liver disease was negative and cirrhosis was presumed to be secondary to ALECT2. Based on the Barcelona Clinic Liver Cancer staging, he was given a stage D. His functional status precluded any liver directed therapies or systemic chemotherapy and he failed to meet the Milan criteria for liver transplantation. Following a discussion of the prognosis he was transitioned to palliative care

Discussion: ALECT2 is a recently described form of systemic amyloidosis that has quickly emerged as a common and possibly underdiagnosed cause of systemic amyloidosis particularly in patients of Hispanic ancestry. ALECT2 can involve various organs but usually spares the heart and brain. ALECT2 in association with HCC has not been reported to date. Interestingly in one study, expression of LECT2 in human HCC biopsies was significantly reduced and over expression of the gene resulted in inhibition of the tumor in an experimental model. ALECT2 is without an identifiable etiology and targeted therapy and hence, it is imperative not to misdiagnose ALECT2 as AL amyloidosis to avoid harmful chemotherapy



PO2215

A Case of Extranodal Rosai-Dorfman Disease Confirmed by Renal Biopsy

Octavio Chavez,[1,2] Timothy M. Chow.[1,2] University of South Florida Nephrology [1]*USF Health Morsani College of Medicine, Tampa, FL;* [2]*James A Haley Veterans Hospital, Tampa, FL.*

Introduction: Perinephric stranding is typically caused by infection or obstruction. In rare cases other etiologies has been found. We present a case of the extremely rare extranodal Rosai Dorfman Disease confirmed by renal biopsy.

Case Description: A 72 yo M with CKD III was found to have perinephric stranding during CT surveillance for ascending thoracic aneurysm. Subsequent imaging revealed similar findings worisome for lymphoma. Renal biopsy was performed and revealed xanthogranulomatous inflammation with prominent plasma cells, dense histiocytic infiltrate mixed with scattered lymphoid aggregated plasma cells, histiocytoid cells with large nuclei and abundant cytoplasm. Immunostains showed histiocytoid cells to be immunoreactive to CD68 and S100 protein which is consistent with Rosai Dorfman Disease. Renal function remained stable and given unresectability of the lesion and stability of renal function, the patient was managed conservatively with serial imaging. Renal scan ruled out an obstructive process

Discussion: Rosai Dorfman Disease is an extremely rare, though benign, disease characterized by proliferation of histiocytes that typically proliferates in lymph nodes in the 2nd -3rd decades of life. While its cause is unknown, consequences of this disease are secondary to mass effect of the lesion. Rarely, RDD can present extra-nodally and pose a risk to renal function. It is important to evaluate causes of renal perinephric stranding. Rosai Dorfman Disease poses a difficult treatment dilemma given unresectability and risk of renal obstruction.

PO2216

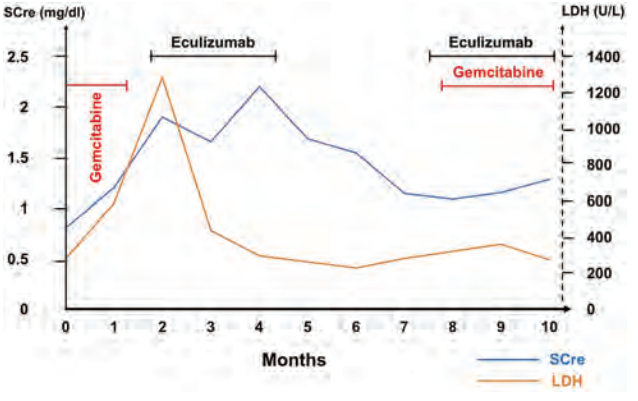
Eculizumab for Treatment and Prevention of Recurrent Gemcitabine-Induced Atypical Hemolytic Uremic Syndrome After Gemcitabine Rechallenge: A Case Report

Orhan Efe,[1,2] John Niles,[1] Reza Zonozi.[1] [1]*Massachusetts General Hospital, Boston, MA;* [2]*Brigham and Women's Hospital, Boston, MA.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare side effect of gemcitabine. Here, we report a case of gemcitabine-induced aHUS successfully treated with eculizumab, with subsequent use of eculizumab to prevent recurrence of aHUS after reinitiating gemcitabine.

Case Description: A 29-year-old male with intrahepatic cholangiocarcinoma on gemcitabine and cisplatin was admitted with AKI. On presentation, he was newly hypertensive to 162/108 mmHg and edematous. His labs were notable for a serum creatinine (SCr) of 1.19 mg/dL (baseline 0.6 mg/dL), hemoglobin 8.8 g/dL (baseline of 12.6 g/dL) with reticulocytosis, platelet count 190 K/μL, LDH 635 U/L, haptoglobin <10 mg/dL, schistocytes on blood smear, and a normal ADAMTS13 level. Urine studies revealed hematuria, proteinuria, and granular casts. Gemcitabine and cisplatin were discontinued, yet his SCr continued to rise to 2.12 mg/dL, LDH to 1222 U/L and platelet count fell to 77 K/uL. Eculizumab was initiated and his creatinine improved to 1.14 mg/dl, and his LDH, platelet count, and haptoglobin normalized. Eculizumab was stopped after 2 months without subsequent recurrence. He was reinitiated on dose-reduced gemcitabine and cisplatin due to progression of his cancer despite multiple alternative chemotherapies. Eculizumab was reinitiated concurrently with gemcitabine and continued biweekly. His blood pressure, SCr, haptoglobin, LDH and platelet count remained stable. Unfortunately, he died due to cancer progression 3 months later. Figure 1 summarizes his treatment and laboratory course.

Discussion: We report a case of successfully utilizing eculizumab to prevent recurrence of gemcitabine-induced aHUS after gemcitabine reinitiation, which has not been previously reported to our knowledge. There are scarce reports of gemcitabine reinitiation without eculizumab, most of which resulted in recurrent renal toxicity. There may be utility in the use of eculizumab in patients who need to reinitiate gemcitabine. Larger studies evaluating this approach are warranted.



PO2217

A Case of Lupus Nephritis Improved by Molecular Targeted Drug Therapy for Multiple Intrapulmonary Metastasis of ROS-1 Gene-Positive Lung Cancer

Miho Karube, Hiroko Uchida, Yoshinori Komagata, Shinya Kaname. *Division of Nephrology and Rheumatology, Kyorin University School of Medicine, Tokyo, Japan.*

Introduction: Systemic lupus erythematosus is a multisystemic disease associated with genetic, environmental and epigenetic factors. The effect of tyrosine kinase inhibitors has only been reported in SLE model mice for imatinib. Here we report a case in which lupus nephritis was improved by a molecular targeted drug for multiple intrapulmonary metastases of ROS-1 gene-positive lung cancer.

Case Description: Thirty-one-year-old woman, who was diagnosed with SLE at the age of 14 years, had been treated with immunosuppressive agents including corticosteroids, cyclophosphamide and mycophenolate mofetil, with frequent relapses. At the age of 30 years, she was admitted to our hospital due to development of systemic erythema, which was diagnosed as drug-induced eruption with increased SLE activities. She was treated with prednisolone (PSL) 50 mg/day and remission was achieved for

SLE, however, during the systemic screening, lung adenocarcinoma was accidentally detected, and thoracoscopic right middle lobectomy was performed. Seven months after surgery, she had an exacerbation of erythema on the face and bilateral arms, arthralgia and urinary proteins, with elevated anti-ds-DNA antibodies and decreased serum complement levels. The dose of PSL was increased, but the symptoms did not improve, when multiple intrapulmonary metastases were detected, indicating recurrence of lung adenocarcinoma. The previous lung specimens revealed a high expression of PD-L1 and positive ROS-1 fusion gene, thus tyrosine kinase inhibitor (crizotinib) was selected as the anti-cancer therapy instead of anti-PD-L1 antibodies. Interestingly, urine protein and erythema/arthralgia improved as the size of lung tumor reduced.

Discussion: Crizotinib is a molecular targeting agent with non-receptor-type tyrosine kinase inhibitory action that competitively binds to the ATP binding site of EML4-ALK tyrosine kinase, resulting in signal transduction inhibition. In this case, the molecular targeting drug induced improvement of lupus nephritis along with regression of lung cancer, suggesting that tyrosine kinase inhibition may be effective for lupus nephritis.

PO2218

Paraneoplastic Minimal Change Disease Associated with High-Grade Neuroendocrine Tumor

Mohankumar Doraiswamy, Jessamyn S. Carter, Sethu M. Madhavan, Jason Prosek. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Minimal Change Disease (MCD) is usually associated with Lymphoma, Leukemia and solid tumors like Lung Cancer, Renal Cell Carcinoma and Thymoma but data on incidence of paraneoplastic glomerular disease are lacking. To our knowledge, only two cases of neuroendocrine tumor (NET) presenting with Paraneoplastic MCD reported in literature. We present a 47 year-old man with duodenal NET presented with nephrotic syndrome and renal biopsy was suggestive of minimal change disease.

Case Description: A 47 year-old-man with history of well-differentiated metastatic NET (not on therapy) and HTN admitted for dyspnea and anasarca for two weeks. His labs were significant for creatinine of 3.9 mg/dL, albumin 1.9 g/dL, proteinuria of 4.3 g/day and Na 118 mmol/L. IV diuretics with albumin infusion initiated, which improved his kidney function. Serologies and proteinuria workup - negative. Renal biopsy performed for nephrotic syndrome, showed prominent podocyte foot process effacement with mild acute tubular necrosis and mild glomerular sclerosis. Diagnosed with paraneoplastic MCD from metastatic NET and treatment with steroids initiated. Chemotherapy not started because of the overall decline in his clinical status and increased tumor burden. One week after steroids, his proteinuria was 42 g/day, and steroid doses were increased. Three weeks later, proteinuria decreased to 6 g/day and his symptoms improving. Unfortunately, he suffered further kidney injury because of hypotension and hemodialysis initiated one month later.

Discussion: The most common paraneoplastic glomerular disease is membranous glomerulopathy in tumors, but MCD should be kept on the differential as well. Like membranous nephropathy, remission of MCD been reported on ablation of the tumor, suggesting a paraneoplastic process, though the precise mechanisms are not fully understood. In our case, since the patient did not qualify for chemotherapy because of increased tumor burden, steroids were initiated which helped in part to reduce symptoms. The etiology of glomerulopathy in cancer does not appear to be related to tumor burden, metastatic spread or the site or extent of invasion, but to the secretion of substances from the tumor cells. Kidney biopsy should be performed early, as prompt diagnosis is important to ensure patients do not receive ineffective and potentially harmful treatments.

PO2219

Management of IgA Nephropathy and Concomitant Breast Cancer

Victoria Gutgarts,[1,2] Steven Salvatore,[2] Roman A. Shingarev.[1,2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medicine, New York, NY.*

Introduction: Immunoglobulin A nephropathy (IgAN) is the most common glomerulonephritis worldwide. Although treatment guidelines have been established, there is little known about the management of IgAN in the setting of solid malignancy. Herein we describe two cases of IgAN and breast cancer diagnosed at our center.

Case Description: Case 1: 42-year-old female with newly diagnosed breast cancer 3 months ago presents to the renal clinic for acute kidney injury (AKI) with creatinine (Cr) 3.5mg/dl from baseline 1.1-1.3mg/dl. Chemotherapy was started one week ago with doxorubicin and cyclophosphamide (ddAC). Two months prior to cancer diagnosis, her doctor noted 4.9g of protein in the urine with few RBCs. She now has 4g of protein with >50 RBCs. She underwent kidney biopsy which showed IgAN (M1 E1 S1 T2 C1). She received a 3g pulse of methylprednisolone (MP) followed by prednisone taper that was shortened to 3 months in light of degree of chronicity on biopsy and concurrent immunosuppressive ddAC treatment with 4 cycles total. Creatinine stabilized at 1.8mg/dL 9 months after last ddAC cycle and proteinuria improved to 1g after re-initiation of losartan. Case 2: 38-year-old female presents to the renal clinic with AKI (Cr 1.8mg/dl from baseline 1.0mg/dl), gross hematuria and nephrotic range proteinuria that were detected incidentally in the emergency department, where she was seen for sore throat after the first 2 monthly ddAC cycles for the new diagnosis of breast cancer. She has a history of arthralgias associated with high citric citrullinated peptide, low myeloperoxidase titers and intermittent hematuria that led to a kidney biopsy demonstrating moderate focal global sclerosis without immune deposits or vasculitic lesions 4 years prior. Her symptoms improved on hydroxychloroquine which she stopped at the time of cancer diagnosis. Her kidney biopsy now shows IgAN (M1 E0 S1 T1 C2) for which she received a 1.6g pulse of MP followed by prednisone tapered over 5 months. She completed 3 cycles of ddAC. Creatinine improved to 0.9mg/dL and proteinuria receded from 7g to 0.5g.

Discussion: These cases highlight the complexity in management of IgAN while patients are undergoing treatment for a concurrent malignancy. Temporal relationship of IgAN and malignancy is unclear, but suggests potential value of cancer screening of patients with newly diagnosed IgA nephropathy.

PO2220

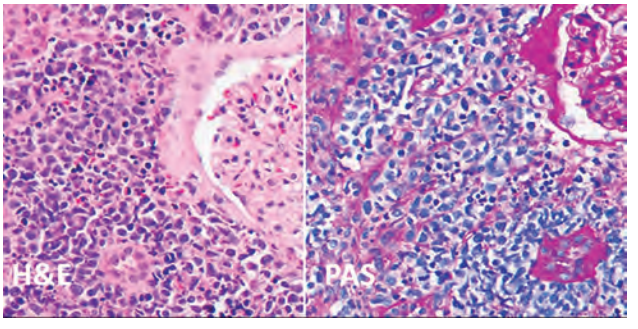
Sezary Syndrome with Renal Involvement

Sheikh B. Khalid,[1,2] J. Charles Jennette,[1] Monica L. Reynolds,[1] Obiajulu Kanu,[1] Vikas Singh.[1] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan.*

Introduction: Sezary Syndrome is a cutaneous T-cell lymphoma that presents with erythroderma, lymphadenopathy, and circulating malignant T cells. While involvement of the spleen, liver, bone marrow and lung are well documented, kidney involvement is rare. We present a case of acute kidney injury (AKI) due to biopsy-proven T cell lymphoma invasion of the kidneys

Case Description: A 69-year-old female with a history of cutaneous T-cell lymphoma was admitted to the oncology service with AKI. Serum creatinine (sCr) 3.3mg/dL (baseline 0.6mg/dL), urine protein-to-creatinine ratio 2.5g/g, urine sediment bland and renal ultrasound unremarkable. A PET scan, performed to evaluate systemic disease burden, revealed diffuse kidney enlargement with high FDG uptake throughout the renal parenchyma. A kidney biopsy was performed Light microscopy showed diffuse interstitial infiltration by atypical small lymphoid cells and prominent focal apoptosis with apoptotic bodies and focal interstitial hemorrhage. The lymphoid cells had the same immunophenotype as the cutaneous T cell lymphoma The glomeruli had slight segmental wrinkling of capillaries and glomerular basement membranes, and segmental podocyte swelling. She also had leptomeningeal involvement. Treatment included dexamethasone, systemic and intrathecal doxorubicin, methotrexate, and cytarabine. SCr returned to baseline. However, her course was complicated by severe mucositis, neutropenic fever, gastrointestinal hemorrhage and refractory shock. The patient was stabilized and opted to return home with hospice

Discussion: AKI caused by kidney involvement in Sezary syndrome has only been reported via case reports. The mechanism of AKI is thought to be tubular compression by the lymphomatous infiltrates impeding tubule function and peritubular capillary blood flow. Our patient's biopsy supports this mechanism. Her AKI resolved with urgent corticosteroids and chemotherapy. Further reporting is needed on the prevalence of this condition and nephrologists should consider renal lymphomatous invasion when evaluating AKI in those with cutaneous T-cell lymphoma



PO2221

Belatacept-Induced Post-Transplant Lymphoproliferative Disorder of the Spleen That Spontaneously Resolved on Withdrawal of the Agent

Alexander Pennekamp,[1] Karl B. Pembaur.[2] *[1]The Christ Hospital, Cincinnati, OH; [2]The Kidney and Hypertension Center, Cincinnati, OH.*

Introduction: PTLD (Post-Transplant Lymphoproliferative Disorder) is a dreaded and serious complication of allograft transplant. Compared to CNIs, allograft rejection prophylaxis with Belatacept is less nephrotoxic, but carries a higher risk of PTLD. B-cell proliferation in PTLD is linked to EBV, and while use of Belatacept is limited to those that are EBV+ pre-transplant, prior EBV infection does not completely ensure that a patient will not develop PTLD. Patients with active PTLD characteristically show B symptoms and an increase in EBV RNA due to active viral replication. Prompt PET, BMB and blood testing must be pursued to determine a potential site of proliferation.

Case Description: 64 year AAM 2 years status-post deceased-donor transplant was admitted for altered mental status, nausea, vomiting, fever of unknown origin, and weight loss. He was found to have splenomegaly on CT without other evidence of adenopathy. LDH was elevated. Patient underwent brain MRI, PET scanning, BMB and LP, all of which were normal. A full ID work-up including CMV, EBV RNA, BK were all negative. Core biopsy of the spleen demonstrated CD20/CD45+ cells with tissue effacement, suggesting a diffuse large B-cell lymphocytic infiltration/monomorphic PTLD. The sample was EBV-negative by IHC. Belatacept was withdrawn. Subsequent splenectomy was required, which showed histopathologic evidence of infarction, but complete resolution of lymphoproliferative infiltration.

Discussion: Even in EBV recipient-positive patients, there is still a risk to develop PTLD. In our case, the patient demonstrated monomorphic PTLD which resolved spontaneously when withdrawing Belatacept. This suggests that overly aggressive immune suppression, rather than induction of dysregulated proliferation, was the culprit. The fact that the patient did not show an acute increase in EBV RNA, and EBV by ISH on core biopsy of the spleen was negative, suggests that pre-transplant serosorting based on EBV seropositivity may not be sufficient to predict risk for developing PTLD. The patient had complete resolution of AMS and B symptoms with discontinuation of Belatacept, with no subsequent recurrence of PTLD after switching to sirolimus/mycophenolate.

PO2222

Heterogeneous Manifestations of Post-Renal Transplant Lymphoma

Rujuta R. Patil,[1] M. Abouljoud,[2] Anita K. Patel.[2] *[1]Wayne State University School of Medicine, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI.*

Introduction: Post-transplant lymphoproliferative disorder (PTLD) is a serious complication occurring in 1-3% of adult renal transplant recipients (RTR). PTLD is often associated with Epstein-Barr Virus (EBV) and over immunosuppression (IS). A majority of PTLD is of B-cell origin. PTLD has a heterogenous presentation, involving the allograft, GI tract, and nervous system. We present a case series of 16 RTR who demonstrate a variety of PTLD manifestations.

Case Description: 50% of RTR were Caucasian and 38% African American. 62% of RTR received a deceased donor and 38% a living donor. 62% received Thymoglobulin induction and 38% Simulect. Maintenance IS was Prednisone, Tacrolimus, and Mycophenolate Mofetil (MMF). RTR presented with GI symptoms, abdominal pain, B symptoms, and neurological deficits. At diagnosis, average time from transplantation was 96.8 months (<1-20 years); 56% of RTR were <60 years old and 44% were >61years old. 31% were EBV mismatched and 12.5% were Cytomegalovirus mismatched. PTLD involved a single site in 44% and multiple sites in 56%. PTLD localized to the GI tract (10), lymph nodes (9), CNS (4), bone marrow (3), lungs (2), mediastinum (2), skin (2), retroperitoneum (1), and native kidney/ureter (2). 6 RTR had purely extranodal involvement. PTLD was EBV+ (8), monomorphic/monoclonal (14), and of B-cell lineage (13; Diffuse Large B Cell Lymphoma in 11). Non-Hodgkin's Lymphoma was diagnosed in 7 RTR. 3 RTR had T-cell PTLD. IS agents (MMF, Tacrolimus) were discontinued in all RTR at diagnosis; maintained on steroid monotherapy. Treatment was chemotherapy either alone or in combination with radiation (2), resection (2), and salvage therapy (1). Post treatment, all RTR remained on steroid monotherapy or with Everolimus (3), Tacrolimus (1), or Azathioprine+Rituximab (1) added. Treatment was complicated by Tumor Lysis Syndrome and infections. 50% of RTR developed renal insufficiency and 31% received dialysis. The mortality rate was 44%, <4 years after diagnosis.

Discussion: PTLD that was EBV-, had T-cell involvement, and localized to the CNS/bone marrow presented with aggressive disease and a higher mortality. Thymoglobulin induction, deceased donor, and donor EBV+ status are potential contributing risk factors for PTLD development; further analysis is still being conducted. Physicians should be aware of the various PTLD manifestations and assertive in management of renal transplant recipients.

PO2223

Richter Transformation (RT): A Rare Complication in Renal Transplant

Nirali V. Maryania, Manju Mavanur. *LifeBridge Health, Baltimore, MD.*

Introduction: RT is conversion of B-cell chronic lymphocytic leukemia (CLL) into diffuse large B-cell lymphoma (DLBCL). We present a rare case of RT in a renal allograft.

Case Description: A 68 year old male was admitted for a syncopal episode and acute renal failure. He had significant medical history of ESRD secondary to diabetes and hypertensive nephrosclerosis, deceased donor renal transplant in 2015 on Mycophenolate and Tacrolimus, CLL diagnosed in 2017 on Ibrutinib, Stage III CKD of allograft with baseline creatinine 1.5 mg/dl. Initial work up revealed orthostatic hypotension and AKI with creatinine of 3.3 mg/dl. Urinalysis and microscopy was negative for proteinuria, hematuria, pyuria, casts or crystals. Renal ultrasound showed the size of transplant kidney was 10.7 x 5.8 x 4.3 cm with normal renal cortex and no demonstrated mass, cyst or hydronephrosis. Administration of IV NS and holding antihypertensive medications to correct orthostasis failed to improve renal function with creatinine rising up to 4.02 mg/dl. Transplant renal biopsy was done. Pathology results revealed no evidence of allograft rejection but extensive infiltration of renal parenchyma with atypical lymphocytes with high Ki-67 expression suggesting transformation to DLBCL in a patient with a known history of CLL. Lymphocytes retained their positivity for CD5 and CD23 which supported diagnosis of RT rather than post-transplant lympho-proliferative disorder (PTLD). Patient was continued on Ibrutinib, Tacrolimus, Prednisone 5mg daily and started on weekly Rituximab infusion. Mycophenolate was discontinued. Patient's renal function returned to its baseline after 2 doses of Rituximab. He was planned to continue Rituximab infusion as an outpatient.

Discussion: Transplant patients have high risk of RT due risk factors including concomitant immunosuppression, Eptstein-Barr virus infection and some with genetic susceptibility. While PTLD is a well-recognized complication of patients with renal transplants, RT is not that common. Immunochemotherapy is usually the preferred treatment for older patients with RT while allogeneic bone marrow transplantation may be curative in younger patients. Discussion between transplant physician and oncologist should be held, taking into account the new molecular prognostic markers prior to renal transplant. This may help in risk stratification of patients for conversion of CLL to RT.

PO2224

Longitudinal Assessment of Unilateral Ureteral Obstruction Kidney Injury by Relaxometry and Spin-Lock Exchange MRI

Feng Wang, Tadashi Otsuka, Keiko Takahashi, Raymond C. Harris, Takamune Takahashi. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Non-invasive imaging technique allows longitudinal and repetitive assessment of renal disease progression. In this study, we assessed the utility of a new MRI technique, quantitative relaxometry and Spin-lock exchange MRI, in detecting renal pathology in unilateral ureter obstructed (UUO) kidneys, focusing on destructive tubular injury (dilatation) and renal fibrosis, the pathological changes commonly observed in progressive kidney disease.

Methods: BALB/c mice (n=6-8) were imaged before and after (day 5, 10 and 15) UUO surgery at 7T magnet. Spin-lock images were acquired in a transverse plane using a fast spin echo sequence preceded by a preparatory spin-lock cluster. The dispersion of $R_{1\rho}$ with locking frequency was fit to Chopra model. The fits provided regional values of transverse relaxation rates R_{2fit}, $R_{1\rho}$ at infinite spin-lock frequency ($R_{1\rho}^{\infty}$), and an exchange rate-weighted parameter S_ρ. Since cortex and outer stripe of outer medulla (OSOM) were clearly identified with T_2-weighted image, even with UUO kidneys, these regions were selected for analysis. Paraffin tissue sections were stained using picrosirius red or anti-collagen I antibody. Histological scores for tubular dilatation and fibrosis, based on luminal space and positive fibrotic areas in sections, were computationally measured and the correlation between MRI parameters and histological scores were assessed.

Results: In histology, evident tubular enlargement was observed at UUO day 5, while tubulointerstitial fibrosis was mild at this stage. Both histological changes became more evident on progression and fibrosis showed larger increases from day 5 to day 15 (tubular dilatation ~25% increase, fibrosis ~3 fold increase). Relaxation rates R_{1obs}, R_{2obs} and $R_{1\rho}$ were progressively dropped (25-50%) in UUO kidneys. Interestingly, R_{1obs} showed the highest sensitivity to tubular dilatation, while S_ρ showed the highest correlation with renal fibrosis.

Conclusions: Relaxation parameters showed high detectability to tubular dilatation and overall changes in UUO progression. S_ρ best detected fibrotic changes. This would be because it depends mainly on the average exchange rate between water and other chemically shifted resonances such as amides and hydroxyls, sensing collagen accumulations. These new MRI parameters could be used for the assessment of kidney disease progression.

Kidney-Specific Landscape of Aging Mitochondrial DNA Mutations by Duplex Sequencing

Mariya T. Sweetwyne, Monica Y. Sanchez-Contreras, Kristine A. Tsantilas, Jeremy A. Whitson, Matthew D. Campbell, David J. Marcinek, Peter S. Rabinovitch, Scott R. Kennedy. *University of Washington School of Medicine, Seattle, WA.*

Background: Accumulation of mutations in the mitochondrial genome (mtDNA) is a potential mechanism of aging in the mitochondrial rich kidney, where mtDNA damage also increases with diabetes, CKD and AKI. Accurately detecting low level somatic mtDNA mutations within the cellular complexity of the kidney was previously confounded by variable levels of mtDNA heteroplasmy. Using ultra-sensitive Duplex Sequencing (DS), a modified next-gen sequencing (NGS) technique, we decreased the error rate relative to conventional NGS by $>10^4$x, allowing us to accurately characterize mtDNA mutation patterns unique to the aging kidney relative to other organs.

Methods: We compared mtDNA mutations in kidneys from cohorts of aged (26-m.o.) and young (5-m.o.) NIA C57Bl/6j mice to multiple organs with high mitochondrial content (heart, eye, liver, skeletal muscle and brain). In both ages, kidney carried the highest burden of mtDNA point mutations. Mutation spectrum analysis showed that mtDNA point mutations in the kidney increased significantly with age and were primarily G>A/C>T, indicative of polymerase error ($2.5x10^{-5}$ $p > 0.0001$ relative to all other tissues) with G>T/C>A mutations, indicative of oxidative damage, the second most common type. Aged kidneys were further separated into glomeruli or tubule-rich whole cortex fractions to determine regional mutation burden.

Results: Glomeruli had ~25% fewer total mtDNA mutations ($p= 0.002$) and specifically ~80% fewer oxidative lesions (G>T/C>A, G>C/C>G, $p= 0.02$). Furthermore, differential accumulation of mtDNA mutation between kidney fractions does not appear to be randomly distributed across the genome but is instead gene-specific as demonstrated by significantly reduced mutations in glomeruli of mt-rRNA gene mtRnr1 but not mtRnr2, and of Complex IV gene mt-Co2, but not mt-Co1 or 3. Finally, we sequenced kidneys from aged mice treated systemically for 8 weeks with SS-31, a mitochondrial therapeutic peptide that reduces oxidative stress in the kidney, and found that mutations stemming from oxidation, but not polymerase error, were significantly reduced.

Conclusions: These data suggest that renal mtDNA mutation is cell specific and that even in old age, accumulation of some mutations is tractable with therapeutic intervention.

Integrated Analysis of the DNA Methylome, Transcriptome, and Proteome in Human Glomerular and Tubulointerstitial Compartments

Samir V. Parikh,[2] Kimberly S. Collins,[1] Ricardo Melo ferreira,[1] Yinghua Cheng,[1] Daria Barwinska,[1] Michael J. Ferkowicz,[1] Ken Dunn,[1] Katherine J. Kelly,[1] Timothy A. Sutton,[1] John P. Shapiro,[2] Brad H. Rovin,[2] Pierre C. Dagher,[1] Tarek M. El-Achkar,[1] Michael T. Eadon.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: The interplay between the human DNA methylome, transcriptome, and proteome in the kidney glomerulus and tubulointerstitium is incompletely understood. Promoter sequence methylation is often thought to contribute to gene and protein expression regulation. We hypothesized that promoter sequence methylation would explain differential protein expression between the glomerulus and tubulointerstitium.

Methods: Nine reference nephrectomies underwent laser microdissection of the glomeruli and tubulointerstitium. DNA methylation sequencing, RNA sequencing, and mass spectrometry quantification of peptides was completed for both compartments in the samples. Datasets were dimensionally reduced to match expressed proteins (N = 4600). Regions of hypermethylation in promoter sequences, introns, and exons were assessed and compared to corresponding protein and mRNA expression.

Results: At least three patterns of hypermethylation were observed across the methylome: promoter sequence, intronic, and exonic methylation. In many cases, promoter sequence or exonic methylation of the tubulointerstitium correlated with a higher glomerular to tubulointerstitial protein and mRNA expression ratio. Likewise, increased tubulointerstitial protein or mRNA expression was associated with glomerular hypermethylation of promoter or exonic regions. For example, Uromodulin (UMOD) protein and mRNA expression were higher in the tubulointerstitium than the glomerulus. The strongest regions of uromodulin hypermethylation were observed in exons 9 and 10 of the glomerular compartment, although hypermethylation was also observed in the promoter sequence and two intronic regions of the tubulointerstitium. In contrast, regions of hypermethylation of Apolipoprotein L1 (APOL1) were exclusively confined to the tubulointerstitium, distributed in all three patterns.

Conclusions: Promoter sequence methylation alone does not explain differential expression patterns between the glomerular and tubulointerstitial compartments. Hypermethylation of exonic regions also contributes to expression regulation.

Single-Cell Transcriptomics of the Peripheral Blood Revealed Inflammation and Infection Were Associated with IgAN

Changwei Wu, Guisen Li, Li Wang. *Renal Department and Nephrology Institute, Sichuan Provincial People's Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China.*

Background: Immunoglobulin A nephropathy (IgAN) is the most common primary glomerular disease worldwide. Due to the diverse clinical manifestations and the complex pathological features, IgAN patients have different response to therapy, and the optimal treatment for IgAN remains controversial. Our study investigated the pathogenesis of IgAN by single-cell transcriptome sequencing.

Methods: Single-cell transcriptome sequencing was performed on peripheral blood monocytes derived from 3 IgAN patients and 1 healthy control, and differential gene expression profiles of peripheral blood single-cell were established. Functional analysis was performed to explore the pathogenesis of IgAN. Meanwhile, RT-PCR was used to validate the differential expression of mRNA and miRNA.

Results: According to quality control and cell selection, we characterized 21739 cells using unbiased single-cell RNA sequencing. 3 IgAN patients included 7847, 5389 and 6609 cells, respectively, and the helthy control included 1894 cells. We used unsupervised clustering to cluster cell clusters. In addition, cells were divided into 14 cell groups, including B lymphocytes and T lymphocytes, based on cell markers (Figure 1). Functional analysis revealed that differential genes were extensively enriched in inflammation / infection-related pathways in each cell type (Figure 2), and the EBV infection pathway focused on antigen presentation (Figure 3). RT-PCR of B lymphocytes demonstrated that SPI1, MXD1 and S100A9 mRNA levels were higher in IgAN patients than controls (Figure 4), which showed the reults of single-cell transcriptome sequencing was avalible.

Conclusions: Differential gene expression profiles of IgAN in peripheral blood single cells were successfully established, and it demonstrated that the inflammation/ infection pathway was associated with IgAN.

Analysis of Urinary Exosomal RNAs After Treatment of Rats with an Nrf2 Activator

Ayae Tanaka, Hiroko Sonoda, Yui Sakaguchi, Masahiro Ikeda. *Veterinary Pharmacology, University of Miyazaki, Miyazaki, Japan.*

Background: Renal NF-E2-related-factor 2 (Nrf2) is known to be increased in the presence of oxidative stress. Administration of an Nrf2 activator has also been reported to lessen the degree of renal damage. However, biomarkers for detection of Nrf2 activation in the kidney are largely unknown. Urinary exosomes, a subset of extracellular vesicles released by renal epithelial cells, contain RNA molecules that are expected to be biomarkers for renal disease. Thus we analyzed urinary exosomal RNAs after administration of bardoxolone methyl (BARD), an Nrf2 activator, in rats.

Methods: Male Sprague-Dawley rats were randomly divided into two groups; the BARD group, intraperitoneally receiving 10 mg/kg BARD, and the control group, receiving only vehicle (100% DMSO). The urine was obtained for 6 hours just after administration, and exosomes were isolated from the urine. At 6 hours after administration, rats were sacrificed and the kidneys were removed. Thereafter RNAs were extracted from the kidneys and urinary exosomes. The RNAs (27,012 mRNAs amd 1,218 miRNAs) were analyzed with microarrays.

Results: BARD altered expression of 98 renal mRNAs and 357 urinary exosomal mRNAs with more than 2.0-fold relative to the control. BARD also changed expression of 15 renal miRNAs and 3 urinary exosomal miRNAs. The correlation coefficients between renal and urinary exosomal mRNAs as well as miRNAs were both less than 0.1. mRNAs that were commonly changed in both the kidney and urinary exosomes were 13. Among them, 8 genes are known to be targets of Nrf2 including Akr1b8, Akr1c19, Bach1, Ephx1, Hmox1, Pir, Slc40a1 and Ugdh. Of 8 genes, Akr1b8 and Pir were increased more than 10-fold in the kidney and more than 4.0-fold in urinary exosomes. For miRNA, only rno-miR-877 was changed in both the kidney and urinary exosomes.

Conclusions: The correlation coefficients between renal and exosomal RNAs were less than 0.1, suggesting that specific RNAs were selectively loaded into exosomes. In addition, Akr1b8 and Pir expression was dramatically increased in both kidney and urinary exosomes. Therefore, they could be potential biomarkers to detect their renal expression changes by renal Nrf2 activation.

PO2229

Urinary Excretion of Extracellular Vesicles in 24 Hours: Time Point Collection and Normalization Strategy

Luca Musante, Sabrina La salvia, Uta Erdbruegger. *University of Virginia Health System, Charlottesville, VA.*

Background: Urinary extracellular vesicles (uEVs) are an ideal source of biomarkers for kidney diseases. Despite the interest generated, little is known about collection time and normalization approach. The majority of the studies on uEVs focus on spot urine collection based on the assumption that it accurately reflects the renal function. However, the practice to collect spot urine does not allow for calculating and standardizing the uEV excretion rate and then assessing the renal function. Moreover, no research has been carried out yet to show the difference between spot urine and 24h collections. The aim of this study is to compare uEVs excreted in all 24 hour urine void as single spot and compare it with 24 hour collection.

Methods: Each single spot void urine was collected and 20% of the volume was used to to create the 24 hours collection. uEVs were enriched by differential centrifugation. Transmission electron microscopy (TEM), western blot (WB), nanoparticle tracking analysis (NTA), tuneable resistive pulse sensing (TRPS), imaging flow cytometry (iFC) and miRNA (miR16 and miR200b) quantitation by qPCR were used to quantify uEVs markers variation during the 24 hour. Creatinine, urine osmolality and particle concentration (NTA, TRPS) were used to normalize the analytes.

Results: TEM showed a heterogeneous population of EVs and WB confirmed the presence of EVs marker (TSG101, ALIX and CD9). RNA was extracted by a column-based method (miRNA extraction kit Qiagen) and cel-39 miRNA was spiked in each sample. A multiparametric detection of nephron markers podocalyxin (PODXL), aquaporin-2 (AQP2) and uEVs pan tetraspanins (CD9 + DC63 + CD81) was performed in imaging flow cytometry. Whereas the uEV composition of did not change across the 24 hours analysis, the quantity of uEVs and related markers (miRNA and protein) fluctuated during the day depending on the hydration and excretion rate. Creatinine, urinary osmolarity and particle count normalization failed to normalize "outliers"

Conclusions: In conclusion, this study represents the very first report which compares single void urine versus 24 hour uEV analysis. We concluded that the 24 hour collection is the preferred choice for a robust and rigorous assessment of uEVs and its associated markers.

Ultra-Fast Clearing Protocol for 3D Optical Renal Pathology

David Unnersjö-Jess,[6,2] Linus Butt,[2,3] Martin Höhne,[2,3] Anna Witasp,[1] Lucas Kuehne,[2,3] Peter Hoyer,[4] Jaakko Patrakka,[1] Paul T. Brinkkoetter,[2] Annika Wernerson,[1] Bernhard Schermer,[2,3] Thomas Benzing,[2,3] Lena Scott,[5] Hjalmar Brismar,[5,6] Hans Blom.[6] *[1]Karolinska Universitetsjukhuset i Huddinge, Huddinge, Sweden; [2]Department II of Internal Medicine and Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany; [3]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; [4]Pediatric Nephrology, Pediatrics II, Univeristy of Duisburg-Essen, Essen, Germany; [5]Science for Life Laboratory, Dept. of Women's and Children's Health, Karolinska Institutet, Solna, Sweden, Solna, Sweden; [6]Science for life Laboratory, Dept. of Applied Physics, Royal Institute of Technology, Solna, Sweden.*

Background: Kidney pathology involves three separate microscopy workflows. *Histology*, typically carried out on paraffin-embedded sections, used to optically visualize large-scale renal morphology. *Immunofluorescence*, used for mapping presence of specific molecular variations, carried out on paraffin-embedded or fresh-frozen thin sections. To visualize renal ultrastructures, *electron microscopy* is applied, with elaborate preparation protocols on ultra-thin sections.

Methods: We have modified published protocols in order to simplify and speed up the workflow of routine optical kidney imaging. The presented protocol induces a slight swelling of a cleared sample, and increase effective resolution enough for 3-D confocal visualization of filtration barrier structures. The duration of the protocol is only 5 hours from harvesting the tissue until full image acquisition.

Results: Our simple and fast protocol can resolve foot processes in mouse and human tissue using standard lab equipment and conventional 3-D confocal microscopy. Importantly, the protocol can be used to visualize various large-scale histopathological features as well as immune deposits in human patient material too. Compared to others, our tissue protocol is simpler and faster, and allow better 3-D in situ imaging capabilities.

Conclusions: We conclude that our simple and fast protocol, allow researchers and pathologists to use a single preparation and microscopy technique, to visualize both renal ultrastructure, histology and protein expression. Our protocol has the potential of, not just to complement, but also merging workflows used today while adding accessing to in situ depth information on all scales.

PO2231

A Novel Model of CKD and Heart Failure with Preserved Ejection Fraction

Alejandro R. Chade, Maxx Williams, Jason E. Engel, Michael Hall. *University of Mississippi Medical Center, Jackson, MS.*

Background: Chronic kidney disease (CKD) has high cardiovascular mortality. We developed a model of CKD that shows major pathological features: low GFR (+/- 60 ml/min), renal inflammation, fibrosis, microvascular disease, and hypertension. We aim to define the cardiac phenotype of the model and, if present, the pathological traits involved

Methods: CKD was induced in 6 pigs (bilateral renovascular disease and dyslipidemia) and observed for 14 weeks. Renal hemodynamics (RBF, GFR) were quantified by multi-detector C, cardiac morphology and function by echocardiography, and mean arterial pressure (MAP) by telemetry. Blood was collected to measure circulating inflammatory cytokines (TNF-α, MCP-1), markers of inflammation (C-reactive protein), and biomarkers of heart failure (ANP, BNP, NT-proBNP). Pigs were then euthanized and kidneys and hearts collected for *ex vivo* studies. Normal pigs were used as time-matched controls

Results: Loss of renal function was accompanied by left ventricular hypertrophy, left atrial dilatation, diastolic dysfunction (E/A ratio) with preserved ejection fraction (pEF), elevated ANP, BNP, and NT-proBNP, and hypertension (MAP of 131.2 mm/Hg, $p<0.05$ vs. normal). CKD also increased renal (but not cardiac) mRNA expression of TNF-α, MCP-1, and IL-6, accompanied by increased circulating inflammatory cytokines (Figure)

Conclusions: CKD leads to cardiac abnormalities that meet the criteria of heart failure with pEF (HFpEF). Our data suggest that hypertension and inflammatory mediators (possibly from kidney origin) target the heart and may contribute to HFpEF

pathophysiology. HFpEF associates with CKD in about 50% of cases and has no specific treatment. Our study offers a new experimental platform to increase our understanding of CKD-HFpEF and to test new treatments in a translational fashion

PO2232

Pathophysiological Insult of the Liver by Gadolinium-Based Contrast Agent Treatment

Joshua Deaguero,[1] Tamara A. Howard,[1] Brent Wagner,[1,2] G. P. Escobar.[1,2] Kidney Institute of New Mexico *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]New Mexico VA Health Care System, Albuquerque, NM.*

Background: The advent and overuse of gadolinium-based contrast agents (GBCAs) lead to consequent iatrogenic systemic fibrosis. Gadolinium may accumulate in tissues in every organ. GBCA treatment induces dyslipidemia and insulin resistance (Do C et al, Toxicol Appl Pharmacol 2019 Jul 15;375: 32-45). Therefore, the impact of gadolinium on the liver was investigated.

Methods: Wild-type male and female C57/BL6 mice were randomized by age and weight to untreated (n = 20) or GBCA-treatment (n = 20) (Omniscan, 2.5mmol/kg, intraperitoneally, 20 doses over 4 weeks). Tissue were isolated, specimens fixed in glutaraldehyde or snap frozen in liquid nitrogen. Metabolites were profiled by capillary electrophoresis mass spectrometry (Human Metabolome Technologies, Japan).

Results: Liver from the GBCA group demonstrated ballooned hepatocytes, lipid-laden vacuoles, and reduction in glycogen. Furthermore, GBCA treatment promoted hepatic steatosis. Gadolinium reduced expression of lipid metabolism and transport metabolites g-butyrobetaine, prostaglandin E2, O-acetylcarnitine, malonylcarnitine, isobutyryl CoA divalent, hexanoic acid, lauroylcarnitine, and decanoic acid (P < 0.05). GBCA treatment alters metabolite expression of metabolites from other pathways, including glycolysis, histidine metabolism, and purine metabolism. Furthermore, gadolinium treatment altered the urea cycle.

Conclusions: GBCA treatment alters several metabolic pathways, particularly lipid metabolism and lipid transport pathway intermediates. GBCA treatment induces ultrastructural and metabolic disruptions that mimic nonalcoholic fatty liver disease. These studies are the first to demonstrate GBCA mediates metabolic perturbations in the liver. GBCAs are not biologically inert.

Expression of Immunoglobulin G in Human Proximal Tubule Epithelial Cell and Its Role in Epithelial Mesenchymal Transformation

Zhenling Deng, Song Wang, Yue Wang. *Peking University Third Hospital, Beijing, China.*

Background: Our previous studies showed that human mesangial cells and podocytes can synthesize and secrete IgA and IgG respectively, participating in cell viability and adhesion. Proximal tubular epithelial cells (PTECs) mediate transcytosis of IgG through neonatal Fc receptor (FcRn). Whether PTECs express IgG has not been reported. The aim of this study was to explore whether PTECs express immunoglobulins

Methods: Kidney cortical tissues were obtained far from the tumor of patients undergoing nephrectomy as a result of renal carcinoma. Immunohistochemical (IHC) staining was used to assay the IgG expression in PTECs. Single PTECs were sorted by FACS from the cell suspension of the cortexes. 10×Genomics and nested PCR combined with Sanger sequencing were used to detect the transcripts and repertoires of Igs in single PTECs. An immortalized PTEC cell line (HK-2) was used to detect Igs protein expression and potential roles in tubular epithelial mesenchymal transformation.

Results: IHC showed positive staining of IgG but not other Igs in PTECs of kidney cortex. High throughput single cell RNA sequencing by 10×Genomics only detected Ig γ transcripts in few PTECs without V(D)J rearrangements. Nested PCR amplified Ig γ transcripts in 82% (91/111) manually picked single PTECs. Sanger sequencing showed that PTEC-derived Ig γ variable region displayed classic V_HDJ_H rearrangements but predominant VH1-24/DH2-15/JH4 sequence, biased VH1 usage and less diversity than B cells derived IgG. Western blot and immunofluorescence staining demonstrated Ig γ (including Ig γ4), Ig κ and Ig λ in HK-2. RP215, which specifically recognizes non-B cell-derived Ig γ, can identify the Ig γ in HK-2. The Ig γ was upregulated by TGF-β1 and accompanied by the up-regulation of α-smooth muscle actin and the down-regulation of E-cadherin. In addition, the transcripts of recombination activating gene 1/2 (RAG1/2, essential for V(D)J rearrangement) and activation-induced cytidine deaminase (AID, essential for class switch recombination) were detected in HK-2.

Conclusions: Our study suggests that PTECs can express IgG in a similar way as B cells. TGF-β1 can upregulate the expression of IgG in PTECs. PTEC-derived IgG may be involved in tubular epithelial mesenchymal transformation and interstitial fibrosis.

PO2234

A Plasma Creatinine- and Urea-Based Equation to Estimate Glomerular Filtration Rate in Rats

Tobias Pieters, Paul J. Besseling, Isabel T. Nguyen, Petra D. Bree, Maarten B. Rookmaaker, Karin G. Gerritsen, Marianne C. Verhaar, Hendrik Gremmels, Jaap A. Joles. Verhaar *Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.*

Background: Monitoring renal function is a vital part of kidney research involving rats. Measurement of Glomerular Filtration Rate (GFR) with an exogenous filtration marker is laborious and does not easily allow serial measurements. Plasma concentrations of creatinine and urea are often used as surrogate, although their correlation with GFR has not been thoroughly investigated in a large cohort of rats. Goal of this study was to develop an eGFR equation for rats.

Methods: We used an in-house collected database of 691 experiments in male rats with gold-standard GFR measurement (inulin clearance, mGFR) and plasma creatinine, plasma urea, weight, and strain (Lewis, Fawn-Hooded, Sprague-Dawley, Wistar). The equation was derived in a development cohort (n=442) and validated in a validation cohort (n=249). Subsequently, we measured plasma cystatin C in a random subset (n=242) to test its added value to the model.

Results: All parameters that were included during model development correlated to mGFR (weight, R^2=0.065; creatinine, R^2=0.756; urea, R^2=0.633; strain, R^2=0.014; all p<0.001). Using linear regression with a piece-wise linear spline for creatinine, we developed the following equations in the development cohort. *Plasma creatinine <48 (μmol/L):* $eGFR=833*W^{0.677}*C^{-0.585}*U^{-0.425}$ *Plasma creatinine ≥48 (μmol/L):* $eGFR=8173*W^{0.677}*C^{-1.175}*U^{-0.425}$ ***eGFR**= estimated GFR (μL/min), **W**= weight (gram), **C**=creatinine (μmol/L), **U**=urea (mmol/L).* Subsequent evaluation in the validation cohort yielded similar precision and accuracy (R^2=0.872, p_{30}=69%) as in the development cohort (R^2=0.801, p_{30}=73%). Inclusion of strain in the model increased neither precision nor accuracy. Although plasma cystatin C correlated with mGFR (R^2=0.242,p<0.001), it did not add predictive power to the model (R2-change=0.0004, p=0.64), and therefore not measured in the entire dataset nor included in the model.

Conclusions: We are the first to develop an equation to estimate GFR in male rats. This equation allows a less labour intensive and invasive repetitive estimation of GFR in rats, and may reduce experimental animal numbers. Validation in an external cohort, in females, and in other disease models is required.

PO2235

Long-Term Mitochondrial Protection Reduces Proteinuria in Obese Aged Mice

Mariya T. Sweetwyne, Rene Coig, Ruby Sue M. Mangalindan, John Morton, Jeremy A. Whitson, Peter S. Rabinovitch, Warren C. Ladiges. *University of Washington School of Medicine, Seattle, WA.*

Background: In humans, obesity is associated with higher rates of kidney disease, which is compounded by aging. As an energetically demanding tissue, it has been proposed that preventing mitochondrial dysfunction is one key to reducing renal decline. Previously, we showed that an 8-week systemic treatment of aged 24-month-old (m.o.) mice with a mitochondrial targeted protective tetrapeptide, SS-31, significantly reduced the burden of age-induced glomerulosclerosis by 26-m.o. and preserved podocyte integrity.

Methods: To determine if SS-31 aging protection also applied with a comorbidity of obesity, 18-m.o. male NIA C57bl/6j mice were fed regular chow (RC) or a high fat, high sucrose diet (HFHS) for 10 months and treated with SS-31 injected 5x/wk (3 mg/kg) or saline vehicle (n= 20/group).

Results: Mice were weighed weekly. RC mice averaged 33g with no change from age or treatment. HFHS mice gained weight in the first month but by 5 mo. of diet, SS-31+HFHS mice weighed significantly less relative to HFHS untreated mice (40.4g vs. 45.9g p= 0.047). Spot urine was collected monthly for albumin/creatinine ratio (ACR μg/mg). At 18-m.o. baseline, ACR averaged 48μg/mg. In RC mice, ACR increased modestly, and not significantly, with age although SS-31 RC mice had lower ACR at endpoint (28-m.o. control 125.9 vs. SS-31 60.0). HFHS untreated mice displayed more renal dysfunction by 23 m.o. (ACR: RC = 32.6 vs HFHS = 243.2, p = 0.003), climbing significantly to an average of 519.8 μg/mg at 28-m.o. ACR increased in SS-31 HFHS mice but leveled off by 23-m.o. (5 mo. treat.), averaging 146.1 μg/mg with no significant increase by 28-m.o. By 9 mo. of treatment, ACR was significantly lower in HFHS+SS-31 treated mice. Preliminary quantification of podocytes by p57 nuclear stain and PAS counter stain (n=4-7) showed that HFHS mice, regardless of treatment, had a 30% decrease in podocyte density relative to RC mice. Control HFHS mice trended to higher tuft volume (glomerular hypertrophy) than in SS-31 HFHS mice. However, results were not significant likely due to small sample size.

Conclusions: Combined with improved ACR our results suggest that podocyte integrity, if not number, may be preserved in mice fed a Western diet by SS-31 intervention and that long-term mitochondrial protection is a potential therapeutic target to preserve renal function with age.

Bacterial and Fungal Communities Entombed Within Calcium Oxalate, Struvite, and Brushite Human Kidney Stones

Elena M. Wilson,[1,2] Jessica J. Saw,[1,3] Mayandi Sivaguru,[1] Dirk Lange,[7] Yiran Dong,[1,9] Robert A. Sanford,[1,2] Christopher J. Fields,[8] Melissa Cregger,[1,4] William J. Bruce,[1,2] Annette Merkel,[1,3] John C. Lieske,[5] Amy E. Krambeck,[5,6] Marcelino E. Rivera,[6] Tim Large,[6] Nicholas L. Chia,[5] Michael F. Romero,[5] Joseph R. Weber,[1,2] Bruce W. Fouke.[1,2] *[1]Carl R. Woese Institute for Genomic Biology, University of Illinois at Urbana-Champaign, Urbana, IL; [2]University of Illinois at Urbana-Champaign, Urbana, IL; [3]Mayo Clinic School of Medicine, Rochester, MN; [4]Oak Ridge National Laboratory, Oak Ridge, TN; [5]Mayo Clinic Minnesota, Rochester, MN; [6]Indiana University School of Medicine, Indianapolis, IN; [7]Jack Bell Research Centre, Vancouver, BC, Canada; [8]Roy J. Carver Biotechnology Center, University of Illinois at Urbana-Champaign, Urbana, IL; [9]China University of Geosciences, Wuhan, China.*

Background: Mechanisms of human kidney stone formation are poorly understood. More than 70% of stones are composed of calcium phosphate and/or oxalate. Recent studies have shown that kidney stone formation follows a continuum of complex biogeochemical transitions and is strongly influenced by the presence of human host and microbial organic matter.

Methods: Kidney stones, removed via percutaneous nephrolithotomy, were prepared as 25-μm thick doubly polished petrographic thin sections and analyzed using brightfield, confocal and super-resolution autofluorescence microscopy. DNA was extracted from 18 calcium oxalate stones, 1 struvite stone, and 1 brushite stone for Fluidigm™ PCR amplification. Paired-end sequencing of bacterial 16S rRNA gene sequences and fungal internal transcribed spacer (ITS) regions was completed using Illumina™ MiSeq. Reads were correlated with patient metadata and analyzed using DADA2, phyloseq v1.22.3 and R software.

Results: A 153-amplicon sequence variant (ASV) fungal community, dominated by *A. niger* (92% of total reads), was present in 11 of 20 total sequenced stones and correlated with higher patient urine calcium excretion (335 ± 131 vs 175 ± 108 mg/day, p=0.01). Petrography of 30 stones documented entombed coccoidal and rod-shaped bacterial cells in the struvite stone and well-preserved fungal borings and hyphae in one calcium oxalate/apatite stone. Entombed bacterial sequences were most closely affiliated with *Acinetobacter* and *Cutibacterium*. The brushite stone microbiome community contained *Capnocytophaga* and *Humibacter* and the struvite stone microbiome community included *Pseudomonas* and *Staphylococcus*.

Conclusions: This study presents the first evidence of a low-diversity fungal and bacterial microbiome community entombed and preserved within calcium oxalate, struvite, and brushite human kidney stones. The macromolecules secreted by the fungal and bacterial communities may play crucial roles in human kidney stone growth, dissolution, and recrystallization, similar to processes that have been documented in natural geologic stone growth.

PO2237

Targeting of Factor D in Cfh-/- Mice Does Not Relieve C3 Glomerulopathy due to the Action of C3(H2O)

Yuzhou Zhang,[1] Adam C. Keenan,[1] Dao-Fu Dai,[2] Kristofer S. May,[1] Gabriella R. Pitcher,[1] Ronald P. Taylor,[3] Richard J. Smith.[1] *[1]Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; [2]Department of Pathology, University of Iowa, Iowa City, IA; [3]University of Virginia School of Medicine, Charlottesville, VA.*

Background: C3 glomerulopathy (C3G) is an ultra-rare kidney disease defined by underlying complement dysregulation and characterized by complement C3 deposition on kidney biopsy. Dysregulation of the alternative pathway (AP) is fundamental to disease expression, although terminal pathway dysregulation is also common. Treatment of C3G with eculizumab is unsuccessful in the majority of patients, consistent with the fact that eculizumab targets the terminal complement cascade while leaving up-stream C3 complement dysregulation untouched. Of up-stream targets, factor D (FD) is appealing because it circulates in the plasma at low concentrations and has a single function, to cleave its substrate, factor B, to generate C3 convertases of the alternative complement pathway. Mice with a targeted deletion of factor H (FH; *Cfh*-/- mice) develop features of C3 glomerulopathy (C3G).

Methods: To assess the impact of FD inhibition, we studied *Cfh*-/-;*Cfd*-/- mice. After crossing the *Cfd*-/- and *Cfh*-/- mice, *Cfh*+/-;*Cfd*+/- progeny were backcrossed to C57BL/6 for 10 generations. Littermates of *Cfh*-/-, *Cfd*-/-, *Cfh*-/-;*Cfd*-/- and wildtype were used for assessing complement dysregulation and renal pathology.

Results: The C3G phenotype in the *Cfh*-/- mouse is not rescued by removing FD. Instead, *Cfh*-/-;*Cfd*-/- mice develop a subtype of C3G and nephrogenic diabetes insipidus. We used serum from the *Cfh*-/-;*Cfd*-/- mouse to show that residual AP function is present when both FD and FH are missing and that hemolytic activity is increased *in vitro* and *in vivo* due to the action of C3(H2O). Therefore, uncontrolled tick-over leads to slow activation of the AP in the *Cfh*-/-;*Cfd*-/- mouse. While a tiny amount of FD suffices to activate complement, a minimal threshold of FH is needed to prevent tissue deposition of C3 in the absence of FD.

Conclusions: These findings suggest that efforts to block AP activity by targeting FD may lead to unanticipated outcomes in subgroups of C3G patients. Sustained complete and persistent FD blockade may be difficult to maintain, and due to the action of C3(H20) might not completely suppress complement activation; substantial breakthrough complement activation may then occur as even minuscule amounts of free FD become available.

A Mutation in Complement Factor B Causing Massive Fluid-Phase Dysregulation of the Alternative Complement Pathway Can Result in Atypical Hemolytic Uremic Syndrome

Yuzhou Zhang,[1] Robin A. Kremsdorf,[2] John Sperati,[3] Kammi J. Henriksen,[4] Mari Mori,[5,6] Renee X. Goodfellow,[1] Gabriella R. Pitcher,[1] Nicolo Ghiringhelli Borsa,[1] Ronald P. Taylor,[7] Carla M. Nester,[1] Richard J. Smith.[1] *[1]Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; [2]Department of Pediatrics, Warren Alpert Medical School of Brown University, Providence, RI; [3]Division of Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD; [4]Department of Pathology, University of Chicago, Chicago, IL; [5]Division of Genetic and Genomic Medicine, Nationwide Children's Hospital, Columbus, OH; [6]Department of Pediatrics, College of Medicine, The Ohio State University, Columbus, OH; [7]University of Virginia School of Medicine, Charlottesville, VA.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is an ultra-rare disease characterized by microangiopathic hemolytic anemia, thrombocytopenia and acute kidney injury. Pathogenesis is driven most frequently by dysregulated *cell-surface* control of the alternative pathway (AP) of complement secondary to inherited and/or acquired factors.

Case Description: We present two unrelated aHUS patients (a 5-year-old female and a 55-year-old female) who presented with the classic signs of thrombotic microangiopathy associated with renal failure with the additional finding of an undetectable C3 level. Circulating levels of C5 and properdin were also low, consistent with over-activity of both the alternative and the terminal pathways of complement. Genetic testing identified a heterozygous novel variant in the complement factor B gene (*CFB* c.1101 C>A, p.Ser367Arg). Functional studies demonstrated strong fluid-phase C3 cleavage when normal and proband sera were mixed. Cell-surface C3b deposition was strongly positive when patient serum was supplemented with C3. *In vitro* control of C3 convertase activity could be restored with increased concentrations of factor H.

Discussion: *CFB* p.Ser367Arg is a gain-of-function pathogenic variant that leads to dysregulation of the AP in the fluid-phase and increased C3b deposition on cell surfaces. This report highlights the complexities of complement-mediated diseases like aHUS and illustrates the importance of functional studies to characterize variants of unknown significance and to gain insight into the disease phenotype.

PO2239

Efficacy of Low-Intensity Pulsed Ultrasound on CKD-Associated Cachexia and Muscle Wasting Prevention in a Mouse Model

Shing-Hwa Liu,[1] Kuan-Yu Hung,[3,4] Chih-Kang Chiang.[1,2] *[1]Institute of Toxicology, National Taiwan University, Taipei, Taiwan; [2]Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; [3]Superintendent Office, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu, Taiwan; [4]Department of Internal Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.*

Background: Low-intensity pulsed ultrasound (LIPUS), a therapeutic ultrasound, is recognized to elevate the bone fracture repair process and help in some soft tissue healing. Here, we tested the prevention of chronic kidney disease (CKD)-associated cachexia and sarcopenia by LIPUS in a renal ischemia/reperfusion injury (IRI) mouse model.

Methods: Adult C57BL/6J male mice were used. A model of unilateral IRI with nephrectomy of the contralateral kidney with or without LIPUS treatment (3 MHz, 0.1 W/cm^2, 20 minutes/day) 5 days before and 14 days after surgery was performed. The CKD-related cachexia/muscle wasting in mice was evaluated. Mice were euthanized 14 days after IRI.

Results: LIPUS treatment significantly alleviated the decrease in the serum albumin/globulin (A/G) ratio and the increases in the serum levels of blood urea nitrogen (BUN), creatinine, cystatin C, and fibroblast growth factor (FGF)-23, and the renal pathological changes and fibrosis in CKD mice ($p<0.05$, n=8; for A/G ratio and FGF-23). The development of epithelial-mesenchymal transition and the induction of senescence-related molecular signals and the decreased protein expressions of α-Klotho and endogenous antioxidant enzymes in the kidneys of CKD mice were significantly alleviated by LIPUS treatment ($p<0.05$, n=4). LIPUS treatment could also significantly reverse the decreased muscle mass, grip strength, and cross-section areas (CSA) of muscle fibers ($p<0.05$, n=8; for soleus muscle weight, hindlimb grip strength), and the increased muscular protein expressions of atrogenes, Atrogin1 and MuRF1, and phosphorylated AMP-activated protein kinase (AMPK), and the decreased muscular protein expressions of phosphorylated Akt, peroxisome proliferator-activated receptor-γ coactivator 1-α (PGC-1α), and mitochondrially encoded cytochrome c oxidase I (MT-CO1) in CKD mice ($p<0.05$, n=5 or 6).

Conclusions: LIPUS treatment showed the benefits for renal and muscular protection in a CKD mouse model via inhibition of renal fibrosis, restoration of antioxidant enzymes, and attenuation renal senescence/aging, and muscle mass loss via prevention of muscular mitochondrial dysfunction, AMPK activation, and Akt downregulation. LIPUS treatment may be potentially applied to an alternative non-invasive therapeutic intervention on CKD-associated cachexia/muscle wasting therapy.

PO2240

Mechanisms of Suppressed Autophagic Flux in the Kidney Caused by Sham Surgery and Unilateral Nephrectomy

Carolyn N. Brown, Daniel Atwood, Deepak Pokhrel, Chris Altmann, Sarah Faubel, Charles L. Edelstein. *Univ Colorado, Aurora, CO.*

Background: Compensatory renal hypertrophy resulting from loss of nephron mass has been implicated in promoting further nephron damage. Unilateral nephrectomy (UNX) is a model of compensatory hypertrophy in the remaining kidney. We previously reported that in the remaining mouse kidney that both sham surgery (SS) and UNX vs. normal kidney (N) resulted in increased mTORC1/2, decreased lysosomal function, suppressed autophagic flux. P62/SQSTM1, is an autophagy receptor that links cargo proteins with the autophagosome membrane. p62 is destroyed by the lysosome and is a marker of autophagic flux, a decrease usually indicating increased autophagic flux. The aim of the study was to measure p62 and other potential mechanisms of suppressed autophagy caused by SS and UNX.

Methods: C57BL6 mice. p62 and ERK was measured by quantitative immunoblot analysis. Cytokines were measured by MesoScale. Mice were treated with the MEK1/2 inhibitor Trametinib (T) (1 mg/kg/d for 3 days) that is a potent ERK1/2 inhibitor

Results: There was an increase in p62 in SS and UNX kidneys. p62/GAPDH (densitometry units) was 0.6 in N, 1.0 in SS ($P<0.05$ vs N) and 1.0 in UNX kidneys ($P<0.05$ vs N). p62 is known to modulate pro-inflammatory cytokines. In the serum, there were increases (fold) in IL-1b (50), IL-4 (10), IL-6 (100), IL-8 (5), IL-12 (5), GMCSF (2), IFNγ (2), IL-10 (0), TNFα (0) in SS and UNX vs N. Pro-inflammatory cytokines can activate ERK1/2, a known autophagy suppressor. There was a large increase in ERK1/2 in SS and UNX kidneys. Phospho/total ERK (densitometry units) was 0.2 in N, 1.4 in SS ($P<0.001$ vs N) and 2.0 in UNX kidneys ($P<0.001$ vs N). Trametinib blocked the increase in pERK in sham surgery and UNX kidneys and resulted in a significant decrease in p62. Phospho/total ERK (densitometry units) was 1.0 in N, 0 in SS+T ($P<0.001$ vs N) and 0 in UNX+T kidneys ($P<0.001$ vs N). p62/GAPDH (densitometry units) was 1.6 in N, 0.4 in SS +T ($P<0.05$ vs N) and 0.4 in UNX+T kidneys ($P<0.05$ vs N).

Conclusions: The mechanism of suppressed autophagy with SS and UNX may be related to an intense systemic inflammatory response and an ERK-mediated increase in p62. It is important that researchers are aware that changes in ERK1/2, systemic pro-inflammatory cytokines and autophagy can be caused by sham surgery as well as the kidney injury/disease itself.

PO2241

Differential Role of NAD$^+$ Deficiency in Acute and Chronic Kidney Disease

Anna Faivre,[1,2] Elena Katsyuba,[3] Thomas Verissimo,[1] Carolyn Heckenmeyer,[1] David Legouis,[1,2] Sophie M. De Seigneux.[1,2] *[1]Universite de Geneve, Geneva, Switzerland; [2]Hopitaux Universitaires de Geneve, Geneve, Switzerland; [3]Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland.*

Background: Nicotinamide adenine dinucleotide (NAD$^+$) is a ubiquitous coenzyme involved in electron transport and a co-substrate for sirtuin function. NAD$^+$ deficiency has been shown in acute kidney injury (AKI), but few is known about chronic kidney disease (CKD).

Methods: We studied the expression of key NAD$^+$ biosynthesis enzymes in kidney biopsies from allograft patients during reperfusion, mimicking AKI, and in patients with CKD at different stages. We used ischaemia–reperfusion injury (IRI) and cisplatin injection to model AKI, unilateral ureteral obstruction (UUO) and tubulointerstitial fibrosis induced by proteinuria (POD-ATTAC) to investigate CKD in mice. Then we assessed the effect of a potent NAD$^+$-replenishment therapy, the nicotinamide riboside (NR), in both AKI and CKD models.

Results: RNA-sequencing analysis of human kidney allograft biopsies during reperfusion showed that the NAD$^+$ *de novo* synthesis is impaired in the immediate post-transplantation period. This decrease in *de novo* NAD$^+$ synthesis was confirmed in two mouse models of IRI where NR supplementation prevented plasma urea and creatinine elevation and tubular injury. In biopsies from CKD patients, the NAD$^+$ *de novo* synthesis was impaired according to CKD stage, with better preservation of the salvage pathway (Figure 1). Similar alterations in gene expression were observed in UUO and POD-ATTAC mouse models. NR supplementation did not prevent CKD progression in contrast to its efficacy in AKI.

Conclusions: Impairment of NAD$^+$ synthesis seems to be a hallmark of AKI and CKD. An oral NR supplementation showed protective effects on AKI but had no effect on CKD in mouse models. This study shows the dual role of NAD$^+$ deficiency in AKI and CKD and the potential of NAD$^+$-replenishment therapies as a preventive strategy for human AKI.

PO2242

Plasminogen Activator Inhibitor 1 (PAI-1) Induction During Kidney Injury Promotes Epithelial Dysfunction via TGF-β1 Receptor Signaling and Klotho Downregulation

Cody C. Gifford,[1] Fei Lian,[1,2] Jiaqi Tang,[1] Angelica Costello,[1] Roel Goldschmeding,[3] Rohan Samarakoon,[1] Paul J. Higgins.[1] *[1]Albany Medical College, Albany, NY; [2]Albany Medical Center, Albany, NY; [3]Department of Pathology, University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Persistent PAI-1 induction is evident in several nephropathies in mice and humans. Although PAI-1 is an established CKD promoting factor, the precise role of PAI-1 in disease progression is unclear and, surprisingly, this fibrogenic response appears to be mediated by uPA-independent mechanisms. Expression of the anti-aging gene klotho is lost during renal injury, predisposing to CKD, and recombinant klotho administration in mice suppresses progressive fibrosis. Whether kidney tubular PAI-1 induction promotes maladaptive repair and orchestrates klotho downregulation is currently unknown.

Methods: To mimic sustained renal epithelial PAI-1 expression during renal injury, we stably expressed PAI-1 via lentiviral transduction in HK2 human kidney epithelial cells (CMV-PAI-1); western blotting confirmed PAI-1 overexpression relative to vector controls (CMV-Con). Double-transgenic cells engineered to express both PAI-1 and klotho were used to assess pathological interplay between PAI-1 and klotho in renal fibrosis.

Results: PAI-1 expressing HK-2 cells robustly upregulated pro-fibrotic factor expression/secretion (fibronectin and collagen-1) and exhibited dedifferentiation (loss of E-cadherin and increased vimentin expression), G2/M growth arrest and susceptibility to apoptosis, evident by increases in pHistone-H-3, pH_2AX, p21 and p53 expression, caspase3 cleavage and annexin V-positivity compared to the CMV-Con population. PAI-1-transductants had increased TGF-β receptor 1/2 levels and SMAD2/3 activation relative to vector controls. TGF-β1 receptor-1 kinase inhibition with SB431542 attenuated the PAI-1-driven fibrotic phenotype, independent of TGF-β1 ligand synthesis. Interestingly, sustained PAI-1 expression also downregulated klotho protein levels compared to controls. Rescue of klotho expression in CMV-PAI-1 cells attenuated fibrogenesis and reversed the proliferative arrest.

Conclusions: Persistent PAI-1 expression promotes a fibrotic maladaptive repair orchestrated, in part, via TGF-β1-receptor1/2 hyperactivity and klotho loss. Our studies identify not only a novel role for PAI-1 in renal tubular dysfunction but also in klotho deregulation in renal fibrosis.

PO2243

Percutaneous Renal Biopsy Using an 18-Gauge Automated Needle Is Not Optimal

George Sousanieh, William L. Whittier, Roger A. Rodby, Vasil Peev, Stephen M. Korbet. *Rush University Medical Center, Chicago, IL.*

Background: As percutaneous renal biopsies (PRB) are increasingly performed by interventional radiologists, an increase in the use of the smaller 18-gauge automated biopsy needle has been observed. The use of smaller gauge needles stands to compromise adequacy, ideally >20 glomeruli per biopsy. We compare the adequacy and safety of PRB with a 14, 16 and 18-gauge automated needles.

Methods: PRB of 592 native (N) and 1023 transplant (T) kidneys was performed by a nephrologist or a supervised nephrology fellow at Rush University Medical Center from 1/2002 to 12/2019 using real-time ultrasound guidance. Baseline clinical and laboratory data, biopsy sample data (number of cores, total glomeruli per biopsy (glomeruli on light + immunofluorescence + electron microscopy) and total glomeruli per core) and outcome data (hematoma on renal US 1-hr post-PRB and complications requiring a transfucion or procedure post-PRB) were collected prospectively. PRB with N14g (n=337) vs N16g (n=255) and T16g (n=892) vs T18g (n=131) needles were compared. A P value of <0.05 was significant.

Results: PRB with an 18g needle yielded the lowest number of total glomeruli per biopsy (N14g vs N16g: 33±13 vs 29±12, P<0.01 and T16g vs T18g: 34±16 vs 21±11, P <0.0001 and N16g vs T18g, P <0.001). PRBs with 18g needle were also less likely to have ≥20 total glomeruli per biopsy (N14g vs N16g: 85% vs 82%, P=0.4 and T16g vs T18g: 83% vs 46%, P<0.0001). The number of cores per biopsy was: N14g-2.3±0.7, N16g-2.2±0.6, T16g-2.8±0.7 and T18g- 2.2±0.6. Adjusting for the number of cores obtained, the total glomeruli per core was significantly less with 18g needle (N14g vs N16g: 15±8 vs 14±6, P=0.1 and T16g vs T18g: 13±6 vs 10±5, P<0.001 and N16g vs T18g, P <0.001). A hematoma by routine screening renal US 1-hr post-PRB was similar for native (14g-35% vs 16g-29%, P=0.2), and transplant biopsies (16g-10% vs 18g-9%, P=0.9) irrespective of needle size. The complication rate for native (14g-8.9% vs 16g-7.1%, P=0.5), and transplant biopsies (16g-4.6% vs 18g-1.5%, P=0.2) as well as the transfusion rate for native (14g-7.7% vs 16g-5.8%, P=0.4), and transplant biopsies (16g-3.8% vs 18g-0.8%, P=0.1) were not significantly different irrespective of needle size.

Conclusions: The use of the smaller, 18g biopsy needle compromises the adequacy and thus, quality of the PRB while not enhancing safety.

PO2244

Deep Neural Network Facilitated Immunofluorescence Assessment of Glomerular Diseases: A Preliminary Report

Peng Xia,[1] Zhilong Lv,[2] Yubing Wen,[1] Xuesong Zhao,[1] Hua Zheng,[1] Xuemei Li,[1] Fei Ren,[2] Limeng Chen.[1] *[1]Nephrology Division, Peking Union Medical College Hospital, Beijing, China; [2]Institute of Computing Technology, Chinese Academy of Sciences, Beijing, China.*

Background: Immunofluorescence (IF) tests of renal tissue are important in diagnosing glomerular diseases. Deep neural network were used to facilitate analysis of pathologic images recently, but not in IF assessment. We proposed a novel Convolutional Residual Dense Network (CR-DenseNet) to facilitate IF assessment of glomerular diseases.

Methods: A dataset with 614 IF images of glomerulus, including IgA Nephropathy, IgAN (n=319), Idiopathic Membranous Nephropathy, IMN (n=211) and Secondary Membranous Nephropathy, SMN (n=84) from Peking Union Medical College Hospital, PUMCH were used for training of CR-DenseNet. Additional 78 IF images from PUMCH (35 IgAN, 15 IMN and 28 SMN) and 98 IF images (36 IgAN, 34 IMN and 28 SMN) from other 3 hospitals were used for validation and human tests. These images were annotated by two nephropathologists independently. Convolutional residual dense blocks were introduced. Each of them consisted of a dense block with a convolutional skip connection to fully exploit the dense local features (Figure 1). Performance was evaluated by overall accuracy, sensitivity, specificity and F1 score. F1 was computed as 2×True Positive, TP / (2×TP + False Positive + False Negative).

Results: The proposed CR-DenseNet outperformed the state-of-the-art method with overall 85.3% recognition accuracy. For the validation data from PUMCH, the sensitivity of recognizing IgAN, IMN and SMN were 78.3% to 93.3% and the specificity were 88.9% to 97.4%. For the validation dataset from other hospitals, the sensitivity and specificity were 79.2% to 93.5% and 88.5% to 98.2%, respectively. Eight nephrologists' average accuracy for recognizing each classification were 50.0% to 76.0%. The F1 score were 0.542 to 0.802. CR-DenseNet demonstrated superior performance. The corresponding accuracy and F1 score were 80.0% to 84.6% and 0.762 to 0.880, respectively.

Conclusions: Our data showed that CR-DenseNet model were useful in IF assessment of typical glomerular diseases.

Funding: Government Support - Non-U.S.

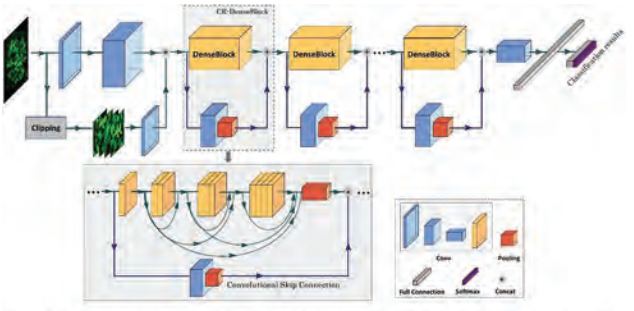

Figure 1. The overview of the proposed Convolutional Residual DenseNet (CR-DenseNet). The input consists of the immunofluorescence image and the local clipped parts of the IF image. The convolutional residual dense block (CR-Denseblock) is composed of traditional dense block and a long convolutional skip connection.

CR-DenseNet Overview

Prognostic Glomerular Morphometric Phenotype Discovery via Clustering Across Large Datasets

Brandon Ginley,[1] Kuang-Yu Jen,[2] Avi Z. Rosenberg,[3] Pinaki Sarder.[1] *[1]University at Buffalo - The State University of New York, Buffalo, NY; [2]University of California Davis, Davis, CA; [3]Johns Hopkins University, Baltimore, MD.*

Background: Microscopic glomerular assessment is diagnostic and prognostic for a diverse array of renal parenchymal disorders. Digital renal pathology enables complex morphometric studies that may identify prognostic information imperceptible to the human eye. We use clustering and feature enrichment to discover morphometric phenotypes that may relate to patient prognosis.

Methods: A convolutional network extracted glomeruli from 29 Periodic acid-Schiff stained transplant biopsies. 315 features were calculated on each glomerulus and clustered with a modularity-based community detection algorithm available in Seurat. Clusters were compared with patient outcome (eGFR decline at 1 year). A Wilcoxon rank sum test identified features enriching each cluster. Uniform manifold approximation and projection (UMAP) was used to visualize the clusters in low dimension.

Results: Clustering revealed 5 glomerular populations (Fig. 1A), and glomeruli of different patients were well admixed across clusters (Simpson's Diversity Index: 0.78 - 0=no diversity, 1=infinite). Patients were separated in two classes (eGFR≥5 or <5 mL/min/year), and these labels were projected into the cluster space (Fig. 1B). We observed the clusters show different frequencies of glomeruli from patients with higher eGFR decline. Two of the clusters (2 and 4) had >90% of their morphometrically similar glomeruli solely from slower eGFR decline patients. The distribution of two example features (glomerular area and total nuclei) per cluster are shown in Figs. 1C & D, though the full analysis revealed hundreds of significant features enriching each cluster.

Conclusions: The adoption of an –omics style analysis for renal histology may be feasible to mine prognostically significant morphometric information.

Funding: NIDDK Support

C) Normalized glomerular area difference between the clusters. D) Normalized glomerular nuclei between the clusters.

PO2246

IgA Staining Patterns Differentiate Between IgA Nephropathy and IgA-Dominant Infection-Associated Glomerulonephritis

Sergey V. Brodsky, Clarissa A. Cassol, Anjali A. Satoskar, Tibor Nadasdy. *The Ohio State University Medical Center, The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Differential diagnosis of primary IgA nephropathy (IgAN) and IgA-dominant infection-related glomerulonephritis, particularly Staphylococcus infection-associated glomerulonephritis (SAGN), on a kidney biopsy can be challenging because of similar morphologic findings by light microscopy, immunofluorescence and electron microscopy. Clinical management approach however, is very different. Immunosuppressive therapy is contraindicated in SAGN because it can lead to sepsis and even death. Antibiotics constitute the first line of therapy. In contrast to that, primary IgAN is treated either with conservative management or with immunosuppression. There are no specific biomarkers to distinguish between these two diseases.

Methods: Kidney biopsies from patients with IgAN or SAGN were analyzed. Immunofluorescence with an antibody to IgA was performed on sections of frozen and paraffin embeded tissue.

Results: In total, 75 biopsies (45 with IgAN and 30 with SAGN) were evaluated. All 75 biopsies showed distinct granular staining for IgA in the non-sclerotic glomeruli (Figure 1). Globally sclerosed glomeruli were identified in 47 biopsies (29 with IgAN and 18 with SAGN). Among the 29 biopsies of IgAN, 20 (69%) had positive granular staining for IgA in the globally sclerosed glomeruli and 9 (31%) cases did not. Among the 18 kidney biopsies with SAGN, only one case (5.6%) showed positive staining for IgA in globally sclerosed glomeruli, whereas the remaining 17 (94.4%) did not (Table 1). The sensitivity of positive IgA staining in globally sclerosed glomeruli for kidney biopsies with IgAN was 68.97%, specificity was 94.44%.

Conclusions: Evaluation of IgA staining in sclerosed glomeruli can help to differentiate between primary IgAN and SAGN in the right clinical context, and aid in patient management in most cases

Table 1. Distribution of staining for IgA in sclerotic glomeruli between cases with IgAN and SAGN

IgA staining in sclerotic glomeruli	IgAN	SAGN	Total
Positive	20	1	21
Negative	9	17	26
Total	29	18	47

PO2247

The Spectrum of Biopsy-Proven Glomerular Diseases in Mexico: Experience at a Tertiary Hospital

Octavio R. Garcia-Flores, Belen Martinez-Vazquez, Virgilia Soto, Bernardo Moguel. *Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Background: Glomerular diseases are still one of the leading causes of end-stage renal disease. The diagnosis of these diseases relies on the interpretation of the renal biopsy.

Methods: This investigation was performed in a tertiary hospital. We assessed the main demographic, clinical and histological data of individuals who underwent native kidney biopsies in one tertiary hospital in Mexico. From January 2011-December 2019, totally 1,541 patients first received renal biopsy. After excluding allograft biopsies, inadequate sampling, and failed interpretation, there are still 853 cases with a clear diagnosis.

Results: We evaluated 853 renal biopsies: female 65.3%, elderly (>60 years) 16.4%. The most frequent biopsy-proven diseases were secondary (59.1%) and primary (28.7%) glomerulonephritis (GN), tubulointerstitial nephritis (TIN) was observed in 2.5 % and vascular diseases in 1.5%, hereditary disease in 1.2%. Among primary GN the most frequent diagnosis were focal segmental glomerulosclerosis (FSGS) (17.2%), membranous GN (MGN) (5.7%) and IgA nephropathy (IgAN) (4.8%). Among secondary GN, lupus nephritis (LN) represented 38.9%, diabetic nephropathy 8.1% and pauci-immune crecentic GN 4.9%. The most common diseases in patients with nephrotic proteinuria were LN 14.8%, FSGS 5.8%, MGN 4.1%. Ultrasound needle guidance was used in 97.8%. The frequency of serious complications was approximately 2.5%.

Conclusions: This report provides representative population-based data on native biopsy-proven renal diseases in Mexico. FSGS and LN are the most frequent primary and secondary GN respectively. FSGS and MGN were the most common diseases in patients with nephrotic proteinuria.

PO2248

Clinical Context and Outcomes of Kidney Biopsy in Pregnant Women: An Institutional Review

Anna R. Gaddy, Karen Trevino, Carrie L. Phillips, Elizabeth Taber-Hight. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Kidney biopsy is an excellent method of gaining insight to causes of renal decline but is not without risk, particularly in pregnant patients. While we await the era of biomarkers which enhance our ability to diagnose diseases of pregnancy, biopsy remains the most inclusive way of reaching a diagnosis. Clinical manifestations warranting biopsy include gross deterioration in renal function, de novo development of nephrotic syndrome, or suspicion for glomerulonephritis. A recent metanalysis found that the risk of complications during pregnancy was 7% and should be limited to patients in whom the diagnosis would warrant urgent therapy. We sought to explore indications for biopsy and histopathology in patients evaluated at our institution.

Methods: Our surgical pathology database was searched for renal biopsy specimens interpreted from 2008 to mid-2020. Patients were either pregnant at the time of biopsy or within 3 months postpartum. Indiana University IRB approved the study. A chart review was completed to obtain lab data at the time of biopsy and post procedure.

Results: We identified biopsy specimens from 38 women who were pregnant during the specified time period. Histopathologic diagnoses included lupus nephritis (n=4), FSGS (8), diabetic kidney disease (3), allergic interstitial nephritis (1), IgA (10) and minimal change disease (3). Chart information was available for 19 women including 15 Caucasian and 4 African American patients, with a mean age of 28.6 years. Eight specimens were obtained during pregnancy and 11 during the postpartum period. Proteinuria was present in 17 patients with a mean value of 3.5g/d. Hematuria was also present in 14 of the patients. Mean serum creatinine was 2.6mg/dL.

Conclusions: Renal biopsy is a procedure with high risk and morbidity for pregnant women. At our institution, biopsy was performed for either worsening renal function or proteinuria. Our population showed diverse diagnoses which justified need for biopsy, including requiring urgent intervention. Our study highlights the need of judicious biopsy in pregnant women. Further studies can be done to determine long term kidney outcomes in pregnant women.

PO2249

Prevalence and Risk Factors Associated with Nephrosclerosis in Renal Parenchyma Specimens of Patients Undergoing Partial or Radical Nephrectomy

Juan D. Salcedo Betancourt,[1] Kenny A. Goodrich,[1] Oleksii Iakymenko,[1] Jhoan B. Rozas,[1] Ragi Philips,[1] Gabriel Contreras,[1] Alessia Fornoni,[1] Laura Barisoni,[2] Jorge A. Florindez,[1] David B. Thomas,[3] Jair Munoz Mendoza.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Duke University School of Medicine, Durham, NC; [3]IYM Health Financial Services, PLLC, Charlotte, NC.*

Background: Evaluation of non-neoplastic renal parenchyma in nephrectomies is part of the College of American Pathologists (CAP) Cancer Protocols. We evaluated the prevalence of histological abnormalities and nephrosclerosis and its association with clinical factors in patients undergoing nephrectomy for any cause at our institution.

Methods: Two nephropathologists evaluated the status of the renal parenchyma in 813 patients who underwent either partial (41%) or radical nephrectomy (59%) between 2013 and 2017. Age-adjusted global glomerulosclerosis (GS), interstitial fibrosis (IF), tubular atrophy (TA), and arteriosclerosis (AS) were evaluated by light microscopy. Nephrosclerosis was defined as the presence of ≥ 2 histologic variables. Clinical, demographic, and pathological data were collected by chart review. Logistic regression analysis was used to evaluate the association between clinical parameters and nephrosclerosis.

Results: The mean age was 60 ± 14 years. 38% were female, 44% were Hispanics. 59% had hypertension, 22% had diabetes mellitus and 24% had a smoking history. The pre-nephrectomy eGFR was 73 ± 27 ml/min/1.73m^2 and 31% had an eGFR <60 ml/min/1.73m^2. The prevalence of age-adjusted GS was 82%, any TA was 80%, more than 5% IF was 78% and any AS was 95%. The prevalence of nephrosclerosis was 88%. Lower pre-nephrectomy eGFR (adjusted odds ratio [OR] per 10 units decrease in eGFR, 1.12 [95% confidence interval (CI), 1.02-1.23]), and age (adjusted OR per 10 years increase, 1.97 [95% CI, 1.64-2.39]) were significantly associated with nephrosclerosis. Gender, history of hypertension, diabetes, and smoking were not associated with nephrosclerosis (p>0.05 for all).

Conclusions: Nephrosclerosis is highly prevalent in renal parenchyma of patients undergoing nephrectomy. Lower pre-nephrectomy eGFR and older age were independently associated with significantly greater odds of nephrosclerosis. Future studies should evaluate the association between nephrosclerosis and post-nephrectomy eGFR.

PO2250

Evaluation of Preexisting Renal Disease in Nephrectomies

Juan D. Salcedo Betancourt,[1] Oleksii Iakymenko,[1] Kenny A. Goodrich,[1] Jhoan B. Rozas,[1] Ragi Philips,[1] Alessia Fornoni,[1] Gabriel Contreras,[1] Dipen Parekh,[1] Laura Barisoni,[2] Jorge A. Florindez,[1] David B. Thomas,[3] Jair Munoz Mendoza.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Duke University School of Medicine, Durham, NC; [3]IYM Health Financial Services, PLLC, Charlotte, NC.*

Background: Evaluation of non-neoplastic renal parenchyma in nephrectomies is part of the College of American Pathologists (CAP) Cancer Protocols. We aimed to determine the prevalence of pre-existing renal diseases in all patients who underwent nephrectomy for any cause in our center.

Methods: The surgical pathology protocol for nephrectomies was modified with a) additional sampling of non-tumoral renal parenchyma, b) Hematoxylin and eosin, Periodic acid-Schiff, trichrome and silver stains, and c) addition of the expanded checklist for reporting nephrectomy from the Renal Pathology Society recommendations. All samples were reviewed by 2 trained nephropathologist (NP). A total of 813 nephrectomies (49% partial and 51% radical) performed between 2013 and 2017 were evaluated and included in the study. Reasons for nephrectomies were malignancy in 645 (79%) of patients, of which 528 (82%) had renal cell carcinoma, 100 (16%) urothelial carcinoma, and 168 (21%) benign lesions (42 oncocytomas, 34 pyelonephritis, 13 trauma, and 8 nephrolithiasis). Clinical, demographic, and pathological data were collected by chart review.

Results: The mean age was 60 ± 14 years. 62% were male and 44% Hispanics, 59% had hypertension, 22% had diabetes mellitus, and 24% had a history of smoking. Baseline eGFR was 73 ± 27 ml/min/1.73m^2 and 31% had an eGFR < 60 ml/min/1.73m^2. Only 41 patients (5%) had a documented pre-operative consult to nephrology. 296 (36%) patients had at least one renal disease diagnosis and only 62 (8%) had a single diagnosis. 374 pathological diagnoses were reported including focal segmental glomerulosclerosis (FSGS) (157), mostly NOS variant (88%), diabetic glomerulosclerosis (57), interstitial nephritis (66), arterionephrosclerosis (39), pyelonephritis (36), acute tubular injury (10), chronic sclerosing glomerulonephritis (4), amyloidosis (1) and atheroembolic renal disease (1).

Conclusions: Pre-existing renal disease are frequently identified in nephrectomy specimens. FSGS was the most common diagnosis. A collaborative effort involving nephrologists, urologists and pathologists is warranted to improve the care of patients undergoing surgical nephrectomy.

PO2251

Kidney Filtration Markers in Human Saliva: Accuracy and Reproducibility of Novel Salivary Cystatin C Measurements

Kamyar Kalantar-Zadeh,[1] Manal Beshay,[2] Connie Rhee,[1] Trong D. Nguyen,[2] Maria Ortega,[2] Michael Shlipak,[3] Danh V. Nguyen.[1] *[1]Univesity of California Irvine, Orange, CA; [2]Intelligent Optical Systems, Inc., Torrance, CA; [3]University of California San Francisco, San Francisco, CA.*

Background: Invasive phlebotomy followed by laborious blood specimen processing is the only reliable approach to assess routinely measured kidney filtration markers including cystatin C (CysC). Non-invasive testing of these markers is urgently needed particularly during the COVID-19 pandemic to enhance social-distancing.

Methods: We developed novel Enhanced Enzyme and Immunoassay-based Lateral Flow (ELF) assays to measure concentrations of CysC in human saliva. Highly selective binding reagents were screened for optimum specificity, followed by applying sample treatment steps to mitigate sample to sample variability using healthy donor saliva samples spiked with known levels of the filtration markers. Standard calibration curves (SCCs) for each marker was developed with nonlinear 4-parameter logistic curve fitting to triplicate measurements at each spiked concentration level. Accuracy/fit of the SCC was assessed using the coefficient of determination (R^2). Intra-assay repeatability was assessed using coefficient of variation (CV) and studies of inter-assay repeatability over time (over ~8 days) examined reproducibility of whole experimental protocol.

Results: SCC fitted to relative optical intensities (ratio of test to control lines vs. spiked CysC (0-14 ng/ml) was excellent (R^2=0.991) and provided accurate estimates of spiked/ true CysC levels (R^2=0.994). Assessment of intra-assay variation showed that repeatability is very good with CV <10% throughout the dynamic range of measurements. Assessment of inter-assay variation (measurements over 8 days) showed that reproducibility is acceptable with CV <13% throughout most of the dynamic range. Preliminary assessment of long-term reproducibility (stability) out to 258 days indicated similar performance. [figure]

Conclusions: We demonstrated feasibility of CysC measurements in human saliva samples with acceptable ELF assay characteristics including accuracy, repeatability, reproducibility, and long-term stability. Validation studies are ongoing to optimize the saliva testing framework for kidney function markers.

PO2252

Examining Accuracy and Reproducibility of Novel Creatinine and Urea Rapid Measurements in Human Saliva

Manal Beshay,[2] Kamyar Kalantar-Zadeh,[1] Trong D. Nguyen,[2] Maria Ortega,[2] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine, Irvine, CA; [2]Intelligent Optical Systems, Inc., Torrance, CA.*

Background: Rapid and frequent point-of-care kidney filtration markers that do not require laborious blood specimen draws/processing can improve CKD patient care. The use of saliva as a non-invasive biofluid for monitoring kidney function biomarkers such as Creatinine (Cr) and Urea, addresses a clinical need in support of telemedicine.

Methods: We developed novel Enhanced Enzyme and Immunoassay-based Lateral Flow (ELF) for quantitative measurement of 2 kidney filtration markers in human saliva using highly selective reagents for optimum specificity. We used healthy donor saliva samples spiked with known levels of Cr and Urea. Standard calibration curves (SCCs) for each marker were established with nonlinear 4-parameter logistic curve fitting in triplicate at each spiked level. Accuracy/fit of the SCC was assessed using the coefficient of determination (R^2).

Results: SCC fitted to relative optical intensities (ratio of test to control lines vs spiked Urea (0-180 mg/dL) and Cr (0- 6 mg/dL) showed excellent correlation (R^2=0.992 and 0.999 respectively). Intra-assay variation showed that repeatability is very good with CV <15%, and CV <10% for Cr and Urea, respectively, throughout the dynamic range of measurements. Assessment of inter-assay variation (measurements over 8 days) showed that reproducibility is acceptable with CV <10% and <13% for Cr and Urea, respectively, throughout most of the dynamic range. Preliminary assessment of long-term reproducibility (stability) up to 91 and 216 days for Urea and Cr assays, respectively indicated similar performance.[figure]

Conclusions: Cr and Urea can be measured in human saliva with acceptable ELF assay characteristics including accuracy, repeatability, reproducibility, and long-term stability. Future validation studies may lead to a saliva testing framework for kidney function markers and a potential paradigm-shift in CKD monitoring.

PO2253

Comparison of Creatinine-Based Estimated Glomerular Filtration Rate Equations with DTPA GFR in Healthy Adults

Varun kumar Bandi, Spoorthi Ramineni. *Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Vijayawada, India*.

Background: Measurement of Glomerular filtration rate (GFR) is a reliable technique but is expensive and cumbersome for routine use. GFR is routinely estimated (eGFR) with serum creatinine. These equations are not widely validated in Indian population.

Methods: The cross-sectional study was done on live kidney donors. DTPA was used to measure GFR, 24 hour creatinine clearance (CrCl) was measured and creatinine based eGFR was calculated using Cockcroft-Gault (CG), Modification of Diet in Renal Disease-fourvariable (MDRD-4), Modification of Diet in Renal Diseasesix-variable(MDRD-6), and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations

Results: 88 subjects were included, of whom 29.5% were male, with a mean age of 46.8 yrs, and BMI of 25.7 kg/m2. Mean GFR (± standard deviation) obtained by CKD-EPI, MDRD-4, MDRD-6, CG, CrCl, and DTPA GFR were 99.8 (±15.2), 96.2 (±17.9), 106.1 (±20.2), 88.3(±38.7), 89.3(±29.2) and 93.6(±11) ml/min/1.73m^2 respectively. The mean absolute difference in GFR and percentage variation between calculated and measured GFR for CKD-EPI, MDRD-4, MDRD-6, CG, CrCl were 14.7 (16.5%), 16.2 (17.9%), 19.8 (22.2%), 33.2 (36.5%), and 23.6(25.7%) respectively. Percentage of valueswithin 20%of DTPA GFR in each equations were CKD-EPI - 69.32%, MDRD-4 – 70.45%, MDRD-6 -54.55%, CG- 38.64%, and CrCl- 45.45%. There was no significant co-relation between the measured GFRs and eGFR using any of the above equations.

Conclusions: All the equations used (CKD-EPI, MDRD4, MDRD6, CG) and CrCl did not correlate significantly with the measured GFR. Among the equations, CKD-EPI had the least variation with about 69% confirming within 20% of DTPA GFR, and about 86% and 97% confirming within 30% and 50% of DTPA GFR.

Table 1: Percentage of eGFR estimations ocurring within 20%, 30%, and 50% variation of DTPA GFR values

Equation	20% of GFR	30% of GFR	50% of GFR
EPI	69.32%	86.36%	96.59%
MDRD4	70.45%	82.95%	95.45%
MDRD6	54.55%	72.73%	93.18%
CG	38.64%	53.41%	62.50%
CrCl	45.45%	68.18%	90.91%

PO2254

Fecal Calprotectin Correlates with Serum Albumin in Patients with CKD

Yura Chae, Eun Sil Koh, Jongho Son, Sungjin Chung. *The Catholic University of Korea, Seoul, Republic of Korea*.

Background: Persistent inflammation, a characteristic feature in chronic kidney disease, contributes to decreased serum albumin levels and plays a central role in the Malnutrition, Inflammation and Atherosclerosis (MIA) syndrome, which is associated with poor clinical outcomes. Altered bowel habit is also a highly frequent status among patients with chronic kidney disease potentially due to their low fiber and fluid intake, medications, multiple comorbidities and dysbiosis of the gut microbiota. In this study, we have explored whether measurement of fecal calprotectin, a commonly used marker for increased neutrophil migration and local inflammation in gastrointestinal diseases, could reflect a state of low serum albumin in patients with chronic kidney disease.

Methods: Clinical and biochemical data including stool samples for calprotectin were collected from 579 cases of patients with no history of inflammatory bowel disease.

Results: Fecal calprotectin was not different according to estimated glomerular filtration rate, degree of proteinuria and medication of polystyrene sulfonate and ferrous sulfate. However, it was significantly and negatively correlated with serum albumin in patients (r=-0.107, p=0.010). Patients with higher tertile of fecal calprotectin were older and likely to have lower hematocrit. Multivariable linear regression analysis showed that fecal calprotectin was significantly correlated with serum albumin (β=-17.702, P=0.010).

Conclusions: These observations that serum albumin were significantly correlated with fecal calprotectin in patients with chronic kidney disease, suggest that the bowel inflammatory response may be another contributing factor.

PO2255

A Case of Sevelamer-Induced Colon Perforation

Venkata R. Manchala, Rajendra Mandalapu, Soumya P. Thumma, Nithin Karakala. *University of Arkansas for Medical Sciences, Little Rock, AR*.

Introduction: Sevelamer is an anion exchange resin used to treat hyperphosphatemia in patients with chronic kidney disease. It does not cause hypercalcemia or vascular calcification associated calcium based phosphate binders. Common adverse effects include nausea, vomiting, diarrhea, dyspepsia and constipation [1]. Case reports of sevelamer associated bowel perforation have been reported in the literature[2]. Here we report a case of sevelamer induced colon perforation.

Case Description: 61 year old Caucasian male with history of ESRD from diabetic nephropathy on automated peritoneal dialysis presented to the emergency department with abdominal pain. Physical exam was notable for epigastric tenderness. Labs were unremarkable except for hyperglycemia of 427 mg/dL. CT scan abdomen showed cholelithiasis and moderate ascites. PD fluid analysis ruled out peritonitis. Patient's abdominal pain persisted despite several days of supportive care, prompting repeat CT scan abdomen which revealed large pneumoperitoneum with possible colon perforation. Patient was emergently taken for exploratory laparotomy requiring right hemicolectomy with ileocolic anastomosis. Histopathological exam of the resected colon showed scattered yellow eosinophilic, acellular crystalline material with "fish scale" morphology within the lumen suggestive of sevelamer resins. Patient was on sevelamer 800mg TID for several years. Patient improved with appropriate medical management. Sevelamer was discontinued prior to discharge.

Discussion: Sevelamer is composed of a non-absorbable hydrogel with ammonia on the hydrochloride (Renagel) or the carbonate (Renvela). In the acid milieu of stomach, the polymer dissociates from its anion, is protonated to ammonium which is available to bind phosphate in the intestine[3]. The exact pathogenesis of intestinal perforation remains unclear. It is hypothesized that presence of sevelamer crystals in the gastrointestinal tract was associated with mucosal abnormalities including inflammation, ischemia and necrosis. Recognition of characteristic sevelamer crystals (typically seen as bright pink linear accentuations with a rusty yellow background and irregularly spaced fish-scales) on pathology along with the supporting clinical history clinches the diagnosis. It is important for clinicians to be aware of this rare but a serious potential complication of bowel perforation associated with sevelamer.

PO2256

Case of Pulmonary-Renal Syndrome Involving Goodpasture Disease and Granulomatosis with Polyangiitis

Shabtab Khan. *AU-UGA Internal Medicine, Athens, GA*.

Introduction: Wegner's granulomatosis and Goodpasture's disease are two rare causes of pulmonary-renal syndromes syndromes. Both have similar presentation and differentiation is crucial for early management. WG is a systemic vasculitis syndrome that affects the respiratory and renal systems and associated with C-ANCA (PR3) antibodies. Goodpasture's disease is an autoimmune condition that is characterized by rapidly progressive glomerulonephritis (RPGN) and severe alveolar hemorrhage. It is most often related to IgG antibodies against type 3 collagen in the glomerulus and renal basement membranes. It is noted that 5% of all ANCA + patients are also positive for anti-GBM and of all the anti-GBM about 1/3rd also have ANCA but that does not always correlate with active clinical disease. This leads to a significantly poor prognosis and worse renal outcomes than either disease process alone.

Case Description: We present a 59-year-old female with initial complaint of weakness, lethargy and sinus congestion. She had a history of untreated hypertension. She was noted to be hypoxic and had rales and rhonchi bilaterally. Labs revealed WBC of 35, Hg 5.6, Hct 15.5 and platelets 594. She had sodium of 98, Potassium 5.8, Bicarbonate 18, BUN of 58 and Creatinine of 8.5. Chest x-rays showed bilateral opacities resembling CAP. Further hypoxemia prompted intubation, revealing copious amounts of alveolar hemorrhage. Vasculitis was in the differential given alveolar hemorrhage and renal failure and she was promptly started on plasmapheresis, high dose IV steroids as well as cyclophosphamide. Complement levels and immunofixation were normal as were studies for lupus and hepatitis B and C. She had + ANA, Anti-GBM and c-ANCA antibodies. Renal biopsy showed predominant sclerosis and >90% focal necrotizing crescentic GN and severe interstitial scarring. Immunofluorescence (IF) demonstrated linear staining of glomerular BM as well as ANCA mediated changes.

Discussion: This case illustrates that both WG and GP can occur in the same patient. Such patients can present with CAP that rapidly deteriorates. Early recognition of pulmonary involvement was crucial to start proper treatment by plasmapheresis and immunosuppressant. Although these patients with severe glomerular involvement will be lifelong dependent on dialysis, their 1- and 2-year survival can be significantly improved with appropriate therapy and follow up.

PO2257

Fibromuscular Dysplasia Masquerading as Polyarteritis Nodosa in a Patient with Raynaud Syndrome

Salar Alam. *Spectrum Health, Grand Rapids, MI*.

Introduction: Fibromuscular dysplasia (FMD) is a non-inflammatory, non-atherosclerotic vascular disease primarily affecting renal and cerebral arteries. Polyarteritis nodosa (PAN) is a small to medium vessel vasculitis that can be fatal if not promptly diagnosed and treated. Both conditions are commonly diagnosed by angiographic findings which may appear similar.

Case Description: A 49-year-old Caucasian woman with a past history of Raynaud's disease presented to the emergency department with acute onset periumbilical abdominal pain. She was mildly hypertensive on presentation; metabolic panel showed no electrolyte abnormalities; urinalysis showed proteinuria and hematuria; ESR was 7 and CRP 22.7. Notably, she had been on prednisone for a skin rash after poison ivy exposure 5 days prior to presentation. Family history was pertinent for rheumatoid arthritis. CT abdomen and pelvis with contrast revealed multiple right renal infarcts. Subsequently a CT angiogram was obtained. During renal arteriography, the right renal artery developed dissection with minimal catheter manipulation suggestive of significant underlying abnormality. The procedure was aborted given risk for further complications including rupture and hemorrhage. Radiology reported findings consistent with medium vessel vasculitis. Autoimmune workup showed positive ANA, Scl 70 and rheumatoid factor, supporting suspicion for systemic vasculitis such as PAN. However, mesenteric vessels were normal. She was advised to continue on prednisone while additional workup was completed. Carotid dopplers were obtained and demonstrated partial dissection of the mid right internal carotid artery, with subsequent CT angiogram of the head and neck showing findings consistent with FMD throughout vertebral arteries and left internal carotid artery. Initial renal CT angiogram was reevaluated by Radiology, with renal artery

beading noted, consistent with a diagnosis of FMD. The patient's creatinine remained stable throughout her hospital stay, and she was initiated on lisinopril prior to discharge.

Discussion: Fibromuscular dysplasia can be diagnosed by histopathology or angiography. It may manifest as a systemic vascular disease involving multiple vascular beds, mimicking systemic vasculitis. Since treatment of PAN and FMD is vastly different, it is important to consider both differentials and have definitive diagnosis prior to initiation of therapy.

PO2258

Asymptomatic Spurious Hyperuricemia Related to Waldenstrom Macroglobulinemia

Pankaj Goyal,[1] Prakash S. Gudsoorkar,[1] Charuhas V. Thakar.[1,2] *[1]Universisty of Cincinnati Academic Health Center, Cincinnati, OH; [2]Cincinnati VA Medical Center, Cincinnati, OH.*

Introduction: Increased IgM has been shown to result in underestimation of uric acid levels and pseudo-hypouricemia; however, there are no reported cases of hyperuricemia in the setting of paraproteinemia. We present a case of Waldenstrom's Macroglobulinemia (WM) resulting in marked elevation of uric acid level in the absence of tumor lysis syndrome (TLS).

Case Description: A 73-year-old man with history of WM was incidentally noticed to have very high uric acid level of 37.2 mg/dl. He had no history of crystal arthropathy or chronic kidney disease. He was started on Acalabrutinib because of high serum viscosity and elevated IgM level. After 30 days of treatment, his serum viscosity and uric acid levels improved significantly, however the treatment had to be discontinued due to development of potential drug related adverse events. After discontinuation of Acalabrutinib, his serum viscosity and uric acid level gradually increased back to the previous level. Laboratory parameters were not suggestive of TLS and potassium, calcium and phosphorus were all normal. 24-hour uric acid excretion was noticed to be low normal (341 mg/24 hours). He was treated with allopurinol and monitored in clinic with serial uric acid checks. He continued to remain asymptomatic despite of having a uric acid level consistently above 35 mg/dl. He was not treated with Rasburicase due to lack of symptoms and potential false elevation of uric acid in the setting of paraproteinemia.

Discussion: Paraproteins often cause factitious biochemical measurements by forming opaque precipitates with the test reagents and interfering with various automated assays. These interferences may be difficult to anticipate as they are intermittent and patient specific. Ultrafiltration of paraproteins, dilution or deproteinization of the samples can sometimes help correct these measuring errors. WM and other paraproteinemia may cause true hyperuricemia in the setting of TLS. However, the absence of other concomitant laboratory abnormalities should raise a suspicion of factitious results. An observant clinician should be aware of these findings in order to avoid unwarranted testing and treatment. Also, a very high level of uric acid in the absence of symptoms may point towards a possibility of undiagnosed paraproteinemia.

PO2259

Is the Well-Recognized Intravascular Tamm-Horsfall Protein Polyp a Misnomer? A Case Report from a Patient with Obstructive Uropathy and Hematuria

Liye Suo, Kyle Meissner, Amal Musa, Vikas D. Reddy, Jade M. Teakell, William F. Glass. *University of Texas Health Science Center at Houston, Houston, TX.*

Introduction: Tamm-Horsfall protein (THP), a renal epithelial glycoprotein, was originally isolated from normal urine and can be the primary constituent of many urinary casts. The phenomenon of THP polyp formation in obstructive uropathy first appears in the literature about 1978. The polyps are described in these reports as being located in veins or sometimes lymphatics. Our case is the first to confirm the location of a THP polyp by immunohistochemical (IHC) analysis.

Case Description: A 64-year-old Caucasian male presented with bilateral flank pain and persistent gross hematuria. On admission, he had mildly elevated BUN (26.0 mg/dL) and serum creatinine (3.2 mg/dL). Urine analysis showed red blood cells > 182 /hpf with negative leukocyte esterase and negative nitrates. He developed azotemia during the hospitalization with the highest creatinine of 7.4 mg/dL on day 3 of admission. Renal ultrasound indicated mild-moderate hydronephrosis with a collapsed bladder. Renal biopsy was performed given lack of proper explanation for his presentation. Biopsy showed Periodic acid-Schiff (PAS) positive THP with polyp formation distended the markedly dilated tubules (confirmed by positive Pan-cytokeratin and negative CD31 immunohistochemical (IHC) stains). The THP polyp also contains delicate elongate-appearing endothelial cells. There was diffuse interstitial edema with mild fibrosis without tubular atrophy, and mild to moderate to focally intense inflammation with numerous eosinophils surrounding the involved tubules. The walls of the inflamed tubules are densely infiltrated by inflammatory cells and has focal fibrinoid necrosis. No significant glomeruli or vascular pathologic changes were identified. The renal pathology findings of acute to subacute tubulointerstitial nephritis with THP polyps consistent with obstructive uropathy.

Discussion: There were a total of four cases of intravenous THP polyps identified in the patients with obstructive uropathy and persistent gross hematuria. It was theorized that acute hydronephrosis may increase the intratubular pressure, with extravasation of THP into the veins forming tubulovenous communications. However, our study suggests that this theory may not be true due to the misidentification of the markedly distended renal tubules as renal veins.

PO2260

Vedolizumab-Induced Acute Interstitial Nephritis and Acute Tubular Necrosis

Abdulrahman Muzib, Rushang Parikh, Vanesa Bijol, Nupur N. Uppal, Mala Sachdeva. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Introduction: Vedolizumab is a humanized monoclonal antibody used in the treatment of ulcerative colitis. To date there has been no reported case of vedolizumab associated acute interstitial nephritis (AIN) and acute tubular necrosis (ATN). We report the first such case.

Case Description: A 58 year old female with history of ulcerative colitis on vedolizumab for one year, primary hyperparathyroidism and calcium oxalate nephrolithiasis presents due to acute kidney injury. Patient received her last dose of vedolizumab two months prior. She had been receiving 300mg IV every eight weeks, making her last dose her seventh dose. Her pre-medication creatinine (Cr) was 0.9mg/dL. Approximately one week prior to admission she was found to have a Cr of 2.0 mg/dL. She denied any NSAID, PPI, antibiotic or herbal use. Her physical exam was unremarkable. Her admission labs were notable for a Cr 2.25mg/dL, potassium 3.1mmol/L, bicarbonate 15mmol/L, phosphorus 2.2mg/dL, uric acid 1.3 mg/dL, urinalysis specific gravity 1.011, pH 6.5, glucose 500 mg/dL, small blood, protein 30 mg/dL, negative leukocyte esterase, nitrite negative, 2 RBC, 4 WBC, negative urine culture, and spot protein/cr of 1.1. Further workup revealed urine electrolytes: Cr 39mg/dL, sodium 77mmol/L, potassium 20mmol/L and phosphorus 22.9mg/dL. FePhos was 61% suggesting renal wasting. Serologic workup was negative for ANA, ANCA, nl c3, nl c4 and spep. Renal sonogram showed normal sized kidneys with two nonobstructing calculi in each kidney. Renal biopsy revealed focal degenerative changes in the tubules with flattening of the epithelium consistent with mild ATN. The interstitium had diffuse inflammation with mononuclear cells and frequent eosinophils consistent with AIN. EM showed tubuloreticular inclusions. She was started on prednisone which was tapered over 8 weeks. Creatinine downtrended to 1.1mg/dL

Discussion: Vedolizumab reported AIN and mild ATN has not thus far not been reported. Here we report the first case which seemed to have a cumulative dose response. Whether this patient has a mild proximal RTA due to this medication remains to be elucidated, as the phosphorus wasting could have been due to her primary hyperparathyroidism. Clinicians should be made aware of such reported associations so that both a timely renal biopsy and therapy could be instituted without delay.

PO2261

An Unusual Case of Granulomatous Interstitial Nephritis (GIN)

Charis E. Whitney, Ronald L. Mars. *University of Florida Health Science Center Jacksonville, Jacksonville, FL.*

Introduction: A 28 Y/O man was admitted with stage 5 CKD. He was entirely asymptomatic with a negative PMH except for recent HTN & proteinuria. Entire proteinuria w/u was negative. PE was unremarkable. Kidney biopsy showed advanced glomerulosclerosis wtih chronic non-caseating GIN. Etiology was uncertain except for history of BCG vaccination. BCG induced GIN was proposed. He was given a trial of ACE-I's, but ultimately required long term hemodialysis (HD).

Case Description: A 28 Y/O Hispanic male with 1 yr PMH of untreated HTN & proteinuria presented with BUN 88, Cr 7.85. 1 day after foot surgery Cr increased to 8.14 & Renal was consulted. 1 yr ago he was diagnosed with HTN & proteinuria but never received f/u or treatment. PMH was negative. FH was significant for a cousin with ESRD s/p kidney transplant & an uncle with diabetes. Full proteinuria w/u was (-). Renal US revealed normal size kidneys & increased cortical echogenicity c/w medical renal disease. He was started on lisinopril with improvement in BP, but no improvement in renal function & was then started on HD. Kidney biopsy revealed acute tubular injury without regeneration changes, acute & chronic interstitial nephritis with a few granulomas, 75% global glomerulosclerosis, mild tubular atrophy & interstitial fibrosis. GMS & AFB stains were negative for fungus & mycobacteria. No electron dense deposits (EDD's) were see on electron microscopy. Further discussion with patient revealed he received BCG vaccine when 2 weeks old.

Discussion: Bacillus Calmette-Guerin (BCG) vaccine is a live but attenuated strain of *Mycobacterium bovis* used to protect against TB in many countries with a high prevalence of TB. BCG has been implicated in the development of granulomatous disease in multiple organs, but rarely in the kidneys. Our patient received an intra-dermal BCG injection 2 wks after birth & had no sequelae or side effects. The historical (-) PMH, absence of prior medications or infectious process, (-) serologic w/u, (-) history of environmental exposures made the incidental discovery of asymptomatic stage 5 CKD with proteinuria all the more surprising. The unexpected finding of GIN raised the consideration for stimulated immunity & granuloma formation from latent BCG vaccine. While literature documents granuloma formation in other organs, its occurrence in kidneys & potential contribution to progressive CKD seems less common, but should not to be overlooked.

PO2262

A Chimeric Case of AKI

Talar Kharadjian, Cynthia Miracle, Haiyan Zhang. *University of California San Diego, La Jolla, CA.*

Introduction: New-onset nephrotic syndrome often requires kidney biopsy for diagnosis. Pathology is at times insufficient.

Case Description: An 81-year-old Hispanic female with HTN, CKD stage III presented with rash, fever, peripheral eosinophilia, AKI and diagnosed with DRESS

syndrome due to allopurinol started 3 weeks ago. Urinalysis showed pyuria, hematuria. Spot urine Pr/Cr was 3.8 with serum albumin 2.5g/dL. Admission creatinine was 4.3mg/dL, increased to 6.5mg/dL prior to starting dialysis. Serologic findings shown below. Steroids were started for DRESS and suspected AIN. Genetic testing for HLA-B*5801, seen in severe cutaneous adverse reactions to allopurinol, was positive. Skeletal survey demonstrated no lesions. Blood counts revealed anemia and thrombocytopenia. Bone marrow biopsy did not show a plasma cell dyscrasia. Kidney biopsy noted amyloidosis (Congo red positive deposits in glomeruli, vessels, interstitium) with 56% global glomerulosclerosis and >60% severe IFTA. Mild interstitial inflammation with occasional eosinophils suggested resolving AIN. Severe findings of hypertensive sequelae noted. Immunofluorescence was 2+ for IgG and kappa. Electron microscopy showed 10nm fibrils and severe podocyte foot process effacement. Mass spectrometry diagnosed ALECT2 amyloidosis.

Discussion: Our case is unusual in having three simultaneous pathologies, namely AIN and ALECT2 amyloidosis superimposed on a background of hypertensive changes; the recognition of disproportionate proteinuria was essential to question the diagnosis and avoid early closure on AIN. Concurrent renal pathologies are a common finding in patients with ALECT2 amyloidosis, underscoring the utility of kidney biopsy in these patients who often have mixed clinical pictures. Circumstances leading to this case raise suspicion for preceding immune dysregulation, in the form of DRESS/steroids, that may have triggered amyloidogenesis. A prior case report describes a patient who developed ALECT2 amyloid after steroids for allergic symptoms. This potential interplay between genetic and environmental factors requires further investigation.

UPEP, urine immunofixation	No monoclonal protein
SPEP, serum immunofixation	Polyclonal
Kappa/lambda light chains	8.42
Beta-2 microglobulin	20.2 mg/dL
ANA, ANCA, anti-GBM	negative
Hepatitis B and C, cryoglobulin	negative
Complements	normal

PO2263

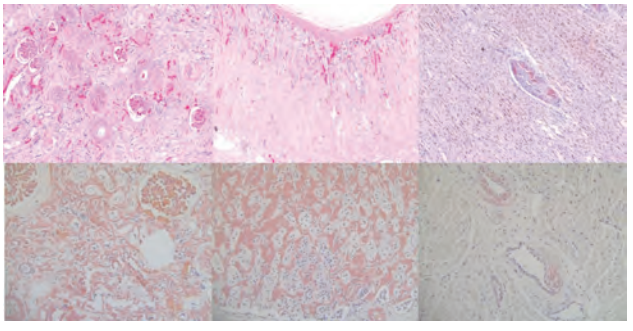
ALECT2 Amyloidosis with Cardiac Involvement Complicating Renal Transplantation

Anthony N. Grieff, Billie S. Fyfe-Kirschner, Mahmoud Ali, Advaith Bongu, Sonika Puri, Kant M. Matsuda. *Rutgers Robert Wood Johnson Medical School, Piscataway, NJ.*

Introduction: ALECT2 amyloidosis may be associated with slowly progressive renal failure that is clinically unsuspected at the time of transplantation. While this is typically not clinically significant, we report a case with extensive systemic ALECT2 amyloidosis that also involved the myocardium, contributing to perioperative death post renal transplantation.

Case Description: A 72-year-old Hispanic woman presented for renal transplantation due to ESRD from hypertension. She was bradycardic on admission. Cardiac workup prior to transplantation had not identified an infiltrative process. Post-transplant hypotensive bradycardiac arrests lead to multiorgan failure, anoxic brain injury and death. Autopsy revealed massive amyoid deposition in the native kidneys, adrenals, spleen, and less extensive infiltration of liver and myocardium. Cardiac intramural vasculature from venules to capillaries, arterioles and arteries showed amyloid deposition. Mass spectrometry revealed ALECT2 as the amyloidogenic protein.

Discussion: ALECT2 is a systemc amyloidosis that typically involves kidneys, adrenals, spleen and liver. It may be clinically unsuspected at the time of renal transplantation and should be considered in older patients, especially from higher ALECT2 amyloid prevalence populations. Complications related to systemic disease may add to morbidity or mortality post-transplantation. Cardiac involvement in ALECT2 amyloidosis has not been previously identified as a significant clinical or autopsy finding, but our case demonstrates that the cardiovascular system may indeed rarely be involved by ALECT2 amyloidosis and be associated with clinical sequelae.



Diffuse amyloid deposition in native kidneys, adrenals and involving vasculature of the myocardium.

PO2264

Cell-Based C5b9-ELISA to Identify Patients with Atypical Hemolytic Uremic Syndrome

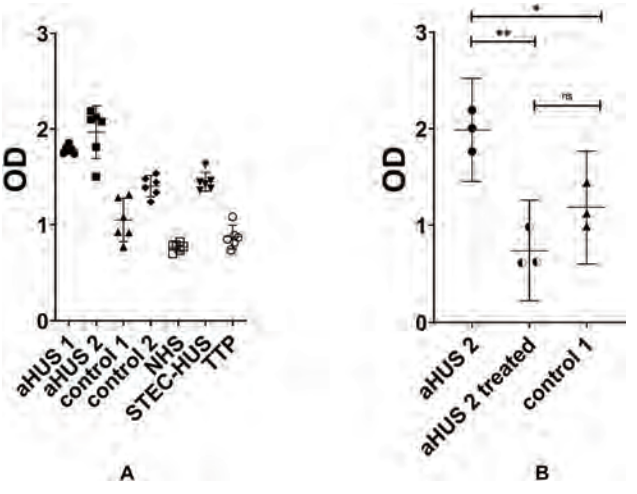
Martin Reinhardt, Hermann G. Haller, Yulia Kiyan. *Medizinische Hochschule Hannover Zentrum Innere Medizin, Hannover, Germany.*

Background: Discrimination between different diseases in patients suffering from thrombotic microangiopathies is often challenging. Measuring C5b9 deposit on endothelial cells using confocal microscopy have been shown to be convenient in diagnostic and therapy monitoring of Atypical hemolytic uremic syndrome (aHUS) but methods are complex and costly.

Methods: We developed a cell-based C5b9-ELISA to measure C5b9-deposits on activated endothelial cells. Patients with suspected aHUS and other thrombotic microangiopathies were identified in early disease stage. Serum was drawn and tested versus healthy controls. After confirmation of the diagnosis aHUS therapy efficiency was monitored using the assay.

Results: In patients with the clinical diagnosis of aHUS we were able to show up to six-fold higher C5b9-deposits in contrast to normalized human serum (NHS) (p-value < 0,0001). In comparison to healthy controls, patients suffering from either Shiga-Toxin-HUS or Thrombotic Thrombocytopenic Purpura (TTP) we could demonstrate a two- to three-fold higher deposit (p-value=0.0103 and below). After onset of eculizumab treatment, the amount of C5b9-deposits becomes lower than in healthy controls, proving the efficiency of the therapy. One-Way-ANOVA shows significant differences between aHUS-groups and controls, but not between aHUS patients using Tukeys-multiple comparisons test.

Conclusions: We described a novel, fast and reproducible ELISA to identify aHUS-patients by measuring C5b9-deposits and monitor disease activity. This can give a rise to diagnostic speed and therapy decisions. Further investigation and validation are needed to show interactions with other complement diseases like systemic lupus erythematosus.



ELISA-results with 95 % CI. A: C5b9-deposits in different patients. B: C5b9-deposits before and after two doses of eculizumab in patient 2 compared to healthy control 1.

PO2265

Chronic Neurological Impairment in Patients with Thrombotic Thrombocytopenic Purpura: Preliminary Findings in a Comprehensive MRI Protocol

Jeff Hamilton, Michael T. Jurkiewicz, Jonathan D. Thiessen, Shih-Han S. Huang. *Western University, London, ON, Canada.*

Background: Thrombotic thrombocytopenic purpura (TTP) is a life-threating blood disorder characterized by insufficient activity in ADAMTS13 (a disintegrin and metalloproteinase with thrombospondin type 1 motif, member 13). This protein prevents blood clotting, so in TTP there is spontaneous clotting throughout the microvasculature. Treatment includes plasma exchange therapy and immunosuppressants to improve fever, thrombocytopenia, and kidney failure. However, neurological changes, such as seizures and confusion, persist. There is limited research on TTP on the brain but it is known that TTP presents similar pathology to stroke. This study aims to better understand the long-term impact of TTP on the brain using a comprehensive magnetic resonance imaging (MRI) protocol and cognitive testing.

Methods: 13 patients (5 male, mean age 44.5) in hematological remission were recruited. Participants had a 65-minute MRI scan (Siemens mMR Biograph 3T) based on best-practice guidelines for imaging stroke. The protocol included five qualitative acqusitions and three quantitative acquisitions. Participants also completed a 40-minute cognitive test (Cambridge Brain Sciences) to assess cognitive impairment.

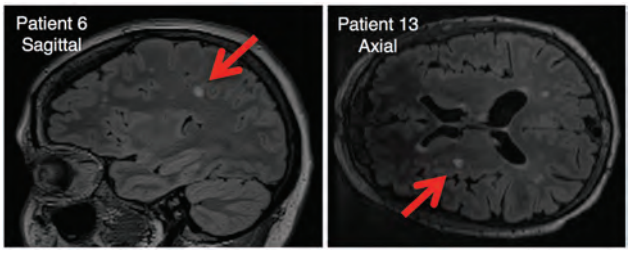
Results: Table 1 summarizes the findings across qualitative acquisitions. The most salient findings were the white matter hyperintensities seen in the T2 FLAIR in Image 1. 12 participants completed the cognitive testing and there is evidence of cognitive impairment.

Conclusions: Patients will be scanned again at six and twelve months. Age-matched healthy controls will be recruited before drawing conclusions on quantitative metrics, namely the amount of white matter. These early results are promising for better understanding the implications of TTP on the brain.

Funding: Private Foundation Support

Summary of qualitative findings

Sequence	Number of Participants with at Least One Abnormality	Example of Abnormality
T2-Weighted (FLAIR)	10	White matter hyperintensity
T1-Weighted	7	Atrophy of white matter or gray matter
Angiography	5	Thrombus
Susceptibility-Weighted	3	Microbleed
Diffusion-Weighted	1	Siderosis



PO2266

Persistent Coagulation Abnormalities in ESRD After 1 Year of Follow-Up

Emily Bontekoe, Vinod K. Bansal, Fakiha Siddiqui, Debra Hoppensteadt, Jawed Fareed. *Loyola University Medical Center, Maywood, IL.*

Background: Common to end-stage renal disease (ESRD), coagulation abnormalities can lead to severe bleeding events or excessive thrombi formation and engender increased morbidity and mortality in this population. Repeated heparin administration to ESRD patients during maintenance hemodialysis may also contribute to changes in the coagulation system. Thus, profiling coagulation parameters in ESRD patients over 1-year may provide insight to long-term coagulation dysfunction in this population.

Methods: Blood samples were collected at baseline and 1-year from ESRD patients undergoing maintenance hemodialysis (n=95) 48-hours post-dialysis. Plasma samples were analyzed using clot-based methods including activated partial thromboplastin time (aPTT), prothrombin time (PT), and thrombin time (TT). Chromogenic assays measured heparin levels by anti-Xa and anti-IIa methods. Patients were categorized by heparin administration during dialysis (n=44) and compared via statistical method and percent change.

Results: In the clotting and chromogenic assays, all parameters were elevated in the baseline and 1-year ESRD cohorts compared to controls, as shown on Figure 1. Only anti-IIa levels demonstrated a significant difference in ESRD patients after 1-year ($p<0.0001$). Heparin administration varied in aPTT, TT, and anti-Xa ($p<0.05$).

Conclusions: These results suggest ESRD patients on dialysis exhibit a long-term, hypo-coagulable state as shown by prolonged aPTT and TT. Elevated parameters maintained over 1-year suggests persistent dysregulation of clotting factors in ESRD patients. Circulating levels of heparin, as evidenced by anti-Xa and anti-IIa assays may be due to impaired clearance of heparin components via dialysis.

PO2267

Using Skin Biopsies to Measure Target Occupancy of a Renal Antifibrotic Monoclonal Antibody (mAb) in a Phase 1 Clinical Study

Rowann Bowcutt,[1] Geoffrey I. Johnston,[1] Linghong Huang,[1] James Z. Song,[2] Tim S. Schmidt,[1] Alison L. Bigley,[3] Graham Ogg,[4] Eric Wong,[1] Elizabeth S. Thomson,[1] Jane Y. Chan,[1] Anastasiia Raievska,[5] Timothy S. Johnson.[1] *[1]UCB Pharma, Slough, United Kingdom; [2]Prisys Biotechnology, Shanghai, China; [3]OracleBio, Chapelhall, United Kingdom; [4]University of Oxford, Oxford, United Kingdom; [5]Veramed, London, United Kingdom.*

Background: Defining the optimal dose of drug required to bind to its mechanistic target (target occupancy, TO) and affect a measurable distal event (target engagement, TE) in damaged kidney is a challenge in the development of anti-fibrotic therapies for chronic kidney disease (CKD). We aimed to identify an accessible surrogate human tissue to predict TO in the kidney, prior to application in a Phase 1 study.

Methods: We developed a 'biopsy-on-biopsy' approach in skin: a 3mm biopsy initiated a wound healing response; a 6mm biopsy at the same site, up to 6 days later, provided tissue where active healing/fibrotic processes were ongoing. This method was used to measure the TO of zampilimab, a humanized mAb specific for human transglutaminase 2 (TG2), in development for fibrosis in CKD. Primate skin TO was correlated with kidney TO and TE in a unilateral ureteric obstruction (UUO) model, before application in a single dose Phase 1 study (NCT02879877). Following dosing of zampilimab, TO in skin biopsies and kidney was measured using a competitive immunofluorescence assay on cryosections. A TRITC-labeled mouse parent of zampilimab (DC1) and a FITC-labeled anti-TG2 antibody binding a distant epitope (DH2) were used. TO was measured by comparing the relative binding of DC1 (competitively inhibited by zampilimab administered *in vivo*) to DH2. TE in kidney was measured using a TG2 *in-situ* activity assay.

Results: In a primate UUO-CKD model treated prophylactically with zampilimab, the 'biopsy-on-biopsy' method showed excellent correlation between TO in the kidney and healing skin (3 days post first biopsy). Importantly, TO and TG2 inhibition (TE) in the kidney were also highly correlated. Subsequent use in the zampilimab Phase 1 study generated data directly comparable to the preclinical model.

Conclusions: Our 'biopsy-on-biopsy' approach allows early identification of a dose range in Phase 1 studies where the target organ is inaccessible, and is applicable to other therapeutic mAbs intended for treatment of fibrotic kidney disease. A Phase 1/2 study of zampilimab in patients with post-renal transplant fibrosis is ongoing (NCT04335578).

PO2268

Standardized Grading of Chronicity in Native Renal Biopsies: A Single-Center Experience

Yuan Huang, Paul J. Lee, Diping Wang. *University of Cincinnati, Cincinnati, OH.*

Background: Chronic changes in native kidney biopsies are important in predicting prognosis and guiding treatment. In this retrospective single-center study, we investigated the applicability of histological chronicity grading in native kidney biopsies, using a newly proposed standardized grading system by Sethi *et. al.* and with modifications.

Methods: 52 consecutive patients (46.8 ± 16.1 yrs, 53.8% F) from January 2017 to December 2019 were recruited and 44 cases were deemed adequate. 9 categories of histopathology were evaluated and scored independently and blindly by two renal pathologists. An accumulated score (Sum1) was obtained from 4 categories the paper proposed. The other 5 categories were included to provide additional histopathologic information, which generated Sum2 score (Figure). Interrater agreement was measured by kappa statistics. eGFR levels both at the time of biopsy and at the end of 12 to 18-month follow-up were obtained from electronic medical records. The correlations between the calculated total scores and continuous variables were determined by bivariate correlation analysis.

Results: Interrater agreement was almost perfect based on the Landis and Koch scale with a kappa value 0.89. Among the 44 analyzed cases, mean baseline eGFR was 39.6 ± 29.7 mL/min/1.73m^2 . At the end of follow-up, eGFR was 47.8 ± 29.3 mL/min/1.73m^2. Sum1 and Sum2 scores were significantly correlated with both baseline eGFR levels ($R=-0.34$, $p<0.05$, and $R=-0.44$, $p<0.01$, respectively) and those at the end of follow-up ($R=-0.56$, $p<0.01$ and $R=-0.44$, $p<0.01$, respectively).

Conclusions: We demonstrated that the modified criteria were comparable to the original criteria; both had good interrater agreement and correlated well with eGFR levels. The modified criteria could provide standardized grading of additional clinically relevant histopathology. Application of standardized chronicity grading will benefit prognosis evaluation and clinical management of renal diseases.

Inadequate Tissue for Renal Biopsy Analysis Has Significantly Increased Since the Switch to Interventional Radiology (IR)

Patrick D. Walker,[1] Vanessa Moreno,[1] Caleb Nissen.[2] *[1]Arkana Laboratories, Little Rock, AR; [2]University of Arkansas for Medical Sciences, Little Rock, AR.*

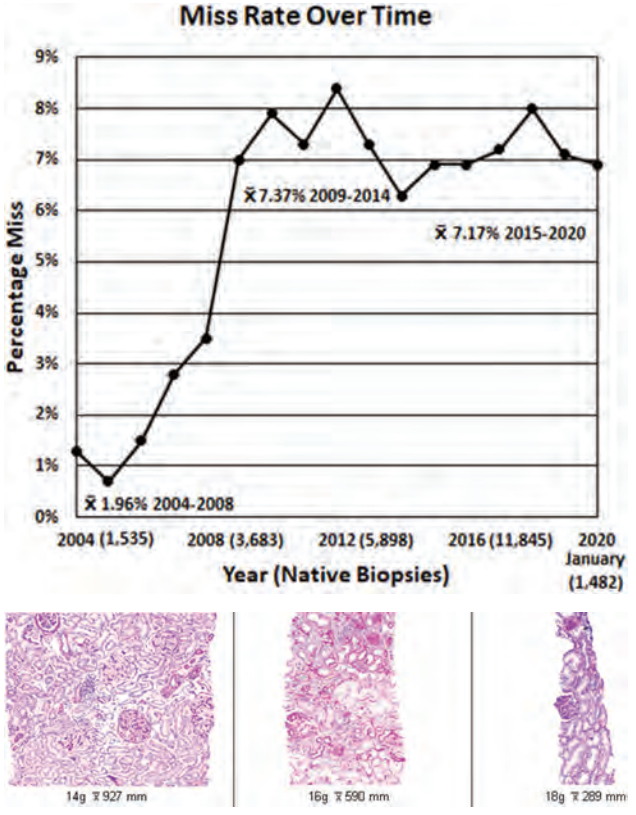
Background: The aim of this study was to determine the incidence of inadequate native renal biopsy (Bx) samples in our laboratory over time.

Methods: A retrospective study of native kidney biopsy adequacy from 2004 through the first month of 2020 was done. Adequacy was defined by the number of glomeruli for light microscopy (LM) as follows: 1. Ideal ≥20; 2 Adequate 10-19; Limited 4-9; Miss ≤3. An in-depth study of kidney biopsies received in 2004 and April-August of 2018 was done to compare Nephrologists (Neph) vs Interventional Radiologists. In 2004, there were 1,535 native Bx's: Neph 1,489 (97%); IR 46 (3%). In the 20-week 2018 study, there were 5,134 native needle Bx's: Neph 250 (5%); IR 4,884 (95%).

Results: The mean miss rate changed from 2% in 2004-2008 to 7% in 2009 through 2020 (figure). This correlates with the change from Neph to IR as operators. The miss rate deep (medulla) v miss rate shallow (peri-renal tissue) also significantly changed from 10% deep in 2004 to 90% deep in 2018. The needle gauge significantly changed from 14g 20%, 16g 73%, 18g 7% in 2004 to 14g 0%, 16g 14%, 18g 86% in 2018. This has resulted in significantly less volume available for serial sections and special stains (Figure).

Conclusions: The availability of advanced tissue analysis techniques and more importantly, the increase in therapeutic options has made the renal biopsy an even more

important diagnostic tool. The change to IR as primary operators has significantly reduced tissue adequacy. An extraordinary educational outreach to IR is needed.



Biopsy Widths 14g, 16g and 18g

Value of Immediate Post-Kidney Biopsy Ultrasound in Excluding Major Hemorrhagic Complications

Alian Albalas, Ammar Almehmi, Sloan Almehmi, Michael Allon. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Hemorrhage is the most serious potential complication of percutaneous kidney biopsy. Patients are typically observed for at least 6-8 hours after a kidney biopsy, with serial measurements of vital signs and hemoglobin to monitor for major hemorrhage. This study assessed whether an immediate post-biopsy ultrasound can reliably predict major hemorrhage.

Methods: We retrospectively evaluated the clinical outcomes in 147 patients undergoing an outpatient native kidney biopsy at a large medical center during a 2.5 year period (January 2017 to June 2019). All patients underwent a standardized post-biopsy ultrasound. We extracted from the medical records vital signs and hemoglobin values obtained before the biopsy and at 2, 4, and 6 hours after it, and ascertained whether the patient developed a major hemorrhage requiring hospitalization.

Results: Each patient underwent 2 or 3 biopsy passes. The mean patient age was 48±17 years, 49% were female, 37% were black, 53% had hypertension and 16% had diabetes. Five patients had evidence of a perinephric hematoma on the ultrasound and were hospitalized. The remaining 142 patients had no evidence of bleeding on ultrasound. Their blood pressure, heart rate, and hemoglobin remained stable during 6 hours of observation. All were discharged after 6 hours, and none had a late bleeding complication.

Conclusions: If the immediate post-kidney biopsy ultrasound does not show hemorrhage, the patient is extremely unlikely to develop a major hemorrhagic complication (negative predictive value, 100%). Such patients can be discharged home safely after a 2-hour observation, thereby simplifying their management.

PO2271

Morphologic Evidence of Excretory Function in Human Mesonephros

Ping L. Zhang,[1] Joseph V. Bonventre.[2] *[1]Beaumont Health, Royal Oak, MI; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Human mesonephros develops at 4 weeks of gestation and regresses at approximately 16 weeks of gestation. It is not clear if the human mesonephros has excretory function. Our goal was to assess morphologic evidence of primordial glomeruli, and renal tubules suggestive of excretory function using special staining and immunohistochemical staining methods.

Methods: Five mesonephric kidneys from human embryos found in miscarriage (missed abortion) or ectopic pregnancy specimens were studied. They were obtained from 4 weeks to 10 weeks gestation. In addition, 8 early metanephric kidneys from 10 weeks to 21 weeks of gestation were identified from our surgical pathology and autopsy cases for comparison with mesonephric specimens. Beside routine hematoxylin and eosin staining, the sections were stained for Periodic Acid Schiff (PAS) to detect proximal tubules (PT) brush borders and glomerular basement membranes (GBM). Furthermore, mesonephros and metanephros sections were immunohistochemically stained for CD133 for progenitor cells, GATA3 for mesangial cells and distal tubules, P504S for proximal tubules, and kidney injury molecule-1 (KIM-1) for PT injury.

Results: CD133 was positive in mesonephric glomerular and tubular structures at 4 weeks but this expression disappeared in the mesonephros from 5 weeks to 10 weeks, implying gradual maturation. GATA3 staining was positive in Wolffian duct, mesangial cells of primordial glomeruli (at 7 weeks the GBM was PAS+) and distal tubules, but not in PT. PT were positively stained for P504S. PT of mesonephric kidneys revealed brush borders on PAS stained sections from 7 to 10 weeks suggestive of reabsorption capacity. The PT of mesonephros at 7 weeks stained positively for KIM-1, suggestive of acute tubular injury during abortion processes. The metanephros showed expression of markers in respective renal compartments, similar to those in mesonephros.

Conclusions: Human mesonephros can have GATA3+ mesangial cells in the glomeruli. Although structures are simplified (no loop of Henle and collecting ducts), the human mesonephric nephrons include primitive glomeruli, PT showing brush borders and distal tubules, having morphological features similar to those of advanced metanephric stages with excretory function. They have react to injury, at least during 7 to 10 weeks of gestation based on identification of brush borders and KIM-1 expression in PT.

PO2272

Monogenic Causes of Nephrolithiasis or Nephrocalcinosis in Korean Children

Jeong yeon Kim,[1] Beomhee Lee,[2] Heeyeon Cho.[1] *[1]Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Department of Pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: Nephrolithiasis (NL) or nephrocalcinosis (NC) can be the early manifestation of hereditary nephropathy in children and early detection of hereditary nephropathy gives us chance to provide therapeutic and preventative intervention. In this study, we present genetic characteristics of NL/NC in pediatric patients who were treated in tertiary medical center in Korea.

Methods: The medical records of pediatric patients (age of 0-18 year) who had NC/NL and underwent genetic test under suspicion of hereditary nephropathy from March of 2013 to January of 2020 in Samsung Medical Center in Korea were reviewed. When specific disease was suspected, the sanger sequencing was done. The whole exome sequencing was performed when suspected mutations were not detected in sanger sequencing or when the disease could not be specified. DNA was extracted from whole blood or saliva. The novel mutations were evaluated by clinical findings and bioinformatics analysis such as *in silico* prediction.

Results: Total 20 patients underwent genetic test and two of them were sibling. The median age at the time of NC/NL detection was 4.8 year and male was predominant (M/F=2.3). Genetic diagnosis was done at the median age of 5.5 year. Three patients had family history of NC/NL (15%). Total 13 pathogenic gene mutations were detected in 16 patients (80%); 5 genes (SCL3A1, GRHPR, CLCN5, OCRL1, CLCNKB) were known to cause monogenic forms of NL/NC and 8 genes (PAX2, PKD1, HNF1B, SCN11A, SLC36A2, BUB1B, VPS33B, PHEX) were not. Three pathogenic autosomal recessive mutations were detected in 3 individuals; BUB1B (n=1), GRHPR (n=1), VPS33B (n=1). We also detected pathogenic mutations in 6 autosomal dominant genes in 7 individuals; CLCNKB (n=1), SLC3A1 (n=1), PAX2 (n=1), HNF1B (n=2), SCN11A (n=1), PKD1 (n=1), SLC36A2 (n=1). Two X-linked recessive genes were detected in 5 individuals; CLCN5 (n=4), OCRL1 (n=1). In one patient, X-linked dominant gene was detected; PHEX. Eight of 16 detected mutations (50%) were novel mutation that have not been previously reported in database of human disease causing mutation.

Conclusions: In conclusion, NL/NC can be the clue to detect monogenic cause of hereditary nephropathy in children. Further large population study is needed to evaluate NL/NC as indicator for genetic analysis to detect monogenic hereditary nephropathy in children.

PO2273

Trans IL-6 Signaling Does Not Distinguish Between Pediatric Patients with and Without Scarring After Febrile Urinary Tract Infection

Sudipti Gupta, Sara E. Lautzenhiser, John D. Spencer, Brian Becknell, Christina B. Ching. *Nationwide Children's Hospital, Columbus, OH.*

Background: The inflammatory response generated in response to infection is believed to be largely responsible for the development of renal scarring after UTI. IL-6 is a cytokine known to be induced during UTI with a pro-inflammatory pathway, known as *trans* signaling. We hypothesized there would be differences in markers of *trans* IL-6 signaling between patients with a history of febrile urinary tract infection (UTI) who had subsequent renal scarring as compared to those with a history of febrile UTI who did not develop renal scarring.

Methods: Urine samples were collected on consenting/assenting pediatric patients with a history of febrile (≥38°C) UTI (urine culture >50K uropathogen) with documented presence or absence of renal scarring on imaging. Patients were not actively infected at time of sample collection. Enzyme-linked immunosorbent assays were performed on samples for markers of *trans* IL-6 signaling: IL-6, soluble (s)IL-6 receptor (R), and soluble

(s)gp130, a buffer in *trans* IL-6 signaling. Values were normalized to urine creatinine. Results were analyzed by t-test or Mann-Whitney *U*. Spearman rank correlation was used. A p-value of <0.05 was considered significant.

Results: 50 urines from patients with a history of febrile UTI were collected: 23 with and 27 without scarring. The groups were not significantly different in age or gender. Urine IL-6, sIL-6R, or sgp130 were not significantly different between those with and without scarring. While IL-6 values significantly correlated with sgp130 values (p=0.0004) in those without renal scarring, the values did not correlate in those with scarring (p>0.05). Ratios of IL-6:sgp130 and sIL-6R:sgp130 were not different between groups.

Conclusions: There is a suggestion of altered buffering of *trans* IL-6 signaling in those with renal scarring compared to those without due to a lack of correlation of sgp130 with IL-6 in those with scarring. The absolute values and ratios of these markers of *trans* IL-6 signaling, however, are not significantly different between individuals with a history of febrile UTI with and without renal scarring in the non-acute setting.

PO2274

Markers of Trans IL-6 Signaling Are Not Differentially Induced During Febrile and Afebrile Urinary Tract Infection

Sudipti Gupta, Sara E. Lautzenhiser, John D. Spencer, Brian Becknell, Christina B. Ching. *Nationwide Children's Hospital, Columbus, OH.*

Background: Febrile urinary tract infections (UTIs) are generally thought to be evidence of tissue inflammation such as pyelonephritis as compared to afebrile UTIs which are thought to be more localized to the bladder. As such, generally the concern for renal damage is more in those with febrile UTI and thought to be a result of the inflammatory response generated. IL-6 is a known mediator of inflammation, particularly through its *trans* signaling pathway. We hypothesized there would be differences in markers of *trans* IL-6 signaling in the urine of children with febrile compared to afebrile UTI.

Methods: Pediatric patients with signs of active UTI were consented/assented for participation. Urine was collected at time of evaluation for active UTI in the urology or nephrology office or at hospitalization and were divided into those with a fever (≥38°C) compared to those without (<38°C). Patients were included for analysis if they had a positive urine culture (>50K CFU of a uropathogen) and for those without a fever if they had urinary symptoms such as dysuria, urgency, frequency, and/or new or worse urinary incontinence. Those with fever were termed a febrile UTI and those without a fever were termed afebrile UTI. Enzyme-linked immunosorbent assays were performed on samples for markers of *trans* IL-6 signaling: IL-6, soluble (s)IL-6 receptor (R), and soluble (s) gp130. Results were normalized to urine creatinine. Results were analyzed by Mann-Whitney *U*. A p-value of <0.05 was considered significant.

Results: 17 patients with febrile UTI and 23 patients with afebrile UTI were included. Two of the patients with febrile UTI were male while all of the afebrile UTI patients were female (p=0.1258). The groups did not differ significantly based on age (p=0.6218). While we found that those with a febrile UTI had a higher IL-6 in their urine at the time of collection (p=0.0479), there was no significant difference in expression of sIL-6R or sgp130. Ratios of these markers also were not significantly different.

Conclusions: Markers of *trans* IL-6 signaling, either as absolute values or ratios, are not different between individuals at the time of febrile or afebrile UTI.

Human Neutrophil Peptide 1-3 Protects the Urinary Tract from Uropathogenic *Escherichia coli* Invasion in Humanized Mouse Model

Jorge J. Canas, Jenaya Hooks, Sam W. Arregui, Andrew L. Schwaderer, David S. Hains. *Division of Pediatric Nephrology, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN.*

Background: Urinary tract infection (UTI) susceptibility is defined by heritable genetic differences associated with the innate immune system development and efficiency. DNA copy number variations in the alpha-defensin *DEFA1A3* locus are associated with UTI susceptibility in children with VUR. In humans, *DEFA1A3* is expressed in neutrophils as well as in the kidney. However, how *DEFA1A3* protects the urinary tract in some individuals is unknown. We hypothesized that *Defa*$^{+/+}$ humanized mouse would be resistant to experimental UTI.

Methods: We induced UTI with two uropathogenic E. coli (UPEC) strains in wild-type (WT) C57Bl/6J and *Defa*$^{+/+}$ transgenic mice, which express human *DEFA1A3*. Bacterial suspension was inoculated with a catheter transurethrally. To asses the colony-forming-unit (CFU) burden, kidneys and bladders were homogenized and colony forming units and clearance were determined by quantifying the plating serial dilutions grown overnight on LB plates at various time points.

Results: Results are presented in Figure 1: Comparing the *Defa*$^{+/+}$ mouse to WT (n=8 for each group), at 6-hours post infection, bacterial burdens were lower in the *Defa*$^{+/+}$ mice kidneys for both UPEC strains (A). At 24-hours after inoculum, the mean bladder Log (CFU/g) was significantly lower in the *Defa*$^{+/+}$ mouse in comparison to the C57Bl/6J group (B).

Conclusions: Our findings support the early protective role of *DEFA1A3* from UPEC challenge in the humanized mouse kidney and bladder when compared to the absence of the antimicrobial peptide in the wild-type mouse. Further investigation is needed to determine whether renal or extra-renal expression of *DEFA1A3* is critical in shielding and clearing UPEC UTIs.

Ribonuclease 6 Is an Intracellular Antimicrobial Peptide That Thwarts Bacterial Cystitis and Pyelonephritis

Hanna H. Cortado, Birong Li, Ashley R. Jackson, Sudipti Gupta, Christina B. Ching, John D. Spencer, Brian Becknell. Nephrology and Urology Research Affinity Group *Nationwide Children's Hospital, Columbus, OH.*

Background: Ribonuclease 6 (RNase 6) is a highly conserved cationic peptide with potent microbicidal activity toward uropathogenic *Escherichia coli* (UPEC) *in vitro*. Here, we determined the cellular sources of RNase 6 along with the consequences of its gain and loss of function during experimental urinary tract infection (UTI).

Methods: We generated female mice with a *Rnase6*^{EGFP} knock-in allele, human *RNASE6* transgene, or controls on a C57BL/6J genetic background. We identified cellular sources of RNase6 by flow cytometry and microscopy. We transurethrally inoculated *Rnase6*$^{EGFP/EGFP}$, *RNASE6* transgenic, and control mice with UPEC strain CFT073 and enumerated bacterial burden. The role of RNase 6 during intracellular killing of UPEC was investigated in bone marrow derived macrophages (BMDM) by gentamicin protection assay.

Results: *Rnase6* is expressed by tissue resident macrophages and circulating monocytes that are recruited to the infected bladder and kidney within hours of UPEC inoculation. *Rnase6* deficiency leads to increased renal UPEC burden relative to controls, whereas *RNASE6* transgenic mice exhibit reduced UPEC burden. *Rnase6* macrophages localize within the urothelium and its underlying stroma at baseline and during UTI. RNase 6 is not secreted by macrophages; instead, it is retained intracellularly within the endolysosomal system. *RNASE6* over-expression in macrophages leads to increased killing of phagocytosed UPEC.

Conclusions: RNase6 is a monocyte/macrophage derived antimicrobial peptide that acts intracellularly to kill phagocytosed UPEC and limit bacterial UTI.

Risk Factors for Urinary Tract Infection Caused by Extended-Spectrum Beta-Lactamase Gram-Negative Bacteria in Infants

Yo Han Ahn,[1] Ji hyun Kim,[2] Juyoung Lee,[3] Seonhee Lim,[1] Hee Gyung Kang.[1]
[1]*Seoul National University Children's Hospital, Seoul, Republic of Korea;* [2]*Seoul National University Bundang Hospital, Seongnam, Republic of Korea;* [3]*Inha University Hospital, Incheon, Republic of Korea.*

Background: Community-acquired extended-spectrum beta-lactamase (ESBL) producing bacterial infections are an evolving public health problem. Urinary tract infections (UTIs) due to ESBL-producing bacteria are increasing even in infants rarely exposed to antibiotic. We aimed to identify risk factors for UTI caused by ESBL-positive bacteria in infants.

Methods: We retrospectively analyzed the medical records of hospitalized infants with the first episode of UTI from 2018 to 2019. Data includes demographic characteristics, birth history, previous use of antibiotics, febrile event, urinalysis results, and urine isolated organisms. Multivariate regression analysis was used to quantify independent risks associated with ESBL-positive UTI.

Results: UTIs were diagnosed in 266 patients at a median age of 3.6 (interquartile range (IQR) 2.3-5.4) months. Sixty-two (30.4%) patients were diagnosed with UTI caused by ESBL-producing bacteria. When we divided patients according to ESBL status, there was no difference in gender, age, birth history, milk type, and use of postpartum care centers. Maternal use of antibiotics during pregnancy and previous antibiotic exposure to patients was higher in the ESBL-positive group than in the ESBL-negative group (32.3% vs. 10.3%, P <0.001, and 22.6% vs. 12.3%, P =0.044, respectively). *Klebsiella* species was more frequently identified in the ESBL-positive group than in the ESBL-negative group (19.4% vs. 4.9%, P =0.002). In multivariate analysis, maternal use of antibiotic during pregnancy (odds ratio (OR), 3.817; 95% confidence interval (CI) 1.812-8.040, P <0.001), previous antibiotic exposure to patients (OR 2.418; 95% CI 1.071-5.461, P =0.034), and *Klebsiella* species as a causative organism (OR 6.222; 95% CI 2.396-16.158, P <0.001) were associated with ESBL positivity. In a comparison of clinical courses of patients, the ESBL-positive group showed severe leukocytosis (WBC 16,795 /μL vs. WBC 14,620 /μL, P =0.04), and stayed longer in hospital than the ESBL-negative group (7.0 days vs. 4.5 days, P <0.001).

Conclusions: In this study, the high rate of ESBL positivity was detected in infantile UTI. Antibiotics exposure on both patients and mothers was associated with UTI caused by ESBL producing bacteria. Identification of underlying risk factors could improve treatment and preventive strategies.

PO2278

Urinary Sodium to Potassium Molar Ratio in Pediatric Stone Patients

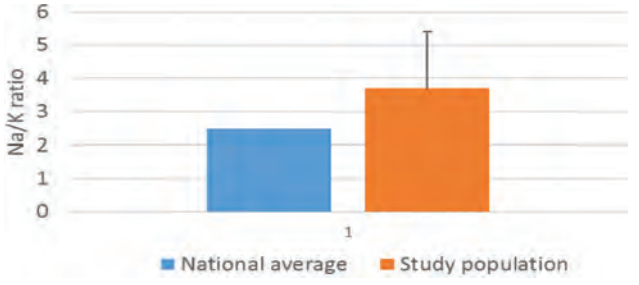
Vimal Master sankar raj. *University of Illinois College of Medicine at Peoria, Peoria, IL.*

Background: The incidence of pediatric stone disease is on the rise. Dietary elements including high salt intake and reduced water consumption remain the major risk factors for stone formation. Urinary stone profile in pediatric literature remains limited. The purpose of the study is to get data on 24 hr urinary mineral excretion in pediatric stone formers with particular emphasis on these two research questions 1, How does urinary sodium/potassium (Na/K) molar ratio in pediatric stone patients compare to the national average intake data in USA? 2, How does risk factors of stone formation such as hypercalciuria correlates with dietary risk factors in pediatric stone formers?

Methods: This retrospective cohort study included all Pediatric stone patients who attended outpatient Nephrology clinic from 03/1/2014 to 10/1/2018. Children with known metabolic/genetic causes for stone disease, incomplete 24 hr urinary collection or on medications that affect mineral excretions were excluded from the study.

Results: 150 patient charts were screened and 89 included in the study. Average age of the study population was 12.7 years with 58% females and 42% males. Mean Na/K molar ratio in pediatric stone patient was 3.7, statistically significantly higher than the national average of 2.5 using one sample T test ($P < 0.001$). Urinary calcium excretion showed a strong linear correlation with sodium excretion (r 0.545, $P < 0.001$). Multiple regression model using urinary calcium excretion as the dependent variable showed correlation with Urinary sodium excretion (P 0.004), urinary volume ($P < 0.0001$) and urinary Ph (P 0.001)

Conclusions: 24 hr urinary sodium potassium molar ratio is significantly higher in stone formers indicating a higher salt and lower potassium consumption when compared to national average intake. Water intake, salt consumption and alteration of urinary Ph remains the main dietary modality to alter calcium excretion and hence reduce risk of stone formation



PO2279

Keratin 5^{+} Urothelial Cells Are Developmental and Tissue Repair Progenitors in the Bladder

Ashley R. Jackson,[1] Birong Li,[1] Brian Becknell.[1,2] *[1]Center for Clinical and Translational Research, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Division of Pediatric Nephrology, Nationwide Children's Hospital, Columbus, OH.*

Background: Urothelium is nearly quiescent during homeostasis, but injury engages a robust regenerative capacity. Several progenitor cell candidates have been implicated, but prevailing models demonstrate conflicting roles discrete urothelial subpopulations. We recently demonstrated that Keratin 5 (K5)-expressing UCs are temporally restricted renal urothelium progenitors. It is unclear whether similar temporal restrictions are imposed on bladder K5-UCs, and whether an investigation into the temporality of the K5-UC progenitor may clarify bladder progenitor models. The objective of this study was to determine temporal progenitor-progeny relationships responsible for bladder urothelium generation and regeneration.

Methods: Using *Krt5*^{CreERT2};*Rosa*^{tdT} mice, K5-UCs were inducibly and permanently labeled with tdTomato (tdT). Tamoxifen (TMX) was administered at postnatal day (P)1, P7, P14, P21 or P41. Mice were sacrificed (SAC) at P42 or subjected to a single round of urothelial injury (cyclophosphamide) and euthanized 2 weeks later. Immunofluorescence microscopy was used to visualize and quantitate tdT, K5, (uroplakin), Upk and K20 expression.

Results: Fate mapping analysis found that 22% (TMX^{P1}-SAC^{P42}) and 23.5% (TMX^{P7}-SAC^{P42}) of neonatal tdT^{K5} UCs differentiated into adult Upk+ UCs (tdT^{K5+};$Upk^{+,}$ mostly intermediate cells) by P42 compared to 9% (TMX^{P14}-SAC^{P42}) or 2.25% (TMX^{P21}-SAC^{P42}) of juvenile tdT^{K5} UCs, and 0% adult (TMX^{P42}-SAC^{P56}) ($P<0.01$, ANOVA). Following urothelial injury, 63% (TMX^{P7}-Cyc^{P42}), 54.33% (TMX^{P14}-Cyc^{P42}) and 69% (TMX^{P21}-CYC^{P42}) of umbrella cells expressed tdT^{K5} (tdT^{K5+};$K5^{-}$;Upk^{+};$K20^{+}$). Adult (TMX^{P41}-CYC^{P42} & TMX^{P35}-CYC^{P42}) tdT^{K5} UCs rarely formed umbrella cells.

Conclusions: K5-UCs form intermediate and superficial cells, but the capacity for K5-UCs to form these derivatives is lost over time. In response to acute adult bladder urothelium injury, neonatal and juvenile tdT^{K5+} UCs regenerate umbrella cells, while adult tdT^{K5+} UCs did not. These studies establish that bladder K5-UCs are context dependent progenitors - responsive to temporal and pathologic cues. Our findings support an intermediate cell acute injury progenitor model, and show that intermediate cells formed by neonatal and juvenile K5-UCs repair acutely injured bladder urothelium.

Perinatal Cystatin C as Biomarker of Nephron Endowment

Beatrice L. Crippa,[1] Stefano Ghirardello,[1] Valentina Capone,[2] Gianluigi Ardissino.[2] *[1]NICU, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; [2]Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy.*

Background: Nephron endowment has a wide individual variability and plays a crucial role in drug toxicity, outcome of kidney diseases and pathogenesis of arterial hypertension (AH), but nephrons count is technically impossible in vivo. During acute dehydration, subject with reduced nephron mass (unilateral renal agenesis or renal hypoplasia) exhibit increased levels of biomarkers of renal function compared to healthy subjects. We hypothesized that healthy newborns with reduced nephron endowment will have high levels of cystatin c (Cys-c) during perinatal dehydration. The aim of the study was to compare Cys-c level during physiological perinatal dehydration in healthy term infants with hypertensive fathers (HF) and normotensive fathers (NF).

Methods: Healthy, Caucasian, born at term neonates were enrolled: infants with fathers on antihypertensive therapy were compared to infants with normotensive fathers > 40 yo. Enrolled infants underwent Cys-c capillary determination at time of expanded newborn screening.

Results: We enrolled 40 infants with HF and 80 infants with NF. Basic characteristics were not different between the two groups except for the number of hypertensive grandparents, that was higher among infants with HF. Cys-c levels was determined at a median of 62.5 hours of life (IQR 55-71) without any difference between groups. Cys-c was significantly higher in infants with HF (1.6 ± 0.3 mg/L vs 1.4 ± 0.3 mg/L; $p < 0.001$), Linear regression analysis corrected for confounders (type of feeding, delivery mode, weight loss velocity) confirmed that paternal hypertension was the only variable significantly associated with high Cys-c level (mean difference 0.2 mg/L, IC 95% 0.1-0.3 in; $p < 0.001$).

Conclusions: Our results support the key role of nephron endowment in the pathogenesis of AH and suggest the possibility of identifying at-risk subjects at birth. This opportunity opens up specific and targeted preventive health measures very early in life.

Elevated Urinary Neutrophil Gelatinase-Associated Lipocalin Predicts Postoperative AKI

Cara L. Slagle, Hailey W. Gavigan, James A. Rowe, Brenda Poindexter, Kelli A. Krallman, Alexandra Schmerge, Chunyan Liu, Shelley Ehrlich, Meera Kotagal, Stuart Goldstein. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Post-operative acute kidney injury (AKI) in neonates remains understudied despite occurring frequently. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) offers promise as a novel predictive biomarker for AKI, yet clinical utilization lags behind in neonatology.

Methods: Infants undergoing a general surgical procedure, excluding gastric tube placement alone, were prospectively enrolled. uNGAL samples were obtained prior to surgery and over post-operative days (POD) 0-3 at six time points. AKI was defined by the 2014 neonatal modified Kidney Diseases: Improving Global Outcomes (KDIGO) definition. Samples were processed using The NGAL Test® (BioPorto, Denmark). Generalized additive mixed effect model (GAMM) was utilized to study the longitudinal trajectory of log transformed uNGAL values. The ability to predict AKI was assessed using receiver operating characteristic curves (AUC-ROC).

Results: A total of 141 neonates underwent 192 surgical procedures. AKI occurred in 18% (35/192). Infants with AKI were more likely to have undergone an emergent procedure (63% vs. 31%, p=<0.001) and had higher uNGAL levels (Table 1). Pre-op uNGAL did not differ between AKI and no AKI patients (26ng/mL vs 59ng/mL, p=0.12). uNGAL levels were higher at all post-op time points even when controlled for pre-operative AKI (p values <0.001 to 0.0356). The AUC-ROC for predictability of post-operative AKI using uNGAL at 24 hours was 0.8 (95% CI: 0.71,0.88).

Conclusions: Post-op uNGAL predicts AKI. In patients undergoing emergent procedures, careful monitoring of renal function should be performed and uNGAL offers clinical utility. In all post-operative patients uNGAL trends could allow clinicians to better understand renal injury in real time and adjust treatment plans and/or avoid or restart nephrotoxic medications.

Funding: NIDDK Support, Private Foundation Support

Table 1: Comparison of predicted uNGAL values (95% CI) following Emergent and Routine Procedures

	Preoperative uNGAL (ng/mL)	12 hour uNGAL (ng/mL)	24 hour uNGAL (ng/mL)	36 hour uNGAL (ng/mL)	48 hour uNGAL (ng/mL)	72 hour uNGAL (ng/mL)	96 hour uNGAL (ng/mL)
Emergent Procedures (95% CI)	270 (164-403)	270 (181-403)	244 (164-365)	244 (164-330)	221 (148-330)	164 (110-244)	121 (81-181)
Routine Procedures (95% CI)	30 (22-40)	33 (25-45)	37 (27-49)	40 (30-55)	40 (30-55)	40 (30-55)	37 (27-49)

AKI in Neonatal Congenital Diaphragmatic Hernia

Brianna M. Liberio,[1,2] Katja M. Gist,[1,2] John T. Brinton,[2] Danielle Soranno,[1,2] Megan J. Kirkley,[2,3] Jason Gien.[1,2] *[1]Children's Hospital Colorado, Aurora, CO; [2]University of Colorado, Denver, CO; [3]Denver Health Medical Center, Denver, CO.*

Background: Acute kidney injury (AKI) occurs in about 30% of hospitalized neonates and is independently associated with mortality. Infants with congenital diaphragmatic hernia (CDH) are frequently exposed to nephrotoxic medications, fluid shifts, surgery, cardiopulmonary compromise, and extracorporeal life support (ECLS). As such, they are cited to have an increased AKI incidence. We sought to determine prenatal characteristics and postnatal exposures associated with an increased risk of AKI in neonates with CDH during the first 30 days of life, as well as the impact of AKI on selected long-term outcomes.

Methods: We performed a single-center retrospective review of neonates with CDH from 2009 to 2017. AKI was defined by the modified neonatal Kidney Disease Improving Global Outcomes serum creatinine criteria. Differences in prenatal characteristics, patient demographics, and long-term outcomes were assessed between those with and without AKI. We used longitudinal models with and without lagged predictions to determine associations between postnatal exposures and AKI.

Results: 90 infants with CDH were included. In the cohort, median gestational age was 38 weeks [IQR: 36, 38], median birthweight was 2.89 kilograms [IQR: 2.5, 3.19], 56% were male, and 50% were outborn. AKI occurred in 34 (37.8%) infants during the first 30 days of life. Specifically, 15 (44%) had stage 1, 10 (29%) had stage 2, 9 (26%) had stage 3, and 8 (24%) received renal replacement therapy. Antenatally, infants with AKI had lower estimates of lung volume (percent predicted lung volume, total lung volume, lung to head ratio, observed to expected lung to head ratio) and higher occurrences of liver up. Postnatally, ECLS, nephrotoxin exposure, CDH repair, abdominal closure, and 10% fluid overload significantly increased the odds of AKI development at varying time-points in the lagged predictions model. Those with AKI had increased mortality and almost two times greater length of stay and duration of mechanical ventilation.

Conclusions: AKI is common among neonates with CDH. In our cohort, greater CDH severity assessed antenatally conferred greater odds of AKI, and those with AKI had worse long-term outcomes. Attention to kidney function should be paid to neonates with fluid overload, on ECLS, exposed to nephrotoxins, or in the post-operative period, given the increased odds of AKI in such situations.

PO2283

Modification of the Renal Angina Index for Identifying Need for Renal Replacement Therapy in Critically Ill Pediatric Patients

Erin K. Stenson,[1,2] Danielle Soranno,[1,2] John T. Brinton,[1,2] Katja M. Gist.[1,2] *[1]Children's Hospital Colorado, Aurora, CO; [2]University of Colorado Denver School of Medicine, Aurora, CO.*

Background: Severe acute kidney injury (AKI) is a common and serious problem affecting critically ill children that lacks effective treatment options. Currently, there are no treatment options for AKI other than supportive care. Continuous renal replacement therapy (CRRT) is employed to reduce fluid overload (FO) burden and treat metabolic disturbances in AKI. Identifying patients upon admission who may require CRRT has potential clinical care implications.

Methods: The analytic cohort consisted of patients who required CRRT and illness severity score matched controls who did not require CRRT at a single center. Patients who required CRRT had higher mortality rates, length of stay, and use of ventilatory and inotropic support. Test characteristics assessed and compared the discriminatory accuracy of three scores: 1) the renal angina index (RAI), 2) serum-creatinine based AKI on day 0 (Day_0AKI) and 3) modified RAI created with an additional RAI injury tranche that corresponded to severe stage 3 AKI serum creatinine (sCr) elevation.

Results: The optimal cutoff for creatinine-based Day_0AKI was found to be stage 3; the optimal cutoff for RAI was identified as ≥ 8. AUCs were comparable at 0.78 (95% CI: 0.70, 0.87) and 0.76 (95% CI: 0.69, 0.82) respectively, although each scoring measure differed in sensitivity and specificity. The modified RAI had an optimal cutoff of ≥ 10 and had the highest AUC (0.79; 95% CI 0.72, 0.85) with a high sensitivity and moderate specificity for prediction of CRRT requirements (table 1).

Conclusions: As a more accurate tool for discriminating patients in need of CRRT, a modified RAI has numerous potential implications. Identifying patients who ultimately require CRRT at an earlier timepoint may influence timing of CRRT initiation in an attempt to avoid further FO, or may influence nephrotoxin administration. Furthermore, the diagnostic capabilities of the modified RAI may be further refined by the addition of urinary biomarkers. These findings should be validated in a larger cohort.

Table 1

Predictor	Threshold	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	Youden	AUC (95% CI)
Day0 AKI	Stage 3	0.63 (0.45, 0.79)	0.93 (0.87, 0.97)	0.76 (0.56, 0.90)	0.89 (0.82, 0.94)	0.57	0.78 (0.70, 0.87)
RAI 12 hours	≥8	0.94 (0.81, 0.99)	0.57 (0.47, 0.66)	0.41 (0.30, 0.52)	0.97 (0.89, 1.00)	0.51	0.76 (0.69, 0.82)
Modified RAI 12 hours	≥10	0.91 (0.77, 0.98)	0.65 (0.56, 0.75)	0.46 (0.34, 0.58)	0.96 (0.89, 0.99)	0.57	0.79 (0.72, 0.85)

PO2284

Peritoneal Dialysis (PD) as the Primary Renal Replacement Modality in Pediatric Shiga Toxin-Producing *Escherichia coli*-Associated Hemolytic-Uremic Syndrome (STEC-HUS): A Single Center's 12-Year Experience

Neha D. Pottanat, Sharon P. Andreoli, Chloe Miller, Myda Khalid. *Indiana University Riley Hospital for Children, Indianapolis, IN.*

Background: Half to 2/3 of children with STEC-HUS require renal replacement therapy. The modality is chosen based on a center's individual experience and its associated complications.

Methods: We performed a retrospective cohort analysis using electronic medical records and chart review of 80 patients with STEC-HUS identified through billing data from July 1, 2008 to May 30, 2020. Cases of Streptococcal pneumoniae associated HUS and atypical HUS were excluded.

Results: Dialysis was required in 47 patients (59%). Except for one patient, acute PD was chosen as the initial modality. 43 patients (91%) received PD successfully immediately after the catheter was placed. Four patients required a modality change to either hemodialysis (HD) or continuous renal replacement therapy (CRRT). Leaking of dialysate around the catheter exit site was noted in only 5 patients, out of which only one underwent a catheter revision and resumed PD successfully, two were switched to HD, and two patients had renal recovery allowing for cessation of dialysis. Peritonitis occurred in a single patient but did not lead to a change in modality. In two patients, PD was unsuccessful due to severe intestinal ischemia/colitis, and these patients were switched to CRRT. A central venous catheter (CVC) was often placed at the time of the PD catheter (40 patients). 46 patients had thrombocytopenia (<100,000/mm3) prior to PD catheter and/or CVC placement. Despite having a mean preoperative platelet count of 42,100/mm3, only 6 patients received a platelet transfusion. Furthermore, 15 patients with preoperative platelets between 15,000 – 35,000/mm3 did not have a bleeding event and did not receive a transfusion.

Conclusions: During a time when HD and CRRT have become the more preferred modalities for acute dialysis in children in the US, acute PD is safe and successful in STEC-HUS. We describe a low complication rate, despite immediate use of the PD catheter, indicating that acute PD can be performed before the exit site heals. Platelet transfusion carries the potential to worsen HUS. We demonstrate that children with STEC-HUS do not have bleeding complications despite low platelets at the time of PD catheter and CVC placement.

PO2285

Post-Operative Fluid Overload Is Associated with AKI and Elevated Urinary Neutrophil Gelatinase-Associated Lipocalin Values

Cara L. Slagle, Hailey W. Gavigan, James A. Rowe, Brenda Poindexter, Kelli A. Krallman, Alexandra Schmerge, Meera Kotagal, Shelley Ehrlich, Chunyan Liu, Stuart Goldstein. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Positive fluid accumulation (FO) in neonates is associated with increased morbidity and mortality and may represent underlying acute kidney injury (AKI). AKI defined by changes in serum creatinine (SCr) and urine output (UOP) can be unreliable in the setting of FO. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) offers promise as an alternative biomarker in assessing AKI in patients with FO.

Methods: Infants undergoing a general surgical procedure, excluding gastric tube placement alone, were prospectively enrolled. uNGAL values were obtained pre-op and on post-op days (0-3) at six time points. FO was defined as 10% weight increase from pre-op weight during PODs 0-5. Percent FO was calculated using post-op net fluid balance(L)/pre-op weight(kg)x100. Adjusted SCr was calculated by SCrx(1+[Net fluid balance post-op(L)/(0.8*Pre-op weight(kg))]). Associations between uNGAL values and

post-op FO and no FO groups were evaluated by Mann-Whitney U tests. Ability to predict FO was assessed by receiver operating characteristic curves (AUC-ROC).

Results: A total of 141 infants underwent 192 procedures. FO occurred after 46% (88/192) procedures (mean %FO = 27±10). Previous medical history of AKI was associated with development of post-op FO (35% vs. 14%, p=<0.001). Development of post-op AKI was also associated with FO even when controlled for pre-op AKI (69% vs. 31%, p=0.005). When SCr was adjusted for FO, AKI increased from 35 to 38 events and stage of AKI increased in 8 events. In FO patients, elevations in uNGAL were higher at all time points (Table 1). The AUC-ROC for uNGAL to predict post-op FO was 0.7 (95% CI: 0.63-0.78).

Conclusions: FO is an indicator of reduced renal function and is associated with AKI. uNGAL offers utility as an additional biomarker to assist in prediction of post-op FO and inability to maintain acceptable fluid balance. Post-op FO should be monitored closely for in all surgical patients, and particularly patients with a previous history of AKI.

Funding: NIDDK Support, Private Foundation Support

PO2286

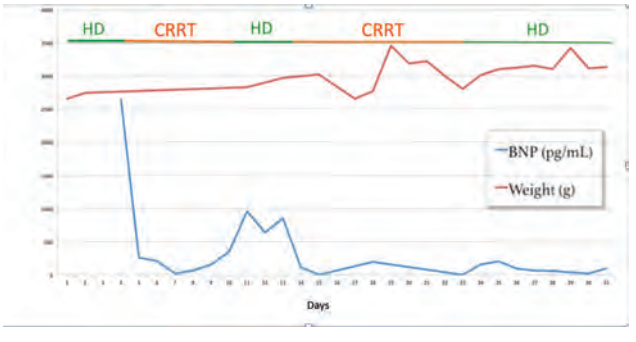
Use of B-Type Natriuretic Peptide as a Quantitative Marker of Fluid Overload in Neonatal Renal Replacement Therapy

Noureddin D. Nourbakhsh,[1,2] Nadine M. Benador.[1,2] Comprehensive Kidney Care Center, Rady Children's Hospital, San Diego *[1]Rady Children's Hospital San Diego, San Diego, CA; [2]University of California San Diego, La Jolla, CA.*

Introduction: Neonatal renal replacement therapy (RRT) remains one of the most challenging dialysis scenarios in Pediatric Nephrology. Evaluation of dry weight can be particularly difficult as fluid overload may be mistaken for adequate nutritional weight gain. Physical exam is insensitive in assessing hypervolemia until significant fluid overload develops. Non-invasive BP measurements are often difficult to obtain as upper extremities are typically used for IV access and the patient's lack of cooperation alters measurement. B-type natriuretic peptide (BNP) has long been used in the evaluation of heart failure and has even been reported to be a marker of fluid overload in adult hemodialysis patients. In this study, we evaluate the role of BNP as a quantitative marker of fluid overload in a neonate with ESRD.

Case Description: A 3 week old child with bilateral renal agenesis required emergent RRT. Following the failure of peritoneal dialysis in this 2.19 kg child, RRT modality was converted to hemodialysis (HD). Despite daily 3 hr HD treatments with ultrafiltration (UF) goals guided by weight, physical exam findings and blood pressure, patient developed bilateral pulmonary edema and an enlarged cardiac silhouette at 3 weeks of age. BNP was found to be > 5,000 pg/mL and RRT modality was changed to CVVHDF. BNP normalized after 4 days of CVVHDF, but upon transition to HD, she again developed fluid overload and required placement back on CVVHDF. Thereafter, BNP was utilized as a quantitative marker of fluid overload with UF goal guided by pre- and post-dialysis BNP levels. Applying this technique, the patient had no further episodes of fluid overload.

Discussion: Providing successful dialysis in infants is more problematic than in older patients. To assess fluid overload in children on dialysis, traditional tools include clinical assessment, serial weights and measuring blood pressure. In this infant, measurement of serial BNP levels allowed for an objective assessment of volume status, which was helpful in maintaining dry weight and lead to successful dialysis therapy.



PO2287

Comparison of Nafamostat Mesylate and Regional Citrate Anticoagulation for Anticoagulation in Pediatric CRRT

Mai J. Miyaji,[1,2] Kelli A. Krallman,[1] Kentaro Ide,[2] Stuart Goldstein.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]National Center for Child Health and Development, Kokuritsu Kenkyu Kaihatsu Hojin Kokuritsu Seiiku Iryo Kenkyu Center, Setagaya-ku, Japan.*

Background: Regional Citrate Anticoagulation (RCA) is the preferred anticoagulant for CRRT in the US in children. Nafamostat Mesilate (NM), a synthetic serine protease, has been widely used for CRRT anticoagulation in Japan and Korea. While NM is considered safe and effective, there is a paucity of evidence in pediatric literature. We describe the safety and efficacy of NM compared to RCA for pediatric CRRT.

Methods: Using one children's hospital in Japan and one in the US, medical records of patients <21 years who received CRRT between 2017-2019 were reviewed. Patients receiving CRRT concurrently with ECMO were excluded. Basic demographics, CRRT characteristics, and outcomes were analyzed between the RCA and NM groups. Filter life (FL), defined as the number of hours a single CRRT filter was in use, was the primary efficacy outcome of efficacy. For Kaplan Meier analysis, circuits were censored for elective filter discontinuation. Safety is assessed by anticoagulation complications.

Results: 28 pts (100 filters) received RCA and 36 pts (90 filters) received NM. Baseline Table1. There was no difference in median FL (42.6h in RCA vs 42h in NM, p=0.17). Kaplan-Meier curves of time to spontaneous filter failure shown in Figure1. The mortality and bleeding rate did not differ between the groups.

Conclusions: NM provides similar efficacy compared to RCA for FL. No significant difference in safety was observed between the two groups.

Patient Demographics	RCA(N=28)	NM (N=36)	p-value
Age [Years; median (IQR)]	11.5 (4-21)	1.7(0.5-6)	<0.001
Baseline disease	BMT (21.43%)	Liver disease (27.8%)	
CRRT Indication	AKI (64.3%)	Metabolic (51.4%)	
CRRT duration Days; median (IQR)]	6 (3-12)	4.5 (2.5-6)	0.12
Filter Data:	RCA (N=100)	NM (N=90)	
Mode of CRRT	CVVHDF (99%)	CVVHD (49%)	
Filter life [Hours; median (IQR)]	42.6(17.3-69.0)	42.0(22.0-89.0)	0.17

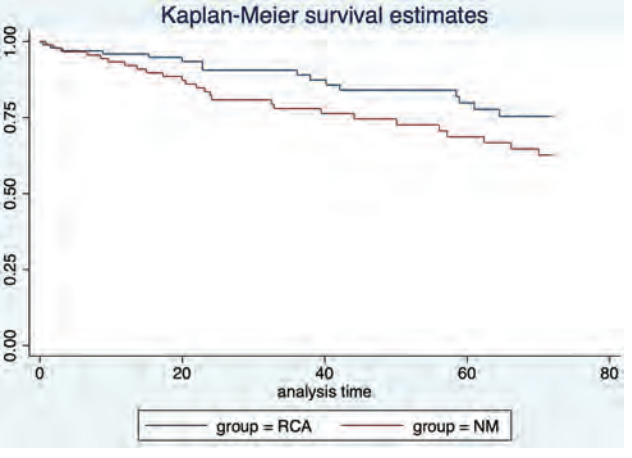


Fig. 1 Kaplan-Meier curves of time to spontaneous filter failure (p=0.085)

PO2288

Renal Replacement Therapy and Mortality Rates for Children with Posterior Urethral Valves and Prune Belly Syndrome

Emily J. Stonebrook,[1] Yuri V. Sebastião,[3] Brian Becknell,[1,2] Christina B. Ching,[1,2] Daryl J. Mcleod.[1,3] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Center For Clinical and Translational Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH; [3]Center for Surgical Outcomes Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Posterior Urethral Valves (PUV) and Prune Belly Syndrome (PBS) cause congenital obstructive uropathy and dysplasia in infants. Resulting chronic kidney disease and pulmonary hypoplasia may lead to renal replacement therapy (RRT), mechanical ventilation and death.

Methods: This retrospective cohort study queried The Pediatric Health Information System (PHIS) database to identify patients with PUV or PBS who were born at or admitted to a PHIS hospital by 3 months of age between 1/1/2006 and 9/20/2016. Ethnicity, race and insurance were investigated as predictor variables for time to RRT or in-hospital mortality. Prematurity and mechanical ventilation were evaluated as predictors of in-hospital mortality.

Results: 1673 PUV and 236 PBS patients met inclusion criteria. There was no difference in time to RRT or mortality based on ethnicity, race, or insurance. 212 patients (11.1%) required RRT by 2 years of age. There was no difference in RRT requirement between the PUV and PBS groups. 130 patients (6.8%) died during the initial admission:

98 PUV patients (5.9%) and 32 PBS patients (13.6%), with a median time to death of 6.5 days and 2.5 days, respectively. PBS patients had an increased risk of death (Adjusted Relative Risk (ARR) 2.12, p <.00001). The difference in median time to death was not significant. Of 381 (20%) premature patients, 79 (20.7%) died prior to discharge. 696 patients (36.5%) required mechanical ventilation, and of these, 118 (17%) died. Prematurity and mechanical ventilation were associated with an increased risk of death (ARR 2.3, p <.0001 and ARR 9.9, p<.0001 respectively).

Conclusions: The severity of the sequelae associated with PUV and PBS is affirmed by the 11.1% risk of early RRT and 6.8% in-hospital mortality. PBS patients did have an increased mortality rate compared to PUV patients. Prematurity or the requirement of mechanical ventilation was associated with an increased mortality rate. Future large, prospective studies will enable investigation of early morbidity and mortality associated with PUV and PBS, as well as long-term outcomes.

PO2289

Preterm Birth in Mice Results in Differential Gene Expression and Premature Cessation of Nephrogenesis

Aleksandra Cwiek,[3] Kimberly Deronde,[3] Masako Suzuki,[1] Kimberly J. Reidy,[2] Jennifer R. Charlton.[3] *[1]Albert Einstein College of Medicine, Department of Genetics, New York, NY; [2]Children's Hospital at Montefiore, Department of Pediatrics, Division of Nephrology, New York, NY; [3]University of Virginia, Department of Pediatrics, Division of Nephrology, Charlottesville, VA.*

Background: Neonates born preterm are at risk of developing chronic kidney disease (CKD). In humans, nephron development is completed by 36 weeks' gestation and the successful formation of nephrons is dependent on self-renewing niches of cells which reside directly under the kidney capsule in the nephrogenic zone (NZ). Little is known about the fate of these progenitor cells or the other compartments of the kidney following premature birth. The objective of this study was to characterize the effect of premature birth on kidney development in murine model of prematurity. We hypothesize that preterm mice will have a shorter period of postnatal nephrogenesis and gene expression profiles will reflect premature differentiation.

Methods: Timed pregnant CD-1 dams were stratified into 2 cohorts. The preterm group was comprised of 59 pups born by Cesarean section at 18 days post-conception (dpc) and the term group contained 79 pups delivered vaginally at 20 dpc. The mice were euthanized on 20-27 dpc. The presence of the nephrogenic zone was determined on histological sections. Genome-wide expression profiles of 20 dpc mice kidneys were evaluated with RNA-seq in both preterm and term groups (n=3 per group).

Results: At 25-27 dpc, kidney to body weight ratios were significantly lower in preterm cohort. In the kidney, the cap mesenchyme was not detectable in the preterm mice a full day (23 dpc) prior to its cessation in the term mice (24 dpc). The expression profiles of 20 dpc kidneys in the preterm group showed distinct alterations compared to the term group. The differentially expressed genes were enriched in a fat-soluble vitamin (including vitamin A and D) metabolic process related pathways.

Conclusions: In a mouse model of prematurity, there is an early differential expression of genes that may be important in nephrogenesis. The shortened window of nephrogenesis may result in a lower nephron number and future risk for CKD in neonates born preterm.

PO2290

Gestational Age (GA) Affects Urine Biomarkers by Postnatal Age but Most Converge by 34 Weeks Post-Menstrual Age (PMA)

David J. Askenazi,[1] Brian A. Halloran,[1] Robert Schmicker,[2] Patrick J. Heagerty,[2] Sandra Juul,[2] Stuart Goldstein,[3] Sangeeta R. Hingorani.[2] PENUT Investigators *[1]The University of Alabama at Birmingham School of Medicine, Birmingham, AL; [2]University of Washington, Seattle, WA; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Urine biomarkers may improve our understanding of kidney development and disease in premature neonates. We evalute how 1-week differences in GA impact 11 biomarkers by postnatal age and PMA.

Methods: Neonates were grouped by GA. Urine was collected on postnatal days 1, 3, 5, 7, 9, 14, 28; on PMA of 30 and 34 weeks; and discharge in 750 neonates without stage 2/3 AKI. Neutrophil-gelatinase associated lipocalin (NGAL), Clusterin, kidney injury molecule 1 (KIM-1), alpha glutathione S-Transferase (a-GST), albumin, beta-2-microglobulin (B2M), cystatin c, epithelial growth factor (EGF), osteopontin (OPN), uromodulin (UMOD), were evaluated by electrochemiluminescence; creatinine by mass spectrometer. Biomarkers are displayed as 7-day rolling mean (day X ± 3 days) on log10 scale. GEE models with mother as a clustering variable were used to determine the association between day, GA, and day*GA for each biomarker. T-tests evaluated differences in 34-week (± 3 day) PMA values.

Results: Figure: Left side plot biomarkers by postnatal age; right side plot biomarkers by PMA. When exploring the values by postnatal age, the most premature neonates have higher NGAL, clusterin, KIM-1, aGST, albumin, B2M, Cystatin C, OPN, and lower EGF, UMOD and Creatinine ($p<0.05$; * in Figure) after adjusting for day. The association of biomarker and time is significantly modified by GA for aGST, Albumin, B2M, Creatinine and Cystatin C (interaction term $p<0.05$; ** in Figure) over the first 30 postnatal days. Only B2M and OPN differ by GA at 34 weeks PMA ($p<0.05$; *** in Figure).

Conclusions: Urine biomarkers differ and are modified by GA during first 30 postnatal days. Most biomarkers converge and are not significantly different by 34 weeks PMA.

PO2291

The Association Between Infantile Pulmonary Hypertension, Sildenafil, and AKI During Hospitalization

Emily E. Zangla, Emily L. Joyce. *University Hospitals, Rainbow Babies and Children's Hospital, Department of Nephrology, Cleveland, OH.*

Background: Pulmonary hypertension (pHTN) is a nidus for poor organ perfusion, and is an understudied potential risk factor for acute kidney injury (AKI) in infants. Neither the association between pHTN and AKI, nor treatment with phosphodiesterase-5 inhibitors (i.e. sildenafil) on renal recovery have been elucidated. We sought to describe AKI in a cohort of hospitalized infants with pHTN.

Methods: A retrospective chart review was performed on 18 infants (less than 1 year of age) during the initial hospitalization for diagnosis of pHTN over one year at a single institution. Adapted neonatal KDIGO criteria was utilized to determine presence of AKI during the hospitalization for each patient.

Results: Out of 18 infants with pHTN, 50% developed AKI during hospitalization. Those who developed AKI were older at the age of diagnosis of pHTN ($p = 0.04$) and more likely to be treated with sildenafil ($p = 0.02$). Within the cohort, 7 (39%) were treated with sildenafil. On univariate analysis, treatment with sildenafil was associated with increased odds of developing AKI (OR 6.7, 95% CI 0.81-55.0). Of those treated with sildenafil who developed AKI, 80% (4/5) developed AKI before initiation of treatment and 20% (1/5) developed AKI after initiation of treatment.

Conclusions: AKI is prevalent in infants diagnosed with pHTN. The increased odds of developing AKI in patients treated with sildenafil is likely a reflection of severity of illness, as most patients developed AKI prior to initiation of treatment. Further research is needed to evaluate the association between pHTN and AKI, as well as determine the role of sildenafil treatment in preventing AKI or promoting renal recovery.

Descriptive Characteristics

	No AKI N = 9/18 (50%)	AKI N = 9/18 (50%)	p-value
Age at diagnosis (mos), mean	1.6 ± 2.1	3.8 ± 2.1	0.04
Gestational Age (weeks), mean	33 ± 6.8	30 ± 7.3	0.36
Males, N (%)	5 (56%)	4 (44%)	0.64
Length of stay (days), mean	170± 195	169 ± 95	0.99
Treated with Sildenafil, N (%)	2 (29%)	5 (71%)	0.07

Baby NINJA (Nephrotoxic Injury Negated by Just-in-Time Action) Transfusion Rates

Hailey W. Gavigan, Cara L. Slagle, Kelli A. Krallman, Brenda Poindexter, David K. Hooper, Stuart Goldstein. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Acute kidney injury (AKI) is associated with poor outcomes in neonates. Nephrotoxic medication (NTM) exposure is a common cause of AKI. Nephrotoxic Injury Negated by Just-in-time Action (NINJA) identifies patients with high NTM burden and recommends daily creatinine (Cr) screening. In neonates, concern for iatrogenic anemia decreases AKI screening. We monitored transfusion rates in our project modeled off the neonatal NINJA adaptation, Baby NINJA.

Methods: Critically ill neonates with high NTM exposure initially received modified Cr monitoring (only with routine labs) before transitioning to standard daily Cr monitoring. Patients transfused 3 days into & up to 7 days after Baby NINJA exposure periods counted as an associated transfusion. Statistical process control methods were used to detect changes from baseline. X^2 and Poisson regression analyses were used to compare metrics between SCr monitoring eras.

Results: Figure 1 shows an increase in transfusions 15 weeks before an increase in Cr compliance. A decrease in transfusions was sustained through the standard Cr era where the highest rate of Cr compliance was seen. The rate of NINJA-associated transfusions was unchanged. Table 1 shows that Cr compliance increased during each era, transfusions decreased between modified & standard Cr eras, NINJA-associated transfusions remained stable, and transfusion rate changes were independent of NINJA-associated transfusions.

Conclusions: There was no association between transfusion rates and daily Cr testing with Baby NINJA implementation; therefore, critically ill neonates with high risk NTM exposure can safely be screened for NTM associated AKI.

Table 1

	Baseline Era	Modified Cr Era	Standard Cr Era	p-value*	p-value**	p-value***
Cr compliance (%)	43.1	49.1	82.6	0.04	<0.01	<0.01
All RBC transfusion rate (per 1000 NICU patient days)	14.6	28.8	24.3	<0.01	<0.01	<0.01
NINJA RBC transfusion rate (per 1000 NICU patient days)	2.1	3.4	2.9	0.13	0.52	0.36

PO2293

Elimination of Intravenous Phthalate Exposure Abrogates Most Neonatal Hypertension in Premature Infants

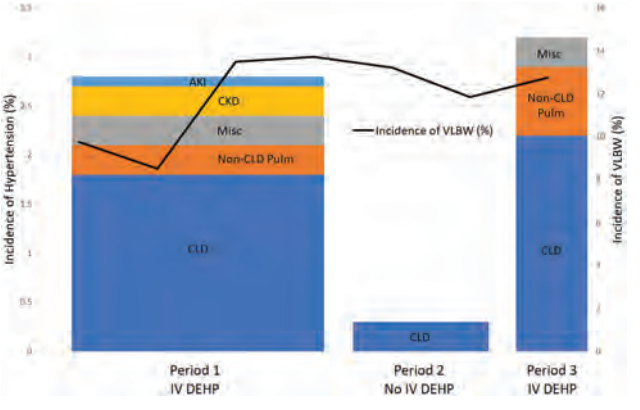
Katherine Farnbach,[1] Ryan Forbush,[2] Sandra Iragorri,[1] Randall Jenkins.[1] *[1]Oregon Health and Science University, Portland, OR; [2]Boise State University, Boise, ID.*

Background: The incidence of hypertension in premature infants in a neonatal intensive care unit (NICU) was noted to transiently drop during a 2-year period when the IV fluid (IVF) temporarily changed to a phthalate-free IVF. The objective of the study is to quantify the effect of varying periods of IVF phthalate exposure on incidence of hypertension in premature infants.

Methods: A chart review was performed of all hypertensive premature infants born at one NICU during the last 6 years including a 3-year baseline period, a 20-month phthalate-free IVF period, and a 10-month period when the original phthalate-containing IVF returned to use. Patients born during 4-month transitions between periods were excluded. Incidence of hypertension for each period were compared for significant difference using Chi-Square analysis.

Results: Incidence of hypertension decreased from 9.7 cases per year (baseline) to 1.2 cases per year when IVF was phthalate-free, rising back to 12.0 cases per year when phthalate-containing IVF returned to use. Most cases met criteria for the pulmonary category of hypertension – for these infants the incidence of hypertension dropped from 7.3 to 1.2, then increased to 10.8 cases per year when evaluated for the same periods of varying phthalate exposure.

Conclusions: Serendipitous removal of IVF containing phthalates resulted in near elimination of hypertension in one NICU – an effect reversing entirely after the same brand of phthalate-containing IVF returned to clinical use. These results suggest that phthalate exposure from IVF plays a major role in neonatal hypertension, especially for those infants in the pulmonary category.



Cases of Neonatal Hypertension by etiology during three time periods, plotted with incidence of very low birthweight during the same time.Width of each bars is scaled according to duration of the time period. Period 1: 36 months, Period 2: 20 months, Period 3: 10 months.

PO2294

Children with a History of Low Birth Weight (LBW) Show Greater Reduction in Kidney Function Than Previously Described Using the Updated Schwartz Equation

Kaye E. Brathwaite,[1] Rebecca Levy,[3] Harini Sarathy,[4] Ilir Agalliu,[2] Tanya S. Johns,[3,2] Kimberly J. Reidy,[1,2] Frederick J. Kaskel,[1,2] Michal L. Melamed.[3,2] *[1]Children's Hospital at Montefiore, Bronx, NY; [2]Yeshiva University Albert Einstein College of Medicine, Bronx, NY; [3]Montefiore Medical Center, Bronx, NY; [4]University of California San Francisco, San Francisco, CA.*

Background: There is a higher risk of reduced kidney function in adults born with LBW (birthweight<2500g). A study using the Counahan-Barrat (CB) eGFR estimation described a modest risk increase in adolescents with LBW. However the CB equation is only validated in children with CKD and underestimates the burden of CKD. Utilizing the updated Schwartz equation, a more sensitive calculation of eGFR validated in healthy children, we sought to assess the prevalence of reduced kidney function in adolescents born with LBW.

Methods: We performed a cross sectional analysis of children aged 12-15 from the National Health and Nutrition Examination Survey from 1999-2016. Reduced kidney function was defined as eGFR <90mL//min/1.73m^2. Participant characteristics were described as weighted sample means and proportions. We constructed logistic regression models adjusted for important sociodemographic factors to evaluate the association of LBW with reduced kidney function.

Results: A total of 6345 individuals were analyzed, representing 13,760,132 adolescents of whom 8% had a history of LBW. Of those born with LBW, the mean age was 13.6 years, 49% were males, 49% were white, 25% were black, 19% were Mexican-American, and 7% were other race. A higher percentage of children with LBW was seen in worse poverty groups. Mean eGFRs in those born LBW were 103 and 107mL/min/1.73m^2 using the updated Schwartz and CB equation, respectively. The prevalence of reduced kidney function in those born LBW was greater using the updated Schwartz equation compared to the CB equation, 30% vs 21.4%. The updated Schwartz equation showed a greater association of LBW and reduced kidney function OR 1.51 (95% CI 1.16-1.97) compared to the CB equation, OR 1.44 (95% CI 1.06-1.96). In an adjusted analysis, the odds of reduced kidney function in adolescents with LBW remained significant OR 1.46 (95% CI 1.1-1.97 using Schwartz but not the CB equation.

Conclusions: A higher prevalence of reduced kidney function was seen in children born with LBW utilizing updated Schwartz compared to the CB equation. The higher risk was sustained in adjusted analyses. These findings may support development of guidelines for CKD screening during long term follow up in the pediatric population with LBW.

PO2295

FCGG Renal Biopsy Network: First Epidemiological Report on Pediatric Renal Disease

Noel Knops,[2] Johan M. De Meester,[1] Amélie Dendooven,[3] Wim Laurens,[1] Ben Sprangers,[2] Elena N. Levtchenko.[2] *[1]AZ Nikolaas, Sint-Niklaas, Belgium; [2]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven Campus Gasthuisberg, Leuven, Belgium; [3]Universitair Ziekenhuis Gent, Gent, Belgium.*

Background: In 2016, a regional renal biopsy network was founded as a collaboration between renal pathologists and nephrologists in order to standardize diagnosis and therapy. Uniform renal biopsy request and renal biopsy report forms were introduced, together with a new comprehensive list of renal pathology diagnoses for coding purposes. The 2017-2018 epidemiological data of the pediatric patients (age 0-17 years) are presented.

Methods: Following informed consent and in compliance with GDPR, data registration consists of basic patient and categorical renal data, semi-structured medical information of renal disease, structured information of renal histopathology, and the clinical renal disease.

Results: In 2017 and 2018, 92 renal biopsies were performed in pediatric patients (age = 0-17 years) or 3.6 per 100,000 pediatric inhabitants per year. Three clinical patterns were equally represented: only proteinuria >1g/day; only hematuria; and combination of proteinuria and hematuria. Acute or chronic renal failure were rare. In the youngest age group (0-5 years; N=26) minimal change disease predominated, followed by Henoch-Schönlein nephritis. The middle age group (6-11 years; N=32) mainly presented with diseases characterized by hematuria: IgA nephropathy, Henoch-Schönlein nephritis and Alport's disease. A more diverse renal disease spectrum was present in the highest age group (12-18 years; N=34): IgA nephropathy, different forms of proliferative glomerulonephritis and of nephrotic syndrome of childhood. Patients with a Caucasian descent presented with IgA nephropathy, while a nephrotic syndrome was more common in those without a Caucasian descent. Alport's disease was particularly diagnosed in female patients, IgA nephropathy in male patients, and the gender distribution was equal in minimal change disease.

Conclusions: The FCGG network provides a better cross-talk between renal pathologists and nephrologists. For the first time, reliable estimates of pediatric renal diseases based on histology are available; genetic analyses are not yet included. Efforts to coordinate clinical care of pediatric renal diseases in the region are ongoing.

PO2296

Developing a Strategy for Routine Reporting of Estimated Glomerular Filtration Rate on Pediatric Laboratory Results

Zubin J. Modi, Brooke A. Blazius, Jonathan P. Troost, Kera E. Luckritz, Ulysses G. Balis, Debbie S. Gipson. *University of Michigan Medical School, Ann Arbor, MI.*

Background: Routine calculation of estimated glomerular filtration rate (eGFR) is not present in laboratory reporting for children, potentially leading to low recognition of decreased eGFR. The study aim was to define options for pediatric eGFR reporting that optimize accuracy and minimize the impact of missing concurrent height in routine lab reporting.

Methods: Data was extracted from the Michigan Medicine Data Warehouse on all patients aged 1-19 years with serum creatinine between 2017-2018. Creatinine-cystatin C-based CKiD (Cr-CysC, Schwartz, 2012) and creatinine-based 'Bedside' (Schwartz 2009) equations were used to calculate eGFR. Correlations were tested between eGFR calculated with same day height values against eGFR calculated with height imputation of 50th percentile for age and sex or patient-specific historical height percentiles. Scatterplots, Pearson's correlation coefficients, and predictive characteristics were calculated.

Results: There were 109,090 serum creatinine measurements, and 35% had concurrent heights. There were 1770 Cystatin C measurements. eGFR by Bedside equation was abnormal (<90 mL/min/1.73m2) in 25% of measurements. Cr-CysC (r=0.99) and Bedside (r=0.98) equations had excellent correlations for measured vs imputed 50th percentile height eGFRs (Figure). Patient-specific height percentile imputed for the Cr-CysC (r=0.99) and Bedside (r=0.99) eGFR also had tight correlations. Discrimination of abnormal eGFR was excellent for the Cr-CysC (94% sensitivity and 95% specificity) and Bedside (90% sensitivity and 97% specificity) equations using 50th percentile height.

Conclusions: Imputation of 50th percentile or patient-specific historic height percentile enables eGFR calculation that correlates with eGFR using same day height. For ease of implementation and with high sensitivity and specificity, use of 50th percentile height may be the preferred approach for pediatric eGFR reporting when patient-specific heights are not available.

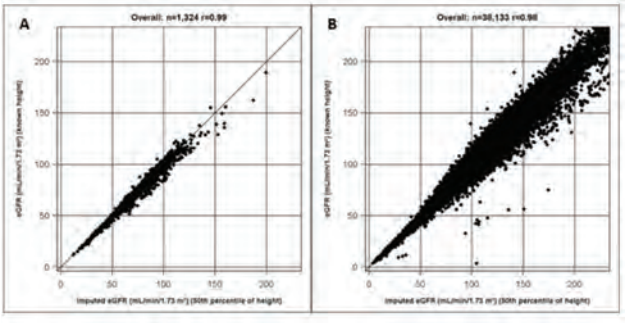


Figure. Concordance of 50th percentile height imputed eGFR compared to eGFR using same day height by creatinine-cystatin c-based CKiD equation (A) and "Bedside Schwartz" (B) equations

PO2297

Factors Related to Significant Albuminuria or Low Glomerular Filtration Rate in Adolescents from a Population with a High Prevalence of CKD of Unknown Origin

Jose M. Arreola Guerra, Cesar M. Gutierrez, Itzel Ovalle, Mariana J. Macias, Andrea L. Garcia Diaz. *Centenario Hospital Miguel Hidalgo, Aguascalientes, Mexico.*

Background: Chronic kidney disease (CKD) of unknown origin has been recognized as the leading cause of kidney disease in young adults in some underdeveloped countries. In Aguascalientes Mexico we report a high prevalence of treated CKD (1997 pmp), with more than half (54%) of unknown cause. The peak of prevalence is between 20 - 30 years (45%), being in that group 73% CKD of unknown origin. For this reason, a CKD screening study was designed in high school students in the state. The aim of this report is to describe the findings of a pilot study obtained in the first three schools.

Methods: Cross-sectional study of high school students. Determination of albumin/creatinine ratio was performed in isolated urine sample and standardized serum creatinine to calculate GFR with Schwartz formula, an abnormal albumin/creatinine ratio>30 mg/gr and GFR≤75 ml/min were defined as CKD. Students and parents were questioned about potentially risk factors. For the multivariate analysis, only students with complete questioning were included.

Results: During March 2020, three high schools in the municipality of Calvillo (Aguascalientes) were visited, accepting entry to the study 187 students out of 260 (72%). The average age was 13.3 years (IQR 12-14) with a predominance of males (n = 109, 58.2%). 33 students with pb CKD were detected (17.6%), 32 of which were due to the presence abnormal albumin/creatinine ratio. Only two patients had low GFR, one with 43 ml/min and the other with 75 ml / min. Four patients presented macro albuminuria, the rest microalbuminuria. In the multivariate analysis, next varibles remainad significant: economic income less than 4,000 Mx$, (OR 4.4, 95% CI, 1.3 - 14.7), frequent NSAID intake (OR 3.8 95% CI 1.16 - 13, p= 0.02), ≥ sweetened beverages per day (OR 4.3, 95% CI1.2 - 14.5, p = 0.01), use of clay dishes by parents and grandparents (OR 4.3 95% CI 1.4 - 12.9, p = <0.01), and BMI <17 kg / m2 (OR 5.8, 95% CI, 1.8 - 18.7, <0.01).

Conclusions: The frequency of abnormal albuminuria or low GFR in adolescents in Aguascalientes is high; follow-up is necessary to confirm these findings. The associated factors significantly guide possible toxics that may be associated with the high prevalence of CKD of unknown cause in our state.

PO2298

Measurement of GFR and Vasoactive Substances in Children with Sickle Cell Anemia

Oluwadamilola Ejike,[1] George J. Schwartz,[2] Susan Legan,[3] Amy M. Becker,[4] Raymond P. Quigley.[3] *[1]Baylor Medical Center, San Antonio, TX; [2]University of Rochester Medical Center, Rochester, NY; [3]University of Texas Southwestern Medical Center at Dallas, Dallas, TX; [4]Driscoll Children's Hospital, Corpus Christi, TX.*

Background: Patients with sickle cell anemia (SCA) have a high risk of developing renal disease. Sickle cell nephropathy is thought to begin in childhood with higher than normal glomerular filtration rates (GFRs) known as hyperfiltration that can lead to proteinuria, sclerosis of the glomeruli, decreased GFR, and eventual renal failure. This model of sickle cell nephropathy has not been validated in clinical studies. This study measured directly the GFRs of patients with sickle cell anemia and age matched control patients. In addition, urinary vasoactive substances were measured to correlate with the GFR.

Methods: Children with sickle cell anemia (SCA) and sickle-β0-thalassemia (HbSb0) were recruited for the study from the Sickle Cell Clinic at Children's Medical Center of Dallas. These sickle cell disease genotypes are phenotypically similar and are the most severe. Healthy siblings of children seen in the Pediatric Nephrology Clinic at Children's Medical Center of Dallas were recruited to serve as controls. GFR was measured directly from iohexol clearance. Urine was obtained to measure vasoactive substances.

Results: Subjects: SCA:32 and Control:13 The GFR of the sickle cell group was 148 ± 36 ml/min/1.73 m² (Mean and SD) and the control group was 130 ± 17 ml/min/1.73 m². The p-value (un-paired t-test) is 0.089 and thus is not statistically significant. However, the SCA group had 21/32 with a GFR ⟩130 while the control group had only 3/13 (p=0.019). Thus, there were more patients in the SCA group with hyperfiltration. There was no difference in urinary cGMP or PGE2. However, PGF2α was higher in the control group. Surprisingly, the urinary angiotensinogen (factored for urinary creatinine) was lower in the SCA group than in the controls (see table).

Conclusions: In conclusion, we have shown that although the GFR in patients with SCA might not be elevated, there appears to be a population of SCA patients with higher than normal GFR. The intrarenal renin-angiotensin system appears to play a role in this hyperfiltration. Further studies are needed to continue to understand this phenomenon.

Urine Angiotensinogen / urine creatinine

	Mean	SD
HbSS	8.0	6.5
Control	14.6	8.3

HbSS urine angiotensinogen/creatinine was significantly lower than control (p<0.005).

PO2299

Food Insecurity During COVID-19 in Children with ESKD: The Second Wave?

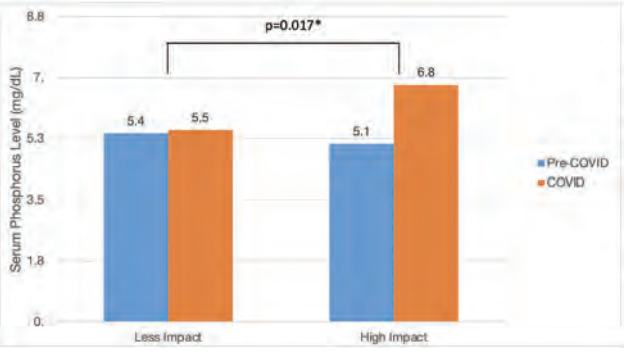
Melvin Chan, Amy C. Wilson, Neha D. Pottanat, Michelle C. Starr. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Food insecurity (FI) affects 1 in 6 children in the US and has increased three-fold during the COVID pandemic. Children with end-stage kidney disease (ESKD) may be at even higher risk of FI due to complex care needs, medication burden and dietary restrictions. A pre-COVID study assessing FI in pediatric hemodialysis (HD) patients described 70% prevalence. No data exists describing the effects of the COVID pandemic on FI in pediatric HD patients.

Methods: We assessed FI among families of patients age 0-18 years with ESKD on chronic HD at a single academic pediatric center. Families were screened for FI by using the Hunger Vital sign, a validated 2 question tool. We assessed impact of COVID on FI. Using demographic features, clinical parameters and medical utilization, we compared "pre-COVID" (2/2020) to "during COVID" (5/2020).

Results: A total of 14 families were enrolled. 12 of 14 (86%) of children with ESKD were FI, and all 12 (100%) reported that COVID had worsened their FI status. The prevalence of FI in our HD unit was five times higher than the general population (86% vs. 15%,p<0.001). Patients with FI had an increase in phosphorus during COVID (5.0 to 5.9 mg/dL, p=0.031). Patients with FI self-described as highly impacted by COVID were more likely to have an increase in serum phosphorus levels during COVID (mean increase of 1.7 vs. 0.1 mg/dL, p=0.017).(Fig 1) No patients with FI highly impacted by COVID had serum phosphorus levels within range compared to those less impacted (0% vs. 38%, p=0.040).

Conclusions: FI is common among children with ESKD on HD and was worsened by the COVID pandemic. The prevalence of FI in COVID was significantly higher than community reported rates and published pre-COVID rates in children with ESKD. FI was associated with increased serum phosphorus levels. Further exploration into how FI during the COVID pandemic influence management and impact outcomes for children with ESRD is essential.



Serum Phosphorus Levels in Children with ESKD and Food Insecurity

PO2300

Incidence of Hypercalcemia with Calcitriol Compared with Paricalcitol in Pediatric Patients Receiving Hemodialysis

Rohan Dwivedi, Jennifer L. Morris, Jessica Geer, Poyyapakkam Srivaths, Sarah J. Swartz. *Texas Children's Hospital, Houston, TX.*

Background: At our institution, both calcitriol and paricalcitol are available for use. Paricalcitol is generally used when adverse effects of calcitriol are observed or during times of calcitriol shortage. There are limited data on the efficacy and safety of vitamin D analogs in pediatric (ped) hemodialysis (HD) patients (pts) to support preference of either agent. This study evaluated the incidence of hypercalcemia in ped HD pts receiving calcitriol compared to paricalcitol.

Methods: Single-center, retrospective review of ped pts on HD treated between January 2012 – December 2018 who received in-center doses of calcitriol or paricalcitol. Pts were excluded if they received in-center doses of both paricalcitol and calcitriol or if they had incomplete data. Pts were not excluded from either group if they had an active prescription for oral calcitriol for home. Data were collected for 6-months from the date of the first in-center calcitriol or paricalcitol dose. The primary objective was to evaluate the incidence of hypercalcemia in those receiving calcitriol compared to paricalcitol. Secondary objectives included the incidence of hyperphosphatemia, high calcium-phosphorus product, and hyperparathyroidism (iPTH). Data were evaluated using descriptive statistics, Mann-Whitney-U and Fisher's Exact test.

Results: 34 pts met the criteria for the study (calcitriol group = 15; paricalcitol group = 19). The groups had no statistically significant differences at baseline. Patients in the paricalcitol group received an average weekly dose of 14 ± 7 mcg, equivalent to 4.67 ± 2.33 mcg of calcitriol compared to 2.36 ± 1.51 mcg in the calcitriol group (p=0.002). There were no differences between the time averaged serum calcium, phosphorous, calcium-phosphorus product, and iPTH between the two groups. Between the paricalcitol and calcitriol groups the incidence of hypercalcemia events per patient (EPP), based on age-related normal calcium was 1.11 and 0.53 (p=0.23), hyperphosphatemia EPP was 3.74 and 2.67 (p=0.20) and high iPTH EPP was 2.63 and 2.2 (p=0.38).

Conclusions: The incidence of hypercalcemia in patients receiving paricalcitol compared to calcitriol was high but did not reach statistical significance. There is no clear advantage seen with the use of paricalcitol when compared to the calcitriol group in peds population.

PO2301

Associations Between Short Stature, Emotional-Behavioral Functioning, and Adaptive Skills in Children with CKD

Rebecca J. Johnson,[1] Lyndsay Harshman,[2] Matthew Matheson,[3] Arlene C. Gerson,[4] Bradley A. Warady,[1] Susan L. Furth,[5] Stephen R. Hooper.[6] *[1]Children's Mercy Kansas City, Kansas City, MO; [2]The University of Iowa Stead Family Children's Hospital, Iowa City, IA; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [4]Johns Hopkins Medical Institute, Baltimore, MD; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]University of North Carolina School of Medicine, Chapel Hill, NC.*

Background: Short stature impacts quality of life (QOL) for children with chronic kidney disease (CKD). Little is known about how short stature impacts emotional-behavioral functioning and adaptive skills in this group of children.

Methods: Baseline and longitudinal data from the Chronic Kidney Disease in Children study were used to evaluate associations between emotional-behavioral functioning, adaptive skills, and short stature (height z score <-2) in children with mild to moderate CKD ages 10+ years. Linear mixed models were used to determine if short stature predicted emotional-behavioral outcomes, using data from both the parent- and self-report BASC2 rating scales. Models were adjusted for sociodemographic and disease-related covariates.

Results: Baseline parent-report data were available for 737 participants (61% male; median age 13 [IQR=11,16]; 32% glomerular CKD; median eGFR 52 ml/min|1.73m2 [IQR=39, 66]; 10% short stature; 8% growth hormone use). BASC2 self-report was available for 229 participants. For BASC2 parent-report, short stature was not associated with the summary scales of internalizing symptoms (e.g., anxiety, sad mood; β=1.46,

CI=-0.51, 3.42; p=.15), adaptive skills (e.g., social skills, adaptability; β=-1.03, CI=-2.95, 0.89; p=29), or behavioral symptoms (e.g., hyperactivity, conduct problems; β=-0.02, CI=-1.63, 1.60; p=.98). Short stature was associated with the clinical subscale of somatization (child health complaints of pain, poor physical health, and illness; β=2.41, CI=0.31, 4.5; p=.02). There was a marginal, but nonsignificant, association with the depression subscale (β=1.73, CI=-0.09, 3.54; p=.06). Short stature was not related to any of the BASC2 self-report ratings.

Conclusions: For most measures of emotional-behavioral functioning and adaptive skills, short stature was not associated with an increase in parent- or self-reported internalizing or externalizing symptoms or adaptive skills. Short stature was associated with parent-reported, but not self-reported, somatization. The present findings offer some reassurance that while short stature may be related to poorer QOL and somatization, preliminary findings suggest that it is not associated with more significant psychopathology or concerns regarding adaptive skills.

Urine Biomarkers of CKD Progression in Children

Jason H. Greenberg,[1] Alison G. Abraham,[2] Yunwen Xu,[2] Jeffrey R. Schelling,[3] Harold I. Feldman,[4] Venkata Sabbisetti,[5] Joachim H. Ix,[6] Bradley A. Warady,[8] Paul L. Kimmel,[7] Joseph V. Bonventre,[5] Michelle Denburg,[4] Chirag R. Parikh,[2] Susan L. Furth.[4] CKD Biomarker Consortium *[1]Yale University School of Medicine, New Haven, CT; [2]Johns Hopkins University, Baltimore, MD; [3]Case Western Reserve University, Cleveland, OH; [4]University of Pennsylvania, Philadelphia, PA; [5]Brigham and Women's Hospital, Boston, MA; [6]University of San Diego, San Diego, CA; [7]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [8]Children's Mercy Hospitals and Clinics, Kansas City, MO*.

Background: Biomarkers of tubular injury, repair, and inflammation may improve the ability to identify children at high risk of rapid kidney function decline and help elucidate the pathophysiology of CKD progression. In this study, we investigated whether the urinary biomarkers EGF, KIM1, MCP1, YKL40, and alpha1 microglobulin are prognostic of CKD progression in children.

Methods: In the prospective CKiD study, children aged 6 months to 16 years old with an eGFR of 30-90 were enrolled and eGFR was assessed annually. We measured urine biomarkers collected 5 months after study enrollment. Urine biomarkers were indexed to urine creatinine. The primary outcome was CKD progression, defined as a composite of a 50% decline in eGFR or ESKD.

Results: Of the 375 children included, median age was 12 years [IQR, 8-15], 227 (61%) were male, and baseline eGFR was 44 [IQR, 35-56]. Overall, 187 children (50%) reached the primary outcome over a median follow-up time of 6.2 years [IQR, 3.0–10.3]. All biomarker levels were higher in children with CKD progression, except for EGF which was lower in those with CKD progression (p for all <0.05). After adjustment for confounders, children with urine EGF concentrations in the highest quartile were at a significantly lower risk of CKD progression compared to those with EGF in the lowest quartile [EGF aHR; 0.20 (95% CI: 0.11-0.39)] (Table). Children with urine KIM1 and MCP1 in the highest quartile were at a significantly higher risk of CKD progression compared to those in the lowest quartile [KIM1 aHR; 2.6 (95% CI: 1.6-4.1), MCP1 aHR; 2.8 (95% CI: 1.7-4.7)].

Conclusions: Low urine EGF and elevated urine KIM1 and MCP1 concentrations are independently associated with CKD progression in children.

Funding: NIDDK Support

PO2303

Effect of Cholecalciferol Supplementation on FGF-23 in Children with CKD

Stephen M. Chu, Meredith A. Atkinson. *Johns Hopkins University, Baltimore, MD*.

Background: Cholecalciferol increases total vitamin D levels in children with chronic kidney disease (CKD), but by increasing serum phosphate levels may also increase levels of fibroblast growth factor 23 (FGF23), which is associated with adverse outcomes in both adults and children with CKD. Our objective was to quantify changes in FGF23, α-klotho and vitamin D binding protein (VDBP) in children participating in a vitamin D supplementation trial.

Methods: We utilized stored serum samples from a 4-week pilot randomized controlled trial of supplementation with 4000 (high dose) vs. 400 (DRI) IU per day of cholecalciferol in children with mild-to-moderate CKD. Intact and C-terminal FGF23, soluble α-klotho, and VDBP were measured using commercially-available ELISAs in the Johns Hopkins Institute for Clinical and Translational Research Core Laboratory. Statistical analyses conducted using Stata 14.

Results: Thirty-four children were included in the analysis; 17 received the intervention dose of 4000 IU cholecalciferol, and 17 received the control dose of 400 IU. The mean (SD) age of the cohort was 10.9 (5.8) years, 26.5% female, 23.5% black, 58.8% white, and 17.7% other race. Mean (SD) GFR at baseline was 60 (17.6) ml/min/1.73m^2. Median (IQR) baseline total vitamin D level was 29 (20, 34) ng/ml in the control arm and 32 (23, 39) in the intervention arm. Total vitamin D level did not change significantly after 4 weeks of supplementation in the control arm, but was increased to 38.5 (31, 50) in the intervention arm (p=0.001). The table compares baseline and 4-week FGF23, α-klotho, and VDBP levels in the control and intervention arms, and no significant differences were noted between the groups who received DRI vs. high dose cholecalciferol.

Conclusions: Cholecalciferol supplementation of 4000 IU/day in children with CKD was not associated with significant differences in FGF23, α-klotho, or VDBP levels compared to children who received only the DRI.

Mean (SD)	400 IU	4000 IU	p-value
C-terminal FGF23, B (RU/ml)	44.5 (32.8)	46.5 (38.6)	0.76
C-terminal FGF23, W (RU/ml)	39.5 (26.9)	45.3 (30.1)	0.61
Intact FGF23, B (pg/ml)	19.1 (14.4)	18.7 (12.9)	0.93
Intact FGF23, W (pg/ml)	20.3 (12.9)	19.6 (11.9)	0.89
α-klotho, B (pg/ml)	3,321.9 (4,4221.82)	1,944.7 (1,257.1)	0.22
α-klotho, W (pg/ml)	3,340.4 (5,146.3)	1,959.4 (1,598.1)	0.36
VDBP, B (ng/ml)	327,437.5 (58,516.6)	332,400 (86,243.1)	0.78
VDBP, W (ng/ml)	328,666.7 (72,235.4)	352,661.5 (74,871.8)	0.40

PO2304

Improving Metabolic Acidosis in Patients with CKD

Heather Morgans, Gina Gregg, Rachel A. Cisneros, Rana E. El Feghaly, Darcy K. Weidemann. *Children's Mercy Hospitals and Clinics, Kansas City, MO*.

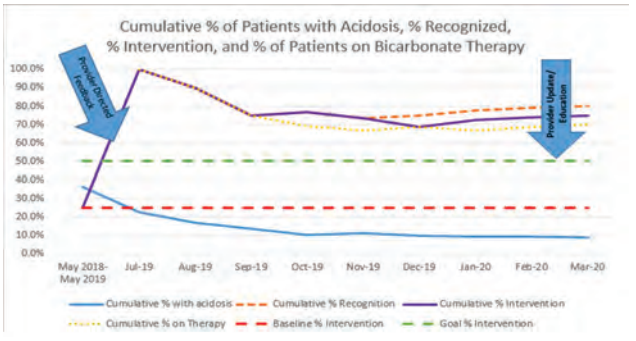
Background: Pediatric chronic kidney disease (CKD) is characterized by multiple metabolic derangements including metabolic acidosis. Untreated acidosis is associated with bone disease, increased mortality, and CKD progression[1,2]. Current guidelines

recommend bicarbonate supplementation for CKD patients with serum bicarbonate < 22mmol/L[3]. Review of our nephrology division's clinical practice in the past year found that 36% of patients with CKD stage 3-5 were acidotic, although only 25% of these received an intervention to address the acidosis. Our aim is to increase the percentage of interventions for acidosis in this population from 25% to 50% by June 30, 2020.

Methods: Monthly reports were generated for patients with CKD stage 3-5 and acidosis in the nephrology clinic. Our outcome measure is the percentage of acidotic patients. Process measures include the percentage of acidosis recognition, appropriate intervention, and patients on bicarbonate treatment. The balancing measure is patients with alkalosis (bicarbonate > 28mmol/L) while on supplementation. A multidisciplinary team identified multiple root causes and baseline data identified that lack of provider recognition of mild acidosis (bicarbonate 20-22) was the primary driver why treatment was not initiated. Countermeasures were developed to address this gap.

Results: Using PDSA cycles, we have implemented 2 countermeasures. Initially, we utilized provider directed feedback to notify those who had patients with untreated acidosis in the past month. Then, an education session was completed in March 2020. Our goal of increasing interventions for acidosis to 50% was exceeded by March 2020 (75%). There was also decrease in the number of acidotic patients, increase in provider recognition and bicarbonate treatment, with no increase in patients with alkalosis (Figure 1).

Conclusions: Utilizing provider directed feedback along with educational sessions have effectively increased the percentage of CKD stage 3-5 patients who are appropriately treated for acidosis. Further interventions are ongoing.



PO2305

Factors Influencing Duration of Dialysis in Children with Shiga Toxin-Producing *Escherichia coli*-Associated Hemolytic Uremic Syndrome (STEC-HUS) at a Single Center

Myda Khalid, Neha D. Pottanat, Chloe Miller, Sharon P. Andreoli. *Indiana University School of Medicine, Indianapolis, IN.*

Background: More than half the children with STEC-HUS require renal replacement therapy. Several factors influence the duration of dialysis.

Methods: We performed a retrospective cohort analysis using electronic medical records and chart review of 67 patients with STEC-HUS identified through billing data from July 1st 2008 to August 30th 2015. Cases of atypical hemolytic uremic syndrome (HUS), *Streptococcal pneumoniae* associated HUS were excluded.

Results: The mean age at presentation with STEC-HUS was 4.9yrs (range 0.99-17.16yrs). 44 (66%) were females compared to 23 (34%) males. Data on intravenous fluids (IVF) administration prior to diagnosis of HUS was available in 54 subjects of which 39 (72%) received IVF anytime during four days prior to presentation, and 15 (28%) did not. Of the patients receiving IVF, 22 (56%) required dialysis for an average duration of 11.4d whereas in subjects without IVF, 7 (47%) required dialysis for an average duration of 14.7d. 9 of 55 subjects received NSAIDS during the illness, and six of the nine required dialysis. For these 6 subjects, the average duration of dialysis was 17d compared to 10.3d in subjects without NSAID exposure. We also evaluated patients for antibiotic exposure before and after the diagnosis of HUS. In 30 (53%) subjects without any antibiotic exposure the average duration on dialysis was 9.8d. For 11 (19 %) subjects receiving antibiotics before the diagnosis of HUS average duration of dialysis was 13.6d. Dialysis duration in the 12 (21%) subjects receiving antibiotics after the diagnosis of HUS was 13.3d.

Conclusions: To our knowledge our study is first to evaluate the impact of NSAIDS on the severity of HUS, and demonstrates that the use of NSAIDS in STEC-HUS increases the duration of dialysis significantly. Confirming previous literature, the use of antibiotics results in prolongation of dialysis regardless of the timing of administration. We also note that IVF administration in the first 4 days prior to the diagnosis of HUS may result in a shorter time on dialysis.

PO2306

Determining the Optimal Dose of Cholecalciferol Supplementation for Children with CKD (C_3 Trial): An Open-Label Multicentre Randomized Controlled Trial

Arpana A. Iyengar,[1] Nivedita Kamath,[1] Hamsa V,[1] Susan Uthup,[3] Jyoti Sharma,[4] Jyoti S. Singhal,[4] Sudha Ekambaram,[2] Mandy Wan,[5] Rukshana Shroff.[5] *[1]St John's Medical College Hospital, Bangalore, India; [2]Mehta Hospitals, Chennai, India; [3]Government medical College Hospital, Trivandrum, India; [4]KEM Hospital, Pune, Pune, India; [5]Great Ormond Hospital for Children, London, United Kingdom.*

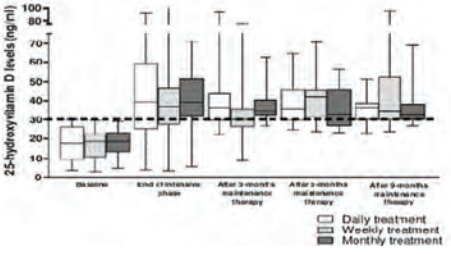
Background: The optimal treatment regimen for correcting 25-hydroxyvitamin D (25OHD) deficiency in children with CKD has not been established. We studied oral cholecalciferol treatment regimens that achieve and maintain 25OHD levels above 30ng/ml in children with CKD stages 2-4.

Methods: We performed an open label, multicentre randomized controlled trial in children with 25OHD <30ng/ml, randomized 1:1:1 to oral cholecalciferol as 3000IU daily, 25,000IU weekly or 100,000IU monthly for 3months intensive phase therapy. A maximum of 3 courses of intensive phase treatment were allowed if 25OHD was <30ng/ml. Patients achieving normal 25OHD entered maintenance phase with 1000IU cholecalciferol daily for 9 months. Primary outcome was achieving 25OHD levels ≥30 ng/ml at end of intensive phase therapy.

Results: Of the 150 children screened, 90 were 25OHD deficient and randomised to daily(n=30), weekly(n=29) or monthly(n=31) treatment arms. Age, gender, renal disease, eGFR and baseline 25OHD were comparable between treatment arms. At end of the intensive phase 68.8% achieved 25OHD ≥30ng/ml with comparable levels between arms(median 44.3 39.4 and 39.3 ng/ml p=0.24) on daily, weekly, monthly regimens respectively. The time taken to achieve 25OHD ≥30 ng/ml was comparable between treatment arms (p=0.28) with 7.7% not achieving normal 25OHD after 3 courses. Irrespective of treatment arm, median 25OHD were lower in children with glomerular disease than non-glomerular disease [25.8 vs 41.8ng/ml; p=0.007]. There was no significant difference in 25OHD between treatment arms at end of intensive(p=0.24) or maintenance phase therapy (p>0.05)[Figure]. There was no hypercalcaemia or hypercalciuria.

Conclusions: Intensive phase therapy with oral cholecalciferol as daily, weekly or monthly regimens achieved similar 25OHD levels without toxicity. Children with glomerular disease require higher doses of cholecalciferol compared to non-glomerular disease.

Figure: Serum 25OHD levels at different time points.



PO2307

ESRD Risk in Type 1 vs. Type 2 Childhood-Onset Diabetes Mellitus

Oren Pleniceanu,[1,2] Gilad Twig,[4] Tomer Erlich,[2] Lital Keinan Boker,[5] Karl Skorecki,[3] Ronit Calderon-margalit,[6] Asaf Vivante.[2] *[1]Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel; [2]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel; [3]Rambam Health Care Campus, Haifa, Israel; [4]Israel Defense Forces, Tel Aviv, Israel; [5]University of Haifa School of Public Health, Haifa, Israel; [6]Hebrew University of Jerusalem Braun School of Public Health and Community Medicine, Jerusalem, Israel.*

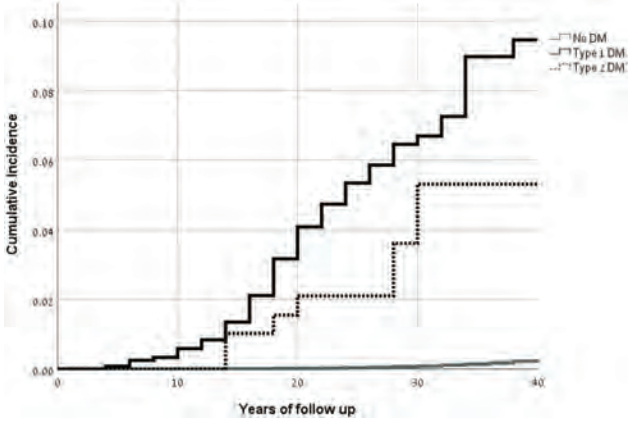
Background: Diabetic kidney disease (DKD) is becoming increasingly common among children. We aimed to estimate the risk of end-stage renal disease (ESRD) and mortality among adolescents with type 1 diabetes mellitus (T1DM) or type 2 diabetes mellitus (T2DM) and normal renal function compared to non-diabetics. We hypothesized that childhood onset T1DM vs T2DM would be associated with a different risk profile for developing ESRD and its complications.

Methods: A nationwide, population-based, retrospective cohort study, including 1,500,522 adolescents examined for military service between 1967-1997, which were classified according to the presence and type of diabetes. Data were linked to the Israeli ESRD registry. Cox proportional-hazards models were used to estimate the hazard ratio (HR) for ESRD.

Results: At study enrolment, 1,183 adolescents had T1DM and 196 had T2DM. ESRD developed in 2,386 non-diabetic individuals (0.2%) compared to 72 individuals (6.1%) with T1DM, and 8 individuals (4.1%) with T2DM. Participants with T1DM were younger at ESRD onset than participants with T2DM (median age: 36.0 vs. 40.5 years, P<0.05). In a multivariate model adjusted for age, sex, paternal origin, enrollment year, BMI, and blood pressure, T1DM and T2DM were associated with HR of 36.4 (95% CI,

28.3-46.9) and 19.3 (95%CI, 9.6-38.8) for ESRD, respectively. Stratification according to sex, ethnicity, immigration and socioeconomic status did not materially change the HR. During the follow-up period, mortality rates were higher in T2DM as compared to T1DM and controls (8.7 %, 2.2% and 2.7% respectively).

Conclusions: T1DM and T2DM in adolescents with normal renal function confer a significantly increased risk for ESRD. T1DM is associated with younger age at ESRD onset while T2DM is associated with higher mortality rate.



Cumulative ESRD incidence

PO2308

Prevalence of Renal Dysfunction in Youth with Epidermolysis Bullosa

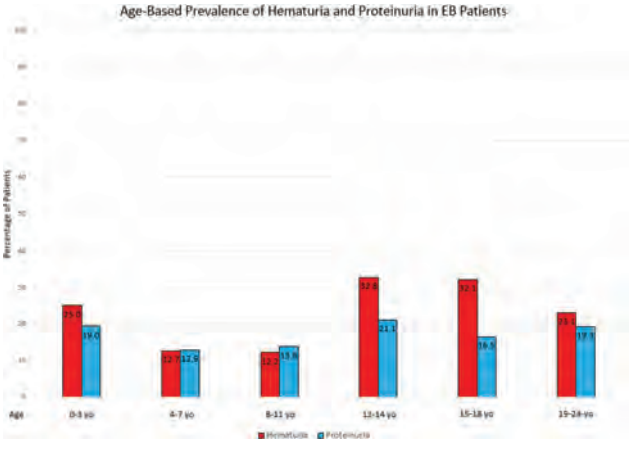
Erica Hughley, Edward Nehus, Bret D. Augsburger, Anne W. Lucky. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Little is known regarding the prevalence of renal disease in youth with epidermolysis bullosa (EB), which we describe here.

Methods: We conducted a retrospective review of electronic health records of 170 (48.8% female, 51.2% male) EB patients aged < 25 years followed by our institution within years 1986-2019. We report the age-based prevalence of hematuria (≥ 1+ on urinalysis [UA] or ≥ 5 red blood cells per high power field) and proteinuria (≥ 30 mg/dL). We also describe the outcomes of those with persistently abnormal UAs, defined as hematuria and proteinuria or nephrotic-range proteinuria on ≥ 2 consecutive tests. Finally, we compare mortality in EB youth with versus without acute kidney injury (AKI), defined per Kidney Disease Improving Global Outcomes.

Results: The overall prevalence of microscopic hematuria was 22.7%, with no significant difference between sex (p = 0.10). Age-based microscopic hematuria followed a bimodal distribution, with increased prevalence among younger (0-3 years) and older (>12 years) children (p=0.003) [Fig. 1]. The overall prevalence of proteinuria was 16.9%, with no significant differences between sex (p = 0.35) or age (p = 0.73) [Fig. 1]. 10 patients (5.9%) had persistently abnormal UAs and were diagnosed with: C3 glomerulopathy (4), urethral stricture (2), infection (2), IgA nephropathy (1), and acute tubular necrosis (1). AKI occurred in 19 patients (11.2%) and was significantly associated with mortality (47.4% in the AKI cohort versus 20.0% in the non-AKI cohort, p = 0.01). Identified causes of death in AKI patients were multiorgan failure including renal failure (3), renal failure alone (1), respiratory failure (1) and severe malnutrition (1).

Conclusions: Many youth with EB have hematuria and/or proteinuria, suggesting glomerulonephritis and/or urologic abnormalities may be underdiagnosed in this population. AKI is significantly associated with mortality in EB youth, with renal failure as a potential common cause of death.



PO2309

Clinical Relevance of Fluid Volume Status Assessment by Bioimpedance Spectroscopy in Children on Maintenance Dialysis

Jeesu Min,[1] Peong Gang Park,[1] Ji hyun Kim,[3,2] Yo Han Ahn,[1,2] IL-Soo Ha,[1,2] Hee Gyung Kang.[1,2] *[1]Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: Bioimpedance spectroscopy (BIS) has been used as a noninvasive method to evaluate body fluid volume status in dialysis patients. However, reports in pediatric dialysis patients about the effectiveness of this method are rare. We asked if there is a correlation in the results of BIS and clinical characteristics, and if there is a subsequent change of cardiovascular characteristics in patients whose dialysis prescription was modified based on BIS.

Methods: Medical records of children on maintenance dialysis who were evaluated by multifrequency BIS between January 2016 and December 2019 were reviewed. Their first result of BIS was assessed and fluid overload status was correlated with hypertension, number of oral antihypertensive medications and echocardiography results. In patients with fluid overload, change of dialysis prescription and clinical characteristics over time were reviewed.

Results: Among the 47 patients (male:female 28:19, hemodialysis:peritoneal dialysis 17:30) with a median age of 13.5 years, 13 children were overhydrated with the proportional overhydration relative to extracellular water more than 15%. Majority of children (76.9%) with fluid overload were taking two or more oral antihypertensive medications, while less than half of those without fluid overload were. 11 out of 13 overhydrated children changed their dialysis prescription to reduce their target body weights. Subsequent BIS in overhydrated children revealed a significantly decreased amount of fluid overload (initial: median 22.9%, follow-up: median 13.4%). However, their mean blood pressure (initial: 89.8 mmHg, follow-up: 84 mmHg) and the number of antihypertensive medications [initial: median 2 (0-4), follow-up: median 2 (0-5)] did not significantly change. Also, none of the children initially overhydrated had their left ventricle hypertrophy changed.

Conclusions: While BIS might be a useful and noninvasive method to assess fluid status, implementation of this tool did not lead to clinically meaningful improvement of cardiovascular characteristics in the children on maintenance dialysis. Long-term follow-up of a larger population and correlation with a more objective clinical indicator of fluid overload such as serum brain natriuretic peptide would be necessary to verify the clinical effectiveness of BIS in pediatric dialysis patients.

PO2310

Variants of SLC34A1, SLC34A3, and AGXT in an Infant with Nephrocalcinosis and Hypercalcemia

Mariah L. Wright, John D. Mahan, Tahagod Mohamed. *Nationwide Children's Hospital, Columbus, OH.*

Introduction: Idiopathic infantile hypercalcemia (IIH) is a rare genetic disorder that can lead to neonatal nephrocalcinosis. It is typically caused by loss of function mutations in *CYP24A1* or less commonly in *SLC34A1*. *SLC34A1* encodes the NaPi-IIa transporter which aids in phosphate reabsorption in the renal proximal tubules. Defects in *AGXT* are responsible for primary hyperoxaluria type 1 (PH1). Defects in either *AGXT* or *SLC34A1* can lead to infantile nephrocalcinosis and subsequent renal damage.

Case Description: A term male infant had bilateral hyperechoic kidneys on prenatal ultrasound. Postnatal labs showed hypercalcemia, hypophosphatemia, high 1,25 dihydroxyvitamin D3 and acute kidney injury. The patient was treated with fluids, furosemide, and calcitonin without significant change in serum calcium. Pamidronate was given which decreased serum calcium and worsened hypophosphatemia. Phosphate supplementation was initiated. Whole exome sequencing revealed two variants in *SLC34A1*, one of which was pathogenic, and a variant in *SLC34A3* of unknown significance. Incidentally, this patient was compound heterozygous for three variants in *AGXT:* one pathogenic and two benign. After these results, patient was found to have generalized aminoaciduria and mild hyperoxaluria for age. Serum calcium decreased with maintenance of adequate plasma phosphate levels.

Discussion: Compound heterozygous mutations of *SLC34A1* can cause IIH type II, and the variant in *SLC34A3* could be contributing to this patient's clinical phenotype in a unique trialleic pattern. The pathologic *AGXT* gene variants could cause this patient to develop PH1. The combined effects of IIH and PH1 could significantly impact the clinical course of this patient. Mutations in both *AGXT* and *SLC34A1* have not been previously described in the literature. During acute severe hypercalcemia, it might be necessary to use pamidronate to lower serum calcium to levels that are safe for the administration of phosphate supplements.

Events	Days after initial presentation	Calcium (8.0-10.5 mg/dL)	Phosphorus (4.2-6.5 mg/dL)	1,25 Dihydroxyvitamin D3 (15-90 pg/mL)	25-Hydroxyvitamin D (30-120 ng/mL)
Initial Presentation	1	15	3.5	32	18
After 1st Pamidronate infusion	10	11.2	2.3		
	23	11.2	4		
After 2nd Pamidronate infusion	24	10.5	3.6		
After Phosphate Supplementation	47	9.6	5.2	212	24
	75	10.5	4.4		
	138	10.4	5	122	34

PO2311

Dent Disease Phenotype Caused by Immunodysregulation Polyendocrinopathy Enteropathy X-Linked (IPEX) Syndrome: Due to Anti-Tubular Basement Membrane Antibody Disease

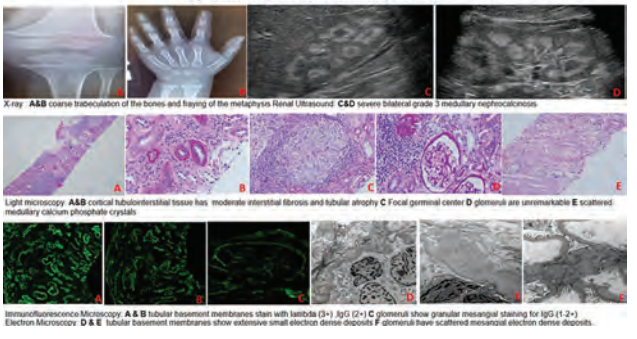
Raja Dandamudi, Keith A. Hruska. *Washington University in Saint Louis School of Medicine, Saint Louis, MO.*

Introduction: Immunodysregulation, polyendocrinopathy, enteropathy, X-linked (IPEX) recessive disorder caused by loss-of-function mutations forkhead box protein 3 gene (FOXP3) transcription factor affecting the function of circulating regulatory T cells. Previously described renal manifestations were immune complex deposition in a membranous- pattern and interstitial nephritis. Here we report novel renal manifestations of IPEX syndrome.

Case Description: 5-year-old male ipresented at the end of the first month of life, with type 1 diabetes mellitus, hypothyroidism, and chronic diarrhea and diagnosed by IPEX syndrome by c.434C>T; p. Ala 145Val mutations in the FOXP3 gene. He underwent stem cell transplant at 6 months of age from a fully matched unrelated donor. Post stem cell transplant he has had mixed chimerism with low but relatively stable donor T cells. He remained relatively stable until 4 years of age when he presented with the clinical picture of Dent's disease: nephrocalcinosis, tubular proteinuria, Fanconi syndrome (proximal RTA, phosphaturia, calciuria, glycosuria and aminoaciduria) and renal insufficiency. No disease-causing mutations in CLCN5 gene or the OCRL1 gene were identified on genetic testing. Renal biopsy demonstrated non-sclerotic glomeruli with no capillary loop spike formation, no crescent formation, no endocapillary proliferation, or segmental necrosis. Immunofluorescence showed tubular basement membranes stain with IgG, C3, kappa and lambda. Glomerular basement membranes were negative. Tubular basement membranes show extensive small electron dense deposits without substructure.

Discussion: In this case report we presented child with confirmed IPEX syndrome with nephrotic-range tubular proteinuria, proximal RTA, phosphaturia, calciuria, medullary nephrocalcinosis, and renal insufficiency, in addition to the classical triad of enteropathy, dermatitis and polyendocrinopathy. Our report is the first to document the anti-tubular basement disease clinically manifesting as the Dent's disease phenotype in association with IPEX syndrome.

Fig. 1 Radiological and Renal biopsy findings



X-ray **A&B** coarse trabeculation of the bones and fraying of the metaphysis Renal Ultrasound **C&D** severe bilateral grade 3 medullary nephrocalcinosis

Light microscopy **A&B** cortical tubulointerstitial tissue has moderate interstitial fibrosis and tubular atrophy **C** Focal germinal center **D** glomeruli are unremarkable **E** scattered medullary calcium phosphate crystals

Immunofluorescence Microscopy: **A & B** tubular basement membranes stain with lattibda (3+) *IgG* (2+) **C** glomeruli show granular mesangial staining for IgG (1-2+)
Electron Microscopy **D & E** tubular basement membranes show extensive small electron dense deposits **F** glomeruli have scattered mesangial electron dense deposits.

PO2312

Severe Hyperkalemia in a 4-Month-Old Female due to Cullin-3 Mutation

Grace C. Yu,[2] Faris Q. Hashim,[2] Christian Hanna.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Baylor Scott and White Central Texas, Temple, TX.*

Introduction: Pseudohypoaldosteronism (PHA) type II, also known as familial hyperkalemic hypertension, is a rare autosomal-dominant disorder that causes renal tubular acidosis (RTA) type 4, characterized by late-onset hypertension, hyperkalemia, non-gap metabolic acidosis, and low or low-normal plasma renin and aldosterone levels. We present a case of a female infant with PHA type II who presented with asymptomatic severe hyperkalemia due to Cullin-3 Mutation. Treatment with thiazide diuretics resulted in rapid correction of her hyperkalemia.

Case Description: A 4-month-old former term female with an unremarkable past medical history presented for management of right neck abscess. Family history was significant for an unspecified seizure and movement disorder in her older sister. She had appropriate growth for her age, with weight, length, and head circumference all measuring around the 20th percentile. Vital signs including blood pressure were normal. Admission laboratories revealed high potassium level of 8.4 mEq/L, low bicarbonate level of 10 mEq/L (normal for age is 19–24), high chloride level of 116 mEq/L (normal for age is 97–108). Anion gap was normal at 10 mEq/L. No electrocardiogram changes were noted. Additional studies revealed positive urine anion gap of 40 mEq/L, a normal serum aldosterone level of 22 ng/L and a low renin activity of 0.2 ng/ml/hr (normal for age is 2–37). She received intravenous calcium gluconate, sodium acetate, and sodium polystyrene sulfonate for hyperkalemia management. Whole exome sequencing revealed a de novo heterozygous c.1376A>T (p.K459M) mutation in the Cullin 3 (*CUL3*) gene consistent with PHA type II. She was treated with thiazide diuretics, which quickly corrected her metabolic abnormalities.

Discussion: Our case of PHA type II with a CUL3 pathogenic variant is exceptionally rare, especially given the patient's age at presentation and the negative family history. Her diagnosis could have been easily missed were she not hospitalized for her neck abscess. Without genetic evaluation and prompt thiazide diuretic treatment, she may have eventually suffered from failure to thrive and hypertension at a later point in life because of chronic hyperkalemia and metabolic acidosis. Primary care physicians and nephrologists should consider the possibility of PHA type II in any child who presents with hyperkalemia and metabolic acidosis with or without hypertension.

PO2313

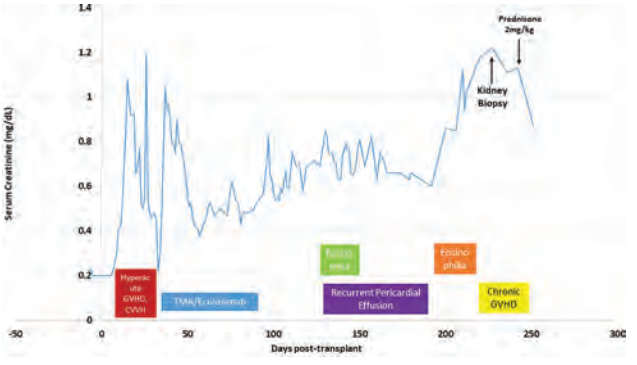
A Rare Pediatric Case of Karyomegalic Tubulointerstitial Nephritis

Carlos C. Becerril romero,[1,2] Sasha R. Kapil,[1,2] April Rahrig,[1,2] Carrie L. Phillips,[1,2] David S. Hains,[1,2] Jodi L. Skiles,[1,2] Sushil Gupta.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University Health, Indianapolis, IN.*

Introduction: Karyomegalic tubulointerstitial nephritis (KIN) is a rare type of interstitial nephritis that often progresses to chronic kidney disease. The pathogenesis is unclear but speculated to result from disruptions to tubular epithelial cell division by genetic predisposition or external insults. Only 6 pediatric cases have been reported and perhaps this condition is underdiagnosed.

Case Description: A 2-year-old male with history of refractory AML received a matched unrelated donor stem-cell transplant following busulfan, fludarabine, and single fraction total body irradiation. His post-transplant course was complicated by engraftment syndrome, hyperacute graft versus host disease (GVHD), thrombotic microangiopathy, and acute kidney injury. He required ICU stay, treatment with eculizumab and two weeks of renal replacement therapy. His kidney function improved but serum creatinine stayed higher than baseline (picture). Four months post-transplant, he was treated with cefepime, acyclovir, ibuprofen for enterococcus bacteremia and pericardial effusion. Seven months post-transplant, while off all immunosuppression, he developed eosinophilia, renal tubular dysfunction with increased serum creatinine. Eosinophilia resolved spontaneously. Bone marrow was negative for leukemia and infectious workup was negative. Eight months post-transplant, he developed GVHD, diagnosed with skin biopsy. He also had persistent high serum creatinine with normal urinalysis. Ultrasound showed echogenic kidneys. Kidney biopsy was performed because of unexplained high serum creatinine. Specimen tissue showed tubulointerstitial nephritis with widespread karyomegaly in medullary tubules. Glomeruli were unaffected. Some cortical tubules showed ultrastructural myelinosomes. His renal function improved with steroids.

Discussion: Our case highlights that KIN can develop in children after chemotherapy. Diagnosis requires high index of suspicion and thorough pathological examination of kidney biopsy specimen. A trial of corticosteroid therapy may be considered.



PO2314

Rescue Therapy with Eculizumab for Catastrophic Antiphospholipid Syndrome in Juvenile Systemic Lupus Erythematosus

Patricia A. Arroyo Parejo Drayer, Malek Al Barbandi, Marissa J. Defreitas, Chryso P. Katsoufis, Jayanthi Chandar, Carolyn L. Abitbol, Wacharee Seeherunvong. *University of Miami School of Medicine, Miami, FL.*

Introduction: Catastrophic antiphospholipid syndrome (CAPS) is a life-threatening condition, and is associated with acute multiorgan failure, small vessels thromboembolism, and elevated markers of antiphospholipid syndrome (APL). Early recognition and promptly treatment can improve the outcome. We present a case of juvenile systemic lupus erythematosus (SLE), who presented with CAPS, refractory to conventional treatment, but rescue with Eculizumab

Case Description: The patient is a 10yo female, previously diagnosis with systemic lupus erythematosus (SLE) without renal involvement and treated with hydroxychloroquine and low dose steroid, who presented with acute kidney injury and hypertensive crisis. On exam, her weight was 31.3 Kg, height 133 cm. Her BP was 185/127 mmHg and pulse 118/min. Initial investigation showed hemoglobin of 7.2 g/dL, platelet count of 182/uL, BUN 99 mg/dL, Cr 7.86 mg/dL, haptoglobin < 10 mg/dL. Urine protein to creatinine ratio was 5 mg/mg. Serum complements were low and had positive serology for Anti-DSDNA, Lupus anticoagulant, Anti-beta2 glycoprotein, and anticardiolipin. The presumptive diagnosis was CAPS associated with SLE and thrombotic microangiopathy (TMA) which was confirmed by kindney biopsy. She underwent Methylprednisone, therapeutic plasma exchange (TPE), renal replacement therapy amd Nicardipine infusion. After 7 sessions of TPE, Methylprednisone, Rituximab, and Mycophenolate Mofetil, her renal function improved and was taken off hemodialysis. Blood pressure was still uncontrolled. She had evidence of on-going hemolysis with undetectable haptoglobin and elevated LDH. Repeat TPE did not control her BP or hemolysis, thus Eculizumab was administered as

a rescue therapy for TMA associated with CAPS. After 2 weekly doses Eculizumab, her renal function, blood pressure and hemolytic markers were much improved. Currently, her serum creatinine was 1 mg/dL, without significant proteinuria. She remained on 3 antihypertensive medications with good BP control

Discussion: This is a rare but challenging case of juvenile SLE, complicated with CAPS and TMA, who responded partially to conventional treatment. Eculizumab served as a rescue therapy with good result. Our case supports the use of Eculizumab for refractory CAPS in SLE.

PO2315

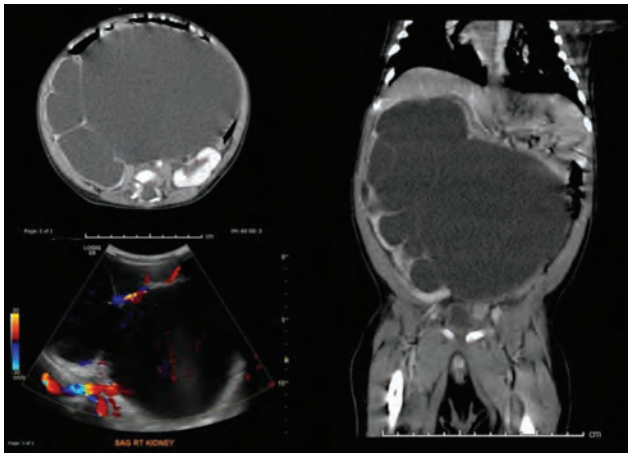
Hypertensive Crisis in an Infant: The Mass Effect

Jonathan S. Chawla,[1] David Manning,[2] Isa Ashoor.[1,2] *[1]Louisiana State University Health Sciences Center, New Orleans, LA; [2]Children's Hospital New Orleans, New Orleans, LA.*

Introduction: It is unusual for congenital hydronephrosis to present with a hypertensive crisis. Recognition of this etiology and prompt urologic intervention to relieve the acute mass effect is critical to prevent further morbidity and mortality.

Case Description: A 3 month-old male with known, mild, right-sided hydronephrosis secondary to ureteropelvic junction obstruction (UPJO) presented to the ED with one week of poor feeding, emesis, and abdominal distension. His recent urine output had been normal. Right upper extremity blood pressure (BP) was recorded as 140/79 mmHg in the ED. Labs were unremarkable with a normal urinalysis and serum creatinine of 0.3 mg/dL. Abdominal ultrasound revealed massive pelvocaliectasis of the right kidney with the kidney parenchyma stretched and thinned over the massively dilated central collecting system. Findings were confirmed on abdominal CT which also revealed profound mass effect on abdominal organs and vessels, specifically compressing and displacing the aorta and inferior vena cava. He was admitted to the pediatric ICU for BP management, which was controlled with IV hydralazine. Pediatric urology placed a percutaneous nephrostomy tube and drained over one liter of urine from the right collecting system. At discharge, the patient was normotensive off medications. A right pyeloplasty was completed shortly following discharge.

Discussion: UPJO is the most common cause of antenatally detected hydronephrosis. The renal pelvis of infants exhibits increased compliance and can accommodate large urine volumes. Kidney function may be preserved or could undergo deterioration depending on UPJO severity. If missed prenatally, infants with UPJO may present with a palpable abdominal mass, urinary tract infection, hematuria, or failure to thrive. Kidney failure and hypertensive crises are rare presentations but are indications for prompt surgical intervention to prevent permanent damage and reduce blood pressure. Infants with preserved function can be monitored conservatively with serial imaging.



PO2316

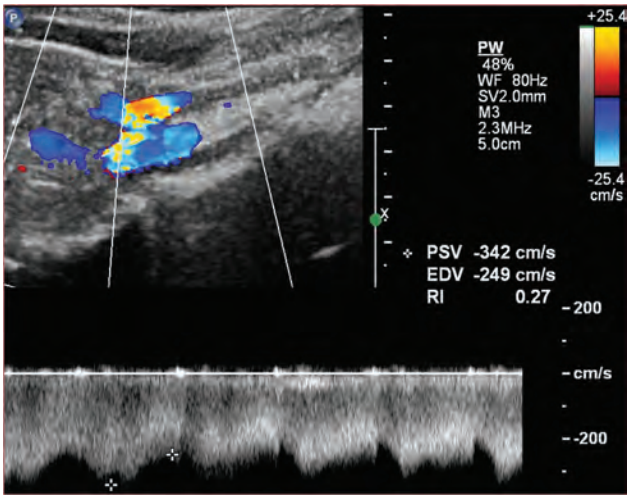
Missed Diagnosis: A Case of Asymptomatic Isolated Orthostatic Proteinuria from Nutcracker Phenomenon

Anna R. Gaddy, Ranjani N. Moorthi. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: In children, proteinuria which exceeds 100 mg/m2 per day or 150 mg per day is considered abnormal. Isolated proteinuria is relatively common, but persistent proteinuria is abnormal and should be investigated. Persistent proteinuria can be further divided into orthostatic subtype if the recumbent Pr/Cr is <0.2mg/mg but this rises to abnormal (>0.2mg/mg) after standing. One cause of orthostatic proteinuria is entrapment of the left renal vein, which is known as the Nutcracker Syndrome. Orthostatic proteinuria, isolated hematuria and pelvic congestion pain are the most common manifestations, however Nutcracker Syndrome is highly heterogeneous and frequently missed.

Case Description: We present an 18 year-old female with intermittent proteinuria, hematuria and occasional flank pain for nine years. The patient had proteinuria on dipstick at age eight. At age 15, she again was noted to have proteinuria on serial urinalyses with up to 500mg/dL protein. ANA, anti-dsDNA, C3, and C4 were normal. Renal ultrasound was performed with unremarkable kidneys and urinary bladder. For several years, proteinuria was mild and intermittently negative and no further workup was done. Split urine collection demonstrated minimal protein on first morning void but over 1g/g Pr/Cr by afternoon. We ordered renal ultrasound with Doppler, which demonstrated Doppler ultrasonography showed the left renal vein had significantly increased flow velocity and appeared to be compressed between the AO and SMA.

Discussion: Differential for etiology of orthostatic proteinuria should include Nutcracker Syndrome as this diagnosis requires a high degree of suspicion. Nutcracker Syndrome can involve proteinuria as well as hematuria but also pelvic pain, back pain, and pelvic congestion symptoms.



Elevated flow velocity in the LRV of 342 cm/s

PO2317

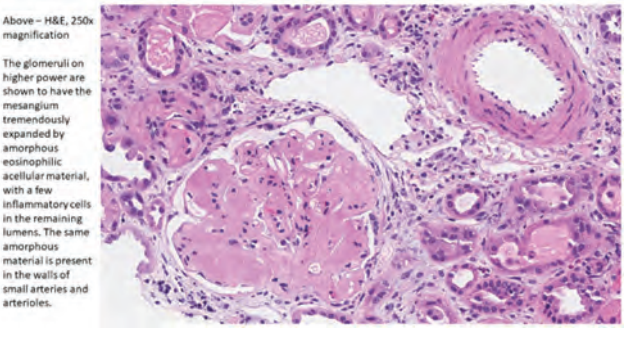
Rare Presentation of Nephrotic Syndrome in 10-Year-Old Male

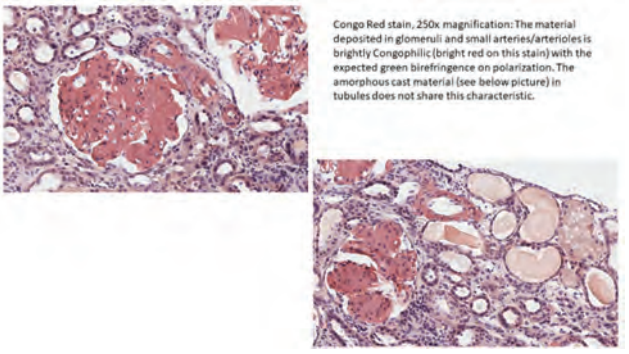
Ellen Cody, Katherine A. Vandenheuvel, Mark Mitsnefes. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Introduction: Review nephrotic syndrome 2/2 amyloidosis due to genetic mutation

Case Description: 10 year male w/ mild proteinuria, progressed to UPC of 4mg/mg over months, Cr 0.4, alb 2.5. Got strep, treated w/ amoxicillin & motrin, after 3 days developed periorbital edema, poor PO, fatigue, admitted. Labs Cr 4.1, alb 1.1, UPC 31 mg/mg, no blood. RUS b/l enlarged, echogenic kidneys. Biopsy w/ glomeruli expanded by amorphous, acellular proteinacous material in mesangium, walls of arteries and arterioles (Image 1), congophilic on Congo red stain (Image 2), apple green on light birefringence, & tubular injury, final read: amyloidosis and AIN. Completed 3 days of IV steroids for AIN, started colchicine for amyloidosis. Genetics w/ pathogenic Cys59Arg variant of TNFRSf1A, c/w TNF Receptor-Associated Periodic Syndrome (TRAPS). Started canakinumab, human monoclonal anti-IL-1 Ab. After 3 months, Cr baseline, no edema, still nephrotic range proteinuria, low alb. MOC w/ ESRD as teen, required dialysis, transplant. Later both kidney and liver failure, died at 31. Diagnosed w/ Familial Mediterranean Fever, as was MGF.

Discussion: Autoinflammatory disease usually presents as intermittent fever, abdominal & joint pain. Second most common is renal involvement, which starts w/ proteinuria, progresses to nephrotic syndrome, renal dysfunction. Diagnosis of amyloidosis based on amyloid fibrils in biopsy of involved tissue, stain positive w/ congo red, apple green birefringence to polarized light. No clear relationship between extent of amyloid deposition & severity of clinical manifestations of renal disease. TRAPS treated w/ directed therapy (IL-1 inhibitor), but difficult to track response to therapy as serum amyloid A not available. Use inflammatory markers (i.e. CRP) given autoinflammatory syndrome.





PO2318

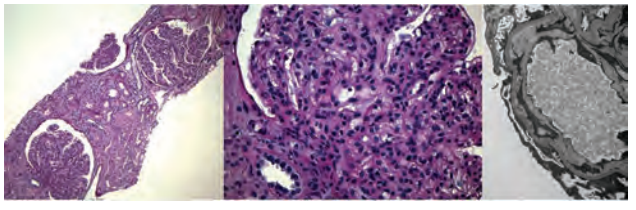
Cyanotic Nephropathy (CN) in Pre-Fontan Congenital Cyanotic Heart Disease (CCHD) with Solitary Kidney

Kimmy T. Vuong,[1,2] Katayoon Shayan,[1] Caitlin E. Carter.[1,2] *[1]Rady Children's Hospital San Diego, San Diego, CA; [2]University of California San Diego, La Jolla, CA.*

Introduction: CN is a glomerulopathy seen in patients with CCHD. Chronic hypoxia leads to proteinuria and reduced GFR through tubular and glomerular injury.

Case Description: 10 yo male with single kidney and pre-Fontan CCHD presented with hematuria and proteinuria on cardiac transplant evaluation. He had 6 months of symptomatic hypoxia requiring increased supplemental O2, but no other recent illness. Exam was notable for 3/6 pansystolic murmur, tachypnea with clear lung fields, hepatosplenomegaly, cyanotic nailbeds with marked clubbing, but no peripheral edema. 24 hour urine protein measured 4.1g (normal < 0.2g), 38% was albumin. Serum albumin was 3.5 g/L (normal) and eGFR by Cystatin C was 72 ml/min/1.73m^2. Hemoglobin was elevated at 20.1 (normal 12.5-16.1 g/dL). C3, C4, ANA, dsDNA, ANCA were normal. Ultrasound showed solitary left kidney with nephromegaly (12.5cm, 100th%ile) and dampened diastolic flow. MRI abdomen showed dilatation of the left renal vein and IVC. Renal biopsy showed marked glomerular enlargement, segmental mesangiolysis with erythrocytolysis, and irregular thickening of glomerular capillaries. EM showed widespread subendothelial widening and remodeling of basement membranes without immune deposits, consistent with CN (Figure 1).

Discussion: CN risk factors include duration of hypoxia, elevated hematocrit >40%, and thrombocytopenia. All were present in our patient. Solitary kidney and elevated venous pressure may have contributed. After heart transplantation, renal function improved with most recent eGFR by Cystatin C 121 ml/min/1.73m^2. Treatment and prevention of CN depend on correction of cyanosis. CN has become less common as most children with CCHD undergo Fontan in early childhood. There are limited data about medical management but proposed treatments include renin angiotensin system blockade, beta blocking drugs, diuretics, ivabradine, digoxin, and hydralazine/isosorbde dinitrate. Therapeutic phlebotomy has been reported. To our knowledge this is the first report of CN in a patient with solitary kidney. Low renal mass and baseline glomerular hyperfiltration may increase the risk of CN progression in this subset of patients.



PO2319

Lupus Vasculopathy Successfully Treated with Eculizumab and Rituximab in an 8-Year-Old Male

Elizabeth A. Black, Erica Winnicki. *University of California San Francisco, San Francisco, CA.*

Introduction: Lupus vasculopathy of the kidney is a rare form of vascular disease in patients with systemic lupus erythematosus characterized by non-inflammatory, necrotizing vessel wall changes. The pathogenesis may be related to immune-mediated vascular injury from accumulation of immunoglobulins and complement in the vascular wall. Lupus vasculopathy carries a poor renal prognosis, and no standardized treatment has been established.

Case Description: An 8-year-old previously healthy male presented to the emergency department with fever, fatigue, headache, diarrhea, nosebleeds, decreased urine output and lower extremity swelling. He was found to have hypertension, fluid overload, active urine sediment and severe acute kidney injury necessitating renal replacement therapy. He had thrombocytopenia and hemolytic anemia without presence of antiphospholipid antibodies or abnormal ADAMTS13 activity. He met criteria for systemic lupus erythematosus including hypocomplementemia, positive ANA and dsDNA antibodies. Renal biopsy showed class III lupus nephritis and multifocal arterial and arteriolar large intimal immune complex deposits with endothelial cell necrosis, consistent with a diagnosis of lupus vasculopathy. He received 6 sessions of plasmapheresis without improvement. Based on renal biopsy, he was treated with cyclophosphamide per Euro Lupus protocol. Eculizumab was started for treatment of lupus vasculopathy. His anemia, thrombocytopenia, and proteinuria improved after initiation of eculizumab, but he remained dialysis dependent. Eculizumab was discontinued after 6 weeks of therapy, but he again developed thrombocytopenia, hemolytic anemia, worsening proteinuria and hypertension. These improved after restarting eculizumab. Due to ongoing evidence of lupus activity, rituximab was given after completion of cyclophosphamide. Hemodialysis was discontinued one month after his first rituximab dose with B-cell depletion. He remains on eculizumab therapy and has stable chronic kidney disease stage 2 despite B-cell repopulation.

Discussion: Prior case reports have documented effective treatment of lupus vasculopathy with rituximab. To our knowledge, no data exists on eculizumab for treatment of lupus vasculopathy. Given our patient's clinical improvement with these therapies, we conclude that more research is needed to define their role in treatment of patients with lupus vasculopathy.

PO2320

Nephrotic Syndrome Relapse due to Bee Sting in Steroid-Resistant Nephrotic Syndrome

Russell S. Whelan,[1,2] Roberto Gordillo.[1] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington, Seattle, WA.*

Introduction: Initial and relapsing presentations of nephrotic syndrome are known to be commonly precipitated by acute illness such as upper respiratory infections and urinary tract infections. Rarely, bee stings can cause development of nephrotic syndrome, with reports of relapses secondary to insect stings being even more sparsely reported. Here we report a patient with steroid-resistant nephrotic syndrome who developed a nephrotic flare after being stung by a bee, and the clinical course to achieve remission.

Case Description: A 14 month old unvaccinated male presented with rapid weight gain, swelling and proteinuria, and was diagnosed with nephrotic syndrome, with renal biopsy consistent with minimal change syndrome. An initial 60mg/m^2 course of prednisolone failed to achieve remission. Mycophenolate mofetil (MMF) treatment was then initiated, which resulted in rapid remission. Two months after initial remission, patient sustained several bee stings, with initially minimal localized swelling. Several days later he was noted to have edema, proteinuria and weight gain, and was diagnosed with a relapse of his nephrotic syndrome. Spontaneous remission did not occur after 2 weeks of expectant management, and a subsequent increase in dosing of MMF also provided no clinical benefit. The patient ultimately achieved remission with a brief course of glucocorticoids, which was successfully tapered without incident. Patient has since been stably maintained on his prior effective dose of MMF, and has had no relapses since.

Discussion: To our knowledge, this is the first report of bee stings resulting in nephrotic relapse in a patient with steroid-resistant nephrotic syndrome treated with MMF. Notably, administration of glucocorticoids provided rapid resolution of this relapse, despite a prior lack of steroid efficacy in this patient. This case report highlights bee stings as a trigger for nephrotic syndrome relapses in patients. While not a common trigger, the prevalent exposure to bee and insect stings, in both the general and pediatric populations, argues for clinical awareness of this etiology for nephrotic syndrome presentation and relapse. This report also provides clinical insight into the management of nephrotic syndrome relapses caused by bee stings, and suggests the possibility that glucocorticoid use may be generally effective, irrespective of underlying nephrotic syndrome classifcation.

PO2321

Managing Pediatric Renal Cell Carcinoma in Jehovah's Witness Patient

Yifeng Zhang, Joanna Luty. *Baystate Medical Center, Springfield, MA.*

Introduction: Pediatric Renal Cell Carcinoma (pRCC) is rare in children and adolescents and only account for about 5% of all pediatric renal neoplasms. The driver mutation of the majority of these tumors is due to cytogenetic translations involving the MiT family of transcription factors. Surgical resection of the mass is the main treatment and depending on the advancement of the cancer, can result in a complete nephrectomy. Due to complexity of surgery and the risk of blood loss, treatment can be complicated by a patient's religion that decline blood product transfusions, such as Jehovah's Witness. This case describes an already rare cancer requiring a unique medical management due to a family's religious belief.

Case Description: A previously healthy 14-year-old male presented complaining of left flank pain. Patient was afebrile, tachycardic to the 120s, and initially hypertensisve to 133/81 that self resolved. Due to persistent pain with unknown etiology imaging was obtained and MRI showed 8 cm solid mass in the left kidney with a dilated and thrombosed left renal vein. The mass could not be differentiated between Wilms Tumor or pRCC, thus a complete nephrectomy was decided to be the best course of treatment. Due to family's religious background of Jehovah's Witness a multi-disciplinary approach was considered to reduce the need for blood transfusions. Patient received daily erythropoietin injections and iron supplementation about three weeks prior to nephrectomy to stimulate production of red blood cells and was continued post-operatively. Additionally, on the day of his procedure, interventional radiology (IR) first embolized the left renal artery leading to tumor followed immediately by a left radical nephrectomy. Patient tolerated the procedure well with minimal blood loss and only had mild anemia. He required no post-surgical transfusion. There was mild increase in creatinine levels with acute kidney injury status-post nephrectomy that has since improved. Pathology report came back and confirmed clear cell renal cell carcinoma. Cytogenetic screen showed a translocation of

the transcription factor E3 (TFE3) gene. Patient did well post-operatively with no signs of cancer on recent imaging and did not require any chemotherapeutics.

Discussion: This case adds to the field of pediatric renal cell carcinoma and highlights a treatment approach that incoroporates religious backgrounds into medical management.

IgG4-Related Disease: Nephropathy and Bone Marrow Failure in a 2-Year-Old Child

Edoardo La Porta,[1,2] Isabella Pisani,[3] Maura Faraci,[1] Francesco P. Pilato,[3] Luca Lanino,[4] Daniela Verzola,[4] Giacomo Garibotto,[4] Angela R. Sementa,[1] Letizia Gnetti,[3] Enrico E. Verrina.[1] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Istituto Clinico Ligure di Alta Specialita, Rapallo, Italy; [3]Ospedale Universitario, Parma, Italy; [4]Ospedale Policlinico San Martino, Genova, Italy*.

Introduction: IgG4 related disease (IgG4 RD) is a systemic immune-mediated disorder that can potentially affect every organ. It is characterized by fibro-inflammatory tissue damage, IgG4 positive plasma cells, and often by elevated serum IgG4. Renal involvement can include tubulointerstitial nephritis (TIN), membranous glomerulopathy (MGP), and retroperitoneal fibrosis. The disease is more frequent over 50 years of age and only a few cases of IgG4 RD are reported in children.

Case Description: A 2-year-old child was diagnosed with a trilinear bone marrow failure. Bone marrow biopsy showed poor and dyshomogeneus cellularity and lymphoplasmacytic infiltrate organized in follicular structures. Hematologic DNA analyses were negative. IgG subclass analysis showed elevated serum levels of IgG4 subclass (353 mg/dL). Kidney failure was also found (creatinine 1.3 mg/dL, microhematuria, proteinuria, and granular casts). A renal biopsy was performed. Light microscopy showed tubulointerstitial inflammatory infiltrate, thickening of the glomerular basement membranes, and subepithelial deposits C4d. IF showed subepithelial glomerular IgG deposits with granular pattern and tubular wall deposits; C3 glomerular deposits and focal tubular deposits. A diagnosis of MGP associated with TIN was made. IHC staining for IgG4 demonstrated plasma cells with overlapping positivity for IgG and IgG4. After the diagnosis of IgG4 RKD, a therapy with steroids was started, without clinical response. Thereafter the patient underwent to bone marrow transplant.

Discussion: IgG4 RKD in adults with simultaneous TIN and MGP has been reported in a few cases. This is the first documented case of IgG4 RKD with simultaneous TIN and MGP in a pediatric patient. IgG4 RD is an emerging systemic disease and it should be taken into account in the differential diagnosis in systemic autoimmune diseases, also in pediatrics.

Is a Single Static Cut Point Useful to Define Ambulatory Hypertension in Youth? The SHIP AHOY Study

Gilad Hamdani,[1] Michael A. Ferguson,[6] Marc Lande,[2] Kevin E. Meyers,[5] Mark Mitsnefes,[3] Joshua A. Samuels,[7] Joseph T. Flynn,[4] Elaine M. Urbina.[3] The SHIP AHOY Investigators *[1]Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [2]University of Rochester Medical Center, Rochester, NY; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Seattle Children's Hospital, Seattle, WA; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]Boston Children's Hospital, Boston, MA; [7]University of Texas Health Science Center at Houston, Houston, TX*.

Background: Ambulatory blood pressure monitoring (ABPM) is increasingly utilized for the diagnosis of hypertension (HTN). While adult guidelines use absolute blood pressure (BP) cut points to define ambulatory HTN, current pediatric guidelines define ambulatory HTN based on a sex- and height-specific 95th percentile derived from limited pediatric normative data, in which many tall adolescents have a threshold for HTN higher than adult cut-points.

Methods: We compared absolute ABP values with sex- and height-specific ABP percentiles as predictors of left ventricular hypertrophy (LVH) in youth. We measured casual BP, ABPM, anthropometrics, and echo for LV mass index (LVMI) in 357 adolescents (mean age 15.5 ±1.7 years, 63% white, 59% male). ABPM was performed with Ontrak device (Spacelabs Inc., Snoqualmie, WA). ABP index was defined as mean ABP/sex- and height-specific 95th percentile. LVH was defined as LVMI ≥38.6 g/m2.7 (pediatric cut-point). Logistic regression was used to assess different ABP measures as predictors of LVH. Sensitivity and specificity of different ABP cut points as predictors of LVH were calculated.

Results: Seventy participants (19.6%) had LVH. Systolic 24-hour, wake and sleep mean BPs and indexes were all significantly associated with LVH. The C-statistics for absolute 24-hour (AUC 0.642 vs. 0.612, p=0.042) and wake (AUC 0.628 vs. 0.590, p=0.03) SBP predicted LVH better than SBP indexes of the same time periods. Absolute SBP cut points also had better balanced sensitivities and specificities in predicting LVH (24-hour SBP 120: 66% and 61%; wake SBP 125: 63% and 59%; sleep 110: 61% and 61%). There was no significant association between diastolic BP measures and LVH.

Conclusions: A single static cut-point using absolute ambulatory SBP is non-inferior to sex-and height- based SBP percentile in predicting LVH in youth. The cut-points for 24-hour and wake ABPM are lower than those for adults but may be used to define ambulatory HTN in this population.

Funding: Private Foundation Support

Table: AUC, sensitivities, and specificities of different ambulatory SBP measures in predicting LVH

Period	Cut-Point	Sensitivity	Specificity	AUC
24-hour	120 mmHg†	66.2%	60.9%	0.6416*
	125 mmHg‡	44.1%	75.8%	
	95th percentile	23.5%	83.3%	0.6121
Wake	125 mmHg†	62.9%	58.6%	0.6284*
	130 mmHg‡	42.9%	74.7%	
	95th percentile	24.3%	84.6%	0.5902
Sleep	110 mmHg†‡	61.4%	60.6%	0.6234
	95th percentile	24.3%	85.3%	0.5988

*AUC of absolute BP significantly higher (p value <0.05) compared with BP index

PO2324

Proteinuria and Dipping on 24-Hour Ambulatory Blood Pressure Monitoring in Children

Christine Y. Bakhoum,[1,2] Kimmy T. Vuong,[1,2] Caitlin E. Carter,[1,2] Pranav S. Garimella,[2] Joachim H. Ix.[2] *[1]Rady Children's Hospital San Diego, San Diego, CA; [2]University of California San Diego, La Jolla, CA.*

Background: Absence of nocturnal blood pressure dipping is associated with adverse cardiovascular outcomes in adults. Risk factors for non-dipping in adults include obesity and proteinuria. In children, risk factors for non-dipping have not been well established.

Methods: We identified consecutive patients aged 5 to 19 years who underwent 24-hour ambulatory blood pressure monitoring (ABPM) at Rady Children's Hospital from August 2018 to January 2019 and had a spot urine protein to creatinine ratio (PCR) measurement within one year of their ABPM. Dipping was defined as ≥10% reduction in systolic and diastolic blood pressure from day to night. Multivariable logistic and linear regression models evaluated the association of proteinuria with dipping, employing backwards selection models to retain important confounders.

Results: Seventy-seven children had ABPM and urine PCR assessments during the study period, among whom 27 (35.1%) were non-dippers. Non-dippers had a higher left ventricular mass index as compared to dippers (mean difference 6.9 g/m$^{2.7}$, 95% CI 1.6 to 12.2). Doubling of urine PCR was associated with 38% higher odds of non-dipping in the multivariable model (**Table**). Doubling of urine PCR was also associated with a lower diastolic dipping percent by 1.33 (95% CI 0.31 to 2.34), after adjusting for age, body mass index, and estimated glomerular filtration rate.

Conclusions: Proteinuria is significantly associated with non-dipping in children. Pediatric patients with non-dipping should be evaluated with urine PCR, and conversely, those with proteinuria may benefit from a 24-hour ABPM.

Funding: NIDDK Support

Table. Association of Log_2 (PCR) with Non-Dipping.

	Unadjusted OR (95% CI)	Mutually Adjusted[a] OR (95% CI)	Backward Selection[b] OR (95% CI)
Log_2(PCR)	1.28 (0.97 -1.69)	1.37 (0.996 – 1.895)	1.38 (1.013 – 1.884)
p-value	0.086	0.053	0.041
BMI (per kg/m^2)	1.06 (0.99 – 1.14)	1.10 (0.999 – 1.221)	1.09 (1.004 – 1.180)
Age (years)	1.06 (0.92 – 1.22)	0.94 (0.782 – 1.137)	
Female	1.46 (0.55 – 3.86)	0.96 (0.325 – 2.808)	
eGFR (ml/min/1.73 m^2)	0.99 (0.98 – 1.01)	0.99 (0.976 – 1.007)

Association of Environmental Tobacco Exposure with Blood Pressure in US Children

Rebecca Levy,[1] Kaye E. Brathwaite,[1] Harini Sarathy,[2] Kimberly J. Reidy,[1] Frederick J. Kaskel,[1] Michal L. Melamed.[1] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]University of California San Francisco, San Francisco, CA.*

Background: Hypertension is a leading cause of cardiovascular and kidney disease in adults, and there is evidence that pathologic sequelae begin in childhood and young adulthood. Nicotine and other tobacco compounds have a variety of toxic effects, but to date their associations with chronic hypertension is unclear, especially in pediatric populations.

Methods: We examined the association between tobacco exposure and high blood pressure (HBP) in children who participated the National Health And Nutrition Examination Survey (NHANES) during 2008-2016. Children were classified as having tobacco exposure if they had blood cotinine levels >0.05ng/dL or reported living with a smoker or smoking themselves. High blood pressure was classified according to the 2017 AAP Clinical Practice Guidelines. Analysis was conducted by logistic regression with adjustment for baseline demographics, income and other possible confounders. Subgroup and sensitivity analyses were conducted.

Results: There was a positive association of high blood pressure with tobacco exposure in the study population. After adjustment for demographics, the odds of having high blood pressure was 1.39 (95% Confidence Interval (CI) 1.04, 1.87) for any tobacco exposure compared to no smoking exposure. The association was similar across participant subgroups. The association remained significant by sensitivity analysis using cotinine exposure as a continuous variable. Separately, the odds of having high blood pressure for passive smokers was 1.35 (CI 0.983, 1.85) while the odds for active smokers was 1.71 (CI 1.14, 2.54) compared to participants with no tobacco exposure.

Conclusions: Tobacco exposure is associated with high blood pressure in US children and adolescents.

Hypertension and CKD at 7 Years After Surgical Repair of Congenital Heart Disease in Children

Jason H. Greenberg,[1] Michael Zappitelli,[2] Heather Thiessen Philbrook,[3] Yaqi Jia,[3] Prasad Devarajan,[4] Chirag R. Parikh.[3] TRIBE-AKI Consortium *[1]Yale University, New Haven, CT; [2]Hospital for Sick Children, Toronto, ON, Canada; [3]Johns Hopkins University, Baltimore, MD; [4]Cincinnati Children's Hospital Medical Center Division of Child and Adolescent Psychiatry, Cincinnati, OH.*

Background: We previously determined that children who require surgery for congenital heart disease (CHD) are at an increased risk for hypertension and CKD 5 years after cardiac surgery. This study assessed the long-term risk of hypertension and CKD after cardiac surgery and if these outcomes are sustained.

Methods: We prospectively enrolled children from 1 month to 18 years old, undergoing cardiopulmonary bypass at three centers. Children who survived their surgical hospitalization had blood pressure, urine albumin to creatinine ratio, and serum creatinine measured at two in-person follow-up visits (median 5.4 years and 7.4 years after surgery). Hypertension was defined using the American Academy of Pediatrics 2017 Hypertension guidelines. Estimated GFR (eGFR) was calculated using the CKiD equation. CKD was defined as the presence of low eGFR (<90 ml/min/1.73m^2) or microalbuminuria. We compared the risk of hypertension and CKD status at the 5 and 7-year visits using the McNemar test.

Results: Of 131 children with a follow-up visit 5 years after cardiac surgery, 88 (67%) children participated in the 7-year follow-up visit. The median age of the cohort at the 7-year follow-up was 10.7 [IQR: 7.8–13.0] years and 47% were female. 32 children had previously had a septal defect repair, 15 an inflow/outflow tract or valve procedure, 34 had a combined procedure, and 7 were not defined. Hypertension, microalbuminuria, eGFR<90, and eGFR<60 was 15%, 8%, 9%, and 1%, respectively, at the 5-year visit and 17%, 4%, 19%, and 1%, respectively, at the 7-year visit. CKD was present in 16% and 18% of children at the 5-year and 7-year visit, respectively, with no statistically significant change in risk at the two visits (p=0.35). Between the 5-year and 7-year visits, hypertension and CKD were sustained in 8 (62%) and 4 (29%) patients, respectively.

Conclusions: The long-term risk of hypertension and CKD were common at the 7-year visit. Compared to the five-year visit, hypertension was sustained in the majority of children. Although CKD was not sustained, there was an increased incidence of new children with GFR<90 at the 7-year visit. The risk factors for sustained hypertension and kidney disease should be further studied in children with congenital heart disease.

PO2327

Evaluating the Role of the Kidneys in Posterior Reversible Encephalopathy Syndrome in Pediatric Patients

Shruti Shah, Andrew M. South. *Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Kidney disease is a known risk factor for posterior reversible encephalopathy syndrome (PRES), but the specific markers of kidney function that are relevant to PRES are undescribed. The objective was to investigate the associations of various markers of kidney function with PRES.

Methods: In a case-control study of high-risk children, we recorded most-recent blood urea nitrogen (BUN), documentation of acute kidney injury (AKI), serum creatinine, serum albumin, and hemoglobin level and calculated the estimated glomerular filtration rate (eGFR). PRES cases were confirmed clinically and radiologically. We applied multivariable regression models to estimate the associations of the exposures with PRES. We utilized directed acyclic graphs to inform the following model adjustments: 1) history of kidney disease and nephrotoxic medication exposure for the kidney function models; 2) history of kidney disease, eGFR, and albumin treatment for the serum albumin model; and 3) age, sex, history of kidney disease, eGFR, fluid overload, and nephrotoxic medication exposure for the hemoglobin model.

Results: The mean age of the study population was 9.5 years (±4.9) and 51% were female. Of that population, 29% had a history of kidney disease, 67% had exposure to nephrotoxic medications, and 29% had AKI prior to the onset of PRES. BUN [adjusted OR (aOR) 1.03 per 1 mg/dl increase, 95% CI 0.99-1.07, p=0.09] and AKI (aOR 3.78, 0.68-21.13, p=0.13) were modestly associated with PRES. eGFR (aOR 1.0 per 1 ml/min/1.73 m^2 increase, 0.98-1.01, p=0.55), albumin (aOR 1.7 per 1 g/dl increase, 0.73-3.93, p=0.22) and hemoglobin (aOR 1.12 per 1 g/dl increase, 0.81-1.56, p=0.48) were not associated with PRES.

Conclusions: In a case-control study of children at high risk for PRES, we demonstrated that among several markers of kidney function, BUN and AKI were modestly associated with PRES. Further prospective studies with larger sample sizes and higher power are necessary to fully evaluate the role of kidney function in the development of PRES.

PO2328

Effect of Hypertension on Childhood-Onset Systemic Lupus Erythematous in a Tertiary Medical Center in Korea

Jeong yeon Kim, Heeyeon Cho. *Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Hypertension (HTN) is prevalent in childhood-onset systemic lupus erythematous (cSLE) and affected either by disease activity itself, cSLE medication or both. The purpose of this study is to evaluate the prevalence, clinical characteristics and long-term clinical effect of HTN in Korean cSLE patients treated in tertiary medical center in Korea.

Methods: The medical records of cSLE patients, diagnosed by 2019 SLE European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria, who visited Samsung Medical Center from January 2009 to May 2019 were reviewed retrospectively. The disease activity was evaluated by Modified Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and renal activity (renal SLEDAI) was measured by scores from SLDEA-2K. The long-term damage was evaluated by The Pediatric Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (Ped-SDI). The sex-, age- and height-blood pressure standards recommended by AAP 2017 guideline was used to define HTN. Left ventricular hypertrophy (LVH) was defined by sex, age specific left ventricular mass index (LVMI) ≥ 95th percentile.

Results: Total 32 patients were enrolled in this study. The median follow-up duration was 7.3 year and female was predominant. Median age at SLE and HTN diagnosis were 14.2 and 14.3 year, respectively. Initial renal involvement was detected in 12.5%. The biopsy proven LN was detected in 84.4% (n=28) and 37.5% of them were class IV (n=12). The prevalence of HTN, including 2 transient HTN, was 34.4% (n=11) and stage 2 HTN was prevalent (n=9). The median dose of steroids, converted to prednisolone, at diagnosis of SLE and HTN were 1.0mg/kg/day and 0.5mg/kg/day. Among cSLE patients with HTN, 2 patients had 3 episodes of posterior reversible encephalopathy syndrome. LVH was detected in 2 patients with HTN. In the cSLE patients with persistent HTN (n=9), lower eGFR (OR=0.9, p=0.031) and higher BMI (OR 1.4, p=0.047) were shown at the time of SLE diagnosis. Every patient with HTN - including transient HTN - in cSLE (n=11) showed lower eGFR at the time of SLE diagnosis (OR 0.9, p=0.029) and higher Ped-SDI (OR 1.8, p=0.047) at last visit.

Conclusions: In conclusion, HTN in cSLE is associated with BMI and renal function at SLE diagnosis. Also, HTN affect long term damage accumulation in cSLE.

PO2329

Hemodiafiltration Maintains a Sustained Improvement in BP Compared with Conventional Hemodialysis in Children: The HDF, Heart and Height (3H) Study

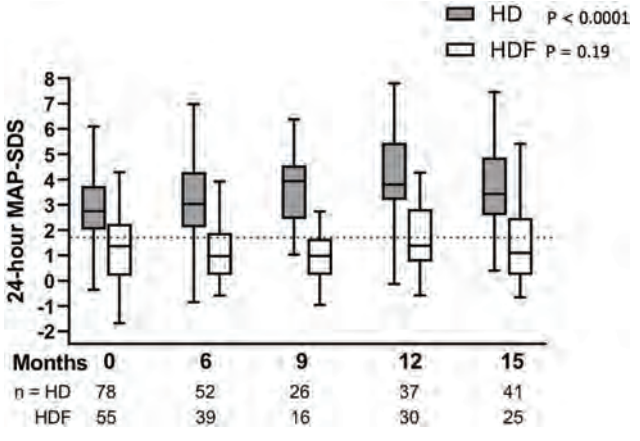
Francesca De Zan,[1] Colette J. Smith,[2] Aysun Bayazit,[3] Karolis Azukaitis,[4] Sevcan A. Bakkaloglu,[5] Fabio Paglialonga,[6] Mohan Shenoy,[7] Manish Sinha,[8] Brankica B. Spasojevic,[9] Claus peter Schmitt,[10] Franz S. Schaefer,[10] Enrico Vidal,[11] Rukshana Shroff.[12] *[1]University Hospital of Padova, Padova, Italy; [2]UCL Institute of Global Health, London, United Kingdom; [3]Cukurova University, Adana, Turkey; [4]Clinic of Pediatrics, Vilnius University, Vilnius, Lithuania; [5]Gazi University Hospital, Ankara, Turkey; [6]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [7]Royal Manchester Children's Hospital, Manchester, United Kingdom; [8]Evelina Children's Hospital, London, United Kingdom; [9]University Children's Hospital, Belgrade, Serbia; [10]Center for Pediatrics and Adolescent Medicine, Heidelberg, Germany; [11]Division of Pediatrics, Department of Medicine, University of Udine, Udine, Italy; [12]Great Ormond Street Hospital for Children NHS Foundation Trust, and University College London Institute of Child Health, London, United Kingdom.*

Background: Hypertension is prevalent in children on dialysis and associated with left ventricular hypertrophy, cardiovascular disease, and mortality. We studied the blood pressure (BP) trends as well as risk factors associated with the evolution of BP over 1-year in children on conventional hemodialysis (HD) vs hemodiafiltration (HDF)

Methods: This is a post-hoc analysis of the "3H - HDF-Hearts-Height" dataset, a multicenter, non-randomized, parallel-arm observational study. Mean arterial pressure (MAP) derived from 24-hour ambulatory BP monitoring was calculated and hypertension defined as 24-hour MAP standard deviation score (SDS) ≥95th percentile

Results: 78 children on HD and 55 on HDF who were followed-up for 1-year and had three ABPM measures were included. MAP-SDS was under-estimated by pre-dialysis systolic BP-SDS (mean difference -0.6; 95% LoA -4.9 to 3.8). At baseline 82% on HD and 44% on HDF were hypertensive, with uncontrolled hypertension (BP>95th centile on medications) in 88% vs 25% respectively; p<0.001. At 12-months children on HDF had lower MAP-SDS compared to those on HD in all age groups (p<0.001). Over the one-year follow-up, the HD group had a mean MAP-SDS increase of +0.98 (95%CI 0.77 to 1.20; p<0.0001), whereas the HDF group had a non-significant increase of +0.15 (95%CI -0.10 to 0.40; p=0.23). Significant and independent predictors of MAP-SDS were dialysis modality (β=0.83 [95%CI 0.51 to 1.15] SDS for HD vs HDF, p<0.0001) and higher IDWG% (β=0.13 [95%CI 0.06 to 0.19] p=0.0003)

Conclusions: Children on HD had a significant and sustained increase in BP over the 1-year study period compared to an attenuated and non-significant increase in HDF. Volume overload with higher IDWG%, but not anti-hypertensive medications, was associated with a higher MAP-SDS in both groups



PO2330

Novel Nephrin Protein/HLA Class II Complexes: A New Mechanism of Steroid-Sensitive Nephrotic Syndrome

Tomoko Horinouchi,[2,1] Yuya Aoto,[2] Shinya Ishiko,[2] Nana Sakakibara,[2] China Nagano,[2] Tomohiko Yamamura,[2] Takeshi Ninchoji,[2] Kandai Nozu,[2] Kazumoto Iijima.[2] *[1]Department of Immunochemistry, Research Institute for Microbial Disease, Osaka University, Suita, Japan; [2]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: We have recently identified the risk allele (HLA-DRB1*08:02) and the protective allele (HLA-DRB1*13:02) in the development of childhood steroid-sensitive nephrotic syndrome (SSNS) in a Japanese population (JASN 2018). HLA-DRB1*07:01-DQA1*02:01-DQB1*02:01 was also identified as a risk haplotype in other populations. In addition, we found that *NPHS1*, coding nephrin, which is a key component of podocytes, was associated with susceptibility to childhood SSNS (Kidney Int 2020). HLA class II genes are associated with susceptibility to many kinds of autoimmune diseases, with one of the mechanisms being misfolded protein/HLA class II complexes that are aberrantly transported to the cell surface inducing immune responses (Jin, Arase *et al.* PNAS 2014). Therefore, we investigated the relationship between each HLA allele and nephrin, based on the hypothesis that nephrin protein/HLA class II complexes might be involved in the development of SSNS.

Methods: Nephrin lacking the transmembrane domain (Neph^{mis}) was used as a model of misfolded protein that is not expressed on the cell surface. We co-transfected Neph^{mis} and HLA-DR to HEK293T cells and assessed the expression patterns by flow cytometry and immunoprecipitation.

Results: Neph^{mis} was detected on the cell surface in the presence of HLA-DR, which was more intense in the risk alleles than in the protective allele (DRB1*07:01>DRB1*08:02>DRB1*13:02). While Neph^{mis} coimmunoprecipitated with HLA-DR, Neph^{mis} was not detected in the absence of HLA-DR. [Discussion] Podocytes are sometimes considered as non-hematopoietic professional antigen presenting cells because they present antigens on the cell surface via HLA class II and stimulate immune signaling. We showed that the risk HLA DR allele tended to present Neph^{mis} stronger than the protective allele, suggesting that an immune response could be more easily induced in the risk alleles than in the protective allele. Although there are a variety of possible mechanisms by which HLA polymorphisms could be associated with SSNS, the binding of specific molecules, such as nephrin or Neph^{mis}, and their presentation may provide new insights into the pathogenesis of SSNS.

Conclusions: Our results suggest that nephrin protein/HLA classII complexes can be involved in the pathogenesis of childhood SSNS.

Efficacy and Safety of Ravulizumab in Pediatric Patients with Atypical Hemolytic Uremic Syndrome Previously Treated with Eculizumab: 26-Week and 1-Year Data

Larry A. Greenbaum,[1] Naoya Fujita,[2] Brigitte V. Adams,[4] Alvaro Madrid Aris,[5] Masayo Ogawa,[3] Stephan Ortiz,[3] Marc Vallee,[3] Kazuki Tanaka.[2] *[1]Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA; [2]Aichi Shoni Hoken Iryo Sogo Center, Obu, Japan; [3]Alexion Pharmaceuticals Inc, Boston, MA; [4]Queen Fabiola Children's University Hospital, Brussels, Belgium; [5]Children's Nephrology and Renal Transplantation Service, Children's Maternity Hospital Sant Joan de Déu, University of Barcelona, Barcelona, Spain.*

Background: The complement C5 inhibitor eculizumab improves outcomes of atypical hemolytic uremic syndrome (aHUS) but must be administered every 2–3 weeks. Ravulizumab, engineered from eculizumab for a longer half–life, is efficacious and safe in adults with 8–week dosing intervals. This analysis was in eculizumab-treated children with aHUS.

Methods: ALXN1210-aHUS-312 (NCT03131219) is a phase 3, single–arm trial in complement inhibitor-naïve children (Cohort 1; reported separately) and children who were receiving treatment with eculizumab without thrombotic microangiopathy (TMA; Cohort 2; reported here). This analysis assessed TMA activity, and the pharmacodynamic measure serum free C5 levels after patients switched from eculizumab to ravulizumab treatment. Patients received loading doses then maintenance treatment with ravulizumab every 4 or 8 weeks, dependent on weight, for 26 weeks. An extension phase is ongoing; here we report data on efficacy through 1 year and safety from all available follow up (median 50.2 weeks).

Results: Ten patients (mean [SD] age 11 [5.0] years) were enrolled into Cohort 2; all completed the 26–week initial evaluation period and entered the extension. Mean eGFR, hematologic outcomes (platelet, lactate dehydrogenase and hemoglobin normalization), and fatigue measures remained stable during both trial periods. At 1-year, the mean (SD) changes from baseline were: eGFR, -3.9 (8.3) mL/min/1.75m^2; platelets, –17.8 (54.6) ×10^9/L; LDH –10.7 (19.2) U/L; hemoglobin +4.5 (7.1) g/L. All patients were in the same eGFR category at 1 year as recorded at baseline (eGFR mL/min/1.73m^2 ≥90, n=8; 60–89, n=1; 49–59, n=1). No patients required dialysis. Despite the increased dosing interval, serum free C5 levels were maintained below the threshold of 0.5 mg/mL. All patients experienced adverse events (AEs) but none discontinued the trial. No meningococcal infections occurred. One patient experienced serious AEs due to a respiratory tract infection.

Conclusions: Continued efficacy, no additional safety concerns and the benefit of reduced dosing frequency was demonstrated in pediatric patients with aHUS who were stable on eculizumab and switched to ravulizumab.

PO2332

Typical Hemolytic Uremic Syndrome in Children: A Single-Center Experience

Siddharth A. Shah. *University of Louisville, Prospect, KY.*

Background: Typical hemolytic-uremic syndrome (HUS) associated with diarrhea can be a fatal disease in children. Diarrhea and blood-stained stools are early symptoms. Oliguria and renal failure can occur anywhere from 3-7 days after onset of diarrhea. Intravenous (iv) fluids in the initial timeline of disease presentation may decrease the need for dialysis. Oligo-anuria at admission and leukocytosis is associated with poor outcomes during hospitalization. After recovery, there is a risk of long-term renal complications such as hypertension, proteinuria, and chronic kidney disease (CKD).

Methods: We performed a retrospective analysis of 43 children admitted with diarrhea associated with HUS at our center in the last ten years. The 'late presentation' defined as serum creatinine>1 mg/dL, oliguria, or anuria at admission. The primary outcome was the presence of long-term renal sequelae. It included proteinuria, hypertension, or chronic kidney disease (CKD) (eGFR <75 ml/min/1.73m2) after one year of disease-onset. The Chi-square and correlation analysis performed on the SPSS platform.

Results: Overall, 32/43 presented late in the disease course, 30/43 required dialysis (median: 8 d), and 8/43 had a recent history of NSAID use. The administration of dextrose and saline containing iv fluids in the early presentation was associated with the decreased requirement of dialysis (p=0.042), but the effect was not significant with NSAID use (p=0.064). Peak white blood cell count (Wbc) had a strong correlation with days of hospitalization (p<0.001). 10/43 children were lost to follow up. 13/33 children showed renal sequelae (includes 3 with CKD and 1 with ESRD who required kidney transplant) after one year of disease onset. Wbc count >20000 cells/mm3 (at p=0.001) and duration of dialysis>14 days (at p=0.002) were associated significantly with the primary outcome. 6/43 children were un-immunized. There was no mortality.

Conclusions: High peak WBC count may be a useful prognostic marker to evaluate the risk of long-term renal complications. These children need monitoring periodically after disease recovery. Early diagnosis and iv fluids before the onset of renal failure may help to prevent dialysis-related morbidity at the time of admission. More awareness is needed to discourage the use of NSAIDs following initial symptoms of HUS.

PO2333

Targeting Bloody Diarrhea to Fight Shiga Toxin-Producing *Escherichia coli*-Hemolytic Uremic Syndrome in Children: The Experience of the ItalKid HUS Network

Gianluigi Ardissino,[1] Rosaria Colombo,[2] Laura Daprai,[2] Valentina Capone,[1] Antonella Dodaro,[2] Sara Testa,[1] Fabio Paglialonga,[1] Chiara Vignati,[2] Carla Masia,[2] Francesca Tel,[3] Ilaria Possenti,[1] Giovanni Montini.[1] *[1]Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; [2]Microbiology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; [3]Pediatric Department, Vittore Buzzi Children's Hospital, Univeristà degli Studi di Milano, Milano, Italy*.

Background: Bloody diarrhea (BD) is often the first distinctive sign of hemolytic uremic syndrome (eHUS), the leading cause of acute kidney injury in infants, caused by shiga toxin (Stx)-producing *Escherichia Coli* (STEC) infection. The few days prior the development of the renal complication, when bloody diarrhea is the only symptom, represent a window for better understanding, preventing or mitigating HUS. The present study aims at identifying patients at risk for HUS early and at evaluating the rate of BDs associated with STEC infection.

Methods: This multicenter case series study was performed between 2010 and 2019 in Pediatric emergency departments and clinics belonging to a network of 63 pediatric hospitals in Northern Italy (referral population: 12 million general population; 2.3 million children). 4767 children (<20 yo) presenting with BD were enrolled. Stool samples were centrally screened for the presence of *Stx* genes (1 and 2) using a Reverse Dot blot assays (Genotype EHEC - Arnika) until 2018 and Real Time PCR (RIDA Gene-Relab) thereafter. *Stx*-positive cases were further investigated for *E.coli* serogroups. Children positive for *Stx* genes were monitored for hemoglobinuria, blood tests to rule in or out the diagnosis of STEC-HUS were done if urine dipstick turned positive for hemoglobinuria.

Results: Out of the 4767 screened samples, 214 (4.5%) turned out to be positive for either Stx1 (n: 62; 29.0%) or Stx2 (n: 97; 45.3%) or both (n: 55; 25.7%). 34 patients out of the 214 positive for Stx (15.9%) developed eHUS (0.71% of BDs). Patients infected with STEC producing Stx2 alone were at higher risk for eHUS compared with Stx1+2 (23.7 vs. 12.7%) while Stx1 alone was only exceptionally associated with eHUS (1.1%). The most frequent serogroup found in patients with Stx+BD was the O157 while in patients with eHUS the O26 was the most (36.5% of cases), followed by O157 (20%).

Conclusions: STEC is all but a rare cause of BD in children thus the screening for Stx of BD is recommended. We also suggest to monitor patients carrying Stx2 closely with urine dipstick for hemoglobinuria every 12 hours for the early detection of eHUS together with providing them with generous fluid infusion.

PO2334

Hemoglobinuria for the Early Identification of STEC-HUS in High-Risk Children

Valentina Capone, Gianluigi Ardissino, Maria Cristina Mancuso, Giovanni Montini. *Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy*.

Background: Shigatoxin-producing *Escherichia coli* – associated hemolytic uremic syndrome (STEC-HUS) represents one of the main causes of acute kidney injury in children and can be associated with several extrarenal complications. Its management is entirely based on supportive care, which includes generous fluid infusions, since dehydrated patients have been described to have a worse outcome, compared to normo- and overhydrated patients. The present study aims at validating urine dipstick/urinalysis for hemoglobinuria as a early test to screen patients at high risk for the development of STEC-HUS (children with bloody diarrhea secondary to Shigatoxin – Stx - 2 or 1+2) for the early diagnosis of the disease.

Methods: Since 2010, a network 63 pediatric units (the ItalKid-HUS Network) has been developed in Northern Italy, with the aim of the early identification and management of STEC infections and STEC-HUS. Once a patient with bloody diarrhea (BD) is identified as Stx positive, he/she is rehydrated as appropriate and followed up with urine dipstick/urinalysis for hemoglobinuria until HUS develops or diarrhea resolves. We here reviewed all the urine dipstick/urinalysis results from pediatric patients with Stx positivity either with BD only (Group 1) or with ongoing HUS (Group 2) from 2010 to 2019.

Results: A total of 100 children were eligible for the study. In Group 1, 22/63 patients had or developed hemoglobinuria while the remaining 41/63 were and remained negative. In 15/22 positive cases, blood tests ruled in a ongoing HUS, while in the remaining 7 the diagnosis was excluded. Among the 41 negative patients no one developed HUS. As expected, the 37 children in Group 2 (already ongoing HUS) all had hemoglobinuria at admission.

Conclusions: Hemoglobinuria shows a sensitivity of 100% (95% CI 93-100%) and a specificity of 85% (95% CI 74-93%), with positive predictive value of 68% and negative predictive value of 100% in diagnosing ongoing HUS. Thus, urine dipstick or urinalysis for the detection of hemoglobinuria can be proposed as an easy, fast, inexpensive and repeatable test to screen patients at high risk for the development of STEC-HUS and to start supportive treatment as soon as possible.

PO2335

Hemoglobinuria for the Early Identification of Atypical Hemolytic Uremic Syndrome Relapse: Data from the ItalKId-HUS Network

Gianluigi Ardissino, Marta Brambilla, Fabio Paglialonga, Sara Testa, Valentina Capone, Antonio Vergori, Donata C. Cresseri, Giovanni Montini. *Ospedale Maggiore Policlinico, Milano, Italy*.

Background: Atypical hemolytic uremic syndrome (aHUS) is at risk of relapse any time, thus patients require lifelong monitoring. We suggested that patients could be monitored for relapses, with hemoglobinuria (twice weekly and during intercurrent diseases) based on the hypotesis that a thrombotic microangiopathy involving the glomerulus, cannot take place without hematuria. However this assumption has not been validated.

Methods: The aim of the study is to analyze our experience with the mentioned approach in patients with aHUS who have never been treated (group 1), on treatment (group 2) and who have discontinued C5 inhibition (group 3). The records of all aHUS patients managed or referred to our Center from January 2009 to March 2020 were included and the analysis for the presence of hemoglobinuria was restricted to the period following primary remission with the aim of validating this biomarker as a reliable one for the early identification of relapses. Patients with persistent hemoglobinuria, although in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥1+. Patients reporting positive urine dipstick were addressed to laboratory investigations to rule in or out, the diagnosis of aHUS relapse.

Results: 84 patients with aHUS (50% females) were included with 1517 determinations of hemoglobinuria during a cumulative observation period of 261 patient-year (Figure). Hemoglobinuria for the early diagnosis of ongoing aHUS relapse shows a sensitivity of 100% and a specificity of 87.4% with a PPV of 10.5% and NPV of 100 %.

Conclusions: Hemoglobinuria is a very sensitive and acceptably specific marker of aHUS relapse. This finding and its validation may have an important positive impact both on patient's quality of life and on the outcome of disease via an early diagnosis of relapses.

Extensive Complement Analysis in a C3 Glomerulopathy Cohort of Dutch Children with Benign Outcome

Kioa L. Wijnsma,[1] Marloes Michels,[1] Roel Kurvers,[7] Joanna Van Wijk,[2] Antonia Bouts,[2] Valentina Gracchi,[3] Flore Horuz-Engels,[7] Mandy G. Keijzer-Veen,[6] Eiske Dorresteijn,[4] Elena Volokhina,[1] Lambertus P. Van den heuvel,[1,5] Nicole Van De Kar.[1] on behalf of the COMBAT consortium *[1]Amalia Children's Hospital, Radboudumc, Nijmegen, Netherlands; [2]Emma Children's Hospital, Amsterdam University Medical Center, Amsterdam, Netherlands; [3]Beatrix Children's Hospital, University of Groningen, Groningen, Netherlands; [4]Sophia Children's Hospital, Erasmus Medical Center, Rotterdam, Netherlands; [5]University Hospitals Leuven, Leuven, Belgium; [6]Wilhelmina Children's Hospital, University Medical Center Utrecht, Utrecht, Netherlands; [7]Maastricht University Medical Center, Maastricht, Netherlands.*

Background: C3 glomerulopathy (C3G) is a rare renal disorder driven by dysregulation of the complement alternative pathway (AP) and characterized by predominant C3 depositions in the glomerulus. C3G can be subdivided in dense deposit disease (DDD) and C3 glomerulonephritis (C3GN). Patient cohort studies including clinical features offer important data in rare renal diseases. Moreover, biomarkers are increasingly used to select patients for clinical trials with novel complement-targeted therapies. This retrospective study describes complement biomarker profiles and outcome of 29 Dutch children.

Methods: Patients with a C3G diagnosis from 5 Dutch university medical centers (1992- 2014) were included. Clinical, genetic, and laboratory findings were retrieved from patient files. Specialized biochemical assays were used to detect complement-directed autoantibodies and complement biomarkers.

Results: A total of 29 patients with DDD (n=19) and C3GN (n=10) were included. Median (IQR) follow-up was 51 months (26-90). Patients presented with proteinuria and hematuria (>90%) and low serum C3 levels (84%). Ten patients (35%; 8 DDD, 3 C3GN) presented with an impaired glomerulation filtration rate (GFR). DDD patients presented at younger age and with a lower GFR (P<0.05). C3 nephritic factors were found in 19 patients, and 3 patients carried rare genetic variants in AP genes. Elevated levels of the complement activation markers C3d, C3bBbP, and C5b-9, combined with lowered C3 and C5 levels, indicated AP activation in the acute phase. Taking longitudinal data into account, a linear mixed model showed that C3GN patients had higher C5b-9 and lower properdin levels than DDD patients (P<0.05). During follow-up, 13 (45%) patients experienced a relapse. No significant differences in clinical or laboratory features were observed between patients with and without a relapse and persistent renal sequelae. At last follow-up, only 4 patients (14%; all DDD) had a GFR below 60 ml/min/1.73m^2.

Conclusions: We present the extensive description of clinical, genetic, and biochemical complement features of a large pediatric C3G cohort. In most patients AP abnormalities were found. Overall, the outcome of the patients we described was relatively benign.

PO2337

Comparison of Clinicopathological Findings Between Childhood IgA Nephropathy and IgA Vasculitis Nephritis Using Oxford Classification

Yuko Shima,[1] Koichi Nakanishi,[2] Hironobu Mukaiyama,[1] Yu Tanaka,[1] Takuzo Wada,[1] Kandai Nozu,[3] Ryojiro Tanaka,[5] Kazumoto Iijima,[3] Norishige Yoshikawa.[4] *[1]Pediatrics, Wakayama Medical University, Wakayama, Japan; [2]Pediatrics, Graduate School of Medicine, University of the Ryukyus, Okinawa, Japan; [3]Pediatrics, Graduate School of Medicine, Kobe University, Kobe, Japan; [4]Clinical Research Center, Takatsuki General Hospital, Kobe, Japan; [5]Pediatric Nephrology, Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan.*

Background: IgA nephropathy (IgAN) and IgA vasculitis nephritis (IgAVN) are nephritis with a common pathological feature of significant mesangial IgA deposition, but it remains controversial whether they are the same disease.

Methods: We compared clinical and pathological findings between 148 patients with IgAN and 100 patients with IgAVN who underwent renal biopsy from April 2000 to April 2019 to clarify the differences.

Results: Clinical findings showed significant differences in onset age (IgAVN vs IgAN, 7.4 vs 10.7 years, p<0.0001), episode of gross hematuria (8.0 vs 24.3%, p=0.0007), duration from onset to renal biopsy (1.7 vs 6.6 months, p<0.0001), and amount of proteinuria (1.8 vs 0.5 g/gCr, p<0.0001). Pathological findings by Oxford classification showed significant differences in the frequency of M1 (94.0 vs 59.2%, p<0.0001), S1 (21.0 vs 42.2%, p=0.0004), T present (28.0 vs 46.1%, p=0.004), C present (72.0 vs 58.1%, p=0.03) and G present (8.0 vs 19.1%, p=0.01), but no difference in that of E1 (52.8 vs 55.0%, p=0.75). Fluorescence findings showed significant difference in the frequency of fibrinogen deposition (93.3 vs 74.6%, p=0.0004) but not in that of glomerular peripheral capillary IgA deposition (9.5 vs 3.5%, p=0.10). Electron microscopic findings showed significant difference in the frequency of GBM lysis (35.2 vs 12.0%, p=0.0001). Degree of proteinuria is positively correlated with the frequency of M1 in IgAVN.

Conclusions: IgAVN has higher frequency of M1 lesion regardless of degree of proteinuria, lower frequency of chronic lesions such as S, T, and G, and higher frequency of acute lesions such as M and C compared with IgAN. Although IgAVN had some pathological similarities to that of IgAN, there seems to be differences which cannot be explained by the timing of renal biopsy.

PO2338

Race and Age at Onset of ESRD in Patients with Alport Syndrome

Sarah J. Kizilbash, Blanche M. Chavers, Clifford E. Kashtan. *University of Minnesota Academic Health Center, Minneapolis, MN.*

Background: Angiotensin-converting enzyme (ACE) inhibitors have been shown to delay the onset of end-stage renal disease (ESRD) in both animal models and humans with Alport syndrome. In 2013, expert guidelines recommended the use of ACE inhibitors to delay the onset of ESRD. We examined temporal changes in the age at onset of end-stage renal disease (ESRD) and interaction between race and age at ESRD for patients with Alport syndrome.

Methods: We used the Scientific Registry of Transplant Recipients to identify all patients who received a kidney transplant in the United States for Alport syndrome between 1987 and 2017. We divided the study period into three equal eras (era 1, 1987-1997; era 2, 1998-2007; and era 3, 2008-2017) to assess changes in age at ESRD using a linear regression model adjusting for race and gender. Age at ESRD was defined as the earlier of the age at dialysis or the age at kidney transplant.

Results: Between 1987 and 2017, 4105 Alport patients received a kidney transplant in the United States. Of these patients 3,115 (75.9%) were male and 3176 (77.4%) were white. Pre-emptive transplants were performed in 962 (23.4%) patients. Table 1 demonstrates temporal changes in *median* age at ESRD, demographic and clinical characteristics for patients with Alport syndrome. After adjusting for race and gender, the age at ESRD increased by a mean of 2.7 years (SE 0.51, p <0.01) for era 2 and 4.4 years (SE 0.51, p <0.01) for era 3 compared with era 1. We also observed that age at ESRD was significantly lower for black (-9.3 years, p < 0.01), Hispanic (-9.4 years, p < 0.01), and other races (-6.9 years, p < 0.01) compared with the white race (Table 2).

Conclusions: The age at ESRD for patients with Alport syndrome has progressively increased over the last 30 years. White patients have delayed onset of ESRD compared with patients of other races.

Temporal changes in ESRD and transplant characteristics

Variables	1987-1997 N= 1461	1998-2007 N= 1299	2008-2017 N= 1345	p value

PO2339

Risk of Rituximab-Associated Severe Adverse Events Increases with Young Age in Children with Nephrotic Syndrome

Camille Laroche,[2] Dominique Lemieux,[2] Anne-Laure Lapeyraque,[2,1] Adrien Flahault.[1] *[1]Centre Hospitalier Universitaire Sainte-Justine Centre de Recherche, Montreal, QC, Canada; [2]Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada.*

Background: Rituximab prevents relapse in steroid-dependent frequently relapsing nephrotic syndrome (SDFRNS). We aimed to assess the safety of rituximab in children with steroid-resistant nephrotic syndrome (SRNS) or SDFRNS.

Methods: This single-center retrospective study included all children with SRNS/SDFRNS treated with rituximab since 2007 at our institution. All information concerning adverse events (AE) were obtained from medical records. Severity of adverse events was graded according to the Common Terminology Criteria for Adverse Events. We performed a survival analysis and log-rank tests or proportional hazards models to determine hazard ratios (HR) with 95% confidence intervals (CI) of risk factors associated with severe AE (SAE).

Results: Of the 38 children included in this study, most had a SDFRNS (n=36, 95%). Median age at diagnostic was 3.4 (interquartile range, 2.4-6.2) years and median age at rituximab initiation was 9.0 (6.8-13.6) years. Median [95% CI] time to relapse was 1.4 [1.16-2.27] years. Median follow-up time was 3.7 (2.2-4.9) years. No patient died during follow-up. Fourteen SAE occurred in 12 (32%) patients, including one case of *Pneumocystis jiroveci* pneumonia, 6 cases of severe neutropenia and 2 cases of inflammatory colitis. Rituximab initiation before 10 years of age was associated with a higher risk of SAE (HR [95%CI], 11.3 [1.44, 88.6], Figure 1) and all SAE occurred in children aged <10 years except for anaphylactic reactions. The occurrence of a SAE was not associated with an increased risk of relapse.

Conclusions: A young age at rituximab initiation for SRNS/SDFRNS is associated with an increased risk of SAE. Rituximab should be used with particular caution in children under 10 years old.

Funding: Government Support - Non-U.S.

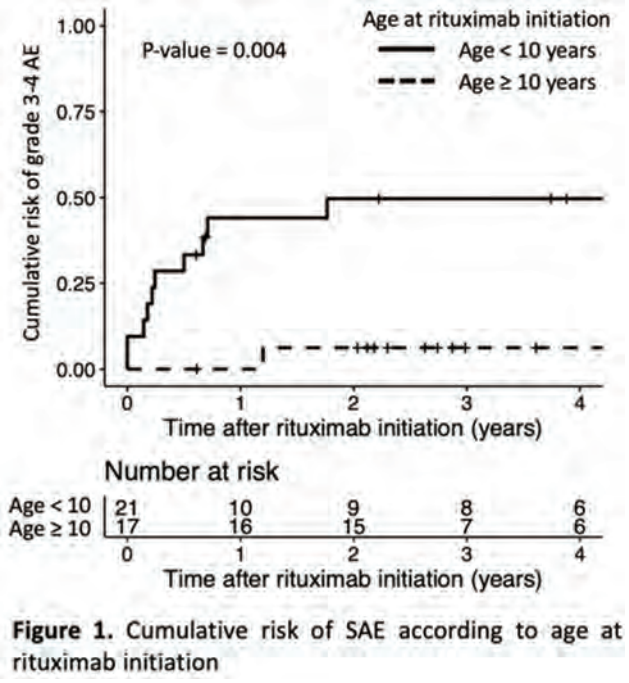

Figure 1. Cumulative risk of SAE according to age at rituximab initiation

PO2340

Evaluating Nephrotic Syndrome Response to Rituximab in Children

Anna E. Williams,[1] Katherine Twombley,[2] Annabelle N. Chua,[1] Rasheed A. Gbadegesin.[1] *[1]Duke University, Durham, NC; [2]Medical University of South Carolina, Charleston, SC.*

Background: Nephrotic syndrome (NS) is the most common cause of glomerular disease in the pediatric population. In children, 80% of cases are steroid sensitive (SSNS) & 20% are steroid resistant (SRNS). Rituximab (RTX) has been identified as a steroid-sparing therapy with minimal nephrotoxic side effects. The determinants of clinical response to rituximab is not completely known.

Methods: A retrospective review of patients aged 0-21 years with idiopathic NS who received at least 2 doses of RTX therapy over 6 years. Data collected included gender, race, ethnicity, age at diagnosis, steroid response, number of RTX doses, CD20 levels post therapy & outcomes. Outcome was defined as complete remission, CR (urine protein to creatinine ratio mg/mg: UPCR ≤ 0.2), partial remission, PR (UPCR 0.3-1.9) & no response, NR (UPCR ≥ 2). Data were compared by Fisher's exact & Wilcoxon Rank Sum tests.

Results: 48 patients met the inclusion criteria for the study comprising of 23(48%) with SSNS & 25(52%) with SRNS. There was no difference in race or age of onset between the patients with SSNS & SRNS. 18/29(62%) of patients who had CD20 lymphocyte levels measured following treatment achieved therapeutic end point of CD20 lymphocyte depletion. There was no difference in the proportion of patients who achieved this therapeutic end point between the patients with SSNS & SRNS (46% vs 72%). Overall, 72% of patients achieved partial or complete remission. The remission rate was significantly higher in the SSNS group compared with the SRNS group (87% versus 58%, p=0.001); however, there was no difference in remission rate between patients who achieved the therapeutic end point of CD20 lymphocyte depletion & those who did not in the entire cohort (56% vs 55%, p=1.0) as well as in subgroup of patients with SSNS & SRNS.

Conclusions: Children with both SSNS & SRNS achieved the desired therapeutic effect of CD20 lymphocyte depletion following treatment with RTX; however, disease remission rate was higher in children with SSNS. This data suggests that RTX can be administered at any phase of the disease (relapse or remission) without jeopardizing clinical response.

PO2341

Clinical Course and Management in Children with Henoch Schönlein Purpura (HSP) Nephritis

Hillarey Stone,[1,2] Edward Nehus,[1,2] Kimberley Dickinson,[3] Evanette K. Burrows,[3] Ingrid Y. Luna,[3] Caroline A. Gluck,[9] Bradley P. Dixon,[5] Vikas R. Dharnidharka,[6] William E. Smoyer,[7] Michael J. Somers,[10] Joseph T. Flynn,[8] Alicia Neu,[4] Susan L. Furth,[3] Christopher B. Forrest,[3] Michelle Denburg,[3] Mark Mitsnefes.[1,2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, US, Cincinnati, OH; [2]University of Cincinnati, University of Cincinnati, Cincinnati, OH, US, Cincinnati, OH; [3]The Children's Hospital of Philadelphia, The Children's Hospital of Philadelphia, Philadelphia, PA, US, Philadelphia, PA; [4]Johns Hopkins University, Baltimore, MD; [5]Children's Hospital Colorado, Aurora, CO; [6]St Louis Children's Hospital, St. Louis, MO, US, St. Louis, MO; [7]Nationwide Children's Hospital, Columbus, OH, US, Columbus, OH; [8]Seattle University, Seattle University, Seattle, WA, US, Seattle, WA; [9]Nemours Children's Hospital, Wilmington, DE; [10]Boston Children's Hospital, Boston Children's Hospital, Boston, MA, US, Boston, MA.*

Background: HSP can lead to serious complications including HSP nephritis (HSPN). Controversy exists regarding outcomes of HSPN, varying between benign, self-limited disease and 2-19% risk of severe chronic kidney disease (CKD). Given this risk, treatment with immunosuppression may be warranted. Unfortunately, evidence-based guidelines for management of HSPN are lacking. The goals of this study were to identify children with HSP and describe the clinical course and management in those with HSPN using a large, multicenter electronic health record (EHR) database.

Methods: Children with HSP were identified using PEDSnet, a network of pediatric health systems with EHR data standardized in a common data model. In patients with HSP, contact with nephrology was used as an indicator of HSPN. Demographics and clinical data among those seen by nephrology were compared to those not seen by nephrology. Outcomes of hypertension, dialysis, and transplant were identified using standard terminologies (SNOMED and CPT4). Among those with HSPN, treatment and outcomes are described.

Results: From 2009 to 2020, 5,360 patients with HSP were identified, including 1,217 (23%) with HSPN. Average length of follow up was 2.7 years. Patients with HSPN were older (7.9 vs 6.2 years, p<0.001), with no difference in sex or race/ethnicity. Among those with HSPN, 128 (10%) had kidney biopsy. Treatment included renin-angiotensin system (RAS) blockade in 166 (14%), corticosteroids in 427 (35%), and other immunosuppressive agents (mostly azathioprine or mycophenolate mofetil) in 97 (8%). Hypertension was diagnosed in 224 (18%) within one year of HSP diagnosis. By the end of follow up, 26 (3%) had estimated glomerular filtration rate <60 mL/min/1.73m^2, including 11 (1%) requiring dialysis or kidney transplant.

Conclusions: In this large study of >5,000 children with HSP, 23% developed HSPN with the majority having mild disease. Management of HSPN by pediatric nephrologists most commonly included observation, steroids, and/or RAS blockade. Children with HSPN in this study had an excellent short-term prognosis, with only 3% with advanced CKD or end stage renal disease at last follow up.

Spectrum of Clinical Manifestations in Children with WT1 Mutation

Patricia A. Arroyo Parejo Drayer, Chryso P. Katsoufis, Marissa J. Defreitas, Tossaporn Seeherunvong, Carolyn L. Abitbol, Jayanthi Chandar, Wacharee Seeherunvong. *University of Miami School of Medicine, Miami, FL.*

Background: Advances in genetic testing increases our ability to diagnose genetic causes of nephrotic syndrome (NS). The WT1 gene is a tumor suppressor gene necessary for kidney and gonadal development. Mutations in the WT1 gene are associated with NS and pose an increased risk of Wilms tumor and gonadoblastoma.

Methods: A retrospective chart review was performed in patients followed at the University of Miami from January 1990 to December 2019 with NS and WT1 gene mutation.

Results: WT1 mutations were identified in 9 children, included 5 Hispanic, 2 Caucasian, 1 Asian and 1 Middle Eastern. The mean age at renal presentation was 2.4 years (1 week to 7 years). Five presented with congenital NS (CNS). Three presented with steroid resistant NS (SRNS), at age 3 to 6 years, and received immunosuppressive treatments. One presented in advanced kidney failure at 7 years. Four had normal female external genitalia, and 5 had various abnormalities of male genitalia. Karyotype study showed XY in all. Two males developed Wilms tumor, found incidentally. All progressed to end stage kidney disease at a median age of 5 years (1 month to 14 years). Genetic diagnosis was delayed in 2 females and ultimately WT1 mutation was confirmed when they presented with primary amenorrhea. All phenotypic females underwent gonadectomy and required long term estrogen. Of two pubertal males, one had hypogonadism, and both were monitored for gonadal tumor. The median age from renal presentation to diagnosis of WT1 mutation was 7.6 years for females and 2.2 years for males ($p < 0.05$), (Figure).

Conclusions: Early recognition of NS associated with WT1 gene mutation is important for management which includes avoidance of immunosuppressive therapy, prevention of complications such as malignancy, and establishing long-term management of reproductive health. All females with infantile CNS or SRNS should get karyotype testing to identify WT1 gene mutation.

Caregiver Perspectives of Pre-Transplant Evaluation for Children

Eloise Salmon,[1] Laura Barr,[2] Douglas Hill,[1] Sandra Amaral.[1] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Pre-transplant evaluation is mandated by Centers for Medicare and Medicaid Services, but there is institutional variation in implementation. The family experience of this process also is incompletely understood. Current literature largely focuses on adult transplant recipients. Our interview study aims to fill the knowledge gap about family experience of the evaluation for children.

Methods: Interviews took place 07/2019 - 02/2020 with caregivers of children referred for kidney transplant at our center 07/2017 - 12/2018. The interview guide included closed- and open-ended questions; responses were audio-recorded and then transcribed for coding of themes. Respondents also completed a brief electronic questionnaire.

Results: Our team interviewed caregivers of 19 children; demographics in Fig. 1. Prominent themes included (1) the pre-transplant evaluation is overwhelming and emotional, (2) prior experiences and background knowledge are influential and (3) frustration with communication among teams was common. Fig. 2 highlights representative quotations from caregivers.

Conclusions: These findings are relevant to efforts by nephrologists to optimize delivery of information about transplant and other complex topics. The data highlight the importance of (1) acknowledging the scope of content and continually reevaluating accessibility of delivery (2) recognizing the influence of prior experiences and tailoring elements accordingly for increased family-centeredness and (3) making concerted efforts to define roles and set expectations, especially when multiple teams are involved in care.

CHILD AND HOUSEHOLD DEMOGRAPHICS			
From chart review (n = 19)			
Transplant Status		**Etiology of CKD**	
Pre-transplant at time of interview	47%	CAKUT	47%
Post-transplant at time of interview	53%	Glomerular disease	11%
		Other (nephronophthisis, cortical necrosis, chronic interstitial nephritis, BK nephropathy, unknown)	42%
Lifetime Dialysis			
Currently on dialysis or on dialysis pre-transplant	74%		
No lifetime dialysis	26%		
From survey (n = 15)			
Travel Distance to Center		**Annual Household Income**	
Less than 20 miles	20%	Less than $20,000	7%
20 to 49 miles	27%	$20,0000 to $39,999	13%
50 to 99 miles	27%	$40,0000 to $79,999	13%
100 miles or more	27%	$80,0000 to $119,000	27%
		$120,000 or more	20%
		No response	13%
Weekly Commitments Outside Home		**Race**	
Less than 5 hours	20%	White	60%
5 to 14 hours	27%	Black	20%
15 to 24 hours	7%	Asian	10%
25 to 39 hours	7%	No response	10%
40 to 59 hours	40%		
60 hours or more	0%		

Fig. 1

Theme	Representative Quotations
Pre-transplant evaluation as overwhelming	"I think that process of the initial visits, those two days, that was extremely overwhelming. It was just so much information and I don't remember half of the people that we met with." "It was overwhelming no matter how you looked at it." "The first day we met the kidney transplant coordinator they told us a lot of different things and it was first very overwhelming."
Prior experiences and background knowledge as influential	"I don't think I realized that there was an approval process for him to have a transplant 'cause we had just been building this up for so long. We knew this was the outcome." "It's still new. It's only been like a year and a half [since diagnosis] but it only feels like two months to me 'cause, like I said, I just wanted to rush everything." "I read a lot on that so I kind of knew what to expect." "So I think that's why, when I got in there, probably what overwhelmed me at that point was that I knew nothing about a kidney transplant cause I didn't look it up."
Frustration with communication among teams	"The waiting for us was more on the donor side; that was the variable that was unknown." "Initially, when we got everything going and we were starting to go through donor testing, I think communication started out pretty good in the beginning and then communication has always been something that we've brought to the attention of many in general [as a problem]." "They're expecting sometimes for families to be the spokespeople in between like "make sure you tell them this or make sure you tell them that" and then when you're sitting there in those meetings, they're like "no I don't think that's all that important."

Treatment-Related Anxiety in Children After Kidney Transplant

Michelle N. Keyser,[1] Elizabeth G. Ingulli,[2] Euyhyun Lee,[1] Paul Riviere.[1] *[1]University of California San Diego, La Jolla, CA; [2]Rady Children's Hospital, UC San Diego, San Diego, CA.*

Background: An increasing number of children experience anxiety and pediatric kidney transplant recipients are particularly susceptible to mental health conditions given the impact of their complex chronic medical histories on their quality of life. We performed a retrospective study to assess the impact of anxiety on health-related quality of life (HRQoL) in pediatric kidney transplant recipients in order to design targeted interventions to improve HRQoL after transplant.

Methods: We retrospectively analyzed scores from the disease-specific PedsQL 3.0 ESRD and Transplant Modules in pediatric ESRD and transplant patients ages 2-18 years between 2014 and 2019 at Rady Children's Hospital. We used a linear mixed-effects model with a random intercept and ANOVA with Tukey *post-hoc* tests to analyze the effect of variables of interest on HRQOL in various groups.

Results: 180 modules were completed by pediatric patients who received dialysis and/or kidney transplantation. Transplant recipients had significantly better total HRQOL scores compared to dialysis patients ($p < 0.001$). Treatment-related Anxiety was the lowest (worst) scoring domain among kidney transplant patients ($p < 0.01$), especially among patients ages 5-7 years old ($p = 0.009$). Patients 13-18 years old had the lowest scores in the Transplant domain, which measures social isolation related to a patient's transplant ($p = 0.008$). Variables such as age at diagnosis, time on dialysis, diagnosis category, and time to transplant were not significant predictors of HRQoL.

Conclusions: These data suggest that children with kidney transplants have better HRQoL compared to children on dialysis. However, transplant recipients experience high rates of anxiety and social isolation. This may simply reflect the psychosocial stress surrounding medical care, but we may also be capturing more nuanced psychological issues in this population that requires further evaluation. Since transplant patients typically have frequent access to medical care, we have established a multi-disciplinary model in our clinic in part based on these data that utilizes psychologists to address acute and chronic psychological concerns simultaneous with their medical visits. This model may improve the HRQoL of transplant patients without increasing the overall burden of medical care and may have broader applicability to the general population of children with anxiety.

PO2345

Vaccination Status in Pediatric Kidney Transplants: An Integrated Pediatric Transplant Research Database Study

Jaya S. Parulekar,[1] Eric J. Mcgrath,[3] Amrish Jain.[2] *[1]Wayne State University School of Medicine, Detroit, MI; [2]Division of Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; [3]Division of Pediatric Infectious Disease, Children's Hospital of Michigan, Detroit, MI.*

Background: The American Society of Transplant recommends candidates be immunized before transplantation. However, there is limited data on pre/post-transplant vaccination status for children with kidney transplants. Our study evaluates vaccination rates & an approach to increasing vaccination in our kidney transplant program.

Methods: Pediatric kidney transplant recipients at Children's Hospital of Michigan from 2013-2019 were included. Official immunization records were obtained from the State of Michigan's Michigan Care Improvement Registry. During the pre-transplant period, age-based catch-up or accelerated immunization was performed at primary care provider's or at the in-house immunization center. Demographic, clinical & serology data were entered into an integrated database created through RedCap and analyzed with SPSS Version 26.

Results: Included were 58 children with mean age at transplant of 11.9±5.7 yrs, 66% Male, 52% African-American, 31% Caucasian, 76% deceased donor transplants & 10% re-transplants. Median duration of follow-up was 3 yrs. Pre-transplant vaccination rates of ≥95% were achieved for all vaccines, except PCV13 (69%), PCV23 (62%) & HPV4/9 (86%). Pre-transplant serology for HepA, HepB and Varicella showed immunogenicity of 95%, 93%, 88% respectively. Catch-up & accelerated immunization increased the vaccination rate to 100% from 53% (Varicella); 57% (HepA); 73% (MCV); 72% (MMR). Post transplant vaccination series was ≥ 95% complete for all vaccines except PCV23 (43%); HPV4/9 (37%); MCV (30%).

Conclusions: A systematic approach using catch-up & accelerated immunization improves vaccination rates. Regular monitoring of immunization record post-transplant is required to maintain up-to-date status.

Decreased CD28 Expression in Memory CD4⁺ T Cells in Children Awaiting Kidney Transplant Is Associated with Increased Expression of Senescence Markers

Charlotte Duneton,[1] Roshan P. George,[1,2] Mandy L. Ford,[1] Pamela D. Winterberg.[1,2] *[1]Emory University, Atlanta, GA; [2]Children's Healthcare of Atlanta Egleston Hospital, Atlanta, GA.*

Background: Despite improved patient and graft outcomes with CD28-CD80/86 costimulation blockade, increased early acute rejection has hindered the widespread use of CTLA-4Ig (belatacept) for kidney transplant. Our group has previously reported lower pre-transplant frequencies of $CD28^+$ effector memory helper T cells ($CD4^+T_{EM}$ $CCR7^-$ $CD45RA^-$) with decreased functional capacity in adults that were subsequently free from early rejection on belatacept. We aimed to determine if a similar T cell phenotype is detectable in children awaiting kidney transplant.

Methods: We analyzed existing flow cytometry data of unstimulated blood cells collected from children on dialysis (n=30) or healthy children (n=18) and examined expression of markers of costimulation (CD28), senescence (CD57, PD1), activation (CD38) and cytotoxicity (Perforin, Granzyme B) on memory $CD4^+$ T cells.

Results: None of the children had $CD28^+CD4^+$ T_{EM} frequencies as low as those we have previously observed in adults that were rejection-free on belatacept. However, 8 children on dialysis (27%) had $CD28^+CD4^+T_{EM}$ frequencies below the minimum value observed in healthy children (Fig1A-B). Patients with this "stable-like" T cell phenotype had higher frequency of $CD4^+T_{EM}$ cells bearing senescence markers ($CD57^+PD1^+$ Fig 1C) and cytolytic effectors (Granzyme B, Perforin, Fig 1D) but decreased activation markers ($CD38^+$ Fig 1E).

Conclusions: Despite their young age and limited antigen experience, a subset of children on dialysis accumulate $CD4^+$ T_{EM} cells that have lost CD28 expression and bear markers suggestive of impaired function, a phenotype reminiscent of adults with decreased risk for early rejection on belatacept. The functional capacity of these cell populations in children needs further study.

PO2347

Predicting Allograft Survival in Young Pediatric Kidney Transplant Recipients

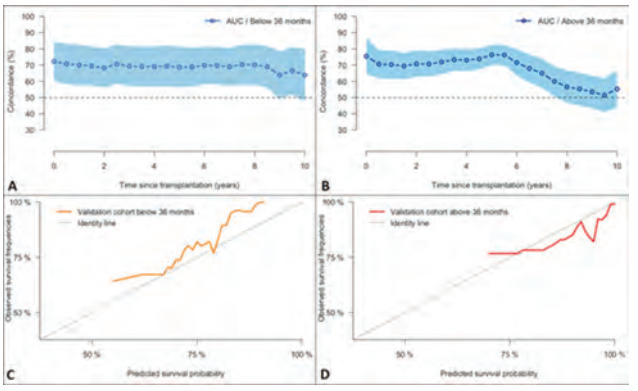
Florian Manca Barayre,[1] Jerome Harambat,[3] Amelia Le Page,[4] Stephen D. Marks,[5] Chanel Prestidge,[6] Matthew P. Sypek,[7] Stephen P. McDonald,[7] Rachel E. Patzer,[1] Julien Hogan.[1,2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Robert-Debré Hospital, APHP, Paris, France; [3]Bordeaux University Hospital, Bordeaux, France; [4]Monash University Faculty of Medicine Nursing and Health Sciences, Clayton, VIC, Australia; [5]Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; [6]Starship Children's Health, Newmarket, New Zealand; [7]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia.*

Background: Kidney transplantation (kTx) presents specific challenges in younger recipients. There are no predictive model of renal allograft loss in young pediatric recipients to inform donor selection. We aimed to develop and validate a predictive model of graft loss in an international cohort of young kTx recipients.

Methods: We included first-time kTX recipients under 5 years of age in the USA, Australia, New Zealand, UK and France between 2005 and 2018. A multivariate Cox regression was used to develop a predictive model of graft loss or death on the US cohort. Model discrimination (C-statistics) and calibration were assessed internally and externally on the non-US cohort.

Results: 2543 kTx in children <5 years old were included. 10-year overall graft survival rate was 80.0% [95% CI = 77.7% – 82.2%]. Given the interaction between some predictors and recipient's age, we developed two models stratified on recipient age (cut-off: 36 months) including donor/recipient body surface area ratio, ischemia time, donor weight and immunological matching. Immunological matching was a stronger predictor among older recipients, while morphological variables were stronger predictors in younger recipients. C-statistics on the training cohort were 0.63 (95% CI = 0.57 –0.68) and 0.65 (95% CI = 0.59 – 0.71) and the models were well calibrated. Figure 1 presents the discrimination of the models at different time horizons and the calibration at 10 years on the validation cohort.

Conclusions: We confirm the overall good renal allograft survival in children transplanted under the age of 5. We developed and validated predictive models of graft loss or death based on pre-transplant factors in this population that may be used to inform donor selection.



AUC and 95% CI at different horizons in the validation cohort and 10-year calibration plots in validation cohorts (A, C: ≤ 36 months old / B, D: > 36 months old)

PO2348

Safety and Efficacy of Low-Dose Rabbit Antithymocyte Globulin in Pediatric Renal Transplant Recipients

Vaka K. Sigurjonsdottir,[2,1] Paul C. Grimm,[2] Abanti Chaudhuri.[2] [1]*Landspitali, Reykjavik, Iceland;* [2]*Stanford University, Stanford, CA.*

Background: Currently there is no consensus among pediatric kidney transplant centers regarding the use and regimen for immunosuppressive induction therapy. The safety and effectiveness of reduced Rabbit Antithymocyte Globulin (ATG) ≤ 3.5 mg/kg cumulative dosing as induction therapy in low risk pediatric kidney transplant recipients is unknown.

Methods: Pediatric renal transplant recipients transplanted 1/1/2013-5/1/2018 were considered for inclusion. Recipients of deceased or living donor organs and with least 12-month follow-up were included. "High risk"was defined by a repeat transplant, preformed donor specific antibodies (DSAs), peak panel-reactive antibodies >20%, or African-American race. Maintenance immunosuppression protocol was tacrolimus and mycophenolate mofetil, steroid free unless high risk. Outcomes were de novo DSA (dnDSA) formation, graft survival, biopsy proved rejection (BPR) and EBV/CMV/BK viremia/infection during the first 12 months. DSAs were routinely screened at 3,6 and 12 months. Protocol biopsies were done at 6 and 12 months and graded with Banff criteria. Subclinical/borderline findings were included with or without treatment. Additional DSA testing and/or biopsies were done if there was a clinical concern. Group 1: low risk patients, ATG dose of ≤ 3.5 mg/kg, Group 2: low risk patients receiving dose of >3.5 mg/kg and Group 3: high risk patients

Results: A total of 181 patients met inclusion criteria. Age of patients was 11 years (11 mo-21 y),(median, range), 21% received a living donor transplant and 49% were female. Graft survival and dnDSA formation did not differ significantly between the three treatment groups. Graft loss at 12 months was a rare event with 99.5% graft survival and patient survival was 100%. Patients outcomes based on groups is shown in the table.

Conclusions: Reduced ATG dosing (≤ 3.5 mg/kg) when compared with higher dosing (>3.5 mg/kg) is safe and effective. Reduced ATG dose was associated with lower rates of BK viremia and BK nephropathy without increasing risk of dnDSA or BPR

Funding: Private Foundation Support

Pediatric-Specific Models Improve Prediction of Kidney Transplant Survival for Children Under 5 Years Old

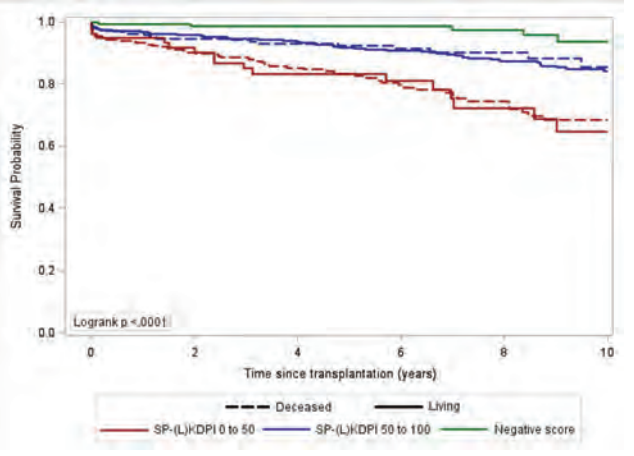
Florian Manca Barayre,[1] Larry A. Greenbaum,[1] Rouba Garro,[1] Pamela D. Winterberg,[1] Rachel E. Patzer,[1] Julien Hogan.[1,2] Emory Transplant Center [1]*Emory University, Atlanta, GA;* [2]*Robert-Debré Hospital, APHP, Paris, France.*

Background: The kidney allocation system directs high-quality kidneys to pediatric recipients, but the kidney donor profile index (KDPI) used to quantify donor quality may not accurately predict graft survival in small pediatric recipients. We aimed to determine if a pediatric-specific KDPI could improve the prediction of graft longevity for young recipients.

Methods: We evaluated first-time kidney transplantations in pediatric recipients between 1/2005 and 8/2018 in the U.S. (SRTR) and used a Cox model to assess KDPI accuracy for combined primary outcome of death or graft loss in young recipients. We developed an adapted KDPI score for recipients <5 years old of deceased (SP-KDPI) or living (SP-LDKPI) adult donor transplants using multivariate cox regression and scaled these models to allow comparison between living and deceased donors. Models' accuracies were validated internally by cross-validation.

Results: KDPI C-statistic was 0.52 (95% CI = 0.50 – 0.54) in recipients less than 5 years old. Ethnicity, age, body surface area, gender, cold ischemia time and number of HLA-B mismatches, were significant predictors for deceased donors (SP-KDPI model) while race, age, HLA-B mismatch and donor/recipient body surface area ratio were used in the living donor model (SP-LKDPI). C-statistics were 0.64 (95% CI = 0.57 – 0.70) for SP-KDPI and 0.65 (95% CI = 0.58 – 0.73) for SP-LKDPI. Figure 1 shows allograft survival by donor type and SP-(L)KDPI stratum. The SP-LKDPI model identified 16.8% of living donors with predicted graft survival superior to any deceased donor (denoted as SP-LKDPI <0).

Conclusions: Our adaptation of the KDPI demonstrated a higher accuracy to predict graft loss in young recipients of deceased donors. Furthermore, our SP-LKDPI model may allow direct comparison of living versus deceased donors offered to the youngest recipients.



Observed graft survivals by type of donor and SP-(L)KDPI

PO2350

Reduced 1-Year Allograft Function in Pediatric Renal Transplant Patients: Role of Subclinical Viral Replications

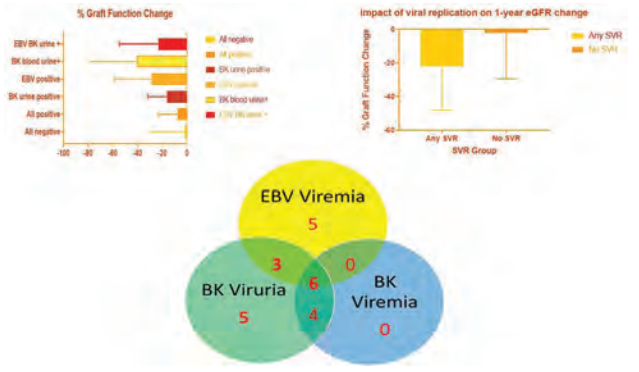
Raja Dandamudi, Stanley P. Hmiel, Vikas R. Dharnidharka. *Washington University in Saint Louis School of Medicine, Saint Louis, MO.*

Background: BK virus (BKV) and Epstein-Barr virus (EBV) subclinical viral replications (SVR) are common after renal transplant. The effects of SVR on the GF in pediatric kidney transplant (pKTx) recipients is not well defined and was the purpose of this study.

Methods: This retrospective study was done in our hospital from Jan 2012 to Dec 2018. 480 serum and urine samples from 39 pKTx were analyzed for viral load by quantitative PCR through the first post-transplantation year. Clinical characteristics, including GF by estimated glomerular filtration rate (eGFR) via bedside Schwartz formula were collected simultaneously. Analysis of differences between GF in patients with and without SVR was performed with t test and differences of $P < 0.05$ was significant.

Results: SVR occurred in 23/39(59%) of pKTx. EBV SVR occurred in 13/39(33%) pKTx at a mean (M) 95.8 days after transplantation (range(R) 14 to 220 days). M EBV level was 9188copies/ml (R 2K to190K copies/ml). BK viremia occurred in 10 pKTx at a M 132 days after transplantation (R 11 to 276 days) with a M level 49769 copies/ml (R 2K to 1,610K copies/ml). BK viruria occurred in 18 pKTx at a M 83 days after transplantation (R 11 to 230 days) with a M level 22,339,360 copies/ml (R 5K to 100,000K copies/ml). There was a significant difference in GF decline in patients with any SVR (M 21.97, SD 26.29) compared to patients with no SVR (M 2.1, SD 27.23), p 0.013. Patients with subclinical EBV/BK viremia and BK viruria experienced a M decrease of 28.9 (SD 29.78) and 40.72 (SD 38.06), and 16.53 (SD15.33) respectively, in GF during the 1-year period follow up. In patients with combined BK viremia, viruria and subclinical EBV RA experienced a M decrease in GF of 7.51 (SD 15.57) a year after transplantation.

Conclusions: BKV and EBV SVR significantly impacted the GF 1-year post transplant and therefore likely on long-term GF. Multicenter studies are required to study whether combined SVRs have more serious impact on GF than the corresponding mono SVR.



PO2351

The Creeping Creatinine in a Growing Child with a Kidney Transplant (KT): Using Absolute GFR Values to Separate Age Effects from Progressive Graft Dysfunction

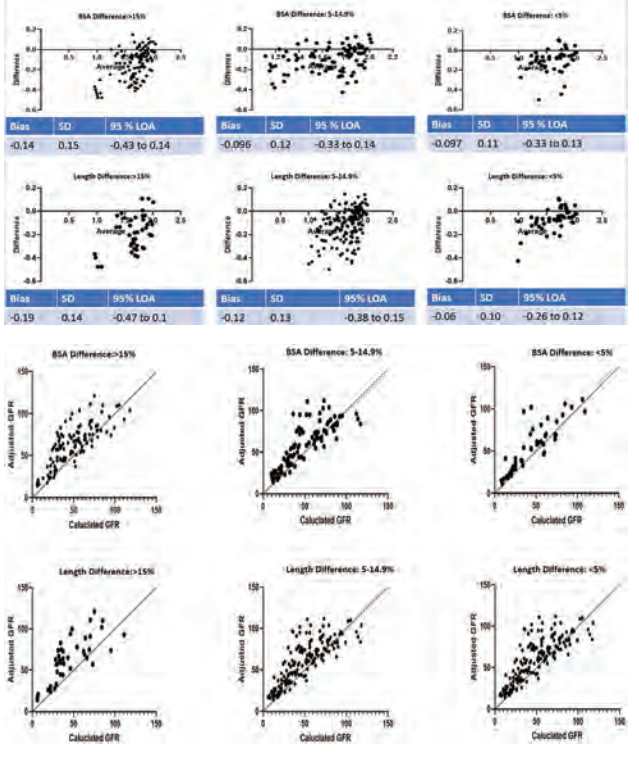
Raja Dandamudi, Stanley P. Hmiel, Vikas R. Dharnidharka. *Washington University in Saint Louis School of Medicine, Saint Louis, MO.*

Background: In very young KT recipients, the serum creatinine rises and glomerular filtration rate (GFR) decreases over the years. Without a biopsy, judging in a less invasive way whether this decline in GFR is due to linear body growth or progressive chronic allograft dysfunction is difficult. In measured glomerular filtration rate (mGFR) assays, the GFR is reported both as ml/min (ABS-GFR) and ml/min/1.73m2 (body surface area or BSA-GFR). We hypothesized that children who had rising serum creatinine predominantly due to linear growth would show a minimal change in ABS-GFR, with greater change in BSA-GFR.

Methods: This is retrospective cross-sectional study of 127 children who were aged < 15 years at time of transplant. We conducted analysis after stratifying basing on the height or BSA changes (< 5% change, 5-14.9% change and >15% change in linear height and BSA) between mGFR tests. Bland–Altman analyses were conducted to determine the agreement between log-ABS-GFR and log-BSA-GFR. We also performed correlation analysis with nonparametric Spearman's rank order correlation coefficient of BSA-GFR and ABS-GFR values.

Results: The bias between ABS-GFR and BSA-GFR increased as the percentage change in height and BSA increases (Figure). Spearman's rank order correlation demonstrated strong correlation when the BSA and length changes are<5% and the correlation weakened as the % changes increased.

Conclusions: We propose that in longitudinal follow up, it is important to use the ABS-GFR to avoid bias with the indexed GFR due to possible BSA change. A stable absolute GFR can be used to infer stable allograft function.



PO2352

Variability in Surveillance Monitoring and Management of Donor-Specific Antibodies Among Pediatric Transplant Programs Participating in the Improving Renal Outcomes Collaborative (IROC)

Lyndsay Harshman,[1] Hiren P. Patel,[2] Gina-Marie Barletta,[3] David K. Hooper,[4] Rouba Garro.[5,6] *[1]The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA; [2]Nationwide Children's Hospital, Columbus, OH; [3]Phoenix Children's Hospital, Phoenix, AZ; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [5]Emory University, Atlanta, GA; [6]Children's Healthcare of Atlanta Inc, Atlanta, GA.*

Background: There have been few advancements in long-term outcome of pediatric kidney transplant (KT) recipients who develop rejection. Many centers perform surveillance monitoring for donor specific antibodies (DSA) to diagnose and treat subclinical rejection. Despite the existence of guidelines, there is variability in monitoring and management of DSA post-pediatric KT.

Methods: An IRB approved survey was distributed using REDCap among pediatric KT programs participating in IROC to evaluate practice patterns in monitoring and management of DSA post KT.

Results: Twenty-nine of 33 (88%) IROC centers completed the survey. Twenty-five of 29 (86%) centers perform surveillance DSA monitoring. Of those 25 centers, 20 (69%) check DSA twice or more in year one post KT. Nineteen (65%) check once in the second year and annually thereafter. Ten (35%) centers check DSA only by indication after year two post KT. Twenty-eight (97%) utilize MFI trend in interpreting DSA results and 10 (34%) centers use C1q complement fixing antibody assay to guide management. Management of patients with +DSA, stable creatinine and no evidence of antibody mediated rejection (AMR) on biopsy varies across centers from monitoring alone (10/29, 34%) to intensifying baseline immunosuppression (19/29, 66%). Very few centers reported giving IVIG alone (3/29, 10%) or IVIG and rituximab (3/29, 10%). Only 34% of centers (10/29) perform kidney biopsy if DSA develops with stable creatinine. When rituximab is used for treatment of DSA+ AMR, 11/29 (41%) centers use one dose and 13/29 (45%) use 2 doses with variable frequency. Of centers that use IVIG as monotherapy for treatment of DSA+ AMR, 12/20 (60%) use 1 g/kg/dose and 6/20 (30%) use 2 g/kg/dose. The frequency of IVIG dosing is monthly in 16/20 (80%). The number of IVIG doses is variable ranging from 1 to 6.

Conclusions: There is significant variability in surveillance monitoring and management of DSA post-KT across pediatric centers. Large, multicenter studies should be considered to evaluate the ideal post-KT surveillance DSA monitoring strategy and to determine the effect of different treatment approaches on long-term outcomes in pediatric KT recipients.

PO2353

Assessment of Pediatric Nephrology Programs' Readiness to Participate in Prospective Clinical Trials

Shyanne Hefley,[1] Noel Howard,[1] H. William Schnaper,[2] William E. Smoyer,[3] Katherine M. Dell,[4] Coleman Gross,[5] Katherine Twombley,[6] Tetyana L. Vasylyeva,[1] Scott E. Wenderfer.[7] *[1]Texas Tech University Health Sciences Center School of Medicine, Amarillo, TX; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Nationwide Children's Hospital, Columbus, OH; [4]Cleveland Clinic, Cleveland, OH; [5]Relypsa Inc, Redwood City, CA; [6]Medical University of South Carolina, Charleston, SC; [7]Baylor College of Medicine, Houston, TX.*

Background: Currently, there is a limited availability of effective, FDA-approved drugs for children with kidney disease in the United States; therefore, there is an increased need for clinical trials to evaluate drug effectiveness and safety for pediatric usage. Implementation and conduction of clinical trials is complex process, which requires a team approach, involves multiple inter-dependent steps, research infrastructure support, legal policies/procedures, equipment, and access to a regulatory oversight board. The conduct of clinical trials in small pediatric subspecialties (i.e. pediatric nephrology) may be hampered by provider clinical demands and small numbers of patients available for such studies. The goal of this survey was to assess the readiness to conduct clinical trials by pediatric nephrologists in institutions of different sizes. Assessment would also give consideration to the sites for prospective trials and educate the programs about steps needed in clinical research.

Methods: The survey was designed and tested by a small group of pediatric nephrology experts. Qualtrics Online Survey Platform and Statistical analysis were used. The survey was distributed to members of ASPN (60 sites in 30 U.S states and 2 Canadian Provinces). Respondents were asked to complete the survey on behalf of the institution/practice, not their individual preferences. There was a total of 17 survey questions, which assessed the respondent's institution's participation/interest in conduction of clinical research, availability of a clinical research coordinator/IRB, and access to equipment for trial execution (dry ice, centrifuges, freezers).

Results: Currently, we have recorded 68 survey responses. Two of the responding institutions had no interest in conducting clinical trials (2.9%). Notably, more respondents practiced at Academic Centers/Universities (91%) than in private practices (8.3%). We noted no major differences in access to clinical trial resources between large and small institutions.

Conclusions: Clinical trials remain vital to finding better treatments and cures for pediatric patients with renal diseases. Overall, pediatric nephrology programs have good infrastructure and readiness to conduct clinical trials independently of the size of the institution.

PO2354

Telemedicine During the COVID-19 Pandemic: Parents' Experience in a Pediatric Nephrology Clinic at the University of Florida

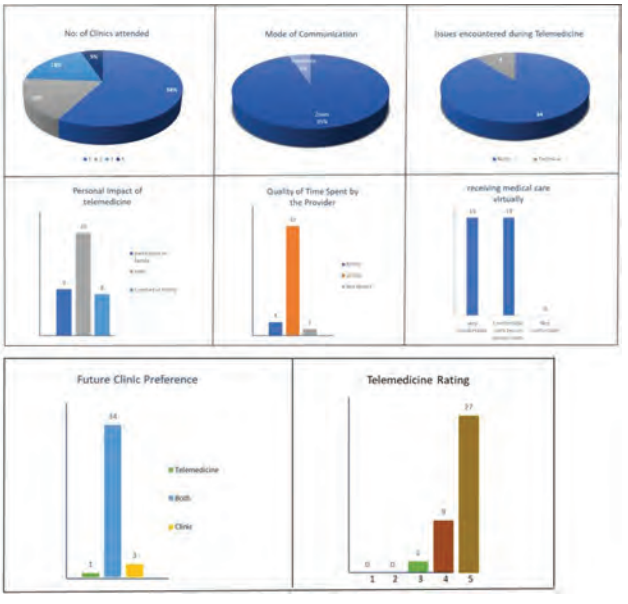
Sai Sudha Mannemuddhu, Lawrence R. Shoemaker. *University of Florida, Gainesville, FL.*

Background: In the setting of the COVID-19 pandemic, pediatric nephrology clinics at the University of Florida were switched to telemedicine. This transition occurred quickly without much education to either providers or families. There are some attempts to study the experience of providers, but there is no data regards to patients' and parents' experience with telemedicine.

Methods: We surveyed parents and patients (>18 years old) who had at least 1 telemedicine encounter via anonymous Qualtrics® survey sent to their email. Results were analyzed via qualitative analysis.

Results: Out of the 80 patents, 47.5% (38) completed the survey. 95% of the patients participated via Zoom and 5% used the telephone. 10.5% experienced technical issues. 100% reported that telemedicine had a positive impact on their family life. In response to the quality of time spent with physicians, 84% reported that telemedicine was similar to the clinic, and 10.5% reported it was better. In terms of receiving virtual medical care, 50% reported that they were very comfortable, 50% reported that they were comfortable but preferred some interim clinic visits. 71% rated telemedicine experience 5, 25% rated 4, and 5% rated 3 out of 5.

Conclusions: We observed that parents perceived the effect of telemedicine clinics as positive in respect to ease in the incorporation, quality of time spent by the physician, receiving virtual medical care, and the impact on the families. Though telemedicine seems to be effective in the current setting, it can only be served as adjunctive to in-person clinic visits in the future, since 90% of families preferred a mixture of clinic and telemedicine visits in our setting. Larger studies are needed to further evaluate the utility and efficacy of telemedicine in a pediatric setting.



PO2355

Prevalence and Determinants of Sickle Cell Nephropathy in Children Living in a Low-Resource Setting

Oyindamola C. Adebayo,[1,2] Dieumerci Betukumesu Kabasele,[3] Agathe B. Nkoy,[3] Pepe M. Ekulu,[3] Veerle Labarque,[2] Lambertus P. Van den heuvel,[1,4] Elena N. Levtchenko.[1] *[1]Laboratory of Pediatric Nephrology, Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium; [2]Centre for Molecular and Vascular Biology, Department of Cardiovascular Sciences, Katholieke Universiteit Leuven, Leuven, Belgium; [3]Division of Nephrology, Department of Pediatrics, University Hospital of Kinshasa, Faculty of Medicine, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the); [4]Department of Pediatric Nephrology, Radboud University Medical Centre, Nijmegen, Netherlands.*

Background: Clinical and genetic factors have been reported to influence the development of sickle cell nephropathy (SCN). However, data on the association between these factors and SCN remain limited in the pediatric population, especially in sub-Saharan Africa. Our study aimed to: (i) determine the prevalence of the reported markers of SCN, including albuminuria, glomerular hyperfiltration and reduced kidney function in a pediatric sickle cell anemia (SCA) population from the Democratic Republic of Congo (DRC); (ii) examine the association between these SCN markers and some clinical and genetic factors.

Methods: Clinical parameters were collected. All participants were genotyped for Apolipoprotein-L1 (*APOL1*) G1 (rs73885319, rs60910145) and G2 (rs71785313) variants, and for Heme oxygenase 1 (*HMOX1*) GT dinucleotide repeats (rs3074372). *APOL1* high-risk genotype (HRG) was defined by the presence of 2 risk variants (G1/G1, G2/G2, and G1/G2) and low risk genotype (LRG) if 0 or 1 risk variants were present. *HMOX1* GT dinucleotide repeats were categorized into two allele classes (≤ 25 repeats as short and > 25 repeats as long). As the main outcomes, albuminuria was defined as albumin-to-creatinine ratio (ACR) ≥ 30mg/g, reduced kidney function (eGFR <60 ml/min per 1.73 m^2) and glomerular hyperfiltration (eGFR > 130 and 140 ml/min/1.73 m^2 for female and male, respectively).

Results: From 361 participants enrolled, 73 (20.2%) presented with albuminuria, 104 (28.8%) with hyperfiltration and 19 (5.26%) had reduced kidney function. Logistic regression analysis revealed that blood transfusions (> 9 per year) were significantly associated with albuminuria (P = 0.036); age (P = 0.015) and diastolic hypertension (P = 0.0099) were significantly associated with hyperfiltration. *APOL1* HRG emerged as the main genetic factor associated with both albuminuria (odds ratio [OR]: 3.70, 95% confidence interval [CI]: -0.0037—2.55; P = 0.041) and hyperfiltration (OR: 21.84, 95% CI: 1.51—5.20; P < 0.001), while no association was found with *HMOX1 GT* repeats.

Conclusions: Kidney disease is highly prevalent in children with SCA in the DRC. *APOL1* HRG is the main determinant associated with the risk of developing SCN.

PO2356

Disparities in Kidney Failure Care for Children: A Global Survey

Rowena Lalji,[1,2] Anna Francis,[1,5] Germaine Wong,[3,4] David W. Johnson.[2,1] on behalf of the Pediatric GKHA working group *[1]The University of Queensland Faculty of Medicine, Herston, QLD, Australia; [2]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [3]The University of Sydney, Sydney, NSW, Australia; [4]Westmead Institute for Medical Research, Westmead, NSW, Australia; [5]Queensland Children's Hospital, South Brisbane, QLD, Australia.*

Background: Globally, the capacity to access and deliver kidney replacement therapies (KRT - dialysis and transplantation) to children has never previously been described. The present study reports current disparities in access to kidney care between children and adults worldwide based on the results of the 2018 International Society of Nephrology Global Kidney Health Atlas (GKHA) survey.

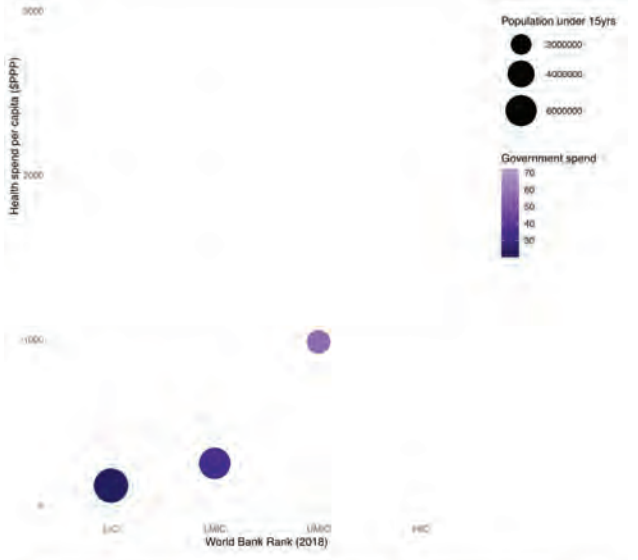
Methods: A mixed methods analysis of pediatric-specific data from the 2018 GKHA survey were used. Respondents were from countries categorized as low (LIC), lower-middle (LMIC), upper-middle (UMIC) or high income (HIC) according to 2018 World Bank income classification. Descriptive statistics were used for the population-based analysis of health expenditure across different world bank countries. Open text responses were thematically analyzed using HyperRESEARCH.

Results: Responses were received from 160 (88%) of 182 countries, including LIC (n=26, 16%), LMIC (n=36, 23%), UMIC (n=39, 24%) and HIC (n=59, 37%). Child access to end stage kidney disease care (ESKD) and KRT differed from adults in 29% and 23% of countries, respectively. Lower income countries were associated with graded increases in disparate access to ESKD (LIC 62%, LMIC 38%, UMIC 18%, HIC 19%) and KRT care (LIC 58%, LMIC 33%, UMIC 13%, HIC 9%). Five themes explained access disparities for children: inadequate resources for KRT; kidney failure care is expensive and incurs lifelong costs; priority and access based on a country's economic status; a lack of child-specific resources; and longer travel distances for children.

Conclusions: There are significant disparities worldwide in care for children with kidney failure when compared with adults, particularly in low resource settings. Future policy and advocacy efforts are needed to promote universal, equitable kidney care for children globally.

Funding: Government Support - Non-U.S.

Figure 1. Health care expenditure (per capita, $PPP) and government spend on kidney failure related care (as a % of the total cost of treatment) stratified by World Bank Income Groups (2018).



Note: the median pediatric population (under 15 years) per income group is directly proportional to the size of each bubble plotted. The color gradient of the bubble represents the mean percentage of the total cost of kidney failure related care covered by a government – the darker the color of the bubble, the more that is spent by the government.

PO2357

Clinical and Biopsy Characteristics in a Pediatric Cohort of C3 Glomerulopathy (C3G) and Immune Complex Membranoproliferative Glomerulonephritis (IC-MPGN)

Bradley P. Dixon,[1,2] Amy Goodwin Davies,[3] Hanieh Razzaghi,[3] Sherin Meloni,[3] Melissa E. Thomas,[3] Joseph T. Flynn,[4] Donna J. Claes,[5] Mark Mitsnefes,[5] Brian R. Stotter,[6] Vikas R. Dharnidharka,[6] Caroline A. Gluck,[7] Joshua Zaritsky,[7] Michael J. Somers,[8] Mahmoud Kallash,[9] William E. Smoyer,[9] Susan L. Furth,[3] Christopher B. Forrest,[3] Benjamin L. Laskin,[3] Michelle Denburg.[3] *[1]Renal Section, Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO; [2]Children's Hospital Colorado, Aurora, CO; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]Seattle Children's Hospital, Seattle, WA; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [6]Washington University in Saint Louis School of Medicine, Saint Louis, MO; [7]Nemours/AI Dupont Hospital for Children, Wilmington, DE; [8]Boston Children's Hospital, Boston, MA; [9]Nationwide Children's Hospital, Columbus, OH.*

Background: C3G and IC-MPGN are rare diseases. The ability to identify and phenotype children with C3G and IC-MPGN using electronic health records (EHR) would aid description of natural history and prognosticate therapeutic response.

Methods: Using a computable phenotype algorithm, a pediatric cohort of children with glomerular disorders was identified in PEDSnet, a national network of pediatric health systems with aggregated EHR data, and refined using MPGN-specific SNOMED-CT codes to identify C3G and IC-MPGN patients at 6 centers. Discrete data elements were captured from electronic health records, and additional clinical data were extracted by standardized chart review. Biopsy diagnosis was classified as C3G or IC-MPGN by applying an automated algorithm to immunofluorescence data.

Results: Of 285 identified patients, 173 were true cases of C3G or IC-MPGN (Tables 1 and 2). Median C3 level at diagnosis was lower in C3G compared to IC-MPGN (p=0.005). There were no significant differences in light microscopic injury pattern or ultrastructure between C3G and IC-MPGN biopsies, but C3 intensity was higher in C3G compared to IC-MPGN (p = 0.006) (Table 3).

Conclusions: Patients with C3G and IC-MPGN can be identified and characterized by the use of a computable phenotype, allowing the creation of robust databases to define clinical predictors of treatment response. This may prove to be a vital asset for recruitment into clinical trials of complement-targeted agents likely beneficial to this patient population.

Efficacy and Safety of Ravulizumab in Pediatric Patients with Atypical Hemolytic Uremic Syndrome Naïve to Complement Inhibitor Treatment: 26-Week and 1-Year Data

Gema Ariceta,[1] Bradley P. Dixon,[2] Seong heon Kim,[3] Gaurav Kapur,[4] Teri Jo Mauch,[5] Stephan Ortiz,[6] Marc Vallee,[6] Andrew E. Denker,[6] Hee Gyung Kang,[8] Larry A. Greenbaum.[7] *[1]Hospital Vall d'Hebron, Barcelona, Spain; [2]University of Colorado School of Medicine, Aurora, CO; [3]Pusan National University Children's Hospital, Seoul, Republic of Korea; [4]Children's Hospital of Michigan, Detroit, MI; [5]University of Nebraska Medical Center, Omaha, NE; [6]Alexion Pharmaceuticals Inc, Boston, MA; [7]Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA; [8]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Ravulizumab is a complement C5 inhibitor derived from eculizumab, with an increased half–life extending the maintenance dosing schedule from every 2–3 to every 4–8 weeks. We evaluated the efficacy and safety of ravulizumab to resolve active thrombotic microangiopathy (TMA) in children with atypical hemolytic uremic syndrome (aHUS) naïve to complement inhibitors.

Methods: ALXN1210-aHUS-312 (NCT03131219) is a phase 3, single–arm trial in children with TMA due to aHUS. Patients received ravulizumab every 4–8 weeks, depending on bodyweight. The primary endpoint was complete TMA response (platelet count and lactate dehydrogenase normalization and ≥25% improvement in serum creatinine from baseline at 2 visits ≥28 days apart) through 26 weeks. Key secondary endpoints included eGFR and dialysis requirement. Patients were then followed in an ongoing extension period. Here we report efficacy outcomes through 1 year and safety from all available follow–up (median 82.6 weeks).

Results: Eighteen patients (mean [SD] age 6.4 [4.5] years; 55.6% female) were enrolled; 14 (77.8%) achieved complete TMA response by 26 weeks, and 3 more patients (94.4%) by 50 weeks. Further improvements in TMA parameters occurred with longer-term treatment (Table). Mean (SD) increase in eGFR from baseline was 85.4 (54.3) mL/min/1.73m^2 at 26 weeks, and 94.1 (50.7) at 50 weeks. Of 6 patients on dialysis at baseline, 5 (83.3%) discontinued dialysis by week 26, and the last patient by week 50. Complete free C5 inhibition was sustained through the trial. No unexpected adverse events, deaths, or meningococcal infections occurred.

Conclusions: Ravulizumab administration every 4–8 weeks improved hematologic and renal outcomes in 94% of patients, with no unexpected safety concerns. Renal function improved with longer-term treatment.

Complete TMA response components over time

Variable	Initial evaluation period (26 weeks) n=18	All available follow-up n=18
Complete TMA response	14 (77.8)	17 (94.4)
Platelet count normalization	17 (94.4)	17 (94.4)
LDH normalization	16 (88.9)	17 (94.4)
25% improvement in serum creatinine from baseline	15 (83.3)	17 (94.4)
Hematologic normalization	16 (88.9)	17 (94.4)

Data shown as n (%). LDH, lactate dehydrogenase; TMA, thrombotic microangiopathy.

PO2359

A Pharmacologic "Stress Test" for Assessing Select Antioxidant Defenses in Patients with CKD

Richard A. Zager,[1,2] Ali C. Johnson,[1] Alvaro F. Guillem,[3] Donald J. Keyser,[3] Bhupinder Singh.[3,4] *[1]Fred Hutchinson Cancer Research Center, Seattle, WA; [2]University of Washington Department of Medicine, Seattle, WA; [3]Renibus Therapeutics, Southlake, TX; [4]University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA.*

Background: Oxidative stress is a hallmark and mediator of CKD. Diminished antioxidant defenses are thought to be partly responsible. However, there is currently no way to prospectively assess antioxidant defenses in humans. RBT-6 (stannous protoporphyrin; SnPP) induces mild, transient oxidant stress in animal models, triggering increased expression of select antioxidant proteins (eg, heme oxygenase 1 [HO-1], NAD[P]H dehydrogenase [quinone] 1 [NQO1], ferritin, p21). Hence, we tested the hypothesis that RBT-6 can also variably increase these proteins in humans and can thus serve as a pharmacologic "stress test" for gauging gene responsiveness and antioxidant reserves.

Methods: A total of 18 healthy volunteers and 24 participants with stage 3 CKD (n=12; eGFR 30–59 ml/min per 1.73m^2) or stage 4 CKD (n=12; eGFR 15–29 ml/min per 1.73m^2) received a single dose of RBT-6 at 9, 27, or 90 mg administered intravenously. Plasma and/or urinary antioxidant proteins were measured at baseline and for up to 4 days post-dosing. Kidney safety was assessed by serial measurements of BUN, creatinine, eGFR, albuminuria, and urinary AKI biomarkers (kidney injury molecule 1, neutrophil gelatinase-associated lipocalin, cystatin C, and N-acetyl glucosaminidase).

Results: Plasma HO-1, ferritin, p21, and urine NQO1 were all elevated at baseline in CKD participants. Plasma HO-1 and urine NQO1 levels each inversely correlated with eGFR (r=-0.85 to -0.95). All four proteins manifested statistically significant dose- and time-dependent elevations after RBT-6 infusion. However, marked inter-subject differences were observed. p21 responses to high-dose RBT-6 and HO-1 responses to low-dose RBT-6 were significantly suppressed in participants with CKD versus healthy volunteers. RBT-6 was well tolerated by all participants, and no evidence of nephrotoxicity was observed.

Conclusions: RBT-6 can be safely administered and, after its infusion, the resulting changes in plasma HO-1, NQO1, ferritin, and p21 concentrations can provide information as to antioxidant gene responsiveness/reserves in subjects with and without kidney disease. Additionally, baseline values of these markers may also be indicative of oxidative stress at baseline, especially in patients in CKD.

PO2360

Prediction of Kidney Drug Clearance: A Comparison of Tubular Secretory Clearance and GFR

Yan Chen,[1,2] Leila R. Zelnick,[2,3] Andrew N. Hoofnagle,[2,4] Catherine K. Yeung,[5,2] Laura M. Shireman,[5] Calder C. Brauchla,[5] Ian H. de Boer,[2,3] Jonathan Himmelfarb,[2,3] Bryan R. Kestenbaum.[2,3] *[1]University of Washington Department of Epidemiology, Seattle, WA; [2]Kidney Research Institute, Seattle, WA; [3]University of Washington Department of Medicine, Seattle, WA; [4]University of Washington Department of Laboratory Medicine, Seattle, WA; [5]University of Washington Department of Pharmacy, Seattle, WA.*

Background: Tubular secretion is the primary mechanism of kidney drug elimination. Few studies have empirically evaluated the role of tubular secretion on the kidney elimination of administered drugs.

Methods: We evaluated 54 participants with and without chronic kidney disease. We administered a single dose of iohexol, furosemide, and famciclovir at the start of the study visit. We used LC-MS/MS to measure furosemide, penciclovir (the active form of famciclovir), and secretory solutes in sequential timed plasma samples and timed urine collections. We compared iohexol GFR (iGFR) with the kidney clearances of secretory solutes for predicting kidney drug clearance using mean absolute errors (MAE) derived from linear regression and leave-one-out cross-validation.

Results: Participants were characterized by a mean age of 55 years and a median iGFR of 73 ml/min/1.73m^2. Using iGFR as a single predictor, the MAE between model-predicted and measured furosemide and penciclovir clearance was 40.1 and 64.1 ml/min, respectively. The MAEs for models of individual secretory solute clearances were statistically similar to that of the iGFR model. The addition of kynurenic acid, pyridoxic acid, isovalerylglycine, and tiglylglycine clearances each individually improved the predictive accuracy of penciclovir clearance compared with the iGFR model.

Conclusions: The kidney clearance of secretory solutes and iGFR showed similar accuracy for predicting the clearances of furosemide and penciclovir, with some improvement from combining both measures. These findings provide cautious optimism that measurements of secretory clearance may improve kidney drug dosing.

Funding: NIDDK Support, Other NIH Support - National Institute of General Medical Sciences

PO2361

Reduction in Proximal Tubular Secretion Precedes Reduction in Glomerular Filtration Rate in the Adenine-Induced CKD Model

Eleni Kougioumtzidou, Tasso Miliotis, Anna Granqvist, Magnus Soderberg. *Astrazeneca, Gothenburg, Sweden.*

Background: Glomerular filtration rate (GFR) is frequently used to instruct dose levels of renally cleared drugs in patients with renal disease. This is based on the assumption that proximal tubule secretory clearance declines equally to GFR during disease progression. We tested this hypothesis in adenine-induced CKD mouse model.

Methods: C57BL/6 mice were fed either control or 0.2% adenine diet to induce progressive kidney damage. Body weight, urinary output, GFR and tubular secretion were monitored and histological analysis performed to assess disease progression at 1 and 3 weeks. Tubular secretion was estimated by measuring renal clearance of the endogenous secretory solutes indoxyl sulfate (IS), hippuric acid (HA) and cinnamoylglycine (CMG) using liquid chromatography couple to mass spectrometry. GFR was estimated by transcutaneous measurements.

Results: Mice on adenine diet developed kidney disease, indicated by progressive GFR decline. Histological assessment showed normal glomeruli throughout the study and a moderate tubular damage at 1 week which progressed to severe at 3 weeks. However, the maximum urinary albumin-creatinine ratio was reached already at 1 week of treatment, as was Kim-1, an early tubular injury marker, suggesting extensive early tubular injury and functional damage preceding structural damage. Likewise, when tubular secretion was assessed directly, a profound decrease in renal clearance of IS was detected already after 1 week on adenine diet with only a small further decrease by the 3rd week. Similar trends were observed for HA and CMG. In direct comparison, the decline in GFR versus tubular secretion over time revealed that at 1 week GFR was decreased by 30% whereas tubular secretion was decreased by >65%, suggesting earlier impact on the latter. Immunohistological analysis revealed a reduction in Oat1 transporter expression, to an extent not fully accounting for the reduction in secretion. This suggests a component of Oat1 inhibition and/or involvement of other transporters.

Conclusions: Our results indicate that tubular secretory function can be dissociated from glomerular filtration. Thus, assessment of tubular function based on GFR alone can be misleading, which has implications for dosing of renally excreted drugs to patients with kidney disease.

The Influence of Vitamin D Status and CKD on the CYP3A Metabolism Substrate Midazolam

Stacey M. Tuey,[1] Linda Prebehalla,[3] Michael F. Wempe,[1] Michel Chonchol,[2] Nirav A. Shah,[4] Thomas D. Nolin,[3,4] Melanie S. Joy.[1,2] *[1]University of Colorado, Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; [2]University of Colorado, Division of Renal Diseases and Hypertension, Aurora, CO; [3]University of Pittsburgh, Department of Pharmacy & Therapeutics, Pittsburgh, PA; [4]University of Pittsburgh, Department of Medicine Renal Electrolyte Division, Pittsburgh, PA.*

Background: Patients with chronic kidney disease (CKD) have a high prevalence of vitamin D (VitD) deficiency. Given its widespread use and knowledge of CYP gene induction, there is a paucity of data on how the pharmacokinetics (PK) of CYP3A substrates may be impacted by VitD in CKD. This study sought to investigate the role of VitD status (deficient vs. replete state) on CYP3A drug metabolism in CKD and healthy control (HC) subjects using midazolam (MDZ) as a prototypical probe substrate.

Methods: CKD (n=19) and HC (n=6) subjects with VitD deficiency (25(OH)D < 30ng/mL) were enrolled in a 2-phase study. In Phase 1, subjects were given one dose of oral cholecalciferol (D_3, 5000 IU) and oral MDZ (2 mg). In Phase 2, subjects received D_3 5000 IU daily for up to 14 weeks to repletion (25(OH)D >30 ng/mL) and were again given one dose of oral D_3 5000 IU and MDZ 2 mg. Blood was serially collected for up to 48 h at each phase. MDZ plasma concentrations were measured by LC-MS/MS. Population PK analysis was performed using Phoenix NLME (v.8.2, Certara®).

Results: A 2-compartment model with delayed absoprtion and a mixed ratio residual error model was fit to the observed MDZ plasma concentration data. Glomerular filtration rate (GFR) and study phase were included as covariates in the model. MDZ population parameter estimates (%RSE) were: central volume of distribution (Vc/F) 95.6 L (26.8%), clearance (CL/F) 31.1 L/h (25.0%), peripheral volume of distribution (Vp/F) 213 L (39.5%), inter-compartmental clearance (Q/F) 36.5 L/h (24.3%), and absorption rate constant (k_a) 16.4 h^{-1} (42%). Individual subject PK parameter estimates were determined from the population PK model (Table).

Conclusions: VitD status did not significantly influence the PK of MDZ in either HC or CKD subjects. There was a trend in CL/F being slower in CKD compared to HC regardless of phase, which may be due to decreased renal elimination or reduced ability for induction of CYP3A secondary to renal impairment. Future analyses will explore additional covariates to further reduce the error on MDZ PK parameters in order to discern differences between subjects in this small study.

Effect of Kidney Disease and Vitamin D Repletion on Drug Transporter Activity

Morgan A. Casal,[1] Linda Prebehalla,[1] Raymond E. West,[1] Nirav A. Shah,[2] Michel Chonchol,[3] Melanie S. Joy,[4,3] Thomas D. Nolin.[1,2] *[1]University of Pittsburgh School of Pharmacy, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University of Colorado School of Medicine, Aurora, CO; [4]University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO.*

Background: CKD patients exhibit altered nonrenal drug clearance, which is reflected in numerous drug metabolism and transport pathways. Vitamin D (VitD) deficiency is common in CKD, and VitD-mediated regulation has been implicated in altering functional expression of renal and nonrenal transporters. This study aimed to elucidate the impact of VitD status (deficiency vs repletion) on drug transporter activity in CKD patients and healthy controls (HC).

Methods: VitD deficient ($25[OH]D_3$ < 30 ng/mL) subjects with CKD stage I-III (n=15), CKD stage IV-V (n=8) and HC (n=9) were enrolled. The phenotypic probe drugs fexofenadine (FEX) and olmesartan (OLM) were used to assess P-glycoprotein (P-gp), organic anion transporter (OAT) and organic anion-transporting polypeptide (OATP) function, and endogenous N-methylnicotinamide (NMN) was used to assess multidrug and toxin extrusion proteins 1 and 2K (MATE1/2K) activity. FEX 60 mg and OLM 10 mg were orally administered at baseline (VitD deficiency) and after 12 weeks of oral therapy with $VitD_3$ 5000 IU daily and confirmed repletion ($25[OH]D_3$ < 30 ng/mL). Serial blood and urine samples were collected for 48 hours. FEX, OLM, and NMN concentrations in plasma and urine were determined by LC/MS/MS and noncompartmental pharmacokinetic (PK) parameters were calculated.

Results: CKD IV-V subjects had 77% higher FEX systemic exposure (AUC, p=0.03), 37% lower clearance (p=0.03), and 68% longer half-life (p=0.0005) than HC at the time of VitD deficiency. In CKD I-III subjects, FEX AUC and C_{max} were increased 28% (p=0.03) and 52% (p=0.004), respectively, after VitD repletion. No differences in OLM PK were observed between VitD phases or subject groups. CKD IV-V subjects exhibited a doubling of AUC_{0-12} and 50% decrease in renal clearance of NMN after VitD repletion, but no differences were statistically significant.

Conclusions: The FEX data suggest that nonrenal transporter function (likely intestinal P-gp and/or hepatic OATP) is decreased in VitD deficient CKD patients and may be improved by VitD repletion. Reasons for unchanged OLM PK likely relate to overlapping substrate specificity with other transporters that are minimally effected by CKD or VitD status. Conversely, NMN results may suggest that MATE1/2-K function is decreased by VitD.

CYP3A and Drug Transporter Activity Changes in Thai Elderly with CKD Assessed Using a Microdose Cocktail

Punyabhorn Rattanacheeworn,[1,2] Wonngarm Kittanamongkolchai,[1,4] Natavudh Townamchai,[5,2] Suwasin Udomkarnjananun,[5] Kearkiat Praditpornsilpa,[5] Stephen J. Kerr,[6] Thanundorn Thanusuwannasak,[3] Udomsak Udomnilobol,[3] Suree Jainmongkol,[3] Boonsri Ongpipattanakul,[3] Thomayant Prueksaritanont,[3] Yingyos Avihingsanon,[5,2] Pajaree Chariyavilaskul.[1,2] Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Chulalongkorn University *[1]Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; [2]Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Chulalongkorn University, Bangkok, Thailand; [3]Chulalongkorn University Drug and Health Products Innovation Promotion Center, Faculty of Pharmaceutical Science, Chulalongkorn University, Bangkok, Thailand; [4]Maha Chakri Sirindhorn Clinical Research Center Under the Royal Patronage, Research Affairs, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [5]Division of Nephrology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [6]Biostatistics Excellence Center, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.*

Background: Chronic kidney disease (CKD) may influences cytochrome P450 (CYP) enzymes and drug transporters activity, resulting in the change of pharmacokinetics. This study investigated the effect of age and renal function on activity of CYP3A and various drug transporters in healthy Thai elderly and CKD patients using a validated microdose probe substrate cocktail.

Methods: Fifty three subjects were studied [healthy young subjects (Gr1, n=20), healthy elderly (Gr2, n=16) and elderly CKD patients (Gr3, n=17)]. Each subject was given a single dose of the microdose cocktail consisted of midazolam (M; for CYP3A), dabigatran etexilate (D; for gut P-gp), pitavastatin (P; for OATP1B), rosuvastatin (R; for BCRP, OATP, P-gp), and atorvastatin (A; for OATP, BCRP, P-gp, CYP3A). Plasma samples were collected at 0, 0.33, 0.67, 1, 1.5, 2, 3, 4, 6, 8, 10, 12, 24, 36 and 48 hours after dosing. All plasma drug concentrations were measured using a fully validated LC/MS/MS. Area under the concentration-time curve (AUC) were calculated by the trapezoidal rule.

Results: No side effect was observed. Multivariate analysis, adjusted for body mass index, co-morbidity and liver functions) showed negative effects of ageing and CKD on drug transporters activity. AUC_{0-last} and maximum plasma drug concentration (C_{max}) were increased in Gr2 and 3 compared to those in Gr1 (AUC_{0-last} in Gr2 and 3, respectively: M 2.19 and 2.68 folds, D 1.65 and 4.43 folds, P 0.99 and 1.57 folds, R 1.43 and 1.83 folds, and A 2.19 and 4.20 folds; C_{max}: M 1.83 and 1.86 folds, D 1.23 and 1.61 folds, P 1.22 and 1.90 folds, R 1.12 and 1.59 folds, and A 2.28 and 4.22 folds). AUC_{0-last} of Gr3 were significantly increased when compared to Gr2 in D, P and A (2.69 ($p<0.001$), 1.59 ($p<0.001$) and 1.92 ($p=0.001$) folds, respectively). C_{max} were significantly increased only in P and A (1.70 ($p<0.001$) and 1.94 ($p<0.001$) folds, respectively).

Conclusions: Independent of ageing, CKD itself further reduces the activity of drug transporters, suggesting that this information has to be taken into account when drugs that pass through those transporters are prescribed to CKD patients.

Tacrolimus and Mycophenolic Acid Pharmacokinetics in Young, Middle-Aged, and Elderly Stable Renal Transplant Recipients

Kathleen M. Tornatore,[1,2] Kris Attwood.[3,1] Transplantation Immunosuppressive Pharmacology Research Program *[1]University at Buffalo - The State University of New York, Buffalo, NY; [2]Erie County Medical Center, Buffalo, NY; [3]Roswell Park Comprehensive Cancer Center, Buffalo, NY.*

Background: Tacrolimus (TAC) and mycophenolic acid (MPA) comprise a critical maintenance immunosuppressive regimen. Limited pharmacokinetic data are available comparing age-related differences of these immunosuppressive drugs which is an important fact considering the increase in renal transplants in older patients. This analysis compared TAC and MPA pharmacokinetics among young, middle age and elderly stable renal transplant recipients (RTR).

Methods: Twelve-hour TAC and MPA pharmacokinetic studies were conducted in 67 stable RTR at least 1-year post renal transplant. Tacrolimus dose regimens were adjusted to troughs (4 to 10 ng/ml) based upon time post-transplant. MPA regimens were adjusted using clinical responses only. Patients were categorized as: young: >21 & ≤ 40 years; middle age: >40 &≤ 60 years and elderly>60 years. Non-compartmental pharmacokinetic analysis determined area under the concentration-time curve 0-12hours (AUC0-12),

AUC4-12/AUC0-12 (to define MPA enterohepatic recirculation), apparent clearance (CL) normalized to BMI (CL/BMI) and 0 hour troughs. Univariate ANOVA was conducted using SAS V 9.4.

Results: Table 1 summarizes the results. No group differences were noted for estimated glomerular filtration rate, MPA and TAC doses. Enterohepatic recirculation and MPA troughs were reduced in elderly compared to young. For MPA target AUC0-12hr of 30 to 60 mg.hr/L, 34.3% of RTR achieved this range with 56.7% above this therapeutic exposure. There were 52.2% of RTR within the therapeutic tacrolimus AUC0-12hr target of 120-200 ng.hr/ml with 46.1% below this range with no age relationship. Reduced tacrolimus CL/BMI was noted in elderly compared to middle age.

Conclusions: Tacrolimus and mycophenolic acid pharmacokinetics demonstrates age-related differences with lower clearances or exposures in the elderly. Tacrolimus and mycophenolic acid immunosuppression may require age-adjusted individualization to achieve therapeutic exposure.

A Single Time Point Plasma Concentration of Mycophenolic Acid Predicts Enteric-Coated Mycophenolate Sodium Exposure in Thai Renal Transplant Recipients

Napatsanan Tanathitipuwarat,[1,2] Pajaree Chariyavilaskul,[1,2] Natavudh Townamchai,[1,2] Supeecha Wittayalertpanya.[1,2] Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Chulalongkorn University *[1]Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; [2]Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Chulalongkorn University, Bangkok, Thailand.*

Background: Enteric-coated mycophenolate sodium (EC-MPS) is a salt form of mycophenolate widely used in renal transplantation. The area under the concentration-time curve (AUC) of an active form of EC-MPS, mycophenolic acid (MPA) of ≥30 μg.h/L is highly associated with drug efficacy. However, this technique is impractical in clinical setting. Little is known regarding metabolites' AUC. This study determined the relationships of a single time point of plasma MPA level and the optimum MPA-AUC and assessed the cut off plasma levet of that single time point to predict AUC. The full profiles of active (7-O-MPA-glucuronide; MPAG) and inactive (acyl mycophenolic acid glucuronide; AcMPAG) metabolites, both free and total form are also measured and related to its AUC.

Methods: Twenty renal transplant recipients with EC-MPS were studied. On day 3 post transplantation, plasma samples were collected at 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 6, 8, 10, and 12 hours post dose. Total and free form levels of MPA and metabolites were measured using a fully validated LC-MS/MS. Receiver operating curve (ROC) was carried out.

Results: The AUC of the MPA total form moderately correlated with a single time point plasma MPA concentration at C_4 ($r^2 = 0.50$) with the concentration cut off 2.5 μg/ml (sensitivity 87%, specificity 80%, area ROC = 0.83). The AUC of the MPA free form poorly correlated with a single time point concentration. The AUCs of total and free forms of MPAG and AcMPAG highly correlated with a single time point concentration at C_6 ($r^2 = 0.97$) and C_8 ($r^2 = 0.95$) for MPAG and C_4 ($r^2 = 0.59$) and C_8 ($r^2 = 0.81$) for AcMPAG. high variability in metabolites concentrations were observed, suggesting inter-individual variability in drug metabolizing enzyme activity.

Conclusions: At the early stage post transplantation, in renal transplant recipients who received EC-MPS, a single time point of the total form plasma MPA concentration is best monitored at 4 hours post dose. The MPA level of 2.5 μg/ml at that time point predicts optimum AUC. Further studies required for the use of metabolites' AUCs to assess drug efficacy and to evaluate a single time point concentration that predicts drug exposure.

PO2367

Preclinical Characterization of MAU868, a Novel Neutralizing Antibody Targeting BK Virus

Atul Sathe,[2] Mark Knapp,[2] Lihong Zhao,[2] Peter Kim,[2] Andreas Hein,[4] Meike Scharenberg,[4] Jacob Shaul,[2] Kelly A. Wong,[2] Steven J. Kovacs,[1] Elisabetta Traggiai,[4] Amy Patick,[3] Johanna R. Abend.[2] *[1]Novartis Institutes for BioMedical Research East Hanover, East Hanover, NJ; [2]Novartis Institutes for BioMedical Research Emeryville, Emeryville, CA; [3]Amplyx Pharmaceuticals, Inc, San Diego, CA; [4]Novartis Institutes for BioMedical Research Basel, Basel, Switzerland.*

Background: Reactivation of BK virus (BKV) can cause significant kidney and bladder disease in immunocompromised patients. There are currently no effective or BKV-specific therapies. MAU868 is a novel human monoclonal IgG1 that binds to the BKV major capsid protein VP1. Its binding affinity, antiviral activity, and resistance profile were investigated *in vitro*.

Methods: Binding affinity was determined using a solution equilibrium titration assay. Neutralization of BKV infection in primary renal proximal tubule epithelial (RPTE) cells was evaluated by quantitating TAg-expressing cells using an immunofluorescence-based high content imaging assay. The emergence of BKV resistance-associated variants (RAVs) with reduced susceptibility to MAU868 was investigated in two long-term selection studies with BKV genotypes I and IV in RPTE and HEK-293 cells. Crystallographic studies were conducted using the MAU868 single-chain variable fragment bound to VP1 pentamers.

Results: MAU868 had pM binding affinity and sub-nM neutralizing activity against the 4 major BKV genotypes, with EC_{50} and EC_{90} values ranging from 0.009 to 0.093 μg/ml (0.062 to 0.645 nM) and 0.102 to 4.160 μg/ml (0.708 to 28.865 nM). No cytotoxicity observed up (highest concentration tested 500 μg/ml). MAU868 also potently neutralized BKV variants constructed to contain VP1 sequences from clinical isolates or highly prevalent VP1 polymorphisms, and JC virus, a related polyomavirus. No RAVs were identified following serial passage of BKV in the presence of MAU868 for up to 182 days. The crystal structure of MAU868 in complex with the VP1 pentamer at 2.66 Å resolution identified a conformational epitope including 3 contact residues in VP1 (Y169, R170, K172) that are strictly conserved across BKV isolates. BKV variants with double or triple alanine substitutions at residues Y169, R170, or K172 were non-viable.

Conclusions: The strict conservation of the contact residues within the conformational epitope of VP1 may explain the broad-spectrum antiviral activity of MAU868 and its high *in vitro* barrier-to-resistance, ideal characteristics for a potential first-in-class therapeutic agent for the treatment or prevention of BKV disease.

PO2368

Pharmacokinetic Evaluation of Drug Interactions Between Vadadustat and HMG-CoA Reductase Inhibitors (Statins)

Ajit B. Chavan,[1] Rishikesh Sawant,[1] Leontia Burke,[2] Susan K. Paulson.[1] *[1]Akebia Therapeutics Inc, Cambridge, MA; [2]AGTC, Cambridge, MA.*

Background: Cardiovascular disease is the most common cause of mortality in patients with chronic kidney disease (CKD). Vadadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI) in late-stage development for the treatment of anemia due to CKD. The prevalence of dyslipidemia in CKD is very high, and nearly 50% of patients have been prescribed statins to decrease cholesterol levels. The disposition of most statins is dependent on metabolic enzymes and transporters. This study evaluated the drug interaction potential for statins when co-administered with vadadustat.

Methods: In this 3-part study (NCT03801733), 108 healthy adults were enrolled for vadadustat-statin pharmacokinetic (PK) evaluation. Vadadustat (600 mg daily) was administered concomitantly with either rosuvastatin (20 mg; n=34), pravastatin (40 mg; n=26), atorvastatin (40 mg; n=24), or simvastatin (40 mg; n=24). PK evaluation of the statins was conducted following a single dose on Day 1 and after the washout period of a single dose when co-administered with steady state vadadustat. After treatment with a statin alone or a statin plus vadadustat, geometric mean ratios were calculated to determine the difference in the PK parameters area under the curve (AUC) and maximum concentration (C_{max}).

Results: Vadadustat was generally well tolerated by healthy subjects when taken alone or with statins. Exposure (AUC and C_{max}) to rosuvastatin, a BCRP and OATP1B1 substrate, increased 2- to 3-fold in the presence of vadadustat. No change in exposure to pravastatin (an OATP1B1 substrate) was observed. The AUC for atorvastatin (a BCRP and OATP1B1 substrate) increased 1.4-fold, although no change in C_{max} was noted; for simvastatin (a BCRP and OATP1B1 substrate), the AUC increased 2-fold and C_{max} increased 1.2-fold in the presence of vadadustat.

Conclusions: There were no clinically significant interactions with pravastatin or atorvastatin, suggesting that vadadustat has a low likelihood for OATP1B1-mediated drug interactions. Increases in exposures to rosuvastatin and simvastatin are possibly due to BCRP inhibition. In summary, these results provide information to aid in the management of concomitant administration of vadadustat with statins. Funded by: Akebia Therapeutics, Inc.

PO2369

Impact of Renal Impairment and Dialysis on the Pharmacokinetics and Pharmacodynamics of Roxadustat

Dorien Groenendaal-van de Meent,[1] Virginie Kerbusch,[2] Rudiger Kaspera,[1] Maria B. Barroso,[1] Piergiorgio Galletti,[1] Gernot Klein,[3] Martin den Adel.[1] *[1]Astellas Pharma Europe B.V., Leiden, Netherlands; [2]PharmAspire, Wijchen, Netherlands; [3]APEX GmbH, Munich, Germany.*

Background: Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor for the treatment of CKD anemia. The objective was to evaluate the pharmacokinetics (PK), metabolic profile, pharmacodynamics, and safety of roxadustat in patients (pts) with varying degrees of renal function (RF).

Methods: In this phase 1, open-label study (EudraCT: 2015-002565-28), pts were enrolled in one of four RF groups: normal (NRF; eGFR ≥90 mL/min/1.73 m^2); severely impaired (SIRF, not on dialysis; eGFR <30 mL/min/1.73 m^2); end-stage renal disease (ESRD) on continuous ambulatory or automated peritoneal dialysis (CAPD/APD); or ESRD on hemodialysis or hemodiafiltration (HD/HDF). Patients in the NRF, SIRF, and CAPD/APD groups received a single dose of 100-mg oral roxadustat on Day 1. Two treatment periods (P1/P2), separated by a washout period, were used for HD/HDF

pts; a single dose of 100-mg oral roxadustat occurred 2 hours after HD/HDF (P1) and 2 hours before HD/HDF, 2 days after the previous session (P2). The PK of roxadustat and its circulating metabolites (*O*-glucuronide-, *O*-glucoside-, and sulphate of hydroxy-roxadustat) were evaluated.

Results: Thirty-four pts were enrolled and received roxadustat (NRF, n=12; SIRF, n=9; CAPD/APD, n=1; HD/HDF, n=12). The geometric least-square mean ratio of AUC_{inf} relative to NRF pts was 223% (90% CI: 185, 268) and 195% (90% CI: 165, 229) in SIRF and HD/HDF, respectively. Roxadustat's C_{max} and $t_{1/2}$ were comparable between groups. The PK of roxadustat and its metabolites were not affected by HD/HDF. In NRF, the amount of unchanged roxadustat excreted in urine was <1%; urinary excretion and renal clearance of roxadustat and its metabolites decreased with lower baseline RF. Mean AUC_{inf} and $t_{1/2}$ for roxadustat's circulating metabolites were higher in SIRF and HD/HDF pts, compared to NRF. Metabolite:parent ratio of AUC_{inf} was <1% for *O*-glucuronide- and *O*-glucoside-roxadustat, and <10% for sulphate of hydroxy-roxadustat. Roxadustat was well tolerated in all groups.

Conclusions: The AUC for roxadustat and its metabolites was higher in SIRF and HD/HDF, compared to NRF. Roxadustat's C_{max} and $t_{1/2}$ were comparable among all groups. Roxadustat and its metabolites were not significantly cleared by HD/HDF.

A Genotype-Guided Antihypertensive Therapy and CKD Care Precision Health Initiative

Judith Maddatu, Ranjani N. Moorthi, Katherine M. Spiech, Nehal Sheth, Michael T. Eadon. *Indiana University School of Medicine, Indianapolis, IN.*

Background: A precision health initiative was implemented, wherein pharmacogenomic predictors of antihypertensive response and genomic predictors of chronic kidney disease (CKD) were provided to clinicians caring for nephrology patients.

Methods: This is a prospective cohort study of 580 individuals who presented to outpatient nephrology clinics. Subjects were genotyped for 60 antihypertensive response variants and chronic kidney disease (CKD) predictors. Predictors included variants of CYP2D6 for metoprolol dosing and CYP2C9 for angiotensin receptor blocker dosing. Variants in APOL1, UMOD, and SHROOM3 were markers of CKD risk prediction. Subjects were followed to ascertain utilization of the genetic information by nephrologists.

Results: The cohort was 46% female and 43% African-American. Actionable variants were found in 85% of subjects. These variants are known to affect metabolism of a drug or contribute to CKD progression. The prevalence of actionable genotypes was 66% for CYP2D6, and 36% for CYP2C9. In African American subjects, 23% of CKD patients had two APOL1 risk variants. Clinicians adapted treatment for 43% of individuals with actionable genotypes. The primary nephrologist was surveyed for each subject. In the 143 subjects who completed follow-up, nephrologists reported a change in diagnosis in 44% of their patients and a change in management in 28.0% based on genotype. Clinicians discussed the genetic testing results with their patients in 83.9% of cases.

Conclusions: Nephrologists utilized a genetic testing panel of up to 60 variants in the routine care of their CKD patients. Pharmacogenomics predictors of disease response may prove to be very valuable the care of patients with chronic kidney disease.

KBP-5074, a Nonsteroidal Mineralocorticoid Receptor Antagonist, Reduces Urine Albumin-to-Creatinine Ratio and the Risk of Hyperkalemia in an Animal Model of CKD

Frederic Jaisser,[3] Liu Jinrong,[2] Shuangshuang Chi,[2] Ping Wang,[2] Judy Tan,[2] Vincent Benn,[1] Y. Fred Yang,[1] Jay Zhang.[1] KBP Biosciences USA Inc *[1]KBP Biosciences USA Inc, Princeton, NJ; [2]Kbp Biosciences Co Ltd, Jinan, China; [3]Centre de Recherche des Cordeliers, Paris, France.*

Background: KBP-5074 is a novel non-steroidal mineralocorticoid receptor antagonist (MRA) being developed for uncontrolled hypertension and advanced chronic kidney disease. The primary objective of this study was to evaluate KBP-5074 and eplerenone for renal protection against aldosterone-mediated renal disease in a uninephrectomized Sprague-Dawley (SD) rat model.

Methods: Uninephrectomized rats were maintained on a 6% high salt diet, and received aldosterone infusion for 27 days. Urinary albumin to creatinine ratio (UACR), urinary Na^+/K^+, and serum K^+ were assessed following 14 and 27 days of treatment. Blood samples were collected on days 1 and 26 to determine PK profiles. PK/PD analyses were performed on urinary Na^+/K^+ ratio, UACR, and serum K^+.

Results: KBP-5074 (1, 3, and 10 mg/kg/day) significantly reduced UACR by 77%, 96%, and 99% respectively on day 14, and 50%, 86% and 99% respectively on day 26 in a dose dependent manner, while eplerenone (100 and 900 mg/kg/day) reduced UACR by 40% and 99% respectively on day 26. PK/PD analysis of Urinary Na^+/K^+ ratio indicated that KBP-5074 was approximately 18-fold more efficacious than eplerenone. Analysis of UACR and serum K^+ indicated that the EC_{50} for serum K^+ increase and UACR reduction was 538 nM and 22.0 nM respectively for KBP-5074, and 666 nM and 1071 nM respectively for eplerenone, resulting in a therapeutic index (TI) against hyperkalemia of 24.24 for KBP-5074 vs 0.62 for eplerenone. Thus, the TI against hyperkalemia of KBP-5074 was 39-fold superior to that of eplerenone, suggesting that the non-steroidal MRA KBP-5074 may present an extended therapeutic window as compared to the steroidal MRA eplerenone.

Conclusions: KBP-5074 demonstrated a significant effect on UACR reduction with less risk for hyperkalemia compared to eplerenone in a rat model of nephropathy.

Pharmacological Inhibition of Vanin 1 Is Not Protective in Models of Acute and Chronic Kidney Disease

Kerstin D. Unterschemmann, Alexander Ehrmann, Ina D. Herzig, Anna Lena Andreevski, Carsten Schmeck, Frank Eitner, Manuel Grundmann. *Bayer AG, Leverkusen, Germany.*

Background: Dysregulated oxidative stress handling is a hallmark of acute and chronic kidney diseases. The pantetheinase Vanin-1 is highly expressed in tubular cells and its reaction product cysteamine is described to negatively affect redox homeostasis by inhibiting the replenishment of cellular anti-oxidative glutathione stores. The aim of this study was to elucidate whether pharmacological inhibition of Vanin-1 protects mice from acute or chronic kidney injury.

Methods: C57Bl6 mice undergoing ischemia reperfusion injury and Col4α3-/- (Alport syndrome) mice were treated orally for 1d and 3wk, respectively, with a potent and selective Vanin-1 inhibitor or placebo. *In vitro* oxidative stress insult was mimicked in human renal proximal tubular epithelial cells either chemically or by hypoxia/reoxygenation. Kidney function was determined by serum and urinary creatinine as well as serum urea and urinary albumin. Furthermore, mRNA and protein expression, Vanin-1 activity, oxidative stress level and tubular apoptosis were monitored.

Results: Oxidative stress levels were elevated in all models. Treatment with the Vanin-1 inhibitor resulted in ample systemic compound exposure and full inhibition of Vanin-1 activity in kidney tissue *in vivo*. However, this did not translate to a relevant reduction of oxidative stress level. Moreover, kidney function (serum Crea, blood urea, albuminuria), fibrosis marker gene expression and tubular cell apoptosis were not improved by Vanin-1 inhibition.

Conclusions: Pharmacological inhibition of Vanin-1 is insufficient to protect kidneys from oxidative stress insults contributing to acute and chronic kidney injury. The biological relevance of pharmacological Vanin-1 inhibition for the treatment of kidney diseases remains to be proven.

PO2373

Evaluation of Veverimer Drug Interaction Potential

Jun Shao,[1] Dawn Parsell,[1] Robert Guttendorf,[2] Yick Sen Wu,[1] Lillian Tsao,[3] Scott Tabakman,[1] Yuri Stasiv,[1] Angela A. Lee,[1] Kalpesh N. Biyani,[1] Gerrit Klaerner.[1] *[1]Tricida, Inc., South San Francisco, CA; [2]Aclairo Pharmaceutical Development Group, Vienna, VA; [3]Unaffiliated, Burlingame, CA.*

Background: Veverimer is an orally administered HCl binder for treatment of metabolic acidosis in CKD. We assessed its potential for drug-drug interactions (DDIs) using a strategy based on its physicochemical characteristics. Since veverimer is a non-absorbed polymer, potential DDIs are limited to effects on absorption of other oral drugs via (1) direct binding or (2) increases in gastric pH resulting from HCl binding.

Methods: Features important for binding to veverimer were determined in vitro. A set of anionic probes and a panel of 16 drugs were used to define characteristics required for binding. Test drugs covered a broad range of size, charge, solubility and permeability characteristics across 14 drug classes. The magnitude and duration of veverimer's effect on gastric pH was determined in fed and fasting healthy subjects via 22-h monitoring with an intragastric pH probe. Results from binding and gastric pH studies informed selection of drugs for human DDI studies.

Results: In vitro studies showed the most important determinant for binding to veverimer is negative charge, with small size as a secondary determinant. Veverimer did not bind any positively charged, neutral or zwitterionic drugs. Negatively charged drugs >435 Da did not bind; the presence of chloride reduced or eliminated binding. The 2 drugs showing the most binding to veverimer in vitro (furosemide, aspirin) were chosen for human DDI studies. Veverimer increased gastric pH by ~3.0 (fasted) and 1.5 (fed) pH units. The gastric pH increase was transient, peaking by 1 h after dosing and returning to baseline after 1.5 (fasting) and 3 (fed) hours. Based on these results, 2 drugs with pH-dependent solubility (warfarin, dabigatran) were chosen for human DDI studies. In human DDI studies, no clinically meaningful changes in bioavailability were observed for furosemide, aspirin, dabigatran, or warfarin when coadministered with veverimer.

Conclusions: We observed: 1) no effect of veverimer on the bioavailability of drugs most susceptible to binding to the polymer; 2) modest, transient effects of veverimer on gastric pH; 3) no effect on bioavailability of drugs with pH-sensitive solubility. We conclude that there is a negligible risk of clinically significant veverimer DDIs.

PO2374

Action of Veverimer on Gastrointestinal Acid Binding Is Not Affected by Omeprazole

Dawn Parsell,[1] Robert Guttendorf,[2] Yuri Stasiv,[1] Elizabeth Li,[3] Gerrit Klaerner,[1] Vandana S. Mathur.[4] *[1]Tricida, Inc., South San Francisco, CA; [2]Aclairo Pharmaceutical Development Group, Vienna, VA; [3]PharmaStat LLC, Fremont, CA; [4]MathurConsulting, Woodside, CA.*

Background: Veverimer, an orally administered, non-absorbed polymer that selectively binds and removes hydrochloric acid (HCl) from the gastrointestinal tract, has been shown to correct metabolic acidosis in patients with CKD. Unlike proton pump inhibitors (PPIs), which do not affect systemic acid-base status, the removal of HCl

from the gastrointestinal tract by veverimer leads to a net increase in blood bicarbonate. Veverimer was designed to bind HCl across a wide range of intraluminal pH, but the effect of veverimer on acid binding in the presence of PPIs has not been previously described.

Methods: To evaluate the effect of veverimer on gastric pH, we conducted a Phase 1, open-label, 2-stage study in which subjects (N=46) were randomized 1:1:1:1 to receive 1 of 4 study drug treatments (water fasted; water fed; veverimer fasted; veverimer fed) in the presence and absence of a steady-state level of omeprazole. Gastric pH was measured continuously for 22 hours (hrs) using a microelectrode pH probe positioned in the gastric fundus.

Results: Ingestion of veverimer caused a modest, transient increase in gastric pH that peaked within 1 hr post-dose. In the absence and presence of food, the median (distribution-free 95% CI) times to peak pH after veverimer administration was 0.25 (0.17, 1.00) and 0.71 (0.25, 1.17) hrs, respectively. Peak pH after veverimer administration was ~3 and ~1.5 pH units greater than that observed after water control in the fasted and fed states, respectively. The magnitudes of these increases were in the same range in the presence of omeprazole. Gastric pH returned to baseline after ~1.5 hrs under fasting conditions and after ~3 hrs under fed conditions. In the presence of omeprazole, the veverimer-induced gastric pH increase dissipated by 4 hrs post-dose or shortly after initiation of the subsequent meal.

Conclusions: The effect of veverimer on gastric pH is transient and similar in the presence or absence of omeprazole. The magnitude of the individual effects of food, veverimer, and omeprazole on gastric pH were similar (increase of 2–4 pH units). These findings are consistent with prior studies in patients with CKD in which the magnitude of efficacy of veverimer was unaffected by use of H2-receptor antagonists and PPIs (Wesson et al. *Lancet*, 2019).

PO2375

Clinical Pharmacology of Apixaban in Nephrotic Syndrome

Vimal K. Derebail,[1] Jing Zhu,[1] Karlyn A. Martin,[2] Russell P. Grant,[3] Sheel M. Patel,[1] Kaitlyn Maffuid,[1] Anne B. Froment,[1] Chad Torrice,[1] Nigel S. Key,[1] Dan Crona.[1] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Laboratory Corporation of America, Burlington, NC.*

Background: Nephrotic syndrome (NS) confers high venous thromboembolism (VTE) risk, but no standard-of-care exists for thromboprophylaxis. Apixaban, an oral direct Factor Xa inhibitor, has favorable renal clearance but is highly protein bound and has not been studied in NS. We evaluated safety, pharmacokinetics (PK) and pharmacodynamics (PD) in NS subjects in a parallel-arm single-dose (apixaban 10mg) Phase 1 study.

Methods: NS subjects were included if: age 18-79 years; urine protein:creatinine >3.5 g/g or serum albumin <3.0 g/dL; non-diabetic NS. Blood was collected at 0, 0.5, 1, 3, 4, 6, 8, 24h for PK (total and free apixaban, anti-Xa levels) and at 0, 3, 6 and 24h for thrombin generation. Apixaban was quantified by liquid chromatography-tandem mass spectrometry, anti-Xa levels by a chromogenic assay, thrombin generation by a fluorescence assay, and D-dimer by ELISA. Non-compartmental analyses for PK utilized Phoenix 8.1, and linear regression models tested associations between PK and PD (SAS JMP 14.0).

Results: 8 NS and 11 healthy subjects completed the study. NS subjects had mean UPC ratio of 6.7 g/g and were older (mean age 28.0 v 42.7 years, P=0.01); other relevant baseline characteristics were similar. Anti-Xa levels and PK measures (C_{max}, T_{max}, AUC_{0-24}, Vd/F, $t_{1/2}$ and CL/F) for total (Figure) and free apixaban were similar between NS and healthy subjects. D-dimer was lower in healthy subjects at 24h (P=0.04). Peak thrombin generation did not differ over 24h. Correlations between free apixaban and peak thrombin generation at 3h were seen in healthy subjects (r^2=0.48, P=0.02 for C_{max}; r^2=0.38, P=0.04 for AUC_{0-24}) but not in NS. No adverse events occurred.

Conclusions: These preliminary data support prospective study of apixaban for thromboprophylaxis in NS. Additional multi-dose data will inform appropriate dosing for patients with proteinuria due to NS.

Total apixaban concentration over time in NS and healthy subjects

PO2376

Circulating Heparin and Its Relevance to Thrombin Generation Profile in ESRD Patients Undergoing Maintenance Hemodialysis

Fakiha Siddiqui, Emily Bontekoe, Debra Hoppensteadt, Walter Jeske, Vinod K. Bansal, Jawed Fareed. *Loyola University Medical Center, Maywood, IL.*

Background: End stage renal disease (ESRD) is a complex pathophysiologic syndrome which results in vascular disorders and hemostatic disturbance. Despite the use of heparin during maintenance hemodialysis some of these patients exhibit hypercoagulable state. The purpose of this study was to characterize the thrombin generation (TG) profile in ESRD patients in relation to circulating heparin levels.

Methods: Citrated blood samples from 95 patients with ESRD undergoing maintenance hemodialysis were collected. NHP was prepared for referencing purposes. Individual samples were supplemented with heparinase. TG was assessed using a kinetic fluorogenic substrate method. TG parameters such as peak thrombin, lag time and area under the curve (AUC) were compiled. Circulating heparin levels were determined using activated partial thromboplastin time (aPTT) and chromogenic anti-Xa and IIa assays. The ESRD cohort was stratified into heparinized and heparin naïve groups.

Results: ESRD group showed decrease in peak thrombin (107.1 vs 168.3 nM) and AUC (589.8 vs 815.7 nM*min) with increase in lag time (2.9 vs 2.2 min) compared to NHP. Heparinase supplementation increase the lag time (3.4 min, p value <0.0001), while decrease the peak thrombin (100.0 nM, p value 0.0245) and AUC (503.4 nM*min, p value <0.0001). Such parameters as aPTT (43.2 vs 31.1 sec), anti Xa (0.21 vs 0.14 U/mL) and anti-IIa (0.27 vs 0.15 U/mL) decreased with heparinase treatment. Heparin naïve group showed decreased peak thrombin and AUC values whereas the lag time was increased. Simultaneously aPTT, anti-Xa and anti-IIa levels were decreased in this group. Heparinized patients did not show any difference in peak thrombin, decrease in AUC values and an increase in lag time. However, the aPTT, anti-Xa and anti-IIa were decreased in this group.

Conclusions: These studies showed that heparinase treatment of plasma samples from ESRD patients resulted in the decrease in the aPTT, anti-Xa and IIa levels suggesting the digestion of heparin. However, contrary to these results, TG parameters such as peak thrombin and AUC were decreased whereas lag time was increased suggesting that the depolymerized heparin fragments possessed thrombin generation inhibitory properties.

PO2377

Clinically Apparent AKI Secondary to Suspected Vancomycin Toxicity: A Cellular Kinetic Analysis

Ryan P. Flood, Matthew Ray, Judith Blaine, Anip Bansal. *University of Colorado Denver School of Medicine, Aurora, CO.*

Background: The use of antimicrobial therapies for treatment of hospitalized patients is abundant. While the usage rate of antibiotics has remained stable over the last decade, however, with the emergence of methicillin-resistant staphylococcus aureus, vancomycin usage has increased during that same time period. Although vancomycin induced AKI or vancomycin associated nephrotoxicity (VAN) has been a topic of debate since its generalized use approximately 50 years ago, the proposed mechanism of VAN is an on-going focus of research. The current study aims to answer whether proximal tubular creatinine secretion, which can account for upwards of 20% of creatinine clearance, is impacted by vancomycin dosing, and whether vancomycin trough levels seen in clinical practice alter this relationship.

Methods: For the cellular kinetic analysis, we took immortalized human proximal tubule epithelial cells, and after allowing them to epithelialize on a semi-permeable membrane, evaluated creatinine secretion in the presence of varying concentrations of both creatinine and vancomycin, while measuring eliminated levels for up to 24 hours. For the patient analysis, IRB approval was obtained to evaluate the cases of possible VAN on the renal consult service.

Results: Creatinine secretion through the cellular epithelium was not affected by vancomycin at levels up to 4X therapeutic, the upper limit of those seen on a cohort of patients in the renal consult service at the university of Colorado. This is consistent with other pharmacokinetic date, indicating that vancomycin is able to inhibit tranporters of creatinine, but at levels not seen in clinical practice. The patient cohort analysis identified thirteen patients who were deemed to have "possible VAN," and in all of these the rise in Cr did happen temporally related to vancomycin, and there were many other factors potentially confounding their AKI.

Conclusions: Proximal tubule dysfunction from vancomycin inhibition of cellular transporters does not cause creatinine elevation in concentrations used clinically. The cases of clinically apparent vancomycin associated nephrotoxicity are multifactorial. Therefore the nephrotoxocity associated with vancomycin administration does not seem to be the sole cause of creatinine elevation in patients with AKI.

PO2378

Systemic Absorption of Vancomycin from Sternal Slurry Contributing to Vancomycin Nephrotoxicity

David Y. Li, Thomas A. Golper. *Vanderbilt University, Nashville, TN.*

Introduction: Vancomycin has come a long way since its start as "Mississippi mud". It has been a valuable and safe agent in general. Adverse reactions include flushing and acute kidney injury. Clinicians are developing strategies to circumvent these problems. One strategy is the use of antibiotic slurry/paste applied to infected tissue. This has

traditionally not been associated with systemic vancomycin toxicity. We report here an incidence of vancomycin nephrotoxicity secondary to a sternal vancomycin slurry that required dialysis.

Case Description: A 62-year-old 91 kg man with Marfan's Syndrome and total aortic arch replacement presented with mediastinal abscess and recurrent sternal osteomyelitis. Exam revealed a fluctuant sternal lump and a trans-thoracic echo revealed a circumferential fluid collection around the aortic graft. He underwent a "redo" sternotomy, exploration and drainage. Plasma creatinine concentration (P_{cr}) on admission was 0.76 mg/dL, his known baseline. He received one dose of 1250 mg IV vancomycin prior to the operation. Intra-operatively 4 grams of vancomycin paste was applied to his sternum. That evening he received cefepime 2g IV and vancomycin 1250 mg IV (see figure), both scheduled to be repeated every 12 hours. P_{cr} and vancomycin troughs are detailed in the figure. On POD2 serum vancomycin trough was 42 mg/L. Intravenous vancomycin was discontinued after he had received 5 doses each of 1250 mg. By POD3 his P_{cr} had risen to 5.29 mg/dL, urine output dropped to 125 mL/day and the Nephrology Service was consulted. On POD4 the serum vancomycin was 48 mg/L and P_{cr} 6.45mg/dL. He was emergently dialyzed. After 5 rounds of dialysis, serum vancomycin concentration lowered to 8 mg/L and P_{cr} to 2.77 mg/dL. Urine output improved to 1200 mL/day. He was discharged on POD14 on daptomycin and ceftriaxone. On POD21 at follow-up, serum vancomycin was undetectable and P_{cr} was 1.08 mg/DL.

Discussion: There can be substantial unaccounted systemic absorption from vancomycin paste. The POD4 4 AM serum level was 48 mg/dL and he was dialyzed 14 hours later under operating conditions such that the level should be reduced by at least one-third. The post dialysis level was 47 mg/dL, so by conservative estimation his predialysis level was about 70 mg/L, suggesting that there was a substantial contribution of vancomycin to the serum level in that 17-hour interval from sternal slurry.

PO2379

Efficacy of the Recommended Ceftazidime/Avibactam Dose in Treating Carbapenem-Resistant Enterobacteriaceae in Critically Ill Patients Using Renal Replacement Therapies

Wasim El Nekidy,[1,2] Leen Oyoun Alsoud,[1] Nizar M. Attallah,[1,2] Laila Rkieh,[4] Fadi A. Hijazi,[1] Ahmad R. Nusair,[1] Jihad Mallat,[1] Islam Ghazi.[3] *[1]Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; [2]Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH; [3]University of the Sciences in Philadelphia, Philadelphia, PA; [4]Trillium Health Partners, Mississauga, ON, Canada.*

Background: Ceftazidime/avibactam (CEF/AVI) is a novel antibiotic used to treat Multi-drug Resistant (MDR) and gram-negative bacteria, including Carbapenem-Resistant Enterobacteriaceae (CRE). Data on CEF/AVI dosing and outcomes in patients with Chronic Kidney Disease stage-5 utilizing hemodialysis are scarce. The purpose of this study was to assess the efficacy of the recommended dose of CEF/AVI in patients utilizing renal replacement therapies.

Methods: A retrospective cohort study was conducted at our quaternary care institution between May 2015 and December 2019. All hospitalized adults who had CRE *Klebsiella Pneumoniae, E.coli*, or MDR *Pseudomonas Aeruginosa* related infections, and received CEF/AVI while utilizing either continuous venovenous hemofiltration (CVVH) or intermittent hemodialysis (IHD) or both were included

Results: Of the 24 patients who met the inclusion criteria, 70.8% were males, mean age was 66.0 ± 15.7 years. Eleven patients had bacteremia, 8 had pneumonia, 3 had urinary tract infection (UTI), and 2 had wound infections. Fourteen patients received CVVH while 10 received IHD during time on therapy. CEF/AVI dose while on CVVH was 1.25 g intravenous every 8 hours while the dose was 0.94 to 1.25 g daily in patients who were treated with IHD. Twenty-two of those patients were admitted to the critical care unit and required mechanical ventilation and 20 of them received vasopressors. A total of 13 patients had microbiological cure, and 10 patients were clinically cured. Nine patients with bacteremia had microbiological cure. Four patients with pneumonia had clinical cure during the follow up periods up to 3 months, recurrence/relapse occurred in 9 of the 24 patients. Eight patients deceased within 30 days of follow up and 4 more within 90 days. Only one patient did not have relapse or recurrence within the 90 days of follow up.

Conclusions: The CEF/AVI recommended dose could achieve uncertain clinical outcomes. Pharmacokinetics and pharmacodynamics studies are urgently needed to determine the adequacy of CEF/AVI dosing in this population

PO2380

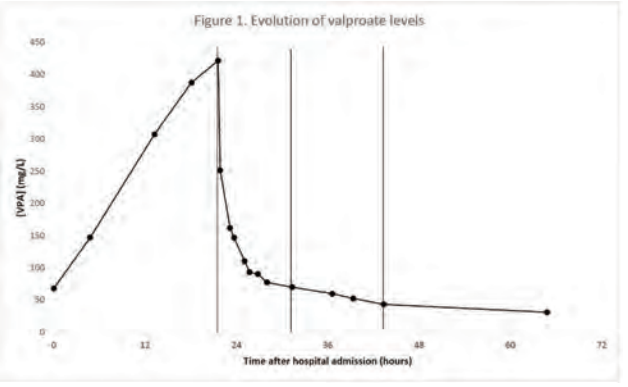
Extracorporeal Removal of Valproic Acid in Overdose: A Case Report

Jessie Beaulieu,[1] Andréanne Côté,[2] Marc Ghannoum.[2] *[1]CHU de Quebec-Universite Laval, Quebec, QC, Canada; [2]Centre integre universitaire de sante et de services sociaux du Nord-de-l'Ile-de-Montreal du Quebec, Montreal, QC, Canada.*

Introduction: Valproic acid (VPA) is considered not dialyzable at therapeutic concentration and dialyzable at supratherapeutic concentration because of saturable protein binding which increases its free fraction (from 10% to 90%).

Case Description: We report a case of a 53-year old 50kg woman admitted for suicidal polydrug intoxication. She had ingested 15g of VPA, 300mg of atorvastatin, 3g of quetiapine, and 750mg of naltrexone 3 hours prior to admission. Her vital signs were stable on admission and she was somnolent but arousable. Toxicology assays for ethanol, acetaminophen, and salicylates were negative. Biochemistry, blood gases, and complete blood count were unremarkable. She was initially treated with intravenous saline, naloxone, and intravenous carnitine. Despite these, she became progressively obtunded over 24 hours during which the serum VPA concentration rose from 69 to 422 mg/L (therapeutic concentration 50-125mg/L) and ammonia concentration rose from 17 to 56 mmol/L. Hemodialysis (HD) was initiated for 6h (GFS-210, Qb=400mL/min, Qd=750mL/min) via a right temporary femoral catheter because of concerns of coma-induced hyperammonemia and reduced access to VPA measurements. Her level of consciousness normalized during HD. No complications occurred during HD. VPA concentration and ammonia concentrations at the end of HD were 78 mg/L and 15 mmol/L, respectively, and did not re-increase thereafter (Figure 1). She was given three 50g doses of activated charcoal after HD and she eventually made a full recovery. VPA half-life was 3.0h during HD, 18.9h during multidose charcoal, and 44.9h without treatment. VPA was 48% unbound at the onset of HD. Instantaneous VPA clearance (calculated using simultaneous plasma and effluent VPA concentrations) decreased from 45 to 22mL/min during HD as protein binding increased.

Discussion: HD removed 1.4gm of VPA which would have been higher had HD been performed sooner after admission. This case illustrates that the dialyzability of VPA depends on its protein binding which itself depends on its serum concentration.



PO2381

Gabapentin Toxicity in Existing and Developing Renal Failure

Zaiyara A. Rivera, Irtiza Hasan, Charles W. Heilig. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: Gabapentin is a medication used to treat partial onset seizures, neuropathic pain caused by diabetic neuropathy, postherpetic neuralgia, & central neuropathic pain. This medication is nearly completely excreted by the kidneys. It is recommended as one of a number of first-line medications for the treatment of pain.

Case Description: Here we report two cases of potential Gabapentin toxicity across the spectrum of renal insufficiency. The first case was a 48-year-old female with a history of ESRD (HD X 3 times/week), HCV, DM, HTN and spinal abscess presented with new onset seizure, body stiffening with head and eye deviation, confusion, fall and hypertensive emergency while awaiting for dialysis. She had a second seizure while in the ED and was started on anti-seizure medication Levetiracetam. Home medications included Gabapentin (800 mg TID). Head CT was unremarkable. The second case was a 69-year-old female patient with a history of DM, peripheral vascular disease, coronary artery disease & atrial fibrillation who presented with worsening of non-healing left heel ulcer. Home medications included Gabapentin (300 mg 3 times daily). The patient developed contrast-induced AKI due to a CT angiogram procedure on admission. Following the development of AKI, the patient became confused without evidence of significant azotemia (BUN 33). Both the cases were found to be arousable and GCS of 12/15, intact strength & sensation of both extremities, no ataxia, dysarthria, hemineglect or signs of pronator drift. In both cases, Gabapentin toxicity was suspected and the dosage of Gabapentin was reduced to 100 mg orally at night. There was a drastic improvement of confusion and other symptoms within 2 to 3 days post dosage adjustment in both patients.

Discussion: Renal insufficiency predisposes patients to increased risk of gabapentin induced toxicity due to reduced clearance. Advanced age and other comorbidities may further accelerate the risk. The range of Gabapentin toxicity across the spectrum of renal insufficiency is underrecognized. In this case report, the patient with AKI only was confused and the patient with ESRD had myoclonus and seizure in addition to confusion. There seems to be a graded increase in toxicity with the corresponding deterioration of renal function. Heightened awareness about medication toxicity developing in renal failure is important to prevent significant adverse effects.

PO2382

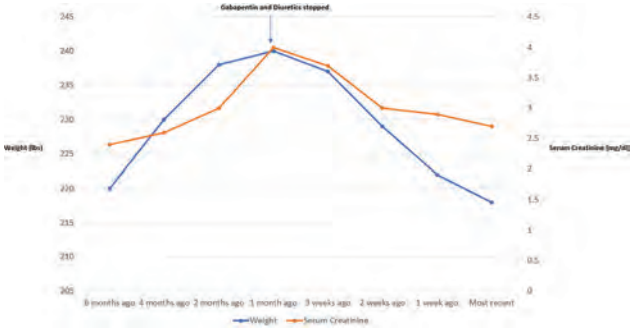
Gabapentin-Induced Edema Masquerading as Treatment-Resistant Heart Failure

Muhammad T. Shakoor, Ankur Shah. *Warren Alpert Medical School of Brown University, Providence, RI.*

Introduction: Gabapentin is widely used in the management of neuropathic pain but has multiple well-known side effects but less recognized is edema. We describe a case of gabapentin induced edema, which was misdiagnosed as CHF exacerbation, resulting in significant diuretic use and stage 3 AKI.

Case Description: An 85-year-old male with a past medical history of stage 4 chronic kidney disease secondary to diabetic nephropathy (baseline serum creatinine 2-2.5mg/dl), Type 2 Diabetes Mellitus, diabetic neuropathy, and hypertension, presented to clinic for worsening of serum creatinine. Pertinent home medications included bumetanide 3 mg BID, metolazone 2.5 mg daily and gabapentin 600 mg TID. Bumetanide and metolazone were up titrated for worsening bilateral lower extremity edema over last 3 months with 20-pound weight gain. Exam was notable for 2+ LE edema. His serum creatinine progressively increased from 2.4 to 4 mg/dl in the setting of aggressive diuresis. A recent TTE showed only grade 1 diastolic dysfunction. The presumed diagnosis was heart failure with preserved ejection fraction. Urine sediment was bland. After identification of gabapentin as potential culprit agent for his edema, both gabapentin as well as his diuretics were discontinued with a resultant significant drop in his weight and serum creatinine to 218lbs and 2.7mg/dl respectively over next one month and complete resolution of his edema.

Discussion: Incidence of gabapentin induced edema varies from 2% to 8% and has been correlated to dosage. Exact mechanism is unknown but possibly related to loss of venoarteriolar reflex leading to increased capillary hydrostatic pressure and hence increased net capillary fluid filtration into the interstitium. Gabapentin induced edema, just like calcium channel blockers induced edema, is not associated with salt and water retention and hence diuretics are ineffective. Physicians, especially nephrologists, should be mindful of uncommon side effect of this commonly prescribed medication as distinguishing this early can prevent a lot of unnecessary work up and potentially prevent harm to the patient.



PO2383

Knowledge Deficits Are Barriers to Living Donor Kidney Transplantations

Terri L. Menser,[1] Mark Hobeika,[2] Hassan N. Ibrahim,[2] Amna Khan,[3] Bethany Cruz,[2] Stephanie G. Yi,[2] Ahmed O. Gaber.[2] *[1]Houston Methodist Research Institute, Houston, TX; [2]Houston Methodist Hospital, Houston, TX; [3]Texas A&M University System, College Station, TX.*

Background: Living kidney donation is an underutilized treatment, and there is a paucity of educational interventions published in the literature describing efforts at increasing living donor kidney transplantation (LDKT); a systematic review of LDKT interventions documented only fifteen such interventions through 2017.[1] Transplant: A Family Journey is a two-hour educational session held prior to preemptive patients' initial transplant evaluation and includes members of patients' support network (e.g., significant other, family members, and/ or friends). Participants are encouraged to ask questions throughout the session, and can direct questions to the clinician and/or the speaker(s), typically a kidney recipient and/or a donor, about their experience with and knowledge of the transplant process.

Methods: Staff took verbatim notes of participants' questions during educational sessions and conducted qualitative thematic analysis on the content of the questions to derive patterns.

Results: There were 7 educational sessions for preemptive patients and their support network between December 2019 and March 2020; 57 patients and 89 family members and/or friends attended these sessions. 126 questions were asked that were classified into six main categories (see Figure 1).

Conclusions: There is still a large degree of confusion about transplantation among patients and their loves ones, specifically concerning LDKT. In addition to lack of familiarity of common terms (i.e., ESRD, preemptive, GFR) and a limited understanding of the waitlist process, patients and family members had questions about differential treatment outcomes. Continued efforts to increase patient understanding of transplantation and to involve their support networks early in the evaluation process are crucial to dispelling living donation misconceptions. 1. Sandal et al. (2019) doi:10.1097/TP.0000000000002715

Glomerular Changes in Transplant Glomerulopathy

Samir Husami, Dina Hammad, Jeffrey H. Miner, Tarek Alhamad, Hani Suleiman. *Washington University in Saint Louis Department of Medicine, Saint Louis, MO.*

Background: Transplant glomerulopathy (TG) affects 20% of transplanted kidneys 5 years post transplantation. It carries an important significance due to its correlation with decreased graft survival. Repeated endothelial cell injury by chronic active antibody mediated rejection (cAMR) leads to glomerular basement membrane (GBM) reduplication and thickening, the hallmark finding of TG. Based on our previous molecular mapping of the GBM, we aim to define the composition of the thickened GBM in TG using super-resolution microscopy.

Methods: Two super-resolution microscopy techniques, STORM (Stochastic optical reconstruction microscopy) and Airyscan, were used to image confirmed TG and control biopsies. For STORM, fresh frozen, 200 nm sections were imaged. While for Airyscan, 1-3 microns, formalin fixed paraffin embedded (FFPE) sections were used. Samples were labeled with antibodies for Laminin a5, Integrin a8, Myosin IIA, Vimentin, Synaptopodin, Integrin b1, Fibronectin, and several Collagen IV chains.

Results: STORM TG samples showed increased distance between Integrin b1 labeled membranes, indicating thickening of the GBM. Collagen a3a4a5(IV) did not change, while Collagen a1a1a2(IV) was increased at the GBM's endothelial aspect. There was an increase in Fibronectin, suggesting a role for the TGFb pathway. Airyscan TG images showed Vimentin- and Integrin a8-positive areas inside the GBM, indicating cellular protrusions extending into the GBM. Since these markers stain mesangial as well as endothelial cells, this suggests dedifferentiation of endothelial cells and transition to mesenchymal cells. We detected alternating Myosin IIA and Synaptopodin labeling in the form of "Sarcomere-like structures".

Conclusions: Our data revealed increased Collagen a1a1a2(IV) secreted from the endothelial side, while Collagen a3a4a5(IV) was unchanged. The increase in Fibronectin, cellular protrusions positive for mesenchymal markers, and sarcomere-like structures inside the diseased GBM suggest an endothelial to mesenchymal transition as culprit for increased Collagen IV rather than injury signals from podocytes.

PO2385

Calcineurin Inhibitor Cyclosporine A but Not Tacrolimus Induces Proapoptotic Endoplasmic Reticulum Stress in Kidney Epithelial Cells

Duygu E. Yilmaz,[1] Karin M. Kirschner,[1] Hasan Demirci,[1] Sebastian Bachmann,[1] Kerim Mutig.[1,2] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]I.M. Sechenov First Moscow State Medical University (Sechenov University), Moskva, Russian Federation.*

Background: Current immunosuppressive strategies in solid organ transplantation rely on the calcineurin inhibitors (CNI), cyclosporine A (CsA) or tacrolimus (Tac). Their nephrotoxicity is a major limitation for long-term usage. We hypothesized that CsA compared to Tac exerts more pronounced toxic side effects at the cellular level, with endoplasmic reticulum (ER)-stress and maladaptive unfolded protein response (UPR) as the most prominent landmarks.

Methods: To test this hypothesis we treated human embryonic kidney (HEK293) cells with CsA (10 μM) or Tac (10 μM) for 6h. The established ER stress-inducing agent, thapsigargin, served as positive control. To study the molecular mechanisms of CNI-induced cell toxicity we studied genetically-modified HEK293 cells lacking the crucial UPR elements, PERK or ATF6. Abundances of the ER-stress sensor IRE1a, adaptive transcription factor XBP1, and proapoptotic transcription factor CHOP were evaluated as endpoints.

Results: Treatment of native HEK293 cells with CsA or Tac equally increased phosphorylation of the known calcineurin substrate, NFAT, verifying the treatment protocols. CsA increased levels of activating IRE1a phosphorylation (pIREa) and stimulated both CHOP and spliced XBP1 (sXBP1) products. In contrast, Tac enhanced pIRE1a abundance only. CsA but not Tac significantly increased the number of cleaved caspase 3-positive cells suggesting enhanced apoptosis rate. Treatment with the chemical chaperone, TUDCA, partially abolished the CsA-induced increases of CHOP but did not affect sXBP1, suggesting alleviation of ER-stress. Knockdown of CsA binding partners, cyclophilin A and B, by siRNA reduced their expression approximately by half and increased CHOP expression suggesting that suppression of cyclophilins may contribute to CsA-induced cellular toxicity. PERK- or ATF6-deficiency blunted the increases of CHOP and sXBP1 in response to CsA, suggesting an implication of these pathways in CsA-induced ER-stress and UPR.

Conclusions: In summary, CsA but not Tac induces pronounced ER-stress and proapoptotic UPR. Pharmacological modulation of UPR bears the potential to alleviate CNI nephrotoxicity.

Tubular Cell Binding of β-Catenin to TCF1 or FoxO1 Associates with Chronic Fibrosis and Adverse Outcomes in Transplanted Kidneys

Guoping Zheng,[1] Ying Yang,[1,4] Brian J. Nankivell,[3] Padmashree Rao,[1] Xiaojun Ren,[1,5] Hong Yu,[6] Titi Chen,[1] Qi Cao,[6] Yiping Wang,[1] Yuan Min Wang,[2] Vincent W. Lee,[3] Stephen I. Alexander,[2] Natasha M. Rogers,[3] David Harris.[1] *[1]University of Sydney, Sydney, NSW, Australia; [2]Children's Hospital at Westmead, Westmead, NSW, Australia; [3]Westmead Hospital, Westmead, NSW, Australia; [4]Shanxi Medical University, Taiyuan, China; [5]Shanxi Bethune Hospital, Taiyuan, China; [6]Westmead Institute for Medical Research, Westmead, NSW, Australia.*

Background: β-catenin is a key transcription factor via which multiple fibrogenic pathways converge. Importantly, it binds to multiple transcription co-factors mediating diverse signaling pathways. Its role in kidney transplantation is unknown.

Methods: A proximity ligation assay was used to assess binding of β-catenin within renal tubular epithelial cells to transcription factors, TCF1 and FoxO1, in 240 transplanted kidneys. Their correlation with pathological and clinical outcomes was evaluated.

Results: β-catenin-FoxO1 binding in 1-month protocol biopsies inversely correlated with contemporaneous chronic fibrosis, and subsequent inflammation and inflammatory fibrosis (P<0.001). The relative binding of β-catenin/TCF1 verus β-catenin/FoxO1 (TF ratio) was the optimal prognostic biomarker compared with individual components, and abnormal in a diverse range of fibrotic transplant diseases. A high 1-month TF ratio was followed by greater tubular atrophy and interstitial fibrosis scores, cortical inflammation, renal impairment, and proteinuria at one year (n=131, all P<0.001). TF ratio predicted reduced eGFR (AUC 0.817), mild fibrosis (AUC 0.717) and moderate fibrosis (AUC 0.769) using receiver-operating-characteristic analysis, exceeding conventional clinical and predictors including baseline fibrosis. An independent validation cohort (n=76) confirmed 1-month TF was associated with 12-month moderate fibrosis (15.8% versus 2.6%, P=0.047), but not with 10-year graft survival.

Conclusions: In conclusion, differential binding of β-catenin to TCF1 rather than FoxO1 is predictive of a fibrogenic response in transplanted kidneys.

Immunosuppression by Cyclosporine A Affects Proximal Tubular Homeostasis via Endoplasmic Reticulum Stress

Suncica Popovic,[1] Junda Hu,[1] Hasan Demirci,[1] Duygu E. Yilmaz,[1] Carsten Dittmayer,[1] Yan Xu,[1] Martin N. Thomson,[1] Kerim Mutig,[1,2] Sebastian Bachmann.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Pervyj Moskovskij gosudarstvennyj medicinskij universitet imeni I M Secenova, Moskva, Russian Federation.*

Background: Calcineurin inhibitors (CNI) such as cyclosporine A (CsA) or tacrolimus are first-line immunosuppressive drugs used after solid organ transplantation. However, renal side effects such as vascular and tubulo-interstitial malformations regularly occur in their long-term usage, especially in patients with renal allografts. Measures to reduce CNI nephrotoxicity by RAS inhibition or calcium antagonism had limited success. Dysfunctions in renal epithelial proteostasis suggested CNI-induced ER stress and malfunction of the unfolded protein response (UPR).

Methods: We have established a rat model for chronic CNI nephrotoxicity to test whether epithelial pathology and loss of functioning nephrons are related to ER stress and UPR dysfunction. Adult male Wistar rats received cyclosporin A (CsA, 25 to 40 mg/kg. b.w.) or vehicle via subcutaneously implanted minipumps. After three weeks, rats were sacrificed and organs removed for protein analysis or perfusion-fixed and kidneys analyzed for histopathology.

Results: Rats with CsA displayed a stimulated RAS and increased distal NaCl transporter activity along with decreased urine volume, GFR, FE_{Na}, and COX-2 expression. Pathological changes in vasculature and glomeruli were inconspicuous, whereas early proximal tubular segments (S1, S2) revealed large lysosomal vacuoles with granular content, their abundance correlating with epithelial dedifferentiation, basement membrane thickening, and subepithelial collagen I accumulation. Protein endocytosis was diminished. Changes in UPR included enhanced peIF2a, pPERK, CHOP, and BiP levels. Parallel studies in cultured cells indicated sensitivity to chemical chaperones ameliorating proteostasis.

Conclusions: These results suggest a so far unrecognized role of proximal tubular homeostasis in long term CsA-induced nephrotoxicity. Addressing UPR failure and restitution of proteostasis in proximal tubule may, therefore, have renoprotective potential.

PO2388

Kidney-Intrinsic TLR/MyD88 Signaling Regulates the Susceptibility of Delayed Graft Function Following Kidney Transplantation

Xingqiang Lai,[1,2] Longhui Qiu,[1] Jiao-Jing Wang,[1] Zheng J. Zhang.[1] *[1]Comprehensive Transplant Center, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Organ Transplant Center, The Second Affiliated Hospital of Guangzhou Medical University, Guangzhou, China.*

Background: Delayed graft function (DGF) due to transplant ischemia/reperfusion injury (IRI) adversely affects up to 50% of deceased-donor kidney transplant (KTx) recipients. However, key factors contributing to the severity of IRI remain unclear. We hypothesize that kidney-intrinsic MyD88/Trif pathways could be a key determinant of DGF.

Methods: Kidneys from MyD88 knockout (KO) or MyD88 and Trif double knockout (DKO) mice were harvested and stored in a cold preservation solution (UW) for 4 hours, and then transplanted into bi-nephrectomized syngeneic or allogeneic recipients. Graft survival, renal function, histology change, phenotype analysis, and expression of involved genes, were observed and/or determined. Primary RTECs isolated from B6 and BALB/c mouse kidneys were stimulated by lipopolysaccharide (LPS) and cytokines in supernatant were measured.

Results: C57BL/6 (B6) kidneys were more susceptible to IRI following syngeneic transplant compared to BALB/c kidneys. Genetic ablation of MyD88 in B6 donors, but not BALB/c donors significantly reduced creatinine levels at post operation day (POD) 1-2, compared with wild-type (WT) kidneys. Moreover, compared with recipients of WT kidneys at POD 1-2, recipients of MyD88/Trif DKO kidney allografts showed improved graft function that was consistent with improved tissue integrity. Strikingly, MyD88/Trif DKO in the donor induced indefinite renal allograft survival and preserved intact renal allograft architecture at POD 100. In vitro study showed that levels of cytokines were increased by both B6 and BALB/c RTECs upon LPS (TLR4 agonist) stimulation, but BALB/c RTECs produced significantly higher levels of cytokines (including TNFα, IL-6, and IL-10) in a dose-dependent manner. Expression of KIM-1, a known biomarker for renal cell injury, were significantly increased by B6 RTECs as compared with that in BALB/c RTECs. These results suggest that kidney-intrinsic innate immunity, especially the TLR/Myd88 pathway, plays a critical role in the susceptibility to transplant IRI and DGF.

Conclusions: Kidney-intrinsic TLR/Myd88 signaling regulates the susceptibility of delayed graft function following kidney transplantation.

Immunohistochemical and Molecular Characterization of Immune Cells in Pediatric Renal Allografts: Mononuclear Phagocytes Correlate with Rejection, Re-Transplantation, Graft Function, and Fibrosis

Jessica Schmitz,[1] Sarah Senger,[1] Abedalrazag A. Khalifa,[1] Helge Stark,[3,4] Danny Jonigk,[3,4] Lars Pape,[2] Jan H. Braesen.[1] *[1]Hannover Medical School, Institute of Pathology, Nephropathology Unit, Hannover, Germany; [2]Hannover Medical School, Pediatric Nephrology, Hannover, Germany; [3]Hannover Medical School, Institute of Pathology, Hannover, Germany; [4]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Hannover, Germany.*

Background: Standardized markers of immune cell infiltration may improve diagnostics in renal grafts. To date, no larger study investigating the role of immune cells in renal pediatric allografts exists and their impact on long-term outcome is poorly understood. Children are more prone to graft tolerance, have a more naive immune system and adaptive immune responses to allografts thus might differ from adults.

Methods: Renal graft samples (n=202) from 59 pediatric patients (63% male, mean age 10 years) transplanted 2000-2017 at our center were re-evaluated according to recent Banff criteria and stained for macrophages, dendritic cells, B cells and T cells (CD68, CD206, CD163L1, CD209, CD20, CD3). Quantification of immune cells was performed in whole slide images (WSI) using image analysis software (QuPath). Results were obtained separately for cortex, medulla and extrarenal tissue and displayed as percentages (%) of positively stained area. Additionally, RNA was isolated from paraffin tissue and used for quantification of >700 gene transcripts related to graft immunology (NanoString Human Organ Transplant Panel).

Results: In TCMR (T cell-mediated) and ABMR (antibody-mediated) rejection cortical macrophages were more frequent than in samples without rejection. B cells were most abundant in TCMR. In re-transplants a higher density of macrophages than in first allografts was observed. Protocol biopsies had lower macrophage numbers than indication biopsies. Infiltration of dendritic cells revealed higher densities in samples with i-IFTA. Macrophage numbers correlated negatively with kidney function (eGFR) and positively with fibrosis. Results obtained by NanoString technology confirmed high expression of macrophage-associated gene trancripts (e.g. CCL2, CXCL10) during graft rejection and stratified samples according to Banff morphological diagnosis.

Conclusions: Infiltrating immune cells, particularly mononuclear phagocytes, are highly abundant in pediatric renal transplants in rejection, re-transplantation and fibrosis and might influence long-term graft function. Gene expression analysis using the NanoString Human Organ Transplant Panel may supplement and confirm morphological diagnosis.

PO2390

IL-6- and IL-17-Mediated Inflammation Amplifier Loop in Chronic Antibody-Mediated Rejection

Narayan Prasad, Mantabya K. Singh, Vikas Agarwal. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Renal fibrosis is a pathological condition associated with chronic inflammation that may result from a cellular injury and repair and result into late graft loss. In chronic inflammation, IL-6 combined with sIL-6R with gp130, together these complex activate the IL-6 trans signalling and control the transition from acute to chronic inflammation by the recruitment of MCP1 by activating NFkB and STAT3 signaling. We studied whether IL-17A and IL-6 mediated synergistic activation of inflammation amplifier loop is operational in CABMR.

Methods: CABMR patients were recruited according to revised Banff 2017 classification for the fibroblast culture from Renal Biopsy patients in vitro. Primary

Fibroblast culture from CABMR patients were cultured to purity and to mimic this condition fibroblast were pre stimulated with IL-6 (20ng/µl), IL-17 (50ng/µl), IL-6 plus IL-17 for 24 hrs and culture supernatant were collected for IL-6 ELISA to see synergistic activation. Serum IL-6 levels of CABMR and Non-CABMR patients were measured by ELISA. mRNA expression of pro-fibrotic genes; COL1A1, FN1, ASMA1, and anti-fibrotic gene; MMP2/TIMP was analyzed with real-time PCR. Student's t-test was used for statistical analysis in SPSS 17 software.

Results: IL-6 in sera of CABMR patients was significantly higher ($p<0.001$) than non-rejection patients. In comparison to IL-6 and IL-17 alone these cytokines synergistically induced more IL-6 production from renal fibroblasts(Fig 1). Together IL+IL-17 signicantly increased the expression of COL1A1, ASMA1, Fibronectin and CCL2(MCP1) and reduced expression of MMP2 gene against GAPDH gene compared to alone IL-6, IL-17 and untreated fibroblasts.

Conclusions: CBMR is perpetuated by inflammation amplifier or synergistic induction of IL-6 and IL-17 which results in chronic inflammation and Allograft rejection. Anti-Il-6 may attenuate the CABMR related injury.

Funding: Government Support - Non-U.S.

B-Cell Maturation Phenotypes and Time Post-Transplant

Alcino Gama, Olivier Desy, Stephanie Beland, François Bouchard-Boivin, Sacha A. De Serres. *CHU de Quebec-Universite Laval, Quebec, QC, Canada*.

Background: Over the past decade, B cell participation in allograft response has been progressively elucidated. Beside the occurrence of DSA (donor-specific alloantibodies), different patterns of B cell phenotypes are also being related to graft outcome. Loss of naive B cells and appearance of memory B cells have been linked to chronic rejection and ultimately to graft loss. Here we show the impact of time post-transplant on phenotypic B cell changes, particularly regarding different distributions of naive B cells.

Methods: Single-center, observational cohort of 82 kidney transplant recipients (KTr), adults and clinically stable. Blood samples were collected between January 2015 and November 2018. Peripheral blood mononuclear cells (PBMCs) were isolated and analyzed on flow cytometry. B cells (CD19+) were stained for CD38 and IgD and classified according to Bm classification (IgD vs CD38).

Results: The median time post-transplant was 2.9 [0.9-9.89] years and the mean age was 54±13 years. 63% of the patients were males and mean eGFR was 49±17mL/min. B cells absolute counts were lower in later phases post-transplant (R -0.4, $p<0.01$). Among all B cell subtypes, Bm2 compartment (comprised mainly by naive B cells) had the most significant reduction in both absolute counts (R -0.62, $p<0.01$) and relative percentage (R -0.58, $p<0.01$) over time. On the opposite, mature B cells (both Bm5 and early Bm5 compartments) absolute counts did not differ over time (R -0.04 and 0.11 respectively, $p>0.05$) whereas the percentages of them were positively correlated with time post-transplant (R 0.40 and 0.56 respectively, $p<0.01$). Linear regression model showed that the absolute reduction in Bm2 cell compartment (i.e. naive B cells) was independent of age, sex, graft function and immunosuppression scheme.

Conclusions: Patients with longer time post-transplant have fewer circulating peripheral B cells. Phenotypic analysis of B cell subsets reveals that this reduction is due to an absolute decrease in naive B cells counts. Mature B cell absolute numbers, on the other hand, did not change significantly. Either exhaustion due to long-term immunosuppression or immunologic accommodation due to chronic alloantigen exposure could explain these observations.

PO2392

Donor Derived Cell-Free DNA in Renal Transplants, AlloSure vs. Prospera

Ali Khalil,[1] Salman Khan,[1] Erica Kalu,[2] Muhammad Saim,[1] Mark J. Lerman.[1] Medical City Dallas Kidney Transplant *[1]Medical City Dallas Hospital, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX*.

Background: The risk for allograft loss remains high due to rejection. Measuring donor cell free DNA has recently become an important noninvasive test for renal allograft injury and rejection. Two of the commercially available tests to measure dd -cfDNA, are Allosure(AS) and Prospera.

Methods: We measured dd -cFDNA in 44 post kidney transplants simultaneously using both tests. Patients were 3 to 50 months post kidney transplant and all samples were drawn for cause. Eleven of the 44 patients had allograft biopsies, see table. All patients had routine labs including trough CNI levels and in some cases DSA and/or BK PCR.

Results: 44 patients had side by side dd cf-DNA done using AS and Prospera for cause. There were 5 patients with either ACR 1a or 1b or AMR on biopsy. 6 patients had no rejection on biopsy. Please see image for statistical analysis.

Conclusions: There was no statistical difference between dd -cfDNA as measured by both commercial tests in all 44 patients, including 5 with ACR or AMR and 6 without rejection by biopsy. We acknowledge the number of patients who underwent biopsies were small. Prospera demonstated larger measurements of dd-cfDNA in comparison to AS, but this was not statistically significant p=0.27. Side by side analysis showed AS had marginally better AUC but no significant differences between diagnostic test characteristics observed. AS had better specificity, PPV, and NPV, but this did not reach statistical significance.

Donor-Derived Cell-Free DNA Kinetics After Kidney Transplant Biopsy

Yousuf Kyeso,[1] Anshul Bhalla,[2] Alyssa P. Smith,[1] Safa Alakhdhair,[1] Mohammad Abuzeineh,[1] Daniel C. Brennan,[1] Sami Alasfar.[1] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Methodist University Hospital, Memphis, TN*.

Background: Donor-derived cell-free DNA (dd-cfDNA) has generated interest as a potential biomarker for kidney transplant (KT) rejection. It is possible that the KT biopsy procedure itself can cause the release of dd-cfDNA in the blood stream, therefore affecting the reliability of this assay in the post biopsy period. In this study we evaluated the effect of KT biopsy on the level dd-cfDNA and assessed the magnitude and duration of this effect.

Methods: We conducted a single arm prospective study. Samples were collected from 16 adult KT recipients undergoing renal allograft biopsy. All participants had samples drawn within eight hours prior to the biopsy (pre-biopsy), within 20 minutes (hour 0), 2 hours after (hour 2), and 24-48 hours (hours 24-48) after the biopsy.

Results: Mean age at the time of biopsy was 50.6 ± 7.02 years. Most participants were men and Caucasian. Mean serum creatinine at the time of biopsy was 2.24 +/- 0.42 mg/dL. The most common reason for obtaining biopsy was rise in serum creatinine, while 4 patients had the biopsy due to elevation in dd-cfDNA. The pre-biopsy time point was compared against all remaining time points. At hour 0 and hour 2, there was a significantly larger log dd-cfDNA mean scores compared to pre-biopsy time point (0.37 vs -0.44, p=0.006), (0.35 vs -0.44, p=0.03) respectively. By 24-28 hours post biopsy there was no significant difference in log dd-cfDNA mean score compared to the pre-biopsy score.

Conclusions: KT biopsy leads to an increase in dd-cfDNA percentage after the procedure, however, this rise is transient and resolves by 24-48 hour after the biopsy. Providers can obtain dd-cfDNA level as soon as 48 hours post biopsy with high confidence that the levels have not been affected by the biopsy.

Observed longitudinal Log-Transformed AlloSure Measurements by Assessment Time Point

PO2394

Development and Clinical Experience with a Cell-Free DNA Monitoring Algorithm for Kidney Re-Transplants

Trudy McKanna, Ebad Ahmed, William Simmons, Meredith Pastrick, Philippe M. Gauthier, Dianne Keen-Kim. *Natera, Inc, San Carlos, CA.*

Background: The presence of donor-derived cell-free DNA (dd-cfDNA) in blood samples from kidney transplant recipients can be utilized as a biomarker for transplant rejection.[1] Failure of the original allograft due to rejection, infection, or recurrent disease leads to retransplants, observed in up to 10% of all kidney transplant patients.[2,3] In these cases, the original transplanted kidney is generally left in-situ. A rapid, accurate, and noninvasive diagnostic test assessing dd-cfDNA using single nucleotide polymorphism (SNP) based massively multiplexed PCR (mmPCR) test (Prospera™) may be utilized to detect allograft rejection.[1] Among retransplant patients, this test can detect both donor fractions in the plasma, when both the new and previously transplanted kidneys are releasing cfDNA. **Objective:** To present the clinical performance of the SNP-based mmPCR test analysis algorithm on samples from patients with kidney retransplants in which allografts are present from two genetically distinct donors.

Methods: Plasma samples from a cohort of second transplant patients were collected and processed as described previously.[1,4] The SNP-based mmPCR test algorithm is designed to detect all donor fractions in the plasma, when both the newly transplanted kidney as well as previously transplanted kidney(s) may be releasing cfDNA into the plasma. This algorithm estimates the total fraction of DNA due to all donor fractions combined.

Results: We present the clinical performance of patients with a second kidney transplant by this retransplant algorithm. In our dataset to date, no significant difference in dd-cfDNA levels compared to single allograft recipients was observed, suggesting limited cfDNA shedding from the initial kidney transplanted. Our results confirm the ability of this assay to analyze and quantify dd-cfDNA levels in kidney retransplant patients.

Conclusions: Our results indicate that performance of this SNP-based mmPCR test is preserved in repeat transplant recipients. Non-invasive assessment of dd-cfDNA in retransplant patients may be used to detect the presence of injury or rejection of the transplanted organ at an early stage, facilitating physician management around change of anti-rejection therapy.

PO2395

Correlation of Donor-Derived Cell-Free DNA with Histology and Molecular Diagnoses of Kidney Transplant Biopsies

Irfan A. Moinuddin,[1] Layla Kamal,[1] Dhiren Kumar,[1] Anne L. King,[1] Ryan Winstead,[1] Philip F. Halloran,[2] Gaurav Gupta.[1] *[1]Virginia Commonwealth University, Richmond, VA; [2]University of Alberta, Edmonton, AB, Canada.*

Background: Circulating donor-derived cell free DNA (ddcfDNA;CareDx, Brisbane, USA), a non-invasive test that could detect rejection in kidney transplants, was validated using histologic diagnoses. The interpretation of these findings could be difficult due to variable inter- and intra-observer agreement with regards to histologic diagnoses and evolving classifications overtime. The centralized Molecular Microscope(MMDx; Edmonton, CA) tissue gene expression platform may provide increased precision to traditional histology

Methods: In this single-center prospective study of 208 biopsies, we present novel data on calibration of cfDNA using simultaneous assessments of all 'for-cause' and surveillance biopsies with histology(Hx) and MMDx. AUC curves were calculated using the previously published ddcfDNA cut-offs of < 0.21% to rule-out rejection and >1% to rule-in rejection

Results: Of 208 biopsies done at a median of 5.8 months post-transplant, 108(52%) were done for allograft dysfunction; 74(36%) for surveillance (due to DSA) and 26(12%) for post-rejection treatment surveillance. There were significant discrepancies between Hx and MMDx; with MMDx(92; 44%) identifying a higher number of rejection cases vs Hx(79; 38%). While MMDx identified a higher number of antibody-mediated rejection cases(65; 31%) than Hx(43; 21%); the opposite was true for T-cell mediated rejection[TCMR; Hx:27(13%) vs MMDx: 13 (6%)]. AUC Curves for cfDNA concentration and prediction of rejection were more robustly correlated with MMDx(AUC=0.830; p<0.001) than with Hx(AUC=0.75; p<0.001). The median cfDNA levels decreased significantly in responders to rejection treatment(median 0.94 to 0.20; p=0.015) vs non-responders(0.76 to 0.82; p=0.25)

Conclusions: In this single-center study, for the first time we describe the calibration of ddcfDNA with simultaneous assessment of kidney transplant biopsy with traditional histology and MMDx. We confirmed and expanded on the data from the DART study where a cut-off≥1% was highly sensitive and specific for ruling-in rejection. We report the correlation of cfDNA with response to rejection therapy. We propose that the combination of tissue gene expression using the molecular microscope and blood-based ddcfDNA may add precision to traditional histology and could change future practice and treatment paradigms

PO2396

Elevated Donor-Derived Cell-Free DNA (dd-cfDNA) Attributed to Angiotensin II Type 1 Receptor Antibodies (AT1R-Ab) in Renal Re-Transplantation

Howard H. Coke,[1] Matthew Van Norman,[1] Akshta Pai,[2] Aleksandra De Golovine,[2] Angelina Edwards.[2] *[1]University of Texas McGovern Medical School, University of Texas John P and Katherine G McGovern Medical School, Houston, TX; [2]Memorial Hermann Texas Medical Center, Houston, TX.*

Introduction: Complications of renal transplants include graft rejection and failure. Noninvasive dd-cfDNA values greater than 1% detect renal allograft injury and rejection, prior to changes in creatinine. Although antibody mediated rejection (AMR) typically involves donor specific antibodies (DSA) to human leukocyte antigens (HLA), non-HLA antibodies may also impact allograft outcomes. This series of re-transplantation patients with graft injury from AT1R-Ab (>10 U/mL) shows improvement in dd-cfDNA levels with initiation of an ARB, Losartan.

Case Description: Case #1: 23 year-old man with history of CKD IV due to hypoplastic kidneys. First transplant living unrelated donor failed due to renal vein thrombosis. Received a 2nd deceased donor transplant (DDRT) with thymoglobulin induction. Combined panel reactive antibodies (cPRA) was 99%, with no DSA. Post-transplant allograft function was excellent with nadir creat of 1.0mg/dL. Non-invasive allograft surveillance was initiated with initial dd-cfDNA (ALLOSURE, CareDx, Brisbane, CA) elevated at 1.8%. Antibody assessment was negative for DSA but positive for AT1R-Ab at 28 U/mL. Losartan was initiated with a sustained decrease in dd-cfDNA to <0.3% and stable creatinine levels. Case #2: 63 year-old woman with ESRD from hypertension. Prior living donor transplant failed due to chronic allograft nephropathy. Received 2nd DDRT with thymoglobulin induction given cPRA of 98%, with no DSA. Post-transplant allograft function was excellent with nadir creatinine of 0.8 mg/dL. Non-invasive allograft injury surveillance showed an acute rise in dd-cfDNA to 3.9% on post-operative week 5. Despite stable creatinine, a renal biopsy showed C4D-negative, mild antibody mediated rejection with peritubular capillaritis (ptc 2) and glomerulitis (g1). Antibody assessment showed no DSA but positive AT1R at 16 U/mL. Following Losartan initiation, dd-cfDNA decreased to <1%, with continued excellent graft function.

Discussion: AT1R-Ab may be more prevalent in the re-transplant population and is a causative factor for accelerated allograft injury, chronic fibrosis, and graft loss. Early detection of kidney injury via dd-cfDNA, prompt assessment of AT1R-Ab, and initiation of ARB therapy may lead to preserved allograft function, particularly in high immunologic risk patients.

PO2397

Class II Donor-Specific Anti-HLA Antibody Level Is the Major Determinant of Elevated Donor-Derived Cell-Free DNA in Renal Allograft Recipients

Maria Butiu,[1] Bogdan Obrisca,[2] Ramasamy Bakthavatsalam,[1] Kelly D. Smith,[1] Iris C. De Castro,[1] Christopher D. Blosser,[1] Lena Sibulesky,[1] Catherine Kling,[1] Gener Ismail,[2] Bogdan M. Sorohan,[2] Nicolae Leca.[1] *[1]University of Washington, Seattle, WA; [2]Fundeni Clinical Institute, Bucharest, Romania.*

Background: Dd-cfDNA is a biomarker of allograft injury used for rejection risk monitoring. We sought to analyze the relationship between dd-cfDNA and DSA.

Methods: We included all kidney transplant recipients (n=171) who underwent DSA and dd-cfDNA testing as part of their clinical care between 9/17-12/19 at our center. We aimed to identify independent predictors of high dd-cfDNA (at a cut-off of 1%).

Results: Table 1 outlines clinical characteristics. There was a strong association between absolute dd-cfDNA level and DSA MFI category (Figure 1). In multivariate logistic regression analysis, DSA MFI was an independent predictor of high dd-cfDNA (Figure 2).

Conclusions: Dd-cfDNA is strongly associated with class II DSAs and MFI level. Variability observed identifies dd-cfDNA as a potential biomarker for monitoring allograft injury status in patients with DSA.

Case Series: Systemic Infection Alters Background Cell-Free DNA and Influences Results of Donor-Derived Cell-Free DNA Transplant Rejection Assays

Suphamai Bunnapradist,[1] Philippe M. Gauthier,[2] Hossein Tabriziani,[2] Ryan Swenerton,[2] Ebad Ahmed,[2] Trudy McKanna,[2] Paul R. Billings.[2] *[1]University of California Los Angeles, Los Angeles, CA; [2]Natera, Inc, San Carlos, CA.*

Introduction: Donor-derived cell-free DNA (dd-cfDNA), a biomarker for kidney transplant rejection (1,2) is reported as a percentage of background cfDNA. Various factors affect total cfDNA levels (3,4). We present 3 cases with elevated background cfDNA where dd-cfDNA was assayed for rejection assessment.

Case Description: 1: A 78 year old man with end-stage renal disease (ESRD) underwent a kidney transplant. A biopsy at +6 months (m, all time points relative transplant date) due to an elevated creatinine level indicated an acute T cell-mediated rejection (TCMR). At +7m, the patient tested positive for BK viremia, and was treated. He was admitted for nephrectomy of his native kidney at +14m and tested positive for herpetic and cytomegalovirus (CMV) esophagitis and treated. A cfDNA analysis was negative for rejection with background cfDNA = 10,326 Arbitrary units (AU)/mL (~21X median cfDNA).) Banff chronic active cellular rejection was confirmed from a subsequent biopsy. **2**: A 62 year old woman with ESRD who underwent a kidney transplant had a cfDNA assay +3 years, that was reported as a negative result. However, the background was elevated at 3,466 AU/mL (~7X median). She had a biopsy that showed BK virus-associated nephropathy and TCMR. **3**: A 53 year old woman with ESRD had a kidney transplant from an ABO incompatible donor. A month later, she was diagnosed with dengue fever followed by acute allograft dysfunction. A biopsy at +6m showed active antibody-mediated rejection (ABMR). On a cfDNA assay at +7m indicated a negative result; however with an elevated background (6344 AU/mL, ~13X median). A biopsy showed resolution of ABMR and borderline acute cellular rejection.

Discussion: In all 3 cases, active viral infections may have caused elevated background cfDNA leading to false negative results in 2 cases. A cfDNA-based rejection assay only reporting a percentage of the total cfDNA may be inaccurate, particularly in patients with viral infections. Dd-cfDNA rejection assays should account for the variable background cfDNA when reporting results. 1. Bloom RD et al. *J Am Soc Nephrol.* 2017; 28(7):2221–32; 2. PO2399

Donor-Derived Cell-Free DNA Identifies Patients with Antibody-Mediated Rejection and Strongly Correlates Histologically with Microvascular Inflammation

Bogdan Obrisca,[2] Maria Butiu,[1] Ramasamy Bakthavatsalam,[1] Kelly D. Smith,[1] Iris C. De Castro,[1] Christopher D. Blosser,[1] Lena Sibulesky,[1] Catherine Kling,[1] Gener Ismail,[2] Bogdan M. Sorohan,[2] Nicolae Leca.[1] *[1]University of Washington, Seattle, WA; [2]Fundeni Clinical Institute, Bucharest, Romania.*

Background: Accurate and timely detection of rejection is central to improving long-term kidney transplant outcomes. We sought to characterize the association of dd-cfDNA level with rejection status and histological lesions.

Methods: We included all patients (n=54) that underwent a kidney transplant biopsy for suspicion of rejection at our center between 9/17-12/19. Concurrent dd-cfDNA and DSA testing was obtained. Rejection type (Banff 2017) and histological lesions were tested for association with dd-cfDNA level.

Results: 18 patients had ABMR (6 mixed ABMR/TCMR), while 12 patients had TCMR alone. Of those with ABMR, 94.4% had a dd-cfDNA level >1%, compared to 16.6% of those with TCMR alone (p<0.001). Of those with a high dd-cfDNA (>1%), 76.2% had both DSAs and ABMR. In multivariate logistic regression analysis, a high dd-cfDNA was a more important predictor of ABMR than a DSA MFI level over 2500 (Fig1). A high dd-cfDNA accurately discriminates ABMR (AUC=0.96; 95%CI, 0.92 to 1.00; p<0.001), with a positive and negative predictive value of 80.9% and 96.9%, respectively. Dd-cfDNA level showed a strong correlation with microvascular inflammation (Fig2), but not with tubulitis or interstitial inflammation.

Conclusions: Our study confirms the high diagnostic accuracy of dd-cfDNA for ABMR, while the strong association with elementary lesions of microvascular inflammation supports the specificity of this test for antibody-mediated allograft injury.

Impact of Body Mass Index on Baseline Donor-Derived Cell-Free DNA in Kidney Transplant Recipients

Harsha Aramada, Bhavna Chopra, Kalathil K. Sureshkumar. *Allegheny Health Network, Pittsburgh, PA.*

Background: Donor derived cell free DNA (dd-cfDNA) is useful in predicting acute rejection in renal allografts. The technology uses next generation sequencing and does not require donor genotyping. dd-cfDNA is expressed as a percentage of the total (including self and non-self) circulating DNA fragments. Since self-portion of cell free DNA can vary according to body size, we aimed to test the hypothesis that expressed percent of baseline dd-cfDNA can vary by the recipient's body mass index (BMI).

Methods: Our center has been doing for-cause as well as surveillance (for high immunologic risk) dd-cfDNA in kidney transplant recipients (KTRs) using AlloSure (CareDx, Brisbane, CA). We identified patients who underwent kidney transplantation between September 2017 and June 2019 and had serial dd-cfDNA levels. A dd-cfDNA value ≥ 1% prompted allograft biopsy. KTR with biopsy evidence for rejection or other injuries were excluded from the analysis. Study subjects were divided into BMI (kg/m^2) groups as follow: <25, 25-29.9, ≥30. Baseline dd-cfDNA values were compared between BMI groups.

Results: There were 88 (81 first-time and 7 repeat) KTRs during the study period who had dd-cfDNA measurements and available BMI. We excluded 16 first-time and 3 repeat KTRs from the analysis due to biopsy evidence of rejection. The remaining 69 patients had 227 dd-cfDNA levels available for analysis. Patients were divided based on BMI categories with stratification of baseline dd-cfDNA values as shown in table 1. There were no significant differences in baseline dd-cfDNA values for BMI groups <25 vs. 25-29.9 (0.63 ± 0.63% vs. 0.41±0.27%, p=0.16) and BMI groups 25-29.9 vs. ≥30 (0.41±0.27% vs. 0.33±0.16%, p= 0.22). However, there was a trend towards significantly higher baseline dd-cfDNA values in BMI group <25 vs. ≥30 (0.63±0.63% vs. 0.33±0.16%, p=0.06).

Conclusions: Our study showed a trend towards significant differences in dd-cfDNA values between extremes of BMI groups. These differences could become significant with larger study subjects. Our findings point towards the need for normalization of dd-cfDNA values with respect to body size for reporting purposes.

Table 1. BMI and dd-cfDNA

BMI (kg/m2) categories	<25	25 -29.9	≥30
Number of patients	19	29	21
Number of dd-cfDNA tests	67	96	64

Protocol-Based Donor-Derived Cell-Free DNA Surveillance in Kidney Transplant Recipients: A Single-Center Experience

Pitchaphon Nissaisorakarn, Het Patel, Martha Pavlakis, Amtul Aala, Nikhil Agrawal. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Kidney biopsy is invasive and has limited utility when used as a surveillance test post-transplant. Donor-derived cell-free DNA (dd-cfDNA) surveillance testing has never been studied in comparison with other routinely performed surveillance tests.

Methods: Our transplant center implemented the dd-cfDNA (Allosure ®) surveillance protocol (1,2,3,4,6 months and then quarterly post-op) in kidney transplant recipients starting July 2018, in addition to our existing protocol measurements of serum Cr, proteinuria and DSA. We retrospectively reviewed all kidney alone transplant recipients transplanted between July 2018- April 2020. Data collection was done at time of dd-cfDNA surveillance and included: dd-cfDNA (positive if >1% dd-cfDNA), elevated Cr (≥0.3mg /dL from Baseline), elevated proteinuria (≥0.3 mg/dL from baseline), DSA (if available).

Results: 366 screening dd-cfDNA test results were reviewed from 84 patients. There were 13/366 positive dd-cfDNA tests in 8/84 patients. 5 of the 8 patients underwent a kidney biopsy which showed: 4 rejections (2 humoral, 2 cellular) (for 1 patient who had cellular rejection, dd-cfDNA test was the only surveillance test that was positive) and 1 ATN (dd-cfDNA test was borderline positive at 1.0%). The remaining 3 patients did not undergo a biopsy and repeat dd-cfDNA testing improved without intervention. In the 353/366 negative dd-cfDNA tests in 76 patients: 8 patients underwent a biopsy: 2 patients who had increased Cr showed borderline acute cellular rejection, 3 had recurrent disease (MPGN, DM, IgAN) and 3 showed ATN/Vascular disease/IFTA. In the 2 patients with borderline acute cellular rejection dd-cfDNA was <0.7%.

Conclusions: We found that the addition of surveillance dd-cfDNA testing to current testing algorithm was able to identify rejection in 1 patient, when others surveillance tests were negative. A negative result may obviate the need for biopsy, including protocol biopsies in centers who perform them.

PO2402

Successful Transplantation Outcomes Using Deceased Donors with AKI

Amy L. Harshman, Luke Preczewski, Meghan Muldoon, Giselle Guerra. *Miami Transplant Institute, Miami, FL.*

Background: Kidneys from deceased donors with acute kidney injury (AKI) are discarded at a higher rate than those without AKI, exacerbating the organ shortage. This paper reviews outcomes of kidneys from deceased donors with AKI over a four-year period at a single transplant center.

Methods: We analyzed 1119 consecutive deceased donor kidney adult recipients transplanted from 2016 through 2019 at our center. Donors were classified using AKIN criteria for AKI based on increase of terminal serum creatinine (SCr) over initial SCr. Death-censored graft survival and eGFR (MDRD) were compared.

Results: 911 recipients received kidneys from donors with no AKI (Stage 0). 208 (18.6%) received kidneys from donors with AKI. 45 (4.02%) had Stage 1 AKI, 59 (5.27%) had Stage 2 AKI, and 104 (9.29%) had Stage 3 AKI. There were no significant differences between the AKI and non-AKI groups in recipient age, gender, ethnicity, or Estimated Post-Transplant Survival score. Using a Cox Proportional Hazards Model, death-censored graft survival at 1 year was not distinguishable between recipients whose donor had any stage of AKI versus donors without AKI (HR 0.94, p=0.854) nor among AKI stages (Figure 1). Mean eGFR by MDRD formula for recipients alive and with followup at 1 year was 60.0 (SD 23.2) in recipients with non-AKI donors and 61.9 (SD 26.1) in recipients with AKI donors, which was of no statistical significance (p=0.4384). The rate of delayed graft function was significantly higher in recipients from AKI donors (62.0%) versus non-AKI donors (31.5%), p<0.0001.

Conclusions: Recipients of AKI donors did not yield inferior outcomes to those of non-AKI donors at 1 year. Increased DGF can be anticipated, but does not appear to have any lasting impact on graft survival or renal function. As such, transplant centers should consider expanding the use of these kidneys for any waitlisted candidate.

PO2403

Combined Impact of Presensitization and Delayed Graft Function on Allograft Outcome in Deceased Donor Kidney Transplantation: Nationwide Cohort Study

Byung ha Chung,[1] Hanbi Lee,[1] Yohan Park,[1] Tae Hyun Ban,[2] Sang Heon Song,[3] Jaeseok Yang,[4] Curie Ahn,[4] Chul Woo Yang.[1] Korean Organ Transplantation Registry Study group *[1]Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; [2]Eunpyeong St. Mary's hospital, Seoul, Republic of Korea; [3]Pusan National University Hospital, Busan, Republic of Korea; [4]Seoul National University College of Medicine Department of Internal Medicine, Seoul, Seoul, Republic of Korea.*

Background: Pre-sensitization to HLA has detrimental effect on allograft rejection, worse allograft function and survival. Delayed graft function (DGF) is associated with poor allograft outcome by ischemia-reperfusion injury. We undertook analysis to determine combined association of pre-sensitization to HLA and DGF on allograft outcome in deceased donor kidney transplantation (DDKT) and whether there is a synergistic effect.

Methods: In our prospective cohort study, between May 2014 and June 2019, 1370 deceased donor kidney transplants were assigned into 2 groups; pre-sensitized and non-pre-sensitized. Each group was divided into 2 subgroups according to DGF. Pre-sensitization was defined as the presence of donor specific antibodies (DSA) or the presence of panel-reactive antibody (PRA), combination with crossmatch positive. DGF was defined as the need for dialysis before discharge. We compared the clinical outcomes including allograft rejection, the change of allograft function, infectious and cardiovascular complication and allograft survival.

Results: Pre-sensitization group were 137 (10.0%) patients and others (n=1233, 90.0%) belonged to non-sensitized group. Pre-sensitization-DGF subgroup was 21 (15.3%) and pre-sensitization-non-DGF group was 116 (84.7%). Non-pre-sensitization-DGF subgroup was 133 (9.7%) and non-pre-sensitization-non-DGF group was 1100 (80.3%). In both pre-sensitization and non-pre-sensitization groups, allograft function using eGFR by CKD-EPI equation (mL/min/1.73m^2) was lower in DGF subgroup than non-DGF subgroup. In contrast, allograft rejection rate showed no significant difference between DGF and non-DGF subgroup within non-pre-sensitization group (15.0% vs 12.9%, *p*=0.493). There was no significant difference between DGF and non-DGF subgroups in both groups in regard to allograft survival and patient survival.

Conclusions: DGF combined with pre-sensitization had much worse effect on allograft outcome in terms of allograft rejection. Therefore, we suggest more careful monitoring or surveillance for allograft rejection when DGF occurred in DDKT with pre-sensitization to HLA.

PO2404

The Clinical Significance of Preformed C1q-Binding Donor-Specific HLA Antibodies in Kidney Transplantation

Sua Lee,[1] Byung ha Chung,[2] Chul Woo Yang.[2] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Catholic University of Korea, Seoul, Republic of Korea.*

Background: The anti-human leukocyte antigen (HLA) antibodies are well known for risk factor of rejection or allograft loss in kidney transplantation (KT). De novo complement component 1q-binding donor-specific anti-HLA antibodies (C1q-binding DSAs) are already reported to be associated with an increased risk of acute allograft rejection in KT. This study investigated the clinical significance of identification of preformed C1q-binding DSAs for predicting graft outcomes in KT.

Methods: From December 2016 to December 2018, 323 recipients underwent KT at Seoul St. Mary's Hospital. If the results of panel reactive antibodies (PRA) were positive in the pre-transplant examination, DSAs and C1q-binding DSAs were performed using Luminex Single Antigen Bead Assay (SAB) at the same time. Graft outcomes in term as Chronic Kidney Disease-Epidemiology Collaboration estimated Glomerular Filtration Rate, biopsy proven acute rejection and graft survival were compared between recipients with preformed C1q-binding DSAs and recipients without preformed C1q-binding DSAs.

Results: Eighty-two of 323 recipients (25.4%) were evaluated DSAs and C1q-binding DSAs before transplantation. Among them, 40 recipients (48.8%) had preformed DSAs and 8 recipients (9.9%) had preformed C1q-binding DSAs. The higher MFI values of DSAs had higher prevalence of C1q-binding DSAs (9263.9 ± 3670.3 vs. 5955.3 ± 5245.5; p = 0.050). There was a strong correlation between the presence of DSAs against Class II and C1q-binding DSAs (p = 0.007; CI 95%, OR 9.333). Five of 21 patients (23.8%) with positive at least one of complement-dependent cytotoxicity (CDC) or flow cytometry crossmatch (FCXM) had preformed C1q-binding DSAs. There was a correlation between positivity of crossmatch and preformed C1q-binding DSAs (p = 0.024; CI 95%, OR 6.042). Four of 8 recipients (50%) in C1q-binding DSAs(+) group were confirmed acute antibody mediated rejection. C1q-binding DSAs(+) group had higher incidence of acute antibody mediated rejection than C1q-binding DSAs(-) group (p=0.044; CI 95%, OR 4.286).

Conclusions: The identification of preformed C1q-binding DSAs may be important in predicting acute antibody mediated rejection. Therefore, the surveillance such as protocol allograft biopsy is required for early detection of acute antibody mediated rejection after transplantation in patients with preformed C1q-binding DSAs.

PO2405

Potential Combined Use of Kidney Donor Profile Index (KDPI) and Estimated Post-Transplant Survival (EPTS) Scales to Predict eGFR Decline in Deceased Donor Kidneys

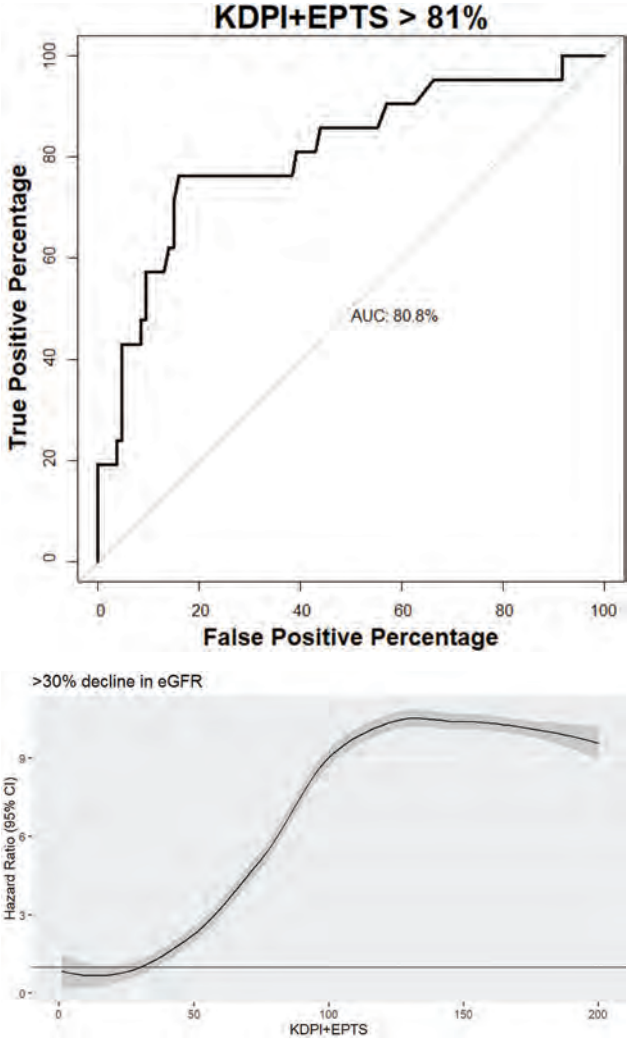
Pablo Maggiani,[1] Sergio Hernández-Estrada,[1] Odette Del Carmen Diaz Avendaño,[1] Christian P. Flores,[2] Benjamin Gomez-Navarro,[3] Maria Guadalupe R. Ramirez,[1] Jose H. Cano,[1] Maria Concepcion Oseguera-Vizcaino,[2] Daniel F. Ovando-Morga,[1] Mayra M. Matias Carmona.[1] *[1]Renal Transplant Unit, National Medical Center "20 de Noviembre", Mexico City, Mexico; [2]Renal Transplant Unit, Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Mexico; [3]Centro Medico Nacional de Occidente, Guadalajara, Mexico.*

Background: Utility of the sum of EPTS and KDPI scales to predict the decline of eGFR in patients who received a cadaveric donor transplant. Assess the reproducibility of the Organ Assignment System of the USA in our country.

Methods: 128 deceased-donor kidney transplant recipients at two National Mexican Hospitals between 2015 – 2017, retrospective, observational cohort study over 36 months following transplant. We include age, gender, primary renal disease, sensitization events, peak panel-reactive antibody, cold ischemia time, dialysis type and vintage, KDPI and EPTS, DGF, PTDM, Acute rejection, eGFR and cause of graft failure P. outcome: Relationship between a decrease >30% eGFR and the different combined scores of the KDPI and EPTS scales.

Results: The sum of the scores of the EPTS and KDPI scales >81% had a sens. 76% and a spec. 84% to predict a >30% decline in eGFR. AUC 80.8% (95% [CI] 0.002 to 0.005, p < 0.001). Multivariable Cox proportional hazard model: the sum of EPTS and KDPI scores >81% was associated with a 9.9-fold increase in losing more than 30% eGFR over the 36-months follow-up ([adjHR] 9.9; 95% [CI] 1.85 to 53.6, p = 0.007). Acute rejection was associated with a 3.1-fold increase in losing more than 30% eGFR ([adjHR] 3.1; 95% [CI] 1.15 to 8.72, p = 0.02).

Conclusions: Observing **the donor and the recipient as a sum can be an new tool** that helps us to predict the decline eGFR in Deceased Donor Kidneys transplants



PO2406

Vasopressin Use After Deceased Donor Kidney Transplant (DDKT): Patient Characteristics, Graft Function, and Clinical Outcomes

Muhammad Y. Jan, William Goggins, Muhammad S. Yaqub, Tim E. Taber, Dennis P. Mishler, Sharon M. Moe, Ranjani N. Moorthi, Michael T. Eadon, Jeanne Chen, Asif A. Sharfuddin. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Vasopressin (AVP) is used for maintenance of volume status and hemodynamics due to its vasopressor activity with less arrhythmogenic and ischemic potential. It has catecholamine sparing effect. AVP has been shown to improve rates of deceased organ donation. We studied AVP use post DDKT for improving hemodynamics with resultant effect on graft function and clinical course.

Methods: A retrospective chart review was done on patients >18 years of age who required AVP post operatively after a DDKT over 5 years (2012-2017). Recipient, donor characteristics, intraoperative parameters, hospital/ICU stay, graft failure, patient survival, and hyponatremia during first 48 hours were reviewed.

Results: A total of 43 patients fulfilled inclusion criteria. Refer to Table for summary. Total of 5 patients (11.6%) required dialysis, 3 of whom received donation of kidney after cardiac death. There were 3 deaths during the first 12 months (6.9%). Mean cold and warm ischemia time were 32.5±12.9 hours and 39.2 ±10.2 minutes, respectively. Mean time to start AVP was 6.8 hours post operatively and mean duration of AVP use was 43.2 with a median of 30 hours. 72.1% of patient also required dopamine. Mean hospital stay was 14.5 days and length of ICU stay was 5.4 days. Mean creatinine at day 7 was 4.0 ± 4.2 mg/dl. There was no incidence of hyponatremia during the first 48 hours. Graft survival was 72% at median follow up time of 7.2 years.

Conclusions: Patient requiring AVP post DDKT have unique characteristics - fewer anti-HTN medications and longer time on dialysis prior to transplant. A longer than median hospital length of stay was noted. To our knowledge this is the first study reviewing AVP use post DDKT. Future studies are needed to compare characteristics and outcomes with patients' who did not require AVP post DDKT.

Recipient Characteristics and Intraoperative BP (n=43)

Differences in Urinary Inflammatory Profiles in Donor-Recipient Pairs

Elizabeth Spiwak, Corina Nailescu, Andrew L. Schwaderer. *Riley Hospital for Children at Indiana University Health, Indianapolis, IN.*

Background: Renal transplant is the most common type of transplant performed in the US. Immunosuppressants are used in transplant recipients to prevent rejection. Kidney transplant recipients are at a higher risk for infection in the pre- and post-transplant state. Urine inflammatory profiles may lend insight to this balance between infection and rejection. Since donor and recipient urine is generated by genetically identical kidneys, it represents an ideal biosample for paired analysis.

Methods: Urine samples were obtained from stable children > 2 months post-transplant along with their donors (n=6) and another 8 recipient donor-recipient pairs (adult and children) that were collected for longitudinal samples; of which a pretransplant sample has been obtained. Using the V_PLEX Human CytoKine Panel (Mesoscale Discovery, Rockville MD) urine inflammatory mediators were quantified. The paired T-test or Wilcoxon test for parametric and nonparametric data respectively

Results: Interleukin (IL)7, IL15, Monocyte chemoattractant protein-1 (MCP-1) and Granulocyte-macrophage colony-stimulating factor (GM-CSF) were higher in the pediatric post-transplant recipients compared to their donors P values of 0.017, 0.037, 0.046 and 0.031 respectively. IL-9 was higher in recipient urine in pre-transplant patients (p=0.004) compared to donors.

Conclusions: Transplant patients have an elevated urine inflammatory mediator profile. Pretransplant patients have elevated IL-9 compared to their donors. Reasons for this altered inflammatory profile include immunologic, hemodynamic or physiologic changes intrinsic to the transplant procedure versus medications used to manage transplant patients.

Funding: NIDDK Support

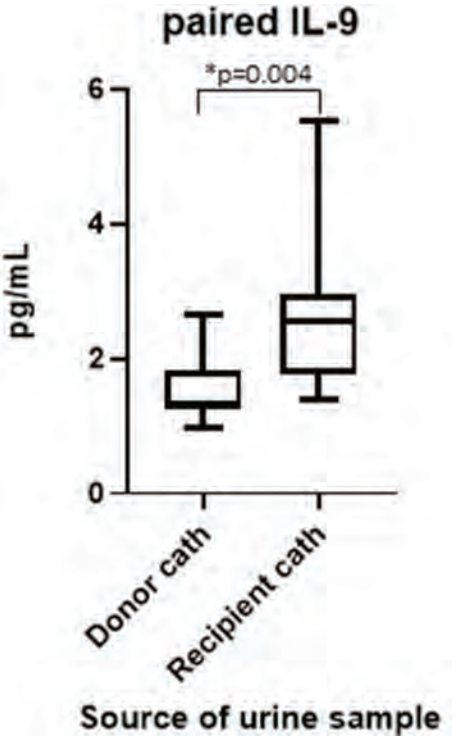

Figure 1. Catheterized urine samples from recipients at time of transplant have higher levels of IL-9 than their donors

PO2408

LIMS1 Gene Mismatching and Risk of Rejection in Kidney Transplant Recipients

Yasar Caliskan,[1] Safak Mirioglu,[2] Halil Yazici,[2] Ahmet B. Dirim,[2] Erol Demir,[2] Ozgur A. Oto,[2] John C. Edwards,[1] Rosemary Ouseph,[1] Aydin Turkmen,[2] Krista L. Lentine.[1] *[1]Saint Louis University, Saint Louis, MO; [2]Istanbul University, Istanbul, Turkey*.

Background: Recent advances in precision medicine have provided new insights into the pathogenesis of kidney transplant (KTx) rejection such as the potential role of genetic risk variants in LIM Zinc Finger Domain Containing 1 (*LIMS1*). We aimed to evaluate the relationship between donor and recipient *LIMS1* genotype matching status and allograft rejection and survival.

Methods: We genotyped 41 prevalent living KTx recipient [24 (59%) males; mean age 34±13 years] and donor [15 (37%) males; mean age 47±13 years] pairs for *LIMS1* rs893403 variant by Sanger sequencing in order to assess their impact on rejection and graft failure. The recipients homozygous for *LIMS1* rs893403 GG genotype which tags a common 1.5-kb deletion (CNVR915.1) received a transplant from a nonhomozygous donor were defined as risk mismatched. CNVR915.1 deletion is confirmed by PCR in recipients with rs893043-AG and GG genotypes. Rejections were defined as T-cell mediated (TCMR) or antibody mediated rejection (ABMR) defined by Banff 2013 criteria. Outcomes were abstracted by review of medical records.

Results: There were no differences between recipients with risk *LIMS1* mismatching (n=5) and recipients without risk *LIMS1* mismatching (n=36) regarding demographic factors, duration of dialysis, pretransplant PRA, HLA mismatching, immunosuppressive protocols and follow up time. After a median post-KTx follow up of 10.5 (IQR 8.7-12.6) years recipients with risk *LIMS1* mismatching had significantly higher risk of allograft rejection (60%; median 1 month) compared to recipients without risk *LIMS1* mismatching (13.9%; median 72 months) (HR=4.32, 95CI% 1.46-12.76, p=0.015). TCMR was higher in recipients with risk *LIMS1* mismatching (40%) compared to recipients without risk *LIMS1* mismatching (11.1%) (p=0.087). There were no significant differences found between patients with and without risk *LIMS1* mismatching regarding risk of post-KTx DSA, ABMR and allograft failure. The mean eGFR levels at last follow up were also similar among recipients with and without risk *LIMS1* mismatching.

Conclusions: Genomic mismatching at *LIMS1* gene appears to impact risk of TCMR. *LIMS1* may be a potential minor histocompatibility antigen and pre-transplant genetic testing may have clinical implications for the prediction and clinical management of KTx rejection.

Monitoring of Gene Expression in Tacrolimus-Treated De Novo Renal Allograft Recipients Facilitates Individualized Immunosuppression: Results of the IMAGEN Study

Claudia Sommerer,[1] Merce Brunet,[2] Klemens Budde,[3] Olga Millan,[2] Lluis Guirado,[4] Petra Glander,[3] Stefan Meuer,[5] Martin G. Zeier,[1] Thomas Giese.[5] *[1]Nephrology, University Hospital Heidelberg, Heidelberg, Germany; [2]Pharmacology and Toxicology Laboratory, Barcelona, Spain; [3]Nephrology, University Hospital Charite, Berlin, Germany; [4]Renal Transplant Unit, Nephrology Department, Fundació Puigvert Barcelona, Barcelona, Spain; [5]Immunology, University Hospital Heidelberg, Heidelberg, Germany*.

Background: The expression of nuclear factor of activated T-cells (NFAT)-regulated genes in the peripheral blood has been suggested as a potentially useful immune monitoring tool to individualize tacrolimus (Tac) therapy. The aim of the present study was to characterize the possibility and clinical utility of monitoring of residual NFAT-regulated gene expression in renal allograft recipients in a multicenter approach.

Methods: The IMAGEN study enrolled 64 de novo renal transplant recipients from three European centers. All patients were treated with Tac, mycophenolic acid, and corticosteroids. NFAT-regulated gene expression (NFAT-RGE; IL-2, IFN-g, GM-CSF) was evaluated by quantitative real-time PCR in whole blood samples at day 7, month 1, 2, 3, and 6 after transplantation.

Results: Altogether, 60 patients could be evaluated. Tac concentrations (C0 and C1.5) correlated inversely with gene expression ($p<0.001$). NFAT-RGE showed a high interindividual variability (1 to 61%). RGE increased in the first two months from 16±9% to 34±21%. Patients (n=20) with high residual gene expression (NFAT-RGE≥30%) were at the increased risk of acute rejection in the following months (35% vs 5%, $p=0.002$), whereas patients (n=40) with low residual gene expression (NFAT-RGE<30%) showed a higher incidence of viral complications, especially cytomegalovirus and BK virus replication (52.5% vs 10%, $p=0.001$).

Conclusions: NFAT-RGE was confirmed as a potential non-invasive early predictive pharmacodynamic marker in the immediate post-transplant period for the risk of acute rejection and infectious complications in Tac-treated renal allograft recipients. Monitoring of NFAT-RGE may provide additional useful information for physicians to achieve individualized treatment adjustments based on the immunomodulatory effect of Tac, thus preventing serious clinical events. The method of NFAT-RGE measurements can be applied in trials with multicenter approach.

PO2410

The Role and Inducers of Nonclassical HLA-G in Renal Transplanted Allografts

Sho Kumano, Keiji Fujimoto, Hiroki Adachi, Kengo Furuichi, Hitoshi Yokoyama. *Department of Nephrology, Kanazawa Medical University School of Medicine, Uchinada, Ishikawa, Japan., Kahokugun, Japan*.

Background: Non-classical class I molecule HLA-G has a high potential to modulate immune response. However, the mechanism of HLA-G induction was still unknown. In this study, the expression of HLA-G on proximal tubular epithelial cells (pTECs) and the inducer of HLA-G were investigated.

Methods: Our subjects comprised 40 adult Japanese subjects whose allograft had survived for at least 1 year (35 patients from a living donor, 5 patients from a deceased donor). They were evaluated for HLA-G1/5 expression using an immunofluorescence method. We investigated inducer of HLA-G using primary cultured human pTECs treated with cytokines and immunosuppressants.

Results: In renal biopsy tissues, 2 to 4 weeks or 1 year following the transplantation, HLA-G expression was noted in the perinuclear region or on the basement membrane side of pTECs in 12 of 40 cases (30 %). Further, for median 8.8 years, the time taken for a 30 % reduction in eGFR was longer in the HLA-G-positive group than in the HLA-G-negative group ($p=0.016$, Figure). HLA-G1/5 expression on pTECs was also found to be an independent predictor of the improvement in renal allograft function by Cox's proportional hazard model ($p=0.030$). *In vitro* study, interferon-beta (IFN-β) was the strongest inducer of HLA-G expression, while immunosuppressants (everolimus, tacrolimus, cyclosporin, and dexamethasone) did not induce expression.

Conclusions: The study showed that HLA-G1/5 expression on pTECs was an independent improving predictor of renal allografts. Furthermore, the strongest HLA-G1/5 inducer was IFN-β, but not the immunosuppressive agents. These results suggested the possibility that acquired expression of HLA-G exhibits a long-term renal preservation effect, different from the effect of immunosuppressants.

PO2411

The Clinical Impact of Preformed HLA-DQ Donor-Specific Antibodies on Graft Outcomes in Kidney Transplantation

Sua Lee,[1] Chul Woo Yang,[2] Byung ha Chung.[2] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Catholic University of Korea, Seoul, Republic of Korea*.

Background: De-novo HLA-DQ donor-specific antibody (DSA) has been identified as a risk factor for graft rejection and loss in kidney transplantation (KT). Recently, the impact of preformed HLA-DQ DSA has been discussed. This study aimed to investigate the clinical impact of preformed HLA-DQ DSA on graft outcomes.

Methods: We evaluated 990 recipients who underwent kideny transplantation at Seoul St. Mary's Hospital from January 2010 to July 2019. According to the result of DSA using luminex single antigen bead assay, recipients were classified as no DSA, only DQ, non-DQ, and DQ + non-DQ. Primary outcomes were the incidence of biopsy-proven acute rejection and the rate of death-censored graft loss.

Results: In total cohort, 611 recipients (61.7%) and 379 recipients (38.3%) underwent living-donor KT and deceased-donor KT, respectively. Recipients were classified as no DSA (909 recipients, 91.8%), only DQ (18 recipients, 1.8 %), non-DQ (57 recipients, 6.3%), and DQ + non-DQ (6 recipients, 0.7%). The overall incidence of acute rejection and acute antibody-mediated rejection (AMR) were 20.3% and 7.5%. Only DQ, non-DQ, and DQ + non-DQ group had significantly higher the incidence of acute AMR compared to no DSA group ($p < 0.05$, respectively). There was no significant difference in the incidence of acute AMR between sensitized groups. There was no difference in the rate of death-censored graft loss between groups. In univariate Cox regression analysis, all of 3 groups with DSA were associated with high risk of acute AMR (Only DQ: HR 5.051; CI 95%, $p = 0.002$, non-DQ: HR 6.005; CI 95%, $p < 0.001$, DQ + non-DQ: HR 7.748; CI 95%, $p = 0.005$, respectively). HLA-DQ DSA and other DSAs (HLA-A, HLA-B, HLA-DR) had a tendency to interact with acute AMR, although no statistical significance ($p = 0.055$).

Conclusions: Preformed HLA-DQ DSA is associated with the development of acute rejection, especially acute AMR. Therefore, the identification of preformed HLA-DQ DSA may be necessary to improve graft outcomes.

PO2412

Outcomes of High Kidney Donor Profile Index Kidneys at a Large Center

Javier Pagan, Luke Preczewski, Meghan Muldoon, Lumen A. Mendez Castaner, Amy L. Harshman, Elizabeth Shipman, Mariella O. Goggins, Giselle Guerra. *Miami Transplant Institute, Miami, FL*.

Background: Kidneys from donors with high Kidney Donor Profile Index (KDPI) are often discarded due to concerns about outcomes. Despite decreased survival, the survival benefit of receiving a transplant and avoiding time on dialysis is beneficial, especially for selected patients.

Methods: We increased use of high KDPI (KDPI>85) deceased donor kidneys (DDKT) over several years. We performed a single-center analysis of 1119 consecutive adult DDKT from 2016-2019. Our endpoints were Kaplan-Meier death-censored

graft survival (HR calculated by the Cox Proportional Hazards model) and eGFR by MDRD equation at 3, 6, and 12 months post-transplant. Mean eGFR was compared for significance using a t-test.

Results: 1119 patients were transplanted: 205 (18.3%) received a kidney from a donor with KDPI > 85% vs. 914 (81.7%) from a donor with a KDPI of <=85%. As expected, the high KDPI group had a higher mean age (66.5 vs. 53.6 ($p < 0.0001$) and a higher mean EPTS (74.7 vs. 50.4 ($p<0.0001$), reflecting deliberate selection. Death-censored graft survival at 1yr was 91.9% (CI: 86.9-95.0) in the high KDPI group vs 96.7% (CI: 95.3-97.7) in other recipients. High KDPI was a significant risk factor for death-censored graft survival (HR: 1.91; p=0.017). 1-yr mean eGFR by MDRD equation in patients alive with followup was 49.0 ml/min/1.73m2 in the high KDPI group vs 62.3 ml/min/1.73m2 in the < 85% KDPI group ($p<0.0001$). Box-and-whiskers plots of 3, 6, and 12-year eGFR are shown (figure 1).

Conclusions: Despite reduced graft survival, high KDPI kidneys offered renal function to 91.9% of surviving patients at 1 year. eGFR was also consistently lower, but provided good function to those recipients. Utilizing high KDPI kidneys in well-selected recipients is an important aspect of reducing waiting time and morbidity and mortality of dialysis.

Funding: Clinical Revenue Support

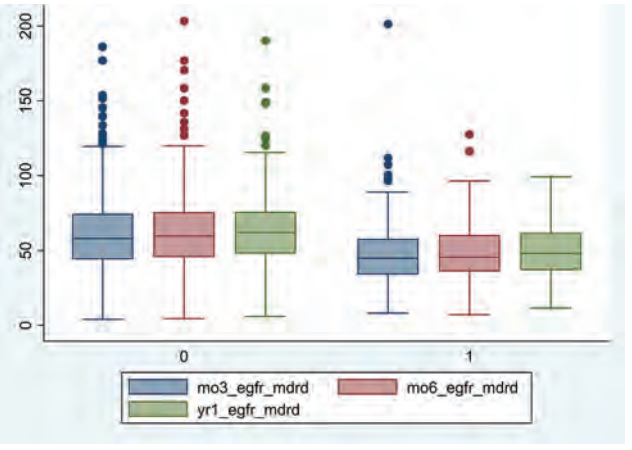

Figure 1. eGFR by MDRD at 3, 6, and 12 months for recipients of KDPI <= 85 (0) vs. KDPI > 85 (1)

PO2413

Could Individually Measured Creatinine Clearances Decrease the Discard Rate of High Kidney Donor Profile Index (86-100) Deceased Donor Kidneys?

Adnan A. Khan, Robert W. Steiner, Hannah L. Turner, Charles K. Wainaina, Ashley S. Hahn. *University of California San Diego, La Jolla, CA.*

Background: The Kidney Donor Profile Index (KDPI) guides center acceptance and allocation of deceased donor kidneys (DDKs). It uses donor factors such as serum creatinine (sCr), diabetes mellitus and hypertension to predict organ quality and corresponsing longivity. Due to this higher KDPI kidneys are often discarded. KDPI offers "only moderate predictability" of long-term transplant function with a *c statistic* of 0.6.

Methods: As an unexplored, but direct measure of deceased donor kidney quality, we determined pre-recovery creatinine clearances (CrCls) in 260 deceased donor candidates (1/2015 -12/2018) using ICU urine collections (Ucolls) and pre- and post- collection serum creatinine (sCr) values. We used CrCl > 80 ml/min as the threshold of interest, as that defines acceptable kidney function for living kidney donor candidates. Donor creatinine production rates were calculated to assess the veracity of CrCls. Organ match sequence was reviewed for all denials and UNOS denial codes and corresponding reasons for denial were reviewed.

Results: Of the 134 kidneys available from 67 high KDPI donors, 32/67 donors had both kidneys transplanted, 7/67 donors had one kidney transplanted and 28/67 donors were not transplanted. Reviewing the 35/67 donors in whom either one or both kidneys were not transplanted; 10 of them had CrCl > 80. This amounts to about 28.6 % (10/35) of the non-transplanted donors with high KDPI; having a CrCl >80 ml/min. In the high KDPI group 28/67 candidates (~42%) had measured CrCl >80 ml/min. In the KDPI 21-85 group, 97/155 (63%) of donors had CrCls that >80 ml/min; while 42/50 (84%) in the KDPI 0-20 group had measured CrCls > 80 ml/min. Lower CrCls did not correlate with higher KDPIs within each subcohort. Donor creatinine production rates were 17.9 +/- 9.1 mg/kg/day, within population expectations. UNOS denial codes for high KDPI organ offers were mostly 830 - donor age or quality or 837 - organ specific donor issue

Conclusions: Our data suggests that about 28.6% of the non-transplanted high KDPI donors had CrCl >80 and these kidneys could have been potentially used and not discarded. Direct measurement of CrCl in deceased kidney donors is not difficult and deserves further study, as it may improve estimates of donor kidney quality and reduce inappropriate discards in a heterogeneous group.

PO2414

Glomerular Blood Flow in Living Donor Kidney Transplant Recipients

Go Kanzaki, Takaya Sasaki, Kotaro Haruhara, Rina Oba, Yusuke Okabayashi, Kentaro Koike, Akimitsu Kobayashi, Izumi Yamamoto, Nobuo Tsuboi, Takashi Yokoo. *The Jikei University School of Medicine, Minato-ku, Japan.*

Background: Renal graft hemodynamics may be a valuable predictor of graft survival and long-term outcomes. Although several studies have reported that renal blood flow was correlated with graft function and decreased remarkably during acute rejection episode, the glomerular hemodynamic changes during kidney transplantation are lacking because there is no method of measuring nephron number in vivo. In this study, we calculate glomerular blood flow (GBF) by estimating the nephron number and investigate changes in GBF after kidney transplantation and their clinicopathological relationship.

Methods: We performed a retrospective analysis of 42 patients who underwent living donor kidney transplantation. The number of glomeruli (Nglom) was calculated as the cortical volume of both kidneys as assessed on computed tomography times the 1-hour posttransplant renal biopsy-determined glomerular density. Effective renal plasma flow (ERPF) was assessed as 99mTc-MAG3 clearance. GBF was calculated as follows: GBF (nl/min) = ERPF/Nglom/(1-hematocrit/100) $x10^6$. We analyzed the GBF before and during a 1-month observation period after transplantation. The GBF ratio as a marker of change in GBF was calculated as follows: (GBF one-month post-transplantation) / (GBF before transplantation in donors).

Results: Prior to transplantation, the GBF in donors was 559.7±257.3 nl/min, whereas the GBF in recipients on day 2 post-transplantation was decreased to 502.6±317.4 nl/min. After successful transplantation, the GBF one-month post-transplantation has settled down to 491.9±291.1 nl/min, while the eGFR progressively rose (48.7±18.4 ml/min/1.73m²) together with the hematocrit (31.1±3.9 %). The GBF at one month was positively associated with eGFR at one month ($p<0.05$). Of note, the GBF ratio was correlated with the eGFR and urinary protein execration at one month and urinary protein execration at 1 year but was not correlated with eGFR at 1 yr.

Conclusions: We first reported the GBF in kidney transplant recipients before and after kidney transplantation. Our findings suggest that abnormal change in GBF may be considered predictive indices for short-term allograft outcomes.

PO2415

Characteristics of Anonymous Living Donors and Their Recipients and Outcomes: Appropriate Use of a Rare and Valuable Gift

Muhammad Y. Jan, Muhammad S. Yaqub, Oluwafisayo O. Adebiyi, Tim E. Taber, Asif A. Sharfuddin. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Anonymous Living Donors are a special select set of donors. We review the trends and the characteristics and utilization of such donors nationally.

Methods: All Living Donors (code=10 "Anonymous") and their recipients who were recorded in the UNOS database from Oct 1997 through Sep 2017 were reviewed for demographics and recipient outcomes.

Results: There were a total of 2286 such donors during the study period. There was an increasing trend of the donors over the time period. Demographics and Outcomes are shown in the Table. DCGS was significantly superior when donor was 20 years or more younger than the Recipient (p=0.019) and significantly inferior when the 20 years older than the recipient (p=0.0005). There was no difference in cumulative graft survival between adult and pediatric graft survival (p=0.055), although DCGS was superior in the adults (p=0.021).

Conclusions: To our knowledge, this is the first comprehensive report on the characteristics of Anonymous Living Kidney Donors and their Recipients and outcomes. Better characteristics matching in a minority of such transplants may improve further longevity from such donors.

Donor, Recipient and Transplant Characteristics

Donor Mean Age / Median (range)	43.6±12.1/ 44 (18-76) yrs

PO2416

Outcomes of Delayed Graft Function: A Systematic Review and Meta-Analysis

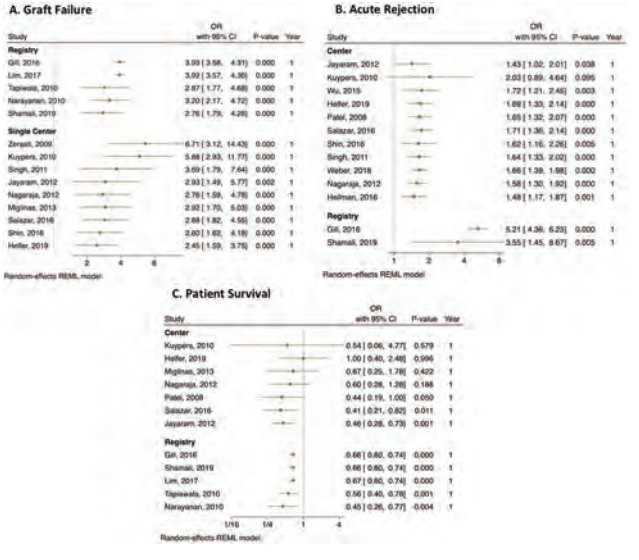
Vanessa Sandra,[1] Navin Sanichar,[1] Emily Daniel,[1] Miah T. Li,[1] Kristen L. King,[1] Jacob Stevens,[1] Syed A. Husain,[1] Tracy J. Mayne,[2] Sumit Mohan.[1] [1]*Columbia University, New York, NY;* [2]*Angion BioMedica, San Fransisco, CA.*

Background: Delayed Graft Function (DGF) is a frequent complication of kidney transplantation, but its impact on long and short-term outcomes remain uncertain.

Methods: We conducted a literature search for studies investigating the association of DGF on subsequent outcomes from 2007-2020. Outcomes were abstracted and used to create cumulative forest plots with pooled odds ratios, stratifying our analysis between center-studies and registry-studies and follow-up time where possible. The outcomes analyzed were graft failure (GF), acute rejection (AR), patient survival, and renal function.

Results: Of the 1464 articles reviewed, 27 were included. In single center-studies, DGF patients experienced higher GF at 1 year (OR 2.45, 95% CI 1.79-4.29, p<0.001), 3 years (OR 1.70, 95% CI 1.01-2.86, p<0.001), increased AR 1-year post-transplant (OR 1.48, 95% CI 1.79-4.28, p=0.001), and decreased 1-year patient survival (OR 0.46, 95% CI 0.28-0.73, p<0.001). Registry-studies showed a similar significant association with GF at 1 year (OR 2.76, 95% CI 1.79-4.28, p<0.001) and 3 years (OR 1.70, 95% CI 1.01-2.86, p=0.046), with AR within 1 year (OR 1.48, 95% CI 1.45-8.67, p=0.005) and 3-years (OR 0.54, 95% CI 0.41-0.72, p<0.001), and 1-year survival (OR 0.45, 95% CI 0.26, 0.77, p<0.001). Qualitative analysis showed that DGF had significant effect on eGFR and creatinine levels, though studies conflict on timeframe. Few studies investigated outcomes stratifying DGF severity or KDPI.

Conclusions: DGF was associated with increased risk of GF, AR, and mortality, although effects were largest within 1 year post-transplant. Our analysis indicated a need for a standardized method to measure DGF severity and further studies on DGF outcomes on varying KDPI. These results should inform the selection process, treatment, and monitoring of transplanted kidneys at high risk for DGF.



PO2417

Duration of Delayed Graft Function Predicts Kidney Allograft Function and Survival

Sanjana Kapoor, Nawras Alshoubaki, Chethan M. Puttarajappa, Sundaram Hariharan. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: The current study evaluated the duration of DGF as a measure of severity of ischemic injury to kidney transplant outcome.

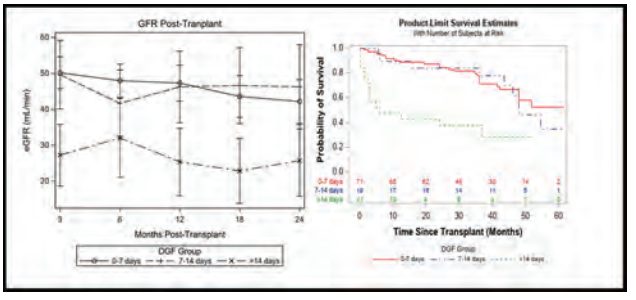
Methods: This single center study evaluated DD kidney transplant recipients with DGF between Jan 2014 and Dec 2019. DGF was defined as the need for dialysis within 7 days post-transplant & were divided into three groups according to post transplant dialysis duration. Group I: dialysis ≤7 days, Group II: dialysis 8-14 days and Group III: dialysis >14 days. All primary & repeat adult kidney recipients of DD transplants were included. We excluded multiorgan recipients and pediatric en-bloc kidneys. We calculated eGFR over time using CKD EPI formula. Statistical analysis was performed to identify differences in variables, Linear Mixed Model for eGFR over time. Log-rank test was used to evaluate differences in graft & patient survival & composite end point (graft loss, patient loss & GFR, 20ml/min) for all 3 subgroups.

Results: A total of 132 DD KT recipients with DGF were identified: Group I: n=84 (64%), Group II: n=24 (18%) & Group III: n=24 (18%). The recipient/donor demographics and Donor (KDPI) & Transplant variables were similar across groups.**Figure 1 (left)** shows significantly lower eGFR values over time using linear mixed model among patients who needed dialysis for >14 days (Gr III vs I&II, P=0.006). **Table 1** shows the incidence of Isolated Graft Loss, Patient death and combination of graft loss & patient death among 3 groups. **Figure 1 (right)** shows significantly lower composite end point (combination of patient loss, graft loss and impending graft loss) for among patients who needed dialysis for >14 days (P=0002).

Conclusions: In conclusion, we found a strong association between prolonged DGF>14 days with lower GFR values and survival outcomes. No differences in eGFR and survival rates were noted among patients with DGF patients < 7 days vs.7-14 days.

Funding: Clinical Revenue Support

	Group I: Dialysis <7days	Group II: Dialysis 7-14 days	Group III: Dialysis >14 days	p-value
Graft loss, n(%)	13 (15.5%)	2 (8.3%)	9 (37.5%)	0.028
Patient death, n(%)	11 (13.1%)	5 (20.8%)	8 (33.3%)	0.07
Graft & patient loss, n(%)	23 (27.4%)	9 (37.5%)	14 (58.3%)	0.019



PO2418

Design of the Graft Improvement Following Transplant (GIFT) Trial, a Phase 3 Study of ANG-3777 in Kidney Transplantation Patients with Delayed Graft Function

Flavio Vincenti,[1] Tracy J. Mayne,[2] Deb Gouveia,[2] John F. Neylan.[2] [1]*University of California San Francisco, San Francisco, CA;* [2]*Angion Biomedica, San Francisco, CA.*

Background: Patients after kidney transplantation can experience acute kidney injury (AKI) resulting in delayed graft function (DGF). The Food and Drug Administration has prioritized the development of new treatments for DGF. A Phase 2 trial demonstrated that treatment with ANG-3777, a hepatocyte growth factor (HGF) mimetic, improved renal function up to 12-months in patients with signs of DGF.

Methods: Objective: To describe the GIFT trial (Study 001-15), designed to evaluate the efficacy and safety of ANG-3777 in renal transplantation patients with signs of DGF

Results: GIFT is a Phase 3, multicenter, prospective, randomized, placebo-controlled, study enrolling patients who have undergone a kidney transplantation with a deceased donor kidney who exhibit signs of DGF (producing a mean of <50cc urine per hour over 8 hours in the first 24-hours post-transplantation). Patients are randomized 1:1 to ANG-3777 (2 mg/kg) or placebo administered intravenously once daily for 3 consecutive days starting within 30 hours after transplantation. The primary endpoint is estimated glomerular filtration rate (eGFR) at 12 months. Secondary endpoints include proportion of subjects with eGFR > 30 mL/min/1.73m^2 at days 30, 90, 180 and 360; proportion of subjects whose graft function is slow, delayed or primary non-function; length of hospitalization; duration of dialysis through day 30. A study schematic is shown in Figure 1. Adverse events are being assessed throughout the study.

Conclusions: No pharmacologic intervention has been demonstrated in a rigorous trial to be effective preventing or improving the outcome of DGF. The GIFT study will generate data that are critical to advancing the treatment of DGF.

Clinical Outcomes of Kidney Transplant Recipients Living Away from Their Home Country

Ramzi A. Rahiman, Maab A. Osman, Hadeel Alfar, Essa Abuhelaiqa, Muhammad Asim, Omar Fituri, Ahmed F. Hamdi, Hassan A. Al-Malki, Mohamad M. Alkadi. *Hamad Medical Corporation, DOHA, Qatar.*

Background: Many people leave their home country looking for better job opportunities and among those are kidney transplant recipients. However, taking care of such recipients might be challenging especially when information regarding induction immunosuppression, donor HLA typing, donor-specific antibodies, crossmatch and/or infections are not available. The aim of this study was to compare clinical outcomes of kidney recipients transplanted in their home conutry with kidney recepients transplanted locally.

Methods: In this retrospective cohort, we included all adult recipients transplanted between 2005 and 2016 and followed at our transplant clinics within their first year of transplant. Patients were categorized into two groups; local group including recipients transplanted at our center and abroad group including recipients transplanted in their home country.

Results: There were 111 patients in local group and 110 patients in abroad group. The mean age at transplant in local and abroad groups were 48 and 42 year-old, respectively. 63% of receipients in local group were from the Middle East, while 53% of patients transplanted abroad were from South Asia. Deceased donation was higher in local group (41% vs. 4%; p<0.0001). There was no difference in recipient sex, native kidney disease, preexisting diabetes mellitus or preemptive transplants. Most patients were on CNI and steroid immunosuppression (n=209; 95%). The mean follow up post transplantation was 6.3 years. The risk of acute cellular rejection was statistically significant in abroad group (13% vs 3%; p=0.005). However, the risk of ABMR or borderline rejections were similar. The incidence of post-transplant diabetes and malignancies was similar in both groups. There was no difference in 1-,3- and 5-year creatinine and proteinuria between both groups. Patient and graft survival rates were excellent in both groups and 5-year patient and death-censored graft survival rates in local and abroad groups were 100% vs. 93% and 95.2% vs. 96.6%, respectively.

Conclusions: Transition of care between countries carry its risks as it may be related to drug disruption or incomplete medical record. Kidney recipients transplanted abroad are at increased risk of acute cellular rejection; however, patient and graft survival rates remain excellent.

PO2420

Factors Associated with the Use of Hypothermic Machine Perfusion in Kidney Transplant Recipients

Nadir Goulamhoussen,[1] Lawrence Slapcoff,[2] Dana Baran,[2] Isabelle Houde,[4] Anne Boucher,[3] Martin Albert,[1] Pierre Marsolais,[1] Heloise Cardinal,[5] Josee Bouchard.[1] *[1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [2]McGill University, Montreal, QC, Canada; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]CHU Québec, Quebec, QC, Canada; [5]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada.*

Background: Delayed graft function (DGF) is associated with an increased risk of graft loss. The use of cold hypothermic machine perfusion (HMP) has been shown to reduce the incidence of DGF in kidney transplant recipients (KTRs), especially when extended-criteria donors (ECDs) are used. However, there is a paucity of data on the determinants of HMP use in real-life setting.

Methods: We aimed to determine the factors associated with the use of HMP in a cohort of donors and KTRs. We collected data on consecutive brain-dead donors admitted to an organ procurement organization and their KTRs between June 2013 and December 2018 in 5 adult transplant centers in Canada. There is no standardized protocol for the use of HMP in the province of Quebec. The use of HMP is left at the discretion of the surgeon recovering organs. However, a HMP device was available for every organ recovered at the organ procurement organization. Generalized estimating equations were used to predict the use of HMP.

Results: The cohort included 159 deceased donors and their 281 KTRs. Thirty-three percent of donors were ECDs, and 59% of KTRs received organs placed on HMP. The median cold ischemia time (CIT) was 12.4 (IQR 7.9-16.2) hours. There were no differences in use of HMP over time. In univariate analysis, none of the donors' characteristics were associated with the use of HMP. The use of HMP was similar in ECD and standard criteria donors (33% vs 34%, p=0.82). For KTRs, in univariate analysis, race (non-Caucasian), cold ischemia time, use of basiliximab/alemtuzumab, and KTR center were associated with the use of HMP. In multivariate analysis, CIT (odds ratio [OR] 1.09, 95% confidence interval [CI] 1.03-1.16) and KTR center were significantly associated with use of HMP.

Conclusions: We found that use of HMP was strongly associated with the transplant center where the surgeons practiced, suggesting that surgeon preference/training plays an important role in determining the use of HMP. The presence of ECD did not influence the use of HMP. The reasons underlying the differences in practice between centers should be explored in further studies.

Microvascular Inflammation Is the Main Determinant of Elevated Donor-Derived Cell-Free DNA in Kidney Transplantation

Bogdan Obrisca,[1] Maria Butiu,[2] Ramasamy Bakthavatsalam,[2] Kelly D. Smith,[2] Iris C. De Castro,[2] Christopher D. Blosser,[2] Lena Sibulesky,[2] Catherine Kling,[2] Gener Ismail,[1] Bogdan M. Sorohan,[1] Nicolae Leca.[2] *[1]Fundeni Clinical Institute, Bucharest, Romania; [2]University of Washington, Seattle, WA.*

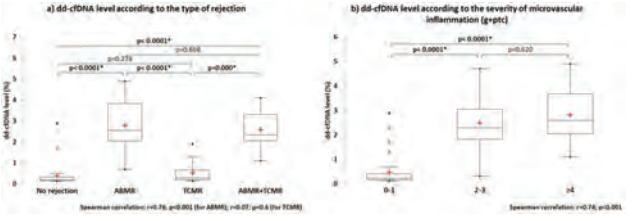
Background: Microvascular inflammation (Mi) is the main histological lesion for ABMR. Mi may occur separate from other ABMR criteria, early in the injury process, and may not be captured by the current Banff criteria. Donor-derived cell-free DNA (dd-cfDNA) has the potential to identify early allograft injury and supplement the current diagnostic criteria for rejection.

Methods: We included all patients(n=54) who underwent a kidney transplant biopsy for suspicion of rejection at our center from 9/17-12/19. Determinants of a biopsy were renal dysfunction, elevated dd-cfDNA, or presence of DSAs.

Results: Dd-cfDNA correlated strongly with the presence of ABMR, Class II DSA>2500, and histological lesions of ABMR. The strongest association was with Mi lesions (OR 192,95%CI: 18.6, 1984, p<0.001). Of the 18 patients with Mi, 2 did not meet the criteria for ABMR and had a dd-cfDNA level of 0.32% and 1.9%. All patients with Mi that met the criteria for ABMR had a dd-cfDNA over 1%. There was no association with renal function or histological lesions of tubulitis or interstitial inflammation (Fig 2).

Conclusions: Dd-cfDNA has the potential to identify early allograft injury and allow for early and less aggressive interventions that can beneficially alter long term outcomes of kidney transplant recipients.

Funding: Commercial Support - CareDx, Clinical Revenue Support



The absolute level of dd-cfDNA and its correlation with rejection type and microvascular inflammation

Variable	Univariate analysis		Multivariate analysis*

Point-of-Care Creatinine Self-Testing in Renal Transplant Patients: An Assessment of Accuracy, Precision, and Patient Experience

Fabiana Fernandes da Costa,[1] Michelle Willicombe,[1,2] Kate Bramham,[3] Clare B. Kelly.[3] *[1]Imperial College NHS TRUST, London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]Department of Women and Children's Health, King's College London, London, United Kingdom.*

Background: During the Covid-19 pandemic it has become increasingly important to provide virtual care for patients with CKD. Point-of-Care testing of capillary creatinine (POC-Cr) is now available and has demonstrated validity, ease of use, improved efficiency and cost-efficiency. We aimed to determine patients' desire to self-monitoring of POC-Cr and their characteristics.

Methods: Renal transplant patients were shown how to perform self-POC-Cr testing with a NovaBio StatSensor®Xpress device, then undertook a test independently and answered survey questions about their attitude to self-testing of POC-Cr.

Results: All patients (N=189; Median age 52 years (IQR 40,64) ; 44 (23%) English as a second language; 128 (68%) male; Median eGFR 49 mls/min/1.73m^2 (IQR 34,64) successfully performed a POC-Cr test and 110/120 (91%) of patients who completed the survey reported they would like to self-monitor POC-Cr. Most patients wished to reduce their clinic attendance and the majority were willing to have telephone consultations. Characteristics of the cohort are described in Table 1.

Conclusions: All transplant patients successfully performed a POC-Cr test with written instructions and a demonstration. Most patients would like to self-monitor POC-Cr and reduce clinic attendance. Limitations include the single-centre design, number of participants and language barrier. Virtual care including patient self-monitoring using POC-Cr should be explored.

Characteristics of patients who would and would not like to self-monitor POC-Cr at home

Characteristics	Would like to self-monitor POC-Cr at home N=110	Would not like to perform testing at home N=10

Would be willing to have video consultations	82 (75%)	5 (50%)

PO2423

Short-Term Variability in Graft Function Is Associated with Long-Term Mortality but Not Allograft Survival in Kidney Transplant Recipients

Beini Lyu, Didier A. Mandelbrot, Arjang Djamali, Brad C. Astor. *University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

Background: It is critical to identify kidney transplant recipients (KTR) at highest risk of graft failure and death to focus on monitoring and interventions to improve long-term outcomes. Variability in native kidney function is associated with the risk of mortality and hospitalization in chronic kidney disease, but it remains uncertain whether such associations exist in KTR. We examined the hypothesis that short-term graft function variability is associated with long-term outcomes in KTRs.

Methods: Using the Wisconsin Allograft Recipient Database (WisARD), we identified 2919 KTRs who had a functioning allograft at least 2 years after transplantation and at least 3 outpatient estimated glomerular filtration rate (eGFR) measurements from 1 to 2 years post-transplant. Graft function variability was defined for each patient as the coefficient of variation based on a linear regression of eGFR from 1 to 2 years. Associations between eGFR variability and total graft loss, death and graft failure were estimated in competing risk models

Results: Patients with greater variability were more likely to be female, have more comorbidities, and have more prior hospitalization events at baseline. Compared to the lowest quartile, the highest quartile of eGFR variability was associated with a higher risk of total graft loss (adjusted HR 1.51, 95% CI: 1.11-2.06) and a higher risk of death (adjusted HR 1.85, 95% CI: 1.23-2.76), but not with a higher risk of graft failure (subHR 1.08, 95% CI: 0.64-1.83 in competing risk analysis), independent of eGFR and slope of eGFR. The associations remained consistent across strata of acute rejection, diabetes, peripheral arterial disease, baseline eGFR, history of cardiovascular disease, baseline hospitalization, and with all variability indicators and modeling approaches.

Conclusions: Short-term eGFR variability is associated with long-term death but not graft failure. Variability in eGFR provides independent prognostic information on transplantation outcomes and may be an indicator to differentiate the risk of death and graft failure.

PO2424

Defining a Minimal Clinically Meaningful Difference (MCMD) in Estimated Glomerular Filtration Rate (eGFR) for Kidney Transplantation

Tracy J. Mayne,[1] Sumit Mohan,[2] Jesse D. Schold,[3] Matthew R. Weir,[4] Bob Nordyke.[1] *[1]Angion Biomedica, San Francisco, CA; [2]Columbia University, New York, NY; [3]Cleveland Clinic, Cleveland, OH; [4]University of Maryland School of Medicine, Baltimore, MD.*

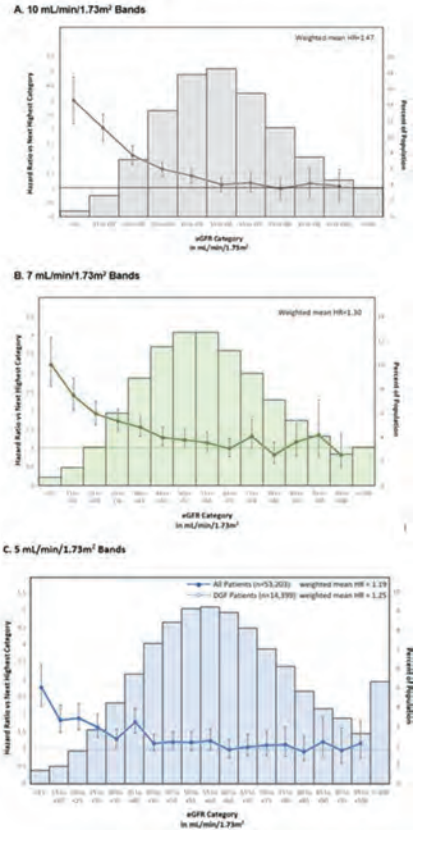
Background: eGFR is an established measure of renal function & predicts clinical outcomes. A MCMD for eGFR has never been clearly defined.

Methods: Data source: United Network for Organ Sharing (OPTN) database Study population: Adults (≥18 years of age); received deceased donor kidney 01/01/2013 to 12/31/2018; multi-organ & non-incident transplants were excluded. Analysis: Cox proportional hazards regression Primary outcome: Death-censored graft survival starting 12-months post-transplantation. Predictors: Recipient (gender, age, race, diabetes, body mass index, panel reactive antibodies); Donor (age, diabetes, hypertension, proteinuria); Transplantation (cold ischemia time, pump, DR locus mismatch, delayed graft function); 12-month eGFR (CKD-EPI). Analysis. eGFR was stratified by bands of 5, 7 or 10 mL/min/1.73m^2. Regressions compared each band to the next sequential band. A weighted mean hazard ratio was calculated using OPTN population eGFR distribution.

Results: The relationship between 12-month eGFR & graft failure is non-linear: HR=~3 to 4 at eGFR <15 mL/min/1.73m^2; HR=~1.1 at eGFRs ≥ 55. Mean HR=1.47 for 10 mL/min/1.73m^2 bands; 1.30 at 7 mL; 1.19 at 5 mL.

Conclusions: Controlling for multiple factors, 12-month eGFR is a strong predictor of death-censored graft survival. Mean HR (1.19) is consistent with an effect size considered significant, clinically meaningful, & supporting of regulatory approval (eg, angiotensin receptor blockers; statins). This supports 5 mL/min/1.73m^2 as the eGFR MCMD in kidney transplantation. **DISCLAIMER**. The interpretation & reporting of these data are the responsibility of the authors & in no way should be seen as an official policy of or interpretation by the OPTN or the US Government.

Figure 1: Hazard Ratio for Death-Censored Graft Failure by eGFR Band by Percent of Population within Each eGFR Band



PO2425

Composite Events Associated with Increased Expected Post-Transplant Survival Scores

Yasmeen Dhindsa,[2] Nakul N. Datta,[1,2] Piyavadee Homkrailas,[1] Suphamai Bunnapradist,[1,2] Erik L. Lum.[1,2] *[1]University of California Los Angeles, Los Angeles, CA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Kidney transplant candidates on the waiting list are assigned an expected post transplant survival (EPTS) score. This score is used to determine allocation of kidneys in the kidney allocation system (KAS). The outcomes of candidates with an EPTS >95% at the time of listing is limited.

Methods: UCLA kidney Transplant Program data of waiting list with EPTS > 80% from January 2015 – December 2018 were included. Median follow up time of waiting list was 845 days. The outcomes included kidney transplant rate, 3 year death censored graft survival and patient survival in candidates with EPTS ≥ 95% compared with EPTS < 95%.

Results: A total of 124 patients were identified with an EPTS score > 95% at the time of listing during the study period. Of these patients 23 received a kidney transplant during the specified time frame (transplant rate of 16.9%). Recipients of kidney transplant had a longer dialysis vintage (2368.6 days vs. 9881 days, P< 0.0001) and were more sensitized at the time of listing (34.8% vs. 11.8%, p=0.018). Compared to a group with an EPTS between 80-94% at time of listing (n=170) there were no differences in mortality (4.35% vs. 4.55%, p=0.969), graft failure (14.3% vs. 6.4%, p=0.254), or 3 year death censored graft survival (70.0% vs. 84.5%, p=0.517). The EPTS > 95% group was older, had a longer dialysis vintage, had a higher proportion of candidates with diabetes as a cause of ESRD, and was less likely to undergo transplantation. Candidates with an EPTS >95% who did not receive a transplant had a mortality rate of 7.9% and waitlist removal rate 16.9%.

Conclusions: Kidney transplantation in candidates with an EPTS > 95% provides comparable outcomes to candidates with an EPTS between 80-94%, which was superior to remaining on dialysis. Despite this benefit, the transplantation rate of this group was low and a quarter of those not transplanted either died or are removed from the waitlist. Strategies are needed to improve transplantation rates in this population.

PO2426

Transition of Renal Transplant Care from Pediatrics to Adolescence and Young Adulthood: Retrospective Study Comparing Serum Creatinine-Based GFR Estimating Equations

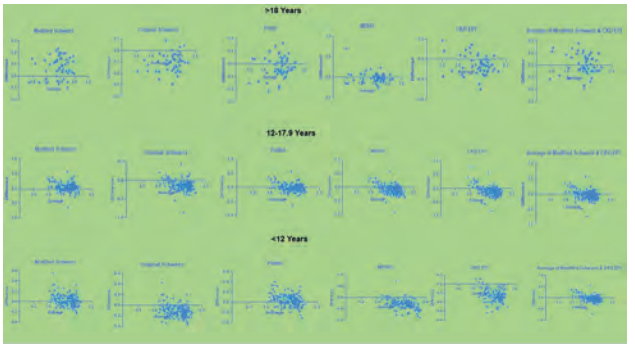
Raja Dandamudi, Stanley P. Hmiel, Vikas R. Dharnidharka. *Washington University in Saint Louis School of Medicine, Saint Louis, MO.*

Background: The evaluation of graft function is vital in the management of pediatric kidney transplant (pKTx) recipients. Measured GFR (mGFR) using exogenous markers, is very accurate, but not suitable for daily use. Estimated glomerular filtration rate (eGFR) using Serum creatinine (Scr) is the easiest way and equations are categorized as either pediatric or adult specific. None of the equations were formally compared in adolescents and young adults with renal transplants. The aim of study was to assess the performance of creatinine-based formulas in a cohort of pKTx in pediatric, adolescents and young adult age groups.

Methods: This retrospective study was conducted at our hospital from January 2000 to March 2019 from 125 pKTx recipients. We compared 415 mGFR values to 5 different Scr-based eGFR formulae (original Schwartz(OS), BS, Pottel, Modification of Diet in Renal Disease (MDRD), CKD-EPI, and average of BS and CKD EPI. Basing on the age at which the GFR was measured we divided the cohort in to 3 categories (children <12 ys, Adolescents (12.1-17.9 ys and young adults >18-21 ys. We used Bland-Altman analysis to evaluate the bias, precision and accuracy between eGFR and mGFR.

Results: Pottel and BS performed well across pediatric and adolescent age groups with high 30% accuracy(figure). MDRD and CKD EPI performance improved in young adults >18 years. Average of BS and CKD EPI outperformed all other equations with minimal bias (0.006 ml/min/1.732 m^2) and 90% accuracy in young adults.

Conclusions: Height independent Pottel and height dependent BS formulae had low bias and high accuracy in children and adolescents. Average of BS and CKD EPI outperformed other equations in young adults and provides an overall unbiased estimate of GFR.



PO2427

A Comparison of the Associations of Urine Markers with the Rate of Decline in Kidney Allograft Function

Yoshitsugu Obi,[1,2] Naotsugu Ichimaru,[3,4] Yoshitaka Isaka,[3] Takayuki Hamano.[3,5] The CANDLE-KIT Trial Inverstigators *[1]Obi Clinic, Osaka, Japan; [2]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [3]Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan; [4]Ippan Zaidan Hojin Sumitomo Byoin, Osaka, Japan; [5]Nagoya Shiritsu Daigaku Daigakuin Igaku Kenkyuka Igakubu, Nagoya, Japan.*

Background: Various urine markers are proposed to predict renal outcomes. However, there are few head-to-head comparison studies comparing their clinical relevance among kidney transplant recipients (KTRs).

Methods: In a prospective clinical trial, we enrolled 153 KTRs with anemia and >1-year history of transplantation across 23 facilities and followed them for 2 years. The annual change in eGFR was estimated based on mixed effects model. We then selected 102 patients who had baseline urine data on total protein, beta 2-microglobulin (β2MG), N-acetyl-beta-D-glucosaminidase (NAG), and L-type fatty acid binding protein (L-FABP). Total protein, NAG, and L-FABP were standardized according to urine creatinine concentration. We then compared the associations of the quintiles of each urine marker with annual decline in eGFR using univariate and multivariable linear regression models.

Results: Patients were 51±12 years-old and 54% were male. The median (IQR) of transplant vintage was 8 (5, 12) years, and the baseline eGFR levels were 31±11 mL/min per 1.73 m^2. The annual eGFR change was -1.6±2.0 mL/min per 1.73 m^2/ year. The median (IQR) urine levels of total protein, β2MG, NAG, and L-FABP at baseline were 0.3 (0.1-1.1) g/g Cr, 1535 (238-4780) μg/L, 0.06 (0.04-0.12) IU/L, and 16.7 (4.2-42.1) μg/g Cr, respectively. The higher levels of L-FABP and total protein were significantly associated with more rapid annual eGFR decline (*P* for trend <0.001 for both; **Figure**) while there was no significant association for β2MG or NAG. R^2 was 0.10 (*P*=0.03) and 0.18 (*P*=0.001) for L-FABP and total protein, respectively. After adjustment for age, gender, mean arterial blood pressure, and baseline eGFR, the association remained significant for total protein but not for L-FABP (**Figure**).

Conclusions: Among urine markers of total protein, L-FABP, NAG, and β2MG, total protein appears to have greatest predictive value for eGFR decline among KTRs.

Funding: Commercial Support - Chugai, Kissei, Roche Diagnostic K.K.

PO2428

Chronic Graft vs. Host Disease in Pancreas After Kidney Transplant Recipient: An Unrecognized Entity

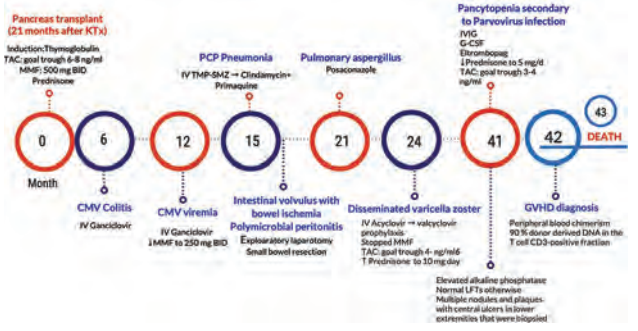
Prince Singh, Aleksandra Kukla. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Graft-versus-host disease (GVHD), a common complication after allogenic bone marrow transplantation is rarely seen after solid organ transplants (SOT). Reports of acute GVHD (maculopapular rash, diarrhea and cholestatic liver disease) described after SOT invariably happened in the early post-transplant period (days to months). In contrast, reports of SOT recipients with clinical features more consistent with chronic GVHD (cGVHD) (resembling autoimmune disease with chronic inflammation/ fibrosis) are lacking. We present a case of cGVHD in pancreas after kidney transplant (PAK) recipient diagnosed at 42 months post transplant.

Case Description: A 43 year old man received a HLA 5/6 mismatch, CMV mismatch (donor positive, recipient negative) deceased donor pancreas transplant two years after receiving a HLA 5/6 mismatch living unrelated kidney transplant. Anti-thymocyte

globulin induction was given along with a maintenance immunosuppression - tacrolimus, mycophenolate mofetil and prednisone. Post-transplant course was complicated by multiple opportunistic infections (Figure 1) leading to immunosuppression reduction. At 42 months post transplant, he developed dry eyes, arthralgia, anorexia, elevated alkaline phosphatase, dyspnea on exertion, lichen simplex chronicus dermatitis, and severe pancytopenia. GVHD was suspected which lead to peripheral blood chimerism testing revealing 90% pancreas donor-derived DNA in CD3-positive fraction of T cells. Patient passed away.

Discussion: The infections may have represented the immune dysfunction associated with cGVHD. De-escalation of immunosuppression could have led to an unopposed activation of donor cytotoxic T-lymphocytes resulting in worsening GVHD. Donor-derived T lymphocytes received during pancreas transplant may have targeted the bone marrow, causing severe pancytopenia, hence compounding the dysregulated immune state. Transplant professionals should be aware of the possibility of the rare but challenging diagnosis of cGVHD in PAK recipients and hence identify it appropriately.



PO2429

Graft vs. Host Disease Following Simultaneous Liver-Kidney Transplant

Bushra Syed, Mohamed Hassanein, Saul Nurko. *Cleveland Clinic, Cleveland, OH.*

Introduction: Solid organ transplant associated GVHD is uncommon with an incidence of 0.5 to 2%. Risk factors include donor HLA homozygosity, younger donor, recipient age >50 years and sex mismatch. We present a case of GVHD following a simultaneous liver kidney transplant (SLK).

Case Description: A 64-year-old female with NASH cirrhosis and CKD due to diabetic nephropathy underwent SLK from a 38-year-old male deceased donor. The pair had 3 HLA AB mismatches and 1 DR mismatch. A total of 3.5mg/kg of thymoglobulin (ATG) was used for induction. Renal and liver parameters were stable at discharge on a maintenance tacrolimus, mycophenolate and prednisone. She was readmitted after 1-month with diarrhea and fever. Infectious work up was unrevealing. She developed a maculopapular rash, mucositis and pancytopenia. Skin biopsy showed grade 2 acute GVHD. Donor lymphocyte chimerism in peripheral blood confirmed diagnosis of GVHD with 65% donor T cells, 10% donor CD8 cells and 42% donor natural killer (NK) cells. Treatment with high dose steroids and ATG was ineffective with worsening in CD8 and NK cell donor chimerism to 91% and 52% respectively. Weekly infliximab (INX) was introduced complicated by development of enterococcal bacteremia. Clinical improvement was seen after three doses INX, however there was a lag of several weeks before an improvement in donor chimerism. Six months later her hematological, renal and liver parameters remained stable, chimerism study showed <5% T cells, CD8 cells and NK cells and a protocol renal biopsy showed no evidence of GVHD associated denovo glomerulonephritis.

Discussion: The non-specific presentation of GVHD with rash, cytopenias and diarrhea leads to delayed diagnosis and high mortality. Detection of donor chimerism through short tandem repeat sequences is used to establish diagnosis and monitor response to treatment. Treatment options include high dose steroids with ATG, TNF a inhibitors or IL-2 antagonists. Adequate immunosuppression has to be balanced with risk of infection and timely use of empiric antibiotics and antifungals is recommended. Despite treatment, rapid progression to marrow aplasia, sepsis and multisystem failure ensues with an estimated mortality of >75%. Further studies are required to better understand this rare complication and explore novel treatments to improve outcomes.

Kidney After Intestinal Transplantation, a Comparison with Combined Kidney with Intestinal Transplant: A UNOS Database Analysis

Muhammad S. Yaqub, Muhammad Ajmal Panezai, Oluwafisayo O. Adebiyi, Tim E. Taber, Asif A. Sharfuddin. *Indiana University School of Medicine, Indianapolis, IN.*

Background: There is limited data on outcomes for patients receiving a isolated kidney transplant (KAIT) after any prior Multi-organ or Isolated Intestinal transplant (IT). We compared the outcomes of such transplants with Combined Intestinal-Kidney Transplants (CIKT).

Methods: The KT database from 1992 through Sep 2017 was cross-linked with the IT database for all kidney transplants performed. Data was analyzed for incidence, demographics, risk factors and outcomes after KT.

Results: There were a total of 2,886 IT recorded from 1990 through Sep 2017. There were a total of 190 (6.6%) Kidney transplants recorded of which 54 (28.4%) were KAIT while the remaining 136 (71.6%) where Combined (CIKT). The Median Duration from Intestinal Transplant to Kidney transplant was 5.6 years (Range 0.47 to 18.9). One year KAIT graft survival was 87% as compared to CIKT 52%. 5 year graft survival was 74% vs 36%. Death censored KAIT graft survival at 1 year was 98% vs 87% and 5 years 83% vs 74%.overall unadjusted kidney graft survival was significantly lower in CIKT as compared to KAIT p=0.009.

Conclusions: Our data shows that isolated kidney transplant after any prior Multi-organ or isolated Intestinal transplant has higher graft survival as compared to combined Intestinal Kidney Transplant. Higher CNI tough levels may be one common factor leading to lower graft survival.

Variable	Total N=190	KAIT 54	CIKT 136

PO2431

Association of the Rate of Kidney Transplant Function Decline with the Risk of Death After Graft Loss

Everly Ramos, Laura Binari, Peter E. Thorne, Guneet S. Kochar, Saed Shawar, Thomas G. Stewart, Heather L. Prigmore, Rachel C. Forbes, Khaled Abdel-Kader, Beatrice P. Concepcion. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Patients with failed kidney transplants are at increased risk of death after graft loss compared to transplant-naïve counterparts. We hypothesized that in this high risk population, a faster decline in eGFR in the 2y prior to graft loss is associated with death after graft loss.

Methods: We retrospectively reviewed all patients with death censored graft loss (DCGL) from 1995-2018 at a single center. We collected demographic, clinical and transplant characteristics at time of transplant and graft loss. Rate of eGFR decline was expressed as eGFR slope, calculated from all SCr values obtained within 2y prior to graft loss. Cox proportional hazards regression was used to determine the association between rate of eGFR decline and death while adjusting for age, gender, race, cause of ESKD, cause of graft loss, dialysis access at graft loss, and nephrectomy after graft loss.

Results: 333 patients with DCGL were included. Baseline characteristics were: median age 45y (IQR 35,57), 59% male, 43% black; 19% DM as cause of ESKD. CAN (65%) and acute rejection (29%) were the top causes of graft loss at a median time from transplant of 4.9y (IQR 2.5,7.9). Rate of eGFR decline (in ml/min/1.73m^2/y) was -14.49 ± 13.24 (mean±SD) and -11.73 (-18.72,-6.19) (median, IQR). At time of DCGL, 46% had a history of acute rejection and 34% had a permanent dialysis access. Of the 251 patients without missing data, 97 (40%) died and 68 (27%) underwent a nephrectomy after graft loss. Median time from graft loss to death was 3.1y (IQR 1.4,7.3). In multivariable analysis, there was a 0.6% increase risk in death for every 1 ml/min/1.73m^2/y increase in rate of eGFR decline though not statistically significant (HR 1.006, 95% CI 1.00-1.01). Exploratory analysis with non-linear modeling of eGFR slope showed that the risk of

death increases up to a rate of decline of 10 ml/min/1.73m²/y. DM as cause of ESKD was associated with an almost 2-fold increase in risk of death after graft loss compared to non-DM (HR 1.95, 95% CI 1.27-2.96).

Conclusions: In this single-center cohort of kidney transplant recipients with DCGL, a faster rate of eGFR decline in the 2y prior to graft loss was not associated with a higher risk of death after graft loss after adjustment for important clinical variables.

PO2432

Renal Recovery After Liver Transplantation Alone in Patients with Liver Cirrhosis and Severe CKD with Normal Kidney Size

Suyun Jung. *Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.*

Background: Most guidelines recommend simultaneous liver-kidney transplantation (SLKT) in patients with liver cirrhosis (LC) and severe chronic kidney disease (CKD) over liver transplantation alone (LTA). CKD, however, is not irreversible. This study evaluates the reversibility of kidney disease after LTA based on kidney size.

Methods: In this single-center retrospective study, we classified 90 patients with LC and severe CKD into 3 groups: normal kidney-LTA (NK-LTA, n=39), small kidney [both <9cm]-LTA (SK-LTA, n=40), and small kidney-SLKT (SK-SLKT, n=11). Baseline characteristics and renal recovery and survival outcomes were compared among 3 groups.

Results: The NK-LTA group had a lower percentage of hepatocellular carcinoma, a higher pre-LT eGFR, and a shorter duration of eGFR at <60 ml/min and pre-LT dialysis. This group, however, was older, received livers from a higher percentage of deceased donors and had a higher Child-Pugh score. Renal recovery, defined as no hemodialysis (HD) after LT, was found in 79% of those in the NK-LTA group, which was higher than 7.5% of those in the SK-LTA group. Renal survival, defined as patient survival without progression to HD or kidney transplant was found in 56% of patients in the NK-LTA group, which was higher than 2.5% of those of the SK-LTA group.

Conclusions: Patients with LC and severe CKD with normal kidney size may experience reversible kidney disease after LTA. Therefore, kidney after liver transplantation is recommended over SLKT for these patients.

Funding: Private Foundation Support

PO2433

Immediate Allograft Function After Liver Transplant (LT) Modifies the Effect of Pre-LT Renal Dysfunction (RD) on Post-LT Survival

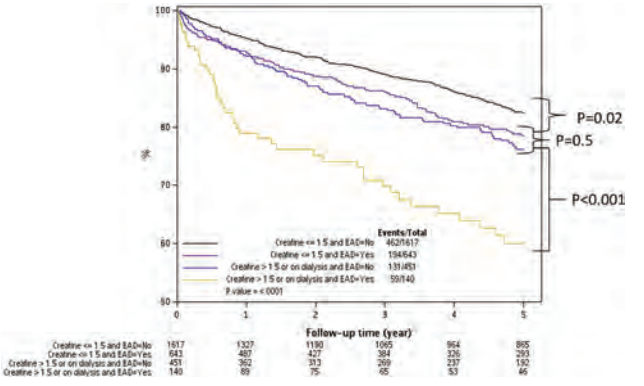
Hani Wadei, Shennen Mao, Martin L. Mai, Nabeel Aslam, Kristopher Croome. *Mayo Clinic's Campus in Florida, Jacksonville, FL.*

Background: Pre-LT RD is associated with higher post-LT mortality. It is unclear if immediate liver allograft function modifies this risk.

Methods: We retrospectively reviewed data on 2,856 primary LT performed in our center from 1998 to 2018. Pre-LT RD was defined as Cr >1.5 mg/dl or on dialysis at LT. Immediate liver allograft function was defined using the validated early allograft dysfunction (EAD) criteria (bilirubin≥10 mg/dl, INR ≥1.6 or ALT/AST ≥2000IU/mL on POD 7). Pre-LT RD was present in 591(21%), of these 429 patients had Cr >1.5 and 165 were on dialysis. EAD developed in 784 (27%). The cohort was divided into 4 groups according to pre-LT RD and EAD. Group 1 (n=1,617): No RD and no EAD, Group 2 (n=643): No RD but had EAD, Group 3 (n=451): had RD and no EAD, Group 4 (n=140): had both RD and EAD. The unadjusted and adjusted post-LT survival was compared between the 4 groups.

Results: Results are presented in Figure 1. Group 1 had the best outcome with 1,3 and 5 year survival of 95%, 89% and 82%, respectively, and group 4 had the worst outcome with 1, 3 and 5 year survival of 79%, 70% and 60%, respectively, P <0.0001. Group 2 and 3 had intermediate and comparable (P=0.5 between group 2&3) outcomes. Survival was better in group 2&3 compared to those in group 4 (P<0.001) but was worse than group 1 (P=0.02). After adjusting for recipient age, female gender, DM, MELD score, cause of ESLD and DRI, group 4 had the highest risk of death (aHR 2.33, CI:1.69-3.21, P<0.001). Patients in group 2 (aHR 1.16, CI:0.95-1.41, P=0.1) and group 3 (aHR 1.23; CI: 0.96-1.58, P=0.09) had comparable adjusted risk of death to group 1 patients.

Conclusions: LT recipients with pre-LT RD who enjoy immediate liver allograft function have comparable adjusted survival to those with normal renal function at LT. Our results indicate that livers at higher risk of EAD should be avoided in LT recipients with RD.



Kaplan-Meier analysis of post-LT patient survival according to pre-LT RD and post-LT EAD

PO2434

Sex and Equity in Pediatric Kidney Transplantation

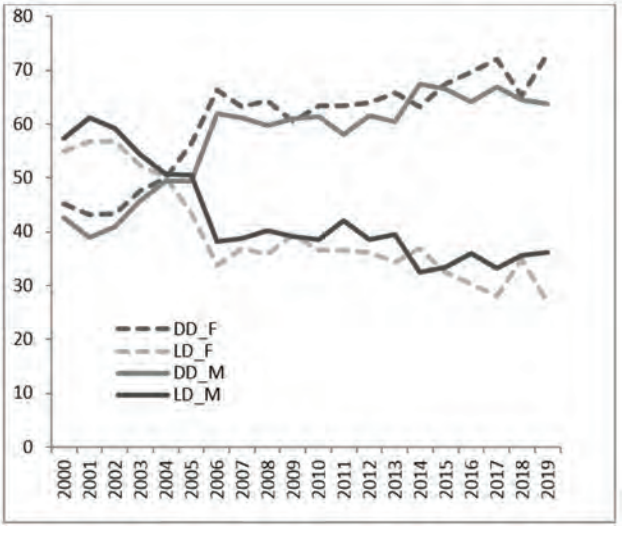
Rita L. McGill, Nevin Murthy, Lainie F. Ross. *University of Chicago, Chicago, IL.*

Background: Mortality in pediatric kidney failure (ESRD) is higher in girls than in boys, in contrast to the general population. In a recent report, correcting for access to transplantation partially ameliorated this risk, prompting an examination of equity in pediatric kidney transplantation.

Methods: USRDS files were used to examine incidence of pediatric ESRD (age≤18) and initial Rx modalities from 2000-15. UNOS data were used to evaluate pediatric kidney recipients between 2000-2019. Logistic regression was used to calculate an odds ratio (OR) for receiving a living donor kidney (LD). Hazard ratios (HR) of death, graft failure and death-censored graft failure (dcGF) were obtained in Cox models stratified for LD/deceased-donor (DD). Models were adjusted for age, sex, and year of transplant and reported with 95% CI.

Results: Among 17,366 incident pediatric ESRD patients in USRDS, 42.8% were female. Mean and median age did not differ. Initial kidney treatment was transplantation in 17.9% of girls and 23.8% of boys, with more hemodialysis in girls (46.0 vs 40.5%, P<0.001). Among 16,811 UNOS recipients, 41.0% were female. Changes in allocation policy were associated with a shift from parental donors to deceased-donors, which was more marked in female recipients (figure). 42.8% of boys and 39.7% of girls received LD (P<0.001); adjusted OR of receiving LD was 0.91 (0.85, 0.98, P=0.007) for girls. Compared to boys, girls had inferior outcomes with DD, with HRs: death 1.51 [1.30, 1.76], graft failure 1.31 [1.21, 1.40], and dcGF 1.30 [1.20,1.40, P<0.001 for all]. LD outcomes did not differ by sex.

Conclusions: Female children have fewer early transplants and higher odds of receiving DD kidney transplants that are associated with inferior outcomes than their male counterparts. Attention to sex-specific disparities may improve ESRD outcomes in girls.



Living (LD) & Deceased-donors (DD) in male (M) and female (F) recipients

PO2435

Outcomes of Emergency Department Visits of Children After Kidney Transplantation

Christian Hanna,[1] Ashish Shah,[2] Mark G. Roback,[4] Priya S. Verghese,[5] Ronald A. Furnival.[3] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]University of Minnesota, Minneapolis, MN; [4]University of Colorado, Denver, CO; [5]Northwestern University - Chicago, Chicago, IL.*

Background: Systematic data evaluating the postoperative Emergency Department (ED) care and outcomes of Pediatric Kidney Transplant (PKTx) recipients is limited. Our study objective is to identify the risk factors, disposition, and outcomes of PKTs recipients presenting to the ED.

Methods: We retrospectively reviewed the medical records of PKTx patients (<18 years of age) who presented to our University Children's Hospital ED from 04/01/2011 to 06/30/2015. Data pertaining to patient demographics, chief complaint, evaluation, interventions, results, length of stay (LOS) and disposition were abstracted. Multiple logistic regression analysis was used to study the associations between admission, the presence of bacteremia, and multiple risk factors.

Results: During the study period, 60 of the 85 PKTx recipients (71%) presented to the ED for acute care (total of 210 visits, range 1-20; mean 3.5 per recipient). The majority (148/210; 70%) of the visits occurred in the first year following transplant. Fever (44%) and gastrointestinal complaints (27%) were the most frequent presentations. Mean ED LOS was 3.5 hours (range 0.22-10.8 hours). Most (109/210; 52%) visits resulted in hospital admission, for a mean inpatient LOS of 4 days (range 1-55 days). After adjusting for age and sex, the following risk factors were significantly predictive of hospital admission: shorter time since transplant (p=0.003), presence of fever (p<0.001), higher heart rate (p<0.001), higher white blood cell count (p=0.004), and presence of Systemic Inflammatory Response Status (SIRS) (p<0.001). Age adjusted systolic and diastolic blood pressure, type of transplant (deceased vs living donor), underlying primary kidney disease, the presence of a central line, or the number of immunosuppressant drugs were not predictive of hospital admission. Multivariate analysis of all significant risk factors found that shorter time since transplant and presence of SIRS were the only factors significantly associated with hospital admission (p<0.05). Only presence of SIRS was significantly associated with positive blood cultures (p=0.03).

Conclusions: Nearly three-quarters of all PKTx recipients presented to ED most frequently in the first postoperative year, with over half requiring hospital admission. Shorter time since transplant and presence of SIRS were significantly predictive of hospital admission.

PO2436

The First Increase in Live Kidney Donation in the United States in 15 Years

Fawaz Al Ammary, Allan Massie, Deidra C. Crews, Dorry L. Segev, Abimereki Muzaale. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: After more than a decade of decline, the first sustained increase in live kidney donation was observed in the US from 2017 to 2019. Understanding these trends in donation may provide opportunities to effectively sustain or even enhance this recent increase in donors.

Methods: We conducted a national registry study of 35,900 donors (70.3% white, 14.5% Hispanic, 9.3% black, 4.4% Asian) to understand the increase in 2017-2019 vs. 2014-2016 using Poisson regression stratified by donor–recipient relationship (biologically related, unrelated, and kidney paired donors).

Results: Among biologically related donors aged <35, 35-49, and ≥50 years, the number of donors did not change across race/ethnicity but increased by 38% and 29% for Hispanic and black ≥50. Among unrelated donors <35, 35-49, and ≥50, white donors increased by 18%, 14%, and 27%; Hispanic donors <35 did not change but increased by 22% and 35% for 35-49 and ≥50; black donors <35 declined by 23% and did not change for 35-49 and ≥50; Asian donors did not change. Among kidney paired donors <35, 35-49, and ≥50, white donors increased by 42%, 50%, and 68%; Hispanic donors <35 and 35-49 increased by 36% and 55% and did not change for ≥50; black donors did not change; Asian donors <35 did not change but increased by 107% and 82% for 35-49 and ≥50.

Conclusions: The increase in live kidney donation was driven predominantly by unrelated and paired white donors. Donation among unrelated black individuals should be promoted.

Annual number of live kidney donors in the US from 2014 to 2019, stratified by donor type

PO2437

Safety and Effect of Alkali Therapy on Vascular Function in Kidney Transplant Recipients: A Pilot Study

Rachel R. Bohling, Monica Grafals, Zhiying You, Jessica B. Kendrick. *University of Colorado Denver School of Medicine, Aurora, CO.*

Background: Acid retention is a common feature of kidney transplant recipients (KTR). Studies have found that lower bicarbonate levels in KTRs are associated with an increased risk of mortality and cardiovascular disease. We tested the hypothesis that alkali therapy was safe and feasible in KTRs and would improve vascular function.

Methods: We performed an 18-week, randomized, double-blind, placebo-controlled crossover safety and feasibility pilot study of the use of sodium bicarbonate therapy in 16 KTRs. We recruited KTRs at least one year from transplant with an eGFR ≥ 45 ml/min per 1.73m^2 and a serum bicarbonate level of 16-24 mEq/L. Patients received study drug therapy (sodium bicarbonate and placebo) at 0.5 mEq/kg/lean body weight for the entire 8-week treatment period. Each treatment period was 8 weeks in duration with a 2-week washout period between treatments. All patients had to be on stable immunosuppression and antihypertensive regimen for at least one month prior to randomization. Each patient served as his or her own control. During each treatment period, patients were assessed at 4 and 8 weeks for adverse events, weight, blood pressure, gastrointestinal symptoms and pill compliance. Brachial artery flow-mediated dilation (FMD) was obtained at beginning and end of each treatment period.

Results: The mean (SD) age, eGFR, and serum bicarbonate levels were 52 (19) years, 71 (21) ml/min/1.73 m^2, and 23 (2) mEq/L, respectively. Serum bicarbonate levels increased by 0.4 mEq/L during treatment. Sodium bicarbonate therapy was not associated with worsening blood pressure, weight gain, or hypokalemia. 46% of patients experienced nausea and/or bloating on sodium bicarbonate therapy compared to 40% while on placebo. The study was not powered to detect differences in FMD, but there was a trend towards improved FMD in the sodium bicarbonate group compared to the control (mean difference 1.6%; 95% confidence interval, -0.39 to 3.6; p=0.1). Additionally, a trend towards decreased 24-hour urine net acid excretion (mean (SD) change -9.0 (17.1) mEq/d, p=0.07) and ammonium excretion (mean (SD) change -6.0 (12.1) mEq/d, p=0.08) was observed.

Conclusions: Sodium bicarbonate therapy is safe and feasible in KTRs. There was a trend towards improvement in FMD, strengthening the need for a larger randomized controlled trial.

PO2438

Demographic Variability of Kidney Function in Live Donors: A Single-Centre Analysis

Tina Thomson, Andreas Kousios, Rawya Charif, Honeylet Orr, Harvinder K. Dulku, Marina Loucaidou. *Imperial College London Department of Medicine, London, United Kingdom.*

Background: Live donation is encouraged as better outcomes in kidney transplant recipients. Donor assessment requires thorough evaluation but kidney function varies with demographics. We compre mGFR with the performance of eGFR formulas and creatinine clearances

Methods: Analysis of 997 live donors between February1995 and October2019. Using pre-donation measured GFR(Tc EDTA-GFR) as the gold standard, we compared the performance of CKD-MDRD,CKD –EPI(ml/min/1.73m^2),24hour creatinine clearance(Cr Cl) and Creatinine clearance by Cockcroft Gault(CrCl C-G)(ml/min) between age, ethnicity, and gender. We also calculated the relative bias(mGFR-eGFR/mGFR), root mean square error and the accuracy(P30)(eGFR between+-30%mGFR)of different eGFR equations

Results: 422(42.32%)male donors. 616(62%) Caucasian, 228(23%) South Asian, 114(11%) Afro Caribbean and39(4%) of other ethnic groups(Arabic, oriental and mixed ethnicity)**(Graph1).**Mean mGFR was 100.08(SD 10.87). Mean mGFR for males and females were 105.77 vs 96.27, respectively(p=0.05).63(6%) donors were >65 years. Mean mGFR comparing young and >65 years old donors were 103.44 vs 82.27, respectively(p= 0.0028). As predicted, there is a linear decline in mGFR with increasing age. Cr Cl C-G has a tendency towards underestimating function in healthy living donors over 65 years old .GFR calculated by CKD-EPI formula was comparable to mGFR amongst all age groups, genders and ethnically diverse living donors .CKD-EPI performed better in terms of least bias and highest accuracy compared to MDRD for all donor subgroups**(Table1).**

Conclusions: mGFR declines with age and healthy older donors have significantly lower mGFR compared to younger donors. Cr Cl overestimates kidney function and should be used with caution.eGFR by CKD EPI comes closest compared to mGFR in all groups. It could be reliably used as first screening tool for assessing function of living donors pre donation, irrespective of age, gender or ethnicity.

Assessment of Kidney Function at 3 and 6 Months in Kidney Donors with Cardio-Metabolic Risk Factors

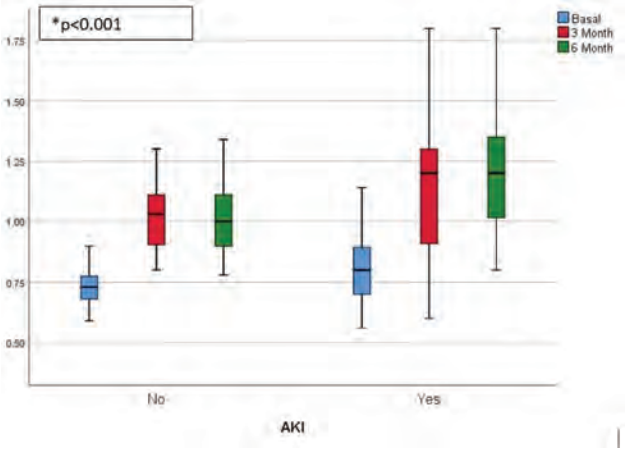
Jesus D. Lima lucero,[1] Rafael Valdez-Ortiz,[1] L. M. Perez-Navarro,[1] Ana G. Ortega,[2] Ernesto C. Lopez.[1,2] *[1]Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; [2]Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.*

Background: Cardio-metabolic risk factors (CRFs) in kidney donors contribute to further deterioration of kidney function after donation, increase their post-donation cardiovascular risk. Objective: To assess the renal function of kidney donors with CRFs at 3 and 6 months after donation.

Methods: Cross-sectional, descriptive study, which included kidney donors who were admitted to the National Medical Center "Dr. Antonio Fraga Mouret" during the period from 2015 to 2019. Descriptive statistics were made, ANOVA with a 95% CI and a value of p <0.05. The CRFs dyslipidemia, hypertension, hyperglycemia, body mass index (BMI) and hyperuricemia were evaluated.

Results: 153 donors were admitted, 34% without social security, 59% women, with a mean age of 42.7 ± 10.7 years. The clinical and biochemical characteristics at hospital admission were: mean SBP / DBP was 106 ± 6.02 /72.9=5.4, BMI, 26.3 ± 3.2, proteinuria 126.4 ± 13.4, hematocrit 44.6 ± 4.9, albumin 4.1 ± 0.4, K 4.1 ± 0.4, Ca 9.2 ± 0.6, Uric acid 5.4 ± 1.2, Total cholesterol 185.6 ± 34.4, triglycerides 156.5 ± 91.7, fasting glucose 91.6 ± 15.2, Creatinine 0.78 ± 0.14. The mean bleeding during surgery was 263.66 ± 447 ml, creatinine after surgery was 1.21 ± 1.8, upon release from hospital it was 1.13 ± 0.27. 72% of donors presented acute kidney injury (AKI) after surgery, with an average of 1.56 ± 1.8 days with AKI, 56% of donors released from hospital with AKI. More than 25% of kidney donors had 2, 3 and 4 CRFs. Figure 1 presents the comparison between groups (AKI vs No AKI) of creatinines at baseline, 3 months and 6 months.

Conclusions: A higher presence of CRFs is associated with higher AKI events after kidney donation. AKI patients during renal donation show a further deterioration of renal function at 3 and 6 months of follow-up. Timely interventions prior to donation could improve the evolution of this group of patients.



PO2440

Direct Acting Antiviral Prophylaxis to Prevent Virus Transmission from Hepatitis C Viremic Donors to Hepatitis C-Negative Kidney Transplant Recipients

Idris Yakubu, Richard Sterling, Marlon F. Levy, Chandra S. Bhati, Dhiren Kumar, Irfan A. Moinuddin, Layla Kamal, Anne L. King, Amit Sharma, Adrian Cotterell, Gaurav Gupta. *Virginia Commonwealth University Health System, Richmond, VA.*

Background: Studies have described a 12-week course of direct-acting anti-viral drugs (DAA) for HCV transmission from infected donors to negative kidney transplant recipients. This strategy is limited by high cost and access to DAA. A prophylactic strategy may be safer and cost-effective. We recently reported the results of our experience where a 2-4 day peri-operative DAA prophylaxis using sofosbuvir/velpatasvir (SOF/VEL) for D+/R- transplants prevented HCV transmission in a majority (88%) of cases. We report our entire experience based upon an adaptive iterative trial design where prophylaxis with SOF/VEL was initially extended to 7 days, and ezetimibe was added for a second cohort.

Methods: Wait listed patients were eligible if they met the following: (absence of living donor; panel reactive antibody≤50%; ≤1 prior transplant; absence of liver disease). The primary outcome was HCV transmission, defined as 2 consecutive positive HCV nucleic acid tests tested at Day 7 and 14-21 post-transplant. Confirmed HCV viremia triggered a12-week course of DAA.

Results: 100 patients (mean age=56 years) received D+/R- transplants from November 2017 to April 2020. Mean wait time to transplant from enrollment was 34 days and the mean KDPI was 67%. At a median follow-up of 10 months (IQR: 1-30months), graft survival was 99% and patient survival was 98% with no cases of liver dysfunction. In Group 1, 10 patients received one dose SOF/VEL immediately pre-transplant and a second dose on post-transplant Day 1. Viral transmission was 30% [3/10]. In Group 2, 42 patients received two additional doses of SOF/VEL on Days 2 and 3 post-transplant. Viral transmission rate dropped down to 9.5% (4/42). All patients then achieved SVR with full DAA therapy in groups 1 and 2. In Group 3 (N=28), prophylaxis was extended to 7 days with further reduction in transmission to 3.5% (1/28). In group 4, 19 patients received ezetimibe and SOF/VEL for 7 days. Viral transmission was 5% (1/19).

Conclusions: A 7-day DAA prophylaxis is effective in preventing donor-derived HCV transmission, can result in significant cost-savings and increase access to transplants. Adding ezetimibe to SOF/VEL did not provide an additional benefit in preventing viral transmission.

PO2441

Donor Hepatitis C Antibody Positivity Misclassifies Kidney Donor Profile Index in Non-Hepatitis C-Infected Donors: Time to Revise the Kidney Donor Profile Index

Masahiko Yazawa,[1,2] Vasanthi Balaraman,[1,2] Makoto Tsujita,[1,2] Ambreen Azhar,[1,2] Manish Talwar,[1,2] Anshul Bhalla,[1,2] Csaba P. Kovesdy,[2] James D. Eason,[1,2] Miklos Z. Molnar.[1,2] Methodist Transplant Epidemiology Research Group *[1]Methodist University Hospital, Memphis, TN; [2]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Kidneys from donors with hepatitis C(HCV) infection are traditionally considered to be at risk for poorer graft outcomes, as reflected in the Kidney Donor Profile Index(KDPI). The KDPI defines an HCV positive donor based on HCV antibody(Ab) testing and/or nucleic acid amplification test(NAT), so not actively infected donor is also

considered as HCV positive. The outcome of kidneys from HCVAb positive but NAT negative donors are unknown.

Methods: A national-registry-based retrospective cohort study was conducted using the SRTR data set. We identified all HCV negative recipients between April 1st, 2015 and March 2nd, 2018, who received kidney transplant from HCV Ab positive and NAT negative (D-HCVAb(+)/NAT(-) n=116) and HCV Ab negative and NAT negative (D-HCVAb(-)/NAT(-); n=25,574) donor kidneys. We then compared recipients' estimated glomerular filtration rate(eGFR) at 6 months in matched cohorts, using combined exact matching (based on KDPI) and propensity score matching. We created two separate matched cohorts to examine differences in outcomes based on how HCV positive status is defined: for the first cohort, we used the allocation KDPI (where HCV is considered positive in D-HCVAb(+)/NAT(-)patients), while for the second cohort we used a modified KDPI, where the HCV component of KDPI was considered negative in D-HCVAb(+)/NAT(-)patients.

Results: The mean±SD age of the allocation KDPI matched cohort at baseline was 59±10 years, 69% were male, 61% and 30% of the patients were white and African American, respectively. The baseline characteristics of the recipients were well-balanced in both matched cohorts. Recipients' eGFR at 6 months after transplantation was significantly higher in the D-HCVAb(+)/NAT (-) group compared to the D-HCVAb(-)/NAT (-) group (61.1±17.9 versus 55.6±18.8 mL/min/1.73m^2, p=0.011) in the allocation KDPI matched cohort, while it was similar (61.8±19.5 vs. 62.1±20.1 mL/min/1.73m^2, p=0.9) in the modified KDPI matched cohort.

Conclusions: Recipients who received HCVAb positive, but NAT negative donor kidneys did not experience worse 6-month eGFR than correctly matched D-HCVAb (-)/NAT (-) recipients. HCVAb positive, but NAT negative donor kidneys should not be allocated as HCV positive kidneys.

PO2442

Transplantation of Kidneys from Hepatitis C-Infected Donors to Hepatitis C-Negative Recipients: 1-Year Renal Allograft Outcomes

Miklos Z. Molnar,[1,2] Ambreen Azhar,[1,2] Makoto Tsujita,[1,2] Manish Talwar,[1,2] Vasanthi Balaraman,[1,2] Anshul Bhalla,[1,2] Csaba P. Kovesdy,[2] Satheesh P. Nair,[1,2] James D. Eason.[1,2] Methodist Transplant Epidemiology Research Group *[1]Methodist University Hospital, Memphis, TN; [2]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Transplant centers in United States are increasingly willing to transplant kidneys from hepatitis C (HCV) infected donors to hepatitis C negative recipients. Long-term renal outcome data of a non-prophylactic HCV treatment approach outside clinical trials is missing.

Methods: We examined 65 HCV negative recipients who received a HCV infected kidney transplant (HCV+) and 59 HCV negative recipients who received a HCV non-infected kidney transplant (HCV-) during 2018 in a single transplant center. We compared estimated glomerular filtration rate (eGFR), cumulative results of per-cause and surveillance protocol biopsies, development of de novo donor specific antibodies (DSAs), co-infection rates and patient and graft outcomes up to 1 year post-transplant between HCV+ versus HCV- groups.

Results: The mean±SD age of recipients was 52±11 years, 43% were female, 19% and 80% of recipients were Caucasian and African-American, respectively. Baseline characteristics were similar between the HCV+ and HCV- groups. The delayed graft function rate, estimated GFRs at post-transplant 3, 6, 9 and 12 months, cumulative rejection rate, development of de novo DSAs and co-infection rates were not statistically significantly different between the HCV+ and HCV- groups (Table).

Conclusions: Recipients of HCV-viremic kidneys have similar renal allograft function, incidence of rejection in the first year after transplantation compared to those who received HCV-non-viremic kidneys.

Renal graft and patient outcome of all kidney transplant recipients

	Entire Cohort	HCV+	HCV-	p-value
Observations (n)	124	65	59	N/A
Delayed Graft Function, N, (%)	12 (10%)	5 (12%)	7 (8%)	0.43
Estimated GFR at 3 months after transplantation (ml/min/1.73m2), mean (SD)	63 (20)	63 (18)	64 (21)	0.85
Estimated GFR at 6 months after transplantation (ml/min/1.73m2), mean (SD)	66 (19)	66 (18)	66 (21)	0.96
Estimated GFR at 9 months after transplantation (ml/min/1.73m2), mean (SD)	67 (18)	66 (15)	67 (20)	0.62
Estimated GFR at 12 months after transplantation (ml/min/1.73m2), mean (SD)	66 (19)	64 (16)	66 (22)	0.69
ACR/ABMR (N of patient / N of patients with biopsy result (%))	26/113 (23%)	13/54 (24%)	13/59 (22%)	0.80
De novo DSA (N of patient / N of patients with DSA result (%))	26/94 (28%)	20/64 (31%)	6/30 (20%)	0.26
BK viremia (> 10,000 copies) (N (%))	19 (16%)	12 (18%)	7 (13%)	0.42
CMV viremia (>1,000 copies) (N (%))	15 (12%)	11 (17%)	4 (7%)	0.10
Death (N (%))	4 (3%)	1 (2%)	3 (5%)	0.26

PO2443

Hepatitis C NAT-Positive Kidney Transplant into Hepatitis C-Negative Recipients: A Single-Center Experience

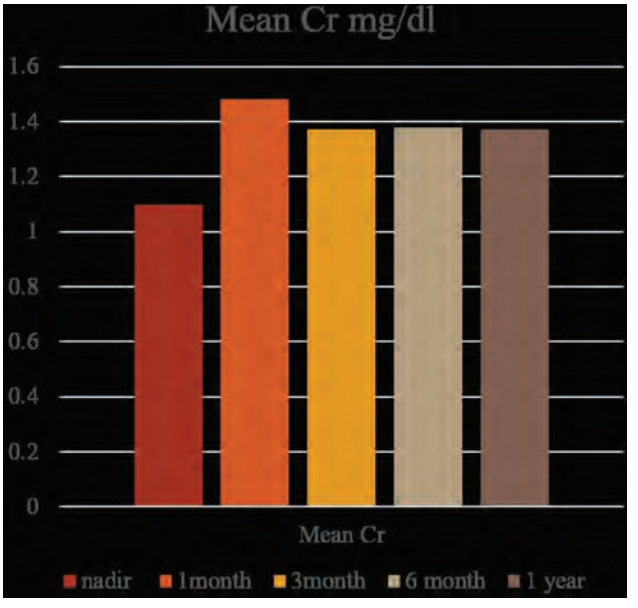
Taranpreet Kaur, Jeongwon Choi, Silvi Shah, Shalini Bumb, Bassam G. Abu Jawdeh, Amit Govil. *University of Cincinnati, Cincinnati, OH.*

Background: Direct-acting antivirals (DAA) for Hepatitis (Hep) C have a 96-100% sustained viral remission (SVR) rate. This makes transplant of Hep C nucleic acid amplification testing (NAT)+ kidneys and treatment post-transplant feasible. We performed a prospective IRB approved trial at our center to validate the use and challenges of this approach.

Methods: Informed consent from eligible patients was obtained. Patients with chronic liver disease, dual organ transplants, HIV and active Hep B infection were excluded. Post-transplant, viral load was tested on day 3-5 and 7-10 and weekly thereafter until viremia was confirmed. All pts. were treated by hepatologist based genotype and insurance company preference. Standard of care immunosuppression protocols was used.

Results: 51 pts. got Hep C NAT+ kidney. The median age of the recipients was 58 years (range 29-72) and the mean wait time was 802 days (range 68-3073). Mean KDPI was 58.8 (range 27-94) with a median donor age of 38 years (range 21-56). Out of 16 implant biopsies, 13/16 (81%) had <5 %of sclerotic glomeruli, 14/16 (88%) had minimal interstitial fibrosis, and 15/16 (94%) had no arteriosclerosis. There was a 100 % transmission rate of Hep C. As of now, 46/51 (90%) have completed a 12-week course of DAA, and 45/46 (98%) have become RNA negative with 34/46 (74%) achieving SVR. So far, there had been no insurance denials of DAA coverage. Among 18 for cause allograft biopsies, 1 showed tubuloreticular inclusion thought to be Hep C related and another showed recurrent C3GN thought to be triggered by Hep C and Hep B

Conclusions: Transplantation of HepC NAT+ kidneys to Hep C negative recipients followed by treatment with DAA is a feasible option as a standard of care outside trials. Recipients should be monitored for Hep C related complications



PO2444

Human Herpesvirus 8-Associated Kaposi Sarcoma Developing in a Kidney Allograft from a Hepatitis C-Positive Donor

Maria T. Story,[1] M. Lee Sanders,[1] Sreedevi koppisetti Jenigiri,[1] Amani Bashir,[1] Jude Longo,[3] Elliot Grodstein,[2] Christie P. Thomas,[1] Daniel Katz.[1] *[1]The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [3]Iowa City VA Medical Center, Iowa City, IA.*

Introduction: Kaposi Sarcoma (KS) is an endothelial malignancy caused by the oncogenic virus Human Herpesvirus-8 (HHV-8) and transmission during kidney transplantation can occur. We describe two cases of donor-to-recipient transmission of HHV-8, with one recipient developing KS in the kidney allograft causing acute kidney injury (AKI).

Case Description: Donor: The donor died from complications of IV drug use and had known hepatitis C (HCV) at the time of organ donation. Recipient 1: 64-year-old male with ESRD, induction with basiliximab. He tested positive for HCV on post-transplant day 2 and was treated with sofosbuvir/velpatasvir for 12 weeks. Two months post-transplant, he developed encephalopathy and was found to have HHV-8 viremia during his workup. Immunosuppression was decreased, HHV-8 PCR levels were monitored and eventually were undetectable. He did not develop KS. Recipient 2: 71-year-old male with ESRD, induction with anti-thymocyte globulin. He was treated pre-emptively for HCV with glecaprevir/pibrentsvir. Five months post-transplant he was admitted for rising creatinine. Initial allograft biopsy was of poor quality but was suggestive of Banff IIA

rejection; IV methylprednisone and anti-thymocyte globulin were administered. Repeat biopsy demonstrated extensive replacement of the allograft tissue with KS. PET scan revealed metastatic KS. Immunosuppression was discontinued and he underwent allograft nephrectomy. He died at home 2 months later. Retroactive testing of samples prior to transplantation revealed the donor was HHV-8 PCR positive at the time of death and both recipients were HHV-8 antibody and PCR negative.

Discussion: We describe donor-to-recipient transmission of HHV-8 during kidney transplantation. HHV-8 associated post-transplant KS is well described but rare in the US. Post-transplant KS typically presents with classic skin lesions and kidney allograft involvement with KS is rare, with only 7 previously reported cases. Public Health Service (PHS) increased risk donors may represent a subset of donors at especially high risk for HHV-8 transmission. Future investigation is needed into this population to determine if post-transplant HHV-8 PCR monitoring or adjustments in immunosuppression are needed for kidney transplant recipients of PHS increased risk organs.

PO2445

John Cunningham Virus (JCV) in Renal Allograft Recipients (RAR)

Bushra Z. Saleem, Sonika Puri, Zahidul H. Mondal. *Rutgers The State University of New Jersey, New Brunswick, NJ.*

Introduction: Both JCV and BK virus belong to Polyoma virus (PV) family and can lead to opportunistic infection in RAR. BK nephritis in RAR is well described in literature (incidence 1- 10 %) in contrast to JCV nephropathy (JCVN) which is a rare entity. Here we describe two cases of JCV in RARs.

Case Description: Case 1: 44-year-old woman with PMH of HTN and ESRD received her first renal transplant in 2009 followed by antibody mediated rejection (AMR) resulting in graft dysfunction. She received a preemptive second renal transplant in 12/2015 followed by multiple RA biopsies within first few months due to elevated serum creatinine (s.cr). The biopsies showed borderline CMRs, acute AMRs and eventually chronic active AMR. Treatment regimen included steroids, rituximab, IVIG and plasmapheresis. Despite repeated treatments, her s.cr remained elevated leading to another biopsy in 6/2016 showing viral cytopathic changes suspicious for PVN. SV40 stain was negative as was serum BK titer. Immunosuppression (IS) was reduced and a biopsy was repeated in 8/2016 that stained positive for SV40. Given repeatedly negative serum BK, serum JCV titer was sent, which was positive and peaked at 350659 copies/ml on 9/2016. Titer improved to 66153 after 2 doses of Cidofovir however, later deteriorated to 334240. She had no neurological involvement. Despite Cidofovir, her renal function deteriorated rapidly requiring bilateral RA nephrectomies with pathology showing JCVN. IS was discontinued following which JCV titer became undetectable. Case 2: 59-year-old man with PMH of HTN and ESRD who received renal transplant in 4/2013 followed by baseline s.cr of 1.6 mg/dl. He was on Myfortic, Sirolimus and Prednisone for IS. He presented with rising s.cr in 9/2019 (2.1mg/dl). He underwent RA biopsy in 11/2019 showing viral cytopathic changes, positive SV40 consistent with PVN. BK by PCR resulted negative x 2 but JCV titer returned at 3896 copies/ml. Myfortic was discontinued. Repeat JCV titer trended down to 2603 in 3/2020. Further follow up was delayed due to COVID-19 pandemic.

Discussion: The diagnosis of JCVN is challenging and easy to miss. Index of suspicion should be high with positive viral cytopathic changes (+/- SV40 stain) on allograft biopsy and negative serum BK. Currently there is no definitive therapy for JCV. Early diagnosis and reduction in IS are critical. Cidofovir may be of utility.

PO2446

Disseminated Adenovirus Treated with Brincidofovir in a Kidney Transplant Recipient

Tiffany Truong, Thanh Cao, Santhi Voora, Thin Thin Maw. *University of Southern California, Los Angeles, CA.*

Introduction: Adenovirus is a common viral infection, with which immunocompromised patients have an increased risk of disseminated disease. It is less frequently described in solid organ transplant recipients and the optimal therapy for disseminated disease is unknown. We present a case of disseminated adenovirus in a kidney transplant recipient who was treated successfully with brincidofovir.

Case Description: A 56 year old female with ESRD of unclear etiology received her second kidney transplant from a deceased donor 2 years ago with thymoglobulin induction. She presented with one day of gross hematuria and right flank pain, as well as 2 weeks of malaise and 5 days of fever, cough, sore throat, nausea and vomiting. She had acute kidney injury with creatinine of 1.75 mg/dl from a baseline of 0.8 mg/dl. She was found to have adenovirus in urine (>2million) and serum. Other infectious etiologies were ruled out. Initial treatment consisted of reduced immunosuppression with discontinuation of mycophenolate mofetil and tacrolimus and increased prednisone from 5mg to 10mg daily due to leukopenia. Given disseminated symptoms, adjunctive treatment was also initiated with cidofovir 1mg/kg IV q48hr alternating with IVIG 500mg/kg q48 hr. She received 4 doses of cidofovir and IVIG, with resolution of hematuria and decreased adenovirus level in urine. Although she received hydration before and after cidofovir, creatinine rose to 2.04 mg/dl. With 2 additional cidofovir doses, she continued to have AKI (peak 3.1 mg/dl), before brincidofovir was started at a dose of 100mg twice weekly. Creatinine was 2.73 mg/dl when initiated on brincidofovir which decreased and stabilized to 2.2 mg/dl. Brincidofovir was discontinued when adenovirus was undetected in serum and <500 copies/ml in urine.

Discussion: The most commonly used adjunctive treatment to reduced immunosuppression in the treatment of adenovirus infection is cidofovir. However, cidofovir is nephrotoxic and renally cleared. This may limit its use, particularly in kidney transplant patients. Brincidofovir is less nephrotoxic due to decreased accumulation in proximal tubules, and may be better tolerated in kidney transplant recipients. We report a case of well tolerated brincidofovir treatment of disseminated adenovirus infection in a kidney transplant recipient who demonstrated clearance of infection and improvement in kidney function.

PO2447

Early Ganciclovir-Resistant Cytomegalovirus Infection in a Kidney Transplant Recipient: Could We Avoid It?

Kaushik Ivaturi, Ekamol Tantisattamo. *University of California Irvine, Irvine, CA.*

Introduction: Although uncommon, ganciclovir-resistant cytomegalovirus (GR-CMV) can lead to a therapeutic challenge given drug nephrotoxicity. Here we report a case of GR-CMV infection during early post-kidney transplant (KT).

Case Description: A 41-year-old woman with ESRD received the second KT in February 2019 with rATG induction. She also received rituximab one dose for pre-KT donor specific HLA antibodies. Maintenance immunosuppression are tacrolimus, mycophenolate sodium (MPS), and prednisone. Serum creatinine slowly trended down to the baseline of 1.3mg/dL at 3 month post-KT. CMV IgG serostatus was D+/R-. She received a 6-month CMV prophylaxis with a renally-adjusted dose of valganciclovir 450 mg twice weekly for 1 month, which was increased to 450 mg twice daily for 5 more months. 4 months after the CMV prophylaxis was completed, she developed asymptomatic CMV viremia with a titer up to peak of 47,643 IU/ml. Valganciclovir 900 mg twice daily was started and MPS was decreased. CMV PCR slowly decreased to 440 IU/ml after 1 month of therapy. Despite continuation of valganciclovir, CMV PCR became rapidly increased to 3,349 IU/ml [Figure]. A CMV genetic resistance test revealed a UL97, but not UL54 gene mutation. Foscarnet was started and CMV PCR was decreased. Allograft function has been at the baseline.

Discussion: Our patient has several risk factors for GR-CMV including high-risk CMV serostatus, prolonged exposure to low-dose oral valganciclovir prophylaxis, and intensified immunosuppression including rituximab. Given current treatment for GR-CMV remains limited with drug toxicity, adequate dose of CMV prophylaxis is critical to avoid GR-CMV. Pattern of CMV PCR after initiation of therapy should also raise a suspicion for GR-CMV and genetic CMV resistance testing is of paramount in early diagnosis. Novel preventive and therapeutic options may mitigate the risk of GR-CMV and drug-induced renal allograft toxicity.

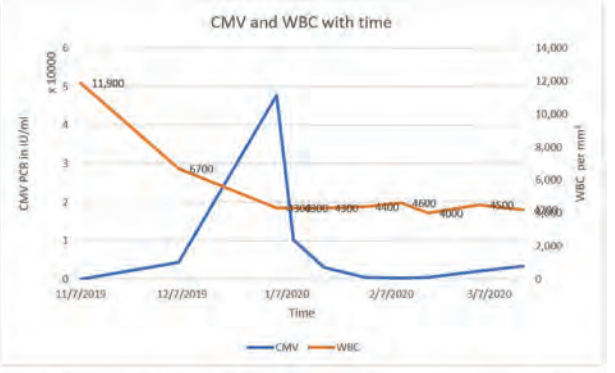


Figure: Clinical course of cytomegalovirus viremia correlated with low-normal white blood cell count from 8 months to 13 months post-kidney transplantation.
CMV, cytomegalovirus, WBC, white blood cell count

PO2448

A Case of Cytomegalovirus Infection with Splenic Infarction in a Renal Transplant Patient

Mita Zahra E. Co, Rafael Villicana, Rungwasee Rattanavich. *Loma Linda University, Loma Linda, CA.*

Introduction: Cytomegalovirus (CMV) infection is common after kidney transplant (KT) but it is not known to be associated with splenic infarction.

Case Description: A 67-year-old female living-related KT recipient for end stage renal disease from systemic lupus erythematosus presented with acute fever, left flank pain, and diarrhea. Her medications included tacrolimus, mycophenolate mofetil (MMF), and prednisone. Examination was significant for fever (101.8°F) and abdominal tenderness. Labs revealed normal blood counts, metabolic profile (creatinine 0.9 mg/dL) and urinalysis. Stool study was negative for *Clostridium difficile*. Quantitative CMV DNA PCR was elevated at 126,000 IU/ml. Sigmoidoscopy with biopsy also showed CMV colitis. CT abdomen and pelvis with contrast (Fig 1A) showed multiple wedge-shaped hypodense foci in the spleen consistent with splenic infarction and a splenic artery that was widely patent. Further investigations including Doppler ultrasound of the lower extremities, lung VQ scan and hypercoagulable studies were all negative. CMV was suspected to be the cause of the splenic infarct. Thus, the patient was started on ganciclovir and anticoagulation and MMF was discontinued. On her 3-month follow-up, she was found to have improved symptoms, undetectable consecutive CMV titers and with interval radiographic resolution of her splenic infarctions (Fig 1B).

Discussion: By inciting an inflammatory response due to direct cytotoxic endothelial cell damage, CMV infection may cause a procoagulant state. This can lead to potentially life-threatening end-organ infarction such as splenic infarction. To our knowledge, this is the first reported case of CMV infection in a KT recipient presenting with splenic infarction. A high index of suspicion for this association is warranted for early recognition and treatment of these potentially reversible conditions.

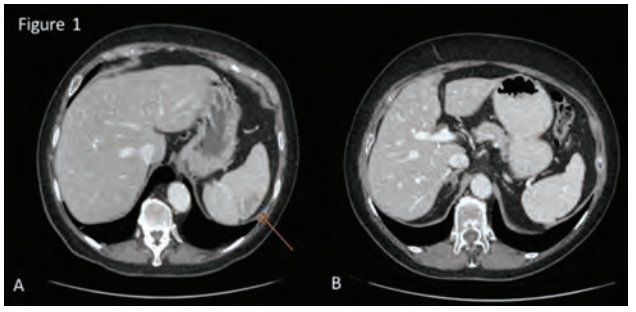

Figure 1: CT image (A) showing splenic infarction with radiologic improvement (B) after CMV treatment.

PO2449

BK Polyomavirus Nephropathy After Kidney Transplantation from HCV-Infected Donor to HCV-Uninfected Recipient

Faisal Abdulameer,[1] Hisham N. Abu Farsak,[1] Barry M. Wall,[1,2] Miklos Z. Molnar.[1] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]VA Medical Center, Memphis, TN.*

Introduction: BK polyomavirus (BKPyV) is an important cause of renal allograft dysfunction. We previously published the potential association of an increased risk of BKPyV DNAemia/nephropathy in kidney transplant recipients receiving Hepatitis C (HCV) infected donor transplantation. Here, we report severe BKPyV DNAemia/nephropathy in a recipient who received HCV infected donor transplantation, which was temporally associated with initial HCV treatment failure.

Case Description: 62-year-old HCV negative African American male received a cadaveric kidney transplant from a HCV infected donor in January 2019, with immediate graft function. Laboratory results 4 weeks later indicated HCV PCR of 9,310,000 IU/mL, serum creatinine 1.62 mg/dL, and BKPyV DNAemia was negative. He received glecaprevir and pibrentasvir (March 2019) for a total of 12 wk. At completion of treatment, HCV PCR was negative. Evaluation 4 weeks later revealed HCV PCR level of 482,446 IU/mL, indicating initial treatment failure. While waiting for insurance approval for coverage of secondary direct acting antiviral (DAA) regimen, he developed acute kidney injury 6 wk after HCV viremia, with serum creatinine peaking at 3.3 mg/dL along with a rapidly rising BKPyV DNAemia to >5,000,000 copies/mL. His immunosuppressive regimen was decreased. Allograft biopsy showed BKPyV nephropathy and proliferative glomerulonephritis (GN) with monoclonal IgG deposits. He was started on cidofovir, levofloxacin and intravenous immunoglobulin, followed by a course of sofosbuvir/velpatasvir/voxilaprevir and ribavirin for a total of 12 wk, achieving SVR at 12 wk. His BKPyV DNAemia slowly responded with 1,257,789 copies/mL at 6 weeks of DAA treatment and 7,378 copies/mL at 12 wk. Serum creatinine gradually improved to 2.04 mg/dL. His 1 year protocol biopsy still showed tubulointerstitial inflammation, rare positive SV40 staining, proliferative GN with improving monoclonal IgG deposits, indicating Banff borderline acute cellular rejection. His immunosuppressive regimen was intensified and graft function has remained stable.

Discussion: Our case report with close proximity of HCV treatment failure and severe BKPyV DNAemia/nephropathy supports the previous finding that transplantation from HCV infected donor kidneys to uninfected recipients may be a risk factor of BKPyV DNAemia/nephropathy.

PO2450

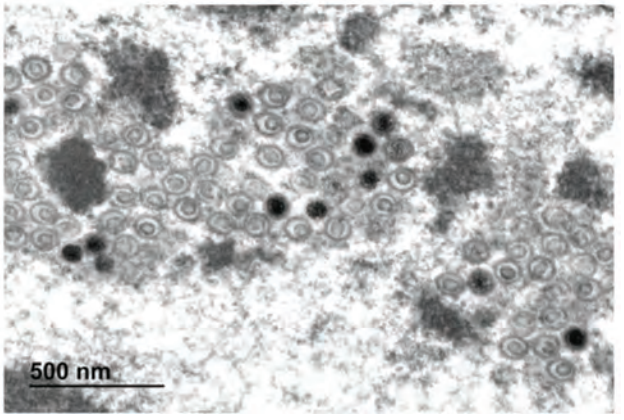
Cytomegalovirus Nephropathy in a Renal Transplant Patient

Sarah Gilligan, Divya Raghavan, Isaac E. Hall, Fuad S. Shihab, Marc Barry, Laith Al-Rabadi, Josephine Abraham. *University of Utah Hospital, Salt Lake City, UT.*

Introduction: Human cytomegalovirus (CMV), a DNA virus in the human herpesviridae family, is a frequent opportunistic infection following renal transplant. It can present as viremia without end organ damage and can affect the GI tract, liver, and lungs. CMV nephropathy is an uncommon complication of systemic CMV infection, occurring in < 1% of infected patients. Here we present a case of a renal transplant patient with CMV viremia was found to have evidence of CMV infection in the kidney.

Case Description: The patient was a 57 year old woman who had undergone deceased donor renal transplant 5 months prior to presentation due to ANCA vasculitis. Pre-transplant serologies were CMV D+/R- and induction was alemtuzumab. Her immune suppressive regime was tacrolimus, mycophenolic acid, and prednisone. She presented to the hospital with progressive fatigue, shortness of breath with new 4 L oxygen requirement, and decreased oral intake for several weeks. Her post-transplant creatinine nadir was 1.2 mg/dl, up to 3.1 mg/dl on admission and uptrended to 5.1 mg/dl, briefly requiring CRRT. She was found to have multiple infections including CMV viremia (peak > 3.9 M copy/mL) and pneumonitis, pseudomonas pneumonia, JC in her CSF and serum, and eventually bacteroides bacteremia due to bowel perforation. She underwent kidney biopsy which showed acute tubular necrosis, scattered glomerular epithelial cells and rare peritubular capillary endothelial cells positive for CMV by immunostaining (negative for BK/JC and rejection). She was treated with ganciclovir with resolution of her CMV viremia and improvement in her renal function, however, unfortunately passed due to her multiple infections.

Discussion: There are several possible manifestations of CMV nephropathy including interstitial nephritis, positive staining for CMV inclusions in glomerular cells, and collapsing focal segmental glomerulosclerosis. CMV nephropathy is an uncommon complication of CMV viremia following renal transplant but should be considered in the differential diagnosis of patients with CMV viremia and AKI.



PO2451

Cytomegalovirus-Associated Collapsing Glomerulopathy in a Renal Transplant Recipient

Chirag Lavani, Alexander J. Gallan. Division of Nephrology *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Collapsing focal segmental glomerulosclerosis also known as collapsing glomerulopathy (CG) is a glomerular disease presenting with nephrotic syndrome and acute kidney injury (AKI), and showing collapse and sclerosis of glomerular capillaries with hypertrophic and injured podocytes on kidney biopsy. CG is most often seen in association with HIV infection and APOL1 nephropathy; however, CG can be associated with non-HIV viral infections. We describe a case of CMV-associated CG in a renal transplant patient.

Case Description: A 73 year old Caucasian male with history of ESRD due to biopsy-proven arterionephrosclerosis, status post deceased donor kidney transplantation (African-American donor) with baseline serum creatinine of 1.6 – 2 mg/dl presented with one day of explosive diarrhea. Lab revealed AKI with serum creatinine of 6.12 mg/dl. The patient was treated with IV fluids for AKI presumably due to volume depletion; however, serum creatinine and renal function failed to improve. Urinalysis was positive for blood and protein, and urine protein/creatinine ratio was 25 g/g cr with serum albumin of 1.6 g/dL. Testing for complements, serum and urine protein electrophoresis, serum free light chains, hepatitis panel, HIV and polyomavirus virus was negative. Serum cytomegalovirus NAAT was positive and the patient was started on IV Valganciclovir (vGCV). Renal allograft biopsy showed CG, including retraction/collapse of the glomerular tuft and podocyte hypertrophy with accumulation of protein reabsorption droplets. CMV immunostain showed positive staining of few glomerular endothelial cells in glomeruli with collapsing features. Electron microscopy demonstrated extensive foot process effacement without immune complex deposition. Immunosuppression was reduced. Patient was treated with cVGC for 10 weeks and a low dose lisinopril; serum creatinine and UPC improved to 1.69 mg/dl and 0.9 g/ g cr respectively without requiring renal replacement therapy. APOL1 genotyping demonstrated that the allograft kidney was heterozygous for the G1[GA1] risk allele, but homozygosity or compound heterozygosity was not present.

Discussion: Collapsing glomerulopathy can occur with non-HIV infection, such as CMV in renal transplant recipients. Allograft function may be preserved with appropriate therapy.

PO2452

Early Increase in Urinary Exosomal BK Virus MicroRNA as a Predictive Marker of BK Virus Nephropathy: A Prospective Kidney Transplantation Cohort

Won-Hee Cho,[1] Su Woong Jung,[1] Ju young Moon,[1] Yang gyun Kim,[2] Kyung hwan Jeong,[2] Sangho Lee.[2] *[1]Kyung Hee University Hospital at Gangdong Department of Orthopedic Surgery, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea.*

Background: Urinary exosomal bkv-miR-B1-5p was associated with BK virus (BKV) nephropathy (BKVN) in a cross-sectional study. However, its time-dependent post-transplantation changes and predictive value for BKVN have not been investigated.

Methods: We carried out a multicenter prospective cohort from which 83 kidney transplant recipients (KRTs) in South Korea (biopsy-proven BKVN [n=10], presumptive BKVN [n=12], and non-BKVN patients [n=61]) were selected for the measurement of urinary exosomal bkv-miR-B1-5p levels at 0.5, 3, 6, and 12 months posttransplant.

Results: At 2 weeks posttransplant, urinary exosomal bkv-miR-B1-5p levels showed an increasing trend (non-BKVN < presumptive BKVN < biopsy-proven BKVN), while plasma BKV DNA levels were undetectable in all groups. Thereafter, both urinary exosomal bkv-miR-B1-5p and plasma BKV DNA levels peaked at 3 months posttransplant and then decreased. Multivariable-adjusted Cox regression showed that urinary exosomal bkv-miR-B1-5p levels at 2 weeks and 3 months posttransplant independently predicted biopsy-proven BKVN development. In particular, the early increase in urinary exosomal bkv-miR-B1-5p makes its predictive ability for biopsy-proven BKVN superior to that of plasma BKV DNA at 2 weeks posttransplant.

Conclusions: Our results suggest that urinary exosomal bkv-miR-B1-5p can be used to identify the KRTs at high risk for BKVN at earlier time than plasma BKV DNA loads, enabling earlier intervention.

Table 1. Baseline characteristics of the study population

	Biopsy-proven BKVN (n = 10)	Presumptive BKVN (n = 12)	Non-BKVN (n = 61)	*P*
Age (years)	50.6 ± 9.8	48.8 ± 14.0	49.1 ± 11.1	0.918

Polyomavirus Nephropathy with Crescent Formation

Laura Binari, Meghan E. Kapp, Heidi M. Schaefer, Beatrice P. Concepcion. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Polyomavirus reactivation in an immunosuppressed transplant patient may cause polyomavirus nephropathy (PVN). Classically seen as a pleomorphic tubulointerstitial inflammatory reaction to the virally infected tubular epithelial cells, there are few reports of glomerular viral tropism. We present unique histopathologic findings of PVN including crescent formation with ultrastructural and immunohistochemical evidence of viral infection of glomerular epithelial cells in a kidney transplant recipient with acute kidney injury.

Case Description: A 52 y/o man s/p DDKT with well-controlled HIV presented with 2 weeks of worsening cough. He was diagnosed with multifocal pneumonia and disseminated CMV and VZV infection. His serum creatinine (SCr) and BK virus PCR were elevated to 3mg/dl (baseline 1.4-2.0 mg/dL) and 3.8M copy/mL respectively. He received ganciclovir and his immunosuppression was reduced. His pneumonia improved, but his BK PCR increased to 13.6M copy/mL and SCr remained elevated at 2.4 mg/dL. A renal biopsy showed a diffuse plasma cell-rich pleomorphic interstitial inflammatory infiltrate, tubulitis, and acute tubular injury. Viral cytopathic effect was evident and an SV40 immunostain was positive in 60-70% tubular profiles, as well as parietal and visceral epithelial cells. EM revealed viral particles measuring 30 nm in diameter in tubular epithelial cells and a parietal epithelial cell. In addition, 7 of 21 total glomeruli had crescent formation with no GBM breaks or fibrinoid necrosis. There was no evidence of concomitant cellular or antibody-mediated rejection or CMV infection. These findings were indicative of PVN, with the rare finding of frequent crescents with glomerular epithelial cell infection.

Discussion: PVN is rarely described as having crescentic glomerular lesions, and if present, only one glomerulus per biopsy was affected. There are no reported cases of rapidly progressive glomerulonephritis in PVN. In our case, we found crescent formation more frequently in 33% of glomeruli. Additionally, viral cytopathic changes uncommonly affect glomeruli, typically only involving parietal epithelial cells when present. We demonstrated viral infection of both parietal and visceral epithelial cells. Our case highlights a pattern of kidney injury not commonly seen in PVN and supports that crescent formation can be caused by viral infection of the parietal epithelial cells.

PO2454

Risk Factors for Detrimental Progression in Kidney Transplant Recipients with BK Viremia

Abish Kharel, Arjang Djamali, Margaret R. Jorgenson, Beyann Alzoubi, Kurtis J. Swanson, Neetika Garg, Fahad Aziz, Maha A. Mohamed, Didier A. Mandelbrot, Sandesh Parajuli. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: The only effective management for BK viremia (BKV) among kidney transplant recipients (KTR) is regular monitoring and adjustment of immunosuppression. With this strategy, the majority of patients will clear BK or have low-level persistent BKV (Group A). However, few will transition toward over-immunosuppression [BKV level > 5 $\log_{10}$ copies/ml or BK nephropathy (BKN) (Group B)], or under-immunosuppression [de novo DSA (dnDSA) or acute rejection (AR) (Group C)]. In this study, we sought to find the characteristics of patients who progress to group B or group C.

Methods: It was a prospective study among KTR transplanted at our University hospital between 01/2015 and 12/2017. All KTR who developed BKV (> 3 $\log_{10}$ copies/ml) within 2 years of transplant were included in the study. Patients were followed up to 2 years of transplant and were divided into 3 groups as above, based on the BK levels or other outcomes. Those patients with progression of BK >5 $\log_{10}$ copies/ml or BKN along with dnDSA or AR, were assigned to the Group B or Group C, whichever event occurred first.

Results: A total of 224 KTR fulfilled our selection criteria, of which 118 (53%) remained in group A, while 64 (28%) and 42 (19%) transitioned to groups B and C, respectively. Compared to group A, in multivariate analysis, female (HR 2.05, 95% CI: 1.08-3.90, p=.02), rejection before BKV (HR 2.90, 95% CI: 1.04-8.12, p=.04) and interval from transplant to first BKV (HR 0.81, 95% CI: 0.72-0.90, p=<0.001) were associated with transition to group B. Conversely, basiliximab induction (HR 2.06, 95% CI: 1.03-4.11, p=.03), HLA mismatch > 3 (HR 2.27, 95% CI: 1.01-5.06, p=.04) and DGF (HR 4.14, 95% CI: 1.12-15.3, p=.03), were associated with progression to group C. At 2 years, graft failure rates were similar between the groups. However, among those with functional graft, group A had significantly better graft function with eGFR of 62 ml/min compared to 46 for group B and 50 for group C.

Conclusions: Our study suggests that in KTR with BK viremia, nearly 50% progress unfavorably toward a state of under-immunosuppression (AR) or over-immunosuppression (worsening BK). Modifiable risk factors including history of rejection, induction therapy, HLA mismatch, and DGF could help preventing untoward disease progression.

PO2455

A First-in-Human Study of MAU868, a Novel Neutralizing Antibody Against BK Virus

Steven J. Kovacs,[2] Johanna R. Abend,[1] Xiaoying Xu,[2] Sachin Desai,[2] Amanda Nguyen,[2] Laura M. Sterling,[3] Michael R. Hodges,[4] Peter Pertel.[2] *[1]Novartis Institutes for BioMedical Research Emeryville, Emeryville, CA; [2]Novartis Institutes for BioMedical Research East Hanover, East Hanover, NJ; [3]Celerion Inc, Lincoln, NE; [4]Amplyx Pharmaceuticals, Inc, San Diego, CA.*

Background: Reactivation of BK virus (BKV) infection can cause significant kidney and bladder disease in immunocompromised patients. BKV nephropathy is a leading cause of allograft loss in kidney transplant recipients. There are currently no effective or BKV-specific therapies. MAU868 is a novel monoclonal human IgG1 that binds to the BKV major capsid protein (VP1) with potent *in vitro* neutralizing activity against the 4 major BKV genotypes (EC_{50}s ranging from 0.009 to 0.093 μg/ml).

Methods: MAU868 was administered i.v. (1, 3, 10, 30, and 100 mg/kg) or s.c. (3 mg/kg) to healthy adults in a randomized, placebo-controlled, blinded, single ascending dose design. Each i.v. cohort was 5 subjects (4 MAU868:1 placebo); the s.c. cohort was 8 subjects (6 MAU868:2 placebo). Subjects were observed for 24 h and followed for 106 d with routine safety monitoring and PK assessments. *Ex vivo* neutralizing activity of serum was measured before and 4 w after dosing. The range of doses included and exceeded the predicted clinically efficacious dose.

Results: 33 subjects completed the study. Adverse events were mild and infrequent; those occurring in more than 1 subject included nasal congestion (3, 9.1%), oropharyngeal pain (3, 9.1%), and injection site hemorrhage (ecchymosis after s.c. injection; 2, 6.1%). There were no infusion reactions. No subject discontinued the study due to an adverse event or developed anti-drug antibodies. MAU868 PK was typical of a human IgG with a half-life of 23 to 30 d. AUC and Cmax were dose-proportional, ranging from 9880 to 1060000 μg*hr/mL and 24.7 to 2740 μg/mL (ie, no evidence of FcRn saturation). Day 29 plasma MAU868 concentrations, adjusted for extravascular distribution to estimate parenchymal exposure, were approximately 7- to 751-fold higher than the highest *in vitro* EC_{50} (0.093 μg/mL). Maximum *ex vivo* neutralizing activity of serum was achieved for doses >10 mg/kg. Bioavailability after s.c. injection was 57.6%.

Conclusions: MAU868 was safe and well tolerated with PK typical for a human IgG. The *ex vivo* neutralizing activity suggests where the therapeutic range may be for the treatment or prevention of BKV disease. These results warrant further clinical investigation of MAU868 in patients with or at risk for BKV disease.

Induction with Alemtuzumab and Thymoglobulin in Kidney Transplant and the Risks of Leukopenia, Cytomegalovirus Infection, and BK Virus Nephropathy

Ali M. Zebi, Aria Ghahramani, Mujahed M. Dauleh, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Induction immunosuppressive therapy at the time of kidney transplantation reduces the risk of allograft rejection and improves graft outcomes. We compared the association between induction with thymoglobulin and alemtuzumab on the risks of leukopenia, CMV infection, and BK virus nephropathy.

Methods: We used TriNetX, a global federated research network that provides access to statistics on the electronic medical record (EMR). The Penn State Health TriNetX searchable database allows the analysis of approximately 1.7 million Penn State Health patient observations dating back to 1997. We analyzed the EMR of 1070 adult patients who had undergone kidney transplant between 1997 and May 10, 2020 (mean age: 60 ± 17; Male: 63%; White: 81%; Hispanic or Latino: 8%). We created two cohorts based on induction with either thymoglobulin or alemtuzumab. We compared the rates of leukopenia, CMV infection and BK virus nephropathy between the two cohorts. We calculated the relative risk (RR) and the 95% confidence interval (CI) for each outcome in the thymoglobulin group compared with the alemtuzumab group. Analyses were done in the TriNetX "analytics" network using the browser-based real-time analytics features.

Results: Study cohorts included 220 patients (mean age: 57 ± 15) in the thymoglobulin group, and 160 patients (mean age: 54 ± 19) in the alemtuzumab group. Leukopenia occurred in 50 patients in the thymoglobulin group and in 70 patients in the alemtuzumab group (RR: 0.52; CI: 0.39 to 0.70; p<0.0001). CMV infection occurred in 40 patients in the thymoglobulin group and in 20 patients in the alemtuzumab induction group (RR: 1.45; CI: 0.89 to 2.39; p = 0.14). BK virus nephropathy occurred in 20 patients in the thymoglobulin group and in 20 patients in the alemtuzumab group (RR: 0.72; CI: 0.41 to 1.31; p = 0.29).

Conclusions: Induction therapy with thymoglobulin is associated with a lower risk of leukopenia compared with alemtuzumab induction. The risks of CMV infection and BK virus nephropathy are not statistically different in the two induction therapies.

PO2457

Effects of Early Conversion to mTOR Inhibitors on Viral Infections in Renal Transplant Recipients: Eight-Year Single-Center Experience

Waleed Hassan,[1] Hisham Mostafa.[2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]Minia Nephrology and Urology University Hospital, Minia, Egypt.*

Background: Mammalian target of rapamycin inhibitors (mTORis) may decrease cytomegalovirus (CMV) and BK infection in renal transplant recipient. long-term effect on rejection rate deserves follow up.

Methods: This is a retrospective analysis of all patients who underwent living unrelated donor kidney transplant at Nasr city Insurance and Nile Badrawy Hospitals from 2011 to 2018, panel reactive antibody zero and no donor specific antibody. Uni- and multi-variate analysis were done to compare between mTORis based regimen and cyclosporin inhibitors (CNI)-based regimen.

Results: We identified 1458 patients who underwent living unrelated kidney transplant with intermediate risk for CMV. All patients received Induction with anti-thymocyte globulin then were maintained on mycophenolate mofetil (MMF)-CNI-prednisone for at least 6 months. They were classified into two groups: *Group I: 658 patients on mTORis (sirolimus or everolimus), who were shifted from CNI to mTOR-I due to different causes. Group II: 800 patients on CNI (cyclosporin or tacrolimus). The overall incidence of CMV infection and BK infection (Table 1) were statistically significant lower in mTORis group compared to CNI group with no statistical differences in incidence of rejections in the first 36 month but late higher rate of BPAR (Table 2).

Conclusions: mTORis/MMF is associated with low incidence of CMV and BK infection with no significant difference in rejection rate in the first 36 months. However, further regiment modification is required to reduce late rejections.

Comparison between m.TOR-I and CNI in the complications rather than rejection: Table (1)

PO2458

The Utility of Procalcitonin in the Management of Kidney and Pancreas Transplant Recipients with Suspected Infection

Sarah Gilligan, Fuad S. Shihab, Divya Raghavan, Laith Al-Rabadi, Josephine Abraham, Isaac E. Hall. *University of Utah Health, Salt Lake City, UT.*

Background: Procalcitonin is used to differentiate between bacterial and viral infections to guide judicious use of antibiotics. It has not, however, been well studied in renal and pancreas transplant recipients. These patients are frequently exposed to antibiotics and are at risk for developing resistant infections. Thus, there is a need for reliable markers of bacterial infection. The purpose of this study was to compare procalcitonin levels in patients with and without bacterial infection to determine whether procalcitonin is a reliable marker of bacterial infection in the transplant population.

Methods: Serum procalcitonin levels were measured on admission on all patients admitted to the Transplant Nephrology service with suspected infection as determined clinically by the on-call physician. We obtained all study data via chart review.

Results: Procalcitonin was measured in 154 patients. Demographics are included in the table. Forty-two patients (27%) had a positive bacterial culture. Mean procalcitonin for those with positive cultures was 5.36 ng/ml vs. 3.35 ng/ml in those without positive cultures, however this was not statistically significant (t=0.642, p=0.522). Patients with positive cultures were more likely to have procalcitonin levels >0.5 mg/ml (p=0.003). Procalcitonin had a modest but significant correlation with WBC count (r=0.249, p=0.002). Receiver operating characteristic analysis demonstrated an area under the curve (AUC) of 0.679 (95% confidence interval: 0.590-0.768, p=0.001) for predicting positive cultures with procalcitonin compared with an AUC of 0.584 (95% confidence interval: 0.474-0.694, p=0.110) for WBC count.

Conclusions: In this cohort of hospitalized kidney and pancreas transplant recipients, serum procalcitonin concentration was associated with bacterial infection and was found to be a better predictor than WBC count. More information is needed to determine the utility of procalcitonin measurements in clinical decision making in this patient population.

Infection Rate at 1 Year of Deceased Donor Kidney Transplant in the Elderly

Wina Yousman, Nicole Low, Wei Xiang Wong, Venkatesh Kumar Ariyamuthu, Bekir Tanriover. *The University of Arizona, Tucson, AZ.*

Background: There is limited publications about infection incidence rate in deceased donor kidney transplant (DDKT) recipients older than 65. The objective of this study is to examine our center specific infection incidence rate within one year of DDKT.

Methods: Retrospective chart review of DDKT (N=176) from July 2016 to December 2019 at Banner Medical Center in Tucson, AZ. Primary outcome was the infection incidence rate among recipients older than 65 year-old, including Cytomegalovirus (CMV) viremia and BK viremia (screened by monthly plasma PCR testing), or urinary tract infection (UTI) (diagnosed with positive urine culture and urinary symptoms within first year of transplant). We also fitted a multivariable logistic regression for the outcomes variables adjusted for demographics, KDPI, CIT, EPTS, and cPRA.

Results: The characteristics of the study cohort was shown in Table 1. Out of 176 patients, 63 patients (35.8%) were older than 65 year-old. There was no significant difference in the incidence rate of total infection, CMV viremia, BK viremia, and UTI in the elderly versus non-elderly patient (63.5% vs 51.3% p=0.11, 20.6% vs 11.5% p=0.10, 15.9% vs 11.5% p=0.41, 32.3% vs 28.3%, p=0.59). The multivariable logistic regression analysis (adjusted for ethnicity, KDPI, EPTS, cPRA, and CMV mismatch) did not show increased odds of all type of infections among older recipients.

Conclusions: The infection rate of elderly versus non-elderly who received DDKT were similar.

Variables		Elderly (n=63, 35.8%)	Non-Elderly (n=113, 64.2%)	p Value
Ethnicity	African American	2 (3.2%)	8 (7.1%)	0.01
	American Indian	0 (0%)	13 (11.5%)

Two Deaths of Acute Transplant Patients from Strongyloides Hyperinfection Syndrome (SHS): Can We Prevent Harm with Screening and Prophylaxis at the Time of Transplantation?

Gerlineke M. Hawkins-van der Cingel, Vivek Sekhawat, Rafez M. Ahmed, Ravindra Rajakariar. *Royal London Hospital, London, United Kingdom.*

Background: A 59 year old Vietnamese man presented with non-specific abdominal pain 8 weeks after a deceased donor kidney transplant. He was thoroughly investigated and no cause for the pain identified. On day three of the admission he became febrile and hypoxic. He died with multi-organ failure. Within three months a patient of Congolese origin presented nine weeks post transplant with abdominal pain. He became febrile with gram positive bacteraemia and was admitted to the ICU with type 1 respiratory failure where he unfortunately died. Autopsy findings revealed SHS. These cases were patients at a transplant centre in a non-endemic area albeit with an ethnically diverse population. A survey of other UK transplant centres showed that none did pre-transplant screening for strongyloides infection.

Methods: As a result of these cases we implemented and evaluated a program to screen for and prophylactically treat Strongyloides infection: Live donor patients were screened with Strongyloides serology in advance of transplantation. All recipients of deceased donor transplants were screened on admission for their transplant unless they had never travelled to an endemic area. At induction recipients received a weight adjusted dose of Ivermectin pending serology results. If positive a second prophylactic dose was administered at day 14. Travel histories and demographic data were recorded.

Results: Between July 2019 and March 2020; 135 patients were transplanted at our unit. Of those 125 had strongyloides serology testing; eight were positive at time of transplant with an additional two patients reported as "borderline". One further patient tested positive on a previous admission for a transplant which was cancelled; but was negative on the admission of the successful transplant. This indicates that at least 8% of our transplant listed patients are positive for strongyloides infection. By May 2020 there were no recorded deaths due to SHS, or morbidity associated with strongyloides infection in this group.

Conclusions: We have demonstrated that there is a significant level of sero-positivity within our pre-transplant population and that a relatively low-cost strategy may help prevent the potentially fatal Strongyloides Hyperinfection Syndrome.

PO2461

Infectious Complications and Malignancy After Kidney Transplant in the Elderly Population

Luz E. Liriano-Ward, Yorg Al Azzi, Cindy T. Pynadath, Maria Ajaimy, Pablo Loarte Campos, Purna Bindu Nandigam, Enver Akalin. *Montefiore Medical Center, Bronx, NY.*

Background: Kidney transplantation improves quality of life and survival in all patients regardless of age. However, older patients are prone to development of side effects related to immunosuppressive medications including infections and malignancy. We aim to evaluate clinical outcomes in recipients >65 years of age.

Methods: We retrospectively reviewed all patients over the age of 18 who received an isolated renal transplant at our center from January 2013 to June 2017. We compared clinical outcomes including allograft and patient survival, as well as the development of infections and malignancy in patients > 65 compared to younger patients.

Results: Of 624 patients analyzed, 148 (24%) were > 65 years of age. There was no difference in terms of gender, race, immunosuppressive or induction therapy between the two groups. Older patients were more likely to receive a deceased donor kidney transplant (92% vs. 81%, p=0.009). During a median 48 months (28, 70) of follow-up, as expected mortality was higher in older patients (16% vs. 6.5%, p=0.0001) but there was

no difference in terms of death-censored graft loss (10.8% to 9%, p=0.52) compared to younger patients. Detailed analysis of infections revealed that there was no difference in terms of BKV and CMV viremia, pneumonia, bacteremia, influenza and c. diff between the two groups. However, older patients had more fungal and urinary tract infections and malignancy. The most common infection in the elderly was PJP pneumonia (4%), candidemia (3%), and cryptococcal infection (2%). The most common malignancy in the elderly was skin cancer (6%) followed by prostate (2%), lung (1%), and colon (1%).

Conclusions: Recipients older than 65 had similar graft survival compared to younger patients, but had a higher incidence of fungal and urinary tract infections and malignancies.

Clinical outcomes	Patients age > 65	Patients age =< 65	p-value
BKV	22%	19%	0.43
CMV	12%	9%	0.25
Influenza	8%	10%	0.47
Pneumonia	23.7%	20%	0.38
Bacteremia	20%	18%	0.55
C diff colitis	8%	4.5%	0.07
Urinary tract infections	49%	31%	< 0.0001
Fungal infections	10.5%	5.1%	0.02
Malignancy	16%	5%	< 0.0001

PO2462

Risk of Active Tuberculosis Infection in Kidney Transplantation Recipients: A Matched Comparative Nationwide Cohort Study

Sehoon Park,[1] Ji Eun Kim,[5] Mi-yeon Yu,[4] Yong Chul Kim,[3] Dong Ki Kim,[3] Kwon Wook Joo,[3] Yon Su Kim,[3] Kyungdo Han,[2] Hajeong Lee.[3] *[1]Armed Forces Capital Hospital, Seongnam, Gyeonggi-do, Republic of Korea; [2]Soongsil University, Dongjak-gu, Seoul, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [4]Hanyang University Guri Hospital, Gyeonggi-do, Gyeonggi-do, Republic of Korea; [5]Korea University Guro Hospital, Seoul, Republic of Korea.*

Background: Although the risk of *mycobacterium tuberculosis* (TB) infection is high in both kidney transplantation (KT) recipients and dialysis patients, a large-scale evidence comparing the risk between the two groups in a nation with moderate or higher TB prevalence was rare.

Methods: We performed a nationwide retrospective cohort study based on the claims database of South Korea where moderate TB prevalence is reported. We included incident KT recipients from 2011 to 2015 and compared their active-TB risks with matched controls. The 1:1 matched general population group was matched for age, sex, and era, while the dialysis group was matched for age, sex, era, underlying hypertension, and diabetes. We excluded the matched pairs with age < 20 years old, a previous TB history, and those matched to a multi-organ transplantation case. The incident active-TB risk was assessed by the multivariable Cox regression analysis. Within KT group, associations between active-TB, as a time-dependent variable, and post-transplant death or death-censored graft failure was investigated.

Results: The number of matched 7,462 subjects (total 22,386) were included to each of the study groups. During median 3.57 years of follow-up duration, the incidence rate for active-TB was 3.92/1,000, 4.38/1,000, and 0.67/1,000 person-years in the KT, dialysis, and general population groups, respectively. The KT group showed a significantly higher risk of active-TB than the general population group [adjusted HR 3.39 (1.88-6.12)] but a similar to the dialysis group [adjusted HR 0.98 (0.73-1.31)]. Active-TB was a significant risk factor for death [adjusted HR 2.24 (1.19-4.42)] or death-censored graft failure [adjusted HR 2.21 (1.36-3.58)] in the KT patients.

Conclusions: In Korea with moderate TB prevalence and active surveillance strategies, KT patients may not have to burden additional risk of active-TB when compared to dialysis patients. Still, clinical attention for active-TB complication should not be overlooked in end-stage kidney disease patients, particularly for KT patients as active-TB was associated with worse post-transplant prognosis.

PO2463

Hydroxychloroquine as an Alternative or Adjunctive Antimetabolite in Kidney Transplant Recipients: Analysis of Linked US Registry and Claims Data

Krista L. Lentine,[1] Tarek Alhamad,[2] Huiling Xiao,[1] Mark Schnitzler,[1] Su-Hsin Chang,[2] Yasar Caliskan,[1] David Axelrod,[3] Daniel C. Brennan.[4] *[1]Saint Louis University, St Louis, MO; [2]Washington University in Saint Louis, Saint Louis, MO; [3]University Iowa, Iowa City, IA; [4]Johns Hopkins University, Baltimore, MD.*

Background: Hydroxychloroquine (HCQ) is an antimalarial drug with immunomodulatory effects in patients with systemic lupus erythematosus (SLE) and scleroderma. The potential anti-viral effects of HCQ have raised attention in the context of the COVID-19 pandemic, although safety is controversial.

Methods: We examined a novel database linking national transplant registry identifiers for kidney transplant recipients (KTx) to records from a large U.S. pharmaceutical claims warehouse (2008–2017) and Medicare claims to study HCQ use among Medicare beneficiaries with kidney failure due to SLE or scleroderma (N=2,550). We compared 3 groups based on immunosuppressive regimen 7–12 mos. post-KTx: 1) **tacrolimus (Tac) + mycophenolic acid (MPA) + prednisone (Pred) – Reference**; 2) **Tac+HCQ+Pred**; or 3) **Tac+HCQ+MPA+Pred**. Associations of regimen with graft failure, death and clinical cardiovascular complications captured in Medicare claims >1-to-3 yrs post-KTx were examined with multivariate Cox regression, adjusted for baseline factors in the registry.

Results: Among the study sample, 18.3% received Tac+HCQ+MPA+Pred 7–12 mos. post-KTx, while 1.7% received Tac+HCQ+Pred. Use of HCQ containing regimens was more common in women (*vs* men), and Black and Hispanic (*vs* white) recipients; use of Tac+HCQ+MPA+Pred was more common in younger patients (*vs* older) patients (**Table**). The unadjusted incidence of adverse events did not differ across the 3 groups (**Fig A**); risks also did not differ with covariate adjustment (**Fig B**).

Conclusions: HCQ is an inexpensive immunomodulatory agent that may be used safely in selected KTx recipients as an alternative or adjunct to standard immunosuppression.

Bacillary Angiomatosis in a Kidney Transplant Recipient

Mohamed Hassanein, Bushra Syed, Jose Morillas, Jessica M. Lum, Aimen Liaqat, Wilma F. Bergfeld, Luis A. Sardina, Richard A. Fatica. *Cleveland Clinic, Cleveland, OH.*

Introduction: Bacillary angiomatosis (BA) is a vascular proliferative manifestation of *Bartonella henselae* (BH) or *Bartonella quintana* (BQ) that usually affects immunocompromised hosts. It usually involves the skin but may affect other organs. Few cases of BA in kidney transplant (KT) recipients have been reported, with most cases presenting years after KT. We describe a case of BA in a KT recipient that occurred early post-transplant.

Case Description: A 67-year-old male KT recipient from a deceased donor developed fevers, night sweats, and fatigue 1-month post-KT. He received antithymocyte

globulin induction, and maintenance tacrolimus, mycophenolate, and prednisone. Two months later, he presented with diffuse violaceous papules (Figure 1A). Biopsy of a papule with Warthin-Starry stain showed clusters of bacteria suggestive for BA (Figure 1B). Diagnosis was confirmed with a positive serum Bartonella polymerase chain reaction (PCR). He was treated with doxycycline with resolution of symptoms. BH and BQ Immunoglobulin G (IgG) were equivocal. A few weeks later, IgG for BH was 1:256 (reference range <1:128). Echocardiogram, abdominal computed tomography, and kidney biopsy were unremarkable. Recipient Bartonella PCR and antibodies on the day of transplant were negative. Donor Bartonella PCR and BH IgG were negative. Donor BQ IgG was equivocal. The recipient had a cat 8 years prior to KT without recent exposure. Allograft function remains intact, and the rash completely resolved. Bartonella PCR 6 months on treatment was negative.

Discussion: Our patient developed signs of BA with positive seroconversion within the first 3 months of KT which is rare. BA should be considered in the differential diagnosis of fever and cutaneous angioma-like lesions in KT recipients, even in the absence of exposures. Combined serology and molecular testing (PCR) is useful in diagnosing BA as serology alone may be unreliable. Early empiric treatment should be considered in transplant recipients while waiting for confirmatory results.

PO2465

Isavuconazole as Consolidation Therapy for Disseminated Histoplasmosis in a Kidney Transplant Recipient

Samar A. Medani, Michael Kessler, Sandesh Parajuli. *University of Wisconsin-Madison, Madison, WI.*

Introduction: The diagnosis of systemic fungal infection may be elusive and requires a high index of suspicion with prompt evaluation, directed laboratory and radiological work-up and if necessary, histological examination. To our knowledge, this is the first case report of isavuconazole use as consolidation therapy for disseminated fungal infection in a kidney transplant recipient.

Case Description: A 76-year-old female with polycystic kidney disease presented 8 years post kidney transplantation with a painful tongue ulcer, anorexia, weight loss, progressive anemia and severe de-conditioning. She was on maintenance mycophenolate, prednisone and tacrolimus. A midline fissure on the dorsal tongue surface (image 1- left). and two non tender nodular masses in the left forearm and right buttock were noted. A diagnosis of disseminated histoplasmosis was made by biopsy of the tongue ulcer, and cultures of blood, tongue tissue and forearm nodule aspirate. Blood and urine histoplasma antigens were positive. The patient was treated with amphotericin for two weeks before transitioning to itraconazole then to Isavuconazole due to QT prolongation. Mycophenolate was stopped. An outstanding clinical response with healing of the tongue ulcer (image 1 - right), shrinking of the subcutaneous lesions, and substantial functional progress to prior independence was seen within 3 months. Histoplasma urinary and plasma antigen levels declined to undetectable levels. Isavuconazole was continued for a year with no adverse side effects reported.

Discussion: Infections with Histoplasma capsulatum are largely asymptomatic but progressive disseminated mycosis can occur in the immunocompromised. There is no specified agent selectively approved for second line maintenance therapy when itraconazole is not tolerated or is ineffective. Limited experience has been reported with other azoles, and even less so with isavuconazole. This case demonstrates an excellent outcome of treating disseminated histoplasmosis with isavuconazole in a kidney transplant recipient.

PO2466

The Diagnostic Dilemma of Diffuse Lymphadenopathy in a Kidney Transplant Recipient

Michael C. Krouse, Priyamvada Singh, Tomas I. Guerrero Nunez. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Immunological balance is critical for transplant recipients. An optimum amount of immunosuppression prevents rejection while avoiding infection and cancers. Constitutional symptoms and lymphadenopathy could be present in both scenarios and could pose a diagnostic challenge.

Case Description: A 36-year-old male immigrant from India (ten years ago) with PMH of ESRD secondary to IgAN received a DDKT (9/2019, EBV D+/R+, on tacrolimus and myfortic). He was admitted with extensive retroperitoneal and mesenteric lymphadenopathy and a hypodense structure in the left upper abdomen (3.8 x 5.1 cm) on CT scan along with constitutional symptoms of fevers, constipation, and abdominal pain for ten days duration three months after transplant. Vital signs and physical examination were unremarkable except for low-grade fever. Aside from mild anemia (Hb 10 mg/dL), laboratory analysis was normal. PET scan revealed hypermetabolic lymphadenopathy in the neck, abdomen, and pelvis and consolidative changes in the left lung base and a right-sided loculated pleural effusion. Extensive workup - CMV PCR, pan-culture, fungal infections, and flow cytometry – was negative. CT-guided retroperitoneal lymph node biopsy, incisional biopsy of the mesenteric mass, and an endobronchial ultrasound-guided transbronchial needle aspiration of subcarinal LN were non-diagnostic. Finally, exploratory laparotomy and resection of the mesenteric mass revealed granuloma formation with multinucleated giant cells concerning for TB. The AFB culture grew mycobacterium tuberculosis on day 24. He is currently on antitubercular treatment.

Discussion: Our case highlights the importance of a high degree of clinical suspicion for infectious etiology in transplant recipients, especially those from countries with a high prevalence of TB. Our patient bore a distant immigration history and a negative tuberculin test and did not have a history of exposure. Still, he was at increased risk of activation of latent TB due to his immunocompromised state. Extra-abdominal TB, like abdominal TB, poses a diagnostic challenge as the presentation can be non-specific and the AFB stain and culture can be non-diagnostic. Thus, a tissue biopsy becomes key to diagnosis. PTLD was high on differential given the PET-avid LAP. PET-avid lesions imply a hypermetabolic state which can happen in both malignancies and infections.

PO2467

Post-Transplant Lymphoproliferative Disorder: Recurrence at an Unusual Site

Aditi Saha, Sohaib Tariq, Lalithaa Thirunavukarasu Murugan, Sunil Sapru, Miguel Conde. *Saint Barnabas Medical Center, Livingston, NJ.*

Introduction: PTLD includes a spectrum of clinical presentations due to lymphoid proliferation ranging from benign hyperplasia to aggressive lymphomas that occur after either a SOT or HSCT. PTLD can involve extra nodal sites like graft tissue, GI tract, and lungs. Skin and soft tissue involvement is very rare. We report a patient with PTLD who had relapsed with axillary lymphadenopathy and a soft tissue mass on the arm.

Case Description: A 59-year-old male was diagnosed with EBV negative PTLD involving retroperitoneal, mediastinal and supraclavicular lymph node, one year after renal transplant. He was treated R-CEOP (Rituximab, Cyclophosphamide, Etoposide, Vincristine, Prednisone). After 6 cycles of chemotherapy repeat PET scan confirmed complete resolution. 3 months later, he presented with LUE pain and swelling. Labs were significant for high LDH and Beta-2 microglobulin. CT LUE revealed 4.8 cm mass over left anterior arm and left axillary adenopathy. Biopsy and flow cytometry of axillary lymph node and left arm mass confirmed relapse. Immunohistochemical stains showed tumor cells positive for CD20, PAX5, BCL2, MUM1, BCL6 with Ki67 of 80-90%. Patient developed compartment syndrome and had to undergo fasciotomy. Patient was started on modified regimen with Rituximab, Gemcitabine and Oxaliplatin (R-GEMOX) for poor performance status.

Discussion: The incidence of PTLD ranges from 1 to 25% with 90% of cases being EBV-associated, CD 20 positive, B cell neoplasms. EBV negative PTLD occurs only in 5-10% cases, appears late with worse prognosis than EBV positive PTLD. EBV negative PTLD is assumed to be related to Tp53 mutation caused by immunosuppressive agents like azathioprine or tacrolimus. Skin and subcutaneous lesions are extremely rare as sites of extra nodal presentation and may take the form of solitary or multiple papules, nodules, plaques with ulceration, comedo-like lesions, follicular keratotic papules, or localized alopecia. Our patient is interesting as he had a relapse of EBV negative PTLD in the form of a soft tissue fibro-adipose mass in the upper extremity. To the best of our knowledge, there have been three cases of PTLD presenting as soft tissue masses on head reported in the literature. Biopsy remains the gold standard for diagnosis. Treatment is includes reduction of immunosuppression and rituximab with additional chemotherapy.

PO2468

Post-Transplant Lymphoproliferative Disorder (PTLD) Presenting as Solitary CNS Lymphoma: A Rare Occurrence

Aditi Saha, Sohaib Tariq, Lalithaa Thirunavukarasu Murugan, Sunil Sapru, Israel R. Grossman. *Saint Barnabas Medical Center, Livingston, NJ.*

Introduction: PTLD associated lymphoma is the second most common malignancy in patients receiving SOT or HSCT with an incidence rate of 1%-3%. PCNS-PTLD occurs in 7%-15% of all PTLD cases. We present a case of isolated PCNS lymphoma two years after renal transplant.

Case Description: A 57 year old woman with PMH of ESRD s/p kidney transplant (D/EBV -,R/ EBV +) with chronic CrCl of 30-40% presented with paresthesia and numbness over the right side of her body with mild ataxia 2 years post transplant. Physical exam revealed only numbness over the right side of body. MRI with contrast revealed a left thalamic lesion with moderate vasogenic edema, and MR spectroscopy confirmed high grade neoplasm involving left thalamus. Stereotactic biopsy showed polymorphic CD-20 and EBV positive PTLD. EBV PCR were elevated. Further evaluation ruled out systemic PTLD. Myfortic was stopped and oral steroids started with mild improvement in symptoms. Choice of systemic chemotherapy was limited due to reduced CrCl and risks of graft failure. She received modified regimen with renally adjusted high dose Methotrexate, Vincristine and Rituximab for 6 cycles with partial remission and then Temozolomide for 7 cycles with complete remission.

Discussion: The incidence of PTLD ranges from 1 to 25% with 90% of cases being EBV-associated, CD20 positive, B cell neoplasms. PCNS-PTLD has a higher incidence in renal SOT, occurs late and is usually monomorphic unlike our patient. Median time of occurrence is 4-5 years after transplant. Risk factors include age, intensity of immunosuppression, time to transplant and EBV status of donor and recipient. Common presenting features include neurological deficits, seizure, and raised intracranial pressure. MRI is the preferred imaging and shows multifocal, ill defined, ring enhancing lesions usually in supratentorial and lobar regions. Positive CSF EBV PCR is highly suggestive but biopsy remains the gold standard for diagnosis. Treatment modalities include reduction of immunosuppression, rituximab, high dose methotrexate, cytarabine and cranial radiotherapy. Use of high dose methotrexate has shown improved outcomes with median survival of 26-47 months. Lack of response to first line therapy is considered the dominant prognostic factor. Early recognition and diagnosis remain crucial for improving outcome.

PO2469

National Trends in Kidney Transplantation Among Patients with ESKD from Plasma Cell Dyscrasias

Jia Hwei Ng,[1,2] Stephanie Izard,[2] Kenar D. Jhaveri,[1,2] Vinay Nair.[1,2] *[1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]Northwell Health, Great Neck, NY.*

Background: Due to relapses and kidney involvement, plasma cell dyscrasias have been a relative contraindication for kidney transplantation. With newer medications and improved prognosis of plasma cell dyscrasias, kidney transplantation in this population is becoming more common. We aimed to describe national trends in the proportion of kidney transplants among recipients who had ESKD from plasma cell dyscrasias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance).

Methods: We used data from the United Network for Organ Sharing/ Organ Procurement and Transplantation Network (UNOS/OPTN) database. Patients 18 years or older, BMI >15 or <45 kg/m^2, received a first kidney transplant between January 1, 2006 to December 31, 2017 were eligible. Recipients of more than one organ transplant were excluded.

Results: A total of 160,966 patients received a first kidney transplant. Among these, 487 (0.3%) had ESKD from plasma cell dyscrasia, 45,570 (28.3%) from diabetes mellitus, and 114,909 (71.4%) from other diagnoses. Clinical characteristics of the plasma cell dyscrasia group are as follows: median age 59.0 (IQR 50.0 - 65.0) years, 294 (60.4%) men, 379 (77.8%) White, 19 (3.9%) with diabetes mellitus, median BMI 26.4 (IQR 23.1-29.0) and 53 (10.9 %) pre-emptive transplant. **Table 1** shows the national trends of kidney transplants among first time recipients and those with plasma cell dyscrasia. Time series analysis shows an increase of 0.1% (95% CI 0.1 - 0.1) over 12 years in the proportion of kidney transplantation for recipients with ESKD from plasma cell dyscrasias.

Conclusions: Despite improvement in the treatment of plasma cell dyscrasias, national trends show only a small rise in the proportion of kidney transplantation for patients with ESKD from plasma cell dyscrasias. Additional analyses are needed to assess the outcomes of these kidney transplant recipients.

Table 1. National trends in kidney transplantation among recipients who had end-stage kidney disease from plasma cell dyscracias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance).

Year	Total transplants (N)	Total plasma cell dyscrasia (%)	Multiple myeloma (%)	Amyloidosis (%)	MGRS (%)
2006	12311	39 (0.32)	4 (0.03)	29 (0.24)	6 (0.05)
2007	12344	33 (0.27)	6 (0.05)	24 (0.19)	3 (0.02)
2008	12635	28 (0.22)	7 (0.06)	19 (0.15)	2 (0.02)
2009	12799	38 (0.30)	6 (0.05)	29 (0.23)	3 (0.02)
2010	13090	33 (0.25)	8 (0.06)	25 (0.19)	0 (0.00)
2011	13175	35 (0.27)	14 (0.11)	21 (0.16)	0 (0.00)
2012	12811	40 (0.31)	9 (0.07)	29 (0.23)	2 (0.02)
2013	13280	31 (0.23)	8 (0.06)	20 (0.15)	3 (0.02)
2014	13551	39 (0.29)	10 (0.07)	29 (0.21)	0 (0.00)
2015	14010	60 (0.43)	16 (0.11)	39 (0.28)	5 (0.04)
2016	15059	58 (0.39)	15 (0.10)	40 (0.27)	3 (0.02)

MGRS: Monoclonal gammopathy of renal significance

PO2470

A Retroperitoneal Cyst of Pancreatic Origin in a Renal Transplant Recipient: Expect the Unexpected

Muhammad O. Saleem,[1] Ambreen Chughtai,[2] Imran Y. Gani,[1] Muhammad I. Saeed,[1] Rajan Kapoor.[1] *[1]Augusta University, Augusta, GA; [2]FMH College of Medicine and Dentistry, Lahore, Pakistan.*

Introduction: The immunosuppression required to maintain a renal allograft function puts the recipient at a higher risk of malignancy. We report a rare case that presented a diagnostic challenge when a retroperitoneal hemorrhagic cystic mass turned out to be an adenocarcinoma of pancreaticobiliary origin.

Case Description: 43-year-old female with a history of End Stage Renal Disease due to IgA Nephropathy and two renal transplantations, first in 1999 from her sister and second in 2005 from a deceased donor, presented with complaint of left sided abdominal pain and distention for one month. Her graft function was stable with creatinine of 1.8mg/dl on immunosuppression with tacrolimus, mycophenolic acid, and prednisone. The CT scan showed a large 12 x 13 x 16 cm well-defined septated cystic mass. She subsequently underwent exploratory laparotomy which revealed a retroperitoneal 1.7L cystic hematoma with no association to native or transplant kidneys. The histopathology showed adenocarcinoma with mucinous and enteric features. Based on the morphology and immunoprofile, the differential diagnosis included an ovarian, gastrointestinal or peritoneal primary. Tumor markers showed elevated CA19-9, but normal CEA and CA-125. Given the positivity for both CK 7 and CK 20, colonic origin was unlikely but could not be completely excluded. Negative EGD and colonoscopy ruled out GI Primary. PET scan was unremarkable. Molecular analysis predicted 90% probability of pancreaticobiliary adenocarcinoma. Subsequently patient was started on adjuvant chemotherapy with Gemcitabine. She failed first and second lines of chemotherapy with progression of cancer. Then she received PD-L1 inhibitor, Nivolumab which could not prevent progression of disease but resulted in renal graft failure. Per last reports, patient was on palliative chemotherapy and in terminal phase of her life.

Discussion: Post-transplant malignancy is one of the most feared complications. It is the third leading cause of mortality and accounts for 8-10% of all deaths in United States and 30% in Australia in kidney transplant recipients. Compared with general population, the risk is increased 2-3 folds and mortality rates are higher. The occurrence of pancreatic cancer is high too. But finding a pancreaticobiliary cancer from a retroperitoneal cyst with negative pancreas imaging is rare.

PO2471

Secondary Malignancy in Kidney Transplant Recipients: University of Southern California Experience

Alexandra K. Wong, Tiffany Truong, Poorva Vaidya, Gino In, Thin Thin Maw. *Keck Hospital of USC, Los Angeles, CA.*

Background: Kidney transplant recipients (KTR) on immunosuppressive therapy are at higher risk of developing secondary malignancy (SM). Although previous studies have demonstrated this increased risk, much remains to be elucidated regarding the spectrum of SM and the contributing factors to morbidity and mortality.

Methods: We conducted a retrospective review of all KTR from April 2005 to December 2017 at our institution. We then selected only those patients with SM, and collected demographics, variables related to kidney transplant, malignancy, and outcomes.

Results: Among 1414 KTR, 84 patients (pts) had post-tx SM. Forty-five percent of pts were Hispanic, 33% Caucasian, 11% Asian and 6% African American. Twenty four pts (28%),11 pts (13%), and 51 pts (59%) developed cutaneous malignancy, hematological malignancy and solid organ malignancy (SOM) respectively. One patient developed both a secondary cutaneous and SOM, while another pt developed 2 different SOM. 46 (55%) pts were deceased by 1/1/20: 25 pts died from malignancy and 9 pts died from infection. Among those 46 pt, 37 pts (80%) had intact graft function at death. Eleven pts (13%) had malignancy prior to tx. The induction was rATG (36%) and basiliximab (41%). 20 pts had biopsy-proven acute rejection; of these 75% was prior to and 25% was post cancer diagnosis. 18 pts were switched to mTOR inhibitor from tacrolimus and cellcept was stopped in 22 pts.

Conclusions: We describe a wide range of SM among a diverse population of KTR, with nearly half of our patients being Hispanic. This highlights the need for further investigation of the impact of ethnicity on SM. Among our KTR, SM was the cause of death for 25 pts and infection was for 9 pts. Regardless of etiology, the majority of pts (80%) had intact graft function at death. Our findings illustrate the need for vigilant cancer screening and additional strategies to decrease cancer risk and death in KTR.

Spectrum and Consistency of Cancer Outcomes in Randomized Trials in Kidney Transplant Recipients: A Systematic Review

Eric H. Au,[1,2] Allison Tong,[1,2] Germaine Wong,[1,2] Jonathan C. Craig.[3] *[1]The University of Sydney Faculty of Medicine and Health, Sydney, NSW, Australia; [2]Children's Hospital at Westmead Centre for Kidney Research, Sydney, NSW, Australia; [3]Flinders University College of Medicine and Public Health, Bedford Park, SA, Australia.*

Background: Cancer is an important cause of morbidity and mortality in kidney transplant recipients. Despite being established as a critically important outcome by patients, caregivers and health professionals, inconsistency in how cancer outcomes are defined and reported in trials of kidney transplant recipients may limit decision-making. The aim of this study was to assess the spectrum and consistency of cancer outcomes in trials involving kidney transplant recipients.

Methods: ClinicialTrials.gov was searched from inception to October 2019 to identify all randomized controlled trials (RCTs) in adult kidney transplants recipients which included cancer as a pre-defined outcome. We extracted the details of all primary and secondary cancer outcomes, including type, timepoint and definition of cancer (histology, grade and stage).

Results: Among the 71 RCTs included, there was a total of 87 cancer outcomes. The majority of trials (n = 61, 86%) included cancer as a secondary outcome only, with 8 trials (11%) including cancer as a primary outcome and 2 (3%) including cancer as part of a composite primary outcome measure. The most common descriptions of cancer in these outcome measures was "malignancy" without specific reference to diagnostic criteria, histology, grade or cancer stage (40, 46%) or "cancer" without specific clarification (8, 9%). Some trials included mention of specific cancer types, with post-transplant lymphoproliferative disorder (13, 15%), non-melanoma skin cancer (10, 11%) and skin cancer (in general) (5, 6%) being the most common, but these were not defined. A range of timepoints were used, with a single timepoint at the end of the primary trial being the most frequent (38, 44%); 13 studies included measurement at several timepoints during the trial (15%). A range of metrics for measuring cancer outcomes were used, including cancer incidence (53, 61%), proportion with cancer (9, 10%), and time-to-event (5, 6%). No measurement metric was specified in 18 (21%) cancer outcome measures.

Conclusions: Cancer is one of the most important outcomes for patients post-transplantation, but cancer outcomes are very poorly defined and highly variable in RCTs. A core outcome for cancer for all trials in kidney transplant recipients should be developed that is consistent and meaningful to patients and clinicians.

PO2473

Acute Rejection and Graft Failure in a Kidney Transplant Recipient with Malignant Melanoma and Treated with Pembrolizumab: A Case Report

Annalise M. Panthofer, Kurtis J. Swanson, Didier A. Mandelbrot, Neetika Garg. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Introduction: Malignancy treatment with immunotherapy in renal transplant recipients is complicated by a very high risk of rejection. Immunochemotherapy increases immune recognition and destruction of immune-evading cancer cells. This can lead to an overly robust immune response leading to allograft injury and failure. Here we present a case of graft failure due to rejection within a week of starting immunochemotherapy.

Case Description: 73-year-old female with a history of end-stage renal disease attributed to hypertensive nephrosclerosis underwent live unrelated kidney donor transplant and presented 6 months post-transplant with a right foot lesion and was diagnosed with stage IIIC malignant melanoma. Her maintenance immunosuppression was decreased from tacrolimus/prednisone to prednisone monotherapy and the lesion was excised. 14 months later, disease surveillance via PET scan revealed metastatic disease. After carefully weighing the risks of mortality without treatment versus graft rejection, pembrolizumab, a programmed cell death one (PD-1) -inhibitor, was initiated. 5 days after administration of the first dose, the patient presented emergently with acute kidney injury with Cr of 4.3 mg/dL, increased from baseline Cr of 0.9-1.0 mg/dL. Ultrasound of her graft demonstrated significant edema and graft thrombosis. Allograft biopsy was consistent with 95% cortical necrosis with thrombotic microangiopathy and grade III acute cellular and antibody mediated rejection. Transplant nephrectomy was performed on day 7 and HD was re-initiated.

Discussion: Immune checkpoint inhibitors have been shown to be effective treatments for certain malignancies (melanoma, renal cell carcinoma namely); however, they can cause acute rejection and graft loss in transplant recipients. Though PD-1 inhibition has been a major scientific breakthrough in late-stage cancer treatment, its risks should be carefully considered in organ transplant recipients due to high risk of graft rejection. Prevention and management of rejection in a transplant recipient with an aggressive melanoma such as ours is not clear.

PO2474

Renal Transplant Recipients Suffer Significantly More Complications After Breast Cancer Surgery but Benefit from Treatment at Transplant Centers

Ankur P. Choubey,[1] Afshin Parsikia,[2] Maria Castaldi,[2] Rifat Latifi,[2] Jorge Ortiz.[1] *[1]The University of Toledo Medical Center, Toledo, OH; [2]Westchester Medical Center, Valhalla, NY.*

Background: Breast Carcinoma has the highest incidence of any cancer in adult females. The impact of kidney transplant (KT) on breast cancer surgery has not been examined. Our objective was to evaluate the influence of a previous KT on the short-term outcomes of mastectomy or lumpectomy.

Methods: A retrospective analysis was conducted using Nationwide Inpatient Sample (NIS) data between 2005 and 2014. Population included adult females with kidney transplant surgically treated for breast malignancy. Weighted multivariate regression models were employed to compare outcomes at transplant and non-transplant centers.

Results: 398 women met the inclusion criteria. There was a greater proportion of African-American (p<0.001), and Hispanic women (p=0.01) compared to the cohort. KT recipients had more comorbidities and higher Elixhauser Comorbidity Index scores (p<0.001). We noted longer length of stay (p<0.001), higher expenditure (p=0.001), and complications (p<0.001). Specifically, rates of hematomas (p=0.041), acute renal failure (p<0.001), blood transfusion (p<0.001), fresh frozen plasma transfusion (p<0.001), cardiovascular (p<001), and other complications (p=0.012) were increased. There was no mortality among transplant recipients. Weighted multivariate analyses highlight that rates of complication (p=0.040), and length of stay (p<0.001) are lower at transplant centers.

Conclusions: History of kidney transplant has a significant impact on the outcomes of mastectomy or lumpectomy. These patients suffer more post-operative adverse events. However, KT recipients experience superior outcomes at transplant centers.

Local Renal Graft Irradiation as Salvage Treatment for Rejection Secondary to Checkpoint Inhibitor: A Case Report

Edgar E. Acuna-Morin, Oscar A. Garcia Valencia, Javier Pagan. *University of Miami, Miami, FL.*

Introduction: Graft rejection after treatment for malignancies with checkpoint inhibitors targeting the CTLA-4 and the PD-L1 pathways has been a growing interest in recent years since the rates of graft rejection are high as 33.3% with a median time to rejection of 8 days. To the best of our knowledge, there are no prior case reports of a renal transplant patient with stage IV gastric adenocarcinoma treated with pembrolizumab (a PD-1 inhibitor) who developed graft rejection and required local irradiation.

Case Description: This is a 65-year-old male with history of ESRD secondary to IgA nephropathy, chronic Hepatitis B and related donor kidney transplant who was diagnosed with gastric malignancy with peritoneal carcinomatosis and outlet obstructionafter 12 years of transplantation. Gastric adenocarcinoma was HER2 equivocal, FISH negative, MMR deficient, PDL1 positive. Initial therapy includede discontinuation of Tacrolimus, steroid monotherapy. Initial chemotherapy included 2 cycles of FLOT followed by ramucirumab. After finding disease progression at 6 months, he received a salvage chemotherapy with pembrolizumab. Two weeks after, presented to the ED with anuric AKI. A Mag-3 scan demonstrated good perfusion and a kidney biopsy showed cortex coagulative necrosis. High dose steroids and sirolimus were given with no response and required initiation of hemodialysis. In the following weeks, presented to the ED complaining of gross hematuria and clots. Cystoscopy with bladder biopsy was performed and showed no bladder origin and normal mucosa. The hematuria was found to be secondary to kidney graft rejection and he was started on high dose of steroids with mild improvement. Nephrectomy was not an option due to poor nutritional status and overall health condition. Palliative radiation therapy to the kidney was the only option for immunosuppression. He received local graft irradiation of 7.5 Gy in 5 fractions with resolution of hematuria.

Discussion: The case illustrates first, that the use of checkpoint inhibitors in patients with kidney transplant conveys a high risk of severe irreversible allograft rejection and can occur after only one dose. Second, the viability of palliative radiation as a non-surgical option for acute kidney graft rejection causing symptomatic hematuria resistant to conventional immunosuppressant therapy.

PO2476

A Rare Presentation of Disseminated Nocardia in a Kidney Transplant Recipient

Ruchi H. Naik, Saed Shawar, Heidi M. Schaefer. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Nocardiosis is a very rare infection caused by the *Nocardia asteroids* bacterium. It most commonly involves the lungs but can spread to other areas of the body and is more likely to infect immunosuppressed patients. We report a case of a kidney transplant patient who presented with a tender lump of his right shoulder.

Case Description: Patient is a 58 year s old African American male with a history ESRD secondary to hypertension and reduced kidney mass status post right radical nephrectomy for renal cell carcinoma in 2001. He underwent deceased donor kidney transplant in May 2017 after being on dialysis for 13 years. He received alemtuzumab and methylprednisolone prednisone for induction followed by maintenance immunosuppression with Tacrolimus, mycophenolate mofetil and prednisone. In January 2020, he presented to the orthopedic clinic with a 10-day history of pain and a soft tissue mass of the right scapula and was diagnosed with a parascapular muscle tear. One week later he presented to an outside hospital with fevers and CT of chest showing pulmonary nodule with satellite lesions in the RUL concerning for malignancy. He was transferred to our hospital where PET CT scan showed multiple intensely FDG avid masses in the lungs, brain, cecum and soft tissue inferior to the right scapula concerning for malignancy. Core tissue biopsy from the right scapular region was negative for bacterial or acid-fast bacilli stain but showed gram positive beaded rods identified as Nocardia. He was initially treated with intravenous sulfamethoxazole/trimethoprim and intravenous meropenem and then based on susceptibility transitioned to intravenous ceftriaxone and oral sulfamethoxazole/trimethoprim. A follow-up MRI two months from diagnosis showed marked improvement in all lesions and he was transitioned to oral doxycycline to complete at least 12 months of therapy.

Discussion: Nocardiosis can present in unusual fashion in transplant recipients and one should have a high suspicion in patients who present with fever and disseminated lesions on imaging with plan for biopsy and culture of tissue early. In most cases, Nocardia can be treated successfully with appropriate antibiotics.

PO2477

Hypercalcemia Associated with *Pneumocystis jirovecii* Pneumonia in Renal Transplant Patients

Sarah Gilligan, Robert C. Hartley, Fuad S. Shihab, Divya Raghavan, Isaac E. Hall, Laith Al-Rabadi, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: *Pneumocystis jirovecii* pneumonia (PJP) is a common complication following solid organ transplantation with an estimated incidence of 5-15%. Although previously reported, hypercalcemia is not classically a sign of PJP. In the past 6 months at our institution, there have been six cases of PJP presenting with varying degrees of hypercalcemia.

Case Description: All patients in the table below presented with signs and symptoms concerning for pneumonia and were diagnosed with PJP by DFA and/or PCR from induced sputum or bronchoscopy. Patient demographics, labs, and calcium trends are outlined in the table. All patients were treated with Bactrim and prednisone for PJP (some later converted to alternative therapy); patients 1 and 2 were also given intravenous fluids and calcitonin specifically for treatment of their hypercalcemia. Patient 6 was initially thought to have aspiration pneumonia but was hypercalcemic on presentation. Because of our experience with the previous patients, when we noted elevated 1,25 vitamin D this prompted testing for PJP, which returned positive.

Discussion: PJP is a common infection following renal transplant and carries significant risk of morbidity and mortality, reported at 13-38%. The diagnosis of PJP can be challenging and confirmatory testing from induced sputum or bronchoscopy may take several days to result. Hypercalcemia has been reported in patients with PJP and is associated with elevated 1,25 OH vitamin levels, likely due to increased activity of 1-alpha hydroxylase in alveolar macrophages. Recognition of hypercalcemia in patients presenting with clinical features concerning for PJP can aid in early diagnosis and treatment.

Patient #	Age(yrs)/ Sex	Time from Transplant (yrs/mo)	Peak Ionized Calcium (ref. range 1.13 - 1.30 mmol/L)	1,25 Vitamin D (ref. range 19.9-79.3 pg/ml)	25 Vitamin D (ref. range 30-80 ng/ml)	PTH (ref. range 15-65 pg/ml)	PTHrP (ref. range 0-2.1 pmol/L)	Post-recovery Ionized Calcium

PO2478

Hypercalcemia: A Prodromal Feature of *Pneumocystis jirovecii* Pneumonia in Kidney Transplant Recipients

Joy C. Chen, Johanan N. Isaac, Raviprasenna K. Parasuraman. *University of Michigan, Ann Arbor, MI.*

Introduction: Hypercalcemia in transplant recipients (KTRs) is frequently caused by persisting hyperparathyroidism. However, hypercalcemia can also be a prodromal feature of serious underlying infections and malignancy. We present 2 cases of parathyroid hormone (PTH) independent hypercalcemia that preceded Pneumocystis jirovecii pneumonia (PJP) diagnosis.

Case Description: Case1. A 21y.o. male with end-stage kidney disease (ESKD) from FSGS presented with 3 weeks of dyspnea and cough 8 months after transplant (Tx). Chest x-ray (CXR) showed interstitial opacities. Lab revealed acute kidney injury and severe hypercalcemia (Table 1). He was treated with IV fluid and calcitonin, and hypercalcemia improved (Figure 1). Workup showed significant elevation in 1,25 dihydroxyvitamin D (1,25(OH)2 VitD)and low PTH level, and his sputum was positive for PJP by DNA PCR. **Case2.** A 26-y.o. male with ESKD from nephronophthisis presented with 2 weeks of cough and dyspnea 10 yrs after Tx. He had severe hypercalcemia, and CXR showed nodular interstitial opacities. He was diagnosed with PJP by sputum DNA PCR. His hypercalcemia workup also revealed elevated 1,25(OH)2 VitD and low PTH.

Discussion: PJP occurs in 5–15% of KTRs without prophylaxis with significant morbidity and mortality. A timely diagnosis is challenging given its indolent presentation. Since hypercalcemia can occur in 20-30% of cases during early stages of PJP from increased production of 1,25(OH)2 VitD via 1-α-hydroxylase from alveolar macrophages, its presence should alert clinicians of its diagnosis. In 2019, 2 out of 5 PJP cases at our center had hypercalcemia at least 2 weeks prior to PJP diagnosis with high 1,25(OH)2 VitD and low PTH. In both cases, hypercalcemia resolved after treatment of PJP. These 2 cases illustrate hypercalcmia could be a prodromal feature in PJP. Early recognition with appropriate treatment would significantly reduce its morbidity and mortality.

Clinical characteristics

Case	Total Calcium (ref: 8.6-10.3 mg/dL)	Ionized calcium (ref: 1.12-1.30 mmol/L)	PTH (ref: 10-65 pg/mL)	1,25(OH)2 VitD (ref: 18-78 pg/mL)	Treatment

Effect of UNOS Kidney Allocation System on Transplantation Rates for Veterans Waitlisted at Veterans Affairs Transplant Centers

Nidhi Aggarwal,[1,2] Sankar D. Navaneethan,[1,2] Jingbo Niu,[2] Jenny S. Pan,[1,2] Chandan Vangala,[1,2] Ronald T. Cotton,[1,2] Venkat Ramanathan.[1,2] *[1]Michael E DeBakey VA Medical Center, Houston, TX; [2]Baylor College of Medicine, Houston, TX.*

Background: Impact of new Kidney Allocation System (KAS) on kidney transplantation (KT) rates for Veterans waitlisted at Veterans Affairs Transplant Centers (VATC) is unknown. This study compares effect of KAS on waitlisted patients at VATC and non-VATC.

Methods: UNOS data on adult patients waitlisted for KT during January 2009 to December 2016 were obtained. Logistic regression was used to assess association between center type (VATC vs. Non-VATC), time period (pre-KAS 2009-2014 vs. post-KAS 2015-2016) and outcomes (receiving KT or death on waitlist) within 2 years of waitlisting. Odds ratio (OR) was calculated adjusting for demographic factors, comorbidities, calculated Panel Reactive Antibodies (cPRA) and Estimated Post-Transplant Survival (EPTS) score.

Results: During study period, a total of 263,410 patients were listed at non-VATC (75% pre-KAS; 25% post-KAS) and 3,150 at VATC (68% pre-KAS; 32% post-KAS). VATC patients were significantly older (58.3 vs.51.7 years), diabetics (55.4% vs. 42.5%), had lower cPRA, higher EPTS (53 vs.39%) and longer duration of dialysis (762 vs. 727 days). Within 2 years of waitlisting, Veterans listed at VATC did not benefit from the new KAS like patients in non-VATC centers. Overall, independent of the era, Veterans tend to be transplanted lesser in this early waitlisting period. But death on waitlist was 29% lower in VATC patients. (Results are shown in the table).

Conclusions: Benefit of new KAS did not extend to Veterans listed at VATC who are older, less immunogenic and have higher EPTS score. Early benefit of KAS seen in non-VATCs could be due to "bolus effect" from transplantation of younger, highly sensitized patients. However, risk of death is significantly lower in VATC waitlisted patients.

Outcomes of patients within 2 years of waitlisting for kidney transplantation

	Kidney transplant rate (OR, 95% CI)	Death on waitlist (OR, 95% CI)
Post-KAS vs Pre-KAS (Non-VATC)	1.30 (1.27, 1.33)*	
Post-KAS vs Pre KAS (VATC)	0.94 (0.76, 1.14)	
VATC vs Non-VATC (Pre-KAS)	0.70 (0.63, 0.79)*	
VATC vs Non-VATC (Post-KAS)	0.49 (0.41, 0.58)*	
Post-KAS vs. Pre-KAS (Overall)		0.78 (0.75, 0.82)*
VATC vs. Non-VATC (Overall)		0.71 (0.60, 0.84)*

PO2480

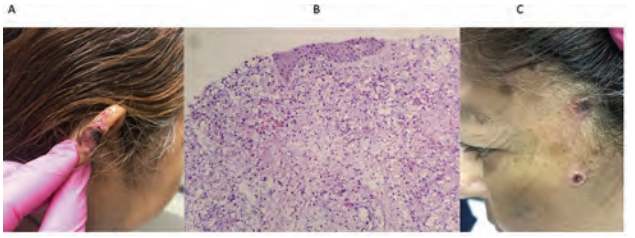
Lend Me Your Ear: An Unusual Presentation of a Transplant Complication

Meredith McAdams, Kruti Yagnik, Swee-Ling Levea, Jeffrey Tessier, Reuben J. Arasaratnam. *University of Texas Southwestern Medical School, Dallas, TX.*

Introduction: Infections are a major complication in solid organ transplant (SOT) patients due to need for life-long immunosuppression. Incidence of fungal infections following solid organ transplant ranges from 5-20%. Cryptococcosis is an invasive fungal infection that can cause several types of infections including meningitis, pulmonary, cutaneous, and disseminated disease.

Case Description: A 66 yo F with past medical history of ESRD s/p deceased donor kidney transplant 15 months ago, DM, HTN presented to renal transplant clinic with right ear pain for the past 4 weeks after being evaluated in the emergency room. Her exam was notable for painful ear and cheek lesions (**Figures A and C**). Fungal serologies were obtained and patient was sent to dermatology clinic for evaluation. Punch biopsies were taken from several lesions and cultures obtained. Serum cryptococcal antigen was positive with titer of 1:4096, fungal culture from lesion grew *Cryptococcus neoformans*. Skin biopsy showed cyryptococcus (**Figure B**). Patient was admitted to the hospital and further testing revealed positive CSF cryptococcal antigen, CT chest with nodular opacities, leading to a diagnosis of disseminated cryptococcus. She was treated with amphotericin B and flucytosine and eventually transitioned to oral fluconazole.

Discussion: Cryptococcal infection is the third most common invasive fungal infection in SOT patients and typically presents later in kidney transplant patients, 16-21 months, compared to other transplanted organs. Risk factors include type of immunosuppressive agent and comorbid conditions such as diabetes. The majority of transplant patients with cryptococcus present with CNS manifestations or disseminated disease, cutaneous involvement is less common. Our patient had risk factors including diabetes, older age, and use of induction immunosuppression. Initial presentation with skin lesions is atypical for cryptococcal infection. It is important to have a high suspicion for fungal infections in immunosuppressed patients even those with atypical presentations.



PO2481

Pegloticase for Uncontrolled Gout in Kidney Transplant Recipients: Early Data Report of a Multicenter, Open-Label Efficacy and Safety Study

Abdul A. Abdellatif,[1] Lin Zhao,[2] Paul M. Peloso,[2] Katya Cherny,[2] Brad A. Marder,[2] John D. Scandling,[3] Kenneth G. Saag.[4] *[1]Baylor College of Medicine, Division of Nephrology, Houston, TX; [2]Horizon Therapeutics plc, Lake Forest, IL; [3]Stanford School of Medicine, Division of Nephrology, Stanford, CA; [4]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL.*

Background: Gout is common and more severe in US kidney transplant (KT) recipients, with prevalence >10x higher than in non-transplant patients. The management of gout can be challenging in KT patients due to decreased urate lowering therapy (ULT) clearance and drug-drug interactions. Recent reports suggest that pegloticase, a pegylated uricase approved for treating uncontrolled gout, has improved efficacy and safety when co-administered with immunosuppressive medications (IMM). We conducted the PROTECT trial (NCT04087720) to examine pegloticase use in KT recipients.

Methods: Patients with uncontrolled gout (sUA ≥7 mg/dL, intolerance of or contraindication to ULT, and ≥1 of the following: tophi, chronic gouty arthritis, ≥2 flares in past yr) and functioning KT graft (eGFR ≥15 mL/min/1.73m^2) are included (KT>1 yr earlier). Pegloticase (8 mg q2w for 24 wks) safety and efficacy are examined. Primary endpoint is % pegloticase responders during Month 6 (sUA <6 mg/dL for ≥80% of time).

Results: 7 patients were enrolled by Apr 30, 2020 (age: 52.0±11.2 yrs, KT 15.3±5.0 yrs ago, sUA: 10.0±1.4 mg/dL, gout duration: 5.9±4.3 yrs; all on stable doses of ≥2 IMM) and received 2-12 infusions. 1 patient discontinued. In the 1 completed and 5 ongoing patients, all central lab sUA levels were <1 mg/dL, indicating treatment response; no infusion reactions occurred. No notable eGFR changes were observed; 2 patients with baseline albuminuria of >300 mg/g showed >35% reduction in UACR by wk 14. 2 SAEs (stomach ulcer, cellulitis) unrelated to pegloticase were reported.

Conclusions: Early data of this ongoing clinical trial are promising and suggest pegloticase is safe and effective for treating uncontrolled gout in KT recipients. Additional efficacy and safety data are planned.

PO2482

Minoxidil-Induced Chylous Ascites in a Renal Transplant Recipient

Vivek Pathak. *Kovai Medical Center and Hospital, Coimbatore, India.*

Introduction: Chylous ascites is generally associated with malignancies and surgical trauma and rarely secondary to administration of drugs(Tsai et al J.Clin.Med.2019,8,466). Calcium channel blockers related chylous ascites is more common is Asian ethnicity we could not find any published report of minoxidil causing chylous ascites.

Case Description: This patient is a 64 years old diabetic and hypertensive male who underwent kidney transplantation on 09.06.2009. He was HBsAg positive for last 9 years. He was taking multiple medications namely carvedilol, amplodipine, lasix minoxidil, prednisolone, MMF, Tacrolimus, insulin, metformin and linagliptin and Entecavir. He came in May 2019 with ascites. Investigation revealed normal kidney function and ultrasound guided ascitic fluid tapping was done and it was found to be chylous. He underwent abdominal paracentesis and about 12 lt of ascitic fluid was drained but he came back within 10 days with ascites again. Portal hypertension was ruled out by transjugular hepatic venous pressure gradient measurement and liver biopsy did not show any evidence of chronic liver disease. An upper GI endoscopy and duodenoscopy including duodenal biopsy were normal. Whole body PET scan did not show any active infection or disease. Meanwhile literature review suggested association of amplodipine with chylous ascites and it was stopped but he continued to develop recurrent ascites. An abdominal CT lymphangiogram was done which did not show any lymphatic leak.

He also underwent diagnostic laparoscopy which also ruled out TB or any malignancy. This recurrent chylous ascitic fluid drainage continued for 6 months then we decided to discontinue minoxidil as it is known to cause fluid accumulation including pleural and percardial. He showed immediate improvement after stopping minoxidil and never developed ascites again. He was fine even 6 months later on follow up.

Discussion: Minoxidil causes vasodilatation like calcium channel blockers though by a different mechanism so the mechanisim of chylous ascites formation could be the same that it is also a lipophilic drug allowing it to pass rapidly into the lymphatic system and causes relaxation of smooth muscles of lymphatic vessels, interferes with lymphatic drainage, increases the hydrostatic pressure in lymph vessels and causing it to leak in the peritoneum. Minoxidil must be considered as a probable cause of atraumatic drug induced chylous ascites.

PO2483

COVID-19 in Kidney Transplant Recipients: Experience from a Large Health System in Louisiana

Aldo E. Torres Ortiz, Joseph B. Walker, Juan Carlos Q. Velez, Jorge C. Garces. Ochsner Nephrology *Ochsner Health System, New Orleans, LA.*

Background: Infections are an important cause of morbidity and mortality among kidney transplant recipients. The novel Coronavirus Disease 2019 (COVID-19) has affected all kinds of populations world-wide. However, the role of immunosuppression in the outcomes of these patients is not well understood.

Methods: We conducted a retrospective study in kidney transplant recipients from a single health system that were diagnosed with COVID-19 based on a positive real-time reverse transcription polymerase chain reaction test for SARS-CoV-2 RNA between 03/01/2020 and 04/30/2020. We compared them with affected patients without a kidney transplant and without any kind of immunosuppressive medication (control). We examined the rates of hospitalization, intensive-care unit (ICU) admission, acute kidney injury (AKI) and mortality as outcome measures.

Results: A total of 8473 patients were diagnosed with COVID-19 within our Health System within the study period. Thirty-three (0.4%) were kidney transplant recipients. Sixteen of the 33 (48%) were admitted to the hospital (median age of 56, 68% males, 93% African American) vs 2201 admissions (25%) for the control group (median age 66, 48% males, 65% African-American), i.e., a significantly greater risk for hospitalization for transplant recipients ($p = 0.002$). Percentage of patients with hypertension in the transplant group was numerically higher (93% vs 80%, $p = 0.06$), as well as the number of ICU admissions (43% vs 28%, $p = 0.055$). AKI was more common in transplant patients (81% vs 33.8% $p<0.0001$). No difference in mortality was observed (31 vs 24%, $p = 0.34$). Among transplant patients, those hospitalized were more likely to be on prednisone (75% vs 35%, $p = 0.025$) and had a post-transplant graft life of 7.9 years compared to 5.5 years for those not hospitalized, p 0.08).

Conclusions: Kidney transplant recipients affected with COVID-19 exhibited a greater incidence of hospitalization, AKI and a trend for more ICU admissions. Use of immunosuppression with prednisone was associated with greater risk for hospitalization

PO2484

Recurrent Anemia due to Chronic Parvovirus B19 Infection in a Kidney Transplant Recipient: Can Everolimus Make a Difference?

Diana Rodriguez-Espinosa, Nuria Esforzado, Fritz Diekmann, Ignacio Revuelta. *Hospital Clínic de Barcelona, Hospital Clinic de Barcelona, Barcelona, Spain.*

Introduction: Parvovirus B19 (PB19) is a common infection among transplant recipients. Usually, it is asymptomatic, but some patients may suffer severe infections, often presenting with recurrent flares despite standard treatment. Relapses are usually managed by reducing immunosuppressive treatment (IST), potentially increasing graft rejection risk.

Case Description: 45-year-old woman with ESKD due to ADPKD, received a living-donor kidney transplant on May 2013. Maintenance IST consisted of mycophenolate mofetil (MMF), prednisone and tacrolimus. A month after transplantation, she presented with fever and anemia. A bone marrow aspirate revealed pure red blood cell aplasia (PRCA) which was attributed to PB19 after positive serum qualitative PCR. She was treated intravenous immunoglobulin (IVIG) at 2g/kg and MMF was stopped with good response. However 3 new relapses occurred (anemia and malaise with viral loads for PB19 over a million copies). A monthly prophylactic dose of IVIG was initiated to control the infection. In spite of this, episodes of anemia and a high PB19 viral load (over half a million copies) continued to happen at least 3 times per year. Finally, given the potential antiviral properties of mTOR inhibitors (mTORi), conversion from tacrolimus to everolimus was decided, Since November 2017 her maintenance IST consists of everolimus and prednisone alone, her last prophylactic IVIG was on December 2017, and since then she has been non-anemic with serum viral loads below 1000 copies, and without IVIG treatment.

Discussion: Incidence of symptomatic PB19 infection is highest during the 1st year after transplantation, like in the case presented. Standard therapy consists of IVIG. However, early KTR, often relapse after the IVIG effect wears off. In such cases, reduction of IST is needed to control the infection and avoid recurrences. There are multiple studies indicating that mTORi have antiviral properites although their effect on PB19 has not been specifically studied. In conclusion, conversion from tacrolimus to an mTORi, could be an interesting approach in difficult-to-manage cases similar to ours, moderating the reduction of IST and minimizing the risk of rejection. Further studies are needed to establish this approach as "treatment of choice" in relapsing PB19 infection.

PO2485

Adjusted Donor Age Score: Validity and Influence on Deceased Donor Offer Decisions

Christoph F. Mahler,[2,1] Emma. Morganti,[1] Dhriti Dosani,[1] Anamika Adwaney,[1] Rupert B. Bright,[1] Damien Ashby.[1] West London Renal and Transplant Centre [1]*Imperial College London, London, United Kingdom;* [2]*Ruprecht Karls Universitat Heidelberg, Heidelberg, Germany*.

Background: Although a number of donor factors are known to affect outcome following deceased donor kidney transplantation, many units have no clear criteria for acceptance. Existing donor scoring systems, such as KDRI, perform poorly in the modern comorbid donor pool, and are difficult for patients to understand. Adjusted Donor Age (ADA) is a patient-friendly scoring system in which donor age is modified according to the presence or absence of a number of risk factors, and categorised by ADA decade (using cut-offs at 50, 60, 70 and 80 years) into quintiles (A – E) representing increasing donor risk (A – C favourable, D marginal, and E unfavourable).

Methods: All deceased-donor kidney offers at a single centre were analysed over a 3 month period (beginning after the September change in UK organ allocation) during which ADA was optionally available to clinicians at the time of considering the offer. The effect of ADA on acceptance decisions and outcome in those transplanted were analysed.

Results: Out of 230 offers median(IQR) ADA was 67(56–76). Kidneys were transplanted in 24%, declined due to concern over donor risk in 44%, with recipient and other factors responsible for non-transplantation in 32%. In those identified as favourable by ADA (quintiles A – C, without exclusion factors), organs were rejected due to donor risk in 28/104 offers (27%), compared to 50/186 (27%) in the 2018 cohort. In those identified as unfavourable by ADA (quintile E) organs were transplanted in 0/38 offers (0%), compared to 10/66 (15%) in the 2018 cohort. At 1 month post-transplantation (N=55, from quintiles A – D only, since no organs from quintile E were accepted) one recipient remained dialysis dependent (from quintile D). In those with functioning transplants (N=54) recipient GFR was strongly correlated with ADA ($R=0.52$, $p<0.001$) and was seen to reduce across quintiles A – D (74, 55, 43 and 38ml/min/1.72m^2).

Conclusions: ADA is a patient-friendly score, calculated from donor age but adjusted for 12 potential risk factors, which can be used to guide acceptance decisions. At this early stage of familiarity, clinicians appear to be more persuaded by an unfavourable ADA quintile, than a favourable one. In this validation cohort, ADA strongly predicts early post-transplant outcome.

PO2486

Kidney Offer Calculator: The Risk of Accepting an Offer vs. Waiting for a Better Offer

Shan Shan Chen,[2] Igor Litvinovich,[2] Ashish Kataria,[2] Yiliang Zhu,[2] Christos Argyropoulos,[2] Yue-Harn Ng.[1] [1]*University of Washington, Seattle, WA;* [2]*University of New Mexico, Albuquerque, NM.*

Background: Currently, no tools exist to facilitate patients with decisions to accep or refuse an offer. Using the scientific registry of transplant recipients database, we formulated a risk calculator for allograft failure and patient mortality risk (if offer accepted) vs. mortality risk if the patient refused.

Methods: Using a multi-state model approach, we created multiple competing risk models for: 1) first kidney offer or dying on wait-list without any offer; 2) if offer is refused, the probability of a) receiving a transplant vs. b) death and 3) if an offer is accepted, the probability of a) allograft failure vs. b) death. All models were adjusted for candidate estimated post-transplant survival (EPTS) score while allograft failure and patient survival was adjusted for recipient EPTS, donor KDPI and cold ischemic time.

Results: Fig.1 shows our multi-state model for which the competing risk models were build. Table 1 depicts the hazard ratio for each stage described above and the kidney offer risk calculator created using the estimates generated from the models. We included a case scenario to demonstrate how the calculator works (Table 1).

Conclusions: In summary, creating a risk calculator is feasible. Next, we will refine our calculator to account for repeated offers and include other variables that may affect allograft offer and survival e.g. panel reactive antibody.

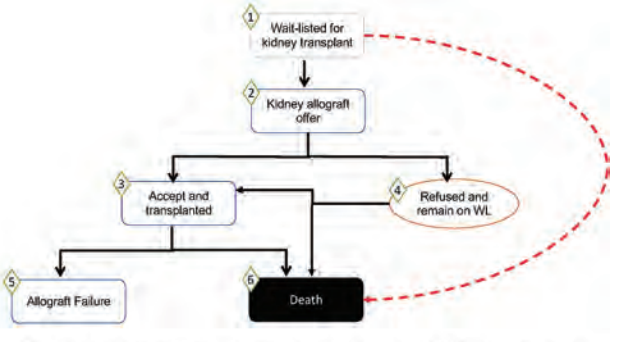

Figure 1. Kidney offer risk calculator multi-state model and associated hazard ratios [95% confidence intervals]

Table 1. Competing risk model summary for each stage of the multi-state model

Variables	Hazard ratio	95% CI	P value	Hazard ratio	95% CI	P value
Table 1a. Competing risk model of 1st kidney offer						
		Offer			Death	
EPTS	1.037	1.036; 1.038	< 0.001	1.093	(1.087; 1.100)	< 0.001
Table 1b. Competing risk model if kidney offer is refused						
		Subsequent transplant			Death	
EPTS	0.927	0.926; 0.929	< 0.001	1.190	1.187; 1.193	< 0.001
Table 1c. Competing risk model if kidney offer is accepted						
		Allograft failure			Death	
EPTS	0.885	0.880; 0.889	< 0.001	1.269	1.263; 1.276	< 0.001
KDPI	1.107	1.102; 1.113	< 0.001	0.990	0.986; 0.994	< 0.001
CIT*	1.090	1.072; 1.109	< 0.001	1.055	1.038; 1.073	< 0.001

Data derived from SRTR candidate file from 1993-2017; transplant file from 2000-2017 and match-run file from 2000-2017
* at increments of 12 hours
Abbreviations:
CI= confidence interval; EPTS= estimated post-transplant survival; KDPI= kidney donor profile index; CIT= cold ischemic time
Table 1a: A total of 482,956 candidates were wait-listed, of which 396,280 received a kidney offer and 25,365 died
Table 1b: A total of 384,042 candidates refused their 1st kidney offer, of which 138,241 subsequently received a kidney transplant and 76,552 died
Table 1c: A total of 190,518 candidates received a transplant, of which 99,43,167 subsequently experienced allograft function failure and 47,417 died before allograft failure

Kidney risk offer calculator

Case scenario: 42 year old candidate with no diabetes or previous transplant, on dialysis for 3 years (EPTS 17%) receives a KDPI 78% kidney offer with cold ischemic time of 10 hours

Based on this scenario, the probability is shown below:

Probability of receiving a kidney offer vs. death while waiting

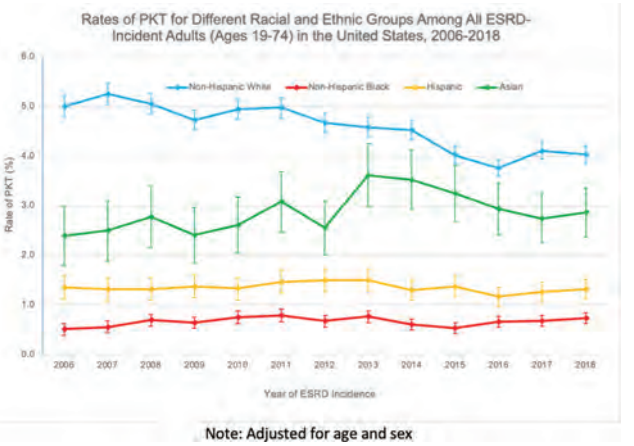
1st Kidney offer:	EPTS decile	Probability	Death:	EPTS decile	Probability
coef	0.0365		coef	0.0893	
value	2		value	2	
coef*value	0.073	0.518	coef*value	0.1786	0.545

If the offer is refused, the probability of subsequent transplant vs. death on dialysis

Transplant:	EPTS decile	Probability	Death:	EPTS decile	Probability
coef	-0.0756		coef	0.1739	
value	2		value	2	
coef*value	-0.1512	0.462	coef*value	0.3478	0.588

If the offer is accepted, the probability of allograft failure vs. death after transplant

Allograft Failure:	EPTS decile	KDPI decile	Cold Ischemic Time (12 hour increments)	Probability	Death:	EPTS decile	KDPI decile	Total Cold Ischemic Time	Probability
coef	-0.1225	0.1020	0.0862		coef	0.2384	-0.0101	0.0539	
value	2	8	1		value	2	8	1	
coef*value	-0.245	0.816	0.0862	0.659	coef*value	0.4768	-0.0808	0.0539	0.611



Note: Adjusted for age and sex

Rates and 95% CI of PKT (%) Among Different Racial and Ethnic Groups Derived from Multivariable Linear Regression Models, 2006-2018

	Non-Hispanic White	Non-Hispanic Black	Hispanic	Asian
Model 0	4.56% [4.50-4.61]	0.65% [0.61-0.68]	1.35% [1.30-1.41]	2.90% [2.75-3.06]
Model 1	4.08% [4.03-4.13]	1.27% [1.23-1.30]	1.66% [1.60-1.72]	2.57% [2.42-2.73]
Model 2	4.00% [3.95-4.06]	1.29% [1.25-1.33]	1.81% [1.74-1.88]	2.61% [2.45-2.78]
Model 3	3.84% [3.79-3.90]	1.55% [1.50-1.59]	2.43% [2.35-2.50]	2.43% [2.25-2.60]
Model 4	3.75% [3.70-3.80]	1.61% [1.57-1.66]	2.59% [2.51-2.67]	2.32% [2.14-2.49]

Note: Model 0 adjusts for age and sex. Model 1 adjusts for clinical factors: age, sex, BMI, primary ESKD cause, & comorbidities. Model 2 further adjusts geography: ESKD network & states. Model 3 further adjusts SES factors: employment status and insurance type. Model 4 further adjusts access to pre-ESKD nephrology care. All models adjust for ESKD incident year. All results are statistically significant ($p < 0.001$).

PO2487

Racial-Ethnic Disparities in Preemptive Kidney Transplantation Among Incident ESKD Adult Patients, 2006 to 2018

Navya Baranwal,[1] Rebecca Thorsness,[2] Shailender Swaminathan,[2,3] Rachel E. Patzer,[5] Rajnish Mehrotra,[4] Amal Trivedi.[2,3] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Brown University School of Public Health, Providence, RI; [3]Providence VA Medical Center, Providence, RI; [4]Harborview Medical Center, Seattle, WA; [5]Division of Transplantation, Department of Surgery, Emory University School of Medicine, Atlanta, GA.*

Background: Preemptive kidney transplantation (PKT) is the preferred treatment for ESKD. Among kidney transplant recipients, black and Hispanics are less likely to receive PKT than whites, but less is known about disparities in PKT among the entire incident ESKD population. This is a critical gap in knowledge given the Advancing American Kidney Health goal of 80% of all new ESKD patients receiving transplant or home dialysis by 2025. This study assessed racial/ethnic disparities in initial treatment with PKT vs. dialysis among all incident kidney failure patients aged 19-74 from 2006 to 2018.

Methods: Treatment modality for incident ESKD patients was identified using the CMS Medical Evidence Report Form. Linear regression models estimated PKT rates for white, blacks, Hispanics and Asians, adjusting for clinical, geographic, socioeconomic, and access factors.

Results: Among 1,133,326 incident ESKD adult patients, the age/sex adjusted PKT rate declined from 3.0% in 2006 to 2.5% in 2018, with varied trends in each racial/ethnic group (white: 5.0% to 4.0%, black: 0.5% to 0.7%, Hispanic: 1.3% to 1.3%, and Asian: 2.4 to 2.9%) (Figure). In age-sex adjusted analyses, whites had 3.9, 3.2, and 1.7 percentage point higher rates of PKT compared to blacks, Hispanics, and Asians, respectively. These differences persisted after adjusting for clinical, geographic, SES, and pre-ESKD nephrology care (Table). Among patients aged 19-44, whites had 8.0, 6.3, and 3.3 higher rates of PKT, compared to blacks, Hispanics, and Asians.

Conclusions: Among incident ESKD adult patients, racial/ethnic disparities in receipt of PKT are substantial, persistent, and not explained by differences in observed clinical factors and socioeconomic status. Efforts to increase preemptive transplantation must address disparities in access to this preferred treatment for ESKD.

PO2488

Lower Prevalence of Kidney Transplant Waitlisting in Micropolitan Areas, Small Towns, and Rural Areas

Eric D. Weinhandl,[1,2] H. E. Hamilton,[1] Lorien S. Dalrymple.[1] *[1]Fresenius Medical Care, Waltham, Anguilla; [2]Chronic Disease Research Group, Minneapolis, MN.*

Background: The Percentage of Prevalent Patients Waitlisted (PPPW) measures the percentage of patients at a dialysis facility who were on the kidney or kidney-pancreas transplant waitlist. This measure joined the End Stage Renal Disease Quality Incentive Program in performance year 2020, with a weight of 4%. PPPW is adjusted for age, but not for other factors. Physical distance between residence and transplant center may influence PPPW. As an indirect test of this hypothesis, we assessed whether PPPW was associated with rural-urban commuting area (RUCA) levels.

Methods: We analyzed data in Dialysis Facility Compare (DFC), as of October 30, 2019. DFC included PPPW values that quantified waitlisting prevalence during 2018. According to ZIP code, we classified the location of each dialysis facility as metropolitan (RUCA values, 1-3), micropolitan (4-6), small town (7-9), or rural (10). We estimated weighted mean PPPW values in each location class, with the weight of each facility equal to the number of patients contributing to PPPW. We fit a linear regression model to test differences in PPPW values between the location classes.

Results: PPPW values were reported in 7086 (94%) of 7566 dialysis facilities, and RUCA values were identified in 6999 (99%) of 7086 facilities. The weighted mean PPPW value among all facilities was 17.5%. There were 5363 (77%) facilities in metropolitan areas, 954 (14%) in micropolitan areas, 550 (8%) in small towns, and 132 (2%) in rural areas. By location class, weighted mean PPPW values were 18.5% in metropolitan areas, 12.8% in micropolitan areas, 12.1% in small towns, and 10.8% in rural areas. Relative to the mean PPPW value in metropolitan areas, mean PPPW values were 5.8, 6.5, and 7.7 percentage points lower in micropolitan areas, small towns, and rural areas, respectively ($P < 0.01$ for each).

Conclusions: The PPPW measure takes significantly lower values in dialysis facilities located in micropolitan areas, small towns, and rural areas, relative to metropolitan areas. The physical distance between residence and transplant center may preclude many patients in non-metropolitan areas from completing the process of kidney transplant evaluation. New processes are needed to improve access to transplantation in outlying areas.

PO2489

Demonstrating Charitable Premium Assistance as a Mechanism for Overcoming the Cost Barrier to Transplant for Low-Income Patients in the United States

Michael Spigler,[1] Morenike Bello,[1] Melanie Paris,[1] Lisa Vo,[1] Silas Norman.[2] *[1]American Kidney Fund, Rockville, MD; [2]University of Michigan Transplant Center, Ann Arbor, MI.*

Background: The optimal treatment for patients with end-stage renal disease (ESRD) is kidney transplantation. Adequate insurance coverage is one requirement for transplant eligibility. Many low-income ESRD patients cannot afford insurance coverage. Patients on dialysis are eligible for Medicare. Because Medicare covers only 80% of healthcare costs, most patients require supplemental insurance, often Medigap. Although Medigap

plans reduce out-of-pocket spending on healthcare services by almost 50%, spending on health insurance premiums more than doubles compared to Medicare premiums alone. For low-income patients who cannot afford such premiums, inadequate insurance coverage can become an insurmountable barrier to qualifying for a kidney transplant (KT). We evaluated a premium assistance program designed to help low-income ESRD patients maintain insurance coverage and the impact on KT access.

Methods: We performed a descriptive analysis of self-reported patient data collected from paper and digital applications submitted to American Kidney Fund's (AKF) Health Insurance Premium Program (HIPP) between November 15, 2018 and December 31, 2019.

Results: HIPP provided financial assistance grants to 1,357 (5.8% of all) kidney patients transplanted in the United States during the study period so they could maintain their health coverage in 2019. Of the 1,357 grants, 36% of grants issued helped patients pay Medigap premiums. Medigap recipients were more likely to be ≥ 65 (20% vs. 12%), more likely to be African American (38% vs. 34%), and had lower median income ($23,622 vs. $27,168 respectively) compared to the overall transplant population.

Conclusions: KT candidates face financial barriers to transplantation. Premium assistance significantly reduced the barrier to transplant among KT candidates who rely on Medigap by ensuring adequate coverage.

PO2490

"Some Person Behind a Desk Is Going to Be Looking at My File": Thematic Analysis of the Health Records of a National Sample of Patients with Advanced Kidney Disease Evaluated for Kidney Transplant

Catherine Butler,[1] Aaron G. Wightman,[3] Janelle S. Taylor,[4] Claire Richards,[1] Chuan-fen Liu,[2,1] Ann M. O'Hare.[1,2] *[1]University of Washington, Seattle, WA; [2]VA Puget Sound Health Care System, Seattle, WA; [3]Seattle Children's Hospital, Seattle, WA; [4]University of Toronto, Toronto, ON, Canada.*

Background: To be considered for kidney transplant, patients with advanced kidney disease must participate in a formal evaluation and selection process. Little is known about how this process unfolds in real-world clinical settings.

Methods: We conducted a thematic analysis of clinician documentation related to the kidney transplant evaluation in the VA-wide electronic medical records of patients who were referred to a transplant center among a random sample of 4,000 adults with advanced kidney disease between 2004 and 2014 who were followed through 2019.

Results: We identified 211 patients (5.2%) who were referred to a VA transplant center during follow-up. Four dominant themes emerged from qualitative analysis of clinician documentation in the electronic medical records of these patients: 1) far-reaching and inflexible medical evaluation: patients were expected to complete a demanding evaluation that could take a substantial physical and emotional toll on them and their family members, made little accommodation for their individual needs, and impacted many other aspects of their care; 2) psychosocial valuation: the psychosocial transplant assessment could be subjective and intrusive and placed substantial demands on patients' family members; 3) surveillance over compliance: clinicians monitored patients' adherence to a wide range of medical recommendations; 4) disempowerment and lack of transparency: patients had a strong desire to receive a transplant, but neither they nor their local clinicians had a clear understanding of what to expect from the evaluation process or the rationale for selection decisions, which left patients and their clinicians with little choice but to adhere to the transplant center's recommendations.

Conclusions: To be considered for kidney transplant, patients had little choice but to engage in a rigid, demanding, and opaque evaluation process over which neither they nor their local clinicians had much control. These findings call for a more evidence-based, transparent, and individualized approach to the kidney transplant evaluation process.

PO2491

Implicit Bias in Recipient Selection

Yousef Sweidan,[1] Christine Mayuga,[1] Kenneth Chavin,[2] Titte Srinivas,[1] Aparna Padiyar.[1] *[1]University Hospitals Cleveland Medical Center Department of Medicine, Cleveland, OH; [2]University Hospitals Cleveland Medical Center Department of Surgery, Cleveland, OH.*

Background: The decision to place or exclude a candidate from the waitlist is not exclusively based on medical criteria. Scant literature exists regarding the intergroup dynamics within selection committees that influence decision making. This study attempts to clarify how the composition of selection committee meetings may affect listing outcome of kidney transplant candidates.

Methods: We performed a single-center retrospective study of kidney transplant selection committee attendance sheets and minutes from January 2012 to December 2015. We sought to determine if candidates who were evaluated by the same providers in attendance at selection committee are more likely to be listed for kidney transplant.

Results: 3205 (48.4%) of 6630 donor and recipient candidates presented during 91 selection meetings from 2012 to 2015 were listed. 8 nephrologists, 9 surgeons and 3 social workers comprised the clinicians that both evaluated potential candidates and attended recipient selection meetings. Table 1 describes the frequency with which clinicians who were in attendance at selection meetings had previously evaluated the candidates being discussed. Using binary logistic regression, the presence of the nephrologist or the surgeon who had evaluated the patient was significantly associated with a greater likelihood of the candidate being listed (OR 4.443 and 3.952 respectively, p=0.000, see Table 2). White race was also associated with an increased propensity to list, OR 1.202, p =0.006. Interestingly, the presence of both the nephrologist and surgeon who evaluated the patient, or the presence of both physicians and the social worker, were associated with reduced likelihood of listing (OR 0.267 for both, p=0.000 ; OR 0.715, p=0.001 for all three, see Table 2).

Conclusions: The composition of attendees at recipient selection meetings may influence listing outcomes of potential kidney transplant candidates.

Table 1. Frequency the Clinician in Attendance at Selection had Evaluated the Patient

Nephrologist	3038 (45.8%)
Surgeon	2912 (43.9%)
Social Worker	2903 (43.8%)
Nephrologist and Surgeon	2520 (38.0%)
Social Worker, Nephrologist and Surgeon	2004 (30.2%)

Table 2. Likelihood of Candidate Being Listed, if the Clinician who Evaluated Patient Present

	OR	95% CI	p value
Age	0.993	0.989, 0.998	0.006
Male gender	1.123	0.981, 1.286	0.092
White race	1.202	1.055, 1.370	0.006
Nephrologist present	4.443	3.556, 5.551	0.000
Surgeon present	3.952	3.148, 4.963	0.000
Social worker present	1.186	1.007, 1.398	0.041
Both physicians present	0.267	0.186, 0.384	0.000
Both physicians and social worker present	0.715	0.584, 0.876	0.001

PO2492

Predictors of Kidney Transplant Evaluation Non-Attendance

Christopher G. Ford,[1] Eric Kruger,[1] Yuridia Leyva,[1] Yiliang Zhu,[1] Kellee Kendall,[2] Emilee J. Croswell,[2] Mary amanda Dew,[2] Chethan M. Puttarajappa,[2] Mark L. Unruh,[1] Yue-Harn Ng,[3] Larissa Myaskovsky.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]University of Washington Medical Center, Seattle, WA.*

Background: We examined which medical and socio-cultural factors predict kidney transplant evaluation (KTE) non-attendance, because missing a KTE appointment precludes access to transplantation, and having empty clinic slots impacts access to care for others.

Methods: We collected patient characteristics in an interview prior to KTE, covering demographics (e.g., income, education), medical factors (e.g., on dialysis, co-morbidities), cultural factors (e.g., medical mistrust), psychosocial characteristics (e.g., social support, depression), and knowledge factors (e.g. knowledge about transplant). We used latent class analysis (LCA) to determine if we could identify meaningful classes (groups of patients with patterns across variables) that were associated with KTE non-attendance.

Results: Our sample (*N*=1119) was 37% female, 76% non-Hispanic White, median age 59.4 years (IQR= 49.2-67.5), 25% had income below federal poverty line, 47% were < high school graduate, 48% were married, 44% had public insurance only, and 142 (13%) did not attend KTE appointment. LCA analyses indicated that a two-class solution consisting of a (1) high burden and (2) low burden group was optimal. Relative to the low burden group, the high burden group was less likely to be married, more likely to be on dialysis, less likely to have potential living donor, had higher kidney disease burden, more experiences of healthcare discrimination, higher medical mistrust, less social support, more depression, less knowledge about transplant, and more worry about kidney transplant harm. Belonging to the high burden group was associated with approximately twice greater odds of KTE non-attendance (*OR*=1.92, *p*<0.001, 95% CI:1.57, 2.34).

Conclusions: Medical and socio-cultural factors predict KTE non-attendance. Transplant teams should consider targeting patients with characteristics indicating high burden for additional support (e.g., exploring motivation and barriers with patients, assisting with resources to attend appointment, and providing additional reminders or notifications). Given the association of clinic non-attendance with being on dialysis, a treatment with significant patient burden, future research should also focus on the benefits of referring patients for transplant evaluation prior to initiating dialysis.

PO2493

Racial Disparities in Receipt of Medications for Secondary Prevention of Cardiovascular Disease in Kidney Transplant Recipients in the FAVORIT Trial

Mohammad Kazem Fallahzadeh Abarghouei,[2] Elaine Ku,[2] Chi D. Chu,[2] Charles E. McCulloch,[1] Delphine S. Tuot.[2] *[1]Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; [2]Division of Nephrology, UCSF, San Francisco, CA.*

Background: Cardiovascular disease (CVD) is the most common cause of death with a functioning graft in kidney transplant recipients. Black patients have been shown to have higher prevalence of cardiovascular (CV) risk factors and less intensive risk factor modification. We evaluated racial disparities in receipt of HMG-Co-A reductase inhibitors (statins) and aspirin for secondary prevention of CVD in kidney transplant patients in the Folic Acid for Vascular Outcome Reduction in Transplantation Trial (FAVORIT) trial.

Methods: FAVORIT was a multicenter international trial of vitamin therapy to lower homocysteine levels and improve CV outcomes in kidney transplant patients. We identified FAVORIT trial participants from US and Canada who had a self-reported

history of established CVD at baseline and/or developed a CVD event during the study. We used parametric interval-censored survival models to evaluate the effect of race on self-reported receipt of statins and aspirin for secondary CV prevention, adjusting for age, gender, ethnicity, and country of enrollment. In addition, we controlled for baseline cyclosporin use in the model assessing statin use and graft vintage in the model assessing aspirin use.

Results: Of the 4110 kidney transplant patients enrolled in FAVORIT, 978 met the inclusion criteria (78% White, 17% Black, 6% Other race). Mean age was 55.7±8.9 years, 70% were male, and mean graft vintage was 5.4±4.7 years. Black race was independently associated with lower hazard of receiving statin for secondary CVD prevention compared with White race (aHR=0.77, 95% CI: 0.60-0.97). There was no significant difference in aspirin use by Black race compared with White race (aHR=0.86, 95% CI: 0.67-1.09).

Conclusions: Findings from a large multicenter trial showed that Black race was associated with lower hazard of receiving statins for secondary CVD prevention. Underutilization of statins represents a potential target to improve CVD preventive care in Black kidney transplant recipients.

PO2494

Patient Barriers to Kidney Transplantation on the Mexican American Border

Armando T. Cardenas, Julio P. Zavala Georffino, Grace Mcnutt. *University of the Incarnate Word, San Antonio, TX*.

Background: Hispanics are the largest minority group in the United states and are more likely to develop end-stage renal disease (ESRD) compared with non-Hispanic whites. However, Hispanics with ESRD are less likely to receive a deceased donor kidney transplant. We reviewed data from clinics on the Mexican American border to evaluate barriers to transplantation.

Methods: We gathered data from three dialysis clinics in Laredo, Texas, a city on the Mexican American border. It has a population of approximately 250,000 inhabitants of which 95.6% are Hispanic. The number of patients that were waitlisted or scheduled for living donor transplantation was evaluated. We also determined the number of patients that were referred but not listed and those that were not referred at all and investigated reasons for non-referral.

Results: A total of 285 patients were included in the analysis. 52 patients (18.2%) were waitlisted or scheduled for living donor transplantation. An additional 91 patients (31.9%) were referred but not yet waitlisted nor scheduled for living donor transplantation. A total of 140 (49.1%) were not referred. Of those not referred, the most common reasons included: advanced age (25%), weight (4.2%), malignancy (2.85%), cardiovascular (4.2%), peripheral vascular disease (3.57%), functional status (5.71%), noncompliance (5.71%), transportation (10.71%), and immigration status (7.14%).

Conclusions: Nearly half of ESRD patients were not referred for transplant evaluation and less than half of those referred were waitlisted or scheduled for living donor transplantation. This is lower than previous studies showing a greater percentage of referred patients as waitlisted (up to 66% in some studies). Major barriers to referral included age, immigration status, and transportation limitations. The latter two barriers are likely more of a factor in a Mexican American border town than in other areas of the United States. Identifying these barriers highlight areas for improvement in access to renal transplantation for Hispanics.

PO2495

The Strength of Weak Ties and Living Donor Offers: A Multi-Site Social Network Analysis of Hemodialysis Patients

Avrum Gillespie,[1] Jonathan Daw,[2] Riley Brown,[1] Jamie Cappiello,[1] Edward L. Fink,[1] Heather M. Gardiner,[1] Crystal A. Gadegbeku,[1] Peter P. Reese,[3] Zoran Obradovic.[1] *[1]Temple University, Philadelphia, PA; [2]Pennsylvania State University, University Park, PA; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Increasing the rate of living donor kidney transplantation is crucial. Little is known about hemodialysis patients' social networks and the members who offer to donate yet are never evaluated.

Methods: We administered a REDCap social network survey in an urban (Philadelphia) and suburban (North Brunswick) hemodialysis clinic. We asked participants to identify their social network members, who offered to donate, whose offers were accepted, and who got tested. We analyzed the associations between living donor offers and the size and strength of the connections in the networks. Strongly connected members are those connected to greater than 2/3 of the other network members.

Results: A total of 105 patients participated. Their mean age was 60 +/- 13 years. Half (54%) identified as male and 75% identified as black. Half were on the waiting list or undergoing testing (56%). The mean size of the networks was 5 members (SD2, range 1-10). Half (53%) of the participants received a living donor offer; 27% recieved one offer and 26% had 2 or more offers. Those with larger networks received more donation offers ($r = 0.39$; $p < 0.01$). Of the total 527 network members identified, 113 offered to donate, 43 of these offers were accepted with 12 being evaluated for donation. Most (83%) network members were strongly interconnected within the participants network, however, a greater of proportion of weakly interconnected network members offered a kidney donation compared to strongly connected members (31% v. 19%, $p = 0.02$). Participants accepted a greater proportion of offers from weakly connected members than strongly connected members (56% vs 33%, $p = 0.03$). Although a greater proportion of strongly connected members were evaluated compared to weaker connected members this was not significantly different (36% v. 17%, $p = 0.16$).

Conclusions: Weakly connected social network members tend to offer to be living kidney donors and a greater percentage of these offers are accepted. Unfortunately, most (89%) social network members who offer to donate never make it to the transplant center. Future interventions should focus on patients accepting living donor offers as well as identify methods to increase testing of interested donors especially those weakly connected in the network.

PO2496

Association of SNAP Benefit Use by Inner-City Kidney Transplant Recipients with Poorer Graft Function, Lower Fruit and Vegetable Intake, and Increased Psychosocial Stress

Elizabeth G. Kasparov, Kingsley Cruickshank, Ahmad Saleh, Soyeon Pak, Mariana Markell. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: Longterm kidney graft survival may be affected by factors other than biologic, including social determinants of health such as food scarcity and psychosocial stress.

Methods: A face-to-face survey was conducted in a random convenience sample of 31 pts in transplant clinic. The Stress and Social Support survey and the Perceived Stress Scale were used. Dietary intake was assessed using 24-hr recall and analyzed with ASA-24 software. All comparisons are by Chi square or t-test.

Results: There were 11 women(36%), 20 men(65%), 22 Black(71%). Mean age was 55.2±1.9 yrs, time since transplant 63.9±14.1 mos. 24 (77%) reported income <$40K, with 12 (39%)<$20K.12 (39%) recieved SNAP benefits (SNAP+). Income or employment rate did not differ for SNAP+ vs SNAP-. SNAP+ had significantly worse kidney function(creatinine 2.17±0.24 vs 1.44±0.11 mg/dl,p=0.014) and eGFR(37.9±3.8 vs 53.7±2.5 ml/min,p=0.003), but did not differ for time since transplant, gender, race, BP, BMI, tacrolimus level or age. SNAP+ also were more likely to disagree with the statement "I feel I am in control of my health and it doesn't control me" (33% vs 0%, p=0.017), to report never or almost never feeling confident about handling personal problems(50% vs 16%, p=0.018), and to be unable to control irritations in their lives(67% vs 16%,p=0.043,p=0.043). No difference in caloric or macronutrient intake existed, but SNAP+ ate less fiber(11.1±1.3 vs 16.7±1.8 gm,p=0.023)and fewer servings of fruits/vegetables(1.5±0.28 vs 3.75±0.85, p=0.021). When asked about missed medication they did not report more missed doses.

Conclusions: In our patient population: 1. Pts receiving SNAP had worse kidney function than those who did not despite similar time since transplant, tacrolimus level, income, and employment status. 2. They ate less fiber and fewer servings of fruits/vegetables despite similar caloric intake, which should be investigated further as higher intake of fruit/vegetables is associated with delayed progression of kidney disease in non-transplant pts. 4..They also reported feeling less control over their health and less ability to handle daily stress. 4. These finding suggests that special attention should be paid to this population who have issues with social determinants that may affect kidney function.

PO2497

Impact of Ethnicity Matching on Kidney Transplant Outcomes Among African Americans: A Mate Kidney Analysis

Kalathil K. Sureshkumar,[1] Bhavna Chopra,[1] Rita L. McGill.[2] *[1]Allegheny General Hospital, Pittsburgh, PA; [2]University of Chicago, Chicago, IL.*

Background: Transplantation of kidneys from African American (AA) donors is associated with poorer outcomes compared to transplants from white Americans. Unmeasured variables such as APOL1 renal risk variants and sickle cell trait could contribute to the heightened risk. We used a mate kidney model to test the hypothesis that enhanced genetic risks associated with AA donor kidneys could be counterbalanced by favorable immunologic matching when AA donor kidneys are transplanted into AA recipients.

Methods: We identified AA deceased donors in OPTN/UNOS database from 2000 to September 2019 in which both kidneys were transplanted into first-time kidney-only recipients, and both recipients received induction therapy followed by tacrolimus/mycophenolic acid maintenance. Marginal models for hazards of graft failure, death censored graft failure (DCGF) and death were constructed, with adjustments for recipient and transplant variables. Outcomes of AA, Hispanic, and Asian recipients were compared, using white American recipients as reference. Results were compared to a parallel analysis of 41,886 recipients of white American donor kidneys.

Results: Median follow up of the study was 3.3 (IQR 1.1-6.5) years among 8194 paired recipients of AA donor kidneys. Despite donor ethnicity matching, DCGF was higher but mortality lower among AA recipients. Graft failure did not differ. Hispanic and Asian recipients had lower hazards of most unfavorable outcomes (table 1). In the parallel analysis, DCGF was again inferior for AA recipient of white American donor kidney (HR 1.37, 95% CI 1.28-1.47, $p<0.001$).

Conclusions: Our data indicate an increased risk of DCGF in AA recipients of AA donor kidneys, despite the potential benefits of favorable immunologic matching and does not support an ethnicity-matching strategy to improve outcomes and reduce disparities. Our observations suggest that other recipient factors predominantly influence graft outcomes. Improved outcomes in Hispanic and Asian patients merit further study.

Funding: Private Foundation Support

Table 1. Adjusted outcomes for paired recipients of AA donor kidneys with white American recipients as reference

Recipient ethnicity	African American		Hispanic		Asian	
	HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)	P
Graft failure	1.07 (0.97-1.19)	0.2	0.72 (0.61-0.84)	<0.001	0.75 (0.59-0.95)	0.02
Death-censored graft failure	1.31 (1.14-1.50)	<0.001	0.80 (0.65-0.99)	0.04	0.79 (0.57-1.10)	0.2
Death	0.87 (0.77-0.98)	0.02	0.57 (0.47-0.69)	<0.001	0.68 (0.52-0.90)	0.006

Cardio-Metabolic Risk Factors in Kidney Donors at a Third-Level Hospital of Care in Mexico

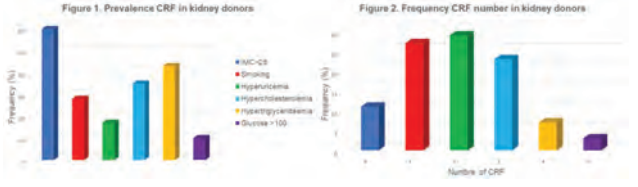
Jesus D. Lima lucero,[1] Ana G. Ortega,[2] Rafael Valdez-Ortiz,[1] L. M. Perez-Navarro,[1] Ernesto C. Lopez.[1,2] *[1]Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; [2]Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.*

Background: Living donor kidney transplantation is the treatment of choice for chronic terminal kidney disease. A high prevalence of cardio-metabolic risk factors (CRFs) in the general population implies challenges when choosing the best candidate for kidney donation. Knowing the frequency of CRFs will allow us to make timely interventions in order to reduce cardiovascular complications after donation.

Methods: Cross-sectional, descriptive study, which included kidney donors who were admitted to the National Medical Center "Dr. Antonio Fraga Mouret" during the period from 2015 to 2019. Descriptive statistics were made, with a 95% IC. CRFs were included; systolic hypertension (SBP) higher than 120mmhg, diastolic hypertension (DBP) higher than 80mmhg, anemia hemoglobin less than 13 g/dl in men and less than 12 g/dl in women; impaired fasting glucose> 110 mg / dl, body mass index (BMI)> 25.

Results: 153 donors were included, 59% were women, 33% were siblings and 31% were the patient's mother; 34% had no social security. The mean age was 42.7 ± 10.7 years; the mean BMI 26.3 ± 5.4, with a mean GFR 101.9 ± 13.4 (61.6 -133) ml / min. 28% of donors smoked, 7% had SBP risk and 27% DBP risk, 60% had BMI> 25, 4% had anemia and 13% hypoalbuminemia; 10% with impaired fasting glucose. Figure 1 shows the prevalence of CRF. More than 25% of kidney donors had 2, 3 and 4 CRFs on admission to hospital for donation. 72% presented acute kidney injury (AKI) after surgery, none required renal replacement therapy. The highest AKI frequency was observed in subjects who had from 1 to 3 CRFs with frequencies of 26-34%.

Conclusions: A BMI higher than 25 was the most prevalent CRFs; associated with AKI when more than 1 CRF was observed. Timely detection of CRFs will allow for timely interventions that will reduce post-donation cardiovascular risk and decrease the risk of AKI.



PO2499

The Effect of Anemia Correction with ESA and Cholecalciferol Supplementation on Post-Transplant Malignancy Among Kidney Transplant Recipients: A Prespecified Analysis of a Randomized Clinical Trial

Yoshitsugu Obi,[1,2] Naotsugu Ichimaru,[3,4] Yoshitaka Isaka,[3] Takayuki Hamano.[3,5] The CANDLE-KIT Trial Investigators *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]Obi Clinic, Osaka, Japan; [3]Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan; [4]Ippan Zaidan Hojin Sumitomo Byoin, Osaka, Japan; [5]Nagoya Shiritsu Daigaku Daigakuin Igaku Kenkyuka Igakubu, Nagoya, Japan.*

Background: Kidney transplant recipients (KTRs) are at increased risk of cancer, and post-transplant malignancy (PTM) is among the leading causes of death with functioning allograft. Aggressive anemia correction with ESA slows the rate of decline in kidney allograft function but may increase the incidence of PTM. Vitamin D is proposed to exert pleiotropic effects including anti-cancer properties and may prevent the development of PTM.

Methods: We enrolled 153 KTRs with anemia and >1-year history of transplantation across 23 facilities in Japan and conducted a multicenter, two-by-two factorial, open-label, randomized clinical trial. Patients were randomly assigned to either a high or low hemoglobin (Hb) target (>12.5 vs <10.5 g/dL) and to either cholecalciferol 1000 IU/day or control. PTM was a prespecified secondary outcome.

Results: Patients were 51±12 years-old, among whom 54% were male. The median (IQR) of transplant vintage was 8 (5, 12) years. Their baseline eGFR, Hb, and serum 25(OH)D levels were 30.6±11.0 mL/min per 1.73 m^2, 10.7±1.2 g/dL, and 14.5±5.2 ng/mL, respectively. There was no between-group difference in the prevalence of prior malignancy in either arm. The mean Hb level was 11.4 g/dL and 10.6 g/dL in the high and low Hb target groups, respectively. The mean serum 25(OH)D level exceeded 30 ng/mL in the cholecalciferol group after Month 6 whereas it did not change in the control group throughout the study period. A total of 7 PTMs developed during 2 years of the follow up; 2 lung cancers, 1 breast cancer, 1 gastric cancer, 1 testicular cancer, 1 renal cell carcinoma, and 1 myelodysplastic syndrome. There was no between-group difference in the incidence of PTM in the hemoglobin target arm (i.e., n=3 [4.1%] vs. 4 [5.1%] in the high vs. low Hb target group, respectively; *P*=0.77). In the cholecalciferol arm, all 7 PTMs developed in the control group while none was observed in the cholecalciferol group (i.e., 9.1% vs. 0%, respectively; *P*=0.007).

Conclusions: The incidence of PTM was not increased by aggressive anemia correction with ESA and was reduced by cholecalciferol supplementation among KTRs. Large clinical trials with a long-follow up period are needed to validate these findings. Registered at ClinicalTrials.gov (NCT01817699).

PO2500

Association Between Elevated Ferritin and Graft Survival During the First Year After Kidney Transplant

Benaya Rozen-zvi,[1,2] Amir Schechter,[1,2] Ruth Rahamimov,[1,2] Anat Gafter-Gvili.[1,2] *[1]Rabin Medical Center, Petah Tikva, Israel; [2]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.*

Background: Both iron deficiency and iron overload are associated with adverse outcomes in patients with end stage kidney disease on chronic hemodialysis. In contrast, the effect of iron metabolism markers post kidney transplantation have not been thouroughly evaluated. In this study we aimed to evaluate the association between serum ferritin and transferrin saturation during the first year post transplantation on patients and graft survival.

Methods: Retrospective cohort study, using the Rabin Medical Center (RMC) kidney transplant registry. We included adults (>18 years) patients transplanted between 1/1/2006 and 31/12/2017 that had at least one available iron, transferrin and ferritin value during the first year post transplantation. Serum ferritin and transferrin saturation were log transformed and serum ferritin was also analyzed as a dichotomous variable with 500 ng/ml as a cutoff value. Primary outcome was the composite of graft and patients' survival. Secondary outcomes included death censored graft loss. Univariate and multivariate Cox models were used for the primary composite outcome of patients' and graft survival.

Results: Seven hundred and twenty-six patients were included in the study, of whom 219 (30.2%) had serum ferritin above 500 mg/dl. Patients with high serum ferritin were older with more diabetes mellitus (DM) and heart disease and tended to have deceased donor transplantation and delayed graft function. By univariate Cox analysis, ferritin level above 500 ng/ml was associated with increased risk of death and graft loss (Hazard Ratio (HR) 2.38, 95% Confidence Interval (CI) 1,69-3.35, p<0.001). By extensive multivariate model ferritin was still highly associated with increased rate of graft loss (HR 1.87, 95% CI 1,29-2.72, p=0.001). High ferritin was also associated with increased risk of the secondary outcome of death censored graft loss (HR 2.09, 95% CI 1,26-3.48, p=0.005). The results were similar when ferritin was evaluated as continuous variable. In contrast, transferrin saturation was not associated with overall and death censored graft survival.

Conclusions: High ferritin during the first year post transplantation was associated with reduced graft survival. Further research is needed to evaluate whether this association is due to inflammation, iron overload or combination of the two.

PO2501

Iron Deficiency in Kidney Transplant Recipients: Impact on Cognitive Functioning

Joanna Sophia J. Vinke,[1] Aaltje L. Ziengs,[2] Lisanne van Sonderen,[2] Antonio W. Gomes Neto,[2] Anne Buunk,[2] Stefan P. Berger,[1] Stephan J. Bakker,[1] Michele F. Eisenga,[1] Martin H. De Borst.[1] *[1]University Medical Center Groningen, Department of Nephrology, Groningen, Netherlands; [2]University Medical Center Groningen, Department of Neuropsychology, Groningen, Netherlands.*

Background: Cognitive function impairment is common in kidney transplant recipients (KTRs). Brain functioning requires energy, for which iron is essential at the level of oxygen delivery and mitochondrial function. Iron deficiency (ID) has been linked to compromised cognitive functioning in premenopausal women. We aimed to investigate whether ID could be a potentially modifiable risk factor for cognitive function impairment in KTRs.

Methods: In a prospective study among KTRs participating in the TransplantLines Biobank and Cohort study, we analyzed KTRs >1 yr post-transplant with data on iron status. All participants underwent neurocognitive testing to measure memory (Digit Span Forward, Immediate and Delayed Recall of the 15 Word Test), attention and mental speed (Symbol Digit Modalities Test, Trail Making Test-A) and executive functioning (Trail Making Test-B, Digit Span Backward). ID was defined as ferritin <100 µg/mL or 100-299 µg/mL with transferrin saturation (TSAT) ≤20%. We used multivariable linear regression analyses to assess associations between ID and neurocognitive outcomes. Analyses were adjusted for hemoglobin, CRP, age, sex, eGFR, BMI, smoking, alcohol intake, time since transplantation, dialysis duration, donor type, educational level and immunosuppressives.

Results: We included 398 KTRs (age 56±14 yrs, 62% male, eGFR 52±14 mL/min/1.73 m^2). ID was present in 289 KTRs (73%). Associations of plasma ferritin, TSAT and ID with neurocognitive scores are presented in the table.

Conclusions: ID, low ferritin and low TSAT are consistently associated with poor performance on neurocognitive tasks measuring verbal memory, executive functioning,

mental speed and attention in KTRs, independent of hemoglobin and other potential confounders. Future studies should address whether ID correction restores cognitive function.

PO2502

Anemia and Decreased Muscle Mass and Muscle Strength in Kidney Transplant Recipients

Joanna Sophia J. Vinke,[1] Hanneke J. Wouters,[2] Adrian Post,[1] Suzanne P. Stam,[1] Rianne M. Douwes,[1] Antonio W. Gomes Neto,[1] Stefan P. Berger,[1] Stephan J. Bakker,[1] Martin H. De Borst,[1] Michele F. Eisenga.[1] *[1]University Medical Center Groningen, Department of Nephrology, Groningen, Netherlands; [2]University Medical Center Groningen, Department of Hematology, Groningen, Netherlands.*

Background: Anemia is highly prevalent in kidney transplant recipients (KTRs). It is known that anemia impairs quality of life, especially physical functioning. Although surmised, data about the latter in KTRs specifically are scarce. Hence, we aimed to investigate the association between anemia and muscle mass and muscle strength in KTRs.

Methods: In a prospective study among KTRs participating in the TransplantLines Biobank and Cohort study, we used KTRs >1 yr post-transplant with data on hemoglobin (Hb) levels and muscle mass. Muscle mass was assessed in two ways: by using 24-hour urinary creatinine excretion and with bioelectrical impedance analysis (BIA). Muscle strength was determined by means of hand grip strength using a dynamometer. The mean overall hand grip strength was calculated out of three attempts of both hands with 30 seconds recovery time in between. Anemia was defined as Hb <12 g/dL for women and <13 g/dL for men, according to WHO definitions. We used multivariable linear regression analyses to assess associations between anemia and muscle mass and strength.

Results: We included 824 KTRs (age 56±13 years, 60% males, eGFR 52±18 mL/min/1.73 m^2, serum Hb 13.5±1.8 g/dL). Anemia was present in 30% of KTRs. Hb levels were associated with creatinine excretion, independent of age, sex, eGFR, BMI, hs-CRP, smoking status, alcohol use and the use of RAAS-inhibitors, statins, calcineurin inhibitors, proliferation inhibitors or prednisolone (st.β=0.14, *P*=0.001). Similarly, the presence of anemia was independently associated with a lower creatinine excretion (st. β=-0.09, *P*=0.021). Hb levels (st.β=0.20, *P*<0.001) were also independently associated with muscle mass, estimated using BIA resistance measurements. In line with muscle mass parameters, Hb (st.β=0.18, *P*<0.001) and anemia (st.β=-0.11, *P*=0.005) were associated with handgrip strength independent of potential confounders as well.

Conclusions: Low hemoglobin levels and anemia are both strongly associated with lower muscle mass and muscle strength in KTRs, likely impairing physical functioning. Future research is needed to address whether correction of anemia improves physical performance in KTRs.

PO2503

Sevelamer-Associated Gastrointestinal Complications in Kidney Transplant Recipients

Mohammad Ahraz Hussain, Stanley Kwong, Julie M. Yabu, Erik L. Lum, Elizabeth A. Kendrick. *University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Introduction: Sevelamer (SV) is a resin based oral phosphate binder used commonly in chronic kidney disease (CKD) patients. Clinical trials performed for approval for clinical use showed mild to moderate gastrointestinal (GI) intolerance in a minority of patients. In general clinical use of SV in CKD patients, there have been case reports of more serious GI problems than were reported in original trials, including GI bleeding and colonic complications including colitis and perforation. The majority of patients receiving kidney transplants have required long term oral phosphate binders at the time they are transplanted, often using SV. Delayed graft function (DGF) early post transplant may require ongoing use of oral phosphate binders to control hyperphosphatemia

Case Description: We report 3 cases of significant GI morbidity in association with SV occurring in transplant recipients within the first 2 weeks after kidney transplantation. In one patient, the post transplant course was complicated by sepsis due to perforated colonic diverticulum in the context of preexisting diverticular disease; surgical specimen showed SV crystals associated within the area of bowel perforation. Two patients had severe upper GI symptoms and abnormal findings on upper endoscopy, including severe esophagitis and esophageal ulceration. SV crystals were found in the biopsies of abnormal areas. Two patients had long-term use of SV prior to transplantation, whereas one patient was treated with SV for a short time only after transplantation. All had required more than one phosphate binder for long-term control of hyperphosphatemia; two required cinacalcet for management of secondary hyperparathyroidism.

Discussion: SV use may have more serious GI adverse effects in CKD patients than noted in the original clinical trials. Preexisting GI disease and/or abnormalities may increase the risk of adverse GI effects related to SV. Recent use of SV prior to kidney transplantation or use of SV for control of hyperphosphatemia in the context of DGF can be associated with GI morbidity in the early post transplant setting. Need for higher doses of phosphate binders and severity of hyperparathyroidism may be contributing factors to this risk.

PO2504

C-Terminal and Intact FGF-23 in Kidney Transplant Recipients and Their Associations with Kidney Transplant Loss and Mortality

Chang Chu,[1] Shufei Zeng,[1] Yingquan Xiong,[3] Ahmed A. Hasan,[3] Bernhard K. Krämer,[2] Berthold Hocher.[2] *[1]Charité - Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany; [2]Fifth Department of Medicine (Nephrology/ Endocrinology/ Rheumatology), University Medical Centre Mannheim, University of Heidelberg, Germany, Mannheim, Germany; [3]Institute of Nutritional Science, University of Potsdam, Potsdam, Germany.*

Background: Increased fibroblast growth factor 23 (FGF23) is a risk factor for mortality, cardiovascular disease, and progression of chronic kidney disease. Limited data exist comparing the association of either c-terminal FGF23 (cFGF23) or intact FGF23 (iFGF23) in kidney transplant at recipients (KTPs) with graft loss and all-cause mortality.

Methods: We conducted a prospective observational cohort study in 562 stable kidney transplant recipients. Patients were followed for graft loss and all-cause mortality for a follow-up of 48 months.

Results: During a median follow-up of 48 months, 94 patients had adverse outcome (graft loss or died). Both cFGF23 and iFGF23 concentrations were significantly higher in patients who had adverse outcome than those without adverse outcome (24.59 [11.43-87.82] versus 10.67 [5.99-22.73] pg/ml; p<0.0001 and 45.24 [18.63-159.0] versus 29.04 [15.23-60.65] pg/ml; p=0.002 for cFGF23 and iFGF23, respectively). cFGF23 and iFGF23 measurements correlated well (rho=0.54, p <0.0001). ROC analysis of cFGF23 and iFGF23 yielded AUC of 0.69 (p <0.0001) and 0.61 (p =0.002) for prediction of the composite endpoint, respectively. Cox regression analyses adjusted for confounding factors, showed that cFGF23 (HR for one unit increase of log transformed cFGF23: 1.35; 95% CI, 1.03-1.77; p=0.028) but not iFGF23 (HR for one unit increase of log transformed iFGF23: 1.03; 95% CI, 0.81-1.31; p=0.827) was associated with the composite endpoint (Figure 1).

Conclusions: Elevated cFGF23 levels at baseline are independently associated with an increased risk all-cause mortality or graft loss. iFGF23 measurements were not independently associated with the study endpoint. The cFGF23 ELISA might detect bioactive FGF23 fragments that are not detected by the iFGF23 ELISA.

Variable	Composite outcome	
	HR (95% CI)	P
Log cFGF23		
Univariate analysis	1.46 (1.31-1.63)	<0.001
Model 1	1.23 (1.07-1.42)	0.005
Model 2	1.28 (1.09-1.50)	0.003
Model 3	1.35 (1.03-1.77)	0.028
Log iFGF23		
Univariate analysis	1.28 (1.14-1.44)	<0.001
Model 1	1.05 (0.92-1.21)	0.473
Model 2	1.06 (0.92-1.23)	0.417
Model 3	1.03 (0.81-1.31)	0.827

Figure 1. Multivariable-adjusted Cox regression analyses of composite endpoint graft loss or all-cause mortality. Model 1 adjusted for eGFR; Model 2 adjusted for eGFR, gender, age; Model 3 adjusted for eGFR, gender, age, time post-transplantation, hemoglobin, albumin, donor's age, cold ischemia time, log serum calcium, log serum phosphorus, log parathyroid hormone, urinary protein excretion.

The Time Is Now: Reducing Waiting Times in Minority Populations

Lumen A. Mendez Castaner, Meghan Muldoon, Luke Preczewski, Amy L. Harshman, Giselle Guerra. *Miami Transplant Institute, Miami, FL.*

Background: A significant limiting factor to transplantation resides on waiting time based on blood type. Historically candidates in blood groups B and O experience higher waiting times for kidney transplantation. Our center has worked to increase the rate of acceptance in kidneys that would have previously been discarded to try to maximize the donor pool for these blood groups.

Methods: We retrospectively analyzed 1287 consecutive deceased donor kidney transplants from 2015 to 2019. This cohort was chosen to ensure baseline was after allocation system changes, so the change is a result of change in practice at our center. Average waiting time to transplantation and renal transplantation rates were analyzed based on ABO stratification as well as ethnicity to compare longitudinal disparities.

Results: We observed a decrease in waiting time across all blood types (Figure 1) over the 5 year period of this study. There was a substantial benefit in blood type B recipients with a 6.4 year decrease in average waiting time from 2015 to 2019. Waiting time in

blood type O recipients decreased by 3.4 years from 2015-2019 (Figure 1). We observed a decrease in disparity between African Americans and Hispanics versus Caucasians, with average waiting times decreasing from 2.5 years to 1.2 years and 1.6 years to 0.5 years, respectively. There were no type B recipients who received A2 donors in this cohort.

Conclusions: Waiting time at our center decreased significantly across all blood types with a disproportional benefit in blood group B recipients despite not utilizing the benefit of A2 donors transplanted into B. Thus, this reflects our increase in volumes by utilizing extended criteria donors such as acute kidney injury and high kidney profile index donors (KDPI). These efforts have reduced the disparities in waiting time particularly in African-American and Hispanic populations.

Ethnic Disparities in Hospitalization After Deceased Donor Kidney Transplantation

Shahidul Islam,[1,2] Sumit Mohan,[3,4] William M. Brown,[8] Stephen O. Pastan,[5] Ajay K. Israni,[6,7] Robert S. Gaston,[9] Alejandra Mena- Gutierrez,[8] Amber M. Reeves-Daniel,[8] Bruce A. Julian,[9] Barry I. Freedman,[8] Jasmin Divers.[1,2] *[1]Division of Health Services Research, Department of Foundations of Medicine, NYU Long Island School of Medicine, Mineola, NY; [2]Winthrop Research Institute, NYU Long Island School of Medicine, Mineola, NY; [3]Division of Nephrology, Department of Medicine, Columbia University College of Physicians & Surgeons, New York, NY; [4]Department of Epidemiology, Mailman School of Public Health, Columbia University, New York, NY; [5]Renal Division, Department of Medicine, Emory University School of Medicine, Atlanta, GA; [6]Division of Nephrology, Department of Medicine, Hennepin County Medical Center, University of Minnesota, Minneapolis, MN; [7]Minneapolis Medical Research Foundation, Minneapolis, MN; [8]Department of Internal Medicine, Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [9]Division of Nephrology, Department of Medicine, University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

Background: African American (AA) recipients of deceased-donor (DD) kidney transplants have shorter allograft survival than recipients of other racial/ethnic groups. However, it remains unclear whether similar patterns are observed for healthcare utilization. Hospitalization rates (HR) for recipients of kidneys from 2,639 AA and 12,043 European American (EA) DDs who had one kidney transplanted into an AA and one into an EA recipient were analyzed. Four donor/recipient pairs (DRP) were studied: AA/AA, AA/EA, EA/AA and EA/EA using data from the Scientific Registry of Transplant Recipients for transplantations performed between January 1, 2001 and June 30, 2016.

Methods: All reported hospitalizations for the duration of the kidney allograft were counted. Negative binomial models were fitted to compare post-transplant HRs with adjustment for transplant era (2001-2005, 2005-2010 and post 2010), the kidney donor risk index (KDRI), estimated post-transplant survival (EPTS), donor- and recipient age and sex, recipient insurance, prior employment status, delayed graft function (DGF) and cold ischemia time.

Results: HRs were higher among recipients of kidneys from AA DDs 419.0 (390.4, 449.7) for AA/AA and 412.7 (379.8, 448.5) for AA/EA, compared to 362.8 (350.1, 375.9) for EA/AA and 331.9 (319.9, 344.3) per 1000 person-years for EA/EA DRPs. The adjusted HR was 67.9% (56.7%, 79.9%) higher for transplantations performed after 2005, compared to those performed during 2001-2005. HRs were also higher for recipients with Medicaid insurance 62.0% (16.4%, 125.5%), or DGF 25.9% (18.7%, 33.5%), but lower for employed recipients, -18.9% (-23.5%, -14.0%). These rates increased by 40.6% (28.4%, 53.8%) for a unit increase in the EPTS and by 24.6% (10.9%, 39.9%) for a unit increase in KDRI. Higher rates were observed among recipients of AA DD kidneys, independently of recipient race/ethnicity 19.2% (11.2%, 27.9%).

Conclusions: HRs among the DRPs have increased over time with higher rates among recipients of AA DD kidneys. Additional donor-level factors may contribute to the hospitalization rate after DD kidney transplantation.

A Randomized Trial of Vitamin D Supplementation on Skeletal Muscle in Patients Early Post Kidney Transplantation

Makoto Tsujita,[1] Yoshitsugu Obi,[2] Takayuki Hamano.[3] *[1]Masuko Kinen Byoin, Nagoya, Japan; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]Nagoya Shiritsu Daigaku Daigakuin Igaku Kenkyuka Igakubu, Nagoya, Japan.*

Background: Developing strategies for managing skeletal muscle weakness and loss in kidney transplant recipients (KTRs) is an important clinical challenge. Little is known about the effect of native vitamin D (VitD) supplementation on skeletal muscle in KTRs.

Methods: We conducted a 11-month, double-blind, randomized, controlled trial to assess the efficacy of VitD for improving skeletal muscle weakness and loss in KTRs receiving kidney transplantation within one month. Eligible patients were randomly assigned to a Vitamin D (cholecalciferol, 4000 IU / day) group or a placebo group in a 1:1 ratio. A prespecified secondary endpoints in this study included a percent (%) change in handgrip strength (HGS), and leg strength (LS) for skeletal muscle strength, and skeletal muscle index (SMI) for skeletal muscle mass.

Results: A total of 193 KTRs were randomized, but 6 KTRs were lost before taking the medication. We analyzed 92 KTRs in Vitamin D group and 95 in Placebo group. Dropouts during this study were 3 KTRs in Vitamin D group and 2 in Placebo group. In Vitamin D group, at baseline the mean age was 52.3 ± 12.5 years old and the number of males was 28 (30.4%), and in Placebo group, 51.7 ± 11.4 years old and 30 (31.5%), respectively. The mean changes in serum 25 hydroxyvitamin D levels from baseline to the end of this study were 11.2 ± 4.1 to 39.8 ± 13.0 ng/mL in Vitamin D group ($p < 0.001$)and 11.2 ± 4.1 to 14.5 ± 5.0 ng/mL in Placebo group ($p < 0.001$). In this study, there were no difference in % changes in HGS, LS, or SMI between those groups, respectively.

Conclusions: VitD supplementation alone appears not to be effective in improving skeletal muscle weakness and loss among KTRs early post-transplantation. Larger-scale trials are warranted to confirm these findings.

PO2508

Effects of Arteriovenous Fistulas on Outcomes of Kidney Transplant Recipients

Yasar Caliskan,[1] Ahmet B. Dirim,[2] Safak Mirioglu,[2] Ozgur A. Oto,[2] Halil Yazici,[2] Erol Demir,[2] Seda Safak,[2] Nurana Guller,[2] Mehmet S. Sever,[2] Krista L. Lentine.[1] *[1]Saint Louis University, Saint Louis, MO; [2]Istanbul School of Medicine, Istanbul, Turkey.*

Background: Arteriovenous fistulas (AVFs) may exacerbate cardiovascular events (CVE) after kidney transplantation (KTx). We aimed to investigate the long-term effects of AVFs on KTx outcomes.

Methods: Prevalent 168 recipients were categorized at median 2yr. after KTx: recipients with functioning AVF (fAVF) (n=73), recipients with non-functioning AVF (nfAVF) (n=62) and recipients without AVFs (noAVF) (n=33) on pre-KTx peritoneal dialysis or underwent preemptive KTx. Baseline characteristics, echo findings and endothelial function were compared. During a median 11yr. follow-up after enrollment, CVE were defined as acute coronary syndromes or cerebrovascular accidents; additional outcomes included eGFRs at baseline and end of follow up, graft failure and death.

Results: Demographic, clinical, laboratory and echo characteristics and endothelial function at enrollment were not significantly different across all groups (Table 1). During follow up, CVE occurred in 9 (12.3%), 5 (8%), and 4 (12.1%) patients in fAVF, nfAVF and noAVF groups, respectively (p=0.70). Groups were comparable regarding graft and patient survival rates (p=0.13 and p=0.87, respectively). During follow-up, functioning AVFs thrombosed in 5 (7%) and were surgically closed in 20 (27%) patients in fAVF group. CVE rate was similar in patients with thrombosed (20%), closed (5%) and still functioning (15%) AVFs (p=0.47). Patient and graft survival rates were significantly lower in recipients with still functioning fAVFs (77% and 73%, respectively) compared to fAVF patients with thrombosed (100% and 100%, respectively) and closed (100% and 95%, respectively) AVFs (p=0.05 and 0.03, respectively).

Conclusions: Long-term CVE rate is similar in KTx recipients with and without patent AVFs. In a subgroup of KTx recipients with functioning AVFs, closure and thrombosis of AVFs may be associated with higher rates of patient and graft survival.

Table 1. Baseline demographic, clinical, laboratory and echocardiographic features of the study patients at enrollment

	fAVF (n=73)	nfAVF (n=62)	noAVF (n=33)	P value

Recurrent Cardiovascular Events After Kidney Transplant Are Associated with Increased Risk for Graft Failure and Mortality

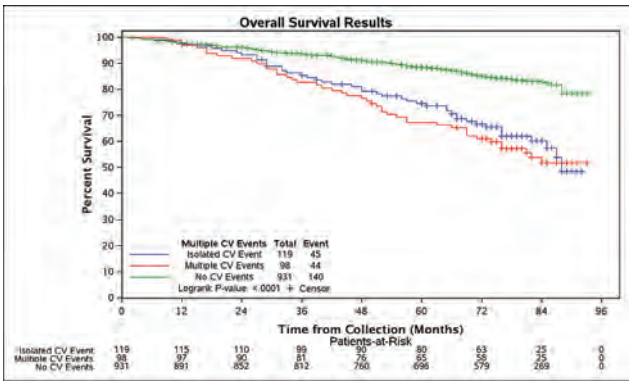
Leyton Galapia,[1] John C. Lieske,[2] Nan Zhang,[1] Richard J. Butterfield,[1] Mira T. Keddis.[1] *[1]Mayo Clinic, Scottsdale, AZ; [2]Mayo Clinic, Rochester, MN.*

Background: Cardiovascular (CV) disease is prevalent after kidney transplant (KTx). The objective of this study was to describe patients with recurrent CV events in association with allograft function and mortality.

Methods: 1148 consecutive adults that received a KTx between 2011-2013 at a single center were evaluated. CV events were defined as: cardiac: myocardial infarction, heart failure, cardiac arrest requiring resuscitation, and vascular, any stroke, or peripheral vascular disease requiring intervention. Recurrent events were defined as more than one event (either cardiac or vascular).

Results: Mean age was 56.0years (SD14.2), 500(44%) were female, 403(35%) had diabetes, 1083(94%) had hypertension, 127(11%) had prior history of CV events, 602(53%) required dialysis, and 867(76%) received living donor KTx. After a median follow-up of 74 months there were 229(20%) deaths and 217(19%) CV events, of which 92(42%) were cardiac, 86(40%) were vascular, 39(18%) had both. 119 patients had an isolated CV event and 98 had recurrent CV events (median 3 (range 2,4)). Multivariate analysis revealed the following independent significant predictors of CV events: older age, prior history of CV event, diabetes, hypoalbuminemia and measured GFR. Compared to recipients with no CV events and those with an isolated event, recipients with recurrent CV events had increased: mortality (15% vs 38% vs 45%,p<0.0001) and graft failure (14% vs 26% vs 40%,p<0.0001). Hazard ratio for mortality associated with isolated CV events was 2.66 (1.90-3.73) compared to a HR 3.06 (2.18-4.29) for recurrent CV events, p<0.0001.[Figure 1]. Predictors of multiple CV events included measured GFR and increased c-reactive protein; on multivariate analysis only measured GFR was predictive.

Conclusions: Prevalence of recurrent CV events after KTx was 8.5%. Patients with recurrent CV events are at increased risk for mortality and graft failure. Decreased graft function was the primary predictor of recurrent CV events.



PO2510

Mitral Regurgitation and Aortic Stenosis After Kidney Transplantation

Yousuf Kyeso, Hashim Abbas, Daniel C. Brennan, Sami Alasfar. *Johns Hopkins Hospital, Baltimore, MD.*

Background: Valvular heart disease (VHD) is highly prevalent in patients with end stage kidney disease and has been associated with poor outcomes. The 5-year mortality rate among patients with at least mild aortic stenosis (AS) or mitral regurgitation (MR) is more than 50% greater than in persons without kidney disease (Samad et al, JAHA 2017). Current knowledge of VHD in patients after kidney transplantation (KT) is scarce.

Methods: This is an ongoing single center retrospective study. In our center, all KT recipients have echocardiograms within one year prior to KT. We included KT recipients at our institution between Jan 2016 and Dec 2016 who had underlying MR and/or AS of any severity. Participants had to have an echocardiogram (Echo) around one year post KT. Our primary objective was to compare the severity of MR and AS at one year post KT to the baseline severity. The secondary objective was to describe changes in left ventricle hypertrophy (LVH).

Results: Two hundred subjects were initially screened. The number of patients who met our inclusion criteria was 22 (Table 1). Mild MR was present in 10 recipients pre KT. MR improved in 4, remained stable in 4, and worsened in 2 out of these 10 recipients at one year post KT. Moderate MR was present in 7 recipients pre KT and all 7 had improvement in severity of MR at one year post KT. Two and three recipients had mild AS and moderate AS respectively pre KT and all of them were observed to have worsening of aortic valve area (AVA) at one year post KT (mean AVA 1.96 versus 1.15 cm2, p 0.07). Nine out of the total 22 recipients included had mild LVH pre KT and all the 9 continued to have mild LVH post KT.

Conclusions: Our study showed that most KT recipients with pre-existing MR had improvement in the severity of MR at one year post KT. However, recipients with AS prior to KT were observed to have worsening in severity of AS at one year post KT. Larger studies are needed to confirm these findings and identify factors that influence progression.

Table 1. Clinical Characteristics

Mean age (yr)	(64)

A Retrospective Analysis of Post-Transplant Erythrocytosis: The Experience of a Tertiary Kidney Transplant Unit

Stuart R. Deoraj, Sophie Ganjavian, Elham Asgari. *Guy's and Saint Thomas' Hospitals NHS Trust, Guy's and Saint Thomas' NHS Foundation Trust, London, United Kingdom.*

Background: Post-transplant erythrocytosis (PTE) defined as persistently raised haemoglobin and haematocrit levels for over 6 months following kidney transplantation reportedly occurs in up to 20% of transplants and can influence physical and mental wellbeing. Reported complications include stroke, hypertension, NODAT and chronic fatigue. Our aim was to investigate the prevalence and potential risk factors of PTE in patients transplanted in our unit between 2013 and 2018.

Methods: We conducted a retrospective study of patients receiving a Kidney or Kidney-pancreas Transplant between 2013 and 2018 and followed up in our local clinic. We collected information on donor and recipient demographics, original kidney

disease, transplant type, CMV transmission, HLA mismatch and Immune-suppression. Independent t-tests were used to analyse age, haemoglobin, haematocrit and ischaemic time. Odds ratios were used for ethnicity, transplant type, index disease and pre-transplant mode of renal replacement therapy (RRT).

Results: Of 568 transplant patients, 46(8%) fulfilled the criteria for PTE given sustained haematocrit >0.5 with a haemoglobin of approximately 161g/L (std. 9.9). We found the risk of PTE was significantly higher in men compared to women (OR 5.375 CI 2.24-12.9 p<0.05) and in DCD SPK transplants compared to other types (OR 5.57, p<0.05). The average age of donors to patients developing PTE was 6.5 years younger than the non-PTE group, p=0.008. IgA nephropathy appeared to convey a higher risk of developing PTE (OR 2.296 p=0.04), as did pre-transplant haemodialysis (OR 3.48 CI 1.34-9.02 p= 0.01). Recipient age, CMV transmission, HLA mismatch, ischaemic times, immune-suppression and prior transplants did not convey significant risk for PTE. Increased incidence of PTE in SPK transplant patients has been previously described. To the best of our knowledge, this is the first study highlighting a potential relationship between PTE and IgA nephropathy, but should be interpreted with caution as a larger study is needed for confirmation.

Conclusions: Although PTE is relatively common after kidney transplant, an understanding of its pathophysiology, epidemiology and prediction remains poor. Our study demonstrates a statistically significant increased risk of developing PTE among men, persons with IgA nephropathy and DCD SPK recipients, particularly from young donors.

PO2512

Utility of the 6-Minute Walk Test in Coronary Artery Disease Screening Before Kidney Transplant

Xingxing S. Cheng,[1] Daniel J. Watford,[1] Hiroyuki Arashi,[1,2] Jane C. Tan,[1] William F. Fearon.[1] *[1]Stanford University School of Medicine, Stanford, CA; [2]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: Coronary artery disease (CAD) screening is a cornerstone of kidney transplant (KTx) evaluation, but existing approaches result in excess testing and low intervention rate. We hypothesize that aerobic performance, based on a simple office test (the 6-minute walk test, 6MWT), may help risk stratify KTx candidates.

Methods: We performed 6MWT in waitlisted patients who were nearing KTx. Results were used for frailty counselling and not for cardiac evaluation. CAD screening was done according to our center protocol: invasive angiogram for patients with long-standing diabetes mellitus (DM) and non-invasive testing for other patients with risk factors and at the evaluating transplant nephrologist's discretion. We used subdistribution Cox regression and time-dependent receiver operator curve to evaluate time to CAD event (revascularization, myocardial infarction, waitlist removal for CAD, or cardiac death), treating waitlist removal for non-CAD and non-cardiac death as competing events.

Results: Of the 360 patients, 200 and 161 patients had 6MWT results <400 meters and >=400 meters (~4 metabolic equivalents), respectively. Patients with lower 6MWT results were older (59±10 vs 50±12 years) and more likely to be female (54% vs 34%), have DM (61% vs 33%) or known atherosclerotic disease (44% vs 22%), and have had prior cardiac evaluation (72% vs 61%). They were also more likely to exhibit cardiac symptom during 6MWT (36% vs 6%) and more likely to be censored due to waitlist removal for non-CAD reasons (follow-up 391±337 vs 541±277 days). 6MWT was not associated with CAD event (subdistribution hazard ratio 1.00 [0.90-1.10], 1-year area under the curve [AUC] 0.54). 196 patients had invasive (52%) or non-invasive (48%) CAD testing within 6 months of 6MWT: 6MWT did not predict the CAD test result (odds ratio 0.96 [0.81-1.14], AUC 0.54). Of the 94 patients who had concurrent non-invasive CAD testing, the 1-year AUC of 6MWT, symptom (at rest or during 6MWT), AST guidelines, or non-invasive testing for CAD event were 0.64, 0.52, 0.46 and 0.66 respectively.

Conclusions: The 6MWT did not perform better in risk stratification for CAD events compared to a symptom- or risk factor-based approach.

PO2514

Median Waiting Time of Kidney Transplant Candidates with Initial Estimated Post Transplant Survival Score >90% According to Organ Procurement Organization Waiting Time

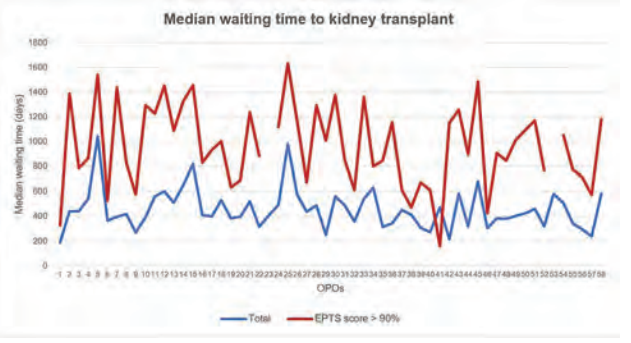
Piyavadee Homkrailas, Erik L. Lum, Nakul N. Datta, Suphamai Bunnapradist. *University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: The kidney allocation system (KAS) and the Estimated Post Transplant Survival (EPTS) score were introduced in the United States in December 2014. The transplant rate among very high EPTS candidates (>90%) may be impacted by lack of KAS priority, geographic factors based on the location of the listed Organ Procurement Organization (OPO), and/or differences in waitlist mortality/delisting. Here we study the impact of new KAS among the candidates with EPTS>90%.

Methods: The Organ Procurement Transplantation Network/United Network for Organ Sharing (OPTN/UNOS) data of newly listed first time transplant candidates from 2015-2018 were included. Individuals listed for multiple organs, at multiple centers, and age < 18 years were excluded. The outcomes included median waiting time to transplant, transplant rate, death rate and delisting rate among candidates with EPTS>90% compared to those with EPTS≤90%. Median waiting time was calculated by Kaplan-Meier model with censoring for still waiting candidates.

Results: A total of 114,870 candidates were included. Candidates with EPTS>90% (9.74%) had a lower rate of overall transplant compared with EPTS≤90% (30.3% vs. 45.9%, p<0.001), higher rate of deceased donor transplant (87.2% vs. 60.9%, p<0.001), lower rate of living donor transplant (12.8% vs. 39.1%, p<0.001), higher death rate (8.8% vs. 5.73%, p<0.001) and higher delisting rate (22.9% vs. 13.3%, p<0.001). Overall median waiting time to transplant was 444 days (range 188-1,042 days among OPOs) compared to 1,025 days (range 160-1,633 days among OPOs) in those with EPTS>90% (p<0.001).

Conclusions: Candidates with EPTS>90% had a longer median waiting time compared to total waitlisted in all but one OPO. Median waiting times were heavily influenced by the lower overall rate of kidney transplantation and living donor transplantation in this group.



PO2515

A Devastating Complication of Encapsulating Peritoneal Sclerosis (EPS) In Two Renal Transplant Recipients

Benjamin Lawson, Zar Chan, Lilly M. Barba. Renal Transplant Program *Los Angeles County Harbor-UCLA Medical Center, Torrance, CA.*

Introduction: EPS is a rare complication of peritoneal dialysis (PD) which carries great morbidity and mortality. The risk of EPS may be higher in PD patients who undergo renal transplantation as compared to PD patients who do not received a transplant. Pre-transplant EPS, progressive peritoneal remodeling, cessation of PD and use of calcineurin inhibitors are potential etiologies. We present two unique cases of post-transplant EPS requiring surgical intervention with devastating outcomes.

Case Description: Case #1 A 47-year-old female with end stage renal disease due to congenital kidney disease on PD for 8 years transitioned to hemodialysis due to peritonitis, underwent a deceased donor kidney transplant (DDRT) presented 4 weeks post operatively with nausea, vomiting, and abdominal pain. Imaging showed dilated loops of small bowel concerning for partial small bowel obstruction treated non-operatively with bowel rest. One month later she presented with similar symptoms and small bowel obstruction. Due to failure to improve, she was taken to surgery and was found to have a frozen abdomen with dense adhesions. Lysis of adhesions was complicated by enterotomies and small bowel resection. Multiple enterocutaneous fistulas prohibited wound closure. She is being evaluated for a small bowel transplant and remains on parenteral nutritional support. Case #2 A 39-year-old African female with history of ESRD secondary to Lupus on PD for 11 years received a DDRT. Eighteen months post-transplant, she presented with nausea, vomiting and abdominal pain. Imaging showed a small bowel obstruction treated non-operatively with bowel rest. Three weeks later she required emergent surgery for an acute abdomen undergoing lysis of adhesions, bowel resection and end ileostomy. She required parental nutrition for five months.

Discussion: We report two cases of EPS after DDRT who required surgical intervention with devastating outcomes. Fluid and nutritional support have complicated management and affected quality of life. Given the multifactorial etiologies and potential devastating outcomes of EPS, the pre-transplant evaluation should include a detailed assessment. Furthermore, long term PD patients and those with a history peritonitis should be monitored closely post-transplant.

PO2516

When a Peritoneal Dialysis Catheter Should Be Removed Post-Kidney Transplantation?

Goni Katz-Greenberg, Anju Yadav, Pooja Singh. *Thomas Jefferson University, Philadelphia, PA.*

Background: Approximately 15% of patients on the kidney transplant (KT) waiting list in the US receive peritoneal dialysis (PD), a growing home dialysis therapy for end stage renal disease (ESRD) patients. European guidelines recommend keeping the peritoneal dialysis catheter (PDC) in-situ during KT, due to the potential risk for delayed graft function (DGF). With this approach, a 10% risk for post-transplant PDC exit-site infections has been reported. In the US guidelines for l PDC removal timing are lacking, and determine by transplant center and operating surgeon's preferences.

Methods: We retrospectively reviewed the electronic medical records of all patients transplanted between 4/2017-7/2019 at our kidney transplant center. We studied basic donor and recipient characteristics, presence of DGF (defined as dialysis in the first week following KT), time interval between KT and PDC removal, and wound related complications.

Results: Of 259 patients received a KT during the study period, 28 were on PD prior to KT. Of those 10patients underwent a living donor transplant, 16had a deceased donor, and 2underwent a simultaneous kidney-pancreas transplant. Sixteen were female, 9were non-Hispanic blacks, and 4were aged >65 years. Three received induction with basiliximab (per center's protocol for recipients aged ≥70 years) and the rest received antithymocyte globulin. PDC was removed at time of KT in 17 patients while in the other 11 recipients PDC was removed 22 days (median) post transplantation. For patients developed DGF, with modality switched to hemodialysis. Three of these had their PDC removed at the time of KT. The 4th patient with DGF who had his PD catheter left in place, received hemodialysis due to hemodynamic instability. Readmission rates (excluding planned hospitalization for PDC removal) and wound infections were similar between Those who had their PDC removed at surgery, and those who did not.

Conclusions: Kidney transplant centers that do not routinely use PD for DGF should remove the PDC at time of kidney transplant to reduce costs and prevent patient and healthcare provider burden of additional surgery. As the prevalence of PD and KT is expected to grow in the near future with the new kidney health initiatives, kidney transplant centers should consider a protocol for optimal care for PDC removal.

PO2517

Could Targeting Dry Weight on Hemodialysis Patients Before Kidney Transplantation Leave Them Too Dry?

Hayam H. Al Dohani,[1,2] Eduard A. Iliescu,[1,2] Frances Macleod,[2] M. Khaled Shamseddin.[1,2] *[1]Queen's University, Kingston, ON, Canada; [2]Kingston Health Sciences Centre, Kingston, ON, Canada.*

Background: Delayed graft function (DGF) after kidney transplantation is associated with inferior kidney and patient outcomes. Studies suggest that avoidance of hypovolemia peri-kidney transplantation is associated with a reduced risk of DGF. Hemodialysis (HD) patients that have HD prior to transplant targeting their usual dry weight may be volume contracted pre-transplant and at increased risk for DGF. By definition the dry weight is the state of near maximal volume contraction for most HD patients. The objective of this study is to examine the proportion of HD patients who have a pre-transplant post-HD weight at or below their usual dry weight.

Methods: This is a retrospective study of sequential kidney transplants in HD patients at our center from Jan 2015 to Dec 2019. The primary outcome was the proportion of patients who had an HD session before transplantation that resulted in a post-HD weight equal to or less than their prevalent set target dry weight. Data was extracted from the electronic medical record and chart review. Recipients on home therapies and pre-emptive transplants were excluded.

Results: Of 68 kidney transplants done in the study period, 40 were in-center HD patients with available HD data. They were mean age 54.8±14.5 years, 12 (30%) female, and majority were Caucasian. Twenty-five (62.5%) patients had a pre-transplant post-HD weight equal to or less than their prevalent set target dry weight (mean - 0.26±0.25 kg). The other 15 (37.5%) patients achieved post-HD weights higher than their usual targets (+0.72±0.41 Kg).

Conclusions: The results of this study suggest that a high proportion of HD patients are at below dry weight after their dialysis and may be hypovolemic before kidney transplantation. This may represent at potentially avoidable increased risk for DGF. Further studies are planned to examine possible associations of achieved post-HD weight prior to transplant with perioperative central venous pressure, IV fluid administration, and graft function. There may be strategies to optimize volume status pre-transplantation to mitigate this risk of DGF including targeting a higher weight on HD or administration of IV fluid to raise weight above the prevalent set target dry weight before transplantation when feasible.

PO2518

Trends in Time to Graft Loss by Dialysis Exposure

Patrick Ahearn, Colin R. Lenihan, John D. Scandling. *Stanford University School of Medicine, Stanford, CA.*

Background: Preemptive transplantation is believed superior to transplantation after dialysis initiation, and transplantation after shorter dialysis exposure is better than with longer exposure. Considering recent registry reports of improved survival on dialysis, we examined temporal trends of graft loss by time on dialysis prior to kidney transplantation.

Methods: Using the US Renal Data System, we identified adults who underwent first kidney transplant between January 1, 1995 and July 31, 2017. We excluded recipients of simultaneous multiorgan transplants. We used an adjusted Cox model to examine the association between dialysis exposure prior to transplantation (categorized as preemptive, <6 months, 6 months-1 year, 1-3 years, 3-5 years, and >5 years) and graft failure within 3 years of transplant. Our model was adjusted for donor and recipient demographic factors, donor type, cause of ESKD, BMI, panel reactive antibodies, diabetes status, and cardiovascular disease status. We organized patients into the following transplant era groupings: 1995-2001, 2002-2006, 2007-2011, and 2012-2017.

Results: A total of 277,158 transplant recipients were studied and 38,364 had graft loss within 3 years. In each era, the hazard ratio for graft loss was lower for preemptive transplant recipients (referent group) compared to all other dialysis exposures except for the group that received less than 6 months of dialysis in the 2012-2017 era (HR 1.06 (95% CI 0.91-1.24)). Those exposed to more than 5 years of dialysis exposure had the highest risk for graft loss within 3 years in all eras, with over 2 times the hazard compared to the referent group in the most recent eras (figure).

Conclusions: Although preemptive transplantation offers the best graft survival across the study period, those transplanted within 6 months of dialysis initiation had similar 3-year graft survival to those transplanted preemptively in the most recent era. The negative association between the longest duration of pre-transplant dialysis and post-transplant survival persists.

PO2519

Does the Timing of Dialysis Initiation Affect Peak Calculated Panel Reactive Antibody in Waitlisted Kidney Transplant Candidates?

Adam Price, Mohamed A. Mohamed Ahmed, Zemin Su, Maria Aurora C. Posadas, Karim M. Soliman, Vinaya Rao, Michael Casey. *Medical University of South Carolina, Charleston, SC.*

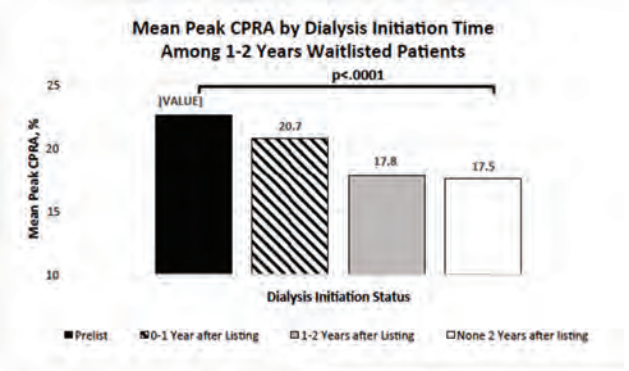
Background: Higher calculated panel reactive antibody (cPRA) restricts access to kidney transplantation, but it's unclear how the timing of dialysis initiation after listing might affect cPRA. We hypothesized that patients with earlier dialysis initiation would have higher cPRA scores.

Methods: This was a retrospective SRTR database study of adults listed for a solitary kidney transplant from 10/1/09 to 11/30/18. Waitlisted patients were stratified by dialysis initiation: prelist, 0-1 year after listing, 1-2 years after listing, or no dialysis within 2 years after listing. The outcomes studied were mean peak CPRA at 0-1 year and 0-2 years after listing. One-way ANOVA was used for statistical analysis.

Results: A total of 173,964 patients were identified who were waitlisted for 1-2 years. With later dialysis initiation, there was a stepwise decline in mean peak CPRA between those who initiated dialysis prelist, 0-1 year after listing, and 1-2 years after listing (Figure 1). There was no difference in mean peak CPRA between the dialysis initiation groups "1-2 years after listing" and "no dialysis 2 years after listing." A similar stepwise decline in mean peak CPRA was seen with patients who were waitlisted for 0-1 year (Table 1).

Conclusions: Our data suggest that waitlisted patients with earlier dialysis initiation may be at risk for developing higher cPRA scores. If verified with further studies, then this may be an incentive for early predialysis referrals for transplant evaluation.

Funding: Commercial Support - Dialysis Clinic Inc.



Graph 1: Mean Peak cPRA by Dialysis Initiation Time Among 1-2 Years Waitlisted Patients

Population	Dialysis Initiation Status	N (%)	Peak CPRA Mean ± SD	p-value
0-1 Year on Waitlist	Prelist	171,335 (65.2%)	19.3 ± 33.4	<.0001
	0-1 year post listing	11,980 (4.6%)	16.5 ± 30.4	
	None	79,424 (30.2%)	14.0 ± 28.0	
1-2 Years on Waitlist	Prelist	116,402 (66.9%)	22.5 ± 35.2	<.0001
	0-1 year post listing	10,693 (6.1%)	20.7 ± 33.5	
	1-2 years post listing	4,038 (2.3%)	17.8 ± 30.7	
	None	42,831 (24.6%)	17.5 ±30.7

PO2520

Variations in Practice Patterns in Eligibility Assessments Across Kidney Transplant Programs in the United States

Adrian Whelan, Brian K. Lee, Deborah B. Adey, Dhiraj Nallapothula, Elaine Ku. *University of California San Francisco, San Francisco, CA.*

Background: Kidney transplant programs are known to vary in terms of their practice patterns given lack of consensus surrounding many aspects of pre-transplant workup. The differences in national practice patterns related to transplant eligibility assessments have not been well described in the contemporary era.

Methods: We conducted a survey of kidney transplant programs in the US to assess current practice patterns as it relates to criteria for prioritizing transplant referrals, candidate evaluation, and determination of eligibility for kidney transplantation. We distributed our survey to 171 adult kidney transplant programs in the US.

Results: 89 (52%) of programs invited to participate in the survey completed it, 45% of which were completed by the Medical Director, 48% by a Transplant Nephrologist, and 7% by other providers. The majority of programs (58%) screened referrals for contraindications to transplantation before scheduling an in-person evaluation (Figure 1). 52% of programs did not prioritize the evaluation of patients with a self-identified living donor candidate when scheduling patients referred for eligibility assessments (Figure 1). Centers differed in the kidney function threshold at which transplant evaluation was begun, and age and body mass index limits for transplantation also varied considerably (Figure 1).

Conclusions: There is wide variation across transplant programs in the assessment of eligibility for kidney transplantation. Further studies are needed to understand how these variations may be associated with access to transplantation and post-transplantation outcomes.

PO2521

Post-Transplant Diabetes Mellitus in a Single Pediatric Kidney Transplant Center: Risk Factors, Outcomes, and Characterization of Clinical Course

Anjali Khanna,[1] Jee-Young N. Ham,[3,2] Margret Kamel,[3] Kathryn M. Ngo,[1] Amanda S. Thomas,[3] Rochelle Liverman,[2] Rouba Garro.[3,2] *[1]Emory University School of Public Health, Atlanta, GA; [2]Children's Healthcare of Atlanta Egleston Hospital, Atlanta, GA; [3]Emory University School of Medicine, Atlanta, GA.*

Background: The prevalence and outcomes of post-transplant diabetes mellitus (PTDM) in pediatric kidney transplant (KT) recipients vary among studies due to the lack of a consistent definition. Risk factors for and pathogenesis of pediatric PTDM are incompletely understood.

Methods: PTDM prevalence, risk factors and disease course was evaluated at a high volume, tertiary care pediatric hospital. We performed a retrospective review of pediatric KT recipients between 2006-2016 to evaluate PTDM prevalence. PTDM was defined as persistent hyperglycemia with serum glucose ≥200 mg/dl, HbA1C ≥6.5%, *and* requiring antihyperglycemic treatment for ≥ 30 days. Full data were available on all patients transplanted between 2010-2016 and were used to compare demographic and clinical characteristics between PTDM (n=9) and non-PTDM patients (n=173) using Chi-square and Wilcoxon rank sum tests.

Results: Between 2006-2016, 312 patients received KT. Five patients with pre-existing DM were excluded. Fifteen developed PTDM with a prevalence estimate of 4.89 % (95% CI: 3% - 8%) and median time from transplant to DM was 17.6 months (25^{th}-75^{th}: 3 – 83). The majority of PTDM patients had a family history of DM in 1st degree relatives (81%) and were maintained on tacrolimus at diagnosis (67%). PTDM diagnosis and insulin initiation occurred in the context of active rejection episode in only two patients. Despite a more stringent definition of PTDM, insulin therapy was discontinued in 3/15 (20%) patients who continued to be normoglycemic. Comparing patients with and without PTDM during the period 2010-2016 revealed that PTDM patients had higher BMI-Z scores at transplant (p=0.053) and higher average blood glucose during the first week post KT (p=0.095), with no difference in age, gender, race, donor status, or dialysis modality.

Conclusions: A more consistent definition of PTDM and larger studies are warranted to better understand the prevalence, risk factors, and pathogenesis of hyperglycemia and PTDM in children. Detailed patient-level data can provide nuance that may be missed with larger registry studies.

PO2522

Diabetic Nephropathy: Is It All About Hyperglycemia?

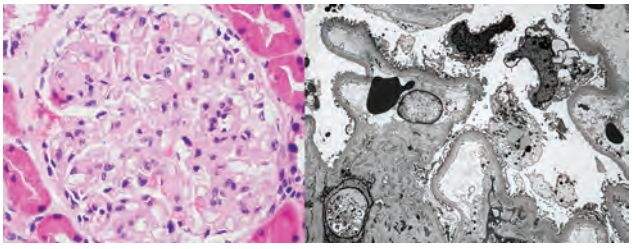
Iyiad Alabdul Razzak,[1] Lois J. Arend,[2] Sami Alasfar.[2] *[1]Alfaisal University, Riyadh, Saudi Arabia; [2]Johns Hopkins University, Baltimore, MD.*

Introduction: Diabetic nephropathy (DN) is the most common cause of end stage renal disease (ESRD). Hyperglyemia has been suggested to be necessary for the development and maintenance of DN. Simultaneous pancreas and kidney transplantation (SPK) has revolutionized the treatment of type 1 diabetic patients with end-stage renal disease (ESRD), and prevention of recurrent DN is one of the main proposed benefits. We present a case of recurrence of DN after SPK despite normal endocrine pancreas allograft function

Case Description: A 47-year-old man with past medical history of ESRD due to diabetes type I who underwent a SPK transplant from a deceased donor in December 2003. His nadir serum Creatinine was 1.5 mg/dl and baseline urine protein creatinine ratio (UPC) is 110-250 mg/g. Maintenance immunosuppression consisted of tacrolimus, mycophenolate, and prednisone. His home medications also included benazepril for hypertension. Sixteen years after transplant, he was noted to have increase in UPC to 2100 mg/g and serum Creatinine to 1.9 mg/dL. Trough tacrolimus levels in the preceding 6 months ranged between 4.8 and 10.9 ng/mL. Donor specific antibodies were negative. He underwent renal allograft biopsy which showed early nodular mesangial matrix expansion and thickened glomerular basement membranes on electron microscopy

consistent with diabetic nephropathy (Figure 1), early chronic transplant glomerulopathy, and severe arteriolar hyalinosis. Additional laboratory findings showed serum lipase 34 (Normal 7-60 U/L), amylase 103 (Normal 21-101 U/L), fasting glucose 79 (Normal 65-99 mg/dL), hemoglobin A1c 5.3, and C peptide was 2.03 (Normal 0.80 - 3.85 ng/mL). Despite increasing Benazepril dose to 40 mg daily, UPC and Cr continued to increase but stabilized in a range of 3800-4500 mg/g and 2.5 mg/dL respectively.

Discussion: Our case suggests that development of DN can be linked to mechanisms independent of hyperglycemia and the usual metabolic disturbances seen in patients with diabetes. A comprehensive restudying of the pathophysiology of DN could further enhance our existing knowledge of the factors implicated in DN, and possibly our ability to develop a more targeted therapy.



PO2523

Use of Weight-Altering Diabetes Medications to Address Obesity as a Barrier to Kidney Transplant Evaluation in Patients with Type 2 Diabetes and Stage 4-5 CKD or ESKD

Kiran Chintam, Prince Mohan, Jamie A. Green, Alex R. Chang. *Geisinger Health, Danville, PA.*

Background: Many patients with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD) are ineligible for kidney transplant due to high body mass index (BMI). Some medication classes are associated with weight loss (glucagon-like peptide-1 receptor agonists [GLP1-RAs]), neutral-weight (dipeptidyl peptidase-4 inhibitors [DPP4i]), or weight gain (sulfonylureas and insulin).

Methods: We examined the relationship between BMI and use of weight-altering diabetes medications in patients with type 2 diabetes mellitus and stage 4-5 CKD or dialysis-dependent ESKD at Geisinger (1/18-3/20). In addition, we examined whether access to kidney transplant evaluation varied by BMI in patients on dialysis.

Results: Out of 4200 patients with T2DM and stage 4-5 CKD or ESKD, 30% had BMI≥35kg/m^2 and 15% had BMI≥40 kg/m^2. Overall, use of T2DM medications with favorable weight effects was low, similar to use of sulfonylureas **(Table)**. Patients with severe obesity had higher GLP1-RA use (BMI ≥ 35 vs. <35 kg/m^2: 11%, 5%), higher insulin use (69%, 53%), and lower DPP4i use (9%, 13%). Similar findings were noted in the subset of patients on dialysis: GLP1-RAs (BMI ≥ 35 vs. <35 kg/m^2: 6% vs. 2%), DPP4is (3% vs. 6%), sulfonylureas (5% vs. 8%), insulin (77%, 74%). In unadjusted analyses, transplant clinic attendance was highest in ESKD patients with BMI 30-34.9 kg/m^2 (23%), followed by BMI 35-39.9 (17%), BMI 25-29.9 (15%), BMI 18.5-24.9 (13%), BMI ≥40 (7%), and BMI < 18.5 (5%).

Conclusions: The vast majority of patients with T2DM and advanced CKD are taking obesogenic rather than weight loss-promoting diabetes medications. Those with BMI ≥40 kg/m^2 were 3.6x less likely to have been evaluated in transplant clinic than those with class I obesity (BMI 30-34.9 kg/m^2). Consideration of the differential impact of certain diabetes medication classes on weight may help improve access to kidney transplantation and long-term outcomes.

Funding: NIDDK Support

Table. Diabetes Medications Use by BMI

	BMI 35+ (n=1103)	BMI <35 (n=3097)	Overall (n=4200)
Weight gain-associated meds			
Insulin	758 (68.7%)	1650 (53.3%)	2,408 (57.3%)
Sulfonylurea	152 (13.8%)	476 (15.4%)	628 (15%)
Meglitinides	28 (2.5%)	101 (3.3%)	129 (3.1%)
Thiazolidinediones	17 (1.5%)	46 (1.5%)	63 (1.5%)
Weight-neutral meds			
DPP4 inhibitor	95 (8.6%)	387 (12.5%)	482 (11.5%)
Alpha-glucosidase inhibitor	0	8 (0.3%)	8 (0.2%)
Weight loss-associated meds			
GLP1-4A inhibitor	119 (10.8%)	142 (4.6%)	261 (6.2%)
Biguanides	85 (7.7%)	203 (6.6%)	288 (6.9%)
SGLT inhibitor	4 (0.4%)	15 (0.5%)	19 (0.5%)

PO2524

Efficacy and Safety of SGLT-2 Inhibitors for Treatment of Diabetes Mellitus Among Kidney Transplant Patients: A Systematic Review and Meta-Analysis

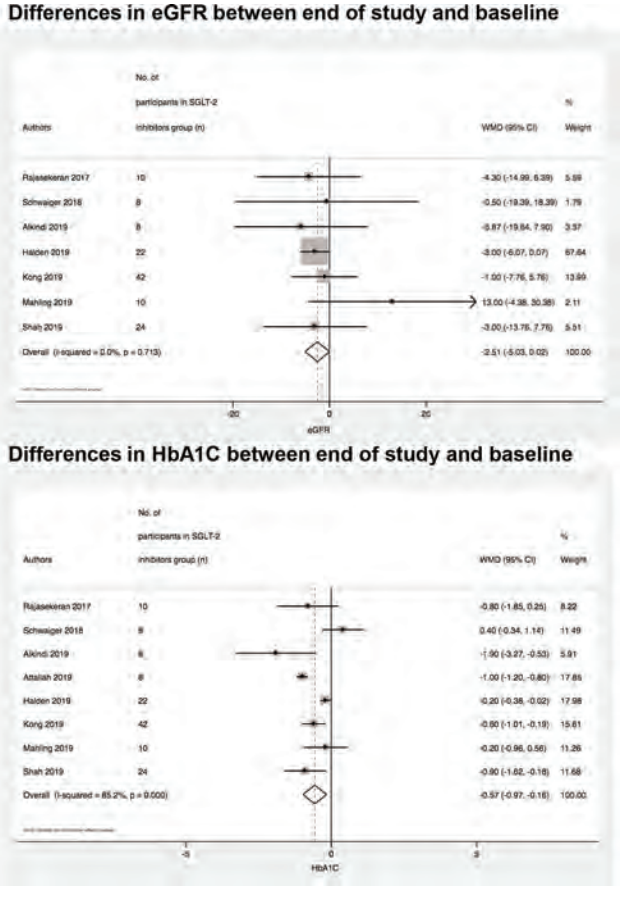
Api Chewcharat,[1,2] Narut Prasitlumkum,[3] Charat Thongprayoon,[2] Wisit Cheungpasitporn.[4] *[1]Mount Auburn Hospital, Cambridge, MA; [2]Mayo Clinic Minnesota, Rochester, MN; [3]University of Hawai'i System, Honolulu, HI; [4]University of Mississippi Medical Center, Jackson, MS.*

Background: The objective of this systematic review was to evaluate the efficacy and safety profiles of sodium glucose co-transporter 2 (SGLT-2) inhibitors for treatment of diabetes mellitus (DM) among kidney transplant (KT) recipients.

Methods: We conducted electronic searches in Medline, Embase, Scopus, and Cochrane databases from inception through April 2020 to identify studies that investigated efficacy and safety of SGLT-2 inhibitors in KT patients with DM. Study results were pooled and analyzed utilizing random-effects model.

Results: Eight studies with 132 patients [baseline estimated glomerular filtration rate (eGFR) of 64.5±19.9 mL/min/1.73m^2] treated with SGLT-2 inhibitors were included in our meta-analysis. SGLT-2 inhibitors demonstrated a significantly lower HbA1C (WMD = -0.56% [95%CI: -0.97, -0.16]; p=0.007) and body weight (WMD = -2.16 kg [95%CI: -3.08, -1.24]; p<0.001) at end of study compared to baseline level. There were no significant changes in eGFR, serum creatinine, urine protein creatinine ratio, and blood pressure. By subgroup analysis, empagliflozin demonstrated a significant reduction in BMI and body weight. Canagliflozin revealed a significant decrease in HbA1C and systolic blood pressure. In terms of safety profiles, 14 patients had urinary tract infection. Only 1 had genital mycosis, 1 had acute kidney injury, and 1 had cellulitis. There were no reported cases of euglycemic ketoacidosis or acute rejection during the treatment.

Conclusions: Among KT recipients with excellent kidney function, SGLT-2 inhibitors for treatment of DM are effective in lowering HbA1C, reducing body weight, and preserving kidney function without reporting of serious adverse events, including euglycemic ketoacidosis and acute rejection.



PO2525

Health System Encounters in Kidney Transplant Recipients Converted from Immediate-Release Tacrolimus Capsules to Extended-Release Tacrolimus Tablets

Yoonhee P. Ha,[1] Jamal Rashid,[2] Mary Putt,[1] Yu Bin Na,[3] Chelsea Sammons,[2] Maxwell Norris,[2] Gregory Malat,[2,4] Brendan Steiner,[2] John H. Holmes,[1] Roy D. Bloom,[3] Peter P. Reese,[1,3] Jennifer Trofe-Clark.[2,3] *[1]Department of Epidemiology, Biostatistics and Informatics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Department of Pharmacy, Hospital of the University of Pennsylvania, Philadelphia, PA; [3]Renal Electrolyte and Hypertension Division, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [4]Drexel College of Medicine, Philadelphia, PA.*

Background: Kidney transplant recipients (KTRs) converted from immediate-release tacrolimus capsules (IR-TAC) to extended-release tacrolimus tablets (ER-TAC) may benefit from reduced dosing frequency and improved bioavailability. However, few studies have characterized health system encounters in these KTRs. Study aims were to (1) determine if conversion to ER-TAC decreased number of dose changes, TAC troughs, and transplant clinic visits and (2) characterize number of dose changes and days to achieve two consecutive therapeutic troughs (5-12 ug/L) under ER-TAC.

Methods: Retrospective review of KTRs at our center transplanted between 2/2010-3/2019, on IR-TAC for ≥90 days, and converted to ER-TAC for ≥90 days. Random-coefficient Poisson regression was used to compare number of dose changes, troughs, and clinic visits during the 90-day periods pre- and post-conversion.

Results: 64 KTRs met inclusion criteria. Mean (SD) age was 52.8 (13.7) years. 38 (59%) were male, 28 (44%) were Black, and 8 (13%) were in an ER-TAC financial assistance program. Median (IQR) time since transplant was 533 (211-1,483) days. KTRs were converted for tremor, 26 (41%); non-adherence, 12 (19%); high IR-TAC dose, 2 (3%); sub-therapeutic troughs, 2 (3%); and other/unknown, 22 (34%). The incidence rate of dose changes but not troughs or clinic visits decreased significantly post-conversion (Table). For the 24 (38%) KTRs with two consecutive therapeutic troughs within 90 days, median (IQR) number of dose changes was 2 (0-1) and days to achieve two consecutive therapeutic troughs was 33.5 (23.5-63).

Conclusions: The incidence rate of dose changes decreased significantly under ER-TAC, but most KTRs did not achieve two consecutive therapeutic troughs within 90 days of conversion. Closer follow up may be beneficial for these KTRs. Future research should determine if reasons for conversion resolved with ER-TAC.

	IR-TAC (90 days)		ER-TAC (90 days)				
	Median no.	IQR	Median no.	IQR	Adjusted IRR*	95% CI	P-value
Dose changes	1	1-1	0.5	0-2	0.59	0.40-0.89	0.011
TAC troughs	2.5	1-7	4	2-6	1.07	0.86-1.33	0.551
Transplant clinic visits	1	0-2	1	0-2	0.76	0.55-1.06	0.104

* Adjusted for age, sex, race, financial assistance, conversion reason, time since transplant, and achievement of two consecutive therapeutic troughs

PO2526

Looking Beyond the Allograft Survival: Long-Term, Five-Year Renal Outcomes in Lung Transplant Recipients

Mohankumar Doraiswamy, Eshetu L. Obole, Priyamvada Singh, Todd E. Pesavento. *Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: With the increase in incidence and overall survival of lung transplant recipients, the risk for chronic sequelae in terms of CKD is on the rise. However, the data on the long-term effect on kidneys in this population is scarce. Our study is the first to assess the five-year renal outcomes in Lung transplant recipients.

Methods: We did a retrospective chart review of 171 adults with lung transplants performed between 1st January 2014 - 1st January 2019 and meeting inclusion/exclusion criteria. Primary outcomes were - the prevalence of CKD/ESRD (requiring RRT), risk of development of CKD in patients with AKI during index hospitalization, and all causes mortality in recipients with CKD when compared to the non-CKD group. Secondary outcomes were calculation of the frequency of utilization of modalities for CKD (urinalysis, renal USG, biopsy, nephrology consults).

Results: 86% of patients were white, with a median age of 61 years, median BMI 27.3 kg/m^2, and 60% were males. Hypertension was present in 55% of recipients at baseline. COPD and IPF were the commonest etiology for lung failure, and 66% received a double lung transplant. Baseline median creatinine and egfr were 0.8mg/dL, and 54mL/min/1.73 m2 respectively. 6% (n=171), 60% (n=161), 67% (n=153), 79% (n=47), and 86% (n=7) had CKD at baseline, 3, 6, 12, 36, 60 months, respectively. Eight percent received dialysis during the index hospitalization. The odds ratio of development of CKD in patients with an AKI episode during index hospitalization versus no AKI was 6.22 (2.87 to 13.06, $p < 0.0001$). Whereas, the odds ratio of all causes mortality in patients with CKD when compared to non-CKD was 3.36 (1.44 to 8.64, p-value 0.005). Hematuria and proteinuria were measured infrequently. Renal biopsy done in 1.1% with renal USG abnormal in 22%, normal in 21 % and never performed in 57%. Sixteen percent of recipients were on dialysis, 3% received a renal transplant, and 27% of mortality noted over a five-year follow up period.

Conclusions: There is a high prevalence of CKD in lung transplant recipients, and increased in the patients who had an AKI during index hospitalization. With increased lung transplant nowadays, early involvement of nephrologists is prudent to prevent and manage CKD effectively in the future. Large prospective trials to delineate the problem is warranted.

PO2527

Incidence, Risk Factors, and Outcomes of Post-Transplant Erythrocytosis After Kidney Transplantation

Beyann Alzoubi, Abish Kharel, Fauzia Osman, Fahad Aziz, Neetika Garg, Maha A. Mohamed, Arjang Djamali, Didier A. Mandelbrot, Sandesh Parajuli. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Post-transplant erythrocytosis(PTE) is a common condition after kidney transplantation. PTE is known to increase the risk of stroke, pulmonary embolism, and deep vein thrombosis, commonly called vascular thromboembolism(VTE). In the current era of immunosuppressive medication and management, the incidence, risk factors, and outcomes of PTE among kidney transplant recipients(KTR) is unknown.

Methods: This was a retrospective study among all adult KTRs transplanted at our university hospital between 01/2001 and 12/2016. All recipients in the PTE group had at least 2 consecutive Hct levels of >51 within the first 2 years of transplant. Controls were selected in a ratio of 5:1 using event density sampling. Patient survival, graft survival, and VTE incidence were outcomes of interest.

Results: Of 4317 kidney transplants during the study period, 214(5%) had PTE and were compared with 1035 controls. While comparing baseline characteristics between PTE and control, KTRs in the PTE group were more likely to be younger, male, have lower BMI, higher prevalence of diabetes as the cause of ESRD and receive a non-preemptive transplant. Similarly, looking at donor characteristics, the PTE group was likely to receive the kidney from a younger donor and have lower KDPI. The median interval from transplant to the diagnosis of PTE was 9.9 months (IQR 5.89). 13 (6.1%) in the PTE group and 71(6.9%) in control had VTE events. In the multivariable analysis, patients with older age (HR: 0.98, 95% CI 0.97-0.99, p=0.005) and higher BMI (HR: 0.97, 95% CI 0.93-0.99, p=0.05) were less likely to develop PTE, while non-preemptive transplant (HR: 3.95, 95% CI 1.74-8.99, p=0.001) was significantly associated with increased risk of PTE. After adjustment for the multiple confounding factors, PTE was not associated with patient mortality (HR: 1.0, 95% CI 0.70-1.43, p=0.99), graft failure (HR: 1.13, 95% CI 0.69-1.83, p=0.61) or VTE (HR: 1.07, 95% CI 0.59-1.96, p=0.81). In a subgroup analysis among PTE with Hct >55 (n=39) compared with controls, similar findings were observed.

Conclusions: In this era, the prevalence of PTE is lower at 5% compared to around 15% in various previous studies. Similarly, there were no detrimental effects of PTE on patient survival, graft survival, or the risk of VTE in the current era.

PO2528

Post-Transplant Outcomes Among Kidney Transplant Recipients with Intentional and Unintentional Weight Loss

Meera N. Harhay,[1] Xiaomeng Chen,[2] Nadia M. Chu,[2] Mara McAdams-DeMarco.[2] *[1]Drexel University, Philadelphia, PA; [2]Johns Hopkins University, Baltimore, MD.*

Background: Research has shown that kidney transplant (KT) recipients who lose weight before KT are at increased risk for post-KT weight gain, all-cause graft loss (ACGL), and mortality. No studies have examined whether these associations differ between KT recipients with intentional and unintentional weight loss.

Methods: Among 366 KT recipients from a prospective cohort study of frailty and KT, we used adjusted mixed effects models to estimate differences in post-KT BMI trajectories, ACGL, and mortality by 1-year pre-KT weight change, defined as stable weight, intentional weight loss, unintentional weight loss, and weight gain.

Results: Mean age was 53 years, 39% were black, and 39% were female. The majority (64%) had stable pre-KT weight, 12% had weight gain, 14% had unintentional weight loss, and 10% had intentional weight loss. By 3 years post-KT, BMI increased by 0.05 kg/m^2 (95% CI 0.02, 0.08 kg/m^2) among those with stable pre-KT weight; the increase was similar among those with pre-KT weight gain and intentional weight loss. Those with pre-KT unintentional weight loss had larger increases in post-KT BMI than those with stable weight (BMI change difference +0.15 kg/m^2 [0.04, 0.25 kg/m^2], p=0.01). Unadjusted cumulative incidence of mortality was similar across weight change categories (Figure). Adjusted for age, sex, race, BMI, and donor type, only unintentional weight loss was associated with higher mortality (aHR 2.31 [1.24,4.31], p=0.008) and ACGL (aHR 2.02 [1.24,3.31], p=0.005) relative to stable weight.

Conclusions: In this study, pre-KT unintentional weight loss was associated with higher post-KT BMI increases, ACGL and mortality than pre-KT intentional weight loss, stable weight, and weight gain. These results suggest that unintentional weight loss should be identified and addressed in KT candidates, independent of BMI.

Cumulative Incidence of Mortality among Kidney Transplant Recipients by Pre-Transplant Weight Change

PO2529

Obesity and Poorer Renal Allograft Function: Analysis of Longitudinal Data

Ekamol Tantisattamo,[1,2] Busara Songtanin,[3] Natnicha Leelaviwat,[4] Sakditad Saowapa,[4] Possawat Vutthikraivit,[5] Chawit Lopimpisuth,[3] Natchaya Polpichai.[6] *[1]Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; [2]Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; [3]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [4]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [5]Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand; [6]Faculty of Medicine Songklanagarin Hospital, Prince of Songkla University, Songkla, Thailand.*

Background: Obesity is associated with worsened allograft function, but its effect on allograft function after established baseline allograft function at a 12-week post kidney transplant (KT) is unclear.

Methods: All 105 KT recipients were divided into obese (BMI ≥30 kg/m^2) and non-obese groups. Longitudinal data were analyzed by linear mixed model to examine association between obesity and eGFR during the 1st year post-KT.

Results: Mean age was 54±11 years and 64 patients (61%) was female. Seventy-one patients (68%) were obese. Generalized estimating equation revealed that eGFR increased 0.16 ml/min/1.73 m^2 (β±SE 0.16±0.04; 95%CI 0.09 to 0.23) for every 1 week after KT. Excluding eGFR at 4-week post-KT when baseline allograft function is generally not established, mean eGFR at 12-week post-KT was the lowest and assigned as the baseline allograft function. Given unequal spreading of time when eGFR were measured, a 1-year follow-up was categorized into every 4 and 12 weeks if eGFR were measured before and after a 12-week post-KT, respectively. Spline interaction term was created at the 12-week post-KT as well as categorized time-spline interaction term. By using a linear mixed model and after adjusted for age, gender, type of KT (deceased vs living donor KT), obesity category and its interaction team with categorized time and spline interaction term, obese group had a higher rate of eGFR decline of 2.9 ml/min/1.73 m^2 every 4 weeks prior to 12-week post-KT, and the rate declined to 1.1 ml/min/1.73 m^2 every 12 weeks after 12-week post-KT. At the 12-week post when baseline eGFR was established, eGFR were 74.1±30.5 and 78.0±30.5 ml/min/1.73 m^2 for obese and non-obese groups, respectively (random intercept); whereas, rate of increase in eGFR of those corresponding groups were 69.3±0.2 and 70.3±0.2 ml/min/1.73 m^2 every 12 weeks (random slope).

Conclusions: Although population-based estimated eGFR was significantly increased overtime, obese KT recipients had lower baseline eGFR at the 12-week post-KT and slower rate of increased eGFR than those of non-obese group when individual baseline eGFR at the 12-week post-KT and rate of eGFR change were taken into the consideration. Pre-KT obesity remains one of the associated factors of poor allograft outcomes, which may be mitigated by pre-KT weight loss.

PO2530

A Call to Action: Finding the Right Kidney for All Potential Recipients

Giselle Guerra, Luke Preczewski, Lumen A. Mendez Castaner, Javier Pagan, Amy L. Harshman, Jose M. Figueiro, Gaetano Ciancio, Rodrigo Vianna. *Miami Transplant Institute, Miami, FL.*

Background: The burden of dialysis among ESRD patients is a huge driver of morbidity, mortality, and cost. Thousands of deceased-donor (DD) kidneys that almost certainly have better outcomes than dialysis are discarded each year. Our center sought to find and transplant kidneys that would reduce waiting time for our patients while preserving post-transplant outcomes consistent with nationally expected results.

Methods: We reviewed 1119 consecutive DDKT recipients transplanted between 1/1/2016 and 12/31/2019 at our center. Endpoints were eGFR by MDRD death-censored graft survival using Kaplan-Meier survival estimation and the Cox Proportional Hazards Model. We reviewed on additional year (2015) for waiting time impact.

Results: DD KT volumes doubled from 2016 to 2019 (191 vs. 384). Growth was attributable to increased acceptance of hard-to-place imported kidneys, including kidneys with AKI (413% increase) and KDPI > 85 (296% increase). In 2016, 46.6% of DD kidneys were imported from outside our DSA and by 2019, 77.3% were imported. Overall one-year patient survival was 96.6% (CI: 95.4-97.6%) and death-censored one-year graft survival was 95.8% (CI: 94.4%-97.6%). Recipients with any stage of AKI saw no additional risk vs. donors without AKI (HR 0.94, p=0.854) while death-censored graft survival at one year was 91.9% for recipients of kidneys with KDPI >85% vs 96.7% with KDPI ≤85%, representing significant additional risk (HR: 1.91; p=0.017). This significantly decreased waiting time at transplant across all blood types (6.4 years in 2015 to 3.9 years in 2019). This benefit was even greater for blood group B (10.7 to 4.3), and significantly reduced the disparity in accrued waiting times for African-American and Hispanic populations. Kidney function was good at 1 year in all groups among those surviving with followup. Mean eGFR by MDRD formula was 60.0 (SD 23.2) in recipients with non-AKI donors and 61.9 (SD 26.1) in recipients with AKI donors (p=0.4384). Mean eGFR 49.0 in the KDPI > 85% group vs 62.3 in the <= 85% KDPI group (p<0.0001).

Conclusions: Transplant centers can answer the growing demands of patients enduring dialysis to better utilize kidneys that have previously been discarded. Our center has demonstrated that it is possible to reduce waiting time, and maintain outcomes using kidneys previously discarded.

Impact of High Body Mass Index on the Allograft Outcomes in Kidney Transplant Recipients with Presensitization to Human Leukocyte Antigen

Byung ha Chung,[1] Yohan Park,[1] Hanbi Lee,[1] Eun jeong Ko,[1] Sua Lee,[2] Tae Hyun Ban,[3] Ji Won Min,[4] Hye Eun Yoon,[5] Chul Woo Yang.[1] *[1]Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Eunpyeong Saint Mary's Hospital, Eunpyeong-gu, Seoul, Republic of Korea; [4]Catholic University of Korea Bucheon Saint Mary's Hospital, Bucheon, Gyeonggi-do, Republic of Korea; [5]Catholic University of Korea Incheon Saint Mary's Hospital, Incheon, Incheon, Republic of Korea.*

Background: The aim of this study was to investigate whether high body mass index (BMI) and pre-sensitization to human leukocyte antigen (HLA) in kidney transplant recipients (KTR) had a synergistic impact on the allograft outcomes.

Methods: From January 2010 to December 2018, 1,290 KTs were performed in Seoul St Mary's Hospital. Of these, 682 cases of ABO compatible KT were enrolled. They were divided into 4 groups (low BMI-non-sensitized, high BMI-non-sensitized, low BMI sensitized, high BMI-sensitized) according to the median BMI value (22.7 kg/m^2) and HLA pre-sensitization status (HLA-DSA MFI >3,000). Short-term and long-term allograft outcomes were compared between the groups.

Results: The rate of late antibody mediated rejection tended to be the highest in the high BMI-sensitized group, and the decline in allograft function in the high BMI-sensitized group was higher than in the other 3 groups. Death-censored graft loss (DCGL) rates and the hazard ratio (HR) for DCGL were the highest in the high BMI-sensitized group (4/21 (19.0%), HR 4.648, P = 0.022) and a significant interaction was detected between high BMI and HLA pre-sensitization status (P value for interaction = 0.008).

Conclusions: Our results suggest that pre-sensitization to HLA and high BMI in KTRs might have a synergistic adverse impact on the allograft outcomes.

Funding: Government Support - Non-U.S.

Table 1. Hazard ratios of death-censored graft loss according to BMI and presensitization status

	Unadjusted HR (95% CI)	P-value	Adjusted HR (95% CI)	P-value	P-value for interaction
Low BMI-non sensitized	Reference		Reference		0.008
High BMI-non sensitized	1.661 (0.849-3.247)	0.138	1.495 (0.735-3.041)	0.267	
Low BMI-sensitized	2.650 (0.872-8.057)	0.086	3.377 (1.082-10.538)	0.036	
High BMI-sensitized	5.656 (1.859-17.211)	0.002	4.648 (1.251-17.276)	0.022	

Multivariate regression model was adjusted with parameters showing significant difference among the 4 groups according to BMI and pre-sensitization status. Parameters were as follows: Age, Sex, DM, HTN, Fasting glucose, Triglyceride, HDL-cholesterol, Hemoglobin A1c, ESRD causes, Dialysis modality, and Prior KT history.

PO2532

Association Between Post-Transplant Visit-to-Visit Pulse Pressure Variability and Late Transplant Systolic Blood Pressure in Non-Elderly Kidney Transplant Recipients

Ekamol Tantisattamo,[1,2] Natnicha Leelaviwat,[3] Busara Songtanin,[4] Sakditad Saowapa,[3] Possawat Vutthikraivit,[5] Chawit Lopimpisuth,[4] Natchaya Polpichai.[6] *[1]Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; [2]Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; [3]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [4]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [5]Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand; [6]Faculty of Medicine Songklanagarin Hospital, Prince of Songkla University, Songkla, Thailand.*

Background: Visit-to-visit blood pressure variability is associated with vascular stiffness and cardiovascular outcomes, particularly in elderly. Association between visit-to-visit pulse pressure variability (VVPPV), which takes SBP and DBP into account, and late post-kidney transplant (KT) blood pressure (BP) in different age groups is unknown.

Methods: VVPPV was examined by average successive variability ASV), which is the average absolute difference between successive BP measured at 4, 12, and 24 weeks post-KT. Since the slope of the linear plot between VVPPV and SBP at 48 week post-KT abruptly changed when VVPPV was 15 mmHg, VVPPV was then categorized into <15 and ≥15 mmHg (Figure1A). Association between the categorized VVPPV and systolic and diastolic hypertension (SHTN, DHTN) at 48 weeks defined by SBP and DBP ≥130 and ≥80 mmHg, respectively was examined by multiple logistic regression and stratified into age <60 and ≥60 years old.

Results: Of all 105 KT recipients from a single KT center, mean age±SD was 54±12 years and 64 patients (61%) was female. Mean VVPPV was 13±9 (range 2 to 50). Mean post-KT SBP and DBP at 48 weeks post-KT were 133±16 and 77±11 mmHg, respectively. In the whole study population adjusted by gender, donor type (deceased vs. living), and types of induction immunosuppressive medications, patients with VVPPV ≥15 mmHg had 3.36 times higher risk of developing SHTN (OR 3.36, P 0.02, 95%CI 1.17, 9.65). However, after additional adjustment by age and interaction term between age and ASV, the association was persist only in patients whose age <60 years old ($OR_{<60\text{-}y/o}$ 3.80, p 0.04, 95%CI 1.04, 13.91 vs. $OR_{\geq 60\text{-}y/o}$ 2.18, p 0.40, 95%CI 0.36, 13.31)(Figure1B). There was no association between VVPPV and DHTN in the whole study and age-stratified populations.

Conclusions: Higher VVPPV is associated with late post-KT SHTN in younger age group (< 60 years old), but not in elderly. Further studies are required to elucidate the mechanism.

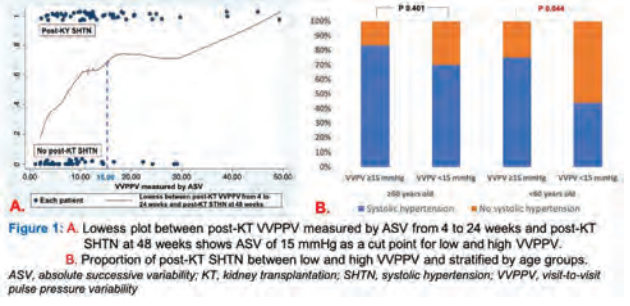

Figure 1: A. Lowess plot between post-KT VVPPV measured by ASV from 4 to 24 weeks and post-KT SHTN at 48 weeks shows ASV of 15 mmHg as a cut point for low and high VVPPV.
B. Proportion of post-KT SHTN between low and high VVPPV and stratified by age groups.
ASV, absolute successive variability; KT, kidney transplantation; SHTN, systolic hypertension; VVPPV, visit-to-visit pulse pressure variability

PO2533

Kidney Transplant Outcomes for Patients with Enteric Oxalosis

Mira T. Keddis, Danica Grujic, Annamaria T. Kausz. *Mayo Foundation for Medical Education and Research, Scottsdale, AZ.*

Background: Patients with enteric disorders associated with hyperoxaluria and systemic oxalate burden (enteric oxalosis) are at increased risk for calcium oxalate deposition causing ESRD. The objective of this study is to evaluate kidney transplant (KTx) recipients with enteric oxalosis at our institution.

Methods: KTx recipients with suspected oxalosis due to any of the following: inflammatory bowel disease, bariatric surgery, or pancreatic insufficiency from 2015 to 2019 were included. At our institution, pre-KTx serum oxalate>30mcmol/L is the threshold for treatment.

Results: 31 patients were identified. Mean age was 58.5 years, 55% were female, 81% white, and 94% first KTx. Most common cause of ESRD was diabetes (45%), and 84% were on dialysis prior to KTx (median 30.5 months). The most common enteric cause was Roux-en-Y gastric bypass (RYGB, 77%) with surgery 11 years (median) prior to KTx. 39% had history of nephrolithiasis. Median peak serum oxalate (SOx) pre-KTx was 24mcmol/L. 87% received deceased donor KTx and 52% had delayed graft function (DGF). Post-KTx, 36% received calcium with meals for oxalate binding, and 39% had low oxalate diet education. 5 patients had pre-KTx SOx >30mcmol/L at the time of KTx, of whom 4 had DGF and required either longer dialysis (up to 5 hours long) or increased dialysis sessions (up to 6 per week) to reduce SOx levels post-KTx. The median duration of dialysis after KTx was 13.5days. After median follow up of 27months, mean (SD) estimated glomerular filtration rate (GFR) was 47.6 ±21.7mL/min/1.73m^2 and 68% of patients had GFR <60. One-year GFR was 48.4±21.4mL/min/1.73m^2 which is lower than expected 1-year GFR for our Transplant Center (mean GFR 58.9 ±20.6ml/min/1.73m^2). RYGB patients (n=24) had lower GFR vs patients with other EH causes (n=7) (1 year: 48.7±20.4 vs 56.7±4.9; last follow-up 47.3±21.1 vs 57.5±14.8 mL/min/1.73m^2). Only 2 patients had oxalate crystals on protocol allograft biopsy, both with RYGB, and one with DGF and died 22 months after KTx. GFR at 1 year was 34±2.83 ml/min/1.73m^2 for these 2 patients.

Conclusions: RYGB is the most common cause of enteric oxalosis in KTx recipients. DGF is common and graft outcomes are inferior compared to deceased donor KTx at our institution. The lower GFR in RYGB patients raise concern for enteric hyperoxaluria as an unrecognized risk for allograft dysfunction.

PO2534

Middle Cerebral Artery Hemodynamics Is Blunted in Kidney Transplant Recipients

Andrew J. Jurgensen,[1] Jaimie Ward,[2] Allegra Morton,[2] Andrew P. Geise,[2] Sandra Billinger,[2] Aditi Gupta.[1] *[1]University of Kansas Medical Center Division of Nephrology, Kansas City, KS; [2]University of Kansas Medical Center Department of Physical Therapy and Rehabilitation, Kansas City, KS.*

Background: Kidney transplant (KT) recipients have a higher risk of dementia and cerebrovascular events than the general population. Cerebrovascular hemodynamic response (CVR) to constant-load moderate-intensity exercise marks the ability of the brain to respond to increased oxygen requirements with exercise. Blunted CVR seen with vascular disease and aging can increase risk of dementia and stroke. We evaluated the middle cerebral artery blood velocity (MCAv) dynamic response in KT recipients and compared it to age matched non-CKD controls.

Methods: 35 KT recipients and 35 healthy controls completed a 90-second rest followed by a 6-minute moderate intensity exercise on a recumbent stepper at a prescribed step rate and workload. We used transcranial doppler (TCD) monitoring for MCAv while continuously monitoring heart rate and beat-to-beat mean blood pressure during rest and exercise. Baseline resting MCAv and steady state response during exercise was recorded. Outcome measures included resting MCAv and CVR (MCAv during steady state exercise – baseline MCAv) and workload needed to achieve target heart rate. Statistical analysis employed independent t-test.

Results: KT recipients were 52.4±1.7 years old, 74.3% male, 91.4% white, 22.9% with diabetes, and 91.4% with hypertension. Controls were 54.4±2.0 years old, 74.3% male, 80% white, without diabetes, and 14.3% with hypertension. Baseline MCAv was similar in the two groups, but the response during moderate intensity exercise differed; CVR for KT recipients was 8.12 ± 0.8 cm/s compared to 12.9 ± 1.4 cm/s for controls (p=0.003) and target workload for KT recipients was 84.1 ± 2.8 watts compared to 123.1 ± 5.3 for controls (p<0.001) (Table 1).

Conclusions: KT recipients have a blunted middle cerebral artery hemodynamic response to exercise compared to healthy controls. This may be due to vascular disease and can explain the higher white matter disease, dementia, and stroke in this population.

Funding: Other NIH Support - Grant K23-AG055666, Commercial Support - Veloxis and Novartis

Table 1. Middle cerebral artery kinetics parameters for rest and response to moderate intensity exercise in kidney transplant recipients and healthy controls.

	KT recipients (n = 35)	Controls (n = 35)	p value
Age	52.4 ± 1.7	54.4 ± 2.0	0.44
Male gender (%)	26 (74.3)	26 (74.3)	1.00
White race (%)	32 (91.4)	28 (80)	0.18
Target workload (Watts)	84.1 ± 2.8	123.1 ± 5.3	< 0.001
Baseline MCAv (cm/s)	51.9 ± 2.1	53.2 ± 1.5	0.62
CVR (cm/s)	8.12 ± 0.8	12.9 ± 1.4	0.003
Baseline MAP (mmHg)	102.1 ± 3.5	81.2 ± 2.4	< 0.001
Steady State MAP (mmHg)	126.1 ± 3.6	106.1 ± 3.3	< 0.001
Baseline HR (bpm)	74.4 ± 2.1	66.5 ± 1.7	0.005
Steady State HR (bpm)	106.3 ± 3.0	111.1 ± 2.0	0.19

Values are means ± SEM. MCAv, middle cerebral artery velocity; CVR, cerebrovascular hemodynamic response; MAP, mean arterial pressure; HR, heart rate.

PO2535

Longitudinal Physical Performance Following Kidney Transplant

Khin N. Chan,[1,2] Daniel J. Watford,[1] Xingxing S. Cheng,[1] Jonathan N. Myers,[2] Jane C. Tan.[1] *[1]Stanford Medicine, Stanford, CA; [2]Veterans Affairs Palo Alto Health Care System, Palo Alto, CA.*

Background: Frailty and poor physical performance are strongly associated with poor outcomes in kidney transplantation (KTx). However, the effect of KTx on physical performance remains poorly understood.

Methods: We measured 6-minute walk test (6MWT, meters) and 1-minute sit-to-stand test (STS, number of repetitions from standing to sitting position) performances within 1 year prior to KTx. Physical performance indices were re-measured at 3 and 6-months, and 1-year post-KTx. Multivariable linear regression was used to assess which baseline characteristics were associated with 6MWT and STS. Trajectories of 6MWT and STS were assessed by baseline performance using a generalized estimating equation.

Results: Among 85 patients who performed baseline assessments, 39, 33 and 40 completed 3, 6, and 12-month evaluations, respectively. Average age was 53 and average dialysis vintage was 7 years. 49% had diabetes mellitus, 18% had coronary artery disease, 5% had cerebrovascular disease, and 10% had peripheral arterial disease (PAD). In the multivariate model, age, female sex, and the presence of PAD were associated with lower 6MWT, while age and female sex were associated with lower STS. Median 6MWT and STS were 419m and 20 repetitions, respectively. 6MWT decreased somewhat after transplant across timepoints, and the trajectory was not significantly modified by baseline 6MWT (Figure 1). In contrast, STS increased post-Tx (Figure 2), but more so in patients with higher baseline STS (*p=0.001*), an effect which persisted after multivariate adjustment for age, sex and PAD (*p=0.002*).

Conclusions: Walking ability did not improve appreciably after KTx. STS, a measure of lower body strength, improved progressively post-KTx, but was mostly observed in patients with higher baseline STS. Results must be interpreted with caution, since all patients, even those with lower physical performance, were selected to proceed with KTx.

Figure 1. 6MWT Post-Transplant

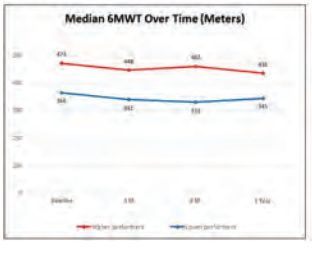

Figure 2. STS Post-Transplant

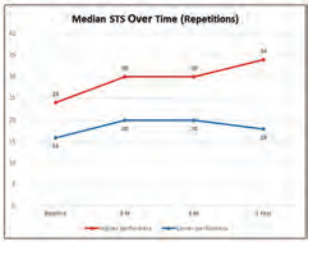

PO2536

Outcomes of Kidney Transplantation in Fabry Disease: A Meta-Analysis

Maria Lourdes Gonzalez Suarez,[1] Charat Thongprayoon,[2] Michael A. Mao,[3] Juan A. Medaura,[1] Wisit Cheungpasitporn.[1] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Mayo Clinic, Rochester, MN; [3]Mayo Clinic, Jacksonville, FL.*

Background: Fabry disease (FD) is a rare X-linked lysosomal storage disorder with progressive systemic deposition of globotriaosylceramide, leading to life-threatening cardiac, central nervous system, and kidney disease. Current therapies involve symptomatic medical management, enzyme replacement therapy (ERT), dialysis, kidney transplantation, and more recently gene therapy. The aim of this systematic review was to assess outcomes of kidney transplantation among patients with FD.

Methods: Comprehensive literature review was conducted utilizing MEDLINE, EMBASE and Cochrane Database, from inception through February 28, 2020 to identify studies that evaluate outcomes of kidney transplantation including patient and allograft survival among kidney transplant patients with FD. Effect estimates from each study were extracted and combined using the random-effects, generic inverse variance method of DerSimonian and Laird.

Results: Eleven studies including 424 kidney transplant recipients with FD were enrolled. The post-transplant median follow-up time ranged from 3 to 11.5 years. Overall, the pooled estimated rates of all-cause graft failure, graft failure before death, and allograft rejection were 32.5% (95%CI: 23.9%-42.5%), 14.5% (95%CI: 8.4%-23.7%), and 20.2% (95%CI: 15.4%-25.9%), respectively. A sensitivity analysis limited only to the recent studies (year 2001 or newer when ERT became available), the pooled estimated rates of all-cause graft failure, graft failure before death, and allograft rejection were 28.1% (95%CI: 20.5%-37.3%), 11.7% (95%CI: 8.4%-16.0%), and 20.2% (95%CI: 15.5%-26.0%), respectively. The pooled estimated rate of biopsy proven FD recurrence was 11.1% (95%CI: 3.6%-29.4%), respectively. There was no significant difference in the risk of all-cause graft failure (P = 0.10) nor mortality (0.48) among recipients with vs. without FD.

Conclusions: Despite possible FD recurrence after transplantation of 11.1%, allograft and patient survival are similar among kidney transplant recipients with vs. without FD.

PO2537

Urine Supersaturation in Patients with Kidney Transplant Nephrolithiasis

Erin E. Bolen, Mitchell Humphreys, Karen L. Stern, Todd Leavitt, Nan Zhang, Mira T. Keddis. *Mayo Clinic Arizona, Scottsdale, AZ.*

Background: Urine supersaturation (SS) has not been reported for kidney transplant (KTx) recipients with de novo transplant-derived nephrolithiasis. The objective of this study is to evaluate supersaturation studies, treatment, and stone and allograft outcomes in KTx recipients with allograft nephrolithiasis.

Methods: Retrospective review from 2009-2019 of KTx recipients with nephrolithiasis at Mayo Clinic was completed. Stone event was defined as radiologic evidence.

Results: Fifty six transplant nephrolithiasis cases were identified. Mean transplant age was 56.5 (±12.1) years, 32 (57.1%) were male, 46 (82.1%) receiving first KTx, 41 (75.9%) required dialysis, and 17 (30.9%) had stone event prior to KTx. Twenty one (37.5%) had at least 2 stones in the allograft, median stone size was 6 mm, and most common location was the lower pole (n=20 [41.7%]). Median time from KTx to stone event was 1 year. Thirty four (60.7%) had a 24-hour SS study at a median of 2 years after KTx. Select results are shown in Table 1. Of the 34, 14 (41.2%) had a stone event prior to KTx, and 6 (19.4%) had a donor-derived stone. Thirty one (91.2%) had increased SS of calcium oxalate, 17 (50%) calcium phosphate, and 9 (26.5%) uric acid. Thirty two (94.1%) had urine citrate <450mg/24hrs. Management of the initial 56 included potassium citrate in 13 (23.2%), calcium citrate in 10 (17.8%), and dietician referral in 18 (32.1%). Forty five (80.4%) were seen by urology, 28 (50%) needed surgical management, and 14 (27.5%) passed the stone. At median follow-up of 4 years after KTx, 37 (66.1%) had persistent stone disease in the allograft, 3 (5.4%) had graft failure, and 2 (3.6%) had died.

Conclusions: This is the first study of urine SS in patients with transplant-derived nephrolithiasis. Profound hypocitraturia was the most prevalent risk, and increased supersaturation for calcium oxalate crystals predominated. Allograft stone clearance was rare, and many required surgical intervention.

Funding: Clinical Revenue Support

Table 1

Select 24-hr urine supersaturation parameters	Median (Range)
Volume (ml)	2174.5 (745, 3960)
Sodium (mmol)	125.5 (26.0, 400)
Calcium (mg)	103.5 (26.0, 592)
Magnesium (mg)	88.5 (22.0, 240)
Citrate (mg)	124.5 (20.0, 763)
Oxalate (mg)	34.35 (9.8, 136)

Exposure to Tacrolimus Trough Levels Below 6 ng/mL During the First Year Is Associated with Inferior Kidney Graft Survival

Timna Agur,[1,2] Ruth Rahamimov,[1,2] Benaya Rozen-zvi.[1,2] *[1]Department of Nephrology and Hypertension, Rabin Medical Center Israel, Petah Tikva, Israel; [2]Sackler Faculty of Medicine, Tel- Aviv University, Tel-Aviv, Israel.*

Background: Accumulating data indicates that sub-therapeutic levels of calcineurin inhibitors are associated with long-term graft loss. However, while tacrolimus (TAC) was shown to provide adequate immunosuppression with lower acute rejection rate, its optimal maintenance dose for long term graft survival is still unknown. The aim of our study was to determine the minimal TAC trough level, which is associated with improved kidney graft survival.

Methods: We conducted a retrospective cohort study based on the RMC registry. We defined five TAC trough level intervals: 3-4, 4-5, 5-6, 6-7, and 7-8ng/ml. We calculated the exposure time for each drug level interval during the first year following transplantation, defined as the cumulative number of days at each interval. This measure

was adjusted to the exposure time below a given interval-level, allowing us to define the threshold for optimal TAC trough level as the upper limit of the interval. We then determined the association between the adjusted exposure time at each TAC level-interval and our primary outcome, death-censored graft survival.

Results: We included 1417 patients with a median follow up of 5.3 years (IQR 2.9-8.5 years). TAC through level interval of 5-6ng/ml was the highest interval which demonstrated a statistically significant association between exposure time and increased risk of graft loss, even after adjustment to the exposure time below 5ng/ml (HR 1.58 per log days, p<0.001). These results remained consistent in an extensive multivariate analysis (HR 1.44, p<0.004) and were not significantly changed when we analyzed for death-included graft survival (HR 1.2, p<0.026) or the first three months and the subsequent nine months separately (HR 1.93, p<0.001, HR 1.56, p<0.001 respectively). Cumulative exposure time above 14 days to TAC trough level< 6ng/ml, was significantly associated with increased risk of graft loss in most studied subgroups including age, gender, low and high immunologic risk recipients, except for the subgroup of recipients with diabetes.

Conclusions: Prolonged exposure time to TAC trough level between 5-6ng/ml within the first-year post-transplant was independently associated with increased risk of long-term graft loss. These results imply that keeping TAC trough levels above 6ng/ml during the first year might improve kidney transplantation outcomes.

PO2539

High Intrapatient Variability of Tacrolimus in Pediatric and Adolescent Renal Transplant Recipients Is Associated with Worse Graft Outcomes

Kim H. Piburn,[1,2] Lynn K. Maestretti,[2] Mary V. Patton,[2] Anne M. Mcgrath,[2] Rajesh R. Shetty,[2] Abanti Chaudhuri,[1,2] Paul C. Grimm,[1,2] Vaka K. Sigurjonsdottir.[1,3] *[1]Stanford University School of Medicine, Stanford, CA; [2]Lucile Salter Packard Children's Hospital at Stanford, Palo Alto, CA; [3]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland.*

Background: High intra-patient variability (IPV) in tacrolimus (TAC) levels has been associated with the development of *de novo* donor-specific antibodies. The degree of TAC IPV in relation to poor graft outcomes in pediatric kidney transplant patients is unknown.

Methods: Patients ages 0-25 years who were transplanted from 01/01/2010-01/01/2018 at a single center were considered for inclusion. Minimum required follow-up time was 12 months. Primary outcomes were formation of C1q+ *de novo* DSAs (*dn*DSAs) and graft loss. *dn*DSAs were identified by routine screening or at investigation of allograft dysfunction. TAC IPV was determined using the mean coefficient of variation (CV) over the immediate 6-month time period prior to each TAC level. All available TAC levels were included in the analysis. Mean CV was calculated using CV from 10 months post-transplant until end of follow-up. Patients were followed until 01/03/2019 or until graft loss. Analyses were performed using descriptive statistics and the Mann-Whitney U test.

Results: 225 pediatric kidney transplant patients met inclusion criteria. Median age was 12.5 years (range 15 mo.-21 yrs.). 46% were female, and 24% received a living donor transplant. 51 formed C1q+ *dn*DSA, and 174 did not. Among patients who formed C1q+ *dn*DSA, 13/51 (25.5%) lost their graft, compared to 2/174 (1.1%) in patients who did not form *dn*DSA by C1q. C1q+ *dn*DSA formers had higher mean CVs compared to patients who did not form *dn*DSA by C1q (median CV 33.9% vs 26.1%, p<0.0001), including when stratified by age subgroups of 0-12 years (p=0.0217) and 13-25 years (p=0.0001) [Figure 1]. Patients with graft loss had higher mean CVs compared to those who did not have graft loss (median CV 39.0% vs 25.8%, p=0.0006).

Conclusions: High tacrolimus IPV was associated with C1q+ *dn*DSA formation and graft loss. Tacrolimus IPV is a potential prognostic tool for optimizing transplantation outcomes.

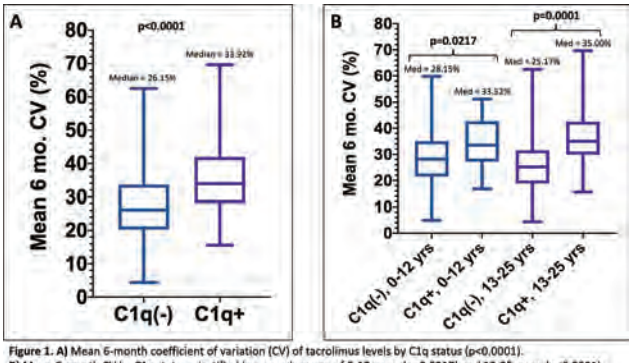

Figure 1. A) Mean 6-month coefficient of variation (CV) of tacrolimus levels by C1q status (p<0.0001).
B) Mean 6-month CV by C1q status, stratified by age subgroups of 0-12 years (p=0.0217) and 13-25 years (p=0.0001). Ages 0-12 yrs: n=117, C1q(-): n=95, C1q+: n=22. Ages 13-25 yrs: n=108, C1q(-): n=79, C1q+: n=29

PO2540

Impact of Renal Transplantation on Functional Status in Tacrolimus Era

Mahmoud M. Mohamed,[1] Karim M. Soliman,[4] Hatem Ali,[2] Ahmed Daoud,[3] Tibor Fulop,[4,5] Vinaya Rao,[4] Maria Aurora C. Posadas,[4] Michael Casey,[4] Ahmed Halawa,[6] Ingi Elsayed.[7] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University hospitals of Birmingham, UK, Birmingham, United Kingdom; [3]Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt; [4]Medical University of South Carolina, Charleston, SC; [5]Ralph H. Johnson VA Medical Center, Charleston, SC, United States, Charleston, SC; [6]Institute of Medical Sciences, Faculty of Medicine, University of Liverpool, Liverpool, UK, Liverpool, United Kingdom; [7]Royal Stoke University Hospital, Stoke-on-Trent, United Kingdom.*

Background: Despite a large body of literature describing survival's outcome after renal transplantation, little is known about the progress of functional capacity post-transplant. Our aim is to assess the effect of renal transplantation and various factors on functional capacity.

Methods: From the United States Organ Procurement and Transplantation Network files, we identified a total of 19,704 renal transplant recipients (RTR) maintained on tacrolimus-based immunotherapy, who had Karnofsky Performance Status Scale (KPSS) defined functional capacity assessment at the time of transplant evaluation with five-years data follow up. Age, gender, ethnicity, functional status, diabetes, body mass index, cold ischemia time, number of previous transplants, panel reactive antibodies, donor type, donor age, HLA-mismatches, number of acute rejection episodes, induction therapies, maintenance immunotherapy on discharge were collected. According to KPSS, RTRs at time of transplant evaluation were divided into 3 groups (A: 13,701 RTRs with mild impairment: >80%, B: 5,557 RTRs with moderate impairment: 40-80%, C: 446 RTRs with severe impairment: <40%). The outcome measured was KPSS functional status five-years post-transplant. Multiple logistic regression analysis was used to assess factors affecting functional status post-transplant.

Results: In group A, 86.45% of patients showed improvement in functional capacity, 65.5% in group B, while 88.56% improved in group C (64.57% improved from severe to mild and 23.99% improved from severe to moderate functional capacity). Furthermore, multiple logistic regression analysis showed that steroid withdrawal protocol was associated with significant improvement in functional capacity (OR=1.28, 95% Confidence Interval (95% CI): 1.1 - 1.49; P=0.007), while dialysis duration before transplantation was associated with abnormal functional capacity post-transplant (OR=0.74, 95% CI: 0.61 - 0.89; P=0.003).

Conclusions: Renal transplantation is associated with substantial improvement in all stages of functional capacity in RTRs. Steroid withdrawal as well as the duration of dialysis are important novel determinant factors of functional capacity post-transplant and merit considerations during transplant selection and subsequent immunosuppressive therapeutic planning.

PO2541

Calcineurin Inhibitor-Based Immunosuppression Has Negligible Negative Effects on Pregnancy Outcomes After Renal Transplantation in the Netherlands

Lisanne M. Koenjer,[1] Jildau R. Meinderts,[3] Olivier W. van der Heijden,[1] Titia Lely,[2] Margriet de Jong,[3] Renate G. van der Molen,[1] Henk W. Van Hamersvelt.[1] Pregnancy After Renal Transplant OUTcomes (PARTOUT) Network *[1]Radboudumc, Nijmegen, Netherlands; [2]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [3]Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

Background: Pregnancy among renal transplant recipients (RTR) has increased over the past years, also in patients with compromised renal function and/or proteinuria. Immunosuppressive regimens may influence pregnancy outcomes and it is not yet clear whether replacing a calcineurin inhibitor (CNI) by a CNI-free (CNI-) regimen has a favourable effect.

Methods: We therefore retrospectively compared the effect of CNI-based (CNI+) and CNI- immunosuppression in the first trimester of pregnancy on maternal and fetal outcomes in Dutch pregnancies between 1986-2017 in RTR.

Results: We identified 129 CNI+ and 125 CNI- singleton pregnancies. Demographics did not differ except for higher BMI in CNI+ (median 25.3 vs 23.7 kg/m2, p=0.01), year of renal transplantation (2000 in CNI+ vs 1989 in CNI-, p<0.01), year of pregnancy (2006 in CNI+ vs 1998 in CNI-; p<0.01) and interval of transplantation to pregnancy (69 in CNI+ vs 104 months in CNI-; p<0.01). In the third trimester creatinine levels were significantly higher in CNI+ (127 vs 105 µmol/L in CNI-, P<0.01) but this difference had disappeared 6-18 months postpartum. The percentual change in creatinine from preconceptional to the third trimester level was slightly different (+3.1% in CNI+ vs 2.2% in CNI-, P=0.05). In both groups, a postpartum 11-12% creatinine increase from preconceptional level was observed (p=0.92). Regarding fetal outcomes, a trend in increased incidence of birthweight <2500 grams was seen in CNI+ (52% vs 40%, p=0.07) and in both groups there was a high rate of preterm delivery <37 weeks (49% vs 45% in CNI-; p=0.55).

Conclusions: Our data indicate that CNI do not negatively influence the course of renal function up to 18 months postpartum, but only lead to a more pronounced increase in serum creatinine levels towards the end of pregnancy. However, the substantial short term loss of renal function and the high rates of premature birth rate and low birthweight classify them as high-risk pregnancies that should be followed carefully in tertiairy obstetric/nephrologic care programs. Our data do not exclude possible long term negative effects of CNI on overall health, renal function or hypertension in the offspring of these women.

PO2542

The Natural History of Waitlist Candidates in the United States

Allan Massie, Dorry L. Segev. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Estimates of time to deceased-donor transplantation (DDKT) generally fail to take into account the competing risks of mortality. Understanding the natural history of KT registrants - their chance of DDKT/LDKT/death based on individual characteristics - can inform referrals for transplantation, counseling for transplant candidates, and allocation policy.

Methods: Using SRTR data on 186,174 waitlist registrants 12/2014-12/2019, we modeled time to DDKT, LDKT, or waitlist mortality in a competing-risks framework, overall and for clinically relevant subgroups of patients (based on candidate age, sex, race, ABO blood type, PRA). Competing-risks regression was used to model individual n-year chance of DDKT/LDKT/mortality based on candidate characteristics.

Results: Among all candidates, 5-year cumulative incidence of LDKT/DDKT/mortality/other removal was 17.3%/34.4%/15.7/18.1% respectively. 85% of LDKT recipients received LDKT within 2 years of listing. Pediatric registrants had substantially higher incidence of DDKT than waitlist mortality (61.7% vs 1.1%), but adults had higher combined of waitlist mortality/other removal DDKT, particularly patients above age 65 (44.4% vs 32.3%) (Figure). Center-level 5-year incidence of LDKT (DDKT) 1.3%-44.8% (4.4%-82.6%) (Figure 2).

Conclusions: Despite a focus in the transplant community on small differences in one-year posttransplant outcomes and a reluctance to transplant kidneys with slightly worse expected outcomes, most adult patients wait >5 years for a kidney, incurring substantial waitlist mortality risk. High incidence of waitlist mortality will only be remedied through aggressive efforts to increase the living and deceased donor organ pool.

PO2543

Unusual Cause of Calcium Oxalate Nephropathy in a Renal Allograft

JoBeth McCoy, Anthony J. Langone. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Crystal nephropathy is a well-known cause of acute kidney injury that is often overlooked. We present a case of oxalate nephropathy in a renal allograft that led to a rare diagnosis.

Case Description: A 63-year-old female with a kidney transplant for end-stage kidney disease (ESKD) caused by acute interstitial nephritis (AIN) presented with acute kidney injury. Her creatinine on presentation was 2.2mg/ dL from her baseline of 1.0mg/dL and increased to around 3.0mg/dL despite hydration. It was decided that she would benefit from allograft biopsy. The biopsy was devoid of any rejection but did have many foci of calcium oxalate crystal deposition with tubular injury. She was planned for a 24-hour urine collection for stone evaluation that showed an elevated urine oxalate level, 140mg. She changed her diet and the 24-hour urine collection was repeated in 3 months with no change. With the continued elevation, genetic testing was sent for primary hyperoxaluria which revealed that she has homozygote mutation in the AGXT gene, confirming that she has type 1 primary hyperoxaluria. Reevaluation of her biopsy diagnosing AIN before transplant was found to have interstitial multinuclear infiltrate with some crystallization consistent with oxalate nephropathy. Her particular mutation responds well to pyridoxine (vitamin B6) so she was started on 600mg per day. Since treatment, her creatinine has stabilized at 3.0mg/dL. Her 24-hour urine evaluation has shown improvement in urine oxalate to 79mg, a 43.5% reduction.

Discussion: Primary hyperoxaluria type 1 (PH 1) is described by recurrence in a renal allograft in only 10% of cases. Delay in the diagnosis is common and results in a significant number of patients who have end-stage kidney disease (ESKD) at initial presentation. The rapidity of progression is determined by the residual enzyme activity and response to pyridoxine(vitamin B6). The definitive cure for PH 1 is liver transplantation that carries significant mortality risk. Medical management includes large fluid intake of greater than 3L/day to decrease tubular fluid oxalate concentration, potassium citrate-citric acid to increase the solubility of calcium oxalate and prevent precipitation, avoidance of oxalate in diet, and high dose pyridoxine to promote the conversion of glyoxylate to glycine rather than to oxalate. A trial of 5mg/kg of pyridoxine is suggested in all PH 1 patients to see how they respond.

PO2544

Secondary Oxalosis with Enteric Oxalate Nephropathy in a Transplant Recipient: Is Mycophenolate the Culprit?

Himmat S. Brar, Nihal M. Ali, Franco H. Cabeza Rivera. *University of Mississippi Medical Center, Jackson, MS.*

Introduction: Secondary oxalosis causing acute kidney injury has been widely reported in native kidneys but its occurrence in allograft kidneys is relatively uncommon. Intestinal malabsorption can be present in transplant recipients as a result of factors that differ from the general population such as immunosuppressive medications and some enteral infections. We present a case of enteric oxalate nephropathy as a result of mycophenolate toxicity.

Case Description: A 66-year-old male status post kidney transplant 3 years back for ESKD due to DM and HTN with a baseline creatinine of 1.5 mg/dL presented with a 2-month history of GI symptoms of vomiting, diarrhea and 22 lbs weight loss. He was on tacrolimus, mycophenolate and prednisone for immunosuppression. The patient denied any recent infection or antibiotic use, any medication change, supplements or OTC drug use. The vitals and the physical examination on admission were unremarkable. Lab findings showed Na 139, K 5.5, Cl 117, Bicarb 11, AG 22, Ca 9.6, BUN 71 and creatinine 3.5. Lactate and serum osmolar gap were normal. Lipase, amylase, Vit B1 and B6 were normal. UA showed trace ketones and blood with no protein or bacteria. Serology for CMV and BK virus was negative. Tacrolimus level was at goal. MPA level was noted to be elevated at 9.7 at an office visit 1 month prior to admission with no recent adjustment in dosing. Plasma oxalate was elevated at 3.9. The stools studies and GI panel were negative. CT scan showed a 3mm non-obstructing stone. The renal biopsy showed interstitial fibrosis, tubular atrophy and calcium oxalate deposits with birefringence within the tubules. MMF was discontinued. The patient was given iv fluids and citrate to alkalize the urine. At discharge, his Cr improved with resolution of symptoms.

Discussion: Medication-induced malabsorption should be considered among potential causes of secondary oxalosis. The MMF metabolites indirectly affect lymphocytes in the GI tract leading to mucosal damage with malabsorption and enteric oxalosis. The hyperoxalosis causes saturation of oxalate crystals creating an interstitial nephritis, macrophage recruitment and inflammation leading to tubular atrophy. The transplant recipients with chronic diarrhea and no infection should be suspected for MMF toxicity. The oxalate and MMF levels must be checked and MMF dose should be adjusted accordingly.

PO2545

Prophylactic Use of Eculizumab and Graft Loss in Kidney Transplant Recipients due to Hemolytic Uremic Syndrome in the United States

Richard A. Plasse,[1,2] Stephen W. Olson,[1,2] Christina M. Yuan,[1,2] Lawrence Agodoa,[3] Kevin C. Abbott,[3] Robert Nee.[1,2] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Uniformed Services University of the Health Sciences F Edward Hebert School of Medicine, Bethesda, MD; [3]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Among kidney transplant recipients (KTRs) with end-stage kidney disease (ESKD) due to hemolytic uremic syndrome (HUS), recurrence is associated with poor allograft outcomes. We examined the prophylactic use of eculizumab, a monoclonal antibody that binds complement protein C5, and graft loss among HUS KTRs.

Methods: We conducted a retrospective cohort study using the United States Renal Data System. Out of 123,624 ESKD patients transplanted between January 1, 2008 and June 1, 2016, we identified 348 (0.28%) patients who had HUS as the primary cause of ESKD. We then linked these HUS patients to datasets containing the Healthcare Common Procedure Coding System (HCPCS) code for eculizumab infusion. We calculated crude incidence rates of overall graft loss and death-censored graft loss and conducted exact logistic regression, adjusted for recipient age and sex. Patients who received eculizumab prior to or within 30 days of transplant represented the exposure group.

Results: Our final study cohort included 335 HUS KTRs (23 received eculizumab, 312 did not). There were no significant differences in baseline demographic and clinical characteristics between the eculizumab vs. non-eculizumab group. For those who received eculizumab, the median number of infusions per patient was 42 (IQR 16, 66). The median payment amount per patient was $706,518 (IQR 241,237, 1,306,453). Eculizumab was discontinued in 9 out of 23 patients (39%), after a median prophylactic duration of 329 days (IQR 127, 791). As shown in the Table, the eculizumab group had no graft loss vs. 20% in the non-eculizumab group, with an adjusted odds ratio of 0.13.

Conclusions: Prophylactic use of eculizumab in HUS KTRs was significantly associated with a lower risk of graft loss. Given the high cost of eculizumab, randomized controlled trials are much-needed to guide prophylactic strategies to prevent graft loss.

	Percentages		Crude incidence rates		Adjusted Odds Ratio	
	Overall graft Loss	Death-censored graft loss	Overall graft Loss (per 1000 patient-years)	Death-censored graft loss (per 1000 patient years)	Overall graft Loss (Eculizumab vs. No Eculizumab)	Death-censored graft loss (Eculizumab vs. No Eculizumab)
Eculizumab	0/23 (0%)	0/23 (0%)	0	0	0.13	0.18
No Eculizumab	64/312 (20.5%)	48/312 (15.4%)	35 (95% CI 27-45)	26 (95% CI 20-35)	(95% CI 0-0.74)	(95% CI 0-1.05)
P value	0.02	0.04	0.02	0.04	0.02	0.06

PO2546

Post-Kidney Transplant Serum Magnesium Exhibits a U-Shaped Association with Subsequent Mortality

Annalise M. Panthofer, Beini Lyu, Brad C. Astor, Tripti Singh, Fahad Aziz, Didier A. Mandelbrot, Sandesh Parajuli, Maha A. Mohamed, Arjang Djamali, Neetika Garg. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Hypomagnesemia is common in kidney transplant recipients (KTR), likely due, at least in part, to renal magnesium (Mg) wasting related to calcineurin-inhibitor (CNI) use. The association of serum Mg levels and KTR outcomes may provide insight into the optimal serum Mg levels in this population.

Methods: KTRs between 01/2000 and 12/2016 at a large US transplant center who were alive with a functioning graft at 6 months post-transplant were included. Mean of the outpatient serum Mg in the baseline period, i.e. 6 to 18 months post-transplant, was used. Cox proportional-hazards regression was used to analyze the association between Mg and all-cause mortality, cause-specific mortality, and risk of new-onset cardiovascular events post-transplant.

Results: 2,131 KTRs met our inclusion criteria. Mean number of Mg measurements per patient in the baseline period was 2.76. A U-shaped association between the mean baseline Mg level and all-cause mortality was observed in both unadjusted analysis and after adjusting for baseline characteristics, including eGFR and CNI levels. A mean Mg of 1.5 - 1.8 mg/dL was associated with the lowest incidence of death (Figure). Compared with Mg of 1.5 - 1.8 mg/dL, Mg level ≤ 1.5 mg/dL was also associated with higher incidence of mortality due to infection and arrhythmia but not ischemic heart disease or heart failure.

Conclusions: The relationship between serum Mg levels and mortality in KTRs is U-shaped. Interestingly, the risk is lowest with Mg levels 1.5 - 1.8 mg/dL; which represents the lower end of normal (1.6 - 2.6 mg/dL). Mg supplements for levels ≤ 1.5 mg/dL may be beneficial, but may cause increased renal wasting and diarrhea. Further studies are needed to understand why Mg > 1.8 mg/dL but well within the normal range was associated with higher risk despite adjustment for eGFR.

PO2547

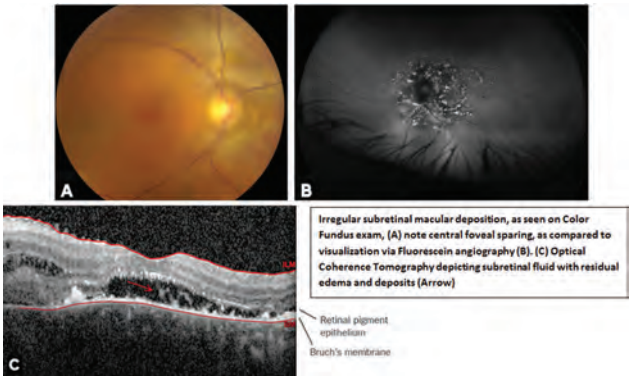
A Case of Subretinal IgA Deposition in a Patient with IgA Nephropathy and Early Allograft Recurrence

Mahnoor M. Khan, Lyle W. Baker, Sarah T. Suliman, Martin L. Mai. *Mayo Clinic's Campus in Florida, Jacksonville, FL.*

Introduction: IgA Nephropathy (IgAN) has variable clinical manifestations and a 30% recurrence, which is typically a late complication in renal transplant recipients. Ocular involvement in patients with IgAN is extremely rare. Thus, eye findings as a predictor of worse prognosis, including higher risk of recurrence, remains unexplored.

Case Description: A 66 year old Caucasian male with end-stage renal disease secondary to a 10 year history of IgAN complicated by retinal detachment and optic neuropathy with recent decline in visual acuity, underwent living related donor renal transplantation from his twin sister with Basiliximab induction. A month prior, Optical Coherence Tomography (OCT) had revealed bilateral macular edema and subretinal pigment deposits with central foveal sparing, consistent with IgA maculopathy. Post-operative course was uneventful with immediate allograft function and normalization of creatinine. 4 months later, repeat OCT showed improved retinopathy and ocular edema. However, renal function declined 2 months later, with persistently elevated Creatinine between 1.4-1.5 mg/dL. Allograft biopsy showed hypercellular endocapillary proliferation, glomerulitis and granular mesangial staining for IgA, IgM, Kappa and Lambda on Immunofluorescence, consistent with recurrent IgAN. Pulse-dose steroids were subsequently initiated.

Discussion: The pivotal role of the complement system has been implicated in IgA deposition between the retinal pigment epithelium (RPE) and Bruch's membrane, a complex exposed to circulating immune complexes similar to glomerular basement membrane. To our knowledge, this is the first reported case of IgA maculopathy involving subretinal deposition with recurrence of primary disease in the renal allograft within 1 year. Given the lack of non-invasive testing and dynamic clinical features encompassed by IgAN, the link between ocular pathology and patient-specific morbidity including recurrence, despite clinical improvement in initial eye disease, needs exploration.



PO2548

Virtual Reality, a New Vision Becoming Our New Actuality: A Retrospective Study Comparing Virtual Crossmatch vs. Physical Crossmatch at Tampa General Hospital

Fernando Moran,[1] Timothy M. Chow,[3] Martin Aldana,[2,5] John Lunz.[4] *[1]Division of Nephrology University of South Florida, Tampa, FL; [2]Nephrology and Transplantation University of South Florida, Tampa, FL; [3]Division of Internal Medicine University of South Florida, Tampa, FL; [4]LifeLink Foundation Transplantation Immunology Laboratory, Tampa, FL; [5]Florida Kidney Physicians, Tampa, FL.*

Background: A crossmatch (XM) is required prior to kidney transplantation to ensure immunological compatibility between recipient and donor. This test is prone to false positive reactivity and can increase cold ischemic time (CIT) especially for organs procured outside the region of the transplanting hospital. Advances in HLA antibody testing and donor HLA antigen typing facilitate the use of a virtual XM (VXM) based on pre-transplant testing results to accurately predict a physical XM (PXM) result. Frequent antibody screening and an accurate history of sensitizing events further ensures that the VXM can predict immunological compatibility, even without retrospective PXM.

Methods: We compared the 6 mo. clinical outcomes of kidney recipients who proceeded to transplant with only a VXM (without retrospective PXM) to those receiving a PXM. 182 recipients with 6 mo. follow-up were reviewed for biopsy data, serum Cr and UPCR. Patients were grouped according to the transplant type (living donor (LD) vs. deceased donor (DD)) and XM type (PXM vs. VXM). LD recipients had a PXM (n=42). Patients with a VXM (n=76) were donor-specific antibody (DSA)-free and had a current tested sample within 30 days. DD recipients had PXM (n=64) due to the presence of DSA (current or historic) or the absence of a current tested sample within 30 days. All patients with PXM had an acceptable flow cytometric XM.

Results: Patients proceeding to transplant with a VXM tended to be less sensitized (32% with PRA >0%) compared to DD-PXM (66%) and LD-PXM (49%). For DD recipients, CIT was significantly reduced in patients receiving a VXM (727 vs 871 min; p=0.013). Within the first 6 mo. of follow-up, 67 for cause biopsies were performed. Rejection (T-cell or antibody mediated) was observed in 15 patients (7 DD-VXM, 6 DD-PXM and 3 LD-PXM). Interestingly, antibody mediated rejection was only observed in DD-PXM (n=3) or LD-PXM (n=1) groups.

Conclusions: In our cohort, kidney transplantation with an acceptable VXM was beneficial in reducing CIT and rejection was similar to DD recipients needing a PXM within the first 6 mo. post-transplant. Utilizing VXM helps facilitate kidney transplantation, permits entertaining offers from greater distances, and reduces laboratory burden with similar outcomes to when a PXM is performed.

PO2549

Reassessing Renal Transplantation in Light-Chain Deposition Disease

Elena Cuadrado, Alicia M. Andújar, Nuria Esforzado, David Cucchiari, Frederic Cofan, Ignacio Revuelta, Esteban Poch, Fritz Diekmann, Luis F. Quintana. *Hospital Clinic de Barcelona, Barcelona, Spain.*

Background: Light chain deposition disease (LCDD) is a systemic rare condition that usually leads to end stage renal disease. Treatment with a bortezomib-based regimen, followed by autologous stem cell transplantation (ASCT) has been increasingly used with improvements in the response rates and the renal graft outcomes in kidney transplant recipients.

Methods: Retrospective study of 6 patients diagnosed of LCDD with complete response but not renal response after hematologic treatment that underwent kidney transplant in our institution between 2010 and 2019.

Results: A total of 6 patients (5 women) were analyzed, with mean age at diagnosis of 47 years, mean eGFR of 18 mL/minute and mean proteinuria of 5.5 g. Deposit was kappa type except in 1 case (heavy and light lambda type chains). In all of them there was an absence of monoclonal component in blood and urine but positive immunofixation in 5 cases (2 only in urine). 3 started chronic hemodialysis during admission and the others at 3, 5 and 44 months after diagnosis. As hematological treatment, all received bortezomib followed by ASCT, being under complete hematological response at the time of kidney transplant, which was performed at 28 months on average from ASCT. Mean kappa/lambda ratio was 2.6. 3 patients received induction with thymoglobulin and 3 with basiliximab, followed by triple therapy with tacrolimus+prednisone+mTOR inhibitor (4 patients) or mycophenolate (2 patients). After 36 months of mean follow-up after kidney transplant, 3 patients have suffered an hematological relapse, one of them including kidney involvement with graft loss at 46 months post-transplant. The remaining 5 continue with a functional graft with a mean creatinine of 1.54 mg/dL.

Conclusions: When sustained complete hematologic response is achieved but renal impairment with dialysis requirement persists, patients could benefit from a kidney transplant with good results.

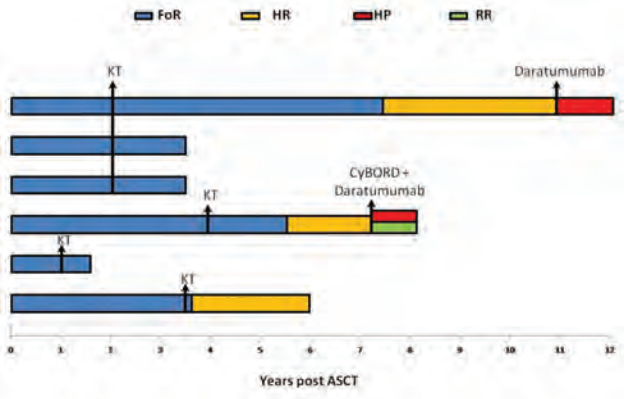


Figure 1. Patient outcomes. ASCT: autologous stem cell transplantation, FoR: free of relapse, HR: hematologic relapse, HP: hematologic progression, RR: renal relapse, KT: kidney transplant, CyBORD: Cyclophosphamide, bortezomib and dexamethasone

PO2550

Granulomatous Interstitial Nephritis and Allograft Failure Secondary to Adenovirus Reactivation

Mahnoor M. Khan, Lyle W. Baker, Sarah T. Suliman, Hani Wadei. *Mayo Clinic, Jacksonville, FL.*

Introduction: With an incidence of about 4% in renal transplant recipients, the typically self-limited adenovirus renders an infrequent propensity to cause allograft failure and life-threatening opportunistic infection in severe cases.

Case Description: A 29 year old female with history of living donor kidney transplant due to Henoch Schonlein Purpura (HSP) Glomerulonephritis with subsequent allograft failure underwent deceased donor re-transplantation with Anti-Thymocyte globulin induction. Post-op course was uneventful. Creatinine was 0.8 mg/dL on 4 month follow up. 6 months post-transplant, patient developed gross hematuria with clots, fever and acute kidney injury with creatinine of 2.82 mg/dL. Biopsy revealed granulomatous tubulointerstitial nephritis, extensive intra-nuclear viral inclusions with positive adenovirus immunohistochemistry (IHC). Mycophenolate Mofetil was discontinued and creatinine improved to 1.1 mg/dL. 3 months later, she was admitted for renal failure with creatinine of 7.2 mg/dL. Adenovirus was detected in the serum and urine. Repeat biopsy revealed markedly reactive tubular epithelium, widespread viral inclusions with negative adenovirus IHC, consistent with adenovirus nephropathy. Following a decrease in immunosuppression with improvement in renal function, adenovirus viral load became undetectable in both plasma and urine. The use of Cidofovir was considered for treatment; however, given risk of nephrotoxicity, was ultimately deferred after response to conservative treatment.

Discussion: Recurrence of HSP was in the broad differential given the initial presentation. Given its rarity, a paucity of cases and epidemiologic literature exists in illustrating allograft failure due to adenovirus nephropathy. Further research is not only needed to expand awareness of its presenting features and characteristic biopsy findings, but also, to limit more familiar culprits in masquerading as the elusive adenovirus infection, particularly in light of indeterminate therapeutic modalities.

PO2551

Phospholipase A2 Receptor Antibody Level Directed Management of Membranous Glomerulopathy After Transplant

Irfan Agha,[1,2] Amna Ilahe,[1,3] Silvi Simon,[1,3] Rama Nadella,[1,2] Diana Mahbod,[1] Richard Dickerman.[3] *[1]Dallas Renal Rroup, Dallas, TX; [2]Medical City Dallas Hospital, Dallas, TX; [3]Methodist Dallas Medical Center, Dallas, TX.*

Introduction: MN can recur after transplantation. Patients with high PLA2R Ab are at higher risk. There is equipoise on how to manage these patients. We present two cases to highlight PLA2R Ab level directed approach to management.

Case Description: Case 1: 35 YO AA female with MN diagnosed in 2013. Failed cytotoxic therapy and started RRT. Received a DD kidney transplant in Sep 2018. Given Thymoglobulin, tacrolimus, mycophenolate and prednisone. Pretransplant PLA2R titer 1:2560 by IIF. Titer serially monitored. After an initial decline, titer increase with precipitation of proteinuria noted. Biopsy confirmed early recurrent MN. Treated with 2 doses of Rituximab. Subsequent titers dropped with complete remission. Case 2: 65 YO W male with biopsy demonstrated MN (2015), on RRT since 2017 underwent DD kidney transplant in May 2019. Given Thymoglobulin and maintained on tacrolimus, mycophenolate and prednisone. Pretransplant PLA2 R Ab level was 164 RU/ml by EIA with 3.5 g/g of protein. His PLA2R Ab levels dropped and proteinuria rapidly & durably resolved after transplant. One year out, his PLA2R Ab is at 24 RU/ml with 0.11 g/g protein in the urine and a creatinine of 1.2 mg/dl.

Discussion: High PLA2 R Ab at the time of transplant is a significant risk factor for recurrent MN. PLA2R Ab levels should be monitored to direct care: decreasing PLA2R Ab should be followed conservatively. If Ab levels increase or proteinuria develops, perform biopsy to confirm diagnosis and initiate therapy expeditiously. PLA2R Ab levels should be monitored post treatment to ensure resolution. This approach allows stratification and directed therapy of patients with MN undergoing transplantation and avoids over treatment.

PO2552

De Novo Membranous Nephropathy and Donor-Specific Alloantibodies: A Path to the Pathophysiology?

Megan A. Tierney, Pradeep Vaitla, Wisit Cheungpasitporn, Franco H. Cabeza Rivera. *University of Mississippi Medical Center, Jackson, MS.*

Introduction: While pathophysiology of post-transplant membranous nephropathy due to recurrence of primary disease is established, less is known about the development of primary de novo membranous nephropathy (dnMN). We report a case of dnMN associated with antibody-mediated rejection in a transplant recipient with end-stage kidney disease secondary to focal segmental glomerulosclerosis (FSGS).

Case Description: A 20-year-old African American female with FSGS status-post deceased donor kidney transplant eight years ago presented with acute lower extremity edema and acute kidney injury concerning for acute rejection. She has no history of prior rejection or medication non-adherence. Ultrasound showed mild hydronephrosis. Biopsy showed Banff Type IB acute-cell mediated rejection (t2, i2) and Stage 1 membranous glomerulopathy. Serum phospholipase A2 receptor (anti-PLA2R) antibodies were negative. Donor specific antibodies (DSA) testing revealed the presence of DQ5, DQ7, and DRB1*01:03. Diagnosis of coexistence of Banff Type IB acute-cell mediated rejection, positive de novo DSA, and dnMN was made. She was treated with five doses of antithymocyte globulin (1.5 mg/kg/dose) and plasma exchange (PLEX) followed by IV immune globulin (IVIg). Repeat DSA after fifth session of PLEX showed clearance of DRB*01:03 and reduced DQ antibody levels; after seventh session of PLEX, however, DQ antibodies had plateaued. Biopsy performed after PLEX and antithymocyte globulin showed chronic active T cell-mediated rejection Grade IB (ti3, t3, and I-IFTA2) and persistent Stage 1 membranous glomerulopathy; in the setting of persistent DQ antibodies, this suggested failure of transplanted organ within the next 6-12 months. The patient was prepared for this eventuality, received a final session of PLEX and IVIg and discharged in otherwise stable condition.

Discussion: Only one case of dnMN associated with HLA-DQ7 DSA has been previously reported (El Kossi Clin Transplant 2008). This case not only reports the unique occurrence of two glomerulonephropathies in one patient, but also provides support that post-transplant dnMN can be seen in the context of humoral alloreactivity, and DSA might play some roles for the pathogenesis in some patients with dnMN after kidney transplantation (Honda Clin Transplant 2011).

PO2553

Histological Predictors of Graft Failure in Kidney Transplant Recipients

Maria Ajaimy, Yorg Al Azzi, Purna Bindu Nandigam, Pablo Loarte Campos, Cindy T. Pynadath, Luz E. Liriano-Ward, Enver Akalin. *Montefiore Medical Center, Bronx, NY.*

Background: We aimed to identify the predictors of allograft failure in a large cohort of kidney recipients who underwent clinically indicated graft biopsies. We aimed to explore the importance of interstitial inflammation in biopsies with interstitial fibrosis and tubular atrophy(IFTA).

Methods: We retrospectively evaluated 516 patients who underwent transplant biopsy between 1/2009 and 1/2018. Acute and chronic allograft injury scores of Banff classification were used. We sub grouped the patients with chronic allograft injury score (ci+ct+cv) ≥ 3 or< 3 and sub grouped per interstitial inflammation (i score=0 and > 0)and compared to biopsies with both ci+ct+cv=0 and i=0.

Results: Biopsies were done at a median 12.5 months after kidney transplantation. The histopathological diagnosis were as following: acute antibody-mediated rejection (AMR) (6%), acute T-cell mediated rejection (9.3%), chronic AMR (6.7%), transplant glomerulopathy without donor-specific antibody (DSA) (10.2%), recurrent/de novo glomerular disease (10.8%), BKV nephropathy (2.5%), and the rest 54.2% had other diagnosis (normal, acute tubular necrosis, or non-specific IFTA). During a median follow up of 59.3 months after kidney biopsy, 36 %recipients lost their graft. In univariate analysis, the following factors were significant for graft loss: Black race (p=0.005), previous rejection (p<0.0001), DSA at the time of biopsy (p=0.014), ci+ct+cv ≥ 3 (p=0.0485), ci+ct+cv ≥ 3 with interstitial inflammation > 0 (p<0.0001), microvascular inflammation (p=0.0052), C4d positivity (p=0.008), serum creatinine at time of the biopsy (p<0.0001), and spot urine protein/creatinine (<0.0001). In the multivariate analysis ci+ct+cv < 3 with i>0 has the highest hazard ratio followed by ci+ct+cv ≥ 3 with i>0, ci+ct+cv ≥ 3 with i=0, black race, creatinine, and proteinuria.

Conclusions: Interstitial inflammation is the best predictor for allograft loss after clinically indicated kidney biopsy regardless of the severity of chronic allograft injury score.

Risk Factor	HR	95% CI	P-value
ci+ct+cv < 3 with i>0	8.38	3.22 – 21.78	<0.0001
ci+ct+cv ≥ 3 with i>0	2.92	1.47-5.82	<0.0001
ci+ct+cv ≥ 3 with i=0	2.69	1.33-5.44	<0.0001
Black Race	2.04	1.43-2.89	<0.0001
Serum Creatinine	1.27	1.18-1.37	<0.0001
Spot urine protein/creatinine	1.11	1.06-1.17	<0.0001

PO2554

A Case of Antibody-Mediated Rejection (ABMR) After Withdrawal of Etanercept in a Renal Transplant Recipient

Iris Jill E. Uy, Mohammad Abuzeineh, Sami Alasfar, Fizza F. Naqvi, Brandon L. Trollinger. *Johns Hopkins Medicine, Baltimore, MD.*

Introduction: Etanercept is a tumor necrosis factor (TNF) receptor fusion protein that is used to manage several forms of inflammatory arthritis and psoriasis. Herein, we present a renal transplant recipient who was concomitantly treated with Etanercept for psoriasis and subsequently developed two episodes of ABMR after the drug's withdrawal

Case Description: A 41-year-old man with history of psoriasis and end stage renal disease due to hypertensive nephrosclerosis and interstitial nephritis who underwent living related kidney transplant from his brother in December 2008. He was being treated for psoriasis with Etanercept which was withdrawn in September 2012. Subsequently he had rising serum creatinine (Cr) from baseline of 1.3 to 1.6 mg/dL and developed de-novo donor specific antibodies (DSA) to DR11 and DQ7 with positive cytotoxicity crossmatch. Renal allograft biopsy showed evidence of Banff 2A acute cellular rejection, ABMR, chronic glomerulonephritis and interstitial nephritis. He was treated with high dose steroids, 10 sessions of plasmapheresis with intravenous immunoglobulin (IVIG), and Rituximab. His Cr improved to 1.2 mg/dL but DSA remained positive. Later on he was restarted on Etanercept which was withdrawn again in March 2019. Accordingly, in September 2019, he developed acute kidney injury with Cr up to 1.7 from baseline of 1.3-1.5 mg/dL associated with nephrotic range proteinuria. He had a rise in DSA to DQ7, and developed new DSA to A2 and B60 with positive cytotoxicity crossmatch. Donor derived cell free DNA was elevated at 4.4%. Allograft biopsy showed glomerulitis, peritubular capillaritis with positive c4d, consistent with ABMR. He was treated with high dose steroids, 5 sessions of plasmapheresis with IVIG and Rituximab. Repeat DSA showed reduction in A2, but no change in DQ7. His serum Cr improved but his proteinuria remained at nephrotic range

Discussion: Despite the use of Etanercept in the treatment of graft versus host disease among transplant recipients, it hasn't been studied as a potential immunosuppressive drug. In our patient, Etanercept seemed to provide anti-rejection effect as shown by two episodes of ABMR with de-novo DSA after the drug's withdrawal. Close monitoring of renal function and DSA may be warranted once Etanercept or other TNF inhibitors are withdrawn in transplant recipients

PO2556

Molecular Analysis of Renal Graft Biopsies: Comparing the Edmonton Molecular Microscope with the NanoString Human Organ Transplant Panel

Jessica Schmitz,[1] Helge Stark,[2,3] Stephan Bartels,[4] Danny Jonigk,[2,3] Philip F. Halloran,[5,6] Gunilla Einecke,[7] Jan H. Braesen.[1] *[1]Hannover Medical School, Medizinische Hochschule Hannover, Institute of Pathology, Nephropathology Unit, Hannover, Germany; [2]Hannover Medical School, Institute of Pathology, Hannover, Germany; [3]Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Hannover, Germany; [4]Hannover Medical School, Institute of Pathology, Molecular Pathology, Hannover, Germany; [5]University of Alberta, Edmonton, Edmonton, AB, Canada; [6]Alberta Transplant Applied Genomics Center, Edmonton, AB, Canada; [7]Hannover Medical School, Department of Nephrology and Hypertension, Hannover, Germany.*

Background: The renal transplant biopsy is the diagnostic gold standard and usually evaluated with the continuously expanded and updated Banff classification which is based on on descriptive, empirically-derived criteria and thus lacks precision. High-resolution determination of the graft inflammation by NanoString analysis, which was developed for formalin-fixed paraffin-embedded-derived (FFPE) RNA, should be a sufficient approach for objective molecular diagnosis of renal transplant biopsies and may improve our understanding of graft biology.

Methods: We used well-annotated surveillance and indication biopsies from 63 patients whose time-matched second biopsy core had been frozen and analyzed by microarray in the INTERCOM/INTERCOMEX study. After reevaluation according to recent Banff consensus, RNA isolation of the FFPE biopsy was performed and led to sufficient RNA yields in 53 samples which were further processed for NanoString analysis using the nCounter Human Organ Transplant Panel.

Results: Morphologically, of the 53 samples analyzed (samples from 2011/12 and 2015), twenty-five patients showed no signs of rejection, twelve had borderline rejection,

four showed cellular rejection, seven had humoral rejection, and five presented with combined rejection. Preliminary analysis of gene expression by T-distributed Stochastic Neighbor Embedding (t- SNE), Random Forest and Principal Component Analysis (PCA) showed clear differences between samples with rejection (humoral and cellular) and without rejection. Rejection samples revealed high expression of chemokine ligands compared to rejection-free tissues. A common pattern of samples without rejection and borderline rejection was observed. Our results displayed good correlation with the former molecular microarray-based diagnosis from the INTERCOM/INTERCOMEX study.

Conclusions: Molecular diagnostic approach using the NanoString platform may supplement morphological diagnosis of renal grafts especially in unclear cases and thus enhance precision diagnostics with small tissue requirement. Morphological and molecular evaluation in the same biopsy core from FFPE tissue enables direct histological-molecular correlation. Additionally, this technology also improves our understanding of pathophysiology in renal and other transplants.

PO2557

Donor Biopsy and Kidney Transplant Outcomes in Pediatric Recipients

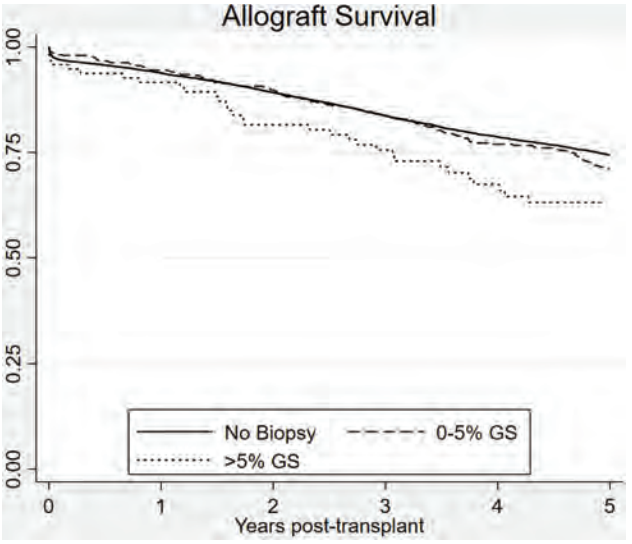
Ahmad Mashmoushi,[3] Christine S. Hwang,[2,4] Malcolm Macconmara.[1,4] *[1]University of Texas Southwestern Department of Surgery, Dallas, TX; [2]University of Texas Southwestern Medical Center, Division of Surgical Transplantation, Department of Surgery, Dallas, TX; [3]University of Texas Southwestern Medical Center, Division of Pediatric Nephrology, Department of Pediatrics, Dallas, TX; [4]Children's Medical Center, Division of Pediatric Transplantation, Dallas, TX.*

Background: Deceased Donor DD kidney biopsies are routinely used in the context of clinical concerns about donor quality in adult kidney transplants. We sought to examine the use of DD kidney biopsies in pediatric transplants. We aim to evaluate prognostic utility of glomerulosclerosis GS level in predicting graft outcomes.

Methods: Data was used from recipients who received kidney transplant between 1994 and 2018 documented in the Scientific Registry of Transplant Recipients database. Pediatric recipients were defined as recipients < 18 years who received DD kidney transplant excluding multi-organ transplants. The recepients were further stratified according to degree of donor kidney GS into 0-5% and > 5% categories. Demographic and outcome data were examined and graft survival was evaluated using STATA 16.

Results: 10,045 pediatric recipients received DDKT during this period. 644 had left and/or right DD kidney biopsies, 548 biopsies had 0-5% GS, 96 biopsies had > 5% GS. Biopsies were mostly performed on kidneys harvested from higher risk donors. There was a significant difference in the number of biopsies performed across regions (region 5 lowest at 2.6% and region 9 highest at 17.5%). There was no significant difference among share characteristics or transplant center volume. Allograft survival was significantly worse for donor kidneys with GS>5% compared to 0-5% group and no biopsy group. There was no significant difference in the incidence of DGF, acute rejection, or chronic rejection.

Conclusions: Although the biopsied kidneys are mostly from higher risk donors, the majority of biopsies have GS level 0-5%. At this level of GS there is no difference in allograft survival compared to DD kidneys without biopsies. Thus utilizing kidneys with GS 0-5% can expand the DD kidney pool and should be strongly considered for use in pediatric population.



Kaplan-Meier curve of 5-year allograft survival for pediatric kidney transplant patients by donor kidney glomerular sclerosis (GS)

PO2558

Predictors and Impact of Nephrocalcinosis in Renal Transplant Population: A Monocenter Retrospective Study

Jessie Beaulieu,[1] Léa Thérien,[1] Julie Riopel,[1] Eva Latulippe,[1] David Simonyan,[2] Isabelle Houde,[1] Mohsen Agharazii,[1] Fabrice Mac-Way.[1] *[1]CHU de Québec-Université Laval, CHU de Quebec-Universite Laval, Quebec, QC, Canada; [2]Centre de recherche du CHUQ, Quebec, QC, Canada.*

Background: Persistence of bone and mineral anomalies in post-transplant population has been suggested as contributing factors to nephrocalcinosis (NC) that could lead to graft dysfunction. However, adequate characterization of calcium deposits in biopsies from renal transplant patients are lacking. We thus aimed to determine: 1) the prevalence of NC in renal transplant patients, 2) the factors associated with NC and 3) the impact of NC on renal graft function.

Methods: This is a monocenter retrospective study using a protocolized renal biopsy from CHU de Québec, l'Hôtel-Dieu de Québec hospital from 2016-2018. All renal biopsies performed in 2016 at renal transplantation, at 6 and 24 months post-transplant were qualitatively and quantitatively analyzed for NC. Demographic, comorbidities and biochemistry parameters were collected from patients' records. Appropriate statistical analyses (Pearson's chi-squared, Wilcoxon-Mann-Whitney, Spearman's correlation and logistic regression) were performed to assess factors associated with NC and its impact on graft function.

Results: We included 53 patients (mean age of 52±13 years, 55% of men, 94% with hypertension, 23% with peripheral arterial disease and 19% with prior parathyroidectomy). Forty-nine patients (92%) were on chronic dialysis treatment before transplant for a mean duration of 34±29 months. The presence of NC was observed in 14% at baseline, 37% at 6 months and 50% at 24 months. The severity of NC as assessed by the number of calcified foci in the tubulointerstitial compartment also tended to increase over time. Analyses showed that the presence of NC at 6 months was associated with male sex, presence of NC at baseline and high PTH levels (> 600 ng/L) at the time of transplant. Presence of NC at 24 months was also associated with prior NC and male sex. Interestingly, the presence of NC at 6 months was associated with use of phosphate supplements immediately after engraftment and with active vitamin D treatment at 6 months. Finally, NC at 24 months was correlated with the level of graft function as expected.

Conclusions: This study reveals that uncontrolled mineral and bone metabolism parameters before renal transplant are associated with development of NC in the post-transplant period that may contribute to deterioration of renal graft function.

PO2559

Outcomes of Biopsy-Proven Acute Rejection (BPAR) in ABO-Incompatible Kidney Transplants (ABOi KTx) Compared with a Propensity-Matched Cohort of ABO-Compatible Transplant Recipients (ABOc KTx)

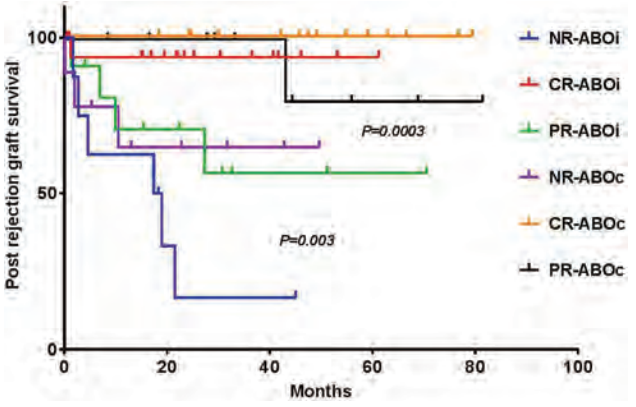
Sabarinath S, Amit Gupta, Manas R. Patel, Ravi S. Kushwaha, Narayan Prasad, Anupama Kaul, Dharmendra Bhadauria. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Although available outome data is equivocal for its non-inferiority compared to ABOc KTx, the data on graft survival after an BPAR episode are scarce in ABOi KTx.

Methods: Single centre, retrospective study, ESRD patients transplanted between 2014 and 2019 were included. Among 100 ABOi KTx, 37 had BPAR and were included. A matched cohort of 37 ABOc KTx with BPAR were identified as controls from 680 ABOc KTx by propensity score matching (nearest neighbour matching) using recipient age and sex, donor age and sex, donor GFR, HLA match and induction agent used as matching covariates. Rejection rates, BANFF score, response to antirejection treatment, overall graft survival, post rejection graft survival were compared between both the groups.

Results: The hazard ratio for BPAR was 1.4 in ABOi KTx, compared with ABOc KTx. Overall graft survival at 1, 3 and 5 years were 86%, 72% and 50% in ABOi KTx; 97%, 91% and 79% in ABOc KTx, respectively. The post BPAR graft survival at 1 and 3 years were 80% and 63% in ABOi KTx; 92% in both 1 and 3 years in ABOc KTx. ABMR was more common in early period in ABOi KTx and ACR was predominant in late period in both the groups. The response to anti-rejection therapy were similar between two groups, no response group (NR) in the ABOi KTx had the poorest graft outcome, complete response group (CR) in the ABOc KTx had the best graft survival. Between CR, PR (partial response) and NR groups, no histopathological parameters were found significant in ABOi KTx, whereas in ABOc KTx, TI scores were higher in PR compared to CR group.

Conclusions: The graft survival after an acute rejection depends upon response to antirejection therapy. After an episode of acute rejection, the overall post rejection graft survival was inferior in ABOi compared to ABOc KTx.



Graft survival after BPAR according to response

PO2560

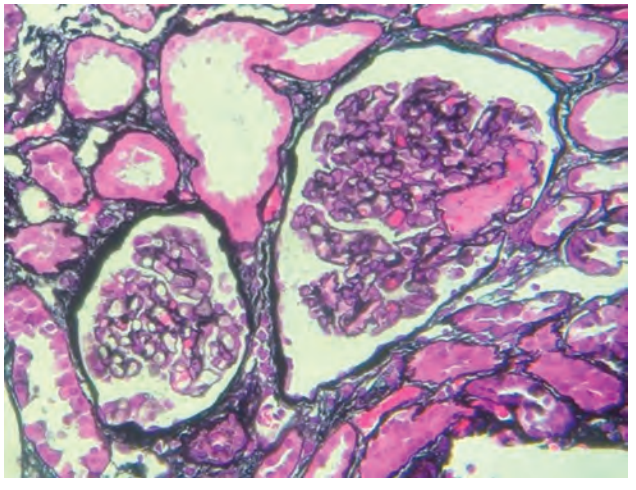
Antiphospholipid Antibody Syndrome Causing Thrombotic Microangiopathy in the Immediate Post-Transplant Patient: A Case Report

Anna R. Gaddy, Muhammad S. Yaqub. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Differential diagnosis of thrombotic microangiopathy on kidney biopsy specimen includes infection, hypertension, malignancy, or inherited complement disorders. In the the post-transplant period the differential also includes calcineurin inhibitor toxicity and rejection.

Case Description: A 29 year-old AA female with ESRD disease due to lupus nephritis and HTN. Her care was provided in another state until 2011- she had a stroke in the past which she reports was secondary to uncontrolled HTN. No h/o blood clot, never been pregnant. Native kidney biopsy in 2015 showed lupus: class V membranous GN, focal segmental and diffuse glomerular sclerosis with collapsing features, and focal acute thrombotic microangiopathy. In 2019, she underwent deceased donor kidney transplant. On post-op day 4, Sr Cr began to increase and biopsy demonstrated thrombotic microangiopathy. Chart review revealed increased aPTT prior to surgery. DsDNA was negative, Tacrolimus troughs were low, donor-specific antibodies were negative. She was treated empirically with high-dose steroids and plasma exchange. Workup revealed positive anti-cardiolipin IgG (46 GPL units/mL) and positive anti-beta-2 glycoprotein IgG (532 units/mL.). She recalled being on warfarin following her CVA in 2010, for embolic stroke. She received a dose of Rituximab, has been maintained on tacrolimus and mycophenolic acid along with warfarin for her antiphospholipid syndrome (APLs) and has normal graft function

Discussion: This case highlights the importance of a complete serological workup to rule out APLs in the pre-transplant patient, even in the presence of alternate explanatory diagnoses. Patients with APLs should be treated with lifelong anticoagulation to prevent further embolic complications, including loss of transplanted organs.



PO2561

Impact of Out-of-Hospital Organ Donor Cardiac Arrest and Cardiopulmonary Resuscitation on Donor Kidney Histology and Function

Sami M. Akram, Claudia G. Olano, Nehemias A. Guevara, Lilly M. Barba. Kidney Transplantation Group *Harbor-UCLA Medical Center Department of Internal Medicine, Torrance, CA.*

Background: The mortality rate of patients listed for kidney transplantation (KT) is 5 per 100-patient years. Due to an organ shortage crisis, expansion of KD pool (KDP) is critical (1). Kidney donors (KD) with out-of-hospital cardiac arrest (OHUS-CA) and cardiopulmonary resuscitation (CPR) have low acceptance rate due to presumed delayed graft function (DGF). Donor CA in controlled setting (in ICU) does not impact KF post engraftment (PE) (2) but impact of OHUS-CA is unknown. We propose that terminal serum creatinine (TSC) and Kidney histology (KH) immediatley prior to Kidney transplantation predict KF post KT. We did a nested cohort study to study the impact of OHUS-CA and CPR of KDs on KF and KH. .

Methods: Our transplant program received thirty-five kidney organ donors offers with a procurement biopsy from UNOS during July to December 2019. Retrospectively we reviewed demographics, pre- hospitalization resuscitation information, hemodynamic data and KH. Four patients were excluded; two had missing data; one patient had ischemic infarct and one patient had kidney tumor. The study cohort (N=31) divided into CA-OHUS (N1 =16 and No Cardiac Arrest (No-CA, N2=15) groups. The change (delta) in serum creatinine (DSC) while under donor management (DM) compared in each group. Hypotension during donor management (H-DM) and acute tubular damage score (ATDS) from donor kidney biopsy compared within each group of the cohort.

Results: TSC and ATDS prior to KT were evaluated as surrogates for KF post engraftment and there was no difference between OHUS-CA and No-CA (standard) donors. Effect of ischemic preconditioning was noted in OHUS-CA group (Table). Longer the duration of CPR greater was the residual KF (Fig 1).

Conclusions: KF and KH in KD with OHUS-CA are similar to standard criteria donors hence should not be prejudiced. This will expand the KDP.

Results

Nested Cohort (N=31)	Delta SC (DSC)	H-DM (P val = 0.56)	ATDS (0 = none; 1=mild)
OHUS-CA (n1=16)	0.34 (SD 0.19), P val = 0.1	9/7	5/11
No-CA (n2=15)	0.72 (SD 0.27, P val = 0.02)	10/5	8/7

Living Donor-Derived APOL1-Associated Collapsing FSGS in a Kidney Transplant Recipient

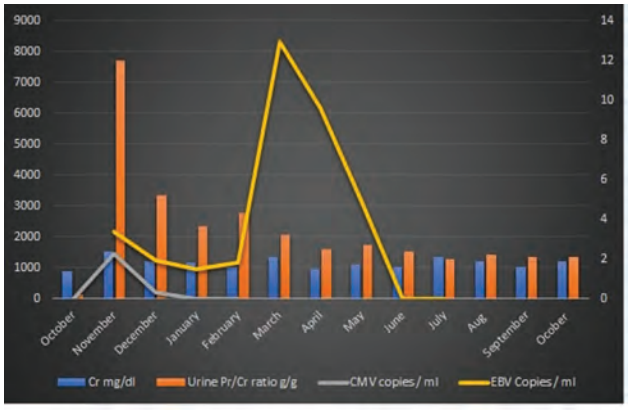
Irfan Agha,[1,2] Amna Ilahe,[1,3] Silvi Simon,[1,3] Rama Nadella,[1,2] Diana Mahbod,[1] Richard Dickerman.[3] *[1]Dallas Renal Group, Dallas, TX; [2]Medical City Dallas Hospital, Dallas, TX; [3]Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Homozygous high risk APOL-1 mutations in donors can drive disease in recipients. We present a living kidney recipient with de-novo collapsing FSGS. His donor was homozygous for high risk mutations.

Case Description: 47 YO AA male with CKD due to biopsy proven diabetic nephropathy s/p LUKT in May 2018. Got thymoglobulin (5 mg/kg) with tacrolimus, mycophenolate sodium and prednisone. High risk for CMV (D+ / R-). EBV IgG +. Donor was his 35 years old AA wife. We were not testing APOL-1 on AA donors at the time. At month 6: Cr 1.4 mg/dl, Ur Pr/Cr of 0.22 g/g. Valganciclovir stopped. Two weeks later, Ur Pr/Cr 2.92 g/g. CMV PCR + 276 copies / ml and EBV PCR + 492 copies / ml. PCR for Parvo Virus B-19 as well as DSA negative. Given steroids, plasmapheresis (X3) and IV ganciclovir. Biopsy C/W collapsing FSGS. IF negative, including CMV and C4d. Donor tested for and found to be homozygous for APOL1 G1 mutations confirming donor derived APOL -1 gene associated collapsing FSGS, presenting as an acute diffuse podocytopathy. Trends in his renal function, CMV, EBV and proteinuria are tabulated in Figure 1. Treated with RAAS blockade, antivirals & immunosuppression. He cleared his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituximab with resolution of EBV viremia. He is 18 months out from presentation. Cr is in the 2 mg/dl range with persistent proteinuria. The life of the allograft will be significantly curtailed. His donor is doing well with stable kidney function and no proteinuria.

Discussion: APOL-1 mutations place recipients of these kidneys at risk for adverse outcomes. Few instances of APOL-1 mutation driven kidney disease in recipients from

living donors are documented. This presentation supports the two-hit hypothesis - The high interferon state due to CMV and EBV viremia precipitated APOl-1 associated FSGS in this kidney with homozygous high risk mutations. APOL-1 screening in AA donors, especially young donors, should be considered for risk stratification and counseling.



Clinical Course

PO2563

Pediatric Donor Glomerulopathy in Pediatric En-Bloc Kidney Transplants

Elizabeth A. Kendrick, Jonathan E. Zuckerman, Julie M. Yabu, Basmah A. Abdalla, Anthony E. Sisk. *University of California Los Angeles, Los Angeles, CA.*

Background: Use of pediatric en-bloc kidneys (EBK) have equivalent outcomes to standard deceased donor kidneys and has helped expand the pool of donor kidneys. The size mismatch related hyperfiltration injury in pediatric EBK and pediatric single kidney allografts is associated with pediatric donor glomerulopathy whose effect on allograft outcomes is not well documented.

Methods: We retrospectively reviewed for cause biopsies of pediatric EBK from 1/2015 to 1/2020. Our center performed 37 transplants using pediatric EBK. Recipient weight criteria was ≤ 75 kg to minimize donor-recipient size mismatch. One recipient died with a functioning graft at 4 months; one graft failed due to fungal infection of the vascular anastomosis requiring nephrectomy at 1 month.

Results: Fourteen biopsies were performed in 10 patients between 1 to 24 months after transplantation. Indications for biopsy were: graft dysfunction (10; 3 with proteinuria), proteinuria alone (2), BK viremia with proteinuria (1), and de novo donor specific antibody (DSA) (1). Biopsies from 5 EBK recipients demonstrated pediatric donor glomerulopathy represented by the presence of glomerular abnormalities including subepithelial multi-layering/remolding of the basement membrane, segmental glomerulosclerosis, mesangial hypercellularity, mesangial sclerosis, podocyte hypertrophy, and/or segmental mild podocyte foot processes effacement. Ten biopsies also showed thin basement membranes (BM) on EM consistent with the age of the donor kidney. Other diagnostic findings among the entire biopsy cohort were acute cellular rejection (ACR), antibody mediated rejection (AMR), or mixed ACR and AMR (5), acute tubular necrosis (ATN) (3), and pyelonephritis (1). Biopsies with pediatric donor glomerulopathy were performed early after transplantation and were associated with proteinuria. Semiquantitative proteinuria in the 5 recipients at the time of biopsy was 1-3+; 1.2-9.5 g/day in 4. Follow up 4-39 months post-transplant (mean 17 months) in patients with pediatric donor glomerulopathy showed serum creatinine 0.55-2.07 mg/dl (mean 1.1) and urine protein 0.4 to 1.2 g/day (mean 0.73).

Conclusions: Overall, pediatric donor glomerulopathy seen early post transplant period did not appear to negatively affect long-term graft function; this outcome may be related to growth of these kidneys occurring early post transplant.

PO2564

Pre-Transplant Genetic Testing of Living Related Donor in a Case of Atypical Hemolytic Uremic Syndrome

Meghna Kurup, Didier A. Mandelbrot, Tripti Singh. *University of Wisconsin SMPH, Madison, WI.*

Introduction: Atypical HUS (aHUS) is a rare thrombotic microangiopathy caused by dysregulation of the alternative complement pathway either through mutations in regulatory genes or autoantibodies directed against regulatory proteins. Here we report a case of genetic testing pre-transplant in a patient who developed aHUS with variants in the *CFH* and *PLG* genes and her living related donor.

Case Description: A 27-year-old female presented to the hospital with diarrhea, abdominal pain, AKI, and microangiopathic hemolytic anemia requiring dialysis. She was initiated on eculuzimab but progressed to ESRD. Renal biopsy showed TMA with focal crescents and severe interstitial fibrosis and tubular atrophy. Workup revealed aHUS with complement dysfunction—low C3 and C4, normal CD46 and Factors H, I, and B, and no autoantibodies to CFH. Genetic testing showed mutation on exon 9 (SCR7) of *CFH* that has been shown to cause aHUS as well as another variant on exon 7 of *PLG*, which is present in 0.3% of European Americans and may be pathogenic but is of uncertain significance for her. Ten months later, she was evaluated for living related renal transplant from her brother. Since she had a mutation known to cause aHUS, genetic testing was done for her brother as part of donor evaluation. He was found to have the same mutation in *CFH* but not *PLG*, despite being asymptomatic with no hemolytic anemia, normal kidney function. The transplant was cancelled because of increased risk of disease in the future in the brother. Genetic counselling was provided to brother about his possible risk of aHUS.

Discussion: Mutations in *CFH* are associated with aHUS; however, it is thought that a trigger—e.g. infection or additional acquired genetic variant leads to progression to aHUS in carriers of complement gene mutations. Genetic testing is recommended for patients with aHUS to determine cause and inform long-term treatment. This patient had a combination of a variant in the complement pathway gene *CFH* and coagulation pathway gene *PLG*, while her brother, a candidate for living related donor, had the same variant in *CFH*. We recommend genetic testing for a living related donor if any mutation is found in the index case to minimize posttransplant recurrence or precipitation of aHUS in the donor.

PO2565

Trouble Brui-ing: A Case of Doppler Discovery

Brandon M. Fairless,[1] Anil S. Paramesh,[2] Isa Ashoor.[1] *[1]Louisiana State University Health Sciences Center, New Orleans, LA; [2]Tulane University School of Medicine, New Orleans, LA.*

Introduction: This case highlights the clinical presentation and management of an uncommon kidney transplant biopsy complication.

Case Description: A 19 year old male with ESKD, now status-post second deceased donor kidney transplant, presented to clinic with hypertension. Post transplant course included 3 prior normal surveillance kidney transplant biopsies. Graft function was stable (creatinine 1 mg/dL), and tacrolimus trough level was therapeutic. His blood pressure was 130/85. Exam showed a palpable thrill with audible bruit over the graft site. Ultrasound showed a sonolucent lesion in the lower pole of the transplant kidney, which was not present on prior imaging. Doppler revealed turbulent flow concerning for an arteriovenous malformation (AVM). Renal angiography confirmed the diagnosis, and he underwent endovascular embolization with coiling **[Image]**. Graft function and blood pressure readings remain normal on most recent follow-up

Discussion: Kidney biopsy is commonly utilized for diagnosis and management of transplant complications. It is generally a safe procedure, with post-biopsy bleeding being the most common complication, often with no clinical significance. However, serious complications can occur, with AVM among them. Patients with kidney transplants have been noted to have a higher incidence of post-biopsy AVM. A portion of AVMs remain asymptomatic and self-resolve, while others manifest as hypertension, graft dysfunction, and hematuria. An ultrasound with Doppler is critical for the diagnosis. Endovascular embolization is an effective and minimally invasive management option for most patients.
Teaching Points -Ultrasound with Doppler assesses for the presence of AVM -Symptoms of post-biopsy AVM include hypertension, renal graft dysfunction, and gross hematuria -Transplant patients are at increased risk for post-biopsy AVM

Renal ultrasound with Doppler (left), renal angiography (middle), post-coiling (right)

PO2566

Renal Transplant Artery Stenosis and Kinking: An Unusual Association

Haridian Sosa Barrios,[1] Victor Burguera,[1] Ester Casillas,[1] Daniel E. Villa,[1] Sara Jimenez Alvaro,[1] Irene Martin Capon,[1] Milagros Fernandez-Lucas,[1,2] Maite Rivera.[1,2] *[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Universidad de Alcala de Henares, Madrid, Spain.*

Introduction: Renal artery stenosis of the kidney graft associated with kinking is not a frequent finding. As a correctable cause of graft dysfunction it is important to diagnose it as soon as possible to avoid further graft damage.

Case Description: A 62 year-old woman with ESRD due to ADPKD had a deceased donor kidney transplant (KTx) in her right iliac fossa (1 vein/1 artery) anastomosed to external iliac vessels. Immunosuppression:basiliximab, tacrolimus, everolimus and steroids. Creatinine drop halted 2 weeks post-op. Blood pressure was normal, CMV load : undetectable. Tacrolimus level:7-9 ng/ml. A KTx US was done, showing high velocities within KTx renal artery close to the anastomosis, increasing near a kinking image adjacent to the hilum (image 1), not present on Doppler US 1 day post-op. A CT angiography confirmed renal artery stenosis at anastomosis level and kinking of the graft renal artery (image 2). Endovascular angioplasty of the stenotic area without stenting was performed, but unsuccessful. Open surgery vascular reconstruction was carried out a week after angioplasty: renal artery was shortened and reimplanted. Within a week, graft function improved and Doppler US was normal.

Discussion: Renal artery stenosis is a correctable cause of hypertension and graft dysfunction in KTx. Graft renal artery kinking is rare, even more in association with stenosis, worsening its prognosis as kinking renders angioplasty less effective. Complete Doppler US mapping of the graft's arteries is essential to make an early diagnosis and nephrologists could do this examination promptly.

PO2567

Proliferative Glomerulonephritis Monoclonal Immunoglobulin Deposits (PGNMID) in a Kidney Allograft Successfully Treated with Rituximab

Rasha Alawieh, Mohankumar Doraiswamy, Seth Scheetz, Anjali A. Satoskar, Todd E. Pesavento, Priyamvada Singh. *The Ohio State University, Columbus, OH.*

Introduction: PGNMID is a rare distinct form of glomerulonephritis (GN) characterized by glomerular monoclonal immunoglobulin deposits. There is no definite treatment for this condition. We present a case of PGNMID in a recurrent renal transplant patient who responded well to rituximab.

Case Description: A 43-year-old male with ESRD secondary to MPGN s/p 3rd renal transplant complicated with failure of previous transplants due to rejections (on cyclosporine and everolimus) presented with worsening pain at the graft site and AKI. Creatinine 5.6 mg/dL (baseline 2.5mg/dL), UPC 1.5 gm/dL, RBC, and RBC casts on microscopy. Detailed serological, immunological, and infectious workup was negative. Renal biopsy showed mesangial, subepithelial, and subendothelial proliferation with electron dense deposits of IgG1 and IgG3 with kappa predominance most consistent with PGNMID. Monoclonal workup was negative and bone marrow biopsy showed no clear evidence of hematologic malignancy. He received two doses of rituximab in addition to home immunosuppression. Renal function improved to baseline (creatinine 2.5, negative blood, UPC 0.5) and has been stable for past year.

Discussion: GN recurrence in kidney allografts is responsible for around 24% of kidney graft losses. Approximately 70% of PGNMID patients have no detectable monoclonal proteins in serum or urine. Multiple regimens have been used for the treatment of PGNMID after renal transplant, including RAAS blockers, steroids, rituximab, bortezomib and plasmapheresis. Few reported cases of PGNMID responded well to rituximab, and a large prospective multicenter controlled study is warranted to better understand this rare disease.

PO2568

Rituximab or Plasmapheresis for Prevention of Focal Segmental Glomerulosclerosis Recurrence After Kidney Transplantation: A Meta-Analysis

Boonphiphop Boonpheng,[1] Charat Thongprayoon,[2] Wisit Cheungpasitporn.[3] *[1]University of California Los Angeles, Los Angeles, CA; [2]Mayo Clinic Minnesota, Rochester, MN; [3]University of Mississippi Medical Center, Jackson, MS.*

Background: Focal segmental glomerulosclerosis (FSGS) can recur after kidney transplantation. Prevention of FSGS recurrence with rituximab and/or plasmapheresis has been evaluated in multiple small studies with conflicting results. We performed this meta-analysis to assess the post-transplant recurrence risk of FSGS with prophylactic rituximab and/or plasmapheresis in addition to standard immunosuppression.

Methods: A systematic review was conducted in MEDLINE, EMBASE, Cochrane databases from inception through April 2020 to identify studies that evaluated the risks of post-transplant FSGS after rituximab with or without plasmapheresis or plasmapheresis alone compared to controls. Effect estimates from the individual study were extracted and combined using random-effects model.

Results: 10 studies with a total of 381 FSGS patients undergoing kidney transplantation evaluated rituximab with or without rituximab and 11 studies with a total of 520 kidney transplant recipients with FSGS evaluated plasmapheresis alone. There was no significant difference in recurrence between the group that received rituximab with or without plasmapheresis and the standard treatment group, with a pooled risk ratio of 0.84 (95% CI, 0.47-1.48, I^2= 67%). Plasmapheresis alone was also not associated with any significant difference in FSGS recurrence compared to no plasmapheresis with a pooled risk ratio of 0.94 (95% CI, 0.65-1.37, I^2= 20%). Subgroup analysis in the pediatric or adult group did not yield significant recurrence risk difference.

Conclusions: Rituximab with or without plasmapheresis or plasmapheresis alone was not associated with lower risk of FSGS recurrence after kidney transplantation.

Case Study of Repository Corticotropin Injection (RCI) Prophylaxis for FSGS Recurrence in Kidney Transplant

Sandheep Venkataraman,[1] Barrett R. Crowther,[1,2] Monica Grafals.[1,2] *[1]University of Colorado, Denver, CO; [2]University of Colorado Health, Aurora, CO.*

Introduction: Idiopathic FSGS recurs post-transplant in one third of cases and is associated with a five-fold higher risk of graft loss[1].

Case Description: In this single center pilot case study, 8 patients with biopsy-proven FSGS were treated with RCI prophylaxis 80 units subcutaneously twice a week for 6 months from day of kidney Tx, compared with a group of 6 patients who were treated with RCI later after the diagnosis of FSGS recurrence.

Discussion: All patients received rATG as induction and were on standard immunosuppression with FK, MMF, and prednisone. Patients in the control group were diagnosed with recurrent FSGS between 5-63 days post Tx. There where 3 patients in the study group that developed recurrent FSGS, 2 of them required plex. Patient 1 in the study group had DGF after a live donor kidney Tx from recurrent FSGS. Her protocol biopsy performed one year after transplant and still shows foot process effacement but no fibrosis or sclerosis in light microscopy. All but one patient in the control group have still functioning allografts. Conclusions: This is a small pilot study, but its findings suggest that use of RCI at time of kidney transplant surgery in patients with FSGS decreases the severity of the disease with less fibrosis in follow up biopsies despite the presence of foot process effacement. There may also be a decreased need for plex in the study group, however, further studies are needed to confirm this

	Sex (M=male, F=female)	Race (C=Caucasian, AA=African-American, H=Hispanic)	Average Proteinuria at 3 months Post Transplant (mg/mg)

Does Therapeutic Plasma Exchange Improve Kidney Function in Renal Transplant-Associated Thrombotic Microangiopathy?

Karen A. Nahmod, Barbara J. Bryant, Sean G. Yates, Marjan Afrouzian. *University of Texas Medical Branch at Galveston, Galveston, TX.*

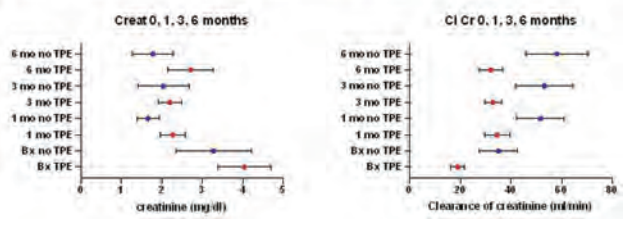
Background: Therapeutic plasma exchange (TPE) is performed in patients with renal transplant thrombotic microangiopathy (t-TMA) to improve the kidney function. The goal of our study is to evaluate the short-term efficacy of TPE in patients with renal t-TMA.

Methods: We retrospectively compared the outcome of TPE-treated vs. non-TPE-treated patients with biopsy-proven diagnosis of t-TMA. Histologic criteria for diagnosis of t-TMA included presence of thrombi in the artery/arteriole/glomeruli, mesangiolysis & double contours, and electron microscopic evidence endothelial cell injury including subendothelial rarefaction/ accumulation of fluffy material and mesangial interposition. Both groups received concomitantly other modalities of treatment. Creatinine and creatinine clearance levels were determined at the time of biopsy (T0) and after 1, 3 and 6-months (T1, T3, T6 respectively).

Results: In 13 TPE-treated and 9 non-TPE-treated patients, the mean creatinine levels at 6 months decreased 32.5% and 45% respectively over baseline, while the creatinine clearance increased by 68% and 65% respectively, although not statistically significant (p>0.05) Graph1.

Conclusions: No significant differences were noted in creatinine or creatinine clearance levels within and between either groups at any time point. Our study suggest that no significant benefit in renal function is associated with performing TPE in patients with renal t-TMA. Larger studies are needed to confirm our data.

Graph 1. Creatinine and Creatinine Clearance Levels (Mean±SEM).



PO2571

Patient and Graft Outcomes of Kidney Transplant Recipients with Anti-Human Neutrophil Antigen Antibodies

Christina Irene Mejia, Goni Katz-Greenberg, Beth W. Colombe, Pooja Singh, Anju Yadav. *Thomas Jefferson University, Philadelphia, PA.*

Background: Antibody mediated rejection (AMR) is a well-established cause of poor graft outcomes in kidney transplant recipients (KTR). While the most common targets are human leukocyte antigen (HLA) antibodies (abs), there are data implicating some non-HLA abs in the process of AMR. Human neutrophil antigens (HNA) are glycoproteins expressed on neutrophil surfaces. Anti-HNA abs have been associated with transfusion-related acute lung injury but their role in AMR in KTR is unclear. The aim of our study was to examine the outcomes of KTR with anti-HNA abs at our center.

Methods: We retrospectively reviewed the medical records of KTR with non-HLA abs between 1/2008-5/2020. Relevant clinical and graft outcome data were obtained. Descriptive statistics were expressed as absolute numbers (%) for categorical data and as medians with interquartile range (IQR) for skewed distribution.

Results: There were 6 KTR with non-HLA abs during the study period, all anti-HNA abs. Three patients (pts) were male (50%), 5 white (83%), and 4 had polycystic kidney disease (PCKD) as primary disease (66%). Median age at KT was 46 (29.75-57). Pts' characteristics, clinical course and outcomes are detailed in Table 1. Five pts developed biopsy-proven AMR at a median of 32 months (13.8-68.2) from KT. During follow-up (f/u), 3 pts had graft loss, 1 of which was re-transplanted while 2 are re-listed but dialysis-dependent. Mean creatinine of the 4 pts with working allografts is 1.21mg/dL(1.14-1.27) at median f/u of 68 months(52-105).

Conclusions: We observed varied clinical courses and graft outcomes in our pts, partly due to our small cohort. Although majority developed AMR, it was not necessarily associated to graft loss or shortened graft survival. Of note, PCKD was the primary kidney disease in the majority of pts, similarly observed in one other case series. More studies are needed to determine the specific significance of anti-HNA abs in KTR.

Table 1. Patient and donor characteristics and allograft outcomes.

Patient	Gender	Race	Age at transplant	Cause of kidney disease	Dialysis Modality	Transplant number	Donor type	Induction	Baseline Immunosuppression (IS)	Delayed Graft Function	Anti-HNA ab Genotype	HLA DSA (at time of biopsy)	Biopsy-proven AMR	Treatment	Graft loss	Current status

PO2572

Transplant Outcomes in Children with Lupus Nephritis

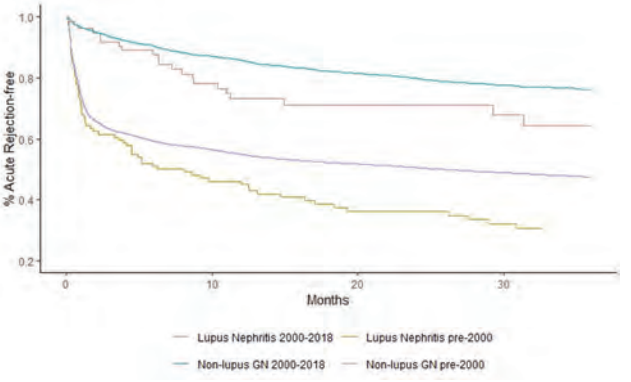
Vimal Chadha,[1] Heather L. Wasik,[4] Shirley Galbiati,[3] Meredith A. Atkinson,[2] Bradley A. Warady.[1] *[1]Children's Mercy, Kansas City, MO; [2]Johns Hopkins University, Baltimore, MD; [3]The Emmes Company LLC, Rockville, MD; [4]State University of New York Upstate Medical University, Syracuse, NY.*

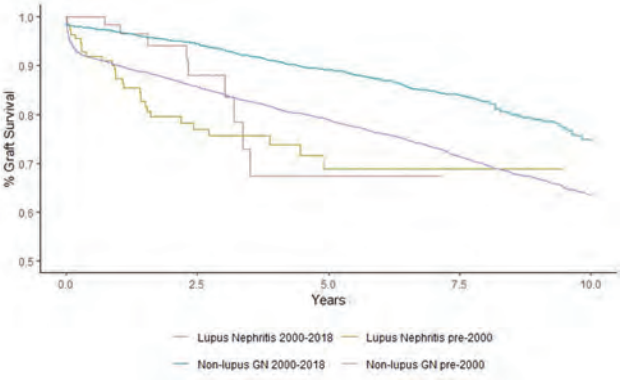
Background: Children receiving dialysis for end stage kidney disease secondary to lupus nephritis (LN) have decreased survival and a lower likelihood of kidney transplantation compared to children with non-lupus glomerular diseases (NLGN). Whereas a previous North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) analysis reported equivalent patient and graft survival for LN patients when compared to matched controls, a comparison of recent transplant outcomes in children with LN and NLGN has not been conducted.

Methods: Retrospective analysis of the NAPRTCS registry data of subjects <21 years old who received a kidney transplant between 1987–2018. Outcomes for LN patients (n=191) were compared to NLGN patients (n=8675) during pre & post 2000 eras. Statistical analyses included Kaplan-Meier curves and multivariable logistic and Cox regression models.

Results: After adjusting for race, LN patients were less likely ($p<0.001$) to receive a preemptive transplant (OR=0.12). There was also a trend for LN patients being less likely to receive a living donor (LD) transplant (OR=0.8). When comparing pre- and post-2000 eras, time to 1st rejection and graft survival improved for both LN and NLGN groups, although the graft survival benefit in LN group was not sustained after 3.5 years of follow-up. Time to 1st rejection and graft survival for LN patients remained inferior to NLGN group during both eras (Figure 1 & 2).

Conclusions: LN patients are less likely to receive a preemptive, and possibly a LD transplant. Overall, outcomes for both LN and NLGN transplant patients improved after 2000, but the outcomes of the LN group were inferior to those of the NLGN group during both time periods.





PO2573

Effect of Rituximab Dose on Induction Therapy in ABO-Incompatible Living Kidney Transplantation: A Network Meta-Analysis

Seon Deok Hwang,[1] Joon Ho Song,[1] Kipyo Kim,[1] Woo Yeong Park,[2] Seoung woo Lee.[1] *[1]Inha University, Incheon, Incheon, Republic of Korea; [2]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.*

Background: Rituximab is an induction immunosuppressant essential for ABO-incompatible kidney transplantation, but studies on its dosing, which differs between countries and transplant centers, are lacking we retrospectively investigated this phenomenon

Methods: we retrospectively investigated this phenomenon by including five groups: ABO compatible; placebo; and rituximab 200 mg, 200–500 mg, and 500 mg. *Publications were retrieved using* CENTRAL, MEDLINE, EMBASE, and Science Citation Index Expanded databases from 1970 to February 2020 and analyzed. Reviews, observational studies, and clinical trials with unclearly defined outcomes or omitted graft failure as an outcome were excluded. We performed direct and indirect network meta-analyses using Bayesian models and ranked different rituximab doses using generation mixed treatment comparison. The GRADE of network meta-analysis approach specified four levels of certainty for a given result: high, moderate, low, and very low. The outcomes were patient survival, graft failure, and infections including bacterial and viral.

Results: Twenty-one trials with 4,256 subjects were analyzed for glomerular filtration rates, graft loss, antibody-mediated rejection, T-cell mediated rejection, fungal infection (*Candida*), and patient survival rates, which did not differ among four groups. However, incidence of sepsis and cytomegalovirus infection (0.728 and 0.855, 95% confidence interval: 0.572–0.926 and 0.724–0.921, respectively) were significantly lower in rituximab 200-mg group than in other groups.

Conclusions: In conclusion, in ABO-incompatible kidney transplantation, low-dose rituximab is more efficacious than higher doses and reduces serious infection risks. Future studies of large-scale, long-term data and further discussions on using lower rituximab doses are necessary.

PO2574

Delayed Diagnosis of Renal Allograft Uroenteric Fistula in a Pediatric Transplant Patient

Malek Al Barbandi, Patricia A. Arroyo Parejo Drayer, Juan C. Infante, George W. Burke, Jayanthi Chandar, Marissa J. Defreitas, Chryso P. Katsoufis, Wacharee Seeherunvong, Carolyn L. Abitbol. *University of Miami School of Medicine, Miami, FL.*

Introduction: The diagnosis of uroenteric fistulae can be challenging and is often delayed for several months after symptoms begin. Here, we describe a rare case of a pediatric patient post en bloc kidney transplant who developed a urinoma post biopsy with a ureteral fistula into the small bowel resulting in profound acidosis and deceptive watery diarrhea.

Case Description: The patient is an 8 year old girl with end stage kidney disease secondary to steroid resistant nephrotic syndrome and focal segmental glomerulosclerosis (FSGS). She underwent a right native nephrectomy and a deceased donor "en bloc" kidney transplant with two separate ureters. She had a renal allograft biopsy for suspected rejection. A few days after the biopsy, she began experiencing watery diarrhea and metabolic acidosis. A comprehensive screening for diarrhea produced inconclusive findings. She was maintained on parenteral nutrition with no oral intake to try to slow the diarrhea. However, the watery diarrhea increased while urine output decreased. Throughout this period, the patient maintained normal kidney function. The watery stool and bladder urine were analyzed for solutes, pH and creatinine. An MRI with contrast was performed which demonstrated fistulization of the distal transplanted ureters into the small bowel. She underwent corrective surgery which identified the fistulous tract which was resected and the ureters were re-implanted. The surgery went well without complications. The diarrhea resolved and she was discharged 2 weeks later with normal renal function.

Discussion: This is a perplexing case of the development of a uroenteric fistula in a pediatric transplant patient that went undiagnosed for almost 3 weeks due to the deceptive nature of the watery diarrhea which was actually urine. An important aspect of the uroenteric fistula is the severe acidosis that results when urine is diverted in to the intestinal tract. This occurs in some cases of bladder augmentations that use the intestine. Another important diagnostic tool is the solute excretion in the diarrhea. Despite the watery nature of the diarrhea, the stool was not hyperosmolar and did not contain reducing substances. This made osmotic diarrhea unlikely and a fistula more likely.

PO2575

Effect of Therapeutic Plasma Exchange on Glomerular Filtration Rate in Patients with Antibody-Mediated Rejection

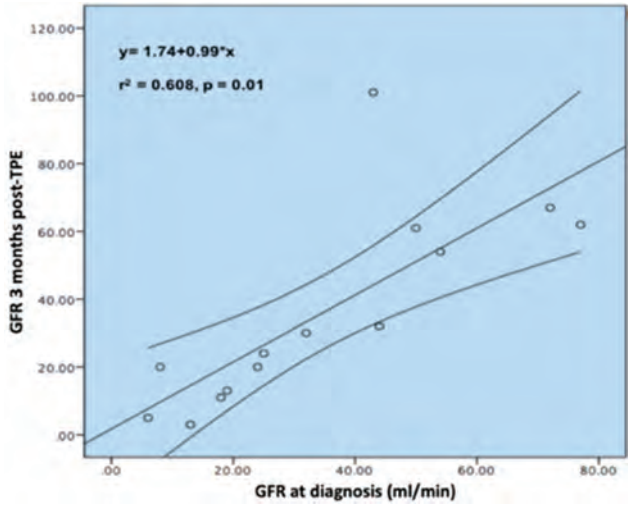
Miguel Maza Moreno, Sergio Hernández-Estrada, Jose H. Cano, Odette Del Carmen Diaz Avendaño, Diana Maldonado Tapia. Nephrology and Transplant Division *National Medical Center 20 de Noviembre, Mexico City, Mexico.*

Background: AMR is the main risk factor for graft loss, especially after the first post-transplant year. Up to 80% of patients achieve response with immunosuppressive treatment and TPE, although the response is lower in patients with lateAMR. The objective was to determine the effect of TPEonGFR at 0,1, and 3 months postTPE.

Methods: Retrospective study that included patients with a renal transplant of the CMN"November 20"in MexicoCity, from 2016to2019, undergoing membrane TPEforAMR. Analysis was performed using student's t or MannWhitneyU, repeated measures analysis, and Spearman or Pearson test. Significant p was less than 0.05.

Results: 25 patients with AMR who received TPE were evaluated. Age:32±11.6 years, 72% from living donor, 52% received Basiliximab. 87% received tacrolimus. 80% of AMR were late. Prevalence of HLAclass II DSA(66%), specifically vs DQandDR (57.2% and 28.8%). There was a significant difference between preTPE GFR and at the end of treatment(p=0.015, r=0.53), and no significant differences between preTPE GFR, with 1or3 monthGFR(p=0.58; p=0.36). When evaluating IFTA or histological score(g+ptc), no difference was detected in the GFR at 1or3 months post-TPE. When comparing the effect of the AMR temporality on the GFR, difference was found at 1and3 months (p=0.022; p=0.01) postTPE, with lower recovery of GFR in patients with early AMR. There was a moderate correlation between GFR at the time of diagnosis of rejection and GFR at 3 months postTPE(r2=0.68,p=0.01), Fig. 1.

Conclusions: Significant difference was demonstrated between the preTPE GFR and immediate postTPE GFR. In our study patients with early AMR presented a poor response to treatment. The GFRupon admission correlated positively with theGFR detected at 3months post-TPE. This suggests a beneficial effect of TPE over GFRfall during the first 3months after diagnosis.



PO2576

Significant Variability in Results from Different Tacrolimus Assays Is a Potential Recipe for Toxicity and Kidney Allograft Rejection

Adnan A. Khan, Jennifer C. Smith. *University of California San Diego, La Jolla, CA.*

Background: Tacrolimus (tac) is an immunosuppressive medication used to prevent organ rejection and prolong graft survival after transplantation. It is the main pillar of any combination immunosuppression regimen. Due to its narrow therapeutic window; it requires timely administration, close monitoring with 12/24 hours trough levels and dose adjustments. Previously done studies have shown a discordance between different assays, with a positive bias for immunoassay (2.8 -9.2%) compared to LC/MS-MS assay; due to cross-reactivity with tac metabolites.

Methods: Results from 33 stable kidney transplant patients who had routine transplant labs drawn at Labcorp® were reviewed. Each of these patients had tac trough levels checked by both LC/MS-MS assay and QMS immunoassay(Thermo-Fischer). The comparison of two assays was done with Deming regression and a Bland-Altman analysis for bias done using XLSTAT®. Linear regression was done using SPSS v26.

Results: Deming regression analysis shows that there is a statistically significant difference between the two assays with *y=1.36x-0.26*. Bias(avg.) calculated by Bland-Altman plot was 2.35 ng/mL(Figure). Percentage difference in tacrolimus immunoassay and LC/MS-MS correlated with tacrolimus dose (p = 0.031).

Conclusions: A significant discordance of tac troughs (upto 85%) was found on our analysis; obtained by the two assays. This is clinically significant as tac has a narrow therapeutic window and adjustments of dose based on these assay results; can risk immunologic injury, DSA formation, rejection and nephrotoxicity at either ends of the spectrum. Standardization of assays in future, would be ideal. In the meantime, nephrologists should be adjusting trough goals based on the assay used, especially when different assays are in play.

Single-Dose Rituximab and Antithymocyte Globulin (ATG) in Hypersensitized Kidney Transplant Recipients

Aileen Wang, Uerica K. Wang, Megan L. Troxell, Stephan Busque, Colin R. Lenihan. *Stanford University School of Medicine, Stanford, CA.*

Background: Hypersensitized kidney transplant recipients (calculated panel reactive antibody (cPRA) ≥ 98%), may represent a population at high risk of posttransplant immunologic events. Their optimal induction regimen so far remain uncertain. The goal of this study was to compare 1-year outcomes of patients receiving rituximab and ATG as induction, the majority of whom were hypersensitized, with highly sensitized recipients (cPRA ≥ 80%) who received ATG alone.

Methods: All patients ≥ 18 years received a flow cross-match compatible kidney transplant between December 2014 and May 2020. We excluded patients who underwent pretransplant desensitization, simultaneous multi-organ transplantation, or received 0-HLA antigen mismatched organ. The exposure of interest was receipt of single dose rituximab (500mg) at induction. The 1-year outcomes were 1) patient and death censored graft survival, 2) glomerular filtration rate (GFR), 3) de novo DSA formation, 4) biopsy proven T-cell or antibody mediated rejection, 5) the composite of dnDSA and rejection, 6) BK viremia, and 7) CMV viremia.

Results: 70 patients received rituximab and ATG (Ritux) and 39 received ATG alone (Control). The Ritux group were (numerically) younger, more sensitized, received kidneys with a longer cold ischemia time, and lower kidney donor profile index. ATG doses were similar. The majority were deceased donor transplants. 1-year patient and death censored graft survival, mean GFR, incidences of BK viremia and CMV viremia were similar for Ritux and Control. 2 patients with primary graft non-function (1 in each group) and 1 patient with early posttransplant death (in Ritux) were excluded from the remaining outcome analyses (Table 1).

Conclusions: The addition of rituximab to ATG as induction for hypersensitized patients appear to be safe and is associated with excellent 1-year outcomes in patient and death cenosred graft survival. Rituximab at induction was associated with reduced incidence of dnDSA formation and/or rejection at 1-year post transplant. Our observations warrant further evaluatoin of anti-B cell therapy induction for hypersensitized kidney transplant recipients.

Table 1

1-Year Outcomes	Ritux (n=68)	Control (n=38)	P Value
Rejection	5 (7.0%)	6 (15.8%)	0.20
De Novo DSA	5 (7.3%)	7 (18.4%)	0.11
De Novo DSA and/or Rejection	9 (13.2%)	12 (31.6%)	0.04

PO2578

Risk Factors and Outcomes of Acute and Refractory Antibody-Mediated Rejection

Allyson Hart,[1] David P. Schladt,[2] Robbin F. Itzler,[3] Ajay K. Israni,[1] Bertram L. Kasiske.[2] *[1]Hennepin Healthcare, Minneaplis, MN; [2]Chronic Disease Research Group, Minneapolis, MN; [3]CSL Behring, King of Prussia, PA.*

Background: Major gaps remain in our understanding of antibody-mediated rejection (AMR) after kidney transplantation. We examined incidence, risk factors, response to treatment, and effects on outcomes of locally-managed AMR at 7 transplant programs in the Long-Term Deterioration of Kidney Allograft Function (DeKAF) prospective study cohort.

Methods: Consecutive kidney or kidney-pancreas transplant recipients were enrolled in the DeKAF study from October 2005 through April 15, 2011. To determine the effect of AMR on death censored graft failure (DCGF), we performed Cox proportional hazards analyses including AMR as a time-dependent covariate.

Results: Among 3131 kidney and kidney-pancreas recipients, there were 194 with a first AMR episode during a mean 4.85±1.86 years of follow-up for the entire cohort. Mean time to first AMR was 0.97 ±1.17 years post-transplant. After adjusting for other risk factors, patients with AMR had 10 times the risk of DCGF compared to patients with no AMR (aHR 10.1, 95% CI 6.5-15.7). Among the 50 (25.8%) patients whose AMR was refractory to treatment, defined as 2nd AMR diagnosis within 100 days or no improvement in eGFR by 42 days, the HR for DCGF was 7.5 (2.2-25.6, P=0.0013) in the first 180 days post biopsy; 3.8 (1.4-9.8, P=0.007) in the 1st year post biopsy, and 1.6 (0.9-3.0, P=0.11) at any time during follow-up compared to patients whose AMR responded to treatment.

Conclusions: Patients with AMR had substantially greater risk of DCGF compared to patients without AMR. While patients with refractory AMR were more likely to lose their graft compared to non-refractory cases in the first year following the AMR diagnosis, the likelihood of graft survival after that year was the same regardless of response to treatment.

Allograft Loss and Patient Death Among Kidney Transplant Recipients: Is Therapy Nonadherence the Underlying Perpetrator?

Kartik Kalra, Puneet Sood, Rajil B. Mehta, Chethan M. Puttarajappa, Christine Wu, Sundaram Hariharan, Nirav A. Shah. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: To ascertain causes of allograft dysfunction, loss and death in a cohort of kidney transplant patients

Methods: Retrospective cohort study, 943 patients with isolated Kidney transplants between years 2013-17 were analyzed for the following transplant outcomes: 1. Death-censored allograft loss 2. Graft dysfunction 3. Death.

Results: 80 of 943 (9%) patients died while 63 (7%) lost their graft and 38 (4%) suffered allograft dysfunction. **Death**- Death was attributed to a combination of infection (29%), Cardiovascular (CV) disease (29%) and malignancy (12%), a significant proportion of patients who died from either CV disease (43%), infection (26%) or malignancy (20%) had prior biopsy proven T-Cell Mediated Rejection (TCMR) in 1st post-transplant year. **Graft Loss**- In this cohort TCMR (39%) was the most widespread factor contributing to allograft loss. While Infection (17%) and surgical causes (14%) were the next common associations, donor related disease accounted for 2% of graft losses. **Graft Dysfunction**- TCMR (42%) was strongly associated with allograft dysfunction in our patient cohort. The other factors associated with Allograft Dysfunction included a). Infection (21%) b). Donor Related causes (11%) and c). Other Causes (15%). Surprisingly ABMR was only noted in 11% of patients with allograft decline. **Rejection and Non-Adherence**- As TCMR was a common contributing factor to all the three hard outcomes in our study cohort, we examined the factors associated with TCMR. 40% of patients with TCMR were found to be non-adherent (defined by > 3 consecutive sub- therapeutic CNI levels, clinic no shows and poor adherence to regular lab draws). Importantly, patients who were non adherent were significantly younger (mean age 38 y vs 55 y; p=0.0001) and a greater proportion of them were of African American (47% vs 22%;p=0.055) compared to those who were adherent to therapy.

Conclusions: While the causes of death, early allograft loss and dysfunction were diverse, TCMR was the most dominant contributor. Non-Adherence was strongly associated with TCMR and was more common in younger patients and those with African American ethnicity. Addressing non adherence in this cohort of patients early with novel interventions could be a key to optimizing patient outcomes in this high risk cohort.

PO2580

Identifying the Causes for Kidney Allograft Failure

Manuel Mayrdorfer, Marcel Naik, Wiebke Duettmann, Klemens Budde. *Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: Since it has been proposed that several causes (C) can contribute to graft loss (GL), we analyzed transplant (Tx) recipients in our center and attributed a C to each persistent decline in renal function, finally leading to GL.

Methods: We retrospectively analyzed 1477 Tx, transplanted between 1997 and 2017 in a single center, of which 303 progressed to GL. An adjudication committee consisting of 3 physicians evaluated biopsies, laboratory data and medical history. Nonreversible decreases in renal function were attributed to primary and secondary C.

Results: Overall graft survival for all patients is 93.7% for 1 year, 80% for 5 years and 60.6% for 10 years. The most frequent C leading to GL were intercurrent medical events in 36.3%, followed by T-cell mediated rejection (TCMR) in 34% and antibody-mediated rejection (ABMR) in 30.7% (table1). For primary C, ABMR (21.5%) was the leading C, followed by medical events (21.1%) and TCMR (12.9%). As expected, we observed an increasing relevance of ABMR in late GL (figure 1). Over 50% of GL had >1 C.

Conclusions: Analyzing GL, we observed that >50% were multifactorial. Our results show a significant role of TCMR in GL. Additionally, we were able to attribute medical events to GL in 36.3% of Tx and to highlight the role of ABMR in late GL.

Assessing Cumulative Immunosuppressive Drug Exposure: Metrics, Outcomes, and Implications for Kidney and Non-Kidney Transplant Patients

Cavizshajan Skanthan, Emily Nguyen, Lakindu Somaweera, Madhumitha Rabindranath, Olusegun Famure, Joseph Kim. *University Health Network, Toronto, ON, Canada*.

Background: Immunosuppressive drugs are used in the long-term management of post-transplant patients to prevent rejection of transplanted organs. Lacking a prior qualitative systematic review on this topic, we aimed to characterize the metrics used to measure cumulative immunosuppressant exposure and their associated outcomes in kidney and non-kidney transplant patients.

Methods: We conducted a literature search using search terms related to immunosuppressants and cumulative exposure in Ovid MEDLINE, Ovid EMBASE, Cochrane CENTRAL, and Cochrane Database of Systematic Reviews. No date restrictions were applied. An additional search was performed on Google Scholar and references of studies included in the primary search were screened. Studies were limited to the English language with adult human transplant patient populations. Study risk of bias was assessed using the Quality in Prognostic Studies Tool where each domain was rated as low, medium, or high risk of bias.

Results: A total of 29 articles were included in our qualitative synthesis. Kidney transplant populations account for 12 (41%) of the studies in our analyses. Fifteen of the articles (51%) calculated the total dose of immunosuppression over the treatment period while 9 (31%) used long term area-under-the-curve (LT-AUC) of trough level concentrations to quantify cumulative immunosuppression exposure. Nine articles found certain cumulative exposure metrics to be predictive of adverse outcomes such as decreased kidney function, cancer recurrence, and bone fractures. Furthermore, an adequate mycophenolic acid LT-AUC was associated with a decreased risk of allograft rejection, while cumulative corticosteroid exposure was not associated with allograft rejection.

Conclusions: This review analyzed a comprehensive set of articles and metrics that predict long-term outcomes of immunosuppressants in transplant patients. The wide variety of metrics studied highlight the lack of agreement on the best measures of drug exposure in transplant patients. Although certain metrics may demonstrate an association with outcomes, future studies should investigate the predictive power and validation of these metrics.

PO2582

Fludrocortisone Corrects Tacrolimus-Associated Hyperkalemia in Renal Transplant Patients

Rouvick Gama, Virginia A. Quan, Mysore K. Phanish. *Epsom and Saint Helier University Hospitals NHS Trust, London, United Kingdom*.

Background: Hyperkalemic metabolic acidosis is commonly observed following kidney transplantation. This is often due to calcineurin inhibitors which are known to cause type 4 renal tubular acidosis either due to hyporeninemic hypoaldosteronism or due to direct effect on aldosterone responsive potassium secretion in the distal nephron.

Methods: We report 5 post-renal transplant patients (5 males) on tacrolimus with hyperkalemia treated with daily doses of either 50 mcg (n=3) or 100 mcg (n=2) of fludrocortisone. We retrospectively collected data at 3 time points before and after fludrocortisone on serum concentrations of sodium, potassium, bicarbonate, creatinine and tacrolimus as well as eGFR and blood pressure (BP). We recorded emergency admissions and length of stay (LoS) for treatment related to hyperkalemia. Data are presented as mean +/-SD and analysed with a paired students t-test.

Results: Pre and post-fludrocortisone serum concentrations for potassium was 6.3 ± 0.3 mmol/L and 5.1 ± 0.3 mmol/L (p=0.002); venous bicarbonate 18.4 ± 1.8 mmol/L and 20.4 ± 2.0 mmol/L (p=0.108); sodium 135 ± 1.6 mmol/L and 135 ± 2.2 mmol/L (p=0.875); creatinine 184 ± 12.2 mmol/L and 155 ± 10.6 mmol/L (p=0.058); eGFR 39 ± 3.4 ml/min and 47 ± 4.2 ml/min (p=0.035); blood tacrolimus levels 9.8 ± 2.1 ng/mL and 11.2 ± 1.0 ng/mL; BP was 133/69 ± 12/9 mmHg and 129/70 ± 8/6 mmHg before and after fludrocortisone respectively. We were able to either reduce or stop sodium bicarbonate after starting fludrocortisone due to increase in serum bicarbonate levels. Prior to fludrocortisone there were 6 episodes of serum potassium greater than 6.5 mEq/L, of which 3 patients required admission for hyperkalaemia management, with LoS 1-3 days. The majority occurred with tacrolimus levels in target range. Reduction in potassium levels to 'safe levels' were noted within 24-48 hours of starting fludrocortisone.

Conclusions: Treatment of hyperkalemic metabolic acidosis with fludrocortisone resulted in rapid normalization of serum potassium. There were no adverse effects on BP, serum sodium levels or clinical evidence of fluid retention. Instigation of fludrocortisone prevented emergency admissions for treatment of hyperkalemia and allowed the clinicians to run adequate tacrolimus levels. Fludrocortisone can be a cheap, safe and effective option for the treatment of hyperkalemia in renal transplant patients on tacrolimus.

PO2583

Changes in Serum Klotho in Kidney Transplant Recipients and Prognostic Marker for Allograft Function: A Systematic Review and Meta-Analysis

Juan A. Medaura,[1] Charat Thongprayoon,[2] Napat Leeaphorn,[5] Javier A. Neyra,[4] Pradeep Vaitla,[1] Franco H. Cabeza Rivera,[1] Michael A. Mao,[3] Wisit Cheungpasitporn.[1] *[1]Division of Nephrology, Department of Internal Medicine, University of Mississippi Medical Center, Jackson, MS; [2]Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; [3]Department of Medicine, Mayo Clinic, Jacksonville, FL; [4]Division of Nephrology, Department of Medicine, University of Kentucky College of Medicine, Lexington, KY; [5]Renal Transplant Program, University of Missouri-Kansas City School of Medicine/Saint Luke's Health System, Kansas City, MO.*

Background: α-Klotho protein is a well-known anti-aging factor that regulates systemic phosphate metabolism. Mutation of klotho in mice can lead to phenotypes resembling human aging. Since klotho expression is highest in the kidney, patients with advanced chronic kidney disease have progressive decline in klotho levels. However, changes in serum klotho levels in kidney transplant (KTx) patients and its prognostic significance on allograft function remain unclear.

Methods: A literature search was conducted using MEDLINE, EMBASE and Cochrane Database from inception through October 2019 to identify studies evaluating 1) change in serum klotho levels after KTx, 2) klotho levels among KTx vs non-KTx patients, and 3) prognostic significance of klotho levels on allograft function after KTx. Study results were pooled and analyzed utilizing random-effects model.

Results: 10 cohort studies with a total of 431 KTx patients were identified. After KTx, there was significant increase in serum klotho levels (at 4 to 13 months post-KTx) with mean difference (MD) of 243.11 (3 studies; 95%CI 67.41 to 418.81). Although KTx patients had lower serum klotho level with MD of = -234.50 (5 studies; 95%CI -444.84 to -24.16) compared to healthy volunteers, a study demonstrated comparable klotho level between KTx patients and eGFR-matched controls. Two studies demonstrated high serum klotho levels in deceased donors as prognostic marker for good allograft function within 1 year after KTx ($p<0.05$).

Conclusions: There is a significant increase in serum klotho levels after KTx. There is potential role of klotho levels as prognostic marker for renal allograft function.

PO2584

Braving the Storm: Cytokine Release Syndrome with Rabbit Antithymocyte Globulin Therapy after Kidney Transplant

Himmat S. Brar, Franco H. Cabeza Rivera. *University of Mississippi Medical Center, Jackson, MS.*

Introduction: Cytokine release syndrome (CRS) is an acute systemic inflammatory syndrome associated with chimeric antigen receptor (CAR)-T cell therapy or therapeutic antibodies. CRS can present with a variety of symptoms ranging from mild flu to severe life-threatening manifestations of shock, vascular leakage, DIC and multi-organ failure. We present a case of a CRS following rATG induction.

Case Description: A 29-year-old female with a history of T1 DM s/p kidney/pancreas transplantation 12 years ago experienced the rejection of transplanted kidney 1 year back. Her home immunosuppression included Tacrolimus, MMF and Prednisone. She underwent a kidney retransplant from a living donor. The induction immunosuppression consisted of rabbit anti-thymocyte globulin (ATG), methylprednisolone and MMF. Two hours after the rATG infusion (1.5mg/kg) on day 1 of transplant; she developed breathing difficulty, temp of 102.7, RR of 23, HR of 160 and fall in BP to 108/55 mmHg. Lab work showed a drop of Hb from 11.4 to 9, platelets from 187 to 126 and WBC from 17 to 9.8. CXR was unremarkable. ECHO showed normal cardiac function. LE Doppler was negative for DVT. The patient was quickly diagnosed to have CRS and instead of giving fluids and causing pulmonary decompensation, she was given Solumedrol, Benadryl and Tylenol. rATG was discontinued. Cultures were obtained that resulted negative. She improved within a couple of hours with stabilization of vitals. We suspect that the CRS following ATG infusion caused the patient's acute decompensation, given the temporal relationship, rapid recovery following withdrawal and lack of proven infectious etiology. She was finally premedicated and given ATG at a slower rate over 12 hrs and tolerated it well.

Discussion: CRS is an inflammatory cascade that develops within minutes to hours after immunotherapy. The case emphasizes the successful rapid recognition and proper management of CRS in preventing the patient decompensation. The massive cytokine release triggers an inflammatory response leading to capillary leakage, severe hypotension and respiratory failure. The management differs from usual shock as the aggressive hydration leads to pulmonary edema and should be avoided. Steroids and pressors are the mainstay of therapy and should be administered early. The treatment is largely supportive with ventilation for respiratory failure and steroids for inflammation.

PO2585

Proton Pump Inhibitor Prevalence and Documented Indication in a Small Kidney Transplant Program

Abdulrahman Alkandari, Frances Macleod, M. Khaled Shamseddin. *Queen's University, Kingston, ON, Canada.*

Background: Proton pump inhibitors (PPIs) are commonly prescribed post kidney transplantation, and their use was prevalent in 44-48% of recipients. Prolonged exposure to PPIs could be associated with renal and non-renal adverse outcomes, including hypomagnesemia and hip fracture (OR: 1.39, 95% CI: 1.04-1.84). The objective of this report is to evaluate the prevalence and the documented indication of PPI use in our kidney transplant program, while exploring the potential PPI withdrawal and GERD recurrence in a future Quality Improvement (QI) project.

Methods: This is a retrospective study to assess the prevalence and the documented indications of PPI use among all of kidney transplant recipients in our program by March 31st, 2020. The primary variables were the prevalence of PPI use and the percentage of patients with documented indication of PPI use in our Health Information System (HIS).

Results: Out of 202 kidney transplant recipients, 113 (55.9%) patients were on PPIs (Mean age 58 years, Male 68 (60.2%), mean post-transplant longevity 106 months), compared with 12 (5.9%) patients on H2 blockers. Thirty three (29.2%) patients who used to be on H2 blockers were switched to PPI in late 2019 due to contaminated and backordered ranitidine resulting in an adjusted prevalence of PPI use of 39.5% (Figure 1). The indication of PPI use was documented in our HIS as gastro-esophageal reflux disease (GERD) in 53 (46.9%) patients, and as peptic ulcer disease (PUD) in 9 (8%) patients, while its indication was undocumented in 51 (45.1%) patients.

Conclusions: PPI use was prevalent among our kidney transplant recipients similar to other studies. Due to its association with multiple adverse outcomes, better documentation of its indication in the medical record is required. Consideration to withdraw PPI in our kidney transplant recipients and to reassess the risk of GERD recurrence will be assessed in a future QI project.

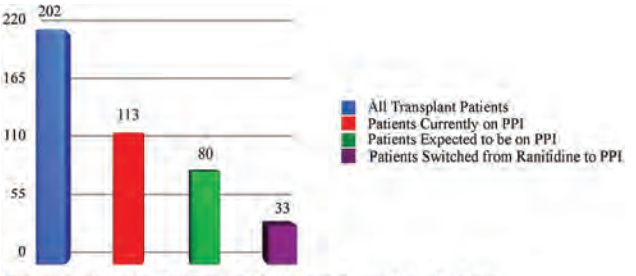

Figure 1: PPI Distribution In All Kidney Transplant Patients

PO2586

Unexpected Recurrence of Undiagnosed ANCA-Associated Vasculitis in a Kidney Transplant Recipient

Ruchi H. Naik, Heidi M. Schaefer, Saed Shawar. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: ANCA Associated Vasculitis (AAV) is one of the leading causes of End-stage Kidney disease (ESKD). The relapses of AAV after kidney transplant are relatively rare. As per the literature, the positive ANCA status in not a contraindication for transplant and patients usually get transplant once in clinical remission. Here, we are describing a unique case of ESKD due to renal limited AAV which was diagnosed retrospectively after the development of the recurrence two months post-transplant.

Case Description: A 69 years old Caucasian female with ESKD presumed due to hypertension received a deceased donor kidney transplant in Oct 2019 after being on dialysis for 4 years. She received alemtuzumab for induction followed by tacrolimus, mycophenolate mofetil, and prednisone for the maintenance immunosuppression. Her immediate post-transplant course was complicated by delayed graft function and her creatinine never went down below 2 mg/dl. Allograft biopsy was planned after 2 months due to persistent microscopic hematuria with progressive sub nephrotic range proteinuria. The immuno-histopathology and electron microscopy was suggestive of pauci-immune crescentic GN. Her serology workup was positive for ANA, ANCA with high titers of MPO. She lacked any other systemic involvement, and drugs induced ANCA was ruled out. She was treated with a pulse dose of methylprednisone and one dose of rituximab. Gradually her creatinine improved to 1.37 mg/dl with down trending MPO antibody titers within 4-6 weeks. The review of her chart retrospectively showed clinically asymptomatic ANCA positivity with high MPO titers 3.5 years back, suggestive of recurrence of AAV more than De novo AAV post-transplant.

Discussion: Physician should always be vigilant about the recurrence of the primary disease after transplant, especially when patients have undiagnosed primary kidney disease like AAV, where early diagnosis and treatment in the early stage of the disease is important to optimize results of renal transplantation. A randomized prospective study is needed to answer the question whether the ANCA positivity at the time of transplant adversely affect the outcomes.

PO2587

A Case of Porphyria Cutanea Tarda After Kidney Transplant

Robert C. Hartley, Laith Al-Rabadi, Fuad S. Shihab, Divya Raghavan. *The University of Utah School of Medicine, Salt Lake City, UT.*

Introduction: Porphyria cutanea tarda (PCT) is the most common subtype of porphyria and can be associated with kidney failure with reports of kidney transplantation curing the disease. We report the case of a patient who had previously undergone kidney transplantation and developed PCT after transplant.

Case Description: A 40-year-old man with end stage renal disease due to unknown chronic glomerulonephritis status post kidney transplant 4.5 years ago was admitted with non-healing blisters on both hands. Patient initially presented one month earlier with similar symptoms and was diagnosed with bullous impetigo due to methicillin resistance staphylococcus aureus. At that time, he was treated with vancomycin followed by trimethoprim-sulfamethoxazole (TMP-SMX) for a total of 14 days. He was also noted to have cytomegalovirus viremia which was treated with valganciclovir. Patient reported ongoing development of lesions despite antibiotic treatment and presented for follow-up where he was noted to have an acute kidney injury and hyperkalemia. At presentation his medications included mycophenolate sodium, tacrolimus, prednisone, triamcinolone cream and mupirocin ointment. There was no family history of skin disease and he did not drink alcohol. He underwent skin biopsy which was consistent with porphyria or pseudoporphyria. Urine and plasma porphyrins were checked showing elevated uroporphyrin and also elevate heptacarboxyl, hexacarboxyl and pentacarboxyl porphyrins with normal coproporphyrin I and III consistent with PCT. Additional workup was notable for a ferritin of 978 ng/mL, hepatitis A, B and C titers inconsistent with current or past infection and HFE gene testing showing the absence of mutations C282Y, H63D and S65C. Patient's kidney injury resolved with cessation of TMP-SMX and fluid resuscitation. Patient was treated with therapeutic phlebotomy and erythropoiesis stimulating agents along with counseling on sunscreen use and wearing sun protective clothing.

Discussion: PCT is the most common form of porphyria and is associated with hepatitis C, iron overload, estrogen administration and alcohol use. It has also been associated with hemodialysis often with resolution at the time of kidney transplantation. However, elevated iron stores are often present in kidney transplant patients and PCT can be misdiagnosed as bullous impetigo as it was in this case.

PO2588

Recurrent Focal Segmental Glomerulosclerosis After Kidney Transplantation: A Single-Center Experience

Muhammad Ajmal Panezai, Priya Yenebere, John K. Guirguis, Dennis P. Mishler, Oluwafisayo O. Adebiyi, Muhammad S. Yaqub, Tim E. Taber, Asif A. Sharfuddin. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Recurrent FSGS (r-FSGS) after Kidney Transplantation has a high risk of graft loss. However, the natural history, clinical predictors, and response to treatment remain unclear.

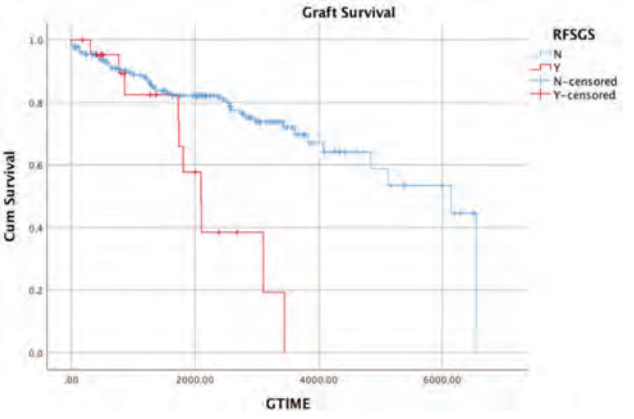
Methods: We retrospectively reviewed all transplant patients at our institition from 2000-2019 with a diagnosis of FSGS and identified and sub-analyzed all cases of recurrent FSGS cases (r-FSGS).

Results: Out of 198 transplants, there were 22 (11.1%) events of biopsy proven r-FSGS. Demographics of the rFSGS cases are described in the Table. 27% of cases had recurrence within 1 month of transplant. Treatments given for r-FSGS included ACE/ARB (100%), Therapeutic Plasma Exchange (40.9%), Rituximab (36.3%), conversion to Cyclosporin (36.3%) and Steroids (27.2%). 65% of cases had either a partial or complete remission. Mean proteinuria decreased and mean eGFR was improved at 1 year of recurrence ($p<0.05$). Over a median follow up period of 4.6 years, there was a 59% graft loss with no patient deaths. 31.8% of patients were re-transplanted after initial graft loss of which 42% had recurrence in their re-transplant. As compared to the cases without any recurrence, cases with rFSGS had a significantly lower long-term graft survival ($p=0.001$). Figure.

Conclusions: Recurrent FSGS continues to be a high risk for graft loss despite a multitude of therapies available.

Demographics & Outcomes of Recurrent FSGS Cases

Mean Age	49.7+/-13.9
Gender (M)	68.5%
Race (W)	68.5%
Living Donor	45%
Re-Transplants	31%
Pre-Emptive	22%
Median Duration to Recurrence	202 days
Mean Proteinuria at recurrence / at 1 yr post-recurrence	5.3±5.9 / 4.1±4.9 g/day
Mean eGFR at recurrence / at 1 yr post-recurrence	28.5±15.2 / 36.6±21.1 ml/min
Initial IS - ATG/MMF/Tac/Pred	72%/100%/100%/13.6%



PO2589

What Is the Safe Anti-A2 Titer for a Successful A2-Incompatible Kidney Transplantation?

Yorg Al Azzi, Pablo Loarte Campos, Gayatri D. Nair, Maria Ajaimy, Luz E. Liriano-Ward, Cindy T. Pynadath, Purna Bindu Nandigam, Enver Akalin. *Montefiore Medical Center, Bronx, NY.*

Background: The new kidney allocation system implemented in December 2014 allowed for use of A2/A2B donors to B recipients. However there is no mandate by UNOS regarding what anti-A2 titers are acceptable. We aimed to investigate the safety of kidney transplant in patients with anti-A2 titers equal or less than 1/16.

Methods: We performed 41 A2-incompatible kidney transplants at our institution if pre transplant anti-A2 titers are equal or less than 1/16. All patients received anti-thymocyte globulin induction. Patients with donor-specific-anti HLA-antibodies (DSA) received intravenous immunoglobulins 500 mg/kg for 3 doses.

Results: Of the 41 recipients, 85% were male, 48% African-American, with a median age of 53 (20-73) years. There were 38 deceased donor renal transplants and 3 living related. Median donor age was 42 (16-65) and median KDPI was 52 (2-86). Twenty-one patients had PRA 0% and 8 had pre transplant DSA. Pretransplant anti-A2 titers were 1/2 in 16, 1/4 in 9, 1/8 in 6, and 1/16 in 5 and too weak to titer in 5 recipients. During a median follow-up of 33 months (6-57) patient and graft survival were 100% and 90.2% respectively. Twelve patients underwent a clinically indicated kidney biopsy at a median 28 days post transplant (6-390). There was one case of acute T cell mediated rejection type IIA, and one chronic antibody-mediated rejection which was due to non-compliance leading to graft loss. Interestingly C4d positivity was seen in 9 biopsies, of which 8 did not have any findings of antibody mediated rejection and no microvascular inflammation. Median serum creatinine level at last follow up was 1.3 mg/dL (0.6-3.2) and only 3 patients had spot urine protein/creatinine more than 1 g/day.

Conclusions: A2-incompatible transplantation appears to be safe in patients with anti-A2 titers equal or less than 1/16 with or without DSAs and excellent short-term kidney allograft outcomes. C4d positivity is frequent in allograft biopsies without acute rejection suggesting accommodation to the allograft.

PO2590

Post-Transplant Outcomes for Highly Sensitized Kidney Transplant Recipients with Non-Highly Sensitized Recipients in the Era of the New Kidney Allocation System: A Single-Center Case-Control Comparison

Gaurav Agarwal,[1,2] Darnell Mompoint-Williams,[1,2] Song C. Ong,[1,2] Jayme E. Locke,[1,2] Vineeta Kumar.[1,2] University of Alabama at Birmingham *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]The University of Alabama at Birmingham Comprehensive Transplant Institute, Birmingham, AL.*

Background: The new UNOS kidney allocation system (KAS) of December 2014, gives substantial priority points to highly sensitized (HS) adult kidney transplant recipients (KTR) with cPRA of 99% or higher. There is a concern of worse post-transplant outcomes in HS KTR compared to non-HS KTR. When comparing pre-KAS to post KAS, similar 3-year patient and graft survival has been reported in HS KTR. The comparative outcomes of HS KTR to non-HS KTR in the post KAS era are unknown

Methods: We studied outcomes in HS adult kidney transplant recipients (KTR) and compared them to non-HS KTR in the post KAS era. We included all recipients of deceased donor kidney transplant at the University of Alabama at Birmingham, from December 2014 to March 2020. HS patients were defined as those with cPRA 99% or higher. The HS patients were matched 1:2 with non-HS patients on age, sex, and time of transplant. A Kaplan Meier analysis was performed for patient survival and the combined endpoint of graft and patient survival

Results: A total of 717 deceased donor kidney transplants were performed during the study period, of which 106 HS KTR were identified. The HS patients were more likely to be female (59.4% vs 34%, $p<0.001$), non-black (42.5% vs 30.9%, $p<0.022$) and were of similar mean age at transplant (49.9 vs 50.3 years, $p=0.46$) compared to non-HS patients. The HS-patients were then compared with 228 matched non-HS deceased donor controls.

The matched controls had a median cPRA of 0% (IQR 0-29.5%). There was no difference in death (p=0.17) or combined endpoint of death or graft survival (p=0.35) in the two groups (figure 1).

Conclusions: HS patients have similar mortality and graft survival as compared with non-HS controls. The results of our study support continuing to give HS patients priority in organ allocation

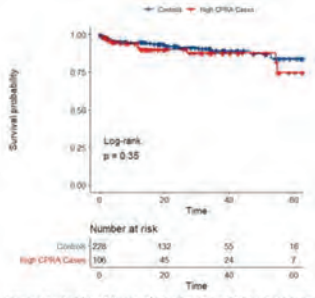


Figure 1. Kaplan-Meier plot comparing time to composite endpoint in highly sensitized patients and non-HS patients, using the log-rank test. Hatch marks represent censored cases in each group.

PO2591

Who Is at Risk for a Transplant Nephrectomy After Graft Loss?

Peter E. Thorne, Everly Ramos, Laura Binari, Guneet S. Kochar, Thomas G. Stewart, Rachel C. Forbes, Saed Shawar, Anthony J. Langone, Khaled Abdel-Kader, Beatrice P. Concepcion. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Patients with failed kidney transplants who subsequently develop clinical symptoms such as fever, allograft pain and gross hematuria usually require a transplant nephrectomy to alleviate symptoms. Identifying patients at risk for a nephrectomy after graft loss may aid clinical decision-making and care at time of, and after graft loss.

Methods: We retrospectively reviewed all patients with death-censored graft loss (DCGL) from 1/2000 to 6/2018 at a single center. We collected baseline demographic and clinical characteristics at time of transplant, at time of, and after DCGL by manual chart abstraction. Data were analyzed using summary statistics. Predictors for nephrectomy were determined *a priori*. A Cox proportional hazards model was used to quantify the association of age, race, gender, body mass index (BMI) at time of graft loss, diabetes, acute rejection as cause of graft loss, and use of prednisone with the risk of nephrectomy.

Results: The study included 333 patients with DCGL of whom 75 (23%) underwent a transplant nephrectomy. Median (IQR) time from graft loss to nephrectomy was 135 (70, 267) days. Among 292 patients without missing data, baseline and transplant characteristics were as follows: age at transplantation 45 (36, 57), 59% male, 40% black, 20% diabetic, 53% with a deceased donor, 83% on calcineurin-based immunosuppression (CNI-IS), 71% on prednisone. Twenty four percent and 69% of patients lost their graft due to acute rejection and chronic allograft nephropathy, respectively. At the time of DCGL: BMI was 25.9 kg/m^2 (22.7, 31.4), SCr 7.5 mg/dl (5.6, 9.6), albumin 3.3 (3.0, 3.8), 86% on CNI-IS, 91% on prednisone. In the Cox model, black race was associated with more than twice greater risk of nephrectomy compared to non-blacks (HR 2.4, 95% CI 1.3-4.3, p=<0.01). Older age had a trend for decreased risk of nephrectomy (HR 0.98, 95% CI 0.95-1.0, p=0.06) but this did not reach statistical significance.

Conclusions: Transplant nephrectomies are common after graft loss and black race is associated with increased risk. Closer monitoring of these patients after graft loss may be warranted. Strategies and interventions to reduce the need for nephrectomy warrant further study.

PO2592

Contraceptive Use Among Women with Kidney Transplants in the United States

Silvi Shah, Kathleen Harrison, Annette Christianson. *University of Cincinnati, Cincinnati, OH.*

Background: Kidney transplant improves reproductive function in women with end-stage kidney disease (ESKD). Little is known about contraceptive use in women with history of kidney transplants.

Methods: Using the United States Renal Data System (2005-2014), we evaluated for each calendar year women with kidney transplantation who were aged 15-44 years with Medicare as the primary payer and linked data from the United Network for Organ Sharing, for up to three entire years after the date of transplantation. We determined rates of contraceptive use and used multivariable logistic regression to identify factors associated with contraceptive use.

Results: The study cohort included 13,150 women and represented 26,624 person-years (PY). The rate of contraceptive use in women with kidney transplant was 9.5% of person-years. Figure 1 shows the rates of types of contraceptive use from 2005-2013. Compared to women aged 15–24 years, contraceptive use was lower in women aged 30–34 years (OR, 0.67; CI, 0.58-0.78), 35-39 years (OR, 0.36; CI, 0.31-0.43), and 40-44 years (OR, 0.23; CI, 0.19-0.28). Compared to white women, contraceptive use was higher in black women (OR, 1.26; CI, 1.10-1.43) and Native American women (OR, 1.52; CI, 1.02-2.26). Women had lower rates of contraceptive use in the second-year post-transplant (OR, 0.87; CI 0.79-0.94) and third-year post-transplant (OR, 0.69; CI 0.62-0.76) than in the first-year post-transplant. Women with a history of diabetes had a lower likelihood of contraceptive use (OR, 0.80; CI, 0.65-0.99).

Conclusions: Among women with kidney transplants, contraceptive use remains low at 9.5%. Factors associated with a higher likelihood of contraceptive use include younger age and black and Native American race/ethnicity; second- and third-year post-transplant and history of diabetes are associated with a lower likelihood of contraceptive use. The study highlights the importance of counseling for contraceptive use in women with kidney transplants.

Evaluation of Reproductive Care Provided to Adolescent Patients in Pediatric Nephrology Clinics

Shyanne Hefley,[1] Noel Howard,[1] Salem Almaani,[2] Isabelle Ayoub,[2] Michelle A. Hladunewich,[3] Michelle M. O'Shaughnessy,[4] Shikha Wadhwani,[5] Jarcy Zee,[6] William E. Smoyer,[7] Scott E. Wenderfer,[8] Katherine Twombley,[9] Tetyana L. Vasylyeva.[1] *[1]Texas Tech University Health Sciences Center, Amarillo, TX; [2]The Ohio State University Wexner Medical Center, Columbus, OH; [3]University of Toronto, Toronto, ON, Canada; [4]University College Cork National University of Ireland, Cork, Ireland; [5]Northwestern University Feinberg School of Medicine, Chicago, IL; [6]Arbor Research Collaborative for Health, Ann Arbor, MI; [7]Nationwide Children's Hospital, Columbus, OH; [8]Baylor College of Medicine, Houston, TX; [9]Medical University of South Carolina, Charleston, SC.*

Background: An increasing number of adolescents are living with end-stage renal disease (ESRD) or chronic kidney disease (CKD) in the US. Therefore; it is important that nephrologists can manage reproductive and women's health issues in adolescents with CKD. In this study, we aimed to determine the confidence levels of nephrologists in the US in managing women's health issues in adolescent females with CKD.

Methods: Using Qualtrics Online Survey Platform, a survey was distributed by email to members of the Pediatric Nephrology Research Consortium. The survey contained 19 questions pertaining to provider demographics, training, current practice, frequency of documenting and/or discussing women's health issues, and level of confidence in managing women's health issues in adolescent female patients.

Results: Seventy-five nephrologists participated, with a majority practicing in academic centers (88%). For most providers, adolescents comprised 25-74% of all patients. Ninety-eight percent denied formal training in women's health or obstetric nephrology. History of pregnancy termination/loss, last menstrual period (LMP), contraceptive use, sexual activity, number of sexual partners, and history of sexually transmitted infections were infrequently documented. Most providers documented discussions about risks of teratogenicity with use of ACEi/ARBs or mycophenolate and risks of infertility and fertility-preserving options with use of cyclophosphamide. Most providers weren't comfortable managing pregnant adolescents and referred them to adult nephrologists. Most were uncomfortable discussing fetal risks with pregnancy in CKD. While most were confident discussing barrier methods, they were much less confident discussing oral contraceptives and long-acting reversible contraceptives (LARCs).

Conclusions: Sexual development and pregnancy appear not to be a focus of nephrologists caring for adolescent females with CKD. Providers also appeared to have a low level of confidence in discussing and managing fertility and pregnancy-related issues in adolescents. Nephrology training needs to incorporate focused women's health content to improve healthcare delivery to adolescent girls.

PO2594

Reproductive Health in Kidney Transplant Recipients

Andrea G. Kattah, Fernando G. Cosio, Vesna D. Garovic. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Women with advanced chronic kidney disease develop menstrual irregularities and infertility that can improve after kidney transplant. However, some women do not have menstrual cycles return after transplant and pregnancy rates are lower than in the general population, which could be due to a combination of biologic and social factors.

Methods: We sent a survey on reproductive health to all women aged 18 to 44 at the time of transplant at all 3 Mayo Clinic sites between 1996 and 2014. We sent a second survey to all non-respondents from the first mailing and then called all remaining women to ask for their participation. We included questions on menstrual cycles, pregnancy, and menopause. Parity at the time of transplant was determined by chart review.

Results: There were 816 unique women, aged 18 to 44 at the time of transplant, in the period from 1996 to 2014. After excluding women who had passed away (n=91), and those with no current address or living outside the US (n=10), there were 715 eligibile women and 190 responded (26.6% response rate). Respondents were more likely to be white and to have had a pregnancy post-transplant. Only 10% of women reported a pregnancy post-transplant, though 14.2% reported actively pursuing pregnancy at some point. Nearly half (42.1%) of women said they were advised not to get pregnant, most often by a nephrologist. There were 61 pregnancies post-transplant, of which 80.1% were planned pregnancies. The majority of pregnancies resulted in livebirths (57%), and miscarriage occurred in 39% of pregnancies. Amenorrhea occurred in 34.2% of women pre-transplant, and 23% of these women did not have cycles return after transplant. The median (interquartile range) age of menopause was 44.5 (36-49) years.

Conclusions: While only 14.2% of respondents reported actively pursuing pregnancy after transplant, nearly half said they were advised not to pursue pregnancy, often by their nephrologists, which could in part explain low pregnancy rates in the kidney transplant population. While amenorrhea prior to transplant occurred in the minority of women, 23% of these women did not have menstrual cycles return post-transplant. Furthermore, the median age of menopause was much earlier than the general population. These findings suggest that kidney disease and/or transplantation itself may impact long-term gonadal function, which should be a target of future study.

Menstrual Irregularities and Subfertility in Women with Glomerular Disease

Monica L. Reynolds, Caroline J. Poulton, Lauren N. Blazek, Susan L. Hogan, Ronald J. Falk, Vimal K. Derebail. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Women with CKD are known to have high rates of irregular menses and subfertility (an extended period of unwanted non-conception). Those with glomerular disease may be at particularly high risk due to exposure to immunosuppression, such as cyclophosphamide, that may lower fertility.

Methods: A women's health survey was distributed to women ages 18-65 in the Glomerular Disease Collaborative Network, a longitudinal research registry in the southeastern United States. Descriptive statistics were employed to assess responses.

Results: The survery was completed by 192 women (response rate 16%) with median age 48 (34-57 interquartile range(IQR)) and BMI 28 (24-35 IQR). The most common diseases were IgA nephropathy/vasculitis (22%), Lupus nephritis (20%), ANCA vasculitis (18%) and FSGS (16%). At the time of the survey, 17% had a kidney transplant or required dialysis. Table 1 describes self-reported menstrual cycle length and permanent cessation of menses by age group. Of those over age 45, 41% reported permanent cessation of menses had occurred at ≤ 44 years old. Cyclophosphamide use was reported by 63 of 192 (33%), and their fertility preservation methods included leuprolide (6, 10%) and oocyte cryopreservation (1, < 2%). One in four women (50/192, 26%) reported a history of attempting to conceive for > 6 months without success. To aid conception, 26% (13/50) reported use of a medication (e.g. clomiphene) and 16% (8/50) underwent intrauterine insemination, in vitro fertilization, or received egg/sperm donation.

Conclusions: Women with glomerular disease and/or vasculitis had high rates of irregular menstruation and early menopause which may contribute to subfertility. Our data is limited as we do not know GFR, nor the timing or amount of cyclophosphamide prescribed. Response bias from women with a positive history may have also played a role. Future efforts should elucidate reproductive endocrinology utilization and success in this population.

Buffy Coat Methylation Is Representative of Methylation Patterns in White Blood Cell Types in Normal Pregnancy

Ranine Ghamrawi,[1] Natasa Milic,[1,2] Sonja Suvakov,[1] Wendy White,[1] Vesna D. Garovic.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Medicinski fakultet Univerzitet u Beogradu, Belgrad, Serbia.*

Background: Epigenetic changes through DNA methylation are increasingly identified in renal diseases and hypertensive disorders. Our previous studies identified an altered methylation pattern in preeclampsia compared to normotensive pergnancies. Epigenetic studies typically use buffy coat- a heterogenous cell population- that varies throughout pregnancy and could potentially interefere with DNA methylation results. The objective of the current study was to assess to what extent the buffy coat methylome is representative of the distinct cell types that it contains namely polymorphonuclear leukocytes(PMN) and lymphocytes(LYM) in normotensive pregnant women.

Methods: We performed a pairwise comparison of the differential methylation in the buffy coat, the polymorphonuclear fraction and the lymphocytic fraction drawn from the same individual in normotensive pregnant women (n=29) within the 24 hours prior to delivery. We analyzed 412481 cytosine-guanine (CpG) sites using an Illumina Human Methylation450 BeadChip.

Results: The three pairwise comparisons yielded a small number of probes that are differentially methylated. After multiple testing corrections, the smallest number of differentially methylated probes was found when comparing the buffy coat to the polymorphonuclear group (2.96%). Pathway analysis of the differentially methylated probes identified a matched process involved in leukocyte lineage. The differentially methylated CpG sites preferentially affected the open seas and shelf regions that have little effect on epigenetic regulation.

Conclusions: The buffy coat DNA methylation profile is representative of the PMN and LYM fractions on an Illumina Human Methylation450 BeadChip. The use of buffy coat is an acceptable approach for DNA sampling in DNA methylation studies and separation is only needed when studying lineage specific diseases.

Pregnancy Outcomes in Women with AKI

Silvi Shah, Kathleen Harrison, Annette Christianson. *University of Cincinnati, Cincinnati, OH.*

Background: Acute kidney injury (AKI) during pregnancy is a public health problem and is associated with maternal and fetal morbidity and mortality. Literature concerning pregnancy outcomes in women with AKI is scarce.

Methods: We evaluated a retrospective single-center cohort of all women who delivered infants between 2012-2019 at our center (N=21,038) to assess the AKI rate and whether the history of AKI during pregnancy was associated with adverse maternal and fetal outcomes. Using multivariate logistic regression models, we determined factors associated with AKI, and associations between AKI and pregnancy outcomes.

Results: Overall, 109 deliveries were identified with AKI during pregnancy. AKI rate was 0.5%. The mean age of women was 28 years, 55% were black, and 36% were white. 25% had a history of diabetes and 24% had a history of hypertension. With regards to maternal outcomes, 46% had preeclampsia, 27% had gestational diabetes, 40% had gestational hypertension, and 57% had cesarean section deliveries. Maternal mortality was 4%. With regards to fetal outcomes, among women with AKI during pregnancy, 19% had preterm deliveries, the live birth rate was 85%, the stillbirth rate was 5%, and neonatal mortality was 5%. Diabetes and hypertension were associated with a higher adjusted likelihood of AKI during pregnancy (OR, 4.59; 95% CI, 2.87-7.50 and OR, 5.97; 95% CI, 3.63-9.80 respectively). In the adjusted model, AKI during pregnancy was associated with a 5.6-fold higher likelihood of preeclampsia (OR, 5.57; 95% CI, 3.70-8.39), 2.2-fold higher likelihood of cesarean section (OR, 2.21; 95% CI, 1.50-3.27), 2-fold higher

likelihood of preterm births (OR, 1.97; 95% CI, 1.22-3.16), 4-fold higher likelihood of stillbirths (OR, 4.04; 95% CI, 1.60-10.20), and a 5.7-fold higher likelihood of neonatal mortality (OR, 5.65; 95% CI, 2.20-14.49).

Conclusions: AKI rate during pregnancy is 0.5%. AKI during pregnancy is associated with a higher likelihood of preeclampsia, preterm births, stillbirths, and neonatal mortality. This study increases our understanding and need for change in policies for the management of AKI during pregnancy.

PO2598

Pregnancy Following Kidney Transplantation: Experience of a Tertiary Renal Obstetric Service Between 1996 and 2020

Sarah Gleeson,[1] Michelle Willicombe,[1,2] Sevda Hassan,[1] Daniel Christiadi,[1] Philip Webster,[1,2] Liz Lightstone.[1,2] *[1]Imperial NHS healthcare Trust, London, United Kingdom; [2]Imperial College London Faculty of Medicine, London, United Kingdom.*

Background: Compared with dialysis, fertility & pregnancy outcomes are more favourable following transplantation. However, pregnancies post kidney transplant remain challenging with a risk of adverse maternal & obstetric outcomes

Methods: All transplanted patients attending the renal-obstetric clinic were identified from an in-house database. Further data were collected from their health records

Results: We identified 52 pregnancies in 39 women. The mean age at delivery was 33±3 years. 57% were white, 17% black & 21% Asian. The cause of ESKD was glomerulonephritis (46%), reflux(17%), unknown/other(27%) & diabetes(10%). 3 patients (5%) miscarried & are not included in further analysis. The mean time from transplantation to pregnancy was 84±56 months. The mean follow up after delivery is 6±5.2 years. The mean eGFR pre-pregnancy was 50.8; at 6 months, 1, 3 & 5 years it was was 49.4, 47.4, 48 & 52.9 ml/min. 1 graft was lost during pregnancy (pre-pregnancy eGFR 25, PCR 150); None were lost in the year postpartum. 5 women(12%) have subsequently lost their graft(mean of 4 years postpartum). 1 woman was presumptively treated for rejection during pregnancy; 2 were treated for rejection within 1 month post-partum. 6 others(14%) had a rejection episode - mean time of 38.6±42.4 months post-partum. There were no maternal deaths. 3/19 women checked for Donor Specific Antibodies(DSA) postpartum had a DSA- 1 present pre pregnancy & 2 de novo. The mean gestational age was 35.7 weeks, with 43% born at term & 43% pre-term(5 born <34 weeks). 18 women(37%) developed preeclampsia. There was one intrauterine death. 66% delivered by caesarean section. The mean birth weight was 2400±588 grams; 24% were <10th percentile

Conclusions: Pregnancy outcomes in patients with transplants are better compared with those on dialysis(PMID: 27083278). However, complications still occur. The rate of preeclampsia (36%) is representative of the current literature & much higher than for women without transplants. Diagnosing preeclampsia in patients with pre-existing hypertension & proteinuria, as for many of our patients, remains challenging. In our experience, reflected here, there are relatively low rates of rejection & graft loss but high rates of obstetric complications. We believe these patients are ideally managed in a joint renal obstetric clinic.

PO2599

Does Nephrologist Involvement Improve Aspirin Prescribing in Pregnant Women with CKD?

Christin M. Giordano McAuliffe,[1] Shelby A. Crants,[2] Lynsa Nguyen,[1] Lisa Zuckerwise,[1] Anna M. Burgner.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University School of Medicine, Nashville, TN.*

Background: Since 2014, the U.S. Preventative Services Task Force has recommended the use of aspirin beginning at 12 weeks gestation in women at high risk for development of preeclampsia including those with chronic kidney disease (CKD). A prior study at the authors' institution revealed overall low prescribing rates for women with CKD with only 50.5% taking aspirin according to the recommended guidelines. The authors hypothesized that having a nephrologist involved in patient care would result in higher aspirin prescribing rates.

Methods: The authors reviewed data from pregnancies with delivery between January 1, 2015 and December 31, 2019. Potential pregnancies were identified with diagnostic codes for pregnancies and then included patients who had diagnostic codes for chronic kidney disease and proteinuria. Pregnancies that ended prior to 12 weeks were excluded. Means, standard deviations, medians, and interquartile ranges were used for continuous variables and frequency. Proportions were used for categorical variables.

Results: In total, 91 pregnancies were included. The mean age at due date was 29.7 (std dev 5.3) with 20.9% being of advanced maternal age. The majority were obese (54.9%), with an overall mean BMI of 33.6 (std dev 8.8). During pregnancy, 64.8% (59/91) of patients with known CKD saw a nephrologist. In addition, 20.3% (12/59) of those with known CKD who had previously seen a nephrologist did not see one during pregnancy. Of those who saw a nephrologist during pregnancy, 50.8% (30/59) were prescribed aspirin. In patients who saw a nephrologist at any time before or after pregnancy, 52.1% were prescribed aspirin while of those who did not see nephrologist during pregnancy, 45% were prescribed aspirin. The odds ratio of receiving aspirin if seen by a nephrologist of 2.33 (0.69-7.89) was not statistically significant.

Conclusions: Nearly two-thirds of pregnant women with CKD saw a nephrologist during pregnancy. The involvement of a nephrologist did not significantly increase aspirin prescribing rates among pregnant women with CKD. Further studies should be done to assess attitudes and knowledge of nephrologists and obstetricians to better understand the reasoning for the low prescribing rates and to assess how to improve aspirin prescribing for preeclampsia risk reduction in pregnant women with CKD.

PO2600

Prepartum 1,3-Butanediol Supplementation Does Not Prevent Onset of Superimposed Preeclampsia in the Dahl S Rat

Jeanne A. Ishimwe, Michael R. Garrett, Jennifer M. Sasser. *University of Mississippi Medical Center, Jackson, MS.*

Background: Chronic hypertension increases the risk of developing superimposed preeclampsia (PE). Previous reports showed that 1,3-Butanediol (BD) lowers blood pressure (BP) in male Dahl salt sensitive (S) rats and female S.SHR(11) rats. The goal of this study was to test if attenuating hypertension before pregnancy through the placentation period via BD prevents the onset of PE and improves kidney function.

Methods: Female Dahl S rats (a spontaneous model of superimposed PE, 11-16 weeks old) were divided into two groups: BD treated (20% via drinking water) and control (ad libitum water). Animals received BD for 7 weeks, baseline BP measurements (telemetry) were taken, and both groups were then mated. On gestation day (GD) 12, treatment was stopped because pilot studies showed that treatment reduced water intake during late pregnancy. Both groups were maintained on normal rodent chow (Teklad 7034, 0.3% NaCl; n=8/group). At GD18 (late pregnancy), uterine artery resistance index (UARI) was measured via Doppler ultrasound, 24h urine was collected on GD19, and tissues were harvested on GD20. Statistical comparisons between groups were done by Student t-test and repeated measures ANOVA used for BP analysis.

Results: Mean arterial pressure was lower in the treated group at baseline (141.9 ± 4.09 vs. 165.7 ± 4.53 mmHg, p= 0.0076), early (135.9 ± 3.42 vs. 168.9 ± 4.55 mmHg, p= 0.0003), mid (142.0 ± 5.16 vs. 170.8 ± 4.61, p= 0.0048) but not late pregnancy (144.9 ± 5.87 vs. 161.9 ± 4.52 mmHg, p= 0.1650). Treated dams had a lower UARI (0.71 ± 0.02 vs. 0.81 ± 0.02, p=0.0077), less fetal resorptions (1.12 ± 0.29 vs. 2.25 ± 0.41, p= 0.0434)) but no differences in pup weight were observed (2.199 ±0.049 vs. 2.199 ± 0.086, p= 0.9938). Proteinuria (39 ± 8 vs. 32 ± 7 mg/day, p=0.5401), blood urea nitrogen (21 ± 0.75 vs. 22 ± 0.78 mg/dL, p=0.2239), creatinine clearance (1.66 ± 0.30 vs. 1.60 ± 0.21 mL/min, p=0.5672) and renal fibrosis (0.55 ± 0.09 vs. 0.75 ±0.08 %, p=0.1382) were unaffected.

Conclusions: In this study, we observed slightly improved placental perfusion and lower fetal demise following prepartum BD treatment; however, the antihypertensive effects of BD were not sustained through late pregnancy when supplementation was stopped at mid-pregnancy. No improvements in renal function were noted.

PO2601

Low Nephron Endowment and Pregnancy-Related Renal Maladaptation in the Pathogenesis of Preeclampsia

Silvia Visentin,[2] Alessandra Gosetto,[2] Giulia Genzone,[2] Eugenio Ragazzi,[3] Valentina Capone,[1] Erich Cosmi,[2] Gianluigi Ardissino.[1] *[1]Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; [2]Dept. of Woman's and Child's Health, Obstetrical and Gynecological Clinic, University of Padova, Padova, Italy; [3]Dept. of Pharmaceutical and Pharmacological Sciences, University of Padova, Padova, Italy.*

Background: Pre-eclampsia (PE), whose pathogenesis is still unclear, complicates 2-8% of pregnancies and is responsible of significant maternal and/or perinatal morbidity and mortality. Given the following premises: 1.the high frequency of PE in renal patients (including solitary kidney); 2.the majority of patients with PE, are healthy before pregnancy and return to well-being after delivery; 3.the familial recurrence of PE and the increased PE recurrence risk in subsequent pregnancies; 4.the increased risk in PE patients of developing hypertension and CKD later in life; 5.the association between intrauterine poor environment, reduced nephron mass and risk of hypertension and CKD. We hypothesize that PE, in otherwise healthy women, is the expression of poor kidney adaptation to the increased functional requirements of pregnancy in subjects with a reduced nephron endowment.

Methods: To test this theoretical explanation, the changes in serum creatinine (sCr) during pregnancy (31st gestational week), used as marker of renal functional adaptation, were analysed in a cohort of 22 pregnant women (mean age 34.7 years; 36% nulliparous).

Results: The 9 uncomplicated pregnancies showed sCr decrease of 12.6±11.2 µmol/L (-18.8±16.9%) compared to 4.2±12.1 µmol/L (-3.8±17.5%); *p*=0.0361 (van der Waerden test) in the 13 pregnancies later on complicated by PE (or pregnancy-related hypertensive disorder).

Conclusions: In conclusion, women who later on developed PE lack the expected pregnancy-related decrease in sCr. It can be speculated that hypertension and proteinuria are due to sub-optimal renal clearance and accumulation of placental-derived metabolites toxic to the endothelium in otherwise healthy subjects with limited nephron endowment thus reduced renal functional reserve

PO2602

Hyponatremia in Preeclampsia: A Diagnostic and Therapeutic Challenge

Nay Seif, Anand Srivastava. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: A 32-year-old female at 35-weeks gestation with twin pregnancy was admitted for hypertension, proteinuria, and hyponatremia (**Figure 1A**).

Case Description: She complained of nausea, blurred vision, and pain. Physical exam revealed 3+ generalized edema. Her blood pressure improved with conservative management, and medications controlled her nausea and pain. **Figure 1B** shows her hospital serum sodium trend. The physical exam, serum and urine studies suggested

hypervolemic hyponatremia due to nephrotic syndrome. She was placed on fluid restriction. Repeat serum sodium and urine protein to creatinine ratio (UPCR) were 118 mEq/L and 4.4 g/g creatinine, respectively. Her obstetrician decided to perform emergency delivery. Prior to oxytocin induction, she received 3% saline, 0.9% saline, and IV furosemide. Three hours after delivery, serum sodium was 125 mEq/L and UPCR was 0.2 g/g creatinine. Fluid restriction continued for the first 24 hours after delivery and her serum sodium remained stable. Over the next 24 hours, her serum sodium corrected to 138 mEq/L with liberalization of the fluid restriction

Discussion: Hyponatremia in pregnancy may be due to antidiuretic hormone (ADH)-dependent factors, such as "reset" osmostat, diffuse vasodilation, nausea, and pain. Administration of oxytocin, which is structurally similar to ADH, can also reduce serum sodium. In preeclampsia, hyponatremia may occur due to decreased effective circulating volume secondary to antiangiogenic factors or nephrotic syndrome, non-osmotic release of ADH with consequent water retention, or SIADH. Worsening hypertension with end organ damage are severe features of preeclampsia often requiring emergent delivery, but severe hyponatremia is often overlooked as a severe feature. This case illustrates that patients with preeclampsia may develop severe hyponatremia, which improves after delivery. Refined guidelines should consider severe hyponatremia and its management in preeclampsia

Figure 1A

	1 week prior to admission	Day 1

PO2603

Proteinuria in Early Pregnancy: Role of sFLT-1:PlGF Ratio

Nay Seif, Carla L. Ellis, Shikha Wadhwani. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: A 32-year-old nulliparous woman at $20^{5/7}$ weeks gestation by in vitro fertilization was admitted for hypertension (HTN), proteinuria, and acute kidney injury.

Case Description: She reported no home medications other than prenatal vitamins. Exam was notable only for trace leg edema. Given nephrotic syndrome early in pregnancy and unremarkable hemolysis work-up (**Figure 1A**), there was concern for acute glomerulonephritis (GN). Renal biopsy showed signs of thrombotic microangiopathy (TMA) (**Figure 1B**) without evidence of immune-complex mediated GN. As Atypical hemolytic uremic syndrome (aHUS) and Preeclampsia (PEC) were both on the differential, serum was tested for sFLT-1 and PlGF. Based on emerging evidence of alternative complement pathway activation in PEC, Eculizumab use was discussed but not pursued due to uncertain fetal viability, even with pregnancy prolongation. Ultimately, patient chose to terminate the pregnancy and subsequent pathology review revealed maternal vascular malperfusion and early intrauterine fetal demise. Levels of sFLT-1 (95,228 pg/ml), PlGF (139.3 pg/ml), and sFLt-1: PlGF ratio (683.6) were all consistent with severe PEC (**Figure 1C**). At 2-month follow-up, proteinuria had resolved and HTN was controlled with Nifedipine.

Discussion: Patients presenting with nephrotic syndrome and hypertension ≦ 20 weeks gestation pose a diagnostic dilemma. Renal biopsy is necessary to distinguish PEC from GN but pathological diagnosis of TMA can lead to persistent diagnostic uncertainty. Measurement of circulating angiogenic factors can be useful, with sFLT-1:PlGF ratio > 38 supporting a diagnosis of PEC. Further validation and widespread availability of such testing is needed to assist in management of early pregnancy complications.

Figure 1A	Initial laboratory values
Serum creatinine (mg/dL)	1.18 (baseline 0.8)
24-hour urine collection (g/d)	9
Urine protein/creatinine (g/g)	10.7
Urinalysis with microscopy	>300 protein, 0-3 RBCs/hpf, 51-100 WBC/hpf
Serum Albumin (g/dL)	2.7
AST, ALT (Unit/L)	15, 11
Uric Acid (mg/dL)	9.9
Hemoglobin (g/dL)	11.8 with normal differential
Platelets (K/UL)	237
LDH (U/L)	252
Haptoglobin (mg/dL)	77
Peripheral blood smear	No evidence of hemolysis
ANA	1:80
C3, C4 (mg/dL)	121, 22
Lupus Anticoagulant	Negative
Anticardiolipin antibody	Negative
Beta-2-Glycoprotein	Negative

Figure 1B

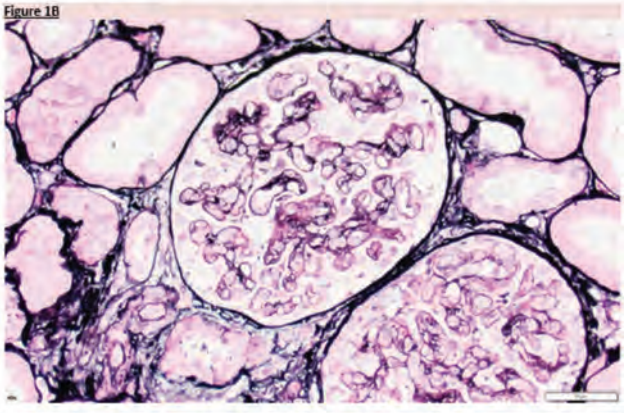

Figure 1C	1 week after discharge
Serum creatinine (mg/dL)	0.9
Urine protein/creatinine (g/g)	3.5
ADAMTS 13 activity	56%
sFLT-1 (pg/ml)	95,228 (5 to 10 x ULN)
PlGF (pg/ml)	139.3 (2 to 3 x LLN)
sFLT-1: PlGF ratio	683.6

PO2604

Hyperemesis Gravidarum-Induced Acute Tubular Necrosis: A Case with More Than Fivefold Rise in Serum Lipase Level Above the Upper Limit of Normal

Samira Z. Chandra,[3,1] Bruna Taveras Garcia,[2] Belinda Jim.[2] *[1]Bangladesh College of Physicians and Surgeons, Dhaka, Bangladesh; [2]Jacobi Medical Center, Bronx, NY; [3]Dhaka Medical College and Hospital, Dhaka, Bangladesh.*

Introduction: Hyperemesis gravidarum (HG) occurs in 0.3 to 10 percent of pregnancies with only 0.8 percent requiring hospitalization. HG usually starts within 4^{th} to 6^{th} week of gestation, peaks around 9^{th} week and fades away between 16^{th} to 20^{th} gestational weeks. In some cases, HG may last until the third trimester. Here we are reporting such a case which was associated with serious complication like acute renal failure. Co-incidentally the patient was also found to have serum lipase level 5 times above the upper limit of normal (ULN). Since HG exerts multisystemic manifestations, the unusual pattern of raised serum lipase is often due to associated renal impairment.

Case Description: A 25-year old primigravida at 16^{th} week of gestation was admitted for severe dehydration and acute kidney injury (S. Creatinine 5.1 mg/dl). She was suffering from HG since the beginning of her pregnancy. A month prior to this admission, the patient was hospitalized on multiple occasions for extreme nausea and blood-tinted vomiting. Her initial labs were suggestive of high anion gap metabolic acidosis (anion gap 31.9mmol/L). Urine electrolytes (Na^+<20mEq/day, K^+ 29mEq/day, Cl^- <20mEq/day) with $FeNa^+$<0.1% indicated pre-renal etiology and urine microscopy showed muddy brown casts suggestive of ATN. Patient's serum ALT (134 IU/L) and AST (93 IU/L) were raised >3 and >2 folds of ULN respectively whereas serum lipase (921 U/L) and amylase (309 U/L) levels were raised >5 and 3 folds of ULN respectively. Patient was treated conservatively with IV 0.9% NaCl saline. Eventually, her serum AST, ALT, lipase and amylase started decreasing with spontaneous recovery of renal function overtime (S. Creatinine 0.5mg/dl). Patient's HG persisted until 32^{nd} week of gestation when symptom subsided completely without medication.

Discussion: In acute pancreatitis, the sensitivity and specificity of serum lipase above 3-times of the ULN range 64%-100% and 99%-100% respectively. More than 3-folds rise of serum lipase above the ULN can also be seen in a variety of other conditions including renal failure. Even in 15% cases of HG with normal renal function, serum Lipase can rise by 5-folds. Therefore, clinical and biochemical co-relation is necessary to rule out acute pancreatitis in pregnancy.

PO2605

Outcomes of Delivery Hospitalizations Among Pregnant Women with Kidney Transplant in the United States

Api Chewcharat,[1,2] Andrea G. Kattah,[1] Charat Thongprayoon,[1] Wisit Cheungpasitporn,[3] Boonphiphop Boonpheng,[4] Maria Lourdes Gonzalez Suarez,[3] Iasmina Craici,[1] Vesna D. Garovic.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mount Auburn Hospital, Cambridge, MA; [3]University of Mississippi Medical Center, Jackson, MS; [4]University of California Los Angeles, Los Angeles, CA.*

Background: Outcomes of delivery hospitalizations, including acute kidney injury, obstetric and fetal events among pregnant women with kidney transplants (KT) compared to those with no known kidney disease and chronic kidney disease (CKD) stage 3-5 are unclear.

Methods: Hospitalizations for delivery were identified using the enhanced delivery identification method in the National Inpatient Sample dataset from the years 2009 to 2014. Diagnoses of CKD stage 3-5, KT along with obstetric events, delivery methods, and fetal events were identified using ICD-9-CM diagnosis and procedure codes. Logistic regression accounting for the survey weights and matched regression were conducted to investigate the risk of maternal and fetal complications in women with KT as compared to women with no kidney-related diagnosis and compared to women with CKD stage 3-5.

Results: A total of 5,408,215 hospitalizations resulting in delivery were identified, including 405 women with CKD stage 3-5, 295 women with functioning KT, and 5,405,499 women with no kidney diagnosis., Pregnant KT recipients were at higher odds of pregnancy-induced hypertension (OR = 3.11, 95%CI [2.26, 4.28]), preeclampsia/eclampsia/HELLP syndrome (OR = 3.42, 95%CI [2.54, 4.60]), preterm delivery (OR = 2.46, 95%CI [1.75, 3.45]), fetal growth restriction (OR = 1.74, 95%CI [1.01, 3.00]), and acute kidney injury (OR = 10.46, 95%CI [5.33, 20.56]) as compared to women with no kidney-related diagnosis. There were no significant differences in rates of gestational diabetes and cesarean section. Pregnant women with KT had 1.30-time longer length of stay and 1.28-time higher cost of hospitalization. However, pregnant women with CKD stage 3-5 were at higher odds of AKI, preeclampsia/eclampsia/HELLP syndrome and fetal death, and had longer hospital stay and cost of hospitalization compared to pregnant women with KT.

Conclusions: Pregnant women with KT were more likely to experience adverse events during delivery when compared to women with no known kidney disease. However, pregnant women with advanced CKD were more likely to experience serious complications than KT recipients. Women with advanced CKD who wish to conceive might consider conception after transplantation for better pregnancy-related outcomes.

PO2606

Successful Pregnancy in a Patient with Congenital Renal Dysplasia After Initiation of Dialysis

Jennifer C. Tang,[1,2] Annika K. Khine.[1,2] *[1]University of Southern California Keck School of Medicine, Los Angeles, CA; [2]Los Angeles County University of Southern California Medical Center, Los Angeles, CA.*

Introduction: Chronic kidney disease (CKD) is a well-known risk factor for adverse maternal and fetal outcomes including preeclampsia and fetal growth restriction. For those on dialysis, increasing the frequency and duration of dialysis has shown to optimize outcomes. However, it remains unclear if and when pregnant patients with CKD should start dialysis to improve outcomes. We present a patient with congenital renal dysplasia who successfully gave birth after starting dialysis.

Case Description: A forty-one-year-old female with an intrauterine pregnancy of 25 weeks and a history of two miscarriages, preeclampsia, and congenital renal dysplasia presented to nephrology clinic. Patient was unaware of her kidney dysfunction and had residual renal function with a creatinine of 3.76 and urine pr/cr ratio of 1.18. A fetal ultrasound revealed a fetal weight in the 12th percentile, head circumference in the 2nd percentile, and biparietal diameter (BPD) in the 33rd percentile. Therefore, the patient started daily dialysis with longer sessions to optimize fetal outcomes. A repeat ultrasound two weeks later revealed interval growth with a fetal weight in the 24th percentile and BPD in the 45th percentile but with abnormal umbilical artery Doppler findings, an indicator of small gestational age. The patient was admitted at 31 weeks due to concern for preeclampsia and continued daily dialysis. Due to labile blood pressures and fetal decelerations, the patient underwent a C-section at 32 weeks and delivered a newborn with an APGARS score of 6/8. Both the patient and her baby were eventually discharged home without complications.

Discussion: Initiation of dialysis resulted in significant interval fetal growth and this patient's first viable infant. Further research is warranted to assess if starting dialysis earlier in pregnant patients with CKD may improve fetal outcomes.

Fetal ultrasound prior to dialysis with a femur length in the 6th percentile and an estimated fetal weight of 635 grams in the 12th percentile.

PO2607

The Ethics of Caring for Pregnant Patients with CKD: A Scoping Review

Elizabeth M. Hendren, Michelle A. Hladunewich, Ariel Lefkowitz. *University of Toronto, Toronto, ON, Canada.*

Background: Physicians must consider many ethical principles when managing patients with chronic disease before and during pregnancy. An ethical framework could guide joint decision making between physicians and their patients, but does not currently exist.

Methods: We performed a scoping literature review to explore the ethical considerations associated with pregnancy in patients with chronic disease. We searched for articles published between 1975 and 2019 using the terms "Ethics" and "High risk Pregnancy/Pregnancy" along with 29 chronic disease-specific MeSH terms (e.g. scleroderma, diabetes, cystic fibrosis).

Results: We identified 968 articles and excluded 947 based on their title or abstract. 12 full text articles were included in the final scoping review representing discussions, case reports, and literature reviews on the ethics of high-risk pregnancy in 8 chronic diseases. The extracted data were examined and integrated into analyses of clinical cases in order to develop recommendations for ethically caring for this patient population.

Conclusions: Physicians have an ethical duty to their patients to facilitate autonomous decision-making and informed consent. Secondarily, they have a duty to protect the fetus and to use resources judiciously as long as it does not negatively impact the care they provide to their patient.

PO2608

Anti-Glomerular Basement Membrane Disease in Pregnancy

Fahad A. Lodhi,[1] Peter E. Umukoro,[2] Syed Sajjad,[1] Rebecca Blonsky.[1] *[1]Marshfield Clinic Health System, Marshfield, WI; [2]Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Anti-glomerular baseline membrane (anti-GBM) disease is a rare cause of renal failure due to the production of IgG antibodies against type IV collagen. Its occurrence during pregnancy is even less common and can lead to poor maternal and fetal outcomes.

Case Description: A 23-year-old female with history of depression presented at 15 weeks 3 days gestation with weakness, nausea and vomiting for one week and anuria for 24 hours. Labs were significant for a creatinine of 19.8 mg/dL, BUN 113 mg/dL and potassium 7.1 mmol/L. Labs six months prior were normal. Nephrology was consulted and the patient was transferred to the intensive care unit for urgent hemodialysis. Further serologic investigation revealed elevated anti-GBM antibodies. A kidney biopsy was performed which demonstrated 100% cellular crescents on light microscopy and linear deposits on immunofluorescence, confirming the diagnosis. In addition to daily hemodialysis, the patient underwent plasmapheresis and immunosuppression with pulse dose steroids followed by a steroid taper as well as azathioprine and tacrolimus. The patient returned to the hospital with hypoxic respiratory failure due to parainfluenza virus further complicated by pre-term premature rupture of membranes at 24 weeks 4 days. As the patient had no signs of renal recovery, her immunosuppression was discontinued. The patient remained inpatient receiving daily hemodialysis until 28 weeks 0 days when the patient developed uncontrollable hypertension requiring an emergent cesarean section. The patient gave birth to a live male weighing 1.1 kg. Her post-partum course was uncomplicated, though the patient remains dialysis dependent.

Discussion: The treatment of choice in anti-GBM disease is plasmapheresis to remove circulating antibodies and immunosuppression to reduce antibody production. However, pregnancy presents a unique challenge in choosing immunosuppressive agents as both maternal and fetal effects need to be considered. The involvement of high risk obstetrics as well as neonatology in the care of these patients is imperative to ensure the best possible outcomes.

PO2609

Identification of Renal Disease in Women with Hypertensive Pregnancies

Hayley Martin,[1] Henry A. Kibble,[1] Kieran R. Palmer,[1] Emmanouil Kountouris,[1] Amelia M. Holloway,[1] Kate Bramham,[1,2] Katherine R. Clark.[1,2] *[1]King's College Hospital NHS Foundation Trust, London, United Kingdom; [2]King's College London School of Lifecourse Sciences, London, United Kingdom.*

Background: Hypertension in pregnancy can be associated with renal injury, which may be masked by gestational change. Additionally, pregnancy affords an opportunity to diagnose asymptomatic renal disease. Postpartum assessment enables detection of on going renal abnormalities. We aimed to determine prevalence of renal disease in postpartum women with chronic hypertension, pregnancy induced hypertension or pre-eclampsia in a previous or current pregnancy.

Methods: Women with singleton pregnancies seen in a specialist clinic for hypertension with estimated GFR (CKD-EPI) below 90mls/min/1.73m^2 and/or proteinuria at six-weeks postpartum were offered specialist renal midwifery clinic follow-up.

Results: 143/341 women offered follow-up attended renal clinic (Median 185 (IQR 246.25) days after delivery). 82 (57.3%) women had proteinuria and/or low eGFR. Subgroup analysis according to hypertensive group is shown in Table 1.

Conclusions: Over half of women with proteinuria and/or reduced eGFR at six weeks postpartum had sustained evidence of renal disease regardless of hypertensive diagnosis. Postpartum assessment may afford an opportunity to detect renal disease.

Table 1

	Chronic Hypertension (N=33)	PIH in current pregnancy (N=20)	PE in current pregnancy (N=80)	History of PE/PIH (N=10)
Six Week Postpartum Visit

PO2610

Senescence Markers in Women with Preeclampsia Pregnancies

Sonja Suvakov,[1] Ranine Ghamrawi,[1] Haitao Tu,[2,1] Wendy White,[1] Natasa Milic,[1] Joseph P. Grande,[1] Vesna D. Garovic.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]The First Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.*

Background: Preeclampsia, a hypertensive disorder of pregnancy, is characterized by impaired angiogenesis and inflammation. Data indicate that preeclampsia is mechanistically related to cellular senescence, an irreversible cell-arrest mechanism which has been increasingly associated with accelerated aging. The aim of this study was to determine if senescence plays a role in the pathophysiology of preeclampsia. To that end, we compared SASP components in blood and fat tissue sections between preeclamptic and normotensive pregnancies, as well as p21 and p16 expression in the fat and kidney tissue samples.

Methods: Blood samples from preeclamptic and normotensive patients at the time of delivery were used to study circulating senescence-associated secretory phenotype (SASP) components. Plasma SASP components were tested using Luminex 200 system. Fat tissue explants (3-5 g) were obtained during the surgery from pregnant women who were clinically indicated for C-section. Kidney sections originated from the autopsy material from patients who died from preeclampsia. Upon protein isolation from fat tissue, SASP components were measured. Fat and kidney tissue sections were immunostained for p16 and p21. Preeclamptic and normotensive participants were matched for age and BMI.

Results: Significant increase of senescence markers were found in blood of preeclamptic pregnancies for NGF (1.30±0.82 vs. 0.77±0.19, p=0.032), MCP1 (316.95±163.95 vs. 207.53±84.78, p=0.047), TNFa (2.79±1.08 vs. 2.06±0.64, p=0.043) and Pai1 (58.03±18.85 vs. 38.12±20.86, p=0.023). Similarly, significant increase in senescence markers was found in preeclamptic pregnancies for MCP1 and TNFa. Expression of p16 was significantly increased in fat tissue, whereas the difference in p21 expression between preeclamptic and normotensive patients was not observed. Expression of p16 in preeclamptic renal sections was significantly higher (p=0.02) than in sections from normotensive pregnancies. The p21 expression did not differ between preeclamptic and normotensive kidney sections.

Conclusions: Women with preeclampsia have higher senescent burden compared to normotensive pregnant women at the time of delivery. Senolytic agents that target senescence may offer the opportunity for mechanisam-based therapies.

PO2611

Sexual Dimorphism and Hard Outcomes in AKI: Is Female Sex Protective? The Jury Is Still Out

Maria Isabel Acosta-Ochoa, Armando Coca, Jimmy R. Sanchez Gil, Alicia Mendiluce. *Hospital Clinico Universitario de Valladolid, Valladolid, Spain.*

Background: Many studies focus on sex dimorphism and it's influence on hard outcomes when suffering an AKI episode. Some report that women, while others report that men are protected against adverse clinical events. In a real world cohort of individuals suffering from AKI, we compared hard outcomes between sexes with a novel approach: paired-matched study.

Methods: Retrospective paired-matched study of in-patients with AKI diagnosis; cases were matched based on sex, age and Charlson's Index. We used KDIGO-2012 criteria to define AKI, analyzed clinical variables, and compared the hard outcomes: length of hospital stay, need for acute HD, HD dependence at discharge, and in-hospital mortality.

Results: We included 383-paired matches. Male individuals suffered from peripheral arterial disease and COPD, and were hospitalized in surgical wards more frequently than women. We found no statistically significant difference between groups regarding to the prevalence of common comorbidities and admission to ICU (Table 1A). The distribution in global KDIGO-AKI Stages was similar, but when analyzing every sub-criterion of the classification we found that women fulfilled the serum creatinine (SCr) increment ≥1.5-1.9x more frequently, and men fulfilled reaching a SCr >4 mg/dl more commonly. We found no statiscally significant differences in hospital stay, need for acute HD, HD dependence at discharge, and in-hospital mortality (Table 1 B).

Conclusions: To our knowledge, a paired-matched design regarding to this topic has not been previously published. Although experimental studies find differences in clinical outcomes between sexes when suffering an AKI episode, in this real world study, we did not observe a clear distinction in the incidence of adverse outcomes between sexes. We conclude that sex (either female or male) may not be protective against AKI's hard outcomes.

	Women (383)	Men (383)	P value

Effects of Veverimer on Serum Bicarbonate and Physical Function in Women with CKD: A Subgroup Analysis from a Randomized Controlled Trial

Vandana S. Mathur,[1] Donald E. Wesson,[2] Navdeep Tangri,[3] Yuri Stasiv,[4] Dawn Parsell,[4] Elizabeth Li,[5] Gerrit Klaerner,[4] David A. Bushinsky.[6] *[1]MathurConsulting, Woodside, CA; [2]Baylor Scott & White Health and Wellness Center, Dallas, TX; [3]University of Manitoba, Winnipeg, MB, Canada; [4]Tricida, Inc., South San Francisco, CA; [5]PharmaStat LLC, Fremont, CA; [6]University of Rochester Medical Center, Rochester, NY.*

Background: More women than men have CKD. However, women have been under-represented in clinical trials. Veverimer is an orally administered, non-absorbed polymer that treats metabolic acidosis by binding and removing HCl from the GI tract. In Phase 3 randomized, double-blind, placebo-controlled trials, veverimer significantly increased serum bicarbonate and improved physical function in acidotic patients with CKD (Wesson et al. *Lancet*, 2019). Here we analyzed efficacy and safety among the women in these studies of up to one year.

Methods: Physical function was assessed using the Kidney Disease and Quality of Life Physical Function Domain (KDQOL-PFD) which quantifies limitations on daily activities and by performance on the repeated chair stand (RCS) test.

Results: Of the 217 pts randomized, 83 (32%) were women, of whom 81% were post-menopausal (≥55 yrs). Select comorbidities included hypertension (95%), diabetes (64%), and congestive heart failure (30%). At Baseline, mean eGFR in women was 28.4 mL/min/1.73m^2 and mean serum bicarbonate was 17.3 mEq/L. More women receiving veverimer met the primary study endpoint, had a significant increase in serum bicarbonate and improved both KDQOL-PFD scores and RCS time (**Table**) compared with placebo. The effects of veverimer exceeded the minimal clinically important difference for both KDQOL-PFD (+3 to +5 points) and RCS (-1.7 seconds). Rates of serious, non-serious and GI adverse events were similar in the groups; none required treatment discontinuation.

Conclusions: Given their lower bone and muscle mass, women with CKD may be particularly vulnerable to the adverse effects of metabolic acidosis. We found that in women with CKD and metabolic acidosis, treatment with veverimer significantly improved how women felt and functioned. The safety of veverimer was similar to placebo.

Funding: Commercial Support - Tricida, Inc.

Efficacy Endpoints	Placebo (N = 33)	Veverimer (N = 50)
Primary Endpoint: proportion increasing serum bicarbonate by ≥ 4 mEq/L or achieving normalization at Week 12	28%	63% P<0.0001
Change from baseline in Serum Bicarbonate (LS mean, mEq/L) at Week 12	+2.0	+4.9 P< 0.0001
Patient-Reported Physical Function (KDQOL-PFD Mean [SD] Total Score at Week 52)*	-5.16 (20.27)	+13.15 (26.11) P = 0.0031
Objective Measurement of Physical Function	+0.77	-4.16 (15.43)

P-values are vs. placebo; An ANCOVA rank-based method was used for physical function endpoints

*Based on evaluable patients enrolled in controlled extension study (placebo, n=31; veverimer, n=46)

Dietary Magnesium Intake, Risk of Kidney Stone, and Survival in the Women's Health Initiative (WHI)

Harshitha Kota,[1] Xuerong Wen,[2] Chao Chen,[3] Jie Tang.[1,4] *[1]Brown University, Providence, RI; [2]University of Rhode Island, Kingston, RI; [3]University of Florida, Gainesville, FL; [4]Brown Urology Brown Physicians Inc, Providence, RI.*

Background: The effect of dietary magnesium intake (DMI) on the risk of stone is controversial, and its effect on survival among kidney stone formers is unknown.

Methods: We examined participants enrolled in WHI, a prospective, longitudinal, multicenter study investigating the health of postmenopausal women, and used Cox regression analyses to determine the independent effects of DMI on the risk of incident kidney stone and survival amoungst the stone formers.

Results: 145,942 participants were identified free of kidney stone history at baseline. 83% were Caucasian, mean age was 63. Among them, 6024 (4%) developed incident kidney stone during 1,601,750 person-years of follow up. The mean daily DMI was 318 mg, with 26% in tertile 1 (<241 mg), 41% in tertile 2 (241-348 mg) and 33% in tertile 3 (>348 mg). The incidence of kidney stone disease was 3.1, 3.3, and 3.9 per 1000 person-year in high, moderate and low DMI groups, respectively. The corresponding multivariable-adjusted hazard ratios were 0.82 (95% CI: 0.71-0.94) for high vs low DMI when dietary oxalate intake (DOI) is high, and 1.01 (95% CI: 0.81-1.26) for high vs low DMI when DOI is low. Among incident stone formers, 82% were Caucasian, 23% were above age 70. Mean daily DMI was 304 mg, 32% in tertile 1, 38% in tertile 2, and 30% in tertile 3. Subsequently, 1346 (22%) died. Older age, histories of hypertension, diabetes and heart disease, low serum vitamin D, cigarette smoking, and hormone replacement associated significantly with mortality, p<0.05. However, DMI had no impact on mortality after adjusting for demographics and potential confounding factors, hazard ratio (HR) 0.91, 95% CI 0.73-1.14, p=0.4 when compared high DMI vs low DMI groups, HR 0.90, 95% CI 0.73-1.11, p=0.3 when compared medium DMI vs low DMI groups.

Conclusions: Our study suggests that higher DMI is associated with lower risk of incident kidney stone disease and this effect is modified by DOI. DMI does not appear to affect survival among post-menopausal women with incident kidney stone disease.

PUB001

Consequences of Improper Interpretation of ANCA

Aswin Srinivasan,[3,4] Sangeeta Mutnuri,[6] Nina Zatikyan,[1] Shabbir Safri,[5] Mahendra L. Agraharkar.[1,2] *[1]University of Texas Medical Branch at Galveston, Galveston, TX; [2]Baylor College of Medicine, Houston, TX; [3]University of Houston, Houston, TX; [4]HCA Gulf Coast Division, Houston, TX; [5]Montefiore Hospital and Medical Center, Montefiore Medical Center, Bronx, NY; [6]Creighton University, Omaha, NE.*

Introduction: Antineutrophil cytoplasmic antibodies (ANCA) is important in suspected vasculitis. False positive or atypical ANCA (A-ANCA) can lead to erroneous interpretation of immunofluoresence (IF) causing disastrous consequences. We present a patient who was initally reported as Perinuclear-ANCA (P-ANCA) positive and was therefore treated with steroids rendering him adrenal insufficient (AI).

Case Description: A 79-yr-old man with history of CKD, A Fib, protein C deficiency, prostate cancer and ANCA positivity that was treated with steroids, presented to the ER with dizziness, bradycardia and hypotension. He was weak, fatigued, and unarousable. In the ER, he was started on vasopressors and methylprednisolone. His creatinine rose from 2.6 to 3.1 mg/dL. RPGN was suspected and kidney biopsy was performed that showed acute interstitial nephritis or pyelonephritis, due to presence of neutrophils in clumps. His AM cortisol level was 3 ug/dL (10-20). Because of hypotention, polyuria and natriuresis, hydrocortisone and fluticortisone were started. His serum K level decreased and fludrocortisone was stopped. Over next few days, he became normotensive and his mentation improved with increasing dose of hydrocortisone. Hypokalemia slowly resolved with potassium supplements.

Discussion: ANCA are a group of antibodies that bind to antigens of neutrophils, causing systemic vascular inflammation. These autoantibodies can be found in the serum of patients with systemic, small vessel vasculitis and is a biomarker for ANCA-associated vasculitis. A positive staining of ANCA can be classified as: Cytoplasmic, Perinuclear, and Atypical, based on the pattern of IF. In cases with C-ANCA, the staining is diffuse throughout the cytoplasm and the cause of staining is due to antibodies directed against Proteinase 3 (PR3). In cases with P-ANCA, the staining is around the nucleus and it is due to antibodies directed against myeloperoxidase (MPO). A-ANCA can be found in conditions other than vasculitis and does not require immunosuppressive steroids for treatment. A-ANCA can be reported erroneously as P-ANCA or C-ANCA and patients can receive aggressive treatment with high dose steroids. Therefore, we suggest to confirm the ANCA results with MPO or PR3 before initiating aggressive therapy for vasculitis to avoid disatrous cosequences.

PUB002

Lymphoma of a Normal Kidney Size

Layth Al Attar, Taqui Khaja, Jingyin Yan. *Baylor College of Medicine, Houston, TX.*

Introduction: Renal injury has been reported in the setting of hematolymphoid neoplasms. The kidneys can be affected by a variety of mechanisms such as acute tubular necrosis (ATN), paraneoplastic glomerulopathy, and lymphocytic infiltration of kidney parenchyma (LIK). Diagnostic evaluation is important in differentiating mechanism of kidney injury, which will affect management and prognosis. LIK is suggested with clinical findings of bilateral kidney enlargement, acute kidney failure (AKI), or proteinuria.

Case Description: 50-year-old male with new diagnosis of high-grade lymphoma found to have severe kidney failure. Initial work up was unable to explain the underlying process of kidney failure. The patient was managed with volume replacement to alleviate the pre-renal component. Kidney ultrasound had no evidence of enlargement. Kidney function worsened over days and a decision to initiated dialysis was determined. After establishing dialysis access, kidney function demonstrated an improvement trend without dialysis initiation. Kidney biopsy revealed infiltration by atypical lymphoid cells consistent with the Double-Hit Diffuse Large B-Cell Lymphoma (DLBCL). Patient's kidney function spontaneously recovered. Patient was discharged with plan to start chemotherapy as an outpatient.

Discussion: Our patient was diagnosed with DLBCL. This type of lymphoma accounts for approximately 25 percent of all Non-Hodgkin Lymphomas in the developed world. Clinical presentation of renal involvement includes AKI, proteinuria, or enlarged kidneys on imaging studies. Location of lymphocytic infiltration determines the extent of renal dysfunction, whether interstitium or glomerulus. Renal involvement incidence is 2% at time of diagnosis. Extranodal renal involvement is diagnosed either by biopsy or imaging. Renal involvement can be diagnosed by imaging in 65% of patients. Cases presenting with AKI of interstitial type of lymphomatous infiltration show bilaterally enlarged kidneys in about 95% of patients. Renal involvement in patients with non-Hodgkin's lymphoma remains uncommon. The presence of acute renal failure, proteinuria, or enlarged kidneys should be suspicious of lymphocytic infiltrate of the kidneys. Nevertheless, absence of radiologic changes or proteinuria, similar to our patient, should not rule out kidney involvement. We recommend a low threshold for kidney biopsy to assist in the diagnosis of renal lymphocytic infiltration.

PUB003

Metabolic Encephalopathy due to AKI in a Patient with Recent Infusion of Intravenous Immunoglobulins (IVIg)

Sheikh Raza Shahzad, Kelly H. Beers. *Albany Medical Center, Albany, NY.*

Introduction: IVIg induced AKI is extremely rare (1% of cases). We present a case of AKI requiring hemodialysis secondary to recent IVIg administration.

Case Description: A 61-year-old woman presented with acute onset altered mental status (AMS) for 2 days. Her past medical history included CKD G3, HTN, COPD, PVD, and CAD. A week prior, she received 3 doses of sucrose-containing IVIg for chronic inflammatory demyelinating polyneuropathy. Shortly thereafter, the patient developed a facial rash, poor oral intake, low urine output, and AMS. Labs showed BUN 71 mg/dL, SCr 10.62 mg/dL, baseline SCr 2.6 mg/dL. ABG showed pH 7.07, pCO2 30 mm Hg and HCO3 8 mmol/L. Toxicology screen was negative, CPK and lactic acid were normal. No NSAIDs use was reported. She required only 1 session of hemodialysis with the recovery of renal function and mental status. AIN due to IVIg and/or IVIg induced osmotic nephropathy was thought to be the culprit for her presentation.

Discussion: IVIg can produce adverse reactions thought to be caused by activation of the complement cascade by the aggregation of IgG. To avoid this, a variety of stabilizing agents, including sucrose, are used. Sucrose is absorbed into proximal convoluted tubular cells and is followed by water due to the changed osmotic pressure. This results in cytoplasmic vacuolization and degeneration of the proximal cells. CKD, HTN, DM, advanced age, dehydration, hyperviscosity, use of sucrose stabilizers, high dose IVIg therapy (400–2000 mg/kg), high rate of IVIg administration, or treatment with other nephrotoxic medications increase the risk of AKI. About 30% of cases require dialysis. The mortality rate is 10%. Adverse renal outcomes usually occur within 10 days of initiation of IVIg, and the duration of renal failure lasts between 3 and 45 days. Most cases resolve spontaneously. Early recovery of renal function can be achieved by dialytic removal of sucrose from the circulation. To make a diagnosis, a temporal association must be established with the administration of IVIg. A clinical diagnosis is made after ruling out other causes and is confirmed with a renal biopsy. Measures to prevent AKI include using sucrose-free IVIg or amino-acid-stabilized formulations, adequate hydration, avoiding other nephrotoxins and diuretics, reductions in dose, concentration (<5%), and/or rate of administration (<3mg sucrose/kg/min) of IVIg.

PUB004

A Patient with a Record High Blood Urea Nitrogen Value Surviving Without Dialysis

Hay Me Me, Urvashi Hooda, Aditi A. Sen, Amol Mittal, Michael Connery. *Westchester Medical Center, Valhalla, NY.*

Introduction: The blood urea nitrogen (BUN) has limited value as an index of glomerular filtration rate to access kidney function. It can be increased not only in the setting of acute or chronic renal failure but also in hypovolemic state, gastrointestinal tract bleeding, high catabolic states, and by certain medications. Dialysis is the effective treatment for uremia. However, there is no consensus on when to initiate the dialysis for high BUN in acute kidney injury.

Case Description: A 64-year female with history of hypertension, hypothyroid, hyperlipidemia, alcohol use disorder, chronic kidney disease (CKD) with baseline creatinine of 1.5 mg/dl was admitted for head trauma after fall. Patient had poor intake and was noticed to be confused lately by family. No history of analgesic or herbal supplements usage was present. Laboratory results were significant for BUN of 298 mg/dl, Creatinine (Cr) of 13.5 mg/dl, serum potassium of 5.4 mEq/L, phosphate of 6.1 mEq/L and severe metabolic acidosis with serum bicarbonate of 10 mEq/l, anion gap of 33 mEq/L, lactate acid of 4.6 mmol/L. Creatine kinase level was 253 U/L. Urine studies showed no proteinuria, mild hematuria, without crystals. Urine electrolytes showed sodium of 23 mmol/l and chloride of less than 20 mmol/l. Corona virus disease 2019 (COVID-19) was negative both by polymerase chain reaction and antibody test. All the sepsis work up, urine toxicology and blood alcohol level were negative. Renal ultrasound showed normal bilateral kidney sizes. Patient was aggressively resuscitated with intravenous fluid including bicarbonate and her cognitive function improved without dialysis. Her BUN eventually decreased to 30 mg/dl and Cr to 1.26 mg/dl.

Discussion: CKD patients are susceptible to infection, dehydration and develop multiple episodes of acute on chronic renal injury, subsequently resulted in end stage renal disease. Our patient was taking metoprolol, lisinopril and hydrochlorothiazide for hypertension which could also have prompted her into hypovolemic state without adequate hydration. Early detection of the underlying cause is crucial and can prevent the unnecessary complications from dialysis. A few cases of strikingly high creatinine up to 61.3 mg/dl have been reported and survived with dialysis. Based on the review of literature, this is the highest reported BUN in acute on chronic renal failure patient who improved without dialysis.

PUB005

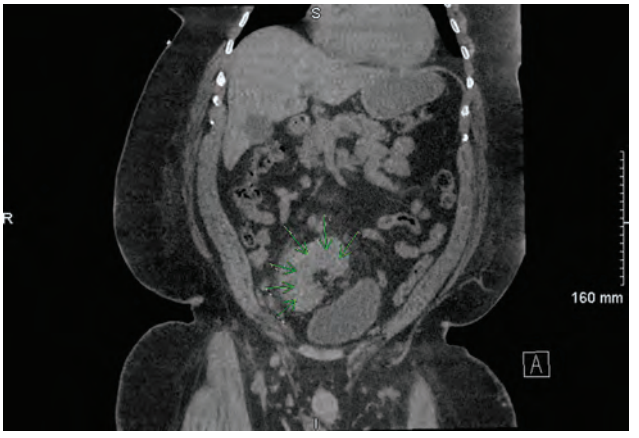
Spontaneous Page Phenomenon in a Pelvic Kidney

Yahya R. Ahmad, William L. Wilson, Megan M. Robinson, Taha Ayach. *University of Kentucky, Lexington, KY.*

Introduction: Page kidney or Page phenomenon refers to compression of the renal parenchyma by subcapsular hematoma. Here we report the first case of spontaneous Page phenomenon in a native pelvic kidney.

Case Description: A 64-year old male with a diagnosis of diabetes mellitus, essential hypertension, chronic kidney disease stage 3b, stage 3 obesity with a body mass index of 53, congenital right-sided pelvic kidney, presented to the emergency room with acute-onset, severe, right lower quadrant abdominal pain. Patient denied having any recent trauma and had no urinary or gastrointestinal complaints. He was not on any antiplatelet or anticoagulation medications. CT angiogram of the abdomen and pelvis was performed which demonstrated a subcapsular hematoma around the right pelvic kidney. He had AKI with a peak creatinine of 4.2 mg/dL from a baseline of 2.2 mg/dL. He remained non-oliguric, with gradual improvement of his renal functions and never required renal replacement therapy or any intervention for Page kidney. He presented with markedly elevated blood pressure of 190/110 mmHg and his hospital course was significant for sustained elevated blood pressure requiring addition of four new anti-hypertensive medications by discharge. Subsequent imaging showed marked decrease in the subcapsular hematoma in a week.

Discussion: Page phenomenon is a rare but potentially fatal condition that can result from trauma, tumor, vasculitis, renal cyst rupture, or procedures like kidney biopsy. External compression of renal parenchyma can result in interstitial ischemia, tubulointerstitial nephritis and compression of intrarenal vessels thus activation of renin angiotensin system (RAS), resulting in AKI and hypertension associated with Page kidney. Persistently elevated blood pressure unresponsive to medical therapy or gradually enlarging hematoma with worsening renal functions might require percutaneous drainage, capsulotomy or even nephrectomy. Optimal medical management of Page kidney includes medications targeting the RAS pathway.



PUB006

Transient Anuric AKI Secondary to Parkinson Disease

Sabine Karam. *Saint George Hospital University Medical Center, Beirut, Lebanon.*

Introduction: Parkinson's disease is a progressive neurodegenerative disease with diverse motor and neuropsychiatric manifestations. At the urological system level, it can cause neurologic dysfunction of the bladder but to our knowledge, no dysfunction of the upper collecting system has been described so far.

Case Description: A 67-year-old Lebanese female with a PMH of Parkinson's disease, HTN, DL, DM II, HF, CKD (1.7), Hypothyroidism, recurrent pyelonephritis and nephrolithiasis was admitted on multiple occasions with a chief complaint of "decreased urination". Physical examination showed no general abnormalities & the patient was afebrile. Upon each admission, a Foley catheter was inserted but with no urine output as she had an empty bladder. Adequate IV fluid hydration did not improve her urine output. The anuria would resolve after a few days with no clear explanation. Renal Scintigraphy using MAG3 technique along with furosemide was performed twice, seven days apart, the first away from an anuric episode and the second during. The first study showed slow cortical emptying into the collecting system but with complete emptying after furosemide while the second study showed accumulation of the tracer in the cortex with minimal spontaneous excretion into the collecting system even after addition of furosemide. There was no evidence of mechanical obstruction or vascular etiology in both studies. An abdominal CT showed no hydronephrosis or evidence of obstructive uropathy. An abdominal MRI showed third spacing and small atrophic kidneys with cortical scarring but no hydronephrosis, calculi, masses, or retroperitoneal fibrosis. The patient had her Parkinson's treatment optimized and the frequency and severity of the episodes decreased.

Discussion: Our findings allow us to speculate that Parkinson's disease could cause neurogenic dysfunction of the upper collecting system that manifests by episodes of intermittent anuria leading to acute kidney injury.

PUB007

Cholesterol Crystal Embolism with End-Stage Renal Failure and Refractory Gastric Ulcers After Abdominal Angiography

Naoki Yamamoto, Koichi Sato, Hisayuki Ogura, Taro Miyagawa, Shinji Kitajima, Tadashi Toyama, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan.*

Introduction: Cholesterol crystal embolism is a systemic disease with various clinical manifestations after intraarterial interventions and vascular surgeries. Here we report a case complicated with acute kidney injury requiring hemodialysis and refractory gastric ulcers after transfemoral angiography of celiac and superior mesenteric arteries.

Case Description: A 78-year-old male with coronary artery disease, hypertension, hyperlipidemia and chronic obstructive pulmonary disease was diagnosed as hepatocellular carcinoma by transfemoral angiography of celiac and superior mesenteric arteries. He was admitted to the hospital for an operation of hepatocellular carcinoma. Serum creatinine level gradually increased from 1.17 to 5.87 mg/dL with eosinophilia (4440/μL) and high C-reactive protein (CRP) level (4.96 mg/dL). He started hemodialysis ten weeks after angiography and had been suffering from nausea. Endoscopy showed multiple gastric ulcers. Treatment with proton pump inhibitor started, but did not improve. Cyanosis was present in his bilateral toes and skin biopsy showed cholesterol crystal clefts. He was diagnosed with cholesterol crystal embolism and treated with intravenous prednisolone (PSL) 20 mg/day, resulting in decrease of eosinophil, CRP levels and improvement of gastric ulcers. However, he was unable to withdraw from dialysis and developed disseminated cutaneous herpes zoster. Finally, he died of sepsis. Autopsy showed severe erosion of atherosclerotic plaques at the level of celiac artery. Cholesterol clefts were present in the vessels of kidney, stomach, intestines, liver, spleen, pancreas, diaphragm, adrenal glands and testes. The distribution of cholesterol crystal embolism was consistent with the site of angiography performed from celiac and superior mesenteric arteries.

Discussion: Cholesterol crystal embolism is caused by not only percutaneous coronary interventions and vascular surgeries, but also preoperative transfemoral angiography. We need to consider cholesterol crystal embolism when acute kidney injury and refractory gastric ulcers after transfemoral angiography. Although PSL is administered for cholesterol crystal embolism, tapering strategies is important for patients on dialysis.

PUB008

Hyperkalemia in Community-Acquired AKI: Associated Factors and Clinical Consequences

Jose M. Pena Porta, Almudena Castellano, Ana Coscojuela Otto, José F. Gascó, Alejandro Tomás, Pablo J. Inigo Gil, Rafael Alvarez lipe. *Nephrology Service. Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain.*

Background: Hyperkalemia (hyperK) frequently occurs in the context of acute kidney injury (AKI). We know little about the associated factors and the clinical consequences in patients with community-acquired acute kidney injury (CA-AKI). The aim of present study was to analyze it.

Methods: The present study is based on a cohort of patients with CA-AKI admitted to the our Nephology Service from January 2010 to February 2015. Hyperkalemia was defined as potassium levels above 5.1 meq / L

Results: A total of 308 patients were included. The mean age was 73,22±13,95 years. 58,4% were men. Charlson comorbidity index (CCI) was 7,16 ±2,7 points. The mean of drugs ingested daily was 7,81±3,66 and the length of stay 12,25±11,69 days. In view of the Etiology of AKI, 69,5% prerenal AKI and 30,5% non-prerenal ones. 212 patients had previous chronic kidney disease (CKD) (68.8%). Hemodialysis (HD) was required in 54 patients (17.15%). 38 patients (12.3%) died during hospital stay. HyperK occurred in 173 cases (56,2 %). Mean potassium was 5,45±1,41 meq/L. There was a significant correlation between potassium and pH as well as between K and CCI. There was an association between hyperK and intake of potassium-sparing diuretics (p<0,001); ACEI/ARB (p=0,003) and beta blocker (p<0,001). Using a multiple linear regression model the equation that predicted serum potassium was: K = 36,44 – (4,4 x pH) + 0,98 (if intake of potassium-sparing diuretics) + (0.10 x CCI). Potassium level did not influence the length stay. Patients with HyperK required HD in a higher proportion (23.7 vs. 9.6%; p 0.01) and also had higher mortality during hospital stay (15.6 vs. 8.1%; p 0.048). After a follow-up of 971±702 days after hospital discharge, Kaplan-Meier survival curves showed a significant difference (Log Rank (Mantel-Cox): p< 0,001) between patients with hyperK and patients that did not present it.

Conclusions: HyperK occurred in just over half of our patients. The potassium level was significantly determined by the previous comorbidity, pH and the intake of potassium-sparing diuretics. HyperK patients required HD and died in a greater proportion during hospital stay. Mortality after discharge was higher in patients who presented hyperK. Appropriate measures must be taken to correct hyperK early in patients with CA-AKI.

PUB009

A Case of Anti-Tubular Basement Membrane Antibody-Associated AKI

Masaaki Terao, Takatsugu Iwashita, Akira Kurosawa, Yuta Kogure, Hiroaki Hara, Taisuke Shimizu, Tomonari Ogawa, Hajime Hasegawa. *Department of Nephrology and Hypeertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Introduction: We report here a case of idiopathic anti-tubular basement membrane (TBM) antibody-related acute interstitial nephritis (AIN).

Case Description: Our patient was a 44 years man and had no history of renal disease. He was pointed out renal dysfunction of serum Cr 1.50 mg/dL in the health checkup 2 months prior to admission. The patient was admitted to our hospital because of worsening of renal function of Cr 2.89 mg/dL. Because renal dysfunction progressed (Cr 10.36 mg/dL), hemodialysis was started on the 8th hospital day. Urine abnormalities such as proteinuria or hematuria was not apparent, however, he showed remarkable elevation of urine NAG and β2-microglobrin excretion, bilateral kidney enlargement, and renal accumulation was shown by Ga scintigraphy. Based on those findings, AIN was suspected and renal biopsy was performed on the 2nd hospital day. Light microscopy revealed diffuse inflammatory cell infiltration in the tubulo-interstitium, and immunostaining showed linear deposition of IgG and C3 in the tubular basement membrane. Similar findings were observed in the tissue sections of other patient with no tubular disorder by the treatment of the serum of this patient, and we diagnosed AIN due to TBM antibody. Prednisolone (PSL) 40 mg/day (0.8 mg/kg/day) was started from the 13th day and methyl PSL 500 mg/day for 3 days was added on the 21st day. Renal dysfunction and inflammatory reaction tended to be improved, however, steroid treatment could not continue because of steroid psychosis. Cyclophosphamide 375-500 mg/day and multiple plasma exchange was added thereafter, however, finally he was shifted to the maintenance dialysis.

Discussion: Cases of TBM antibody-related AIN are very rare, and most of the reported cases are those induced by drugs and those developed after kidney transplantation, and few cases are considered to be idiopathic. Antigen of TBM antibody are thought to be a non-collagen protein that interacts with type-4 collagen, laminin and integrin, which is present in the proximal tubular basement membrane, but the mechanisms and clinical course that cause AINs are unknown. Accumulation of cases including this case is considered necessary.

PUB010

A Triple Threat? Baclofen Toxicity and Posterior Reversible Encephalopathy Syndrome in the Setting of AKI

Daniella E. Lipnick,[1] Kevin C. Roe.[2] *[1]Penn State College of Medicine, State College, PA; [2]Mount Nittany Medical Center, State College, PA.*

Introduction: This is a case of apparent baclofen toxicity and posterior reversible encephalopathy syndrome (PRES). Both conditions are seen in patients with kidney dysfunction but direct association between the two conditions has otherwise been defined. The case highlights areas of special consideration in the evaluation and management of mental status changes in patients with acute kidney injury (AKI). No other reported cases of the combined diagnoses were found on literature review.

Case Description: A 71-year-old female admitted with sepsis due to ESBL E. coli bacteremia and pyelonephritis became unresponsive on her 7th day of hospitalization. There were no abnormal neurologic findings prior to the episode. The patient had been given baclofen 10 mg x 2 doses for back pain within 24 hours of her acute change in mental status. She was non-verbal but opening eyes and withdrawing to pain. The initial presenting signs of infection had been improving with ceftolozane and tazobactam. Serum creatinine was 4.2 mg/dL on admission and had improved to 2.2 mg/dL (baseline 1.5 mg/dL). AKI was attributed to prerenal physiology and sepsis-associated ATN. Mental status changes were attributed to baclofen neurotoxicity. She then developed evidence of partial complex seizures and subsequent imaging revealed findings of PRES. Levetiracetam, antihypertensives, and continued antibiotic therapy were provided. Systolic blood pressure increased to 180 mmHg with a MAP of 115 during the hospitalization. After several days, the patient recovered completely. Creatinine stabilized at 2.0 mg/dL.

Discussion: Medications are a leading cause of acute mental status changes, especially in patients with impaired kidney function. Our case highlights the risks of baclofen toxicity in improving but impaired kidney function. The clinical-radiopathologic diagnosis of PRES may have been missed without imaging. The varying presentations of this condition are a reminder the importance of an expanded differential diagnosis and the need for a better understanding of the pathology. There is no reported association between PRES and baclofen. The role of AKI in the development of PRES is not entirely understood; however, the hypertension-hyperperfusion theory remains a leading consideration in our patient. Management decisions in our patient included forgoing dialysis, blood pressure control, and the use of anti-seizure medications.

PUB011

Renal Zygomycosis: A Rare Presentation in an Immunocompetent Patient

Muhammad Nadeem,[1] Ali Hakami,[1] Mansoor A. Qaisar,[2] Bushra Iqbal.[1] *[1]King Fahd Central Hospital, Jazan, Saudi Arabia; [2]diaverum regional dialysis centre, Hail, Saudi Arabia.*

Introduction: Zygomycosis is a broad term which refers to the infections caused by bread mold fungi belonging to zygomycota phylum. It is an agio-vascular opportunistic infection which can usually present in four different ways including pulmonary, gastrointestinal, renal and disseminated disease. Like other opportunistic infections it has predilection for immunocompromised patients however very rarely, it has been reported in immunocompetent patients.

Case Description: Here we report a case of an immunocompetent patient who was affected by renal zygomycosis and presented as a picture mimicking rapidly progressive glomerulonephritis (RPGN). The patient presented with hematuria, proteinuria and high creatinine and was suspected as a case of RPGN initially. CT scan abdomen showed bilateral smoothly tapered distal ends of the renal arteries with non-perfused enlarged kidneys. These findings were consistent with the diagnosis of Zygomycosis which has angio-invasive nature. Bilateral nephrectomy was done and diagnosis was confirmed on histopathology report as well. Post operatively, the patient was extubated from ventilator, recovered from shock and improved a lot. He was doing fine on maintenance hemodialysis until two weeks later he developed septic shock due to Acinetobacter Baumannii which could have triggered the re-activation of disseminated zygomycosis due to metabolic acidosis and the patient could not survive.

Discussion: Isolated renal zygomycosis is very rare, although few cases have been described in literature. In our case, patient was referred to us as glomerulonephritis as his clinical picture initially resembled rapidly progressive glomerulonephritis. We want to highlight that isolated renal zygomycosis can have presentation mimicking glomerulonephritis, so young nephrologists should rule out infections like zygomycosis before embarking on the diagnosis of Acute glomerulonephritis as misdiagnosis can be catastrophic.

PUB012

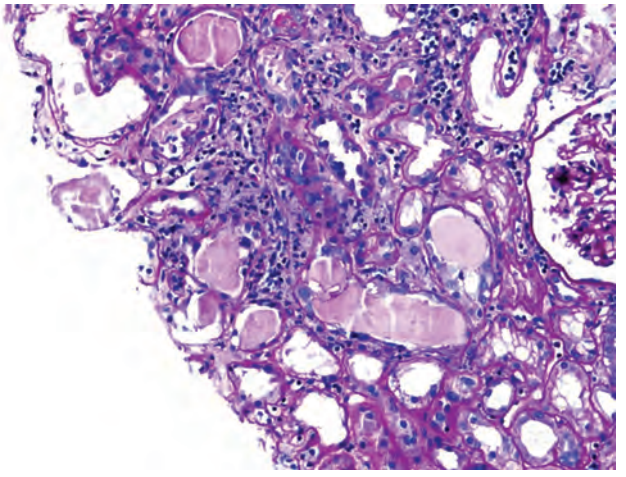
Light Chain Cast Nephropathy in an African-American Woman with Waldenström Macroglobulinemia

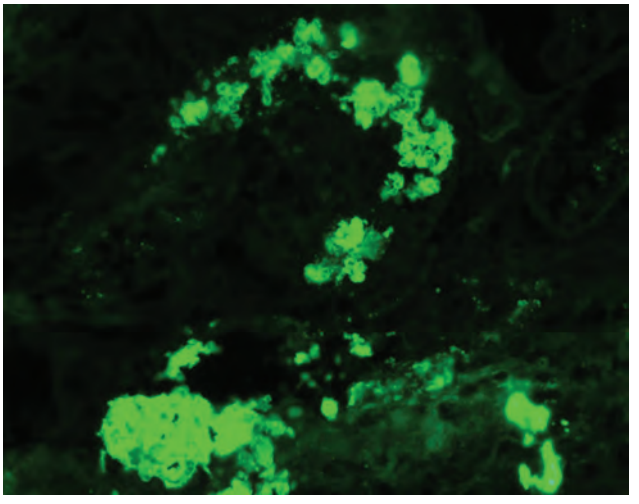
Mohamedanwar M. Ghandour, Hillel Sternlicht. *Wayne State University School of Medicine, Detroit, MI.*

Introduction: Waldenström's macroglobulinemia (WM) is a rare cancer of the lymphatic system due to excess IgM monoclonal protein with a rare renal involvement. Renal involvement is rare with an incidence of 3 cases per million people per year. We describe a case of MW presenting with acute renal failure.

Case Description: A 63-year-old female who admitted to our hospital for influenza B complicated by acute renal failure during the hospital stay, with creatinine up to 6 mg/dL, despite adequate hydration. Electrophoresis revealed a monoclonal component in the gamma region, which classified as an IgM k. A kidney biopsy was performed, showing light cast chains suggested the possibility of myeloma kidney. Furthermore, bone marrow histology was performed, revealing lymphoplasmacytic lymphoma. The patient was treated with bortezomib, dexamethasone, and cyclophosphamide, with complete recovery of renal function.

Discussion: Overall, renal manifestations are not commonly seen in Waldenström's macroglobulinemia. Approximately one-third of patients are asymptomatic at the time of diagnosis. Like our patient who did not have renal symptoms and acute kidney injury discovered serendipitously. Moreover, reported rates of full renal recovery following adequate treatment are almost more than 50 percent. Patients with reversibly renal failure had longer median survival compared with patients who did not restore renal function.





PUB013

AKI in a Patient with Erythema Elevatum Diutinum

Mrinalini Sarkar.[1,2] *[1]University of California Los Angeles, Los Angeles, CA; [2]VA Greater Los Angeles Healthcare System, Los Angeles, CA.*

Introduction: Erythema elevatum diutinum (EDD) is a rare cutaneous small vessel vasculitis with dapsone being the drug of choice. EED has been associated with hematological disorders, autoimmune diseases and cancer in <5% of cases. Drug-induced acute interstitial nephritis (DI-AIN) represents 20% of patients with unexplained AKI. The classic triad of rash, fever, and eosinophilia occurs in <10% of patients, and onset may be delayed by weeks or months after drug initiation

Case Description: 55-year-old male with history of EDD admitted for infected lower extremity lesions Vital signs and remainder of physical exam was normal. Patient was on dapsone in the past for over 10 years, however in the last 6months was not taking any medications. Vancomycin, zosyn and dapsone 200mg BID were started on admission. By day 3 only dapsone was continued as imaging was without evidence of deep infection. On day 4 he developed AKI, creatinine (Crt) 4.44mg/dL from 0.7mg/dL on admission. Labs also included Hb of 8.8g/dL, WBC 9.2 k/uL with 5% eosinophils, ESR 118mm/hr. Urinalysis with 3 wbc/hpf, UPCR of 0.18 and urine microscopy showed 1-2 WBC casts/LPF. Serum immunofixation revealed IgA-kappa in the beta region and a faint IgA-kappa monoclonal protein in the gamma region. Autoimmune and infectious serologic work-up negative. Dapsone was stopped on day 5 and renal biopsy was performed due to ongoing rise in Crt on day 8. Biopsy confirmed diffuse active interstitial nephritis with prominent eosinophilic inflammation along with low grade membranous nephropathy favoring secondary, PLA2R negative. Patient started on IV solumedrol followed by oral prednisone taper over 6 weeks. Creatinine improved to 1mg/dL at 3 month follow-up.

Discussion: DI-AIN was attributed to dapsone. Despite withholding this medication, the Crt continued to rise prompting renal biopsy. Studies suggest that early corticosteroid initiation is associated with better outcomes and be considered in patients with no prior kidney dysfunction. In patients with suspected DI-AIN where a biopsy cannot be performed, a trial of empiric steroid therapy may be considered. The finding of secondary membranous nephropathy (MN) was unexpected as to date there has not been any reports of renal disease and EDD. We report a case of secondary MN in a patient with EDD now undergoing a full malignancy investigation.

PUB014

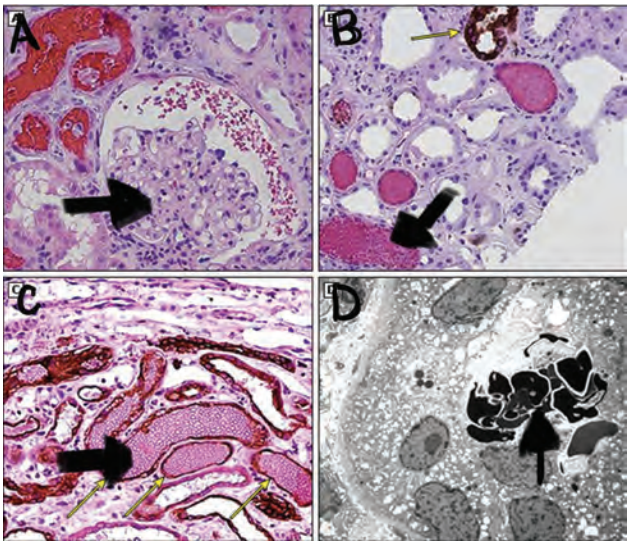
AKI from Tubular Bleeding from Rivaroxaban (XARELTO)

Aamir Zuberi,[1] Fatima Zuberi,[3] Nabia A. Syed,[2] Marissa L. Henderson,[1] Safi Ahmad,[4] Hafsa Zuberi.[5] *[1]Aamir Zuberi MD PA, Decatur, TX; [2]University of Texas at Austin, Austin, TX; [3]University of Texas Southwestern Medical Center at Dallas, Dallas, TX; [4]Wake Forest University, Winston-Salem, NC; [5]Texas Tech University System, Lubbock, TX.*

Introduction: Anticoagulation induced acute kidney injury

Case Description: 68-year-old male with history of 7kg weight gain in the preceding 3- 4 wks. & fatigue. History of CAD, COPD and Pulmonary Embolism treated with Rivaroxaban Exam essentially negative except for edema Creatinine 8.4, ultrasound negative, previous creatinine normal, UA positive for blood & protein Dialysis initiated. All serologies negative IVC filter was placed, anticoagulation stopped, and kidney biopsy performed Biopsy showed diffuse intratubular red blood cells, red cells casts, acute tubular epithelial injury, mild interstitial fibrosis, few eosinophils and negative for crescents or vasculitis (images shown below) On follow-up, Pt. regained kidney function in 2 months and creatinine remained normal at 1 year

Discussion: Warfarin related nephropathy is a rare but well-recognized phenomenon, which has also been reported with other anti-coagulation like Dabigatran (Predaxa), however has not been reported with Rivaroxaban (Xarelto). Warfarin related nephropathy (WRN) and acute kidney injury is sometimes caused by excessive anticoagulation. A biopsy is needed to confirm this condition. Pathogenesis of anticoagulant related nephropathy is glomerular injury, obstruction of renal tubules by RBC casts, and tubular epithelial injury. Histologically, WRN and the biopsy from the patient receiving Rivaroxaban appeared very similar.



A.Normal glomerulus, no crescentsB.& C. Blood in tubules

D. Fragmented RBCs in tubules (Electron Microscopy)

Misleading Serologies in Thrombotic Microangiopathy due to Malignant Hypertension

Taqui Khaja,[1] Rajeev Raghavan,[1] William F. Glass,[2] Carl P. Walther.[1] *[1]Baylor College of Medicine, Houston, TX; [2]University of Texas Health Science Center at Houston, Houston, TX.*

Introduction: Nephrologists use autoimmune panels to screen for glomerular disease. Some of these markers cause false positives in other systemic diseases which leads to misdiagnosis. We report a rare case of false positive MPO-ANCA and ANA in patient with thrombotic microangiopathy (TMA) due malignant hypertension.

Case Description: A 65 year old African American patient with a history of hypertension, breast cancer s/p right mastectomy, and CKD with baseline creatinine of 1 was admitted hypertensive urgency with pressures of 239/123. She had Acute Kidney Injury with creatinine of 6.6 and her work-up revealed new pericardial effusion, thrombocytopenia (platelets of 90), and anemia (hemoglobin of 9). Autoimmune panel was positive for ANA (1:320, speckled) and positive RNP (>8). The presumptive diagnosis was mixed connective tissue disease. Pericardiocentesis was negative for malignancy and infections. She began dialysis but her renal function never improved. She was discharged dialysis dependent. The patient refused outpatient dialysis and her medications. She was re-admitted few weeks later with uremia and hypertensive urgency with pressures of 209/104. A repeat evaluation showed a newly positive MPO-ANCA (13.4), ANA (1:640, speckled), and a low C3 (72.8). Given the concern for vasculitis, a kidney biopsy was performed. Her biopsy was significant for global glomerulosclerosis, glomerular ischemia, and severe interstitial fibrosis with tubular atrophy. There was extensive arteriolar onion skin intimal fibroplasia with red blood cell fragments. Based on her clinical history, patient had TMA secondary to hypertension. Her biopsy lacked findings of vasculitis due to an absence of necrotizing crescentic glomerulonephritis and negative immunofluorescent stains. The patient was maintained on hemodialysis and hypertension medications.

Discussion: Diseases associated with TMA can have false positive autoimmune markers and they require early recognition. There are cases that show Thrombotic Thrombocytopenic Purpura can produce MPO-ANCA and anti-DNA markers. The markers were correlated to intensity of the disease because the patients with active disease had higher tighters. These markers are created secondary to immune dysfunction during TMA. This case also emphasizes the importance of kidney biopsy in order to distinguish between active vasculitis and non-vasculitic diseases.

PUB016

AKI, Diplopia, and Altered Psyche: One Rare Case of Extrapulmonary Sarcoidosis

Hillary DeRose-Caldera. *Western Reserve Health Education, Youngstown, OH.*

Introduction: Sarcoid is a multi-organ system disease primarily affecting the lungs. Pathological diagnosis requires the presence of non-caseating granulomas. Sarcoidosis is a genetic associated autoimmune disease more prevalent in African Americans. Renal sarcoidosis manifests in about 5-20% of patients with hypercalcemia, hypercalciuria, and nephrocalinosis on normal screening. Renal parenchymal involvement is typically granulomatous tubulointerstitial nephritis. Neuro-sarcoid also occurs in about ¼ of patients, affecting primarily the cranial nerves. CNS involvement can present with visual and occasionally behavioral changes. Ocular sarcoid presentations include uveitis and retinal lesions.

Case Description: 63-year-old white male with a history of rheumatoid arthritis, pulmonary nodules, glaucoma, presented with one year of blurry vision and weird psyche. He was referred to nephrology after an ophthalmologist found intermittent diplopia, transient optic disc swelling and intraretinal hemorrhage. Abnormal labs from 5/2019 with 11/2018 in parenthesis: Scr 2.73 (1.51 mg/dL), BUN 27 (22), Egfr naa 28 (49ml/min), Ser Calcium 8.6 (9.2 mg/dl) ACE 73 U/l, A1c 5.4. Given the worsening CKD IV; the following were drawn: ANA-IFA: positive, speckled pat 1:640, UA bld 10, fn gran cast; 0-5, crs gran cst 0-5, ur prot rand 24. Renal biopsy demonstrated noncaseating granulomatous interstitial nephritis, numerous noncaseating granulomas with giant cells. He was referred to Cleveland Clinic Sarcoid Clinic and started on 40mg prednisone for renal sarcoid. CXR with prior noddles, no hilar or parenchymal changes. CC Ophthalmology clinic's fundal exam revealed peripheral hypo-pigmented lesions possibly consistent with ocular sarcoid. Vision had resolved. At 1 month, steroids were tapered with plans to start Azathioprine. The patient's Scr improved on tapering steroids.

Discussion: Less than one in ten patients present solely with extrapulmonary sarcoid. This case demonstrates a rare presentation of neuro-ocular and renal sarcoidosis in the absence of lung findings. Sarcoidosis ought to be considered in AKI or new chronic kidney disease, particularly if a patient presents with other atypical findings such as retinal or optic nerve changes representing a syndrome of multi-organ involvement. Multiple system involvement is a predictor of progression to ESRD. Glucocorticoids are first-line therapy. Most cases respond to steroids.

PUB017

Dynamics of Tissue Injury mRNA Expression to Bilateral Renal Ischemia-Reperfusion Injury

Samuel J. Pfaff,[1] Toni L. Richards,[2] Kenneth Minor,[2] Yan Zhang,[1] Craig F. Plato,[2] Kristopher Kuchenbecker.[1] *[1]Silver Creek Pharmaceuticals, San Francisco, CA; [2]Plato BioPharma, Inc., Westminster, CO.*

Background: Acute kidney injury (AKI) secondary to acute renal ischemia is associated with high mortality and morbidity with few effective treatments. The bilateral renal ischemia reperfusion injury (IRI) model is commonly employed in rodent studies of AKI. While disease progression is well characterized at the organism level, the dynamics of the molecular responses are less well understood. To improve the translational potential of compounds, the current study sought to temporally and mechanistically define the tissue mRNA expression profiles following discrete durations of IRI.

Methods: Rats underwent sham or warm, bilateral renal ischemia (30' or 40') surgery using PBI's proprietary vascular clamps. Subsets of rats were sacrificed at 8 timepoints following reperfusion (0-48hr), with blood and kidneys harvested at each timepoint for subsequent analyses. Plasma BUN and creatinine were assessed via clinical chemistry. The expression of 100 mRNA transcripts surveying genes across apoptosis, kidney injury, and inflammation/fibrosis pathways were measured by Quantigene.

Results: Plasma creatinine, the classical index of renal dysfunction in AKI was ischemia- and reperfusion time-dependently increased upon inception of reperfusion. Concomitantly, kidney injury and inflammation genes were upregulated early (<4hr) and remained elevated compared to shams throughout study duration. Upregulation of pro-apoptotic genes occurred ≥4hr post-reperfusion, indicating the initiation of programmed cell death. Last, pro-fibrotic genes were upregulated 24-48hr post-reperfusion indicating onset of remodeling. The information content provided by each mRNA expression profile and clinical parameter was determined using a novel statistical framework to identify measures best able to distinguish disease state over 48hr of reperfusion.

Conclusions: This study demonstrated the temporal dynamics of response to renal IRI in rats. The early injury phase (<4hr) was defined by mild, but significantly increased plasma creatinine indicating promptly reduced renal function along with upregulated injury response genes. Induction of pro-apoptotic and pro-fibrotic genes occurred during the later phase, in line with exacerbated renal function. Our novel statistical method identified "high information" genes/parameters that can serve as reliable, mechanistic indicators of AKI in future studies.

PUB018

Antioxidant Ameliorates Pulmonary Renal Injury in an Experimental Model of COVID-19 Organ Failure

Firoozeh Farahmand. *Saint Louis University, Saint Louis, MO.*

Background: Since the outbreak and rapid global spread of COVID-19 multi-organ involvement has largely influenced prognosis and severe AKI has been an ominous clinical predictor with high mortality. The hyperinflammatory response of the body, associated with oxidative stress is a key player in mechansim of multiple organ failure.

Methods: In an experimental model of multiple organ failure of Covid 19 similar to human disease with single injection of Toxoid (TOX) rats were treated with antioxidant carvedilol started daily 1wk pre-TOX-injection and continued for 1 wk post-TOX injection. At 1-week post injection in both TOX+ Antioxidant and TOX groups lungs wet/dry weight ratios were measured to assess edema and lungs and kidneys from both group were analyzed for antioxidant enzyme activities including superoxide dismutase, glutathione peroxidase, catalase and oxidative stress. After sacrificing the animals, kidney and the lung were removed for histology

Results: Antioxidant treatment attenuated TOX induced lung and kidney injury and there was histopathological evidence of its beneficial effects. This was associated with decreased oxidative stress and increased activities of SOD and GSHPx in the lung and the kidney.

Conclusions: In this experimental model that mimics human Covid 19 multiorgan failure, antiooxidant improved survival, lung and kidney injury and also oxidative stress in the kidney. This suggest the beneficial effects of antioxidant as a kidney–lung protective strategy in patients with COVID-19.

PUB019

SRP14 Regulated Renal Tubular Apoptosis Induced by Ischemia-Reperfusion Injury via Interaction with RPS7

Yun Tang, Yanmei Wang, Guisen Li, Li Wang, Yi Li. *Department of Nephrology, School of Medicine, Sichuan Academy of Medical Science and Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chengdu, China.*

Background: AKI could easily progress to CKD with increased incidence and mortality. Due to the complex pathogenesis, there is a lack of effective early warning to intervene in AKI.

Methods: We performed LFQ proteomic analysis in HK_2 renal tubular epithelial cells after Hypoxia/Reoxygenation to find SRP14 as novel molecule target to prevent AKI upon apoptosis in renal tubular epithelial cells. This study will further study the role and mechanism of SRP14 in regulating MDM2-p53 pathway in apoptosis of renal tubular epithelial cells in AKI. Then analyze the clinical correlation of SRP14 in AKI and explore the possibility of SRP14 as a potential therapeutic target for AKI.

Results: We identified that SRP14 could be involved in apoptosis of renal tubular epithelial cells induced by IRI. SRP14 could regulate the MDM2-p53 loop through RPS7 in renal tubular epithelial cells to regulate apoptosis of renal tubular epithelial cells induced by IRI. The AUC value of SRP14 ($AUC_{[SRP14]}$ = 0.774) was close to serum creatinine ($AUC_{[creatinine]}$ = 0.796), suggesting the potential prognostic value of serum SRP14 to AKI.

Conclusions: This study found that SRP14 regulated renal tubular apoptosis induced by ischemia reperfusion injury via interaction with RPS7 involving MDM2-p53 loop. This finding could provide some novel targets and ideas for AKI control in the future.

PUB020

A Case of Masked AKI

Sitalakshmi J. Iyer,[1,2] Clay A. Block.[3] *[1]NYU Langone Health, New York, NY; [2]VA New York Harbor Healthcare System, Manhattan, NY; [3]Dartmouth College Geisel School of Medicine, Hanover, NH.*

Introduction: Despite wide recognition of pitfalls, changes in serum creatinine (Cr) and/or a decline in urine output (UO) remain the mainstay of AKI diagnosis. We report a patient whose extremely low Cr and preserved UO demonstrate the problem in reliance on these parameters.

Case Description: 57 F was admitted for respiratory failure due to COVID-19. Her management included tocilizumab, mechanical ventilation, vasopressors, ECMO, and antibiotics. On entry she weighed 54kg and Cr was 0.5 mg/dL. After 5 days, Cr nadired at 0.1 then gradually rose to 0.6 where it remained (day 15). Net fluid balance was 20L. By Cr, her eGFR was 110 ml/min/1.73m^2 but by cystatin C (CysC) it was 56.

Discussion: AKIN defines AKI by an absolute rise in Cr 0.3mg/dl within 48 hrs, a relative increase 150% of baseline within 1 week, or reduction in UO to <0.5mL/kg/hr for at least 6 hrs. Cr is a flawed AKI biomarker due to uncertainty of the baseline, variability in rate of generation, and elimination by secretion and filtration. Cr generation falls rapidly with critical illness. The impact of volume expansion resulting in hyperfiltration or hemodilution are underrecognized. Antibiotics, diuretics, glucose, ketones and bilirubin may interfere with measurement. UO too is flawed since oliguria may occur in the absence of AKI due to antidiuretic hormone or conversely, UO may be maintained despite AKI due to osmotic diuresis, failure of tubular function or diuretic use. The choice of baseline Cr influences our patient's diagnosis. If 0.5 is chosen, she fails to meet AKIN criteria, but based on nadir Cr, she has severe stage III AKI. AKI can also be demonstrated by adjusting Cr for volume expansion: measured Cr x (initial total body water [TBW] + cumulative fluid gain) ÷ initial TBW = 1.4 in our patient. Our patient received tube feeds, suffered hyperglycemia resulting in high osmolar load driving an osmotic diuresis. Also, periodic furosemide was given to mitigate her positive fluid balance. Below normal Cr is generally seen in myopathies, cirrhosis or with drug interference, but hyperfiltration can occur with volume expansion contributing to low Cr. In his case, we believe a baseline small muscle mass, critical illness sarcopenia, and marked volume expansion conspired to mask significant AKI in our patient. Documentation of AKI by measuring CysC led to adjustments in drug dosing.

PUB021

Online Medical Education Significantly Improves Nephrologists' Knowledge and Confidence for Intravenous (IV) Iron Use in Patients with Iron-Deficiency Anemia (IDA) in CKD

George Boutsalis,[1] Siggi D. Trier,[1] Chris Allen,[1] Jay B. Wish.[2] *[1]Medscape LLC, New York, NY; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Purpose: To determine if online medical education for nephrologists (Neph) could improve their evidence-based knowledge and confidence to use iv iron to treat IDA in non-dialysis (ND) and dialysis dependent CKD patients

Methods: Participants completed a 3-item questionnaire plus confidence assessment before and after watching a 30-minute online video series of 4 expert interviews with slides. A matched pair design was used pre-/post-assessment, with scores compared to assess changes in the proportion of correct responses. A chi-square test assessed statistical significance at the P <.05 level. Launch 01/29/20; data through 04/13/20. Total Neph learners (n=572), Neph assessment completers (n=122)

Results: At baseline, 20% of Neph (n=122) answered all 3 questions correctly, increasing to 61% (P < .001) post-assessment. An average of 61% of all responses were correct pre-assessment increasing to 83% post (P <.001). 36% of Neph had a measurable increase in confidence using iv iron therapies to manage IDA. The activity significantly increased knowledge on the differences between iv and oral iron in delaying the need for erythropoiesis-stimulating agents when treating IDA in ND-CKD patients (pre: 64%, post: 85%, P <.001) and using a pro-active high dose iv iron strategy in CKD patients on dialysis to reduce cardiovascular risk versus a low dose approach (pre: 29%, post: 71% P <.001). Neph already chose to start iv iron therapy in an IDA patient on hemodialysis currently on ESA but not meeting their hemoglobin goals in adherence to KDIGO guidelines (pre: 91%, post: 93% P =.641). Polling showed 1 in 4 Neph to start IDA treatment with iv iron in <50% of CKD patients.

Conclusions: Online medical education can significantly improve data recall from pivotal clinical trials on iv iron therapy to treat IDA in CKD patients with or without dialysis. This activity was also successful to facilitate application of such evidence into clinical practice and boost confidence using iv iron therapies, specifically with regards to iron repletion before ESA initiation in ND-CKD patients and using higher iv iron doses to mitigate cardiovascular risk in HD-CKD patients. Further nephrologist education on iv iron use in earlier IDA stages could be helpful to optimize patient outcomes.

PUB022

Predicting PTH and Calcium Trajectories for ESKD Patients on Intravenous Calcimimetics

Benjamin Lobo,[1] Dennis Hu,[2] Brendan T. Bowman.[2] *[1]University of Virginia School of Engineering and Applied Science, Charlottesville, VA; [2]University of Virginia School of Medicine, Charlottesville, VA.*

Background: Patients with End-Stage Kidney Disease (ESKD) often experience secondary and tertiary hyperparathyroidism leading to increased fracture risk, vascular calcification, and increased cardiovascular risk. Traditional pharmacotherapy includes phosphorus binders, Vitamin D analogues, and oral calcimimetics. Despite this, many ESKD patients still have elevated parathyroid hormone (PTH) levels. Etelcalcetide is an intravenously delivered calcimimetic approved to treat hyperparathyroidism. Advantages include a long half-life and IV administration which guarantees drug delivery. Despite this, response of PTH and calcium levels to etelcalcetide remains difficult to predict. A predictive algorithm could assist clinicians in assessing the potential effect of a given dose. As a first step in developing a dosing decision support tool, we present a predictive model that forecasts the 1-, 2-, and 3-month PTH and calcium values for patients receiving etelcalcetide.

Methods: We used tree ensemble (RandomForest) models for their ability to model the data non-linearities. Model inputs were historic data (calcimimetic dosing, labs, dialysis records, demographics, and phosphorus binder orders) and future calcimimetic dosing.

Results: The Mean Absolute Error (MAE) is 205, 227, and 249 pg/mL for the 1-, 2-, and 3-month PTH predictions, respectively. In addition, for the 1-, 2-, and 3-month predictions, 70%, 65%, and 59% of the predictions, respectively, lie within ±250 pg/mL of the actual PTH value. The MAE for the 1-, 2-, and 3-month calcium predictions is 0.410, 0.458, and 0.496 mg/dL, respectively. In addition, for the 1-, 2-, and 3-month predictions, 71%, 65%, and 63% of the predictions, respectively, lie within ±0.5 mg/dL of the actual calcium value.

Conclusions: The error distribution of the predictions is such that they 1) may be clinically meaningful as part of an effort to better control PTH, while potentially reducing excessive up-titration of etelcalcetide (and thus cost) and 2) may serve as a benchmark for future modeling efforts. Limitations include: a relatively small data set which precluded the use of other models (e.g., recurrent neural networks) and the dialysis program's strict criteria for receiving etelcalcetide which led to a study population with significantly higher PTH values than may be encountered in the general dialysis population.

PUB023

A Rare Case of Staghorn Calculi Complicated by Bilateral Xanthogranulomatous Pyelonephritis

Michael Chang, Gary Dellacerra, Deep Sharma, Joshua M. Stern, Peter Nauka, Wei Chen. *Montefiore Medical Center, Bronx, NY.*

Introduction: Staghorn calculi are usually unilateral and typically occur in women. Chronic obstruction and infection of staghorn calculi can cause xanthogranulomatous pyelonephritis (XGP), a rare destructive granulomatous process of renal parenchyma. We describe a case of bilateral staghorn calculi in a man complicated with XGP and worsening renal function.

Case Description: A 64-year-old man with bilateral staghorn calculi and chronic kidney disease (CKD) stage 4 was admitted for fatigue and worsening renal function. He tested positive for COVID-19 by nuclei acid-based test. Serum creatinine increased from 3.5 (2 months ago) to 6.2 mg/dL. Renal ultrasound showed dilated left calyces and large shadowing calculi without hydronephrosis. History was notable for persistently alkaline urine (urine pH >6.5), 100% carbonate apatite (dahllite) on stone analysis, and urinary tract infection with *Proteus mirabilis.* CT imaging revealed bilateral staghorn calculi with "bear paw" signs (left > right), a typical appearance of XGP [Figure]. Compared to a CT scan completed 10 months ago, the left kidney was enlarged with greater low-attenuating spaces indicating worsened XGP; the right kidney decreased in size with less stone burden corresponding to the right percutaneous nephrolithotomy performed 7 months prior. AKI was thought to be related to COVID-19, and surgical intervention was deemed unnecessary. Bilateral XGP likely increased his risk of AKI and hampered renal recovery, and he was subsequently initiated on hemodialysis.

Discussion: In this rare case of staghorn calculi progressed to bilateral XGP, we observed the detrimental effects of staghorn calculi on the kidneys. More research on staghorn calculi is needed to improve the high morbidity and mortality associated with this disease.

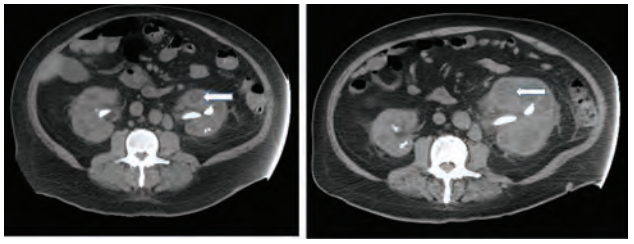

Figure. Abdominal CT- 10 months prior (left): bilateral staghorn calculi with rounded areas of low-attenuation replacing renal parenchyma representing "bear paw" signs (white arrows). Present (right): interval enlargement of left kidney with larger low-attenuating spaces consistent with worsened XGP; smaller right kidney with less stone burden.

PUB024

Factors Associated with Serum Concentrations of 25-Hydroxyvitamin D (25D) and 1,25-Dihydroxyvitamin D (1,25D) in Stable Hemodialysis Patients

Eiji Ishimura,[1] Takahiro Fujimoto,[1] Kazunori Masutani,[1] Kazunari Higashimoto,[1] Nobuya Murakami,[1] Shuko Ueda,[1] Nobuyuki Kuwamura,[1] Akihiro Tsuda,[2] Shinya Nakatani,[2] Katuhito Mori,[2] Senji Okuno,[3] Ruusuke Kakiya,[1] Masanari Emoto.[2] *[1]Meijibashi Hospital, Osaka, Japan; [2]Osaka City University Graduate School of Medicine, Osaka, Japan; [3]Shirasagi Hospital, Osaka, Japan.*

Background: Serum 1,25D, an active form synthesized from 25D, is present in CKD patients (Ishimura, Kidney Int 1999; Wolf, Kidney Int 2007). However, factors associated with 1,25D and 25D are not well known. The aim of the present study is to examine the relationship between 1,25D, 25D and clinical parameters in hemodialysis patients.

Methods: Serum 1,25D and 25D were measured by a RIA2-Ab method and an ECLIA method, respectively, in 108 stable maintenance hemodialysis patients (72 ± 10 years, 64 males, hemodialysis duration: 6.9 ± 7.5 years, 45 diabetics) from December 2019 to February 2020, i.e., in the winter.

Results: Serum 1,25D were 14.6 ± 8.0 pg/ml, demonstrating that 77 patients showed values less than reference ranges of healthy subjects (30-60 pg/mL). Serum 25D were 12.0 ± 4.8 ng/mL, demonstrating that 101 patients showed vitamin D deficiency of < 20 ng/mL. There was no significant correlation between serum 1,25D and 25D in maintenance hemodialysis patients in the present study, although 1,25D and 25D had been reported to show significant, positive correlations both in pre-dialysis CKD patients (Ishimura, Kidney Int, 1999) and in incident dialysis patients (Wolf, Kidney Int 2007). There were no significant correlations between 25D and clinical parameters. However, there were significant, negative correlations between 1,25D and intact PTH ($r = -0.344$, $p < 0.001$) and between 1,25D and ALP ($r = -0.309$, $p < 0.02$), although no significant correlations were seen between 1,25D and other parameters, such as Ca and P. In multiple regression analyses, 1,25D was significantly, independently associated with intact PTH and with ALP after adjustments of several clinical parameters ($R^2 = 0.345$, $p < 0.001$: $R^2 = 0.256$, $p < 0.001$, respectively).

Conclusions: In maintenance hemodialysis patients, all patients showed hypovitaminosis D, in terms of serum 25D. 1,25D, even in low serum levels, correlated significantly and negatively with intact PTH and ALP. These results indicated that even low levels of serum active vitamin D, 1,25D, affect the status of CKD-MBD. The results may further indicate that the metabolism of vitamin D should be considered in the pathogenesis and treatment of CKD-MBD.

PUB025

A Case of Parathyroid Hyperplasia with Single Explosive Growth

Bei Hou,[1] Bing Tang,[1] Yong Xu,[2] Yuanming Li,[2] Xinxin Liu.[1] Xiang yijia Doctor Group *[1]Jewel Hospital, Changsha, China; [2]Xiangya Hospital Central South University, Changsha, China.*

Introduction: Exploration of parathyroid hyperplasia with single explosive growth

Case Description: A 46.Y.O Asian man with ESRD has been undergoing regular hemodialysis for 20 years due to glomerulonephritis. The patient has had bone and joint pain for 10 years. In 2018, the measurement of his serum iPTH was elevated and the value was over 1000pg/ml (no data about serum calcium and phosphate levels), and he didn't have regular treatment. Serum calcium, phosphate and alkali phosphatase were 2.46mmol/L, 2.4mmol/L and 380u/L respectively, and serum iPTH was 2205pg/ml in this admission examination. The ultrasonography showed two hyperplastic parathyroid glands. They are 13*5mm on the right lower side of thyroid gland and 43*18mm on the left lower side. Parathyroid nuclide scanning showed three hyperplastic parathyroid glands. That is located in bilateral hypothyroidism and left upper sternum,consider parathyroid development, Total parathyroidectomy was successfully carried out with the general anesthesia in May 15, 2020. Four parathyroids were excised, which were 0.6*0.5cm in the upper left, 4.9*3.0cm in the lower left, 0.8*0.5cm in the upper right, and 1.5*1.0cm in the lower right (the maximum diameter and length). Pathological diagnosis showed that there was parathyroid nodular hyperplasia in the upper left, lower left, upper right and lower right. PTH values a week after surgery was less than 1.2pg/ml, serum calcium 2.13mmol/L, phosphate was 0.85mmol/L, Patient bone pain disappeared. Patient has been discharged and will be close followed up.

Discussion: Total parathyroidectomy is effective in uremic patients with secondary hyperparathyroidism which has explosive hyperplasia with parathyroid glands.

Acute Changes in Plasma Phosphate After Phosphorus-Standardized Meals in Peritoneal Dialysis: A Randomized Cross-Over Trial

Martin T. Lundin,[1] Iain O. Bressendorff,[1] Niklas R. Jørgensen,[2] Rizwan Butt,[1] Ditte Hansen.[1] *[1]Herlev Hospital, Herlev, Denmark; [2]Rigshospitalet Glostrup, Glostrup, Denmark.*

Background: Hyperphosphatemia is associated with increased morbidity and mortality in patients with chronic kidney disease. The aim of this study was to assess whether a meal with high phosphorus content affects plasma phosphate in the hours following such a meal among subjects with end-stage kidney disease on peritoneal dialysis.

Methods: This was a single-blinded randomized cross-over trial of 12 subjects on maintenance peritoneal dialysis, in which subjects were randomized to consume a meal with either high or low phosphorus content on two separate trial days. On each trial day plasma phosphate was measured immediately before consumption of the standardized meal, and after one, two, three and five hours.

Results: The mean fasting plasma phosphate at baseline was 1.69 ± 0.22 mmol/L. Plasma phosphate was similar between the two meals at baseline, as well as at one, two, three, and five hours after consumption. The largest observed difference in plasma phosphate between the two meals was 0.15 mmol/L, which occurred five hours after consumption (high phosphorus meal 1.75 ± 0.32 mmol/L versus low phosphorus meal 1.60 ± 0.14 mmol/L ($p = 0.06$)). Using summary analyses for repeated measures we observed a significant difference in the plasma phosphate between the two meals ($p = 0.03$).

Conclusions: Our results show that in subjects with end-stage kidney disease a meal with high phosphorus content has only a negligible effect on plasma phosphate compared to a meal with low phosphorus content. Thus, large increases in plasma phosphate cannot be accounted for by a high intake of phosphorus in the hours prior to blood sampling.

A Rare Case of Severe Tertiary Hyperparathyroidism in a Patient with ESRD

Jose S. Reyes Oliva, Irtiza Hasan, Zaiyara A. Rivera, Ljubomir M. Ilic. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: Refractory tertiary hyperparathyroidism is defined as severe, persistent & progressive elevation of PTH which cannot be lowered by medical management & associated hypercalcemia, hyperphosphatemia, bone/joint pain and/or fracture, extra skeletal calcification, calciphylaxis & pruritus.

Case Description: A 43-year-old undocumented Hispanic male with PMH of uncontrolled DM, HTN, ESRD (HDX 3/week) & persistent tertiary hyperparathyroidism (on Cinacalcet) presented with multiple bone fractures, bilateral leg weakness, soft tissue calcification & severe renal osteodystrophy. Significant lab findings included PTH 3518pg/mL, phosp 6.7mg/dL, Ca+ 10.9mg/dL & ak phosp 804 IU/L were all above goal. X-ray of lower ext. revealed diffuse osteopenia with chronic fracture in distal fibula, midfoot, distal tibia & dislocation of talonavicular joint as well as extensive atherosclerotic vascular calcification & multiple punctate soft tissue calcification. CT spine reported demineralized appearance of vertebral bodies & sacrum, wide erosion of sacroiliac joints bilaterally & calcified atherosclerotic disease of abdominal aorta & bilateral interiliac arteries. Patient was diagnosed as refractory tertiary hyperparathyroidism & treated with doxercalciferol, phosphate binders & advised for parathyroidectomy on multiple previous encounters but was unable to do due to health care access issue.

Discussion: Parathyroidectomy which has mortality benefit is indicated in the setting of severe & sustained PTH value above 800-1000 pg/mL, refractory to medical treatment & associated to others indicators like hypercalcemia, refractory hyperphosphatemia, bone pain/fractures & our case has majority of the above mentioned indications. Various other factors including immigration, insurance issues and post-operative intensive care requirements complicated the potential for parathyroidectomy in this patient. Although with advancement of medical field, the symptoms of severe hyperparathyroidism are rarely observed but the manifestations are real if not treated on time as per guideline recommendations.

Progression of CKD Stage G3a Among African Americans

Yelyzaveta Prysyazhnyuk, Isha Puri, Jie Ouyang, Ernie Yap. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: Chronic kidney disease (CKD) stage 3 represents the most of all CKD patients. Stage G3 is divided into G3a (GFR 45–59 ml/min/1.73m^2) and G3b (30–44 ml/min/1.73 m^2) based on findings that showed differential kidney outcomes. Stage G3a has several unresolved paradigms. Firstly, it does not always imply kidney damage. It is recommended that cystatin C be used to confirm in people without manifestations of kidney damage to avoid over-diagnosis. Secondly, it primarily comprises of the elderly, and most will not progress to advanced CKD before succumbing to other causes of death. Thirdly, in people with manifestations of kidney damage, stage G3a becomes an important predictor of disease progression. The influence of ethnicity on eGFR in delineating these aberrancies in CKD G3a is unclear. In this study, we sought to analyze the progression of CKD G3a patients in a predominantly African American cohort.

Methods: We performed retrospective chart reviews of patients at our CKD clinic. GFR was estimated based on the MDRD formula. Continuous variables are presented as mean±SD. Comparison of continuous variables were performed using one-way ANOVA. Univariate and age and body mass index (BMI)-adjustment analyses was performed by Cox proportional hazards model. IBM ***SPSS*** v. 25 was used.

Results: 319 patients were analyzed. Median follow-up was 79.7 months (IQR: 93.1). 259 (81.2%) patients had at least 2-years follow-up. In these patients, the mean annual GFR declines were 4.4±3.8, 2.3±2.1, 1.6±2.7 and 1.4±2.2 ml/min/1.73 m^2 for stages G2, G3a, G3b and G4 respectively (p<0.001). Univariate Cox proportional hazard analysis showed that CKD G3a, Gb and G4 had relative risks (RR) of progression to G5 of 1.0 (95% CI: 0.5-2.2; p=0.98), 3.8 (1.6-9.1; 0.003) and 19.4 (8.7-43.0; <0.005) respectively. When adjusted for age and BMI, risks of progression to G5 were: RR=1.3 (0.6-3.0; 0.5), 5.8 (2.3-14.7; <0.005) and 29.6 (12.1-72.2; <0.005) for CKD G3a, G3b and G4 respectively.

Conclusions: In our cohort of predominant African Americans, CKD G3a does not predict disease progression.

Characteristics	All (n=319)	CKD Stage G2 (n=162)	CKD Stage G3a (n=92)	CKD Stage G3b (n=41)	CKD Stage G4 (n=24)

Is Routine Screening with Serum and Urine Protein Electrophoresis in Evaluation of CKD Justified?

Omar T. Ashour,[1,2] Christine A. White,[1,2] Eduard A. Iliescu.[1,2] *[1]Queen's University, Kingston, ON, Canada; [2]Kingston Health Sciences Centre, Kingston, ON, Canada.*

Background: Current guidelines for the evaluation of chronic kidney disease (CKD) in Ontario, Canada do not include routine screening with serum and urine protein electrophoresis (SPEP and UPEP). Previous studies suggest that M-spike is more common in CKD compared to the general population (1,2). This study aims to examine the use and cost of screening SPEP and UPEP in the evaluation of CKD pts.

Methods: This is a retrospective study of 149 sequential incident pts referred to a teaching General Nephrology clinic for evaluation of CKD between Jan and Nov, 2018. The SPEP and UPEP testing frequency, and proportion with M-spike were obtained by chart review, along with the routinely performed clinical, blood and urine tests, imaging, as well as reports of any Hematology consultation, renal and bone marrow biopsies performed.

Results: Screening SPEP and UPEP tests were done in 104 (70 %) pts, mean age 72.2 yrs, 42 (40 %) female, 52 (50 %) DM, and Caucasian majority. M-spike was present in 11 pts (10.6 %, 96 % CI 5.4 – 18.8 %), 2 IgG-κ, 5 IgG-λ, 1 IgA-λ, 2 LC-κ, and 1 LC-λ. Eight had Hematology consultation, 6 had bone marrow biopsy, and 3 had renal biopsy. Diagnoses were 7 MGUS, 2 myeloma (MM), 1 amyloid (AL), and 1 both MM + AL. There were no differences in clinical, demographic, CBC, serum calcium, urine albumin to creatinine ratio, urinalysis, or renal imaging among pts with and without M-spike but sample size did not allow multivariate analysis.

Conclusions: In this study, the prevalence of M-spike in CKD is higher than has been reported in the literature in the general population (5.4 - 18.8 % vs. 3 – 4 %). The cost for testing and interpretation fees for SPEP and UPEP are CDN $ 25.53 and $ 32.99 respectively, with detection costs of $ 553.28 per M-spike and $ 1,521.25 per myeloma or amyloid. These costs are consistent with previous studies controlled for inflation (1,2). Routine screening with SPEP and UPEP in the evaluation of CKD may be useful and cost-effective. Larger prospective studies are needed to identify subgroups with higher likelihood of M-spike to target testing. 1. Al-Hwiesh et al. J Am Soc Nephrol 2003 14:295A. 2. Chew et al. Is Yakima County a CKDu Hot Spot? A Case Series of CKD in Latino Agriculture Workers

Mark D. Baldwin, Katherine Ackerman, Tara L. Kronen, Polly Wiltz, Lizzie Lamb. PNWU CKDu Investigative Task Foce *Pacific Northwest University of Health Sciences College of Osteopathic Medicine, Yakima, WA.*

Introduction: The first case series of chronic kidney disease of unknown etiology (CKDu) was described in 2002 in sugar cane cutters in El Salvador. This unique diagnosis presented in relatively young men without any of the traditional risk factor associated with renal disease. The common feature amongst cases was strenuous work in extremely hot environments. Yakima, Washington, an agricultural community in the Pacific Northwest, has had the highest average temperature increase in the Pacific Northwest at 3°F over the past 30 years. Average summer temperatures for July and August are 88°F and 89°F, respectively. Yakima County is 49.5% Latino and 27.5% (29,331) of the total population is involved in agriculture. The majority of labor-intensive agriculture jobs are performed by Latino workers, drawing attention to Yakima as an unexpected hotspot for CKDu.

Case Description: We describe three Latino agricultural workers seen by a nephrologist (MDB) in a local free clinic in the span of 8 months. The ages ranged from 58-68 and all worked ten years or more for local farms. Each patient had at least Stage 3 CKD (<60 ml/min/m^2), hypertension, hyperuricemia, without proteinuria nor albuminuria; there was no history of diabetes mellitus. Renal ultrasounds were unremarkable. Treatment was focused on controlling hypertension and hyperuricemia, however little disease modifying interventions are available.

Discussion: These cases, collected over a relatively short period of time, demonstrate that CKDu is more common than previously thought amongst agricultural workers in

northern regions. At 46.6021° N latitude, Yakima is closer to the North Pole than the Equator, and much farther north than other areas where CKDu has been documented. With increasing global temperatures, agricultural workers are on the frontline of climate-related health issues. Further study is necessary to develop awareness, earlier risk factor detection, and effective interventions for these essential and vulnerable members of our communities.

PUB031

The Correlation Among Management of the Comorbidities and Progression of Renal Dysfunction or Adverse Events for CKD Patients

Takahiro Kuragano, Takeshi Nakanishi. *Hyogo college of Medicine Kidney and dialysis, Nishinomiya, Japan.*

Background: It is well established that several factors including anemia, hypertension, hyperuricemia, metabolic acidosis, and CKD-MBD are associated with progression of CKD or adverse events of these patients. However, the significant factors which associated with progression of CKD or adverse events under the condition of appropriate control which according to guidelines have not been cleared.

Methods: The study was an observational study in a single center for a period of 3 years. In 88 patients with various stages of CKD (not on dialysis) who were treated by nephrologists, Hb, ferritin, iron and albumin and high sensitive C reactive protein (hCRP), β2microglbulin (MG), $HCO3^-$, and intact-parathyroid hormone (iPTH), in addition to urinary sodium, potassium, calcium, phosphorus protein, and β2MG levels, were measured. All patients were treated according to the clinical practice guideline for CKD. A time-dependent Cox hazard model was applied to evaluate the association between clinical parameters and adverse events.

Results: In multiple regression analysis, baseline of lower Hb (β=0.497, P<0.001) and vitamin D 125 (β=0.258, P=0.006), and higher int-PTH (β=-0.334, P=0.001), urinary phosphorus (β=0.328, P=0.001), urinary β2MG (β=-0.225, P=0.031) and urinary protein (β=0.280, P=0.02) levels were selected as significant predictors of decline of estimated glomerular filtration rate (eGFR) or 1/ creatinine(Cr) at the end of the study. In the Cox hazard model, low calcium (HR: 0.37, P=0.026), high phosphate (HR:5.90, P<0.001), low 125 vitamin D (HR: 0.94, P=0.013), high int-PTH (HR:1.02, P<0.001) level, use of a phosphate binder (HR: 4.95, P=0.012), and use of vitamin D analogs (HR:3.75, P=0.014) are selected as risks for adverse event including initiation of dialysis.

Conclusions: In this study, we found that among several factors, anemia and CKD-MBD related factors (phosphate, calcium, vitamin D, int-PTH) were selected as significant predictors for the progression of renal dysfunction. Furthermore, although phosphate binder or vitamin D analogs were administered appropriately, CKD-MBD factors were associated with dialysis initiation or adverse events of these patients. From these results, we presumed that the early intervention or strict control for CKD-MBD factors might attenuate the risk for adverse events of CKD patients.

PUB032

Association of Anion Gap with the Risk of CKD Progression

Ashish Verma,[1] Jing Liu,[2] Maria Clarissa Tio,[1] Ankit B. Patel,[1] Sushrut S. Waikar.[2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Boston University Medical Campus, Boston, MA.*

Background: Increased anion gap is a marker of acid retention most reflected in patients with CKD. This study's objective is to assess whether a higher anion gap is a risk factor for CKD progression.

Methods: This prospective cohort study assessed 4131 participants with CKD stage 2 to 4, who enrolled in a chronic renal insufficiency cohort study. Three types of anion gap were used as exposures, traditional anion gap (AG1), Albumin corrected anion gap(AG2), full anion gap(AG3). Multivariable adjusted Cox proportional hazard models were built using the lowest tertile as the reference of all three anion gaps for the composite outcome (50% decline in eGFR or ESRD) and ESRD. Models were adjusted for relevant covariates and baseline eGFR.

Results: This study included 4131participants [mean (SD) age, 60.48(10.21) years; 1788 (43.28%) female]. During 26673.46 person years of follow up, 805 participants reached ESRD and 1138 participants reached a composite outcome of a 50 % decline in GFR or ESRD. In a multivariable adjusted model each SD increase in AG1, AG2 and AG3 were independently associated with 10%, 10% and 12% increased risk for CKD progression: [hazard ratio (HR) 1.10; 95% CI (1.01-1.21): HR 1.10 ; 95% CI (1.02-1.20), HR 1.12 ;95% CI (1.03-1.21)], however each SD increased in AG2 and AG3 was independently associated with a 11 % increased risk for ESRD [HR 1.11; 95% CI (1.02-1.21), HR 1.11; 95% CI (1.02-1.22)]. In multivariable adjusted models compared to tertile 1 (<10) those in tertile 3 (>12) had a 33% and 41% higher risk for CKD progression [HR 1.33;95% CI (1.09-1.62), HR 1.41;95% CI (1.16-1.71)] and 32% and 60% higher risk for ESRD [HR 1.32; 95% CI (1.06-1.64), HR 1.60;95 %CI (1.28-2.01)].

Conclusions: Higher albumin corrected and full anion gap may be a risk factor for CKD progression and ESRD.

Childhood Risk Factors for Adulthood CKD

Michal Stern Zimmer, Asaf Vivante. *Sheba medical center, Ramat Gan, Israel.*

Background: Chronic Kidney Disease (CKD) is a demographic health challenge, affecting - as much as 8 to 18% of the world population. Identifying childhood risk factors for future CKD may help clinicians make early diagnoses facilitating complication monitoring and initiation of preventive interventions for CKD and its accompanying comorbidities. We aim to describe these childhood risk factors that may predict development of overt kidney disease later in life.

Methods: PubMed publications (January 2009 - January 2019) were searched for publications by using terms and synonyms for chronic kidney disease (CKD) and specific childhood kidney related risk factors. We also manually searched the reference lists of key articles, reviews and meta-analyses.

Results: There are a multitude of childhood risk factors associated with future onset and progression of CKD. These risk factors can be grouped into five categories: genetic factors (e.g. monogenic or risk alleles), perinatal factors (e.g. low birth weight and prematurity), childhood kidney diseases (e.g. congenital anomalies, pyelonephritis, glomerular diseases and acute kidney injury), childhood onset of chronic conditions (e.g. cancer, diabetes, hypertension, dyslipidemia and obesity) and different lifestyle factors (e.g. physical activity and diet).

Conclusions: The available published information suggests that the lifelong risk for CKD can be attributed to multiple factors which appear already during childhood. However, results are conflicting on the effects of childhood physical activity, diet and dyslipidemia on future renal function. On the other hand, there is consistent evidence to support close monitoring for high risk populations.

Therapeutic Interventions to Assess Outcomes and Disparities in Chronic Kidney Disease Among Veterans (TRI-CKD)

Keiichi Sumida,[1] Ankur A. Dashputre,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] Miklos Z. Molnar,[1] Cachet Wenziger,[2] Elani Streja,[2] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA.*

Background: There continues to be a large unmet need in the management of CKD, due in part to a lack of effective intervention strategies to prevent CKD progression or decrease morbidity/mortality in patients with CKD. There is also a lack of race-specific application of clinical interventions, despite evidence suggesting racial differences in response to various therapies. High quality, large observational studies are essential to provide preliminary results in support of future clinical trials, and to offer large-scale, widely applicable evidence to inform clinical practice in this population when clinical trials are not feasible.

Methods: We established a cohort of 3,565,367 individuals with stable eGFR >60 mL/min/1.73m^2 during October 1, 2004-September 30, 2006, using an algorithm based on repeated serum creatinine measurements. Data about patients' demographics, socioeconomic characteristics, comorbid conditions, administered medications, labs, vital signs, vital status, incident CKD and ESRD outcomes were obtained from various VA databases, from Centers for Medicare & Medicaid Services, and from USRDS.

Results: The mean (SD) age of the cohort is 59 (14) years; 93% are male; 16% are African-American; and 24% are diabetic. The mean baseline eGFR is 84 mL/min/1.73m^2. Individuals are followed longitudinally for up to 13 years. Overall, the crude rates of all-cause death and ESRD are 31 and 0.63 per 1000 patient-years (**Figure**).

Conclusions: We established a large nationwide cohort of US veterans with normal eGFR. Studies from this cohort will generate a wealth of information to examine therapeutic interventions used to treat various conditions associated with poor outcomes in patients with all levels of kidney function, potentially providing significant clinical, social, and policy implications for the care of US veterans and also for patients with kidney diseases in general.

Treatment Response in Patients with Uncontrolled Gout Co-Treated with Pegloticase and Leflunomide

Karim R. Masri,[1] Kevin W. Winterling,[2] Brian LaMoreaux.[2] *[1]Ben Secours Rheumatology Center, Richmond, VA; [2]Horizon Therapeutics, Lake Forest, IL.*

Background: Many patients with CKD develop gout with a prevalence ≤36% in later stage disease. Though oral urate-lowering therapies are used in CKD patients, some may not respond to or cannot tolerate them. Uncontrolled (refractory) gout can be treated with pegloticase (PEGylated uricase enzyme), however, anti-drug antibodies (ADAs) can cause loss of therapeutic efficacy. Compared with pegloticase alone, recent case series show markedly higher response rates with methotrexate/pegloticase co-therapy (42% vs. 80-100%). However, certain considerations with methotrexate use including significant renal or hepatic disease may not be as restricting with leflunomide. This study examined pegloticase response rate in patients co-treated with pegloticase and leflunomide.

Methods: This chart review study included uncontrolled gout patients treated with pegloticase (biweekly 8 mg infusions) and oral leflunomide (20 mg/day). Patient, disease, and treatment parameters were examined, along with safety data. Patients receiving ≥12 pegloticase infusions with a serum uric acid level (sUA) <6 mg/dL at infusion 12 were considered responders.

Results: 10 patients were identified and included (5 men, 72.7±12.5 years, pre-therapy sUA: 7.1±2.4 mg/dL). Common comorbidities were CKD (90%), hypertension (70%), diabetes mellitus (60%), obesity (60%), congestive heart failure (50%), and coronary artery disease (20%). 7 patients (70%) met responder criteria (26.6±14.0 infusions, sUA at infusion 12: 0.9±1.5 mg/dL). 3 patients were lost to follow-up or discontinued therapy. Gout flare (1 patient, 3 flares), wooziness/loss of consciousness (1 patient; before pegloticase infusion, deemed solumedrol related), worsening of kidney/cardiac issues (1 patient, deemed unrelated to treatment), and mild, transient ALT/AST increases (2 episodes, 1 patient) were observed. All treatment-related AEs were known effects of pegloticase or leflunomide.

Conclusions: These findings suggest that leflunomide/pegloticase co-therapy can increase the proportion of pegloticase responders, likely due to attenuation of ADAs. While methotrexate has been shown to increase pegloticase response rates, many gout patients have advanced CKD and leflunomide potentially represents an alternative option for minimizing ADAs.

A Double-Blind, Randomized, Placebo-Controlled with an Open-Label Rollover Extension Phase 2/3 Clinical Trial to Evaluate Safety and Efficacy of US-APR2020 in Subjects with CKD Stage IV

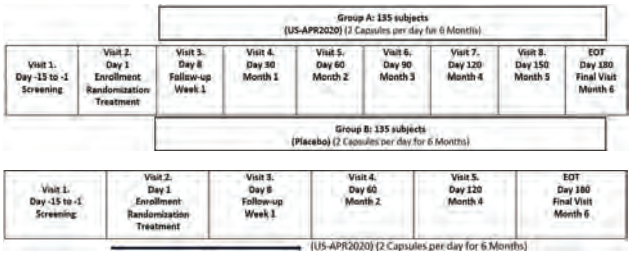
Natarajan Ranganathan,[1] Usha N. Vyas,[1] Pari Ranganathan,[1] Anthony Irvin,[1] Alan D. Weinberg.[2] *[1]Kibow Biotech, Newtown Square, PA; [2]Mount Sinai Health System, New York, NY.*

Background: CKD patients experience poor quality of life due to high levels of uremic toxins in the blood. Renadyl™, a Pro/Prebiotic dietary supplement has been in the market since 2010. It is proven to reduce several uremic toxins in 3 pilot clinical trials with no adverse outcomes. The product is now awaiting FDA-IND approval for a drug trial. This will be a large scale 12-month RCT to validate US-APR2020 as a Live Bio-Therapeutic drug product (LBP) under CBER guidelines.

Methods: (A) 6-month randomized placebo-controlled parallel design in an outpatient setting followed by (B) 6 month Open-Label Rollover Extension which will enroll all patients from study A.

Results: Study end points: As compared to placebo**; Primary**: 1: Less than 10% adverse event in the study population. 2: Arrest the decline of eGFR as per NKF-USFDA guidelines. **Secondary**: 1: Improvement in any of the basic blood uremic metabolic markers. 2: Improvement in any of the complete blood count (CBC) and hematology parameters. 3**:** Reduction in C-Reactive Protein (CRP) levels. 4: Percent change from baseline in rating scale (Modified SF36 QOL questionnaire) at the end of 6 and 12 month. **Tertiary (IN FEW SELECTED SITES):** Blood levels of Kidney Injury Molecule (Kim-1), Neutrophil Gelatinase-associated Lipocalin (NGAL), gut microbiome derived uremic toxins: Indoxyl Sulfate (IS), para-cresyl sulfate (pCS) and Trimethylamine-N-Oxide (TMAO).

Conclusions: This is the first-ever clinical trial proposed using Pre/probiotics US-APR2020 as a Live Bio-Therapeutic drug product (LBP) for CKD IV patients. Being noninvasive the intervention avoids any possible infection. The addition of US-APR2020 with standard care of therapy may possess excellent potential towards CKD applications worldwide. Formal IND process under CBER/US FDA in progress. Seriously interested clinical PI's please contact: rangan@kibowbiotech.com



PUB037

Effects of Tolvaptan on Long-Term Prognosis in CKD Patients

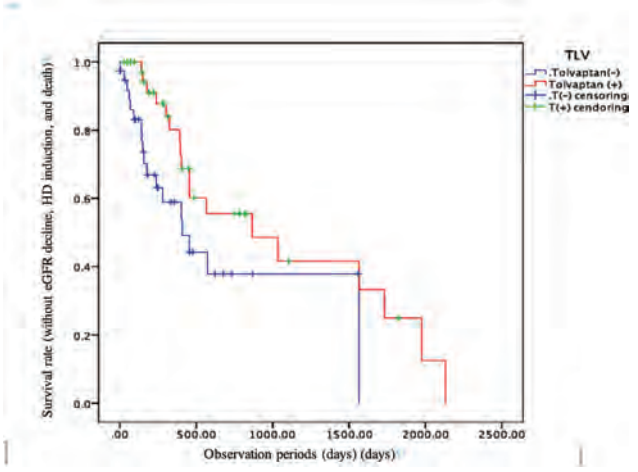
Kazuhito Fukuoka, Yuko Shibata, Shinya Kaname. Kyorin University School of Medicine, department of Nephrology and Rheumatology *Kyorin Daigaku, Mitaka, Japan.*

Background: Tolvaptan is a novel diuretic agent used for the treatment of intractable edema and SIADH in Japan, as well as polycystic kidney disease. Purpose: To determine whether tolvaptan prevent worsening renal function or prolongs the time to dialysis induction in pre-dialysis CKD patients.

Methods: A retrospective observational study (case-control study). Eligible patients were CKD patients treated with tolvaptan more than 30 days at our hospital between 2012 and 2018. The control patients were selected from CKD patients without the use of tolvaptan at our hospital that matched base line characteristics using the generated propensity variables. The endpoints were a decline in eGFR of more than 30%, introduction of dialysis, and death. The logistic regression analysis was performed on the indicator of the presence or absence of tolvaptan. Survival analysis was analyzed by the Kaplan-Meier method and tested with log rank, generalized Wilcoxon, and Rarone-Ware. The software for the statistics was IBM® SPSS® Statistics ver. 24.

Results: A total of 106 patients received tolvaptan during the study period, including 52 who met the study criteria. The median age was 65 years, the mean duration of treatment was 533 days, and the dose was 8.16 mg/day. Of these, there were 15 cases of diabetes and 6 cases of nephrosis. The normal patient group matched to these cases was selected from 63209 cases. Tolvaptan was administered after hospitalization, with an 82.1% increase in urine output and a weight of -4.2% at discharge. The tolvaptan combination group had a significant prolongation of days to endpoint: control group (746.0, p=0.013; 95% CI 479-1012) vs Tolvaptan group (1076.3, 95% CI 761-1391).

Conclusions: Tolvaptan is expected to improve prognosis because of its ability to improve edema even in advanced CKD cases. Tolvaptan has been shown to improve edema in advanced CKD as well as inhibit the deterioration of renal function with long-term use.



PUB038

Serum Calcium Changes and Renal Function: A Dual Path Track

Julia Lauar, Tiago E. Costa, Giovanni G. Nascimento Santos, Rosa M. Moyses, Rosilene M. Elias. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: Although hypercalcemia is associated with an impairment of renal function, the literature is scarce in demonstrating this relationship in clinical practice. We hypothesized that fluctuations in serum total calcium (tCa) may impact renal function in patients with chronic kidney disease (CKD).

Methods: This is a retrospective study which enrolled 148 patients with at least 2 clinical appointments with concomitant tCa and estimated glomerular filtration rate (eGFR) measurement in the period between January-2017 and December-2019. We collected demographic, clinical, and biochemical data. Up to 3 consecutive measurements were analyzed.

Results: Patients were mostly Caucasian women, aging 66 ± 15 years. Mean eGFR was 45.1 ml/min/1.73m^2. Hyperparathyroidism (parathyroid hormone > 65pg/ml) was associated with a 2.8-fold increased risk for hypercalcemia (p=0.030). There was a non-linear relationship between change in tCa and change in eGFR, so that when tCa increased above the normal limit, there was a reduction in eGFR. Patients with hyperparathyroidism seem to present a significant lower risk of impairment in eGFR in the consecutive measurements when compared to other causes of hypercalcemia.

Conclusions: The development of hypercalcemia in patients with CKD is associated with a deterioration of renal function. Therefore, the strict control of serum calcium is advised in these patients.

PUB039

The Tri-POCUS Approach for Assessment of Volume Status in Critically Ill Patients with COVID-19

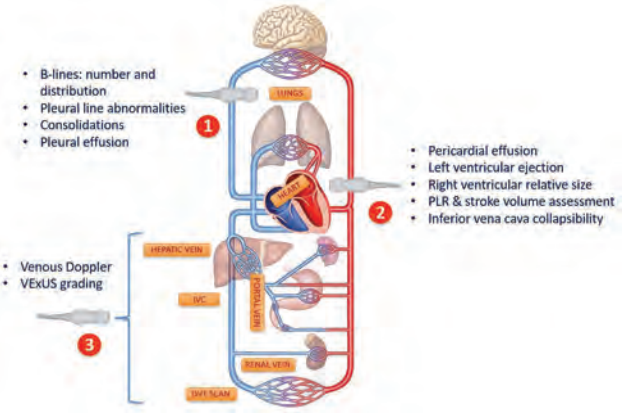
Abhilash Koratala,[3] Claudio Ronco,[2] Olanrewaju A. Olaoye,[1] Amir Kazory.[1] *[1]University of Florida, Gainesville, FL; [2]Universita degli Studi di Padova, Padova, Italy; [3]Medical College of Wisconsin, Milwaukee, WI.*

Background: The volume status of patients with coronavirus disease 2019 (COVID-19) is dynamic and can range from severe hypovolemia (on initial presentation) to overt hypervolemia (after fluid resuscitation) due to its distinct clinical features such as cytokine storm. While lung point-of-care ultrasound (POCUS) is established as an invaluable bedside tool in assessment of volume status of the critically-ill, its use in this setting is limited by expanding lung infiltrates and a tendency for acute respiratory distress syndrome (ARDS).

Methods: We developed a combinational bedside ultrasound program to overcome the limitations of the individual methods of POCUS and provide a more precise evaluation of the volume status in critically ill patients with COVID-19. The Tri-POCUS approach represents concurrent bedside assessment of the lungs, heart (focused cardiac ultrasound [FoCUS]), and the venous system (blood flow pattern in the hepatic, portal and intra-renal veins) (Figure-1).

Results: In patients with COVID-19, distinguishing ARDS from cardiogenic pulmonary edema by lung POCUS alone is challenging due to several overlapping features. FoCUS allows for both static measures of preload as well as dynamic assessment (e.g. volume responsiveness to passive leg raise maneuver). Evaluation of blood flow pattern in the hepatic, portal and intra-renal veins not only can gauge fluid status but it also allows for direct assessment of the congestive state in end organs hence monitoring response to therapy.

Conclusions: The Tri-POCUS program is an extension of our previously published work on focused renal POCUS curriculum. The components of this combinational approach have been selected based on their ability to cover the limitations of each individual method and provide a synergistic effect, especially in clinical settings such as COVID-19 where there is a tendency for rapidly changing volume status confounded by distracting features (e.g. expanding lung lesions).



PUB040

New-Onset Nephrotic Syndrome in a Child Associated with COVID-19 Infection

Siddharth A. Shah. *University of Louisville, Louisville, KY.*

Introduction: The COVID-19 outbreak has turned into worldwide public health emergency. The renal histo-pathological features of acute tubular necrosis or thrombotic microangiopathy are-reported in adults previously with severe COVID-19 infections. In children, the renal manifestations associated with COVID-19 infection are not widely reported. Here, we describe a case report of a child with new onset nephrotic syndrome associated with COVID-19 infection.

Case Description: 8-year-old boy with no previous significant medical history presented with bilateral eye and facial swelling soon after his parents were-diagnosed with COVID-19 infection. He had diarrhea but no fever or shortness of breath. One week after onset of swelling, the boy was also tested positive for COVID-19 infection. Based on clinical findings of significant proteinuria (Urine protein and creatinine ratio of 11.4), hypoalbuminemia (serum albumin of 2 g/dL) and hypercholesterolemia (Total Cholesterol of 384 mg/dL), he was diagnosed having nephrotic syndrome. He responded well to standard-dose prednisone treatment for nephrotic syndrome. In one week of starting prednisone treatment, he went into clinical remission. Lymphopenia continued to be present for 2 weeks after onset of symptoms. There were no complications related to clot formation or secondary infections with this presentation.

Discussion: This is the first case report to our knowledge of pediatric patient presenting with new-onset nephrotic syndrome associated with COVID-19 infection. Although, the burden of disease from COVID-19 is less severe in children, they can present with immune system related kidney disease like nephrotic syndrome. The patient responded well to standard-dose prednisone treatment used typically for new onset nephrotic syndrome.

PUB041

Recurrent Arteriovenous Graft Thrombosis in COVID-19

Namrata Singhania,[2] Saurabh Bansal,[3] Girish Singhania.[1] *[1]CHI Saint Vincent Health System, Little Rock, AR; [2]Mount Carmel East, Columbus, OH; [3]University of Illinois at Peoria, Peoria, IL.*

Introduction: COVID-19 has been associated with increased risk of hypercoagulability. We report a case of COVID-19-associated coagulopathy leading to recurrent arteriovenous (AV) graft thrombosis in an end-stage renal dialysis (ESRD) patient.

Case Description: 84 yo African American female with ESRD on dialysis via lower extremity AV graft, diabetes and atrial fibrillation on warfarin who was diagnosed with COVID-19 came back again 1 week later and was admitted due to hypoxemia. COVID-19 PCR was again positive. INR was 1.4, D-dimer 3.28mcg/mL, platelet count 114K/mm^3, mildly prolonged PT, aPTT. She had elevated venous pressures during dialysis. Doppler suggested AV graft thrombosis. Heparin drip was started. Angiography and intravascular ultrasound (IVUS) showed thrombosed AV graft. (Figure 1a,1b) Thrombectomy was successful (Figure 1c,1d) with uneventful hemodialysis afterwards. She was discharged. Next day, she came back again with diarrhea. Coronavirus PCR was still positive. INR was 1.9. She again had high venous pressures. Doppler found recurrent thrombosis. Heparin drip was started. Vascular surgery placed dialysis catheter and held thrombectomy till her coronavirus PCR turns negative.

Discussion: Incidence of venous thromboembolism (VTE) can be as high as 58% in patients with COVID-19. All categories of 'Virchow's triad' are involved, endothelial injury (increased cytokines and complements), stasis (immobilization) and hypercoagulable state (changes in prothrombotic factors). Risk factors are males, obesity, heart disease, hypertension, diabetes and ESRD. High D-dimer, mildly prolonged PT, aPTT and thrombocytopenia are common. Full-dose anticoagulation is recommended for documented VTE.

Manage of a Peritoneal Dialysis Unit During the COVID-19 Pandemic

Ana T. Domingos, Roberto C. Marques, Anabela M. Guedes, Céu Laranjo, Idalécio Bernardo, Pedro L. Neves. *Centro Hospitalar do Algarve EPE, Faro, Portugal*.

Background: Peritoneal Dialysis (PD) patients are special, as they are mainly independent in a "life-support technique" but susceptible to various potential complications related. This pandemic brought new challenges and PD Units had to be reorganized considering their specific population, human and material resources. We aimed to understand the impact of our restructuration and discuss some lessons learned.

Methods: We retrospectively reviewed the activity and intercurrences at our Unit during the COVID-19 state of emergency declared by our Government, from 19th March to 2nd May (6 weeks), and compared it to the correspondent past two years (table 1). In a normal period, most of our patients are evaluated in a monthly basis. Simple descriptive and Student's paired T-test analysis were performed.

Results: We managed 34 patients in the correspondent period of 2018, 36 in 2019 and 38 in 2020. Clinical appointments in this 2020 period were realized by phone. Necessary dislocations to the Unit in 2020 included peritonitis, exit-site infections and catheter malfunctioning. No dropouts occurred. There were no positive cases of COVID-19. Student's paired T-test analysis between 2020 and 2019, plus 2020 and 2018, showed no statistically significant differences in every evaluated phenomenon (except for non-presential appointments; this discrepancy is justified by the Unit's dynamic, without clinical implications).

Conclusions: Despite the restructuring, we were able to provide more teleassistance and the mean of complications/hospital admissions weren't statically worse. Some activities were postponed, but its true impact isn't yet clear. Will suboptimal care bring long-term complications? Nonetheless, PD technique stands out for favorably, mainly if all the necessary support from medical and nurse staff is guarantee.

Activity and intercurrences at our PD Unit.

Exploration on Renal Protective Compounds and COVID-19-Induced Renal Injuries Based on Network Pharmacology and Molecular Docking

Yue-Yu Gu,[1,2] Min Zhang,[1,2] Yifan Wu,[1,2] Xusheng Liu.[1,2] *[1]Department of Nephrology, Guangdong Provincial Hospital of Chinese Medicine, Second Affiliated Hospital, Guangzhou, China; [2]Guangzhou University of Traditional Chinese Medicine, Guangzhou, China.*

Background: The fullscreen of COVID-19 is getting revealed as some of the infected patients had developed severe renal complications. Natural compounds may have protective effects against COVID-19-induced renal injuries. The aim of this study is to explore the interactions and underlying mechanisms between active compounds and COVID-19-induced renal injuries.

Methods: The interaction network of 8 collected natural compounds (Hederagenin, β-sitosterol, Luteolin, Quercetin, Kaempferol, Jaranol, Formononetin and Calycosin) and COVID-19-related target proteins was established by using the pharmacological database. GO and KEGG pathways were also analyzed. Molecular docking was run by AutoDockTools and Discovery Studio.

Results: 259 target genes are potentially related to COVID-19, AKI and CKD. Active compounds may improve COVID-19-induced renal injuries by alleviating the inflammatory response, vascular abnormal changes, cell apoptosis and necrosis in kidneys. The docking results had indicated that 8 compounds may show great possibilities to interact with SARS-CoV-2 main protease 3CL and ACE2 by showing significant binding energy.

Conclusions: Our study may provide molecular evidence and support on compounds from herbal medicines or dietary supplements may serve as potential perspective drugs to protect kidneys from COVID-19-induced renal injuries.

Funding: Government Support - Non-U.S.

PUB044

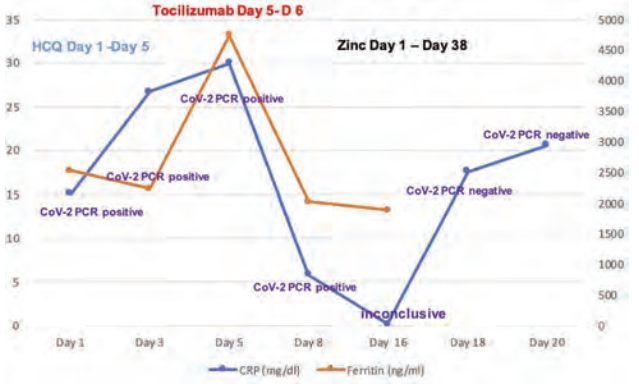
Complete Recovery from COVID-19 Infection in an ESRD Patient

Ravi K. Thimmisetty,[1] Zeenat Y. Bhat,[2] Noreen F. Rossi.[2] *[1]Nephrology Associates, Cape Girardeau, MO; [2]Wayne State University, Detroit, MI.*

Introduction: We report a hemodialysis case having both influenza and COVID-19 who presented without respiratory symptoms and recovered fully with treatment by Interleukin-6 (IL-6) inhibitor

Case Description: 68-year-old Caucasian woman with history of hypertension, diabetes mellitus, obesity, sleep apnea, atrial fibrillation, and ESRD on hemodialysis came to hospital with fever of 102°F. Her symptoms were fatigue, mental status changes, and decreased energy levels. There was no travel history and no contact with COVID positive or suspected COVID patients. On arrival to ER she had temperature of 99.4 f, bp 117/63, HR 102, RR 18, oxygen saturation of 99% on 2liters of oxygen. Examination revealed normal breathing sounds, no wheezing, and functional left forearm arteriovenous fistula. Rest of the exam was with in normal limits. Laboratory results showed sodium 138, potassium 5.7, chloride 96, bicarbonate 24, blood urea nitrogen 71, creatinine 13.5, C-reactive protein 15.06, ferritin 2532, She was positive for both influenza and SARS COV-2 PCR. Blood and urine cultures showed no growth. Imaging showed prominent interstitial vascular prominence; underlying pneumonia could not be excluded. Patient was admitted to COVID-19 isolation unit and empirically started on oseltamivir, Hydroxychloroquine, Zinc sulfate, vancomycin and, piperacillin-tazobactum for influenza, possible COVID and bacterial infection. Maintenance hemodialysis was resumed with challenging fluid removal because of pulmonary vascular congestion. She was positive for SARS COV-2 PCR on four subsequent tests. She developed progressive hypoxia. Oxygen requirements increased to 15 liters salter oxygen consistent with acute respiratory distress syndrome. Two doses of Tocilizumab (IL-6 inhibitor) were given. Patient improved significantly and discharged home with two SARS CoV-2 PCR negative results

Discussion: Our case is unique of having both influenza and COVID-19 infection and improved. More studies are warranted to evaluate clinical benefit of the above therapies



PUB045

AKI with Minimal Pulmonary Pathology in SARS-CoV2 Infection

Yasnowski Frank,[2] Rajeev Rohatgi.[1,2] *[1]Northport VA Medical Center, Northport, NY; [2]Stony Brook University Renaissance School of Medicine, Stony Brook, NY.*

Introduction: SARS-CoV2 transmission occurs through infection of the upper airway epithelial cells. Though many cases are asymptomatic or mild, a significant fraction require hospitalization that is associated with morbidity and mortality. Primarily a pulmonary illness causing hypoxia and an acute respiratory distress syndrome (ARDS), SARS-CoV2 is also associated with AKI and other life-threatening systemic disorders. Generally, AKI occurs late in the course of SARS-CoV2 infection after severe pulmonary manifestations.

Case Description: 49 year old African American male presented to the emergency department with 3-4 days of nausea and vomiting. He was diagnosed 10 days prior with SARS-CoV2. His past medical history is significant for pulmonary interstitial fibrosis, lupus nephritis diagnosed in 2017 with baseline serum creatinine of 3 mg/dL, and hypertension. His outpatient medications included lisinopril and hydroxychloquine. On admission his serum creatinine 28.9 mg/dL, blood urea nitrogen was 230 mg/dL, Na 133 meq/L, K 7.4 meq/L, Bicarb 11 meq/L, Cl 96 meq/L, and albumin 2.9 g/dL. His serum aldosterone 2.3 ng/dL, ACE 6 U/L, procalcitonin 1.29 ng/mL, and D-Dimer 2055. His urine dipstick showed 500mg /dL protein with moderate blood. On arterial blood gas, he had a compensated metabolic acidosis, a partial pressure of oxygen of 92.6 mm Hg on room air, and no respiratory distress. No hypotension was observed. CXR showed hazy patchy bilateral opacities, most pronounced in the lower lungs. A dialysis catheter was placed, and the patient dialyzed. The patient's pulse oximeter remained between 96-100% on room air, D-Dimer 2055-2613, and procalcitonin < 1.29 ng/mL during his 12 day hospitalization. He was discharged on TIW hemodialysis.

Discussion: AKI due to SARS-CoV2 usually occurs in the setting of severe pulmonary disease with hypoxemia and is likely related to multiple factors including hypotension, activation of coagulation and complement cascades, and cytokine storm. On the other hand, other evidence points to renal specific tropism due to abundance of TMPRSS2 and ACE2 in renal epithelia and autopsy findings of SARS-CoV2 nucleocapsid in renal epithelia. Though the case is confounded by (1) chronic kidney disease and (2) hydroxychloroquine use, this case illustrates pure kidney failure in a patient with minimal pulmonary disease and suggests a renal specific disease due to SARS-CoV2.

PUB046

Dialysis Care During the COVID-19 (C19) Pandemic: A Large Urban Academic Dialysis Center Experience

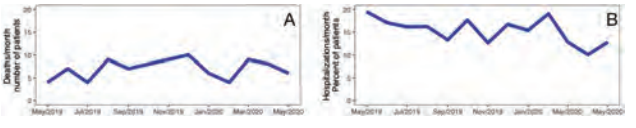
Jose E. Navarrete,[1] Kathy Oliver,[2] Tomiwa Ishmail,[2] Harold A. Franch,[1] Ibironke W. Apata.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]HSM dialysis services, Atlanta, GA.*

Background: Effective dialysis care during the C19 pandemic has required implemetation of new policies and procedures to ensure adequate care, to avoid contagion in dialysis centers and to minimize unnecesary expossure to medical personnel.

Methods: Emory dialysis program provides dialysis care for ~ 750 patients in 4 hemodialysis centers and 3 home dialysis locations in the metro Atlanta area. The first cases of C19 in Georgia were reported on March 2, 2020 and plans to contain the spreading of the disease were implemented in our dialysis units, including mask use, triaging of patients and personnel based on symptoms, telemedicine rounds, cohorting of C19+ patients in a single shift in a designated unit, and physical isolation of nursing home residents while receiving hemodialysis. This report describe the clinical outcomes related to these interventions.

Results: Until May 30/2020, 106 patients had been tested (14%). 22 patients were positive for C19 (2.9%) of which 20 were on HD and 2 on PD. Five C19+ patients died (mortality 23%). Patients that tested positive were older (65±13 vs 60±13y/o), mainly African-Americans (90%) with a higher BMI (29 vs 26), more likely to be diabetics (51% vs 44%) and to reside in a Nursing Home (20 vs 10%), with higher prevalence of cardiovascular disease (45 vs 30%). Dialysis-related parameters (albumin, hemoglobin, phophorus, PTH, Kt/V and blood pressure) were similar between those that tested positive vs negative. 4% (31 patients) of our entire dialysis population resides in Nursing Homes. 12 of them have been tested and 8 were C19+ (26%). The dialysis patients that expired were older (69 vs 57y), all were African-Americans and had higher BMI (30 vs 26) and time on dialysis (12.3 vs 5.6 y) than those that survived. We did not observe an increase frequency of hospitalizations or deaths compared to previous months (Figure 1).

Conclusions: In our dialysis population the incidence of C19 infection was 2.9% with 14% of patients tested. Mortality was 24%. Deceased patients were older, had a higher BMI and were on dialysis for longer time compared to those that survived. We did not observe an increase rate of hospitalizations or deaths during initial 3 months of the pandemic.



PUB047

A Case of Severe Rhabdomyolysis Associated with COVID-19 Infection Without AKI

Genta Uehara, Keisuke Okamoto, Tibor Fulop. Division of Nephrology *Medical University of South Carolina - College of Medicine, Charleston, SC.*

Introduction: We present a case of severe rhabdomyolysis associated with COVID-19 infection without acute kidney injury (AKI).

Case Description: A 43 year-old African American male with a history of medication-induced rhabdomyolysis 6 years ago, renal cell carcinoma status post partial right nephrectomy, hypertension, type 2 diabetes, and morbid obesity presented to emergency department with upper respiratory symptoms, myalgia and discoloration of urine for one week. He reported taking atorvastatin and diltiazem for a long time but has never

developed myalgia. There was no family history of myopathies, or binge alcohol intake beforehand. On physical examination, patient was hypertensive, euvolemic, and afebrile, with normal oxygenation. Chest x-ray showed subtle increased interstitial reticulation in the perihilar regions and COVID-19 rapid test returned positive. Laboratory data showed very high creatine kinase (CK) (208,456 U/L). Urinalysis showed trace proteinuria, large blood but only few red blood cells and confirmed myoglobinuria. However, his creatinine was normal (0.8 mg/dL), as well as serum calcium (8.4 mg/dL), phosphate (3.9 mg/dL), and uric acid (5.2mg/dL) levels. Patient was admitted for treatment of assumed severe rhabdomyolysis. COVID-19 was treated conservatively with oxygen supplementation. Atorvastatin and diltiazem were held, and normal saline and isotonic sodium bicarbonate fluids were administered. CK continued to rise with a peak of 499,020 U/L on day 3, but decreased steadily to 58,745 U/L on day 7. Renal function remained stable all the time during the treatment (serum Cr 0.68 – 0.82 mg/dL), with maintained urine output and well-preserved electrolytes and uric acid levels throughout.

Discussion: There are increasing number of reports of COVID-19-associated rhabdomyolysis, but risk factors and characteristics are fairly known. The clinical and laboratory manifestations are suggestive of COVID-19 associated rhabdomyolysis rather than statin-induced. We are not aware of any other reports documenting such extreme CK values – with a proper rise and fall of CK – without impacting renal function. As far as we know, this is the first case of COVID-19 associated rhabdomyolysis with peak CK of 499,020 U/L, without AKI and concurrent electrolyte abnormalities. The relationship to COVID-19 vs. individual genetic susceptibility remains to be explored.

PUB048

CKD Patients on Hemodialysis (HD) with COVID-19 Infection: Characteristics and Outcome

Suresh Sankarasubbaiyan, Mallikarjuna Gowda B. Gowda, Mohammad S. Husain, Satyanarayana R. Puvvada, Vikram A. Sonawane, Kaparaboina K. Kumar, Guruvulu Venkata, Kamal D. Shah. *Nephroplus, Hyderabad, India*.

Background: The COVID-19 pandemic has special significance for Chronic Kidney Disease patients on HD. Clinical characteristics and outcome from low resource settings are not well known

Methods: From March 15 2020 until May 20, 2020, quality managers reviewed all patients with confirmed COVID-19 infections in 200 HD centres among MHD patients. For patients with COVID-19 infections: age, gender, geographical zone, type of Insurance, continuity of care was noted, HD characteristics and outcome were reviewed. Comparison of median was done with Mann Whitney/Wilcoxon 2 sample test and proportion with Fisther exact test. All patients were transferred to public hospital for regulatory compliance limiting follow up of HD sessions.

Results: 39 out of 18402 patients developed COVID-19 infection. M: F: 28: 11, Age; 54.62 + 14.92 years. Geographically: East zone:3(7%), North:12(31%), South:5(12%), West:19(50%). Payers: self pay:19(49%), government insurance:15 (38%) and private Insurance:5(13%). 32(82%) hypertensives, 23(59%)diabetics. Outcome: 8(20%) expired, 18(46%) discharged, 12(31%) in hospital and 1 at home. Mean Hb (77%) : 9.81 ±1.71 g%, Adequacy (74%): 1.30 ± .44, Vascular access (72%): 75% permanent access, 7% temporary catheter, 18% tunneled catheter, Albumin (64%): 3.69 ±.31.

Conclusions: Maintenance HD patients have increased mortality as compared to reports in normal population and is associated with need for intensive care, steroid use and ventilatory support.

Comparison of survivors and non-survivors in maintenance HD patients with COVID-19 infection

	Survivors n = 31	Non-Survivors n= 8	p value

Starvation-Induced Metabolic Acidosis in a COVID-19-Infected Pregnant Patient

Muhammad R. Mustafa. *Stony Brook University, Stony Brook, NY*.

Introduction: Suffolk County in NY was hardest hit with COVID 19. We present a case of a pregnant female with COVID 19 infection and high anion gap acidosis.

Case Description: 34 yo female, 33 weeks twin pregnancy, a/w fever, SOB and polyuria. Her oral intake was poor. She was positive for COVID 19. Her T - 100 F,O2 sat 99% with O2 by NC at 2 L. She had bibasilar crackles. Both babies were moving. CXR showed multifocal pneumonia. Nephrology was consulted for metabolic acidosis. A diagnosis of starvation ketosis of pregnancy was made due to anion gap acidosis, high serum beta-hydroxybutyrate and ketonueia. Dextrose 5% with sodium bicarbonate was given. She had C section, remained intubated for 24 hours, recovered well and was discharged on hospital day 7.

Discussion: Almost 15% of pregnant patients develop server COVID 19, Pregnant patients with COVID infection are a higher risk group.

Slow Low-Efficiency Dialysis (SLED) Implementation During the COVID-19 Pandemic Surge

Richard L. Barnett, Kenar D. Jhaveri, Bessy Suyin Flores Chang, Azzour D. Hazzan, Shamir Hasan, Steven Fishbane, Mark A. Finger. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY*.

Background: The high rate of ARF in COVID-19 hospitalized patients increased the demand for critical care renal replacement therapy 2-3 fold at Northwell Health (NW). At the 2 largest hospitals, Long Island Jewish (LIJ) and North Shore University Hospital (NSUH), bedside HD was provided by HD RNs and continuous renal replacement therapy (CRRT) by critical care (CC) RNs. RN workload in these hypercatabolic patients soared as HD treatments more than doubled and CRRT increased from 9 to 30,. Shortages of CRRT fluid and filter sets ensued. SLED, a technique utilizing standard HD dialysate and filters, combined with a collaboratiive approach between CC and HD RNs was considered.

Methods: In late March, a cohort CC bedside HD program, was initiated. Based on this success, a leadership panel of CC/HD RN and Renal/CC MDs created a SLED project plan. Details were reviewed with stakeholders on Friday prior to the Tuesday "Go-Live." 3 patients previously treated with HD or CRRT via a Shiley catheter were selected as a pilot for three 6-8 hour sessions, Fresenius 2008T, Revaclear 300 filters with dialysate flow rate 300 cc/min and blood flow rate 200-300 cc/min were ordered. HD RN initiated treatments and available throughout, while clinical stability was monitored by CC RN.

Results: NSUH pilot involved 5 patients over 3 sessions. Suboptimal cohorting required remote tablet monitoring and frequent presence of several HD RNs. One patient was terminated in one session due to persistent hypotension. Clearances and UF goals were achieved throughout. A week later the LIJ pilot used the design and advantage of NSUH experience with a 3 bed "SLED Room" model. The same 3 patients participated in all 3 sessions supervised by a single HD RN with no discontinuation. CC RN satisfaction with SLED was ranked "high" at both sites and by LIJ HD RNs but "Spread SLED" rated only "fair" by NSUH HD RNs. Pilots were extended 10 days. During this period SLED was initiated at 2 other NH sites. Future SLED programs will be focused on NH hospitals lacking CRRT.

Conclusions: SLED is an efficient alternative to CC HD and CRRT. The challenges of effective cohorting in a pandemic surge relegate its role to a piece of a comprehensive renal critical care program. It imay be particularly valuable for hospitals lacking CRRT options.

PUB051

Kidney Transplantation in the United States During the Coronavirus Disease 2019 Pandemic: An Interrupted Time Series Analysis

Ekamol Tantisattamo,[1,2] Natnicha Leelaviwat,[3] Sakditad Saowapa,[3] Natchaya Polpichai,[4] Busara Songtanin,[5] Possawat Vutthikraivit,[6] Chawit Lopimpisuth.[5] *[1]Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; [2]Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; [3]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [4]Faculty of Medicine Songklanagarin Hospital, Prince of Songkla University, Songkla, Thailand; [5]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [6]Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand.*

Background: The number of kidney transplant (KT) in the United States (US) has decreased during COVID-19 pandemic; however, the magnitude of this impact is unclear.

Methods: A period from January 5 to April 18, 2020 was divided into pre- and post-COVID-19 periods by assigning March 1, 2020 as the first day of the post-COVID-19 outbreak in the US. The number of waitlist candidates (WLC) and new KT every 7 days were obtained from OPTN/SRTR. An interrupted time series analysis was performed to examine an incidence rate ratio (IRR) between pre- and post-COVID-19 period by using multiple Poisson regression.

Results: Compared to pre-COVID-19 period, the average number of new KT during post-COVID-19 period decreased (479±33 vs 318±119 cases/week, mean difference±SEM 161±44, 95%CI 67, 255). The number of WLC was relatively stable (mean±SD 65,937±959 cases/week); whereas, it decreased during post-COVID-19 period (61,759±2203 cases/week). Mean incidence rates (IR) of new KT during pre- and post-COVID-19 periods were 727±58 and 511±176 cases/10^5 WLC-week, respectively (Figure1). The IR of new KT during post-COVID-19 period was 29% lower than those during pre-COVID-19 period(IRR 0.71, 95%CI 1.96, 2.11) and each one additional week was associated with a 4% decrease in the new KT (IRR 0.96, 95%CI 2.60, 2.63). After adjusted by age group, transplant areas, and time-study period interaction term, the IR of new KT was 3% increase for every one more week during pre-COVID-19 period (IRR 1.03); whereas, there were 12% decrease for every one more week after March 1, 2020(IRR 0.88). Compared to pre-COVID-19 period, the IR of new KT during post-COVID-19 period was 9% lower for every additional week for each corresponding period (IRR 0.91).

Conclusions: COVID-19 outbreak in the US since March 2020 is an independent factor of a significant decline in the number of new KT. Further information regarding ability of control COVID-19 may direct KT.

Spectrum of AKI in Patients with COVID-19 Infection

Irtiza Hasan, Vishal Jaikaransingh, Abdalagani A. Abakar Baher, Jose S. Reyes Oliva, Charles W. Heilig. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: With the gradual unfolding of the full spectrum of COVID19 manifestations, Acute Kidney Injury (AKI) is emerging as a frequent association & a predictor of disease severity & mortality. We present 3 cases of AKI in COVID19 patients & illustrate the clinical course, management & outcome.

Case Description: The first case was a 50-yr old male with DM, HTN, & obesity, admitted with pneumonia, dyspnea & diarrhea, developed hypotension, arrhythmia, & required intubation on day 31 of admission. The next case was a hypertensive, obese 57-year old female, admitted with pneumonia, worsening dyspnea & respiratory failure without hypotension, was intubated on day 30 of admission. Both of the cases developed AKI with oliguria & progressed to anuria 24 hrs post-intubation. Case 3 was a 72-year old female with hypothyroidism admitted with pneumonia, dyspnea, diarrhea, & AKI, was intubated on day 12. All cases had bilateral pneumonia on chest radiograph & significantly raised inflammatory markers (CRP, LDH, Procalcitonin, Ferritin, ALT/AST, d-Dimer, & INR). Peak S. Creat. was 4.1, 6.6, & 3.07 for cases 1, 2, & 3 respectively. Urinalysis for all cases revealed proteinuria, hematuria, plus 4+ budding yeast & signs of UTI for cases 1 & 2. Ultrasound revealed structurally normal kidneys for all cases. Case 1 & 2 were diagnosed as stage III AKI & Case 3 with stage II AKI. All cases received some form of antibiotics, hydroxychloroquine, & heparin for COVID19 and CVVHD for renal support & later iHD for case 2. Glomerulonephritis specific workup could not be done due to the patient's clinical status. Among the cases, case 2 made full recovery & discharged, case 1 was stable but hospitalized, case 3 expired on day 14 of hospitalization due to multiorgan failure.

Discussion: Our cases highlight the inherent variability in causation & clinical course for AKI in COVID19. Interestingly, all 3 cases had the full spectrum of kidney involvement from proteinuria, hematuria to AKI. Although difficult to discern in the absence of biopsy, some potential causes of AKI in these patients include ischemia (respiratory failure, hypotension) (cases1 & 2), cytokine storm syndrome (case 3), or direct COVID19 induced acute tubular injury. Increased vigilance is required to recognize probable causes for AKI and to develop adequate management protocols to limit AKI–related morbidity or mortality.

PUB053

COVID-19 Infection in Renal Transplant Patients

Azm U. Hussain, Kashif Eqbal, Rafeea Shah, Mary Dutton, Miriam Berry. *University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Background: The SARS CoV-2 pandemic has disproportionately affected vulnerable patient populations including kidney transplant recipients (KTR).

Methods: Our transplant centre covers a large multi-ethnic urban population with high rates of co-morbidity and social deprivation, and provides follow-up care for approximately 1500 kidney transplant recipients. In line with national guidance, COVID-19 testing was largely restricted to those patients presenting to secondary care. Where COVID-19 was confirmed or suspected, anti-proliferative drugs were stopped, maintenance corticosteroids increased, and calcineurin inhibitor was stopped in patients requiring admission. We performed a retrospective analysis of clinical presentations and outcomes in kidney transplant recipients with confirmed COVID-19 between 20th March and 10th May 2020.

Results: 25 patients (approximately 1.6%) had confirmed COVID-19. 11 (44%) were female and 14 (56%) male. The median age was 61 years (range 33 – 84 years). 11 (44%) were White - British, 12 (48%) Asian and 2 (8%) Afro-Caribbean. Median time post-transplant was 84 months (range 6 – 360), and more recently transplanted patients were not at increased risk. Respiratory symptoms were the predominant presenting complaint in 19 patients (76%) followed by GI symptoms in 4 (16%). Acute kidney injury (stages 1-3) occurred in 15 patients (60%) with 7 patients (28% of whole population 46% of patients with AKI) requiring renal replacement therapy. 6 patients (40%) recovered renal function at a median follow up period of 26 days (range 10 - 51). 4 (16%) were admitted to ITU for ventilation. 10 patients (40%) died (although one death was not related to COVID-19). Among the patients who died, median age was 65 years and 6 (60%) were male with ethnicity proportionate to the study population.

Conclusions: The strategy of performing COVID-19 testing only in patients requiring secondary care likely i) underestimates the incidence and ii) overestimates the disease severity. However, our data show that COVID-19 confers significant morbidity and mortality in kidney transplant recipients despite prompt reduction of immunosuppression. These data will inform a revised consent process for those patients awaiting kidney transplantation. Follow up studies are required to assess longer term outcomes, and potential complications in KTRs who have recovered from COVID-19.

PUB054

COVID-19 Induces a Wasting Syndrome in Hemodialysis Outpatients: Outcomes in Rochester, New York

Rebeca D. Monk,[1] Kristian Vitu,[1] Samantha J. Mauser,[2] Jaime L. Oneil.[3] *[1]University of Rochester Medical Center, Rochester, NY; [2]University of Rochester, Rochester, NY; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: COVID-19 (COV) has infected 2852 residents of Monroe County with a death toll of 218 to date. Hemodialysis (HD) patients (pts) are at high risk for developing COV due to multiple comorbidities. Many patients also reside in Skilled Nursing Facilities (SNF) which have high infection rates. One single Fresenius Medical Care (FMC) dialysis facility in the Rochester, NY area with no Tues/Thurs/Sat (TTS) shifts became the designated unit to provide maintenance HD for all COV positive (+) pts in our region until they had 2 negative COV tests. This is a quality improvement review of our patients.

Methods: The study included all 18 pts thus far who received at least one HD treatment in our COV + unit. Demographics and labs ~ 2 months prior to their first COV + test and during the first month in our COV unit were analyzed and compared with data from the 33 COV negative (-) Mon/Wed/Fri (MWF) patients in the same facility. Paired and unpaired T tests were used to determine the statistical significance of observed differences in weight (wt) and labs pre and post COV+ and between COV + and - pts.

Results: Of our 18 pts, 50% were African American and 50% Caucasian American. Mean age 67, BMI 29.2. 50% resided in SNF prior to COV. All had ESRD. 3 initiated HD in the last 2 months. 8 pts were on HD ≤ 1 yr. 11 were hospitalized, 3 were intubated and 2 died. 78% had DM. Compared to 2 months prior to COV + testing, pts lost a mean wt of 8.6 (± 1.8) kg in the first month in our COV + unit (p= 0.0002). Albumin decreased from 3.75 (± 0.60) to 3.33 (± 0.54) (p= 0.0005) and ferritin rose from 753 (± 512) to 1526 (± 1147) (p = 0.0019). Potassium and Phos did not change. COV - pts lost no wt. Ferritin was higher in COV+ pts (1526 vs 993, p = 0.026). Mean time to first neg COV test was 26 days (range 13 - 55). Importantly, no MWF pts or any staff became COV + during the 2 months of caring for COV+ TTS pts.

Conclusions: While respiratory symptoms of COV are often stressed we noted few symptoms other than anorexia and substantial wt loss in the 89% of pts that survived COV. This was associated with a significant decrease in albumin and increase in Ferritin consistent with inflammation and malnutrition. On average it took ~ 4 weeks for pts to test negative once infected. With good infection control practice and PPE, nurses and COVID - pts remained free of COVID in our facility.

PUB055

AKI in Hospitalized Patients with COVID-19: A Mexican Population

Victor H. Gomez Johnson,[1] Gina C. Gonzalez-Calderon,[1] Antonio Camiro Zúñiga,[1] José A. García Gordillo,[1] Adolfo Diaz Cabral,[1] Alfredo Fonseca Chávez,[2] Julio C. Arriaga,[1] Jose S. Lopez Gil,[2,1] Javier Zúñiga-Varga,[1] Juan Pablo Herrera Felix.[1] *[1]Centro Medico ABC, Mexico City, Mexico; [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Background: Although severe acute respiratory syndrome coronavirus (SARS-CoV-2) infection is primarily a respiratory disease, other organs are also affected. Several pathological studies confirm that SARS-CoV-2 invades kidney tissue causing endothelial damage, glomerular and vascular changes, extensive acute tubular injury and podocyte viral infection. AKI in COVID-19 appears to be frequent, with an AKI incidence of up to 46%, and a 20% requirement for renal replacement therapy (RRT). Patients with AKI show a trend towards worse outcomes and increased mortality. Information on Latin-American population is scarce.

Methods: We created a cohort to describe the incidence, risk factors, and outcomes associated with AKI in hospitalized patients with COVID-19 in Mexico City, excluding patients with a known chronic kidney disease. AKI was defined and classified according to KDIGO guidelines.

Results: We included 127 patients. 11 patients (8.66%) met the criteria for severe COVID-19, and were more likely to have AKI (81.82% vs. 54.31%, p=0.078). Of the 72 (56.69%) patients that had AKI, 48% were diagnosed at the time of admission. Patients with AKI were more likely to be men (61.7% vs. 42.42%, p=0.043) and older (55.68 years vs. 48.89 years, 0.018). With regards disease severity, 72% of them had a grade 1 AKI. 7 patients (9.72%) had grade 3 AKI, 4 of which needed renal replacement therapy. Overall length of stay was longer in patients with AKI (12 days vs. 7 days, p=0.003). A nonsignificant trend towards stay in critical care units was observed. 3 out of 127 patients died, all 3 had AKI.

Conclusions: Amongst our studied population, AKI was associated with a longer length of stay and with a trend towards a more use of critical care services. The lack of association of AKI with mortality could be due to the low overall in-hospital mortality of COVID-19 patients (2.40%).

PUB056

AKI Lingering in a Patient with Novel Coronavirus

Marc Saad, Brandon Kirshner, Reuben K. Ellis. *Mercer University, Macon, GA.*

Introduction: Renal manifestations of the novel Coronavirus infection has been reported during the actual pandemic. While the renal injury was more pronounced in critically ill patients, the levels of AKI, proteinuria and hematuria predicted the severity of the infection. We are reporting a severe case of AKI and proteinuria with SARS-CoV- 2 infection out of proportion of its clinical manifestation.

Case Description: This is a 55 year old African American male patient with PMH of hypertension, aortic valve replacement on Warfarin anticoagulation and CKDIII-b with baseline eGFR of 50 ml/min/1.73m2 (creatinine of 1.5 mg/dL) and recent diagnosis of COVID-19 related gastroenteritis 10 days prior to presentation, was admitted with general malaise and decreased intake. He had no cardiac nor respiratory symptoms. He was afebrile and physical examination was non remarkable. His labs were significant for BUN level of 129 mg/dL and creatinine of 22.0 mg/dL. His blood glucose was 88 mg/dL. Urinalysis showed glucose 100 mg/dL, 0-3 RBCs, 3-10 WBC with a protein/creatinine ratio of 12.8 g/g. His renal ultrasound showed increased cortical echogenicity with edema. His serological workup was unrevealing with negative hepatitis B and C testing, low ASO levels, negative ANA, Anti-PR3, Anti-MPO and Anti-GBM antibodies. He had normal C3, C4 and negative serum immunofixation with free Kappa/lambda ratio of 1.7. His Alb was 1.7g/dL with triglycerides levels of 184 mg/dL. A kidney biopsy was deferred for its high complication risk. Repeatedly, the patient tested positive for SARS-CoV-2 on reverse transcription polymerase chain reaction assay with a nasopharyngeal swab. During the hospital stay, the patient was non-oliguric and afebrile and was treated with supportive medical care. On day 8 of hospitalization, his labs showed creatinine of 14 mg/dL and BUN of 99 mg/dL with persistent proteinuria estimated at 14 g/g. At present, he continues to asymptomatic and is being monitored outpatient for his kidney recovery.

Discussion: Variable histopathological lesions (FSGS, collapsing glomerulopathy, podocytopathy and tubular interstitial disease) has been described in the renal manifestations of the novel coronavirus. While its physiopathological mechanisms remain unclear, the severity of proteinuria and renal injury observed in this clinically asymptomatic patient highlight an unusual infection-driven mechanism.

PUB057

Patients with COVID-19 and Kidney Disease: Who Fared Best?

Micaela Antonius, David Jackson, Sadananda V. Aithal, Michael T. Shiel, Huw Davies. *Swansea Bay University Health Board, Swansea, United Kingdom.*

Background: COVID-19 poses the greatest global challenge in modern day healthcare. Chronic Kidney Disease (CKD) patients are classed as 'high risk' in terms of the morbidity and mortality associated with COVID-19. We present data from a large centre encompassing a 24-bed inpatient renal ward, 2 in-centre haemodialysis (HD) units and a large ITU. We aim to compare and contrast clinical outcomes for COVID-19 patients with renal disease.

Methods: Observational analysis was performed on 61 patients (mean age 65y), all positive for COVID-19. Patients were stratified according to their renal status at the point of contracting the virus (table 1).

Results: Acute Kidney Injury (AKI) (n=24; mean age 67y) – 23 of 24 patients were intubated and ventilated in ITU. 18 died. 4 remain on haemofiltration (1 patient transferred for Extracorporeal Membrane Oxygenation). Only 1 patient required no ventilatory support and survived with resolution of the AKI. 1 patient requiring invasive ventilation survived with recovery of renal function. **Chronic HD (n=20; mean age 60y)** – 20 prevalent adult HD patients tested positive for COVID-19. 10 recovered and remain on HD. 10 died. **Kidney Transplant Recipients (KTR) (n=4; mean age 59y)** – 3 were managed as outpatients and have recovered with functioning grafts. 1 died. **Peritoneal Dialysis (PD) (n=2; mean age 68y)** – 1 was managed as an outpatient and has made a good respiratory recovery. 1 patient died. **CKD (without renal replacement therapy (RRT)) (n=11; mean age 72y)** - 11 patients with pre-existing CKD (stages 3-5) contracted COVID-19. 5 made a recovery with no progression to RRT. 2 died without RRT. 2 received acute HD and subsequently died. 1 remains on acute HD and 1 has progressed to chronic HD.

Conclusions: AKI patients had the poorest outcomes in terms of need for ventilatory support and mortality. 50% of chronic HD patients with COVID-19 died. Despite immunosuppressants, only 4 KTRs (total cohort of 352) contracted COVID-19. The introduction of virtual transplant clinics, minimisation of face-to-face contact and effective shielding may have influenced this. These data aim to reinforce the international collaborative against this global pandemic.

Table 1: Outcomes for people with kidney disease infected with COVID-19

At time of COVID-19 diagnosis			Outcome (post treatment for COVID-19)										
Status	n	Mean age (years)	CKD without RRT	Functioning transplant	Chronic HD	PD	Acute HD		Filtered (CVVHD/CVVHF)			AKI-not filtered	Died
							Ongoing HD	Died	Recovered function	Died	Ongoing	Recovered function

COVID-19: Angiotensin Receptor Blocker to the Rescue?

Srikanth Thiruvarudsothy,[1] Theesitha Srikanth.[2] *[1]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [2]Sichuan University West China Hospital, Chengdu, China.*

Background: An unusual suspect has been incriminated in the Coronavirus outbreak, Renin-angiotensin-aldosterone system (RAAS). RAAS is an intriguing system that holds many mysteries that are still waiting to be unraveled and explored.

Methods: Angiotensin-II (Ang II) is well known for its proliferative and vasocontrictive effects and we have been using ACE1 inhibitors (ACEI) to prevent Ang II formation and angiotensin receptor blockers (ARB) for inhibition of Ang II receptor binding. Angiotensin 1-7 (Ang 1-7) along with ACE2, in the other hand, proven to have vasodilatory, antiproliferative and overall protective effects. Given the beneficial effects of ACE2 and Ang 1-7, it would make sense to potentiate this pathway for our sake, especially in the setting of lung injury.

Results: In the recent years, it's been shown that Coronavirus is not only using the ACE2 to enter the cell, but also decreasing ACE2 expression at the same time. This is detrimental. ACE2 expression seems to be decreased in elderly and elevated in obese. It is very interesting to see that COVID severity varied among these individuals, likely due to the precarious balance between the amount of viral entry and activity of ACE2/ Ang 1-7. If we can upregulate the expression of ACE2 by some mechanism, this would in turn increase the production of beneficial Ang 1-7. But with upregulated ACE2, one must make sure that there is a competitive substrate for ACE2, in order to make the Coronavirus binding of ACE2 difficult. A suitable candidate for that substrate, is Ang II. ARB, as opposed to ACEI, would seem to increase the levels of Ang II, while upregulating the expression of ACE2. Theoretically, we can reap the benefits of enhanced ACE2 expression while competitively inhibiting Coronavirus binding to ACE2, by the increased levels of Ang II. Titrating up ARB dosing as tolerated by the patient, will be necessary for the above mechanism to work effectively.

Conclusions: Individual variability in expressing ACE2 and Ang 1-7 receptor binding, will determine the degree of benefit of ARBs in diminishing Coronavirus infectivity and severity. Tolerability to ARBs, will also be a limiting factor when treating the patients. Studying ACE2 levels, Ang 1-7/Mas receptor activity in different patient populations and the correlation between Coronavirus infection and severity, would be of great value in the outbreak and provide more insights into the world of RAAS.

PUB059

COVID-19 Financial Ramifications on the Pediatric Nephrology Workforce

Darcy K. Weidemann,[1,2] Allison C. Redpath,[4] Isa Ashoor.[3] *[1]Children's Mercy Hospitals and Clinics, Kansas City, MO; [2]University of Missouri Kansas City, Kansas City, MO; [3]LSU Health New Orleans, New Orleans, LA; [4]University of Wisconsin System, Madison, WI.*

Background: The adverse impact of the COVID-19 pandemic on state and federal budgets, coupled with widespread lockdown measures, and reduced non-COVID-19 clinical volume has forced healthcare and academic organizations to adapt to declining revenues. We examined the financial ramifications of the pandemic on the pediatric nephrology workforce.

Methods: Online survey distributed to active members of the American Society of Pediatric Nephrology (n=897) over 2 weeks in May 2020.

Results: Response rate was 16% (n=144). Most respondents (34%) were 35-44 years old, followed by 45-54 years old (24%). Most were White (65%) followed by Asians (24%). Respondents resided in the South (31%) followed by the Northeast (29%) and Midwest (22%). Most were faculty (92%) in early career stage (Assistant Professor, 31%), affiliated with a free-standing children's hospital (55%) or a children's hospital within an adult hospital (36%), working full time (79%) with an average of 60% effort dedicated to clinical activities. Most acknowledged feeling worried about the long-term financial ramifications of COVID-19 on their employer (88%) and their own financial future (75%). **Figure 1** summarizes the financial repercussions reported. The majority (47%) were unclear whether they will be expected to assume increased clinical duties once stay-at-home orders are lifted, however, 44% reported new childcare or eldercare responsibilities.

Conclusions: Overwhelming concern regarding employee and employer financial security exists among practicing pediatric nephrologists in the context of the COVID-19 pandemic. Uncertainty, institutional hiring freezes, compensation reduction, and increased duties in one's personal life all pose additional threats to a specialty with an already looming workforce shortage. Comprehensive strategies to prevent attrition and burnout are required to sustain the pediatric nephrology workforce during recovery from the COVID-19 pandemic.

Not All Coronvirus a Patients Are Dying from Broncho-Pneumonia: Most Might Be Dying from Cerebro-Neurologic-Vascular Diseases and Cardiovascular Complications

Yahya Sagliker,[1,2] Hasan S. Sagliker,[3,2] Piril Sagliker Ozkaynak,[4,2] Nuray Paylar.[2,5] Sagliker Nephrology and Hypertension Unit *[1]Cukurova Universitesi Tip Fakultesi, Adana, Turkey; [2]Sagliker Nephrology and Hypertension Unit, Adana, Turkey; [3]Ceyhan State Hospital, Ceyhan, Turkey; [4]Karliova State Hospital, Bingol, Turkey; [5]Karaisali Community Health Center, Adana, Turkey*.

Introduction: Acute bronchopneumonia is not sufficient to explain deaths. Lungs, brain-nerves - hearth- cardiovascular system might be playing for key roles. Three are playing togethers. In last days, lungs and brain and heart suddenly are stopping.

Case Description: Key places are neurological conjunction systems between **brain, lungs and cardiological systems. All o**rgans are being regulated by last two systems. All mentioned activities are being regulated in those systems. All decisions and functions of human are giving there

Discussion: A neurologist and a cardiologist must be involved in treatment in late stages. This is vital. 1-Pulmonologists are following lungs. 2-Pulmonary-toracal surgeons shoul think two sided bronchial tubes from outside. 3-Cardiologist must follow EKG continiously. Echocardiography must be performed every day..They must know well inside of hearth and must question which drugs are taking. 4-Neurologists must perform MRG for **brain**, **back lower brain** and should make EEG, every day. AFFECTION-REACTION-EFFECTING-INFORMING BACK rules must be controlled. A Case of Novel Coronavirus Disease 19 in a Chronic Hemodialysis Patient with Severe Cardiovascular Disease

Weichen Zhang,[1] Huaizhou You,[1] Li Yuan,[2] Min Song,[2] Kangjie Wang,[1] Shengqing Li,[3] Yijian Chen,[4] Li Ni.[1] *[1]Department of Nephrology, Huashan Hospital Fudan University, Shanghai, China; [2]Department of Nursing, Huashan Hospital Fudan University, Shanghai, China; [3]Department of Pulmonary and Critical Care Medicine, Huashan Hospital, Fudan University, Shanghai, China; [4]Institute of Antibiotics, Huashan Hospital, Fudan University, Shanghai, China.*

Introduction: Patients on maintenance hemodialysis (MHD) are vulnerable to COVID-19. MHD individuals are usually old with chronic comorbidities while these features are all risk factors of poor prognosis.

Case Description: Our patient was a 79-year-old female with ESRD and had been on MHD for 12 years in Wuhan. She had a history of severe coronary heart disease. The patient firstly reported fever, chest tightness and cough. One week later, she developed diarrhea and the chest CT indicated "viral pneumonia". Her COVID-19 testing was reported positive, and she was admitted to the hospital with SpO2 of 92% and high level of hs-CRP, cardiac troponin I (TNI) and creatine kinase MB isoenzyme. She was prescribed oxygen therapy, methylprednisolone, intravenous immunoglobulin, prophylactic anticoagulation and CRRT therapy. Her respiratory condition improved gradually and COVID-19 testing showed negative. However, on admission day 19, the patient presented psychiatric symptom, and was considered as secondary higher-level cognitive impairment since she received regular CRRT therapy without using drugs which could cause mental disorders. Two days later, her chest X-ray showed lung infection advanced with increased hs-CRP and PCT indicating bacterial infection. We prescribed meropenem and vancomycin. Meanwhile, there was an increasing trend of TNI, and electrocardiogram indicated acute coronary syndrome (ACS). Clopidogrel, aspirin and atorvastatin were prescribed immediately. Unfortunately, on admission day 22, the patient suffered cardiac arrest and was declared dead after active rescue. The cause of death was considered as cardiogenic shock and ACS.

Discussion: To our experience, personalized immunomodulation therapies against "cytokine storm" including steroid, intravenous immunoglobulin and CRRT might play

important role in treating severe COVID-19 patients with MHD. Cardiovascular disease is the leading cause of death in ESRD patients. The cardiovascular events of this patient might be combined with COVID-19 associated heart injury and worsen of pre-existing CHD. We suggested lack of family support during quarantine might be a reason of psychiatric symptom. In conclusion, personalized immunomodulation therapies might be helpful in treating severe COVID-19 patients with MHD. Cardiovascular events were associated with poor outcome.

PUB062

Clinical Presentation of Hemodialysis Patients with COVID-19: A Single-Center Study with 18 Patients

Eliana Dina-Batlle,[1] Hector A. Pantaleon,[1] Mirtha C. Almanzar,[1] Noemí Acevedo Rodríguez.[2] *[1]Hospital Metropolitano de Santiago, Santiago, Dominican Republic; [2]Pontificia Universidad Catolica Madre y Maestra Facultad de Ciencias de la Salud, Santiago De Los Caballeros, Dominican Republic.*

Background: SARS-CoV-2 has affected every nation around the world. The 1st case in the Dominican Republic was reported in early March, with the most affected being the elderly and patients with comorbidities like cardiovascular diseases. Most hemodialysis patients share these comorbidities, in addition to a weaker immune system and health care facility exposure, it is thought to be a vulnerable population. The aim is to describe the clinical manifestation, main laboratory abnormalities, imaging findings at the moment of presentation, and the clinical course of patients on hemodialysis diagnosed with COVID-19

Methods: Exploratory study on 18 dialysis patients with Covid-19 in a renal replacement therapy facility. Demographics, symptoms, laboratories, CTscan, hospital course, ventilation requirement, treatment and complications were described

Results: With a population of 204 patients, 18 were diagnosed with Covid-19 in the first 2 months of the outbreak in our facility. 77.8% were males, mean age was 60 years, and 44% had known contact with infected people outside the facility. All patients had cardiovascular disease and 12 had diabetes. Cough was the most common manifestation 77.8%, dyspnea 66.7%, fever 55.6%, and malaise 44.4%, among others manifestations. Oxygen therapy was required in 66.7%, with 11.1% needing mechanical ventilation. All presented abnormal CTscan findings, 60% with a COVID-RADS grade 3. Three patients were positive and asymptomatic on a round RT-PCR test taken for all facility patients, 2 of them with CTscan graded COVID-RADS 3. Only symptomatic patients were admitted, 3 were directly admitted to the ICU, and 2 were later transferred from inpatient floor to ICU. The mean duration of hospitalization was 11 days and just 1 lethal outcome. At the moment of admission, 22.2% presented negative results on RT-PCR but had clinical and imaging findings consistent with Covid-19, with serologic conversion later

Conclusions: Even with the increased risk of exposure, comorbidities, and a weaker immune system, these didn't necessarily determine a higher probability of infection. We have found a high incidence of respiratory symptoms, in contrast to other case reports. Asymptomatic cases had imaging with COVID-RADS grade 3, this made us consider that the COVID-RADS grade on CT scan its a helpful tool for diagnosis of Covid-19

PUB063

Pink Urine in a Patient with COVID-19

Mengqing Ma. *Sir Run Run Hospital, Nanjing Medical University, Nanjing, China.*

Introduction: Pink urine syndrome has been reported as a rare symptom described after surgery and propofol anesthesia. COVID-19 is not only manifested as a respiratory disease characterized by viral pneumonia, but also damage such as kidney, heart, blood and nervous system especially in severely ill patients.

Case Description: A 56-year-old man was diagnosed as severe COVID-19. He was admitted to ICU and underwent the tracheal intubation. During this treatment, propofol was used to sedate. He suddenly excreted cloudy pink urine on that day (Figure 1). There were some pink crystals in the urine bag and pink sediment at the bottom of the urine bag (Figure 2, Figure 3). His urine dipstick showed a specific gravity of 1.02, pH 5.5, blood (1+) and protein (1+). He had no urinary tract symptoms and his urine cultures were normal. His blood gas analysis showed pH was 7.3. His colour of urine gradually returned to normal when the patient was given intravenous Sodium bicarbonate injection.

Discussion: Pink urine syndrome is a phenomenon in which uric acid precipitates into the urine due to reduced urinary pH. Propofol can increase the excretion of uric acid in the urine. Lower urine pH will reduce the solubility of uric acid, promoting the formation of amorphous uric acid crystals, which exhibit a characteristic pink color. At the same time, metabolic acidosis may aggravate this phenomenon. COVID-19 has been reported to invade cells mainly through ACE2 receptors. ACE2 receptor is strongly expressed in the proximal tubule of the kidney, causing acute tubular necrosis. It has suggested that the kidney is one of the main targets of COVID-19. While considering the pink urine syndrome might caused by propofol, we speculate that COVID-19 could damage the renal tubule which affect its reabsorption of uric acid, which may worsen the uric acid crystallinity.

Pink urine deposits observed.

PUB064

Telemedicine in the Care of Kidney Transplant Recipients with COVID-19

Fawaz Al Ammary, Mohammad Abuzeineh, Abimereki Muzaale, Deidra C. Crews, Robin K. Avery, Daniel C. Brennan, Dorry L. Segev. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Introduction: Kidney transplant (KT) recipients with COVID-19 symptoms are bringing challenges to providers given the risk of COVID-19 exposure to health care workers, patients, and the public.

Case Description: Three KT recipients with COVID-19 were managed using telemedicine via synchronous video visits integrated with an electronic medical records system, from home to inpatient settings (Figure 1-2). Patient 1 is a 53-year-old male s/p KT in 2012; Patient 2 is a 56-year-old female s/p KT in 2019; and Patient 3 is a 53-year-old female s/p simultaneous liver-kidney transplant in 2014. Patients 1 and 3 had follow-up COVID-19 NAT testing: Patient 1 converted to be negative at 24 & 28 days, whereas Patient 2 converted to be negative at 45 & 48 days.

Discussion: Telemedicine helped assess, diagnose, triage, and treat patients with COVID-19 while avoiding an ER or outpatient clinic visit. We highlight the value of telemedicine in the maintenance of uninterrupted follow-up care for immunosupressed patients with prolong viral shedding.

	Patient 1			Patient 2			Reference range(unit)

Urinary Abnormalities and Urinary Sediment Findings in COVID-19 Patients

Alejandro Garcia Rivera, Luz Y. Villegas, Ríos C. Katia yuritzi, Arantxa K. Aguilar, Marcos Adrian E. Lopez, Jesús A. Rico sánchez, Carlos A. Villavicencio López, Ernesto Ojeda, Luis A. Salazar Soltero, Rafael A. Ayala cortés, Carolina R. Alvarez, Jesús A. Vega López de Nava, Nidia Rodriguez Plascencia, Renato Parra Michel. *Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Hospital General Regional No.46, Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Background: Coronavirus disease 2019 (COVID-19) is a new disease of pandemic proportions. There are only a few reports about urinary abnormalities in this disease, and to our knowledge there are no reports about the usefulness of urinary sediment on prognosis. Our aim was to describe the urinary abnormalities in COVID-19 and to assess the utility of urinary sediment on prognosis in COVID-19.

Methods: Prospective, single-center study, in patients diagnosed with COVID-19 (with a positive RT-PCR test), who were admitted in our hospital, from April 2020 to date, and whose urine sample could be obtained at admission to the isolation wing.

Results: 22 patients were included; 17 (77.3%) had proteinuria, 12 (54.5%) had microscopic hematuria, and 9 (40.9%) had leukocyturia. Granular casts (with a Chawla cast scoring index greater than 3) were present in 8 (36.4%) patients. Of the 8 patients with granular cast, 6 developed an AKI (75%), 2 required Hemodialysis (25%) and 3 died (37.5%). Of the 14 patients whose urinary sediment was classified as bland, 5 developed an AKI (35.7%), none of them required hemodialysis, and 2 subsequently died (14.2%). There was a statistically significant difference between a bland urinary sediment and a sediment showing granular casts for the need of hemodialysis or death (p=0.02), with a positive LR of 3.5.

Conclusions: The urinary sediment is a cheap, available tool for the prognosis of need for hemodialysis or death in patients diagnosed with COVID-19, and should be taken into consideration in the assessment of these patients by the Nephrology department.

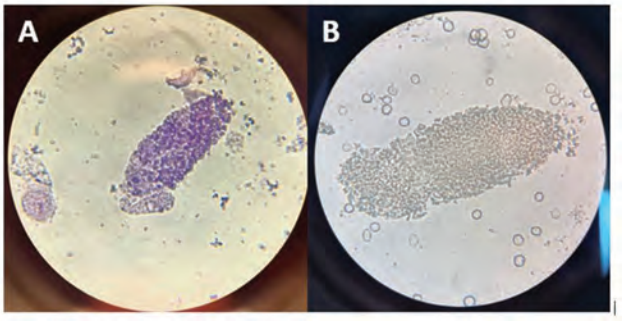

Figure 1. Urinary sediment slides showing: A) a granular cast with a renal tubular cell within; B) a granular cast with several isomorphic erythrocytes.

Repurposing Baby Monitors in COVID-19

Sobia N. Khan, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

Introduction: As of May 2, total of 1,130,075 confirmed cases resulting in 65,605 deaths were reported in US. Nearly 3.2% of individuals with COVID-19 develop AKI and have been reported to require dialysis. Initial reports from Wuhan, the burden of acute kidney injury was relatively low, about 3% -9%, subsequent analysis have demonstrated increase in the incidence to 15%

Case Description: In February, 376 hemodialysis and 59 CRRT while in March, 273 hemodialysis and 30 CRRT offered in our hospital. During pandemic bed capacity doubled from 650 to 1317 beds. Physical space gained by converting ambulatory surgical center and ambulatory locations. In April, observed 1,811 COVID-19 patients admitted to the hospital with 50 chronic hemodialysis patients, 30 were COVID positive. 334 hemodialysis treatments while 136 continuous renal replacement therapy offered 12.8% therapy given in February increase surgency of 27.9% in April for CRRT whereas the number of hemodialysis treatments offered stayed stable at average of 355 hemodialysis treatment.

Discussion: To minimize the risk of exposure in COVID-19 isolation rooms we implemented telemonitoring strategy. We identified baby monitors could serve "read-to-go" telemonitoring. VTech Baby Monitor 7" display. HD camera uses WiFi connection to capture movements and sounds which helps in monitoring the patients in real-time. The camera ability to pan 360 degrees, tilts 82-degrees and zooms ten times to enable viewing of the dialysis monitor and patient. Two-way voice communication allows easy communication between patient and nursing. Before hemodialysis nurse sets up camera by the patient's bedside (1 camera facing the dialysis monitor other camera facing patient and the dialysis access). Dialysis nurse visualize through the handheld monitor. Telemonitoring system COVID19 patients undergoing hemodialysis we observed zero positive COVID-19 dialysis staff

PUB067

Impact of Ethnicity on COVID-19 Infection and Mortality Amongst In-Centre Haemodialysis Patients

Gregor D. Young, Noam Roth, Kieran Mccafferty, Suzanne H. Forbes, Andrea Cove-smith. *Royal London Hospital, London, United Kingdom.*

Background: It is reported that patients of BAME origin are at greater risk of infection and death due to COVID-19. We describe outcomes in an inner city, ethnically diverse in-centre haemodialysis (HD) population during the pandemic.

Methods: A total of 1253 patient electronic records were analysed retrospectively. 207 infections were recorded -197 patients tested positive for Sars-Cov-2 on validated nasopharyngeal PCR analysis and 10 patients included due to high clinical suspicion. Ethnicity data is self-reported. All COVID-19 positive patients were isolated for subsequent dialysis sessions. Whole-cohort screening confirmed the rates of infection.

Results: Overall rate of infection amongst the group was 16.5% (n=207), hospitalisation 7.5% (n=94) and death 3.5% (n=44). Within COVID-19 infections, hospitalization rate was 45% and mortality 21%. Seven patients received critical care and two were intubated. Ethnicity data are shown in table 1: There was no significant difference in rates of COVID infection between ethnic groups. The risk of infection in BAME patients was not significantly greater than in white patients (p=0.24, OR 0.79, 95%CI 0.55-1.14). The mean age of those who died from COVID did not differ from the entire cohort (62 vs 63.2 years). Males made up the majority of both the baseline cohort (61.2%) and those infected with COVID (58.5%). 71% of those who died were male. Body mass index did not differ between the group as a whole and those infected with COVID. Rates of diabetes mellitus did not differ significantly between those infected with COVID and those who died.

Conclusions: We have defined COVID infections and outcomes within a real-life, large haemodialysis population. Hospitalisation and mortality rates were high, and patients self-reporting as black or Asian were over-represented in the infected group compared to the baseline prevalent HD population. Higher rates of death were observed in black and asian groups but conclusions are limited by small numbers. Larger collaborative studies are required to expand on these findings.

Ethnic breakdown of HD cohort and COVID cases

Ethnicity	Baseline HD Cohort (% of total population (n))	COVID Cases (% of cases (n))	COVID Deaths (% of deaths (n))
Black	23.9 (300)	28.5 (59)	31 (13)
Asian	27.5 (345)	31.9 (66)	35.7 (15)
White	23.9 (300)	23.2 (48)	23.8 (10)
Other	24.6 (308)	16.4 (34)	9.5 (4)

PUB068

COVID-19 Management in New York City Kidney Transplant Recipients: Before and After the Apex

Michelle L. Lubetzky, Rebecca Craig-Schapiro, Meredith J. Aull, Thalia Salinas, John R. Lee, Samuel Sultan, Jun B. Lee, Choli Hartono, Sandip Kapur, Thangamani Muthukumar, Manikkam Suthanthiran, Darshana M. Dadhania. *Weill Cornell Medicine, New York, NY.*

Background: Kidney graft recipients receiving immunosuppressive therapy may be at heightened risk for Covid-19 and adverse outcomes. We aimed to study how practice patterns and outcomes changed before and after the peak incidence of cases in New York City.

Methods: We reviewed 68 consecutive adult kidney graft recipients from our center diagnosed with SARS-CoV-2 from March 13, 2020 to May 25, 2020. We compared outcomes of those treated from March 13 until the apex of infections on April 14 (Phase 1), and those treated from April 15th to May 25, 2020 (Phase 2).

Results: Characteristics of both Phase 1 and Phase 2 patients are described in Table 1. Inflammatory markers were lower in the second phase as was patient mortality. Changes in management strategies between the two phases are highlighted in Figure 2. Graft loss occurred in 4 patients (6%) and there were 5 deaths (7%).

Conclusions: Data from our study suggest that management strategies of immunosuppressed patients changed over the course of the Covid-19 Pandemic in New York City, including less use of hydroxychloroquine, and increased use of novel agents such as remdesivir. Additional data are needed to better understand if the decrease in patient mortality during the second phase is attributable to better management or lower inflammatory response in the setting of Covid-19 illness.

Effect of COVID-19 Infection in Three Patients Treated with Rituximab

Anushya Jeyabalan, Reza Zonozi, Jillian Rosenthal, Karen A. Laliberte, John Niles. *Massachusetts General Hospital, Boston, MA.*

Background: Rituximab (RTX), a monoclonal antibody against the CD20 antigen found on B lymphocytes, is widely used for glomerular diseases. It may be advantageous in COVID19 given the exaggerated immune response and cytokine storm elicited by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) or could be detrimental given the impaired response to infections in immunocompromised patients.

Methods: We examined the clinical presentation and outcomes of 3 patients undergoing treatment with RTX who were infected with SARS-CoV-2.

Results: 2/3 patients had complication of severe hypoxemia with evidence of pulmonary infiltrates on imaging. Both had underlying ANCA vasculitis with a history of pulmonary involvement. Both were treated with remdesivir and one received convalescent plasma. The patient who received convalescent plasma was SARS-CoV-2 RNA negative at 3 weeks. The patient who received remdesivir but not plasma remained positive for SARS-CoV-2 RNA at 7 weeks and was negative for IgM and IgG antibodies at 4 weeks. The third patient recovered without hospitalization and had a first negative RNA test at 3 weeks and was positive for IgG antibodies when tested at 7 weeks despite a confirmed zero B cells by flow cytometry.

Conclusions: 3 out of 3 patients who developed SARS-CoV-2 infections while on RTX recovered. A larger review of individuals on RTX therapy infected with SARS-CoV-2 should be examined to study the association between B cell depletion and COVID19.

Patient Characteristics and Outcomes

AKI Following Hemolysis Related to Hydroxychloroquine Treatment for COVID-19 in a G6PD-Deficient Patient

Prochore N. Kamgang Semeu, Evelyne K. Maillart, Agnieszka Pozdzik, David De Bels, Philippe K. Clevenbergh. *UVC Brugmann, Brussels, Belgium.*

Introduction: COVID-19 is associated with significant morbidity and mortality. As a potential treatment, Hydroxychloroquine (HCQ) is actually widely used. Concern has arisen about side effects of HCQ. Here, we describe severe AKI following HCQ administration for COVID-19.

Case Description: A 65-year-old patient has been admitted for fatigue. His treatment was gliclazide, lercanidipine for T2DM and arterial hypertension. Initial evaluation revealed: SpO2 91%. Blood tests are detailed in the table1. COVID-19 pneumonia was diagnosed. HCQ and azithromycin were given, including a loading dose of HCQ. Patient developed severe acute hemolytic anemia (AHA) and AKI (table1, Day7). Blood tests were consistent with acute hemolytic anemia (AHA). Glucose-6-phosphate dehydrogenase (G6PD) activity showed <0.2IU/g hgb (7.0-17.0) consistent with AHA triggered by HCQ in a G6PD deficient patient, and further complicated with AKI. Given the ongoing oliguria, hemodialysis was commenced. 23 days later, recovery of kidney function allowed him to stop dialysis. There remains a slight impairment of kidney function tests (table1, Day72).

Discussion: The residual enzyme activity of G6PD deficiency determines the severity of clinical manifestations which are usually triggered either by fava bean ingestion or drugs, and are dose-dependent. This patient had a severe deficiency and he received a loading dose of an at-risk drug. Both induced hemolysis crisis. AKI is a rare complication of AHA related to G6PD deficiency. The need for renal replacement therapy seems exceptional. Renal recovery could be incomplete. Severe G6PD deficiency can manifest late in life. HCQ should be used with caution given potential severe side effects. We then recommend early monitoring of hemolysis parameters.

	Day1	Day7	Day 72	Units
Hemoglobin	15,1	6,7	12,7	g/dl
Platelets	160	388	259	x10³ G/L
White Blood Cells	4,09	12,96	4,8	x10³ G/L
CRP	78,3	380	1,6	mg/L
Na	134	135	140	mmol/L
K	4,1	4,7	3,9	mmol/L
Cl	95	98	105	mmol/L
HCO3	26	22	25	mmol/L
Creatinine	0,83	4,75	1,03	mg/dl
LDH (<210)	274	1956	235	U/L
Bilirubin (6.8-17.1)	6,8	83.8	6,8	µmol/L
Haptoglobin (30-200)	-	<10	88	mg/dL

Table 1: Selected blood tests

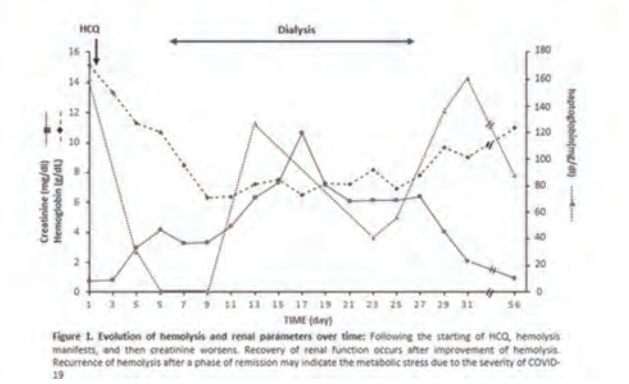

Figure 1. Evolution of hemolysis and renal parameters over time: Following the starting of HCQ, hemolysis manifests, and then creatinine worsens. Recovery of renal function occurs after improvement of hemolysis. Recurrence of hemolysis after a phase of remission may indicate the metabolic stress due to the severity of COVID-19

PUB071

Pragmatic Approach Toward Nephrology Practice in the COVID-19 Era: Shared Learnings and Experiences Toward Consensus Through a Virtual Educational Platform Involving 404 Nephrologists

Dinesh Khullar,[1] Madan Bahadur,[2] Krishnaswamy Sampathkumar,[3] Raja Ramachandran.[4] PIVOT *[1]Max Hospital, Delhi, India; [2]Jaslok Hospital and Research Centre, Mumbai, India; [3]Meenakshi Mission Hospital, Madurai, India; [4]PGIMER, Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

Background: COVID19 rapidly spread globally, imposing the need for change in nephrology practices guided by the recommendations, issued by scientific associations

Methods: We conducted a nationwide virtual educational initiative with an inbuilt technological platform to enable live sharing of experiences of new modes for nephrology practice during COVID 19 pandemic, based on the adoption of current recommendations and evidences to enable indigenous, adaptive experiences of 404 nephrologists with approximately 8,000-man hours of cumulative clinical experience. The four zones across the country were represented by an individual educational task force member

Results: There was a uniform consensus that suspected patients need to be treated similar to a COVID 19 positive patient, with dialysis facility provided in isolation area, to mitigate direct risk to both healthcare providers and patients and indirect risk of contamination of the hospital system. Multiple screening procedures and prohibition of eatables in dialysis area is the new mandate. Role and importance of CRRT, PIRRT and peritoneal dialysis was highlighted. Femoral catheterization is the preferred route. The experience of Tenckhoff catheter technique in peritoneal dialysis in 38 patients was discussed. Higher dose of anticoagulants is being utilised for extracorporeal procedures to reduce risk of enhanced risk of thrombus formation in COVID 19. The varied, emerging clinical presentation, including asymptomatic cases has made COVID 19 testing compulsory at most of the institutions. The nephrologists were informed about the emerging evidence for the need to continue the ongoing ARBs or ACE inhibitors. Renal transplantation with careful precautionary practice is being performed with modulation of dose of immunosuppressive agents in COVID 19 positive patients

Conclusions: Safe and efficient delivery of nephrology care practices needs a uniform acceptance. Even minor liberties and deviations from established safe practice protocols could compromise the safety of the health care workers

PUB072

COVID-19 in Kidney Transplant Recipients

Rachana Marathi, Paul W. Davis, Franco H. Cabeza Rivera, Wisit Cheungpasitporn, Swetha Rani Kanduri, Karthik Kovvuru, Pradeep Vaitla. *University of Mississippi Medical Center, Jackson, MS.*

Background: Coronavirus disease 2019 (COVID-19) is caused by Severe acute respiratory syndrome corona virus 2 (SARS-CoV-2). Kidney transplant recipients are at a higher risk for complications due to comorbid conditions and concurrent immunosuppression. We like to describe a small cohort of kidney transplant recipients with COVID-19

Methods: A single-center, retrospective observational cohort study describing short term outcomes of COVID-19 infection in kidney transplant recipients.

Results: A total of 8 kidney transplant recipients were diagnosed with COVID-19 with a mean age of 58 yrs (26-78), predominantly African American (7/8), mean duration

from transplant 3.5 yrs (1.5-11 yrs). All patients have HTN (8/8), half the patients have Diabetes mellitus-2 (4/8). Common presenting symptoms are fever and shortness of breath. 6/8 patients required hospitalization. 8/8 patients were managed with a reduction of immunosuppression, primarily by decreasing the dose or holding the anti-proliferative agent. 1/8 patients died, 4/6 discharged from hospital, 1/6 still admitted to the hospital with respiratory failure. 5/6 patients required supplemental oxygen. 2/6 patients required ICU stay and 1/6 required mechanical ventilation and renal replacement therapy. 3/6 hospitalized patients received hydroxychloroquine/ Azithromycin combination and 1/6 received Remdesivir. Median hospital stay is 5 days with a mean of 9 days. The patient who required mechanical ventilation and renal replacement is the only recipient who died from COVID-19 at our transplant center.

Conclusions: COVID-19 is a novel infection primarily presenting with fever and shortness of breath. The course of illness appears to be severe with the majority of patients requiring supplemental oxygen and a third of hospital admitted patients required ICU stay. Reduction of immunosuppression appears to be helpful, however, no control group available. COVID-19 affected population is predominantly African American (7/8) and older recipients with age > 50 yrs (7/8).

Cases of COVID-19 Reported in a Predominantly White Rural Hemodialysis Cohort

Ravi K. Thimmisetty. *Nephrology Associates, Cape Girardeau, MO.*

Background: COVID-19 is a novel coronavirus disease causes by the severe acute respiratory syndrome coronavirus 2. Because of its high infectivity rate, WHO described the disease as a Pandemic on March 11th 2020. Severe infections were reported in adults with underlying comorbid conditions, therefore hemodialysis patients are not an exception. We are reporting COVID-19 cases in a rural hemodialysis center predominantly Caucasian patients

Methods: We reviewed the cases of confirmed and suspected COVID-19 infections in our dialysis center. Precautions were taken promptly after COVID-19 infection become Pandemic. All patients were taken temperature check at the entrance door, surgical face mask was provided, sanitizers were provided, and social distance was followed. All physicians and dialysis staff followed the same guidelines. All suspected and confirmed cases should get two negative SARS CoV-2 PCR tests for acceptance at our dialysis center.

Results: Out of 71 dialysis patients, men and women were 56% and 43%. 73.2% of them were Caucasians and 23.9% were African Americans. There were one confirmed COVID-19 disease who was hospitalized for about a month. She acquired from a community spread. She improved and resumed schedule after two negative SARS CoV-2 PCR results. Four people were sent to hospital for having cough, fever, dyspnea, all of them were negative for COVID 19 infection. In our dialysis unit, 55.7% of patients have diabetes, 83% have hypertension, 47.8% of them have both diabetes and hypertension. Patient with confirmed COVID-19 fall into age group of 65-79 yrs. 35.2% of the patients fall into this category. Octogenarians constitute 15.4%. 29.5% of patients were of 50-64 yrs. 19.7% of the patients were less than 50 yrs. of age. There is only one patient got infected with COVID-19, representing around 0.01% of our dialysis population which is very low. There were no deaths from COVID-19. None of octogenarians and African American patients were infected in our dialysis center

Conclusions: Immune status is impaired in dialysis patients and may explain to some extent how body response to COVID-19 infection. And because of same reason, even antibody testing may also not helpful in dialysis patients. It is early to come to conclusion, need further observations from large scale studies once we have full spectrum of pathophysiology and management of COVID-19 disease in hemodialysis patients.

PUB074

Severe AKI in COVID-19: Not Irrecoverable

Latoya N. Gayle, Gene C. Otuonye, Nia Flemming, Deborah A. Fein. *Englewood Hospital and Medical Center, Englewood, NJ.*

Introduction: COVID-19 infection has varied presentations inclusive of pneumonia(PNA), gastroenteritis(GE) & AKI. Prompt identification with aggressive therapy is needed to reduce morbidity & mortality. This is a case of COVID-19 infection with septic shock & severe AKI, successfully treated.

Case Description: 65-year-old female presented with 7-days of vomiting, diarrhea, fever, dry cough, fatigue & confusion. Multiple household members recently positive for SARS CoV-19. She had a history of HTN & CKD3a. Baseline creatinine(Cr) 3 months ago was 1.2. On exam, BP 86/48,T95F,RR 27. She had dry mucous membranes, bilateral coarse breath sounds & rales on auscultation, confusion & flapping wrist tremor. Labs showed Cr of 21.5,BUN 162, CO2 9,D-dimer >20,CRP 55.ABG on 3L nasal cannula showed PH 7.21,PO2 104,PCO2 30.CXR noted right upper lobe infiltrate. CT head & EEG were unremarkable. SARS-CoV-2 PCR was positive. She was taken to ICU for septic shock from COVID-19 PNA & GE with severe AKI. She required phenylephrine for pressor support. She received IV D5 ½ NS with bicarbonate, doxycycline, ceftriaxone & vancomycin. Dialysis was considered but renal function rapidly improved:within 24 hours phenylephrine was weaned off & Cr decreased to 12. She recieved Enoxaparin due to high D-dimer & low PO2. In 5 days she had complete return of mentation, improved ventilation & resolution of asterixis. On discharge day 10,Cr was 1.0,BUN 17,D-dimer 8.5 & CRP 24. She was discharged on Apixaban.

Discussion: The Covid-19 global pandemic has resulted in significant mortality. Prompt identification & aggressive treatment of the critically ill is paramount to prevent multi-organ failure. AKI occurs in up to 23% of patients & confers increased mortality especially when associated with septic shock. In our patient, with severe AKI, uremia with encephalopathy she had marked improvement & resolution with supportive therapy. Renal recovery with this degree of impairment is unusual as a majority of patients with similar characteristics have poor outcomes. This recovery may be attributed to aggressive fluid resuscitation, correction of metabolic acidosis & early initiation of anticoagulation. It is well known that AKI in critically ill Covid-19 patients is associated with high mortality. This case shows that renal & overall clinical recovery is still possible. More research is needed to identify predictors of prompt recovery.

PUB075

A COVID-19 Patient with AKI

Jinhua Zhao.[1,2] *[1]Louis Stokes VA Medical Center, Cleveland, OH; [2]Case Western Reserve University School of Medicine, Cleveland, OH.*

Introduction: Patients with COVID-19 typically present with respiratory illness. AKI is a common complication of COVID-19. Although the etiology of AKI remains unclear, it is thought to be secondary to hemodynamic changes, cytokine release and/or direct viral (SARS-CoV-2) cytotoxicity. The following case describes a patient who presented only with GI symptoms, which led to the diagnosis of COVID-19 and AKI.

Case Description: 71 year-old white male, a nursing home resident, has DM2, HTN, CKD stage 3 and dementia/cognitive impairment. His baseline serum Cr was 1.49 in 2019. He was brought to our hospital for a new diagnosis of AKI and COVID-19. Three days ago, he started to have nausea/vomiting, and was treated with Zofran. No improvement the next day. Bp 96/63, P 107, Temp 97.7. COVID-19 test was positive. On the following day he was brought to a local ER after 3 large projectile emesis. Labs revealed BUN/Cr 80/9.4. He was given1 liter IVF and was transferred to our hospital. He had watery brown-greenish stools, although he denies diarrhea or abdominal pain. Meds included Insulin, statins, heparin, SSRI, and donepezil. At our ER, the patient was awake, alert, orietented to self and year. T 98.3, BP 119/71, P 119, RR 18, SpO2: 95% on RA. PE was unremarkable. Blader scan: 150 ml. Lab: WBC 10.9, Hb 13.3, Plt 207. Na 130, K 4.0, Cl 97, bicarb 17, BUN 85, Cr 8.6, Ca 7.3, Phos 6.6, Alb 3.2. LFT was normal. FeNa = 1.5%. UA: pH 5, prot 1+, Glu 50, RBC 5, WBC 4, with amorphous sediments. CXR: lungs were clear. Renal ultrasound: kidneys with normal size and echogenicity. No obstruction. Patient was admitted to the COVID ward. Patient's nausea and vomiting stopped upon his admission, although his watery stools lingered. He was treated with iv fluid to optimize his hemodynamics. Over the next 5 days patient's serum Cr decreased to 2.0mg/dL.

Discussion: Since the COVID-19 pandemic, GI symptoms and AKI are often regarded as complications of the overall respiratory illnesses. Patients with only GI symptoms were often not suspected for COVID-19. The causes of this patient's AKI include hemodynamically mediated +/- ATN +/- possible cytokine release. Regarding direct viral cytotoxicity, postmortem data has shown the presence of coronavirus-like particles in podocytes and tubule cells. While the direct viral effect to the kidneys is still not understood, treatment with conventional approaches may significantly improve renal outcome.

PUB076

De-Differentiation of Human Urine-Derived Stem Cells to SIX2+/ CITED1+ Cells by 3D Tubuloid Culture

Julie Bejoy, Richard C. Welch, Lauren E. Woodard. Woodard Lab *Vanderbilt University Medical Center, Nashville, TN.*

Background: In contrast to pluripotent stem cell-derived organoids which take nearly one month to derive for kidney, adult stem cell (ASC) derived organoids can be derived within 7 days of culture without needing tedious direction through embryonic development. Protocols have been generated to derive organoids or spheroids of intestine, liver, prostate, pancreas, stomach, salivary gland, breast, colon and taste buds from ASCs. These 3D cultures have been used for disease modeling and personalized medicine approaches. Recent work from the Hans Clevers lab showed that cells derived from the urine of a patient with cystic fibrosis could be made into kidney epithelial tubular organoid structures termed "tubuloids."

Methods: These tubuloids cultures developed quickly and exhibited many of the hallmark features of an intact tubular epithelium. The tubuloid culture media includes Wnt signaling enhancers, EMT inhibitors, and fibroblast growth factors which are all reported to be essential for kidney development. We applied this tubuloid 3D culture protocol [MOU1] to our cultures of human urine-derived stem cells (USCs). USCs are hypothesized to be the pariental epithelial cells lining the glomerulus that are shed into the urine. The USCs from healthy adult donors were grown on 96 well U-bottom suspension culture plates in tubuloid media for 10 days. The 3D tubuloid-like structures harvested at Day 10 were stained for both early nephron progenitor markers and tubular precursor markers.

Results: Tubuloid-like spheres derived from USCs expressed both nephron progenitor markers SIX2 and CITED1 as well as tubular cell precursors PAX2 and PAX8.

In contrast, the starting USCs lack PAX2, SIX2 and CITED1. [MOU1] We will next quantify the expression of these and other nephron progenitor markers over the time course of 3D culture.

Conclusions: Our results suggest a new method to derive patient-matched SIX2+/CITED1+ cells from non-invasive urine samples.

Comparative Evaluation of Orthostatic Hypotension in Patients with Diabetic Nephropathy

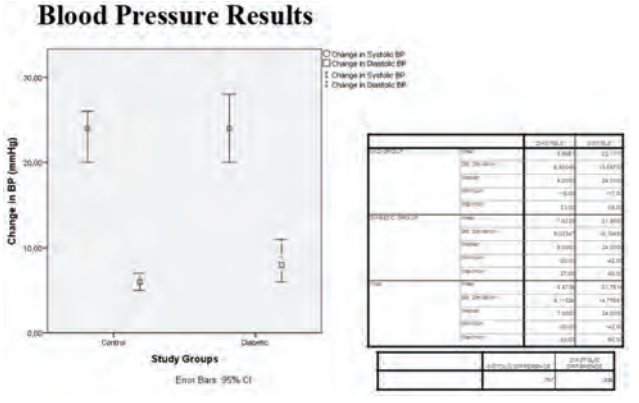
Gamze Aytas, Rumeyza Kazancioglu, Omer C. Elcioglu, Meltem Gursu, Serra Artan, Aysegul Yabaci. *Bezmialem Vakif Universitesi Tip Fakultesi, Istanbul, Turkey*.

Background: Orthostatic Hypotension (OH) affects 5-20% of population. Our study investigates the presence of OH in diabetic nephropathy patients (DNP) and the factors affecting OH in comparison with other chronic kidney disease patients (CKDP).

Methods: Patients presented to the nephrology clinic and consented were included in the study. DNP were defined by renal biopsy and/or clinical criteria. CKDP of same sex, age and eGFR were matched to DNP. Demographic parameters and medications were obtained from the records. OH was determined by mayo clinic criteria. Same researcher used the electronic device to measure the blood pressures (BP). All samples were taken and analyzed the same day for biochemical and hematologic parameters and albuminuria. Statistical analyzes were performed with IBM SPSS22.0 program.

Results: 112(51F,61M, mean age:62,56±9,35 years) DNP and 94(40F,54M, mean age:62,23±10,08 years) CKDP were included. 70.5% DNP vs 61.7% CKDP had OH (p=0,181). The mean change in systolic BP in DNP was 21,50+16,10mmHg and it was 7,63+9,03mmHg in diastolic BP. In CKDP mean change in systolic BP was 22,1+13,09mmHg and it was 5,96+6,80mmHg in diastolic BP. There was no difference between the groups in systolic BP (p=0.797), but it was present for diastolic BP (p=0.025). 60.0%F and 74.7%M patients had OH (p=0.026). Uric acid levels were 7.18mg/dl in OH patients and 6.36mg/dl in nonOH (p=0,017). Blood albumin level was not different in two groups (p=0,902). 73.7% of patients on calcium channel blockers developed OH (p=0,015) and OH developed in 80.6% of 36 patients on alpha blockers (p=0,049).

Conclusions: Our study demonstrated OH is frequent among DNP and there was no difference compared to CKDP. It is important to check OH in all CKDP as it is more common than thought.



PUB078

Clinical Practice Gap Analysis of CKD in Type 2 Diabetes from Identification to Diagnosis to Management

Amy Larkin,[1] Kelly L. Hanley,[1] George L. Bakris.[2] *[1]Medscape LLC, New York, NY; [2]UChicago Medicine, Chicago, IL*.

Background: Understanding clinical practice gaps in the identification, diagnosis and management of CKD in patients with T2D can inform development of tools to improve physician practices.

Methods: A survey instrument of 25 multiple choice, knowledge- and case-based questions allowed participants to assess their knowledge, attitudes, and confidence with regard to CKD in T2D. The survey was available online to physicians across the globe without monetary compensation or charge. Respondent confidentiality was maintained and responses were de-identified and aggregated prior to analyses. Initial data collection occurred from February 26, 2020, to April 20, 2020.

Results: To date, 193 nephrologists completed the full assessment. Physicians demonstrated gaps in the following areas. When asked how satisfied nephrologists were with current treatment approaches for managing CKD in patients with T2D, 10% selected very satisfied, 74% selected moderately-mostly satisfied, and 16% slightly-not satisfied.

Topic	Incorrect Responses to Knowledge and Clinical Decision-Making Questions (%)
Assessment to diagnose kidney disease stage	38%
Evidence-based strategies to delay progression of CKD in patients with diabetes	73%
SGLT2 inhibitors CVOT data comparisons	89%
Results from CREDENCE trial	36%
Mechanism of cardiorenal syndrome	87%
Link between diabetes, kidney disease, and the cardiorenal syndrome	48%
Fibrosis as a component of progression of CKD	66%
Knowledge of billing procedure for CKD screening	65%
Comparison of safety profiles for approved MRAs	49%
Differences in emerging MRAs compared to traditional MRAs	62%
Clinical trial data for emerging MRA	35%

Conclusions: This educational research on assessment of physicians' clinical practices yielded important insights into clinical gaps related to identification, screening, diagnosis, and management of CKD in patients with T2D. Further studies are planned to assess the effect of medical education on decreasing these clinical practice gaps.

PUB079

Practice Patterns of SGLT2 Inhibitor and GLP-1 Agonist Treatment in Eligible Type 2 Diabetic Patients Before and After the Publication of the 2018 ADA/EASD Position Statement

Bijin Thajudeen, Wei Xiang Wong, Saeed Bidar, Sevag C. Boyadjian, Wina Yousman, Amy N. Sussman, Frank C. Brosius. *Banner University Medical Center Tuscon, Tucson, AZ*.

Background: The ADA/ EASD published a position statement in October, 2018 on the prevention of atherosclerotic CVD events in diabetic patients focusing on the use of SGLT2 inhibitors (SGLT1I) and GLP-1 agonists(GLP1A). The objective of this study is to determine the practice patterns of endocrinologists and nephrologists in implementing current societal recommendations for use of SGLT2I and GLP1A.

Methods: This study had two phases, a retrospective phase and prospective phase to determine use of SGLT2I/GLP1A before and after the publication of ADA/EASD position statement. All subjects with type 2 diabetes and CVD/CKD who were at least 18 years of age and who were followed at the endocrinology and/or nephrology clinics were included in the study. Eligible patients had a minimum of two clinic visits in either endocrinology and/or nephrology clinics during either the retrospective phase (October 2017- September 2018) or prospective phase (October 2018 – September, 2019). Information collected included utilization of SGLT2I/GLP1A, HbA1c, eGFR, new CVD events and adverse effects of SGLT2I/GLP1A therapy. Primary outcomes measured was the change in percentage of eligible patients treated with an SGLT2I/GLP1A.

Results: A total of 113 charts were reviewed. Only 18 patients(15.9 %) were on either SGLT2I/GLP1A at the end of retrospective phase. By the end of prospective phase, 25 patients (22.1%) were on one of these agents. Out of 28 patients with Hba1c more than 8 at the end of restrospective phase, percentage of patients on SGLT2I/GLP1A at the end of prospective phase remained the same. Utilization of SGLT2I/GLP1A ranged 11% to 28.9%. There was no statistically significant difference between the groups treated with SGLT2I/GLP1A compared to group not treated with these agents in terms of HbA1c (P value 0.94) or eGFR (P value 0.35).

Conclusions: Despite the new recommendations, a substantial number of patients are not on SGLT2I/GLP1A even if the diabetes is not controlled adequately. However this lack of adherence to protocol doesn't seem to affect the diabetes control or change in renal function. We need larger studies to further explore the practice patterns of physicians and its impact on outcomes.

PUB080

A Study on an Early Marker of Renal Damage in Known Diabetics Living in an Urban Slum of Hyderabad, India

Raghav K. Ranga,[1] Mahesh Kumar Mummadi,[2] Rhonda Dzakpasu.[1] *[1]Georgetown University, Washington, DC; [2]National Institute of Nutrition, Hyderabad, India*.

Background: India is the nation with the second largest prevalence of type 2 diabetes mellitus in the world, with an estimated 69.2 million people having the condition as of 2015. In the surrounding as a whole, 78.3 million people live with type 2 diabetes, out of which 52.1% are undiagnosed. 44% of all cases of nephropathy are caused by type 2 diabetes mellitus.

Methods: There are two goals for this cross-sectional study: i) to measure the prevalence of microalbuminuria and albuminuria in type 2 diabetic patients and ii) to determine associated factors that elevate a diabetic's risk for kidney disease. The study was done with 100 type 2 diabetics from Adda Gutta, Hyderabad, India. We performed urinalyses to measure urinary albumin, and gave a modified WHO STEPS questionnaire to assess lifestyle risks.

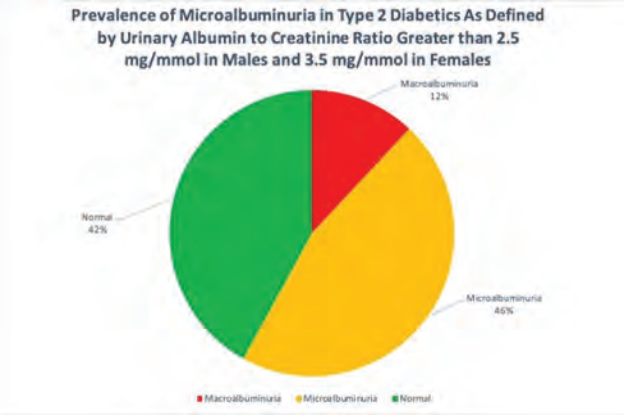
Results: 42 of the 100 patients surveyed were normoalbuminuric, 46 were microalbuminuric, and 12 were albuminuric. Significant risk factors were: being older than 44, having type 2 diabetes for longer than 6 years, drinking alcohol, and smoking.

Conclusions: The prevalence of microalbuminuria in type 2 diabetic people is quite a bit higher than it was in previous studies. Primary prevention needs to be emphasized in this population so that future generations don't get type 2 diabetes mellitus. If patients get their serum creatinine checked, then should nephropathy arise, then it will be detected earlier, and treatment could start earlier. Future studies could ask questions regarding stress on the questionnaires, as well as check the patients' serum creatinine, blood pressure, and lipid profiles.

Funding: Private Foundation Support, Government Support - Non-U.S.

Table 1. Summary of the status of the patients' kidneys. Patients, based on the ACR, were classified into three groups: normoalbuminuric, microalbuminuric, and macroalbuminuric. (n=100)

Status:	Number (n=100)
Normoalbuminuric:	42
Microalbuminuric:	46
Macroalbuminuric:	12



PUB081

The Miraculous Shrinking Kidney

Alonso R. Diaz, Shubha Ananthakrishnan, Joshua B. Crane. *University of California Davis, Davis, CA.*

Introduction: Glomerular hyperfiltration is common in conditions such as diabetes and obesity and can result in glomerular hypertrophy and organ growth as well as corresponding GFR increase. When hyperfiltration results in proteinuria this is a poor prognostic sign for ckd progression and needs to be managed appropriately. With this case report, we document dynamic progressive reduction in sizes of almost 18 and 16 cm kidneys, associated with resolution in proteinuria, after weight loss.

Case Description: A 70-year-old man with type II diabetes mellitus with retinopathy, hypertension and morbid obesity was referred to nephrology for very enlarged kidneys and proteinuria. Of note, two weeks prior he had undergone a gastric bypass surgery. Prior to gastric surgery his BMI had been as high as 41.6 kg/m2. Kidneys measured 17.7 cm on the right and 15.9 cm on the left. His spot protein to creatinine ratio pre-gastric bypass was 2,388 mg/g. Due to the significant growth of the kidneys, concern was initially for an infiltrative process and kidney biopsy was considered. However, the patient had just had gastric bypass surgery for weight loss, so the decision was made to serially monitor kidney sizes as hyperfiltration was high on the differential. With weight loss surgery and dietary changes, within six months, the patient had lost sixty pounds and decreased his BMI to 32.5 kg/m2. His A1c had decreased from 8.1 to 6.9. He was able to stop insulin and was maintained on metformin 1000mg bid and sitagliptin 100mg. His urine protein to creatinine ratio dramatically reduced from around 2388 mg/d to normal level of 78 mg/g Twenty-nine months post-surgery he has lost roughly ninety pounds and his BMI has decreased to 30. Remarkably his kidneys have decreased in size to 14.7 and 13 cm in size.

Discussion: This case illustrates dynamic change in kidney size by imaging with large weight loss as well as successful remission of sub-nephrotic range proteinuria following gastric sleeve surgery, extensive weight loss and glucose control.

PUB082

Multiple Targets on Sodium Excretion with SGLT2 Inhibitors, Furosemide, and Spironolactone Improves Diuretic Resistance in Patients with Diabetic Nephropathy on CKD Stage 3-4: A Pilot Study

Wei Liang. *Renmin Hospial of Wuhan University, Wuhan, China.*

Background: At stage 3-4 of chronic renal disease, patients with diabetic-induced renal dysfunction are not sensitive to the conventional diuretic therapy based on loop diuretics and thiazide diuretics, leading to the earlier renal replacement at stage CKD 3-4. The lower sodium excretion could contribute to the development of diuretic resistance. The protective effects of SGLT2 inhibitors on cardiovascular is contributed by metabolic regulation and osmotic diuretic effect of glucose due to extra excretion of Glucose. The present study aims to investigate the efficacy and safety of SGLT2 inhibitors on the diuretic resistance of diabetic nephropathy at CKD 3-4 stage.

Methods: Patients with Diabetic nephropathy at CKD3-4 stage were administrated with furosemide + hydrochlorothiazide for 3 days with urine volume <1000ml, urine sodium excretion <90mmol followed by Dapagliflozin/Canagliflozin once a day for 7 days.

Results: 3 male and 7 female patients with diabetic nephropathy were included, aged 51-80 years, with eGFR 60-4.6ml/min, and 3 patients presented with cardiac insufficiency. Urine volume was 800±300ml/24 hours before treatment and 2000±500ml/24 hours after treatment. Sodium excretion in urine was 80±20mmol/24 hours before treatment and 150±50mmol/24 hours before treatment. The average net weight change was -3.5±2.2kg. The Scr increased by 30%±5% before and after treatment, and the renal function in 2 patients increased by >30% after 7 days of treatment, and returned to the level of Scr before treatment after 7 days of withdrawal of Dapagliflozin/ Canagliflozin. Electrolyte levels were comparable before and after treatment.

Conclusions: The diuretic regimen based on SGLT2i could significantly improve the resistance of diabetic nephropathy patients to loop diuretics, increase urinary sodium excretion, and slightly elevate renal function in the short term without affecting blood electrolyte level. The efficacy and safety of long-term use of SGLT2i in diabetic nephropathy patients at CKD3-4 stage need further investigate in larger sample size.

Peripheral Neuropathy in a Hemodialysis Patient with a Normal Serum Vitamin B12 Level: Possible Vitamin B12 Deficiency in Target Tissues

Yadanar W. Lei,[1] Thinn E. San,[2,1] Htun M. Aung,[3,1] Aye M. Thida,[4,1] Myat E. Mon,[1] Kyaw M. Thein,[5,1] Kyaw Hla,[1] Alexander M. Swan.[1,6] *[1]Nephrology Hypertension Renal Transplant & Renal Therapy, LLC., Avenel, NJ; [2]Icahn School of Medicine at Mount Sinai Elmhurst Hospital Center, Elmhurst, NY; [3]Interfaith Medical Center, Brooklyn, NY; [4]Woodhull Medical and Mental Health Center, Brooklyn, NY; [5]South East Regional Health Authority, Kingston, Jamaica; [6]Rutgers New Jersey Medical School, Newark, NJ.*

Introduction: Many hemodialysis patients suffer from vitamin B12 deficiency, usually due to inadequate nutritional intake. Besides, food sources of vitamin B12 contain high concentrations of electrolytes, which are harmful to these patients. Thus, they are restricted to foods with low vitamin B12 content. Moreover, high-flux dialyzers remove vitamin B12 molecules from circulation, leading to vitamin B12 deficiency. We report a hemodialysis patient presenting with peripheral neuropathy and a normal serum vitamin B12 level whose symptoms improved with monthly vitamin B12 injections after excluding other differential diagnoses of peripheral neuropathy.

Case Description: An 86-year-old man with a history of ESRD on hemodialysis for 3 years along with HTN and CAD presented with fatigue, muscle weakness, and numbness of his extremities for 3 weeks. He was taking aspirin, dipyridamole, finasteride, tamsulosin, and pravastatin. His dietary history was significant for poor nutritional intake. Laboratory findings showed Hb 10.6 g/dL, MCV 102 fL, RBS 87 mg/dL, potassium 4.6 mmol/L, and BUN 42 mg/dL. Common causes of peripheral neuropathy in ESRD patients, such as uremic neuropathy, diabetic neuropathy, and hyperkalemia were excluded. Further evaluation revealed a normal serum vitamin B12 level of 421 pg/dL and a normal folic acid level of 11.4 ng/mL. Given his risk factors for possible vitamin B12 deficiency in target tissues, he was treated with monthly vitamin B12 1000 mcg injections and followed up regularly. His symptoms improved significantly after four months of injections.

Discussion: In hemodialysis patients, chronic inflammation impairs uptake of circulating vitamin B12 by peripheral tissues leading to decreased production of transcobalamin II, increased synthesis of transcobalamins I and III with further accumulation of vitamin B12 in blood. In addition, despite normal or high serum vitamin B12 levels, these patients may suffer from vitamin B12 deficiency in target tissues and show symptoms such as fatigue and peripheral neuropathy. Therefore, it seems reasonable to consider vitamin B12 supplementation in these patients after excluding other causes of peripheral neuropathy. Further studies are highly recommended.

Hemodialysis Prescription in Ethylene Glycol Overdose: A Mathematical Approach

Muhammad T. Shakoor, Jie Tang. *Warren Alpert Medical School of Brown University, Providence, RI.*

Introduction: The timely management of Ethylene glycol (EG) overdose is essential. Hemodialysis (HD) is indicated for rapid elimination of its toxic metabolites. We introduce a case diagnosed shortly after presentation prior to the availability of the blood EG level and share calculations that were used to precisely and accurately estimate the clearance of EG through HD.

Case Description: A 61-year-old male presented with unresponsiveness. Labs were notable for anion positive metabolic acidosis with anion gap 28, osmolal gap 57, along with stage 2 AKI. His whole blood lactate was >17.1 meq/L, with a venous lactate of 0.5 meq/L. EG intoxication was diagnosed based on high lactate gap (16.6) and calcium oxalate monohydrate crystals in his urine sediment. He was given fomepizole and emergently hemodialyzed. We calculated HD prescription based on a simple calculation which we have been using reliably to calculate HD duration and post HD EG level. His predialysis EG level was 71 mg/dl. To calculate the EG removal via HD, we need patient's weight and EG clearance (Cl_{EG}) for specific filters used in HD. Our patient weighed 98kg (TBW 59L) and Cl_{EG} for the F200 filter under Qb400 ml/min and Qd 800 ml/min is 147 ml/min. We decided to dialyze him for 4 hours. His post HD EG level was estimated to be: Kt of EG= 240 min (HD time) * 147ml/min (Cl_{EG})= 35L Kt/V of EG = 35L/59L= 59% Post HD EG level = 71 mg/dl (pre-HD EG level) x (1-59%) = 29 mg/dl After HD was completed, the post HD EG level was 30 mg/dl.

Discussion: Generally, the diagnosis of EG intoxication is delayed and calculation of HD prescription remains a challenge due to lag in obtaining serial EG assays in clinically useful time frame. We present a case of EG toxicity that we were able to diagnose promptly without having to wait for EG blood levels, and we present a simplified approach to determine the duration of HD based on a single EG assay. This calculation can be used to individualize HD treatments and avoid over or undertreatment of intoxication.

The Estimation Formula of Phosphorous, Potassium, and Salt Amounts Excreted into Urine in Hemodialysis Patients

Momoko Fukazawa,[1] Shunichiro Urabe,[1] Motoko Kato,[1] Yukie Kitajima,[2] Akihiro C. Yamashita,[3] Toru Hyodo.[1] *[1]Eijin Clinic, Hiratsuka, Japan; [2]Tokyo University of Technology School of Health Sciences, Shinagawa, Japan; [3]Hosei University, Koganeishi, Japan.*

Background: We elucidated the contribution of residual renal function (RRF) to the phosphorous, potassium and salt excretion and established the estimation formula of these amounts which are excreted into urine by RRF of hemodialysis patients.

Methods: We collected the 24 hours urine from 22 hemodialysis patients (mean age: 73.1±12.1 years old, dialysis history: 31.1±29.3 months, 15 males, 12 diabetics). The urine volume, phosphorous, potassium and salt amounts in the 24 hours urine and creatinine clearance were determined. The correlation coefficients among the urine volume, amounts of phosphorous, potassium and salt, creatinine clearance (Ccr).

Results: The mean urine volume was 862±421mL/day. The mean phosphorous amounts in the urine was 114.5±55.9 mg/day, potassium 418.2±212.4 mg/day, and salt 4.7±2.6 g/day. Ccr was 3.7±1.8 mL/min. There was a significant positive correlation: urine volume vs phosphorous amounts ($r=0.759$, $p<0.001$), urine volume vs potassium amounts ($r=0.662$, $p<0.001$). (Phosphorous amounts in the urine=101× [24 hours urine(L)]-28) (Potassium amounts in the urine=334× [24 hours urine(L)] +130). There was a significant positive correlation between urine volume and salt amounts excreted into urine ($r=0.915$, $r^2=0.84$, P,0.001).(Salt amounts in the urine=5.7×[24 hours urine(L)–0.2].

Conclusions: As for phosphorous and potassium, if 24 hours urine volume is known, the amount of urinary excretion of phosphorous and potassium can be roughly estimated. As for salt, if 24 hours urine volume is known, the amounts of urinary excretion of salt can be estimated with 84 % accuracy. Measuring urine volume in hemodialysis patients can estimate solute excretion roughly.

PUB086

Treatment of Uremic Tumoral Calcinosis in Maintenance Hemodialysis Patients

Guibao Ke, Fengxia Zhang, Xueqin Chen, Hong Zhang, Shuai C. Dou, Zhiwen Liang, Shi Wei, Xinling Liang, Shuangxin Liu. *Department of Nephrology, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.*

Background: Uremic tumoral calcinosis (UTC) is a rare disease with metastatic tissue calcification in maintenance hemodialysis (HD) patients. However, limited data are available on treatment of UTC in HD patients. This article mainly discusses the diagnostic findings and efficacy of treatment in HD patients with UTC.

Methods: A retrospective analysis was conducted on the data of 13 cases of UTC, including their clinical features, biochemical indicators, imaging findings, diagnosis, therapeutic methods and follow-up results. Parathyroidectomy (PTX) or drug treatment were determined based on intact parathyroid hormone (iPTH) levels and clinical symptoms.

Results: All of 13 patients were diagnosed as UTC definitely by imaging examination. The predominant areas involved were the buttocks (4 cases, 30.77%), shoulders (4 cases, 30.77%), and elbows (3 cases, 23.08%). Based on the levels of iPTH, cases were categorized into two different groups: PTX treatment group was associated with high levels of iPTH, while drug treatment group (lanthanum carbonate or sevelamer with STS) was lower iPTH. After PTX treatment, there was a significant decrease in serum iPTH, calcium (Ca), phosphate (P) and alkaline phosphatase (ALP) levels ($p<0.05$). In drug treatment group, the serum P levels was decreased significantly, along with a finding that hemoglobin levels was increased ($p<0.05$). All the UTC had lessened or even disappeared after treatment 4 to 6 months.

Conclusions: Although most UTC patients have an increased iPTH, a small number had lower iPTH levels. Based on iPTH levels and clinical symptoms, the patients were treated with PTX or drug therapy. With proper treatment, UTC disappeared without the need for surgery to remove calcinosis tissue.

Survival Analysis of Hemodialysis Patients: Impact of Uremic Toxins

Mari Sargsyan,[1] Juan Robles bauza,[1] Sheila Cabello Pelegrin,[1] Joana M. Ferrer,[1] Miguel Uriol Rivera,[1] Juan Rey Valeriano,[1] Sonia Jimenez,[1] Cristina Egea,[1] Tania Villagrasa,[1] Gonzalo Gómez marqués,[1,2] Bernardino Barcelo,[1,2] Joan M. Gasco.[1,2] *[1]Hospital Universitari Son Espases, Palma de Mallorca, Spain; [2]Universitat de les Illes Balears, Palma de Mallorca, Spain.*

Background: HEMO study showed that β_2M serum level over time was predictive of mortality in hemodialysis (HD) patients (p). The aim of the study was to analyse β_2M and indoxyl sulfate (IS) as predictor factors of mortality.

Methods: 5 years follow-up of 60 prevalent HD p. Baseline midweek pre-HD serum β_2M by nephelometry and total IS levels by HPLC connected to a UV detector. High serum β_2M group ≥ 27,5 mg/L. As to IS, p were divided into quartiles (1q <9,7 mg/L, 2-3q ≥9.7-26.5mg/L, 4q>26.5 mg/L). Kaplan–Meier analysis at 1,2,3 and 5 years in univariate analysis for albumin (≥38 g/L or lower), β_2M, and total IS groups. Multivariate analysis by proportional hazards Cox's model.

Results: 60 prevalent p with mean vintage of 46,8 months (range 3-299 months). 60±20 years. Females 46,6%. 35% diabetic. 51,6% HD, 48,3% post-dilution haemodiafiltration, with mean convective volume of 23,8±2,8L. Mean eKt/V 1,67±0,4, mean nPCR 1±0,27g/kg/day. 8,3% of p had urine volume>500cc/24 hours. Mean β_2M level 5,6±1,9mg/L (X±SE). Mean total IS level 18,9±1,6mg/L. Overall mortality at 5 years was 57%. Albuminemia lower than 38g/L was associated with mortality at 2, 3, and 5-years in univariate analysis (Cox's F test p=0.03, figure). No difference in survival rate between p with high or low serum β2M levels at 3 or 5 years analysis (Cox's F test p=0.27). At 2 years analysis, p in the lower β_2M group had better survival (Cox's F test p=0.04, figure). There was no statistically significant association between albumin, β_2M, IS level and mortality on multivariate analysis. We observe no statistically significant associated between IS levels and all-cause mortality.

Conclusions: β_2M < 27,5 mg/l was associated with better survival at 2 years univariate analysis. IS had no statistically significant association with all-cause mortality in our cohort.

PUB088

A Novel Optimised Approach to Flow Balance and Fluid Removal During Haemodialysis

Paul Komenda, John Milad, Clive Buckberry. *Quanta Dialysis Technologies, Alcester, United Kingdom.*

Background: Fluid management is an integral component for managing patients to correct abnormalities in plasma composition and maintain fluid balance. Consequently, accurate fluid removal during treatment is a critical design element of haemodialysis machines. The SC+ haemodialysis system developed by Quanta Dialysis Technologies, is a compact, simple-to-use dialysis system designed to improve patient access to self-care and home haemodialysis. This paper describes the design, evaluation and performance of the flow balance and ultrafiltration module of SC+ to deliver specified fluid removal in accordance with the international technical standards for haemodialysis defined in IEC 60601-2-16 using a number of unique proprietary technologies.

Methods: SC+ uses volumetric flow balancing chambers contained within a single use disposable cartridge. During normal operation, dialysis fluid flows through the cartridge in discrete packets achieved by the application of pneumatic pressure and vacuum to manipulate a flexible PVC membrane that, in turn, opens and closes a sequential series of valves and pump cavities that constitute the flow balance chambers. Proof of system performance was undertaken using a range of dialysers and venous pressures, with and without ultrafiltration, to quantify the net fluid removal error, in order to simulate a range of patient conditions in typical clinical practice.

Results: In total, the tests comprised 22 separate runs on multiple machines, with 88 individual 30-minute measurement samples, taken over a range of environmental conditions, dialyser types (with differing KuF), dialysate flowrates, and venous pressures. Across all results, there was a mean error of 7.4g/hour rate error, (max allowed is 100g/hr) of positive flow from the blood to the dialysate side with a standard deviation of 19.88g/hr.

Conclusions: It has been demonstrated that flow balance error and fluid removal attainable with SC+ lies well within the acceptable standards permitted for haemodialysis machines, demonstrated across a range of clinically relevant parameters at dialysate flow rates of up to 500ml/min.

Clinical Performance of the Optiflux® F160NR Dialyzer

Jill M. Meyer,[1] Dylan Steer,[2] Lisa A. Weber,[3] Mayuri Thakuria,[4] Chiang-Hong Ho,[4] Claudy Mullon,[4] Robert J. Kossmann.[4] *[1]California Institute of Renal Research, Chula Vista, CA; [2]California Institute of Renal Research, San Diego, CA; [3]Research Management Inc./ Kansas Nephrology Research, Wichita, KS; [4]Fresenius Medical Care North America, Waltham, MA.*

Background: Subjects in the clinical trial (NCT# 03536663), *An Open-Label Clinical Study to Assess the Performance of the Dialyzer with Endexo™ in End-Stage Renal Disease Subjects*, were dialyzed with the Optiflux® F160NR dialyzer, followed by the new dialyzer with Endexo. This sub-analysis reports the safety and performance of the Optiflux® F160NR dialyzer.

Methods: Subjects prescribed thrice-weekly HD for at least 30 days at three US study sites were enrolled in the study. The Optiflux F160NR dialyzer study period included 12 HD treatments. Performance and safety assessments included URR, spKt/V, serum albumin and ß-2-microglobulin levels with removal rates measured pre and post HD, complement activation, and Adverse Events (AEs).

Results: Twenty-six subjects were screened. Twenty-three subjects were enrolled in the study (median age 64 years, females 73.91% and white 73.91%) and completed 268 HD treatments with the Optiflux F160NR dialyzer. Four subjects discontinued the study due to missed visits, not related to adverse events. 19 subjects completed all 12 HD treatments per protocol (n =228 dialysis sessions). Delivered HD parameters are presented in Table 1. No SAEs were reported during the study. Four subjects reported at least one adverse event not device related. Mean (SD) reported for enrolled subjects were: 80.5% (4.5) for URR, 1.9 (0.3) for spKt/V, 47.1% (7.4) for corrected ß-2-microglobulin removal rate and an increase of 8.3% (8.2) post HD for serum albumin. Complement activation was measured Pre HD and 30 min Post HD start and showed no overt activation for C3a, C5a and sC5b-9.

Conclusions: HD treatments were well tolerated and URR and spKT/V were high with Optiflux® F160NR dialyzer. Serum albumin levels increased post HD. Complements showed no overt activation.

Dialysis Disequilibrium Syndrome: Severe Irreversible Brain Injury Following Hemodialysis

Fatima Ballout, Pravir V. Baxi, Roger A. Rodby. *Rush University Medical Center, Chicago, IL.*

Introduction: Dialysis disequilibrium syndrome (DDS) is a clinical complication of hemodialysis (HD) characterized by neurological symptoms attributed to cerebral edema that rarely occurs in ESKD patients following their first HD treatment. Treatment is primarily preventative, aimed at decreasing the rate of urea clearance to reduce subsequent osmotic fluid shifts. We describe a case of DDS with severe neurological sequelae in a patient with acute on chronic kidney disease.

Case Description: A 39 yo man with CKD 4 presented with dyspnea, lethargy and confusion. Initial labs showed a Na 133 mmol/L, K 7.9 mmol/L, BUN 281 mg/dl and creatinine 38.6 mg/dL. HD was initiated for treatment of uremia and hyperkalemia. Two hours after the start of HD, the patient had a tonic-clonic seizure followed by cardiopulmonary arrest. Lab data post-arrest showed a Na 133 mmol/L and BUN of 112 mg/dL (Fig 1). In the subsequent days, the patient remained in a comatose state. MRI of the brain revealed cortical restricted diffusion in both cerebral hemispheres and bilateral basal ganglia, concerning for hypoxic-ischemic injury. His clinical status did not improve over 3 months. He required a tracheostomy and PEG tube placement with HD dependency on discharge.

Discussion: DDS remains a rare clinical phenomenon which typically occurs with initiation of HD in those with severe azotemia and advanced CKD. Risk factors include pre-existing neurological conditions, hyponatremia, and higher starting BUN levels. While the pathogenesis remains debated, DDS is believed to be due to a reverse osmotic effect that occurs due to a faster decline of urea within the blood versus the brain creating osmotic disequilibrium with subsequent movement of water into the brain causing cerebral edema. Idiogenic osmoles may also be involved. Recognition of patients at high risk is crucial as it provides an opportunity to implement preventative strategies including reduced HD treatment time with lower blood flows aimed at more gradual clearance of urea.

PUB091

Sustained High-Dose Chronic CRRT Fails to Attenuate Severe Lactic Acidosis in an Immunotherapy-Resistant Case of Malignant Melanoma with Liver Visceral Crisis

Mabel S. Tan, Han K. Tan. *Singapore General Hospital, Department of Renal Medicine, Singapore, Singapore.*

Introduction: Lactic acidosis is the most common cause of metabolic acidosis in hospitalized patients. Though of little proven benefit, continuous renal replacement therapy (CRRT) has been suggested as treatment in some patients. We describe a rare case of a patient with lactic acidosis who received nineteen days of high dose CRRT.

Case Description: A 60-kg young Chinese female with melanoma and extensive liver metastasis presented in a visceral crisis. She was given combination of nivolumab and ipilumab which was projected to take 1 month to work. She had severe lactic acidosis with serum lactate of 17mmol/L on admission despite normal renal function. After a failed trial of medical therapy, CRRT was started purely for lactic acidosis. A spot measurement of effluent lactate was 15mmol/L while the corresponding plasma lactate was 16.3mmol/L, suggesting sieving coefficient of 0.92. Switching to a lactate free dialysis fluid multiBic did not help. Despite uninterrupted CRRT for 19 days, and repeated increase of effluent dose to peak of 5L/hour, giving lactate clearance of 76.7ml per minute, there was no improvement. She eventually demised 4 days after cessation of CRRT.

Discussion: We describe an unfortunate case where 2 specialties tried hard to save this young patient from the fatal complications of her aggressive tumor. Type B lactic acidosis is better described in hematological malignancies but there are increasing reports in solid organ tumors, most with extensive hepatic involvement. We present the first case of melanoma causing lactic acidosis reported in literature till date. While CRRT, convective therapies, bicarbonate-based dialysis fluids have been suggested as treatment for lactic acidosis, there is little proven benefit. In our case, we combined all 3 strategies, persisted at high dose for 19 days with no success. 2 learning points: Firstly, lactic acidosis in the absence of hypoperfusion (Type B) is not uncommon and equally dangerous. Secondly, while dialysis removes lactate to some extent, it is at best a temporizing measure. Addressing the underlying cause takes priority. Dialysis, regardless of dose, modality and timing is less likely to affect outcome.

PUB092

Primary Caregiver Burden in a Hemodialysis Clinic in Mexico: Prevalence and Caregiver-Related Risk Factors

Edgar Solis, Joselyn Rivera, Juan M. Ardavin Ituarte. *Medica Santa Carmen, San Miguel de Allende, Mexico.*

Background: Dialysis treatment is defined as a family disease. Primary caregiver is the main person who takes the responsibility for and supports the patient; caregiver burden can be defined as the strain or load borne by a person who cares for a chronically ill family member. The Zarit survey is a psychometric instrument designed to grade caregiver burden, recommended and validated among caregivers of patients in hemodialysis.

Methods: A descriptive study was conducted among primary hemodialysis caregivers from a dialysis clinic in Guanajuato, Mexico. Zarit Scale (A validated 22-item questionnaire with five item ranged from 0=never to 4=always) was applied in order to identify presence and level of caregiver burden. Caregivers of patients less than 3 months were excluded. Social and demographic data related were also collected. Data was analyzed for descriptive statistics using T-test and Chi square for comparation between groups.

Results: A total of 86 primary dialysis caregivers answered the survey via personal interview with one of the investigators. Most responders were female (77%) with a mean age of 47±15 years old. Seventy seven percent were married and almost all had an occupation (95%): homemaker (43%) was the most common. We found that couples take care of patients in 42% of cases, followed by parents (27%). Interestingly, 46% of responders did not take own recreational time and some of them (38%) were diagnosed with some chronic illness. More than half (56%) usually take care of 1 to 3 more persons along with the patient and meantime of life spent caring was 2 years. Any level of caregiver burden was identified in 67%, most of them (86%) in a slight level. There were not statistical differences between groups with none and any burden.

Conclusions: ESRD affects not only patients but also the people who takes care of them. Caregivers burden is prevalent in our clinic. Caregivers are predominantly female

partners who have to cope with patients care along with attendance of other relatives and often the need to work for economic support of their families. These results should be added to the public health burden of ESRD in Mexico.

Burden Level	
None (0 - 20)	28 (33)
Mild (21 - 40)	40 (46)
Moderate (41 - 60)	14 (16)
Severe (61 - 88)	4 (5)

PUB093

Within-Patient Relationships Between Ultrafiltration and Fluid Gains in Haemodialysis Patients

Mai Nguyen, Richard W. Corbett, Damien Ashby. *Hammersmith Hospital, London, United Kingdom.*

Background: Despite the now-widespread use of haemodialysis treatment, optimal fluid management in long-term dialysis patients remains challenging. Whilst the between-patient factors affecting target weight and ultrafiltration have been well studied, little is known regarding the within-patient factors affecting these relationships.

Methods: Dialysis data for a group of stable haemodialysis patients, from 4 dialysis units, were analysed over a period of one year. All weights and volumes are expressed as percentage of target weight.

Results: From 100 patients (aged 28–89, mean 65.4, 54% male) observed over a year, complete data were available for 15530 dialysis sessions, and 13027 combinations of dialysis session plus the following inter-dialytic interval. Mean arterial pressure dropped by 3.5(+/-14.6)mmHg during dialysis, with a significant correlation ($p<0.05$) between pressure drop and ultrafiltration volume in 26 patients (mean R=0.09, mean regression gradient 3.2). In 87 patients, inter-dialytic fluid gain correlated strongly ($p<0.05$) with the previous dialysis session's ultrafiltration volume (mean R=0.37, mean regression gradient 0.20) suggesting a significant role of ultrafiltration volume in driving subsequent fluid intake behaviour (thirst). Unsurprisingly, more fluid was gained over longer inter-dialytic intervals: mean(sd) weight at the start of dialysis was 103.2(1.0)% after a 3-day gap and 102.5(1.0)% after a 2-day gap, with this difference being significant ($p<0.05$) in 87 patients. However, fluid gain was non-linear, diminishing during longer inter-dialytic intervals: mean(sd) daily inter-dialytic fluid gain was 1.13(0.38)% during the 3-day gap vs 1.21(0.53)% during the 2-day gap ($p<0.05$ in 36 patients), implying that at least a third of patients consume less fluid during the 3rd post-dialysis day.

Conclusions: Inter-dialytic fluid gain is strongly dependent on ultrafiltration during the previous dialysis session, and diminishes during the inter-dialytic interval. Large ultrafiltration volumes, which have historically been perceived as the inevitable result of large fluid intakes, are actually a cause of thirst and large fluid intakes in haemodialysis patients. These data, derived from within-patient analyses, strongly challenge our conventional understanding of dialytic fluid management.

PUB094

Medical Waste Management: How Industry Can Help Us Protect the Environment and Money

Jacek P. Zawierucha,[1] Tomasz R. Prystacki,[2] Wojciech Marcinkowski,[2] Jolanta Malyszko.[3] *[1]Fresenius Medical Care Polska S.A., Poznan, Poland; [2]Fresenius NephroCare Polska Sp zoo, Poznan, Poland; [3]Warsaw Medical University, Warszawa, Poland.*

Background: The global climate change and it's consequences force us to remodel our processes and rething current model of providing the HD treatments. One of the crucial point, which have massive impact on the environment and the economy is the waste management. Every HD session produce above 1 kg of medical waste, which should be properly stored and destroyed. Well thought out processes and our choices can improve dialysis unit budget as well as decrease CO2 emission nascented during the waste incineration.

Methods: The weight of dialyser is one of the crucial components of the medical waste produced during dialysis session. The authors checked the weight of different dialysers regulary used in dialysis centers in Poland. The Kern CM 320-IN scale was used for the measurement. The measurement accuracy was 0,1 g. Also the filling volume of each dialyser has been taken into consideration.

Results: The the weight difference between dialyser produced by different manufacturers is 95 grams from the heaviest to lightest ones. The ligthest dialysers are Fresenius FX class filters, the heaviest ones are Baxters Polyflux. that it's mass should be taken into consideration, when we are choosing the type of the filter. Of course the most important are still the medical parameters of the dialyser but in case of comparable performance data, the weight can be tip the balance during decision making. The dialysis center, treated 100 patients can save 1.482 kilos of medical waste yearly only by using the lightest dialysers, in comparison with the heaviest ones. In global perspective the saving are much more noticeable. Authors also noticed the difference in priming volume of checked dialyser. The biggest one was in Elysio dialysers, the smallest in FX series and Leoceed ones.

Conclusions: Everyone of us should be aware how our daily activity influence on the environment. Both, medical industry and nephrologists are responsible for decreasing the quantity and weight of medical waste produced during dialysis treatment. Careful proceeding with the disposables (proper procedures, medical staff training and awareness) will directly help to make the HD treatment more cost-effective and help to protect our planet.

PUB095

Early Intervention of Continuous Hemodialysis Filtration Is Effective to Improve Acute Kidney Injuries and Mortality in Patient with Propofol-Related Infusion Syndrome

Masako Iwasaki,[1] Hitoshi Suzuki,[1,2] Aiko Wakayama,[2] Maiko Akira,[1] Yusuke Suzuki.[2] *[1]Juntendo University Urayasu Hospital, Urayasu, Japan; [2]Juntendo University Faculty of Medicine, Tokyo, Japan.*

Introduction: Propofol related infusion syndrome (PRIS) is a fatal syndrome that often develops under the long-term propofol infusion at high doses. The main features of the PRIS consist of cardiac failure, rhabdomyolysis, acute kidney injury, and severe metabolic acidosis. High dose propofol, but also supportive treatments with catecholamines and corticosteroids, act as triggering factors. Propofol is usually administered at 0.3~4.0 mg/kg/hr or less to the sedation of adult patients, and is not administered beyond 7 days to prevent PRIS. We report here a case of PRIS developed rhabdomyolysis, acute kidney injury, and severe metabolic acidosis under the dose of propofol within the safety dose.

Case Description: A 41-year-old woman was operated cervicothoracic posterior longitudinal ligament ossification. After the operation, maximum 3.5 mg/kg/hr of propofol was used for sedation for treatment of severe pneumonia under the mechanical ventilator. Catecholamines was also used to support hemodynamics. However, unidentified hyperthermia and impaired blood pressure were prolonged, then administration of propofol was discontinued on POD6. Acute kidney injuries (sCr2.3mg/dl), metabolic acidosis and high serum CK (79300U/L) due to rhabdomyolysis were observed on POD8. Continuous hemodialysis filtration (CHDF) therapy was initiated, and hyperthermia, oxygenation, impaired hemodynamics and renal dysfunction were gradually improved. Finally, cardiac failure and renal function were totally recovered.

Discussion: Propofol impairs free fatty acid utilisation and mitochondrial activity. Imbalance between energy demand and utilisation is a key pathogenetic mechanism, which may lead to cardiac and peripheral muscle necrosis. CHDF may effective to maintain renal function and acid-base equilibrium through removal of metabolites induced by mitochondrial damage, such as lactate and creatine kinase. PRIS particularly when combined with catecholamines can be lethal and we suggest early intervention of CHDF is effective to improve renal injuries and mortality.

The Conduct of Sponsored Trials Has No Association with Dialysis Facility Clinical Quality Outcomes

Vladimir Rigodon,[1] Yue Jiao,[2] Lori Vienneau,[3] Joanna Willetts,[2] Sheetal Chaudhuri,[2] John W. Larkin,[2] Len A. Usvyat,[2] Jeffrey L. Hymes,[3] Robert J. Kossmann,[3] Franklin W. Maddux,[4] Kurt Mussina.[1] *[1]Frenova Renal Research, Waltham, MA; [2]Fresenius Medical Care, Global Medical Office, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA; [4]Fresenius Medical Care AG & Co. KGaA, Global Medical Office, Bad Homburg, Germany.*

Background: There is a paucity of clinical trials conducted in nephrology vis-à-vis other fields (Baigent, et al. 2017). The lack of knowledge on impacts of trial conduct on dialysis facility operations can create barriers between stakeholders. We aimed to assess clinical quality target achievement in dialysis facilities conducting trials versus matched facilities with similar attributes that were not involved in research activities.

Methods: We used data from adult (age ≥18 years) hemodialysis patients treated at a dialysis provider network in the United States during 2017 to 2018. Facilities that did not participate in trials were matched to research facilities using 1:1 matching on logit of propensity score for patient years of follow-up, years of certification, % of Medicare patients, % of ESCO facilities and geographical region. We cross-sectionally compared mean facility-level quality metrics for: anemia (% Hgb ≥10 & <10g/dL), mineral bone disorder (% calcium ≤10.0mg/dL, % phosphate 3.0-5.5mg/dL & % iPTH 150-600pg/dL), and event outcomes (% catheter exposure >90 days, % treatment non-adherence, 30 day readmission rates, hospital days/patient year).

Results: We found no significant differences between mean facility-level quality metrics in dialysis facilities that conducted trials versus matched facilities not involved in research (**Figure 1**).

Conclusions: We found the conduct of trials in dialysis facilities had no association with achievement of quality targets, as compared to matched facilities not participating in trials. These insights are of importance to providers and stakeholders participating in/considering nephrology research activities that are necessary for advancing the state of the art.

The Kt/V Measurement Provides Little Useful Information to Help Manage a Patient

Jack Rubin. Medicine and Nephrology of Los Alamitos California *Medicine and Nephrology Associates, Los Alamitos, CA.*

Background: We measure KT/V monthly but to what purpose? Does this reflect adequate dialysis? Can one predict needed information such as albumin, calcium phosphorus product or potassium?

Methods: To this end we reviewed our montly May 2020 dialysis laboratory studies to see if there was any meaningful relationship with the standard pooled KT/V measurement. We indexed albumin. calcium phosphorus product and whether thes parameters correlated with KT/V.

Results: Our population consisted of 106 patients of which 61 were males with an average age of 64 ± sd 12 years and on dialysis an average of 1785 ± sd 1713 days and 45 females of average age 65 ± sd 17 years on dialysis 1137 ± sd 979 days. The median time on dialysis was 842 days for males and 846 days for females. The mean albumin was 3.7 ± 0.36 g/100 ml. The mean hemoglobin was 9.6 g /100 ml ± sd 1.4, Th mean calcium phosphorus product was 48 ± sd 16. Th calcium averaged 9.2 ± sd 0.7 mg/100 ml and phosphorus 5.3 ± sd 1.7 mg/100 ml. The mean KT/V was 1.48 ± sd 0.30. Using Excel a correlation coefficient was calcuated between albumin and KT/V = 0.28, hemoglobin versus KT/V = -0.03, calcium and phosphorus product versus KT/V = -0.19 and potassium versus KT/V = 0.05. Vintage of dialysis corelated poorly with albumin = 0.09 and with potassium 0.09.

Conclusions: In summary KT/V as a standalone measurement has minimal if any relationship to the parameters investigated and its continued use should be reconsidered.

PUB098

Impact of Major Surgical Operations on Clinical Outcome in Dialysis Patients

Rezzan Eren Sadioglu, Gizem Kumru, Sim Kutlay, Sule Sengul, Kenan Keven, Gokhan Nergizoglu, Kenan Ates, Neval Duman, Sehsuvar Erturk. *Ankara Universitesi Tip Fakultesi, Ankara, Turkey.*

Background: We aimed to study the impact of major surgical operations on clinical outcome in patients with haemodialysis (HD) or peritoneal dialysis (PD).

Methods: We retrospectively evaluated the records of all patients on HD and PD, who had been treated for at least 3 months at our outpatient clinics between January 1, 2014 and December 31, 2018. In addition to clinical and laboratory parameters, data on all major surgical operations were recorded.

Results: Among the 202 patients, 133 (66%) were on HD and 69 (34%) on PD. The mean age (±SD) was 58.3±14.5 years, 48% were female and 28% had diabetes mellitus. Forty-seven patients (23%) had a major surgical operation. The operation types were cardiovascular in 14 patients, orthopaedic in 11, gastrointestinal in 8, genitourinary in 6, parathyroidectomy in 5 and brain, pulmonary and breast in 1 patient each. Operations were emergent in 10 patients (21%) and elective in the others (79%). Among the whole study population, 59 patients (29%) died during the study period. In Kaplan-Meier analysis (Figure), mean (95% CI) survival time in operated patients was 43 months (37 to 49 months), while it was 49 months (46 to 52 months) in the others (p=0.023). Fifteen out of 23 deaths (65%) among the operated patients occurred in the first month after surgery. Severe perioperative complications (arrhythmias, hypervolemia, hypotension, bleeding, acute coronary syndrome, respiratory failure and cerebrovascular event) were recorded in 17 (36%) of the operated patients, of whom 16 died (p=0.001). Although did not reach a significant level, mortality rate tended to be higher after emergent operations than that after elective operations. Cox regression analyses revealed that age (RR 1.033, 95% CI 1.010-1.057, p=0.005), diabetes (RR 2.581, 95% CI 1.474-4.521, p=0.001), preoperative C-reactive protein level (RR 1.005, 95% CI 1.002-1.007, p<0.0001) and having a major surgical operation (RR 1.868, 95% CI 1.068-3.268, p=0.028) were the independent predictors of mortality.

Conclusions: Although prospective studies with a higher patient number are needed to confirm, our study shows that, in addition to age, diabetes and inflammatory status, having a major surgical operation is an independent risk factor for mortality in dialysis patients.

PUB099

Outcomes of Ceftolozane/Tazobactam Recommended Doses in Treating Multidrug-Resistant Bacteria in Critically Ill Patients Using Renal Replacement Therapy

Wasim El Nekidy,[1,2] Leen Oyoun Alsoud,[1] Nizar M. Attallah,[1] Laila Rkieh,[4] Fadi A. Hijazi,[1] Ahmad R. Nusair,[1] Jihad Mallat,[1] Islam Ghazi.[3] *[1]Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; [2]Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH; [3]University of the Sciences in Philadelphia, Philadelphia, PA; [4]Trillium Health Partners, Mississauga, ON, Canada.*

Background: Ceftolozane/tazobactam (CEF/TAZ) is a new broad spectrumn cephalosporin effective against Multi-drug Resistant (MDR) bacteria. The clinical outcomes of the recommended dose of CEF/TAZ in patients utilizing renal replacement therapies are lacking. The purpose of this study was to evaluate the clinical and microbiological efficacy of CEF/TAZ in treating MDR in pateints utlizing continous venovenous hemofiltraion (CVVH) and intermittent hemodialsyis (IHD).

Methods: A retrospective cohort study was conducted at our quaternary care hospital between May 2015 and December 2019. We reviewed all hospitalized adults who had MDR *Pseudomonas aeruginosa* or MDR *enterobacteriaceae* treated with CEF/TAZ while utilizing CVVH or IHD

Results: We identified 11 patients who met the inclusion criteria with a mean age of 63.0 ± 17.8 years and a mean weight of 63.8±15.7 kg. All patients were critically ill, needed mechanical ventilation, and used vasopressors. All 11 patients had pneumonia, one of them developed secondary bacteremia and two had decubitus ulcer. Nine patients had MDR *pseudomonas aeruginosa* while two had MDR *E. coli* and *Klebsiella Pneumonia.* Six patients were on IHD, while the remaining 5 patients were on CVVH. The most commonly used dose for CVVH was 450 or 750 mg intravenous (IV) every 8 hours (only one received 1500 mg at the same frequency). For IHD, the common dose was 450 mg IV every 8 hours. Of the 7 pateints who had repeated cultures, three had microbiological cure and four had clinical cure. Two pateints expired within 30 days and 3 more expired within 90 days. Two of the patients who had clinical cure, had recurrence within 4 weeks.

Conclusions: The efficacy of the recommended CEF/TAZ dose in patients utilizing RRT is uncertain. Pharmacokinetics and pharmacodynamics studies are urgently needed to determine the adequacy of CEF/AVI dosing in this population

PUB100

Does Dialyzer Surface Area Alone Adjusted to Body Surface Area Have Any Clinical Impact on Adequacy: A Single-Center Observation Study in Saudi Arabia

Najlaa Almalki, Ahmad S. Ghanem, Azharuddin Mohammed. *Armed Forces Hospitals Administration in Taif Region, Taif, Saudi Arabia.*

Background: Dialysis adequacy using sp Kt/V is a standard KPI in HD units, determined by dialyzer clearance(K), Volume of distribution urea(V) and treatment time(t). Increase in larger dialyzer size (t, V being constant) is a norm to improve Kt/V during HD as the patients gradually lose residual kidney function. However initial and subsequent dialyzer prescription using Body Surface Area(BSA) instead of Weight(V) is less well studied. We looked into effect of BSA and DSA on Kt/V.

Methods: 163(n=) patients receiving in-center HD on Gambro dialyzers (Polyflux, Revaclear) studied. Demographic and clinical data collected. Patients were stratified into 4 groups based on their dialyzer surface area (DSA) as 1.4, 1.7, 1.8 and 2.1 m^2. For each group, we then calculated BSA(Du Bois method), HD vintage, treatment time(hours), Access type, sp Kt/V (Dougirdas) and % pts with inadequate sp Kt/V, <1.2. Hemoglobin for each group was compared too.

Results: Our patients were representative of any HD center in terms of demographics; age 57.8 ±18.3, 50.9%Males, 28.2% DM, vintage 59.3±51.2 m, BMI 25.1±6, BSA 1.7±0.3 and Kt/V 1.7±0.4. The use of dialyzer with DSA's 1.4, 1.7, 1.8 and 2.1 were 63.2%, 5.5%, 8.6% and 22.1 %. Among 4 groups, there was no significant difference in terms of age, treatment time, vascular access and hemoglobin, Image 1. But when DSA and BSA were stratified for adequacy, there was a modest linear trend of decreasing Kt/V with increasing BSA among 4 increasing DSA groups. Although all met the minimum spKt/V of 1.2, the proportion of patients with inadequate Kt/V were increasing despite their increasing dialyzer sizes. Factoring for equilibrated Kt/V, adequacy could just be borderline for larger patients.

Conclusions: Dialyzer size change in itself may not be effective in achieving target Kt/V as BSA increases; attention must be paid to increasing dialysis time. Dialyzer prescription, adjusting for BSA may be more appropriate, particularly in large patients.

Table 1 . Dialysis variables

DSA M²	AGE, YEARS	HOURS/ SESSION	FISTULA (%)	HEMOGLOBIN G/DL

High Ultrafiltration Rate: Is It Bad? A Case Report of a Patient on Hemodialysis for 29 Years with High Ultrafiltration Rate

Aziz U. Syed. *Diaverum, Riyadh, Saudi Arabia*.

Introduction: High ultrafiltration on Hemodialysis stresses cardiovascular and could have negative effect on survival. This is the notion of many studies done in line with High ultrafiltration. However, are we missing the other side of coin, cumulated effect of fluid overload on cardiovascular system?

Case Description: We present a case 60 year male develop protein urea lost follow up, presented with CKD 5, started on hemodialysis which he is on for 29 years now. He was hypertensive to start with later became normotensive. His intradialytic weight gain is 4.5 to 5.5 liters, which he tolerates well without any episode of intradialytic hypotension.

Discussion: Except Carpal, tunnel Syndrome for which he had surgery, clinically stable, normal biochemical parameters and acceptable cardiovascular status with this entire very remarkable journey.

PUB102

The Influence of Different Hemodialysis Frequency on Maintenance Hemodialysis Patients

Hua Liu. *the first affiliated hospital of Xi'an Jiaotong University, Xi'an, China*.

Background: To investigate the effects of different dialysis frequencies on anemia, nutritional status, calcium and phosphorus metabolism, renal function indicators in patients.

Methods: The general data of MHD patients in our center from 2017 to 2019 and annual laboratory monitoring indicators (including HGB, SF, Bun, Scr, Ca, P, iPTH, ALP, ALB), urine volume and eGFR, were used to compare in patients with different hemodialysis frequency groups (Group A: 2 times/week, B: 5 times/2 weeks, C: 3times/ week).

Results: There were 269 patients (163 males, 106 females), with an average age of 52.650±14.982 years. There were statistical differences among HGB, Ca and ALB, but no statistical differences among SF, P, iPTH, ALP, Bun and Scr. The three-year overall compliance rate evaluation found that the overall compliance rate of HBG and Ca significantly increased. It was found that the compliance rates of HGB and Ca at the dialysis frequency of 2 times a week were significantly lower than those of the other two groups, but there is no difference for P, iPTH and ALB.

Conclusions: Different from western countries countries or developed areas, the the frequency less than 3 times is more than two-thirds in the western region in China. In this study, the average of HGB and Ca in patients with dialysis 3 times a week is significantly higher than other groups with low-frequency, and the compliance rate of HGB and Ca in group with the dialysis 3 times a week increased significantly. The results suggested that the higher frequency group was better in anemia and calcium correction.

Achromobacter Xylosoxidans, Subspecies Denitrificans, Exit Site Infection, and Aeromonas Hydrophilia Peritonitis: Rare Infections in Peritoneal Dialysis Patients

Akshay Verma, Faisal N. Khan. *Victoria Nephrology Associates, Victoria, TX*.

Background: Achromobacter xylosoxidans, subspecies denitrificans, exit site infection in peritoneal dialysis patient is rare and will be reported. A second case of rare peritoneal infection caused by Aeromonas hydrophilia peritonitis will also be reported. Both are gram-negative micro-organisms and are usually found in wet environments, causing infections in immunocompromised patients. Both cases occurred in the same rural city and in the same dialysis facility.

Methods: The cases involved conducting interviews with patients and documenting each visit. All observations and visitations were assessed in the dialysis center of a rural area. Previous data of cases with similar rare pathogen caused peritonitis were also analyzed.

Results: The patient with exit site infection, Achromobacter xylosoxidans, was treated with oral ciprofloxacin for 3 weeks resulting in a slow improvement of the exit site. During treatment the patient experienced erythema, discomfort, and discharge. At the end of the treatment, repeat cultures drawn from the exit site were negative. The patient with Aeromonas hydrophilia peritonitis is currently being treated with intraperitoneal Gentamicin.

Conclusions: Achromobacter xylosoxidans and Aeromonas hydrophila are both rare bacterial infections that have a history of causing infections in immunocompromised individuals exhibiting multiple risk factors. We reported exit site infections and peritonitis in end stage kidney disease patients. Both infections have been treated without any adverse effects or removal of peritoneal dialysis catheters.

PUB104

Bicarbonate-Rich Peritoneal Dialysis as Salvage Therapy for Metabolic Acidosis

Elise L. Stephenson, Ryan A. Carver, Jessica R. Burgess, Thomas R. McCune. *Eastern Virginia Medical School, Norfolk, VA.*

Introduction: Use of peritoneal dialysis (PD) in ICUs in developed nations is limited. The need for emergent dialysis is often considered a contraindication for peritoneal dialysis and the large peritoneal surface area is often neglected in the resuscitation of critically ill patients. We report a case of successful emergent PD with high bicarb dialysate in an actively dying patient not tolerating standard renal replacement therapies.

Case Description: A 36 yo male with no medical history sustained multiple gunshots. He was found to have multiple injuries in the small bowel including the duodenum. Two 15-french drains were placed at the time of surgery. While initially stable, he gradually developed worsening hypotension and developed abdominal compartment syndrome requiring a bedside laparotomy that evening. A severe metabolic acidosis remained refractory to standard therapy. CRRT was started briefly but he was unable to tolerate due to worsening hypotension. His pH worsened (pH 6.97) with bicarb 6mmol/L and lactate (LA) 26.9mmol/L. Family said their goodbyes and he was made DNR. Methylene blue was given without hemodynamic change. Given his young age, inability to tolerate CRRT and intraperitoneal access already available, decision was made for emergent PD as a final effort to control refractory acidosis. Approximately 1L of 1.5% peritoneal dialysate with an additional 300 mEq sodium bicarb/2L bag was instilled for a 30 minute dwell time. Within an hour, his labs showed pH 7.12, bicarb 15mmol/L, LA 16mmol/L and his vasopressor requirements decreased. After four exchanges, CRRT was initiated. His acidosis resolved within 24 hours and he was vasopressor free by 36 hours. He was extubated, dialysis dependent and continues to recuperate.

Discussion: PD in developed nations is often a forgotten modality for acute renal failure. We found only 2 published reports since 1980 using PD in the ICU for metabolic control. Our case describes successful use of high bicarbonate PD in the ICU to control refractory acidosis and achieve hemodynamic control. Data is lacking on the use of emergent PD in trauma patients and within ICUs despite its relative ease and low cost. High bicarbonate PD is an option for refractory acidosis in the critically ill.

PUB105

Myoclonic Seizures and Altered Mental Status in a Patient on Peritoneal Dialysis Treated with Piperazine

Sandra J. Jimenez Acosta,[2,1] Gustavo A. Guzman,[2,3] Daniel F. Arroyo Ariza.[2,1] *[1]Universidad de los Andes, Bogota, Colombia; [2]Hospital Universitario Fundación Santa Fe de Bogotá, Bogotá, Colombia; [3]Healthy Medical Center, Zipaquira, Colombia*.

Introduction: Here we present the case of a man on automated peritoneal dialysis (APD) with altered mental status and myoclonus after the self-administration of piperazine, an anthelmintic. This case illustrates how dangerous self-medication can be in patients with chronic kidney disease. Additionally, it shows that neither peritoneal dialysis nor hemodialysis appear effective methods for piperazine clearance in patients on renal replacement therapy (RRT).

Case Description: A 66-year-old man was brought unresponsive and with myoclonus to the ER. His past medical history included diabetes mellitus, with diabetic nephropathy that lead to ESRD. He was started on RRT 1 year before presentation; initially hemodialysis but later APD. He had no history of seizures or any other neurological disease. Physical examination on admission revealed a dehydrated, ill-looking patient. He was unresponsive to verbal commands. Myoclonus predominantly in his left arm was noticed. Initially we

suspected bacterial infection as the cause of the altered mental status, empirical antibiotic treatment was initiated. However, the patient's symptoms persisted, requiring care at the ICU and intubation. Further interrogation of the patient's family revealed that he had self-administered a full bottle of piperazine hexahydrate. An infectious cause was ruled out and no clinical improvement was achieved with antiepileptics. At this point piperazine intoxication was our most likely diagnosis. After a week of APD we decided to switch RRT to sustained low efficiency hemodialisys (SLED). He received two sessions. Gradually the patient's mental status improved and was discharged with his usual APD.

Discussion: The most common symptoms of piperazine intoxication are myoclonus, decreased level of consciousness and ataxia. Few data is available regarding the dializability of this medication, and neither PD nor HD seem effective treatment options. Hemoperfusion seems a suitable alternative. Clinical improvement in this case may be due drug metabolism, independent of treatment. We want to highlight the importance of education in renal patients, specially in the dangers of self-medication. Fortunately, our patient had a full recovery. But that may not be the case of other patients who inadvertently poison themselves with "safe" medications; like piperazine.

PUB106

Two-Year Follow-Up of Quality Indicator Compliance in a Large International Peritoneal Dialysis Institution

Belen Marron, Suzanne H. Pearce, Charlotta Wollheim, Carlos Lucas, Marietta Török, Israel P. Silva, Filiz Akdeniz, Fernando Macario. *Diaverum Renal Services. Corporate Medical Office, Hyllie, Mälmo, Sweden.*

Background: Peritoneal dialysis (PD) practice is not universally homogeneous, best clinical practices are not completely understood as reference values are often obtained from small sized populations and/or frequently based on chronic kidney disease (CKD) and/or hemodialysis data. **Objectives:** To evaluate two years of follow up of compliance with PD-related quality indicators (QIs) following definition of new targets in an international PD network.

Methods: All English and Spanish language CKD and PD guidelines were reviewed. Twelve Qis were considered being of significant relevance and targets for these QIs were defined (see table). Retrospective data analysis

Results: Achievement of QI targets for years 2017-2018 is shown in table (image). Variability among countries not shown.

Conclusions: There was a significant increase in QIs achievement in 2018 vs. 2017. ≥75% of patients met the target for the following variables: total weekly Kt/Vurea, 24 h fluid removal, mean arterial blood pressure and serum albumin. Peritonitis rates are clearly over International objectives and were improving. Due to the lack of referral source data, these series may help to understand PD practice and outcomes in a global setting.

Acyclovir-Induced Encephalopathy in a Patient on Peritoneal Dialysis

Aireen Kate M. Kuan, Shamir Hasan, Yuriy Khanin, Hugo Andrade paz, Nupur N. Uppal, Mala Sachdeva. *Northwell Health, Great Neck, NY.*

Introduction: Acyclovir is an antiviral agent that is used for treatment of diverse viral pathologies. The regular pharmacokinetics for acyclovir is altered with kidney dysfunction. At present, our knowledge regarding treatment of acyclovir neurotoxicity in patients undergoing peritoneal dialysis (PD) is limited, as only few case reports have been published. We describe a case of acyclovir induced encephalopathy in a PD patient that was successfully treated with hemodialysis.

Case Description: 34F with a history of systemic erythematous lupus (on prednisone, cellcept and plaquenil), ESKD on peritoneal dialysis (PD), subclinical hypothyroidism, anemia and hypertension was admitted for herpetic lesions of her lips and right eyelid. She was initiated on intravenous acyclovir at a dose of 500mg daily. 24 hours later, she developed acute confusion which progressed to include myoclonus, lethargy and coma. Labs on admission revealed hemoglobin 10, Na 137, K 4.6, Cl 92, CO2 22, BUN 64, Cr 20.85. CT head was negative. EEG did not reveal any epileptiform activity. Lumbar puncture and brain MRI did not show any evidence of viral encephalitis. Acyclovir neurotoxicity was considered as the etiology for her severe encephalopathy. Acyclovir was held and her CCPD prescription was increased but she continued to remain encephalopathic. A decision to initiate hemodialysis (HD) was made. After the first HD session, her mentation slightly improved. She received a total of 3 HD sessions, after which her mental status completely returned to baseline. Given that she improved after discontinuation of acyclovir and with HD this confirmed her diagnosis of acyclovir induced neurotoxicity. She was switched back to PD after recovery.

Discussion: Dose adjustment for acyclovir is recommended in patients with ESKD. Even when the acyclovir dose is adjusted for these patients, it can still cause neurotoxicity. This complication seems to be more common in those on PD likely due to the slower removal of the medication with PD. Clinicians need to be aware of this potential adverse event, as this diagnosis needs prompt recognition and treatment. Clearance of acyclovir with PD is not completely understood and in fact PD was not adequate to help with clearance in our patient despite increasing her prescription. The modality of choice for clearance of acyclovir in toxicity is hemodialysis.

PUB108

The Analysis of Risk Factors for the Patients with Venous Needle Dislodgment and Bleeding During Hemodialysis

Hsuan Ming Lin,[1] Wen H. Wu,[2] Hsiang Wei Hu.[3,4] *[1]An Nan Hospital, China Medical University, Tainan, Taiwan, Tainan City, Taiwan; [2]Department of Healthcare Administration of I-Shou University, Taiwan, Kaohsiung, Kaohsiung, Taiwan; [3]National Cheng Kung University, Tainan, Taiwan; [4]Acusense Biomedical Corp., Tainan City, Taiwan.*

Background: A puncture of vascular access is commonly used in clinical treatment, such as hemodialysis or central venous catheters. Leakage or infection associated with Venous needle dislodgement (VND) is a high risk of fatality. However, only a few studies are focusing on patient disease, medication, and other risk assessments. Therefore, this study aims to explore the risk factors of patients with venous needle dislodgment and bleeding and hope to establish the risk classification.

Methods: This study was a prospective study conducted in the hemodialysis unit of Tainan Regional Hospital. During the three months from July 2019 to Sep 2019, we collected clinical data, including patient sex, gender, diseases, records of dialysis access leakage, anti-coagulant dose, and a risk assessment form. We compared the data between the two groups of patients who have at least one risk in the risk assessment form. We analyzed the data with STATA™. P<0.05 was defined as significant.

Results: In the study period, seventy-one patients were included in this study, with an average age of 63.0 (± 1.19 years) and 46 males (64.79%). The patients with any risk in the risk assessment form were considered the high-risk group. There were 72 venous needle dislodgment and bleeding in 32 patients during the study period. In the below feature, gender, high-risk group or not, diabetes, high blood pressure, exposure to Benzodiazepine, the experience of Intradialytic hypotension, exposure to warfarin, or dosage of anti-coagulant, there was no statistic significant between the patients experienced at least one episode of VND and others.

Conclusions: Between patients experience VND or not, we did not find any significant association in not only conventional factors or other factors. However, this study provides a reference for future research.

Association between Venous Needle dislodgement and bleeding and other risk factors

PUB109

Catheter Malposition: Unacceptable Reason for Access Dysfunction

Yuliya Sharakova, Mohamed Hassanein, Evamaria Anvari, Tushar J. Vachharajani. *Cleveland Clinic, Cleveland, OH.*

Introduction: In 2017, 80% incident and 20% prevalent patients in the US received hemodialysis (HD) with a catheter (CVC). CVC placement with ultrasonography and fluoroscopy guidance (FG) is an accepted standard of care to avoid early mechanical complications. Early dysfunctional CVC (dCVC), defined as malfunction in <1 week of insertion is often due to a malpositioned tip leading to inadequate HD and a higher risk of bacteremia. We present a series of early dCVC, a preventable complication.

Case Description: Case 1: 42 y/o male had left IJ non-tunneled CVC placed for continuous dialysis therapy. Encountered multiple episodes of circuit clotting soon after initiation of therapy despite heparinization. The dCVC tip was found to be abutting against the innominate vein wall preventing adequate blood flows. An attempt to place a tunneled right subclavian vein catheter at bedside, without fluoroscopy was unsuccessful. Chest XR showed the CVC tip in the left IJ. **Case 2:** 30 y/o male with a pre-existing right portacath presented with several episodes of non-sustained ventricular tachycardia, 2 days after a newly placed left dialysis CVC. Chest XR showed portacath had disconnected and migrated to the right ventricle. Removal of the dislodged portacath led to resolution of arrhythmia. Dialysis CVC was preserved. **Case 3:** 49 y/o obese female had poor blood flows (300 ml/min) in catheter and frequent alarms that failed to improve despite tPA and port reversal. dCVC resulted from tip retraction from right atrium into SVC requiring replacing with a longer CVC. **Case 4:** 65 y/o female with left IJ tunneled CVC, placed under FG, had poor blood return 2 days after placement. The CVC tip had migrated to the right innominate vein. Catheter was replaced successfully. **Case 5:** 70 y/o male encountered clotting of the continuous dialysis circuit soon after initiation with a left IJ CVC, requiring replacement of circuit to continue with therapy. Evaluation showed a short CVC with tip abutting against superior vena cava (SVC) wall and required replacing with a longer CVC.

Discussion: Recognizing and troubleshooting early dCVC is an essential learning milestone for a nephrology trainee. Evaluation of a dCVC includes chest XR, forceful saline flush and appropriate use of tPA. Most of these mechanical complications are preventable with proper training and utilizing imaging tools during the procedure.

PUB110

Percutaneous Transluminal Angioplasty in Arteriovenous Fistula Dysfunction Secondary to Vascular Stenosis

Mohammed Shoeb Ahmed Khan, Vinod Kumar. Aster Medcity *Aster Medcity, Kochi, India*.

Background: Arterio-venous fistula (AVF) is the lifeline of a hemodialysis patient and the number of vascular access sites are limited in a patient. Vascular stenosis necessitates vascular intervention or creation of a "de novo" AVF. In this study we aimed to evaluate the outcome of percutaneous transluminal angioplasty (PTA) in arterio-venous fistula due to vascular stenosis.

Methods: This is a prospective study of two years (02.05.17 to 02.05.19). Records of patients admitted to our hospital were obtained from hospital archives and images from the hospital radiology archive system. Demographic characteristics, duration of dialysis, stenosis or occlusion level, patency rates of AVF were evaluated. All procedures were performed by interventional radiologists in a hybrid cath lab. Antegrade, retrograde, or both antegrade and retrograde punctures were used, depending on the site of the stenosis as deemed on preoperative ultrasound. A complete angiogram from the proximal arteriovenous anastomosis to the central venous outflow was performed in all cases. A successful percutaneous balloon angioplasty was defined when there was no more than 30% residual stenosis (KDOQI). AVF patency rates were assessed at six months and one year.

Results: Total number of patients studied were 16. The average age was 66.6 years. All were hypertensive and diabetics comprised 75% of study group. Coronary artery disease was established in 81.25%, and two patients were known to have chronic liver disease. Most common type of AVF was the left brachio-cephalic (62.5%), followed by radio-cephalic (37.5%). Average dialysis vintage of AVF at the time of procedure was one year. Previously failed AVF was present in two patients. There were 18 vascular stenosis in 16 patients. The most common site of stenosis was the venous cannulation zone (62.5%), followed by anastomotic site stenosis (31.5%) and central vein stenosis (18.75%). Successful PTA was done in 12 patients. There were no complications; hemodialysis was resumed within 24 hours after the procedure. The primary patency rate at three months was 100%, six months was 75% and at one year it was 37.5%. Four patients were lost to follow up. Mean follow up was 9.41 ±6.79 months. None underwent a repeat PTA.

Conclusions: Percutaneous transluminal angioplasty is effective for salvaging arterio-venous fistula in majority of hemodialysis patients

PUB111

A Tale of Two Accesses: The "Less Is More"

Sherif Metwally, Anil K. Agarwal, Khaled Boubes. *The Ohio State University, Columbus, OH.*

Introduction: Well-functioning dialysis access is of utmost importance as the lifeline of those with end stage kidney disease (ESKD). We present 2 patients with 'imperfect' accesses where a conservative approach avoided potentially problematic interventions.

Case Description: Case 1 A 24 year old man started hemodialysis (HD) in 1992 due to IgA nephropathy. He received a kidney transplant in 2000 which failed in 2005 requiring resumption of HD. His vascular access history is complex, including multiple bilateral failed arteriovenous (AV) fistulae and AV grafts requiring numerous access interventions including tunneled HD catheter placements, angioplasties, and thrombectomies. He has also developed severe contrast allergy, making any further endovascular interventions difficult. Since 2005 he has been dialyzing through a right upper extremity AVF complicated by central venous occlusion causing mild right arm swelling. Last resort vascular access options including a femoral AVG and a HeRO graft were contemplated. However, clinical decision making based on the presence of extensive collateral circulation, we opted for a conservative approach instead utilizing low blood flow rates. He has been doing well on this prescription for the last 3 years with adequate dialysis and swelling resolution. Case 2 A 67 year old woman with ESKD started peritoneal dialysis (PD) 2 years ago. PD was complicated by recurrent malpositioning of PD catheter with the catheter tip repeatedly migrating to the right upper quadrant. Changing the catheter insertion site and suturing it to the bladder wall did not prevent tip migration. Transition to HD was contemplated but she was able to continue with PD albeit with position changes to allow for complete drainage of PD fluid. Despite occasional sluggish drainage of PD fluid, the patient continued on PD for a total of 15 months before receiving a kidney transplant.

Discussion: These 2 cases illustrate the importance of dialysis access function as well as the dilemma of both the patient and provider when it becomes dysfunctional. The cases, however, also demonstrate that anatomical perfection is not always necessary to achieve adequate function. In both cases, a conservative approach allowed the patient to optimize dialysis through their existing 'malfunctioning' access and avoided further interventions that could result in worse complications, proving the adage 'Less is More' still true for dialysis access.

PUB112

What Are Nephrologists' Preferences Related to Continuing Medical Education?

Amy Larkin, Donald Blatherwick. *Medscape LLC, New York, NY.*

Background: Understanding how clinicians prefer to learn and participate in continuing medical education (CME) can help providers of such education design more engaging and effective activities that can potentially further improve nephrologists' clinical performance.

Methods: Medscape conducted a 10 question, online, incentivized survey in November 2018. Respondents' confidentiality was maintained and responses were de-identified and aggregated prior to analyses.

Results: Most preferred duration for a CME activity: 30 minutes (51%) Followed by 15 minutes (31%) Most preferred format for a CME activity: online (70%) Followed by live events at a medical conference (13%) Most preferred format for an online CME activity: video and text (45% each) For online CME/CE, most preferred instructional design format: case-based (56%) Most important factors in selecting online CME/CE activities: content description (60%) and learning objectives (56%) The most important factors in selecting which symposia to attend at a scientific congress were content description (60%), learning objectives (41%), and faculty (37%) Most common ways of becoming aware of available professional education activities: invitation from online providers (79%) and societies (74%) The majority of participants reported that in the past 12 months they have learned something from CME that changed their practice (86%) Serial learning is more impactful and clinically meaningful than a single activity (80%)

Conclusions: CME activities have an impact on changing clinician practices. Learner preferences for nephrologists related to live and online CME were identified. Most prefer participation in multiple activities that are online, 15-30 minutes, case-based, video and text. Content description, learning objectives, and faculty play an important role in learner participation. These data should inform development of future CME activities that are engaging and impactful.

PUB113

Online Education Effectively Improves Nephrologists' Knowledge, Competence, and Confidence Related to Hyperkalemia Management

Amy Larkin, David R. Anderson, George Boutsalis. *Medscape LLC, New York, NY.*

Background: To improve outcomes for patients, clinicians must be able to implement evolving standards of care and apply relevant data on hyperkalemia management. We sought to determine if an online continuing medical education (CME) curriculum could improve hyperkalemia management.

Methods: The online CME curriculum consisted of 4 activities. Of these, 3 were 30-minute video panel discussions. A repeated pairs pre-/post-assessment study design was used and McNemar's test assessed educational effect for each activity. The last activity comprised two patients presenting in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments in a manner matching the scope and depth of actual practice. Tailored clinical guidance (CG), based on current evidence and expert recommendation, was provided following each decision, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user's baseline (pre-CG) decisions using a 2-tailed paired t-test to determine *P* values. The activities launched in 2019 and data were collected for 4-12 weeks.

Results: Education significantly improved physicians' knowledge, competence, and performance managing and treating hyperkalemia. A 40% relative increase was observed among nephrologists related to knowledge of clinical trial data related to hyperkalemia. Nephrologists also significantly improved their knowledge and competence regarding the use of therapies in practice, with a relative increase of 16% observed. Case based simulation had a strong and significant positive impact on physicians' performance in the treatment of hyperkalemia. The % of physicians who decided to start preferred potassium-binder more than tripled after education.

Conclusions: Some gaps still remain after education. Over 40% physicians are still not equipped with the right information regarding clinical trial data and the use of therapies in practice. In addition, an average of 40% physicians are still not making the right decision to start preferred potassium-binder. As such, further education needed in these areas.

Funding: Commercial Support - independent educational grant from Astrazeneca and Fibrogen

Themes	N	% Correct Pre	% Correct Post	% Relative Change
Knowledge/Competence: Clinical Trial Data	225	38%	53%	40% (P < .001)
Knowledge/Competence: Use in Practice	230	49%	57%	16% (P< .05)
Performance: Initiate Newer Potassium-binder	160	15%	66%	340% (P < .001)

PUB114

Renal Clinic Quality Improvement Education Initiative

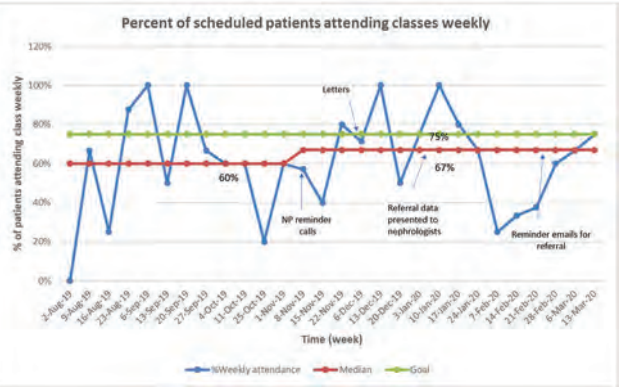
Rui Song,[1] Iryna Danylyuk,[1] Colleen Rabbitt,[1] Diane Y. Woodford,[1] Wayne A. Satz,[1] Mark G. Weiner,[2] Suma Prakash.[1] *[1]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [2]Weill Cornell Medicine, New York, NY.*

Background: Benefits of timely CKD modality education include increased knowledge and home dialysis. At our centre, attendance of scheduled CKD 4/5 patients to education sessions was low. This quality improvement study was initiated and aims to increase the prevalent percentage of CKD 4/5 patients who received CKD modality education from 40% to 55% over one year.

Methods: Outcome measure was prevalent weekly percentage of CKD 4/5 patients who completed education. Process measures were 1) weekly percentage of scheduled patient education attendance and 2) weekly number of incident CKD 4/5 patient education referrals by nephrologists. Ishikawa diagram was utilized to determine system gaps and develop changes to test in plan-do-study-act (PDSA) cycles. Changes tested were: a) NPs tracking weekly class attendance, b) NP reminder calls, c) information letter mailed to patients, d) referral data presented to nephrologists, e) reminder emails to nephrologists on education eligible patients. Discussion with primary care colleagues and 5-whys tool resulted in developing an information webpage for patient education including NPs' zoom recorded sessions. Median outcome and processes were calculated and plotted on run charts.

Results: Prevalent percentage of CKD 4/5 patients educated decreased from 40.6% to 29.4%. All referred patients have not yet been educated due to COVID19 and number of new patients increased over time. Median weekly session attendance increased from 60-67% with PDSA cycles a-c (Figure 1). Monthly incident education referral number increased from 5-18/month.

Conclusions: Weekly session attendance and incident education referrals increased. Prevalent percent patients educated deceased but number of incident referrals increased. To provide a virtual information option for patients with barriers to attending sessions and for use during COVD19 pandemic, the webpage described is a helpful resource developed as a result this project. We anticipate this tool will increase the outcome and both process measures over time.



PUB115

Optimizing On-the-Go Learning Utilizing Short Modules on Topics Related to Nephrology

Kiran Munir, Farah Daccueil. *Stony Brook University Hospital, Stony Brook, NY.*

Background: Residents and medical students are expected to formulate evidence-based treatment plans by keeping up with the most recent guidelines but that can be difficult given our schedules. In such circumstances, it is ideal to learn bite-sized pieces on the go.

Methods: We created two modules about Phosphorus Binders and Oral Hypoglycemic Agents using a friendly graphic interface called Prezi. These modules were estimated to take 10-15 minutes and were accompanied by a total of seven content related questions that were compiled from Uworld Step 3 Question Bank, John Hopkins Primary Modules, and hospital courses of patients seen at Stony Brook. Survey monkey was utilized to create the pre and posttest. The modules were sent to third and fourth year medical students. Data was collected for 10 days.

Results: Wilcoxon signed rank test was utilized to evaluate the effectiveness of the modules. Unfortunately, only six students completed the hypoglycemic module of which two had no improvement in scores, so no statistical significance was achieved. However, four of the six students had improvement in posttest scores by at least one point. Improvement in the posttest scores for the phosphorus module was significant as of the nine students who completed the phosphorus module, eight had an improvement by at least 1 point (W 36, p=0.008).

Conclusions: The observation of improved posttest scores for the phosphorus module supports the use of short lessons using a friendly graphic interface such as Prezi.

PUB116

Wabishki Bizhiko Skaanj: A Learning Pathway to Foster Better Indigenous Cultural Competence Within Canadian Kidney Research

Helen Robinson-Settee, Craig Settee. *Can-SOLVE CKD Network, Vancouver, BC, Canada.*

Background: Can-SOLVE CKD is a kidney research network in Canada within which Indigenous patients, caregivers, researchers, and community leaders have created an Indigenous Peoples' Engagement and Research Council (IPERC). A key component of IPERC's work is the creation of a new learning pathway, Wabishki Bizhiko Skaanj ("White Horse" in Anishinaabemowin), that will help researchers build respectful partnerships with Indigenous peoples within the health research setting. Wabishki Bizhiko Skaanj aims to enhance researchers' knowledge of racial biases, Indigenous voices and stories, the impact of colonization, and culturally safe health research practices.

Methods: A working group including members of the Can-SOLVE CKD Network, Diabetes Action Canada, First Nations Health Authority (BC), Provincial Health Services Authority (BC), and First Nations Health and Social Secretariat of Manitoba is leading the pathway's development. Two in-person workshops were held in October 2017 and March 2018 to develop the concept and identity of the curriculum, which consists of interactive learning exercises, facilitated online modules, and webinars. Several components of the pathway have been piloted and feedback is being gathered via surveys, pledges, and stories.

Results: The pathway's content is designed to help participants understand, recognize, and correct the racism that occurs in health care and research, in some cases caused by their own conscious and unconscious biases. Through enhanced knowledge, self-awareness and strengthened cultural competency, Wabishki Bizhiko Skaanj aims to support all partners in health care and research to close the gaps in health outcomes between Indigenous and non-Indigenous communities.

Conclusions: Wabishki Bizhiko Skaanj represents a novel learning platform for Indigenous cultural safety in Canadian health research. While Wabishki Bizhiko Skaanj was developed in the context of kidney health, the learning pathway can be adopted by networks and institutions across Canada, to help reduce and ultimately eliminate the racism that Indigenous people face within the health care system.

PUB117

Ethylene Glycol Poisoning with Near-Normal Osmolal Gap: A Diagnostic Challenge

Moeed Ahmed, Cliff Janikowski, Aiza Ahmad, Lee E. Morrow. *Creighton University School of Medicine, Omaha, NE.*

Introduction: Ethylene glycol poisoning is classically associated with a high anion gap metabolic acidosis (HAGMA). Neurological and gastrointestinal symptoms predominate early while renal failure and death occur if not diagnosed and treated promptly. The diagnosis is usually suggested by HAGMA and an elevated serum osmolal gap in the setting of a suspected ingestion. Rarely, the serum osmolal gap may be close to normal which can delay the diagnosis or lead to a misdiagnosis. We report a case of ethylene glycol ingestion with near-normal serum osmolal gap.

Case Description: An 85-year-old man with a past medical history of Dementia presented to the Emergency Department with altered mental status, restlessness and elevated creatinine of 1.4 mg/dl (baseline 1.2mg/dl). History was difficult to obtain. Vital signs were normal and the physical exam was remarkable only for altered mental status. CT scan of the head did not reveal any acute abnormality. Laboratory workup revealed HAGMA (anion gap = 21 mEq/L, arterial blood pH = 7.26, serum bicarbonate = 9.3 mmol/L, lactic acid = 2.2 mmol/L) with a near-normal serum osmolal gap (12 mOsm/kg). Urinalysis, urine drug screen, blood ethanol, beta-hydroxybutyrate, acetaminophen and salicylate levels were normal. Given a high clinical suspicion for toxic alcohol ingestion, the patient was treated with IV fluids and fomepizole. Over the next few days, his mental status improved, and repeat laboratory workup demonstrated correction of the anion and serum osmolal gaps. Additional history obtained later from his family increased the suspicion for toxic alcohol ingestion. Ethylene glycol level, a send out lab, eventually resulted at an elevated level.

Discussion: The workup for a HAGMA should include evaluation of the serum osmolal gap in the setting of a suspected toxic alcohol ingestion. Although uncommon, the absence of an elevated serum osmolal gap should not prohibit treatment for toxic alcohol ingestion when the clinical suspicion is sufficiently high.

PUB118

A Not-So-Primeval Case Report of Elevated Creatinine Levels Following Work-Out Supplement Ingestion

Trevor W. Tobin, John S. Thurlow. Walter Reed National Military Medical Center Nephrology *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Creatine is widely used and may be associated with acute kidney injury (AKI). They also may cause elevated serum creatinine (sCr) levels without AKI. We present a case of elevated sCr levels following supplement ingestion in a healthy male. To our knowledge, this degree of sCr elevation following supplement ingestion has not been reported in the absence of AKI.

Case Description: A 26 year old male with no medical history was seen for an elevated sCr (2.9 mg/dL) found on labs 3 weeks earlier. Baseline sCr was 1.3-1.4 mg/dL. He endorsed polyuria for 1 year. He denied ingestion of supplements, but reported working out 6 days per week. His BP and physical exam were normal. On UA, specific gravity was 1020, pH was 6.5, and sediment was unremarkable. He was asked to obtain a renal panel and a cystatin C (CyC), followed by a 24 hour urine collection to document urinary volume clearances. SCr had declined to 1.57 mg/dL that day, but on turning in his 24 hour urine sample, sCr was 16.21 mg/dL. A renal panel was repeated in the ER. He received only one urine collection container and filled it after 12 hours. He also reported taking two exercise supplements with work outs: Primeval Labs EAA Max™ and Protein Whey. BP, examination, and urine microscopy remained unremarkable. See Table for laboratory results. At appointment (apt) 2, the patient had abstained from supplements for 72 hours. He was counseled to continue to avoid these in the future.

Discussion: We present a case of elevated sCr's following ingestion of workout supplements in a healthy male. This case was unique given the degree of sCr elevation. The patient had normal CrCl, CyC eGFR, and a pattern of osmolar and electrolyte free water clearance consistent with a solute diuresis. Cr is usually not considered an effective osmole because it is present in insignificant amounts, but very large amounts of ingested creatine can increase Cr levels and also act as an effective osmole.

Creatinine and Cystatin C Levels

Date	Cr (mg/dL)	CyC (mg/L)
7/19	1.4	
8/19	1.3	
3/20	2.9

Compensatory Rules for Simple Acid-Base Disorders

Mohammad Amin Fallahzadeh,[1] Mohammad Kazem Fallahzadeh Abarghouei,[2] Michael Emmett.[1] *[1]Department of Internal Medicine, Baylor University Medical Center, Dallas, TX; [2]Division of Nephrology, Unverisity of California San Francisco, San Francisco, CA.*

Background: Most acid-base compensatory equations are based on limited numbers of human observations. We searched the literature for all studies addressing the issue of acid-base disorder compensation. We then utilized all the available data to create an acid-base compensation diagram and generate more accurate compensatory equations.

Methods: We used 84 published articles that evaluated the acid-base blood gas parameters of patients with simple acid-base disorders. We extracted the measured bicarbonate and PCO_2 values of the observations in these articles to calculate the most accurate compensatory formulas for simple acid-base disorders.

Results: Our database was comprised of 3806 observations with simple acid-base disorders. Our results generally agreed with the Goldberg acid-base nomogram except for patients with severe metabolic alkalosis (Figure 1). The best proposed formula in the literature for simple acid-base disorders and the compensatory formulas generated by our data are illustrated in Table 1.

Conclusions: Although the formulas described in the literature perform relatively well in predicting the appropriate compensatory response to simple acid-base disorders, more accurate predictive formulas were developed.

Table 1. The best proposed equations in the literature and most accurate formulas for simple acid-base disorders

Primary acid-base disorder	The best proposed formula in the literature	Most accurate formula (Regression line)
Metabolic acidosis	$PCO2 = (1.5 \times HCO3) + 8 \pm 2$ (Winters' equation)	$PCO2 = (1.29 \times HCO3) + 9.82$
Metabolic alkalosis	$PCO2 = HCO3 + 15$	$PCO2 = (0.77 \times HCO3) + 20.41$
Acute respiratory acidosis	$\Delta HCO3 = (0.1 \times \Delta PCO2)$	$\Delta HCO3 = (0.07 \times \Delta PCO2) + 1.26$
Chronic respiratory acidosis	$\Delta HCO3 = (0.4 \times \Delta PCO2)$	$\Delta HCO3 = (0.24 \times \Delta PCO2) + 4.26$
Acute respiratory alkalosis	$\Delta HCO3 = (0.2 \times \Delta PCO2)$	$\Delta HCO3 = (0.33 \times \Delta PCO2) - 1.20$
Chronic respiratory alkalosis	$\Delta HCO3 = (0.5 \times \Delta PCO2)$	$\Delta HCO3 = (0.46 \times \Delta PCO2) - 0.19$

PUB120

Hypernatremia Three Ways

Jordan R. Evans,[1,2] Shweta Bansal.[2] *[1]US Army Brooke Army Medical Center, Fort Sam Houston, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Introduction: Hypernatremia is a disorder commonly seen in hospitalized patients. It is often caused by dehydration from low water intake, GI, or urine losses. We present a case in which there were 3 distinct etiologies of hypernatremia that developed during the same admission.

Case Description: A 55 year old male with Down Syndrome and epilepsy was admitted from his nursing home for altered mental status and a 2 day history of lethargy and low oral intake. On admission, he had hypotension, tachycardia, and altered cognition from baseline but otherwise had unremarkable exam. He was diagnosed with klebsiella UTI, acute kidney injury, and hyponatremia. He was started on ceftriaxone and given 1 L of normal saline for hypovolemic hypernatremia, later switched to a continuous D5W infusion. Pertinent blood and urine chemistry after a liter of saline is shown in table 1. Over the next 4 days, sodium corrected slowly to 144 mEq/L, creatinine returned to baseline, and the D5W infusion was replaced with tube feeds. On day 6, he was again found to be hypernatremic but with polyuria. Urine chemistry (table 1) suggested osmotic diuresis which was attributed to high protein tube feeds. The polyuria and hypernatremia resolved with a change in feeds and D5W infusion. Meanwhile, he was found to be in status epilepticus and intubated for prolonged hypoxia. Despite maximal anti-epileptic treatment, he continued to have frequent seizures. On day 9, he again had polyuria and hypernatremia but this time with lower urine osmolality (table 1). A central DI process was considered due to hypothalamic injury from status epilepticus, which has been reported seldomly. The urine osmolality increased to 413 mOsm/kg 2 hours after desmopressin 2 mcg SQ, confirming the suspicion. His serum sodium and urine volume remained within

normal limits on scheduled desmopressin doses over next week; however, on day 15 family requested withdrawal of care due to ongoing seizures and futility of care.

Discussion: Our patient developed 3 episodes of hypernatremia during same admission, all due to different etiologies. This case highlights the importance of careful ongoing assessment of history and lab parameters since the best treatment strategy may change for the same diagnosis during the same admission.

Admission day	Serum sodium (mEq/L)	24 hr urine output (mL)	Urine osmolality (mOsm/kg)	Urine sodium (mEq/L)	Urine potassium (mEq/L)
1	179	200	514	115	37
6	156	5460	505	115	33
9	150	5125	244	31	23

PUB121

Pyroglutamic Acidosis: A Painful Gap in the MUDPILE

William L. Wilson, Yahya R. Ahmad, Javier A. Neyra, Taha Ayach. *University of Kentucky Medical Center, Lexington, KY.*

Introduction: Pyroglutamic acid (5-oxoproline) is a rare cause of metabolic acidosis most often associated with sub-acute or chronic acetaminophen intake in the presence of unique risk factors.

Case Description: A 25-year old female with Crohn's disease presented with one month of worsening abdominal pain, diarrhea, and anorexia with reported 20 kg weight loss. She developed septic shock secondary to sigmoid colon perforation and underwent sub-total colectomy and end-ileostomy. Her hospital course was complicated by stage 2 acute kidney injury (AKI) secondary to acute tubular necrosis with a peak creatinine of 0.8 mg/dL from baseline of 0.3 mg/dL. Her AKI gradually resolved with supportive treatment. Over a 10-day period, she received a total of 20 g of acetaminophen with a total daily dose <4 g/day. Subsequently, a persistent unexplained high-anion gap metabolic acidosis developed with serum bicarbonate levels as low as 11 mmol/L and a corrected anion gap of 26 mmol/L. Further laboratory data showed normal serum osmolality, blood urea nitrogen, beta-hydroxybutyrate, L-lactate, D-lactate, acetaminophen, and salicylate levels. Upon subsequent investigation, a urine 5-oxoproline level was markedly elevated at 26,740 mmol/mol creatinine. The patient's severe metabolic acidosis resolved with discontinuation of acetaminophen and oral bicarbonate supplementation.

Discussion: Pyroglutamic acidosis is an often underrecognized condition requiring a high index of clinical suspicion for diagnosis. Urine or serum 5-oxoproline levels are needed for diagnosis, which may not always be readily available. Chronic acetaminophen use depletes intracellular glutathione resulting in increased levels of 5-oxoproline. Patients, like the one reported here, with malnutrition, female gender, sepsis, and kidney dysfuction are especially susceptible as they have lower glutathione levels leading to faster 5-oxoproline accumulation despite standard dosing of acetaminophen. Prompt recognition is essential for treatment with acetaminophen cessation and bicarbonate supplementation. The use of acetaminophen as an analgesic alternative to opioids is growing, especially in peri-operative and critical care settings. Clinical awareness of predisposing conditions and close monitoring of patient's acid-base and kidney status can help us mitigate this underrecognized complication of acetaminophen use.

PUB122

Amphotericin B Lipid Complex Inducing Distal Renal Tubular Acidosis

Ian J. Da Silva Lugo, Heydee M. Fournier, Carla I. Colon Nunez, Yamiris Rodriguez, Keysha Lopez vega, Alejandra A. Villagrasa Flores, Ileana E. Ocasio Melendez. *Univesity of Puerto Rico, Medical Sciences Campus, San Juan, Puerto Rico.*

Introduction: Amphotericin B is the drug of choice for most life-threatening fungal infections. Nephrotoxicity is a common adverse reaction of this medication and its lipid complex formulation is an alternative to ameliorate this risk. Renal Tubular Acidosis (RTA) is an uncommon but major complication that can occur, and close monitoring should be performed for rapid identification and management. We hereby present the case of a patient who developed distal RTA secondary to amphotericin B lipid complex.

Case Description: A 59-year-old male patient without known medical history was admitted to Hematology-Oncology Ward with Acute Myeloid Leukemia. Chemotherapy with cytarabine and idarubicin was initiated. The patient developed pancytopenia secondary to chemotherapy nadir and septic shock dependent of vasopressors. In addition, the patient suffered an intractable sinus congestion that lead to a biopsy in which invasive fungal sinusitis secondary to Aspergillus was revealed. Amphotericin B lipid complex was started and resulted in improvement of the infectious process. However, the patient developed a stage three acute kidney injury with associated hypokalemia of 2.9 mmol/L, hyponatremia of 129 mmol/L, and mixed high and normal anion gap metabolic acidosis of 21.4 mEq/L. Noted findings were consistent with distal RTA and high anion gap component due to renal failure. Amphotericin B was changed to another antifungal and potassium and bicarbonate were replaced. Treatment led to resolution of azotemia, electrolyte, and acid-base disturbances.

Discussion: Nephrotoxicity is induced after amphotericin B inserts into tubular cell membranes and creates pores that increase permeability, leading to kaliuresis and back diffusion of secreted hydrogen ions. Although this effect is less common with liposomal amphotericin, it has been described in the literature. In addition, the risk increases in the presence of other nephrotoxic agents or non-modifiable risks such as critical illness. This case highlights the importance of prompt recognition of distal RTA in the at-risk population as it can lead to an early adequate management and prevention of further deterioration.

PUB123

Treatment Pattern of Hyperkalemia Among Patients Presenting Emergency Department in China

Jianming Bian, Li Zuo, Houyu Zhao, Xu Han. *Department of Pharmacology, Chinese People's Liberation Army General Hospital, Beijing, China.*

Background: In China, the treatment pattern of hyperkalemia (HK) among patients presenting emergency department (ED) is not well described.

Methods: Data containing hospital information system (HIS) records of 157 hospitals, covering 30 provinces in China were extracted from Beijing Data Center for Rational Use of Drugs. Patients (aged ≥18 years old) in ED with record(s) of HK, defined as serum potassium (S-K) >5.0mmol/L, from 2015.1.1 to 2017.12.31 were included. The diagnosis rate was defined as the proportion of HK episodes that have diagnoses records. Treatment rate was defined as the proportion of HK episodes that have records of any HK treatment including diuretics, glucose injection + insulin (G+I), calcium injection, sodium bicarbonate, potassium binder or dialysis. Retesting rate was defined as the proportion of HK records that have potassium retest record(s) within 1 day.

Results: A total of 36,615 ED patients with at least one S-K record >5.0mmol/L each were included. The overall HK diagnosis rate was 9.2%. Diagnosis rates increased by the severity of HK, patients with S-K ≥7.0 mmol/L showed the highest diagnosis rate of 31%. The overall treatment rate within 2 days was 45.2%, treatment rates increased by the severity of HK. Analyzing the HK episodes with HK treatment, G+I (used in 72.4% of HK episodes), loop diuretics injection (used in 50.36% of HK episodes) were most commonly used, while oral potassium binders, including sodium polystyrene sulfonate and calcium polystyrene calcium, were used in only 0.2% of HK episodes. Combined treatments were observed, among which a combination of G+I and loop diuretics injection was used in 10.4% of episodes and a combination of G+I, diuretics injection, calcium injection and sodium bicarbonate was used in 7.4% of episodes. Subgroup analysis of HK treatment in patients with chronic kidney disease showed that, G+I (used in 71.7% of episodes), loop diuretics injection (used in 61.2% of episodes) were most commonly used. The overall retesting rate within 1 day was 19.36%. Patients with S-K 5.0-5.5 mmol/L were retested less frequently (15%) than those with S-K ≥5.5 mmol/L (22.4-30.6%).

Conclusions: In China, the diagnosis and retesting rates of HK in ED patients was relatively low. Glucose injection + insulin was commonly used to treat HK in ED, while oral potassium binders were rarely used. Combination of treatments was common.

PUB124

Factors Associated with Volume Overload in Pulmonary Arterial Hypertension

Shweta Bansal, Ahmad Altarawneh, Chakradhar Velagapudi. *The University of Texas Health Science Center at San Antonio Long School of Mediciine, San Antonio, TX.*

Background: Knowledge about the pathophysiology of volume overload in pulmonary arterial hypertension (PAH), a frequent and early complication, and major contributor to the development of right heart failure, is scant. We aimed to identify factors associated with volume overload in PAH patients.

Methods: We reviewed medical charts of consecutive 32 patients with PAH. Patients on loop diuretic were considered volume overloaded. Repeated measures of clinical and lab variables recorded at the time of each right heart catheterization (RHC) were included for analysis. For comparisons between diuretic and not-on-diuretic groups, we used independent t-test for normally distributed and Mann-Whitney U test for nonparametric variables.

Results: Mean age at last follow up was 51.2 ± 11.6 years, 100% were white, 94% were female, and mean estimated glomerular filtration rate (GFR) was 93 ± 19ml/min. Median follow-up was four years. Fifty-six percent patients were on loop diuretic. These patients on diuretic were significantly more edematous (1.24 ± 1.37 vs. 0.27 ± 0.63 score, p=0.005), had higher BMI (30.5 ± 6.3 vs. 25.1 ± 4.9 kg/m^2, p=0.002) and covered less distance on 6 minute-walk test (360 [300,413] vs. 420 [385,464] meters, p=0.012) than patients not on diuretic. No difference was noted in age, gender, BP, NYHA class, or oxygen saturation. RHC were performed ≥2 times more often in diuretic vs. non-diuretic group (68% vs. 28.6%, p=0.03). On RHC, right atrial pressure (RAP) was significantly higher (7.9±4.2 vs. 3.8±3.2 mmHg, p=0.006) and there was trend towards higher mean pulmonary artery pressure (49 ± 13.3 vs. 42 ± 12.5 mmHg, p=0.08) in diuretic group with no difference in cardiac index or pulmonary vascular resistance. Serum alkaline phosphatase was higher (106.8 ± 34.3 vs. 76.2 ± 35.3 U/L, p=0.02) in diuretic group with no difference in other blood work including BNP and estimated GFR. There was no difference in proportion of patients on PAH-specific therapies. On follow-up, four patients in each group died or were lost to follow-up.

Conclusions: High BMI and RAP, well-known factors associated with volume overload in other edematous disorders were applicable in our PAH cohort as well suggestive of presence of similar pathways of impaired natriuresis despite normal GFR. Further studies are required to confirm these pathways which can guide appropriate early-on therapeutics.

PUB125

A Negative Anion Gap with a Positive Outcome

Samantha E. Blank, Casey N. Gashti, William L. Whittier. *Rush University Medical Center, Chicago, IL.*

Introduction: The utility of an increased serum anion gap (SAG) in clinical practice has long been established. A decreased or negative SAG, however, often remains undiscovered or neglected. Overproduction of paraproteins, such as IgG (cationic) and

IgA (anionic), will cause deviations in SAG. In IgG myeloma, the combination of cationic IgG accumulation as well as hypercalcemia and hypoalbuminemia can lead to a low or negative SAG. We report a patient who presented with an unrelated chief complaint and was found to have a myriad of electrolyte abnormalities causing a negative SAG, eventually leading to a diagnosis of multiple myeloma.

Case Description: A 56 year old woman presented with right knee pain due to septic arthritis. Her admission labs were notable for a sodium of 124 meq/L, Cr 4.76 mg/dL. Her anion gap was -3 and her serum osmolality was measured as 316 mOsm/kg with a 50 mOsm/kg osmolar gap. Her total protein was noted to be 12.6 g/dL, albumin 2.1 g/dL, with hypercalcemia to 11.1 mg/dL and glucose 104 mg/dL. Her blood gas sodium was 137 mEq/L consistent with pseudohyponatremia. UAC and UPC were 187 mg/g and 780 mg/g respectively. SIEP and UIEP ultimately demonstrated monoclonal IgG Kappa. Her total protein increased to 13.7 g/dL; she subsequently became lethargic and developed epistaxis due to hyperviscosity syndrome with a serum viscosity of 9.2 relative to water. She underwent 3 sessions of plasmapheresis and her pseudohyponatremia resolved (Na 139 meq/L) and total protein improved to 8.9 g/dL. SAG increased to 7. Her mental status and epistaxis improved. Subsequent bone marrow biopsy confirmed 65% plasma cells. Patient was started on dexamethasone and bortezomib.

Discussion: This case illustrates the myriad presenting electrolyte derangements of multiple myeloma. The combination of pseudohyponatremia, negative SAG, increased osmolar gap, and high protein gap raised the suspicion of a cationic hyperproteinemia, which eventually led to the diagnosis of IgG multiple myeloma. The hypercalcemia and AKI were also classic features of her myeloma. Her mental status changes, which were thought to be from hyperviscosity, were indications to treat with plasmapheresis. A negative SAG is rare and has a limited differential diagnosis, with IgG myeloma as perhaps its most significant clinical etiology.

PUB126

A Surprising Complication Following Steroid Therapy: Tumor Lysis Syndrome

Jesus D. Vega Colon, Stephen Burry, Dev Boodoosingh. *Saint Luke Episcopal Hospital, Ponce, PR.*

Introduction: Tumor Lysis Syndrome (TLS) is a known lethal complication of chemotherapy and radiotherapy in malignancies with high tumor bulk. It is characterized by lysis of malignant cells causing hyperuricemia, hyperkalemia, hyperphosphatemia, hypocalcemia and acute renal failure. Few cases have been able to demonstrate the occurrence of TLS following steroid therapy alone in the absence of chemotherapy or radiotherapy.

Case Description: We report a 76-year-old female with Past Medical History of Hypertension, Diabetes Mellitus Type-II and Chronic Kidney Disease that came to our hospital complaining of pleuritic chest pain since 3 days. Vital signs and physical exam were unremarkable. Labs results were remarkable for hemoglobin 7.8 g/dl and serum creatinine 1.60 mg/dl. No evidence of leukocytosis, electrolytes disorders or positive cardiac markers were present. Patient was admitted with diagnosis of symptomatic anemia. During blood transfusion, patient developed an acute allergic reaction evidenced by generalized urticaria and bronchospasm. Single dose intravenous steroid therapy (methylprednisolone 20 mg) was given. After 48 hours post transfusion clinical condition continued to worsen. New labs showed leukocytosis (49.7 $10^3/\mu L$) and lactic acidosis (8.5mmol/L). Severe hypotension led the patient to developed acute respiratory failure requiring mechanical ventilation and vasopressors therapy. Further labs revealed typical findings of TLS including hyperuricemia:15.6mg/dL, hyperkalemia: 6.5mEq/L, hyperphosphatemia: 5.90mg/dL and hypocalcemia: 6.0mg/dL. Due to persistent leukocytosis (103 $10^3/\mu L$) flow cytometry studies were done showing evidence of monoclonal B lymphocytosis consistent with Chronic Lymphocytic leukemia. Treatment was initiated with aggressive hydration, allopurinol and rasburicase. Follow up labs revealed normalization of uric acid: 3.0mg/dl, potassium: 4.3 meq/L, phosphorus: 2.23mg/dl, calcium: 8.0 mg/dl and creatinine: 2.30mg/dl. Despite correction of metabolic abnormalities, patient was pronounced dead at day 15 hospital stay due to multiorgan failure.

Discussion: This case demonstrates the importance of early recognition of TLS following steroid therapy. Prompt prophylactic management prior to the use of steroid therapy is of utmost importance in patients with clinical suspicion of a hematologic malignancy, since this complication caries a high mortality risk.

PUB127

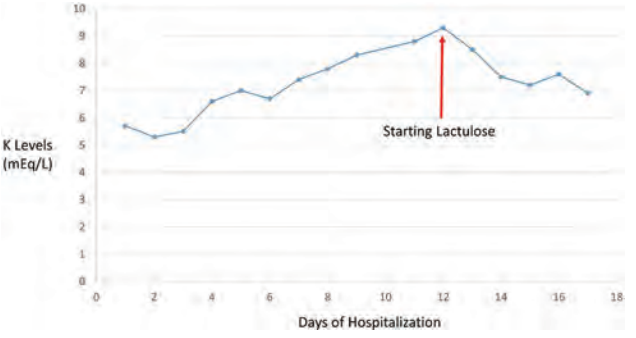
Laxative Use in Acute Hyperkalemia

Faisal Abdulameer,[1] Barry M. Wall,[1,2] Csaba P. Kovesdy.[1,2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]VA Medical Center, Memphis, TN.*

Introduction: The most effective treatment of severe hyperkalemia is hemodialysis. Treatment options for patients who are not candidates for renal replacement therapy are limited. Oral potassium binders, available for treatment of chronic hyperkalemia, are not approved for acute hyperkalemia. We describe a stage 5 CKD patient with severe hyperkalemia who was not a hemodialysis candidate in whom lactulose was used after other measures failed to lower serum potassium (K^+).

Case Description: 66 year old female with stage 5 CKD who was not a candidate for renal replacement therapy due to severe schizoaffective disorder was being managed medically. Her serum K^+ was controlled with patiromer 8.4 mg/day during the previous year. She presented with volume overload and uremic encephalopathy with hyperkalemia (K^+, 5.7 meq/l), high anion gap metabolic acidosis (serum CO_2 10 mEq/L) and serum creatinine, 20 mg/dl. She received 10 units of insulin with D50, 150 mEq of IV sodium bicarbonate, furosemide 60 mg IV daily, and patiromer 8.4 g/day. Her serum K^+ decreased to 5.3 meq/l after 24 hr, but increasesd to 7.0 mEq/L after 72hr. Patiromer dose was doubled to 16.8 g/day, and sodium bicitrate was added. Serum K^+ initially decreased to 6.7 meq/l, but subsequently progressively increased despite improvement of metabolic acidosis, repeated administration of insulin+D50 and albuterol, patiromer, and use of high dose loop diuretics, peaking at 9.3 mEq/L on day 11. Daily lactulose dose of 17 g daily was added, resulting in diarrhea and gradual decline in serum K^+ at an average rate of 0.7 mEq/L/day, reaching a nadir of 6.9 mEq/L after 72 hr. The patient unfortunately passed away on that day due to other uremic complications.

Discussion: Lactulose is a non absorbable disaccharide metabolized by colonic bacteria to noncarbohydrate organic acids, which acts as an osmotic cathartic. In this case lactulose was successfully implemented in treating severe hyperkalemia when all other measures failed. Controlled use of laxatives can be considered as a means to control hyperkalemia in patients who are not candidates for renal replacement therapy.



PUB128

Battling Warburg: Type B Lactic Acidosis in a Patient with Diffuse Large B-Cell Lymphoma

Stephen P. Regina,[1] Roberto L. Collazo-Maldonado.[2,1] Methodist Health System *[1]Methodist Health System, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: The Warburg effect is a rare paraneoplastic syndrome seen in patients with hematologic malignancy. The metabolism of cancerous cells converts to aerobic glycolysis and results in type B lactic acidosis.

Case Description: The patient is a 62-year-old man with diffuse large B-cell lymphoma and prior hemophagocytic syndrome (HS) diagnosed 6 months prior, on chemotherapy. He presented with several weeks of fever and respiratory symptoms. Clinical exam and diagnostics did not reveal a source of sepsis. Chest radiography and CT chest were without infiltrates. COVID-19 PCR was negative. Labs- WBC 1,500 /mm3, Hemoglobin 8.8 g/dL, Platelets 63,000 /mm3, creatinine 1.1 mg/dL, lactate 2.6 mmol/L, ferritin 417 ng/mL, serum triglycerides 349 mg/dL. Patient was placed on vancomycin and cefepime and volume expanded, but continued febrile with persistent lactic acidosis. Abdominal CT revealed splenomegaly with focal hypodensities, mild descending and sigmoid diverticulosis without diverticulitis. CT mesenteric angiography revealed moderate narrowing of celiac artery and severe narrowing of the inferior mesenteric artery origin. For suspected ischemic colitis, the patient was taken emergently for exploratory laparotomy, but findings did not support ischemia. Creatinine trended up to 2.0 mg/dL with increasing lactate of 11 mmol/L, bicarbonate 13 mmol/L, and serum pH of 7.0. At this point, without septic or ischemic processes identified, the lactate production was attributed to DLBCL, and not HS as ferritin was not substantially elevated. CRRT was initiated for anuric AKI. Lactate continued to trend up to 21.7 mmol/L with bicarbonate 6 mmol/L. Family discussions were held, and the patient was transitioned to palliative care.

Discussion: Type B lactic acidosis should be considered in the differential diagnosis in patients with increased anion gap metabolic acidosis and malignancy. One rare and potentially fatal Type B lactic acidosis is due to the Warburg effect, a rare and potentially lethal paraneoplastic syndrome of hematologic malignancies.

PUB129

An Uncommon Indication for Renal Replacement Therapy in Tumor Lysis Syndrome

Ian J. Da Silva Lugo, Samuel A. Collazo, Noelia C. Morales, Keysha Lopez vega, Alejandra A. Villagrasa Flores, Yamiris Rodriguez, Ileana E. Ocasio Melendez. *Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, Puerto Rico.*

Introduction: Tissue damage in Tumor Lysis Syndrome (TLS) results largely from the precipitation of uric acid and calcium phosphate. As calcium phosphate arises the risk for calciphylaxis increases, which can lead to severe renal failure in addition to other systemic complications. We hereby present a case with an uncommon indication for hemodialysis in a patient with tumor lysis syndrome.

Case Description: A 62-year-old male patient with Mantle Cell Lymphoma presented to the emergency room with a one-day history of hemoptysis, emesis, and fatigue. Laboratory workup revealed severe anemia of 6 g/dL, marked leukocytosis of 265.27 thousand/μL, increased uric acid 15.1 mg/dL, and elevated lactate dehydrogenase of 1,261 U/L. These findings were consistent with active disease, and upon admission, the patient

was started on IV hydration, dexamethasone, rasburicase, and allopurinol. On the fifth inpatient day, chemotherapy regimen was started, and white blood cell count decreased by approximately 50 thousand/μL. Two days after, laboratory values were remarkable for hyperkalemia of 6.1 mmol/L, blood urea nitrogen of 66.2 mg/dL, creatinine of 2.61 mg/dL, hyperphosphatemia of 8.5 mg/dL, and a corrected calcium of 7.1 mg/dL. These findings were suggestive of TLS following chemotherapy, along with the development of a non-oliguric stage three acute kidney injury. The next day, the patient had adequate urine output, stable blood pressures, no signs of volume overload or uremia, but laboratory values revealed worsening renal parameters and an increased calcium-phosphate product above 70 mg^2/dL^2. Consequently, hemodialysis was performed with good tolerance and response to treatment.

Discussion: The criteria for hemodialysis in this case of a non-oliguric euvolemic patient with acute renal failure secondary to TLS was founded on an elevated calcium-phosphate product, as opposed to more common indications such as anuria, fluid overload, or persistent electrolyte disturbances. The prognosis for complete recovery of renal function is excellent if dialysis is initiated early to rapidly reduce serum uric acid and phosphate concentration. This emphasizes the importance of a prompt assessment of the calcium-phosphate product as an indication for renal replacement therapy in the setting of tumor lysis syndrome.

PUB130

Hypomagnesemia and Proton Pump Inhibitors

Pooja Kalantri,[1] Jason M. Kurland.[2,3] *[1]Saint Vincent Hospital, Worcester, MA; [2]UMass Memorial Medical Center University Campus, Worcester, MA; [3]UMass Memorial Marlborough Hospital, Marlborough, MA.*

Introduction: Proton pump inhibitors (PPIs) are commonly used for GERD. They are associated with acute interstitial nephritis, B12 deficiency, Clostridium difficile infection, gastric malignancy, atrophic gastritis, bone fractures, and rarely, hypomagnesemia. We present a case of hypomagnesemia manifesting with unexplained hypocalcemia, refractory hypokalemia, and neuromuscular disturbances.

Case Description: A 63 year old male with GERD and prostate cancer (scheduled for prostatectomy), was found to have abnormal electrolyte values on routine preoperative evaluation. Two months ago, they were all normal. He had carpopedal spasms, facial twitching, frequency and weak urine stream for two months. He denied diarrhea, nausea, vomiting, fever, chills, medication changes or use of supplements. He drank alcohol socially. Trousseau sign was positive. Labs showed potassium 2.8 mmol/L, bicarbonate 27 mmol/L, BUN 12 mg/dL, creatinine 0.87 mg/dL, calcium 6.1 mg/dL, albumin 4 mg/dL, magnesium 0.9 mg/dL, and phosphorus 3.2 mg/dL. 25-OH vitamin D was 9 ng/mL, with normal 1, 25 (OH)2 vitamin D. PTH was elevated at 122 pg/mL. Fractional excretion of magnesium (measured after changing his PPI to an H2-receptor antagonist) was 2.5%. It was suspected that PPI use may have driven hypomagnesemia (which accelerated renal K+ losses), with associated PTH resistance and vitamin D deficiency (causing hypocalcemia). Symptoms resolved with electrolyte supplementation.

Discussion: Hypomagnesemia can result from gastrointestinal or renal losses. The presumed mechanism for PPI-induced hypomagnesemia involves impaired absorption of magnesium by intestinal epithelial cells caused by PPI-induced inhibition of transient receptor potential melastatin-6 (TRPM6) and melastatin-7 (TRPM7) channels. The aim of treatment is correction of magnesium and vitamin D first, resulting in rapid improvement of potassium and calcium. Our case is unique, as he developed the abnormalities so acutely. He was also restarted back on his PPI, along with magnesium supplements, and repeat electrolytes over the ensuing 4 months have been normal.

PUB131

Rising from Death: A Case of Life-Threatening Hyperkalemia

Sonali Gupta, Jeremy G. Taylor. *University of Rochester Medical Center, Rochester, NY.*

Introduction: Hyperkalemia affects the cardiac conduction and can result in fatal consequences. We describe a rare case of life threatening hyperkalemia presenting in setting of hyperglycemia, sepsis and shock and manifesting as new ST elevation in anterior leads, which resolved with correction of hyperglycemia.

Case Description: A 63-year-old male with intellectual disability and diabetes presented in state of shock after refusing his medications for last 5 days. His vitals on arrival were pertinent for hypothermia (T 29.1C) and hypotension (56/30 mm Hg). He had cold and clammy extremities and Glasgow Coma Scale of 5. Cardiovascular and abdominal examination were unremarkable. Laboratory result showed arterial pH of 6.9, serum potassium [K] of 11.1mg/dL, serum bicarbonate level of <6 mmol/L, serum phosphorus of 11.8 mg/dL, serum creatinine of 2.4 mg/dl (baseline 0.6 mg/dl), blood glucose of 1100mg/dL and serum sodium [Na] of 129mg/dL. Chest radiograph showed cardiac enlargement and electrocardiography (EKG) revealed absent P waves, prolonged QRS intervals, ST elevation in anterior leads, marked left axis deviation and tented T waves. The creatine kinase (CK) levels were normal but troponin T high sensitivity were elevated. He was treated with intravenous fluids, sodium bicarbonate, calcium gluconate, insulin drip, broad-spectrum antibiotics and norepinephrine. The blood glucose, potassium and bicarbonate levels improved with conservative management without need for renal replacement therapy. Subsequent transthoracic echocardiogram was negative for acute ischemic changes and repeat EKG showed sinus rhythm and resolution of ST changes.

Discussion: Severe hyperkalemia is dangerous and can result in cardiac arrest. Our patient presented with very high potassium levels, however hypothermic state might have reduced the metabolic demands and prevented immediate cardiac arrest. Hyperkalemia in setting of uncontrolled hyperglycemia usually responds to medical management if the patient is not anuric. Moreover, pseudo infarction as seen in this case is a rare manifestation of hyperkalemia. With the recent emphasis on reducing door-to-balloon times in ST elevation myocardial infarction, it is important to be aware of its association with hyperkalemia as it usually resolves with reduction of the serum potassium levels.

PUB132

Analysis by Bioimpedenziometria of Three Cohorts with Expanded Extracellular Volume: Critically Ill, Nephrotic, and Hemodialysis Patients

Waldo Bernales,[1] Patricio Vargas,[2] Gonzalo Correa,[3] Maria E. Sanhueza,[4] Fernando Gonzalez.[3] *[1]Hospital de Coyhaique, Coyhaique, Chile; [2]Clinica Alemana de Santiago SA, Vitacura, Chile; [3]Hospital Del Salvador, Santiago, Chile; [4]Hospital Clinico Universidad de Chile, Santiago, Chile.*

Background: By applying current, bioimpedanciometry provides information on body composition, estimating total body water (TBW) and extracellular water (ECW) with formulas. However, these estimates are imprecise in edematous patients. Fortunately, there are variables that are directly measured: resistance (R), reactance (Xc) and phase angle (AF), which in theory reflect the cells' ability to maintain adequate function. In our work, we mainly wanted to analyze this second group of variables in patients with increased ECV and additionally compare them with a group of healthy volunteers

Methods: Using a multifrequency bioimpedanciometer, we performed measurements on edematous patients in the ICU, edematous patients with nephrotic syndrome (NS), and anuric patients on hemodialysis (HD) before starting a random session. The control group were healthy volunteers (V) of the same age as the studied patients. A *t-test* was performed to compare each group against V and a *pearson's correlation test* was performed to assess correlation between variables

Results: During 6 weeks measurements were made getting data of 14 V, 11 HD, 13 SN and 11 ICU. When comparing against V, significant differences were obtained in R, Xc and AF, ($p<0.05$) in all groups except R in the HD group. When comparing among them the most edematous groups (ICU and NS), surprisingly no differences were obtained ($p>0.05$). In the estimated variables related to water distribution (ECW, TBW and ECW/TBW), the 3 groups show significant differences compared to V, except in TBW of the HD. Finally, when looking for a correlation between measured and estimated variables, we found that Xc has a high negative correlation (r: -0.75) with ECW; AF has a high negative correlation (r: -0.83) with ECW/TBW, while R has a moderate negative correlation (r: -0.67) with ECW and TBW

Conclusions: Our results show, the studied groups have differences in measured and estimated variables compared to V, theoretically reflecting a state of cellular malfunction in addition to the expansion of the ECV. Surprisingly, patients with NS and ICU are "electrically" the same, despite their very different clinical contexts. However, we cannot rule out that it is only due to expansion of the ECV of a similar amount since the measured variables depend to some degree on the estimated variables

PUB133

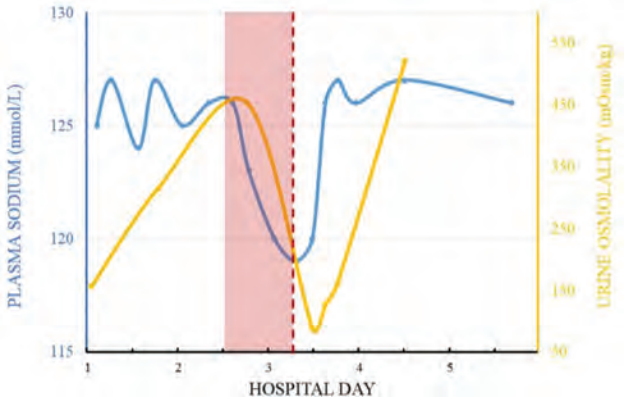
Intractable Hyponatremia, Polydipsia, and the Reset Osmostat: A Case Report

Mohamed T. Hassan Kamel, Ashish Upadhyay, Steven C. Borkan. *Boston Medical Center, Boston, MA.*

Introduction: Water intake in excess of water excretion results in hyponatremia, the most common electrolyte abnormality in clinical practice. Typically, ADH secretion fluctuates to maintain a physiologic serum osmolality, the so called "ADH osmostat". This threshold can be altered by multiple physiologic and pathologic stimuli.

Case Description: A 71-year-old man with severe depression, type II diabetes mellitus and chronic obstructive pulmonary disease presented to the hospital with diffuse weakness, difficulty with focused attention and suicidal ideations. He admitted to drinking more than 15 liters of liquid daily. Home medications included metformin, insulin, lisinopril, amlodipine, metoclopramide, pantoprazole, and trazodone. Physical exam revealed hypertension and truncal obesity, but was otherwise unremarkable. Laboratory investigation revealed a plasma sodium concentration of 120 mEq/L, blood urea nitrogen of 9 mg/dl, creatinine of 0.82 mg/dL, serum osmolality of 263 mOsm/kg and urine osmolality of 155 mOsm/kg with a urine sodium of 38 mEq/L. Because of neurological symptoms and worsening hyponatremia, the patient received 3% hypertonic saline infusion. Serum sodium was noted to fluctuate during periods of unsupervised access to fluid, hypertonic saline infusion and fluid restriction. Urine osmolality was also noted to flucutate, dropping appropriately with worsening hyponatremia and rising with fluid restriction, hypertonic saline and resultant rise in serum sodium. The rise in urine osmolality occured without normalization of serum sodium.

Discussion: In this report, we present a case of symptomatic hyponatremia associated with polydipsia in an elderly patient with psychiatric comorbidities and chronic hyponatremia. We describe the accompanying laboratory findings that support the diagnosis of reset osmostat. We postulate that chronc hyponatremia secondary to polydipsia related to psychiatric illness could have reset this patient's osmostat and discuss potential therapeutic strategies.



PUB134

An Unusual Cause of Rhabdomyolysis

Esilida Sula Karreci, Larissa Kruger gomes, Ruth Schulman, Krishna A. Agarwal, Amar Pandit, Bradley M. Denker. Beth Israel Deaconess *BIDMC, Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Rhabdomyolysis results from muscle cell injury and often leads to AKI. Common causes include trauma, medications, electrolyte abnormalities, and metabolic myopathies. The clinical presentation includes muscle pain, dark urine, and possibly oliguria. Here, we present an unusual etiology of rhabdomyolysis resulting from sustained hyperosmolarity due to severe hyperglycemia and hypernatremia.

Case Description: 23-year-old male with no significant medical history presented with fatigue, poor appetite for 10 days. He denied fever, nausea, vomiting, abdominal pain, diarrhea,. Despite drinking large amounts of fluids, he felt thirsty, with frequent urination. Family history: diabetes. Social history; no alcohol, smoking or drug use. No prescription/OTC medicines, or herbal supplements. Vital signs were notable for a heart rate of 110-120 beats/min. He appeared lethargic. Physical exam showed dry mucous membranes and tachycardia, otherwise unremarkable. Initial laboratory values showed blood glucose of 1132 mg/dL, Cr 3.5 mg/dl, Na 147 mEq/L (see table). Urine showed glucosuria and ketones, sediment was bland. He was started on an insulin drip. Corrected Na was 172 with a free water deficit 10L. Initially given 3L NS bolus followed by1/2NS to correct hypernatremia, with goal correction of 10-12 mEq in the first day. On day 3, he complained of weakness and difficulty getting up but no muscle soreness. He developed a temperature of 101oF and his exam was unremarkable. Creatinine and Na improved (see table), however, ALT/AST continued to rise. Right upper quadrant US showed hepatic steatosis. Repeat UA showed large blood, but no red blood cells on sediment. CPK returned at 111850 IU/L, and peaked at 195380 IU/L on day 5. He was given isotonic fluids at 500cc/h. He remained tachycardic with low grade fevers and on day 9, CTA showed bilateral pulmonary emboli.

Discussion: This case highlights an unusual cause of rhabdomyolysis caused by hyperosmolarity in HHS. Although, the literature suggests that rhabdomyolysis may be present in up to 50% of HHS cases, this is an extreme case and highlights the importance of looking for rhabdomyolysis in HHS. It is unclear why our patient showed such a severe phenotype.

PUB135

An Atypical Case of Hypocalcemia Associated with the Use of Patiromer

Muhammad T. Baig, Eshetu L. Obole, Jason Prosek, Khaled Boubes. *The Ohio State University, Columbus, OH.*

Introduction: Novel potassium (K) binders were approved a few years ago and introduced to the market. With their increased use, more side effects are surfacing. We report an atypical case of hypocalcemia that was associated with the use of patiromer.

Case Description: An 86 year-old male with stage 3 chronic kidney disease secondary to left radical nephrectomy from urothelial cancer, who was on patiromer for chronic hyperkalemia, presented with obstructive acute kidney injury (AKI) that was associated with hypocalcemia (6.3 mg/dL [8.6-10.5 mg/dL]), hypomagnesemia (0.6 mg/dL [1.6-2.6mg/dL]) and metabolic acidosis (CO2 16 [22-30 mmol/L]). Ionized calcium (iCa) was low at 3.34 [4.60 - 5.30 mg/dL] and phosphorus 4.6mg/dL [2.2 - 4.6 mg/dL]. His intact parathyroid hormone (PTH) was elevated at 121 [14.0 - 72.0 pg/mL], however, this was relatively lower than his baseline of 200-250 pg/mL. After adequate magnesium repletion and discontinuation of patiromer, his Calcium improved to 8.4 mg/dL, iCa improved to 4.20mg/dL, and his PTH went back up to his previous baseline at 220 pg/mL. His AKI improved following placement of a ureteral stent.

Discussion: Hypercalcemia is a known side effect of patiromer use since it exchanges calcium ion with potassium. To our knowledge, however, hypocalcemia has never been attributed to patiromer use. In this unique case, hypocalcemia was an indirect side effect caused by severe hypomagnesemia that was probably exacerbated by the use of patiromer. Hypomagnesemia can cause hypocalcemia through suppression of PTH secretion, which was evident in this case, along with increasing PTH resistance. Novel potassium binders have a myriad of useful indications; however, one should be vigilant to their effects on other electrolytes.

PUB136

Hypokalemic Periodic Paralysis

Margaret Mallari, Tamim H. Naber, Omar M. Shahateet. *AtlantiCare Regional Medical Center, Atlantic City, NJ.*

Introduction: Hypokalemic periodic paralysis (HOKPP) is characterized by transient episodes of muscle weakness and inability of muscle movement associated with hypokalemia. The paralysis typically affects the arms and legs, though the diaphragm and the tongue may also be affected.

Case Description: A 50-year-old female with tobacco use and significant alcohol consumption presented with progressive upper and lower limb weakness, numbness, and paresthesias that worsened over the past 2-3 months. She also reported fever, sweats, and unintentional 40-lb weight loss over the past 3 months. The patient denied use of diuretics and laxatives. Labs revealed serum potassium 1.9 mmol/L (3.5 - 5.2), phosphorous 2.2 mg/dL (2.5 - 4.5), bicarb 43 mmol/L (21-30), and a venous blood gas of 7.61/50/25/50, which is consistent with metabolic alkalosis. EKG demonstrated U waves and ST depressions significant for severe hypokalemia. She was admitted for severe hypokalemia and was given oral and IV potassium. Vitamin D was 16.0 ng/mL (30-100), which is suggestive of hypovitaminosis D. TSH and cortisol were normal, thus ruling out thyrotoxicosis and Cushing's, respectively. Serum aldosterone and renin levels were normal, thus ruling out adrenal involvement. The Transtubular K+ Gradient was calculated to be 4, indicating a renal tubular wasting of potassium. In addition to renal potassium wasting, the cellular shift of potassium in the setting of chronic malnutrition and prolonged alcohol use exacerbated the severe hypokalemia. The patient's potassium was repleted, and she was discharged from the hospital with close outpatient follow up.

Discussion: Hypokalemic periodic paralysis is characterized by transient episodes of muscle weakness in the setting of hypokalemia. HOKPP manifests itself as a sudden onset of weakness ranging from mild transient weakness of the arms and legs to paralysis of the diaphragm and accessory muscles, resulting in lethal respiratory failure. HOKPP can be triggered by a stressor, such as a viral illness or by specific medications, such as insulin or beta-agonists. HOKPP is important to rule out when evaluating a patient with abrupt onset of paralysis or weakness, especially in patients with no history or risk factors of other pertinent disease, such as stroke. The failure to diagnose and properly treat HOKPP can be fatal. It is vital to address the underlying cause of hypokalemia to prevent the recurrence of HOKPP.

PUB137

Screening Fabry Disease in CKD Patients in a Single Center of Middle Taiwan

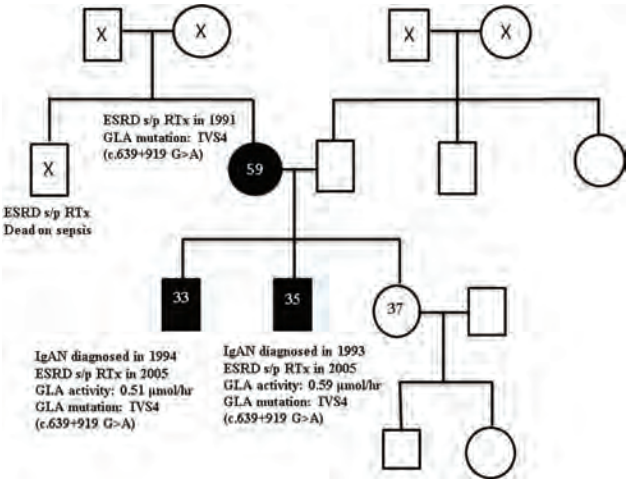
Cheng-Hsu Chen,[1,2] Tung-Min Yu,[1] Ya-Wen Chuang.[1] *[1]Division of Nephrology, Taichung Veterans General Hospital, Taichung, Taiwan; [2]Department of Science, Tunghai University, Taichung, Taiwan.*

Background: Fabry's disease (FD) is an X-linked inherited rare, progressive, lysosomal storage disorder affecting multiple organs due to the deficient activity of alpha-galactosidase (a-Gal A) enzyme. The prevalence has been reported to be 0.15–1% in hemodialysis patients; however, the information on the prevalence in chronic kidney disease (CKD) is lacking in Taiwan. This study aimed to determine the prevalence of FD in our CKD patients.

Methods: We screen male patients older than 18 years in our dialysis, renal transplantation (RTx) and Pre-End Stage Renal Disease (pre-ESRD) program patients. A total of 611 male CKD patients were screened using an assay of α-Gal A activity by dried blood spots (DBS). A Fabry confirm test by GLA gene analysis was done for those with low enzyme activity.

Results: There were 2 cases with positive (a-Gal A activity <0.6 μmol/hr) and 6 patients with borderline (0.6~1.5 μmol/hr). Interestingly, the 2 positive cases were brothers diagnosed IgA nephropathy (IgAN) in their childhood and received RTx identified as late-onset FD with GLA mutation in c.639+919G>A, a popular mutation site found in studies of male newborns screening for cardiac variant FD in Taiwan, and their mother was the carrier of GLA mutation. We also found 3 cases with borderline of a-Gal A activity with mutation on nonfunctional region. The prevalence of FD is about 0.33 % (2 in 611) in the high-risk population group with CKD. The clinical symptoms of FD patients are nonspecific except in those with various degrees of renal failure. Those patients' correct diagnosis was delayed, taking years and even decades.

Conclusions: FD should be considered in the differential diagnosis of any CKD patients even with knowing their renal disease entities without symptoms and signs suggestive of FD. Clinicians should be aware FD might be not only renal involvement, but also affected heart and brain.



PUB138

A Novel Frameshift Mutation of COL4A5 Identified by Whole-Exome Sequencing in a Chinese Family with Alport Syndrome

Jun Zhang, Wenyu Gong, Haixia Xiong, Hui-qun Li. *Division of Nephrology, Department of medicine, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Alport syndrome is an inherited kidney disease caused by the defects in type IV collagen, approximately 80% of which is caused by X-linked mutations in the *COL4A5* gene. This study explores a novel frameshift mutation of *COL4A5* responsible for renal disorder in a 3-generation Han Chinese pedigree.

Methods: We enrolled the proband and his family members from a village in Sichuan province, and collected the family history and clinical data. Clinical examinations were performed to evaluate the phenotypes of the family. Blood samples from the proband and the other eight family members were collected for genetic screen. Whole exome sequencing (WES) was applied in the proband to find out the potential genetic variants, and then the variant within the family was verified by Sanger sequencing.

Results: The 31-year-old male proband and his elder brother had ESRD, binaural sensorineural hearing loss and ocular lesions. Further, his three male cousins received hemodialysis and all died from ESRD between 18 and 25 years old. The 90-year-old maternal grandmother, one maternal aunt and one female cousin had only microscopic hematuria without gross hematuria, proteinuria, impaired kidney function or extrarenal symptoms. Genetic analysis identified a novel deletion mutation (c.422_428del) in exon 7 of *COL4A5* gene which located on the X chromosome in the proband. The c.422_428del variant was also detected in the proband's grandmother and four other affected family members. The proband's farther and three unaffected family members had not found this variant. This mutation was results into frameshift followed by formation of a truncated (p.Leu142Valfs*11) COL4A5 protein product with only 152 amino acids including an aberrant 10 residues. This mutation was not present neither in the Exome Variant Server of the NHLBI-ESP database, ExAC database or in the 1000 Genomes database. According to the variant interpretation guidelines of American College of Medical Genetics and Genomics (ACMG), this novel variant was classified as "likely pathogenic" variant for Alport syndrome in this pedigree.

Conclusions: Our study identified a novel *COL4A5* frameshift mutation in a Chinese family with Alport syndrome, expanding the mutational spectra of *COL4A5* gene, which were significant for screening and genetic diagnosis for Alport syndrome.

PUB139

Elevated Ambulatory Blood Pressure Is Associated with a Progressive Form of Fabry Disease

Federica Rossi,[1] Einar Svarstad,[2] Hassan O. Elsaid,[3] Agnese Binaggia,[4] Letizia Roggero,[1] Sara Auricchio,[4] Hans-Peter Marti,[2,3] Federico Pieruzzi.[1,4] *[1]Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [2]Department of Clinical Medicine, University of Bergen, Bergen, Norway; [3]Department of Medicine, Haukeland University Hospital, Bergen, Norway; [4]Nephrology and Dialysis Unit, ASST-Monza, San Gerardo Hospital, Monza, Italy.*

Background: Published data on hypertension incidence and management in Fabry Disease (FD) are scanty and it remains to be shown how much high blood pressure (BP) contributes to organ damage in these patients. Therefore, we have assessed BP values and their correlations with clinical findings in a cohort of FD patients.

Methods: Between January 2015 and May 2019, all adult FD patients (n=32) referred to our institute were enrolled; they were Caucasians (n=24 females, n=8 males) with an average age of 50±12.2 years. Data regarding hypertension were obtained by ambulatory BP monitoring (ABPM), home self-monitoring and office measurements. Patients were defined as hypertensive according to 2018 ESC/ESH Guidelines. The severity and the stability of FD were assessed with the Fabry Stabilization Index (FASTEX). Organ involvement and hypertension risk factors were also evaluated.

Results: The ABPM revealed elevated BP in 18.75% (n=6) of the FD population and 50% (n=3) of this group was diagnosed with masked hypertension. All these patients were females with an average age of 58±9.9 years. They presented a lower (p=0.046) glomerular filtration rate compared with the normotensive patients (77±17.7 and 89.3±21.4 ml/min/1.73m^2, respectively) and a more advanced cardiac hypertrophy with a higher LVPWd (p=0.044) and LVMi (p=0.033). Four of them (66.7%) were classified as progressive by the FASTEX score while the majority of the normotensives (84.6%) were stable (Figure 1). No correlation (p=0.428) was found between the category of GLA mutation and the development of hypertension.

Conclusions: Newly detected hypertension is found in a restricted portion of stable FD patients, while it becomes more prevalent in clinically progressive cases. The use of ABPM is of paramount importance to reveal masked hypertension which can contribute to the progressive worsening of the organ failure. We recommend a standardised ambulatory long-term BP monitoring program and timely antihypertensive intervention to improve the outcome of FD patients.

PUB140

Digenic Inheritance of Extracellular Matrix Mutations in a Family with FSGS

Saidah Hack Hack,[1] Poornima Vijayan,[3] Tony Yao,[1] Mohammad Azfar Qureshi,[1] Rohan John,[1] Andrew Paterson,[2] York P. Pei,[1] Moumita Barua.[1] *[1]Toronto General Hospital, Toronto, ON, Canada; [2]Hospital for Sick Children, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada.*

Background: Focal and segmental glomerulosclerosis (FSGS) is a histologic pattern of injury that characterizes a wide spectrum of diseases with different pathophysiologies and for which current diagnostic methods often fail to distinguish molecular mechanisms. We have recently reported whole exome sequencing (WES) in an adult FSGS cohort but most disease still remains unexplained.

Methods: In an unexplained family with adult-onset autosomal dominant FSGS, WES was performed in 3 affected relatives to identify candidate genes.

Results: The proband presented with proteinuria in his 20s and a renal biopsy at age 41 demonstrated FSGS (**Figure 1**). His two brothers also had FSGS documented in the 4th and 5th decades of life. The proband and his elder brother developed end-stage renal disease (ESRD) in the 5th decade of life while the youngest brother has stage 3b A3 CKD at age 59. Of the proband's 3 sisters, one developed proteinuria at the time of last follow-up at age 54. Her daughter whose renal biopsy also demonstrated FSGS at age 23, had approximately 3.3 g/d of proteinuria and an eGFR of 48 ml/min at age 30. After WES, five heterozygous rare variants were identified and sequenced in all affected relatives. Two of these variants segregated in affected family members and encoded extracellular mesangial matrix proteins. Renal biopsies showed classic segmental sclerosis/hyalinosis lesion on a background of mild mesangial hypercellularity. One of these genes is already reported to cause an autosomal recessive neurologic disorder.

Conclusions: We postulate that the additive effect of heterozygous mutations in extracellular matrix proteins leads to adult-onset FSGS. The absence of clinically significant extra-renal symptoms is likely as a result of the impact of the mutation which should lead to translated protein rather than complete deficiency seen in autosomal recessive disorders. Our results provide a signal of more complicated genetic inheritance patterns in unexplained families.

Funding: Private Foundation Support, Government Support - Non-U.S.

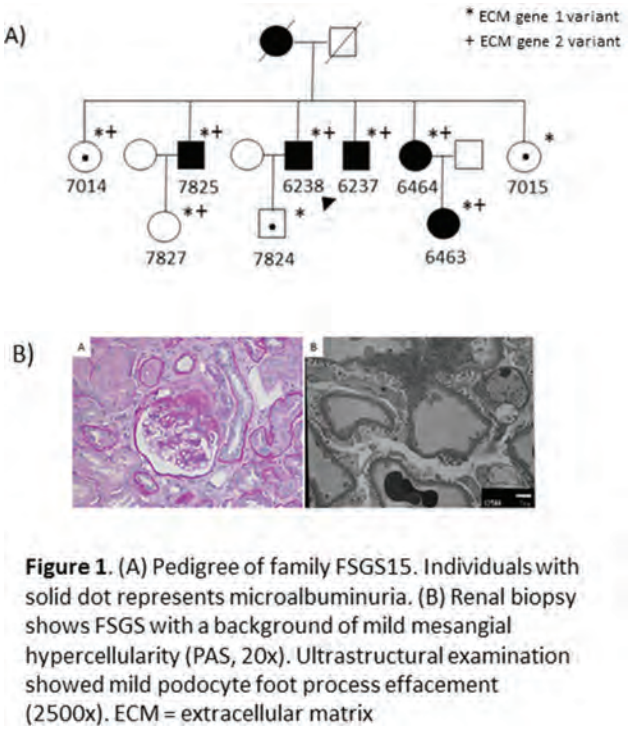

Figure 1. (A) Pedigree of family FSGS15. Individuals with solid dot represents microalbuminuria. (B) Renal biopsy shows FSGS with a background of mild mesangial hypercellularity (PAS, 20x). Ultrastructural examination showed mild podocyte foot process effacement (2500x). ECM = extracellular matrix

PUB141

Findings of Whole-Exome Sequencing in a Tunisian Man with Congenital Anomalies of Kidney and Ureteral Tract and Dilated Cardiomyopathy

Sabra Aloui,[1] Majdi Nagara,[3] Salima Ltaief,[1] Ahmed Letaief,[1] Manel Ben salah,[1] Mouna Hamouda,[1] Meriem Ben salem,[1] Habib Skhiri,[1] Ridha Mrad,[2] Sonia Abdelhak.[3] *[1]Department of Nephrology, Monastir University, Monastir, Tunisia; [2]Department of Human Genetics, Charles Nicolle Hospital, Tunis, Tunisia; [3]Laboratory of Biomedical Genomics and Oncogenetics, Institut Pasteur de Tunis, Tunis, Tunisia*.

Background: Congenital Anomalies of Kidney and Ureteral Tract (CAKUT) is a paediatric concern but can be diagnosed in adults adding challenges in the identification of CAKUT's etiology. To date, there are more than 50 single-gene disorders known to underlie CAKUT. Furthermore, a substantial number of CAKUT causes are extremely rare in the general population. Whole exome sequencing (WES) has been proposed as the solution in some cases.

Methods: Whole exome sequencing and case study of an adulte with CAKUT, cardiomyopathy, factor7 and other anomalies

Results: It is about a 30-years-old Tunisian man. He was referred to our unit for renal failure. His parents are second degree consanguine. He was hospitalized at age 2 years for dehydration. He had a brother with Parkinson disease started early at age of 20 years. He was hospitalised at age 29 in cardiology unit for heart failure. Explorations revealed dilated cardiomyopathy (DCM) and an elevated plasmatic creatinine. Physical examination showed a peculiar facies with crying facial expression when laughing, dental anomalies, mild mental retardation, strabismus, large prominent earlobes, brachydactylia, right cryptorchidism and normal blood pressure. Laboratory exams confirmed kidney failure: creatinine at 900µmol / L without proteinuria or haematuria. Prothrombin level was low to 50%, the exploration revealed a factor VII deficiency. Ultrasound scans showed a single right kidney of reduced size. We concluded at chronic renal failure due to tubulointerstitial nephritis associated with urofacial syndrome, DCM and factorVII deficiency. The diagnosis of a CAKUT with OCHOA syndrome was suspected but heart failure and factor VII deficiency were not explained. A whole sequencing exome was performed. It reversed the Oshoa syndrome and revealed two other possible genetic etiologies of CAKUT: a Kabuki syndrome and a Sensenbrenner syndrome. It also revealed a mutation of TTN, the gene encoding the sarcomere protein titin, explaining the DCM.

Conclusions: Exome Sequencing have a dual role as a discovery and diagnostic Tool. It's clinical utility will be discussed especially in in countries with strong consanguinity and low-income as in North Africa

PUB142

Non-Compliance and Acute Dehydration Are Main Reasons for Acute Kidney Failure in Patients with Non-Infantile Primary Hyperoxaluria Type 1

Cristina Martin Higueras,[1] Bodo B. Beck,[2] Bernd Hoppe.[3] *[1]Dept. Ciencias Médicas Básicas, Fac. Medicina, Universidad de la Laguna, Tenerife, Spain; [2]Institute of Human Genetics, University Hospital Cologne, Cologne, Germany; [3]German Hyperoxaluria Center, Bonn, Germany*.

Background: Patients with primary hyperoxaluria type 1 (PH1) have an increased risk of acute or chronic kidney failure (AKF/CKF). There are two risk groups: infantile oxalosis patients with an unremarkable family history and adult patients with only an oligosymptomatic course (minor stone events), who get into end-stage renal disease (ESRD) due to oxalate-induced chronic inflammatory processes in the kidney. We were interested in the prevalence of acute kidney failure in patients with non-infantile PH1 seen in our Hyperoxaluria Center over the last 10 years.

Methods: We retrospectively analyzed the database of the German Hyperoxaluria Center for patients being seen in our outpatient clinic for AKF. AKF was defined as a sudden onset of kidney failure and the necessity of dialysis installment in patients, but a documented stable kidney function (no worse than stage 2-3 CKD) prior to onset of AKF.

Results: There were 117 PH1 patients in the center, of whom 6 had infantile oxalosis and thus early ESRD, 8 patients are currently on dialysis, and 6 patients have died. Transplantations were performed in 35 patients with PH1 (liver & kidney in 28 patients, liver-only in 4 patients, and kidney-only in 3 patients). Currently, we routinely follow up (3-4 times a year) 49 of 117 PH1 patients. Out of these 49 patients, AKF was diagnosed in 8 patients aged 11-56 years (1 pediatric patient, 3 patients 18-19 years old, and 4 patients 29-56 years old), which led to CKF and subsequently, maintenance hemodialysis in 7 patients and death in 1 patient. Non-compliance regarding medication or recommended fluid intake was the reason for AKF in 6 of the 8 patients. Acute massive diarrhea without adequate fluid substitution led to AKF in the other 2 patients.

Conclusions: AKF is not uncommon in patients with PH1. It is frequently related to either non-compliance or to situations of severe fluid losses with inadequate fluid substitution and not based on already extremely altered renal function. Therefore, interruption of medication or lack of fluid intake, even for short periods of time, can lead to severe clinical consequences in these patients.

PUB143

ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis: A Positively Rare Cause of RPGN

Anand Narayanan, Wafa Dawahir, Paru P. Kathpalia. *Mercy Hospital Medical Center, Chicago, IL*.

Introduction: Pauci-immune crescentic necrotizing glomerulonephritis (PICGN) is the most common subset of RPGN. Most cases of PICGN are antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis; however, about 10-30% of patients are ANCA negative. Several studies have suggested that ANCA-negative PICGN has a lower incidence of extra-renal involvement, a poorer prognosis, and often dialysis dependent. Unfortunately given our limited understanding of the pathophysiology of ANCA-negative PICGN, current therapy is similar to ANCA-positive despite its worse prognosis.

Case Description: 60-year-old female presented for hypertension emergency. She had an elevated creatinine (Cr) of 1.48; baseline was 1.29 two weeks ago. Her Cr worsened to 2.05 and nephrology was consulted. Initial differential included acute drop in BP from restarting medications. UA showed 2+ protein, quantified 2 grams/gCr and RBC > 100. Findings of proteinuria and hematuria suggested RPGN however testing for ANCA, Anti-GBM, HIV, Hepatitis B and C, ANA, C3, C4 were negative. AKI due to ATN from infection was included in the differential for MDRO UTI. Despite treatment for infection and liberalized BP control, Cr continued to worsen and she became oliguric, acidotic and was started on dialysis. Given infiltrates seen on Chest CT, she had bronchoscopy with biopsy suggestive of bleeding that raised the possibility of pulmonary-renal syndrome. A renal biopsy was performed which showed pauci immune ANCA negative crescentic GN. Pathology showed almost 100% of glomeruli involved with global scarring and fibrinoid necrosis. She was started on steroids and Cytoxan. Six months later, she is off both medications but still on dialysis.

Discussion: Since patients with ANCA-negative PICGN have few extra-renal manifestations, are often dialysis dependent and have a worse prognosis, early recognition is crucial. The diagnosis primarily relies on performing a kidney biopsy rather than serological testing, otherwise the diagnosis may be missed. Early initiation of empiric therapy is appropriate to minimize the degree of irreversible injury and delay dialysis initiation. The degree of sclerotic fibrotic lesions in renal biopsy may predict treatment response. ANCA negative PICGN is a rare diagnosis; this case highlights why it is important to keep this diagnosis in the differential and why novel treatment options are needed.

PUB144

Collapsing Focal Segmental Glomerulosclerosis Associated with Parvovirus B19 Infection

Mandeep K. Babbra, Paul S. Bhamrah, Phani P. Morisetti. *Ochsner-LSU Health Sciences Center, Shreveport, LA.*

Introduction: Focal segmental glomerulosclerosis (FSGS) can be subdivided based upon its histologic classification. The collapsing subtype of FSGS is not only of the rarer forms of FSGS, but also carries the worst prognosis. We present a case of collapsing FSGS secondary to Parvovirus B19 infection in a patient with a relatively unremarkable past medical history.

Case Description: A 32-year-old female with prior history of gestational hypertension presented to emergency with a three-day history of bilateral lower extremity edema and periorbital swelling. On exam, profound periorbital edema and 2+ pitting edema up to the knees bilaterally was noted. Labs were consistent with a creatinine level of 5.0 mg/dL up from her baseline of 0.5 mg/dL three months prior. Urinalysis and random urine testing confirmed proteinuria of almost 19 grams per day. Renal ultrasound was obtained showing normal sized kidneys with increased echogenicity. Kidney biopsy was obtained and results were consistent with collapsing FSGS. Secondary workup for etiology of FSGS came back positive for Parvovirus B19 infection. Along with diuresis, decision was made to start IVIG and prednisone therapy. Initially, patient had improvement in kidney function post treatment and patient was followed up in clinic. However, required hemodialysis for one month.

Discussion: FSGS is commonly associated with nephrotic syndrome and stems from podocyte abnormalities. Podocyte detachment and death lead to segmental sclerosis, which is the hallmark pathophysiology of FSGS. Kidney biopsy is used to diagnose FSGS and characterized by the presence of sclerosis of at least one glomerulus on histologic examination. Histologically there are five classifications of FSGS with collapsing carrying the worst prognosis. Treatment is typically aimed at controlling proteinuria, edema, and cholesterol. In our patient with Parvovirus B19 induced FSGS, we used IVIG with prednisone therapy but no improvement. Further research is needed to find treatments for Parvovirus B19 induced FSGS for better outcome.

PUB145

A Whole Genome-Wide Arrayed CRISPR Screen in Primary Organ Fibroblasts to Identify Regulators of Kidney Fibrosis

Ina Sternberger. Evotec International GmbH *Evotec SE, Hamburg, Germany*.

Background: Robert J. Turner, Stefan Golz, Carina Wollnik, Nils Burkhardt, Ina Sternberger, Uwe Andag, Hauke Cornils Kidney fibrosis presents a hallmark of chronic kidney disease. With ever-increasing patient numbers and limited treatment options available, novel strategies for therapeutic intervention in kidney disease are warranted. Fibrosis commonly results from a wound healing response to repeated or chronic tissue damage, irrespective of the underlying etiology, and can occur in virtually any solid organ or tissue.

Methods: whole genome-wide arrayed CRISPR screening high content imaging

Results: In order to identify targets relevant for kidney fibrosis, we employed CRISPR screening in primary human kidney fibroblasts. Selected ht genes were validated.

Conclusions: We demonstrate that CRISPR technology can be applied in primary kidney fibroblasts and can furthermore be used to conduct arrayed CRISPR screening using a high-content imaging readout in a whole genome-wide manner. Hits coming out of this screen were validated using orthogonal approaches and present starting points for validation of novel targets relevant to kidney disease.

PUB146

Dual Positive Anti-Glomerular Basement Membrane Disease and ANCA Disease: A Diagnostic Challenge

Niloufarsadat Yarandi,[1] Kevin Fu,[1] Avi Z. Rosenberg,[2] Renu Regunathan-Shenk.[1] *[1]Division of Kidney Disease and Hypertension, George Washington School of Medicine and Health Sciences, Washington, DC; [2]Department of Pathology, Johns Hopkins School of Medicine, Baltimore, MD.*

Introduction: Double-positive disease (DPD), defined as coexistence of anti-glomerular basement membrane (Anti-GBM) disease and an anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV), is rare disease associated with variable outcomes. These patients often do not have typical presentation of either anti-GBM disease or AAV, making diagnosis a challenge.

Case Description: A 59-year-old male with history of hypertension presented with 1 week of fatigue and decreased urine output. Initial labs revealed a serum creatinine of 11.6 mg/dL and blood urea nitrogen of 133 mg/dL. Urinalysis showed specific gravity of 1.025, pH 5.0, 1+ protein, large blood, and 11-20 RBCs/hpf. Serological workup including anti-nuclear antibody, complement C3 and C4, HIV, hepatitis B and C were all unremarkable. The patient then developed hemoptysis and anuria. He was initiated on hemodialysis. Renal biopsy revealed extensive cellular and fibrocellular crescents, diffuse tubular injury with RBC casts, and 30% interstitial fibrosis and tubular atrophy. Immunofluorescence was negative. Further investigation revealed an elevated Anti-GBM titer, elevated anti-myeloperoxidase antibody and negative anti-proteinase 3 antibody. He was treated with methylprednisolone 1g intravenous for 3 days then daily prednisone 60mg and one dose of cyclophosphamide 1g intravenously. He was then transferred for initiation of plasmapheresis and received 8 sessions with normalization of Anti-GBM and ANCA titers. He also received another dose of cyclophosphamide 1g. He remained dialysis-dependent upon discharge.

Discussion: The varied presentation of DPD may cause a delay in diagnosis. DPD patients have a greater tendency to recover renal function but a higher risk of relapse. Early recognition and aggressive treatment is essential.

PUB147

Transcriptomic Profiling of Collagens in Proteinuric Kidney Disease

Prakash Narayan, Sony Dalapati, Ping Zhou, Natalia Prakash, Itzhak D. Goldberg. *Angion Biomedica Corp, Uniondale, NY.*

Background: The puromycin aminonucleoside nephropathy (PAN) model is associated with proteinuria and matrix accumulation. We tested the hypothesis that renal *COL1A1* and *COL3A1* are differentially expressed genes in PAN nephropathy.

Methods: Adult Wistar rats were administered water (sham) or PAN (~100 mg/kg, IP) and urine protein (24-hour) was measured on Days 4, 8, 12 and 21. Animals were sacrificed on Day 21, the left kidneys retrieved, and renal *COL1A1* and *COL3A1* mRNA levels measured using quantitative polymerase chain reaction.

Results: The rat PAN model was associated with increased proteinuria (*, $p<0.01$ vs. sham). Compared to the sham cohort, renal *COL1A1* and *COL3A1* mRNA expression levels were increased, 1.86-fold ($p<0.05$) and 8.4-fold ($p<0.01$), respectively, in the PAN cohort. Proteinuria correlated directly ($r=0.9$) and significantly ($p<0.01$) with renal *COL3A1* mRNA expression level.

Conclusions: Renal *COL1A1* and *COL3A1* mRNA expression levels are elevated in proteinuric kidney disease. Since *COL3A1* mRNA expression is associated with increasing proteinuria, targeting type III collagen might prove beneficial. Funded By: United States Department of Defense - PR180780/ W81XWH1910448

PUB148

C3 Glomerulonephritis: Diagnostic Challenges and Overlap Syndromes

Krishna A. Agarwal, Esilida Sula Karreci, Larissa Kruger gomes, Ruth Schulman, Isaac E. Stillman, Stewart H. Lecker, Theodore I. Steinman, Bradley M. Denker. BIDMC *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: C3-glomerulonephritis (C3GN) is a rare complement-mediated GN, with an incidence of 1-3:1,000,000. Spectrum of presentation can range from asymptomatic hematuria and proteinuria to a full blown acute GN with hypertension, hematuria, and renal insufficiency. Serum C3 levels are typically low. Diagnosis is confirmed by renal biopsy. The underlying mechanism appears to be dysregulated alternate complement pathway, triggered by genetic, environmental or a combination of both factors. Medical management addresses blood pressure, proteinuria, and dyslipidemia. Immunosuppression with glucocorticoids, antimetabolites, and anti-complement agents is used alone or in combination. Here we present 2 cases of biopsy-proven C3GN, mimicking infection-associated GN (IAGN) and TTP/HUS.

Case Description: Case 1: A 49-year-old man presented with 4-5 days of fevers, chills, nausea, vomiting and diarrhea. Labs revealed mild thrombocytopenia, proteinuria, microscopic hematuria and a low C3 level. Blood cultures revealed Streptococcus pyogenes. His hospital course was marked by rapidly progressive pancytopenia and hemodialysis-requiring acute renal failure. He received a single dose of eculizumab empirically due to concern for atypical HUS, but platelet counts improved too rapidly

to be consistent with eculizumab benefit. Kidney biopsy revealed acute tubular injury with glomerular C3 deposition. EM did not reveal immune deposits. Subsequent renal recovery followed 4 hemodialysis sessions. One-month post-discharge, he had normal renal function and hematologic cell counts. Case 2: A 74-year-old man with CKD III was admitted with altered mental status, septic shock, and acute kidney injury. Extensive workup did not detect infection or altered autoimmune status. His course was complicated by worsening renal failure, proteinuria, and hematuria. Renal biopsy demonstrated acute tubular injury and glomerular C3 deposition without immune deposits on EM. Eculizumab was deferred due to normal C3 and C4 levels. A steroid pulse was associated with an improvement in creatinine beginning on day 4 and return to baseline kidney function by day 17.

Discussion: Our cases highlight the variable presentation and complexity associated with accurate diagnosis of C3GN, including considerable overlap with IAGN and TTP/HUS.

PUB149

To Treat or Not to Treat? The Dilemma of C3 Glomerulonephritis vs. Infection-Related Glomerulonephritis

Rehan Ansari, Miroslav Sekulic. *University Hospitals, Cleveland, OH.*

Introduction: With a paradigm shift of infection related glomerulonephritis (IRGN) from a post-streptococcal infection of the young in developing countries to a poly-microbial infection of the elderly in the western world, the differentials have broadened. This has coincided with an evolving phenomenon of C3 glomerulopathy [C3G- C3 glomerulonephritis (C3GN) & Dense Deposit Disease (DDD)]. In all these entities a common feature is C3 dominant staining. Although subtle differences have been described in the nature of these deposits, we present a case in which the clinical course & biopsy findings highlight the challenges of identifying C3GN vs. IRGN.

Case Description: A 62 y/o female with HTN, hypothyroidism, epidural abscess, & recent MSSA bacteremia presents with AKI & anemia. Her creatinine was 2.92mg/dL vs. 0.53mg/dL (three weeks ago). Labs: Total Protein/Creatinine 4.29 mg/mg, negative blood cultures, unremarkable ANA, ANCA, SPEP, UPEP, K/L, Antistreptolysin O (ASO) Antibodies 541 IU/mL (0-200) & C3 77mg/dL (87-200), C4 47 mg/dL (10-50). Kidney biopsy: C3 dominant glomerulonephritis, >50% crescents, 3+/4 staining for C3 in mesangium & capillary loops, EM revealed finely granular mesangial, intramembranous, & subepithelial electron-dense deposits. She was started on steroids & C3 improved to 95 mg/dL after three weeks. Creatinine plateaued ~4.1mg/dL prior to discharge. Full complement profile available after one month (C1 Inhibitor 84.6mg/mL (21-39), C3 Nephritic 0units/mL (0), C4Bp 136.3% (61- 116), Factor H AutoAB 30unit/mL (<=22), SC5b-9 313ng/mL (<= 244).

Discussion: Classically, neutrophilic infiltration, occasional crescents (<50%) & subepithelial humps with co-deposition of C3 & IgG or IgA are described with IRGN, while mesangial & diffuse endocapillary proliferation exclusively with C3 deposition is expected with C3G. However biopsy alone is not specific for identifying the underlying etiology. ASO titers are elevated in >50% cases of C3GN and 25% of IRGN cases present with only C3 staining. Based on a strong history of infection, & improvement of C3, we treated as IRGN. Although testing for complement pathway mutations is recommended, results are not readily available. The clinical significance of these mutations remain under scrutiny. Until issues of testing & treatment can be generalized a holistic approach with close follow up is needed in cases of C3 dominant glomerulonephritis.

PUB150

A Young Asian Man with Heavy Chain Deposition Disease

Xuguang Yu,[1] Najia Nan,[1] Jingting Lin,[1] Muhammad T. Shakoor,[2] Jie Tang.[2] *[1]Wenzhou Medical College Affiliated Yueqing Hospital, Yueqing, China; [2]Brown University, Providence, RI.*

Introduction: Heavy chain deposition disease (HCDD) is an exceedingly rare condition characterized by nonamyloid tissue deposition of monoclonal immunoglobulin heavy chain. It typically presents in patients above age 50. Here, we report a case of a young Asian male who presented with acute kidney injury (AKI) and nephrotic syndrome (NS).

Case Description: A 32-year-old Chinese man presented with anasarca. He has no significant past medical history and his family history was also unremarkable. On presentation, he was afebrile with an elevated blood pressure to 205/136. Exam showed peri-orbital and 2+ lower extremity edema. Laxed skin was noted in his neck and abdomen. Laboratory studies showed an initial serum creatinine of 1.5 mg/dl with unknown baseline, it quickly rose to 10.4 mg/dl over the next 4 weeks requiring dialysis support. His LFT was normal, serum albumin was 2.0 g/dl, total cholesterol was 224 mg/dl. 24-hour urine total protein was 10.9 gm with albumin 7.7 gm. Serologies showed negative ANA, dsDNA, hepatitis and HIV panel, SPEP and UPEP for m-spikes. His complement levels were also normal. Urine sediment revealed 360 RBC with acanthocytes and 10 WBC under high power field. His kidney ultrasound was unremarkable. Kidney biopsy revealed nodular mesangial sclerosis with membranoproliferative features. There were intense immunoglobulin G1 staining in the mesangium, glomerular and tubular basement membranes and vessel walls. Kappa, lambda, IgM and IgA immunofluorescence were undetectable. Thus, a diagnosis of γ-type HCDD was made. The patient was started on treatment with bortezomib and dexamethasone. Within 2 months, he came off dialysis, 24hr urine total protein improved to 5.9 gm. Four months after starting bortezomib therapy, serum creatinine improved to 1.4 mg/dl and 24hr urine protein was down to 1.6 gm.

Discussion: In summary, this is a unique HCDD case diagnosed in a young Asian gentleman. He did not have detectable monoclonal serum protein. Like other reported cases, he responded well to a bortezomib based regimen.

PUB151

A Challenging Case of Renal-Limited Vasculitis

Moeed Ahmed, Bashar Ramadan, Eric Magliulo, Dongpo M. Salas, Jocelyn A. Taylor, Khalid Bashir. *Creighton University School of Medicine, Omaha, NE.*

Introduction: Anti-neutrophil cytoplasmic autoantibody (ANCA)-Associated Vasculitis (AAV) is an autoimmune disease that causes inflammation of blood vessels and has a wide spectrum of clinical presentation. It can present as multisystem or renal-limited disease. The typical renal presentationis that of a rapidly progressive glomerulonephritis (RPGN). We present an interesting case of renal-limited vasculitis with atypical features.

Case Description: A 76 year old male with a past medical history of Hypertension (treated with hydralazine) and CKD Stage 3 presented with weakness and shortness of breath for about two weeks. Physical exam and vitals were unremarkable. Laboratory workup revealed AKI with creatinine of 6.5 mg/dl. Urinalysis revealed microscopic hematuria and proteinuria (urine protein/creatinine ratio of 0.9). Renal ultrasound was unremarkable. Serologic workup including ANA, C3, C4, anti-GBM Ab, HBsAg, HBsAb and HBcAb was unremarkable. However, p-ANCA titer was high (1:160). He was treated with IV fluids. Interestingly, he continued to have good urine output as well as improvement in serum creatinine to 4.8 mg/dl and was discharged from the hospital. Follow-up renal function panel in two weeks showed worsening serum creatinine of 6.8 mg/dl. The patient was readmitted to the hospital. Repeat serologic workup revealed p-ANCA titer of 1:320 and elevated MPO IgG of 78 U/ml. Renal biopsy revealed pauci-immune glomerulonephritis. Steroids and rituximab were initiated as treatment. Due to worsening kidney function, patient was started on hemodialysis. He remained dialysis dependent with no significant renal recovery. Given atypical features of disease presentation, hydralazine was considered to be an etiologic agent hence, and was discontinued.

Discussion: We present a case of renal-limited vasculitis with atypical features making the diagnosis very challenging. Firstly, the patient remained nonoliguric throught the first hospital course. Secondly, his serum creatinine improved with supportive treatment leading to his discharge with presumptive diagnosis of ATN. In summary, ANCA associated GN may present with nonoliguria as well as waxing and waning renal function. Atypical features of AAV should raise concern for drug-induced etiology.

PUB152

Collapsing Focal and Segmental Glomerulosclerosis with Thrombotic Microangiopathy Found on Renal Biopsy in a Patient Receiving Intravitreal Aflibercept for Age-Related Macular Degeneration

Ramy M. Hanna,[1] Gautam M. Phadke,[4] Kenar D. Jhaveri,[3] Ira Kurtz,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, University of California Irvine, Orange, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]Northwell Health, Great Neck, NY; [4]University of North Dakota, Columbus, OH.*

Introduction: Intravitreal Vascular Endothelial Growth Factor (VEGF) Receptor blockade is used for a variety of retinal pathologies. These include age related macular degeneration (AMD), diabetic macular edema (DME), and central retinal vein obstruction (CRVO). Reports of absorption of intravitreal agents into systemic circulation have increased in number, and confirmation of depletion of VEGF has been confirmed. Increasingly there are studies and case reports showing worsening hypertension, proteinuria, renal dysfunction, and glomerular disease. The pathognomonic findings of systemic VEGF blockade, thrombotic microangiopathies (TMAs) are also being increasingly reported. One variant of TMAs that has been described is collapsing focal and segmental glomerulosclerosis (cFSGS). CFSGS has been postulated to occur due to TMA induced chronic glomerular hypoxia. We present the third reported case of cFSGS in the setting of intravitreal VEGF blockade, a chronic TMA component was crucially found on biopsy.

Case Description: This patient is a 74-year-old non-diabetic male receiving aflibercept for AMD. Of the two prior cases of cFSGS in setting of VEGF blockade, one had AMD and the other had DME.

Discussion: This case solidifies the finding of cFSGS and its association with chronic TMA as a lesion that may be frequently encountered in patients receiving intravitreal VEGF inhibitors.

PUB153

A Case of IgA Vasculitis in Liver Cirrhosis

Jayesh B. Patel, Swe Zin Mar Winhtutoo, Danniele G. Holanda, Lama A. Noureddine. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: IgA vasculitis (previously termed Henoch-Schönlein purpura) is a systemic immune-complex mediated condition characterized by predominant IgA1 deposition in microvessels. We present a case of biopsy-proven IgA vasculitis involving skin and kidneys in a patient with known liver cirrhosis.

Case Description: A 71-year-old man with liver cirrhosis due to chronic ETOH use presented to ER with a one-month history of progressive rash and pedal edema. He denied arthralgias, melena, hematemesis, abdominal pain, or fever. Diffuse, erythematous, palpable, non-pruritic petechial lesions were noticed on bilateral thighs, arms, and anterior abdominal wall with few lesions coalescing to purpura. Laboratory evaluation revealed an elevated creatinine at 1.7 mg/dl. Urinalysis showed dysmorphic erythrocytes, leucocytes, and proteinuria. ANA was positive (1:320), C3 slightly low with normal C4. Cryoglobulin, RA factor, SPEP, ANCA, anti-dsDNA, HBsAg, antibodies to HIV, HCV, rickettsia, and syphilis were negative. Peritoneal fluid culture was sterile. Kidney biopsy revealed severe proliferative glomerulonephritis, cellular/fibrocellular crescents and mild interstitial fibrosis. Skin biopsy revealed dense perivascular neutrophilic infiltration with fibrin deposition and erythrocyte extravasation consistent with leukocytoclastic vasculitis. He was diagnosed with IgA vasculitis and treated with pulse IV steroids followed by oral taper along with monthly IV cyclophosphamide infusions. Petechial lesions improved markedly but renal function was unchanged at 4-month follow-up. Unfortunately, the patient died 5 months after initial presentation due to complications of underlying liver disease and secondary infection.

Discussion: IgA vasculitis, more commonly observed among children than adults, manifests clinically as palpable non-blanching purpura, arthritis, intussusception, and kidney injury. Adults commonly develop ESRD in one-third of cases. Similar to crescentic IgA nephropathy, a combination of IV followed by oral steroids and IV cyclophosphamide is recommended in patients with rapidly progressive renal failure with more than 50% crescents on renal histology. In our case, the patient had an underlying liver disease which is an independent risk factor associated with glomerular IgA deposition due to inadequate clearance. The degree of contribution to the pathogenesis of IgA vasculitis remains unknown.

PUB154

Poststreptococcal Glomerulonephritis in an Elderly Patient: A Rare but Often Overlooked Differential in AKI

Enoemem M. Okpokpo, Navneet Kaur, Lilibeth Jauregui, Anika Bethel. *Florida Atlantic University Charles E Schmidt College of Science, Boca Raton, FL.*

Introduction: Poststreptococcal glomerulonephritis (PSGN) is a complication of specific Streptococcal strains. Presentation ranges from asymptomatic microscopic hematuria to acute nephritic syndrome, with oliguria, edema, hypertension, and acute kidney injury (AKI). It mostly occurs in children of developing countries. Its incidence is not well characterized in elderly individuals but is thought to be extremely rare. We report a case of PSGN in an elderly female complicated by hypertensive urgency and heart failure.

Case Description: An 89-year-old female with history of COPD, HFpEF, CKD stage 3a presented with lethargy and weakness. She was treated for bronchitis 3 weeks prior and initially improved but then developed progressive dyspnea and swelling in her lower extremities. On presentation, BP was 252/120, CXR showed cardiomegaly and pulmonary edema. Labs revealed a creatinine of 2.72 (baseline 1.4). She was started on IV diuretics, BiPAP, and nitroglycerin drip with improved BP control. She remained oliguric. Nephrology was consulted due to no improvement in urine output despite bumetanide and thiazide diuretic challenge. Renal ultrasound was unremarkable. Autoimmune workup was negative. She required emergent hemodialysis (HD) as her kidney function failed to recover. A renal biopsy showed chronic tubular and arteriolar changes with noted glomerular endocapillary immune-complex glomerulonephritis, concerning for post-infectious GN. She ultimately required an arteriovenous fistula for longterm HD.

Discussion: PSGN primarily occurs after an upper respiratory infection or impetigo. It is less common in adults, however, is associated with a worse prognosis compared to children, with less than 25% achieving full recovery of renal function. Unlike children, the elderly tend to present with etiologies of lower respiratory infections (LRI) and UTIs. Studies show the time between infection and renal injury may be little to none, as infections in the elderly are often nonspecific and might go unrecognized. Our patient had an AKI after a LRI, resulting in significant oliguria and lack of renal recovery leading further work up with a biopsy. It is therefore imperative that providers consider PSGN as a differential diagnosis in elderly patients with severe AKI. Treatment is mainly supportive, and patients, like ours, might require HD.

PUB155

Staphylococcal-Associated Glomerulonephritis due to Necrotizing Panton Valentine Leukocidin-Positive Methicillin-Resistant *Staphylococcus aureus* Pneumonia: A Case Report

Alex Plamm,[1] Analise Douglas,[1] Smita Mahendrakar,[1] Surya V. Seshan.[2] *[1]Rutgers New Jersey Medical School, Newark, NJ; [2]Weill Cornell Medicine, New York, NY.*

Introduction: Post-infectious glomerulonephritis (GN) occurs due to cross-reactivity of host and pathogen antigens and antibodies, leading to immune complex deposition in the glomerulus and acute kidney injury after a bacterial infection. Staphylococcal-associated GN differs in its pathogenicity, occurring during an active infection. Staphylococcal-associated GN usually occurs due endocarditis, soft tissue or bone infections, while pneumonia is an uncommon cause. This is a case of GN in a 39-year-old man that resulted from Panton-Valentine Leukocidin (PVL) positive MRSA necrotizing pneumonia complicated by septic emboli, leading to GN requiring renal replacement therapy (RRT).

Case Description: A 39-year-old man with a past medical history of cocaine abuse, intravenous heroin abuse and hypertension presented initially with four days of nausea, vomiting, pleuritic chest pain and cough. His labs were notable for BUN of 80 mg/dL and a creatinine of 4.9 mg/dL and WNC of 14,900. Urinalysis > 500 mg/dL of protein, 50 >182 RBCs/hpf. HIV assay was nonreactive, as was his hepatitis panel. C3 was 101 mg/dL, C4 was 7 mg/dL. 24 hour urine protein was 4.8 g/day. A CT chest showed septic emboli and a right middle lobe consolidation consistent with pneumonia. Blood cultures were positive for MRSA. TEE did not reveal valvular vegetations. Renal biopsy showed C3 deposits by immunofluorescence and scattered subepithelial and intramembranous electron deposits by electron microscopy concerning for staphylococcal-associated GN. The patient was started on RRT and had persistent bacteremia for nearly 2 weeks despite being on vancomycin and cefepime. After a positive PVL assay, these were switched to linezolid and ceftaroline with clearance of bacteremia. Interdialytic creatinine decreased and RRT was stopped.

Discussion: Staphylococcal-associated GN differs from PSGN by occurring during active infection. This rarely occurs in pneumonia. PVL is an under-recognized virulence factor that contributes to the pathogenicity of MRSA especially in the case of necrotizing pneumonia. It can lead to higher virulence and prolonged antigen exposure, increasing the risk of immune complex formation and deposition.

PUB156

A Remission Case with Obsolescent IgA Nephropathy in Aspirin Plus Eicosapentaenoic Acid

Shinichiro Koga. *Section for Nephrology and Hypertension, Department of Medicine, Tokyo Metropolitan Police Hospital, Tokyo 1868541, Japan.*

Introduction: In case of evacuating immunosuppression therapy to IgA nephropathy, ACEI, ARB, or both has statistically improved renal prognosis evaluated in urine protein(UP)[1)]. Eicosapentaenoic acid(EPA) on IgA nephropathy has documented alternative effects and side effects to steroids[2,3)].

Case Description: A 68-year-old woman was referred to nephrologist with complaint of bilateral leg edema accompanied with proteinemia and microscopic hematuria. She had been treated on diabetes, dyslipidemia, hypertension, and obesity in this clinic, then already pointed out that urine abnormality at 2 years ago. Her BP was 177/93mmHg, body weight 61 Kg, OB(3+), urine RBC 10-30/HPF, UP 2.2g/day, serum Cr 0.63mg/dl, HbA1c 7.6%, IgA 331mg/dl, and IgG 1,059mg/dl, on 20mg valsartan[1)]. Paraproteinemia was screened out. Percutaneous kidney biopsy show mild focal segmental proliferative glomerulonephritis with 2/19 segmental sclerosis and fibrous crescent, and 6/19 obsolescence glomeruli, IgA nephropathy, Oxford:M0,E1,S1,T1. In addition to this obsolescence glomeruli, her high BP and blood glucose led us add 100mg aspirin(ASA) plus 1,800mg EPA to reduce UP[4,5)]. Daily salt intake was restricted to 6g. After 4 years, TP/Cr,OB, urine RBC has normalized(**Table**).

Discussion: This case is diagnosed as chronic IgA nephropathy; this pathology might illustrate why her UP had not reduced with valsartan. On the other hand, acute lesion such as necrotized, or cellular or fibrocellular crescents was not detected. This finding gave us discussion on alternative medication which could evacuate from steroids and immunosuppressants. In addition to EPA 900-1,800mg per day on ARB[4)], ASA on EPA[5)] has reported to significantly reduce UP. Those authors speculated that ASA superimposed physiological effect on antiinflammatory lipids mediators[6,7)]. Taken together, this chronic IgA nephropathy has been normalizedurine dipstick findings by means of ASA plus

The Masquerading Diagnosis of Secondary Thrombotic Microangiopathy

Janany J. Sabescumar, Justin Komisarof, David Levy, Bruce Goldman. *University of Rochester Medical Center, Rochester, NY.*

Introduction: Thrombotic microangiopathy (TMA) is an umbrella term defined by hemolytic anemia, thrombocytopenia and end organ damage secondary to microvascular thrombi. TMA is subclassified as either inherited or acquired (i.e lupus). We report a case of secondary TMA initially masquerading as atypical HUS.

Case Description: A 27 year old female with no significant medical history presented with shortness of breath for one month. She was noted to have acute kidney injury and new onset congestive heart failure. An echocardiogram revealed a dilated left ventricular and a severely reduced ejection fraction (10%). Her admission labs were notable for platelet count of 57, creatinine of 7.4 and schistocytes on peripheral smear. Given the concern for thrombotic thrombocytopenic purpura (TTP), an ADAMST13 level was drawn and plasmapheresis was initiated. Despite therapy, her kidney function worsened. As there were no overt causes of TMA, such as anti-phospholipid syndrome, infections, malignancy, or drugs, we strongly suspected aHUS and administered one dose of eculizumab. On hospital day 4, a kidney biopsy was performed which revealed an immune complex deposition driven glomerulonephritis with significant TMA as well as membranoproliferative changes consistent with class IV/V lupus nephritis. Eculizumab was discontinued and she was started on cyclophosphamide and pulse dose steroids. Her kidney function continued to decline and she eventually required hemodialysis. Serial echocardiograms revealed improvement in cardiac function and she was discharged from the hospital on dialysis.

Discussion: TMA can occur with autoimmune diseases. Although the mechanism remains unclear, there is evidence of complement activation leading to injury. For these cases, there is no evidence that treating TMA itself changes outcomes. It is important to distinguish between the causes of TMA as treatment differs between primary and secondary. There are current ongoing trials of the use of eculizumab in lupus nephritis, however current guidelines recommend induction treatment using cyclophosphamide and steroids. The cause of her heart failure remained unclear, thought was secondary to microvascular coronary damage from SLE.

PUB158

Membranous Nephropathy and Autoimmune Thyroid Disease

Brandon Bates,[1] Maria T. Story,[2] Kathleen Robinson,[2] Jeydith Gutierrez.[2] *[1]Roy J. and Lucille A. Carver College of Medicine, Iowa City, IA; [2]The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: The relationship between thyroid dysfunction and nephrotic syndrome (NS) has been recognized since the 1970s, yet the mechanisms connecting them are poorly understood. Here we present a patient with profound hypothyroidism and idiopathic membranous nephropathy (iMN).

Case Description: 54-year-old Caucasian female with a 32-year history of hypothyroidism and BMI 54 kg/m^2, sought care for 3 months of dyspnea, bilateral leg edema and a 30 kg weight gain. She was admitted to her local hospital and had workup for anasarca. Physical exam: Vitals: BP 145/71 mmHg, pulse: 86 bpm and spO2 of 98%. Thyroid was normal size, morbid obesity and anasarca noted. Labs: creatinine 1.2 mg/dL, albumin 0.9 g/dL, and a thyroid stimulating hormone (TSH) 97.55 m[IU]/L. Urine protein/creatinine ratio of 12.6 g/g. A kidney biopsy demonstrated MN with phospholipase A2 receptor (PLA2R) positive antibody staining. Supportive treatment for iMN was initiated and she sought a second opinion at our institution. Additional testing revealed elevated anti-thyroid peroxidase antibodies (TPO), consistent with Hashimoto's Thyroiditis (HT). Treatment with the modified Ponticelli protocol and 200 mcg of levothyroxine daily was initiated.

Discussion: An association between HT and iMN has been described, but the underlying mechanism connecting these conditions remains poorly understood. Hypothyroidism is associated with increased serum creatinine, decreased glomerular filtration rate and higher risk of chronic kidney disease. Similarly, nephrotic patients with thyroid dysfunction have increased proteinuria and lower albumin levels compared to those without thyroid disease. In addition, loss of TSH and thyroid binding globulins due to NS can cause or exacerbate hypothyroidism. Interestingly, a recent study reports the presence of elevated anti-PLA2R antibodies in patients with isolated HT, raising the question of an autoimmune phenomenon affecting both organs. Although we cannot definitively determine that the same autoimmune process was affecting both organs in our patient, it is an intriguing question based on new evidence. Certainly, her underlying hypothyroidism was worsened by the development of NS. Nephrologists should consider screening for hypothyroidism when diagnosing NS, as treatment has the potential to significantly improve patient symptoms.

PUB159

Patient Journey, Perceptions, and Burden Associated with Immunoglobulin A Nephropathy (IgAN): A Qualitative Study

Nancy Zaour,[1] Miriam Mayländer,[2] Susann Walda,[2] Aneesh T. George.[3] *[1]Novartis Pharma AG, Basel, Switzerland; [2]IPSOS SA, Basel, Switzerland; [3]Novartis India Hyderabad, Hyderabad, India.*

Background: There is a lack of published evidence on patient perspectives in IgAN; a rare condition that can progress to end stage renal disease (ESRD). The objective of this study was to understand the patient journey, disease perceptions and burden of disease from the patients' perspective.

Methods: This qualitative study was conducted after review board approval through a moderated online bulletin board platform and by telephone interviews, to allow comprehensive answering of pre-defined questions. Participants were recruited via physician referral and were screened to ensure eligibility and willingness to participate. Analysis was conducted using a combination of various qualitative analytical tools.

Results: Eight participants with a confirmed diagnosis of IgAN from North America and Europe, aged 29–58 years participated. Diagnosis was often incidental as symptoms were underestimated or unnoticed. Participants were overwhelmed to learn they were diagnosed with a chronic disease and many did not understand the seriousness of the outcomes associated with the same. Post diagnosis, participants were referred to a nutritionist to discuss diet changes and received blood pressure medications. Some participants also received steroids and immunosuppressants. Frequency of monitoring visits varied and created anxiety if the disease progressed, based on new lab values. Speed of disease progression was different amongst patients. Besides symptoms like fatigue and lack of energy, some participants had to deal with emotional burden of feeling alone and fearful of the future with potential dialysis, transplantation and shortened life expectancy. According to the participants, the lack of standard procedures for early screening and diagnosis along with the absence of adequate information in patient friendly language and counselling were some of their needs. Additionally, participants expressed the need for a support mechanism with similar peers to learn to live with the disease and to counteract the feeling of being alone.

Conclusions: This study provides insights into how differently IgAN patients perceive and live with their disease. The insights obtained can be used to inform drug development and include what matters most to patients. Finally, this study highlights that a comprehensive education program for patients and caregivers is needed.

Retinal Drusen in Antibody-Mediated and Pauci-Immune Glomerulonephritis

Philip A. Harraka,[1] Heather G. Mack,[2,3] Deb J. Colville,[1] David Barit,[1] David Langsford,[1] Timothy J. Pianta,[1] Judith A. Savige.[1] *[1]The University of Melbourne Department of Medicine, Northern Health, Melbourne, VIC, Australia; [2]The University of Melbourne Department of Surgery (Ophthalmology), Melbourne, VIC, Australia; [3]Department of Ophthalmology, Melbourne Health, Melbourne, VIC, Australia.*

Background: Membranous and anti-glomerular basement membrane (GBM) glomerulonephritis are autoantibody-mediated diseases, where the antigens (PLA2R, THSD7A and collagen IV a3 respectively) are also expressed in the retina. Drusen are retinal deposits caused by complement activation and lipid debris in Bruch's membrane. Drusen have been described in one individual with membranous nephropathy and linear IgG deposits in Bruch's membrane of another with anti-GBM disease. In contrast, pauci-immune anti-neutrophil cytoplasm antibody (ANCA) vasculitis triggers complement but does not produce glomerular immune deposits. This study examined individuals with antibody-mediated or pauci-immune glomerulonephritis to determine how often drusen occurred in each group.

Methods: This was a cross-sectional observational case-series of individuals with antibody-mediated (n=15, membranous n=9, anti-GBM disease n=6) or pauci-immune (n=16, granulomatosis with polyangiitis n=7, microscopic polyangiitis n=7, eosinophilic granulomatosis with polyangiitis n=2) glomerulonephritis recruited from a general renal clinic in an Australian tertiary-care hospital. Two-field colour fundus images were obtained with a non-mydriatic camera (CANON, Japan). Images were coded and assessed for drusen count, location and size by two trained graders using the Wisconsin Age-Related Maculopathy Grading Grid. Central drusen counts ≥10 were considered abnormal.

Results: Four (27%) individuals with antibody-mediated disease (membranous n=2, anti-GBM disease n=2) but only one (6%) with a pauci-immune vasculitis had ≥10 central drusen. Gender, mean age and disease duration were not different between the two groups.

Conclusions: These results suggest that retinal disease occurs together with glomerular disease when the target antigen is found in both locations. Retinal drusen may be a useful biomarker for some forms of glomerulonephritis, and drusen pathogenesis may explain in part the pathogenesis of glomerular immune deposits. In addition, treatments that target retinal drusen may also be useful in antibody-mediated glomerulonephritis.

PUB161

Long-Term Therapeutic Plasma Exchange (TPE) in Management of Focal Segmental Glomerulosclerosis (FSGS) in Native Kidneys

Ibrahim Tawhari, Lorenzo G. Gallon, Yashpal S. Kanwar, Vikram Aggarwal. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Circulating permeability factors (CPF) may be involved in the pathogenesis of some forms of FSGS that are non-responsive to intensified immunosuppression and exhibit a rapidly progressive course. The role of CPF-mediated FSGS is indicated by the post-transplant recurrence of proteinuria and its response to TPE. Moreover, experimental animals injected with plasma from patients with FSGS can develop proteinuria. While TPE in patients with post-transplant recurrence can prevent graft failure, evidence to support its use in resistant FSGS in native kidneys is lacking.

Case Description: A 62-year-old Caucasian female presented with anasarca and nephrotic-range proteinuria (5.0 g/day) in March 2018. Kidney biopsy revealed minimal change disease. The first 14 months of her course were complicated by steroid resistance, side effects of high-dose steroids and calcineurin inhibitors (CNI), recurrent AKI, CNI/ARB-induced hyperkalemia, and worsening of proteinuria with CNI reduction. She received 4 doses of rituximab (375 mg/m2) during that period. Genetic testing for the steroid-resistant nephrotic syndrome was negative. In June 2019, a trial of 10 TPE sessions resulted in a significant improvement in proteinuria (UPCR= 1.8-2.0), which worsened over the following 4 months after discontinuation of TPE (UPCR= 4.0). Repeat kidney biopsy revealed FSGS. Given the previous response to TPE, a central-venous port was placed for long-term TPE in December 2019. The patient received TPE twice a week for the first 6 weeks. With improved proteinuria, TPE was tapered to twice a month with maintained partial remission (PR) (UPCR= 1.5) for the last 5 months. The patient is off ARB, on a minimal dose of CNI. The symptoms associated with nephrotic state and the side-effects of multiple drugs have resolved.

Discussion: This case highlights the dilemma of therapeutic decision-making in patients with resistant FSGS. Long-term TPE successfully maintained symptom-free sustained PR and stabilized renal function. TPE has become the preferred choice of our patient to avoid the toxic effects of long-term intensive immunosuppression. More studies are required to study the efficacy and safety of TPE in patients with native kidney FSGS resistant to therapy.

PUB162

Association Between Anti-GBM Titers and Kidney Inflammation with a New Activity Score

Diana Rodriguez-Espinosa, Evelyn Hermida Lama, David Cucchiari, Josep miquel Blasco pelicano, Adriana Garcia, Esteban Poch, Luis F. Quintana, Alicia M. Andújar. *Hospital Clinic de Barcelona, Barcelona, Spain.*

Background: Anti-glomerular basement membrane (anti-GBM) disease is a rare glomerulopathy characterized by rapidly progressive loss of kidney function, leading to end stage kidney disease in a significant amount of cases. The main objective of our study is to determine whether anti-GBM titer correlate with rate of activity in renal biopsy and long-term kidney survival in patients with anti-GBM, hence identifying patients who would potentially benefit from more intensive treatments.

Methods: A retrospective analysis was performed on anti-GBM cases from 2007 to 2018 with both positive biopsy and serology. Anti-GBM levels and kidney function at admission and discharge, treatment, and kidney biopsy findings were collected. All biopsies were reevaluated by a single, blinded pathologist. Based on a recent study by Van Daalen et al, we developed an activity score. The score was divided in a glomerular and interstitial section. In the glomerular section, a sclerotic pattern (>50% of glomeruli) was given 0 pts in activity and 3 in chronicity, a mixed pattern was given 1 pt in activity and chronicity, and a crescentic pattern (>50% with cellular crescents) was given 3 pts in activity and 0 in chronicity. In the interstitial section, the presence of fibrosis and atrophy was given between 0 and 3 pts in chronicity and the presence of tubulitis or interstitial infiltrate with neutrophils were given points in activity (0 to 3 respectively). Spearman correlation was performed between anti-GBM levels, our biopsy score, and kidney survival at follow-up.

Results: Twelve cases were identified, 9 were males, mean age was 54. Anti-GBM at admission ranged from 40 to 1517 U/mL. Ten patients were treated with cyclophosphamide, 1 with rituximab plus cyclophosphamide and 1 with only rituximab. The median number of therapeutic plasma exchange sessions was 8 (range 6-12). High antibody titers correlated with greater activity on biopsy (r 0.6, p= 0.04) and lesser chronicity (r -0.7, p= 0.02). Kidney loss at follow-up (35 months) was 92%.

Conclusions: These results suggest that patients who present higher titers have more acute inflammation, and therefore could benefit from more intensive treatment. It would be interesting to study this score in larger cohorts in order to produce more definitive conclusions.

PUB163

Antisynthetase Syndrome and Nephrotic Syndrome

Noe Martinez murillo, Jorge J. Font, Jonathan Chavez, Joana G. Navarro gallardo, Jose A. Torres, Christian P. Flores. *Universidad de Guadalajara, Guadalajara, Mexico.*

Introduction: The presence of anti-synthase syndrome and IgA nephropathy is unusual. symptoms similar to other diseases that affect the connective tissue: Lupus, Rheumatoid arthritis or polyomyositis

Case Description: A healthy female 19-year-old patient starting with oligoarthritis on knees and wrists as well as low grade fever, viral pharyngitis was suspected and ibuprofen was started, without any improvement, ciprofloxacin, naproxen and acetaminophen because urinary tract infection was suspected. Edema of extremities is added as well as persistence fever, again revalued, finding the presence of proteinuria and rhabdomyolysis with CPK 33,000, reasons why it is referred to our center. Hepatomegaly was confirmed with transaminasemia, rhabdomyolysis and 4.2 g of proteinuria in 24-hour collection, hypoalbuminemia of 1.8gr/dL compatible with nephrotic syndrome, renal biopsy was performed. Because the persistence of fever, it starts an approach discarding infectious causes such as hepatotropic agents (HCV, HBV, HIV, EBV, CMV, HAV, Leptospira and Tuberculosis) as well as fever of unknown origin such as liver abscess, endocarditis, brucellosis, all these being negative. Collecting blood cultures and urine cultures, without bacterial growth. During the 4 day of in-hospital stay, muscle weakness with predominant involvement of the proximal arms (scapular and pelvic girdle), later it begins with dysphagia to solids then to liquids. The diagnostic approach for causes of rheumatological diseases is addressed, with negative ANA, positive ANCAs 1:10 (MPO (-) and PR3 (–), Low C3 complement and positive Anti JO1 and Anti Ro 52 +++. Electromyography was performed reporting normal sensory neuroconduction as well as motor conduction. Muscle biopsy shown the presence of perimissial infiltrate. Renal biopsy shown mesangial proliferation and immunofluorescence with IgA. Symptoms progress to type 2 respiratory insufficiency, severe hypercapnia, starting with methylprednisolone 3 doses with slight improvement, adding immunoglobulin at dose of 2 g / kg, recovering muscle strength, respiratory parameters and decreasing CPK.

Discussion: IgA nephropathy is an atypical manifestation in patients with antisintetase syndrome, only 3 cases have been reported, the pathophysiological origin is unknown, the most accepted hypothesis is humoral activation.

PUB164

Efficacy and Safety of Induction Treatment with Rituximab, Mycophenolate, and Low Doses of Corticoids in Patients with ANCA-Associated Vasculitis

Jose Luis Garcia Villa, Miguel Uriol Rivera, Aina Obrador, Cristina Egea, Tania Villagrasa. *Son Espases University Hospital, Hospital Universitari Son Espases, Palma de Mallorca, Illes Balears, ES, Palma de Mallorca, Spain.*

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (VAA) increases considerably the risk of requiring chronic renal support therapy (CRST) and death. Induction treatment with cyclophosphamide and corticosteroids is not always effective and has adverse effects. The kidney biopsy (KB) is usually required prior to the start of treatment; however, the clinical presentation and the systemic nature may influence the time of its performance. We report the efficacy and safety of pre-KB initiation of induction therapy using Rituximab, low-dose steroids, and mycophenolate. We report the adverse effects during follow-up. Induction protocol methylprednisolone 250mg (x3), Rituximab 1gr (x2), mycophenolate 500mg / 12h. Maintenance therapy consisted in mycophenolate and prednisone.

Methods: Nineteen consecutive patients were included. Follow-up period: means (min-max): 28 (3-64) months. Average age 65 years. Patients treated pre-KB 17 (90%). It was also administered during induction: immunoglulins in 10 (53%) patients and plasmapheresis in 8 (42%). 2 patients (11%) required Eculizumab as rescue therapy. 15 (79%) patients were anti-MPO + [title: median: 281 (84-570) AU / ml]. Berden's classification selected the following patterns: sclerotic: 5 (26%), focal: 5 (26%), crescentic 2 (11%), 3 (16%) insufficient material, mixed: 1 (5%) and 3 (16%) patients were not biopsied.

Results: The current survival it was 100% and only 2 (11%) require CRST (one of them had a baseline GFR of 9ml / min / 1.73m2). The median (p25-p75) of eGFR at the momento of presentation was 17.9 (7.8–27.2) ml / min / 1.73m2. The average eGFR increased globally during follow-up in 9.9ml / min / 1.73m2 (P <0.01, eta2partial: 0.46); those with sclerotic histology 7.3ml / min / m2 (P = 0.26) and in those without available histology 10ml / min / 1.73m2 (P = 0.04, eta2parcial: 0.21). The regimen was tolerated satisfactorely, we registred 5 patients with infections issues (26%) [2 (11%) required hospital admission]. No patient developed steroid-induced DM.

Conclusions: The early use of this induction regimen was associated with excellent overall and renal survival. The safety profile and systemic nature of VAAs seems to justify the early use of immunosuppression even in those treated without available histology.

PUB165

A 39-YearOld Female with Acute Renal Failure of Unclear Etiology

Kaltrina Sedaliu, Samuel Rednor. *Montefiore Medical Center, Bronx, NY.*

Introduction: Rapidly progressive glomerulonephritis, or RPGN, is a disorder of the kidney with accelerated loss of kidney function that manifests histologically by glomerular crescent formation. This rare entity may be caused by pauci-immune crescentic glomerulonephritis, which is strongly associated with antineutrophil cytoplasmic antibody (ANCA) vasculitis. Nevertheless, a small portion of patients lack ANCA. There is limited literature on the comparison of ANCA positive and ANCA negative patients. We present the case of a 39 year old female presenting with shortness of breath, hypoxemic respiratory failure, and acute renal failure. Her lack of ANCA rendered her disease entity mystifying and puzzled providers in terms of how to proceed with treatment.

Case Description: A 39-year-old Caucasian female was admitted to the hospital with a one day history of shortness of breath. Her admission was complicated by rapidly progressive hypoxemic respiratory failure, warranting intubation and subsequent placement on venovenous extracorporeal membrane oxygenation. Labs showed acute kidney injury (AKI) with a serum creatinine of 3.70 mg/dL. Urinalysis demonstrated

large blood, 4–10 red blood cells, and proteinuria > 1000 mg/dL. Urine protein creatinine ratio was 3,895 mg/g. She developed bloody endotracheal tube secretions, warranting performance of bronchoscopy that was consistent with diffuse alveolar hemorrhage. Given that serological work up, including ANCA, returned unremarkable, the etiology of her renal failure was unclear. Her AKI became oliguric and she was initiated on continuous venovenous hemodialysis (CVVHD). Given the uncertainty regarding the etiology of her renal failure, and therefore how to proceed with treatment, despite her hemodynamic instability, renal biopsy was performed. Findings were consistent with segmental sclerosing pauci-immune glomerulonephritis with small cellular crescents.

Discussion: Studies on the characteristics of patients with ANCA negative pauci-immune GN, as well as prognosis, are vital, as up to 30% of patients with pauci-immune glomerulonephritis lack ANCAs. Prompt recognition and appropriate treatment has proved essential to preservation of renal function. Additional literature regarding ANCA negative pauci-immune GN may ameliorate the need for renal biopsy in unstable patients, and may guide more timely treatment.

PUB166

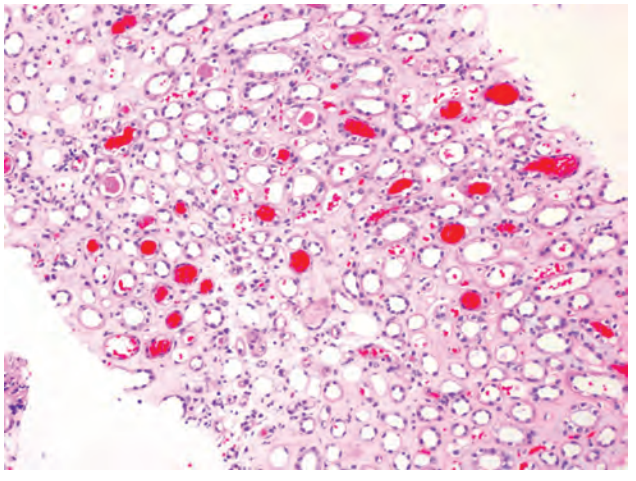
Bloody Tubules: Is It the Warfarin?

Hira Yousaf,[1] Jenny Bhatt,[1] Mohammad H. Wadud,[1] Emma Horton,[2] Sunil Patel,[1] Tauseef A. Sarguroh.[1] *[1]Franciscan Health Inc, Mishawaka, IN; [2]Midwestern University - Downers Grove Campus, Downers Grove, IL.*

Introduction: Acute kidney injury(AKI) with gross hematuria can have a myriad of urological and glomerular etiologies. Anticoagulation related nephropathy is one of them and has been known to cause AKI in the setting of warfarin use. This is a case of a pateint with primary biliary cirrhosis(PBC) on warfarin that presented with persistent hematuria and AKI requiring hemodialysis. Her renal biopsy revealed warfarin nephrotoxicity with secondary IgA nephropathy from liver disease.

Case Description: 72 year old hispanic female with history of PBC and osteoarthritis underwent a right knee arthroplasty and was started on warfarin for DVT prophylaxis by orthopedics for a month. She subsequently developed persistent gross hematuria and underwent a cystoscopy that was unremarkable. Labs showed creatinine: 5.5mg/dl, UPCR: 5.81g/g and INR: 1.0 as the patient by then had stopped taking warfarin. Serologies were all negative and a renal biopsy was performed that revealed acute tubular necrosis with numerous intratubular red blood cell casts suggestive of warfarin nephropathy. The biopsy also showed mesangial, subendothelial and capillary wall IgA deposits likely secondary to her underlying liver disease(PBC).

Discussion: Previsouly known as warfarin induced nephropathy; this renal etiology is now recognized as anticoagulation related nephropathy as it is seen with other anticoagulants as well. Characteristic histology shows tubular injury and occlusive red blood cell casts that lead to ischemia and hemorrhage into the tubules and bowmans capsule. Risk factors include supratherapeutic INR and underlying chronic kidney disease. Our case report is unique as her undiagnosed secondary IgA nephropathy from primary biliary cirrhosis precipitated the warfarin nephrotoxicity. The pateint is currently stable on bi-weekly hemadialysis.



Intratublar casts-warfarin nephrotoxicity.

PUB167

Staphylococcal Infection-Associated Glomerulonephritis and Nephrotic Syndrome in an Intravenous Drug User with Hepatitis C: A Challenging Clinical Scenario

Ghansham Das, Haris Mobeen, Syed H. Bukhari. *State University of New York Upstate Medical University, Syracuse, NY.*

Introduction: Renal disease in intravenous drug users, especially those with Hepatitis C, can present with challenging clinical scenario and biopsy picture. We describe a case of a 46-year-old male who presented with shortness of breath, chest pain and acute kidney injury.

Case Description: A 46-year-old male with a history of Intravenous (IV) drug use and untreated Hepatitis C presented with shortness of breath and chest pain. Patient was found to have Methicillin Resistant Staphylococcal bacteremia and tricuspid valve endocarditis. Physical examination was positive for bilateral leg edema and pan systolic murmur over left lateral sternal border. Initial serum creatinine was 1.54 mg/dl (baseline creatinine 0.94 mg/dl). Urine analysis revealed proteinuria 2+ and hematuria and the sediment was consistent with isomorphic WBCs and RBCs with many granular casts. Renal US revealed right kidney 11.6 cm and left kidney 13.5 cm in maximum dimension with no hydronephrosis. All serology tests were negative except for a low C3 and positive c-ANCA with negative MPO and PR3 levels. A percutaneous renal biopsy showed proliferative GN (diffuse proliferative GN) with focal MPGN pattern in few glomeruli and rare crescent (in one glomerulus), full house immunofluorescence (IF) with IgA co-dominance and both capillary wall and mesangial staining (IgA 3+, IgG1-2+, IgM 2+, C3 3+, C1q 1+, kappa 1-2+ and lambda 3+) and small subepithelial (hump-like) and both small and large subendothelial deposits on ultramicroscopy. Final biopsy diagnosis was given as IgA-codominant staphylococcal infection-associated glomerulonephritis (SAGN). Patient was treated with eight weeks of IV antibiotics and underwent supportive hemodialysis during hospitalization. He was discharged home off hemodialysis and followed up in outpatient clinic for Chronic Kidney Disease stage IV.

Discussion: The presence of nephrotic syndrome in this patient presents a challenging scenario and MPGN secondary to hepatitis C may be considered a differential here although SAGN is a stronger contender based on clinical and biopsy findings and nephrotic-range proteinuria, though not common, has been described in SAGN and endocarditis-associated GN cases in variable percentages, ranging from 6-48%.

PUB168

Unmasking of Pancreatobiliary Carcinoma in a Patient with Fibrillary Glomerulonephritis

Avneek Singh Sandhu,[1] Harold J. Duarte,[1] Natallia Maroz.[1,2] *[1]Kettering Health Network, Dayton, OH; [2]Wright State University, Dayton, OH.*

Introduction: Fibrillary Glomerulonephritis (FGN) is a rare disease with known malignancy correlation. Cancer can be discovered simultaneously with the diagnosis of FGN or later in the course of the disease. As per our knowledge, this case is a first description of rapidly progressing pancreatobiliary carcinoma (PBC) associated with FGN.

Case Description: 49 y/o white woman presented to the nephrology office with proteinuria of 1.3 g/day and hematuria. She had a past medical history of smoking (>20 years) and hysterectomy for endometriosis. Serologic workup and urology evaluation were unrevealing. Kidney biopsy reported FGN with minimal interstitial scarring. Oncology referral was made to rule out hidden malignancy. She had an unremarkable CT scan of the chest and abdomen, PAP smear, mammogram, colonoscopy as well as normal chemical evaluation and ultrasound of thyroid. Patient quit smoking and had conservative management for the first 11 months. Introduction of ACE-I led to reduction in proteinuria to 0.6 g/day. Unfortunately, she had decline in creatinine from 0.6 to 1.0 mg/dl, and worsening of proteinuria to 1.3 g/day associated with edema and weight gain. Therapy with Acthar® injections was initiated at the dose of 80 units thrice weekly. Patient had rapid improvement in proteinuria and swelling, and after 12 months of therapy, Acthar® dose was reduced to 40 units twice weekly. Creatinine remained stable. 24 months after the initial presentation and 13 months from Acthar® therapy initiation, she developed acute pancreatitis. Imaging studies showed pancreatic pseudocyst. Unfortunately, her pain did not resolve. During the second hospitalization, a month later, HIDA scan and EGD were performed with unrevealing results. She was managed with pain medications and Acthar® therapy was uninterrupted. Patient underwent MRCP 3 months after the initial presentation, which showed pancreatic mass and multiple liver lesions. Biopsy of the liver lesion demonstrated poorly differentiated PBC. Palliative chemotherapy was initiated but was not tolerated by the patient. Patient deceased 4 months after the development of pain symptoms.

Discussion: Consideration of a hidden malignancy is a part of FGN management. PBC is a devastating cancer with dismal survival. Conducting an aggressive and repetitive work up for malignancy in patients with a new diagnosis of FGN may improve outcomes.

PUB169

A Case of Proliferative Glomerulonephritis with Monoclonal IgG Deposits Following Influenza Infection

Merve Postalcioglu.[1,2] *[1]Kent Hospital, Warwick, RI; [2]Brown University Department of Medicine, Providence, RI.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is relatively a new entity. It is a form of monoclonal gammopathy with renal significance. Our patient is presented with this rare disease triggered by very common illness, influenza infection.

Case Description: A 61-year-old female with a past medical history of chronic kidney disease stage IIIB, and type 2 diabetes mellitus presented to the hospital with gross hematuria for 1 week and right-sided flank pain started within last 24 hours. The patient was diagnosed with influenza A infection 10-days before her hospital admission and treated with Oseltamivir. She was started on ciprofloxacin after 1 week due to concern for pneumonia. In the emergency room, she was hypertensive otherwise hemodynamically stable. Her physical exam was significant for right-sided costovertebral angle tenderness. BMP showed creatinine as 2.73 mg/dl which was 1.33 mg/dl at baseline. She was diagnosed with acute kidney injury and started on IV fluid resuscitation. Her urinalysis revealed 58/HPF red blood cells and 7/HPF white blood cells. The kidney ultrasound was unremarkable. CT abdomen and pelvis did not show any evidence of

urolithiasis or hydronephrosis. Urine albumin/creatinine ratio was 470.8 mg/g in a spot urine sample which was 104 mg/g before admission. Serum C3 level was normal at 134 mg/dl (reference: 88-201). Anti-streptolysin O antibody (ab), c-ANCA (antinuclear ab), p-ANCA, anti-glomerular basement membrane ab were negative. Her immunoglobulin G level elevated to 1,740 mg/dl (reference 649-1618), kappa level elevated to 1,470 mg/dl (reference 574-1276), and lambda level elevated to 774 mg/dl (reference 269-638). Serum electrophoresis did not show M-spike and serum immunofixation study was negative for monoclonal gammopathy. Kidney biopsy was recommended by nephrology which revealed endocapillary-proliferative glomerulonephritis with linear glomerular capillary wall staining for IgG1-kappa. She did not receive any immunosuppressive treatment as her kidney function returned to baseline without intervention.

Discussion: PGNMID is a rare form of glomerulonephritis which can mimic immune-complex glomerulonephritis especially in a patient with an infection. Therefore, considering renal biopsy with light-chain and IgG staining is crucial for proper diagnosis.

PUB170

Dual Positive Myeloperoxidase and Proteinase 3 Antibodies and Class V Lupus Nephritis in an Elderly Female with Cocaine Use

Anirudh R. Gone,[1] Molly Fisher,[2] Daniel Schwartz,[2] Mary J. Dominguez,[2] James M. Pullman.[2] *[1]Montefiore Medical Center Jack D Weiler Hospital, Bronx, NY; [2]Montefiore Medical Center, Bronx, NY.*

Introduction: Cocaine contaminated with levamisole is a reported cause of dual positive ANCA vasculitis and rarely has been associated with lupus nephritis. We present a case of an elderly female who presented with unexplained acute kidney injury (AKI) and chronic cocaine use and was found to have dual positive ANCA and Class V lupus nephritis.

Case Description: A 70-year-old female with a history of hypertension, coronary artery disease, atrial fibrillation on warfarin, pre-diabetes, remote history of breast cancer status post lumpectomy, baseline serum creatinine (SCr) 0.8 mg/dL was sent to the emergency room after being found to have a SCr 6.0 mg/dL on outpatient labs. Urinalysis was significant for proteinuria and microscopic hematuria. Urine protein/creatinine ratio was 2.7 g/g. Workup revealed positive anti-nuclear antibody titer of >1:320, double-stranded DNA antibody titer 270 IU, myeloperoxidase (MPO) antibody of 5 AI and proteinase 3 (PR3) antibody of 1 AI. Serum complement 3 was 149 mg/dL and complement 4 was 31 mg/dL. She had no clinical symptoms of systemic erythematous lupus (SLE) or systemic vasculitis. Urine toxicology was positive for cocaine. She was pulsed with steroids due to concern for a rapidly progressive glomerulonephritis and then underwent kidney biopsy, which demonstrated full house immunofluorescence with IgG predominant subepithelial deposits, few mesangial deposits and mild acute tubular injury. No proliferative glomerular lesions or crescents were observed. She was initiated on mycophenolate mofetil with improvement in SCr to 3.8mg/dL and proteinuria to 1.2g/g.

Discussion: Dual positive (MPO and PR3) ANCAs have been reported in patients with lupus nephritis, but rarely in the setting of class V lupus nephritis. Although our patient's history of cocaine use may explain positive MPO and PR3 antibodies, she did not have the pauci-immune crescentic glomerulonephritis often seen with ANCA, but rather an immune complex, non-inflammatory glomerulopathy. Given her unusual manifestation of late-onset lupus nephritis, we hypothesized that chronic cocaine use may have led to an altered immune response and autoimmune disease, as rarely described for SLE in young men with chronic cocaine use.

PUB171

Collapsing Glomerulopathy due to Hemophagocytic Lymphohistiocytosis: A Case Report

Janame J. Kottey, Niraj K. Yadav, Monique E. Cho, Kalani L. Raphael, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Collapsing glomerulopathy (cFSGS) is most commonly seen in association with Human Immunodeficiency Virus infection (HIVAN) and can also occur in association with viral and non viral infections, autoimmune diseases, malignancy and drug exposure. Patients typically present with rapidly worsening renal function and nephrotic syndrome. We report a case of cFSGS due to Hemophagocytic lymphohistiocytosis (HLH)

Case Description: A 41-year-old man with acute myeloid leukemia and allogenic hematopoetic stem cell transplant with graft versus host disease on Ruxolitinib, was admitted for hypervolemia, respiratory failure, rapidly rising creatinine and nephrotic range proteinuria. He was noted to have anemia, thrombocytopenia, high LDH, low haptoglobin and abnormal liver function tests. He underwent renal biopsy that showed collapse of capillary loops and podocyte hyperplasia on light microscopy with marked foot process effacement on electron microscopy. Extensive work up was pursued to identify the etiology of cFSGS. Infectious work up including HIV, hepatitis B and C, parvo virus B19, BK virus, CMV, EBV, HSV, Human herpes virus 6, SARS-COV-2, Mycobacteria, fungal, and parasitic organisms was negative. He had marked elevation of ferritin at 35,000ng/ml and triglycerides at 1,529 mg/dL in the setting of severe pancytopenia and fever raising concern for HLH. He underwent bone marrow biopsy that showed hemophagocytosis of nucleated cells supporting diagnosis of HLH. Soluble interleukin 2 receptor levels (sCD25) were normal consistent with the use of Ruxolitinib. Despite receiving Anakinra, Rituximab, and Dexamathasone for HLH he deteriorated clinically and was transitioned to comfort care

Discussion: cFSGS has been associated lupus, IgA nephropathy, diabetic nephropathy, thrombotic microangiopathy/acute glomerular ischemia, bisphosphonate therapy, HLH, and infections like HIV, Parvo virus B19, pulmonary tuberculosis, CMV and more recently SARS-COV-2. Treatment of cFSGS is directed towards the underlying cause. cFSGS complicating HLH is rare. Excessive immune activation with release of pro inflammatory cytokines targeting the podocytes is hypothesized to cause cFSGS in HLH. Renal prognosis appears to be poor despite therapy and most patients remain dialysis dependent. HLH has been reported post stem cell transplant and should be considered in the differential diagnosis of cFSGS

PUB172

Epidemiology of Glomerular Diseases in Minia Governorate: A 5-Year Single-Center Experience

Waleed Hassan,[1] Hisham Mostafa.[2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]Minia Nephrology and Urology University Hospital, Minia, Egypt.*

Background: Studying the pattern of glomerular diseases gives an important insights about factors associated with its development or progression.

Methods: This is a retropective study includes 312 patients underwent kidney biopsy at Minia university hospital between 2014 to 2019. The aim of this study was to highlight the histopathological patterns of glomerular disease in Minia governorate.

Results: A total of 312 biopsy-proven glomerular diseases were reported. The mean age was 31.65±13.77 years, 61.5% were females Table (1). The most common clinical presentation was nephrotic Syndrome (39.4%). Lupus Nephritis contributed 27.9%, followed by Membranoproliferative glomerulonephritis (15.4%) Focal segmental glomerulosclerosis (13.5%), IgA nephropathy (11.5%), amyloidosis (7.7%), Crescentic glomerulonephritis (5.8%), Thrombotic microangiopathy (4.8%), Vascular nephropathies (3.8%), Minimal change disease (3.8%), Membranous nephropathy (2.9%), Postinfectious glomerulonephritis (1.9%) and Diabetic nephropathy (0.96%). Table (2). Eighteen patients (62.1%) of lupus nephritis belonged to ISN/RPS class IV, seven patients belonged to class III, and four patients belonged to class V.

Conclusions: Histopathological patterns of glomerular disease may indicate regional and ethnic variations that could point towards genetic or environmental influence. This might help in effectively managing this disease by identifying the predisposing factors.

Percentage of glomerular patterns: Table (2)

Renal Diseases	Number	Overall percentage
Minimal change disease (MCD)	12	3.8%
Focal segmental glomerulosclerosis (FSGS)	42	13.5%
Membranous nephropathy (MN)	9	2.9%
Lupus nephritis (LN)	87	27.9%
Membranoproliferative glomerulonephritis (MPGN)	48	15.4%
Postinfectious glomerulonephritis (PIGN)	6	1.9%
Crescentic glomerulonephritis (CresGN)	18	5.8%
Amyloid	24	7.7%
Diabetic nephropathy (DN)	3	0.96%
Vascular nephropathies (VN)	12	3.8%
IgA	36	11.5%
Thrombotic microangiopathy	15	4.8%

Demographic and clinical data: Table (1)

	Descriptive statistics (n=312)
Males	120(38.5%)
Females	192(61.5%)
Male to female	0.63
Mean age (years)	31.65 ± 13.77
Age range (years)	13-75
Hypertension	51(16.3%)

PUB173

A for Amyloidosis

Muhammad Y. Jan, Simit Doshi. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: We present a case of osteomyelitis related amyloidosis presenting as acute injury injury (AKI) with nephrotic range proteinuria.

Case Description: A 62 years old male with type 2 diabetes mellitus and hepatitis C (treated) was admitted with complaints of bilateral foot pain of 3 weeks duration leading to inability to ambulate. Work up revealed pedal wounds with drainage and imaging was consistent with osteomyelitis. Blood cultures were positive for methicillin sensitive staphylococcus aureus (MSSA) which was treated with IV antibiotics. Baseline serum creatinine (sCr) was 2.0 mg/dL and sCr on admission was 3.85 mg/dL, which was thought to be from acute tubular necrosis related to sepsis from osteomyelitis. Work up of AKI revealed nephrotic range proteinuria of 4.7g, hematuria without dysmorphic red blood cells and monoclonal kappa IgM spike on serum protein electrophoresis. Kappa/Lambda ratio was 1.86. Total protein was 8.5 g/dl with serum albumin of 1.9 g/dl. Hemoglobin A1c level was 4.6%.Left below knee amputation was performed and patient was transitioned to 4 weeks of oral cephalexin. sCr on discharge was 2.9 On clinic follow up, repeat labs showed non-resolution of AKI as well as nephrotic range proteinuria of 6.8g and a kidney biopsy was obtained. His wound was healing slowly and antibiotic duration was extended. Kidney biopsy showed no glomerular obsolescence or hypercellularity. Mesangial and glomerular capillary walls showed Congo Red Positive deposits. Thickening of glomeruli was noted with segmental duplication. Tubular atrophy and interstitial fibrosis was 20%. Staining was positive for serum amyloid A (AA) in glomeruli, arterioles, and tubular basement membranes. Immunofluorescent staining was negative. Electron microscopy showed mesangial expansion with randomly arrayed extracellular fibrils with solid cores and a mean diameter of 9.8 nanometer.

Discussion: Patient completed extended oral antibiotic therapy for osteomyelitis with resolution of M spike on SPEP and improvement of creatinine to baseline. Deposition of serum amyloid A (SAA) protein, an acute phase reactant is a potential complication of chronic inflammatory conditions. Most commonly involved organ is the kidney presenting as nephrotic syndrome. Clinical evaluation for secondary amyloid is important in the setting of infection. Unusual disease course should prompt evaluation for less common causes even in presence of comorbidities such as diabetes and hepatitis C.

PUB174

Factors Related to Clinical Efficacy of Corticosterone Combined with Tonsillectomy for IgA Nephropathy

Ryo Yamamoto, Yuta Kogure, Mai Aoyagi, Kaori Takayanagi, Minoru Hatano, Takatsugu Iwashita, Hajime Hasegawa. *Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Background: IgA nephropathy (IgAN) is the most frequent primary glomerulonephritis in Japan. Treatment combining tonsillectomy with intermittent intravenous methyl prednisolone (PSL) and alternate-day oral PSL (TSP therapy) may be sometimes chosen, and results from multiple prospective multicentered studies have been reported for its clinical usefulness. However, the treatment selection criterion has not been cleared. We retrospectively analyzed the patients who underwent TSP therapy in our facility and investigated the factors associated with efficacy of this therapy.

Methods: Subjects are 63 patients with IgAN who underwent TSP in our hospital from April 2012 to July 2019. Intravenous methyl PSL 500 mg/day was administered for 3 days in the first 2 weeks after tonsillectomy, followed by oral PSL 30 mg every other day. The protocol was repeated 3-times every 2 months, then PSL was tapered off. Treatment evaluation was performed 6 months after initiation of the therapy. When urinary protein was 0.5 g/gCr or less or decreased by 50% or more, and the urine red blood cell count was less than 20 per microscopic field, the treatment was considered to be effective.

Results: The mean age of enrolled patients was 36.2.±13.5 year, eGFR 75.2±23.6 mL/min, urine protein 0.92±0.81 g/gCr, and serum IgA 332. 9±141.2 mg/dL. Thirty-two patients were effective and 31 patients were non-effective at 6 months after the start of the therapy. Clinical parameters showing significant difference between the two groups were age (33.2±15.2 in responder vs 39.4±10.9 in non-responder, p=0.02), diastolic blood pressure (71.2±10.1 in responder vs 78.5±13.2 in non-responder, p=0.017) and serum IgA (368.3±174.3 in responder vs 296.2±84.0 in non-responder, p=0.024). Logistic-regression showed a significant association with respect to efficacy only for serum-IgA (OR=1.010, 95% CI 1.00-1.02, p=0.047). Cut-off level of serum IgA to the efficacy of TSP therapy by ROC-analysis was 291 mg/dL (AUC=0.675, sensitivity=0.842, selectivity=0.571).

Conclusions: Serum IgA levels may be a reference for predicting the efficacy of TSP therapy for IgAN.

PUB175

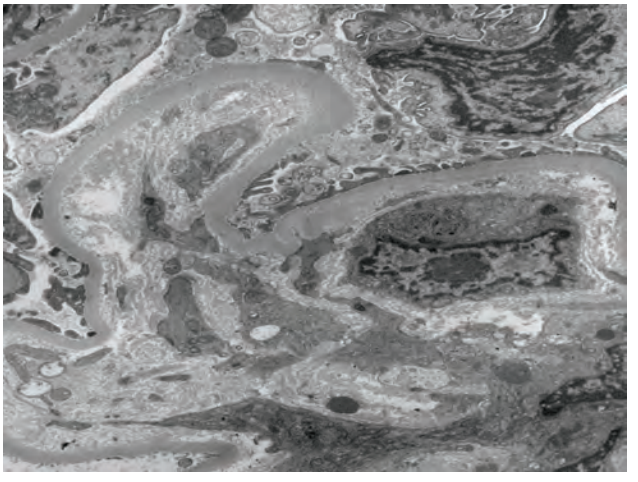
An Elusive Case of Renal Failure in a Patient with Atypical Hemolytic Uremic Syndrome

Frank A. Portugal, Ayesha Ahmed. *Robert Wood Johnson University Hospital, New Brunswick, NJ.*

Introduction: AHUS is microangiopathic hemolysis, thrombocytopenia, and AKI with normal ADAMTS13 and absence of STEC. It involves activation of complement via alternative pathway causing TMA with end-organ involvement. Causes can be complement regulation deficits, infections, and drugs. Here is a rare case of AHUS after a *C.difficile* infection, requiring dialysis.

Case Description: 19-year-old man with OSA, ADHD, and obesity had a 3-week course of diarrhea and fever. Cr was 2.15, platelet 143, and tested + for C.diff and was on po vanco then flagyl. Given worsening symptoms, he went to the ER and Hb was 13.9, platelets 24, WBC 14.8, BUN 130 and Cr 8.4. He had low complements (C4 <7.9, C3 46.2), few schistocytes on peripheral smear, mildly elevated LDH and high-normal haptoglobin. He began dialysis, plasmapheresis and had a renal biopsy. Imaging showed splenomegaly (15-20 cm) and lymphadenopathy (negative BM and lymph node biopsy). ADAM13 level was 50 and plasmapheresis was stopped. Further infectious and autoimmune workup was negative. Renal biopsy showed a TMA process and C5b-9 staining was positive in the glomerulus and arteriolar vessels. Serum C5b-9 level was elevated (343). A genetics panel showed no variant associated with AHUS nor predisposition to poor response to eculizumab. He was discharged with eculizumab maintenance and dialysis. Recently, his labs improved with a Cr of 1.5 and platelets of 163.

Discussion: Here, typical features of hemolysis were missing, and diagnosis was made on renal biopsy with findings of TMA and + C5b-9 stain. Ongoing understanding of causes for AHUS include hereditary (complement and DGKE gene mutations) and acquired (infection, autoantibodies to complement, drug toxicity and autoimmune). Although genetic panel was negative, it cannot be ruled out as genetic mutations are only identified in 50-70% of cases. Shiga-toxin and pneumococcal-HUS are causes, but here we found rare *C.difficile*-induced cause. Patient was successfully treated with eculizumab. Thus, AHUS is elusive and clinically challenging in diagnosis.



PUB176

IgA Nephropathy in a Patient with Beta-Thalassemia Minor: A Case Report

Andric C. Perez-Ortiz,[1] Carmen Avila-Casado,[2] Gregorio T. Obrador.[1] *[1]Universidad Panamericana, Ciudad de Mexico, Mexico; [2]University Health Network, Toronto, ON, Canada.*

Introduction: IgA nephropathy (IgAN) is the most prevalent type of primary glomerulonephritis worldwide. There are few reports on IgAN development in thalassemia, especially among beta-thalassemia trait (minor) carriers.

Case Description: A 52-year-old male Mexican patient was evaluated for hypertension, hematuria, proteinuria, and rising serum creatinine levels. His history included an ischemic cerebrovascular accident and beta-thalassemia minor (trait). He was treated initially, by another provider, with hydrochlorothiazide/irbesartan and carvedilol for hypertensive nephropathy. Despite treatment, he continued with rising creatinine levels. Then, he was switched to irbesartan only. During this period, the patient developed metabolic acidosis treated with NaHCO3. When referred to our care, we began our approach by completing biochemical and immunodiagnostics assessments (IF), ultrasound imaging (USG), and pathology for glomerulonephritis. On biopsy, we observed IgA nephropathy with advanced nodular glomerulosclerosis and grade II interstitial fibrosis. On IF, IgA, C3, lambda, and kappa chains (mild) were positive. IgG, IgM, C1q were negative. On USG, we documented renal replacement lipomatosis. The patient had microcytic hypochromic anemia, but GBM, C3, C4, ANA antibodies were negative. We managed successfully with irbesartan, amlodipine, NaHCO3 then furosemide.

Discussion: To our knowledge, there are only three additional cases of IgA nephropathy among beta-thalassemia minor. All, including ours, shared as chief complaint rising serum creatinine, hypertension, and persistent microscopic hematuria. However, one report noted bilateral sensorineural hearing loss and prior psychosis under treatment, which may be a syndromic disease presentation. A common feature also is negative antinuclear, anti-DNA, anti-neutrophil cytoplasmic, anti-glomerular basement membrane antibody, HBV, HIV, serum complements antibodies. Significantly, at the time of biopsy, all cases had fibrosis in various degrees ranging from partial to global sclerosis with fibrous crescents. Notably, prior cases occurred in Asian ethnicities, were IgAN is prevalent; our case is the first Hispanic affected patient.

PUB177

Sudden Explosive Onset of Collapsing FSGS in the Setting of Influenza: An Unusual Presentation

Amaresh R. Vanga, Varun Malhotra. *Eastern Virginia Medical School, Norfolk, VA.*

Introduction: Collapsing FSGS(Focal Segmental Glomerulosclerosis) is often seen in the setting of HIV, pamidronate use, parvovirus infections. Here we present a case that was explosive in onset and was associated with influenza.

Case Description: Elderly African American male in his 60s presents with flu-like symptoms. His influenza swab was positive. His past medical history was significant was occasional cocaine use, hypertension, parathyroid adenoma, hypercalcemia, prostate cancer. His vitals revealed BP 107/64 | Pulse 61 | Temp 97.2 °F (36.2 °C) | Resp 16 | SpO2 97%. Physical examination was benign. His creatinine was 6.9. His baseline creatinine was 1.8(for the past few years) and thought to be related to his hypertension. Other labs indicated corrected calcium of 11, potassium of 5.9, Co2 of 18, hemoglobin of 8 with normal platelets, and WBC. USG(Ultrasound) of kidneys revealed obstructing 3mm left UJV stone with hydroureteronephrosis. UA revealed 3 plus protein with moderate blood, 10-20 RBC per HPF, bacteria. He was started on antibiotics and a double JJ stent was placed. His stone disease is probably a manifestation of parathyroid adenoma. He was awaiting parathyroidectomy and was maintained on sensipar in the interim. His creatinine continued to increase and peaked at 7.5 mg/dl. However repeat urinalysis revealed significant proteinuria and on quantification, it was 17g with albumin of 2. He also had lower extremity edema indicative of nephrotic syndrome. Of note, he did not have proteinuria a week before his hospital admission. At this point, a renal biopsy was undertaken and was noted to have collapsing glomerulopathy with 80-90 percent effacement of foot processes. The patient continued to improve to creatinine of 2.4 with improvement in urine output at which point he was discharged on ACE-I.

Discussion: Collapsing FSGS in probably related to complex interplay of multiple factors like infection, acute kidney injury due to other etiologies, genetic risk factors such as APOL1. Recent cases of COVID-19 related AKI point towards the possibility of collapsing FSGS as the etiological mechanism, especially with APOL1 association. Though it is traditionally described in the setting of infections like parvovirus and HIV, there could underlying common mechanisms for infections that may not be exclusive to these and may expand to other infectious etiologies like influenza, COVID.

PUB178

Hypoalbuminemia Out of Proportion to Proteinuria in a Patient with Nephrotic Syndrome

Chidi Egwim, Javier Jaramillo Morales, Laura Binari, Gautam B. Bhave. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Hypoalbuminemia is a fundamental characteristic of nephrotic syndrome, with most of the albumin loss resulting from urinary excretion. As such, the degree of proteinuria in a glomerular process often mirrors the serum albumin. The differential and work-up changes when there is discordance between the two.

Case Description: A 68-year-old African American male presented with three weeks of a worsening cough, diarrhea, and progressive swelling. His past medical history was notable for dysphagia secondary to esophageal rings with dilations in the past, acute myeloid leukemia s/p allogenic stem cell transplant and deep vein thrombosis. His stem cell transplant was a year prior to presentation, and he was tapered off MMF and to a lower dose of tacrolimus with prednisone. On physical exam, he had gross anasarca. His labs were notable for a serum creatinine of 1.5 mg/dL from a prior baseline of 1.3 mg/dL. His albumin was 1.2 g/dL with a spot urine protein to creatinine ratio of 3.12 and 24-hour urine protein of 3.5 gm/day. A lipid panel showed a cholesterol of 391 and a LDL of 292. Serologies for hepatitis and lupus were negative. Complement levels were normal and no monoclonal protein was seen on serum/urine electrophoresis. A serum PLA2-R was negative. He underwent a kidney biopsy that demonstrated subepithelial glomerular, mesangial, and tubular basement membrane deposits consistent with secondary membranous nephropathy. Staining for PLA-2R was positive. He was started on Rituximab and continued treatment as an outpatient.

Discussion: Here we describe a case of nephrotic syndrome in which the degree of hypoalbuminemia was not consistent with the amount of proteinuria. This discordance represents a defect in the homeostasis of albumin typically seen in nephrotic syndrome. At a steady state, albumin synthesis is balanced by albumin catabolism and urinary loss. In nephrotic syndrome, catabolism is decreased while synthesis and urinary loss increases. The patient's history of diarrhea and dysphagia suggested that he had either increased catabolism from non-renal GI losses or decreased synthesis due to poor intake. This case highlights alternative laboratory findings in membranous nephropathy and a framework for understanding the differences.

PUB179

Renal Response and Its Predictive Factors of Lupus Nephritis: A Two-Year Cohort of 77 Hospital-Based Patients

Zhiming Lin,[1] Junmei Feng,[1] Jun Zhang,[2] Changlin Zhao,[3] Zhen Wu.[3] *[1]Department of Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; [2]Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; [3]Department of Vasculocardiology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: To evaluate the renal response rates of lupus nephritis (LN) patients undergoing standard treatment during a two-year follow-up and investigate its predictive factors.

Methods: A prospective cohort study enrolled 77 clinically diagnosed LN patients was carried out. All patients underwent standard treatment according to Joint European League Against Rheumatism and European Renal Association–European Dialysis and Transplant Association (EULAR/ERA-EDTA) recommendations or American College of Rheumatology (ACR) guidelines for the management of LN. Regular visits were performed every 6 months until 2 years. Data on renal response and clinical characteristics were collected and analyzed.

Results: Among 77 patients, 41(53.2%) and 15(19.5%) patients achieved complete response (CR) and partial response (PR) at 6 months after induction therapy, respectively. With every 6-months visits, 53(68.8%) patients completed the whole 2-year follow-up. 38(71.7%) and 5(9.4%) patients developed CR and PR at 2 years. During follow-up, serum creatinine (SCr) and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score showed a significant decrease as compared to baseline data, while estimated glomerular filtration rate (eGFR) and C3 level gradually elevated. In multivariate regression model, immunological disorder (OR 4.73, 95%CI 1.00-22.40, p=0.05), eGFR (OR 1.04, 95%CI 1.02-1.07, p<0.001) and SLEDAI (OR 1.21, 95%CI 1.05-1.40, p=0.01) at baseline were found to be associated with CR/PR at 6 months as compared to non-responders.

Conclusions: Nearly 70% LN patients achieved renal response after 6-months standard induction therapy, and the renal response rates were higher after 2 years. Renal function and disease activity showed a significant improvement during follow-up. Besides, immunological disorder, higher baseline eGFR and SLEDAI were predictive factors for renal response.

PUB180

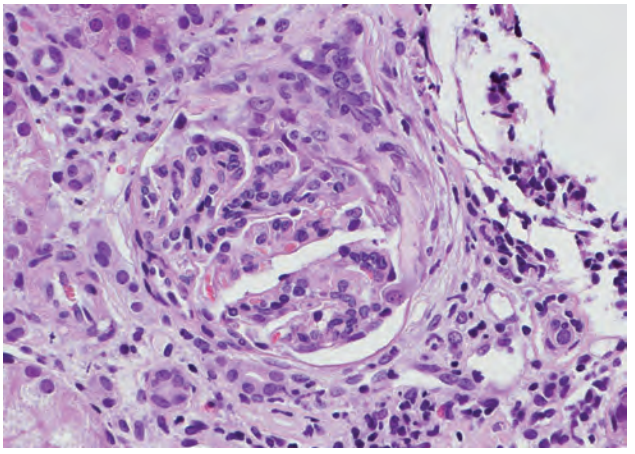
An A-Tip-ical Side Effect of Lithium

Casie James, Randall Craver, Isa Ashoor. *Louisiana State University Health Sciences Center, New Orleans, LA.*

Introduction: Lithium is a mood stabilizer approved for bipolar disorder treatment in children as young as 12 years. Though effective in the pediatric population, lithium requires close monitoring for toxicity and adverse effects.

Case Description: An 18 year old male with Hashimoto's thyroiditis, bipolar I disorder, and anxiety presented with 10 days of edema, weight gain, progressive abdominal pain, emesis, diarrhea, and decreased urine output with frothy urine. Medications included levothyroxine, Risperdal, and lithium. Creatinine was 1.2 mg/dl, up from baseline of 0.8 mg/dl. There was nephrotic-range proteinuria, with spot urine protein/creatinine ratio of 9. Serum lithium level was 2.5 mmol/L (therapeutic range 1-1.2 mmol/L). Renal biopsy showed tip variant focal segmental glomerulosclerosis (FSGS), with diffuse fusion of foot processes, but no tubular epithelial changes. Lithium was discontinued, and the patient underwent diuresis with Lasix/albumin infusions. Proteinuria resolved within two months, and he remains in remission. Bipolar disorder is now treated with Lamictal and Risperdal.

Discussion: Lithium has a wide side effect profile, requiring close monitoring. Lithium-induced nephrotic syndrome is a known, idiopathic side effect. Most renal biopsies show minimal change disease; however, FSGS has also been associated with lithium use. To our knowledge, this is the first documented case of tip variant FSGS in a teenager. While lithium may have induced nephrosis, the low effective circulating volume in nephrotic syndrome with subsequent decrease in glomerular filtration rate likely led to poor excretion of lithium, leading toxic levels and protracted recovery from adverse effects. Despite atypical histology, the patient followed a favorable course and remains in remission without immunosuppressive therapy.



Glomerulus with hilum toward left, slightly below center, and sclerotic segment at the apex adherent to the proximal tubule, at mid-upper right. Variable visceral cell hyperplasia. (Hematoxylin and eosin, 400X)

PUB181

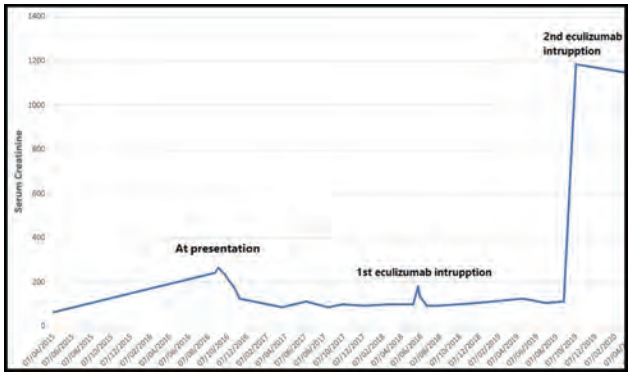
AKI After Eculizumab Interruption in a Case of C3 Glomerulopathy

Mostafa F. Elshirbeny, Mohammed E. Hussain, Essa Abuhelaiqa, Awais Nauman. *Hamad Medical Corporation, Doha, Qatar*.

Introduction: C3 glomerulopathy (C3G) is a newly recognized rare disease characterized by predominantly glomerular deposition of complement C3. Treatment with the C5 complement inhibitor eculizumab may be a therapeutic option but due to rarity of the disease, predicting tools of the outcomes remain largely unknown.

Case Description: Here we report 25-year old female patient who was referred to nephrology clinic with renal impairment, hematuria, and proteinuria. Kidney biopsy results revealed membranoproliferative changes with predominant C3 deposits, suggestive of C3 glomerulopathy. Genetic testing revealed two unrelated mutation in C3 gene, likely not related to C3G. Patient was responding well to oral steroid and MMF with remission of proteinuria and normalized serum creatinine. She was relapsed again, 1 year later with hematuria and nephrotic proteinuria. Steroids and MMF were resumed with no response then started on eculizumab, after which she achieved partial remission with reduction in serum creatinine and urine protein. During next 2 years, patient missed eculizumab in 2 occasions. The first, when she missed one dose followed by mild rise in serum creatinine which improved after eculizumab resuming and few months later she missed two doses then presented with severe AKI requiring dialysis. Was started on steroids and eculizumab was resumed with no improvement in kidney function and patient still dialysis dependent.

Discussion: Despite looks like safe and valuable therapeutic option in patients with C3G but the response to eculizumab is heterogeneous and when to discontinue the therapy still unsolved problem as transient interruption of the therapy sometimes complicated with AKI which may be severe enough to end with ESRD like this case.



Serum creatinine results during 40 months of follow up

PUB182

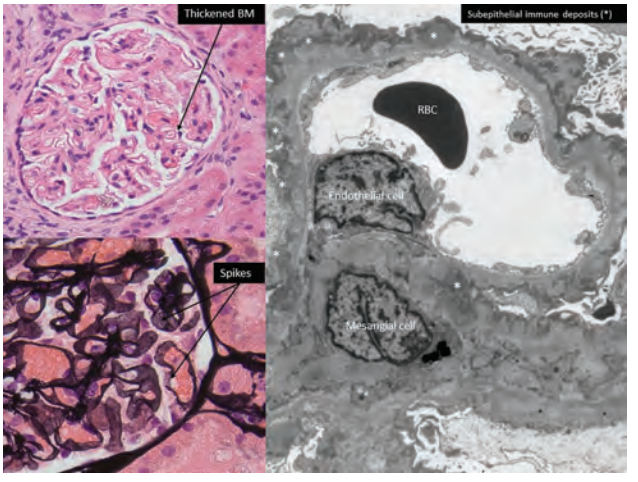
A Rare Case of Primary Membranous Glomerulonephritis in HIV Successfully Treated with Adrenocorticotropin Injection Gel (Acthar)

Mohammed Nazmul, Neil Alouch. *Creighton University, Omaha, NE*.

Introduction: HIV patients are immunocompromised and treatment with steroids or cytotoxic agents for glomerulonephritis (GN) is challenging, There is paucity of data regarding Adrenocorticotropin injection like Acthar gel as an alternative immunosuppressive agent for Primary membranous GN in HIV patients.

Case Description: Our patient is a 55 years old African American lady with PMH of HTN, HIV on remission with Emtricitabine, Tenofovir alafenamide, CKD with baseline creatinine 1.0-1.5 mg/dl. February 2018, patient's urine showed protein: creatinine ratio 6.1. Secondary work ups for proteinuria were negative. On renal biopsy, light /EM revealed membranous GN, minimal mesangial deposits favoring primary. Serum PLA2R antibody was 1:1120 (Normal <1.10), malignancy screening was negative. Patient started on Lisinopril then switched to Losartan to maxmum dose, proteinuria improved to 1.5 gram in February 2019 but increased again to 10.9 gram on November 2019, serum creatinine rose to 2.32 mg/dl. HIV specialist recommended against steroid, Acathr gel was started in April, 40 units s/q twice a week. Patient tolerated the medication well, HIV viral load undetectable, normal CD4 count and after 1 month proteinuria decreased to 4.9 gram, creatinine improved to 2.0 range and PLA2R antibody titer went down to 1:140. Acthar gel dose being uptitrated further accrding to patient's clinical response.

Discussion: This case study highlights the efficacy and tolerance of ACTH hormone therapy with RAAS blockade in HIV patient with primary membranous GN. Acthar gel may improve proteinuria due to its anti-inflammatory properties similar to steroid and can be considered as steroid sparing agents in difficult situations such as underlying HIV or other immunosuppressive diseases like HCV, HBV, malignancy. We conclude that, combination of RAAS blockade and Acthar gel can be a reasonable treatment regimen in complex case of primary membranous GN with coexistent HIV.



PUB183

Pathological Features and Clinical Course of IgA Nephropathy Patients with Isolated Hematuria

Yusuke Fukao,[1] Hitoshi Suzuki,[1,2] Toshiki Kano,[1] Yuko Makita,[1] Maiko Nakayama,[1] Mingfeng Lee,[1] Rina Kato,[1] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrology, Juntendo University Faculty of Medicine, Chiba, Japan*.

Background: Microscopic hematuria is the most common manifestation of IgA nephropathy (IgAN). There are a few studies identifying the remission rate of microscopic hematuria as an important clinical predictor of deterioration of renal function. Microscopic hematuria caused by glomerular microvasculitis may have clinical significance. Renal biopsy was performed rarely in case with isolated hematuria. Renal pathological features and the renal prognosis of IgAN patients with isolated hematuria are unclear. Thus, there are no established treatments guides. In present study, we evaluated the pathological features and clinical course in IgAN patients with isolated hematuria in our cohort.

Methods: We retrospectively recruited 47 biopsy proven patients with IgA nephropathy who showed isolated hematuria at real biopsy from 2012 to 2017. We evaluated renal pathological findings in those patients. Moreover, we analyzed clinical course during 24 months from the diagnosis. Thirty of these patients were treated with steroid pulse therapy combined with tonsillectomy (TSP group) and the others were conservatively treated (CT group). In CT group, only three patients were treated with renin-angiotensin system inhibitor. We analyzed clinical parameters, such as, levels of urinary red blood cells, onset of proteinuria, eGFR and serum IgA.

Results: Although age, sex and degree of hematuria at the time of renal biopsy were not significantly different between the TSP and CT group, baseline eGFR was significantly lower in TSP group (88.7 versus 105.9mL/min/1.73 m2). Of note, 51% of patients showed crescent or endocapillary proliferation. At the end of observation period,

remission rate of hematuria in TSP group (100%) was much higher than that in CT group (71%). Moreover, immunosuppression therapy was effective to prevent significant decline in kidney function.

Conclusions: We clarified that more than half of patients with isolated hematuria showed crescent or endocapillary proliferation in present study. Immunosuppression therapy is effective for those lesions. Thus, even in the patients with isolated hematuria, conservative treatment can be a risk for deterioration of renal function.

PUB184

Indolent Pauci-Immune Crescentic Glomerulonephritis

Elizabeth Pepper,[1] Jalal E. Hakmei.[2] *[1]Edward Via College of Osteopathic Medicine - Carolinas Campus, Spartanburg, SC; [2]Palmetto Nephrology, Orangeburg, SC.*

Introduction: Pauci-immune glomerulonephritis (PIGN) is most commonly associated with a rapidly progressive course towards renal failure, although rarely, an indolent course may be observed. PIGN has a frequent association with either MPO- or PR3-antibodies and is associated with extra-renal manifestations. We report a patient with slowly declining renal function over the course of two years that had a renal-limited MPO-antibody associated pauci-immune glomerulonephritis.

Case Description: A 61 year old Caucasian female with controlled hypertension, hypercholesterolemia, and prediabetes without complaints was noted by her PCP to have a slowly rising creatinine over two years. A nephrology referral was made with new onset 1+ pitting edema in the bilateral, distal lower extremities and a creatinine of 1.7mg/dL. Urinalysis at this point showed a sediment and 2g/g of creatinine to protein. A renal ultrasound showed structurally sound kidneys. Common infectious causes of renal disease to include hepatitis B, C, and HIV were ruled out. MPO, PR-3, ANA, C3, and C4 were sent to see if there was an autoimmune cause. A positive MPO prompted a renal biopsy which yielded a sample of 50 glomeruli with 15 completely sclerosed, 4 with crescent formation, and moderate to severe interstitial fibrosis and tubular atrophy. This confirmed the diagnosis of MPO associated PIGN. Immunosuppression was begun with a rituximab based therapy, but the second dose of rituximab was interrupted due to severe back pain combined with nausea and vomiting. Creatinine was elevated at 3.6mg/dL from 2.2mg/dL the day before. Methylprednisolone was tapered and further infusions were not pursued due to development of deranged liver function tests, hospitalization for diverticulitis, development of uncontrolled DM, and severe psychological symptoms. Over the following two months, the patient's creatinine has trended down to 1.5 mg/dL.

Discussion: Her consistently rising creatinine was the main driver to begin immunosuppressive therapy despite having moderate to severe interstitial fibrosis and tubular atrophy. Rituximab based therapy was shown in the RAVE trial to be non-inferior to cyclophosphamide for induction of remission in ANCA associated disease. This combination may also have superior relapse rates and a better safety profile in comparison with cyclophosphamide. Her improving creatinine suggests that even an incomplete regimen might have conferred some benefit.

PUB185

IgG4-Related Disease Presenting with Membranous Nephropathy

Elena Zakharova.[1,2] *[1]City Clinical Hospital n.a. S.P. Botkin, Moscow, Russian Federation; [2]Rossijskaa medicinskaa akademia nepreryvnogo professional'nogo obrazovania, Moskva, Russian Federation.*

Introduction: Immunoglobulin G4-related disease (IgG4-RD) is a condition, affecting multiple organs. Retroperitoneal fibrosis with obstructive nephropathy and interstitial nephritis are most typical kidney damage. Rare cases of glomerular disease, including membranous nephropathy (MN), had been described. Search for IgG4-RD cases in the database of our nephrology unit found 11 patients, in three cases kidney biopsy showed MN, and we present one of them

Case Description: 73 years old Caucasian female with a history of arterial hypertension, diabetes, skin patchy hyperpigmentation, asthma and nasal polyposis manifested in 2016 with the weight loss and skin rush. 9 months later, at admission, she was undernourished, with multiple skin scratches, pedal edema, and otherwise unremarkable physical exam; her blood pressure was 150/90 mm Hg, vital signs were normal. Work up demonstrated nephrotic syndrome and marked eosinophilia (32.6% - 2.6*10^9/L). Her blood chemistry tests, serum and urine immunochemistry, p and c ANCA, anti Scl-70, anti-RNT and anti-CENP-B antibodies were within normal range. Kidney biopsy showed MN with IgG, C3, kappa and lambda fine granular deposits on the capillary loops periphery. Her anti-PLAR2 antibodies titer was <1:10; kidneys, abdomen, neck and pelvis ultrasound, chest CT, gastroscopy and colonoscopy were unremarkable. Tests for parasitic infections and myeloid hypereosinophilic syndrome markers (FIP1L1-PDGFRα and ETV6-PDGFRβ) were negative. IgG4 level was 1.9g/L (0.8-1.4) – 29.2% (4.0-5.0). We diagnosed IgG4-RD and started her on oral prednisone 40 mg daily. Her skin rush resolved immediately, in a month her eosinophil count became normal, two months later she achieved partial remission of nephrotic syndrome. We added cyclosporin A and slowly tapered prednisone. At the latest follow-up visit January 2020, she was doing well, with the complete remission of nephrotic syndrome, preserved kidney function and normal IgG4 level

Discussion: Clinical presentation was suggestive for ANCA-associated vasculitis or systemic sclerosis, not confirmed by serology and kidney pathology findings. The search for the hypereosinophilic syndrome causes was negative, and only IgG4 testing gave a clue to the diagnosis. Steroids allowed controlling hypereosinophilia symptoms, but not kidney disease, which responded to cyclosporin. We conclude that IgG4-RD should be considered in differential diagnostics of membranous nephropathy

PUB186

Role of Therapeutic Plasmapheresis in ANCA-Associated Vasculitis: A Single-Center Study

Aglaia Chalkia,[1] Alexandros G. Panagiotopoulos,[2] Panagiota E. Giannou,[1] Dimitris Kourniotis,[1] Athanasia Kapota,[1] Margarita Mpora,[1] Dimitrios Vassilopoulos,[2] Dimitrios I. Petras.[1] *[1]Nephrology Department, Hippokration General Hospital, Athens, Greece; [2]Joint Rheumatology Program, National and Kapodistrian University of Athens, School of Medicine - Clinical Immunology - Rheumatology Unit, 2nd Department of Medicine, Athens, Greece.*

Background: Recently Pexivas trial showed no benefit of plasmapheresis (PEX) in ANCA-associated vasculitis (AAV), even in patients with alveolar hemorrhage, but is this the end of PEX in AAV? The aim of this study is to describe the indications, method and complications of PEX, as well as whether PEX is associated with improvement in renal function and survival at 12 months.

Methods: Retrospective study of 28 patients with severe manifestations of AAV, who had received PEX adjunctive to conventional therapy for the first episode of AAV or in relapse.

Results: We recorded twelve patients receiving PEX. This group (n=12) had an average age at diagnosis 79years and was followed for a median period of 20 months. In 75% of the patients MPO-ANCA was positive, in 17% ANCA negative and in 8% double positive anti-GBM/ANCA. On admission, all patients had abnormal renal function with average creatinine 5mg/dl±2.12 and the majority of patients (9/12) were dialysis dependent. Indications for plasmapheresis were: alveolar hemorrhage in 33%, renal impairment in 25% and combination of the two above in 42%. Plasmapheresis was performed using filtration and fresh frozen plasma as replacement fluid. The mean number of plasmapheresis treatment was 8 (1-19 days) and the average internal time between admission and first plasmapheresis treatment was 3 days. No episodes of severe infection or death were recorded during plasmapheresis. All patients received concomitant therapy with Cyclophosphamide and corticosteroids while Rituximab was added in 3 patients. Alveolar hemorrhage was resolved in all patients (100%). After one year, 75% of the patients had renal recovery (cre=5mg/dl±2.12 vs cre=2.6mg/dl±1.6, p=0.06) and 67% of the patients who required hemodialysis at the time of diagnosis, during the first year became independent of dialysis (75% vs 33%, p=0.5). Finally, survival rate at the end of the first year was 83%.

Conclusions: Plasmapheresis is quite often used in daily clinical practice with remarkable results in dialysis independence and survival, without serious complications.

PUB187

Retrospective Analysis of Five Cases of Proliferative Glomerulonephritis with Monoclonal IgG Deposition Regarding Their Clinical Course and Responses to Therapy

Takatsugu Iwashita, Minoru Hatano, Koki Ogawa, Ryo Yamamoto, Yuta Kogure, Hajime Hasegawa. *Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Introduction: Background At present, limited knowledge is obtained regarding pathophysiology and clinical course of proliferative glomerulonephritis with monoclonal IgG deposition (PGNMID). It is rarely diagnosed by renal biopsy, and there is no established therapeutic strategy for this disease. We report clinical course and responses to the therapy of 5 cases diagnosed as PGNMID in our facility.

Case Description: Method Five cases (3 males and 2 females, median age 62 years) with renal biopsies and diagnosed as PGNMID between January 2016 and December 2019 were retrospectively analyzed regarding the transition of eGFR and urine protein level by the treatment. Three of 5 cases were treated by steroid alone in combination with intravenous methyl Prednisolone (PSL) 500 mg/day for 3 days and oral PSL 30 mg/day. Remaining 2 cases were treated with intravenous methyl PSL and oral PSL followed by Cyclophosphamide intravenously (750 mg/day, twice) or orally (100 mg/day, daily) administration and Rituximab (500 mg/body, twice) administration. **Results** Light microscopic findings were MPGN type in all cases, and immunofluorescent staining showed 4 cases were IgG3-kappa and only 1 case was IgG3-lambda. Three cases in the first month of the treatment had partial remission (KDIGO diagnostic criteria, defined as a urinary protein level of < 0.3-3.5 g/day and a reduction of ≧ 50% from baseline), and all had partial remission at 6 months. Hematuria was observed at the start of treatment in three cases and disappeared in only one case by the treatment. And, the remarkable deterioration of renal function was not observed during the clinical coourse. However, two cases showed the increase of urine protein after about one year from mPSL administration, and IVCY and RTX were administered, but urine protein and hematuria were not decreased, and mPSL was administered again. In one case, the improvement of the urinary finding was scarce even after the increase in the administered steroid.

Discussion: Conclusion Our results suggest that the treatment responsiveness to IVCY and RTX is poor, that steroids are more responsive to initial therapy, that disease activity increases with dose reduction (a steroid-dependent condition), and that treatment responsiveness to steroids may decrease after relapse.

PUB188

AA Amyloidosis and CKD in a Patient with Coexisting Hepatitis C Infection and Crohn Disease

Arteen Pirverdian, Monica E. Corral, Grace Mcnutt, Julio P. Zavala Georffino. *University of the Incarnate Word, San Antonio, TX*.

Introduction: AA amyloidosis is in the differential diagnosis of patients with proteinuria and may lead to chronic kidney disease (CKD). It is usually associated with chronic inflammatory conditions like rheumatoid arthritis which is implicated in 40% of cases. Crohn's disease (CD) is also recognized as an underlying etiology. We present a patient with chronic Hepatitis C infection (HCV) and CD who developed proteinuria and CKD in a relatively short period of time.

Case Description: 33-year-old man with a past medical history of CD, HCV, and cocaine/heroin abuse with frequent IV drug use presented to the ED with complaints of bilateral lower extremity swelling and tenderness. Initial laboratory studies were significant for a creatinine of 4.56 and nephrotic range proteinuria. On review, his creatinine had been trending up from 0.75 mg/dl to 4.09 mg/dl in the last year. Secondary work-up for proteinuria including: ANA, RPR, RF, ANCA, C3, C4, Cryoglobulin with reflex, ds DNA Ab, UPEP, and SPEP w/ immunofixation screenings all yielded negative results. S. cerevisiae Ab IgA was 51.5, a positive confirmation of patient's CD. HCV antibody test was positive with a positive HCV RNA. Renal biopsy was performed and revealed AA amyloidosis with severe interstitial fibrosis and tubular atrophy.

Discussion: AA amyloidosis is a disorder characterized by the overproduction of extracellular proteins that deposit and subsequently cause organ and tissue impairment. It is often attributed to chronic inflammatory/infectious diseases. Though literature about the incidence of AA amyloidosis in people afflicted with HCV is limited, incidence in individuals afflicted with CD has been reported to be between 0.5%-8%. AA amyloidosis has also been found to be a major cause of CKD in IV drug users. One UK study found that up to 35% of these patients have associated HCV. There are reports of increased CD "flares" in patients undergoing treatment for chronic HCV, which may suggest that the coexistence of both diseases may lead to worse morbidity. Our case is unique due to the coexistence of two chronic diseases that lead to inflammatory/infections processes known to be involved in the pathophysiology of AA amyloidosis. This co-existence may lead to a faster progression of CKD and overall worsening outcomes.

PUB189

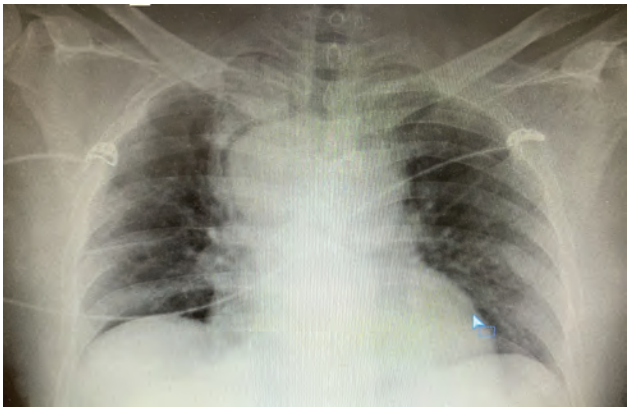
Awareness of Association of ANCA Vasculitis and Aortic Aneurysm Can Improve Survival

Sonalika Agarwal, Jitendra Kumar. *QRG Hospital, Faridabad, India*.

Introduction: ANCA vasculitis is a small-medium vessel vasculitis which is characterized by systemic necrotizing inflammation of blood vessels. Aortic aneurysm is a very rare complication of ANCA vasculitis. We describe a case of such association and highlight the need for guidelines for its screening in patients diagnosed with ANCA vasculitis.

Case Description: 40 year old man with no known medical history presented with renal failure and was started on dialysis. Kidney biopsy showed pauci immune crescentic glomerulonephritis. As per KDIGO guidelines, he was treated with steroids, cyclophosphamide and plasmapheresis after which he recovered from dialysis. 3 months later, he presented with hematemesis and shock. Due to worsening hematemesis and shock, upper endoscopy was done which revealed aorto-esophageal fistula and patient died of shock with no time for surgical intervention. On retrospective analysis, we found that unfolding of aorta seen on chest xray 3 months ago was likely aortic aneurysm which had increased in size and ruptured.

Discussion: To the best of our knowledge, this is the first case reported from India. The reason we think ANCA vasculitis is associated with aortic aneurysm is because it has been proven by biopsy in case reports in the past and in few of them, aneurysm had even decreased in size with chemotherapy. Also, it is surprising that such degenerative condition would occur without any risk factor like smoking, atherosclerosis, history of hypertension, or family history of connective tissue disorders in such a young patient. Since both ANCA vasculitis and aortic aneurysm are rare pathologies, it is reasonable to consider that they are related when occurring together. Again, Its rapid expansion and rupture within a span of 3 months favors an underlying association. This case highlights that nephrologists should be aware of such association, screen the patient on presentation and then at intervals likely earlier than recommended for aortic aneurysm of other etiologies.



PUB190

Atypical Presentation of Microscopic Polyangiitis

Alejandro Garcia Rivera, Luz Y. Villegas, Marcos Adrian E. Lopez, Ríos C. Katia yuritzi, Carlos A. Villavicencio López, Teresa Muñoz, Arantxa K. Aguilar, Jesús A. Rico sánchez, Jesús A. Vega López de Nava, Isela Márquez magaña, Ana M. Molgado castillo, Arisbeth Villanueva Perez. *Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Hospital General Regional No.46, Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Introduction: MPA is an uncommon disease, more common in men, in white and Asian populations and whose incidence increases with age. We describe an atypical presentation of MPA

Case Description: 48-year-old female patient, no relevant past medical history, who came to the ER with a 2-week history of bradypsychia, gait disturbances, arthralgia, lower limb pain. On PE non-blanching red-purple papules were noted. A lab panel showed increased creatinine at 5.79 mg/dL (baseline Cr was 1.09), microscopic hematuria and sub-nephrotic proteinuria. Kidney ultrasound was normal, urinary sediment showed dysmorphic RBC with RBC casts She was placed an acute catheter for HD prior biopsy. Immunological panel showed positive ANCA, specificity for PR3 antigen; C3 and C4 levels were normal; the rest of the panel and HIV, HBB and HCV serologies were negative. CT showed maxillary sinusitis, lungs were normal Skin biopsy showed a leukocytoclastic vasculitis and kidney biopsy showed a pauci-immune necrotizing glomerulonephritis, with diffuse extra-capillary proliferative lesions, mild interstitial fibrosis; no granulomas. Patient was diagnosed with a MPA, and treatment was started with IV GC and RTX. Patient was discharged to continue treatment in the out-patient clinic and currently has received a second dose of rituximab, with no need for hemodialysis and a creatinine of 2.5 mg/dL (7 days after starting treatment)

Discussion: MPA is a rare disease with unknown frequency in Mexico. Our case was atypical since it presented in a Hispanic female younger patient, with a histopathological phenotype of MPA but positive to PR3, with no respiratory involvement and no upper airway destructive lesions

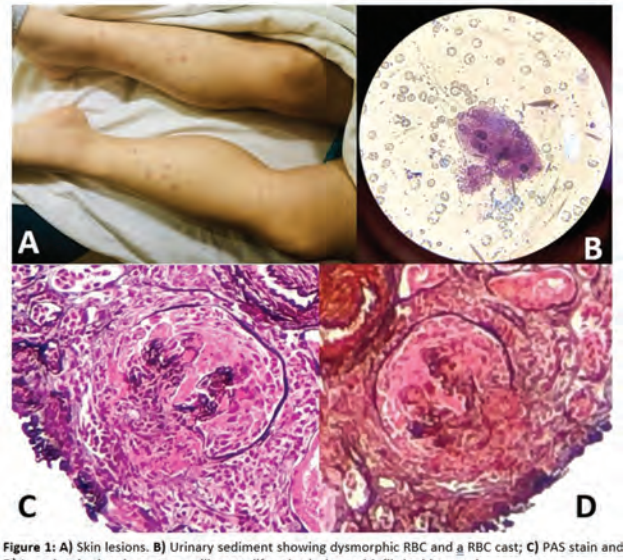


Figure 1: A) Skin lesions. **B)** Urinary sediment showing dysmorphic RBC and a RBC cast; **C)** PAS stain and **D)** Jones' stain showing extra-capillary proliferative lesions with fibrinoid necrosis.

PUB191

Kidney Crashes: Stop That Drug!

Latoya N. Gayle, Gene C. Otuonye, Nia Flemming, Marc S. Zelkowitz. *Englewood Hospital and Medical Center, Englewood, NJ*.

Introduction: Drug associated antineutrophilic cytoplasmic antibody(ANCA) associated vasculitis(DAV) with rapidly progressive glomerulonephritis(RPGN) is rare. Historically linked to antithyroid drugs, new evidence implicates almost every pharmacologic class. Unrecognized, it is catastrophic. Prompt diagnosis & cessation of the offending agent is paramount. This is a case of DAV-RPGN secondary to diltiazem

Case Description: 76-year-old male with T2DM, cirrhosis, HTN & MM in remission, on diltiazem, propranolol, insulin, presented to an outside hospital with 10-days of weakness, reduced appetite & leg swelling. On exam BP 191/79,T97°F & anasarca was present. Labs showed Na128, K5.3, Cl100, HCO3 19, BUN79, creatinine(Cr) 2.8, increased to 4.18 by admission day 10, Ca 7.6, phos 4.7, WBC 8.8, Hb 9.4 & PLT 214. CT abdomen showed renal cysts, mild ascites & no hydronephrosis. Renal biopsy showed crescentic pauci-immune vasculitis & severe necrotizing arteritis with positive pANCA, MPO, ANA, DS-DNA, RhF & low C3. He received IV methylprednisolone for 3 days, followed by prednisone 60mg od, transferred to our hospital, then started on cyclophosphamide 15mg/kg q2 weeks with plasmapheresis. There was suspicion for DAV secondary to diltiazem. Antihistone Ab(AHa) was sent & diltiazem stopped. Electron microscopy showed subendothelial deposits & intracellular macrophages suggestive of SLE. AHa was positive with negative cryoglobulin. Diagnosis of drug induced SLE from diltiazem with p-ANCA positive RPGN was made. He was discharged on prednisone 60mg daily with slow taper & Rituximab. Cr at discharge was 3

Discussion: DAV is an elusive diagnosis due to limited epidemiological data & identical features to primary ANCA associated vasculitis (PAAV). Although there is no clear definition, CHCC2012 describes it as "Vasculitis associated with probable specific etiology".Pathophysiology of drug induced ANCA formation & DAV is poorly understood. Possible mechanisms include reversal of epigenetic silencing & increased MPO & PR3 autoantigen expression in neutrophils, as in hydralazine, or formation of reactive intermediate species by PTU that act as MPO substrates. Regardless DAV must be differentiated from PAAV. It may present with lower Cr, urinary protein & CRP levels, tends to be ANA+ & AHa can be present, as in this case. Treatment involves prompt cessation of the offending agent & immunosuppression, with improved prognosis compared to PAAV

PUB192

C3 Glomerulonephritis: Can Therapy Be Individualized?

Sarah M. Moran,[1] Marina Noris,[2] Richard J. Smith.[3] *[1]Queen's University, Kingston, ON, Canada; [2]Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy; [3]Iowa State University, Ames, IA*.

Introduction: C3GN is a rare form of glomerulonephritis with variable clinical course. Therapeutics traditionally include corticosteroids, MMF and plasma exchange. Complement directed therapies remain under investigation. We report a case ofC4Nef and C5Nef positive C3GN treated with eculizumab.

Case Description: A 31 year old female was diagnosed with membranoproliferative glomerulonephritis (MPGN) in 2006 at age 19. She was treated with high dose prednisone for six months with no response. Conservative therapy was instituted. She was referred for to our centre for evaluation in 2018. At this time she was nephrotic with proteinuria 12g/day, serum albumin 21 g/L, serum creatinine 101umol/L with low C3 was 0.15 (0.8-1.9) and normal C4 at 0.13 (0.13-0.4). Repeat kidney biopsy revealed C3GN, with MPGN pattern, 4/34 globally sclerotic glomeruli and moderate interstitial fibrosis. Immunofluorescence showed C3 3+; IgM 1+; C1Q negative. There were no dense deposits on electron microscopy. Complement function studies demonstrated elevated C5b-9 level, low C5, C5 nephritic factor (C5Nef) positive at 1+ and C4 nephritic factor (C4Nef) strongly positive at 4+. C3 nephritic factor was negative. The positive C5Nef and C4Nef prompted testing for C5b-9 deposition on endothelial cells. sC5b-9 was elevated at 160% (normal < 150%). As complement functional testing suggested targeted terminal complement pathway for treatment may benefit this patient. We commenced eculizumab was commenced. At 6 months follow up, proteinuria has decreased (urine ACR 427mg/mmol), creatinine improved at 84 umol/L, and albumin increased to 33 (versus 21). C3 remains low at 0.11.

Discussion: We have demonstrated a case of C3GN with positive C3 adn C5Nef with cell surface activation of complement, classical and terminal complement pathway involvement. This highlights the importance of complement function studies to help aid the localization of complement pathway defect, and to individualize therapy.

PUB193

A Rare Case of NSAID-Induced Minimal Change Disease

Navneet Kaur,[1] Sanja H. Patino,[1] Gopika Dasari,[1] Eric J. Chacko,[1] Marc Richards.[2] *[1]Florida Atlantic University Charles E Schmidt College of Science, Boca Raton, FL; [2]Boca Raton Regional Hospital Inc, Boca Raton, FL*.

Introduction: Nonsteroidal anti-inflammatory drugs (NSAIDs) can cause acute tubular necrosis (ATN) via inhibition of prostaglandin synthesis, and vasoconstriction. Drug-induced minimal change disease (MCD) is postulated to be due to a reduction in renal perfusion and glomerular filtration rate. We present a case of NSAID induced acute renal failure (ARF) due to ATN and MCD in a healthy 37-year-old adult.

Case Description: A 37-year-old male with no medical history came to the ED with 1 week of vomiting, abdominal pain, and reduced urine output. He attributed his symptoms to food poisoning but sought evaluation after no improvement. Over the last 2 weeks, he had an upper respiratory infection and dental pain for which he took 1g of ibuprofen daily. Labs yielded a BUN of 104mg/dl, creatinine (Cr) of 16.9mg/dl, and urine protein to creatinine ratio of 5.85. Renal ultrasound showed no hydronephrosis. Abdominal CT showed diffuse colitis. Dialysis was initiated for uremic colitis. Workup for ARF was negative for hepatitis, HIV, and autoimmune markers. Kidney biopsy revealed podocyte effacement and nonspecific minimal deposits with severe ATN. Immunofluorescence showed nonspecific mild granular tubular and glomerular IgG deposition. Electron microscopy noted widespread podocyte effacement consistent with MCD. Prednisone 60 mg daily was started. Within 48 hours oliguria resolved and dialysis was discontinued. Cr at discharge was 3.6. After a slow taper of steroids, he had a full recovery.

Discussion: Although NSAID-induced ATN is well understood, it is unusual to see ATN causing ARF with oliguria in a young patient with no comorbidities. Nephrotic syndrome induced ATN has been specifically documented in association with MCD. This is likely the mechanism of ATN development in our patient with drug-induced MCD. MCD is the most common cause of nephrotic syndrome in children but accounts for only 10-15% of adult cases. Data evaluating drug-induced MCD in adults is limited to a few case series and retrospective studies associating NSAIDs with acute interstitial nephritis, rather than ATN, as the cause of MCD. Contrary to our case, NSAIDs have shown to reduce proteinuria in idiopathic nephrotic syndrome. Corticosteroids are the first-line therapy, and adults with MCD require prolonged therapy with a slow taper. The majority of ARF induced by MCD is reversible, with complete recovery of renal function.

PUB194

Kidney Aging and Estimation Equations for GFR in Beijing

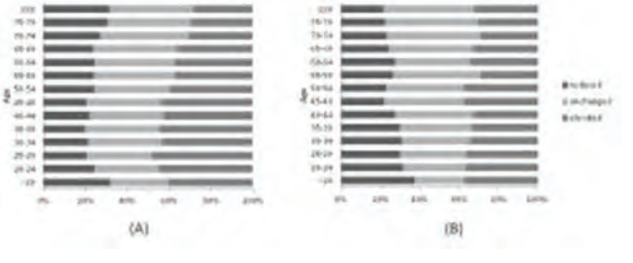
Lengnan Xu, Yonghui Mao. *Beijing Hospital, National Center of Gerontology; Institute of Geriatric Medicine, Chineses Academy of Medical Sciences, Beijing, China*.

Background: When evaluating renal function, eGFR data show significant variation across different equations, particularly in elderly patients. Here, we investigated how age affected renal function in healthy subjects in Beijing and compared different eGFR equations for the evaluation of renal function.

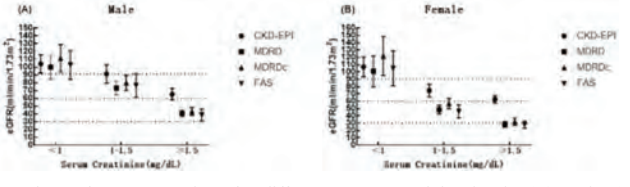
Methods: We recruited all patients undergoing routine assessment in our hospital between January 2012 and December 2014. For each patient, we recorded age, gender, and sCr. Kidney function was evaluated by five equations: CKD-EPI, MDRD, MDRDc, FAS and BIS.

Results: A total of 46,713 subjects were enrolled. Subjects were 16 - 100 years-of-age and were followed-up for 3 years. All subjects showed an increase in sCr and decrease in eGFR with increasing age. For males, there was a more obvious and significant reduction of eGFR in the elderly; butin older females, eGFR did not tend to change. Different equations showed good consistency[the intraclass correlation coefficients (ICC) was 0.849 for males, and 0.817 for females.];The CKD-EPI equation yielded scores that were indicative of more advanced CKD(according to sCr levels). There was no obvious trend for age-related change in the 3-year mean rate of eGFR change when compared across age groups. For subjects aged over 70 years, the MDRD and MDRDc equations yielded significantly higher eGFR data and the BIS produced the lowest eGFR values.

Conclusions: The annual rate of GFR change was not associated with age. Different eGFR equations yielded data that varied across different populations of patients and sCr levels. We were unable to identify a specific equation for use in the elderly Chinese population.



A comparison of different eGFR equations across all age groups. (A) Male. (B) Female.



Comparison of eGFR equations for different serum creatinine levels. (A) Male. (B) Female.

PUB195

A Workplace Wellness Program Results in Improvements in Physical Activity and Blood Pressure in the Staff of a Hemodialysis Clinic

Alexis King,[1] Alana P. Harris,[1] Luis M. Perez,[2] Kenneth R. Wilund.[1,2] *[1]University of Illinois at Urbana-Champaign, Department of Kinesiology and Community Health, Urbana, IL; [2]University of Illinois at Urbana-Champaign, Division of Nutritional Sciences, Urbana, IL.*

Background: Evidence indicates that health and wellness programs in the workplace provide numerous benefits with respect to altering indices of health. The purpose of this study was to assess the feasibility of a workplace wellness program (WOW) as a means of improving blood pressure by participation in habitual physical activity (PA) and improving dietary choices among the staff at a hemodialysis clinic.

Methods: 26-staff members (age:46.8±12.2;BMI: 28.7±5.6 kg/m2) from a hemodialysis clinic (nurses, technicians, social workers, dieticians, and administrative staff) participated in the 12-week WOW program that consisted of weekly counseling sessions, the provision of educational resources, PA incentive challenges, and healthy dietary choices challenges. Body weight(kg), height(cm), blood pressure, BMI, 24-hr dietary recalls, PA behaviors (IPAQ), and waist/hip circumference(cm) were collected at weeks 0(baseline), 6, and 12 following the conclusion of the intervention. Statistical analysis was performed using SPSSv.24. All primary and secondary outcomes were assessed by one-way Analysis of Variance (ANOVA) comparing values at the different testing time points, with significance at ($p<0.05$). Paired sample t-test was used to for the questionnaire (IPAQ) data that was collected at baseline and post intervention.

Results: The program also resulted in improvements in several health related metrics. This included reductions in body weight (1.07kg±21.4; $p<0.05$), body mass index ($p<0.05$), waist circumference cm (96.9±14.8; $p<0.05$), and hip circumference cm (111.7±13.6;$p<0.05$). Systolic blood pressure change was non-significant but trending toward significance ($p=0.08$), while diastolic blood pressure was reduced ($p<0.05$). There were significant changes in PA behavior, specifically walking behavior ($p<0.05$), as indicated by the IPAQ

Conclusions: The WOW program demonstrated increased measures in the staff's PA. As a result, this led to the improved health outcomes which included body weight reductions, BMI improvements, lowered hip and waist circumference, and improved diastolic blood pressures values. The study suggests that a workplace wellness program has the potential to improve health indices of the staff of hemodialysis clinics and may positively impact the health behaviors in the hemodialysis patients under their care.

PUB196

Frailty Changes in Patients on Hemodialysis After an 8-Week Exercise Intervention

Rick Ward. Wise Health System Dialysis Center *Wise Health System, Decatur, TX.*

Background: The Fried frailty phenotype defines frailty as having at least 3 of the following: unintentional weight loss, decreased grip strength, slow gait speed, exhaustion, and decreased physical activity. The vulnerability inherent in frailty is exacerbated in people with end-stage renal disease, but frailty assessments are typically not used. Exercise during dialysis has been shown to have positive effects on functional outcome and physiologic measures, but are not standard clinical care. The purpose of this study was to investigate the effects of an 8-week, supervised resistance and cycling program on frailty and function measures of patients undergoing dialysis.

Methods: 11 patients from the Wise Health System Dialysis Center in Decatur, TX (6 in the experimental group, 5 in the control group). The experimental group received a supervised elastic band resistance and cycling ergometer program 3 days per week for 8 weeks during dialysis. The resistance component included: ankle dorsiflexion and plantarflexion, knee flexion and extension, and hip abduction. A repeated measures 2-way ANOVA was conducted on the dependent variables of: frailty scores, gait speed, grip strength, 2-Minute Step Test, exhaustion, Timed Up and Go, and 30-second Sit to Stand Test.

Results: There was a significant difference in pre- to post-test frailty scores [$F(1, 9)=6.14$, $p=.035$, $\eta^2=.41$]. Specifically, the exercise group's frailty score dropped from 3.67 to 2.67 while the control group's score did not change. This change in frailty score was influenced by the change in the exhaustion component of the frailty score from a mean of 1.00 to 0.17 [$F(1, 9)=16.05$, $p=.003$, $\eta^2=.64$)]. There were no significant differences found in the other dependent variables. There were no adverse reactions to the exercise intervention.

Conclusions: The results of this feasibility study support the hypothesis that an exercise program during dialysis can change frailty scores in people with ESRD, as the exercise group decreased their frailty classification from frail to pre-frail. It is not clear if the benefit would persist after this time or if results would change based on the length of the program, which provides support for additional longitudinal research designs. In conclusion, it appears that a resistance and cycling exercise intervention can mitigate frailty effects in persons with ESRD.

PUB197

Relation Between Anxiety, Depression, and Frailty in Maintenance Hemodialysis Patients

Fanna Liu. *The First Affiliated Hospital of Jinan Universtiy, Nephrology, Guangzhou, China.*

Background: Both psychological disorders and frailty are prevalent and burdensome in MHD patient. However, the relationships between these entities are unclear. The aim of this study was to investigate the prevalence and associations between frailty and psychological disorders in Southern Chinese MHD patients.

Methods: This was a multicenter, cross-sectional and observational investigation conducted at 4 institutions. Frailty was evaluatd with the Tilburg Frailty Indicator (TFI) and it was used as the self-reported questionnaire. Anxiety symptoms was assessed by the Self-Rating Anxiety Scale(SAS, depressive symptoms was assessed by the Self-Rating Depressive Scale(SDS). We collect sociodemographic and clinical characteristics the patients who complete the scale. Statistical analysis was performed using SPSS20.0 for Windows.

Results: Of the 623 patients visiting each institution, 300 were enrolled in this study. The mean age was 61.95±13.64 years, with mean duration of HD 30.7 (43.39±2.36) months.116 patients (38.7%) were female and 133 (44.3%) had diabetic kidney disease. In total, there were 225 patients (75%) were evaluated as frailty. The prevalence of frailty increased steadily with age and was more prevalent in the diabetes mellitus patients. A multivariate logistic regression analysis revealed that the factors independently associated with frailty were the following: age, Charlson comorbidity index, DM,SAS, SDS. There was no relationship between the duration of HD and frailty status. Anxiety and depression symptoms by SAS and SDS were identified in 52.6% and 72.0% of MHD patients. MHD patients with both anxiety and depression generally had higher frailty score. The coexisting frailty and psychological disorder were present in 45.0% patients. There was an additive effect of psychological disorder and frailty on nutritional status. For the groups with frail and psychological conditions and no frail and no psychological conditions, both serum albumin and creatinine decreased.

Conclusions: This study demonstrated that anxiety and depressive symptoms are associated with prevalent frailty in Southern Chinese MHD patients. Older age, diabetes mellitus, CCI and lower serum albumin were associated with frailty among patients on MHD. Anxiety and depressive symptoms are independent risk factors of frailty.

Potassium Binders for Treatment of Hyperkalemia: Patient Survey Examining Side Effects, Tolerability, Palatability, and Interference with Daily Activity

Myungjin G. Kim, Maura A. Watson, Christina M. Yuan. *Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Even mild hyperkalemia is associated with increased mortality. There are three FDA-approved oral potassium binders for outpatient treatment of non-life-threatening hyperkalemia: sodium polystyrene sulfonate (SPS), patiromer, and sodium zirconium cyclosilicate (ZS-9). Specific studies of patient experience, satisfaction, and adherence have not been conducted for any of the three agents. We surveyed outpatients regarding their experience with these medications, including taste, texture, tolerability, and interference with daily activity.

Methods: An online, anonymous survey of outpatients ≥18 years old who were dispensed SPS, patiromer, and/or ZS-9 from September 2017 to August 2019 at military treatment facilities in the National Capital Region was conducted over 8 weeks. Respondents were invited by letter including the survey url (with a reminder at 4 weeks). Survey questions included queries about demographics, medical diagnoses, medications associated with hyperkalemia, side effects, taste, palatability, and daily activity interference.

Results: 212 qualifying individuals were invited to participate. Response rate was 16% (34/212). All respondents were ≥51 years old. 36% were on RAASI. 28 respondents had used SPS, 6 had used patiromer, and 1 had used ZS-9. 18% of respondents treated with SPS vs. 0% treated with patiromer reported side effects. 1 reported discontinuing SPS without informing their physician due to side effects. 48% reported diarrhea with SPS. 50% reported constipation with patiromer. Respondents favored taste and texture of patiromer vs. SPS (72 vs. 56 for taste, and 70 vs. 50 for texture, with a scale rating of 100 being best), and reported more difficulty swallowing SPS vs. patiromer (3% vs. 0%). Side effect severity and interference with daily activity were the same (2 and 3 respectively for both SPS and patiromer; scale of 0-10, 10 being worst).

Conclusions: Respondents who used patiromer reported better palatability and fewer side effects than those who took SPS. However, side effect severity and daily activity interference were equivalent between SPS and patiromer. Disclaimer: The views expressed are those of the authors and do not necessarily reflect the official policy or position of the Department of the Army/Navy/Air Force, the Department of Defense, nor the US Government.

PUB199

Evaluation of the Establishment of a Nutrition Care Process in a Group of Spanish Haemodialysis Patients

Christian Mañas Ortiz, Antonio Galan Serrano. *Hospital General Universitario de Valencia, Valencia, Spain.*

Background: Keeping a good nutritional status during hemodialysis must be a priority goal of the treatment to prevent complications and mortality, as well as, to improve patients quality of life. The main objective of this survey will be to evaluate if the establishment of a nutritional care process adapted to the chronic kidney disease, could improve anthropometrics and biochemical parameters in a hemodialysis hospital group of patients. We will also try to asses if the compiled results of the questionnaire about malnutrition and inflammation are correlated to the biochemical results obtained.

Methods: Information about sex, gender, dry weight, IMC, albumin status, PCR and Malnutrition Inflammation Score were collected during the months of July 2019 and March 2020. 38 haemodialysis patients participated in this study. A descriptive and frequency analysis has been carried out with all the parameters obtained. The T of Student for a related sample test was used due to the normality of the data and the participants condition of intervention - control.

Results: The results indicate that since the month of July 2019 until March 2020, 81,7% of the patients stayed on the hemodialysis program, 13,1% of the patients died, 2,6% changed hemodialysis to peritoneal dialysis, and 2,6% were transplanted. 42,1% of the total number of patients decreased their dry weight, 13,2% maintained it, and 26,3% increased it. The medium values obtained in July and March respectively were: dry weight (70.2±14.44 y 68.9±12.4kg), IMC (26.8±5.62 y 26.3±4.9kg/m^2), albumin (3.6±0.3 y 3.7±0.3mg/dL), PCR (1.5±2.6 y 1.4±1.8) and MIS (6±2.8 y 6.1±2.8). No statistical significance in any of the values has been found, being dry weight and IMC (p = 0.08) the closer parameters to get this condition.

Conclusions: The establishment of a nutritional care process seems to be a helpful and efficient method to improve anthropometrics and biochemical parameters in hemodialysis patients. Likewise, the use of malnutrition inflammation questionnaire as a tool to evaluate the nutrition status, seems to be effective when correlating with better biochemical nutritional parameters in hemodialysis patients.

PUB200

Scope and Consistency of Physical Fitness Outcome Measures in CKD: A Systematic Review

Dev K. Jegatheesan,[1,2] Richard S. Modderman,[2] Rathika Krishnasamy,[1,3] Allison Tong,[4,5] Jeff S. Coombes,[1] Andrea K. Viecelli,[1,2] David W. Johnson,[1,2] Nicole Isbel.[1,2] *[1]The University of Queensland, Brisbane, QLD, Australia; [2]Princess Alexandra Hospital, Brisbane, QLD, Australia; [3]Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; [4]University of Sydney, Sydney, NSW, Australia; [5]The Children's Hospital at Westmead, Sydney, NSW, Australia.*

Background: Impaired physical fitness is prevalent in people with chronic kidney disease (CKD), associating with an increased risk of mortality, falls and hospitalization. A plethora of physical fitness outcomes have been reported in randomized trials. This study aimed to assess the scope and consistency of physical fitness outcomes and outcome measures reported in trials in CKD.

Methods: A systematic review of randomized trials reporting physical fitness outcomes in adults with CKD (not requiring kidney replacement therapy), receiving hemodialysis or peritoneal dialysis, and kidney transplant recipients was conducted. Studies were identified from MEDLINE, Embase and the Cochrane Library from 2000 to 2019. The scope, frequency and characteristics of outcome measures were categorized and analyzed.

Results: From 112 trials and 6,047 participants, 87 tests/measurements were used to evaluate 30 outcomes measures that reported on 23 outcomes, categorized into five domains of physical fitness: neuromuscular fitness (reported in 76% of trials), exercise capacity (64%), physiological-metabolic (49%), body composition (36%) and cardiorespiratory fitness (30%). Neuromuscular fitness was examined by 37 tests/measurements including the physical function component of questionnaires (27%), 1-repetition maximum (9%) and hand-grip strength (9%). Outcome measures were assessed by lab-based (58% of all trials), field-based (31%) and patient-reported measures (11%), and commonly evaluated at 12 (30%), 26 (23%) and 52 weeks (10%).

Conclusions: There is large heterogeneity in the reporting of physical fitness outcomes, with inconsistencies in the use of validated and patient-important outcome measures. Standardization in the assessment of physical fitness is required to improve the comparability of trial outcomes and enhance clinical recommendations.

PUB201

Diet Composition and Understanding of Plant-Based Eating (PBE) in an Inner-City Population of CKD Compared with Family Medicine Patients

Kingsley Cruickshank, Ahmad Saleh, Takisha Morancy, Elizabeth G. Kasparov, Mariana Markell. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: Patients with CKD may benefit from PBE but dietary restrictions may create confusion regarding implementation. We compared attitudes toward plant-based eating and dietary components in an indigent, immigrant population of patients with CKD and those attending Family Medicine clinic (FM).

Methods: A face-to-face survey was conducted in a random convenience sample of pts in CKD (23) and FM (22) clinics. Patients chose answers from 5 Likert style questions about PBE assessing their beliefs regarding difficulty in finding foods in restaurants, affordability, ability to get proteins and vitamins, and ability to find good tasting recipes. A mean score was calculated with lower score indicating more difficulty (PBE-score). Diet analysis was based on 24hr recall and analyzed using ASA-24 software. Comparisons are by t-test unless noted.

Results: Mean age was 54.3±2.5 yrs. There were 16 (36%) males and 29 (64%) females with 40 black (89%). 36 (80%) had not completed college. 23 (51%) had an income < $20K. 16 (35%) were employed. 20 (44%) had diabetes. Mean BMI was 30.4±1.6 with 41% >30. There were no differences in these variables between clinics. CKD pts had a higher creatinine (2.01±0.39 vs 0.85±0.05) more positive attitude towards PBE (PBE-score 2.57±0.1 vs 2.21±0.13, p<0.05) and ate more cholesterol (411.6±65.2 vs 248.7±30.3, p=0.031), fatty seafood (1.41±0.54 vs 0.17±0.1, p=0.034) eggs (1.05±0.27 vs 0.42±0.16, p=0.048) and drank more fluid (2499.0±335.6 vs 1367.9±167.1, p=0.005) than FM pts, but fruit/veg intake was poor. PBE-score did not correlate with dietary intake of any nutrient in either group.

Conclusions: In our populations 1. Pts with CKD had a more positive attitude towards plant-based eating. 2. CKD pts ate more cholesterol with higher intake of eggs and fatty seafood. 3. Despite difference in attitude there was no difference in actual vegetable intake between groups. 4. The positive attitude of CKD pts towards PBE suggests that education will be successful in this group, especially as they appear to be following the recommendation to increase fluid intake. The poorer attitude in FM patients should be addressed as the population as a whole has a high prevalence of hypertension, obesity and diabetes and all patients could benefit from PBE.

PUB202

Low Influenza Vaccination Rates and Patient Misconceptions in Inner-City CKD and Kidney Transplant (KTR) Patients

Takisha Morancy, Iqra Nadeem, Kingsley Cruickshank, Ahmad Saleh, Mariana Markell. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

Background: Pts refuse vaccination for unclear reasons. Vaccination rates and attitudes towards vaccination were studied in an inner-City population of CKD pts and KTRs.

Methods: A face-to-face survey was conducted in a random convenience sample of pts with kidney disease attending CKD (30) and Transplant clinic (45). Pts were asked if they refused or accepted the influenza vaccine and assocations between beliefs about vaccines and cause of vaccine refusal examined.

Results: There were 37 (49.3%) women and 38 (50.7%) men with 60 black (80%). 40 (40%) did not attend any college. 17 (22.7%) were employed. Mean age was 56.8±1.4 yrs. 34/65 pts (45.3%) reported having had influenza with more TXP pts (63% vs 31%, p=0.009) and more men (62% vs 37%, p=0.035) in the group by Chi-square. 18/36 (50%) who answered did not take the flu vaccine the previous year, with no difference between CKD and KTRs. Reasons were believeing thet were not at risk (28%), experience with side effects (33%), fear related to 3rd party information (22%) and other. Pts who did not think illnesse prevented by vaccines were severe agreed they should question shots (r=0.58, p<0.0001), felt knowledgeable about vaccines (r=0.36, p=0.012), trusted information they received (r=0.55, p<0.0001) and felt they could discuss concerns with their doctor (r=0.58, p<0.0001). They were more likely to receive information from friends and family (r=0.58,p<0.0001). Pts who were concerned about side effects were concerned with vaccine safety (r=0.77, p<0.001) and felt they may be ineffective (r=0.76, p<0.0001) but they did not feel knowledgeable about how vaccines work (r=-0.372, p=0.01).

Conclusions: In our population 1. Influenza vaccination rates are low and prevalence of self-reported influenza high. 2. Patients who refuse vaccines believe they are low risk for the disease, and have concerns about vaccine safety and side effects. 3. Pts who believed preventable illnesses were not severe were more likely to receive information from friends and family, felt knowledgeable but did feel comfortable discussing concerns with their doctor. 4. Pts who were concerned with vaccine safety did admit to lack of knowledge. 5. Effective education regarding how vaccines work as well as efficacy and side effect profiles may help improve vaccination rates in this high risk population.

PUB203

Time to Revisit Contemporary Heart Failure Risk Prediction Models: Chloride, the Neglected Electrolyte

Gajapathiraju Chamarthi, Amardeep Singh, Eddy J. De Jesus, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: While the prognostic role of hyponatremia has been extensively studied in patients with heart failure (HF), more recent studies have identified chloride as an independent and possibly stronger predictor of outcomes in this setting. Since the clinical course of HF is known to be variable, several predictive models have been developed that simultaneously take into account multiple factors to refine their prognostication ability. We sought to explore the inclusion of serum chloride levels in contemporary risk prediction models of HF.

Methods: Articles cited in the PubMed database using keywords "heart failure", "prediction", and "model" were searched. Available data from clinical trials performed between January 1995 and December 2019 were included. The studies were selected if they prognosticated outcomes in the HF population through a predictive model that consisted of at least 2 factors. Pertinent data on clinical and laboratory parameters (e.g. hypochloremia and hyponatremia) were extracted and reviewed.

Results: A total of 15 studies with 82,706 participants were included, of which 5 were validated in a HF cohort different from the model derivation cohort. They consisted of

a variety of HF populations (e.g. acute, chronic, carrying mechanical circulatory device) and the median number of included parameters was 7. There was substantial variation across models in the reporting of the kidney related parameters as well as the studied outcomes. While no study included eGFR, serum creatinine and BUN were included in only 6 and 4 studies respectively. Interestingly, serum chloride level was included in none of the included models, while 4 did contain data on serum sodium level.

Conclusions: The emerging clinical evidence on the paramount prognostic value of hypochloremia for adverse outcomes in HF is in keeping with distinctive physiologic mechanisms relating it to renin secretion and modulation of renal tubular sodium transporters. However, we found that there is still a lag in its integration into contemporary predictive models of HF. This observation highlights the need for revisiting these models in backdrop of emerging data and explore whether incorporation of hypochloremia, or replacing hyponatremia by hypochloremia, would add to their predictive value.

PUB204

Long-Term Ambient PM2.5 Exposure Associated with Major Cardiovascular Risk Factors in a Large Chinese Population-Based Study

Jianfeng Lin, Hua Zheng, Peng Xia, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: The association between long-term exposure to ambient air pollution and hyperlipidemia or overweight is still controversial. We aimed to investigate the relationship between long-term exposure of PM2.5 and cardiovascular risk factors in a large multi-provincial and multi-ethnical Chinese adult sample.

Methods: We recruited 19,236 adult participants from 2007 to 2010 in 6 provinces of China (Chinese Physiological Constant and Health Condition Study, CPCHC). A questionnaire, physical examination, and biochemical tests were performed. The PM2.5 data used were derived from aerosol optical depth with the GWR model and GEOSChem method.

Results: The average age of the participants 42.79±16.12 years and nearly half were male (47.0%). Annual average PM 2.5 exposure 1-year before the CPCHC study was 33.4 (14.8-53.4) $\mu g/m^3$. Multivariate linear regression showed that each 10$\mu g/m^3$ increment of PM2.5 was associated with 0.025% (95%CI: 0.011%, 0.040%) decrease of cholesterol and 0.098% (95%CI: 0.083%, 0.113%) decline of BMI. Adjusted by age, sex, education, ethnicity, physical activity, and smoking, logistic regression indicated that PM2.5 exposing still associated with the prevalence of hyperlipidemia (OR = 0.958, 95%CI: 0.942, 0.974) and overweight (OR = 0.925, 95%CI: 0.911, 0.939). PM2.5 exposure was also corresponded to elevated SBP (0.048%, 95%CI: 0.034%, 0.063%) and an increased prevalence of hypertension (OR=1.020, 95%CI: 1.001, 1.039).

Conclusions: Long-term PM2.5 exposure was associated with an increased prevalence of hypertension, decreased prevalence of hyperlipidemia and overweight.

Predictive Models for Prognosis of Cardiovascular Events (in 5 Years) in Asian Patients with CKD

Wentao Hu, Xun Liu, Shaomin Li. *the Third Affiliated Hospital of Sun Yat-sen University, Guang Zhou, China.*

Background: Chronic kidney disease (CKD) is viewed as a major health problem worldwide. However, independent influencing factors related to the prognosis with CKD patients (especially in cardiovascular events) is still potential to be exploited, and few researches on predictive models for individualized prognosis in CKD patients were published, especially in Asian area. Therefore, we are willing to evaluate independent influencing factors in regard to prognosis of CKD patients and build predictive models for individualized prognosis in CKD patients.

Methods: 1246 participants were included in this cross-sectional study. All date were used In univariate Cox proportional hazards regression models and multiariable Cox regression analyses (P<0.05). Then, 1246 participant were divided into two cohort(development cohort and validation cohort). we will establish one best predictive model by the means of CINDEX, AIC, NRI, IDI.

Results: In the Cox regression analysis of cardiovascular events, we found that HGB, K, Pre-albumin, APOB, Heart failure, CKD progression are independent influencing factors of cardiovascular events, and lower HGB is independent protecting factor, and Higher K, Pre-albumin, APOB, Heart failure, CKD progression are independent risk factors. In the development cohorts, we found that the model 6(K, pre-albumin, HGB, HF, CKD)is the best prediction model of cardiovascular events(P=0.088e^(1.93584*APOB + 0.00356*pre-albumin + 0.00679*HGB + 1.11488*heart failure - 0.22131*K - 0.10215*CKD progression)is the best prediction model of cardiovascular events.

Conclusions: Lower HGB is independent protecting factor of cardiovascular events, and higher K, Pre-albumin, APOB, heart failure, CKD progression are independent risk factors of it. And we establish the best prediction model (P=0.088e^(1.93584*APOB + 0.00356*pre-albumin + 0.00679*HGB + 1.11488*heart failure - 0.22131*K - 0.10215*CKD progression) of cardiovascular events (in 5 years).

Epidemiology of Cardiovascular Risk Factors in Hemodialysis Patients in a Tertiary Care Hospital

Muntazir Ali Sayed,[3] Navneet K. Guru,[4] Adil A. Akbani,[3] Ali Hamza,[1] Sadiq Ali Sayed,[2] Farhin N. Sayyad,[3] Sayed Mohd Tahir Rizvi.[5] Desi Doctors *[1]Avicenna Medical College, Lahore, Pakistan; [2]National Pirogov Memorial Medical University, Vinnytsya, Ukraine; [3]Rajarshi Chhatrapati Shahu Maharaj Government Medical College and CPR Hospital, Kolhapur, India; [4]Government Medical College, Patiala, India; [5]KJ Somaiya College of Engineering, Mumbai, India.*

Background: Cardiovascular events remains the leading cause of mortality in patients with end stage renal disease (ESRD) and the risk of cardiovascular events is 10 to 20 times higher in ESRD as compared to general population. The main objective of this study was to evaluate the prevalence of traditional cardiovascular risk factors in the population of ESRD outpatients on chronic hemodialysis in a tertiary care center in Kolhapur city of Western India.

Methods: All patients undergoing regular hemodialysis for ESRD in the tertiary care center of CPR Hospital were considered for inclusion in the retrospective study. Clinical and demographic data were obtained from the medical records, whereas laboratory data were obtained as the most recent result in the six preceding months. Adequate statistical tests were carried out and for all tests, a p-value <0.05 was considered statistically significant.

Results: A total of 1937 patients were included from the data of 2 years from May 2018 to April 2020 at our institute. Their average age was 61.3 years old, 69.3% were males. The prevalence of cardiovascular risk factors observed was 89.3% for hypertension, 83.9% for dyslipidemia, 75.3% for sedentary lifestyle, 49.7% for tobacco use, and 43.5% for diabetes. In a multivariate adjusted analysis, we found that sedentary lifestyle (p = 0.041, PR 1.15 – 95%CI: 1.09 - 1.17), dyslipidemia (p = 0.021, PR 1.05 – 95%CI: 1.01 - 1.11), and obesity (p < 0.0001, PR 1.88 – 95%CI: 1.59 - 2.95) were more frequent in women; and hypertension (p = 0.019, PR 1.03 – 95%CI: 1.01-1.17) and tobacco use (p = 0.009, PR 3.1 – 95%CI: 1.97 - 4.67) were more often found among patients under 65 years old. Sedentary lifestyle was independently associated with time in dialysis less than 12 months (p < 0.001, PR 1.33 – 95% CI: 1.19 - 1.43).

Conclusions: The population in chronic hemodialysis in the city of Kolhapur presents a high prevalence of cardiovascular risk factors. These findings confirm the high-risk cardiovascular profile of hemodialysis patients. Prospective studies and clinical trials are needed to further clarify interventions that can be transformed in public health strategies to prevent cardiovascular death in hemodialysis patients.

PUB207

Prevalence and Associated Risk Factors of Pre-Hypertension and Hypertension Among University Students in Bahrain

Amgad E. El Agroudy. *Arabian Gulf University, Manama, Bahrain.*

Background: The increase of hypertension in the developing countries may be connected with the economic transition within those countries. This study aimed to assess the prevalence of prehypertension and hypertension among university students and their associated risk factors.

Methods: The study used a cross-sectional design. Data were collected from February 2019 to May 2019 at the Arabian Gulf University Campus in Bahrain. A total of 411, randomly selected students aged 17 to 24 years (196 males, 215 females) were included in the study. The data were obtained through a self-completed structured questionnaire, which included data about nutritional lifestyle, sleep, exercises, family history and smoking pattern. In addition, blood pressure and body mass index were measured. Systolic and diastolic blood pressure measurements were taken by trained personnel.

Results: The mean age was 19.4±1.9 years. Normotensives constituted 61.3% (n=252), prehypertensives formed 30.7% (n = 126), and hypertensive students comprised of 8% (n = 33). The overall proportions of hypertension and prehypertension were higher among male students (81.8 and 69.8%) than female students (18.2 and 30.2%), respectively.

Higher body mass index was associated with significantly higher prevalence of hypertension (normal weight 27.3%, overweight 33.3%, and obesity 39.4%) but not with pre-hypertension (normal weight 47.6%, overweight 32.5%, and obesity 17.5%). The Univariate analysis showed an association between hypertension and age, sex, body mass index (BMI), nutritional lifestyle, sleep duration, physical activity, smoking pattern and family history of hypertension ($p < .05$). Multivariate logistic regression analysis revealed a significant association between hypertension and the above stated factors.

Conclusions: The findings of the present study highlighted the prevalence of hypertension (8%) and prehypertension (30.7%) among university students in Bahrain. The blood pressure values increased with associated risk factors (age, sex, body mass index, smoking, sleep duration, physical activity and family history of hypertension). The results of this study recommended that periodic screening and monitoring of students for hypertension should be done to the university students.

PUB208

A Combined Effect of Sacubitril/Valsartan and Evolocumab on Chronic Heart Failure in an ESRD Patient

Htun M. Aung,[1,2] Aye M. Thida,[3,2] Myat E. Mon,[2] Phyo Wai Khine,[2] May T. Zin,[2] Banya M. Win,[2] Kyaw Hla,[2] Alexander M. Swan.[2,4] *[1]Interfaith Medical Center, Brooklyn, NY; [2]Nephrology Hypertension Renal Transplant & Renal Therapy, LLC., Avenel, NJ; [3]Woodhull Medical and Mental Health Center, Brooklyn, NY; [4]Rutgers New Jersey Medical School, Newark, NJ.*

Introduction: End-stage renal disease (ESRD) patients generally have underlying risk factors for coronary artery disease and heart failure (HF) such as hypertension and diabetes mellitus. In fact, chronic HF is highly prevalent and is one of the leading causes of death in these patients. We report a combined effect of sacubitril/valsartan and evolocumab on chronic HF in an ESRD patient.

Case Description: A 63-year-old man with a history of chronic HF for 3 years, along with hypertension, diabetes mellitus, hypercholesterolemia, coronary artery disease status post coronary artery bypass graft with multiple stents, and ESRD on hemodialysis, presented with worsening dyspnea over 2 months (NYHA Class IV). His medication list included enalapril, valsartan, carvedilol, clonidine, amlodipine, hydralazine, isosorbide mononitrate, ranolazine, aspirin, warfarin, amiodarone, erythropoietin, rosuvastatin, sevelamer, linagliptin, and insulin. An echocardiogram revealed an ejection fraction (EF) of 15%. He was placed on a cardiac transplant waiting list after receiving an implantable cardioverter defibrillator. Meanwhile, enalapril and valsartan were replaced by sacubitril/valsartan for chronic HF, and evolocumab was added to reduce the risk of myocardial infarction. During an initial follow-up for 10 months, his dyspneic symptoms improved significantly to NYHA Class I. An echocardiogram later revealed an EF of 60%. He was followed up for 4 years without any hospitalizations, worsening of HF, or side effects of the medications such as hypotension, hyperkalemia, and nasopharyngitis.

Discussion: Sacubitril/valsartan, an angiotensin receptor-neprilysin inhibitor, has multiple mechanisms of action and is known to reduce the risk of cardiovascular death and HF hospitalization in patients with chronic HF with reduced EF. Besides, evolocumab, a PCSK9-inhibitor antibody, is known to promote plaque regression and stabilization. The combined use of sacubitril/valsartan and evolocumab in our patient for 10 months resulted in an improvement of his EF from 15% to 60%, most likely due to a significant improvement of coronary blood flow with a recovery of hibernating ischemic myocardium. Therefore, additional studies are highly recommended to explore the beneficial effect of these medications used in combination.

PUB209

Fanconi Syndrome and Acute Interstitial Nephritis: A Toxic Combination Associated with Ifosfamide

Hafsa Tariq, Nissreen El Fadawy, Miroslav Sekulic, Arash Rashidi. *University Hospitals, Cleveland, OH.*

Introduction: Ifosfamide is an alkylating chemotherapeutic agent used in the treatment of various soft tissue tumors. Nephrotoxicity associated with ifosfamide is less frequently reported in adults. We describe a patient with Ewing sarcoma, who presented with AKI and Fanconi syndrome. Worsening renal function prompted renal biopsy which showed acute interstitial nephritis. AIN associated with ifosfamide may portend a bad prognosis due to lack of response to steroids.

Case Description: 33-year-old female with chest wall Ewing Sarcoma presented with neutropenic fever. She had received 5cycles of chemotherapy with VIDE (Vincristine/Ifosfamide/Doxorubicin/Etoposide), last two cycles included only ifosfamide(3000mg/m^2) and doxorubicin. On presentation, she had AKI, hypokalemia, hypophosphatemia, hypouricemia, without hyperglycemia. UA showed proteinuria and glycosuria. Urine electrolytes showed potassium and phosphorus renal loss. She was diagnosed with ifosfamide associated Fanconi syndrome. Spot urine protein to creatinine ratio was 2.13gm/gm proteinuria. Renal function continued to worsen. Kidney biopsy revealed acute tubular injury with cytomorphologic changes consistent with ifosfamide associated effect and AIN. She was started on prednisone 60mg/day. She received prednisone for about 11weeks with no improvement. After extensive discussion, steroids were tapered off and she is being prepared for dialysis.

Discussion: Ifosfamide frequently causes proximal tubular dysfunction. Risk of renal toxicity has been associated with higher doses of ifosfamide(>100g/m^2). We describe hypokalemia as the first manifestation of proximal tubular dysfunction which resulted in complete Fanconi syndrome. Renal function never returned to baseline, prompting renal biopsy. Biopsy evidence of AIN was treated with steroids with no recovery. This was consistent with ifosfamide associated renal toxicity which often results in irreversible damage. Our patient received a total of 15g/m^2 of ifosfamide, which is way below the cumulative dose associated with nephrotoxicity. Since ifosfamide associated AIN has been associated with high resistance to steroids, alternate agents for treatment should be explored. More studies are warranted to see if occurrence of Fanconi syndrome with acute interstitial nephritis is associated with worse prognosis.

PUB210

Case Report: Membranous Nephropathy and Tyrosine Kinase Inhibitor

Shahrzad Zonoozi, Abdallah Sassine Geara. *Penn Medicine, Philadelphia, PA.*

Introduction: Tyrosine kinase inhibitors (TKI) have been used as adjuvant therapy in the treatment of a number of malignancies including gastrointestinal stromal tumors (GIST). TKIs have been associated with a number adverse events including hypertension and proteinuria.

Case Description: A 70-year-old male with metastatic GIST on TKI therapy for 6 years (initially on imatinib for 2 years and switched to sunitinib due to serositis) was referred for difficult to manage hypertension. Two years into the use of sunitinib, he had worsening hypertension, edema and hypoalbuminemia with a rising creatinine leading to sunitinib being stopped (see Table 1). Further work up confirmed the presence of nephrotic syndrome (urine protein to creatinine ratio (UPCR) of 20.76 mg/mg of creatinine) and an elevated phospholipase A2 receptor (PLA2R) immunoglobulin G titer of 1:640. Renal biopsy showed findings consistent with membranous glomerulopathy with PLA2R positive immunofluorescence, interstitial fibrosis and arterial sclerosis. Given these findings, a diagnosis of PLA2R associated membranous nephropathy was made. Bumetanide was started for management of fluid overload with good effect. Given proteinuria improved significantly after stopping therapy, sunitinib may have contributed to worsening of the underlying nephrotic syndrome. Ultimately, a decision was made to restart sunitinib with a plan to treat the membranous nephropathy with rituximab.

Discussion: Our patient developed hypertension and nephrotic syndrome, ultimately found to be PLA2R associated membranous nephropathy, in the setting of sunitinib use. It is possible that in our patient, sunitinib contributed to worsening of the nephrotic syndrome, as evidenced by the fact that proteinuria improved with stopping the TKI. While TKIs have been implicated in the development of proteinuria and nephrotic syndrome, it is important to rule out other possible causes to allow for continuation of oncological therapy if deemed necessary.

Table 1. Trend of laboratory testing

	Cr (mg/dL)	Alb (g/dL)	PLA2R	UPCR
Day 0	1.34	2.2	–	20.76
Day 2	1.38	2	–	18.73
Stopped TKI				
Day 13	1.23	2.3	1:640	4.42
Day 20	1.7	2.9	1:1280	1.62
Day 27	1.42	2.5	1:1280	4.27
Day 36	1.37	2.6	1:320	5.44
Restarted TKI				
Day 63	1.38	2.5	1:640	8.63

PUB211

Biopsy-Proven Cast Nephropathy from Lambda Light Chain Measured at 3684 mg/dL in a Multiple Myeloma Patient

Jeremy Carlson, Hasan Zahid, Muhammad usama shah Hamdani, Chintan V. Shah. *University of Florida, Gainesville, FL.*

Introduction: Kidney injury is a common presentation of underlying Multiple Myeloma. In a recently published study, considered the largest analysis to date between free light chain (FLC) and biopsy confirmed MCN (myeloma cast nephropathy), median lambda light chain at diagnosis was 426.7mg/dL. Here, we present a case of a patient presenting in stage III acute renal failure with Lamba light chains measured at a level almost 9 fold greater at 3684mg/dL.

Case Description: A 78 year old female with past medical history significant for breast cancer 20 years ago is electively admitted from her primary care doctor's appointment after having symptomatic anemia with a measured hemoglobin (hgb) of 6.3 g/dL. She was feeling weak, with weight loss of 30 pounds in 2 years as well as persistent watery diarrhea and decreased intake over the previous 2 months. She was transfused 2 units of packed red blood cells and labwork showed creatinine on 10.79mg/dL, BUN 94 mg/dL, bicarbonate 16mmol/L, potassium 5.9 mmol/L, phosphorous 10mg/dL calcium 7.5mg/dL, and urinalysis with <30 mg/dL albumin. She was volume resuscitated and nephrology consulted for acute kidney injury. Further workup significant for urinary protein of 404 mg/dL and 43mg/dL creatinine, with urine pro/cr ratio of 9.3. 24 hour urine collection showed total 24 hour protein of 4.4g. FLC assay showed Lambda load of 3,694 mg/dL, kappa 3.41 mg/dL. Kidney biopsy revealed interstitial fibrosis and tubular atrophy of 50-60% and glomerulosclerosis 30-40% with strong lambda staining casts present. Hematology consulted and performed bone marrow biopsy which revealed over 90% plasma cells, confirming MM. Patient was started on hemodialysis for metabolic complications, and started on treatment with CyBorD therapy.

Discussion: Our patient presented with an extremely high light chain burden, and was treated aggressively with hemodialysis and immediate chemotherapy. The fairly recent development of the free light chain assay provides a tool to screen for MM and measuring serum light chain quantitatively. Currently, there are conflicting results as to whether or not overall light chain burdens have direct correlation and impact on overall kidney survival and salvageability. Further testing and meta-analyses are needed to determine if this can be used a prognostic tool.

PUB212

AKI Associated with Immune-Checkpoint Inhibitors: Management Challenges and Dilemmas Without Renal Biopsy

Hui Zhuan Tan, Jason Choo Chon Jun. *Singapore General Hospital, Singapore, Singapore.*

Introduction: There is much to be learnt about renal lesions seen in patients with acute kidney injury (AKI) associated with the use of immune-checkpoint inhibitors (ICI). Acute tubulointerstitial nephritis is the most common, with glomerulonephritis (GN) being increasingly recognised.

Case Description: A 61 Chinese male presented with generalised arthritis and AKI with nephritic-nephrotic syndrome on a background of Stage IV metastatic clear cell RCC and left radical nephrectomy. At presentation, he was on treatment with pembrolizumab (PD-1 inhibitor) and axitinib (VEGF receptor TKI). Investigations revealed 24hr TUP of 8.26g/day and peak serum creatinine (sCr) of 605 μmol/L (CTCAE G3; baseline sCr 117 μmol/L). Autoimmune markers and complements were negative. Patient was counselled for but refused a high-risk renal biopsy. Pembrolizumab was discontinued. High dose prednisolone was initiated for renal and rheumatological IRAE. SCr improved to 224 μmol/L at 3 months but his nephritic-nephrotic state persisted. Risks and benefits of empiric mycophenolate mofetil were discussed extensively and patient opted to continue with corticosteroid (CS) monotherapy. His subsequent clinical course was complicated by community acquired pneumonia and herpes simplex viral oral mucositis, before eventually succumbing to polymicrobial sepsis from acute cholecystitis despite optimal management.

Discussion: The clinical presentation of our patient is highly suggestive of an underlying GN. In view of concurrent rheumatological IRAE, we postulated that his AKI was related to ICI use. Empiric use of high-dose CS resulted in partial improvement in renal function but persistence of nephritic-nephrotic state, suggesting that CS monotherapy is suboptimal. Without histological data, directed therapy was not possible. However, given the rarity and heterogeneity of ICI associated GN, success of previously tried agents was limited to case reports and optimal treatment remains unknown. In view of this uncertainty, hesitancy with the empiric use of immunosuppressants beyond CS is understandable. While we await further research, in-depth discussion of treatment risk and benefits, especially infective complications, during shared decision making remains a key element in the optimal care of this unique population with advanced malignancies and often, limited life expectancy.

PUB213

Abiraterone-Induced Rhabdomyolysis as an Unusual Cause of AKI Requiring Hemodialysis

Juan Carlos Garcia Yanez.[1,2] *[1]Hospital Aranda de la Parra, Leon, Mexico; [2]Universidad de Guanajuato - Campus Leon, Leon de los Aldama, Mexico.*

Introduction: A 86-year-old male diagnosed with metastatic, castration-resistant prostate cancer (mCRPC) treated with abiraterone (Zitiga) for 3 months was admited to the emergency department due to hyporexia, worsening fatigue and lethargy.

Case Description: After being diagnosed with prostate cancer, the patient had been subject to a radical prostatectomy 10 years prior to admission; 12 months prior to admission he developed deep-vein thrombosis that required endovascular treatment. The patient was prescribed daily 10mg rivaroxaban and 5mg prednisone for 1 year. For over 4 years, the patient had an irregular consumption of esomeprazole, atorvastatin and risperidone. Upon admission to the emergency department laboratory analysis revealed a dialytic emergency: serum creatinine of 6.1mg/dL, urea 295 mg/dL, BUN 138mg/dL and potassium of 7.3mEq/L. The patient refused renal replacement therapy. Agressive hydration and treatment with calcium gluconate, IV insulin and beta-agonist micronebulizations were prescribed to treat hyperkalemia. 24 hours later the patient persisted with serum creatinine 5.8, urea 276, BUN 128 and potassium of 7.0 despite optimal hydration management and potassium-lowering measures. As the clinical status didn't improve wiwth the previously described measures, the patient agreed to hemodialysis. Neurological symptoms improved, but the patient persisted with localized muscle pain in both legs, and it was decided to measure myolisis enzymes, with the following results: CPK 425 CPK-MB 92 and Myoglobin of 500 ng/mL. (7 times over the reference value). The patient was subject to three additional hemodialysis sessions, until creatinine, urea, BUN, K, CPK, and myoglobin levels were at reference parameters. The patient was discharged and at the follow-up appointment one month later he had complete resolution of symptoms and laboratory values, with the following parameters: serum creatinine 1.6 mg/dL urea 47.9 mg/dL BUN 13 mg/DL, K 4.1 mEq/L, myoglobin 41 ng/mL, CPK 34 U/L.

Discussion: There are only a few case reports that describe an association betweent abiraterone and rhabdomyolysis requiring renal replacement therapy. In Mexico, this is the first reported case. It is an important lesson, particularly in an oncologic hospital, as this unusual cause of acute kidney injury may be under-recognized in patients with prostate cancer undergoing treatment with this medication.

PUB214

A Unique Case of CKD with Multiple Primary Genitourinary Tumors

Shreya Arora,[1] Aiman Haider.[2] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University College London, London, United Kingdom.*

Introduction: Studies in pre and post dialysis chronic kidney disease (CKD) patients have shown a high risk for urinary system malignancy. There is a 44% higher risk of malignancy in patients with eGFRs less than 45 mL/min/1.73 m. Renal cell carcinoma (RCC) represents 3% of all adult cancers. Primary penile melanoma is rare with an incidence less than 0.2% of all melanomas. Multiple primary genitourinary tumors are uncommon. Here we highlight an unusual case of a CKD patient with bilateral RCC and penile melanoma.

Case Description: We present a 78-year-old man with history of gout, osteoarthritis, and hypertension who underwent radical left nephrectomy for an incidental RCC (Fuhrman grade 2, pT1A). He went on to develop a spindle cell penile melanoma (pT3b). He was treated with a glansectomy and received a neophallus. Moreover, he was diagnosed with stage 3 CKD. He subsequently developed RCC (Fuhrman grade 2-3, pT1A) in the right kidney and was treated with cryoablation. His serum creatinine ranged from 136-185 mM/L, GFR from 31-45 mL/min/1.73m^2, urea from 14.8-17.4 mmol/L, and potassium from 4.5-4.7 mmol/L. Unfortunately, his melanoma progressed with multiple recurrences and he subsequently passed away.

Discussion: Moderate CKD may be a risk factor for malignancies in the genitourinary tract, particularly in older men. As the prevalence of CKD in the aging population increases globally, the importance of the recognition of CKD as a risk factor for genitourinary cancers must also increase. Our case highlights the association of CKD with multiple genitourinary tumors. There is a need for assessing the impact of CKD on treatment and prognosis of genitourinary cancers.

PUB215

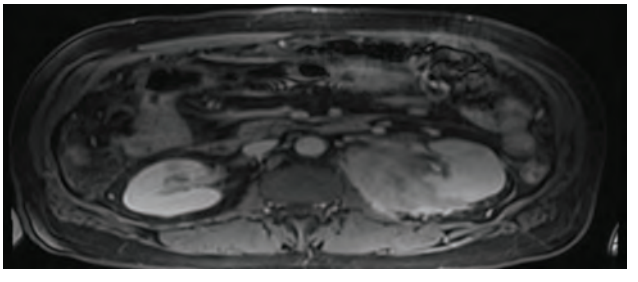
Bilateral Renal Burkitt Lymphoma Presenting with Persistent Lactic Acidosis in an HIV-Negative Patient

Oscar A. Garcia Valencia,[1,2] Juan D. Salcedo Betancourt,[1,2] Victor G. Becerra-Gonzales,[1,2] Karla G. Carias martinez,[1,2] Marco A. LadinoAvellaneda.[3,2] *[1]Jackson Memorial Hospital, Miami, FL; [2]University of Miami, Coral Gables, FL; [3]Miami VA Healthcare System, Miami, FL.*

Introduction: Burkitt lymphoma is an uncommon and aggressive B-Cell lymphoma accounting for <1% of adult Non-Hodgkin Lymphomas. The ileocecal region is the most common affected area, but it can involve extra nodal sites including the kidney. Renal involvement is usually asymptomatic and requires a high degree of suspicion to prevent early complications

Case Description: 63 years old non-smoker, HIV negative male with a history of an incidentally found left medial upper pole exophytic perinephric hematoma on CT 2 months prior to presentation, presented to the ED complaining of acute on chronic lumbar back pain. Noted afebrile, BP 86/52 mmHg with orthostatic changes, HR 92bpm, RR 20rpm and SO2 96% on RA somnolent but arousable, pale, no abdominal, spinal or costovertebral tenderness. Laboratories showed Hb 8.2 (14.7 a month prior), WBC 17,000, Na 126, Sodium bicarbonate 16, Anion gap of 22, Lactic acid 5.0 and SCr 1.5 (baseline 0.8). UA unremarkable. CT-CAP w/o contrast with interval increase of perinephric hematoma and rectus abdominis hematoma. Urology recommended no surgical intervention. He was resuscitated with isotonic IV fluids, with resolution of shock. Subsequent MRA showed no evidence of enhancing left perinephric hematoma but multiple rounded hypo enhancing lesions in the renal parenchyma bilaterally. He remained with persistent anion gap metabolic acidosis with increasing lactic acid up to 14.5. A kidney biopsy was planned but aborted as patient became hypotensive and confused with a drop-in hemoglobin to 5.6. Patient endorsed dark stools so, when hemodynamically stable, EGD was performed and gastric biopsies showed aggressive Burkitt's lymphoma.

Discussion: Lactic acidosis (LA) can occur in the presence or absence of tissue hypoxia (type A and type-B LA respectively). Persistent LA without identifiable causes of tissue hypoxia should prompt clinicians to suspect non-hypoxic etiologies, including occult high-grade malignancies. Hematological malignancies constitute and uncommon cause of type-B LA, carrying a poor prognosis.



PUB216

Oxaliplatin-Induced Hypomagnesemia

Yuriy Khanin, Mala Sachdeva, Nupur N. Uppal. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Platinum based chemotherapy is used in the treatment of several malignancies including lung, colorectal, ovarian, breast, head/neck, bladder and testicular cancers. We present a case of profound electrolyte disturbances in the setting of oxaliplatin therapy.

Case Description: 78-year-old Caucasian male diagnosed with pancreatic cancer three months prior to admission, on oxaliplatin therapy, presented to emergency room with new onset atrial fibrillation. He was afebrile, hemodynamically stable, and without respiratory distress. He endorsed a history of chronic diarrhea since beginning chemotherapy, however he began to have weakness and dizziness three days prior to

admission. Laboratory analysis revealed hypokalemia: 2.9mmol/L, hypomagnesemia: 0.8mg/dL, hypocalcemia: 6.2mg/dL with ionized calcium of 0.8mmol/L. Urine magnesium (Mg) was 10.2mg/dL, and urinary fractional excretion of Mg was calculated to be 2.75%, consistent with renal Mg wasting. The atrial fibrillation resolved after adequate repletion of electrolytes, and he was transitioned from intravenous to oral supplements. He was discharged home on oral calcium carbonate, magnesium oxide, and potassium chloride supplements. Repeat labs one week post hospitalization showed stable potassium of 4.2 mmol/L and calcium 9.3mg/dl, however hypomagnesemia persisted to 1.3mg/dL, requiring an increase in Mg supplementation.

Discussion: Platinum based chemotherapy agents including cisplatin and to a lesser extent carboplatin have been known to cause electrolyte disturbances, in particular hypomagnesemia. However, case reports of oxaliplatin associated magnesium wasting are limited. This can be partially explained by the fact that oxaliplatin is protein bound and cannot readily accumulate in the kidney tubules to mediate nephrotoxicity, as is the case with carboplatin which is not protein bound. Magnesium deficiency is an under recognized entity, however it can precipitate potentially fatal cardiovascular dysfunction. Clinicians need to be aware of this potential adverse effect related to oxaliplatin therapy, as its prompt diagnosis and treatment can prevent the associated complications.

PUB217

Immune Checkpoint Inhibitor-Induced Renal and Cardiac Sarcoidosis

Jamie Lin,[1] Nicolas L. Palaskas,[1] Omar Mamlouk,[1] William F. Glass,[2] Louis M. Buja,[2] Ala Abudayyeh.[1] *[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]University of Texas Health Science Center at Houston, Houston, TX.*

Introduction: Immune related adverse events (irAEs) associated with immune checkpoint inhibitors (ICI) are increasingly recognized as a side effect in patients receiving this therapy. Sarcoid-like / granulomatous lesions from ICIs are reported to be as high as 5% based on case series and registries. In all reported cases, patients presented with lymph node, skin, or lung involvement. We present the first case of sarcoid lesions in the kidney and heart in a patient being treated with immune checkpoint therapy.

Case Description: A 62-year-old male with stage IV metastatic melanoma received two cycles of pembrolizumab in November 2019 followed by three cycles of with ipilimumab and nivolumab. In March 2020 he was admitted with acute kidney injury, creatinine peaked at 2.85 mg/dl (baseline 0.88-0.94 mg/dl). Urinalysis and serologies were unremarkable. A kidney biopsy was obtained and revealed granulomatosis tubulointerstitial nephritis with focal necrotizing granuloma. Acid-Fast Bacilli (AFB) and Grocott methenamine silver (GMS) stains were negative. Incidentally, the patient was noted to have increased shortness of breath. Echo revealed new-onset cardiomyopathy with ejection fraction (EF) of 22% and SVT. Cardiac catherization was negative for coronary artery disease, but endomyocardial biopsy revealed lymphohistiocytic infiltrate with granulomatous myocarditis consistent with cardiac sarcoidosis. He was initiated on pulse IV steroids with improvement of both his cardiac and renal function. EF improved to 46% and creatinine improved to 1.0 mg/dl. Follow-up PET/CT imaging showed small inguinal nodes that could be sarcoidosis otherwise no indication of melanoma.

Discussion: Use of ICI has dramatically improved patient survival; however, there is a growing appreciation for adverse events that can be associated with increased morbidity. To our knowledge, this is the first case of sarcoid involvement in both the kidney and heart. Our case highlights the need for aggressive approach to ICI toxicity when clinical work-up is unrevealing. The timely manner that both kidney and heart biopsies were performed, allowed for definitive diagnosis and guided treatment. Despite holding his ICI therapy to treat his irAEs, he continues to have cancer response from checkpoint therapy. Further follow-up is needed to determine long-term outcomes of both irAEs and cancer status.

PUB218

Drug-Induced AKI from Gemcitabine

Taqui Khaja, Sara Faiz, Layth Al Attar, Rajeev Raghavan. *Baylor College of Medicine, Houston, TX.*

Introduction: The current decade has ushered in an incredible number of novel chemotherapeutics that has improved patient survival. These drugs cause various patterns of kidney injury, contributing to the burgeoning field of Onco-Nephrology. AKI in patients with cancer is linked with increased mortality. Since 1995, Gemcitabine has remained the first- or second- line treatment for patients with pancreatic cancer. We present a case of tubular injury and thrombotic microangiopathy in a patient on Gemcitabine and novel immunotherapy drug called LOKON.

Case Description: A 43 year old Caucasian male with history of stage 4 pancreatic cancer on active chemotherapy (Cycle 2 of LOKON clinical trial drug/ Gemcitabine/ Paclitaxel) was admitted to the hospital for Stage 3 AKI (Creatinine of 2.39 mg/dL), hemolytic anemia with schistocytes, thrombocytopenia, and leukopenia. The patient had received his second cycle of Gemcitabine one week prior to hospitalization. Patient reported generalized fatigue and fever after his treatment. Given his acute presentation and abnormalities, we suspected thrombotic microangiopathy. His ADAMTS13 was negative for Thrombotic Thrombocytopenic Purpura. Urine microscopy showed RBC casts and coarse granular casts. The haptoglobin was 187 mg/dL and LDH was 223 U/L. We performed a kidney biopsy to confirm the diagnosis of a drug-induced TMA and to guide further chemotherapy management because this patient is part of a trial. His biopsy revealed acute tubular injury with 10 % interstitial fibrosis with tubular atrophy. Proximal tubules lacked brush border which was consistent with ATN. Glomerulus contained segmental sclerosis with thick capillary basement membrane, double contouring, and smudgy mesangial tissue - consistent with chronic TMA. There were no vascular thrombi, RBC fragmentation, or crescent. Gemcitabine was discontinued and the patient was treated with supportive care. Four weeks after presentation, the creatinine remained elevated at 2.0 mg/dL.

Discussion: The nephrotoxicity associated with Gemcitabine can occur weeks to months after the drug is initiated. The mechanism of injury is driven by antibody formation to the drug and resulting endothelial injury and microvascular occlusion within the glomeruli. Treatment consists of discontinuation of this drug. Neither steroids nor plasma exchange have been reported as beneficial. AKI from this drug is reversible with supportive care.

PUB219

Gemcitabine-Induced Thrombotic Microangiopathy in Breast Cancer

Arun Rajasekaran, Ashita J. Tolwani. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Thrombotic microangiopathies (TMA) are potentially life-threatening conditions caused by small-vessel platelet microthrombi and are characterized by microangiopathic hemolytic anemia, kidney injury, and thrombocytopenia. TMA secondary to gemcitabine therapy (GiTMA) is extremely rare and is associated with a poor prognosis, with nearly 50% of cases progressing to end stage kidney disease. The mainstay of management is withdrawal of the offending drug and supportive care.

Case Description: A 65-year-old Black female with a history of metastatic invasive ductal breast cancer on gemcitabine therapy, well-controlled hypertension, well-controlled type 2 diabetes mellitus without proteinuria, and normal baseline kidney function presented with a 1 month history of poor oral intake, worsening hypertension, and progressive decline in kidney function. She was receiving 1250 mg/m^2/week of gemcitabine for 3 weeks/month for the preceding 1 year, with the last dose being 4 weeks prior to presentation. On admission, BP was 210/110 mm Hg, serum creatinine 2.7 mg/dl (baseline creatinine 0.9 mg/dl), serum albumin 2.6 g/dl (4 g/dl a month ago), new onset anemia (hemoglobin 6.9 g/dl) and thrombocytopenia (platelet count 51,000/mm^3), lactate dehydrogenase 928 IU/L, and had schistocytes on blood film. Urinalysis revealed numerous acanthocytes and RBC casts. 24 hour urine protein was 1.8 g. Testing for ANA, ANCA, and hepatitis B and C serologies were negative and complements within normal range. Renal ultrasound was unremarkable. A diagnosis of GiTMA was suspected. She was transfused 1 unit of blood, started on intravenous crystalloids and gemcitabine was held. BP normalized, serum creatinine improved to 2.4 mg/dl and platelet count 81,000/mm^3 within 3 days and she was subsequently discharged with discontinuation of gemcitabine.

Discussion: Gemcitabine, a deoxycytidine analog antimetabolite, is a commonly used chemotherapeutic agent for cancers of the pancreas, breast, lung, and ovaries. GiTMA is a very rare and highly fatal condition with mortality rates ranging from 50 to 70%. It is thought to be immune and non-immune mediated. Physicians should have a high index of suspicion to diagnose GiTMA early in the course of the disease. Mainstay of management is discontinuation of gemcitabine therapy, supportive care, and treatment of kidney injury with dialysis if necessary.

PUB220

Recurrent Mesenteric Cyst in an ESRD Patient on Maintenance Hemodialysis

Muhammad Awais,[1] Salman O. Khokhar,[1] Muhammad F. Akhtar,[1] Fateh S. Chattah,[1] Syed Rizwan A. Bokhari.[2] *[1]Prince Sultan Military Medical City, Riyadh, Saudi Arabia; [2]Bassett Healthcare, Cooperstown, NY.*

Introduction: Mesenteric cyst is a rare tumor reported with an incidence of 1:100,000 in normal population. Here we report a case of recurrent mesenteric cyst in hemodialysis (HD) patients.

Case Description: We chronicle a case of 47 years old male on hemodialysis for last 15 years with an unknown primary cause of end stage renal disease (ESRD). He never underwent peritoneal dialysis and had no prior history of abdominal surgery. He presented with gradual onset of abdominal pain and altered bowel habits. CT scan of abdomen and pelvis revealed encysted fluid in mesentery, measuring 10 x 5 cm, located behind the anterior abdominal wall. Patient refused enucleation procedure. Later, aspiration was done, which drained three liters transudative fluid. Cytology was negative for malignant cells, Histopathology demonstrated cuboidal epithelial cells of enteric origin and was not suggestive of cells of mesothelial origin. One month after first aspiration, patient presented with re- accumulation of cystic fluid and underwent second session of aspiration. Patient presented with worsening symptoms of abdominal distension and pain within two months of last aspiration. Repeat CT scan showed large intra-abdominal cystic lesion measuring 14 x 20 x 16 cm in mid- abdominal region, pushing all the adjacent abdominal viscera to the left side. At this time, cystic mass was surgically removed. Abdominal ultrasound and CT scan were negative for cirrhosis or Budd chiari malformation. Hepatobiliary system was also unremarkable. It re -demonstrated large mesenteric cyst 13 x 10.3 x 14.1 cm, located in the small bowel mesentery around the ligament of Teitz, extending down and exerting mass effects on the adjacent bowel loops. The extensive workup for causes of ascites, including liver disease, hepatitis panel, Tuberculosis, Brucellosis, Hydatid cyst and malignancy screening with markers namely CEA, CA 125, CA 19-9, CA 15-3, were all unremarkable. Erythrocyte Sedimentation Rate (ESR) was mildly elevated at 35 mm/ hour.

Discussion: This is the first reported case of recurrent mesenteric cyst in ESRD patient from KSA. Recurrent mesenteric cysts are extremely rare and are very difficult to manage. Enucleation and aspiration, both are ineffective modalities for such cysts.

PUB221

Urinothorax: A Rare Cause of Pleural Effusion

Abigayle Sullivan, Nidrit Bohra, Brigid K. Ellis. *Reading Hospital, Reading, PA.*

Introduction: Urinothorax [UT], the accumulation of urine in the pleural space, is an uncommon cause of pleural effusions resulting from trauma, obstruction, or iatrogenic causes. Thoracentesis with pleural fluid analysis and evaluation of biochemical characteristics, such as pleural fluid creatinine (PCr) to serum creatinine (Scr) ratio, is necessary to diagnosis.

Case Description: A 93-year-old man with a history of chronic kidney disease, right kidney transitional cell carcinoma with hydronephrosis, adenocarcinoma of the prostate status post brachytherapy complicated by proctosis and urinary obstruction was hospitalized for worsening hematuria and suprapubic pain. CXR showed a large right pleural effusion. CT of the abdomen and pelvis illustrated severe right-sided hydronephrosis and hydroureter with a heterogeneous density in the right renal pelvis and diffuse mural thickening in the posterior and right lateral bladder walls. An ultrasound guided thoracentesis was performed with the removal of 2L clear yellow fluid and analysis resulted: pH 7.423, LDH 48 IU/L, glucose 164 mg/dL, and PCr 2.5 mg/dL. Cytology was negative for malignancy. Scr was 2.59 mg/dL and thus PCr to Scr ratio of 0.96. A repeat thoracentesis was performed removing 1.85L clear yellow fluid. PCr and SCr were 4.1 mg/dl and 3.94 mg/dL respectively. Again, this confirmed the diagnosis of UT with a PCr to SCr ratio of 1.04. Bilateral retrograde ureteropyelograms with right ureteral stent placement failed to correct and an indwelling pleural catheter was placed.

Discussion: UT is a rare cause of transudative pleural effusion due to the mismatch of the rate of accumulation of pleural fluid and rate of reabsorption via pleural lymphatics. The most common etiologies resulting in a UT include trauma and obstructive uropathy. Diagnosis requires pleural fluid analysis and is associated with a paucicellular, transudative effusion with an ammonia-like odor, acidotic pH less than 7.4, and a PCr to SCr ratio greater than 1.0. Management is dependent on correcting the underlying pathology, such as repairing traumatic GU injury or obstruction.

PUB222

An Interesting Case of Proximal Renal Tubular Acidosis and Fanconi Syndrome due to Ifosfamide Nephrotoxicity

Anusha Sundararajan, Jeffrey M. Turner. *Yale University School of Medicine, New Haven, CT.*

Introduction: Ifosfamide is an alkalyting agent that is used in treatment of lymphoma, sarcoma and germ cell tumors. Ifosfamide causes kidney injury as an important adverse effect- Proximal tubular injury, Fanconi syndrome and Nephrogenic diabetes insipidus.

Case Description: 50 year old male with past medical history of hypertension, kidney stones and peripheral T cell lymphoma since 1.5 years who was on multiple chemotherapy in past who was admitted for ICE chemotherapy. Patient reported fatigue and chills, sore throat and non-productive cough. Patient did not have any vomiting or diarrhea or fever or rash or leg swelling or shortness of breath. Had dizziness for 2 days. No lower urinary tract symptoms. No NSAID use. No IV contrast exposure. No hypotension. Patient got chemotherapy with ifosfamide, carboplatin, etoposide (carboplatin and etoposide -day 1 to day 3) with ifosfamide 5 g/m2 on day 2 along with mesna for 24 hrs. Patient's baseline creatinine was 0.9 to 1.2. Patient's creatinine went up to 1.48 (4 days after ifosfamide dose) and then progressively went up to 1.8 -> 2.4 (in 10-12 days after dose). Patient developed a non-anion gap hyperchloremic metabolic acidosis around that time. There was associated hypokalemia and hypophosphatemia. Urine pH was 8 and patient had 2+ proteinuria and 3+ glycosuria and protein creatinine ratio was 4.69 and on repeat, it was 10 g/mg creat. Urine sediment exam showed granular casts. He had proximal RTA and Fanconi syndrome due to ifosfamide nephrotoxicity. He was managed with supportive treatment with repletion of potassium and phosphate and bicarbonate drip. This was notable given lower cumulative dose (11.25g) resulting in nephrotoxicity. Case reports mention nephrotoxicity mostly in children with 60-120 g cumulative dose.

Discussion: Ifosfamide induced AKI is reversible but can be permanent. Biopsy shows tubular injury/necrosis with swollen mitochondria. Ifosfamide enters proximal tubule cells via OCT 2. Chloracetaldehyde is the toxic metabolite produced by ifosfamide that causes kidney injury. Usually, CKD, previous cisplatin exposure and cumulative dose >90 -120 g/m^2 are risk factors for AKI. Management is mainly supportive such as repletion of deficient electrolytes and renal replacement therapy if indicated. Possible long term complications include permanent proximal tubulopathy, renal phosphaturia, CKD and ESRD.

PUB223

PLA2R-Positive Membranous Nephropathy in a Patient with Rectal Cancer

Aneesh S. Kallapur,[2] Gargi Sharma Priamvada,[1] Koyal Jain.[1] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India.*

Introduction: Malignancy associated Membranous Nephropathy(MA-MN) is well-recognized as a common paraneoplastic glomerulopathy, especially in solid tumors. Prevalence is around 10% of all membranous nephropathy(MN) cases. Anti M-type Phospholipase A2 receptor antibodies(Anti PLA_2R) are seen in 70-80% of Primary MN but have been detected in up to 30% MA-MN cases. Case reports of thrombospondin type-1 domain-containing protein 7A(THSD7A) antibodies in MA-MN also exist. Pathological features of MA-MN usually resolve with successful medical or surgical treatment of the malignancy, or even undergo spontaneous remission. However, proteinuria may persist for months after remission of the cancer. We highlight a unique case of MA-MN that did not resolve despite successful treatment of the primary disease.

Case Description: A 48 year old male with no known co-morbidities presented for evaluation of nephrotic syndrome. He had a urine protein creatinine ratio(UPC) of 6.8 g/g and hypoalbuminemia(serum albumin 2.6 mg/dL). Anti PLA_2R levels were 198 RU/mL. Renal biopsy showed membranous nephropathy stage III/IV, 1+ PLA_2R staining. IF showed granular 4+ IgG4 subtype, 3+ Kappa, 3-4+ Lambda staining. Workup revealed adenocarcinoma of the rectum and was started on a 5-week combination chemoradiotherapy protocol, along with Losartan. Despite being in remission from malignancy for 12 months, he continued to be nephrotic with UPC of 4-6 g/g and albumin 2.9 mg/dL. Thus, he was treated with tacrolimus initially and then rituximab. Currently, he is in remission from malignancy and nephrotic syndrome with a UPC of 0.3 g/g and albumin 4.1 g/g. Last anti PLA_2R titre was negative.

Discussion: Our case highlights a rare clinical course different from the known natural progression of the disease and established therapeutic guidelines. Typically, MA-MN either resolves spontaneously or with management of the primary cancer without additional immunosuppressive therapy. If nephrotic syndrome persists despite cancer remission, as in our patient, it is reasonable to consider immunosuppression after 12-18 months. Recurrence of proteinuria after initial remission should also raise suspicion for possible recurrence of underlying cancer. Additionally, age-appropriate cancer screening for all newly diagnosed MN cases is essential. We hope this report shall serve as a means for further discussion and research in onco-nephrology.

PUB224

An Unusual Presentation of Atypical Hemolytic Uremic Syndrome in a Patient with Skin Ulcerations

Ira H. Blau, Matthew Palmer, Sadichhya Lohani. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Introduction: Atypical hemolytic uremic syndrome (aHUS), characterized by microangiopathic anemia and acute kidney injury (AKI), is a rare and debilitating disease, but its diagnosis can be difficult because of potential overlap with several other autoimmune conditions. We present a case of aHUS-induced acute renal failure with skin ulcerations as initial presentation.

Case Description: A 61-year-old female presented with progressively worsening skin ulcerations on her hands after two cycles of rituximab and bendamustine for B-Cell chronic lymphocytic leukaemia. She also reported cocaine use. On presentation, her physical exam was notable for bilateral ulcers on her knuckles and ankles. She was treated empirically for osteomyelitis without improvement. Skin biopsy was non-diagnostic. She was noted to have anemia, thrombocytopenia and AKI with nephrotic-range proteinuria. Other remarkable labs included a low haptoglobin and a high LDH. Urinalysis revealed dysmorphic red blood cells, and peripheral smear showed schistocytes. An autoimmune process was suspected; thus, pulse steroids was initiated. A renal biopsy was suggestive of thrombotic microangiopathy (TMA). A full immunological work-up eventually returned unremarkable. Plasmapheresis was initiated before her ADAMTS13 activity resulted at > 10%. She was then started on eculizumab. After one session of plasmapheresis and four doses of weekly eculizumab 900 mg, her platelet counts improved. However, she required initiation of renal replacement therapy. TMA panel and genetic testing showed a low factor H level and dysregulated complement cascade consistent with aHUS despite negative CFH-CFHR5 mutation. She had some improvement in urine output but continued to require hemodialysis on discharge. Biweekly eculizumab 1200 mg was continued with plan to closely monitor for renal recovery.

Discussion: Although a rare disease with features that may overlap with other autoimmune processes, aHUS can cause rapid decline in renal function, thus requiring early recognition and treatment. CHF-CFHR5 mutation can be negative in ~40% of the patients. In the presence of the dysregulated complement cascade, microangiopathic process and renal failure, early treatment with eculizumab is crucial in renal recovery, but the renal response to treatment can be delayed compared to the hematologic response.

PUB225

Renal Medullary Carcinoma Causing Obstructive Uropathy

Ramon A. Seneriz,[2,1] Yanetsy Olivera Arencibia,[2,1] Oscar A. Garcia Valencia,[2,1] Juan D. Salcedo Betancourt,[2,1] Oliver Lenz.[2,1] *[1]University of Miami, Coral Gables, FL; [2]Jackson Memorial Hospital, Miami, FL.*

Introduction: Hypertrophy of the prostate (BPH) is a common cause of obstructive uropathy in older men. Here we present the case of a 62-year-old Hispanic man with BPH who was found to have an additional rare cause of hydronephrosis, metastatic renal medullary carcinoma (RMC).

Case Description: A 62-year-old Cuban male with a history of hypertension and BPH presented for urodynamic testing for worsening lower urinary tract symptoms. Further questioning revealed fever, chills, and 20-pound weight loss over 2 months. Laboratory data were remarkable for serum creatinine of 2.7 mg/dl. Urinalysis showed pyuria and bacteriuria but no casts. After placement of an indwelling urinary catheter and drainage of 500 ml of urine, a renal ultrasound showed increased kidney size (right: 16.2 cm, left: 15.2 cm) and moderate left-sided hydronephrosis for which a percutaneous nephrostomy was placed. A computed tomography revealed multiple nodular lesions in the liver, bones, right adrenal gland, and lungs, and tissue retrieved by liver biopsy was suspicious for PAX8-positive carcinoma. MRI demonstrated findings concerning for urothelial malignancy in the left renal pelvis extending into the renal parenchyma. Percutaneous biopsy of the mass showed tissue positive for PAX8, Pan-K, and CA-IX (focal) and negative for INI-1, confirming the diagnosis of RMC.

Discussion: RMC is a very rare malignancy that accounts for less than 1% of all renal neoplasms. It was first described by Davis et al in 1995. It is known to be very aggressive and often metastatic at the time of diagnosis, with a median survival of about 4 months. It has been associated with sickle trait, rarely sickle cell disease and is most prevalent in patients with African heritage in the age group 10 - 40 years. Our patient did have sickle cell trait. Given his significant renal failure he was deemed not to be a candidate for platinum-based chemotherapy and was started on Paclitaxel.

PUB226

Effect of Gemfibrozil on Kynurenine Aminotransferases Activity and Kynurenic Acid Production in Rat Kidney

Izabela N. Zakrocka,[1] Katarzyna M. Targowska-Duda,[2] Artur Wnorowski,[2] Tomasz Kocki,[3] Krzysztof Jozwiak,[2] Waldemar Turski,[3] Wojciech T. Zaluska.[1] *[1]Department of Nephrology, Medical University of Lublin, Lublin, Poland; [2]Department of Biopharmacy, Medical University of Lublin, Lublin, Poland; [3]Department of Experimental and Clinical Pharmacology, Medical University of Lublin, Lublin, Poland.*

Background: Hypertriglyceridemia is the most common lipid disorder in chronic kidney disease. A tryptophan metabolite, kynurenic acid (KYNA), is produced from L - kynurenine (L KYN) by kynurenine aminotransferases (KATs). KAT I and KAT II isoenzymes are the best analyzed KATs. KYNA acts predominantly as a nonselective antagonist of ionotropic glutamatergic receptors. Diet rich in fatty acids was reported to elevate central and peripheral KYNA level. The goal of presented study was to analyze the influence of gemfibrozil, on KYNA production and the activity of KAT I and KAT II, in rat kidney *in vitro*. Additionally, the molecular docking of gemfibrozil to KAT I and KAT II structures was performed. On the final step the microarray datamining was carried out to investigate if gemfibrozil affects the expression of KAT coding genes.

Methods: The effect of gemfibrozil on KYNA synthesis together with KAT I and KAT II activity was tested in rat kidney homogenates *in vitro* after 2 hours incubation in the presence of L KYN and gemfibrozil. The drug was examined at the concentration of 1 μM, 10 μM, 50 μM, 100 μM, 500 μM and 1 mM. Production of KYNA was analyzed using the high performance liquid chromatography (HPLC) with fluorometric detector.

Results: Gemfibrozil at 100 μM, 500 μM and 1 mM decreased KYNA production in kidney homogenates *in vitro* to 66% ($P < 0.05$), 58% ($P < 0.01$) and 41% ($P < 0.01$) of control value, respectively. At 100 μM, 500 μM and 1 mM concentration gemfibrozil lowered renal KAT I activity *in vitro* to 68% ($P < 0.05$), 56% ($P < 0.01$) and 52% ($P < 0.01$) of control value, respectively. Moreover, gemfibrozil at 500 μM and 1 mM concentration decreased kidney KAT II activity *in vitro* to 47% ($P < 0.001$) and 26% ($P < 0.001$) of control value, respectively. Results of the molecular docking suggested that gemfibrozil may affect the active site of both KAT I and KAT II. Publicly available microarray datasets suggested that the expression of KAT-coding genes does not change after gemfibrozil administration.

Conclusions: Gemfibrozil decreases KYNA production in rat kidney *in vitro* through inhibition of KAT I and KAT II isoenzymes. Presented results indicate a novel mechanism of gemfibrozil's action in the kidney. Its potential role in nephrotoxicity needs verification in upcoming studies.

PUB227

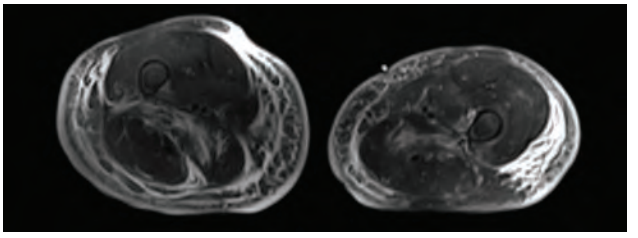
Lowest Reported Serum Creatinine in a Normal-Weight Adult Highlights the Limitations of Serum Creatinine in Estimating Glomerular Filtration Rate

Rachana Marathi, Swetha Rani Kanduri, Karthik Kovvuru, Pradeep Vaitla. *University of Mississippi Medical Center, Jackson, MS.*

Introduction: Estimated glomerular filtration rate (eGFR) based on serum creatinine (SCr) is the most common way of measuring kidney function. Creatinine is a product of muscle breakdown that is filtered through the kidneys and is at a steady-state in people with normal kidney function.

Case Description: 31-year-old African American female with a history of systemic lupus erythematosus, polymyositis, chronic respiratory failure presented with sepsis & respiratory failure. Physical exam: weight 63 kg, height 62 inches. 3 days after admission she deteriorated with worsening septic shock, requiring multiple pressors. She became anuric secondary to acute kidney injury from septic shock, however, labs revealed a serum creatinine of 0.4 mg/dL and eGFR > 60 mL/min/1.73m^2. Prior to current admission, her SCr ranged from 0.06 to 0.08 mg/dL with an eGFR ≥ 60 mL/min/1.73m^2. Low baseline SCr is due to the patient's lack of muscle mass. Muscle biopsy was performed which showed "skeletal muscle was almost entirely replaced by fat and the few remaining fibers were mostly necrotic". Although the patient's SCr continued to rise compared to baseline, it was still well below or within normal limits with a peak of 0.54 mg/dL and eGFR remained ≥ 60 mL/min/1.73m^2 despite the patient being anuric and required renal replacement therapy for metabolic clearance and volume management

Discussion: As SCr is directly related to muscle mass and muscle breakdown, it is not surprising that our patient with little to no muscle mass maintained an unusually low SCr despite being in renal failure. SCr value of 0.06 mg/dL in a normal weight adult is one of the lowest reported values in the medical literature. eGFR based on SCr is the most common method of estimating kidney function it is important to recognize that the eGFR based on SCr may not be an accurate representation of the renal function, especially in persons with low muscle mass.



MRI lower extremity: Diffuse fatty replacement of all of the muscles of the bilateral thighs, with no loss of overall muscle bulk. This could be due to muscular dystrophy or end-stage myositis.

Successful Treatment of the Pediatric Case with Anti-MDA5 Antibody-Positive Interstitial Lung Disease by Plasma Exchange Therapy

Daichi Yomogida,[1] Shinji Kitajima,[1] Hisayuki Ogura,[1] Koichi Sato,[1] Taro Miyagawa,[1] Tadashi Toyama,[1] Akinori Hara,[1] Yasunori Iwata,[1] Norihiko Sakai,[1] Miho Shimizu,[1] Taizo Wada,[2] Takashi Wada.[1] *[1]Kanazawa University Hospital Department of Nephrology, Kanazawa, Japan; [2]Kanazawa University Hospital Department of Pediatrics, Kanazawa, Japan.*

Introduction: Anti-melanoma differentiation-associated gene 5 (MDA5) antibodies are a type of myositis-specific autoantibodies. They are strongly related to rapid progressive lethal interstitial lung disease (ILD) with dermatomyositis. We experienced the 2 years old pediatric case with refractory anti-MDA5 antibody positive ILD and successfully treated with plasma exchange (PE).

Case Description: Two years old girl with normal development showed acute lower extremity weakness, dysphagia and face erythema three months before admission. She developed non-productive cough and fever. She visited nearby hospital one month before admission and was diagnosed as bilateral pneumonia with high KL-6 titer (2500 U/mL). Antibiotics had no effect and she admitted to another hospital. Additional examination revealed the high titer of anti-MDA5 antibody (1270 index) and normal creatinine kinase (48 IU/L) but high aldolase (10.1 IU/L). She also exhibited Heliotrope rash and Gottron's sign. She diagnosed as anti-MDA5 antibody positive juvenile dermatomyositis with ILD. Methylprednisolone pulse therapy (mPSL) and intravenous cyclophosphamide therapy were started but ILD was sustained. She transferred to our hospital for additional therapies. On the second hospital day, intravenous immunoglobulin was given and intravenous rituximab therapy was added on day 7 and 16. In spite of eradication of CD20-positive cells, her symptom was not improved. Therefore, we carried on PE with albumin-based replacement solution. After three courses of PE, the titer of anit-MDA5 antibody decreased to 83 index from 980 index on admission and her respiratory status was significantly improved.

Discussion: The mortality of anti-MDA5 antibody-positive ILD was reported as 20-30% regardless of intensive immunosuppressive therapy. Previous studies reported that anti-MDA5 antibody-positive ILD patients had high level of serum inflammatory cytokines and cytokine levels were related to the disease activity of ILD. Lowering them in addition to the titer of anti-MDA5 antibodies by PE may have a crucial therapeutic effect for anti-MDA5 antibody-positive ILD. Plasmapheresis therapy might be one of options to treat anti-MDA5 antibody positive patients with dermatomyositis complicated ILD.

PUB229

Use of Lisinopril in an Adolescent with "Extreme Dipper" Autonomic Hypertension Profile

Siddharth A. Shah. *University of Louisville, Louisville, KY.*

Introduction: The interaction between renin angiotensin aldosterone system and autonomic nervous system for blood pressure (BP) control is described. Angiotensin type-1 receptor activation in hypothalamus increases activity of paraventricular pre-sympathetic neurons as well as increases permeability of blood brain barrier to angiotensin. ADHD stimulant medication may be associated with cardiac autonomic dysfunction in children. Standard deviation (SD) of systolic BP (SBP) may be a better measure to study autonomic BP pattern particularly with nightime extreme dipper hypertensive profile.

Case Description: A 16-year-old non obese male presents with hypertensive urgency; BP of 168/102 mm Hg and symptoms of headache and vomiting. He was maintained on stimulant medication for ADHD that was stopped at initial presentation. The evaluation of secondary causes of hypertension was negative. He was started on Ca channel blocker. Four months after initial presentation, the 24-hour ambulatory BP monitoring (ABPM) study was done that showed hypertensive profile with extreme nighttime dipping. SD of SBP was high at 24.29 suggesting significant BP fluctuations (Figure-1). He was started on Lisinopril at the dose of 20 mg daily. ABPM study was repeated 3 months latter (Figure-2). There was marked improvement in daytime BP fluctuations (daytime SD of SBP-8.48) without worsening nightime BP dipping. Dizziness on changing posture was not reported.

Discussion: ACE inhibitors may be considered as an option for treatment of autonomic hypertension in adolescents with extreme nighttime dipping BP profile.

PUB230

Influence of Biopsy Prognosis on Graft Survival

Cristina Andrades Gómez, Jorge Calvillo-Arbizu, Miguel angel Pérez valdivia, Gabriel Bernal blanco, Jose Luis Rocha Castilla. *Hospital Universitario Virgen del Rocio, Sevilla, Spain.*

Background: Renal transplantation is the best alternative renal replacement option for patients with advanced chronic kidney disease. However, the supply of young donors is limited, and does not cover the demand of patients on the renal transplant waiting list. For this reason, older donors are being used, and a high discard rate of those organs exists based on pathological results (*score*) of the preimplant renal biopsy. There are several methods to evaluate the quality of the kidneys and the Kidney Donor Profile Index (KDPI) has acquired special relevance to decide the performance of preimplant renal biopsy. Based on the score, a preimplant renal biopsy is performed, which is decisive in certain cases. However, there is poor evidence to support this decision, which can be described as "conservative," since there is not enough certainty that there is influence of the preimplant biopsy score influences graft survival.

Methods: 389 biopsies of kidney transplant donors of cadaver donors in brain death and asystole type III were included. Donors in asystole type II, combined and live, were excluded. Samples were examined by the same pathologist and in paraffin (no case by freezing). A graft survival analysis was performed based on the results of the renal biopsy (*score*). Likewise, a multivariate analysis of graft survival was carried out including, in addition to the results of the renal biopsy, results such as the age of the donor and recipient and the KDPI.

Results: Graft survival was compared between two transplant subpopulations in our hospital based on whether a preimplant biopsy was performed. According to the data used there are no significant differences in graft survival between transplants in which biopsy has been performed or not.

Conclusions: The preimplant biopsy score by itself and the evaluation of the different histological components in the biopsy have no infuence on graft survival. We believe that predictive indices that combine donor and recipient histological and clinical variables should be implented.

PUB231

De Novo Post Kidney Transplantation Thrombotic Microangiopathy

Janany J. Sabescumar,[1] Jeremy G. Taylor,[1] Rauf Shahbazov,[2] David M. Dewolfe.[1] [1]*University of Rochester, Rochester, NY;* [2]*State University of New York Upstate Medical University, Syracuse, NY.*

Introduction: De novo post kidney transplantation thrombotic microangiopathy (TMA) is rare. We present two cases of post kidney transplant TMA acquired from the donor kidney

Case Description: A 26 year old male with a significant past medical history of end-stage kidney disease secondary to hereditary focal segmental glomerulosclerosis (FSGS) requiring initially presented for deceased donor kidney transplantation. The kidney donation was from a brain death donor with no significant medical history. The preliminary kidney biopsy of the donor kidney revealed focal patchy acute tubular necrosis (ATN). Induction immunosuppression included a total dose of 5 mg/kg of thymoglobulin and followed by initiation of tacrolimus for goal trough of 8 - 10 mg, prednisone 40 mg, and mycophenolate 1000 mg twice daily. The patient had delayed graft function with a creatinine initially at 18 mg/dL which only reduced to 17 mg/dL over the next couple of days. On postoperative day 5, the patient was dialyzed due to symptomatic uremia. In addition, he was noted to have developed worsening anemia and thrombocytopenia with a platelet count dropping from 208 to 47 per microliter of blood. A renal biopsy was pursued and the pathology results revealed post-transplant thrombotic microangiopathy (TMA) due to hemolytic uremic syndrome. In addition, the final donor kidney biopsy had later revealed thrombotic microangiopathy within approximately 60% of the glomeruli. The patient who received the second kidney had a similar clinical course. Both recipients received one dose of eculizumab with improvement in allograft function. They were both discharged without hemodialysis with close follow up.

Discussion: TMA was acquired by the donor TMA which was likely caused by ATN. It wasn't until later in the course that the final biopsy report of the donor kidney revealed TMA which confused the diagnosis of allograft kidney injury.

PUB232

Hypercalcemia Secondary to Hyperthyroidism: A Unique Cause of Renal Failure in a Kidney Donor

Ashish Sharma, Harsha Aramada, Kalathil K. Sureshkumar, Bhavna Chopra. *Allegheny Health Network, Pittsburgh, PA.*

Introduction: Hyperthyroidism is associated with increased bone resorption resulting in hypercalcemia (HCa). Chronic HCa leads to defect in concentrating ability of kidneys by downregulation of aquaporin-2, calcium deposition in medulla, impairing osmotic gradient resulting in polyuria and persistent pre-renal state. HCa causes renal vasoconstriction leading to acute tubular injury (ATI) followed by atrophy and interstitial fibrosis (IFTA).

Case Description: We present a case of a 70 yr old female who donated a kidney 5 yrs ago with serum creatinine (Cr): 1.18mg/dL and Calcium (Ca): 10.2mg/dL at 2 yr f/u. At routine 3 yr f/u, Cr of 4.4mg/dL, BUN of 70 mg/dL, and Ca of 12.6mg/dl were noted. Kidney biopsy showed ATI, severe IFTA, negative for any immune deposits (Figure 1A). Work up of HCa revealed; PTH: 5 (18.5-88 pg/ml), 25(OH)VitD: 55 ng/ml, 1-25(OH) VitD: 70 ng/ml, angiotensin converting enzyme level: 42 (9-47U/L), serum/urine protein electrophoresis: negative, PTHrp: <2 pmol/L, Vit A: 76.6(22-69.5ug/dl) and detailed cancer work up was negative. CT scan revealed enlarged thyroid nodule (biopsy negative for cancer) and nuclear scan showed overactive thyroid nodule(Figure 1B). Thyroid studies [TSH: <0.005 (0.35-3.7 uIU/ml), FreeT4: 2.49 (0.76-1.46ng/dl)] were treated with radioactive iodine, methimazole and low dose steroids. After 9 months labs improved-TSH: 0.01 uIu/ml, FreeT4:0.93 ng/dL, Ca: 9 mg/dl and PTH: 42pg/ml. Unfortunately, Cr remained at 4.0mg/dL due to prolonged HCa leading to stage 5 CKD which eventually resulted in successful kidney transplant (KTx).

Discussion: To our knowledge we report the first case of irreversible renal failure in a kidney donor due to prolonged HCa from hyperthyroidism eventually requiring KTx. Progression of renal disease from prolonged HCa may be due to limited renal mass as a solitary kidney. Hence, prompt treatment and correction of hyperthyroidism and hypercalcemia may help in preventing progression of renal disease.

Outcomes in Kidney Transplantation from Increased-Risk Donor Organs: A Single-Center Experience

Maria L. Safar-Boueri,[1,2] Jean M. Francis.[2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Boston University, Boston, MA.*

Background: Despite their lower Kidney Donor Profile Index (KDPI) score and demonstrated survival benefit of transplantation as compared with remain on dialysis, Public Health Service increased-risk donor (IRD) organs continue an underutilized source for transplantation.

Methods: This is a single-center retrospective cohort conducted at Boston Medical Center. Patients receiving IRD organs from 2016 and 2019 were evaluated. Baseline characteristics and outcomes one year after transplantation were described.

Results: We included 41 patients receiving IRD organs. Donors tended to be younger, with lower KDPI scores and good kidney function. Most common cause of death was anoxia from drug intoxication. Patients receiving IRD organs had stable kidney function at one year, with >70% having an estimated glomerular filtration rate (eGFR) of >60 mL/min (Table 1). None of the patients became positive for HBV, HCV or HIV.

Conclusions: Patients receiving IRD organs did not show a higher risk of infection or poor renal outcomes in this single-center population.

Post-Transplant Lymphoproliferative Disorder (PTLD): A Single Institutional Experience

Inês D. Coelho,[3] Sofia Cerqueira,[1] Catarina Romãozinho,[2] Rita Leal,[2] Rui Alves,[2] Arnaldo Figueiredo.[2] *[1]Centro Hospitalar De Trás-Os-Montes E Alto Douro, E.P.E., Vila Real, Portugal; [2]Centro Hospitalar e Universitario de Coimbra EPE, Centro Hospitalar e Universitario de Coimbra EPE, Coimbra, Coimbra, PT, Coimbra, Portugal; [3]Hospital Amato Lusitano, Castelo Branco, Portugal.*

Background: PTLD are a group of heterogeneous lymphoid proliferations in chronic immunosuppressed recipients of solid organ and hematopoietic stem cell transplantation. This study aimed to evaluate the clinical outcomes and to identify the predictors of mortality in adult renal transplant recipients who developed PTLD.

Methods: We have studied the incidence of PTLD in adult renal transplant recipients who were transplanted in our hospital from 1996 to 2019. Data was collected for demographics, transplant and immunosuppression history, EBV and CMV serostatus, diagnosis, treatment and outcomes. We performed uni and multivariate analysis to identify prognostic factors. PTLD was classified according to 2018 WHO lymphoma classification.

Results: Twenty-four patients (12 males and 12 females) were eligible for the analysis. Mean age at time of the transplant was 43.1 ± 16.9 years, with a time between grafting and PTLD of 66 months (IQR 36-98 months). Mean follow-up time was 87 months (IQR 61-117 months). 25% of patients received a living donor renal transplant. 5 cases were from Epstein-Barr virus (EBV) mismatched (D+/R-) transplants and there was seroconversion at time of PTLD diagnosis. 25% of patients have central nervous system involvement. 19 patients have monomorphic PTLD and the most common histological diagnosis was diffuse large B cell lymphoma. We identified that age >30 years at time of the transplant was predictor of mortality (HR 33.01; 95% CI: 3.24-336.14; p=0.003). Presence of B symptoms at time of PTLD diagnosis confer a better prognosis (HR 0,143; 95% CI: 0,035-0,579; p=0.006). All cases were managed with reduction in immunosuppression. 8 patients were treated with rituximab and there was no significant difference in the survival. 7 patients went into remission, 1 returned to chronic dialysis, and 16 patients died (15 of them due to the disease). Mean time between PTLD and death was 3 months (IQR 1-6 months).

Conclusions: PTLD is a infrequent disease with a poor prognosis. Some cases have a close relationship with EBV, but it can also develop in the absence of the classical risk factors. The factor affecting mortality in our population was age >30 years at time of the transplant. Presence of B symptoms at time of PTLD diagnosis seems to confer a better prognosis probably due to early investigation and diagnosis of the disease.

PUB235

Serum Phosphorus as a Predictor of Optimal Kidney Function in Immediate Kidney Transplantation

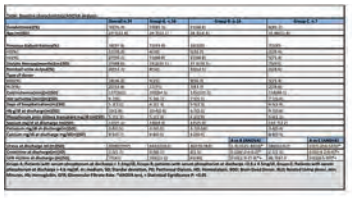
Daniel Murillo brambila,[1] Monica C. Jimenez Cornejo,[2] Maria Concepcion Oseguera-Vizcaino,[1] Eduardo Solano,[1] Ana Paula B. Rubio,[1] Marco A. Covarrubias.[1] *[1]Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; [2]Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico.*

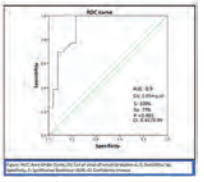
Background: In patients with CKD, there are alterations in serum phosphorus by widely known mechanisms, including in kidney transplant patients. The objective is to demonstrate that patients who decrease serum phosphorus in immediate kidney transplantation during hospitalization predict a GFR> 60 ml / min at discharge.

Methods: Prospective longitudinal study, 39 patients transplanted were analyzed, they were followed up daily until their discharge, they were divided into three groups according to their serum phosphorus**(p)** levels after transplantation; (Group **A**: p=<2.5, **B**: p=2.6 to 4.5, **C**: p=>4.6 mg/dl), the data were obtained on the days of hospitalization after his kidney transplant, obtaining this variables gender, age, type of donor, cold ischemia, days of hospitalization, uresis, creatinine and GFR dayle until discharge, data are shown in numbers, percentages, mean, ANOVA test and ROC curve.

Results: A total of 39 patients, 30(76.9%) patients were male, a mean age(29.5), 38(97.4%) had a history of dialysis, 21(53.8%) they were transplanted by a living donor, cold ischemia an average of 127min, days in hospital an avarage of 5.3, serum phosphorum prior kidney trasplant an average 5.7(2.3)mg/dl, in the ANOVA analysis a mean serum creatinine (Group A=0.9, B=2, C=2.1 mg/dl), a mean GFR (Group A=101, B=65, C=48.7 ml/min), a mean uresis (Group A=4423, B=3027, C=1865 ml/day) at discharge were compared; A vs B uresis P=0.3 IC=-1121/3913, creatinine at discharge P=0.1 IC=-2.6/0.2, GFR discharge P=0.03 IC=1.9/71, A vs C; uresis P=0.07 IC=-256/5372, creatinine at discharge P=0.01 IC=-4.2/0.4, GFR at discharge P=0.01 IC=8.5/97), AUC of 0.9, with a cutoff value of 3.05mg/dl have a TFG >60ml/min P=<0.001.

Conclusions: Patients who decrease serum phosphorus to normal or inclusive ranges of hypophosphatemia after immediate kidney transplantation, have better renal function than those who have hyperphosphatemia at discharge, serum phosphorus may be a predictor of optimal GFR in this patients.





Baseline characteristic, ANOVA test, ROC curve.

PUB236

Routine Monitoring of Donor-Specific Antibodies During the First Year of Kidney Transplant: Is It Underrated?

Sai Sudha Mannemuddhu, Shahab Bozorgmehri, Kiran K. Upadhyay. *University of Florida, Gainesville, FL.*

Background: Kidney transplant (KT) recipients with *de novo* donor-specific antibodies (DSA) are at risk of graft loss. DSA could lead to a decline in kidney function due to antibody-mediated rejection (ABMR), or be asymptomatic. Efficacy and cost-effectiveness of routine DSA monitoring are not known. Confirmation of ABMR with kidney biopsy is advised. We aim to study the utility of routine DSA monitoring (RDM) in predicting rejection in asymptomatic pediatric KT recipients.

Methods: After IRB approval, a retrospective chart review of patients who had RDM was done. Patients with clinical suspicion of rejection were excluded from the study. Demographic data and clinical features were analyzed using descriptive statistics. Continuous and categorical variables were analyzed using the student's t-test and Fisher's exact test respectively. A p-value <0.05 was considered statistically significant.

Results: Four out of 17 (24%) patients were tested positive for *de novo* DSA. There were no significant differences in age, gender, race, type of transplant, or serum creatinine between patients with positive and negative DSA. Three out of four (75%) patients had positive DSA at 4-6 months that persisted till the end of the year (1 had ABMR, 1 had T cell-mediated rejection and 1 had no rejection on biopsy), and one(25%) had positive DSA at 10-12 months with ABMR on biopsy. All patients with biopsy-proven rejection (BPR) received steroids, anti-thymocyte globulin, plasmapheresis, intravenous immunoglobulin, and/ or rituximab based on the type of rejection.

Conclusions: In our small cohort, we found that for every 5.7 asymptomatic patients who underwent routine DSA testing, one had *de novo* DSA with BPR. Larger, controlled studies are required to further evaluate the efficacy of RDM.

De Novo Thrombotic Microangiopathy Associated with Cytomegalovirus Infection and Alloreactivity: A Fork in the Road of Immunomodulation

Samar A. Medani, Karim M. Soliman, Michael Casey, Maria Aurora C. Posadas, Vinaya Rao. *Medical University of South Carolina, Charleston, SC.*

Introduction: De novo thrombotic microangiopathy (TMA) may yield cross-roads of diverging therapeutic approaches, not well delineated. We describe such a case in the setting of Cytomegalovirus (CMV) viremia and suspected rejection.

Case Description: A 52-year-old female with presumed hypertensive nephropathy received a deceased donor kidney transplant (KDPI 73%) complicated by progressive allograft dysfunction after 6 months. Anti-thymocyte globulin was used for induction, with tacrolimus (FK506), mycophenolate and prednisone for maintenance of immunosuppression. With step-wise rise in serum creatinine (baseline 1.7 mg/dL) to 2.5,3-4 and 5-7 mg/dL at 6, 8 and 9 months post-transplant respectively, three allograft biopsies were obtained. Secondary focal segmental glomerulosclerosis, moderate- severe interstitial fibrosis and tubular atrophy, and a mild tubulitis were seen in all biopsies;mild glomerulitis and peritubular capillaritis in the last two, and TMA in the last biopsy. C4d and HLA DSA were consistently negative. Despite methylprednisone given at month 8, creatinine continued to rise to 7 mg/dL by month 9. The course was complicated by leukopenia, brief thrombocytopenia (platelet count ~ 100 K/mm), progressive anemia (Hemoglobin 11.5 to 6.8 g/dl) and diarrhea in the setting of newly diagnosed CMV viremia (CMV DNA 1164 to 9177 IU/mL at months 8 and 9 respectively). Lactate dehydrogenase increased to 841 U/L with a normal haptoglobin and no reticulocytosis. Schistocytes were seen on a peripheral blood smear. ADAMTS-13, complement factors H, I, B, C3, C4, and stool pathogen panel were unremarkable. FK506 was switched to Cyclosporin (CYC) after diagnosing TMA. After clearance of CMV viremia and stopping valganciclovir, neutropenia resolved. Creatinine fell from 7 to averagely 5.8 mg/dL at month 10-11. Plasmapheresis (PP) and IVIG were initiated for suspected non-HLA antibody mediated rejection (AMR) with TMA.

Discussion: The constellation of TMA, CMV viremia, tubulitis, microvascular inflammation and myelosuppression, poses dilemmas in balancing management as FK506, CMV and AMR may all be contributory, in isolation or combination to TMA. We elected to maintain a calcineurin inhibitor and mycophenolate regimen in the face of TMA and CMV due to the risk of florid rejection, and initiated PP with IVIG.

PUB238

Hypofibrinogenemia as a Risk Factor of Bleeding After Plasmapheresis with Centrifuge in Renal Transplantations with Active Humoral Rejection

Mayra M. Matias Carmona,[1,2] Sergio Hernández-Estrada,[1,2] Jose H. Cano,[1,2] Odette Del Carmen Diaz Avendaño.[1] *[1]Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico; [2]Universidad Nacional Autónoma de México Facultad de Medicina, Universidad Nacional Autonoma de Mexico Facultad de Medicina, Mexico, Mexico.*

Background: Humoral rejection represents an important cause of graft loss, multiple therapeutics have been implemented;therapeutic plasma exchange(TPE)is part of them, however one of its main complications as hypofibrinogenemia due to the risk of bleeding, which represents a challenge due to the risk of immunization in the event of a transfusion and even limiting the continuity of treatment due to the risk of bleeding imminent due to consecutive low figures during the passage of the sessions. Objective:to determine if hypofibrinogenemia(<100 mg/dl)after sessions of TPE with centrifuge is an absolute risk factor for bleeding that warrants the need for transfusion or cessation of therapy

Methods: In the period from June2017-May2019, 25 Mexican kidney transplant patients with diagnosis of active humoral rejection, without previous coagulation abnormalities, were submitted to TPE;a total of 5 sessions per patient were granted in an average of 10±2 days, with measurement of fibrinogen levels before and after each session;as well as daily clinical evaluation of active bleeding

Results: The age range was 21-35 years, 44% were female, the causes of ERCT up to 52% were not reported, cadaveric donor transplantation predominated in 52%.The initial average fibrinogen value was 397mg/dl, after the 1°session a reduction of 33% was observed, with an average value of 133mg/dl. The lowest level was 43mg/dl, the most important reduction after the 4°session. Only 1 major bleeding event was documented due to epistaxis that required transfusion. This event was after the 3°session, with fibrinogen of 79mg/dl. At the end of TPE treatment, fibrinogen levels normalized in all patients, with no further bleeding events

Conclusions: Despite the strong association of hypofibrinogenemia and bleeding, only one major bleeding event was reported in our population. There were no other events despite having level as low as<50mg/dl, therefore we consider close surveillance as the main measure during TPE;leaving the transfusion only in the context of active bleeding. The blood tissue is rich in immunoglobulins and therefore favors the host's immune response;It is paradoxical to remove antibodies and grant new ones with transfusions. Hypofibrinogenemia did not limit the continuity of treatment, concluding its treatment in a timely manner

PUB239

Kidney Transplant Recipients Suffer Fewer Complications After Adrenal Surgery

Ankur P. Choubey,[1] Darren Abbas,[1] Jonathan Demeter,[1] Afshin Parsikia,[2] Jorge Ortiz.[1] *[1]The University of Toledo Medical Center, Toledo, OH; [2]Westchester Medical Center, Valhalla, NY.*

Background: Chronic immunosuppression after kidney transplant (KT) is a known risk factor for developing a malignancy. While occurrences of other cancers have been well documented, there is a paucity of data regarding the incidence and effects of adrenal tumors after renal transplant. We aim to evaluate the differences in short-term outcomes between renal allograft recipients and the general population undergoing adrenal surgery.

Methods: A retrospective analysis was conducted using Nationwide Inpatient Sample (NIS) data between 2005 and 2014. The population of interest was adults with a kidney transplant undergoing adrenal surgery. ICD-9 codes were used to identify the procedures. Sample mean with standard deviations, and Student's t tests were calculated for categorical variables. Odds ratios were computed using weighted data. Multivariate linear regressions were utilized to compare outcomes at transplant and non-transplant centers.

Results: 54 patients met the inclusion criteria. KT recipients were older (p<0.001), more likely to be African American p<0.001), and had higher Elixhauser Comorbidity Index scores (p<0.001). We noted shorter length of stay (p=0.011), lower rates of any complications (p=0.001), and fewer packed RBC transfusion (p=0.039) compared to the non-transplant cohort. There was no mortality among transplant recipients. Weighted multivariate analyses highlight that total expenditures were lower for renal allograft recipients treated at transplant centers (p=0.021).

Conclusions: Previous publications have demonstrated that history of kidney transplant has deleterious effects on surgical outcomes. In the largest national cohort analysis of adrenal surgery after KT, we discovered that despite higher age and more comorbidities, renal transplant recipients benefitted from fewer post-operative adverse events. There was additional benefit from seeking treatment at transplant centers.

PUB240

Granulomatous Tubulointerstitial Nephritis in a Kidney Transplant Recipient

Mohamed Hassanein, Leal C. Herlitz, Cyndee Miranda, Aimen Liaqat, Richard A. Fatica. *Cleveland Clinic, Cleveland, OH.*

Introduction: Granulomatous tubulointerstitial nephritis (GTIN) is a rare pathological diagnosis accounting for 6% of all causes of tubulointerstitial nephritis (TIN). Causes of GTIN include fungal and tuberculous infections, sarcoidosis, and medications. We describe a case of GTIN in a kidney transplant recipient (KTR).

Case Description: A 65-year-old male with a history of diabetes mellitus, hypertension, active pulmonary and ocular tuberculosis (TB), and a deceased donor kidney transplant 8 years prior was admitted for acute kidney injury (AKI). Medications included isoniazid, rifampin, carvedilol, insulin, and tacrolimus. Serum labs showed: creatinine (Cr) 2.65 mg/dL (baseline Cr 1.3 mg/dL), corrected calcium 13.2 mg/dL, and tacrolimus trough level 7.6 ng/mL. Urine sediment examination and kidney ultrasound were unremarkable. Further workup for hypercalcemia revealed: parathormone (PTH) 7 pg/mL, 1-25 dihydroxy-vitamin D 54.3 pg/mL, PTH related peptide <2 pg/mL, and angiotensin-converting enzyme 47 U/L. Kidney biopsy showed TIN and non-caseating granulomas (figure A) with negative acid-fast bacilli (AFB) staining, bacterial, and fungal polymerase chain reaction. He was treated with prednisone taper over 6 weeks with complete resolution of AKI and hypercalcemia.

Discussion: GTIN in KTRs is rare, with an incidence of <1% in transplanted kidney biopsies. AKI and PTH-independent hypercalcemia with a negative workup for other causes of AKI should prompt a kidney biopsy. Granulomas with multinucleated giant cells can help differentiate GTIN from acute rejection – the most common cause of TIN in KTRs. Despite negative AFB staining of the biopsy tissue sample, it was impossible to exclude tuberculous GTIN in our patient who was on anti-tuberculous therapy. Cautious initiation of steroid therapy can be effective in these cases.

PUB241

Kidney Transplants from Deceased Donor After 11 Days of Hemodialysis

Ankur P. Choubey, Obi Ekwenna, Michael Rees, Jorge Ortiz. *The University of Toledo Medical Center, Toledo, OH.*

Introduction: There is little consensus on the use of organs from donors with acute kidney injury (AKI) for kidney transplant. Previously, the longest reported duration of dialysis before donation was 4 days. We detail the first successful kidney transplants from a donor after 11 days of hemodialysis.

Case Description: Donor was a healthy 41-year-old male with severe injuries from a car accident. He suffered severe AKI from rhabdomyolysis requiring 11 days of hemodialysis. Peak and terminal creatinine (Cr) were 4.55 and 3.23, creatine kinase was 10,582 U/L, and KDPI was 37%. Biopsy showed no vessel or interstitial injury, or global glomerulosclerosis. No casts were seen on urinalysis. Recipient 1 was a 60-year-old Asian male with ESRD from IgA nephropathy, on dialysis for 2 years with EPTS of 41%. Cold ischemia time (CIT) and pump time were 32 and 10.3 hours. Post-operative DGF required two dialysis sessions. Recipient 2 was a 61-year-old white male with ESRD from diabetes, on dialysis for 6 years with an EPTS of 90%. CIT and pump time were 26 and 17.5 hours. Profuse bleeding from graft biopsy site and pseudoaneurysm formation required treatment with transfusions, and dialysis for DGF. He was readmitted with hydronephrosis and carbapenem resistant enterobacteriae sepsis, requiring nephrostomy tube and antibiotics.

Discussion: Careful selection based on donor youth, good health without comorbidities, and injury by rhabdomyolysis were crucial in this case. Moreover, biopsies revealed excellent histology, with good flow and resistance on perfusion pump. These factors made the kidneys acceptable for transplant despite DCD donor with prolonged dialysis and CIT. Both patients received Tacrolimus, Mycophenolate and Prednisone. On follow up, recipients were dialysis independent and making urine. Complications in recipient 2 required prolonged hospitalizations, but none of the adverse events were due to donor AKI. Take Aways This case report is a novel opportunity to understand the extent of kidney transplantation after AKI. Despite 11 days of hemodialysis and DCD donor, procurement was possible because AKI due to rhabdomyolysis is transient and resolves within weeks. AKI donor-recipient matching is an individualized process. Clinician decision-making with rigorous donor and recipient selection is paramount in transplanting AKI organs. Post-operative DGF management is crucial in restoring graft function.

PUB242

Acute Rejection of Renal Allograft Caused by Drug-Induced Acute Interstitial Nephritis

Wina Yousman,[1] Wei Xiang Wong,[1] Sevag C. Boyadjian,[1] Erika R. Bracamonte,[1] Pablo Loarte Campos.[2] *[1]University of Arizona College of Medicine, Tucson, AZ; [2]Montefiore Medical Center, The Bronx, NY.*

Introduction: We report a case of a 42-year-old man who had a living-unrelated kidney transplant in 2017 due to ESRD from post-infectious glomerulonephritis. He had an uncomplicated course with no episodes of rejection. He has been on a triple immunosuppressive regimen. Other past medical history was refractory autoimmune hemolytic anemia at age 20 that required splenectomy.

Case Description: In 2019, he developed fever and rash shortly after taking a 5 days course of azithromycin. This was associated with marked eosinophilia and an increase in his serum creatinine (sCr) from 1.0 mg/dl to 3.1 mg/dl. Donor Specific Antibody (DSA) was negative. Kidney biopsy showed active tubule interstitial nephritis with prominent eosinophils. He received pulse steroids followed by tapering oral steroids. His sCr improved to 2.7 mg/dl. A month later, he was admitted for hematuria and acute kidney injury. His sCr was 4.2 mg/dl. Urinalysis showed trace protein, RBC >50/HPF, and WBC 11-20/HPF. Tacrolimus level was within the therapeutic range. DSA was positive for class II; DQA1*05:01, DR17, DR52 with 18,000 MFI. Kidney biopsy showed mixed rejection; acute cellular rejection (ACR) Banff 1B and acute antibody-mediated rejection (ABMR)/ C4d positive. He was treated with high dose IV steroid, thymoglobulin, plasma exchange, and Rituximab. His sCr did not improve. Repeat biopsy showed improvement of ACR Banff 1A along with capillaritis and glomerulitis, suggesting ongoing ABMR but C4d staining became negative. On the last biopsy, there was diffuse interstitial fibrosis.

Discussion: We hypothesize that Acute Interstitial Nephritis (AIN) primed the T-cell lymphocytes to react against the allograft. His sCr improved after treatment of AIN but subsequently worsened reflecting mixed rejection. The treatment of rejection led to some improvement but did not resolve the ongoing damage that ultimately caused significant fibrosis with poor chances for recovery. To our knowledge, this is the first case where AIN is followed shortly by a mixed allograft rejection even in a patient with a previous splenectomy. In the past, splenectomy was the treatment for refractory ABMR. In conclusion, rejection should be considered as one of the differential diagnoses when renal function worsens after the treatment of AIN.

PUB243

Kaposi Sarcoma: A 30-year Experience of a Portuguese Kidney-Transplant Center

Filipa Ferreira, Rui Silva, Ana T. Nunes, Ana Cerqueira, Manuela Bustorff, Isabel Tavares, Inês C. Ferreira, Ana Rocha, Susana M. Norton, Manuel Pestana. *Hospital de Sao Joao, Porto, Portugal.*

Background: Kaposi sarcoma (KS) is a low-grade angioproliferative tumor associated with human herpesvirus 8 (HHV-8) infection, which incidence is higher in kidney-transplant recipients (KTR). This study aimed to review all cases of KS diagnosed in KTR, over the past 30 years, at our center. A total of 1476 transplants were performed during this period.

Methods: We reviewed all histologically diagnosed KS in KTR. Data were collected from electronic and paper medical records.

Results: Seven KTR were diagnosed with KS, of which 6 were men and 1 was HIV positive, all caucasian. The mean age at the time of KT was 51± 18y. Six cases occurred before 2010 and the last case in 2018, in an HIV positive patient and the only one to receive induction immunosuppression - IS (basiliximab). All but 1 patient were on maintenance IS with prednisolone (PDN), a calcineurin inhibitor (CNI) and mycophenolate mofetil (MMF). The median time of transplant at KS diagnosis was 9 (2 – 99) months. Six patients had only cutaneous lesions, mainly in lower limbs and one had also abdominal lymph nodes involvement. HHV-8 viremia, evaluated in 2 patients, was positive. In 6 patients the CNI and MMF were replaced by an mTOR inhibitor. The other one was maintained with PDN and reduced dosage of CNI. All except one received antineoplastic

treatment: 3 were submitted to radiotherapy (RT), 1 to chemotherapy (CT) and 2 had both RT and CT. Pegylated liposomal doxorubicin was the drug of choice. At follow-up, 1 patient remains with normal kidney function, 1 with chronic graft dysfunction and 2 lost their KT (one by antibody-mediated rejection 3 months after KS diagnosis, and one by chronic graft dysfunction after 19y of KT, 14y after KS). Three patients have already died (with graft function), one directly to the KS.

Conclusions: Despite the scarcity of published series on KTR, the experience of KS in our center is in line with the literature, since it's more common in man, the incidence is higher in the first 2 years after transplant and cutaneous lesions were the main manifestation. In our series, a lower incidence of KS in the last decade has been reported. However, thorough surveillance in higher-risk groups, as HIV patients, should not be forgotten.

PUB244

Rapid Renal Allograft Failure Following Recurrence of Lupus Nephritis 12 Years After Renal Transplant

Sreedevi koppisetti Jenigiri, Jayesh B. Patel, Prerna Kumar, Christie P. Thomas, Sarat C. Kuppachi. *University of Iowa, Iowa City, IA.*

Introduction: End stage kidney disease (ESRD) secondary to lupus nephritis (LN) is an important complication of systemic lupus erythematosus (SLE) for which the treatment of choice is to undergo a kidney transplant (KT). Following a KT, patients rarely develop recurrent lupus nephritis (RLN), but when they do, most events of recurrence occur within a few years after KT. We describe the case of a young Caucasian lady who underwent a living related KT for LN and maintained stable renal function for 12 years, and then developed severe RLN that was unresponsive to treatment.

Case Description: A 39-year-old developed ESRD from LN and her kidney biopsy (KB) demonstrated global sclerosis with immune complex glomerulonephritis with positive serum antinuclear (ANA) and anticardiolipin antibodies (ACA) in 2006. She received living related KT in 2/2007. Her post-transplant course was complicated with the development of Banff grade IIA acute cellular rejection 1-month later, which was treated with steroids. She responded to treatment and attained a baseline creatinine (Cr) measuring 1.2 to 1.3 mg/dL. She was maintained on tacrolimus, mycophenolate mofetil (MMF) and prednisone. Her MMF was replaced with azathioprine during an uneventful pregnancy in 2011. She had a slight increase in her baseline Cr over the years but maintained a stable Cr measuring 1.4- 1.6 mg/dl. In 7/2019, the Cr suddenly increased to 3.9 mg/dl with proteinuria and microscopic hematuria. Her platelet counts, complement, ANA, ANCA and double stranded DNA levels were normal. A KB demonstrated features of thrombotic microangiopathy, diffuse proliferative GN with focally crescentic LN and full house pattern on IF. Despite treatment with intravenous steroids and cyclophosphamide her renal allograft function deteriorated, she required dialysis by 11/2019.

Discussion: Even patients with stable renal function maintained on standard immunosuppressive medications many years after transplantation are at risk of RLN. Our case demonstrates that RLN can manifest suddenly, and with a lack of usual laboratory features characteristic of a lupus flare. Further studies are necessary to better identify reasons for lupus recurrence in patients with long standing stable renal function.

PUB245

Simultaneous Disseminated Adenovirus Infection and Rejection in a Kidney Transplant Patient

Vatsalya Kosuru, Imran Y. Gani, Azeem A. Mohammed, Rajan Kapoor, Sandeep A. Padala. *Augusta University, Augusta, GA.*

Introduction: Adenovirus can lead to serious conditions in the immunocompromised transplant recipients. It infects urothelium and causes acute hemorrhagic cystitis and either nephritis or acute rejection causing functional deterioration of transplanted kidney.

Case Description: A 55-year-old male with history of ESRD on hemodialysis received a deceased donor renal transplant. After induction with steroids and Thymoglobulin, he was maintained on mycophenolate mofetil (MMF), tacrolimus and prednisone with stable creatinine of 1.1-1.3 mg/dL. After 6 months, he presented with right lower quadrant abdominal pain, hematuria, dysuria, productive cough, fever, conjunctivitis, sore throat and diarrhea. Labs showed mild elevation of creatinine (1.5 mg/dL). Urine microscopy showed non-deformed RBCs without glomerular casts. Chest x-ray and ultrasound of transplant kidney were normal. Patient was started on intravenous fluids and azithromycin for URTI along with home immunosuppressive regimen. Respiratory pathogen panel (RPP) was negative for any pathogen. Urine culture had no growth. Cystoscopy was unremarkable. Patient had worsening leukopenia and proteinuria of 3.3 grams. A repeat RPP was positive for adenovirus and serum Adenovirus PCR was 28,600 copies/ml. Biopsy of transplant kidney showed mild tubulo-interstitial rejection with transplant glomerulitis and negative for adenovirus nephritis. Due to simultaneous occurrence of infection and acute transplant rejection, MMF was reduced to 250mg BID and pulse steroids were started for 5 days. Serum adenovirus PCR was decreased to 1200 copies/ml in 7 days. On day 21, patient had increase in Adenovirus PCR to 1900 copies/ml. Decreasing immunosuppression was avoided given recent rejection episode. Patient's IgG level was low at 549 mg/dL and a dose of 300 mg/kg IVIG was administered. Repeat urinalysis showed resolution of hematuria and proteinuria. Serum Adenovirus PCR was undetectable at 2, 3 and 4 months follow up.

Discussion: Disseminated adenovirus infection after renal transplantation is becoming more prevalent. The treatment includes reducing the immunosuppressive therapy, IVIG infusions, anti-viral agents, or combination of these therapies. The approach to therapy is unclear due to no standard guidelines for selection, timing and efficacy of treatment modalities, which requires further investigation.

PUB246

A Case Report of Transplant Renal Artery Stenosis Presenting as Acute Encephalopathy and Cardiac Arrhythmia in a 28-Year-Old Man

Neilbert Jay B. Olivares. Davao Medical School Foundation Hospital, Inc. *Davao Medical School Foundation, Davao Medical School Foundation Hospital, Davao City, PH, Davao City, Philippines.*

Introduction: Transplant renal artery stenosis (TRAS), defined as narrowing of the transplanted renal artery, is one of the most serious vascular complications post kidney transplantation. TRAS presents as hypertension and allograft dysfunction at 3 to 12 months after transplantation. Unique to this case is the early presentation with behavior changes and cardiac arrhythmia. No report of such has been published as of this writing, especially in a third world setting.

Case Description: This is a case of a 28-year-old filipino male patient with post kidney transplantation one month prior to admission. Donor and recipient matching revealed low immunologic risk for rejection with four HLA matched. Transplantation was unremarkable. He presented at the ER with behavioral changes, incoherence and SVT on ECG. Medical cardioversion with adenosine and verapamil was done. He was immediately dialyzed and noted resolution of symptoms. Course in the ward was unremarkable except for the persistence of hypertension and elevated creatinine. Doppler ultrasound is suggestive of TRAS on main renal artery allograft. Renal CT angiography confirmed 50 to 60% stenosis of right renal artery graft. He was given amlodipine 10mg/day and eventually underwent renal angioplasty as the definitive procedure to correct stenosis. Post angioplasty blood pressure was normal and remained on this level for the following days. Serum Creatinine lowered down to 110 umol/L. Repeat Doppler ultrasound showed an angioplasty stent in the proximal main renal artery of the graft. On his follow-up check up, his serum creatinine and BP rmained on normal levels.

Discussion: The case proves that although TRAS usually presents at 3 to 12 month post kidney transplant, it may occur earlier and unusually with encephalopathy and arrhythmia. Doppler ultrasound is essential in early detection, however, Renal CT angiogram is the imaging of choice for the confirmatory diagnosis. TRAS is catastrophic but early diagnosis and prompt medical-surgical intervention with amlodipine and renal angioplasty can lead to improved allograft survival and good prognosis for the patient.

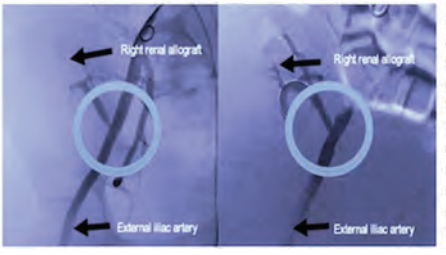

Figure 3. Renal CT angiography showing stenosis of right main renal artery graft at end to side anastomosis *(left-blue circle)*. Renal angioplasty with stent mounted across the stenotic site showing successful dilatation *(right-blue circle)*.

PUB247

Management of Kidney Transplant Waiting List in Belarus

Aleh Kalachyk. *Minsk Scientific and Practical Center of Surgery Transplantology and Hematology, Minsk, Belarus.*

Background: The reasons for establishing an automated waiting list system were as follow: the main clinical information about patients was available only on paper, there was a problem of optimal choice from the list of compatible donor-recipient pairs based on a large number of factors, there were difficulties with information transfer rate, security and reliability.

Methods: The project was implemented as a web-application. The program's interface includes several parts: Unit "file-cabinet" that contains patients' passport data and contact information Unit "Clinical information" includes immunological and clinical data of recipients Units "Examination" and "Conclusion of the consilium" is based on examination results and determines the suitability waiting list Unit "Recipient selection" Unit "Calculator of graft function".

Results: Web application helps to allocate donor organs by medical and social principles of selection. The social principles are: priority of patients who waited kidney transplant longer considering of donor and recipient territorial compatibility increased chances for kidney transplant patients with "incomplete" phenotype (homozygotes) priority for highly sensitized patients priority for children priority for patients who needed multiple-organ transplantation Medical principles: balance between the potential kidney transplant and recipient survival stratified accounting of histocompatibility degree between donor and recipient reduction of kidney transplant cold preservation time creation of transplantation priority conditions for patients who needed urgent kidney transplantation initial kidney graft function prognosis accounting Scoring system is based on the fact that the main feature of social justice (maximum waiting period) is equated tomain medical principle of effectiveness (maximum compatibility degree). The allocation of organs accounts the risk of early graft dysfunction (automatic kidney graft functioncalculator based on multifactor analysis of donor - and recipient-dependent risk factors is integrated). The final result is a prioritized list of recipients with a score of each factor and to perform the final selection of the council of physicians.

Conclusions: The software application allows to keep records, make statistical data analysis of potential recipient, distribute the organs anytime, anywhere in the world where the Internet is available.

PUB248

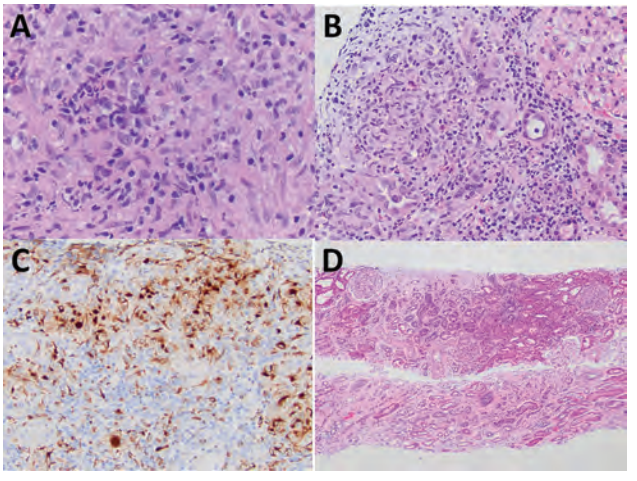
Late-Onset Recurrent Granulomatous Interstitial Nephritis in Transplanted Kidney with Successful Treatment: A Case Report

Fatmah Yamani,[1] Miroslav Sekulic,[1,2] Arksarapuk Jittirat.[1,2] *[1]Case Western Reserve University, Cleveland, OH; [2]University Hospitals Cleveland Medical Center, Cleveland, OH.*

Introduction: End stage renal disease (ESRD) secondary renal sarcoidosis is rare and likely due to hypercalcemic nephropathy. There is limited data on recurrent renal sarcoidosis post kidney transplant. We report a case of unusually late onset, recurrent sarcoidosis in transplanted kidney with successful treatment.

Case Description: A 65 year-old female with history of pulmonary sarcoidosis and ESRD due to sarcoidosis related-granulomatous interstitial nephritis (GIN) received a renal transplant in 2008. She was maintained on tacrolimus, mycophenolate(MMF) and prednisone. Baseline serum creatinine (SCr) had been 1.5 mg/dL. In 2017, patient was diagnosed with recurrent metastatic colorectal cancer. In 2019, her SCr increased to 3 mg/dL. A transplant kidney biopsy showed non-necrotizing GIN. She was treated with prednisone 40 mg daily. SCr decreased to 2.3 mg/dL. 3 months later, a repeat transplant kidney biopsy showed resolution of GIN. Prednisone dosage was tapered.

Discussion: GIN related to sarcoidosis has an overall estimated occurrence at 0.18 % of native kidney biopsies. GIN in transplanted kidney due to recurrent sarcoidosis has been reported ~17%. Risk factors for recurrence include primary renal disease related to sarcoidosis and a shorter delay between the last sarcoidosis flare and renal transplantation. Recurrence typically occurred shortly after transplantation, averaging 13 months after transplantation. More studies on treatment of recurrent renal sarcoidosis are warranted. We report a case of late onset recurrent GIN, occurring 11 years after transplantation with successful treatment.



Native kidney biopsy showed prominent, non-necrotizing GIN (A). Transplant kidney biopsy showed non-necrotizing GIN, similar to that of the native kidney biopsy (B). Immunoperoxidase staining for CD68 highlighted the interstitial histiocytes (C). Repeat allograft kidney biopsy did not show previously identified non-necrotizing GIN (D)

PUB249

Elevated Donor-Derived Cell-Free DNA as an Indication for Kidney Transplant Biopsy

Aileen Wang, John D. Scandling, Colin R. Lenihan. *Stanford University School of Medicine, Stanford, CA.*

Background: Donor derived cell-free DNA testing (dd cf-DNA) is increasingly employed for post-kidney transplant monitoring and may influence the decision to proceed with indication biopsy. The goal of this study was to identify those patients in whom the finding of an elevated dd cf-DNA was a key factor in the decision to obtain a kidney biopsy and to review 1) their biopsy findings and 2) any resulting treatment.

Methods: We reviewed the charts of 73 patients who underwent kidney transplant biopsy and had at least 1 dd cf-DNA (AlloSure) test performed. Ten patients underwent biopsy prompted primarily by an elevated dd cf-DNA level. Biopsy findings and resultant therapeutic interventions were abstracted.

Results: The median time from transplant to biopsy was 25.5 months. 2/10 patients had a normal biopsy. 5/10 had histological findings consistent with antibody mediated rejection (ABMR) with or without concurrent T-cell mediated rejection (TCMR). 2/10 had TCMR and 1/10 had recurrent glomerulonephritis. Of those with ABMR, 1/5 had a de novo HLA donor specific antibody (DSA) and 3/5 had positive non-HLA antibody (AT1 receptor antibody (AT1R)). 8/10 patients had a therapeutic intervention following biopsy. Dd cf-DNA decreased following treatment in 4/7 patients and did not change or worsened in 3/7 patients with available follow-up dd cf-DNA testing.

Conclusions: Kidney transplant biopsies in patients with an elevated dd cf-DNA frequently yield findings that warrant therapeutic intervention. Kidney transplant biopsy should be considered in patients with elevated dd cf-DNA, even if otherwise stable. Our observations warrant further examination on the uilitziation of long term dd cf-DNA monitoring, particularly in immunologically high risk kidney transplant recipients.

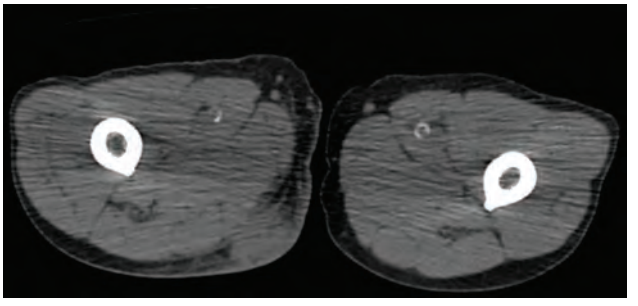
Disseminated Nocardiosis in Renal Transplant Recipient

Mohamedanwar M. Ghandour, Mareena S. Zachariah. *Wayne State University School of Medicine, Detroit, MI.*

Introduction: Nocardiosis is an uncommon opportunistic Gram-positive bacterial infection caused by aerobic actinomycetes in the genus Nocardia. Nocardia can cause localized or systemic suppurative diseases involving eyes, kidneys, skin, lungs, bone, and Central nervous system. Disseminated Nocardia is a rare condition, seen among immunocompromised patients.

Case Description: We report the case of a 55-year-old African American kidney transplant recipient on maintenance immunosuppression, who was diagnosed with cutaneous and pulmonary Nocardiosis. Presenting symptoms were shortness of breath, bilateral lower extremities pain and swelling. Tissue culture grew gram-positive bacilli specified as Nocardia farcinica from thigh and gluteal abscesses (figure 1). CT thorax showed bilateral reticulonodular opacities (figure 2). Patient was managed with immunosuppression reduction and specific treatment with high dose Bactrim in conjunction with linezolid. Combination antibiotics were continued for four weeks, thereafter Bactrim alone was continued for twelve months, at which point all lesions had healed.

Discussion: Nocardiosis with systemic involvement carries a poor prognosis. The reported patient had disseminated Nocardiosis involving lungs and skin, though lungs were thought to be the primary source of infection. However, early diagnosis and appropriate antibiotic coverage, had a favorable outcome, in a renal transplant recipient. Recommended treatment duration is 6 to 12 months with frequent imaging.



PUB251

Native Kidney Cytomegalovirus Nephritis

Sandiya Bindroo, Paul D. Killen, Mona D. Doshi. *University of Michigan, Ann Arbor, MI.*

Introduction: Cytomegalovirus (CMV) is the most common opportunistic infection in solid organ transplant (SOT) recipients and is estimated to affect 15-30% of high-risk SOT recipients. Typical manifestations of CMV end-organ disease includes colitis, esophagitis, gastritis, and pneumonitis. However, native CMV nephritis is rare, reported in less than 1% of renal biopsies. We present a case of CMV nephritis in a high risk liver transplant recipient who completed six months of CMV prophylaxis four weeks prior to presentation.

Case Description: A 66-year old man with history of liver transplantation was hospitalized on post-transplant day 230 for worsening kidney function (serum creatinine 4.40 mg/dL, baseline 2.0 mg/dL) and fatigability. The patient's history was notable for cryptogenic cirrhosis and hepato-renal syndrome. Immunotherapy consisted of tacrolimus (target trough 6-10ng/mL), mycophenolate mofetil (MMF), and prednisone. The recipient was CMV seronegative and the donor was CMV seropositive. He received valganciclovir for CMV prophylaxis in first six months of transplantation, per protocol. The early post-transplant course was complicated by reactivation of muco-cutaneous herpes simplex virus-1, and *Clostridium difficile* colitis. On presentation, patient reported fatigue, loose stools, and nausea. He was afebrile and had a normal white blood cell count. Serum creatinine was 4.40 mg/dL (baseline 2.0 mg/dL). Urinalysis was positive for 3+ leucocyte esterase with a full field of leucocytes and 10-50 red blood cells per high power field. Urine culture grew > 10^5 cfu/mL of *Pseudomonas aeruginosa* species. A normal renal ultrasound was noted. He was treated with intravenous (IV) cefepime. To evaluate the cause of the persistent renal failure, a renal biopsy was performed, revealing acute tubular injury and focal severe interstitial nephritis. CMV intra-nuclear and cytoplasmic inclusions were visualized and confirmed by immunohistochemical staining. Plasma CMV DNA levels by quantitative PCR were 40862 IU/mL. Treatment consisted of IV ganciclovir at induction doses adjusted for renal clearance, followed by maintenance dose valganciclovir. His renal functions improved.

Discussion: We report a rare manifestation of CMV disease with evidence of CMV in native kidney. Clinicians should have a high suspicion for late onset CMV diseases as a diagnosis in at risk SOT recipients with signs and symptoms of genitourinary tract.

PUB252

Incidence and Risk Factors in Mexican Patients with Diarrhea After Kidney Transplantation

Daniel F. Ovando-Morga, Sergio Hernández-Estrada, Jose H. Cano. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

Background: Diarrhea is one of the most frequent complications after kidney transplantation. Leads to dehydration, alteration of immunosuppressants serum levels, kidney function deterioration and graft loss. The prevalence of diarrhea varies from 20-50% globally. Focusing treatment on guidelines or recommendations, without considering local microbiology, may lead to mistakes in the management of this patients.

Methods: Cohort, analytical, retrospective study, were included kidney transplant patients from January 2014 to December 2018 in the Nephrology and Kidney Transplant Department at the Centro Medico Nacional 20 de Noviembre in Mexico City. Annual cumulative incidence calculation was performed. Binary logistic regression was used for the evaluation of risk factors. Survival analysis made by Kaplan-Meier curves.

Results: 92 patients were evaluated. Thirty two diarrhea episodes were recorded in 28 patients. 25% of the cases were in the first month after transplant, 40.6% of the episodes occurred in the 1-6 month period and 34.4% more than 6 months period. 71.9% of the cases were infectious etiology suspected, but only 45.8% had microbiological isolation. The most frequently isolated microorganism was Entamoeba histolytica in 45.5% of the cases. The cumulative incidence was 34%. There was no difference in graft survival in patients who developed diarrhea and those who did not ($p = 0.17$). Thymoglobulin induction increases up to 5 times the probability of developing post-transplant diarrhea (HR 5.98 p=0.01).

Conclusions: In our center, the cumulative incidence of diarrhea after transplantation is similar to reported in international series. The microbiology of diarrhea events, unlike that described in developed countries, is mainly associated with parasites. The impact of this complication on graft survival and accumulated survival is the same in patients who developed it versus in those who do not. Limited epidemiological data exist in our country and Latin America, for these reasons we must have better approach to research local epidemiological information and thereby improve therapeutics options for this patients.

PUB253

Unusual Presentation of Ramsay-Hunt Syndrome in a Kidney Transplant Recipient

Daniela Via Reque Cortes, Géssica S. Braga Barbosa, Marcelo P. Menezes filho, Tomas D. Ferreira, Jose O. Reusing, Elias David-Neto. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Introduction: Herpes-virus reactivation has long been recognized as occurring more frequently in immunocompromised individuals. There are only a few cases of Ramsay-Hunt Syndrome described after transplantation. We report a well-documented case of a kidney transplant recipient (KTR) with an atypical course due to multiple cranial nerve involvement.

Case Description: After treatment of esophageal candidiasis, a 50yo male KTR presented with persistent odynophagia, dysphagia, dysphonia, fever, hipoacusis, otalgia and vesicular lesions in the external left auditory canal, compatible with Herpes Zoster Oticus. He had underwent a deceased-donor kidney transplant ten years before, and maintained on mycophelonate mofetil (1.5 g/d), tacrolimus (2 mg/d) and prednisone (7.5 mg/d) immunosuppression. His past medical record included chickenpox in his childhood. A nasofibrolaringoscopy showed unilateral paralysis of the left vocal cord with saliva aspiration. Computed tomography scan of cranium, neck and thorax excluded expansive lesions. Blood polymerase chain reaction test detected Varicella-Zoster Virus (VZV). Only seven days later, he developed unilateral left facial and palatal paralysis. A cranium magnetic resonance image revealed linear enhancement of the left facial nerve. All these findings led to the diagnosis of Ramsay-Hunt Syndrome. Mycophenolate was withdrawn and the patient received intravenous acyclovir and prednisone 1mg/kg/day for 4 weeks. Due to severe dysphagia with significant weight loss, reaching 35 kg, he received enteral nutrition through a nasogastric feeding tube during 12 weeks. He gradually recovered motor function of the 7th and 10th cranial nerves. Six months after the onset of symptoms, the patient is under full immunosuppressive therapy and feeding through mouth with occasional choking to some solids.

Discussion: Reactivation of pre-existing VZV in craniospinal sensory ganglia causes Herpes Zoster, which is characterized by a painful erythematous rash in the affected dermatome. Ramsay-Hunt Syndrome occurs when VZV affects neurons of the geniculate ganglion. When it occurs unusually with multiple cranial neuropathies it leads to a potential missed diagnosis and delayed treatment.

PUB254

Tacrolimus: A Worth-Considering Culprit for Post-Transplant Anaemia Secondary to Parvovirus B19

Myint T. Aye, Arvind Singh. *University Hospitals of Plymouth NHS Trust, Plymouth, United Kingdom.*

Introduction: Haematological side effects of tacrolimus seem to be rare and their aetiology is unclear. Parvovirus B19 is an uncommon yet clinically significant infection that manifests as refractory anaemia in post-transplant patient. The exact mechanism by which tacrolimus can aggravate pure red cell apasia (PRCA) is still unclear. Here we report a case of post-transplant anaemia where withdrawal of tacrolimus demonstrated significant improvement in chronic transfusion dependent anaemia.

Case Description: A 66-year-old male with end stage renal failure due to accelerated hypertension had a diseased donor transplantation in 2018. Before receiving his transplant, his peripheral blood counts were relatively normal. Patient was discharged nine days after operation with haemoglobin of 82 g/dl. Approximately five weeks following transplantation, the patient was found to have profound anaemia with haemoglobin level falling to 57 g/dl but white cell and platelet count remained normal. Following investigations, patient was found to have parvovirus B19 with positive DNA titre. Since then patient was transfusion dependent with two weekly red cell transfusion. Patient had two courses of IVIG, however, showed only transient improvement in viral DNA titre with no haematological improvement. Finally, tacrolimus was switched to cyclosporin A and showed rapid improvement within two weeks.

Discussion: Persistent parvovirus B19 infection can occur in immunocompromised host due to impairment of the neutralizing antibody response and/or cellular immunity thus failure to clear the virus. Tacrolimus, on the other hand, is believed to be an immunosuppressive agent without significant potential for myelosuppression. In this case, temporal relation of withdrawal of tacrolimus with improvement of anaemia suggests an etiological role of tacrolimus. The close inverse relationship between viral DNA PCR titre and erythropoietic activity reflected by the improvement of refractory anaemia showed that the direct cause of red cell aplasia was viral infection, rather than direct drug effect. Several authors postulated that parvovirus B19 infection in transplant patients is aggravated by the use of tacrolimus through impairment of its clearance by tacrolimus, which cannot be simply explained by a state of heightened immunosuppression.

PUB255

Use of Donor-Derived Cell-Free DNA to Identify Allograft at Risk by Late Surveillance

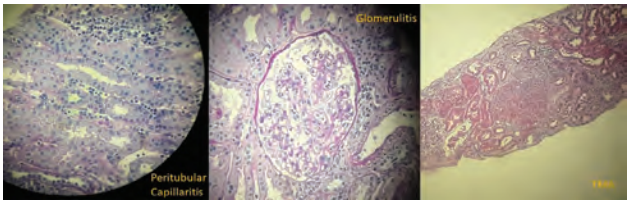
Amna Ilahe,[1,2] Diana Mahbod,[1] Rama Nadella,[1] Irfan Agha.[1,3] *[1]Dallas Renal Group, Dallas, TX; [2]Methodist Dallas Medical Center, Dallas, TX; [3]Medical City Dallas Hospital, Dallas, TX.*

Introduction: Monitoring allograft function remains inadequate. Many allografts sustain subacute injury not detected in time resulting in poor long-term outcomes. Traditional tools utilized (creatinine, proteinuria and DSA) are insensitive and imprecise. The gold standard, allograft biopsy, is invasive and expensive. DD CF DNA has emerged as a sensitive and specific marker of allograft injury. This test is valuable in the early post-transplant period but also can be of great use for allograft surveillance late after transplant. We present a case where use of DD CF DNA helped identify simmering allograft dysfunction not picked up by traditional means, allowing active intervention and change in management.

Case Description: 36 YO WF with a H/O SLE leading to CKD, S/P LUKT in 2018. Induced with Campath, maintained steroid free on Tacrolimus and MMF. Nadir Cr 0.8 mg/dl. Current Cr 1.0 mg/dl. Urine Pr/Cr ratio 0.06 g/g. Seen for routine visit. Surveillance DD CF DNA (Allosure) done - 4.8%. Repeat after a few weeks - 5.4%. No DSA. ANA was at 1:40. ds DNA Ab negative. Normal complements. Biopsy was suggestive of acute active antibody mediated rejection with severe microvascular injury and renal limited TMA. C4d only focally positive. DSA repeated and negative. MICA Ab negative. AT1R

Ab positive by EIA with a level > 40 units/ml. Treated for Acute active ABMR due to AT1R Ab with plasmapheresis and IVIG for four sessions. Creatinine stable at 0.9 mg/dl. Allosure down to 1% after treatment.

Discussion: Monitoring allograft function, especially late after transplant, can be difficult given lack of sensitivity and precision of traditional markers. DD CF DNA is emerging as a sensitive and specific marker to detect allograft injury. In this case, significant allograft injury was detected on a biopsy performed solely because of abnormal surveillance DD CF DNA result. This led to aggressive intervention and management change. This test adds another tool available to monitor allograft health and may allow us to pick up allograft injury even when traditional markers remain silent.



Severe Microvascular Injury and TMA

PUB256

Infections in the Early Period After Kidney Transplantation

Andreea Ioana Berechet,[1] Bogdan M. Sorohan,[1,2] Bogdan Obrisca,[1,2] Andreea G. Andronesi,[1,2] Gener Ismail.[1,2] *[1]Fundeni Clinical Institute, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.*

Background: Infectious complications remain an important cause of morbidity and mortality in kidney transplant recipients, especially in the first year after kidney transplantation (KT). The aim of our study was to evaluate incidence, type of infectious complications and also, to identify risk factors and graft survival impact of these infections in the first 90 days after KT.

Methods: We performed a prospective cohort study, which included 67 adult patients (age ≥ 18 years), transplanted in our center between the 1st of October 2018 the 1st of October 2019. Demographics data, recipient, donor, transplant, treatment and infections parameters were analyzed.

Results: Among the 67 patients, the mean age was 41.3± 10.5 years, male was the predominant recipient gender (59.7%) and 65.7% received a graft from a cadaveric donor. During the first 90 days after KT, 26 infectious episodes occurred in 22 kidney recipients (32.8%). The majority of patients (68%) developed infection in the first 30 days after KT. The most common infectious site was the urinary tract (53.8%). The most frequent pathogens identified were Klebsiella pneumoniae (9 times) and Escherichia Coli (7 times). Median time of antibiotherapy was 10 days (7-15). Patients from the infection group received a graft from a significantly older donor (p=0.02), had a significantly higher cold ischemia time (p=0.02) and tended to received more frequent antithymocyte globulin (ATG) induction therapy (p= 0.09). No significant difference between patients with infectious and without infectious complications, in terms of delayed graft function (DGF) (p=0.14), acute rejection (p=0.13) and graft failure (p=0.17). Multivariate Cox regression analysis, showed that induction therapy with ATG (HR=3.02; CI 95%=1.08-8.42; p=0.03), DGF (HR= 3.61; CI 95%=1.09-11.91; p=0.03) and donor age (HR=1.04; CI 95%= 1.006-1.082; p=0.02) were independent risk factors for infection in the first 90 days after KT. Five out of 67 patients developed graft failure, and 3 of them (60%) lost their graft due to acute graft pyelonephritis (p<0.001).

Conclusions: We showed that infections in the early period after KT remain a common complication with negative impact on graft function, specially urinary tract infections. Likewise, induction therapy with ATG, DGF and donor age were independent risk factors for infectious complications.

PUB257

AKI in Kidney Transplant Patients: A Single-Center Experience

Hay Me Me, Neha Deval, Aditi A. Sen, Shruti Kore, Sanjeev Gupta, Daniel Glicklich. *Westchester Medical Center, Valhalla, NY.*

Background: The incidence of acute kidney injury (AKI) after kidney transplantation varies depending on the centers but it is a significant risk factor for graft failure. Kidney transplantation recipients have various risk factors for AKI according to the time after transplantation, most commonly being infection, ischemic-perfusion injury, volume depletion, calcineurin induced nephropathy and acute rejection. We present the common causes of acute kidney injury in our center and the related outcomes.

Methods: A retrospective study was conducted and gathered the information from their first episode of acute kidney injury event starting from January 2011. Out of 180 patients, 65 patients were excluded due to the lack of detailed documentation. We looked up the causes of acute kidney injury from biopsy reports and serology data and the subsequent renal outcomes.

Results: Among 115 patients, 105 patients (88%) had non-oliguric AKI and 10 patients (8%) developed oliguric AKI. Biopsy results revealed the most common cause of AKI being the transplant glomerulopathy (chronic rejection) at 23% in non-oliguric groups and 60% in oliguric groups. Only a few patients (9.5%) recovered and most of them developed chronic kidney disease with 41% in non-oliguric group. Acute cellular mediated rejection was found in 18% patients in non-oliguric group. Dialysis was needed in 50% in oliguric patients.

Conclusions: Our data shows that non-oliguric AKI is the most common presentation in kidney transplant patients and had poor outcome. Surprisingly, the most common etiology of AKI is chronic rejection in our center. Close follow up and early detection with biopsy might help to prevent chronic kidney disease due to chronic rejection.

PUB258

Early Graft Dysfunction due to Banff 2A Rejection in a Non-Sensitized Cross-Match-Negative Recipient

Thanh Cao, Neeraj Sharma. University of Southern California *University of Southern California, Los Angeles, CA.*

Introduction: With the introduction of potent immunosuppression, the incidence of acute rejection in the first year following transplant is 1-2% lower in living donor kidney transplants (LDKT) compared to deceased donor kidney transplants (DDKT). Ideally, immediate graft function should be expected after LDKT. We present a case report of early acute cellular rejection 26 hours after an ABO compatible, HLA crossmatch negative LDKT.

Case Description: A 65-year-old Caucasian male with ESRD due to anti-GBM disease presented for a LDKT from his 68-year-old wife. He was ABO compatible, HLA crossmatch negative, and 0% for both T-flow and B-flow PRA. Induction was with Basiliximab 20mg and Methylprednisilone 500mg and achieved immediate diuresis. He became anuric by 16 hours post-op, and a for-cause biopsy was done on POD 2 which showed Banff 2A acute cellular rejection with negative C4D. Patient was treated with rabbit anti-thymocyte globulin (rATG) with total dose 3mg/kg divided over 4 doses and pulse intravenous steroid at 250mg for 5 days. Immunosuppression was intensified and target tacrolimus levels were increased to achieve trough levels between 10-12 ng/mL. The patient has maintained excellent allograft function six months post-transplant with baseline serum creatinine baseline 1.8-2.0 and eGFR 34-38.

Discussion: Risk factors for acute rejection include multiple human leukocyte antigen (HLA) mismatches, a high panel reactive antibody (PRA), presence of donor specific antibodies (DSA), ABO blood group incompatibility, positive HLA crossmatch, prolonged cold ischemia time greater than 24 hours, African American ethnicity, and inadequate induction regimen. For patients with high risk factors for rejection, 2009 KDIGO guidelines recommend induction regimen with lymphocyte-depleting agents such as rATG rather than IL-2 receptor monoclonal antibody such as Basiliximab. This case report focuses specifically on the development of ACR in a low risk living donor transplant. We speculate that the development of ACR in this low risk patient was likely due to the HLA mismatches and possibly induction with Basiliximab. This case report poses the question of whether more intensive induction therapy should be considered in low risk patients with presence of HLA mismatches and the long-term allograft outcomes following acute rejection.

PUB259

Aspirin Prescribing Practices and Characteristics of Pregnant Women with CKD

Christin M. Giordano McAuliffe,[1] Shelby A. Crants,[2] Lynsa Nguyen,[1] Lisa Zuckerwise,[1] Anna M. Burgner.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University School of Medicine, Nashville, TN.*

Background: Women with chronic kidney disease (CKD) are at a higher risk for preeclampsia compared to women without CKD. The U.S. Preventative Services Task Force has recommended use of low-dose aspirin in women with a high risk for development of preeclampsia, including women with renal disease since 2014. The authors sought assess the characteristics of pregnant women with CKD and aspirin prescribing practices at their institution.

Methods: The authors performed a retrospective chart review of data from pregnancies in women with CKD who delivered between January 1, 2015 and December 31, 2019. Potential pregnancies were identified with diagnostic codes for pregnancies and then included patients who had diagnostic codes for chronic kidney disease and proteinuria. We included pregnancies that had a formal diagnosis of CKD and those in whom baseline creatinine did not decrease at least 0.3 mg/dl during pregnancy. We excluded pregnancies that ended prior to 12 weeks. Means, standard deviations, medians, and interquartile ranges were used for continuous variables, and frequency and proportions were used for categorical variables, as appropriate.

Results: A total of 149 pregnancies were included. The mean age at due date was 30.8 (std. dev 5.6) with 27.5% of advanced maternal age. The majority (51.7%) were obese, with an overall mean BMI of 32.8 kg/m2 (std. dev 8.2). 15.4% had a history of prior pre-eclampsia. Just over half (57.5%) had been diagnosed with CKD prior to or during pregnancy with the most common underlying etiologies being type 2 diabetes mellitus. Of these, the mean baseline creatinine, obtained within 1 year of pregnancy, was 1.13 mg/dL (std. dev 0.64). Of 149 pregnancies included, 63 (42.3%) were prescribed aspirin prior to 28 weeks of gestation. Overall, 36.2% (54/149) were diagnosed with pre-eclampsia. Of those with a formal diagnosis of CKD prior to pregnancy, 52.9% were prescribed aspirin and 42.4% developed pre-eclampsia.

Conclusions: Chronic kidney disease is a well-recognized risk factor for pre-eclampsia with guidelines recommending the prescribing of aspirin to pregnant women with CKD. This study demonstrated low overall aspirin prescribing rates with relatively high rates of pre-eclampsia at a single institution.

PUB260

Magnesium Intake, Bone Mineral Density, and the Risks of Falls and Fractures in Post-Menopausal Women with Kidney Stone

Harshitha Kota,[1] Xuerong Wen,[2] Chao Chen,[3] Jie Tang.[1,4] *[1]Brown University, Providence, RI; [2]University of Rhode Island, Kingston, RI; [3]University of Florida, Gainesville, FL; [4]University Medicine Foundation Inc, Providence, RI.*

Background: Kidney stone formers are a unique patient population at high risk for fall and fractures due to dysregulated calcium homeostasis and early bone loss. Magnesium is an important component of bone, but its relation to falls and fractures among stone formers is unclear.

Methods: We performed regression analyses to determine the independent effect of dietary magnesium intake (DMI) on bone mineral density (BMD), and risks of fall and bone fracture among incident stone formers identified in the Women's Health Initiative (WHI), a prospective longitudinal multicenter study investiating the health of post-menopausal women.

Results: Out of a total of 145,942 WHI participants free of kidney stone history at baseline, 6024 developed kidney stone after 1,601,750 patient years of follow up. Among these incident stone formers, 82% were Caucasian, 23% were above age 70. Mean DMI was 304 mg/day, 30% had high DMI defined as >348 mg/day, 38% had medium DMI defined as 241-348 mg/day and 32% had low DMI defined as <241 mg/day. A total of 238 (4%), and 2581 (43%) incident stone formers had low BMD and new falls or fractures, respectively. Both low dietary calcium intake and active smoking associated with reduced BMD ($p<0.05$), but DMI did not affect BMD in the multivariate regression analysis, $\beta= 1.6$, $p=0.4$. Older age, black race, history of diabetes, history of either parent having broken bones after age 40 all associated strongly with risks of fall and bone fracture ($p<0.05$). However, DMI again did not have such significant association after adjustment for demographics and potential confounding factors, $\beta=1.7$, $p=0.4$.

Conclusions: DMI does not appear to affect BMD and the risk of fall or bone fracture among post-menopausal women.

Effect of Finerenone on CKD Outcomes in Type 2 Diabetes

George L. Bakris,[1] Rajiv Agarwal,[2] Stefan D. Anker,[3] Bertram Pitt,[4] Luis M. Ruilope,[5,6] Peter Rossing,[7,8] Peter Kolkhof,[9] Christina Nowack,[10] Patrick Schloemer,[11] Amer Joseph,[12] Gerasimos Filippatos.[13] on behalf of the FIDELIO-DKD Investigators *[1]Department of Medicine, University of Chicago Medicine, Chicago, IL; [2]Richard L. Roudebush VA Medical Center and Indiana University, Indianapolis, IN; [3]Department of Cardiology (CVK) and Berlin Institute of Health Center for Regenerative Therapies, German Centre for Cardiovascular Research Partner Site Berlin, Charité Universitätsmedizin, Berlin, Germany; [4]Department of Medicine, University of Michigan School of Medicine, Ann Arbor, MI; [5]Cardiorenal Translational Laboratory and Hypertension Unit, Institute of Research imas12, Madrid, Spain; [6]CIBER-CV, Hospital Universitario 12 de Octubre, & Faculty of Sport Sciences, European University of Madrid, Madrid, Spain; [7]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [8]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [9]Research and Development, Preclinical Research Cardiovascular, Bayer AG, Wuppertal, Germany; [10]Research and Development, Clinical Development Operations, Bayer AG, Wuppertal, Germany; [11]Research and Development, Statistics and Data Insights, Bayer AG, Berlin, Germany; [12]Cardiology and Nephrology Clinical Development, Bayer AG, Berlin, Germany; [13]School of Medicine, Department of Cardiology, Attikon University Hospital, National and Kapodistrian University of Athens, Athens, Greece.*

Background: Patients with chronic kidney disease (CKD) and type 2 diabetes (T2D) remain at risk of CKD progression despite guideline-directed therapies. Mineralocorticoid receptor (MR) overactivation may drive CKD progression through inflammatory and fibrotic processes. Finerenone, a novel, nonsteroidal MR antagonist, reduces albuminuria independent of hemodynamic effects. We assessed the long-term efficacy and safety of finerenone in slowing CKD progression in patients with CKD and T2D.

Methods: This global, phase 3, double-blind study randomized 5734 patients from 48 countries (1:1) to oral finerenone or placebo. Patients with T2D, urine albumin-to-creatinine ratio 30–5000 mg/g and estimated glomerular filtration rate (eGFR) 25–<75 mL/min/1.73 m^2, treated with optimized renin–angiotensin system blockade, were included. The primary outcome was time to kidney failure, sustained eGFR decline ≥40% from baseline or renal death. The key secondary outcome was time to cardiovascular (CV) death, non-fatal myocardial infarction, non-fatal stroke or heart failure hospitalization. (NCT02540993)

Results: Mean patient age was 65.6 years; 70.2% were male. At baseline, mean eGFR was 44.3 mL/min/1.73 m^2 and median UACR 852 mg/g. The primary outcome occurred in 504/2833 (17.8%) and 600/2841 (21.1%) patients treated with finerenone and placebo, respectively (hazard ratio [HR]=0.82; 95% confidence interval [CI] 0.73–0.93; *p*=0.0014). The prespecified secondary outcome was also reduced with finerenone (13.0%) vs placebo (14.8%; HR=0.86; 95% CI 0.75–0.99, *p*=0.0339). Overall treatment-emergent adverse events were balanced between groups. The incidence of hyperkalemia-related treatment discontinuation was higher with finerenone than placebo (2.3% and 0.9%, respectively).

Conclusions: Finerenone significantly reduced kidney and CV outcomes in patients with T2D and advanced CKD and was well tolerated. While the primary adverse event was hyperkalemia, it only necessitated treatment discontinuation in 2.3% of patients compared to 0.9% in placebo. These data support the use of finerenone to slow CKD progression and reduce CV risk in patients with CKD and T2D.

EMPEROR-Reduced: Empagliflozin and Outcomes in Heart Failure and CKD

Faiez Zannad. The EMPEROR Reduced trial steering committe and investigators *INI CRCT, Univesrite de Lorraine, Nancy, France*.

Background: In EMPEROR-Reduced, empagliflozin reduced cardiovascular death and heart failure hospitalizations and slowed the progressive decline in kidney function in heart failure and a reduced ejection fraction (HFrEF), with or without diabetes. We explored the effect of empagliflozin on cardiovascular and kidney outcomes, across the spectrum of kidney function.

Methods: 3730 patients were randomized, of whom 1978 (53%) had prevalent chronic kidney disease (CKD) (eGFR<60ml/min/1.73m^2 or an UACR>300mg/g). The key outcomes were (1) a composite of cardiovascular death or hospitalization for heart failure; (2) total hospitalizations for heart failure, and (3) eGFR slope; the last was supported by a prespecified composite renal outcome (defined as a profound sustained decline in eGFR, chronic dialysis or transplant). The median follow-up was 16 months.

Results: Patients with prevalent CKD had a higher rate of CV and kidney events. Empagliflozin reduced the risk of cardiovascular death and hospitalization for heart failure by 25% (P< 0.001), reduced total hospitalizations for heart failure by 30% (P<0.001) and reduced the composite of chronic dialysis, transplant and renal death by 50% (P<0.01). All three benefits were seen consistently in patients with and without CKD (figure) and were apparent even in patients with severe impairment (eGFR from 20 to 30ml/min/1.73m^2). Empagliflozin significantly slowed the yearly loss of eGFR and was well tolerated regardless of the level of baseline kidney function.

Conclusions: In patients with HFrEF, empagliflozin reduced serious heart failure and serious adverse kidney outcomes, and slowed the decline in kidney function, regardless of the presence or absence of CKD and across a broad spectrum of baseline kidney function.

Sequential Treatment with Tacrolimus and Rituximab vs. Alternating Corticosteroids and Cyclophosphamide in Primary Membranous Nephropathy (PMN)

Gema Fernandez Juarez,[1] Jorge E. Rojas-Rivera,[7] Anne-Els van de Logt,[12] Joana Justino,[5] Angel M. Sevillano,[2] Fernando Caravaca-Fontan,[2] Ana Avila,[13] Cristina Rabasco,[8] Virginia Cabello,[6] Marian Goicoechea,[9] Luis F. Quintana,[3] Irene Agraz,[10] Ana M. Romera segorbe,[11] Amir Shabaka,[1] Mario Espinosa,[8] Jesus Egido,[7] Gerard J. Lambeau,[5] Pierre M. Ronco,[4] Manuel Praga.[2] *[1]Nephrology, Hospital Univesitario Fundacion Alcorcón, Madrid, Spain; [2]Nephrology, Hospital Universitario 12Octubre, Madrid, Spain; [3]Nephrology, Hospital Clnic, Barcelona, Spain; [4]Nephrology, Tenon Hospital, Paris, Spain; [5]Institut de Pharmacologie Moleculaire et Cellulaire, Valbonne, France; [6]Nephrology, Hospital Virgen del Rocio, Sevilla, Spain; [7]Nephrology, Fundacion Jimenez Diaz, Madrid, Spain; [8]Nephrology, Hospital Reina Sofia, Córdoba, Spain; [9]Nephrology, Hospital Universitario Gregorio Marañón, Madrid, Spain; [10]Nephrology, Vall d'Hebron Hospital Universitari, Barcelona, Spain; [11]Nephrology, Hospital General Ciudad Real, Ciudad Real, Spain; [12]Nephrology, 3 Radboud University Medical Center, Nijmegen, Netherlands; [13]Nephrology, Hospital Dr. Peset, Valencia, Spain.*

Background: A cyclical corticosteroid-cyclophosphamide regimen is recommended for patients with PMN at high risk of progression. RTX monotherapy and calcineurin inhibitors have shown efficacy in inducing remission, but relapses are very common after discontinuation of calcineurin inhibitors.

Methods: In a randomized and open-label controlled trial, 86 patients (pts) with PMN and persistent nephrotic syndrome after a 6m observation period were assigned to receive a 6-m cyclical treatment with corticosteroid and cyclophosphamide (n=43) or sequential treatment with tacrolimus (full-dose for 6m and tapering for another 3m) and RTX (1 g at 6thm) (n=43). Primary outcome was complete or partial remission of nephrotic syndrome at 24m.

Results: The primary outcome occurred in 36 pts (84%) in the Ct-cyclophosphamide group and in 25 pts (58%) in the tacrolimus-RTX group (RR 1.44 95%CI 1.08-1.92). Complete remission at 24m occurred in 26pts (60%) in the corticosteroid-cyclophosphamide group and in 11pts (26%) in the tacrolimus-RTX group (RR 2.36 95%CI 1.34-4.16). Immunological response was faster in the corticosteroid-cyclophosphamide group and associated with remission at 24 m. Relapses occurred in 1 pt (2.7%) in the corticosteroid-cyclophosphamide group, and 3 pts (12%) in the tacrolimus-RTX group. The rate of serious adverse events was similar in both groups.

Conclusions: Treatment with corticosteroid-cyclophosphamide induced remission in a significantly greater number of patients with PMN than tacrolimus-rituximab. (NCT01955187).

Funding: Government Support - Non-U.S.

Global Phase 3 Clinical Trials of Vadadustat vs. Darbepoetin Alfa for Treatment of Anemia in Patients with Non-Dialysis-Dependent CKD

Glenn M. Chertow. PRO2TECT Author Group *Stanford University School of Medicine, Stanford, CA.*

Background: Vadadustat (VADA) is an investigational, oral, hypoxia-inducible factor prolyl hydroxylase inhibitor which has completed patient enrollment in its phase 3 development for treatment of anemia of chronic kidney disease (CKD). In phase 2 trials, VADA safely raised and maintained hemoglobin (Hb) concentrations.

Methods: We conducted two randomized, phase 3, global, open-label, sponsor-blind, parallel-group, active-controlled noninferiority trials comparing oral daily VADA to parenteral darbepoetin alfa (DA) in patients with anemia of non-dialysis dependent (NDD)-CKD (PRO_2TECT program). The PRO_2TECT program included (1) Correction trial of patients previously not on erythropoiesis-stimulating agents (ESA) (ESA-untreated NDD-CKD trial, NCT02648347) and (2) Conversion trial of patients previously on an ESA (ESA-treated NDD-CKD trial, **NCT**02680574). The primary safety endpoint of PRO_2TECT program was time to first major adverse cardiovascular event (all-cause mortality, nonfatal myocardial infarction, nonfatal stroke), prespecified as a pooled event-driven analysis of both trials. Primary and key secondary efficacy endpoints, prespecified as separate analyses for each trial, were difference in mean change in Hb between baseline and weeks 24-36 and weeks 40-52, respectively, comparing VADA vs DA.

Results: In total, 4708 patients were screened for the ESA-untreated NDD-CKD trial, and 1751 were randomized. Most (N=1061) were from the United States; the remainder were from Europe or elsewhere. A total of 2961 patients were screened for the ESA-treated NDD-CKD trial, 1725 of whom were randomized. Most (N=1060) were from Europe or non-United States/non-European countries; the remainder were from the United States. The database was locked on July 31, 2020. Topline data and results of these global trials will be available in September 2020.

Conclusions: The trials will test if oral daily VADA is noninferior to parenteral DA, a common ESA, in patients with anemia of NDD-CKD, with respect to cardiovascular safety and hematologic efficacy.

FR-OR55

Oral Intradialytic Nutritional Supplements and Mortality in Hemodialysis Patients: A Cluster-Randomized, Pragmatic Clinical Trial

Daniel E. Weiner,[1] Karen M. Majchrzak,[2] Cindy D. Kinnard,[2] Hocine Tighiouart,[1] Todd Marren,[2] Eduardo K. Lacson,[2] Doug Johnson.[2] on behalf of Dialysis Clinic, Inc *[1]Tufts Medical Center, Boston, MA; [2]Dialysis Clinic Inc, Nashville, TN.*

Background: Dialysis is a catabolic state and observational studies suggest that administering oral nutritional supplements to hemodialysis patients with low serum albumin during the dialysis session may reduce mortality. Whether there are benefits in patients with normal serum albumin remains unstudied.

Methods: The Health Effects of oraL Protein Supplements in HD (HELPS-HD) Trial was an open-label cluster randomized pragmatic trial, comparing the effects of an intensive oral nutritional supplement protocol in which prevalent hemodialysis patients received supplements at every dialysis session regardless of serum albumin to standard care, in which supplements were administered to patients with albumin below 3.5 g/dL. As part of standard care, all incident patients received supplements for the first 90 days of dialysis. Following randomization of facilities to either the intensive or standard protocol, patients in facilities provided informed consent via waiver of consent documentation. The study intervention lasted from January 2017 to March 2020, and patients were enrolled through December 2019. The primary outcome, all-cause mortality, was assessed from medical records.

Results: Among 10,043 hemodialysis patients randomized from 105 participating DCI facilities, mean age was 63 years, 56% were men, 36% Black, and 46% had diabetes as primary cause of kidney failure; 32% were incident to dialysis. Supplement use was 2-fold higher in the 53 clinics randomized to the intensive protocol. Over median follow-up of 21 months, there were 3628 deaths, 35.8% in the intensive and 36.5% in the standard group, with an unadjusted rate of 20 deaths per 100-person years in both groups. In unadjusted Cox models, those randomized to the intensive protocol had similar outcomes to those randomized to the standard protocol (HR 1.02 [0.92, 1.14]); results were similar in models adjusted for age, sex and race and between incident and prevalent patients.

Conclusions: Discussion In a large, national population of hemodialysis patients, there was no difference in mortality between patients randomized to a standard oral nutritional supplement protocol, with receipt of supplements only when serum albumin was low, as compared to an intensive protocol, with receipt of supplements regardless of serum albumin.

Reducing the Burden of Dialysis Catheter Complications: A National Approach (REDUCCTION)

Martin P. Gallagher,[1,2] Sradha S. Kotwal,[1,3] Girish S. Talaulikar,[4] Nicholas A. Gray,[5] Kevan Polkinghorne,[6] Stephen P. McDonald,[7] Alan Cass.[8] on behalf of the REDUCCTION Investigators *[1]The George Institute for Global Health, Newtown, NSW, Australia; [2]University of Sydney, Sydney, NSW, Australia; [3]Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; [4]Renal Services, ACT Health, Canberra City, ACT, Australia; [5]Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; [6]Monash University, Clayton, VIC, Australia; [7]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; [8]Menzies School of Health Research, Charles Darwin University, Casuarina, NT, Australia.*

Background: The major morbidity and cost from the use of central venous hemodialysis catheters is the increased risk of catheter-related blood stream infection (HD-CRBSI). Clinical practice remains variable and broad-scale, systematic interventions to reduce this burden have not been tested in randomized trials. The REDUCCTION trial aimed to systematically measure the rate of HD-CRBSI at a national level and test the effect of a multifaceted, evidence-based intervention upon the rate of HD-CRBSI in Australia.

Methods: This stepped wedge, randomized trial, clustered at the renal service level, included all patients receiving a central venous hemodialysis catheter in a participating renal service. After baseline data collection, services were randomly assigned to one of three time points (April 2018, Sept 2018, March 2019) for implementation of an intervention package based upon current evidence and guidelines. The primary outcome was the intervention's effect upon the study wide service-level rate of HD-CRBSI (per 1000 catheter days).

Results: A total of 37 renal services in all Australian states and territories participated in the trial between Dec 2016 and March 2020. Preliminary analysis shows that 5246 catheters (3506 patients) were inserted during the baseline phase and 4610 catheters (3144 patients) in the intervention phase, representing more than 1.1 million catheter days of exposure and over 300 adjudicated HD-CRBSI events. Final analysis is currently in progress with results presented at the Annual Meeting.

Conclusions: The REDUCCTION trial has systematically measured the use of HD CVCs in near real-time and demonstrated the feasibility of implementing a suite of evidence-based interventions in haemodialysis care. The study outcomes will have implications for future research and practice in dialysis access.

Regional Citrate vs. Systemic Heparin Anticoagulation During Continuous Kidney Replacement Therapy Among Critically Ill Patients with AKI: A Randomized Clinical Trial

Alexander Zarbock,[1] Mira Kuellmar,[1] Detlef Kindgen-milles,[5] Peter Rosenberger,[4] Sean M. Bagshaw,[3] John A. Kellum,[2] Melanie Meersch.[1] *[1]Department of Anesthesiology, Intensive Care and Pain Medicine, Universitatsklinikum Munster, Munster, Germany; [2]Center for Critical Care Nephrology, University of Pittsburgh, Pittsburgh, PA; [3]University of Alberta, Edmonton, AB, Canada; [4]Universitatsklinikum Tubingen Medizinische Universitatsklinik, Tubingen, Germany; [5]Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany.*

Background: Although current guidelines suggest the use of regional citrate anticoagulation as first-line treatment for continuous kidney replacement therapy in critically ill patients, the evidence for this recommendation is based on few clinical trials and meta-analyses.

Methods: To determine the effect of anticoagulation strategies on filter lifespan and mortality, a parallel-group, randomized multicenter clinical trial was conducted in 26 centers across Germany between March 2016 and December 2018. Patients were randomized to receive either regional citrate (n=300) or systemic heparin anticoagulation (n=296) for continuous kidney replacement therapy. The two co-primary outcomes were filter lifespan and 90-day all-cause mortality. Secondary endpoints included bleeding complications and new infections.

Results: Among 638 patients randomized, 596 (93.4%) patients (mean age, 67.5 (±12.4) years, 183 (30.7%) women) completed the trial. Median filter lifespan was 47h [IQR, 19-70h] in the regional citrate and 26h [IQR, 2-51h] in the systemic heparin group; absolute difference (AD), 15h [95%CI, 11h to 20h]; *P*<0.001). 90-day all-cause mortality was 51.2% (150/300) in the regional citrate and 53.6% (156/296) in the systemic heparin anticoagulation group (adjusted AD, -6.1% [95%CI, -12.6% to 0.4%]; adjusted HR, 0.79 [95%CI, 0.63 to 1.004]; adjusted P=0.054; unadjusted AD, -2.4% [95%CI, -10.5% to 5.8%]; unadjusted HR, 0.91 [95%CI, 0.72 to 1.13]; unadjusted *P*=0.38). Compared with systemic heparin anticoagulation, the regional citrate anticoagulation group had significantly fewer bleeding complications (15/300 [5.1%] vs. 49/296 [16.9%]; AD, -11.8% [95% CI, -16.8% to 6.8%]; P<0.001) and significantly more new infections (204/300 [68.0%] vs. 164/296 [55.4%]; AD, 12.6% [95% CI, 4.9% to 20.3%]; P=0.002).

Conclusions: Among critically ill patients with acute kidney injury receiving continuous kidney replacement therapy, anticoagulation with regional citrate, compared with systemic heparin anticoagulation, resulted in significantly longer filter lifespan. The trial was terminated early and was therefore underpowered to reach conclusions about the effect of anticoagulation strategy on mortality.

Effects of Dapagliflozin on Kidney Function, Cardiovascular Events, and All-Cause Mortality According to Cause of Kidney Disease in the DAPA-CKD Trial

David C. Wheeler,[1,2] Bergur V. Stefansson,[3] Ricardo Correa-Rotter,[4] Glenn M. Chertow,[5] Tom Greene,[6] Fan Fan Hou,[7] Niels Jongs,[8] John McMurray,[9] Peter Rossing,[10,11] David Sjostrom,[3] Robert D. Toto,[12] Anna Maria Langkilde,[3] Hiddo J. L Heerspink.[1,8] DAPA-CKD Investigators *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]University College London, London, United Kingdom; [3]AstraZeneca, Gothenburg, Sweden; [4]National Medical Science and Nutrition Institute Salvador Zubirán, Mexico City, Mexico; [5]Stanford University School of Medicine, Stanford, CA; [6]University of Utah Health Sciences, Salt Lake City, UT; [7]Southern Medical University Nanfang Hospital, Guangzhou, China; [8]University of Groningen, Groningen, Netherlands; [9]University of Glasgow Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom; [10]Steno Diabetes Center, Copenhagen, Denmark; [11]University of Copenhagen, Copenhagen, Denmark; [12]UT Southwestern Medical Center, Dallas, TX.*

Background: The Dapagliflozin And Prevention of Adverse outcomes in Chronic Kidney Disease trial (DAPA-CKD) assessed the sodium glucose co-transporter 2 inhibitor dapagliflozin in patients with chronic kidney disease (CKD) with and without type 2 diabetes. This pre-specified analysis explores outcomes according to underlying cause of kidney disease.

Methods: 4304 participants with eGFR 25–75 mL/min/1.73m^2 and UACR 200–5000 mg/g were randomized to receive dapagliflozin 10mg once daily or placebo. The effects of dapagliflozin versus placebo on the primary outcome (composite of sustained decline in eGFR ≥50%, end-stage kidney disease, or death from cardiovascular [CV] or kidney causes) and secondary outcomes (CV death or heart failure hospitalizations and all-cause mortality) were assessed in patients with diabetic nephropathy (n=2510), chronic glomerulonephritides (n=695), ischemic/hypertensive CKD (n=687) and CKD due to unknown/other causes (n=412).

Results: The effect of dapagliflozin on the primary outcome (hazard ratio [HR] 0.61, 95% Confidence Interval [CI] 0.51–0.72) was consistent in patients with diabetic nephropathy (HR 0.63, 95%CI 0.51–0.78), glomerulonephritides (HR 0.43, 95%CI 0.26–0.71), ischemic/hypertensive CKD (HR 0.75, 95%CI 0.44–1.26) and CKD of other/unknown cause (HR 0.58, 95%CI 0.29–1.19; p-interaction 0.53). The reduction in CV death or heart failure hospitalizations (HR 0.71, 95%CI 0.55–0.92) was also similar across kidney disease etiologies (p-interaction 0.24) as was reduction in all-cause mortality (HR 0.69, 95%CI 0.53-0.88; p-interaction 0.55). The proportion of patients who discontinued study drug due to adverse events or experienced serious adverse events was similar across kidney disease etiologies, with no clear evidence of difference (p-interaction 0.04 and 0.14).

Conclusions: In patients with CKD, dapagliflozin reduced the risks of kidney failure, death from CV causes or heart failure hospitalizations, and all-cause mortality, regardless of underlying etiology of kidney disease in this study.

Electronic Health Record Alerts for AKI: A MultiCenter Randomized Clinical Trial

Francis P. Wilson,[1] Melissa Martin,[1] Yu Yamamoto,[1] Harold I. Feldman,[2] Jason H. Greenberg,[1] Sherry Mansour,[1] Dennis G. Moledina,[1] Paul M. Palevsky,[3] Chirag R. Parikh,[4] Michael Simonov.[1] *[1]Medicine, Yale University School of Medicine, New Haven, CT; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Pittsburgh, Pittsburgh, PA; [4]Johns Hopkins University, Baltimore, MD.*

Background: Despite its strong association with adverse clinical outcomes, acute kidney injury (AKI) is often not recognized during clinical care. It is unclear whether automated alerts for AKI imrpove clinical outcomes.

Methods: Double-blinded, multicenter, parallel, randomized, controlled trial of an electronic AKI alert versus usual care (no alert). Adult participants across 6 hospitals were electronically identified and randomized via a best practice alert build in 1:1 fashion to the two study arms. The primary outcome was a composite of AKI progression, receipt of dialysis, or death at 14 days.

Results: 6,030 patients were randomized over 22 months. The primary outcome occurred in 653 (21.4%) patients in the alert group and 622 (20.9%) in the usual care group (relative risk 1.02, 95% confidence interval [CI] 0.93 to 1.13, p=0.67). Per-hospital analysis revealed worse outcomes in the two non-teaching hospitals (N=765, 13%), where alerts were associated with a higher risk of the primary outcome of 1.49 (95% CI, 1.12 to 1.98, p=0.006). More deaths occurred at these centers (15.6% in the alert group vs. 8.6% in the usual care group, p=0.003). Certain AKI care practices were increased in the alert group but did not appear to mediate these outcomes.

Conclusions: Alerts did not reduce the risk of our primary outcome among hospitalized patients with AKI. The heterogeneity of effect across clinical centers should lead to a re-evaluation of existing AKI alerting systems.

Results from a Phase 3 Study Comparing the Efficacy and Safety of Molidustat vs. Darbepoetin Alfa in Patients Receiving Hemodialysis and Treated with Erythropoiesis-Stimulating Agents (ESAs)

Tadao Akizawa,[1] Takashi Yamada,[2] Kiyoshi Nobori,[3] Yoshimi Matsuda,[4] Yasuhiro Hayashi,[5] Takanori Hayasaki,[5] Hiroyasu Yamamoto.[6] *[1]Division of Nephrology, Showa University School of Medicine, Tokyo, Japan; [2]TA Thrombosis & Nephrology, Research & Development, Bayer Yakuhin Ltd, Osaka, Japan; [3]TA Cardio-Pulmonology/Women's/Hematology, Research & Development Japan, Bayer Yakuhin Ltd, Osaka, Japan; [4]Statistics & Data Insights, Data Sciences & Analytics, Research & Development Japan, Bayer Yakuhin Ltd, Osaka, Japan; [5]Cardiovascular and Nephrology, Medical Affairs & Pharmacovigilance, Bayer Yakuhin Ltd, Osaka, Japan; [6]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Molidustat is a novel inhibitor of hypoxia-inducible factor-prolyl hydroxylase under investigation as an alternative to ESAs for the treatment of renal anemia.

Methods: This 52-week, phase 3 randomized, active-controlled, double-blinded, double-dummy, parallel-group, multi-center study (NCT03543657) compared the efficacy and safety of molidustat with darbepoetin alfa in Japanese patients with end-stage kidney disease receiving hemodialysis and ESA treatment. The dose of oral molidustat (5–200 mg/day) or intravenous darbepoetin alfa (10–180 μg every 1 or 2 weeks) was adjusted to maintain hemoglobin (Hb) concentrations within the target range 10.0–12.0 g/dL. The primary variables were mean Hb level during evaluation period (Weeks 33–36) and its change from baseline.

Results: Of 229 patients randomized to molidustat (n=153) or darbepoetin alfa (n=76), 180 completed 52 weeks of treatment (n=115 and 65). Median treatment duration was 364 days with molidustat and 364 days with darbepoetin alfa. Baseline characteristics were generally well balanced between groups: patients' mean age was 65.7, mean BMI was 22.5 and 61% were male. Mean baseline central Hb levels were 10.77 g/dL for molidustat and 10.84 g/dL for darbepoetin alfa. The mean (95% CI) for mean Hb level during the evaluation period were within the target range for both groups: 10.63 (10.42–10.84) g/dL with molidustat and 10.77 (10.59–10.95) g/dL with darbepoetin alfa. Noninferiority of molidustat to darbepoetin alfa for the change in mean Hb level from baseline to the evaluation period was established, with a margin of 1.0 g/dL (least square mean difference [95% CI] for molidustat vs darbepoetin alfa: -0.13 (-0.46–0.19] g/dL). There were no apparent between-group differences in incidence of treatment-emergent adverse events (TEAEs) (molidustat, 95.4%; darbepoetin alfa, 94.7%), serious TEAEs (24.2%; 18.4%), TEAEs with an outcome of death (1.3%; 2.6%) or AEs of special interest (4.6%; 3.9%).

Conclusions: In Japanese patients receiving hemodialysis and previously treated with ESAs, molidustat was noninferior to darbepoetin alfa for maintaining Hb levels, and no new safety concerns were observed.

Continuous Low-Dose Iron Sucrose or Periodic High-Dose Ferric Carboxymaltose Therapy in Hemodialysis Patients (COPEFER): A Randomized Controlled Noninferiority Trial

Bernhard O. Bielesz,[1] Matthias Lorenz,[3] Rossella Monteforte,[1] Thomas Prikoszovich,[3] Michaela Gabriel,[3] Michael Wolzt,[4] Andreas Gleiss,[2] Gere Sunder-Plassmann.[1] *[1]Nephrology and Dialysis, Medizinische Universitat Wien Universitatsklinik fur Innere Medizin III, Wien, Austria; [2]Center for Medical Statistics, Informatics, and Intelligent Systems, Medizinische Universitat Wien, Wien, Austria; [3]Vienna Dialysis Center, Vienna, Austria, Wien, Austria; [4]Section for Medical Statistics, and Department of Clinical Pharmacology, Medical University of Vienna, Austria, Wien, Austria.*

Background: Intravenous iron therapy is a cornerstone in the treatment of anemia in chronic hemodialysis patients. However, optimal dosing and frequency of administration is unknown and varies widely between centers. We compared the impact of equal cumulative doses of ferric carboxymaltose (FCM), which is not yet approved for use in hemodialysis patients, and iron sucrose (IS) administered as either a high dose bolus or low dose maintenance iron dosing strategy on hemoglobin concentration, iron balance, use of erythropoiesis stimulating agents (ESA), and adverse events in prevalent chronic hemodialysis patients.

Methods: We performed an open-label randomized controlled non-inferiority trial in two centers over 40 weeks (n=142). A total cumulative dose of two grams of iron was administered. The IS arm received 100 mg every two weeks, the FCM arm 500 mg every 10 weeks. Hemoglobin, iron markers, ESA use, C-reactive protein (CRP), phosphate, and liver enzymes were assessed. Primary end-point was the difference in hemoglobin at week 40 from baseline. A non-inferiority margin of -0.8 g/dl between both groups was pre-specified. Secondary end-points were differences in ferritin, transferrin saturation (TSAT), and ESA use.

Results: 108 patients completed the study. By 40 weeks non-inferiority criterion was not met as hemoglobin differed by -0.47 g/dl (95% CI: -0.95 to 0.01) in the FCM compared to the IS arm. In intention-to-treat analysis hemoglobin was significantly lower in the FCM arm compared to the IS arm (-0.46 g/dl (95% CI -0.92 to -0.01). At week 40, ferritin was 29.7% (95% CI 6.6 to 46.1) and TSAT was 27.7% (95% CI 16.3 to 36.6) lower in the FCM compared to the IS arm. ESA dosing, CRP, phosphate, and liver function parameters did not differ between groups. Adverse events that caused intermittent drug discontinuations and infections occurred more often in the IS arm.

Conclusions: IS administered more frequently at lower doses maintained hemoglobin and iron stores more effectively than FCM administered less frequently but at higher doses. However, FCM appeared safe in dialysis patients where we observed less infections compared to the IS group.

Associations Between Achieved Hemoglobin and Cardiovascular Outcomes in the Pooled Phase 3 Roxadustat Studies of Non-Dialysis-Dependent Patients with Anemia of CKD

Steven Fishbane,[1] Robert Provenzano,[2] Pablo E. Pergola,[3] Lynda Szczech,[4] Robert Leong,[4] Khalil G. Saikali,[4] Ming Zhong,[4] Tyson T. Lee,[4] Dustin J. Little,[5] Lars Frison,[6] John Houghton,[5] Kin-Hung P. Yu.[4] *[1]Northwell Health, Great Neck, NY; [2]Wayne State University, Detroit, MI; [3]Renal Associates, PA, San Antonio, TX; [4]FibroGen Inc, San Francisco, CA; [5]AstraZeneca, Gaithersburg, MD; [6]AstraZeneca, Molndal, Sweden.*

Background: Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, promotes erythropoiesis and increases bioavailability of iron. In phase 3 studies, roxadustat-treated patients achieved and maintained hemoglobin (Hb) values of 11±1 g/dL. We examined the associations between achieved Hb levels and cardiovascular outcomes in non-dialysis-dependent (NDD) patients with anemia of chronic kidney disease (CKD).

Methods: We analyzed pooled data from 3 pivotal, phase 3 studies of patients with anemia of NDD-CKD who received roxadustat. Incidence rates of adjudicated MACE (all-cause mortality, MI, and stroke) and MACE+ (MACE plus heart failure and unstable angina requiring hospitalization) were evaluated based on 1) Hb level immediately before the event and 2) maximum Hb level in the first 12 treatment weeks.

Results: Overall, 2391 patients were randomized to roxadustat. The mean (SD) baseline Hb of 9.1 (0.74) g/dL increased to 10.95 (0.76) g/dL over weeks 28-52. The MACE and MACE+ rates were highest when Hb was < 8 g/dl decreasing as Hb increased to 11-12 g/dL and ≥12 g/dL (Table).

Conclusions: In the NDD-CKD population, roxadustat corrected anemia and maintained Hb to 11±1 g/dL during weeks 28-52. MACE and MACE+ incidence rates were lowest when achieved Hb levels were ≥11g/dL.

Funding: Commercial Support - Fibrogen, Inc.

MACE and MACE+ rates in roxadustat-treated patients with anemia of NDD-CKD by Hb achieved

Parameter		Maximum Hemoglobin

Abstract Withdrawn

PO2628

A Prospective, Double-Blind, Randomized, Placebo-Controlled Interventional Study to Evaluate the Safety and Efficacy of Enzobiotics in Pre-Dialysis CKD Patients

Anita Saxena,[1] Chakko K. Jacob,[2] Sanjay Sreenivasa,[6] Ilangovan Veerappan,[4] Amol R. Mahaldar,[3] Amit Gupta,[1] Anantha subramani Rajagopal.[5] *[1]Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India; [2]Nephrology, Baptiste hospital, Bangalore, India; [3]Nephrology, Vision and Manipal Hospitals, GOA, India; [4]Nephrology, KG Hospital, Coimbatore, India; [5]Statistics, Indian Statistical Institute Delhi Centre, Coimbatore, India; [6]Nephrology, Saptagiri Institute of Medical science, Bangalore, India.*

Background: Synbiotics and proteolytic enzymes supplemented in CKD prevent formation of uremic toxins (UT) generated by undigested protein. Aim : Affect of Enzobiotics in reducing generation of P-Cresols and Indoxylsulfhate and quality of life in pre dialysis patients.

Methods: Double blind, randomized, placebo controlled multicentric clinical trial **CTRI/2019/01/017070** conducted over 90 Days. Eighty CKD stages 3-5 ND subjects from 5 centers divided into two groups of 40 each: group A received 1 Enzobiotic capsule TID, Group B 1 placebo capsules TID, for three months 5 minutes before food. Blood samples taken on visits 1 and 4 to measure *serum creatinine,* p- cresols, indoxyl sulphate (IS), **platelet count (PC) hsCRP** etc.

Results: Placebo increased p-cresol by 21% while drug reduced by 23%. Enzobiotic reduced indoxyl sulfate by 500 µg/ml (from 17200 to below 16700) with reductiion in creatinine. The potential patients above p-cresol level of 20 mg/lt between drug and placebo after 90 days were found to be 53% for placebo against 33% for drug. If testing is not available, Indoxyl sulfate and p-Cresol can be predicted by 2 equations (applied for patency) SF36 standard questionnaire revealed improvement in quality of life of treatment group. A**dversity ratio reduced significantly from 0.3362 to 0.1736 P-Value 0.000 over 90 days. Daily activity limitation, emotional problems and general health reduced adversity from** 60% to 47% (5.6%) **50% to 30%, 49% to 19% respectively.**

Conclusions: Enzobiotics improve make gut microbiome favourable, can delay dialysis in CKD patients by reducing uremic toxins, CRP, thrombocytopenia and improve cardiac performance, lipid profile, and quality of life.

Effect of Ertugliflozin on Initial eGFR Decline and Chronic Slope: Analyses from the VERTIS CV Trial

David Cherney,[1] Bernard Charbonnel,[2] Francesco Cosentino,[3] Richard E. Pratley,[4] Samuel Dagogo-Jack,[5] Weichung J. Shih,[6,7] Darren K. Mcguire,[8,9] Robert Frederich,[10] Mario Maldonado,[11] Jie Liu,[12] Annpey Pong,[12] Chih-Chin Liu,[12] Christopher P. Cannon.[13] *[1]University of Toronto, Toronto, ON, Canada; [2]Universite de Nantes, Nantes, France; [3]Karolinska Institute & Karolinska University Hospital Solna, Stockholm, Sweden; [4]AdventHealth Translational Research Institute, Orlando, FL; [5]University of Tennessee Health Science Center, Memphis, TN; [6]Rutgers School of Public Health, Piscataway, NJ; [7]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; [8]University of Texas Southwestern Medical Center, Dallas, TX; [9]Parkland Health and Hospital System, Dallas, TX; [10]Pfizer Inc., Collegeville, PA; [11]MSD Limited, London, United Kingdom; [12]Merck & Co., Inc., Kenilworth, NJ; [13]Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA.*

Background: SGLT2 inhibitors induce an initial reversible eGFR dip, based on natriuresis-induced reductions in glomerular pressure, with a return toward baseline over time in adults with T2DM. Preservation of the chronic eGFR slope by ≥0.75 mL/min/1.73m^2/year with treatment predicts protection against CKD progression. We aimed to assess the impact of initial eGFR dip and chronic eGFR slope in the VERTIS CV trial (NCT01986881).

Methods: Patients with T2DM and ASCVD were randomized (1:1:1) to ertugliflozin 5 mg, 15 mg or placebo. Analyses assessed pooled ertugliflozin (n=5499) and placebo (n=2747). Patients were divided into 3 tertiles based on initial eGFR change at Week 6 (increase, small change or decrease). Changes in eGFR, hematocrit and uric acid were assessed at Weeks 6, 18, 52 and 156. Chronic eGFR slope/year by random coefficient models was also assessed.

Results: Glucosuria-associated effects (ie, uric acid) were larger in the eGFR increase tertile; natriuresis-associated effects (ie, hematocrit) were larger in the eGFR decrease tertile (Fig A, B). The ertugliflozin eGFR decrease tertile had the smallest decline in chronic eGFR slope (Fig C, D). Chronic slopes were similar across the placebo group tertiles and the rate of decline uniformly more rapid (Fig D). Mean placebo-adjusted effect of ertugliflozin on chronic eGFR slope (Weeks 6–156 [95% CI]) was 1.19 (0.95, 1.42) mL/min/1.73 m^2/year (Fig E) and >0.75 mL/min/1.73 m^2/year in all subgroups.

Conclusions: The initial eGFR dip may influence several clinical effects of ertugliflozin. Ertugliflozin has favorable effects on eGFR slope in patients with T2DM and ASCVD.

Canagliflozin Across the Spectrum of Kidney Function and Albuminuria: Integrated Data from CANVAS and CREDENCE

Brendon L. Neuen,[1] Jie Yu,[1] Qiang Li,[1] Vlado Perkovic,[2,1] Clare G. Arnott,[1] Bruce Neal,[1] Hiddo J. L Heerspink,[5] Rajiv Agarwal,[4] George L. Bakris,[3] Christopher P. Cannon,[11] Dick de Zeeuw,[5] David M. Charytan,[6] Adeera Levin,[7] Gian Luca Di Tanna,[1] David R. Matthews,[12] Carol A. Pollock,[8] David C. Wheeler,[9] Kenneth W. Mahaffey,[10] Meg J. Jardine.[1] *[1]The George Institute for Global Health, Newtown, NSW, Australia; [2]UNSW Sydney, Sydney, NSW, Australia; [3]University of Chicago, Chicago, IL; [4]Indiana University School of Medicine, Indianapolis, IN; [5]Rijksuniversiteit Groningen, Groningen, Netherlands; [6]New York University School of Medicine, New York, NY; [7]The University of British Columbia, Vancouver, BC, Canada; [8]The University of Sydney, Sydney, NSW, Australia; [9]University College London, London, United Kingdom; [10]Stanford University School of Medicine, Stanford, CA; [11]Harvard University, Cambridge, MA; [12]University of Oxford, Oxford, United Kingdom.*

Background: People with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD) are at very high risk of cardiovascular events and kidney failure. While canagliflozin reduces the risk of these outcomes, the consistency of this effect across all levels of estimated glomerular filtration rate (eGFR) and urinary albumin:creatinine ratio (UACR) remains uncertain.

Methods: We pooled individual participant data from the CANVAS Program (n=10,142) and CREDENCE trial (n=4,401) to assess the effect of canagliflozin on a primary composite outcome of myocardial infarction, stroke, heart failure, doubling of serum creatinine, kidney failure, cardiovascular or kidney death. The effect of canagliflozin was assessed using Cox regression models with treatment by subgroup interaction terms stratified by trial.

Results: 2,051/14,543 (14%) participants experienced the primary outcome over a median follow-up of 2.5 years. Overall, canagliflozin reduced the risk of the primary outcome (HR 0.77, 95% 0.70-0.84; Figure). The magnitude of relative benefit increased as eGFR declined (P-trend=0.0067; Figure) with some evidence of greater relative benefit at higher UACR (P-trend=0.057; Figure). Lower eGFR and higher UACR levels were independently associated with cardio-renal risk. Consequently, absolute risk reductions increased more than 5-fold across lower eGFR categories and more than 9-fold across higher UACR categories (Figure).

Conclusions: Canagliflozin reduces the risk of cardio-renal outcomes in people with T2DM; the magnitude of relative and absolute protection varies by severity of CKD.

Funding: Commercial Support - Janssen funded the CANVAS and CREDENCE trials. This analysis was not specifically funded and conducted independent of the trial sponsors.

Ferric Pyrophosphate Citrate Injection: No Clinical Drug Interaction with Unfractionated Heparin in Hemodialysis Patients

Raymond D. Pratt. *R&D, Rockwell Medical Inc, Wixom, MI.*

Background: Ferric pyrophosphate citrate (FPC) is a unique iron (Fe) replacement product indicated to maintain Fe balance and hemoglobin (Hgb) concentration in adult hemodialysis patients (HD). FPC can be administered via the dialysate (D) or as an intravenous (IV) preparation (Triferic® AVNU injection 6.75 mg Fe/4.5 mL for IV administration). A clinical study of the effects of unfractionated heparin (UFH) mixed with FPC was conducted.

Methods: An open-label, randomized 3-period, crossover trial, investigated the effects of FPC mixed with UFH compared with delivery of UFH and FPC by separate routes in 12 HD patients. The primary endpoint was the Anti Xa activity of UFH + FPC compared to UFH alone and UFH and FPC administered IV separately. Secondary endpoints were the activated prothrombin time (aPTT), thrombin time (TT) and serum iron profile (sFe). Effects were analyzed using the bioequivalence parameter of area under the concentration-time curve (AUC_{0-t}). Safety was assessed by recording adverse events (AE) and a visual dialyzer clotting scale (VCS).

Results: Coadministration of FPC+UFH pre dialyzer, met bioequivalence criteria for anti Xa activity of UFH compared to UFH alone or UFH and FPC separately. [Figure 1]. The FPC +UFH mixture had no impact on the AUC_{0-t} values of PTT or TT. The concentration-time profiles for sFe and TSAT were comparable. FPC was well tolerated with no reported adverse events. The VCS showed no detectable clotting of the dialyzer with any combination of UFH and FPC.

Conclusions: The results of this study demonstrates no clinically significant drug-drug interaction between FPC and UFH on the anticoagulation effect as assessed by anti Xa activity, aPTT, and TT or on the ability of FPC to deliver iron when these agents are co-administered as a single admixture. All treatments were well tolerated. These results support coadministration of IV FPC and UFH as an admixture to HD patients.

Funding: Commercial Support - Rockwell Medical Inc.

Underline represents presenting author/disclosure.

A Pilot Trial of Fistula vs. Graft Access Strategy in Older Adults on Hemodialysis

Mariana Murea, Todd W. Robinson, Shahriar Moossavi, Gregory B. Russell. *Wake Forest School of Medicine, Winston-Salem, NC.*

Background: It is unclear whether surgical placement of an AVF confers significant clinical benefits over an AVG in older adults with ESKD.

Methods: In this pilot randomized, parallel-group, open-label trial, patients ≥65 years old with ESKD, no prior AV access, on HD via a tunneled central venous catheter (CVC), referred for AV access placement by their nephrologist, were randomly assigned (1:1) to surgical placement of AVG or AVF.

Results: Of 122 older adults on HD with no prior AV access, 24% expired before or were too sick for surgery referral. Of 46 eligible patients, 36 consented and randomized to AVG (n=18) and AVF (n=18) placement; 13 (72%) and 16 (89%) underwent index AV access placement, respectively (Figure 1). At median follow-up of 321.0 days, primary AV access failure was noted in 31% in each group. Successful cannulation occurred in 8 (62%) in AVG and 8 (50%) in AVF group; median time to successful cannulation was 75.0 and 113.5 days, respectively. Endovascular procedures were recorded in 38% and 44%, and surgical re-interventions in 23% and 25% (Table 1). AV access infection was seen in 23% and 13% patients, respectively.

Conclusions: Based on these limited results, there is little reason to favor either AVF or AVG in this population until results from a larger randomized clinical trial become available.

Health Economic Evaluation of the Theranova 400 Dialyzer Among Hemodialysis Patients in the United States: Results from a Randomized-Controlled Trial

Michael J. Blackowicz,[2] Luke Falzon,[1] Mengqi Xiao,[2] Angelito A. Bernardo,[1] Ha Tran.[2] *[1]Worldwide Medical, Baxter Healthcare Corp Malta, San Gwann, Malta; [2]Worldwide Medical, Baxter International Inc, Deerfield, IL.*

Background: In a 24-week, open-label RCT, expanded hemodialysis (HDx) via the Theranova 400 medium cut-off dialyzer had superior reduction ratios of large middle molecule uremic toxins such as κ and λ free light chains, complement factor D, TNF-α, and β2-microglobulin, compared to a high-flux dialyzer (Elisio-17H) in the US (Weiner et al. 2020). The purpose of this study is to perform a cost-consequence analysis for comparison of healthcare costs between HDx and conventional high-flux hemodialysis (HD).

Methods: Hemodialysis patients were randomized to receive treatment with either Theranova 400 or Elisio-17H over 24 weeks in the US. Hospitalization rate and average length of stay were calculated directly from trial data. Frequency of erythropoiesis stimulating agent (ESA) and iron use were calculated at baseline and carried forward over a 1-year time horizon. ESA and iron doses were calculated as the average of median total monthly doses. Unit costs of medication were obtained from the Centers for Medicare and Medicaid Service (CMS) and hospital costs from the Kaiser Family Foundation. Both deterministic (±20%) and probabilistic (95% confidence intervals) sensitivity analyses were conducted to account for variability in model inputs.

Results: There were 86 patients (389 patient-months) in the Theranova group and 85 patients (366 patient-months) in the Elisio group. All-cause hospitalization rate was 43% lower with Theranova compared to Elisio (RR=0.57; p=0.069). Frequency of ESA use was 46.5% in the Theranova group compared to 55.8% in the Elisio group, but doses were similar between the two groups. Both frequency and dose of iron were similar between the two groups. Average annual cost of hospitalization was $3,925 lower with Theranova compared to Elisio. Annual cost of ESAs and iron were similar between the two groups, although the cost of ESAs was $400 lower in the Theranova group. Compared to Elisio, the average annual cost of Theranova was $4,340 lower per patient. Hospitalization rate and length of stay were the main drivers of cost in the model.

Conclusions: This study provides evidence that, in addition to Theranova's superior removal of large middle molecules, Theranova may also be a cost-saving therapy driven largely by reduction in patient hospitalization events.

PO2634

Intermittent Pneumatic Compression Promotes Presurgery Cephalic Vein Dilation: Preliminary FACT Trial Results

Tej M. Singh. *Vascular Surgery, El Camino Hospital, Mountain View, CA.*

Background: Arteriovenous fistulas (AVF) are the preferred for hemodialysis access with suitable (2.0-2.5 mm) veins. AVF maturation has been poor globally and often leads to increased catheter contact time and costs. Intermittent compression of upper arm veins may aid in forearm vein dilation pre-surgery to assist in AVF placement and maturation with size expectations and effectiveness.

Methods: This is was a prospective, IRB approved trial. A novel intermittent pneumatic compression device [Fist Assist® (FA)] was applied to upper arms below the shoulder to allow cyclic compression of 60 mm Hg four hours daily for 90 days. Sixteen (n=16) Stage 4 chronic renal failure (CRF) patients were in the study arm to test arm cephalic vein dilation. Vein size was measured and recorded at baseline and after 90 days by duplex measurement of the cephalic vein with a tourniquet. Clinical results: vein dilation at particular locations was recorded and tested for significance using a paired-difference t-test.

Underline represents presenting author/disclosure.

Results: Sixteen (n=16) mostly African American patients were involved in the first interim evaluation of the device in a USA FACT trial. All patients were in compliance with the study and followed the study protocol. No major complications or adverse effects were noted in any patient except one non-device related rash. Differences were noted with the measurements done with a cuff in the vein sizes in the forearm (FA) and upper arm (UA). Both were significant. **FA3M : 3-Month- Vein diameter (AP), with cuff, at 5 cm from radial bone UA3M : 3-Month- Vein diameter (AP), with cuff, at 1 cm above elbow UA : Enrollment-Vein diameter (AP), with cuff, at 1 cm above elbow FA : Enrollment-Vein diameter (AP), with cuff, at 5 cm from radial bone Difference between mean of (UA3M-UA) : t = 1.74, p-value = 0.05 Difference between mean of (FA3m-FA) : t = 1.72, p-value = 0.04 For Clinical Effectiveness:** FA: 18% ≥ 2.5 mm and 33% reached 2.0 mm or greater UA: 44% ≥2.5mm and 20% reached 3.0 mm or greater

Conclusions: Early application of a novel, intermittent pneumatic compression device may be successful in preparing forearm veins in Stage 4 CRF patients. The early study results of the FACT trial show statistical significance in vein size improvement, distensibility, and clinical effectiveness to reach predetermined size goals.

A Randomized Controlled Trial of Dialysate Sodium in Hospitalized Hemodialysis Patients

Finnian R. McCausland,[1,2] Katherine M. Scovner,[1,2] Katherine Curtis,[1] Zoé A. Kibbelaar,[2] Samuel Short,[3] Anika T. Singh,[1,2] Simon Correa,[1,2] Sushrut S. Waikar.[4] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]University of Vermont College of Medicine, Burlington, VT; [4]Boston University, Boston, MA.*

Background: Several large dialysis organizations have lowered the dialysate sodium concentration (DNa) in an effort to ameliorate hypervolemia. The implications of lower DNa on intra-dialytic hypotension (IDH) during hospitalizations of hemodialysis (HD) patients is unclear.

Methods: In this double-blind single center randomized controlled trial, hospitalized maintenance HD patients were randomized to receive higher (142 mmol/L) or lower (138 mmol/L) DNa for up to six sessions. Blood pressure (BP) was measured in a standardized fashion pre-HD, post-HD and every 15 minutes during HD. The primary endpoints were: 1) the average decline in systolic BP; and 2) the proportion of total sessions complicated by IDH (defined as a drop of ≥20 mmHg from the pre-HD SBP).

Results: A total of 139 patients completed the trial, contributing 311 study visits (Table 1). There were no significant differences in the average SBP decline between the higher and lower DNa groups (23 ±16 vs. 26 ±16 mmHg; P=0.31). The proportion of total sessions complicated by IDH was similar in the higher DNa group compared with the lower DNa group (54% vs. 59%; OR 0.72; 95%CI 0.36 to 1.44; P=0.35). In post-hoc analyses adjusting for imbalances in baseline characteristics, higher DNa was associated with an 8 mmHg (95%CI 2 to 14 mmHg) lesser decline in SBP, compared with lower DNa.

Conclusions: In this RCT for hospitalized maintenance HD patients, we found no difference in the absolute SBP decline between those who received higher versus lower DNa. Larger multi-center studies to confirm these findings are warranted.

Funding: NIDDK Support

Table 1

Characteristic	Lower DNa 138 mmol/L (n=69)	Higher DNa 142 mmol/L (n=70)
Age (yrs)	61 ± 14	58 ± 15
Male (n, %)	43 (62%)	36 (51%)
Black (n, %)	21 (30%)	25 (36%)
Diabetes (n, %)	36 (52%)	39 (56%)
Heart Failure (n, %)	28 (43%)	21 (32%)
Catheter Access (n, %)	16 (23%)	14 (20%)
Pre-HD SBP (mmHg)	135 ± 24	139 ± 24
Pre-HD Weight (kg)	80.4 ± 23.2	73.3 ± 21.6
Serum Sodium (mmol/L)	137 ± 4	137 ± 3
Blood Urea Nitrogen (mg/dL)	49 ± 19	48 ± 17
Hemoglobin (g/dL)	9.6 ± 1.5	9.5 ± 1.5

PO2636

Efficacy and Safety of Rapid Intermittent Correction vs. Slow Continuous Correction with Hypertonic Saline in Patients with Symptomatic Hyponatremia: A Randomized Clinical Trial (SALSA Trial)

Seon Ha Baek,[1] Sejoong Kim.[2] *[1]Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: Few high-quality evidences have clarified whether hypertonic saline is best administered as slow continuous infusion therapy (SCI) or rapid intermittent bolus therapy (RIB) for symptomatic severe hyponatremia.

Methods: Objective To compare the efficacy and safety of RIB and SCI with hypertonic saline in patients with symptomatic severe hyponatremia. **Design** Prospective, investigator-initiated, multi center, open-label, randomized controlled study from 24 August 2016 until 21 August 2019 **Setting** Emergency rooms and wards of three general hospitals in South Korea **Participants** 178 patients aged >18 years with symptoms and glucose-corrected serum sodium (sNa) ≤125 mmol/L were included. **Interventions** Either RIB or SCI of 3% hypertonic saline for 24-48 hours stratified by the severity of clinical symptoms. **Main outcome and Measures** The primary outcome was overcorrection at any given period, defined as follows: increase in the sNa level by >12/18 mmol/L within 24/48 hours. Secondary outcomes included efficacy and safety of the treatment approaches. SNa concentrations were measured at every 6 hours for 2 days.

Results: Patients (mean age 73.1 years, 45% male, mean sNa concentrations 118.2 ± 5.0 mmol/L) were randomly assigned to RIB group (n=87) or SCI group (n=91). Overcorrection occurred in 17.2% and 24.2% in RIB and SCI groups, respectively (absolute risk difference, -6.9% [95% CI -18.8% to 4.9%]). RIB group showed lower incidence of re-lowering treatment than SCI group (41.4% vs 57.1%; absolute risk difference, -15.8% [95% CI -30.3% to -1.3%]; number needed to treat [NNT]=6.3). Groups did not differ in terms of efficacy in increasing sNa concentrations or improving symptoms but RIB showed better efficacy in achieving target correction rate within 1 hour (32.2% vs 17.6%, absolute risk difference 14.6% [95% CI 2% to 27.2%]; NNT=6.8).

Conclusions: Both RIB and SIC therapies of hypertonic saline for treating hyponatremic encephalopathy were effective and safe, with no difference in the overcorrection risk. However, RIB had a lower incidence of therapeutic re-lowering treatment and tended to have a better efficacy in achieving sNa within 1 hour than SCI. RIB could be suggested as the preferred treatment of symptomatic hyponatremia, consistent with the current consensus guidelines.

Moochhala,[13] Martin Coenen,[14] Eva Simkova,[15] Sander F. Garrelfs,[2] David J. Sas,[16] Kristin Meliambro,[1] Taylor Ngo,[17] Kenji Fujita,[17] John M. Gansner,[17] Tracy McGregor,[17] John C. Lieske.[16] *[1]The Icahn School of Medicine at Mount Sinai, New York, NY; [2]Department of Pediatric Nephrology, Emma Kinderziekenhuis Amsterdam UMC, Amsterdam, Netherlands; [3]Division of Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel; [4]Department of Nephrology, Birmingham Women's and Children's Hospital, Birmingham, United Kingdom; [5]Jacksonville Center for Clinical Research, Jacksonville, FL; [6]eStudySite, San Diego, CA; [7]Hospices Civils de Lyon, Lyon, France; [8]Hôpital Robert-Debré, Paris, France; [9]Pediatric Nephrology Unit, Galilee Medical Center, Nahariya, Israel; [10]Department of Pediatric Nephrology, Great Ormond Street Hospital, London, United Kingdom; [11]Bern University Hospital, University of Bern, Bern, Switzerland; [12]Pediatric Nephrology Institute, Rambam Health Care Campus, Haifa, Israel; [13]Royal Free Hospital, London, United Kingdom; [14]University Hospital Bonn, Bonn, Germany; [15]Al Jalila Children's Hospital, Dubai, United Arab Emirates; [16]Mayo Clinic Minnesota, Rochester, MN; [17]Alnylam Pharmaceuticals, Cambridge, MA.*

Background: ILLUMINATE-A is a Phase 3 trial of lumasiran, an investigational RNAi therapeutic that reduces hepatic oxalate production.

Methods: The trial enrolled 39 patients ≥6 years with primary hyperoxaluria type 1 (PH1) and eGFR≥30 mL/min/1.73m^2. The trial had a 6-month (M) double-blind, placebo-controlled period (DBP) and an extension period (EP).

Results: During the DBP, the least square mean treatment difference in 24hr urinary oxalate (UOx) excretion for lumasiran compared to placebo was –53.5% ($p=1.7\times10^{-14}$), and 84% of lumasiran-treated patients achieved near-normalization or normalization of 24hr UOx excretion at M6 (vs 0% placebo-treated patients). In the EP, the 13 patients initially randomized to placebo crossed over to lumasiran (P/L), demonstrating a similar time course and magnitude of UOx reduction. After 6M of treatment, their 24hr UOx mean percent reduction was 57.3% and a comparable proportion (77%) achieved near-normalization or normalization of 24hr UOx excretion. In patients initially randomized to lumasiran (L/L), the reduction in 24hr UOx was sustained through M12. The calculated rate (per 100 person-days) of renal stone events (RSE) in the L/L group decreased from a reported rate of 0.87 (95% CI: 0.70, 1.08) over the 12M prior to consent, to observed rates of 0.30 (95% CI: 0.17, 0.51) for the 6M DBP, to 0.23 (95% CI: 0.13, 0.43) with an additional 6M of lumasiran. In the P/L group, RSE rates remained stable from a reported rate of 0.15 (95% CI: 0.07, 0.31) over the 12M prior to consent, to 0.18 (95% CI: 0.07, 0.48) during the 6M DBP, followed by a decrease to 0.05 (95% CI: 0.01, 0.32) during the first 6M of lumasiran treatment. Consistent with the DBP, the most common adverse events related to lumasiran in the EP were mild, transient injection site reactions.

Conclusions: The UOx reduction observed in the DBP was replicated by placebo crossover patients, confirming the robustness of the result. Lower RSE rates after 6-12M of treatment with lumasiran are encouraging.

Rituximab vs. Cyclophosphamide in the Treatment of Membranous Nephropathy: The RI-CYCLO Trial

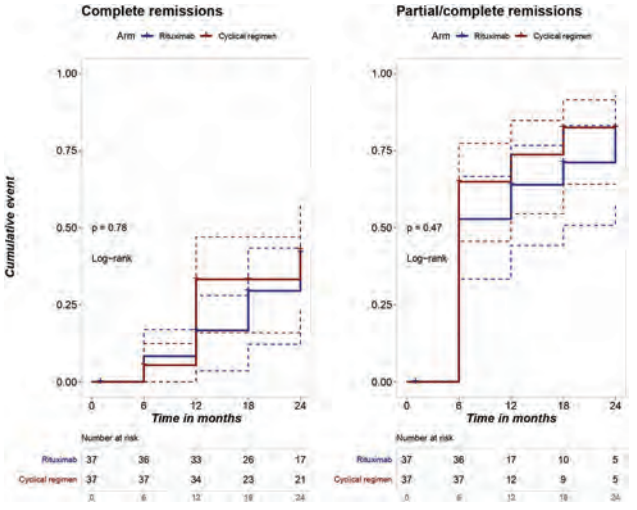
Elisa Delbarba,[1] Domenico Santoro,[2] Loreto Gesualdo,[7] Antonello Pani,[6] Federico Alberici,[4] Gian Marco Ghiggeri,[3] Pietro Ravani,[5] Francesco Scolari.[4]
[1]ASST Spedali Civili di Brescia, Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Lombardia, IT, public/health, Brescia, Italy; [2]University of Messina, Universita degli Studi di Messina, Messina, Sicilia, IT, academic, Messina, Italy; [3]Istituto Giannina Gaslini, Genova, Italy; [4]Universita degli Studi di Brescia, Brescia, Italy; [5]University of Calgary, Calgary, AB, Canada; [6]Azienda Ospedaliera Brotzu, Cagliari, Italy; [7]Azienda Ospedale Policlinico, Bari, Italy.

Background: Guidelines for membranous nephropathy (MN) management recommend cyclical corticosteroid-cyclophosphamide regimen (CYC) in patients with heavy proteinuria. Rituximab (RTX) may be a viable alternative, but head-to-head comparison is lacking.

Methods: Aim of this pilot RCT was to estimate the effects of RTX vs CYC regimen in MN, while assessing the feasibility of a larger trial. After a run-in of at least 3 months, patients with nephrotic syndrome were randomized to receive RTX (1g two weeks apart) or CYC. Complete remission (CR) was defined as proteinuria ≤0.3 g/day, partial remission (PR) as a reduction of proteinuria >50% and an absolute value of 0.3-3.5 g/day. Primary outcome was CR at 12 months; secondary outcomes included CR+PR at 12 and 24 months.

Results: 116 pts were screened, 74 randomized. Baseline median serum albumin was 2 g/dL and proteinuria 6 g/day in both arms. At 12 months, 6/37 pts (16%) in the RTX arm and 12/37 (32%) in the CYC arm had CR (OR according to "intention to treat_ ITT" analysis 0.4, 95% CI, 0.13-1.23, OR "according to per protocol_PP"0.28, 95% CI, 0.08-0.95), 23/37 (62%) in the RTX arm and 27/37 (73%) in the cyclical regimen arm had a CR+PR (OR ITT analysis 0.61, 95% CI 0.23-1.63, OR PP 1.11, 95% CI 0.42-2.98). Probabilities of CR and CR+PR at 24 months were 0.42 (CI 0.26-0.62) and 0.83 (CI 0.65-0.95) in the RTX arm and 0.43 (0.28-0.61) and 0.82 (0.68-0.93) in the CYC arm. Serious adverse events occurred in 7 and 5 pts, in the RTX and CYC arm, respectively.

Conclusions: Although the probability of CR was lower in the RTX arm at 12 months, the probability of CR at 24 months and of CR+PR at 12 and 24 months was similar in the two groups. No difference in side effects was found. While the efficacy of RTX and CYC in MN appears to be similar, a larger trial adequately powered would be difficult to perform.



PO2639

The Immunoglobulin G Degrading Enzyme Imlifidase for the Treatment of Anti-GBM Disease: The GOOD-IDES 01 Trial

Marten Segelmark,[1,2] Fredrik Uhlin,[2] Elisabeth Sonesson.[3] The GOOD-IDES Study Team
[1]Clinical Sciences, Lunds Universitet, Lund, Sweden; [2]Medical and Health Sciences, Linkopings universitet, Linkoping, Sweden; [3]Hansa Biopharma, Lund, Sweden.

Background: Anti-GBM disease is an ultra-rare small vessel vasculitis with a yearly incidence below 2 per million. Most cases present with rapidly progressive glomerulonephritis and despite aggressive treatment with plasma exchange and cyclophosphamide renal survival is poor, at least for those presenting with advanced kidney injury. Imlifidase has been shown to cause depletion of circulating and kidney bound anti-GBM within a few hours, but it is not known if this leads to an improved outcome.

Methods: We conducted an international multi-center one-arm open-label study giving a single dose of 0.25mg/kg of imlifidase (non-proprietary name for IdeS = Immunoglobulin G Degrading Enzyme of *Streptococcus pyogenes*) on top of standard of care (ClinicalTrials.gov: NCT03157037). Main inclusion criteria were eGFR <15 ml/min/1.73m^2 and circulating anti-GBM antibodies. Main exclusion criteria were moderate or severe lung hemorrhage, dialysis dependency > 5 days and/or oliguria >48 hours. The primary outcome was dialysis free survival at 6 months.

Results: At 17 tertiary referral hospitals in 5 European countries 15 patients (6 women) were recruited between June 2017 and January 2020. Their median age was 60 years (range 19-77) and 5 were double positive for anti-GBM and ANCA. At inclusion 10 patients were dialysis dependent including 5 that were oliguric/anuric; the remaining 5 patients had eGFR of 7-14 ml/min. 6h hours after imflidase no patient had anti-GBM above the reference range. Return of antibodies prompting plasma exchange was seen in 10 patient 4 to 22 days after imlifidase (median 7 days), and they received a median of 8 session (range 2-17). At six months 10 patients were dialysis independent (median eGFR 27 ml/min, range 16-67), one was dead and 4 had developed ESRD. A favorable response was seen also in some patients that were anuric on inclusion and in some with 100% crescents. The safety profile was good; there were 7 serious adverse events (SAEs) reported but no serious unexpected suspected adverse reaction (SUSAR).

Conclusions: Imflidase leads to rapid clearance of anti-GBM which seems to widen the window of opportunity for treatment thereby increasing the chance of renal survival in difficult to treat patients with anti-GBM disease.

Background: Sialic acid residues provide anionic charges to proteins, including those of the glomerular filtration barrier. Lectin analysis of kidney biopsies showed glomerular hyposialylation in nephrotic diseases, this may contribute to podocyte dysfunction and proteinuria. We showed in nephrotic mouse models that oral ManNAc, an uncharged precursor of sialic acid, normalized glomerular sialylation and markedly decreased proteinuria. ManNAc is also being studied to treat the rare hyposialylation disorder *GNE* myopathy (NCT04231266); it could be repurposed for patients with glomerular hyposialylation.

Methods: Phase 1 Results: A phase 1 study (NCT02639260; IND 125,192) of ManNAc in 7 nephrotic subjects showed that oral ManNAc was safe and well-tolerated. Plasma free sialic acid levels peaked ~10h after ManNAc dosing, remained elevated beyond 48h, and continued to increase during twice daily dosing, particularly in subjects with low eGFR. No adverse events occurred with increased plasma free sialic acid levels. Most subjects receiving ManNAc twice daily showed a 26-54% reduction in urine protein/creatinine ratio (UPCR), which appeared to correlate with the degree of glomerular hyposialylation.

Results: Phase 2 Design: An open-label phase 2 study will include assessment of longer-term pharmacokinetics, safety and efficacy. We will enroll 12 adults with focal segmental glomerulosclerosis, minimal change disease or membranous nephropathy, UPCR >2g/g, eGFR >45 ml/min/1.73m2 and glomerular hyposialylation. Glomerular sialylation will be assessed by lectin analysis of previous diagnostic biopsies. Subjects will receive oral ManNAc twice daily for 12 weeks, with clinical evaluations at baseline, interim and at the end of the study. Study outcomes will include safety and reduction of UPCR. Exploratory outcomes will include quality of life, patient-reported outcomes and improvement in eGFR.

Conclusions: Oral ManNAc therapy might benefit subjects with glomerular hyposialylation. ManNAc has minimal toxicity, is well tolerated, is easily administered, shows a trend to reduction of proteinuria, and could replace or augment existing therapies. The results of the planned phase 2 trial might offer a new therapeutic approach for primary and perhaps secondary glomerular diseases. Such results may change medical practice by including assessment of glomerular sialylation in the analysis of renal biopsies.
